<code>@kms_key_arn</code>	A customer managed KMS key. If you encrypt your DB instance with an AWS managed KMS key, you must create a customer managed key. If you encrypt your DB instance with a customer managed key, you can use the same KMS key ARN.
<code>@backup_file_start_time</code>	The UTC timestamp as provided from the <code>[backup_file_time_utc]</code> column of the <code>rds_fn_list_tlog_backup_metadata</code> function.

Parameter	Description
@backup_file_end_time	The UTC timestamp as provided from the [backup_file_time_utc] column of the rds_fn_list_tlog_backup_metadata function.
@starting_lsn	The log sequence number (LSN) as provided from the [starting_lsn] column of the rds_fn_list_tlog_backup_metadata function
@ending_lsn	The log sequence number (LSN) as provided from the [ending_lsn] column of the rds_fn_list_tlog_backup_metadata function.
@rds_backup_starting_seq_id	The sequence ID as provided from the [rds_backup_seq_id] column of the rds_fn_list_tlog_backup_metadata function.
@rds_backup_ending_seq_id	The sequence ID as provided from the [rds_backup_seq_id] column of the rds_fn_list_tlog_backup_metadata function.

You can specify a set of either the time, LSN, or sequence ID parameters. Only one set of parameters are required.

You can also specify just a single parameter in any of the sets. For example, by providing a value for only the backup\_file\_end\_time parameter, all available transaction log backup files prior to that time within the seven-day limit will be copied to your Amazon S3 bucket.

Following are the valid input parameter combinations for the rds\_tlog\_backup\_copy\_to\_S3 stored procedure.

Parameters provided	Expected result
<pre>exec msdb.dbo.rds_tlog_</pre>	Copies transaction log backups from the last seven days

Parameters provided	Expected result	
<pre> backup_copy_to_S3 @db_name = 'testdb1',  @backup_file_start_time='2022-08-23 00:00:00',  @backup_file_end_time='2022-08-30 00:00:00'; </pre>	<p>and exist between the provided range of backup_file_start_time and backup_file_end_time .</p> <p>In this example, the stored procedure will copy transaction log backups that were generated between '2022-08-23 00:00:00' and '2022-08-30 00:00:00'.</p>	
<pre> exec msdb.dbo.rds_tlog_backup_copy_to_S3  @db_name = 'testdb1',  @backup_file_start_time='2022-08-23 00:00:00'; </pre>	<p>Copies transaction log backups from the last seven days and starting from the provided backup_file_start_time . In this example, the stored procedure will copy transaction log backups from '2022-08-23 00:00:00' up to the latest transaction log backup.</p>	

Parameters provided	Expected result	
<pre>exec msdb.dbo. rds_tlog_ backup_co py_to_S3  @db_name = 'testdb1',  @backup_f ile_end_t ime='2022 -08-30 00:00:00';</pre>	<p>Copies transaction log backups from the last seven days up to the provided backup_file_end_time . In this example, the stored procedure will copy transaction log backups from '2022-08-23 00:00:00 up to '2022-08-30 00:00:00'.</p>	

Parameters provided	Expected result	
<pre>exec msdb.dbo. rds_tlog_ backup_co py_to_S3  @db_name= 'testdb1',  @starting _lsn =149000000 00040007,  @ending_lsn = 149000000 0050009;</pre>	<p>Copies transaction log backups that are available from the last seven days and are between the provided range of the starting_lsn and ending_lsn . In this example, the stored procedure will copy transaction log backups from the last seven days with an LSN range between 1490000000040007 and 1490000000050009.</p>	

Parameters provided	Expected result	
<pre>exec msdb.dbo. rds_tlog_ backup_co py_to_S3  @db_name= 'testdb1',  @starting _lsn =14900000 00040007;</pre>	<p>Copies transaction log backups that are available from the last seven days, beginning from the provided starting_lsn . In this example, the stored procedure will copy transaction log backups from LSN 1490000000040007 up to the latest transaction log backup.</p>	
<pre>exec msdb.dbo. rds_tlog_ backup_co py_to_S3  @db_name= 'testdb1',  @ending_lsn =14900000 00050009;</pre>	<p>Copies transaction log backups that are available from the last seven days, up to the provided ending_lsn . In this example, the stored procedure will copy transaction log backups beginning from the last seven days up to lsn 1490000000050009.</p>	

Parameters provided	Expected result	
<pre>exec msdb.dbo. rds_tlog_ backup_co py_to_S3  @db_name= 'testdb1',  @rds_back up_starti ng_seq_id= 2000,  @rds_back up_ending _seq_id= 5000;</pre>	<p>Copies transaction log backups that are available from the last seven days, and exist between the provided range of <code>rds_backup_starting_seq_id</code> and <code>rds_backup_ending_seq_id</code>. In this example, the stored procedure will copy transaction log backups beginning from the last seven days and within the provided <code>rds_backup_sequence_id</code> range, starting from <code>seq_id 2000</code> up to <code>seq_id 5000</code>.</p>	

Parameters provided	Expected result	
<pre>exec msdb.dbo. rds_tlog_ backup_co py_to_S3  @db_name= 'testdb1',  @rds_back up_starti ng_seq_id= 2000;</pre>	<p>Copies transacti on log backups that are available from the last seven days, beginning from the provided rds_backu p_startin g_seq_id . In this example, the stored procedure will copy transacti on log backups beginning from seq_id 2000, up to the latest transacti on log backup.</p>	
<pre>exec msdb.dbo. rds_tlog_ backup_co py_to_S3     @db_name= 'testdb1',     @rds_back up_ending _seq_id= 5000;</pre>	<p>Copies transaction log backups that are available from the last seven days, up to the provided rds_backu p_ending_ seq_id . In this example, the stored procedure will copy transaction log backups beginning from the last seven days, up to seq_id 5000.</p>	

Parameters provided	Expected result	
<pre>exec msdb.dbo. rds_tlog_ backup_co py_to_S3     @db_name= 'testdb1',     @rds_back up_starti ng_seq_id= 2000;     @rds_back up_endin g_seq_id= 2000;</pre>	<p>Copies a single transaction log backup with the provided <code>rds_backu</code> <code>p_startin</code> <code>g_seq_id</code> , if available within the last seven days. In this example, the stored procedure will copy a single transaction log backup that has a <code>seq_id</code> of 2000, if it exists within the last seven days.</p>	

## Validating the transaction log backup log chain

Databases configured for access to transaction log backups must have automated backup retention enabled. Automated backup retention sets the databases on the DB instance to the FULL recovery model. To support point in time restore for a database, avoid changing the database recovery model, which can result in a broken log chain. We recommend keeping the database set to the FULL recovery model.

To manually validate the log chain before copying transaction log backups, call the `rds_fn_list_tlog_backup_metadata` function and review the values in the `is_log_chain_broken` column. A value of "1" indicates the log chain was broken between the current log backup and the previous log backup.

The following example shows a broken log chain in the output from the `rds_fn_list_tlog_backup_metadata` stored procedure.

rds_sequence_id	first_lsn	last_lsn	is_log_chain_broken
43	90023	90457	0
44	90457	90985	0
45	90987	92034	1

In a normal log chain, the log sequence number (LSN) value for `first_lsn` for given `rds_sequence_id` should match the value of `last_lsn` in the preceding `rds_sequence_id`. In the image, the `rds_sequence_id` of 45 has a `first_lsn` value 90987, which does not match the `last_lsn` value of 90985 for preceding `rds_sequence_id` 44.

For more information about SQL Server transaction log architecture and log sequence numbers, see [Transaction Log Logical Architecture](#) in the Microsoft SQL Server documentation.

## Amazon S3 bucket folder and file structure

Transaction log backups have the following standard structure and naming convention within an Amazon S3 bucket:

- A new folder is created under the `target_s3_arn` path for each database with the naming structure as `{db_id}.{family_guid}`.
- Within the folder, transaction log backups have a filename structure as `{db_id}.{family_guid}.{rds_backup_seq_id}.{backup_file_epoch}`.
- You can view the details of `family_guid`, `db_id`, `rds_backup_seq_id` and `backup_file_epoch` with the `rds_fn_list_tlog_backup_metadata` function.

The following example shows the folder and file structure of a set of transaction log backups within an Amazon S3 bucket.

Amazon S3 > Buckets > rds-sql-server-kms-bucket > 10.36a85812-2b1e-47c6-b956-a020776fff66/

10.36a85812-2b1e-47c6-b956-a020776fff66/ Copy S3 URI

Objects | Properties

**Objects (87)**  
Objects are the fundamental entities stored in Amazon S3. You can use [Amazon S3 inventory](#) to get a list of all objects in your bucket. For others to access your objects, you'll need to explicitly grant them permissions. [Learn more](#)

## Tracking the status of tasks

To track the status of your copy tasks, call the `rds_task_status` stored procedure. If you don't provide any parameters, the stored procedure returns the status of all tasks.

### Example usage:

```
exec msdb.dbo.rds_task_status
  @db_name='database_name',
  @task_id=ID_number;
```

The following parameters are optional:

- `@db_name` – The name of the database to show the task status for.
- `@task_id` – The ID of the task to show the task status for.

### Example of listing the status for a specific task ID:

```
exec msdb.dbo.rds_task_status @task_id=5;
```

### Example of listing the status for a specific database and task:

```
exec msdb.dbo.rds_task_status@db_name='my_database',@task_id=5;
```

### Example of listing all tasks and their status for a specific database:

```
exec msdb.dbo.rds_task_status @db_name='my_database';
```

### Example of listing all tasks and their status on the current DB instance:

```
exec msdb.dbo.rds_task_status;
```

## Canceling a task

To cancel a running task, call the `rds_cancel_task` stored procedure.

### Example usage:

```
exec msdb.dbo.rds_cancel_task @task_id=ID_number;
```

The following parameter is required:

- `@task_id` – The ID of the task to cancel. You can view the task ID by calling the `rds_task_status` stored procedure.

For more information on viewing and canceling running tasks, see [Importing and exporting SQL Server databases using native backup and restore](#).

## Troubleshooting access to transaction log backups

The following are issues you might encounter when you use the stored procedures for access to transaction log backups.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_copy_setup	Backups are disabled on this DB instance. Enable DB instance backups with a retention of at least "1" and try again.	Automated backups are not enabled for the DB instance.	DB instance backup retention must be enabled with a retention of at least one day. For more information on enabling automated backups and configuring backup retention, see <a href="#">Backup retention period</a> .
rds_tlog_copy_setup	Error running the rds_tlog_copy_setup stored procedure. Reconnect to the RDS endpoint and try again.	An internal error occurred.	Reconnect to the RDS endpoint and run the rds_tlog_copy_setup stored procedure again.
rds_tlog_copy_setup	Running the rds_tlog_backup_copy_setup stored procedure inside a transacti	The stored procedure was attempted within a transaction using BEGIN and END.	Avoid using BEGIN and END when running the rds_tlog_copy_setup stored procedure.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
	on is not supported . Verify that the session has no open transactions and try again.		
rds_tlog_copy_setup	The S3 bucket name for the input parameter @target_s3_arn should contain at least one character other than a space.	An incorrect value was provided for the input parameter @target_s3_arn .	Ensure the input parameter @target_s3_arn specifies the complete Amazon S3 bucket ARN.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_copy_setup	The SQLSERVER_BACKUP_RESTORE option isn't enabled or is in the process of being enabled. Enable the option or try again later.	The SQLSERVER_BACKUP_RESTORE option is not enabled on the DB instance or was just enabled and pending internal activation.	Enable the SQLSERVER_BACKUP_RESTORE option as specified in the Requirements section. Wait a few minutes and run the rds_tlog_copy_setup stored procedure again.
rds_tlog_copy_setup	The target S3 arn for the input parameter @target_s3_arn can't be empty or null.	An NULL value was provided for the input parameter @target_s3_arn , or the value wasn't provided.	Ensure the input parameter @target_s3_arn specifies the complete Amazon S3 bucket ARN.
rds_tlog_copy_setup	The target S3 arn for the input parameter @target_s3_arn must begin with arn:aws.	The input parameter @target_s3_arn was provide without arn:aws on the front.	Ensure the input parameter @target_s3_arn specifies the complete Amazon S3 bucket ARN.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_copy_setup	The target S3 ARN is already set to the provided value.	The rds_tlog_copy_setup stored procedure previously ran and was configured with an Amazon S3 bucket ARN.	To modify the Amazon S3 bucket value for access to transaction log backups, provide a different target S3 ARN.
rds_tlog_copy_setup	Unable to generate credentials for enabling Access to Transaction Log Backups. Confirm the S3 path ARN provided with rds_tlog_copy_setup, and try again later.	There was an unspecified error while generating credentials to enable access to transaction log backups.	Review your setup configuration and try again.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_copy_setup	You cannot run the rds_tlog_copy_setup stored procedure while there are pending tasks. Wait for the pending tasks to complete and try again.	Only two tasks may run at any time. There are pending tasks awaiting completion.	View pending tasks and wait for them to complete. For more information on monitoring task status, see <a href="#">Tracking the status of tasks</a> .
rds_tlog_backup_copy_to_S3	A T-log backup file copy task has already been issued for database: %s with task Id: %d, please try again later.	Only one copy task may run at any time for a given database. There is a pending copy task awaiting completion.	View pending tasks and wait for them to complete. For more information on monitoring task status, see <a href="#">Tracking the status of tasks</a> .

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	<p>At least one of these three parameter sets must be provided.</p> <p>SET-1:(@backup_file_start_time, @backup_file_end_time)  </p> <p>SET-2:(@starting_lsn, @ending_lsn)  </p> <p>SET-3:(@rds_backup_starting_seq_id, @rds_backup_ending_seq_id)</p>	<p>None of the three parameter sets were provided, or a provided parameter set is missing a required parameter.</p>	<p>You can specify either the time, lsn, or sequence ID parameters. One set from these three sets of parameters are required. For more information on required parameters, see <a href="#">Copying transaction log backups</a>.</p>

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	Backups are disabled on your instance. Please enable backups and try again in some time.	Automated backups are not enabled for the DB instance.	For more information on enabling automated backups and configuring backup retention, see <a href="#">Backup retention period</a> .
rds_tlog_backup_copy_to_S3	Cannot find the given database %s.	The value provided for input parameter @db_name does not match a database name on the DB instance.	Use the correct database name. To list all databases by name, run <code>SELECT * from sys.databases</code>
rds_tlog_backup_copy_to_S3	Cannot run the rds_tlog_backup_copy_to_S3 stored procedure for SQL Server system databases or the rdsadmin database.	The value provided for input parameter @db_name matches a SQL Server system database name or the RDSAdmin database.	The following databases are not allowed to be used with access to transaction log backups: master, model, msdb, tempdb, RDSAdmin.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	Database name for the input parameter @db_name can't be empty or null.	The value provided for input parameter @db_name was empty or NULL.	Use the correct database name. To list all databases by name, run <code>SELECT * from sys.databases</code>
rds_tlog_backup_copy_to_S3	DB instance backup retention period must be set to at least 1 to run the rds_tlog_backup_copy_setup stored procedure.	Automated backups are not enabled for the DB instance.	For more information on enabling automated backups and configuring backup retention, see <a href="#">Backup retention period</a> .
rds_tlog_backup_copy_to_S3	Error running the stored procedure rds_tlog_backup_copy_to_S3. Reconnect to the RDS endpoint and try again.	An internal error occurred.	Reconnect to the RDS endpoint and run the rds_tlog_backup_copy_to_S3 stored procedure again.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	Only one of these three parameter sets can be provided. SET-1:(@backup_file_start_time, @backup_file_end_time)   SET-2:(@starting_lsn, @ending_lsn)   SET-3:(@rds_backup_starting_seq_id, @rds_backup_ending_seq_id)	Multiple parameter sets were provided.	You can specify either the time, lsn, or sequence ID parameters. One set from these three sets of parameters are required. For more information on required parameters, see <a href="#">Copying transaction log backups</a> .

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	Running the rds_tlog_backup_copy_to_S3 stored procedure inside a transaction is not supported. Verify that the session has no open transactions and try again.	The stored procedure was attempted within a transaction using BEGIN and END.	Avoid using BEGIN and END when running the rds_tlog_backup_copy_to_S3 stored procedure.

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	The provided parameters fall outside of the transaction backup log retention period. To list of available transaction log backup files, run the rds_fn_list_tlog_backup_metadata function.	There are no available transactional log backups for the provided input parameters that fit in the copy retention window.	Try again with a valid set of parameters. For more information on required parameters, see <a href="#">Copying transaction log backups</a> .

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	There was a permissions error in processing the request. Ensure the bucket is in the same Account and Region as the DB Instance, and confirm the S3 bucket policy permissions against the template in the public documentation.	There was an issue detected with the provided S3 bucket or its policy permissions.	Confirm your setup for access to transaction log backups is correct. For more information on setup requirements for your S3 bucket, see <a href="#">Requirements</a> .

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	Running the rds_tlog_backup_copy_to_S3 stored procedure on an RDS read replica instance isn't permitted.	The stored procedure was attempted on a RDS read replica instance.	Connect to the RDS primary DB instance to run the rds_tlog_backup_copy_to_S3 stored procedure.
rds_tlog_backup_copy_to_S3	The LSN for the input parameter @starting_lsn must be less than @ending_lsn .	The value provided for input parameter @starting_lsn was greater than the value provided for input parameter @ending_lsn .	Ensure the value provided for input parameter @starting_lsn is less than the value provided for input parameter @ending_lsn .

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	The rds_tlog_backup_copy_to_S3 stored procedure can only be performed by the members of db_owner role in the source database.	The db_owner role has not been granted for the account attempting to run the rds_tlog_backup_copy_to_S3 stored procedure on the provided db_name.	Ensure the account running the stored procedure is permissioned with the db_owner role for the provided db_name.
rds_tlog_backup_copy_to_S3	The sequence ID for the input parameter @rds_backup_starting_seq_id must be less than or equal to @rds_backup_ending_seq_id .	The value provided for input parameter @rds_backup_starting_seq_id was greater than the value provided for input parameter @rds_backup_ending_seq_id .	Ensure the value provided for input parameter @rds_backup_starting_seq_id is less than the value provided for input parameter @rds_backup_ending_seq_id .

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	The SQLSERVER_BACKUP_RESTORE option isn't enabled or is in the process of being enabled. Enable the option or try again later.	The SQLSERVER_BACKUP_RESTORE option is not enabled on the DB instance or was just enabled and pending internal activation.	Enable the SQLSERVER_BACKUP_RESTORE option as specified in the Requirements section. Wait a few minutes and run the rds_tlog_backup_copy_to_S3 stored procedure again.
rds_tlog_backup_copy_to_S3	The start time for the input parameter @backup_file_start_time must be less than @backup_file_end_time .	The value provided for input parameter @backup_file_start_time was greater than the value provided for input parameter @backup_file_end_time .	Ensure the value provided for input parameter @backup_file_start_time is less than the value provided for input parameter @backup_file_end_time .

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	We were unable to process the request due to a lack of access. Please check your setup and permissions for the feature.	There may be an issue with the Amazon S3 bucket permissions, or the Amazon S3 bucket provided is in another account or Region.	Ensure the Amazon S3 bucket policy permissions are permitted to allow RDS access. Ensure the Amazon S3 bucket is in the same account and Region as the DB instance.
rds_tlog_backup_copy_to_S3	You cannot provide a KMS Key ARN as input parameter to the stored procedure for instances that are not storage-encrypted.	When storage encryption is not enabled on the DB instance, the input parameter <code>@kms_key_arn</code> should not be provided.	Do not provide an input parameter for <code>@kms_key_arn</code> .

Stored Procedure	Error Message	Issue	Troubleshooting suggestions
rds_tlog_backup_copy_to_S3	You must provide a KMS Key ARN as input parameter to the stored procedure for storage encrypted instances.	When storage encryption is enabled on the DB instance, the input parameter @kms_key_arn must be provided.	Provide an input parameter for @kms_key_arn with a value that matches the ARN of the Amazon S3 bucket to use for transaction log backups.
rds_tlog_backup_copy_to_S3	You must run the rds_tlog_copy_setup stored procedure and set the @target_s3_arn , before running the rds_tlog_backup_copy_to_S3 stored procedure.	The access to transaction log backups setup procedure was not completed before attempting to run the rds_tlog_backup_copy_to_S3 stored procedure.	Run the rds_tlog_copy_setup stored procedure before running the rds_tlog_backup_copy_to_S3 stored procedure . For more information on running the setup procedure for access to transaction log backups, see <a href="#">Setting up access to transaction log backups</a> .

## Options for the Microsoft SQL Server database engine

In this section, you can find descriptions for options that are available for Amazon RDS instances running the Microsoft SQL Server DB engine. To enable these options, you add them to an option group, and then associate the option group with your DB instance. For more information, see [Working with option groups](#).

If you're looking for optional features that aren't added through RDS option groups (such as SSL, Microsoft Windows Authentication, and Amazon S3 integration), see [Additional features for Microsoft SQL Server on Amazon RDS](#).

Amazon RDS supports the following options for Microsoft SQL Server DB instances.

Option	Option ID	Engine editions
<a href="#">Linked Servers with Oracle OLEDB</a>	OLEDB_ORACLE	SQL Server Enterprise Edition  SQL Server Standard Edition
<a href="#">Native backup and restore</a>	SQLSERVER_BACKUP_RESTORE	SQL Server Enterprise Edition  SQL Server Standard Edition  SQL Server Web Edition  SQL Server Express Edition
<a href="#">Transparent Data Encryption</a>	TRANSPARENT_DATA_ENCRYPTION (RDS console)	SQL Server 2016–2022 Enterprise Edition  SQL Server 2022 Standard Edition

Option	Option ID	Engine editions
	TDE (AWS CLI and RDS API)	
<a href="#">SQL Server Audit</a>	SQLSERVER_AUDIT	<p>In RDS, starting with SQL Server 2016, all editions of SQL Server support server-level audits, and Enterprise Edition also supports database-level audits.</p> <p>Starting with SQL Server SQL Server 2016 (13.x) SP1, all editions support both server-level and database-level audits.</p> <p>For more information, see <a href="#">SQL Server Audit (database engine)</a> in the SQL Server documentation.</p>
<a href="#">SQL Server Analysis Services</a>	SSAS	<p>SQL Server Enterprise Edition</p> <p>SQL Server Standard Edition</p>

Option	Option ID	Engine editions
<a href="#">SQL Server Integration Services</a>	SSIS	SQL Server Enterprise Edition  SQL Server Standard Edition
<a href="#">SQL Server Reporting Services</a>	SSRS	SQL Server Enterprise Edition  SQL Server Standard Edition
<a href="#">Microsoft Distributed Transaction Coordinator</a>	MSDTC	In RDS, starting with SQL Server 2016, all editions of SQL Server support distributed transactions.

## Listing the available options for SQL Server versions and editions

You can use the `describe-option-group-options` AWS CLI command to list the available options for SQL Server versions and editions, and the settings for those options.

The following example shows the options and option settings for SQL Server 2019 Enterprise Edition. The `--engine-name` option is required.

```
aws rds describe-option-group-options --engine-name sqlserver-ee --major-engine-version 15.00
```

The output resembles the following:

```
{
  "OptionGroupOptions": [
    {
      "Name": "MSDTC",
      "Description": "Microsoft Distributed Transaction Coordinator",
```

```

    "EngineName": "sqlserver-ee",
    "MajorEngineVersion": "15.00",
    "MinimumRequiredMinorEngineVersion": "4043.16.v1",
    "PortRequired": true,
    "DefaultPort": 5000,
    "OptionsDependedOn": [],
    "OptionsConflictsWith": [],
    "Persistent": false,
    "Permanent": false,
    "RequiresAutoMinorEngineVersionUpgrade": false,
    "VpcOnly": false,
    "OptionGroupOptionSettings": [
      {
        "SettingName": "ENABLE_SNA_LU",
        "SettingDescription": "Enable support for SNA LU protocol",
        "DefaultValue": "true",
        "ApplyType": "DYNAMIC",
        "AllowedValues": "true,false",
        "IsModifiable": true,
        "IsRequired": false,
        "MinimumEngineVersionPerAllowedValue": []
      },
      ...
    ]
  {
    "Name": "TDE",
    "Description": "SQL Server - Transparent Data Encryption",
    "EngineName": "sqlserver-ee",

    "RequiresAutoMinorEngineVersionUpgrade": false,
    "VpcOnly": false,
    "OptionGroupOptionSettings": []
  }
]
}

```

# Support for Linked Servers with Oracle OLEDB in Amazon RDS for SQL Server

Linked servers with the Oracle Provider for OLEDB on RDS for SQL Server lets you access external data sources on an Oracle database. You can read data from remote Oracle data sources and run commands against remote Oracle database servers outside of your RDS for SQL Server DB instance. Using linked servers with Oracle OLEDB, you can:

- Directly access data sources other than SQL Server
- Query against diverse Oracle data sources with the same query without moving the data
- Issue distributed queries, updates, commands, and transactions on data sources across an enterprise ecosystem
- Integrate connections to an Oracle database from within the Microsoft Business Intelligence suite (SSIS, SSRS, SSAS)
- Migrate from an Oracle database to RDS for SQL Server

You can activate one or more linked servers for Oracle on either an existing or new RDS for SQL Server DB instance. Then you can integrate external Oracle data sources with your DB instance.

## Contents

- [Supported versions and Regions](#)
- [Limitations and recommendations](#)
- [Activating linked servers with Oracle](#)
  - [Creating the option group for OLEDB\\_ORACLE](#)
  - [Adding the OLEDB\\_ORACLE option to the option group](#)
  - [Associating the option group with your DB instance](#)
- [Modifying OLEDB provider properties](#)
- [Modifying OLEDB driver properties](#)
- [Deactivating linked servers with Oracle](#)

## Supported versions and Regions

RDS for SQL Server supports linked servers with Oracle OLEDB in all Regions for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2022, all versions
- SQL Server 2019, all versions
- SQL Server 2017, all versions

Linked servers with Oracle OLEDB is supported for the following Oracle Database versions:

- Oracle Database 21c, all versions
- Oracle Database 19c, all versions
- Oracle Database 18c, all versions

## Limitations and recommendations

Keep in mind the following limitations and recommendations that apply to linked servers with Oracle OLEDB:

- Allow network traffic by adding the applicable TCP port in the security group for each RDS for SQL Server DB instance. For example, if you're configuring a linked server between an EC2 Oracle DB instance and an RDS for SQL Server DB instance, then you must allow traffic from the IP address of the EC2 Oracle DB instance. You also must allow traffic on the port that SQL Server is using to listen for database communication. For more information on security groups, see [Controlling access with security groups](#).
- Perform a reboot of the RDS for SQL Server DB instance after turning on, turning off, or modifying the OLEDB\_ORACLE option in your option group. The option group status displays `pending_reboot` for these events and is required.
- Only simple authentication is supported with a user name and password for the Oracle data source.
- Open Database Connectivity (ODBC) drivers are not supported. Only the latest version of the OLEDB driver is supported.
- Distributed transactions (XA) are supported. To activate distributed transactions, turn on the MSDTC option in the Option Group for your DB instance and make sure XA transactions are turned on. For more information, see [Support for Microsoft Distributed Transaction Coordinator in RDS for SQL Server](#).
- Creating data source names (DSNs) to use as a shortcut for a connection string is not supported.
- OLEDB driver tracing is not supported. You can use SQL Server Extended Events to trace OLEDB events. For more information, see [Set up Extended Events in RDS for SQL Server](#).

- Access to the catalogs folder for an Oracle linked server is not supported using SQL Server Management Studio (SSMS).

## Activating linked servers with Oracle

Activate linked servers with Oracle by adding the OLEDB\_ORACLE option to your RDS for SQL Server DB instance. Use the following process:

1. Create a new option group, or choose an existing option group.
2. Add the OLEDB\_ORACLE option to the option group.
3. Choose a version of the OLEDB driver to use.
4. Associate the option group with the DB instance.
5. Reboot the DB instance.

## Creating the option group for OLEDB\_ORACLE

To work with linked servers with Oracle, create an option group or modify an option group that corresponds to the SQL Server edition and version of the DB instance that you plan to use. To complete this procedure, use the AWS Management Console or the AWS CLI.

### Console

The following procedure creates an option group for SQL Server Standard Edition 2019.

#### To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** window, do the following:
  - a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **oracle-oledb-se-2019**. The name can contain only letters, digits, and hyphens.
  - b. For **Description**, enter a brief description of the option group, such as **OLEDB\_ORACLE option group for SQL Server SE 2019**. The description is used for display purposes.

- c. For **Engine**, choose **sqlserver-se**.
  - d. For **Major engine version**, choose **15.00**.
5. Choose **Create**.

## CLI

The following procedure creates an option group for SQL Server Standard Edition 2019.

### To create the option group

- Run one of the following commands.

#### Example

For Linux, macOS, or Unix:

```
aws rds create-option-group \  
  --option-group-name oracle-oledb-se-2019 \  
  --engine-name sqlserver-se \  
  --major-engine-version 15.00 \  
  --option-group-description "OLEDB_ORACLE option group for SQL Server SE 2019"
```

For Windows:

```
aws rds create-option-group ^  
  --option-group-name oracle-oledb-se-2019 ^  
  --engine-name sqlserver-se ^  
  --major-engine-version 15.00 ^  
  --option-group-description "OLEDB_ORACLE option group for SQL Server SE 2019"
```

### Adding the OLEDB\_ORACLE option to the option group

Next, use the AWS Management Console or the AWS CLI to add the OLEDB\_ORACLE option to your option group.

## Console

### To add the OLEDB\_ORACLE option

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created, which is **oracle-oledb-se-2019** in this example.
4. Choose **Add option**.
5. Under **Option details**, choose **OLEDB\_ORACLE** for **Option name**.
6. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
7. Choose **Add option**.

## CLI

### To add the OLEDB\_ORACLE option

- Add the OLEDB\_ORACLE option to the option group.

### Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \  
  --option-group-name oracle-oledb-se-2019 \  
  --options OptionName=OLEDB_ORACLE \  
  --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^  
  --option-group-name oracle-oledb-se-2019 ^  
  --options OptionName=OLEDB_ORACLE ^  
  --apply-immediately
```

## Associating the option group with your DB instance

To associate the OLEDB\_ORACLE option group and parameter group with your DB instance, use the AWS Management Console or the AWS CLI

### Console

To finish activating linked servers for Oracle, associate your OLEDB\_ORACLE option group with a new or existing DB instance:

- For a new DB instance, associate them when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
- For an existing DB instance, associate them by modifying the instance. For more information, see [Modifying an Amazon RDS DB instance](#).

### CLI

You can associate the OLEDB\_ORACLE option group and parameter group with a new or existing DB instance.

### To create an instance with the OLEDB\_ORACLE option group and parameter group

- Specify the same DB engine type and major version that you used when creating the option group.

### Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \  
  --db-instance-identifier mytestsqlserveroracleoledbinstance \  
  --db-instance-class db.m5.2xlarge \  
  --engine sqlserver-se \  
  --engine-version 15.0.4236.7.v1 \  
  --allocated-storage 100 \  
  --manage-master-user-password \  
  --master-username admin \  
  --storage-type gp2 \  
  --license-model li \  
  --domain-iam-role-name my-directory-iam-role \  
  --domain my-domain-id \  
  --option-group-name oracle-oledb-se-2019 \  
  --parameter-group-name oracle-oleddb-se-2019 \  
  --security-groups sg-12345678 \  
  --tags Key=Value \  
  --vpc-subnet-id vpc-subnet-id \  
  --availability-zone us-east-1a \  
  --db-instance-profile-name db-instance-profile-name \  
  --db-instance-identifier mytestsqlserveroracleoledbinstance \  
  --db-instance-class db.m5.2xlarge \  
  --engine sqlserver-se \  
  --engine-version 15.0.4236.7.v1 \  
  --allocated-storage 100 \  
  --manage-master-user-password \  
  --master-username admin \  
  --storage-type gp2 \  
  --license-model li \  
  --domain-iam-role-name my-directory-iam-role \  
  --domain my-domain-id \  
  --option-group-name oracle-oledb-se-2019 \  
  --parameter-group-name oracle-oleddb-se-2019 \  
  --security-groups sg-12345678 \  
  --tags Key=Value \  
  --vpc-subnet-id vpc-subnet-id \  
  --availability-zone us-east-1a \  
  --db-instance-profile-name db-instance-profile-name
```

```
--db-parameter-group-name my-parameter-group-name
```

### For Windows:

```
aws rds create-db-instance ^
  --db-instance-identifier mytestsqlserveroracleoledbinstance ^
  --db-instance-class db.m5.2xlarge ^
  --engine sqlserver-se ^
  --engine-version 15.0.4236.7.v1 ^
  --allocated-storage 100 ^
  --manage-master-user-password ^
  --master-username admin ^
  --storage-type gp2 ^
  --license-model li ^
  --domain-iam-role-name my-directory-iam-role ^
  --domain my-domain-id ^
  --option-group-name oracle-oledb-se-2019 ^
  --db-parameter-group-name my-parameter-group-name
```

## To modify an instance and associate the OLEDB\_ORACLE option group

- Run one of the following commands.

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier mytestsqlserveroracleoledbinstance \  
  --option-group-name oracle-oledb-se-2019 \  
  --db-parameter-group-name my-parameter-group-name \  
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mytestsqlserveroracleoledbinstance ^
  --option-group-name oracle-oledb-se-2019 ^
  --db-parameter-group-name my-parameter-group-name ^
  --apply-immediately
```

## Modifying OLEDB provider properties

You can view and change the properties of the OLEDB provider. Only the `master` user can perform this task. All linked servers for Oracle that are created on the DB instance use the same properties of that OLEDB provider. Call the `sp_MSset_oledb_prop` stored procedure to change the properties of the OLEDB provider.

To change the OLEDB provider properties

```
USE [master]
GO
EXEC sp_MSset_oledb_prop N'OraOLEDB.Oracle', N'AllowInProcess', 1
EXEC sp_MSset_oledb_prop N'OraOLEDB.Oracle', N'DynamicParameters', 0
GO
```

The following properties can be modified:

Property name	Recommended Value (1 = On, 0 = Off)	Description
Dynamic parameter	1	Allows SQL placeholders (represented by '?') in parameterized queries.
Nested queries	1	Allows nested SELECT statements in the FROM clause, such as sub-queries.
Level zero only	0	Only base-level OLEDB interfaces are called against the provider.
Allow inprocess	1	If turned on, Microsoft SQL Server allows the provider to be instantiated as an in-process server. Set this property to 1 to use Oracle linked servers.
Non transacted updates	0	If non-zero, SQL Server allows updates.

Property name	Recommended Value (1 = On, 0 = Off)	Description
Index as access path	False	If non-zero, SQL Server attempts to use indexes of the provider to fetch data.
Disallow adhoc access	False	If set, SQL Server does not allow running pass-through queries against the OLEDB provider. While this option can be checked, it is sometimes appropriate to run pass-through queries.
Supports LIKE operator	1	Indicates that the provider supports queries using the LIKE keyword.

## Modifying OLEDB driver properties

You can view and change the properties of the OLEDB driver when creating a linked server for Oracle. Only the `master` user can perform this task. Driver properties define how the OLEDB driver handles data when working with a remote Oracle data source. Driver properties are specific to each Oracle linked server created on the DB instance. Call the `master.dbo.sp_addlinkedserver` stored procedure to change the properties of the OLEDB driver.

Example: To create a linked server and change the OLEDB driver `FetchSize` property

```
EXEC master.dbo.sp_addlinkedserver
@server = N'Oracle_link2',
@srvproduct=N'Oracle',
@provider=N'OraOLEDB.Oracle',
@datasrc=N'my-oracle-test.cnetsipka.us-west-2.rds.amazonaws.com:1521/ORCL',
@provstr='FetchSize=200'
GO
```

```
EXEC master.dbo.sp_addlinkedsrvlogin
@rmtsrvname=N'Oracle_link2',
@useself=N'False',
@locallogin=NULL,
```

```
@rmtuser=N'master',  
@rmtpassword='Test#1234'  
GO
```

### Note

Specify a password other than the prompt shown here as a security best practice.

## Deactivating linked servers with Oracle

To deactivate linked servers with Oracle, remove the OLEDB\_ORACLE option from its option group.

### Important

Removing the option doesn't delete the existing linked server configurations on the DB instance. You must manually drop them to remove them from the DB instance.

You can reactivate the OLEDB\_ORACLE option after removal to reuse the linked server configurations that were previously configured on the DB instance.

## Console

The following procedure removes the OLEDB\_ORACLE option.

### To remove the OLEDB\_ORACLE option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the OLEDB\_ORACLE option (oracle-oledb-se-2019 in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **OLEDB\_ORACLE** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it during the next maintenance window.
7. Choose **Delete**.

## CLI

The following procedure removes the OLEDB\_ORACLE option.

### To remove the OLEDB\_ORACLE option from its option group

- Run one of the following commands.

#### Example

For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \  
  --option-group-name oracle-oledb-se-2019 \  
  --options OLEDB_ORACLE \  
  --apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group ^  
  --option-group-name oracle-oledb-se-2019 ^  
  --options OLEDB_ORACLE ^  
  --apply-immediately
```

## Support for native backup and restore in SQL Server

By using native backup and restore for SQL Server databases, you can create a differential or full backup of your on-premises database and store the backup files on Amazon S3. You can then restore to an existing Amazon RDS DB instance running SQL Server. You can also back up an RDS for SQL Server database, store it on Amazon S3, and restore it in other locations. In addition, you can restore the backup to an on-premises server, or a different Amazon RDS DB instance running SQL Server. For more information, see [Importing and exporting SQL Server databases using native backup and restore](#).

Amazon RDS supports native backup and restore for Microsoft SQL Server databases by using differential and full backup files (.bak files).

### Adding the native backup and restore option

The general process for adding the native backup and restore option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the `SQLSERVER_BACKUP_RESTORE` option to the option group.
3. Associate an AWS Identity and Access Management (IAM) role with the option. The IAM role must have access to an S3 bucket to store the database backups.

That is, the option must have as its option setting a valid Amazon Resource Name (ARN) in the format `arn:aws:iam::account-id:role/role-name`. For more information, see [Amazon Resource Names \(ARNs\)](#) in the *AWS General Reference*.

The IAM role must also have a trust relationship and a permissions policy attached. The trust relationship allows RDS to assume the role, and the permissions policy defines the actions that the role can perform. For more information, see [Manually creating an IAM role for native backup and restore](#).

4. Associate the option group with the DB instance.

After you add the native backup and restore option, you don't need to restart your DB instance. As soon as the option group is active, you can begin backing up and restoring immediately.

## Console

### To add the native backup and restore option

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Create a new option group or use an existing option group. For information on how to create a custom DB option group, see [Creating an option group](#).

To use an existing option group, skip to the next step.

4. Add the **SQLSERVER\_BACKUP\_RESTORE** option to the option group. For more information about adding options, see [Adding an option to an option group](#).
5. Do one of the following:
  - To use an existing IAM role and Amazon S3 settings, choose an existing IAM role for **IAM Role**. If you use an existing IAM role, RDS uses the Amazon S3 settings configured for this role.
  - To create a new role and configure Amazon S3 settings, do the following:
    1. For **IAM role**, choose **Create a new role**.
    2. For **S3 bucket**, choose an S3 bucket from the list.
    3. For **S3 prefix (optional)**, specify a prefix to use for the files stored in your Amazon S3 bucket.

This prefix can include a file path but doesn't have to. If you provide a prefix, RDS attaches that prefix to all backup files. RDS then uses the prefix during a restore to identify related files and ignore irrelevant files. For example, you might use the S3 bucket for purposes besides holding backup files. In this case, you can use the prefix to have RDS perform native backup and restore only on a particular folder and its subfolders.

If you leave the prefix blank, then RDS doesn't use a prefix to identify backup files or files to restore. As a result, during a multiple-file restore, RDS attempts to restore every file in every folder of the S3 bucket.

4. Choose the **Enable encryption** check box to encrypt the backup file. Leave the check box cleared (the default) to have the backup file unencrypted.

If you chose **Enable encryption**, choose an encryption key for **AWS KMS key**. For more information about encryption keys, see [Getting started](#) in the *AWS Key Management Service Developer Guide*.

6. Choose **Add option**.
7. Apply the option group to a new or existing DB instance:
  - For a new DB instance, apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
  - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](#).

## CLI

This procedure makes the following assumptions:

- You're adding the `SQLSERVER_BACKUP_RESTORE` option to an option group that already exists. For more information about adding options, see [Adding an option to an option group](#).
- You're associating the option with an IAM role that already exists and has access to an S3 bucket to store the backups.
- You're applying the option group to a DB instance that already exists. For more information, see [Modifying an Amazon RDS DB instance](#).

## To add the native backup and restore option

1. Add the `SQLSERVER_BACKUP_RESTORE` option to the option group.

### Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \  
  --apply-immediately \  
  --option-group-name mybackupgroup \  
  --options "OptionName=SQLSERVER_BACKUP_RESTORE, \  
    OptionSettings=[{Name=IAM_ROLE_ARN, Value=arn:aws:iam::account-id:role/role-  
name}]"
```

## For Windows:

```
aws rds add-option-to-option-group ^
--option-group-name mybackupgroup ^
--options "[{"OptionName\": \"SQLSERVER_BACKUP_RESTORE\", ^
\"OptionSettings\": [{"Name\": \"IAM_ROLE_ARN\", ^
\"Value\": \"arn:aws:iam::account-id:role/role-name"}]}]" ^
--apply-immediately
```

### Note

When using the Windows command prompt, you must escape double quotes (") in JSON code by prefixing them with a backslash (\).

2. Apply the option group to the DB instance.

## Example

### For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
--db-instance-identifier mydbinstance \  
--option-group-name mybackupgroup \  
--apply-immediately
```

### For Windows:

```
aws rds modify-db-instance ^  
--db-instance-identifier mydbinstance ^  
--option-group-name mybackupgroup ^  
--apply-immediately
```

## Modifying native backup and restore option settings

After you enable the native backup and restore option, you can modify the settings for the option. For more information about how to modify option settings, see [Modifying an option setting](#).

## Removing the native backup and restore option

You can turn off native backup and restore by removing the option from your DB instance. After you remove the native backup and restore option, you don't need to restart your DB instance.

To remove the native backup and restore option from a DB instance, do one of the following:

- Remove the option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group](#).
- Modify the DB instance and specify a different option group that doesn't include the native backup and restore option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance](#).

## Support for Transparent Data Encryption in SQL Server

Amazon RDS supports using Transparent Data Encryption (TDE) to encrypt stored data on your DB instances running Microsoft SQL Server. TDE automatically encrypts data before it is written to storage, and automatically decrypts data when the data is read from storage.

Amazon RDS supports TDE for the following SQL Server versions and editions:

- SQL Server 2022 Standard and Enterprise Editions
- SQL Server 2019 Standard and Enterprise Editions
- SQL Server 2017 Enterprise Edition
- SQL Server 2016 Enterprise Edition

Transparent Data Encryption for SQL Server provides encryption key management by using a two-tier key architecture. A certificate, which is generated from the database master key, is used to protect the data encryption keys. The database encryption key performs the actual encryption and decryption of data on the user database. Amazon RDS backs up and manages the database master key and the TDE certificate.

Transparent Data Encryption is used in scenarios where you need to encrypt sensitive data. For example, you might want to provide data files and backups to a third party, or address security-related regulatory compliance issues. You can't encrypt the system databases for SQL Server, such as the `model` or `master` databases.

A detailed discussion of Transparent Data Encryption is beyond the scope of this guide, but make sure that you understand the security strengths and weaknesses of each encryption algorithm and key. For information about Transparent Data Encryption for SQL Server, see [Transparent Data Encryption \(TDE\)](#) in the Microsoft documentation.

### Topics

- [Turning on TDE for RDS for SQL Server](#)
- [Encrypting data on RDS for SQL Server](#)
- [Backing up and restoring TDE certificates on RDS for SQL Server](#)
- [Backing up and restoring TDE certificates for on-premises databases](#)
- [Turning off TDE for RDS for SQL Server](#)

## Turning on TDE for RDS for SQL Server

To turn on Transparent Data Encryption for an RDS for SQL Server DB instance, specify the TDE option in an RDS option group that's associated with that DB instance:

1. Determine whether your DB instance is already associated with an option group that has the TDE option. To view the option group that a DB instance is associated with, use the RDS console, the [describe-db-instance](#) AWS CLI command, or the API operation [DescribeDBInstances](#).
2. If the DB instance isn't associated with an option group that has TDE turned on, you have two choices. You can create an option group and add the TDE option, or you can modify the associated option group to add it.

### Note

In the RDS console, the option is named `TRANSPARENT_DATA_ENCRYPTION`. In the AWS CLI and RDS API, it's named `TDE`.

For information about creating or modifying an option group, see [Working with option groups](#). For information about adding an option to an option group, see [Adding an option to an option group](#).

3. Associate the DB instance with the option group that has the TDE option. For information about associating a DB instance with an option group, see [Modifying an Amazon RDS DB instance](#).

### Option group considerations

The TDE option is a persistent option. You can't remove it from an option group unless all DB instances and backups are no longer associated with the option group. After you add the TDE option to an option group, the option group can be associated only with DB instances that use TDE. For more information about persistent options in an option group, see [Option groups overview](#).

Because the TDE option is a persistent option, you can have a conflict between the option group and an associated DB instance. You can have a conflict in the following situations:

- The current option group has the TDE option, and you replace it with an option group that doesn't have the TDE option.

- You restore from a DB snapshot to a new DB instance that doesn't have an option group that contains the TDE option. For more information about this scenario, see [Option group considerations](#).

## SQL Server performance considerations

Using Transparent Data Encryption can affect the performance of a SQL Server DB instance.

Performance for unencrypted databases can also be degraded if the databases are on a DB instance that has at least one encrypted database. As a result, we recommend that you keep encrypted and unencrypted databases on separate DB instances.

## Encrypting data on RDS for SQL Server

When the TDE option is added to an option group, Amazon RDS generates a certificate that's used in the encryption process. You can then use the certificate to run SQL statements that encrypt data in a database on the DB instance.

The following example uses the RDS-created certificate called `RDSTDECertificateName` to encrypt a database called `myDatabase`.

```
----- Turning on TDE -----  
  
-- Find an RDS TDE certificate to use  
USE [master]  
GO  
SELECT name FROM sys.certificates WHERE name LIKE 'RDSTDECertificate%'  
GO  
  
USE [myDatabase]  
GO  
-- Create a database encryption key (DEK) using one of the certificates from the  
previous step  
CREATE DATABASE ENCRYPTION KEY WITH ALGORITHM = AES_256  
ENCRYPTION BY SERVER CERTIFICATE [RDSTDECertificateName]  
GO  
  
-- Turn on encryption for the database  
ALTER DATABASE [myDatabase] SET ENCRYPTION ON  
GO
```

```
-- Verify that the database is encrypted
USE [master]
GO
SELECT name FROM sys.databases WHERE is_encrypted = 1
GO
SELECT db_name(database_id) as DatabaseName, * FROM sys.dm_database_encryption_keys
GO
```

The time that it takes to encrypt a SQL Server database using TDE depends on several factors. These include the size of the DB instance, whether the instance uses Provisioned IOPS storage, the amount of data, and other factors.

## Backing up and restoring TDE certificates on RDS for SQL Server

RDS for SQL Server provides stored procedures for backing up, restoring, and dropping TDE certificates. RDS for SQL Server also provides a function for viewing restored user TDE certificates.

User TDE certificates are used to restore databases to RDS for SQL Server that are on-premises and have TDE turned on. These certificates have the prefix `UserTDECertificate_`. After restoring databases, and before making them available to use, RDS modifies the databases that have TDE turned on to use RDS-generated TDE certificates. These certificates have the prefix `RDSTDECertificate`.

User TDE certificates remain on the RDS for SQL Server DB instance, unless you drop them using the `rds_drop_tde_certificate` stored procedure. For more information, see [Dropping restored TDE certificates](#).

You can use a user TDE certificate to restore other databases from the source DB instance. The databases to restore must use the same TDE certificate and have TDE turned on. You don't have to import (restore) the same certificate again.

### Topics

- [Prerequisites](#)
- [Limitations](#)
- [Backing up a TDE certificate](#)
- [Restoring a TDE certificate](#)
- [Viewing restored TDE certificates](#)
- [Dropping restored TDE certificates](#)

## Prerequisites

Before you can back up or restore TDE certificates on RDS for SQL Server, make sure to perform the following tasks. The first three are described in [Setting up for native backup and restore](#).

1. Create Amazon S3 buckets for storing files to back up and restore.

We recommend that you use separate buckets for database backups and for TDE certificate backups.

2. Create an IAM role for backing up and restoring files.

The IAM role must be both a user and an administrator for the AWS KMS key.

In addition to the permissions required for SQL Server native backup and restore, the IAM role also requires the following permissions:

- `s3:GetBucketACL`, `s3:GetBucketLocation`, and `s3:ListBucket` on the S3 bucket resource
- `s3:ListAllMyBuckets` on the `*` resource

3. Add the `SQLSERVER_BACKUP_RESTORE` option to an option group on your DB instance.

This is in addition to the `TRANSPARENT_DATA_ENCRYPTION` (TDE) option.

4. Make sure that you have a symmetric encryption KMS key. You have the following options:

- If you have an existing KMS key in your account, you can use it. No further action is necessary.
- If you don't have an existing symmetric encryption KMS key in your account, create a KMS key by following the instructions in [Creating keys](#) in the *AWS Key Management Service Developer Guide*.

5. Enable Amazon S3 integration to transfer files between the DB instance and Amazon S3.

For more information on enabling Amazon S3 integration, see [Integrating an Amazon RDS for SQL Server DB instance with Amazon S3](#).

## Limitations

Using stored procedures to back up and restore TDE certificates has the following limitations:

- Both the `SQLSERVER_BACKUP_RESTORE` and `TRANSPARENT_DATA_ENCRYPTION` (TDE) options must be added to the option group that you associated with your DB instance.
- TDE certificate backup and restore aren't supported on Multi-AZ DB instances.

- Canceling TDE certificate backup and restore tasks isn't supported.
- You can't use a user TDE certificate for TDE encryption of any other database on your RDS for SQL Server DB instance. You can use it to restore only other databases from the source DB instance that have TDE turned on and that use the same TDE certificate.
- You can drop only user TDE certificates.
- The maximum number of user TDE certificates supported on RDS is 10. If the number exceeds 10, drop unused TDE certificates and try again.
- The certificate name can't be empty or null.
- When restoring a certificate, the certificate name can't include the keyword `RDSTDECERTIFICATE`, and must start with the `UserTDECertificate_` prefix.
- The `@certificate_name` parameter can include only the following characters: a-z, 0-9, @, \$, #, and underscore (`_`).
- The file extension for `@certificate_file_s3_arn` must be `.cer` (case-insensitive).
- The file extension for `@private_key_file_s3_arn` must be `.pvk` (case-insensitive).
- The S3 metadata for the private key file must include the `x-amz-meta-rds-tde-pwd` tag. For more information, see [Backing up and restoring TDE certificates for on-premises databases](#).

## Backing up a TDE certificate

To back up TDE certificates, use the `rds_backup_tde_certificate` stored procedure. It has the following syntax.

```
EXECUTE msdb.dbo.rds_backup_tde_certificate
    @certificate_name='UserTDECertificate_certificate_name |
RDSTDECertificatetimestamp',
    @certificate_file_s3_arn='arn:aws:s3:::bucket_name/certificate_file_name.cer',
    @private_key_file_s3_arn='arn:aws:s3:::bucket_name/key_file_name.pvk',
    @kms_password_key_arn='arn:aws:kms:region:account-id:key/key-id',
    [@overwrite_s3_files=0/1];
```

The following parameters are required:

- `@certificate_name` – The name of the TDE certificate to back up.
- `@certificate_file_s3_arn` – The destination Amazon Resource Name (ARN) for the certificate backup file in Amazon S3.

- `@private_key_file_s3_arn` – The destination S3 ARN of the private key file that secures the TDE certificate.
- `@kms_password_key_arn` – The ARN of the symmetric KMS key used to encrypt the private key password.

The following parameter is optional:

- `@overwrite_s3_files` – Indicates whether to overwrite the existing certificate and private key files in S3:

- `0` – Doesn't overwrite the existing files. This value is the default.

Setting `@overwrite_s3_files` to `0` returns an error if a file already exists.

- `1` – Overwrites an existing file that has the specified name, even if it isn't a backup file.

### Example of backing up a TDE certificate

```
EXECUTE msdb.dbo.rds_backup_tde_certificate
  @certificate_name='RDSTDECertificate20211115T185333',
  @certificate_file_s3_arn='arn:aws:s3::TDE_certs/mycertfile.cer',
  @private_key_file_s3_arn='arn:aws:s3::TDE_certs/mykeyfile.pvk',
  @kms_password_key_arn='arn:aws:kms:us-
west-2:123456789012:key/AKIAIOSFODNN7EXAMPLE',
  @overwrite_s3_files=1;
```

### Restoring a TDE certificate

You use the `rds_restore_tde_certificate` stored procedure to restore (import) user TDE certificates. It has the following syntax.

```
EXECUTE msdb.dbo.rds_restore_tde_certificate
  @certificate_name='UserTDECertificate_certificate_name',
  @certificate_file_s3_arn='arn:aws:s3::bucket_name/certificate_file_name.cer',
  @private_key_file_s3_arn='arn:aws:s3::bucket_name/key_file_name.pvk',
  @kms_password_key_arn='arn:aws:kms:region:account-id:key/key-id';
```

The following parameters are required:

- `@certificate_name` – The name of the TDE certificate to restore. The name must start with the `UserTDECertificate_` prefix.

- `@certificate_file_s3_arn` – The S3 ARN of the backup file used to restore the TDE certificate.
- `@private_key_file_s3_arn` – The S3 ARN of the private key backup file of the TDE certificate to be restored.
- `@kms_password_key_arn` – The ARN of the symmetric KMS key used to encrypt the private key password.

### Example of restoring a TDE certificate

```
EXECUTE msdb.dbo.rds_restore_tde_certificate
  @certificate_name='UserTDECertificate_myTDEcertificate',
  @certificate_file_s3_arn='arn:aws:s3:::TDE_certs/mycertfile.cer',
  @private_key_file_s3_arn='arn:aws:s3:::TDE_certs/mykeyfile.pvk',
  @kms_password_key_arn='arn:aws:kms:us-
west-2:123456789012:key/AKIAIOSFODNN7EXAMPLE';
```

### Viewing restored TDE certificates

You use the `rds_fn_list_user_tde_certificates` function to view restored (imported) user TDE certificates. It has the following syntax.

```
SELECT * FROM msdb.dbo.rds_fn_list_user_tde_certificates();
```

The output resembles the following. Not all columns are shown here.

name	certif te_id	princi _id	pvt_ke ncrypt _type_ c	issuere me	cert_s al_nur t	thumbp t	subjec e	start_ e	expiry te	pvt_key_1 ast_backu p_date

## Dropping restored TDE certificates

To drop restored (imported) user TDE certificates that you aren't using, use the `rds_drop_tde_certificate` stored procedure. It has the following syntax.

```
EXECUTE msdb.dbo.rds_drop_tde_certificate
@certificate_name='UserTDECertificate_certificate_name';
```

The following parameter is required:

- `@certificate_name` – The name of the TDE certificate to drop.

You can drop only restored (imported) TDE certificates. You can't drop RDS-created certificates.

## Example of dropping a TDE certificate

```
EXECUTE msdb.dbo.rds_drop_tde_certificate
@certificate_name='UserTDECertificate_myTDEcertificate';
```

## Backing up and restoring TDE certificates for on-premises databases

You can back up TDE certificates for on-premises databases, then later restore them to RDS for SQL Server. You can also restore an RDS for SQL Server TDE certificate to an on-premises DB instance.

The following procedure backs up a TDE certificate and private key. The private key is encrypted using a data key generated from your symmetric encryption KMS key.

## To back up an on-premises TDE certificate

1. Generate the data key using the AWS CLI [generate-data-key](#) command.

```
aws kms generate-data-key \
  --key-id my_KMS_key_ID \
  --key-spec AES_256
```

The output resembles the following.

```
{
  "CiphertextBlob": "AQIDAHimL2NEoA10Y6Bn7LJfnxi/0Ze9kTQo/
XQXduug1rmerwGiL7g5ux4av9GfZLxYTDATAAAAfjB8BgkqhkiG9w0B
BwagbzBtAgEAMGgGCSqGSIb3DQEHATAeBg1ghkgBZQMEAS4wEQQMyCxLMi7GRZgKqD65AgEQgDtjvZLJo2cQ31Vetng
2RezQy3sAS6ZHrCjfnfn0c65bFdhsXxjSMnudIY7AKw==",
  "Plaintext": "U/fpGtmzGCYBi8A2+0/9qcRQRK2zmG/a0n939ZnKi/0=",
  "KeyId": "arn:aws:kms:us-west-2:123456789012:key/1234abcd-00ee-99ff-88dd-
aa11bb22cc33"
}
```

You use the plain text output in the next step as the private key password.

2. Back up your TDE certificate as shown in the following example.

```
BACKUP CERTIFICATE myOnPremTDEcertificate TO FILE = 'D:\tde-cert-backup.cer'
WITH PRIVATE KEY (
FILE = 'C:\Program Files\Microsoft SQL Server\MSSQL14.MSSQLSERVER\MSSQL\DATA\cert-
backup-key.pvk',
ENCRYPTION BY PASSWORD = 'U/fpGtmzGCYBi8A2+0/9qcRQRK2zmG/a0n939ZnKi/0=');
```

3. Save the certificate backup file to your Amazon S3 certificate bucket.
4. Save the private key backup file to your S3 certificate bucket, with the following tag in the file's metadata:
  - Key – `x-amz-meta-rds-tde-pwd`
  - Value – The `CiphertextBlob` value from generating the data key, as in the following example.

```
AQIDAHimL2NEoA10Y6Bn7LJfnxi/0Ze9kTQo/
XQXduug1rmerwGiL7g5ux4av9GfZLxYTDATAAAAfjB8BgkqhkiG9w0B
BwagbzBtAgEAMGgGCSqGSIb3DQEHATAeBg1ghkgBZQMEAS4wEQQMyCxLMi7GRZgKqD65AgEQgDtjvZLJo2cQ31Vetng
```

```
2RezQy3sAS6ZHrCjfnfn0c65bFdhsXxjSMnudIY7AKw==
```

The following procedure restores an RDS for SQL Server TDE certificate to an on-premises DB instance. You copy and restore the TDE certificate on your destination DB instance using the certificate backup, corresponding private key file, and data key. The restored certificate is encrypted by the database master key of the new server.

### To restore a TDE certificate

1. Copy the TDE certificate backup file and private key file from Amazon S3 to the destination instance. For more information on copying files from Amazon S3, see [Transferring files between RDS for SQL Server and Amazon S3](#).
2. Use your KMS key to decrypt the output cipher text to retrieve the plain text of the data key. The cipher text is located in the S3 metadata of the private key backup file.

```
aws kms decrypt \  
  --key-id my_KMS_key_ID \  
  --ciphertext-blob fileb://exampleCiphertextFile | base64 -d \  
  --output text \  
  --query Plaintext
```

You use the plain text output in the next step as the private key password.

3. Use the following SQL command to restore your TDE certificate.

```
CREATE CERTIFICATE myOnPremTDEcertificate FROM FILE='D:\tde-cert-backup.cer'  
WITH PRIVATE KEY (FILE = N'D:\tde-cert-key.pvk',  
DECRYPTION BY PASSWORD = 'plain_text_output');
```

For more information on KMS decryption, see [decrypt](#) in the KMS section of the *AWS CLI Command Reference*.

After the TDE certificate is restored on the destination DB instance, you can restore encrypted databases with that certificate.

**Note**

You can use the same TDE certificate to encrypt multiple SQL Server databases on the source DB instance. To migrate multiple databases to a destination instance, copy the TDE certificate associated with them to the destination instance only once.

## Turning off TDE for RDS for SQL Server

To turn off TDE for an RDS for SQL Server DB instance, first make sure that there are no encrypted objects left on the DB instance. To do so, either decrypt the objects or drop them. If any encrypted objects exist on the DB instance, you can't turn off TDE for the DB instance. When you use the console to remove the TDE option from an option group, the console indicates that it's processing. In addition, an error event is created if the option group is associated with an encrypted DB instance or DB snapshot.

The following example removes the TDE encryption from a database called `customerDatabase`.

```
----- Removing TDE -----  
  
USE [customerDatabase]  
GO  
  
-- Turn off encryption of the database  
ALTER DATABASE [customerDatabase]  
SET ENCRYPTION OFF  
GO  
  
-- Wait until the encryption state of the database becomes 1. The state is 5  
  (Decryption in progress) for a while  
SELECT db_name(database_id) as DatabaseName, * FROM sys.dm_database_encryption_keys  
GO  
  
-- Drop the DEK used for encryption  
DROP DATABASE ENCRYPTION KEY  
GO  
  
-- Alter to SIMPLE Recovery mode so that your encrypted log gets truncated  
USE [master]  
GO  
ALTER DATABASE [customerDatabase] SET RECOVERY SIMPLE
```

GO

When all objects are decrypted, you have two options:

1. You can modify the DB instance to be associated with an option group without the TDE option.
2. You can remove the TDE option from the option group.

## SQL Server Audit

In Amazon RDS, you can audit Microsoft SQL Server databases by using the built-in SQL Server auditing mechanism. You can create audits and audit specifications in the same way that you create them for on-premises database servers.

RDS uploads the completed audit logs to your S3 bucket, using the IAM role that you provide. If you enable retention, RDS keeps your audit logs on your DB instance for the configured period of time.

For more information, see [SQL Server Audit \(database engine\)](#) in the Microsoft SQL Server documentation.

### SQL Server Audit with Database Activity Streams

You can use Database Activity Streams for RDS to integrate SQL Server Audit events with database activity monitoring tools from Imperva, McAfee, and IBM. For more information about auditing with Database Activity Streams for RDS SQL Server, see [Auditing in Microsoft SQL Server](#)

#### Topics

- [Support for SQL Server Audit](#)
- [Adding SQL Server Audit to the DB instance options](#)
- [Using SQL Server Audit](#)
- [Viewing audit logs](#)
- [Using SQL Server Audit with Multi-AZ instances](#)
- [Configuring an S3 bucket](#)
- [Manually creating an IAM role for SQL Server Audit](#)

### Support for SQL Server Audit

In Amazon RDS, starting with SQL Server 2016, all editions of SQL Server support server-level audits, and the Enterprise edition also supports database-level audits. Starting with SQL Server 2016 (13.x) SP1, all editions support both server-level and database-level audits. For more information, see [SQL Server Audit \(database engine\)](#) in the SQL Server documentation.

RDS supports configuring the following option settings for SQL Server Audit.

Option setting	Valid values	Description
IAM_ROLE_ARN	A valid Amazon Resource Name (ARN) in the format <code>arn:aws:iam:: <i>account-id</i> :role/<i>role-name</i> .</code>	The ARN of the IAM role that grants access to the S3 bucket where you want to store your audit logs. For more information, see <a href="#">Amazon Resource Names (ARNs)</a> in the <i>AWS General Reference</i> .
S3_BUCKET_ARN	A valid ARN in the format <code>arn:aws:s3::: <i>amzn-s3-demo-bucket</i> </code> or <code>arn:aws:s3::: <i>amzn-s3-demo-bucket</i> /key-prefix</code>	The ARN for the S3 bucket where you want to store your audit logs.
ENABLE_COMPRESSION	true or false	Controls audit log compression. By default, compression is enabled (set to true).
RETENTION_TIME	0 to 840	The retention time (in hours) that SQL Server audit records are kept on your RDS instance. By default, retention is disabled.

## Adding SQL Server Audit to the DB instance options

Enabling SQL Server Audit requires two steps: enabling the option on the DB instance, and enabling the feature inside SQL Server. The process for adding the SQL Server Audit option to a DB instance is as follows:

1. Create a new option group, or copy or modify an existing option group.
2. Add and configure all required options.
3. Associate the option group with the DB instance.

After you add the SQL Server Audit option, you don't need to restart your DB instance. As soon as the option group is active, you can create audits and store audit logs in your S3 bucket.

### To add and configure SQL Server Audit on a DB instance's option group

1. Choose one of the following:
  - Use an existing option group.
  - Create a custom DB option group and use that option group. For more information, see [Creating an option group](#).
2. Add the **SQLSERVER\_AUDIT** option to the option group, and configure the option settings. For more information about adding options, see [Adding an option to an option group](#).
  - For **IAM role**, if you already have an IAM role with the required policies, you can choose that role. To create a new IAM role, choose **Create a New Role**. For information about the required policies, see [Manually creating an IAM role for SQL Server Audit](#).
  - For **Select S3 destination**, if you already have an S3 bucket that you want to use, choose it. To create an S3 bucket, choose **Create a New S3 Bucket**.
  - For **Enable Compression**, leave this option chosen to compress audit files. Compression is enabled by default. To disable compression, clear **Enable Compression**.
  - For **Audit log retention**, to keep audit records on the DB instance, choose this option. Specify a retention time in hours. The maximum retention time is 35 days.
3. Apply the option group to a new or existing DB instance. Choose one of the following:
  - If you are creating a new DB instance, apply the option group when you launch the instance.
  - On an existing DB instance, apply the option group by modifying the instance and then attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](#).

### Modifying the SQL Server Audit option

After you enable the SQL Server Audit option, you can modify the settings. For information about how to modify option settings, see [Modifying an option setting](#).

### Removing SQL Server Audit from the DB instance options

You can turn off the SQL Server Audit feature by disabling audits and then deleting the option.

## To remove auditing

1. Disable all of the audit settings inside SQL Server. To learn where audits are running, query the SQL Server security catalog views. For more information, see [Security catalog views](#) in the Microsoft SQL Server documentation.
2. Delete the SQL Server Audit option from the DB instance. Choose one of the following:
  - Delete the SQL Server Audit option from the option group that the DB instance uses. This change affects all DB instances that use the same option group. For more information, see [Removing an option from an option group](#).
  - Modify the DB instance, and then choose an option group without the SQL Server Audit option. This change affects only the DB instance that you modify. You can specify the default (empty) option group, or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance](#).
3. After you delete the SQL Server Audit option from the DB instance, you don't need to restart the instance. Remove unneeded audit files from your S3 bucket.

## Using SQL Server Audit

You can control server audits, server audit specifications, and database audit specifications the same way that you control them for on-premises database servers.

### Creating audits

You create server audits in the same way that you create them for on-premises database servers. For information about how to create server audits, see [CREATE SERVER AUDIT](#) in the Microsoft SQL Server documentation.

To avoid errors, adhere to the following limitations:

- Don't exceed the maximum number of supported server audits per instance of 50.
- Instruct SQL Server to write data to a binary file.
- Don't use RDS\_ as a prefix in the server audit name.
- For FILEPATH, specify D:\rdsdbdata\SQLAudit.
- For MAXSIZE, specify a size between 2 MB and 50 MB.
- Don't configure MAX\_ROLLOVER\_FILES or MAX\_FILES.

- Don't configure SQL Server to shut down the DB instance if it fails to write the audit record.

## Creating audit specifications

You create server audit specifications and database audit specifications the same way that you create them for on-premises database servers. For information about creating audit specifications, see [CREATE SERVER AUDIT SPECIFICATION](#) and [CREATE DATABASE AUDIT SPECIFICATION](#) in the Microsoft SQL Server documentation.

To avoid errors, don't use RDS\_ as a prefix in the name of the database audit specification or server audit specification.

## Viewing audit logs

Your audit logs are stored in D:\rdsdbdata\SQLAudit.

After SQL Server finishes writing to an audit log file—when the file reaches its size limit—Amazon RDS uploads the file to your S3 bucket. If retention is enabled, Amazon RDS moves the file into the retention folder: D:\rdsdbdata\SQLAudit\transmitted.

For information about configuring retention, see [Adding SQL Server Audit to the DB instance options](#).

Audit records are kept on the DB instance until the audit log file is uploaded. You can view the audit records by running the following command.

```
SELECT *
FROM msdb.dbo.rds_fn_get_audit_file
      ('D:\rdsdbdata\SQLAudit\*.sqlaudit'
      , default
      , default )
```

You can use the same command to view audit records in your retention folder by changing the filter to D:\rdsdbdata\SQLAudit\transmitted\\*.sqlaudit.

```
SELECT *
FROM msdb.dbo.rds_fn_get_audit_file
      ('D:\rdsdbdata\SQLAudit\transmitted\*.sqlaudit'
      , default
```

```
, default )
```

## Using SQL Server Audit with Multi-AZ instances

For Multi-AZ instances, the process for sending audit log files to Amazon S3 is similar to the process for Single-AZ instances. However, there are some important differences:

- Database audit specification objects are replicated to all nodes.
- Server audits and server audit specifications aren't replicated to secondary nodes. Instead, you have to create or modify them manually.

To capture server audits or a server audit specification from both nodes:

1. Create a server audit or a server audit specification on the primary node.
2. Fail over to the secondary node and create a server audit or a server audit specification with the same name and GUID on the secondary node. Use the `AUDIT_GUID` parameter to specify the GUID.

## Configuring an S3 bucket

The audit log files are automatically uploaded from the DB instance to your S3 bucket. The following restrictions apply to the S3 bucket that you use as a target for audit files:

- It must be in the same AWS Region as the DB instance.
- It must not be open to the public.
- The bucket owner must also be the IAM role owner.
- Your IAM role must have permissions for the customer-managed KMS key associated with the S3 bucket server-side encryption.

The target key that is used to store the data follows this naming schema: *amzn-s3-demo-bucket*/key-prefix/instance-name/audit-name/node\_file-name.ext

### Note

You set both the bucket name and the key prefix values with the `(S3_BUCKET_ARN)` option setting.

The schema is composed of the following elements:

- ***amzn-s3-demo-bucket*** – The name of your S3 bucket.
- **key-prefix** – The custom key prefix you want to use for audit logs.
- **instance-name** – The name of your Amazon RDS instance.
- **audit-name** – The name of the audit.
- **node** – The identifier of the node that is the source of the audit logs (node1 or node2). There is one node for a Single-AZ instance and two replication nodes for a Multi-AZ instance. These are not primary and secondary nodes, because the roles of primary and secondary change over time. Instead, the node identifier is a simple label.
  - **node1** – The first replication node (Single-AZ has one node only).
  - **node2** – The second replication node (Multi-AZ has two nodes).
- **file-name** – The target file name. The file name is taken as-is from SQL Server.
- **ext** – The extension of the file (zip or sqlaudit):
  - **zip** – If compression is enabled (default).
  - **sqlaudit** – If compression is disabled.

## Manually creating an IAM role for SQL Server Audit

Typically, when you create a new option, the AWS Management Console creates the IAM role and the IAM trust policy for you. However, you can manually create a new IAM role to use with SQL Server Audits, so that you can customize it with any additional requirements you might have. To do this, you create an IAM role and delegate permissions so that the Amazon RDS service can use your Amazon S3 bucket. When you create this IAM role, you attach trust and permissions policies. The trust policy allows Amazon RDS to assume this role. The permission policy defines the actions that this role can do. For more information, see [Creating a role to delegate permissions to an AWS service](#) in the *AWS Identity and Access Management User Guide*.

You can use the examples in this section to create the trust relationships and permissions policies you need.

The following example shows a trust relationship for SQL Server Audit. It uses the *service principal* `rds.amazonaws.com` to allow RDS to write to the S3 bucket. A *service principal* is an identifier that is used to grant permissions to a service. Anytime you allow access to `rds.amazonaws.com` in this way, you are allowing RDS to perform an action on your behalf. For more information about service principals, see [AWS JSON policy elements: Principal](#).

## Example trust relationship for SQL Server Audit

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

We recommend using the [aws:SourceArn](#) and [aws:SourceAccount](#) global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the [confused deputy problem](#).

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role. For SQL Server Audit, make sure to include both the DB option group and the DB instances, as shown in the following example.

## Example trust relationship with global condition context key for SQL Server Audit

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
```

```

        "Service": "rds.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
        "StringEquals": {
            "aws:SourceArn": [
                "arn:aws:rds:Region:my_account_ID:db:db_instance_identifier",
                "arn:aws:rds:Region:my_account_ID:og:option_group_name"
            ]
        }
    }
}
]
}

```

In the following example of a permissions policy for SQL Server Audit, we specify an ARN for the Amazon S3 bucket. You can use ARNs to identify a specific account, user, or role that you want grant access to. For more information about using ARNs, see [Amazon resource names \(ARNs\)](#).

### Example permissions policy for SQL Server Audit

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "s3:ListAllMyBuckets",
      "Resource": "*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket",
        "s3:GetBucketACL",
        "s3:GetBucketLocation"
      ],
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:ListMultipartUploadParts",

```

```
        "s3:AbortMultipartUpload"
    ],
    "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/key_prefix/*"
}
]
```

**Note**

The `s3:ListAllMyBuckets` action is required for verifying that the same AWS account owns both the S3 bucket and the SQL Server DB instance. The action lists the names of the buckets in the account.

S3 bucket namespaces are global. If you accidentally delete your bucket, another user can create a bucket with the same name in a different account. Then the SQL Server Audit data is written to the new bucket.

# Support for SQL Server Analysis Services in Amazon RDS for SQL Server

Microsoft SQL Server Analysis Services (SSAS) is part of the Microsoft Business Intelligence (MSBI) suite. SSAS is an online analytical processing (OLAP) and data mining tool that is installed within SQL Server. You use SSAS to analyze data to help make business decisions. SSAS differs from the SQL Server relational database because SSAS is optimized for queries and calculations common in a business intelligence environment.

You can turn on SSAS for existing or new DB instances. It's installed on the same DB instance as your database engine. For more information on SSAS, see the Microsoft [Analysis services documentation](#).

Amazon RDS supports SSAS for SQL Server Standard and Enterprise Editions on the following versions:

- Tabular mode:
  - SQL Server 2019, version 15.00.4043.16.v1 and higher
  - SQL Server 2017, version 14.00.3223.3.v1 and higher
  - SQL Server 2016, version 13.00.5426.0.v1 and higher
- Multidimensional mode:
  - SQL Server 2019, version 15.00.4153.1.v1 and higher
  - SQL Server 2017, version 14.00.3381.3.v1 and higher
  - SQL Server 2016, version 13.00.5882.1.v1 and higher

- [Restoring an SSAS database](#)
  - [Restoring a DB instance to a specified time](#)
- [Changing the SSAS mode](#)
- [Turning off SSAS](#)
- [Troubleshooting SSAS issues](#)

## Limitations

The following limitations apply to using SSAS on RDS for SQL Server:

- RDS for SQL Server supports running SSAS in Tabular or Multidimensional mode. For more information, see [Comparing tabular and multidimensional solutions](#) in the Microsoft documentation.
- You can only use one SSAS mode at a time. Before changing modes, make sure to delete all of the SSAS databases.

For more information, see [Changing the SSAS mode](#).

- Multi-AZ instances aren't supported.
- Instances must use self-managed Active Directory or AWS Directory Service for Microsoft Active Directory for SSAS authentication. For more information, see [Working with Active Directory with RDS for SQL Server](#).
- Users aren't given SSAS server administrator access, but they can be granted database-level administrator access.
- The only supported port for accessing SSAS is 2383.
- You can't deploy projects directly. We provide an RDS stored procedure to do this. For more information, see [Deploying SSAS projects on Amazon RDS](#).

- Processing during deployment isn't supported.
- Using .xmla files for deployment isn't supported.
- SSAS project input files and database backup output files can only be in the D:\S3 folder on the DB instance.

## Turning on SSAS

Use the following process to turn on SSAS for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the SSAS option to the option group.
3. Associate the option group with the DB instance.
4. Allow inbound access to the virtual private cloud (VPC) security group for the SSAS listener port.
5. Turn on Amazon S3 integration.

## Creating an option group for SSAS

Use the AWS Management Console or the AWS CLI to create an option group that corresponds to the SQL Server engine and version of the DB instance that you plan to use.

### Note

You can also use an existing option group if it's for the correct SQL Server engine and version.

## Console

The following console procedure creates an option group for SQL Server Standard Edition 2017.

### To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** pane, do the following:

- a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **ssas-se-2017**. The name can contain only letters, digits, and hyphens.
  - b. For **Description**, enter a brief description of the option group, such as **SSAS option group for SQL Server SE 2017**. The description is used for display purposes.
  - c. For **Engine**, choose **sqlserver-se**.
  - d. For **Major engine version**, choose **14.00**.
5. Choose **Create**.

## CLI

The following CLI example creates an option group for SQL Server Standard Edition 2017.

### To create the option group

- Use one of the following commands.

#### Example

For Linux, macOS, or Unix:

```
aws rds create-option-group \  
  --option-group-name ssas-se-2017 \  
  --engine-name sqlserver-se \  
  --major-engine-version 14.00 \  
  --option-group-description "SSAS option group for SQL Server SE 2017"
```

For Windows:

```
aws rds create-option-group ^  
  --option-group-name ssas-se-2017 ^  
  --engine-name sqlserver-se ^  
  --major-engine-version 14.00 ^  
  --option-group-description "SSAS option group for SQL Server SE 2017"
```

### Adding the SSAS option to the option group

Next, use the AWS Management Console or the AWS CLI to add the SSAS option to the option group.

## Console

### To add the SSAS option

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created.
4. Choose **Add option**.
5. Under **Option details**, choose **SSAS** for **Option name**.
6. Under **Option settings**, do the following:
  - a. For **Max memory**, enter a value in the range 10–80.

**Max memory** specifies the upper threshold above which SSAS begins releasing memory more aggressively to make room for requests that are running, and also new high-priority requests. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80, and the default is 45.

- b. For **Mode**, choose the SSAS server mode, **Tabular** or **Multidimensional**.

If you don't see the **Mode** option setting, it means that Multidimensional mode isn't supported in your AWS Region. For more information, see [Limitations](#).

**Tabular** is the default.

- c. For **Security groups**, choose the VPC security group to associate with the option.

#### Note

The port for accessing SSAS, 2383, is prepopulated.

7. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
8. Choose **Add option**.

## CLI

### To add the SSAS option

1. Create a JSON file, for example `ssas-option.json`, with the following parameters:
  - `OptionGroupName` – The name of option group that you created or chose previously (`ssas-se-2017` in the following example).
  - `Port` – The port that you use to access SSAS. The only supported port is 2383.
  - `VpcSecurityGroupMemberships` – Memberships for VPC security groups for your RDS DB instance.
  - `MAX_MEMORY` – The upper threshold above which SSAS should begin releasing memory more aggressively to make room for requests that are running, and also new high-priority requests. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80, and the default is 45.
  - `MODE` – The SSAS server mode, either `Tabular` or `Multidimensional`. `Tabular` is the default.

If you receive an error that the `MODE` option setting isn't valid, it means that `Multidimensional` mode isn't supported in your AWS Region. For more information, see [Limitations](#).

The following is an example of a JSON file with SSAS option settings.

```
{
  "OptionGroupName": "ssas-se-2017",
  "OptionsToInclude": [
    {
      "OptionName": "SSAS",
      "Port": 2383,
      "VpcSecurityGroupMemberships": ["sg-0abcdef123"],
      "OptionSettings": [{"Name": "MAX_MEMORY", "Value": "60"},
        {"Name": "MODE", "Value": "Multidimensional"}]
    }
  ],
  "ApplyImmediately": true
}
```

2. Add the SSAS option to the option group.

## Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \  
  --cli-input-json file://ssas-option.json \  
  --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^  
  --cli-input-json file://ssas-option.json ^  
  --apply-immediately
```

## Associating the option group with your DB instance

You can use the console or the CLI to associate the option group with your DB instance.

### Console

Associate your option group with a new or existing DB instance:

- For a new DB instance, associate the option group with the DB instance when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
- For an existing DB instance, modify the instance and associate the new option group with it. For more information, see [Modifying an Amazon RDS DB instance](#).

#### Note

If you use an existing instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see [Working with Active Directory with RDS for SQL Server](#).

### CLI

You can associate your option group with a new or existing DB instance.

**Note**

If you use an existing instance, it must already have an Active Directory domain and IAM role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see [Working with Active Directory with RDS for SQL Server](#).

**To create a DB instance that uses the option group**

- Specify the same DB engine type and major version that you used when creating the option group.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-db-instance \  
  --db-instance-identifier myssasinstance \  
  --db-instance-class db.m5.2xlarge \  
  --engine sqlserver-se \  
  --engine-version 14.00.3223.3.v1 \  
  --allocated-storage 100 \  
  --manage-master-user-password \  
  --master-username admin \  
  --storage-type gp2 \  
  --license-model li \  
  --domain-iam-role-name my-directory-iam-role \  
  --domain my-domain-id \  
  --option-group-name ssas-se-2017
```

For Windows:

```
aws rds create-db-instance ^  
  --db-instance-identifier myssasinstance ^  
  --db-instance-class db.m5.2xlarge ^  
  --engine sqlserver-se ^  
  --engine-version 14.00.3223.3.v1 ^  
  --allocated-storage 100 ^  
  --manage-master-user-password ^  
  --master-username admin ^
```

```
--storage-type gp2 ^  
--license-model li ^  
--domain-iam-role-name my-directory-iam-role ^  
--domain my-domain-id ^  
--option-group-name ssas-se-2017
```

## To modify a DB instance to associate the option group

- Use one of the following commands.

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier myssasinstance \  
  --option-group-name ssas-se-2017 \  
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^  
  --db-instance-identifier myssasinstance ^  
  --option-group-name ssas-se-2017 ^  
  --apply-immediately
```

## Allowing inbound access to your VPC security group

Create an inbound rule for the specified SSAS listener port in the VPC security group associated with your DB instance. For more information about setting up security groups, see [Provide access to your DB instance in your VPC by creating a security group](#).

## Enabling Amazon S3 integration

To download model configuration files to your host for deployment, use Amazon S3 integration. For more information, see [Integrating an Amazon RDS for SQL Server DB instance with Amazon S3](#).

## Deploying SSAS projects on Amazon RDS

On RDS, you can't deploy SSAS projects directly by using SQL Server Management Studio (SSMS). To deploy projects, use an RDS stored procedure.

### Note

Using .xmla files for deployment isn't supported.

Before you deploy projects, make sure of the following:

- Amazon S3 integration is turned on. For more information, see [Integrating an Amazon RDS for SQL Server DB instance with Amazon S3](#).
- The Processing Option configuration setting is set to Do Not Process. This setting means that no processing happens after deployment.
- You have both the *myssasproject.asdatabase* and *myssasproject.deploymentoptions* files. They're automatically generated when you build the SSAS project.

### To deploy an SSAS project on RDS

1. Download the .asdatabase (SSAS model) file from your S3 bucket to your DB instance, as shown in the following example. For more information on the download parameters, see [Downloading files from an Amazon S3 bucket to a SQL Server DB instance](#).

```
exec msdb.dbo.rds_download_from_s3
@s3_arn_of_file='arn:aws:s3:::bucket_name/myssasproject.asdatabase',
[@rds_file_path='D:\S3\myssasproject.asdatabase'],
[@overwrite_file=1];
```

2. Download the .deploymentoptions file from your S3 bucket to your DB instance.

```
exec msdb.dbo.rds_download_from_s3
@s3_arn_of_file='arn:aws:s3:::bucket_name/myssasproject.deploymentoptions',
[@rds_file_path='D:\S3\myssasproject.deploymentoptions'],
[@overwrite_file=1];
```

3. Deploy the project.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_DEPLOY_PROJECT',
@file_path='D:\S3\myssasproject.asdatabase';
```

## Monitoring the status of a deployment task

To track the status of your deployment (or download) task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be NULL because it doesn't apply to SSAS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to NULL and the second parameter to 0, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,0);
```

To get a specific task, set the first parameter to NULL and the second parameter to the task ID, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,42);
```

The `rds_fn_task_status` function returns the following information.

Output parameter	Description
<code>task_id</code>	The ID of the task.
<code>task_type</code>	For SSAS, tasks can have the following task types: <ul style="list-style-type: none"> <li>SSAS_DEPLOY_PROJECT</li> <li>SSAS_ADD_DB_ADMIN_MEMBER</li> <li>SSAS_BACKUP_DB</li> <li>SSAS_RESTORE_DB</li> </ul>
<code>database_name</code>	Not applicable to SSAS tasks.
<code>% complete</code>	The progress of the task as a percentage.

Output parameter	Description
duration (mins)	The amount of time spent on the task, in minutes.
lifecycle	<p>The status of the task. Possible statuses are the following:</p> <ul style="list-style-type: none"><li>• <b>CREATED</b> – After you call one of the SSAS stored procedures, a task is created and the status is set to <b>CREATED</b>.</li><li>• <b>IN_PROGRESS</b> – After a task starts, the status is set to <b>IN_PROGRESS</b>. It can take up to five minutes for the status to change from <b>CREATED</b> to <b>IN_PROGRESS</b>.</li><li>• <b>SUCCESS</b> – After a task completes, the status is set to <b>SUCCESS</b>.</li><li>• <b>ERROR</b> – If a task fails, the status is set to <b>ERROR</b>. For more information about the error, see the <code>task_info</code> column.</li><li>• <b>CANCEL_REQUESTED</b> – After you call <code>rds_cancel_task</code>, the status of the task is set to <b>CANCEL_REQUESTED</b>.</li><li>• <b>CANCELLED</b> – After a task is successfully canceled, the status of the task is set to <b>CANCELLED</b>.</li></ul>

Output parameter	Description
task_info	Additional information about the task. If an error occurs during processing, this column contains information about the error.  For more information, see <a href="#">Troubleshooting SSAS issues</a> .
last_updated	The date and time that the task status was last updated.
created_at	The date and time that the task was created.
S3_object_arn	Not applicable to SSAS tasks.
overwrite_S3_backup_file	Not applicable to SSAS tasks.
KMS_master_key_arn	Not applicable to SSAS tasks.
filepath	Not applicable to SSAS tasks.
overwrite_file	Not applicable to SSAS tasks.
task_metadata	Metadata associated with the SSAS task.

## Using SSAS on Amazon RDS

After deploying the SSAS project, you can directly process the OLAP database on SSMS.

### To use SSAS on RDS

1. In SSMS, connect to SSAS using the user name and password for the Active Directory domain.
2. Expand **Databases**. The newly deployed SSAS database appears.
3. Locate the connection string, and update the user name and password to give access to the source SQL database. Doing this is required for processing SSAS objects.

- a. For Tabular mode, do the following:
  1. Expand the **Connections** tab.
  2. Open the context (right-click) menu for the connection object, and then choose **Properties**.
  3. Update the user name and password in the connection string.
- b. For Multidimensional mode, do the following:
  1. Expand the **Data Sources** tab.
  2. Open the context (right-click) menu for the data source object, and then choose **Properties**.
  3. Update the user name and password in the connection string.
4. Open the context (right-click) menu for the SSAS database that you created and choose **Process Database**.

Depending on the size of the input data, the processing operation might take several minutes to complete.

## Topics

- [Setting up a Windows-authenticated user for SSAS](#)
- [Adding a domain user as a database administrator](#)
- [Creating an SSAS proxy](#)
- [Scheduling SSAS database processing using SQL Server Agent](#)
- [Revoking SSAS access from the proxy](#)

## Setting up a Windows-authenticated user for SSAS

The main administrator user (sometimes called the master user) can use the following code example to set up a Windows-authenticated login and grant the required procedure permissions. Doing this grants permissions to the domain user to run SSAS customer tasks, use S3 file transfer procedures, create credentials, and work with the SQL Server Agent proxy. For more information, see [Credentials \(database engine\)](#) and [Create a SQL Server Agent proxy](#) in the Microsoft documentation.

You can grant some or all of the following permissions as needed to Windows-authenticated users.

## Example

```
-- Create a server-level domain user login, if it doesn't already exist
USE [master]
GO
CREATE LOGIN [mydomain\user_name] FROM WINDOWS
GO

-- Create domain user, if it doesn't already exist
USE [msdb]
GO
CREATE USER [mydomain\user_name] FOR LOGIN [mydomain\user_name]
GO

-- Grant necessary privileges to the domain user
USE [master]
GO
GRANT ALTER ANY CREDENTIAL TO [mydomain\user_name]
GO

USE [msdb]
GO
GRANT EXEC ON msdb.dbo.rds_msbi_task TO [mydomain\user_name] with grant option
GRANT SELECT ON msdb.dbo.rds_fn_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_cancel_task TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_download_from_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_upload_to_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_delete_from_filesystem TO [mydomain\user_name] with grant
option
GRANT EXEC ON msdb.dbo.rds_gather_file_details TO [mydomain\user_name] with grant
option
GRANT EXEC ON msdb.dbo.sp_add_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_update_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_grant_login_to_proxy TO [mydomain\user_name] with grant
option
GRANT EXEC ON msdb.dbo.sp_revoke_login_from_proxy TO [mydomain\user_name] with grant
option
GRANT EXEC ON msdb.dbo.sp_delete_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_login_for_proxy to [mydomain\user_name] with grant
option
GRANT EXEC ON msdb.dbo.sp_enum_proxy_for_subsystem TO [mydomain\user_name] with grant
option
GRANT EXEC ON msdb.dbo.rds_sqlagent_proxy TO [mydomain\user_name] with grant option
```

```
ALTER ROLE [SQLAgentUserRole] ADD MEMBER [mydomain\user_name]
GO
```

## Adding a domain user as a database administrator

You can add a domain user as an SSAS database administrator in the following ways:

- A database administrator can use SSMS to create a role with admin privileges, then add users to that role.
- You can use the following stored procedure.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_ADD_DB_ADMIN_MEMBER',
@database_name='myssasdb',
@ssas_role_name='exampleRole',
@ssas_role_member='domain_name\domain_user_name';
```

The following parameters are required:

- @task\_type – The type of the MSBI task, in this case SSAS\_ADD\_DB\_ADMIN\_MEMBER.
- @database\_name – The name of the SSAS database to which you're granting administrator privileges.
- @ssas\_role\_name – The SSAS database administrator role name. If the role doesn't already exist, it's created.
- @ssas\_role\_member – The SSAS database user that you're adding to the administrator role.

## Creating an SSAS proxy

To be able to schedule SSAS database processing using SQL Server Agent, create an SSAS credential and an SSAS proxy. Run these procedures as a Windows-authenticated user.

### To create the SSAS credential

- Create the credential for the proxy. To do this, you can use SSMS or the following SQL statement.

```
USE [master]
GO
CREATE CREDENTIAL [SSAS_Credential] WITH IDENTITY = N'mydomain\user_name', SECRET =
N'mysecret'
```

```
GO
```

**Note**

IDENTITY must be a domain-authenticated login. Replace *mysecret* with the password for the domain-authenticated login.

**To create the SSAS proxy**

1. Use the following SQL statement to create the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_add_proxy
    @proxy_name=N'SSAS_Proxy',@credential_name=N'SSAS_Credential',@description=N''
GO
```

2. Use the following SQL statement to grant access to the proxy to other users.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_grant_login_to_proxy
    @proxy_name=N'SSAS_Proxy',@login_name=N'mydomain\user_name'
GO
```

3. Use the following SQL statement to give the SSAS subsystem access to the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
    @task_type='GRANT_SUBSYSTEM_ACCESS',@proxy_name='SSAS_Proxy',@proxy_subsystem='SSAS'
GO
```

**To view the proxy and grants on the proxy**

1. Use the following SQL statement to view the grantees of the proxy.

```
USE [msdb]
GO
```

```
EXEC sp_help_proxy
GO
```

2. Use the following SQL statement to view the subsystem grants.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_enum_proxy_for_subsystem
GO
```

## Scheduling SSAS database processing using SQL Server Agent

After you create the credential and proxy and grant SSAS access to the proxy, you can create a SQL Server Agent job to schedule SSAS database processing.

### To schedule SSAS database processing

- Use SSMS or T-SQL for creating the SQL Server Agent job. The following example uses T-SQL. You can further configure its job schedule through SSMS or T-SQL.
  - The `@command` parameter outlines the XML for Analysis (XMLA) command to be run by the SQL Server Agent job. This example configures SSAS Multidimensional database processing.
  - The `@server` parameter outlines the target SSAS server name of the SQL Server Agent job.

To call the SSAS service within the same RDS DB instance where the SQL Server Agent job resides, use `localhost:2383`.

To call the SSAS service from outside the RDS DB instance, use the RDS endpoint. You can also use the Kerberos Active Directory (AD) endpoint (*your-DB-instance-name.your-AD-domain-name*) if the RDS DB instances are joined by the same domain. For external DB instances, make sure to properly configure the VPC security group associated with the RDS DB instance for a secure connection.

You can further edit the query to support various XMLA operations. Make edits either by directly modifying the T-SQL query or by using the SSMS UI following SQL Server Agent job creation.

```
USE [msdb]
GO
```

```

DECLARE @jobId BINARY(16)
EXEC msdb.dbo.sp_add_job @job_name=N'SSAS_Job',
    @enabled=1,
    @notify_level_eventlog=0,
    @notify_level_email=0,
    @notify_level_netsend=0,
    @notify_level_page=0,
    @delete_level=0,
    @category_name=N'[Uncategorized (Local)]',
    @job_id = @jobId OUTPUT
GO
EXEC msdb.dbo.sp_add_jobserver
    @job_name=N'SSAS_Job',
    @server_name = N'(local)'
GO
EXEC msdb.dbo.sp_add_jobstep @job_name=N'SSAS_Job',
    @step_name=N'Process_SSAS_Object',
    @step_id=1,
    @cmdexec_success_code=0,
    @on_success_action=1,
    @on_success_step_id=0,
    @on_fail_action=2,
    @on_fail_step_id=0,
    @retry_attempts=0,
    @retry_interval=0,
    @os_run_priority=0, @subsystem=N'ANALYSISCOMMAND',
    @command=N'<Batch xmlns="http://schemas.microsoft.com/analysisisservices/2003/
engine">
    <Parallel>
        <Process xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"

analysisservices/2012/engine/400/400" xmlns:ddl500="http://schemas.microsoft.com/
analysisservices/2013/engine/500"
        xmlns:ddl500_500="http://schemas.microsoft.com/
analysisservices/2013/engine/500/500">
        <Object>
            <DatabaseID>Your_SSAS_Database_ID</DatabaseID>
        </Object>
        <Type>ProcessFull</Type>
        <WriteBackTableCreation>UseExisting</WriteBackTableCreation>
    </Process>
</Parallel>
</Batch>',
@server=N'localhost:2383',
@database_name=N'master',
@flags=0,
@proxy_name=N'SSAS_Proxy'
GO

```

## Revoking SSAS access from the proxy

You can revoke access to the SSAS subsystem and delete the SSAS proxy using the following stored procedures.

### To revoke access and delete the proxy

1. Revoke subsystem access.

```

USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
    @task_type='REVOKE_SUBSYSTEM_ACCESS',@proxy_name='SSAS_Proxy',@proxy_subsystem='SSAS'
GO

```

2. Revoke the grants on the proxy.

```

USE [msdb]
GO
EXEC msdb.dbo.sp_revoke_login_from_proxy
    @proxy_name=N'SSAS_Proxy',@name=N'mydomain\user_name'
GO

```

### 3. Delete the proxy.

```
USE [msdb]
GO
EXEC dbo.sp_delete_proxy @proxy_name = N'SSAS_Proxy'
GO
```

## Backing up an SSAS database

You can create SSAS database backup files only in the D:\S3 folder on the DB instance. To move the backup files to your S3 bucket, use Amazon S3.

You can back up an SSAS database as follows:

- A domain user with the admin role for a particular database can use SSMS to back up the database to the D:\S3 folder.

For more information, see [Adding a domain user as a database administrator](#).

- You can use the following stored procedure. This stored procedure doesn't support encryption.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_BACKUP_DB',
@database_name='myssasdb',
@file_path='D:\S3\ssas_db_backup.abf',
[@ssas_apply_compression=1],
[@ssas_overwrite_file=1];
```

The following parameters are required:

- @task\_type – The type of the MSBI task, in this case SSAS\_BACKUP\_DB.
- @database\_name – The name of the SSAS database that you're backing up.
- @file\_path – The path for the SSAS backup file. The .abf extension is required.

The following parameters are optional:

- @ssas\_apply\_compression – Whether to apply SSAS backup compression. Valid values are 1 (Yes) and 0 (No).
- @ssas\_overwrite\_file – Whether to overwrite the SSAS backup file. Valid values are 1 (Yes) and 0 (No).

## Restoring an SSAS database

Use the following stored procedure to restore an SSAS database from a backup.

You can't restore a database if there is an existing SSAS database with the same name. The stored procedure for restoring doesn't support encrypted backup files.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_RESTORE_DB',
@database_name='mynewssasdb',
@file_path='D:\S3\ssas_db_backup.abf';
```

The following parameters are required:

- @task\_type – The type of the MSBI task, in this case SSAS\_RESTORE\_DB.
- @database\_name – The name of the new SSAS database that you're restoring to.
- @file\_path – The path to the SSAS backup file.

### Restoring a DB instance to a specified time

Point-in-time recovery (PITR) doesn't apply to SSAS databases. If you do PITR, only the SSAS data in the last snapshot before the requested time is available on the restored instance.

#### To have up-to-date SSAS databases on a restored DB instance

1. Back up your SSAS databases to the D:\S3 folder on the source instance.
2. Transfer the backup files to the S3 bucket.
3. Transfer the backup files from the S3 bucket to the D:\S3 folder on the restored instance.
4. Run the stored procedure to restore the SSAS databases onto the restored instance.

You can also reprocess the SSAS project to restore the databases.

## Changing the SSAS mode

You can change the mode in which SSAS runs, either Tabular or Multidimensional. To change the mode, use the AWS Management Console or the AWS CLI to modify the options settings in the SSAS option.

**⚠ Important**

You can only use one SSAS mode at a time. Make sure to delete all of the SSAS databases before changing the mode, or you receive an error.

**Console**

The following Amazon RDS console procedure changes the SSAS mode to Tabular and sets the MAX\_MEMORY parameter to 70 percent.

**To modify the SSAS option**

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSAS option that you want to modify (ssas-se-2017 in the previous examples).
4. Choose **Modify option**.
5. Change the option settings:
  - a. For **Max memory**, enter **70**.
  - b. For **Mode**, choose **Tabular**.
6. Choose **Modify option**.

**AWS CLI**

The following AWS CLI example changes the SSAS mode to Tabular and sets the MAX\_MEMORY parameter to 70 percent.

For the CLI command to work, make sure to include all of the required parameters, even if you're not modifying them.

**To modify the SSAS option**

- Use one of the following commands.

## Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \  
  --option-group-name ssas-se-2017 \  
  --options  
  "OptionName=SSAS,VpcSecurityGroupMemberships=sg-12345e67,OptionSettings=[{Name=MAX_MEMORY,  
{Name=MODE,Value=Tabular}]" \  
  --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^  
  --option-group-name ssas-se-2017 ^  
  --options  
  OptionName=SSAS,VpcSecurityGroupMemberships=sg-12345e67,OptionSettings=[{Name=MAX_MEMORY,V  
{Name=MODE,Value=Tabular}] ^  
  --apply-immediately
```

## Turning off SSAS

To turn off SSAS, remove the SSAS option from its option group.

### Important

Before you remove the SSAS option, delete your SSAS databases. We highly recommend that you back up your SSAS databases before deleting them and removing the SSAS option.

## Console

### To remove the SSAS option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.

3. Choose the option group with the SSAS option that you want to remove (`ssas-se-2017` in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **SSAS** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

## AWS CLI

### To remove the SSAS option from its option group

- Use one of the following commands.

#### Example

For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
  --option-group-name ssas-se-2017 \
  --options SSAS \
  --apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group ^
  --option-group-name ssas-se-2017 ^
  --options SSAS ^
  --apply-immediately
```

## Troubleshooting SSAS issues

You might encounter the following issues when using SSAS.

Issue	Type	Troubleshooting suggestions
Unable to configure the SSAS option. The requested SSAS mode	RDS event	You can't change the SSAS mode if you still have SSAS databases that use the current

Issue	Type	Troubleshooting suggestions
<p>is <i>new_mode</i>, but the current DB instance has <i>number current_mode</i> databases. Delete the existing databases before switching to <i>new_mode</i> mode. To regain access to <i>current_mode</i> mode for database deletion, either update the current DB option group, or attach a new option group with %s as the MODE option setting value for the SSAS option.</p>		<p>mode. Delete the SSAS databases, then try again.</p>
<p>Unable to remove the SSAS option because there are <i>number mode</i> existing databases. The SSAS option can't be removed until all SSAS databases are deleted. Add the SSAS option again, delete all SSAS databases, and try again.</p>	RDS event	<p>You can't turn off SSAS if you still have SSAS databases. Delete the SSAS databases , then try again.</p>
<p>The SSAS option isn't enabled or is in the process of being enabled. Try again later.</p>	RDS stored procedure	<p>You can't run SSAS stored procedures when the option is turned off, or when it's being turned on.</p>

Issue	Type	Troubleshooting suggestions
<p>The SSAS option is configured incorrectly. Make sure that the option group membership status is "in-sync" , and review the RDS event logs for relevant SSAS configuration error messages. Following these investigations, try again. If errors continue to occur, contact AWS Support.</p>	<p>RDS stored procedure</p>	<p>You can't run SSAS stored procedures when your option group membership isn't in the in-sync status. This puts the SSAS option in an incorrect configuration state.</p> <p>If your option group membership status changes to failed due to SSAS option modification, there are two possible reasons:</p> <ol style="list-style-type: none"> <li>1. The SSAS option was removed without the SSAS databases being deleted.</li> <li>2. The SSAS mode was updated from Tabular to Multidimensional, or from Multidimensional to Tabular, without the existing SSAS databases being deleted.</li> </ol> <p>Reconfigure the SSAS option, because RDS allows only one SSAS mode at a time, and doesn't support SSAS option removal with SSAS databases present.</p> <p>Check the RDS event logs for configuration errors for your SSAS instance, and resolve the issues accordingly.</p>
<p>Deployment failed. The change can only be deployed on a server running in <i>deployment_file_mode</i> mode. The current server mode is <i>current_mode</i> .</p>	<p>RDS stored procedure</p>	<p>You can't deploy a Tabular database to a Multidimensional server, or a Multidimensional database to a Tabular server.</p> <p>Make sure that you're using files with the correct mode, and verify that the MODE option setting is set to the appropriate value.</p>

Issue	Type	Troubleshooting suggestions
<p>The restore failed. The backup file can only be restored on a server running in <i>restore_file_mode</i> mode. The current server mode is <i>current_mode</i> .</p>	<p>RDS stored procedure</p>	<p>You can't restore a Tabular database to a Multidimensional server, or a Multidimensional database to a Tabular server.</p> <p>Make sure that you're using files with the correct mode, and verify that the MODE option setting is set to the appropriate value.</p>
<p>The restore failed. # Support for SQL Server Integration Services in Amazon RDS for SQL Server

Microsoft SQL Server Integration Services (SSIS) is a component that you can use to perform a broad range of data migration tasks. SSIS is a platform for data integration and workflow applications. It features a data warehousing tool used for data extraction, transformation, and loading (ETL). You can also use this tool to automate maintenance of SQL Server databases and updates to multidimensional cube data.

SSIS projects are organized into packages saved as XML-based .dtsx files. Packages can contain control flows and data flows. You use data flows to represent ETL operations. After deployment, packages are stored in SQL Server in the SSISDB database. SSISDB is an online transaction processing (OLTP) database in the full recovery mode.

Amazon RDS for SQL Server supports running SSIS directly on an RDS DB instance. You can enable SSIS on an existing or new DB instance. SSIS is installed on the same DB instance as your database engine.

RDS supports SSIS for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2022, all versions
- SQL Server 2019, version 15.00.4043.16.v1 and higher
- SQL Server 2017, version 14.00.3223.3.v1 and higher
- SQL Server 2016, version 13.00.5426.0.v1 and higher

## Limitations and recommendations

The following limitations and recommendations apply to running SSIS on RDS for SQL Server:

- The DB instance must have an associated parameter group with the `clr` enabled parameter set to 1. For more information, see [Modifying the parameter for SSIS](#).

### Note

If you enable the `clr` enabled parameter on SQL Server 2017 or 2019, you can't use the common language runtime (CLR) on your DB instance. For more information, see [Features not supported and features with limited support](#).

- The following control flow tasks are supported:
  - Analysis Services Execute DDL Task
  - Analysis Services Processing Task
  - Bulk Insert Task
  - Check Database Integrity Task
  - Data Flow Task
  - Data Mining Query Task
  - Data Profiling Task
  - ~~Execute Package Task~~

- Execute SQL Server Agent Job Task
- Execute SQL Task
- Execute T-SQL Statement Task
- Notify Operator Task
- Rebuild Index Task
- Reorganize Index Task
- Shrink Database Task
- Transfer Database Task
- Transfer Jobs Task
- Transfer Logins Task
- Transfer SQL Server Objects Task
- Update Statistics Task
- Only project deployment is supported.
- Running SSIS packages by using SQL Server Agent is supported.
- SSIS log records can be inserted only into user-created databases.
- Use only the D:\S3 folder for working with files. Files placed in any other directory are deleted. Be aware of a few other file location details:
  - Place SSIS project input and output files in the D:\S3 folder.
  - For the Data Flow Task, change the location for `BLOBTempStoragePath` and `BufferTempStoragePath` to a file inside the D:\S3 folder. The file path must start with D:\S3\.
  - Ensure that all parameters, variables, and expressions used for file connections point to the D:\S3 folder.
  - On Multi-AZ instances, files created by SSIS in the D:\S3 folder are deleted after a failover. For more information, see [Multi-AZ limitations for S3 integration](#).
  - Upload the files created by SSIS in the D:\S3 folder to your Amazon S3 bucket to make them durable.
- Import Column and Export Column transformations and the Script component on the Data Flow Task aren't supported.
- You can't enable dump on running SSIS packages, and you can't add data taps on SSIS packages.

---

The SSIS Scale Out feature isn't supported.

- You can't deploy projects directly. We provide RDS stored procedures to do this. For more information, see [Deploying an SSIS project](#).
- Build SSIS project (.ispac) files with the DoNotSavePasswords protection mode for deploying on RDS.
- SSIS isn't supported on Always On instances with read replicas.
- You can't back up the SSISDB database that is associated with the SSIS option.
- Importing and restoring the SSISDB database from other instances of SSIS isn't supported.
- You can connect to other SQL Server DB instances or to an Oracle data source. Connecting to other database engines, such as MySQL or PostgreSQL, isn't supported for SSIS on RDS for SQL Server. For more information on connecting to an Oracle data source, see [Linked Servers with Oracle OLEDB](#).

## Enabling SSIS

You enable SSIS by adding the SSIS option to your DB instance. Use the following process:

1. Create a new option group, or choose an existing option group.
2. Add the SSIS option to the option group.
3. Create a new parameter group, or choose an existing parameter group.
4. Modify the parameter group to set the `clr enabled` parameter to 1.
5. Associate the option group and parameter group with the DB instance.
6. Enable Amazon S3 integration.

### Note

If a database with the name SSISDB or a reserved SSIS login already exists on the DB instance, you can't enable SSIS on the instance.

## Creating the option group for SSIS

To work with SSIS, create an option group or modify an option group that corresponds to the SQL Server edition and version of the DB instance that you plan to use. To do this, use the AWS Management Console or the AWS CLI.

## Console

The following procedure creates an option group for SQL Server Standard Edition 2016.

### To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** window, do the following:
  - a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **ssis-se-2016**. The name can contain only letters, digits, and hyphens.
  - b. For **Description**, enter a brief description of the option group, such as **SSIS option group for SQL Server SE 2016**. The description is used for display purposes.
  - c. For **Engine**, choose **sqlserver-se**.
  - d. For **Major engine version**, choose **13.00**.
5. Choose **Create**.

## CLI

The following procedure creates an option group for SQL Server Standard Edition 2016.

### To create the option group

- Run one of the following commands.

#### Example

For Linux, macOS, or Unix:

```
aws rds create-option-group \  
  --option-group-name ssis-se-2016 \  
  --engine-name sqlserver-se \  
  --major-engine-version 13.00 \  
  --option-group-description "SSIS option group for SQL Server SE 2016"
```

For Windows:

```
aws rds create-option-group ^
  --option-group-name ssis-se-2016 ^
  --engine-name sqlserver-se ^
  --major-engine-version 13.00 ^
  --option-group-description "SSIS option group for SQL Server SE 2016"
```

## Adding the SSIS option to the option group

Next, use the AWS Management Console or the AWS CLI to add the SSIS option to your option group.

### Console

#### To add the SSIS option

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created, **ssis-se-2016** in this example.
4. Choose **Add option**.
5. Under **Option details**, choose **SSIS** for **Option name**.
6. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
7. Choose **Add option**.

### CLI

#### To add the SSIS option

- Add the SSIS option to the option group.

#### Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \  
  --option-group-name ssis-se-2016 \  
  --option-name SSIS \  
  --option-version 13.00 \  
  --option-scheduling Immediately \  
  --option-maintenance-window 0:00-0:30 \  
  --option-engine sqlserver-se \  
  --option-engine-version 13.00 \  
  --option-description SSIS option group for SQL Server SE 2016
```

```
--options OptionName=SSIS \  
--apply-immediately
```

### For Windows:

```
aws rds add-option-to-option-group ^  
  --option-group-name ssis-se-2016 ^  
  --options OptionName=SSIS ^  
  --apply-immediately
```

## Creating the parameter group for SSIS

Create or modify a parameter group for the `clr` enabled parameter that corresponds to the SQL Server edition and version of the DB instance that you plan to use for SSIS.

### Console

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

#### To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
4. In the **Create parameter group** pane, do the following:
  - a. For **Parameter group family**, choose **sqlserver-se-13.0**.
  - b. For **Group name**, enter an identifier for the parameter group, such as **ssis-sqlserver-se-13**.
  - c. For **Description**, enter **clr enabled parameter group**.
5. Choose **Create**.

### CLI

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

## To create the parameter group

- Run one of the following commands.

### Example

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \  
  --db-parameter-group-name ssis-sqlserver-se-13 \  
  --db-parameter-group-family "sqlserver-se-13.0" \  
  --description "clr enabled parameter group"
```

For Windows:

```
aws rds create-db-parameter-group ^  
  --db-parameter-group-name ssis-sqlserver-se-13 ^  
  --db-parameter-group-family "sqlserver-se-13.0" ^  
  --description "clr enabled parameter group"
```

## Modifying the parameter for SSIS

Modify the `clr enabled` parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance. For SSIS, set the `clr enabled` parameter to 1.

### Console

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016.

### To modify the parameter group

- Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
- In the navigation pane, choose **Parameter groups**.
- Choose the parameter group, such as **ssis-sqlserver-se-13**.
- Under **Parameters**, filter the parameter list for **clr**.
- Choose **clr enabled**.
- Choose **Edit parameters**.

7. From **Values**, choose **1**.
8. Choose **Save changes**.

## CLI

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016.

### To modify the parameter group

- Run one of the following commands.

#### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name ssis-sqlserver-se-13 \  
  --parameters "ParameterName='clr  
enabled',ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^  
  --db-parameter-group-name ssis-sqlserver-se-13 ^  
  --parameters "ParameterName='clr  
enabled',ParameterValue=1,ApplyMethod=immediate"
```

### Associating the option group and parameter group with your DB instance

To associate the SSIS option group and parameter group with your DB instance, use the AWS Management Console or the AWS CLI

#### Note

If you use an existing instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance,

specify an existing Active Directory domain and IAM role. For more information, see [Working with Active Directory with RDS for SQL Server](#).

## Console

To finish enabling SSIS, associate your SSIS option group and parameter group with a new or existing DB instance:

- For a new DB instance, associate them when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
- For an existing DB instance, associate them by modifying the instance. For more information, see [Modifying an Amazon RDS DB instance](#).

## CLI

You can associate the SSIS option group and parameter group with a new or existing DB instance.

### To create an instance with the SSIS option group and parameter group

- Specify the same DB engine type and major version as you used when creating the option group.

### Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \  
  --db-instance-identifier myssisinstance \  
  --db-instance-class db.m5.2xlarge \  
  --engine sqlserver-se \  
  --engine-version 13.00.5426.0.v1 \  
  --allocated-storage 100 \  
  --manage-master-user-password \  
  --master-username admin \  
  --storage-type gp2 \  
  --license-model li \  
  --domain-iam-role-name my-directory-iam-role \  
  --domain my-domain-id \  
  --option-group-name ssis-se-2016 \  
  --
```

```
--db-parameter-group-name ssis-sqlserver-se-13
```

### For Windows:

```
aws rds create-db-instance ^  
  --db-instance-identifier myssisinstance ^  
  --db-instance-class db.m5.2xlarge ^  
  --engine sqlserver-se ^  
  --engine-version 13.00.5426.0.v1 ^  
  --allocated-storage 100 ^  
  --manage-master-user-password ^  
  --master-username admin ^  
  --storage-type gp2 ^  
  --license-model li ^  
  --domain-iam-role-name my-directory-iam-role ^  
  --domain my-domain-id ^  
  --option-group-name ssis-se-2016 ^  
  --db-parameter-group-name ssis-sqlserver-se-13
```

## To modify an instance and associate the SSIS option group and parameter group

- Run one of the following commands.

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier myssisinstance \  
  --option-group-name ssis-se-2016 \  
  --db-parameter-group-name ssis-sqlserver-se-13 \  
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^  
  --db-instance-identifier myssisinstance ^  
  --option-group-name ssis-se-2016 ^  
  --db-parameter-group-name ssis-sqlserver-se-13 ^  
  --apply-immediately
```

## Enabling S3 integration

To download SSIS project (.ispac) files to your host for deployment, use S3 file integration. For more information, see [Integrating an Amazon RDS for SQL Server DB instance with Amazon S3](#).

## Administrative permissions on SSISDB

When the instance is created or modified with the SSIS option, the result is an SSISDB database with the `ssis_admin` and `ssis_logreader` roles granted to the master user. The master user has the following privileges in SSISDB:

- alter on `ssis_admin` role
- alter on `ssis_logreader` role
- alter any user

Because the master user is a SQL-authenticated user, you can't use the master user for executing SSIS packages. The master user can use these privileges to create new SSISDB users and add them to the `ssis_admin` and `ssis_logreader` roles. Doing this is useful for giving access to your domain users for using SSIS.

## Setting up a Windows-authenticated user for SSIS

The master user can use the following code example to set up a Windows-authenticated login in SSISDB and grant the required procedure permissions. Doing this grants permissions to the domain user to deploy and run SSIS packages, use S3 file transfer procedures, create credentials, and work with the SQL Server Agent proxy. For more information, see [Credentials \(database engine\)](#) and [Create a SQL Server Agent proxy](#) in the Microsoft documentation.

### Note

You can grant some or all of the following permissions as needed to Windows-authenticated users.

## Example

```
-- Create a server-level SQL login for the domain user, if it doesn't already exist
USE [master]
GO
CREATE LOGIN [mydomain\user_name] FROM WINDOWS
```

```
GO

-- Create a database-level account for the domain user, if it doesn't already exist

USE [SSISDB]
GO
CREATE USER [mydomain\user_name] FOR LOGIN [mydomain\user_name]

-- Add SSIS role membership to the domain user
ALTER ROLE [ssis_admin] ADD MEMBER [mydomain\user_name]
ALTER ROLE [ssis_logreader] ADD MEMBER [mydomain\user_name]
GO

-- Add MSDB role membership to the domain user
USE [msdb]
GO
CREATE USER [mydomain\user_name] FOR LOGIN [mydomain\user_name]

-- Grant MSDB stored procedure privileges to the domain user
GRANT EXEC ON msdb.dbo.rds_msbi_task TO [mydomain\user_name] with grant option
GRANT SELECT ON msdb.dbo.rds_fn_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_cancel_task TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_download_from_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_upload_to_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_delete_from_filesystem TO [mydomain\user_name] with grant
option
GRANT EXEC ON msdb.dbo.rds_gather_file_details TO [mydomain\user_name] with grant
option
GRANT EXEC ON msdb.dbo.sp_add_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_update_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_grant_login_to_proxy TO [mydomain\user_name] with grant
option
GRANT EXEC ON msdb.dbo.sp_revoke_login_from_proxy TO [mydomain\user_name] with grant
option
GRANT EXEC ON msdb.dbo.sp_delete_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_login_for_proxy to [mydomain\user_name] with grant
option
GRANT EXEC ON msdb.dbo.sp_enum_proxy_for_subsystem TO [mydomain\user_name] with grant
option
GRANT EXEC ON msdb.dbo.rds_sqlagent_proxy TO [mydomain\user_name] WITH GRANT OPTION

-- Add the SQLAgentUserRole privilege to the domain user
```

```
USE [msdb]
GO
ALTER ROLE [SQLAgentUserRole] ADD MEMBER [mydomain\user_name]
GO

-- Grant the ALTER ANY CREDENTIAL privilege to the domain user
USE [master]
GO
GRANT ALTER ANY CREDENTIAL TO [mydomain\user_name]
GO
```

## Deploying an SSIS project

On RDS, you can't deploy SSIS projects directly by using SQL Server Management Studio (SSMS) or SSIS procedures. To download project files from Amazon S3 and then deploy them, use RDS stored procedures.

To run the stored procedures, log in as any user that you granted permissions for running the stored procedures. For more information, see [Setting up a Windows-authenticated user for SSIS](#).

### To deploy the SSIS project

1. Download the project (.ispac) file.

```
exec msdb.dbo.rds_download_from_s3
@s3_arn_of_file='arn:aws:s3:::bucket_name/ssisproject.ispac',
[@rds_file_path='D:\S3\ssisproject.ispac'],
[@overwrite_file=1];
```

2. Submit the deployment task, making sure of the following:

- The folder is present in the SSIS catalog.
- The project name matches the project name that you used while developing the SSIS project.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSIS_DEPLOY_PROJECT',
@folder_name='DEMO',
@project_name='ssisproject',
@file_path='D:\S3\ssisproject.ispac';
```

## Monitoring the status of a deployment task

To track the status of your deployment task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be NULL because it doesn't apply to SSIS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to NULL and the second parameter to 0, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,0);
```

To get a specific task, set the first parameter to NULL and the second parameter to the task ID, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,42);
```

The `rds_fn_task_status` function returns the following information.

Output parameter	Description
<code>task_id</code>	The ID of the task.
<code>task_type</code>	SSIS_DEPLOY_PROJECT
<code>database_name</code>	Not applicable to SSIS tasks.
<code>% complete</code>	The progress of the task as a percentage.
<code>duration (mins)</code>	The amount of time spent on the task, in minutes.
<code>lifecycle</code>	<p>The status of the task. Possible statuses are the following:</p> <ul style="list-style-type: none"> <li> <b>CREATED</b> – After you call the <code>msdb.dbo.rds_msbi_task</code> stored procedure, a task is created and the status is set to <b>CREATED</b>. </li> </ul>

Output parameter	Description
	<ul style="list-style-type: none"> <li>• <b>IN_PROGRESS</b> – After a task starts, the status is set to <b>IN_PROGRESS</b> . It can take up to five minutes for the status to change from <b>CREATED</b> to <b>IN_PROGRESS</b> .</li> <li>• <b>SUCCESS</b> – After a task completes, the status is set to <b>SUCCESS</b>.</li> <li>• <b>ERROR</b> – If a task fails, the status is set to <b>ERROR</b>. For more information about the error, see the <code>task_info</code> column.</li> <li>• <b>CANCEL_REQUESTED</b> – After you call <code>rds_cancel_task</code> , the status of the task is set to <b>CANCEL_REQUESTED</b> .</li> <li>• <b>CANCELLED</b> – After a task is successfully canceled, the status of the task is set to <b>CANCELLED</b> .</li> </ul>
task_info	Additional information about the task. If an error occurs during processing, this column contains information about the error.
last_updated	The date and time that the task status was last updated.
created_at	The date and time that the task was created.
S3_object_arn	Not applicable to SSIS tasks.
overwrite_S3_backup_file	Not applicable to SSIS tasks.
KMS_master_key_arn	Not applicable to SSIS tasks.

Output parameter	Description
filepath	Not applicable to SSIS tasks.
overwrite_file	Not applicable to SSIS tasks.
task_metadata	Metadata associated with the SSIS task.

## Using SSIS

After deploying the SSIS project into the SSIS catalog, you can run packages directly from SSMS or schedule them by using SQL Server Agent. You must use a Windows-authenticated login for executing SSIS packages. For more information, see [Setting up a Windows-authenticated user for SSIS](#).

### Topics

- [Setting database connection managers for SSIS projects](#)
- [Creating an SSIS proxy](#)
- [Scheduling an SSIS package using SQL Server Agent](#)
- [Revoking SSIS access from the proxy](#)

## Setting database connection managers for SSIS projects

When you use a connection manager, you can use these types of authentication:

- For local database connections using AWS Managed Active Directory, you can use SQL authentication or Windows authentication. For Windows authentication, use *DB\_instance\_name.fully\_qualified\_domain\_name* as the server name of the connection string.

An example is `myssisinstance.corp-ad.example.com`, where `myssisinstance` is the DB instance name and `corp-ad.example.com` is the fully qualified domain name.

- For remote connections, always use SQL authentication.

- For local database connections using self-managed Active Directory, you can use SQL authentication or Windows authentication. For Windows authentication, use `.` or `LocalHost` as the server name of the connection string.

## Creating an SSIS proxy

To be able to schedule SSIS packages using SQL Server Agent, create an SSIS credential and an SSIS proxy. Run these procedures as a Windows-authenticated user.

### To create the SSIS credential

- Create the credential for the proxy. To do this, you can use SSMS or the following SQL statement.

```
USE [master]
GO
CREATE CREDENTIAL [SSIS_Credential] WITH IDENTITY = N'mydomain\user_name', SECRET =
N'mysecret'
GO
```

#### Note

IDENTITY must be a domain-authenticated login. Replace *mysecret* with the password for the domain-authenticated login. Whenever the SSISDB primary host is changed, alter the SSIS proxy credentials to allow the new host to access them.

### To create the SSIS proxy

1. Use the following SQL statement to create the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_add_proxy
@proxy_name=N'SSIS_Proxy',@credential_name=N'SSIS_Credential',@description=N''
GO
```

2. Use the following SQL statement to grant access to the proxy to other users.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_grant_login_to_proxy
    @proxy_name=N'SSIS_Proxy',@login_name=N'mydomain\user_name'
GO
```

3. Use the following SQL statement to give the SSIS subsystem access to the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
    @task_type='GRANT_SUBSYSTEM_ACCESS',@proxy_name='SSIS_Proxy',@proxy_subsystem='SSIS'
GO
```

### To view the proxy and grants on the proxy

1. Use the following SQL statement to view the grantees of the proxy.

```
USE [msdb]
GO
EXEC sp_help_proxy
GO
```

2. Use the following SQL statement to view the subsystem grants.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_enum_proxy_for_subsystem
GO
```

### Scheduling an SSIS package using SQL Server Agent

After you create the credential and proxy and grant SSIS access to the proxy, you can create a SQL Server Agent job to schedule the SSIS package.

#### To schedule the SSIS package

- You can use SSMS or T-SQL for creating the SQL Server Agent job. The following example uses T-SQL.

```

USE [msdb]
GO
DECLARE @jobId BINARY(16)
EXEC msdb.dbo.sp_add_job @job_name=N'MYSSISJob',
@enabled=1,
@notify_level_eventlog=0,
@notify_level_email=2,
@notify_level_page=2,
@delete_level=0,
@category_name=N'[Uncategorized (Local)]',
@job_id = @jobId OUTPUT
GO
EXEC msdb.dbo.sp_add_jobserver @job_name=N'MYSSISJob',@server_name=N'(local)'
GO
EXEC msdb.dbo.sp_add_jobstep
@job_name=N'MYSSISJob',@step_name=N'ExecuteSSISPackage',
@step_id=1,
@cmdexec_success_code=0,
@on_success_action=1,
@on_fail_action=2,
@retry_attempts=0,
@retry_interval=0,
@os_run_priority=0,
@subsystem=N'SSIS',
@command=N'/ISSERVER "\\SSISDB\MySSISFolder\MySSISProject\MySSISPackage.dtsx\"'" /
SERVER "\"my-rds-ssis-instance.corp-ad.company.com\"'"
/Par "\"$ServerOption::LOGGING_LEVEL(Int16)\\"";1 /Par
"\"$ServerOption::SYNCHRONIZED(Boolean)\\"";True /CALLERINFO SQLAGENT /REPORTING
E',
@database_name=N'master',
@flags=0,
@proxy_name=N'SSIS_Proxy'
GO

```

## Revoking SSIS access from the proxy

You can revoke access to the SSIS subsystem and delete the SSIS proxy using the following stored procedures.

## To revoke access and delete the proxy

### 1. Revoke subsystem access.

```
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
    @task_type='REVOKE_SUBSYSTEM_ACCESS',@proxy_name='SSIS_Proxy',@proxy_subsystem='SSIS'
GO
```

### 2. Revoke the grants on the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_revoke_login_from_proxy
    @proxy_name=N'SSIS_Proxy',@name=N'mydomain\user_name'
GO
```

### 3. Delete the proxy.

```
USE [msdb]
GO
EXEC dbo.sp_delete_proxy @proxy_name = N'SSIS_Proxy'
GO
```

## Disabling SSIS

To disable SSIS, remove the SSIS option from its option group.

### Important

Removing the option doesn't delete the SSISDB database, so you can safely remove the option without losing the SSIS projects.

You can re-enable the SSIS option after removal to reuse the SSIS projects that were previously deployed to the SSIS catalog.

## Console

The following procedure removes the SSIS option.

## To remove the SSIS option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSIS option (`ssis-se-2016` in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **SSIS** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

## CLI

The following procedure removes the SSIS option.

## To remove the SSIS option from its option group

- Run one of the following commands.

### Example

For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \  
  --option-group-name ssis-se-2016 \  
  --options SSIS \  
  --apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group ^  
  --option-group-name ssis-se-2016 ^  
  --options SSIS ^  
  --apply-immediately
```

## Dropping the SSISDB database

After removing the SSIS option, the SSISDB database isn't deleted. To drop the SSISDB database, use the `rds_drop_ssis_database` stored procedure after removing the SSIS option.

### To drop the SSIS database

- Use the following stored procedure.

```
USE [msdb]
GO
EXEC dbo.rds_drop_ssis_database
GO
```

After dropping the SSISDB database, if you re-enable the SSIS option you get a fresh SSISDB catalog.

# Support for SQL Server Reporting Services in Amazon RDS for SQL Server

Microsoft SQL Server Reporting Services (SSRS) is a server-based application used for report generation and distribution. It's part of a suite of SQL Server services that also includes SQL Server Analysis Services (SSAS) and SQL Server Integration Services (SSIS). SSRS is a service built on top of SQL Server. You can use it to collect data from various data sources and present it in a way that's easily understandable and ready for analysis.

Amazon RDS for SQL Server supports running SSRS directly on RDS DB instances. You can use SSRS with existing or new DB instances.

RDS supports SSRS for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2022, all versions
- SQL Server 2019, version 15.00.4043.16.v1 and higher
- SQL Server 2017, version 14.00.3223.3.v1 and higher
- SQL Server 2016, version 13.00.5820.21.v1 and higher

## Contents

- [Limitations and recommendations](#)
- [Turning on SSRS](#)
  - [Creating an option group for SSRS](#)
  - [Adding the SSRS option to your option group](#)
  - [Associating your option group with your DB instance](#)
  - [Allowing inbound access to your VPC security group](#)
- [Report server databases](#)
- [SSRS log files](#)
- [Accessing the SSRS web portal](#)
  - [Using SSL on RDS](#)
  - [Granting access to domain users](#)
  - [Accessing the web portal](#)
- [Deploying reports to SSRS](#)
- [Configuring the report data source](#)

- [Using SSRS Email to send reports](#)
- [Revoking system-level permissions](#)
- [Monitoring the status of a task](#)
- [Turning off SSRS](#)
- [Deleting the SSRS databases](#)

## Limitations and recommendations

The following limitations and recommendations apply to running SSRS on RDS for SQL Server:

- You can't use SSRS on DB instances that have read replicas.
- Instances must use self-managed Active Directory or AWS Directory Service for Microsoft Active Directory for SSRS web portal and web server authentication. For more information, see [Working with Active Directory with RDS for SQL Server](#).
- You can't back up the reporting server databases that are created with the SSRS option.
- Importing and restoring report server databases from other instances of SSRS isn't supported. For more information, see [Report server databases](#).
- You can't configure SSRS to listen on the default SSL port (443). The allowed values are 1150–49511, except 1234, 1434, 3260, 3343, 3389, and 47001.
- Subscriptions through a Microsoft Windows file share aren't supported.
- Using Reporting Services Configuration Manager isn't supported.
- Creating and modifying roles isn't supported.
- Modifying report server properties isn't supported.
- System administrator and system user roles aren't granted.
- You can't edit system-level role assignments through the web portal.

## Turning on SSRS

Use the following process to turn on SSRS for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the SSRS option to the option group.
3. Associate the option group with the DB instance.

4. Allow inbound access to the virtual private cloud (VPC) security group for the SSRS listener port.

## Creating an option group for SSRS

To work with SSRS, create an option group that corresponds to the SQL Server engine and version of the DB instance that you plan to use. To do this, use the AWS Management Console or the AWS CLI.

### Note

You can also use an existing option group if it's for the correct SQL Server engine and version.

## Console

The following procedure creates an option group for SQL Server Standard Edition 2017.

### To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** pane, do the following:
  - a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **ssrs-se-2017**. The name can contain only letters, digits, and hyphens.
  - b. For **Description**, enter a brief description of the option group, such as **SSRS option group for SQL Server SE 2017**. The description is used for display purposes.
  - c. For **Engine**, choose **sqlserver-se**.
  - d. For **Major engine version**, choose **14.00**.
5. Choose **Create**.

## CLI

The following procedure creates an option group for SQL Server Standard Edition 2017.

## To create the option group

- Run one of the following commands.

### Example

For Linux, macOS, or Unix:

```
aws rds create-option-group \  
  --option-group-name ssrs-se-2017 \  
  --engine-name sqlserver-se \  
  --major-engine-version 14.00 \  
  --option-group-description "SSRS option group for SQL Server SE 2017"
```

For Windows:

```
aws rds create-option-group ^  
  --option-group-name ssrs-se-2017 ^  
  --engine-name sqlserver-se ^  
  --major-engine-version 14.00 ^  
  --option-group-description "SSRS option group for SQL Server SE 2017"
```

## Adding the SSRS option to your option group

Next, use the AWS Management Console or the AWS CLI to add the SSRS option to your option group.

### Console

#### To add the SSRS option

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created, then choose **Add option**.
4. Under **Option details**, choose **SSRS** for **Option name**.
5. Under **Option settings**, do the following:
  - a. Enter the port for the SSRS service to listen on. The default is 8443. For a list of allowed values, see [Limitations and recommendations](#).

- b. Enter a value for **Max memory**.  
  
**Max memory** specifies the upper threshold above which no new memory allocation requests are granted to report server applications. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80.
  - c. For **Security groups**, choose the VPC security group to associate with the option. Use the same security group that is associated with your DB instance.
6. To use SSRS Email to send reports, choose the **Configure email delivery options** check box under **Email delivery in reporting services**, and then do the following:

- a. For **Sender email address**, enter the email address to use in the **From** field of messages sent by SSRS Email.

Specify a user account that has permission to send mail from the SMTP server.

- b. For **SMTP server**, specify the SMTP server or gateway to use.

It can be an IP address, the NetBIOS name of a computer on your corporate intranet, or a fully qualified domain name.

- c. For **SMTP port**, enter the port to use to connect to the mail server. The default is 25.
- d. To use authentication:

- i. Select the **Use authentication** check box.
- ii. For **Secret Amazon Resource Name (ARN)** enter the AWS Secrets Manager ARN for the user credentials.

Use the following format:

**arn:aws:secretsmanager:Region:AccountId:secret:SecretName-6RandomChara**

For example:

**arn:aws:secretsmanager:us-west-2:123456789012:secret:MySecret-a1b2c3**

For more information on creating the secret, see [Using SSRS Email to send reports](#).

- e. Select the **Use Secure Sockets Layer (SSL)** check box to encrypt email messages using SSL.

7. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
8. Choose **Add option**.

## CLI

### To add the SSRS option

1. Create a JSON file, for example `ssrs-option.json`.
  - a. Set the following required parameters:
    - `OptionGroupName` – The name of option group that you created or chose previously (`ssrs-se-2017` in the following example).
    - `Port` – The port for the SSRS service to listen on. The default is 8443. For a list of allowed values, see [Limitations and recommendations](#).
    - `VpcSecurityGroupMemberships` – VPC security group memberships for your RDS DB instance.
    - `MAX_MEMORY` – The upper threshold above which no new memory allocation requests are granted to report server applications. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80.
  - b. (Optional) Set the following parameters to use SSRS Email:
    - `SMTP_ENABLE_EMAIL` – Set to `true` to use SSRS Email. The default is `false`.
    - `SMTP_SENDER_EMAIL_ADDRESS` – The email address to use in the **From** field of messages sent by SSRS Email. Specify a user account that has permission to send mail from the SMTP server.
    - `SMTP_SERVER` – The SMTP server or gateway to use. It can be an IP address, the NetBIOS name of a computer on your corporate intranet, or a fully qualified domain name.
    - `SMTP_PORT` – The port to use to connect to the mail server. The default is 25.
    - `SMTP_USE_SSL` – Set to `true` to encrypt email messages using SSL. The default is `true`.
    - `SMTP_EMAIL_CREDENTIALS_SECRET_ARN` – The Secrets Manager ARN that holds the user credentials. Use the following format:

**arn:aws:secretsmanager:Region:AccountId:secret:SecretName-6RandomCharact**

For more information on creating the secret, see [Using SSRS Email to send reports](#).

- SMTP\_USE\_ANONYMOUS\_AUTHENTICATION – Set to true and don't include SMTP\_EMAIL\_CREDENTIALS\_SECRET\_ARN if you don't want to use authentication.

The default is false when SMTP\_ENABLE\_EMAIL is true.

The following example includes the SSRS Email parameters, using the secret ARN.

```
{
  "OptionGroupName": "ssrs-se-2017",
  "OptionsToInclude": [
    {
      "OptionName": "SSRS",
      "Port": 8443,
      "VpcSecurityGroupMemberships": ["sg-0abcdef123"],
      "OptionSettings": [
        {"Name": "MAX_MEMORY", "Value": "60"},
        {"Name": "SMTP_ENABLE_EMAIL", "Value": "true"},
        {"Name": "SMTP_SENDER_EMAIL_ADDRESS", "Value": "nobody@example.com"},
        {"Name": "SMTP_SERVER", "Value": "email-smtp.us-west-2.amazonaws.com"},
        {"Name": "SMTP_PORT", "Value": "25"},
        {"Name": "SMTP_USE_SSL", "Value": "true"},
        {"Name": "SMTP_EMAIL_CREDENTIALS_SECRET_ARN", "Value":
          "arn:aws:secretsmanager:us-west-2:123456789012:secret:MySecret-a1b2c3"}
      ]
    }
  ],
  "ApplyImmediately": true
}
```

2. Add the SSRS option to the option group.

### Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
  --cli-input-json file://ssrs-option.json \
  --apply-immediately
```

## For Windows:

```
aws rds add-option-to-option-group ^  
  --cli-input-json file://ssrs-option.json ^  
  --apply-immediately
```

## Associating your option group with your DB instance

Use the AWS Management Console or the AWS CLI to associate your option group with your DB instance.

If you use an existing DB instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see [Working with Active Directory with RDS for SQL Server](#).

### Console

You can associate your option group with a new or existing DB instance:

- For a new DB instance, associate the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
- For an existing DB instance, modify the instance and associate the new option group. For more information, see [Modifying an Amazon RDS DB instance](#).

### CLI

You can associate your option group with a new or existing DB instance.

## To create a DB instance that uses your option group

- Specify the same DB engine type and major version as you used when creating the option group.

### Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
```

```
--db-instance-identifier myssrsinstance \  
--db-instance-class db.m5.2xlarge \  
--engine sqlserver-se \  
--engine-version 14.00.3223.3.v1 \  
--allocated-storage 100 \  
--manage-master-user-password \  
--master-username admin \  
--storage-type gp2 \  
--license-model li \  
--domain-iam-role-name my-directory-iam-role \  
--domain my-domain-id \  
--option-group-name ssrs-se-2017
```

### For Windows:

```
aws rds create-db-instance ^  
  --db-instance-identifier myssrsinstance ^  
  --db-instance-class db.m5.2xlarge ^  
  --engine sqlserver-se ^  
  --engine-version 14.00.3223.3.v1 ^  
  --allocated-storage 100 ^  
  --manage-master-user-password ^  
  --master-username admin ^  
  --storage-type gp2 ^  
  --license-model li ^  
  --domain-iam-role-name my-directory-iam-role ^  
  --domain my-domain-id ^  
  --option-group-name ssrs-se-2017
```

## To modify a DB instance to use your option group

- Run one of the following commands.

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier myssrsinstance \  
  --option-group-name ssrs-se-2017 \  
  --apply-immediately
```

## For Windows:

```
aws rds modify-db-instance ^  
  --db-instance-identifier myssrsinstance ^  
  --option-group-name ssrs-se-2017 ^  
  --apply-immediately
```

## Allowing inbound access to your VPC security group

To allow inbound access to the VPC security group associated with your DB instance, create an inbound rule for the specified SSRS listener port. For more information about setting up security groups, see [Provide access to your DB instance in your VPC by creating a security group](#).

## Report server databases

When your DB instance is associated with the SSRS option, two new databases are created on your DB instance:

- `rdsadmin_ReportServer`
- `rdsadmin_ReportServerTempDB`

These databases act as the ReportServer and ReportServerTempDB databases. SSRS stores its data in the ReportServer database and caches its data in the ReportServerTempDB database. For more information, see [Report Server Database](#) in the Microsoft documentation.

RDS owns and manages these databases, so database operations on them such as ALTER and DROP aren't permitted. Access isn't permitted on the `rdsadmin_ReportServerTempDB` database. However, you can perform read operations on the `rdsadmin_ReportServer` database.

## SSRS log files

You can list, view, and download SSRS log files. SSRS log files follow a naming convention of `ReportServerService_timestamp.log`. These report server logs are located in the `D:\rdsdbdata\Log\SSRS` directory. (The `D:\rdsdbdata\Log` directory is also the parent directory for error logs and SQL Server Agent logs.) For more information, see [Viewing and listing database log files](#).

For existing SSRS instances, restarting the SSRS service might be necessary to access report server logs. You can restart the service by updating the SSRS option.

For more information, see [Working with Microsoft SQL Server logs](#).

## Accessing the SSRS web portal

Use the following process to access the SSRS web portal:

1. Turn on Secure Sockets Layer (SSL).
2. Grant access to domain users.
3. Access the web portal using a browser and the domain user credentials.

## Using SSL on RDS

SSRS uses the HTTPS SSL protocol for its connections. To work with this protocol, import an SSL certificate into the Microsoft Windows operating system on your client computer.

For more information on SSL certificates, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#). For more information about using SSL with SQL Server, see [Using SSL with a Microsoft SQL Server DB instance](#).

## Granting access to domain users

In a new SSRS activation, there are no role assignments in SSRS. To give a domain user or user group access to the web portal, RDS provides a stored procedure.

### To grant access to a domain user on the web portal

- Use the following stored procedure.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSRS_GRANT_PORTAL_PERMISSION',
@ssrs_group_or_username=N'AD_domain\user';
```

The domain user or user group is granted the RDS\_SSRS\_ROLE system role. This role has the following system-level tasks granted to it:

- Run reports
- Manage jobs
- Manage shared schedules

- View shared schedules

The item-level role of Content Manager on the root folder is also granted.

## Accessing the web portal

After the `SSRS_GRANT_PORTAL_PERMISSION` task finishes successfully, you have access to the portal using a web browser. The web portal URL has the following format.

```
https://rds_endpoint:port/Reports
```

In this format, the following applies:

- *rds\_endpoint* – The endpoint for the RDS DB instance that you're using with SSRS.

You can find the endpoint on the **Connectivity & security** tab for your DB instance. For more information, see [Connecting to a DB instance running the Microsoft SQL Server database engine](#).

- *port* – The listener port for SSRS that you set in the SSRS option.

## To access the web portal

1. Enter the web portal URL in your browser.

```
https://myssrsinstance.cg034itsfake.us-east-1.rds.amazonaws.com:8443/Reports
```

2. Log in with the credentials for a domain user that you granted access with the `SSRS_GRANT_PORTAL_PERMISSION` task.

## Deploying reports to SSRS

After you have access to the web portal, you can deploy reports to it. You can use the Upload tool in the web portal to upload reports, or deploy directly from [SQL Server data tools \(SSDT\)](#). When deploying from SSDT, ensure the following:

- The user who launched SSDT has access to the SSRS web portal.
- The `TargetServerURL` value in the SSRS project properties is set to the HTTPS endpoint of the RDS DB instance suffixed with `ReportServer`, for example:

```
https://mysrsinstance.cg034itsfake.us-east-1.rds.amazonaws.com:8443/ReportServer
```

## Configuring the report data source

After you deploy a report to SSRS, you should configure the report data source. When configuring the report data source, ensure the following:

- For RDS for SQL Server DB instances joined to AWS Directory Service for Microsoft Active Directory, use the fully qualified domain name (FQDN) as the data source name of the connection string. An example is *mysrsinstance.corp-ad.example.com*, where *mysrsinstance* is the DB instance name and *corp-ad.example.com* is the fully qualified domain name.
- For RDS for SQL Server DB instances joined to self-managed Active Directory, use *.*, or *LocalHost* as the data source name of the connection string.

## Using SSRS Email to send reports

SSRS includes the SSRS Email extension, which you can use to send reports to users.

To configure SSRS Email, use the SSRS option settings. For more information, see [Adding the SSRS option to your option group](#).

After configuring SSRS Email, you can subscribe to reports on the report server. For more information, see [Email delivery in Reporting Services](#) in the Microsoft documentation.

Integration with AWS Secrets Manager is required for SSRS Email to function on RDS. To integrate with Secrets Manager, you create a secret.

### Note

If you change the secret later, you also have to update the SSRS option in the option group.

## To create a secret for SSRS Email

1. Follow the steps in [Create a secret](#) in the *AWS Secrets Manager User Guide*.
  - a. For **Select secret type**, choose **Other type of secrets**.

- b. For **Key/value pairs**, enter the following:
  - **SMTP\_USERNAME** – Enter a user with permission to send mail from the SMTP server.
  - **SMTP\_PASSWORD** – Enter a password for the SMTP user.
- c. For **Encryption key**, don't use the default AWS KMS key. Use your own existing key, or create a new one.

The KMS key policy must allow the `kms:Decrypt` action, for example:

```
{
  "Sid": "Allow use of the key",
  "Effect": "Allow",
  "Principal": {
    "Service": [
      "rds.amazonaws.com"
    ]
  },
  "Action": [
    "kms:Decrypt"
  ],
  "Resource": "*"
}
```

2. Follow the steps in [Attach a permissions policy to a secret](#) in the *AWS Secrets Manager User Guide*. The permissions policy gives the `secretsmanager:GetSecretValue` action to the `rds.amazonaws.com` service principal.

We recommend that you use the `aws:sourceAccount` and `aws:sourceArn` conditions in the policy to avoid the *confused deputy* problem. Use your AWS account for `aws:sourceAccount` and the option group ARN for `aws:sourceArn`. For more information, see [Preventing cross-service confused deputy problems](#).

The following example shows a permissions policy.

```
{
  "Version" : "2012-10-17",
  "Statement" : [ {
    "Effect" : "Allow",
    "Principal" : {
      "Service" : "rds.amazonaws.com"
    }
  },
```

```
"Action" : "secretsmanager:GetSecretValue",
"Resource" : "*",
"Condition" : {
  "StringEquals" : {
    "aws:sourceAccount" : "123456789012"
  },
  "ArnLike" : {
    "aws:sourceArn" : "arn:aws:rds:us-west-2:123456789012:og:ssrs-se-2017"
  }
}
} ]
}
```

For more examples, see [Permissions policy examples for AWS Secrets Manager](#) in the *AWS Secrets Manager User Guide*.

## Revoking system-level permissions

The RDS\_SSRS\_ROLE system role doesn't have sufficient permissions to delete system-level role assignments. To remove a user or user group from RDS\_SSRS\_ROLE, use the same stored procedure that you used to grant the role but use the SSRS\_REVOKE\_PORTAL\_PERMISSION task type.

### To revoke access from a domain user for the web portal

- Use the following stored procedure.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSRS_REVOKE_PORTAL_PERMISSION',
@ssrs_group_or_username=N'AD_domain\user';
```

Doing this deletes the user from the RDS\_SSRS\_ROLE system role. It also deletes the user from the Content Manager item-level role if the user has it.

## Monitoring the status of a task

To track the status of your granting or revoking task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be NULL because it doesn't apply to SSRS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to NULL and the second parameter to 0, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,0);
```

To get a specific task, set the first parameter to NULL and the second parameter to the task ID, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,42);
```

The `rds_fn_task_status` function returns the following information.

Output parameter	Description
<code>task_id</code>	The ID of the task.
<code>task_type</code>	For SSRS, tasks can have the following task types: <ul style="list-style-type: none"> <li>SSRS_GRANT_PORTAL_PERMISSION</li> <li>SSRS_REVOKE_PORTAL_PERMISSION</li> </ul>
<code>database_name</code>	Not applicable to SSRS tasks.
<code>% complete</code>	The progress of the task as a percentage.
<code>duration (mins)</code>	The amount of time spent on the task, in minutes.
<code>lifecycle</code>	The status of the task. Possible statuses are the following: <ul style="list-style-type: none"> <li>CREATED – After you call one of the SSRS stored procedures, a task is created and the status is set to CREATED.</li> <li>IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS . It can take</li> </ul>

Output parameter	Description
	<p>up to five minutes for the status to change from <code>CREATED</code> to <code>IN_PROGRESS</code> .</p> <ul style="list-style-type: none"> <li>• <code>SUCCESS</code> – After a task completes, the status is set to <code>SUCCESS</code>.</li> <li>• <code>ERROR</code> – If a task fails, the status is set to <code>ERROR</code>. For more information about the error, see the <code>task_info</code> column.</li> <li>• <code>CANCEL_REQUESTED</code> – After you call the <code>rds_cancel_task</code> stored procedure, the status of the task is set to <code>CANCEL_REQUESTED</code> .</li> <li>• <code>CANCELLED</code> – After a task is successfully canceled, the status of the task is set to <code>CANCELLED</code> .</li> </ul>
task_info	Additional information about the task. If an error occurs during processing, this column contains information about the error.
last_updated	The date and time that the task status was last updated.
created_at	The date and time that the task was created.
S3_object_arn	Not applicable to SSRS tasks.
overwrite_S3_backup_file	Not applicable to SSRS tasks.
KMS_master_key_arn	Not applicable to SSRS tasks.
filepath	Not applicable to SSRS tasks.
overwrite_file	Not applicable to SSRS tasks.

Output parameter	Description
task_metadata	Metadata associated with the SSRS task.

## Turning off SSRS

To turn off SSRS, remove the SSRS option from its option group. Removing the option doesn't delete the SSRS databases. For more information, see [Deleting the SSRS databases](#).

You can turn SSRS on again by adding back the SSRS option. If you have also deleted the SSRS databases, readding the option on the same DB instance creates new report server databases.

### Console

#### To remove the SSRS option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSRS option (`ssrs-se-2017` in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **SSRS** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

### CLI

#### To remove the SSRS option from its option group

- Run one of the following commands.

#### Example

For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \  
  --option-group-name ssrs-se-2017 \  
  --option-name ssrs
```

```
--options SSRS \  
--apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group ^  
  --option-group-name ssrs-se-2017 ^  
  --options SSRS ^  
  --apply-immediately
```

## Deleting the SSRS databases

Removing the SSRS option doesn't delete the report server databases. To delete them, use the following stored procedure.

To delete the report server databases, be sure to remove the SSRS option first.

### To delete the SSRS databases

- Use the following stored procedure.

```
exec msdb.dbo.rds_drop_ssrs_databases
```

# Support for Microsoft Distributed Transaction Coordinator in RDS for SQL Server

A *distributed transaction* is a database transaction in which two or more network hosts are involved. RDS for SQL Server supports distributed transactions among hosts, where a single host can be one of the following:

- RDS for SQL Server DB instance
- On-premises SQL Server host
- Amazon EC2 host with SQL Server installed
- Any other EC2 host or RDS DB instance with a database engine that supports distributed transactions

In RDS, starting with SQL Server 2012 (version 11.00.5058.0.v1 and later), all editions of RDS for SQL Server support distributed transactions. The support is provided using Microsoft Distributed Transaction Coordinator (MSDTC). For in-depth information about MSDTC, see [Distributed Transaction Coordinator](#) in the Microsoft documentation.

## Contents

- [Limitations](#)
- [Enabling MSDTC](#)
  - [Creating the option group for MSDTC](#)
  - [Adding the MSDTC option to the option group](#)
  - [Creating the parameter group for MSDTC](#)
  - [Modifying the parameter for MSDTC](#)
  - [Associating the option group and parameter group with the DB instance](#)
- [Using distributed transactions](#)
- [Using XA transactions](#)
- [Using transaction tracing](#)
- [Modifying the MSDTC option](#)
- [Disabling MSDTC](#)
- [Troubleshooting MSDTC for RDS for SQL Server](#)

## Limitations

The following limitations apply to using MSDTC on RDS for SQL Server:

- MSDTC isn't supported on instances using SQL Server Database Mirroring. For more information, see [Transactions - availability groups and database mirroring](#).
- The `in-doubt xact resolution` parameter must be set to 1 or 2. For more information, see [Modifying the parameter for MSDTC](#).
- MSDTC requires all hosts participating in distributed transactions to be resolvable using their host names. RDS automatically maintains this functionality for domain-joined instances. However, for standalone instances make sure to configure the DNS server manually.
- Java Database Connectivity (JDBC) XA transactions are supported for SQL Server 2017 version 14.00.3223.3 and higher, and SQL Server 2019.
- Distributed transactions that depend on client dynamic link libraries (DLLs) on RDS instances aren't supported.
- Using custom XA dynamic link libraries isn't supported.

## Enabling MSDTC

Use the following process to enable MSDTC for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the MSDTC option to the option group.
3. Create a new parameter group, or choose an existing parameter group.
4. Modify the parameter group to set the `in-doubt xact resolution` parameter to 1 or 2.
5. Associate the option group and parameter group with the DB instance.

## Creating the option group for MSDTC

Use the AWS Management Console or the AWS CLI to create an option group that corresponds to the SQL Server engine and version of your DB instance.

**Note**

You can also use an existing option group if it's for the correct SQL Server engine and version.

**Console**

The following procedure creates an option group for SQL Server Standard Edition 2016.

**To create the option group**

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** pane, do the following:
  - a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **msdtc-se-2016**. The name can contain only letters, digits, and hyphens.
  - b. For **Description**, enter a brief description of the option group, such as **MSDTC option group for SQL Server SE 2016**. The description is used for display purposes.
  - c. For **Engine**, choose **sqlserver-se**.
  - d. For **Major engine version**, choose **13.00**.
5. Choose **Create**.

**CLI**

The following example creates an option group for SQL Server Standard Edition 2016.

**To create the option group**

- Use one of the following commands.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-option-group \  
  --option-group-name msdtc-se-2016 \  
  --engine-name sqlserver-se \  
  --major-engine-version 13.00 \  
  --option-group-description "MSDTC option group for SQL Server SE 2016"
```

For Windows:

```
aws rds create-option-group ^  
  --option-group-name msdtc-se-2016 ^  
  --engine-name sqlserver-se ^  
  --major-engine-version 13.00 ^  
  --option-group-description "MSDTC option group for SQL Server SE 2016"
```

## Adding the MSDTC option to the option group

Next, use the AWS Management Console or the AWS CLI to add the MSDTC option to the option group.

The following option settings are required:

- **Port** – The port that you use to access MSDTC. Allowed values are 1150–49151 except for 1234, 1434, 3260, 3343, 3389, and 47001. The default value is 5000.

Make sure that the port you want to use is enabled in your firewall rules. Also, make sure as needed that this port is enabled in the inbound and outbound rules for the security group associated with your DB instance. For more information, see [Can't connect to Amazon RDS DB instance](#).

- **Security groups** – The VPC security group memberships for your RDS DB instance.
- **Authentication type** – The authentication mode between hosts. The following authentication types are supported:
  - **Mutual** – The RDS instances are mutually authenticated to each other using integrated authentication. If this option is selected, all instances associated with this option group must be domain-joined.
  - **None** – No authentication is performed between hosts. We don't recommend using this mode in production environments.

- **Transaction log size** – The size of the MSDTC transaction log. Allowed values are 4–1024 MB. The default size is 4 MB.

The following option settings are optional:

- **Enable inbound connections** – Whether to allow inbound MSDTC connections to instances associated with this option group.
- **Enable outbound connections** – Whether to allow outbound MSDTC connections from instances associated with this option group.
- **Enable XA** – Whether to allow XA transactions. For more information on the XA protocol, see [XA specification](#).
- **Enable SNA LU** – Whether to allow the SNA LU protocol to be used for distributed transactions. For more information on SNA LU protocol support, see [Managing IBM CICS LU 6.2 transactions](#) in the Microsoft documentation.

## Console

### To add the MSDTC option

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created.
4. Choose **Add option**.
5. Under **Option details**, choose **MSDTC** for **Option name**.
6. Under **Option settings**:
  - a. For **Port**, enter the port number for accessing MSDTC. The default is **5000**.
  - b. For **Security groups**, choose the VPC security group to associate with the option.
  - c. For **Authentication type**, choose **Mutual** or **None**.
  - d. For **Transaction log size**, enter a value from 4–1024. The default is **4**.
7. Under **Additional configuration**, do the following:
  - a. For **Connections**, as needed choose **Enable inbound connections** and **Enable outbound connections**.

- b. For **Allowed protocols**, as needed choose **Enable XA** and **Enable SNA LU**.
8. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
9. Choose **Add option**.

To add this option, no reboot is required.

## CLI

### To add the MSDTC option

1. Create a JSON file, for example `msdtc-option.json`, with the following required parameters.

```
{
  "OptionGroupName": "msdtc-se-2016",
  "OptionsToInclude": [
    {
      "OptionName": "MSDTC",
      "Port": 5000,
      "VpcSecurityGroupMemberships": ["sg-0abcdef123"],
      "OptionSettings": [{"Name": "AUTHENTICATION", "Value": "MUTUAL"},
        {"Name": "TRANSACTION_LOG_SIZE", "Value": "4"}]
    }
  ],
  "ApplyImmediately": true
}
```

2. Add the MSDTC option to the option group.

### Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
  --cli-input-json file://msdtc-option.json \
  --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
```

```
--cli-input-json file://msdtc-option.json ^  
--apply-immediately
```

No reboot is required.

## Creating the parameter group for MSDTC

Create or modify a parameter group for the `in-doubt xact resolution` parameter that corresponds to the SQL Server edition and version of your DB instance.

### Console

The following example creates a parameter group for SQL Server Standard Edition 2016.

#### To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
4. In the **Create parameter group** pane, do the following:
  - a. For **Parameter group family**, choose **sqlserver-se-13.0**.
  - b. For **Group name**, enter an identifier for the parameter group, such as **msdtc-sqlserver-se-13**.
  - c. For **Description**, enter **in-doubt xact resolution**.
5. Choose **Create**.

### CLI

The following example creates a parameter group for SQL Server Standard Edition 2016.

#### To create the parameter group

- Use one of the following commands.

#### Example

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \  
  --db-parameter-group-name msdtc-sqlserver-se-13 \  
  --db-parameter-group-family "sqlserver-se-13.0" \  
  --description "in-doubt xact resolution"
```

For Windows:

```
aws rds create-db-parameter-group ^  
  --db-parameter-group-name msdtc-sqlserver-se-13 ^  
  --db-parameter-group-family "sqlserver-se-13.0" ^  
  --description "in-doubt xact resolution"
```

## Modifying the parameter for MSDTC

Modify the `in-doubt xact resolution` parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

For MSDTC, set the `in-doubt xact resolution` parameter to one of the following:

- 1 – `Presume commit`. Any MSDTC in-doubt transactions are presumed to have committed.
- 2 – `Presume abort`. Any MSDTC in-doubt transactions are presumed to have stopped.

For more information, see [in-doubt xact resolution server configuration option](#) in the Microsoft documentation.

## Console

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

### To modify the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group, such as **msdtc-sqlserver-se-13**.
4. Under **Parameters**, filter the parameter list for **xact**.

5. Choose **in-doubt xact resolution**.
6. Choose **Edit parameters**.
7. Enter **1** or **2**.
8. Choose **Save changes**.

## CLI

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

### To modify the parameter group

- Use one of the following commands.

#### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name msdtc-sqlserver-se-13 \  
  --parameters "ParameterName='in-doubt xact  
resolution',ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^  
  --db-parameter-group-name msdtc-sqlserver-se-13 ^  
  --parameters "ParameterName='in-doubt xact  
resolution',ParameterValue=1,ApplyMethod=immediate"
```

## Associating the option group and parameter group with the DB instance

You can use the AWS Management Console or the AWS CLI to associate the MSDTC option group and parameter group with the DB instance.

### Console

You can associate the MSDTC option group and parameter group with a new or existing DB instance.

- For a new DB instance, associate them when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
- For an existing DB instance, associate them by modifying the instance. For more information, see [Modifying an Amazon RDS DB instance](#).

**Note**

If you use an domain-joined existing DB instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new domain-joined instance, specify an existing Active Directory domain and IAM role. For more information, see [Working with AWS Managed Active Directory with RDS for SQL Server](#).

**CLI**

You can associate the MSDTC option group and parameter group with a new or existing DB instance.

**Note**

If you use an existing domain-joined DB instance, it must already have an Active Directory domain and IAM role associated with it. If you create a new domain-joined instance, specify an existing Active Directory domain and IAM role. For more information, see [Working with AWS Managed Active Directory with RDS for SQL Server](#).

**To create a DB instance with the MSDTC option group and parameter group**

- Specify the same DB engine type and major version as you used when creating the option group.

**Example**

For Linux, macOS, or Unix:

```
aws rds create-db-instance \  
  --db-instance-identifier mydbinstance \  
  --db-instance-class db.m5.2xlarge \  
  --option-group-name msdctc-og \  
  --parameter-group-name msdctc-pg \  
  --tags Key=Value
```

```

--engine sqlserver-se \
--engine-version 13.00.5426.0.v1 \
--allocated-storage 100 \
--manage-master-user-password \
--master-username admin \
--storage-type gp2 \
--license-model li \
--domain-iam-role-name my-directory-iam-role \
--domain my-domain-id \
--option-group-name msdtc-se-2016 \
--db-parameter-group-name msdtc-sqlserver-se-13

```

### For Windows:

```

aws rds create-db-instance ^
--db-instance-identifier mydbinstance ^
--db-instance-class db.m5.2xlarge ^
--engine sqlserver-se ^
--engine-version 13.00.5426.0.v1 ^
--allocated-storage 100 ^
--manage-master-user-password ^
--master-username admin ^
--storage-type gp2 ^
--license-model li ^
--domain-iam-role-name my-directory-iam-role ^
--domain my-domain-id ^
--option-group-name msdtc-se-2016 ^
--db-parameter-group-name msdtc-sqlserver-se-13

```

## To modify a DB instance and associate the MSDTC option group and parameter group

- Use one of the following commands.

### Example

For Linux, macOS, or Unix:

```

aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--option-group-name msdtc-se-2016 \
--db-parameter-group-name msdtc-sqlserver-se-13 \

```

```
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^  
  --db-instance-identifier mydbinstance ^  
  --option-group-name msdtc-se-2016 ^  
  --db-parameter-group-name msdtc-sqlserver-se-13 ^  
  --apply-immediately
```

## Using distributed transactions

In Amazon RDS for SQL Server, you run distributed transactions in the same way as distributed transactions running on-premises:

- Using .NET framework `System.Transactions` promotable transactions, which optimizes distributed transactions by deferring their creation until they're needed.

In this case, promotion is automatic and doesn't require you to make any intervention. If there's only one resource manager within the transaction, no promotion is performed. For more information about implicit transaction scopes, see [Implementing an implicit transaction using transaction scope](#) in the Microsoft documentation.

Promotable transactions are supported with these .NET implementations:

- Starting with ADO.NET 2.0, `System.Data.SqlClient` supports promotable transactions with SQL Server. For more information, see [System.Transactions integration with SQL Server](#) in the Microsoft documentation.
- ODP.NET supports `System.Transactions`. A local transaction is created for the first connection opened in the `TransactionScope` scope to Oracle Database 11g release 1 (version 11.1) and later. When a second connection is opened, this transaction is automatically promoted to a distributed transaction. For more information about distributed transaction support in ODP.NET, see [Microsoft Distributed Transaction Coordinator integration](#) in the Microsoft documentation.
- Using the `BEGIN DISTRIBUTED TRANSACTION` statement. For more information, see [BEGIN DISTRIBUTED TRANSACTION \(Transact-SQL\)](#) in the Microsoft documentation.

## Using XA transactions

Starting from RDS for SQL Server 2017 version 14.00.3223.3, you can control distributed transactions using JDBC. When you set the `Enable XA` option setting to `true` in the MSDTC option, RDS automatically enables JDBC transactions and grants the `SqlJDBCXAUser` role to the guest user. This allows executing distributed transactions through JDBC. For more information, including a code example, see [Understanding XA transactions](#) in the Microsoft documentation.

## Using transaction tracing

RDS supports controlling MSDTC transaction traces and downloading them from the RDS DB instance for troubleshooting. You can control transaction tracing sessions by running the following RDS stored procedure.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'trace_action',
[@traceall='0/1'],
[@traceaborted='0/1'],
[@tracelong='0/1'];
```

The following parameter is required:

- `trace_action` – The tracing action. It can be `START`, `STOP`, or `STATUS`.

The following parameters are optional:

- `@traceall` – Set to 1 to trace all distributed transactions. The default is 0.
- `@traceaborted` – Set to 1 to trace canceled distributed transactions. The default is 0.
- `@tracelong` – Set to 1 to trace long-running distributed transactions. The default is 0.

### Example of `START` tracing action

To start a new transaction tracing session, run the following example statement.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'START',
@traceall='0',
@traceaborted='1',
@tracelong='1';
```

**Note**

Only one transaction tracing session can be active at one time. If a new tracing session START command is issued while a tracing session is active, an error is returned and the active tracing session remains unchanged.

**Example of STOP tracing action**

To stop a transaction tracing session, run the following statement.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'STOP'
```

This statement stops the active transaction tracing session and saves the transaction trace data into the log directory on the RDS DB instance. The first row of the output contains the overall result, and the following lines indicate details of the operation.

The following is an example of a successful tracing session stop.

**OK: Trace session has been successfully stopped.**

```
Setting log file to: D:\rdsdbdata\MSDTC\Trace\dtctrace.log
Examining D:\rdsdbdata\MSDTC\Trace\msdtctr.mof for message formats, 8 found.
Searching for TMF files on path: (null)
Logfile D:\rdsdbdata\MSDTC\Trace\dtctrace.log:
OS version      10.0.14393 (Currently running on 6.2.9200)
Start Time      <timestamp>
End Time        <timestamp>
Timezone is     @tzres.dll,-932 (Bias is 0mins)
BufferSize      16384 B
Maximum File Size 10 MB
Buffers Written  Not set (Logger may not have been stopped).
Logger Mode Settings (11000002) ( circular paged
ProcessorCount  1
Processing completed Buffers: 1, Events: 3, EventsLost: 0 :: Format Errors: 0,
Unknowns: 3
Event traces dumped to d:\rdsdbdata\Log\msdtc_<timestamp>.log
```

You can use the detailed information to query the name of the generated log file. For more information about downloading log files from the RDS DB instance, see [Monitoring Amazon RDS log files](#).

The trace session logs remain on the instance for 35 days. Any older trace session logs are automatically deleted.

### Example of STATUS tracing action

To trace the status of a transaction tracing session, run the following statement.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'STATUS'
```

This statement outputs the following as separate rows of the result set.

```
OK
SessionStatus: <Started/Stopped>
TraceAll: <True/False>
TraceAborted: <True/False>
TraceLongLived: <True/False>
```

The first line indicates the overall result of the operation: OK or ERROR with details, if applicable. The subsequent lines indicate details about the tracing session status:

- SessionStatus can be one of the following:
  - Started if a tracing session is running.
  - Stopped if no tracing session is running.
- The tracing session flags can be True or False depending on how they were set in the START command.

### Modifying the MSDTC option

After you enable the MSDTC option, you can modify its settings. For information about how to modify option settings, see [Modifying an option setting](#).

#### Note

Some changes to MSDTC option settings require the MSDTC service to be restarted. This requirement can affect running distributed transactions.

## Disabling MSDTC

To disable MSDTC, remove the MSDTC option from its option group.

### Console

#### To remove the MSDTC option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the MSDTC option (`msdtc-se-2016` in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **MSDTC** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

### CLI

#### To remove the MSDTC option from its option group

- Use one of the following commands.

#### Example

For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
  --option-group-name msdtc-se-2016 \
  --options MSDTC \
  --apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group ^
  --option-group-name msdtc-se-2016 ^
  --options MSDTC ^
```

```
--apply-immediately
```

## Troubleshooting MSDTC for RDS for SQL Server

In some cases, you might have trouble establishing a connection between MSDTC running on a client computer and the MSDTC service running on an RDS for SQL Server DB instance. If so, make sure of the following:

- The inbound rules for the security group associated with the DB instance are configured correctly. For more information, see [Can't connect to Amazon RDS DB instance](#).
- Your client computer is configured correctly.
- The MSDTC firewall rules on your client computer are enabled.

### To configure the client computer

1. Open **Component Services**.

Or, in **Server Manager**, choose **Tools**, and then choose **Component Services**.

2. Expand **Component Services**, expand **Computers**, expand **My Computer**, and then expand **Distributed Transaction Coordinator**.
3. Open the context (right-click) menu for **Local DTC** and choose **Properties**.
4. Choose the **Security** tab.
5. Choose all of the following:
  - **Network DTC Access**
  - **Allow Inbound**
  - **Allow Outbound**
6. Make sure that the correct authentication mode is chosen:
  - **Mutual Authentication Required** – The client machine is joined to the same domain as other nodes participating in distributed transaction, or there is a trust relationship configured between domains.
  - **No Authentication Required** – All other cases.
7. Choose **OK** to save your changes.
8. If prompted to restart the service, choose **Yes**.

## To enable MSDTC firewall rules

1. Open Windows Firewall, then choose **Advanced settings**.

Or, in **Server Manager**, choose **Tools**, and then choose **Windows Firewall with Advanced Security**.

### **Note**

Depending on your operating system, Windows Firewall might be called Windows Defender Firewall.

2. Choose **Inbound Rules** in the left pane.
3. Enable the following firewall rules, if they are not already enabled:
  - **Distributed Transaction Coordinator (RPC)**
  - **Distributed Transaction Coordinator (RPC)-EPMAP**
  - **Distributed Transaction Coordinator (TCP-In)**
4. Close Windows Firewall.

# Common DBA tasks for Microsoft SQL Server

This section describes the Amazon RDS-specific implementations of some common DBA tasks for DB instances that are running the Microsoft SQL Server database engine. In order to deliver a managed service experience, Amazon RDS does not provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges.

## Note

When working with a SQL Server DB instance, you can run scripts to modify a newly created database, but you cannot modify the [model] database, the database used as the model for new databases.

## Topics

- [Working with trace and dump files](#)

## Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS

You can access the tempdb database on your Microsoft SQL Server DB instances on Amazon RDS. You can run code on tempdb by using Transact-SQL through Microsoft SQL Server Management Studio (SSMS), or any other standard SQL client application. For more information about connecting to your DB instance, see [Connecting to a DB instance running the Microsoft SQL Server database engine](#).

The master user for your DB instance is granted CONTROL access to tempdb so that this user can modify the tempdb database options. The master user isn't the database owner of the tempdb database. If necessary, the master user can grant CONTROL access to other users so that they can also modify the tempdb database options.

### Note

You can't run Database Console Commands (DBCC) on the tempdb database.

## Modifying tempdb database options

You can modify the database options on the tempdb database on your Amazon RDS DB instances. For more information about which options can be modified, see [tempdb database](#) in the Microsoft documentation.

Database options such as the maximum file size options are persistent after you restart your DB instance. You can modify the database options to optimize performance when importing data, and to prevent running out of storage.

### Optimizing performance when importing data

To optimize performance when importing large amounts of data into your DB instance, set the SIZE and FILEGROWTH properties of the tempdb database to large numbers. For more information about how to optimize tempdb, see [Optimizing tempdb performance](#) in the Microsoft documentation.

The following example demonstrates setting the size to 100 GB and file growth to 10 percent.

```
alter database[tempdb] modify file (NAME = N'templog', SIZE=100GB, FILEGROWTH = 10%)
```

## Preventing storage problems

To prevent the tempdb database from using all available disk space, set the MAXSIZE property. The following example demonstrates setting the property to 2048 MB.

```
alter database [tempdb] modify file (NAME = N'templog', MAXSIZE = 2048MB)
```

## Shrinking the tempdb database

There are two ways to shrink the tempdb database on your Amazon RDS DB instance. You can use the `rds_shrink_tempdbfile` procedure, or you can set the SIZE property,

### Using the `rds_shrink_tempdbfile` procedure

You can use the Amazon RDS procedure `msdb.dbo.rds_shrink_tempdbfile` to shrink the tempdb database. You can only call `rds_shrink_tempdbfile` if you have CONTROL access to tempdb. When you call `rds_shrink_tempdbfile`, there is no downtime for your DB instance.

The `rds_shrink_tempdbfile` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
@temp_filename	SYSNAME	—	required	The logical name of the file to shrink.
@target_size	int	null	optional	The new size for the file, in megabytes.

The following example gets the names of the files for the tempdb database.

```
use tempdb;
GO

select name, * from sys.sysfiles;
GO
```

The following example shrinks a tempdb database file named `test_file`, and requests a new size of 10 megabytes:

```
exec msdb.dbo.rds_shrink_tempdbfile @temp_filename = N'test_file', @target_size = 10;
```

## Setting the SIZE property

You can also shrink the tempdb database by setting the SIZE property and then restarting your DB instance. For more information about restarting your DB instance, see [Rebooting a DB instance](#).

The following example demonstrates setting the SIZE property to 1024 MB.

```
alter database [tempdb] modify file (NAME = N'templog', SIZE = 1024MB)
```

## TempDB configuration for Multi-AZ deployments

If your RDS for SQL Server DB instance is in a Multi-AZ Deployment using Database Mirroring (DBM) or Always On Availability Groups (AGs), keep in mind the following considerations for using the tempdb database.

You can't replicate tempdb data from your primary DB instance to your secondary DB instance. When you fail over to a secondary DB instance, tempdb on that secondary DB instance will be empty.

You can synchronize the configuration of the tempdb database options, including its file sizing and autogrowth settings, from your primary DB instance to your secondary DB instance. Synchronizing the tempDB configuration is supported on all RDS for SQL Server versions. You can turn on automatic synchronization of the tempdb configuration by using the following stored procedure:

```
EXECUTE msdb.dbo.rds_set_system_database_sync_objects @object_types = 'TempDbFile';
```

### Important

Before using the `rds_set_system_database_sync_objects` stored procedure, ensure you've set your preferred tempdb configuration on your primary DB instance, rather than on your secondary DB instance. If you made the configuration change on your secondary DB instance, your preferred tempdb configuration could be deleted when you turn on automatic synchronization.

You can use the following function to confirm whether automatic synchronization of the tempdb configuration is turned on:

```
SELECT * from msdb.dbo.rds_fn_get_system_database_sync_objects();
```

When automatic synchronization of the tempdb configuration is turned on, there will be a return value for the `object_class` field. When it's turned off, no value is returned.

You can use the following function to find the last time objects were synchronized, in UTC time:

```
SELECT * from msdb.dbo.rds_fn_server_object_last_sync_time();
```

For example, if you modified the tempdb configuration at 01:00 and then run the `rds_fn_server_object_last_sync_time` function, the value returned for `last_sync_time` should be after 01:00, indicating that an automatic synchronization occurred.

If you are also using SQL Server Agent job replication, you can enable replication for both SQL Agent jobs and the tempdb configuration by providing them in the `@object_type` parameter:

```
EXECUTE msdb.dbo.rds_set_system_database_sync_objects @object_types =  
'SQLAgentJob,TempDbFile';
```

For more information on SQL Server Agent job replication, see [Turning on SQL Server Agent job replication](#).

As an alternative to using the `rds_set_system_database_sync_objects` stored procedure to ensure that tempdb configuration changes are automatically synchronized, you can use one of the following manual methods:

#### Note

We recommend turning on automatic synchronization of the tempdb configuration by using the `rds_set_system_database_sync_objects` stored procedure. Using automatic synchronization prevents the need to perform these manual tasks each time you change your tempdb configuration.

- First modify your DB instance and turn Multi-AZ off, then modify tempdb, and finally turn Multi-AZ back on. This method doesn't involve any downtime.

For more information, see [Modifying an Amazon RDS DB instance](#).

- First modify tempdb in the original primary instance, then fail over manually, and finally modify tempdb in the new primary instance. This method involves downtime.

For more information, see [Rebooting a DB instance](#).

## Analyzing your database workload on an Amazon RDS for SQL Server DB instance with Database Engine Tuning Advisor

Database Engine Tuning Advisor is a client application provided by Microsoft that analyzes database workload and recommends an optimal set of indexes for your Microsoft SQL Server databases based on the kinds of queries you run. Like SQL Server Management Studio, you run Tuning Advisor from a client computer that connects to your Amazon RDS DB instance that is running SQL Server. The client computer can be a local computer that you run on premises within your own network or it can be an Amazon EC2 Windows instance that is running in the same region as your Amazon RDS DB instance.

This section shows how to capture a workload for Tuning Advisor to analyze. This is the preferred process for capturing a workload because Amazon RDS restricts host access to the SQL Server instance. For more information, see [Database Engine Tuning Advisor](#) in the Microsoft documentation.

To use Tuning Advisor, you must provide what is called a workload to the advisor. A workload is a set of Transact-SQL statements that run against a database or databases that you want to tune. Database Engine Tuning Advisor uses trace files, trace tables, Transact-SQL scripts, or XML files as workload input when tuning databases. When working with Amazon RDS, a workload can be a file on a client computer or a database table on an Amazon RDS for SQL Server DB accessible to your client computer. The file or the table must contain queries against the databases you want to tune in a format suitable for replay.

For Tuning Advisor to be most effective, a workload should be as realistic as possible. You can generate a workload file or table by performing a trace against your DB instance. While a trace is running, you can either simulate a load on your DB instance or run your applications with a normal load.

There are two types of traces: client-side and server-side. A client-side trace is easier to set up and you can watch trace events being captured in real-time in SQL Server Profiler. A server-side trace is more complex to set up and requires some Transact-SQL scripting. In addition, because the trace is written to a file on the Amazon RDS DB instance, storage space is consumed by the trace. It is

important to track of how much storage space a running server-side trace uses because the DB instance could enter a storage-full state and would no longer be available if it runs out of storage space.

For a client-side trace, when a sufficient amount of trace data has been captured in the SQL Server Profiler, you can then generate the workload file by saving the trace to either a file on your local computer or in a database table on a DB instance that is available to your client computer. The main disadvantage of using a client-side trace is that the trace may not capture all queries when under heavy loads. This could weaken the effectiveness of the analysis performed by the Database Engine Tuning Advisor. If you need to run a trace under heavy loads and you want to ensure that it captures every query during a trace session, you should use a server-side trace.

For a server-side trace, you must get the trace files on the DB instance into a suitable workload file or you can save the trace to a table on the DB instance after the trace completes. You can use the SQL Server Profiler to save the trace to a file on your local computer or have the Tuning Advisor read from the trace table on the DB instance.

## Running a client-side trace on a SQL Server DB instance

### To run a client-side trace on a SQL Server DB instance

1. Start SQL Server Profiler. It is installed in the Performance Tools folder of your SQL Server instance folder. You must load or define a trace definition template to start a client-side trace.
2. In the SQL Server Profiler File menu, choose **New Trace**. In the **Connect to Server** dialog box, enter the DB instance endpoint, port, master user name, and password of the database you would like to run a trace on.
3. In the **Trace Properties** dialog box, enter a trace name and choose a trace definition template. A default template, *TSQL\_Replay*, ships with the application. You can edit this template to define your trace. Edit events and event information under the **Events Selection** tab of the **Trace Properties** dialog box.

For more information about trace definition templates and using the SQL Server Profiler to specify a client-side trace, see [Database Engine Tuning Advisor](#) in the Microsoft documentation.

4. Start the client-side trace and watch SQL queries in real-time as they run against your DB instance.
5. Select **Stop Trace** from the **File** menu when you have completed the trace. Save the results as a file or as a trace table on you DB instance.

## Running a server-side trace on a SQL Server DB instance

Writing scripts to create a server-side trace can be complex and is beyond the scope of this document. This section contains sample scripts that you can use as examples. As with a client-side trace, the goal is to create a workload file or trace table that you can open using the Database Engine Tuning Advisor.

The following is an abridged example script that starts a server-side trace and captures details to a workload file. The trace initially saves to the file RDSTrace.trc in the D:\RDSDBDATA\Log directory and rolls-over every 100 MB so subsequent trace files are named RDSTrace\_1.trc, RDSTrace\_2.trc, etc.

```
DECLARE @file_name NVARCHAR(245) = 'D:\RDSDBDATA\Log\RDSTrace';
DECLARE @max_file_size BIGINT = 100;
DECLARE @on BIT = 1
DECLARE @rc INT
DECLARE @traceid INT

EXEC @rc = sp_trace_create @traceid OUTPUT, 2, @file_name, @max_file_size
IF (@rc = 0) BEGIN
    EXEC sp_trace_setevent @traceid, 10, 1, @on
    EXEC sp_trace_setevent @traceid, 10, 2, @on
    EXEC sp_trace_setevent @traceid, 10, 3, @on
    . . .
    EXEC sp_trace_setfilter @traceid, 10, 0, 7, N'SQL Profiler'
    EXEC sp_trace_setstatus @traceid, 1
END
```

The following example is a script that stops a trace. Note that a trace created by the previous script continues to run until you explicitly stop the trace or the process runs out of disk space.

```
DECLARE @traceid INT
SELECT @traceid = traceid FROM ::fn_trace_getinfo(default)
WHERE property = 5 AND value = 1 AND traceid <> 1

IF @traceid IS NOT NULL BEGIN
    EXEC sp_trace_setstatus @traceid, 0
    EXEC sp_trace_setstatus @traceid, 2
END
```

You can save server-side trace results to a database table and use the database table as the workload for the Tuning Advisor by using the `fn_trace_gettable` function. The following commands load the results of all files named `RDSTrace.trc` in the `D:\rdsdbdata\Log` directory, including all rollover files like `RDSTrace_1.trc`, into a table named `RDSTrace` in the current database.

```
SELECT * INTO RDSTrace
FROM fn_trace_gettable('D:\rdsdbdata\Log\RDSTrace.trc', default);
```

To save a specific rollover file to a table, for example the `RDSTrace_1.trc` file, specify the name of the rollover file and substitute 1 instead of `default` as the last parameter to `fn_trace_gettable`.

```
SELECT * INTO RDSTrace_1
FROM fn_trace_gettable('D:\rdsdbdata\Log\RDSTrace_1.trc', 1);
```

## Running Tuning Advisor with a trace

Once you create a trace, either as a local file or as a database table, you can then run Tuning Advisor against your DB instance. Using Tuning Advisor with Amazon RDS is the same process as when working with a standalone, remote SQL Server instance. You can either use the Tuning Advisor UI on your client machine or use the `dta.exe` utility from the command line. In both cases, you must connect to the Amazon RDS DB instance using the endpoint for the DB instance and provide your master user name and master user password when using Tuning Advisor.

The following code example demonstrates using the `dta.exe` command line utility against an Amazon RDS DB instance with an endpoint of `dta.cnazcmklsdei.us-east-1.rds.amazonaws.com`. The example includes the master user name `admin` and the master user password `test`, the example database to tune is named machine named `C:\RDSTrace.trc`. The example command line code also specifies a trace session named `RDSTrace1` and specifies output files to the local machine named `RDSTrace.sql` for the SQL output script, `RDSTrace.txt` for a result file, and `RDSTrace.xml` for an XML file of the analysis. There is also an error table specified on the `RDSDTA` database named `RDSTraceErrors`.

```
dta -S dta.cnazcmklsdei.us-east-1.rds.amazonaws.com -U admin -P test -D RDSDTA -
if C:\RDSTrace.trc -s RDSTrace1 -of C:\ RDSTrace.sql -or C:\ RDSTrace.txt -ox C:\
RDSTrace.xml -e RDSDTA.dbo.RDSTraceErrors
```

Here is the same example command line code except the input workload is a table on the remote Amazon RDS instance named `RDSTrace` which is on the `RDSDTA` database.

```
dta -S dta.cnazcmklsdei.us-east-1.rds.amazonaws.com -U admin -P test -D RSDTA -it
RSDTA.dbo.RDSTrace -s RDSTrace1 -of C:\ RDSTrace.sql -or C:\ RDSTrace.txt -ox C:\
RDSTrace.xml -e RSDTA.dbo.RDSTraceErrors
```

For a full list of dta utility command-line parameters, see [dta Utility](#) in the Microsoft documentation.

## Changing the db\_owner to the rdsa account for your database

When you create or restore a database in an RDS for SQL Server DB instance, Amazon RDS sets the owner of the database to `rdsa`. If you have a Multi-AZ deployment using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs), Amazon RDS sets the owner of the database on the secondary DB instance to `NT AUTHORITY\SYSTEM`. The owner of the secondary database can't be changed until the secondary DB instance is promoted to the primary role. In most cases, setting the owner of the database to `NT AUTHORITY\SYSTEM` isn't problematic when executing queries, however, can throw errors when executing system stored procedures such as `sys.sp_updatestats` that require elevated permissions to execute.

You can use the following query to identify the owner of the databases owned by `NT AUTHORITY\SYSTEM`:

```
SELECT name FROM sys.databases WHERE SUSER_SNAME(owner_sid) = 'NT AUTHORITY\SYSTEM';
```

You can use the Amazon RDS stored procedure `rds_changedbowner_to_rdsa` to change the owner of the database to `rdsa`. The following databases are not allowed to be used with `rds_changedbowner_to_rdsa`: `master`, `model`, `msdb`, `rdsadmin`, `rdsadmin_ReportServer`, `rdsadmin_ReportServerTempDB`, `SSISDB`.

To change the owner of the database to `rdsa`, call the `rds_changedbowner_to_rdsa` stored procedure and provide the name of the database.

### Example usage:

```
exec msdb.dbo.rds_changedbowner_to_rdsa 'TestDB1';
```

The following parameter is required:

- `@db_name` – The name of the database to change the owner of the database to `rdsa`.

**⚠ Important**

You can't use `rds_changedbowner_to_rdsa` to change ownership of a database to a login other than `rdsa`. For example, you can't change the ownership to the login with which you created the database. To restore lost membership in the `db_owner` role for your master user when no other database user can be used to grant the membership, reset the master user password to obtain membership in the `db_owner` role. For more information, see [Resetting the db\\_owner role membership for master user](#).

## Collations and character sets for Microsoft SQL Server

SQL Server supports collations at multiple levels. You set the default server collation when you create the DB instance. You can override the collation in the database, table, or column level.

### Topics

- [Server-level collation for Microsoft SQL Server](#)
- [Database-level collation for Microsoft SQL Server](#)

### Server-level collation for Microsoft SQL Server

When you create a Microsoft SQL Server DB instance, you can set the server collation that you want to use. If you don't choose a different collation, the server-level collation defaults to `SQL_Latin1_General_CP1_CI_AS`. The server collation is applied by default to all databases and database objects.

**📘 Note**

You can't change the collation when you restore from a DB snapshot.

Currently, Amazon RDS supports the following server collations:

Collation	Description
Arabic_CI_AS	Arabic, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive

Collation	Description
Chinese_PRC_BIN2	Chinese-PRC, binary code point sort order
Chinese_PRC_CI_AS	Chinese-PRC, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Chinese_Taiwan_Stroke_CI_AS	Chinese-Taiwan-Stroke, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Danish_Norwegian_CI_AS	Danish-Norwegian, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Finnish_Swedish_CI_AS	Finnish, Swedish, and Swedish (Finland), case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
French_CI_AS	French, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Hebrew_BIN	Hebrew, binary sort
Hebrew_CI_AS	Hebrew, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Japanese_BIN	Japanese, binary sort
Japanese_CI_AS	Japanese, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Japanese_CS_AS	Japanese, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Japanese_XJIS_140_CI_AS	Japanese, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive, supplementary characters, variation selector insensitive

Collation	Description
Japanese_XJIS_140_CI_AS_KS_VSS	Japanese, case-insensitive, accent-sensitive, kanatype-sensitive, width-insensitive, supplementary characters, variation selector sensitive
Japanese_XJIS_140_CI_AS_VSS	Japanese, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive, supplementary characters, variation selector sensitive
Japanese_XJIS_140_CS_AS_KS_WS	Japanese, case-sensitive, accent-sensitive, kanatype-sensitive, width-sensitive, supplementary characters, variation selector insensitive
Korean_Wansung_CI_AS	Korean-Wansung, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Latin1_General_100_BIN	Latin1-General-100, binary sort
Latin1_General_100_BIN2	Latin1-General-100, binary code point sort order
Latin1_General_100_BIN2_UTF8	Latin1-General-100, binary code point sort order, UTF-8 encoded
Latin1_General_100_CI_AS	Latin1-General-100, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Latin1_General_100_CI_AS_SC_UTF8	Latin1-General-100, case-insensitive, accent-sensitive, supplementary characters, UTF-8 encoded
Latin1_General_BIN	Latin1-General, binary sort
Latin1_General_BIN2	Latin1-General, binary code point sort order

Collation	Description
Latin1_General_CI_AI	Latin1-General, case-insensitive, accent-insensitive, kanatype-insensitive, width-insensitive
Latin1_General_CI_AS	Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Latin1_General_CI_AS_KS	Latin1-General, case-insensitive, accent-sensitive, kanatype-sensitive, width-insensitive
Latin1_General_CS_AS	Latin1-General, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Modern_Spanish_CI_AS	Modern-Spanish, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Polish_CI_AS	Polish, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
SQL_1xCompat_CP850_CI_AS	Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 49 on Code Page 850 for non-Unicode Data
SQL_Latin1_General_CP1_CI_AI	Latin1-General, case-insensitive, accent-insensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 54 on Code Page 1252 for non-Unicode Data
<b>SQL_Latin1_General_CP1_CI_AS (default)</b>	Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 52 on Code Page 1252 for non-Unicode Data

Collation	Description
SQL_Latin1_General_CP1_CS_AS	Latin1-General, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 51 on Code Page 1252 for non-Unicode Data
SQL_Latin1_General_CP437_CI_AI	Latin1-General, case-insensitive, accent-insensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 34 on Code Page 437 for non-Unicode Data
SQL_Latin1_General_CP850_BIN	Latin1-General, binary sort order for Unicode Data, SQL Server Sort Order 40 on Code Page 850 for non-Unicode Data
SQL_Latin1_General_CP850_BIN2	Latin1-General, binary code point sort order for Unicode Data, SQL Server Sort Order 40 on Code Page 850 for non-Unicode Data
SQL_Latin1_General_CP850_CI_AI	Latin1-General, case-insensitive, accent-insensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 44 on Code Page 850 for non-Unicode Data
SQL_Latin1_General_CP850_CI_AS	Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 42 on Code Page 850 for non-Unicode Data
SQL_Latin1_General_CP1256_CI_AS	Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 146 on Code Page 1256 for non-Unicode Data

Collation	Description
Thai_CI_AS	Thai, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Turkish_CI_AS	Turkish, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive

To choose the collation:

- If you're using the Amazon RDS console, when creating a new DB instance choose **Additional configuration**, then enter the collation in the **Collation** field. For more information, see [Creating an Amazon RDS DB instance](#).
- If you're using the AWS CLI, use the `--character-set-name` option with the `create-db-instance` command. For more information, see [create-db-instance](#).
- If you're using the Amazon RDS API, use the `CharacterSetName` parameter with the `CreateDBInstance` operation. For more information, see [CreateDBInstance](#).

## Database-level collation for Microsoft SQL Server

You can change the default collation at the database, table, or column level by overriding the collation when creating a new database or database object. For example, if your default server collation is `SQL_Latin1_General_CP1_CI_AS`, you can change it to `Mohawk_100_CI_AS` for Mohawk collation support. Even arguments in a query can be type-cast to use a different collation if necessary.

For example, the following query would change the default collation for the `AccountName` column to `Mohawk_100_CI_AS`

```
CREATE TABLE [dbo].[Account]
(
    [AccountID] [nvarchar](10) NOT NULL,
    [AccountName] [nvarchar](100) COLLATE Mohawk_100_CI_AS NOT NULL
) ON [PRIMARY];
```

The Microsoft SQL Server DB engine supports Unicode by the built-in `NCHAR`, `NVARCHAR`, and `NTEXT` data types. For example, if you need CJK support, use these Unicode data types for

character storage and override the default server collation when creating your databases and tables. Here are several links from Microsoft covering collation and Unicode support for SQL Server:

- [Working with collations](#)
- [Collation and international terminology](#)
- [Using SQL Server collations](#)
- [International considerations for databases and database engine applications](#)

## Creating a database user

You can create a database user for your Amazon RDS for Microsoft SQL Server DB instance by running a T-SQL script like the following example. Use an application such as SQL Server Management Suite (SSMS). You log into the DB instance as the master user that was created when you created the DB instance.

```
--Initially set context to master database
USE [master];
GO
--Create a server-level login named theirname with password theirpassword
CREATE LOGIN [theirname] WITH PASSWORD = 'theirpassword';
GO
--Set context to msdb database
USE [msdb];
GO
--Create a database user named theirname and link it to server-level login theirname
CREATE USER [theirname] FOR LOGIN [theirname];
GO
```

For an example of adding a database user to a role, see [Adding a user to the SQLAgentUser role](#).

### Note

If you get permission errors when adding a user, you can restore privileges by modifying the DB instance master user password. For more information, see [Resetting the db\\_owner role membership for master user](#).

## Determining a recovery model for your Microsoft SQL Server database

In Amazon RDS, the recovery model, retention period, and database status are linked.

It's important to understand the consequences before making a change to one of these settings. Each setting can affect the others. For example:

- If you change a database's recovery model to `SIMPLE` or `BULK_LOGGED` while backup retention is enabled, Amazon RDS resets the recovery model to `FULL` within five minutes. This also results in RDS taking a snapshot of the DB instance.
- If you set backup retention to `0` days, RDS sets the recovery mode to `SIMPLE`.
- If you change a database's recovery model from `SIMPLE` to any other option while backup retention is set to `0` days, RDS resets the recovery model to `SIMPLE`.

### Important

Never change the recovery model on Multi-AZ instances, even if it seems you can do so—for example, by using `ALTER DATABASE`. Backup retention, and therefore `FULL` recovery mode, is required for Multi-AZ. If you alter the recovery model, RDS immediately changes it back to `FULL`.

This automatic reset forces RDS to completely rebuild the mirror. During this rebuild, the availability of the database is degraded for about 30-90 minutes until the mirror is ready for failover. The DB instance also experiences performance degradation in the same way it does during a conversion from Single-AZ to Multi-AZ. How long performance is degraded depends on the database storage size—the bigger the stored database, the longer the degradation.

For more information on SQL Server recovery models, see [Recovery models \(SQL Server\)](#) in the Microsoft documentation.

## Determining the last failover time

To determine the last failover time, use the following stored procedure:

```
execute msdb.dbo.rds_failover_time;
```

This procedure returns the following information.

Output parameter	Description
errorlog_available_from	Shows the time from when error logs are available in the log directory.
recent_failover_time	Shows the last failover time if it's available from the error logs. Otherwise it shows null.

### Note

The stored procedure searches all of the available SQL Server error logs in the log directory to retrieve the most recent failover time. If the failover messages have been overwritten by SQL Server, then the procedure doesn't retrieve the failover time.

### Example of no recent failover

This example shows the output when there is no recent failover in the error logs. No failover has happened since 2020-04-29 23:59:00.01.

errorlog_available_from	recent_failover_time
2020-04-29 23:59:00.0100000	null

### Example of recent failover

This example shows the output when there is a failover in the error logs. The most recent failover was at 2020-05-05 18:57:51.89.

errorlog_available_from	recent_failover_time
2020-04-29 23:59:00.0100000	2020-05-05 18:57:51.8900000

## Deny or allow viewing database names

The master user cannot set DENY VIEW ANY DATABASE TO *LOGIN* to hide databases from a user.

To change this permission, use the following stored procedure instead:

- Denying database view access to *LOGIN*:

```
EXEC msdb.dbo.rds_manage_view_db_permission @permission='DENY',  
    @server_principal='LOGIN'  
  
go
```

- Allowing database view access to *LOGIN*:

```
EXEC msdb.dbo.rds_manage_view_db_permission @permission='GRANT',  
    @server_principal='LOGIN'  
  
go
```

Consider the following when using this stored procedure:

- Database names are hidden from the SSMS and internal DMV (dynamic management views). However, database names are still visible from audit, logs and metadata tables. These are secured VIEW ANY DATABASE server permissions. For more information, see [DENY Server Permissions](#).
- Once the permission is reverted to GRANT (allowed), the *LOGIN* can view all databases.
- If you delete and recreate *LOGIN*, the view permission related to the LOGIN is reset to ALLOW.
- For Multi-AZ instances, set the DENY or GRANT permission only for the *LOGIN* on the primary host. The changes are propagated to the secondary host automatically.
- This permission only changes whether a login can view the database names. However, access to databases and objects within are managed separately.

## Disabling fast inserts during bulk loading

Starting with SQL Server 2016, fast inserts are enabled by default. Fast inserts leverage the minimal logging that occurs while the database is in the simple or bulk logged recovery model

to optimize insert performance. With fast inserts, each bulk load batch acquires new extents, bypassing the allocation lookup for existing extents with available free space to optimize insert performance.

However, with fast inserts bulk loads with small batch sizes can lead to increased unused space consumed by objects. If increasing batch size isn't feasible, enabling trace flag 692 can help reduce unused reserved space, but at the expense of performance. Enabling this trace flag disables fast inserts while bulk loading data into heap or clustered indexes.

You enable trace flag 692 as a startup parameter using DB parameter groups. For more information, see [Parameter groups for Amazon RDS](#).

Trace flag 692 is supported for Amazon RDS on SQL Server 2016 and later. For more information on trace flags, see [DBCC TRACEON - trace flags](#) in the Microsoft documentation.

## Dropping a Microsoft SQL Server database

You can drop a database on an Amazon RDS DB instance running Microsoft SQL Server in a Single-AZ or Multi-AZ deployment. To drop the database, use the following command:

```
--replace your-database-name with the name of the database you want to drop  
EXECUTE msdb.dbo.rds_drop_database N'your-database-name'
```

### Note

Use straight single quotes in the command. Smart quotes will cause an error.

After you use this procedure to drop the database, Amazon RDS drops all existing connections to the database and removes the database's backup history.

## Renaming a Microsoft SQL Server database in a Multi-AZ deployment

To rename a Microsoft SQL Server database instance that uses Multi-AZ, use the following procedure:

1. First, turn off Multi-AZ for the DB instance.
2. Rename the database by running `rdsadmin.dbo.rds_modify_db_name`.
3. Then, turn on Multi-AZ Mirroring or Always On Availability Groups for the DB instance, to return it to its original state.

For more information, see [Adding Multi-AZ to a Microsoft SQL Server DB instance](#).

**Note**

If your instance doesn't use Multi-AZ, you don't need to change any settings before or after running `rdsadmin.dbo.rds_modify_db_name`.

**Example:** In the following example, the `rdsadmin.dbo.rds_modify_db_name` stored procedure renames a database from **MOO** to **ZAR**. This is similar to running the statement `DDL ALTER DATABASE [MOO] MODIFY NAME = [ZAR]`.

```
EXEC rdsadmin.dbo.rds_modify_db_name N'MOO', N'ZAR'  
GO
```

## Resetting the `db_owner` role membership for master user

If you lock your master user out of the `db_owner` role membership on your RDS for SQL Server database and no other database user can grant the membership, you can restore lost membership by modifying the DB instance master user password.

By changing the DB instance master user password, RDS grants the `db_owner` membership to the databases in the DB instance that might have been accidentally revoked. You can change the DB instance password by using the Amazon RDS console, the AWS CLI command [modify-db-instance](#), or by using the [ModifyDBInstance](#) API operation. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#).

## Restoring license-terminated DB instances

Microsoft has requested that some Amazon RDS customers who did not report their Microsoft License Mobility information terminate their DB instance. Amazon RDS takes snapshots of these DB instances, and you can restore from the snapshot to a new DB instance that has the License Included model.

You can restore from a snapshot of Standard Edition to either Standard Edition or Enterprise Edition.

You can restore from a snapshot of Enterprise Edition to either Standard Edition or Enterprise Edition.

## To restore from a SQL Server snapshot after Amazon RDS has created a final snapshot of your instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the snapshot of your SQL Server DB instance. Amazon RDS creates a final snapshot of your DB instance. The name of the terminated instance snapshot is in the format *instance\_name*-final-snapshot. For example, if your DB instance name is **mytest.cdxgahslksma.us-east-1.rds.com**, the final snapshot is called **mytest-final-snapshot** and is located in the same AWS Region as the original DB instance.
4. For **Actions**, choose **Restore Snapshot**.

The **Restore DB Instance** window appears.

5. For **License Model**, choose **license-included**.
6. Choose the SQL Server DB engine that you want to use.
7. For **DB Instance Identifier**, enter the name for the restored DB instance.
8. Choose **Restore DB Instance**.

For more information about restoring from a snapshot, see [Restoring to a DB instance](#).

## Transitioning a Microsoft SQL Server database from OFFLINE to ONLINE

You can transition your Microsoft SQL Server database on an Amazon RDS DB instance from OFFLINE to ONLINE.

SQL Server method	Amazon RDS method
ALTER DATABASE <i>db_name</i> SET ONLINE;	EXEC rdsadmin.dbo.rds_set_database_online <i>db_name</i>

## Using change data capture

Amazon RDS supports change data capture (CDC) for your DB instances running Microsoft SQL Server. CDC captures changes that are made to the data in your tables. It stores metadata about each change, which you can access later. For more information about how CDC works, see [Change data capture](#) in the Microsoft documentation.

Before you use CDC with your Amazon RDS DB instances, enable it in the database by running `msdb.dbo.rds_cdc_enable_db`. You must have master user privileges to enable CDC in the Amazon RDS DB instance. After CDC is enabled, any user who is `db_owner` of that database can enable or disable CDC on tables in that database.

### Important

During restores, CDC will be disabled. All of the related metadata is automatically removed from the database. This applies to snapshot restores, point-in-time restores, and SQL Server Native restores from S3. After performing one of these types of restores, you can re-enable CDC and re-specify tables to track.

To enable CDC for a DB instance, run the `msdb.dbo.rds_cdc_enable_db` stored procedure.

```
exec msdb.dbo.rds_cdc_enable_db 'database_name'
```

To disable CDC for a DB instance, run the `msdb.dbo.rds_cdc_disable_db` stored procedure.

```
exec msdb.dbo.rds_cdc_disable_db 'database_name'
```

### Topics

- [Tracking tables with change data capture](#)
- [Change data capture jobs](#)
- [Change data capture for Multi-AZ instances](#)

## Tracking tables with change data capture

After CDC is enabled on the database, you can start tracking specific tables. You can choose the tables to track by running [sys.sp\\_cdc\\_enable\\_table](#).

```
--Begin tracking a table
exec sys.sp_cdc_enable_table
    @source_schema          = N'source_schema'
,   @source_name           = N'source_name'
,   @role_name             = N'role_name'

--The following parameters are optional:

--, @capture_instance       = 'capture_instance'
--, @supports_net_changes  = supports_net_changes
--, @index_name            = 'index_name'
--, @captured_column_list  = 'captured_column_list'
--, @filegroup_name        = 'filegroup_name'
--, @allow_partition_switch = 'allow_partition_switch'
;
```

To view the CDC configuration for your tables, run [sys.sp\\_cdc\\_help\\_change\\_data\\_capture](#).

```
--View CDC configuration
exec sys.sp_cdc_help_change_data_capture

--The following parameters are optional and must be used together.
-- 'schema_name', 'table_name'
;
```

For more information on CDC tables, functions, and stored procedures in SQL Server documentation, see the following:

- [Change data capture stored procedures \(Transact-SQL\)](#)
- [Change data capture functions \(Transact-SQL\)](#)
- [Change data capture tables \(Transact-SQL\)](#)

## Change data capture jobs

When you enable CDC, SQL Server creates the CDC jobs. Database owners (`db_owner`) can view, create, modify, and delete the CDC jobs. However, the RDS system account owns them. Therefore, the jobs aren't visible from native views, procedures, or in SQL Server Management Studio.

To control behavior of CDC in a database, use native SQL Server procedures such as [sp\\_cdc\\_enable\\_table](#) and [sp\\_cdc\\_start\\_job](#). To change CDC job parameters, like `maxtrans` and `maxscans`, you can use [sp\\_cdc\\_change\\_job](#).

To get more information regarding the CDC jobs, you can query the following dynamic management views:

- `sys.dm_cdc_errors`
- `sys.dm_cdc_log_scan_sessions`
- `sysjobs`
- `sysjobhistory`

## Change data capture for Multi-AZ instances

If you use CDC on a Multi-AZ instance, make sure the mirror's CDC job configuration matches the one on the principal. CDC jobs are mapped to the `database_id`. If the database IDs on the secondary are different from the principal, then the jobs won't be associated with the correct database. To try to prevent errors after failover, RDS drops and recreates the jobs on the new principal. The recreated jobs use the parameters that the principal recorded before failover.

Although this process runs quickly, it's still possible that the CDC jobs might run before RDS can correct them. Here are three ways to force parameters to be consistent between primary and secondary replicas:

- Use the same job parameters for all the databases that have CDC enabled.
- Before you change the CDC job configuration, convert the Multi-AZ instance to Single-AZ.
- Manually transfer the parameters whenever you change them on the principal.

To view and define the CDC parameters that are used to recreate the CDC jobs after a failover, use `rds_show_configuration` and `rds_set_configuration`.

The following example returns the value set for `cdc_capture_maxtrans`. For any parameter that is set to `RDS_DEFAULT`, RDS automatically configures the value.

```
-- Show configuration for each parameter on either primary and secondary replicas.  
exec rdsadmin.dbo.rds_show_configuration 'cdc_capture_maxtrans';
```

To set the configuration on the secondary, run `rdsadmin.dbo.rds_set_configuration`. This procedure sets the parameter values for all of the databases on the secondary server. These settings are used only after a failover. The following example sets the `maxtrans` for all CDC capture jobs to `1000`:

```
--To set values on secondary. These are used after failover.  
exec rdsadmin.dbo.rds_set_configuration 'cdc_capture_maxtrans', 1000;
```

To set the CDC job parameters on the principal, use [sys.sp\\_cdc\\_change\\_job](#) instead.

## Using SQL Server Agent

With Amazon RDS, you can use SQL Server Agent on a DB instance running Microsoft SQL Server Enterprise Edition, Standard Edition, or Web Edition. SQL Server Agent is a Microsoft Windows service that runs scheduled administrative tasks that are called jobs. You can use SQL Server Agent to run T-SQL jobs to rebuild indexes, run corruption checks, and aggregate data in a SQL Server DB instance.

When you create a SQL Server DB instance, the master user is enrolled in the `SQLAgentUserRole` role.

SQL Server Agent can run a job on a schedule, in response to a specific event, or on demand. For more information, see [SQL Server Agent](#) in the Microsoft documentation.

### Note

Avoid scheduling jobs to run during the maintenance and backup windows for your DB instance. The maintenance and backup processes that are launched by AWS could interrupt a job or cause it to be canceled.

In Multi-AZ deployments, SQL Server Agent jobs are replicated from the primary host to the secondary host when the job replication feature is turned on. For more information, see [Turning on SQL Server Agent job replication](#).

Multi-AZ deployments have a limit of 10,000 SQL Server Agent jobs. If you need a higher limit, request an increase by contacting AWS Support. Open the [AWS Support Center](#) page, sign in if necessary, and choose **Create case**. Choose **Service limit increase**. Complete and submit the form.

To view the history of an individual SQL Server Agent job in SQL Server Management Studio (SSMS), open Object Explorer, right-click the job, and then choose **View History**.

Because SQL Server Agent is running on a managed host in a DB instance, some actions aren't supported:

- Running replication jobs and running command-line scripts by using ActiveX, Windows command shell, or Windows PowerShell aren't supported.
- You can't manually start, stop, or restart SQL Server Agent.
- Email notifications through SQL Server Agent aren't available from a DB instance.
- SQL Server Agent alerts and operators aren't supported.
- Using SQL Server Agent to create backups isn't supported. Use Amazon RDS to back up your DB instance.
- Currently, RDS for SQL Server does not support the use SQL Server Agent tokens.

## Turning on SQL Server Agent job replication

You can turn on SQL Server Agent job replication by using the following stored procedure:

```
EXECUTE msdb.dbo.rds_set_system_database_sync_objects @object_types = 'SQLAgentJob';
```

You can run the stored procedure on all SQL Server versions supported by Amazon RDS for SQL Server. Jobs in the following categories are replicated:

- [Uncategorized (Local)]
- [Uncategorized (Multi-Server)]
- [Uncategorized]
- Data Collector
- Database Engine Tuning Advisor
- Database Maintenance
- Full-Text

Only jobs that use T-SQL job steps are replicated. Jobs with step types such as SQL Server Integration Services (SSIS), SQL Server Reporting Services (SSRS), Replication, and PowerShell aren't replicated. Jobs that use Database Mail and server-level objects aren't replicated.

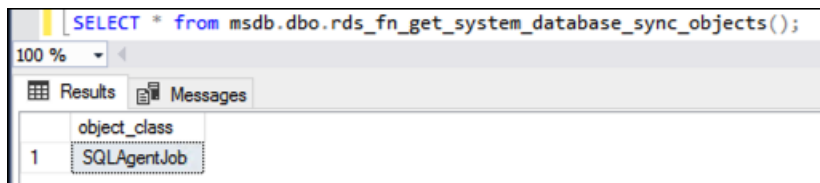

**⚠ Important**

The primary host is the source of truth for replication. Before turning on job replication, make sure that your SQL Server Agent jobs are on the primary. If you don't do this, it could lead to the deletion of your SQL Server Agent jobs if you turn on the feature when newer jobs are on the secondary host.

You can use the following function to confirm whether replication is turned on.

```
SELECT * from msdb.dbo.rds_fn_get_system_database_sync_objects();
```

The T-SQL query returns the following if SQL Server Agent jobs are replicating. If they're not replicating, it returns nothing for `object_class`.

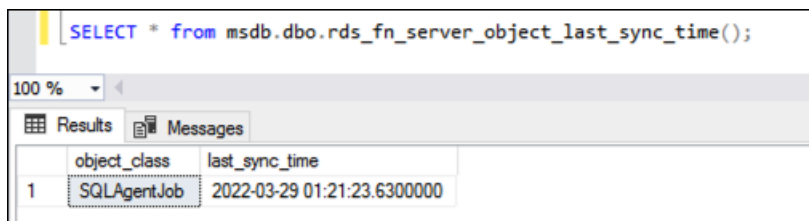

object_class
1 SQLAgentJob

You can use the following function to find the last time objects were synchronized in UTC time.

```
SELECT * from msdb.dbo.rds_fn_server_object_last_sync_time();
```

For example, suppose that you modify a SQL Server Agent job at 01:00. You expect the most recent synchronization time to be after 01:00, indicating that synchronization has taken place.

After synchronization, the values returned for `date_created` and `date_modified` on the secondary node are expected to match.

object_class	last_sync_time
1 SQLAgentJob	2022-03-29 01:21:23.6300000

If you are also using `tempdb` replication, you can enable replication for both SQL Agent jobs and the `tempdb` configuration by providing them in the `@object_type` parameter:

```
EXECUTE msdb.dbo.rds_set_system_database_sync_objects @object_types =  
'SQLAgentJob,TempDbFile';
```

For more information on tempdb replication, see [TempDB configuration for Multi-AZ deployments](#).

## Adding a user to the SQLAgentUser role

To allow an additional login or user to use SQL Server Agent, log in as the master user and do the following:

1. Create another server-level login by using the `CREATE LOGIN` command.
2. Create a user in `msdb` using `CREATE USER` command, and then link this user to the login that you created in the previous step.
3. Add the user to the `SQLAgentUserRole` using the `sp_addrolemember` system stored procedure.

For example, suppose that your master user name is **admin** and you want to give access to SQL Server Agent to a user named **theirname** with a password **theirpassword**. In that case, you can use the following procedure.

### To add a user to the SQLAgentUser role

1. Log in as the master user.
2. Run the following commands:

```
--Initially set context to master database  
USE [master];  
GO  
--Create a server-level login named theirname with password theirpassword  
CREATE LOGIN [theirname] WITH PASSWORD = 'theirpassword';  
GO  
--Set context to msdb database  
USE [msdb];  
GO  
--Create a database user named theirname and link it to server-level login  
  theirname  
CREATE USER [theirname] FOR LOGIN [theirname];  
GO  
--Added database user theirname in msdb to SQLAgentUserRole in msdb
```

```
EXEC sp_addrolemember [SQLAgentUserRole], [theirname];
```

## Deleting a SQL Server Agent job

You use the `sp_delete_job` stored procedure to delete SQL Server Agent jobs on Amazon RDS for Microsoft SQL Server.

You can't use SSMS to delete SQL Server Agent jobs. If you try to do so, you get an error message similar to the following:

```
The EXECUTE permission was denied on the object 'xp_regread', database 'mssqlsystemresource', schema 'sys'.
```

As a managed service, RDS is restricted from running procedures that access the Windows registry. When you use SSMS, it tries to run a process (`xp_regread`) for which RDS isn't authorized.

### Note

On RDS for SQL Server, only members of the `sysadmin` role are allowed to update or delete jobs owned by a different login.

## To delete a SQL Server Agent job

- Run the following T-SQL statement:

```
EXEC msdb..sp_delete_job @job_name = 'job_name';
```

## Working with Microsoft SQL Server logs

You can use the Amazon RDS console to view, watch, and download SQL Server Agent logs, Microsoft SQL Server error logs, and SQL Server Reporting Services (SSRS) logs.

### Watching log files

If you view a log in the Amazon RDS console, you can see its contents as they exist at that moment. Watching a log in the console opens it in a dynamic state so that you can see updates to it in near-real time.

Only the latest log is active for watching. For example, suppose you have the following logs shown:

Name	Last written	Logs
<input checked="" type="radio"/> log/ERROR	April 19, 2023, 10:06 (UTC-05:00)	19.8 kB
<input type="radio"/> log/ERROR.1	April 18, 2023, 18:59 (UTC-05:00)	2.6 kB
<input type="radio"/> log/ERROR.10	April 18, 2023, 18:59 (UTC-05:00)	2.6 kB
<input type="radio"/> log/ERROR.11	April 18, 2023, 18:59 (UTC-05:00)	2.6 kB
<input type="radio"/> log/ERROR.12	April 18, 2023, 18:59 (UTC-05:00)	2.6 kB

Only log/ERROR, as the most recent log, is being actively updated. You can choose to watch others, but they are static and will not update.

## Archiving log files

The Amazon RDS console shows logs for the past week through the current day. You can download and archive logs to keep them for reference past that time. One way to archive logs is to load them into an Amazon S3 bucket. For instructions on how to set up an Amazon S3 bucket and upload a file, see [Amazon S3 basics](#) in the *Amazon Simple Storage Service Getting Started Guide* and click **Get Started**.

## Viewing error and agent logs

To view Microsoft SQL Server error and agent logs, use the Amazon RDS stored procedure `rds_read_error_log` with the following parameters:

- **@index** – the version of the log to retrieve. The default value is 0, which retrieves the current error log. Specify 1 to retrieve the previous log, specify 2 to retrieve the one before that, and so on.
- **@type** – the type of log to retrieve. Specify 1 to retrieve an error log. Specify 2 to retrieve an agent log.

## Example

The following example requests the current error log.

```
EXEC rdsadmin.dbo.rds_read_error_log @index = 0, @type = 1;
```

For more information on SQL Server errors, see [Database engine errors](#) in the Microsoft documentation.

## Working with trace and dump files

This section describes working with trace files and dump files for your Amazon RDS DB instances running Microsoft SQL Server.

### Generating a trace SQL query

```
declare @rc int
declare @TraceID int
declare @maxfilesize bigint

set @maxfilesize = 5

exec @rc = sp_trace_create @TraceID output, 0, N'D:\rdsdbdata\log\rdstest',
    @maxfilesize, NULL
```

### Viewing an open trace

```
select * from ::fn_trace_getinfo(default)
```

### Viewing trace contents

```
select * from ::fn_trace_gettable('D:\rdsdbdata\log\rdstest.trc', default)
```

### Setting the retention period for trace and dump files

Trace and dump files can accumulate and consume disk space. By default, Amazon RDS purges trace and dump files that are older than seven days.

To view the current trace and dump file retention period, use the `rds_show_configuration` procedure, as shown in the following example.

```
exec rdsadmin..rds_show_configuration;
```

To modify the retention period for trace files, use the `rds_set_configuration` procedure and set the `tracefile retention` in minutes. The following example sets the trace file retention period to 24 hours.

```
exec rdsadmin..rds_set_configuration 'tracefile retention', 1440;
```

To modify the retention period for dump files, use the `rds_set_configuration` procedure and set the `dumpfile retention` in minutes. The following example sets the dump file retention period to 3 days.

```
exec rdsadmin..rds_set_configuration 'dumpfile retention', 4320;
```

For security reasons, you cannot delete a specific trace or dump file on a SQL Server DB instance. To delete all unused trace or dump files, set the retention period for the files to 0.

# Amazon RDS for MySQL

Amazon RDS supports several versions of MySQL for DB instances. For complete information about the supported versions, see [MySQL on Amazon RDS versions](#).

To create an Amazon RDS for MySQL DB instance, use the Amazon RDS management tools or interfaces. You can then do the following:

- Resize your DB instance
- Authorize connections to your DB instance
- Create and restore from backups or snapshots
- Create Multi-AZ secondaries
- Create read replicas
- Monitor the performance of your DB instance

To store and access the data in your DB instance, you use standard MySQL utilities and applications.

Amazon RDS for MySQL is compliant with many industry standards. For example, you can use RDS for MySQL databases to build HIPAA-compliant applications. You can use RDS for MySQL databases to store healthcare related information, including protected health information (PHI) under a Business Associate Agreement (BAA) with AWS. Amazon RDS for MySQL also meets Federal Risk and Authorization Management Program (FedRAMP) security requirements. In addition, Amazon RDS for MySQL has received a FedRAMP Joint Authorization Board (JAB) Provisional Authority to Operate (P-ATO) at the FedRAMP HIGH Baseline within the AWS GovCloud (US) Regions. For more information on supported compliance standards, see [AWS cloud compliance](#).

For information about the features in each version of MySQL, see [The main features of MySQL](#) in the MySQL documentation.

Before creating a DB instance, complete the steps in [Setting up for Amazon RDS](#). When you create a DB instance, the RDS master user gets DBA privileges, with some limitations. Use this account for administrative tasks such as creating additional database accounts.

You can create the following:

- DB instances
- DB snapshots

- Point-in-time restores
- Automated backups
- Manual backups

You can use DB instances running MySQL inside a virtual private cloud (VPC) based on Amazon VPC. You can also add features to your MySQL DB instance by turning on various options. Amazon RDS supports Multi-AZ deployments for MySQL as a high-availability, failover solution.

### Important

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need advanced privileges. You can access your database using standard SQL clients such as the mysql client. However, you can't access the host directly by using Telnet or Secure Shell (SSH).

# MySQL feature support on Amazon RDS

RDS for MySQL supports most of the features and capabilities of MySQL. Some features might have limited support or restricted privileges.

You can filter new Amazon RDS features on the [What's New with Database?](#) page. For **Products**, choose **Amazon RDS**. Then search using keywords such as **MySQL 2022**.

## Note

The following lists are not exhaustive.

## Topics

- [Supported storage engines for RDS for MySQL](#)
- [Using memcached and other options with MySQL on Amazon RDS](#)
- [InnoDB cache warming for MySQL on Amazon RDS](#)
- [MySQL features not supported by Amazon RDS](#)

## Supported storage engines for RDS for MySQL

While MySQL supports multiple storage engines with varying capabilities, not all of them are optimized for recovery and data durability. Amazon RDS fully supports the InnoDB storage engine for MySQL DB instances. Amazon RDS features such as Point-In-Time restore and snapshot restore require a recoverable storage engine and are supported for the InnoDB storage engine only. For more information, see [MySQL memcached support](#).

The Federated Storage Engine is currently not supported by Amazon RDS for MySQL.

For user-created schemas, the MyISAM storage engine does not support reliable recovery and can result in lost or corrupt data when MySQL is restarted after a recovery, preventing Point-In-Time restore or snapshot restore from working as intended. However, if you still choose to use MyISAM with Amazon RDS, snapshots can be helpful under some conditions.

## Note

System tables in the `mysql` schema can be in MyISAM storage.

If you want to convert existing MyISAM tables to InnoDB tables, you can use the `ALTER TABLE` command (for example, `alter table TABLE_NAME engine=innodb;`). Bear in mind that MyISAM and InnoDB have different strengths and weaknesses, so you should fully evaluate the impact of making this switch on your applications before doing so.

MySQL 5.1, 5.5, and 5.6 are no longer supported in Amazon RDS. However, you can restore existing MySQL 5.1, 5.5, and 5.6 snapshots. When you restore a MySQL 5.1, 5.5, or 5.6 snapshot, the DB instance is automatically upgraded to MySQL 5.7.

## Using memcached and other options with MySQL on Amazon RDS

Most Amazon RDS DB engines support option groups that allow you to select additional features for your DB instance. RDS for MySQL DB instances support the memcached option, a simple, key-based cache. For more information about memcached and other options, see [Options for MySQL DB instances](#). For more information about working with option groups, see [Working with option groups](#).

## InnoDB cache warming for MySQL on Amazon RDS

InnoDB cache warming can provide performance gains for your MySQL DB instance by saving the current state of the buffer pool when the DB instance is shut down, and then reloading the buffer pool from the saved information when the DB instance starts up. This bypasses the need for the buffer pool to "warm up" from normal database use and instead preloads the buffer pool with the pages for known common queries. The file that stores the saved buffer pool information only stores metadata for the pages that are in the buffer pool, and not the pages themselves. As a result, the file does not require much storage space. The file size is about 0.2 percent of the cache size. For example, for a 64 GiB cache, the cache warming file size is 128 MiB. For more information on InnoDB cache warming, see [Saving and restoring the buffer pool state](#) in the MySQL documentation.

RDS for MySQL DB instances support InnoDB cache warming. To enable InnoDB cache warming, set the `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` parameters to 1 in the parameter group for your DB instance. Changing these parameter values in a parameter group will affect all MySQL DB instances that use that parameter group. To enable InnoDB cache warming for specific MySQL DB instances, you might need to create a new parameter group for those instances. For information on parameter groups, see [Parameter groups for Amazon RDS](#).

InnoDB cache warming primarily provides a performance benefit for DB instances that use standard storage. If you use PIOPS storage, you do not commonly see a significant performance benefit.

### Important

If your MySQL DB instance does not shut down normally, such as during a failover, then the buffer pool state will not be saved to disk. In this case, MySQL loads whatever buffer pool file is available when the DB instance is restarted. No harm is done, but the restored buffer pool might not reflect the most recent state of the buffer pool prior to the restart. To ensure that you have a recent state of the buffer pool available to warm the InnoDB cache on startup, we recommend that you periodically dump the buffer pool "on demand." You can create an event to dump the buffer pool automatically and on a regular interval. For example, the following statement creates an event named `periodic_buffer_pool_dump` that dumps the buffer pool every hour.

```
CREATE EVENT periodic_buffer_pool_dump
ON SCHEDULE EVERY 1 HOUR
DO CALL mysql.rds_innodb_buffer_pool_dump_now();
```

For more information on MySQL events, see [Event syntax](#) in the MySQL documentation.

## Dumping and loading the buffer pool on demand

You can save and load the InnoDB cache "on demand."

- To dump the current state of the buffer pool to disk, call the [mysql.rds\\_innodb\\_buffer\\_pool\\_dump\\_now](#) stored procedure.
- To load the saved state of the buffer pool from disk, call the [mysql.rds\\_innodb\\_buffer\\_pool\\_load\\_now](#) stored procedure.
- To cancel a load operation in progress, call the [mysql.rds\\_innodb\\_buffer\\_pool\\_load\\_abort](#) stored procedure.

## MySQL features not supported by Amazon RDS

Amazon RDS doesn't currently support the following MySQL features:

- Authentication Plugin
- Error Logging to the System Log
- InnoDB Tablespace Encryption
- Password Strength Plugin
- Persisted system variables
- Rewriter Query Rewrite Plugin
- Semisynchronous replication
- Transportable tablespace
- X Plugin

 **Note**

Global transaction IDs are supported for all RDS for MySQL 5.7 versions, and for RDS for MySQL 8.0.26 and higher 8.0 versions.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection. When you create a DB instance, you are assigned as *db\_owner* for all databases on that instance, and you have all database-level permissions except for those used for backups. Amazon RDS manages backups for you.

# MySQL on Amazon RDS versions

For MySQL, version numbers are organized as version = X.Y.Z. In Amazon RDS terminology, X.Y denotes the major version, and Z is the minor version number. For Amazon RDS implementations, a version change is considered major if the major version number changes—for example, going from version 5.7 to 8.0. A version change is considered minor if only the minor version number changes—for example, going from version 8.0.32 to 8.0.34.

## Supported MySQL minor versions on Amazon RDS

Amazon RDS currently supports the following minor versions of MySQL.

### Note

Dates with only a month and a year are approximate and are updated with an exact date when it's known.

Amazon RDS Extended Support isn't available for minor versions.

The following table shows the minor versions of MySQL 8.0 that Amazon RDS currently supports.

MySQL engine version	Community release date	RDS release date	RDS end of standard support date
8.0.39	23 July 2024	12 August 2024	September 2025
8.0.37	30 April 2024	18 June 2024	September 2025
8.0.36	16 January 2024	12 February 2024	March 2025
8.0.35	25 October 2023	9 November 2023	March 2025
8.0.34	18 July 2023	9 August 2023	March 2025
8.0.33	18 April 2023	15 June 2023	March 2025
8.0.32	17 January 2023	7 February 2023	March 2025

The following table shows the minor versions of MySQL 5.7 that are available under Amazon RDS Extended Support.

MySQL engine version	Community release date	RDS release date	RDS end of Extended Support date
5.7.44-RDS.20240808*	Not applicable	28 August 2024	September 2025
5.7.44-RDS.20240529*	Not applicable	25 June 2024	September 2025
5.7.44-RDS.20240408*	Not applicable	17 May 2024	September 2025
5.7.44	25 October 2023	2 November 2023	March 2025

\* MySQL Community retired major version 5.7 and won't be releasing new minor versions. This is a minor version that Amazon RDS released with critical security patches and bug fixes for MySQL 5.7 databases that are covered under RDS Extended Support. For more information about these

minor versions, see [the section called “RDS Extended Support versions for RDS for MySQL”](#). For more information about RDS Extended Support, see [Using Amazon RDS Extended Support](#).

Minor versions can reach end of standard support before major versions do. For example, minor version 8.0.28 reached its end of standard support date on March 28, 2024 while major version 8.0 will reach this date on July 31, 2026. RDS will support additional 8.0.\* minor versions that the MySQL community releases between these dates.

You can specify any currently supported MySQL version when creating a new DB instance. You can specify the major version (such as MySQL 5.7), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified. To see a list of supported versions, as well as defaults for newly created DB instances, use the [describe-db-engine-versions](#) AWS CLI command.

For example, to list the supported engine versions for RDS for MySQL, run the following CLI command:

```
aws rds describe-db-engine-versions --engine mysql --query "*[].[Engine:Engine,EngineVersion:EngineVersion]" --output text
```

The default MySQL version might vary by AWS Region. To create a DB instance with a specific minor version, specify the minor version during DB instance creation. You can determine the default minor version for an AWS Region using the following AWS CLI command:

```
aws rds describe-db-engine-versions --default-only --engine mysql --engine-version major-engine-version --region region --query "*[].[Engine:Engine,EngineVersion:EngineVersion]" --output text
```

Replace *major-engine-version* with the major engine version, and replace *region* with the AWS Region. For example, the following AWS CLI command returns the default MySQL minor engine version for the 5.7 major version and the US West (Oregon) AWS Region (us-west-2):

```
aws rds describe-db-engine-versions --default-only --engine mysql --engine-version 5.7 --region us-west-2 --query "*[].[Engine:Engine,EngineVersion:EngineVersion]" --output text
```

With Amazon RDS, you control when to upgrade your MySQL instance to a new major version supported by Amazon RDS. You can maintain compatibility with specific MySQL versions, test new versions with your application before deploying in production, and perform major version upgrades at times that best fit your schedule.

When automatic minor version upgrade is enabled, your DB instance will be upgraded automatically to new MySQL minor versions as they are supported by Amazon RDS. This patching occurs during your scheduled maintenance window. You can modify a DB instance to enable or disable automatic minor version upgrades.

If you opt out of automatically scheduled upgrades, you can manually upgrade to a supported minor version release by following the same procedure as you would for a major version update. For information, see [Upgrading a DB instance engine version](#).

Amazon RDS currently supports the major version upgrades from MySQL version 5.6 to version 5.7, and from MySQL version 5.7 to version 8.0. Because major version upgrades involve some compatibility risk, they do not occur automatically; you must make a request to modify the DB instance. You should thoroughly test any upgrade before upgrading your production instances. For information about upgrading a MySQL DB instance, see [Upgrading the MySQL DB engine](#).

You can test a DB instance against a new version before upgrading by creating a DB snapshot of your existing DB instance, restoring from the DB snapshot to create a new DB instance, and then initiating a version upgrade for the new DB instance. You can then experiment safely on the upgraded clone of your DB instance before deciding whether or not to upgrade your original DB instance.

## MySQL minor versions on Amazon RDS

### Minor versions

- [MySQL version 8.0.39](#)
- [MySQL version 8.0.37](#)

### MySQL version 8.0.39

MySQL version 8.0.39 is now available on Amazon RDS. This release contains fixes and improvements added by the MySQL community and Amazon RDS.

### New features and enhancements

- Fixed a bug that prevented `sql_log_off` from working properly with the `SESSION_VARIABLES_ADMIN` privilege.
- Fixed a bug that prevented the master user from being able to grant the `SESSION_VARIABLE_ADMIN` privilege other database users.
- Fixed a bug that caused an illegal mix of collation while executing RDS-provided stored procedures.

## MySQL version 8.0.37

MySQL version 8.0.37 is now available on Amazon RDS. This release contains fixes and improvements added by the MySQL community and Amazon RDS.

### New features and enhancements

Fixed a bug with executing an instant DDL statement followed by an UPDATE that lead to an assertion failure.

## Supported MySQL major versions on Amazon RDS

RDS for MySQL major versions are available under standard support at least until community end of life for the corresponding community version. You can continue running a major version past its RDS end of standard support date for a fee. For more information, see [Using Amazon RDS Extended Support](#) and [Amazon RDS for MySQL pricing](#).

You can use the following dates to plan your testing and upgrade cycles.

### Note

Dates with only a month and a year are approximate and are updated with an exact date when it's known.

MySQL major version	Community release date	RDS release date	Community end of life date	RDS end of standard support date	RDS start of Extended Support year 1 pricing date	RDS start of Extended Support year 3 pricing date	RDS end of Extended Support date
MySQL 8.0	19 April 2018	23 October 2018	April 2026	31 July 2026	1 August 2026	1 August 2028	31 July 2029
MySQL 5.7*	21 October 2015	22 February 2016	October 2023	29 February 2024	1 March 2024	1 March 2026	28 February 2027

\* MySQL 5.7 is now only available under RDS Extended Support. For more information, see [Using Amazon RDS Extended Support](#).

## Amazon RDS Extended Support versions for RDS for MySQL

The following content lists all releases of RDS Extended Support for RDS for MySQL versions.

### Releases

- [RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240808](#)
- [RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240529](#)
- [RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240408](#)

### RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240808

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240808 is available.

### Bugs fixed:

- Fixed assertion failure related to dictionary column index.
- Fixed issue with the `is_binlog_cache_empty()` function.

- Fixed heap-use-after-free errors in `sql/item.cc` files.
- Fixed several spatial index issues by disabling them for `index-only` reads.
- Fixed instrumentation issue with the `LOCK_ORDER: CONNECTION_CONTROL` plugin.
- Fixed threads getting stuck with the `CONNECTION_CONTROL` plugin.
- Fixed `PSI_THREAD_INFO` not updating for `PREPARED STATEMENTS`.
- Fixed double processing of FTS index words with `innodb_optimize_fulltext_only`.

**CVEs fixed:**

- [CVE-2024-21177](#)

**RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240529**

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240529 is available.

**Bugs fixed:**

- Fixed `field.cc` assertion failure by implementing `fix_after_pullout`.
- Fixed a null pointer failure when returning metadata to the client for certain SQL queries. These queries contained dynamic parameters and subqueries in `SELECT` clauses.
- Fixed incorrect results when using `GROUP BY` for loose index scans, or scans of noncontiguous ranges of an index.
- Fixed loss of GTID information on MySQL crash during persistence.
- Fixed a race condition that could cause an InnoDB transaction to hang indefinitely.
- Fixed a race condition in Group Replication's certification information cleanup.
- Fixed backward index scan issue with concurrent page operations.
- Fixed an inconsistent full-text search (FTS) state issue in concurrent scenarios.
- Fixed assertion issue with change buffer on deleting tables.
- Unified behavior for calling `deinit` function across all plugin types.

**CVEs fixed:**

- [CVE-2024-20963](#)
- [CVE-2024-20993](#)

- [CVE-2024-20998](#)
- [CVE-2024-21009](#)
- [CVE-2024-21054](#)
- [CVE-2024-21055](#)
- [CVE-2024-21057](#)
- [CVE-2024-21062](#)
- [CVE-2024-21008](#)
- [CVE-2024-21013](#)
- [CVE-2024-21047](#)
- [CVE-2024-21087](#)
- [CVE-2024-21096](#)

## RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240408

RDS Extended Support for RDS for MySQL version 5.7.44-RDS.20240408 is available.

This release contains patches for the following CVEs:

- [CVE-2024-20963](#)

## Working with the Database Preview environment

In July 2023, Oracle announced a new release model for MySQL. This model includes two types of releases: Innovation Releases and LTS releases. Amazon RDS makes MySQL Innovation Releases available in the RDS Preview environment. To learn more about the MySQL Innovation releases, see [Introducing MySQL Innovation and Long-Term Support \(LTS\) versions](#).

RDS for MySQL DB instances in the Database Preview environment are functionally similar to other RDS for MySQL DB instances. However, you can't use the Database Preview environment for production workloads.

Preview environments have the following limitations:

- Amazon RDS deletes all DB instances 60 days after you create them, along with any backups and snapshots.

- You can only use General Purpose SSD and Provisioned IOPS SSD storage.
- You can't get help from AWS Support with DB instances. Instead, you can post your questions to the AWS-managed Q&A community, [AWS re:Post](#).
- You can't copy a snapshot of a DB instance to a production environment.

The following options are supported by the preview.

- You can create DB instances using db.m6i, db.r6i, db.m6g, db.m5, db.t3, db.r6g, and db.r5 DB instance classes. For more information about RDS instance classes, see [DB instance classes](#).
- You can use both single-AZ and multi-AZ deployments.
- You can use standard MySQL dump and load functions to export databases from or import databases to the Database Preview environment.

## Features not supported in the Database Preview environment

The following features aren't available in the Database Preview environment:

- Cross-Region snapshot copy
- Cross-Region read replicas
- RDS Proxy

## Creating a new DB instance in the Database Preview environment

You can create a DB instance in the Database Preview environment using the AWS Management Console, AWS CLI, or RDS API.

### Console

#### To create a DB instance in the Database Preview environment

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Dashboard** from the navigation pane.
3. In the **Dashboard** page, locate the **Database Preview Environment** section, as shown in the following image.

**Amazon RDS** ×

**Dashboard**

- Databases
- Query Editor
- Performance insights
- Snapshots
- Exports in Amazon S3
- Automated backups
- Reserved instances
- Proxies

---

- Subnet groups
- Parameter groups
- Option groups
- Custom engine versions
- Zero-ETL integrations [New](#)

---

- Events
- Event subscriptions

---

- Recommendations **1**
- Certificate update **1**

**Create database**

Amazon Relational Database Service (RDS) makes it easy to set up, operate, and scale a relational database in the cloud.

[Restore from S3](#) [Create database](#)

Note: your DB instances will launch in the US West (Oregon) region

**Service health** [View service health dashboard](#)

Current status	Details
<span>✔</span> Amazon Relational Database Service (Oregon)	Service is operating normally

- [Forums](#)

**Database Preview Environment**

Get early access to new DB engine versions. The Amazon RDS database Preview environment lets you work with upcoming beta, release candidate, early production versions of PostgreSQL, and Innovation Releases of MySQL. Preview environment instances are fully functional, so you can easily test new features and functionality with your applications.

[Preview RDS for MySQL and PostgreSQL in US EAST \(Ohio\)](#)

You can navigate directly to the [Database Preview environment](#). Before you can proceed, you must acknowledge and accept the limitations.

### Database Preview Environment Service Agreement ✕

The Amazon RDS Database Preview Environment is not covered by the Amazon RDS service level agreement (SLA), published at <https://aws.amazon.com/rds/sla> 

Do not use the Amazon RDS Database Preview Environment for production purposes. You should only use this environment for development and testing.

Certain use cases might fail in this environment - for example, upgrading from a previous version is not supported.

I acknowledge this limited service agreement for the Amazon RDS Database Preview Environment and that I should only use this environment for development and testing.

Cancel Accept

4. To create the RDS for MySQL DB instance, follow the same process that you would for creating any Amazon RDS DB instance. For more information, see the [Console](#) procedure in [Creating a DB instance](#).

## AWS CLI

To create a DB instance in the Database Preview environment using the AWS CLI, use the following endpoint.

```
rds-preview.us-east-2.amazonaws.com
```

To create the RDS for MySQL DB instance, follow the same process that you would for creating any Amazon RDS DB instance. For more information, see the [AWS CLI](#) procedure in [Creating a DB instance](#).

## RDS API

To create a DB instance in the Database Preview environment using the RDS API, use the following endpoint.

```
rds-preview.us-east-2.amazonaws.com
```

To create the RDS for MySQL DB instance, follow the same process that you would for creating any Amazon RDS DB instance. For more information, see the [RDS API](#) procedure in [Creating a DB instance](#).

## MySQL version 8.4 in the Database Preview environment

MySQL version 8.4 is now available in the Amazon RDS Database Preview environment. MySQL version 8.4 is the latest LTS release from the community, and contains several improvements that are described in [Changes in MySQL 8.4.0](#). You can use the Database Preview environment to test your workloads against this release before it is available in all AWS Regions for production workloads.

MySQL version 8.4 in the Database Preview environment might differ from what Amazon RDS releases in all AWS Regions for production workloads. The following list includes features that could change. This list isn't exhaustive.

- The RDS for MySQL 8.4 parameter group definition. For example, Amazon RDS might add, remove, or rename parameters, and might change the parameter default values.
- The privilege model.
- The TLS library.

For information on the Database Preview environment, see [the section called “ The Database Preview environment”](#). To access the Preview Environment from the console, select <https://console.aws.amazon.com/rds-preview/>.

## MySQL version 8.3 in the Database Preview environment

MySQL version 8.3 is now available in the Amazon RDS Database Preview environment. MySQL version 8.3 contains several improvements that are described in [Changes in MySQL 8.3.0](#).

For information on the Database Preview environment, see [the section called “ The Database Preview environment”](#). To access the Preview Environment from the console, select <https://console.aws.amazon.com/rds-preview/>.

## MySQL version 8.2 in the Database Preview environment

MySQL version 8.2 is now available in the Amazon RDS Database Preview environment. MySQL version 8.2 contains several improvements that are described in [Changes in MySQL 8.2.0](#).

For information on the Database Preview environment, see [the section called "The Database Preview environment"](#). To access the Preview Environment from the console, select <https://console.aws.amazon.com/rds-preview/>.

## MySQL version 8.1 in the Database Preview environment

MySQL version 8.1 is now available in the Amazon RDS Database Preview environment. MySQL version 8.1 contains several improvements that are described in [Changes in MySQL 8.1.0](#).

For information on the Database Preview environment, see [the section called "The Database Preview environment"](#). To access the Preview Environment from the console, select <https://console.aws.amazon.com/rds-preview/>.

## Deprecated versions for Amazon RDS for MySQL

Amazon RDS for MySQL version 5.1, 5.5, and 5.6 are deprecated.

For information about the Amazon RDS deprecation policy for MySQL, see [Amazon RDS FAQs](#).

# Connecting to a DB instance running the MySQL database engine

Before you can connect to a DB instance running the MySQL database engine, you must create a DB instance. For information, see [Creating an Amazon RDS DB instance](#). After Amazon RDS provisions your DB instance, you can use any standard MySQL client application or utility to connect to the instance. In the connection string, you specify the DNS address from the DB instance endpoint as the host parameter, and specify the port number from the DB instance endpoint as the port parameter.

To authenticate to your RDS DB instance, you can use one of the authentication methods for MySQL and AWS Identity and Access Management (IAM) database authentication:

- To learn how to authenticate to MySQL using one of the authentication methods for MySQL, see [Authentication method](#) in the MySQL documentation.
- To learn how to authenticate to MySQL using IAM database authentication, see [IAM database authentication for MariaDB, MySQL, and PostgreSQL](#).

You can connect to a MySQL DB instance by using tools like the MySQL command-line client. For more information on using the MySQL command-line client, see [mysql - the MySQL command-line client](#) in the MySQL documentation. One GUI-based application you can use to connect is MySQL Workbench. For more information, see the [Download MySQL Workbench](#) page. For information about installing MySQL (including the MySQL command-line client), see [Installing and upgrading MySQL](#).

To connect to a DB instance from outside of its Amazon VPC, the DB instance must be publicly accessible, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see [Can't connect to Amazon RDS DB instance](#).

You can use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) encryption on connections to a MySQL DB instance. For information, see [Using SSL/TLS with a MySQL DB instance](#). If you are using AWS Identity and Access Management (IAM) database authentication, make sure to use an SSL/TLS connection. For information, see [IAM database authentication for MariaDB, MySQL, and PostgreSQL](#).

You can also connect to a DB instance from a web server. For more information, see [Tutorial: Create a web server and an Amazon RDS DB instance](#).

**Note**

For information on connecting to a MariaDB DB instance, see [Connecting to a DB instance running the MariaDB database engine](#).

**Contents**

- [Finding the connection information for an RDS for MySQL DB instance](#)
- [Installing the MySQL command-line client](#)
- [Connecting from the MySQL command-line client \(unencrypted\)](#)

## Finding the connection information for an RDS for MySQL DB instance

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, suppose that an endpoint value is `mydb.123456789012.us-east-1.rds.amazonaws.com`. In this case, the port value is `3306`, and the database user is `admin`. Given this information, you specify the following values in a connection string:

- For host or host name or DNS name, specify `mydb.123456789012.us-east-1.rds.amazonaws.com`.
- For port, specify `3306`.
- For user, specify `admin`.

To connect to a DB instance, use any client for the MySQL DB engine. For example, you might use the MySQL command-line client or MySQL Workbench.

To find the connection information for a DB instance, you can use the AWS Management Console, the AWS CLI [describe-db-instances](#) command, or the Amazon RDS API [DescribeDBInstances](#) operation to list its details.

## Console

### To find the connection information for a DB instance in the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases** to display a list of your DB instances.
3. Choose the name of the MySQL DB instance to display its details.
4. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

RDS > Databases > mydb

# mydb

## Summary

DB identifier mydb	CPU 2.33%
Role Instance	Current activity 0 Connections

**Connectivity & security** | Monitoring | Logs & events | Configuration

## Connectivity & security

Endpoint & port	Network
Endpoint mydb. [REDACTED].us-east-1.rds.amazonaws.com	Availability Zone us-east-1
Port 3306	VPC vpc-65
	Subnet default

5. If you need to find the master user name, choose the **Configuration** tab and view the **Master username** value.

## AWS CLI

To find the connection information for a MySQL DB instance by using the AWS CLI, call the [describe-db-instances](#) command. In the call, query for the DB instance ID, endpoint, port, and master user name.

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
  --filters "Name=engine,Values=mysql" \
  --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

For Windows:

```
aws rds describe-db-instances ^
  --filters "Name=engine,Values=mysql" ^
  --query "*[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

Your output should be similar to the following.

```
[
  [
    "mydb1",
    "mydb1.123456789012.us-east-1.rds.amazonaws.com",
    3306,
    "admin"
  ],
  [
    "mydb2",
    "mydb2.123456789012.us-east-1.rds.amazonaws.com",
    3306,
    "admin"
  ]
]
```

## RDS API

To find the connection information for a DB instance by using the Amazon RDS API, call the [DescribeDBInstances](#) operation. In the output, find the values for the endpoint address, endpoint port, and master user name.

## Installing the MySQL command-line client

Most Linux distributions include the MariaDB client instead of the Oracle MySQL client. To install the MySQL command-line client on Amazon Linux 2023, run the following command:

```
sudo dnf install mariadb105
```

To install the MySQL command-line client on Amazon Linux 2, run the following command:

```
sudo yum install mariadb
```

To install the MySQL command-line client on most DEB-based Linux distributions, run the following command:

```
apt-get install mariadb-client
```

To check the version of your MySQL command-line client, run the following command:

```
mysql --version
```

To read the MySQL documentation for your current client version, run the following command:

```
man mysql
```

## Connecting from the MySQL command-line client (unencrypted)

### Important

Only use an unencrypted MySQL connection when the client and server are in the same VPC and the network is trusted. For information about using encrypted connections, see [Connecting from the MySQL command-line client with SSL/TLS \(encrypted\)](#).

To connect to a DB instance using the MySQL command-line client, enter the following command at the command prompt. For the `-h` parameter, substitute the DNS name (endpoint) for your DB instance. For the `-P` parameter, substitute the port for your DB instance. For the `-u` parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com -P 3306 -  
u mymasteruser -p
```

After you enter the password for the user, you should see output similar to the following.

```
Welcome to the MySQL monitor.  Commands end with ; or \g.  
Your MySQL connection id is 9738  
Server version: 8.0.28 Source distribution  
  
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.  
  
mysql>
```

## Connecting from MySQL Workbench

### To connect from MySQL Workbench

1. Download and install MySQL Workbench at [Download MySQL Workbench](#).
2. Open MySQL Workbench.

3. From **Database**, choose **Manage Connections**.
4. In the **Manage Server Connections** window, choose **New**.
5. In the **Connect to Database** window, enter the following information:
  - **Stored Connection** – Enter a name for the connection, such as **MyDB**.
  - **Hostname** – Enter the DB instance endpoint.

- **Port** – Enter the port used by the DB instance.
- **Username** – Enter the user name of a valid database user, such as the master user.
- **Password** – Optionally, choose **Store in Vault** and then enter and save the password for the user.

The window looks similar to the following:

You can use the features of MySQL Workbench to customize connections. For example, you can use the **SSL** tab to configure SSL/TLS connections. For information about using MySQL Workbench, see the [MySQL Workbench documentation](#). Encrypting client connections to MySQL DB instances with SSL/TLS, see [Encrypting client connections to MySQL DB instances with SSL/TLS](#).

6. Optionally, choose **Test Connection** to confirm that the connection to the DB instance is successful.
7. Choose **Close**.
8. From **Database**, choose **Connect to Database**.

9. From **Stored Connection**, choose your connection.
10. Choose **OK**.

## Connecting to RDS for MySQL with the Amazon Web Services (AWS) JDBC Driver

The Amazon Web Services (AWS) JDBC Driver is designed as an advanced JDBC wrapper. This wrapper is complementary to and extends the functionality of an existing JDBC driver. The driver is drop-in compatible with the community MySQL Connector/J driver and the community MariaDB Connector/J driver.

To install the AWS JDBC Driver, append the AWS JDBC Driver .jar file (located in the application CLASSPATH), and keep references to the respective community driver. Update the respective connection URL prefix as follows:

- `jdbc:mysql://` to `jdbc:aws-wrapper:mysql://`
- `jdbc:mariadb://` to `jdbc:aws-wrapper:mariadb://`

For more information about the AWS JDBC Driver and complete instructions for using it, see the [Amazon Web Services \(AWS\) JDBC Driver GitHub repository](#).

## Connecting to RDS for MySQL with the Amazon Web Services (AWS) Python Driver

The Amazon Web Services (AWS) Python Driver is designed as an advanced Python wrapper. This wrapper is complementary to and extends the functionality of the open-source Pycopg driver. The AWS Python Driver supports Python versions 3.8 and higher. You can install the `aws-advanced-python-wrapper` package using the `pip` command, along with the `psycopg` open-source packages.

For more information about the AWS Python Driver and complete instructions for using it, see the [Amazon Web Services \(AWS\) Python Driver GitHub repository](#).

# Connecting to RDS for MySQL with the Amazon Web Services (AWS) ODBC Driver for MySQL

The AWS ODBC Driver for MySQL is a client driver designed for the high availability of RDS for MySQL. The driver can exist alongside the MySQL Connector/ODBC driver and is compatible with the same workflows.

For more information about the AWS ODBC Driver for MySQL and complete instructions for installing and using it, see the [Amazon Web Services \(AWS\) ODBC Driver for MySQL](#) GitHub repository.

## Troubleshooting connections to your MySQL DB instance

Two common causes of connection failures to a new DB instance are:

- The DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the MySQL application or utility is running. The DB instance must have a VPC security group that authorizes the connections. For more information, see [Amazon VPC and Amazon RDS](#).

You can add or edit an inbound rule in the security group. For **Source**, choose **My IP**. This allows access to the DB instance from the IP address detected in your browser.

- The DB instance was created using the default port of 3306, and your company has firewall rules blocking connections to that port from devices in your company network. To fix this failure, recreate the instance with a different port.

For more information on connection issues, see [Can't connect to Amazon RDS DB instance](#).

# Securing MySQL DB instance connections

You can manage the security of your MySQL DB instances.

## Topics

- [MySQL security on Amazon RDS](#)
- [Using the Password Validation Plugin for RDS for MySQL](#)
- [Encrypting client connections to MySQL DB instances with SSL/TLS](#)
- [Updating applications to connect to MySQL DB instances using new SSL/TLS certificates](#)
- [Using Kerberos authentication for MySQL](#)

## MySQL security on Amazon RDS

Security for MySQL DB instances is managed at three levels:

- AWS Identity and Access Management controls who can perform Amazon RDS management actions on DB instances. When you connect to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see [Identity and access management for Amazon RDS](#).
- When you create a DB instance, you use a VPC security group to control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance. These connections can be made using Secure Sockets Layer (SSL) and Transport Layer Security (TLS). In addition, firewall rules at your company can control whether devices running at your company can open connections to the DB instance.
- To authenticate login and permissions for a MySQL DB instance, you can take either of the following approaches, or a combination of them.

You can take the same approach as with a stand-alone instance of MySQL. Commands such as CREATE USER, RENAME USER, GRANT, REVOKE, and SET PASSWORD work just as they do in on-premises databases, as does directly modifying database schema tables. However, directly modifying the database schema tables isn't a best practice, and starting from RDS for MySQL version 8.0.36, it isn't supported. For information, see [Access control and account management](#) in the MySQL documentation.

You can also use IAM database authentication. With IAM database authentication, you authenticate to your DB instance by using an IAM user or IAM role and an authentication token.

An *authentication token* is a unique value that is generated using the Signature Version 4 signing process. By using IAM database authentication, you can use the same credentials to control access to your AWS resources and your databases. For more information, see [IAM database authentication for MariaDB, MySQL, and PostgreSQL](#).

Another option is Kerberos authentication for RDS for MySQL. The DB instance works with AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to enable Kerberos authentication. When users authenticate with a MySQL DB instance joined to the trusting domain, authentication requests are forwarded. Forwarded requests go to the domain directory that you create with AWS Directory Service. For more information, see [Using Kerberos authentication for MySQL](#).

When you create an Amazon RDS DB instance, the master user has the following default privileges:

Engine version	System privilege	Database role
RDS for MySQL version 8.0.36 and higher	SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD, PROCESS, REFERENCES , INDEX, ALTER, SHOW DATABASES , CREATE TEMPORARY TABLES, LOCK TABLES, EXECUTE, REPLICATION SLAVE, REPLICATION CLIENT , CREATE VIEW, SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, CREATE ROLE, DROP ROLE, APPLICATION_PASSWORD_ADMIN , ROLE_ADMIN , SET_USER_ID , XA_RECOVER_ADMIN	rds_superuser_role  For more information about rds_superuser_role , see <a href="#">Role-based privilege model</a> .
RDS for MySQL versions lower than 8.0.36	SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD, PROCESS, REFERENCES , INDEX, ALTER, SHOW DATABASES , CREATE TEMPORARY TABLES, LOCK TABLES, EXECUTE, REPLICATION CLIENT , CREATE VIEW, SHOW VIEW, CREATE ROUTINE, ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, REPLICATION SLAVE	—

**Note**

Although it is possible to delete the master user on the DB instance, it is not recommended. To recreate the master user, use the [ModifyDBInstance](#) RDS API operation or the [modify-db-instance](#) AWS CLI command and specify a new master user password with the appropriate parameter. If the master user does not exist in the instance, the master user is created with the specified password.

To provide management services for each DB instance, the `rdsadmin` user is created when the DB instance is created. Attempting to drop, rename, change the password, or change privileges for the `rdsadmin` account will result in an error.

To allow management of the DB instance, the standard `kill` and `kill_query` commands have been restricted. The Amazon RDS commands `rds_kill` and `rds_kill_query` are provided to allow you to end user sessions or queries on DB instances.

## Using the Password Validation Plugin for RDS for MySQL

MySQL provides the `validate_password` plugin for improved security. The plugin enforces password policies using parameters in the DB parameter group for your MySQL DB instance. The plugin is supported for DB instances running MySQL version 5.7 and 8.0. For more information about the `validate_password` plugin, see [The Password Validation Plugin](#) in the MySQL documentation.

### To enable the `validate_password` plugin for a MySQL DB instance

1. Connect to your MySQL DB instance and run the following command.

```
INSTALL PLUGIN validate_password SONAME 'validate_password.so';
```

2. Configure the parameters for the plugin in the DB parameter group used by the DB instance.

For more information about the parameters, see [Password Validation Plugin options and variables](#) in the MySQL documentation.

For more information about modifying DB instance parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

After installing and enabling the `password_validate` plugin, reset existing passwords to comply with your new validation policies.

Amazon RDS doesn't validate passwords. The MySQL DB instance performs password validation. If you set a user password with the AWS Management Console, the `modify-db-instance` AWS CLI command, or the `ModifyDBInstance` RDS API operation, the change can succeed even if the new password doesn't satisfy your password policies. However, a new password is set in the MySQL DB instance only if it satisfies the password policies. In this case, Amazon RDS records the following event.

```
"RDS-EVENT-0067" - An attempt to reset the master password for the DB instance has failed.
```

For more information about Amazon RDS events, see [Working with Amazon RDS event notification](#).

## Encrypting client connections to MySQL DB instances with SSL/TLS

Secure Sockets Layer (SSL) is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to Transport Layer Security (TLS). Amazon RDS supports SSL/TLS encryption for MySQL DB instances. Using SSL/TLS, you can encrypt a connection between your application client and your MySQL DB instance. SSL/TLS support is available in all AWS Regions for MySQL.

### Topics

- [Using SSL/TLS with a MySQL DB instance](#)
- [Requiring SSL/TLS for all connections to a MySQL DB instance](#)
- [Connecting from the MySQL command-line client with SSL/TLS \(encrypted\)](#)

## Using SSL/TLS with a MySQL DB instance

Amazon RDS creates an SSL/TLS certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The SSL/TLS certificate includes the DB instance endpoint as the Common Name (CN) for the SSL/TLS certificate to guard against spoofing attacks.

An SSL/TLS certificate created by Amazon RDS is the trusted root entity and should work in most cases but might fail if your application does not accept certificate chains. If your application does not accept certificate chains, you might need to use an intermediate certificate to connect to your AWS Region. For example, you must use an intermediate certificate to connect to the AWS GovCloud (US) Regions using SSL/TLS.

For information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#). For more information about using SSL/TLS with MySQL, see [Updating applications to connect to MySQL DB instances using new SSL/TLS certificates](#).

MySQL uses OpenSSL for secure connections. Amazon RDS for MySQL supports Transport Layer Security (TLS) versions 1.0, 1.1, 1.2, and 1.3. TLS support depends on the MySQL version. The following table shows the TLS support for MySQL versions.

MySQL version	TLS 1.0	TLS 1.1	TLS 1.2	TLS 1.3
MySQL 8.0	Not supported	Not supported	Supported	Supported
MySQL 5.7	Supported	Supported	Supported	Not supported

You can require SSL/TLS connections for specific users accounts. For example, you can use one of the following statements, depending on your MySQL version, to require SSL/TLS connections on the user account `encrypted_user`.

To do so, use the following statement.

```
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

For more information on SSL/TLS connections with MySQL, see the [Using encrypted connections](#) in the MySQL documentation.

## Requiring SSL/TLS for all connections to a MySQL DB instance

Use the `require_secure_transport` parameter to require that all user connections to your MySQL DB instance use SSL/TLS. By default, the `require_secure_transport` parameter is set to `OFF`. You can set the `require_secure_transport` parameter to `ON` to require SSL/TLS for connections to your DB instance.

You can set the `require_secure_transport` parameter value by updating the DB parameter group for your DB instance. You don't need to reboot your DB instance for the change to take effect.

When the `require_secure_transport` parameter is set to `ON` for a DB instance, a database client can connect to it if it can establish an encrypted connection. Otherwise, an error message similar to the following is returned to the client:

```
MySQL Error 3159 (HY000): Connections using insecure transport are prohibited while --require_secure_transport=ON.
```

For information about setting parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

For more information about the `require_secure_transport` parameter, see the [MySQL documentation](#).

## Connecting from the MySQL command-line client with SSL/TLS (encrypted)

The `mysql` client program parameters are slightly different if you are using the MySQL 5.7 version, the MySQL 8.0 version, or the MariaDB version.

To find out which version you have, run the `mysql` command with the `--version` option. In the following example, the output shows that the client program is from MariaDB.

```
$ mysql --version
mysql Ver 15.1 Distrib 10.5.15-MariaDB, for osx10.15 (x86_64) using readline 5.1
```

Most Linux distributions, such as Amazon Linux, CentOS, SUSE, and Debian have replaced MySQL with MariaDB, and the `mysql` version in them is from MariaDB.

To connect to your DB instance using SSL/TLS, follow these steps:

### To connect to a DB instance with SSL/TLS using the MySQL command-line client

1. Download a root certificate that works for all AWS Regions.

For information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

2. Use a MySQL command-line client to connect to a DB instance with SSL/TLS encryption. For the `-h` parameter, substitute the DNS name (endpoint) for your DB instance. For the `--ssl-ca`

parameter, substitute the SSL/TLS certificate file name. For the `-P` parameter, substitute the port for your DB instance. For the `-u` parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

The following example shows how to launch the client using the `--ssl-ca` parameter using the MySQL 5.7 client or later:

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-mode=REQUIRED -P 3306 -u myadmin -p
```

To require that the SSL/TLS connection verifies the DB instance endpoint against the endpoint in the SSL/TLS certificate, enter the following command:

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl-mode=VERIFY_IDENTITY -P 3306 -u myadmin -p
```

The following example shows how to launch the client using the `--ssl-ca` parameter using the MariaDB client:

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=global-bundle.pem --ssl -P 3306 -u myadmin -p
```

3. Enter the master user password when prompted.

You will see output similar to the following.

```
Welcome to the MySQL monitor.  Commands end with ; or \g.
Your MySQL connection id is 9738
Server version: 8.0.28 Source distribution

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

## Updating applications to connect to MySQL DB instances using new SSL/TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security

(SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances. If they do, you can further check whether those applications require certificate verification to connect.

### Note

Some applications are configured to connect to MySQL DB instances only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.

You can specify the following SSL modes: `disabled`, `preferred`, and `required`. When you use the `preferred` SSL mode and the CA certificate doesn't exist or isn't up to date, the connection falls back to not using SSL and connects without encryption.

Because these later versions use the OpenSSL protocol, an expired server certificate doesn't prevent successful connections unless the `required` SSL mode is specified.

We recommend avoiding `preferred` mode. In `preferred` mode, if the connection encounters an invalid certificate, it stops using encryption and proceeds unencrypted.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see [Rotating your SSL/TLS certificate](#). For more information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#). For information about using SSL/TLS with MySQL DB instances, see [Using SSL/TLS with a MySQL DB instance](#).

## Topics

- [Determining whether any applications are connecting to your MySQL DB instance using SSL](#)
- [Determining whether a client requires certificate verification to connect](#)
- [Updating your application trust store](#)
- [Example Java code for establishing SSL connections](#)

## Determining whether any applications are connecting to your MySQL DB instance using SSL

If you are using Amazon RDS for MySQL version 5.7 or 8.0 and the Performance Schema is enabled, run the following query to check if connections are using SSL/TLS. For information about enabling the Performance Schema, see [Performance Schema quick start](#) in the MySQL documentation.

```
mysql> SELECT id, user, host, connection_type
        FROM performance_schema.threads pst
        INNER JOIN information_schema.processlist isp
        ON pst.processlist_id = isp.id;
```

In this sample output, you can see both your own session (admin) and an application logged in as webapp1 are using SSL.

```
+-----+-----+-----+-----+
| id | user          | host          | connection_type |
+-----+-----+-----+-----+
|  8 | admin         | 10.0.4.249:42590 | SSL/TLS         |
|  4 | event_scheduler | localhost     | NULL            |
| 10 | webapp1       | 159.28.1.1:42189 | SSL/TLS       |
+-----+-----+-----+-----+
3 rows in set (0.00 sec)
```

## Determining whether a client requires certificate verification to connect

You can check whether JDBC clients and MySQL clients require certificate verification to connect.

### JDBC

The following example with MySQL Connector/J 8.0 shows one way to check an application's JDBC connection properties to determine whether successful connections require a valid certificate. For more information on all of the JDBC connection options for MySQL, see [Configuration properties](#) in the MySQL documentation.

When using the MySQL Connector/J 8.0, an SSL connection requires verification against the DB server certificate if your connection properties have `sslMode` set to `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);
```

### Note

If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use SSL/TLS when connecting to your databases, these client drivers default to using SSL/TLS. In addition, when using SSL/TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.

## MySQL

The following examples with the MySQL Client show two ways to check a script's MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see [Client-side configuration for encrypted connections](#) in the MySQL documentation.

When using the MySQL 5.7 or MySQL 8.0 Client, an SSL connection requires verification against the server CA certificate if for the `--ssl-mode` option you specify `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem
--ssl-mode=VERIFY_CA
```

When using the MySQL 5.6 Client, an SSL connection requires verification against the server CA certificate if you specify the `--ssl-verify-server-cert` option, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem  
--ssl-verify-server-cert
```

## Updating your application trust store

For information about updating the trust store for MySQL applications, see [Installing SSL certificates](#) in the MySQL documentation.

For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

For sample scripts that import certificates, see [Sample script for importing certificates into your trust store](#).

### Note

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

If you are using the mysql JDBC driver in an application, set the following properties in the application.

```
System.setProperty("javax.net.ssl.trustStore", certs);  
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

When you start the application, set the following properties.

```
java -Djavax.net.ssl.trustStore=/path_to_trust_store/MyTruststore.jks -  
Djavax.net.ssl.trustStorePassword=my_trust_store_password com.companyName.MyApplication
```

### Note

Specify a password other than the prompt shown here as a security best practice.

## Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection that validates the server certificate using JDBC.

```
public class MySQLSSLTest {

    private static final String DB_USER = "username";
    private static final String DB_PASSWORD = "password";
    // This trust store has only the prod root ca.
    private static final String TRUST_STORE_FILE_PATH = "file-path-to-trust-store";
    private static final String TRUST_STORE_PASS = "trust-store-password";

    public static void test(String[] args) throws Exception {
        Class.forName("com.mysql.jdbc.Driver");

        System.setProperty("javax.net.ssl.trustStore", TRUST_STORE_FILE_PATH);
        System.setProperty("javax.net.ssl.trustStorePassword", TRUST_STORE_PASS);

        Properties properties = new Properties();
        properties.setProperty("sslMode", "VERIFY_IDENTITY");
        properties.put("user", DB_USER);
        properties.put("password", DB_PASSWORD);

        Connection connection = null;
        Statement stmt = null;
        ResultSet rs = null;
        try {
            connection =
                DriverManager.getConnection("jdbc:mysql://mydatabase.123456789012.us-
                east-1.rds.amazonaws.com:3306",properties);
            stmt = connection.createStatement();
            rs=stmt.executeQuery("SELECT 1 from dual");
        } finally {
            if (rs != null) {
                try {
                    rs.close();
                } catch (SQLException e) {
                }
            }
            if (stmt != null) {
```

```
        try {
            stmt.close();
        } catch (SQLException e) {
        }
    }
    if (connection != null) {
        try {
            connection.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
return;
}
```

### Important

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the `rds-ca-rsa2048-g1` certificates. For instructions, see step 3 in [Updating your CA certificate by modifying your DB instance or cluster](#).

Specify a password other than the prompt shown here as a security best practice.

## Using Kerberos authentication for MySQL

You can use Kerberos authentication to authenticate users when they connect to your MySQL DB instance. The DB instance works with AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to enable Kerberos authentication. When users authenticate with a MySQL DB instance joined to the trusting domain, authentication requests are forwarded. Forwarded requests go to the domain directory that you create with AWS Directory Service.

Keeping all of your credentials in the same directory can save you time and effort. With this approach, you have a centralized place for storing and managing credentials for multiple DB instances. Using a directory can also improve your overall security profile.

## Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of Amazon RDS with Kerberos authentication, see [Supported Regions and DB engines for Kerberos authentication in Amazon RDS](#).

## Overview of Setting up Kerberos authentication for MySQL DB instances

To set up Kerberos authentication for a MySQL DB instance, complete the following general steps, described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the AWS Directory Service to create the directory. For details about doing so, see [Create your AWS Managed Microsoft AD directory](#) in the *AWS Directory Service Administration Guide*.
2. Create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. The role allows Amazon RDS to make calls to your directory.

For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see [Activating and deactivating AWS STS in an AWS Region](#) in the *IAM User Guide*.

3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see [Manage users and groups in AWS managed Microsoft AD](#) in the *AWS Directory Service Administration Guide*.
4. Create or modify a MySQL DB instance. If you use either the CLI or RDS API in the create request, specify a domain identifier with the `Domain` parameter. Use the `d-*` identifier that was generated when you created your directory and the name of the role that you created.

If you modify an existing MySQL DB instance to use Kerberos authentication, set the domain and IAM role parameters for the DB instance. Locate the DB instance in the same VPC as the domain directory.

5. Use the Amazon RDS master user credentials to connect to the MySQL DB instance. Create the user in MySQL using the `CREATE USER` clause `IDENTIFIED WITH 'auth_pam'`. Users that you create this way can log in to the MySQL DB instance using Kerberos authentication.

## Setting up Kerberos authentication for MySQL DB instances

You use AWS Managed Microsoft AD to set up Kerberos authentication for a MySQL DB instance. To set up Kerberos authentication, you take the following steps.

### Step 1: Create a directory using AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name System (DNS) servers on your behalf. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

#### Note

Be sure to save this password. AWS Directory Service doesn't store it. You can reset it, but you can't retrieve it.

- Creates a security group for the directory controllers.

When you launch an AWS Managed Microsoft AD, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU has the NetBIOS name that you typed when you created your directory and is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers

- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run AD and DNS Windows PowerShell modules on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

### To create a directory with AWS Managed Microsoft AD

1. Sign in to the AWS Management Console and open the AWS Directory Service console at <https://console.aws.amazon.com/directoryservicev2/>.
2. In the navigation pane, choose **Directories** and choose **Set up Directory**.
3. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option that you can currently use with Amazon RDS.
4. Enter the following information:

#### Directory DNS name

The fully qualified name for the directory, such as **corp.example.com**.

#### Directory NetBIOS name

The short name for the directory, such as **CORP**.

#### Directory description

(Optional) A description for the directory.

#### Admin password

The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

The directory administrator password and can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Non-alphanumeric characters (~!@#\$%^&\* \_+= ` \(){}[]:;'"<>,.?/)

### Confirm password

The administrator password retyped.

5. Choose **Next**.
6. Enter the following information in the **Networking** section and then choose **Next**:

### VPC

The VPC for the directory. Create the MySQL DB instance in this same VPC.

### Subnets

Subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Review the directory information and make any necessary changes. When the information is correct, choose **Create directory**.

## Review & create

### Review

Directory type Microsoft AD	VPC vpc-8b6b78e9 ( [REDACTED] )
Directory DNS name corp.example.com	Subnets subnet-75128d10 ( [REDACTED] , us-east-1a) subnet-f51665dd ( [REDACTED] , us-east-1b)
Directory NetBIOS name CORP	
Directory description My directory	

### Pricing

Edition Standard	Free trial eligible <a href="#">Learn more</a> 30-day limited trial
~USD [REDACTED] *	
* Includes two domain controllers, USD [REDACTED] /mo for each additional domain controller.	

Cancel Previous **Create directory**

It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory name in the directory listing. Note the **Directory ID** value because you need this value when you create or modify your MySQL DB instance.

Directory Service > Directories > d-90670a8d36

### Directory details

[Reset user password](#)

Edition Standard	Subnets <a href="#">subnet-7d36a227</a> <a href="#">subnet-a2ab49c6</a>	Last updated Tuesday, January 7, 2020
<b>Directory ID</b> d-90670a8d36	Availability zones us-east-1c, us-east-1d	Launch time Tuesday, January 7, 2020
Directory DNS name corp.example.com	DNS address 	
Directory NetBIOS name CORP		
Description - <a href="#">Edit</a> My directory		

[Application management](#) | [Scale & share](#) | [Networking & security](#) | [Maintenance](#)

## Step 2: Create the IAM role for use by Amazon RDS

For Amazon RDS to call AWS Directory Service for you, an IAM role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess` is required. This role allows Amazon RDS to make calls to the AWS Directory Service.

When a DB instance is created using the AWS Management Console and the console user has the `iam:CreateRole` permission, the console creates this role automatically. In this case, the role name is `rds-directoryservice-kerberos-access-role`. Otherwise, you must create the

IAM role manually. When you create this IAM role, choose **Directory Service**, and attach the AWS managed policy `AmazonRDSDirectoryServiceAccess` to it.

For more information about creating IAM roles for a service, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.

**Note**

The IAM role used for Windows Authentication for RDS for SQL Server can't be used for RDS for MySQL.

Optionally, you can create policies with the required permissions instead of using the managed IAM policy `AmazonRDSDirectoryServiceAccess`. In this case, the IAM role must have the following IAM trust policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "directoryservice.rds.amazonaws.com",
          "rds.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The role must also have the following IAM role policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ds:DescribeDirectories",

```

```
        "ds:AuthorizeApplication",
        "ds:UnauthorizeApplication",
        "ds:GetAuthorizedApplicationDetails"
    ],
    "Effect": "Allow",
    "Resource": "*"
  }
]
```

### Step 3: Create and configure users

You can create users with the Active Directory Users and Computers tool. This tool is part of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. Users represent individual people or entities that have access to your directory.

To create users in an AWS Directory Service directory, you must be connected to an Amazon EC2 instance based on Microsoft Windows. This instance must be a member of the AWS Directory Service directory and be logged in as a user that has privileges to create users. For more information, see [Manage users and groups in AWS Managed Microsoft AD](#) in the *AWS Directory Service Administration Guide*.

### Step 4: Create or modify a MySQL DB instance

Create or modify a MySQL DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new MySQL DB instance using the console, the [create-db-instance](#) CLI command, or the [CreateDBInstance](#) RDS API operation.

For instructions, see [Creating an Amazon RDS DB instance](#).

- Modify an existing MySQL DB instance using the console, the [modify-db-instance](#) CLI command, or the [ModifyDBInstance](#) RDS API operation.

For instructions, see [Modifying an Amazon RDS DB instance](#).

- Restore a MySQL DB instance from a DB snapshot using the console, the [restore-db-instance-from-db-snapshot](#) CLI command, or the [RestoreDBInstanceFromDBSnapshot](#) RDS API operation.

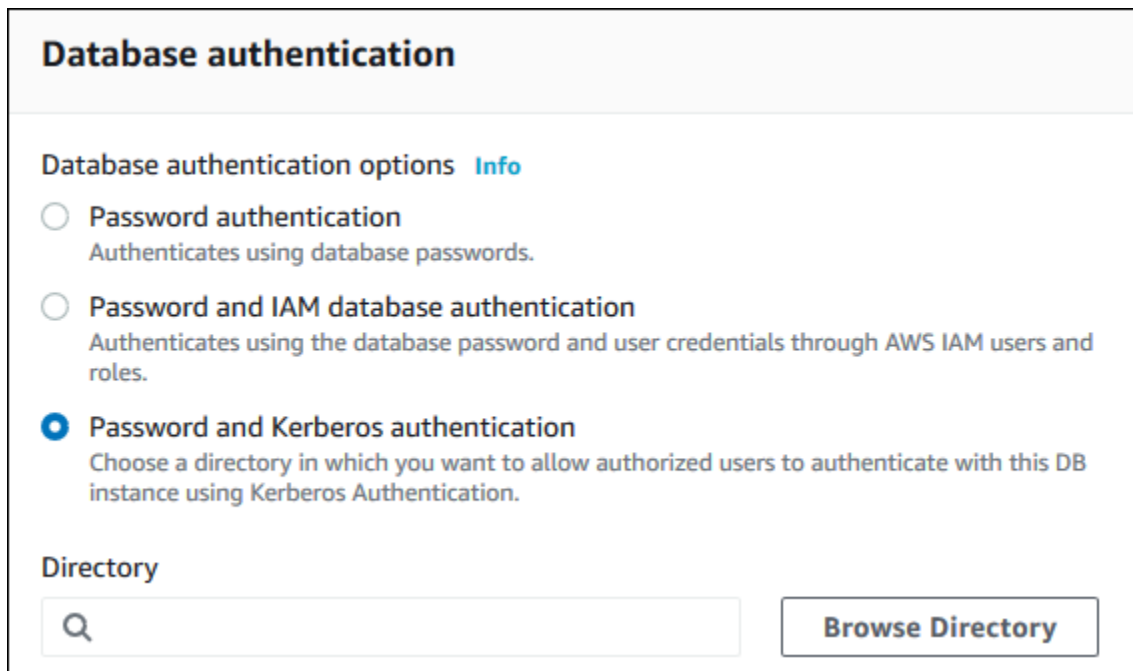

For instructions, see [Restoring to a DB instance](#).

- Restore a MySQL DB instance to a point-in-time using the console, the [restore-db-instance-to-point-in-time](#) CLI command, or the [RestoreDBInstanceToPointInTime](#) RDS API operation.

For instructions, see [Restoring a DB instance to a specified time](#).

Kerberos authentication is only supported for MySQL DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. The DB instance must use a security group that allows egress within the directory's VPC so the DB instance can communicate with the directory.

When you use the console to create, modify, or restore a DB instance, choose **Password and Kerberos authentication** in the **Database authentication** section. Choose **Browse Directory** and then select the directory, or choose **Create a new directory**.

The screenshot shows the 'Database authentication' configuration page. At the top, the title 'Database authentication' is displayed. Below it, the section 'Database authentication options' includes an 'Info' link and three radio button options: 'Password authentication' (described as authenticating with database passwords), 'Password and IAM database authentication' (described as using database passwords and AWS IAM credentials), and 'Password and Kerberos authentication' (which is selected and described as allowing users to authenticate with a directory using Kerberos). Below the options is a 'Directory' section with a search input field containing a magnifying glass icon and a 'Browse Directory' button.

When you use the AWS CLI or RDS API, associate a DB instance with a directory. The following parameters are required for the DB instance to use the domain directory you created:

- For the `--domain` parameter, use the domain identifier ("d-\*" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier mydbinstance \  
  --domain d-ID \  
  --domain-iam-role-name role-name
```

For Windows:

```
aws rds modify-db-instance ^  
  --db-instance-identifier mydbinstance ^  
  --domain d-ID ^  
  --domain-iam-role-name role-name
```

### Important

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

## Step 5: Create Kerberos authentication MySQL logins

Use the Amazon RDS master user credentials to connect to the MySQL DB instance as you do any other DB instance. The DB instance is joined to the AWS Managed Microsoft AD domain. Thus, you can provision MySQL logins and users from the Active Directory users in your domain. Database permissions are managed through standard MySQL permissions that are granted to and revoked from these logins.

You can allow an Active Directory user to authenticate with MySQL. To do this, first use the Amazon RDS master user credentials to connect to the MySQL DB instance as with any other DB instance. After you're logged in, create an externally authenticated user with PAM (Pluggable Authentication Modules) in MySQL by running the following command. Replace *testuser* with the user name.

```
CREATE USER 'testuser'@'%' IDENTIFIED WITH 'auth_pam';
```

Users (both humans and applications) from your domain can now connect to the DB instance from a domain joined client machine using Kerberos authentication.

**⚠ Important**

We strongly recommend that clients use SSL/TLS connections when using PAM authentication. If they don't use SSL/TLS connections, the password might be sent as clear text in some cases. To require an SSL/TLS encrypted connection for your AD user, run the following command and replace *testuser* with the user name:

```
ALTER USER 'testuser'@'%' REQUIRE SSL;
```

For more information, see [Using SSL/TLS with a MySQL DB instance](#).

## Managing a DB instance in a domain

You can use the CLI or the RDS API to manage your DB instance and its relationship with your managed Active Directory. For example, you can associate an Active Directory for Kerberos authentication and disassociate an Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Active Directory to another.

For example, using the Amazon RDS API, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the `ModifyDBInstance` API operation and specify the current membership's directory ID.
- To update the IAM role name for membership, use the `ModifyDBInstance` API operation and specify the current membership's directory ID and the new IAM role.
- To disable Kerberos authentication on a DB instance, use the `ModifyDBInstance` API operation and specify `none` as the domain parameter.
- To move a DB instance from one domain to another, use the `ModifyDBInstance` API operation and specify the domain identifier of the new domain as the domain parameter.
- To list membership for each DB instance, use the `DescribeDBInstances` API operation.

## Understanding domain membership

After you create or modify your DB instance, it becomes a member of the domain. You can view the status of the domain membership for the DB instance by running the [describe-db-instances](#) CLI command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.
- `pending-enable-kerberos` – The enabling of Kerberos authentication is pending on this DB instance.
- `pending-maintenance-enable-kerberos` – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – The disabling of Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `enable-kerberos-failed` – A configuration problem has prevented AWS from enabling Kerberos authentication on the DB instance. Check and fix your configuration before reissuing the DB instance modify command.
- `disabling-kerberos` – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. For example, suppose that you create a DB instance or modify an existing DB instance and the attempt to enable Kerberos authentication fails. If this happens, re-issue the modify command or modify the newly created DB instance to join the domain.

## Connecting to MySQL with Kerberos authentication

To connect to MySQL with Kerberos authentication, you must log in using the Kerberos authentication type.

To create a database user that you can connect to using Kerberos authentication, use an `IDENTIFIED WITH` clause on the `CREATE USER` statement. For instructions, see [Step 5: Create Kerberos authentication MySQL logins](#).

To avoid errors, use the MariaDB `mysql` client. You can download MariaDB software at <https://downloads.mariadb.org/>.

At a command prompt, connect to one of the endpoints associated with your MySQL DB instance. Follow the general procedures in [Connecting to a DB instance running the MySQL database engine](#).

When you're prompted for the password, enter the Kerberos password associated with that user name.

## Restoring a MySQL DB instance and adding it to a domain

You can restore a DB snapshot or complete a point-in-time restore for a MySQL DB instance and then add it to a domain. After the DB instance is restored, modify the DB instance using the process explained in [Step 4: Create or modify a MySQL DB instance](#) to add the DB instance to a domain.

## Kerberos authentication MySQL limitations

The following limitations apply to Kerberos authentication for MySQL:

- Only an AWS Managed Microsoft AD is supported. However, you can join RDS for MySQL DB instances to shared Managed Microsoft AD domains owned by different accounts in the same AWS Region.
- You must reboot the DB instance after enabling the feature.
- The domain name length can't be longer than 61 characters.
- You can't enable Kerberos authentication and IAM authentication at the same time. Choose one authentication method or the other for your MySQL DB instance.
- Don't modify the DB instance port after enabling the feature.
- Don't use Kerberos authentication with read replicas.
- If you have auto minor version upgrade turned on for a MySQL DB instance that is using Kerberos authentication, you must turn off Kerberos authentication and then turn it back on after an automatic upgrade. For more information about auto minor version upgrades, see [Automatic minor version upgrades for MySQL](#).
- To delete a DB instance with this feature enabled, first disable the feature. To do so, use the `modify-db-instance` CLI command for the DB instance and specify `none` for the `--domain` parameter.

If you use the CLI or RDS API to delete a DB instance with this feature enabled, expect a delay.

- RDS for MySQL doesn't support Kerberos authentication across a forest trust between your on-premise or self-hosted AD and the AWS Managed Microsoft AD.

# Improving query performance for RDS for MySQL with Amazon RDS Optimized Reads

You can achieve faster query processing for RDS for MySQL with Amazon RDS Optimized Reads. An RDS for MySQL DB instance or Multi-AZ DB cluster that uses RDS Optimized Reads can achieve up to 2x faster query processing compared to a DB instance or cluster that doesn't use it.

## Topics

- [Overview of RDS Optimized Reads](#)
- [Use cases for RDS Optimized Reads](#)
- [Best practices for RDS Optimized Reads](#)
- [Using RDS Optimized Reads](#)
- [Monitoring DB instances that use RDS Optimized Reads](#)
- [Limitations for RDS Optimized Reads](#)

## Overview of RDS Optimized Reads

When you use an RDS for MySQL DB instance or Multi-AZ DB cluster that has RDS Optimized Reads turned on, it achieves faster query performance through the use of an instance store. An *instance store* provides temporary block-level storage for your DB instance or Multi-AZ DB cluster. The storage is located on Non-Volatile Memory Express (NVMe) solid state drives (SSDs) that are physically attached to the host server. This storage is optimized for low latency, high random I/O performance, and high sequential read throughput.

RDS Optimized Reads is turned on by default when a DB instance or Multi-AZ DB cluster uses a DB instance class with an instance store, such as db.m5d or db.m6gd. With RDS Optimized Reads, some temporary objects are stored on the instance store. These temporary objects include internal temporary files, internal on-disk temp tables, memory map files, and binary log (binlog) cache files. For more information about the instance store, see [Amazon EC2 instance store](#) in the *Amazon Elastic Compute Cloud User Guide for Linux Instances*.

The workloads that generate temporary objects in MySQL for query processing can take advantage of the instance store for faster query processing. This type of workload includes queries involving sorts, hash aggregations, high-load joins, Common Table Expressions (CTEs), and queries on unindexed columns. These instance store volumes provide higher IOPS and performance,

regardless of the storage configurations used for persistent Amazon EBS storage. Because RDS Optimized Reads offloads operations on temporary objects to the instance store, the input/output operations per second (IOPS) or throughput of the persistent storage (Amazon EBS) can now be used for operations on persistent objects. These operations include regular data file reads and writes, and background engine operations, such as flushing and insert buffer merges.

### Note

Both manual and automated RDS snapshots only contain engine files for persistent objects. The temporary objects created in the instance store aren't included in RDS snapshots.

## Use cases for RDS Optimized Reads

If you have workloads that rely heavily on temporary objects, such as internal tables or files, for their query execution, then you can benefit from turning on RDS Optimized Reads. The following use cases are candidates for RDS Optimized Reads:

- Applications that run analytical queries with complex common table expressions (CTEs), derived tables, and grouping operations
- Read replicas that serve heavy read traffic with unoptimized queries
- Applications that run on-demand or dynamic reporting queries that involve complex operations, such as queries with `GROUP BY` and `ORDER BY` clauses
- Workloads that use internal temporary tables for query processing

You can monitor the engine status variable `created_tmp_disk_tables` to determine the number of disk-based temporary tables created on your DB instance.

- Applications that create large temporary tables, either directly or in procedures, to store intermediate results
- Database queries that perform grouping or ordering on non-indexed columns

## Best practices for RDS Optimized Reads

Use the following best practices for RDS Optimized Reads:

- Add retry logic for read-only queries in case they fail because the instance store is full during the execution.

- Monitor the storage space available on the instance store with the CloudWatch metric `FreeLocalStorage`. If the instance store is reaching its limit because of workload on the DB instance, modify the DB instance to use a larger DB instance class.
- When your DB instance or Multi-AZ DB cluster has sufficient memory but is still reaching the storage limit on the instance store, increase the `binlog_cache_size` value to maintain the session-specific binlog entries in memory. This configuration prevents writing the binlog entries to temporary binlog cache files on disk.

The `binlog_cache_size` parameter is session-specific. You can change the value for each new session. The setting for this parameter can increase the memory utilization on the DB instance during peak workload. Therefore, consider increasing the parameter value based on the workload pattern of your application and available memory on the DB instance.

- Use the default value of `MIXED` for the `binlog_format`. Depending on the size of the transactions, setting `binlog_format` to `ROW` can result in large binlog cache files on the instance store.
- Set the [internal\\_tmp\\_mem\\_storage\\_engine](#) parameter to `TempTable`, and set the [temptable\\_max\\_mmap](#) parameter to match the size of the available storage on the instance store.
- Avoid performing bulk changes in a single transaction. These types of transactions can generate large binlog cache files on the instance store and can cause issues when the instance store is full. Consider splitting writes into multiple small transactions to minimize storage use for binlog cache files.
- Use the default value of `ABORT_SERVER` for the `binlog_error_action` parameter. Doing so avoids issues with the binary logging on DB instances with backups enabled.

## Using RDS Optimized Reads

When you provision an RDS for MySQL DB instance with one of the following DB instance classes in a Single-AZ DB instance deployment, Multi-AZ DB instance deployment, or Multi-AZ DB cluster deployment, the DB instance automatically uses RDS Optimized Reads.

To turn on RDS Optimized Reads, do one of the following:

- Create an RDS for MySQL DB instance or Multi-AZ DB cluster using one of these DB instance classes. For more information, see [Creating an Amazon RDS DB instance](#).

- Modify an existing RDS for MySQL DB instance or Multi-AZ DB cluster to use one of these DB instance classes. For more information, see [Modifying an Amazon RDS DB instance](#).

RDS Optimized Reads is available in all AWS Regions RDS where one or more of the DB instance classes with local NVMe SSD storage are supported. For information about DB instance classes, see [the section called “DB instance classes”](#).

DB instance class availability differs for AWS Regions. To determine whether a DB instance class is supported in a specific AWS Region, see [the section called “Determining DB instance class support in AWS Regions”](#).

If you don't want to use RDS Optimized Reads, modify your DB instance or Multi-AZ DB cluster so that it doesn't use a DB instance class that supports the feature.

## Monitoring DB instances that use RDS Optimized Reads

You can monitor DB instances that use RDS Optimized Reads with the following CloudWatch metrics:

- FreeLocalStorage
- ReadIOPSLocalStorage
- ReadLatencyLocalStorage
- ReadThroughputLocalStorage
- WriteIOPSLocalStorage
- WriteLatencyLocalStorage
- WriteThroughputLocalStorage

These metrics provide data about available instance store storage, IOPS, and throughput. For more information about these metrics, see [Amazon CloudWatch instance-level metrics for Amazon RDS](#).

## Limitations for RDS Optimized Reads

The following limitations apply to RDS Optimized Reads:

- RDS Optimized Reads is supported for RDS for MySQL version 8.0.28 and higher. For information about RDS for MySQL versions, see [MySQL on Amazon RDS versions](#).

- You can't change the location of temporary objects to persistent storage (Amazon EBS) on the DB instance classes that support RDS Optimized Reads.
- When binary logging is enabled on a DB instance, the maximum transaction size is limited by the size of the instance store. In MySQL, any session that requires more storage than the value of `binlog_cache_size` writes transaction changes to temporary binlog cache files, which are created on the instance store.
- Transactions can fail when the instance store is full.

# Improving write performance with RDS Optimized Writes for MySQL

You can improve the performance of write transactions with RDS Optimized Writes for MySQL. When your RDS for MySQL database uses RDS Optimized Writes, it can achieve up to two times higher write transaction throughput.

## Topics

- [Overview of RDS Optimized Writes](#)
- [Using RDS Optimized Writes](#)
- [Enabling RDS Optimized Writes on an existing database](#)
- [Limitations for RDS Optimized Writes](#)

## Overview of RDS Optimized Writes

When you turn on RDS Optimized Writes, your RDS for MySQL databases write only once when flushing data to durable storage without the need for the doublewrite buffer. The databases continue to provide ACID property protections for reliable database transactions, along with improved performance.

Relational databases, like MySQL, provide the *ACID properties* of atomicity, consistency, isolation, and durability for reliable database transactions. To help provide these properties, MySQL uses a data storage area called the *doublewrite buffer* that prevents partial page write errors. These errors occur when there is a hardware failure while the database is updating a page, such as in the case of a power outage. A MySQL database can detect partial page writes and recover with a copy of the page in the doublewrite buffer. While this technique provides protection, it also results in extra write operations. For more information about the MySQL doublewrite buffer, see [Doublewrite Buffer](#) in the MySQL documentation.

With RDS Optimized Writes turned on, RDS for MySQL databases write only once when flushing data to durable storage without using the doublewrite buffer. RDS Optimized Writes is useful if you run write-heavy workloads on your RDS for MySQL databases. Examples of databases with write-heavy workloads include ones that support digital payments, financial trading, and gaming applications.

These databases run on DB instance classes that use the AWS Nitro System. Because of the hardware configuration in these systems, the database can write 16-KiB pages directly to data files reliably and durably in one step. The AWS Nitro System makes RDS Optimized Writes possible.

You can set the new database parameter `rds.optimized_writes` to control the RDS Optimized Writes feature for RDS for MySQL databases. Access this parameter in the DB parameter groups of RDS for MySQL version 8.0. Set the parameter using the following values:

- **AUTO** – Turn on RDS Optimized Writes if the database supports it. Turn off RDS Optimized Writes if the database doesn't support it. This setting is the default.
- **OFF** – Turn off RDS Optimized Writes even if the database supports it.

If you have an existing database with an engine version, DB instance class, and/or file system format that doesn't support RDS Optimized Writes, you can enable the feature by creating a blue/green deployment. For more information, see [the section called “Enabling on an existing database”](#).

If you migrate an RDS for MySQL database that is configured to use RDS Optimized Writes to a DB instance class that doesn't support the feature, RDS automatically turns off RDS Optimized Writes for the database.

When RDS Optimized Writes is turned off, the database uses the MySQL doublewrite buffer.

To determine whether an RDS for MySQL database is using RDS Optimized Writes, view the current value of the `innodb_doublewrite` parameter for the database. If the database is using RDS Optimized Writes, this parameter is set to `FALSE (0)`.

## Using RDS Optimized Writes

You can turn on RDS Optimized Writes when you create an RDS for MySQL database with the RDS console, the AWS CLI, or the RDS API. RDS Optimized Writes is turned on automatically when both of the following conditions apply during database creation:

- You specify a DB engine version and DB instance class that support RDS Optimized Writes.
  - RDS Optimized Writes is supported for RDS for MySQL version 8.0.30 and higher. For information about RDS for MySQL versions, see [MySQL on Amazon RDS versions](#).
  - RDS Optimized Writes is supported for RDS for MySQL databases that use the following DB instance classes:

- db.m7g
- db.m6g
- db.m6gd
- db.m6i
- db.m5
- db.m5d
- db.r7g
- db.r6g
- db.r6gd
- db.r6i
- db.r5
- db.r5b
- db.r5d
- db.x2idn
- db.x2iedn

For information about DB instance classes, see [the section called “DB instance classes”](#).

DB instance class availability differs for AWS Regions. To determine whether a DB instance class is supported in a specific AWS Region, see [the section called “Determining DB instance class support in AWS Regions”](#).

To upgrade your database to a DB instance class that supports RDS Optimized Writes, you can create a blue/green deployment. For more information, see [the section called “Enabling on an existing database”](#).

- In the parameter group associated with the database, the `rds.optimized_writes` parameter is set to `AUTO`. In default parameter groups, this parameter is always set to `AUTO`.

If you want to use a DB engine version and DB instance class that support RDS Optimized Writes, but you don't want to use this feature, then specify a custom parameter group when you create the database. In this parameter group, set the `rds.optimized_writes` parameter to `OFF`. If you want the database to use RDS Optimized Writes later, you can set the parameter to `AUTO` to turn it on. For information about creating custom parameter groups and setting parameters, see

[Parameter groups for Amazon RDS](#).

For information about creating a DB instance, see [Creating an Amazon RDS DB instance](#).

## Console

When you use the RDS console to create an RDS for MySQL database, you can filter for the DB engine versions and DB instance classes that support RDS Optimized Writes. After you turn on the filters, you can choose from the available DB engine versions and DB instance classes.

To choose a DB engine version that supports RDS Optimized Writes, filter for the RDS for MySQL DB engine versions that support it in **Engine version**, and then choose a version.

### Engine options

Engine type [Info](#)

<input type="radio"/> Aurora (MySQL Compatible) 	<input type="radio"/> Aurora (PostgreSQL Compatible)

Include previous generation classes

After you make these selections, you can choose other settings that meet your requirements and finish creating the RDS for MySQL database with the console.

## AWS CLI

To create a DB instance by using the AWS CLI, use the [create-db-instance](#) command. Make sure the `--engine-version` and `--db-instance-class` values support RDS Optimized Writes. In addition, make sure the parameter group associated with the DB instance has the `rds.optimized_writes` parameter set to `AUTO`. This example associates the default parameter group with the DB instance.

### Example Creating a DB instance that uses RDS Optimized Writes

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --db-instance-identifier mydbinstance \
  --engine mysql \
  --engine-version 8.0.30 \
  --db-instance-class db.r5b.large \
  --manage-master-user-password \
  --master-username admin \
  --allocated-storage 200
```

For Windows:

```
aws rds create-db-instance ^
  --db-instance-identifier mydbinstance ^
  --engine mysql ^
```

```
--engine-version 8.0.30 ^  
--db-instance-class db.r5b.large ^  
--manage-master-user-password ^  
--master-username admin ^  
--allocated-storage 200
```

## RDS API

You can create a DB instance using the [CreateDBInstance](#) operation. When you use this operation, make sure the `EngineVersion` and `DBInstanceClass` values support RDS Optimized Writes. In addition, make sure the parameter group associated with the DB instance has the `rds.optimized_writes` parameter set to `AUTO`.

## Enabling RDS Optimized Writes on an existing database

In order to modify an existing RDS for MySQL database to turn on RDS Optimized Writes, the database must have been created with a supported DB engine version and DB instance class. In addition, the database must have been created *after* RDS Optimized Writes was released on November 27, 2022, as the required underlying file system configuration is incompatible with that of databases created before it was released. If these conditions are met, you can turn on RDS Optimized Writes by setting the `rds.optimized_writes` parameter to `AUTO`.

If your database was *not* created with a supported engine version, instance class, or file system configuration, you can use RDS Blue/Green Deployments to migrate to a supported configuration. While creating the blue/green deployment, do the following:

- Select **Enable Optimized Writes on green database**, then specify an engine version and DB instance class that supports RDS Optimized Writes. For a list of supported engine versions and instance classes, see [Using RDS Optimized Writes](#).
- Under **Storage**, choose **Upgrade storage file system configuration**. This option upgrades the database to a compatible underlying file system configuration.

When you create the blue/green deployment, if the `rds.optimized_writes` parameter is set to `AUTO`, RDS Optimized Writes will be automatically enabled on the green environment. You can then switch over the blue/green deployment, which promotes the green environment to be the new production environment.

For more information, see [the section called "Creating a blue/green deployment"](#).

## Limitations for RDS Optimized Writes

When you're restoring an RDS for MySQL database from a snapshot, you can only turn on RDS Optimized Writes for the database if all of the following conditions apply:

- The snapshot was created from a database that supports RDS Optimized Writes.
- The snapshot was created from a database that was created *after* RDS Optimized Writes was released.
- The snapshot is restored to a database that supports RDS Optimized Writes.
- The restored database is associated with a parameter group that has the `rds.optimized_writes` parameter set to `AUTO`.

# Upgrading the MySQL DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for MySQL databases: major version upgrades and minor version upgrades.

## Major version upgrades

*Major version upgrades* can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. Before you perform a major version upgrade, we recommend that you follow the instructions in [Major version upgrades for MySQL](#).

For major version upgrades of Multi-AZ DB instance deployments, Amazon RDS simultaneously upgrades both the primary and standby replicas. Your DB instance won't be available until the upgrade completes. Currently, Amazon RDS doesn't support major version upgrades for Multi-AZ DB cluster deployments.

### Tip

You can minimize the downtime required for a major version upgrade by using a blue/green deployment. For more information, see [Using Amazon RDS Blue/Green Deployments for database updates](#).

## Minor version upgrades

*Minor version upgrades* include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Or, you can enable the **Auto minor version upgrade** option when creating or modifying a DB instance. Doing so means that Amazon RDS automatically upgrades your DB instance after testing and approving the new version. For information about performing an upgrade, see [Upgrading a DB instance engine version](#).

When you perform a minor version upgrade of a Multi-AZ DB cluster, Amazon RDS upgrades the reader DB instances one at a time. Then, one of the reader DB instances switches to be the new writer DB instance. Amazon RDS then upgrades the old writer instance (which is now a reader instance).

**Note**

The downtime for a minor version upgrade of a Multi-AZ DB *instance* deployment can last for several minutes. Multi-AZ DB clusters typically reduce the downtime of minor version upgrades to approximately 35 seconds. When used with RDS Proxy, you can further reduce downtime to one second or less. For more information, see [Using RDS Proxy](#). Alternately, you can use an open source database proxy such as [ProxySQL](#), [PgBouncer](#), or the [AWS JDBC Driver for MySQL](#).

If your MySQL DB instance uses read replicas, then you must upgrade all of the read replicas before upgrading the source instance.

**Topics**

- [Overview of upgrading](#)
- [MySQL version numbers](#)
- [RDS version number](#)
- [Major version upgrades for MySQL](#)
- [Testing an upgrade](#)
- [Upgrading a MySQL DB instance](#)
- [Automatic minor version upgrades for MySQL](#)
- [Using a read replica to reduce downtime when upgrading a MySQL database](#)

## Overview of upgrading

When you use the AWS Management Console to upgrade a DB instance, it shows the valid upgrade targets for the DB instance. You can also use the following AWS CLI command to identify the valid upgrade targets for a DB instance:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \  
  --engine mysql \  
  --engine-version version-number \  
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --  
output text
```

## For Windows:

```
aws rds describe-db-engine-versions ^
  --engine mysql ^
  --engine-version version-number ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For example, to identify the valid upgrade targets for a MySQL version 8.0.28 DB instance, run the following AWS CLI command:

## For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
  --engine mysql \
  --engine-version 8.0.28 \
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

## For Windows:

```
aws rds describe-db-engine-versions ^
  --engine mysql ^
  --engine-version 8.0.28 ^
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

Amazon RDS takes two or more DB snapshots during the upgrade process. Amazon RDS takes up to two snapshots of the DB instance *before* making any upgrade changes. If the upgrade doesn't work for your databases, you can restore one of these snapshots to create a DB instance running the old version. Amazon RDS takes another snapshot of the DB instance when the upgrade completes. Amazon RDS takes these snapshots regardless of whether AWS Backup manages the backups for the DB instance.

### Note

Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see [Modifying an Amazon RDS DB instance](#).

After the upgrade is complete, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore the first DB snapshot taken to create a new DB instance.

You control when to upgrade your DB instance to a new version supported by Amazon RDS. This level of control helps you maintain compatibility with specific database versions and test new versions with your application before deploying in production. When you are ready, you can perform version upgrades at the times that best fit your schedule.

If your DB instance uses read replication, then you must upgrade all of the read replicas before upgrading the source instance.

## MySQL version numbers

The version numbering sequence for the RDS for MySQL database engine is either in the form of *major.minor.patch.YYYYMMDD* or *major.minor.patch*, for example, 8.0.33.R2.20231201 or 5.7.44. The format used depends on the MySQL engine version. For information about RDS Extended Support version numbering, see [Amazon RDS Extended Support version naming](#).

### major

The major version number is both the integer and the first fractional part of the version number, for example, 8.0. A major version upgrade increases the major part of the version number. For example, an upgrade from 5.7.44 to 8.0.33 is a major version upgrade, where 5.7 and 8.0 are the major version numbers.

### minor

The minor version number is the third part of the version number, for example, the 33 in 8.0.33.

### patch

The patch is the fourth part of the version number, for example, the R2 in 8.0.33.R2. An RDS patch version includes important bug fixes added to a minor version after its release.

### YYYYMMDD

The date is the fifth part of the version number, for example, the 20231201 in 8.0.33.R2.20231201. An RDS date version is a security patch that includes important security fixes added to a minor version after its release. It doesn't include any fixes that might change an engine's behavior.

The following table explains the naming scheme for RDS for MySQL version 8.0.

8.0 minor version	Naming scheme
$\geq 33$	<p>New DB instances use <i>major.minor.patch.YYMMDD</i>, for example, 8.0.33.R2.20231201.</p> <p>Existing DB instances might use <i>major.minor.patch</i>, for example, 8.0.33.R2, until your next major or minor version upgrade.</p>
$< 33$	Existing DB instances use <i>major.minor.patch</i> , for example, 8.0.32.R2.

The following table explains the naming scheme for RDS for MySQL version 5.7.

5.7 minor version	Naming scheme
$\geq 42$	<p>New DB instances use <i>major.minor.patch.YYMMDD</i>, for example, 5.7.42.R2.20231201.</p> <p>Existing DB instances might use <i>major.minor.patch</i>, for example, 5.7.42.R2, until your next major or minor version upgrade.</p>

## RDS version number

RDS version numbers use either the *major.minor.patch* or the *major.minor.patch.YYYYMMDD* naming scheme. An RDS patch version includes important bug fixes added to a minor version after its release. An RDS date version (*YYMMDD*) is a security patch. A security patch doesn't include any fixes that might change the engine's behavior. For information about RDS Extended Support version numbering, see [Amazon RDS Extended Support version naming](#).

To identify the Amazon RDS version number of your database, you must first create the `rds_tools` extension by using the following command:

```
CREATE EXTENSION rds_tools;
```

You can find out the RDS version number of your RDS for MySQL database with the following SQL query:

```
mysql> select mysql.rds_version();
```

For example, querying an RDS for MySQL 8.0.34 database returns the following output:

```
+-----+
| mysql.rds_version() |
+-----+
| 8.0.34.R2.20231201  |
+-----+
1 row in set (0.01 sec)
```

## Major version upgrades for MySQL

Amazon RDS supports the following in-place upgrades for major versions of the MySQL database engine:

- MySQL 5.6 to MySQL 5.7
- MySQL 5.7 to MySQL 8.0

### Note

You can only create MySQL version 5.7 and 8.0 DB instances with latest-generation and current-generation DB instance classes, in addition to the db.m3 previous-generation DB instance class.

In some cases, you want to upgrade a MySQL version 5.6 DB instance running on a previous-generation DB instance class (other than db.m3) to a MySQL version 5.7 DB instance. In these cases, first modify the DB instance to use a latest-generation or current-generation DB instance class. After you do this, you can then modify the DB instance to use the MySQL version 5.7 database engine. For information on Amazon RDS DB instance classes, see [DB instance classes](#).

## Topics

- [Overview of MySQL major version upgrades](#)
- [Upgrades to MySQL version 5.7 might be slow](#)
- [Prechecks for upgrades from MySQL 5.7 to 8.0](#)
- [Rollback after failure to upgrade from MySQL 5.7 to 8.0](#)

## Overview of MySQL major version upgrades

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, Amazon RDS doesn't apply major version upgrades automatically; you must manually modify your DB instance. We recommend that you thoroughly test any upgrade before applying it to your production instances.

To perform a major version upgrade for a MySQL version 5.6 DB instance on Amazon RDS to MySQL version 5.7 or later, first perform any available OS updates. After OS updates are complete, upgrade to each major version: 5.6 to 5.7 and then 5.7 to 8.0. MySQL DB instances created before April 24, 2014, show an available OS update until the update has been applied. For more information on OS updates, see [Applying updates for a DB instance](#).

During a major version upgrade of MySQL, Amazon RDS runs the MySQL binary `mysql_upgrade` to upgrade tables, if necessary. Also, Amazon RDS empties the `slow_log` and `general_log` tables during a major version upgrade. To preserve log information, save the log contents before the major version upgrade.

MySQL major version upgrades typically complete in about 10 minutes. Some upgrades might take longer because of the DB instance class size or because the instance doesn't follow certain operational guidelines in [Best practices for Amazon RDS](#). If you upgrade a DB instance from the Amazon RDS console, the status of the DB instance indicates when the upgrade is complete. If you upgrade using the AWS Command Line Interface (AWS CLI), use the [describe-db-instances](#) command and check the `Status` value.

## Upgrades to MySQL version 5.7 might be slow

MySQL version 5.6.4 introduced a new date and time format for the `datetime`, `time`, and `timestamp` columns that allows fractional components in date and time values. When upgrading a DB instance to MySQL version 5.7, MySQL forces the conversion of all date and time column types to the new format.

Because this conversion rebuilds your tables, it might take a considerable amount of time to complete the DB instance upgrade. The forced conversion occurs for any DB instances that are running a version before MySQL version 5.6.4. It also occurs for any DB instances that were upgraded from a version before MySQL version 5.6.4 to a version other than 5.7.

If your DB instance runs a version before MySQL version 5.6.4, or was upgraded from a version before 5.6.4, we recommend an extra step. In these cases, we recommend that you convert the `datetime`, `time`, and `timestamp` columns in your database before upgrading your DB instance to MySQL version 5.7. This conversion can significantly reduce the amount of time required to upgrade the DB instance to MySQL version 5.7. To upgrade your date and time columns to the new format, issue the `ALTER TABLE <table_name> FORCE;` command for each table that contains date or time columns. Because altering a table locks the table as read-only, we recommend that you perform this update during a maintenance window.

To find all tables in your database that have `datetime`, `time`, or `timestamp` columns and create an `ALTER TABLE <table_name> FORCE;` command for each table, use the following query.

```
SET show_old_temporals = ON;
  SELECT table_schema, table_name, column_name, column_type
  FROM information_schema.columns
  WHERE column_type LIKE '%/* 5.5 binary format */';
SET show_old_temporals = OFF;
```

## Prechecks for upgrades from MySQL 5.7 to 8.0

MySQL 8.0 includes a number of incompatibilities with MySQL 5.7. These incompatibilities can cause problems during an upgrade from MySQL 5.7 to MySQL 8.0. So, some preparation might be required on your database for the upgrade to be successful. The following is a general list of these incompatibilities:

- There must be no tables that use obsolete data types or functions.
- There must be no orphan `*.frm` files.
- Triggers must not have a missing or empty definer or an invalid creation context.
- There must be no partitioned table that uses a storage engine that does not have native partitioning support.
- There must be no keyword or reserved word violations. Some keywords might be reserved in MySQL 8.0 that were not reserved previously.

For more information, see [Keywords and reserved words](#) in the MySQL documentation.

- There must be no tables in the MySQL 5.7 `mysql` system database that have the same name as a table used by the MySQL 8.0 data dictionary.
- There must be no obsolete SQL modes defined in your `sql_mode` system variable setting.
- There must be no tables or stored procedures with individual ENUM or SET column elements that exceed 255 characters or 1020 bytes in length.
- Before upgrading to MySQL 8.0.13 or higher, there must be no table partitions that reside in shared InnoDB tablespaces.
- There must be no queries and stored program definitions from MySQL 8.0.12 or lower that use ASC or DESC qualifiers for GROUP BY clauses.
- Your MySQL 5.7 installation must not use features that are not supported in MySQL 8.0.

For more information, see [Features removed in MySQL 8.0](#) in the MySQL documentation.

- There must be no foreign key constraint names longer than 64 characters.
- For improved Unicode support, consider converting objects that use the `utf8mb3` charset to use the `utf8mb4` charset. The `utf8mb3` character set is deprecated. Also, consider using `utf8mb4` for character set references instead of `utf8`, because currently `utf8` is an alias for the `utf8mb3` charset.

For more information, see [The utf8mb3 character set \(3-byte UTF-8 unicode encoding\)](#) in the MySQL documentation.

When you start an upgrade from MySQL 5.7 to 8.0, Amazon RDS runs prechecks automatically to detect these incompatibilities. For information about upgrading to MySQL 8.0, see [Upgrading MySQL](#) in the MySQL documentation.

These prechecks are mandatory. You can't choose to skip them. The prechecks provide the following benefits:

- They enable you to avoid unplanned downtime during the upgrade.
- If there are incompatibilities, Amazon RDS prevents the upgrade and provides a log for you to learn about them. You can then use the log to prepare your database for the upgrade to MySQL 8.0 by reducing the incompatibilities. For detailed information about removing incompatibilities, see [Preparing your installation for upgrade](#) in the MySQL documentation and [Upgrading to MySQL 8.0? Here is what you need to know...](#) on the MySQL Server Blog.

The prechecks include some that are included with MySQL and some that were created specifically by the Amazon RDS team. For information about the prechecks provided by MySQL, see [Upgrade checker utility](#).

The prechecks run before the DB instance is stopped for the upgrade, meaning that they don't cause any downtime when they run. If the prechecks find an incompatibility, Amazon RDS automatically cancels the upgrade before the DB instance is stopped. Amazon RDS also generates an event for the incompatibility. For more information about Amazon RDS events, see [Working with Amazon RDS event notification](#).

Amazon RDS records detailed information about each incompatibility in the log file `PrePatchCompatibility.log`. In most cases, the log entry includes a link to the MySQL documentation for correcting the incompatibility. For more information about viewing log files, see [Viewing and listing database log files](#).

Due to the nature of the prechecks, they analyze the objects in your database. This analysis results in resource consumption and increases the time for the upgrade to complete.

#### Note

Amazon RDS runs all of these prechecks only for an upgrade from MySQL 5.7 to MySQL 8.0. For an upgrade from MySQL 5.6 to MySQL 5.7, prechecks are limited to confirming that there are no orphan tables and that there is enough storage space to rebuild tables. Prechecks aren't run for upgrades to releases lower than MySQL 5.7.

## Rollback after failure to upgrade from MySQL 5.7 to 8.0

When you upgrade a DB instance from MySQL version 5.7 to MySQL version 8.0, the upgrade can fail. In particular, it can fail if the data dictionary contains incompatibilities that weren't captured by the prechecks. In this case, the database fails to start up successfully in the new MySQL 8.0 version. At this point, Amazon RDS rolls back the changes performed for the upgrade. After the rollback, the MySQL DB instance is running MySQL version 5.7. When an upgrade fails and is rolled back, Amazon RDS generates an event with the event ID RDS-EVENT-0188.

Typically, an upgrade fails because there are incompatibilities in the metadata between the databases in your DB instance and the target MySQL version. When an upgrade fails, you can view the details about these incompatibilities in the `upgradeFailure.log` file. Resolve the incompatibilities before attempting to upgrade again.

During an unsuccessful upgrade attempt and rollback, your DB instance is restarted. Any pending parameter changes are applied during the restart and persist after the rollback.

For more information about upgrading to MySQL 8.0, see the following topics in the MySQL documentation:

- [Preparing Your Installation for Upgrade](#)
- [Upgrading to MySQL 8.0? Here is what you need to know...](#)

### Note

Currently, automatic rollback after upgrade failure is supported only for MySQL 5.7 to 8.0 major version upgrades.

## Testing an upgrade

Before you perform a major version upgrade on your DB instance, thoroughly test your database for compatibility with the new version. In addition, thoroughly test all applications that access the database for compatibility with the new version. We recommend that you use the following procedure.

### To test a major version upgrade

1. Review the upgrade documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications:
  - [Changes in MySQL 5.6](#)
  - [Changes in MySQL 5.7](#)
  - [Changes in MySQL 8.0](#)
2. If your DB instance is a member of a custom DB parameter group, create a new DB parameter group with your existing settings that is compatible with the new major version. Specify the new DB parameter group when you upgrade your test instance, so your upgrade testing ensures that it works correctly. For more information about creating a DB parameter group, see [Parameter groups for Amazon RDS](#).
3. Create a DB snapshot of the DB instance to be upgraded. For more information, see [Creating a DB snapshot for a Single-AZ DB instance](#).

4. Restore the DB snapshot to create a new test DB instance. For more information, see [Restoring to a DB instance](#).
5. Modify this new test DB instance to upgrade it to the new version, using one of the methods detailed following. If you created a new parameter group in step 2, specify that parameter group.
6. Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage.
7. Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version. Implement any new tests needed to evaluate the impact of any compatibility issues that you identified in step 1. Test all stored procedures and functions. Direct test versions of your applications to the upgraded DB instance.
8. If all tests pass, then perform the upgrade on your production DB instance. We recommend that you don't allow write operations to the DB instance until you confirm that everything is working correctly.

## Upgrading a MySQL DB instance

For information about manually or automatically upgrading a MySQL DB instance, see [Upgrading a DB instance engine version](#).

### Automatic minor version upgrades for MySQL

If you specify the following settings when creating or modifying a DB instance, you can have your DB instance automatically upgraded.

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.

In the AWS Management Console, these settings are under **Additional configuration**. The following image shows the **Auto minor version upgrade** setting.

## Maintenance

Auto minor version upgrade [Info](#)

**Enable auto minor version upgrade**  
 Enabling auto minor version upgrade will automatically upgrade to new minor versions as they are released. The automatic upgrades occur during the maintenance window for the database.

**Maintenance window** [Info](#)  
 Select the period you want pending modifications or maintenance applied to the database by Amazon RDS.

**Select window**

**No preference**

Start day: Monday ▼      Start time: 00 ▼ : 00 ▼ UTC      Duration: 0.5 ▼ hours

For more information about these settings, see [Settings for DB instances](#).

For some RDS for MySQL major versions in some AWS Regions, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the MySQL community version
- Overall fleet stability since the minor version was released

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified MySQL minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mysql \
--engine-version minor-version \
--region region \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
```

```
--output text
```

### For Windows:

```
aws rds describe-db-engine-versions ^
--engine mysql ^
--engine-version minor-version ^
--region region ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for MySQL minor version 8.0.11 in the US East (Ohio) AWS Region (us-east-2).

### For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mysql \
--engine-version 8.0.11 \
--region us-east-2 \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \
--output table
```

### For Windows:

```
aws rds describe-db-engine-versions ^
--engine mysql ^
--engine-version 8.0.11 ^
--region us-east-2 ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output table
```

Your output is similar to the following.

```
-----
| DescribeDBEngineVersions |
+-----+-----+
```

AutoUpgrade	EngineVersion
False	8.0.15
False	8.0.16
False	8.0.17
False	8.0.19
False	8.0.20
False	8.0.21
<b>True</b>	<b>8.0.23</b>
False	8.0.25

In this example, the AutoUpgrade value is `True` for MySQL version 8.0.23. So, the automatic minor upgrade target is MySQL version 8.0.23, which is highlighted in the output.

A MySQL DB instance is automatically upgraded during your maintenance window if the following criteria are met:

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.
- The DB instance is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see [Automatically upgrading the minor engine version](#).

## Using a read replica to reduce downtime when upgrading a MySQL database

In most cases, a blue/green deployment is the best option to reduce downtime when upgrading a MySQL DB instance. For more information, see [Using Amazon RDS Blue/Green Deployments for database updates](#).

If you can't use a blue/green deployment and your MySQL DB instance is currently in use with a production application, you can use the following procedure to upgrade the database version for your DB instance. This procedure can reduce the amount of downtime for your application.

By using a read replica, you can perform most of the maintenance steps ahead of time and minimize the necessary changes during the actual outage. With this technique, you can test and prepare the new DB instance without making any changes to your existing DB instance.

The following procedure shows an example of upgrading from MySQL version 5.7 to MySQL version 8.0. You can use the same general steps for upgrades to other major versions.

 **Note**

When you are upgrading from MySQL version 5.7 to MySQL version 8.0, complete the prechecks before performing the upgrade. For more information, see [Prechecks for upgrades from MySQL 5.7 to 8.0](#).

### To upgrade a MySQL database while a DB instance is in use

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Create a read replica of your MySQL 5.7 DB instance. This process creates an upgradable copy of your database. Other read replicas of the DB instance might also exist.
  - a. In the console, choose **Databases**, and then choose the DB instance that you want to upgrade.
  - b. For **Actions**, choose **Create read replica**.
  - c. Provide a value for **DB instance identifier** for your read replica and ensure that the **DB instance class** and other settings match your MySQL 5.7 DB instance.
  - d. Choose **Create read replica**.
3. (Optional) When the read replica has been created and **Status** shows **Available**, convert the read replica into a Multi-AZ deployment and enable backups.

By default, a read replica is created as a Single-AZ deployment with backups disabled. Because the read replica ultimately becomes the production DB instance, it is a best practice to configure a Multi-AZ deployment and enable backups now.

- a. In the console, choose **Databases**, and then choose the read replica that you just created.
- b. Choose **Modify**.
- c. For **Multi-AZ deployment**, choose **Create a standby instance**.
- d. For **Backup Retention Period**, choose a positive nonzero value, such as 3 days, and then choose **Continue**.
- e. For **Scheduling of modifications**, choose **Apply immediately**.

- f. Choose **Modify DB instance**.
4. When the read replica **Status** shows **Available**, upgrade the read replica to MySQL 8.0:
  - a. In the console, choose **Databases**, and then choose the read replica that you just created.
  - b. Choose **Modify**.
  - c. For **DB engine version**, choose the MySQL 8.0 version to upgrade to, and then choose **Continue**.
  - d. For **Scheduling of modifications**, choose **Apply immediately**.
  - e. Choose **Modify DB instance** to start the upgrade.
5. When the upgrade is complete and **Status** shows **Available**, verify that the upgraded read replica is up-to-date with the source MySQL 5.7 DB instance. To verify, connect to the read replica and run the `SHOW REPLICA STATUS` command. If the `Seconds_Behind_Master` field is `0`, then replication is up-to-date.

 **Note**

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

6. (Optional) Create a read replica of your read replica.

If you want the DB instance to have a read replica after it is promoted to a standalone DB instance, you can create the read replica now.

- a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.
- b. For **Actions**, choose **Create read replica**.
- c. Provide a value for **DB instance identifier** for your read replica and ensure that the **DB instance class** and other settings match your MySQL 5.7 DB instance.
- d. Choose **Create read replica**.
7. (Optional) Configure a custom DB parameter group for the read replica.

If you want the DB instance to use a custom parameter group after it is promoted to a standalone DB instance, you can create the DB parameter group now and associate it with the read replica.

- a. Create a custom DB parameter group for MySQL 8.0. For instructions, see [Creating a DB parameter group in Amazon RDS](#).
  - b. Modify the parameters that you want to change in the DB parameter group you just created. For instructions, see [Modifying parameters in a DB parameter group in Amazon RDS](#).
  - c. In the console, choose **Databases**, and then choose the read replica.
  - d. Choose **Modify**.
  - e. For **DB parameter group**, choose the MySQL 8.0 DB parameter group you just created, and then choose **Continue**.
  - f. For **Scheduling of modifications**, choose **Apply immediately**.
  - g. Choose **Modify DB instance** to start the upgrade.
8. Make your MySQL 8.0 read replica a standalone DB instance.

**⚠ Important**

When you promote your MySQL 8.0 read replica to a standalone DB instance, it is no longer a replica of your MySQL 5.7 DB instance. We recommend that you promote your MySQL 8.0 read replica during a maintenance window when your source MySQL 5.7 DB instance is in read-only mode and all write operations are suspended. When the promotion is completed, you can direct your write operations to the upgraded MySQL 8.0 DB instance to ensure that no write operations are lost.

In addition, we recommend that, before promoting your MySQL 8.0 read replica, you perform all necessary data definition language (DDL) operations on your MySQL 8.0 read replica. An example is creating indexes. This approach avoids negative effects on the performance of the MySQL 8.0 read replica after it has been promoted. To promote a read replica, use the following procedure.

- a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.
- b. For **Actions**, choose **Promote**.
- c. Choose **Yes** to enable automated backups for the read replica instance. For more information, see [Introduction to backups](#).
- d. Choose **Continue**.

- e. Choose **Promote Read Replica**.
9. You now have an upgraded version of your MySQL database. At this point, you can direct your applications to the new MySQL 8.0 DB instance.

# Upgrading a MySQL DB snapshot engine version

With Amazon RDS, you can create a storage volume DB snapshot of your MySQL DB instance. When you create a DB snapshot, the snapshot is based on the engine version used by your DB instance. In addition to upgrading the DB engine version of your DB instance, you can also upgrade the engine version for your DB snapshots. For RDS for MySQL, you can upgrade a version 5.7 snapshot to version 8.0. You can upgrade encrypted or unencrypted DB snapshots.

The following versions support MySQL DB snapshot upgrade:

- You can upgrade from RDS for MySQL snapshot version 5.7.16 and higher 5.7 versions.
- You can upgrade to RDS for MySQL snapshot version 8.0.28 and higher, except for versions 8.0.29, 8.0.30, and 8.0.31.

You can't upgrade versions 5.7.40, 5.7.41, and 5.7.42 to version 8.0.28, but you can upgrade these versions to version 8.0.32 and higher.

After restoring a DB snapshot upgraded to a new engine version, make sure to test that the upgrade was successful. For more information about a major version upgrade, see [the section called “Upgrading the MySQL DB engine”](#). To learn how to restore a DB snapshot, see [the section called “Restoring to a DB instance”](#).

## Note

You can't upgrade automated DB snapshots that were created during the automated backup process.

You can upgrade a DB snapshot using the AWS Management Console, AWS CLI, or RDS API.

## Console

### To upgrade a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the snapshot that you want to upgrade.

4. For **Actions**, choose **Upgrade snapshot**. The **Upgrade snapshot** page appears.
5. Choose the **New engine version** to upgrade to.
6. Choose **Save changes** to upgrade the snapshot.

During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from **Available** to **Upgrading**, and then changes to **Active** upon completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to **Unavailable**. You can't recover the snapshot from this state.

#### Note

If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

## AWS CLI

To upgrade a DB snapshot to a new database engine version, use the AWS CLI [modify-db-snapshot](#) command.

### Options

- `--db-snapshot-identifier` – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see [Amazon Resource Names \(ARNs\) in Amazon RDS](#).
- `--engine-version` – The engine version to upgrade the DB snapshot to.

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot \  
  --db-snapshot-identifier my_db_snapshot \  
  --engine-version new_version
```

For Windows:

```
aws rds modify-db-snapshot ^
```

```
--db-snapshot-identifier my_db_snapshot ^  
--engine-version new_version
```

## RDS API

To upgrade a DB snapshot to a new database engine version, call the RDS API [ModifyDBSnapshot](#) operation.

### Parameters

- `DBSnapshotIdentifier` – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see [Amazon Resource Names \(ARNs\) in Amazon RDS](#).
- `EngineVersion` – The engine version to upgrade the DB snapshot to.

## Importing data into a MySQL DB instance

You can use several different techniques to import data into an RDS for MySQL DB instance. The best approach depends on the source of the data, the amount of data, and whether the import is done one time or is ongoing. If you are migrating an application along with the data, also consider the amount of downtime that you are willing to experience.

### Overview

Find techniques to import data into an RDS for MySQL DB instance in the following table.

Source	Amount of data	One time or ongoing	Application on downtime	Technique	More information
Existing MySQL database on premises or on Amazon EC2	Any	One time	Some	Create a backup of your on-premises database, store it on Amazon S3, and then restore the backup file to a new Amazon RDS DB instance running MySQL.	<a href="#">Restoring a backup into a MySQL DB instance</a>
Any existing database	Any	One time or ongoing	Minimal	Use AWS Database Migration Service to migrate the database with minimal downtime and, for many database DB engines, continue ongoing replication.	<a href="#">What is AWS Database Migration Service and Using a MySQL-compatible database as a target</a>

Source	Amount of data	One time or ongoing	Application downtime	Technique	More information
					<a href="#">for AWS DMS in the AWS Database Migration Service User Guide</a>
Existing MySQL DB instance	Any	One time or ongoing	Minimal	Create a read replica for ongoing replication. Promote the read replica for one-time creation of a new DB instance.	<a href="#">Working with DB instance read replicas</a>
Existing MariaDB or MySQL database	Small	One time	Some	Copy the data directly to your MySQL DB instance using a command-line utility.	<a href="#">Importing data from an external MariaDB or MySQL database to an RDS for MariaDB or RDS for MySQL DB instance</a>

Source	Amount of data	One time or ongoing	Application downtime	Technique	More information
Data not stored in an existing database	Medium	One time	Some	Create flat files and import them using MySQL LOAD DATA LOCAL INFILE statements.	<a href="#">Importing data from any source to a MariaDB or MySQL DB instance</a>

Source	Amount of data	One time or ongoing	Application downtime	Technique	More information
Existing MariaDB or MySQL database on premises or on Amazon EC2	Any	Ongoing	Minimal	Configure replication with an existing MariaDB or MySQL database as the replication source.	<a href="#">Configuring binary log file position replication with an external source instance</a>  <a href="#">Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime</a>

**Note**

The 'mysql' system database contains authentication and authorization information required to log in to your DB instance and access your data. Dropping, altering, renaming, or truncating tables, data, or other contents of the 'mysql' database in your DB instance can result in error and might render the DB instance and your data inaccessible. If this occurs, you can restore the DB instance from a snapshot using the AWS CLI `restore-db-`

`instance-from-db-snapshot` command. You can recover the DB instance using the AWS CLI `restore-db-instance-to-point-in-time` command.

## Importing data considerations

Following, you can find additional technical information related to loading data into MySQL. This information is intended for advanced users who are familiar with the MySQL server architecture.

### Binary log

Data loads incur a performance penalty and require additional free disk space (up to four times more) when binary logging is enabled versus loading the same data with binary logging turned off. The severity of the performance penalty and the amount of free disk space required is directly proportional to the size of the transactions used to load the data.

### Transaction size

Transaction size plays an important role in MySQL data loads. It has a major influence on resource consumption, disk space utilization, resume process, time to recover, and input format (flat files or SQL). This section describes how transaction size affects binary logging and makes the case for disabling binary logging during large data loads. As noted earlier, binary logging is enabled and disabled by setting the Amazon RDS automated backup retention period. Non-zero values enable binary logging, and zero disables it. We also describe the impact of large transactions on InnoDB and why it's important to keep transaction sizes small.

### Small transactions

For small transactions, binary logging doubles the number of disk writes required to load the data. This effect can severely degrade performance for other database sessions and increase the time required to load the data. The degradation experienced depends in part upon the upload rate, other database activity taking place during the load, and the capacity of your Amazon RDS DB instance.

The binary logs also consume disk space roughly equal to the amount of data loaded until they are backed up and removed. Fortunately, Amazon RDS minimizes this by backing up and removing binary logs on a frequent basis.

## Large transactions

Large transactions incur a 3X penalty for IOPS and disk consumption with binary logging enabled. This is due to the binary log cache spilling to disk, consuming disk space and incurring additional IO for each write. The cache cannot be written to the binlog until the transaction commits or rolls back, so it consumes disk space in proportion to the amount of data loaded. When the transaction commits, the cache must be copied to the binlog, creating a third copy of the data on disk.

Because of this, there must be at least three times as much free disk space available to load the data compared to loading with binary logging disabled. For example, 10 GiB of data loaded as a single transaction consumes at least 30 GiB disk space during the load. It consumes 10 GiB for the table + 10 GiB for the binary log cache + 10 GiB for the binary log itself. The cache file remains on disk until the session that created it terminates or the session fills its binary log cache again during another transaction. The binary log must remain on disk until backed up, so it might be some time before the extra 20 GiB is freed.

If the data was loaded using `LOAD DATA LOCAL INFILE`, yet another copy of the data is created if the database has to be recovered from a backup made before the load. During recovery, MySQL extracts the data from the binary log into a flat file. MySQL then runs `LOAD DATA LOCAL INFILE`, just as in the original transaction. However, this time the input file is local to the database server. Continuing with the example preceding, recovery fails unless there is at least 40 GiB free disk space available.

## Disable binary logging

Whenever possible, disable binary logging during large data loads to avoid the resource overhead and additional disk space requirements. In Amazon RDS, disabling binary logging is as simple as setting the backup retention period to zero. If you do this, we recommend that you take a DB snapshot of the database instance immediately before the load. By doing this, you can quickly and easily undo changes made during loading if you need to.

After the load, set the backup retention period back to an appropriate (no zero) value.

You can't set the backup retention period to zero if the DB instance is a source DB instance for read replicas.

## InnoDB

The information in this section provides a strong argument for keeping transaction sizes small when using InnoDB.

## Undo

InnoDB generates undo to support features such as transaction rollback and MVCC. Undo is stored in the InnoDB system tablespace (usually `ibdata1`) and is retained until removed by the purge thread. The purge thread cannot advance beyond the undo of the oldest active transaction, so it is effectively blocked until the transaction commits or completes a rollback. If the database is processing other transactions during the load, their undo also accumulates in the system tablespace and cannot be removed even if they commit and no other transaction needs the undo for MVCC. In this situation, all transactions (including read-only transactions) that access any of the rows changed by any transaction (not just the load transaction) slow down. The slowdown occurs because transactions scan through undo that could have been purged if not for the long-running load transaction.

Undo is stored in the system tablespace, and the system tablespace never shrinks in size. Thus, large data load transactions can cause the system tablespace to become quite large, consuming disk space that you can't reclaim without recreating the database from scratch.

## Rollback

InnoDB is optimized for commits. Rolling back a large transaction can take a very, very long time. In some cases, it might be faster to perform a point-in-time recovery or restore a DB snapshot.

## Input data format

MySQL can accept incoming data in one of two forms: flat files and SQL. This section points out some key advantages and disadvantages of each.

### Flat files

Loading flat files with `LOAD DATA LOCAL INFILE` can be the fastest and least costly method of loading data as long as transactions are kept relatively small. Compared to loading the same data with SQL, flat files usually require less network traffic, lowering transmission costs and load much faster due to the reduced overhead in the database.

### One big transaction

`LOAD DATA LOCAL INFILE` loads the entire flat file as one transaction. This isn't necessarily a bad thing. If the size of the individual files can be kept small, this has a number of advantages:

- Resume capability – Keeping track of which files have been loaded is easy. If a problem arises during the load, you can pick up where you left off with little effort. Some data might have to be retransmitted to Amazon RDS, but with small files, the amount retransmitted is minimal.
- Load data in parallel – If you've got IOPS and network bandwidth to spare with a single file load, loading in parallel might save time.
- Throttle the load rate – Data load having a negative impact on other processes? Throttle the load by increasing the interval between files.

## Be careful

The advantages of `LOAD DATA LOCAL INFILE` diminish rapidly as transaction size increases. If breaking up a large set of data into smaller ones isn't an option, SQL might be the better choice.

## SQL

SQL has one main advantage over flat files: it's easy to keep transaction sizes small. However, SQL can take significantly longer to load than flat files and it can be difficult to determine where to resume the load after a failure. For example, `mysqldump` files are not restartable. If a failure occurs while loading a `mysqldump` file, the file requires modification or replacement before the load can resume. The alternative is to restore to the point in time before the load and replay the file after the cause of the failure has been corrected.

## Take checkpoints using Amazon RDS snapshots

If you have a load that's going to take several hours or even days, loading without binary logging isn't a very attractive prospect unless you can take periodic checkpoints. This is where the Amazon RDS DB snapshot feature comes in very handy. A DB snapshot creates a point-in-time consistent copy of your database instance which can be used restore the database to that point in time after a crash or other mishap.

To create a checkpoint, simply take a DB snapshot. Any previous DB snapshots taken for checkpoints can be removed without affecting durability or restore time.

Snapshots are fast too, so frequent checkpointing doesn't add significantly to load time.

## Decreasing load time

Here are some additional tips to reduce load times:

- Create all secondary indexes before loading. This is counter-intuitive for those familiar with other databases. Adding or modifying a secondary index causes MySQL to create a new table with the index changes, copy the data from the existing table to the new table, and drop the original table.
- Load data in PK order. This is particularly helpful for InnoDB tables, where load times can be reduced by 75–80 percent and data file size cut in half.
- Disable foreign key constraints `foreign_key_checks=0`. For flat files loaded with `LOAD DATA LOCAL INFILE`, this is required in many cases. For any load, disabling FK checks provides significant performance gains. Just be sure to enable the constraints and verify the data after the load.
- Load in parallel unless already near a resource limit. Use partitioned tables when appropriate.
- Use multi-value inserts when loading with SQL to minimize overhead when running statements. When using `mysqldump`, this is done automatically.
- Reduce InnoDB log IO `innodb_flush_log_at_trx_commit=0`
- If you are loading data into a DB instance that does not have read replicas, set the `sync_binlog` parameter to 0 while loading data. When data loading is complete, set the `sync_binlog` parameter to back to 1.
- Load data before converting the DB instance to a Multi-AZ deployment. However, if the DB instance already uses a Multi-AZ deployment, switching to a Single-AZ deployment for data loading is not recommended, because doing so only provides marginal improvements.

**Note**

Using `innodb_flush_log_at_trx_commit=0` causes InnoDB to flush its logs every second instead of at each commit. This provides a significant speed advantage, but can lead to data loss during a crash. Use with caution.

- [Importing data from an external MariaDB or MySQL database to an RDS for MariaDB or RDS for MySQL DB instance](#)
- [Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime](#)
- [Importing data from any source to a MariaDB or MySQL DB instance](#)

## Restoring a backup into a MySQL DB instance

Amazon RDS supports importing MySQL databases by using backup files. You can create a backup of your database, store it on Amazon S3, and then restore the backup file onto a new Amazon RDS DB instance running MySQL.

The scenario described in this section restores a backup of an on-premises database. You can use this technique for databases in other locations, such as Amazon EC2 or non-AWS cloud services, as long as the database is accessible.

You can find the supported scenario in the following diagram.

Importing backup files from Amazon S3 is supported for MySQL in all AWS Regions.

We recommend that you import your database to Amazon RDS by using backup files if your on-premises database can be offline while the backup file is created, copied, and restored. If your database can't be offline, you can use binary log (binlog) replication to update your database after you have migrated to Amazon RDS through Amazon S3 as explained in this topic. For more information, see [Configuring binary log file position replication with an external source instance](#). You can also use the AWS Database Migration Service to migrate your database to Amazon RDS. For more information, see [What is AWS Database Migration Service?](#)

### Limitations and recommendations for importing backup files from Amazon S3 to Amazon RDS

The following are some limitations and recommendations for importing backup files from Amazon S3:

- You can only import your data to a new DB instance, not an existing DB instance.
- You must use Percona XtraBackup to create the backup of your on-premises database.
- You can't import data from a DB snapshot export to Amazon S3.
- You can't migrate from a source database that has tables defined outside of the default MySQL data directory.
- You must import your data to the default minor version of your MySQL major version in your AWS Region. For example, if your major version is MySQL 8.0, and the default minor version for your AWS Region is 8.0.35, then you must import your data into a MySQL version 8.0.35 DB instance. You can upgrade your DB instance after importing. For information about determining the default minor version, see [MySQL on Amazon RDS versions](#).
- Backward migration is not supported for both major versions and minor versions. For example, you can't migrate from version 8.0 to version 5.7, and you can't migrate from version 8.0.32 to version 8.0.31.
- You can't import a MySQL 5.5 or 5.6 database.
- You can't import an on-premises MySQL database from one major version to another. For example, you can't import a MySQL 5.7 database to an RDS for MySQL 8.0 database. You can upgrade your DB instance after you complete the import.
- You can't restore from an encrypted source database, but you can restore to an encrypted Amazon RDS DB instance.
- You can't restore from an encrypted backup in the Amazon S3 bucket.
- You can't restore from an Amazon S3 bucket in a different AWS Region than your Amazon RDS DB instance.
- Importing from Amazon S3 is not supported on the db.t2.micro DB instance class. However, you can restore to a different DB instance class, and change the DB instance class later. For more information about instance classes, see [Hardware specifications for DB instance classes](#).
- Amazon S3 limits the size of a file uploaded to an Amazon S3 bucket to 5 TB. If a backup file exceeds 5 TB, then you must split the backup file into smaller files.
- When you restore the database, the backup is copied and then extracted on your DB instance. Therefore, provision storage space for your DB instance that is equal to or greater than the sum of the backup size, plus the original database's size on disk.
- Amazon RDS limits the number of files uploaded to an Amazon S3 bucket to 1 million. If the backup data for your database, including all full and incremental backups, exceeds 1 million files, use a Gzip (.gz), tar (.tar.gz), or Percona xstream (.xstream) file to store full and incremental

backup files in the Amazon S3 bucket. Percona XtraBackup 8.0 only supports Percona xstream for compression.

- User accounts are not imported automatically. Save your user accounts from your source database and add them to your new DB instance later.
- Functions are not imported automatically. Save your functions from your source database and add them to your new DB instance later.
- Stored procedures are not imported automatically. Save your stored procedures from your source database and add them to your new DB instance later.
- Time zone information is not imported automatically. Record the time zone information for your source database, and set the time zone of your new DB instance later. For more information, see [Local time zone for MySQL DB instances](#).
- The `innodb_data_file_path` parameter must be configured with only one data file that uses the default data file name `"ibdata1:12M:autoextend"`. Databases with two data files, or with a data file with a different name, can't be migrated using this method.

The following are examples of file names that are not allowed:

`"innodb_data_file_path=ibdata1:50M; ibdata2:50M:autoextend"` and  
`"innodb_data_file_path=ibdata01:50M:autoextend"`.

- The maximum size of the restored database is the maximum database size supported minus the size of the backup. So, if the maximum database size supported is 64 TiB, and the size of the backup is 30 TiB, then the maximum size of the restored database is 34 TiB, as in the following example:

$$64 \text{ TiB} - 30 \text{ TiB} = 34 \text{ TiB}$$

For information about the maximum database size supported by Amazon RDS for MySQL, see [General Purpose SSD storage](#) and [Provisioned IOPS SSD storage](#).

## Overview of setting up to import backup files from Amazon S3 to Amazon RDS

These are the components you need to set up to import backup files from Amazon S3 to Amazon RDS:

- An Amazon S3 bucket to store your backup files.
- A backup of your on-premises database created by Percona XtraBackup.
- An AWS Identity and Access Management (IAM) role to allow Amazon RDS to access the bucket.

If you already have an Amazon S3 bucket, you can use that. If you don't have an Amazon S3 bucket, you can create a new one. If you want to create a new bucket, see [Creating a bucket](#).

Use the Percona XtraBackup tool to create your backup. For more information, see [Creating your database backup](#).

If you already have an IAM role, you can use that. If you don't have an IAM role, you can create a new one manually. Alternatively, you can choose to have a new IAM role created for you in your account by the wizard when you restore the database by using the AWS Management Console. If you want to create a new IAM role manually, or attach trust and permissions policies to an existing IAM role, see [Creating an IAM role manually](#). If you want to have a new IAM role created for you, follow the procedure in [Console](#).

## Creating your database backup

Use the Percona XtraBackup software to create your backup. We recommend that you use the latest version of Percona XtraBackup. You can install Percona XtraBackup from [Download Percona XtraBackup](#).

### Warning

When creating a database backup, XtraBackup might save credentials in the `xtrabackup_info` file. Make sure you examine that file so that the `tool_command` setting in it doesn't contain any sensitive information.

### Note

For MySQL 8.0 migration, you must use Percona XtraBackup 8.0. Percona XtraBackup 8.0.12 and higher versions support migration of all versions of MySQL. If you are migrating to RDS for MySQL 8.0.20 or higher, you must use Percona XtraBackup 8.0.12 or higher. For MySQL 5.7 migrations, you can also use Percona XtraBackup 2.4. For migrations of earlier MySQL versions, you can also use Percona XtraBackup 2.3 or 2.4.

You can create a full backup of your MySQL database files using Percona XtraBackup. Alternatively, if you already use Percona XtraBackup to back up your MySQL database files, you can upload your existing full and incremental backup directories and files.

For more information about backing up your database with Percona XtraBackup, see [Percona XtraBackup - documentation](#) and [The xtrabackup binary](#) on the Percona website.

## Creating a full backup with Percona XtraBackup

To create a full backup of your MySQL database files that can be restored from Amazon S3, use the Percona XtraBackup utility (`xtrabackup`) to back up your database.

For example, the following command creates a backup of a MySQL database and stores the files in the folder `/on-premises/s3-restore/backup` folder.

```
xtrabackup --backup --user=<myuser> --password=<password> --target-dir=</on-premises/s3-restore/backup>
```

If you want to compress your backup into a single file (which can be split later, if needed), you can save your backup in one of the following formats:

- Gzip (.gz)
- tar (.tar)
- Percona xstream (.xstream)

### Note

Percona XtraBackup 8.0 only supports Percona xstream for compression.

The following command creates a backup of your MySQL database split into multiple Gzip files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar \  
--target-dir=</on-premises/s3-restore/backup> | gzip - | split -d --bytes=500MB \  
- </on-premises/s3-restore/backup/backup>.tar.gz
```

The following command creates a backup of your MySQL database split into multiple tar files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar \  
--target-dir=</on-premises/s3-restore/backup> | split -d --bytes=500MB \  
- </on-premises/s3-restore/backup/backup>.tar
```

The following command creates a backup of your MySQL database split into multiple xstream files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=xstream \  
--target-dir=</on-premises/s3-restore/backup> | split -d --bytes=500MB \  
- </on-premises/s3-restore/backup/backup>.xstream
```

### Note

If you see the following error, it might be caused by mixing file formats in your command:

```
ERROR:/bin/tar: This does not look like a tar archive
```

## Using incremental backups with Percona XtraBackup

If you already use Percona XtraBackup to perform full and incremental backups of your MySQL database files, you don't need to create a full backup and upload the backup files to Amazon S3. Instead, you can save a significant amount of time by copying your existing backup directories and files to your Amazon S3 bucket. For more information about creating incremental backups using Percona XtraBackup, see [Incremental backup](#).

When copying your existing full and incremental backup files to an Amazon S3 bucket, you must recursively copy the contents of the base directory. Those contents include the full backup and also all incremental backup directories and files. This copy must preserve the directory structure in the Amazon S3 bucket. Amazon RDS iterates through all files and directories. Amazon RDS uses the `xtrabackup-checkpoints` file that is included with each incremental backup to identify the base directory, and to order incremental backups by log sequence number (LSN) range.

## Backup considerations for Percona XtraBackup

Amazon RDS consumes your backup files based on the file name. Name your backup files with the appropriate file extension based on the file format—for example, `.xstream` for files stored using the Percona xstream format.

Amazon RDS consumes your backup files in alphabetical order and also in natural number order. Use the `split` option when you issue the `xtrabackup` command to ensure that your backup files are written and named in the proper order.

Amazon RDS doesn't support partial backups created using Percona XtraBackup. You can't use the following options to create a partial backup when you back up the source files for your database: `--tables`, `--tables-exclude`, `--tables-file`, `--databases`, `--databases-exclude`, or `--databases-file`.

Amazon RDS supports incremental backups created using Percona XtraBackup. For more information about creating incremental backups using Percona XtraBackup, see [Incremental backup](#).

## Creating an IAM role manually

If you don't have an IAM role, you can create a new one manually. However, if you restore the database by using the AWS Management Console, we recommend that you follow the procedure in [Console](#) and choose to have RDS create this new IAM role for you.

To manually create a new IAM role for importing your database from Amazon S3, create a role to delegate permissions from Amazon RDS to your Amazon S3 bucket. When you create an IAM role, you attach trust and permissions policies. To import your backup files from Amazon S3, use trust and permissions policies similar to the following examples. For more information about creating the role, see [Creating a role to delegate permissions to an AWS service](#).

The trust and permissions policies require that you provide an Amazon Resource Name (ARN). For more information about ARN formatting, see [Amazon Resource Names \(ARNs\) and AWS service namespaces](#).

### Example trust policy for importing from Amazon S3

```
{
  "Version": "2012-10-17",
  "Statement":
  [
    {
      "Effect": "Allow",
      "Principal": {"Service": "rds.amazonaws.com"},
      "Action": "sts:AssumeRole"
    }
  ]
}
```

### Example permissions policy for importing from Amazon S3 — IAM user permissions

In the following example, replace *iam\_user\_id* with your own value.

```
{
  "Version": "2012-10-17",
  "Statement":
  [
    {
      "Sid": "AllowS3AccessRole",
      "Effect": "Allow",
      "Action": "iam:PassRole",
      "Resource": "arn:aws:iam::iam_user_id:role/S3Access"
    }
  ]
}
```

### Example permissions policy for importing from Amazon S3 — role permissions

In the following example, replace *amzn-s3-demo-bucket* and *prefix* with your own values.

```
{
  "Version": "2012-10-17",
  "Statement":
  [
    {
      "Effect": "Allow",
      "Action":
      [
        "s3:ListBucket",
        "s3:GetBucketLocation"
      ],
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket"
    },
    {
      "Effect": "Allow",
      "Action":
      [
        "s3:GetObject"
      ],
      "Resource": "arn:aws:s3:::amzn-s3-demo-bucket/prefix*"
    },
    { // If your bucket is encrypted, include the following permission. This
      permission allows decryption of your AWS KMS key.
      "Effect": "Allow",
      "Action":
      [
```

```
        "kms:Decrypt"
      ],
      "Resource": [
        "arn:aws:kms:region:customer_id:key/key_id*"
      ]
    }
  ]
}
```

**Note**

If you include a file name prefix, include the asterisk (\*) after the prefix. If you don't want to specify a prefix, specify only an asterisk.

## Importing data from Amazon S3 to a new MySQL DB instance

You can import data from Amazon S3 to a new MySQL DB instance using the AWS Management Console, AWS CLI, or RDS API.

### Console

#### To import data from Amazon S3 to a new MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the top right corner of the Amazon RDS console, choose the AWS Region in which to create your DB instance. Choose the same AWS Region as the Amazon S3 bucket that contains your database backup.
3. In the navigation pane, choose **Databases**.
4. Choose **Restore from S3**.

The **Create database by restoring from S3** page appears.

RDS > Databases > Restore from S3

## Create database by restoring from S3

### S3 destination ↻

**Write audit logs to S3**  
Enter a destination in Amazon S3 where your audit logs will be stored. Amazon S3 is object storage build to store and retrieve any amount of data from anywhere

S3 bucket  
db-backup-bucket-1234.xyz ▼

S3 prefix (optional) [Info](#)

### Engine options

Engine type [Info](#)

Aurora (MySQL Compatible) 

MySQL 

Edition  
 MySQL Community

Source engine version [Info](#)  
8.0 ▼

Engine Version  
MySQL 8.0.33 ▼

5. Under **S3 destination**:
  - a. Choose the **S3 bucket** that contains the backup.

- b. (Optional) For **S3 prefix**, enter the file path prefix for the files stored in your Amazon S3 bucket.

If you don't specify a prefix, then RDS creates your DB instance using all of the files and folders in the root folder of the S3 bucket. If you do specify a prefix, then RDS creates your DB instance using the files and folders in the S3 bucket where the path for the file begins with the specified prefix.

For example, suppose that you store your backup files on S3 in a subfolder named `backups`, and you have multiple sets of backup files, each in its own directory (`gzip_backup1`, `gzip_backup2`, and so on). In this case, you specify a prefix of `backups/gzip_backup1` to restore from the files in the `gzip_backup1` folder.

6. Under **Engine options**:

- a. For **Engine type**, choose **MySQL**.
- b. For **Source engine version**, choose the MySQL major version of your source database.
- c. For **Engine Version**, choose the default minor version of your MySQL major version in your AWS Region.

In the AWS Management Console, only the default minor version is available. You can upgrade your DB instance after importing.

7. For **IAM role**, create or choose IAM role with the required trust policy and permissions policy that allows Amazon RDS to access your Amazon S3 bucket. Perform one of the following actions:

- (Recommended) Choose **Create a new role**, and enter the **IAM role name**. With this option, RDS automatically creates the role with the trust policy and permissions policy for you.
- Choose an existing IAM role. Make sure that this role meets all of the criteria in [the section called "Creating an IAM role manually"](#).

8. Specify your DB instance information. For information about each setting, see [Settings for DB instances](#).

 **Note**

Be sure to allocate enough memory for your new DB instance so that the restore operation can succeed.

You can also choose **Enable storage autoscaling** to allow for future growth automatically.

9. Choose additional settings as needed.
10. Choose **Create database**.

## AWS CLI

To import data from Amazon S3 to a new MySQL DB instance by using the AWS CLI, call the [restore-db-instance-from-s3](#) command with the following parameters. For information about each setting, see [Settings for DB instances](#).

### Note

Be sure to allocate enough memory for your new DB instance so that the restore operation can succeed.

You can also use the `--max-allocated-storage` parameter to enable storage autoscaling and allow for future growth automatically.

- `--allocated-storage`
- `--db-instance-identifier`
- `--db-instance-class`
- `--engine`
- `--master-username`
- `--manage-master-user-password`
- `--s3-bucket-name`
- `--s3-ingestion-role-arn`
- `--s3-prefix`
- `--source-engine`
- `--source-engine-version`

## Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-s3 \  
  --allocated-storage 250 \  
  --db-instance-identifier myidentifier \  
  --db-instance-class db.m5.large \  
  --engine mysql \  
  --master-username admin \  
  --manage-master-user-password \  
  --s3-bucket-name amzn-s3-demo-bucket \  
  --s3-ingestion-role-arn arn:aws:iam::account-number:role/rolename \  
  --s3-prefix bucketprefix \  
  --source-engine mysql \  
  --source-engine-version 8.0.32 \  
  --max-allocated-storage 1000
```

For Windows:

```
aws rds restore-db-instance-from-s3 ^  
  --allocated-storage 250 ^  
  --db-instance-identifier myidentifier ^  
  --db-instance-class db.m5.large ^  
  --engine mysql ^  
  --master-username admin ^  
  --manage-master-user-password ^  
  --s3-bucket-name amzn-s3-demo-bucket ^  
  --s3-ingestion-role-arn arn:aws:iam::account-number:role/rolename ^  
  --s3-prefix bucketprefix ^  
  --source-engine mysql ^  
  --source-engine-version 8.0.32 ^  
  --max-allocated-storage 1000
```

## RDS API

To import data from Amazon S3 to a new MySQL DB instance by using the Amazon RDS API, call the [RestoreDBInstanceFromS3](#) operation.

## Importing data from an external MariaDB or MySQL database to an RDS for MariaDB or RDS for MySQL DB instance

You can also import data from an existing MariaDB or MySQL database to a MySQL or MariaDB DB instance. You do so by copying the database with [mysqldump](#) and piping it directly into the MariaDB or MySQL DB instance. The `mysqldump` command line utility is commonly used to make

backups and transfer data from one MariaDB or MySQL server to another. It's included with MySQL and MariaDB client software.

### Note

If you are importing or exporting large amounts of data with a MySQL DB instance, it's more reliable and faster to move data in and out of Amazon RDS by using `xtrabackup` backup files and Amazon S3. For more information, see [Restoring a backup into a MySQL DB instance](#).

A typical `mysqldump` command to move data from an external database to an Amazon RDS DB instance looks similar to the following.

```
mysqldump -u local_user \  
  --databases database_name \  
  --single-transaction \  
  --compress \  
  --order-by-primary \  
-plocal_password | mysql -u RDS_user \  
  --port=port_number \  
  --host=host_name \  
-pRDS_password
```

### Important

Make sure not to leave a space between the `-p` option and the entered password. Specify credentials other than the prompts shown here as a security best practice.

Make sure that you're aware of the following recommendations and considerations:

- Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The `mysqldump` utility excludes these schemas by default.
- If you need to migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the [pt-show-grants](#) utility.
- To perform the import, make sure the user doing so has access to the DB instance. For more information, see [Controlling access with security groups](#).

The parameters used are as follows:

- `-u local_user` – Use to specify a user name. In the first usage of this parameter, you specify the name of a user account on the local MariaDB or MySQL database identified by the `--databases` parameter.
- `--databases database_name` – Use to specify the name of the database on the local MariaDB or MySQL instance that you want to import into Amazon RDS.
- `--single-transaction` – Use to ensure that all of the data loaded from the local database is consistent with a single point in time. If there are other processes changing the data while `mysqldump` is reading it, using this parameter helps maintain data integrity.
- `--compress` – Use to reduce network bandwidth consumption by compressing the data from the local database before sending it to Amazon RDS.
- `--order-by-primary` – Use to reduce load time by sorting each table's data by its primary key.
- `-plocal_password` – Use to specify a password. In the first usage of this parameter, you specify the password for the user account identified by the first `-u` parameter.
- `-u RDS_user` – Use to specify a user name. In the second usage of this parameter, you specify the name of a user account on the default database for the MariaDB or MySQL DB instance identified by the `--host` parameter.
- `--port port_number` – Use to specify the port for your MariaDB or MySQL DB instance. By default, this is 3306 unless you changed the value when creating the instance.
- `--host host_name` – Use to specify the Domain Name System (DNS) name from the Amazon RDS DB instance endpoint, for example, `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.
- `-pRDS_password` – Use to specify a password. In the second usage of this parameter, you specify the password for the user account identified by the second `-u` parameter.

Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, then exclude them when you run `mysqldump`. To do so, include the following parameters with your `mysqldump` command: `--routines=0 --triggers=0 --events=0`.

The following example copies the `world` sample database on the local host to a MySQL DB instance.

## For Linux, macOS, or Unix:

```
sudo mysqldump -u localuser \  
  --databases world \  
  --single-transaction \  
  --compress \  
  --order-by-primary \  
  --routines=0 \  
  --triggers=0 \  
  --events=0 \  
-plocalpassword | mysql -u rdsuser \  
  --port=3306 \  
  --host=myinstance.123456789012.us-east-1.rds.amazonaws.com \  
-prdspassword
```

For Windows, run the following command in a command prompt that has been opened by right-clicking **Command Prompt** on the Windows programs menu and choosing **Run as administrator**:

```
mysqldump -u localuser ^  
  --databases world ^  
  --single-transaction ^  
  --compress ^  
  --order-by-primary ^  
  --routines=0 ^  
  --triggers=0 ^  
  --events=0 ^  
-plocalpassword | mysql -u rdsuser ^  
  --port=3306 ^  
  --host=myinstance.123456789012.us-east-1.rds.amazonaws.com ^  
-prdspassword
```

### Note

Specify credentials other than the prompts shown here as a security best practice.

## Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime

In some cases, you might need to import data from an external MariaDB or MySQL database that supports a live application to a MariaDB DB instance, a MySQL DB instance, or a MySQL Multi-AZ

DB cluster. Use the following procedure to minimize the impact on availability of applications. This procedure can also help if you are working with a very large database. Using this procedure, you can reduce the cost of the import by reducing the amount of data that is passed across the network to AWS.

In this procedure, you transfer a copy of your database data to an Amazon EC2 instance and import the data into a new Amazon RDS database. You then use replication to bring the Amazon RDS database up-to-date with your live external instance, before redirecting your application to the Amazon RDS database. Configure MariaDB replication based on global transaction identifiers (GTIDs) if the external instance is MariaDB 10.0.24 or higher and the target instance is RDS for MariaDB. Otherwise, configure replication based on binary log coordinates. We recommend GTID-based replication if your external database supports it because GTID-based replication is a more reliable method. For more information, see [Global transaction ID](#) in the MariaDB documentation.

### Note

If you want to import data into a MySQL DB instance and your scenario supports it, we recommend moving data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see [Restoring a backup into a MySQL DB instance](#).

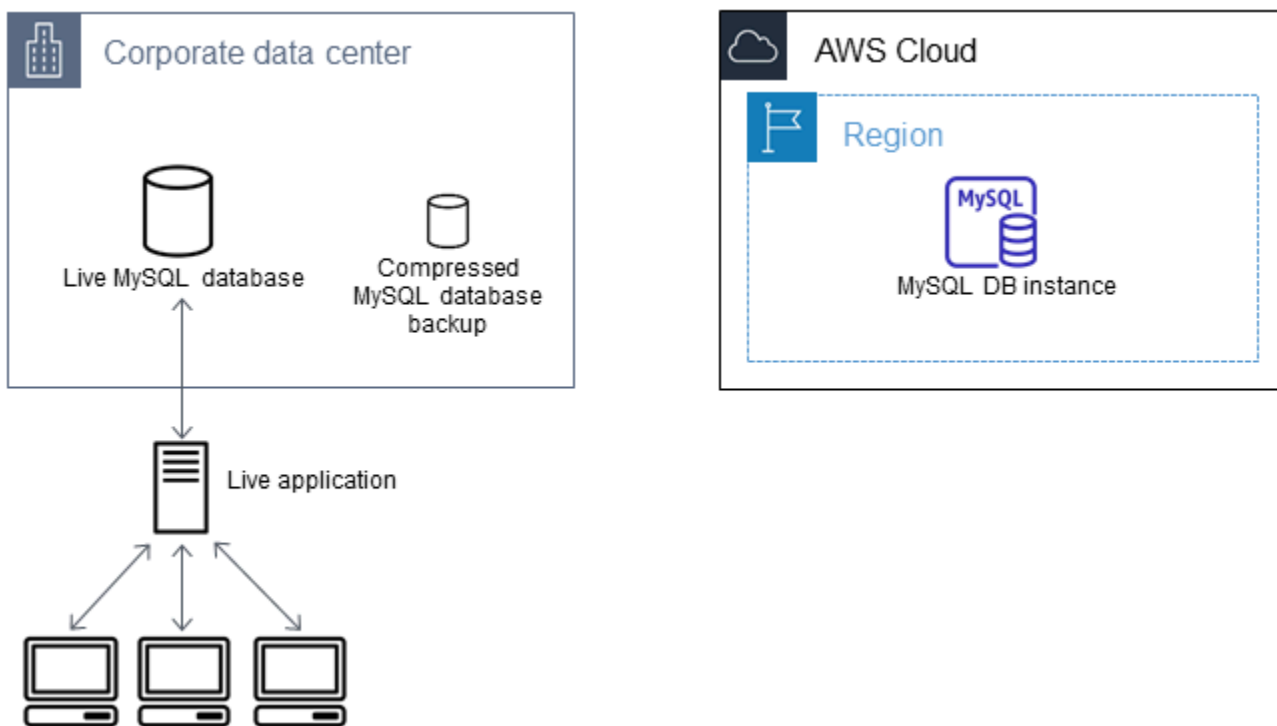

### Note

We don't recommend that you use this procedure with source MySQL databases from MySQL versions earlier than version 5.5 because of potential replication issues. For more information, see [Replication compatibility between MySQL versions](#) in the MySQL documentation.

## Create a copy of your existing database

The first step in the process of migrating a large amount of data to an RDS for MariaDB or RDS for MySQL database with minimal downtime is to create a copy of the source data.

You can use the `mysqldump` utility to create a database backup in either SQL or delimited-text format. We recommend that you do a test run with each format in a non-production environment to see which method minimizes the amount of time that `mysqldump` runs.

We also recommend that you weigh `mysqldump` performance against the benefit offered by using the delimited-text format for loading. A backup using delimited-text format creates a tab-separated text file for each table being dumped. To reduce the amount of time required to import your database, you can load these files in parallel using the `LOAD DATA LOCAL INFILE`

command. For more information about choosing a mysqldump format and then loading the data, see [Using mysqldump for backups](#) in the MySQL documentation.

Before you start the backup operation, make sure to set the replication options on the MariaDB or MySQL database that you are copying to Amazon RDS. The replication options include turning on binary logging and setting a unique server ID. Setting these options causes your server to start logging database transactions and prepares it to be a source replication instance later in this process.

### Note

Use the `--single-transaction` option with `mysqldump` because it dumps a consistent state of the database. To ensure a valid dump file, don't run data definition language (DDL) statements while `mysqldump` is running. You can schedule a maintenance window for these operations.

Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The `mysqldump` utility excludes these schemas by default.

To migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the [pt-show-grants](#) utility.

## To set replication options

1. Edit the `my.cnf` file (this file is usually under `/etc`).

```
sudo vi /etc/my.cnf
```

Add the `log_bin` and `server_id` options to the `[mysqld]` section. The `log_bin` option provides a file name identifier for binary log files. The `server_id` option provides a unique identifier for the server in source-replica relationships.

The following example shows the updated `[mysqld]` section of a `my.cnf` file.

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

For more information, see [the MySQL documentation](#).

2. For replication with a Multi-AZ DB cluster, set the `ENFORCE_GTID_CONSISTENCY` and the `GTID_MODE` parameter to `ON`.

```
mysql> SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = ON;
```

```
mysql> SET @@GLOBAL.GTID_MODE = ON;
```

These settings aren't required for replication with a DB instance.

3. Restart the `mysql` service.

```
sudo service mysqld restart
```

## To create a backup copy of your existing database

1. Create a backup of your data using the `mysqldump` utility, specifying either SQL or delimited-text format.

Specify `--master-data=2` to create a backup file that can be used to start replication between servers. For more information, see the [mysqldump](#) documentation.

To improve performance and ensure data integrity, use the `--order-by-primary` and `--single-transaction` options of `mysqldump`.

To avoid including the MySQL system database in the backup, do not use the `--all-databases` option with `mysqldump`. For more information, see [Creating a data snapshot using mysqldump](#) in the MySQL documentation.

Use `chmod` if necessary to make sure that the directory where the backup file is being created is writable.

### Important

On Windows, run the command window as an administrator.

- To produce SQL output, use the following command.

For Linux, macOS, or Unix:

```
sudo mysqldump \  
  --databases database_name \  
  --master-data=2 \  
  --single-transaction \  
  --order-by-primary \  
  -r backup.sql \  
  -u local_user \  
  -p password
```

**Note**

Specify credentials other than the prompts shown here as a security best practice.

For Windows:

```
mysqldump ^  
  --databases database_name ^  
  --master-data=2 ^  
  --single-transaction ^  
  --order-by-primary ^  
  -r backup.sql ^  
  -u local_user ^  
  -p password
```

**Note**

Specify credentials other than the prompts shown here as a security best practice.

- To produce delimited-text output, use the following command.

For Linux, macOS, or Unix:

```
sudo mysqldump \  
  --tab=target_directory \  
  --fields-terminated-by ',' \  
  --fields-enclosed-by '"' \  
  --lines-terminated-by 0x0d0a \  
  database_name \  
  local_user \  
  password
```

```
--master-data=2 \  
--single-transaction \  
--order-by-primary \  
-p password
```

For Windows:

```
mysqldump ^  
--tab=target_directory ^  
--fields-terminated-by "," ^  
--fields-enclosed-by "" ^  
--lines-terminated-by 0x0d0a ^  
database_name ^  
--master-data=2 ^  
--single-transaction ^  
--order-by-primary ^  
-p password
```

### Note

Specify credentials other than the prompts shown here as a security best practice. Make sure to create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, exclude them when you run `mysqldump`. To do so, include the following arguments with your `mysqldump` command: `--routines=0 --triggers=0 --events=0`.

When using the delimited-text format, a `CHANGE MASTER TO` comment is returned when you run `mysqldump`. This comment contains the master log file name and position. If the external instance is other than MariaDB version 10.0.24 or higher, note the values for `MASTER_LOG_FILE` and `MASTER_LOG_POS`. You need these values when setting up replication.

```
-- Position to start replication or point-in-time recovery from  
--  
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031',  
MASTER_LOG_POS=107;
```

If you are using SQL format, you can get the master log file name and position in the `CHANGE MASTER TO` comment in the backup file. If the external instance is MariaDB version 10.0.24 or higher, you can get the GTID in the next step.

2. If the external instance you are using is MariaDB version 10.0.24 or higher, you use GTID-based replication. Run `SHOW MASTER STATUS` on the external MariaDB instance to get the binary log file name and position, then convert them to a GTID by running `BINLOG_GTID_POS` on the external MariaDB instance.

```
SELECT BINLOG_GTID_POS('binary log file name', binary log file position);
```

Note the GTID returned; you need it to configure replication.

3. Compress the copied data to reduce the amount of network resources needed to copy your data to the Amazon RDS database. Note the size of the backup file. You need this information when determining how large an Amazon EC2 instance to create. When you are done, compress the backup file using GZIP or your preferred compression utility.
  - To compress SQL output, use the following command.

```
gzip backup.sql
```

- To compress delimited-text output, use the following command.

```
tar -zcvf backup.tar.gz target_directory
```

## Create an Amazon EC2 instance and copy the compressed database

Copying your compressed database backup file to an Amazon EC2 instance takes fewer network resources than doing a direct copy of uncompressed data between database instances. After your data is in Amazon EC2, you can copy it from there directly to your MariaDB or MySQL database. For you to save on the cost of network resources, your Amazon EC2 instance must be in the same AWS Region as your Amazon RDS DB instance. Having the Amazon EC2 instance in the same AWS Region as your Amazon RDS database also reduces network latency during the import.

## To create an Amazon EC2 instance and copy your data

1. In the AWS Region where you plan to create the RDS database, create a virtual private cloud (VPC), a VPC security group, and a VPC subnet. Ensure that the inbound rules for your VPC security group allow the IP addresses required for your application to connect to AWS. You can specify a range of IP addresses (for example, `203.0.113.0/24`), or another VPC security group. You can use the [Amazon VPC Management Console](#) to create and manage VPCs, subnets, and security groups. For more information, see [Getting started with Amazon VPC](#) in the *Amazon Virtual Private Cloud Getting Started Guide*.
2. Open the [Amazon EC2 Management Console](#) and choose the AWS Region to contain both your Amazon EC2 instance and your Amazon RDS database. Launch an Amazon EC2 instance using the VPC, subnet, and security group that you created in Step 1. Ensure that you select an instance type with enough storage for your database backup file when it is uncompressed. For details on Amazon EC2 instances, see [Getting started with Amazon EC2 Linux instances](#) in the *Amazon Elastic Compute Cloud User Guide for Linux*.
3. To connect to your Amazon RDS database from your Amazon EC2 instance, edit your VPC security group. Add an inbound rule specifying the private IP address of your EC2 instance. You can find the private IP address on the **Details** tab of the **Instance** pane in the EC2 console window. To edit the VPC security group and add an inbound rule, choose **Security Groups** in the EC2 console navigation pane, choose your security group, and then add an inbound rule for

MySQL or Aurora specifying the private IP address of your EC2 instance. To learn how to add an inbound rule to a VPC security group, see [Adding and removing rules](#) in the *Amazon VPC User Guide*.

4. Copy your compressed database backup file from your local system to your Amazon EC2 instance. Use `chmod` if necessary to make sure that you have write permission for the target directory of the Amazon EC2 instance. You can use `scp` or a Secure Shell (SSH) client to copy the file. The following is an example.

```
scp -r -i key pair.pem backup.sql.gz ec2-user@EC2 DNS:/target_directory/backup.sql.gz
```

### Important

Be sure to copy sensitive data using a secure network transfer protocol.

5. Connect to your Amazon EC2 instance and install the latest updates and the MySQL client tools using the following commands.

```
sudo yum update -y
sudo yum install mysql -y
```

For more information, see [Connect to your instance](#) in the *Amazon Elastic Compute Cloud User Guide for Linux*.

### Important

This example installs the MySQL client on an Amazon Machine Image (AMI) for an Amazon Linux distribution. To install the MySQL client on a different distribution, such as Ubuntu or Red Hat Enterprise Linux, this example doesn't work. For information about installing MySQL, see [Installing and Upgrading MySQL](#) in the MySQL documentation.

6. While connected to your Amazon EC2 instance, decompress your database backup file. The following are examples.
  - To decompress SQL output, use the following command.

```
gzip backup.sql.gz -d
```

- To decompress delimited-text output, use the following command.

```
tar xzvf backup.tar.gz
```

## Create a MySQL or MariaDB database and import data from your Amazon EC2 instance

By creating a MariaDB DB instance, a MySQL DB instance, or a MySQL Multi-AZ DB cluster in the same AWS Region as your Amazon EC2 instance, you can import the database backup file from EC2 faster than over the internet.

### To create a MariaDB or MySQL database and import your data

1. Determine which DB instance class and what amount of storage space is required to support the expected workload for this Amazon RDS database. As part of this process, decide what is sufficient space and processing capacity for your data load procedures. Also decide what is required to handle the production workload. You can estimate this based on the size and resources of the source MariaDB or MySQL database. For more information, see [DB instance classes](#).
2. Create a DB instance or Multi-AZ DB cluster in the AWS Region that contains your Amazon EC2 instance.

To create a MySQL Multi-AZ DB cluster, follow the instructions in [Creating a Multi-AZ DB cluster](#).

To create a MariaDB or MySQL DB instance, follow the instructions in [Creating an Amazon RDS DB instance](#) and use the following guidelines:

- Specify a DB engine version that is compatible with your source DB instance, as follows:
    - If your source instance is MySQL 5.5.x, the Amazon RDS DB instance must be MySQL.
    - If your source instance is MySQL 5.6.x or 5.7.x, the Amazon RDS DB instance must be MySQL or MariaDB.
    - If your source instance is MySQL 8.0.x, the Amazon RDS DB instance must be MySQL 8.0.x.
    - If your source instance is MariaDB 5.5 or higher, the Amazon RDS DB instance must be MariaDB.
  - Specify the same virtual private cloud (VPC) and VPC security group as for your Amazon EC2 instance. This approach ensures that your Amazon EC2 instance and your Amazon RDS instance are visible to each other over the network. Make sure your DB instance is publicly accessible. To set up replication with your source database as described later, your DB instance must be publicly accessible.
  - Don't configure multiple Availability Zones, backup retention, or read replicas until after you have imported the database backup. When that import is completed, you can configure Multi-AZ and backup retention for the production instance.
3. Review the default configuration options for the Amazon RDS database. If the default parameter group for the database doesn't have the configuration options that you want, find a different one that does or create a new parameter group. For more information on creating a parameter group, see [Parameter groups for Amazon RDS](#).
  4. Connect to the new Amazon RDS database as the master user. Create the users required to support the administrators, applications, and services that need to access the instance. The hostname for the Amazon RDS database is the **Endpoint** value for this instance without including the port number. An example is `mysamp1edb.123456789012.us-west-2.rds.amazonaws.com`. You can find the endpoint value in the database details in the Amazon RDS Management Console.
  5. Connect to your Amazon EC2 instance. For more information, see [Connect to your instance](#) in the *Amazon Elastic Compute Cloud User Guide for Linux*.

6. Connect to your Amazon RDS database as a remote host from your Amazon EC2 instance using the `mysql` command. The following is an example.

```
mysql -h host_name -P 3306 -u db_master_user -p
```

The hostname is the Amazon RDS database endpoint.

7. At the `mysql` prompt, run the `source` command and pass it the name of your database dump file to load the data into the Amazon RDS DB instance:
  - For SQL format, use the following command.

```
mysql> source backup.sql;
```

- For delimited-text format, first create the database, if it isn't the default database you created when setting up the Amazon RDS database.

```
mysql> create database database_name;  
mysql> use database_name;
```

Then create the tables.

```
mysql> source table1.sql  
mysql> source table2.sql  
etc...
```

Then import the data.

```
mysql> LOAD DATA LOCAL INFILE 'table1.txt' INTO TABLE table1 FIELDS TERMINATED BY  
' ,' ENCLOSED BY '''' LINES TERMINATED BY '\0x0d0a';  
mysql> LOAD DATA LOCAL INFILE 'table2.txt' INTO TABLE table2 FIELDS TERMINATED BY  
' ,' ENCLOSED BY '''' LINES TERMINATED BY '\0x0d0a';  
etc...
```

To improve performance, you can perform these operations in parallel from multiple connections so that all of your tables are created and then loaded at the same time.

**Note**

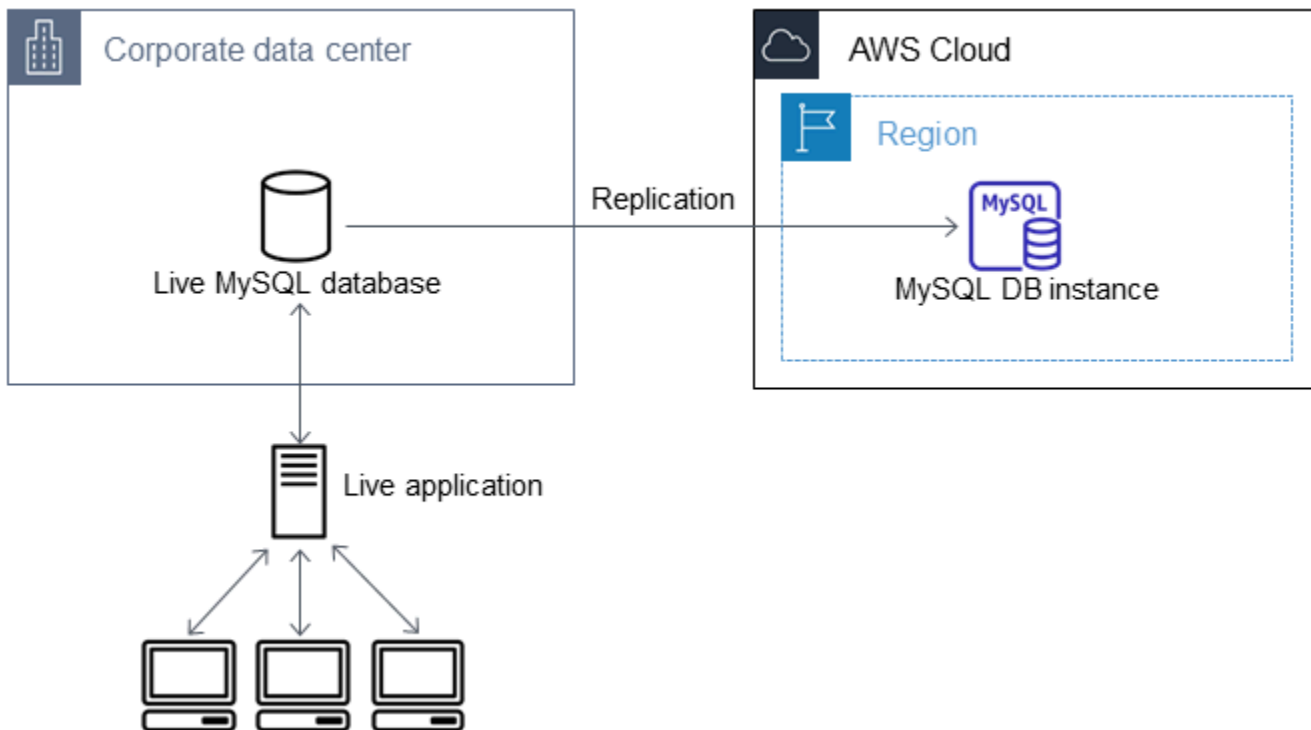

If you used any data-formatting options with `mysqldump` when you initially dumped the table, make sure to use the same options with `LOAD DATA LOCAL INFILE` to ensure proper interpretation of the data file contents.

8. Run a simple `SELECT` query against one or two of the tables in the imported database to verify that the import was successful.

If you no longer need the Amazon EC2 instance used in this procedure, terminate the EC2 instance to reduce your AWS resource usage. To terminate an EC2 instance, see [Terminating an instance](#) in the *Amazon EC2 User Guide*.

## Replicate between your external database and new Amazon RDS database

Your source database was likely updated during the time that it took to copy and transfer the data to the MariaDB or MySQL database. Thus, you can use replication to bring the copied database up-to-date with the source database.

The permissions required to start replication on an Amazon RDS database are restricted and not available to your Amazon RDS master user. Because of this, make sure to use either the

Amazon RDS [mysql.rds\\_set\\_external\\_master](#) command or the [mysql.rds\\_set\\_external\\_master\\_gtid](#) command to configure replication, and the [mysql.rds\\_start\\_replication](#) command to start replication between your live database and your Amazon RDS database.

## To start replication

Earlier, you turned on binary logging and set a unique server ID for your source database. Now you can set up your Amazon RDS database as a replica with your live database as the source replication instance.

1. In the Amazon RDS Management Console, add the IP address of the server that hosts the source database to the VPC security group for the Amazon RDS database. For more information on modifying a VPC security group, see [Security groups for your VPC](#) in the *Amazon Virtual Private Cloud User Guide*.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS database, so that it can communicate with your source instance. To find the IP address of the Amazon RDS database, use the host command.

```
host rds_db_endpoint
```

The hostname is the DNS name from the Amazon RDS database endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

2. Using the client of your choice, connect to the source instance and create a user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

### MySQL 5.5, 5.6, and 5.7

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password' ;
```

### MySQL 8.0

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password' ;
```

**Note**

Specify credentials other than the prompts shown here as a security best practice.

3. For the source instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the `'repl_user'` user for your domain, issue the following command.

**MySQL 5.5, 5.6, and 5.7**

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'  
IDENTIFIED BY 'password';
```

**MySQL 8.0**

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

**Note**

Specify credentials other than the prompts shown here as a security best practice.

4. If you used SQL format to create your backup file and the external instance is not MariaDB 10.0.24 or higher, look at the contents of that file.

```
cat backup.sql
```

The file includes a `CHANGE MASTER TO` comment that contains the master log file name and position. This comment is included in the backup file when you use the `--master-data` option with `mysqldump`. Note the values for `MASTER_LOG_FILE` and `MASTER_LOG_POS`.

```
--  
-- Position to start replication or point-in-time recovery from  
--  
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;
```

If you used delimited text format to create your backup file and the external instance isn't MariaDB 10.0.24 or higher, you should already have binary log coordinates from step 1 of the procedure at "To create a backup copy of your existing database" in this topic.

If the external instance is MariaDB 10.0.24 or higher, you should already have the GTID from which to start replication from step 2 of the procedure at "To create a backup copy of your existing database" in this topic.

5. Make the Amazon RDS database the replica. If the external instance isn't MariaDB 10.0.24 or higher, connect to the Amazon RDS database as the master user and identify the source database as the source replication instance by using the [mysql.rds\\_set\\_external\\_master](#) command. Use the master log file name and master log position that you determined in the previous step if you have a SQL format backup file. Or use the name and position that you determined when creating the backup files if you used delimited-text format. The following is an example.

```
CALL mysql.rds_set_external_master ('myserver.mydomain.com', 3306,  
    'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

 **Note**

Specify credentials other than the prompts shown here as a security best practice.

If the external instance is MariaDB 10.0.24 or higher, connect to the Amazon RDS database as the master user and identify the source database as the source replication instance by using the [mysql.rds\\_set\\_external\\_master\\_gtid](#) command. Use the GTID that you determined in step 2 of the procedure at "To create a backup copy of your existing database" in this topic.. The following is an example.

```
CALL mysql.rds_set_external_master_gtid ('source_server_ip_address', 3306,  
    'ReplicationUser', 'password', 'GTID', 0);
```

The `source_server_ip_address` is the IP address of source replication instance. An EC2 private DNS address is currently not supported.

**Note**

Specify credentials other than the prompts shown here as a security best practice.

6. On the Amazon RDS database, issue the [mysql.rds\\_start\\_replication](#) command to start replication.

```
CALL mysql.rds_start_replication;
```

7. On the Amazon RDS database, run the [SHOW REPLICA STATUS](#) command to determine when the replica is up-to-date with the source replication instance. The results of the `SHOW REPLICA STATUS` command include the `Seconds_Behind_Master` field. When the `Seconds_Behind_Master` field returns 0, then the replica is up-to-date with the source replication instance.

**Note**

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

For a MariaDB 10.5, 10.6, or 10.11 DB instance, run the [mysql.rds\\_replica\\_status](#) procedure instead of the MySQL command.

8. After the Amazon RDS database is up-to-date, turn on automated backups so you can restore that database if needed. You can turn on or modify automated backups for your Amazon RDS database using the [Amazon RDS Management Console](#). For more information, see [Introduction to backups](#).

## Redirect your live application to your Amazon RDS instance

After the MariaDB or MySQL database is up-to-date with the source replication instance, you can now update your live application to use the Amazon RDS instance.

## To redirect your live application to your MariaDB or MySQL database and stop replication

1. To add the VPC security group for the Amazon RDS database, add the IP address of the server that hosts the application. For more information on modifying a VPC security group, see [Security groups for your VPC](#) in the *Amazon Virtual Private Cloud User Guide*.
2. Verify that the `Seconds_Behind_Master` field in the [SHOW REPLICA STATUS](#) command results is 0, which indicates that the replica is up-to-date with the source replication instance.

```
SHOW REPLICA STATUS;
```

### Note

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

For a MariaDB 10.5, 10.6, or 10.11 DB instance, run the [mysql.rds\\_replica\\_status](#) procedure instead of the MySQL command.

3. Close all connections to the source when their transactions complete.

4. Update your application to use the Amazon RDS database. This update typically involves changing the connection settings to identify the hostname and port of the Amazon RDS database, the user account and password to connect with, and the database to use.
5. Connect to the DB instance.

For a Multi-AZ DB cluster, connect to the writer DB instance.

6. Stop replication for the Amazon RDS instance using the [mysql.rds\\_stop\\_replication](#) command.

```
CALL mysql.rds_stop_replication;
```

7. Run the [mysql.rds\\_reset\\_external\\_master](#) command on your Amazon RDS database to reset the replication configuration so this instance is no longer identified as a replica.

```
CALL mysql.rds_reset_external_master;
```

8. Turn on additional Amazon RDS features such as Multi-AZ support and read replicas. For more information, see [Configuring and managing a Multi-AZ deployment](#) and [Working with DB instance read replicas](#).

## Importing data from any source to a MariaDB or MySQL DB instance

We recommend creating DB snapshots of the target Amazon RDS DB instance before and after the data load. Amazon RDS DB snapshots are complete backups of your DB instance that can be used to restore your DB instance to a known state. When you initiate a DB snapshot, I/O operations to your DB instance are momentarily suspended while your database is backed up.

Creating a DB snapshot immediately before the load makes it possible for you to restore the database to its state before the load, if you need to. A DB snapshot taken immediately after the load protects you from having to load the data again in case of a mishap and can also be used to seed new database instances.

The following list shows the steps to take. Each step is discussed in more detail following.

1. Create flat files containing the data to be loaded.
2. Stop any applications accessing the target DB instance.
3. Create a DB snapshot.
4. Consider turning off Amazon RDS automated backups.

5. Load the data.
6. Enable automated backups again.

## Step 1: Create flat files containing the data to be loaded

Use a common format, such as comma-separated values (CSV), to store the data to be loaded. Each table must have its own file; you can't combine data for multiple tables in the same file. Give each file the same name as the table it corresponds to. The file extension can be anything you like. For example, if the table name is `sales`, the file name might be `sales.csv` or `sales.txt`, but not `sales_01.csv`.

Whenever possible, order the data by the primary key of the table being loaded. Doing this drastically improves load times and minimizes disk storage requirements.

The speed and efficiency of this procedure depends on keeping the size of the files small. If the uncompressed size of any individual file is larger than 1 GiB, split it into multiple files and load each one separately.

On Unix-like systems (including Linux), use the `split` command. For example, the following command splits the `sales.csv` file into multiple files of less than 1 GiB, splitting only at line breaks (`-C 1024m`). The new files are named `sales.part_00`, `sales.part_01`, and so on.

```
split -C 1024m -d sales.csv sales.part_
```

Similar utilities are available for other operating systems.

## Step 2: Stop any applications accessing the target DB instance

Before starting a large load, stop all application activity accessing the target DB instance that you plan to load to. We recommend this particularly if other sessions will be modifying the tables being loaded or tables that they reference. Doing this reduces the risk of constraint violations occurring during the load and improves load performance. It also makes it possible to restore the DB instance to the point just before the load without losing changes made by processes not involved in the load.

Of course, this might not be possible or practical. If you can't stop applications from accessing the DB instance before the load, take steps to ensure the availability and integrity of your data. The specific steps required vary greatly depending upon specific use cases and site requirements.

### Step 3: Create a DB snapshot

If you plan to load data into a new DB instance that contains no data, you can skip this step. Otherwise, creating a DB snapshot of your DB instance makes it possible for you to restore the DB instance to the point just before the load, if it becomes necessary. As previously mentioned, when you initiate a DB snapshot, I/O operations to your DB instance are suspended for a few minutes while the database is backed up.

The example following uses the AWS CLI `create-db-snapshot` command to create a DB snapshot of the `AcmeRDS` instance and give the DB snapshot the identifier `preload`.

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \  
  --db-instance-identifier AcmeRDS \  
  --db-snapshot-identifier preload
```

For Windows:

```
aws rds create-db-snapshot ^  
  --db-instance-identifier AcmeRDS ^  
  --db-snapshot-identifier preload
```

You can also use the restore from DB snapshot functionality to create test DB instances for dry runs or to undo changes made during the load.

Keep in mind that restoring a database from a DB snapshot creates a new DB instance that, like all DB instances, has a unique identifier and endpoint. To restore the DB instance without changing the endpoint, first delete the DB instance so that you can reuse the endpoint.

For example, to create a DB instance for dry runs or other testing, you give the DB instance its own identifier. In the example, `AcmeRDS-2` is the identifier. The example connects to the DB instance using the endpoint associated with `AcmeRDS-2`.

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \  
  --db-instance-identifier AcmeRDS-2 \  
  --db-snapshot-identifier preload
```

### For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
  --db-instance-identifier AcmeRDS-2 ^
  --db-snapshot-identifier preload
```

To reuse the existing endpoint, first delete the DB instance and then give the restored database the same identifier.

### For Linux, macOS, or Unix:

```
aws rds delete-db-instance \  
  --db-instance-identifier AcmeRDS \  
  --final-db-snapshot-identifier AcmeRDS-Final  
  
aws rds restore-db-instance-from-db-snapshot \  
  --db-instance-identifier AcmeRDS \  
  --db-snapshot-identifier preload
```

### For Windows:

```
aws rds delete-db-instance ^
  --db-instance-identifier AcmeRDS ^
  --final-db-snapshot-identifier AcmeRDS-Final  
  
aws rds restore-db-instance-from-db-snapshot ^
  --db-instance-identifier AcmeRDS ^
  --db-snapshot-identifier preload
```

The preceding example takes a final DB snapshot of the DB instance before deleting it. This is optional but recommended.

## Step 4: Consider turning off Amazon RDS automated backups

### Warning

Do not turn off automated backups if you need to perform point-in-time recovery.

Turning off automated backups erases all existing backups, so point-in-time recovery isn't possible after automated backups have been turned off. Disabling automated backups is a performance

optimization and isn't required for data loads. Manual DB snapshots aren't affected by turning off automated backups. All existing manual DB snapshots are still available for restore.

Turning off automated backups reduces load time by about 25 percent and reduces the amount of storage space required during the load. If you plan to load data into a new DB instance that contains no data, turning off backups is an easy way to speed up the load and avoid using the additional storage needed for backups. However, in some cases you might plan to load into a DB instance that already contains data. If so, weigh the benefits of turning off backups against the impact of losing the ability to perform point-in-time-recovery.

DB instances have automated backups turned on by default (with a one day retention period). To turn off automated backups, set the backup retention period to zero. After the load, you can turn backups back on by setting the backup retention period to a nonzero value. To turn on or turn off backups, Amazon RDS shuts the DB instance down and restarts it to turn MariaDB or MySQL logging on or off.

Use the AWS CLI `modify-db-instance` command to set the backup retention to zero and apply the change immediately. Setting the retention period to zero requires a DB instance restart, so wait until the restart has completed before proceeding.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier AcmeRDS \  
  --apply-immediately \  
  --backup-retention-period 0
```

For Windows:

```
aws rds modify-db-instance ^  
  --db-instance-identifier AcmeRDS ^  
  --apply-immediately ^  
  --backup-retention-period 0
```

You can check the status of your DB instance with the AWS CLI `describe-db-instances` command. The following example displays the DB instance status of the `AcmeRDS` DB instance.

```
aws rds describe-db-instances --db-instance-identifier AcmeRDS --query "*[  
{DBInstanceStatus:DBInstanceStatus}]"
```

When the DB instance status is available, you're ready to proceed.

## Step 5: Load the data

Use the MySQL `LOAD DATA LOCAL INFILE` statement to read rows from your flat files into the database tables.

The following example shows you how to load data from a file named `sales.txt` into a table named `Sales` in the database.

```
mysql> LOAD DATA LOCAL INFILE 'sales.txt' INTO TABLE Sales FIELDS TERMINATED BY ' '
      ENCLOSED BY '' ESCAPED BY '\\';
Query OK, 1 row affected (0.01 sec)
Records: 1 Deleted: 0 Skipped: 0 Warnings: 0
```

For more information about the `LOAD DATA` statement, see [the MySQL documentation](#).

## Step 6: Turn Amazon RDS automated backups back on

After the load is finished, turn Amazon RDS automated backups on by setting the backup retention period back to its preload value. As noted earlier, Amazon RDS restarts the DB instance, so be prepared for a brief outage.

The following example uses the AWS CLI `modify-db-instance` command to turn on automated backups for the `AcmeRDS` DB instance and set the retention period to one day.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier AcmeRDS \
  --backup-retention-period 1 \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier AcmeRDS ^
  --backup-retention-period 1 ^
  --apply-immediately
```

# Working with MySQL replication in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see [Working with DB instance read replicas](#). For specific information about working with read replicas on Amazon RDS for MySQL, see [Working with MySQL read replicas](#).

You can use global transaction identifiers (GTIDs) for replication with RDS for MySQL. For more information, see [Using GTID-based replication](#).

You can also set up replication between an RDS for MySQL DB instance and a MariaDB or MySQL instance that is external to Amazon RDS. For information about configuring replication with an external source, see [Configuring binary log file position replication with an external source instance](#).

For any of these replication options, you can use either row-based replication, statement-based, or mixed replication. Row-based replication only replicates the changed rows that result from a SQL statement. Statement-based replication replicates the entire SQL statement. Mixed replication uses statement-based replication when possible, but switches to row-based replication when SQL statements that are unsafe for statement-based replication are run. In most cases, mixed replication is recommended. The binary log format of the DB instance determines whether replication is row-based, statement-based, or mixed. For information about setting the binary log format, see [Configuring RDS for MySQL binary logging](#).

## Note

You can configure replication to import databases from a MariaDB or MySQL instance that is external to Amazon RDS, or to export databases to such instances. For more information, see [Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime](#) and [Exporting data from a MySQL DB instance by using replication](#).

### Configuring read replicas with MySQL

Before a MySQL DB instance can serve as a replication source, make sure to enable automatic backups on the source DB instance. To do this, set the backup retention period to a value other than 0. This requirement also applies to a read replica that is the source DB instance for another read replica. Automatic backups are supported for read replicas running any version of MySQL. You can configure replication based on binary log coordinates for a MySQL DB instance.

On RDS for MySQL version 5.7.44 and higher MySQL 5.7 versions and RDS for MySQL 8.0.28 and higher 8.0 versions, you can configure replication using global transaction identifiers (GTIDs). For more information, see [Using GTID-based replication](#).

You can create up to 15 read replicas from one DB instance within the same Region. For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

RDS for MySQL supports cascading read replicas. To learn how to configure cascading read replicas, see [Using cascading read replicas with RDS for MySQL](#).

You can run multiple read replica create and delete actions at the same time that reference the same source DB instance. When you perform these actions, stay within the limit of 15 read replicas for each source instance.

A read replica of a MySQL DB instance can't use a lower DB engine version than its source DB instance.

### Preparing MySQL DB instances that use MyISAM

If your MySQL DB instance uses a nontransactional engine such as MyISAM, you need to perform the following steps to successfully set up your read replica. These steps are required to make sure that the read replica has a consistent copy of your data. These steps are not required if all of your tables use a transactional engine such as InnoDB.

1. Stop all data manipulation language (DML) and data definition language (DDL) operations on non-transactional tables in the source DB instance and wait for them to complete. SELECT statements can continue running.
2. Flush and lock the tables in the source DB instance.
3. Create the read replica using one of the methods in the following sections.
4. Check the progress of the read replica creation using, for example, the DescribeDBInstances API operation. Once the read replica is available, unlock the tables of the source DB instance and resume normal database operations.

### Configuring replication filters with MySQL

You can use replication filters to specify which databases and tables are replicated with a read replica. Replication filters can include databases and tables in replication or exclude them from replication.

The following are some use cases for replication filters:

- To reduce the size of a read replica. With replication filtering, you can exclude the databases and tables that aren't needed on the read replica.
- To exclude databases and tables from read replicas for security reasons.
- To replicate different databases and tables for specific use cases at different read replicas. For example, you might use specific read replicas for analytics or sharding.
- For a DB instance that has read replicas in different AWS Regions, to replicate different databases or tables in different AWS Regions.

**Note**

You can also use replication filters to specify which databases and tables are replicated with a primary MySQL DB instance that is configured as a replica in an inbound replication topology. For more information about this configuration, see [Configuring binary log file position replication with an external source instance](#).

**Topics**

- [Setting replication filtering parameters for RDS for MySQL](#)
- [Replication filtering limitations for RDS for MySQL](#)
- [Replication filtering examples for RDS for MySQL](#)
- [Viewing the replication filters for a read replica](#)

**Setting replication filtering parameters for RDS for MySQL**

To configure replication filters, set the following replication filtering parameters on the read replica:

- `replicate-do-db` – Replicate changes to the specified databases. When you set this parameter for a read replica, only the databases specified in the parameter are replicated.
- `replicate-ignore-db` – Don't replicate changes to the specified databases. When the `replicate-do-db` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-do-table` – Replicate changes to the specified tables. When you set this parameter for a read replica, only the tables specified in the parameter are replicated. Also, when the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- `replicate-ignore-table` – Don't replicate changes to the specified tables. When the `replicate-do-table` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-wild-do-table` – Replicate tables based on the specified database and table name patterns. The % and \_ wildcard characters are supported. When the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- `replicate-wild-ignore-table` – Don't replicate tables based on the specified database and table name patterns. The % and \_ wildcard characters are supported. When the `replicate-do-`

`table` or `replicate-wild-do-table` parameter is set for a read replica, this parameter isn't evaluated.

The parameters are evaluated in the order that they are listed. For more information about how these parameters work, see the MySQL documentation:

- For general information, see [Replica Server Options and Variables](#).
- For information about how database replication filtering parameters are evaluated, see [Evaluation of Database-Level Replication and Binary Logging Options](#).
- For information about how table replication filtering parameters are evaluated, see [Evaluation of Table-Level Replication Options](#).

By default, each of these parameters has an empty value. On each read replica, you can use these parameters to set, change, and delete replication filters. When you set one of these parameters, separate each filter from others with a comma.

You can use the `%` and `_` wildcard characters in the `replicate-wild-do-table` and `replicate-wild-ignore-table` parameters. The `%` wildcard matches any number of characters, and the `_` wildcard matches only one character.

The binary logging format of the source DB instance is important for replication because it determines the record of data changes. The setting of the `binlog_format` parameter determines whether the replication is row-based or statement-based. For more information, see [Configuring RDS for MySQL binary logging](#).

#### Note

All data definition language (DDL) statements are replicated as statements, regardless of the `binlog_format` setting on the source DB instance.

## Replication filtering limitations for RDS for MySQL

The following limitations apply to replication filtering for RDS for MySQL:

- Each replication filtering parameter has a 2,000-character limit.

- Commas aren't supported in replication filters for parameter values. In a list of parameters, commas can only be used as value separators. For example, `ParameterValue='`a,b`'` isn't supported, but `ParameterValue='a,b'` is.
- The MySQL `--binlog-do-db` and `--binlog-ignore-db` options for binary log filtering aren't supported.
- Replication filtering doesn't support XA transactions.

For more information, see [Restrictions on XA Transactions](#) in the MySQL documentation.

## Replication filtering examples for RDS for MySQL

To configure replication filtering for a read replica, modify the replication filtering parameters in the parameter group associated with the read replica.

### Note

You can't modify a default parameter group. If the read replica is using a default parameter group, create a new parameter group and associate it with the read replica. For more information on DB parameter groups, see [Parameter groups for Amazon RDS](#).

You can set parameters in a parameter group using the AWS Management Console, AWS CLI, or RDS API. For information about setting parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#). When you set parameters in a parameter group, all of the DB instances associated with the parameter group use the parameter settings. If you set the replication filtering parameters in a parameter group, make sure that the parameter group is associated only with read replicas. Leave the replication filtering parameters empty for source DB instances.

The following examples set the parameters using the AWS CLI. These examples set `ApplyMethod` to `immediate` so that the parameter changes occur immediately after the CLI command completes. If you want a pending change to be applied after the read replica is rebooted, set `ApplyMethod` to `pending-reboot`.

The following examples set replication filters:

- [Including databases in replication](#)
- [Including tables in replication](#)
- [Including tables in replication with wildcard characters](#)

- [Excluding databases from replication](#)
- [Excluding tables from replication](#)
- [Excluding tables from replication using wildcard characters](#)

## Example Including databases in replication

The following example includes the mydb1 and mydb2 databases in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name myparametergroup \  
  --parameters "ParameterName=replicate-do-  
db,ParameterValue='mydb1,mydb2',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^  
  --db-parameter-group-name myparametergroup ^  
  --parameters "ParameterName=replicate-do-  
db,ParameterValue='mydb1,mydb2',ApplyMethod=immediate"
```

## Example Including tables in replication

The following example includes the table1 and table2 tables in database mydb1 in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name myparametergroup \  
  --parameters "ParameterName=replicate-do-  
table,ParameterValue='mydb1.table1,mydb1.table2',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^  
  --db-parameter-group-name myparametergroup ^
```

```
--parameters "ParameterName=replicate-do-  
table,ParameterValue='mydb1.table1,mydb1.table2',ApplyMethod=immediate"
```

## Example Including tables in replication using wildcard characters

The following example includes tables with names that begin with `order` and `return` in database `mydb` in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name myparametergroup \  
  --parameters "ParameterName=replicate-wild-do-table,ParameterValue='mydb.order  
%,mydb.return%',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^  
  --db-parameter-group-name myparametergroup ^  
  --parameters "ParameterName=replicate-wild-do-table,ParameterValue='mydb.order  
%,mydb.return%',ApplyMethod=immediate"
```

## Example Excluding databases from replication

The following example excludes the `mydb5` and `mydb6` databases from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name myparametergroup \  
  --parameters "ParameterName=replicate-ignore-  
db,ParameterValue='mydb5,mydb6',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^  
  --db-parameter-group-name myparametergroup ^
```

```
--parameters "ParameterName=replicate-ignore-  
db,ParameterValue='mydb5,mydb6',ApplyMethod=immediate"
```

## Example Excluding tables from replication

The following example excludes tables `table1` in database `mydb5` and `table2` in database `mydb6` from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name myparametergroup \  
  --parameters "ParameterName=replicate-ignore-  
table,ParameterValue='mydb5.table1,mydb6.table2',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^  
  --db-parameter-group-name myparametergroup ^  
  --parameters "ParameterName=replicate-ignore-  
table,ParameterValue='mydb5.table1,mydb6.table2',ApplyMethod=immediate"
```

## Example Excluding tables from replication using wildcard characters

The following example excludes tables with names that begin with `order` and `return` in database `mydb7` from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name myparametergroup \  
  --parameters "ParameterName=replicate-wild-ignore-table,ParameterValue='mydb7.order  
%,mydb7.return%',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^  
  --db-parameter-group-name myparametergroup ^  
  --parameters "ParameterName=replicate-wild-ignore-table,ParameterValue='mydb7.order  
%,mydb7.return%',ApplyMethod=immediate"
```

## Viewing the replication filters for a read replica

You can view the replication filters for a read replica in the following ways:

- Check the settings of the replication filtering parameters in the parameter group associated with the read replica.

For instructions, see [Viewing parameter values for a DB parameter group in Amazon RDS](#).

- In a MySQL client, connect to the read replica and run the `SHOW REPLICA STATUS` statement.

In the output, the following fields show the replication filters for the read replica:

- `Replicate_Do_DB`
- `Replicate_Ignore_DB`
- `Replicate_Do_Table`
- `Replicate_Ignore_Table`
- `Replicate_Wild_Do_Table`
- `Replicate_Wild_Ignore_Table`

For more information about these fields, see [Checking Replication Status](#) in the MySQL documentation.

### Note

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

## Configuring delayed replication with MySQL

You can use delayed replication as a strategy for disaster recovery. With delayed replication, you specify the minimum amount of time, in seconds, to delay replication from the source to the read replica. In the event of a disaster, such as a table deleted unintentionally, you complete the following steps to recover from the disaster quickly:

- Stop replication to the read replica before the change that caused the disaster is sent to it.

Use the [mysql.rds\\_stop\\_replication](#) stored procedure to stop replication.

- Start replication and specify that replication stops automatically at a log file location.

You specify a location just before the disaster using the [mysql.rds\\_start\\_replication\\_until](#) stored procedure.

- Promote the read replica to be the new source DB instance by using the instructions in [Promoting a read replica to be a standalone DB instance](#).

### Note

- On RDS for MySQL 8.0, delayed replication is supported for MySQL 8.0.28 and higher. On RDS for MySQL 5.7, delayed replication is supported for MySQL 5.7.44 and higher.
- Use stored procedures to configure delayed replication. You can't configure delayed replication with the AWS Management Console, the AWS CLI, or the Amazon RDS API.
- On RDS for MySQL 5.7.44 and higher MySQL 5.7 versions and RDS for MySQL 8.0.28 and higher 8.0 versions, you can use replication based on global transaction identifiers (GTIDs) in a delayed replication configuration. If you use GTID-based replication, use the [mysql.rds\\_start\\_replication\\_until\\_gtid](#) stored procedure instead of the [mysql.rds\\_start\\_replication\\_until](#) stored procedure. For more information about GTID-based replication, see [Using GTID-based replication](#).

## Topics

- [Configuring delayed replication during read replica creation](#)
- [Modifying delayed replication for an existing read replica](#)
- [Setting a location to stop replication to a read replica](#)
- [Promoting a read replica](#)

## Configuring delayed replication during read replica creation

To configure delayed replication for any future read replica created from a DB instance, run the [mysql.rds\\_set\\_configuration](#) stored procedure with the `target_delay` parameter.

## To configure delayed replication during read replica creation

1. Using a MySQL client, connect to the MySQL DB instance to be the source for read replicas as the master user.

2. Run the [mysql.rds\\_set\\_configuration](#) stored procedure with the target delay parameter.

For example, run the following stored procedure to specify that replication is delayed by at least one hour (3,600 seconds) for any read replica created from the current DB instance.

```
call mysql.rds_set_configuration('target delay', 3600);
```

### Note

After running this stored procedure, any read replica you create using the AWS CLI or Amazon RDS API is configured with replication delayed by the specified number of seconds.

## Modifying delayed replication for an existing read replica

To modify delayed replication for an existing read replica, run the [mysql.rds\\_set\\_source\\_delay](#) stored procedure.

### To modify delayed replication for an existing read replica

1. Using a MySQL client, connect to the read replica as the master user.
2. Use the [mysql.rds\\_stop\\_replication](#) stored procedure to stop replication.
3. Run the [mysql.rds\\_set\\_source\\_delay](#) stored procedure.

For example, run the following stored procedure to specify that replication to the read replica is delayed by at least one hour (3600 seconds).

```
call mysql.rds_set_source_delay(3600);
```

4. Use the [mysql.rds\\_start\\_replication](#) stored procedure to start replication.

## Setting a location to stop replication to a read replica

After stopping replication to the read replica, you can start replication and then stop it at a specified binary log file location using the [mysql.rds\\_start\\_replication\\_until](#) stored procedure.

## To start replication to a read replica and stop replication at a specific location

1. Using a MySQL client, connect to the source MySQL DB instance as the master user.
2. Run the [mysql.rds\\_start\\_replication\\_until](#) stored procedure.

The following example initiates replication and replicates changes until it reaches location 120 in the `mysql-bin-changelog.000777` binary log file. In a disaster recovery scenario, assume that location 120 is just before the disaster.

```
call mysql.rds_start_replication_until(  
    'mysql-bin-changelog.000777',  
    120);
```

Replication stops automatically when the stop point is reached. The following RDS event is generated: Replication has been stopped since the replica reached the stop point specified by the `rds_start_replication_until` stored procedure.

### Promoting a read replica

After replication is stopped, in a disaster recovery scenario, you can promote a read replica to be the new source DB instance. For information about promoting a read replica, see [Promoting a read replica to be a standalone DB instance](#).

### Updating read replicas with MySQL

Read replicas are designed to support read queries, but you might need occasional updates. For example, you might need to add an index to optimize the specific types of queries accessing the replica.

Although you can enable updates by setting the `read_only` parameter to 0 in the DB parameter group for the read replica, we recommend that you don't do so because it can cause problems if the read replica becomes incompatible with the source DB instance. For maintenance operations, we recommend that you use blue/green deployments. For more information, see [Using Blue/Green Deployments for database updates](#).

If you disable read-only on a read replica, change the value of the `read_only` parameter back to 1 as soon as possible.

## Working with Multi-AZ read replica deployments with MySQL

You can create a read replica from either single-AZ or Multi-AZ DB instance deployments. You use Multi-AZ deployments to improve the durability and availability of critical data, but you can't use the Multi-AZ secondary to serve read-only queries. Instead, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. If the source instance of a Multi-AZ deployment fails over to the secondary, any associated read replicas automatically switch to use the secondary (now primary) as their replication source. For more information, see [Configuring and managing a Multi-AZ deployment](#).

You can create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

## Using cascading read replicas with RDS for MySQL

RDS for MySQL supports cascading read replicas. With *cascading read replicas*, you can scale reads without adding overhead to your source RDS for MySQL DB instance.

With cascading read replicas, your RDS for MySQL DB instance sends data to the first read replica in the chain. That read replica then sends data to the second replica in the chain, and so on. The end result is that all read replicas in the chain have the changes from the RDS for MySQL DB instance, but without the overhead solely on the source DB instance.

You can create a series of up to three read replicas in a chain from a source RDS for MySQL DB instance. For example, suppose that you have an RDS for MySQL DB instance, `mysql-main`. You can do the following:

- Starting with `mysql-main`, create the first read replica in the chain, `read-replica-1`.
- Next, from `read-replica-1`, create the next read replica in the chain, `read-replica-2`.
- Finally, from `read-replica-2`, create the third read replica in the chain, `read-replica-3`.

You can't create another read replica beyond this third cascading read replica in the series for `mysql-main`. A complete series of instances from an RDS for MySQL source DB instance through to the end of a series of cascading read replicas can consist of at most four DB instances.

For cascading read replicas to work, each source RDS for MySQL DB instance must have automated backups turned on. To turn on automatic backups on a read replica, first create the read replica,

and then modify the read replica to turn on automatic backups. For more information, see [Creating a read replica](#).

As with any read replica, you can promote a read replica that's part of a cascade. Promoting a read replica from within a chain of read replicas removes that replica from the chain. For example, suppose that you want to move some of the workload from your `mysql-main` DB instance to a new instance for use by the accounting department only. Assuming the chain of three read replicas from the example, you decide to promote `read-replica-2`. The chain is affected as follows:

- Promoting `read-replica-2` removes it from the replication chain.
  - It is now a full read/write DB instance.
  - It continues replicating to `read-replica-3`, just as it was doing before promotion.
- Your `mysql-main` continues replicating to `read-replica-1`.

For more information about promoting read replicas, see [Promoting a read replica to be a standalone DB instance](#).

## Monitoring MySQL read replicas

For MySQL read replicas, you can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric. The `ReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the `SHOW REPLICA STATUS` command.

### Note

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

Common causes for replication lag for MySQL are the following:

- A network outage.
- Writing to tables that have different indexes on a read replica. If the `read_only` parameter is set to `0` on the read replica, replication can break if the read replica becomes incompatible with the source DB instance. After you've performed maintenance tasks on the read replica, we recommend that you set the `read_only` parameter back to `1`.

- Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB storage engine on MySQL.

When the `ReplicaLag` metric reaches 0, the replica has caught up to the source DB instance. If the `ReplicaLag` metric returns -1, then replication is currently not active. `ReplicaLag = -1` is equivalent to `Seconds_Behind_Master = NULL`.

## Starting and stopping replication with MySQL read replicas

You can stop and restart the replication process on an Amazon RDS DB instance by calling the system stored procedures [mysql.rds\\_stop\\_replication](#) and [mysql.rds\\_start\\_replication](#). You can do this when replicating between two Amazon RDS instances for long-running operations such as creating large indexes. You also need to stop and start replication when importing or exporting databases. For more information, see [Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime](#) and [Exporting data from a MySQL DB instance by using replication](#).

If replication is stopped for more than 30 consecutive days, either manually or due to a replication error, Amazon RDS terminates replication between the source DB instance and all read replicas. It does so to prevent increased storage requirements on the source DB instance and long failover times. The read replica DB instance is still available. However, replication can't be resumed because the binary logs required by the read replica are deleted from the source DB instance after replication is terminated. You can create a new read replica for the source DB instance to reestablish replication.

## Troubleshooting a MySQL read replica problem

For MySQL DB instances, in some cases read replicas present replication errors or data inconsistencies (or both) between the read replica and its source DB instance. This problem occurs when some binary log (binlog) events or InnoDB redo logs aren't flushed during a failure of the read replica or the source DB instance. In these cases, manually delete and recreate the read replicas. You can reduce the chance of this happening by setting the following parameter values: `sync_binlog=1` and `innodb_flush_log_at_trx_commit=1`. These settings might reduce performance, so test their impact before implementing the changes in a production environment.

### Warning

In the parameter group associated with the source DB instance, we recommend keeping these parameter values: `sync_binlog=1` and `innodb_flush_log_at_trx_commit=1`.

These parameters are dynamic. If you don't want to use these settings, we recommend temporarily setting those values before executing any operation on the source DB instance that might cause it to restart. These operations include, but are not limited to, rebooting, rebooting with failover, upgrading the database version, and changing the DB instance class or its storage. The same recommendation applies to creating new read replicas for the source DB instance.

Failure to follow this guidance increases the risk of read replicas presenting replication errors or data inconsistencies (or both) between the read replica and its source DB instance.

The replication technologies for MySQL are asynchronous. Because they are asynchronous, occasional `BinLogDiskUsage` increases on the source DB instance and `ReplicaLag` on the read replica are to be expected. For example, a high volume of write operations to the source DB instance can occur in parallel. In contrast, write operations to the read replica are serialized using a single I/O thread, which can lead to a lag between the source instance and read replica. For more information about read-only replicas in the MySQL documentation, see [Replication implementation details](#).

You can do several things to reduce the lag between updates to a source DB instance and the subsequent updates to the read replica, such as the following:

- Sizing a read replica to have a storage size and DB instance class comparable to the source DB instance.
- Ensuring that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter later in this section.

Amazon RDS monitors the replication status of your read replicas and updates the `Replication State` field of the read replica instance to `Error` if replication stops for any reason. An example might be if DML queries run on your read replica conflict with the updates made on the source DB instance.

You can review the details of the associated error thrown by the MySQL engine by viewing the `Replication Error` field. Events that indicate the status of the read replica are also generated, including [RDS-EVENT-0045](#), [RDS-EVENT-0046](#), and [RDS-EVENT-0047](#). For more information about events and subscribing to events, see [Working with Amazon RDS event notification](#). If a MySQL error message is returned, review the error number in the [MySQL error message documentation](#).

One common issue that can cause replication errors is when the value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance. The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group. You use `max_allowed_packet` to specify the maximum size of DML code that can be run on the database. In some cases, the `max_allowed_packet` value in the DB parameter group associated with a read replica is smaller than the `max_allowed_packet` value in the DB parameter group associated with the source DB instance. In these cases, the replication process can throw the error `Packet bigger than 'max_allowed_packet' bytes` and stop replication. To fix the error, have the source DB instance and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.

Other common situations that can cause replication errors include the following:

- Writing to tables on a read replica. In some cases, you might create indexes on a read replica that are different from the indexes on the source DB instance. If you do, set the `read_only` parameter to `0` to create the indexes. If you write to tables on the read replica, it might break replication if the read replica becomes incompatible with the source DB instance. After you perform maintenance tasks on the read replica, we recommend that you set the `read_only` parameter back to `1`.
- Using a non-transactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the InnoDB storage engine on MySQL.
- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see [Determination of safe and unsafe statements in binary logging](#).

If you decide that you can safely skip an error, you can follow the steps described in the section [Skipping the current replication error](#). Otherwise, you can first delete the read replica. Then you create an instance using the same DB instance identifier so that the endpoint remains the same as that of your old read replica. If a replication error is fixed, the `Replication State` changes to *replicating*.

## Using GTID-based replication

The following content explains how to use global transaction identifiers (GTIDs) with binary log (binlog) replication among Amazon RDS for MySQL DB instances.

If you use binlog replication and aren't familiar with GTID-based replication with MySQL, see [Replication with global transaction identifiers](#) in the MySQL documentation.

GTID-based replication is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL version 8.0.26 and higher MySQL 8.0 versions. All MySQL DB instances in a replication configuration must meet this requirement.

## Topics

- [Overview of global transaction identifiers \(GTIDs\)](#)
- [Parameters for GTID-based replication](#)
- [Configuring GTID-based replication for new read replicas](#)
- [Configuring GTID-based replication for existing read replicas](#)
- [Disabling GTID-based replication for a MySQL DB instance with read replicas](#)

## Overview of global transaction identifiers (GTIDs)

*Global transaction identifiers (GTIDs)* are unique identifiers generated for committed MySQL transactions. You can use GTIDs to make binlog replication simpler and easier to troubleshoot.

MySQL uses two different types of transactions for binlog replication:

- *GTID transactions* – Transactions that are identified by a GTID.
- *Anonymous transactions* – Transactions that don't have a GTID assigned.

In a replication configuration, GTIDs are unique across all DB instances. GTIDs simplify replication configuration because when you use them, you don't have to refer to log file positions. GTIDs also make it easier to track replicated transactions and determine whether the source instance and replicas are consistent.

You can use GTID-based replication to replicate data with RDS for MySQL read replicas. You can configure GTID-based replication when you are creating new read replicas, or you can convert existing read replicas to use GTID-based replication.

You can also use GTID-based replication in a delayed replication configuration with RDS for MySQL. For more information, see [Configuring delayed replication with MySQL](#).

## Parameters for GTID-based replication

Use the following parameters to configure GTID-based replication.

Parameter	Valid values	Description
<code>gtid_mode</code>	<code>OFF</code> , <code>OFF_PERMISSIVE</code> , <code>ON_PERMISSIVE</code> , <code>ON</code>	<p><code>OFF</code> specifies that new transactions are anonymous transactions (that is, don't have GTIDs), and a transaction must be anonymous to be replicated.</p> <p><code>OFF_PERMISSIVE</code> specifies that new transactions are anonymous transactions, but all transactions can be replicated.</p> <p><code>ON_PERMISSIVE</code> specifies that new transactions are GTID transactions, but all transactions can be replicated.</p> <p><code>ON</code> specifies that new transactions are GTID transactions, and a transaction must be a GTID transaction to be replicated.</p>
<code>enforce_gtid_consistency</code>	<code>OFF</code> , <code>ON</code> , <code>WARN</code>	<p><code>OFF</code> allows transactions to violate GTID consistency.</p> <p><code>ON</code> prevents transactions from violating GTID consistency.</p> <p><code>WARN</code> allows transactions to violate GTID consistency but generates a warning when a violation occurs.</p>

### Note

In the AWS Management Console, the `gtid_mode` parameter appears as `gtid-mode`.

For GTID-based replication, use these settings for the parameter group for your DB instance or read replica:

- `ON` and `ON_PERMISSIVE` apply only to outgoing replication from an RDS DB instance. Both of these values cause your RDS DB instance to use GTIDs for transactions that are replicated. `ON` requires that the target database also use GTID-based replication. `ON_PERMISSIVE` makes GTID-based replication optional on the target database.
- `OFF_PERMISSIVE`, if set, means that your RDS DB instances can accept incoming replication from a source database. They can do this regardless of whether the source database uses GTID-based replication.
- `OFF`, if set, means that your RDS DB instance only accepts incoming replication from source databases that don't use GTID-based replication.

For more information about parameter groups, see [Parameter groups for Amazon RDS](#).

## Configuring GTID-based replication for new read replicas

When GTID-based replication is enabled for an RDS for MySQL DB instance, GTID-based replication is configured automatically for read replicas of the DB instance.

### To enable GTID-based replication for new read replicas

1. Make sure that the parameter group associated with the DB instance has the following parameter settings:
  - `gtid_mode` – `ON` or `ON_PERMISSIVE`
  - `enforce_gtid_consistency` – `ON`

For more information about setting configuration parameters using parameter groups, see [Parameter groups for Amazon RDS](#).

2. If you changed the parameter group of the DB instance, reboot the DB instance. For more information on how to do so, see [Rebooting a DB instance](#).
3. Create one or more read replicas of the DB instance. For more information on how to do so, see [Creating a read replica](#).

Amazon RDS attempts to establish GTID-based replication between the MySQL DB instance and the read replicas using the `MASTER_AUTO_POSITION`. If the attempt fails, Amazon RDS uses log file positions for replication with the read replicas. For more information about the `MASTER_AUTO_POSITION`, see [GTID auto-positioning](#) in the MySQL documentation.

## Configuring GTID-based replication for existing read replicas

For an existing MySQL DB instance with read replicas that doesn't use GTID-based replication, you can configure GTID-based replication between the DB instance and the read replicas.

### To enable GTID-based replication for existing read replicas

1. If the DB instance or any read replica is using an 8.0 version of RDS for MySQL version lower than 8.0.26, upgrade the DB instance or read replica to 8.0.26 or a higher MySQL 8.0 version. All RDS for MySQL 5.7 versions support GTID-based replication.

For more information, see [Upgrading the MySQL DB engine](#).

2. (Optional) Reset the GTID parameters and test the behavior of the DB instance and read replicas:
  - a. Make sure that the parameter group associated with the DB instance and each read replica has the `enforce_gtid_consistency` parameter set to `WARN`.

For more information about setting configuration parameters using parameter groups, see [Parameter groups for Amazon RDS](#).

- b. If you changed the parameter group of the DB instance, reboot the DB instance. If you changed the parameter group for a read replica, reboot the read replica.

For more information, see [Rebooting a DB instance](#).

- c. Run your DB instance and read replicas with your normal workload and monitor the log files.

If you see warnings about GTID-incompatible transactions, adjust your application so that it only uses GTID-compatible features. Make sure that the DB instance is not generating any warnings about GTID-incompatible transactions before proceeding to the next step.

3. Reset the GTID parameters for GTID-based replication that allows anonymous transactions until the read replicas have processed all of them.

- a. Make sure that the parameter group associated with the DB instance and each read replica has the following parameter settings:
    - `gtid_mode` – `ON_PERMISSIVE`
    - `enforce_gtid_consistency` – `ON`
  - b. If you changed the parameter group of the DB instance, reboot the DB instance. If you changed the parameter group for a read replica, reboot the read replica.
4. Wait for all of your anonymous transactions to be replicated. To check that these are replicated, do the following:

- a. Run the following statement on your source DB instance.

```
SHOW MASTER STATUS;
```

Note the values in the `File` and `Position` columns.

- b. On each read replica, use the file and position information from its source instance in the previous step to run the following query.

```
SELECT MASTER_POS_WAIT('file', position);
```

For example, if the file name is `mysql-bin-changelog.000031` and the position is `107`, run the following statement.

```
SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);
```

If the read replica is past the specified position, the query returns immediately. Otherwise, the function waits. Proceed to the next step when the query returns for all read replicas.

5. Reset the GTID parameters for GTID-based replication only.
  - a. Make sure that the parameter group associated with the DB instance and each read replica has the following parameter settings:
    - `gtid_mode` – `ON`
    - `enforce_gtid_consistency` – `ON`
  - b. Reboot the DB instance and each read replica.
6. On each read replica, run the following procedure.

```
CALL mysql.rds_set_master_auto_position(1);
```

## Disabling GTID-based replication for a MySQL DB instance with read replicas

You can disable GTID-based replication for a MySQL DB instance with read replicas.

### To disable GTID-based replication for a MySQL DB instance with read replicas

1. On each read replica, run the following procedure:

```
CALL mysql.rds_set_master_auto_position(0);
```

2. Reset the `gtid_mode` to `ON_PERMISSIVE`.
  - a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has `gtid_mode` set to `ON_PERMISSIVE`.

For more information about setting configuration parameters using parameter groups, see [Parameter groups for Amazon RDS](#).

- b. Reboot the MySQL DB instance and each read replica. For more information about rebooting, see [Rebooting a DB instance](#).
3. Reset the `gtid_mode` to `OFF_PERMISSIVE`.
    - a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has `gtid_mode` set to `OFF_PERMISSIVE`.
    - b. Reboot the MySQL DB instance and each read replica.
  4. Wait for all of the GTID transactions to be applied on all of the read replicas. To check that these are applied, do the following steps:
    - a. On the MySQL DB instance, run the `SHOW MASTER STATUS` command.

Your output should be similar to the following output.

File	Position
mysql-bin-changelog.000031	107

-----

Note the file and position in your output.

- b. On each read replica, use the file and position information from its source instance in the previous step to run the following query:

For MySQL 8.0.26 and higher MySQL 8.0 versions

```
SELECT SOURCE_POS_WAIT('file', position);
```

For MySQL 5.7 versions

```
SELECT MASTER_POS_WAIT('file', position);
```

For example, if the file name is `mysql-bin-changelog.000031` and the position is `107`, run the following statement:

For MySQL 8.0.26 and higher MySQL 8.0 versions

```
SELECT SOURCE_POS_WAIT('mysql-bin-changelog.000031', 107);
```

For MySQL 5.7 versions

```
SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);
```

5. Reset the GTID parameters to disable GTID-based replication.
  - a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has the following parameter settings:
    - `gtid_mode` – OFF
    - `enforce_gtid_consistency` – OFF
  - b. Reboot the MySQL DB instance and each read replica.

# Configuring binary log file position replication with an external source instance

You can set up replication between an RDS for MySQL or MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS using binary log file replication.

## Topics

- [Before you begin](#)
- [Configuring binary log file position replication with an external source instance](#)

## Before you begin

You can configure replication using the binary log file position of replicated transactions.

The permissions required to start replication on an Amazon RDS DB instance are restricted and not available to your Amazon RDS master user. Because of this, make sure that you use the Amazon RDS [mysql.rds\\_set\\_external\\_master](#) and [mysql.rds\\_start\\_replication](#) commands to set up replication between your live database and your Amazon RDS database.

To set the binary logging format for a MySQL or MariaDB database, update the `binlog_format` parameter. If your DB instance uses the default DB instance parameter group, create a new DB parameter group to modify `binlog_format` settings. We recommend that you use the default setting for `binlog_format`, which is `MIXED`. However, you can also set `binlog_format` to `ROW` or `STATEMENT` if you need a specific binary log (binlog) format. Reboot your DB instance for the change to take effect.

For information about setting the `binlog_format` parameter, see [Configuring RDS for MySQL binary logging](#). For information about the implications of different MySQL replication types, see [Advantages and disadvantages of statement-based and row-based replication](#) in the MySQL documentation.

### Note

Starting with RDS for MySQL version 8.0.36, Amazon RDS doesn't replicate the `mysql` database. Therefore, if there are users on the external database that you need on the Amazon RDS replica, make sure to create them manually.

## Configuring binary log file position replication with an external source instance

Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:

- Monitor failover events for the Amazon RDS DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see [Working with Amazon RDS event notification](#).
- Maintain the binlogs on your source instance until you have verified that they have been applied to the replica. This maintenance makes sure that you can restore your source instance in the event of a failure.
- Turn on automated backups on your Amazon RDS DB instance. Turning on automated backups makes sure that you can restore your replica to a particular point in time if you need to re-synchronize your source instance and replica. For information on backups and point-in-time restore, see [Backing up, restoring, and exporting data](#).

### To configure binary log file replication with an external source instance

1. Make the source MySQL or MariaDB instance read-only.

```
mysql> FLUSH TABLES WITH READ LOCK;  
mysql> SET GLOBAL read_only = ON;
```

2. Run the `SHOW MASTER STATUS` command on the source MySQL or MariaDB instance to determine the binlog location.

You receive output similar to the following example.

```
File                Position  
-----  
mysql-bin-changelog.000031    107  
-----
```

3. Copy the database from the external instance to the Amazon RDS DB instance using `mysqldump`. For very large databases, you might want to use the procedure in [Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime](#).

For Linux, macOS, or Unix:

```
mysqldump --databases database_name \  
  --single-transaction \  
  --compress \  
  --order-by-primary \  
  -u local_user \  
  -plocal_password | mysql \  
  --host=hostname \  
  --port=3306 \  
  -u RDS_user_name \  
  -pRDS_password
```

For Windows:

```
mysqldump --databases database_name ^  
  --single-transaction ^  
  --compress ^  
  --order-by-primary ^  
  -u local_user ^  
  -plocal_password | mysql ^  
  --host=hostname ^  
  --port=3306 ^  
  -u RDS_user_name ^  
  -pRDS_password
```

 **Note**

Make sure that there isn't a space between the -p option and the entered password.

To specify the host name, user name, port, and password to connect to your Amazon RDS DB instance, use the --host, --user (-u), --port and -p options in the mysql command. The host name is the Domain Name Service (DNS) name from the Amazon RDS DB instance endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the AWS Management Console.

4. Make the source MySQL or MariaDB instance writeable again.

```
mysql> SET GLOBAL read_only = OFF;  
mysql> UNLOCK TABLES;
```

For more information on making backups for use with replication, see [the MySQL documentation](#).

5. In the AWS Management Console, add the IP address of the server that hosts the external database to the virtual private cloud (VPC) security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see [Security groups for your VPC](#) in the *Amazon Virtual Private Cloud User Guide*.

The IP address can change when the following conditions are met:

- You are using a public IP address for communication between the external source instance and the DB instance.
- The external source instance was stopped and restarted.

If these conditions are met, verify the IP address before adding it.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance. You do this so that your local network can communicate with your external MySQL or MariaDB instance. To find the IP address of the Amazon RDS DB instance, use the `host` command.

```
host db_instance_endpoint
```

The host name is the DNS name from the Amazon RDS DB instance endpoint.

6. Using the client of your choice, connect to the external instance and create a user to use for replication. Use this account solely for replication and restrict it to your domain to improve security. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

 **Note**

Specify a password other than the prompt shown here as a security best practice.

7. For the external instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. For example, to grant the `REPLICATION CLIENT` and `REPLICATION`

SLAVE privileges on all databases for the 'repl\_user' user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

8. Make the Amazon RDS DB instance the replica. To do so, first connect to the Amazon RDS DB instance as the master user. Then identify the external MySQL or MariaDB database as the source instance by using the [mysql.rds\\_set\\_external\\_master](#) command. Use the master log file name and master log position that you determined in step 2. The following is an example.

```
CALL mysql.rds_set_external_master ('mymasterserver.mydomain.com', 3306,  
'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

### Note

On RDS for MySQL, you can choose to use delayed replication by running the [mysql.rds\\_set\\_external\\_master\\_with\\_delay](#) stored procedure instead. On RDS for MySQL, one reason to use delayed replication is to turn on disaster recovery with the [mysql.rds\\_start\\_replication\\_until](#) stored procedure. Currently, RDS for MariaDB supports delayed replication but doesn't support the `mysql.rds_start_replication_until` procedure.

9. On the Amazon RDS DB instance, issue the [mysql.rds\\_start\\_replication](#) command to start replication.

```
CALL mysql.rds_start_replication;
```

## Configuring multi-source-replication for RDS for MySQL

With multi-source replication, you can set up an Amazon RDS for MySQL DB instance as a replica that receives binary log events from more than one RDS for MySQL source DB instance. Multi-source replication is supported for RDS for MySQL DB instances running the following engine versions:

- 8.0.35 and higher minor versions
- 5.7.44 and higher minor versions

For information about MySQL multi-source replication, see [MySQL Multi-Source Replication](#) in the MySQL documentation. The MySQL documentation contains detailed information about this feature, while this topic describes how to configure and manage the multi-source replication channels on your RDS for MySQL DB instances.

## Topics

- [Use cases for multi-source replication](#)
- [Considerations and best practices for multi-source replication](#)
- [Prerequisites for multi-source replication](#)
- [Configuring multi-source replication channels on RDS for MySQL DB instances](#)
- [Using filters with multi-source replication](#)
- [Monitoring multi-source replication channels](#)
- [Limitations for multi-source replication on RDS for MySQL](#)

## Use cases for multi-source replication

The following cases are good candidates for using multi-source replication on RDS for MySQL:

- Applications that need to merge or combine multiple shards on separate DB instances into a single shard.
- Applications that need to generate reports from data consolidated from multiple sources.
- Requirements to create consolidated long-term backups of data that's distributed among multiple RDS for MySQL DB instances.

## Considerations and best practices for multi-source replication

Before you use multi-source replication on RDS for MySQL, review the following considerations and best practices:

- Make sure that a DB instance configured as a multi-source replica has sufficient resources such as throughput, memory, CPU, and IOPS to handle the workload from multiple source instances.
- Regularly monitor resource utilization on your multi-source replica and adjust the storage or instance configuration to handle the workload without straining resources.
- You can configure multi-threaded replication on a multi-source replica by setting the system variable `replica_parallel_workers` to a value greater than 0. In this case, the number of

threads allocated to each channel is the value of this variable, plus one coordinator thread to manage the applier threads.

- Configure replication filters appropriately to avoid conflicts. To replicate an entire database to another database on a replica, you can use the `--replicate-rewrite-db` option. For example, you can replicate all tables in database A to database B on a replica instance. This approach can be helpful when all source instances are using the same schema naming convention. For information about the `--replicate-rewrite-db` option, see [Replica Server Options and Variables](#) in the MySQL documentation.
- To avoid replication errors, avoid writing to the replica. We recommended that you enable the `read_only` parameter on multi-source replicas to block write operations. Doing so helps to eliminate replication issues caused by conflicting write operations.
- To increase the performance of read operations such as sorts and high-load joins that are executed on the multi-source replica, consider using RDS Optimized Reads. This feature can help with queries that depend on large temporary tables or sort files. For more information, see [the section called "Improving query performance with RDS Optimized Reads"](#).
- To minimize replication lag and improve the performance of a multi-source replica, consider enabling optimized writes. For more information, see [the section called "Improving write performance with RDS Optimized Writes for MySQL"](#).
- Perform management operations (such as changing configuration) on one channel at a time, and avoid performing changes to multiple channels from multiple connections. These practices can lead to conflicts in replication operations. For example, simultaneously executing `rds_skip_repl_error_for_channel` and `rds_start_replication_for_channel` procedures from multiple connections can cause skipping of events on a different channel than intended.
- You can enable backups on a multi-source replication instance and export data from that instance to an Amazon S3 bucket to store it for long-term purposes. However, it's important to also configure backups with appropriate retention on the individual source instances. For information about exporting snapshot data to Amazon S3, see [the section called "Exporting DB snapshot data to Amazon S3"](#).
- To distribute the read workload on a multi-source replica, you can create read replicas from a multi-source replica. You can locate these read replicas in different AWS Regions based on your application's requirements. For more information about read replicas, see [the section called "Working with MySQL read replicas"](#).

## Prerequisites for multi-source replication

Before you configure multi-source replication, complete the following prerequisites.

- Make sure that each source RDS for MySQL DB instance has automatic backups enabled. Enabling automatic backups enables binary logging. To learn how to enable automatic backups, see [the section called “Enabling automated backups”](#).
- To avoid replication errors, we recommended that you block write operations to the source DB instances. You can do so by setting the `read-only` parameter to `ON` in a custom parameter group attached to the RDS for MySQL source DB instance. You can use the AWS Management Console or the AWS CLI to create a new custom parameter group or to modify an existing one. For more information, see [the section called “Creating a DB parameter group”](#) and [the section called “Modifying parameters in a DB parameter group”](#).
- For each source DB instance, add the IP address of the instance to the Amazon virtual private cloud (VPC) security group for the multi-source DB instance. To identify the IP address of a source DB instance, you can run the command `dig RDS Endpoint`. Run the command from an Amazon EC2 instance in the same VPC as the destination multi-source DB instance.
- For each source DB instance, use a client to connect to the DB instance and create a database user with the required privileges for replication, as in the following example.

```
CREATE USER 'repl_user' IDENTIFIED BY 'password';
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user';
```

## Configuring multi-source replication channels on RDS for MySQL DB instances

Configuring multi-source replication channels is similar to configuring single source replication. For multi-source replication, you first turn on binary logging on the source instance. Then, you import data from the sources to the multi-source replica. Then, you start replication from each source by using the binary log coordinates or by using GTID auto-positioning.

To configure an RDS for MySQL DB instance as a multi-source replica of two or more RDS for MySQL DB instances, perform the following steps.

### Topics

- [Step 1: Import data from the source DB instances to the multi-source replica](#)
- [Step 2: Start replication from the source DB instances to the multi-source replica](#)

## Step 1: Import data from the source DB instances to the multi-source replica

Perform the following steps on each source DB instance.

Before you import the data from a source to the multi-source replica, determine the current binary log file and position by running the `SHOW MASTER STATUS` command. Take note of these details for use in the next step. In this example output, the file is `mysql-bin-changelog.000031` and the position is `107`.

```
File                Position
-----
mysql-bin-changelog.000031    107
-----
```

Now copy the database from the source DB instance to the multi-source replica by using `mysqldump`, as in the following example.

```
mysqldump --databases database_name \
  --single-transaction \
  --compress \
  --order-by-primary \
  -u RDS_user_name \
  -p RDS_password \
  --host=RDS Endpoint | mysql \
  --host=RDS Endpoint \
  --port=3306 \
  -u RDS_user_name \
  -p RDS_password
```

After copying the database, you can set the read-only parameter to `OFF` on the source DB instance.

## Step 2: Start replication from the source DB instances to the multi-source replica

For each source DB instance, use the master user credentials to connect to the instance, and run the following two stored procedures. These stored procedures configure replication on a channel and start replication. This example uses the binlog file name and position from the example output in the previous step.

```
CALL mysql.rds_set_external_source_for_channel('mysourcehost.example.com', 3306,
  'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0, 'channel_1');
```

```
CALL mysql.rds_start_replication_for_channel('channel_1');
```

For more information about using these stored procedures and others to set up and manage your replication channels, see [the section called “Managing multi-source replication”](#).

## Using filters with multi-source replication

You can use replication filters to specify which databases and tables are replicated with in multi-source replica. Replication filters can include databases and tables in replication or exclude them from replication. For more information on replication filters, see [the section called “Configuring replication filters with MySQL”](#).

With multi-source replication, you can configure replication filters globally or at the channel level. Channel-level filtering is available only with supported DB instances running version 8.0. The following examples show how to configure filters globally or at the channel level.

Note the following requirements and behavior with filtering in multi-source replication:

- Back quotes (``) around the channel names are required.
- If you change replication filters in the parameter group, the multi-source replica's `sql_thread` for all channels with updates are restarted to apply the changes dynamically. If an update involves a global filter, then all replication channels in the running state are restarted.
- All global filters are applied before any channel-specific filters.
- If a filter is applied globally and at the channel level, then only the channel-level filter is applied. For example, if the filters are `replicate_ignore_db="db1, `channel_22`:db2"`, then `replicate_ignore_db` set to `db1` is applied to all channels except for `channel_22`, and only `channel_22` ignores changes from `db2`.

### Example 1: Setting a global filter

In the following example, the `temp_data` database is excluded from replication in every channel.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \  
--db-parameter-group-name myparametergroup \  
--parameters "ParameterName=replicate-ignore-  
db,ParameterValue='temp_data',ApplyMethod=immediate"
```

## Example 2: Setting a channel-level filter

In the following example, changes from the `sample22` database are only included in channel `channel_22`. Similarly, changes from the `sample99` database are only included in channel `channel_99`.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \  
--db-parameter-group-name myparametergroup \  
--parameters "ParameterName=replicate-do-db,ParameterValue='\`channel_22\`:sample22,\  
\`channel_99\`:sample99',ApplyMethod=immediate"
```

## Monitoring multi-source replication channels

You can monitor individual channels in a multi-source replica by using the following methods:

- To monitor the status of all channels or a specific channel, connect to the multi-source replica and run the `SHOW REPLICA STATUS` or `SHOW REPLICA STATUS FOR CHANNEL 'channel_name'` command. For more information, see [Checking Replication Status](#) in the MySQL documentation.
- To receive notification when a replication channel is started, stopped, or removed, use RDS event notification. For more information, see [the section called “Working with Amazon RDS event notification”](#).
- To monitor the lag for a specific channel, check the `ReplicationChannelLag` metric for it. Data points for this metric have a period of 60 seconds (1 minute) and are available for 15 days. To locate the replication channel lag for a channel, use the instance identifier and the replication channel name. To receive notification when this lag exceeds a particular threshold, you can set up a CloudWatch alarm. For more information, see [the section called “Monitoring RDS with CloudWatch”](#).

## Limitations for multi-source replication on RDS for MySQL

The following limitations apply to multi-source replication on RDS for MySQL:

- Currently, RDS for MySQL supports configuring a maximum of 15 channels for a multi-source replica.
- A read replica instance can't be configured as a multi-source replica.

- To configure multi-source replication on RDS for MySQL running engine version 5.7, Performance Schema must be enabled on the replica instance. Enabling Performance Schema is optional on RDS for MySQL running engine version 8.0.
- For RDS for MySQL running engine version 5.7, replication filters apply to all replication channels. For RDS for MySQL running engine version 8.0, you can configure filters that apply to all replication channels or to individual channels.
- Restoring an RDS snapshot or performing a Point-in-time-Restore (PITR) doesn't restore multi-source replica channel configurations.
- When you create a read replica of a multi-source replica, it only replicates data from the multi-source instance. It doesn't restore any channel configuration.
- MySQL doesn't support setting up a different number of parallel workers for each channel. Every channel gets the same number of parallel workers based on the `replica_parallel_workers` value.

The following additional limitations apply if your multi-source replication target is a Multi-AZ DB cluster:

- A channel must be configured for a source RDS for MySQL instance before any writes to that instance occur.
- Each source RDS for MySQL instance must have GTID-based replication enabled.
- A failover event on the DB cluster removes the multi-source replication configuration. Restoring that configuration requires repeating the configuration steps.

# Configuring active-active clusters for RDS for MySQL

You can set up an active-active cluster for RDS for MySQL by using the MySQL Group Replication plugin. The Group Replication plugin is supported for RDS for MySQL DB instances running version 8.0.35 and higher minor versions.

For information about MySQL Group Replication, see [Group Replication](#) in the MySQL documentation. The MySQL documentation contains detailed information about this feature, while this topic describes how to configure and manage the plugin on your RDS for MySQL DB instances.

## Note

For the sake of brevity, all mentions of "active-active" cluster in this topic refer to active-active clusters using the MySQL Group Replication plugin.

## Topics

- [Use cases for active-active clusters](#)
- [Considerations and best practices for active-active clusters](#)
- [Prerequisites for a cross-VPC active-active cluster](#)
- [Required parameter settings for active-active clusters](#)
- [Converting an existing DB instance to an active-active cluster](#)
- [Setting up an active-active cluster with new DB instances](#)
- [Adding a DB instance to an active-active cluster](#)
- [Monitoring active-active clusters](#)
- [Stopping Group Replication on a DB instance in an active-active cluster](#)
- [Renaming a DB instance in an active-active cluster](#)
- [Removing a DB instance from an active-active cluster](#)
- [Limitations for RDS for MySQL active-active clusters](#)

## Use cases for active-active clusters

The following cases are good candidates for using active-active clusters:

- Applications that need all of the DB instances in the cluster to support write operations. The Group Replication plugin keeps the data consistent on each DB instance in the active-active cluster. For more information about how this works, see [Group Replication](#) in the MySQL documentation.
- Applications that require continuous availability of the database. With an active-active cluster, the data is retained on all of the DB instances in the cluster. If one DB instance fails, the application can reroute traffic to another DB instance in the cluster.
- Applications that might need to split read and write operations among different DB instances in the cluster for load balancing purposes. With an active-active cluster, your applications can send read traffic to specific DB instances and write traffic to others. You can also switch which DB instances to send reads or writes to at any time.

## Considerations and best practices for active-active clusters

Before you use RDS for MySQL active-active clusters, review the following considerations and best practices:

- Active-active clusters can't have more than nine DB instances.
- With the Group Replication plugin, you can control the transaction consistency guarantees of the active-active cluster. For more information, see [Transaction Consistency Guarantees](#) in the MySQL documentation.
- Conflicts are possible when different DB instances update the same row in an active-active cluster. For information about conflicts and conflict resolution, see [Group Replication](#) in the MySQL documentation.
- For fault tolerance, include at least three DB instances in your active-active cluster. It is possible to configure an active-active cluster with only one or two DB instances, but the cluster won't be fault tolerant. For information about fault tolerance, see [Fault-tolerance](#) in the MySQL documentation.
- When a DB instance joins an existing active-active cluster and is running the same engine version as the lowest engine version in the cluster, the DB instance joins in read-write mode.
- When a DB instance joins an existing active-active cluster and is running a higher engine version than the lowest engine version in the cluster, the DB instance must remain in read-only mode.
- If you enable Group Replication for a DB instance by setting its `rds.group_replication_enabled` parameter to 1 in the DB parameter group, but replication hasn't started or has failed to start, the DB instance is placed in super-read-only mode to

prevent data inconsistencies. For information about super-read-only mode, see the [MySQL documentation](#).

- You can upgrade a DB instance in an active-active cluster, but the DB instance is read-only until all of the other DB instances in the active-active cluster are upgraded to same engine version or a higher engine version. When you upgrade a DB instance, the DB instance automatically joins the same active-active cluster when the upgrade completes. To avoid an unintended switch to read-only mode for a DB instance, disable automatic minor version upgrades for it. For information about upgrading a MySQL DB instance, see [Upgrading the MySQL DB engine](#).
- You can add a DB instance in a Multi-AZ DB instance deployment to an existing active-active cluster. You can also convert a Single-AZ DB instance in an active-active cluster to a Multi-AZ DB instance deployment. If a primary DB instance in a Multi-AZ deployment fails, that primary instance fails over to the standby instance. The new primary DB instance automatically joins the same cluster after failover completes. For more information about Multi-AZ DB instance deployments, see [Multi-AZ DB instance deployments](#).
- We recommend that the DB instances in an active-active cluster have different time ranges for their maintenance windows. This practice avoids multiple DB instances in the cluster going offline for maintenance at the same time. For more information, see [The Amazon RDS maintenance window](#).
- Active-active clusters can use SSL for connections between DB instances. To configure SSL connections, set the [group\\_replication\\_recovery\\_use\\_ssl](#) and [group\\_replication\\_ssl\\_mode](#) parameters. The values for these parameters must match for all DB instances in the active-active cluster.

Currently, active-active clusters don't support certificate authority (CA) verification for connections between AWS Regions. So, the [group\\_replication\\_ssl\\_mode](#) parameter must be set to DISABLED (the default) or REQUIRED for cross-Region clusters.

- An RDS for MySQL active-active cluster runs in multi-primary mode. The default value of the [group\\_replication\\_enforce\\_update\\_everywhere\\_checks](#) is ON and the parameter is static. When this parameter is set to ON, applications can't insert into a table that has cascading foreign key constraints.
- An RDS for MySQL active-active cluster uses the MySQL communication stack for connection security instead of XCOM. For more information, see [Communication Stack for Connection Security Management](#) in the MySQL documentation.

- When a DB parameter group is associated with a DB instance in an active-active cluster, we recommend only associating this DB parameter group with other DB instances that are in the cluster.
- Active-active clusters only support RDS for MySQL DB instances. These DB instances must be running supported versions of the DB engine.
- When a DB instance in an active-active cluster has an unexpected failure, RDS starts recovery of the DB instance automatically. If the DB instance doesn't recover, we recommend replacing it with a new DB instance by performing a point-in-time recovery with a healthy DB instance in the cluster. For instructions, see [Adding a DB instance to an active-active cluster using point-in-time recovery](#).
- You can delete a DB instance in an active-active cluster without affecting the other DB instances in the cluster. For information about deleting a DB instance, see [Deleting a DB instance](#).

## Prerequisites for a cross-VPC active-active cluster

You can configure an active-active cluster with DB instances in more than one VPC. The VPCs can be in the same AWS Region or different AWS Regions.

### Note

Sending traffic between multiple AWS Regions might incur additional costs. For more information, see [Overview of Data Transfer Costs for Common Architectures](#).

If you are configuring an active-active cluster in a single VPC, you can skip these steps and move on to [Setting up an active-active cluster with new DB instances](#).

### To prepare for an active-active cluster with DB instances in more than one VPC

1. Make sure the IPv4 address ranges in the CIDR blocks meet the following requirements:
  - The IPv4 address ranges in the CIDR blocks of the VPCs can't overlap.
  - All of the IPv4 address ranges in the CIDR blocks either must be lower than `128.0.0.0/subnet_mask` or higher than `128.0.0.0/subnet_mask`.

The following ranges illustrate these requirements:

- 10.1.0.0/16 in one VPC and 10.2.0.0/16 in the other VPC is supported.
- 172.1.0.0/16 in one VPC and 172.2.0.0/16 in the other VPC is supported.
- 10.1.0.0/16 in one VPC and 10.1.0.0/16 in the other VPC *is not* supported because the ranges overlap.
- 10.1.0.0/16 in one VPC and 172.1.0.0/16 in the other VPC *is not* supported because one is below 128.0.0.0/*subnet\_mask* and the other is above 128.0.0.0/*subnet\_mask*.

For information about CIDR blocks, see [VPC CIDR blocks](#) in the *Amazon VPC User Guide*.

2. In each VPC, make sure DNS resolution and DNS hostnames are both enabled.

For instructions, see [View and update DNS attributes for your VPC](#) in the *Amazon VPC User Guide*.

3. Configure the VPCs so that you can route traffic between them in one of the following ways:
  - Create a VPC peering connection between the VPCs.

For instructions, see [Create a VPC peering connection](#) in the *Amazon VPC Peering Guide*.

In each VPC, make sure there are inbound rules for your security groups that reference security groups in the peered VPC. Doing so allows traffic to flow to and from instances that are associated with the referenced security group in the peered VPC. For instructions, see [Update your security groups to reference peer security groups](#) in the *Amazon VPC Peering Guide*.

- Create a transit gateway between the VPCs.

For instructions, see [Getting started with transit gateways](#) in *Amazon VPC Transit Gateways*.

In each VPC, make sure there are inbound rules for your security groups that allow traffic from the other VPC, such as inbound rules that specify the CIDR of the other VPC. Doing so allows traffic to flow to and from instances that are associated with the referenced security group in the active-active cluster. For more information, see [Control traffic to your AWS resources using security groups](#) in the *Amazon VPC User Guide*.

## Required parameter settings for active-active clusters

The following parameter settings are required when you are setting up an RDS for MySQL active-active cluster.

Parameter	Description	Required setting
<code>binlog_format</code>	Sets the binary logging format. The default value for RDS for MySQL is MIXED. For more information, see <a href="#">the MySQL documentation</a> .	ROW
<code>enforce_gtid_consistency</code>	Enforces GTID consistency for statement execution. The default value for RDS for MySQL is OFF. For more information, see <a href="#">the MySQL documentation</a> .	ON
<code>group_replication_group_name</code>	Sets the Group Replication name to a UUID. The UUID format is 11111111-2222-3333-4444-555555555555 . You can generate a MySQL UUID by connecting to a MySQL DB instance and running <code>SELECT UUID()</code> . The value must be the same for all of the DB instances in the active-active cluster. For more information, see <a href="#">the MySQL documentation</a> .	A MySQL UUID
<code>gtid-mode</code>	Controls GTID-based logging. The default value for RDS for MySQL is OFF_PERMISSIVE . For more information, see <a href="#">the MySQL documentation</a> .	ON

Parameter	Description	Required setting
<code>rds.custom_dns_resolution</code>	Specifies whether to allow DNS resolution from the Amazon DNS server in your VPC. DNS resolution must be enabled when Group Replication is enabled with the <code>rds.group_replication_enabled</code> parameter. DNS resolution can't be enabled when Group Replication is disabled with the <code>rds.group_replication_enabled</code> parameter. For more information, see <a href="#">Amazon DNS server</a> in the <i>Amazon VPC User Guide</i> .	1
<code>rds.group_replication_enabled</code>	Specifies whether Group Replication is enabled for a DB instance. Group Replication must be enabled on a DB instance in an active-active cluster.	1
<code>slave_preserve_commit_order</code>	Controls the order that transactions are committed on a replica. The default value for RDS for MySQL is ON. For more information, see <a href="#">the MySQL documentation</a> .	ON

## Converting an existing DB instance to an active-active cluster

The DB engine version of the DB instance you want to migrate to an active-active cluster must be MySQL 8.0.35 or higher. If you need to upgrade the engine version, see [Upgrading the MySQL DB engine](#).

If you are setting up an active-active cluster with DB instances in more than one VPC, make sure you complete the prerequisites in [Prerequisites for a cross-VPC active-active cluster](#).

Complete the following steps to migrate an existing DB instance to an active-active cluster for RDS for MySQL.

### Topics

- [Step 1: Set the active-active cluster parameters in one or more custom parameter groups](#)
- [Step 2: Associate the DB instance with a DB parameter group that has the required Group Replication parameters set](#)
- [Step 3: Create the active-active cluster](#)
- [Step 4: Create additional RDS for MySQL DB instances for the active-active cluster](#)
- [Step 5: Initialize the group on the DB instance you are converting](#)
- [Step 6: Start replication on the other DB instances in the active-active cluster](#)
- [Step 7: \(Recommended\) Check the status of the active-active cluster](#)

### Step 1: Set the active-active cluster parameters in one or more custom parameter groups

The RDS for MySQL DB instances in an active-active cluster must be associated with a custom parameter group that has the correct setting for required parameters. For information about the parameters and the required setting for each one, see [Required parameter settings for active-active clusters](#).

You can set these parameters in new parameter groups or in existing parameter groups. However, to avoid accidentally affecting DB instances that aren't part of the active-active cluster, we strongly recommend that you create a new custom parameter group. The DB instances in an active-active cluster can be associated with the same DB parameter group or with different DB parameter groups.

You can use the AWS Management Console or the AWS CLI to create a new custom parameter group. For more information, see [Creating a DB parameter group in Amazon RDS](#). The following example runs the [create-db-parameter-group](#) AWS CLI command to create a custom DB parameter group named *myactivepg*:

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \  
  --db-parameter-group-name myactivepg \  
  --db-parameter-group-family mysql8.0 \  
  --description "Parameter group for active-active clusters"
```

For Windows:

```
aws rds create-db-parameter-group ^  
  --db-parameter-group-name myactivepg ^  
  --db-parameter-group-family mysql8.0 ^  
  --description "Parameter group for active-active clusters"
```

You can also use the AWS Management Console or the AWS CLI to set the parameters in the custom parameter group. For more information, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

The following example runs the [modify-db-parameter-group](#) AWS CLI command to set the parameters:

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name myactivepg \  
  --parameters  
  "ParameterName='rds.group_replication_enabled',ParameterValue='1',ApplyMethod=pending-  
reboot" \  
  
  "ParameterName='rds.custom_dns_resolution',ParameterValue='1',ApplyMethod=pending-  
reboot" \  
  
  "ParameterName='enforce_gtid_consistency',ParameterValue='ON',ApplyMethod=pending-  
reboot" \  
      "ParameterName='gtid-mode',ParameterValue='ON',ApplyMethod=pending-  
reboot" \  
  \
```

```
"ParameterName='binlog_format',ParameterValue='ROW',ApplyMethod=immediate" \
"ParameterName='slave_preserve_commit_order',ParameterValue='ON',ApplyMethod=immediate" \
"ParameterName='group_replication_group_name',ParameterValue='11111111-2222-3333-4444-55555555'
reboot"
```

### For Windows:

```
aws rds modify-db-parameter-group ^
  --db-parameter-group-name myactivepg ^
  --parameters
  "ParameterName='rds.group_replication_enabled',ParameterValue='1',ApplyMethod=pending-
reboot" ^

  "ParameterName='rds.custom_dns_resolution',ParameterValue='1',ApplyMethod=pending-
reboot" ^

  "ParameterName='enforce_gtid_consistency',ParameterValue='ON',ApplyMethod=pending-
reboot" ^
    "ParameterName='gtid-mode',ParameterValue='ON',ApplyMethod=pending-
reboot" ^

  "ParameterName='binlog_format',ParameterValue='ROW',ApplyMethod=immediate" ^

  "ParameterName='slave_preserve_commit_order',ParameterValue='ON',ApplyMethod=immediate"
^

  "ParameterName='group_replication_group_name',ParameterValue='11111111-2222-3333-4444-55555555'
reboot"
```

## Step 2: Associate the DB instance with a DB parameter group that has the required Group Replication parameters set

Associate the DB instance with a parameter group you created or modified in the previous step. For instructions, see [Associating a DB parameter group with a DB instance in Amazon RDS](#).

Reboot the DB instance for the new parameter settings to take effect. For instructions, see [Rebooting a DB instance](#).

### Step 3: Create the active-active cluster

In the DB parameter group associated with the DB instance, set the `group_replication_group_seeds` parameter to the endpoint of the DB instance you are converting.

You can use the AWS Management Console or the AWS CLI to set the parameter. You don't need to reboot the DB instance after setting this parameter. For more information about setting parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

The following example runs the [modify-db-parameter-group](#) AWS CLI command to set the parameters:

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name myactivepg \  
  --parameters  
  "ParameterName='group_replication_group_seeds',ParameterValue='myactivedb1.123456789012.us-east-1.rds.amazonaws.com:3306',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^  
  --db-parameter-group-name myactivepg ^  
  --parameters  
  "ParameterName='group_replication_group_seeds',ParameterValue='myactivedb1.123456789012.us-east-1.rds.amazonaws.com:3306',ApplyMethod=immediate"
```

### Step 4: Create additional RDS for MySQL DB instances for the active-active cluster

To create additional DB instances for the active-active cluster, perform point-in-time recovery on the DB instance you are converting. For instructions, see [Adding a DB instance to an active-active cluster using point-in-time recovery](#).

An active-active cluster can have up to nine DB instances. Perform point-in-time recovery on the DB instance until you have the number of DB instances you want for the cluster. When you perform point-in-recovery, make sure you associate the DB instance you are adding with a DB parameter group that has `rds.group_replication_enabled` set to 1. Otherwise, Group Replication won't start on the newly added DB instance.

## Step 5: Initialize the group on the DB instance you are converting

Initialize the group and start replication:

1. Connect to that DB instance you are converting in a SQL client. For more information about connecting to an RDS for MySQL DB instance, see [Connecting to a DB instance running the MySQL database engine](#).
2. In the SQL client, run the following stored procedures and replace *group\_replication\_user\_password* with the password for the `rdsgrepladmin` user. The `rdsgrepladmin` user is reserved for Group Replication connections in an active-active cluster. The password for this user must be the same on all of the DB instances in an active-active cluster.

```
call mysql.rds_set_configuration('binlog retention hours', 168); -- 7 days binlog
call mysql.rds_group_replication_create_user('group_replication_user_password');
call
  mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
call mysql.rds_group_replication_start(1);
```

This example sets the `binlog retention hours` value to 168, which means that binary log files are retained for seven days on the DB instance. You can adjust this value to meet your requirements.

This example specifies 1 in the `mysql.rds_group_replication_start` stored procedure to initialize a new group with the current DB instance.

For more information about the stored procedures called in the example, see [Managing active-active clusters](#).

## Step 6: Start replication on the other DB instances in the active-active cluster

For each of the DB instances in the active-active cluster, use a SQL client to connect to the instance, and run the following stored procedures. Replace *group\_replication\_user\_password* with the password for the `rdsgrepladmin` user.

```
call mysql.rds_set_configuration('binlog retention hours', 168); -- 7 days binlog
call mysql.rds_group_replication_create_user('group_replication_user_password');
call
  mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
```

```
call mysql.rds_group_replication_start(0);
```

This example sets the `binlog retention hours` value to 168, which means that binary log files are retained for seven days on each DB instance. You can adjust this value to meet your requirements.

This example specifies 0 in the `mysql.rds_group_replication_start` stored procedure to join the current DB instance to an existing group.

### Tip

Make sure you run these stored procedures on all of the other DB instances in the active-active cluster.

## Step 7: (Recommended) Check the status of the active-active cluster

To make sure each member of the cluster is configured correctly, check the status of the cluster by connecting to a DB instance in the active-active cluster, and running the following SQL command:

```
SELECT * FROM performance_schema.replication_group_members;
```

Your output should show `ONLINE` for the `MEMBER_STATE` of each DB instance, as in the following sample output:

```
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
+-----+
| CHANNEL_NAME          | MEMBER_ID                               | MEMBER_HOST      |
| MEMBER_PORT | MEMBER_STATE | MEMBER_ROLE | MEMBER_VERSION | MEMBER_COMMUNICATION_STACK
|
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
+-----+
| group_replication_applier | 9854d4a2-5d7f-11ee-b8ec-0ec88c43c251 | ip-10-15-3-137 | | |
|      3306 | ONLINE      | PRIMARY    | 8.0.35         | MySQL              |
| group_replication_applier | 9e2e9c28-5d7f-11ee-8039-0e5d58f05fef | ip-10-15-3-225 |
|      3306 | ONLINE      | PRIMARY    | 8.0.35         | MySQL              |
| group_replication_applier | a6ba332d-5d7f-11ee-a025-0a5c6971197d | ip-10-15-1-83  |
|      3306 | ONLINE      | PRIMARY    | 8.0.35         | MySQL              |
```

```
+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+
+-----+
3 rows in set (0.00 sec)
```

For information about the possible MEMBER\_STATE values, see [Group Replication Server States](#) in the MySQL documentation.

## Setting up an active-active cluster with new DB instances

Complete the following steps to set up an active-active cluster using new RDS for MySQL DB instances.

If you are setting up an active-active cluster with DB instances in more than one VPC, make sure you complete the prerequisites in [Prerequisites for a cross-VPC active-active cluster](#).

### Topics

- [Step 1: Set the active-active cluster parameters in one or more custom parameter groups](#)
- [Step 2: Create new RDS for MySQL DB instances for the active-active cluster](#)
- [Step 4: Specify the DB instances in the active-active cluster](#)
- [Step 5: Initialize the group on a DB instance and start replication](#)
- [Step 6: Start replication on the other DB instances in the active-active cluster](#)
- [Step 7: \(Recommended\) Check the status of the active-active cluster](#)
- [Step 8: \(Optional\) Import data into a DB instance in the active-active cluster](#)

### Step 1: Set the active-active cluster parameters in one or more custom parameter groups

The RDS for MySQL DB instances in an active-active cluster must be associated with a custom parameter group that has the correct setting for required parameters. For information about the parameters and the required setting for each one, see [Required parameter settings for active-active clusters](#).

You can set these parameters in new parameter groups or in existing parameter groups. However, to avoid accidentally affecting DB instances that aren't part of the active-active cluster, we strongly recommend that you create a new custom parameter group. The DB instances in an active-active

cluster can be associated with the same DB parameter group or with different DB parameter groups.

You can use the AWS Management Console or the AWS CLI to create a new custom parameter group. For more information, see [Creating a DB parameter group in Amazon RDS](#). The following example runs the [create-db-parameter-group](#) AWS CLI command to create a custom DB parameter group named *myactivepg*:

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \  
  --db-parameter-group-name myactivepg \  
  --db-parameter-group-family mysql8.0 \  
  --description "Parameter group for active-active clusters"
```

For Windows:

```
aws rds create-db-parameter-group ^  
  --db-parameter-group-name myactivepg ^  
  --db-parameter-group-family mysql8.0 ^  
  --description "Parameter group for active-active clusters"
```

You can also use the AWS Management Console or the AWS CLI to set the parameters in the custom parameter group. For more information, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

The following example runs the [modify-db-parameter-group](#) AWS CLI command to set the parameters:

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name myactivepg \  
  --parameters  
  "ParameterName='rds.group_replication_enabled',ParameterValue='1',ApplyMethod=pending-  
reboot" \  
  
  "ParameterName='rds.custom_dns_resolution',ParameterValue='1',ApplyMethod=pending-  
reboot" \  
  
  "ParameterName='enforce_gtid_consistency',ParameterValue='ON',ApplyMethod=pending-  
reboot" \  
  \
```

```

        "ParameterName='gtid-mode',ParameterValue='ON',ApplyMethod=pending-
reboot" \

    "ParameterName='binlog_format',ParameterValue='ROW',ApplyMethod=immediate" \

    "ParameterName='slave_preserve_commit_order',ParameterValue='ON',ApplyMethod=immediate"
\

    "ParameterName='group_replication_group_name',ParameterValue='11111111-2222-3333-4444-55555555
reboot"

```

### For Windows:

```

aws rds modify-db-parameter-group ^
  --db-parameter-group-name myactivepg ^
  --parameters
    "ParameterName='rds.group_replication_enabled',ParameterValue='1',ApplyMethod=pending-
reboot" ^

    "ParameterName='rds.custom_dns_resolution',ParameterValue='1',ApplyMethod=pending-
reboot" ^

    "ParameterName='enforce_gtid_consistency',ParameterValue='ON',ApplyMethod=pending-
reboot" ^

        "ParameterName='gtid-mode',ParameterValue='ON',ApplyMethod=pending-
reboot" ^

    "ParameterName='binlog_format',ParameterValue='ROW',ApplyMethod=immediate" ^

    "ParameterName='slave_preserve_commit_order',ParameterValue='ON',ApplyMethod=immediate"
^

    "ParameterName='group_replication_group_name',ParameterValue='11111111-2222-3333-4444-55555555
reboot"

```

## Step 2: Create new RDS for MySQL DB instances for the active-active cluster

Active-active clusters are supported for version 8.0.35 and higher RDS for MySQL DB instances. You can create up to nine new DB instances for the cluster.

You can use the AWS Management Console or the AWS CLI to create new DB instances. For more information about creating a DB instance, see [Creating an Amazon RDS DB instance](#). When you

create the DB instance, associate it with a DB parameter group that you created or modified in the previous step.

## Step 4: Specify the DB instances in the active-active cluster

In the DB parameter group associated with each DB instance, set the `group_replication_group_seeds` parameter to the endpoints of the DB instances you want to include in the cluster.

You can use the AWS Management Console or the AWS CLI to set the parameter. You don't need to reboot the DB instance after setting this parameter. For more information about setting parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

The following example runs the [modify-db-parameter-group](#) AWS CLI command to set the parameters:

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name myactivepg \  
  --parameters  
  "ParameterName='group_replication_group_seeds',ParameterValue='myactivedb1.123456789012.us-east-1.rds.amazonaws.com:3306,myactivedb2.123456789012.us-east-1.rds.amazonaws.com:3306,myactivedb3.123456789012.us-east-1.rds.amazonaws.com:3306',ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^  
  --db-parameter-group-name myactivepg ^  
  --parameters  
  "ParameterName='group_replication_group_seeds',ParameterValue='myactivedb1.123456789012.us-east-1.rds.amazonaws.com:3306,myactivedb2.123456789012.us-east-1.rds.amazonaws.com:3306,myactivedb3.123456789012.us-east-1.rds.amazonaws.com:3306',ApplyMethod=immediate"
```

### Tip

Make sure you set the `group_replication_group_seeds` parameter in each DB parameter group that is associated with a DB instance in the active-active cluster.

## Step 5: Initialize the group on a DB instance and start replication

You can choose any new DB to initialize the group and start replication. To do so, complete the following steps:

1. Choose a DB instance in the active-active cluster, and connect to that DB instance in a SQL client. For more information about connecting to an RDS for MySQL DB instance, see [Connecting to a DB instance running the MySQL database engine](#).
2. In the SQL client, run the following stored procedures and replace *group\_replication\_user\_password* with the password for the `rdsgrepladmin` user. The `rdsgrepladmin` user is reserved for Group Replication connections in an active-active cluster. The password for this user must be the same on all of the DB instances in an active-active cluster.

```
call mysql.rds_set_configuration('binlog retention hours', 168); -- 7 days binlog
call mysql.rds_group_replication_create_user('group_replication_user_password');
call
  mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
call mysql.rds_group_replication_start(1);
```

This example sets the `binlog retention hours` value to 168, which means that binary log files are retained for seven days on the DB instance. You can adjust this value to meet your requirements.

This example specifies 1 in the `mysql.rds_group_replication_start` stored procedure to initialize a new group with the current DB instance.

For more information about the stored procedures called in the example, see [Managing active-active clusters](#).

## Step 6: Start replication on the other DB instances in the active-active cluster

For each of the DB instances in the active-active cluster, use a SQL client to connect to the instance, and run the following stored procedures. Replace *group\_replication\_user\_password* with the password for the `rdsgrepladmin` user.

```
call mysql.rds_set_configuration('binlog retention hours', 168); -- 7 days binlog
call mysql.rds_group_replication_create_user('group_replication_user_password');
```

```
call
mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
call mysql.rds_group_replication_start(0);
```

This example sets the `binlog retention hours` value to 168, which means that binary log files are retained for seven days on each DB instance. You can adjust this value to meet your requirements.

This example specifies 0 in the `mysql.rds_group_replication_start` stored procedure to join the current DB instance to an existing group.

### Tip

Make sure you run these stored procedures on all of the other DB instances in the active-active cluster.

## Step 7: (Recommended) Check the status of the active-active cluster

To make sure each member of the cluster is configured correctly, check the status of the cluster by connecting to a DB instance in the active-active cluster, and running the following SQL command:

```
SELECT * FROM performance_schema.replication_group_members;
```

Your output should show `ONLINE` for the `MEMBER_STATE` of each DB instance, as in the following sample output:

```
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
+-----+
| CHANNEL_NAME          | MEMBER_ID          | MEMBER_HOST      |
| MEMBER_PORT | MEMBER_STATE | MEMBER_ROLE | MEMBER_VERSION | MEMBER_COMMUNICATION_STACK
|
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
+-----+
| group_replication_applier | 9854d4a2-5d7f-11ee-b8ec-0ec88c43c251 | ip-10-15-3-137 | | |
| 3306 | ONLINE      | PRIMARY    | 8.0.35        | MySQL                |
| group_replication_applier | 9e2e9c28-5d7f-11ee-8039-0e5d58f05fef | ip-10-15-3-225 |
| 3306 | ONLINE      | PRIMARY    | 8.0.35        | MySQL                |
```

```

| group_replication_applier | a6ba332d-5d7f-11ee-a025-0a5c6971197d | ip-10-15-1-83 |
  3306 | ONLINE      | PRIMARY      | 8.0.35      | MySQL      |
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
+-----+
3 rows in set (0.00 sec)

```

For information about the possible MEMBER\_STATE values, see [Group Replication Server States](#) in the MySQL documentation.

## Step 8: (Optional) Import data into a DB instance in the active-active cluster

You can import data from a MySQL database into a DB instance in the active-active cluster. After the data is imported, Group Replication replicates it to the other DB instances in the cluster.

For information about importing data, see [Importing data to an Amazon RDS MariaDB or MySQL database with reduced downtime](#).

## Adding a DB instance to an active-active cluster

You can add a DB instance to an active-active cluster by restoring a DB snapshot or by restoring a DB instance to a point in time. An active-active cluster can include up to nine DB instances.

When you recover a DB instance to a point in time, it usually includes more recent transactions than a DB instance that was restored from a DB snapshot. When the DB instance has more recent transactions, fewer transactions need to be applied when you start replication. So, using point-in-time recovery to add a DB instance to a cluster is usually faster than restoring from a DB snapshot.

### Topics

- [Adding a DB instance to an active-active cluster using point-in-time recovery](#)
- [Adding a DB instance to an active-active cluster using a DB snapshot](#)

## Adding a DB instance to an active-active cluster using point-in-time recovery

You can add a DB instance to an active-active cluster by performing point-in-time recovery on a DB instance in the cluster.

For information about recovering a DB instance to a point in time in a different AWS Region, see [Replicating automated backups to another AWS Region](#).

## To add a DB instance to an active-active cluster using point-in-time recovery

1. Create a new DB instance by performing point-in-time recovery on a DB instance in the active-active cluster.

You can perform point-in-time recovery on any DB instance in the cluster to create the new DB instance. For instructions, see [Restoring a DB instance to a specified time](#).

### Important

During point-in-time-recovery, associate the new DB instance with a DB parameter group that has the active-active cluster parameters set. Otherwise, Group Replication won't start on the new DB instance. For information about the parameters and the required setting for each one, see [Required parameter settings for active-active clusters](#).

### Tip

If you take a snapshot of the DB instance before you start point-in-time recovery, you might be able to reduce the amount of time required to apply transactions on the new DB instance.

2. Add the DB instance to the `group_replication_group_seeds` parameter in each DB parameter group associated with a DB instance in the active-active cluster, including the DB parameter group that you associated with the new DB instance.

For more information about setting parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

3. In a SQL client, connect to the new DB instance, and call the [mysql.rds\\_group\\_replication\\_set\\_recovery\\_channel](#) stored procedure. Replace `group_replication_user_password` with the password for the `rdsgprepladmin` user.

```
call
mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
```

4. Using the SQL client, call the [mysql.rds\\_group\\_replication\\_start](#) stored procedure to start replication:

```
call mysql.rds_group_replication_start(0);
```

## Adding a DB instance to an active-active cluster using a DB snapshot

You can add a DB instance to an active-active cluster by creating a DB snapshot of a DB instance in the cluster and then restoring the DB snapshot.

For information about copying a snapshot to a different AWS Region, see [the section called “Cross-Region copying”](#).

### To add a DB instance to an active-active cluster using a DB snapshot

1. Create a DB snapshot of a DB instance in the active-active cluster.

You can create a DB snapshot of any DB instance in the cluster. For instructions, see [Creating a DB snapshot for a Single-AZ DB instance](#).

2. Restore a DB instance from the DB snapshot.

During the snapshot restore operation, associate the new DB instance with a DB parameter group that has the active-active cluster parameters set. For information about the parameters and the required setting for each one, see [Required parameter settings for active-active clusters](#).

For information about restoring a DB instance from a DB snapshot, see [Restoring to a DB instance](#).

3. Add the DB instance to the `group_replication_group_seeds` parameter in each DB parameter group associated with a DB instance in the active-active cluster, including the DB parameter group that you associated with the new DB instance.

For more information about setting parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

4. In a SQL client, connect to the new DB instance, and call the [mysql.rds\\_group\\_replication\\_set\\_recovery\\_channel](#) stored procedure. Replace `group_replication_user_password` with the password for the `rdsgrprepladmin` user.

```
call
mysql.rds_group_replication_set_recovery_channel('group_replication_user_password');
```

- Using the SQL client, call the [mysql.rds\\_group\\_replication\\_start](#) stored procedure to start replication:

```
call mysql.rds_group_replication_start(0);
```

## Monitoring active-active clusters

You can monitor your active-active cluster by connecting to a DB instance in the cluster, and running the following SQL command:

```
SELECT * FROM performance_schema.replication_group_members;
```

Your output should show ONLINE for the MEMBER\_STATE of each DB instance, as in the following sample output:

```
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
+-----+
| CHANNEL_NAME          | MEMBER_ID          | MEMBER_HOST      |
| MEMBER_PORT | MEMBER_STATE | MEMBER_ROLE | MEMBER_VERSION | MEMBER_COMMUNICATION_STACK
|
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
+-----+
| group_replication_applier | 9854d4a2-5d7f-11ee-b8ec-0ec88c43c251 | ip-10-15-3-137 | | |
| 3306 | ONLINE      | PRIMARY    | 8.0.35        | MySQL                |
| group_replication_applier | 9e2e9c28-5d7f-11ee-8039-0e5d58f05fef | ip-10-15-3-225 |
| 3306 | ONLINE      | PRIMARY    | 8.0.35        | MySQL                |
| group_replication_applier | a6ba332d-5d7f-11ee-a025-0a5c6971197d | ip-10-15-1-83  |
| 3306 | ONLINE      | PRIMARY    | 8.0.35        | MySQL                |
+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+
+-----+
3 rows in set (0.00 sec)
```

For information about the possible MEMBER\_STATE values, see [Group Replication Server States](#) in the MySQL documentation.

## Stopping Group Replication on a DB instance in an active-active cluster

You can stop Group Replication on a DB instance in an active-active cluster. When you stop Group Replication, the DB instance is placed in super-read-only mode until replication is restarted or that DB instance is removed from the active-active cluster. For information about super-read-only mode, see the [MySQL documentation](#).

### To stop Group Replication temporarily for an active-active cluster

1. Connect to a DB instance in the active-active cluster using a SQL client.

For more information about connecting to an RDS for MySQL DB instance, see [Connecting to a DB instance running the MySQL database engine](#).

2. In the SQL client, call the [mysql.rds\\_group\\_replication\\_stop](#) stored procedure:

```
call mysql.rds_group_replication_stop();
```

## Renaming a DB instance in an active-active cluster

You can change the name of a DB instance in an active-active cluster. To rename more than one DB instance in an active-active cluster, do so one DB instance at a time. So, rename one DB instance and rejoin it to the cluster before you rename the next DB instance.

### To rename a DB instance in an active-active cluster

1. Connect to the DB instance in a SQL client, and call the [mysql.rds\\_group\\_replication\\_stop](#) stored procedure:

```
call mysql.rds_group_replication_stop();
```

2. Rename the DB instance by following the instructions in [Renaming a DB instance](#).
3. Modify the `group_replication_group_seeds` parameter in each DB parameter group associated with a DB instance in the active-active cluster.

In the parameter setting, replace the old DB instance endpoint with the new DB instance endpoint. For more information about setting parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

4. Connect to the DB instance in a SQL client, and call the [mysql.rds\\_group\\_replication\\_start](#) stored procedure:

```
call mysql.rds_group_replication_start(0);
```

## Removing a DB instance from an active-active cluster

When you remove a DB instance from an active-active cluster, it reverts to a standalone DB instance.

### To remove a DB instance from an active-active cluster

1. Connect to the DB instance in a SQL client, and call the [mysql.rds\\_group\\_replication\\_stop](#) stored procedure:

```
call mysql.rds_group_replication_stop();
```

2. Modify the `group_replication_group_seeds` parameter for the DB instances that will remain in the active-active cluster.

In the `group_replication_group_seeds` parameter, delete the DB instance that you are removing from the active-active cluster. For more information about setting parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

3. Modify the parameters of the DB instance you are removing from the active-active cluster so that it is no longer part of the cluster.

You can either associate the DB instance with a different parameter group, or modify the parameters in the DB parameter group associated with the DB instance. The parameters to modify include `group_replication_group_name`, `rds.group_replication_enabled`, and `group_replication_group_seeds`. For more information about active-active cluster parameters, see [Required parameter settings for active-active clusters](#).

If you modify the parameters in a DB parameter group, make sure the DB parameter group isn't associated with other DB instances in the active-active cluster.

4. Reboot the DB instance you removed from the active-active cluster for the new parameter settings to take effect.

For instructions, see [Rebooting a DB instance](#).

## Limitations for RDS for MySQL active-active clusters

The following limitations apply to active-active clusters for RDS for MySQL:

- The master user name can't be `rdsgirprepladmin` for DB instances in an active-active cluster. This user name is reserved for Group Replication connections.
- For DB instances with read replicas in active-active clusters, a prolonged replication status other than `Replicating` can cause log files to exceed storage limits. For information about the status of read replicas, see [Monitoring read replication](#).
- Blue/green deployments aren't supported for DB instances in an active-active cluster. For more information, see [Using Amazon RDS Blue/Green Deployments for database updates](#).
- Kerberos authentication isn't supported for DB instances in an active-active cluster. For more information, see [Using Kerberos authentication for MySQL](#).
- The DB instances in a Multi-AZ DB cluster can't be added to an active-active cluster.

However, the DB instances in a Multi-AZ DB instance deployment can be added to an active-active cluster.

For more information, see [Configuring and managing a Multi-AZ deployment](#).

- Tables that don't have a primary key aren't replicated in an active-active cluster because writes are rejected by the Group Replication plugin.
- Non-InnoDB tables aren't replicated in an active-active cluster.
- Active-active clusters don't support concurrent DML and DDL statements on different DB instances in the cluster.
- You can't configure an active-active cluster to use single-primary mode for the group's replication mode. For this configuration, we recommend using a Multi-AZ DB cluster instead. For more information, see [Multi-AZ DB cluster deployments](#).
- Multi-source replication isn't supported for DB instances in an active-active cluster.
- A cross-Region active-active cluster can't enforce certificate authority (CA) verification for Group Replication connections.

## Exporting data from a MySQL DB instance by using replication

To export data from an RDS for MySQL DB instance to a MySQL instance running external to Amazon RDS, you can use replication. In this scenario, the MySQL DB instance is the *source MySQL DB instance*, and the MySQL instance running external to Amazon RDS is the *external MySQL database*.

The external MySQL database can run either on-premises in your data center, or on an Amazon EC2 instance. The external MySQL database must run the same version as the source MySQL DB instance, or a later version.

Replication to an external MySQL database is only supported during the time it takes to export a database from the source MySQL DB instance. The replication should be terminated when the data has been exported and applications can start accessing the external MySQL instance.

The following list shows the steps to take. Each step is discussed in more detail in later sections.

1. Prepare an external MySQL DB instance.
2. Prepare the source MySQL DB instance for replication.
3. Use the `mysqldump` utility to transfer the database from the source MySQL DB instance to the external MySQL database.
4. Start replication to the external MySQL database.
5. After the export completes, stop replication.

### Prepare an external MySQL database

Perform the following steps to prepare the external MySQL database.

#### To prepare the external MySQL database

1. Install the external MySQL database.
2. Connect to the external MySQL database as the master user. Then create the users required to support the administrators, applications, and services that access the database.
3. Follow the directions in the MySQL documentation to prepare the external MySQL database as a replica. For more information, see [Setting the Replica Configuration](#) in the MySQL documentation.

4. Configure an egress rule for the external MySQL database to operate as a read replica during the export. The egress rule allows the external MySQL database to connect to the source MySQL DB instance during replication. Specify an egress rule that allows Transmission Control Protocol (TCP) connections to the port and IP address of the source MySQL DB instance.

Specify the appropriate egress rules for your environment:

- If the external MySQL database is running in an Amazon EC2 instance in a virtual private cloud (VPC) based on the Amazon VPC service, specify the egress rules in a VPC security group. For more information, see [Controlling access with security groups](#).
  - If the external MySQL database is installed on-premises, specify the egress rules in a firewall.
5. If the external MySQL database is running in a VPC, configure rules for the VPC access control list (ACL) rules in addition to the security group egress rule:
    - Configure an ACL ingress rule allowing TCP traffic to ports 1024–65535 from the IP address of the source MySQL DB instance.
    - Configure an ACL egress rule allowing outbound TCP traffic to the port and IP address of the source MySQL DB instance.

For more information about Amazon VPC network ACLs, see [Network ACLs](#) in *Amazon VPC User Guide*.

6. (Optional) Set the `max_allowed_packet` parameter to the maximum size to avoid replication errors. We recommend this setting.

## Prepare the source MySQL DB instance

Perform the following steps to prepare the source MySQL DB instance as the replication source.

### To prepare the source MySQL DB instance

1. Ensure that your client computer has enough disk space available to save the binary logs while setting up replication.
2. Connect to the source MySQL DB instance, and create a replication account by following the directions in [Creating a User for Replication](#) in the MySQL documentation.
3. Configure ingress rules on the system running the source MySQL DB instance to allow the external MySQL database to connect during replication. Specify an ingress rule that allows

TCP connections to the port used by the source MySQL DB instance from the IP address of the external MySQL database.

4. Specify the egress rules:
  - If the source MySQL DB instance is running in a VPC, specify the ingress rules in a VPC security group. For more information, see [Controlling access with security groups](#).
5. If source MySQL DB instance is running in a VPC, configure VPC ACL rules in addition to the security group ingress rule:
  - Configure an ACL ingress rule to allow TCP connections to the port used by the Amazon RDS instance from the IP address of the external MySQL database.
  - Configure an ACL egress rule to allow TCP connections from ports 1024–65535 to the IP address of the external MySQL database.

For more information about Amazon VPC network ACLs, see [Network ACLs](#) in the *Amazon VPC User Guide*.

6. Ensure that the backup retention period is set long enough that no binary logs are purged during the export. If any of the logs are purged before the export has completed, you must restart replication from the beginning. For more information about setting the backup retention period, see [Introduction to backups](#).
7. Use the `mysql.rds_set_configuration` stored procedure to set the binary log retention period long enough that the binary logs aren't purged during the export. For more information, see [Accessing MySQL binary logs](#).
8. Create an Amazon RDS read replica from the source MySQL DB instance to further ensure that the binary logs of the source MySQL DB instance are not purged. For more information, see [Creating a read replica](#).
9. After the Amazon RDS read replica has been created, call the `mysql.rds_stop_replication` stored procedure to stop the replication process. The source MySQL DB instance no longer purges its binary log files, so they are available for the replication process.
10. (Optional) Set both the `max_allowed_packet` parameter and the `slave_max_allowed_packet` parameter to the maximum size to avoid replication errors. The maximum size for both parameters is 1 GB. We recommend this setting for both parameters. For information about setting parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

## Copy the database

Perform the following steps to copy the database.

### To copy the database

1. Connect to the RDS read replica of the source MySQL DB instance, and run the MySQL `SHOW REPLICA STATUS\G` statement. Note the values for the following:

- `Master_Host`
- `Master_Port`
- `Master_Log_File`
- `Exec_Master_Log_Pos`

#### Note

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

2. Use the `mysqldump` utility to create a snapshot, which copies the data from Amazon RDS to your local client computer. Ensure that your client computer has enough space to hold the `mysqldump` files from the databases to be replicated. This process can take several hours for very large databases. Follow the directions in [Creating a Data Snapshot Using mysqldump](#) in the MySQL documentation.

The following example runs `mysqldump` on a client and writes the dump to a file.

For Linux, macOS, or Unix:

```
mysqldump -h source_MySQL_DB_instance_endpoint \  
  -u user \  
  -ppassword \  
  --port=3306 \  
  --single-transaction \  
  --routines \  
  --triggers \  
  --databases database database2 > path/rds-dump.sql
```

## For Windows:

```
mysqldump -h source_MySQL_DB_instance_endpoint ^  
  -u user ^  
  -ppassword ^  
  --port=3306 ^  
  --single-transaction ^  
  --routines ^  
  --triggers ^  
  --databases database database2 > path\rds-dump.sql
```

You can load the backup file into the external MySQL database. For more information, see [Reloading SQL-Format Backups](#) in the MySQL documentation. You can run another utility to load the data into the external MySQL database.

## Complete the export

Perform the following steps to complete the export.

### To complete the export

1. Use the MySQL `CHANGE MASTER` statement to configure the external MySQL database. Specify the ID and password of the user granted `REPLICATION SLAVE` permissions. Specify the `Master_Host`, `Master_Port`, `Relay_Master_Log_File`, and `Exec_Master_Log_Pos` values that you got from the MySQL `SHOW REPLICATION STATUS` statement that you ran on the RDS read replica. For more information, see [CHANGE MASTER TO Statement](#) in the MySQL documentation.

#### Note

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICATION STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

2. Use the MySQL `START REPLICATION` command to initiate replication from the source MySQL DB instance to the external MySQL database.

Doing this starts replication from the source MySQL DB instance and exports all source changes that have occurred after you stopped replication from the Amazon RDS read replica.

 **Note**

Previous versions of MySQL used `START SLAVE` instead of `START REPLICA`. If you are using a MySQL version before 8.0.23, then use `START SLAVE`.

3. Run the MySQL `SHOW REPLICA STATUS\G` command on the external MySQL database to verify that it is operating as a read replica. For more information about interpreting the results, see [SHOW SLAVE | REPLICA STATUS Statement](#) in the MySQL documentation.
4. After replication on the external MySQL database has caught up with the source MySQL DB instance, use the MySQL `STOP REPLICA` command to stop replication from the source MySQL DB instance.

 **Note**

Previous versions of MySQL used `STOP SLAVE` instead of `STOP REPLICA`. If you are using a MySQL version before 8.0.23, then use `STOP SLAVE`.

5. On the Amazon RDS read replica, call the `mysql.rds_start_replication` stored procedure. Doing this allows Amazon RDS to start purging the binary log files from the source MySQL DB instance.

## Options for MySQL DB instances

Following, you can find a description of options, or additional features, that are available for Amazon RDS instances running the MySQL DB engine. To enable these options, you can add them to a custom option group, and then associate the option group with your DB instance. For more information about working with option groups, see [Working with option groups](#).

Amazon RDS supports the following options for MySQL:

Option	Option ID	Engine versions
<a href="#">MariaDB Audit Plugin support for MySQL</a>	MARIADB_AUDIT_PLUGIN	MySQL 8.0.28 and higher 8.0 versions  All MySQL 5.7 versions
<a href="#">MySQL memcached support</a>	MEMCACHED	All MySQL 5.7 and 8.0 versions

## MariaDB Audit Plugin support for MySQL

Amazon RDS offers an audit plugin for MySQL database instances based on the open source MariaDB Audit Plugin. For more information, see the [Audit Plugin for MySQL Server GitHub repository](#).

### Note

The audit plugin for MySQL is based on the MariaDB Audit Plugin. Throughout this article, we refer to it as MariaDB Audit Plugin.

The MariaDB Audit Plugin records database activity, including users logging on to the database and queries run against the database. The record of database activity is stored in a log file.

### Note

Currently, the MariaDB Audit Plugin is only supported for the following RDS for MySQL versions:

- MySQL 8.0.28 and higher 8.0 versions
- All MySQL 5.7 versions

## Audit Plugin option settings

Amazon RDS supports the following settings for the MariaDB Audit Plugin option.

Option setting	Valid values	Default value	Description
SERVER_AUDIT_FILE_PATH	/rdsdbdata/log/audit/	/rdsdbdata/log/audit/	The location of the log file. The log file contains the record of the activity specified in <code>SERVER_AUDIT_EVENTS</code> . For more information, see <a href="#">Viewing and listing database log files</a> and <a href="#">MySQL database log files</a> .

Option setting	Valid values	Default value	Description
SERVER_AUDIT_FILE_ROTATE_SIZE	1–100000000	1000000	The size in bytes that when reached, causes the file to rotate. For more information, see <a href="#">Overview of RDS for MySQL database logs</a> .
SERVER_AUDIT_FILE_ROTATIONS	0–100	9	The number of log rotations to save when <code>server_audit_output_type=file</code> . If set to 0, then the log file never rotates. For more information, see <a href="#">Overview of RDS for MySQL database logs</a> and <a href="#">Downloading a database log file</a> .

Option setting	Valid values	Default value	Description
SERVER_AUDIT_EVENTS	CONNECT, QUERY, QUERY_DDL, , QUERY_DML, , QUERY_DML_NO_SELECT, , QUERY_DCL	CONNECT, QUERY	<p>The types of activity to record in the log. Installing the MariaDB Audit Plugin is itself logged.</p> <ul style="list-style-type: none"> <li>• <b>CONNECT</b>: Log successful and unsuccessful connections to the database, and disconnections from the database.</li> <li>• <b>QUERY</b>: Log the text of all queries run against the database.</li> <li>• <b>QUERY_DDL</b> : Similar to the <b>QUERY</b> event, but returns only data definition language (DDL) queries (CREATE, ALTER, and so on).</li> <li>• <b>QUERY_DML</b> : Similar to the <b>QUERY</b> event, but returns only data manipulation language (DML) queries (INSERT, UPDATE, and so on, and also SELECT).</li> <li>• <b>QUERY_DML_NO_SELECT</b> : Similar to the <b>QUERY_DML</b> event, but doesn't log SELECT queries.</li> </ul> <p>The <b>QUERY_DML_NO_SELECT</b> setting is supported only for RDS for MySQL 5.7.34 and higher 5.7 versions, and 8.0.25 and higher 8.0 versions.</p> <ul style="list-style-type: none"> <li>• <b>QUERY_DCL</b> : Similar to the <b>QUERY</b> event, but returns only data control language (DCL) queries (GRANT, REVOKE, and so on).</li> </ul> <p>For MySQL, <b>TABLE</b> is not supported.</p>

Option setting	Valid values	Default value	Description
SERVER_AUDIT_INCL_USERS	Multiple comma-separated values	None	<p>Include only activity from the specified users. By default, activity is recorded for all users. <code>SERVER_AUDIT_INCL_USERS</code> and <code>SERVER_AUDIT_EXCL_USERS</code> are mutually exclusive. If you add values to <code>SERVER_AUDIT_INCL_USERS</code>, make sure no values are added to <code>SERVER_AUDIT_EXCL_USERS</code>.</p>
SERVER_AUDIT_EXCL_USERS	Multiple comma-separated values	None	<p>Exclude activity from the specified users. By default, activity is recorded for all users. <code>SERVER_AUDIT_INCL_USERS</code> and <code>SERVER_AUDIT_EXCL_USERS</code> are mutually exclusive. If you add values to <code>SERVER_AUDIT_EXCL_USERS</code>, make sure no values are added to <code>SERVER_AUDIT_INCL_USERS</code>.</p> <p>The <code>rdsadmin</code> user queries the database every second to check the health of the database. Depending on your other settings, this activity can possibly cause the size of your log file to grow very large, very quickly. If you don't need to record this activity, add the <code>rdsadmin</code> user to the <code>SERVER_AUDIT_EXCL_USERS</code> list.</p> <div data-bbox="829 1423 1507 1692" style="border: 1px solid #00a0e3; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p> <b>Note</b></p> <p>CONNECT activity is always recorded for all users, even if the user is specified for this option setting.</p> </div>

Option setting	Valid values	Default value	Description
SERVER_AUDIT_LOGGING	ON	ON	Logging is active. The only valid value is ON. Amazon RDS does not support deactivating logging. If you want to deactivate logging, remove the MariaDB Audit Plugin. For more information, see <a href="#">Removing the MariaDB Audit Plugin</a> .
SERVER_AUDIT_QUERY_LOG_LIMIT	0–2147483647	1024	The limit on the length of the query string in a record.

## Adding the MariaDB Audit Plugin

The general process for adding the MariaDB Audit Plugin to a DB instance is the following:

- Create a new option group, or copy or modify an existing option group
- Add the option to the option group
- Associate the option group with the DB instance

After you add the MariaDB Audit Plugin, you don't need to restart your DB instance. As soon as the option group is active, auditing begins immediately.

### Important

Adding the MariaDB Audit Plugin to a DB instance might cause an outage. We recommend adding the MariaDB Audit Plugin during a maintenance window or during a time of low database workload.

## To add the MariaDB Audit Plugin

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step.

Otherwise, create a custom DB option group. Choose **mysql** for **Engine**, and choose **5.7** or **8.0** for **Major engine version**. For more information, see [Creating an option group](#).

2. Add the **MARIADB\_AUDIT\_PLUGIN** option to the option group, and configure the option settings. For more information about adding options, see [Adding an option to an option group](#). For more information about each setting, see [Audit Plugin option settings](#).
3. Apply the option group to a new or existing DB instance.
  - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
  - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](#).

## Audit log format

Log files are represented as comma-separated variable (CSV) files in UTF-8 format.

### Tip

Log file entries are not in sequential order. To order the entries, use the timestamp value. To see the latest events, you might have to review all log files. For more flexibility in sorting and searching the log data, turn on the setting to upload the audit logs to CloudWatch and view them using the CloudWatch interface.

To view audit data with more types of fields and with output in JSON format, you can also use the Database Activity Streams feature. For more information, see [Monitoring Amazon RDS with Database Activity Streams](#).

The audit log files include the following comma-delimited information in rows, in the specified order:

Field	Description
timestamp	The YYYYMMDD followed by the HH:MI:SS (24-hour clock) for the logged event.
serverhost	The name of the instance that the event is logged for.

Field	Description
username	The connected user name of the user.
host	The host that the user connected from.
connectionid	The connection ID number for the logged operation.
queryid	The query ID number, which can be used for finding the relational table events and related queries. For TABLE events, multiple lines are added.
operation	The recorded action type. Possible values are: CONNECT, QUERY, READ, WRITE, CREATE, ALTER, RENAME, and DROP.
database	The active database, as set by the USE command.
object	For QUERY events, this value indicates the query that the database performed. For TABLE events, it indicates the table name.
retcode	The return code of the logged operation.
connection_type	<p>The security state of the connection to the server. Possible values are:</p> <ul style="list-style-type: none"> <li>• 0 – Undefined</li> <li>• 1 – TCP/IP</li> <li>• 2 – Socket</li> <li>• 3 – Named pipe</li> <li>• 4 – SSL/TLS</li> <li>• 5 – Shared memory</li> </ul> <p>This field is included only for RDS for MySQL version 5.7.34 and higher 5.7 versions, and all 8.0 versions.</p>

## Viewing and downloading the MariaDB Audit Plugin log

After you enable the MariaDB Audit Plugin, you access the results in the log files the same way you access any other text-based log files. The audit log files are located at `/rdsdbdata/log/audit/`.

For information about viewing the log file in the console, see [Viewing and listing database log files](#). For information about downloading the log file, see [Downloading a database log file](#).

## Modifying MariaDB Audit Plugin settings

After you enable the MariaDB Audit Plugin, you can modify the settings. For more information about how to modify option settings, see [Modifying an option setting](#). For more information about each setting, see [Audit Plugin option settings](#).

## Removing the MariaDB Audit Plugin

Amazon RDS doesn't support turning off logging in the MariaDB Audit Plugin. However, you can remove the plugin from a DB instance. When you remove the MariaDB Audit Plugin, the DB instance is restarted automatically to stop auditing.

To remove the MariaDB Audit Plugin from a DB instance, do one of the following:

- Remove the MariaDB Audit Plugin option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group](#)
- Modify the DB instance and specify a different option group that doesn't include the plugin. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance](#).

## MySQL memcached support

Amazon RDS supports using the memcached interface to InnoDB tables that was introduced in MySQL 5.6. The memcached API enables applications to use InnoDB tables in a manner similar to NoSQL key-value data stores.

The memcached interface is a simple, key-based cache. Applications use memcached to insert, manipulate, and retrieve key-value data pairs from the cache. MySQL 5.6 introduced a plugin that implements a daemon service that exposes data from InnoDB tables through the memcached protocol. For more information about the MySQL memcached plugin, see [InnoDB integration with memcached](#).

### To enable memcached support for an RDS for MySQL DB instance

1. Determine the security group to use for controlling access to the memcached interface. If the set of applications already using the SQL interface are the same set that will access the memcached interface, you can use the existing VPC security group used by the SQL interface. If a different set of applications will access the memcached interface, define a new VPC or DB security group. For more information about managing security groups, see [Controlling access with security groups](#)
2. Create a custom DB option group, selecting MySQL as the engine type and version. For more information about creating an option group, see [Creating an option group](#).
3. Add the MEMCACHED option to the option group. Specify the port that the memcached interface will use, and the security group to use in controlling access to the interface. For more information about adding options, see [Adding an option to an option group](#).
4. Modify the option settings to configure the memcached parameters, if necessary. For more information about how to modify option settings, see [Modifying an option setting](#).
5. Apply the option group to an instance. Amazon RDS enables memcached support for that instance when the option group is applied:
  - You enable memcached support for a new instance by specifying the custom option group when you launch the instance. For more information about launching a MySQL instance, see [Creating an Amazon RDS DB instance](#).
  - You enable memcached support for an existing instance by specifying the custom option group when you modify the instance. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#).

6. Specify which columns in your MySQL tables can be accessed through the memcached interface. The memcached plug-in creates a catalog table named `containers` in a dedicated database named `innodb_memcache`. You insert a row into the `containers` table to map an InnoDB table for access through memcached. You specify a column in the InnoDB table that is used to store the memcached key values, and one or more columns that are used to store the data values associated with the key. You also specify a name that a memcached application uses to refer to that set of columns. For details on inserting rows in the `containers` table, see [InnoDB memcached plugin internals](#). For an example of mapping an InnoDB table and accessing it through memcached, see [Writing applications for the InnoDB memcached plugin](#).
7. If the applications accessing the memcached interface are on different computers or EC2 instances than the applications using the SQL interface, add the connection information for those computers to the VPC security group associated with the MySQL instance. For more information about managing security groups, see [Controlling access with security groups](#).

You turn off the memcached support for an instance by modifying the instance and specifying the default option group for your MySQL version. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#).

## MySQL memcached security considerations

The memcached protocol does not support user authentication. For more information about MySQL memcached security considerations, see [Security Considerations for the InnoDB memcached Plugin](#) in the MySQL documentation.

You can take the following actions to help increase the security of the memcached interface:

- Specify a different port than the default of 11211 when adding the MEMCACHED option to the option group.
- Ensure that you associate the memcached interface with a VPC security group that limits access to known, trusted client addresses and EC2 instances. For more information about managing security groups, see [Controlling access with security groups](#).

## MySQL memcached connection information

To access the memcached interface, an application must specify both the DNS name of the Amazon RDS instance and the memcached port number. For example, if an instance has a DNS name of my-

cache-instance.cg034hpkmmjt.region.rds.amazonaws.com and the memcached interface is using port 11212, the connection information specified in PHP would be:

```
<?php
$cache = new Memcache;
$cache->connect('my-cache-instance.cg034hpkmmjt.region.rds.amazonaws.com',11212);
?>
```

## To find the DNS name and memcached port of a MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the top right corner of the AWS Management Console, select the region that contains the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose the MySQL DB instance name to display its details.
5. In the **Connect** section, note the value of the **Endpoint** field. The DNS name is the same as the endpoint. Also, note that the port in the **Connect** section is not used to access the memcached interface.
6. In the **Details** section, note the name listed in the **Option Group** field.
7. In the navigation pane, choose **Option groups**.
8. Choose the name of the option group used by the MySQL DB instance to show the option group details. In the **Options** section, note the value of the **Port** setting for the **MEMCACHED** option.

## MySQL memcached option settings

Amazon RDS exposes the MySQL memcached parameters as option settings in the Amazon RDS MEMCACHED option.

### MySQL memcached parameters

- DAEMON\_MEMCACHED\_R\_BATCH\_SIZE – an integer that specifies how many memcached read operations (get) to perform before doing a COMMIT to start a new transaction. The allowed

values are 1 to 4294967295; the default is 1. The option does not take effect until the instance is restarted.

- `DAEMON_MEMCACHED_W_BATCH_SIZE` – an integer that specifies how many memcached write operations, such as add, set, or incr, to perform before doing a COMMIT to start a new transaction. The allowed values are 1 to 4294967295; the default is 1. The option does not take effect until the instance is restarted.
- `INNODB_API_BK_COMMIT_INTERVAL` – an integer that specifies how often to auto-commit idle connections that use the InnoDB memcached interface. The allowed values are 1 to 1073741824; the default is 5. The option takes effect immediately, without requiring that you restart the instance.
- `INNODB_API_DISABLE_ROWLOCK` – a Boolean that disables (1 (true)) or enables (0 (false)) the use of row locks when using the InnoDB memcached interface. The default is 0 (false). The option does not take effect until the instance is restarted.
- `INNODB_API_ENABLE_MDL` – a Boolean that when set to 0 (false) locks the table used by the InnoDB memcached plugin, so that it cannot be dropped or altered by DDL through the SQL interface. The default is 0 (false). The option does not take effect until the instance is restarted.
- `INNODB_API_TRX_LEVEL` – an integer that specifies the transaction isolation level for queries processed by the memcached interface. The allowed values are 0 to 3. The default is 0. The option does not take effect until the instance is restarted.

Amazon RDS configures these MySQL memcached parameters, and they cannot be modified: `DAEMON_MEMCACHED_LIB_NAME`, `DAEMON_MEMCACHED_LIB_PATH`, and `INNODB_API_ENABLE_BINLOG`. The parameters that MySQL administrators set by using `daemon_memcached_options` are available as individual MEMCACHED option settings in Amazon RDS.

### MySQL `daemon_memcached_options` parameters

- `BINDING_PROTOCOL` – a string that specifies the binding protocol to use. The allowed values are `auto`, `ascii`, or `binary`. The default is `auto`, which means the server automatically negotiates the protocol with the client. The option does not take effect until the instance is restarted.
- `BACKLOG_QUEUE_LIMIT` – an integer that specifies how many network connections can be waiting to be processed by memcached. Increasing this limit may reduce errors received by a client that is not able to connect to the memcached instance, but does not improve the performance of the server. The allowed values are 1 to 2048; the default is 1024. The option does not take effect until the instance is restarted.

- `CAS_DISABLED` – a Boolean that enables (1 (true)) or disables (0 (false)) the use of compare and swap (CAS), which reduces the per-item size by 8 bytes. The default is 0 (false). The option does not take effect until the instance is restarted.
- `CHUNK_SIZE` – an integer that specifies the minimum chunk size, in bytes, to allocate for the smallest item's key, value, and flags. The allowed values are 1 to 48. The default is 48 and you can significantly improve memory efficiency with a lower value. The option does not take effect until the instance is restarted.
- `CHUNK_SIZE_GROWTH_FACTOR` – a float that controls the size of new chunks. The size of a new chunk is the size of the previous chunk times `CHUNK_SIZE_GROWTH_FACTOR`. The allowed values are 1 to 2; the default is 1.25. The option does not take effect until the instance is restarted.
- `ERROR_ON_MEMORY_EXHAUSTED` – a Boolean that when set to 1 (true) specifies that memcached will return an error rather than evicting items when there is no more memory to store items. If set to 0 (false), memcached will evict items if there is no more memory. The default is 0 (false). The option does not take effect until the instance is restarted.
- `MAX_SIMULTANEOUS_CONNECTIONS` – an integer that specifies the maximum number of concurrent connections. Setting this value to anything under 10 prevents MySQL from starting. The allowed values are 10 to 1024; the default is 1024. The option does not take effect until the instance is restarted.
- `VERBOSITY` – a string that specifies the level of information logged in the MySQL error log by the memcached service. The default is `v`. The option does not take effect until the instance is restarted. The allowed values are:
  - `v` – Logs errors and warnings while running the main event loop.
  - `vv` – In addition to the information logged by `v`, also logs each client command and the response.
  - `vvv` – In addition to the information logged by `vv`, also logs internal state transitions.

Amazon RDS configures these MySQL `DAEMON_MEMCACHED_OPTIONS` parameters, they cannot be modified: `DAEMON_PROCESS`, `LARGE_MEMORY_PAGES`, `MAXIMUM_CORE_FILE_LIMIT`, `MAX_ITEM_SIZE`, `LOCK_DOWN_PAGE_MEMORY`, `MASK`, `IDFILE`, `REQUESTS_PER_EVENT`, `SOCKET`, and `USER`.

# Parameters for MySQL

By default, a MySQL DB instance uses a DB parameter group that is specific to a MySQL database. This parameter group contains parameters for the MySQL database engine. For information about working with parameter groups and setting parameters, see [Parameter groups for Amazon RDS](#).

RDS for MySQL parameters are set to the default values of the storage engine that you have selected. For more information about MySQL parameters, see the [MySQL documentation](#). For more information about MySQL storage engines, see [Supported storage engines for RDS for MySQL](#).

You can view the parameters available for a specific RDS for MySQL version using the RDS console or the AWS CLI. For information about viewing the parameters in a MySQL parameter group in the RDS console, see [Viewing parameter values for a DB parameter group in Amazon RDS](#).

Using the AWS CLI, you can view the parameters for an RDS for MySQL version by running the [describe-engine-default-parameters](#) command. Specify one of the following values for the `--db-parameter-group-family` option:

- `mysql8.0`
- `mysql5.7`

For example, to view the parameters for RDS for MySQL version 8.0, run the following command.

```
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0
```

Your output looks similar to the following.

```
{
  "EngineDefaults": {
    "Parameters": [
      {
        "ParameterName": "activate_all_roles_on_login",
        "ParameterValue": "0",
        "Description": "Automatically set all granted roles as active after the
user has authenticated successfully.",
        "Source": "engine-default",
        "ApplyType": "dynamic",
        "DataType": "boolean",
        "AllowedValues": "0,1",
        "IsModifiable": true
      }
    ]
  }
}
```

```

    },
    {
      "ParameterName": "allow-suspicious-udfs",
      "Description": "Controls whether user-defined functions that have only
an xxx symbol for the main function can be loaded",
      "Source": "engine-default",
      "ApplyType": "static",
      "DataType": "boolean",
      "AllowedValues": "0,1",
      "IsModifiable": false
    },
    {
      "ParameterName": "auto_generate_certs",
      "Description": "Controls whether the server autogenerates SSL key and
certificate files in the data directory, if they do not already exist.",
      "Source": "engine-default",
      "ApplyType": "static",
      "DataType": "boolean",
      "AllowedValues": "0,1",
      "IsModifiable": false
    },
    },
    ...

```

To list only the modifiable parameters for RDS for MySQL version 8.0, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0 \
--query 'EngineDefaults.Parameters[?IsModifiable==`true`]'
```

For Windows:

```
aws rds describe-engine-default-parameters --db-parameter-group-family mysql8.0 ^
--query "EngineDefaults.Parameters[?IsModifiable==`true`]"
```

# Common DBA tasks for MySQL DB instances

In the following content, you can find descriptions of the Amazon RDS-specific implementations of some common DBA tasks for DB instances running the MySQL database engine. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Also, it restricts access to certain system procedures and tables that require advanced privileges.

For information about working with MySQL log files on Amazon RDS, see [MySQL database log files](#).

## Topics

- [Understanding predefined users](#)
- [Role-based privilege model](#)
- [Dynamic privileges](#)
- [Ending a session or query](#)
- [Skipping the current replication error](#)
- [Working with InnoDB tablespaces to improve crash recovery times](#)
- [Managing the Global Status History](#)

## Understanding predefined users

Amazon RDS automatically creates several predefined users with new RDS for MySQL DB instances. Predefined users and their privileges can't be changed. You can't drop, rename, or modify privileges for these predefined users. Attempting to do so results in an error.

- **rdsadmin** – A user that's created to handle many of the management tasks that the administrator with `superuser` privileges would perform on a standalone MySQL database. This user is used internally by RDS for MySQL for many management tasks.
- **rdsrepladmin** – A user that's used internally by Amazon RDS to support replication activities on RDS for MySQL DB instances and clusters.

## Role-based privilege model

Starting with RDS for MySQL version 8.0.36, you can't modify the tables in the `mysql` database directly. In particular, you can't create database users by performing data manipulation language (DML) operations on the `grant` tables. Instead, you use MySQL account-management statements

such as `CREATE USER`, `GRANT`, and `REVOKE` to grant role-based privileges to users. You also can't create other kinds of objects such as stored procedures in the `mysql` database. You can still query the `mysql` tables. If you use binary log replication, changes made directly to the `mysql` tables on the source DB instance aren't replicated to the target cluster.

In some cases, your application might use shortcuts to create users or other objects by inserting into the `mysql` tables. If so, change your application code to use the corresponding statements such as `CREATE USER`.

To export metadata for database users during the migration from an external MySQL database, use one of the following methods:

- Use MySQL Shell's instance dump utility with a filter to exclude users, roles, and grants. The following example shows you the command syntax to use. Make sure that `outputUrl` is empty.

```
mysqlsh user@host -- util.dumpInstance(outputUrl,{excludeSchemas:['mysql'],users:
true})
```

For more information, see [Instance Dump Utility, Schema Dump Utility, and Table Dump Utility](#) in the MySQL Reference Manual.

- Use the `mysqlpump` client utility. This example includes all tables except for tables in the `mysql` system database. It also includes `CREATE USER` and `GRANT` statements to reproduce all MySQL users in the migrated database.

```
mysqlpump --exclude-databases=mysql --users
```

To simplify managing permissions for many users or applications, you can use the `CREATE ROLE` statement to create a role that has a set of permissions. Then you can use the `GRANT` and `SET ROLE` statements and the `current_role` function to assign roles to users or applications, switch the current role, and check which roles are in effect. For more information on the role-based permission system in MySQL 8.0, see [Using Roles](#) in the MySQL Reference Manual.

### Important

We strongly recommend that you do not use the master user directly in your applications. Instead, adhere to the best practice of using a database user created with the minimal privileges required for your application.

Starting with version 8.0.36, RDS for MySQL includes a special role that has all of the following privileges. This role is named `rds_superuser_role`. The primary administrative user for each DB instance already has this role granted. The `rds_superuser_role` role includes the following privileges for all database objects:

- ALTER
- APPLICATION\_PASSWORD\_ADMIN
- ALTER ROUTINE
- CREATE
- CREATE ROLE
- CREATE ROUTINE
- CREATE TEMPORARY TABLES
- CREATE USER
- CREATE VIEW
- DELETE
- DROP
- DROP ROLE
- EVENT
- EXECUTE
- INDEX
- INSERT
- LOCK TABLES
- PROCESS
- REFERENCES
- RELOAD
- REPLICATION CLIENT
- REPLICATION SLAVE
- ROLE\_ADMIN
- SET\_USER\_ID
- SELECT
- SHOW DATABASES

- SHOW VIEW
- TRIGGER
- UPDATE
- XA\_RECOVER\_ADMIN

The role definition also includes `WITH GRANT OPTION` so that an administrative user can grant that role to other users. In particular, the administrator must grant any privileges needed to perform binary log replication with the MySQL cluster as the target.

### Tip

To see the full details of the permissions, use the following statement.

```
SHOW GRANTS FOR rds_superuser_role@'%';
```

When you grant access by using roles in RDS for MySQL version 8.0.36 and higher, you also activate the role by using the `SET ROLE role_name` or `SET ROLE ALL` statement. The following example shows how. Substitute the appropriate role name for `CUSTOM_ROLE`.

```
# Grant role to user
mysql> GRANT CUSTOM_ROLE TO 'user'@'domain-or-ip-address'

# Check the current roles for your user. In this case, the CUSTOM_ROLE role has not
# been activated.
# Only the rds_superuser_role is currently in effect.
mysql> SELECT CURRENT_ROLE();
+-----+
| CURRENT_ROLE()          |
+-----+
| `rds_superuser_role`@`%` |
+-----+
1 row in set (0.00 sec)

# Activate all roles associated with this user using SET ROLE.
# You can activate specific roles or all roles.
# In this case, the user only has 2 roles, so we specify ALL.
mysql> SET ROLE ALL;
Query OK, 0 rows affected (0.00 sec)
```

```
# Verify role is now active
mysql> SELECT CURRENT_ROLE();
+-----+
| CURRENT_ROLE() |
+-----+
| `CUSTOM_ROLE`@`%`,`rds_superuser_role`@`%` |
+-----+
```

## Dynamic privileges

Dynamic privileges are MySQL privileges that you can explicitly grant by using the GRANT statement. Depending on your version of RDS for MySQL, RDS allows you to grant only specific dynamic privileges. RDS disallows some of these privileges because they can interfere with the specific database operations, such as replication and backup.

The following table shows which of these privileges you can grant for different MySQL versions. If you are upgrading from a MySQL version lower than 8.0.36 to version 8.0.36 or higher, you might have to update your application code if granting a particular privilege is no longer allowed.

Privilege	MySQL 8.0.35 and lower	MySQL 8.0.36 and higher
<a href="#">APPLICATION_PASSWORD_ADMIN</a>	Allowed	Allowed
<a href="#">AUDIT_ABORT_EXEMPT</a>	Allowed	Disallowed
<a href="#">AUDIT_ADMIN</a>	Disallowed	Disallowed
<a href="#">AUTHENTICATION_PLUGIN_ADMIN</a>	Allowed	Disallowed
<a href="#">BACKUP_ADMIN</a>	Allowed	Disallowed
<a href="#">BINLOG_ADMIN</a>	Allowed	Disallowed
<a href="#">BINLOG_ENCRYPTION_ADMIN</a>	Disallowed	Disallowed
<a href="#">CLONE_ADMIN</a>	Disallowed	Disallowed

<b>Privilege</b>	<b>MySQL 8.0.35 and lower</b>	<b>MySQL 8.0.36 and higher</b>
<a href="#"><u>CONNECTION_ADMIN</u></a>	Allowed	Disallowed
<a href="#"><u>ENCRYPTION_KEY_ADMIN</u></a>	Disallowed	Disallowed
<a href="#"><u>FIREWALL_ADMIN</u></a>	Disallowed	Disallowed
<a href="#"><u>FIREWALL_EXEMPT</u></a>	Allowed	Disallowed
<a href="#"><u>FIREWALL_USER</u></a>	Disallowed	Disallowed
<a href="#"><u>FLUSH_OPTIMIZER_COSTS</u></a>	Allowed	Allowed
<a href="#"><u>FLUSH_STATUS</u></a>	Allowed	Allowed
<a href="#"><u>FLUSH_TABLES</u></a>	Allowed	Allowed
<a href="#"><u>FLUSH_USER_RESOURCES</u></a>	Allowed	Allowed
<a href="#"><u>GROUP_REPLICATION_ADMIN</u></a>	Disallowed	Disallowed
<a href="#"><u>GROUP_REPLICATION_STREAM</u></a>	Disallowed	Disallowed
<a href="#"><u>INNODB_REDO_LOG_ENABLE</u></a>	Disallowed	Disallowed
<a href="#"><u>MASKING_DICTIONARIES_ADMIN</u></a>	Disallowed	Disallowed

## Ending a session or query

You can end user sessions or queries on DB instances by using the `rds_kill` and `rds_kill_query` commands. First connect to your MySQL DB instance, then issue the appropriate command as shown following. For more information, see [Connecting to a DB instance running the MySQL database engine](#).

```
CALL mysql.rds_kill(thread-ID)
CALL mysql.rds_kill_query(thread-ID)
```

For example, to end the session that is running on thread 99, you would type the following:

```
CALL mysql.rds_kill(99);
```

To end the query that is running on thread 99, you would type the following:

```
CALL mysql.rds_kill_query(99);
```

## Skipping the current replication error

You can skip an error on your read replica if the error is causing your read replica to stop responding and the error doesn't affect the integrity of your data.

### Note

First verify that the error in question can be safely skipped. In a MySQL utility, connect to the read replica and run the following MySQL command.

```
SHOW REPLICA STATUS\G
```

For information about the values returned, see [the MySQL documentation](#).

Previous versions of and MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

You can skip an error on your read replica in the following ways.

## Topics

- [Calling the `mysql.rds\_skip\_repl\_error` procedure](#)
- [Setting the `slave\_skip\_errors` parameter](#)

## Calling the `mysql.rds_skip_repl_error` procedure

Amazon RDS provides a stored procedure that you can call to skip an error on your read replicas. First connect to your read replica, then issue the appropriate commands as shown following. For more information, see [Connecting to a DB instance running the MySQL database engine](#).

To skip the error, issue the following command.

```
CALL mysql.rds_skip_repl_error;
```

This command has no effect if you run it on the source DB instance, or on a read replica that hasn't encountered a replication error.

For more information, such as the versions of MySQL that support `mysql.rds_skip_repl_error`, see [mysql.rds\\_skip\\_repl\\_error](#).

### Important

If you attempt to call `mysql.rds_skip_repl_error` and encounter the following error: `ERROR 1305 (42000): PROCEDURE mysql.rds_skip_repl_error does not exist`, then upgrade your MySQL DB instance to the latest minor version or one of the minimum minor versions listed in [mysql.rds\\_skip\\_repl\\_error](#).

## Setting the `slave_skip_errors` parameter

To skip one or more errors, you can set the `slave_skip_errors` static parameter on the read replica. You can set this parameter to skip one or more specific replication error codes. Currently, you can set this parameter only for RDS for MySQL 5.7 DB instances. After you change the setting for this parameter, make sure to reboot your DB instance for the new setting to take effect. For information about setting this parameter, see the [MySQL documentation](#).

We recommend setting this parameter in a separate DB parameter group. You can associate this DB parameter group only with the read replicas that need to skip errors. Following this best practice reduces the potential impact on other DB instances and read replicas.

**⚠ Important**

Setting a nondefault value for this parameter can lead to replication inconsistency. Only set this parameter to a nondefault value if you have exhausted other options to resolve the problem and you are sure of the potential impact on your read replica's data.

## Working with InnoDB tablespaces to improve crash recovery times

Every table in MySQL consists of a table definition, data, and indexes. The MySQL storage engine InnoDB stores table data and indexes in a *tablespace*. InnoDB creates a global shared tablespace that contains a data dictionary and other relevant metadata, and it can contain table data and indexes. InnoDB can also create separate tablespaces for each table and partition. These separate tablespaces are stored in files with a .ibd extension and the header of each tablespace contains a number that uniquely identifies it.

Amazon RDS provides a parameter in a MySQL parameter group called `innodb_file_per_table`. This parameter controls whether InnoDB adds new table data and indexes to the shared tablespace (by setting the parameter value to 0) or to individual tablespaces (by setting the parameter value to 1). Amazon RDS sets the default value for `innodb_file_per_table` parameter to 1, which allows you to drop individual InnoDB tables and reclaim storage used by those tables for the DB instance. In most use cases, setting the `innodb_file_per_table` parameter to 1 is the recommended setting.

You should set the `innodb_file_per_table` parameter to 0 when you have a large number of tables, such as over 1000 tables when you use standard (magnetic) or general purpose SSD storage or over 10,000 tables when you use Provisioned IOPS storage. When you set this parameter to 0, individual tablespaces are not created and this can improve the time it takes for database crash recovery.

MySQL processes each metadata file, which includes tablespaces, during the crash recovery cycle. The time it takes MySQL to process the metadata information in the shared tablespace is negligible compared to the time it takes to process thousands of tablespace files when there are multiple tablespaces. Because the tablespace number is stored within the header of each file, the aggregate time to read all the tablespace files can take up to several hours. For example, a million InnoDB tablespaces on standard storage can take from five to eight hours to process during a crash recovery cycle. In some cases, InnoDB can determine that it needs additional cleanup after a crash recovery cycle so it will begin another crash recovery cycle, which will extend the recovery time.

Keep in mind that a crash recovery cycle also entails rolling-back transactions, fixing broken pages, and other operations in addition to the processing of tablespace information.

Since the `innodb_file_per_table` parameter resides in a parameter group, you can change the parameter value by editing the parameter group used by your DB instance without having to reboot the DB instance. After the setting is changed, for example, from 1 (create individual tables) to 0 (use shared tablespace), new InnoDB tables will be added to the shared tablespace while existing tables continue to have individual tablespaces. To move an InnoDB table to the shared tablespace, you must use the `ALTER TABLE` command.

## Migrating multiple tablespaces to the shared tablespace

You can move an InnoDB table's metadata from its own tablespace to the shared tablespace, which will rebuild the table metadata according to the `innodb_file_per_table` parameter setting. First connect to your MySQL DB instance, then issue the appropriate commands as shown following. For more information, see [Connecting to a DB instance running the MySQL database engine](#).

```
ALTER TABLE table_name ENGINE = InnoDB, ALGORITHM=COPY;
```

For example, the following query returns an `ALTER TABLE` statement for every InnoDB table that is not in the shared tablespace.

### For MySQL 5.7 DB instances:

```
SELECT CONCAT('ALTER TABLE `',  
REPLACE(LEFT(NAME , INSTR((NAME), '/') - 1), '`', '``'), `.`',  
REPLACE(SUBSTR(NAME FROM INSTR(NAME, '/') + 1), '`', '``'), ` ` ENGINE=InnoDB,  
ALGORITHM=COPY;') AS Query  
FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES  
WHERE SPACE <> 0 AND LEFT(NAME, INSTR((NAME), '/') - 1) NOT IN ('mysql','');
```

### For MySQL 8.0 DB instances:

```
SELECT CONCAT('ALTER TABLE `',  
REPLACE(LEFT(NAME , INSTR((NAME), '/') - 1), '`', '``'), `.`',  
REPLACE(SUBSTR(NAME FROM INSTR(NAME, '/') + 1), '`', '``'), ` ` ENGINE=InnoDB,  
ALGORITHM=COPY;') AS Query  
FROM INFORMATION_SCHEMA.INNODB_TABLES
```

```
WHERE SPACE <> 0 AND LEFT(NAME, INSTR((NAME), '/') - 1) NOT IN ('mysql','');
```

Rebuilding a MySQL table to move the table's metadata to the shared tablespace requires additional storage space temporarily to rebuild the table, so the DB instance must have storage space available. During rebuilding, the table is locked and inaccessible to queries. For small tables or tables not frequently accessed, this might not be an issue. For large tables or tables frequently accessed in a heavily concurrent environment, you can rebuild tables on a read replica.

You can create a read replica and migrate table metadata to the shared tablespace on the read replica. While the ALTER TABLE statement blocks access on the read replica, the source DB instance is not affected. The source DB instance will continue to generate its binary logs while the read replica lags during the table rebuilding process. Because the rebuilding requires additional storage space and the replay log file can become large, you should create a read replica with storage allocated that is larger than the source DB instance.

To create a read replica and rebuild InnoDB tables to use the shared tablespace, take the following steps:

1. Make sure that backup retention is enabled on the source DB instance so that binary logging is enabled.
2. Use the AWS Management Console or AWS CLI to create a read replica for the source DB instance. Because the creation of a read replica involves many of the same processes as crash recovery, the creation process can take some time if there is a large number of InnoDB tablespaces. Allocate more storage space on the read replica than is currently used on the source DB instance.
3. When the read replica has been created, create a parameter group with the parameter settings `read_only = 0` and `innodb_file_per_table = 0`. Then associate the parameter group with the read replica.
4. Issue the following SQL statement for all tables that you want migrated on the replica:

```
ALTER TABLE name ENGINE = InnoDB
```

5. When all of your ALTER TABLE statements have completed on the read replica, verify that the read replica is connected to the source DB instance and that the two instances are in sync.
6. Use the console or CLI to promote the read replica to be the instance. Make sure that the parameter group used for the new standalone DB instance has the `innodb_file_per_table` parameter set to 0. Change the name of the new standalone DB instance, and point any applications to the new standalone DB instance.

## Managing the Global Status History

### Tip

To analyze database performance, you can also use Performance Insights on Amazon RDS. For more information, see [Monitoring DB load with Performance Insights on Amazon RDS](#).

MySQL maintains many status variables that provide information about its operation. Their value can help you detect locking or memory issues on a DB instance. The values of these status variables are cumulative since last time the DB instance was started. You can reset most status variables to 0 by using the `FLUSH STATUS` command.

To allow for monitoring of these values over time, Amazon RDS provides a set of procedures that will snapshot the values of these status variables over time and write them to a table, along with any changes since the last snapshot. This infrastructure, called Global Status History (GoSH), is installed on all MySQL DB instances starting with versions 5.5.23. GoSH is disabled by default.

To enable GoSH, you first enable the event scheduler from a DB parameter group by setting the parameter `event_scheduler` to `ON`. For MySQL DB instances running MySQL 5.7, also set the parameter `show_compatibility_56` to 1. For information about creating and modifying a DB parameter group, see [Parameter groups for Amazon RDS](#). For information about the side effects of enabling this parameter, see [show\\_compatibility\\_56](#) in the *MySQL 5.7 Reference Manual*.

You can then use the procedures in the following table to enable and configure GoSH. First connect to your MySQL DB instance, then issue the appropriate commands as shown following. For more information, see [Connecting to a DB instance running the MySQL database engine](#). For each procedure, run the following command and replace *procedure-name*:

```
CALL procedure-name;
```

The following table lists all of the procedures that you can use for *procedure-name* in the previous command.

Procedure	Description
<code>mysql.rds_enable_gsh_collector</code>	Enables GoSH to take default snapshots at intervals specified by <code>rds_set_gsh_collector</code> .

Procedure	Description
<code>mysql.rds_set_gsh_collector</code>	Specifies the interval, in minutes, between snapshots. Default value is 5.
<code>mysql.rds_disable_gsh_collector</code>	Disables snapshots.
<code>mysql.rds_collect_global_status_history</code>	Takes a snapshot on demand.
<code>mysql.rds_enable_gsh_rotation</code>	Enables rotation of the contents of the <code>mysql.rds_global_status_history</code> table to <code>mysql.rds_global_status_history_old</code> at intervals specified by <code>rds_set_gsh_rotation</code> .
<code>mysql.rds_set_gsh_rotation</code>	Specifies the interval, in days, between table rotations. Default value is 7.
<code>mysql.rds_disable_gsh_rotation</code>	Disables table rotation.
<code>mysql.rds_rotate_global_status_history</code>	Rotates the contents of the <code>mysql.rds_global_status_history</code> table to <code>mysql.rds_global_status_history_old</code> on demand.

When GoSH is running, you can query the tables that it writes to. For example, to query the hit ratio of the InnoDB buffer pool, you would issue the following query:

```
select a.collection_end, a.collection_start, (( a.variable_Delta-b.variable_delta)/
a.variable_delta)*100 as "HitRatio"
  from mysql.rds_global_status_history as a join mysql.rds_global_status_history as b
 on a.collection_end = b.collection_end
  where a.variable_name = 'InnoDB_buffer_pool_read_requests' and b.variable_name =
'InnoDB_buffer_pool_reads'
```

## Local time zone for MySQL DB instances

By default, the time zone for a MySQL DB instance is Universal Time Coordinated (UTC). You can set the time zone for your DB instance to the local time zone for your application instead.

To set the local time zone for a DB instance, set the `time_zone` parameter in the parameter group for your DB instance to one of the supported values listed later in this section. When you set the `time_zone` parameter for a parameter group, all DB instances and read replicas that are using that parameter group change to use the new local time zone. For information on setting parameters in a parameter group, see [Parameter groups for Amazon RDS](#).

After you set the local time zone, all new connections to the database reflect the change. If you have any open connections to your database when you change the local time zone, you won't see the local time zone update until after you close the connection and open a new connection.

You can set a different local time zone for a DB instance and one or more of its read replicas. To do this, use a different parameter group for the DB instance and the replica or replicas and set the `time_zone` parameter in each parameter group to a different local time zone.

If you are replicating across AWS Regions, then the source DB instance and the read replica use different parameter groups (parameter groups are unique to an AWS Region). To use the same local time zone for each instance, you must set the `time_zone` parameter in the instance's and read replica's parameter groups.

When you restore a DB instance from a DB snapshot, the local time zone is set to UTC. You can update the time zone to your local time zone after the restore is complete. If you restore a DB instance to a point in time, then the local time zone for the restored DB instance is the time zone setting from the parameter group of the restored DB instance.

The Internet Assigned Numbers Authority (IANA) publishes new time zones at <https://www.iana.org/time-zones> several times a year. Every time RDS releases a new minor maintenance release of MySQL, it ships with the latest time zone data at the time of the release. When you use the latest RDS for MySQL versions, you have recent time zone data from RDS. To ensure that your DB instance has recent time zone data, we recommend upgrading to a higher DB engine version. Alternatively, you can modify the time zone tables in MariaDB DB instances manually. To do so, you can use SQL commands or run the [mysql\\_tzinfo\\_to\\_sql tool](#) in a SQL client. After updating the time zone data manually, reboot your DB instance so that the changes take effect. RDS doesn't modify or reset the time zone data of running DB instances. New time zone data is installed only when you perform a database engine version upgrade.

You can set your local time zone to one of the following values.

Zone	Time zone
Africa/Cairo	Asia/Riyadh
Africa/Casablanca	Asia/Seoul
Africa/Harare	Asia/Shanghai
Africa/Monrovia	Asia/Singapore
Africa/Nairobi	Asia/Taipei

# Known issues and limitations for Amazon RDS for MySQL

Known issues and limitations for working with Amazon RDS for MySQL are as follows.

## Topics

- [InnoDB reserved word](#)
- [Storage-full behavior for Amazon RDS for MySQL](#)
- [Inconsistent InnoDB buffer pool size](#)
- [Index merge optimization returns incorrect results](#)
- [MySQL parameter exceptions for Amazon RDS DB instances](#)
- [MySQL file size limits in Amazon RDS](#)
- [MySQL Keyring Plugin not supported](#)
- [Custom ports](#)
- [MySQL stored procedure limitations](#)
- [GTID-based replication with an external source instance](#)
- [MySQL default authentication plugin](#)
- [Overriding innodb\\_buffer\\_pool\\_size](#)

## InnoDB reserved word

InnoDB is a reserved word for RDS for MySQL. You can't use this name for a MySQL database.

## Storage-full behavior for Amazon RDS for MySQL

When storage becomes full for a MySQL DB instance, there can be metadata inconsistencies, dictionary mismatches, and orphan tables. To prevent these issues, Amazon RDS automatically stops a DB instance that reaches the `storage-full` state.

A MySQL DB instance reaches the `storage-full` state in the following cases:

- The DB instance has less than 20,000 MiB of storage, and available storage reaches 200 MiB or less.
- The DB instance has more than 102,400 MiB of storage, and available storage reaches 1024 MiB or less.

- The DB instance has between 20,000 MiB and 102,400 MiB of storage, and has less than 1% of storage available.

After Amazon RDS stops a DB instance automatically because it reached the storage-full state, you can still modify it. To restart the DB instance, complete at least one of the following:

- Modify the DB instance to enable storage autoscaling.

For more information about storage autoscaling, see [Managing capacity automatically with Amazon RDS storage autoscaling](#).

- Modify the DB instance to increase its storage capacity.

For more information about increasing storage capacity, see [Increasing DB instance storage capacity](#).

After you make one of these changes, the DB instance is restarted automatically. For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#).

## Inconsistent InnoDB buffer pool size

For MySQL 5.7, there is currently a bug in the way that the InnoDB buffer pool size is managed. MySQL 5.7 might adjust the value of the `innodb_buffer_pool_size` parameter to a large value that can result in the InnoDB buffer pool growing too large and using up too much memory. This effect can cause the MySQL database engine to stop running or can prevent it from starting. This issue is more common for DB instance classes that have less memory available.

To resolve this issue, set the value of the `innodb_buffer_pool_size` parameter to a multiple of the product of the `innodb_buffer_pool_instances` parameter value and the `innodb_buffer_pool_chunk_size` parameter value. For example, you might set the `innodb_buffer_pool_size` parameter value to a multiple of eight times the product of the `innodb_buffer_pool_instances` and `innodb_buffer_pool_chunk_size` parameter values, as shown in the following example.

```
innodb_buffer_pool_chunk_size = 536870912
innodb_buffer_pool_instances = 4
innodb_buffer_pool_size = (536870912 * 4) * 8 = 17179869184
```

For details on this MySQL 5.7 bug, see <https://bugs.mysql.com/bug.php?id=79379> in the MySQL documentation.

## Index merge optimization returns incorrect results

Queries that use index merge optimization might return incorrect results due to a bug in the MySQL query optimizer that was introduced in MySQL 5.5.37. When you issue a query against a table with multiple indexes, the optimizer scans ranges of rows based on the multiple indexes, but does not merge the results together correctly. For more information on the query optimizer bug, see <http://bugs.mysql.com/bug.php?id=72745> and <http://bugs.mysql.com/bug.php?id=68194> in the MySQL bug database.

For example, consider a query on a table with two indexes where the search arguments reference the indexed columns.

```
SELECT * FROM table1
WHERE indexed_col1 = 'value1' AND indexed_col2 = 'value2';
```

In this case, the search engine will search both indexes. However, due to the bug, the merged results are incorrect.

To resolve this issue, you can do one of the following:

- Set the `optimizer_switch` parameter to `index_merge=off` in the DB parameter group for your MySQL DB instance. For information on setting DB parameter group parameters, see [Parameter groups for Amazon RDS](#).
- Upgrade your MySQL DB instance to MySQL version 5.7 or 8.0. For more information, see [Upgrading the MySQL DB engine](#).
- If you cannot upgrade your instance or change the `optimizer_switch` parameter, you can work around the bug by explicitly identifying an index for the query, for example:

```
SELECT * FROM table1
USE INDEX covering_index
WHERE indexed_col1 = 'value1' AND indexed_col2 = 'value2';
```

For more information, see [Index merge optimization](#) in the MySQL documentation.

## MySQL parameter exceptions for Amazon RDS DB instances

Some MySQL parameters require special considerations when used with an Amazon RDS DB instance.

### **lower\_case\_table\_names**

Because Amazon RDS uses a case-sensitive file system, setting the value of the `lower_case_table_names` server parameter to 2 (names stored as given but compared in lowercase) is not supported. The following are the supported values for Amazon RDS for MySQL DB instances:

- 0 (names stored as given and comparisons are case-sensitive) is supported for all RDS for MySQL versions.
- 1 (names stored in lowercase and comparisons are not case-sensitive) is supported for RDS for MySQL version 5.7 and version 8.0.28 and higher 8.0 versions.

Set the `lower_case_table_names` parameter in a custom DB parameter group before creating a DB instance. Then, specify the custom DB parameter group when you create the DB instance.

When a parameter group is associated with a MySQL DB instance with a version lower than 8.0, we recommend that you avoid changing the `lower_case_table_names` parameter in the parameter group. Changing it could cause inconsistencies with point-in-time recovery backups and read replica DB instances.

When a parameter group is associated with a version 8.0 MySQL DB instance, you can't modify the `lower_case_table_names` parameter in the parameter group.

Read replicas should always use the same `lower_case_table_names` parameter value as the source DB instance.

### **long\_query\_time**

You can set the `long_query_time` parameter to a floating point value so that you can log slow queries to the MySQL slow query log with microsecond resolution. You can set a value such as 0.1 seconds, which would be 100 milliseconds, to help when debugging slow transactions that take less than one second.

## MySQL file size limits in Amazon RDS

For MySQL DB instances, the maximum provisioned storage limit constrains the size of a table to a maximum size of 16 TB when using InnoDB file-per-table tablespaces. This limit also constrains the system tablespace to a maximum size of 16 TB. InnoDB file-per-table tablespaces (with tables each in their own tablespace) is set by default for MySQL DB instances.

### Note

Some existing DB instances have a lower limit. For example, MySQL DB instances created before April 2014 have a file and table size limit of 2 TB. This 2 TB file size limit also applies to DB instances or read replicas created from DB snapshots taken before April 2014, regardless of when the DB instance was created.

There are advantages and disadvantages to using InnoDB file-per-table tablespaces, depending on your application. To determine the best approach for your application, see [File-per-table tablespaces](#) in the MySQL documentation.

We don't recommend allowing tables to grow to the maximum file size. In general, a better practice is to partition data into smaller tables, which can improve performance and recovery times.

One option that you can use for breaking up a large table into smaller tables is partitioning. Partitioning distributes portions of your large table into separate files based on rules that you specify. For example, if you store transactions by date, you can create partitioning rules that distribute older transactions into separate files using partitioning. Then periodically, you can archive the historical transaction data that doesn't need to be readily available to your application. For more information, see [Partitioning](#) in the MySQL documentation.

Because there is no single system table or view that provides the size of all the tables and the InnoDB system tablespace, you must query multiple tables to determine the size of the tablespaces.

### To determine the size of the InnoDB system tablespace and the data dictionary tablespace

- Use the following SQL command to determine if any of your tablespaces are too large and are candidates for partitioning.

**Note**

The data dictionary tablespace is specific to MySQL 8.0.

```
select FILE_NAME, TABLESPACE_NAME, ROUND(((TOTAL_EXTENTS*EXTENT_SIZE)
/1024/1024/1024), 2) as "File Size (GB)" from information_schema.FILES
where tablespace_name in ('mysql','innodb_system');
```

**To determine the size of InnoDB user tables outside of the InnoDB system tablespace (for MySQL 5.7 versions)**

- Use the following SQL command to determine if any of your tables are too large and are candidates for partitioning.

```
SELECT SPACE, NAME, ROUND((ALLOCATED_SIZE/1024/1024/1024), 2)
as "Tablespace Size (GB)"
FROM information_schema.INNODB_SYS_TABLESPACES ORDER BY 3 DESC;
```

**To determine the size of InnoDB user tables outside of the InnoDB system tablespace (for MySQL 8.0 versions)**

- Use the following SQL command to determine if any of your tables are too large and are candidates for partitioning.

```
SELECT SPACE, NAME, ROUND((ALLOCATED_SIZE/1024/1024/1024), 2)
as "Tablespace Size (GB)"
FROM information_schema.INNODB_TABLESPACES ORDER BY 3 DESC;
```

**To determine the size of non-InnoDB user tables**

- Use the following SQL command to determine if any of your non-InnoDB user tables are too large.

```
SELECT TABLE_SCHEMA, TABLE_NAME, round(((DATA_LENGTH + INDEX_LENGTH+DATA_FREE)
/ 1024 / 1024/ 1024), 2) As "Approximate size (GB)" FROM information_schema.TABLES
```

```
WHERE TABLE_SCHEMA NOT IN ('mysql', 'information_schema', 'performance_schema')
and ENGINE<>'InnoDB';
```

## To enable InnoDB file-per-table tablespaces

- Set the `innodb_file_per_table` parameter to 1 in the parameter group for the DB instance.

## To disable InnoDB file-per-table tablespaces

- Set the `innodb_file_per_table` parameter to 0 in the parameter group for the DB instance.

For information on updating a parameter group, see [Parameter groups for Amazon RDS](#).

When you have enabled or disabled InnoDB file-per-table tablespaces, you can issue an ALTER TABLE command to move a table from the global tablespace to its own tablespace, or from its own tablespace to the global tablespace as shown in the following example:

```
ALTER TABLE table_name TABLESPACE=innodb_file_per_table;
```

## MySQL Keyring Plugin not supported

Currently, Amazon RDS for MySQL doesn't support the MySQL `keyring_aws` Amazon Web Services Keyring Plugin.

## Custom ports

Amazon RDS blocks connections to custom port 33060 for the MySQL engine. Choose a different port for your MySQL engine.

## MySQL stored procedure limitations

The [mysql.rds\\_kill](#) and [mysql.rds\\_kill\\_query](#) stored procedures can't terminate sessions or queries owned by MySQL users with usernames longer than 16 characters on the following RDS for MySQL versions:

- 8.0.32 and lower 8 versions
- 5.7.41 and lower 5.7 versions

## GTID-based replication with an external source instance

Amazon RDS doesn't support replication based on global transaction identifiers (GTIDs) from an external MySQL instance into an Amazon RDS for MySQL DB instance that requires setting `GTID_PURGED` during configuration.

## MySQL default authentication plugin

RDS for MySQL version 8.0.34 and higher use the `mysql_native_password` plugin. You can't change the `default_authentication_plugin` setting.

## Overriding `innodb_buffer_pool_size`

With micro or small DB instance classes, the default value for the `innodb_buffer_pool_size` parameter might differ from the value returned by running the following command:

```
mysql> SELECT @@innodb_buffer_pool_size;
```

This difference can occur when Amazon RDS needs to override the default value as part of managing the DB instance classes. If necessary, you can override the default value and set it to a value that your DB instance class supports. To determine a valid value, add the memory usage and the total memory available on your DB instance. For more information, see [Amazon RDS instance types](#).

If your DB instance has only 4 GB of memory, you can't set `innodb_buffer_pool_size` to 8 GB but you might be able to set it to 3 GB, depending on how much memory you allocated for other parameters.

If the value that you input is too large, Amazon RDS lowers the value to the following limits:

- Micro DB instance classes: 256 MB
- db.t4g.micro DB instance classes: 128 MB

## RDS for MySQL stored procedure reference

These topics describe system stored procedures that are available for Amazon RDS instances running the MySQL DB engine. The master user must run these procedures.

### Topics

- [Collecting and maintaining the Global Status History](#)
- [Configuring, starting, and stopping binary log \(binlog\) replication](#)
- [Ending a session or query](#)
- [Managing active-active clusters](#)
- [Managing multi-source replication](#)
- [Replicating transactions using GTIDs](#)
- [Rotating the query logs](#)
- [Setting and showing binary log configuration](#)
- [Warming the InnoDB cache](#)

## Collecting and maintaining the Global Status History

Amazon RDS provides a set of procedures that take snapshots of the values of status variables over time and write them to a table, along with any changes since the last snapshot. This infrastructure is called Global Status History. For more information, see [Managing the Global Status History](#).

The following stored procedures manage how the Global Status History is collected and maintained.

### Topics

- [mysql.rds\\_collect\\_global\\_status\\_history](#)
- [mysql.rds\\_disable\\_gsh\\_collector](#)
- [mysql.rds\\_disable\\_gsh\\_rotation](#)
- [mysql.rds\\_enable\\_gsh\\_collector](#)
- [mysql.rds\\_enable\\_gsh\\_rotation](#)
- [mysql.rds\\_rotate\\_global\\_status\\_history](#)
- [mysql.rds\\_set\\_gsh\\_collector](#)
- [mysql.rds\\_set\\_gsh\\_rotation](#)

### mysql.rds\_collect\_global\_status\_history

Takes a snapshot on demand for the Global Status History.

#### Syntax

```
CALL mysql.rds_collect_global_status_history;
```

### mysql.rds\_disable\_gsh\_collector

Turns off snapshots taken by the Global Status History.

#### Syntax

```
CALL mysql.rds_disable_gsh_collector;
```

## **mysql.rds\_disable\_gsh\_rotation**

Turns off rotation of the `mysql.global_status_history` table.

### **Syntax**

```
CALL mysql.rds_disable_gsh_rotation;
```

## **mysql.rds\_enable\_gsh\_collector**

Turns on the Global Status History to take default snapshots at intervals specified by `rds_set_gsh_collector`.

### **Syntax**

```
CALL mysql.rds_enable_gsh_collector;
```

## **mysql.rds\_enable\_gsh\_rotation**

Turns on rotation of the contents of the `mysql.global_status_history` table to `mysql.global_status_history_old` at intervals specified by `rds_set_gsh_rotation`.

### **Syntax**

```
CALL mysql.rds_enable_gsh_rotation;
```

## **mysql.rds\_rotate\_global\_status\_history**

Rotates the contents of the `mysql.global_status_history` table to `mysql.global_status_history_old` on demand.

### **Syntax**

```
CALL mysql.rds_rotate_global_status_history;
```

## **mysql.rds\_set\_gsh\_collector**

Specifies the interval, in minutes, between snapshots taken by the Global Status History.

## Syntax

```
CALL mysql.rds_set_gsh_collector(intervalPeriod);
```

## Parameters

### *intervalPeriod*

The interval, in minutes, between snapshots. Default value is 5.

## mysql.rds\_set\_gsh\_rotation

Specifies the interval, in days, between rotations of the `mysql.global_status_history` table.

## Syntax

```
CALL mysql.rds_set_gsh_rotation(intervalPeriod);
```

## Parameters

### *intervalPeriod*

The interval, in days, between table rotations. Default value is 7.

## Configuring, starting, and stopping binary log (binlog) replication

The following stored procedures control how transactions are replicated from an external database into RDS for MySQL, or from RDS for MySQL to an external database.

### Topics

- [mysql.rds\\_next\\_master\\_log](#)
- [mysql.rds\\_reset\\_external\\_master](#)
- [mysql.rds\\_set\\_external\\_master](#)
- [mysql.rds\\_set\\_external\\_master\\_with\\_auto\\_position](#)
- [mysql.rds\\_set\\_external\\_master\\_with\\_delay](#)
- [mysql.rds\\_set\\_master\\_auto\\_position](#)
- [mysql.rds\\_set\\_source\\_delay](#)
- [mysql.rds\\_skip\\_repl\\_error](#)
- [mysql.rds\\_start\\_replication](#)
- [mysql.rds\\_start\\_replication\\_until](#)
- [mysql.rds\\_stop\\_replication](#)

### mysql.rds\_next\_master\_log

Changes the source database instance log position to the start of the next binary log on the source database instance. Use this procedure only if you are receiving replication I/O error 1236 on a read replica.

### Syntax

```
CALL mysql.rds_next_master_log(  
curr_master_log  
);
```

## Parameters

### *curr\_master\_log*

The index of the current master log file. For example, if the current file is named `mysql-bin-change.log.012345`, then the index is 12345. To determine the current master log file name, run the `SHOW REPLICA STATUS` command and view the `Master_Log_File` field.

#### Note

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

## Usage notes

The master user must run the `mysql.rds_next_master_log` procedure.

#### Warning

Call `mysql.rds_next_master_log` only if replication fails after a failover of a Multi-AZ DB instance that is the replication source, and the `Last_IO_Errno` field of `SHOW REPLICA STATUS` reports I/O error 1236.

Calling `mysql.rds_next_master_log` can result in data loss in the read replica if transactions in the source instance were not written to the binary log on disk before the failover event occurred.

You can reduce the chance of this happening by setting the source instance parameters `sync_binlog` and `innodb_support_xa` to 1, although this might reduce performance. For more information, see [Troubleshooting a MySQL read replica problem](#).

## Examples

Assume replication fails on an RDS for MySQL read replica. Running `SHOW REPLICA STATUS\G` on the read replica returns the following result:

```
***** 1. row *****
      Replica_IO_State:
      Source_Host: myhost.XXXXXXXXXXXXXXXXXX.rr-rrrr-1.rds.amazonaws.com
```

```
Source_User: MasterUser
Source_Port: 3306
Connect_Retry: 10
Source_Log_File: mysql-bin-changelog.012345
Read_Source_Log_Pos: 1219393
Relay_Log_File: relaylog.012340
Relay_Log_Pos: 30223388
Relay_Source_Log_File: mysql-bin-changelog.012345
Replica_IO_Running: No
Replica_SQL_Running: Yes
Replicate_Do_DB:
Replicate_Ignore_DB:
Replicate_Do_Table:
Replicate_Ignore_Table:
Replicate_Wild_Do_Table:
Replicate_Wild_Ignore_Table:
Last_Errno: 0
Last_Error:
Skip_Counter: 0
Exec_Source_Log_Pos: 30223232
Relay_Log_Space: 5248928866
Until_Condition: None
Until_Log_File:
Until_Log_Pos: 0
Source_SSL_Allowed: No
Source_SSL_CA_File:
Source_SSL_CA_Path:
Source_SSL_Cert:
Source_SSL_Cipher:
Source_SSL_Key:
Seconds_Behind_Master: NULL
Source_SSL_Verify_Server_Cert: No
Last_IO_Errno: 1236
Last_IO_Error: Got fatal error 1236 from master when reading data from
binary log: 'Client requested master to start replication from impossible position;
the first event 'mysql-bin-changelog.013406' at 1219393, the last event read from
'/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4, the last byte read from '/
rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4.'
Last_SQL_Errno: 0
Last_SQL_Error:
Replicate_Ignore_Server_Ids:
Source_Server_Id: 67285976
```

The `Last_IO_Errno` field shows that the instance is receiving I/O error 1236. The `Master_Log_File` field shows that the file name is `mysql-bin-changelog.012345`, which means that the log file index is 12345. To resolve the error, you can call `mysql.rds_next_master_log` with the following parameter:

```
CALL mysql.rds_next_master_log(12345);
```

### Note

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

## mysql.rds\_reset\_external\_master

Reconfigures an RDS for MySQL DB instance to no longer be a read replica of an instance of MySQL running external to Amazon RDS.

### Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

## Syntax

```
CALL mysql.rds_reset_external_master;
```

## Usage notes

The master user must run the `mysql.rds_reset_external_master` procedure. This procedure must be run on the MySQL DB instance to be removed as a read replica of a MySQL instance running external to Amazon RDS.

**Note**

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see [Working with DB instance read replicas](#).

For more information about using replication to import data from an instance of MySQL running external to Amazon RDS, see [Configuring binary log file position replication with an external source instance](#).

## mysql.rds\_set\_external\_master

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

**Important**

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

**Note**

You can use the [mysql.rds\\_set\\_external\\_master\\_with\\_delay](#) stored procedure to configure an external source database instance and delayed replication.

## Syntax

```
CALL mysql.rds_set_external_master (  
    host_name
```

```
, host_port
, replication_user_name
, replication_user_password
, mysql_binary_log_file_name
, mysql_binary_log_file_location
, ssl_encryption
);
```

## Parameters

### *host\_name*

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

### *host\_port*

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

### *replication\_user\_name*

The ID of a user with REPLICATION CLIENT and REPLICATION SLAVE permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

### *replication\_user\_password*

The password of the user ID specified in `replication_user_name`.

### *mysql\_binary\_log\_file\_name*

The name of the binary log on the source database instance that contains the replication information.

### *mysql\_binary\_log\_file\_location*

The location in the `mysql_binary_log_file_name` binary log at which replication starts reading the replication information.

You can determine the binlog file name and location by running `SHOW MASTER STATUS` on the source database instance.

## *ssl\_encryption*

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

### Note

The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

## Usage notes

The master user must run the `mysql.rds_set_external_master` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run `mysql.rds_set_external_master`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify `replication_user_name` and `replication_user_password` values that indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external instance of MySQL.

## To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

### MySQL 5.7

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

### MySQL 8.0

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';
```

**Note**

Specify a password other than the prompt shown here as a security best practice.

2. On the external instance of MySQL, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the `'repl_user'` user for your domain.

**MySQL 5.7**

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'  
IDENTIFIED BY 'password';
```

**MySQL 8.0**

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

To use encrypted replication, configure source database instance to use SSL connections.

**Note**

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see [Working with DB instance read replicas](#).

After calling `mysql.rds_set_external_master` to configure an Amazon RDS DB instance as a read replica, you can call [mysql.rds\\_start\\_replication](#) on the read replica to start the replication process. You can call [mysql.rds\\_reset\\_external\\_master](#) to remove the read replica configuration.

When `mysql.rds_set_external_master` is called, Amazon RDS records the time, user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

## Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

```
call mysql.rds_set_external_master(  
  'Externaldb.some.com',  
  3306,  
  'repl_user',  
  'password',  
  'mysql-bin-changelog.0777',  
  120,  
  0);
```

## mysql.rds\_set\_external\_master\_with\_auto\_position

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. This procedure also configures delayed replication and replication based on global transaction identifiers (GTIDs).

### Important

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

## Syntax

```
CALL mysql.rds_set_external_master_with_auto_position (  
  host_name  
  , host_port  
  , replication_user_name  
  , replication_user_password  
  , ssl_encryption  
  , delay  
);
```

## Parameters

### *host\_name*

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

### *host\_port*

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

### *replication\_user\_name*

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

### *replication\_user\_password*

The password of the user ID specified in `replication_user_name`.

### *ssl\_encryption*

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

#### **Note**

The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

### *delay*

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86,400 seconds).

## Usage notes

The master user must run the `mysql.rds_set_external_master_with_auto_position` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

Before you run `mysql.rds_set_external_master_with_auto_position`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external instance of MySQL.

### To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassw0rd'
```

2. On the external instance of MySQL, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the `'repl_user'` user for your domain.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'  
IDENTIFIED BY 'SomePassw0rd'
```

For more information, see [Configuring binary log file position replication with an external source instance](#).

#### Note

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored

procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see [Working with DB instance read replicas](#).

After calling `mysql.rds_set_external_master_with_auto_position` to configure an Amazon RDS DB instance as a read replica, you can call [mysql.rds\\_start\\_replication](#) on the read replica to start the replication process. You can call [mysql.rds\\_reset\\_external\\_master](#) to remove the read replica configuration.

When you call `mysql.rds_set_external_master_with_auto_position`, Amazon RDS records the time, the user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

For disaster recovery, you can use this procedure with the [mysql.rds\\_start\\_replication\\_until](#) or [mysql.rds\\_start\\_replication\\_until\\_gtid](#) stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_external_master_with_auto_position` procedure. After the `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in [Promoting a read replica to be a standalone DB instance](#).

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the [mysql.rds\\_skip\\_transaction\\_with\\_gtid](#) stored procedure. For more information about working with GTID-based replication, see [Using GTID-based replication](#).

## Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. It sets the minimum replication delay to one hour (3,600 seconds) on the MySQL DB instance. A change from the MySQL source database instance running external to Amazon RDS isn't applied on the MySQL DB instance read replica for at least one hour.

```
call mysql.rds_set_external_master_with_auto_position(
  'Externaldb.some.com',
  3306,
  'repl_user',
```

```
'SomePassW0rd',  
0,  
3600);
```

## mysql.rds\_set\_external\_master\_with\_delay

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS and configures delayed replication.

### Important

To run this procedure, autocommit must be enabled. To enable it, set the autocommit parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

## Syntax

```
CALL mysql.rds_set_external_master_with_delay (  
  host_name  
  , host_port  
  , replication_user_name  
  , replication_user_password  
  , mysql_binary_log_file_name  
  , mysql_binary_log_file_location  
  , ssl_encryption  
  , delay  
);
```

## Parameters

### *host\_name*

The host name or IP address of the MySQL instance running external to Amazon RDS that will become the source database instance.

### *host\_port*

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes SSH port replication that converts the port number, specify the port number that is exposed by SSH.

### *replication\_user\_name*

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

### *replication\_user\_password*

The password of the user ID specified in `replication_user_name`.

### *mysql\_binary\_log\_file\_name*

The name of the binary log on the source database instance contains the replication information.

### *mysql\_binary\_log\_file\_location*

The location in the `mysql_binary_log_file_name` binary log at which replication will start reading the replication information.

You can determine the binlog file name and location by running `SHOW MASTER STATUS` on the source database instance.

### *ssl\_encryption*

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

#### **Note**

The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

### *delay*

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86400 seconds).

## Usage notes

The master user must run the `mysql.rds_set_external_master_with_delay` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run `mysql.rds_set_external_master_with_delay`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external instance of MySQL.

### To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
```

2. On the external instance of MySQL, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the `'repl_user'` user for your domain.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'  
IDENTIFIED BY 'SomePassW0rd'
```

For more information, see [Configuring binary log file position replication with an external source instance](#).

#### Note

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to

Amazon RDS. For information about managing replication between Amazon RDS DB instances, see [Working with DB instance read replicas](#).

After calling `mysql.rds_set_external_master_with_delay` to configure an Amazon RDS DB instance as a read replica, you can call [mysql.rds\\_start\\_replication](#) on the read replica to start the replication process. You can call [mysql.rds\\_reset\\_external\\_master](#) to remove the read replica configuration.

When you call `mysql.rds_set_external_master_with_delay`, Amazon RDS records the time, the user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

For disaster recovery, you can use this procedure with the [mysql.rds\\_start\\_replication\\_until](#) or [mysql.rds\\_start\\_replication\\_until\\_gtid](#) stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_external_master_with_delay` procedure. After the `mysql.rds_start_replication_until` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in [Promoting a read replica to be a standalone DB instance](#).

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the [mysql.rds\\_skip\\_transaction\\_with\\_gtid](#) stored procedure. For more information about working with GTID-based replication, see [Using GTID-based replication](#).

The `mysql.rds_set_external_master_with_delay` procedure is available in these versions of RDS for MySQL:

- MySQL 8.0.26 and higher 8.0 versions
- All 5.7 versions

## Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. It sets the minimum replication delay to one hour (3,600 seconds) on the MySQL DB instance. A change from the MySQL source database instance running external to Amazon RDS isn't applied on the MySQL DB instance read replica for at least one hour.

```
call mysql.rds_set_external_master_with_delay(  
  'Externaldb.some.com',  
  3306,  
  'repl_user',  
  'SomePassW0rd',  
  'mysql-bin-changelog.000777',  
  120,  
  0,  
  3600);
```

## mysql.rds\_set\_master\_auto\_position

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

### Syntax

```
CALL mysql.rds_set_master_auto_position (  
auto_position_mode  
);
```

### Parameters

#### *auto\_position\_mode*

A value that indicates whether to use log file position replication or GTID-based replication:

- 0 – Use the replication method based on binary log file position. The default is 0.
- 1 – Use the GTID-based replication method.

### Usage notes

The master user must run the `mysql.rds_set_master_auto_position` procedure.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

## mysql.rds\_set\_source\_delay

Sets the minimum number of seconds to delay replication from source database instance to the current read replica. Use this procedure when you are connected to a read replica to delay replication from its source database instance.

### Syntax

```
CALL mysql.rds_set_source_delay(  
  delay  
);
```

### Parameters

*delay*

The minimum number of seconds to delay replication from the source database instance.

The limit for this parameter is one day (86400 seconds).

### Usage notes

The master user must run the `mysql.rds_set_source_delay` procedure.

For disaster recovery, you can use this procedure with the [mysql.rds\\_start\\_replication\\_until](#) stored procedure or the [mysql.rds\\_start\\_replication\\_until\\_gtid](#) stored procedure.

To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_source_delay` procedure. After the `mysql.rds_start_replication_until` or `mysql.rds_start_replication_until_gtid` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in [Promoting a read replica to be a standalone DB instance](#).

To use the `mysql.rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the [mysql.rds\\_skip\\_transaction\\_with\\_gtid](#) stored procedure. For more information on GTID-based replication, see [Using GTID-based replication](#).

The `mysql.rds_set_source_delay` procedure is available in these versions of RDS for MySQL:

- MySQL 8.0.26 and higher 8.0 versions

- All 5.7 versions

## Examples

To delay replication from source database instance to the current read replica for at least one hour (3,600 seconds), you can call `mysql.rds_set_source_delay` with the following parameter:

```
CALL mysql.rds_set_source_delay(3600);
```

## mysql.rds\_skip\_repl\_error

Skips and deletes a replication error on a MySQL DB read replica.

### Syntax

```
CALL mysql.rds_skip_repl_error;
```

### Usage notes

The master user must run the `mysql.rds_skip_repl_error` procedure on a read replica. For more information about this procedure, see [Calling the mysql.rds\\_skip\\_repl\\_error procedure](#).

To determine if there are errors, run the MySQL `SHOW REPLICA STATUS\G` command. If a replication error isn't critical, you can run `mysql.rds_skip_repl_error` to skip the error. If there are multiple errors, `mysql.rds_skip_repl_error` deletes the first error, then warns that others are present. You can then use `SHOW REPLICA STATUS\G` to determine the correct course of action for the next error. For information about the values returned, see [SHOW REPLICA STATUS statement](#) in the MySQL documentation.

#### Note

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

For more information about addressing replication errors with Amazon RDS, see [Troubleshooting a MySQL read replica problem](#).

## Replication stopped error

When you call the `mysql.rds_skip_repl_error` procedure, you might receive an error message stating that the replica is down or disabled.

This error message appears if you run the procedure on the primary instance instead of the read replica. You must run this procedure on the read replica for the procedure to work.

This error message might also appear if you run the procedure on the read replica, but replication can't be restarted successfully.

If you need to skip a large number of errors, the replication lag can increase beyond the default retention period for binary log (binlog) files. In this case, you might encounter a fatal error due to binlog files being purged before they have been replayed on the read replica. This purge causes replication to stop, and you can no longer call the `mysql.rds_skip_repl_error` command to skip replication errors.

You can mitigate this issue by increasing the number of hours that binlog files are retained on your source database instance. After you have increased the binlog retention time, you can restart replication and call the `mysql.rds_skip_repl_error` command as needed.

To set the binlog retention time, use the [mysql.rds\\_set\\_configuration](#) procedure and specify a configuration parameter of `'binlog retention hours'` along with the number of hours to retain binlog files on the DB cluster. The following example sets the retention period for binlog files to 48 hours.

```
CALL mysql.rds_set_configuration('binlog retention hours', 48);
```

## mysql.rds\_start\_replication

Initiates replication from an RDS for MySQL DB instance.

### Note

You can use the [mysql.rds\\_start\\_replication\\_until](#) or [mysql.rds\\_start\\_replication\\_until\\_gtid](#) stored procedure to initiate replication from an RDS for MySQL DB instance and stop replication at the specified binary log file location.

## Syntax

```
CALL mysql.rds_start_replication;
```

## Usage notes

The master user must run the `mysql.rds_start_replication` procedure.

To import data from an instance of MySQL external to Amazon RDS, call `mysql.rds_start_replication` on the read replica to start the replication process after you call `mysql.rds_set_external_master` to build the replication configuration. For more information, see [Restoring a backup into a MySQL DB instance](#).

To export data to an instance of MySQL external to Amazon RDS, call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see [Exporting data from a MySQL DB instance by using replication](#).

You can also call `mysql.rds_start_replication` on the read replica to restart any replication process that you previously stopped by calling `mysql.rds_stop_replication`. For more information, see [Working with DB instance read replicas](#).

## mysql.rds\_start\_replication\_until

Initiates replication from an RDS for MySQL DB instance and stops replication at the specified binary log file location.

## Syntax

```
CALL mysql.rds_start_replication_until (  
  replication_log_file  
  , replication_stop_point  
);
```

## Parameters

*replication\_log\_file*

The name of the binary log on the source database instance that contains the replication information.

## *replication\_stop\_point*

The location in the `replication_log_file` binary log at which replication will stop.

### Usage notes

The master user must run the `mysql.rds_start_replication_until` procedure.

The `mysql.rds_start_replication_until` procedure is available in these versions of RDS for MySQL:

- MySQL 8.0.26 and higher 8.0 versions
- All 5.7 versions

You can use this procedure with delayed replication for disaster recovery. If you have delayed replication configured, you can use this procedure to roll forward changes to a delayed read replica to the time just before a disaster. After this procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in [Promoting a read replica to be a standalone DB instance](#).

You can configure delayed replication using the following stored procedures:

- [mysql.rds\\_set\\_configuration](#)
- [mysql.rds\\_set\\_external\\_master\\_with\\_delay](#)
- [mysql.rds\\_set\\_source\\_delay](#)

The file name specified for the `replication_log_file` parameter must match the source database instance binlog file name.

When the `replication_stop_point` parameter specifies a stop location that is in the past, replication is stopped immediately.

### Examples

The following example initiates replication and replicates changes until it reaches location 120 in the `mysql-bin-change.log.000777` binary log file.

```
call mysql.rds_start_replication_until(
```

```
'mysql-bin-changelog.000777',  
120);
```

## mysql.rds\_stop\_replication

Stops replication from a MySQL DB instance.

### Syntax

```
CALL mysql.rds_stop_replication;
```

### Usage notes

The master user must run the `mysql.rds_stop_replication` procedure.

If you are configuring replication to import data from an instance of MySQL running external to Amazon RDS, you call `mysql.rds_stop_replication` on the read replica to stop the replication process after the import has completed. For more information, see [Restoring a backup into a MySQL DB instance](#).

If you are configuring replication to export data to an instance of MySQL external to Amazon RDS, you call `mysql.rds_start_replication` and `mysql.rds_stop_replication` on the read replica to control some replication actions, such as purging binary logs. For more information, see [Exporting data from a MySQL DB instance by using replication](#).

You can also use `mysql.rds_stop_replication` to stop replication between two Amazon RDS DB instances. You typically stop replication to perform a long running operation on the read replica, such as creating a large index on the read replica. You can restart any replication process that you stopped by calling [mysql.rds\\_start\\_replication](#) on the read replica. For more information, see [Working with DB instance read replicas](#).

## Ending a session or query

The following stored procedures end a session or query.

### Topics

- [mysql.rds\\_kill](#)
- [mysql.rds\\_kill\\_query](#)

### mysql.rds\_kill

Ends a connection to the MySQL server.

### Syntax

```
CALL mysql.rds_kill(processID);
```

### Parameters

*processID*

The identity of the connection thread to be ended.

### Usage notes

Each connection to the MySQL server runs in a separate thread. To end a connection, use the `mysql.rds_kill` procedure and pass in the thread ID of that connection. To obtain the thread ID, use the MySQL [SHOW PROCESSLIST](#) command.

For information about limitations, see [MySQL stored procedure limitations](#).

### Examples

The following example ends a connection with a thread ID of 4243:

```
CALL mysql.rds_kill(4243);
```

### mysql.rds\_kill\_query

Ends a query running against the MySQL server.

## Syntax

```
CALL mysql.rds_kill_query(processID);
```

## Parameters

*processID*

The identity of the process or thread that is running the query to be ended.

## Usage notes

To stop a query running against the MySQL server, use the `mysql_rds_kill_query` procedure and pass in the connection ID of the thread that is running the query. The procedure then terminates the connection.

To obtain the ID, query the MySQL [INFORMATION\\_SCHEMA.PROCESSLIST table](#) or use the MySQL [SHOW PROCESSLIST](#) command. The value in the ID column from `SHOW PROCESSLIST` or `SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST` is the *processID*.

For information about limitations, see [MySQL stored procedure limitations](#).

## Examples

The following example stops a query with a query thread ID of 230040:

```
CALL mysql.rds_kill_query(230040);
```

## Managing active-active clusters

The following stored procedures set up and manage RDS for MySQL active-active clusters. For more information, see [the section called “Configuring active-active clusters”](#).

These stored procedures are only available with RDS for MySQL DB instances running version 8.0.35 and higher minor versions.

### Topics

- [mysql.rds\\_group\\_replication\\_advance\\_gtid](#)
- [mysql.rds\\_group\\_replication\\_create\\_user](#)
- [mysql.rds\\_group\\_replication\\_set\\_recovery\\_channel](#)
- [mysql.rds\\_group\\_replication\\_start](#)
- [mysql.rds\\_group\\_replication\\_stop](#)

### mysql.rds\_group\_replication\_advance\_gtid

Creates placeholder GTIDs on the current DB instance.

### Syntax

```
CALL mysql.rds_group_replication_advance_gtid(  
  begin_id  
  , end_id  
  , server_uuid  
);
```

### Parameters

*begin\_id*

The start transaction ID to be created.

*end\_id*

The end transaction ID to be created.

## *begin\_id*

The `group_replication_group_name` for the transaction to be created. The `group_replication_group_name` is specified as a UUID in the DB parameter group associated with the DB instance.

### Usage notes

In an active-active cluster, for a DB instance to join a group, all GTID transactions executed on the new DB instance must exist on the other members in the cluster. In unusual cases, a new DB instance might have more transactions when transactions are executed before joining the instance to group. In this case, you can't remove any existing transactions, but you can use this procedure to create the corresponding placeholder GTIDs on the other DB instances in the group. Before doing so, verify that the transactions *don't affect the replicated data*.

When you call this procedure, GTID transactions of `server_uuid:begin_id-end_id` are created with empty content. To avoid replication issues, don't use this procedure under any other conditions.

#### Important

Avoid calling this procedure when the active-active cluster is functioning normally. Don't call this procedure unless you understand the possible consequences of the transactions you are creating. Calling this procedure might result in inconsistent data.

### Example

The following example creates placeholder GTIDs on current DB instance.:

```
CALL mysql.rds_group_replication_advance_gtid(5, 6,  
'11111111-2222-3333-4444-555555555555');
```

### `mysql.rds_group_replication_create_user`

Creates the replication user `rdsgprpladmin` for group replication on the DB instance.

### Syntax

```
CALL mysql.rds_group_replication_create_user(  

```

```
replication_user_password
);
```

## Parameters

*replication\_user\_password*

The password of the replication user `rdsgprprepladmin`.

## Usage notes

- The password of the replication user `rdsgprprepladmin` must be the same on all of the DB instances in an active-active cluster.
- The `rdsgprprepladmin` user name is reserved for group replication connections. No other user, including the master user, can have this user name.

## Example

The following example creates the replication user `rdsgprprepladmin` for group replication on the DB instance:

```
CALL mysql.rds_group_replication_create_user('password');
```

## `mysql.rds_group_replication_set_recovery_channel`

Sets the `group_replication_recovery` channel for an active-active cluster. The procedure uses the reserved `rdsgprprepladmin` user to configure the channel.

## Syntax

```
CALL mysql.rds_group_replication_set_recovery_channel(
replication_user_password);
```

## Parameters

*replication\_user\_password*

The password of the replication user `rdsgprprepladmin`.

## Usage notes

The password of the replication user `rdsgrpadmin` must be the same on all of the DB instances in an active-active cluster. A call to the `mysql.rds_group_replication_create_user` specifies the password.

## Example

The following example sets the `group_replication_recovery` channel for an active-active cluster:

```
CALL mysql.rds_group_replication_set_recovery_channel('password');
```

## mysql.rds\_group\_replication\_start

Starts group replication on the current DB instance.

## Syntax

```
CALL mysql.rds_group_replication_start(  
bootstrap  
);
```

## Parameters

### *bootstrap*

A value that specifies whether to initialize a new group or join an existing group. `1` initializes a new group with the current DB instance. `0` joins the current DB instance to an existing group by connecting to the endpoints defined in `group_replication_group_seeds` parameter in the `of DB` parameter group associated with the DB instance.

## Example

The following example initializes a new group with the current DB instance:

```
CALL mysql.rds_group_replication_start(1);
```

## mysql.rds\_group\_replication\_stop

Stops group replication on the current DB instance.

## Syntax

```
CALL mysql.rds_group_replication_stop();
```

## Usage notes

When you stop replication on a DB instance, it doesn't affect any other DB instance in the active-active cluster.

## Managing multi-source replication

The following stored procedures set up and manage replication channels on a RDS for MySQL multi-source replica. For more information, see [the section called “Configuring multi-source replication”](#).

These stored procedures are only available with RDS for MySQL DB instances running the following engine versions:

- 8.0.35 and higher minor versions
- 5.7.44 and higher minor versions

### Note

Although this documentation refers to source DB instances as RDS for MySQL DB instances, these procedures also work for MySQL instances running external to Amazon RDS.

### Topics

- [mysql.rds\\_next\\_source\\_log\\_for\\_channel](#)
- [mysql.rds\\_reset\\_external\\_source\\_for\\_channel](#)
- [mysql.rds\\_set\\_external\\_source\\_for\\_channel](#)
- [mysql.rds\\_set\\_external\\_source\\_with\\_auto\\_position\\_for\\_channel](#)
- [mysql.rds\\_set\\_external\\_source\\_with\\_delay\\_for\\_channel](#)
- [mysql.rds\\_set\\_source\\_auto\\_position\\_for\\_channel](#)
- [mysql.rds\\_set\\_source\\_delay\\_for\\_channel](#)
- [mysql.rds\\_skip\\_repl\\_error\\_for\\_channel](#)
- [mysql.rds\\_start\\_replication\\_for\\_channel](#)
- [mysql.rds\\_start\\_replication\\_until\\_for\\_channel](#)
- [mysql.rds\\_start\\_replication\\_until\\_gtid\\_for\\_channel](#)
- [mysql.rds\\_stop\\_replication\\_for\\_channel](#)

## mysql.rds\_next\_source\_log\_for\_channel

Changes the source DB instance log position to the start of the next binary log on the source DB instance for the channel. Use this procedure only if you are receiving replication I/O error 1236 on a multi-source replica.

### Syntax

```
CALL mysql.rds_next_source_log_for_channel(  
curr_master_log,  
channel_name  
);
```

### Parameters

#### *curr\_master\_log*

The index of the current source log file. For example, if the current file is named `mysql-bin-change.log.012345`, then the index is 12345. To determine the current source log file name, run the `SHOW REPLICA STATUS FOR CHANNEL 'channel_name'` command and view the `Source_Log_File` field.

#### Note

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICA STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

#### *channel\_name*

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

### Usage notes

The master user must run the `mysql.rds_next_source_log_for_channel` procedure. If there is an `IO_Thread` error, for example, you can use this procedure to skip all the events in the current

binary log file and resume the replication from the next binary log file for the channel specified in `channel_name`.

## Example

Assume replication fails on a channel on a multi-source replica. Running `SHOW REPLICA STATUS FOR CHANNEL 'channel_1'\G` on the multi-source replica returns the following result:

```
mysql> SHOW REPLICA STATUS FOR CHANNEL 'channel_1'\G
***** 1. row *****
      Replica_IO_State: Waiting for source to send event
      Source_Host: myhost.XXXXXXXXXXXXXXXXXX.rr-rrrr-1.rds.amazonaws.com
      Source_User: ReplicationUser
      Source_Port: 3306
      Connect_Retry: 60
      Source_Log_File: mysql-bin-changelog.012345
      Read_Source_Log_Pos: 1219393
      Relay_Log_File: replica-relay-bin.000003
      Relay_Log_Pos: 30223388
      Relay_Source_Log_File: mysql-bin-changelog.012345
      Replica_IO_Running: No
      Replica_SQL_Running: Yes
      Replicate_Do_DB:.
      .
      .
      Last_IO_Errno: 1236
      Last_IO_Error: Got fatal error 1236 from master when reading data from
      binary log: 'Client requested master to start replication from impossible position;
      the first event 'mysql-bin-changelog.013406' at 1219393, the last event read from
      '/rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4, the last byte read from '/
      rdsdbdata/log/binlog/mysql-bin-changelog.012345' at 4.'
      Last_SQL_Errno: 0
      Last_SQL_Error:
      .
      .
      Channel_name: channel_1
      .
      .
      -- Some fields are omitted in this example output
```

The `Last_IO_Errno` field shows that the instance is receiving I/O error 1236. The `Source_Log_File` field shows that the file name is `mysql-bin-changelog.012345`,

which means that the log file index is 12345. To resolve the error, you can call `mysql.rds_next_source_log_for_channel` with the following parameters:

```
CALL mysql.rds_next_source_log_for_channel(12345, 'channel_1');
```

### Note

Previous versions of MySQL used `SHOW SLAVE STATUS` instead of `SHOW REPLICATION STATUS`. If you are using a MySQL version before 8.0.23, then use `SHOW SLAVE STATUS`.

## `mysql.rds_reset_external_source_for_channel`

Stops the replication process on the specified channel, and removes the channel and associated configurations from the multi-source replica.

### Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

## Syntax

```
CALL mysql.rds_reset_external_source_for_channel (channel_name);
```

## Parameters

### *channel\_name*

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

## Usage notes

The master user must run the `mysql.rds_reset_external_source_for_channel` procedure. This procedure deletes all relay logs that belong to the channel being removed.

## mysql.rds\_set\_external\_source\_for\_channel

Configures a replication channel on an RDS for MySQL DB instance to replicate the data from another RDS for MySQL DB instance.

### Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

### Note

You can use the [the section called “mysql.rds\\_set\\_external\\_source\\_with\\_delay\\_for\\_channel”](#) stored procedure instead to configure this channel with delayed replication.

## Syntax

```
CALL mysql.rds_set_external_source_for_channel (  
  host_name  
  , host_port  
  , replication_user_name  
  , replication_user_password  
  , mysql_binary_log_file_name  
  , mysql_binary_log_file_location  
  , ssl_encryption  
  , channel_name  
);
```

## Parameters

### *host\_name*

The host name or IP address of the RDS for MySQL source DB instance.

### *host\_port*

The port used by the RDS for MySQL source DB instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

### *replication\_user\_name*

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the RDS for MySQL source DB instance. We recommend that you provide an account that is used solely for replication with the source DB instance.

### *replication\_user\_password*

The password of the user ID specified in `replication_user_name`.

### *mysql\_binary\_log\_file\_name*

The name of the binary log on the source DB instance that contains the replication information.

### *mysql\_binary\_log\_file\_location*

The location in the `mysql_binary_log_file_name` binary log at which replication starts reading the replication information.

You can determine the binlog file name and location by running `SHOW MASTER STATUS` on the source DB instance.

### *ssl\_encryption*

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

#### **Note**

The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

## *channel\_name*

The name of the replication channel. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

### Usage notes

The master user must run the `mysql.rds_set_external_source_for_channel` procedure. This procedure must be run on the target RDS for MySQL DB instance on which you're creating the replication channel.

Before you run `mysql.rds_set_external_source_for_channel`, configure a replication user on the source DB instance with the privileges required for the multi-source replica. To connect the multi-source replica to the source DB instance, you must specify `replication_user_name` and `replication_user_password` values of a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the source DB instance.

### To configure a replication user on the source DB instance

1. Using the MySQL client of your choice, connect to the source DB instance and create a user account to be used for replication. The following is an example.

#### Important

As a security best practice, specify a password other than the placeholder value shown in the following examples.

### MySQL 8.0

```
CREATE USER 'repl_user'@'example.com' IDENTIFIED WITH mysql_native_password BY  
'password';
```

### MySQL 5.7

```
CREATE USER 'repl_user'@'example.com' IDENTIFIED BY 'password';
```

2. On the source DB instance, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the `'repl_user'` user for your domain.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'example.com';
```

To use encrypted replication, configure the source DB instance to use SSL connections.

After calling `mysql.rds_set_external_source_for_channel` to configure this replication channel, you can call [mysql.rds\\_start\\_replication\\_for\\_channel](#) on the replica to start the replication process on the channel. You can call [the section called "mysql.rds\\_reset\\_external\\_source\\_for\\_channel"](#) to stop replication on the channel and remove the channel configuration from the replica.

When you call `mysql.rds_set_external_source_for_channel`, Amazon RDS records the time, user, and an action of `set channel source` in the `mysql.rds_history` table without channel-specific details, and in the `mysql.rds_replication_status` table, with the channel name. This information is recorded only for internal usage and monitoring purposes. To record the complete procedure call for auditing purpose, consider enabling audit logs or general logs, based on the specific requirements of your application.

## Examples

When run on a RDS for MySQL DB instance, the following example configures a replication channel named `channel_1` on this DB instance to replicate data from the source specified by host `sourcedb.example.com` and port `3306`.

```
call mysql.rds_set_external_source_for_channel(  
  'sourcedb.example.com',  
  3306,  
  'repl_user',  
  'password',  
  'mysql-bin-changelog.0777',  
  120,  
  0,  
  'channel_1');
```

## mysql.rds\_set\_external\_source\_with\_auto\_position\_for\_channel

Configures a replication channel on an RDS for MySQL DB instance with an optional replication delay. The replication is based on global transaction identifiers (GTIDs).

### Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

### Syntax

```
CALL mysql.rds_set_external_source_with_auto_position_for_channel (  
    host_name  
    , host_port  
    , replication_user_name  
    , replication_user_password  
    , ssl_encryption  
    , delay  
    , channel_name  
);
```

### Parameters

#### *host\_name*

The host name or IP address of the RDS for MySQL source DB instance.

#### *host\_port*

The port used by the RDS for MySQL source DB instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

#### *replication\_user\_name*

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the RDS for MySQL source DB instance. We recommend that you provide an account that is used solely for replication with the source DB instance.

### *replication\_user\_password*

The password of the user ID specified in `replication_user_name`.

### *ssl\_encryption*

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

#### **Note**

The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

### *delay*

The minimum number of seconds to delay replication from source DB instance.

The limit for this parameter is one day (86,400 seconds).

### *channel\_name*

The name of the replication channel. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

## Usage notes

The master user must run the `mysql.rds_set_external_source_with_auto_position_for_channel` procedure. This procedure must be run on the target RDS for MySQL DB instance on which you're creating the replication channel.

Before you run `rds_set_external_source_with_auto_position_for_channel`, configure a replication user on the source DB instance with the privileges required for the multi-source replica. To connect the multi-source replica to the source DB instance, you must specify `replication_user_name` and `replication_user_password` values of a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the source DB instance.

## To configure a replication user on the source DB instance

1. Using the MySQL client of your choice, connect to the source DB instance and create a user account to be used for replication. The following is an example.

### Important

As a security best practice, specify a password other than the placeholder value shown in the following examples.

### MySQL 8.0

```
CREATE USER 'repl_user'@'example.com' IDENTIFIED WITH mysql_native_password BY  
'password';
```

### MySQL 5.7

```
CREATE USER 'repl_user'@'example.com' IDENTIFIED BY 'password';
```

2. On the source DB instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl\_user' user for your domain.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'example.com';
```

To use encrypted replication, configure the source DB instance to use SSL connections.

After calling `mysql.rds_set_external_source_with_auto_position_for_channel` to configure an Amazon RDS DB instance as a read replica on a specific channel, you can call [the section called “mysql.rds\\_start\\_replication\\_for\\_channel”](#) on the read replica to start the replication process on that channel.

After calling `mysql.rds_set_external_source_with_auto_position_for_channel` to configure this replication channel, you can call [mysql.rds\\_start\\_replication\\_for\\_channel](#) on the replica to start the replication process on the channel. You can call [the section called “mysql.rds\\_reset\\_external\\_source\\_for\\_channel”](#) to stop replication on the channel and remove the channel configuration from the replica.

## Examples

When run on a RDS for MySQL DB instance, the following example configures a replication channel named `channel_1` on this DB instance to replicate data from the source specified by host `sourcedb.example.com` and port `3306`. It sets the minimum replication delay to one hour (3,600 seconds). This means that a change from the source RDS for MySQL DB instance isn't applied on the multi-source replica for at least one hour.

```
call mysql.rds_set_external_source_with_auto_position_for_channel(  
  'sourcedb.example.com',  
  3306,  
  'repl_user',  
  'password',  
  0,  
  3600,  
  'channel_1');
```

## mysql.rds\_set\_external\_source\_with\_delay\_for\_channel

Configures a replication channel on an RDS for MySQL DB instance with a specified replication delay.

### Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

## Syntax

```
CALL mysql.rds_set_external_source_with_delay_for_channel (  
  host_name  
  , host_port  
  , replication_user_name  
  , replication_user_password  
  , mysql_binary_log_file_name  
  , mysql_binary_log_file_location  
  , ssl_encryption
```

```
, delay  
, channel_name  
);
```

## Parameters

### *host\_name*

The host name or IP address of the RDS for MySQL source DB instance.

### *host\_port*

The port used by the RDS for MySQL source DB instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

### *replication\_user\_name*

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the RDS for MySQL source DB instance. We recommend that you provide an account that is used solely for replication with the source DB instance.

### *replication\_user\_password*

The password of the user ID specified in `replication_user_name`.

### *mysql\_binary\_log\_file\_name*

The name of the binary log on the source DB instance contains the replication information.

### *mysql\_binary\_log\_file\_location*

The location in the `mysql_binary_log_file_name` binary log at which replication will start reading the replication information.

You can determine the binlog file name and location by running `SHOW MASTER STATUS` on the source database instance.

### *ssl\_encryption*

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

**Note**

The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

*delay*

The minimum number of seconds to delay replication from source DB instance.

The limit for this parameter is one day (86400 seconds).

*channel\_name*

The name of the replication channel. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

**Usage notes**

The master user must run the `mysql.rds_set_external_source_with_delay_for_channel` procedure. This procedure must be run on the target RDS for MySQL DB instance on which you're creating the replication channel.

Before you run `mysql.rds_set_external_source_with_delay_for_channel`, configure a replication user on the source DB instance with the privileges required for the multi-source replica. To connect the multi-source replica to the source DB instance, you must specify `replication_user_name` and `replication_user_password` values of a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the source DB instance.

**To configure a replication user on the source DB instance**

1. Using the MySQL client of your choice, connect to the source DB instance and create a user account to be used for replication. The following is an example.

**Important**

As a security best practice, specify a password other than the placeholder value shown in the following examples.

## MySQL 8.0

```
CREATE USER 'repl_user'@'example.com' IDENTIFIED WITH mysql_native_password BY  
'password';
```

## MySQL 5.7

```
CREATE USER 'repl_user'@'example.com' IDENTIFIED BY 'password';
```

2. On the source DB instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl\_user' user for your domain.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'example.com';
```

To use encrypted replication, configure the source DB instance to use SSL connections.

After calling `mysql.rds_set_external_source_with_delay_for_channel` to configure this replication channel, you can call [mysql.rds\\_start\\_replication\\_for\\_channel](#) on the replica to start the replication process on the channel. You can call [the section called "mysql.rds\\_reset\\_external\\_source\\_for\\_channel"](#) to stop replication on the channel and remove the channel configuration from the replica.

When you call `mysql.rds_set_external_source_with_delay_for_channel`, Amazon RDS records the time, user, and an action of `set_channel_source` in the `mysql.rds_history` table without channel-specific details, and in the `mysql.rds_replication_status` table, with the channel name. This information is recorded only for internal usage and monitoring purposes. To record the complete procedure call for auditing purpose, consider enabling audit logs or general logs, based on the specific requirements of your application.

## Examples

When run on a RDS for MySQL DB instance, the following example configures a replication channel named `channel_1` on this DB instance to replicate data from the source specified by host `sourcedb.example.com` and port `3306`. It sets the minimum replication delay to one hour (3,600 seconds). This means that a change from the source RDS for MySQL DB instance isn't applied on the multi-source replica for at least one hour.

```
call mysql.rds_set_external_source_with_delay_for_channel(  
  'sourcedb.example.com',  
  3306,  
  'repl_user',  
  'password',  
  'mysql-bin-changelog.000777',  
  120,  
  0,  
  3600,  
  'channel_1');
```

## mysql.rds\_set\_source\_auto\_position\_for\_channel

Sets the replication mode for the specified channel to be based on either binary log file positions or on global transaction identifiers (GTIDs).

### Syntax

```
CALL mysql.rds_set_source_auto_position_for_channel (  
auto_position_mode  
  , channel_name  
);
```

### Parameters

#### *auto\_position\_mode*

A value that indicates whether to use log file position replication or GTID-based replication:

- 0 – Use the replication method based on binary log file position. The default is 0.
- 1 – Use the GTID-based replication method.

#### *channel\_name*

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

## Usage notes

The master user must run the `mysql.rds_set_source_auto_position_for_channel` procedure. This procedure restarts replication on the specified channel to apply the specified auto position mode.

## Examples

The following example sets the auto position mode for `channel_1` to use the GTID-based replication method.

```
call mysql.rds_set_source_auto_position_for_channel(1, 'channel_1');
```

## `mysql.rds_set_source_delay_for_channel`

Sets the minimum number of seconds to delay replication from the source database instance to the multi-source replica for the specified channel.

## Syntax

```
CALL mysql.rds_set_source_delay_for_channel(delay, channel_name);
```

## Parameters

### *delay*

The minimum number of seconds to delay replication from the source DB instance.

The limit for this parameter is one day (86400 seconds).

### *channel\_name*

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

## Usage notes

The master user must run the `mysql.rds_set_source_delay_for_channel` procedure. To use this procedure, first call `mysql.rds_stop_replication_for_channel` to stop the replication. Then, call this procedure to set the replication delay value. When the delay is set, call `mysql.rds_start_replication_for_channel` to restart the replication.

## Examples

The following example sets the delay for replication from the source database instance on `channel_1` of the multi-source replica for at least one hour (3,600 seconds).

```
CALL mysql.rds_set_source_delay_for_channel(3600, 'channel_1');
```

## mysql.rds\_skip\_repl\_error\_for\_channel

Skips a binary log event and deletes a replication error on a MySQL DB multi-source replica for the specified channel.

### Syntax

```
CALL mysql.rds_skip_repl_error_for_channel(channel_name);
```

### Parameters

#### *channel\_name*

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

### Usage notes

The master user must run the `mysql.rds_skip_repl_error_for_channel` procedure on a read replica. You can use this procedure in a similar way `mysql.rds_skip_repl_error` is used to skip an error on a read replica. For more information, see [Calling the mysql.rds\\_skip\\_repl\\_error procedure](#).

#### Note

To skip errors in GTID-based replication, we recommend that you use the procedure [the section called “mysql.rds\\_skip\\_transaction\\_with\\_gtid”](#) instead.

To determine if there are errors, run the MySQL `SHOW REPLICA STATUS FOR CHANNEL 'channel_name'\G` command. If a replication error isn't critical, you can run

`mysql.rds_skip_repl_error_for_channel` to skip the error. If there are multiple errors, `mysql.rds_skip_repl_error_for_channel` deletes the first error on the specified replication channel, then warns that others are present. You can then use `SHOW REPLICA STATUS FOR CHANNEL 'channel_name'\G` to determine the correct course of action for the next error. For information about the values returned, see [SHOW REPLICA STATUS statement](#) in the MySQL documentation.

## mysql.rds\_start\_replication\_for\_channel

Initiates replication from an RDS for MySQL DB instance to a multi-source replica on the specified channel.

### Note

You can use the [mysql.rds\\_start\\_replication\\_until\\_for\\_channel](#) or [mysql.rds\\_start\\_replication\\_until\\_gtid\\_for\\_channel](#) stored procedure to initiate replication from an RDS for MySQL DB instance and stop replication at the specified binary log file location.

## Syntax

```
CALL mysql.rds_start_replication_for_channel(channel_name);
```

## Parameters

### *channel\_name*

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

## Usage notes

The master user must run the `mysql.rds_start_replication_for_channel` procedure. After you import the data from the source RDS for MySQL DB instance, run this command on the multi-source replica to start replication on the specified channel.

## Examples

The following example starts replication on `channel_1` of the multi-source replica.

```
CALL mysql.rds_start_replication_for_channel('channel_1');
```

## `mysql.rds_start_replication_until_for_channel`

Initiates replication from an RDS for MySQL DB instance on the specified channel and stops replication at the specified binary log file location.

## Syntax

```
CALL mysql.rds_start_replication_until_for_channel (  
  replication_log_file  
  , replication_stop_point  
  , channel_name  
);
```

## Parameters

### *replication\_log\_file*

The name of the binary log on the source DB instance contains the replication information.

### *replication\_stop\_point*

The location in the `replication_log_file` binary log at which replication will stop.

### *channel\_name*

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

## Usage notes

The master user must run the `mysql.rds_start_replication_until_for_channel` procedure. With this procedure, replication starts and then stops when the specified binlog file

position is reached. For version 8.0, the procedure stops only the SQL\_Thread. For version 5.7, the procedure stops both the SQL\_Thread and the IO\_Thread.

The file name specified for the `replication_log_file` parameter must match the source DB instance binlog file name.

When the `replication_stop_point` parameter specifies a stop location that's in the past, replication is stopped immediately.

## Examples

The following example initiates replication on `channel_1`, and replicates changes until it reaches location 120 in the `mysql-bin-changelog.000777` binary log file.

```
call mysql.rds_start_replication_until_for_channel(  
  'mysql-bin-changelog.000777',  
  120,  
  'channel_1'  
);
```

## mysql.rds\_start\_replication\_until\_gtid\_for\_channel

Initiates replication on the specified channel from an RDS for MySQL DB instance and stops replication at the specified global transaction identifier (GTID).

### Syntax

```
CALL mysql.rds_start_replication_until_gtid_for_channel(gtid, channel_name);
```

### Parameters

#### *gtid*

The GTID after which to stop replication.

#### *channel\_name*

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

## Usage notes

The master user must run the `mysql.rds_start_replication_until_gtid_for_channel` procedure. The procedure starts replication on the specified channel and applies all changes up to the specified GTID value. Then, it stops replication on the channel.

When the `gtid` parameter specifies a transaction that has already been run by the replica, replication is stopped immediately.

Before you run this procedure, you must disable multi-threaded replication by setting the value of `replica_parallel_workers` or `slave_parallel_workers` to 0.

## Examples

The following example initiates replication on `channel_1`, and replicates changes until it reaches GTID `3E11FA47-71CA-11E1-9E33-C80AA9429562:23`.

```
call mysql.rds_start_replication_until_gtid_for_channel('3E11FA47-71CA-11E1-9E33-C80AA9429562:23', 'channel_1');
```

## mysql.rds\_stop\_replication\_for\_channel

Stops replication from a MySQL DB instance on the specified channel.

### Syntax

```
CALL mysql.rds_stop_replication_for_channel(channel_name);
```

### Parameters

#### *channel\_name*

The name of the replication channel on the multi-source replica. Each replication channel receives the binary log events from a single source RDS for MySQL DB instance running on a specific host and port.

## Usage notes

The master user must run the `mysql.rds_stop_replication_for_channel` procedure.

## Examples

The following example stops replication on `channel_1` of the multi-source replica.

```
CALL mysql.rds_stop_replication_for_channel('channel_1');
```

## Replicating transactions using GTIDs

The following stored procedures control how transactions are replicated using global transaction identifiers (GTIDs) with RDS for MySQL. For more information about replication based on GTIDs with RDS for MySQL, see [Using GTID-based replication](#).

### Topics

- [mysql.rds\\_skip\\_transaction\\_with\\_gtid](#)
- [mysql.rds\\_start\\_replication\\_until\\_gtid](#)

### mysql.rds\_skip\_transaction\_with\_gtid

Skips replication of a transaction with the specified global transaction identifier (GTID) on a MySQL DB instance.

You can use this procedure for disaster recovery when a specific GTID transaction is known to cause a problem. Use this stored procedure to skip the problematic transaction. Examples of problematic transactions include transactions that disable replication, delete important data, or cause the DB instance to become unavailable.

### Syntax

```
CALL mysql.rds_skip_transaction_with_gtid (  
  gtid_to_skip  
);
```

### Parameters

*gtid\_to\_skip*

The GTID of the replication transaction to skip.

### Usage notes

The master user must run the `mysql.rds_skip_transaction_with_gtid` procedure.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

## Examples

The following example skips replication of the transaction with the GTID 3E11FA47-71CA-11E1-9E33-C80AA9429562:23.

```
CALL mysql.rds_skip_transaction_with_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

## mysql.rds\_start\_replication\_until\_gtid

Initiates replication from an RDS for MySQL DB instance and stops replication immediately after the specified global transaction identifier (GTID).

### Syntax

```
CALL mysql.rds_start_replication_until_gtid(gtid);
```

### Parameters

*gtid*

The GTID after which replication is to stop.

### Usage notes

The master user must run the `mysql.rds_start_replication_until_gtid` procedure.

This procedure is supported for all RDS for MySQL 5.7 versions, and RDS for MySQL 8.0.26 and higher 8.0 versions.

You can use this procedure with delayed replication for disaster recovery. If you have delayed replication configured, you can use this procedure to roll forward changes to a delayed read replica to the time just before a disaster. After this procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in [Promoting a read replica to be a standalone DB instance](#).

You can configure delayed replication using the following stored procedures:

- [mysql.rds\\_set\\_configuration](#)
- [mysql.rds\\_set\\_external\\_master\\_with\\_delay](#)

- [mysql.rds\\_set\\_source\\_delay](#)

When the `gtid` parameter specifies a transaction that has already been run by the replica, replication is stopped immediately.

### Examples

The following example initiates replication and replicates changes until it reaches GTID `3E11FA47-71CA-11E1-9E33-C80AA9429562:23`.

```
call mysql.rds_start_replication_until_gtid('3E11FA47-71CA-11E1-9E33-C80AA9429562:23');
```

## Rotating the query logs

The following stored procedures rotate MySQL logs to backup tables. For more information, see [MySQL database log files](#).

### Topics

- [mysql.rds\\_rotate\\_general\\_log](#)
- [mysql.rds\\_rotate\\_slow\\_log](#)

### mysql.rds\_rotate\_general\_log

Rotates the `mysql.general_log` table to a backup table.

### Syntax

```
CALL mysql.rds_rotate_general_log;
```

### Usage notes

You can rotate the `mysql.general_log` table to a backup table by calling the `mysql.rds_rotate_general_log` procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the `mysql.general_log` table is named `mysql.general_log_backup`.

You can run this procedure only when the `log_output` parameter is set to `TABLE`.

### mysql.rds\_rotate\_slow\_log

Rotates the `mysql.slow_log` table to a backup table.

### Syntax

```
CALL mysql.rds_rotate_slow_log;
```

## Usage notes

You can rotate the `mysql.slow_log` table to a backup table by calling the `mysql.rds_rotate_slow_log` procedure. When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If a backup log table already exists, then it is deleted before the current log table is copied to the backup.

You can query the backup log table if needed. The backup log table for the `mysql.slow_log` table is named `mysql.slow_log_backup`.

## Setting and showing binary log configuration

The following stored procedures set and show configuration parameters, such as for binary log file retention.

### Topics

- [mysql.rds\\_set\\_configuration](#)
- [mysql.rds\\_show\\_configuration](#)

### mysql.rds\_set\_configuration

Specifies the number of hours to retain binary logs or the number of seconds to delay replication.

### Syntax

```
CALL mysql.rds_set_configuration(name, value);
```

### Parameters

#### *name*

The name of the configuration parameter to set.

#### *value*

The value of the configuration parameter.

### Usage notes

The `mysql.rds_set_configuration` procedure supports the following configuration parameters:

- [binlog retention hours](#)
- [source delay](#)
- [target delay](#)

The configuration parameters are stored permanently and survive any DB instance reboot or failover.

## binlog retention hours

The `binlog retention hours` parameter is used to specify the number of hours to retain binary log files. Amazon RDS normally purges a binary log as soon as possible, but the binary log might still be required for replication with a MySQL database external to RDS.

The default value of `binlog retention hours` is `NULL`. For RDS for MySQL, `NULL` means binary logs aren't retained (0 hours).

To specify the number of hours to retain binary logs on a DB instance, use the `mysql.rds_set_configuration` stored procedure and specify a period with enough time for replication to occur, as shown in the following example.

```
call mysql.rds_set_configuration('binlog retention hours', 24);
```

### Note

You can't use the value `0` for `binlog retention hours`.

For MySQL DB instances, the maximum `binlog retention hours` value is 168 (7 days).

After you set the retention period, monitor storage usage for the DB instance to make sure that the retained binary logs don't take up too much storage.

For Multi-AZ DB cluster deployments, you can only configure binary log retention from the writer DB instance, and the setting is propagated to all reader DB instances asynchronously. If binary logs on the DB cluster exceed half of the total local storage space, Amazon RDS automatically moves stale logs to the EBS volume. However, the newest logs remain in local storage, so they're subject to be lost if there's a failure that requires a host replacement, or if you scale the database up or down.

## source delay

Use the `source delay` parameter in a read replica to specify the number of seconds to delay replication from the read replica to its source DB instance. Amazon RDS normally replicates changes as soon as possible, but you might want some environments to delay replication. For example, when replication is delayed, you can roll forward a delayed read replica to the time just before a disaster. If a table is dropped accidentally, you can use delayed replication to quickly recover it. The default value of `target delay` is `0` (don't delay replication).

When you use this parameter, it runs [mysql.rds\\_set\\_source\\_delay](#) and applies CHANGE primary TO MASTER\_DELAY = input value. If successful, the procedure saves the source\_delay parameter to the mysql.rds\_configuration table.

To specify the number of seconds for Amazon RDS to delay replication to a source DB instance, use the mysql.rds\_set\_configuration stored procedure and specify the number of seconds to delay replication. In the following example, the replication is delayed by at least one hour (3,600 seconds).

```
call mysql.rds_set_configuration('source_delay', 3600);
```

The procedure then runs mysql.rds\_set\_source\_delay(3600).

The limit for the source\_delay parameter is one day (86400 seconds).

#### Note

The source\_delay parameter isn't supported for RDS for MySQL version 8.0 or MariaDB versions below 10.2.

## target\_delay

Use the target\_delay parameter to specify the number of seconds to delay replication between a DB instance and any future RDS-managed read replicas created from this instance. This parameter is ignored for non-RDS-managed read replicas. Amazon RDS normally replicates changes as soon as possible, but you might want some environments to delay replication. For example, when replication is delayed, you can roll forward a delayed read replica to the time just before a disaster. If a table is dropped accidentally, you can use delayed replication to recover it quickly. The default value of target\_delay is 0 (don't delay replication).

For disaster recovery, you can use this configuration parameter with the [mysql.rds\\_start\\_replication\\_until](#) stored procedure or the [mysql.rds\\_start\\_replication\\_until\\_gtid](#) stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the mysql.rds\_set\_configuration procedure with this parameter set. After the mysql.rds\_start\_replication\_until or mysql.rds\_start\_replication\_until\_gtid procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in [Promoting a read replica to be a standalone DB instance](#).

To use the `mysql.rds_rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the [mysql.rds\\_skip\\_transaction\\_with\\_gtid](#) stored procedure. For more information about working with GTID-based replication, see [Using GTID-based replication](#).

To specify the number of seconds for Amazon RDS to delay replication to a read replica, use the `mysql.rds_set_configuration` stored procedure and specify the number of seconds to delay replication. The following example specifies that replication is delayed by at least one hour (3,600 seconds).

```
call mysql.rds_set_configuration('target delay', 3600);
```

The limit for the `target delay` parameter is one day (86400 seconds).

#### Note

The `target delay` parameter isn't supported for RDS for MySQL version 8.0 or MariaDB versions earlier than 10.2.

## mysql.rds\_show\_configuration

The number of hours that binary logs are retained.

### Syntax

```
CALL mysql.rds_show_configuration;
```

### Usage notes

To verify the number of hours that Amazon RDS retains binary logs, use the `mysql.rds_show_configuration` stored procedure.

### Examples

The following example displays the retention period:

```
call mysql.rds_show_configuration;
```

name	value	description
------	-------	-------------

```
binlog retention hours    24    binlog retention hours specifies
the duration in hours before binary logs are automatically deleted.
```

## Warming the InnoDB cache

The following stored procedures save, load, or cancel loading the InnoDB buffer pool on RDS for MySQL DB instances. For more information, see [InnoDB cache warming for MySQL on Amazon RDS](#).

### Topics

- [mysql.rds\\_innodb\\_buffer\\_pool\\_dump\\_now](#)
- [mysql.rds\\_innodb\\_buffer\\_pool\\_load\\_abort](#)
- [mysql.rds\\_innodb\\_buffer\\_pool\\_load\\_now](#)

### mysql.rds\_innodb\_buffer\_pool\_dump\_now

Dumps the current state of the buffer pool to disk.

#### Syntax

```
CALL mysql.rds_innodb_buffer_pool_dump_now();
```

#### Usage notes

The master user must run the `mysql.rds_innodb_buffer_pool_dump_now` procedure.

### mysql.rds\_innodb\_buffer\_pool\_load\_abort

Cancels a load of the saved buffer pool state while in progress.

#### Syntax

```
CALL mysql.rds_innodb_buffer_pool_load_abort();
```

#### Usage notes

The master user must run the `mysql.rds_innodb_buffer_pool_load_abort` procedure.

### mysql.rds\_innodb\_buffer\_pool\_load\_now

Loads the saved state of the buffer pool from disk.

## Syntax

```
CALL mysql.rds_innodb_buffer_pool_load_now();
```

## Usage notes

The master user must run the `mysql.rds_innodb_buffer_pool_load_now` procedure.

# Amazon RDS for Oracle

Amazon RDS supports DB instances that run the following versions and editions of Oracle Database:

- Oracle Database 21c (21.0.0.0)
- Oracle Database 19c (19.0.0.0)

## Note

Oracle Database 11g, Oracle Database 12c, and Oracle Database 18c are legacy versions that are no longer supported in Amazon RDS.

Before creating a DB instance, complete the steps in the [Setting up for Amazon RDS](#) section of this guide. When you create a DB instance using your master account, the account gets DBA privileges, with some limitations. Use this account for administrative tasks such as creating additional database accounts. You can't use SYS, SYSTEM, or other Oracle-supplied administrative accounts.

You can create the following:

- DB instances
- DB snapshots
- Point-in-time restores
- Automated backups
- Manual backups

You can use DB instances running Oracle inside a VPC. You can also add features to your Oracle DB instance by enabling various options. Amazon RDS supports Multi-AZ deployments for Oracle as a high-availability, failover solution.

## Important

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that need advanced privileges. You can access your database using standard SQL clients such as

Oracle SQL\*Plus. However, you can't access the host directly by using Telnet or Secure Shell (SSH).

- [Oracle Database engine release notes](#)

## Overview of Oracle on Amazon RDS

You can read the following sections to get an overview of RDS for Oracle.

### Topics

- [RDS for Oracle features](#)
- [RDS for Oracle releases](#)
- [RDS for Oracle licensing options](#)
- [RDS for Oracle users and privileges](#)
- [RDS for Oracle DB instance classes](#)
- [RDS for Oracle database architecture](#)
- [RDS for Oracle parameters](#)
- [RDS for Oracle character sets](#)
- [RDS for Oracle limitations](#)

## RDS for Oracle features

Amazon RDS for Oracle supports most of the features and capabilities of Oracle Database. Some features might have limited support or restricted privileges. Some features are only available in Enterprise Edition, and some require additional licenses. For more information about Oracle Database features for specific Oracle Database versions, see the *Oracle Database Licensing Information User Manual* for the version you're using.

You can filter new Amazon RDS features on the [What's New with Database?](#) page. For **Products**, choose **Amazon RDS**. Then search using keywords such as **Oracle 2022**.

### Note

The following lists are not exhaustive.

### Topics

- [New features in RDS for Oracle](#)
- [Supported features in RDS for Oracle](#)
- [Unsupported features in RDS for Oracle](#)

## New features in RDS for Oracle

To see new features in RDS for Oracle, use the following techniques:

- Search [Document history](#) for the keyword **Oracle**.
- Filter new Amazon RDS features on the [What's New with Database?](#) page. For **Products**, choose **Amazon RDS**. Then search for **Oracle YYYY**, where **YYYY** is a year such as **2024**.

## Supported features in RDS for Oracle

Amazon RDS for Oracle supports the following Oracle Database features:

- Advanced Compression
- Application Express (APEX)

For more information, see [Oracle Application Express \(APEX\)](#).

- Automatic Memory Management
- Automatic Undo Management
- Automatic Workload Repository (AWR)

For more information, see [Generating performance reports with Automatic Workload Repository \(AWR\)](#).

- Active Data Guard with Maximum Performance in the same AWS Region or across AWS Regions

For more information, see [Working with read replicas for Amazon RDS for Oracle](#).

- Blockchain tables (Oracle Database 21c and higher)

For more information, see [Managing Blockchain Tables](#) in the Oracle Database documentation.

- Continuous Query Notification

For more information, see [Using Continuous Query Notification \(CQN\)](#) in the Oracle documentation.

- Data Redaction
- Continuous Query Notification

For more information, see [Database Change Notification](#) in the Oracle documentation.

- Database In-Memory
- Distributed Queries and Transactions
- Edition-Based Redefinition

For more information, see [Setting the default edition for a DB instance](#).

- EM Express (12c and higher)

For more information, see [Oracle Enterprise Manager](#).

- Fine-Grained Auditing
- Flashback Table, Flashback Query, Flashback Transaction Query
- Gradual password rollover for applications (Oracle Database 21c and higher)

For more information, see [Managing Gradual Database Password Rollover for Applications](#) in the Oracle Database documentation.

- HugePages

For more information, see [Turning on HugePages for an RDS for Oracle instance](#).

- Import/export (legacy and Data Pump) and SQL\*Loader

For more information, see [Importing data into Oracle on Amazon RDS](#).

- Java Virtual Machine (JVM)

For more information, see [Oracle Java virtual machine](#).

- JavaScript (Oracle Database 21c and higher)

For more information, see [DBMS\\_MLE](#) in the Oracle Database documentation.

- Label Security

For more information, see [Oracle Label Security](#).

- Locator

For more information, see [Oracle Locator](#).

- Materialized Views
- Multitenant

The Oracle multitenant architecture is supported for all Oracle Database 19c and higher releases. For more information, see [Working with CDBs in RDS for Oracle](#).

- Network encryption

For more information, see [Oracle native network encryption](#) and [Oracle Secure Sockets Layer](#).

- Partitioning
- Real Application Testing

To use the full capture and replay capabilities, you must use Amazon Elastic File System (Amazon EFS) to access files generated by Oracle Real Application Testing. For more information, see [Amazon EFS integration](#) and the blog post [Use Oracle Real Application Testing features with Amazon RDS for Oracle](#).

- Sharding at the application level (but not the Oracle Sharding feature)
- Spatial and Graph

For more information, see [Oracle Spatial](#).

- Star Query Optimization

- Streams and Advanced Queuing
- Summary Management – Materialized View Query Rewrite
- Text (File and URL data store types are not supported)
- Total Recall
- Transparent Data Encryption (TDE)

For more information, see [Oracle Transparent Data Encryption](#).

- Unified Auditing, Mixed Mode

For more information, see [Mixed mode auditing](#) in the Oracle documentation.

- XML DB (without the XML DB Protocol Server)

For more information, see [Oracle XML DB](#).

- Virtual Private Database

## Unsupported features in RDS for Oracle

Amazon RDS for Oracle doesn't support the following Oracle Database features:

- Automatic Storage Management (ASM)
- Database Vault
- Flashback Database

### Note

For alternative solutions, see the AWS Database Blog entry [Alternatives to the Oracle flashback database feature in Amazon RDS for Oracle](#).

- FTP and SFTP
- Hybrid partitioned tables
- Messaging Gateway
- Oracle Enterprise Manager Cloud Control Management Repository
- Real Application Clusters (Oracle RAC)
- Real Application Security (RAS)
- Unified Auditing, Pure Mode

- Workspace Manager (WMSYS) schema

**Note**

The preceding list is not exhaustive.

**Warning**

In general, Amazon RDS doesn't prevent you from creating schemas for unsupported features. However, if you create schemas for Oracle features and components that require SYSDBA privileges, you can damage the data dictionary and affect the availability of your DB instance. Use only supported features and schemas that are available in [Adding options to Oracle DB instances](#).

## RDS for Oracle releases

RDS for Oracle for Oracle supports multiple Oracle Database releases.

**Note**

For information about upgrading your releases, see [Upgrading the RDS for Oracle DB engine](#).

### Topics

- [Oracle Database 21c with Amazon RDS](#)
- [Oracle Database 19c with Amazon RDS](#)

## Oracle Database 21c with Amazon RDS

Amazon RDS supports Oracle Database 21c, which includes Oracle Enterprise Edition and Oracle Standard Edition 2. Oracle Database 21c (21.0.0.0) includes many new features and updates from the previous version. A key change is that Oracle Database 21c supports only the multitenant architecture: you can no longer create a database as a traditional non-CDB. To learn more about the differences between CDBs and non-CDBs, see [Limitations of RDS for Oracle CDBs](#).

In this section, you can find the features and changes important to using Oracle Database 21c (21.0.0.0) on Amazon RDS. For a complete list of the changes, see the [Oracle database 21c](#) documentation. For a complete list of features supported by each Oracle Database 21c edition, see [Permitted features, options, and management packs by Oracle database offering](#) in the Oracle documentation.

## Amazon RDS parameter changes for Oracle Database 21c (21.0.0.0)

Oracle Database 21c (21.0.0.0) includes several new parameters and parameters with new ranges and new default values.

### Topics

- [New parameters](#)
- [Changes for the compatible parameter](#)
- [Removed parameters](#)

### New parameters

The following table shows the new Amazon RDS parameters for Oracle Database 21c (21.0.0.0).

Name	Range of values	Default value	Modifiable	Description
<a href="#">blockchain_table_max_no_drop</a>	NONE   0	NONE	Y	Lets you control the maximum amount of idle time that can be specified when creating a blockchain table.
<a href="#">dbnest_enable</a>	NONE   CDB_RESOURCE_PDB_ALL	NONE	N	Allows you to enable or disable dbNest. DbNest provides operating system resource isolation and management, file system isolation, and secure computing for PDBs.

Name	Range of values	Default value	Modifiable	Description
<a href="#">dbnest_pdb_fs_conf</a>	NONE   <i>pathname</i>	NONE	N	Specifies the dbNest file system configuration file for a PDB.
<a href="#">diagnostics_control</a>	ERROR   WARNING   IGNORE	IGNORE	Y	Allows you to control and monitor the users who perform potentially unsafe database diagnostic operations.
<a href="#">drcp_dedicated_opt</a>	YES   NO	YES	Y	Enables or disables the use of dedicated optimization with Database Resident Connection Pooling (DRCP).
<a href="#">enable_per_pdb_drpc</a>	true   false	true	N	Controls whether Database Resident Connection Pooling (DRCP) configures one connection pool for the entire CDB or one isolated connection pool for each PDB.
<a href="#">inmemory_deep_vectorization</a>	true   false	true	Y	Enables or disables the deep vectorization framework.
<a href="#">mandatory_user_profile</a>	<i>profile_name</i>	N/A	N	Specifies the mandatory user profile for a CDB or PDB.
<a href="#">optimizer_capture_sql_quarantine</a>	true   false	false	Y	Enables or disables the deep vectorization framework.
<a href="#">optimizer_use_sql_quarantine</a>	true   false	false	Y	Enables or disables the automatic creation of SQL Quarantine configurations.

Name	Range of values	Default value	Modifiable	Description
<a href="#"><u>result_cache_execution_threshold</u></a>	0 to 68719476736	2	Y	Specifies the maximum number of times a PL/SQL function can be executed before its result is stored in the result cache.
<a href="#"><u>result_cache_max_temp_result</u></a>	0 to 100	5	Y	Specifies the percentage of RESULT_CACHE_MAX_TEMP_SIZE that any single cached query result can consume.
<a href="#"><u>result_cache_max_temp_size</u></a>	0 to 219902325552	RESULT_CACHE_SIZE * 10	Y	Specifies the maximum amount of temporary tablespace (in bytes) that can be consumed by the result cache.
<a href="#"><u>sga_min_size</u></a>	0 to 219902325552 (maximum value is 50% of sga_target )	0	Y	Indicates a possible minimum value for SGA usage of a pluggable database (PDB).

Name	Range of values	Default value	Modifiable	Description
<a href="#">tablespace_encryption_default_algorithm</a>	GOST256   SEED128   ARIA256   ARIA192   ARIA128   3DES168   AES256   AES192   AES128	AES128	Y	Specifies the default algorithm the database uses when encrypting a tablespace.

### Changes for the compatible parameter

The `compatible` parameter has a new maximum value for Oracle Database 21c (21.0.0.0) on Amazon RDS. The following table shows the new default value.

Parameter name	Oracle Database 21c (21.0.0.0) maximum value
<a href="#">compatible</a>	21.0.0

### Removed parameters

The following parameters were removed in Oracle Database 21c (21.0.0.0):

- `remote_os_authent`
- `sec_case_sensitive_logon`
- `unified_audit_sga_queue_size`

### Oracle Database 19c with Amazon RDS

Amazon RDS supports Oracle Database 19c, which includes Oracle Enterprise Edition and Oracle Standard Edition Two.

Oracle Database 19c (19.0.0.0) includes many new features and updates from the previous version. In this section, you can find the features and changes important to using Oracle Database 19c (19.0.0.0) on Amazon RDS. For a complete list of the changes, see the [Oracle database 19c](#) documentation. For a complete list of features supported by each Oracle Database 19c edition, see [Permitted features, options, and management packs by Oracle database offering](#) in the Oracle documentation.

## Amazon RDS parameter changes for Oracle Database 19c (19.0.0.0)

Oracle Database 19c (19.0.0.0) includes several new parameters and parameters with new ranges and new default values.

### Topics

- [New parameters](#)
- [Changes to the compatible parameter](#)
- [Removed parameters](#)

### New parameters

The following table shows the new Amazon RDS parameters for Oracle Database 19c (19.0.0.0).

Name	Values	Modifiable	Description
<a href="#">lob_signature_enable</a>	TRUE, FALSE (default)	Y	Enables or disables the LOB locator signature feature.
<a href="#">max_datapump_parallel_per_job</a>	1 to 1024, or AUTO	Y	Specifies the maximum number of parallel processes allowed for each Oracle Data Pump job.

### Changes to the compatible parameter

The `compatible` parameter has a new maximum value for Oracle Database 19c (19.0.0.0) on Amazon RDS. The following table shows the new default value.

Parameter name	Oracle Database 19c (19.0.0.0) maximum value
<a href="#">compatible</a>	19.0.0

## Removed parameters

The following parameters were removed in Oracle Database 19c (19.0.0.0):

- `exafusion_enabled`
- `max_connections`
- `o7_dictionary_access`

## RDS for Oracle licensing options

Amazon RDS for Oracle has two licensing options: License Included (LI) and Bring Your Own License (BYOL). After you create an Oracle DB instance on Amazon RDS, you can change the licensing model by modifying the DB instance. For more information, see [Modifying an Amazon RDS DB instance](#).

### Important

Make sure that you have the appropriate Oracle Database license, with Software Update License and Support, for your DB instance class and Oracle Database edition. Also make sure that you have licenses for any separately licensed Oracle Database features.

## Topics

- [License Included model for SE2](#)
- [Bring Your Own License \(BYOL\) for EE and SE2](#)
- [Licensing Oracle Multi-AZ deployments](#)

## License Included model for SE2

In the License Included model, you don't need to purchase Oracle Database licenses separately. AWS holds the license for the Oracle database software. The License Included model is only supported on Amazon RDS for Oracle Database Standard Edition 2 (SE2).

In this model, if you have an AWS Support account with case support, contact AWS Support for both Amazon RDS and Oracle Database service requests. Your use of RDS for Oracle the LI option is subject to Section 10.3.1 of the [AWS Service Terms](#).

## Bring Your Own License (BYOL) for EE and SE2

In the BYOL model, you can use your existing Oracle Database licenses to deploy databases on Amazon RDS. Amazon RDS supports the BYOL model only for Oracle Database Enterprise Edition (EE) and Oracle Database Standard Edition 2 (SE2).

Make sure that you have the appropriate Oracle Database license (with Software Update License and Support) for the DB instance class and Oracle Database edition you wish to run. You must also follow Oracle's policies for licensing Oracle Database software in the cloud computing environment. For more information on Oracle's licensing policy for Amazon EC2, see [Licensing Oracle software in the cloud computing environment](#).

In this model, you continue to use your active Oracle support account, and you contact Oracle directly for Oracle Database service requests. If you have an AWS Support account with case support, you can contact AWS Support for Amazon RDS issues. Amazon Web Services and Oracle have a multi-vendor support process for cases that require assistance from both organizations.

## Integrating with AWS License Manager

To make it easier to monitor Oracle license usage in the BYOL model, [AWS License Manager](#) integrates with Amazon RDS for Oracle. License Manager supports tracking of RDS for Oracle engine editions and licensing packs based on virtual cores (vCPUs). You can also use License Manager with AWS Organizations to manage all of your organizational accounts centrally.

The following table shows the product information filters for RDS for Oracle.

Filter	Name	Description
Engine Edition	oracle-ee	Oracle Database Enterprise Edition (EE)
	oracle-se2	Oracle Database Standard Edition 2 (SE2)
License Pack	data guard	See <a href="#">Working with read replicas for Amazon RDS for Oracle</a> (Oracle Active Data Guard)
	olap	See <a href="#">Oracle OLAP</a>

Filter	Name	Description
	ols	See <a href="#">Oracle Label Security</a>
	diagnostic pack sqlt	See <a href="#">Oracle SQLT</a>
	tuning pack sqlt	See <a href="#">Oracle SQLT</a>

To track license usage of your Oracle DB instances, you can create a self-managed license using AWS License Manager. In this case, RDS for Oracle resources that match the product information filter are automatically associated with the self-managed license. Discovery of Oracle DB instances can take up to 24 hours. You can also track a license across accounts by using AWS Resource Access Manager.

## Console

### To create a self-managed license in AWS License Manager to track the license usage of your RDS for Oracle DB instances

1. Go to <https://console.aws.amazon.com/license-manager/>.
2. Choose **Create self-managed license**.

For instructions, see [Create a self-managed license](#) in the *AWS License Manager User Guide*.

Add a rule for an **RDS Product Information Filter** in the **Product Information** panel.

For more information, see [ProductInformation](#) in the *AWS License Manager API Reference*.

3. (Cross-account tracking only) Use AWS Resource Access Manager to share your self-managed licenses with any AWS account or through AWS Organizations. For more information, see [Sharing your AWS resources](#).

## AWS CLI

To create a self-managed license by using the AWS CLI, call the [create-license-configuration](#) command. Use the `--cli-input-json` or `--cli-input-yaml` parameters to pass the parameters to the command.

## Example

The following example creates a self-managed license for Oracle Enterprise Edition.

```
aws license-manager create-license-configuration --cli-input-json file://rds-oracle-ee.json
```

The following is the sample `rds-oracle-ee.json` file used in the example.

```
{
  "Name": "rds-oracle-ee",
  "Description": "RDS Oracle Enterprise Edition",
  "LicenseCountingType": "vCPU",
  "LicenseCountHardLimit": false,
  "ProductInformationList": [
    {
      "ResourceType": "RDS",
      "ProductInformationFilterList": [
        {
          "ProductInformationFilterName": "Engine Edition",
          "ProductInformationFilterValue": ["oracle-ee"],
          "ProductInformationFilterComparator": "EQUALS"
        }
      ]
    }
  ]
}
```

For more information about product information, see [Automated discovery of resource inventory](#) in the *AWS License Manager User Guide*.

For more information about the `--cli-input` parameter, see [Generating AWS CLI skeleton and input parameters from a JSON or YAML input file](#) in the *AWS CLI User Guide*.

## Migrating between Oracle Database editions

If you have an unused BYOL Oracle Database license appropriate for the edition and class of DB instance that you plan to run, you can migrate from Standard Edition 2 (SE2) to Enterprise Edition (EE). You can't migrate from EE to other editions.

### To change your Oracle Database edition and retain your data

1. Create a snapshot of the DB instance.

For more information, see [Creating a DB snapshot for a Single-AZ DB instance](#).

2. Restore the snapshot to a new DB instance, and select the Oracle database edition you want to use.

For more information, see [Restoring to a DB instance](#).

3. (Optional) Delete the old DB instance, unless you want to keep it running and have the appropriate Oracle Database licenses for it.

For more information, see [Deleting a DB instance](#).

## Licensing Oracle Multi-AZ deployments

Amazon RDS supports Multi-AZ deployments for Oracle as a high-availability, failover solution. We recommend Multi-AZ for production workloads. For more information, see [Configuring and managing a Multi-AZ deployment](#).

If you use the Bring Your Own License model, you must have a license for both the primary DB instance and the standby DB instance in a Multi-AZ deployment.

## RDS for Oracle users and privileges

When you create an Amazon RDS for Oracle DB instance, the default master user has most of the maximum user permissions on the DB instance. Use the master user account for any administrative tasks, such as creating additional user accounts in your database. Because RDS is a managed service, you aren't allowed to log in as SYS and SYSTEM, and thus don't have SYSDBA privileges.

### Topics

- [Limitations for Oracle DBA privileges](#)
- [How to manage privileges on SYS objects](#)

## Limitations for Oracle DBA privileges

In the database, a *role* is a collection of privileges that you can grant to or revoke from a user. An Oracle database uses roles to provide security. For more information, see [Configuring Privilege and Role Authorization](#) in the Oracle Database documentation.

The predefined role DBA normally allows all administrative privileges on an Oracle database. When you create a DB instance, your master user account gets DBA privileges (with some limitations). To deliver a managed experience, an RDS for Oracle database doesn't provide the following privileges for the DBA role:

- ALTER DATABASE
- ALTER SYSTEM
- CREATE ANY DIRECTORY
- DROP ANY DIRECTORY
- GRANT ANY PRIVILEGE
- GRANT ANY ROLE

For more RDS for Oracle system privilege and role information, see [Master user account privileges](#).

## How to manage privileges on SYS objects

You can manage privileges on SYS objects by using the `rdsadmin.rdsadmin_util` package. For example, if you create the database user `myuser`, you could use the `rdsadmin.rdsadmin_util.grant_sys_object` procedure to grant SELECT privileges on `V_$SQLAREA` to `myuser`. For more information, see the following topics:

- [Granting SELECT or EXECUTE privileges to SYS objects](#)
- [Revoking SELECT or EXECUTE privileges on SYS objects](#)
- [Granting privileges to non-master users](#)

## RDS for Oracle DB instance classes

The computation and memory capacity of an RDS for Oracle DB instance is determined by its instance class. The DB instance class you need depends on your processing power and memory requirements.

## Supported RDS for Oracle DB instance classes

The supported RDS for Oracle instance classes are a subset of the RDS DB instance classes. For the complete list of RDS instance classes, see [DB instance classes](#).

## RDS for Oracle preconfigured DB instance classes

RDS for Oracle also offers instance classes that are preconfigured for workloads that require additional memory, storage, and I/O per vCPU. These instance classes use the following naming convention:

```
db.r5b.instance_size.tpcthreads_per_core.memratio
db.r5.instance_size.tpcthreads_per_core.memratio
```

The following is an example of an instance class that is preconfigured for additional memory:

```
db.r5b.4xlarge.tpc2.mem2x
```

The components of the preceding instance class name are as follows:

- `db.r5b.4xlarge` – The name of the instance class.
- `tpc2` – The threads per core. A value of 2 means that multithreading is turned on. A value of 1 means that multithreading is turned off.
- `mem2x` – The ratio of additional memory to the standard memory for the instance class. In this example, the optimization provides twice as much memory as a standard `db.r5.4xlarge` DB instance.

## Supported edition, instance class, and licensing combinations in RDS for Oracle

If you're using the RDS console, you can find out whether a specific edition, instance class, and license combination is supported by choosing **Create database** and specifying different option. In the AWS CLI, you can run the following command:

```
aws rds describe-orderable-db-instance-options --engine engine-type --license-model license-type
```

The following table lists all editions, instance classes, and license types supported for RDS for Oracle. For information about the memory attributes of each type, see [RDS for Oracle instance types](#). For information about pricing, see [Amazon RDS for Oracle pricing models](#).

Oracle edition	Oracle Database 19c and higher
Enterprise Edition (EE)	<b>Standard instance classes</b>

<b>Oracle edition</b>	<b>Oracle Database 19c and higher</b>
Bring Your Own License (BYOL)	db.m6i.large–db.m6i.32xlarge
	db.m5d.large–db.m5d.24xlarge

**Note**

We encourage all BYOL customers to consult their licensing agreement to assess the impact of Amazon RDS for Oracle deprecations. For more information on the compute capacity of DB instance classes supported by RDS for Oracle, see [DB instance classes](#) and [Configuring the processor for a DB instance class in RDS for Oracle](#).

**Note**

If you have DB snapshots of DB instances that were using deprecated DB instance classes, you can choose a DB instance class that is not deprecated when you restore the DB snapshots. For more information, see [Restoring to a DB instance](#).

## Deprecated RDS for Oracle DB instance classes

The following DB instance classes are deprecated for RDS for Oracle:

- db.m1, db.m2, db.m3, db.m4
- db.t1, db.t2
- db.r1, db.r2, db.r3, db.r4

The preceding DB instance classes have been replaced by better performing DB instance classes that are generally available at a lower cost. If you have DB instances that use deprecated DB instance classes, you have the following options:

- Allow Amazon RDS to modify each DB instance automatically to use a comparable non-deprecated DB instance class. For deprecation timelines, see [DB instance class types](#).
- Change the DB instance class yourself by modifying the DB instance. For more information, see [Modifying an Amazon RDS DB instance](#).

If you have DB snapshots of DB instances that were using deprecated DB instance classes, you can choose a DB instance class that is not deprecated when you restore the DB snapshots. For more information, see [Restoring to a DB instance](#).

## RDS for Oracle database architecture

The *Oracle multitenant architecture*, also known as the *CDB architecture*, enables an Oracle database to function as a *multitenant container database (CDB)*. A CDB can include customer-created *pluggable databases (PDBs)*. A *non-CDB* is an Oracle database that uses the traditional architecture, which can't contain PDBs. For more information about the multitenant architecture, see [Oracle Multitenant Administrator's Guide](#).

For Oracle Database 19c and higher, you can create an RDS for Oracle DB instance that uses the CDB architecture. Your client applications connect at the PDB level rather than the CDB level. RDS for Oracle supports the following configurations of the CDB architecture:

### Multi-tenant configuration

This RDS platform feature allows an RDS for Oracle CDB instance to contain between 1–30 tenant databases, depending on the database edition and any required option licenses tenant databases (PDBs). The multi-tenant configuration doesn't support application PDBs or proxy PDBs. You can use RDS APIs to add, modify, and remove tenant databases.

#### Note

The Amazon RDS feature is called "multi-tenant" rather than "multitenant" because it is a capability of the RDS platform, not just the Oracle DB engine. The term "Oracle multitenant" refers exclusively to the Oracle database architecture, which is compatible with both on-premises and RDS deployments.

### Single-tenant configuration

This RDS platform feature limits an RDS for Oracle CDB instance to 1 tenant database (PDB). You can't add more PDBs using RDS APIs. The single-tenant configuration uses the same RDS APIs as the non-CDB architecture. Thus, the experience of working with a CDB in the single-tenant configuration is mostly the same as working with a non-CDB.

You can convert a CDB that uses the single-tenant configuration to the multi-tenant configuration, thus allowing you to add PDBs to your CDB. This architecture change is permanent and irreversible. For more information, see [Converting the single-tenant configuration to multi-tenant](#).

#### Note

You can't access the CDB itself.

In Oracle Database 21c and higher, all databases are CDBs. In contrast, you can create an Oracle Database 19c DB instance as either a CDB or non-CDB. You can't upgrade a non-CDB to a CDB, but

you convert an Oracle Database 19c non-CDB to a CDB, and then upgrade it. You can't convert a CDB to a non-CDB.

For more information, see the following resources:

- [Working with CDBs in RDS for Oracle](#)
- [Limitations of RDS for Oracle CDBs](#)
- [Creating an Amazon RDS DB instance](#)

## RDS for Oracle parameters

### DB parameter groups

In Amazon RDS, you manage parameters using DB parameter groups. For more information, see [Parameter groups for Amazon RDS](#). To view the supported initialization parameters for a specific Oracle Database edition and version, run the AWS CLI command [describe-engine-default-parameters](#).

For example, to view the supported initialization parameters for the Enterprise Edition of Oracle Database 19c, run the following command.

```
aws rds describe-engine-default-parameters \  
  --db-parameter-group-family oracle-ee-19
```

### Oracle database initialization parameters

To find documentation for the initialization parameters, see [Initialization Parameters](#) in the Oracle Database documentation. The following initialization parameters have special considerations:

- ARCHIVE\_LAG\_TARGET

This parameter forces a redo log switch after the specified time elapses. In RDS for Oracle, ARCHIVE\_LAG\_TARGET is set to 300 because the recovery point objective (RPO) is 5 minutes. To honor this objective, RDS for Oracle switches the online redo log every 5 minutes and stores it in an Amazon S3 bucket. If the frequency of the log switch causes a performance issue for your RDS for Oracle database, you can scale your DB instance and storage to one with higher IOPS and throughput. Alternatively, if you use RDS Custom for Oracle or deploy an Oracle database on Amazon EC2, you can adjust the setting of the ARCHIVE\_LAG\_TARGET initialization parameter.

## RDS for Oracle character sets

RDS for Oracle supports two types of character sets: the DB character set and national character set.

### DB character set

The Oracle database character set is used in the CHAR, VARCHAR2, and CLOB data types. The database also uses this character set for metadata such as table names, column names, and SQL statements. The Oracle database character set is typically referred to as the *DB character set*.

You set the character set when you create a DB instance. You can't change the DB character set after you create the database.

### Supported DB character sets

The following table lists the Oracle DB character sets that are supported in Amazon RDS. You can use a value from this table with the `--character-set-name` parameter of the AWS CLI [create-db-instance](#) command or with the `CharacterSetName` parameter of the Amazon RDS API [CreateDBInstance](#) operation.

#### Note

The character set for a CDB is always AL32UTF8. You can set a different character set for the PDB only.

Value	Description
AL32UTF8	Unicode 5.0 UTF-8 Universal character set (default)
AR8ISO8859P6	ISO 8859-6 Latin/Arabic
AR8MSWIN1256	Microsoft Windows Code Page 1256 8-bit Latin/Arabic
BLT8ISO8859P13	ISO 8859-13 Baltic

Value	Description
BLT8MSWIN1257	Microsoft Windows Code Page 1257 8-bit Baltic
CL8ISO8859P5	ISO 8859-5 Latin/Cyrillic
CL8MSWIN1251	Microsoft Windows Code Page 1251 8-bit Latin/Cyrillic
EE8ISO8859P2	ISO 8859-2 East European
EL8ISO8859P7	ISO 8859-7 Latin/Greek
EE8MSWIN1250	Microsoft Windows Code Page 1250 8-bit East European
EL8MSWIN1253	Microsoft Windows Code Page 1253 8-bit Latin/Greek
IW8ISO8859P8	ISO 8859-8 Latin/Hebrew
IW8MSWIN1255	Microsoft Windows Code Page 1255 8-bit Latin/Hebrew
JA16EUC	EUC 24-bit Japanese
JA16EUCTILDE	Same as JA16EUC except for mapping of wave dash and tilde to and from Unicode
JA16SJIS	Shift-JIS 16-bit Japanese
JA16SJISTILDE	Same as JA16SJIS except for mapping of wave dash and tilde to and from Unicode
KO16MSWIN949	Microsoft Windows Code Page 949 Korean
NE8ISO8859P10	ISO 8859-10 North European
NEE8ISO8859P4	ISO 8859-4 North and Northeast European

Value	Description
TH8TISASCII	Thai Industrial Standard 620-2533-ASCII 8-bit
TR8MSWIN1254	Microsoft Windows Code Page 1254 8-bit Turkish
US7ASCII	ASCII 7-bit American
UTF8	Unicode 3.0 UTF-8 Universal character set, CESU-8 compliant
VN8MSWIN1258	Microsoft Windows Code Page 1258 8-bit Vietnamese
WE8ISO8859P1	Western European 8-bit ISO 8859 Part 1
WE8ISO8859P15	ISO 8859-15 West European
WE8ISO8859P9	ISO 8859-9 West European and Turkish
WE8MSWIN1252	Microsoft Windows Code Page 1252 8-bit West European
ZHS16GBK	GBK 16-bit Simplified Chinese
ZHT16HKSCS	Microsoft Windows Code Page 950 with Hong Kong Supplementary Character Set HKSCS-2001. Character set conversion is based on Unicode 3.0.
ZHT16MSWIN950	Microsoft Windows Code Page 950 Traditional Chinese
ZHT32EUC	EUC 32-bit Traditional Chinese

### NLS\_LANG environment variable

A *locale* is a set of information addressing linguistic and cultural requirements that corresponds to a given language and country. Setting the NLS\_LANG environment variable in your client's

environment is the simplest way to specify locale behavior for Oracle. This variable sets the language and territory used by the client application and the database server. It also indicates the client's character set, which corresponds to the character set for data entered or displayed by a client application. For more information on NLS\_LANG and character sets, see [What is a character set or code page?](#) in the Oracle documentation.

## NLS initialization parameters

You can also set the following National Language Support (NLS) initialization parameters at the instance level for an Oracle DB instance in Amazon RDS:

- NLS\_DATE\_FORMAT
- NLS\_LENGTH\_SEMANTICS
- NLS\_NCHAR\_CONV\_EXCP
- NLS\_TIME\_FORMAT
- NLS\_TIME\_TZ\_FORMAT
- NLS\_TIMESTAMP\_FORMAT
- NLS\_TIMESTAMP\_TZ\_FORMAT

For information about modifying instance parameters, see [Parameter groups for Amazon RDS](#).

You can set other NLS initialization parameters in your SQL client. For example, the following statement sets the NLS\_LANGUAGE initialization parameter to GERMAN in a SQL client that is connected to an Oracle DB instance:

```
ALTER SESSION SET NLS_LANGUAGE=GERMAN;
```

For information about connecting to an Oracle DB instance with a SQL client, see [Connecting to your RDS for Oracle DB instance](#).

## National character set

The national character set is used in the NCHAR, NVARCHAR2, and NLOB data types. The national character set is typically referred to as the *NCHAR character set*. Unlike the DB character set, the NCHAR character set doesn't affect database metadata.

The NCHAR character set supports the following character sets:

- AL16UTF16 (default)
- UTF8

You can specify either value with the `--nchar-character-set-name` parameter of the [create-db-instance](#) command (AWS CLI version 2 only). If you use the Amazon RDS API, specify the `NcharCharacterSetName` parameter of [CreateDBInstance](#) operation. You can't change the national character set after you create the database.

For more information about Unicode in Oracle databases, see [Supporting multilingual databases with unicode](#) in the Oracle documentation.

## RDS for Oracle limitations

In the following sections, you can find important limitations of using RDS for Oracle. For limitations specific to CDBs, see [Limitations of RDS for Oracle CDBs](#).

### Note

This list is not exhaustive.

## Topics

- [Oracle file size limits in Amazon RDS](#)
- [Public synonyms for Oracle-supplied schemas](#)
- [Schemas for unsupported features](#)
- [Limitations for Oracle DBA privileges](#)
- [Deprecation of TLS 1.0 and 1.1 Transport Layer Security](#)

## Oracle file size limits in Amazon RDS

The maximum size of a single file on RDS for Oracle DB instances is 16 TiB (tebibytes). This limit is imposed by the ext4 filesystem used by the instance. Thus, Oracle bigfile data files are limited to 16 TiB. If you try to resize a data file in a bigfile tablespace to a value over the limit, you receive an error such as the following.

```
ORA-01237: cannot extend datafile 6
ORA-01110: data file 6: '/rdsdbdata/db/mydir/datafile/myfile.dbf'
```

```
ORA-27059: could not reduce file size
Linux-x86_64 Error: 27: File too large
Additional information: 2
```

## Public synonyms for Oracle-supplied schemas

Don't create or modify public synonyms for Oracle-supplied schemas, including SYS, SYSTEM, and RDSADMIN. Such actions might result in invalidation of core database components and affect the availability of your DB instance.

You can create public synonyms referencing objects in your own schemas.

## Schemas for unsupported features

In general, Amazon RDS doesn't prevent you from creating schemas for unsupported features. However, if you create schemas for Oracle features and components that require SYS privileges, you can damage the data dictionary and affect your instance availability. Use only supported features and schemas that are available in [Adding options to Oracle DB instances](#).

## Limitations for Oracle DBA privileges

In the database, a *role* is a collection of privileges that you can grant to or revoke from a user. An Oracle database uses roles to provide security.

The predefined role DBA normally allows all administrative privileges on an Oracle database. When you create a DB instance, your master user account gets DBA privileges (with some limitations). To deliver a managed experience, an RDS for Oracle database doesn't provide the following privileges for the DBA role:

- ALTER DATABASE
- ALTER SYSTEM
- CREATE ANY DIRECTORY
- DROP ANY DIRECTORY
- GRANT ANY PRIVILEGE
- GRANT ANY ROLE

Use the master user account for administrative tasks such as creating additional user accounts in the database. You can't use SYS, SYSTEM, and other Oracle-supplied administrative accounts.

## Deprecation of TLS 1.0 and 1.1 Transport Layer Security

Transport Layer Security protocol versions 1.0 and 1.1 (TLS 1.0 and TLS 1.1) are deprecated. In accordance with security best practices, Oracle has deprecated the use of TLS 1.0 and TLS 1.1. To meet your security requirements, RDS for Oracle strongly recommends that you use TLS 1.2 instead.

# Connecting to your RDS for Oracle DB instance

After Amazon RDS provisions your Oracle DB instance, you can use any standard SQL client application to log in to your DB instance. Because RDS is a managed service, you can't log in as SYS or SYSTEM. For more information, see [RDS for Oracle users and privileges](#).

In this topic, you learn how to use Oracle SQL Developer or SQL\*Plus to connect to an RDS for Oracle DB instance. For an example that walks you through the process of creating and connecting to a sample DB instance, see [Creating and connecting to an Oracle DB instance](#).

## Topics

- [Finding the endpoint of your RDS for Oracle DB instance](#)
- [Connecting to your DB instance using Oracle SQL developer](#)
- [Connecting to your DB instance using SQL\\*Plus](#)
- [Considerations for security groups](#)
- [Considerations for process architecture](#)
- [Troubleshooting connections to your Oracle DB instance](#)
- [Modifying connection properties using sqlnet.ora parameters](#)

## Finding the endpoint of your RDS for Oracle DB instance

Each Amazon RDS DB instance has an endpoint, and each endpoint has the DNS name and port number for the DB instance. To connect to your DB instance using a SQL client application, you need the DNS name and port number for your DB instance.

You can find the endpoint for a DB instance using the Amazon RDS console or the AWS CLI.

### Note

If you are using Kerberos authentication, see [Connecting to Oracle with Kerberos authentication](#).

## Console

### To find the endpoint using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the console, choose the AWS Region of your DB instance.
3. Find the DNS name and port number for your DB instance.
  - a. Choose **Databases** to display a list of your DB instances.
  - b. Choose the Oracle DB instance name to display the instance details.
  - c. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

The screenshot shows the Amazon RDS console interface for a database instance named 'database-test1'. The instance is in the 'Available' state. The 'Connectivity & security' tab is active, displaying the endpoint and port information. The endpoint is 'database-test1.123456789012.us-east-1.rds.amazonaws.com' and the port is '1521'. The 'Networking' section shows the instance is in the 'us-east-1d' Availability Zone and connected to the 'vpc-1a2c3c4d' VPC. The 'Security' section shows the instance is associated with two VPC security groups: 'rds-ec2-1 (sg-0a1234567b8cd9e01)' and 'default (sg-0a1bcd2e)', both of which are active.

database-test1 <span>Modify</span>			
<b>Summary</b>			
DB identifier database-test1	CPU 1.88%	Status Available	Class db.m5.large
Role Instance	Current activity 0.00 sessions	Engine Oracle Standard Edition Two	Region & AZ us-east-1d
<b>Connectivity &amp; security</b>			
<b>Endpoint &amp; port</b>	<b>Networking</b>	<b>Security</b>	
Endpoint database-test1.123456789012.us-east-1.rds.amazonaws.com	Availability Zone us-east-1d	VPC security groups	
Port 1521	VPC vpc-1a2c3c4d	rds-ec2-1 (sg-0a1234567b8cd9e01) Active	
		default (sg-0a1bcd2e) Active	

## AWS CLI

To find the endpoint of an Oracle DB instance by using the AWS CLI, call the [describe-db-instances](#) command.

### Example To find the endpoint using the AWS CLI

```
aws rds describe-db-instances
```

Search for `Endpoint` in the output to find the DNS name and port number for your DB instance. The `Address` line in the output contains the DNS name. The following is an example of the JSON endpoint output.

```
"Endpoint": {  
  "HostedZoneId": "Z1PVIF0B656C1W",  
  "Port": 3306,  
  "Address": "myinstance.123456789012.us-west-2.rds.amazonaws.com"  
},
```

#### Note

The output might contain information for multiple DB instances.

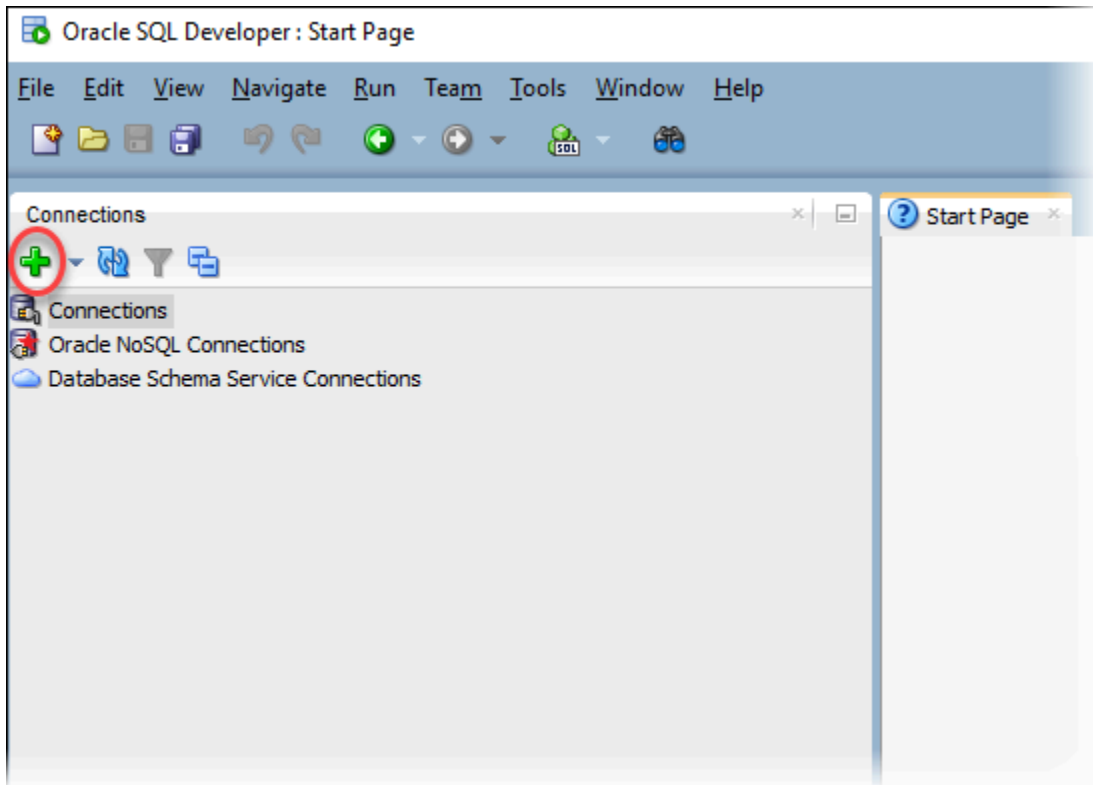

## Connecting to your DB instance using Oracle SQL developer

In this procedure, you connect to your DB instance by using Oracle SQL Developer. To download a standalone version of this utility, see the [Oracle SQL developer downloads page](#).

To connect to your DB instance, you need its DNS name and port number. For information about finding the DNS name and port number for a DB instance, see [Finding the endpoint of your RDS for Oracle DB instance](#).

### To connect to a DB instance using SQL developer

1. Start Oracle SQL Developer.
2. On the **Connections** tab, choose the **add (+)** icon.

3. In the **New/Select Database Connection** dialog box, provide the information for your DB instance:
  - For **Connection Name**, enter a name that describes the connection, such as Oracle-RDS.
  - For **Username**, enter the name of the database administrator for the DB instance.
  - For **Password**, enter the password for the database administrator.
  - For **Hostname**, enter the DNS name of the DB instance.
  - For **Port**, enter the port number.
  - For **SID**, enter the DB name. You can find the DB name on the **Configuration** tab of your database details page.

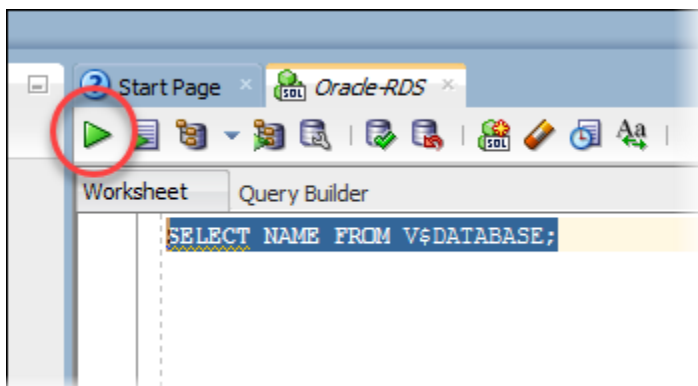

The completed dialog box should look similar to the following.

4. Choose **Connect**.
5. You can now start creating your own databases and running queries against your DB instance and databases as usual. To run a test query against your DB instance, do the following:
  - a. In the **Worksheet** tab for your connection, enter the following SQL query.

```
SELECT NAME FROM V$DATABASE;
```

- b. Choose the **execute** icon to run the query.

SQL Developer returns the database name.

## Connecting to your DB instance using SQL\*Plus

You can use a utility like SQL\*Plus to connect to an Amazon RDS DB instance running Oracle. To download Oracle Instant Client, which includes a standalone version of SQL\*Plus, see [Oracle Instant Client Downloads](#).

To connect to your DB instance, you need its DNS name and port number. For information about finding the DNS name and port number for a DB instance, see [Finding the endpoint of your RDS for Oracle DB instance](#).

### Example To connect to an Oracle DB instance using SQL\*Plus

In the following examples, substitute the user name of your DB instance administrator. Also, substitute the DNS name for your DB instance, and then include the port number and the Oracle SID. The SID value is the name of the DB instance's database that you specified when you created the DB instance, and not the name of the DB instance.

For Linux, macOS, or Unix:

```
sqlplus 'user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=dns_name)(PORT=port))  
(CONNECT_DATA=(SID=database_name)))'
```

For Windows:

```
sqlplus user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=dns_name)(PORT=port))  
(CONNECT_DATA=(SID=database_name)))
```

You should see output similar to the following.

```
SQL*Plus: Release 12.1.0.2.0 Production on Mon Aug 21 09:42:20 2017
```

After you enter the password for the user, the SQL prompt appears.

```
SQL>
```

### Note

The shorter format connection string (EZ Connect), such as `sqlplus USER/PASSWORD@longer-than-63-chars-rds-endpoint-here:1521/database-identifier`, might encounter a maximum character limit, so you we recommend that you don't use it to connect.

## Considerations for security groups

For you to connect to your DB instance, it must be associated with a security group that contains the necessary IP addresses and network configuration. Your DB instance might use the default security group. If you assigned a default, nonconfigured security group when you created the DB instance, the firewall prevents connections. For information about creating a new security group, see [Controlling access with security groups](#).

After you create the new security group, you modify your DB instance to associate it with the security group. For more information, see [Modifying an Amazon RDS DB instance](#).

You can enhance security by using SSL to encrypt connections to your DB instance. For more information, see [Oracle Secure Sockets Layer](#).

## Considerations for process architecture

Server processes handle user connections to an Oracle DB instance. By default, the Oracle DB instance uses dedicated server processes. With dedicated server processes, each server process services only one user process. You can optionally configure shared server processes. With shared server processes, each server process can service multiple user processes.

You might consider using shared server processes when a high number of user sessions are using too much memory on the server. You might also consider shared server processes when sessions connect and disconnect very often, resulting in performance issues. There are also disadvantages to using shared server processes. For example, they can strain CPU resources, and they are more complicated to configure and administer.

For more information about dedicated and shared server processes, see [About dedicated and shared server processes](#) in the Oracle documentation. For more information about configuring shared server processes on an RDS for Oracle DB instance, see [How do I configure Amazon RDS for Oracle database to work with shared servers?](#) in the Knowledge Center.

## Troubleshooting connections to your Oracle DB instance

The following are issues you might encounter when you try to connect to your Oracle DB instance.

Issue	Troubleshooting suggestions
Unable to connect to your DB instance.	For a newly created DB instance, the DB instance has a status of <b>creating</b> until it is ready to use. When the state changes to <b>available</b> , you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new DB instance is available.
Unable to connect to your DB instance.	If you can't send or receive communications over the port that you specified when you created the DB instance, you can't connect to the DB instance. Check with your network administrator to verify that the port you specified for your DB instance allows inbound and outbound communication.
Unable to connect to your DB instance.	The access rules enforced by your local firewall and the IP addresses you authorized to access your DB instance in the

Issue	Troubleshooting suggestions
	<p>security group for the DB instance might not match. The problem is most likely the inbound or outbound rules on your firewall.</p> <p>You can add or edit an inbound rule in the security group. For <b>Source</b>, choose <b>My IP</b>. This allows access to the DB instance from the IP address detected in your browser. For more information, see <a href="#">Amazon VPC and Amazon RDS</a>.</p> <p>For more information about security groups, see <a href="#">Controlling access with security groups</a>.</p> <p>To walk through the process of setting up rules for your security group, see <a href="#">Tutorial: Create a VPC for use with a DB instance (IPv4 only)</a>.</p>
<p><b>Connect failed because target host or object does not exist – Oracle, Error: ORA-12545</b></p>	<p>Make sure that you specified the server name and port number correctly. For <b>Server name</b>, enter the DNS name from the console.</p> <p>For information about finding the DNS name and port number for a DB instance, see <a href="#">Finding the endpoint of your RDS for Oracle DB instance</a>.</p>
<p><b>Invalid username/ password; logon denied – Oracle, Error: ORA-01017</b></p>	<p>You were able to reach the DB instance, but the connection was refused. This is usually caused by providing an incorrect user name or password. Verify the user name and password, and then retry.</p>
<p><b>TNS:listener does not currently know of SID given in connect descriptor - Oracle, ERROR: ORA-12505</b></p>	<p>Ensure the correct SID is entered. The SID is the same as your DB name. Find the DB name in the <b>Configuration</b> tab of the <b>Databases</b> page for your instance. You can also find the DB name using the AWS CLI:</p> <pre data-bbox="548 1556 1507 1675">aws rds describe-db-instances --query 'DBInstances[*].[DBInstanceIdentifier,DBName]' --output text</pre>

For more information on connection issues, see [Can't connect to Amazon RDS DB instance](#).

## Modifying connection properties using sqlnet.ora parameters

The sqlnet.ora file includes parameters that configure Oracle Net features on Oracle database servers and clients. Using the parameters in the sqlnet.ora file, you can modify properties for connections in and out of the database.

For more information about why you might set sqlnet.ora parameters, see [Configuring profile parameters](#) in the Oracle documentation.

### Setting sqlnet.ora parameters

Amazon RDS for Oracle parameter groups include a subset of sqlnet.ora parameters. You set them in the same way that you set other Oracle parameters. The sqlnetora. prefix identifies which parameters are sqlnet.ora parameters. For example, in an Oracle parameter group in Amazon RDS, the default\_sdu\_size sqlnet.ora parameter is sqlnetora.default\_sdu\_size.

For information about managing parameter groups and setting parameter values, see [Parameter groups for Amazon RDS](#).

### Supported sqlnet.ora parameters

Amazon RDS supports the following sqlnet.ora parameters. Changes to dynamic sqlnet.ora parameters take effect immediately.

Parameter	Valid values	Static/Dynamic	Description
sqlnetora.default_sdu_size	512 to 209715	Dynamic	The session data unit (SDU) size, in bytes.  The SDU is the amount of data that is put in a buffer and sent across the network at one time.
sqlnetora.diag_adr_enabled	ON, OFF	Dynamic	A value that enables or disables Automatic Diagnostic Repository (ADR) tracing.

Parameter	Valid values	Static/Dynamic	Description
			ON specifies that ADR file tracing is used.  OFF specifies that non-ADR file tracing is used.
<code>sqlnetora.recv_buf_size</code>	8192 to 268435	Dynamic	The buffer space limit for receive operations of sessions, supported by the TCP/IP, TCP/IP with SSL, and SDP protocols.
<code>sqlnetora.send_buf_size</code>	8192 to 268435	Dynamic	The buffer space limit for send operations of sessions, supported by the TCP/IP, TCP/IP with SSL, and SDP protocols.
<code>sqlnetora.sqlnet.allowed_login_version_client</code>	8, 10, 11, 12	Dynamic	Minimum authentication protocol version allowed for clients, and servers acting as clients, to establish a connection to Oracle DB instances.
<code>sqlnetora.sqlnet.allowed_login_version_server</code>	8, 9, 10, 11, 12, 12a	Dynamic	Minimum authentication protocol version allowed to establish a connection to Oracle DB instances.

Parameter	Valid values	Static/Dynamic	Description
<code>sqlnetora.sqlnet.expire_time</code>	0 to 1440	Dynamic	Time interval, in minutes, to send a check to verify that client-server connections are active.
<code>sqlnetora.sqlnet.inbound_connect_timeout</code>	0 or 10 to 7200	Dynamic	Time, in seconds, for a client to connect with the database server and provide the necessary authentication information.
<code>sqlnetora.sqlnet.outbound_connect_timeout</code>	0 or 10 to 7200	Dynamic	Time, in seconds, for a client to establish an Oracle Net connection to the DB instance.
<code>sqlnetora.sqlnet.recv_timeout</code>	0 or 10 to 7200	Dynamic	Time, in seconds, for a database server to wait for client data after establishing a connection.
<code>sqlnetora.sqlnet.send_timeout</code>	0 or 10 to 7200	Dynamic	Time, in seconds, for a database server to complete a send operation to clients after establishing a connection.
<code>sqlnetora.tcp.connect_timeout</code>	0 or 10 to 7200	Dynamic	Time, in seconds, for a client to establish a TCP connection to the database server.

Parameter	Valid values	Static/Dynamic	Description
<code>sqlnetora.trace_level_server</code>	0, 4, 10, 16, OFF, USER, ADMIN, SUPPOF	Dynamic	For non-ADR tracing, turns server tracing on at a specified level or turns it off.

The default value for each supported `sqlnet.ora` parameter is the Oracle Database default for the release.

## Viewing `sqlnet.ora` parameters

You can view `sqlnet.ora` parameters and their settings using the AWS Management Console, the AWS CLI, or a SQL client.

### Viewing `sqlnet.ora` parameters using the console

For information about viewing parameters in a parameter group, see [Parameter groups for Amazon RDS](#).

In Oracle parameter groups, the `sqlnetora.` prefix identifies which parameters are `sqlnet.ora` parameters.

### Viewing `sqlnet.ora` parameters using the AWS CLI

To view the `sqlnet.ora` parameters that were configured in an Oracle parameter group, use the AWS CLI [describe-db-parameters](#) command.

To view the all of the `sqlnet.ora` parameters for an Oracle DB instance, call the AWS CLI [download-db-log-file-portion](#) command. Specify the DB instance identifier, the log file name, and the type of output.

### Example

The following code lists all of the `sqlnet.ora` parameters for `mydbinstance`.

## For Linux, macOS, or Unix:

```
aws rds download-db-log-file-portion \  
  --db-instance-identifier mydbinstance \  
  --log-file-name trace/sqlnet-parameters \  
  --output text
```

## For Windows:

```
aws rds download-db-log-file-portion ^  
  --db-instance-identifier mydbinstance ^  
  --log-file-name trace/sqlnet-parameters ^  
  --output text
```

## Viewing sqlnet.ora parameters using a SQL client

After you connect to the Oracle DB instance in a SQL client, the following query lists the sqlnet.ora parameters.

```
SELECT * FROM TABLE  
  (rdsadmin.rds_file_util.read_text_file(  
    p_directory => 'BDUMP',  
    p_filename  => 'sqlnet-parameters'));
```

For information about connecting to an Oracle DB instance in a SQL client, see [Connecting to your RDS for Oracle DB instance](#).

# Securing Oracle DB instance connections

Amazon RDS for Oracle supports SSL/TLS encrypted connections and also the Oracle Native Network Encryption (NNE) option to encrypt connections between your application and your Oracle DB instance. For more information about the Oracle Native Network Encryption option, see [Oracle native network encryption](#).

## Topics

- [Using SSL with an RDS for Oracle DB instance](#)
- [Updating applications to connect to Oracle DB instances using new SSL/TLS certificates](#)
- [Using native network encryption with an RDS for Oracle DB instance](#)
- [Configuring Kerberos authentication for Amazon RDS for Oracle](#)
- [Configuring UTL\\_HTTP access using certificates and an Oracle wallet](#)

## Using SSL with an RDS for Oracle DB instance

Secure Sockets Layer (SSL) is an industry-standard protocol for securing network connections between client and server. After SSL version 3.0, the name was changed to Transport Layer Security (TLS), but we still often refer to the protocol as SSL. Amazon RDS supports SSL encryption for Oracle DB instances. Using SSL, you can encrypt a connection between your application client and your Oracle DB instance. SSL support is available in all AWS Regions for Oracle.

To enable SSL encryption for an Oracle DB instance, add the Oracle SSL option to the option group associated with the DB instance. Amazon RDS uses a second port, as required by Oracle, for SSL connections. Doing this allows both clear text and SSL-encrypted communication to occur at the same time between a DB instance and an Oracle client. For example, you can use the port with clear text communication to communicate with other resources inside a VPC while using the port with SSL-encrypted communication to communicate with resources outside the VPC.

For more information, see [Oracle Secure Sockets Layer](#).

### Note

You can't use both SSL and Oracle native network encryption (NNE) on the same DB instance. Before you can use SSL encryption, you must disable any other connection encryption.

# Updating applications to connect to Oracle DB instances using new SSL/TLS certificates

As of January 13, 2023, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances.

## Important

When you change the certificate for an Amazon RDS for Oracle DB instance, only the database listener is restarted. The DB instance isn't restarted. Existing database connections are unaffected, but new connections will encounter errors for a brief period while the listener is restarted.

## Note

For client applications that use SSL/TLS to connect to your DB instances, you must update your client application trust stores to include the new CA certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see [Rotating your SSL/TLS certificate](#). For more information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#). For information about using SSL/TLS with Oracle DB instances, see [Oracle Secure Sockets Layer](#).

## Topics

- [Finding out whether applications connect using SSL](#)
- [Updating your application trust store](#)
- [Example Java code for establishing SSL connections](#)

## Finding out whether applications connect using SSL

If your Oracle DB instance uses an option group with the SSL option added, you might be using SSL. Check this by following the instructions in [Listing the options and option settings for an option group](#). For information about the SSL option, see [Oracle Secure Sockets Layer](#).

Check the listener log to determine whether there are SSL connections. The following is sample output in a listener log.

```
date time * (CONNECT_DATA=(CID=(PROGRAM=program)
(HOST=host)(USER=user))(SID=sid)) *
(ADDRESS=(PROTOCOL=tcps)(HOST=host)(PORT=port)) * establish * ORCL * 0
```

When PROTOCOL has the value `tcps` for an entry, it shows an SSL connection. However, when HOST is `127.0.0.1`, you can ignore the entry. Connections from `127.0.0.1` are a local management agent on the DB instance. These connections aren't external SSL connections. Therefore, you have applications connecting using SSL if you see listener log entries where PROTOCOL is `tcps` and HOST is *not* `127.0.0.1`.

To check the listener log, you can publish the log to Amazon CloudWatch Logs. For more information, see [Publishing Oracle logs to Amazon CloudWatch Logs](#).

## Updating your application trust store

You can update the trust store for applications that use SQL\*Plus or JDBC for SSL/TLS connections.

### Updating your application trust store for SQL\*Plus

You can update the trust store for applications that use SQL\*Plus for SSL/TLS connections.

#### Note

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

### To update the trust store for SQL\*Plus applications

1. Download the new root certificate that works for all AWS Regions and put the file in the `ssl_wallet` directory.

For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

2. Run the following command to update the Oracle wallet.

```
prompt>orapki wallet add -wallet $ORACLE_HOME/ssl_wallet -trusted_cert -cert
$ORACLE_HOME/ssl_wallet/ssl-cert.pem -auto_login_only
```

Replace the file name with the one that you downloaded.

3. Run the following command to confirm that the wallet was updated successfully.

```
prompt>orapki wallet display -wallet $ORACLE_HOME/ssl_wallet
```

Your output should contain the following.

```
Trusted Certificates:
Subject: CN=Amazon RDS Root 2019 CA,OU=Amazon RDS,O=Amazon Web Services\,
Inc.,L=Seattle,ST=Washington,C=US
```

## Updating your application trust store for JDBC

You can update the trust store for applications that use JDBC for SSL/TLS connections.

For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

For sample scripts that import certificates, see [Sample script for importing certificates into your trust store](#).

## Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection using JDBC.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.util.Properties;

public class OracleSslConnectionTest {
    private static final String DB_SERVER_NAME = "<dns-name-provided-by-amazon-rds>";
```

```
private static final Integer SSL_PORT = "<ssl-option-port-configured-in-option-
group>";
private static final String DB_SID = "<oracle-sid>";
private static final String DB_USER = "<user name>";
private static final String DB_PASSWORD = "<password>";
// This key store has only the prod root ca.
private static final String KEY_STORE_FILE_PATH = "<file-path-to-keystore>";
private static final String KEY_STORE_PASS = "<keystore-password>";

public static void main(String[] args) throws SQLException {
    final Properties properties = new Properties();
    final String connectionString = String.format(
        "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=
%d))(CONNECT_DATA=(SID=%s)))",
        DB_SERVER_NAME, SSL_PORT, DB_SID);
    properties.put("user", DB_USER);
    properties.put("password", DB_PASSWORD);
    properties.put("oracle.jdbc.J2EE13Compliant", "true");
    properties.put("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
    properties.put("javax.net.ssl.trustStoreType", "JKS");
    properties.put("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);
    final Connection connection = DriverManager.getConnection(connectionString,
properties);
    // If no exception, that means handshake has passed, and an SSL connection can
be opened
    }
}
```

### Important

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the `rds-ca-rsa2048-g1` certificates. For instructions, see step 3 in [Updating your CA certificate by modifying your DB instance or cluster](#).

## Using native network encryption with an RDS for Oracle DB instance

Oracle Database offers two ways to encrypt data over the network: native network encryption (NNE) and Transport Layer Security (TLS). NNE is a proprietary Oracle security feature, whereas TLS is an industry standard. RDS for Oracle supports NNE for all editions of Oracle Database.

NNE has the following advantages over TLS:

- You can control NNE on the client and server using settings in the NNE option:
  - `SQLNET.ALLOW_WEAK_CRYPTOClients` and `SQLNET.ALLOW_WEAK_CRYPTO`
  - `SQLNET.CRYPTO_CHECKSUM_CLIENT` and `SQLNET.CRYPTO_CHECKSUM_SERVER`
  - `SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT` and `SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER`
  - `SQLNET.ENCRYPTION_CLIENT` and `SQLNET.ENCRYPTION_SERVER`
  - `SQLNET.ENCRYPTION_TYPES_CLIENT` and `SQLNET.ENCRYPTION_TYPES_SERVER`
- In most cases, you don't need to configure your client or server. In contrast, TLS requires you to configure both client and server.
- No certificates are required. In TLS, the server requires a certificate (which eventually expires), and the client requires a trusted root certificate for the certificate authority that issued the server's certificate.

To enable NNE encryption for an Oracle DB instance, add the Oracle NNE option to the option group associated with the DB instance. For more information, see [Oracle native network encryption](#).

 **Note**

You can't use both NNE and TLS on the same DB instance.

## Configuring Kerberos authentication for Amazon RDS for Oracle

You can use Kerberos authentication to authenticate users when they connect to your Amazon RDS for Oracle DB instance. In this configuration, your DB instance works with AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD. When users authenticate with an RDS for Oracle DB instance joined to the trusting domain, authentication requests are forwarded to the directory that you create with AWS Directory Service.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized place for storing and managing credentials for multiple database instances. A directory can also improve your overall security profile.

## Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of RDS for Oracle with Kerberos authentication, see [Supported Regions and DB engines for Kerberos authentication in Amazon RDS](#).

### Note

Kerberos authentication isn't supported for DB instance classes that are deprecated for RDS for Oracle DB instances. For more information, see [RDS for Oracle DB instance classes](#).

## Topics

- [Setting up Kerberos authentication for Oracle DB instances](#)
- [Managing a DB instance in a domain](#)
- [Connecting to Oracle with Kerberos authentication](#)

## Setting up Kerberos authentication for Oracle DB instances

Use AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to set up Kerberos authentication for an Oracle DB instance. To set up Kerberos authentication, complete the following steps:

- [Step 1: Create a directory using the AWS Managed Microsoft AD](#)
- [Step 2: Create a trust](#)
- [Step 3: Configure IAM permissions for Amazon RDS](#)
- [Step 4: Create and configure users](#)
- [Step 5: Enable cross-VPC traffic between the directory and the DB instance](#)
- [Step 6: Create or modify an Oracle DB instance](#)
- [Step 7: Create Kerberos authentication Oracle logins](#)
- [Step 8: Configure an Oracle client](#)

**Note**

During the setup, RDS creates an Oracle database user named *managed\_service\_user@example.com* with the CREATE SESSION privilege, where *example.com* is your domain name. This user corresponds to the user that Directory Service creates inside your Managed Active Directory. Periodically, RDS uses the credentials provided by the Directory Service to log in to your Oracle database. Afterwards, RDS immediately destroys the ticket cache.

**Step 1: Create a directory using the AWS Managed Microsoft AD**

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name System (DNS) servers on your behalf. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

**Note**

Be sure to save this password. AWS Directory Service doesn't store it. You can reset it, but you can't retrieve it.

- Creates a security group for the directory controllers.

When you launch an AWS Managed Microsoft AD, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU has the NetBIOS name that you typed when you created your directory and is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run AD and DNS Windows PowerShell modules on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

To create the directory, use the AWS Management Console, the AWS CLI, or the AWS Directory Service API. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the Oracle DB instance.

### To create a directory with AWS Managed Microsoft AD

1. Sign in to the AWS Management Console and open the AWS Directory Service console at <https://console.aws.amazon.com/directoryservicev2/>.
2. In the navigation pane, choose **Directories** and choose **Set up Directory**.
3. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option that you can currently use with Amazon RDS.
4. Enter the following information:

#### Directory DNS name

The fully qualified name for the directory, such as **corp.example.com**.

#### Directory NetBIOS name

The short name for the directory, such as **CORP**.

## Directory description

(Optional) A description for the directory.

## Admin password

The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

The directory administrator password and can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Non-alphanumeric characters (~!@#\$%^&\* \_+= `|\(){}[];:"'<>,.?/)

## Confirm password

The administrator password retyped.

5. Choose **Next**.
6. Enter the following information in the **Networking** section and then choose **Next**:

## VPC

The VPC for the directory. Create the Oracle DB instance in this same VPC.

## Subnets

Subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Review the directory information and make any necessary changes. When the information is correct, choose **Create directory**.

## Review & create

### Review

Directory type Microsoft AD	VPC vpc-8b6b78e9 ( [REDACTED] )
Directory DNS name corp.example.com	Subnets subnet-75128d10 ( [REDACTED] , us-east-1a) subnet-f51665dd ( [REDACTED] , us-east-1b)
Directory NetBIOS name CORP	
Directory description My directory	

### Pricing

Edition Standard	Free trial eligible <a href="#">Learn more</a> 30-day limited trial
~USD [REDACTED] *	
* Includes two domain controllers, USD [REDACTED] /mo for each additional domain controller.	

Cancel Previous **Create directory**

It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory name in the directory listing. Note the **Directory ID** value because you need this value when you create or modify your Oracle DB instance.

Directory Service > Directories > d-90670a8d36

My directory		

[Application management](#) | [Scale & share](#) | [Networking & security](#) | [Maintenance](#)

## Step 2: Create a trust

If you plan to use AWS Managed Microsoft AD only, move on to [Step 3: Configure IAM permissions for Amazon RDS](#).

To get Kerberos authentication using an on-premises or self-hosted Microsoft Active Directory, create a forest trust or external trust. The trust can be one-way or two-way. For more information about setting up forest trusts using AWS Directory Service, see [When to create a trust relationship](#) in the *AWS Directory Service Administration Guide*.

### Step 3: Configure IAM permissions for Amazon RDS

To call AWS Directory Service for you, Amazon RDS requires an IAM role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. This role allows Amazon RDS to make calls to the AWS Directory Service.

#### Note

For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see [Activating and deactivating AWS STS in an AWS Region](#) in the *IAM User Guide*.

### Creating an IAM role

When you create a DB instance using the AWS Management Console, and the console user has the `iam:CreateRole` permission, the console creates `rds-directoryservice-kerberos-access-role` automatically. Otherwise, you must create the IAM role manually. When you create an IAM role manually, choose `Directory Service`, and attach the AWS managed policy `AmazonRDSDirectoryServiceAccess` to it.

For more information about creating IAM roles for a service, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.

#### Note

The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for RDS for Oracle.

### Creating an IAM trust policy manually

Optionally, you can create resource policies with the required permissions instead of using the managed IAM policy `AmazonRDSDirectoryServiceAccess`. Specify both `directoryservice.rds.amazonaws.com` and `rds.amazonaws.com` as principals.

To limit the permissions that Amazon RDS gives another service for a specific resource, we recommend using the [aws:SourceArn](#) and [aws:SourceAccount](#) global condition context keys in

resource policies. The most effective way to protect against the confused deputy problem is to use the `aws:SourceArn` global condition context key with the full ARN of an Amazon RDS resource. For more information, see [Preventing cross-service confused deputy problems](#).

The following example shows how you can use the `aws:SourceArn` and `aws:SourceAccount` global condition context keys in Amazon RDS to prevent the confused deputy problem.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "directoryservice.rds.amazonaws.com",
          "rds.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "ArnLike": {
          "aws:SourceArn": "arn:aws:rds:us-east-1:123456789012:db:mydbinstance"
        },
        "StringEquals": {
          "aws:SourceAccount": "123456789012"
        }
      }
    }
  ]
}
```

For opt-in Regions, you must also include a service principal for that Region in the form of `directoryservice.rds.region_name.amazonaws.com`. For example, in the Africa (Cape Town) Region, use the following trust policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
```

```

    "Principal": {
      "Service": [
        "directoryservice.rds.amazonaws.com",
        "directoryservice.rds.af-south-1.amazonaws.com",
        "rds.amazonaws.com"
      ]
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "ArnLike": {
        "aws:SourceArn": "arn:aws:rds:af-south-1:123456789012:db:mydbinstance"
      },
      "StringEquals": {
        "aws:SourceAccount": "123456789012"
      }
    }
  }
}

```

The role must also have the following IAM policy.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ds:DescribeDirectories",
        "ds:AuthorizeApplication",
        "ds:UnauthorizeApplication",
        "ds:GetAuthorizedApplicationDetails"
      ],
      "Effect": "Allow",
      "Resource": "*"
    }
  ]
}

```

#### Step 4: Create and configure users

You can create users with the Active Directory Users and Computers tool, which is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. In this case, *users* are individual people or entities that have access to your directory.

To create users in an AWS Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance that is a member of the AWS Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information about creating users in your Microsoft Active Directory, see [Manage users and groups in AWS Managed Microsoft AD](#) in the *AWS Directory Service Administration Guide*.

### Step 5: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to [Step 6: Create or modify an Oracle DB instance](#).

If you plan to locate the directory and the DB instance in different AWS accounts or VPCs, configure cross-VPC traffic using VPC peering or [AWS Transit Gateway](#). The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in [What is VPC peering?](#) in the *Amazon Virtual Private Cloud Peering Guide*.

#### To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance's security group can receive inbound traffic from the directory's security group. For more information, see [Best practices for AWS Managed Microsoft AD](#) in the *AWS Directory Service Administration Guide*.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

#### To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in [Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 Domain-join](#) in the *AWS Directory Service Administration Guide*.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the **Directory ID** value. You use this directory ID to join the DB instance to the domain.

## Step 6: Create or modify an Oracle DB instance

Create or modify an Oracle DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new Oracle DB instance using the console, the [create-db-instance](#) CLI command, or the [CreateDBInstance](#) RDS API operation.

For instructions, see [Creating an Amazon RDS DB instance](#).

- Modify an existing Oracle DB instance using the console, the [modify-db-instance](#) CLI command, or the [ModifyDBInstance](#) RDS API operation.

For instructions, see [Modifying an Amazon RDS DB instance](#).

- Restore an Oracle DB instance from a DB snapshot using the console, the [restore-db-instance-from-db-snapshot](#) CLI command, or the [RestoreDBInstanceFromDBSnapshot](#) RDS API operation.

For instructions, see [Restoring to a DB instance](#).

- Restore an Oracle DB instance to a point-in-time using the console, the [restore-db-instance-to-point-in-time](#) CLI command, or the [RestoreDBInstanceToPointInTime](#) RDS API operation.

For instructions, see [Restoring a DB instance to a specified time](#).

Kerberos authentication is only supported for Oracle DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. When you create or modify the DB instance, do the following:

- Provide the domain identifier (d- \* identifier) that was generated when you created your directory.
- Provide the name of the IAM role that you created.
- Ensure that the DB instance security group can receive inbound traffic from the directory security group and send outbound traffic to the directory.

When you use the console to create a DB instance, choose **Password and Kerberos authentication** in the **Database authentication** section. Choose **Browse Directory** and then select the directory, or choose **Create a new directory**.

## Database authentication

---

**Database authentication options** [Info](#)

Password authentication  
Authenticates using database passwords.

Password and IAM database authentication  
Authenticates using the database password and user credentials through AWS IAM users and roles.

Password and Kerberos authentication  
Choose a directory in which you want to allow authorized users to authenticate with this DB instance using Kerberos Authentication.

**Directory**

When you use the console to modify or restore a DB instance, choose the directory in the **Kerberos authentication** section, or choose **Create a new directory**.

## Kerberos authentication

Choose a directory in which you want to allow authorized users to authenticate with this DB instance using Kerberos authentication.

---

**Directory**

None ▼

[Create a new directory](#)

By choosing a directory and continuing with database instance creation you authorize Amazon RDS to create the IAM role necessary for using Kerberos authentication

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the `--domain` parameter, use the domain identifier ("d-\*" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB instance to use a directory.

## For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier mydbinstance \  
  --domain d-ID \  
  --domain-iam-role-name role-name
```

## For Windows:

```
aws rds modify-db-instance ^  
  --db-instance-identifier mydbinstance ^  
  --domain d-ID ^  
  --domain-iam-role-name role-name
```

### Important

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

### Note

*MANAGED\_SERVICE\_USER* is a service account whose name is randomly generated by Directory Service for RDS. During the Kerberos authentication setup, RDS for Oracle creates a user with the same name and assigns it the CREATE SESSION privilege. The Oracle DB user is identified externally as *MANAGED\_SERVICE\_USER@EXAMPLE.COM*, where *EXAMPLE.COM* is the name of your domain. Periodically, RDS uses the credentials provided by the Directory Service to log in to your Oracle database. Afterward, RDS immediately destroys the ticket cache.

## Step 7: Create Kerberos authentication Oracle logins

Use the Amazon RDS master user credentials to connect to the Oracle DB instance as you do any other DB instance. The DB instance is joined to the AWS Managed Microsoft AD domain. Thus, you can provision Oracle logins and users from the Microsoft Active Directory users and groups in your domain. To manage database permissions, you grant and revoke standard Oracle permissions to these logins.

## To allow a Microsoft Active Directory user to authenticate with Oracle

1. Connect to the Oracle DB instance using your Amazon RDS master user credentials.
2. Create an externally authenticated user in Oracle database.

In the following example, replace *KRBUSER@CORP.EXAMPLE.COM* with the user name and domain name.

```
CREATE USER "KRBUSER@CORP.EXAMPLE.COM" IDENTIFIED EXTERNALLY;  
GRANT CREATE SESSION TO "KRBUSER@CORP.EXAMPLE.COM";
```

Users (both humans and applications) from your domain can now connect to the Oracle DB instance from a domain joined client machine using Kerberos authentication.

### Step 8: Configure an Oracle client

To configure an Oracle client, meet the following requirements:

- Create a configuration file named `krb5.conf` (Linux) or `krb5.ini` (Windows) to point to the domain. Configure the Oracle client to use this configuration file.
- Verify that traffic can flow between the client host and AWS Directory Service over DNS port 53 over TCP/UDP, Kerberos ports (88 and 464 for managed AWS Directory Service) over TCP, and LDAP port 389 over TCP.
- Verify that traffic can flow between the client host and the DB instance over the database port.

Following is sample content for AWS Managed Microsoft AD.

```
[libdefaults]  
  default_realm = EXAMPLE.COM  
[realms]  
EXAMPLE.COM = {  
  kdc = example.com  
  admin_server = example.com  
}  
[domain_realm]  
.example.com = CORP.EXAMPLE.COM  
example.com = CORP.EXAMPLE.COM
```

Following is sample content for on-premise Microsoft AD. In your `krb5.conf` or `krb5.ini` file, replace *on-prem-ad-server-name* with the name of your on-premises AD server.

```
[libdefaults]
  default_realm = ONPREM.COM
[realms]
  AWSAD.COM = {
    kdc = awsad.com
    admin_server = awsad.com
  }
  ONPREM.COM = {
    kdc = on-prem-ad-server-name
    admin_server = on-prem-ad-server-name
  }
[domain_realm]
  .awsad.com = AWSAD.COM
  awsad.com= AWSAD.COM
  .onprem.com = ONPREM.COM
  onprem.com= ONPREM.COM
```

 **Note**

After you configure your `krb5.ini` or `krb5.conf` file, we recommend that you reboot the server.

The following is sample `sqlnet.ora` content for a SQL\*Plus configuration:

```
SQLNET.AUTHENTICATION_SERVICES=(KERBEROS5PRE,KERBEROS5)
SQLNET.KERBEROS5_CONF=path_to_krb5.conf_file
```

For an example of a SQL Developer configuration, see [Document 1609359.1](#) from Oracle Support.

## Managing a DB instance in a domain

You can use the console, the CLI, or the RDS API to manage your DB instance and its relationship with your Microsoft Active Directory. For example, you can associate a Microsoft Active Directory to enable Kerberos authentication. You can also disassociate a Microsoft Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the [modify-db-instance](#) CLI command and specify the current membership's directory ID for the `--domain` option.
- To disable Kerberos authentication on a DB instance, use the [modify-db-instance](#) CLI command and specify `none` for the `--domain` option.
- To move a DB instance from one domain to another, use the [modify-db-instance](#) CLI command and specify the domain identifier of the new domain for the `--domain` option.

### Viewing the status of domain membership

After you create or modify your DB instance, the DB instance becomes a member of the domain. You can view the status of the domain membership for the DB instance in the console or by running the [describe-db-instances](#) CLI command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.
- `pending-enable-kerberos` – Enabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-enable-kerberos` – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – Disabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `enable-kerberos-failed` – A configuration problem has prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.
- `disabling-kerberos` – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. If the attempt to enable Kerberos authentication fails when you create or modify a DB instance, make sure that you're using the correct IAM role. Then modify the DB instance to join the domain.

**Note**

Only Kerberos authentication with Amazon RDS for Oracle sends traffic to the domain's DNS servers. All other DNS requests are treated as outbound network access on your DB instances running Oracle. For more information about outbound network access with Amazon RDS for Oracle, see [Setting up a custom DNS server](#).

### Force-rotating Kerberos keys

A secret key is shared between AWS Managed Microsoft AD and Amazon RDS for Oracle DB instance. This key is rotated automatically every 45 days. You can use the following Amazon RDS procedure to force the rotation of this key.

```
SELECT rdsadmin.rdsadmin_kerberos_auth_tasks.rotate_kerberos_keytab AS TASK_ID FROM DUAL;
```

**Note**

In a read replica configuration, this procedure is available only on the source DB instance and not on the read replica.

The SELECT statement returns the ID of the task in a VARCHAR2 data type. You can view the status of an ongoing task in a bdump file. The bdump files are located in the `/rdsdbdata/log/trace` directory. Each bdump file name is in the following format.

```
dbtask-task-id.log
```

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-task-id.log'));
```

Replace *task-id* with the task ID returned by the procedure.

**Note**

Tasks are executed asynchronously.

## Connecting to Oracle with Kerberos authentication

This section assumes that you have set up your Oracle client as described in [Step 8: Configure an Oracle client](#). To connect to the Oracle DB with Kerberos authentication, log in using the Kerberos authentication type. For example, after launching Oracle SQL Developer, choose **Kerberos Authentication** as the authentication type, as shown in the following example.

To connect to Oracle with Kerberos authentication with SQL\*Plus:

1. At a command prompt, run the following command:

```
kinit username
```

Replace *username* with the user name and, at the prompt, enter the password stored in the Microsoft Active Directory for the user.

2. Open SQL\*Plus and connect using the DNS name and port number for the Oracle DB instance.

For more information about connecting to an Oracle DB instance in SQL\*Plus, see [Connecting to your DB instance using SQL\\*Plus](#).

## Configuring UTL\_HTTP access using certificates and an Oracle wallet

Amazon RDS supports outbound network access on your RDS for Oracle DB instances. To connect your DB instance to the network, you can use the following PL/SQL packages:

### UTL\_HTTP

This package makes HTTP calls from SQL and PL/SQL. You can use it to access data on the Internet over HTTP. For more information, see [UTL\\_HTTP](#) in the Oracle documentation.

### UTL\_TCP

This package provides TCP/IP client-side access functionality in PL/SQL. This package is useful to PL/SQL applications that use Internet protocols and email. For more information, see [UTL\\_TCP](#) in the Oracle documentation.

### UTL\_SMTP

This package provides interfaces to the SMTP commands that enable a client to dispatch emails to an SMTP server. For more information, see [UTL\\_SMTP](#) in the Oracle documentation.

By completing the following tasks, you can configure UTL\_HTTP.REQUEST to work with websites that require client authentication certificates during the SSL handshake. You can also configure password authentication for UTL\_HTTP access to websites by modifying the Oracle wallet generation commands and the DBMS\_NETWORK\_ACL\_ADMIN.APPEND\_WALLET\_ACE procedure. For more information, see [DBMS\\_NETWORK\\_ACL\\_ADMIN](#) in the Oracle Database documentation.

#### Note

You can adapt the following tasks for UTL\_SMTP, which enables you to send emails over SSL/TLS (including [Amazon Simple Email Service](#)).

## Topics

- [Considerations when configuring UTL\\_HTTP access](#)
- [Step 1: Get the root certificate for a website](#)
- [Step 2: Create an Oracle wallet](#)
- [Step 3: Download your Oracle wallet to your RDS for Oracle instance](#)
- [Step 4: Grant user permissions for the Oracle wallet](#)
- [Step 5: Configure access to a website from your DB instance](#)
- [Step 6: Test connections from your DB instance to a website](#)

## Considerations when configuring UTL\_HTTP access

Before configuring access, consider the following:

- You can use SMTP with the UTL\_MAIL option. For more information, see [Oracle UTL\\_MAIL](#).
- The Domain Name Server (DNS) name of the remote host can be any of the following:
  - Publicly resolvable.
  - The endpoint of an Amazon RDS DB instance.
  - Resolvable through a custom DNS server. For more information, see [Setting up a custom DNS server](#).
  - The private DNS name of an Amazon EC2 instance in the same VPC or a peered VPC. In this case, make sure that the name is resolvable through a custom DNS server. Alternatively, to use the DNS provided by Amazon, you can enable the `enableDnsSupport` attribute in the VPC settings and enable DNS resolution support for the VPC peering connection. For more information, see [DNS support in your VPC](#) and [Modifying your VPC peering connection](#).
  - To connect securely to remote SSL/TLS resources, we recommend that you create and upload customized Oracle wallets. By using the Amazon S3 integration with Amazon RDS for Oracle feature, you can download a wallet from Amazon S3 into Oracle DB instances. For information about Amazon S3 integration for Oracle, see [Amazon S3 integration](#).
- You can establish database links between Oracle DB instances over an SSL/TLS endpoint if the Oracle SSL option is configured for each instance. No further configuration is required. For more information, see [Oracle Secure Sockets Layer](#).

## Step 1: Get the root certificate for a website

For the RDS for Oracle DB instance to make secure connections to a website, add the root CA certificate. Amazon RDS uses the root certificate to sign the website certificate to the Oracle wallet.

You can get the root certificate in various ways. For example, you can do the following:

1. Use a web server to visit the website secured by the certificate.
2. Download the root certificate that was used for signing.

For AWS services, root certificates typically reside in the [Amazon trust services repository](#).

## Step 2: Create an Oracle wallet

Create an Oracle wallet that contains both the web server certificates and the client authentication certificates. The RDS Oracle instance uses the web server certificate to establish a secure connection to the website. The website needs the client certificate to authenticate the Oracle database user.

You might want to configure secure connections without using client certificates for authentication. In this case, you can skip the Java keystore steps in the following procedure.

### To create an Oracle wallet

1. Place the root and client certificates in a single directory, and then change into this directory.
2. Convert the .p12 client certificate to the Java keystore.

#### Note

If you're not using client certificates for authentication, you can skip this step.

The following example converts the client certificate named *client\_certificate.p12* to the Java keystore named *client\_keystore.jks*. The keystore is then included in the Oracle wallet. The keystore password is *P12PASSWORD*.

```
orapki wallet pkcs12_to_jks -wallet ./client_certificate.p12 -  
jksKeyStoreLoc ./client_keystore.jks -jksKeyStorepwd P12PASSWORD
```

3. Create a directory for your Oracle wallet that is different from the certificate directory.

The following example creates the directory `/tmp/wallet`.

```
mkdir -p /tmp/wallet
```

4. Create an Oracle wallet in your wallet directory.

The following example sets the Oracle wallet password to `P12PASSWORD`, which is the same password used by the Java keystore in a previous step. Using the same password is convenient, but not necessary. The `-auto_login` parameter turns on the automatic login feature, so that you don't need to specify a password every time you want to access it.

**Note**

Specify a password other than the prompt shown here as a security best practice.

```
orapki wallet create -wallet /tmp/wallet -pwd P12PASSWORD -auto_login
```

5. Add the Java keystore to your Oracle wallet.

**Note**

If you're not using client certificates for authentication, you can skip this step.

The following example adds the keystore `client_keystore.jks` to the Oracle wallet named `/tmp/wallet`. In this example, you specify the same password for the Java keystore and the Oracle wallet.

```
orapki wallet jks_to_pkcs12 -wallet /tmp/wallet -pwd P12PASSWORD -  
keystore ./client_keystore.jks -jkspwd P12PASSWORD
```

6. Add the root certificate for your target website to the Oracle wallet.

The following example adds a certificate named `Root_CA.cer`.

```
orapki wallet add -wallet /tmp/wallet -trusted_cert -cert ./Root_CA.cer -  
pwd P12PASSWORD
```

## 7. Add any intermediate certificates.

The following example adds a certificate named *Intermediate.cer*. Repeat this step as many times as need to load all intermediate certificates.

```
orapki wallet add -wallet /tmp/wallet -trusted_cert -cert ./Intermediate.cer -  
pwd P12PASSWORD
```

## 8. Confirm that your newly created Oracle wallet has the required certificates.

```
orapki wallet display -wallet /tmp/wallet -pwd P12PASSWORD
```

## Step 3: Download your Oracle wallet to your RDS for Oracle instance

In this step, you upload your Oracle wallet to Amazon S3, and then download the wallet from Amazon S3 to your RDS for Oracle instance.

### To download your Oracle wallet to your RDS for Oracle DB instance

1. Complete the prerequisites for Amazon S3 integration with Oracle, and add the S3\_INTEGRATION option to your Oracle DB instance. Ensure that the IAM role for the option has access to the Amazon S3 bucket you are using.

For more information, see [Amazon S3 integration](#).

2. Log in to your DB instance as the master user, and then create an Oracle directory to hold the Oracle wallet.

The following example creates an Oracle directory named *WALLET\_DIR*.

```
EXEC rdsadmin.rdsadmin_util.create_directory('WALLET_DIR');
```

For more information, see [Creating and dropping directories in the main data storage space](#).

3. Upload the Oracle wallet to your Amazon S3 bucket.

You can use any supported upload technique.

4. If you're re-uploading an Oracle wallet, delete the existing wallet. Otherwise, skip to the next step.

The following example removes the existing wallet, which is named *wallet.sso*.

```
EXEC UTL_FILE.FREMOVE ('WALLET_DIR','cwallet.sso');
```

5. Download the Oracle wallet from your Amazon S3 bucket to the Oracle DB instance.

The following example downloads the wallet named *cwallet.sso* from the Amazon S3 bucket named *my\_s3\_bucket* to the DB instance directory named *WALLET\_DIR*.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(  
    p_bucket_name => 'my_s3_bucket',  
    p_s3_prefix   => 'cwallet.sso',  
    p_directory_name => 'WALLET_DIR')  
AS TASK_ID FROM DUAL;
```

6. (Optional) Download a password-protected Oracle wallet.

Download this wallet only if you want to require a password for every use of the wallet. The following example downloads password-protected wallet *ewallet.p12*.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(  
    p_bucket_name => 'my_s3_bucket',  
    p_s3_prefix   => 'ewallet.p12',  
    p_directory_name => 'WALLET_DIR')  
AS TASK_ID FROM DUAL;
```

7. Check the status of your DB task.

Substitute the task ID returned from the preceding steps for *dbtask-1234567890123-4567.log* in the following example.

```
SELECT TEXT FROM  
TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-1234567890123-4567.log'));
```

8. Check the contents of the directory that you're using to store the Oracle wallet.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'WALLET_DIR'));
```

For more information, see [Listing files in a DB instance directory](#).

## Step 4: Grant user permissions for the Oracle wallet

You can either create a new database user or configure an existing user. In either case, you must configure the user to access the Oracle wallet for secure connections and client authentication using certificates.

### To grant user permissions for the Oracle wallet

1. Log in your RDS for Oracle DB instance as the master user.
2. If you don't want to configure an existing database user, create a new user. Otherwise, skip to the next step.

The following example creates a database user named *my-user*.

```
CREATE USER my-user IDENTIFIED BY my-user-pwd;  
GRANT CONNECT TO my-user;
```

3. Grant permission to your database user on the directory containing your Oracle wallet.

The following example grants read access to user *my-user* on directory *WALLET\_DIR*.

```
GRANT READ ON DIRECTORY WALLET_DIR TO my-user;
```

4. Grant permission to your database user to use the UTL\_HTTP package.

The following PL/SQL program grants UTL\_HTTP access to user *my-user*.

```
BEGIN  
  rdsadmin.rdsadmin_util.grant_sys_object('UTL_HTTP', UPPER('my-user'));  
END;  
/
```

5. Grant permission to your database user to use the UTL\_FILE package.

The following PL/SQL program grants UTL\_FILE access to user *my-user*.

```
BEGIN  
  rdsadmin.rdsadmin_util.grant_sys_object('UTL_FILE', UPPER('my-user'));  
END;  
/
```

## Step 5: Configure access to a website from your DB instance

In this step, you configure your Oracle database user so that it can connect to your target website using UTL\_HTTP, your uploaded Oracle Wallet, and the client certificate. For more information, see [Configuring Access Control to an Oracle Wallet](#) in the Oracle Database documentation.

### To configure access to a website from your RDS for Oracle DB instance

1. Log in your RDS for Oracle DB instance as the master user.
2. Create a Host Access Control Entry (ACE) for your user and the target website on a secure port.

The following example configures *my-user* to access *secret.encrypted-website.com* on secure port 443.

```
BEGIN
  DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
    host      => 'secret.encrypted-website.com',
    lower_port => 443,
    upper_port => 443,
    ace       => xs$ace_type(privilege_list => xs$name_list('http'),
                          principal_name => 'my-user',
                          principal_type => xs_acl.ptype_db));
  -- If the program unit results in PLS-00201, set
  -- the principal_type parameter to 2 as follows:
  -- principal_type => 2));
END;
/
```

#### Important

The preceding program unit can result in the following error: PLS-00201: identifier 'XS\_ACL' must be declared. If this error is returned, replace the line that assigns a value to `principal_type` with the following line, and then rerun the program unit:

```
principal_type => 2));
```

For more information about constants in the PL/SQL package XS\_ACL, see [Real Application Security Administrator's and Developer's Guide](#) in the Oracle Database documentation.

For more information, see [Configuring Access Control for External Network Services](#) in the Oracle Database documentation.

3. (Optional) Create an ACE for your user and target website on the standard port.

You might need to use the standard port if some web pages are served from the standard web server port (80) instead of the secure port (443).

```
BEGIN
  DBMS_NETWORK_ACL_ADMIN.APPEND_HOST_ACE(
    host      => 'secret.encrypted-website.com',
    lower_port => 80,
    upper_port => 80,
    ace       => xs$ace_type(privilege_list => xs$name_list('http'),
                             principal_name => 'my-user',
                             principal_type => xs_acl.ptype_db));
    -- If the program unit results in PLS-00201, set
    -- the principal_type parameter to 2 as follows:
    -- principal_type => 2));
END;
/
```

4. Confirm that the access control entries exist.

```
SET LINESIZE 150
COLUMN HOST FORMAT A40
COLUMN ACL FORMAT A50

SELECT HOST, LOWER_PORT, UPPER_PORT, ACL
  FROM DBA_NETWORK_ACLS
 ORDER BY HOST;
```

5. Grant permission to your database user to use the UTL\_HTTP package.

The following PL/SQL program grants UTL\_HTTP access to user *my-user*.

```
BEGIN
  rdsadmin.rdsadmin_util.grant_sys_object('UTL_HTTP', UPPER('my-user'));
END;
/
```

## 6. Confirm that related access control lists exist.

```
SET LINESIZE 150
COLUMN ACL FORMAT A50
COLUMN PRINCIPAL FORMAT A20
COLUMN PRIVILEGE FORMAT A10

SELECT ACL, PRINCIPAL, PRIVILEGE, IS_GRANT,
       TO_CHAR(START_DATE, 'DD-MON-YYYY') AS START_DATE,
       TO_CHAR(END_DATE, 'DD-MON-YYYY') AS END_DATE
FROM DBA_NETWORK_ACL_PRIVILEGES
ORDER BY ACL, PRINCIPAL, PRIVILEGE;
```

## 7. Grant permission to your database user to use certificates for client authentication and your Oracle wallet for connections.

### Note

If you're not using client certificates for authentication, you can skip this step.

```
DECLARE
  l_wallet_path all_directories.directory_path%type;
BEGIN
  SELECT DIRECTORY_PATH
         INTO l_wallet_path
         FROM ALL_DIRECTORIES
         WHERE UPPER(DIRECTORY_NAME)='WALLET_DIR';
  DBMS_NETWORK_ACL_ADMIN.APPEND_WALLET_ACE(
    wallet_path => 'file:/' || l_wallet_path,
    ace         => xs$ace_type(privilege_list => xs
$name_list('use_client_certificates'),
                                principal_name => 'my-user',
                                principal_type => xs_acl.ptype_db));
END;
```

/

## Step 6: Test connections from your DB instance to a website

In this step, you configure your database user so that it can connect to the website using UTL\_HTTP, your uploaded Oracle Wallet, and the client certificate.

### To configure access to a website from your RDS for Oracle DB instance

1. Log in your RDS for Oracle DB instance as a database user with UTL\_HTTP permissions.
2. Confirm that a connection to your target website can resolve the host address.

The following example gets the host address from *secret.encrypted-website.com*.

```
SELECT UTL_INADDR.GET_HOST_ADDRESS(host => 'secret.encrypted-website.com')
FROM DUAL;
```

3. Test a failed connection.

The following query fails because UTL\_HTTP requires the location of the Oracle wallet with the certificates.

```
SELECT UTL_HTTP.REQUEST('secret.encrypted-website.com') FROM DUAL;
```

4. Test website access by using UTL\_HTTP.SET\_WALLET and selecting from DUAL.

```
DECLARE
  l_wallet_path all_directories.directory_path%type;
BEGIN
  SELECT DIRECTORY_PATH
  INTO l_wallet_path
  FROM ALL_DIRECTORIES
  WHERE UPPER(DIRECTORY_NAME)='WALLET_DIR';
  UTL_HTTP.SET_WALLET('file:/' || l_wallet_path);
END;
/

SELECT UTL_HTTP.REQUEST('secret.encrypted-website.com') FROM DUAL;
```

## 5. (Optional) Test website access by storing your query in a variable and using EXECUTE IMMEDIATE.

```
DECLARE
  l_wallet_path all_directories.directory_path%type;
  v_webpage_sql VARCHAR2(1000);
  v_results      VARCHAR2(32767);
BEGIN
  SELECT DIRECTORY_PATH
         INTO l_wallet_path
         FROM ALL_DIRECTORIES
         WHERE UPPER(DIRECTORY_NAME)='WALLET_DIR';
  v_webpage_sql := 'SELECT UTL_HTTP.REQUEST(''secret.encrypted-website.com'', '',
'file:/' ||l_wallet_path||'') FROM DUAL';
  DBMS_OUTPUT.PUT_LINE(v_webpage_sql);
  EXECUTE IMMEDIATE v_webpage_sql INTO v_results;
  DBMS_OUTPUT.PUT_LINE(v_results);
END;
/
```

## 6. (Optional) Find the file system location of your Oracle wallet directory.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'WALLET_DIR'));
```

Use the output from the previous command to make an HTTP request. For example, if the directory is *rdsdbdata/userdirs/01*, run the following query.

```
SELECT UTL_HTTP.REQUEST('https://secret.encrypted-website.com/', '',
'file://rdsdbdata/userdirs/01')
FROM   DUAL;
```

# Working with CDBs in RDS for Oracle

In the Oracle multitenant architecture, a container database (CDB) can include customer-created pluggable databases (PDBs). For more information about CDBs, see [Introduction to the Multitenant Architecture](#) in the Oracle Database documentation.

## Topics

- [Overview of RDS for Oracle CDBs](#)
- [Configuring an RDS for Oracle CDB](#)
- [Backing up and restoring a CDB](#)
- [Converting an RDS for Oracle non-CDB to a CDB](#)
- [Converting the single-tenant configuration to multi-tenant](#)
- [Adding an RDS for Oracle tenant database to your CDB instance](#)
- [Modifying an RDS for Oracle tenant database](#)
- [Deleting an RDS for Oracle tenant database from your CDB](#)
- [Viewing tenant database details](#)
- [Upgrading your CDB](#)

## Overview of RDS for Oracle CDBs

You can create an RDS for Oracle DB instance as a container database (CDB) when you run Oracle Database 19c or higher. Starting with Oracle Database 21c, all databases are CDBs. A CDB differs from a non-CDB because it can contain pluggable databases (PDBs), which are called *tenant databases* in RDS for Oracle. A PDB is a portable collection of schemas and objects that appears to an application as a separate database.

You create your initial tenant database (PDB) when you create your CDB instance. In RDS for Oracle, your client application interacts with a PDB rather than the CDB. Your experience with a PDB is mostly identical to your experience with a non-CDB.

## Topics

- [Multi-tenant configuration of the CDB architecture](#)
- [Single-tenant configuration of the CDB architecture](#)
- [Creation and conversion options for CDBs](#)

- [User accounts and privileges in a CDB](#)
- [Parameter group families in a CDB](#)
- [Limitations of RDS for Oracle CDBs](#)

## Multi-tenant configuration of the CDB architecture

RDS for Oracle supports the *multi-tenant configuration* of the Oracle multitenant architecture, also called the *CDB architecture*. In this configuration, your RDS for Oracle CDB instance can contain 1–30 tenant databases, depending on the database edition and any required option licenses. In Oracle database, a tenant database is a PDB. Your DB instance must use Oracle database release 19.0.0.0.ru-2022-01.rur-2022.r1 or higher.

### Note

The Amazon RDS feature is called "multi-tenant" rather than "multitenant" because it is a capability of the RDS platform, not just the Oracle DB engine. The term "Oracle multitenant" refers exclusively to the Oracle database architecture, which is compatible with both on-premises and RDS deployments.

You can configure the following settings:

- Tenant database name
- Tenant database master username
- Tenant database master password
- Tenant database character set
- Tenant database national character set

The tenant database character set can be different from the CDB character set. The same applies to the national character set. After you create your initial tenant database, you can create, modify, or delete tenant databases using RDS APIs. The CDB name defaults to RDSCDB and can't be changed. For more information, see [Settings for DB instances](#) and [Modifying an RDS for Oracle tenant database](#).

## Single-tenant configuration of the CDB architecture

RDS for Oracle supports a legacy configuration of the Oracle multitenant architecture called the *single-tenant configuration*. In this configuration, an RDS for Oracle CDB instance can contain only one tenant (PDB). You can't create more PDBs later.

## Creation and conversion options for CDBs

Oracle Database 21c supports only CDBs, whereas Oracle Database 19c supports both CDBs and non-CDBs. All RDS for Oracle CDB instances support both the multi-tenant and single-tenant configurations.

### Creation, conversion, and upgrade options for the Oracle database architecture

The following table shows the different architecture options for creating and upgrading RDS for Oracle databases.

Release	Database creation options	Architecture conversion options	Major version upgrade targets
Oracle Database 21c	CDB architecture only	N/A	N/A
Oracle Database 19c	CDB or non-CDB architecture	Non-CDB to CDB architecture (April 2021 RU or higher)	Oracle Database 21c CDB

As shown in the preceding table, you can't directly upgrade a non-CDB to a CDB in a new major database version. But you can convert an Oracle Database 19c non-CDB to an Oracle Database 19c CDB, and then upgrade the Oracle Database 19c CDB to an Oracle Database 21c CDB. For more information, see [Converting an RDS for Oracle non-CDB to a CDB](#).

### Conversion options for CDB architecture configurations

The following table shows the different options for converting the architecture configuration of an RDS for Oracle DB instance.

Current architecture and configuration	Conversion to the single-tenant configuration of the CDB architecture	Conversion to the multi-tenant configuration of the CDB architecture	Conversion to the non-CDB architecture
Non-CDB	Supported	Supported*	N/A
CDB using the single-tenant configuration	N/A	Supported	Not supported
CDB using the multi-tenant configuration	Not supported	N/A	Not supported

\* You can't convert a non-CDB to the multi-tenant configuration in a single operation. When you convert a non-CDB to a CDB, the CDB is in the single-tenant configuration. You can then convert the single-tenant to the multi-tenant configuration in a separate operation.

## User accounts and privileges in a CDB

In the Oracle multitenant architecture, all user accounts are either *common users* or *local users*. A CDB common user is a database user whose single identity and password are known in the CDB root and in every existing and future PDB. In contrast, a local user exists only in a single PDB.

The RDS master user is a local user account in the PDB, which you name when you create your DB instance. If you create new user accounts, these users will also be local users residing in the PDB. You can't use any user accounts to create new PDBs or modify the state of the existing PDB.

The `rdsadmin` user is a common user account. You can run RDS for Oracle packages that exist in this account, but you can't log in as `rdsadmin`. For more information, see [About Common Users and Local Users](#) in the Oracle documentation.

## Parameter group families in a CDB

CDBs have their own parameter group families and default parameter values. The CDB parameter group families are as follows:

- `oracle-ee-cdb-21`

- oracle-se2-cdb-21
- oracle-ee-cdb-19
- oracle-se2-cdb-19

## Limitations of RDS for Oracle CDBs

RDS for Oracle supports a subset of features available in an on-premises CDB.

### CDB limitations

The following limitations apply to RDS for Oracle at the CDB level:

- You can't connect to a CDB. You always connect to the tenant database (PDB) rather than the CDB. Specify the endpoint for the PDB just as for a non-CDB. The only difference is that you specify *pdb\_name* for the database name, where *pdb\_name* is the name you chose for your PDB.
- You can't convert a CDB in the multi-tenant configuration to a CDB in the single-tenant conversion. Conversion to the multi-tenant configuration is one-way and irreversible.
- You can't enable or convert to the multi-tenant configuration if your DB instance uses an Oracle database release lower than 19.0.0.0.ru-2022-01.rur-2022.r1.
- You can't use an RDS for Oracle CDB with ORDS 22 and higher. As a workaround, you can either use a lower version of ORDS or use an Oracle Database 19c non-CDB.
- You can enable auditing from within CDB\$ROOT. You must enable auditing within each PDB individually.

Support for the following features depends on the architecture configuration.

Feature	Supported in single-tenant	Supported in multi-tenant
Oracle Data Guard	Yes	No
Oracle Label Security	No	No
Oracle Enterprise Manager (OEM)	No	No
OEM Agent	No	No

Feature	Supported in single-tenant	Supported in multi-tenant
Database Activity Streams	Yes	No

## Tenant database (PDB) limitations

The following limitations apply to tenant databases in the RDS for Oracle multi-tenant configuration:

- You can't defer tenant database operations to the maintenance window. All changes occur immediately.
- You can't add a tenant database to a CDB that uses the single-tenant configuration.
- You can't add or modify multiple tenant databases in a single operation. You can only add or modify them one at a time.
- You can't modify a tenant database to be named CDB\$ROOT or PDB\$SEED.
- You can't delete a tenant database if it is the only tenant in the CDB.
- Not all DB instance class types have sufficient resources to support multiple PDBs in an RDS for Oracle CDB instance. An increased PDB count affects the performance and stability of the smaller instance classes and increases the time of most instance-level operations, for example, database upgrades.
- You can't use multiple AWS accounts to create PDBs in the same CDB. PDBs must be owned by the same account as the DB instance that the PDBs are hosted on.
- All PDBs in a CDB use the same endpoint and database listener.
- The following operations aren't supported at the PDB level but are supported at the CDB level:
  - Backup and recovery
  - Database upgrades
  - Maintenance actions
- The following features aren't supported at the PDB level but are supported at the CDB level:
  - Option groups (options are installed on all PDBs on your CDB instance)
  - Parameter groups (all parameters are derived from the parameter group associated with your CDB instance)
- PDB-level operations that are supported in the on-premises CDB architecture but aren't supported in an RDS for Oracle CDB include the following:

**Note**

The following list is not exhaustive.

- Application PDBs
- Proxy PDBs
- Starting and stopping a PDB
- Unplugging and plugging in PDBs

To move data into or out of your CDB, use the same techniques as for a non-CDB. For more information about migrating data, see [Importing data into Oracle on Amazon RDS](#).

- Setting options at the PDB level

The PDB inherits options settings from the CDB option group. For more information about setting options, see [Parameter groups for Amazon RDS](#). For best practices, see [Working with DB parameter groups](#).

- Configuring parameters in a PDB

The PDB inherits parameter settings from the CDB. For more information about setting option, see [Adding options to Oracle DB instances](#).

- Configuring different listeners for PDBs in the same CDB
- Oracle Flashback features

## Configuring an RDS for Oracle CDB

Configuring a CDB is similar to configuring a non-CDB.

### Topics

- [Creating an RDS for Oracle CDB instance](#)
- [Connecting to a PDB in your RDS for Oracle CDB](#)

## Creating an RDS for Oracle CDB instance

In RDS for Oracle, creating a CDB is almost identical to creating a non-CDB. The difference is that you choose the Oracle multitenant architecture when creating your DB instance and also choose an architecture configuration: multi-tenant or single-tenant. If you create tags when you create a CDB in the multi-tenant configuration, RDS propagates the tags to the initial tenant database. To create a CDB, use the AWS Management Console, the AWS CLI, or the RDS API.

### Console

#### To create a CDB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the CDB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. In **Choose a database creation method**, select **Standard Create**.
6. In **Engine options**, choose **Oracle**.
7. For **Database management type**, choose **Amazon RDS**.
8. For **Architecture settings**, choose **Oracle multitenant architecture**.
9. For **Architecture configuration**, do either of the following:
  - Choose **Multi-tenant configuration** and proceed to the next step.
  - Choose **Single-tenant configuration** and skip to Step 11.
10. (Multi-tenant configuration) For **Tenant database settings**, make the following changes:
  - For **Tenant database name**, enter the name of your initial PDB. The PDB name must be different from the CDB name, which defaults to RDSCDB.
  - For **Tenant database master username**, enter the master username of your PDB. You can't use the tenant database master username to log in to the CDB itself.
  - Either enter a password in **Tenant database master password** or choose **Auto generate a password**.
  - For **Tenant database character set**, choose a character set for the PDB. You can choose a tenant database character set that is different from the CDB character set.

The default PDB character set is **AL32UTF8**. If you choose a nondefault PDB character set, CDB creation might be slower.

 **Note**

You can't create multiple tenant databases as part of the CDB creation process. You can only add PDBs to an already existing CDB.

11. (Single-tenant configuration) Choose the settings that you want based on the options listed in [Settings for DB instances](#). Note the following:
  - For **Master username**, enter the name for a local user in your PDB. You can't use the master username to log in to the CDB root.
  - For **Initial database name**, enter the name of your PDB. You can't name the CDB, which has the default name RDSCDB.
12. Choose **Create database**.

## AWS CLI

To create a CDB in the multi-tenant configuration, use the [create-db-instance](#) command with the following parameters:

- `--db-instance-identifier`
- `--db-instance-class`
- `--engine { oracle-ee-cdb | oracle-se2-cdb }`
- `--master-username`
- `--master-user-password`
- `--multi-tenant` (for the single-tenant configuration, either don't specify `multi-tenant` or specify `--no-multi-tenant`)
- `--allocated-storage`
- `--backup-retention-period`

For information about each setting, see [Settings for DB instances](#).

This following example creates an RDS for Oracle DB instance named *my-cdb-inst* in the multi-tenant configuration. If you specify `--no-multi-tenant` or don't specify `--multi-tenant`, the default CDB configuration is single-tenant. The engine is `oracle-ee-cdb`: a command that specifies `oracle-ee` and `--multi-tenant` fails with an error. The initial tenant database is named *mypdb*.

## Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \  
  --engine oracle-ee-cdb \  
  --db-instance-identifier my-cdb-inst \  
  --multi-tenant \  
  --db-name mypdb \  
  --allocated-storage 250 \  
  --db-instance-class db.t3.large \  
  --master-username pdb_admin \  
  --master-user-password pdb_admin_password \  
  --backup-retention-period 3
```

For Windows:

```
aws rds create-db-instance ^  
  --engine oracle-ee-cdb ^  
  --db-instance-identifier my-cdb-inst ^  
  --multi-tenant ^  
  --db-name mypdb ^  
  --allocated-storage 250 ^  
  --db-instance-class db.t3.large ^  
  --master-username pdb_admin ^  
  --master-user-password pdb_admin_password ^  
  --backup-retention-period 3
```

### Note

Specify a password other than the prompt shown here as a security best practice.

This command produces output similar to the following. The database name, character set, national character set, and master user aren't included in the output. You can view this information by using the CLI command `describe-tenant-databases`.

```
{
  "DBInstance": {
    "DBInstanceIdentifier": "my-cdb-inst",
    "DBInstanceClass": "db.t3.large",
    "MultiTenant": true,
    "Engine": "oracle-ee-cdb",
    "DBResourceId": "db-ABCDEFGHJKLMNOPQRSTUVWXYZ",
    "DBInstanceStatus": "creating",
    "AllocatedStorage": 250,
    "PreferredBackupWindow": "04:59-05:29",
    "BackupRetentionPeriod": 3,
    "DBSecurityGroups": [],
    "VpcSecurityGroups": [
      {
        "VpcSecurityGroupId": "sg-0a1bcd2e",
        "Status": "active"
      }
    ],
    "DBParameterGroups": [
      {
        "DBParameterGroupName": "default.oracle-ee-cdb-19",
        "ParameterApplyStatus": "in-sync"
      }
    ],
    "DBSubnetGroup": {
      "DBSubnetGroupName": "default",
      "DBSubnetGroupDescription": "default",
      "VpcId": "vpc-1234567a",
      "SubnetGroupStatus": "Complete",
      ...
    }
  }
}
```

## RDS API

To create a DB instance by using the Amazon RDS API, call the [CreateDBInstance](#) operation.

For information about each setting, see [Settings for DB instances](#).

## Connecting to a PDB in your RDS for Oracle CDB

You can use a utility like SQL\*Plus to connect to a PDB. To download Oracle Instant Client, which includes a standalone version of SQL\*Plus, see [Oracle Instant Client Downloads](#).

To connect SQL\*Plus to your PDB, you need the following information:

- PDB name
- Database user name and password
- Endpoint for your DB instance
- Port number

For information about finding the preceding information, see [Finding the endpoint of your RDS for Oracle DB instance](#).

### Example To connect to your PDB using SQL\*Plus

In the following examples, substitute your master user for *master\_user\_name*. Also, substitute the endpoint for your DB instance, and then include the port number and the Oracle SID. The SID value is the name of the PDB that you specified when you created your DB instance, and not the DB instance identifier.

For Linux, macOS, or Unix:

```
sqlplus 'master_user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=endpoint)
(PORT=port)))(CONNECT_DATA=(SID=pdb_name)))'
```

For Windows:

```
sqlplus master_user_name@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=endpoint)
(PORT=port)))(CONNECT_DATA=(SID=pdb_name)))
```

You should see output similar to the following.

```
SQL*Plus: Release 19.0.0.0.0 Production on Mon Aug 21 09:42:20 2021
```

After you enter the password for the user, the SQL prompt appears.

```
SQL>
```

**Note**

The shorter format connection string (Easy connect or EZCONNECT), such as `sqlplus username/password@LONGER-THAN-63-CHARS-RDS-ENDPOINT-HERE:1521/database-identifier`, might encounter a maximum character limit and should not be used to connect.

## Backing up and restoring a CDB

You can back up and restore your CDB using either RDS DB snapshots or Recovery Manager (RMAN).

### Backing up and restoring a CDB using DB snapshots

DB snapshots work similarly in the CDB and non-CDB architectures. The principal differences are as follows:

- When you restore a DB snapshot of a CDB, you can't rename the CDB. The CDB is named `RDSCDB` and can't be changed.
- When you restore a DB snapshot of a CDB, you can't rename PDBs. You can modify the PDB name by using the [modify-tenant-database](#) command.
- To find tenant databases in a snapshot, use the CLI command [describe-db-snapshot-tenant-databases](#).
- You can't directly interact with the tenant databases in a CDB snapshot that uses the multi-tenant architecture configuration. If you restore the DB snapshot, you restore all its tenant databases.
- RDS for Oracle implicitly copies tags on a tenant database to the tenant database in a DB snapshot. When you restore a tenant database, the tags appear in the restored database.
- If you restore a DB snapshot and specify new tags using the `--tags` parameter, the new tags overwrite all existing tags.
- If you take a DB snapshot of a CDB instance that has tags, and you specify `--copy-tags-to-snapshot`, RDS for Oracle copies tags from the tenant databases to the tenant databases in the snapshot.

For more information, see [Oracle Database considerations](#).

## Backing up and restoring a CDB using RMAN

To learn how to back up and restore a CDB or individual tenant database using RMAN, see [Performing common RMAN tasks for Oracle DB instances](#).

## Converting an RDS for Oracle non-CDB to a CDB

You can change the architecture of an Oracle database from the non-CDB architecture to the Oracle multitenant architecture, also called the *CDB architecture*, with the `modify-db-instance` command. In most cases, this technique is preferable to creating a new CDB and importing data. The conversion operation incurs downtime.

When you upgrade your database engine version, you can't change the database architecture in the same operation. Therefore, to upgrade an Oracle Database 19c non-CDB to an Oracle Database 21c CDB, you first need to convert the non-CDB to a CDB in one step, and then upgrade the 19c CDB to a 21c CDB in a separate step.

The non-CDB conversion operation has the following requirements:

- You must specify `oracle-ee-cdb` or `oracle-se2-cdb` for the DB engine type. These are the only supported values.
- Your DB engine must use Oracle Database 19c with an April 2021 or later release update (RU).

The operation has the following limitations:

- You can't convert a CDB to a non-CDB. You can only convert a non-CDB to a CDB.
- You can't convert a non-CDB to the multi-tenant configuration in a single `modify-db-instance` call. After you convert a non-CDB to a CDB, your CDB is in the single-tenant configuration. To convert the single-tenant configuration to the multi-tenant configuration, run `modify-db-instance` again. For more information, see [Converting the single-tenant configuration to multi-tenant](#).
- You can't convert a primary or replica database that has Oracle Data Guard enabled. To convert a non-CDB that has read replicas, first delete all read replicas.
- You can't upgrade the DB engine version and convert a non-CDB to a CDB in the same operation.

Before converting your non-CDB, consider the following:

- The considerations for option and parameter groups are the same as for upgrading the DB engine. For more information, see [Considerations for Oracle DB upgrades](#).
- If your DB instance has the OEMAGENT option installed, a best practice is to remove this option before you convert your non-CDB. After your non-CDB is converted to a CDB, reinstall the option. For more information, see [Oracle Management Agent for Enterprise Manager Cloud Control](#).

## Console

### To convert a non-CDB to a CDB

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where your DB instance resides.
3. In the navigation pane, choose **Databases**, and then choose the non-CDB instance that you want to convert to a CDB instance.
4. Choose **Modify**.
5. For **Architecture settings**, select **Oracle multitenant architecture**. After conversion, your CDB will be in the single-tenant configuration.
6. (Optional) For **DB parameter group**, choose a new parameter group for your CDB instance. The same parameter group considerations apply when converting a DB instance as when upgrading a DB instance. For more information, see [Parameter group considerations](#).
7. (Optional) For **Option group**, choose a new option group for your CDB instance. The same option group considerations apply when converting a DB instance as when upgrading a DB instance. For more information, see [Option group considerations](#).
8. When all the changes are as you want them, choose **Continue** and check the summary of modifications.
9. (Optional) Choose **Apply immediately** to apply the changes immediately. Choosing this option can cause downtime in some cases. For more information, see [Schedule modifications setting](#).
10. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance**.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

## AWS CLI

To convert the non-CDB on your DB instance to a CDB in the single-tenant configuration, set `--engine` to `oracle-ee-cdb` or `oracle-se2-cdb` in the AWS CLI command [modify-db-instance](#). For more information, see [Settings for DB instances](#).

The following example converts the DB instance named *my-non-cdb* and specifies a custom option group and parameter group.

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier my-non-cdb \  
  --engine oracle-ee-cdb \  
  --option-group-name custom-option-group \  
  --db-parameter-group-name custom-parameter-group
```

For Windows:

```
aws rds modify-db-instance ^  
  --db-instance-identifier my-non-cdb ^  
  --engine oracle-ee-cdb ^  
  --option-group-name custom-option-group ^  
  --db-parameter-group-name custom-parameter-group
```

## RDS API

To convert a non-CDB to a CDB, specify `Engine` in the RDS API operation [ModifyDBInstance](#).

## Converting the single-tenant configuration to multi-tenant

You can modify the architecture of an RDS for Oracle CDB from the single-tenant configuration to the multi-tenant configuration. Before and after the conversion, your CDB contains a single tenant database (PDB).

During the conversion, RDS for Oracle migrates the following metadata to the new tenant database:

- The master username

- The database name
- The character set
- The national character set

Before the conversion, you could view the preceding information by using the `describe-db-instances` command. After the conversion, you view the information by using the `describe-tenant-database` command.

The conversion has the following requirements and limitations:

- After you convert the single-tenant architecture configuration to the multi-tenant configuration, you can't later convert the architecture back to the single-tenant configuration. The operation is irreversible.
- The tags for the DB instance propagate to the initial tenant DB created during the conversion.
- You can't convert a primary or replica database that has Oracle Data Guard enabled.
- You can't upgrade the DB engine version and convert to the multi-tenant configuration in the same operation.
- Your IAM policy must have permission to create a tenant database.

## Console

### To convert a CDB using the single-tenant configuration to the multi-tenant configuration

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where your DB instance resides.
3. In the navigation pane, choose **Databases**, and then choose the non-CDB instance that you want to convert to a CDB instance.
4. Choose **Modify**.
5. For **Architecture settings**, select **Oracle multitenant architecture**.
6. For **Architecture configuration**, select **Multi-tenant configuration**.
7. (Optional) For **DB parameter group**, choose a new parameter group for your CDB instance. The same parameter group considerations apply when converting a DB instance as when upgrading a DB instance.

8. (Optional) For **Option group**, choose a new option group for your CDB instance. The same option group considerations apply when converting a DB instance as when upgrading a DB instance.
9. When all the changes are as you want them, choose **Continue** and check the summary of modifications.
10. Choose **Apply immediately**. This option is required when you switch to a multi-tenant configuration. Note that this option can cause downtime in some cases.
11. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance**.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

## AWS CLI

To convert a CDB using the single-tenant configuration to the multi-tenant configuration, specify `--multi-tenant` in the AWS CLI command [modify-db-instance](#).

The following example converts the DB instance named `my-st-cdb` from the single-tenant configuration to the multi-tenant configuration. The `--apply-immediately` option is required.

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance --region us-east-1 \  
  --db-instance-identifier my-st-cdb \  
  --multi-tenant \  
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance --region us-east-1 ^ \  
  --db-instance-identifier my-st-cdb ^ \  
  --multi-tenant ^ \  
  --apply-immediately
```

The output looks something like the following.

```
{
```

```
"DBInstance": {
  "DBInstanceIdentifier": "my-st-cdb",
  "DBInstanceClass": "db.r5.large",
  "MultiTenant": false,
  "Engine": "oracle-ee-cdb",
  "DBResourceId": "db-AB1CDE2FGHIJK34LMNOPRLXTXU",
  "DBInstanceStatus": "modifying",
  "MasterUsername": "admin",
  "DBName": "ORCL",
  ...
  "EngineVersion": "19.0.0.0.ru-2022-01.rur-2022-01.r1",
  "AutoMinorVersionUpgrade": true,
  "ReadReplicaDBInstanceIdentifiers": [],
  "LicenseModel": "bring-your-own-license",
  "OptionGroupMemberships": [
    {
      "OptionGroupName": "default:oracle-ee-cdb-19",
      "Status": "in-sync"
    }
  ],
  ...
  "PendingModifiedValues": {
    "MultiTenant": "true"
  }
}
```

## Adding an RDS for Oracle tenant database to your CDB instance

In the RDS for Oracle multi-tenant configuration, a tenant database is a PDB. To add a tenant database, make sure you meet the following prerequisites:

- Your CDB has the multi-tenant configuration enabled. For more information, see [Multi-tenant configuration of the CDB architecture](#).
- You have the necessary IAM permissions to create the tenant database.

You can add a tenant database using the AWS Management Console, the AWS CLI, or the RDS API. You can't add multiple tenant databases in a single operation: you must add them one at a time. If the CDB has backup retention enabled, Amazon RDS backs up the DB instance before and after it adds a new tenant database.

## Console

### To add a tenant database to your DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the tenant database.
3. In the navigation pane, choose **Databases**.
4. Choose the CDB instance to which you want to add a tenant database. Your DB instance must use the multi-tenant configuration of the CDB architecture.
5. Choose **Actions** and then **Add tenant database**.
6. For **Tenant database settings**, do the following:
  - For **Tenant database name**, enter the name of your new PDB.
  - For **Tenant database master username**, enter the name of the master user for your PDB. This master user is different from the master user of the CDB.
  - Either enter a password in **Tenant database master password** or select **Auto generate a password**.
  - For **Tenant database character set**, choose a character set for the PDB. The default is **AL32UTF8**. You can choose a PDB character set that is different from the CDB character set.
  - For **Tenant database national character set**, choose a national character set for the PDB. The default is **AL32UTF8**. The national character set specifies the encoding only for columns that use the NCHAR data type (NCHAR, NVARCHAR2, and NCLOB) and doesn't affect database metadata.

For more information about the preceding settings, see [Settings for DB instances](#).

7. Choose **Add tenant**.

## AWS CLI

To add a tenant database to your CDB with the AWS CLI, use the command [create-tenant-database](#) with the following required parameters:

- `--db-instance-identifier`

- `--tenant-db-name`
- `--master-username`
- `--master-user-password`

This following example creates a tenant database named *mypdb2* in the RDS for Oracle CDB instance named *my-cdb-inst*. The PDB character set is UTF-16.

### Example

For Linux, macOS, or Unix:

```
aws rds create-tenant-database --region us-east-1 \  
  --db-instance-identifier my-cdb-inst \  
  --tenant-db-name mypdb2 \  
  --master-username mypdb2-admin \  
  --master-user-password mypdb2-pwd \  
  --character-set-name UTF-16
```

For Windows:

```
aws rds create-tenant-database --region us-east-1 \  
  --db-instance-identifier my-cdb-inst ^  
  --tenant-db-name mypdb2 ^  
  --master-username mypdb2-admin ^  
  --master-user-password mypdb2-pwd ^  
  --character-set-name UTF-16
```

The output looks similar to the following.

```
...}  
  "TenantDatabase" :  
    {  
      "DbiResourceId" : "db-abc123",  
      "TenantDatabaseResourceId" : "tdb-bac567",  
      "TenantDatabaseArn" : "arn:aws:rds:us-east-1:123456789012:db:my-cdb-  
inst:mypdb2",  
      "DBInstanceIdentifier" : "my-cdb-inst",  
      "TenantDBName" : "mypdb2",  
      "Status" : "creating",  
      "MasterUsername" : "mypdb2",
```

```
        "CharacterSetName" : "UTF-16",  
        ...  
    }  
}...
```

## Modifying an RDS for Oracle tenant database

You can modify only the PDB name and the master user password of a tenant database in your CDB. Note the following requirements and limitations:

- To modify the settings of a tenant database in your DB instance, the tenant database must exist.
- You can't modify multiple tenant databases in a single operation. You can only modify one tenant database at a time.
- You can't change the name of a tenant database to CDB\$ROOT or PDB\$SEED.

You can modify PDBs using the AWS Management Console, the AWS CLI, or the RDS API.

### Console

#### To modify the PDB name or master password of a tenant database

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the tenant database.
3. In the navigation pane, choose **Databases**.
4. Choose the tenant database whose database name or master user password you want to modify.
5. Choose **Modify**.
6. For **Tenant database settings**, do any of the following:
  - For **Tenant database name**, enter the new name of your new PDB.
  - For **Tenant database master password**, enter a new password.
7. Choose **Modify tenant**.

## AWS CLI

To modify a tenant database using the AWS CLI, call the [modify-tenant-database](#) command with the following parameters:

- `--db-instance-identifier` *value*
- `--tenant-db-name` *value*
- `[--new-tenant-db-name` *value*]
- `[--master-user-password` *value*]

The following example renames tenant database `pdb1` to `pdb-hr` on DB instance `my-cdb-inst`.

### Example

For Linux, macOS, or Unix:

```
aws rds modify-tenant-database --region us-east-1 \  
  --db-instance-identifier my-cdb-inst \  
  --tenant-db-name pdb1 \  
  --new-tenant-db-name pdb-hr
```

For Windows:

```
aws rds modify-tenant-database --region us-east-1 ^  
  --db-instance-identifier my-cdb-inst ^  
  --tenant-db-name pdb1 ^  
  --new-tenant-db-name pdb-hr
```

This command produces output similar to the following.

```
{  
  "TenantDatabase" : {  
    "DbiResourceId" : "db-abc123",  
    "TenantDatabaseResourceId" : "tdb-bac567",  
    "TenantDatabaseArn" : "arn:aws:rds:us-east-1:123456789012:db:my-cdb-inst:pdb1",  
    "DBInstanceIdentifier" : "my-cdb-inst",  
    "TenantDBName" : "pdb1",  
    "Status" : "modifying",  
    "MasterUsername" : "tenant-admin-user"  }  
}
```

```
    "Port" : "6555",
    "CharacterSetName" : "UTF-16",
    "MaxAllocatedStorage" : "1000",
    "ParameterGroups": [
      {
        "ParameterGroupName": "pdb1-params",
        "ParameterApplyStatus": "in-sync"
      }
    ],
    "OptionGroupMemberships": [
      {
        "OptionGroupName": "pdb1-options",
        "Status": "in-sync"
      }
    ],
    "PendingModifiedValues": {
      "TenantDBName": "pdb-hr"
    }
  }
}
```

## Deleting an RDS for Oracle tenant database from your CDB

You can delete a tenant database (PDB) using the AWS Management Console, the AWS CLI, or the RDS API. Consider the following prerequisites and limitations:

- The tenant database and DB instance must exist.
- For the deletion to succeed, one of the following situations must exist:
  - The tenant database and DB instance are available.

### Note

You can take a final snapshot, but only if the tenant database and DB instance were in an available state before you issued the `delete-tenant-database` command.

- The tenant database is being created.
- The DB instance is modifying the tenant database.
- You can't delete multiple tenant databases in a single operation.
- You can't delete a tenant database if it is the only tenant in the CDB.

## Console

### To delete a tenant database

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the tenant database that you want to delete.
3. For **Actions**, choose **Delete**.
4. To create a final DB snapshot for the DB instance, choose **Create final snapshot?**.
5. If you chose to create a final snapshot, enter the **Final snapshot name**.
6. Enter **delete me** in the box.
7. Choose **Delete**.

## AWS CLI

To delete a tenant database using the AWS CLI, call the [delete-tenant-database](#) command with the following parameters:

- `--db-instance-identifier` *value*
- `--tenant-db-name` *value*
- `[--skip-final-snapshot | --no-skip-final-snapshot]`
- `[--final-snapshot-identifier` *value*]

This following example deletes the tenant database named *pdb-test* from the CDB named *my-cdb-inst*. By default, the operation creates a final snapshot.

### Example

For Linux, macOS, or Unix:

```
aws rds delete-tenant-database --region us-east-1 \  
  --db-instance-identifier my-cdb-inst \  
  --tenant-db-name pdb-test \  
  --final-snapshot-identifier final-snap-pdb-test
```

## For Windows:

```
aws rds delete-tenant-database --region us-east-1 ^
--db-instance-identifier my-cdb-inst ^
--tenant-db-name pdb-test ^
--final-snapshot-identifier final-snap-pdb-test
```

This command produces output similar to the following.

```
{
  "TenantDatabase" : {
    "DbiResourceId" : "db-abc123",
    "TenantDatabaseResourceId" : "tdb-bac456",
    "TenantDatabaseArn" : "arn:aws:rds:us-east-1:123456789012:db:my-cdb-inst:pdb-
test",
    "DBInstanceIdentifier" : "my-cdb-inst",
    "TenantDBName" : "pdb-test",
    "Status" : "deleting",
    "MasterUsername" : "pdb-test-admin"
    "Port" : "6555",
    "CharacterSetName" : "UTF-16",
    "MaxAllocatedStorage" : "1000",
    "ParameterGroups": [
      {
        "ParameterGroupName": "tenant-1-params",
        "ParameterApplyStatus": "in-sync"
      }
    ],
    "OptionGroupMemberships": [
      {
        "OptionGroupName": "tenant-1-options",
        "Status": "in-sync"
      }
    ]
  }
}
```

## Viewing tenant database details

You can view details about a tenant database in the same way that you can for a non-CDB or CDB.

## Console

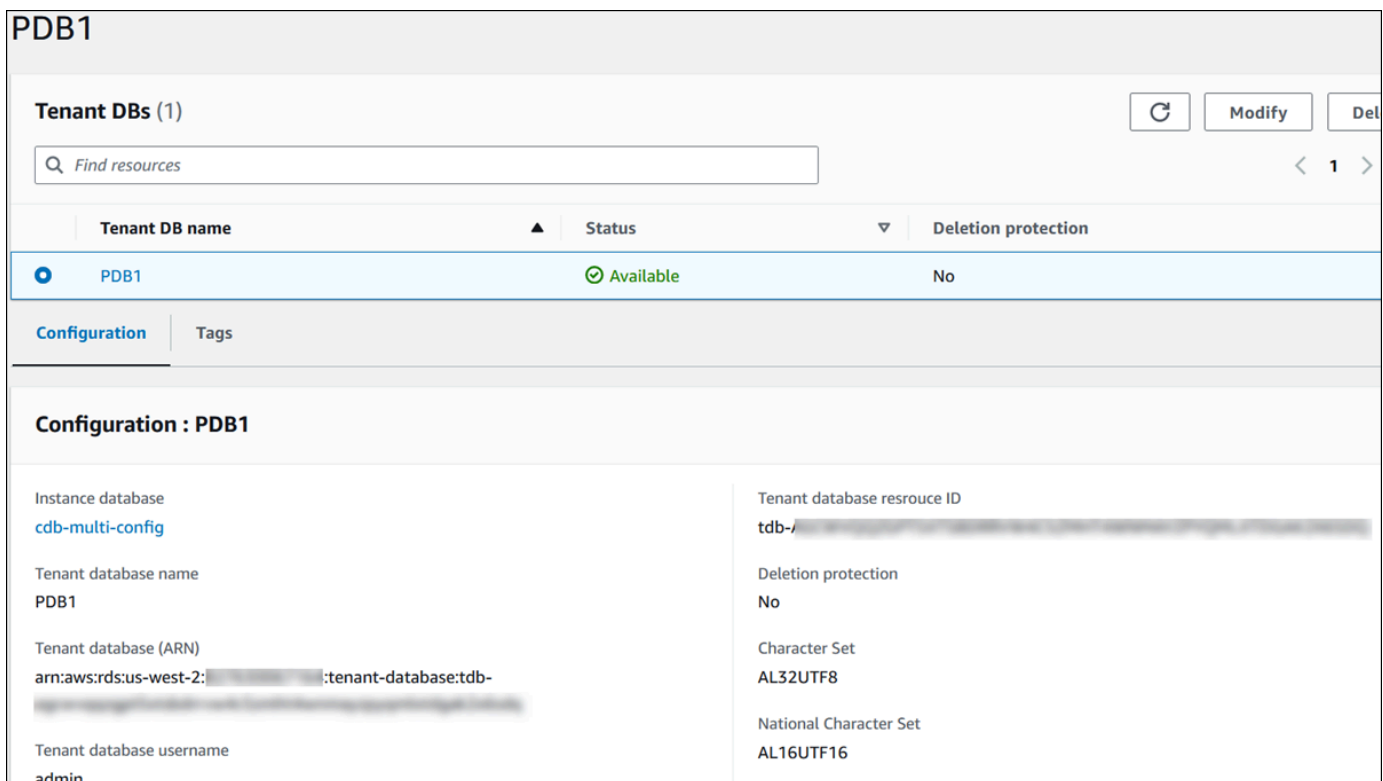

### To view details about a tenant database

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where your DB instance resides.
3. In the navigation pane, choose **Databases**.

In the preceding image, the sole tenant database (PDB) appears as a child of the DB instance.

4. Choose the name of a tenant database.

## AWS CLI

To see details about your PDBs, use the AWS CLI command [describe-tenant-databases](#).

This following example describes all tenant databases in the specified Region.

### Example

For Linux, macOS, or Unix:

```
aws rds describe-tenant-databases --region us-east-1
```

For Windows:

```
aws rds describe-tenant-databases --region us-east-1
```

This command produces output similar to the following.

```
"TenantDatabases" : [
  {
    "DBInstanceIdentifier" : "my-cdb-inst",
    "TenantDBName" : "pdb-test",
    "Status" : "available",
    "MasterUsername" : "pdb-test-admin",
    "DbiResourceId" : "db-abc123",
    "TenantDatabaseResourceId" : "tdb-bac456",
    "TenantDatabaseArn" : "arn:aws:rds:us-east-1:123456789012:db:my-cdb-
inst:pdb-test",
    "CharacterSetName": "AL32UTF8",
    "NcharCharacterSetName": "AL16UTF16",
    "DeletionProtection": false,
    "PendingModifiedValues": {
      "MasterUserPassword": "*****"
    },
    "TagList": []
  },
  {
    "DBInstanceIdentifier" : "my-cdb-inst2",
    "TenantDBName" : "pdb-dev",
    "Status" : "modifying",
    "MasterUsername" : "masterrdsuser"
```

```

    "DbiResourceId" : "db-xyz789",
    "TenantDatabaseResourceId" : "tdb-ghp890",
    "TenantDatabaseArn" : "arn:aws:rds:us-east-1:123456789012:db:my-cdb-
inst2:pdb-dev",
    "CharacterSetName": "AL32UTF8",
    "NcharCharacterSetName": "AL16UTF16",
    "DeletionProtection": false,
    "PendingModifiedValues": {
        "MasterUserPassword": "*****"
    },
    "TagList": []
},
... other truncated data

```

The following example describes the tenant databases on DB instance `my-cdb-inst` in the specified Region.

### Example

For Linux, macOS, or Unix:

```
aws rds describe-tenant-databases --region us-east-1 \
  --db-instance-identifier my-cdb-inst
```

For Windows:

```
aws rds describe-tenant-databases --region us-east-1 ^
  --db-instance-identifier my-cdb-inst
```

This command produces output similar to the following.

```

{
  "TenantDatabase": {
    "TenantDatabaseCreateTime": "2023-10-19T23:55:30.046Z",
    "DBInstanceIdentifier": "my-cdb-inst",
    "TenantDBName": "pdb-hr",
    "Status": "creating",
    "MasterUsername": "tenant-admin-user",
    "DbiResourceId": "db-abc123",
    "TenantDatabaseResourceId": "tdb-bac567",
    "TenantDatabaseARN": "arn:aws:rds:us-west-2:579508833180:pdb-hr:tdb-
abcdefghijklmno2p3qrst4uvw5xy6zabc7defghi8jklmn90op",

```

```

    "CharacterSetName": "AL32UTF8",
    "NcharCharacterSetName": "AL16UTF16",
    "DeletionProtection": false,
    "PendingModifiedValues": {
      "MasterUserPassword": "*****"
    },
    "TagList": [
      {
        "Key": "TEST",
        "Value": "testValue"
      }
    ]
  }
}

```

The following example describes tenant database `pdb1` on DB instance `my-cdb-inst` in the US East (N. Virginia) Region.

### Example

For Linux, macOS, or Unix:

```

aws rds describe-tenant-databases --region us-east-1 \
--db-instance-identifier my-cdb-inst \
--tenant-db-name pdb1

```

For Windows:

```

aws rds describe-tenant-databases --region us-east-1 ^
--db-instance-identifier my-cdb-inst ^
--tenant-db-name pdb1

```

This command produces output similar to the following.

```

{
  "TenantDatabases" : [
    {
      "DbiResourceId" : "db-abc123",
      "TenantDatabaseResourceId" : "tdb-bac567",
      "TenantDatabaseArn" : "arn:aws:rds:us-east-1:123456789012:db:my-cdb-
inst:pdb1"
      "DBInstanceIdentifier" : "my-cdb-inst",

```

```
"TenantDBName" : "pdb1",
"Status" : "ACTIVE",
"MasterUsername" : "masterawsuser"
"Port" : "1234",
"CharacterSetName": "UTF-8",
"ParameterGroups": [
  {
    "ParameterGroupName": "tenant-custom-pg",
    "ParameterApplyStatus": "in-sync"
  }
],
{
  "OptionGroupMemberships": [
    {
      "OptionGroupName": "tenant-custom-og",
      "Status": "in-sync"
    }
  ]
}
]
```

## Upgrading your CDB

You can upgrade a CDB to a different Oracle Database release. For example, you can upgrade an Oracle Database 19c CDB to an Oracle Database 21c CDB. You can't change the database architecture during an upgrade. Thus, you can't upgrade a non-CDB to a CDB or upgrade a CDB to a non-CDB.

The procedure for upgrading a CDB to a CDB is the same as for upgrading a non-CDB to a non-CDB. For more information, see [Upgrading the RDS for Oracle DB engine](#).

# Administering your RDS for Oracle DB instance

Following are the common management tasks that you perform with an RDS for Oracle DB instance. Some tasks are the same for all RDS DB instances. Other tasks are specific to RDS for Oracle.

The following tasks are common to all RDS databases, but Oracle Database has special considerations. For example, you connect to an Oracle database using the Oracle clients SQL\*Plus and SQL Developer.

Task area	Relevant documentation
<b>Instance classes, storage, and PIOPS</b>  If you are creating a production instance, learn how instance classes, storage types, and Provisioned IOPS work in Amazon RDS.	<a href="#">RDS for Oracle DB instance classes</a>  <a href="#">Amazon RDS storage types</a>
<b>Multi-AZ deployments</b>  A production DB instance should use Multi-AZ deployments. Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances.	<a href="#">Configuring and managing a Multi-AZ deployment</a>
<b>Amazon VPC</b>  If your AWS account has a default virtual private cloud (VPC), then your DB instance is automatically created inside the default VPC. If your account doesn't have a default VPC, and you want the DB instance in a VPC, create the VPC and subnet groups before you create the instance.	<a href="#">Working with a DB instance in a VPC</a>
<b>Security groups</b>  By default, DB instances use a firewall that prevents access. Make sure that you create a security group with the correct IP addresses and network configuration to access the DB instance.	<a href="#">Controlling access with security groups</a>
<b>Parameter groups</b>	<a href="#">Parameter groups for Amazon RDS</a>

Task area	Relevant documentation
<p>If your DB instance is going to require specific database parameters, create a parameter group before you create the DB instance.</p>	
<p><b>Option groups</b></p> <p>If your DB instance requires specific database options, create an option group before you create the DB instance.</p>	<p><a href="#">Adding options to Oracle DB instances</a></p>
<p><b>Connecting to your DB instance</b></p> <p>After creating a security group and associating it to a DB instance, you can connect to the DB instance using any standard SQL client application such as Oracle SQL*Plus.</p>	<p><a href="#">Connecting to your RDS for Oracle DB instance</a></p>
<p><b>Backup and restore</b></p> <p>You can configure your DB instance to take automated backups, or take manual snapshots, and then restore instances from the backups or snapshots.</p>	<p><a href="#">Backing up, restoring, and exporting data</a></p>
<p><b>Monitoring</b></p> <p>You can monitor an Oracle DB instance by using CloudWatch Amazon RDS metrics, events, and enhanced monitoring.</p>	<p><a href="#">Viewing metrics in the Amazon RDS console</a></p> <p><a href="#">Viewing Amazon RDS events</a></p>
<p><b>Log files</b></p> <p>You can access the log files for your Oracle DB instance.</p>	<p><a href="#">Monitoring Amazon RDS log files</a></p>

Following, you can find a description for Amazon RDS–specific implementations of common DBA tasks for RDS Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Also, RDS restricts access to certain system procedures and tables that require advanced privileges. In many of the tasks, you run the `rdsadmin` package, which is an Amazon RDS–specific tool that enables you to administer your database.

The following are common DBA tasks for DB instances running Oracle:

- [System tasks](#)

<a href="#">Disconnecting a session</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.disconnect</code></p> <p>Oracle method: <code>alter system disconnect session</code></p>
<a href="#">Terminating a session</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.kill</code></p> <p>Oracle method: <code>alter system kill session</code></p>
<a href="#">Canceling a SQL statement in a session</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.cancel</code></p> <p>Oracle method: <code>alter system cancel sql</code></p>
<a href="#">Enabling and disabling restricted sessions</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.restricted_session</code></p> <p>Oracle method: <code>alter system enable restricted session</code></p>
<a href="#">Flushing the shared pool</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.flush_shared_pool</code></p> <p>Oracle method: <code>alter system flush shared_pool</code></p>
<a href="#">Flushing the buffer cache</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.flush_buffer_cache</code></p> <p>Oracle method: <code>alter system flush buffer_cache</code></p>
<a href="#">Granting SELECT or EXECUTE privileges to SYS objects</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.grant_sys_object</code></p> <p>Oracle method: <code>grant</code></p>
<a href="#">Revoking SELECT or EXECUTE privileges on SYS objects</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.revoke_sys_object</code></p> <p>Oracle method: <code>revoke</code></p>

<a href="#">Managing RDS_X\$ views for Oracle DB instances</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.create_sys_x\$_view</code></p> <p>Oracle method: <code>CREATE VIEW</code></p>
<a href="#">Granting privileges to non-master users</a>	<p>Amazon RDS method: <code>grant</code></p>
<a href="#">Creating custom functions to verify passwords</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_password_verify.create_verify_function</code></p> <p>Amazon RDS method: <code>rdsadmin.rdsadmin_password_verify.create_passthrough_verify_fcn</code></p>
<a href="#">Setting up a custom DNS server</a>	—
<a href="#">Listing allowed system diagnostic events</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.list_allowed_system_events</code></p> <p>Oracle method: —</p>
<a href="#">Setting system diagnostic events</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.set_allowed_system_events</code></p> <p>Oracle method: <code>ALTER SYSTEM SET EVENTS 'set_event_clause'</code></p>
<a href="#">Listing system diagnostic events that are set</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.list_set_system_events</code></p> <p>Oracle method: <code>ALTER SESSION SET EVENTS 'IMMEDIATE EVENTDUMP(SYSTEM)'</code></p>
<a href="#">Unsetting system diagnostic events</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.unset_system_event</code></p> <p>Oracle method: <code>ALTER SYSTEM SET EVENTS 'unset_event_clause'</code></p>

- [Database tasks](#)

<a href="#">Changing the global name of a database</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.rename_global_name</code></p> <p>Oracle method: <code>alter database rename</code></p>
<a href="#">Creating and sizing tablespaces</a>	<p>Amazon RDS method: <code>create tablespace</code></p> <p>Oracle method: <code>alter database</code></p>
<a href="#">Setting the default tablespace</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.alter_default_tablespace</code></p> <p>Oracle method: <code>alter database default tablespace</code></p>
<a href="#">Setting the default temporary tablespace</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.alter_default_temp_tablespace</code></p> <p>Oracle method: <code>alter database default temporary tablespace</code></p>
<a href="#">Creating a temporary tablespace on the instance store</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.create_inst_store_tmp_tbspace</code></p> <p>Oracle method: <code>create temporary tablespace</code></p>
<a href="#">Checkpointing a database</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.checkpoint</code></p> <p>Oracle method: <code>alter system checkpoint</code></p>
<a href="#">Setting distributed recovery</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.enable_distr_recovery</code></p> <p>Oracle method: <code>alter system enable distributed recovery</code></p>

<a href="#">Setting the database time zone</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_util.alter_db_time_zone</code></p> <p>Oracle method: <code>alter database set time_zone</code></p>
<a href="#">Working with Oracle external tables</a>	<p>—</p>
<a href="#">Generating performance reports with Automatic Workload Repository (AWR)</a>	<p>Amazon RDS method: <code>rdsadmin.rdsadmin_diagnostic_util</code> procedures</p> <p>Oracle method: <code>dbms_workload_repository</code> package</p>

You can also use Amazon RDS procedures for Amazon S3 integration with Oracle and for running OEM Management Agent database tasks. For more information, see [Amazon S3 integration](#) and [Administering the Management Agent](#).

## Performing common system tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to the system on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

### Disconnecting a session

To disconnect the current session by ending the dedicated server process, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.disconnect`. The `disconnect` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
sid	number	—	Yes	The session identifier.
serial	number	—	Yes	The serial number of the session.
method	vvarchar	'IMMEDIATE'	No	Valid values are 'IMMEDIATE' or 'POST_TRANSACTION'.

The following example disconnects a session.

```
begin
  rdsadmin.rdsadmin_util.disconnect(
    sid    => sid,
    serial => serial_number);
end;
/
```

To get the session identifier and the session serial number, query the V\$SESSION view. The following example gets all sessions for the user AWSUSER.

```
SELECT SID, SERIAL#, STATUS FROM V$SESSION WHERE USERNAME = 'AWSUSER';
```

The database must be open to use this method. For more information about disconnecting a session, see [ALTER SYSTEM](#) in the Oracle documentation.

## Terminating a session

To terminate a session, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.kill`. The `kill` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
sid	number	—	Yes	The session identifier.

Parameter name	Data type	Default	Required	Description
serial	number	—	Yes	The serial number of the session.
method	vvarchar	null	No	<p>Valid values are 'IMMEDIATE' or 'PROCESS'. If you specify IMMEDIATE, it has the same effect as running the following statement:</p> <pre>ALTER SYSTEM KILL   SESSION 'sid,serial#' IMMEDIATE</pre> <p>If you specify PROCESS, you terminate the processes associated with a session. Only specify PROCESS if terminating the session using IMMEDIATE was unsuccessful.</p>

To get the session identifier and the session serial number, query the V\$SESSION view. The following example gets all sessions for the user *AWSUSER*.

```
SELECT SID, SERIAL#, STATUS FROM V$SESSION WHERE USERNAME = 'AWSUSER';
```

The following example terminates a session.

```
BEGIN
  rdsadmin.rdsadmin_util.kill(
    sid    => sid,
    serial => serial_number,
    method => 'IMMEDIATE');
```

```
END;
/
```

The following example terminates the processes associated with a session.

```
BEGIN
  rdsadmin.rdsadmin_util.kill(
    sid    => sid,
    serial => serial_number,
    method => 'PROCESS');
END;
/
```

## Canceling a SQL statement in a session

To cancel a SQL statement in a session, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.cancel`.

### Note

This procedure is supported for Oracle Database 19c (19.0.0) and all higher major and minor versions of RDS for Oracle.

The `cancel` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>sid</code>	number	—	Yes	The session identifier.
<code>serial</code>	number	—	Yes	The serial number of the session.
<code>sql_id</code>	varchar2	null	No	The SQL identifier of the SQL statement.

The following example cancels a SQL statement in a session.

```
begin
```

```

rdsadmin.rdsadmin_util.cancel(
    sid    => sid,
    serial => serial_number,
    sql_id => sql_id);
end;
/

```

To get the session identifier, the session serial number, and the SQL identifier of a SQL statement, query the V\$SESSION view. The following example gets all sessions and SQL identifiers for the user AWSUSER.

```
select SID, SERIAL#, SQL_ID, STATUS from V$SESSION where USERNAME = 'AWSUSER';
```

## Enabling and disabling restricted sessions

To enable and disable restricted sessions, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.restricted_session`. The `restricted_session` procedure has the following parameters.

Parameter name	Data type	Default	Yes	Description
<code>p_enable</code>	boolean	true	No	Set to true to enable restricted sessions, false to disable restricted sessions.

The following example shows how to enable and disable restricted sessions.

```

/* Verify that the database is currently unrestricted. */

SELECT LOGINS FROM V$INSTANCE;

LOGINS
-----
ALLOWED

/* Enable restricted sessions */

EXEC rdsadmin.rdsadmin_util.restricted_session(p_enable => true);

```

```
/* Verify that the database is now restricted. */

SELECT LOGINS FROM V$INSTANCE;

LOGINS
-----
RESTRICTED

/* Disable restricted sessions */

EXEC rdsadmin.rdsadmin_util.restricted_session(p_enable => false);

/* Verify that the database is now unrestricted again. */

SELECT LOGINS FROM V$INSTANCE;

LOGINS
-----
ALLOWED
```

## Flushing the shared pool

To flush the shared pool, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_shared_pool`. The `flush_shared_pool` procedure has no parameters.

The following example flushes the shared pool.

```
EXEC rdsadmin.rdsadmin_util.flush_shared_pool;
```

## Flushing the buffer cache

To flush the buffer cache, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_buffer_cache`. The `flush_buffer_cache` procedure has no parameters.

The following example flushes the buffer cache.

```
EXEC rdsadmin.rdsadmin_util.flush_buffer_cache;
```

## Flushing the database smart flash cache

To flush the database smart flash cache, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.flush_flash_cache`. The `flush_flash_cache` procedure has no parameters. The following example flushes the database smart flash cache.

```
EXEC rdsadmin.rdsadmin_util.flush_flash_cache;
```

For more information about using the database smart flash cache with RDS for Oracle, see [Storing temporary data in an RDS for Oracle instance store](#).

## Granting SELECT or EXECUTE privileges to SYS objects

Usually you transfer privileges by using roles, which can contain many objects. To grant privileges to a single object, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.grant_sys_object`. The procedure grants only privileges that the master user has already been granted through a role or direct grant.

The `grant_sys_object` procedure has the following parameters.

### Important

For all parameter values, use uppercase unless you created the user with a case-sensitive identifier. For example, if you run `CREATE USER myuser` or `CREATE USER MYUSER`, the data dictionary stores `MYUSER`. However, if you use double quotes in `CREATE USER "MyUser"`, the data dictionary stores `MyUser`.

Parameter name	Data type	Default	Required	Description
<code>p_obj_name</code>	<code>varchar2</code>	—	Yes	The name of the object to grant privileges for. The object can be a directory, function, package, procedure, sequence, table, or view.

Parameter name	Data type	Default	Required	Description
				Object names must be spelled exactly as they appear in <code>DBA_OBJECTS</code> . Most system objects are defined in uppercase, so we recommend that you try that first.
<code>p_grantee</code>	<code>varchar2</code>	—	Yes	The name of the object to grant privileges to. The object can be a schema or a role.
<code>p_privilege</code>	<code>varchar2</code>	<code>null</code>	Yes	—
<code>p_grant_option</code>	<code>boolean</code>	<code>false</code>	No	Set to <code>true</code> to use the <code>with grant option</code> .

The following example grants select privileges on an object named `V_$SESSION` to a user named `USER1`.

```
begin
  rdsadmin.rdsadmin_util.grant_sys_object(
    p_obj_name => 'V_$SESSION',
    p_grantee  => 'USER1',
    p_privilege => 'SELECT');
end;
/
```

The following example grants select privileges on an object named `V_$SESSION` to a user named `USER1` with the grant option.

```
begin
  rdsadmin.rdsadmin_util.grant_sys_object(
    p_obj_name      => 'V_$SESSION',
    p_grantee       => 'USER1',
    p_privilege     => 'SELECT',
```

```

        p_grant_option => true);
end;
/

```

To be able to grant privileges on an object, your account must have those privileges granted to it directly with the grant option, or via a role granted using `with admin option`. In the most common case, you may want to grant `SELECT` on a DBA view that has been granted to the `SELECT_CATALOG_ROLE` role. If that role isn't already directly granted to your user using `with admin option`, then you can't transfer the privilege. If you have the DBA privilege, then you can grant the role directly to another user.

The following example grants the `SELECT_CATALOG_ROLE` and `EXECUTE_CATALOG_ROLE` to `USER1`. Since the `with admin option` is used, `USER1` can now grant access to `SYS` objects that have been granted to `SELECT_CATALOG_ROLE`.

```

GRANT SELECT_CATALOG_ROLE TO USER1 WITH ADMIN OPTION;
GRANT EXECUTE_CATALOG_ROLE to USER1 WITH ADMIN OPTION;

```

Objects already granted to `PUBLIC` do not need to be re-granted. If you use the `grant_sys_object` procedure to re-grant access, the procedure call succeeds.

## Revoking `SELECT` or `EXECUTE` privileges on `SYS` objects

To revoke privileges on a single object, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.revoke_sys_object`. The procedure only revokes privileges that the master account has already been granted through a role or direct grant.

The `revoke_sys_object` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>p_obj_name</code>	<code>varchar2</code>	—	Yes	The name of the object to revoke privileges for. The object can be a directory, function, package, procedure, sequence, table, or view. Object names must be spelled exactly as they

Parameter name	Data type	Default	Required	Description
				appear in DBA_OBJECTS . Most system objects are defined in upper case, so we recommend you try that first.
p_revokee	varchar2	—	Yes	The name of the object to revoke privileges for. The object can be a schema or a role.
p_privilege	varchar2	null	Yes	—

The following example revokes select privileges on an object named V\_\$SESSION from a user named USER1.

```
begin
  rdsadmin.rdsadmin_util.revoke_sys_object(
    p_obj_name => 'V_$SESSION',
    p_revokee  => 'USER1',
    p_privilege => 'SELECT');
end;
/
```

## Managing RDS\_X\$ views for Oracle DB instances

You might need to access SYS.X\$ fixed tables, which are only accessible by SYS. To create SYS.RDS\_X\$ views on eligible X\$ tables, use the procedures in the rdsadmin.rdsadmin\_util package. Your master user is automatically granted the privilege SELECT ... WITH GRANT OPTION on the RDS\_X\$ views.

The rdsadmin.rdsadmin\_util procedures are available in the following database engine versions:

- 21.0.0.0.ru-2023-10.rur-2023-10.r1 and higher Oracle Database 21c versions
- 19.0.0.0.ru-2023-10.rur-2023-10.r1 and higher Oracle Database 19c versions

**⚠ Important**

Internally, the `rdsadmin.rdsadmin_util` package creates views on X\$ tables. The X\$ tables are internal system objects that aren't described in the Oracle Database documentation. We recommend that you test specific views in your non-production database and only create views in your production database under the guidance of Oracle Support.

**List X\$ fixed tables eligible for use in RDS\_X\$ views**

To list X\$ tables that are eligible for use in RDS\_X\$ views, use the RDS procedure `rdsadmin.rdsadmin_util.list_allowed_sys_x$_views`. This procedure accepts no parameters. The following statements lists all eligible X\$ tables (sample output included).

```
SQL> SET SERVEROUTPUT ON
SQL> SELECT * FROM TABLE(rdsadmin.rdsadmin_util.list_allowed_sys_x$_views);

'X$BH'
'X$K2GTE'
'X$KCBWBDP'
'X$KCBWDS'
'X$KGLLK'
'X$KGLOBAL'
'X$KGLPN'
'X$KSLHOT'
'X$KSMSP'
'X$KSPPCV'
'X$KSPPI'
'X$KSPPSV'
'X$KSQEQ'
'X$KSQRS'
'X$KTUXE'
'X$KQRF'P
```

The list of eligible X\$ tables can change over time. To make sure that your list of eligible X\$ fixed tables is current, rerun `list_allowed_sys_x$_views` periodically.

## Creating SYS.RDS\_X\$ views

To create an RDS\_X\$ view on an eligible X\$ table, use the RDS procedure `rdsadmin.rdsadmin_util.create_sys_x$_view`. You can only create views for the tables listed in the output of `rdsadmin.rdsadmin_util.list_allowed_sys_x$_views`. The `create_sys_x$_view` procedure accepts the following parameters.

Parameter name	Data type	Default	Required	Description
<code>p_x\$_tbl</code>	<code>varchar2</code>	Null	Yes	A valid X\$ table name. The value must be one of the X\$ tables reported by <code>list_allowed_sys_x\$_views</code> .
<code>p_force_creation</code>	Boolean	FALSE	No	A value indicating whether to force creation of an RDS_X\$ view that already exists for an X\$ table. By default, RDS won't create a view if it already exists. To force creation, set this parameter to TRUE.

The following example creates the `SYS.RDS_X$KGLOBAL` view on the table `X$KGLOBAL`. The format for the view name is `RDS_X$tablename`.

```
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.create_sys_x$_view('X$KGLOBAL');

PL/SQL procedure successfully completed.
```

The following data dictionary query lists the view `SYS.RDS_X$KGLOBAL` and shows its status. Your master user is automatically granted the privilege `SELECT ... WITH GRANT OPTION` on this view.

```
SQL> SET SERVEROUTPUT ON
```

```
SQL> COL OWNER FORMAT A30
SQL> COL OBJECT_NAME FORMAT A30
SQL> COL STATUS FORMAT A30
SQL> SET LINESIZE 200
SQL> SELECT OWNER, OBJECT_NAME, STATUS
FROM DBA_OBJECTS
WHERE OWNER = 'SYS' AND OBJECT_NAME = 'RDS_X$KGLOBAL';
```

OWNER	OBJECT_NAME	STATUS
SYS	RDS_X\$KGLOBAL	VALID

### Important

X\$ tables aren't guaranteed to stay the same before and after an upgrade. RDS for Oracle drops and recreates the RDS\_X\$ views on X\$ tables during an engine upgrade. Then it grants the `SELECT ... WITH GRANT OPTION` privilege to the master user. After an upgrade, grant privileges to database users as needed on the corresponding RDS\_X\$ views.

## Listing SYS.RDS\_X\$ views

To list existing RDS\_X\$ views, use the RDS procedure `rdsadmin.rdsadmin_util.list_created_sys_x$_views`. The procedure lists only views that were created by the procedure `create_sys_x$_view`. The following example lists X\$ tables that have corresponding RDS\_X\$ views (sample output included).

```
SQL> SET SERVEROUTPUT ON
SQL> COL XD_TBL_NAME FORMAT A30
SQL> COL STATUS FORMAT A30
SQL> SET LINESIZE 200
SQL> SELECT * FROM TABLE(rdsadmin.rdsadmin_util.list_created_sys_x$_views);
```

XD_TBL_NAME	STATUS
X\$BH	VALID
X\$K2GTE	VALID
X\$KCBWBD	VALID

3 rows selected.

## Dropping RDS\_X\$ views

To drop a SYS.RDS\_X\$ view, use the RDS procedure `rdsadmin.rdsadmin_util.drop_sys_x$_view`. You can only drop views listed in the output of `rdsadmin.rdsadmin_util.list_allowed_sys_x$_views`. The `drop_sys_x$_view` procedure accepts the following parameter.

Parameter name	Data type	Default	Required	Description
<code>p_x\$_tbl</code>	<code>varchar2</code>	Null	Yes	A valid X\$ fixed table name. The value must be one of the X\$ fixed tables reported by <code>list_created_sys_x\$_views</code> .

The following example drops the RDS\_X\$KGLOBAL view, which was created on the table X\$KGLOBAL.

```
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.drop_sys_x$_view('X$KGLOBAL');

PL/SQL procedure successfully completed.
```

The following example shows that the view SYS.RDS\_X\$KGLOBAL has been dropped (sample output included).

```
SQL> SET SERVEROUTPUT ON
SQL> COL OWNER FORMAT A30
SQL> COL OBJECT_NAME FORMAT A30
SQL> COL STATUS FORMAT A30
SQL> SET LINESIZE 200
SQL> SELECT OWNER, OBJECT_NAME, STATUS
FROM DBA_OBJECTS
WHERE OWNER = 'SYS' AND OBJECT_NAME = 'RDS_X$KGLOBAL';

no rows selected
```

## Granting privileges to non-master users

You can grant select privileges for many objects in the SYS schema by using the SELECT\_CATALOG\_ROLE role. The SELECT\_CATALOG\_ROLE role gives users SELECT privileges on data dictionary views. The following example grants the role SELECT\_CATALOG\_ROLE to a user named `user1`.

```
GRANT SELECT_CATALOG_ROLE TO user1;
```

You can grant EXECUTE privileges for many objects in the SYS schema by using the EXECUTE\_CATALOG\_ROLE role. The EXECUTE\_CATALOG\_ROLE role gives users EXECUTE privileges for packages and procedures in the data dictionary. The following example grants the role EXECUTE\_CATALOG\_ROLE to a user named `user1`.

```
GRANT EXECUTE_CATALOG_ROLE TO user1;
```

The following example gets the permissions that the roles SELECT\_CATALOG\_ROLE and EXECUTE\_CATALOG\_ROLE allow.

```
SELECT *  
  FROM ROLE_TAB_PRIVS  
  WHERE ROLE IN ('SELECT_CATALOG_ROLE', 'EXECUTE_CATALOG_ROLE')  
 ORDER BY ROLE, TABLE_NAME ASC;
```

The following example creates a non-master user named `user1`, grants the CREATE SESSION privilege, and grants the SELECT privilege on a database named `sh.sales`.

```
CREATE USER user1 IDENTIFIED BY PASSWORD;  
GRANT CREATE SESSION TO user1;  
GRANT SELECT ON sh.sales TO user1;
```

## Creating custom functions to verify passwords

You can create a custom password verification function in the following ways:

- To use standard verification logic, and to store your function in the SYS schema, use the `create_verify_function` procedure.
- To use custom verification logic, or to avoid storing your function in the SYS schema, use the `create_passthrough_verify_fcn` procedure.

## The create\_verify\_function procedure

You can create a custom function to verify passwords by using the Amazon RDS procedure `rdsadmin.rdsadmin_password_verify.create_verify_function`. The `create_verify_function` procedure is supported for all versions of RDS for Oracle.

The `create_verify_function` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>p_verify_function_name</code>	<code>varchar2</code>	—	Yes	The name for your custom function. This function is created for you in the SYS schema. You assign this function to user profiles.
<code>p_min_length</code>	<code>number</code>	8	No	The minimum number of characters required.
<code>p_max_length</code>	<code>number</code>	256	No	The maximum number of characters allowed.
<code>p_min_letters</code>	<code>number</code>	1	No	The minimum number of letters required.
<code>p_min_uppercase</code>	<code>number</code>	0	No	The minimum number of uppercase letters required.
<code>p_min_lowercase</code>	<code>number</code>	0	No	The minimum number of lowercase letters required.
<code>p_min_digits</code>	<code>number</code>	1	No	The minimum number of digits required.

Parameter name	Data type	Default	Required	Description
<code>p_min_special</code>	number	0	No	The minimum number of special characters required.
<code>p_min_different_chars</code>	number	3	No	The minimum number of different characters required between the old and new password.
<code>p_disallow_username</code>	boolean	true	No	Set to <code>true</code> to disallow the user name in the password.
<code>p_disallow_reverse</code>	boolean	true	No	Set to <code>true</code> to disallow the reverse of the user name in the password.
<code>p_disallow_db_name</code>	boolean	true	No	Set to <code>true</code> to disallow the database or server name in the password.
<code>p_disallow_simple_strings</code>	boolean	true	No	Set to <code>true</code> to disallow simple strings as the password.
<code>p_disallow_whitespace</code>	boolean	false	No	Set to <code>true</code> to disallow white space characters in the password.
<code>p_disallow_at_sign</code>	boolean	false	No	Set to <code>true</code> to disallow the <code>@</code> character in the password.

You can create multiple password verification functions.

There are restrictions on the name of your custom function. Your custom function can't have the same name as an existing system object. The name can be no more than 30 characters long. Also, the name must include one of the following strings: PASSWORD, VERIFY, COMPLEXITY, ENFORCE, or STRENGTH.

The following example creates a function named CUSTOM\_PASSWORD\_FUNCTION. The function requires that a password has at least 12 characters, 2 uppercase characters, 1 digit, and 1 special character, and that the password disallows the @ character.

```
begin
  rdsadmin.rdsadmin_password_verify.create_verify_function(
    p_verify_function_name => 'CUSTOM_PASSWORD_FUNCTION',
    p_min_length           => 12,
    p_min_uppercase       => 2,
    p_min_digits          => 1,
    p_min_special         => 1,
    p_disallow_at_sign    => true);
end;
/
```

To see the text of your verification function, query DBA\_SOURCE. The following example gets the text of a custom password function named CUSTOM\_PASSWORD\_FUNCTION.

```
COL TEXT FORMAT a150

SELECT TEXT
  FROM DBA_SOURCE
 WHERE OWNER = 'SYS'
    AND NAME = 'CUSTOM_PASSWORD_FUNCTION'
 ORDER BY LINE;
```

To associate your verification function with a user profile, use alter profile. The following example associates a verification function with the DEFAULT user profile.

```
ALTER PROFILE DEFAULT LIMIT PASSWORD_VERIFY_FUNCTION CUSTOM_PASSWORD_FUNCTION;
```

To see what user profiles are associated with what verification functions, query DBA\_PROFILES. The following example gets the profiles that are associated with the custom verification function named CUSTOM\_PASSWORD\_FUNCTION.

```
SELECT * FROM DBA_PROFILES WHERE RESOURCE_NAME = 'PASSWORD' AND LIMIT =
'CUSTOM_PASSWORD_FUNCTION';
```

PROFILE	RESOURCE_NAME	RESOURCE	LIMIT
-----	-----	-----	
-----			
DEFAULT	PASSWORD_VERIFY_FUNCTION	PASSWORD	
CUSTOM_PASSWORD_FUNCTION			

The following example gets all profiles and the password verification functions that they are associated with.

```
SELECT * FROM DBA_PROFILES WHERE RESOURCE_NAME = 'PASSWORD_VERIFY_FUNCTION';
```

PROFILE	RESOURCE_NAME	RESOURCE	LIMIT
-----	-----	-----	
-----			
DEFAULT	PASSWORD_VERIFY_FUNCTION	PASSWORD	
CUSTOM_PASSWORD_FUNCTION			
RDSADMIN	PASSWORD_VERIFY_FUNCTION	PASSWORD	NULL

### The create\_passthrough\_verify\_fcn procedure

The create\_passthrough\_verify\_fcn procedure is supported for all versions of RDS for Oracle.

You can create a custom function to verify passwords by using the Amazon RDS procedure rdsadmin.rdsadmin\_password\_verify.create\_passthrough\_verify\_fcn. The create\_passthrough\_verify\_fcn procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_verify_function_name	varchar2	—	Yes	The name for your custom verification function. This is a wrapper function that is created for you in the SYS schema, and

Parameter name	Data type	Default	Required	Description
				it doesn't contain any verification logic. You assign this function to user profiles.
p_target_owner	varchar2	—	Yes	The schema owner for your custom verification function.
p_target_function_name	varchar2	—	Yes	The name of your existing custom function that contains the verification logic. Your custom function must return a boolean. Your function should return <code>true</code> if the password is valid and <code>false</code> if the password is invalid.

The following example creates a password verification function that uses the logic from the function named `PASSWORD_LOGIC_EXTRA_STRONG`.

```
begin
  rdsadmin.rdsadmin_password_verify.create_passthrough_verify_fcn(
    p_verify_function_name => 'CUSTOM_PASSWORD_FUNCTION',
    p_target_owner         => 'TEST_USER',
    p_target_function_name => 'PASSWORD_LOGIC_EXTRA_STRONG');
end;
/
```

To associate the verification function with a user profile, use `alter profile`. The following example associates the verification function with the `DEFAULT` user profile.

```
ALTER PROFILE DEFAULT LIMIT PASSWORD_VERIFY_FUNCTION CUSTOM_PASSWORD_FUNCTION;
```

## Setting up a custom DNS server

Amazon RDS supports outbound network access on your DB instances running Oracle. For more information about outbound network access, including prerequisites, see [Configuring UTL\\_HTTP access using certificates and an Oracle wallet](#).

Amazon RDS Oracle allows Domain Name Service (DNS) resolution from a custom DNS server owned by the customer. You can resolve only fully qualified domain names from your Amazon RDS DB instance through your custom DNS server.

After you set up your custom DNS name server, it takes up to 30 minutes to propagate the changes to your DB instance. After the changes are propagated to your DB instance, all outbound network traffic requiring a DNS lookup queries your DNS server over port 53.

To set up a custom DNS server for your Amazon RDS for Oracle DB instance, do the following:

- From the DHCP options set attached to your virtual private cloud (VPC), set the `domain-name-servers` option to the IP address of your DNS name server. For more information, see [DHCP options sets](#).

### Note

The `domain-name-servers` option accepts up to four values, but your Amazon RDS DB instance uses only the first value.

- Ensure that your DNS server can resolve all lookup queries, including public DNS names, Amazon EC2 private DNS names, and customer-specific DNS names. If the outbound network traffic contains any DNS lookups that your DNS server can't handle, your DNS server must have appropriate upstream DNS providers configured.
- Configure your DNS server to produce User Datagram Protocol (UDP) responses of 512 bytes or less.
- Configure your DNS server to produce Transmission Control Protocol (TCP) responses of 1024 bytes or less.
- Configure your DNS server to allow inbound traffic from your Amazon RDS DB instances over port 53. If your DNS server is in an Amazon VPC, the VPC must have a security group that contains inbound rules that permit UDP and TCP traffic on port 53. If your DNS server is not in an Amazon VPC, it must have appropriate firewall allow-listing to permit UDP and TCP inbound traffic on port 53.

For more information, see [Security groups for your VPC](#) and [Adding and removing rules](#).

- Configure the VPC of your Amazon RDS DB instance to allow outbound traffic over port 53. Your VPC must have a security group that contains outbound rules that allow UDP and TCP traffic on port 53.

For more information, see [Security groups for your VPC](#) and [Adding and removing rules](#).

- The routing path between the Amazon RDS DB instance and the DNS server has to be configured correctly to allow DNS traffic.
  - If the Amazon RDS DB instance and the DNS server are not in the same VPC, a peering connection has to be set up between them. For more information, see [What is VPC peering?](#)

## Setting and unsetting system diagnostic events

To set and unset diagnostic events at the session level, you can use the Oracle SQL statement `ALTER SESSION SET EVENTS`. However, to set events at the system level you can't use Oracle SQL. Instead, use the system event procedures in the `rdsadmin.rdsadmin_util` package. The system event procedures are available in the following engine versions:

- All Oracle Database 21c versions
- 19.0.0.0.ru-2020-10.rur-2020-10.r1 and higher Oracle Database 19c versions

For more information, see [Version 19.0.0.0.ru-2020-10.rur-2020-10.r1](#) in the *Amazon RDS for Oracle Release Notes*

### Important

Internally, the `rdsadmin.rdsadmin_util` package sets events by using the `ALTER SYSTEM SET EVENTS` statement. This `ALTER SYSTEM` statement isn't documented in the Oracle Database documentation. Some system diagnostic events can generate large amounts of tracing information, cause contention, or affect database availability. We recommend that you test specific diagnostic events in your nonproduction database, and only set events in your production database under guidance of Oracle Support.

## Listing allowed system diagnostic events

To list the system events that you can set, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.list_allowed_system_events`. This procedure accepts no parameters.

The following example lists all system events that you can set.

```
SET SERVEROUTPUT ON
EXEC rdsadmin.rdsadmin_util.list_allowed_system_events;
```

The following sample output lists event numbers and their descriptions. Use the Amazon RDS procedures `set_system_event` to set these events and `unset_system_event` to unset them.

```
604 - error occurred at recursive SQL level
942 - table or view does not exist
1401 - inserted value too large for column
1403 - no data found
1410 - invalid ROWID
1422 - exact fetch returns more than requested number of rows
1426 - numeric overflow
1427 - single-row subquery returns more than one row
1476 - divisor is equal to zero
1483 - invalid length for DATE or NUMBER bind variable
1489 - result of string concatenation is too long
1652 - unable to extend temp segment by in tablespace
1858 - a non-numeric character was found where a numeric was expected
4031 - unable to allocate bytes of shared memory ("", "", "", "")
6502 - PL/SQL: numeric or value error
10027 - Specify Deadlock Trace Information to be Dumped
10046 - enable SQL statement timing
10053 - CBO Enable optimizer trace
10173 - Dynamic Sampling time-out error
10442 - enable trace of kst for ORA-01555 diagnostics
12008 - error in materialized view refresh path
12012 - error on auto execute of job
12504 - TNS:listener was not given the SERVICE_NAME in CONNECT_DATA
14400 - inserted partition key does not map to any partition
31693 - Table data object failed to load/unload and is being skipped due to error:
```

**Note**

The list of the allowed system events can change over time. To make sure that you have the most recent list of eligible events, use `rdsadmin.rdsadmin_util.list_allowed_system_events`.

**Setting system diagnostic events**

To set a system event, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.set_system_event`. You can only set events listed in the output of `rdsadmin.rdsadmin_util.list_allowed_system_events`. The `set_system_event` procedure accepts the following parameters.

Parameter name	Data type	Default	Required	Description
<code>p_event</code>	number	—	Yes	The system event number. The value must be one of the event numbers reported by <code>list_allowed_system_events</code> .
<code>p_level</code>	number	—	Yes	The event level. See the Oracle Database documentation or Oracle Support for descriptions of different level values.

The procedure `set_system_event` constructs and runs the required `ALTER SYSTEM SET EVENTS` statements according to the following principles:

- The event type (context or errorstack) is determined automatically.
- A statement in the form `ALTER SYSTEM SET EVENTS 'event' LEVEL event_level` sets the context events. This notation is equivalent to `ALTER SYSTEM SET EVENTS 'event' TRACE NAME CONTEXT FOREVER, LEVEL event_level`.

- A statement in the form `ALTER SYSTEM SET EVENTS 'event ERRORSTACK (event_level)'` sets the error stack events. This notation is equivalent to `ALTER SYSTEM SET EVENTS 'event TRACE NAME ERRORSTACK LEVEL event_level'`.

The following example sets event 942 at level 3, and event 10442 at level 10. Sample output is included.

```
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.set_system_event(942,3);
Setting system event 942 with: alter system set events '942 errorstack (3)'

PL/SQL procedure successfully completed.

SQL> EXEC rdsadmin.rdsadmin_util.set_system_event(10442,10);
Setting system event 10442 with: alter system set events '10442 level 10'

PL/SQL procedure successfully completed.
```

### Listing system diagnostic events that are set

To list the system events that are currently set, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.list_set_system_events`. This procedure reports only events set at system level by `set_system_event`.

The following example lists the active system events.

```
SET SERVEROUTPUT ON
EXEC rdsadmin.rdsadmin_util.list_set_system_events;
```

The following sample output shows the list of events, the event type, the level at which the events are currently set, and the time when the event was set.

```
942 errorstack (3) - set at 2020-11-03 11:42:27
10442 level 10 - set at 2020-11-03 11:42:41

PL/SQL procedure successfully completed.
```

## Unsetting system diagnostic events

To unset a system event, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.unset_system_event`. You can only unset events listed in the output of `rdsadmin.rdsadmin_util.list_allowed_system_events`. The `unset_system_event` procedure accepts the following parameter.

Parameter name	Data type	Default	Required	Description
<code>p_event</code>	number	—	Yes	The system event number. The value must be one of the event numbers reported by <code>list_allowed_system_events</code> .

The following example unsets events 942 and 10442. Sample output is included.

```
SQL> SET SERVEROUTPUT ON
SQL> EXEC rdsadmin.rdsadmin_util.unset_system_event(942);
Unsetting system event 942 with: alter system set events '942 off'

PL/SQL procedure successfully completed.

SQL> EXEC rdsadmin.rdsadmin_util.unset_system_event(10442);
Unsetting system event 10442 with: alter system set events '10442 off'

PL/SQL procedure successfully completed.
```

## Performing common database tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to databases on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. Amazon RDS also restricts access to some system procedures and tables that require advanced privileges.

### Topics

- [Changing the global name of a database](#)

## Changing the global name of a database

To change the global name of a database, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.rename_global_name`. The `rename_global_name` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>p_new_global_name</code>	<code>varchar2</code>	—	Yes	The new global name for the database.

The database must be open for the name change to occur. For more information about changing the global name of a database, see [ALTER DATABASE](#) in the Oracle documentation.

The following example changes the global name of a database to `new_global_name`.

```
EXEC rdsadmin.rdsadmin_util.rename_global_name(p_new_global_name => 'new_global_name');
```

## Creating and sizing tablespaces

Amazon RDS only supports Oracle Managed Files (OMF) for data files, log files, and control files. When you create data files and log files, you can't specify the physical file names.

By default, if you don't specify a data file size, tablespaces are created with the default of `AUTOEXTEND ON`, and no maximum size. In the following example, the tablespace `users1` is autoextensible.

```
CREATE TABLESPACE users1;
```

Because of these default settings, tablespaces can grow to consume all allocated storage. We recommend that you specify an appropriate maximum size on permanent and temporary tablespaces, and that you carefully monitor space usage.

The following example creates a tablespace named `users2` with a starting size of 1 gigabyte. Because a data file size is specified, but `AUTOEXTEND ON` isn't specified, the tablespace isn't autoextensible.

```
CREATE TABLESPACE users2 DATAFILE SIZE 1G;
```

The following example creates a tablespace named `users3` with a starting size of 1 gigabyte, autoextend turned on, and a maximum size of 10 gigabytes.

```
CREATE TABLESPACE users3 DATAFILE SIZE 1G AUTOEXTEND ON MAXSIZE 10G;
```

The following example creates a temporary tablespace named `temp01`.

```
CREATE TEMPORARY TABLESPACE temp01;
```

You can resize a bigfile tablespace by using ALTER TABLESPACE. You can specify the size in kilobytes (K), megabytes (M), gigabytes (G), or terabytes (T). The following example resizes a bigfile tablespace named *users\_bf* to 200 MB.

```
ALTER TABLESPACE users_bf RESIZE 200M;
```

The following example adds an additional data file to a smallfile tablespace named *users\_sf*.

```
ALTER TABLESPACE users_sf ADD DATAFILE SIZE 100000M AUTOEXTEND ON NEXT 250m
MAXSIZE UNLIMITED;
```

## Setting the default tablespace

To set the default tablespace, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_default_tablespace`. The `alter_default_tablespace` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>tablespace_name</code>	<code>varchar</code>	—	Yes	The name of the default tablespace.

The following example sets the default tablespace to *users2*:

```
EXEC rdsadmin.rdsadmin_util.alter_default_tablespace(tablespace_name => 'users2');
```

## Setting the default temporary tablespace

To set the default temporary tablespace, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_default_temp_tablespace`. The `alter_default_temp_tablespace` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>tablespace_name</code>	<code>varchar</code>	—	Yes	The name of the default temporary tablespace.

The following example sets the default temporary tablespace to *temp01*.

```
EXEC rdsadmin.rdsadmin_util.alter_default_temp_tablespace(tablespace_name => 'temp01');
```

## Creating a temporary tablespace on the instance store

To create a temporary tablespace on the instance store, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace`. The `create_inst_store_tmp_tblspace` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>p_tablespace_name</code>	<code>varchar</code>	—	Yes	The name of the temporary tablespace.

The following example creates the temporary tablespace *temp01* in the instance store.

```
EXEC rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace(p_tablespace_name => 'temp01');
```

### Important

When you run `rdsadmin_util.create_inst_store_tmp_tblspace`, the newly created temporary tablespace is not automatically set as the default temporary tablespace. To set it as the default, see [Setting the default temporary tablespace](#).

For more information, see [Storing temporary data in an RDS for Oracle instance store](#).

## Adding a tempfile to the instance store on a read replica

When you create a temporary tablespace on a primary DB instance, the read replica doesn't create tempfiles. Assume that an empty temporary tablespace exists on your read replica for either of the following reasons:

- You dropped a tempfile from the tablespace on your read replica. For more information, see [Dropping tempfiles on a read replica](#).

- You created a new temporary tablespace on the primary DB instance. In this case, RDS for Oracle synchronizes the metadata to the read replica.

You can add a tempfile to the empty temporary tablespace, and store the tempfile in the instance store. To create a tempfile in the instance store, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.add_inst_store_tempfile`. You can use this procedure only on a read replica. The procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>p_tablespace_name</code>	<code>varchar</code>	—	Yes	The name of the temporary tablespace on your read replica.

In the following example, the empty temporary tablespace `temp01` exists on your read replica. Run the following command to create a tempfile for this tablespace, and store it in the instance store.

```
EXEC rdsadmin.rdsadmin_util.add_inst_store_tempfile(p_tablespace_name => 'temp01');
```

For more information, see [Storing temporary data in an RDS for Oracle instance store](#).

## Dropping tempfiles on a read replica

You can't drop an existing temporary tablespace on a read replica. You can change the tempfile storage on a read replica from Amazon EBS to the instance store, or from the instance store to Amazon EBS. To achieve these goals, do the following:

- Drop the current tempfiles in the temporary tablespace on the read replica.
- Create new tempfiles on different storage.

To drop the tempfiles, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_replica_tempfiles`. You can use this procedure only on read replicas. The `drop_replica_tempfiles` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_tablespace_name	varchar	—	Yes	The name of the temporary tablespace on your read replica.

Assume that a temporary tablespace named *temp01* resides in the instance store on your read replica. Drop all tempfiles in this tablespace by running the following command.

```
EXEC rdsadmin.rdsadmin_util.drop_replica_tempfiles(p_tablespace_name => 'temp01');
```

For more information, see [Storing temporary data in an RDS for Oracle instance store](#).

## Checkpointing a database

To checkpoint the database, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.checkpoint`. The checkpoint procedure has no parameters.

The following example checkpoints the database.

```
EXEC rdsadmin.rdsadmin_util.checkpoint;
```

## Setting distributed recovery

To set distributed recovery, use the Amazon RDS procedures `rdsadmin.rdsadmin_util.enable_distr_recovery` and `disable_distr_recovery`. The procedures have no parameters.

The following example enables distributed recovery.

```
EXEC rdsadmin.rdsadmin_util.enable_distr_recovery;
```

The following example disables distributed recovery.

```
EXEC rdsadmin.rdsadmin_util.disable_distr_recovery;
```

## Setting the database time zone

You can set the time zone of your Amazon RDS Oracle database in the following ways:

- The `Timezone` option

The `Timezone` option changes the time zone at the host level and affects all date columns and values such as `SYSDATE`. For more information, see [Oracle time zone](#).

- The Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_db_time_zone`

The `alter_db_time_zone` procedure changes the time zone for only certain data types, and doesn't change `SYSDATE`. There are additional restrictions on setting the time zone listed in the [Oracle documentation](#).

**Note**

You can also set the default time zone for Oracle Scheduler. For more information, see [Setting the time zone for Oracle Scheduler jobs](#).

The `alter_db_time_zone` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>p_new_tz</code>	<code>varchar2</code>	—	Yes	The new time zone as a named region or an absolute offset from Coordinated Universal Time (UTC). Valid offsets range from -12:00 to +14:00.

The following example changes the time zone to UTC plus three hours.

```
EXEC rdsadmin.rdsadmin_util.alter_db_time_zone(p_new_tz => '+3:00');
```

The following example changes the time zone to the Africa/Algiers time zone.

```
EXEC rdsadmin.rdsadmin_util.alter_db_time_zone(p_new_tz => 'Africa/Algiers');
```

After you alter the time zone by using the `alter_db_time_zone` procedure, reboot your DB instance for the change to take effect. For more information, see [Rebooting a DB instance](#). For information about upgrading time zones, see [Time zone considerations](#).

## Working with Oracle external tables

*Oracle external tables* are tables with data that is not in the database. Instead, the data is in external files that the database can access. By using external tables, you can access data without loading it into the database. For more information about external tables, see [Managing external tables](#) in the Oracle documentation.

With Amazon RDS, you can store external table files in directory objects. You can create a directory object, or you can use one that is predefined in the Oracle database, such as the `DATA_PUMP_DIR` directory. For information about creating directory objects, see [Creating and dropping directories in the main data storage space](#). You can query the `ALL_DIRECTORIES` view to list the directory objects for your Amazon RDS Oracle DB instance.

### Note

Directory objects point to the main data storage space (Amazon EBS volume) used by your instance. The space used—along with data files, redo logs, audit, trace, and other files—counts against allocated storage.

You can move an external data file from one Oracle database to another by using the [DBMS\\_FILE\\_TRANSFER](#) package or the [UTL\\_FILE](#) package. The external data file is moved from a directory on the source database to the specified directory on the destination database. For information about using `DBMS_FILE_TRANSFER`, see [Importing using Oracle Data Pump](#).

After you move the external data file, you can create an external table with it. The following example creates an external table that uses the `emp_xt_file1.txt` file in the `USER_DIR1` directory.

```
CREATE TABLE emp_xt (  
  emp_id      NUMBER,  
  first_name  VARCHAR2(50),  
  last_name   VARCHAR2(50),  
  user_name   VARCHAR2(20)  
)  
ORGANIZATION EXTERNAL (  
  DIRECTORY = USER_DIR1  
  FILENAME = emp_xt_file1.txt
```

```
TYPE ORACLE_LOADER
DEFAULT DIRECTORY USER_DIR1
ACCESS PARAMETERS (
  RECORDS DELIMITED BY NEWLINE
  FIELDS TERMINATED BY ','
  MISSING FIELD VALUES ARE NULL
  (emp_id,first_name,last_name,user_name)
)
LOCATION ('emp_xt_file1.txt')
)
PARALLEL
REJECT LIMIT UNLIMITED;
```

Suppose that you want to move data that is in an Amazon RDS Oracle DB instance into an external data file. In this case, you can populate the external data file by creating an external table and selecting the data from the table in the database. For example, the following SQL statement creates the `orders_xt` external table by querying the `orders` table in the database.

```
CREATE TABLE orders_xt
ORGANIZATION EXTERNAL
(
  TYPE ORACLE_DATAPUMP
  DEFAULT DIRECTORY DATA_PUMP_DIR
  LOCATION ('orders_xt.dmp')
)
AS SELECT * FROM orders;
```

In this example, the data is populated in the `orders_xt.dmp` file in the `DATA_PUMP_DIR` directory.

## Generating performance reports with Automatic Workload Repository (AWR)

To gather performance data and generate reports, Oracle recommends Automatic Workload Repository (AWR). AWR requires Oracle Database Enterprise Edition and a license for the Diagnostics and Tuning packs. To enable AWR, set the `CONTROL_MANAGEMENT_PACK_ACCESS` initialization parameter to either `DIAGNOSTIC` or `DIAGNOSTIC+TUNING`.

### Working with AWR reports in RDS

To generate AWR reports, you can run scripts such as `awr.rpt.sql`. These scripts are installed on the database host server. In Amazon RDS, you don't have direct access to the host. However, you can get copies of SQL scripts from another installation of Oracle Database.

You can also use AWR by running procedures in the `SYS.DBMS_WORKLOAD_REPOSITORY` PL/SQL package. You can use this package to manage baselines and snapshots, and also to display ASH and AWR reports. For example, to generate an AWR report in text format run the `DBMS_WORKLOAD_REPOSITORY.AWR_REPORT_TEXT` procedure. However, you can't reach these AWR reports from the AWS Management Console.

When working with AWR, we recommend using the `rdsadmin.rdsadmin_diagnostic_util` procedures. You can use these procedures to generate the following:

- AWR reports
- Active Session History (ASH) reports
- Automatic Database Diagnostic Monitor (ADDM) reports
- Oracle Data Pump Export dump files of AWR data

The `rdsadmin_diagnostic_util` procedures save the reports to the DB instance file system. You can access these reports from the console. You can also access reports using the `rdsadmin.rds_file_util` procedures, and you can access reports that are copied to Amazon S3 using the S3 Integration option. For more information, see [Reading files in a DB instance directory](#) and [Amazon S3 integration](#).

You can use the `rdsadmin_diagnostic_util` procedures in the following Amazon RDS for Oracle DB engine versions:

- All Oracle Database 21c versions
- 19.0.0.0.ru-2020-04.rur-2020-04.r1 and higher Oracle Database 19c versions

For a blog that explains how to work with diagnostic reports in a replication scenario, see [Generate AWR reports for Amazon RDS for Oracle read replicas](#).

### Common parameters for the diagnostic utility package

You typically use the following parameters when managing AWR and ADDM with the `rdsadmin_diagnostic_util` package.

Parameter	Data type	Default	Required	Description
<code>begin_snap_id</code>	NUMBER	—	Yes	The ID of the beginning snapshot.
<code>end_snap_id</code>	NUMBER	—	Yes	The ID of the ending snapshot.
<code>dump_directory</code>	VARCHAR	BDUMP	No	The directory to write the report or export file to. If you specify a nondefault directory, the user that runs the <code>rdsadmin_diagnostic_util</code> procedures must have write permissions for the directory.
<code>p_tag</code>	VARCHAR	—	No	<p>A string that can be used to distinguish between backups to indicate the purpose or usage of backups, such as <code>incremental</code> or <code>daily</code>.</p> <p>You can specify up to 30 characters. Valid characters are a-z, A-Z, 0-9, an underscore (<code>_</code>), a dash (<code>-</code>), and a period (<code>.</code>). The tag is not case-sensitive. RMAN always stores tags in uppercase, regardless of the case used when entering them.</p> <p>Tags don't need to be unique, so multiple backups can have the same tag. If you don't specify a tag, RMAN assigns a default tag automatically using the format <code>TAGYYYYMMDDTHHMMSS</code>, where <code>YYYY</code> is the year, <code>MM</code> is the month, <code>DD</code> is the day, <code>HH</code> is the hour (in 24-hour format), <code>MM</code> is the minutes, and <code>SS</code> is the seconds. The date and time indicate when RMAN started the backup. For example, a backup with the default tag <code>TAG20190927T214517</code> indicates a backup that started on 2019-09-27 at 21:45:17.</p> <p>The <code>p_tag</code> parameter is supported for the following RDS for Oracle DB engine versions:</p>

Parameter	Data type	Default	Required	Description
				<ul style="list-style-type: none"> <li>Oracle Database 21c (21.0.0)</li> <li>Oracle Database 19c (19.0.0), using 19.0.0.0.ru-2021-10.rur-2021-10.r1 and higher</li> </ul>
report_type	VARCHAR2	HTML	No	The format of the report. Valid values are TEXT and HTML.
dbid	NUMBER	—	No	A valid database identifier (DBID) shown in the <code>DBA_HIST_DATABASE_INSTANCE</code> view for Oracle. If this parameter is not specified, RDS uses the current DBID, which is shown in the <code>V\$DATABASE.DBID</code> view.

You typically use the following parameters when managing ASH with the `rdsadmin_diagnostic_util` package.

Parameter	Data type	Default	Required	Description
begin_time	DATE	—	Yes	The beginning time of the ASH analysis.
end_time	DATE	—	Yes	The ending time of the ASH analysis.
slot_width	NUMBER	0	No	The duration of the slots (in seconds) used in the "Top Activity" section of the ASH report. If this parameter isn't specified, the time interval between <code>begin_time</code> and <code>end_time</code> uses no more than 10 slots.
sid	NUMBER	Null	No	The session ID.
sql_id	VARCHAR2	Null	No	The SQL ID.
wait_classes	VARCHAR2	Null	No	The wait class name.

Parameter	Data type	Default	Required	Description
service_hash	NUMBER	Null	No	The service name hash.
module_name	VARCHAR2	Null	No	The module name.
action_name	VARCHAR2	Null	No	The action name.
client_id	VARCHAR2	Null	No	The application-specific ID of the database session.
plsql_entry	VARCHAR2	Null	No	The PL/SQL entry point.

## Generating an AWR report

To generate an AWR report, use the `rdsadmin.rdsadmin_diagnostic_util.awr_report` procedure.

The following example generates a AWR report for the snapshot range 101–106. The output text file is named `awrrpt_101_106.txt`. You can access this report from the AWS Management Console.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_report(101,106,'TEXT');
```

The following example generates an HTML report for the snapshot range 63–65. The output HTML file is named `awrrpt_63_65.html`. The procedure writes the report to the nondefault database directory named `AWR_RPT_DUMP`.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_report(63,65,'HTML','AWR_RPT_DUMP');
```

## Extracting AWR data into a dump file

To extract AWR data into a dump file, use the `rdsadmin.rdsadmin_diagnostic_util.awr_extract` procedure.

The following example extracts the snapshot range 101–106. The output dump file is named `awrextract_101_106.dmp`. You can access this file through the console.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_extract(101,106);
```

The following example extracts the snapshot range 63–65. The output dump file is named `awrextract_63_65.dmp`. The file is stored in the nondefault database directory named `AWR_RPT_DUMP`.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.awr_extract(63,65,'AWR_RPT_DUMP');
```

### Generating an ADDM report

To generate an ADDM report, use the `rdsadmin.rdsadmin_diagnostic_util.addm_report` procedure.

The following example generates an ADDM report for the snapshot range 101–106. The output text file is named `addmrpt_101_106.txt`. You can access the report through the console.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.addm_report(101,106);
```

The following example generates an ADDM report for the snapshot range 63–65. The output text file is named `addmrpt_63_65.txt`. The file is stored in the nondefault database directory named `ADDM_RPT_DUMP`.

```
EXEC rdsadmin.rdsadmin_diagnostic_util.addm_report(63,65,'ADDM_RPT_DUMP');
```

### Generating an ASH report

To generate an ASH report, use the `rdsadmin.rdsadmin_diagnostic_util.ash_report` procedure.

The following example generates an ASH report that includes the data from 14 minutes ago until the current time. The name of the output file uses the format `ashrpt $begin\_time$  $end\_time$ .txt`, where  *$begin\_time$*  and  *$end\_time$*  use the format `YYYYMMDDHH24MISS`. You can access the file through the console.

```
BEGIN
  rdsadmin.rdsadmin_diagnostic_util.ash_report(
```

```
begin_time => SYSDATE-14/1440,  
end_time   => SYSDATE,  
report_type => 'TEXT');  
  
END;  
/
```

The following example generates an ASH report that includes the data from November 18, 2019, at 6:07 PM through November 18, 2019, at 6:15 PM. The name of the output HTML report is `ashrpt_20190918180700_20190918181500.html`. The report is stored in the nondefault database directory named `AWR_RPT_DUMP`.

```
BEGIN  
  rdsadmin.rdsadmin_diagnostic_util.ash_report(  
    begin_time   => TO_DATE('2019-09-18 18:07:00', 'YYYY-MM-DD HH24:MI:SS'),  
    end_time     => TO_DATE('2019-09-18 18:15:00', 'YYYY-MM-DD HH24:MI:SS'),  
    report_type  => 'html',  
    dump_directory => 'AWR_RPT_DUMP');  
  
END;  
/
```

## Accessing AWR reports from the console or CLI

To access AWR reports or export dump files, you can use the AWS Management Console or AWS CLI. For more information, see [Downloading a database log file](#).

## Adjusting database links for use with DB instances in a VPC

To use Oracle database links with Amazon RDS DB instances inside the same virtual private cloud (VPC) or peered VPCs, the two DB instances should have a valid route between them. Verify the valid route between the DB instances by using your VPC routing tables and network access control list (ACL).

The security group of each DB instance must allow ingress to and egress from the other DB instance. The inbound and outbound rules can refer to security groups from the same VPC or a peered VPC. For more information, see [Updating your security groups to reference peered VPC security groups](#).

If you have configured a custom DNS server using the DHCP Option Sets in your VPC, your custom DNS server must be able to resolve the name of the database link target. For more information, see [Setting up a custom DNS server](#).

For more information about using database links with Oracle Data Pump, see [Importing using Oracle Data Pump](#).

## Setting the default edition for a DB instance

You can redefine database objects in a private environment called an edition. You can use edition-based redefinition to upgrade an application's database objects with minimal downtime.

You can set the default edition of an Amazon RDS Oracle DB instance using the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_default_edition`.

The following example sets the default edition for the Amazon RDS Oracle DB instance to `RELEASE_V1`.

```
EXEC rdsadmin.rdsadmin_util.alter_default_edition('RELEASE_V1');
```

The following example sets the default edition for the Amazon RDS Oracle DB instance back to the Oracle default.

```
EXEC rdsadmin.rdsadmin_util.alter_default_edition('ORA$BASE');
```

For more information about Oracle edition-based redefinition, see [About editions and edition-based redefinition](#) in the Oracle documentation.

## Enabling auditing for the SYS.AUD\$ table

To enable auditing on the database audit trail table `SYS.AUD$`, use the Amazon RDS procedure `rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table`. The only supported audit property is `ALL`. You can't audit or not audit individual statements or operations.

Enabling auditing is supported for Oracle DB instances running the following versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The `audit_all_sys_aud_table` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_by_access	boolean	true	No	Set to true to audit BY ACCESS. Set to false to audit BY SESSION.

The following query returns the current audit configuration for SYS.AUD\$ for a database.

```
SELECT * FROM DBA_OBJ_AUDIT_OPTS WHERE OWNER='SYS' AND OBJECT_NAME='AUD$';
```

The following commands enable audit of ALL on SYS.AUD\$ BY ACCESS.

```
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table;
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table(p_by_access => true);
```

The following command enables audit of ALL on SYS.AUD\$ BY SESSION.

```
EXEC rdsadmin.rdsadmin_master_util.audit_all_sys_aud_table(p_by_access => false);
```

For more information, see [AUDIT \(traditional auditing\)](#) in the Oracle documentation.

## Disabling auditing for the SYS.AUD\$ table

To disable auditing on the database audit trail table SYS.AUD\$, use the Amazon RDS procedure `rdsadmin.rdsadmin_master_util.noaudit_all_sys_aud_table`. This procedure takes no parameters.

The following query returns the current audit configuration for SYS.AUD\$ for a database:

```
SELECT * FROM DBA_OBJ_AUDIT_OPTS WHERE OWNER='SYS' AND OBJECT_NAME='AUD$';
```

The following command disables audit of ALL on SYS.AUD\$.

```
EXEC rdsadmin.rdsadmin_master_util.noaudit_all_sys_aud_table;
```

For more information, see [NOAUDIT \(traditional auditing\)](#) in the Oracle documentation.

## Cleaning up interrupted online index builds

To clean up failed online index builds, use the Amazon RDS procedure `rdsadmin.rdsadmin_dbms_repair.online_index_clean`.

The `online_index_clean` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>object_id</code>	binary_integer	ALL_INDEX_ID	No	The object ID of the index. Typically, you can use the object ID from the ORA-08104 error text.
<code>wait_for_lock</code>	binary_integer	<code>rdsadmin.rdsadmin_dbms_repair.lock_wait</code>	No	Specify <code>rdsadmin.rdsadmin_dbms_repair.lock_wait</code> , the default, to try to get a lock on the underlying object and retry until an internal limit is reached if the lock fails.  Specify <code>rdsadmin.rdsadmin_dbms_repair.lock_nowait</code> to try to get a lock on the underlying object but not retry if the lock fails.

The following example cleans up a failed online index build:

```
declare
  is_clean boolean;
begin
```

```
is_clean := rdsadmin.rdsadmin_dbms_repair.online_index_clean(  
    object_id      => 1234567890,  
    wait_for_lock => rdsadmin.rdsadmin_dbms_repair.lock_nowait  
);  
end;  
/
```

For more information, see [ONLINE\\_INDEX\\_CLEAN function](#) in the Oracle documentation.

## Skipping corrupt blocks

To skip corrupt blocks during index and table scans, use the `rdsadmin.rdsadmin_dbms_repair` package.

The following procedures wrap the functionality of the `sys.dbms_repair.admin_table` procedure and take no parameters:

- `rdsadmin.rdsadmin_dbms_repair.create_repair_table`
- `rdsadmin.rdsadmin_dbms_repair.create_orphan_keys_table`
- `rdsadmin.rdsadmin_dbms_repair.drop_repair_table`
- `rdsadmin.rdsadmin_dbms_repair.drop_orphan_keys_table`
- `rdsadmin.rdsadmin_dbms_repair.purge_repair_table`
- `rdsadmin.rdsadmin_dbms_repair.purge_orphan_keys_table`

The following procedures take the same parameters as their counterparts in the `DBMS_REPAIR` package for Oracle databases:

- `rdsadmin.rdsadmin_dbms_repair.check_object`
- `rdsadmin.rdsadmin_dbms_repair.dump_orphan_keys`
- `rdsadmin.rdsadmin_dbms_repair.fix_corrupt_blocks`
- `rdsadmin.rdsadmin_dbms_repair.rebuild_freelists`
- `rdsadmin.rdsadmin_dbms_repair.segment_fix_status`
- `rdsadmin.rdsadmin_dbms_repair.skip_corrupt_blocks`

For more information about handling database corruption, see [DBMS\\_REPAIR](#) in the Oracle documentation.

## Example Responding to corrupt blocks

This example shows the basic workflow for responding to corrupt blocks. Your steps will depend on the location and nature of your block corruption.

### Important

Before attempting to repair corrupt blocks, review the [DBMS\\_REPAIR](#) documentation carefully.

### To skip corrupt blocks during index and table scans

1. Run the following procedures to create repair tables if they don't already exist.

```
EXEC rdsadmin.rdsadmin_dbms_repair.create_repair_table;
EXEC rdsadmin.rdsadmin_dbms_repair.create_orphan_keys_table;
```

2. Run the following procedures to check for existing records and purge them if appropriate.

```
SELECT COUNT(*) FROM SYS.REPAIR_TABLE;
SELECT COUNT(*) FROM SYS.ORPHAN_KEY_TABLE;
SELECT COUNT(*) FROM SYS.DBA_REPAIR_TABLE;
SELECT COUNT(*) FROM SYS.DBA_ORPHAN_KEY_TABLE;

EXEC rdsadmin.rdsadmin_dbms_repair.purge_repair_table;
EXEC rdsadmin.rdsadmin_dbms_repair.purge_orphan_keys_table;
```

3. Run the following procedure to check for corrupt blocks.

```
SET SERVEROUTPUT ON
DECLARE v_num_corrupt INT;
BEGIN
  v_num_corrupt := 0;
  rdsadmin.rdsadmin_dbms_repair.check_object (
    schema_name => '&corruptionOwner',
    object_name => '&corruptionTable',
    corrupt_count => v_num_corrupt
  );
  dbms_output.put_line('number corrupt: '||to_char(v_num_corrupt));
END;
/
```

```
COL CORRUPT_DESCRIPTION FORMAT a30
COL REPAIR_DESCRIPTION FORMAT a30

SELECT OBJECT_NAME, BLOCK_ID, CORRUPT_TYPE, MARKED_CORRUPT,
       CORRUPT_DESCRIPTION, REPAIR_DESCRIPTION
FROM   SYS.REPAIR_TABLE;

SELECT SKIP_CORRUPT
FROM   DBA_TABLES
WHERE  OWNER = '&corruptionOwner'
AND    TABLE_NAME = '&corruptionTable';
```

4. Use the `skip_corrupt_blocks` procedure to enable or disable corruption skipping for affected tables. Depending on the situation, you may also need to extract data to a new table, and then drop the table containing the corrupt block.

Run the following procedure to enable corruption skipping for affected tables.

```
begin
  rdsadmin.rdsadmin_dbms_repair.skip_corrupt_blocks (
    schema_name => '&corruptionOwner',
    object_name => '&corruptionTable',
    object_type => rdsadmin.rdsadmin_dbms_repair.table_object,
    flags => rdsadmin.rdsadmin_dbms_repair.skip_flag);
end;
/
select skip_corrupt from dba_tables where owner = '&corruptionOwner' and table_name
= '&corruptionTable';
```

Run the following procedure to disable corruption skipping.

```
begin
  rdsadmin.rdsadmin_dbms_repair.skip_corrupt_blocks (
    schema_name => '&corruptionOwner',
    object_name => '&corruptionTable',
    object_type => rdsadmin.rdsadmin_dbms_repair.table_object,
    flags => rdsadmin.rdsadmin_dbms_repair.noskip_flag);
end;
/
```

```
select skip_corrupt from dba_tables where owner = '&corruptionOwner' and table_name
= '&corruptionTable';
```

- When you have completed all repair work, run the following procedures to drop the repair tables.

```
EXEC rdsadmin.rdsadmin_dbms_repair.drop_repair_table;
EXEC rdsadmin.rdsadmin_dbms_repair.drop_orphan_keys_table;
```

## Resizing tablespaces, data files, and temp files

By default, Oracle tablespaces are created with auto-extend turned on and no maximum size. Because of these default settings, tablespaces can sometimes grow too large. We recommend that you specify an appropriate maximum size on permanent and temporary tablespaces, and that you carefully monitor space usage.

### Resizing permanent tablespaces

To resize a permanent tablespace in an RDS for Oracle DB instance, use any of the following Amazon RDS procedures:

- `rdsadmin.rdsadmin_util.resize_datafile`
- `rdsadmin.rdsadmin_util.autoextend_datafile`

The `resize_datafile` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>p_data_file_id</code>	number	—	Yes	The identifier of the data file to resize.
<code>p_size</code>	varchar2	—	Yes	The size of the data file. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).

The `autoextend_datafile` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>p_data_file_id</code>	number	—	Yes	The identifier of the data file to resize.
<code>p_autoextend_state</code>	vvarchar2	—	Yes	The state of the autoextension feature. Specify ON to extend the data file automatically and OFF to turn off autoextension.
<code>p_next</code>	vvarchar2	—	No	The size of the next data file increment. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).
<code>p_maxsize</code>	vvarchar2	—	No	The maximum disk space allowed for automatic extension. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G). You can specify UNLIMITED to remove the file size limit.

The following example resizes data file 4 to 500 MB.

```
EXEC rdsadmin.rdsadmin_util.resize_datafile(4,'500M');
```

The following example turns off autoextension for data file 4. It also turns on autoextension for data file 5, with an increment of 128 MB and no maximum size.

```
EXEC rdsadmin.rdsadmin_util.autoextend_datafile(4,'OFF');
EXEC rdsadmin.rdsadmin_util.autoextend_datafile(5,'ON','128M','UNLIMITED');
```

## Resizing temporary tablespaces

To resize a temporary tablespaces in an RDS for Oracle DB instance, including a read replica, use any of the following Amazon RDS procedures:

- `rdsadmin.rdsadmin_util.resize_temp_tablespace`
- `rdsadmin.rdsadmin_util.resize_tempfile`
- `rdsadmin.rdsadmin_util.autoextend_tempfile`

The `resize_temp_tablespace` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>p_temp_tablespace_name</code>	<code>varchar2</code>	—	Yes	The name of the temporary tablespace to resize.
<code>p_size</code>	<code>varchar2</code>	—	Yes	The size of the tablespace. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).

The `resize_tempfile` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>p_temp_file_id</code>	<code>number</code>	—	Yes	The identifier of the temp file to resize.
<code>p_size</code>	<code>varchar2</code>	—	Yes	The size of the temp file. Specify the size in bytes (the default), kilobytes

Parameter name	Data type	Default	Required	Description
				(K), megabytes (M), or gigabytes (G).

The `autoextend_tempfile` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>p_temp_file_id</code>	number	—	Yes	The identifier of the temp file to resize.
<code>p_autoextend_state</code>	varchar2	—	Yes	The state of the autoextension feature. Specify ON to extend the temp file automatically and OFF to turn off autoextension.
<code>p_next</code>	varchar2	—	No	The size of the next temp file increment. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G).
<code>p_maxsize</code>	varchar2	—	No	The maximum disk space allowed for automatic extension. Specify the size in bytes (the default), kilobytes (K), megabytes (M), or gigabytes (G). You can specify UNLIMITED to remove the file size limit.

The following examples resize a temporary tablespace named TEMP to the size of 4 GB.

```
EXEC rdsadmin.rdsadmin_util.resize_temp_tablespace('TEMP','4G');
```

```
EXEC rdsadmin.rdsadmin_util.resize_temp_tablespace('TEMP','4096000000');
```

The following example resizes a temporary tablespace based on the temp file with the file identifier 1 to the size of 2 MB.

```
EXEC rdsadmin.rdsadmin_util.resize_tempfile(1,'2M');
```

The following example turns off autoextension for temp file 1. It also sets the maximum autoextension size of temp file 2 to 10 GB, with an increment of 100 MB.

```
EXEC rdsadmin.rdsadmin_util.autoextend_tempfile(1,'OFF');  
EXEC rdsadmin.rdsadmin_util.autoextend_tempfile(2,'ON','100M','10G');
```

For more information about read replicas for Oracle DB instances see [Working with read replicas for Amazon RDS for Oracle](#).

## Purging the recycle bin

When you drop a table, your Oracle database doesn't immediately remove its storage space. The database renames the table and places it and any associated objects in a recycle bin. Purging the recycle bin removes these items and releases their storage space.

To purge the entire recycle bin, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.purge_dba_recyclebin`. However, this procedure can't purge the recycle bin of SYS and RDSADMIN objects. If you need to purge these objects, contact AWS Support.

The following example purges the entire recycle bin.

```
EXEC rdsadmin.rdsadmin_util.purge_dba_recyclebin;
```

## Setting the default displayed values for full redaction

To change the default displayed values for full redaction on your Amazon RDS Oracle instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val`.

Note that you create a redaction policy with the DBMS\_REDACT PL/SQL package, as explained in the Oracle Database documentation. The `dbms_redact_upd_full_rdct_val` procedure specifies the characters to display for different data types affected by an existing policy.

The `dbms_redact_upd_full_rdct_val` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>p_number_val</code>	number	Null	No	Modifies the default value for columns of the NUMBER data type.
<code>p_binfloat_val</code>	binary_float	Null	No	Modifies the default value for columns of the BINARY_FLOAT data type.
<code>p_bindouble_val</code>	binary_double	Null	No	Modifies the default value for columns of the BINARY_DOUBLE data type.
<code>p_char_val</code>	char	Null	No	Modifies the default value for columns of the CHAR data type.
<code>p_varchar_val</code>	varchar2	Null	No	Modifies the default value for columns of the VARCHAR2 data type.
<code>p_nchar_val</code>	nchar	Null	No	Modifies the default value for columns of the NCHAR data type.
<code>p_nvarchar_val</code>	nvarchar2	Null	No	Modifies the default value for columns of the NVARCHAR2 data type.

Parameter name	Data type	Default	Required	Description
p_date_val	date	Null	No	Modifies the default value for columns of the DATE data type.
p_ts_val	timestamp	Null	No	Modifies the default value for columns of the TIMESTAMP data type.
p_tswtz_val	timestamp with time zone	Null	No	Modifies the default value for columns of the TIMESTAMP WITH TIME ZONE data type.
p_blob_val	blob	Null	No	Modifies the default value for columns of the BLOB data type.
p_clob_val	clob	Null	No	Modifies the default value for columns of the CLOB data type.
p_nclob_val	nclob	Null	No	Modifies the default value for columns of the NCLOB data type.

The following example changes the default redacted value to \* for the CHAR data type:

```
EXEC rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val(p_char_val => '*');
```

The following example changes the default redacted values for NUMBER, DATE, and CHAR data types:

```
BEGIN
rdsadmin.rdsadmin_util.dbms_redact_upd_full_rdct_val(
  p_number_val=>1,
  p_date_val=>to_date('1900-01-01', 'YYYY-MM-DD'),
```

```
p_varchar_val=>'X');  
END;  
/
```

After you alter the default values for full redaction with the `dbms_redact_upd_full_rdct_val` procedure, reboot your DB instance for the change to take effect. For more information, see [Rebooting a DB instance](#).

## Performing common log-related tasks for Oracle DB instances

Following, you can find how to perform certain common DBA tasks related to logging on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

For more information, see [Oracle database log files](#).

### Topics

- [Setting force logging](#)
- [Setting supplemental logging](#)
- [Switching online log files](#)
- [Adding online redo logs](#)
- [Dropping online redo logs](#)
- [Resizing online redo logs](#)
- [Retaining archived redo logs](#)
- [Accessing online and archived redo logs](#)
- [Downloading archived redo logs from Amazon S3](#)

### Setting force logging

In force logging mode, Oracle logs all changes to the database except changes in temporary tablespaces and temporary segments (NOLOGGING clauses are ignored). For more information, see [Specifying FORCE LOGGING mode](#) in the Oracle documentation.

To set force logging, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.force_logging`. The `force_logging` procedure has the following parameters.

Parameter name	Data type	Default	Yes	Description
p_enable	boolean	true	No	Set to true to put the database in force logging mode, false to remove the database from force logging mode.

The following example puts the database in force logging mode.

```
EXEC rdsadmin.rdsadmin_util.force_logging(p_enable => true);
```

## Setting supplemental logging

If you enable supplemental logging, LogMiner has the necessary information to support chained rows and clustered tables. For more information, see [Supplemental logging](#) in the Oracle documentation.

Oracle Database doesn't enable supplemental logging by default. To enable and disable supplemental logging, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.alter_supplemental_logging`. For more information about how Amazon RDS manages the retention of archived redo logs for Oracle DB instances, see [Retaining archived redo logs](#).

The `alter_supplemental_logging` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_action	varchar2	—	Yes	'ADD' to add supplemental logging, 'DROP' to drop supplemental logging.
p_type	varchar2	null	No	The type of supplemental logging. Valid values are 'ALL', 'FOREIGN KEY', 'PRIMARY

Parameter name	Data type	Default	Required	Description
				KEY', 'UNIQUE', or PROCEDURAL .

The following example enables supplemental logging.

```
begin
  rdsadmin.rdsadmin_util.alter_supplemental_logging(
    p_action => 'ADD');
end;
/
```

The following example enables supplemental logging for all fixed-length maximum size columns.

```
begin
  rdsadmin.rdsadmin_util.alter_supplemental_logging(
    p_action => 'ADD',
    p_type   => 'ALL');
end;
/
```

The following example enables supplemental logging for primary key columns.

```
begin
  rdsadmin.rdsadmin_util.alter_supplemental_logging(
    p_action => 'ADD',
    p_type   => 'PRIMARY KEY');
end;
/
```

## Switching online log files

To switch log files, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.switch_logfile`. The `switch_logfile` procedure has no parameters.

The following example switches log files.

```
EXEC rdsadmin.rdsadmin_util.switch_logfile;
```

## Adding online redo logs

An Amazon RDS DB instance running Oracle starts with four online redo logs, 128 MB each. To add additional redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.add_logfile`.

The `add_logfile` procedure has the following parameters.

### Note

The parameters are mutually exclusive.

Parameter name	Data type	Default	Required	Description
bytes	positive	null	No	The size of the log file in bytes.
p_size	varchar2	—	Yes	The size of the log file. You can specify the size in kilobytes (K), megabytes (M), or gigabytes (G).

The following command adds a 100 MB log file.

```
EXEC rdsadmin.rdsadmin_util.add_logfile(p_size => '100M');
```

## Dropping online redo logs

To drop redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_logfile`. The `drop_logfile` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
grp	positive	—	Yes	The group number of the log.

The following example drops the log with group number 3.

```
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 3);
```

You can only drop logs that have a status of unused or inactive. The following example gets the statuses of the logs.

```
SELECT GROUP#, STATUS FROM V$LOG;
```

GROUP#	STATUS
1	CURRENT
2	INACTIVE
3	INACTIVE
4	UNUSED

## Resizing online redo logs

An Amazon RDS DB instance running Oracle starts with four online redo logs, 128 MB each. The following example shows how you can use Amazon RDS procedures to resize your logs from 128 MB each to 512 MB each.

```
/* Query V$LOG to see the logs. */
/* You start with 4 logs of 128 MB each. */

SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#    BYTES    STATUS
-----
1         134217728  INACTIVE
2         134217728  CURRENT
3         134217728  INACTIVE
4         134217728  INACTIVE

/* Add four new logs that are each 512 MB */

EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
EXEC rdsadmin.rdsadmin_util.add_logfile(bytes => 536870912);
```

```

/* Query V$LOG to see the logs. */
/* Now there are 8 logs.          */

SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#      BYTES      STATUS
-----
1           134217728  INACTIVE
2           134217728  CURRENT
3           134217728  INACTIVE
4           134217728  INACTIVE
5           536870912  UNUSED
6           536870912  UNUSED
7           536870912  UNUSED
8           536870912  UNUSED

/* Drop each inactive log using the group number. */

EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 1);
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 3);
EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 4);

/* Query V$LOG to see the logs. */
/* Now there are 5 logs.          */

select GROUP#, BYTES, STATUS from V$LOG;

GROUP#      BYTES      STATUS
-----
2           134217728  CURRENT
5           536870912  UNUSED
6           536870912  UNUSED
7           536870912  UNUSED
8           536870912  UNUSED

/* Switch logs so that group 2 is no longer current. */

EXEC rdsadmin.rdsadmin_util.switch_logfile;

```

```
/* Query V$LOG to see the logs.          */
/* Now one of the new logs is current. */

SQL>SELECT GROUP#, BYTES, STATUS FROM V$LOG;

GROUP#      BYTES      STATUS
-----
2           134217728  ACTIVE
5           536870912  CURRENT
6           536870912  UNUSED
7           536870912  UNUSED
8           536870912  UNUSED

/* If the status of log 2 is still "ACTIVE", issue a checkpoint to clear it to
"INACTIVE". */

EXEC rdsadmin.rdsadmin_util.checkpoint;

/* Query V$LOG to see the logs.          */
/* Now the final original log is inactive. */

select GROUP#, BYTES, STATUS from V$LOG;

GROUP#      BYTES      STATUS
-----
2           134217728  INACTIVE
5           536870912  CURRENT
6           536870912  UNUSED
7           536870912  UNUSED
8           536870912  UNUSED

# Drop the final inactive log.

EXEC rdsadmin.rdsadmin_util.drop_logfile(grp => 2);

/* Query V$LOG to see the logs.          */
/* Now there are four 512 MB logs. */

SELECT GROUP#, BYTES, STATUS FROM V$LOG;
```

GROUP#	BYTES	STATUS
5	536870912	CURRENT
6	536870912	UNUSED
7	536870912	UNUSED
8	536870912	UNUSED

## Retaining archived redo logs

You can retain archived redo logs locally on your DB instance for use with products like Oracle LogMiner (DBMS\_LOGMNR). After you have retained the redo logs, you can use LogMiner to analyze the logs. For more information, see [Using LogMiner to analyze redo log files](#) in the Oracle documentation.

To retain archived redo logs, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.set_configuration`. The `set_configuration` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
name	vvarchar	—	Yes	The name of the configuration to update.
value	vvarchar	—	Yes	The value for the configuration.

The following example retains 24 hours of redo logs.

```
begin
  rdsadmin.rdsadmin_util.set_configuration(
    name => 'archivelog retention hours',
    value => '24');
end;
/
commit;
```

### Note

The commit is required for the change to take effect.

To view how long archived redo logs are kept for your DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.show_configuration`.

The following example shows the log retention time.

```
set serveroutput on
EXEC rdsadmin.rdsadmin_util.show_configuration;
```

The output shows the current setting for `archivelog retention hours`. The following output shows that archived redo logs are kept for 48 hours.

```
NAME:archivelog retention hours
VALUE:48
DESCRIPTION:ArchiveLog expiration specifies the duration in hours before archive/redo
log files are automatically deleted.
```

Because the archived redo logs are retained on your DB instance, ensure that your DB instance has enough allocated storage for the retained logs. To determine how much space your DB instance has used in the last X hours, you can run the following query, replacing X with the number of hours.

```
SELECT SUM(BLOCKS * BLOCK_SIZE) bytes
FROM V$ARCHIVED_LOG
WHERE FIRST_TIME >= SYSDATE-(X/24) AND DEST_ID=1;
```

RDS for Oracle only generates archived redo logs when the backup retention period of your DB instance is greater than zero. By default the backup retention period is greater than zero.

When the archived log retention period expires, RDS for Oracle removes the archived redo logs from your DB instance. To support restoring your DB instance to a point in time, Amazon RDS retains the archived redo logs outside of your DB instance based on the backup retention period. To modify the backup retention period, see [Modifying an Amazon RDS DB instance](#).

#### Note

In some cases, you might be using JDBC on Linux to download archived redo logs and experience long latency times and connection resets. In such cases, the issues might be caused by the default random number generator setting on your Java client. We recommend setting your JDBC drivers to use a nonblocking random number generator.

## Accessing online and archived redo logs

You might want to access your online and archived redo log files for mining with external tools such as GoldenGate, Attunity, Informatica, and others. To access these files, do the following:

1. Create directory objects that provide read-only access to the physical file paths.

Use `rdsadmin.rdsadmin_master_util.create_archivelog_dir` and `rdsadmin.rdsadmin_master_util.create_onlinelog_dir`.

2. Read the files using PL/SQL.

You can read the files by using PL/SQL. For more information about reading files from directory objects, see [Listing files in a DB instance directory](#) and [Reading files in a DB instance directory](#).

Accessing transaction logs is supported for the following releases:

- Oracle Database 21c
- Oracle Database 19c

The following code creates directories that provide read-only access to your online and archived redo log files:

### Important

This code also revokes the `DROP ANY DIRECTORY` privilege.

```
EXEC rdsadmin.rdsadmin_master_util.create_archivelog_dir;  
EXEC rdsadmin.rdsadmin_master_util.create_onlinelog_dir;
```

The following code drops the directories for your online and archived redo log files.

```
EXEC rdsadmin.rdsadmin_master_util.drop_archivelog_dir;  
EXEC rdsadmin.rdsadmin_master_util.drop_onlinelog_dir;
```

The following code grants and revokes the `DROP ANY DIRECTORY` privilege.

```
EXEC rdsadmin.rdsadmin_master_util.revoke_drop_any_directory;
```

```
EXEC rdsadmin.rdsadmin_master_util.grant_drop_any_directory;
```

## Downloading archived redo logs from Amazon S3

You can download archived redo logs on your DB instance using the `rdsadmin.rdsadmin_archive_log_download` package. If archived redo logs are no longer on your DB instance, you might want to download them again from Amazon S3. Then you can mine the logs or use them to recover or replicate your database.

### Note

You can't download archived redo logs on read replica instances.

## Downloading archived redo logs: basic steps

The availability of your archived redo logs depends on the following retention policies:

- Backup retention policy – Logs inside of this policy are available in Amazon S3. Logs outside of this policy are removed.
- Archived log retention policy – Logs inside of this policy are available on your DB instance. Logs outside of this policy are removed.

If logs aren't on your instance but are protected by your backup retention period, use `rdsadmin.rdsadmin_archive_log_download` to download them again. RDS for Oracle saves the logs to the `/rdsdbdata/log/arch` directory on your DB instance.

## To download archived redo logs from Amazon S3

1. Configure your retention period to ensure your downloaded archived redo logs are retained for the duration you need them. Make sure to COMMIT your change.

RDS retains your downloaded logs according to the archived log retention policy, starting from the time the logs were downloaded. To learn how to set the retention policy, see [Retaining archived redo logs](#).

2. Wait up to 5 minutes for the archived log retention policy change to take effect.
3. Download the archived redo logs from Amazon S3 using `rdsadmin.rdsadmin_archive_log_download`.

For more information, see [Downloading a single archived redo log](#) and [Downloading a series of archived redo logs](#).

**Note**

RDS automatically checks the available storage before downloading. If the requested logs consume a high percentage of space, you receive an alert.

4. Confirm that the logs were downloaded from Amazon S3 successfully.

You can view the status of your download task in a bdump file. The bdump files have the path name `/rdsdbdata/log/trace/dbtask-task-id.log`. In the preceding download step, you run a SELECT statement that returns the task ID in a VARCHAR2 data type. For more information, see similar examples in [Monitoring the status of a file transfer](#).

### Downloading a single archived redo log

To download a single archived redo log to the `/rdsdbdata/log/arch` directory, use `rdsadmin.rdsadmin_archive_log_download.download_log_with_seqnum`. This procedure has the following parameter.

Parameter name	Data type	Default	Required	Description
seqnum	number	—	Yes	The sequence number of the archived redo log.

The following example downloads the log with sequence number 20.

```
SELECT rdsadmin.rdsadmin_archive_log_download.download_log_with_seqnum(seqnum => 20)
       AS TASK_ID
FROM   DUAL;
```

### Downloading a series of archived redo logs

To download a series of archived redo logs to the `/rdsdbdata/log/arch` directory, use `download_logs_in_seqnum_range`. Your download is limited to 300 logs per request. The `download_logs_in_seqnum_range` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
start_seq	number	—	Yes	The starting sequence number for the series.
end_seq	number	—	Yes	The ending sequence number for the series.

The following example downloads the logs from sequence 50 to 100.

```
SELECT rdsadmin.rdsadmin_archive_log_download.download_logs_in_seqnum_range(start_seq
=> 50, end_seq => 100)
      AS TASK_ID
FROM   DUAL;
```

## Performing common RMAN tasks for Oracle DB instances

In the following section, you can find how you can perform Oracle Recovery Manager (RMAN) DBA tasks on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that require advanced privileges.

Use the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to perform RMAN backups of your Amazon RDS for Oracle database to disk. The `rdsadmin.rdsadmin_rman_util` package supports full and incremental database file backups, tablespace backups, and archived redo log backups.

After an RMAN backup has finished, you can copy the backup files off the Amazon RDS for Oracle DB instance host. You might do this for the purpose of restoring to a non-RDS host or for long-term storage of backups. For example, you can copy the backup files to an Amazon S3 bucket. For more information, see using [Amazon S3 integration](#).

The backup files for RMAN backups remain on the Amazon RDS DB instance host until you remove them manually. You can use the `UTL_FILE.FREMOVE` Oracle procedure to remove files from a directory. For more information, see [FREMOVE procedure](#) in the Oracle Database documentation.

You can't use the RMAN to restore RDS for Oracle DB instances. However, you can use RMAN to restore a backup to an on-premises or Amazon EC2 instance. For more information, see the blog article [Restore an Amazon RDS for Oracle instance to a self-managed instance](#).

**Note**

For backing up and restoring to another Amazon RDS for Oracle DB instance, you can continue to use the Amazon RDS backup and restore features. For more information, see [Backing up, restoring, and exporting data](#).

**Topics**

- [Prerequisites for RMAN backups](#)
- [Common parameters for RMAN procedures](#)
- [Validating database files in RDS for Oracle](#)

- [Backing up a tablespace](#)
- [Backing up a control file](#)
- [Performing block media recovery](#)

**Prerequisites for RMAN backups**

Before backing up your database using the `rdsadmin.rdsadmin_rman_util` package, make sure that you meet the following prerequisites:

- Make sure that your RDS for Oracle database is in ARCHIVELOG mode. To enable this mode, set the backup retention period to a non-zero value.
- When backing up archived redo logs or performing a full or incremental backup that includes archived redo logs, and when backing up the database, make sure that redo log retention is set to a nonzero value. Archived redo logs are required to make database files consistent during recovery. For more information, see [Retaining archived redo logs](#).

- Make sure that your DB instance has sufficient free space to hold the backups. When back up your database, you specify an Oracle directory object as a parameter in the procedure call. RMAN places the files in the specified directory. You can use default directories, such as DATA\_PUMP\_DIR, or create a new directory. For more information, see [Creating and dropping directories in the main data storage space](#).

You can monitor the current free space in an RDS for Oracle instance using the CloudWatch metric FreeStorageSpace. We recommend that your free space exceeds the current size of the database, though RMAN backs up only formatted blocks and supports compression.

## Common parameters for RMAN procedures

You can use procedures in the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to perform tasks with RMAN. Several parameters are common to the procedures in the package. The package has the following common parameters.

Parameter name	Data type	Valid values	Default	Required	Description
<code>p_directory_name</code>	<code>varchar</code>	A valid database directory name.	—	Yes	The name of the directory to contain the backup files.
<code>p_label</code>	<code>varchar</code>	a-z, A-Z, 0-9, '_', '-', '.'	—	No	A unique string that is included in the backup file names. <div data-bbox="938 1402 1510 1575" style="border: 1px solid #add8e6; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p> <b>Note</b> The limit is 30 characters.</p> </div>
<code>p_owner</code>	<code>varchar</code>	A valid owner of the directory specified in	—	Yes	The owner of the directory to contain the backup files.

Parameter name	Data type	Valid values	Default	Required	Description
		p_directory_name .			

Parameter name	Data type	Valid values	Default	Required	Description
p_tag	varchar	a-z, A-Z, 0-9, '_', '-', '.'	NULL	No	<p>A string that can be used to distinguish between backups to indicate the purpose or usage of backups, such as daily, weekly, or incremental-level backups.</p> <p>The limit is 30 characters. The tag is not case-sensitive. Tags are always stored in uppercase, regardless of the case used when entering them.</p> <p>Tags don't need to be unique, so multiple backups can have the same tag.</p> <p>If you don't specify a tag, then RMAN assigns a default tag automatically using the format <code>TAGYYYYMMDDT HHMMSS</code>, where <i>YYYY</i> is the year, <i>MM</i> is the month, <i>DD</i> is the day, <i>HH</i> is the hour (in 24-hour format), <i>MM</i> is the minutes, and <i>SS</i> is the seconds. The date and time refer to when RMAN started the backup.</p> <p>For example, a backup might receive a tag <code>TAG20190927T214517</code> for a backup that started on 2019-09-27 at 21:45:17.</p> <p>The p_tag parameter is supported for the following Amazon RDS for Oracle DB engine versions:</p> <ul style="list-style-type: none"> <li>Oracle Database 21c (21.0.0)</li> </ul>

Parameter name	Data type	Valid values	Default	Required	Description
					<ul style="list-style-type: none"> <li>Oracle Database 19c (19.0.0), using 19.0.0.0.ru-2021-10.rur-2021-10.r1 or higher</li> </ul>
p_compress	boolean	TRUE, FALSE	FALSE	No	<p>Specify TRUE to enable BASIC backup compression.</p> <p>Specify FALSE to disable BASIC backup compression.</p>
p_include_archive_logs	boolean	TRUE, FALSE	FALSE	No	<p>Specify TRUE to include archived redo logs in the backup.</p> <p>Specify FALSE to exclude archived redo logs from the backup.</p> <p>If you include archived redo logs in the backup, set retention to one hour or greater using the <code>rdsadmin.rdsadmin_util.set_configuration</code> procedure. Also, call the <code>rdsadmin.rdsadmin_rman_util.crosscheck_archivelog</code> procedure immediately before running the backup. Otherwise, the backup might fail due to missing archived redo log files that have been deleted by Amazon RDS management procedures.</p>
p_include_controlfile	boolean	TRUE, FALSE	FALSE	No	<p>Specify TRUE to include the control file in the backup.</p> <p>Specify FALSE to exclude the control file from the backup.</p>

Parameter name	Data type	Valid values	Default	Required	Description
p_optimize	boolean	TRUE, FALSE	TRUE	No	Specify TRUE to enable backup optimization, if archived redo logs are included, to reduce backup size.  Specify FALSE to disable backup optimization.
p_parallel	number	A valid integer between 1 and 254 for Oracle Database Enterprise Edition (EE)  1 for other Oracle Database editions	1	No	Number of channels.
p_rman_to_dbms_output	boolean	TRUE, FALSE	FALSE	No	When TRUE, the RMAN output is sent to the DBMS_OUTPUT package in addition to a file in the BDUMP directory. In SQL*Plus, use SET SERVEROUTPUT ON to see the output.  When FALSE, the RMAN output is only sent to a file in the BDUMP directory.

Parameter name	Data type	Valid values	Default	Required	Description
p_section_size_mb	number	A valid integer	NULL	No	<p>The section size in megabytes (MB).</p> <p>Validates in parallel by dividing each file into the specified section size.</p> <p>When NULL, the parameter is ignored.</p>
p_validation_type	varchar	'PHYSICAL', 'PHYSICAL+LOGICAL'	'PHYS'	No	<p>The level of corruption detection.</p> <p>Specify 'PHYSICAL' to check for physical corruption. An example of physical corruption is a block with a mismatch in the header and footer.</p> <p>Specify 'PHYSICAL+LOGICAL' to check for logical inconsistencies in addition to physical corruption. An example of logical corruption is a corrupt block.</p>

## Validating database files in RDS for Oracle

You can use the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to validate Amazon RDS for Oracle database files, such as data files, tablespaces, control files, and server parameter files (SPFILES).

For more information about RMAN validation, see [Validating database files and backups](#) and [VALIDATE](#) in the Oracle documentation.

### Topics

- [Validating a database](#)
- [Validating a tenant database](#)
- [Validating a tablespace](#)
- [Validating a control file](#)

- [Validating an SPFILE](#)
- [Validating an Oracle data file](#)

## Validating a database

To validate all of the relevant files used by an Oracle database in RDS for Oracle, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_database`.

This procedure uses the following common parameters for RMAN tasks:

- `p_validation_type`
- `p_parallel`
- `p_section_size_mb`
- `p_rman_to_dbms_output`

For more information, see [Common parameters for RMAN procedures](#).

The following example validates the database using the default values for the parameters.

```
EXEC rdsadmin.rdsadmin_rman_util.validate_database;
```

The following example validates the database using the specified values for the parameters.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.validate_database(
    p_validation_type    => 'PHYSICAL+LOGICAL',
    p_parallel           => 4,
    p_section_size_mb   => 10,
    p_rman_to_dbms_output => FALSE);
END;
/
```

When the `p_rman_to_dbms_output` parameter is set to `FALSE`, the RMAN output is written to a file in the `BDUMP` directory.

To view the files in the `BDUMP` directory, run the following `SELECT` statement.

```
SELECT * FROM table(rdsadmin.rds_file_util.listdir('BDUMP')) order by mtime;
```

To view the contents of a file in the BDUMP directory, run the following SELECT statement.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','rds-rman-validate-nnn.txt'));
```

Replace the file name with the name of the file you want to view.

## Validating a tenant database

To validate the data files of the tenant database in a container database (CDB), use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_tenant`.

This procedure applies only to the current tenant database and uses the following common parameters for RMAN tasks:

- `p_validation_type`
- `p_parallel`
- `p_section_size_mb`
- `p_rman_to_dbms_output`

For more information, see [Common parameters for RMAN procedures](#). This procedure is supported for the following DB engine versions:

- Oracle Database 21c (21.0.0) CDB
- Oracle Database 19c (19.0.0) CDB

The following example validates the current tenant database using the default values for the parameters.

```
EXEC rdsadmin.rdsadmin_rman_util.validate_tenant;
```

The following example validates the current tenant database using the specified values for the parameters.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.validate_tenant(
    p_validation_type => 'PHYSICAL+LOGICAL',
```

```
p_parallel          => 4,  
p_section_size_mb  => 10,  
p_rman_to_dbms_output => FALSE);  
END;  
/
```

When the `p_rman_to_dbms_output` parameter is set to `FALSE`, the RMAN output is written to a file in the `BDUMP` directory.

To view the files in the `BDUMP` directory, run the following `SELECT` statement.

```
SELECT * FROM table(rdsadmin.rds_file_util.listdir('BDUMP')) order by mtime;
```

To view the contents of a file in the `BDUMP` directory, run the following `SELECT` statement.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','rds-rman-  
validate-nnn.txt'));
```

Replace the file name with the name of the file you want to view.

## Validating a tablespace

To validate the files associated with a tablespace, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_tablespace`.

This procedure uses the following common parameters for RMAN tasks:

- `p_validation_type`
- `p_parallel`
- `p_section_size_mb`
- `p_rman_to_dbms_output`

For more information, see [Common parameters for RMAN procedures](#).

This procedure also uses the following additional parameter.

Parameter name	Data type	Valid values	Default	Required	Description
<code>p_tablespace_name</code>	<code>varchar2</code>	A valid tablespace name	—	Yes	The name of the tablespace.

### Validating a control file

To validate only the control file used by an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_current_controlfile`.

This procedure uses the following common parameter for RMAN tasks:

- `p_validation_type`
- `p_rman_to_dbms_output`

For more information, see [Common parameters for RMAN procedures](#).

### Validating an SPFILE

To validate only the server parameter file (SPFILE) used by an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_spfile`.

This procedure uses the following common parameter for RMAN tasks:

- `p_validation_type`
- `p_rman_to_dbms_output`

For more information, see [Common parameters for RMAN procedures](#).

### Validating an Oracle data file

To validate a data file, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.validate_datafile`.

This procedure uses the following common parameters for RMAN tasks:

- `p_validation_type`

- `p_parallel`
- `p_section_size_mb`
- `p_rman_to_dbms_output`

For more information, see [Common parameters for RMAN procedures](#).

This procedure also uses the following additional parameters.

Parameter name	Data type	Valid values	Default	Required	Description
<code>p_datafile</code>	<code>varchar2</code>	A valid datafile ID number or a valid datafile name including complete path	—	Yes	The datafile ID number (from <code>v\$datafile.file#</code> ) or the full datafile name including the path (from <code>v\$datafile.name</code> ).
<code>p_from_block</code>	<code>number</code>	A valid integer	NULL	No	The number of the block where the validation starts within the data file. When this is NULL, 1 is used.
<code>p_to_block</code>	<code>number</code>	A valid integer	NULL	No	The number of the block where the validation ends within the data file. When this is NULL, the maximum block in the data file is used.

## Enabling and disabling block change tracking

Block changing tracking records changed blocks in a tracking file. This technique can improve the performance of RMAN incremental backups. For more information, see [Using Block Change Tracking to Improve Incremental Backup Performance](#) in the Oracle Database documentation.

RMAN features aren't supported in a read replica. However, as part of your high availability strategy, you might choose to enable block tracking in a read-only replica using the procedure `rdsadmin.rdsadmin_rman_util.enable_block_change_tracking`. If you promote this read-only replica to a source DB instance, block change tracking is enabled for the new source instance. Thus, your instance can benefit from fast incremental backups.

Block change tracking procedures are supported in Enterprise Edition only for the following DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

### Note

In a single-tenant CDB, the following operations work, but no customer-visible mechanism can detect the current status of the operations. See also [Limitations of RDS for Oracle CDBs](#).

To enable block change tracking for a DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.enable_block_change_tracking`. To disable block change tracking, use `disable_block_change_tracking`. These procedures take no parameters.

To determine whether block change tracking is enabled for your DB instance, run the following query.

```
SELECT STATUS, FILENAME FROM V$BLOCK_CHANGE_TRACKING;
```

The following example enables block change tracking for a DB instance.

```
EXEC rdsadmin.rdsadmin_rman_util.enable_block_change_tracking;
```

The following example disables block change tracking for a DB instance.

```
EXEC rdsadmin.rdsadmin_rman_util.disable_block_change_tracking;
```

## Crosschecking archived redo logs

You can crosscheck archived redo logs using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.crosscheck_archive_log`.

You can use this procedure to crosscheck the archived redo logs registered in the control file and optionally delete the expired logs records. When RMAN makes a backup, it creates a record in the control file. Over time, these records increase the size of the control file. We recommend that you remove expired records periodically.

### Note

Standard Amazon RDS backups don't use RMAN and therefore don't create records in the control file.

This procedure uses the common parameter `p_rman_to_dbms_output` for RMAN tasks.

For more information, see [Common parameters for RMAN procedures](#).

This procedure also uses the following additional parameter.

Parameter name	Data type	Valid values	Default	Required	Description
<code>p_delete_expired</code>	boolean	TRUE, FALSE	TRUE	No	When TRUE, delete expired archived redo log records from the control file.  When FALSE, retain the expired archived redo log records in the control file.

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The following example marks archived redo log records in the control file as expired, but does not delete the records.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.crosscheck_archivelog(
    p_delete_expired      => FALSE,
    p_rman_to_dbms_output => FALSE);
END;
/
```

The following example deletes expired archived redo log records from the control file.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.crosscheck_archivelog(
    p_delete_expired      => TRUE,
    p_rman_to_dbms_output => FALSE);
END;
/
```

## Backing up archived redo log files

You can use the Amazon RDS package `rdsadmin.rdsadmin_rman_util` to back up archived redo logs for an Amazon RDS Oracle DB instance.

The procedures for backing up archived redo logs are supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

### Topics

- [Backing up all archived redo logs](#)
- [Backing up an archived redo log from a date range](#)
- [Backing up an archived redo log from an SCN range](#)
- [Backing up an archived redo log from a sequence number range](#)

## Backing up all archived redo logs

To back up all of the archived redo logs for an Amazon RDS Oracle DB instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_all`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](#).

The following example backs up all archived redo logs for the DB instance.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_archivelog_all(
    p_owner          => 'SYS',
    p_directory_name => 'MYDIRECTORY',
    p_parallel       => 4,
    p_tag           => 'MY_LOG_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/
```

## Backing up an archived redo log from a date range

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a date range, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_date`. The date range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](#).

This procedure also uses the following additional parameters.

Parameter name	Data type	Valid values	Default	Required	Description
<code>p_from_date</code>	date	A date that is between the <code>start_date</code> and <code>next_date</code> of an archived redo log that exists on disk. The value must be less than or equal to the value specified	—	Yes	The starting date for the archived log backups.

Parameter name	Data type	Valid values	Default	Required	Description
		for p_to_date .			
p_to_date	date	A date that is between the start_date and next_date of an archived redo log that exists on disk. The value must be greater than or equal to the value specified for p_from_date .	—	Yes	The ending date for the archived log backups.

The following example backs up archived redo logs in the date range for the DB instance.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_archivelog_date(
    p_owner          => 'SYS',
```

```

    p_directory_name      => 'MYDIRECTORY',
    p_from_date           => '03/01/2019 00:00:00',
    p_to_date             => '03/02/2019 00:00:00',
    p_parallel            => 4,
    p_tag                 => 'MY_LOG_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/

```

## Backing up an archived redo log from an SCN range

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a system change number (SCN) range, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archive_log_scn`. The SCN range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](#).

This procedure also uses the following additional parameters.

Parameter name	Data type	Valid values	Default	Required	Description
<code>p_from_scn</code>	number	An SCN of an archived redo	—	Yes	The starting SCN for the archived log backups.

Parameter name	Data type	Valid values	Default	Required	Description
		log that exists on disk. The value must be less than or equal to the value specified for p_to_scn.			
p_to_scn	number	An SCN of an archived redo log that exists on disk. The value must be greater than or equal to the value specified for p_from_scn .	—	Yes	The ending SCN for the archived log backups.

The following example backs up archived redo logs in the SCN range for the DB instance.

```

BEGIN
  rdsadmin.rdsadmin_rman_util.backup_archivelog_scn(
    p_owner          => 'SYS',
    p_directory_name => 'MYDIRECTORY',
    p_from_scn       => 1533835,
    p_to_scn         => 1892447,
    p_parallel       => 4,
    p_tag            => 'MY_LOG_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/

```

## Backing up an archived redo log from a sequence number range

To back up specific archived redo logs for an Amazon RDS Oracle DB instance by specifying a sequence number range, use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_archivelog_sequence`. The sequence number range specifies which archived redo logs to back up.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](#).

This procedure also uses the following additional parameters.

Parameter name	Data type	Valid values	Default	Required	Description
<code>p_from_sequence</code>	number	A sequence	—	Yes	The starting sequence number

Parameter name	Data type	Valid values	Default	Required	Description
		number an archived redo log that exists on disk. The value must be less than or equal to the value specified for p_to_seq ence .			for the archived log backups.

Parameter name	Data type	Valid values	Default	Required	Description
p_to_sequence	number	A sequence number of an archived redo log that exists on disk. The value must be greater than or equal to the value specified for p_from_sequence .	—	Yes	The ending sequence number for the archived log backups.

The following example backs up archived redo logs in the sequence number range for the DB instance.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_archivelog_sequence(
    p_owner          => 'SYS',
    p_directory_name => 'MYDIRECTORY',
    p_from_sequence  => 11160,
    p_to_sequence    => 11160,
    p_parallel       => 4,
    p_tag            => 'MY_LOG_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/
```

## Performing a full database backup

You can perform a backup of all blocks of data files included in the backup using Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_database_full`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](#).

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The following example performs a full backup of the DB instance using the specified values for the parameters.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_database_full(
    p_owner          => 'SYS',
    p_directory_name => 'MYDIRECTORY',
    p_parallel       => 4,
    p_section_size_mb => 10,
    p_tag            => 'FULL_DB_BACKUP',
    p_rman_to_dbms_output => FALSE);
```

```
END;  
/
```

## Performing a full backup of a tenant database

You can perform a backup of all data blocks included a tenant database in a container database (CDB). Use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_tenant_full`. This procedure applies only to the current database backup and uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](#).

The `rdsadmin_rman_util.backup_tenant_full` procedure is supported for the following RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0) CDB
- Oracle Database 19c (19.0.0) CDB

The following example performs a full backup of the current tenant database using the specified values for the parameters.

```
BEGIN  
  rdsadmin.rdsadmin_rman_util.backup_tenant_full(  
    p_owner          => 'SYS',
```

```
p_directory_name      => 'MYDIRECTORY',
p_parallel            => 4,
p_section_size_mb    => 10,
p_tag                => 'FULL_TENANT_DB_BACKUP',
p_rman_to_dbms_output => FALSE);
END;
/
```

## Performing an incremental database backup

You can perform an incremental backup of your DB instance using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_database_incremental`.

For more information about incremental backups, see [Incremental backups](#) in the Oracle documentation.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_include_controlfile`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](#).

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

This procedure also uses the following additional parameter.

Parameter name	Data type	Valid values	Default	Required	Description
p_level	number	0, 1	0	No	Specify 0 to enable a full incremental backup.  Specify 1 to enable a non-cumulative incremental backup.

The following example performs an incremental backup of the DB instance using the specified values for the parameters.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_database_incremental(
    p_owner          => 'SYS',
    p_directory_name => 'MYDIRECTORY',
    p_level          => 1,
    p_parallel       => 4,
    p_section_size_mb => 10,
    p_tag            => 'MY_INCREMENTAL_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/
```

## Performing an incremental backup of a tenant database

You can perform an incremental backup of the current tenant database in your CDB. Use the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_tenant_incremental`.

For more information about incremental backups, see [Incremental backups](#) in the Oracle Database documentation.

This procedure applies only to the current tenant database and uses the following common parameters for RMAN tasks:

- p\_owner

- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_include_controlfile`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](#).

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0) CDB
- Oracle Database 19c (19.0.0) CDB

This procedure also uses the following additional parameter.

Parameter name	Data type	Valid values	Default	Required	Description
<code>p_level</code>	number	0, 1	0	No	Specify 0 to enable a full incremental backup.  Specify 1 to enable a non-cumulative incremental backup.

The following example performs an incremental backup of the current tenant database using the specified values for the parameters.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_tenant_incremental(
    p_owner          => 'SYS',
    p_directory_name => 'MYDIRECTORY',
    p_level          => 1,
    p_parallel       => 4,
    p_section_size_mb => 10,
    p_tag            => 'MY_INCREMENTAL_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/
```

## Backing up a tablespace

You can back up a tablespace using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_tablespace`.

This procedure uses the following common parameters for RMAN tasks:

- `p_owner`
- `p_directory_name`
- `p_label`
- `p_parallel`
- `p_section_size_mb`
- `p_include_archive_logs`
- `p_include_controlfile`
- `p_optimize`
- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](#).

This procedure also uses the following additional parameter.

Parameter name	Data type	Valid values	Default	Required	Description
p_tablespace_name	varchar2	A valid tablespace name.	—	Yes	The name of the tablespace to back up.

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The following example performs a tablespace backup using the specified values for the parameters.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_tablespace(
    p_owner          => 'SYS',
    p_directory_name => 'MYDIRECTORY',
    p_tablespace_name => 'MYTABLESPACE',
    p_parallel       => 4,
    p_section_size_mb => 10,
    p_tag            => 'MYTABLESPACE_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/
```

## Backing up a control file

You can back up a control file using the Amazon RDS procedure `rdsadmin.rdsadmin_rman_util.backup_current_controlfile`.

This procedure uses the following common parameters for RMAN tasks:

- p\_owner
- p\_directory\_name
- p\_label

- `p_compress`
- `p_rman_to_dbms_output`
- `p_tag`

For more information, see [Common parameters for RMAN procedures](#).

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The following example backs up a control file using the specified values for the parameters.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.backup_current_controlfile(
    p_owner          => 'SYS',
    p_directory_name => 'MYDIRECTORY',
    p_tag            => 'CONTROL_FILE_BACKUP',
    p_rman_to_dbms_output => FALSE);
END;
/
```

## Performing block media recovery

You can recovery individual data blocks, known as *block media recovery*, using the Amazon RDS procedures `rdsadmin.rdsadmin_rman_util.recover_datafile_block`. You can use this overloaded procedure to recover either an individual data block or a range of data blocks.

This procedure uses the following common parameter for RMAN tasks:

- `p_rman_to_dbms_output`

For more information, see [Common parameters for RMAN procedures](#).

This procedure uses the following additional parameters.

Parameter name	Data type	Valid values	Default	Required	Description
p_datafile	NUMBER	A valid data file ID number.	—	Yes	<p>The data file containin g the corrupt blocks. Specify the data file in either of the following ways:</p> <ul style="list-style-type: none"> <li>The data file ID number, which is located in V\$DATAFILE . FILE#</li> <li>The full data file name, including the path, located in V \$DATAFILE . NAME</li> </ul>
p_block	NUMBER	A valid integer.	—	Yes	<p>The number of an individual block to be recovered.</p> <p>The following parameter s are mutually exclusive:</p> <ul style="list-style-type: none"> <li>p_block</li> <li>p_from_block and p_to_block</li> </ul>
p_from_block	NUMBER	A valid integer.	—	Yes	<p>The first block number in a range of blocks to be recovered.</p> <p>The following parameter s are mutually exclusive:</p> <ul style="list-style-type: none"> <li>p_block</li> </ul>

Parameter name	Data type	Valid values	Default	Required	Description
					<ul style="list-style-type: none"> <li>p_from_block and p_to_block</li> </ul>
p_to_block	NUMBER	A valid integer.	—	Yes	<p>The last block number in a range of blocks to be recovered.</p> <p>The following parameters are mutually exclusive:</p> <ul style="list-style-type: none"> <li>p_block</li> <li>p_from_block and p_to_block</li> </ul>

This procedure is supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

The following example recovers block 100 in data file 5.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.recover_datafile_block(
    p_datafile      => 5,
    p_block         => 100,
    p_rman_to_dbms_output => TRUE);
END;
/
```

The following example recovers blocks 100 to 150 in data file 5.

```
BEGIN
  rdsadmin.rdsadmin_rman_util.recover_datafile_block(
    p_datafile      => 5,
    p_from_block    => 100,
    p_to_block      => 150,
```

```

p_rman_to_dbms_output => TRUE);
END;
/

```

## Performing common scheduling tasks for Oracle DB instances

Some scheduler jobs owned by SYS can interfere with normal database operations. Oracle Support recommends you disable these jobs or modify the schedule. To perform tasks for Oracle Scheduler jobs owned by SYS, use the Amazon RDS package `rdsadmin.rdsadmin_dbms_scheduler`.

The `rdsadmin.rdsadmin_dbms_scheduler` procedures are supported for the following Amazon RDS for Oracle DB engine versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c

## Common parameters for Oracle Scheduler procedures

To perform tasks with Oracle Scheduler, use procedures in the Amazon RDS package `rdsadmin.rdsadmin_dbms_scheduler`. Several parameters are common to the procedures in the package. The package has the following common parameters.

Parameter name	Data type	Valid values	Default	Required	Description
name	varchar2	'SYS.BSLN_ — _MAINTAIN _STATS_J( — B' , 'SYS. NUP_ONLI E_IND_BU: LD'		Yes	The name of the job to modify.  <div data-bbox="1187 1413 1511 1885" style="border: 1px solid #add8e6; border-radius: 10px; padding: 10px;"> <p><b>Note</b></p> <p>Currently , you can only modify SYS.CLEANUP_ONLINE_IND_BUILT and SYS.BSLN_</p> </div>

Parameter name	Data type	Valid values	Default	Required	Description
					MAINTAIN_STATS_JOB jobs.
attribute	varchar2	'REPEAT_INTERVAL' '_NAME'	–	Yes	Attribute to modify.  To modify the repeat interval for the job, specify 'REPEAT_INTERVAL' .  To modify the schedule name for the job, specify 'SCHEDULE_NAME' .
value	varchar2	A valid schedule interval or schedule name, depending on attribute used.	–	Yes	The new value of the attribute.

## Modifying DBMS\_SCHEDULER jobs

To modify certain components of Oracle Scheduler, use the Oracle procedure `dbms_scheduler.set_attribute`. For more information, see [DBMS\\_SCHEDULER](#) and [SET\\_ATTRIBUTE procedure](#) in the Oracle documentation.

When working with Amazon RDS DB instances, prepend the schema name SYS to the object name. The following example sets the resource plan attribute for the Monday window object.

```
BEGIN
  DBMS_SCHEDULER.SET_ATTRIBUTE(
    name      => 'SYS.MONDAY_WINDOW',
    attribute => 'RESOURCE_PLAN',
    value     => 'resource_plan_1');
END;
/
```

## Modifying AutoTask maintenance windows

Amazon RDS for Oracle instances are created with default settings for maintenance windows. Automated maintenance tasks such as optimizer statistics collection run during these windows. By default, the maintenance windows turn on Oracle Database Resource Manager.

To modify the window, use the DBMS\_SCHEDULER package. You might need to modify the maintenance window settings for the following reasons:

- You want maintenance jobs to run at a different time, with different settings, or not at all. For example, might want to modify the window duration, or change the repeat time and interval.
- You want to avoid the performance impact of enabling Resource Manager during maintenance. For example, if the default maintenance plan is specified, and if the maintenance window opens while the database is under load, you might see wait events such as `resmgr:cpu quantum`. This wait event is related to Database Resource Manager. You have the following options:
  - Ensure that maintenance windows are active during off-peak times for your DB instance.
  - Disable the default maintenance plan by setting the `resource_plan` attribute to an empty string.
  - Set the `resource_manager_plan` parameter to `FORCE`: in your parameter group. If your instance uses Enterprise Edition, this setting prevents Database Resource Manager plans from activating.

### To modify your maintenance window settings

1. Connect to your database using an Oracle SQL client.
2. Query the current configuration for a scheduler window.

The following example queries the configuration for MONDAY\_WINDOW.

```
SELECT ENABLED, RESOURCE_PLAN, DURATION, REPEAT_INTERVAL
FROM   DBA_SCHEDULER_WINDOWS
WHERE  WINDOW_NAME='MONDAY_WINDOW';
```

The following output shows that the window is using the default values.

ENABLED	RESOURCE_PLAN	DURATION	REPEAT_INTERVAL
TRUE	DEFAULT_MAINTENANCE_PLAN	+000 04:00:00	
	freq=daily;byday=MON;byhour=22		;byminute=0;
	bysecond=0		

### 3. Modify the window using the DBMS\_SCHEDULER package.

The following example sets the resource plan to null so that the Resource Manager won't run during the maintenance window.

```
BEGIN
  -- disable the window to make changes
  DBMS_SCHEDULER.DISABLE(name=>'SYS"."MONDAY_WINDOW"', force=>TRUE);

  -- specify the empty string to use no plan
  DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'SYS"."MONDAY_WINDOW"',
    attribute=>'RESOURCE_PLAN', value=> '');

  -- re-enable the window
  DBMS_SCHEDULER.ENABLE(name=>'SYS"."MONDAY_WINDOW"');
END;
/
```

The following example sets the maximum duration of the window to 2 hours.

```
BEGIN
  DBMS_SCHEDULER.DISABLE(name=>'SYS"."MONDAY_WINDOW"', force=>TRUE);
  DBMS_SCHEDULER.SET_ATTRIBUTE(name=>'SYS"."MONDAY_WINDOW"',
    attribute=>'DURATION', value=>'0 2:00:00');
  DBMS_SCHEDULER.ENABLE(name=>'SYS"."MONDAY_WINDOW"');
```

```
END;  
/
```

The following example sets the repeat interval to every Monday at 10 AM.

```
BEGIN  
  DBMS_SCHEDULER.DISABLE(name=>' "SYS"."MONDAY_WINDOW" ', force=>TRUE);  
  DBMS_SCHEDULER.SET_ATTRIBUTE(name=>' "SYS"."MONDAY_WINDOW" ',  
    attribute=>'REPEAT_INTERVAL',  
    value=>'freq=daily;byday=MON;byhour=10;byminute=0;bysecond=0');  
  DBMS_SCHEDULER.ENABLE(name=>' "SYS"."MONDAY_WINDOW" ');  
END;  
/
```

## Setting the time zone for Oracle Scheduler jobs

To modify the time zone for Oracle Scheduler, you can use the Oracle procedure `dbms_scheduler.set_scheduler_attribute`. For more information about the `dbms_scheduler` package, see [DBMS\\_SCHEDULER](#) and [SET\\_SCHEDULER\\_ATTRIBUTE](#) in the Oracle documentation.

### To modify the current time zone setting

1. Connect to the database using a client such as SQL Developer. For more information, see [Connecting to your DB instance using Oracle SQL developer](#).
2. Set the default time zone as following, substituting your time zone for *time\_zone\_name*.

```
BEGIN  
  DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE(  
    attribute => 'default_timezone',  
    value => 'time_zone_name'  
  );  
END;  
/
```

In the following example, you change the time zone to Asia/Shanghai.

Start by querying the current time zone, as shown following.

```
SELECT VALUE FROM DBA_SCHEDULER_GLOBAL_ATTRIBUTE WHERE  
ATTRIBUTE_NAME='DEFAULT_TIMEZONE';
```

The output shows that the current time zone is ETC/UTC.

```
VALUE  
-----  
Etc/UTC
```

Then you set the time zone to Asia/Shanghai.

```
BEGIN  
  DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE(  
    attribute => 'default_timezone',  
    value => 'Asia/Shanghai'  
  );  
END;  
/
```

For more information about changing the system time zone, see [Oracle time zone](#).

## Turning off Oracle Scheduler jobs owned by SYS

To disable an Oracle Scheduler job owned by the SYS user, use the `rdsadmin.rdsadmin_dbms_scheduler.disable` procedure.

This procedure uses the name common parameter for Oracle Scheduler tasks. For more information, see [Common parameters for Oracle Scheduler procedures](#).

The following example disables the `SYS.CLEANUP_ONLINE_IND_BUILD` Oracle Scheduler job.

```
BEGIN  
  rdsadmin.rdsadmin_dbms_scheduler.disable('SYS.CLEANUP_ONLINE_IND_BUILD');  
END;  
/
```

## Turning on Oracle Scheduler jobs owned by SYS

To turn on an Oracle Scheduler job owned by SYS, use the `rdsadmin.rdsadmin_dbms_scheduler.enable` procedure.

This procedure uses the name common parameter for Oracle Scheduler tasks. For more information, see [Common parameters for Oracle Scheduler procedures](#).

The following example enables the `SYS.CLEANUP_ONLINE_IND_BUILD` Oracle Scheduler job.

```
BEGIN
  rdsadmin.rdsadmin_dbms_scheduler.enable('SYS.CLEANUP_ONLINE_IND_BUILD');
END;
/
```

## Modifying the Oracle Scheduler repeat interval for jobs of CALENDAR type

To modify the repeat interval to modify a SYS-owned Oracle Scheduler job of CALENDAR type, use the `rdsadmin.rdsadmin_dbms_scheduler.disable` procedure.

This procedure uses the following common parameters for Oracle Scheduler tasks:

- name
- attribute
- value

For more information, see [Common parameters for Oracle Scheduler procedures](#).

The following example modifies the repeat interval of the `SYS.CLEANUP_ONLINE_IND_BUILD` Oracle Scheduler job.

```
BEGIN
  rdsadmin.rdsadmin_dbms_scheduler.set_attribute(
    name      => 'SYS.CLEANUP_ONLINE_IND_BUILD',
    attribute => 'repeat_interval',
    value     => 'freq=daily;byday=FRI,SAT;byhour=20;byminute=0;bysecond=0');
END;
/
```

## Modifying the Oracle Scheduler repeat interval for jobs of NAMED type

Some Oracle Scheduler jobs use a schedule name instead of an interval. For this type of jobs, you must create a new named schedule in the master user schema. Use the standard Oracle `sys.dbms_scheduler.create_schedule` procedure to do this. Also, use the

`rdsadmin.rdsadmin_dbms_scheduler.set_attribute` procedure to assign the new named schedule to the job.

This procedure uses the following common parameter for Oracle Scheduler tasks:

- `name`
- `attribute`
- `value`

For more information, see [Common parameters for Oracle Scheduler procedures](#).

The following example modifies the repeat interval of the `SYS.BSLN_MAINTAIN_STATS_JOB` Oracle Scheduler job.

```
BEGIN
  DBMS_SCHEDULER.CREATE_SCHEDULE (
    schedule_name => 'rds_master_user.new_schedule',
    start_date    => SYSTIMESTAMP,
    repeat_interval =>
'freq=daily;byday=MON,TUE,WED,THU,FRI;byhour=0;byminute=0;bysecond=0',
    end_date      => NULL,
    comments      => 'Repeats daily forever');
END;
/

BEGIN
  rdsadmin.rdsadmin_dbms_scheduler.set_attribute (
    name          => 'SYS.BSLN_MAINTAIN_STATS_JOB',
    attribute     => 'schedule_name',
    value         => 'rds_master_user.new_schedule');
END;
/
```

## Turning off autocommit for Oracle Scheduler job creation

When `DBMS_SCHEDULER.CREATE_JOB` creates Oracle Scheduler jobs, it creates the jobs immediately and commits the changes. You might need to incorporate the creation of Oracle Scheduler jobs in the user transaction to do the following:

- Roll back the Oracle Schedule job when the user transaction is rolled back.

- Create the Oracle Scheduler job when the main user transaction is committed.

You can use the procedure `rdsadmin.rdsadmin_dbms_scheduler.set_no_commit_flag` to turn on this behavior. This procedure takes no parameters. You can use this procedure in the following RDS for Oracle releases:

- 21.0.0.0.ru-2022-07.rur-2022-07.r1 and higher
- 19.0.0.0.ru-2022-07.rur-2022-07.r1 and higher

The following example turns off autocommit for Oracle Scheduler, creates an Oracle Scheduler job, and then rolls back the transaction. Because autocommit is turned off, the database also rolls back the creation of the Oracle Scheduler job.

```
BEGIN
  rdsadmin.rdsadmin_dbms_scheduler.set_no_commit_flag;
  DBMS_SCHEDULER.CREATE_JOB(job_name => 'EMPTY_JOB',
                           job_type => 'PLSQL_BLOCK',
                           job_action => 'begin null; end;',
                           auto_drop => false);

  ROLLBACK;
END;
/

PL/SQL procedure successfully completed.

SELECT * FROM DBA_SCHEDULER_JOBS WHERE JOB_NAME='EMPTY_JOB';

no rows selected
```

## Performing common diagnostic tasks for Oracle DB instances

Oracle Database includes a fault diagnosability infrastructure that you can use to investigate database problems. In Oracle terminology, a *problem* is a critical error such as a code bug or data corruption. An *incident* is the occurrence of a problem. If the same error occurs three times, then the infrastructure shows three incidents of this problem. For more information, see [Diagnosing and resolving problems](#) in the Oracle Database documentation.

The Automatic Diagnostic Repository Command Interpreter (ADRCI) utility is an Oracle command-line tool that you use to manage diagnostic data. For example, you can use this tool to investigate

problems and package diagnostic data. An *incident package* includes diagnostic data for an incident or all incidents that reference a specific problem. You can upload an incident package, which is implemented as a .zip file, to Oracle Support.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to ADRCI. To perform diagnostic tasks for your Oracle instance, instead use the Amazon RDS package `rdsadmin.rdsadmin_adrci_util`.

By using the functions in `rdsadmin_adrci_util`, you can list and package problems and incidents, and also show trace files. All functions return a task ID. This ID forms part of the name of log file that contains the ADRCI output, as in `dbtask-task_id.log`. The log file resides in the BDUMP directory. You can download the log file by following the procedure described in [Downloading a database log file](#).

## Common parameters for diagnostic procedures

To perform diagnostic tasks, use functions in the Amazon RDS package `rdsadmin.rdsadmin_adrci_util`. The package has the following common parameters.

Parameter name	Data type	Valid values	Default	Required	Description
<code>incident_id</code>	number	A valid incident ID or null	Null	No	If the value is null, the function shows all incidents. If the value isn't null and represents a valid incident ID, the function shows the specified incident.
<code>problem_id</code>	number	A valid problem ID or null	Null	No	If the value is null, the function shows all problems. If the value isn't null and represents a valid problem ID, the

Parameter name	Data type	Valid values	Default	Required	Description
					function shows the specified problem.
last	number	A valid integer greater than 0 or null	Null	No	If the value is null, then the function displays at most 50 items. If the value isn't null, the function displays the specified number.

## Listing incidents

To list diagnostic incidents for Oracle, use the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.list_adrci_incidents`. You can list incidents in either basic or detailed mode. By default, the function lists the 50 most recent incidents.

This function uses the following common parameters:

- `incident_id`
- `problem_id`
- `last`

If you specify `incident_id` and `problem_id`, then `incident_id` overrides `problem_id`. For more information, see [Common parameters for diagnostic procedures](#).

This function uses the following additional parameter.

Parameter name	Data type	Valid values	Default	Required	Description
detail	boolean	TRUE or FALSE	FALSE	No	If TRUE, the function lists incidents in detail mode. If

Parameter name	Data type	Valid values	Default	Required	Description
					FALSE, the function lists incidents in basic mode.

To list all incidents, query the `rdsadmin.rdsadmin_adrci_util.list_adrci_incidents` function without any arguments. The query returns the task ID.

```
SQL> SELECT rdsadmin.rdsadmin_adrci_util.list_adrci_incidents AS task_id FROM DUAL;

TASK_ID
-----
1590786706158-3126
```

Or call the `rdsadmin.rdsadmin_adrci_util.list_adrci_incidents` function without any arguments and store the output in a SQL client variable. You can use the variable in other statements.

```
SQL> VAR task_id VARCHAR2(80);
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_incidents;

PL/SQL procedure successfully completed.
```

To read the log file, call the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`. Supply the task ID as part of the file name. The following output shows three incidents: 53523, 53522, and 53521.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
'dbtask-'||:task_id||'.log'));

## Listing problems

To list diagnostic problems for Oracle, use the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.list_adrci_problems`.

By default, the function lists the 50 most recent problems.

This function uses the common parameters `problem_id` and `last`. For more information, see [Common parameters for diagnostic procedures](#).

To get the task ID for all problems, call the `rdsadmin.rdsadmin_adrci_util.list_adrci_problems` function without any arguments, and store the output in a SQL client variable.

```
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.list_adrci_problems;
```

```
PL/SQL procedure successfully completed.
```

To read the log file, call the `rdsadmin.rds_file_util.read_text_file` function, supplying the task ID as part of the file name. In the following output, the log file shows three problems: 1, 2, and 3.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
'dbtask-'||:task_id||'.log'));

## Creating incident packages

You can create incident packages using the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.create_adrci_package`. The output is a .zip file that you can supply to Oracle Support.

This function uses the following common parameters:

- `problem_id`
- `incident_id`

Make sure to specify one of the preceding parameters. If you specify both parameters, `incident_id` overrides `problem_id`. For more information, see [Common parameters for diagnostic procedures](#).

To create a package for a specific incident, call the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.create_adrci_package` with the `incident_id` parameter. The following example creates a package for incident 53523.

```
SQL> EXEC :task_id :=
  rdsadmin.rdsadmin_adrci_util.create_adrci_package(incident_id=>53523);

PL/SQL procedure successfully completed.
```

To read the log file, call the `rdsadmin.rds_file_util.read_text_file`. You can supply the task ID as part of the file name. The output shows that you generated incident package `ORA700EVE_20200529212043_COM_1.zip`.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
  'dbtask-'||:task_id||'.log'));

TEXT
-----
2020-05-29 21:20:43.031 UTC [INFO ] The ADRCI package is being created.

2020-05-29 21:20:47.642 UTC [INFO ] The task finished successfully.
```

To package diagnostic data for a particular problem, specify its ID using the `problem_id` parameter. In the following example, you package data for problem 3 only.

```
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.create_adrci_package(problem_id=>3);

PL/SQL procedure successfully completed.
```

To read the task output, call `rdsadmin.rds_file_util.read_text_file`, supplying the task ID as part of the file name. The output shows that you generated incident package `ORA700EVE_20200529212111_COM_1.zip`.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
'dbtask-'||:task_id||'.log'));

TEXT
-----
2020-05-29 21:21:11.050 UTC [INFO ] The ADRCI package is being created.
2020-05-29 21:21:15.646 UTC [INFO ] Generated package 2 in file /rdsbdbdata/log/trace/
ORA700EVE_20200529212111_COM_1.zip, mode complete
2020-05-29 21:21:15.646 UTC [INFO ] The ADRCI package was successfully created.
2020-05-29 21:21:15.646 UTC [INFO ] The task finished successfully.
```

You can also download the log file. For more information, see [Downloading a database log file](#).

## Showing trace files

You can use the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile` to list trace files under the trace directory and all incident directories under the current ADR home. You can also show the contents of trace files and incident trace files.

This function uses the following parameter.

Parameter name	Data type	Valid values	Default	Required	Description
<code>filename</code>	<code>varchar2</code>	A valid trace file name	Null	No	If the value is null, the function shows all trace files. If it isn't null, the function

Parameter name	Data type	Valid values	Default	Required	Description
					shows the specified file.

To show the trace file, call the Amazon RDS function `rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile`.

```
SQL> EXEC :task_id := rdsadmin.rdsadmin_adrci_util.show_adrci_tracefile;

PL/SQL procedure successfully completed.
```

To list the trace file names, call the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, supplying the task ID as part of the file name.

```
SQL> SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
'dbtask-||:task_id||'.log')) WHERE TEXT LIKE '%/alert_%';
```

TEXT

```
-----
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-28
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-27
diag/rdbms/orcl_a/ORCL/trace/alert_ORCL.log.2020-05-26

You can also download the log file. For more information, see [Downloading a database log file](#).

## Performing miscellaneous tasks for Oracle DB instances

Following, you can find how to perform miscellaneous DBA tasks on your Amazon RDS DB instances running Oracle. To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and restricts access to certain system procedures and tables that require advanced privileges.

### Topics

- [Creating and dropping directories in the main data storage space](#)
- [Listing files in a DB instance directory](#)
- [Reading files in a DB instance directory](#)
- [Accessing Opatch files](#)
- [Managing advisor tasks](#)
- [Transporting tablespaces](#)

## Creating and dropping directories in the main data storage space

To create directories, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.create_directory`. You can create up to 10,000 directories, all located in your main data storage space. To drop directories, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.drop_directory`.

The `create_directory` and `drop_directory` procedures have the following required parameter.

Parameter name	Data type	Default	Required	Description
<code>p_directory_name</code>	VARCHAR2	—	Yes	The name of the directory.

The following example creates a new directory named `PRODUCT_DESCRIPTIONS`.

```
EXEC rdsadmin.rdsadmin_util.create_directory(p_directory_name =>
'product_descriptions');
```

The data dictionary stores the directory name in uppercase. You can list the directories by querying `DBA_DIRECTORIES`. The system chooses the actual host pathname automatically. The following example gets the directory path for the directory named `PRODUCT_DESCRIPTIONS`:

```
SELECT DIRECTORY_PATH
FROM DBA_DIRECTORIES
WHERE DIRECTORY_NAME='PRODUCT_DESCRIPTIONS';

DIRECTORY_PATH
-----
/rdsdbdata/userdirs/01
```

The master user name for the DB instance has read and write privileges in the new directory, and can grant access to other users. EXECUTE privileges are not available for directories on a DB instance. Directories are created in your main data storage space and will consume space and I/O bandwidth.

The following example drops the directory named `PRODUCT_DESCRIPTIONS`.

```
EXEC rdsadmin.rdsadmin_util.drop_directory(p_directory_name => 'product_descriptions');
```

### Note

You can also drop a directory by using the Oracle SQL command `DROP DIRECTORY`.

Dropping a directory doesn't remove its contents. Because the `rdsadmin.rdsadmin_util.create_directory` procedure can reuse pathnames, files in dropped directories can appear in a newly created directory. Before you drop a directory, we recommend that you use `UTL_FILE.FREMOVE` to remove files from the directory. For more information, see [FREMOVE procedure](#) in the Oracle documentation.

## Listing files in a DB instance directory

To list the files in a directory, use the Amazon RDS procedure `rdsadmin.rds_file_util.listdir`. This procedure isn't supported on an Oracle replica. The `listdir` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>p_directory</code>	<code>varchar2</code>	—	Yes	The name of the directory to list.

The following example grants read/write privileges on the directory `PRODUCT_DESCRIPTIONS` to user `rdsadmin`, and then lists the files in this directory.

```
GRANT READ,WRITE ON DIRECTORY PRODUCT_DESCRIPTIONS TO rdsadmin;
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory =>
'PRODUCT_DESCRIPTIONS'));
```

## Reading files in a DB instance directory

To read a text file, use the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`. The `read_text_file` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_directory	varchar2	—	Yes	The name of the directory that contains the file.
p_filename	varchar2	—	Yes	The name of the file to read.

The following example creates the file `rice.txt` in the directory `PRODUCT_DESCRIPTIONS`.

```
declare
  fh sys.utl_file.file_type;
begin
  fh := utl_file.fopen(location=>'PRODUCT_DESCRIPTIONS', filename=>'rice.txt',
    open_mode=>'w');
  utl_file.put(file=>fh, buffer=>'AnyCompany brown rice, 15 lbs');
  utl_file.fclose(file=>fh);
end;
/
```

The following example reads the file `rice.txt` from the directory `PRODUCT_DESCRIPTIONS`.

```
SELECT * FROM TABLE
  (rdsadmin.rds_file_util.read_text_file(
    p_directory => 'PRODUCT_DESCRIPTIONS',
    p_filename => 'rice.txt'));
```

## Accessing Opatch files

Opatch is an Oracle utility that enables the application and rollback of patches to Oracle software. The Oracle mechanism for determining which patches have been applied to a database is the `opatch lsinventory` command. To open service requests for Bring Your Own Licence (BYOL) customers, Oracle Support requests the `lsinventory` file and sometimes the `lsinventory_detail` file generated by Opatch.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to Opatch. Instead, the `lsinventory-dbv.txt` in the `BDUMP` directory contains the patch information

related to your current engine version. When you perform a minor or major upgrade, Amazon RDS updates `lsinventory-dbv.txt` within an hour of applying the patch. To verify the applied patches, read `lsinventory-dbv.txt`. This action is similar to running the `opatch lsinventory` command.

### Note

The examples in this section assume that the BDUMP directory is named BDUMP. On a read replica, the BDUMP directory name is different. To learn how to get the BDUMP name by querying `V$DATABASE.DB_UNIQUE_NAME` on a read replica, see [Listing files](#).

The inventory files use the Amazon RDS naming convention `lsinventory-dbv.txt` and `lsinventory_detail-dbv.txt`, where *dbv* is the full name of your DB version. The `lsinventory-dbv.txt` file is available on all DB versions. The corresponding `lsinventory_detail-dbv.txt` is available on 19.0.0.0, ru-2020-01.rur-2020-01.r1 or later.

For example, if your DB version is 19.0.0.0.ru-2021-07.rur-2021-07.r1, then your inventory files have the following names.

```
lsinventory-19.0.0.0.ru-2021-07.rur-2021-07.r1.txt
lsinventory_detail-19.0.0.0.ru-2021-07.rur-2021-07.r1.txt
```

Ensure that you download the files that match the current version of your DB engine.

## Console

### To download an inventory file using the console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. In the **Logs** section, search for `lsinventory`.
7. Select the file that you want to access, and then choose **Download**.

## SQL

To read the `lsinventory-dbv.txt` in a SQL client, you can use a `SELECT` statement. For this technique, use either of the following `rdsadmin` functions: `rdsadmin.rds_file_util.read_text_file` or `rdsadmin.tracefile_listing`.

In the following sample query, replace *dbv* with your Oracle DB version. For example, your DB version might be `19.0.0.0.ru-2020-04.rur-2020-04.r1`.

```
SELECT text
FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP', 'lsinventory-dbv.txt'));
```

## PL/SQL

To read the `lsinventory-dbv.txt` in a SQL client, you can write a PL/SQL program. This program uses `utl_file` to read the file, and `dbms_output` to print it. These are Oracle-supplied packages.

In the following sample program, replace *dbv* with your Oracle DB version. For example, your DB version might be `19.0.0.0.ru-2020-04.rur-2020-04.r1`.

```
SET SERVEROUTPUT ON
DECLARE
  v_file          SYS.UTL_FILE.FILE_TYPE;
  v_line         VARCHAR2(1000);
  v_oracle_home_type VARCHAR2(1000);
  c_directory    VARCHAR2(30) := 'BDUMP';
  c_output_file  VARCHAR2(30) := 'lsinventory-dbv.txt';
BEGIN
  v_file := SYS.UTL_FILE.FOPEN(c_directory, c_output_file, 'r');
  LOOP
    BEGIN
      SYS.UTL_FILE.GET_LINE(v_file, v_line, 1000);
      DBMS_OUTPUT.PUT_LINE(v_line);
    EXCEPTION
      WHEN no_data_found THEN
        EXIT;
    END;
  END LOOP;
END;
/
```

Or query `rdsadmin.tracefile_listing`, and spool the output to a file. The following example spools the output to `/tmp/tracefile.txt`.

```
SP00L /tmp/tracefile.txt
SELECT *
FROM   rdsadmin.tracefile_listing
WHERE  FILENAME LIKE 'lsinventory%';
SP00L OFF;
```

## Managing advisor tasks

Oracle Database includes a number of advisors. Each advisor supports automated and manual tasks. You can use procedures in the `rdsadmin.rdsadmin_util` package to manage some advisor tasks.

The advisor task procedures are available in the following engine versions:

- Oracle Database 21c (21.0.0)
- Version 19.0.0.0.ru-2021-01.rur-2021-01.r1 and higher Oracle Database 19c versions

For more information, see [Version 19.0.0.0.ru-2021-01.rur-2021-01.r1](#) in the *Amazon RDS for Oracle Release Notes*.

### Topics

- [Setting parameters for advisor tasks](#)
- [Disabling AUTO\\_STATS\\_ADVISOR\\_TASK](#)
- [Re-enabling AUTO\\_STATS\\_ADVISOR\\_TASK](#)

### Setting parameters for advisor tasks

To set parameters for some advisor tasks, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.advisor_task_set_parameter`. The `advisor_task_set_parameter` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
p_task_name	varchar2	—	Yes	<p>The name of the advisor task whose parameters you want to change. The following values are valid:</p> <ul style="list-style-type: none"> <li>AUTO_STATS_ADVISOR_TASK</li> <li>INDIVIDUAL_STATS_ADVISOR_TASK</li> <li>SYS_AUTO_SPM_EVOLVE_TASK</li> <li>SYS_AUTO_SQL_TUNING_TASK</li> </ul>
p_parameter	varchar2	—	Yes	<p>The name of the task parameter. To find valid parameters for an advisor task, run the following query. Substitute <i>p_task_name</i> with a valid value for p_task_name :</p> <pre>COL PARAMETER_NAME FORMAT a30 COL PARAMETER_VALUE FORMAT a30 SELECT PARAMETER_NAME, PARAMETER_VALUE FROM DBA_ADVISOR_PARAMETERS WHERE TASK_NAME=' <i>p_task_name</i> ' AND PARAMETER_VALUE != 'UNUSED' ORDER BY PARAMETER_NAME;</pre>
p_value	varchar2	—	Yes	<p>The value for a task parameter. To find valid values for task parameters, run the following query. Substitute <i>p_task_name</i> with a valid value for p_task_name :</p> <pre>COL PARAMETER_NAME FORMAT a30 COL PARAMETER_VALUE FORMAT a30 SELECT PARAMETER_NAME, PARAMETER_VALUE FROM DBA_ADVISOR_PARAMETERS WHERE TASK_NAME=' <i>p_task_name</i> ' AND PARAMETER_VALUE != 'UNUSED'</pre>

Parameter name	Data type	Default	Require	Description
				ORDER BY PARAMETER_NAME;

The following PL/SQL program sets `ACCEPT_PLANS` to `FALSE` for `SYS_AUTO_SPM_EVOLVE_TASK`. The SQL Plan Management automated task verifies the plans and generates a report of its findings, but does not evolve the plans automatically. You can use a report to identify new SQL plan baselines and accept them manually.

```
BEGIN
  rdsadmin.rdsadmin_util.advisor_task_set_parameter(
    p_task_name => 'SYS_AUTO_SPM_EVOLVE_TASK',
    p_parameter => 'ACCEPT_PLANS',
    p_value     => 'FALSE');
END;
```

The following PL/SQL program sets `EXECUTION_DAYS_TO_EXPIRE` to `10` for `AUTO_STATS_ADVISOR_TASK`. The predefined task `AUTO_STATS_ADVISOR_TASK` runs automatically in the maintenance window once per day. The example sets the retention period for the task execution to 10 days.

```
BEGIN
  rdsadmin.rdsadmin_util.advisor_task_set_parameter(
    p_task_name => 'AUTO_STATS_ADVISOR_TASK',
    p_parameter => 'EXECUTION_DAYS_TO_EXPIRE',
    p_value     => '10');
END;
```

## Disabling `AUTO_STATS_ADVISOR_TASK`

To disable `AUTO_STATS_ADVISOR_TASK`, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.advisor_task_drop`. The `advisor_task_drop` procedure accepts the following parameter.

Parameter name	Data type	Default	Required	Description
p_task_name	varchar2	—	Yes	The name of the advisor task to be disabled. The only valid value is AUTO_STAT S_ADVISOR_TASK .

The following command drops AUTO\_STATS\_ADVISOR\_TASK.

```
EXEC rdsadmin.rdsadmin_util.advisor_task_drop('AUTO_STATS_ADVISOR_TASK')
```

You can re-enable AUTO\_STATS\_ADVISOR\_TASK using rdsadmin.rdsadmin\_util.dbms\_stats\_init.

### Re-enabling AUTO\_STATS\_ADVISOR\_TASK

To re-enable AUTO\_STATS\_ADVISOR\_TASK, use the Amazon RDS procedure rdsadmin.rdsadmin\_util.dbms\_stats\_init. The dbms\_stats\_init procedure takes no parameters.

The following command re-enables AUTO\_STATS\_ADVISOR\_TASK.

```
EXEC rdsadmin.rdsadmin_util.dbms_stats_init()
```

## Transporting tablespaces

Use the Amazon RDS package rdsadmin.rdsadmin\_transport\_util to copy a set of tablespaces from an on-premises Oracle database to an RDS for Oracle DB instance. At the physical level, the transportable tablespace feature incrementally copies source data files and metadata files to your target instance. You can transfer the files using either Amazon EFS or Amazon S3. For more information, see [Migrating using Oracle transportable tablespaces](#).

### Topics

- [Importing transported tablespaces to your DB instance](#)
- [Importing transportable tablespace metadata into your DB instance](#)
- [Listing orphaned files after a tablespace import](#)

- [Deleting orphaned data files after a tablespace import](#)

## Importing transported tablespaces to your DB instance

Use the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces` to restore tablespaces that you have previously exported from a source DB instance. In the transport phase, you back up your read-only tablespaces, export Data Pump metadata, transfer these files to your target DB instance, and then import the tablespaces. For more information, see [Phase 4: Transport the tablespaces](#).

### Syntax

```
FUNCTION import_xtts_tablespaces(
  p_tablespace_list IN CLOB,
  p_directory_name  IN VARCHAR2,
  p_platform_id     IN NUMBER DEFAULT 13,
  p_parallel        IN INTEGER DEFAULT 0) RETURN VARCHAR2;
```

### Parameters

Parameter name	Data type	Default	Required	Description
<code>p_tablespace_list</code>	CLOB	—	Yes	The list of tablespaces to import.
<code>p_directory_name</code>	VARCHAR2	—	Yes	The directory that contains the tablespace backups.
<code>p_platform_id</code>	NUMBER	13	No	Provide a platform ID that matches the one specified during the backup phase. To find a list of platforms, query <code>V\$TRANSPORTABLE_PLATFOM</code> . The default platform is Linux x86 64-bit, which is little endian.

Parameter name	Data type	Default	Required	Description
p_parallel	INTEGER	0	No	The degree of parallelism. By default, parallelism is disabled.

## Examples

The following example imports the tablespaces *TBS1*, *TBS2*, and *TBS3* from the directory *DATA\_PUMP\_DIR*. The source platform is AIX-Based Systems (64-bit), which has the platform ID of 6. You can find the platform IDs by querying V\$TRANSPORTABLE\_PLATFORM.

```

VAR task_id CLOB

BEGIN
  :task_id:=rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces(
    'TBS1, TBS2, TBS3',
    'DATA_PUMP_DIR',
    p_platform_id => 6);
END;
/

PRINT task_id

```

## Importing transportable tablespace metadata into your DB instance

Use the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_metadata` to import transportable tablespace metadata into your RDS for Oracle DB instance. During the operation, the status of the metadata import is shown in the table `rdsadmin.rds_xtts_operation_info`. For more information, see [Step 5: Import tablespace metadata on your target DB instance](#).

## Syntax

```

PROCEDURE import_xtts_metadata(
  p_datapump_metadata_file IN SYS.DBA_DATA_FILES.FILE_NAME%TYPE,
  p_directory_name         IN VARCHAR2,
  p_exclude_stats          IN BOOLEAN DEFAULT FALSE,
  p_remap_tablespace_list  IN CLOB DEFAULT NULL,
  p_remap_user_list        IN CLOB DEFAULT NULL);

```

## Parameters

Parameter name	Data type	Default	Required	Description
p_datapump_metadata_file	SYS.DBA_DATA_FILES .FILE_NAME%TYPE	—	Yes	The name of the Oracle Data Pump file that contains the metadata for your transportable tablespaces.
p_directory_name	VARCHAR2	—	Yes	The directory that contains the Data Pump file.
p_exclude_stats	BOOLEAN	FALSE	No	Flag that indicates whether to exclude statistics.
p_remap_tablespaces_list	CLOB	NULL	No	A list of tablespaces to be remapped during the metadata import. Use the format <i>from_tbs:to_tbs</i> . For example, specify <code>users:use_r_data</code> .
p_remap_user_list	CLOB	NULL	No	A list of user schemas to be remapped during the metadata import. Use the format <i>from_schema_name:to_schema_name</i> . For example, specify

Parameter name	Data type	Default	Required	Description
				hr:human_resources .

## Examples

The example imports the tablespace metadata from the file *xtdump.dmp*, which is located in directory *DATA\_PUMP\_DIR*.

```
BEGIN
  rdsadmin.rdsadmin_transport_util.import_xtts_metadata('xtdump.dmp', 'DATA_PUMP_DIR');
END;
/
```

## Listing orphaned files after a tablespace import

Use the `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files` procedure to list data files that were orphaned after a tablespace import. After you identify the data files, you can delete them by calling `rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import`.

## Syntax

```
FUNCTION list_xtts_orphan_files RETURN xtts_orphan_files_list_t PIPELINED;
```

## Examples

The following example runs the procedure `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files`. The output shows two data files that are orphaned.

```
SQL> SELECT * FROM TABLE(rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files);

FILENAME          FILESIZE
-----
datafile_7.dbf   104865792
datafile_8.dbf   104865792
```

## Deleting orphaned data files after a tablespace import

Use the `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files` procedure to delete data files that were orphaned after a tablespace import. Running this command generates a log file that uses the name format `rds-xtts-delete_xtts_orphaned_files-YYYY-MM-DD.HH24-MI-SS.FF.log` in the `BDUMP` directory. Use the procedure `rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import` to find the orphaned files. You can read the log file by calling the procedure `rdsadmin.rds_file_util.read_text_file`. For more information, see [Phase 6: Clean up leftover files](#).

### Syntax

```
PROCEDURE cleanup_incomplete_xtts_import(
    p_directory_name IN VARCHAR2);
```

### Parameters

Parameter name	Data type	Default	Required	Description
<code>p_directory_name</code>	<code>VARCHAR2</code>	—	Yes	The directory that contains the orphaned data files.

### Examples

The following example deletes the orphaned data files in `DATA_PUMP_DIR`.

```
BEGIN
    rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import('DATA_PUMP_DIR');
END;
/
```

The following example reads the log file generated by the previous command.

```
SELECT *
FROM TABLE(rdsadmin.rds_file_util.read_text_file(
    p_directory => 'BDUMP',
```

```
p_filename => 'rds-xtts-  
delete_xtts_orphaned_files-2023-06-01.09-33-11.868894000.log')));
```

TEXT

```
-----  
orphan transported datafile datafile_7.dbf deleted.  
orphan transported datafile datafile_8.dbf deleted.
```

# Configuring advanced RDS for Oracle features

RDS for Oracle supports various advanced features, including HugePages, an instance store, and extended data types.

## Topics

- [Storing temporary data in an RDS for Oracle instance store](#)
- [Turning on HugePages for an RDS for Oracle instance](#)
- [Turning on extended data types in RDS for Oracle](#)

## Storing temporary data in an RDS for Oracle instance store

Use an instance store for the temporary tablespaces and the Database Smart Flash Cache (the flash cache) on supported RDS for Oracle DB instance classes.

## Topics

- [Working with an instance store on an Oracle read replica](#)
- [Configuring a temporary tablespace group on an instance store and Amazon EBS](#)
- [Removing an RDS for Oracle instance store](#)

## Overview of the RDS for Oracle instance store

An *instance store* provides temporary block-level storage for an RDS for Oracle DB instance. You can use an instance store for temporary storage of information that changes frequently.

An instance store is based on Non-Volatile Memory Express (NVMe) devices that are physically attached to the host computer. The storage is optimized for low latency, random I/O performance, and sequential read throughput.

The size of the instance store varies by DB instance type. For more information about the instance store, see [Amazon EC2 instance store](#) in the *Amazon Elastic Compute Cloud User Guide for Linux Instances*.

## Topics

- [Types of data in the RDS for Oracle instance store](#)
- [Benefits of the RDS for Oracle instance store](#)
- [Supported instance classes for the RDS for Oracle instance store](#)
- [Supported engine versions for the RDS for Oracle instance store](#)
- [Supported AWS Regions for the RDS for Oracle instance store](#)
- [Cost of the RDS for Oracle instance store](#)

## Types of data in the RDS for Oracle instance store

You can place the following types of RDS for Oracle temporary data in an instance store:

### A temporary tablespace

Oracle Database uses temporary tablespaces to store intermediate query results that don't fit in memory. Larger queries can generate large amounts of intermediate data that needs to be cached temporarily, but doesn't need to persist. In particular, a temporary tablespace is useful for sorts, hash aggregations, and joins. If your RDS for Oracle DB instance uses the Enterprise Edition or Standard Edition 2, you can place a temporary tablespace in an instance store.

### The flash cache

The flash cache improves the performance of single-block random reads in the conventional path. A best practice is to size the cache to accommodate most of your active data set. If your RDS for Oracle DB instance uses the Enterprise Edition, you can place the flash cache in an instance store.

By default, an instance store is configured for a temporary tablespace but not for the flash cache. You can't place Oracle data files and database log files in an instance store.

## Benefits of the RDS for Oracle instance store

You might consider using an instance store to store temporary files and caches that you can afford to lose. If you want to improve DB performance, or if an increasing workload is causing performance problems for your Amazon EBS storage, consider scaling to an instance class that supports an instance store.

By placing your temporary tablespace and flash cache on an instance store, you get the following benefits:

- Lower read latencies
- Higher throughput
- Reduced load on your Amazon EBS volumes
- Lower storage and snapshot costs because of reduced Amazon EBS load
- Less need to provision high IOPS, possibly lowering your overall cost

By placing your temporary tablespace on the instance store, you deliver an immediate performance boost to queries that use temporary space. When you place the flash cache on the instance store, cached block reads typically have much lower latency than Amazon EBS reads. The flash cache needs to be "warmed up" before it delivers performance benefits. The cache warms up by itself because the database writes blocks to the flash cache as they age out of the database buffer cache.

 **Note**

In some cases, the flash cache causes performance overhead because of cache management. Before you turn on the flash cache in a production environment, we recommend that you analyze your workload and test the cache in a test environment.

## Supported instance classes for the RDS for Oracle instance store

Amazon RDS supports the instance store for the following DB instance classes:

- db.m5d
- db.r5d
- db.x2idn
- db.x2iedn

RDS for Oracle supports the preceding DB instance classes for the BYOL licensing model only. For more information, see [Supported RDS for Oracle DB instance classes](#) and [Bring Your Own License \(BYOL\) for EE and SE2](#).

To see the total instance storage for the supported DB instance types, run the following command in the AWS CLI.

## Example

```
aws ec2 describe-instance-types \
  --filters "Name=instance-type,Values=*5d.*large*" \
  --query "InstanceTypes[?contains(InstanceType, 'm5d')] || contains(InstanceType, 'r5d')]" \
  --output table
```

The preceding command returns the raw device size for the instance store. RDS for Oracle uses a small portion of this space for configuration. The space in the instance store that is available for temporary tablespaces or the flash cache is slightly smaller.

### Supported engine versions for the RDS for Oracle instance store

The instance store is supported for the following RDS for Oracle engine versions:

- 21.0.0.0.ru-2022-01.rur-2022-01.r1 or higher Oracle Database 21c versions
- 19.0.0.0.ru-2021-10.rur-2021-10.r1 or higher Oracle Database 19c versions

### Supported AWS Regions for the RDS for Oracle instance store

The instance store is available in all AWS Regions where one or more of these instance types are supported. For more information on the db.m5d and db.r5d instance classes, see [DB instance classes](#). For more information on the instance classes supported by Amazon RDS for Oracle, see [RDS for Oracle DB instance classes](#).

### Cost of the RDS for Oracle instance store

The cost of the instance store is built into the cost of the instance-store turned on instances. You don't incur additional costs by enabling an instance store on an RDS for Oracle DB instance. For more information about instance-store turned on instances, see [Supported instance classes for the RDS for Oracle instance store](#).

### Turning on an RDS for Oracle instance store

To turn on the instance store for RDS for Oracle temporary data, do one of the following:

- Create an RDS for Oracle DB instance using a supported instance class. For more information, see [Creating an Amazon RDS DB instance](#).

- Modify an existing RDS for Oracle DB instance to use a supported instance class. For more information, see [Modifying an Amazon RDS DB instance](#).

## Configuring an RDS for Oracle instance store

By default, 100% of instance store space is allocated to the temporary tablespace. To configure the instance store to allocate space to the flash cache and temporary tablespace, set the following parameters in the parameter group for your instance:

**`db_flash_cache_size={DBInstanceStore*{0,2,4,6,8,10}/10}`**

This parameter specifies the amount of storage space allocated for the flash cache.

This parameter is valid only for Oracle Database Enterprise Edition. The default value is `{DBInstanceStore*0/10}`. If you set a nonzero value for `db_flash_cache_size`, your RDS for Oracle instance enables the flash cache after you restart the instance.

**`rds.instance_store_temp_size={DBInstanceStore*{0,2,4,6,8,10}/10}`**

This parameter specifies the amount of storage space allocated for the temporary tablespace. The default value is `{DBInstanceStore*10/10}`. This parameter is modifiable for Oracle Database Enterprise Edition and read-only for Standard Edition 2. If you set a nonzero value for `rds.instance_store_temp_size`, Amazon RDS allocates space in the instance store for the temporary tablespace.

You can set the `db_flash_cache_size` and `rds.instance_store_temp_size` parameters for DB instances that don't use an instance store. In this case, both settings evaluate to `0`, which turns off the feature. In this case, you can use the same parameter group for different instance sizes and for instances that don't use an instance store. If you modify these parameters, make sure to reboot the associated instances so that the changes can take effect.

### Important

If you allocate space for a temporary tablespace, Amazon RDS doesn't create the temporary tablespace automatically. To learn how to create the temporary tablespace on the instance store, see [Creating a temporary tablespace on the instance store](#).

The combined value of the preceding parameters must not exceed 10/10, or 100%. The following table illustrates valid and invalid parameter settings.

db_flash_cache_size setting	rds.instance_store_temp_size setting	Explanation
db_flash_cache_size={DBInstanceStore*0/10}	rds.instance_store_temp_size={DBInstanceStore*10/10}	This is a valid configuration for all editions of Oracle Database. Amazon RDS allocates 100% of instance store space to the temporary tablespace. This is the default.
db_flash_cache_size={DBInstanceStore*10/10}	rds.instance_store_temp_size={DBInstanceStore*0/10}	This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 100% of instance store space to the flash cache.
db_flash_cache_size={DBInstanceStore*2/10}	rds.instance_store_temp_size={DBInstanceStore*8/10}	This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 20% of instance store space to

db_flash_cache_size setting	rds.instance_store_temp_size setting	Explanation
		the flash cache, and 80% of instance store space to the temporary tablespace.
db_flash_cache_size={DBInstanceStore*6/10}	rds.instance_store_temp_size={DBInstanceStore*4/10}	This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 60% of instance store space to the flash cache, and 40% of instance store space to the temporary tablespace.

db_flash_cache_size setting	rds.instance_store_temp_size setting	Explanation
db_flash_cache_size={DBInstanceStore*2/10}	rds.instance_store_temp_size={DBInstanceStore*4/10}	This is a valid configuration for Oracle Database Enterprise Edition only. Amazon RDS allocates 20% of instance store space to the flash cache, and 40% of instance store space to the temporary tablespace.
db_flash_cache_size={DBInstanceStore*8/10}	rds.instance_store_temp_size={DBInstanceStore*8/10}	This is an invalid configuration because the combined percentage of instance store space exceeds 100%. In such cases, Amazon RDS fails the attempt.

## Considerations when changing the DB instance type

If you change your DB instance type, it can affect the configuration of the flash cache or the temporary tablespace on the instance store. Consider the following modifications and their effects:

## You scale up or scale down the DB instance that supports the instance store.

The following values increase or decrease proportionally to the new size of the instance store:

- The new size of the flash cache.
- The space allocated to the temporary tablespaces that reside in the instance store.

For example, the setting `db_flash_cache_size={DBInstanceStore*6/10}` on a `db.m5d.4xlarge` instance provides around 340 GB of flash cache space. If you scale up the instance type to `db.m5d.8xlarge`, the flash cache space increases to around 680 GB.

## You modify a DB instance that doesn't use an instance store to an instance that does use an instance store.

If `db_flash_cache_size` is set to a value larger than 0, the flash cache is configured. If `rds.instance_store_temp_size` is set to a value larger than 0, the instance store space is allocated for use by a temporary tablespace. RDS for Oracle doesn't move tempfiles to the instance store automatically. For information about using the allocated space, see [Creating a temporary tablespace on the instance store](#) or [Adding a tempfile to the instance store on a read replica](#).

## You modify a DB instance that uses an instance store to an instance that doesn't use an instance store.

In this case, RDS for Oracle removes the flash cache. RDS re-creates the tempfile that is currently located on the instance store on an Amazon EBS volume. The maximum size of the new tempfile is the former size of the `rds.instance_store_temp_size` parameter.

## Working with an instance store on an Oracle read replica

Read replicas support the flash cache and temporary tablespaces on an instance store. While the flash cache works the same way as on the primary DB instance, note the following differences for temporary tablespaces:

- You can't create a temporary tablespace on a read replica. If you create a new temporary tablespace on the primary instance, RDS for Oracle replicates the tablespace information without tempfiles. To add a new tempfile, use either of the following techniques:
  - Use the Amazon RDS procedure `rdsadmin.rdsadmin_util.add_inst_store_tempfile`. RDS for Oracle creates a tempfile in the instance store on your read replica, and adds it to the specified temporary tablespace.

- Run the `ALTER TABLESPACE ... ADD TEMPFILE` command. RDS for Oracle places the tempfile on Amazon EBS storage.

**Note**

The tempfile sizes and storage types can be different on the primary DB instance and the read replica.

- You can manage the default temporary tablespace setting only on the primary DB instance. RDS for Oracle replicates the setting to all read replicas.
- You can configure the temporary tablespace groups only on the primary DB instance. RDS for Oracle replicates the setting to all read replicas.

## Configuring a temporary tablespace group on an instance store and Amazon EBS

You can configure a temporary tablespace group to include temporary tablespaces on both an instance store and Amazon EBS. This technique is useful when you want more temporary storage than is allowed by the maximum setting of `rds.instance_store_temp_size`.

When you configure a temporary tablespace group on both an instance store and Amazon EBS, the two tablespaces have significantly different performance characteristics. Oracle Database chooses the tablespace to serve queries based on an internal algorithm. Therefore, similar queries can vary in performance.

Typically, you create a temporary tablespace in the instance store as follows:

1. Create a temporary tablespace in the instance store.
2. Set the new tablespace as the database default temporary tablespace.

If the tablespace size in the instance store is insufficient, you can create additional temporary storage as follows:

1. Assign the temporary tablespace in the instance store to a temporary tablespace group.
2. Create a new temporary tablespace in Amazon EBS if one doesn't exist.
3. Assign the temporary tablespace in Amazon EBS to the same tablespace group that includes the instance store tablespace.
4. Set the tablespace group as the default temporary tablespace.

The following example assumes that the size of the temporary tablespace in the instance store doesn't meet your application requirements. The example creates the temporary tablespace `temp_in_inst_store` in the instance store, assigns it to tablespace group `temp_group`, adds the existing Amazon EBS tablespace named `temp_in_ebs` to this group, and sets this group as the default temporary tablespace.

```
SQL> EXEC rdsadmin.rdsadmin_util.create_inst_store_tmp_tblspace('temp_in_inst_store');
```

```
PL/SQL procedure successfully completed.
```

```
SQL> ALTER TABLESPACE temp_in_inst_store TABLESPACE GROUP temp_group;
```

```
Tablespace altered.
```

```
SQL> ALTER TABLESPACE temp_in_ebs TABLESPACE GROUP temp_group;
```

```
Tablespace altered.
```

```
SQL> EXEC rdsadmin.rdsadmin_util.alter_default_temp_tablespace('temp_group');
```

```
PL/SQL procedure successfully completed.
```

```
SQL> SELECT * FROM DBA_TABLESPACE_GROUPS;
```

GROUP_NAME	TABLESPACE_NAME
TEMP_GROUP	TEMP_IN_EBS
TEMP_GROUP	TEMP_IN_INST_STORE

```
SQL> SELECT PROPERTY_VALUE FROM DATABASE_PROPERTIES WHERE  
PROPERTY_NAME='DEFAULT_TEMP_TABLESPACE';
```

```
PROPERTY_VALUE  
-----  
TEMP_GROUP
```

## Removing an RDS for Oracle instance store

To remove the instance store, modify your RDS for Oracle DB instance to use an instance type that doesn't support instance store, such as `db.m5` or `db.r5`.

## Turning on HugePages for an RDS for Oracle instance

Amazon RDS for Oracle supports Linux kernel HugePages for increased database scalability. HugePages results in smaller page tables and less CPU time spent on memory management, increasing the performance of large database instances. For more information, see [Overview of HugePages](#) in the Oracle documentation.

You can use HugePages with all supported versions and editions of RDS for Oracle.

The `use_large_pages` parameter controls whether HugePages are turned on for a DB instance. The possible settings for this parameter are `ONLY`, `FALSE`, and `{DBInstanceClassHugePagesDefault}`. The `use_large_pages` parameter is set to `{DBInstanceClassHugePagesDefault}` in the default DB parameter group for Oracle.

To control whether HugePages are turned on for a DB instance automatically, you can use the `DBInstanceClassHugePagesDefault` formula variable in parameter groups. The value is determined as follows:

- For the DB instance classes mentioned in the table following, `DBInstanceClassHugePagesDefault` always evaluates to `FALSE` by default, and `use_large_pages` evaluates to `FALSE`. You can turn on HugePages manually for these DB instance classes if the DB instance class has at least 14 GiB of memory.
- For DB instance classes not mentioned in the table following, if the DB instance class has less than 14 GiB of memory, `DBInstanceClassHugePagesDefault` always evaluates to `FALSE`. Also, `use_large_pages` evaluates to `FALSE`.
- For DB instance classes not mentioned in the table following, if the instance class has at least 14 GiB of memory and less than 100 GiB of memory, `DBInstanceClassHugePagesDefault` evaluates to `TRUE` by default. Also, `use_large_pages` evaluates to `ONLY`. You can turn off HugePages manually by setting `use_large_pages` to `FALSE`.
- For DB instance classes not mentioned in the table following, if the instance class has at least 100 GiB of memory, `DBInstanceClassHugePagesDefault` always evaluates to `TRUE`. Also, `use_large_pages` evaluates to `ONLY` and HugePages can't be disabled.

HugePages are not turned on by default for the following DB instance classes.

DB instance class family	DB instance classes with HugePages not turned on by default
db.m5	db.m5.large
db.m4	db.m4.large, db.m4.xlarge, db.m4.2xlarge, db.m4.4xlarge, db.m4.10xlarge
db.t3	db.t3.micro, db.t3.small, db.t3.medium, db.t3.large

For more information about DB instance classes, see [Hardware specifications for DB instance classes](#).

To turn on HugePages for new or existing DB instances manually, set the `use_large_pages` parameter to `ONLY`. You can't use HugePages with Oracle Automatic Memory Management (AMM). If you set the parameter `use_large_pages` to `ONLY`, then you must also set both `memory_target` and `memory_max_target` to `0`. For more information about setting DB parameters for your DB instance, see [Parameter groups for Amazon RDS](#).

You can also set the `sga_target`, `sga_max_size`, and `pga_aggregate_target` parameters. When you set system global area (SGA) and program global area (PGA) memory parameters, add the values together. Subtract this total from your available instance memory (`DBInstanceClassMemory`) to determine the free memory beyond the HugePages allocation. You must leave free memory of at least 2 GiB, or 10 percent of the total available instance memory, whichever is smaller.

After you configure your parameters, you must reboot your DB instance for the changes to take effect. For more information, see [Rebooting a DB instance](#).

#### Note

The Oracle DB instance defers changes to SGA-related initialization parameters until you reboot the instance without failover. In the Amazon RDS console, choose **Reboot** but *do not* choose **Reboot with failover**. In the AWS CLI, call the `reboot-db-instance` command with the `--no-force-failover` parameter. The DB instance does not process the SGA-related parameters during failover or during other maintenance operations that cause the instance to restart.

The following is a sample parameter configuration for HugePages that enables HugePages manually. You should set the values to meet your needs.

```
memory_target          = 0
memory_max_target      = 0
pga_aggregate_target   = {DBInstanceClassMemory*1/8}
sga_target             = {DBInstanceClassMemory*3/4}
sga_max_size           = {DBInstanceClassMemory*3/4}
use_large_pages        = ONLY
```

Assume the following parameters values are set in a parameter group.

```
memory_target          = IF({DBInstanceClassHugePagesDefault}, 0,
  {DBInstanceClassMemory*3/4})
memory_max_target      = IF({DBInstanceClassHugePagesDefault}, 0,
  {DBInstanceClassMemory*3/4})
pga_aggregate_target   = IF({DBInstanceClassHugePagesDefault},
  {DBInstanceClassMemory*1/8}, 0)
sga_target             = IF({DBInstanceClassHugePagesDefault},
  {DBInstanceClassMemory*3/4}, 0)
sga_max_size           = IF({DBInstanceClassHugePagesDefault},
  {DBInstanceClassMemory*3/4}, 0)
use_large_pages        = {DBInstanceClassHugePagesDefault}
```

The parameter group is used by a db.r4 DB instance class with less than 100 GiB of memory. With these parameter settings and `use_large_pages` set to `{DBInstanceClassHugePagesDefault}`, HugePages are turned on for the db.r4 instance.

Consider another example with following parameters values set in a parameter group.

```
memory_target          = IF({DBInstanceClassHugePagesDefault}, 0,
  {DBInstanceClassMemory*3/4})
memory_max_target      = IF({DBInstanceClassHugePagesDefault}, 0,
  {DBInstanceClassMemory*3/4})
pga_aggregate_target   = IF({DBInstanceClassHugePagesDefault},
  {DBInstanceClassMemory*1/8}, 0)
sga_target             = IF({DBInstanceClassHugePagesDefault},
  {DBInstanceClassMemory*3/4}, 0)
sga_max_size           = IF({DBInstanceClassHugePagesDefault},
  {DBInstanceClassMemory*3/4}, 0)
use_large_pages        = FALSE
```

The parameter group is used by a db.r4 DB instance class and a db.r5 DB instance class, both with less than 100 GiB of memory. With these parameter settings, HugePages are turned off on the db.r4 and db.r5 instance.

### Note

If this parameter group is used by a db.r4 DB instance class or db.r5 DB instance class with at least 100 GiB of memory, the FALSE setting for `use_large_pages` is overridden and set to ONLY. In this case, a customer notification regarding the override is sent.

After HugePages are active on your DB instance, you can view HugePages information by enabling enhanced monitoring. For more information, see [Monitoring OS metrics with Enhanced Monitoring](#).

## Turning on extended data types in RDS for Oracle

Amazon RDS for Oracle supports extended data types. With extended data types, the maximum size is 32,767 bytes for the VARCHAR2, NVARCHAR2, and RAW data types. To use extended data types, set the `MAX_STRING_SIZE` parameter to EXTENDED. For more information, see [Extended data types](#) in the Oracle documentation.

If you don't want to use extended data types, keep the `MAX_STRING_SIZE` parameter set to STANDARD (the default). In this case, the size limits are 4,000 bytes for the VARCHAR2 and NVARCHAR2 data types, and 2,000 bytes for the RAW data type.

You can turn on extended data types on a new or existing DB instance. For new DB instances, DB instance creation time is typically longer when you turn on extended data types. For existing DB instances, the DB instance is unavailable during the conversion process.

### Considerations for extended data types

Consider the following when you enable extended data types for your DB instance:

- When you turn on extended data types for a new or existing DB instance, you must reboot the instance for the change to take effect.
- After you turn on extended data types, you can't change the DB instance back to use the standard size for data types. If you set the `MAX_STRING_SIZE` parameter back to STANDARD it results in the `incompatible-parameters` status.

- When you restore a DB instance that uses extended data types, you must specify a parameter group with the `MAX_STRING_SIZE` parameter set to `EXTENDED`. During restore, if you specify the default parameter group or any other parameter group with `MAX_STRING_SIZE` set to `STANDARD` it results in the `incompatible-parameters` status.
- When the DB instance status is `incompatible-parameters` because of the `MAX_STRING_SIZE` setting, the DB instance remains unavailable until you set the `MAX_STRING_SIZE` parameter to `EXTENDED` and reboot the DB instance.

## Turning on extended data types for a new DB instance

When you create a DB instance with `MAX_STRING_SIZE` set to `EXTENDED`, the instance shows `MAX_STRING_SIZE` set to the default `STANDARD`. Reboot the instance to enable the change.

### To turn on extended data types for a new DB instance

1. Set the `MAX_STRING_SIZE` parameter to `EXTENDED` in a parameter group.

To set the parameter, you can either create a new parameter group or modify an existing parameter group.

For more information, see [Parameter groups for Amazon RDS](#).

2. Create a new RDS for Oracle DB instance.

For more information, see [Creating an Amazon RDS DB instance](#).

3. Associate the parameter group with `MAX_STRING_SIZE` set to `EXTENDED` with the DB instance.

For more information, see [Creating an Amazon RDS DB instance](#).

4. Reboot the DB instance for the parameter change to take effect.

For more information, see [Rebooting a DB instance](#).

## Turning on extended data types for an existing DB instance

When you modify a DB instance to turn on extended data types, RDS converts the data in the database to use the extended sizes. The conversion and downtime occur when you next reboot the database after the parameter change. The DB instance is unavailable during the conversion.

The amount of time it takes to convert the data depends on the DB instance class, the database size, and the time of the last DB snapshot. To reduce downtime, consider taking a snapshot immediately before rebooting. This shortens the time of the backup that occurs during the conversion workflow.

**Note**

After you turn on extended data types, you can't perform a point-in-time restore to a time during the conversion. You can restore to the time immediately before the conversion or after the conversion.

### To turn on extended data types for an existing DB instance

1. Take a snapshot of the database.

If there are invalid objects in the database, Amazon RDS tries to recompile them. The conversion to extended data types can fail if Amazon RDS can't recompile an invalid object. The snapshot enables you to restore the database if there is a problem with the conversion. Always check for invalid objects before conversion and fix or drop those invalid objects. For production databases, we recommend testing the conversion process on a copy of your DB instance first.

For more information, see [Creating a DB snapshot for a Single-AZ DB instance](#).

2. Set the `MAX_STRING_SIZE` parameter to `EXTENDED` in a parameter group.

To set the parameter, you can either create a new parameter group or modify an existing parameter group.

For more information, see [Parameter groups for Amazon RDS](#).

3. Modify the DB instance to associate it with the parameter group with `MAX_STRING_SIZE` set to `EXTENDED`.

For more information, see [Modifying an Amazon RDS DB instance](#).

4. Reboot the DB instance for the parameter change to take effect.

For more information, see [Rebooting a DB instance](#).

# Importing data into Oracle on Amazon RDS

How you import data into an Amazon RDS for Oracle DB instance depends on the following:

- The amount of data you have
- The number of database objects in your database
- The variety of database objects in your database

For example, you can use the following tools, depending on your requirements:

- Oracle SQL Developer – Import a simple, 20 MB database.
- Oracle Data Pump – Import complex databases, or databases that are several hundred megabytes or several terabytes in size. For example, you can transport tablespaces from an on-premises database to your RDS for Oracle DB instance. You can use Amazon S3 or Amazon EFS to transfer the data files and metadata. For more information, see [Migrating using Oracle transportable tablespaces](#), [Amazon EFS integration](#), and [Amazon S3 integration](#).
- AWS Database Migration Service (AWS DMS) – Migrate databases without downtime. For more information about AWS DMS, see [What is AWS Database Migration Service](#) and the blog post [Migrating Oracle databases with near-zero downtime using AWS DMS](#).

## Important

Before you use the preceding migration techniques, we recommend that you back up your database. After you import the data, you can back up your RDS for Oracle DB instances by creating snapshots. Later, you can restore the snapshots. For more information, see [Backing up, restoring, and exporting data](#).

For many database engines, ongoing replication can continue until you are ready to switch over to the target database. You can use AWS DMS to migrate to RDS for Oracle from either the same database engine or a different engine. If you migrate from a different database engine, you can use the AWS Schema Conversion Tool to migrate schema objects that AWS DMS doesn't migrate.

## Topics

- [Importing using Oracle SQL Developer](#)
- [Migrating using Oracle transportable tablespaces](#)

- [Importing using Oracle Data Pump](#)
- [Importing using Oracle Export/Import](#)
- [Importing using Oracle SQL\\*Loader](#)
- [Migrating with Oracle materialized views](#)

## Importing using Oracle SQL Developer

Oracle SQL Developer is a graphical Java tool distributed without cost by Oracle. SQL Developer provides options for migrating data between two Oracle databases, or for migrating data from other databases, such as MySQL, to an Oracle database. This tool is best for migrating small databases.

You can install this tool on your desktop computer (Windows, Linux, or Mac) or on one of your servers. After you install SQL Developer, you can use it to connect to your source and target databases. Use the **Database Copy** command on the Tools menu to copy your data to your RDS for Oracle DB instance.

To download SQL Developer, go to <http://www.oracle.com/technetwork/developer-tools/sql-developer>.

We recommend that you read the Oracle SQL Developer product documentation before you begin migrating your data. Oracle also has documentation on how to migrate from other databases, including MySQL and SQL Server. For more information, see <http://www.oracle.com/technetwork/database/migration> in the Oracle documentation.

## Migrating using Oracle transportable tablespaces

You can use the Oracle transportable tablespaces feature to copy a set of tablespaces from an on-premises Oracle database to an RDS for Oracle DB instance. At the physical level, you transfer source data files and metadata files to your target DB instance using either Amazon EFS or Amazon S3. The transportable tablespaces feature uses the `rdadmin.rdsadmin_transport_util` package. For syntax and semantics of this package, see [Transporting tablespaces](#).

For blog posts that explain how to transport tablespaces, see [Migrate Oracle Databases to AWS using transportable tablespace](#) and [Amazon RDS for Oracle Transportable Tablespaces using RMAN](#).

### Topics

- [Overview of Oracle transportable tablespaces](#)
- [Phase 1: Set up your source host](#)
- [Phase 2: Prepare the full tablespace backup](#)
- [Phase 3: Make and transfer incremental backups](#)
- [Phase 4: Transport the tablespaces](#)
- [Phase 5: Validate the transported tablespaces](#)
- [Phase 6: Clean up leftover files](#)

## Overview of Oracle transportable tablespaces

A transportable tablespace set consists of data files for the set of tablespaces being transported and an export dump file containing tablespace metadata. In a physical migration solution such as transportable tablespaces, you transfer physical files: data files, configuration files, and Data Pump dump files.

### Topics

- [Advantages and disadvantages of transportable tablespaces](#)
- [Limitations for transportable tablespaces](#)
- [Prerequisites for transportable tablespaces](#)

### Advantages and disadvantages of transportable tablespaces

We recommend that you use transportable tablespaces when you need to migrate one or more large tablespaces to RDS with minimum downtime. Transportable tablespaces offer the following advantages over logical migration:

- Downtime is lower than most other Oracle migration solutions.
- Because the transportable tablespace feature copies only physical files, it avoids the data integrity errors and logical corruption that can occur in logical migration.
- No additional license is required.
- You can migrate a set of tablespaces across different platforms and endianness types, for example, from an Oracle Solaris platform to Linux. However, transporting tablespaces to and from Windows servers isn't supported.

**Note**

Linux is fully tested and supported. Not all UNIX variations have been tested.

If you use transportable tablespaces, you can transport data using either Amazon S3 or Amazon EFS:

- When you use EFS, your backups remain in the EFS file system for the duration of the import. You can remove the files afterward. In this technique, you don't need to provision EBS storage for your DB instance. For this reason, we recommend using Amazon EFS instead of S3. For more information, see [Amazon EFS integration](#).
- When you use S3, you download RMAN backups to EBS storage attached to your DB instance. The files remain in your EBS storage during the import. After the import, you can free up this space, which remains allocated to your DB instance.

The primary disadvantage of transportable tablespaces is that you need relatively advanced knowledge of Oracle Database. For more information, see [Transporting Tablespaces Between Databases](#) in the *Oracle Database Administrator's Guide*.

### Limitations for transportable tablespaces

Oracle Database limitations for transportable tablespaces apply when you use this feature in RDS for Oracle. For more information, see [Limitations on Transportable Tablespaces](#) and [General Limitations on Transporting Data](#) in the *Oracle Database Administrator's Guide*. Note the following additional limitations for transportable tablespaces in RDS for Oracle:

- Neither the source or target database can use Standard Edition 2 (SE2). Only Enterprise Edition is supported.
- You can't use an Oracle Database 11g database as a source. The RMAN cross-platform transportable tablespaces feature relies on the RMAN transport mechanism, which Oracle Database 11g doesn't support.
- You can't migrate data from an RDS for Oracle DB instance using transportable tablespaces. You can only use transportable tablespaces to migrate data to an RDS for Oracle DB instance.
- The Windows operating system isn't supported.

- You can't transport tablespaces into a database at a lower release level. The target database must be at the same or later release level as the source database. For example, you can't transport tablespaces from Oracle Database 21c into Oracle Database 19c.
- You can't transport administrative tablespaces such as SYSTEM and SYSAUX.
- You can't transport non-data objects such as PL/SQL packages, Java classes, views, triggers, sequences, users, roles, and temporary tables. To transport non-data objects, create them manually or use Data Pump metadata export and import. For more information, see [My Oracle Support Note 1454872.1](#).
- You can't transport tablespaces that are encrypted or use encrypted columns.
- If you transfer files using Amazon S3, the maximum supported file size is 5 TiB.
- If the source database uses Oracle options such as Spatial, you can't transport tablespaces unless the same options are configured on the target database.
- You can't transport tablespaces into an RDS for Oracle DB instance in an Oracle replica configuration. As a workaround, you can delete all replicas, transport the tablespaces, and then recreate the replicas.

## Prerequisites for transportable tablespaces

Before you begin, complete the following tasks:

- Review the requirements for transportable tablespaces described in the following documents in My Oracle Support:
  - [Reduce Transportable Tablespace Downtime using Cross Platform Incremental Backup \(Doc ID 2471245.1\)](#)
  - [Transportable Tablespace \(TTS\) Restrictions and Limitations: Details, Reference, and Version Where Applicable \(Doc ID 1454872.1\)](#)
  - [Primary Note for Transportable Tablespaces \(TTS\) -- Common Questions and Issues \(Doc ID 1166564.1\)](#)
- Plan for endianness conversion. If you specify the source platform ID, RDS for Oracle converts the endianness automatically. To learn how to find platform IDs, see [Data Guard Support for Heterogeneous Primary and Physical Standbys in Same Data Guard Configuration \(Doc ID 413484.1\)](#).
- Make sure that the transportable tablespace feature is enabled on your target DB instance. The feature is enabled only if you don't get an ORA-20304 error when you run the following query:

```
SELECT * FROM TABLE(rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files);
```

If the transportable tablespace feature isn't enabled, reboot your DB instance. For more information, see [Rebooting a DB instance](#).

- If you plan to transfer files using Amazon S3, do the following:
  - Make sure that an Amazon S3 bucket is available for file transfers, and that the Amazon S3 bucket is in the same AWS Region as your DB instance. For instructions, see [Create a bucket](#) in the *Amazon Simple Storage Service Getting Started Guide*.
  - Prepare the Amazon S3 bucket for Amazon RDS integration by following the instructions in [Configuring IAM permissions for RDS for Oracle integration with Amazon S3](#).
- If you plan to transfer files using Amazon EFS, make sure that you have configured EFS according to the instructions in [Amazon EFS integration](#).
- We strongly recommend that you turn on automatic backups in your target DB instance. Because the [metadata import step](#) can potentially fail, it's important to be able to restore your DB instance to its state before the import, thereby avoiding the necessity to back up, transfer, and import your tablespaces again.

## Phase 1: Set up your source host

In this step, you copy the transport tablespaces scripts provided by My Oracle Support and set up necessary configuration files. In the following steps, the *source host* is running the database that contains the tablespaces to be transported to your *target instance*.

### To set up your source host

1. Log in to your source host as the owner of your Oracle home.
2. Make sure that your ORACLE\_HOME and ORACLE\_SID environment variables point to your source database.
3. Log in to your database as an administrator, and verify that the time zone version, DB character set, and national character set are the same as in your target database.

```
SELECT * FROM V$TIMEZONE_FILE;  
SELECT * FROM NLS_DATABASE_PARAMETERS  
WHERE PARAMETER IN ('NLS_CHARACTERSET', 'NLS_NCHAR_CHARACTERSET');
```

4. Set up the transportable tablespace utility as described in [Oracle Support note 2471245.1](#).

The setup includes editing the `xtt.properties` file on your source host. The following sample `xtt.properties` file specifies backups of three tablespaces in the `/dsk1/backups` directory. These are the tablespaces that you intend to transport to your target DB instance. It also specifies the source platform ID to convert the endianness automatically.

**Note**

For valid platform IDs, see [Data Guard Support for Heterogeneous Primary and Physical Standbys in Same Data Guard Configuration \(Doc ID 413484.1\)](#).

```
#linux system
platformid=13
#list of tablespaces to transport
tablespaces=TBS1, TBS2, TBS3
#location where backup will be generated
src_scratch_location=/dsk1/backups
#RMAN command for performing backup
usermantransport=1
```

## Phase 2: Prepare the full tablespace backup

In this phase, you back up your tablespaces for the first time, transfer the backups to your target host, and then restore them using the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces`. When this phase is complete, the initial tablespace backups reside on your target DB instance and can be updated with incremental backups.

### Topics

- [Step 1: Back up the tablespaces on your source host](#)
- [Step 2: Transfer the backup files to your target DB instance](#)
- [Step 3: Import the tablespaces on your target DB instance](#)

## Step 1: Back up the tablespaces on your source host

In this step, you use the `xtdriver.pl` script to make a full backup of your tablespaces. The output of `xtdriver.pl` is stored in the `TMPDIR` environment variable.

### To back up your tablespaces

1. If your tablespaces are in read-only mode, log in to your source database as a user with the `ALTER TABLESPACE` privilege, and place your tablespaces in read/write mode. Otherwise, skip to the next step.

The following example places `tbs1`, `tbs2`, and `tbs3` in read/write mode.

```
ALTER TABLESPACE tbs1 READ WRITE;
ALTER TABLESPACE tbs2 READ WRITE;
ALTER TABLESPACE tbs3 READ WRITE;
```

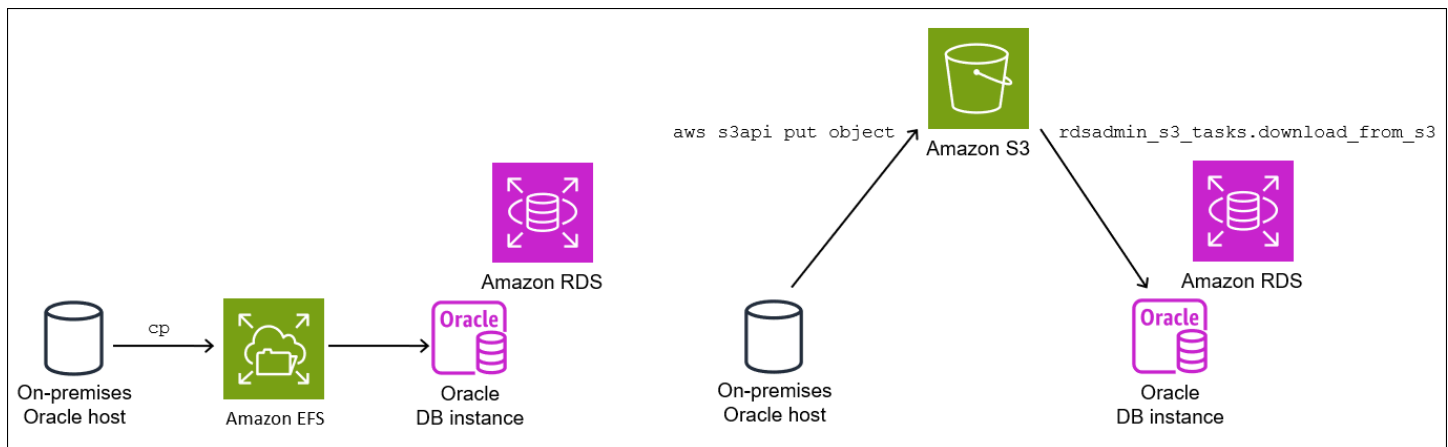

2. Back up your tablespaces using the `xtdriver.pl` script. Optionally, you can specify `--debug` to run the script in debug mode.

```
export TMPDIR=location_of_log_files
cd location_of_xtdriver.pl
$ORACLE_HOME/perl/bin/perl xtdriver.pl --backup
```

## Step 2: Transfer the backup files to your target DB instance

In this step, copy the backup and configuration files from your scratch location to your target DB instance. Choose one of the following options:

- If the source and target hosts share an Amazon EFS file system, use an operating system utility such as `cp` to copy your backup files and the `res.txt` file from your scratch location to a shared directory. Then skip to [Step 3: Import the tablespaces on your target DB instance](#).
- If you need to stage your backups to an Amazon S3 bucket, complete the following steps.

## Step 2.2: Upload the backups to your Amazon S3 bucket

Upload your backups and the `res.txt` file from your scratch directory to your Amazon S3 bucket. For more information, see [Uploading objects](#) in the *Amazon Simple Storage Service User Guide*.

## Step 2.3: Download the backups from your Amazon S3 bucket to your target DB instance

In this step, you use the procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3` to download your backups to your RDS for Oracle DB instance.

### To download your backups from your Amazon S3 bucket

1. Start SQL\*Plus or Oracle SQL Developer and log in to your RDS for Oracle DB instance.
2. Download the backups from the Amazon S3 bucket to your target DB instance by using the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3` to d. The following example downloads all of the files from an Amazon S3 bucket named *amzn-s3-demo-bucket* to the *DATA\_PUMP\_DIR* directory.

```
EXEC UTL_FILE.FREMOVE ('DATA_PUMP_DIR', 'res.txt');
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
  p_bucket_name    => 'amzn-s3-demo-bucket',
  p_directory_name => 'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The SELECT statement returns the ID of the task in a VARCHAR2 data type. For more information, see [Downloading files from an Amazon S3 bucket to an Oracle DB instance](#).

### Step 3: Import the tablespaces on your target DB instance

To restore your tablespaces to your target DB instance, use the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces`. This procedure automatically converts the data files to the correct endian format.

If you import from a platform other than Linux, specify the source platform using the parameter `p_platform_id` when you call `import_xtts_tablespaces`. Make sure that the platform ID that you specify matches the one specified in the `xtt.properties` file in [Step 2: Export tablespace metadata on your source host](#).

#### Import the tablespaces on your target DB instance

1. Start an Oracle SQL client and log in to your target RDS for Oracle DB instance as the master user.
2. Run the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces`, specifying the tablespaces to import and the directory containing the backups.

The following example imports the tablespaces *TBS1*, *TBS2*, and *TBS3* from the directory *DATA\_PUMP\_DIR*. The source platform is AIX-Based Systems (64-bit), which has the platform ID of 6. You can find the platform IDs by querying `V$TRANSPORTABLE_PLATFORM`.

```
VAR task_id CLOB

BEGIN
  :task_id:=rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces(
    'TBS1, TBS2, TBS3',
    'DATA_PUMP_DIR',
    p_platform_id => 6);
END;
/

PRINT task_id
```

3. (Optional) Monitor progress by querying the table `rdsadmin.rds_xtts_operation_info`. The `xtts_operation_state` column shows the value EXECUTING, COMPLETED, or FAILED.

```
SELECT * FROM rdsadmin.rds_xtts_operation_info;
```

**Note**

For long-running operations, you can also query `V$SESSION_LONGOPS`, `V$RMAN_STATUS`, and `V$RMAN_OUTPUT`.

4. View the log of the completed import by using the task ID from the previous step.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
'dbtask- ' || '&task_id' || '.log'));
```

Make sure that the import succeeded before continuing to the next step.

### Phase 3: Make and transfer incremental backups

In this phase, you make and transfer incremental backups periodically while the source database is active. This technique reduces the size of your final tablespace backup. If you take multiple incremental backups, you must copy the `res.txt` file after the last incremental backup before you can apply it on the target instance.

The steps are the same as in [Phase 2: Prepare the full tablespace backup](#), except that the import step is optional.

### Phase 4: Transport the tablespaces

In this phase, you back up your read-only tablespaces and export Data Pump metadata, transfer these files to your target host, and import both the tablespaces and the metadata.

#### Topics

- [Step 1: Back up your read-only tablespaces](#)
- [Step 2: Export tablespace metadata on your source host](#)
- [Step 3: \(Amazon S3 only\) Transfer the backup and export files to your target DB instance](#)
- [Step 4: Import the tablespaces on your target DB instance](#)
- [Step 5: Import tablespace metadata on your target DB instance](#)

## Step 1: Back up your read-only tablespaces

This step is identical to [Step 1: Back up the tablespaces on your source host](#), with one key difference: you place your tablespaces in read-only mode before backing up your tablespaces for the last time.

The following example places tbs1, tbs2, and tbs3 in read-only mode.

```
ALTER TABLESPACE tbs1 READ ONLY;  
ALTER TABLESPACE tbs2 READ ONLY;  
ALTER TABLESPACE tbs3 READ ONLY;
```

## Step 2: Export tablespace metadata on your source host

Export your tablespace metadata by running the expdp utility on your source host. The following example exports tablespaces *TBS1*, *TBS2*, and *TBS3* to dump file *xttdump.dmp* in directory *DATA\_PUMP\_DIR*.

```
expdp username/pwd \  
dumpfile=xttdump.dmp \  
directory=DATA_PUMP_DIR \  
statistics=NONE \  
transport_tablespaces=TBS1,TBS2,TBS3 \  
transport_full_check=y \  
logfile=tts_export.log
```

If *DATA\_PUMP\_DIR* is a shared directory in Amazon EFS, skip to [Step 4: Import the tablespaces on your target DB instance](#).

## Step 3: (Amazon S3 only) Transfer the backup and export files to your target DB instance

If you are using Amazon S3 to stage your tablespace backups and Data Pump export file, complete the following steps.

### Step 3.1: Upload the backups and dump file from your source host to your Amazon S3 bucket

Upload your backup and dump files from your source host to your Amazon S3 bucket. For more information, see [Uploading objects](#) in the *Amazon Simple Storage Service User Guide*.

### Step 3.2: Download the backups and dump file from your Amazon S3 bucket to your target DB instance

In this step, you use the procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3` to download your backups and dump file to your RDS for Oracle DB instance. Follow the steps in [Step 2.3: Download the backups from your Amazon S3 bucket to your target DB instance](#).

### Step 4: Import the tablespaces on your target DB instance

Use the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces` to restore the tablespaces. For syntax and semantics of this procedure, see [Importing transported tablespaces to your DB instance](#)

#### Important

After you complete your final tablespace import, the next step is [importing the Oracle Data Pump metadata](#). If the import fails, it's important to return your DB instance to its state before the failure. Thus, we recommend that you create a DB snapshot of your DB instance by following the instructions in [Creating a DB snapshot for a Single-AZ DB instance](#). The snapshot will contain all imported tablespaces, so if the import fails, you don't need to repeat the backup and import process.

If your target DB instance has automatic backups turned on, and Amazon RDS doesn't detect that a valid snapshot was initiated before you import the metadata, RDS attempts to create a snapshot. Depending on your instance activity, this snapshot might or might not succeed. If a valid snapshot isn't detected or a snapshot can't be initiated, the metadata import exits with errors.

### Import the tablespaces on your target DB instance

1. Start an Oracle SQL client and log in to your target RDS for Oracle DB instance as the master user.
2. Run the procedure `rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces`, specifying the tablespaces to import and the directory containing the backups.

The following example imports the tablespaces *TBS1*, *TBS2*, and *TBS3* from the directory *DATA\_PUMP\_DIR*.

```
BEGIN
```

```
:task_id:=rdsadmin.rdsadmin_transport_util.import_xtts_tablespaces('TBS1,TBS2,TBS3','DATA_
END;
/
PRINT task_id
```

3. (Optional) Monitor progress by querying the table `rdsadmin.rds_xtts_operation_info`. The `xtts_operation_state` column shows the value EXECUTING, COMPLETED, or FAILED.

```
SELECT * FROM rdsadmin.rds_xtts_operation_info;
```

**Note**

For long-running operations, you can also query `V$SESSION_LONGOPS`, `V$RMAN_STATUS`, and `V$RMAN_OUTPUT`.

4. View the log of the completed import by using the task ID from the previous step.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP',
'dbtask-||&task_id||.log'));
```

Make sure that the import succeeded before continuing to the next step.

5. Take a manual DB snapshot by following the instructions in [Creating a DB snapshot for a Single-AZ DB instance](#).

## Step 5: Import tablespace metadata on your target DB instance

In this step, you import the transportable tablespace metadata into your RDS for Oracle DB instance using the procedure

`rdsadmin.rdsadmin_transport_util.import_xtts_metadata`. For syntax and semantics of this procedure, see [Importing transportable tablespace metadata into your DB instance](#). During the operation, the status of the import is shown in the table `rdsadmin.rds_xtts_operation_info`.

**⚠ Important**

Before you import metadata, we strongly recommend that you confirm that a DB snapshot was successfully created after you imported your tablespaces. If the import step fails, restore your DB instance, address the import errors, and then attempt the import again.

**Import the Data Pump metadata into your RDS for Oracle DB instance**

1. Start your Oracle SQL client and log in to your target DB instance as the master user.
2. Create the users that own schemas in your transported tablespaces, if these users don't already exist.

```
CREATE USER tbs_owner IDENTIFIED BY password;
```

3. Import the metadata, specifying the name of the dump file and its directory location.

```
BEGIN  
  
  rdsadmin.rdsadmin_transport_util.import_xtts_metadata('xttdump.dmp', 'DATA_PUMP_DIR');  
END;  
/
```

4. (Optional) Query the transportable tablespace history table to see the status of the metadata import.

```
SELECT * FROM rdsadmin.rds_xtts_operation_info;
```

When the operation completes, your tablespaces are in read-only mode.

5. (Optional) View the log file.

The following example lists the contents of the BDUMP directory and then queries the import log.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => 'BDUMP'));  
  
SELECT * FROM TABLE(rdsadmin.rds_file_util.read_text_file(  
  p_directory => 'BDUMP',
```

```
p_filename => 'rds-xtts-  
import_xtts_metadata-2023-05-22.01-52-35.560858000.log')));
```

## Phase 5: Validate the transported tablespaces

In this optional step, you validate your transported tablespaces using the procedure `rdsadmin.rdsadmin_rman_util.validate_tablespace`, and then place your tablespaces in read/write mode.

### To validate the transported data

1. Start SQL\*Plus or SQL Developer and log in to your target DB instance as the master user.
2. Validate the tablespaces using the procedure `rdsadmin.rdsadmin_rman_util.validate_tablespace`.

```
SET SERVEROUTPUT ON  
BEGIN  
  rdsadmin.rdsadmin_rman_util.validate_tablespace(  
    p_tablespace_name      => 'TBS1',  
    p_validation_type      => 'PHYSICAL+LOGICAL',  
    p_rman_to_dbms_output => TRUE);  
  rdsadmin.rdsadmin_rman_util.validate_tablespace(  
    p_tablespace_name      => 'TBS2',  
    p_validation_type      => 'PHYSICAL+LOGICAL',  
    p_rman_to_dbms_output => TRUE);  
  rdsadmin.rdsadmin_rman_util.validate_tablespace(  
    p_tablespace_name      => 'TBS3',  
    p_validation_type      => 'PHYSICAL+LOGICAL',  
    p_rman_to_dbms_output => TRUE);  
END;  
/
```

3. Place your tablespaces in read/write mode.

```
ALTER TABLESPACE TBS1 READ WRITE;  
ALTER TABLESPACE TBS2 READ WRITE;  
ALTER TABLESPACE TBS3 READ WRITE;
```

## Phase 6: Clean up leftover files

In this optional step, you remove any unneeded files. Use the `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files` procedure to list data files that were orphaned after a tablespace import, and then use `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files` procedure to delete them. For syntax and semantics of these procedures, see [Listing orphaned files after a tablespace import](#) and [Deleting orphaned data files after a tablespace import](#).

### To clean up leftover files

1. Remove old backups in `DATA_PUMP_DIR` as follows:
  - a. List the backup files by running `rdsadmin.rdsadmin_file_util.listdir`.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory =>
'DATA_PUMP_DIR'));
```

- b. Remove the backups one by one by calling `UTL_FILE.FREMOVE`.

```
EXEC UTL_FILE.FREMOVE ('DATA_PUMP_DIR', 'backup_filename');
```

2. If you imported tablespaces but didn't import metadata for these tablespaces, you can delete the orphaned data files as follows:
  - a. List the orphaned data files that you need to delete. The following example runs the procedure `rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files`.

```
SQL> SELECT * FROM
TABLE(rdsadmin.rdsadmin_transport_util.list_xtts_orphan_files);
```

FILENAME	FILESIZE
-----	-----
datafile_7.dbf	104865792
datafile_8.dbf	104865792

- b. Delete the orphaned files by running the procedure `rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import`.

```
BEGIN
```

```
rdsadmin.rdsadmin_transport_util.cleanup_incomplete_xtts_import('DATA_PUMP_DIR');
END;
/
```

The cleanup operation generates a log file that uses the name format `rds-xtts-delete_xtts_orphaned_files-YYYY-MM-DD.HH24-MI-SS.FF.log` in the BDUMP directory.

- c. Read the log file generated in the previous step. The following example reads log `rds-xtts-delete_xtts_orphaned_files-2023-06-01.09-33-11.868894000.log`.

```
SELECT *
FROM TABLE(rdsadmin.rds_file_util.read_text_file(
    p_directory => 'BDUMP',
    p_filename => 'rds-xtts-
delete_xtts_orphaned_files-2023-06-01.09-33-11.868894000.log'));

TEXT
-----
orphan transported datafile datafile_7.dbf deleted.
orphan transported datafile datafile_8.dbf deleted.
```

3. If you imported tablespaces and imported metadata for these tablespaces, but you encountered compatibility errors or other Oracle Data Pump issues, clean up the partially transported data files as follows:
  - a. List the tablespaces that contain partially transported data files by querying `DBA_TABLESPACES`.

```
SQL> SELECT TABLESPACE_NAME FROM DBA_TABLESPACES WHERE PLUGGED_IN='YES';

TABLESPACE_NAME
-----
TBS_3
```

- b. Drop the tablespaces and the partially transported data files.

```
DROP TABLESPACE TBS_3 INCLUDING CONTENTS AND DATAFILES;
```

## Importing using Oracle Data Pump

Oracle Data Pump is a utility that allows you to export Oracle data to a dump file and import it into another Oracle database. It is a long-term replacement for the Oracle Export/Import utilities. Oracle Data Pump is the recommended way to move large amounts of data from an Oracle database to an Amazon RDS DB instance.

The examples in this section show one way to import data into an Oracle database, but Oracle Data Pump supports other techniques. For more information, see the [Oracle Database documentation](#).

The examples in this section use the DBMS\_DATAPUMP package. You can accomplish the same tasks using the Oracle Data Pump command line utilities `impdp` and `expdp`. You can install these utilities on a remote host as part of an Oracle Client installation, including Oracle Instant Client. For more information, see [How do I use Oracle Instant Client to run Data Pump Import or Export for my Amazon RDS for Oracle DB instance?](#)

### Topics

- [Overview of Oracle Data Pump](#)
- [Importing data with Oracle Data Pump and an Amazon S3 bucket](#)
- [Importing data with Oracle Data Pump and a database link](#)

## Overview of Oracle Data Pump

Oracle Data Pump is made up of the following components:

- Command-line clients `expdp` and `impdp`
- The DBMS\_DATAPUMP PL/SQL package
- The DBMS\_METADATA PL/SQL package

You can use Oracle Data Pump for the following scenarios:

- Import data from an Oracle database, either on-premises or on an Amazon EC2 instance, to an RDS for Oracle DB instance.
- Import data from an RDS for Oracle DB instance to an Oracle database, either on-premises or on an Amazon EC2 instance.
- Import data between RDS for Oracle DB instances, for example, to migrate data from EC2-Classical to VPC.

To download Oracle Data Pump utilities, see [Oracle database software downloads](#) on the Oracle Technology Network website. For compatibility considerations when migrating between versions of Oracle Database, see the [Oracle Database documentation](#).

## Oracle Data Pump workflow

Typically, you use Oracle Data Pump in the following stages:

1. Export your data into a dump file on the source database.
2. Upload your dump file to your destination RDS for Oracle DB instance. You can transfer using an Amazon S3 bucket or by using a database link between the two databases.
3. Import the data from your dump file into your RDS for Oracle DB instance.

## Oracle Data Pump best practices

When you use Oracle Data Pump to import data into an RDS for Oracle instance, we recommend the following best practices:

- Perform imports in schema or table mode to import specific schemas and objects.
- Limit the schemas you import to those required by your application.
- Don't import in full mode or import schemas for system-maintained components.

Because RDS for Oracle doesn't allow access to SYS or SYSDBA administrative users, these actions might damage the Oracle data dictionary and affect the stability of your database.

- When loading large amounts of data, do the following:
  1. Transfer the dump file to the target RDS for Oracle DB instance.
  2. Take a DB snapshot of your instance.
  3. Test the import to verify that it succeeds.

If database components are invalidated, you can delete the DB instance and re-create it from the DB snapshot. The restored DB instance includes any dump files staged on the DB instance when you took the DB snapshot.

- Don't import dump files that were created using the Oracle Data Pump export parameters `TRANSPORT_TABLESPACES`, `TRANSPORTABLE`, or `TRANSPORT_FULL_CHECK`. RDS for Oracle DB instances don't support importing these dump files.
- Don't import dump files that contain Oracle Scheduler objects in SYS, SYSTEM, RDSADMIN, RDSSEC, and RDS\_DATAGUARD, and belong to the following categories:

- Jobs
- Programs
- Schedules
- Chains
- Rules
- Evaluation contexts
- Rule sets

RDS for Oracle DB instances don't support importing these dump files.

- To exclude unsupported Oracle Scheduler objects, use additional directives during the Data Pump export. If you use DBMS\_DATAPUMP, you can add an additional METADATA\_FILTER before the DBMS\_METADATA.START\_JOB:

```
DBMS_DATAPUMP.METADATA_FILTER(
  v_hdn1,
  'EXCLUDE_NAME_EXPR',
  q'[IN (SELECT NAME FROM SYS.OBJ$
        WHERE TYPE# IN (66,67,74,79,59,62,46)
        AND OWNER# IN
          (SELECT USER# FROM SYS.USER$
           WHERE NAME IN ('RDSADMIN', 'SYS', 'SYSTEM', 'RDS_DATAGUARD', 'RDSSEC')
          )
        )
  ]',
  'PROCOBJ'
);
```

If you use expdp, create a parameter file that contains the exclude directive shown in the following example. Then use PARFILE=*parameter\_file* with your expdp command.

```
exclude=procobj:"IN
(SELECT NAME FROM sys.OBJ$
 WHERE TYPE# IN (66,67,74,79,59,62,46)
 AND OWNER# IN
  (SELECT USER# FROM SYS.USER$
   WHERE NAME IN ('RDSADMIN', 'SYS', 'SYSTEM', 'RDS_DATAGUARD', 'RDSSEC')
  )
)"
```

## Importing data with Oracle Data Pump and an Amazon S3 bucket

The following import process uses Oracle Data Pump and an Amazon S3 bucket. The steps are as follows:

1. Export data on the source database using the Oracle [DBMS\\_DATAPUMP](#) package.
2. Place the dump file in an Amazon S3 bucket.
3. Download the dump file from the Amazon S3 bucket to the DATA\_PUMP\_DIR directory on the target RDS for Oracle DB instance.
4. Import the data from the copied dump file into the RDS for Oracle DB instance using the package DBMS\_DATAPUMP.

### Topics

- [Requirements for Importing data with Oracle Data Pump and an Amazon S3 bucket](#)
- [Step 1: Grant privileges to the database user on the RDS for Oracle target DB instance](#)
- [Step 2: Export data into a dump file using DBMS\\_DATAPUMP](#)
- [Step 3: Upload the dump file to your Amazon S3 bucket](#)
- [Step 4: Download the dump file from your Amazon S3 bucket to your target DB instance](#)
- [Step 5: Import your dump file into your target DB instance using DBMS\\_DATAPUMP](#)
- [Step 6: Clean up](#)

### Requirements for Importing data with Oracle Data Pump and an Amazon S3 bucket

The process has the following requirements:

- Make sure that an Amazon S3 bucket is available for file transfers, and that the Amazon S3 bucket is in the same AWS Region as the DB instance. For instructions, see [Create a bucket](#) in the *Amazon Simple Storage Service Getting Started Guide*.
- The object that you upload into the Amazon S3 bucket must be 5 TB or less. For more information about working with objects in Amazon S3, see [Amazon Simple Storage Service User Guide](#).

**Note**

If your dump file exceeds 5 TB, you can run the Oracle Data Pump export with the parallel option. This operation spreads the data into multiple dump files so that you do not exceed the 5 TB limit for individual files.

- You must prepare the Amazon S3 bucket for Amazon RDS integration by following the instructions in [Configuring IAM permissions for RDS for Oracle integration with Amazon S3](#).
- You must ensure that you have enough storage space to store the dump file on the source instance and the target DB instance.

**Note**

This process imports a dump file into the DATA\_PUMP\_DIR directory, a preconfigured directory on all Oracle DB instances. This directory is located on the same storage volume as your data files. When you import the dump file, the existing Oracle data files use more space. Thus, you should make sure that your DB instance can accommodate that additional use of space. The imported dump file is not automatically deleted or purged from the DATA\_PUMP\_DIR directory. To remove the imported dump file, use [UTL\\_FILE.FREMOVE](#), found on the Oracle website.

**Step 1: Grant privileges to the database user on the RDS for Oracle target DB instance**

In this step, you create the schemas into which you plan to import data and grant the users necessary privileges.

**To create users and grant necessary privileges on the RDS for Oracle target instance**

1. Use SQL\*Plus or Oracle SQL Developer to log in as the master user to the RDS for Oracle DB instance into which the data will be imported. For information about connecting to a DB instance, see [Connecting to your RDS for Oracle DB instance](#).
2. Create the required tablespaces before you import the data. For more information, see [Creating and sizing tablespaces](#).

3. Create the user account and grant the necessary permissions and roles if the user account into which the data is imported doesn't exist. If you plan to import data into multiple user schemas, create each user account and grant the necessary privileges and roles to it.

For example, the following SQL statements create a new user and grant the necessary permissions and roles to import the data into the schema owned by this user. Replace *schema\_1* with the name of your schema in this step and in the following steps.

```
CREATE USER schema_1 IDENTIFIED BY my_password;  
GRANT CREATE SESSION, RESOURCE TO schema_1;  
ALTER USER schema_1 QUOTA 100M ON users;
```

#### Note

Specify a password other than the prompt shown here as a security best practice.

The preceding statements grant the new user the CREATE SESSION privilege and the RESOURCE role. You might need additional privileges and roles depending on the database objects that you import.

## Step 2: Export data into a dump file using DBMS\_DATAPUMP

To create a dump file, use the DBMS\_DATAPUMP package.

### To export Oracle data into a dump file

1. Use SQL Plus or Oracle SQL Developer to connect to the source RDS for Oracle DB instance with an administrative user. If the source database is an RDS for Oracle DB instance, connect with the Amazon RDS master user.
2. Export the data by calling DBMS\_DATAPUMP procedures.

The following script exports the *SCHEMA\_1* schema into a dump file named `sample.dmp` in the `DATA_PUMP_DIR` directory. Replace *SCHEMA\_1* with the name of the schema that you want to export.

```
DECLARE  
  v_hdn1 NUMBER;
```

```

BEGIN
  v_hdn1 := DBMS_DATAPUMP.OPEN(
    operation => 'EXPORT',
    job_mode  => 'SCHEMA',
    job_name  => null
  );
  DBMS_DATAPUMP.ADD_FILE(
    handle     => v_hdn1      ,
    filename  => 'sample.dmp' ,
    directory => 'DATA_PUMP_DIR',
    filetype  => dbms_datapump.ku$_file_type_dump_file
  );
  DBMS_DATAPUMP.ADD_FILE(
    handle     => v_hdn1,
    filename  => 'sample_exp.log',
    directory => 'DATA_PUMP_DIR' ,
    filetype  => dbms_datapump.ku$_file_type_log_file
  );
  DBMS_DATAPUMP.METADATA_FILTER(v_hdn1, 'SCHEMA_EXPR', 'IN (''SCHEMA_1'')');
  DBMS_DATAPUMP.METADATA_FILTER(
    v_hdn1,
    'EXCLUDE_NAME_EXPR',
    q'[IN (SELECT NAME FROM SYS.OBJ$
      WHERE TYPE# IN (66,67,74,79,59,62,46)
      AND OWNER# IN
        (SELECT USER# FROM SYS.USER$
          WHERE NAME IN ('RDSADMIN', 'SYS', 'SYSTEM', 'RDS_DATAGUARD', 'RDSSEC')
        )
      )
    ]',
    'PROCOBJ'
  );
  DBMS_DATAPUMP.START_JOB(v_hdn1);
END;
/

```

### Note

Data Pump starts jobs asynchronously. For information about monitoring a Data Pump job, see [Monitoring job status](#) in the Oracle documentation.

3. (Optional) View the contents of the export log by calling the `rdsadmin.rds_file_util.read_text_file` procedure. For more information, see [Reading files in a DB instance directory](#).

### Step 3: Upload the dump file to your Amazon S3 bucket

Use the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.upload_to_s3` to copy the dump file to the Amazon S3 bucket. The following example uploads all of the files from the `DATA_PUMP_DIR` directory to an Amazon S3 bucket named *amzn-s3-demo-bucket*.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
  p_bucket_name    => 'amzn-s3-demo-bucket',
  p_directory_name => 'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The SELECT statement returns the ID of the task in a VARCHAR2 data type. For more information, see [Uploading files from your RDS for Oracle DB instance to an Amazon S3 bucket](#).

### Step 4: Download the dump file from your Amazon S3 bucket to your target DB instance

Perform this step using the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3`. When you download a file to a directory, the procedure `download_from_s3` skips the download if an identically named file already exists in the directory. To remove a file from the download directory, use [UTL\\_FILE.FREMOVE](#), found on the Oracle website.

#### To download your dump file

1. Start SQL\*Plus or Oracle SQL Developer and log in as the master on your Amazon RDS target Oracle DB instance
2. Download the dump file using the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3`.

The following example downloads all files from an Amazon S3 bucket named *amzn-s3-demo-bucket* to the directory `DATA_PUMP_DIR`.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
  p_bucket_name    => 'amzn-s3-demo-bucket',
  p_directory_name => 'DATA_PUMP_DIR')
```

```
AS TASK_ID FROM DUAL;
```

The SELECT statement returns the ID of the task in a VARCHAR2 data type. For more information, see [Downloading files from an Amazon S3 bucket to an Oracle DB instance](#).

## Step 5: Import your dump file into your target DB instance using DBMS\_DATAPUMP

Use DBMS\_DATAPUMP to import the schema into your RDS for Oracle DB instance. Additional options such as METADATA\_REMAP might be required.

### To import data into your target DB instance

1. Start SQL\*Plus or SQL Developer and log in as the master user to your RDS for Oracle DB instance.
2. Import the data by calling DBMS\_DATAPUMP procedures.

The following example imports the *SCHEMA\_1* data from `sample_copied.dmp` into your target DB instance.

```
DECLARE
  v_hdn1 NUMBER;
BEGIN
  v_hdn1 := DBMS_DATAPUMP.OPEN(
    operation => 'IMPORT',
    job_mode  => 'SCHEMA',
    job_name  => null);
  DBMS_DATAPUMP.ADD_FILE(
    handle     => v_hdn1,
    filename   => 'sample_copied.dmp',
    directory  => 'DATA_PUMP_DIR',
    filetype   => dbms_datapump.ku$_file_type_dump_file);
  DBMS_DATAPUMP.ADD_FILE(
    handle     => v_hdn1,
    filename   => 'sample_imp.log',
    directory  => 'DATA_PUMP_DIR',
    filetype   => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdn1, 'SCHEMA_EXPR', 'IN (''SCHEMA_1'')');
  DBMS_DATAPUMP.START_JOB(v_hdn1);
END;
/
```

**Note**

Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see [Monitoring job status](#) in the Oracle documentation. You can view the contents of the import log by using the `rdsadmin.rds_file_util.read_text_file` procedure. For more information, see [Reading files in a DB instance directory](#).

3. Verify the data import by listing the schema tables on your target DB instance.

For example, the following query returns the number of tables for *SCHEMA\_1*.

```
SELECT COUNT(*) FROM DBA_TABLES WHERE OWNER='SCHEMA_1';
```

**Step 6: Clean up**

After the data has been imported, you can delete the files that you don't want to keep.

**To remove unneeded files**

1. Start SQL\*Plus or SQL Developer and log in as the master user to your RDS for Oracle DB instance.
2. List the files in DATA\_PUMP\_DIR using the following command.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('DATA_PUMP_DIR')) ORDER BY MTIME;
```

3. Delete files in DATA\_PUMP\_DIR that you no longer require, use the following command.

```
EXEC UTL_FILE.REMOVE('DATA_PUMP_DIR', 'filename');
```

For example, the following command deletes the file named `sample_copied.dmp`.

```
EXEC UTL_FILE.REMOVE('DATA_PUMP_DIR', 'sample_copied.dmp');
```

## Importing data with Oracle Data Pump and a database link

The following import process uses Oracle Data Pump and the Oracle [DBMS\\_FILE\\_TRANSFER](#) package. The steps are as follows:

1. Connect to a source Oracle database, which can be an on-premises database, Amazon EC2 instance, or an RDS for Oracle DB instance.
2. Export data using the [DBMS\\_DATAPUMP](#) package.
3. Use `DBMS_FILE_TRANSFER.PUT_FILE` to copy the dump file from the Oracle database to the `DATA_PUMP_DIR` directory on the target RDS for Oracle DB instance that is connected using a database link.
4. Import the data from the copied dump file into the RDS for Oracle DB instance using the `DBMS_DATAPUMP` package.

The import process using Oracle Data Pump and the `DBMS_FILE_TRANSFER` package has the following steps.

### Topics

- [Requirements for importing data with Oracle Data Pump and a database link](#)
- [Step 1: Grant privileges to the user on the RDS for Oracle target DB instance](#)
- [Step 2: Grant privileges to the user on the source database](#)
- [Step 3: Create a dump file using DBMS\\_DATAPUMP](#)
- [Step 4: Create a database link to the target DB instance](#)
- [Step 5: Copy the exported dump file to the target DB instance using DBMS\\_FILE\\_TRANSFER](#)
- [Step 6: Import the data file to the target DB instance using DBMS\\_DATAPUMP](#)
- [Step 7: Clean up](#)

### Requirements for importing data with Oracle Data Pump and a database link

The process has the following requirements:

- You must have execute privileges on the `DBMS_FILE_TRANSFER` and `DBMS_DATAPUMP` packages.
- You must have write privileges to the `DATA_PUMP_DIR` directory on the source DB instance.
- You must ensure that you have enough storage space to store the dump file on the source instance and the target DB instance.

**Note**

This process imports a dump file into the DATA\_PUMP\_DIR directory, a preconfigured directory on all Oracle DB instances. This directory is located on the same storage volume as your data files. When you import the dump file, the existing Oracle data files use more space. Thus, you should make sure that your DB instance can accommodate that additional use of space. The imported dump file is not automatically deleted or purged from the DATA\_PUMP\_DIR directory. To remove the imported dump file, use [UTL\\_FILE.FREMOVE](#), found on the Oracle website.

**Step 1: Grant privileges to the user on the RDS for Oracle target DB instance**

To grant privileges to the user on the RDS for Oracle target DB instance, take the following steps:

1. Use SQL Plus or Oracle SQL Developer to connect to the RDS for Oracle DB instance into which you intend to import the data. Connect as the Amazon RDS master user. For information about connecting to the DB instance, see [Connecting to your RDS for Oracle DB instance](#).
2. Create the required tablespaces before you import the data. For more information, see [Creating and sizing tablespaces](#).
3. If the user account into which the data is imported doesn't exist, create the user account and grant the necessary permissions and roles. If you plan to import data into multiple user schemas, create each user account and grant the necessary privileges and roles to it.

For example, the following commands create a new user named *schema\_1* and grant the necessary permissions and roles to import the data into the schema for this user.

```
CREATE USER schema_1 IDENTIFIED BY my-password;  
GRANT CREATE SESSION, RESOURCE TO schema_1;  
ALTER USER schema_1 QUOTA 100M ON users;
```

**Note**

Specify a password other than the prompt shown here as a security best practice.

The preceding example grants the new user the CREATE SESSION privilege and the RESOURCE role. Additional privileges and roles might be required depending on the database objects that you import.

**Note**

Replace *schema\_1* with the name of your schema in this step and in the following steps.

**Step 2: Grant privileges to the user on the source database**

Use SQL\*Plus or Oracle SQL Developer to connect to the RDS for Oracle DB instance that contains the data to be imported. If necessary, create a user account and grant the necessary permissions.

**Note**

If the source database is an Amazon RDS instance, you can skip this step. You use your Amazon RDS master user account to perform the export.

The following commands create a new user and grant the necessary permissions.

```
CREATE USER export_user IDENTIFIED BY my-password;  
GRANT CREATE SESSION, CREATE TABLE, CREATE DATABASE LINK TO export_user;  
ALTER USER export_user QUOTA 100M ON users;  
GRANT READ, WRITE ON DIRECTORY data_pump_dir TO export_user;  
GRANT SELECT_CATALOG_ROLE TO export_user;  
GRANT EXECUTE ON DBMS_DATAPUMP TO export_user;  
GRANT EXECUTE ON DBMS_FILE_TRANSFER TO export_user;
```

**Note**

Specify a password other than the prompt shown here as a security best practice.

**Step 3: Create a dump file using DBMS\_DATAPUMP**

To create a dump file, do the following:

1. Use SQL\*Plus or Oracle SQL Developer to connect to the source Oracle instance with an administrative user or with the user you created in step 2. If the source database is an Amazon RDS for Oracle DB instance, connect with the Amazon RDS master user.
2. Create a dump file using the Oracle Data Pump utility.

The following script creates a dump file named *sample.dmp* in the DATA\_PUMP\_DIR directory.

```

DECLARE
  v_hdn1 NUMBER;
BEGIN
  v_hdn1 := DBMS_DATAPUMP.OPEN(
    operation => 'EXPORT' ,
    job_mode  => 'SCHEMA' ,
    job_name  => null
  );
  DBMS_DATAPUMP.ADD_FILE(
    handle     => v_hdn1,
    filename  => 'sample.dmp' ,
    directory => 'DATA_PUMP_DIR' ,
    filetype  => dbms_datapump.ku$_file_type_dump_file
  );
  DBMS_DATAPUMP.ADD_FILE(
    handle     => v_hdn1 ,
    filename  => 'sample_exp.log' ,
    directory => 'DATA_PUMP_DIR' ,
    filetype  => dbms_datapump.ku$_file_type_log_file
  );
  DBMS_DATAPUMP.METADATA_FILTER(
    v_hdn1 ,
    'SCHEMA_EXPR' ,
    'IN (''SCHEMA_1'')'
  );
  DBMS_DATAPUMP.METADATA_FILTER(
    v_hdn1,
    'EXCLUDE_NAME_EXPR',
    q'[IN (SELECT NAME FROM sys.OBJ$
          WHERE TYPE# IN (66,67,74,79,59,62,46)
          AND OWNER# IN
            (SELECT USER# FROM SYS.USER$
             WHERE NAME IN ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC')
            )
          )
    ]',

```

```
'PROCOBJ'  
);  
DBMS_DATAPUMP.START_JOB(v_hdn1);  
END;  
/
```

**Note**

Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see [Monitoring job status](#) in the Oracle documentation. You can view the contents of the export log by using the `rdsadmin.rds_file_util.read_text_file` procedure. For more information, see [Reading files in a DB instance directory](#).

#### Step 4: Create a database link to the target DB instance

Create a database link between your source DB instance and your target DB instance. Your local Oracle instance must have network connectivity to the DB instance in order to create a database link and to transfer your export dump file.

Perform this step connected with the same user account as the previous step.

If you are creating a database link between two DB instances inside the same VPC or peered VPCs, the two DB instances should have a valid route between them. The security group of each DB instance must allow ingress to and egress from the other DB instance. The security group inbound and outbound rules can refer to security groups from the same VPC or a peered VPC. For more information, see [Adjusting database links for use with DB instances in a VPC](#).

The following command creates a database link named `to_rds` that connects to the Amazon RDS master user at the target DB instance.

```
CREATE DATABASE LINK to_rds  
CONNECT TO <master_user_account> IDENTIFIED BY <password>  
USING '(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=<dns or ip address of remote db>)  
(PORT=<listener port>))(CONNECT_DATA=(SID=<remote SID>)))';
```

## Step 5: Copy the exported dump file to the target DB instance using DBMS\_FILE\_TRANSFER

Use DBMS\_FILE\_TRANSFER to copy the dump file from the source database instance to the target DB instance. The following script copies a dump file named `sample.dmp` from the source instance to a target database link named `to_rds` (created in the previous step).

```
BEGIN
  DBMS_FILE_TRANSFER.PUT_FILE(
    source_directory_object    => 'DATA_PUMP_DIR',
    source_file_name           => 'sample.dmp',
    destination_directory_object => 'DATA_PUMP_DIR',
    destination_file_name      => 'sample_copied.dmp',
    destination_database       => 'to_rds' );
END;
/
```

## Step 6: Import the data file to the target DB instance using DBMS\_DATAPUMP

Use Oracle Data Pump to import the schema in the DB instance. Additional options such as METADATA\_REMAP might be required.

Connect to the DB instance with the Amazon RDS master user account to perform the import.

```
DECLARE
  v_hdn1 NUMBER;
BEGIN
  v_hdn1 := DBMS_DATAPUMP.OPEN(
    operation => 'IMPORT',
    job_mode  => 'SCHEMA',
    job_name  => null);
  DBMS_DATAPUMP.ADD_FILE(
    handle     => v_hdn1,
    filename   => 'sample_copied.dmp',
    directory  => 'DATA_PUMP_DIR',
    filetype   => dbms_datapump.ku$_file_type_dump_file );
  DBMS_DATAPUMP.ADD_FILE(
    handle     => v_hdn1,
    filename   => 'sample_imp.log',
    directory  => 'DATA_PUMP_DIR',
    filetype   => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdn1, 'SCHEMA_EXPR', 'IN (''SCHEMA_1'')');
  DBMS_DATAPUMP.START_JOB(v_hdn1);
```

```
END;  
/
```

**Note**

Data Pump jobs are started asynchronously. For information about monitoring a Data Pump job, see [Monitoring job status](#) in the Oracle documentation. You can view the contents of the import log by using the `rdsadmin.rds_file_util.read_text_file` procedure. For more information, see [Reading files in a DB instance directory](#).

You can verify the data import by viewing the user's tables on the DB instance. For example, the following query returns the number of tables for *schema\_1*.

```
SELECT COUNT(*) FROM DBA_TABLES WHERE OWNER='SCHEMA_1';
```

**Step 7: Clean up**

After the data has been imported, you can delete the files that you don't want to keep. You can list the files in `DATA_PUMP_DIR` using the following command.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('DATA_PUMP_DIR')) ORDER BY MTIME;
```

To delete files in `DATA_PUMP_DIR` that you no longer require, use the following command.

```
EXEC UTL_FILE.REMOVE('DATA_PUMP_DIR', '<file name>');
```

For example, the following command deletes the file named "sample\_copied.dmp".

```
EXEC UTL_FILE.REMOVE('DATA_PUMP_DIR', 'sample_copied.dmp');
```

## Importing using Oracle Export/Import

You might consider Oracle Export/Import utilities for migrations in the following conditions:

- Your data size is small.
- Data types such as binary float and double aren't required.

The import process creates the necessary schema objects. Thus, you don't need to run a script to create the objects beforehand.

The easiest way to install the Oracle the export and import utilities is to install the Oracle Instant Client. To download the software, go to <https://www.oracle.com/database/technologies/instant-client.html>. For documentation, see [Instant Client for SQL\\*Loader, Export, and Import](#) in the *Oracle Database Utilities* manual.

## To export tables and then import them

1. Export the tables from the source database using the exp command.

The following command exports the tables named tab1, tab2, and tab3. The dump file is exp\_file.dmp.

```
exp cust_dba@ORCL FILE=exp_file.dmp TABLES=(tab1,tab2,tab3) LOG=exp_file.log
```

The export creates a binary dump file that contains both the schema and data for the specified tables.

2. Import the schema and data into a target database using the imp command.

The following command imports the tables tab1, tab2, and tab3 from dump file exp\_file.dmp.

```
imp cust_dba@targetdb FROMUSER=cust_schema TOUSER=cust_schema \  
TABLES=(tab1,tab2,tab3) FILE=exp_file.dmp LOG=imp_file.log
```

Export and Import have other variations that might be better suited to your requirements. See the Oracle Database documentation for full details.

## Importing using Oracle SQL\*Loader

You might consider Oracle SQL\*Loader for large databases that contain a limited number of objects. Because the process of exporting from a source database and loading to a target database is specific to the schema, the following example creates the sample schema objects, exports from a source, and then loads the data into a target database.

The easiest way to install Oracle SQL\*Loader is to install the Oracle Instant Client. To download the software, go to <https://www.oracle.com/database/technologies/instant-client.html>. For

documentation, see [Instant Client for SQL\\*Loader, Export, and Import](#) in the *Oracle Database Utilities* manual.

## To import data using Oracle SQL\*Loader

1. Create a sample source table using the following SQL statement.

```
CREATE TABLE customer_0 TABLESPACE users
AS (SELECT ROWNUM id, o.*
FROM ALL_OBJECTS o, ALL_OBJECTS x
WHERE ROWNUM <= 1000000);
```

2. On the target RDS for Oracle DB instance, create a destination table for loading the data. The clause `WHERE 1=2` ensures that you copy the structure of `ALL_OBJECTS`, but don't copy any rows.

```
CREATE TABLE customer_1 TABLESPACE users
AS (SELECT 0 AS ID, OWNER, OBJECT_NAME, CREATED
FROM ALL_OBJECTS
WHERE 1=2);
```

3. Export the data from the source database to a text file. The following example uses SQL\*Plus. For your data, you will likely need to generate a script that does the export for all the objects in the database.

```
ALTER SESSION SET NLS_DATE_FORMAT = 'YYYY/MM/DD HH24:MI:SS'

SET LINESIZE 800 HEADING OFF FEEDBACK OFF ARRAY 5000 PAGESIZE 0
SPOOL customer_0.out
SET MARKUP HTML PREFORMAT ON
SET COLSEP ','

SELECT id, owner, object_name, created
FROM customer_0;

SPOOL OFF
```

4. Create a control file to describe the data. You might need to write a script to perform this step.

```
cat << EOF > sqlldr_1ctl
load data
infile customer_0.out
```

```
into table customer_1
APPEND
fields terminated by "," optionally enclosed by '"'
(
  id          POSITION(01:10)    INTEGER EXTERNAL,
  owner       POSITION(12:41)    CHAR,
  object_name POSITION(43:72)    CHAR,
  created     POSITION(74:92)    date "YYYY/MM/DD HH24:MI:SS"
)
```

If needed, copy the files generated by the preceding code to a staging area, such as an Amazon EC2 instance.

5. Import the data using SQL\*Loader with the appropriate user name and password for the target database.

```
sqlldr cust_dba@targetdb CONTROL=sqlldr_1.ct1 BINDSIZE=10485760 READSIZE=10485760
ROWS=1000
```

## Migrating with Oracle materialized views

To migrate large datasets efficiently, you can use Oracle materialized view replication. With replication, you can keep the target tables synchronized with the source tables. Thus, you can switch over to Amazon RDS later, if needed.

Before you can migrate using materialized views, make sure that you meet the following requirements:

- Configure access from the target database to the source database. In the following example, access rules were enabled on the source database to allow the RDS for Oracle target database to connect to the source over SQL\*Net.
- Create a database link from the RDS for Oracle DB instance to the source database.

### To migrate data using materialized views

1. Create a user account on both source and RDS for Oracle target instances that can authenticate with the same password. The following example creates a user named `dblink_user`.

```
CREATE USER dblink_user IDENTIFIED BY my-password
  DEFAULT TABLESPACE users
  TEMPORARY TABLESPACE temp;

GRANT CREATE SESSION TO dblink_user;

GRANT SELECT ANY TABLE TO dblink_user;

GRANT SELECT ANY DICTIONARY TO dblink_user;
```

**Note**

Specify a password other than the prompt shown here as a security best practice.

2. Create a database link from the RDS for Oracle target instance to the source instance using your newly created user.

```
CREATE DATABASE LINK remote_site
  CONNECT TO dblink_user IDENTIFIED BY my-password
  USING '(description=(address=(protocol=tcp) (host=my-host)
    (port=my-listener-port)) (connect_data=(sid=my-source-db-sid)))';
```

**Note**

Specify a password other than the prompt shown here as a security best practice.

3. Test the link:

```
SELECT * FROM V$INSTANCE@remote_site;
```

4. Create a sample table with primary key and materialized view log on the source instance.

```
CREATE TABLE customer_0 TABLESPACE users
  AS (SELECT ROWNUM id, o.*
    FROM ALL_OBJECTS o, ALL_OBJECTS x
    WHERE ROWNUM <= 1000000);

ALTER TABLE customer_0 ADD CONSTRAINT pk_customer_0 PRIMARY KEY (id) USING INDEX;
```

```
CREATE MATERIALIZED VIEW LOG ON customer_0;
```

5. On the target RDS for Oracle DB instance, create a materialized view.

```
CREATE MATERIALIZED VIEW customer_0  
  BUILD IMMEDIATE REFRESH FAST  
  AS (SELECT *  
       FROM cust_dba.customer_0@remote_site);
```

6. On the target RDS for Oracle DB instance, refresh the materialized view.

```
EXEC DBMS_MVIEW.REFRESH('CUSTOMER_0', 'f');
```

7. Drop the materialized view and include the `PRESERVE TABLE` clause to retain the materialized view container table and its contents.

```
DROP MATERIALIZED VIEW customer_0 PRESERVE TABLE;
```

The retained table has the same name as the dropped materialized view.

# Working with read replicas for Amazon RDS for Oracle

To configure replication between Oracle DB instances, you can create replica databases. For an overview of Amazon RDS read replicas, see [Overview of Amazon RDS read replicas](#). For a summary of the differences between Oracle replicas and other DB engines, see [Differences among read replicas for DB engines](#).

## Topics

- [Overview of RDS for Oracle replicas](#)
- [Requirements and considerations for RDS for Oracle replicas](#)
- [Preparing to create an Oracle replica](#)
- [Creating an RDS for Oracle replica in mounted mode](#)
- [Modifying the RDS for Oracle replica mode](#)
- [Working with RDS for Oracle replica backups](#)
- [Performing an Oracle Data Guard switchover](#)
- [Troubleshooting RDS for Oracle replicas](#)

## Overview of RDS for Oracle replicas

An *Oracle replica* database is a physical copy of your primary database. An Oracle replica in read-only mode is called a *read replica*. An Oracle replica in mounted mode is called a *mounted replica*. Oracle Database doesn't permit writes in a replica, but you can promote a replica to make it writable. The promoted read replica has the replicated data to the point when the request was made to promote it.

The following video provides a helpful overview of RDS for Oracle disaster recovery.

For more information, see the blog post [Managed disaster recovery with Amazon RDS for Oracle cross-Region automated backups - Part 1](#) and [Managed disaster recovery with Amazon RDS for Oracle cross-Region automated backups - Part 2](#).

## Topics

- [Read-only and mounted replicas](#)
- [Read replicas of CDBs](#)

- [Archived redo log retention](#)
- [Outages during Oracle replication](#)

## Read-only and mounted replicas

When creating or modifying an Oracle replica, you can place it in either of the following modes:

### Read-only

This is the default. Active Data Guard transmits and applies changes from the source database to all read replica databases.

You can create up to five read replicas from one source DB instance. For general information about read replicas that applies to all DB engines, see [Working with DB instance read replicas](#). For information about Oracle Data Guard, see [Oracle Data Guard concepts and administration](#) in the Oracle documentation.

### Mounted

In this case, replication uses Oracle Data Guard, but the replica database doesn't accept user connections. The primary use for mounted replicas is cross-Region disaster recovery.

A mounted replica can't serve a read-only workload. The mounted replica deletes archived redo log files after it applies them, regardless of the archived log retention policy.

You can create a combination of mounted and read-only DB replicas for the same source DB instance. You can change a read-only replica to mounted mode, or change a mounted replica to read-only mode. In either case, the Oracle database preserves the archived log retention setting.

## Read replicas of CDBs

RDS for Oracle supports Data Guard read replicas for Oracle Database 19c and 21c CDBs in the single-tenant configuration only. You can create, manage, and promote read replicas in a CDB just as you can in a non-CDB. Mounted replicas are also supported. You get the following benefits:

- Managed disaster recovery, high availability, and read-only access to your replicas
- The ability to create read replicas in a different AWS Region.
- Integration with the existing RDS read replica APIs: [CreateDBInstanceReadReplica](#), [PromoteReadReplica](#), and [SwitchoverReadReplica](#)

To use this feature, you need an Active Data Guard license and an Oracle Database Enterprise Edition license for both the replica and primary DB instances. There are no additional costs related to using CDB architecture. You pay only for your DB instances.

For more information about the single-tenant and multi-tenant configurations of the CDB architecture, see [Overview of RDS for Oracle CDBs](#).

## Archived redo log retention

If a primary DB instance has no cross-Region read replicas, Amazon RDS for Oracle keeps a minimum of two hours of archived redo logs on the source DB instance.

This is true regardless of the setting for `archive_log_retention_hours` in `rdsadmin.rdsadmin_util.set_configuration`.

RDS purges logs from the source DB instance after two hours or after the archive log retention hours setting has passed, whichever is longer. RDS purges logs from the read replica after the archive log retention hours setting has passed only if they have been successfully applied to the database.

In some cases, a primary DB instance might have one or more cross-Region read replicas. If so, Amazon RDS for Oracle keeps the transaction logs on the source DB instance until they have been transmitted and applied to all cross-Region read replicas. For information about `rdsadmin.rdsadmin_util.set_configuration`, see [Retaining archived redo logs](#).

## Outages during Oracle replication

When you create a read replica, Amazon RDS takes a DB snapshot of your source DB instance and begins replication. The source DB instance experiences a very brief I/O suspension when the DB snapshot operation begins. The I/O suspension typically lasts about one second. You can avoid the I/O suspension if the source DB instance is a Multi-AZ deployment, because in that case the snapshot is taken from the secondary DB instance.

The DB snapshot becomes the Oracle replica. Amazon RDS sets the necessary parameters and permissions for the source database and replica without service interruption. Similarly, if you delete a replica, no outage occurs.

## Requirements and considerations for RDS for Oracle replicas

Before creating an Oracle replica, familiarize yourself with the following requirements and considerations.

## Topics

- [Version and licensing requirements for RDS for Oracle replicas](#)
- [Option group limitations for RDS for Oracle replicas](#)
- [Backup and restore considerations for RDS for Oracle replicas](#)
- [Oracle Data Guard requirements and limitations for RDS for Oracle replicas](#)
- [Miscellaneous considerations for RDS for Oracle replicas](#)

## Version and licensing requirements for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following:

- If the replica is in read-only mode, make sure that you have an Active Data Guard license. If you place the replica in mounted mode, you don't need an Active Data Guard license. Only the Oracle DB engine supports mounted replicas.
- Oracle replicas are supported only for Oracle Enterprise Edition (EE).
- Oracle replicas of non-CDBs are supported only for DB instances created using non-CDB instances running Oracle Database 19c.
- Oracle replicas are available for DB instances running only on DB instance classes with two or more vCPUs. A source DB instance can't use the db.t3.small instance class.
- The Oracle DB engine version of the source DB instance and all its replicas must be the same. Amazon RDS upgrades the replicas immediately after upgrading the source DB instance, regardless of a replica's maintenance window. For major version upgrades of cross-Region replicas, Amazon RDS automatically does the following:
  - Generates an option group for the target version.
  - Copies all options and option settings from the original option group to the new option group.
  - Associates the upgraded cross-Region replica with the new option group.

For more information about upgrading the DB engine version, see [Upgrading the RDS for Oracle DB engine](#).

## Option group limitations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following:

- If your Oracle replica is in the same AWS Region as its source DB instance, the replica can't use a different option group from the source DB instance. Modifications to the source option group or source option group membership propagate to Oracle replicas. These changes are applied to the replicas immediately after they are applied to the source DB instance, regardless of the replica's maintenance window.

For more information about option groups, see [Working with option groups](#).

- You can't remove an RDS for Oracle cross-Region replica from its dedicated option group, which is automatically created for the replica.
- You can't add the dedicated option group for an RDS for Oracle cross-Region replica to a different DB instance.
- You can only add or remove the following nonreplicated options from a dedicated option group for an RDS for Oracle cross-Region replica:
  - NATIVE\_NETWORK\_ENCRYPTION
  - OEM
  - OEM\_AGENT
  - SSL

To add other options to an RDS for Oracle cross-Region replica, add them to the source DB instance's option group. The option is also installed on all of the source DB instance's replicas. For licensed options, make sure that there are sufficient licenses for the replicas.

When you promote an RDS for Oracle cross-Region replica, the promoted replica behaves the same as other Oracle DB instances, including the management of its options. You can promote a replica explicitly or implicitly by deleting its source DB instance.

For more information about option groups, see [Working with option groups](#).

- The EFS\_INTEGRATION option isn't supported for RDS for Oracle cross-Region replicas.

## Backup and restore considerations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following:

- To create snapshots of RDS for Oracle replicas or turn on automatic backups, make sure to set the backup retention period manually. Automatic backups aren't turned on by default.

- When you restore a replica backup, you restore to the database time, not the time that the backup was taken. The *database time* refers to the latest applied transaction time of the data in the backup. The difference is significant because a replica can lag behind the primary for minutes or hours.

To find the difference, use the `describe-db-snapshots` command. Compare the `snapshotDatabaseTime`, which is the database time of the replica backup, and the `OriginalSnapshotCreateTime` field, which is the latest applied transaction on the primary database.

## Oracle Data Guard requirements and limitations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, note the following requirements and limitations:

- If your primary DB instance uses the single-tenant configuration of the multitenant architecture, consider the following:
  - You must use Oracle Database 19c or higher with the Enterprise Edition.
  - Your primary CDB instance must be in an ACTIVE lifecycle.
  - You can't convert a non-CDB primary instance to a CDB instance and convert its replicas in the same operation. Instead, delete the non-CDB replicas, convert the primary DB instance to a CDB, and then create new replicas
- Make sure that a logon trigger on a primary DB instance permits access to the RDS\_DATAGUARD user and to any user whose AUTHENTICATED\_IDENTITY value is RDS\_DATAGUARD or rdsdb. Also, the trigger must not set the current schema for the RDS\_DATAGUARD user.
- To avoid blocking connections from the Data Guard broker process, don't enable restricted sessions. For more information about restricted sessions, see [Enabling and disabling restricted sessions](#).

## Miscellaneous considerations for RDS for Oracle replicas

Before you create an RDS for Oracle replica, consider the following:

- If your DB instance is a source for one or more cross-Region replicas, the source DB retains its archived redo log files until they are applied on all cross-Region replicas. The archived redo logs might result in increased storage consumption.

- To avoid disrupting RDS automation, system triggers must permit specific users to log on to the primary and replica database. [System triggers](#) include DDL, logon, and database role triggers. We recommend that you add code to your triggers to exclude the users listed in the following sample code:

```
-- Determine who the user is
SELECT SYS_CONTEXT('USERENV','AUTHENTICATED_IDENTITY') INTO CURRENT_USER FROM DUAL;
-- The following users should always be able to login to either the Primary or
  Replica
IF CURRENT_USER IN ('master_user', 'SYS', 'SYSTEM', 'RDS_DATAGUARD', 'rdsdb') THEN
RETURN;
END IF;
```

- Block change tracking is supported for read-only replicas, but not for mounted replicas. You can change a mounted replica to a read-only replica, and then enable block change tracking. For more information, see [Enabling and disabling block change tracking](#).

## Preparing to create an Oracle replica

Before you can begin using your replica, perform the following tasks.

### Topics

- [Enabling automatic backups](#)
- [Enabling force logging mode](#)
- [Changing your logging configuration](#)
- [Setting the MAX\\_STRING\\_SIZE parameter](#)
- [Planning compute and storage resources](#)

### Enabling automatic backups

Before a DB instance can serve as a source DB instance, make sure to enable automatic backups on the source DB instance. To learn how to perform this procedure, see [Enabling automated backups](#).

### Enabling force logging mode

We recommend that you enable force logging mode. In force logging mode, the Oracle database writes redo records even when NOLOGGING is used with data definition language (DDL) statements.

## To enable force logging mode

1. Log in to your Oracle database using a client tool such as SQL Developer.
2. Enable force logging mode by running the following procedure.

```
exec rdsadmin.rdsadmin_util.force_logging(p_enable => true);
```

For more information about this procedure, see [Setting force logging](#).

## Changing your logging configuration

For  $n$  online redo logs of size  $m$ , RDS automatically creates  $n+1$  standby logs of size  $m$  on the primary DB instance and all replicas. Whenever you change the logging configuration on the primary, the changes propagate automatically to the replicas.

If you change your logging configuration, consider the following guidelines:

- We recommend that you complete the changes before making a DB instance the source for replicas. RDS for Oracle also supports updating the instance after it becomes a source.
- Before you change the logging configuration on the primary DB instance, check that each replica has enough storage to accommodate the new configuration.

You can modify the logging configuration for a DB instance by using the Amazon RDS procedures `rdsadmin.rdsadmin_util.add_logfile` and `rdsadmin.rdsadmin_util.drop_logfile`. For more information, see [Adding online redo logs](#) and [Dropping online redo logs](#).

## Setting the MAX\_STRING\_SIZE parameter

Before you create an Oracle replica, ensure that the setting of the `MAX_STRING_SIZE` parameter is the same on the source DB instance and the replica. You can do this by associating them with the same parameter group. If you have different parameter groups for the source and the replica, you can set `MAX_STRING_SIZE` to the same value. For more information about setting this parameter, see [Turning on extended data types for a new DB instance](#).

## Planning compute and storage resources

Ensure that the source DB instance and its replicas are sized properly, in terms of compute and storage, to suit their operational load. If a replica reaches compute, network, or storage resource

capacity, the replica stops receiving or applying changes from its source. Amazon RDS for Oracle doesn't intervene to mitigate high replica lag between a source DB instance and its replicas. You can modify the storage and CPU resources of a replica independently from its source and other replicas.

## Creating an RDS for Oracle replica in mounted mode

By default, Oracle replicas are read-only. To create a replica in mounted mode, use the console, the AWS CLI, or the RDS API.

### Console

#### To create a mounted replica from a source Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the Oracle DB instance that you want to use as the source for a mounted replica.
4. For **Actions**, choose **Create replica**.
5. For **Replica mode**, choose **Mounted**.
6. Choose the settings that you want to use. For **DB instance identifier**, enter a name for the read replica. Adjust other settings as needed.
7. For **Regions**, choose the Region where the mounted replica will be launched.
8. Choose your instance size and storage type. We recommend that you use the same DB instance class and storage type as the source DB instance for the read replica.
9. For **Multi-AZ deployment**, choose **Create a standby instance** to create a standby of your replica in another Availability Zone for failover support for the mounted replica. Creating your mounted replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.
10. Choose the other settings that you want to use.
11. Choose **Create replica**.

In the **Databases** page, the mounted replica has the role **Replica**.

## AWS CLI

To create an Oracle replica in mounted mode, set `--replica-mode` to `mounted` in the AWS CLI command [create-db-instance-read-replica](#).

### Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \  
  --db-instance-identifier myreadreplica \  
  --source-db-instance-identifier mydbinstance \  
  --replica-mode mounted
```

For Windows:

```
aws rds create-db-instance-read-replica ^  
  --db-instance-identifier myreadreplica ^  
  --source-db-instance-identifier mydbinstance ^  
  --replica-mode mounted
```

To change a read-only replica to a mounted state, set `--replica-mode` to `mounted` in the AWS CLI command [modify-db-instance](#). To place a mounted replica in read-only mode, set `--replica-mode` to `open-read-only`.

## RDS API

To create an Oracle replica in mounted mode, specify `ReplicaMode=mounted` in the RDS API operation [CreateDBInstanceReadReplica](#).

## Modifying the RDS for Oracle replica mode

To change the replica mode of an existing replica, use the console, AWS CLI, or RDS API. When you change to mounted mode, the replica disconnects all active connections. When you change to read-only mode, Amazon RDS initializes Active Data Guard.

The change operation can take a few minutes. During the operation, the DB instance status changes to **modifying**. For more information about status changes, see [Viewing Amazon RDS DB instance status](#).

## Console

### To change the replica mode of an Oracle replica from mounted to read-only

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the mounted replica database.
4. Choose **Modify**.
5. For **Replica mode**, choose **Read-only**.
6. Choose the other settings that you want to change.
7. Choose **Continue**.
8. For **Scheduling of modifications**, choose **Apply immediately**.
9. Choose **Modify DB instance**.

## AWS CLI

To change a read replica to mounted mode, set `--replica-mode` to `mounted` in the AWS CLI command [modify-db-instance](#). To change a mounted replica to read-only mode, set `--replica-mode` to `open-read-only`.

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier myreadreplica \  
  --replica-mode mode
```

For Windows:

```
aws rds modify-db-instance ^  
  --db-instance-identifier myreadreplica ^  
  --replica-mode mode
```

## RDS API

To change a read-only replica to mounted mode, set `ReplicaMode=mounted` in [ModifyDBInstance](#). To change a mounted replica to read-only mode, set `ReplicaMode=read-only`.

## Working with RDS for Oracle replica backups

You can create and restore backups of an RDS for Oracle replica. Both automatic backups and manual snapshots are supported. For more information, see [Backing up, restoring, and exporting data](#). The following sections describe the key differences between managing backups of a primary and an RDS for Oracle replica.

### Turning on RDS for Oracle replica backups

An Oracle replica doesn't have automated backups turned on by default. You turn on automated backups by setting the backup retention period to a positive nonzero value.

### Console

#### To enable automated backups immediately

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance or Multi-AZ DB cluster that you want to modify.
3. Choose **Modify**.
4. For **Backup retention period**, choose a positive nonzero value, for example 3 days.
5. Choose **Continue**.
6. Choose **Apply immediately**.
7. Choose **Modify DB instance** or **Modify cluster** to save your changes and enable automated backups.

### AWS CLI

To enable automated backups, use the AWS CLI [modify-db-instance](#) or [modify-db-cluster](#) command.

Include the following parameters:

- `--db-instance-identifier` (or `--db-cluster-identifier` for a Multi-AZ DB cluster)
- `--backup-retention-period`
- `--apply-immediately` or `--no-apply-immediately`

In the following example, we enable automated backups by setting the backup retention period to three days. The changes are applied immediately.

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier mydbinstance \  
  --backup-retention-period 3 \  
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^  
  --db-instance-identifier mydbinstance ^  
  --backup-retention-period 3 ^  
  --apply-immediately
```

### RDS API

To enable automated backups, use the RDS API [ModifyDBInstance](#) or [ModifyDBCluster](#) operation with the following required parameters:

- `DBInstanceIdentifier` or `DBClusterIdentifier`
- `BackupRetentionPeriod`

### Restoring an RDS for Oracle replica backup

You can restore an Oracle replica backup just as you can restore a backup of the primary instance. For more information, see the following:

- [Restoring to a DB instance](#)

- [Restoring a DB instance to a specified time](#)

The main consideration when you restore a replica backup is determining the point in time to which you are restoring. The *database time* refers to the latest applied transaction time of the data in the backup. When you restore a replica backup, you restore to the database time, not the time when the backup completed. The difference is significant because an RDS for Oracle replica can lag behind the primary by minutes or hours. Thus, the database time of a replica backup, and thus the point in time to which you restore it, might be much earlier than the backup creation time.

To find the difference between database time and creation time, use the `describe-db-snapshots` command. Compare the `SnapshotDatabaseTime`, which is the database time of the replica backup, and the `OriginalSnapshotCreateTime` field, which is the latest applied transaction on the primary database. The following example shows the difference between the two times:

```
aws rds describe-db-snapshots \
  --db-instance-identifier my-oracle-replica
  --db-snapshot-identifier my-replica-snapshot

{
  "DBSnapshots": [
    {
      "DBSnapshotIdentifier": "my-replica-snapshot",
      "DBInstanceIdentifier": "my-oracle-replica",
      "SnapshotDatabaseTime": "2022-07-26T17:49:44Z",
      ...
      "OriginalSnapshotCreateTime": "2021-07-26T19:49:44Z"
    }
  ]
}
```

## Performing an Oracle Data Guard switchover

A *switchover* is a role reversal between a primary database and a standby database. During a switchover, the original primary database transitions to a standby role, while the original standby database transitions to the primary role.

In an Oracle Data Guard environment, a primary database supports one or more standby databases. You can perform a managed, switchover-based role transition from a primary database

to a standby database. A *switchover* is a role reversal between a primary database and a standby database. During a switchover, the original primary database transitions to a standby role, while the original standby database transitions to the primary role.

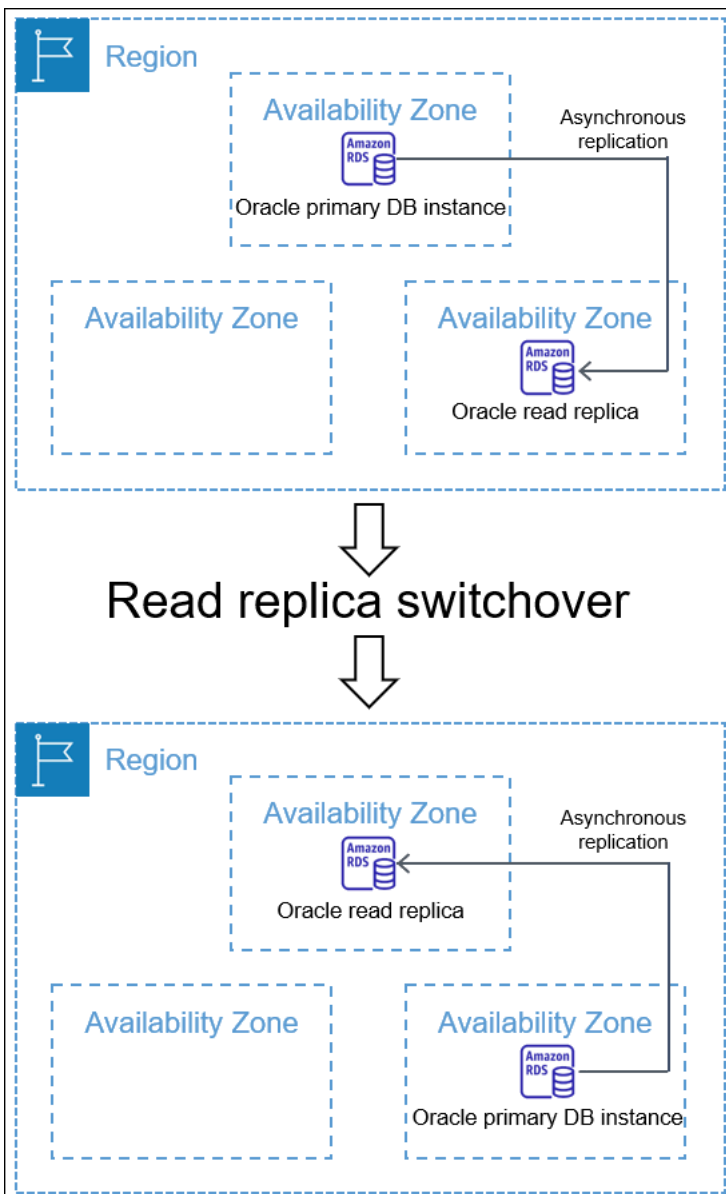

## Topics

- [Overview of Oracle Data Guard switchover](#)
- [Requirements for the Oracle Data Guard switchover](#)
- [Initiating the Oracle Data Guard switchover](#)
- [Monitoring the Oracle Data Guard switchover](#)

## Overview of Oracle Data Guard switchover

Amazon RDS supports a fully managed, switchover-based role transition for Oracle Database replicas. You can only initiate a switchover to a standby database that is mounted or open read-only.

The replicas can reside in separate AWS Regions or in different Availability Zones (AZs) of a single Region. All AWS Regions are supported.

A switchover differs from a read replica promotion. In a switchover, the source and replica DB instances change roles. In a promotion, a read replica becomes a source DB instance, but the source DB instance doesn't become a replica. For more information, see [Promoting a read replica to be a standalone DB instance](#).

## Topics

- [Benefits of Oracle Data Guard switchover](#)
- [Supported Oracle Database versions](#)
- [Cost of Oracle Data Guard switchover](#)
- [How Oracle Data Guard switchover works](#)

## Benefits of Oracle Data Guard switchover

Just as for RDS for Oracle read replicas, a managed switchover relies on Oracle Data Guard. The operation is designed to have zero data loss. Amazon RDS automates the following aspects of the switchover:

- Reverses the roles of your primary database and specified standby database, putting the new standby database in the same state (mounted or read-only) as the original standby
- Ensures data consistency
- Maintains your replication configuration after the transition
- Supports repeated reversals, allowing your new standby database to return to its original primary role

## Supported Oracle Database versions

Oracle Data Guard switchover is supported for Oracle Database 19c and higher releases.

## Cost of Oracle Data Guard switchover

The Oracle Data Guard switchover feature doesn't incur additional costs. Oracle Database Enterprise Edition includes support for standby databases in mounted mode. To open standby databases in read-only mode, you need the Oracle Active Data Guard option.

## How Oracle Data Guard switchover works

Oracle Data Guard switchover is a fully managed operation. You initiate the switchover for a standby database by issuing the CLI command `switchover-read-replica`. Then Amazon RDS modifies the primary and standby roles in your replication configuration.

The *original standby* and *original primary* are the roles that exist before the switchover. The *new standby* and *new primary* are the roles that exist after the switchover. A *bystander replica* is a replica database that serves as a standby database in the Oracle Data Guard environment but is not switching roles.

## Topics

- [Stages of the Oracle Data Guard switchover](#)
- [After the Oracle Data Guard switchover](#)

## Stages of the Oracle Data Guard switchover

To perform the switchover, Amazon RDS must take the following steps:

1. Block new transactions on the original primary database. During the switchover, Amazon RDS interrupts replication for all databases in your Oracle Data Guard configuration. During the switchover, the original primary database can't process write requests.
2. Ship unapplied transactions to the original standby database, and apply them.
3. Restart the new standby database in read-only or mounted mode. The mode depends on the open state of the original standby database before the switchover.
4. Open the new primary database in read/write mode.

## After the Oracle Data Guard switchover

Amazon RDS switches the roles of the primary and standby database. You are responsible for reconnecting your application and performing any other desired configuration.

### Topics

- [Success criteria](#)
- [Connection to the new primary database](#)
- [Configuration of the new primary database](#)

### Success criteria

The Oracle Data Guard switchover is successful when the original standby database does the following:

- Transitions to its role as new primary database
- Completes its reconfiguration

To limit downtime, your new primary database becomes active as soon as possible. Because Amazon RDS configures bystander replicas asynchronously, these replicas might become active after the original primary database.

## Connection to the new primary database

Amazon RDS won't propagate your current database connections to the new primary database after the switchover. After the Oracle Data Guard switchover completes, reconnect your application to the new primary database.

## Configuration of the new primary database

To perform a switchover to the new primary database, Amazon RDS changes the mode of the original standby database to open. The change in role is the only change to the database. Amazon RDS doesn't set up features such as Multi-AZ replication.

If you perform a switchover to a cross-Region replica with different options, the new primary database keeps its own options. Amazon RDS won't migrate the options on the original primary database. If the original primary database had options such as SSL, NNE, OEM, and OEM\_AGENT, Amazon RDS doesn't propagate them to the new primary database.

## Requirements for the Oracle Data Guard switchover

Before initiating the Oracle Data Guard switchover, make sure that your replication environment meets the following requirements:

- The original standby database is mounted or open read-only.
- Automatic backups are enabled on the original standby database.
- The original primary database and the original standby database are in an available state.
- The original primary database and the original standby database have no pending maintenance actions.
- The original standby database is in the replicating state.
- You aren't attempting to initiate a switchover when either the primary database or standby database is currently in a switchover lifecycle. If a replica database is reconfiguring after a switchover, Amazon RDS prevents you from initiating another switchover.

### Note

A *bystander replica* is a replica in the Oracle Data Guard configuration that isn't the target of the switchover. Bystander replicas can be in any state during the switchover.

- The original standby database has a configuration that is as close as desired to the original primary database. Assume a scenario where the original primary and original standby databases

have different options. After the switchover completes, Amazon RDS doesn't automatically reconfigure the new primary database to have the same options as the original primary database.

- You configure your desired Multi-AZ deployment before initiating a switchover. Amazon RDS doesn't manage Multi-AZ as part of the switchover. The Multi-AZ deployment remains as it is.

Assume that `db_maz` is the primary database in a Multi-AZ deployment, and `db_saz` is a Single-AZ replica. You initiate a switchover from `db_maz` to `db_saz`. Afterward, `db_maz` is a Multi-AZ replica database, and `db_saz` is a Single-AZ primary database. The new primary database is now unprotected by a Multi-AZ deployment.

- In preparation for a cross-Region switchover, the primary database doesn't use the same option group as a DB instance outside of the replication configuration. For a cross-Region switchover to succeed, the current primary database and its read replicas must be the only DB instances to use the option group of the current primary database. Otherwise, Amazon RDS prevents the switchover.

## Initiating the Oracle Data Guard switchover

You can switch over an RDS for Oracle read replica to the primary role, and the former primary DB instance to a replica role.

### Console

#### To switch over an Oracle read replica to the primary DB role

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the Amazon RDS console, choose **Databases**.

The **Databases** pane appears. Each read replica shows **Replica** in the **Role** column.

3. Choose the read replica that you want to switch over to the primary role.
4. For **Actions**, choose **Switch over replica**.
5. Choose **I acknowledge**. Then choose **Switch over replica**.
6. On the **Databases** page, monitor the progress of the switchover.

DB identifier	Role	Region & AZ	Status	Current activity
[Redacted]	Regional cluster	us-east-1	Available	
orcl190ee	Source	us-east-1f	Modifying	0.00 s
oracle190ee-replica1	Replica	us-east-1a	Available	0.05 s

When the switchover completes, the role of the switchover target changes from **Replica** to **Source**.

DB identifier	Role	Region & AZ	Status	Current activity
[Redacted]	Regional cluster	us-east-1	Available	
oracle190ee-replica1	Source	us-east-1a	Available	0.04 s
orcl190ee	Replica	us-east-1f	Available	0.00 s

## AWS CLI

To switch over an Oracle replica to the primary DB role, use the AWS CLI [switchover-read-replica](#) command. The following examples make the Oracle replica named *replica-to-be-made-primary* into the new primary database.

### Example

For Linux, macOS, or Unix:

```
aws rds switchover-read-replica \
  --db-instance-identifier replica-to-be-made-primary
```

For Windows:

```
aws rds switchover-read-replica ^
  --db-instance-identifier replica-to-be-made-primary
```

## RDS API

To switch over an Oracle replica to the primary DB role, call the Amazon RDS API [SwitchoverReadReplica](#) operation with the required parameter `DBInstanceIdentifier`. This parameter specifies the name of the Oracle replica that you want to assume the primary DB role.

## Monitoring the Oracle Data Guard switchover

To check the status of your instances, use the AWS CLI command `describe-db-instances`. The following command checks the status of the DB instance `orcl2`. This database was a standby database before the switchover, but is the new primary database after the switchover.

```
aws rds describe-db-instances \  
  --db-instance-identifier orcl2
```

To confirm that the switchover completed successfully, query `V$DATABASE.OPEN_MODE`. Check that the value for the new primary database is `READ WRITE`.

```
SELECT OPEN_MODE FROM V$DATABASE;
```

To look for switchover-related events, use the AWS CLI command `describe-events`. The following example looks for events on the `orcl2` instance.

```
aws rds describe-events \  
  --source-identifier orcl2 \  
  --source-type db-instance
```

## Troubleshooting RDS for Oracle replicas

This section describes possible replication problems and solutions.

### Topics

- [Monitoring Oracle replication lag](#)
- [Troubleshooting Oracle replication failure after adding or modifying triggers](#)

## Monitoring Oracle replication lag

To monitor replication lag in Amazon CloudWatch, view the Amazon RDS ReplicaLag metric. For more information about replication lag time, see [Monitoring read replication](#) and [Amazon CloudWatch metrics for Amazon RDS](#).

For a read replica, if the lag time is too long, query the following views:

- V\$ARCHIVED\_LOG – Shows which commits have been applied to the read replica.
- V\$DATAGUARD\_STATS – Shows a detailed breakdown of the components that make up the ReplicaLag metric.
- V\$DATAGUARD\_STATUS – Shows the log output from Oracle's internal replication processes.

For a mounted replica, if the lag time is too long, you can't query the V\$ views. Instead, do the following:

- Check the ReplicaLag metric in CloudWatch.
- Check the alert log file for the replica in the console. Look for errors in the recovery messages. The messages include the log sequence number, which you can compare to the primary sequence number. For more information, see [Oracle database log files](#).

## Troubleshooting Oracle replication failure after adding or modifying triggers

If you add or modify any triggers, and if replication fails afterward, the problem may be the triggers. Ensure that the trigger excludes the following user accounts, which are required by RDS for replication:

- User accounts with administrator privileges
- SYS
- SYSTEM
- RDS\_DATAGUARD
- rdsdb

For more information, see [Miscellaneous considerations for RDS for Oracle replicas](#).

# Adding options to Oracle DB instances

In Amazon RDS, an *option* is an additional feature. Following, you can find a description of options that you can add to Amazon RDS instances running the Oracle DB engine.

## Topics

- [Overview of Oracle DB options](#)
- [Amazon S3 integration](#)
- [Oracle Application Express \(APEX\)](#)
- [Amazon EFS integration](#)
- [Oracle Java virtual machine](#)
- [Oracle Enterprise Manager](#)
- [Oracle Label Security](#)
- [Oracle Locator](#)
- [Oracle native network encryption](#)
- [Oracle OLAP](#)
- [Oracle Secure Sockets Layer](#)
- [Oracle Spatial](#)
- [Oracle SQLT](#)
- [Oracle Statspack](#)
- [Oracle time zone](#)
- [Oracle time zone file autoupgrade](#)
- [Oracle Transparent Data Encryption](#)
- [Oracle UTL\\_MAIL](#)
- [Oracle XML DB](#)

## Overview of Oracle DB options

To enable options for your Oracle database, add them to an option group, and then associate the option group with your DB instance. For more information, see [Working with option groups](#).

## Topics

- [Summary of Oracle Database options](#)
- [Options supported for different editions](#)
- [Memory requirements for specific options](#)

## Summary of Oracle Database options

You can add the following options for Oracle DB instances.

Option	Option ID
<a href="#">Amazon S3 integration</a>	S3_INTEGRATION
<a href="#">Oracle Application Express (APEX)</a>	APEX APEX-DEV
<a href="#">Oracle Enterprise Manager</a>	OEM OEM_AGENT
<a href="#">Oracle Java virtual machine</a>	JVM
<a href="#">Oracle Label Security</a>	OLS
<a href="#">Oracle Locator</a>	LOCATOR
<a href="#">Oracle native network encryption</a>	NATIVE_NETWORK_ENCRYPTION
<a href="#">Oracle OLAP</a>	OLAP
<a href="#">Oracle Secure Sockets Layer</a>	SSL
<a href="#">Oracle Spatial</a>	SPATIAL
<a href="#">Oracle SQLT</a>	SQLT
<a href="#">Oracle Statspack</a>	STATSPACK
<a href="#">Oracle time zone</a>	Timezone

Option	Option ID
<a href="#">Oracle time zone file autoupgrade</a>	TIMEZONE_FILE_AUTO UPGRADE
<a href="#">Oracle Transparent Data Encryption</a>	TDE
<a href="#">Oracle UTL_MAIL</a>	UTL_MAIL
<a href="#">Oracle XML DB</a>	XMLDB

## Options supported for different editions

RDS for Oracle prevents you from adding options to an edition if they aren't supported. To find out which RDS options are supported in different Oracle Database editions, use the command `aws rds describe-option-group-options`. The following example lists supported options for Oracle Database 19c Enterprise Edition.

```
aws rds describe-option-group-options \  
  --engine-name oracle-ee \  
  --major-engine-version 19
```

For more information, see [describe-option-group-options](#) in the *AWS CLI Command Reference*.

## Memory requirements for specific options

Some options require additional memory to run on your DB instance. For example, Oracle Enterprise Manager Database Control uses about 300 MB of RAM. If you enable this option for a small DB instance, you might encounter performance problems due to memory constraints. You can adjust the Oracle parameters so that the database requires less RAM. Alternatively, you can scale up to a larger DB instance.

## Amazon S3 integration

You can transfer files between your RDS for Oracle DB instance and an Amazon S3 bucket. You can use Amazon S3 integration with Oracle Database features such as Oracle Data Pump. For example, you can download Data Pump files from Amazon S3 to your RDS for Oracle DB instance. For more information, see [Importing data into Oracle on Amazon RDS](#).

### Note

Your DB instance and your Amazon S3 bucket must be in the same AWS Region.

### Topics

- [Configuring IAM permissions for RDS for Oracle integration with Amazon S3](#)
- [Adding the Amazon S3 integration option](#)
- [Transferring files between Amazon RDS for Oracle and an Amazon S3 bucket](#)
- [Troubleshooting Amazon S3 integration](#)
- [Removing the Amazon S3 integration option](#)

## Configuring IAM permissions for RDS for Oracle integration with Amazon S3

For RDS for Oracle to integrate with Amazon S3, your DB instance must have access to an Amazon S3 bucket. The Amazon VPC used by your DB instance doesn't need to provide access to the Amazon S3 endpoints.

RDS for Oracle supports transferring files between a DB instance in one account and an Amazon S3 bucket in a different account. Where additional steps are required, they are noted in the following sections.

### Topics

- [Step 1: Create an IAM policy for your Amazon RDS role](#)
- [Step 2: \(Optional\) Create an IAM policy for your Amazon S3 bucket](#)
- [Step 3: Create an IAM role for your DB instance and attach your policy](#)
- [Step 4: Associate your IAM role with your RDS for Oracle DB instance](#)

## Step 1: Create an IAM policy for your Amazon RDS role

In this step, you create an AWS Identity and Access Management (IAM) policy with the permissions required to transfer files between your Amazon S3 bucket and your RDS DB instance. This step assumes that you have already created an S3 bucket.

Before you create the policy, note the following pieces of information:

- The Amazon Resource Name (ARN) for your bucket
- The ARN for your AWS KMS key, if your bucket uses SSE-KMS or SSE-S3 encryption

### Note

An RDS for Oracle DB instance can't access Amazon S3 buckets encrypted with SSE-C.

For more information, see [Protecting data using server-side encryption](#) in the *Amazon Simple Storage Service User Guide*.

## Console

### To create an IAM policy to allow Amazon RDS to access your Amazon S3 bucket

1. Open the [IAM Management Console](#).
2. Under **Access management**, choose **Policies**.
3. Choose **Create Policy**.
4. On the **Visual editor** tab, choose **Choose a service**, and then choose **S3**.
5. For **Actions**, choose **Expand all**, and then choose the bucket permissions and object permissions required to transfer files from an Amazon S3 bucket to Amazon RDS. For example, do the following:
  - Expand **List**, and then select **ListBucket**.
  - Expand **Read**, and then select **GetObject**.
  - Expand **Write**, and then select **PutObject** and **DeleteObject**.
  - Expand **Permissions management**, and then select **PutObjectAcl**. This permission is necessary if you plan to upload files to a bucket owned by a different account, and this account needs full control of the bucket contents.

*Object permissions* are permissions for object operations in Amazon S3. You must grant them for objects in a bucket, not the bucket itself. For more information, see [Permissions for object operations](#).

6. Choose **Resources**, and then do the following:
  - a. Choose **Specific**.
  - b. For **bucket**, choose **Add ARN**. Enter your bucket ARN. The bucket name is filled in automatically. Then choose **Add**.
  - c. If the **object** resource is shown, either choose **Add ARN** to add resources manually or choose **Any**.

 **Note**

You can set **Amazon Resource Name (ARN)** to a more specific ARN value to allow Amazon RDS to access only specific files or folders in an Amazon S3 bucket. For more information about how to define an access policy for Amazon S3, see [Managing access permissions to your Amazon S3 resources](#).

7. (Optional) Choose **Add additional permissions** to add resources to the policy. For example, do the following:
  - a. If your bucket is encrypted with a custom KMS key, select **KMS** for the service.
  - b. For **Manual actions**, select the following:
    - **Encrypt**
    - **ReEncrypt from** and **ReEncrypt to**
    - **Decrypt**
    - **DescribeKey**
    - **GenerateDataKey**
  - c. For **Resources**, choose **Specific**.
  - d. For **key**, choose **Add ARN**. Enter the ARN of your custom key as the resource, and then choose **Add**.

For more information, see [Protecting Data Using Server-Side Encryption with KMS keys Stored in AWS Key Management Service \(SSE-KMS\)](#) in the *Amazon Simple Storage Service User Guide*.

- e. If you want Amazon RDS to access to access other buckets, add the ARNs for these buckets. Optionally, you can also grant access to all buckets and objects in Amazon S3.
8. Choose **Next: Tags** and then **Next: Review**.
9. For **Name**, enter a name for your IAM policy, for example `rds-s3-integration-policy`. You use this name when you create an IAM role to associate with your DB instance. You can also add an optional **Description** value.
10. Choose **Create policy**.

## AWS CLI

Create an AWS Identity and Access Management (IAM) policy that grants Amazon RDS access to an Amazon S3 bucket. After you create the policy, note the ARN of the policy. You need the ARN for a subsequent step.

Include the appropriate actions in the policy based on the type of access required:

- `GetObject` – Required to transfer files from an Amazon S3 bucket to Amazon RDS.
- `ListBucket` – Required to transfer files from an Amazon S3 bucket to Amazon RDS.
- `PutObject` – Required to transfer files from Amazon RDS to an Amazon S3 bucket.

The following AWS CLI command creates an IAM policy named *rds-s3-integration-policy* with these options. It grants access to a bucket named *amzn-s3-demo-bucket*.

## Example

For Linux, macOS, or Unix:

```
aws iam create-policy \  
  --policy-name rds-s3-integration-policy \  
  --policy-document '{  
    "Version": "2012-10-17",  
    "Statement": [  
      {
```

```

    "Sid": "s3integration",
    "Action": [
      "s3:GetObject",
      "s3:ListBucket",
      "s3:PutObject"
    ],
    "Effect": "Allow",
    "Resource": [
      "arn:aws:s3:::amzn-s3-demo-bucket",
      "arn:aws:s3:::amzn-s3-demo-bucket/*"
    ]
  }
]
}'

```

The following example includes permissions for custom KMS keys.

```

aws iam create-policy \
  --policy-name rds-s3-integration-policy \
  --policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Sid": "s3integration",
        "Action": [
          "s3:GetObject",
          "s3:ListBucket",
          "s3:PutObject",
          "kms:Decrypt",
          "kms:Encrypt",
          "kms:ReEncrypt*",
          "kms:GenerateDataKey",
          "kms:DescribeKey",
        ],
        "Effect": "Allow",
        "Resource": [
          "arn:aws:s3:::amzn-s3-demo-bucket",
          "arn:aws:s3:::amzn-s3-demo-bucket/*",
          "arn:aws:kms:::your-kms-arn"
        ]
      }
    ]
  }'

```

**For Windows:**

```
aws iam create-policy ^
--policy-name rds-s3-integration-policy ^
--policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "s3integration",
      "Action": [
        "s3:GetObject",
        "s3:ListBucket",
        "s3:PutObject"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-bucket",
        "arn:aws:s3:::amzn-s3-demo-bucket/*"
      ]
    }
  ]
}'
```

The following example includes permissions for custom KMS keys.

```
aws iam create-policy ^
--policy-name rds-s3-integration-policy ^
--policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "s3integration",
      "Action": [
        "s3:GetObject",
        "s3:ListBucket",
        "s3:PutObject",
        "kms:Decrypt",
        "kms:Encrypt",
        "kms:ReEncrypt",
        "kms:GenerateDataKey",
        "kms:DescribeKey",
      ],
      "Effect": "Allow",
```

```
"Resource": [  
  "arn:aws:s3:::amzn-s3-demo-bucket",  
  "arn:aws:s3:::amzn-s3-demo-bucket/*",  
  "arn:aws:kms:::your-kms-arn"  
]  
}  
]
```

## Step 2: (Optional) Create an IAM policy for your Amazon S3 bucket

This step is necessary only in the following conditions:

- You plan to upload files to an Amazon S3 bucket from one account (account A) and access them from a different account (account B).
- Account B owns the bucket.
- Account B needs full control of objects loaded into the bucket.

If the preceding conditions don't apply to you, skip to [Step 3: Create an IAM role for your DB instance and attach your policy](#).

To create your bucket policy, make sure you have the following:

- The account ID for account A
- The user name for account A
- The ARN value for the Amazon S3 bucket in account B

## Console

### To create or edit a bucket policy

1. Sign in to the AWS Management Console and open the Amazon S3 console at <https://console.aws.amazon.com/s3/>.
2. In the **Buckets** list, choose the name of the bucket that you want to create a bucket policy for or whose bucket policy you want to edit.
3. Choose **Permissions**.
4. Under **Bucket policy**, choose **Edit**. This opens the Edit bucket policy page.

5. On the **Edit bucket policy** page, explore **Policy examples** in the *Amazon S3 User Guide*, choose **Policy generator** to generate a policy automatically, or edit the JSON in the **Policy** section.

If you choose **Policy generator**, the AWS Policy Generator opens in a new window:

- a. On the **AWS Policy Generator** page, in **Select Type of Policy**, choose **S3 Bucket Policy**.
- b. Add a statement by entering the information in the provided fields, and then choose **Add Statement**. Repeat for as many statements as you would like to add. For more information about these fields, see the [IAM JSON policy elements reference](#) in the *IAM User Guide*.

 **Note**

For convenience, the **Edit bucket policy** page displays the **Bucket ARN** (Amazon Resource Name) of the current bucket above the **Policy** text field. You can copy this ARN for use in the statements on the **AWS Policy Generator** page.

- c. After you finish adding statements, choose **Generate Policy**.
  - d. Copy the generated policy text, choose **Close**, and return to the **Edit bucket policy** page in the Amazon S3 console.
6. In the **Policy** box, edit the existing policy or paste the bucket policy from the Policy generator. Make sure to resolve security warnings, errors, general warnings, and suggestions before you save your policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Example permissions",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::account-A-ID:account-A-user"
      },
      "Action": [
        "s3:PutObject",
        "s3:PutObjectAcl"
      ],
      "Resource": [
        "arn:aws:s3:::amzn-s3-demo-destination-bucket",
        "arn:aws:s3:::amzn-s3-demo-destination-bucket/*"
      ]
    }
  ]
}
```

```
}  
  ]  
}
```

7. Choose **Save changes**, which returns you to the Bucket Permissions page.

### Step 3: Create an IAM role for your DB instance and attach your policy

This step assumes that you have created the IAM policy in [Step 1: Create an IAM policy for your Amazon RDS role](#). In this step, you create a role for your RDS for Oracle DB instance and then attach your policy to the role.

#### Console

##### To create an IAM role to allow Amazon RDS to access an Amazon S3 bucket

1. Open the [IAM Management Console](#).
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. Choose **AWS service**.
5. For **Use cases for other AWS services**, choose **RDS** and then **RDS – Add Role to Database**. Then choose **Next**.
6. For **Search** under **Permissions policies**, enter the name of the IAM policy you created in [Step 1: Create an IAM policy for your Amazon RDS role](#), and select the policy when it appears in the list. Then choose **Next**.
7. For **Role name**, enter a name for your IAM role, for example, `rds-s3-integration-role`. You can also add an optional **Description** value.
8. Choose **Create role**.

#### AWS CLI

##### To create a role and attach your policy to it

1. Create an IAM role that Amazon RDS can assume on your behalf to access your Amazon S3 buckets.

We recommend using the [aws:SourceArn](#) and [aws:SourceAccount](#) global condition context keys in resource-based trust relationships to limit the service's permissions to a specific resource. This is the most effective way to protect against the [confused deputy problem](#).

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role.

The following AWS CLI command creates the role named *rds-s3-integration-role* for this purpose.

## Example

For Linux, macOS, or Unix:

```
aws iam create-role \
  --role-name rds-s3-integration-role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": my_account_ID,
            "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
          }
        }
      }
    ]
  }
```

```
]
}'
```

### For Windows:

```
aws iam create-role ^
--role-name rds-s3-integration-role ^
--assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": my_account_ID,
          "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
        }
      }
    }
  ]
}'
```

For more information, see [Creating a role to delegate permissions to an IAM user](#) in the *IAM User Guide*.

2. After the role is created, note the ARN of the role. You need the ARN for a subsequent step.
3. Attach the policy you created to the role you created.

The following AWS CLI command attaches the policy to the role named *rds-s3-integration-role*.

### Example

For Linux, macOS, or Unix:

```
aws iam attach-role-policy \  
--policy-arn your-policy-arn \  

```

```
--role-name rds-s3-integration-role
```

For Windows:

```
aws iam attach-role-policy ^  
  --policy-arn your-policy-arn ^  
  --role-name rds-s3-integration-role
```

Replace *your-policy-arn* with the policy ARN that you noted in a previous step.

#### Step 4: Associate your IAM role with your RDS for Oracle DB instance

The last step in configuring permissions for Amazon S3 integration is associating your IAM role with your DB instance. Note the following requirements:

- You must have access to an IAM role with the required Amazon S3 permissions policy attached to it.
- You can only associate one IAM role with your RDS for Oracle DB instance at a time.
- Your DB instance must be in the **Available** state.

#### Console

##### To associate your IAM role with your RDS for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Databases** from the navigation pane.
3. Choose the RDS for Oracle DB instance name to display its details.
4. On the **Connectivity & security** tab, scroll down to the **Manage IAM roles** section at the bottom of the page.
5. For **Add IAM roles to this instance**, choose the role that you created in [Step 3: Create an IAM role for your DB instance and attach your policy](#).
6. For **Feature**, choose **S3\_INTEGRATION**.

7. Choose **Add role**.

## AWS CLI

The following AWS CLI command adds the role to an Oracle DB instance named *mydbinstance*.

### Example

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \
  --db-instance-identifier mydbinstance \
  --feature-name S3_INTEGRATION \
  --role-arn your-role-arn
```

For Windows:

```
aws rds add-role-to-db-instance ^
  --db-instance-identifier mydbinstance ^
  --feature-name S3_INTEGRATION ^
  --role-arn your-role-arn
```

Replace *your-role-arn* with the role ARN that you noted in a previous step. S3\_INTEGRATION must be specified for the --feature-name option.

## Adding the Amazon S3 integration option

To integrate Amazon RDS for Oracle with Amazon S3, your DB instance must be associated with an option group that includes the S3\_INTEGRATION option.

## Console

### To configure an option group for Amazon S3 integration

1. Create a new option group or identify an existing option group to which you can add the S3\_INTEGRATION option.

For information about creating an option group, see [Creating an option group](#).

2. Add the S3\_INTEGRATION option to the option group.

For information about adding an option to an option group, see [Adding an option to an option group](#).

3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

For information about creating a DB instance, see [Creating an Amazon RDS DB instance](#).

For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance](#).

## AWS CLI

### To configure an option group for Amazon S3 integration

1. Create a new option group or identify an existing option group to which you can add the S3\_INTEGRATION option.

For information about creating an option group, see [Creating an option group](#).

2. Add the S3\_INTEGRATION option to the option group.

For example, the following AWS CLI command adds the S3\_INTEGRATION option to an option group named **myoptiongroup**.

### Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \  
  --option-group-name myoptiongroup \  
  --options OptionName=S3_INTEGRATION,OptionVersion=1.0
```

### For Windows:

```
aws rds add-option-to-option-group ^  
  --option-group-name myoptiongroup ^  
  --options OptionName=S3_INTEGRATION,OptionVersion=1.0
```

3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

For information about creating a DB instance, see [Creating an Amazon RDS DB instance](#).

For information about modifying an RDS for Oracle DB instance, see [Modifying an Amazon RDS DB instance](#).

## Transferring files between Amazon RDS for Oracle and an Amazon S3 bucket

To transfer files between an RDS for Oracle DB instance and an Amazon S3 bucket, you can use the Amazon RDS package `rdsadmin_s3_tasks`. You can compress files with GZIP when uploading them, and decompress them when downloading.

### Topics

- [Requirements and limitations for file transfers](#)
- [Uploading files from your RDS for Oracle DB instance to an Amazon S3 bucket](#)
- [Downloading files from an Amazon S3 bucket to an Oracle DB instance](#)
- [Monitoring the status of a file transfer](#)

### Requirements and limitations for file transfers

Before transferring files between your DB instance and an Amazon S3 bucket, note the following:

- The `rdsadmin_s3_tasks` package transfers files located in a single directory. You can't include subdirectories in a transfer.
- The maximum object size in an Amazon S3 bucket is 5 TB.
- Tasks created by `rdsadmin_s3_tasks` run asynchronously.
- You can upload files from the Data Pump directory, such as `DATA_PUMP_DIR`, or any user-created directory. You can't upload files from a directory used by Oracle background processes, such as the `adump`, `bdump`, or `trace` directories.

- The download limit is 2000 files per procedure call for `download_from_s3`. If you need to download more than 2000 files from Amazon S3, split your download into separate actions, with no more than 2000 files per procedure call.
- If a file exists in your download folder, and you attempt to download a file with the same name, `download_from_s3` skips the download. To remove a file from the download directory, use the PL/SQL procedure [UTL\\_FILE.REMOVE](#).

## Uploading files from your RDS for Oracle DB instance to an Amazon S3 bucket

To upload files from your DB instance to an Amazon S3 bucket, use the procedure `rdsadmin.rdsadmin_s3_tasks.upload_to_s3`. For example, you can upload Oracle Recovery Manager (RMAN) backup files or Oracle Data Pump files. For more information about working with objects, see [Amazon Simple Storage Service User Guide](#). For more information about performing RMAN backups, see [Performing common RMAN tasks for Oracle DB instances](#).

The `rdsadmin.rdsadmin_s3_tasks.upload_to_s3` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>p_bucket_name</code>	VARCHAR2	–	required	The name of the Amazon S3 bucket to upload files to.
<code>p_directory_name</code>	VARCHAR2	–	required	The name of the Oracle directory object to upload files from. The directory can be any user-created directory object or the Data Pump directory, such as <code>DATA_PUMP_DIR</code> . You can't upload files from a directory used by background processes, such as <code>adump</code> , <code>bdump</code> , and <code>trace</code> .

Parameter name	Data type	Default	Required	Description
				<div style="border: 1px solid #0070C0; border-radius: 10px; padding: 10px; background-color: #E6F2FF;"> <p> <b>Note</b></p> <p>You can only upload files from the specified directory. You can't upload files in subdirectories in the specified directory.</p> </div>
p_s3_prefix	VARCHAR2	–	required	<p>An Amazon S3 file name prefix that files are uploaded to. An empty prefix uploads all files to the top level in the specified Amazon S3 bucket and doesn't add a prefix to the file names.</p> <p>For example, if the prefix is <code>folder_1/oradb</code> , files are uploaded to <code>folder_1</code>. In this case, the <code>oradb</code> prefix is added to each file.</p>
p_prefix	VARCHAR2	–	required	<p>A file name prefix that file names must match to be uploaded. An empty prefix uploads all files in the specified directory.</p>

Parameter name	Data type	Default	Required	Description
p_compression_level	NUMBER	0	optional	<p>The level of GZIP compression. Valid values range from 0 to 9:</p> <ul style="list-style-type: none"> <li>• 0 – No compression</li> <li>• 1 – Fastest compression</li> <li>• 9 – Highest compression</li> </ul>
p_bucket_owner_full_control	VARCHAR2	–	optional	<p>The access control setting for the bucket. The only valid values are null or FULL_CONTROL. This setting is required only if you upload files from one account (account A) into a bucket owned by a different account (account B), and account B needs full control of the files.</p>

The return value for the `rdsadmin.rdsadmin_s3_tasks.upload_to_s3` procedure is a task ID.

The following example uploads all of the files in the `DATA_PUMP_DIR` directory to the Amazon S3 bucket named `amzn-s3-demo-bucket`. The files aren't compressed.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
  p_bucket_name    => 'amzn-s3-demo-bucket',
  p_prefix         => '',
  p_s3_prefix      => '',
  p_directory_name => 'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The following example uploads all of the files with the prefix *db* in the *DATA\_PUMP\_DIR* directory to the Amazon S3 bucket named *amzn-s3-demo-bucket*. Amazon RDS applies the highest level of GZIP compression to the files.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name      => 'amzn-s3-demo-bucket',
    p_prefix           => 'db',
    p_s3_prefix        => '',
    p_directory_name   => 'DATA_PUMP_DIR',
    p_compression_level => 9)
AS TASK_ID FROM DUAL;
```

The following example uploads all of the files in the *DATA\_PUMP\_DIR* directory to the Amazon S3 bucket named *amzn-s3-demo-bucket*. The files are uploaded to a *dbfiles* folder. In this example, the GZIP compression level is *1*, which is the fastest level of compression.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name      => 'amzn-s3-demo-bucket',
    p_prefix           => '',
    p_s3_prefix        => 'dbfiles/',
    p_directory_name   => 'DATA_PUMP_DIR',
    p_compression_level => 1)
AS TASK_ID FROM DUAL;
```

The following example uploads all of the files in the *DATA\_PUMP\_DIR* directory to the Amazon S3 bucket named *amzn-s3-demo-bucket*. The files are uploaded to a *dbfiles* folder and *ora* is added to the beginning of each file name. No compression is applied.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
    p_bucket_name      => 'amzn-s3-demo-bucket',
    p_prefix           => '',
    p_s3_prefix        => 'dbfiles/ora',
    p_directory_name   => 'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The following example assumes that the command is run in account A, but account B requires full control of the bucket contents. The command `rdsadmin_s3_tasks.upload_to_s3` transfers all files in the *DATA\_PUMP\_DIR* directory to the bucket named *s3bucketOwnedByAccountB*. Access control is set to `FULL_CONTROL` so that account B can access the files in the bucket. The GZIP compression level is *6*, which balances speed and file size.

```
SELECT rdsadmin.rdsadmin_s3_tasks.upload_to_s3(
  p_bucket_name      => 's3bucketOwnedByAccountB',
  p_prefix           => '',
  p_s3_prefix        => '',
  p_directory_name   => 'DATA_PUMP_DIR',
  p_bucket_owner_full_control => 'FULL_CONTROL',
  p_compression_level   => 6)
AS TASK_ID FROM DUAL;
```

In each example, the SELECT statement returns the ID of the task in a VARCHAR2 data type.

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-task-id.log'));
```

Replace *task-id* with the task ID returned by the procedure.

### Note

Tasks are executed asynchronously.

## Downloading files from an Amazon S3 bucket to an Oracle DB instance

To download files from an Amazon S3 bucket to an RDS for Oracle instance, use the Amazon RDS procedure `rdsadmin.rdsadmin_s3_tasks.download_from_s3`.

The `download_from_s3` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>p_bucket_name</code>	VARCHAR	–	Required	The name of the Amazon S3 bucket to download files from.
<code>p_directory_name</code>	VARCHAR	–	Required	The name of the Oracle directory object to download files to. The directory can be any user-created

Parameter name	Data type	Default	Required	Description
				directory object or the Data Pump directory, such as DATA_PUMP_DIR .
p_error_on_zero_downloads	VARCHAR	FALSE	Optional	<p>A flag that determines whether the task raises an error when no objects in the Amazon S3 bucket match the prefix. If this parameter is not set or set to FALSE (default), the task prints a message that no objects were found, but doesn't raise an exception or fail. If this parameter is TRUE, the task raises an exception and fails.</p> <p>Examples of prefix specifications that can fail match tests are spaces in prefixes, as in ' import/test9.log' , and case mismatches, as in test9.log and test9.LOG .</p>

Parameter name	Data type	Default	Required	Description
<code>p_s3_prefix</code>	VARCHAR	–	Required	<p>A file name prefix that file names must match to be downloaded. An empty prefix downloads all of the top level files in the specified Amazon S3 bucket, but not the files in folders in the bucket.</p> <p>The procedure downloads Amazon S3 objects only from the first level folder that matches the prefix. Nested directory structures matching the specified prefix are not downloaded.</p> <p>For example, suppose that an Amazon S3 bucket has the folder structure <code>folder_1/folder_2/folder_3</code> . You specify the <code>'folder_1/folder_2/'</code> prefix. In this case, only the files in <code>folder_2</code> are downloaded, not the files in <code>folder_1</code> or <code>folder_3</code>.</p> <p>If, instead, you specify the <code>'folder_1/folder_2'</code> prefix, all files in <code>folder_1</code> that match the <code>'folder_2'</code> prefix are downloaded, and no files in <code>folder_2</code> are downloaded.</p>
<code>p_decompression_format</code>	VARCHAR	–	Optional	The decompression format. Valid values are NONE for no decompression and GZIP for decompression.

The return value for the `rdsadmin.rdsadmin_s3_tasks.download_from_s3` procedure is a task ID.

The following example downloads all files in the Amazon S3 bucket named *amzn-s3-demo-bucket* to the *DATA\_PUMP\_DIR* directory. The files aren't compressed, so no decompression is applied.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name => 'amzn-s3-demo-bucket',
    p_directory_name => 'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

The following example downloads all of the files with the prefix *db* in the Amazon S3 bucket named *amzn-s3-demo-bucket* to the *DATA\_PUMP\_DIR* directory. The files are compressed with GZIP, so decompression is applied. The parameter *p\_error\_on\_zero\_downloads* turns on prefix error checking, so if the prefix doesn't match any files in the bucket, the task raises an exception and fails.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name => 'amzn-s3-demo-bucket',
    p_s3_prefix => 'db',
    p_directory_name => 'DATA_PUMP_DIR',
    p_decompression_format => 'GZIP',
    p_error_on_zero_downloads => 'TRUE')
AS TASK_ID FROM DUAL;
```

The following example downloads all of the files in the folder *myfolder/* in the Amazon S3 bucket named *amzn-s3-demo-bucket* to the *DATA\_PUMP\_DIR* directory. Use the *p\_s3\_prefix* parameter to specify the Amazon S3 folder. The uploaded files are compressed with GZIP, but aren't decompressed during the download.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
    p_bucket_name => 'amzn-s3-demo-bucket',
    p_s3_prefix => 'myfolder/',
    p_directory_name => 'DATA_PUMP_DIR',
    p_decompression_format => 'NONE')
AS TASK_ID FROM DUAL;
```

The following example downloads the file *mydumpfile.dmp* in the Amazon S3 bucket named *amzn-s3-demo-bucket* to the *DATA\_PUMP\_DIR* directory. No decompression is applied.

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
```

```
p_bucket_name    => 'amzn-s3-demo-bucket',  
p_s3_prefix      => 'mydumpfile.dmp',  
p_directory_name => 'DATA_PUMP_DIR')  
AS TASK_ID FROM DUAL;
```

In each example, the SELECT statement returns the ID of the task in a VARCHAR2 data type.

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-task-id.log'));
```

Replace *task-id* with the task ID returned by the procedure.

### Note

Tasks are executed asynchronously.

You can use the UTL\_FILE.FREMOVE Oracle procedure to remove files from a directory.

For more information, see [FREMOVE procedure](#) in the Oracle documentation.

## Monitoring the status of a file transfer

File transfer tasks publish Amazon RDS events when they start and when they complete. The event message contains the task ID for the file transfer. For information about viewing events, see [Viewing Amazon RDS events](#).

You can view the status of an ongoing task in a bdump file. The bdump files are located in the / rdsbdbdata/log/trace directory. Each bdump file name is in the following format.

```
dbtask-task-id.log
```

Replace *task-id* with the ID of the task that you want to monitor.

### Note

Tasks are executed asynchronously.

You can use the `rdsadmin.rds_file_util.read_text_file` stored procedure to view the contents of bdump files. For example, the following query returns the contents of the `dbtask-1234567890123-1234.log` bdump file.

```
SELECT text FROM
  table(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-1234567890123-1234.log'));
```

The following sample shows the log file for a failed transfer.

TASK\_ID

-----  
1234567890123-1234

TEXT

-----  
2023-04-17 18:21:33.993 UTC [INFO ] File #1: Uploading the file /rdsdbdata/datapump/A123B4CDEF567890G1234567890H1234/sample.dmp to Amazon S3 with bucket name *amzn-s3-demo-bucket* and key sample.dmp.  
2023-04-17 18:21:34.188 UTC [ERROR] RDS doesn't have permission to write to Amazon S3 bucket name *amzn-s3-demo-bucket* and key sample.dmp.  
2023-04-17 18:21:34.189 UTC [INFO ] The task failed.

## Troubleshooting Amazon S3 integration

For troubleshooting tips, see the AWS re:Post article [How do troubleshoot issues when I integrate Amazon RDS for Oracle with Amazon S3?](#)

### Removing the Amazon S3 integration option

You can remove Amazon S3 integration option from a DB instance.

To remove the Amazon S3 integration option from a DB instance, do one of the following:

- To remove the Amazon S3 integration option from multiple DB instances, remove the S3\_INTEGRATION option from the option group to which the DB instances belong. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group](#).
- To remove the Amazon S3 integration option from a single DB instance, modify the instance and specify a different option group that doesn't include the S3\_INTEGRATION option. You can specify the default (empty) option group or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance](#).

## Oracle Application Express (APEX)

Amazon RDS supports Oracle Application Express (APEX) through the use of the APEX and APEX-DEV options. You can deploy Oracle APEX as a runtime environment or as a full development environment for web-based applications. Using Oracle APEX, you can build applications entirely within the web browser. For more information, see [Oracle application Express](#) in the Oracle documentation.

### Topics

- [Unlocking the public user account on your DB instance](#)
- [Configuring RESTful services for Oracle APEX](#)
- [Preparing to install ORDS on a separate host](#)
- [Installing and configuring ORDS 21 and lower](#)
- [Installing and configuring ORDS 22 and higher](#)
- [Setting up Oracle APEX listener](#)
- [Upgrading the APEX version](#)
- [Removing the APEX option](#)

### APEX components

Oracle APEX consists of the following main components:

- A *repository* that stores the metadata for APEX applications and components. The repository consists of tables, indexes, and other objects that are installed in your Amazon RDS DB instance.
- A *listener* that manages HTTP communications with Oracle APEX clients. The listener resides on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. The listener accepts incoming connections from web browsers, forwards them to the Amazon RDS DB instance for processing, and then sends results from the repository back to the browsers.

RDS for Oracle supports the following types of listeners:

- For APEX version 5.0 and later, use Oracle REST Data Services (ORDS) version 19.1 and higher. We recommend that you use the latest supported version of Oracle APEX and ORDS. This documentation describes older versions for backwards compatibility only.
- For APEX version 4.1.1, you can use Oracle APEX Listener version 1.1.4.
- You can use Oracle HTTP Server and `mod_plsql` listeners.

### Note

Amazon RDS doesn't support the Oracle XML DB HTTP server with the embedded PL/SQL gateway as a listener for APEX. In general, Oracle recommends against using the embedded PL/SQL gateway for applications that run on the internet.

For more information about these listener types, see [About choosing a web listener](#) in the Oracle documentation.

When you add the Amazon RDS APEX options to your RDS for Oracle DB instance, Amazon RDS installs the Oracle APEX repository only. Install your listener on a separate host.

## APEX version requirements

The APEX option uses storage on the DB instance class for your DB instance. Following are the supported versions and approximate storage requirements for Oracle APEX.

APEX version	Storage requirements	Supported Oracle Database versions	Notes
Oracle APEX version 23.2.v1	110 MiB	All	This version includes patch 35895964: PSE BUNDLE FOR APEX 23.2 (PSES ON TOP OF 23.2.0), PATCH_VERSION 6.
Oracle APEX version 23.1.v1	106 MiB	All	This version includes patch 35283657: PSE BUNDLE FOR APEX 23.1 (PSES ON TOP OF 23.1.0), PATCH_VERSION 2.

APEX version	Storage requirements	Supported Oracle Database versions	Notes
Oracle APEX version 22.2.v1	106 MiB	All	This version includes patch 34628174: PSE BUNDLE FOR APEX 22.2 (PSES ON TOP OF 22.2.0), PATCH_VERSION 4.
Oracle APEX version 22.1.v1	124 MiB	All	This version includes patch 34020981: PSE BUNDLE FOR APEX 22.1 (PSES ON TOP OF 22.1.0), PATCH_VERSION 6.
Oracle APEX version 21.2.v1	125 MiB	All	This version includes patch 33420059: PSE BUNDLE FOR APEX 21.2 (PSES ON TOP OF 21.2.0), PATCH_VERSION 8.
Oracle APEX version 21.1.v1	125 MiB	All	This version includes patch 32598392: PSE BUNDLE FOR APEX 21.1, PATCH_VERSION 3.
Oracle APEX version 20.2.v1	148 MiB	All except Oracle Database 21c	<p>This version includes patch 32006852: PSE BUNDLE FOR APEX 20.2, PATCH_VERSION 2020.11.12. You can see the patch number and date by running the following query:</p> <pre>SELECT PATCH_VERSION, PATCH_NUMBER FROM APEX_PATCHES;</pre>
Oracle APEX version 20.1.v1	173 MiB	All except Oracle Database 21c	This version includes patch 30990551: PSE BUNDLE FOR APEX 20.1, PATCH_VERSION 2020.07.15.
Oracle APEX version 19.2.v1	149 MiB	All except Oracle Database 21c	

APEX version	Storage requirements	Supported Oracle Database versions	Notes
Oracle APEX version 19.1.v1	148 MiB	All except Oracle Database 21c	

For downloadable APEX .zip files, see [Oracle APEX Prior Release Archives](#) on the Oracle website.

## Oracle APEX and ORDS requirements

Note the following requirements for APEX and ORDS:

- Your system must use the Java Runtime Environment (JRE).
- Your Oracle client installation must include the following:
  - SQL\*Plus or SQL Developer for administration tasks
  - Oracle Net Services for configuring connections to your RDS for Oracle DB instance

## Adding the APEX and APEX-DEV options to your DB instance

To add the APEX and APEX-DEV options to your RDS for Oracle DB instance, do the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the APEX and APEX-DEV options to the option group.
3. Associate the option group with your DB instance.

When you add the Amazon RDS APEX options, a brief outage occurs while your DB instance is automatically restarted.

**Note**

APEX\_MAIL is available when the APEX option is installed. The execute privilege for the APEX\_MAIL package is granted to PUBLIC so you don't need the APEX administrative account to use it.

**To add the APEX options to a DB instance**

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
  - a. For **Engine**, choose the Oracle edition that you want to use. The APEX options are supported on all editions.
  - b. For **Major engine version**, choose the version of your DB instance.

For more information, see [Creating an option group](#).

2. Add the options to the option group. If you want to deploy only the Oracle APEX runtime environment, add only the APEX option. To deploy the full development environment, add both the APEX and APEX-DEV options.

For **Version**, choose the version of APEX that you want to use.

**Important**

If you add the APEX options to an existing option group that is already attached to one or more DB instances, a brief outage occurs. During this outage, all the DB instances are automatically restarted.

For more information about adding options, see [Adding an option to an option group](#).

3. Apply the option group to a new or existing DB instance:
  - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).

- For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the APEX options to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see [Modifying an Amazon RDS DB instance](#).

## Unlocking the public user account on your DB instance

After the Amazon RDS APEX options are installed on your DB instance, make sure to do the following:

1. Change the password for the APEX public user account.
2. Unlock the account.

You can do this by using the Oracle SQL\*Plus command line utility. Connect to your DB instance as the master user, and issue the following commands. Replace `new_password` with a password of your choice.

```
ALTER USER APEX_PUBLIC_USER IDENTIFIED BY new_password;  
ALTER USER APEX_PUBLIC_USER ACCOUNT UNLOCK;
```

## Configuring RESTful services for Oracle APEX

To configure RESTful services in APEX (not needed for APEX 4.1.1.V1), use SQL\*Plus to connect to your DB instance as the master user. After you do this, run the `rdsadmin.rdsadmin_run_apex_rest_config` stored procedure. When you run the stored procedure, you provide passwords for the following users:

- APEX\_LISTENER
- APEX\_REST\_PUBLIC\_USER

The stored procedure runs the `apex_rest_config.sql` script, which creates new database accounts for these users.

**Note**

Configuration isn't required for Oracle APEX version 4.1.1.v1. For this Oracle APEX version only, you don't need to run the stored procedure.

The following command runs the stored procedure.

```
EXEC rdsadmin.rdsadmin_run_apex_rest_config('apex_listener_password',  
'apex_rest_public_user_password');
```

## Preparing to install ORDS on a separate host

Install ORDS on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. The examples in this section, assume that your host runs Linux and is named `myapexhost.example.com`.

Before you can install ORDS, you need to create a nonprivileged OS user, and then download and unzip the APEX installation file.

### To prepare for ORDS installation

1. Log in to `myapexhost.example.com` as `root`.
2. Create a nonprivileged OS user to own the listener installation. The following command creates a new user named `apexuser`.

```
useradd -d /home/apexuser apexuser
```

The following command assigns a password to the new user.

```
passwd apexuser;
```

3. Log in to `myapexhost.example.com` as `apexuser`, and download the APEX installation file from Oracle to your `/home/apexuser` directory:
  - <http://www.oracle.com/technetwork/developer-tools/apex/downloads/index.html>
  - [Oracle application Express prior release archives](#)
4. Unzip the file in the `/home/apexuser` directory.

```
unzip apex_version.zip
```

After you unzip the file, there is an apex directory in the `/home/apexuser` directory.

5. While you are still logged into `myapexhost.example.com` as `apexuser`, download the Oracle REST Data Services file from Oracle to your `/home/apexuser` directory: <http://www.oracle.com/technetwork/developer-tools/apex-listener/downloads/index.html>.

## Installing and configuring ORDS 21 and lower

You are now ready to install and configure Oracle Rest Data Services (ORDS) for use with Oracle APEX. For APEX version 5.0 and later, use ORDS versions 19.1 to 21. To learn how to install ORDS 22 and higher, see [Installing and configuring ORDS 22 and higher](#).

Install the listener on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. For the examples in this section, we assume that the name of your host is `myapexhost.example.com`, and that your host is running Linux.

### To install and configure ORDS 21 and lower for use with Oracle APEX

1. Go to [Oracle REST data services](#), and examine the Readme. Make sure that you have the required version of Java installed.
2. Create a new directory for your ORDS installation.

```
mkdir /home/apexuser/ORDS  
cd /home/apexuser/ORDS
```

3. Download the file `ords.version.number.zip` from [Oracle REST data services](#).
4. Unzip the file into the `/home/apexuser/ORDS` directory.
5. If you're installing ORDS in a multitenant database, add the following line to the file `/home/apexuser/ORDS/params/ords_params.properties`:

```
pdb.disable.lockdown=false
```

6. Grant the master user the required privileges to install ORDS.

After the Amazon RDS APEX option is installed, give the master user the required privileges to install the ORDS schema. You can do this by connecting to the database and running the following commands. Replace *MASTER\_USER* with the uppercase name of your master user.

### Important

When you enter the user name, use uppercase unless you created the user with a case-sensitive identifier. For example, if you run `CREATE USER myuser` or `CREATE USER MYUSER`, the data dictionary stores MYUSER. However, if you use double quotes in `CREATE USER "MyUser"`, the data dictionary stores MyUser. For more information, see [Granting SELECT or EXECUTE privileges to SYS objects](#).

```
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_OBJECTS', 'MASTER_USER',
'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_ROLE_PRIVS', 'MASTER_USER',
'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_TAB_COLUMNS', 'MASTER_USER',
'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONS_COLUMNS', 'MASTER_USER',
'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONSTRAINTS', 'MASTER_USER',
'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_OBJECTS', 'MASTER_USER',
'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER PROCEDURES', 'MASTER_USER',
'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TAB_COLUMNS', 'MASTER_USER',
'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TABLES', 'MASTER_USER',
'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_VIEWS', 'MASTER_USER', 'SELECT',
true);
exec rdsadmin.rdsadmin_util.grant_sys_object('WPIUTL', 'MASTER_USER', 'EXECUTE',
true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_SESSION', 'MASTER_USER',
'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_UTILITY', 'MASTER_USER',
'EXECUTE', true);
```

**Note**

These commands apply to ORDS version 19.1 and later.

7. Install the ORDS schema using the downloaded ords.war file.

```
java -jar ords.war install advanced
```

The program prompts you for the following information. The default values are in brackets. For more information, see [Introduction to Oracle REST data services](#) in the Oracle documentation.

- Enter the location to store configuration data:

Enter */home/apexuser/ORDS*. This is the location of the ORDS configuration files.

- Specify the database connection type to use. Enter number for [1] Basic [2] TNS [3] Custom URL [1]:

Choose the desired connection type.

- Enter the name of the database server [localhost]: *DB\_instance\_endpoint*

Choose the default or enter the correct value.

- Enter the database listener port [1521]: *DB\_instance\_port*

Choose the default or enter the correct value.

- Enter 1 to specify the database service name, or 2 to specify the database SID [1]:

Choose 2 to specify the database SID.

- Database SID [xe]

Choose the default or enter the correct value.

- Enter 1 if you want to verify/install Oracle REST Data Services schema or 2 to skip this step [1]:

Choose 1. This step creates the Oracle REST Data Services proxy user named ORDS\_PUBLIC\_USER.

- Enter the database password for ORDS\_PUBLIC\_USER:

Enter the password, and then confirm it.

- Requires to login with administrator privileges to verify Oracle REST Data Services schema.

Enter the administrator user name: *master\_user*

Enter the database password for *master\_user*: *master\_user\_password*

Confirm the password: *master\_user\_password*

 **Note**

Specify a password other than the prompt shown here as a security best practice.

- Enter the default tablespace for ORDS\_METADATA [SYSAUX].

Enter the temporary tablespace for ORDS\_METADATA [TEMP].

Enter the default tablespace for ORDS\_PUBLIC\_USER [USERS].

Enter the temporary tablespace for ORDS\_PUBLIC\_USER [TEMP].

- Enter 1 if you want to use PL/SQL Gateway or 2 to skip this step. If you're using Oracle Application Express or migrating from mod\_plsql, you must enter 1 [1].

Choose the default.

- Enter the PL/SQL Gateway database user name [APEX\_PUBLIC\_USER]

Choose the default.

- Enter the database password for APEX\_PUBLIC\_USER:

Enter the password, and then confirm it.

- Enter 1 to specify passwords for Application Express RESTful Services database users (APEX\_LISTENER, APEX\_REST\_PUBLIC\_USER) or 2 to skip this step [1]:

Choose 2 for APEX 4.1.1.V1; choose 1 for all other APEX versions.

- [Not needed for APEX 4.1.1.v1] Database password for APEX\_LISTENER

Enter the password (if required), and then confirm it.

- [Not needed for APEX 4.1.1.v1] Database password for APEX\_REST\_PUBLIC\_USER

Enter the password (if required), and then confirm it.

- Enter a number to select a feature to enable:

Enter 1 to enable all features: SQL Developer Web, REST Enabled SQL, and Database API.

- Enter 1 if you wish to start in standalone mode or 2 to exit [1]:

Enter 1.

- Enter the APEX static resources location:

If you unzipped APEX installation files into `/home/apexuser`, enter `/home/apexuser/apex/images`. Otherwise, enter `unzip_path/apex/images`, where `unzip_path` is the directory where you unzipped the file.

- Enter 1 if using HTTP or 2 if using HTTPS [1]:

If you enter 1, specify the HTTP port. If you enter 2, specify the HTTPS port and the SSL host name. The HTTPS option prompts you to specify how you will provide the certificate:

- Enter 1 to use the self-signed certificate.
- Enter 2 to provide your own certificate. If you enter 2, specify the path for the SSL certificate and the path for the SSL certificate private key.

8. Set a password for the APEX admin user. To do this, use SQL\*Plus to connect to your DB instance as the master user, and then run the following commands.

```
EXEC rdsadmin.rdsadmin_util.grant_apex_admin_role;  
grant APEX_ADMINISTRATOR_ROLE to master;  
@/home/apexuser/apex/apxchpwd.sql
```

Replace `master` with your master user name. When the `apxchpwd.sql` script prompts you, enter a new admin password.

9. Start the ORDS listener. Run the following code.

```
java -jar ords.war
```

The first time you start ORDS, you are prompted to provide the location of the APEX Static resources. This images folder is located in the `/apex/images` directory in the installation directory for APEX.

10. Return to the APEX administration window in your browser and choose **Administration**. Next, choose **Application Express Internal Administration**. When you are prompted for credentials, enter the following information:

- **User name** – admin
- **Password** – the password you set using the `apxchpwd.sql` script

Choose **Login**, and then set a new password for the admin user.

Your listener is now ready for use.

## Installing and configuring ORDS 22 and higher

You are now ready to install and configure Oracle Rest Data Services (ORDS) for use with Oracle APEX. For the examples in this section, we assume that the name of your separate host is `myapexhost.example.com`, and that your host is running Linux. The instructions for ORDS 22 differ from the instructions for previous releases.

### To install and configure ORDS 22 and higher for use with Oracle APEX

1. Go to [Oracle REST data services](#), and examine the Readme for the ORDS version that you plan to download. Make sure that you have the required version of Java installed.
2. Create a new directory for your ORDS installation.

```
mkdir /home/apexuser/ORDS
cd /home/apexuser/ORDS
```

3. Download the file `ords.version.number.zip` or `ords-latest.zip` from [Oracle REST data services](#).
4. Unzip the file into the `/home/apexuser/ORDS` directory.
5. Grant the master user the required privileges to install ORDS.

After the Amazon RDS APEX option is installed, give the master user the required privileges to install the ORDS schema. You can do this by logging in to the database and running the following commands. Replace `MASTER_USER` with the uppercase name of your master user.

**⚠ Important**

When you enter the user name, use uppercase unless you created the user with a case-sensitive identifier. For example, if you run `CREATE USER myuser` or `CREATE USER MYUSER`, the data dictionary stores MYUSER. However, if you use double quotes in `CREATE USER "MyUser"`, the data dictionary stores MyUser. For more information, see [Granting SELECT or EXECUTE privileges to SYS objects](#).

```
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_OBJECTS', 'MASTER_USER',
  'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_ROLE_PRIVS', 'MASTER_USER',
  'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_TAB_COLUMNS', 'MASTER_USER',
  'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONS_COLUMNS', 'MASTER_USER',
  'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_CONSTRAINTS', 'MASTER_USER',
  'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_OBJECTS', 'MASTER_USER',
  'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_PROCEDURES', 'MASTER_USER',
  'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TAB_COLUMNS', 'MASTER_USER',
  'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_TABLES', 'MASTER_USER',
  'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('USER_VIEWS', 'MASTER_USER', 'SELECT',
  true);
exec rdsadmin.rdsadmin_util.grant_sys_object('WPIUTL', 'MASTER_USER', 'EXECUTE',
  true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_SESSION', 'MASTER_USER',
  'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_UTILITY', 'MASTER_USER',
  'EXECUTE', true);

exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_LOB', 'MASTER_USER', 'EXECUTE',
  true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_ASSERT', 'MASTER_USER',
  'EXECUTE', true);
```

```
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_OUTPUT', 'MASTER_USER',
'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_SCHEDULER', 'MASTER_USER',
'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('HTP', 'MASTER_USER', 'EXECUTE',
true);
exec rdsadmin.rdsadmin_util.grant_sys_object('OWA', 'MASTER_USER', 'EXECUTE',
true);
exec rdsadmin.rdsadmin_util.grant_sys_object('WPG_DOCLOAD', 'MASTER_USER',
'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_CRYPT0', 'MASTER_USER',
'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_METADATA', 'MASTER_USER',
'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_SQL', 'MASTER_USER', 'EXECUTE',
true);
exec rdsadmin.rdsadmin_util.grant_sys_object('UTL_SMTP', 'MASTER_USER', 'EXECUTE',
true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBMS_NETWORK_ACL_ADMIN',
'MASTER_USER', 'EXECUTE', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('SESSION_PRIVS', 'MASTER_USER',
'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_USERS', 'MASTER_USER', 'SELECT',
true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_NETWORK_ACL_PRIVILEGES',
'MASTER_USER', 'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_NETWORK_ACLS', 'MASTER_USER',
'SELECT', true);
exec rdsadmin.rdsadmin_util.grant_sys_object('DBA_REGISTRY', 'MASTER_USER',
'SELECT', true);
```

**Note**

The preceding commands apply to ORDS 22 and later.

6. Install the ORDS schema using the downloaded ords script. Specify directories to contain configuration files and log files. Oracle Corporation recommends not placing these directories inside the directory that contains the ORDS product software.

```
mkdir -p /home/apexuser/ords_config /home/apexuser/ords_logs

/home/apexuser/ORDS/bin/ords \
```

```
--config /home/apexuser/ords_config \  
install --interactive --log-folder /home/apexuser/ords_logs
```

For DB instances running the container database (CDB) architecture, use ORDS 23.2 and higher and pass the `--pdb-skip-disable-lockdown` argument when installing ORDS.

```
/home/apexuser/ORDS/bin/ords \  
--config /home/apexuser/ords_config \  
install --interactive --log-folder /home/apexuser/ords_logs --pdb-skip-disable-  
lockdown
```

The program prompts you for the following information. The default values are in brackets. For more information, see [Introduction to Oracle REST data services](#) in the Oracle documentation.

- Choose the type of installation:

Choose **2** to install ORDS schemas in the database and create a database connection pool in the local ORDS configuration files.

- Specify the database connection type to use. Enter number for [1] Basic [2] TNS [3] Custom URL:

Choose the desired connection type. This example assumes that you choose **1**.

- Enter the name of the database server [localhost]:

***DB\_instance\_endpoint***

Choose the default or enter the correct value.

- Enter the database listener port [1521]: ***DB\_instance\_port***

Choose the default **1521** or enter the correct value.

- Enter the database service name [orcl]:

Enter the database name used by your RDS for Oracle DB instance.

- Provide database user name with administrator privileges

Enter the master user name for your RDS for Oracle DB instance.

- Enter the database password for [username]:

Enter the master user password for your RDS for Oracle DB instance.

- Enter the default tablespace for ORDS\_METADATA and ORDS\_PUBLIC\_USER [SYSAUX]:
- Enter the temporary tablespace for ORDS\_METADATA [TEMP]. Enter the default tablespace for ORDS\_PUBLIC\_USER [USERS]. Enter the temporary tablespace for ORDS\_PUBLIC\_USER [TEMP].
- Enter a number to select additional feature(s) to enable [1]:
- Enter a number to configure and start ORDS in standalone mode [1]:

Choose 2 to skip starting ORDS immediately in standalone mode.

- Enter a number to select the protocol [1] HTTP
- Enter the HTTP port [8080]:
- Enter the APEX static resources location:

Enter the path to APEX installation files (/home/apexuser/apex/images).

7. Set a password for the APEX admin user. To do this, use SQL\*Plus to connect to your DB instance as the master user, and then run the following commands.

```
EXEC rdsadmin.rdsadmin_util.grant_apex_admin_role;
grant APEX_ADMINISTRATOR_ROLE to master;
@/home/apexuser/apex/apxchpwd.sql
```

Replace *master* with your master user name. When the apxchpwd.sql script prompts you, enter a new admin password.

8. Run ORDS in standalone mode using the ords script with the serve command. For production deployments, consider using supported Java EE application servers such as Apache Tomcat or Oracle WebLogic Server. For more information, see [Deploying and Monitoring Oracle REST Data Services](#) in the Oracle Database documentation.

```
/home/apexuser/ORDS/bin/ords \  
  --config /home/apexuser/ords_config serve \  
  --port 8193 \  
  --apex-images /home/apexuser/apex/images
```

If ORDS is running but unable to access the APEX installation, you might see the following error, particularly on non-CDB instances.

The procedure named `apex_admin` could not be accessed, it may not be declared, or the user executing this request may not have been granted `execute` privilege on the procedure, or a function specified by `security.requestValidationFunction` configuration property has prevented access.

To fix this error, change the request validation function used by ORDS by running the `ords` script with the `config` command. By default, ORDS uses the `ords_util.authorize_plsql_gateway` procedure, which is only supported on CDB instances. For non-CDB instances, you can change this procedure to the `wwv_flow_epg_include_modules.authorize` package. See the Oracle Database documentation and Oracle Support for best practices on configuring the proper request validation function for your use case.

- Return to the APEX administration window in your browser and choose **Administration**. Next, choose **Application Express Internal Administration**. When you are prompted for credentials, enter the following information:

- User name** – `admin`
- Password** – the password you set using the `apxchpwd.sql` script

Choose **Login**, and then set a new password for the `admin` user.

Your listener is now ready for use.

## Setting up Oracle APEX listener

### Note

Oracle APEX Listener is deprecated.

Amazon RDS for Oracle continues to support APEX version 4.1.1 and Oracle APEX Listener version 1.1.4. We recommend that you use the latest supported versions of Oracle APEX and ORDS.

Install Oracle APEX Listener on a separate host such as an Amazon EC2 instance, an on-premises server at your company, or your desktop computer. We assume that the name of your host is `myapexhost.example.com`, and that your host is running Linux.

## Preparing to install Oracle APEX listener

Before you can install Oracle APEX Listener, you need to create a nonprivileged OS user, and then download and unzip the APEX installation file.

### To prepare for Oracle APEX listener installation

1. Log in to `myapexhost.example.com` as `root`.
2. Create a nonprivileged OS user to own the listener installation. The following command creates a new user named `apexuser`.

```
useradd -d /home/apexuser apexuser
```

The following command assigns a password to the new user.

```
passwd apexuser;
```

3. Log in to `myapexhost.example.com` as `apexuser`, and download the APEX installation file from Oracle to your `/home/apexuser` directory:
  - <http://www.oracle.com/technetwork/developer-tools/apex/downloads/index.html>
  - [Oracle application Express prior release archives](#)
4. Unzip the file in the `/home/apexuser` directory.

```
unzip apex_<version>.zip
```

After you unzip the file, there is an `apex` directory in the `/home/apexuser` directory.

5. While you are still logged into `myapexhost.example.com` as `apexuser`, download the Oracle APEX Listener file from Oracle to your `/home/apexuser` directory.

## Installing and configuring Oracle APEX listener

Before you can use APEX, you need to download the `apex.war` file, use Java to install Oracle APEX Listener, and then start the listener.

### To install and configure Oracle APEX listener

1. Create a new directory based on Oracle APEX Listener and open the listener file.

Run the following code:

```
mkdir /home/apexuser/apexlistener
cd /home/apexuser/apexlistener
unzip ../apex_listener.version.zip
```

2. Run the following code.

```
java -Dapex.home=./apex -Dapex.images=/home/apexuser/apex/images -Dapex.erase -
jar ./apex.war
```

3. Enter information for the program prompts following:

- The APEX Listener Administrator user name. The default is *adminlistener*.
- A password for the APEX Listener Administrator.
- The APEX Listener Manager user name. The default is *managerlistener*.
- A password for the APEX Listener Administrator.

The program prints a URL that you need to complete the configuration, as follows.

```
INFO: Please complete configuration at: http://localhost:8080/apex/
listenerConfigure
Database is not yet configured
```

4. Leave Oracle APEX Listener running so that you can use Oracle Application Express. When you have finished this configuration procedure, you can run the listener in the background.

5. From your web browser, go to the URL provided by the APEX Listener program. The Oracle Application Express Listener administration window appears. Enter the following information:

- **Username** – APEX\_PUBLIC\_USER
- **Password** – the password for *APEX\_PUBLIC\_USER*. This password is the one that you specified earlier when you configured the APEX repository. For more information, see [Unlocking the public user account on your DB instance](#).
- **Connection type** – Basic
- **Hostname** – the endpoint of your Amazon RDS DB instance, such as `mydb.f91bfa893tft.us-east-1.rds.amazonaws.com`.
- **Port** – 1521

- **SID** – the name of the database on your Amazon RDS DB instance, such as mydb.
6. Choose **Apply**. The APEX administration window appears.
  7. Set a password for the APEX admin user. To do this, use SQL\*Plus to connect to your DB instance as the master user, and then run the following commands.

```
EXEC rdsadmin.rdsadmin_util.grant_apex_admin_role;  
grant APEX_ADMINISTRATOR_ROLE to master;  
@/home/apexuser/apex/apxchpwd.sql
```

Replace *master* with your master user name. When the apxchpwd.sql script prompts you, enter a new admin password.

8. Return to the APEX administration window in your browser and choose **Administration**. Next, choose **Application Express Internal Administration**. When you are prompted for credentials, enter the following information:
  - **User name** – admin
  - **Password** – the password you set using the apxchpwd.sql script

Choose **Login**, and then set a new password for the admin user.

Your listener is now ready for use.

## Upgrading the APEX version

### Important

Back up your DB instance before you upgrade APEX. For more information, see [Creating a DB snapshot for a Single-AZ DB instance](#) and [Testing an Oracle DB upgrade](#).

To upgrade APEX with your DB instance, do the following:

- Create a new option group for the upgraded version of your DB instance.
- Add the upgraded versions of APEX and APEX-DEV to the new option group. Be sure to include any other options that your DB instance uses. For more information, see [Option group considerations](#).

- When you upgrade your DB instance, specify the new option group for your upgraded DB instance.

After you upgrade your version of APEX, the APEX schema for the previous version might still exist in your database. If you don't need it anymore, you can drop the old APEX schema from your database after you upgrade.

If you upgrade the APEX version and RESTful services were not configured in the previous APEX version, we recommend that you configure RESTful services. For more information, see [Configuring RESTful services for Oracle APEX](#).

In some cases when you plan to do a major version upgrade of your DB instance, you might find that you're using an APEX version that isn't compatible with your target database version. In these cases, you can upgrade your version of APEX before you upgrade your DB instance. Upgrading APEX first can reduce the amount of time that it takes to upgrade your DB instance.

#### Note

After upgrading APEX, install and configure a listener for use with the upgraded version. For instructions, see [Setting up Oracle APEX listener](#).

## Removing the APEX option

You can remove the Amazon RDS APEX options from a DB instance. To remove the APEX options from a DB instance, do one of the following:

- To remove the APEX options from multiple DB instances, remove the APEX options from the option group they belong to. This change affects all DB instances that use the option group. When you remove the APEX options from an option group that is attached to multiple DB instances, a brief outage occurs while all the DB instances are restarted.

For more information, see [Removing an option from an option group](#).

- To remove the APEX options from a single DB instance, modify the DB instance and specify a different option group that doesn't include the APEX options. You can specify the default (empty) option group, or a different custom option group. When you remove the APEX options, a brief outage occurs while your DB instance is automatically restarted.

For more information, see [Modifying an Amazon RDS DB instance](#).

When you remove the APEX options from a DB instance, the APEX schema is removed from your database.

## Amazon EFS integration

Amazon Elastic File System (Amazon EFS) provides serverless, fully elastic file storage so that you can share file data without provisioning or managing storage capacity and performance. With Amazon EFS, you can create a file system and then mount it in your VPC through the NFS versions 4.0 and 4.1 (NFSv4) protocol. Then you can use the EFS file system like any other POSIX-compliant file system. For general information, see [What is Amazon Elastic File System?](#) and the AWS blog [Integrate Amazon RDS for Oracle with Amazon EFS](#).

### Topics

- [Overview of Amazon EFS integration](#)
- [Configuring network permissions for RDS for Oracle integration with Amazon EFS](#)
- [Configuring IAM permissions for RDS for Oracle integration with Amazon EFS](#)
- [Adding the EFS\\_INTEGRATION option](#)
- [Configuring Amazon EFS file system permissions](#)
- [Transferring files between RDS for Oracle and an Amazon EFS file system](#)
- [Removing the EFS\\_INTEGRATION option](#)
- [Troubleshooting Amazon EFS integration](#)

### Overview of Amazon EFS integration

With Amazon EFS, you can transfer files between your RDS for Oracle DB instance and an EFS file system. For example, you can use EFS to support the following use cases:

- Share a file system between applications and multiple database servers.
- Create a shared directory for migration-related files, including transportable tablespace data files. For more information, see [Migrating using Oracle transportable tablespaces](#).
- Store and share archived redo log files without allocating additional storage space on the server.
- Use Oracle Database utilities such as UTL\_FILE to read and write files.

### Advantages to Amazon EFS integration

When you choose an EFS file system over alternative data transfer solutions, you get the following benefits:

- You can transfer Oracle Data Pump files between Amazon EFS and your RDS for Oracle DB instance. You don't need to copy these files locally because Data Pump imports directly from the EFS file system. For more information, see [Importing data into Oracle on Amazon RDS](#).
- Data migration is faster than using a database link.
- You avoid allocating storage space on your RDS for Oracle DB instance to hold the files.
- An EFS file systems can automatically scale storage without requiring you to provision it.
- Amazon EFS integration has no minimum fees or setup costs. You pay only for what you use.
- Amazon EFS integration supports two forms of encryption: encryption of data in transit and encryption at rest. Encryption of data in transit is enabled by default using TLS version 1.2. You can enable encryption of data at rest when creating an Amazon EFS file system. For more information, see [Encrypting data at rest](#) in the *Amazon Elastic File System User Guide*.

## Requirements for Amazon EFS integration

Make sure that you meet the following requirements:

- Your database runs database version 19.0.0.0.ru-2022-07.rur-2022-07.r1 or later.
- Your DB instance and your EFS file system are in the same AWS Region, VPC, and AWS account. RDS for Oracle doesn't support cross-account and cross-Region access for EFS.
- Your VPC has the `enableDnsSupport` attribute enabled. For more information, see [DNS attributes in your VPC](#) in the *Amazon Virtual Private Cloud User Guide*.
- Your EFS file system uses the Standard or Standard-IA storage class.
- To be able to use a DNS name in the `mount` command, the following must be true:
  - The connecting DB instance is inside a VPC and is configured to use the DNS server provided by Amazon. Custom DNS servers aren't supported.
  - The VPC of the connecting instance must have both **DNS Resolution** and **DNS Hostnames** enabled.
  - The connecting instance must be inside the same VPC as the EFS file system.
- You use non-RDS solutions to back up your EFS file system. RDS for Oracle doesn't support automated backups or manual DB snapshots of an EFS file system. For more information, see [Backing up your Amazon EFS file systems](#).

## Configuring network permissions for RDS for Oracle integration with Amazon EFS

For RDS for Oracle to integrate with Amazon EFS, make sure that your DB instance has network access to an EFS file system. For more information, see [Controlling network access to Amazon EFS file systems for NFS clients](#) in the *Amazon Elastic File System User Guide*.

### Topics

- [Controlling network access with security groups](#)
- [Controlling network access with file system policies](#)

### Controlling network access with security groups

You can control your DB instance access to EFS file systems using network layer security mechanisms such as VPC security groups. To allow access to an EFS file system for your DB instance, make sure that your EFS file system meets the following requirements:

- An EFS mount target exists in every Availability Zone used by an RDS for Oracle DB instance.

An *EFS mount target* provides an IP address for an NFSv4 endpoint at which you can mount an EFS file system. You mount your file system using its DNS name, which resolves to the IP address of the EFS mount target in the used by the Availability Zone of your DB instance.

You can configure DB instances in different AZs to use the same EFS file system. For Multi-AZ, you need a mount point for each AZ in your deployment. You might need to move a DB instance to a different AZ. For these reasons, we recommend that you create an EFS mount point in each AZ in your VPC. By default, when you create a new EFS file system using the console, RDS creates mount targets for all AZs.

- A security group is attached to the mount target.
- The security group has an inbound rule to allow the network subnet or security group of the RDS for Oracle DB instance on TCP/2049 (Type NFS).

For more information, see [Creating Amazon EFS file systems](#) and [Creating and managing EFS mount targets and security groups](#) in the *Amazon Elastic File System User Guide*.

### Controlling network access with file system policies

Amazon EFS integration with RDS for Oracle works with the default (empty) EFS file system policy. The default policy doesn't use IAM to authenticate. Instead, it grants full access to any anonymous

client that can connect to the file system using a mount target. The default policy is in effect whenever a user-configured file system policy isn't in effect, including at file system creation. For more information, see [Default EFS file system policy](#) in the *Amazon Elastic File System User Guide*.

To strengthen access to your EFS file system for all clients, including RDS for Oracle, you can configure IAM permissions. In this approach, you create a file system policy. For more information, see [Creating file system policies](#) in the *Amazon Elastic File System User Guide*.

## Configuring IAM permissions for RDS for Oracle integration with Amazon EFS

By default, Amazon EFS integration feature doesn't use an IAM role: the `USE_IAM_ROLE` option setting is `FALSE`. To integrate RDS for Oracle with Amazon EFS and an IAM role, your DB instance must have IAM permissions to access an Amazon EFS file system.

### Topics

- [Step 1: Create an IAM role for your DB instance and attach your policy](#)
- [Step 2: Create a file system policy for your Amazon EFS file system](#)
- [Step 3: Associate your IAM role with your RDS for Oracle DB instance](#)

### Step 1: Create an IAM role for your DB instance and attach your policy

In this step, you create a role for your RDS for Oracle DB instance to allow Amazon RDS to access your EFS file system.

### Console

#### To create an IAM role to allow Amazon RDS access to an EFS file system

1. Open the [IAM Management Console](#).
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. For **AWS service**, choose **RDS**.
5. For **Select your use case**, choose **RDS – Add Role to Database**.
6. Choose **Next**.
7. Don't add any permissions policies. Choose **Next**.
8. Set **Role name** to a name for your IAM role, for example `rds-efs-integration-role`. You can also add an optional **Description** value.

## 9. Choose **Create role**.

### AWS CLI

To limit the service's permissions to a specific resource, we recommend using the [aws:SourceArn](#) and [aws:SourceAccount](#) global condition context keys in resource-based trust relationships. This is the most effective way to protect against the [confused deputy problem](#).

You might use both global condition context keys and have the `aws:SourceArn` value contain the account ID. In this case, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the trust relationship, make sure to use the `aws:SourceArn` global condition context key with the full Amazon Resource Name (ARN) of the resources accessing the role.

The following AWS CLI command creates the role named *rds-efs-integration-role* for this purpose.

### Example

For Linux, macOS, or Unix:

```
aws iam create-role \
  --role-name rds-efs-integration-role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": my_account_ID,
            "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
          }
        }
      }
    ]
  }
```

```

    }
  }
]
}'

```

### For Windows:

```

aws iam create-role ^
--role-name rds-efs-integration-role ^
--assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "rds.amazonaws.com"
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "aws:SourceAccount": my_account_ID,
          "aws:SourceArn": "arn:aws:rds:Region:my_account_ID:db:dbname"
        }
      }
    }
  ]
}'

```

For more information, see [Creating a role to delegate permissions to an IAM user](#) in the *IAM User Guide*.

## Step 2: Create a file system policy for your Amazon EFS file system

In this step, you create a file system policy for your EFS file system.

### To create or edit an EFS file system policy

1. Open the [EFS Management Console](#).
2. Choose **File Systems**.
3. On the **File systems** page, choose the file system that you want to edit or create a file system policy for. The details page for that file system is displayed.

#### 4. Choose the **File system policy** tab.

If the policy is empty, then the default EFS file system policy is in use. For more information, see [Default EFS file system policy](#) in the *Amazon Elastic File System User Guide*.

#### 5. Choose **Edit**. The **File system policy** page appears.

#### 6. In **Policy editor**, enter a policy such as the following, and then choose **Save**.

```
{
  "Version": "2012-10-17",
  "Id": "ExamplePolicy01",
  "Statement": [
    {
      "Sid": "ExampleStatement01",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::123456789012:role/rds-efs-integration-role"
      },
      "Action": [
        "elasticfilesystem:ClientMount",
        "elasticfilesystem:ClientWrite",
        "elasticfilesystem:ClientRootAccess"
      ],
      "Resource": "arn:aws:elasticfilesystem:us-east-1:123456789012:file-
system/fs-1234567890abcdef0"
    }
  ]
}
```

### Step 3: Associate your IAM role with your RDS for Oracle DB instance

In this step, you associate your IAM role with your DB instance. Be aware of the following requirements:

- You must have access to an IAM role with the required Amazon EFS permissions policy attached to it.
- You can associate only one IAM role with your RDS for Oracle DB instance at a time.
- The status of your instance must be **Available**.

For more information, see [Identity and access management for Amazon EFS](#) in the *Amazon Elastic File System User Guide*.

## Console

### To associate your IAM role with your RDS for Oracle DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Databases**.
3. If your database instance is unavailable, choose **Actions** and then **Start**. When the instance status shows **Started**, go to the next step.
4. Choose the Oracle DB instance name to display its details.
5. On the **Connectivity & security** tab, scroll down to the **Manage IAM roles** section at the bottom of the page.
6. Choose the role to add in the **Add IAM roles to this instance** section.
7. For **Feature**, choose **EFS\_INTEGRATION**.
8. Choose **Add role**.

## AWS CLI

The following AWS CLI command adds the role to an Oracle DB instance named *mydbinstance*.

### Example

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \  
  --db-instance-identifier mydbinstance \  
  --feature-name EFS_INTEGRATION \  
  --role-arn your-role-arn
```

For Windows:

```
aws rds add-role-to-db-instance ^  
  --db-instance-identifier mydbinstance ^  
  --feature-name EFS_INTEGRATION ^
```

```
--role-arn your-role-arn
```

Replace *your-role-arn* with the role ARN that you noted in a previous step. EFS\_INTEGRATION must be specified for the `--feature-name` option.

## Adding the EFS\_INTEGRATION option

To integrate Amazon RDS for Oracle with Amazon EFS, your DB instance must be associated with an option group that includes the EFS\_INTEGRATION option.

Multiple Oracle DB instances that belong to the same option group share the same EFS file system. Different DB instances can access the same data, but access can be divided by using different Oracle directories. For more information see [Transferring files between RDS for Oracle and an Amazon EFS file system](#).

### Console

#### To configure an option group for Amazon EFS integration

1. Create a new option group or identify an existing option group to which you can add the EFS\_INTEGRATION option.

For information about creating an option group, see [Creating an option group](#).

2. Add the EFS\_INTEGRATION option to the option group. You need to specify the EFS\_ID file system ID and set the USE\_IAM\_ROLE flag.

For more information, see [Adding an option to an option group](#).

3. Associate the option group with your DB instance in either of the following ways:
  - Create a new Oracle DB instance and associate the option group with it. For information about creating a DB instance, see [Creating an Amazon RDS DB instance](#).
  - Modify an Oracle DB instance to associate the option group with it. For information about modifying an Oracle DB instance, see [Modifying an Amazon RDS DB instance](#).

### AWS CLI

#### To configure an option group for EFS integration

1. Create a new option group or identify an existing option group to which you can add the EFS\_INTEGRATION option.

For information about creating an option group, see [Creating an option group](#).

2. Add the EFS\_INTEGRATION option to the option group.

For example, the following AWS CLI command adds the EFS\_INTEGRATION option to an option group named **myoptiongroup**.

### Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \  
  --option-group-name myoptiongroup \  
  --options "OptionName=EFS_INTEGRATION,OptionSettings=\  
  [{Name=EFS_ID,Value=fs-1234567890abcdef0},{Name=USE_IAM_ROLE,Value=TRUE}]"
```

For Windows:

```
aws rds add-option-to-option-group ^  
  --option-group-name myoptiongroup ^  
  --options "OptionName=EFS_INTEGRATION,OptionSettings=^  
  [{Name=EFS_ID,Value=fs-1234567890abcdef0},{Name=USE_IAM_ROLE,Value=TRUE}]"
```

3. Associate the option group with your DB instance in either of the following ways:
  - Create a new Oracle DB instance and associate the option group with it. For information about creating a DB instance, see [Creating an Amazon RDS DB instance](#).
  - Modify an Oracle DB instance to associate the option group with it. For information about modifying an Oracle DB instance, see [Modifying an Amazon RDS DB instance](#).

## Configuring Amazon EFS file system permissions

By default, only the root user (UID 0) has read, write, and execute permissions for a newly created EFS file system. For other users to modify the file system, the root user must explicitly grant them access. The user for the RDS for Oracle DB instance is in the `others` category. For more information, see [Working with users, groups, and permissions at the Network File System \(NFS\) Level](#) in the *Amazon Elastic File System User Guide*.

To allow your RDS for Oracle DB instance to read and write files on an EFS file system, do the following:

- Mount an EFS file system locally on your Amazon EC2 or on-premises instance.
- Configure fine grain permissions.

For example, to grant other users permissions to write to the EFS file system root, run `chmod 777` on this directory. For more information, see [Example Amazon EFS file system use cases and permissions](#) in the *Amazon Elastic File System User Guide*.

## Transferring files between RDS for Oracle and an Amazon EFS file system

To transfer files between an RDS for Oracle instance and an Amazon EFS file system, create at least one Oracle directory and configure EFS file system permissions to control DB instance access.

### Topics

- [Creating an Oracle directory](#)
- [Transferring data to and from an EFS file system: examples](#)

### Creating an Oracle directory

To create an Oracle directory, use the procedure `rdsadmin.rdsadmin_util.create_directory_efs`. The procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>p_directory_name</code>	VARCHAR2	–	Yes	The name of the Oracle directory.
<code>p_path_on_efs</code>	VARCHAR2	–	Yes	The path on the EFS file system. The prefix of the path name uses the pattern <code>/rdsefs-<i>fsid</i>/</code> , where <i>fsid</i> is a placeholder for your EFS file system ID.  For example, if your EFS file system is named <code>fs-1234567890abcdef0</code> , and you create a subdirectory on this file system named <code>mydir</code> , you could specify the following value:

Parameter name	Data type	Default	Required	Description
				/rdsefs-fs-1234567890abcdef0/mydir

Assume that you create a subdirectory named /datapump1 on the EFS file system fs-1234567890abcdef0. The following example creates an Oracle directory DATA\_PUMP\_DIR\_EFS that points to the /datapump1 directory on the EFS file system. The file system path value for the p\_path\_on\_efs parameter is prefixed with the string /rdsefs-.

```
BEGIN
  rdsadmin.rdsadmin_util.create_directory_efs(
    p_directory_name => 'DATA_PUMP_DIR_EFS',
    p_path_on_efs    => '/rdsefs-fs-1234567890abcdef0/datapump1');
END;
/
```

## Transferring data to and from an EFS file system: examples

The following example uses Oracle Data Pump to export the table named MY\_TABLE to file datapump.dmp. This file resides on an EFS file system.

```
DECLARE
  v_hdn1 NUMBER;
BEGIN
  v_hdn1 := DBMS_DATAPUMP.OPEN(operation => 'EXPORT', job_mode => 'TABLE',
    job_name=>null);
  DBMS_DATAPUMP.ADD_FILE(
    handle     => v_hdn1,
    filename  => 'datapump.dmp',
    directory => 'DATA_PUMP_DIR_EFS',
    filetype  => dbms_datapump.ku$_file_type_dump_file);
  DBMS_DATAPUMP.ADD_FILE(
    handle     => v_hdn1,
    filename  => 'datapump-exp.log',
    directory => 'DATA_PUMP_DIR_EFS',
    filetype  => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdn1, 'NAME_EXPR', 'IN (''MY_TABLE'')');
  DBMS_DATAPUMP.START_JOB(v_hdn1);
END;
```

/

The following example uses Oracle Data Pump to import the table named MY\_TABLE from file datapump.dmp. This file resides on an EFS file system.

```

DECLARE
  v_hdn1 NUMBER;
BEGIN
  v_hdn1 := DBMS_DATAPUMP.OPEN(
    operation => 'IMPORT',
    job_mode  => 'TABLE',
    job_name  => null);
  DBMS_DATAPUMP.ADD_FILE(
    handle     => v_hdn1,
    filename   => 'datapump.dmp',
    directory  => 'DATA_PUMP_DIR_EFS',
    filetype   => dbms_datapump.ku$_file_type_dump_file );
  DBMS_DATAPUMP.ADD_FILE(
    handle     => v_hdn1,
    filename   => 'datapump-imp.log',
    directory  => 'DATA_PUMP_DIR_EFS',
    filetype   => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(v_hdn1, 'NAME_EXPR', 'IN (''MY_TABLE'')');
  DBMS_DATAPUMP.START_JOB(v_hdn1);
END;
/

```

For more information, see [Importing data into Oracle on Amazon RDS](#).

## Removing the EFS\_INTEGRATION option

The steps for removing the EFS\_INTEGRATION option depend on whether you're removing the option from multiple DB instances or a single instance.

Number of DB instances	Action	Related information
Multiple	Remove the EFS_INTEGRATION option from the option group to which the DB instances belong. This change affects all instances that use the option group.	<a href="#">Removing an option from an option group</a>

Number of DB instances	Action	Related information
Single	Modify the DB instance and specify a different option group that doesn't include the <code>EFS_INTEGRATION</code> option. You can specify the default (empty) option group or a different custom option group.	<a href="#">Modifying an Amazon RDS DB instance</a>

After you remove the `EFS_INTEGRATION` option, you can optionally delete the EFS file system that was connected to your DB instances.

## Troubleshooting Amazon EFS integration

Your RDS for Oracle DB instance monitors the connectivity to an Amazon EFS file system. When monitoring detects an issue, it might try to correct the issue and publish an event in the RDS console. For more information, see [Viewing Amazon RDS events](#).

Use the information in this section to help you diagnose and fix common issues when you work with Amazon EFS integration.

Notification	Description	Action
The EFS for RDS Oracle instance <i>instance_name</i> isn't available on the primary host. NFS port 2049 of your EFS isn't reachable.	The DB instance can't communicate with the EFS file system.	Make sure of the following: <ul style="list-style-type: none"> <li>The EFS file system exists.</li> <li>The security group that is attached to the EFS mount target has an inbound rule to allow the security group or network subnet of the RDS for Oracle DB instance on TCP/2049 (Type NFS).</li> </ul>
The EFS isn't reachable.	An error occurred during the installation of the <code>EFS_INTEGRATION</code> option.	Make sure of the following: <ul style="list-style-type: none"> <li>The EFS file system exists.</li> </ul>

Notification	Description	Action
		<ul style="list-style-type: none"> <li>• The security group that is attached to the EFS mount target has an inbound rule to allow the security group or network subnet of the RDS for Oracle DB instance on TCP/2049 (Type NFS).</li> <li>• The <code>enableDnsSupport</code> attribute is turned on for your VPC.</li> <li>• You are using the Amazon provided DNS server in your VPC. Amazon EFS integration doesn't work with a custom DHCP DNS.</li> </ul>
The associated role with your DB instance wasn't found.	An error occurred during the installation of the <code>EFS_INTEGRATION</code> option.	Make sure that you associated an IAM role with your RDS for Oracle DB instance.
The associated role with your DB instance wasn't found.	An error occurred during the installation of the <code>EFS_INTEGRATION</code> option. RDS for Oracle was restored from a DB snapshot with the <code>USE_IAM_ROLE</code> option setting of <code>TRUE</code> .	Make sure that you associated an IAM role with your RDS for Oracle DB instance.

Notification	Description	Action
The associated role with your DB instance wasn't found.	An error occurred during the installation of the EFS_INTEGRATION option. RDS for Oracle was created from an all-in-one CloudFormation template with the USE_IAM_ROLE option setting of TRUE.	As a workaround, complete the following steps: <ol style="list-style-type: none"> <li>1. Create a DB instance with the IAM role and default option group.</li> <li>2. On a subsequent stack update, add the custom option group with the EFS_INTEGRATION option.</li> </ol>
PLS-00302: component 'CREATE_DIRECTORY_EFS' must be declared	This error can occur when you're using a version of RDS for Oracle that doesn't support Amazon EFS.	Make sure that you are using RDS for Oracle DB instance version 19.0.0.0.ru-2022-07.rur-2022-07.r1 or higher.
Read access of your EFS is denied. Check your file system policy.	Your DB instance can't read the EFS file system.	Make sure that your EFS file system allows read access through the IAM role or on the EFS file system level.
N/A	Your DB instance can't write to the EFS file system.	Take the following steps: <ol style="list-style-type: none"> <li>1. Make sure that your EFS file system is mounted on an Amazon EC2 instance.</li> <li>2. Give the others group write access to your RDS user. The simplest technique is to run the <code>chmod 777</code> command on the top directory of the EFS file system.</li> </ol>

Notification	Description	Action
The <code>host -s</code> command returns <i>hostname</i> not found: 3(NXDOMAIN)	You're using a custom DNS server.	<p>To be able to use a DNS name in the mount command, the following must be true:</p> <ul style="list-style-type: none"><li>• The connecting DB instance is inside a VPC and is configured to use the DNS server provided by Amazon. Custom DNS servers aren't supported.</li><li>• The VPC of the connecting instance must have both <b>DNS Resolution</b> and <b>DNS Hostnames</b> enabled.</li><li>• The connecting instance must be inside the same VPC as the EFS file system.</li></ul>

## Oracle Java virtual machine

Amazon RDS supports Oracle Java Virtual Machine (JVM) through the use of the JVM option. Oracle Java provides a SQL schema and functions that facilitate Oracle Java features in an Oracle database. For more information, see [Introduction to Java in Oracle database](#) in the Oracle documentation. You can use Oracle JVM with all versions of Oracle Database 21c (21.0.0) and Oracle Database 19c (19.0.0).

### Considerations for Oracle JVM

Java implementation in Amazon RDS has a limited set of permissions. The master user is granted the RDS\_JAVA\_ADMIN role, which grants a subset of the privileges granted by the JAVA\_ADMIN role. To list the privileges granted to the RDS\_JAVA\_ADMIN role, run the following query on your DB instance:

```
SELECT * FROM dba_java_policy
WHERE grantee IN ('RDS_JAVA_ADMIN', 'PUBLIC')
AND enabled = 'ENABLED'
ORDER BY type_name, name, grantee;
```

### Prerequisites for Oracle JVM

The following are prerequisites for using Oracle Java:

- Your DB instance must be of a large enough class. Oracle Java isn't supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see [DB instance classes](#).
- Your DB instance must have **Auto Minor Version Upgrade** enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available. Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see [Modifying an Amazon RDS DB instance](#).

### Best practices for Oracle JVM

The following are best practices for using Oracle Java:

- For maximum security, use the JVM option with Secure Sockets Layer (SSL). For more information, see [Oracle Secure Sockets Layer](#).

- Configure your DB instance to restrict network access. For more information, see [Scenarios for accessing a DB instance in a VPC](#) and [Working with a DB instance in a VPC](#).
- Update the configuration of your HTTPS endpoints to support TLSv1.2 if you meet the following conditions:
  - You use Oracle Java Virtual Machine (JVM) to connect an HTTPS endpoint over TLSv1 or TLSv1.1 protocols.
  - Your endpoint doesn't support the TLSv1.2 protocol.
  - You haven't applied the April 2021 release update to your Oracle DB.

By updating your endpoint configuration, you ensure that the connectivity of the JVM to the HTTPS endpoint will continue to work. For more information about TLS changes in the Oracle JRE and JDK, see [Oracle JRE and JDK Cryptographic Roadmap](#).

## Adding the Oracle JVM option

The following is the general process for adding the JVM option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

There is a brief outage while the JVM option is added. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Java is available.

### Note

During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

## To add the JVM option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:

- For **Engine**, choose the DB engine used by the DB instance (**oracle-ee**, **oracle-se**, **oracle-se1**, or **oracle-se2**).
- For **Major engine version**, choose the version of your DB instance.

For more information, see [Creating an option group](#).

2. Add the **JVM** option to the option group. For more information about adding options, see [Adding an option to an option group](#).
3. Apply the option group to a new or existing DB instance:
  - For a new DB instance, apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
  - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](#).
4. Grant the required permissions to users.

The Amazon RDS master user has the permissions to use the JVM option by default. If other users require these permissions, connect to the DB instance as the master user in a SQL client and grant the permissions to the users.

The following example grants the permissions to use the JVM option to the test\_proc user.

```
create user test_proc identified by password;  
CALL dbms_java.grant_permission('TEST_PROC',  
  'oracle.aurora.security.JServerPermission', 'LoadClassInPackage.*', '');
```

 **Note**

Specify a password other than the prompt shown here as a security best practice.

After the user is granted the permissions, the following query should return output.

```
select * from dba_java_policy where grantee='TEST_PROC';
```

**Note**

The Oracle user name is case-sensitive, and it usually has all uppercase characters.

## Removing the Oracle JVM option

You can remove the JVM option from a DB instance. There is a brief outage while the option is removed. After you remove the JVM option, you don't need to restart your DB instance.

**Warning**

Removing the JVM option can result in data loss if the DB instance is using data types that were enabled as part of the option. Back up your data before proceeding. For more information, see [Backing up, restoring, and exporting data](#).

To remove the JVM option from a DB instance, do one of the following:

- Remove the JVM option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group](#).
- Modify the DB instance and specify a different option group that doesn't include the JVM option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance](#).

## Oracle Enterprise Manager

Amazon RDS supports Oracle Enterprise Manager (OEM). OEM is the Oracle product line for integrated management of enterprise information technology.

Amazon RDS supports OEM on Oracle Database 19c non-CDBs or CDBs. The following table describes the supported OEM options.

Option	Option ID	Supported OEM releases
<a href="#">OEM Database Express</a>	OEM	OEM Database Express 19c
<a href="#">OEM Management Agent</a>	OEM_AGENT	OEM Cloud Control for 13c

### Note

You can use OEM Database or OEM Management Agent, but not both.

## Oracle Enterprise Manager Database Express

Amazon RDS supports Oracle Enterprise Manager Database Express (EM Express) through the use of the OEM option. Amazon RDS supports EM Express for Oracle Database 19c using the CDB or non-CDB architecture.

EM Express is a web-based database management tool included in your database and is only available when it is open. It supports key performance management and basic database administration functions. For more information, see [Introduction to Oracle Enterprise Manager Database Express](#) in the Oracle Database documentation.

### Note

EM Express isn't supported on the db.t3.small DB instance class. For more information about DB instance classes, see [RDS for Oracle DB instance classes](#).

### OEM option settings

Amazon RDS supports the following settings for the OEM option.

Option setting	Valid values	Description
Port	An integer value	The port on the RDS for Oracle DB instance that listens for EM Express. The default is 5500.
Security Groups	—	A security group that has access to <b>Port</b> .

### Step 1: Adding the OEM option

The general process for adding the OEM option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with your DB instance.

When you add the OEM option, a brief outage occurs while your DB instance is automatically restarted.

### To add the OEM option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
  - a. For **Engine** choose the oracle edition for your DB instance.
  - b. For **Major engine version** choose the version of your DB instance.

For more information, see [Creating an option group](#).

2. Add the OEM option to the option group, and configure the option settings. For more information about adding options, see [Adding an option to an option group](#). For more information about each setting, see [OEM option settings](#).

#### Note

If you add the OEM option to an existing option group that is already attached to one or more DB instances, a brief outage occurs while all the DB instances are automatically restarted.

3. Apply the option group to a new or existing DB instance:
  - For a new DB instance, apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
  - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. When you add the OEM option, a brief outage occurs while your DB instance is automatically restarted. For more information, see [Modifying an Amazon RDS DB instance](#).

#### Note

You can also use the AWS CLI to add the OEM option. For examples, see [Adding an option to an option group](#).

## Step 2: (CDB only) Unlocking the DBSNMP user account

If your DB instance uses the CDB architecture, you must log in to EM Express as DBSNMP. In a CDB, DBSNMP is a common user. By default, this account is locked. If your DB instance doesn't use the CDB architecture, skip this step.

### To unlock the DBSNMP user account in a CDB instance

1. In SQL\*Plus or another Oracle SQL application, log in to your DB instance as your master user.
2. Run the following stored procedure to unlock the DBSNMP account:

```
EXEC rdsadmin.rdsadmin_util.reset_oem_agent_password('new_password');
```

If you receive an error stating that the procedure doesn't exist, reboot your CDB instance to install it automatically. For more information, see [Rebooting a DB instance](#).

## Step 3: Accessing EM Express through your browser

When you access EM Express from your web browser, a login window appears that prompts you for a user name and password.

### To access EM Express through your browser

1. Identify the endpoint and EM Express port for your Amazon RDS DB instance. For information about finding the endpoint for your Amazon RDS DB instance, see [Finding the endpoint of your RDS for Oracle DB instance](#).
2. Enter a URL in your browser locator bar using the following format.

```
https://endpoint.rds.amazonaws.com:port/em
```

For example, if the endpoint for your Amazon RDS DB instance is `mydb.a1bcde234fgh.us-east-1.rds.amazonaws.com`, and your EM Express port is 1158, then use the following URL to access EM Express.

```
https://mydb.f9rbfa893tft.us-east-1.rds.amazonaws.com:1158/em
```

3. When prompted for your login details, do one of the following actions, depending on your database architecture:

### Your database is a non-CDB.

Type the master user name and master password for your DB instance.

### Your database is a CDB.

Enter DBSNMP for the user and the DBSNMP password. Leave the Container field empty.

## Modifying OEM Database settings

After you enable OEM Database, you can modify the Security Groups setting for the option.

You can't modify the OEM port number after you have associated the option group with a DB instance. To change the OEM port number for a DB instance, do the following:

1. Create a new option group.
2. Add the OEM option with the new port number to the new option group.
3. Remove the existing option group from the DB instance.
4. Add the new option group to the DB instance.

For more information about how to modify option settings, see [Modifying an option setting](#). For more information about each setting, see [OEM option settings](#).

## Running OEM Database Express tasks

You can use Amazon RDS procedures to run certain OEM Database Express tasks. By running these procedures, you can do the tasks listed following.

### Note

OEM Database Express tasks run asynchronously.

## Tasks

- [Switching the website front end for OEM Database Express to Adobe Flash](#)
- [Switching the website front end for OEM Database Express to Oracle JET](#)

## Switching the website front end for OEM Database Express to Adobe Flash

### Note

This task is available only for Oracle Database 19c non-CDBs.

Starting with Oracle Database 19c, Oracle has deprecated the former OEM Database Express user interface, which was based on Adobe Flash. Instead, OEM Database Express now uses an interface built with Oracle JET. If you experience difficulties with the new interface, you can switch back to the deprecated Flash-based interface. Difficulties you might experience with the new interface include being stuck on a Loading screen after logging in to OEM Database Express. You might also miss certain features that were present in the Flash-based version of OEM Database Express.

To switch the OEM Database Express website front end to Adobe Flash, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash`. This procedure is equivalent to the `execemx emx` SQL command.

Security best practices discourage the use of Adobe Flash. Although you can revert to the Flash-based OEM Database Express, we recommend the use of the JET-based OEM Database Express websites if possible. If you revert to using Adobe Flash and want to switch back to using Oracle JET, use the `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet` procedure. After an Oracle database upgrade, a newer version of Oracle JET might resolve JET-related issues in OEM Database Express. For more information about switching to Oracle JET, see [Switching the website front end for OEM Database Express to Oracle JET](#).

### Note

Running this task from the source DB instance for a read replica also causes the read replica to switch its OEM Database Express website front ends to Adobe Flash.

The following procedure invocation creates a task to switch the OEM Database Express website to Adobe Flash and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash() as TASK_ID from DUAL;
```

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-task-id.log'));
```

Replace *task-id* with the task ID returned by the procedure. For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see [Reading files in a DB instance directory](#)

You can also view the contents of the task's output file in the AWS Management Console by searching the log entries in the **Logs & events** section for the `task-id`.

## Switching the website front end for OEM Database Express to Oracle JET

### Note

This task is available only for Oracle Database 19c non-CDBs.

To switch the OEM Database Express website front end to Oracle JET, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet`. This procedure is equivalent to the `execemx omx SQL` command.

By default, the OEM Database Express websites for Oracle DB instances running 19c or later use Oracle JET. If you used the `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_flash` procedure to switch the OEM Database Express website front end to Adobe Flash, you can switch back to Oracle JET. To do this, use the `rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet` procedure. For more information about switching to Adobe Flash, see [Switching the website front end for OEM Database Express to Adobe Flash](#).

### Note

Running this task from the source DB instance for a read replica also causes the read replica to switch its OEM Database Express website front ends to Oracle JET.

The following procedure invocation creates a task to switch the OEM Database Express website to Oracle JET and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_tasks.em_express_frontend_to_jet() as TASK_ID from DUAL;
```

You can view the result by displaying the task's output file.

```
SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-task-id.log'));
```

Replace *task-id* with the task ID returned by the procedure. For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see [Reading files in a DB instance directory](#)

You can also view the contents of the task's output file in the AWS Management Console by searching the log entries in the **Logs & events** section for the `task-id`.

### Removing the OEM Database option

You can remove the OEM option from a DB instance. When you remove the OEM option, a brief outage occurs while your instance is automatically restarted. Therefore, after you remove the OEM option, you don't need to restart your DB instance.

To remove the OEM option from a DB instance, do one of the following:

- Remove the OEM option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group](#).
- Modify the DB instance and specify a different option group that doesn't include the OEM option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance](#).

## Oracle Management Agent for Enterprise Manager Cloud Control

Oracle Enterprise Manager (OEM) Management Agent is a software component that monitors targets running on hosts and communicates that information to the middle-tier Oracle Management Service (OMS). Amazon RDS supports Management Agent through the use of the OEM\_AGENT option.

For more information, see [Overview of Oracle Enterprise Manager cloud control 12c](#) and [Overview of Oracle Enterprise Manager cloud control 13c](#) in the Oracle documentation.

### Topics

- [Requirements for Management Agent](#)
- [OMS host communication prerequisites](#)
- [Limitations for Management Agent](#)
- [Option settings for Management Agent](#)
- [Step 1: Adding the Management Agent option to your DB instance](#)
- [Step 2: Unlocking the DBSNMP user account](#)
- [Step 3: Adding your targets to the Management Agent console](#)
- [Administering the Management Agent](#)
- [Removing the Management Agent option](#)

### Requirements for Management Agent

Following are general requirements for using Management Agent:

- Your DB instance must run Oracle Database 19c (19.0.0.0). You can use either the CDB or non-CDB architecture.
- You must use an Oracle Management Service (OMS) that is configured to connect to your DB instance. Note the following OMS requirements:
  - Management Agent version 13.5.0.0.v1 requires OMS version 13.5.0.0 or later.
  - Management Agent version 13.4.0.9.v1 requires OMS version 13.4.0.9 or later and patch 32198287.
- In most cases, you must configure your VPC to allow connections from OMS to your DB instance. If you aren't familiar with Amazon Virtual Private Cloud (Amazon VPC), we recommend that

you complete the steps in [Tutorial: Create a VPC for use with a DB instance \(IPv4 only\)](#) before continuing.

- You can use Management Agent with Oracle Enterprise Manager Cloud Control for 12c and 13c. Ensure that you have sufficient storage space for your OEM release:
  - At least 8.5 GiB for OEM 13c Release 5
  - At least 8.5 GiB for OEM 13c Release 4
  - At least 8.5 GiB for OEM 13c Release 3
  - At least 5.5 GiB for OEM 13c Release 2
  - At least 4.5 GiB OEM 13c Release 1
  - At least 2.5 GiB for OEM 12c
- If you're using Management Agent versions OEM\_AGENT 13.2.0.0.v3 and 13.3.0.0.v2, and if you want to use TCPS connectivity, follow the instructions in [Configuring third party CA certificates for communication with target databases](#) in the Oracle documentation. Also, update the JDK on your OMS by following the instructions in the Oracle document with the Oracle Doc ID 2241358.1. This step ensures that OMS supports all the cipher suites that the database supports.

#### Note

TCPS connectivity between the Management Agent and the DB instance is supported for Management Agent OEM\_AGENT 13.2.0.0.v3, 13.3.0.0.v2, 13.4.0.9.v1, and higher versions.

## OMS host communication prerequisites

Make sure that your OMS host and your Amazon RDS DB instance can communicate. Do the following:

- To connect from the Management Agent to your OMS, if your OMS is behind a firewall, add the IP addresses of your DB instances to your OMS.

Make sure the firewall for the OMS allows traffic from both the DB listener port (default 1521) and the OEM Agent port (default 3872), originating from the IP address of the DB instance.

- To connect from your OMS to the Management Agent, if your OMS has a publicly resolvable host name, add the OMS address to a security group. Your security group must have inbound

rules that allow access to the DB listener port and the Management Agent port. For an example of creating a security and adding inbound rules, see [Tutorial: Create a VPC for use with a DB instance \(IPv4 only\)](#).

- To connect from your OMS to the Management Agent, if your OMS doesn't have a publicly resolvable host name, use one of the following:
  - If your OMS is hosted on an Amazon Elastic Compute Cloud (Amazon EC2) instance in a private VPC, you can set up VPC peering to connect from OMS to Management Agent. For more information, see [A DB instance in a VPC accessed by an EC2 instance in a different VPC](#).
  - If your OMS is hosted on-premises, you can set up a VPN connection to allow access from OMS to Management Agent. For more information, see [A DB instance in a VPC accessed by a client application through the internet](#) or [VPN connections](#).

## Limitations for Management Agent

Following are some limitations to using Management Agent:

- You can't provide custom Oracle Management Agent images.
- Administrative tasks such as job execution and database patching, that require host credentials, aren't supported.
- Host metrics and the process list aren't guaranteed to reflect the actual system state. Thus, you shouldn't use OEM to monitor the root file system or mount point file system. For more information about monitoring the operating system, see [Monitoring OS metrics with Enhanced Monitoring](#).
- Autodiscovery isn't supported. You must manually add database targets.
- OMS module availability depends on your database edition. For example, the database performance diagnosis and tuning module is only available for Oracle Database Enterprise Edition.
- Management Agent consumes additional memory and computing resources. If you experience performance problems after enabling the OEM\_AGENT option, we recommend that you scale up to a larger DB instance class. For more information, see [DB instance classes](#) and [Modifying an Amazon RDS DB instance](#).
- The user running the OEM\_AGENT on the Amazon RDS host doesn't have operating system access to the alert log. Thus, you can't collect metrics for DB Alert Log and DB Alert Log Error Status in OEM.

## Option settings for Management Agent

Amazon RDS supports the following settings for the Management Agent option.

Option setting	Required	Valid values	Description
<b>Version</b> (AGENT_VERSION )	Yes	13.5.0.0.v1 13.4.0.9.v1 13.3.0.0.v2 13.3.0.0.v1 13.2.0.0.v3 13.2.0.0.v2 13.2.0.0.v1 13.1.0.0.v1	<p>The version of the Management Agent software. The minimum supported version is 13.1.0.0.v1 .</p> <p>The AWS CLI option name is <code>OptionVersion</code> .</p> <div data-bbox="938 716 1507 982" style="border: 1px solid #add8e6; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p><b>Note</b></p> <p>In the AWS GovCloud (US) Regions, 13.1 versions aren't available.</p> </div>
<b>Port</b> (AGENT_PORT )	Yes	An integer value	<p>The port on the DB instance that listens for the OMS host. The default is 3872. Your OMS host must belong to a security group that has access to this port.</p> <p>The AWS CLI option name is <code>Port</code>.</p>

Option setting	Required	Valid values	Description
<b>Security Groups</b>	Yes	Existing security groups	<p>A security group that has access to <b>Port</b>. Your OMS host must belong to this security group.</p> <p>The AWS CLI option name is <code>VpcSecurityGroupMemberships</code> or <code>DBSecurityGroupMemberships</code>.</p>
<b>OMS_HOST</b>	Yes	A string value, for example <i>my.example.oms</i>	<p>The publicly accessible host name or IP address of the OMS.</p> <p>The AWS CLI option name is <code>OMS_HOST</code>.</p>
<b>OMS_PORT</b>	Yes	An integer value	<p>The HTTPS upload port on the OMS Host that listens for the Management Agent.</p> <p>To determine the HTTPS upload port, connect to the OMS host, and run the following command (which requires the SYSMAN password):</p> <pre>emctl status oms -details</pre> <p>The AWS CLI option name is <code>OMS_PORT</code>.</p>

Option setting	Required	Valid values	Description
<b>AGENT_REGISTRATION_PASSWORD</b>	Yes	A string value	<p>The password that the Management Agent uses to authenticate itself with the OMS. We recommend that you create a persistent password in your OMS before enabling the OEM_AGENT option. With a persistent password you can share a single Management Agent option group among multiple Amazon RDS databases.</p> <p>The AWS CLI option name is AGENT_REGISTRATION_PASSWORD .</p>
<b>ALLOW_TLS_ONLY</b>	No	true, false (default)	<p>A value that configures the OEM Agent to support only the TLSv1 protocol while the agent listens as a server. This setting is no longer supported. Management Agent versions 13.1.0.0.v1 and higher support Transport Layer Security (TLS) by default.</p>
<b>MINIMUM_TLS_VERSION</b>	No	TLSv1 (default), TLSv1.2	<p>A value that specifies the minimum TLS version supported by the OEM Agent while the agent listens as a server. Desupported agent versions only support the TLSv1 setting.</p>
<b>TLS_CIPHER_SUITE</b>	No	See <a href="#">Option settings for Management Agent</a> .	<p>A value that specifies the TLS cipher suite used by the OEM Agent while the agent listens as a server.</p>

The following table lists the TLS cipher suites that the Management Agent option supports.

Cipher suite	Agent version supported	FedRAMP compliant
TLS_RSA_WITH_AES_128_CBC_SHA	All	No
TLS_RSA_WITH_AES_128_CBC_SHA256	13.1.0.0.v1 and higher	No
TLS_RSA_WITH_AES_256_CBC_SHA	13.2.0.0.v3 and higher	No
TLS_RSA_WITH_AES_256_CBC_SHA256	13.2.0.0.v3 and higher	No
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA	13.2.0.0.v3 and higher	Yes
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA	13.2.0.0.v3 and higher	Yes
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256	13.2.0.0.v3 and higher	Yes
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384	13.2.0.0.v3 and higher	Yes

### Step1: Adding the Management Agent option to your DB instance

To add the Management Agent option to your DB instance, do the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If you encounter errors, check [My Oracle Support](#) documents for information about resolving specific problems.

After you add the Management Agent option, you don't need to restart your DB instance. As soon as the option group is active, the OEM Agent is active.

If your OMS host is using an untrusted third-party certificate, Amazon RDS returns the following error.

```
You successfully installed the OEM_AGENT option. Your OMS host is using an untrusted
third party certificate.
Configure your OMS host with the trusted certificates from your third party.
```

If this error is returned, the Management Agent option isn't enabled until the problem is corrected. For information about correcting the problem, see the My Oracle Support document [2202569.1](#).

## Console

### To add the Management Agent option to your DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
  - a. For **Engine** choose the oracle edition for your DB instance.
  - b. For **Major engine version** choose the version of your DB instance.

For more information, see [Creating an option group](#).

2. Add the **OEM\_AGENT** option to the option group, and configure the option settings. For more information about adding options, see [Adding an option to an option group](#). For more information about each setting, see [Option settings for Management Agent](#).
3. Apply the option group to a new or existing DB instance:
  - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
  - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](#).

## AWS CLI

The following example uses the AWS CLI [add-option-to-option-group](#) command to add the OEM\_AGENT option to an option group called myoptiongroup.

## For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \  
  --option-group-name "myoptiongroup" \  
  --options  
  OptionName=OEM_AGENT,OptionVersion=13.1.0.0.v1,Port=3872,VpcSecurityGroupMemberships=sg-123456  
{Name=OMS_PORT,Value=4903},{Name=AGENT_REGISTRATION_PASSWORD,Value=password}] \  
  --apply-immediately
```

## For Windows:

```
aws rds add-option-to-option-group ^  
  --option-group-name "myoptiongroup" ^  
  --options  
  OptionName=OEM_AGENT,OptionVersion=13.1.0.0.v1,Port=3872,VpcSecurityGroupMemberships=sg-123456  
{Name=OMS_PORT,Value=4903},{Name=AGENT_REGISTRATION_PASSWORD,Value=password}] ^  
  --apply-immediately
```

## Step 2: Unlocking the DBSNMP user account

The Management Agent uses the DBSNMP user account to connect to the database and report issues to Oracle Enterprise Manager. In a CDB, DBSNMP is a common user. This user account is necessary for both the Management Agent and OEM Database Express. By default, this account is locked. The procedure for unlocking this account differs depending on whether your database uses the non-CDB or CDB architecture.

### To unlock the DBSNMP user account

1. In SQL\*Plus or another Oracle SQL application, log in to your DB instance as your master user.
2. Do either of the following actions, depending on the database architecture:

#### Your database is a non-CDB.

Run the following SQL statement:

```
ALTER USER dbsnmp IDENTIFIED BY new_password ACCOUNT UNLOCK;
```

#### Your database is a CDB.

Run the following stored procedure to unlock the DBSNMP account:

```
EXEC rdsadmin.rdsadmin_util.reset_oem_agent_password('new_password');
```

If you receive an error stating that the procedure doesn't exist, reboot your CDB instance to install it automatically. For more information, see [Rebooting a DB instance](#).

### Step 3: Adding your targets to the Management Agent console

To add a DB instance as a target, make sure you know the endpoint and port. For information about finding the endpoint for your Amazon RDS DB instance, see [Finding the endpoint of your RDS for Oracle DB instance](#). If your database uses the CDB architecture, then add the CDB\$ROOT container separately as a target.

#### To add targets to the Management Agent console

1. In your OMS console, choose **Setup, Add Target, Add Targets Manually**.
2. Choose **Add Targets Declaratively by Specifying Target Monitoring Properties**.
3. For **Target Type**, choose **Database Instance**.
4. For **Monitoring Agent**, choose the agent with the identifier that is the same as your RDS DB instance identifier.
5. Choose **Add Manually**.
6. Enter the endpoint for your Amazon RDS DB instance, or choose it from the host name list. Make sure that the specified host name matches the endpoint of the Amazon RDS DB instance.
7. Specify the following database properties:
  - For **Target name**, enter a name.
  - For **Database system name**, enter a name.
  - For **Monitor username**, enter **dbsnmp**.
  - For **Monitor password**, enter the password from [Step 2: Unlocking the DBSNMP user account](#).
  - For **Role**, enter **normal**.
  - For **Oracle home path**, enter **/oracle**.
  - For **Listener Machine name**, the agent identifier already appears.
  - For **Port**, enter the database port. The RDS default port is 1521.

- For **Database name**, enter the name of your database. If your database is a CDB, this name is RDSADB.
8. Choose **Test Connection**.
  9. Choose **Next**. The target database appears in your list of monitored resources.

## Administering the Management Agent

You can use Amazon RDS procedures to run certain EMCTL commands on the Management Agent. By running these procedures, you can do the tasks listed following.

### Note

Tasks are executed asynchronously.

## Tasks

- [Getting the status of the Management Agent](#)
- [Restarting the Management Agent](#)
- [Listing the targets monitored by the Management Agent](#)
- [Listing the collection threads monitored by the Management Agent](#)
- [Clearing the Management Agent state](#)
- [Making the Management Agent upload its OMS](#)
- [Pinging the OMS](#)
- [Viewing the status of an ongoing task](#)

## Getting the status of the Management Agent

To get the status of the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.get_status_oem_agent`. This procedure is equivalent to the `emctl status agent` command.

The following procedure creates a task to get the Management Agent's status and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.get_status_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see [Viewing the status of an ongoing task](#).

## Restarting the Management Agent

To restart the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.restart_oem_agent`. This procedure is equivalent to running the `emctl stop agent` and `emctl start agent` commands.

The following procedure creates a task to restart the Management Agent and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.restart_oem_agent as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see [Viewing the status of an ongoing task](#).

## Listing the targets monitored by the Management Agent

To list the targets monitored by the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.list_targets_oem_agent`. This procedure is equivalent to running the `emctl config agent listtargets` command.

The following procedure creates a task to list the targets monitored by the Management Agent and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.list_targets_oem_agent as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see [Viewing the status of an ongoing task](#).

## Listing the collection threads monitored by the Management Agent

To list of all the running, ready, and scheduled collection threads monitored by the Management Agent, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.list_clxn_threads_oem_agent`. This procedure is equivalent to the `emctl status agent scheduler` command.

The following procedure creates a task to list the collection threads and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.list_clxn_threads_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see [Viewing the status of an ongoing task](#).

## Clearing the Management Agent state

To clear the Management Agent's state, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.clearstate_oem_agent`. This procedure is equivalent to running the `emctl clearstate agent` command.

The following procedure creates a task that clears the Management Agent's state and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.clearstate_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see [Viewing the status of an ongoing task](#).

## Making the Management Agent upload its OMS

To make the Management Agent upload the Oracle Management Server (OMS) associated with it, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.upload_oem_agent`. This procedure is equivalent to running the `emctl upload agent` command.

The following procedure creates a task that makes the Management Agent upload its associated OMS and return the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.upload_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see [Viewing the status of an ongoing task](#).

## Pinging the OMS

To ping the Management Agent's OMS, run the Amazon RDS procedure `rdsadmin.rdsadmin_oem_agent_tasks.ping_oms_oem_agent`. This procedure is equivalent to running the `emctl pingOMS` command.

The following procedure creates a task that pings the Management Agent's OMS and returns the ID of the task.

```
SELECT rdsadmin.rdsadmin_oem_agent_tasks.ping_oms_oem_agent() as TASK_ID from DUAL;
```

To view the result by displaying the task's output file, see [Viewing the status of an ongoing task](#).

## Viewing the status of an ongoing task

You can view the status of an ongoing task in a bdump file. The bdump files are located in the `/rdsdbdata/log/trace` directory. Each bdump file name is in the following format.

```
dbtask-task-id.log
```

When you want to monitor a task, replace *task-id* with the ID of the task that you want to monitor.

To view the contents of bdump files, run the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`. The following query returns the contents of the `dbtask-1546988886389-2444.log` bdump file.

```
SELECT text FROM  
table(rdsadmin.rds_file_util.read_text_file('BDUMP', 'dbtask-1546988886389-2444.log'));
```

For more information about the Amazon RDS procedure `rdsadmin.rds_file_util.read_text_file`, see [Reading files in a DB instance directory](#).

## Removing the Management Agent option

You can remove the OEM Agent from a DB instance. After you remove the OEM Agent, you don't need to restart your DB instance.

To remove the OEM Agent from a DB instance, do one of the following:

- Remove the OEM Agent option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group](#).
- Modify the DB instance and specify a different option group that doesn't include the OEM Agent option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance](#).

## Oracle Label Security

Amazon RDS supports Oracle Label Security for the Enterprise Edition of Oracle Database through the use of the OLS option.

Most database security controls access at the object level. Oracle Label Security provides fine-grained control of access to individual table rows. For example, you can use Label Security to enforce regulatory compliance with a policy-based administration model. You can use Label Security policies to control access to sensitive data, and restrict access to only users with the appropriate clearance level. For more information, see [Introduction to Oracle Label Security](#) in the Oracle documentation.

### Topics

- [Requirements for Oracle Label Security](#)
- [Considerations when using Oracle Label Security](#)
- [Adding the Oracle Label Security option](#)
- [Troubleshooting](#)

### Requirements for Oracle Label Security

Familiarize yourself with the following requirements for Oracle Label Security:

- Your DB instance must use the Bring Your Own License model. For more information, see [RDS for Oracle licensing options](#).
- You must have a valid license for Oracle Enterprise Edition with Software Update License and Support.
- Your Oracle license must include the Label Security option.

### Considerations when using Oracle Label Security

To use Oracle Label Security, you create policies that control access to specific rows in your tables. For more information, see [Creating an Oracle Label Security policy](#) in the Oracle documentation.

Consider the following:

- Oracle Label Security is a permanent and persistent option. Because the option is permanent, you can't remove it from an option group. If you add Oracle Label Security to an option group

and associate it with your DB instance, you can later associate a different option group with your DB instance, but this group must also contain the Oracle Label Security option.

- When you work with Label Security, you perform all actions as the LBAC\_DBA role. The master user for your DB instance is granted the LBAC\_DBA role. You can grant the LBAC\_DBA role to other users so that they can administer Label Security policies.
- Make sure to grant access to the OLS\_ENFORCEMENT package to any new users who require access to Oracle Label Security. To grant access to the OLS\_ENFORCEMENT package, connect to the DB instance as the master user and run the following SQL statement:

```
GRANT ALL ON LBACSYS.OLS_ENFORCEMENT TO username;
```

- You can configure Label Security through Oracle Enterprise Manager (OEM) Cloud Control. Amazon RDS supports OEM Cloud Control through the Management Agent option. For more information, see [Oracle Management Agent for Enterprise Manager Cloud Control](#).

## Adding the Oracle Label Security option

The general process for adding the Oracle Label Security option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.

### Important

Oracle Label Security is a permanent and persistent option.

3. Associate the option group with the DB instance.

After you add the Label Security option, as soon as the option group is active, Label Security is active.

## To add the label security option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
  - a. For **Engine**, choose **oracle-ee**.

- b. For **Major engine version**, choose the version of your DB instance.

For more information, see [Creating an option group](#).

2. Add the **OLS** option to the option group. For more information about adding options, see [Adding an option to an option group](#).

### Important

If you add Label Security to an existing option group that is already attached to one or more DB instances, all the DB instances are restarted.

3. Apply the option group to a new or existing DB instance:
  - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
  - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. When you add the Label Security option to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see [Modifying an Amazon RDS DB instance](#).

## Troubleshooting

The following are issues you might encounter when you use Oracle Label Security.

Issue	Troubleshooting suggestions
<p>When you try to create a policy, you see an error message similar to the following:</p> <pre>insufficient authorization for the SYSDBA package.</pre>	<p>A known issue with Oracle's Label Security feature prevents users with usernames of 16 or 24 characters from running Label Security commands. You can create a new user with a different number of characters, grant LBAC_DBA to the new user, log in as the new user, and run the OLS commands as the new user. For additional information, contact Oracle Support.</p>

## Oracle Locator

Amazon RDS supports Oracle Locator through the use of the LOCATOR option. Oracle Locator provides capabilities that are typically required to support internet and wireless service-based applications and partner-based GIS solutions. Oracle Locator is a limited subset of Oracle Spatial. For more information, see [Oracle Locator](#) in the Oracle documentation.

### Important

If you use Oracle Locator, Amazon RDS automatically updates your DB instance to the latest Oracle PSU if there are security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+ or other announced security vulnerabilities.

## Supported database releases for Oracle Locator

RDS for Oracle supports Oracle Locator for Oracle Database 19c. Oracle Locator isn't supported for Oracle Database 21c, but its functionality is available in the Oracle Spatial option. Formerly, the Spatial option required additional licenses. Oracle Locator represented a subset of Oracle Spatial features and didn't require additional licenses. In 2019, Oracle announced that all Oracle Spatial features were included in the Enterprise Edition and Standard Edition 2 licenses without additional cost. Consequently, the Oracle Spatial option no longer required additional licensing. For more information, see [Machine Learning, Spatial and Graph - No License Required!](#) in the Oracle Database Insider blog.

## Prerequisites for Oracle Locator

The following are prerequisites for using Oracle Locator:

- Your DB instance must be of sufficient class. Oracle Locator is not supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see [RDS for Oracle DB instance classes](#).
- Your DB instance must have **Auto Minor Version Upgrade** enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see [Modifying an Amazon RDS DB instance](#).

## Best practices for Oracle Locator

The following are best practices for using Oracle Locator:

- For maximum security, use the LOCATOR option with Secure Sockets Layer (SSL). For more information, see [Oracle Secure Sockets Layer](#).
- Configure your DB instance to restrict access to your DB instance. For more information, see [Scenarios for accessing a DB instance in a VPC](#) and [Working with a DB instance in a VPC](#).

## Adding the Oracle Locator option

The following is the general process for adding the LOCATOR option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the LOCATOR option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Locator is available.

### Note

During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

## To add the LOCATOR option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
  - a. For **Engine**, choose the oracle edition for your DB instance.
  - b. For **Major engine version**, choose the version of your DB instance.

For more information, see [Creating an option group](#).

2. Add the **LOCATOR** option to the option group. For more information about adding options, see [Adding an option to an option group](#).
3. Apply the option group to a new or existing DB instance:
  - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
  - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](#).

## Using Oracle Locator

After you enable the Oracle Locator option, you can begin using it. You should only use Oracle Locator features. Don't use any Oracle Spatial features unless you have a license for Oracle Spatial.

For a list of features that are supported for Oracle Locator, see [Features Included with Locator](#) in the Oracle documentation.

For a list of features that are not supported for Oracle Locator, see [Features Not Included with Locator](#) in the Oracle documentation.

## Removing the Oracle Locator option

After you drop all objects that use data types provided by the **LOCATOR** option, you can remove the option from a DB instance. If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the **LOCATOR** option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the **LOCATOR** option, you don't need to restart your DB instance.

### To drop the **LOCATOR** option

1. Back up your data.

**⚠ Warning**

If the instance uses data types that were enabled as part of the option, and if you remove the LOCATOR option, you can lose data. For more information, see [Backing up, restoring, and exporting data](#).

2. Check whether any existing objects reference data types or features of the LOCATOR option.

If LOCATOR options exist, the instance can get stuck when applying the new option group that doesn't have the LOCATOR option. You can identify the objects by using the following queries:

```
SELECT OWNER, SEGMENT_NAME, TABLESPACE_NAME, BYTES/1024/1024 mbytes
FROM   DBA_SEGMENTS
WHERE  SEGMENT_TYPE LIKE '%TABLE%'
AND    (OWNER, SEGMENT_NAME) IN
      (SELECT DISTINCT OWNER, TABLE_NAME
       FROM   DBA_TAB_COLUMNS
       WHERE  DATA_TYPE='SDO_GEOMETRY'
       AND    OWNER <> 'MDSYS')
ORDER BY 1,2,3,4;

SELECT OWNER, TABLE_NAME, COLUMN_NAME
FROM   DBA_TAB_COLUMNS
WHERE  DATA_TYPE = 'SDO_GEOMETRY'
AND    OWNER <> 'MDSYS'
ORDER BY 1,2,3;
```

3. Drop any objects that reference data types or features of the LOCATOR option.
4. Do one of the following:
  - Remove the LOCATOR option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group](#).
  - Modify the DB instance and specify a different option group that doesn't include the LOCATOR option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance](#).

## Oracle native network encryption

Amazon RDS supports Oracle native network encryption (NNE). With the `NATIVE_NETWORK_ENCRYPTION` option, you can encrypt data as it moves to and from a DB instance. Amazon RDS supports NNE for all editions of Oracle Database.

A detailed discussion of Oracle native network encryption is beyond the scope of this guide, but you should understand the strengths and weaknesses of each algorithm and key before you decide on a solution for your deployment. For information about the algorithms and keys that are available through Oracle native network encryption, see [Configuring network data encryption](#) in the Oracle documentation. For more information about AWS security, see the [AWS security center](#).

### Note

You can use Native Network Encryption or Secure Sockets Layer, but not both. For more information, see [Oracle Secure Sockets Layer](#).

## NATIVE\_NETWORK\_ENCRYPTION option settings

You can specify encryption requirements on both the server and the client. The DB instance can act as a client when, for example, it uses a database link to connect to another database. You might want to avoid forcing encryption on the server side. For example, you might not want to force all client communications to use encryption because the server requires it. In this case, you can force encryption on the client side using the `SQLNET.*CLIENT` options.

Amazon RDS supports the following settings for the `NATIVE_NETWORK_ENCRYPTION` option.

### Note

When you use commas to separate values for an option setting, don't put a space after the comma.

Option setting	Valid values	Default values	Description
<code>SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS</code>	TRUE, FALSE	TRUE	The behavior of the server when a client using a non-secure cipher

Option setting	Valid values	Default values	Description
			<p>attempts to connect to the database. If TRUE, clients can connect even if they aren't patched with the July 2021 PSU.</p> <p>If the setting is FALSE, clients can connect to the database only when they are patched with the July 2021 PSU. Before you set <code>SQLNET.ALLOW_WEAK_CRYPTO_CLIENTS</code> to FALSE, make sure that the following conditions are met:</p> <ul style="list-style-type: none"> <li>• <code>SQLNET.ENCRYPTION_TYPES_SERVER</code> and <code>SQLNET.ENCRYPTION_TYPES_CLIENT</code> have one matching encryption method that is not DES, 3DES, or RC4 (all key lengths).</li> <li>• <code>SQLNET.CHECKSUM_TYPES_SERVER</code> and <code>SQLNET.CHECKSUM_TYPES_CLIENT</code> have one matching secure checksumming method that is not MD5.</li> <li>• The client is patched with the July 2021 PSU. If the client isn't patched, the client loses the connection and receives the ORA-12269 error.</li> </ul>

Option setting	Valid values	Default values	Description
SQLNET.ALLOW_WEAK_CRYPTO	TRUE, FALSE	TRUE	<p>The behavior of the server when a client using a non-secure cipher attempts to connect to the database. The following ciphers are considered not secure:</p> <ul style="list-style-type: none"> <li>• DES encryption method (all key lengths)</li> <li>• 3DES encryption method (all key lengths)</li> <li>• RC4 encryption method (all key lengths)</li> <li>• MD5 checksumming method</li> </ul> <p>If the setting is TRUE, clients can connect when they use the preceding non-secure ciphers.</p> <p>If the setting is FALSE, the database prevents clients from connecting when they use the preceding non-secure ciphers. Before you set SQLNET.ALLOW_WEAK_CRYPTO to FALSE, make sure that the following conditions are met:</p> <ul style="list-style-type: none"> <li>• SQLNET.ENCRYPTION_TYPES_SERVER and SQLNET.ENCRYPTION_TYPES_CLIENT have one matching encryption method that is not DES, 3DES, or RC4 (all key lengths).</li> </ul>

Option setting	Valid values	Default values	Description
			<ul style="list-style-type: none"> <li>SQLNET.CHECKSUM_TYPES_SERVER and SQLNET.CHECKSUM_TYPES_CLIENT have one matching secure checksumming method that is not MD5.</li> <li>The client is patched with the July 2021 PSU. If the client isn't patched, the client loses the connection and receives the ORA-12269 error.</li> </ul>
SQLNET.CRYPTO_CHECKSUM_CLIENT	Accepted Rejected Requested , Required	Requested	<p>The data integrity behavior when a DB instance connects to the client, or a server acting as a client. When a DB instance uses a database link, it acts as a client.</p> <p>Requested indicates that the client doesn't require the DB instance to perform a checksum.</p>
SQLNET.CRYPTO_CHECKSUM_SERVER	Accepted Rejected Requested , Required	Requested	<p>The data integrity behavior when a client, or a server acting as a client, connects to the DB instance. When a DB instance uses a database link, it acts as a client.</p> <p>Requested indicates that the DB instance doesn't require the client to perform a checksum.</p>

Option setting	Valid values	Default values	Description
SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT	SHA256, SHA384, SHA512, SHA1, MD5	SHA256, SHA384, SHA512	<p>A list of checksum algorithms.</p> <p>You can specify either one value or a comma-separated list of values. If you use a comma, don't insert a space after the comma; otherwise, you receive an <code>InvalidParameterValue</code> error.</p> <p>This parameter and <code>SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER</code> must have a common cipher.</p>
SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER	SHA256, SHA384, SHA512, SHA1, MD5	SHA256, SHA384, SHA512, SHA1, MD5	<p>A list of checksum algorithms.</p> <p>You can specify either one value or a comma-separated list of values. If you use a comma, don't insert a space after the comma; otherwise, you receive an <code>InvalidParameterValue</code> error.</p> <p>This parameter and <code>SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT</code> must have a common cipher.</p>
SQLNET.ENCRYPTION_CLIENT	Accepted Rejected Requested ,	Requested	<p>The encryption behavior of the client when a client, or a server acting as a client, connects to the DB instance. When a DB instance uses a database link, it acts as a client.</p> <p><code>Requested</code> indicates that the client does not require traffic from the server to be encrypted.</p>

Option setting	Valid values	Default values	Description
SQLNET.ENCRYPTION_SERVER	Accepted Rejected Requested , Required	Requested	<p>The encryption behavior of the server when a client, or a server acting as a client, connects to the DB instance. When a DB instance uses a database link, it acts as a client.</p> <p>Requested indicates that the DB instance does not require traffic from the client to be encrypted.</p>

Option setting	Valid values	Default values	Description
SQLNET.ENCRYPTION_TYPES_CLIENT	RC4_256, AES256, AES192, 3DES168, RC4_128, AES128, 3DES112, RC4_56, DES, RC4_40, DES40	RC4_256, AES256, AES192, 3DES168, RC4_128, AES128, 3DES112, RC4_56, DES, RC4_40, DES40	<p>A list of encryption algorithms used by the client. The client attempts to decrypt the server input by trying each algorithm in order, proceeding until an algorithm succeeds or the end of the list is reached.</p> <p>Amazon RDS uses the following default list from Oracle. RDS starts with RC4_256 and proceeds down the list in order. You can change the order or limit the algorithms that the DB instance will accept.</p> <ol style="list-style-type: none"> <li>1. RC4_256: RSA RC4 (256-bit key size)</li> <li>2. AES256: AES (256-bit key size)</li> <li>3. AES192: AES (192-bit key size)</li> <li>4. 3DES168: 3-key Triple-DES (112-bit effective key size)</li> <li>5. RC4_128: RSA RC4 (128-bit key size)</li> <li>6. AES128: AES (128-bit key size)</li> <li>7. 3DES112: 2-key Triple-DES (80-bit effective key size)</li> <li>8. RC4_56: RSA RC4 (56-bit key size)</li> <li>9. DES: Standard DES (56-bit key size)</li> <li>10. RC4_40: RSA RC4 (40-bit key size)</li> <li>11. DES40: DES40 (40-bit key size)</li> </ol> <p>You can specify either one value or a comma-separated list of values. If you use a comma, don't insert a space after</p>

Option setting	Valid values	Default values	Description
			<p>the comma; otherwise, you receive an <code>InvalidParameterValue</code> error.</p> <p>This parameter and <code>SQLNET.SQLNET.ENCRYPTION_TY</code> <code>PES_SERVER</code> must have a common cipher.</p>

Option setting	Valid values	Default values	Description
SQLNET.ENCRYPTION_TYPES_SERVER	RC4_256, AES256, AES192, 3DES168, RC4_128, AES128, 3DES112, RC4_56, DES, RC4_40, DES40	RC4_256, AES256, AES192, 3DES168, RC4_128, AES128, 3DES112, RC4_56, DES, RC4_40, DES40	<p>A list of encryption algorithms used by the DB instance. The DB instance uses each algorithm, in order, to attempt to decrypt the client input until an algorithm succeeds or until the end of the list is reached.</p> <p>Amazon RDS uses the following default list from Oracle. You can change the order or limit the algorithms that the client will accept.</p> <ol style="list-style-type: none"> <li>1. RC4_256: RSA RC4 (256-bit key size)</li> <li>2. AES256: AES (256-bit key size)</li> <li>3. AES192: AES (192-bit key size)</li> <li>4. 3DES168: 3-key Triple-DES (112-bit effective key size)</li> <li>5. RC4_128: RSA RC4 (128-bit key size)</li> <li>6. AES128: AES (128-bit key size)</li> <li>7. 3DES112: 2-key Triple-DES (80-bit effective key size)</li> <li>8. RC4_56: RSA RC4 (56-bit key size)</li> <li>9. DES: Standard DES (56-bit key size)</li> <li>10. RC4_40: RSA RC4 (40-bit key size)</li> <li>11. DES40: DES40 (40-bit key size)</li> </ol> <p>You can specify either one value or a comma-separated list of values. If you use a comma, don't insert a space after the comma; otherwise, you receive an <code>InvalidParameterValue</code> error.</p>

Option setting	Valid values	Default values	Description
			This parameter and SQLNET .SQLNET . ENCRYPTION_TY PES_SERVER must have a common cipher.

## Adding the NATIVE\_NETWORK\_ENCRYPTION option

The general process for adding the NATIVE\_NETWORK\_ENCRYPTION option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

When the option group is active, NNE is active.

### To add the NATIVE\_NETWORK\_ENCRYPTION option to a DB instance using the AWS Management Console

1. For **Engine**, choose the Oracle edition that you want to use. NNE is supported on all editions.
2. For **Major engine version**, choose the version of your DB instance.

For more information, see [Creating an option group](#).

3. Add the **NATIVE\_NETWORK\_ENCRYPTION** option to the option group. For more information about adding options, see [Adding an option to an option group](#).

#### Note

After you add the **NATIVE\_NETWORK\_ENCRYPTION** option, you don't need to restart your DB instances. As soon as the option group is active, NNE is active.

4. Apply the option group to a new or existing DB instance:

- For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
- For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. After you add the **NATIVE\_NETWORK\_ENCRYPTION** option, you don't need to restart your DB instance. As soon as the option group is active, NNE is active. For more information, see [Modifying an Amazon RDS DB instance](#).

## Setting NNE values in the sqlnet.ora

With Oracle native network encryption, you can set network encryption on the server side and client side. The client is the computer used to connect to the DB instance. You can specify the following client settings in the sqlnet.ora:

- `SQLNET.ALLOW_WEAK_CRYPT0`
- `SQLNET.ALLOW_WEAK_CRYPT0_CLIENTS`
- `SQLNET.CRYPTO_CHECKSUM_CLIENT`
- `SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT`
- `SQLNET.ENCRYPTION_CLIENT`
- `SQLNET.ENCRYPTION_TYPES_CLIENT`

For information, see [Configuring network data encryption and integrity for Oracle servers and clients](#) in the Oracle documentation.

Sometimes, the DB instance rejects a connection request from an application. For example, a rejection can occur when the encryption algorithms on the client and on the server don't match. To test Oracle native network encryption, add the following lines to the sqlnet.ora file on the client:

```
DIAG_ADR_ENABLED=off
TRACE_DIRECTORY_CLIENT=/tmp
TRACE_FILE_CLIENT=nettrace
TRACE_LEVEL_CLIENT=16
```

When a connection is attempted, the preceding lines generate a trace file on the client called `/tmp/nettrace*`. The trace file contains information about the connection. For more information about connection-related issues when you are using Oracle Native Network Encryption, see [About negotiating encryption and integrity](#) in the Oracle Database documentation.

## Modifying NATIVE\_NETWORK\_ENCRYPTION option settings

After you enable the NATIVE\_NETWORK\_ENCRYPTION option, you can modify its settings. Currently, you can modify NATIVE\_NETWORK\_ENCRYPTION option settings only with the AWS CLI or RDS API. You can't use the console. The following example modifies two settings in the option.

```
aws rds add-option-to-option-group \
  --option-group-name my-option-group \
  --options
  "OptionName=NATIVE_NETWORK_ENCRYPTION,OptionSettings=[{Name=SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER,Value=SHA256},{Name=SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER,Value=SHA256}]" \
  --apply-immediately
```

To learn how to modify option settings using the CLI, see [AWS CLI](#). For more information about each setting, see [NATIVE\\_NETWORK\\_ENCRYPTION option settings](#).

### Topics

- [Modifying CRYPTO\\_CHECKSUM\\_\\* values](#)
- [Modifying ALLOW\\_WEAK\\_CRYPTO\\* settings](#)

### Modifying CRYPTO\_CHECKSUM\_\* values

If you modify **NATIVE\_NETWORK\_ENCRYPTION** option settings, make sure that the following option settings have at least one common cipher:

- SQLNET.CRYPTO\_CHECKSUM\_TYPES\_SERVER
- SQLNET.CRYPTO\_CHECKSUM\_TYPES\_CLIENT

The following example shows a scenario in which you modify SQLNET.CRYPTO\_CHECKSUM\_TYPES\_SERVER. The configuration is valid because the CRYPTO\_CHECKSUM\_TYPES\_CLIENT and CRYPTO\_CHECKSUM\_TYPES\_SERVER both use SHA256.

Option setting	Values before modification	Values after modification
SQLNET.CRYPTO_CHECKSUM_TYPES_CLIENT	SHA256, SHA384, SHA512	No change

Option setting	Values before modification	Values after modification
SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER	<b>SHA256</b> , SHA384, SHA512, SHA1, MD5	SHA1, MD5, <b>SHA256</b>

For another example, assume that you want to modify SQLNET.CRYPTO\_CHECKSUM\_TYPES\_SERVER from its default setting to SHA1, MD5. In this case, make sure you set SQLNET.CRYPTO\_CHECKSUM\_TYPES\_CLIENT to SHA1 or MD5. These algorithms aren't included in the default values for SQLNET.CRYPTO\_CHECKSUM\_TYPES\_CLIENT.

### Modifying ALLOW\_WEAK\_CRYPT0\* settings

To set the SQLNET.ALLOW\_WEAK\_CRYPT0\* options from the default value to FALSE, make sure that the following conditions are met:

- SQLNET.ENCRYPTION\_TYPES\_SERVER and SQLNET.ENCRYPTION\_TYPES\_CLIENT have one matching secure encryption method. A method is considered secure if it's not DES, 3DES, or RC4 (all key lengths).
- SQLNET.CHECKSUM\_TYPES\_SERVER and SQLNET.CHECKSUM\_TYPES\_CLIENT have one matching secure checksumming method. A method is considered secure if it's not MD5.
- The client is patched with the July 2021 PSU. If the client isn't patched, the client loses the connection and receives the ORA-12269 error.

The following example shows sample NNE settings. Assume that you want to set SQLNET.ENCRYPTION\_TYPES\_SERVER and SQLNET.ENCRYPTION\_TYPES\_CLIENT to FALSE, thereby blocking non-secure connections. The checksum option settings meet the prerequisites because they both have SHA256. However, SQLNET.ENCRYPTION\_TYPES\_CLIENT and SQLNET.ENCRYPTION\_TYPES\_SERVER use the DES, 3DES, and RC4 encryption methods, which are non-secure. Therefore, to set the SQLNET.ALLOW\_WEAK\_CRYPT0\* options to FALSE, first set SQLNET.ENCRYPTION\_TYPES\_SERVER and SQLNET.ENCRYPTION\_TYPES\_CLIENT to a secure encryption method such as AES256.

Option setting	Values
SQLNET.CRYPTO_CHEC KSUM_TYPES_CLIENT	SHA256, SHA384, SHA512
SQLNET.CRYPTO_CHEC KSUM_TYPES_SERVER	SHA1, MD5, SHA256
SQLNET.ENCRYPTION_ TYPES_CLIENT	RC4_256, 3DES168, DES40
SQLNET.ENCRYPTION_ TYPES_SERVER	RC4_256, 3DES168, DES40

## Removing the NATIVE\_NETWORK\_ENCRYPTION option

You can remove NNE from a DB instance.

To remove the NATIVE\_NETWORK\_ENCRYPTION option from a DB instance, do one of the following:

- To remove the option from multiple DB instances, remove the NATIVE\_NETWORK\_ENCRYPTION option from the option group they belong to. This change affects all DB instances that use the option group. After you remove the NATIVE\_NETWORK\_ENCRYPTION option, you don't need to restart your DB instances. For more information, see [Removing an option from an option group](#).
- To remove the option from a single DB instance, modify the DB instance and specify a different option group that doesn't include the NATIVE\_NETWORK\_ENCRYPTION option. You can specify the default (empty) option group, or a different custom option group. After you remove the NATIVE\_NETWORK\_ENCRYPTION option, you don't need to restart your DB instance. For more information, see [Modifying an Amazon RDS DB instance](#).

## Oracle OLAP

Amazon RDS supports Oracle OLAP through the use of the OLAP option. This option provides On-line Analytical Processing (OLAP) for Oracle DB instances. You can use Oracle OLAP to analyze large amounts of data by creating dimensional objects and cubes in accordance with the OLAP standard. For more information, see [the Oracle documentation](#).

### Important

If you use Oracle OLAP, Amazon RDS automatically updates your DB instance to the latest Oracle PSU if there are security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+ or other announced security vulnerabilities.

Amazon RDS supports Oracle OLAP for the Enterprise Edition of Oracle Database 19c and higher.

## Prerequisites for Oracle OLAP

The following are prerequisites for using Oracle OLAP:

- You must have an Oracle OLAP license from Oracle. For more information, see [Licensing Information](#) in the Oracle documentation.
- Your DB instance must be of a sufficient instance class. Oracle OLAP isn't supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see [RDS for Oracle DB instance classes](#).
- Your DB instance must have **Auto Minor Version Upgrade** enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see [Modifying an Amazon RDS DB instance](#).
- Your DB instance must not have a user named OLAPSYS. If it does, the OLAP option installation fails.

## Best practices for Oracle OLAP

The following are best practices for using Oracle OLAP:

- For maximum security, use the OLAP option with Secure Sockets Layer (SSL). For more information, see [Oracle Secure Sockets Layer](#).
- Configure your DB instance to restrict access to your DB instance. For more information, see [Scenarios for accessing a DB instance in a VPC](#) and [Working with a DB instance in a VPC](#).

## Adding the Oracle OLAP option

The following is the general process for adding the OLAP option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the OLAP option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle OLAP is available.

### To add the OLAP option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
  - For **Engine**, choose the Oracle edition for your DB instance.
  - For **Major engine version**, choose the version of your DB instance.

For more information, see [Creating an option group](#).

2. Add the **OLAP** option to the option group. For more information about adding options, see [Adding an option to an option group](#).
3. Apply the option group to a new or existing DB instance:
  - For a new DB instance, apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
  - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](#).

## Using Oracle OLAP

After you enable the Oracle OLAP option, you can begin using it. For a list of features that are supported for Oracle OLAP, see [the Oracle documentation](#).

## Removing the Oracle OLAP option

After you drop all objects that use data types provided by the OLAP option, you can remove the option from a DB instance. If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the OLAP option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the OLAP option, you don't need to restart your DB instance.

### To drop the OLAP option

1. Back up your data.

#### Warning

If the instance uses data types that were enabled as part of the option, and if you remove the OLAP option, you can lose data. For more information, see [Backing up, restoring, and exporting data](#).

2. Check whether any existing objects reference data types or features of the OLAP option.
3. Drop any objects that reference data types or features of the OLAP option.
4. Do one of the following:
  - Remove the OLAP option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group](#).
  - Modify the DB instance and specify a different option group that doesn't include the OLAP option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance](#).

## Oracle Secure Sockets Layer

To enable SSL encryption for an RDS for Oracle DB instance, add the Oracle SSL option to the option group associated with the DB instance. Amazon RDS uses a second port, as required by Oracle, for SSL connections. This approach allows both clear text and SSL-encrypted communication to occur at the same time between a DB instance and SQL\*Plus. For example, you can use the port with clear text communication to communicate with other resources inside a VPC while using the port with SSL-encrypted communication to communicate with resources outside the VPC.

### Note

You can use either SSL or Native Network Encryption (NNE) on the same RDS for Oracle DB instance, but not both. If you use SSL encryption, make sure to turn off any other connection encryption. For more information, see [Oracle native network encryption](#).

SSL/TLS and NNE are no longer part of Oracle Advanced Security. In RDS for Oracle, you can use SSL encryption with all licensed editions of the following database versions:

- Oracle Database 21c (21.0.0)
- Oracle Database 19c (19.0.0)

## TLS versions for the Oracle SSL option

Amazon RDS for Oracle supports Transport Layer Security (TLS) versions 1.0 and 1.2. When you add a new Oracle SSL option, set `SQLNET.SSL_VERSION` explicitly to a valid value. The following values are allowed for this option setting:

- "1.0" – Clients can connect to the DB instance using TLS version 1.0 only. For existing Oracle SSL options, `SQLNET.SSL_VERSION` is set to "1.0" automatically. You can change the setting if necessary.
- "1.2" – Clients can connect to the DB instance using TLS 1.2 only.
- "1.2 or 1.0" – Clients can connect to the DB instance using either TLS 1.2 or 1.0.

## Cipher suites for the Oracle SSL option

Amazon RDS for Oracle supports multiple SSL cipher suites. By default, the Oracle SSL option is configured to use the `SSL_RSA_WITH_AES_256_CBC_SHA` cipher suite. To specify a different cipher suite to use over SSL connections, use the `SQLNET.CIPHER_SUITE` option setting.

You can specify multiple values for `SQLNET.CIPHER_SUITE`. This technique is useful if you have database links between your DB instances and decide to update your cipher suites.

The following table summarizes SSL support for RDS for Oracle in all editions of Oracle Database 19c and 21c.

Cipher suite (SQLNET.CIPHER_SUITE)	TLS version support (SQLNET.SSL_VERSION)	FIPS support	FedRAMP compliant
SSL_RSA_WITH_AES_256_CBC_SHA (default)	1.0 and 1.2	Yes	No
SSL_RSA_WITH_AES_256_CBC_SHA256	1.2	Yes	No
SSL_RSA_WITH_AES_256_GCM_SHA384	1.2	Yes	No
TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384	1.2	Yes	Yes
TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256	1.2	Yes	Yes
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384	1.2	Yes	Yes
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256	1.2	Yes	Yes
TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA	1.2	Yes	Yes
TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA	1.2	Yes	Yes

## FIPS support

RDS for Oracle allows you to use the Federal Information Processing Standard (FIPS) standard for 140-2. FIPS 140-2 is a United States government standard that defines cryptographic module security requirements. You turn on the FIPS standard by setting `FIPS.SSLFIPS_140` to `TRUE` for the Oracle SSL option. When FIPS 140-2 is configured for SSL, the cryptographic libraries encrypt data between the client and the RDS for Oracle DB instance.

Clients must use the cipher suite that is FIPS-compliant. When establishing a connection, the client and RDS for Oracle DB instance negotiate which cipher suite to use when transmitting messages back and forth. The table in [Cipher suites for the Oracle SSL option](#) shows the FIPS-compliant SSL cipher suites for each TLS version. For more information, see [Oracle database FIPS 140-2 settings](#) in the Oracle Database documentation.

## Adding the SSL option

To use SSL, your RDS for Oracle DB instance must be associated with an option group that includes the SSL option.

### Console

#### To add the SSL option to an option group

1. Create a new option group or identify an existing option group to which you can add the SSL option.

For information about creating an option group, see [Creating an option group](#).

2. Add the SSL option to the option group.

If you want to use only FIPS-verified cipher suites for SSL connections, set the option `FIPS.SSLFIPS_140` to `TRUE`. For information about the FIPS standard, see [FIPS support](#).

For information about adding an option to an option group, see [Adding an option to an option group](#).

3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

For information about creating an DB instance, see [Creating an Amazon RDS DB instance](#).

For information about modifying an DB instance, see [Modifying an Amazon RDS DB instance](#).

## AWS CLI

### To add the SSL option to an option group

1. Create a new option group or identify an existing option group to which you can add the SSL option.

For information about creating an option group, see [Creating an option group](#).

2. Add the SSL option to the option group.

Specify the following option settings:

- `Port` – The SSL port number
- `VpcSecurityGroupMemberships` – The VPC security group for which the option is enabled
- `SQLNET.SSL_VERSION` – The TLS version that client can use to connect to the DB instance

For example, the following AWS CLI command adds the SSL option to an option group named `ora-option-group`.

### Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group --option-group-name ora-option-group \  
  --options  
  'OptionName=SSL,Port=2484,VpcSecurityGroupMemberships="sg-68184619",OptionSettings=[{Name=
```

For Windows:

```
aws rds add-option-to-option-group --option-group-name ora-option-group ^  
  --options  
  'OptionName=SSL,Port=2484,VpcSecurityGroupMemberships="sg-68184619",OptionSettings=[{Name=
```

3. Create a new RDS for Oracle DB instance and associate the option group with it, or modify an RDS for Oracle DB instance to associate the option group with it.

For information about creating an DB instance, see [Creating an Amazon RDS DB instance](#).

For information about modifying an DB instance, see [Modifying an Amazon RDS DB instance](#).

## Configuring SQL\*Plus to use SSL with an RDS for Oracle DB instance

Before you can connect to an RDS for Oracle DB instance that uses the Oracle SSL option, you must configure SQL\*Plus before connecting.

### Note

To allow access to the DB instance from the appropriate clients, ensure that your security groups are configured correctly. For more information, see [Controlling access with security groups](#). Also, these instructions are for SQL\*Plus and other clients that directly use an Oracle home. For JDBC connections, see [Setting up an SSL connection over JDBC](#).

### To configure SQL\*Plus to use SSL to connect to an RDS for Oracle DB instance

1. Set the ORACLE\_HOME environment variable to the location of your Oracle home directory.

The path to your Oracle home directory depends on your installation. The following example sets the ORACLE\_HOME environment variable.

```
prompt>export ORACLE_HOME=/home/user/app/user/product/19.0.0/dbhome_1
```

For information about setting Oracle environment variables, see [SQL\\*Plus environment variables](#) in the Oracle documentation, and also see the Oracle installation guide for your operating system.

2. Append \$ORACLE\_HOME/lib to the LD\_LIBRARY\_PATH environment variable.

The following is an example that sets the LD\_LIBRARY\_PATH environment variable.

```
prompt>export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:$ORACLE_HOME/lib
```

3. Create a directory for the Oracle wallet at \$ORACLE\_HOME/ssl\_wallet.

The following is an example that creates the Oracle wallet directory.

```
prompt>mkdir $ORACLE_HOME/ssl_wallet
```

4. Download the certificate bundle .pem file that works for all AWS Regions and put the file in the `ssl_wallet` directory. For information, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).
5. In the `$ORACLE_HOME/network/admin` directory, modify or create the `tnsnames.ora` file and include the following entry.

```

net_service_name =
  (DESCRIPTION =
    (ADDRESS_LIST =
      (ADDRESS =
        (PROTOCOL = TCPS)
        (HOST = endpoint)
        (PORT = ssl_port_number)
      )
    )
    (CONNECT_DATA =
      (SID = database_name)
    )
    (SECURITY =
      (SSL_SERVER_CERT_DN =
        "C=US,ST=Washington,L=Seattle,O=Amazon.com,OU=RDS,CN=endpoint")
      )
    )
  )

```

6. In the same directory, modify or create the `sqlnet.ora` file and include the following parameters.

### Note

To communicate with entities over a TLS secured connection, Oracle requires a wallet with the necessary certificates for authentication. You can use Oracle's ORAPKI utility to create and maintain Oracle wallets, as shown in step 7. For more information, see [Setting up Oracle wallet using ORAPKI](#) in the Oracle documentation.

```

WALLET_LOCATION = (SOURCE = (METHOD = FILE) (METHOD_DATA = (DIRECTORY =
  $ORACLE_HOME/ssl_wallet)))
SSL_CLIENT_AUTHENTICATION = FALSE
SSL_VERSION = 1.0
SSL_CIPHER_SUITES = (SSL_RSA_WITH_AES_256_CBC_SHA)

```

```
SSL_SERVER_DN_MATCH = ON
```

**Note**

You can set `SSL_VERSION` to a higher value if your DB instance supports it.

7. Run the following command to create the Oracle wallet.

```
prompt>orapki wallet create -wallet $ORACLE_HOME/ssl_wallet -auto_login_only
```

8. Extract each certificate in the .pem bundle file into a separate .pem file using an OS utility.
9. Add each certificate to your wallet using separate `orapki` commands, replacing *certificate-pem-file* with the absolute file name of the .pem file.

```
prompt>orapki wallet add -wallet $ORACLE_HOME/ssl_wallet -trusted_cert -cert  
certificate-pem-file -auto_login_only
```

For more information, see [Rotating your SSL/TLS certificate](#).

## Connecting to an RDS for Oracle DB instance using SSL

After you configure SQL\*Plus to use SSL as described previously, you can connect to the RDS for Oracle DB instance with the SSL option. Optionally, you can first export the `TNS_ADMIN` value that points to the directory that contains the `tnsnames.ora` and `sqlnet.ora` files. Doing so ensures that SQL\*Plus can find these files consistently. The following example exports the `TNS_ADMIN` value.

```
export TNS_ADMIN = ${ORACLE_HOME}/network/admin
```

Connect to the DB instance. For example, you can connect using SQL\*Plus and a *<net\_service\_name>* in a `tnsnames.ora` file.

```
sqlplus mydbuser@net_service_name
```

You can also connect to the DB instance using SQL\*Plus without using a `tnsnames.ora` file by using the following command.

```
sqlplus 'mydbuser@(DESCRIPTION = (ADDRESS = (PROTOCOL = TCPS)(HOST = endpoint) (PORT = ssl_port_number))(CONNECT_DATA = (SID = database_name)))'
```

You can also connect to the RDS for Oracle DB instance without using SSL. For example, the following command connects to the DB instance through the clear text port without SSL encryption.

```
sqlplus 'mydbuser@(DESCRIPTION = (ADDRESS = (PROTOCOL = TCP)(HOST = endpoint) (PORT = port_number))(CONNECT_DATA = (SID = database_name)))'
```

If you want to close Transmission Control Protocol (TCP) port access, create a security group with no IP address ingresses and add it to the instance. This addition closes connections over the TCP port, while still allowing connections over the SSL port that are specified from IP addresses within the range permitted by the SSL option security group.

## Setting up an SSL connection over JDBC

To use an SSL connection over JDBC, you must create a keystore, trust the Amazon RDS root CA certificate, and use the code snippet specified following.

To create the keystore in JKS format, you can use the following command. For more information about creating the keystore, see the [Creating a keystore](#) in the Oracle documentation. For reference information, see [keytool](#) in the *Java Platform, Standard Edition Tools Reference*.

```
keytool -genkey -alias client -validity 365 -keyalg RSA -keystore clientkeystore
```

Take the following steps to trust the Amazon RDS root CA certificate.

### To trust the Amazon RDS root CA certificate

1. Download the certificate bundle .pem file that works for all AWS Regions and put the file in the `ssl_wallet` directory.

For information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

2. Extract each certificate in the .pem file into a separate file using an OS utility.
3. Convert each certificate to .der format using a separate `openssl` command, replacing *certificate-pem-file* with the name of the certificate .pem file (without the .pem extension).

```
openssl x509 -outform der -in certificate-pem-file.pem -out certificate-pem-file.der
```

4. Import each certificate into the keystore using the following command.

```
keytool -import -alias rds-root -keystore clientkeystore.jks -file certificate-pem-file.der
```

For more information, see [Rotating your SSL/TLS certificate](#).

5. Confirm that the key store was created successfully.

```
keytool -list -v -keystore clientkeystore.jks
```

Enter the keystore password when you are prompted for it.

The following code example shows how to set up the SSL connection using JDBC.

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.SQLException;
import java.util.Properties;

public class OracleSslConnectionTest {
    private static final String DB_SERVER_NAME = "dns-name-provided-by-amazon-rds";
    private static final Integer SSL_PORT = "ssl-option-port-configured-in-option-group";
    private static final String DB_SID = "oracle-sid";
    private static final String DB_USER = "user-name";
    private static final String DB_PASSWORD = "password";
    // This key store has only the prod root ca.
    private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
    private static final String KEY_STORE_PASS = "keystore-password";

    public static void main(String[] args) throws SQLException {
        final Properties properties = new Properties();
        final String connectionString = String.format(
            "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=%d))(CONNECT_DATA=(SID=%s)))",
            DB_SERVER_NAME, SSL_PORT, DB_SID);
    }
}
```

```
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);
properties.put("oracle.jdbc.J2EE13Compliant", "true");
properties.put("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
properties.put("javax.net.ssl.trustStoreType", "JKS");
properties.put("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);
final Connection connection = DriverManager.getConnection(connectionString,
properties);
    // If no exception, that means handshake has passed, and an SSL connection can
    be opened
    }
}
```

**Note**

Specify a password other than the prompt shown here as a security best practice.

## Enforcing a DN match with an SSL connection

You can use the Oracle parameter `SSL_SERVER_DN_MATCH` to enforce that the distinguished name (DN) for the database server matches its service name. If you enforce the match verifications, then SSL ensures that the certificate is from the server. If you don't enforce the match verification, then SSL performs the check but allows the connection, regardless if there is a match. If you do not enforce the match, you allow the server to potentially fake its identity.

To enforce DN matching, add the DN match property and use the connection string specified below.

Add the property to the client connection to enforce DN matching.

```
properties.put("oracle.net.ssl_server_dn_match", "TRUE");
```

Use the following connection string to enforce DN matching when using SSL.

```
final String connectionString = String.format(
    "jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(HOST=%s)(PORT=%d))" +
    "(CONNECT_DATA=(SID=%s)))" +
    "(SECURITY = (SSL_SERVER_CERT_DN =
    \"C=US,ST=Washington,L=Seattle,O=Amazon.com,OU=RDS,CN=%s\")))",
```

```
DB_SERVER_NAME, SSL_PORT, DB_SID, DB_SERVER_NAME);
```

## Troubleshooting SSL connections

You might query your database and receive the ORA-28860 error.

```
ORA-28860: Fatal SSL error
28860. 00000 - "Fatal SSL error"
*Cause: An error occurred during the SSL connection to the peer. It is likely that this
side sent data which the peer rejected.
*Action: Enable tracing to determine the exact cause of this error.
```

This error occurs when the client attempts to connect using a version of TLS that the server doesn't support. To avoid this error, edit the `sqlnet.ora` and set `SSL_VERSION` to the correct TLS version. For more information, see [Oracle Support Document 2748438.1](#) in My Oracle Support.

## Oracle Spatial

Amazon RDS supports Oracle Spatial through the use of the SPATIAL option. Oracle Spatial provides a SQL schema and functions that facilitate the storage, retrieval, update, and query of collections of spatial data in an Oracle database. For more information, see [Spatial Concepts](#) in the Oracle documentation.

### Important

If you use Oracle Spatial, Amazon RDS automatically updates your DB instance to the latest Oracle PSU when any of the following exist:

- Security vulnerabilities with a Common Vulnerability Scoring System (CVSS) score of 9+
- Other announced security vulnerabilities

Amazon RDS supports Oracle Spatial only in Oracle Enterprise Edition (EE) and Oracle Standard Edition 2 (SE2). The following table shows the versions of the DB engine that support EE and SE2.

Oracle database version	Enterprise Edition	Standard Edition 2
21.0.0.0, all versions	Yes	Yes
19.0.0.0, all versions	Yes	Yes

### Note

In Oracle Database 19c, Spatial patch bundles are separate from the database Patch Set Updates (PSUs) and Release Updates (RUs). RDS for Oracle doesn't support applying Spatial batch bundles.

## Prerequisites for Oracle Spatial

The following are prerequisites for using Oracle Spatial:

- Make sure that your DB instance is of a sufficient instance class. Oracle Spatial isn't supported for the db.t3.micro or db.t3.small DB instance classes. For more information, see [RDS for Oracle DB instance classes](#).
- Make sure that your DB instance has **Auto Minor Version Upgrade** enabled. This option enables your DB instance to receive minor DB engine version upgrades automatically when they become available and is required for any options that install the Oracle Java Virtual Machine (JVM). Amazon RDS uses this option to update your DB instance to the latest Oracle Patch Set Update (PSU) or Release Update (RU). For more information, see [Modifying an Amazon RDS DB instance](#).

## Best practices for Oracle Spatial

The following are best practices for using Oracle Spatial:

- For maximum security, use the SPATIAL option with Secure Sockets Layer (SSL). For more information, see [Oracle Secure Sockets Layer](#).
- Configure your DB instance to restrict access to your DB instance. For more information, see [Scenarios for accessing a DB instance in a VPC](#) and [Working with a DB instance in a VPC](#).

## Adding the Oracle Spatial option

The following is the general process for adding the SPATIAL option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the SPATIAL option is added. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you add the option, you don't need to restart your DB instance. As soon as the option group is active, Oracle Spatial is available.

### Note

During this outage, password verification functions are disabled briefly. You can also expect to see events related to password verification functions during the outage. Password verification functions are enabled again before the Oracle DB instance is available.

## To add the SPATIAL option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
  - a. For **Engine**, choose the Oracle edition for your DB instance.
  - b. For **Major engine version**, choose the version of your DB instance.

For more information, see [Creating an option group](#).

2. Add the **SPATIAL** option to the option group. For more information about adding options, see [Adding an option to an option group](#).
3. Apply the option group to a new or existing DB instance:
  - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
  - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](#).

## Removing the Oracle Spatial option

After you drop all objects that use data types provided by the SPATIAL option, you can drop the option from a DB instance. If Oracle Java Virtual Machine (JVM) is *not* installed on the DB instance, there is a brief outage while the SPATIAL option is removed. There is no outage if Oracle Java Virtual Machine (JVM) is already installed on the DB instance. After you remove the SPATIAL option, you don't need to restart your DB instance.

## To drop the SPATIAL option

1. Back up your data.

### **Warning**

If the instance uses data types that were enabled as part of the option, and if you remove the SPATIAL option, you can lose data. For more information, see [Backing up, restoring, and exporting data](#).

2. Check whether any existing objects reference data types or features of the SPATIAL option.

If SPATIAL options exist, the instance can get stuck when applying the new option group that doesn't have the SPATIAL option. You can identify the objects by using the following queries:

```
SELECT OWNER, SEGMENT_NAME, TABLESPACE_NAME, BYTES/1024/1024 mbytes
FROM   DBA_SEGMENTS
WHERE  SEGMENT_TYPE LIKE '%TABLE%'
AND    (OWNER, SEGMENT_NAME) IN
       (SELECT DISTINCT OWNER, TABLE_NAME
        FROM   DBA_TAB_COLUMNS
        WHERE  DATA_TYPE='SDO_GEOMETRY'
        AND    OWNER <> 'MDSYS')
ORDER BY 1,2,3,4;

SELECT OWNER, TABLE_NAME, COLUMN_NAME
FROM   DBA_TAB_COLUMNS
WHERE  DATA_TYPE = 'SDO_GEOMETRY'
AND    OWNER <> 'MDSYS'
ORDER BY 1,2,3;
```

3. Drop any objects that reference data types or features of the SPATIAL option.
4. Do one of the following:
  - Remove the SPATIAL option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group](#).
  - Modify the DB instance and specify a different option group that doesn't include the SPATIAL option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance](#).

## Oracle SQLT

Amazon RDS supports Oracle SQLTXPLAIN (SQLT) through the use of the SQLT option. You can use SQLT with any edition of Oracle Database 19c and higher.

The Oracle EXPLAIN PLAN statement can determine the execution plan of a SQL statement. It can verify whether the Oracle optimizer chooses a certain execution plan, such as a nested loops join. It also helps you understand the optimizer's decisions, such as why it chose a nested loops join over a hash join. So EXPLAIN PLAN helps you understand the statement's performance.

SQLT is an Oracle utility that produces a report. The report includes object statistics, object metadata, optimizer-related initialization parameters, and other information that a database administrator can use to tune a SQL statement for optimal performance. SQLT produces an HTML report with hyperlinks to all of the sections in the report.

Unlike Automatic Workload Repository or Statspack reports, SQLT works on individual SQL statements. SQLT is a collection of SQL, PL/SQL, and SQL\*Plus files that collect, store, and display performance data.

Following are the supported Oracle versions for each SQLT version.

SQLT version	Oracle Database 21c	Oracle Database 19c
2018-07-25.v1	Supported	Supported
2018-03-31.v1	Not supported	Not supported
2016-04-29.v1	Not supported	Not supported

To download SQLT and access instructions for using it:

- Log in to your My Oracle Support account, and open the following documents:
- To download SQLT: [Document 215187.1](#)
- For SQLT usage instructions: [Document 1614107.1](#)
- For frequently asked questions about SQLT: [Document 1454160.1](#)
- For information about reading SQLT output: [Document 1456176.1](#)
- For interpreting the Main report: [Document 1922234.1](#)

Amazon RDS doesn't support the following SQLT methods:

- XPLORE
- XHUME

## Prerequisites for SQLT

The following are prerequisites for using SQLT:

- You must remove users and roles that are required by SQLT, if they exist.

The SQLT option creates the following users and roles on a DB instance:

- SQLTXPLAIN user
- SQLTXADMIN user
- SQLT\_USER\_ROLE role

If your DB instance has any of these users or roles, log in to the DB instance using a SQL client, and drop them using the following statements:

```
DROP USER SQLTXPLAIN CASCADE;  
DROP USER SQLTXADMIN CASCADE;  
DROP ROLE SQLT_USER_ROLE CASCADE;
```

- You must remove tablespaces that are required by SQLT, if they exist.

The SQLT option creates the following tablespaces on a DB instance:

- RDS\_SQLT\_TS
- RDS\_TEMP\_SQLT\_TS

If your DB instance has these tablespaces, log in to the DB instance using a SQL client, and drop them.

## SQLT option settings

SQLT can work with licensed features that are provided by the Oracle Tuning Pack and the Oracle Diagnostics Pack. The Oracle Tuning Pack includes the SQL Tuning Advisor, and the Oracle

Diagnostics Pack includes the Automatic Workload Repository. The SQLT settings enable or disable access to these features from SQLT.

Amazon RDS supports the following settings for the SQLT option.

Option setting	Valid values	Default value	Description
LICENSE_PACK	T, D, N	N	<p>The Oracle Management Packs that you want to access with SQLT. Enter one of the following values:</p> <ul style="list-style-type: none"> <li>• T indicates that you have a license for the Oracle Tuning Pack and the Oracle Diagnostics Pack, and you want to access the SQL Tuning Advisor and Automatic Workload Repository from SQLT.</li> <li>• D indicates that you have a license for the Oracle Diagnostics Pack, and you want to access the Automatic Workload Repository from SQLT.</li> <li>• N indicates that you don't have a license for the Oracle Tuning Pack and the Oracle Diagnostics Pack, or that you have a license for one or both of them, but you don't want SQLT to access them.</li> </ul> <div data-bbox="954 1556 1511 1885" style="border: 1px solid #add8e6; border-radius: 10px; padding: 10px; margin-top: 20px;"> <p><b>Note</b></p> <p>Amazon RDS does not provide licenses for these Oracle Management Packs. If you indicate that you want to use a pack that is not included in</p> </div>

Option setting	Valid values	Default value	Description
			<p>your DB instance, you can use SQLT with the DB instance. However, SQLT can't access the pack, and the SQLT report doesn't include the data for the pack. For example, if you specify T, but the DB instance doesn't include the Oracle Tuning Pack, SQLT works on the DB instance, but the report it generates doesn't contain data related to the Oracle Tuning Pack.</p>
VERSION	2016-04-29.v1  2018-03-31.v1  2018-07-25.v1	2016-04-29.v1	<p>The version of SQLT that you want to install.</p> <div data-bbox="954 1073 1507 1436" style="border: 1px solid #add8e6; border-radius: 10px; padding: 10px;"> <p><b>Note</b></p> <p>For Oracle Database 19c and 21c, the only supported version is 2018-07-25.v1 . This version is the default for these releases.</p> </div>

## Adding the SQLT option

The following is the general process for adding the SQLT option to a DB instance:

1. Create a new option group, or copy or modify an existing option group.
2. Add the SQLT option to the option group.
3. Associate the option group with the DB instance.

After you add the SQLT option, as soon as the option group is active, SQLT is active.

## To add the SQLT option to a DB instance

1. Determine the option group that you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
  - a. For **Engine**, choose the Oracle edition that you want to use. The SQLT option is supported on all editions.
  - b. For **Major engine version**, choose the version of your DB instance.

For more information, see [Creating an option group](#).

2. Add the **SQLT** option to the option group. For more information about adding options, see [Adding an option to an option group](#).
3. Apply the option group to a new or existing DB instance:
  - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
  - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](#).
4. (Optional) Verify the SQLT installation on each DB instance with the SQLT option.
  - a. Use a SQL client to connect to the DB instance as the master user.

For information about connecting to an Oracle DB instance using a SQL client, see [Connecting to your RDS for Oracle DB instance](#).

- b. Run the following query:

```
SELECT sqltxplain.sqlt$a.get_param('tool_version') sqlt_version FROM DUAL;
```

The query returns the current version of the SQLT option on Amazon RDS. 12.1.160429 is an example of a version of SQLT that is available on Amazon RDS.

5. Change the passwords of the users that are created by the SQLT option.
  - a. Use a SQL client to connect to the DB instance as the master user.
  - b. Run the following SQL statement to change the password for the SQLTXADMIN user:

```
ALTER USER SQLTXADMIN IDENTIFIED BY new_password ACCOUNT UNLOCK;
```

 **Note**

Specify a password other than the prompt shown here as a security best practice.

- c. Run the following SQL statement to change the password for the SQLTXPLAIN user:

```
ALTER USER SQLTXPLAIN IDENTIFIED BY new_password ACCOUNT UNLOCK;
```

 **Note**

Specify a password other than the prompt shown here as a security best practice.

 **Note**

Upgrading SQLT requires uninstalling an older version of SQLT and then installing the new version. So, all SQLT metadata can be lost when you upgrade SQLT. A major version upgrade of a database also uninstalls and re-installs SQLT. An example of a major version upgrade is an upgrade from Oracle Database 19c to Oracle Database 21c.

## Using SQLT

SQLT works with the Oracle SQL\*Plus utility.

## To use SQLT

1. Download the SQLT .zip file from [Document 215187.1](#) on the My Oracle Support site.

### Note

You can't download SQLT 12.1.160429 from the My Oracle Support site. Oracle has deprecated this older version.

2. Unzip the SQLT .zip file.
3. From a command prompt, change to the sqlt/run directory on your file system.
4. From the command prompt, open SQL\*Plus, and connect to the DB instance as the master user.

For information about connecting to a DB instance using SQL\*Plus, see [Connecting to your RDS for Oracle DB instance](#).

5. Get the SQL ID of a SQL statement:

```
SELECT SQL_ID FROM V$SQL WHERE SQL_TEXT='sql_statement';
```

Your output is similar to the following:

```
SQL_ID  
-----  
chvsmttqjzjkn
```

6. Analyze a SQL statement with SQLT:

```
START sqltextract.sql sql_id sqltexplain_user_password
```

For example, for the SQL ID chvsmttqjzjkn, enter the following:

```
START sqltextract.sql chvsmttqjzjkn sqltexplain_user_password
```

SQLT generates the HTML report and related resources as a .zip file in the directory from which the SQLT command was run.

7. (Optional) To enable application users to diagnose SQL statements with SQLT, grant SQLT\_USER\_ROLE to each application user with the following statement:

```
GRANT SQLT_USER_ROLE TO application_user_name;
```

#### Note

Oracle does not recommend running SQLT with the SYS user or with users that have the DBA role. It is a best practice to run SQLT diagnostics using the application user's account, by granting SQLT\_USER\_ROLE to the application user.

## Upgrading the SQLT option

With Amazon RDS for Oracle, you can upgrade the SQLT option from your existing version to a higher version. To upgrade the SQLT option, complete steps 1–3 in [Using SQLT](#) for the new version of SQLT. Also, if you granted privileges for the previous version of SQLT in step 7 of that section, grant the privileges again for the new SQLT version.

Upgrading the SQLT option results in the loss of the older SQLT version's metadata. The older SQLT version's schema and related objects are dropped, and the newer version of SQLT is installed. For more information about the changes in the latest SQLT version, see [Document 1614201.1](#) on the My Oracle Support site.

#### Note

Version downgrades are not supported.

## Modifying SQLT settings

After you enable SQLT, you can modify the LICENSE\_PACK and VERSION settings for the option.

For more information about how to modify option settings, see [Modifying an option setting](#). For more information about each setting, see [SQLT option settings](#).

## Removing the SQLT option

You can remove SQLT from a DB instance.

To remove SQLT from a DB instance, do one of the following:

- To remove SQLT from multiple DB instances, remove the SQLT option from the option group to which the DB instances belong. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group](#).
- To remove SQLT from a single DB instance, modify the DB instance and specify a different option group that doesn't include the SQLT option. You can specify the default (empty) option group or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance](#).

## Oracle Statspack

The Oracle Statspack option installs and enables the Oracle Statspack performance statistics feature. Oracle Statspack is a collection of SQL, PL/SQL, and SQL\*Plus scripts that collect, store, and display performance data. For information about using Oracle Statspack, see [Oracle Statspack](#) in the Oracle documentation.

### Note

Oracle Statspack is no longer supported by Oracle and has been replaced by the more advanced Automatic Workload Repository (AWR). AWR is available only for Oracle Enterprise Edition customers who have purchased the Diagnostics Pack. You can use Oracle Statspack with any Oracle DB engine on Amazon RDS. You can't run Oracle Statspack on Amazon RDS read replicas.

## Setting up Oracle Statspack

To run Statspack scripts, you must add the Statspack option.

### To set up Oracle Statspack

1. In a SQL client, log in to the Oracle DB with an administrative account.
2. Do either of the following actions, depending on whether Statspack is installed:
  - If Statspack is installed, and the PERFSTAT account is associated with Statspack, skip to Step 4.
  - If Statspack is not installed, and the PERFSTAT account exists, drop the account as follows:

```
DROP USER PERFSTAT CASCADE;
```

Otherwise, attempting to add the Statspack option generates an error and RDS-Event-0058.

3. Add the Statspack option to an option group. See [Adding an option to an option group](#).

Amazon RDS automatically installs the Statspack scripts on the DB instance and then sets up the PERFSTAT account.

4. Reset the password using the following SQL statement, replacing *pwd* with your new password:

```
ALTER USER PERFSTAT IDENTIFIED BY pwd ACCOUNT UNLOCK;
```

You can log in using the PERFSTAT user account and run the Statspack scripts.

5. Grant the CREATE JOB privilege to the PERFSTAT account using the following statement:

```
GRANT CREATE JOB TO PERFSTAT;
```

6. Ensure that idle wait events in the PERFSTAT.STATS\$IDLE\_EVENT table are populated.

Because of Oracle Bug 28523746, the idle wait events in PERFSTAT.STATS\$IDLE\_EVENT may not be populated. To ensure all idle events are available, run the following statement:

```
INSERT INTO PERFSTAT.STATS$IDLE_EVENT (EVENT)
SELECT NAME FROM V$EVENT_NAME WHERE WAIT_CLASS='Idle'
MINUS
SELECT EVENT FROM PERFSTAT.STATS$IDLE_EVENT;
COMMIT;
```

## Generating Statspack reports

A Statspack report compares two snapshots.

### To generate Statspack reports

1. In a SQL client, log in to the Oracle DB with the PERFSTAT account.
2. Create a snapshot using either of the following techniques:
  - Create a Statspack snapshot manually.
  - Create a job that takes a Statspack snapshot after a given time interval. For example, the following job creates a Statspack snapshot every hour:

```
VARIABLE jn NUMBER;
exec dbms_job.submit(:jn, 'statspack.snap;',SYSDATE, 'TRUNC(SYSDATE
+1/24, 'HH24')');
COMMIT;
```

### 3. View the snapshots using the following query:

```
SELECT SNAP_ID, SNAP_TIME FROM STATS$SNAPSHOT ORDER BY 1;
```

### 4. Run the Amazon RDS procedure `rdsadmin.rds_run_spreport`, replacing `begin_snap` and `end_snap` with the snapshot IDs:

```
exec rdsadmin.rds_run_spreport(begin_snap,end_snap);
```

For example, the following command creates a report based on the interval between Statspack snapshots 1 and 2:

```
exec rdsadmin.rds_run_spreport(1,2);
```

The file name of the Statspack report includes the number of the two snapshots. For example, a report file created using Statspack snapshots 1 and 2 would be named `ORCL_spreport_1_2.lst`.

### 5. Monitor the output for errors.

Oracle Statspack performs checks before running the report. Therefore, you could also see error messages in the command output. For example, you might try to generate a report based on an invalid range, where the beginning Statspack snapshot value is larger than the ending value. In this case, the output shows the error message, but the DB engine does not generate an error file.

```
exec rdsadmin.rds_run_spreport(2,1);
*
ERROR at line 1:
ORA-20000: Invalid snapshot IDs. Find valid ones in perfstat.stats$snapshot.
```

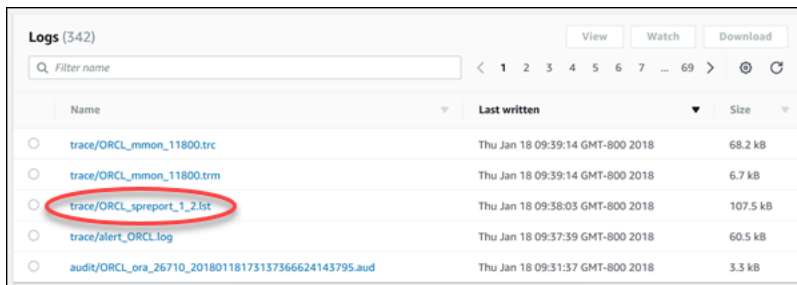

If you use an invalid number a Statspack snapshot, the output shows an error. For example, if you try to generate a report for snapshots 1 and 50, but snapshot 50 doesn't exist, the output shows an error.

```
exec rdsadmin.rds_run_spreport(1,50);
*
ERROR at line 1:
ORA-20000: Could not find both snapshot IDs
```

## 6. (Optional)

To retrieve the report, call the trace file procedures, as explained in [Working with Oracle trace files](#).

Alternatively, download the Statspack report from the RDS console. Go to the **Log** section of the DB instance details and choose **Download**. The following example shows `trace/ORCL_spreport_1_2.lst`

The screenshot shows the 'Logs (342)' section of the Amazon RDS console. It features a search bar, navigation buttons (View, Watch, Download), and a table of log files. The table has columns for Name, Last written, and Size. The file 'trace/ORCL\_spreport\_1\_2.lst' is circled in red.

Name	Last written	Size
<a href="#">trace/ORCL_mmon_11800.trc</a>	Thu Jan 18 09:39:14 GMT-800 2018	68.2 kB
<a href="#">trace/ORCL_mmon_11800.trm</a>	Thu Jan 18 09:39:14 GMT-800 2018	6.7 kB
<a href="#">trace/ORCL_spreport_1_2.lst</a>	Thu Jan 18 09:38:03 GMT-800 2018	107.5 kB
<a href="#">trace/alert_ORCL.log</a>	Thu Jan 18 09:37:39 GMT-800 2018	60.5 kB
<a href="#">audit/ORCL_ora_26710_201801181751373566624145795.aud</a>	Thu Jan 18 09:51:37 GMT-800 2018	3.3 kB

If an error occurs while generating a report, the DB engine uses the same naming conventions as for a report but with an extension of `.err`. For example, if an error occurred while creating a report using Statspack snapshots 1 and 7, the report file would be named `ORCL_spreport_1_7.err`. You can download the error report using the same techniques as for a standard Snapshot report.

## Removing Statspack snapshots

To remove a range of Oracle Statspack snapshots, use the following command:

```
exec statspack.purge(begin snap, end snap);
```

## Oracle time zone

To change the system time zone used by your Oracle DB instance, use the time zone option. For example, you might change the time zone of a DB instance to be compatible with an on-premises environment, or a legacy application. The time zone option changes the time zone at the host level. Changing the time zone impacts all date columns and values, including SYSDATE and SYSTIMESTAMP.

The time zone option differs from the `rdsadmin_util.alter_db_time_zone` command. The `alter_db_time_zone` command changes the time zone only for certain data types. The time zone option changes the time zone for all date columns and values. For more information about `alter_db_time_zone`, see [Setting the database time zone](#). For more information about upgrade considerations, see [Time zone considerations](#).

### Restrictions for setting the time zone

The time zone option is a permanent and persistent option. Therefore, you can't do the following:

- Remove the option from an option group after you add the time zone option.
- Remove the option group from a DB instance after you add the group.
- Modify the time zone setting of the option to a different time zone.

### Recommendations for setting the time zone

Before you add the time zone option to your production database, we strongly recommend that you do the following:

- Take a snapshot of your DB instance. If you accidentally set the time zone incorrectly, you must recover your DB instance to its previous time zone setting. For more information, see [Creating a DB snapshot for a Single-AZ DB instance](#).
- Add the time zone option to a test DB instance. Adding the time zone option can cause problems with tables that use the system date to add dates or times. We recommend that you analyze your data and applications on the test instance. This way you can assess the impact of changing the time zone on your production instance.

### Time zone option settings

Amazon RDS supports the following settings for the time zone option.

Option setting	Valid values	Description
TIME_ZONE	One of the available time zones. For the full list, see <a href="#">Available time zones</a> .	The new time zone for your DB instance.

## Adding the time zone option

Complete the following steps to add the time zone option to your DB instance:

1. (Recommended) Take a snapshot of your DB instance.
2. Do one of the following tasks:
  - Create a new option group from scratch. For more information, see [Creating an option group](#).
  - Copy an existing option group using the AWS CLI or API. For more information, see [Copying an option group](#).
  - Reuse an existing non-default option group. A best practice is to use an option group that isn't currently associated with any DB instances or snapshots.
3. Add the new option to the option group from the preceding step.
4. If the option group that is currently associated with your DB instance has options enabled, add these options to your new option group. This strategy prevents the existing options from being uninstalled while enabling the new option.
5. Add the new option group to your DB instance.

When you add the time zone option, a brief outage occurs while your DB instance is automatically restarted.

## Console

### To add the time zone option to an option group and associate it with a DB instance

1. In the RDS console, choose **Option groups**.
2. Choose the name of the option group to which you want to add the option.
3. Choose **Add option**.
4. For **Option name**, choose **Timezone**, and then configure the option settings.

## 5. Associate the option group with a new or existing DB instance:

- For a new DB instance, apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
- For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. When you add the new option to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see [Modifying an Amazon RDS DB instance](#).

## AWS CLI

The following example uses the AWS CLI [add-option-to-option-group](#) command to add the Timezone option and the TIME\_ZONE option setting to an option group called `myoptiongroup`. The time zone is set to `Africa/Cairo`.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \  
  --option-group-name "myoptiongroup" \  
  --options "OptionName=Timezone,OptionSettings=[{Name=TIME_ZONE,Value=Africa/  
Cairo}]" \  
  --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^  
  --option-group-name "myoptiongroup" ^  
  --options "OptionName=Timezone,OptionSettings=[{Name=TIME_ZONE,Value=Africa/  
Cairo}]" ^  
  --apply-immediately
```

## Modifying time zone settings

The time zone option is a permanent and persistent option. You can't remove the option from an option group after you add it. You can't remove the option group from a DB instance after you add it. You can't modify the time zone setting of the option to a different time zone. If you set the time zone incorrectly, restore a snapshot of your DB instance from before you added the time zone option.

## Removing the time zone option

The time zone option is a permanent and persistent option. You can't remove the option from an option group after you add it. You can't remove the option group from a DB instance after you add it. To remove the time zone option, restore a snapshot of your DB instance from before you added the time zone option.

## Available time zones

You can use the following values for the time zone option.

Zone	Time zone
Africa	Africa/Cairo, Africa/Casablanca, Africa/Harare, Africa/Lagos, Africa/Luanda, Africa/Monrovia, Africa/Nairobi, Africa/Tripoli, Africa/Windhoek
America	America/Araguaina, America/Argentina/Buenos_Aires, America/Asuncion, America/Bogota, America/Caracas, America/Chicago, America/Chihuahua, America/Cuiaba, America/Denver, America/Detroit, America/Fortaleza, America/Godthab, America/Guatemala, America/Halifax, America/Lima, America/Los_Angeles, America/Manaus, America/Matamoros, America/Mexico_City, America/Monterrey, America/Montevideo, America/New_York, America/Phoenix, America/Santiago, America/Sao_Paulo, America/Tijuana, America/Toronto
Asia	Asia/Amman, Asia/Ashgabat, Asia/Baghdad, Asia/Baku, Asia/Bangkok, Asia/Beirut, Asia/Calcutta, Asia/Damascus, Asia/Dhaka, Asia/Hong_Kong, Asia/Irkutsk, Asia/Jakarta, Asia/Jerusalem, Asia/Kabul, Asia/Karachi, Asia/Kathmandu, Asia/Kolkata, Asia/Krasnoyarsk, Asia/Magadan, Asia/Manila, Asia/Muscat, Asia/Novosibirsk, Asia/Rangoon, Asia/Riyadh, Asia/Seoul, Asia/Shanghai, Asia/Singapore, Asia/Taipei, Asia/Tehran, Asia/Tokyo, Asia/Ulaanbaatar, Asia/Vladivostok, Asia/Yakutsk, Asia/Yerevan
Atlantic	Atlantic/Azores, Atlantic/Cape_Verde
Australia	Australia/Adelaide, Australia/Brisbane, Australia/Darwin, Australia/Eucla, Australia/Hobart, Australia/Lord_Howe, Australia/Perth, Australia/Sydney
Brazil	Brazil/DeNoronha, Brazil/East

<b>Zone</b>	<b>Time zone</b>
Canada	Canada/Newfoundland, Canada/Saskatchewan
Etc	Etc/GMT-3
Europe	Europe/Amsterdam, Europe/Athens, Europe/Berlin, Europe/Dublin, Europe/Helsinki, Europe/Kaliningrad, Europe/London, Europe/Madrid, Europe/Moscow, Europe/Paris, Europe/Prague, Europe/Rome, Europe/Sarajevo
Pacific	Pacific/Apia, Pacific/Auckland, Pacific/Chatham, Pacific/Fiji, Pacific/Guam, Pacific/Honolulu, Pacific/Kiritimati, Pacific/Marquesas, Pacific/Samoa, Pacific/Tongatapu, Pacific/Wake
US	US/Alaska, US/Central, US/East-Indiana, US/Eastern, US/Pacific
UTC	UTC

# Oracle time zone file autoupgrade

With the `TIMEZONE_FILE_AUTOUPGRADE` option, you can upgrade the current time zone file to the latest version on your RDS for Oracle DB instance.

## Topics

- [Overview of Oracle time zone files](#)
- [Strategies for updating your time zone file](#)
- [Downtime during the time zone file update](#)
- [Preparing to update the time zone file](#)
- [Adding the time zone file autoupgrade option](#)
- [Checking your data after the update of the time zone file](#)

## Overview of Oracle time zone files

An Oracle Database *time zone file* stores the following information:

- Offset from Coordinated Universal Time (UTC)
- Transition times for Daylight Saving Time (DST)
- Abbreviations for standard time and DST

Oracle Database supplies multiple versions of time zone files. When you create an Oracle database in an on-premises environment, you choose the time zone file version. For more information, see [Choosing a Time Zone File](#) in the *Oracle Database Globalization Support Guide*.

If the rules change for DST, Oracle publishes new time zone files. Oracle releases these new time zone files independently of the schedule for quarterly Release Updates (RUs) and Release Update Revisions (RURs). The time zone files reside on the database host in the directory `$ORACLE_HOME/oracore/zoneinfo/`. The time zone file names use the format `DSTvversion`, as in `DSTv35`.

## How the time zone file affects data transfer

In Oracle Database, the `TIMESTAMP WITH TIME ZONE` data type stores time stamp and time zone data. Data with the `TIMESTAMP WITH TIME ZONE` data type uses the rules in the associated time zone file version. Thus, existing `TIMESTAMP WITH TIME ZONE` data is affected when you update the time zone file.

Problems can occur when you transfer data between databases that use different versions of the time zone file. For example, if you import data from a source database with a higher time zone file version than the target database, the database issues the ORA-39405 error. Previously, you had to work around this error by using either of the following techniques:

- Create an RDS for Oracle DB instance with the desired time zone file, export data from your source database, and then import it into the new database.
- Use AWS DMS or logical replication to migrate your data.

### Automatic updates using the `TIMEZONE_FILE_AUTOUPGRADE` option

When the option group attached to your RDS for Oracle DB instance includes the `TIMEZONE_FILE_AUTOUPGRADE` option, RDS updates your time zone files automatically. By ensuring that your Oracle databases use the same time zone file version, you avoid time-consuming manual techniques when you move data between different environments. The `TIMEZONE_FILE_AUTOUPGRADE` option is supported for both container databases (CDBs) and non-CDBs.

When you add the `TIMEZONE_FILE_AUTOUPGRADE` option to your option group, you can choose whether to add the option immediately or during the maintenance window. After your DB instance applies the new option, RDS checks whether it can install a newer `DSTvversion` file. The target `DSTvversion` depends on the following:

- The minor engine version that your DB instance is currently running
- The minor engine version to which you want to upgrade your DB instance

For example, your current time zone file version might be `DSTv33`. When RDS applies the update to your option group, it might determine that `DSTv34` is currently available on your DB instance file system. RDS will then update your time zone file to `DSTv34` automatically.

To find the available DST versions in the supported RDS release updates, look at the patches in [Release notes for Amazon Relational Database Service \(Amazon RDS\) for Oracle](#). For example, [version 19.0.0.0.ru-2022-10.rur-2022-10.r1](#) lists patch 34533061: RDBMS - DSTV39 UPDATE - TZDATA2022C.

## Strategies for updating your time zone file

Upgrading your DB engine and adding the `TIMEZONE_FILE_AUTOUPGRADE` option to an option group are separate operations. Adding the `TIMEZONE_FILE_AUTOUPGRADE` option initiates the update of your time zone file if a more current one is available. You run the following commands (only relevant options are shown) either immediately or at the next maintenance window:

- Upgrade your DB engine only using the following RDS CLI command:

```
modify-db-instance --engine-version name ...
```

- Add the `TIMEZONE_FILE_AUTOUPGRADE` option only using the following CLI command:

```
add-option-to-option-group --option-group-name name --options  
OptionName=TIMEZONE_FILE_AUTOUPGRADE ...
```

- Upgrade your DB engine and add a new option group to your instance using the following CLI command:

```
modify-db-instance --engine-version name --option-group-name name ...
```

Your update strategy depends on whether you want to upgrade your database and time zone file together or perform just one of these operations. Keep in mind that if you update your option group and then upgrade your DB engine in separate API operations, it's possible for a time zone file update to be currently in progress when you upgrade your DB engine.

The examples in this section assume the following:

- You have not yet added `TIMEZONE_FILE_AUTOUPGRADE` to the option group currently associated with your DB instance.
- Your DB instance uses database version `19.0.0.0.ru-2019-07.rur-2019-07.r1` and time zone file `DSTv33`.
- Your DB instance file system includes file `DSTv34`.
- Release update `19.0.0.0.ru-2022-10.rur-2022-10.r1` includes `DSTv35`.

To update your time zone file, you can use the following strategies.

### Topics

- [Update the time zone file without upgrading the engine](#)
- [Upgrade the time zone file and DB engine version](#)
- [Upgrade your DB engine version without updating the time zone file](#)

## Update the time zone file without upgrading the engine

In this scenario, your database is using DSTv33, but DSTv34 is available on your DB instance file system. You want to update the time zone file used by your DB instance from DSTv33 to DSTv34, but you don't want to upgrade your engine to a new minor version, which includes DSTv35.

In an `add-option-to-option-group` command, add `TIMEZONE_FILE_AUTOUPGRADE` to the option group used by your DB instance. Specify whether to add the option immediately or defer it to the maintenance window. After applying the `TIMEZONE_FILE_AUTOUPGRADE` option, RDS does the following:

1. Checks for a new DST version.
2. Determines that DSTv34 is available on the file system.
3. Updates the time zone file immediately.

## Upgrade the time zone file and DB engine version

In this scenario, your database is using DSTv33, but DSTv34 is available on your DB instance file system. You want to upgrade your DB engine to minor version `19.0.0.0.ru-2022-10.rur-2022-10.r1`, which includes DSTv35, and update your time zone file to DSTv35 during the engine upgrade. Thus, your goal is to skip DSTv34 and update your time zone files directly to DSTv35.

To upgrade the engine and time zone file together, run `modify-db-instance` with the `--option-group-name` and `--engine-version` options. You can run the command immediately or defer it to maintenance window. In `--option-group-name`, specify an option group that includes the `TIMEZONE_FILE_AUTOUPGRADE` option. For example:

```
aws rds modify-db-instance
  --db-instance-identifier my-instance \
  --engine-version new-version \
  ----option-group-name og-with-timezone-file-autoupgrade \
  --apply-immediately
```

RDS begins upgrading your engine to 19.0.0.0.ru-2022-10.rur-2022-10.r1. After applying the `TIMEZONE_FILE_AUTOUPGRADE` option, RDS checks for a new DST version, sees that DSTv35 is available in 19.0.0.0.ru-2022-10.rur-2022-10.r1, and immediately starts the update to DSTv35.

To upgrade your engine immediately and then upgrade your a timezone file, perform the operations in sequence:

1. Upgrade your DB engine only using the following CLI command:

```
aws rds modify-db-instance \  
  --db-instance-identifier my-instance \  
  --engine-version new-version \  
  --apply-immediately
```

2. Add the `TIMEZONE_FILE_AUTOUPGRADE` option to the option group attached to your instance using the following CLI command:

```
aws rds add-option-to-option-group \  
  --option-group-name og-in-use-by-your-instance \  
  --options OptionName=TIMEZONE_FILE_AUTOUPGRADE \  
  --apply-immediately
```

## Upgrade your DB engine version without updating the time zone file

In this scenario, your database is using DSTv33, but DSTv34 is available on your DB instance file system. You want to upgrade your DB engine to version 19.0.0.0.ru-2022-10.rur-2022-10.r1, which includes DSTv35, but retain time zone file DSTv33. You might choose this strategy for the following reasons:

- Your data doesn't use the `TIMESTAMP WITH TIME ZONE` data type.
- Your data uses the `TIMESTAMP WITH TIME ZONE` data type, but your data is not affected by the time zone changes.
- You want to postpone updating the time zone file because you can't tolerate the extra downtime.

Your strategy depends on which of the following possibilities are true:

- Your DB instance isn't associated with an option group that includes `TIMEZONE_FILE_AUTOUPGRADE`. In your `modify-db-instance` command, don't specify a new option group so that RDS doesn't update your time zone file.
- Your DB instance is currently associated with an option group that includes `TIMEZONE_FILE_AUTOUPGRADE`. Within a single `modify-db-instance` command, associate your DB instance with an option group that doesn't include `TIMEZONE_FILE_AUTOUPGRADE` and upgrade your DB engine to `19.0.0.0.ru-2022-10.rur-2022-10.r1`.

## Downtime during the time zone file update

When RDS updates your time zone file, existing data that uses `TIMESTAMP WITH TIME ZONE` might change. In this case, your primary consideration is downtime.

### Warning

If you add the `TIMEZONE_FILE_AUTOUPGRADE` option, your engine upgrade might have prolonged downtime. Updating time zone data for a large database might take hours or even days.

The length of the time zone file update depends on factors such as the following:

- The amount of `TIMESTAMP WITH TIME ZONE` data in your database
- The DB instance configuration
- The DB instance class
- The storage configuration
- The database configuration
- The database parameter settings

Additional downtime can occur when you do the following:

- Add the option to the option group when the DB instance uses an outdated time zone file
- Upgrade the Oracle database engine when the new engine version contains a new version of the time zone file

**Note**

During the time zone file update, RDS for Oracle calls PURGE DBA\_RECYCLEBIN.

## Preparing to update the time zone file

A time zone file upgrade has two separate phases: prepare and upgrade. While not required, we strongly recommend that you perform the prepare step. In this step, you find out which data will be affected by running the PL/SQL procedure `DBMS_DST.FIND_AFFECTED_TABLES`. For more information about the prepare window, see [Upgrading the Time Zone File and Timestamp with Time Zone Data](#) in the Oracle Database documentation.

### To prepare to update the time zone file

1. Connect to your Oracle database using a SQL client.
2. Determine the current timezone file version used.

```
SELECT * FROM V$TIMEZONE_FILE;
```

3. Determine the latest timezone file version available on your DB instance.

```
SELECT DBMS_DST.GET_LATEST_TIMEZONE_VERSION FROM DUAL;
```

4. Determine the total size of tables that have columns of type `TIMESTAMP WITH LOCAL TIME ZONE` or `TIMESTAMP WITH TIME ZONE`.

```
SELECT SUM(BYTES)/1024/1024/1024 "Total_size_w_TSTZ_columns_GB"  
FROM   DBA_SEGMENTS  
WHERE  SEGMENT_TYPE LIKE 'TABLE%'  
AND    (OWNER, SEGMENT_NAME) IN  
        (SELECT OWNER, TABLE_NAME  
         FROM   DBA_TAB_COLUMNS  
         WHERE  DATA_TYPE LIKE 'TIMESTAMP%TIME ZONE');
```

5. Determine the names and sizes of segments that have columns of type `TIMESTAMP WITH LOCAL TIME ZONE` or `TIMESTAMP WITH TIME ZONE`.

```
SELECT OWNER, SEGMENT_NAME, SUM(BYTES)/1024/1024/1024  
       "SEGMENT_SIZE_W_TSTZ_COLUMNS_GB"
```

```

FROM    DBA_SEGMENTS
WHERE   SEGMENT_TYPE LIKE 'TABLE%'
AND     (OWNER, SEGMENT_NAME) IN
        (SELECT OWNER, TABLE_NAME
         FROM    DBA_TAB_COLUMNS
         WHERE   DATA_TYPE LIKE 'TIMESTAMP%TIME ZONE')
GROUP BY OWNER, SEGMENT_NAME;

```

## 6. Run the prepare step.

- The procedure `DBMS_DST.CREATE_AFFECTED_TABLE` creates a table to store any affected data. You pass the name of this table to the `DBMS_DST.FIND_AFFECTED_TABLES` procedure. For more information, see [CREATE\\_AFFECTED\\_TABLE Procedure](#) in the Oracle Database documentation.
- This procedure `CREATE_ERROR_TABLE` creates a table to log errors. For more information, see [CREATE\\_ERROR\\_TABLE Procedure](#) in the Oracle Database documentation.

The following example creates the affected data and error tables, and finds all affected tables.

```

EXEC DBMS_DST.CREATE_ERROR_TABLE('my_error_table')
EXEC DBMS_DST.CREATE_AFFECTED_TABLE('my_affected_table')

EXEC DBMS_DST.BEGIN_PREPARE(new_version);
EXEC DBMS_DST.FIND_AFFECTED_TABLES('my_affected_table', TRUE, 'my_error_table');
EXEC DBMS_DST.END_PREPARE;

SELECT * FROM my_affected_table;
SELECT * FROM my_error_table;

```

## 7. Query the affected and error tables.

```

SELECT * FROM my_affected_table;
SELECT * FROM my_error_table;

```

## Adding the time zone file autoupgrade option

When you add the option to an option group, the option group is in one of the following states:

- An existing option group is currently attached to at least one DB instance. When you add the option, all DB instances that use this option group automatically restart. This causes a brief outage.
- An existing option group is not attached to any DB instance. You plan to add the option and then associate the existing option group with existing DB instances or with a new DB instance.
- You create a new option group and add the option. You plan to associate the new option group with existing DB instances or with a new DB instance.

## Console

### To add the time zone file autoupgrade option to a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
  - a. For **Engine** choose the Oracle Database edition for your DB instance.
  - b. For **Major engine version** choose the version of your DB instance.

For more information, see [Creating an option group](#).

4. Choose the option group that you want to modify, and then choose **Add option**.
5. In the **Add option** window, do the following:
  - a. Choose **TIMEZONE\_FILE\_AUTOUPGRADE**.
  - b. To enable the option on all associated DB instances as soon as you add it, for **Apply Immediately**, choose **Yes**. If you choose **No** (the default), the option is enabled for each associated DB instance during its next maintenance window.
6. When the settings are as you want them, choose **Add option**.

## AWS CLI

The following example uses the AWS CLI [add-option-to-option-group](#) command to add the `TIMEZONE_FILE_AUTOUPGRADE` option to an option group called `myoptiongroup`.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \  
  --option-group-name "myoptiongroup" \  
  --options "OptionName=TIMEZONE_FILE_AUTOUPGRADE" \  
  --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^  
  --option-group-name "myoptiongroup" ^  
  --options "OptionName=TIMEZONE_FILE_AUTOUPGRADE" ^  
  --apply-immediately
```

## Checking your data after the update of the time zone file

We recommend that you check your data after you update the time zone file. During the prepare step, RDS for Oracle automatically creates the following tables:

- `rdsadmin.rds_dst_affected_tables` – Lists the tables that contain data affected by the update
- `rdsadmin.rds_dst_error_table` – Lists the errors generated during the update

These tables are independent of any tables that you create in the prepare window. To see the results of the update, query the tables as follows.

```
SELECT * FROM rdsadmin.rds_dst_affected_tables;  
SELECT * FROM rdsadmin.rds_dst_error_table;
```

For more information about the schema for the affected data and error tables, see [FIND\\_AFFECTED\\_TABLES Procedure](#) in the Oracle documentation.

# Oracle Transparent Data Encryption

Amazon RDS supports Oracle Transparent Data Encryption (TDE), a feature of the Oracle Advanced Security option available in Oracle Enterprise Edition. This feature automatically encrypts data before it is written to storage and automatically decrypts data when the data is read from storage. This option is only supported for the Bring Your Own License (BYOL) model.

TDE is useful in scenarios where you need to encrypt sensitive data in case data files and backups are obtained by a third party. TDE is also useful when you need to comply with security-related regulations.

A detailed explanation about TDE in Oracle Database is beyond the scope of this guide. For information, see the following Oracle Database resources:

- [Introduction to Transparent Data Encryption](#) in the Oracle Database documentation
- [Oracle advanced security](#) in the Oracle Database documentation
- [Oracle advanced security Transparent Data Encryption best practices](#), which is an Oracle whitepaper

For more information about using TDE with RDS for Oracle, see the following blogs:

- [Oracle Database Encryption Options on Amazon RDS](#)
- [Migrate a cross-account TDE-enabled Amazon RDS for Oracle DB instance with reduced downtime using AWS DMS](#)

## TDE encryption modes

Oracle Transparent Data Encryption supports two encryption modes: TDE tablespace encryption and TDE column encryption. TDE tablespace encryption is used to encrypt entire application tables. TDE column encryption is used to encrypt individual data elements that contain sensitive data. You can also apply a hybrid encryption solution that uses both TDE tablespace and column encryption.

### Note

Amazon RDS manages the Oracle Wallet and TDE master key for the DB instance. You do not need to set the encryption key using the command `ALTER SYSTEM set encryption key`.

After you enable the TDE option, you can check the status of the Oracle Wallet by using the following command:

```
SELECT * FROM v$encryption_wallet;
```

To create an encrypted tablespace, use the following command:

```
CREATE TABLESPACE encrypt_ts ENCRYPTION DEFAULT STORAGE (ENCRYPT);
```

To specify the encryption algorithm, use the following command:

```
CREATE TABLESPACE encrypt_ts ENCRYPTION USING 'AES256' DEFAULT STORAGE (ENCRYPT);
```

The previous statements for encrypting a tablespace are the same as you would use on an on-premises Oracle database.

## Restrictions for the TDE option

The TDE option is permanent and persistent. After you associate your DB instance with an option group that has the TDE option enabled, you can't do the following actions:

- Disable the TDE option in the currently associated option group.
- Associate your DB instance with a different option group that doesn't include the TDE option.
- Share a DB snapshot that uses the TDE option. For more information about sharing DB snapshots, see [Sharing a DB snapshot](#).

For more information about persistent and permanent options, see [Persistent and permanent options](#).

## Determining whether your DB instance is using TDE

You might want to determine whether your DB instance is associated with an option group that has the TDE option enabled. To view the option group that a DB instance is associated with, use the RDS console, the [describe-db-instance](#) AWS CLI command, or the API operation [DescribeDBInstances](#).

## Adding the TDE option

To add the TDE option to your DB instance, complete the following steps:

1. (Recommended) Take a snapshot of your DB instance.
2. Do one of the following tasks:
  - Create a new option group from scratch. For more information, see [Creating an option group](#).
  - Copy an existing option group using the AWS CLI or API. For more information, see [Copying an option group](#).
  - Reuse an existing non-default option group. A best practice is to use an option group that isn't currently associated with any DB instances or snapshots.
3. Add the new option to the option group from the preceding step.
4. If the option group that is currently associated with your DB instance has options enabled, add these options to your new option group. This strategy prevents the existing options from being uninstalled while enabling the new option.
5. Add the new option group to your DB instance.

## Console

### To add the TDE option to an option group and associate it with your DB instance

1. In the RDS console, choose **Option groups**.
2. Choose the name of the option group to which you want to add the option.
3. Choose **Add option**.
4. For **Option name**, choose **TDE**, and then configure the option settings.
5. Choose **Add option**.

#### **Important**

If you add the **TDE** option to an option group that is currently attached to one or more DB instances, a brief outage occurs while all the DB instances are automatically restarted.

For more information about adding options, see [Adding an option to an option group](#).

6. Associate the option group with a new or existing DB instance:
  - For a new DB instance, apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).

- For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. When you add the new option to an existing DB instance, a brief outage occurs while your DB instance is automatically restarted. For more information, see [Modifying an Amazon RDS DB instance](#).

## AWS CLI

In the following example, you use the AWS CLI [add-option-to-option-group](#) command to add the TDE option to an option group called `myoptiongroup`. For more information, see [Getting started: Flink 1.13.2](#).

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \  
  --option-group-name "myoptiongroup" \  
  --options "OptionName=TDE" \  
  --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^  
  --option-group-name "myoptiongroup" ^  
  --options "OptionName=TDE" ^  
  --apply-immediately
```

## Copying your data to a DB instance that doesn't include the TDE option

You can't remove the TDE option from a DB instance or associate it with an option group that doesn't include the TDE option. To migrate your data to an instance that doesn't include the TDE option, do the following:

1. Decrypt the data on your DB instance.
2. Copy the data to a new DB instance that is not associated with an option group that has TDE enabled.
3. Delete your original DB instance.

You can use the same name for the new instance as the previous DB instance.

## Considerations when using TDE with Oracle Data Pump

You can use Oracle Data Pump to import or export encrypted dump files. Amazon RDS supports the password encryption mode (`ENCRYPTION_MODE=PASSWORD`) for Oracle Data Pump. Amazon RDS does not support transparent encryption mode (`ENCRYPTION_MODE=TRANSPARENT`) for Oracle Data Pump. For more information, see [Importing using Oracle Data Pump](#).

## Oracle UTL\_MAIL

Amazon RDS supports Oracle UTL\_MAIL through the use of the UTL\_MAIL option and SMTP servers. You can send email directly from your database by using the UTL\_MAIL package. Amazon RDS supports UTL\_MAIL for the following versions of Oracle:

- Oracle Database 21c (21.0.0.0), all versions
- Oracle Database 19c (19.0.0.0), all versions

The following are some limitations to using UTL\_MAIL:

- UTL\_MAIL does not support Transport Layer Security (TLS) and therefore emails are not encrypted.

To connect securely to remote SSL/TLS resources by creating and uploading custom Oracle wallets, follow the instructions in [Configuring UTL\\_HTTP access using certificates and an Oracle wallet](#).

The specific certificates that are required for your wallet vary by service. For AWS services, these can typically be found in the [Amazon trust services repository](#).

- UTL\_MAIL does not support authentication with SMTP servers.
- You can only send a single attachment in an email.
- You can't send attachments larger than 32 K.
- You can only use ASCII and Extended Binary Coded Decimal Interchange Code (EBCDIC) character encodings.
- SMTP port (25) is throttled based on the elastic network interface owner's policies.

When you enable UTL\_MAIL, only the master user for your DB instance is granted the execute privilege. If necessary, the master user can grant the execute privilege to other users so that they can use UTL\_MAIL.

### Important

We recommend that you enable Oracle's built-in auditing feature to track the use of UTL\_MAIL procedures.

## Prerequisites for Oracle UTL\_MAIL

The following are prerequisites for using Oracle UTL\_MAIL:

- One or more SMTP servers, and the corresponding IP addresses or public or private Domain Name Server (DNS) names. For more information about private DNS names resolved through a custom DNS server, see [Setting up a custom DNS server](#).

## Adding the Oracle UTL\_MAIL option

The general process for adding the Oracle UTL\_MAIL option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

After you add the UTL\_MAIL option, as soon as the option group is active, UTL\_MAIL is active.

### To add the UTL\_MAIL option to a DB instance

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group with the following settings:
  - a. For **Engine**, choose the edition of Oracle you want to use.
  - b. For **Major engine version**, choose the version of your DB instance.

For more information, see [Creating an option group](#).

2. Add the **UTL\_MAIL** option to the option group. For more information about adding options, see [Adding an option to an option group](#).
3. Apply the option group to a new or existing DB instance:
  - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance](#).
  - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance](#).

## Using Oracle UTL\_MAIL

After you enable the UTL\_MAIL option, you must configure the SMTP server before you can begin using it.

You configure the SMTP server by setting the SMTP\_OUT\_SERVER parameter to a valid IP address or public DNS name. For the SMTP\_OUT\_SERVER parameter, you can specify a comma-separated list of the addresses of multiple servers. If the first server is unavailable, UTL\_MAIL tries the next server, and so on.

You can set the default SMTP\_OUT\_SERVER for a DB instance by using a [DB parameter group](#). You can set the SMTP\_OUT\_SERVER parameter for a session by running the following code on your database on your DB instance.

```
ALTER SESSION SET smtp_out_server = mailserver.domain.com:25;
```

After the UTL\_MAIL option is enabled, and your SMTP\_OUT\_SERVER is configured, you can send mail by using the SEND procedure. For more information, see [UTL\\_MAIL](#) in the Oracle documentation.

## Removing the Oracle UTL\_MAIL option

You can remove Oracle UTL\_MAIL from a DB instance.

To remove UTL\_MAIL from a DB instance, do one of the following:

- To remove UTL\_MAIL from multiple DB instances, remove the UTL\_MAIL option from the option group they belong to. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group](#).
- To remove UTL\_MAIL from a single DB instance, modify the DB instance and specify a different option group that doesn't include the UTL\_MAIL option. You can specify the default (empty) option group, or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance](#).

## Troubleshooting

The following are issues you might encounter when you use UTL\_MAIL with Amazon RDS.

- **Throttling.** SMTP port (25) is throttled based on the elastic network interface owner's policies. If you can successfully send email by using UTL\_MAIL, and you see the error `ORA-29278: SMTP transient error: 421 Service not available`, you are possibly being throttled. If you experience throttling with email delivery, we recommend that you implement a backoff algorithm. For more information about backoff algorithms, see [Error retries and exponential backoff in AWS](#) and [How to handle a "throttling – Maximum sending rate exceeded" error](#).

You can request that this throttle be removed. For more information, see [How do I remove the throttle on port 25 from my EC2 instance?](#).

## Oracle XML DB

Oracle XML DB adds native XML support to your DB instance. With XML DB, you can store and retrieve structured or unstructured XML and relational data. The XML DB protocol server isn't supported on RDS for Oracle.

XML DB is preinstalled on Oracle Database 12c and higher. Thus, you don't need to use an option group to explicitly install XML DB as an additional feature.

To learn how to configure and use XML DB, see [Oracle XML DB Developer's Guide](#) in the Oracle Database documentation.

# Upgrading the RDS for Oracle DB engine

When Amazon RDS supports a new version of Oracle Database, you can upgrade your DB instances to the new version. For information about which Oracle versions are available on Amazon RDS, see [Amazon RDS for Oracle Release Notes](#).

## Important

RDS for Oracle Databases 11g, 12c, and 18c are no longer supported. If you maintain Oracle Database 11g, 12c, or 18c snapshots, you can upgrade them to a later release. For more information, see [Upgrading an Oracle DB snapshot](#).

## Topics

- [Overview of RDS for Oracle engine upgrades](#)
- [Oracle major version upgrades](#)
- [Oracle minor version upgrades](#)
- [Considerations for Oracle DB upgrades](#)
- [Testing an Oracle DB upgrade](#)
- [Upgrading the version of an RDS for Oracle DB instance](#)
- [Upgrading an Oracle DB snapshot](#)

## Overview of RDS for Oracle engine upgrades

Before upgrading your RDS for Oracle DB instance, familiarize yourself with the following concepts.

## Topics

- [Major and minor version upgrades](#)
- [Expected support dates for RDS for Oracle major releases](#)
- [Oracle engine version management](#)
- [Automatic snapshots during engine upgrades](#)
- [Oracle upgrades in a Multi-AZ deployment](#)
- [Oracle upgrades of read replicas](#)

## Major and minor version upgrades

Major versions are major releases of Oracle Database that occur every 1-2 years. Examples of major releases are Oracle Database 19c and Oracle Database 21c.

Minor versions, which are also called Release Updates (RUs), are typically released by Oracle every quarter. Minor versions contain small feature enhancements and bug fixes. Examples of minor versions are 21.0.0.0.ru-2023-10.rur-2023-10.r1 and 19.0.0.0.ru-2023-10.rur-2023-10.r1. For more information, see [Release notes for Amazon Relational Database Service \(Amazon RDS\) for Oracle](#).

RDS for Oracle supports the following upgrades to a DB instance.

Upgrade type	Application compatibility	Upgrade methods	Sample upgrade path
Major version	A major version upgrade can introduce changes that aren't compatible with existing applications.	Manual only	From Oracle Database 19c to Oracle Database 21c
Minor version	A minor version upgrade includes only changes that are backward-compatible with existing applications.	Automatic or manual	From 21.0.0.0.ru-2023-07.rur-2022-07.r1 to 21.0.0.0.ru-2023-10.rur-2022-10.r1

### Important

When you upgrade your DB engine, an outage occurs. The duration of the outage depends on your engine version and DB instance size.

Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. For more information, see [Testing an Oracle DB upgrade](#).

## Expected support dates for RDS for Oracle major releases

RDS for Oracle major versions remain available at least until the end of support date for the corresponding Oracle Database release version. You can use the following dates to plan your testing and upgrade cycles. These dates represent the earliest date that an upgrade to a newer version might be required. If Amazon extends support for an RDS for Oracle version for longer than originally stated, we plan to update this table to reflect the later date.

Oracle Database major release version	Expected date for upgrading to a newer version
Oracle Database 19c	<p>April 30, 2026 with BYOL Premier Support (fees waived for Extended Support)</p> <p>April 30, 2027 with BYOL Extended Support (extra cost) or an Unlimited License Agreement</p> <p>April 30, 2027 with License Included (LI)</p>
Oracle Database 21c	April 30, 2025 (not available for Extended Support)

Before we ask you to upgrade to a newer major version, we remind you at least 12 months in advance. We detail the upgrade process, including the timing of important milestones, the impact on your DB instances, and recommended actions. You should thoroughly test your applications with new RDS for Oracle versions before you upgrade to a major version.

After this advance notification period, an automatic upgrade to the subsequent major version might be applied to any RDS for Oracle DB instance still running the older version. If so, the upgrade is started during scheduled maintenance windows.

For more information, see [Release Schedule of Current Database Releases](#) in My Oracle Support.

## Oracle engine version management

With DB engine version management, you control when and how the database engine is patched and upgraded. You get the flexibility to maintain compatibility with database engine patch versions. You can also test new patch versions of RDS for Oracle to ensure they work with your application before deploying them in production. In addition, you upgrade the versions on your own terms and timelines.

**Note**

Amazon RDS periodically aggregates official Oracle database patches using an Amazon RDS-specific DB engine version. To see a list of which Oracle patches are contained in an Amazon RDS Oracle-specific engine version, go to [Amazon RDS for Oracle Release Notes](#).

## Automatic snapshots during engine upgrades

During upgrades of an Oracle DB instance, snapshots offer protection against upgrade issues. If the backup retention period for your DB instance is greater than 0, Amazon RDS takes the following DB snapshots during the upgrade:

1. A snapshot of the DB instance before any upgrade changes have been made. If the upgrade fails, you can restore this snapshot to create a DB instance running the old version.
2. A snapshot of the DB instance after the upgrade completes.

**Note**

To change your backup retention period, see [Modifying an Amazon RDS DB instance](#).

After an upgrade, you can't revert to the previous engine version. However, you can create a new Oracle DB instance by restoring the pre-upgrade snapshot.

## Oracle upgrades in a Multi-AZ deployment

If your DB instance is in a Multi-AZ deployment, Amazon RDS upgrades both the primary and standby replicas. If no operating system updates are required, the primary and standby upgrades occur simultaneously. The instances are not available until the upgrade completes.

If operating system updates are required in a Multi-AZ deployment, Amazon RDS applies the updates when you request the database upgrade. Amazon RDS performs the following steps:

1. Updates the operating system on the current standby DB instance.
2. Fails over the primary DB instance to the standby DB instance.
3. Upgrades the database version on the new primary DB instance, which was formerly the standby instance. The primary database is unavailable during the upgrade.

4. Updates the operating system on the new standby DB instance, which was formerly the primary DB instance.
5. Upgrades the database version on the new standby DB instance.
6. Fails over the new primary DB instance back to the original primary DB instance, and the new standby DB instance back to the original standby DB instance. Thus, Amazon RDS returns the replication configuration to its original state.

## Oracle upgrades of read replicas

The Oracle DB engine version of the source DB instance and all of its read replicas must be the same. Amazon RDS performs the upgrade in the following stages:

1. Upgrades the source DB instance. The read replicas are available during this stage.
2. Upgrades the read replicas in parallel, regardless of the replica maintenance windows. The source DB is available during this stage.

For major version upgrades of cross-Region read replicas, Amazon RDS performs additional actions:

- Generates an option group for the target version automatically
- Copies all options and option settings from the original option group to the new option group
- Associates the upgraded cross-Region read replica with the new option group

## Oracle major version upgrades

To perform a major version upgrade, modify the DB instance manually. Major version upgrades don't occur automatically.

### Important

Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. For more information, see [Testing an Oracle DB upgrade](#).

## Topics

- [Supported versions for major upgrades](#)
- [Supported instance classes for major upgrades](#)
- [Gathering statistics before major upgrades](#)
- [Allowing major upgrades](#)

## Supported versions for major upgrades

Amazon RDS supports the following major version upgrades.

Current version	Upgrade supported
19.0.0.0 using the CDB architecture	21.0.0.0

A major version upgrade of Oracle Database must upgrade to a Release Update (RU) that was released in the same month or later. Major version downgrades aren't supported for any Oracle Database versions.

## Supported instance classes for major upgrades

Your current Oracle DB instance might run on a DB instance class that isn't supported for the version to which you are upgrading. In this case, before you upgrade, migrate the DB instance to a supported DB instance class. For more information about the supported DB instance classes for each version and edition of Amazon RDS for Oracle, see [DB instance classes](#).

## Gathering statistics before major upgrades

Before you perform a major version upgrade, Oracle recommends that you gather optimizer statistics on the DB instance that you are upgrading. This action can reduce DB instance downtime during the upgrade.

To gather optimizer statistics, connect to the DB instance as the master user, and run the `DBMS_STATS.GATHER_DICTIONARY_STATS` procedure, as in the following example.

```
EXEC DBMS_STATS.GATHER_DICTIONARY_STATS;
```

For more information, see [GATHER\\_DICTIONARY\\_STATS Procedure](#) in the Oracle documentation.

## Allowing major upgrades

A major engine version upgrade might be incompatible with your application. The upgrade is irreversible. If you specify a major version for the `EngineVersion` parameter that is different from the current major version, you must allow major version upgrades.

If you upgrade a major version using the CLI command [modify-db-instance](#), specify `--allow-major-version-upgrade`. This setting isn't persistent, so you must specify `--allow-major-version-upgrade` whenever you perform a major upgrade. This parameter has no impact on upgrades of minor engine versions. For more information, see [Upgrading a DB instance engine version](#).

If you upgrade a major version using the console, you don't need to choose an option to allow the upgrade. Instead, the console displays a warning that major upgrades are irreversible.

## Oracle minor version upgrades

A minor version upgrade applies an Oracle Database Patch Set Update (PSU) or Release Update (RU) to a major engine version. For example, if your DB instance runs major version Oracle Database 21c and minor version 21.0.0.0.ru-2022-07.rur-2022-07.r1, you can upgrade your upgrade to minor version 21.0.0.0.ru-2022-10.rur-2022-10.r1. Typically, a new minor version is available every quarter.

### Note

RDS for Oracle doesn't support minor version downgrades.

You can upgrade your DB engine to a minor version manually or automatically. To learn how to upgrade manually, see [Manually upgrading the engine version](#). To learn how to configure automatic upgrades, see [Automatically upgrading the minor engine version](#). Whether you upgrade manually or automatically, a minor version upgrade entails downtime. Keep this in mind when planning your upgrades.

### Important

Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. For more information, see [Testing an Oracle DB upgrade](#).

## Topics

- [Turning on automatic minor version upgrades for Oracle](#)
- [Before an automatic minor version upgrade for Oracle is scheduled](#)
- [When RDS schedules automatic minor version upgrades for Oracle](#)
- [Managing an automatic minor version upgrade for Oracle](#)

## Turning on automatic minor version upgrades for Oracle

In an automatic minor version upgrade, RDS applies the latest available minor version to your Oracle database without manual intervention. An Amazon RDS for Oracle DB instance schedules your upgrade during the next maintenance window in the following circumstances:

- Your DB instance has the **Auto minor version upgrade** option turned on.
- Your DB instance isn't already running the latest minor DB engine version.
- Your DB instance doesn't already have a pending upgrade scheduled.

To learn how to turn on automatic upgrades, see [Automatically upgrading the minor engine version](#).

## Before an automatic minor version upgrade for Oracle is scheduled

RDS publishes an advance notice before it begins scheduling automatic upgrades. You can find the notification in the **Maintenance & backups** tab of the database details page. The message has the following format:

```
An automatic minor version upgrade to engine version will become available
on availability-date and will be applied during a subsequent maintenance window.
```

The *availability-date* in the preceding message is the date when RDS starts scheduling upgrades for DB instances in your AWS Region. It is not the date on which the upgrade of your DB instance is scheduled to occur.

You can also get the upgrade availability date by using the `describe-pending-maintenance-actions` command in the AWS CLI, as shown in the following example:

```
aws rds describe-pending-maintenance-actions
```

```

{
  "PendingMaintenanceActions": [
    {
      "ResourceIdentifier": "arn:aws:rds:us-east-1:123456789012:db:orclinst1",
      "PendingMaintenanceActionDetails": [
        {
          "Action": "db-upgrade",
          "Description": "Automatic minor version upgrade to
21.0.0.0.rur-2022-10.rur-2022-10.r1",
          "CurrentApplyDate": "2022-12-02T08:10:00Z",
          "OptInStatus": "next-maintenance"
        }
      ]
    }
  ], ...
}

```

The following table describes your options for each type of pending maintenance action message.

Pending maintenance action message	When message appears	Eligible to be applied at the next maintenance window?	Eligible to be applied immediately?	Eligible to have the opt-in undone?
An automatic minor version upgrade to <i>engine-version</i> will become available on <i>availability-date</i> and should be applied during a subsequent maintenance window.	4-6 weeks before automatic upgrades are scheduled.	Yes	Yes	Yes
Automatic minor version upgrade to <i>engine-version</i>	On or after <i>availability-date</i> . RDS automatically applies this upgrade in the next maintenance	Yes	Yes	No

Pending maintenance action message	When message appears	Eligible to be applied at the next maintenance window?	Eligible to be applied immediately?	Eligible to have the opt-in undone?
	window of the DB instance.			

For more information about [describe-pending-maintenance-actions](#), see the *AWS CLI Command Reference*.

## When RDS schedules automatic minor version upgrades for Oracle

When the availability date for automatic upgrades arrives, RDS begins scheduling upgrades. For most AWS Regions, RDS schedules your upgrade to the latest quarterly RU approximately four to six weeks after the availability date. The scheduled date varies depending on the AWS Region and other factors. For more information about RUs and RURs, see [Amazon RDS for Oracle Release Notes](#).

When RDS schedules the upgrade, the following notification appears in the **Maintenance & backups** tab of the database details page:

```
Automatic minor version upgrade to engine-version
```

The preceding message indicates that RDS has scheduled your DB engine to be upgraded in the next maintenance window.

## Managing an automatic minor version upgrade for Oracle

When a new minor version becomes available, you can upgrade your DB instance to this version manually. The following example upgrades the DB instance named `orclinst1` immediately:

```
aws rds apply-pending-maintenance-action \
  --resource-identifier arn:aws:rds:us-east-1:123456789012:db:orclinst1 \
  --apply-action db-upgrade \
  --opt-in-type immediate
```

To opt out of an automatic minor version upgrade that hasn't been scheduled yet, set `opt-in-type` to `undo-opt-in`, as in the following example:

```
aws rds apply-pending-maintenance-action \
  --resource-identifier arn:aws:rds:us-east-1:123456789012:db:orclinst1 \
  --apply-action db-upgrade \
  --opt-in-type undo-opt-in
```

If RDS has already scheduled an upgrade for your DB instance, you can't use `apply-pending-maintenance-action` to cancel it. But you can modify your DB instance and turn off the automatic minor upgrade feature, which then unschedules the upgrade.

To learn how to turn off automatic minor version upgrades, see [Automatically upgrading the minor engine version](#). For more information about [apply-pending-maintenance-action](#), see the *AWS CLI Command Reference*.

## Considerations for Oracle DB upgrades

Before you upgrade your Oracle instance, review the following information.

### Topics

- [Oracle Multitenant considerations](#)
- [Option group considerations](#)
- [Parameter group considerations](#)
- [Time zone considerations](#)

### Oracle Multitenant considerations

The following table describes the Oracle Database architectures supported in different releases.

Oracle Database release	RDS support status	Architecture
Oracle Database 21c	Supported	CDB only
Oracle Database 19c	Supported	CDB or non-CDB

The following table describes supported and unsupported upgrade paths.

Upgrade path	Supported?
CDB to CDB	Yes
Non-CDB to CDB	No, but you can convert a non-CDB to a CDB and then upgrade it
CDB to non-CDB	No

For more information about Oracle Multitenant in RDS for Oracle, see [Single-tenant configuration of the CDB architecture](#).

## Option group considerations

If your DB instance uses a custom option group, sometimes Amazon RDS can't automatically assign a new option group. For example, this situation occurs when you upgrade to a new major version. In such cases, specify a new option group when you upgrade. We recommend that you create a new option group, and add the same options to it as in your existing custom option group.

For more information, see [Creating an option group](#) or [Copying an option group](#).

If your DB instance uses a custom option group that contains the APEX option, you can sometimes reduce the upgrade time. To do this, upgrade your version of APEX at the same time as your DB instance. For more information, see [Upgrading the APEX version](#).

## Parameter group considerations

If your DB instance uses a custom parameter group, sometimes Amazon RDS can't automatically assign your DB instance a new parameter group. For example, this situation occurs when you upgrade to a new major version. In such cases, make sure to specify a new parameter group when you upgrade. We recommend that you create a new parameter group, and configure the parameters as in your existing custom parameter group.

For more information, see [Creating a DB parameter group in Amazon RDS](#) or [Copying a DB parameter group in Amazon RDS](#).

## Time zone considerations

You can use the time zone option to change the *system time zone* used by your Oracle DB instance. For example, you might change the time zone of a DB instance to be compatible with an on-

premises environment, or a legacy application. The time zone option changes the time zone at the host level. Amazon RDS for Oracle updates the system time zone automatically throughout the year. For more information about the system time zone, see [Oracle time zone](#).

When you create an Oracle DB instance, the database automatically sets the *database time zone*. The database time zone is also known as the Daylight Saving Time (DST) time zone. The database time zone is distinct from the system time zone.

Between Oracle Database releases, patch sets or individual patches may include new DST versions. These patches reflect the changes in transition rules for various time zone regions. For example, a government might change when DST takes effect. Changes to DST rules may affect existing data of the `TIMESTAMP WITH TIME ZONE` data type.

If you upgrade an RDS for Oracle DB instance, Amazon RDS doesn't upgrade the database time zone file automatically. To upgrade the time zone file automatically, you can include the `TIMEZONE_FILE_AUTOUPGRADE` option in the option group associated with your DB instance during or after the engine version upgrade. For more information, see [Oracle time zone file autoupgrade](#).

Alternatively, to upgrade the database time zone file manually, create a new Oracle DB instance that has the desired DST patch. However, we recommend that you upgrade the database time zone file using the `TIMEZONE_FILE_AUTOUPGRADE` option.

After upgrading the time zone file, migrate the data from your current instance to the new instance. You can migrate data using several techniques, including the following:

- AWS Database Migration Service
- Oracle GoldenGate
- Oracle Data Pump
- Original Export/Import (desupported for general use)

 **Note**

When you migrate data using Oracle Data Pump, the utility raises the error ORA-39405 when the target time zone version is lower than the source time zone version.

For more information, see [TIMESTAMP WITH TIMEZONE restrictions](#) in the Oracle documentation.

## Testing an Oracle DB upgrade

Before you upgrade your DB instance to a major version, thoroughly test your database and all applications that access the database for compatibility with the new version. We recommend that you use the following procedure.

### To test a major version upgrade

1. Review the Oracle upgrade documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications. For more information, see [Database Upgrade Guide](#) in the Oracle documentation.
2. If your DB instance uses a custom option group, create a new option group compatible with the new version you are upgrading to. For more information, see [Option group considerations](#).
3. If your DB instance uses a custom parameter group, create a new parameter group compatible with the new version you are upgrading to. For more information, see [Parameter group considerations](#).
4. Create a DB snapshot of the DB instance to be upgraded. For more information, see [Creating a DB snapshot for a Single-AZ DB instance](#).
5. Restore the DB snapshot to create a new test DB instance. For more information, see [Restoring to a DB instance](#).
6. Modify this new test DB instance to upgrade it to the new version, by using one of the following methods:
  - [Console](#)
  - [AWS CLI](#)
  - [RDS API](#)
7. Perform testing:
  - Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version.
  - Implement any new tests needed to evaluate the impact of any compatibility issues that you identified in step 1.
  - Test all stored procedures, functions, and triggers.
  - Direct test versions of your applications to the upgraded DB instance. Verify that the applications work correctly with the new version.

- Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage. You might need to choose a larger instance class to support the new version in production. For more information, see [DB instance classes](#).
8. If all tests pass, upgrade your production DB instance. We recommend that you confirm that the DB instance working correctly before allowing write operations to the DB instance.

## Upgrading the version of an RDS for Oracle DB instance

To manually upgrade the DB engine version of an RDS for Oracle DB instance, use the AWS Management Console, the AWS CLI, or the RDS API. For general information about database upgrades in RDS, see [Upgrading the version of an RDS for Oracle DB instance](#). To get valid upgrade targets, use the AWS CLI [describe-db-engine-versions](#) command.

### Console

#### To upgrade the engine version of an RDS for Oracle DB instance by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to upgrade.
3. Choose **Modify**.
4. For **DB engine version**, choose a higher database version.
5. Choose **Continue** and check the summary of modifications. Make sure that you understand the implications of a database version upgrade. You can't convert an upgraded DB instance back to the previous version. Make sure you have tested both your database and your application with the new version before continuing.
6. Decide when to schedule your DB instance upgrade. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see [Schedule modifications setting](#).
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance** to save your changes.

Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

## AWS CLI

To upgrade the engine version of an RDS for Oracle DB instance, you can use the CLI [modify-db-instance](#) command. Specify the following parameters:

- `--db-instance-identifier` – the name of the RDS for Oracle DB instance.
- `--engine-version` – the version number of the database engine to upgrade to.

For information about valid engine versions, use the AWS CLI [describe-db-engine-versions](#) command.

- `--allow-major-version-upgrade` – to upgrade the DB engine version.
- `--no-apply-immediately` – to apply changes during the next maintenance window. To apply changes immediately, use `--apply-immediately`.

### Example

The following example upgrades a CDB instance named `myorainst` from its current version of `19.0.0.0.ru-2024-01.rur-2024-01.r1` to version `21.0.0.0.ru-2024-04.rur-2024-04.r1`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --db-instance-identifier myorainst \  
  --engine-version 21.0.0.0.ru-2024-04.rur-2024-04.r1 \  
  --allow-major-version-upgrade \  
  --no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^  
  --db-instance-identifier myorainst ^  
  --engine-version 21.0.0.0.ru-2024-04.rur-2024-04.r1 ^  
  --allow-major-version-upgrade ^  
  --no-apply-immediately
```

## RDS API

To upgrade an RDS for Oracle DB instance, use the [ModifyDBInstance](#) action. Specify the following parameters:

- `DBInstanceIdentifier` – the name of the DB instance, for example *myorainst*.
- `EngineVersion` – the version number of the database engine to upgrade to. For information about valid engine versions, use the [DescribeDBEngineVersions](#) operation.
- `AllowMajorVersionUpgrade` – whether to allow a major version upgrade. To do so, set the value to `true`.
- `ApplyImmediately` – whether to apply changes immediately or during the next maintenance window. To apply changes immediately, set the value to `true`. To apply changes during the next maintenance window, set the value to `false`.

## Upgrading an Oracle DB snapshot

If you have existing manual DB snapshots, you can upgrade them to a later version of the Oracle database engine.

When Oracle stops providing patches for a version, and Amazon RDS deprecates the version, you can upgrade your snapshots that correspond to the deprecated version. For more information, see [Oracle engine version management](#).

Amazon RDS supports upgrading snapshots in all AWS Regions.

### Console

#### To upgrade an Oracle DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**, and then select the DB snapshot that you want to upgrade.
3. For **Actions**, choose **Upgrade snapshot**. The **Upgrade snapshot** page appears.
4. Choose the **New engine version** to upgrade the snapshot to.
5. (Optional) For **Option group**, choose the option group for the upgraded DB snapshot. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see [Option group considerations](#).
6. Choose **Save changes** to save your changes.

During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from **available** to **upgrading**, and then changes to **active** upon

completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to **unavailable**. You can't recover the snapshot from this state.

### Note

If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

## AWS CLI

To upgrade an Oracle DB snapshot by using the AWS CLI, call the [modify-db-snapshot](#) command with the following parameters:

- `--db-snapshot-identifier` – The name of the DB snapshot.
- `--engine-version` – The version to upgrade the snapshot to.

You might also need to include the following parameter. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see [Option group considerations](#).

- `--option-group-name` – The option group for the upgraded DB snapshot.

## Example

The following example upgrades a DB snapshot.

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot \  
  --db-snapshot-identifier mydbsnapshot \  
  --engine-version 19.0.0.0.ru-2020-10.rur-2020-10.r1 \  
  --option-group-name default:oracle-se2-19
```

For Windows:

```
aws rds modify-db-snapshot ^  
  --db-snapshot-identifier mydbsnapshot ^  
  --engine-version 19.0.0.0.ru-2020-10.rur-2020-10.r1 ^
```

```
--option-group-name default:oracle-se2-19
```

## RDS API

To upgrade an Oracle DB snapshot by using the Amazon RDS API, call the [ModifyDBSnapshot](#) operation with the following parameters:

- `DBSnapshotIdentifier` – The name of the DB snapshot.
- `EngineVersion` – The version to upgrade the snapshot to.

You might also need to include the `OptionGroupName` parameter. The same option group considerations apply when upgrading a DB snapshot as when upgrading a DB instance. For more information, see [Option group considerations](#).

# Using third-party software with your RDS for Oracle DB instance

You can host an RDS for Oracle DB instance that supports tools and third-party software.

## Topics

- [Using Oracle GoldenGate with Amazon RDS for Oracle](#)
- [Using the Oracle Repository Creation Utility on RDS for Oracle](#)
- [Configuring Oracle Connection Manager on an Amazon EC2 instance](#)
- [Installing a Siebel database on Oracle on Amazon RDS](#)

## Using Oracle GoldenGate with Amazon RDS for Oracle

Oracle GoldenGate collects, replicates, and manages transactional data between databases. It is a log-based change data capture (CDC) and replication software package used with databases for online transaction processing (OLTP) systems. Oracle GoldenGate creates trail files that contain the most recent changed data from the source database. It then pushes these files to the server, where a process converts the trail file into standard SQL to be applied to the target database.

Oracle GoldenGate with RDS for Oracle supports the following features:

- Active-Active database replication
- Disaster recovery
- Data protection
- In-Region and cross-Region replication
- Zero-downtime migration and upgrades
- Data replication between an RDS for Oracle DB instance and a non-Oracle database

### Note

For a list of supported databases, see [Oracle Fusion Middleware Supported System Configurations](#) in the Oracle documentation.

You can use Oracle GoldenGate with RDS for Oracle to upgrade to major versions of Oracle Database. For example, you can use Oracle GoldenGate to upgrade from an Oracle Database 11g on-premises database to Oracle Database 19c on an Amazon RDS DB instance.

### Topics

- [Supported versions and licensing options for Oracle GoldenGate](#)
- [Requirements and limitations for Oracle GoldenGate](#)
- [Oracle GoldenGate architecture](#)
- [Setting up Oracle GoldenGate](#)
- [Working with the EXTRACT and REPLICAT utilities of Oracle GoldenGate](#)
- [Monitoring Oracle GoldenGate](#)
- [Troubleshooting Oracle GoldenGate](#)

## Supported versions and licensing options for Oracle GoldenGate

You can use Standard Edition 2 (SE2) or Enterprise Edition (EE) of RDS for Oracle with Oracle GoldenGate version 12c and higher. You can use the following Oracle GoldenGate features:

- Oracle GoldenGate Remote Capture (extract) is supported.
- Capture (extract) is supported on RDS for Oracle DB instances that use the traditional non-CDB database architecture. Oracle GoldenGate Remote PDB capture is supported on Oracle Database 21c container databases (CDBs).
- Oracle GoldenGate Remote Delivery (replicat) is supported on RDS for Oracle DB instances that use either the non-CDB or CDB architectures. Remote Delivery supports Integrated Replicat, Parallel Replicat, Coordinated Replicat, and classic Replicat.
- RDS for Oracle supports the Classic and Microservices architectures of Oracle GoldenGate.
- Oracle GoldenGate DDL and Sequence value replication is supported when using Integrated capture mode.

You are responsible for managing Oracle GoldenGate licensing (BYOL) for use with Amazon RDS in all AWS Regions. For more information, see [RDS for Oracle licensing options](#).

## Requirements and limitations for Oracle GoldenGate

When you're working with Oracle GoldenGate and RDS for Oracle, consider the following requirements and limitations:

- You're responsible for setting up and managing Oracle GoldenGate for use with RDS for Oracle.
- You're responsible for setting up an Oracle GoldenGate version that is certified with the source and the target databases. For more information, see [Oracle Fusion Middleware Supported System Configurations](#) in the Oracle documentation.
- You can use Oracle GoldenGate on many different AWS environments for many different use cases. If you have a support-related issue relating to Oracle GoldenGate, contact Oracle Support Services.
- You can use Oracle GoldenGate on RDS for Oracle DB instances that use Oracle Transparent Data Encryption (TDE). To maintain the integrity of replicated data, configure encryption on the Oracle GoldenGate hub using Amazon EBS encrypted volumes or trail file encryption. Also configure encryption for data sent between the Oracle GoldenGate hub and the source and

target database instances. RDS for Oracle DB instances support encryption with [Oracle Secure Sockets Layer](#) or [Oracle native network encryption](#).

## Oracle GoldenGate architecture

The Oracle GoldenGate architecture for use with Amazon RDS consists of the following decoupled modules:

### Source database

Your source database can be either an on-premises Oracle database, an Oracle database on an Amazon EC2 instance, or an Oracle database on an Amazon RDS DB instance.

### Oracle GoldenGate hub

An Oracle GoldenGate hub moves transaction information from the source database to the target database. Your hub can be either of the following:

- An Amazon EC2 instance with Oracle Database and Oracle GoldenGate installed
- An on-premises Oracle installation

You can have more than one Amazon EC2 hub. We recommend that you use two hubs if you use Oracle GoldenGate for cross-Region replication.

### Target database

Your target database can be on either an Amazon RDS DB instance, an Amazon EC2 instance, or an on-premises location.

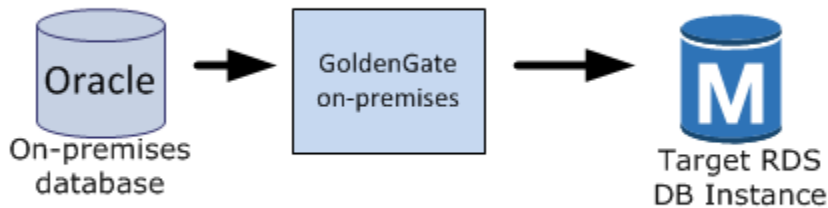

The following sections describe common scenarios for Oracle GoldenGate on Amazon RDS.

## Topics

- [On-premises source database and Oracle GoldenGate hub](#)
- [On-premises source database and Amazon EC2 hub](#)
- [Amazon RDS source database and Amazon EC2 hub](#)
- [Amazon EC2 source database and Amazon EC2 hub](#)
- [Amazon EC2 hubs in different AWS Regions](#)

## On-premises source database and Oracle GoldenGate hub

In this scenario, an on-premises Oracle source database and on-premises Oracle GoldenGate hub provides data to a target Amazon RDS DB instance.

## On-premises source database and Amazon EC2 hub

In this scenario, an on-premises Oracle database acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.

## Amazon RDS source database and Amazon EC2 hub

In this scenario, an RDS for Oracle DB instance acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.

### Amazon EC2 source database and Amazon EC2 hub

In this scenario, an Oracle database on an Amazon EC2 instance acts as the source database. It's connected to an Amazon EC2 instance hub. This hub provides data to a target RDS for Oracle DB instance.

### Amazon EC2 hubs in different AWS Regions

In this scenario, an Oracle database on an Amazon RDS DB instance is connected to an Amazon EC2 instance hub in the same AWS Region. The hub is connected to an Amazon EC2 instance hub in a

different AWS Region. This second hub provides data to the target RDS for Oracle DB instance in the same AWS Region as the second Amazon EC2 instance hub.

### Note

Any issues that affect running Oracle GoldenGate on an on-premises environment also affect running Oracle GoldenGate on AWS. We strongly recommend that you monitor the Oracle GoldenGate hub to ensure that EXTRACT and REPLICAT are resumed if a failover occurs. Because the Oracle GoldenGate hub is run on an Amazon EC2 instance, Amazon RDS does not manage the Oracle GoldenGate hub and cannot ensure that it is running.

## Setting up Oracle GoldenGate

To set up Oracle GoldenGate using Amazon RDS, configure the hub on an Amazon EC2 instance, and then configure the source and target databases. The following sections give an example of how to set up Oracle GoldenGate for use with Amazon RDS for Oracle.

### Topics

- [Setting up an Oracle GoldenGate hub on Amazon EC2](#)
- [Setting up a source database for use with Oracle GoldenGate on Amazon RDS](#)
- [Setting up a target database for use with Oracle GoldenGate on Amazon RDS](#)

## Setting up an Oracle GoldenGate hub on Amazon EC2

To create an Oracle GoldenGate hub on an Amazon EC2 instance, you first create an Amazon EC2 instance with a full client installation of Oracle RDBMS. The Amazon EC2 instance must also have Oracle GoldenGate software installed. The Oracle GoldenGate software versions depend on the source and target database versions. For more information about installing Oracle GoldenGate, see the [Oracle GoldenGate documentation](#).

The Amazon EC2 instance that serves as the Oracle GoldenGate hub stores and processes the transaction information from the source database into trail files. To support this process, make sure that you meet the following requirements:

- You have allocated enough storage for the trail files.
- The Amazon EC2 instance has enough processing power to manage the amount of data.
- The EC2 instance has enough memory to store the transaction information before it's written to the trail file.

### To set up an Oracle GoldenGate classic architecture hub on an Amazon EC2 instance

1. Create subdirectories in the Oracle GoldenGate directory.

In the Amazon EC2 command line shell, start `ggsci`, the Oracle GoldenGate command interpreter. The `CREATE SUBDIRS` command creates subdirectories under the `/gg` directory for parameter, report, and checkpoint files.

```
prompt$ cd /gg
prompt$ ./ggsci

GGSCI> CREATE SUBDIRS
```

2. Configure the `mgr.prm` file.

The following example adds lines to the `$GGHOME/dirprm/mgr.prm` file.

```
PORT 8199
PurgeOldExtracts ./dirdat/*, UseCheckpoints, MINKEEPDAYS 5
```

3. Start the manager.

The following example starts `ggsci` and runs the `start mgr` command.

```
GGSCI> start mgr
```

The Oracle GoldenGate hub is now ready for use.

## Setting up a source database for use with Oracle GoldenGate on Amazon RDS

Complete the following tasks to set up a source database for use with Oracle GoldenGate.

### Setup steps

- [Step 1: Turn on supplemental logging on the source database](#)
- [Step 2: Set the ENABLE\\_GOLDENGATE\\_REPLICATION initialization parameter to true](#)
- [Step 3: Set the log retention period on the source database](#)
- [Step 4: Create an Oracle GoldenGate user account on the source database](#)
- [Step 5: Grant user account privileges on the source database](#)
- [Step 6: Add a TNS alias for the source database](#)

### Step 1: Turn on supplemental logging on the source database

To turn on the minimum database-level supplemental logging, run the following PL/SQL procedure:

```
EXEC rdsadmin.rdsadmin_util.alter_supplemental_logging(p_action => 'ADD')
```

### Step 2: Set the ENABLE\_GOLDENGATE\_REPLICATION initialization parameter to true

When you set the ENABLE\_GOLDENGATE\_REPLICATION initialization parameter to `true`, it allows database services to support logical replication. If your source database is on an Amazon RDS DB instance, make sure that you have a parameter group assigned to the DB instance with the ENABLE\_GOLDENGATE\_REPLICATION initialization parameter set to `true`. For more information about the ENABLE\_GOLDENGATE\_REPLICATION initialization parameter, see the [Oracle Database documentation](#).

### Step 3: Set the log retention period on the source database

Make sure that you configure the source database to retain archived redo logs. Consider the following guidelines:

- Specify the duration for log retention in hours. The minimum value is one hour.
- Set the duration to exceed any potential downtime of the source DB instance, any potential period of communication, and any potential period of networking issues for the source instance. Such a duration lets Oracle GoldenGate recover logs from the source instance as needed.
- Ensure that you have sufficient storage on your instance for the files.

For example, set the retention period for archived redo logs to 24 hours.

```
EXEC rdsadmin.rdsadmin_util.set_configuration('archivelog retention hours',24)
```

If you don't have log retention enabled, or if the retention value is too small, you receive an error message similar to the following.

```
2022-03-06 06:17:27 ERROR OGG-00446 error 2 (No such file or directory)
opening redo log /rdsbdbdata/db/GGTEST3_A/onlinelog/o1_mf_2_9k4bp1n6_.log for sequence
1306
Not able to establish initial position for begin time 2022-03-06 06:16:55.
```

Because your DB instance retains your archived redo logs, make sure that you have sufficient space for the files. To see how much space you have used in the last *num\_hours* hours, run the following query, replacing *num\_hours* with the number of hours.

```
SELECT SUM(BLOCKS * BLOCK_SIZE) BYTES FROM V$ARCHIVED_LOG
WHERE NEXT_TIME>=SYSDATE-num_hours/24 AND DEST_ID=1;
```

#### Step 4: Create an Oracle GoldenGate user account on the source database

Oracle GoldenGate runs as a database user and requires the appropriate database privileges to access the redo and archived redo logs for the source database. To provide these, create a user account on the source database. For more information about the permissions for an Oracle GoldenGate user account, see the [Oracle documentation](#).

The following statements create a user account named oggadm1.

```
CREATE TABLESPACE administrator;
CREATE USER oggadm1 IDENTIFIED BY "password"
DEFAULT TABLESPACE ADMINISTRATOR TEMPORARY TABLESPACE TEMP;
```

```
ALTER USER oggadm1 QUOTA UNLIMITED ON administrator;
```

**Note**

Specify a password other than the prompt shown here as a security best practice.

**Step 5: Grant user account privileges on the source database**

In this task, you grant necessary account privileges for database users on your source database.

**To grant account privileges on the source database**

1. Grant the necessary privileges to the Oracle GoldenGate user account using the SQL command `grant` and the `rdsadmin.rdsadmin_util.grant_sys_object` procedure `grant_sys_object`. The following statements grant privileges to a user named `oggadm1`.

```
GRANT CREATE SESSION, ALTER SESSION TO oggadm1;
GRANT RESOURCE TO oggadm1;
GRANT SELECT ANY DICTIONARY TO oggadm1;
GRANT FLASHBACK ANY TABLE TO oggadm1;
GRANT SELECT ANY TABLE TO oggadm1;
GRANT SELECT_CATALOG_ROLE TO rds_master_user_name WITH ADMIN OPTION;
EXEC rdsadmin.rdsadmin_util.grant_sys_object ('DBA_CLUSTERS', 'OGGADM1');
GRANT EXECUTE ON DBMS_FLASHBACK TO oggadm1;
GRANT SELECT ON SYS.V_$DATABASE TO oggadm1;
GRANT ALTER ANY TABLE TO oggadm1;
```

2. Grant the privileges needed by a user account to be an Oracle GoldenGate administrator. Run the following PL/SQL program.

```
EXEC rdsadmin.rdsadmin_dbms_goldengate_auth.grant_admin_privilege (
  grantee           => 'OGGADM1',
  privilege_type    => 'capture',
  grant_select_privileges => true,
  do_grants         => TRUE);
```

To revoke privileges, use the procedure `revoke_admin_privilege` in the same package.

## Step 6: Add a TNS alias for the source database

Add the following entry to `$ORACLE_HOME/network/admin/tnsnames.ora` in the Oracle home to be used by the EXTRACT process. For more information on the `tnsnames.ora` file, see the [Oracle documentation](#).

```
OGGSOURCE=
  (DESCRIPTION=
    (ENABLE=BROKEN)
    (ADDRESS_LIST=
      (ADDRESS=(PROTOCOL=TCP)(HOST=goldengate-source.abcdef12345.us-
west-2.rds.amazonaws.com)(PORT=8200))
    (CONNECT_DATA=(SERVICE_NAME=ORCL))
  )
```

## Setting up a target database for use with Oracle GoldenGate on Amazon RDS

In this task, you set up a target DB instance for use with Oracle GoldenGate.

### Setup steps

- [Step 1: Set the ENABLE\\_GOLDENGATE\\_REPLICATION initialization parameter to true](#)
- [Step 2: Create an Oracle GoldenGate user account on the target database](#)
- [Step 3: Grant account privileges on the target database](#)
- [Step 4: Add a TNS alias for the target database](#)

### Step 1: Set the ENABLE\_GOLDENGATE\_REPLICATION initialization parameter to true

When you set the `ENABLE_GOLDENGATE_REPLICATION` initialization parameter to `true`, it allows database services to support logical replication. If your source database is on an Amazon RDS DB instance, make sure that you have a parameter group assigned to the DB instance with the `ENABLE_GOLDENGATE_REPLICATION` initialization parameter set to `true`. For more information about the `ENABLE_GOLDENGATE_REPLICATION` initialization parameter, see the [Oracle Database documentation](#).

### Step 2: Create an Oracle GoldenGate user account on the target database

Oracle GoldenGate runs as a database user and requires the appropriate database privileges. To make sure it has these privileges, create a user account on the target database.

The following statement creates a user named `oggadm1`.

```
CREATE TABLESPACE administrator;  
CREATE USER oggadm1 IDENTIFIED BY "password"  
    DEFAULT TABLESPACE administrator  
    TEMPORARY TABLESPACE temp;  
ALTER USER oggadm1 QUOTA UNLIMITED ON administrator;
```

**Note**

Specify a password other than the prompt shown here as a security best practice.

### Step 3: Grant account privileges on the target database

In this task, you grant necessary account privileges for database users on your target database.

#### To grant account privileges on the target database

1. Grant necessary privileges to the Oracle GoldenGate user account on the target database. In the following example, you grant privileges to oggadm1.

```
GRANT CREATE SESSION          TO oggadm1;  
GRANT ALTER SESSION          TO oggadm1;  
GRANT CREATE CLUSTER          TO oggadm1;  
GRANT CREATE INDEXTYPE        TO oggadm1;  
GRANT CREATE OPERATOR          TO oggadm1;  
GRANT CREATE PROCEDURE        TO oggadm1;  
GRANT CREATE SEQUENCE          TO oggadm1;  
GRANT CREATE TABLE            TO oggadm1;  
GRANT CREATE TRIGGER          TO oggadm1;  
GRANT CREATE TYPE              TO oggadm1;  
GRANT SELECT ANY DICTIONARY    TO oggadm1;  
GRANT CREATE ANY TABLE        TO oggadm1;  
GRANT ALTER ANY TABLE         TO oggadm1;  
GRANT LOCK ANY TABLE         TO oggadm1;  
GRANT SELECT ANY TABLE        TO oggadm1;  
GRANT INSERT ANY TABLE        TO oggadm1;  
GRANT UPDATE ANY TABLE        TO oggadm1;  
GRANT DELETE ANY TABLE        TO oggadm1;
```

2. Grant the privileges needed by a user account to be an Oracle GoldenGate administrator. Run the following PL/SQL program.

```
EXEC rdsadmin.rdsadmin_dbms_goldengate_auth.grant_admin_privilege (  
  grantee           => 'OGGADM1',  
  privilege_type    => 'apply',  
  grant_select_privileges => true,  
  do_grants         => TRUE);
```

To revoke privileges, use the procedure `revoke_admin_privilege` in the same package.

#### Step 4: Add a TNS alias for the target database

Add the following entry to `$ORACLE_HOME/network/admin/tnsnames.ora` in the Oracle home to be used by the REPLICAT process. For Oracle Multitenant databases, make sure that the TNS alias points to the service name of the PDB. For more information on the `tnsnames.ora` file, see the [Oracle documentation](#).

```
OGGTARGET=  
  (DESCRIPTION=  
    (ENABLE=BROKEN)  
    (ADDRESS_LIST=  
      (ADDRESS=(PROTOCOL=TCP)(HOST=goldengate-target.abcdef12345.us-  
west-2.rds.amazonaws.com)(PORT=8200))  
    (CONNECT_DATA=(SERVICE_NAME=ORCL))  
  )
```

## Working with the EXTRACT and REPLICAT utilities of Oracle GoldenGate

The Oracle GoldenGate utilities EXTRACT and REPLICAT work together to keep the source and target databases in sync via incremental transaction replication using trail files. All changes that occur on the source database are automatically detected by EXTRACT, then formatted and transferred to trail files on the Oracle GoldenGate on-premises or Amazon EC2 instance hub. After initial load is completed, the data is read from these files and replicated to the target database by the REPLICAT utility.

### Running the Oracle GoldenGate EXTRACT utility

The EXTRACT utility retrieves, converts, and outputs data from the source database to trail files. The basic process is as follows:

1. EXTRACT queues transaction details to memory or to temporary disk storage.

2. The source database commits the transaction.
3. EXTRACT writes the transaction details to a trail file.
4. The trail file routes these details to the Oracle GoldenGate on-premises or the Amazon EC2 instance hub and then to the target database.

The following steps start the EXTRACT utility, capture the data from `EXAMPLE.TABLE` in source database `OGGSOURCE`, and create the trail files.

### To run the EXTRACT utility

1. Configure the EXTRACT parameter file on the Oracle GoldenGate hub (on-premises or Amazon EC2 instance). The following listing shows an example EXTRACT parameter file named `$GGHOME/dirprm/eabc.prm`.

```
EXTRACT EABC

USERID oggadm1@OGGSOURCE, PASSWORD "my-password"
EXTTRAIL /path/to/goldengate/dirdat/ab

IGNOREREPLICATES
GETAPPLOPS
TRANLOGOPTIONS EXCLUDEUSER OGGADM1

TABLE EXAMPLE.TABLE;
```

2. On the Oracle GoldenGate hub, log in to the source database and launch the Oracle GoldenGate command line interface `ggsci`. The following example shows the format for logging in.

```
dblogin oggadm1@OGGSOURCE
```

3. Add transaction data to turn on supplemental logging for the database table.

```
add trandata EXAMPLE.TABLE
```

4. Using the `ggsci` command line, enable the EXTRACT utility using the following commands.

```
add extract EABC tranlog, INTEGRATED tranlog, begin now
add exttrail /path/to/goldengate/dirdat/ab
extract EABC,
```

```
MEGABYTES 100
```

5. Register the EXTRACT utility with the database so that the archive logs are not deleted. This task allows you to recover old, uncommitted transactions if necessary. To register the EXTRACT utility with the database, use the following command.

```
register EXTRACT EABC, DATABASE
```

6. Start the EXTRACT utility with the following command.

```
start EABC
```

## Running the Oracle GoldenGate REPLICAT utility

The REPLICAT utility "pushes" transaction information in the trail files to the target database.

The following steps enable and start the REPLICAT utility so that it can replicate the captured data to the table EXAMPLE.TABLE in target database OGGTARGET.

### To run the REPLICATE utility

1. Configure the REPLICAT parameter file on the Oracle GoldenGate hub (on-premises or EC2 instance). The following listing shows an example REPLICAT parameter file named \$GGHOME/dirprm/rabc.prm.

```
REPLICAT RABC  
  
USERID oggadm1@OGGTARGET, password "my-password"  
  
ASSUMETARGETDEFS  
MAP EXAMPLE.TABLE, TARGET EXAMPLE.TABLE;
```

#### Note

Specify a password other than the prompt shown here as a security best practice.

2. Log in to the target database and launch the Oracle GoldenGate command line interface (ggsci). The following example shows the format for logging in.

```
dblogin userid oggadm1@OGGTARGET
```

- Using the `ggsci` command line, add a checkpoint table. The user indicated should be the Oracle GoldenGate user account, not the target table schema owner. The following example creates a checkpoint table named `gg_checkpoint`.

```
add checkpointtable oggadm1.oggchkpt
```

- To enable the REPLICAT utility, use the following command.

```
add replicat RABC EXTTRAIL /path/to/goldengate/dirdat/ab CHECKPOINTTABLE  
oggadm1.oggchkpt
```

- Start the REPLICAT utility by using the following command.

```
start RABC
```

## Monitoring Oracle GoldenGate

When you use Oracle GoldenGate for replication, make sure that the Oracle GoldenGate process is up and running and the source and target databases are synchronized. You can use the following monitoring tools:

- [Amazon CloudWatch](#) is a monitoring service that is used in this pattern to monitor GoldenGate error logs.
- [Amazon SNS](#) is a message notification service that is used in this pattern to send email notifications.

For detailed instructions, see [Monitor Oracle GoldenGate logs by using Amazon CloudWatch](#).

## Troubleshooting Oracle GoldenGate

This section explains the most common issues when using Oracle GoldenGate with Amazon RDS for Oracle.

### Topics

- [Error opening an online redo log](#)

- [Oracle GoldenGate appears to be properly configured but replication is not working](#)
- [Integrated REPLICAT slow due to query on SYS."\\_DBA\\_APPLY\\_CDR\\_INFO"](#)

## Error opening an online redo log

Make sure that you configure your databases to retain archived redo logs. Consider the following guidelines:

- Specify the duration for log retention in hours. The minimum value is one hour.
- Set the duration to exceed any potential downtime of the source DB instance, any potential period of communication, and any potential period of networking issues for the source DB instance. Such a duration lets Oracle GoldenGate recover logs from the source DB instance as needed.
- Ensure that you have sufficient storage on your instance for the files.

If you don't have log retention enabled, or if the retention value is too small, you receive an error message similar to the following.

```
2022-03-06 06:17:27 ERROR OGG-00446 error 2 (No such file or directory)
opening redo log /rdsbdbdata/db/GGTEST3_A/onlineolog/o1_mf_2_9k4bp1n6_.log for sequence
1306
Not able to establish initial position for begin time 2022-03-06 06:16:55.
```

## Oracle GoldenGate appears to be properly configured but replication is not working

For pre-existing tables, you must specify the SCN that Oracle GoldenGate works from.

### To fix this issue

1. Log in to the source database and launch the Oracle GoldenGate command line interface (ggsci). The following example shows the format for logging in.

```
dblogin userid oggadm1@OGGSOURCE
```

2. Using the ggsci command line, set up the start SCN for the EXTRACT process. The following example sets the SCN to 223274 for the EXTRACT.

```
ALTER EXTRACT EABC SCN 223274
```

```
start EABC
```

3. Log in to the target database. The following example shows the format for logging in.

```
dblogin userid oggadm1@OGGTARGET
```

4. Using the `ggsci` command line, set up the start SCN for the REPLICAT process. The following example sets the SCN to 223274 for the REPLICAT.

```
start RABC atcsn 223274
```

### Integrated REPLICAT slow due to query on SYS."\_DBA\_APPLY\_CDR\_INFO"

Oracle GoldenGate Conflict Detection and Resolution (CDR) provides basic conflict resolution routines. For example, CDR can resolve a unique conflict for an INSERT statement.

When CDR resolves a collision, it can insert records into the exception table `_DBA_APPLY_CDR_INFO` temporarily. Integrated REPLICAT deletes these records later. In a rare scenario, the integrated REPLICAT can process a large number of collisions, but a new integrated REPLICAT does not replace it. Instead of being removed, the existing rows in `_DBA_APPLY_CDR_INFO` are orphaned. Any new integrated REPLICAT processes slow down because they are querying orphaned rows in `_DBA_APPLY_CDR_INFO`.

To remove all rows from `_DBA_APPLY_CDR_INFO`, use the Amazon RDS procedure `rdsadmin.rdsadmin_util.truncate_apply$cdr_info`. This procedure is released as part of the October 2020 release and patch update. The procedure is available in the following database versions:

- [Version 21.0.0.0.ru-2022-01.rur-2022-01.r1](#) and higher
- [Version 19.0.0.0.ru-2020-10.rur-2020-10.r1](#) and higher

The following example truncates the table `_DBA_APPLY_CDR_INFO`.

```
SET SERVEROUTPUT ON SIZE 2000  
EXEC rdsadmin.rdsadmin_util.truncate_apply$cdr_info;
```

## Using the Oracle Repository Creation Utility on RDS for Oracle

You can use Amazon RDS to host an RDS for Oracle DB instance that holds the schemas to support your Oracle Fusion Middleware components. Before you can use Fusion Middleware components, create and populate schemas for them in your database. You create and populate the schemas by using the Oracle Repository Creation Utility (RCU).

### Supported versions and licensing options for RCU

Amazon RDS supports Oracle Repository Creation Utility (RCU) version 12c only. You can use the RCU in the following configurations:

- RCU 12c with Oracle Database 21c
- RCU 12c with Oracle Database 19c

Before you can use RCU, make sure that you do the following:

- Obtain a license for Oracle Fusion Middleware.
- Follow the Oracle licensing guidelines for the Oracle database that hosts the repository. For more information, see [Oracle Fusion Middleware Licensing Information User Manual](#) in the Oracle documentation.

Fusion MiddleWare supports repositories on Oracle Database Enterprise Edition and Standard Edition 2. Oracle recommends Enterprise Edition for production installations that require partitioning and installations that require online index rebuild.

Before you create your RDS for Oracle instance, confirm the Oracle database version that you need to support the components that you want to deploy. To find the requirements for the Fusion Middleware components and versions you want to deploy, use the Certification Matrix. For more information, see [Oracle Fusion Middleware Supported System Configurations](#) in the Oracle documentation.

Amazon RDS supports Oracle database version upgrades as needed. For more information, see [Upgrading a DB instance engine version](#).

### Requirements and limitations for RCU

To use RCU, you need an Amazon VPC. Your Amazon RDS DB instance must be available only to your Fusion Middleware components, and not to the public Internet. Thus, host your Amazon RDS

DB instance in a private subnet, which provides greater security. You also need an RDS for Oracle DB instance. For more information, see [Creating and connecting to an Oracle DB instance](#).

You can store the schemas for any Fusion Middleware components in your Amazon RDS DB instance. The following schemas have been verified to install correctly:

- Analytics (ACTIVITIES)
- Audit Services (IAU)
- Audit Services Append (IAU\_APPEND)
- Audit Services Viewer (IAU\_VIEWER)
- Discussions (DISCUSSIONS)
- Metadata Services (MDS)
- Oracle Business Intelligence (BIPLATFORM)
- Oracle Platform Security Services (OPSS)
- Portal and Services (WEBCENTER)
- Portlet Producers (PORTLET)
- Service Table (STB)
- SOA Infrastructure (SOAINFRA)
- User Messaging Service (UCSUMS)
- WebLogic Services (WLS)

## Guidelines for using RCU

The following are some recommendations for working with your DB instance in this scenario:

- We recommend that you use Multi-AZ for production workloads. For more information about working with multiple Availability Zones, see [Regions, Availability Zones, and Local Zones](#).
- For additional security, Oracle recommends that you use Transparent Data Encryption (TDE) to encrypt your data at rest. If you have an Enterprise Edition license that includes the Advanced Security Option, you can enable encryption at rest by using the TDE option. For more information, see [Oracle Transparent Data Encryption](#).

Amazon RDS also provides an encryption at rest option for all database editions. For more information, see [Encrypting Amazon RDS resources](#).

- Configure your VPC Security Groups to allow communication between your application servers and your Amazon RDS DB instance. The application servers that host the Fusion Middleware components can be on Amazon EC2 or on-premises.

## Running RCU

To create and populate the schemas to support your Fusion Middleware components, use the Oracle Repository Creation Utility (RCU). You can run RCU in different ways.

### Topics

- [Running RCU using the command line in one step](#)
- [Running RCU using the command line in multiple steps](#)
- [Running RCU in interactive mode](#)

### Running RCU using the command line in one step

If you don't need to edit any of your schemas before populating them, you can run RCU in a single step. Otherwise, see the following section for running RCU in multiple steps.

You can run the RCU in silent mode by using the command-line parameter `-silent`. When you run RCU in silent mode, you can avoid entering passwords on the command line by creating a text file containing the passwords. Create a text file with the password for `dbUser` on the first line, and the password for each component on subsequent lines. You specify the name of the password file as the last parameter to the RCU command.

### Example

The following example creates and populates schemas for the SOA Infrastructure component (and its dependencies) in a single step.

For Linux, macOS, or Unix:

```
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu \
-silent \
-createRepository \
-connectString ${dbhost}:${dbport}:${dbname} \
-dbUser ${dbuser} \
```

```
-dbRole Normal \  
-honorOMF \  
-schemaPrefix `${SCHEMA_PREFIX}` \  
-component MDS \  
-component STB \  
-component OPSS \  
-component IAU \  
-component IAU_APPEND \  
-component IAU_VIEWER \  
-component UCSUMS \  
-component WLS \  
-component SOAINFRA \  
-f < /tmp/passwordfile.txt
```

For more information, see [Running Repository Creation Utility from the command line](#) in the Oracle documentation.

## Running RCU using the command line in multiple steps

To manually edit your schema scripts, run RCU in multiple steps:

1. Run RCU in **Prepare Scripts for System Load** mode by using the `-generateScript` command-line parameter to create the scripts for your schemas.
2. Manually edit and run the generated script `script_systemLoad.sql`.
3. Run RCU again in **Perform Product Load** mode by using the `-dataLoad` command-line parameter to populate the schemas.
4. Run the generated cleanup script `script_postDataLoad.sql`.

To run RCU in silent mode, specify the command-line parameter `-silent`. When you run RCU in silent mode, you can avoid typing passwords on the command line by creating a text file containing the passwords. Create a text file with the password for `dbUser` on the first line, and the password for each component on subsequent lines. Specify the name of the password file as the last parameter to the RCU command.

## Example

The following example creates schema scripts for the SOA Infrastructure component and its dependencies.

For Linux, macOS, or Unix:

```
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu \
-silent \
-generateScript \
-connectString ${dbhost}:${dbport}:${dbname} \
-dbUser ${dbuser} \
-dbRole Normal \
-honorOMF \
[-encryptTablespace true] \
-schemaPrefix ${SCHEMA_PREFIX} \
-component MDS \
-component STB \
-component OPSS \
-component IAU \
-component IAU_APPEND \
-component IAU_VIEWER \
-component UCSUMS \
-component WLS \
-component SOAINFRA \
-scriptLocation /tmp/rcuscripts \
-f < /tmp/passwordfile.txt
```

Now you can edit the generated script, connect to your Oracle DB instance, and run the script. The generated script is named `script_systemLoad.sql`. For information about connecting to your Oracle DB instance, see [Step 3: Connect your SQL client to an Oracle DB instance](#).

The following example populates the schemas for the SOA Infrastructure component (and its dependencies).

For Linux, macOS, or Unix:

```
export JAVA_HOME=/usr/java/jdk1.8.0_65
${ORACLE_HOME}/oracle_common/bin/rcu \
-silent \
-dataLoad \
-connectString ${dbhost}:${dbport}:${dbname} \
-dbUser ${dbuser} \
-dbRole Normal \
-honorOMF \
-schemaPrefix ${SCHEMA_PREFIX} \
-component MDS \
```

```
-component STB \  
-component OPSS \  
-component IAU \  
-component IAU_APPEND \  
-component IAU_VIEWER \  
-component UCSUMS \  
-component WLS \  
-component SOAINFRA \  
-f < /tmp/passwordfile.txt
```

To finish, you connect to your Oracle DB instance, and run the clean-up script. The script is named `script_postDataLoad.sql`.

For more information, see [Running Repository Creation Utility from the command line](#) in the Oracle documentation.

## Running RCU in interactive mode

To use the RCU graphical user interface, run RCU in interactive mode. Include the `-interactive` parameter and omit the `-silent` parameter. For more information, see [Understanding Repository Creation Utility screens](#) in the Oracle documentation.

## Example

The following example starts RCU in interactive mode and pre-populates the connection information.

For Linux, macOS, or Unix:

```
export ORACLE_HOME=/u01/app/oracle/product/12.2.1.0/fmw  
export JAVA_HOME=/usr/java/jdk1.8.0_65  
`${ORACLE_HOME}`/oracle_common/bin/rcu \  
-interactive \  
-createRepository \  
-connectString `${dbhost}`:`${dbport}`:`${dbname}` \  
-dbUser `${dbuser}` \  
-dbRole Normal
```

## Troubleshooting RCU

Be mindful of the following issues.

## Topics

- [Oracle Managed Files \(OMF\)](#)
- [Object privileges](#)
- [Enterprise Scheduler Service](#)

## Oracle Managed Files (OMF)

Amazon RDS uses OMF data files to simplify storage management. You can customize tablespace attributes, such as size and extent management. However, if you specify a data file name when you run RCU, the tablespace code fails with `ORA-20900`. You can use RCU with OMF in the following ways:

- In RCU 12.2.1.0 and later, use the `-honorOMF` command-line parameter.
- In RCU 12.1.0.3 and later, use multiple steps and edit the generated script. For more information, see [Running RCU using the command line in multiple steps](#).

## Object privileges

Because Amazon RDS is a managed service, you don't have full SYSDBA access to your RDS for Oracle DB instance. However, RCU 12c supports users with lower privileges. In most cases, the master user privilege is sufficient to create repositories.

The master account can directly grant privileges that it has already been granted WITH GRANT OPTION. In some cases, when you attempt to grant SYS object privileges, the RCU might fail with `ORA-01031`. You can retry and run the `rdsadmin_util.grant_sys_object` stored procedure, as shown in the following example:

```
BEGIN
  rdsadmin.rdsadmin_util.grant_sys_object('GV_$SESSION', 'MY_DBA', 'SELECT');
END;
/
```

If you attempt to grant SYS privileges on the object `SCHEMA_VERSION_REGISTRY`, the operation might fail with `ORA-20199: Error in rdsadmin_util.grant_sys_object`. You can qualify the table `SCHEMA_VERSION_REGISTRY$` and the view `SCHEMA_VERSION_REGISTRY` with the schema owner name, which is `SYSTEM`, and retry the operation. Or, you can create a synonym. Log in as the master user and run the following statements:

```
CREATE OR REPLACE VIEW SYSTEM.SCHEMA_VERSION_REGISTRY
  AS SELECT * FROM SYSTEM.SCHEMA_VERSION_REGISTRY$;
CREATE OR REPLACE PUBLIC SYNONYM SCHEMA_VERSION_REGISTRY FOR
  SYSTEM.SCHEMA_VERSION_REGISTRY;
CREATE OR REPLACE PUBLIC SYNONYM SCHEMA_VERSION_REGISTRY$ FOR SCHEMA_VERSION_REGISTRY;
```

## Enterprise Scheduler Service

When you use the RCU to drop an Enterprise Scheduler Service repository, the RCU might fail with **Error: Component drop check failed.**

## Configuring Oracle Connection Manager on an Amazon EC2 instance

Oracle Connection Manager (CMAN) is a proxy server that forwards connection requests to database servers or other proxy servers. You can use CMAN to configure the following:

### Access control

You can create rules that filter out user-specified client requests and accept others.

### Session multiplexing

You can funnel multiple client sessions through a network connection to a shared server destination.

Typically, CMAN resides on a host separate from the database server and client hosts. For more information, see [Configuring Oracle Connection Manager](#) in the Oracle Database documentation.

### Topics

- [Supported versions and licensing options for CMAN](#)
- [Requirements and limitations for CMAN](#)
- [Configuring CMAN](#)

## Supported versions and licensing options for CMAN

CMAN supports the Enterprise Edition of all versions of Oracle Database that Amazon RDS supports. For more information, see [RDS for Oracle releases](#).

You can install Oracle Connection Manager on a separate host from the host where Oracle Database is installed. You don't need a separate license for the host that runs CMAN.

## Requirements and limitations for CMAN

To provide a fully managed experience, Amazon RDS restricts access to the operating system. You can't modify database parameters that require operating system access. Thus, Amazon RDS doesn't support features of CMAN that require you to log in to the operating system.

## Configuring CMAN

When you configure CMAN, you perform most of the work outside of your RDS for Oracle database.

## Topics

- [Step 1: Configure CMAN on an Amazon EC2 instance in the same VPC as the RDS for Oracle instance](#)
- [Step 2: Configure database parameters for CMAN](#)
- [Step 3: Associate your DB instance with the parameter group](#)

### Step 1: Configure CMAN on an Amazon EC2 instance in the same VPC as the RDS for Oracle instance

To learn how to set up CMAN, follow the detailed instructions in the blog post [Configuring and using Oracle Connection Manager on Amazon EC2 for Amazon RDS for Oracle](#).

### Step 2: Configure database parameters for CMAN

For CMAN features such as Traffic Director Mode and session multiplexing, set REMOTE\_LISTENER parameter to the address of CMAN instance in a DB parameter group. Consider the following scenario:

- The CMAN instance resides on a host with IP address 10.0.159.100 and uses port 1521.
- The databases orcl\_a, orcl\_b, and orcl\_c reside on separate RDS for Oracle DB instances.

The following table shows how to set the REMOTE\_LISTENER value. The LOCAL\_LISTENER value is set automatically by Amazon RDS.

DB instance name	DB instance IP	Local listener value (set automatically)	Remote listener value (set by user)
orcl_a	10.0.159.200	( address= (protocol=tcp) (host=10.0.159.200) (port=1521) )	10.0.159.100:1521
orcl_b	10.0.159.300	( address= (protocol=tcp) (host=10.0.159.300)	10.0.159.100:1521

DB instance name	DB instance IP	Local listener value (set automatically)	Remote listener value (set by user)
		<pre>(port=1521) )</pre>	
orclc	10.0.159.400	<pre>( address= (protocol=tcp) (host=10.0.159.400) (port=1521) )</pre>	10.0.159.100:1521

### Step 3: Associate your DB instance with the parameter group

Create or modify your DB instance to use the parameter group that you configured in [Step 2: Configure database parameters for CMAN](#). For more information, see [Associating a DB parameter group with a DB instance in Amazon RDS](#).

## Installing a Siebel database on Oracle on Amazon RDS

You can use Amazon RDS to host a Siebel Database on an Oracle DB instance. The Siebel Database is part of the Siebel Customer Relationship Management (CRM) application architecture. For an illustration, see [Generic architecture of Siebel business application](#).

Use the following topic to help set up a Siebel Database on an Oracle DB instance on Amazon RDS. You can also find out how to use Amazon Web Services to support the other components required by the Siebel CRM application architecture.

### Note

To install a Siebel Database on Oracle on Amazon RDS, you need to use the master user account. You don't need SYSDBA privilege; master user privilege is sufficient. For more information, see [Master user account privileges](#).

## Licensing and versions

To install a Siebel Database on Amazon RDS, you must use your own Oracle Database license, and your own Siebel license. You must have the appropriate Oracle Database license (with Software Update License and Support) for the DB instance class and Oracle Database edition. For more information, see [RDS for Oracle licensing options](#).

Oracle Database Enterprise Edition is the only edition certified by Siebel for this scenario. Amazon RDS supports Siebel CRM version 15.0 or 16.0.

Amazon RDS supports database version upgrades. For more information, see [Upgrading a DB instance engine version](#).

## Before you begin

Before you begin, you need an Amazon VPC. Because your Amazon RDS DB instance needs to be available only to your Siebel Enterprise Server, and not to the public Internet, your Amazon RDS DB instance is hosted in a private subnet, providing greater security. For information about how to create an Amazon VPC for use with Siebel CRM, see [Creating and connecting to an Oracle DB instance](#).

Before you begin, you also need an Oracle DB instance. For information about how to create an Oracle DB instance for use with Siebel CRM, see [Creating an Amazon RDS DB instance](#).

## Installing and configuring a Siebel database

After you create your Oracle DB instance, you can install your Siebel Database. You install the database by creating table owner and administrator accounts, installing stored procedures and functions, and then running the Siebel Database Configuration Wizard. For more information, see [Installing the Siebel database on the RDBMS](#).

To run the Siebel Database Configuration Wizard, you need to use the master user account. You don't need SYSDBA privilege; master user privilege is sufficient. For more information, see [Master user account privileges](#).

## Using other Amazon RDS features with a Siebel database

After you create your Oracle DB instance, you can use additional Amazon RDS features to help you customize your Siebel Database.

### Collecting statistics with the Oracle Statspack option

You can add features to your DB instance through the use of options in DB option groups. When you created your Oracle DB instance, you used the default DB option group. If you want to add features to your database, you can create a new option group for your DB instance.

If you want to collect performance statistics on your Siebel Database, you can add the Oracle Statspack feature. For more information, see [Oracle Statspack](#).

Some option changes are applied immediately, and some option changes are applied during the next maintenance window for the DB instance. For more information, see [Working with option groups](#). After you create a customized option group, modify your DB instance to attach it. For more information, see [Modifying an Amazon RDS DB instance](#).

### Performance tuning with parameters

You manage your DB engine configuration through the use of parameters in a DB parameter group. When you created your Oracle DB instance, you used the default DB parameter group. If you want to customize your database configuration, you can create a new parameter group for your DB instance.

When you change a parameter, depending on the type of the parameter, the changes are applied either immediately or after you manually reboot the DB instance. For more information, see [Parameter groups for Amazon RDS](#). After you create a customized parameter group, modify your DB instance to attach it. For more information, see [Modifying an Amazon RDS DB instance](#).

To optimize your Oracle DB instance for Siebel CRM, you can customize certain parameters. The following table shows some recommended parameter settings. For more information about performance tuning Siebel CRM, see [Siebel CRM Performance Tuning Guide](#).

Parameter name	Default value	Guidance for optimal Siebel CRM performance
_always_semi_join	CHOOSE	OFF
_b_tree_bitmap_plans	TRUE	FALSE
_like_with_bind_as_equality	FALSE	TRUE
_no_or_expansion	FALSE	FALSE
_optimize_r_join_sel_sanity_check	TRUE	TRUE
_optimize_r_max_permutations	2000	100
_optimize_r_sortmerge_join_enabled	TRUE	FALSE
_partition_view_enabled	TRUE	FALSE

Parameter name	Default value	Guidance for optimal Siebel CRM performance
open_cursors	300	At least <b>2000</b> .

## Creating snapshots

After you create your Siebel Database, you can copy the database by using the snapshot features of Amazon RDS. For more information, see [Creating a DB snapshot for a Single-AZ DB instance](#) and [Restoring to a DB instance](#).

## Support for other Siebel CRM components

In addition to your Siebel Database, you can also use Amazon Web Services to support the other components of your Siebel CRM application architecture. You can find more information about the support provided by Amazon AWS for additional Siebel CRM components in the following table.

Siebel CRM component	Amazon AWS Support
Siebel Enterprise (with one or more Siebel Servers)	<p>You can host your Siebel Servers on Amazon Elastic Compute Cloud (Amazon EC2) instances. You can use Amazon EC2 to launch as many or as few virtual servers as you need. Using Amazon EC2, you can scale up or down easily to handle changes in requirements. For more information, see <a href="#">What is Amazon EC2?</a></p> <p>You can put your servers in the same VPC with your DB instance and use the VPC security group to access the database. For more information, see <a href="#">Working with a DB instance in a VPC</a>.</p>
Web Servers (with Siebel Web Server Extensions)	<p>You can install multiple Web Servers on multiple EC2 instances. You can then use Elastic Load Balancing to distribute incoming traffic among the instances. For more information, see <a href="#">What is Elastic Load Balancing?</a></p>

Siebel CRM component	Amazon AWS Support
Siebel Gateway Name Server	You can host your Siebel Gateway Name Server on an EC2 instance. You can then put your server in the same VPC with the DB instance and use the VPC security group to access the database. For more information, see <a href="#">Working with a DB instance in a VPC</a> .

## Oracle Database engine release notes

Updates to your Amazon RDS for Oracle DB instances keep them current. If you apply updates, you can be confident that your DB instance is running a version of the database software that has been tested by both Oracle and Amazon. We don't support applying one-off patches to individual RDS for Oracle DB instances.

You can specify any currently supported Oracle Database version when you create a new DB instance. You can specify the major version, such as Oracle Database 19c, and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version that you have specified. To see a list of supported versions and defaults for newly created DB instances, use the [describe-db-engine-versions](#) AWS CLI command.

For details about the Oracle Database versions that Amazon RDS supports, see the [Amazon RDS for Oracle Release Notes](#).

# Amazon RDS for PostgreSQL

Amazon RDS supports DB instances running several versions of PostgreSQL. For a list of available versions, see [Available PostgreSQL database versions](#).

## Note

Deprecation of PostgreSQL 9.6 is scheduled for April 26, 2022. For more information, see [Deprecation of PostgreSQL version 9.6](#).

You can create DB instances and DB snapshots, point-in-time restores and backups. DB instances running PostgreSQL support Multi-AZ deployments, read replicas, Provisioned IOPS, and can be created inside a virtual private cloud (VPC). You can also use Secure Socket Layer (SSL) to connect to a DB instance running PostgreSQL.

Before creating a DB instance, make sure to complete the steps in [Setting up for Amazon RDS](#).

You can use any standard SQL client application to run commands for the instance from your client computer. Such applications include pgAdmin, a popular Open Source administration and development tool for PostgreSQL, or psql, a command line utility that is part of a PostgreSQL installation. To deliver a managed service experience, Amazon RDS doesn't provide host access to DB instances. Also, it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet or Secure Shell (SSH).

Amazon RDS for PostgreSQL is compliant with many industry standards. For example, you can use Amazon RDS for PostgreSQL databases to build HIPAA-compliant applications and to store healthcare-related information. This includes storage for protected health information (PHI) under a completed Business Associate Agreement (BAA) with AWS. Amazon RDS for PostgreSQL also meets Federal Risk and Authorization Management Program (FedRAMP) security requirements. Amazon RDS for PostgreSQL has received a FedRAMP Joint Authorization Board (JAB) Provisional Authority to Operate (P-ATO) at the FedRAMP HIGH Baseline within the AWS GovCloud (US) Regions. For more information on supported compliance standards, see [AWS cloud compliance](#).

To import PostgreSQL data into a DB instance, follow the information in the [Importing data into PostgreSQL on Amazon RDS](#) section.

## Common management tasks for Amazon RDS for PostgreSQL

The following are the common management tasks you perform with an Amazon RDS for PostgreSQL DB instance, with links to relevant documentation for each task.

Task area	Relevant documentation
<p><b>Setting up Amazon RDS for first-time use</b></p> <p>Before you can create your DB instance, make sure to complete a few prerequisites. For example, DB instances are created by default with a firewall that prevents access to it. So you need to create a security group with the correct IP addresses and network configuration to access the DB instance.</p>	<p><a href="#">Setting up for Amazon RDS</a></p>
<p><b>Understanding Amazon RDS DB instances</b></p> <p>If you are creating a DB instance for production purposes, you should understand how instance classes, storage types, and Provisioned IOPS work in Amazon RDS.</p>	<p><a href="#">DB instance classes</a></p> <p><a href="#">Amazon RDS storage types</a></p> <p><a href="#">Provisioned IOPS SSD storage</a></p>
<p><b>Finding available PostgreSQL versions</b></p> <p>Amazon RDS supports several versions of PostgreSQL.</p>	<p><a href="#">Available PostgreSQL database versions</a></p>
<p><b>Setting up high availability and failover support</b></p> <p>A production DB instance should use Multi-AZ deployments. Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances.</p>	<p><a href="#">Configuring and managing a Multi-AZ deployment</a></p>
<p><b>Understanding the Amazon Virtual Private Cloud (VPC) network</b></p> <p>If your AWS account has a default VPC, then your DB instance is automatically created inside the default VPC. In some cases, your account might not have a default VPC, and you might want the DB instance in a VPC. In these cases, create the VPC and subnet groups before you create the DB instance.</p>	<p><a href="#">Working with a DB instance in a VPC</a></p>
<p><b>Importing data into Amazon RDS PostgreSQL</b></p> <p>You can use several different tools to import data into your PostgreSQL DB instance on Amazon RDS.</p>	<p><a href="#">Importing data into PostgreSQL on Amazon RDS</a></p>

Task area	Relevant documentation
<p><b>Setting up read-only read replicas (primary and standbys)</b></p> <p>RDS for PostgreSQL supports read replicas in both the same AWS Region and in a different AWS Region from the primary instance.</p>	<p><a href="#">Working with DB instance read replicas</a></p> <p><a href="#">Working with read replicas for Amazon RDS for PostgreSQL</a></p> <p><a href="#">Creating a read replica in a different AWS Region</a></p>
<p><b>Understanding security groups</b></p> <p>By default, DB instances are created with a firewall that prevents access to them. To provide access through that firewall, you edit the inbound rules for the VPC security group associated with the VPC hosting the DB instance.</p>	<p><a href="#">Controlling access with security groups</a></p>
<p><b>Setting up parameter groups and features</b></p> <p>To change the default parameters for your DB instance, create a custom DB parameter group and change settings to that. If you do this before creating your DB instance, you can choose your custom DB parameter group when you create the instance.</p>	<p><a href="#">Parameter groups for Amazon RDS</a></p>
<p><b>Connecting to your PostgreSQL DB instance</b></p> <p>After creating a security group and associating it to a DB instance, you can connect to the DB instance using any standard SQL client application such as <code>psql</code> or <code>pgAdmin</code>.</p>	<p><a href="#">Connecting to a DB instance running the PostgreSQL database engine</a></p> <p><a href="#">Using SSL with a PostgreSQL DB instance</a></p>
<p><b>Backing up and restoring your DB instance</b></p> <p>You can configure your DB instance to take automated backups, or take manual snapshots, and then restore instances from the backups or snapshots.</p>	<p><a href="#">Backing up, restoring, and exporting data</a></p>

Task area	Relevant documentation
<b>Monitoring the activity and performance of your DB instance</b> You can monitor a PostgreSQL DB instance by using CloudWatch, Amazon RDS metrics, events, and enhanced monitoring.	<a href="#">Viewing metrics in the Amazon RDS console</a> <a href="#">Viewing Amazon RDS events</a>
<b>Upgrading the PostgreSQL database version</b> You can do both major and minor version upgrades for your PostgreSQL DB instance.	<a href="#">Upgrading the PostgreSQL DB engine for Amazon RDS</a> <a href="#">Choosing a major version upgrade for PostgreSQL</a>
<b>Working with log files</b> You can access the log files for your PostgreSQL DB instance.	<a href="#">RDS for PostgreSQL database log files</a>
<b>Understanding the best practices for PostgreSQL DB instances</b> Find some of the best practices for working with PostgreSQL on Amazon RDS.	<a href="#">Best practices for working with PostgreSQL</a>

Following is a list of other sections in this guide that can help you understand and use important features of RDS for PostgreSQL:

- [Understanding PostgreSQL roles and permissions](#)
- [Controlling user access to the PostgreSQL database](#)
- [Working with parameters on your RDS for PostgreSQL DB instance](#)
- [Understanding logging mechanisms supported by RDS for PostgreSQL](#)
- [Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL](#)
- [Using a custom DNS server for outbound network access](#)

## Working with the Database Preview environment

The PostgreSQL community continuously releases new PostgreSQL version and extensions, including beta versions. This gives PostgreSQL users the opportunity to try out a new PostgreSQL version early. To learn more about the PostgreSQL community beta release process, see [Beta Information](#) in the PostgreSQL documentation. Similarly, Amazon RDS makes certain PostgreSQL beta versions available as Preview releases. This allows you to create DB instances using the Preview version and test out its features in the Database Preview Environment.

RDS for PostgreSQL DB instances in the Database Preview Environment are functionally similar to other RDS for PostgreSQL instances. However, you can't use a Preview version for production.

Keep in mind the following important limitations:

- All DB instances are deleted 60 days after you create them, along with any backups and snapshots.
- You can only create a DB instance in a virtual private cloud (VPC) based on the Amazon VPC service.
- You can only use General Purpose SSD and Provisioned IOPS SSD storage.
- You can't get help from AWS Support with DB instances. Instead, you can post your questions to the AWS-managed Q&A community, [AWS re:Post](#).
- You can't copy a snapshot of a DB instance to a production environment.

The following options are supported by the Preview.

- You can create DB instances using M6i, R6i, M6g, M5, T3, R6g, and R5 instance types only. For more information about RDS instance classes, see [DB instance classes](#).
- You can use both single-AZ and multi-AZ deployments.
- You can use standard PostgreSQL dump and load functions to export databases from or import databases to the Database Preview Environment.

## Features not supported in the Database Preview environment

The following features aren't available in the Database Preview environment:

- Cross-Region snapshot copy

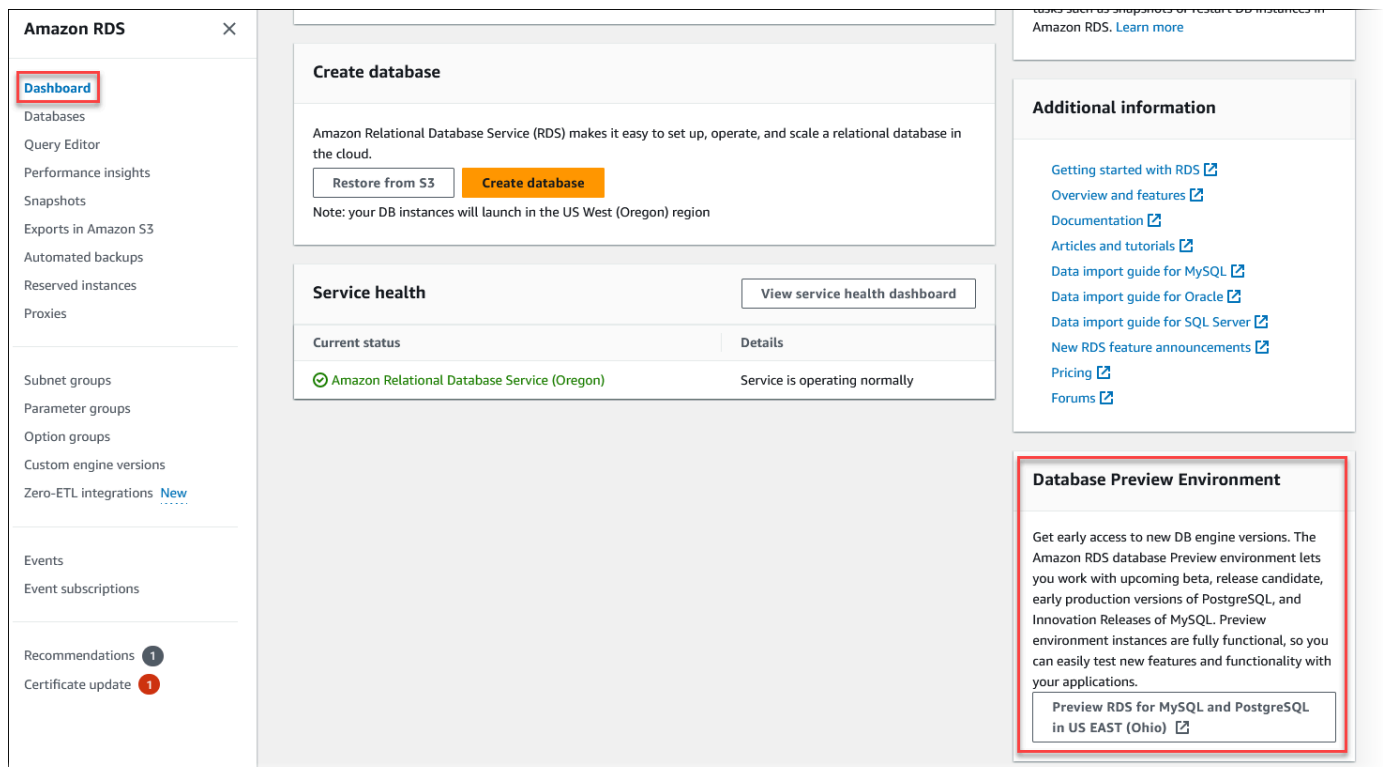

- Cross-Region read replicas

## Creating a new DB instance in the Database Preview environment

Use the following procedure to create a DB instance in the preview environment.

### To create a DB instance in the Database Preview environment

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Dashboard** from the navigation pane.
3. In the Dashboard page, locate the **Database Preview Environment** section on the Dashboard page, as shown in the following image.

You can navigate directly to the [Database Preview environment](#). Before you can proceed, you must acknowledge and accept the limitations.

### Database Preview Environment Service Agreement ✕

The Amazon RDS Database Preview Environment is not covered by the Amazon RDS service level agreement (SLA), published at <https://aws.amazon.com/rds/sla> 

Do not use the Amazon RDS Database Preview Environment for production purposes. You should only use this environment for development and testing.

Certain use cases might fail in this environment - for example, upgrading from a previous version is not supported.

I acknowledge this limited service agreement for the Amazon RDS Database Preview Environment and that I should only use this environment for development and testing.

Cancel Accept

4. To create the RDS for PostgreSQL DB instance, follow the same process as that for creating any Amazon RDS DB instance. For more information, see the [Console](#) procedure in [Creating a DB instance](#).

To create an instance in the Database Preview Environment using the RDS API or the AWS CLI, use the following endpoint.

```
rds-preview.us-east-2.amazonaws.com
```

## PostgreSQL version 17 in the Database Preview environment

### Note

This is preview documentation for Amazon RDS PostgreSQL version 17. It is subject to change.

PostgreSQL version 17 RC1 is now available in the Amazon RDS Database Preview environment. PostgreSQL version 17 RC1 contains several improvements that are described in the following PostgreSQL documentation, [PostgreSQL 17 RC1 Released!](#)

For information on the Database Preview Environment, see [the section called “ The Database Preview environment”](#). To access the Preview Environment from the console, select <https://console.aws.amazon.com/rds-preview/>.

## Available PostgreSQL database versions

Amazon RDS supports DB instances running several editions of PostgreSQL. You can specify any currently available PostgreSQL version when creating a new DB instance. You can specify the major version (such as PostgreSQL 14), and any available minor version for the specified major version. If no version is specified, Amazon RDS defaults to an available version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified.

To see a list of available versions, as well as defaults for newly created DB instances, use the [describe-db-engine-versions](#) AWS CLI command. For example, to display the default PostgreSQL engine version, use the following command:

```
aws rds describe-db-engine-versions --default-only --engine postgres
```

For details about the PostgreSQL versions that are supported on Amazon RDS, see the [Amazon RDS for PostgreSQL Release Notes](#).

If you aren't ready to manually upgrade to a new major engine version before the RDS end of standard support date, Amazon RDS will automatically enroll your databases in Amazon RDS Extended Support after the RDS end of standard support date. Then, you can continue to run RDS for PostgreSQL version 11 and higher. For more information, see [Using Amazon RDS Extended Support](#) and [Amazon RDS pricing](#).

## Deprecation of PostgreSQL version 10

On April 17, 2023, Amazon RDS plans to deprecate PostgreSQL 10 using the following schedule. We recommend that you take action and upgrade your PostgreSQL databases running on major version 10 to a later version, such as PostgreSQL version 14. To upgrade your RDS for PostgreSQL major version 10 DB instance from a PostgreSQL version older than 10.19, we recommend that you first upgrade to version 10.19 and then upgrade to version 14. For more information, see [Upgrading the PostgreSQL DB engine for Amazon RDS](#).

Action or recommendation	Dates
The PostgreSQL community plans to deprecate PostgreSQL 10 and won't provide any security patches after this date.	November 10, 2022

Action or recommendation	Dates
Start upgrading RDS for PostgreSQL 10 DB instances to a later major version, such as PostgreSQL 14. Although you can continue to restore PostgreSQL 10 snapshots and create read replicas with version 10, be aware of the other critical dates in this deprecation schedule and their impact.	Until February 14, 2023
After this date, you can't create new Amazon RDS instances with PostgreSQL major version 10 from either the AWS Management Console or the AWS CLI.	February 14, 2023
After this date, Amazon RDS automatically upgrades PostgreSQL 10 instances to version 14. If you restore a PostgreSQL 10 database snapshot, Amazon RDS automatically upgrades the restored database to PostgreSQL 14.	April 17, 2023

For more information about RDS for PostgreSQL version 10 deprecation, see [\[Announcement\]: RDS for PostgreSQL 10 deprecation](#) in AWS re:Post.

## Deprecation of PostgreSQL version 9.6

On March 31, 2022, Amazon RDS plans to deprecate PostgreSQL 9.6 using the following schedule. This extends the previously announced date of January 18, 2022 to April 26, 2022. You should upgrade all your PostgreSQL 9.6 DB instances to PostgreSQL 12 or higher as soon as possible. We recommend that you first upgrade to minor version 9.6.20 or higher and then upgrade directly to PostgreSQL 12 rather than upgrading to an intermediate major version. For more information, see [Upgrading the PostgreSQL DB engine for Amazon RDS](#).

Action or recommendation	Dates
The PostgreSQL community discontinued support for PostgreSQL 9.6, and will no longer provide bug fixes or security patches for this version.	November 11, 2021
Start upgrading RDS for PostgreSQL 9.6 DB instances to PostgreSQL 12 or higher as soon as possible. Although you can continue to restore PostgreSQL 9.6 snapshots and create read replicas with version 9.6, be aware of the other critical dates in this deprecation schedule and their impact.	Until March 31, 2022
After this date, you can't create new Amazon RDS instances with PostgreSQL major version 9.6 from either the AWS Management Console or the AWS CLI.	March 31, 2022
After this date, Amazon RDS automatically upgrades PostgreSQL 9.6 instances to version 12. If you restore a PostgreSQL 9.6 database snapshot, Amazon RDS automatically upgrades the restored database to PostgreSQL 12.	April 26, 2022

## Deprecated versions for Amazon RDS for PostgreSQL

RDS for PostgreSQL 9.5 is deprecated as of March, 2021. For more information about RDS for PostgreSQL 9.5 deprecation, see [Upgrading from Amazon RDS for PostgreSQL version 9.5](#).

To learn more about deprecation policy for RDS for PostgreSQL, see [Amazon RDS FAQs](#). For more information about PostgreSQL versions, see [Versioning Policy](#) in the PostgreSQL documentation.

## Supported PostgreSQL extension versions

RDS for PostgreSQL supports many PostgreSQL extensions. The PostgreSQL community sometimes refers to these as modules. Extensions expand on the functionality provided by the PostgreSQL engine. You can find a list of extensions supported by Amazon RDS in the default DB parameter group for that PostgreSQL version. You can also see the current extensions list using `psql` by showing the `rds.extensions` parameter as in the following example.

```
SHOW rds.extensions;
```

### Note

Parameters added in a minor version release might display inaccurately when using the `rds.extensions` parameter in `psql`.

As of RDS for PostgreSQL 13, certain extensions can be installed by database users other than the `rds_superuser`. These are known as *trusted extensions*. To learn more, see [PostgreSQL trusted extensions](#).

Certain versions of RDS for PostgreSQL support the `rds.allowed_extensions` parameter. This parameter lets an `rds_superuser` limit the extensions that can be installed in the RDS for PostgreSQL DB instance. For more information, see [Restricting installation of PostgreSQL extensions](#).

For lists of PostgreSQL extensions and versions that are supported by each available RDS for PostgreSQL version, see [PostgreSQL extensions supported on Amazon RDS](#) in *Amazon RDS for PostgreSQL Release Notes*.

## Restricting installation of PostgreSQL extensions

You can restrict which extensions can be installed on a PostgreSQL DB instance. By default, this parameter isn't set, so any supported extension can be added if the user has permissions to do so. To do so, set the `rds.allowed_extensions` parameter to a string of comma-separated extension names. By adding a list of extensions to this parameter, you explicitly identify the extensions that your RDS for PostgreSQL DB instance can use. Only these extensions can then be installed in the PostgreSQL DB instance.

The default string for the `rds.allowed_extensions` parameter is `'*'`, which means that any extension available for the engine version can be installed. Changing the `rds.allowed_extensions` parameter does not require a database restart because it's a dynamic parameter.

The PostgreSQL DB instance engine must be one of the following versions for you to use the `rds.allowed_extensions` parameter:

- All PostgreSQL 16 versions
- PostgreSQL 15 and all higher versions
- PostgreSQL 14 and all higher versions
- PostgreSQL 13.3 and higher minor versions
- PostgreSQL 12.7 and higher minor versions

To see which extension installations are allowed, use the following `psql` command.

```
postgres=> SHOW rds.allowed_extensions;
 rds.allowed_extensions
-----
*
```

If an extension was installed prior to it being left out of the list in the `rds.allowed_extensions` parameter, the extension can still be used normally, and commands such as `ALTER EXTENSION` and `DROP EXTENSION` will continue to work. However, after an extension is restricted, `CREATE EXTENSION` commands for the restricted extension will fail.

Installation of extension dependencies with `CREATE EXTENSION CASCADE` are also restricted. The extension and its dependencies must be specified in `rds.allowed_extensions`. If an extension dependency installation fails, the entire `CREATE EXTENSION CASCADE` statement will fail.

If an extension is not included with the `rds.allowed_extensions` parameter, you will see an error such as the following if you try to install it.

```
ERROR: permission denied to create extension "extension-name"
HINT: This extension is not specified in "rds.allowed_extensions".
```

## PostgreSQL trusted extensions

To install most PostgreSQL extensions requires `rds_superuser` privileges. PostgreSQL 13 introduced trusted extensions, which reduce the need to grant `rds_superuser` privileges to regular users. With this feature, users can install many extensions if they have the `CREATE` privilege on the current database instead of requiring the `rds_superuser` role. For more information, see the SQL [CREATE EXTENSION](#) command in the PostgreSQL documentation.

The following lists the extensions that can be installed by a user who has the `CREATE` privilege on the current database and do not require the `rds_superuser` role:

- `bool_plperl`
- [btree\\_gin](#)
- [btree\\_gist](#)
- [citext](#)
- [cube](#)
- [dict\\_int](#)
- [fuzzystrmatch](#)
- [hstore](#)
- [intarray](#)
- [isn](#)
- `jsonb_plperl`
- [ltree](#)
- [pg\\_trgm](#)
- [pgcrypto](#)
- [plperl](#)
- [plpgsql](#)
- [pltcl](#)
- [tablefunc](#)
- [tsm\\_system\\_rows](#)
- [tsm\\_system\\_time](#)
- [unaccent](#)
- [uuid-osp](#)

For lists of PostgreSQL extensions and versions that are supported by each available RDS for PostgreSQL version, see [PostgreSQL extensions supported on Amazon RDS](#) in *Amazon RDS for PostgreSQL Release Notes*.

# Working with PostgreSQL features supported by Amazon RDS for PostgreSQL

Amazon RDS for PostgreSQL supports many of the most common PostgreSQL features. For example, PostgreSQL has an autovacuum feature that performs routine maintenance on the database. The autovacuum feature is active by default. Although you can turn off this feature, we highly recommend that you keep it on. Understanding this feature and what you can do to make sure it works as it should is a basic task of any DBA. For more information about the autovacuum, see [Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL](#). To learn more about other common DBA tasks, [Common DBA tasks for Amazon RDS for PostgreSQL](#).

RDS for PostgreSQL also supports extensions that add important functionality to the DB instance. For example, you can use the PostGIS extension to work with spatial data, or use the pg\_cron extension to schedule maintenance from within the instance. For more information about PostgreSQL extensions, see [Using PostgreSQL extensions with Amazon RDS for PostgreSQL](#).

Foreign data wrappers are a specific type of extension designed to let your RDS for PostgreSQL DB instance work with other commercial databases or data types. For more information about foreign data wrappers supported by RDS for PostgreSQL, see [Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL](#).

Following, you can find information about some other features supported by RDS for PostgreSQL.

## Topics

- [Custom data types and enumerations with RDS for PostgreSQL](#)
- [Event triggers for RDS for PostgreSQL](#)
- [Huge pages for RDS for PostgreSQL](#)
- [Performing logical replication for Amazon RDS for PostgreSQL](#)
- [RAM disk for the stats\\_temp\\_directory](#)
- [Tablespaces for RDS for PostgreSQL](#)
- [RDS for PostgreSQL collations for EBCDIC and other mainframe migrations](#)

## Custom data types and enumerations with RDS for PostgreSQL

PostgreSQL supports creating custom data types and working with enumerations. For more information about creating and working with enumerations and other data types, see [Enumerated types](#) in the PostgreSQL documentation.

The following is an example of creating a type as an enumeration and then inserting values into a table.

```
CREATE TYPE rainbow AS ENUM ('red', 'orange', 'yellow', 'green', 'blue', 'purple');
CREATE TYPE
CREATE TABLE t1 (colors rainbow);
CREATE TABLE
INSERT INTO t1 VALUES ('red'), ('orange');
INSERT 0 2
SELECT * from t1;
colors
-----
red
orange
(2 rows)
postgres=> ALTER TYPE rainbow RENAME VALUE 'red' TO 'crimson';
ALTER TYPE
postgres=> SELECT * from t1;
colors
-----
crimson
orange
(2 rows)
```

## Event triggers for RDS for PostgreSQL

All current PostgreSQL versions support event triggers, and so do all available versions of RDS for PostgreSQL. You can use the main user account (default, postgres) to create, modify, rename, and delete event triggers. Event triggers are at the DB instance level, so they can apply to all databases on an instance.

For example, the following code creates an event trigger that prints the current user at the end of every data definition language (DDL) command.

```
CREATE OR REPLACE FUNCTION raise_notice_func()
```

```
    RETURNS event_trigger
    LANGUAGE plpgsql AS
$$
BEGIN
    RAISE NOTICE 'In trigger function: %', current_user;
END;
$$;

CREATE EVENT TRIGGER event_trigger_1
    ON ddl_command_end
EXECUTE PROCEDURE raise_notice_func();
```

For more information about PostgreSQL event triggers, see [Event triggers](#) in the PostgreSQL documentation.

There are several limitations to using PostgreSQL event triggers on Amazon RDS. These include the following:

- You can't create event triggers on read replicas. You can, however, create event triggers on a read replica source. The event triggers are then copied to the read replica. The event triggers on the read replica don't fire on the read replica when changes are pushed from the source. However, if the read replica is promoted, the existing event triggers fire when database operations occur.
- To perform a major version upgrade to a PostgreSQL DB instance that uses event triggers, make sure to delete the event triggers before you upgrade the instance.

## Huge pages for RDS for PostgreSQL

*Huge pages* are a memory management feature that reduces overhead when a DB instance is working with large contiguous chunks of memory, such as that used by shared buffers. This PostgreSQL feature is supported by all currently available RDS for PostgreSQL versions. You allocate huge pages for your application by using calls to `mmap` or `SYSV` shared memory. RDS for PostgreSQL supports both 4-KB and 2-MB page sizes.

You can turn huge pages on or off by changing the value of the `huge_pages` parameter. The feature is turned on by default for all the DB instance classes other than micro, small, and medium DB instance classes.

RDS for PostgreSQL uses huge pages based on the available shared memory. If the DB instance can't use huge pages due to shared memory constraints, Amazon RDS prevents the DB instance

from starting. In this case, Amazon RDS sets the status of the DB instance to an incompatible parameters state. If this occurs, you can set the `huge_pages` parameter to `off` to allow Amazon RDS to start the DB instance.

The `shared_buffers` parameter is key to setting the shared memory pool that is required for using huge pages. The default value for the `shared_buffers` parameter uses a database parameters macro. This macro sets a percentage of the total 8 KB pages available for the DB instance's memory. When you use huge pages, those pages are located with the huge pages. Amazon RDS puts a DB instance into an incompatible parameters state if the shared memory parameters are set to require more than 90 percent of the DB instance memory.

To learn more about PostgreSQL memory management, see [Resource Consumption](#) in the PostgreSQL documentation.

## Performing logical replication for Amazon RDS for PostgreSQL

Starting with version 10.4, RDS for PostgreSQL supports the publication and subscription SQL syntax that was introduced in PostgreSQL 10. To learn more, see [Logical replication](#) in the PostgreSQL documentation.

### Note

In addition to the native PostgreSQL logical replication feature introduced in PostgreSQL 10, RDS for PostgreSQL also supports the `pglogical` extension. For more information, see [Using pglogical to synchronize data across instances](#).

Following, you can find information about setting up logical replication for an RDS for PostgreSQL DB instance.

### Topics

- [Understanding logical replication and logical decoding](#)
- [Working with logical replication slots](#)

## Understanding logical replication and logical decoding

RDS for PostgreSQL supports the streaming of write-ahead log (WAL) changes using PostgreSQL's logical replication slots. It also supports using logical decoding. You can set up logical replication

slots on your instance and stream database changes through these slots to a client such as `pg_recvlogical`. You create logical replication slots at the database level, and they support replication connections to a single database.

The most common clients for PostgreSQL logical replication are AWS Database Migration Service or a custom-managed host on an Amazon EC2 instance. The logical replication slot has no information about the receiver of the stream. Also, there's no requirement that the target be a replica database. If you set up a logical replication slot and don't read from the slot, data can be written and quickly fill up your DB instance's storage.

You turn on PostgreSQL logical replication and logical decoding for Amazon RDS with a parameter, a replication connection type, and a security role. The client for logical decoding can be any client that can establish a replication connection to a database on a PostgreSQL DB instance.

### To turn on logical decoding for an RDS for PostgreSQL DB instance

1. Make sure that the user account that you're using has these roles:
  - The `rds_superuser` role so you can turn on logical replication
  - The `rds_replication` role to grant permissions to manage logical slots and to stream data using logical slots
2. Set the `rds.logical_replication` static parameter to 1. As part of applying this parameter, also set the parameters `wal_level`, `max_wal_senders`, `max_replication_slots`, and `max_connections`. These parameter changes can increase WAL generation, so set the `rds.logical_replication` parameter only when you are using logical slots.
3. Reboot the DB instance for the static `rds.logical_replication` parameter to take effect.
4. Create a logical replication slot as explained in the next section. This process requires that you specify a decoding plugin. Currently, RDS for PostgreSQL supports the `test_decoding` and `wal2json` output plugins that ship with PostgreSQL.

For more information on PostgreSQL logical decoding, see the [PostgreSQL documentation](#).

### Working with logical replication slots

You can use SQL commands to work with logical slots. For example, the following command creates a logical slot named `test_slot` using the default PostgreSQL output plugin `test_decoding`.

```
SELECT * FROM pg_create_logical_replication_slot('test_slot', 'test_decoding');
slot_name      | xlog_position
-----+-----
regression_slot | 0/16B1970
(1 row)
```

To list logical slots, use the following command.

```
SELECT * FROM pg_replication_slots;
```

To drop a logical slot, use the following command.

```
SELECT pg_drop_replication_slot('test_slot');
pg_drop_replication_slot
-----
(1 row)
```

For more examples on working with logical replication slots, see [Logical decoding examples](#) in the PostgreSQL documentation.

After you create the logical replication slot, you can start streaming. The following example shows how logical decoding is controlled over the streaming replication protocol. This example uses the program `pg_recvlogical`, which is included in the PostgreSQL distribution. Doing this requires that client authentication is set up to allow replication connections.

```
pg_recvlogical -d postgres --slot test_slot -U postgres
--host -instance-name.111122223333.aws-region.rds.amazonaws.com
-f - --start
```

To see the contents of the `pg_replication_origin_status` view, query the `pg_show_replication_origin_status` function.

```
SELECT * FROM pg_show_replication_origin_status();
local_id | external_id | remote_lsn | local_lsn
-----+-----+-----+-----
(0 rows)
```

## RAM disk for the stats\_temp\_directory

You can use the RDS for PostgreSQL parameter `rds.pg_stat_ramdisk_size` to specify the system memory allocated to a RAM disk for storing the PostgreSQL `stats_temp_directory`. The RAM disk parameter is only available in RDS for PostgreSQL version 14 and lower versions.

Under certain workloads, setting this parameter can improve performance and decrease I/O requirements. For more information about the `stats_temp_directory`, see [the PostgreSQL documentation](#).

To set up a RAM disk for your `stats_temp_directory`, set the `rds.pg_stat_ramdisk_size` parameter to an integer literal value in the parameter group used by your DB instance. This parameter denotes MB, so you must use an integer value. Expressions, formulas, and functions aren't valid for the `rds.pg_stat_ramdisk_size` parameter. Be sure to reboot the DB instance so that the change takes effect. For information about setting parameters, see [Parameter groups for Amazon RDS](#).

For example, the following AWS CLI command sets the RAM disk parameter to 256 MB.

```
aws rds modify-db-parameter-group \  
  --db-parameter-group-name pg-95-ramdisk-testing \  
  --parameters "ParameterName=rds.pg_stat_ramdisk_size, ParameterValue=256, \  
  ApplyMethod=pending-reboot"
```

After you reboot, run the following command to see the status of the `stats_temp_directory`.

```
postgres=> SHOW stats_temp_directory;
```

The command should return the following.

```
stats_temp_directory  
-----  
/rdsdbramdisk/pg_stat_tmp  
(1 row)
```

## Tablespaces for RDS for PostgreSQL

RDS for PostgreSQL supports tablespaces for compatibility. Because all storage is on a single logical volume, you can't use tablespaces for I/O splitting or isolation. Our benchmarks and experience indicate that a single logical volume is the best setup for most use cases.

To create and use tablespaces with your RDS for PostgreSQL DB instance requires the `rds_superuser` role. Your RDS for PostgreSQL DB instance's main user account (default name, `postgres`) is a member of this role. For more information, see [Understanding PostgreSQL roles and permissions](#).

If you specify a file name when you create a tablespace, the path prefix is `/rdsdbdata/db/base/tablespace`. The following example places tablespace files in `/rdsdbdata/db/base/tablespace/data`. This example assumes that a `dbadmin` user (role) exists and that it's been granted the `rds_superuser` role needed to work with tablespaces.

```
postgres=> CREATE TABLESPACE act_data
           OWNER dbadmin
           LOCATION '/data';
CREATE TABLESPACE
```

To learn more about PostgreSQL tablespaces, see [Tablespaces](#) in the PostgreSQL documentation.

## RDS for PostgreSQL collations for EBCDIC and other mainframe migrations

RDS for PostgreSQL versions 10 and higher include ICU version 60.2, which is based on Unicode 10.0 and includes collations from the Unicode Common Locale Data Repository, CLDR 32. These software internationalization libraries ensure that character encodings are presented in a consistent way, regardless of operating system or platform. For more information about Unicode CLDR-32, see the [CLDR 32 Release Note](#) on the Unicode CLDR website. You can learn more about the internationalization components for Unicode (ICU) at the [ICU Technical Committee \(ICU-TC\)](#) website. For information about ICU-60, see [Download ICU 60](#).

Starting with version 14.3, RDS for PostgreSQL also includes collations that help with data integration and conversion from EBCDIC-based systems. The extended binary coded decimal interchange code or *EBCDIC* encoding is commonly used by mainframe operating systems. These Amazon RDS-provided collations are narrowly defined to sort only those Unicode characters that directly map to EBCDIC code pages. The characters are sorted in EBCDIC code-point order to allow for data validation after conversion. These collations don't include denormalized forms, nor do they include Unicode characters that don't directly map to a character on the source EBCDIC code page.

The character mappings between EBCDIC code pages and Unicode code points are based on tables published by IBM. The complete set is available from IBM as a [compressed file](#) for download. RDS

for PostgreSQL used these mappings with tools provided by the ICU to create the collations listed in the tables in this section. The collation names include a language and country as required by the ICU. However, EBCDIC code pages don't specify languages, and some EBCDIC code pages cover multiple countries. That means that the language and country portion of the collation names in the table are arbitrary, and they don't need to match the current locale. In other words, the code page number is the most important part of the collation name in this table. You can use any of the collations listed in the following tables in any RDS for PostgreSQL database.

- [Unicode to EBCDIC collations table](#) – Some mainframe data migration tools internally use LATIN1 or LATIN9 to encode and process data. Such tools use round-trip schemes to preserve data integrity and support reverse conversion. The collations in this table can be used by tools that process data using LATIN1 encoding, which doesn't require special handling.
- [Unicode to LATIN9 collations table](#) – You can use these collations in any RDS for PostgreSQL database.

In the following table, you find collations available in RDS for PostgreSQL that map EBCDIC code pages to Unicode code points. We recommend that you use the collations in this table for application development that requires sorting based on the ordering of IBM code pages.

PostgreSQL collation name	Description of code-page mapping and sort order
da-DK-cp277-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 277 (per conversion tables) are sorted in IBM CP 277 code point order
de-DE-cp273-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 273 (per conversion tables) are sorted in IBM CP 273 code point order
en-GB-cp285-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 285 (per conversion tables) are sorted in IBM CP 285 code point order

PostgreSQL collation name	Description of code-page mapping and sort order
en-US-cp037-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 037 (per conversion tables) are sorted in IBM CP 37 code point order
es-ES-cp284-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 284 (per conversion tables) are sorted in IBM CP 284 code point order
fi-FI-cp278-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 278 (per conversion tables) are sorted in IBM CP 278 code point order
fr-FR-cp297-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 297 (per conversion tables) are sorted in IBM CP 297 code point order
it-IT-cp280-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 280 (per conversion tables) are sorted in IBM CP 280 code point order
nl-BE-cp500-x-icu	Unicode characters that directly map to IBM EBCDIC Code Page 500 (per conversion tables) are sorted in IBM CP 500 code point order

Amazon RDS provides a set of additional collations that sort Unicode code points that map to LATIN9 characters using the tables published by IBM, in the order of the original code points according to the EBCDIC code page of the source data.

PostgreSQL collation name	Description of code-page mapping and sort order
da-DK-cp1142m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1142 (per conversion

PostgreSQL collation name	Description of code-page mapping and sort order
	tables) are sorted in IBM CP 1142 code point order
de-DE-cp1141m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1141 (per conversion tables) are sorted in IBM CP 1141 code point order
en-GB-cp1146m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1146 (per conversion tables) are sorted in IBM CP 1146 code point order
en-US-cp1140m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1140 (per conversion tables) are sorted in IBM CP 1140 code point order
es-ES-cp1145m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1145 (per conversion tables) are sorted in IBM CP 1145 code point order
fi-FI-cp1143m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1143 (per conversion tables) are sorted in IBM CP 1143 code point order

PostgreSQL collation name	Description of code-page mapping and sort order
fr-FR-cp1147m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1147 (per conversion tables) are sorted in IBM CP 1147 code point order
it-IT-cp1144m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1144 (per conversion tables) are sorted in IBM CP 1144 code point order
nl-BE-cp1148m-x-icu	Unicode characters that map to LATIN9 characters originally converted from IBM EBCDIC Code Page 1148 (per conversion tables) are sorted in IBM CP 1148 code point order

In the following, you can find an example of using an RDS for PostgreSQL collation.

```
db1=> SELECT pg_import_system_collations('pg_catalog');
pg_import_system_collations
-----
                                36
db1=> SELECT 'a' < 'a' coll1;
coll1
-----
t
db1=> SELECT 'a' < 'a' COLLATE "da-DK-cp277-x-icu" coll1;
coll1
-----
f
```

We recommend that you use the collations in the [Unicode to EBCDIC collations table](#) and in the [Unicode to LATIN9 collations table](#) for application development that requires sorting based on the

ordering of IBM code pages. The following collations (suffixed with the letter “b”) are also visible in `pg_collation`, but are intended for use by mainframe data integration and migration tools at AWS that map code pages with specific code point shifts and require special handling in collation. In other words, the following collations aren't recommended for use.

- da-DK-277b-x-icu
- da-DK-1142b-x-icu
- de-DE-cp273b-x-icu
- de-DE-cp1141b-x-icu
- en-GB-cp1146b-x-icu
- en-GB-cp285b-x-icu
- en-US-cp037b-x-icu
- en-US-cp1140b-x-icu
- es-ES-cp1145b-x-icu
- es-ES-cp284b-x-icu
- fi-FI-cp1143b-x-icu
- fr-FR-cp1147b-x-icu
- fr-FR-cp297b-x-icu
- it-IT-cp1144b-x-icu
- it-IT-cp280b-x-icu
- nl-BE-cp1148b-x-icu
- nl-BE-cp500b-x-icu

To learn more about migrating applications from mainframe environments to AWS, see [What is AWS Mainframe Modernization?](#)

For more information about managing collations in PostgreSQL, see [Collation Support](#) in the PostgreSQL documentation.

# Connecting to a DB instance running the PostgreSQL database engine

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the instance. Before you can connect, the DB instance must be available and accessible. Whether you can connect to the instance from outside the VPC depends on how you created the Amazon RDS DB instance:

- If you created your DB instance as *public*, devices and Amazon EC2 instances outside the VPC can connect to your database.
- If you created your DB instance as *private*, only Amazon EC2 instances and devices inside the Amazon VPC can connect to your database.

To check whether your DB instance is public or private, use the AWS Management Console to view the **Connectivity & security** tab for your instance. Under **Security**, you can find the "Publicly accessible" value, with No for private, Yes for public.

To learn more about different Amazon RDS and Amazon VPC configurations and how they affect accessibility, see [Scenarios for accessing a DB instance in a VPC](#).

## Installing the psql client

To connect to your DB instance from an EC2 instance, you can install a PostgreSQL client on the EC2 instance. To install the psql client on Amazon Linux 2023, run the following command:

```
sudo dnf install postgresql15
```

To install the psql client on Amazon Linux 2, run the following command:

```
sudo amazon-linux-extras install postgresql14
```

To install the psql client on Ubuntu, run the following command:

```
sudo apt-get install -y postgresql14
```

## Finding the connection information for an RDS for PostgreSQL DB instance

If the DB instance is available and accessible, you can connect by providing the following information to the SQL client application:

- The DB instance endpoint, which serves as the host name (DNS name) for the instance.
- The port on which the DB instance is listening. For PostgreSQL, the default port is 5432.
- The user name and password for the DB instance. The default 'master username' for PostgreSQL is postgres.
- The name and password of the database (DB name).

You can obtain these details by using the AWS Management Console, the AWS CLI [describe-db-instances](#) command, or the Amazon RDS API [DescribeDBInstances](#) operation.

### To find the endpoint, port number, and DB name using the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Open the RDS console and then choose **Databases** to display a list of your DB instances.
3. Choose the PostgreSQL DB instance name to display its details.

4. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

RDS > Databases > database-test1

## database-test1

### Summary

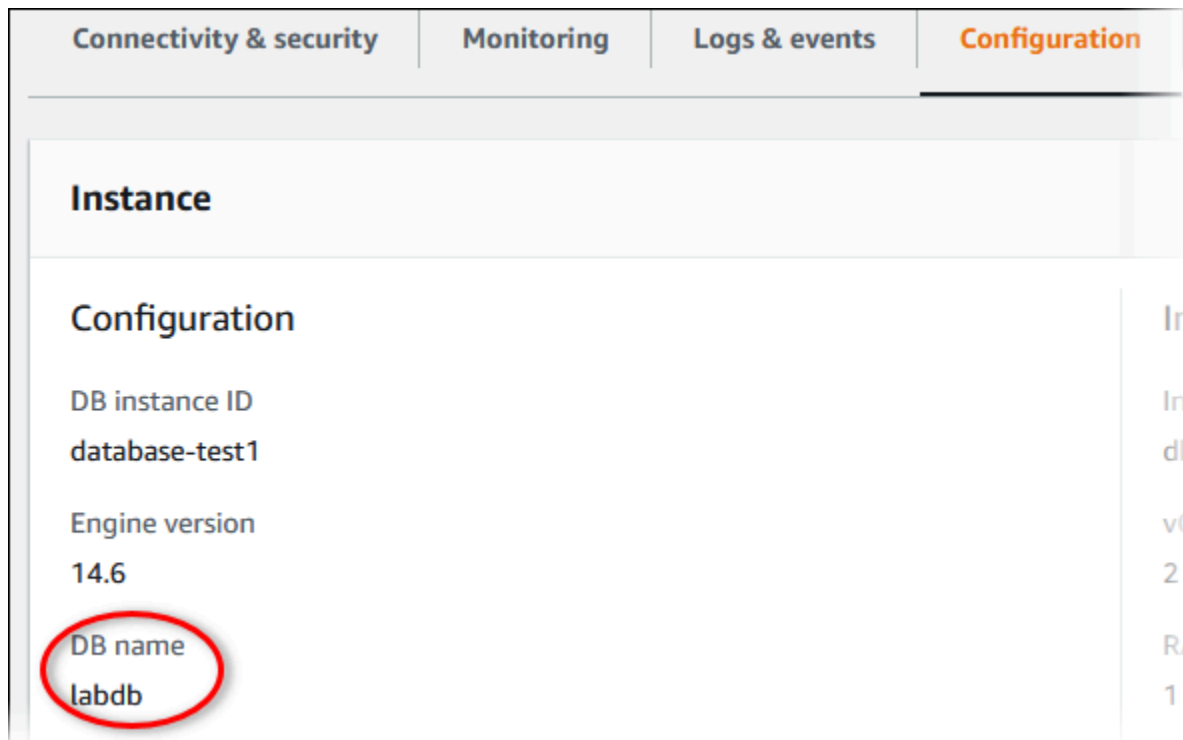

DB identifier database-test1	CPU 5.82%
Role Instance	Current activity 0 Connections

**Connectivity & security** | Monitoring | Logs & events | Configuration

### Connectivity & security

<b>Endpoint &amp; port</b>	<b>Networking</b>
Endpoint database-test1.123456789012.us-east-1.rds.amazonaws.com	Availability Zone us-east-1c
Port 5432	VPC vpc-
	Subnet group default

5. On the **Configuration** tab, note the DB name. If you created a database when you created the RDS for PostgreSQL instance, you see the name listed under DB name. If you didn't create a database, the DB name displays a dash (-).

Following are two ways to connect to a PostgreSQL DB instance. The first example uses pgAdmin, a popular open-source administration and development tool for PostgreSQL. The second example uses psql, a command line utility that is part of a PostgreSQL installation.

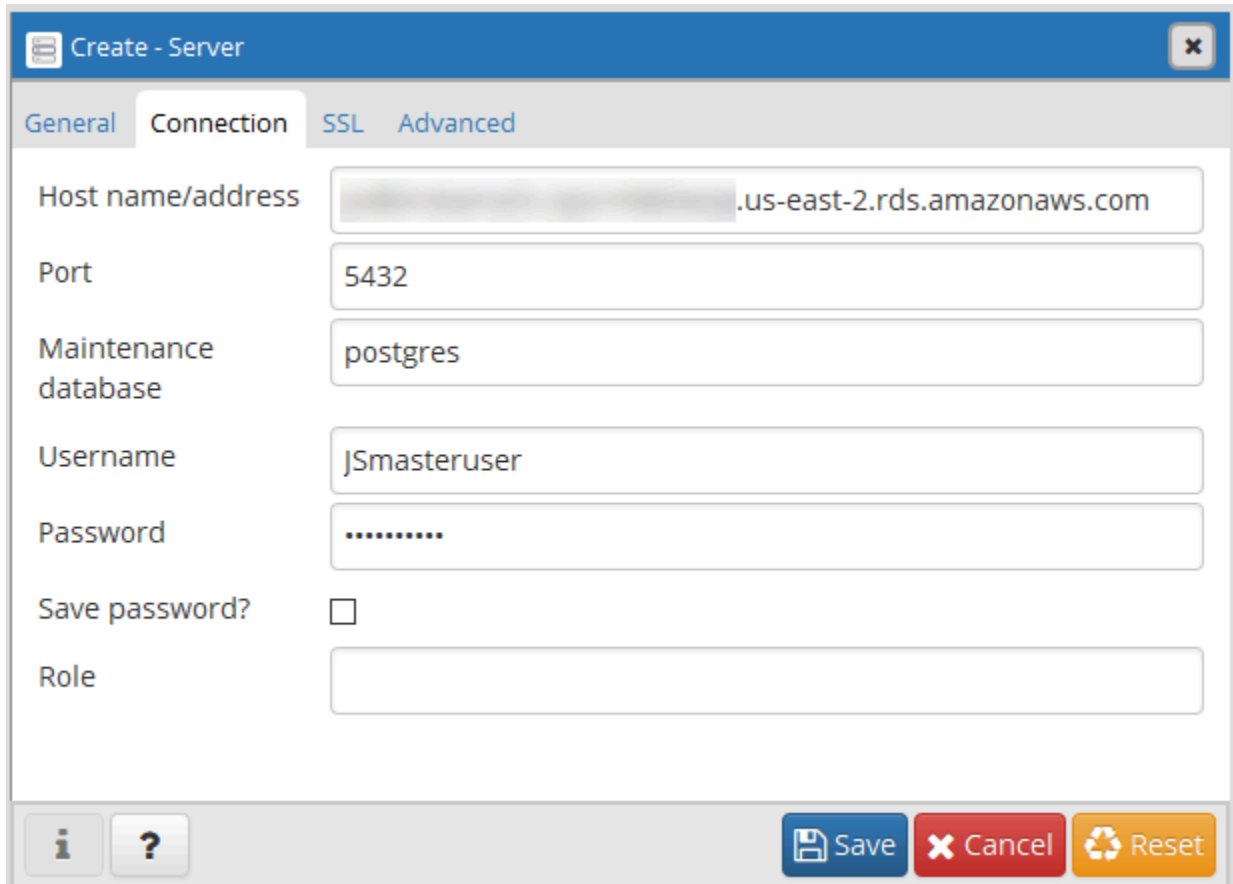

## Using pgAdmin to connect to a RDS for PostgreSQL DB instance

You can use the open-source tool pgAdmin to connect to your RDS for PostgreSQL DB instance. You can download and install pgAdmin from <http://www.pgadmin.org/> without having a local instance of PostgreSQL on your client computer.

### To connect to your RDS for PostgreSQL DB instance using pgAdmin

1. Launch the pgAdmin application on your client computer.
2. On the **Dashboard** tab, choose **Add New Server**.
3. In the **Create - Server** dialog box, type a name on the **General** tab to identify the server in pgAdmin.
4. On the **Connection** tab, type the following information from your DB instance:
  - For **Host**, type the endpoint, for example `mypostgresql.c6c8dntfzzhgv0.us-east-2.rds.amazonaws.com`.

- For **Port**, type the assigned port.
- For **Username**, type the user name that you entered when you created the DB instance (if you changed the 'master username' from the default, postgres).
- For **Password**, type the password that you entered when you created the DB instance.

The screenshot shows a 'Create - Server' dialog box with the following fields and values:

Field	Value
Host name/address	[redacted].us-east-2.rds.amazonaws.com
Port	5432
Maintenance database	postgres
Username	JSmasteruser
Password	.....
Save password?	<input type="checkbox"/>
Role	

Buttons at the bottom: Save (blue), Cancel (red), Reset (yellow).

5. Choose **Save**.

If you have any problems connecting, see [Troubleshooting connections to your RDS for PostgreSQL instance](#).

6. To access a database in the pgAdmin browser, expand **Servers**, the DB instance, and **Databases**. Choose the DB instance's database name.

7. To open a panel where you can enter SQL commands, choose **Tools, Query Tool**.

## Using psql to connect to your RDS for PostgreSQL DB instance

You can use a local instance of the psql command line utility to connect to a RDS for PostgreSQL DB instance. You need either PostgreSQL or the psql client installed on your client computer.

You can download the PostgreSQL client from the [PostgreSQL](https://www.postgresql.org/) website. Follow the instructions specific to your operating system version to install psql.

To connect to your RDS for PostgreSQL DB instance using psql, you need to provide host (DNS) information, access credentials, and the name of the database.

Use one of the following formats to connect to your RDS for PostgreSQL DB instance. When you connect, you're prompted for a password. For batch jobs or scripts, use the `--no-password` option. This option is set for the entire session.

**Note**

A connection attempt with `--no-password` fails when the server requires password authentication and a password is not available from other sources. For more information, see the [psql documentation](#).

If this is the first time you are connecting to this DB instance, or if you didn't yet create a database for this RDS for PostgreSQL instance, you can connect to the **postgres** database using the 'master username' and password.

For Unix, use the following format.

```
psql \  
  --host=<DB instance endpoint> \  
  --port=<port> \  
  --username=<master username> \  
  --password \  
  --dbname=<database name>
```

For Windows, use the following format.

```
psql ^  
  --host=<DB instance endpoint> ^  
  --port=<port> ^  
  --username=<master username> ^  
  --password ^  
  --dbname=<database name>
```

For example, the following command connects to a database called `mypgdb` on a PostgreSQL DB instance called `mypostgresql` using fictitious credentials.

```
psql --host=mypostgresql.c6c8mwvfdgv0.us-west-2.rds.amazonaws.com --port=5432 --  
username=awsuser --password --dbname=mypgdb
```

## Connecting to RDS for PostgreSQL with the Amazon Web Services (AWS) JDBC Driver

The Amazon Web Services (AWS) JDBC Driver is designed as an advanced JDBC wrapper. This wrapper is complementary to and extends the functionality of an existing JDBC driver. The driver is drop-in compatible with the community pgJDBC driver.

To install the AWS JDBC Driver, append the AWS JDBC Driver .jar file (located in the application CLASSPATH), and keep references to the respective community driver. Update the respective connection URL prefix as follows:

- `jdbc:postgresql://` to `jdbc:aws-wrapper:postgresql://`

For more information about the AWS JDBC Driver and complete instructions for using it, see the [Amazon Web Services \(AWS\) JDBC Driver GitHub repository](#).

## Connecting to RDS for PostgreSQL with the Amazon Web Services (AWS) Python Driver

The Amazon Web Services (AWS) Python Driver is designed as an advanced Python wrapper. This wrapper is complementary to and extends the functionality of the open-source Psycopg driver. The AWS Python Driver supports Python versions 3.8 and higher. You can install the `aws-advanced-python-wrapper` package using the `pip` command, along with the `psycopg` open-source packages.

For more information about the AWS Python Driver and complete instructions for using it, see the [Amazon Web Services \(AWS\) Python Driver GitHub repository](#).

## Troubleshooting connections to your RDS for PostgreSQL instance

### Topics

- [Error – FATAL: database name does not exist](#)
- [Error – Could not connect to server: Connection timed out](#)
- [Errors with security group access rules](#)

## Error – FATAL: database *name* does not exist

If when trying to connect you receive an error like FATAL: database *name* does not exist, try using the default database name **postgres** for the `--dbname` option.

## Error – Could not connect to server: Connection timed out

If you can't connect to the DB instance, the most common error is `Could not connect to server: Connection timed out`. If you receive this error, check the following:

- Check that the host name used is the DB instance endpoint and that the port number used is correct.
- Make sure that the DB instance's public accessibility is set to **Yes** to allow external connections. To modify the **Public access** setting, see [Modifying an Amazon RDS DB instance](#).
- Make sure that the user connecting to the database has **CONNECT** access to it. You can use the following query to provide connect access to the database.

```
GRANT CONNECT ON DATABASE database name TO username;
```

- Check that the security group assigned to the DB instance has rules to allow access through any firewall your connection might go through. For example, if the DB instance was created using the default port of 5432, your company might have firewall rules blocking connections to that port from external company devices.

To fix this, modify the DB instance to use a different port. Also, make sure that the security group applied to the DB instance allows connections to the new port. To modify the **Database port** setting, see [Modifying an Amazon RDS DB instance](#).

- See also [Errors with security group access rules](#).

## Errors with security group access rules

By far the most common connection problem is with the security group's access rules assigned to the DB instance. If you used the default security group when you created the DB instance, the security group likely didn't have access rules that allow you to access the instance.

For the connection to work, the security group you assigned to the DB instance at its creation must allow access to the DB instance. For example, if the DB instance was created in a VPC, it must have a VPC security group that authorizes connections. Check if the DB instance was created using a

security group that doesn't authorize connections from the device or Amazon EC2 instance where the application is running.

You can add or edit an inbound rule in the security group. For **Source**, choosing **My IP** allows access to the DB instance from the IP address detected in your browser. For more information, see [Provide access to your DB instance in your VPC by creating a security group](#).

Alternatively, if the DB instance was created outside of a VPC, it must have a database security group that authorizes those connections.

For more information about Amazon RDS security groups, see [Controlling access with security groups](#).

# Securing connections to RDS for PostgreSQL with SSL/TLS

RDS for PostgreSQL supports Secure Socket Layer (SSL) encryption for PostgreSQL DB instances. Using SSL, you can encrypt a PostgreSQL connection between your applications and your PostgreSQL DB instances. You can also force all connections to your PostgreSQL DB instance to use SSL. RDS for PostgreSQL also supports Transport Layer Security (TLS), the successor protocol to SSL.

To learn more about Amazon RDS and data protection, including encrypting connections using SSL/TLS, see [Data protection in Amazon RDS](#).

## Topics

- [Using SSL with a PostgreSQL DB instance](#)
- [Updating applications to connect to PostgreSQL DB instances using new SSL/TLS certificates](#)

## Using SSL with a PostgreSQL DB instance

Amazon RDS supports Secure Socket Layer (SSL) encryption for PostgreSQL DB instances. Using SSL, you can encrypt a PostgreSQL connection between your applications and your PostgreSQL DB instances. By default, RDS for PostgreSQL uses and expects all clients to connect using SSL/TLS, but you can also require it. RDS for PostgreSQL supports Transport Layer Security (TLS) versions 1.1, 1.2, and 1.3.

For general information about SSL support and PostgreSQL databases, see [SSL support](#) in the PostgreSQL documentation. For information about using an SSL connection over JDBC, see [Configuring the client](#) in the PostgreSQL documentation.

SSL support is available in all AWS Regions for PostgreSQL. Amazon RDS creates an SSL certificate for your PostgreSQL DB instance when the instance is created. If you enable SSL certificate verification, then the SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks.

## Topics

- [Connecting to a PostgreSQL DB instance over SSL](#)
- [Requiring an SSL connection to a PostgreSQL DB instance](#)
- [Determining the SSL connection status](#)

- [SSL cipher suites in RDS for PostgreSQL](#)

## Connecting to a PostgreSQL DB instance over SSL

### To connect to a PostgreSQL DB instance over SSL

1. Download the certificate.

For information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

2. Connect to your PostgreSQL DB instance over SSL.

When you connect using SSL, your client can choose whether to verify the certificate chain. If your connection parameters specify `sslmode=verify-ca` or `sslmode=verify-full`, then your client requires the RDS CA certificates to be in their trust store or referenced in the connection URL. This requirement is to verify the certificate chain that signs your database certificate.

When a client, such as `psql` or `JDBC`, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default `sslmode` mode used is different between `libpq`-based clients (such as `psql`) and `JDBC`. The `libpq`-based clients default to `prefer`, and `JDBC` clients default to `verify-full`.

Use the `sslrootcert` parameter to reference the certificate, for example `sslrootcert=rds-ssl-ca-cert.pem`.

The following is an example of using `psql` to connect to a PostgreSQL DB instance using SSL with certificate verification.

```
$ psql "host=db-name.5555555555.ap-southeast-1.rds.amazonaws.com
port=5432 dbname=testDB user=testuser sslrootcert=rds-ca-rsa2048-g1.pem
sslmode=verify-full"
```

## Requiring an SSL connection to a PostgreSQL DB instance

You can require that connections to your PostgreSQL DB instance use SSL by using the `rds.force_ssl` parameter. The `rds.force_ssl` parameter default value is 1 (on) for RDS for

PostgreSQL version 15 and later. For all other RDS for PostgreSQL major versions 14 and older, the default value of this parameter is 0 (off). You can set the `rds.force_ssl` parameter to 1 (on) to require SSL/TLS for connections to your DB cluster. You can set the `rds.force_ssl` parameter to 1 (on) to require SSL for connections to your DB instance.

To change the value of this parameter, you need to create a custom DB parameter group. You then change the value for `rds.force_ssl` in your custom DB parameter group to 1 to turn on this feature. If you prepare the custom DB parameter group before creating your RDS for PostgreSQL DB instance you can choose it (instead of a default parameter group) during the creation process. If you do this after your RDS for PostgreSQL DB instance is already running, you need to reboot the instance so that your instance uses the custom parameter group. For more information, see [Parameter groups for Amazon RDS](#).

When the `rds.force_ssl` feature is active on your DB instance, connection attempts that aren't using SSL are rejected with the following message:

```
$ psql -h db-name.555555555555.ap-southeast-1.rds.amazonaws.com port=5432 dbname=testDB
user=testuser
psql: error: FATAL: no pg_hba.conf entry for host "w.x.y.z", user "testuser", database
"testDB", SSL off
```

## Determining the SSL connection status

The encrypted status of your connection is shown in the logon banner when you connect to the DB instance:

```
Password for user master:
psql (10.3)
SSL connection (cipher: DHE-RSA-AES256-SHA, bits: 256)
Type "help" for help.
postgres=>
```

You can also load the `sslinfo` extension and then call the `ssl_is_used()` function to determine if SSL is being used. The function returns `t` if the connection is using SSL, otherwise it returns `f`.

```
postgres=> CREATE EXTENSION sslinfo;
CREATE EXTENSION
postgres=> SELECT ssl_is_used();
ssl_is_used
```

```

-----
t
(1 row)

```

For more detailed information, you can use the following query to get information from `pg_settings`:

```

SELECT name as "Parameter name", setting as value, short_desc FROM pg_settings WHERE
name LIKE '%ssl%';

```

Parameter name	value	short_desc
ssl	on	Enables SSL connections.
ssl_ca_file	/rdsdbdata/rds-metadata/ca-cert.pem	Location of the SSL certificate authority file.
ssl_cert_file	/rdsdbdata/rds-metadata/server-cert.pem	Location of the SSL server certificate file.
ssl_ciphers	HIGH:!aNULL:!3DES	Sets the list of allowed SSL ciphers.
ssl_crl_file		Location of the SSL certificate revocation list file.
ssl_dh_params_file		Location of the SSL DH parameters file.
ssl_ecdh_curve	prime256v1	Sets the curve to use for ECDH.
ssl_key_file	/rdsdbdata/rds-metadata/server-key.pem	Location of the SSL server private key file.
ssl_library	OpenSSL	Name of the SSL library.
ssl_max_protocol_version		Sets the maximum SSL/TLS protocol version to use.
ssl_min_protocol_version	TLSv1.2	Sets the minimum SSL/TLS protocol version to use.
ssl_passphrase_command		Command to obtain passphrases for SSL.
ssl_passphrase_command_supports_reload	off	Also use <code>ssl_passphrase_command</code> during server reload.
ssl_prefer_server_ciphers	on	Give priority to server ciphersuite order.

(14 rows)

You can also collect all the information about your RDS for PostgreSQL DB instance's SSL usage by process, client, and application by using the following query:

```
SELECT datname as "Database name", username as "User name", ssl, client_addr,
       application_name, backend_type
FROM pg_stat_ssl
JOIN pg_stat_activity
ON pg_stat_ssl.pid = pg_stat_activity.pid
ORDER BY ssl;
```

Database name	User name	ssl	client_addr	application_name	backend_type
launcher		f			autovacuum
replication launcher	rdsadmin	f			logical
writer		f			background
checkpointer		f			
rdsadmin backend	rdsadmin	t	127.0.0.1		walwriter client
rdsadmin backend	rdsadmin	t	127.0.0.1	PostgreSQL JDBC Driver	client
postgres backend	postgres	t	204.246.162.36	psql	client

(8 rows)

To identify the cipher used for your SSL connection, you can query as follows:

```
postgres=> SELECT ssl_cipher();
ssl_cipher
-----
DHE-RSA-AES256-SHA
(1 row)
```

To learn more about the `sslmode` option, see [Database connection control functions](#) in the *PostgreSQL documentation*.

## SSL cipher suites in RDS for PostgreSQL

The PostgreSQL configuration parameter [ssl\\_ciphers](#) specifies the categories of cipher suites that are allowed for SSL connections. The following table lists the default cipher suites used in RDS for PostgreSQL.

PostgreSQL engine version	Cipher suites
16	HIGH:!aNULL:!3DES
15	HIGH:!aNULL:!3DES
14	HIGH:!aNULL:!3DES
13	HIGH:!aNULL:!3DES
12	HIGH:!aNULL:!3DES
11.4 and higher minor versions	HIGH:MEDIUM:+3DES:!aNULL:!RC4
11.1, 11.2	HIGH:MEDIUM:+3DES:!aNULL
10.9 and higher minor versions	HIGH:MEDIUM:+3DES:!aNULL:!RC4
10.7 and lower minor versions	HIGH:MEDIUM:+3DES:!aNULL

## Updating applications to connect to PostgreSQL DB instances using new SSL/TLS certificates

Certificates used for Secure Socket Layer or Transport Layer Security (SSL/TLS) typically have a set lifetime. When service providers update their Certificate Authority (CA) certificates, clients must update their applications to use the new certificates. Following, you can find information about how to determine if your client applications use SSL/TLS to connect to your Amazon RDS for PostgreSQL DB instance. You also find information about how to check if those applications verify the server certificate when they connect.

**Note**

A client application that's configured to verify the server certificate before SSL/TLS connection must have a valid CA certificate in the client's trust store. Update the client trust store when necessary for new certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a nonproduction environment before implementing them in your production environments.

For more information about certificate rotation, see [Rotating your SSL/TLS certificate](#). For more information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#). For information about using SSL/TLS with PostgreSQL DB instances, see [Using SSL with a PostgreSQL DB instance](#).

**Topics**

- [Determining whether applications are connecting to PostgreSQL DB instances using SSL](#)
- [Determining whether a client requires certificate verification in order to connect](#)
- [Updating your application trust store](#)
- [Using SSL/TLS connections for different types of applications](#)

**Determining whether applications are connecting to PostgreSQL DB instances using SSL**

Check the DB instance configuration for the value of the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off) for DB instances using PostgreSQL versions before version 15. By default, `rds.force_ssl` is set to 1 (on) for DB instances using PostgreSQL version 15 and later major versions. If the `rds.force_ssl` parameter is set to 1 (on), clients are required to use SSL/TLS for connections. For more information about parameter groups, see [Parameter groups for Amazon RDS](#).

If you are using RDS PostgreSQL version 9.5 or later major version and `rds.force_ssl` is not set to 1 (on), query the `pg_stat_ssl` view to check connections using SSL. For example, the following query returns only SSL connections and information about the clients using SSL.

```
SELECT datname, username, ssl, client_addr
```

```
FROM pg_stat_ssl INNER JOIN pg_stat_activity ON pg_stat_ssl.pid =
pg_stat_activity.pid
WHERE ssl is true and username<>'rdsadmin';
```

Only rows using SSL/TLS connections are displayed with information about the connection. The following is sample output.

```
datname | username | ssl | client_addr
-----+-----+----+-----
benchdb | pgadmin  | t   | 53.95.6.13
postgres | pgadmin  | t   | 53.95.6.13
(2 rows)
```

This query displays only the current connections at the time of the query. The absence of results doesn't indicate that no applications are using SSL connections. Other SSL connections might be established at a different time.

## Determining whether a client requires certificate verification in order to connect

When a client, such as psql or JDBC, is configured with SSL support, the client first tries to connect to the database with SSL by default. If the client can't connect with SSL, it reverts to connecting without SSL. The default `sslmode` mode used for both libpq-based clients (such as psql) and JDBC is set to `prefer`. The certificate on the server is verified only when `sslrootcert` is provided with `sslmode` set to `verify-ca` or `verify-full`. An error is thrown if the certificate is invalid.

Use `PGSSLR00TCERT` to verify the certificate with the `PGSSLMODE` environment variable, with `PGSSLMODE` set to `verify-ca` or `verify-full`.

```
PGSSLMODE=verify-full PGSSLR00TCERT=/fullpath/ssl-cert.pem psql -h
pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com -U masteruser -d postgres
```

Use the `sslrootcert` argument to verify the certificate with `sslmode` in connection string format, with `sslmode` set to `verify-ca` or `verify-full` to verify the certificate.

```
psql "host=pgdbidentifier.cxxxxxxxx.us-east-2.rds.amazonaws.com sslmode=verify-full
sslrootcert=/full/path/ssl-cert.pem user=masteruser dbname=postgres"
```

For example, in the preceding case, if you are using an invalid root certificate, then you see an error similar to the following on your client.

```
psql: SSL error: certificate verify failed
```

## Updating your application trust store

For information about updating the trust store for PostgreSQL applications, see [Secure TCP/IP connections with SSL](#) in the PostgreSQL documentation.

For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB instance or cluster](#).

For sample scripts that import certificates, see [Sample script for importing certificates into your trust store](#).

### Note

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

## Using SSL/TLS connections for different types of applications

The following provides information about using SSL/TLS connections for different types of applications:

- **psql**

The client is invoked from the command line by specifying options either as a connection string or as environment variables. For SSL/TLS connections, the relevant options are `sslmode` (environment variable `PGSSLMODE`), `sslrootcert` (environment variable `PGSSLROOTCERT`).

For the complete list of options, see [Parameter key words](#) in the PostgreSQL documentation. For the complete list of environment variables, see [Environment variables](#) in the PostgreSQL documentation.

- **pgAdmin**

This browser-based client is a more user-friendly interface for connecting to a PostgreSQL database.

For information about configuring connections, see the [pgAdmin documentation](#).

- **JDBC**

JDBC enables database connections with Java applications.

For general information about connecting to a PostgreSQL database with JDBC, see [Connecting to the database](#) in the PostgreSQL JDBC driver documentation. For information about connecting with SSL/TLS, see [Configuring the client](#) in the PostgreSQL JDBC driver documentation.

- **Python**

A popular Python library for connecting to PostgreSQL databases is `psycopg2`.

For information about using `psycopg2`, see the [psycopg2 documentation](#). For a short tutorial on how to connect to a PostgreSQL database, see [Psycopg2 tutorial](#). You can find information about the options the connect command accepts in [The psycopg2 module content](#).

**⚠ Important**

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the `rds-ca-rsa2048-g1` certificates. For instructions, see step 3 in [Updating your CA certificate by modifying your DB instance or cluster](#).

# Using Kerberos authentication with Amazon RDS for PostgreSQL

You can use Kerberos to authenticate users when they connect to your DB instance running PostgreSQL. To do so, configure your DB instance to use AWS Directory Service for Microsoft Active Directory for Kerberos authentication. AWS Directory Service for Microsoft Active Directory is also called AWS Managed Microsoft AD. It's a feature available with AWS Directory Service. To learn more, see [What is AWS Directory Service?](#) in the *AWS Directory Service Administration Guide*.

To start, create an AWS Managed Microsoft AD directory to store user credentials. Then, provide to your PostgreSQL DB instance the Active Directory's domain and other information. When users authenticate with the PostgreSQL DB instance, authentication requests are forwarded to the AWS Managed Microsoft AD directory.

Keeping all of your credentials in the same directory can save you time and effort. You have a centralized location for storing and managing credentials for multiple DB instances. Using a directory can also improve your overall security profile.

In addition, you can access credentials from your own on-premises Microsoft Active Directory. To do so, create a trusting domain relationship so that the AWS Managed Microsoft AD directory trusts your on-premises Microsoft Active Directory. In this way, your users can access your PostgreSQL instances with the same Windows single sign-on (SSO) experience as when they access workloads in your on-premises network.

A database can use password authentication or password authentication with either Kerberos or AWS Identity and Access Management (IAM) authentication. For more information about IAM authentication, see [IAM database authentication for MariaDB, MySQL, and PostgreSQL](#).

## Topics

- [Region and version availability](#)
- [Overview of Kerberos authentication for PostgreSQL DB instances](#)
- [Setting up Kerberos authentication for PostgreSQL DB instances](#)
- [Managing an RDS for PostgreSQL DB instance in an Active Directory domain](#)
- [Connecting to PostgreSQL with Kerberos authentication](#)

## Region and version availability

Feature availability and support varies across specific versions of each database engine, and across AWS Regions. For more information on version and Region availability of RDS for PostgreSQL with Kerberos authentication, see [Supported Regions and DB engines for Kerberos authentication in Amazon RDS](#).

## Overview of Kerberos authentication for PostgreSQL DB instances

To set up Kerberos authentication for a PostgreSQL DB instance, take the following steps, described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the AWS Directory Service API to create the directory. Make sure to open the relevant outbound ports on the directory security group so that the directory can communicate with the instance.
2. Create a role that provides Amazon RDS access to make calls to your AWS Managed Microsoft AD directory. To do so, create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For the IAM role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the correct AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see [Activating and deactivating AWS STS in an AWS Region](#) in the *IAM User Guide*.

3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see [Manage users and groups in AWS Managed Microsoft AD](#) in the *AWS Directory Service Administration Guide*.
4. If you plan to locate the directory and the DB instance in different AWS accounts or virtual private clouds (VPCs), configure VPC peering. For more information, see [What is VPC peering?](#) in the *Amazon VPC Peering Guide*.
5. Create or modify a PostgreSQL DB instance either from the console, CLI, or RDS API using one of the following methods:
  - [Creating an Amazon RDS DB instance](#)
  - [Modifying an Amazon RDS DB instance](#)
  - [Restoring to a DB instance](#)

- [Restoring a DB instance to a specified time](#)

You can locate the instance in the same Amazon Virtual Private Cloud (VPC) as the directory or in a different AWS account or VPC. When you create or modify the PostgreSQL DB instance, do the following:

- Provide the domain identifier (d- \* identifier) that was generated when you created your directory.
  - Provide the name of the IAM role that you created.
  - Ensure that the DB instance security group can receive inbound traffic from the directory security group.
6. Use the RDS master user credentials to connect to the PostgreSQL DB instance. Create the user in PostgreSQL to be identified externally. Externally identified users can log in to the PostgreSQL DB instance using Kerberos authentication.

## Setting up Kerberos authentication for PostgreSQL DB instances

You use AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to set up Kerberos authentication for a PostgreSQL DB instance. To set up Kerberos authentication, take the following steps.

### Topics

- [Step 1: Create a directory using AWS Managed Microsoft AD](#)
- [Step 2: \(Optional\) Create a trust relationship between your on-premises Active Directory and AWS Directory Service](#)
- [Step 3: Create an IAM role for Amazon RDS to access the AWS Directory Service](#)
- [Step 4: Create and configure users](#)
- [Step 5: Enable cross-VPC traffic between the directory and the DB instance](#)
- [Step 6: Create or modify a PostgreSQL DB instance](#)
- [Step 7: Create PostgreSQL users for your Kerberos principals](#)
- [Step 8: Configure a PostgreSQL client](#)

## Step 1: Create a directory using AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and DNS servers for you. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within your VPC.
- Creates a directory administrator account with the user name `Admin` and the specified password. You use this account to manage your directory.

### Important

Make sure to save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

- Creates a security group for the directory controllers. The security group must permit communication with the PostgreSQL DB instance.

When you launch AWS Directory Service for Microsoft Active Directory, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU, which has the NetBIOS name that you entered when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.

The `Admin` account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin

- Run Active Directory and Domain Name Service (DNS) modules for Windows PowerShell on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

### To create a directory with AWS Managed Microsoft AD

1. In the [AWS Directory Service console](#) navigation pane, choose **Directories**, and then choose **Set up directory**.
2. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option currently supported for use with Amazon RDS.
3. Choose **Next**.
4. On the **Enter directory information** page, provide the following information:

#### **Edition**

Choose the edition that meets your requirements.

#### **Directory DNS name**

The fully qualified name for the directory, such as **corp.example.com**.

#### **Directory NetBIOS name**

An optional short name for the directory, such as CORP.

#### **Directory description**

An optional description for the directory.

#### **Admin password**

The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

The directory administrator password can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Nonalphanumeric characters (~!@#%&\* \_-+= `|\(){}[];'"<>.,?/)

### Confirm password

Retype the administrator password.

#### Important

Make sure that you save this password. AWS Directory Service doesn't store this password, and it can't be retrieved or reset.

5. Choose **Next**.
6. On the **Choose VPC and subnets** page, provide the following information:

#### VPC

Choose the VPC for the directory. You can create the PostgreSQL DB instance in this same VPC or in a different VPC.

#### Subnets

Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Choose **Next**.
8. Review the directory information. If changes are needed, choose **Previous** and make the changes. When the information is correct, choose **Create directory**.

## Review & create

### Review

Directory type	VPC
Microsoft AD	vpc-8b6b78e9 ( )
Directory DNS name	Subnets
corp.example.com	subnet-75128d10 ( , us-east-1a)
Directory NetBIOS name	subnet-f51665dd ( , us-east-1b)
CORP	
Directory description	
My directory	

### Pricing

Edition	Free trial eligible <a href="#">Learn more</a>
Standard	30-day limited trial
~USD ( ) *	
* Includes two domain controllers, USD ( )/mo for each additional domain controller.	

Cancel Previous **Create directory**

It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory ID in the directory listing. Make a note of the **Directory ID** value. You need this value when you create or modify your PostgreSQL DB instance.

Directory Service > Directories > d-90670a8d36

<b>Directory ID</b> d-90670a8d36	Availability zones	Launch time
Directory DNS name	us-east-1c, us-east-1d	Tuesday, January 7, 2020
Directory NetBIOS name	DNS address	
CORP		
Description - <a href="#">Edit</a>		
My directory		

[Application management](#) | [Scale & share](#) | [Networking & security](#) | [Maintenance](#)

## Step 2: (Optional) Create a trust relationship between your on-premises Active Directory and AWS Directory Service

If you don't plan to use your own on-premises Microsoft Active Directory, skip to [Step 3: Create an IAM role for Amazon RDS to access the AWS Directory Service](#).

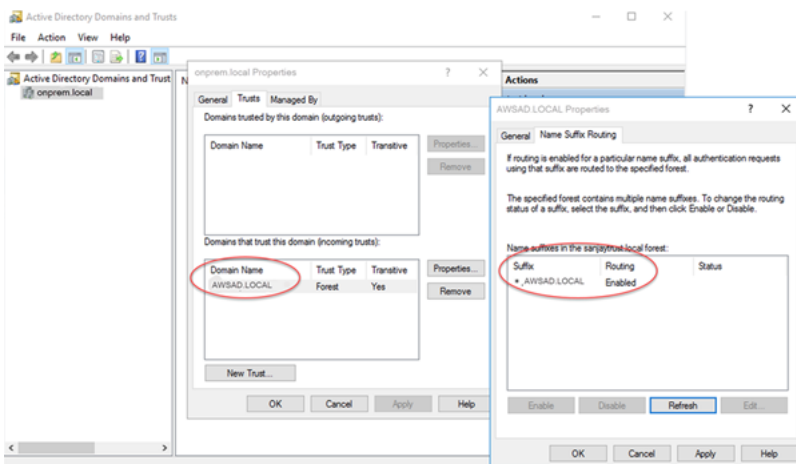

To get Kerberos authentication using your on-premises Active Directory, you need to create a trusting domain relationship using a forest trust between your on-premises Microsoft Active Directory and the AWS Managed Microsoft AD directory (created in [Step 1: Create a directory using AWS Managed Microsoft AD](#)). The trust can be one-way, where the AWS Managed Microsoft

AD directory trusts the on-premises Microsoft Active Directory. The trust can also be two-way, where both Active Directories trust each other. For more information about setting up trusts using AWS Directory Service, see [When to create a trust relationship](#) in the *AWS Directory Service Administration Guide*.

### Note

If you use an on-premises Microsoft Active Directory, Windows clients connect using the domain name of the AWS Directory Service in the endpoint rather than `rds.amazonaws.com`. To learn more, see [Connecting to PostgreSQL with Kerberos authentication](#).

Make sure that your on-premises Microsoft Active Directory domain name includes a DNS suffix routing that corresponds to the newly created trust relationship. The following screenshot shows an example.

### Step 3: Create an IAM role for Amazon RDS to access the AWS Directory Service

For Amazon RDS to call AWS Directory Service for you, your AWS account needs an IAM role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. This role allows Amazon RDS to make calls to AWS Directory Service.

When you create a DB instance using the AWS Management Console and your console user account has the `iam:CreateRole` permission, the console creates the needed IAM role automatically. In this case, the role name is `rds-directoryservice-kerberos-access-role`. Otherwise, you must create the IAM role manually. When you create this IAM role, choose `Directory Service`, and attach the AWS managed policy `AmazonRDSDirectoryServiceAccess` to it.

For more information about creating IAM roles for a service, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.

**Note**

The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for Amazon RDS for PostgreSQL.

As an alternative to using the `AmazonRDSDirectoryServiceAccess` managed policy, you can create policies with the required permissions. In this case, the IAM role must have the following IAM trust policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "",
      "Effect": "Allow",
      "Principal": {
        "Service": [
          "directoryservice.rds.amazonaws.com",
          "rds.amazonaws.com"
        ]
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```

The role must also have the following IAM role policy.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [
        "ds:DescribeDirectories",
        "ds:AuthorizeApplication",
        "ds:UnauthorizeApplication",
        "ds:GetAuthorizedApplicationDetails"
      ]
    }
  ]
}
```

```
    ],  
    "Effect": "Allow",  
    "Resource": "*"    
  }  
]  
}
```

## Step 4: Create and configure users

You can create users by using the Active Directory Users and Computers tool. This is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. For more information, see [Add Users and Computers to the Active Directory domain](#) in the Microsoft documentation. In this case, users are individuals or other entities, such as their computers that are part of the domain and whose identities are being maintained in the directory.

To create users in an AWS Directory Service directory, you must be connected to a Windows-based Amazon EC2 instance that's a member of the AWS Directory Service directory. At the same time, you must be logged in as a user that has privileges to create users. For more information, see [Create a user](#) in the *AWS Directory Service Administration Guide*.

## Step 5: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to [Step 6: Create or modify a PostgreSQL DB instance](#).

If you plan to locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or [AWS Transit Gateway](#).

The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in [What is VPC peering?](#) in the *Amazon Virtual Private Cloud Peering Guide*.

### To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance security group can receive inbound traffic from the directory security group.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

## To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in [Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 Domain-join](#) in the *AWS Directory Service Administration Guide*.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the **Directory ID** value. You use this directory ID to join the DB instance to the domain.

## Step 6: Create or modify a PostgreSQL DB instance

Create or modify a PostgreSQL DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new PostgreSQL DB instance using the console, the [create-db-instance](#) CLI command, or the [CreateDBInstance](#) RDS API operation. For instructions, see [Creating an Amazon RDS DB instance](#).
- Modify an existing PostgreSQL DB instance using the console, the [modify-db-instance](#) CLI command, or the [ModifyDBInstance](#) RDS API operation. For instructions, see [Modifying an Amazon RDS DB instance](#).
- Restore a PostgreSQL DB instance from a DB snapshot using the console, the [restore-db-instance-from-db-snapshot](#) CLI command, or the [RestoreDBInstanceFromDBSnapshot](#) RDS API operation. For instructions, see [Restoring to a DB instance](#).
- Restore a PostgreSQL DB instance to a point-in-time using the console, the [restore-db-instance-to-point-in-time](#) CLI command, or the [RestoreDBInstanceToPointInTime](#) RDS API operation. For instructions, see [Restoring a DB instance to a specified time](#).

Kerberos authentication is only supported for PostgreSQL DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. The DB instance must use a security group that allows ingress and egress within the directory's VPC so the DB instance can communicate with the directory.

## Console

When you use the console to create, modify, or restore a DB instance, choose **Password and Kerberos authentication** in the **Database authentication** section. Then choose **Browse Directory**. Select the directory or choose **Create a new directory** to use the Directory Service.

**Database authentication**

Database authentication options [Info](#)

- Password authentication  
Authenticates using database passwords.
- Password and IAM database authentication  
Authenticates using the database password and user credentials through AWS IAM users and roles.
- Password and Kerberos authentication  
Choose a directory in which you want to allow authorized users to authenticate with this DB instance using Kerberos Authentication.

Directory

docs-lab-active-dir.com (d-9...)

Browse Directory

## AWS CLI

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the `--domain` parameter, use the domain identifier ("d-\*" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB instance to use a directory.

```
aws rds modify-db-instance --db-instance-identifier mydbinstance --domain d-Directory-ID --domain-iam-role-name role-name
```

### **⚠ Important**

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

## Step 7: Create PostgreSQL users for your Kerberos principals

At this point, your RDS for PostgreSQL DB instance is joined to the AWS Managed Microsoft AD domain. The users that you created in the directory in [Step 4: Create and configure users](#) need to be set up as PostgreSQL database users and granted privileges to login to the database. You do that by signing in as the database user with `rds_superuser` privileges. For example, if you accepted the defaults when you created your RDS for PostgreSQL DB instance, you use `postgres`, as shown in the following steps.

### To create PostgreSQL database users for Kerberos principals

1. Use `psql` to connect to your RDS for PostgreSQL DB instance endpoint using `psql`. The following example uses the default `postgres` account for the `rds_superuser` role.

```
psql --host=cluster-instance-1.111122223333.aws-region.rds.amazonaws.com --  
port=5432 --username=postgres --password
```

2. Create a database user name for each Kerberos principal (Active Directory username) that you want to have access to the database. Use the canonical username (identity) as defined in the Active Directory instance, that is, a lower-case `alias` (username in Active Directory) and the upper-case name of the Active Directory domain for that user name. The Active Directory user name is an externally authenticated user, so use quotes around the name as shown following.

```
postgres=> CREATE USER "username@CORP.EXAMPLE.COM" WITH LOGIN;  
CREATE ROLE
```

3. Grant the `rds_ad` role to the database user.

```
postgres=> GRANT rds_ad TO "username@CORP.EXAMPLE.COM";  
GRANT ROLE
```

After you finish creating all the PostgreSQL users for your Active Directory user identities, users can access the RDS for PostgreSQL DB instance by using their Kerberos credentials.

It's required that the database users who authenticate using Kerberos are doing so from client machines that are members of the Active Directory domain.

Database users that have been granted the `rds_ad` role can't also have the `rds_iam` role. This also applies to nested memberships. For more information, see [IAM database authentication for MariaDB, MySQL, and PostgreSQL](#).

## Step 8: Configure a PostgreSQL client

To configure a PostgreSQL client, take the following steps:

- Create a `krb5.conf` file (or equivalent) to point to the domain.
- Verify that traffic can flow between the client host and AWS Directory Service. Use a network utility such as Netcat for the following:
  - Verify traffic over DNS for port 53.
  - Verify traffic over TCP/UDP for port 53 and for Kerberos, which includes ports 88 and 464 for AWS Directory Service.
- Verify that traffic can flow between the client host and the DB instance over the database port. For example, use `psql` to connect and access the database.

The following is sample `krb5.conf` content for AWS Managed Microsoft AD.

```
[libdefaults]
  default_realm = EXAMPLE.COM
[realms]
EXAMPLE.COM = {
  kdc = example.com
  admin_server = example.com
}
[domain_realm]
.example.com = EXAMPLE.COM
example.com = EXAMPLE.COM
```

The following is sample `krb5.conf` content for an on-premises Microsoft Active Directory.

```
[libdefaults]
  default_realm = EXAMPLE.COM
[realms]
EXAMPLE.COM = {
  kdc = example.com
  admin_server = example.com
}
ONPREM.COM = {
```

```
kdc = onprem.com
admin_server = onprem.com
}
[domain_realm]
.example.com = EXAMPLE.COM
example.com = EXAMPLE.COM
.onprem.com = ONPREM.COM
onprem.com = ONPREM.COM
.rds.amazonaws.com = EXAMPLE.COM
.amazonaws.com.cn = EXAMPLE.COM
.amazon.com = EXAMPLE.COM
```

## Managing an RDS for PostgreSQL DB instance in an Active Directory domain

You can use the console, the CLI, or the RDS API to manage your DB instance and its relationship with your Microsoft Active Directory. For example, you can associate an Active Directory to enable Kerberos authentication. You can also remove the association for an Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Microsoft Active Directory to another.

For example, using the CLI, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the [modify-db-instance](#) CLI command. Specify the current membership's directory ID for the `--domain` option.
- To disable Kerberos authentication on a DB instance, use the [modify-db-instance](#) CLI command. Specify `none` for the `--domain` option.
- To move a DB instance from one domain to another, use the [modify-db-instance](#) CLI command. Specify the domain identifier of the new domain for the `--domain` option.

### Understanding Domain membership

After you create or modify your DB instance, it becomes a member of the domain. You can view the status of the domain membership in the console or by running the [describe-db-instances](#) CLI command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.

- `pending-enable-kerberos` – Enabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-enable-kerberos` – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – Disabling Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `enable-kerberos-failed` – A configuration problem prevented AWS from enabling Kerberos authentication on the DB instance. Correct the configuration problem before reissuing the command to modify the DB instance.
- `disabling-kerberos` – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. In some cases, the attempt to enable Kerberos authentication might fail when you create or modify a DB instance. If so, make sure that you are using the correct IAM role, then modify the DB instance to join the domain.

 **Note**

Only Kerberos authentication with RDS for PostgreSQL sends traffic to the domain's DNS servers. All other DNS requests are treated as outbound network access on your DB instances running PostgreSQL. For more information about outbound network access with RDS for PostgreSQL, see [Using a custom DNS server for outbound network access](#).

## Connecting to PostgreSQL with Kerberos authentication

You can connect to PostgreSQL with Kerberos authentication with the pgAdmin interface or with a command-line interface such as `psql`. For more information about connecting, see [Connecting to a DB instance running the PostgreSQL database engine](#). For information about obtaining the endpoint, port number, and other details needed for connection, see [Step 3: Connect to a PostgreSQL DB instance](#).

## pgAdmin

To use pgAdmin to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. Launch the pgAdmin application on your client computer.
2. On the **Dashboard** tab, choose **Add New Server**.
3. In the **Create - Server** dialog box, enter a name on the **General** tab to identify the server in pgAdmin.
4. On the **Connection** tab, enter the following information from your RDS for PostgreSQL database.
  - For **Host**, enter the endpoint for the RDS for PostgreSQL DB instance. An endpoint looks similar to the following:

```
RDS-DB-instance.111122223333.aws-region.rds.amazonaws.com
```

To connect to an on-premises Microsoft Active Directory from a Windows client, you use the domain name of the AWS Managed Active Directory instead of `rds.amazonaws.com` in the host endpoint. For example, suppose that the domain name for the AWS Managed Active Directory is `corp.example.com`. Then for **Host**, the endpoint would be specified as follows:

```
RDS-DB-instance.111122223333.aws-region.corp.example.com
```

- For **Port**, enter the assigned port.
  - For **Maintenance database**, enter the name of the initial database to which the client will connect.
  - For **Username**, enter the user name that you entered for Kerberos authentication in [Step 7: Create PostgreSQL users for your Kerberos principals](#).
5. Choose **Save**.

## Psql

To use psql to connect to PostgreSQL with Kerberos authentication, take the following steps:

1. At a command prompt, run the following command.

```
kinit username
```

Replace *username* with the user name. At the prompt, enter the password stored in the Microsoft Active Directory for the user.

2. If the PostgreSQL DB instance is using a publicly accessible VPC, put IP address for your DB instance endpoint in your `/etc/hosts` file on the EC2 client. For example, the following commands obtain the IP address and then put it in the `/etc/hosts` file.

```
% dig +short PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com
;; Truncated, retrying in TCP mode.
ec2-34-210-197-118.AWS-Region.compute.amazonaws.com.
34.210.197.118

% echo " 34.210.197.118 PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com" >> /etc/
hosts
```

If you're using an on-premises Microsoft Active Directory from a Windows client, then you need to connect using a specialized endpoint. Instead of using the Amazon domain `rds.amazonaws.com` in the host endpoint, use the domain name of the AWS Managed Active Directory.

For example, suppose that the domain name for your AWS Managed Active Directory is `corp.example.com`. Then use the format *PostgreSQL-endpoint.AWS-Region.corp.example.com* for the endpoint and put it in the `/etc/hosts` file.

```
% echo " 34.210.197.118 PostgreSQL-endpoint.AWS-Region.corp.example.com" >> /etc/
hosts
```

3. Use the following `psql` command to log in to a PostgreSQL DB instance that is integrated with Active Directory.

```
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-Region.rds.amazonaws.com postgres
```

To log in to the PostgreSQL DB cluster from a Windows client using an on-premises Active Directory, use the following `psql` command with the domain name from the previous step (`corp.example.com`):

```
psql -U username@CORP.EXAMPLE.COM -p 5432 -h PostgreSQL-endpoint.AWS-Region.corp.example.com postgres
```

# Using a custom DNS server for outbound network access

RDS for PostgreSQL supports outbound network access on your DB instances and allows Domain Name Service (DNS) resolution from a custom DNS server owned by the customer. You can resolve only fully qualified domain names from your RDS for PostgreSQL DB instance through your custom DNS server.

## Topics

- [Turning on custom DNS resolution](#)
- [Turning off custom DNS resolution](#)
- [Setting up a custom DNS server](#)

## Turning on custom DNS resolution

To turn on DNS resolution in your customer VPC, first associate a custom DB parameter group to your RDS for PostgreSQL instance. Then turn on the `rds.custom_dns_resolution` parameter by setting it to 1, and then restart the DB instance for the changes to take place.

## Turning off custom DNS resolution

To turn off DNS resolution in your customer VPC, first turn off the `rds.custom_dns_resolution` parameter of your custom DB parameter group by setting it to 0. Then restart the DB instance for the changes to take place.

## Setting up a custom DNS server

After you set up your custom DNS name server, it takes up to 30 minutes to propagate the changes to your DB instance. After the changes are propagated to your DB instance, all outbound network traffic requiring a DNS lookup queries your DNS server over port 53.

### Note

If you don't set up a custom DNS server and `rds.custom_dns_resolution` is set to 1, hosts are resolved using an Amazon Route 53 private zone. For more information, see [Working with private hosted zones](#).

## To set up a custom DNS server for your RDS for PostgreSQL DB instance

1. From the Dynamic Host Configuration Protocol (DHCP) options set attached to your VPC, set the `domain-name-servers` option to the IP address of your DNS name server. For more information, see [DHCP options sets](#).

### Note

The `domain-name-servers` option accepts up to four values, but your Amazon RDS DB instance uses only the first value.

2. Ensure that your DNS server can resolve all lookup queries, including public DNS names, Amazon EC2 private DNS names, and customer-specific DNS names. If the outbound network traffic contains any DNS lookups that your DNS server can't handle, your DNS server must have appropriate upstream DNS providers configured.
3. Configure your DNS server to produce User Datagram Protocol (UDP) responses of 512 bytes or less.
4. Configure your DNS server to produce Transmission Control Protocol (TCP) responses of 1,024 bytes or less.
5. Configure your DNS server to allow inbound traffic from your Amazon RDS DB instances over port 53. If your DNS server is in an Amazon VPC, the VPC must have a security group that contains inbound rules that allow UDP and TCP traffic on port 53. If your DNS server is not in an Amazon VPC, it must have appropriate firewall settings to allow UDP and TCP inbound traffic on port 53.

For more information, see [Security groups for your VPC](#) and [Adding and removing rules](#).

6. Configure the VPC of your Amazon RDS DB instance to allow outbound traffic over port 53. Your VPC must have a security group that contains outbound rules that allow UDP and TCP traffic on port 53.

For more information, see [Security groups for your VPC](#) and [Adding and removing rules](#) in the *Amazon VPC User Guide*.

7. Make sure that the routing path between the Amazon RDS DB instance and the DNS server is configured correctly to allow DNS traffic.

Also, if the Amazon RDS DB instance and the DNS server are not in the same VPC, make sure that a peering connection is set up between them. For more information, see [What is VPC peering?](#) in *Amazon VPC Peering Guide*.

# Upgrading the PostgreSQL DB engine for Amazon RDS

There are two types of upgrades that you can manage for your PostgreSQL database:

- Operating system updates – Occasionally, Amazon RDS might need to update the underlying operating system of your database to apply security fixes or OS changes. You can decide when Amazon RDS applies OS updates by using the RDS console, AWS Command Line Interface (AWS CLI), or RDS API. For more information about OS updates, see [Applying updates for a DB instance](#).
- Database engine upgrades – When Amazon RDS supports a new version of a database engine, you can upgrade your databases to the new version.

A *database* in this context is an RDS for PostgreSQL DB instance or Multi-AZ DB cluster.

There are two kinds of engine upgrades for PostgreSQL databases: major version upgrades and minor version upgrades.

## Major version upgrades

*Major version upgrades* can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your databases. You can initiate a major version upgrade by modifying your DB instance or Multi-AZ DB cluster. Before you perform a major version upgrade, we recommend that you follow the steps described in [Choosing a major version upgrade for PostgreSQL](#).

If you're upgrading a DB instance that has in-Region read replicas, Amazon RDS upgrades the replicas along with the primary DB instance.

Amazon RDS doesn't upgrade Multi-AZ DB cluster read replicas. If you perform a major version upgrade of a Multi-AZ DB cluster, then the replication state of its read replicas changes to **terminated**. You must manually delete and recreate the read replicas after the upgrade completes.

### Tip

You can minimize the downtime required for a major version upgrade by using a blue/green deployment. For more information, see [Using Blue/Green Deployments for database updates](#).

## Minor version upgrades

In contrast, *minor version upgrades* include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your database. Or, you can enable the **Auto minor version upgrade** option when creating or modifying a database. Doing so means that Amazon RDS automatically upgrades your database after testing and approving the new version. If your PostgreSQL database uses read replicas, you must first upgrade all of the read replicas before upgrading the source instance or cluster.

If your database is a Multi-AZ DB instance deployment, Amazon RDS simultaneously upgrades the primary and any standby instances. Therefore, your database might not be available until the upgrade completes. If your database is a Multi-AZ DB cluster deployment, Amazon RDS upgrades the reader DB instances one at a time. Then, one of the reader DB instances switches to be the new writer DB instance. Amazon RDS then upgrades the old writer instance (which is now a reader instance).

### Note

The downtime for a minor version upgrade of a Multi-AZ DB *instance* deployment can last for several minutes. Multi-AZ DB clusters typically reduce the downtime of minor version upgrades to approximately 35 seconds. When used with RDS Proxy, you can further reduce downtime to one second or less. For more information, see [Using RDS Proxy](#). Alternately, you can use an open source database proxy such as [ProxySQL](#), [PgBouncer](#), or the [AWS JDBC Driver for MySQL](#),

For more information, see [Automatic minor version upgrades for PostgreSQL](#). For information about manually performing a minor version upgrade, see [Manually upgrading the engine version](#).

For more information about database engine versions and the policy for deprecating database engine versions, see [Database Engine Versions](#) in the Amazon RDS FAQs.

## Overview of upgrading PostgreSQL

To safely upgrade your databases, Amazon RDS uses the `pg_upgrade` utility described in the [PostgreSQL documentation](#),

When you use the AWS Management Console to upgrade a database, it shows the valid upgrade targets for the database. You can also use the following AWS CLI command to identify the valid upgrade targets for a database:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \  
  --engine postgres \  
  --engine-version version-number \  
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --  
  output text
```

For Windows:

```
aws rds describe-db-engine-versions ^  
  --engine postgres ^  
  --engine-version version-number ^  
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --  
  output text
```

For example, to identify the valid upgrade targets for a PostgreSQL version 12.13 database, run the following AWS CLI command:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \  
  --engine postgres \  
  --engine-version 12.13 \  
  --query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --  
  output text
```

```
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --  
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^  
--engine postgres ^  
--engine-version 12.13 ^  
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --  
output text
```

If your backup retention period is greater than 0, Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the database before any upgrade changes have been made. If the upgrade fails for your databases, you can restore this snapshot to create a database running the old version. The second DB snapshot is taken after the upgrade completes.

#### Note

Amazon RDS takes DB snapshots during the upgrade process only if you have set the backup retention period for your database to a number greater than 0. To change the backup retention period for a DB instance, see [the section called “Modifying a DB instance”](#). You can't configure a custom backup retention period for a Multi-AZ DB cluster.

When you perform a major version upgrade of a DB instance, any in-Region read replicas are also automatically upgraded. After the upgrade workflow starts, the read replicas wait for the `pg_upgrade` to complete successfully on the primary DB instance. Then the primary DB instance upgrade waits for the read replica upgrades to complete. You experience an outage until the upgrade is complete. When you perform a major version upgrade of a Multi-AZ DB cluster, the replication state of its read replicas changes to **terminated**.

After an upgrade is complete, you can't revert to the previous version of the DB engine. If you want to return to the previous version, restore the DB snapshot that was taken before the upgrade to create a new database.

## PostgreSQL version numbers

The version numbering sequence for the PostgreSQL database engine is as follows:

- For PostgreSQL versions 10 and later, the engine version number is in the form *major.minor*. The major version number is the integer part of the version number. The minor version number is the fractional part of the version number.

A major version upgrade increases the integer part of the version number, such as upgrading from 10.*minor* to 11.*minor*.

- For PostgreSQL versions earlier than 10, the engine version number is in the form *major.major.minor*. The major engine version number is both the integer and the first fractional part of the version number. For example, 9.6 is a major version. The minor version number is the third part of the version number. For example, for version 9.6.12, the 12 is the minor version number.

A major version upgrade increases the major part of the version number. For example, an upgrade from 9.6.12 to 11.14 is a major version upgrade, where 9.6 and 11 are the major version numbers.

For information about RDS Extended Support version numbering, see [Amazon RDS Extended Support version naming](#).

## RDS version number

RDS version numbers use the *major.minor.patch* naming scheme. An RDS patch version includes important bug fixes added to a minor version after its release. For information about RDS Extended Support version numbering, see [Amazon RDS Extended Support version naming](#).

To identify the Amazon RDS version number of your database, you must first create the `rds_tools` extension by using the following command:

```
CREATE EXTENSION rds_tools;
```

Starting with the release of PostgreSQL version 15.2-R2, you can find out the RDS version number of your RDS for PostgreSQL database with the following SQL query:

```
postgres=> SELECT rds_tools.rds_version();
```

For example, querying an RDS for PostgreSQL 15.2 database returns the following:

```
rds_version  
-----
```

```
15.2.R2
(1 row)
```

## Choosing a major version upgrade for PostgreSQL

Major version upgrades can contain changes that are not backward-compatible with previous versions of the database. New functionality can cause your existing applications to stop working correctly. For this reason, Amazon RDS doesn't apply major version upgrades automatically. To perform a major version upgrade, you modify your database manually. Make sure that you thoroughly test any upgrade to verify that your applications work correctly before applying the upgrade to your production databases. When you do a PostgreSQL major version upgrade, we recommend that you follow the steps described in [How to perform a major version upgrade](#).

When you upgrade a PostgreSQL Single-AZ DB instance or Multi-AZ DB instance deployment to its next major version, any read replicas associated with the database are also upgraded to that next major version. In some cases, you can skip to a higher major version when upgrading. If your upgrade skips a major version, the read replicas are also upgraded to that target major version. Upgrades to version 11 that skip other major versions have certain limitations. You can find the details in the steps described in [How to perform a major version upgrade](#).

Most PostgreSQL extensions aren't upgraded during a PostgreSQL engine upgrade. These must be upgraded separately. For more information, see [Upgrading PostgreSQL extensions](#).

You can find out which major versions are available for your RDS for PostgreSQL database by running the following AWS CLI query:

```
aws rds describe-db-engine-versions --engine postgres --engine-version your-version
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

The following table summarizes the results of this query for all available versions. An asterisk (\*) on the version number means that version is no longer supported. If your current version is unsupported, we recommend that you upgrade to the newest minor version upgrade target or to one of the other available upgrade targets for that version.

Current source version	Newest major version upgrade target	Other available upgrade targets
16.3	none	<a href="#">16.4</a>

## How to perform a major version upgrade

We recommend the following process when performing a major version upgrade on an Amazon RDS for PostgreSQL database:

- 1. Have a version-compatible parameter group ready** – If you are using a custom parameter group, you have two options. You can specify a default parameter group for the new DB engine version. Or you can create your own custom parameter group for the new DB engine version. For more information, see [the section called “Parameter groups”](#) and [the section called “Working with DB cluster parameter groups”](#).
- 2. Check for unsupported database classes** – Check that your database's instance class is compatible with the PostgreSQL version you are upgrading to. For more information, see [Supported DB engines for DB instance classes](#).
- 3. Check for unsupported usage:**

- **Prepared transactions** – Commit or roll back all open prepared transactions before attempting an upgrade.

You can use the following query to verify that there are no open prepared transactions on your database.

```
SELECT count(*) FROM pg_catalog.pg_prepared_xacts;
```

- **Reg\* data types** – Remove all uses of the *reg\** data types before attempting an upgrade. Except for *regtype* and *regclass*, you can't upgrade the *reg\** data types. The *pg\_upgrade* utility can't persist this data type, which is used by Amazon RDS to do the upgrade.

To verify that there are no uses of unsupported *reg\** data types, use the following query for each database.

```
SELECT count(*) FROM pg_catalog.pg_class c, pg_catalog.pg_namespace n,
pg_catalog.pg_attribute a
WHERE c.oid = a.attrelid
      AND NOT a.attisdropped
      AND a.atttypid IN ('pg_catalog.regproc'::pg_catalog.regtype,
                        'pg_catalog.regprocedure'::pg_catalog.regtype,
                        'pg_catalog.regoper'::pg_catalog.regtype,
                        'pg_catalog.regoperator'::pg_catalog.regtype,
                        'pg_catalog.regconfig'::pg_catalog.regtype,
                        'pg_catalog.regdictionary'::pg_catalog.regtype)
      AND c.relnamespace = n.oid
      AND n.nspname NOT IN ('pg_catalog', 'information_schema');
```

4. **Handle logical replication slots** – An upgrade can't occur if the database has any logical replication slots. Logical replication slots are typically used for AWS DMS migration and for replicating tables from the database to data lakes, BI tools, and other targets. Before upgrading, make sure that you know the purpose of any logical replication slots that are in use, and confirm that it's okay to delete them. If the logical replication slots are still being used, you shouldn't delete them, and you can't proceed with the upgrade.

If the logical replication slots aren't needed, you can delete them using the following SQL:

```
SELECT * FROM pg_replication_slots;
```

```
SELECT pg_drop_replication_slot(slot_name);
```

Logical replication setups that use the `pglogical` extension also need to have slots dropped for a successful major version upgrade. For information about how to identify and drop slots created using the `pglogical` extension, see [Managing logical replication slots for RDS for PostgreSQL](#).

- 5. Handle read replicas** – An upgrade of a Single-AZ DB instance or Multi-AZ DB instance deployment also upgrades the in-Region read replicas along with the primary DB instance. Amazon RDS doesn't upgrade Multi-AZ DB cluster read replicas.

You can't upgrade read replicas separately. If you could, it could lead to situations where the primary and replica databases have different PostgreSQL major versions. However, read replica upgrades might increase downtime on the primary DB instance. To prevent a read replica upgrade, promote the replica to a standalone instance or delete it before starting the upgrade process.

The upgrade process recreates the read replica's parameter group based on the read replica's current parameter group. You can apply a custom parameter group to a read replica only after the upgrade completes by modifying the read replica. For more information about read replicas, see [Working with read replicas for Amazon RDS for PostgreSQL](#).

- 6. Perform a backup** – We recommend that you perform a backup before performing the major version upgrade so that you have a known restore point for your database. If your backup retention period is greater than 0, the upgrade process creates DB snapshots of your database before and after upgrading. To change your backup retention period, see [Modifying an Amazon RDS DB instance](#) and [the section called "Modifying a Multi-AZ DB cluster"](#).

To perform a backup manually, see [the section called "Creating a DB snapshot for a Single-AZ DB instance"](#) and [the section called "Creating a Multi-AZ DB cluster snapshot"](#).

- 7. Upgrade certain extensions before a major version upgrade** – If you plan to skip a major version with the upgrade, you need to update certain extensions *before* performing the major version upgrade. For example, upgrading from versions 9.5.x or 9.6.x to version 11.x skips a major version. The extensions to update include PostGIS and related extensions for processing spatial data.
  - `address_standardizer`
  - `address_standardizer_data_us`
  - `postgis_raster`

- `postgis_tiger_geocoder`
- `postgis_topology`

Run the following command for each extension that you're using:

```
ALTER EXTENSION PostgreSQL-extension UPDATE TO 'new-version';
```

For more information, see [Upgrading PostgreSQL extensions](#). To learn more about upgrading PostGIS, see [Step 6: Upgrade the PostGIS extension](#).

- 8. Drop certain extensions before the major version upgrade** – An upgrade that skips a major version to version 11.x doesn't support updating the `pgRouting` extension. Upgrading from versions 9.4.x, 9.5.x, or 9.6.x to versions 11.x skips a major version. It's safe to drop the `pgRouting` extension and then reinstall it to a compatible version after the upgrade. For the extension versions you can update to, see [Supported PostgreSQL extension versions](#).

The `tsearch2` and `chpasswd` extensions are no longer supported for PostgreSQL versions 11 or later. If you are upgrading to version 11.x, drop the `tsearch2`, and `chpasswd` extensions before the upgrade.

- 9. Drop unknown data types** – Drop unknown data types depending on the target version.

PostgreSQL version 10 stopped supporting the unknown data type. If a version 9.6 database uses the unknown data type, an upgrade to a version 10 shows an error message such as the following:

```
Database instance is in a state that cannot be upgraded: PreUpgrade checks failed:  
The instance could not be upgraded because the 'unknown' data type is used in user  
tables.  
Please remove all usages of the 'unknown' data type and try again."
```

To find the unknown data type in your database so you can remove the offending column or change it to a supported data type, use the following SQL:

```
SELECT DISTINCT data_type FROM information_schema.columns WHERE data_type ILIKE  
'unknown';
```

- 10 Perform an upgrade dry run** – We highly recommend testing a major version upgrade on a duplicate of your production database before attempting the upgrade on your production database. You can monitor the execution plans on the duplicate test database for any possible

execution plan regressions and to evaluate its performance. To create a duplicate test instance, you can either restore your database from a recent snapshot or do a point-in-time restore of your database to its latest restorable time.

For more information, see [the section called “Restoring from a snapshot”](#) or [the section called “Point-in-time recovery”](#). For Multi-AZ DB clusters, see [the section called “Restoring from a snapshot to a Multi-AZ DB cluster”](#) or [the section called “Restoring a Multi-AZ DB cluster to a specified time”](#).

For details on performing the upgrade, see [the section called “Manually upgrading the engine version”](#).

In upgrading a version 9.6 database to version 10, be aware that PostgreSQL 10 enables parallel queries by default. You can test the impact of parallelism *before* the upgrade by changing the `max_parallel_workers_per_gather` parameter on your test database to 2.

 **Note**

The default value for `max_parallel_workers_per_gather` parameter in the `default.postgresql10` DB parameter group is 2.

For more information, see [Parallel Query](#) in the PostgreSQL documentation. To disable parallelism on version 10, set the `max_parallel_workers_per_gather` parameter to 0.

During the major version upgrade, the `public` and `template1` databases and the `public` schema in every database are temporarily renamed. These objects appear in the logs with their original name and a random string appended. The string is appended so that custom settings such as `locale` and `owner` are preserved during the major version upgrade. After the upgrade completes, the objects are renamed back to their original names.

 **Note**

During the major version upgrade process, you can't do a point-in-time restore of your DB instance or Multi-AZ DB cluster. After Amazon RDS performs the upgrade, it takes an automatic backup of the database. You can perform a point-in-time restore to times before the upgrade began and after the automatic backup of your database has completed.

**11 If an upgrade fails with precheck procedure errors, resolve the issues** – During the major version upgrade process, Amazon RDS for PostgreSQL first runs a precheck procedure to identify any issues that might cause the upgrade to fail. The precheck procedure checks all potential incompatible conditions across all databases in the instance.

If the precheck encounters an issue, it creates a log event indicating the upgrade precheck failed. The precheck process details are in an upgrade log named `pg_upgrade_precheck.log` for all the databases of a database. Amazon RDS appends a timestamp to the file name. For more information about viewing logs, see [Monitoring Amazon RDS log files](#).

If a read replica upgrade fails at precheck, replication on the failed read replica is broken and the read replica is put in the terminated state. Delete the read replica and recreate a new read replica based on the upgraded primary DB instance.

Resolve all of the issues identified in the precheck log and then retry the major version upgrade. The following is an example of a precheck log.

```
-----
Upgrade could not be run on Wed Apr 4 18:30:52 2018
-----
The instance could not be upgraded from 9.6.11 to 10.6 for the following reasons.
Please take appropriate action on databases that have usage incompatible with the
requested major engine version upgrade and try the upgrade again.

* There are uncommitted prepared transactions. Please commit or rollback all prepared
transactions.* One or more role names start with 'pg_'. Rename all role names that
start with 'pg_'.

* The following issues in the database 'my"million$"db' need to be corrected before
upgrading:** The ["line","reg*"] data types are used in user tables. Remove all
usage of these data types.
** The database name contains characters that are not supported by RDS for
PostgreSQL. Rename the database.
** The database has extensions installed that are not supported on the target
database version. Drop the following extensions from your database: ["tsearch2"].

* The following issues in the database 'mydb' need to be corrected before
upgrading:** The database has views or materialized views that depend on
'pg_stat_activity'. Drop the views.
```

**12 If a read replica upgrade fails while upgrading the database, resolve the issue** – A failed read replica is placed in the `incompatible-restore` state and replication is terminated on the database. Delete the read replica and recreate a new read replica based on the upgraded primary DB instance.

**Note**

Amazon RDS doesn't upgrade read replicas for Multi-AZ DB clusters. If you perform a major version upgrade on a Multi-AZ DB cluster, then the replication state of its read replicas changes to **terminated**.

A read replica upgrade might fail for the following reasons:

- It was unable to catch up with the primary DB instance even after a wait time.
- It was in a terminal or incompatible lifecycle state such as `storage-full`, `incompatible-restore`, and so on.
- When the primary DB instance upgrade started, there was a separate minor version upgrade running on the read replica.
- The read replica used incompatible parameters.
- The read replica was unable to communicate with the primary DB instance to synchronize the data folder.

**13 Upgrade your production database** – When the dry-run major version upgrade is successful, you should be able to upgrade your production database with confidence. For more information, see [Manually upgrading the engine version](#).

**14 Run the ANALYZE operation to refresh the pg\_statistic table.** You should do this for every database on all your PostgreSQL databases. Optimizer statistics aren't transferred during a major version upgrade, so you need to regenerate all statistics to avoid performance issues. Run the command without any parameters to generate statistics for all regular tables in the current database, as follows:

```
ANALYZE VERBOSE;
```

The `VERBOSE` flag is optional, but using it shows you the progress. For more information, see [ANALYZE](#) in the PostgreSQL documentation.

**Note**

Run ANALYZE on your system after the upgrade to avoid performance issues.

After the major version upgrade is complete, we recommend the following:

- A PostgreSQL upgrade doesn't upgrade any PostgreSQL extensions. To upgrade extensions, see [Upgrading PostgreSQL extensions](#).
- Optionally, use Amazon RDS to view two logs that the `pg_upgrade` utility produces. These are `pg_upgrade_internal.log` and `pg_upgrade_server.log`. Amazon RDS appends a timestamp to the file name for these logs. You can view these logs as you can any other log. For more information, see [Monitoring Amazon RDS log files](#).

You can also upload the upgrade logs to Amazon CloudWatch Logs. For more information, see [Publishing PostgreSQL logs to Amazon CloudWatch Logs](#).

- To verify that everything works as expected, test your application on the upgraded database with a similar workload. After the upgrade is verified, you can delete this test instance.

## Automatic minor version upgrades for PostgreSQL

If you enable the **Auto minor version upgrade** option when creating or modifying a DB instance or Multi-AZ DB cluster, you can have your database automatically upgraded.

For each RDS for PostgreSQL major version, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the PostgreSQL community version
- Overall fleet stability since the minor version was released

You can use the following AWS CLI command to determine the current automatic minor upgrade target version for a specified PostgreSQL minor version in a specific AWS Region.

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \  
--engine postgres \  
--engine-version minor-version \  
--region region \  
--query "DBEngineVersions[*].ValidUpgradeTarget[*].  
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \  
--output text
```

For Windows:

```
aws rds describe-db-engine-versions ^  
--engine postgres ^  
--engine-version minor-version ^  
--region region ^  
--query "DBEngineVersions[*].ValidUpgradeTarget[*].  
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^  
--output text
```

For example, the following AWS CLI command determines the automatic minor upgrade target for PostgreSQL minor version 12.13 in the US East (Ohio) AWS Region (us-east-2).

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \  
--engine postgres \  
--engine-version 12.13 \  
--region us-east-2 \  
--query "DBEngineVersions[*].ValidUpgradeTarget[*].  
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" \  
--output table
```

For Windows:

```
aws rds describe-db-engine-versions ^  
--engine postgres ^
```

```
--engine-version 12.13 ^
--region us-east-2 ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].
{AutoUpgrade:AutoUpgrade,EngineVersion:EngineVersion}" ^
--output table
```

Your output is similar to the following.

```
-----
| DescribeDBEngineVersions |
+-----+-----+
| AutoUpgrade | EngineVersion |
+-----+-----+
| True      | 12.14      |
| False       | 12.15        |
| False       | 13.9         |
| False       | 13.10        |
| False       | 13.11        |
| False       | 14.6         |
+-----+-----+
```

In this example, the AutoUpgrade value is True for PostgreSQL version 12.14. So, the automatic minor upgrade target is PostgreSQL version 12.14, which is highlighted in the output.

A PostgreSQL database is automatically upgraded during your maintenance window if the following criteria are met:

- The database has the **Auto minor version upgrade** option enabled.
- The database is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see [Automatically upgrading the minor engine version](#).

#### Note

A PostgreSQL upgrade doesn't upgrade PostgreSQL extensions. To upgrade extensions, see [Upgrading PostgreSQL extensions](#).

## Upgrading PostgreSQL extensions

A PostgreSQL engine upgrade doesn't upgrade most PostgreSQL extensions. To update an extension after a version upgrade, use the `ALTER EXTENSION UPDATE` command.

### Note

For information about updating the PostGIS extension, see [Managing spatial data with the PostGIS extension \(Step 6: Upgrade the PostGIS extension\)](#).

To update the `pg_repack` extension, drop the extension and then create the new version in the upgraded database. For more information, see [pg\\_repack installation](#) in the `pg_repack` documentation.

To upgrade an extension, use the following command.

```
ALTER EXTENSION extension_name UPDATE TO 'new_version';
```

For the list of supported versions of PostgreSQL extensions, see [Supported PostgreSQL extension versions](#).

To list your currently installed extensions, use the PostgreSQL [pg\\_extension](#) catalog in the following command.

```
SELECT * FROM pg_extension;
```

To view a list of the specific extension versions that are available for your installation, use the PostgreSQL [pg\\_available\\_extension\\_versions](#) view in the following command.

```
SELECT * FROM pg_available_extension_versions;
```

# Upgrading a PostgreSQL DB snapshot engine version

With Amazon RDS, you can create a storage volume DB snapshot of your PostgreSQL DB instance. When you create a DB snapshot, the snapshot is based on the engine version used by your Amazon RDS instance. In addition to upgrading the DB engine version of your DB instance, you can also upgrade the engine version for your DB snapshots.

After restoring a DB snapshot upgraded to a new engine version, make sure to test that the upgrade was successful. For more information about a major version upgrade, see [Upgrading the PostgreSQL DB engine for Amazon RDS](#). To learn how to restore a DB snapshot, see [Restoring to a DB instance](#).

You can upgrade manual DB snapshots that are either encrypted or not encrypted.

For the list of engine versions that are available for upgrading a DB snapshot, see [Upgrading the PostgreSQL DB engine for Amazon RDS](#).

## Note

You can't upgrade automated DB snapshots that are created during the automated backup process.

## Console

### To upgrade a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the snapshot that you want to upgrade.
4. For **Actions**, choose **Upgrade snapshot**. The **Upgrade snapshot** page appears.
5. Choose the **New engine version** to upgrade to.
6. Choose **Save changes** to upgrade the snapshot.

During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from **available** to **upgrading**, and then changes to **active** upon

completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to **unavailable**. You can't recover the snapshot from this state.

### Note

If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

## AWS CLI

To upgrade a DB snapshot to a new database engine version, use the AWS CLI [modify-db-snapshot](#) command.

### Parameters

- `--db-snapshot-identifier` – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see [Amazon Resource Names \(ARNs\) in Amazon RDS](#).
- `--engine-version` – The engine version to upgrade the DB snapshot to.

### Example

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot \  
  --db-snapshot-identifier my_db_snapshot \  
  --engine-version new_version
```

For Windows:

```
aws rds modify-db-snapshot ^  
  --db-snapshot-identifier my_db_snapshot ^  
  --engine-version new_version
```

## RDS API

To upgrade a DB snapshot to a new database engine version, call the Amazon RDS API [ModifyDBSnapshot](#) operation.

- `DBSnapshotIdentifier` – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see [Amazon Resource Names \(ARNs\) in Amazon RDS](#).
- `EngineVersion` – The engine version to upgrade the DB snapshot to.

# Working with read replicas for Amazon RDS for PostgreSQL

You can scale reads for your Amazon RDS for PostgreSQL DB instances by adding read replicas to the instances. As with other Amazon RDS database engines, RDS for PostgreSQL uses native replication mechanisms of PostgreSQL to keep read replicas up to date with changes on the source DB. For general information about read replicas and Amazon RDS, see [Working with DB instance read replicas](#).

Following, you can find information specific to working with read replicas with RDS for PostgreSQL.

## Logical decoding on a read replica

RDS for PostgreSQL supports logical replication from standbys with PostgreSQL 16.1. This allows you to create logical decoding from a read-only standby that reduces the load on the primary DB instance. You can achieve higher-availability for your applications that need to synchronize data across multiple systems. This feature boosts the performance of your data warehouse and data analytics.

Also, replication slots on a given standby persist the promotion of that standby to a primary. This means that in the event of a primary DB instance failover or the promotion of a standby to be the new primary, the replication slots will persist and the former standby subscribers will not be affected.

### To create logical decoding on a read replica

1. **Turn on logical replication** – To create logical decoding on a standby, you must turn on logical replication on your source DB instance and its physical replica. For more information, see [Read replica configuration with PostgreSQL](#).
  - **To turn on logical replication for a newly created RDS for PostgreSQL DB instance** – Create a new DB custom parameter group and set the static parameter `rds.logical_replication` to 1. Then, associate this DB parameter group with the Source DB instance and its physical read replica. For more information, see [Associating a DB parameter group with a DB instance in Amazon RDS](#).
  - **To turn on logical replication for an existing RDS for PostgreSQL DB instance** – Modify the DB custom parameter group of the source DB instance and its physical read replica to set the static parameter `rds.logical_replication` to 1. For more information, see [Modifying parameters in a DB parameter group in Amazon RDS](#).

**Note**

You must reboot the DB instance to apply these parameter changes.

You can use the following query to verify the values for `wal_level` and `rds.logical_replication` on the source DB instance and its physical read replica.

```
Postgres=>SELECT name,setting FROM pg_settings WHERE name IN
('wal_level','rds.logical_replication');
```

name	setting
rds.logical_replication	on
wal_level	logical

(2 rows)

2. **Create a table in the source database** – Connect to the database in your source DB instance. For more information, see [Connecting to a DB instance running the PostgreSQL database engine](#).

Use the following queries to create table in your source database and to insert values:

```
Postgres=>CREATE TABLE LR_test (a int PRIMARY KEY);
CREATE TABLE
```

```
Postgres=>INSERT INTO LR_test VALUES (generate_series(1,10000));
INSERT 0 10000
```

3. **Create a publication for the source table** – Use the following query to create a publication for the table on the source DB instance.

```
Postgres=>CREATE PUBLICATION testpub FOR TABLE LR_test;
CREATE PUBLICATION
```

Use a `SELECT` query to verify the details of the publication that was created on both the source DB instance and the physical read replica instance.

```
Postgres=>SELECT * from pg_publication;

oid      | pubname | pubowner | puballtables | pubinsert | pubupdate | pubdelete |
pubtruncate | pubviaroot
-----+-----+-----+-----+-----+-----+-----+-----
16429 | testpub | 16413 | f           | t         | t         | t         |
      | f
(1 row)
```

4. **Create a subscription from logical replica instance** – Create another RDS for PostgreSQL DB instance as the logical replica instance. Make sure that VPC is setup correctly to ensure that this logical replica instance can access the physical read replica instance. For more information, see [Amazon VPC and Amazon RDS](#). If your source DB instance is idle, connectivity issues might occur and the primary doesn't send the data to standby.

```
Postgres=>CREATE SUBSCRIPTION testsub CONNECTION 'host=Physical replica host name
port=port
          dbname=source_db_name user=user password=password
PUBLICATION testpub;
NOTICE: created replication slot "testsub" on publisher
CREATE SUBSCRIPTION
```

```
Postgres=>CREATE TABLE LR_test (a int PRIMARY KEY);
CREATE TABLE
```

Use a SELECT query to verify the details of the subscription on the logical replica instance.

```
Postgres=>SELECT oid,subname,subenabled,subslotname,subpublications FROM
pg_subscription;

oid      | subname | subenabled | subslotname | subpublications
-----+-----+-----+-----+-----
16429 | testsub | t         | testsub     | {testpub}
(1 row)
postgres=> select count(*) from LR_test;
count
-----
10000
(1 row)
```

5. **Inspect logical replication slot state** – You can only see the physical replication slot on your source DB instance.

```
Postgres=>select slot_name, slot_type, confirmed_flush_lsn from
pg_replication_slots;
```

slot_name	slot_type	confirmed_flush_lsn
rds_us_west_2_db_dhqfsmo5wbbjqrn3m6b6ivdhu4	physical	

(1 row)

However, on your read replica instance, you can see the logical replication slot and the `confirmed_flush_lsn` value changes as the application actively consumes logical changes.

```
Postgres=>select slot_name, slot_type, confirmed_flush_lsn from
pg_replication_slots;
```

slot_name	slot_type	confirmed_flush_lsn
testsub	logical	0/500002F0

(1 row)

```
Postgres=>select slot_name, slot_type, confirmed_flush_lsn from
pg_replication_slots;
```

slot_name	slot_type	confirmed_flush_lsn
testsub	logical	0/5413F5C0

(1 row)

## Read replica limitations with PostgreSQL

The following are limitations for PostgreSQL read replicas:

### Note

A read replica for RDS for PostgreSQL Multi-AZ and Single-AZ DB instance running PostgreSQL version 12 and earlier, reboots automatically to apply the password rotation

during the 60 to 90 days maintenance window. If the connection from replica to source breaks before the scheduled reboot, the instance will still be rebooted for the replication to resume.

- PostgreSQL read replicas are read-only. Although a read replica isn't a writeable DB instance, you can promote it to become a standalone RDS for PostgreSQL DB instance. However, the process isn't reversible.
- You can't create a read replica from another read replica if your RDS for PostgreSQL DB instance is running a PostgreSQL version earlier than 14.1. RDS for PostgreSQL supports cascading read replicas on RDS for PostgreSQL version 14.1 and higher releases only. For more information, see [Using cascading read replicas with RDS for PostgreSQL](#).
- If you promote a PostgreSQL read replica, it becomes a writable DB instance. It stops receiving write-ahead log (WAL) files from a source DB instance, and it's no longer a read-only instance. You can create new read replicas from the promoted DB instance as you do for any RDS for PostgreSQL DB instance. For more information, see [Promoting a read replica to be a standalone DB instance](#).
- If you promote a PostgreSQL read replica from within a replication chain (a series of cascading read replicas), any existing downstream read replicas continue receiving WAL files from the promoted instance automatically. For more information, see [Using cascading read replicas with RDS for PostgreSQL](#).
- If no user transactions are running on the source DB instance, the associated PostgreSQL read replica reports a replication lag of up to five minutes. The replica lag is calculated as `currentTime - lastCommittedTransactionTimestamp`, which means that when no transactions are being processed, the value of replica lag increases for a period of time until the write-ahead log (WAL) segment switches. By default RDS for PostgreSQL switches the WAL segment every 5 minutes, which results in a transaction record and a decrease in the reported lag.
- You can't turn on automated backups for PostgreSQL read replicas for RDS for PostgreSQL versions earlier than 14.1. Automated backups for read replicas are supported for RDS for PostgreSQL 14.1 and higher versions only. For RDS for PostgreSQL 13 and earlier versions, create a snapshot from a read replica if you want a backup of it.
- Point-in-time recovery (PITR) isn't supported for read replicas. You can use PITR with a primary (writer) instance only, not a read replica. To learn more, see [Restoring a DB instance to a specified time](#).

## Read replica configuration with PostgreSQL

RDS for PostgreSQL uses PostgreSQL native streaming replication to create a read-only copy of a source DB instance. This read replica DB instance is an asynchronously created physical replica of the source DB instance. It's created by a special connection that transmits write ahead log (WAL) data from the source DB instance to the read replica. For more information, see [Streaming Replication](#) in the PostgreSQL documentation.

PostgreSQL asynchronously streams database changes to this secure connection as they're made on the source DB instance. You can encrypt communications from your client applications to the source DB instance or any read replicas by setting the `ssl` parameter to 1. For more information, see [Using SSL with a PostgreSQL DB instance](#).

PostgreSQL uses a *replication* role to perform streaming replication. The role is privileged, but you can't use it to modify any data. PostgreSQL uses a single process for handling replication.

You can create a PostgreSQL read replica without affecting operations or users of the source DB instance. Amazon RDS sets the necessary parameters and permissions for you, on the source DB instance and the read replica, without affecting the service. A snapshot is taken of the source DB instance, and this snapshot is used to create the read replica. If you delete the read replica at some point in the future, no outage occurs.

You can create up to 15 read replicas from one source DB instance within the same Region. As of RDS for PostgreSQL 14.1, you can also create up to three levels of read replica in a chain (cascade) from a source DB instance. For more information, see [Using cascading read replicas with RDS for PostgreSQL](#). In all cases, the source DB instance needs to have automated backups configured. You do this by setting the backup retention period on your DB instance to any value other than 0. For more information, see [Creating a read replica](#).

You can create read replicas for your RDS for PostgreSQL DB instance in the same AWS Region as your source DB instance. This is known as *in-Region* replication. You can also create read replicas in different AWS Regions than the source DB instance. This is known as *cross-Region* replication. For more information about setting up cross-Region read replicas, see [Creating a read replica in a different AWS Region](#). The various mechanisms supporting the replication process for in-Region and cross-Region differ slightly depending on the RDS for PostgreSQL version as explained in [How streaming replication works for different RDS for PostgreSQL versions](#).

For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, be sure to also scale the read replicas.

Amazon RDS overrides any incompatible parameters on a read replica if they prevent the read replica from starting. For example, suppose that the `max_connections` parameter value is higher on the source DB instance than on the read replica. In that case, Amazon RDS updates the parameter on the read replica to be the same value as that on the source DB instance.

RDS for PostgreSQL read replicas have access to external databases that are available through foreign data wrappers (FDWs) on the source DB instance. For example, suppose that your RDS for PostgreSQL DB instance is using the `mysql_fdw` wrapper to access data from RDS for MySQL. If so, your read replicas can also access that data. Other supported FDWs include `oracle_fdw`, `postgres_fdw`, and `tds_fdw`. For more information, see [Working with the supported foreign data wrappers for Amazon RDS for PostgreSQL](#).

## Using RDS for PostgreSQL read replicas with Multi-AZ configurations

You can create a read replica from a single-AZ or Multi-AZ DB instance. You can use Multi-AZ deployments to improve the durability and availability of critical data, with a standby replica. A *standby replica* is a dedicated read replica that can assume the workload if the source DB fails over. You can't use your standby replica to serve read traffic. However, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. To learn more about Multi-AZ deployments, see [Multi-AZ DB instance deployments](#).

If the source DB instance of a Multi-AZ deployment fails over to a standby, the associated read replicas switch to using the standby (now primary) as their replication source. The read replicas might need to restart, depending on the RDS for PostgreSQL version, as follows:

- **PostgreSQL 13 and higher versions** – Restarting isn't required. The read replicas are automatically synchronized with the new primary. However, in some cases your client application might cache Domain Name Service (DNS) details for your read replicas. If so, set the time-to-live (TTL) value to less than 30 seconds. Doing this prevents the read replica from holding on to a stale IP address (and thus, prevents it from synchronizing with the new primary). To learn more about this and other best practices, see [Amazon RDS basic operational guidelines](#).
- **PostgreSQL 12 and all earlier versions** – The read replicas restart automatically after a fail over to the standby replica because the standby (now primary) has a different IP address and a different instance name. Restarting synchronizes the read replica with the new primary.

To learn more about failover, see [Failover process for Amazon RDS](#). To learn more about how read replicas work in a Multi-AZ deployment, see [Working with DB instance read replicas](#).

To provide failover support for a read replica, you can create the read replica as a Multi-AZ DB instance so that Amazon RDS creates a standby of your replica in another Availability Zone (AZ). Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

## Using cascading read replicas with RDS for PostgreSQL

As of version 14.1, RDS for PostgreSQL supports cascading read replicas. With *cascading read replicas*, you can scale reads without adding overhead to your source RDS for PostgreSQL DB instance. Updates to the WAL log aren't sent by the source DB instance to each read replica. Instead, each read replica in a cascading series sends WAL log updates to the next read replica in the series. This reduces the burden on the source DB instance.

With cascading read replicas, your RDS for PostgreSQL DB instance sends WAL data to the first read replica in the chain. That read replica then sends WAL data to the second replica in the chain, and so on. The end result is that all read replicas in the chain have the changes from the RDS for PostgreSQL DB instance, but without the overhead solely on the source DB instance.

You can create a series of up to three read replicas in a chain from a source RDS for PostgreSQL DB instance. For example, suppose that you have an RDS for PostgreSQL 14.1 DB instance, `rpg-db-main`. You can do the following:

- Starting with `rpg-db-main`, create the first read replica in the chain, `read-replica-1`.
- Next, from `read-replica-1`, create the next read replica in the chain, `read-replica-2`.
- Finally, from `read-replica-2`, create the third read replica in the chain, `read-replica-3`.

You can't create another read replica beyond this third cascading read replica in the series for `rpg-db-main`. A complete series of instances from an RDS for PostgreSQL source DB instance through to the end of a series of cascading read replicas can consist of at most four DB instances.

For cascading read replicas to work, turn on automatic backups on your RDS for PostgreSQL. Create the read replica first and then turn on automatic backups on the RDS for PostgreSQL DB instance. The process is the same as for other Amazon RDS DB engines. For more information, see [Creating a read replica](#).

As with any read replica, you can promote a read replica that's part of a cascade. Promoting a read replica from within a chain of read replicas removes that replica from the chain. For example, suppose that you want to move some of the workload off of your `rpg-db-main` DB instance to a new instance for use by the accounting department only. Assuming the chain of three read replicas from the example, you decide to promote `read-replica-2`. The chain is affected as follows:

- Promoting `read-replica-2` removes it from the replication chain.
  - It is now a full read/write DB instance.
  - It continues replicating to `read-replica-3`, just as it was doing before promotion.
- Your `rpg-db-main` continues replicating to `read-replica-1`.

For more information about promoting read replicas, see [Promoting a read replica to be a standalone DB instance](#).

#### Note

For cascading read replicas, RDS for PostgreSQL supports 15 read replicas for each source DB instance at first level of replication, and 5 read replicas for each source DB instance at the second and third level of replication.

## Creating cross-Region cascading read replicas with RDS for PostgreSQL

RDS for PostgreSQL supports cross-Region cascading read replicas. You can create a cross-Region replica from the source DB instance, and then create same-Region replicas from it. You can also create a same-Region replica from the source DB instance, and then create cross-Region replicas from it.

### Create a cross-Region replica and then create same-Region replicas

You can use an RDS for PostgreSQL DB instance with version 14.1 or higher, `rpg-db-main`, to do the following:

1. Start with `rpg-db-main` (US-EAST-1), create the first cross-Region read replica in the chain, `read-replica-1` (US-WEST-2).
2. Using the first cross-Region `read-replica-1` (US-WEST-2), create the second read replica in the chain, `read-replica-2` (US-WEST-2).

3. Using `read-replica-2`, create the third read replica in the chain, `read-replica-3` (US-WEST-2).

### Create a same-Region replica and then create cross-Region replicas

You can use an RDS for PostgreSQL DB instance with version 14.1 or higher, `rpg-db-main`, to do the following:

1. Starting with `rpg-db-main` (US-EAST-1), create the first read replica in the chain, `read-replica-1` (US-EAST-1).
2. Using `read-replica-1` (US-EAST-1), create the first cross-Region read replica in the chain, `read-replica-2` (US-WEST-2).
3. Using `read-replica-2` (US-WEST-2), create the third read replica in the chain, `read-replica-3` (US-WEST-2).

### Limitations in creating cross-Region read replicas

- A cross-Region cascading chain of database replicas can span a maximum of two Regions, with a maximum of four levels. The four levels include the database source and three read replicas.

### Advantages of using cascading read replicas

- Improved read scalability – By distributing read queries across multiple replicas, cascading replication helps balance the load. This improves performance, especially in read-heavy applications, by reducing the strain on the writer database.
- Geographical distribution – Cascading replicas can be located in different geographic locations. This reduces latency for users located far from the primary database and provides a local read replica, enhancing performance and user experience.
- High availability and disaster recovery – In the event of a primary server failure, replicas can be promoted to primary, ensuring continuity. cascading replication further enhances this by providing multiple layers of failover options, improving the overall resilience of the system.
- Flexibility and modular growth – As the system grows, new replicas can be added at different levels without major reconfiguration of the primary database. This modular approach allows for scalable and manageable growth of the replication setup.

For more information about the advantages of using replication, see [About replication in Cloud SQL](#).

### Best practice for using cross-Region read replicas

- Before promoting a replica, create additional replicas. This will save time, and provide efficient handling of the workload.

## How streaming replication works for different RDS for PostgreSQL versions

As discussed in [Read replica configuration with PostgreSQL](#), RDS for PostgreSQL uses PostgreSQL's native streaming replication protocol to send WAL data from the source DB instance. It sends source WAL data to read replicas for both in-Region and cross-Region read replicas. With version 9.4, PostgreSQL introduced physical replication slots as a supporting mechanism for the replication process.

A *physical replication slot* prevents a source DB instance from removing WAL data before it's consumed by all read replicas. Each read replica has its own physical slot on the source DB instance. The slot keeps track of the oldest WAL (by logical sequence number, LSN) that might be needed by the replica. After all slots and DB connections have progressed beyond a given WAL (LSN), that LSN becomes a candidate for removal at the next checkpoint.

Amazon RDS uses Amazon S3 to archive WAL data. For in-Region read replicas, you can use this archived data to recover the read replica when necessary. An example of when you might do so is if the connection between source DB and read replica is interrupted for any reason.

In the following table, you can find a summary of differences between PostgreSQL versions and the supporting mechanisms for in-Region and cross-Region used by RDS for PostgreSQL.

Version	In-Region	Cross-Region
PostgreSQL 14.1 and higher versions	<ul style="list-style-type: none"> <li>• Replication slots</li> <li>• Amazon S3 archive</li> </ul>	<ul style="list-style-type: none"> <li>• Replication slots</li> </ul>
PostgreSQL 13 and lower versions	<ul style="list-style-type: none"> <li>• Amazon S3 archive</li> </ul>	<ul style="list-style-type: none"> <li>• Replication slots</li> </ul>

For more information, see [Monitoring and tuning the replication process](#).

## Understanding the parameters that control PostgreSQL replication

The following parameters affect the replication process and determine how well read replicas stay up to date with the source DB instance:

### **max\_wal\_senders**

The `max_wal_senders` parameter specifies the maximum number of connections that the source DB instance can support at the same time over the streaming replication protocol. The default for RDS for PostgreSQL 13 and higher releases is 20. This parameter should be set to slightly higher than the actual number of read replicas. If this parameter is set too low for the number of read replicas, replication stops.

For more information, see [max\\_wal\\_senders](#) in the PostgreSQL documentation.

### **wal\_keep\_segments**

The `wal_keep_segments` parameter specifies the number of write-ahead log (WAL) files that the source DB instance keeps in the `pg_wal` directory. The default setting is 32.

If `wal_keep_segments` isn't set to a large enough value for your deployment, a read replica can fall so far behind that streaming replication stops. If that happens, Amazon RDS generates a replication error and begins recovery on the read replica. It does so by replaying the source DB instance's archived WAL data from Amazon S3. This recovery process continues until the read replica has caught up enough to continue streaming replication. You can see this process in action as captured by the PostgreSQL log in [Example: How a read replica recovers from replication interruptions](#).

#### **Note**

In PostgreSQL version 13, the `wal_keep_segments` parameter is named `wal_keep_size`. It serves the same purpose as `wal_keep_segments`, but its default value is in megabytes (MB) (2048 MB) rather than the number of files. For more information, see [wal\\_keep\\_segments](#) and [wal\\_keep\\_size](#) in the PostgreSQL documentation.

## max\_slot\_wal\_keep\_size

The `max_slot_wal_keep_size` parameter controls the quantity of WAL data that the RDS for PostgreSQL DB instance retains in the `pg_wal` directory to serve slots. This parameter is used for configurations that use replication slots. The default value for this parameter is `-1`, meaning that there's no limit to how much WAL data is kept on the source DB instance. For information about monitoring your replication slots, see [Monitoring replication slots for your RDS for PostgreSQL DB instance](#).

For more information about this parameter, see [max\\_slot\\_wal\\_keep\\_size](#) in the PostgreSQL documentation.

Whenever the stream that provides WAL data to a read replica is interrupted, PostgreSQL switches into recovery mode. It restores the read replica by using archived WAL data from Amazon S3 or by using the WAL data associated with the replication slot. When this process is complete, PostgreSQL re-establishes streaming replication.

### Example: How a read replica recovers from replication interruptions

In the following example, you find the log details that demonstrate the recovery process for a read replica. The example is from an RDS for PostgreSQL DB instance running PostgreSQL version 12.9 in the same AWS Region as the source DB, so replication slots aren't used. The recovery process is the same for other RDS for PostgreSQL DB instances running PostgreSQL earlier than version 14.1 with in-Region read replicas.

When the read replica lost contact with the source DB instance, Amazon RDS records the issue in the log as `FATAL: could not receive data from WAL stream message`, along with the `ERROR: requested WAL segment ... has already been removed`. As shown in the bold line, Amazon RDS recovers the replica by replaying an archived WAL file.

```
2014-11-07 19:01:10 UTC::@[23180]:DEBUG: switched WAL source from archive to stream
after failure
2014-11-07 19:01:10 UTC::@[11575]:LOG: started streaming WAL from primary at 1A/
D3000000 on timeline 1
2014-11-07 19:01:10 UTC::@[11575]:FATAL: could not receive data from WAL stream:
ERROR: requested WAL segment 000000010000001A000000D3 has already been removed
2014-11-07 19:01:10 UTC::@[23180]:DEBUG: could not restore file "00000002.history"
from archive: return code 0
2014-11-07 19:01:15 UTC::@[23180]:DEBUG: switched WAL source from stream to archive
after failure recovering 000000010000001A000000D3
```

```
2014-11-07 19:01:16 UTC::@[23180]:LOG: restored log file "000000010000001A000000D3"
from archive
```

When Amazon RDS replays enough archived WAL data on the replica to catch up, streaming to the read replica begins again. When streaming resumes, Amazon RDS writes an entry to the log file similar to the following.

```
2014-11-07 19:41:36 UTC::@[24714]:LOG:started streaming WAL from primary at 1B/
B6000000 on timeline 1
```

## Setting the parameters that control shared memory

The parameters you set determine the size of shared memory for tracking transaction IDs, locks, and prepared transactions. **The shared memory structure of a standby instance must be equal or greater than that of a primary instance.** This ensures that the former doesn't run out of shared memory during recovery. If the parameter values on the replica are less than the parameter values on the primary, Amazon RDS will automatically adjust the replica parameters and restart the engine.

The parameters affected are:

- `max_connections`
- `max_worker_processes`
- `max_wal_senders`
- `max_prepared_transactions`
- `max_locks_per_transaction`

To avoid RDS reboots of replicas due to insufficient memory, we recommend applying the parameter changes as a rolling reboot to each replica. You must apply the following rules, when you set the parameters:

- **Increasing the parameter values:**
  - You should always increase the parameter values of all the read replicas first, and perform a rolling reboot of all replicas. Then, apply the parameter changes on the primary instance and reboot.
- **Decreasing the parameter values:**

- You should first decrease the parameter values of the primary instance and perform a reboot. Then, apply the parameter changes to all the associated read replicas and perform a rolling reboot.

## Monitoring and tuning the replication process

We strongly recommend that you routinely monitor your RDS for PostgreSQL DB instance and read replicas. You need to ensure that your read replicas are keeping up with changes on the source DB instance. Amazon RDS transparently recovers your read replicas when interruptions to the replication process occur. However, it's best to avoid needing to recover at all. Recovering using replication slots is faster than using the Amazon S3 archive, but any recovery process can affect read performance.

To determine how well your read replicas are keeping up with the source DB instance, you can do the following:

- **Check the amount of ReplicaLag between source DB instance and replicas.** *Replica lag* is the amount of time, in seconds, that a read replica lags behind its source DB instance. This metric reports the result of the following query.

```
SELECT extract(epoch from now() - pg_last_xact_replay_timestamp()) AS "ReplicaLag";
```

Replica lag is an indication of how well a read replica is keeping up with the source DB instance. It's the amount of latency between the source DB instance and a specific read instance. A high value for replica lag can indicate a mismatch between the DB instance classes or storage types (or both) used by the source DB instance and its read replicas. The DB instance class and storage types for DB source instance and all read replicas should be the same.

Replica lag can also be the result of intermittent connection issues. You can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS ReplicaLag metric. To learn more about ReplicaLag and other metrics for Amazon RDS, see [Amazon CloudWatch metrics for Amazon RDS](#).

- **Check the PostgreSQL log for information you can use to adjust your settings.** At every checkpoint, the PostgreSQL log captures the number of recycled transaction log files, as shown in the following example.

```
2014-11-07 19:59:35 UTC::@[26820]:LOG: checkpoint complete: wrote 376 buffers
(0.2%);
0 transaction log file(s) added, 0 removed, 1 recycled; write=35.681 s, sync=0.013 s,
total=35.703 s;
sync files=10, longest=0.013 s, average=0.001 s
```

You can use this information to figure out how many transaction files are being recycled in a given time period. You can then change the setting for `wal_keep_segments` if necessary. For example, suppose that the PostgreSQL log at `checkpoint complete` shows `35 recycled` for a 5-minute interval. In this case, the `wal_keep_segments` default value of 32 isn't sufficient to keep pace with the streaming activity, so you should increase the value of this parameter.

- **Use Amazon CloudWatch to monitor metrics that can predict replication issues.**

Rather than analyzing the PostgreSQL log directly, you can use Amazon CloudWatch to check metrics that have been collected. For example, you can check the value of the `TransactionLogsGeneration` metric to see how much WAL data is being generated by the source DB instance. In some cases, the workload on your DB instance might generate a large amount of WAL data. If so, you might need to change the DB instance class for your source DB instance and read replicas. Using an instance class with high (10 Gbps) network performance can reduce replica lag.

## Monitoring replication slots for your RDS for PostgreSQL DB instance

All versions of RDS for PostgreSQL use replication slots for cross-Region read replicas. RDS for PostgreSQL 14.1 and higher versions use replication slots for in-Region read replicas. In-region read replicas also use Amazon S3 to archive WAL data. In other words, if your DB instance and read replicas are running PostgreSQL 14.1 or higher, replication slots and Amazon S3 archives are both available for recovering the read replica. Recovering a read replica using its replication slot is faster than recovering from Amazon S3 archive. So, we recommend that you monitor the replication slots and related metrics.

You can view the replication slots on your RDS for PostgreSQL DB instances by querying the `pg_replication_slots` view, as follows.

```
postgres=> SELECT * FROM pg_replication_slots;
slot_name          | plugin | slot_type | datoid | database | temporary |
active | active_pid | xmin | catalog_xmin | restart_lsn | confirmed_flush_lsn |
wal_status | safe_wal_size | two_phase
```

```

-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
rds_us_west_1_db_55555555 |          | physical |          | f          | t
|      13194 |          | 23/D8000060 |          | reserved  |
          | f
(1 row)

```

The `wal_status` of `reserved` value means that the amount of WAL data held by the slot is within the bounds of the `max_wal_size` parameter. In other words, the replication slot is properly sized. Other possible status values are as follows:

- `extended` – The slot exceeds the `max_wal_size` setting, but the WAL data is retained.
- `unreserved` – The slot no longer has the all required WAL data. Some of it will be removed at the next checkpoint.
- `lost` – Some required WAL data has been removed. The slot is no longer usable.

The `unreserved` and `lost` states of the `wal_status` are seen only when `max_slot_wal_keep_size` is non-negative.

The `pg_replication_slots` view shows you the current state of your replication slots. To assess the performance of your replication slots, you can use Amazon CloudWatch and monitor the following metrics:

- **OldestReplicationSlotLag** – Lists the slot that has the most lag, that is the one that's furthest behind the primary. This lag can be associated with the read replica but also the connection.
- **TransactionLogsDiskUsage** – Shows how much storage is being used for WAL data. When a read replica lags significantly, the value of this metric can increase substantially.

To learn more about using Amazon CloudWatch and its metrics for RDS for PostgreSQL, see [Monitoring Amazon RDS metrics with Amazon CloudWatch](#). For more information about monitoring streaming replication on your RDS for PostgreSQL DB instances, see [Best practices for Amazon RDS PostgreSQL replication](#) on the *AWS Database Blog*.

## Troubleshooting for RDS for PostgreSQL read replica

Following, you can find troubleshooting ideas for some common RDS for PostgreSQL read replica issues.

### Terminate the query that causes the read replica lag

Transactions either in active or idle in transaction state that are running for a long time in the database might interfere with the WAL replication process, thereby increasing the replication lag. Therefore, be sure to monitor the runtime of these transactions with the PostgreSQL `pg_stat_activity` view.

Run a query on the primary instance similar to the following to find the process ID (PID) of the query that's running for a long time:

```
SELECT datname, pid, username, client_addr, backend_start,
xact_start, current_timestamp - xact_start AS xact_runtime, state,
backend_xmin FROM pg_stat_activity WHERE state='active';
```

```
SELECT now() - state_change as idle_in_transaction_duration, now() - xact_start as
xact_duration,*
FROM pg_stat_activity
WHERE state = 'idle in transaction'
AND xact_start is not null
ORDER BY 1 DESC;
```

After identifying the PID of the query, you can choose to end the query.

Run a query on the primary instance similar to the following to terminate the query that's running for a long time:

```
SELECT pg_terminate_backend(PID);
```

# Improving query performance for RDS for PostgreSQL with Amazon RDS Optimized Reads

You can achieve faster query processing for RDS for PostgreSQL with Amazon RDS Optimized Reads. An RDS for PostgreSQL DB instance or Multi-AZ DB cluster that uses RDS Optimized Reads can achieve up to 50% faster query processing compared to one that doesn't use it.

## Topics

- [Overview of RDS Optimized Reads in PostgreSQL](#)
- [Use cases for RDS Optimized Reads](#)
- [Best practices for RDS Optimized Reads](#)
- [Using RDS Optimized Reads](#)
- [Monitoring DB instances that use RDS Optimized Reads](#)
- [Limitations for RDS Optimized Reads in PostgreSQL](#)

## Overview of RDS Optimized Reads in PostgreSQL

Optimized Reads is available by default on RDS for PostgreSQL versions 15.2 and higher, 14.7 and higher, and 13.10 and higher.

When you use an RDS for PostgreSQL DB instance or Multi-AZ DB cluster that has RDS Optimized Reads turned on, it achieves up to 50% faster query performance using the local Non-Volatile Memory Express (NVMe) based solid state drive (SSD) block-level storage. You can achieve faster query processing by placing the temporary tables that are generated by PostgreSQL on the local storage, which reduces the traffic to Elastic Block Storage (EBS) over the network.

In PostgreSQL, temporary objects are assigned to a temporary namespace that drops automatically at the end of the session. The temporary namespace while dropping removes any objects that are session-dependent, including schema-qualified objects, such as tables, functions, operators, or even extensions.

In RDS for PostgreSQL, the `temp_tablespaces` parameter is configured for this temporary work area where the temporary objects are stored.

The following queries return the name of the tablespace and its location.

```
postgres=> show temp_tablespaces;
temp_tablespaces
-----
rds_temp_tablespace
(1 row)
```

The `rds_temp_tablespace` is a tablespace configured by RDS that points to the NVMe local storage. You can always switch back to Amazon EBS storage by modifying this parameter in the Parameter group using the AWS Management Console to point to any tablespace other than `rds_temp_tablespace`. For more information, see [Modifying parameters in a DB parameter group](#). You can also use the SET command to modify the value of the `temp_tablespaces` parameter to `pg_default` at the session level using SET command. Modifying the parameter redirects the temporary work area to Amazon EBS. Switching back to Amazon EBS helps when the local storage for your RDS instance or cluster isn't sufficient to perform a specific SQL operation.

```
postgres=> SET temp_tablespaces TO 'pg_default';
SET
```

```
postgres=> show temp_tablespaces;

temp_tablespaces
-----
pg_default
```

## Use cases for RDS Optimized Reads

The following are some use cases that can benefit from Optimized Reads:

- Analytical queries that include Common Table Expressions (CTEs), derived tables, and grouping operations.
- Read replicas that handle the unoptimized queries for an application.
- On-demand or dynamic reporting queries with complex operations such as GROUP BY and ORDER BY that can't always use appropriate indexes.
- Other workloads that use internal temporary tables.
- CREATE INDEX or REINDEX operations for sorting.

## Best practices for RDS Optimized Reads

Use the following best practices for RDS Optimized Reads:

- Add retry logic for read-only queries in case they fail because the instance store is full during the execution.
- Monitor the storage space available on the instance store with the CloudWatch metric `FreeLocalStorage`. If the instance store is reaching its limit because of the workload on the DB instance or Multi-AZ DB cluster, modify it to use a larger DB instance class.

## Using RDS Optimized Reads

When you provision an RDS for PostgreSQL DB instance with one of the NVMe based DB instance classes in a Single-AZ DB instance deployment, Multi-AZ DB instance deployment, or Multi-AZ DB cluster deployment, the DB instance automatically uses RDS Optimized Reads.

For more information about Multi-AZ deployment, see [Configuring and managing a Multi-AZ deployment](#).

To turn on RDS Optimized Reads, do one of the following:

- Create an RDS for PostgreSQL DB instance or Multi-AZ DB cluster using one of the NVMe based DB instance classes. For more information, see [Creating an Amazon RDS DB instance](#).
- Modify an existing RDS for PostgreSQL DB instance or Multi-AZ DB cluster to use one of the NVMe based DB instance classes. For more information, see [Modifying an Amazon RDS DB instance](#).

RDS Optimized Reads is available in all AWS Regions where one or more of the DB instance classes with local NVMe SSD storage are supported. For more information, see [DB instance classes](#).

To switch back to a non-optimized reads RDS instance, modify the DB instance class of your RDS instance or cluster to the similar instance class that only supports EBS storage for your database workloads. For example, if the current DB instance class is `db.r6gd.4xlarge`, choose `db.r6g.4xlarge` to switch back. For more information, see [Modifying an Amazon RDS DB instance](#).

## Monitoring DB instances that use RDS Optimized Reads

You can monitor DB instances that use RDS Optimized Reads using the following CloudWatch metrics:

- FreeLocalStorage
- ReadIOPSLocalStorage
- ReadLatencyLocalStorage
- ReadThroughputLocalStorage
- WriteIOPSLocalStorage
- WriteLatencyLocalStorage
- WriteThroughputLocalStorage

These metrics provide data about available instance store storage, IOPS, and throughput. For more information about these metrics, see [Amazon CloudWatch instance-level metrics for Amazon RDS](#).

To monitor current usage of your local storage, log in to your database using the following query:

```
SELECT
    spcname AS "Name",
    pg_catalog.pg_size_pretty(pg_catalog.pg_tablespace_size(oid)) AS "size"
FROM
    pg_catalog.pg_tablespace
WHERE
    spcname IN ('rds_temp_tablespace');
```

For more information about the temporary files and their usage, see [Managing temporary files with PostgreSQL](#).

## Limitations for RDS Optimized Reads in PostgreSQL

The following limitation apply to RDS Optimized Reads in PostgreSQL:

- Transactions can fail when the instance store is full.

## Importing data into PostgreSQL on Amazon RDS

Suppose that you have an existing PostgreSQL deployment that you want to move to Amazon RDS. The complexity of your task depends on the size of your database and the types of database objects that you're transferring. For example, consider a database that contains datasets on the order of gigabytes, along with stored procedures and triggers. Such a database is going to be more complicated than a simple database with only a few megabytes of test data and no triggers or stored procedures.

We recommend that you use native PostgreSQL database migration tools under the following conditions:

- You have a homogeneous migration, where you are migrating from a database with the same database engine as the target database.
- You are migrating an entire database.
- The native tools allow you to migrate your system with minimal downtime.

In most other cases, performing a database migration using AWS Database Migration Service (AWS DMS) is the best approach. AWS DMS can migrate databases without downtime and, for many database engines, continue ongoing replication until you are ready to switch over to the target database. You can migrate to either the same database engine or a different database engine using AWS DMS. If you are migrating to a different database engine than your source database, you can use the AWS Schema Conversion Tool (AWS SCT). You use AWS SCT to migrate schema objects that are not migrated by AWS DMS. For more information about AWS DMS, see [What is AWS Database Migration Service?](#)

Modify your DB parameter group to include the following settings *for your import only*. You should test the parameter settings to find the most efficient settings for your DB instance size. You also need to revert back to production values for these parameters after your import completes.

Modify your DB instance settings to the following:

- Disable DB instance backups (set `backup_retention` to 0).
- Disable Multi-AZ.

Modify your DB parameter group to include the following settings. You should only use these settings when importing data. You should test the parameter settings to find the most efficient

settings for your DB instance size. You also need to revert back to production values for these parameters after your import completes.

Parameter	Recommended value when importing	Description
<code>maintenance_work_mem</code>	524288, 1048576, 2097152, or 4194304 (in KB). These settings are comparable to 512 MB, 1 GB, 2 GB, and 4 GB.	The value for this setting depends on the size of your host. This parameter is used during CREATE INDEX statements and each parallel command can use this much memory. Calculate the best value so that you don't set this value so high that you run out of memory.
<code>max_wal_size</code>	256 (for version 9.6), 4096 (for versions 10 and higher)	<p>Maximum size to let the WAL grow during automatic checkpoints. Increasing this parameter can increase the amount of time needed for crash recovery. This parameter replaces <code>checkpoint_segments</code> for PostgreSQL 9.6 and later.</p> <p>For PostgreSQL version 9.6, this value is in 16 MB units. For later versions, the value is in 1 MB units. For example, in version 9.6, 128 means 128 chunks that are each 16 MB in size. In version 12.4, 2048 means 2048 chunks that are each 1 MB in size.</p>
<code>checkpoint_timeout</code>	1800	The value for this setting allows for less frequent WAL rotation.
<code>synchronous_commit</code>	Off	Disable this setting to speed up writes. Turning this parameter off can increase the risk of data loss in the event of a server crash (do not turn off <code>FSYNC</code> ).
<code>wal_buffers</code>	8192	This value is in 8 KB units. This again helps your WAL generation speed

Parameter	Recommended value when importing	Description
autovacuum	0	Disable the PostgreSQL auto vacuum parameter while you are loading data so that it doesn't use resources

Use the `pg_dump -Fc` (compressed) or `pg_restore -j` (parallel) commands with these settings.

**Note**

The PostgreSQL command `pg_dumpall` requires `super_user` permissions that are not granted when you create a DB instance, so it cannot be used for importing data.

## Topics

- [Importing a PostgreSQL database from an Amazon EC2 instance](#)
- [Using the `\copy` command to import data to a table on a PostgreSQL DB instance](#)
- [Importing data from Amazon S3 into an RDS for PostgreSQL DB instance](#)
- [Transporting PostgreSQL databases between DB instances](#)

## Importing a PostgreSQL database from an Amazon EC2 instance

If you have data in a PostgreSQL server on an Amazon EC2 instance and want to move it to a PostgreSQL DB instance, you can use the following process. The following list shows the steps to take. Each step is discussed in more detail in the following sections.

1. Create a file using `pg_dump` that contains the data to be loaded
2. Create the target DB instance
3. Use `psql` to create the database on the DB instance and load the data
4. Create a DB snapshot of the DB instance

## Step 1: Create a file using `pg_dump` that contains the data to load

The `pg_dump` utility uses the `COPY` command to create a schema and data dump of a PostgreSQL database. The dump script generated by `pg_dump` loads data into a database with the same name and recreates the tables, indexes, and foreign keys. You can use the `pg_restore` command and the `-d` parameter to restore the data to a database with a different name.

Before you create the data dump, you should query the tables to be dumped to get a row count so you can confirm the count on the target DB instance.

The following command creates a dump file called `mydb2dump.sql` for a database called `mydb2`.

```
prompt>pg_dump dbname=mydb2 -f mydb2dump.sql
```

## Step 2: Create the target DB instance

Create the target PostgreSQL DB instance using either the Amazon RDS console, AWS CLI, or API. Create the instance with the backup retention setting set to 0 and disable Multi-AZ. Doing so allows faster data import. You must create a database on the instance before you can dump the data. The database can have the same name as the database that is contained the dumped data. Alternatively, you can create a database with a different name. In this case, you use the `pg_restore` command and the `-d` parameter to restore the data into the newly named database.

For example, the following commands can be used to dump, restore, and rename a database.

```
pg_dump -Fc -v -h [endpoint of instance] -U [master username] [database]
> [database].dump
createdb [new database name]
pg_restore -v -h [endpoint of instance] -U [master username] -d [new database
name] [database].dump
```

## Step 3: Use `psql` to create the database on the DB instance and load data

You can use the same connection you used to run the `pg_dump` command to connect to the target DB instance and recreate the database. Using `psql`, you can use the master user name and master password to create the database on the DB instance

The following example uses `psql` and a dump file named `mydb2dump.sql` to create a database called `mydb2` on a PostgreSQL DB instance called `mypginstance`:

## For Linux, macOS, or Unix:

```
psql \  
-f mydb2dump.sql \  
--host mypginstance.555555555555.aws-region.rds.amazonaws.com \  
--port 8199 \  
--username myawsuser \  
--password password \  
--dbname mydb2
```

## For Windows:

```
psql ^  
-f mydb2dump.sql ^  
--host mypginstance.555555555555.aws-region.rds.amazonaws.com ^  
--port 8199 ^  
--username myawsuser ^  
--password password ^  
--dbname mydb2
```

### Note

Specify a password other than the prompt shown here as a security best practice.

## Step 4: Create a DB snapshot of the DB instance

Once you have verified that the data was loaded into your DB instance, we recommend that you create a DB snapshot of the target PostgreSQL DB instance. DB snapshots are complete backups of your DB instance that can be used to restore your DB instance to a known state. A DB snapshot taken immediately after the load protects you from having to load the data again in case of a mishap. You can also use such a snapshot to seed new DB instances. For information about creating a DB snapshot, see [Creating a DB snapshot for a Single-AZ DB instance](#).

## Using the \copy command to import data to a table on a PostgreSQL DB instance

The PostgreSQL \copy command is a meta-command available from the psql interactive client tool. You can use \copy to import data into a table on your RDS for PostgreSQL DB instance. To

use the `\copy` command, you need to first create the table structure on the target DB instance so that `\copy` has a destination for the data being copied.

You can use `\copy` to load data from a comma-separated values (CSV) file, such as one that's been exported and saved to your client workstation.

To import the CSV data to the target RDS for PostgreSQL DB instance, first connect to the target DB instance using `psql`.

```
psql --host=db-instance.111122223333.aws-region.rds.amazonaws.com --port=5432 --  
username=postgres --password --dbname=target-db
```

You then run `\copy` command with the following parameters to identify the target for the data and its format.

- `target_table` – The name of the table that should receive the data being copied from the CSV file.
- `column_list` – Column specifications for the table.
- `'filename'` – The complete path to the CSV file on your local workstation.

```
\copy target_table from '/path/to/local/filename.csv' WITH DELIMITER ',' CSV;
```

If your CSV file has column heading information, you can use this version of the command and parameters.

```
\copy target_table (column-1, column-2, column-3, ...)  
from '/path/to/local/filename.csv' WITH DELIMITER ',' CSV HEADER;
```

If the `\copy` command fails, PostgreSQL outputs error messages.

Creating a new DB instance in the Database Preview environment using `psql` command with the `\copy` meta-command as shown in the following examples. This example uses `source-table` as the source table name, `source-table.csv` as the `.csv` file, and `target-db` as the target database:

For Linux, macOS, or Unix:

```
$psql target-db \  
-U <admin user> \  
>
```

```
-p <port> \  
-h <DB instance name> \  
-c "\copy source-table from 'source-table.csv' with DELIMITER ','"
```

For Windows:

```
$psql target-db ^  
-U <admin user> ^  
-p <port> ^  
-h <DB instance name> ^  
-c "\copy source-table from 'source-table.csv' with DELIMITER ','"
```

For complete details about the `\copy` command, see the [psql](#) page in the PostgreSQL documentation, in the *Meta-Commands* section.

## Importing data from Amazon S3 into an RDS for PostgreSQL DB instance

You can import data that's been stored using Amazon Simple Storage Service into a table on an RDS for PostgreSQL DB instance. To do this, you first install the RDS for PostgreSQL `aws_s3` extension. This extension provides the functions that you use to import data from an Amazon S3 bucket. A *bucket* is an Amazon S3 container for objects and files. The data can be in a comma-separated value (CSV) file, a text file, or a compressed (gzip) file. Following, you can learn how to install the extension and how to import data from Amazon S3 into a table.

Your database must be running PostgreSQL version 10.7 or higher to import from Amazon S3 into RDS for PostgreSQL.

If you don't have data stored on Amazon S3, you need to first create a bucket and store the data. For more information, see the following topics in the *Amazon Simple Storage Service User Guide*.

- [Create a bucket](#)
- [Add an object to a bucket](#)

Cross-account import from Amazon S3 is supported. For more information, see [Granting cross-account permissions](#) in the *Amazon Simple Storage Service User Guide*.

You can use the customer managed key for encryption while importing data from S3. For more information, see [KMS keys stored in AWS KMS](#) in the *Amazon Simple Storage Service User Guide*.

**Note**

Importing data from Amazon S3 isn't supported for Aurora Serverless v1. It is supported for Aurora Serverless v2.

**Topics**

- [Installing the aws\\_s3 extension](#)
- [Overview of importing data from Amazon S3 data](#)
- [Setting up access to an Amazon S3 bucket](#)
- [Importing data from Amazon S3 to your RDS for PostgreSQL DB instance](#)
- [Function reference](#)

**Installing the aws\_s3 extension**

Before you can use Amazon S3 with your RDS for PostgreSQL DB instance, you need to install the `aws_s3` extension. This extension provides functions for importing data from an Amazon S3. It also provides functions for exporting data from an RDS for PostgreSQL DB instance to an Amazon S3 bucket. For more information, see [Exporting data from an RDS for PostgreSQL DB instance to Amazon S3](#). The `aws_s3` extension depends on some of the helper functions in the `aws_commons` extension, which is installed automatically when needed.

**To install the aws\_s3 extension**

1. Use `psql` (or `pgAdmin`) to connect to the RDS for PostgreSQL DB instance as a user that has `rds_superuser` privileges. If you kept the default name during the setup process, you connect as `postgres`.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --  
username=postgres --password
```

2. To install the extension, run the following command.

```
postgres=> CREATE EXTENSION aws_s3 CASCADE;  
NOTICE: installing required extension "aws_commons"  
CREATE EXTENSION
```

3. To verify that the extension is installed, you can use the `psql \dx` metacommand.

```

postgres=> \dx
      List of installed extensions
  Name      | Version | Schema  | Description
-----+-----+-----+-----
aws_commons | 1.2     | public  | Common data types across AWS services
aws_s3      | 1.1     | public  | AWS S3 extension for importing data from S3
plpgsql     | 1.0     | pg_catalog | PL/pgSQL procedural language
(3 rows)

```

The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

## Overview of importing data from Amazon S3 data

### To import S3 data into Amazon RDS

First, gather the details that you need to supply to the function. These include the name of the table on your RDS for PostgreSQL DB instance, and the bucket name, file path, file type, and AWS Region where the Amazon S3 data is stored. For more information, see [View an object](#) in the *Amazon Simple Storage Service User Guide*.

#### Note

Multi part data import from Amazon S3 isn't currently supported.

1. Get the name of the table into which the `aws_s3.table_import_from_s3` function is to import the data. As an example, the following command creates a table `t1` that can be used in later steps.

```

postgres=> CREATE TABLE t1
  (col1 varchar(80),
   col2 varchar(80),
   col3 varchar(80));

```

2. Get the details about the Amazon S3 bucket and the data to import. To do this, open the Amazon S3 console at <https://console.aws.amazon.com/s3/>, and choose **Buckets**. Find the bucket containing your data in the list. Choose the bucket, open its Object overview page, and then choose Properties.

Make a note of the bucket name, path, the AWS Region, and file type. You need the Amazon Resource Name (ARN) later, to set up access to Amazon S3 through an IAM role. For more more information, see [Setting up access to an Amazon S3 bucket](#). The image following shows an example.

3. You can verify the path to the data on the Amazon S3 bucket by using the AWS CLI command `aws s3 cp`. If the information is correct, this command downloads a copy of the Amazon S3 file.

```
aws s3 cp s3://amzn-s3-demo-bucket/sample_file_path ./
```

4. Set up permissions on your RDS for PostgreSQL DB instance to allow access to the file on the Amazon S3 bucket. To do so, you use either an AWS Identity and Access Management (IAM) role or security credentials. For more information, see [Setting up access to an Amazon S3 bucket](#).
5. Supply the path and other Amazon S3 object details gathered (see step 2) to the `create_s3_uri` function to construct an Amazon S3 URI object. To learn more about this function, see [aws\\_commons.create\\_s3\\_uri](#). The following is an example of constructing this object during a `psql` session.

```
postgres=> SELECT aws_commons.create_s3_uri(
  'docs-lab-store-for-rpg',
  'versions_and_jdks_listing.csv',
  'us-west-1'
) AS s3_uri \gset
```

In the next step, you pass this object (`aws_commons._s3_uri_1`) to the `aws_s3.table_import_from_s3` function to import the data to the table.

6. Invoke the `aws_s3.table_import_from_s3` function to import the data from Amazon S3 into your table. For reference information, see [aws\\_s3.table\\_import\\_from\\_s3](#). For examples, see [Importing data from Amazon S3 to your RDS for PostgreSQL DB instance](#).

## Setting up access to an Amazon S3 bucket

To import data from an Amazon S3 file, give the RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket containing the file. You provide access to an Amazon S3 bucket in one of two ways, as described in the following topics.

### Topics

- [Using an IAM role to access an Amazon S3 bucket](#)
- [Using security credentials to access an Amazon S3 bucket](#)
- [Troubleshooting access to Amazon S3](#)

### Using an IAM role to access an Amazon S3 bucket

Before you load data from an Amazon S3 file, give your RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket the file is in. This way, you don't have to manage additional credential information or provide it in the [aws\\_s3.table\\_import\\_from\\_s3](#) function call.

To do this, create an IAM policy that provides access to the Amazon S3 bucket. Create an IAM role and attach the policy to the role. Then assign the IAM role to your DB instance.

#### Note

You can't associate an IAM role with an Aurora Serverless v1 DB cluster, so the following steps don't apply.

## To give an RDS for PostgreSQL DB instance access to Amazon S3 through an IAM role

### 1. Create an IAM policy.

This policy provides the bucket and object permissions that allow your RDS for PostgreSQL DB instance to access Amazon S3.

Include in the policy the following required actions to allow the transfer of files from an Amazon S3 bucket to Amazon RDS:

- `s3:GetObject`
- `s3:ListBucket`

Include in the policy the following resources to identify the Amazon S3 bucket and objects in the bucket. This shows the Amazon Resource Name (ARN) format for accessing Amazon S3.

- `arn:aws:s3:::amzn-s3-demo-bucket`
- `arn:aws:s3:::amzn-s3-demo-bucket/*`

For more information on creating an IAM policy for RDS for PostgreSQL, see [Creating and using an IAM policy for IAM database access](#). See also [Tutorial: Create and attach your first customer managed policy](#) in the *IAM User Guide*.

The following AWS CLI command creates an IAM policy named `rds-s3-import-policy` with these options. It grants access to a bucket named `amzn-s3-demo-bucket`.

#### Note

Make a note of the Amazon Resource Name (ARN) of the policy returned by this command. You need the ARN in a subsequent step when you attach the policy to an IAM role.

### Example

For Linux, macOS, or Unix:

```
aws iam create-policy \
```

```
--policy-name rds-s3-import-policy \  
--policy-document '{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Sid": "s3import",  
      "Action": [  
        "s3:GetObject",  
        "s3:ListBucket"  
      ],  
      "Effect": "Allow",  
      "Resource": [  
        "arn:aws:s3:::amzn-s3-demo-bucket",  
        "arn:aws:s3:::amzn-s3-demo-bucket/*"  
      ]  
    }  
  ]  
}'
```

#### For Windows:

```
aws iam create-policy ^  
--policy-name rds-s3-import-policy ^  
--policy-document '{  
  "Version": "2012-10-17",  
  "Statement": [  
    {  
      "Sid": "s3import",  
      "Action": [  
        "s3:GetObject",  
        "s3:ListBucket"  
      ],  
      "Effect": "Allow",  
      "Resource": [  
        "arn:aws:s3:::amzn-s3-demo-bucket",  
        "arn:aws:s3:::amzn-s3-demo-bucket/*"  
      ]  
    }  
  ]  
}'
```

## 2. Create an IAM role.

You do this so Amazon RDS can assume this IAM role to access your Amazon S3 buckets. For more information, see [Creating a role to delegate permissions to an IAM user](#) in the *IAM User Guide*.

We recommend using the [aws:SourceArn](#) and [aws:SourceAccount](#) global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the [confused deputy problem](#).

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-import-role`.

## Example

For Linux, macOS, or Unix:

```
aws iam create-role \
  --role-name rds-s3-import-role \
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": "111122223333",
            "aws:SourceArn": "arn:aws:rds:us-east-1:111122223333:db:dbname"
          }
        }
      }
    ]
  }
```

```

    }
  }
]
}'

```

### For Windows:

```

aws iam create-role ^
  --role-name rds-s3-import-role ^
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": "111122223333",
            "aws:SourceArn": "arn:aws:rds:us-east-1:111122223333:db:dbname"
          }
        }
      }
    ]
  }'

```

3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created in the previous step to the role named `rds-s3-import-role`. Replace *your-policy-arn* with the policy ARN that you noted in an earlier step.

### Example

For Linux, macOS, or Unix:

```

aws iam attach-role-policy \
  --policy-arn your-policy-arn \
  --role-name rds-s3-import-role

```

## For Windows:

```
aws iam attach-role-policy ^
  --policy-arn your-policy-arn ^
  --role-name rds-s3-import-role
```

4. Add the IAM role to the DB instance.

You do so by using the AWS Management Console or AWS CLI, as described following.

## Console

### To add an IAM role for a PostgreSQL DB instance using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose the PostgreSQL DB instance name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the role to add under **Add IAM roles to this instance**.
4. Under **Feature**, choose **s3Import**.
5. Choose **Add role**.

## AWS CLI

### To add an IAM role for a PostgreSQL DB instance using the CLI

- Use the following command to add the role to the PostgreSQL DB instance named `my-db-instance`. Replace `your-role-arn` with the role ARN that you noted in a previous step. Use `s3Import` for the value of the `--feature-name` option.

### Example

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \  
  --db-instance-identifier my-db-instance \  
  --feature-name s3Import \  
  --role-arn your-role-arn \  
  --
```

```
--region your-region
```

For Windows:

```
aws rds add-role-to-db-instance ^  
  --db-instance-identifier my-db-instance ^  
  --feature-name s3Import ^  
  --role-arn your-role-arn ^  
  --region your-region
```

## RDS API

To add an IAM role for a PostgreSQL DB instance using the Amazon RDS API, call the [AddRoleToDBInstance](#) operation.

### Using security credentials to access an Amazon S3 bucket

If you prefer, you can use security credentials to provide access to an Amazon S3 bucket instead of providing access with an IAM role. You do so by specifying the `credentials` parameter in the [aws\\_s3.table\\_import\\_from\\_s3](#) function call.

The `credentials` parameter is a structure of type `aws_commons._aws_credentials_1`, which contains AWS credentials. Use the [aws\\_commons.create\\_aws\\_credentials](#) function to set the access key and secret key in an `aws_commons._aws_credentials_1` structure, as shown following.

```
postgres=> SELECT aws_commons.create_aws_credentials(  
  'sample_access_key', 'sample_secret_key', '')  
AS creds \gset
```

After creating the `aws_commons._aws_credentials_1` structure, use the [aws\\_s3.table\\_import\\_from\\_s3](#) function with the `credentials` parameter to import the data, as shown following.

```
postgres=> SELECT aws_s3.table_import_from_s3(  
  't', '', '(format csv)',  
  :'s3_uri',  
  :'creds'  
);
```

Or you can include the [aws\\_commons.create\\_aws\\_credentials](#) function call inline within the `aws_s3.table_import_from_s3` function call.

```
postgres=> SELECT aws_s3.table_import_from_s3(
  't', '', '(format csv)',
  :s3_uri,
  aws_commons.create_aws_credentials('sample_access_key', 'sample_secret_key', '')
);
```

## Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to import data from Amazon S3, see the following for recommendations:

- [Troubleshooting Amazon RDS identity and access](#)
- [Troubleshooting Amazon S3](#) in the *Amazon Simple Storage Service User Guide*
- [Troubleshooting Amazon S3 and IAM](#) in the *IAM User Guide*

## Importing data from Amazon S3 to your RDS for PostgreSQL DB instance

You import data from your Amazon S3 bucket by using the `table_import_from_s3` function of the `aws_s3` extension. For reference information, see [aws\\_s3.table\\_import\\_from\\_s3](#).

### Note

The following examples use the IAM role method to allow access to the Amazon S3 bucket. Thus, the `aws_s3.table_import_from_s3` function calls don't include credential parameters.

The following shows a typical example.

```
postgres=> SELECT aws_s3.table_import_from_s3(
  't1',
  '',
  '(format csv)',
  :s3_uri
);
```

The parameters are the following:

- `t1` – The name for the table in the PostgreSQL DB instance to copy the data into.
- `' '` – An optional list of columns in the database table. You can use this parameter to indicate which columns of the S3 data go in which table columns. If no columns are specified, all the columns are copied to the table. For an example of using a column list, see [Importing an Amazon S3 file that uses a custom delimiter](#).
- `(format csv)` – PostgreSQL COPY arguments. The copy process uses the arguments and format of the [PostgreSQL COPY](#) command to import the data. Choices for format include comma-separated value (CSV) as shown in this example, text, and binary. The default is text.
- `s3_uri` – A structure that contains the information identifying the Amazon S3 file. For an example of using the [aws\\_commons.create\\_s3\\_uri](#) function to create an `s3_uri` structure, see [Overview of importing data from Amazon S3 data](#).

For more information about this function, see [aws\\_s3.table\\_import\\_from\\_s3](#).

The `aws_s3.table_import_from_s3` function returns text. To specify other kinds of files for import from an Amazon S3 bucket, see one of the following examples.

 **Note**

Importing 0 bytes file will cause an error.

## Topics

- [Importing an Amazon S3 file that uses a custom delimiter](#)
- [Importing an Amazon S3 compressed \(gzip\) file](#)
- [Importing an encoded Amazon S3 file](#)

## Importing an Amazon S3 file that uses a custom delimiter

The following example shows how to import a file that uses a custom delimiter. It also shows how to control where to put the data in the database table using the `column_list` parameter of the [aws\\_s3.table\\_import\\_from\\_s3](#) function.

For this example, assume that the following information is organized into pipe-delimited columns in the Amazon S3 file.

```
1|foo1|bar1|elephant1
2|foo2|bar2|elephant2
3|foo3|bar3|elephant3
4|foo4|bar4|elephant4
...
```

## To import a file that uses a custom delimiter

1. Create a table in the database for the imported data.

```
postgres=> CREATE TABLE test (a text, b text, c text, d text, e text);
```

2. Use the following form of the [aws\\_s3.table\\_import\\_from\\_s3](#) function to import data from the Amazon S3 file.

You can include the [aws\\_commons.create\\_s3\\_uri](#) function call inline within the `aws_s3.table_import_from_s3` function call to specify the file.

```
postgres=> SELECT aws_s3.table_import_from_s3(
    'test',
    'a,b,d,e',
    'DELIMITER '|' | ''',
    aws_commons.create_s3_uri('amzn-s3-demo-bucket', 'pipeDelimitedSampleFile', 'us-
east-2')
);
```

The data is now in the table in the following columns.

```
postgres=> SELECT * FROM test;
a | b | c | d | e
---+-----+---+---+-----+-----
1 | foo1 | | bar1 | elephant1
2 | foo2 | | bar2 | elephant2
3 | foo3 | | bar3 | elephant3
4 | foo4 | | bar4 | elephant4
```

## Importing an Amazon S3 compressed (gzip) file

The following example shows how to import a file from Amazon S3 that is compressed with gzip. The file that you import needs to have the following Amazon S3 metadata:

- Key: Content-Encoding
- Value: gzip

If you upload the file using the AWS Management Console, the metadata is typically applied by the system. For information about uploading files to Amazon S3 using the AWS Management Console, the AWS CLI, or the API, see [Uploading objects](#) in the *Amazon Simple Storage Service User Guide*.

For more information about Amazon S3 metadata and details about system-provided metadata, see [Editing object metadata in the Amazon S3 console](#) in the *Amazon Simple Storage Service User Guide*.

Import the gzip file into your RDS for PostgreSQL DB instance as shown following.

```
postgres=> CREATE TABLE test_gzip(id int, a text, b text, c text, d text);
postgres=> SELECT aws_s3.table_import_from_s3(
  'test_gzip', '', '(format csv)',
  'amzn-s3-demo-bucket', 'test-data.gz', 'us-east-2'
);
```

## Importing an encoded Amazon S3 file

The following example shows how to import a file from Amazon S3 that has Windows-1252 encoding.

```
postgres=> SELECT aws_s3.table_import_from_s3(
  'test_table', '', 'encoding ''WIN1252''',
  aws_commons.create_s3_uri('amzn-s3-demo-bucket', 'SampleFile', 'us-east-2')
);
```

## Function reference

### Functions

- [aws\\_s3.table\\_import\\_from\\_s3](#)
- [aws\\_commons.create\\_s3\\_uri](#)
- [aws\\_commons.create\\_aws\\_credentials](#)

## aws\_s3.table\_import\_from\_s3

Imports Amazon S3 data into an Amazon RDS table. The `aws_s3` extension provides the `aws_s3.table_import_from_s3` function. The return value is text.

### Syntax

The required parameters are `table_name`, `column_list` and `options`. These identify the database table and specify how the data is copied into the table.

You can also use the following parameters:

- The `s3_info` parameter specifies the Amazon S3 file to import. When you use this parameter, access to Amazon S3 is provided by an IAM role for the PostgreSQL DB instance.

```
aws_s3.table_import_from_s3 (  
    table_name text,  
    column_list text,  
    options text,  
    s3_info aws_commons._s3_uri_1  
)
```

- The `credentials` parameter specifies the credentials to access Amazon S3. When you use this parameter, you don't use an IAM role.

```
aws_s3.table_import_from_s3 (  
    table_name text,  
    column_list text,  
    options text,  
    s3_info aws_commons._s3_uri_1,  
    credentials aws_commons._aws_credentials_1  
)
```

### Parameters

#### *table\_name*

A required text string containing the name of the PostgreSQL database table to import the data into.

### *column\_list*

A required text string containing an optional list of the PostgreSQL database table columns in which to copy the data. If the string is empty, all columns of the table are used. For an example, see [Importing an Amazon S3 file that uses a custom delimiter](#).

### *options*

A required text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied into the PostgreSQL table. For more details, see the [PostgreSQL COPY documentation](#).

### *s3\_info*

An `aws_commons._s3_uri_1` composite type containing the following information about the S3 object:

- `bucket` – The name of the Amazon S3 bucket containing the file.
- `file_path` – The Amazon S3 file name including the path of the file.
- `region` – The AWS Region that the file is in. For a listing of AWS Region names and associated values, see [Regions, Availability Zones, and Local Zones](#).

### *credentials*

An `aws_commons._aws_credentials_1` composite type containing the following credentials to use for the import operation:

- Access key
- Secret key
- Session token

For information about creating an `aws_commons._aws_credentials_1` composite structure, see [aws\\_commons.create\\_aws\\_credentials](#).

## **Alternate syntax**

To help with testing, you can use an expanded set of parameters instead of the `s3_info` and `credentials` parameters. Following are additional syntax variations for the `aws_s3.table_import_from_s3` function:

- Instead of using the `s3_info` parameter to identify an Amazon S3 file, use the combination of the `bucket`, `file_path`, and `region` parameters. With this form of the function, access to Amazon S3 is provided by an IAM role on the PostgreSQL DB instance.

```
aws_s3.table_import_from_s3 (  
    table_name text,  
    column_list text,  
    options text,  
    bucket text,  
    file_path text,  
    region text  
)
```

- Instead of using the `credentials` parameter to specify Amazon S3 access, use the combination of the `access_key`, `session_key`, and `session_token` parameters.

```
aws_s3.table_import_from_s3 (  
    table_name text,  
    column_list text,  
    options text,  
    bucket text,  
    file_path text,  
    region text,  
    access_key text,  
    secret_key text,  
    session_token text  
)
```

## Alternate parameters

### *bucket*

A text string containing the name of the Amazon S3 bucket that contains the file.

### *file\_path*

A text string containing the Amazon S3 file name including the path of the file.

### *region*

A text string identifying the AWS Region location of the file. For a listing of AWS Region names and associated values, see [Regions, Availability Zones, and Local Zones](#).

### *access\_key*

A text string containing the access key to use for the import operation. The default is NULL.

### *secret\_key*

A text string containing the secret key to use for the import operation. The default is NULL.

### *session\_token*

(Optional) A text string containing the session key to use for the import operation. The default is NULL.

## **aws\_commons.create\_s3\_uri**

Creates an `aws_commons._s3_uri_1` structure to hold Amazon S3 file information. Use the results of the `aws_commons.create_s3_uri` function in the `s3_info` parameter of the [aws\\_s3.table\\_import\\_from\\_s3](#) function.

### **Syntax**

```
aws_commons.create_s3_uri(  
    bucket text,  
    file_path text,  
    region text  
)
```

### **Parameters**

#### *bucket*

A required text string containing the Amazon S3 bucket name for the file.

#### *file\_path*

A required text string containing the Amazon S3 file name including the path of the file.

#### *region*

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see [Regions, Availability Zones, and Local Zones](#).

## `aws_commons.create_aws_credentials`

Sets an access key and secret key in an `aws_commons._aws_credentials_1` structure. Use the results of the `aws_commons.create_aws_credentials` function in the `credentials` parameter of the [aws\\_s3.table\\_import\\_from\\_s3](#) function.

### Syntax

```
aws_commons.create_aws_credentials(  
    access_key text,  
    secret_key text,  
    session_token text  
)
```

### Parameters

#### *access\_key*

A required text string containing the access key to use for importing an Amazon S3 file. The default is NULL.

#### *secret\_key*

A required text string containing the secret key to use for importing an Amazon S3 file. The default is NULL.

#### *session\_token*

An optional text string containing the session token to use for importing an Amazon S3 file. The default is NULL. If you provide an optional `session_token`, you can use temporary credentials.

## Transporting PostgreSQL databases between DB instances

By using PostgreSQL transportable databases for Amazon RDS, you can move a PostgreSQL database between two DB instances. This is a very fast way to migrate large databases between different DB instances. To use this approach, your DB instances must both run the same major version of PostgreSQL.

This capability requires that you install the `pg_transport` extension on both the source and the destination DB instance. The `pg_transport` extension provides a physical transport mechanism

that moves the database files with minimal processing. This mechanism moves data much faster than traditional dump and load processes, with less downtime.

### Note

PostgreSQL transportable databases are available in RDS for PostgreSQL 11.5 and higher, and RDS for PostgreSQL version 10.10 and higher.

To transport a PostgreSQL DB instance from one RDS for PostgreSQL DB instance to another, you first set up the source and destination instances as detailed in [Setting up a DB instance for transport](#). You can then transport the database by using the function described in [Transporting a PostgreSQL database](#).

## Topics

- [Limitations for using PostgreSQL transportable databases](#)
- [Setting up to transport a PostgreSQL database](#)
- [Transporting a PostgreSQL database to the destination from the source](#)
- [What happens during database transport](#)
- [Transportable databases function reference](#)
- [Transportable databases parameter reference](#)

## Limitations for using PostgreSQL transportable databases

Transportable databases have the following limitations:

- **Read replicas** – You can't use transportable databases on read replicas or parent instances of read replicas.
- **Unsupported column types** – You can't use the `reg` data types in any database tables that you plan to transport with this method. These types depend on system catalog object IDs (OIDs), which often change during transport.
- **Tablespaces** – All source database objects must be in the default `pg_default` tablespace.
- **Compatibility** – Both the source and destination DB instances must run the same major version of PostgreSQL.
- **Extensions** – The source DB instance can have only the `pg_transport` installed.

- **Roles and ACLs** – The source database's access privileges and ownership information aren't carried over to the destination database. All database objects are created and owned by the local destination user of the transport.
- **Concurrent transports** – A single DB instance can support up to 32 concurrent transports, including both imports and exports, if worker processes have been configured properly.
- **RDS for PostgreSQL DB instances only** – PostgreSQL transportable databases are supported on RDS for PostgreSQL DB instances only. You can't use it with on-premises databases or databases running on Amazon EC2.

## Setting up to transport a PostgreSQL database

Before you begin, make sure that your RDS for PostgreSQL DB instances meet the following requirements:

- The RDS for PostgreSQL DB instances for source and destination must run the same version of PostgreSQL.
- The destination DB can't have a database of the same name as the source DB that you want to transport.
- The account you use to run the transport needs `rds_superuser` privileges on both the source DB and the destination DB.
- The security group for the source DB instance must allow inbound access from the destination DB instance. This might already be the case if your source and destination DB instances are located in the VPC. For more information about security groups, see [Controlling access with security groups](#).

Transporting databases from a source DB instance to a destination DB instance requires several changes to the DB parameter group associated with each instance. That means that you must create a custom DB parameter group for the source DB instance and create a custom DB parameter group for the destination DB instance.

### Note

If your DB instances are already configured using custom DB parameter groups, you can start with step 2 in the following procedure.

## To configure the custom DB group parameters for transporting databases

For the following steps, use an account that has `rds_superuser` privileges.

1. If the source and destination DB instances use a default DB parameter group, you need to create a custom DB parameter group using the appropriate version for your instances. You do this so you can change values for several parameters. For more information, see [Parameter groups for Amazon RDS](#).
2. In the custom DB parameter group, change values for the following parameters:
  - `shared_preload_libraries` – Add `pg_transport` to the list of libraries.
  - `pg_transport.num_workers` – The default value is 3. Increase or reduce this value as needed for your database. For a 200 GB database, we recommend no larger than 8. Keep in mind that if you increase the default value for this parameter, you should also increase the value of `max_worker_processes`.
  - `pg_transport.work_mem` – The default value is either 128 MB or 256 MB, depending on the PostgreSQL version. The default setting can typically be left unchanged.
  - `max_worker_processes` – The value of this parameter needs to be set using the following calculation:

```
(3 * pg_transport.num_workers) + 9
```

This value is required on the destination to handle various background worker processes involved in the transport. To learn more about `max_worker_processes`, see [Resource Consumption](#) in the PostgreSQL documentation.

For more information about `pg_transport` parameters, see [Transportable databases parameter reference](#).

3. Reboot the source RDS for PostgreSQL DB instance and the destination instance so that the settings for the parameters take effect.
4. Connect to your RDS for PostgreSQL source DB instance.

```
psql --host=source-instance.111122223333.aws-region.rds.amazonaws.com --port=5432  
--username=postgres --password
```

5. Remove extraneous extensions from the public schema of the DB instance. Only the `pg_transport` extension is allowed during the actual transport operation.

## 6. Install the `pg_transport` extension as follows:

```
postgres=> CREATE EXTENSION pg_transport;
CREATE EXTENSION
```

## 7. Connect to your RDS for PostgreSQL destination DB instance. Remove any extraneous extensions, and then install the `pg_transport` extension.

```
postgres=> CREATE EXTENSION pg_transport;
CREATE EXTENSION
```

## Transporting a PostgreSQL database to the destination from the source

After you complete the process described in [Setting up to transport a PostgreSQL database](#), you can start the transport. To do so, run the `transport.import_from_server` function on the destination DB instance. In the syntax following you can find the function parameters.

```
SELECT transport.import_from_server(
  'source-db-instance-endpoint',
  source-db-instance-port,
  'source-db-instance-user',
  'source-user-password',
  'source-database-name',
  'destination-user-password',
  false);
```

The `false` value shown in the example tells the function that this is not a dry run. To test your transport setup, you can specify `true` for the `dry_run` option when you call the function, as shown following:

```
postgres=> SELECT transport.import_from_server(
  'docs-lab-source-db.666666666666aws-region.rds.amazonaws.com', 5432,
  'postgres', '*****', 'labdb', '*****', true);
INFO: Starting dry-run of import of database "labdb".
INFO: Created connections to remote database          (took 0.03 seconds).
INFO: Checked remote cluster compatibility          (took 0.05 seconds).
INFO: Dry-run complete                               (took 0.08 seconds total).
import_from_server
-----
```

```
(1 row)
```

The INFO lines are output because the `pg_transport.timing` parameter is set to its default value, `true`. Set the `dry_run` to `false` when you run the command and the source database is imported to the destination, as shown following:

```
INFO: Starting import of database "labdb".
INFO: Created connections to remote database          (took 0.02 seconds).
INFO: Marked remote database as read only           (took 0.13 seconds).
INFO: Checked remote cluster compatibility          (took 0.03 seconds).
INFO: Signaled creation of PITR blackout window     (took 2.01 seconds).
INFO: Applied remote database schema pre-data      (took 0.50 seconds).
INFO: Created connections to local cluster          (took 0.01 seconds).
INFO: Locked down destination database              (took 0.00 seconds).
INFO: Completed transfer of database files          (took 0.24 seconds).
INFO: Completed clean up                            (took 1.02 seconds).
INFO: Physical transport complete                   (took 3.97 seconds total).
import_from_server
-----
(1 row)
```

This function requires that you provide database user passwords. Thus, we recommend that you change the passwords of the user roles you used after transport is complete. Or, you can use SQL bind variables to create temporary user roles. Use these temporary roles for the transport and then discard the roles afterwards.

If your transport isn't successful, you might see an error message similar to the following:

```
pg_transport.num_workers=8 25% of files transported failed to download file data
```

The "failed to download file data" error message indicates that the number of worker processes isn't set correctly for the size of the database. You might need to increase or decrease the value set for `pg_transport.num_workers`. Each failure reports the percentage of completion, so you can see the impact of your changes. For example, changing the setting from 8 to 4 in one case resulted in the following:

```
pg_transport.num_workers=4 75% of files transported failed to download file data
```

Keep in mind that the `max_worker_processes` parameter is also taken into account during the transport process. In other words, you might need to modify both `pg_transport.num_workers`

and `max_worker_processes` to successfully transport the database. The example shown finally worked when the `pg_transport.num_workers` was set to 2:

```
pg_transport.num_workers=2 100% of files transported
```

For more information about the `transport.import_from_server` function and its parameters, see [Transportable databases function reference](#).

## What happens during database transport

The PostgreSQL transportable databases feature uses a pull model to import the database from the source DB instance to the destination. The `transport.import_from_server` function creates the in-transit database on the destination DB instance. The in-transit database is inaccessible on the destination DB instance for the duration of the transport.

When transport begins, all current sessions on the source database are ended. Any databases other than the source database on the source DB instance aren't affected by the transport.

The source database is put into a special read-only mode. While it's in this mode, you can connect to the source database and run read-only queries. However, write-enabled queries and some other types of commands are blocked. Only the specific source database that is being transported is affected by these restrictions.

During transport, you can't restore the destination DB instance to a point in time. This is because the transport isn't transactional and doesn't use the PostgreSQL write-ahead log to record changes. If the destination DB instance has automatic backups enabled, a backup is automatically taken after transport completes. Point-in-time restores are available for times *after* the backup finishes.

If the transport fails, the `pg_transport` extension attempts to undo all changes to the source and destination DB instances. This includes removing the destination's partially transported database. Depending on the type of failure, the source database might continue to reject write-enabled queries. If this happens, use the following command to allow write-enabled queries.

```
ALTER DATABASE db-name SET default_transaction_read_only = false;
```

## Transportable databases function reference

The `transport.import_from_server` function transports a PostgreSQL database by importing it from a source DB instance to a destination DB instance. It does this by using a physical database connection transport mechanism.

Before starting the transport, this function verifies that the source and the destination DB instances are the same version and are compatible for the migration. It also confirms that the destination DB instance has enough space for the source.

### Syntax

```
transport.import_from_server(  
    host text,  
    port int,  
    username text,  
    password text,  
    database text,  
    local_password text,  
    dry_run bool  
)
```

### Return Value

None.

### Parameters

You can find descriptions of the `transport.import_from_server` function parameters in the following table.

Parameter	Description
<code>host</code>	The endpoint of the source DB instance.
<code>port</code>	An integer representing the port of the source DB instance.  PostgreSQL DB instances often use port 5432.
<code>username</code>	The user of the source DB instance. This user must be a member of the <code>rds_superuser</code> role.

Parameter	Description
<code>password</code>	The user password of the source DB instance.
<code>database</code>	The name of the database in the source DB instance to transport.
<code>local_password</code>	The local password of the current user for the destination DB instance. This user must be a member of the <code>rds_superuser</code> role.
<code>dry_run</code>	An optional Boolean value specifying whether to perform a dry run. The default is <code>false</code> , which means the transport proceeds. To confirm compatibility between the source and destination DB instances without performing the actual transport, set <code>dry_run</code> to <code>true</code> .

## Example

For an example, see [Transporting a PostgreSQL database to the destination from the source](#).

## Transportable databases parameter reference

Several parameters control the behavior of the `pg_transport` extension. Following, you can find descriptions of these parameters.

### `pg_transport.num_workers`

The number of workers to use for the transport process. The default is 3. Valid values are 1–32. Even the largest database transports typically require fewer than 8 workers. The value of this setting on the destination DB instance is used by both destination and source during transport.

### `pg_transport.timing`

Specifies whether to report timing information during the transport. The default is `true`, meaning that timing information is reported. We recommend that you leave this parameter set to `true` so you can monitor progress. For example output, see [Transporting a PostgreSQL database to the destination from the source](#).

### `pg_transport.work_mem`

The maximum amount of memory to allocate for each worker. The default is 131072 kilobytes (KB) or 262144 KB (256 MB), depending on the PostgreSQL version. The minimum value is 64

megabytes (65536 KB). Valid values are in kilobytes (KBs) as binary base-2 units, where 1 KB = 1024 bytes.

The transport might use less memory than is specified in this parameter. Even large database transports typically require less than 256 MB (262144 KB) of memory per worker.

# Exporting data from an RDS for PostgreSQL DB instance to Amazon S3

You can query data from an RDS for PostgreSQL DB instance and export it directly into files stored in an Amazon S3 bucket. To do this, you first install the RDS for PostgreSQL `aws_s3` extension. This extension provides you with the functions that you use to export the results of queries to Amazon S3. Following, you can find out how to install the extension and how to export data to Amazon S3.

## Note

Cross-account export to Amazon S3 isn't supported.

All currently available versions of RDS for PostgreSQL support exporting data to Amazon Simple Storage Service. For detailed version information, see [Amazon RDS for PostgreSQL updates](#) in the *Amazon RDS for PostgreSQL Release Notes*.

If you don't have a bucket set up for your export, see the following topics the *Amazon Simple Storage Service User Guide*.

- [Setting up Amazon S3](#)
- [Create a bucket](#)

By default, the data exported from RDS for PostgreSQL to Amazon S3 uses server-side encryption with an AWS managed key. If you are using bucket encryption, the Amazon S3 bucket must be encrypted with an AWS Key Management Service (AWS KMS) key (SSE-KMS). Currently, buckets encrypted with Amazon S3 managed keys (SSE-S3) are not supported.

## Note

You can save DB snapshot data to Amazon S3 using the AWS Management Console, AWS CLI, or Amazon RDS API. For more information, see [Exporting DB snapshot data to Amazon S3](#).

## Topics

- [Installing the aws\\_s3 extension](#)
- [Overview of exporting data to Amazon S3](#)
- [Specifying the Amazon S3 file path to export to](#)
- [Setting up access to an Amazon S3 bucket](#)
- [Exporting query data using the aws\\_s3.query\\_export\\_to\\_s3 function](#)
- [Function reference](#)
- [Troubleshooting access to Amazon S3](#)

## Installing the aws\_s3 extension

Before you can use Amazon Simple Storage Service with your RDS for PostgreSQL DB instance, you need to install the `aws_s3` extension. This extension provides functions for exporting data from an RDS for PostgreSQL DB instance to an Amazon S3 bucket. It also provides functions for importing data from an Amazon S3. For more information, see [Importing data from Amazon S3 into an RDS for PostgreSQL DB instance](#). The `aws_s3` extension depends on some of the helper functions in the `aws_commons` extension, which is installed automatically when needed.

### To install the aws\_s3 extension

1. Use `psql` (or `pgAdmin`) to connect to the RDS for PostgreSQL DB instance as a user that has `rds_superuser` privileges. If you kept the default name during the setup process, you connect as `postgres`.

```
psql --host=111122223333.aws-region.rds.amazonaws.com --port=5432 --  
username=postgres --password
```

2. To install the extension, run the following command.

```
postgres=> CREATE EXTENSION aws_s3 CASCADE;  
NOTICE: installing required extension "aws_commons"  
CREATE EXTENSION
```

3. To verify that the extension is installed, you can use the `psql \dx` metacommand.

```
postgres=> \dx  
List of installed extensions  
Name      | Version | Schema | Description  
-----+-----+-----+-----
```

```
aws_commons | 1.2 | public | Common data types across AWS services
aws_s3      | 1.1 | public | AWS S3 extension for importing data from S3
plpgsql    | 1.0 | pg_catalog | PL/pgSQL procedural language
(3 rows)
```

The functions for importing data from Amazon S3 and exporting data to Amazon S3 are now available to use.

## Verify that your RDS for PostgreSQL version supports exports to Amazon S3

You can verify that your RDS for PostgreSQL version supports export to Amazon S3 by using the `describe-db-engine-versions` command. The following example verifies support for version 10.14.

```
aws rds describe-db-engine-versions --region us-east-1
--engine postgres --engine-version 10.14 | grep s3Export
```

If the output includes the string "s3Export", then the engine supports Amazon S3 exports. Otherwise, the engine doesn't support them.

## Overview of exporting data to Amazon S3

To export data stored in an RDS for PostgreSQL database to an Amazon S3 bucket, use the following procedure.

### To export RDS for PostgreSQL data to S3

1. Identify an Amazon S3 file path to use for exporting data. For details about this process, see [Specifying the Amazon S3 file path to export to](#).
2. Provide permission to access the Amazon S3 bucket.

To export data to an Amazon S3 file, give the RDS for PostgreSQL DB instance permission to access the Amazon S3 bucket that the export will use for storage. Doing this includes the following steps:

1. Create an IAM policy that provides access to an Amazon S3 bucket that you want to export to.
2. Create an IAM role.
3. Attach the policy you created to the role you created.

4. Add this IAM role to your DB instance.

For details about this process, see [Setting up access to an Amazon S3 bucket](#).

3. Identify a database query to get the data. Export the query data by calling the `aws_s3.query_export_to_s3` function.

After you complete the preceding preparation tasks, use the [aws\\_s3.query\\_export\\_to\\_s3](#) function to export query results to Amazon S3. For details about this process, see [Exporting query data using the aws\\_s3.query\\_export\\_to\\_s3 function](#).

## Specifying the Amazon S3 file path to export to

Specify the following information to identify the location in Amazon S3 where you want to export data to:

- Bucket name – A *bucket* is a container for Amazon S3 objects or files.

For more information on storing data with Amazon S3, see [Create a bucket](#) and [View an object](#) in the *Amazon Simple Storage Service User Guide*.

- File path – The file path identifies where the export is stored in the Amazon S3 bucket. The file path consists of the following:
  - An optional path prefix that identifies a virtual folder path.
  - A file prefix that identifies one or more files to be stored. Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_partXX` appended. The `XX` represents 2, then 3, and so on.

For example, a file path with an `exports` folder and a `query-1-export` file prefix is `exports/query-1-export`.

- AWS Region (optional) – The AWS Region where the Amazon S3 bucket is located. If you don't specify an AWS Region value, then Amazon RDS saves your files into Amazon S3 in the same AWS Region as the exporting DB instance.

### Note

Currently, the AWS Region must be the same as the region of the exporting DB instance.

For a listing of AWS Region names and associated values, see [Regions, Availability Zones, and Local Zones](#).

To hold the Amazon S3 file information about where the export is to be stored, you can use the [aws\\_commons.create\\_s3\\_uri](#) function to create an `aws_commons._s3_uri_1` composite structure as follows.

```
psql=> SELECT aws_commons.create_s3_uri(  
    'amzn-s3-demo-bucket',  
    'sample-filepath',  
    'us-west-2'  
) AS s3_uri_1 \gset
```

You later provide this `s3_uri_1` value as a parameter in the call to the [aws\\_s3.query\\_export\\_to\\_s3](#) function. For examples, see [Exporting query data using the aws\\_s3.query\\_export\\_to\\_s3 function](#).

## Setting up access to an Amazon S3 bucket

To export data to Amazon S3, give your PostgreSQL DB instance permission to access the Amazon S3 bucket that the files are to go in.

To do this, use the following procedure.

### To give a PostgreSQL DB instance access to Amazon S3 through an IAM role

1. Create an IAM policy.

This policy provides the bucket and object permissions that allow your PostgreSQL DB instance to access Amazon S3.

As part of creating this policy, take the following steps:

- a. Include in the policy the following required actions to allow the transfer of files from your PostgreSQL DB instance to an Amazon S3 bucket:
  - `s3:PutObject`
  - `s3:AbortMultipartUpload`

- b. Include the Amazon Resource Name (ARN) that identifies the Amazon S3 bucket and objects in the bucket. The ARN format for accessing Amazon S3 is: `arn:aws:s3:::amzn-s3-demo-bucket/*`

For more information on creating an IAM policy for Amazon RDS for PostgreSQL, see [Creating and using an IAM policy for IAM database access](#). See also [Tutorial: Create and attach your first customer managed policy](#) in the *IAM User Guide*.

The following AWS CLI command creates an IAM policy named `rds-s3-export-policy` with these options. It grants access to a bucket named *amzn-s3-demo-bucket*.

### Warning

We recommend that you set up your database within a private VPC that has endpoint policies configured for accessing specific buckets. For more information, see [Using endpoint policies for Amazon S3](#) in the Amazon VPC User Guide.

We strongly recommend that you do not create a policy with all-resource access. This access can pose a threat for data security. If you create a policy that gives `S3:PutObject` access to all resources using `"Resource": "*"` , then a user with export privileges can export data to all buckets in your account. In addition, the user can export data to *any publicly writable bucket within your AWS Region*.

After you create the policy, note the Amazon Resource Name (ARN) of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

```
aws iam create-policy --policy-name rds-s3-export-policy --policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "s3export",
      "Action": [
        "s3:PutObject*",
        "s3:ListBucket",
        "s3:GetObject*",
        "s3:DeleteObject*",
        "s3:GetBucketLocation",
        "s3:AbortMultipartUpload"
      ],
    }
  ],
}
```

```
    "Effect": "Allow",
    "Resource": [
      "arn:aws:s3:::amzn-s3-demo-bucket/*"
    ]
  }
]
```

## 2. Create an IAM role.

You do this so Amazon RDS can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see [Creating a role to delegate permissions to an IAM user](#) in the *IAM User Guide*.

We recommend using the [aws:SourceArn](#) and [aws:SourceAccount](#) global condition context keys in resource-based policies to limit the service's permissions to a specific resource. This is the most effective way to protect against the [confused deputy problem](#).

If you use both global condition context keys and the `aws:SourceArn` value contains the account ID, the `aws:SourceAccount` value and the account in the `aws:SourceArn` value must use the same account ID when used in the same policy statement.

- Use `aws:SourceArn` if you want cross-service access for a single resource.
- Use `aws:SourceAccount` if you want to allow any resource in that account to be associated with the cross-service use.

In the policy, be sure to use the `aws:SourceArn` global condition context key with the full ARN of the resource. The following example shows how to do so using the AWS CLI command to create a role named `rds-s3-export-role`.

### Example

For Linux, macOS, or Unix:

```
aws iam create-role \
  --role-name rds-s3-export-role \
  --assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
```

```

    "Principal": {
      "Service": "rds.amazonaws.com"
    },
    "Action": "sts:AssumeRole",
    "Condition": {
      "StringEquals": {
        "aws:SourceAccount": "111122223333",
        "aws:SourceArn": "arn:aws:rds:us-east-1:111122223333:db:dbname"
      }
    }
  }
]
}'

```

### For Windows:

```

aws iam create-role ^
  --role-name rds-s3-export-role ^
  --assume-role-policy-document '{
    "Version": "2012-10-17",
    "Statement": [
      {
        "Effect": "Allow",
        "Principal": {
          "Service": "rds.amazonaws.com"
        },
        "Action": "sts:AssumeRole",
        "Condition": {
          "StringEquals": {
            "aws:SourceAccount": "111122223333",
            "aws:SourceArn": "arn:aws:rds:us-east-1:111122223333:db:dbname"
          }
        }
      }
    ]
  }'

```

3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created earlier to the role named `rds-s3-export-role`. Replace *your-policy-arn* with the policy ARN that you noted in an earlier step.

```
aws iam attach-role-policy --policy-arn your-policy-arn --role-name rds-s3-export-role
```

4. Add the IAM role to the DB instance. You do so by using the AWS Management Console or AWS CLI, as described following.

## Console

### To add an IAM role for a PostgreSQL DB instance using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose the PostgreSQL DB instance name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the role to add under **Add IAM roles to this instance**.
4. Under **Feature**, choose **s3Export**.
5. Choose **Add role**.

## AWS CLI

### To add an IAM role for a PostgreSQL DB instance using the CLI

- Use the following command to add the role to the PostgreSQL DB instance named `my-db-instance`. Replace `your-role-arn` with the role ARN that you noted in a previous step. Use `s3Export` for the value of the `--feature-name` option.

### Example

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \  
  --db-instance-identifier my-db-instance \  
  --feature-name s3Export \  
  --role-arn your-role-arn \  
  --region your-region
```

For Windows:

```
aws rds add-role-to-db-instance ^
  --db-instance-identifier my-db-instance ^
  --feature-name s3Export ^
  --role-arn your-role-arn ^
  --region your-region
```

## Exporting query data using the `aws_s3.query_export_to_s3` function

Export your PostgreSQL data to Amazon S3 by calling the [aws\\_s3.query\\_export\\_to\\_s3](#) function.

### Topics

- [Prerequisites](#)
- [Calling `aws\_s3.query\_export\_to\_s3`](#)
- [Exporting to a CSV file that uses a custom delimiter](#)
- [Exporting to a binary file with encoding](#)

### Prerequisites

Before you use the `aws_s3.query_export_to_s3` function, be sure to complete the following prerequisites:

- Install the required PostgreSQL extensions as described in [Overview of exporting data to Amazon S3](#).
- Determine where to export your data to Amazon S3 as described in [Specifying the Amazon S3 file path to export to](#).
- Make sure that the DB instance has export access to Amazon S3 as described in [Setting up access to an Amazon S3 bucket](#).

The examples following use a database table called `sample_table`. These examples export the data into a bucket called *amzn-s3-demo-bucket*. The example table and data are created with the following SQL statements in `psql`.

```
psql=> CREATE TABLE sample_table (bid bigint PRIMARY KEY, name varchar(80));
psql=> INSERT INTO sample_table (bid,name) VALUES (1, 'Monday'), (2,'Tuesday'), (3,
'Wednesday');
```

## Calling `aws_s3.query_export_to_s3`

The following shows the basic ways of calling the [aws\\_s3.query\\_export\\_to\\_s3](#) function.

These examples use the variable `s3_uri_1` to identify a structure that contains the information identifying the Amazon S3 file. Use the [aws\\_commons.create\\_s3\\_uri](#) function to create the structure.

```
psql=> SELECT aws_commons.create_s3_uri(  
    'amzn-s3-demo-bucket',  
    'sample-filepath',  
    'us-west-2'  
) AS s3_uri_1 \gset
```

Although the parameters vary for the following two `aws_s3.query_export_to_s3` function calls, the results are the same for these examples. All rows of the `sample_table` table are exported into a bucket called *amzn-s3-demo-bucket*.

```
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM  
sample_table', :s3_uri_1);  
  
psql=> SELECT * FROM aws_s3.query_export_to_s3('SELECT * FROM  
sample_table', :s3_uri_1, options :='format text');
```

The parameters are described as follows:

- `'SELECT * FROM sample_table'` – The first parameter is a required text string containing an SQL query. The PostgreSQL engine runs this query. The results of the query are copied to the S3 bucket identified in other parameters.
- `:s3_uri_1` – This parameter is a structure that identifies the Amazon S3 file. This example uses a variable to identify the previously created structure. You can instead create the structure by including the `aws_commons.create_s3_uri` function call inline within the `aws_s3.query_export_to_s3` function call as follows.

```
SELECT * from aws_s3.query_export_to_s3('select * from sample_table',  
    aws_commons.create_s3_uri('amzn-s3-demo-bucket', 'sample-filepath', 'us-west-2')  
);
```

- `options := 'format text'` – The options parameter is an optional text string containing PostgreSQL COPY arguments. The copy process uses the arguments and format of the [PostgreSQL COPY](#) command.

If the file specified doesn't exist in the Amazon S3 bucket, it's created. If the file already exists, it's overwritten. The syntax for accessing the exported data in Amazon S3 is the following.

```
s3-region://bucket-name[/path-prefix]/file-prefix
```

Larger exports are stored in multiple files, each with a maximum size of approximately 6 GB. The additional file names have the same file prefix but with `_partXX` appended. The `XX` represents 2, then 3, and so on. For example, suppose that you specify the path where you store data files as the following.

```
s3-us-west-2://amzn-s3-demo-bucket/my-prefix
```

If the export has to create three data files, the Amazon S3 bucket contains the following data files.

```
s3-us-west-2://amzn-s3-demo-bucket/my-prefix  
s3-us-west-2://amzn-s3-demo-bucket/my-prefix_part2  
s3-us-west-2://amzn-s3-demo-bucket/my-prefix_part3
```

For the full reference for this function and additional ways to call it, see [aws\\_s3.query\\_export\\_to\\_s3](#). For more about accessing files in Amazon S3, see [View an object](#) in the *Amazon Simple Storage Service User Guide*.

## Exporting to a CSV file that uses a custom delimiter

The following example shows how to call the [aws\\_s3.query\\_export\\_to\\_s3](#) function to export data to a file that uses a custom delimiter. The example uses arguments of the [PostgreSQL COPY](#) command to specify the comma-separated value (CSV) format and a colon (:) delimiter.

```
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :s3_uri_1',  
options := 'format csv, delimiter $$:$$');
```

## Exporting to a binary file with encoding

The following example shows how to call the [aws\\_s3.query\\_export\\_to\\_s3](#) function to export data to a binary file that has Windows-1253 encoding.

```
SELECT * from aws_s3.query_export_to_s3('select * from basic_test', :s3_uri_1',
options :='format binary, encoding WIN1253');
```

## Function reference

### Functions

- [aws\\_s3.query\\_export\\_to\\_s3](#)
- [aws\\_commons.create\\_s3\\_uri](#)

### aws\_s3.query\_export\_to\_s3

Exports a PostgreSQL query result to an Amazon S3 bucket. The `aws_s3` extension provides the `aws_s3.query_export_to_s3` function.

The two required parameters are `query` and `s3_info`. These define the query to be exported and identify the Amazon S3 bucket to export to. An optional parameter called `options` provides for defining various export parameters. For examples of using the `aws_s3.query_export_to_s3` function, see [Exporting query data using the aws\\_s3.query\\_export\\_to\\_s3 function](#).

### Syntax

```
aws_s3.query_export_to_s3(  
    query text,  
    s3_info aws_commons._s3_uri_1,  
    options text,  
    kms_key text  
)
```

### Input parameters

#### *query*

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the `s3_info` parameter.

#### *s3\_info*

An `aws_commons._s3_uri_1` composite type containing the following information about the S3 object:

- `bucket` – The name of the Amazon S3 bucket to contain the file.

- `file_path` – The Amazon S3 file name and path.
- `region` – The AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see [Regions, Availability Zones, and Local Zones](#).

Currently, this value must be the same AWS Region as that of the exporting DB instance. The default is the AWS Region of the exporting DB instance.

To create an `aws_commons._s3_uri_1` composite structure, see the [aws\\_commons.create\\_s3\\_uri](#) function.

### *options*

An optional text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied when exported. For more details, see the [PostgreSQL COPY documentation](#).

## Alternate input parameters

To help with testing, you can use an expanded set of parameters instead of the `s3_info` parameter. Following are additional syntax variations for the `aws_s3.query_export_to_s3` function.

Instead of using the `s3_info` parameter to identify an Amazon S3 file, use the combination of the `bucket`, `file_path`, and `region` parameters.

```
aws_s3.query_export_to_s3(  
    query text,  
    bucket text,  
    file_path text,  
    region text,  
    options text,  
)
```

### *query*

A required text string containing an SQL query that the PostgreSQL engine runs. The results of this query are copied to an S3 bucket identified in the `s3_info` parameter.

### *bucket*

A required text string containing the name of the Amazon S3 bucket that contains the file.

### *file\_path*

A required text string containing the Amazon S3 file name including the path of the file.

### *region*

An optional text string containing the AWS Region that the bucket is in. For a listing of AWS Region names and associated values, see [Regions, Availability Zones, and Local Zones](#).

Currently, this value must be the same AWS Region as that of the exporting DB instance. The default is the AWS Region of the exporting DB instance.

### *options*

An optional text string containing arguments for the PostgreSQL COPY command. These arguments specify how the data is to be copied when exported. For more details, see the [PostgreSQL COPY documentation](#).

## Output parameters

```
aws_s3.query_export_to_s3(  
    OUT rows_uploaded bigint,  
    OUT files_uploaded bigint,  
    OUT bytes_uploaded bigint  
)
```

### *rows\_uploaded*

The number of table rows that were successfully uploaded to Amazon S3 for the given query.

### *files\_uploaded*

The number of files uploaded to Amazon S3. Files are created in sizes of approximately 6 GB. Each additional file created has `_partXX` appended to the name. The `XX` represents 2, then 3, and so on as needed.

### *bytes\_uploaded*

The total number of bytes uploaded to Amazon S3.

## Examples

```
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'amzn-s3-demo-bucket', 'sample-filepath');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'amzn-s3-demo-bucket', 'sample-filepath', 'us-west-2');
psql=> SELECT * from aws_s3.query_export_to_s3('select * from sample_table', 'amzn-s3-demo-bucket', 'sample-filepath', 'us-west-2', 'format text');
```

## aws\_commons.create\_s3\_uri

Creates an `aws_commons._s3_uri_1` structure to hold Amazon S3 file information. You use the results of the `aws_commons.create_s3_uri` function in the `s3_info` parameter of the [aws\\_s3.query\\_export\\_to\\_s3](#) function. For an example of using the `aws_commons.create_s3_uri` function, see [Specifying the Amazon S3 file path to export to](#).

## Syntax

```
aws_commons.create_s3_uri(  
    bucket text,  
    file_path text,  
    region text  
)
```

## Input parameters

### *bucket*

A required text string containing the Amazon S3 bucket name for the file.

### *file\_path*

A required text string containing the Amazon S3 file name including the path of the file.

### *region*

A required text string containing the AWS Region that the file is in. For a listing of AWS Region names and associated values, see [Regions, Availability Zones, and Local Zones](#).

## Troubleshooting access to Amazon S3

If you encounter connection problems when attempting to export data to Amazon S3, first confirm that the outbound access rules for the VPC security group associated with your DB instance permit network connectivity. Specifically, the security group must have a rule that allows the DB instance to send TCP traffic to port 443 and to any IPv4 addresses (0.0.0.0/0). For more information, see [Provide access to your DB instance in your VPC by creating a security group](#).

See also the following for recommendations:

- [Troubleshooting Amazon RDS identity and access](#)
- [Troubleshooting Amazon S3](#) in the *Amazon Simple Storage Service User Guide*
- [Troubleshooting Amazon S3 and IAM](#) in the *IAM User Guide*

# Invoking an AWS Lambda function from an RDS for PostgreSQL DB instance

AWS Lambda is an event-driven compute service that lets you run code without provisioning or managing servers. It's available for use with many AWS services, including RDS for PostgreSQL. For example, you can use Lambda functions to process event notifications from a database, or to load data from files whenever a new file is uploaded to Amazon S3. To learn more about Lambda, see [What is AWS Lambda?](#) in the *AWS Lambda Developer Guide*.

## Note

Invoking an AWS Lambda function is supported in these RDS for PostgreSQL versions:

- All PostgreSQL 16 versions
- All PostgreSQL 15 versions
- PostgreSQL 14.1 and higher minor versions
- PostgreSQL 13.2 and higher minor versions
- PostgreSQL 12.6 and higher minor versions

Setting up RDS for PostgreSQL to work with Lambda functions is a multi-step process involving AWS Lambda, IAM, your VPC, and your RDS for PostgreSQL DB instance. Following, you can find summaries of the necessary steps.

For more information about Lambda functions, see [Getting started with Lambda](#) and [AWS Lambda foundations](#) in the *AWS Lambda Developer Guide*.

## Topics

- [Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda](#)
- [Step 2: Configure IAM for your RDS for PostgreSQL DB instance and AWS Lambda](#)
- [Step 3: Install the aws\\_lambda extension for an RDS for PostgreSQL DB instance](#)
- [Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance \(Optional\)](#)
- [Step 5: Invoke a Lambda function from your RDS for PostgreSQL DB instance](#)
- [Step 6: Grant other users permission to invoke Lambda functions](#)

- [Examples: Invoking Lambda functions from your RDS for PostgreSQL DB instance](#)
- [Lambda function error messages](#)
- [AWS Lambda function and parameter reference](#)

## Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda

Lambda functions always run inside an Amazon VPC that's owned by the AWS Lambda service. Lambda applies network access and security rules to this VPC and it maintains and monitors the VPC automatically. Your RDS for PostgreSQL DB instance sends network traffic to the Lambda service's VPC. How you configure this depends on whether your DB instance is public or private.

- **Public RDS for PostgreSQL DB instance** – A DB instance is public if it's located in a public subnet on your VPC, and if the instance's "PubliclyAccessible" property is `true`. To find the value of this property, you can use the [describe-db-instances](#) AWS CLI command. Or, you can use the AWS Management Console to open the **Connectivity & security** tab and check that **Publicly accessible** is **Yes**. To verify that the instance is in the public subnet of your VPC, you can use the AWS Management Console or the AWS CLI.

To set up access to Lambda, you use the AWS Management Console or the AWS CLI to create an outbound rule on your VPC's security group. The outbound rule specifies that TCP can use port 443 to send packets to any IPv4 addresses (0.0.0.0/0).

- **Private RDS for PostgreSQL DB instance** – In this case, the instance's "PubliclyAccessible" property is `false` or it's in a private subnet. To allow the instance to work with Lambda, you can use a Network Address Translation) NAT gateway. For more information, see [NAT gateways](#). Or, you can configure your VPC with a VPC endpoint for Lambda. For more information, see [VPC endpoints](#) in the *Amazon VPC User Guide*. The endpoint responds to calls made by your RDS for PostgreSQL DB instance to your Lambda functions. The VPC endpoint uses its own private DNS resolution. RDS for PostgreSQL can't use the Lambda VPC endpoint until you change the value of the `rds.custom_dns_resolution` from its default value of 0 (not enabled) to 1. To do so:
  - Create a custom DB parameter group.
  - Change the value of the `rds.custom_dns_resolution` parameter from its default of 0 to 1.
  - Modify your DB instance to use your custom DB parameter group.
  - Reboot the instance to have the modified parameter take effect.

Your VPC can now interact with the AWS Lambda VPC at the network level. Next, you configure the permissions using IAM.

## Step 2: Configure IAM for your RDS for PostgreSQL DB instance and AWS Lambda

Invoking Lambda functions from your RDS for PostgreSQL DB instance requires certain privileges. To configure the necessary privileges, we recommend that you create an IAM policy that allows invoking Lambda functions, assign that policy to a role, and then apply the role to your DB instance. This approach gives the DB instance privileges to invoke the specified Lambda function on your behalf. The following steps show you how to do this using the AWS CLI.

### To configure IAM permissions for using your Amazon RDS instance with Lambda

1. Use the [create-policy](#) AWS CLI command to create an IAM policy that allows your RDS for PostgreSQL DB instance to invoke the specified Lambda function. (The statement ID (Sid) is an optional description for your policy statement and has no effect on usage.) This policy gives your DB instance the minimum permissions needed to invoke the specified Lambda function.

```
aws iam create-policy --policy-name rds-lambda-policy --policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "AllowAccessToExampleFunction",
      "Effect": "Allow",
      "Action": "lambda:InvokeFunction",
      "Resource": "arn:aws:lambda:aws-region:444455556666:function:my-function"
    }
  ]
}'
```

Alternatively, you can use the predefined `AWSLambdaRole` policy that allows you to invoke any of your Lambda functions. For more information, see [Identity-based IAM policies for Lambda](#)

2. Use the [create-role](#) AWS CLI command to create an IAM role that the policy can assume at runtime.

```
aws iam create-role --role-name rds-lambda-role --assume-role-policy-document '{
  "Version": "2012-10-17",
  "Statement": [
    {
```

```
    "Effect": "Allow",
    "Principal": {
      "Service": "rds.amazonaws.com"
    },
    "Action": "sts:AssumeRole"
  }
]
```

3. Apply the policy to the role by using the [attach-role-policy](#) AWS CLI command.

```
aws iam attach-role-policy \
  --policy-arn arn:aws:iam::444455556666:policy/rds-lambda-policy \
  --role-name rds-lambda-role --region aws-region
```

4. Apply the role to your RDS for PostgreSQL DB instance by using the [add-role-to-db-instance](#) AWS CLI command. This last step allows your DB instance's database users to invoke Lambda functions.

```
aws rds add-role-to-db-instance \
  --db-instance-identifier my-instance-name \
  --feature-name Lambda \
  --role-arn arn:aws:iam::444455556666:role/rds-lambda-role \
  --region aws-region
```

With the VPC and the IAM configurations complete, you can now install the `aws_lambda` extension. (Note that you can install the extension at any time, but until you set up the correct VPC support and IAM privileges, the `aws_lambda` extension adds nothing to your RDS for PostgreSQL DB instance's capabilities.)

### Step 3: Install the `aws_lambda` extension for an RDS for PostgreSQL DB instance

To use AWS Lambda with your RDS for PostgreSQL DB instance, add the `aws_lambda` PostgreSQL extension to your RDS for PostgreSQL DB instance. This extension provides your RDS for PostgreSQL DB instance with the ability to call Lambda functions from PostgreSQL.

## To install the `aws_lambda` extension in your RDS for PostgreSQL DB instance

Use the PostgreSQL `psql` command-line or the pgAdmin tool to connect to your RDS for PostgreSQL DB instance.

1. Connect to your RDS for PostgreSQL DB instance as a user with `rds_superuser` privileges. The default `postgres` user is shown in the example.

```
psql -h instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
```

2. Install the `aws_lambda` extension. The `aws_commons` extension is also required. It provides helper functions to `aws_lambda` and many other Aurora extensions for PostgreSQL. If it's not already on your RDS for PostgreSQLDB instance, it's installed with `aws_lambda` as shown following.

```
CREATE EXTENSION IF NOT EXISTS aws_lambda CASCADE;  
NOTICE: installing required extension "aws_commons"  
CREATE EXTENSION
```

The `aws_lambda` extension is installed in your DB instance. You can now create convenience structures for invoking your Lambda functions.

## Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance (Optional)

You can use the helper functions in the `aws_commons` extension to prepare entities that you can more easily invoke from PostgreSQL. To do this, you need to have the following information about your Lambda functions:

- **Function name** – The name, Amazon Resource Name (ARN), version, or alias of the Lambda function. The IAM policy created in [Step 2: Configure IAM for your instance and Lambda](#) requires the ARN, so we recommend that you use your function's ARN.
- **AWS Region** – (Optional) The AWS Region where the Lambda function is located if it's not in the same Region as your RDS for PostgreSQL DB instance.

To hold the Lambda function name information, you use the [aws\\_commons.create\\_lambda\\_function\\_arn](#) function. This helper function creates an

`aws_commons._lambda_function_arn_1` composite structure with the details needed by the `invoke` function. Following, you can find three alternative approaches to setting up this composite structure.

```
SELECT aws_commons.create_lambda_function_arn(  
    'my-function',  
    'aws-region'  
) AS aws_lambda_arn_1 \gset
```

```
SELECT aws_commons.create_lambda_function_arn(  
    '111122223333:function:my-function',  
    'aws-region'  
) AS lambda_partial_arn_1 \gset
```

```
SELECT aws_commons.create_lambda_function_arn(  
    'arn:aws:lambda:aws-region:111122223333:function:my-function'  
) AS lambda_arn_1 \gset
```

Any of these values can be used in calls to the [aws\\_lambda.invoke](#) function. For examples, see [Step 5: Invoke a Lambda function from your RDS for PostgreSQL DB instance](#).

## Step 5: Invoke a Lambda function from your RDS for PostgreSQL DB instance

The `aws_lambda.invoke` function behaves synchronously or asynchronously, depending on the `invocation_type`. The two alternatives for this parameter are `RequestResponse` (the default) and `Event`, as follows.

- **RequestResponse** – This invocation type is *synchronous*. It's the default behavior when the call is made without specifying an invocation type. The response payload includes the results of the `aws_lambda.invoke` function. Use this invocation type when your workflow requires receiving results from the Lambda function before proceeding.
- **Event** – This invocation type is *asynchronous*. The response doesn't include a payload containing results. Use this invocation type when your workflow doesn't need a result from the Lambda function to continue processing.

As a simple test of your setup, you can connect to your DB instance using `psql` and invoke an example function from the command line. Suppose that you have one of the basic functions set up on your Lambda service, such as the simple Python function shown in the following screenshot.

## To invoke an example function

1. Connect to your DB instance using `psql` or pgAdmin.

```
psql -h instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
```

2. Invoke the function using its ARN.

```

SELECT * from
  aws_lambda.invoke(aws_commons.create_lambda_function_arn('arn:aws:lambda:aws-
region:444455556666:function:simple', 'us-west-1'), '{"body": "Hello from
Postgres!}':::json );

```

The response looks as follows.

```

status_code |                               payload                               |
executed_version | log_result
-----+-----
+-----+-----
          200 | {"statusCode": 200, "body": "\"Hello from Lambda!\""} | $LATEST
|
(1 row)

```

If your invocation attempt doesn't succeed, see [Lambda function error messages](#).

## Step 6: Grant other users permission to invoke Lambda functions

At this point in the procedures, only you as `rds_superuser` can invoke your Lambda functions. To allow other users to invoke any functions that you create, you need to grant them permission.

### To grant others permission to invoke Lambda functions

1. Connect to your DB instance using `psql` or `pgAdmin`.

```
psql -h instance.444455556666.aws-region.rds.amazonaws.com -U postgres -p 5432
```

2. Run the following SQL commands:

```
postgres=> GRANT USAGE ON SCHEMA aws_lambda TO db_username;  
GRANT EXECUTE ON ALL FUNCTIONS IN SCHEMA aws_lambda TO db_username;
```

## Examples: Invoking Lambda functions from your RDS for PostgreSQL DB instance

Following, you can find several examples of calling the [aws\\_lambda.invoke](#) function. Most of the examples use the composite structure `aws_lambda_arn_1` that you create in [Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance \(Optional\)](#) to simplify passing the function details. For an example of asynchronous invocation, see [Example: Asynchronous \(Event\) invocation of Lambda functions](#). All the other examples listed use synchronous invocation.

To learn more about Lambda invocation types, see [Invoking Lambda functions](#) in the *AWS Lambda Developer Guide*. For more information about `aws_lambda_arn_1`, see [aws\\_commons.create\\_lambda\\_function\\_arn](#).

### Examples list

- [Example: Synchronous \(RequestResponse\) invocation of Lambda functions](#)
- [Example: Asynchronous \(Event\) invocation of Lambda functions](#)
- [Example: Capturing the Lambda execution log in a function response](#)
- [Example: Including client context in a Lambda function](#)
- [Example: Invoking a specific version of a Lambda function](#)

## Example: Synchronous (RequestResponse) invocation of Lambda functions

Following are two examples of a synchronous Lambda function invocation. The results of these `aws_lambda.invoke` function calls are the same.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json);
```

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json, 'RequestResponse');
```

The parameters are described as follows:

- `'aws_lambda_arn_1'` – This parameter identifies the composite structure created in [Step 4: Use Lambda helper functions with your RDS for PostgreSQL DB instance \(Optional\)](#), with the `aws_commons.create_lambda_function_arn` helper function. You can also create this structure inline within your `aws_lambda.invoke` call as follows.

```
SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-function', 'aws-region'), '{"body": "Hello from Postgres!"}'::json);
```

- `'{"body": "Hello from PostgreSQL!"}'::json` – The JSON payload to pass to the Lambda function.
- `'RequestResponse'` – The Lambda invocation type.

## Example: Asynchronous (Event) invocation of Lambda functions

Following is an example of an asynchronous Lambda function invocation. The Event invocation type schedules the Lambda function invocation with the specified input payload and returns immediately. Use the Event invocation type in certain workflows that don't depend on the results of the Lambda function.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from Postgres!"}'::json, 'Event');
```

## Example: Capturing the Lambda execution log in a function response

You can include the last 4 KB of the execution log in the function response by using the `log_type` parameter in your `aws_lambda.invoke` function call. By default, this parameter is set to `None`, but you can specify `Tail` to capture the results of the Lambda execution log in the response, as shown following.

```
SELECT *, select convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM
aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':::json,
'RequestResponse', 'Tail');
```

Set the [aws\\_lambda.invoke](#) function's `log_type` parameter to `Tail` to include the execution log in the response. The default value for the `log_type` parameter is `None`.

The `log_result` that's returned is a base64 encoded string. You can decode the contents using a combination of the `decode` and `convert_from` PostgreSQL functions.

For more information about `log_type`, see [aws\\_lambda.invoke](#).

## Example: Including client context in a Lambda function

The `aws_lambda.invoke` function has a `context` parameter that you can use to pass information separate from the payload, as shown following.

```
SELECT *, convert_from(decode(log_result, 'base64'), 'utf-8') as log FROM
aws_lambda.invoke(:'aws_lambda_arn_1', '{"body": "Hello from Postgres!"}':::json,
'RequestResponse', 'Tail');
```

To include client context, use a JSON object for the [aws\\_lambda.invoke](#) function's `context` parameter.

For more information about the `context` parameter, see the [aws\\_lambda.invoke](#) reference.

## Example: Invoking a specific version of a Lambda function

You can specify a particular version of a Lambda function by including the `qualifier` parameter with the `aws_lambda.invoke` call. Following, you can find an example that does this using `'custom_version'` as an alias for the version.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from
Postgres!"}':::json, 'RequestResponse', 'None', NULL, 'custom_version');
```

You can also supply a Lambda function qualifier with the function name details instead, as follows.

```
SELECT * FROM aws_lambda.invoke(aws_commons.create_lambda_function_arn('my-  
function:custom_version', 'us-west-2'),  
'{"body": "Hello from Postgres!"}'::json);
```

For more information about `qualifier` and other parameters, see the [aws\\_lambda.invoke](#) reference.

## Lambda function error messages

In the following list you can find information about error messages, with possible causes and solutions.

- **VPC configuration issues**

VPC configuration issues can raise the following error messages when trying to connect:

```
ERROR: invoke API failed  
DETAIL: AWS Lambda client returned 'Unable to connect to endpoint'.  
CONTEXT: SQL function "invoke" statement 1
```

A common cause for this error is improperly configured VPC security group. Make sure you have an outbound rule for TCP open on port 443 of your VPC security group so that your VPC can connect to the Lambda VPC.

If your DB instance is private, check the private DNS setup for your VPC. Make sure that you set the `rds.custom_dns_resolution` parameter to 1 and setup AWS PrivateLink as outlined in [Step 1: Configure your RDS for PostgreSQL DB instance for outbound connections to AWS Lambda](#). For more information, see [Interface VPC endpoints \(AWS PrivateLink\)](#).

- **Lack of permissions needed to invoke Lambda functions**

If you see either of the following error messages, the user (role) invoking the function doesn't have proper permissions.

```
ERROR: permission denied for schema aws_lambda
```

```
ERROR: permission denied for function invoke
```

A user (role) must be given specific grants to invoke Lambda functions. For more information, see [Step 6: Grant other users permission to invoke Lambda functions](#).

- **Improper handling of errors in your Lambda functions**

If a Lambda function throws an exception during request processing, `aws_lambda.invoke` fails with a PostgreSQL error such as the following.

```
SELECT * FROM aws_lambda.invoke('aws_lambda_arn_1', '{"body": "Hello from
Postgres!"} '::json);
ERROR:  lambda invocation failed
DETAIL:  "arn:aws:lambda:us-west-2:555555555555:function:my-function" returned error
"Unhandled", details: "<Error details string>".
```

Be sure to handle errors in your Lambda functions or in your PostgreSQL application.

## AWS Lambda function and parameter reference

Following is the reference for the functions and parameters to use for invoking Lambda with RDS for PostgreSQL.

### Functions and parameters

- [aws\\_lambda.invoke](#)
- [aws\\_commons.create\\_lambda\\_function\\_arn](#)
- [aws\\_lambda.parameters](#)

### aws\_lambda.invoke

Runs a Lambda function for an RDS for PostgreSQL DB instance.

For more details about invoking Lambda functions, see also [Invoke](#) in the *AWS Lambda Developer Guide*.

### Syntax

#### JSON

```
aws_lambda.invoke(
```

```
IN function_name TEXT,  
IN payload JSON,  
IN region TEXT DEFAULT NULL,  
IN invocation_type TEXT DEFAULT 'RequestResponse',  
IN log_type TEXT DEFAULT 'None',  
IN context JSON DEFAULT NULL,  
IN qualifier VARCHAR(128) DEFAULT NULL,  
OUT status_code INT,  
OUT payload JSON,  
OUT executed_version TEXT,  
OUT log_result TEXT)
```

```
aws_lambda.invoke(  
IN function_name aws_commons._lambda_function_arn_1,  
IN payload JSON,  
IN invocation_type TEXT DEFAULT 'RequestResponse',  
IN log_type TEXT DEFAULT 'None',  
IN context JSON DEFAULT NULL,  
IN qualifier VARCHAR(128) DEFAULT NULL,  
OUT status_code INT,  
OUT payload JSON,  
OUT executed_version TEXT,  
OUT log_result TEXT)
```

## JSONB

```
aws_lambda.invoke(  
IN function_name TEXT,  
IN payload JSONB,  
IN region TEXT DEFAULT NULL,  
IN invocation_type TEXT DEFAULT 'RequestResponse',  
IN log_type TEXT DEFAULT 'None',  
IN context JSONB DEFAULT NULL,  
IN qualifier VARCHAR(128) DEFAULT NULL,  
OUT status_code INT,  
OUT payload JSONB,  
OUT executed_version TEXT,  
OUT log_result TEXT)
```

```
aws_lambda.invoke(  
IN function_name aws_commons._lambda_function_arn_1,  
IN payload JSONB,
```

```
IN invocation_type TEXT DEFAULT 'RequestResponse',
IN log_type TEXT DEFAULT 'None',
IN context JSONB DEFAULT NULL,
IN qualifier VARCHAR(128) DEFAULT NULL,
OUT status_code INT,
OUT payload JSONB,
OUT executed_version TEXT,
OUT log_result TEXT
)
```

## Input parameters

### *function\_name*

The identifying name of the Lambda function. The value can be the function name, an ARN, or a partial ARN. For a listing of possible formats, see [Lambda function name formats](#) in the *AWS Lambda Developer Guide*.

### *payload*

The input for the Lambda function. The format can be JSON or JSONB. For more information, see [JSON Types](#) in the PostgreSQL documentation.

### *region*

(Optional) The Lambda Region for the function. By default, RDS resolves the AWS Region from the full ARN in the `function_name` or it uses the RDS for PostgreSQL DB instance Region. If this Region value conflicts with the one provided in the `function_name` ARN, an error is raised.

### *invocation\_type*

The invocation type of the Lambda function. The value is case-sensitive. Possible values include the following:

- `RequestResponse` – The default. This type of invocation for a Lambda function is synchronous and returns a response payload in the result. Use the `RequestResponse` invocation type when your workflow depends on receiving the Lambda function result immediately.
- `Event` – This type of invocation for a Lambda function is asynchronous and returns immediately without a returned payload. Use the `Event` invocation type when you don't need results of the Lambda function before your workflow moves on.
- `DryRun` – This type of invocation tests access without running the Lambda function.

### *log\_type*

The type of Lambda log to return in the `log_result` output parameter. The value is case-sensitive. Possible values include the following:

- `Tail` – The returned `log_result` output parameter will include the last 4 KB of the execution log.
- `None` – No Lambda log information is returned.

### *context*

Client context in JSON or JSONB format. Fields to use include `custom` and `env`.

### *qualifier*

A qualifier that identifies a Lambda function's version to be invoked. If this value conflicts with one provided in the `function_name` ARN, an error is raised.

## Output parameters

### *status\_code*

An HTTP status response code. For more information, see [Lambda Invoke response elements](#) in the *AWS Lambda Developer Guide*.

### *payload*

The information returned from the Lambda function that ran. The format is in JSON or JSONB.

### *executed\_version*

The version of the Lambda function that ran.

### *log\_result*

The execution log information returned if the `log_type` value is `Tail` when the Lambda function was invoked. The result contains the last 4 KB of the execution log encoded in Base64.

## **aws\_commons.create\_lambda\_function\_arn**

Creates an `aws_commons._lambda_function_arn_1` structure to hold Lambda function name information. You can use the results of the `aws_commons.create_lambda_function_arn` function in the `function_name` parameter of the `aws_lambda.invoke` [aws\\_lambda.invoke](#) function.

## Syntax

```
aws_commons.create_lambda_function_arn(
    function_name TEXT,
    region TEXT DEFAULT NULL
)
RETURNS aws_commons._lambda_function_arn_1
```

### Input parameters

#### *function\_name*

A required text string containing the Lambda function name. The value can be a function name, a partial ARN, or a full ARN.

#### *region*

An optional text string containing the AWS Region that the Lambda function is in. For a listing of Region names and associated values, see [Regions, Availability Zones, and Local Zones](#).

### aws\_lambda parameters

In this table, you can find parameters associated with the `aws_lambda` function.

Parameter	Description
<code>aws_lambda.connect_timeout_ms</code>	This is a dynamic parameter and it sets the maximum wait time while connecting to AWS Lambda. The default values is 1000. Allowed values for this parameter are 1 - 900000.
<code>aws_lambda.request_timeout_ms</code>	This is a dynamic parameter and it sets the maximum wait time while waiting for response from AWS Lambda. The default values is 3000. Allowed values for this parameter are 1 - 900000.
<code>aws_lambda.endpoint_override</code>	Specifies the endpoint that can be used to connect to AWS Lambda. An empty string selects the default AWS Lambda endpoint for the region. You must restart the database for this static parameter change to take effect.

# Common DBA tasks for Amazon RDS for PostgreSQL

Database administrators (DBAs) perform a variety of tasks when administering an Amazon RDS for PostgreSQL DB instance. If you're a DBA already familiar with PostgreSQL, you need to be aware of some of the important differences between running PostgreSQL on your hardware and RDS for PostgreSQL. For example, because it's a managed service, Amazon RDS doesn't allow shell access to your DB instances. That means that you don't have direct access to `pg_hba.conf` and other configuration files. For RDS for PostgreSQL, changes that are typically made to the PostgreSQL configuration file of an on-premises instance are made to a custom DB parameter group associated with the RDS for PostgreSQL DB instance. For more information, see [Parameter groups for Amazon RDS](#).

You also can't access log files in the same way that you do with an on-premises PostgreSQL instance. To learn more about logging, see [RDS for PostgreSQL database log files](#).

As another example, you don't have access to the PostgreSQL `superuser` account. On RDS for PostgreSQL, the `rds_superuser` role is the most highly privileged role, and it's granted to `postgres` at set up time. Whether you're familiar with using PostgreSQL on-premises or completely new to RDS for PostgreSQL, we recommend that you understand the `rds_superuser` role, and how to work with roles, users, groups, and permissions. For more information, see [Understanding PostgreSQL roles and permissions](#).

Following are some common DBA tasks for RDS for PostgreSQL.

## Topics

- [Collations supported in RDS for PostgreSQL](#)
- [Understanding PostgreSQL roles and permissions](#)
- [Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL](#)
- [Working with logging mechanisms supported by RDS for PostgreSQL](#)
- [Managing temporary files with PostgreSQL](#)
- [Using pgBadger for log analysis with PostgreSQL](#)
- [Using PGSnapper for monitoring PostgreSQL](#)
- [Working with parameters on your RDS for PostgreSQL DB instance](#)

## Collations supported in RDS for PostgreSQL

Collations are set of rules that determine how character strings stored in the database are sorted and compared. Collations play a fundamental role in the computer system and are included as part of the operating system. Collations change over time when new characters are added to languages or when ordering rules change.

Collation libraries define specific rules and algorithms for a collation. The most popular collation libraries used within PostgreSQL are GNU C (glibc) and Internationalization components for Unicode (ICU). By default, RDS for PostgreSQL uses the glibc collation that includes unicode character sort orders for multi-byte character sequences.

When you create a new DB instance in RDS for PostgreSQL, it checks the operating system for the available collation. The PostgreSQL parameters of the `CREATE DATABASE` command `LC_COLLATE` and `LC_CTYPE` are used to specify a collation, which stands as the default collation in that database. Alternatively, you can also use the `LOCALE` parameter in `CREATE DATABASE` to set these parameters. This determines the default collation for character strings in the database and the rules for classifying characters as letters, numbers, or symbols. You can also choose a collation to use on a column, index, or on a query.

RDS for PostgreSQL depends on the glibc library in the operating system for collation support. RDS for PostgreSQL instance is periodically updated with the latest versions of the operating system. These updates sometimes include a newer version of the glibc library. Rarely, newer versions of glibc change the sort order or collation of some characters, which can cause the data to sort differently or produce invalid index entries. If you discover sort order issues for collation during an update, you might need to rebuild the indexes.

To reduce the possible impacts of the glibc updates, RDS for PostgreSQL now includes an independent default collation library. This collation library is available in RDS for PostgreSQL 14.6, 13.9, 12.13, 11.18, 10.23 and newer minor version releases. It is compatible with glibc 2.26-59.amzn2, and provides sort order stability to prevent incorrect query results.

## Understanding PostgreSQL roles and permissions

When you create an RDS for PostgreSQL DB instance using the AWS Management Console, an administrator account is created at the same time. By default, its name is `postgres`, as shown in the following screenshot:

▼ Credentials Settings

**Master username** [Info](#)  
Type a login ID for the master user of your DB instance.

postgres

1 to 16 alphanumeric characters. First character must be a letter.

**Auto generate a password**  
Amazon RDS can generate a password for you, or you can specify your own password.

**Master password** [Info](#)

\*\*\*\*\*

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), ' (single quote), " (double quote) and @ (at sign).

**Confirm password** [Info](#)

\*\*\*\*\*

You can choose another name rather than accept the default (`postgres`). If you do, the name you choose must start with a letter and be between 1 and 16 alphanumeric characters. For simplicity's sake, we refer to this main user account by its default value (`postgres`) throughout this guide.

If you use the `create-db-instance` AWS CLI rather than the AWS Management Console, you create the name by passing it with the `master-username` parameter in the command. For more information, see [Creating an Amazon RDS DB instance](#).

Whether you use the AWS Management Console, the AWS CLI, or the Amazon RDS API, and whether you use the default `postgres` name or choose a different name, this first database user account is a member of the `rds_superuser` group and has `rds_superuser` privileges.

## Topics

- [Understanding the `rds\_superuser` role](#)
- [Controlling user access to the PostgreSQL database](#)
- [Delegating and controlling user password management](#)
- [Using SCRAM for PostgreSQL password encryption](#)

## Understanding the `rds_superuser` role

In PostgreSQL, a *role* can define a user, a group, or a set of specific permissions granted to a group or user for various objects in the database. PostgreSQL commands to `CREATE USER` and `CREATE GROUP` have been replaced by the more general, `CREATE ROLE` with specific properties to distinguish database users. A database user can be thought of as a role with the `LOGIN` privilege.

**Note**

The `CREATE USER` and `CREATE GROUP` commands can still be used. For more information, see [Database Roles](#) in the PostgreSQL documentation.

The `postgres` user is the most highly privileged database user on your RDS for PostgreSQL DB instance. It has the characteristics defined by the following `CREATE ROLE` statement.

```
CREATE ROLE postgres WITH LOGIN NOSUPERUSER INHERIT CREATEDB CREATEROLE NOREPLICATION
VALID UNTIL 'infinity'
```

The properties `NOSUPERUSER`, `NOREPLICATION`, `INHERIT`, and `VALID UNTIL 'infinity'` are the default options for `CREATE ROLE`, unless otherwise specified.

By default, `postgres` has privileges granted to the `rds_superuser` role, and permissions to create roles and databases. The `rds_superuser` role allows the `postgres` user to do the following:

- Add extensions that are available for use with Amazon RDS. For more information, see [Working with PostgreSQL features supported by Amazon RDS for PostgreSQL](#)
- Create roles for users and grant privileges to users. For more information, see [CREATE ROLE](#) and [GRANT](#) in the PostgreSQL documentation.
- Create databases. For more information, see [CREATE DATABASE](#) in the PostgreSQL documentation.
- Grant `rds_superuser` privileges to user roles that don't have these privileges, and revoke privileges as needed. We recommend that you grant this role only to those users who perform superuser tasks. In other words, you can grant this role to database administrators (DBAs) or system administrators.
- Grant (and revoke) the `rds_replication` role to database users that don't have the `rds_superuser` role.
- Grant (and revoke) the `rds_password` role to database users that don't have the `rds_superuser` role.
- Obtain status information about all database connections by using the `pg_stat_activity` view. When needed, `rds_superuser` can stop any connections by using `pg_terminate_backend` or `pg_cancel_backend`.

In the `CREATE ROLE postgres . . .` statement, you can see that the `postgres` user role specifically disallows PostgreSQL `superuser` permissions. RDS for PostgreSQL is a managed service, so you can't access the host OS, and you can't connect using the PostgreSQL `superuser` account. Many of the tasks that require `superuser` access on a stand-alone PostgreSQL are managed automatically by Amazon RDS.

For more information about granting privileges, see [GRANT](#) in the PostgreSQL documentation.

The `rds_superuser` role is one of several *predefined* roles in an RDS for PostgreSQL DB instance.

 **Note**

In PostgreSQL 13 and earlier releases, *predefined* roles are known as *default* roles.

In the following list, you find some of the other predefined roles that are created automatically for a new RDS for PostgreSQL DB instance. Predefined roles and their privileges can't be changed. You can't drop, rename, or modify privileges for these predefined roles. Attempting to do so results in an error.

- **rds\_password** – A role that can change passwords and set up password constraints for database users. The `rds_superuser` role is granted with this role by default, and can grant the role to database users. For more information, see [Controlling user access to the PostgreSQL database](#).
  - For RDS for PostgreSQL versions older than 14, `rds_password` role can change passwords and set up password constraints for database users and users with `rds_superuser` role. From RDS for PostgreSQL version 14 and later, `rds_password` role can change passwords and set up password constraints only for database users. Only users with `rds_superuser` role can perform these actions on other users with `rds_superuser` role.
- **rdsadmin** – A role that's created to handle many of the management tasks that the administrator with `superuser` privileges would perform on a standalone PostgreSQL database. This role is used internally by RDS for PostgreSQL for many management tasks.
- **rdstopmgr** – A role that's used internally by Amazon RDS to support Multi-AZ deployments.

To see all predefined roles, you can connect to your RDS for PostgreSQL DB instance and use the `psql \du` metacommand. The output looks as follows:

List of roles

Role name	Attributes	Member of
postgres	Create role, Create DB Password valid until infinity	{rds_superuser}
rds_superuser	Cannot login	{pg_monitor, pg_signal_backend, rds_replication, rds_password}
...		

In the output, you can see that `rds_superuser` isn't a database user role (it can't login), but it has the privileges of many other roles. You can also see that database user `postgres` is a member of the `rds_superuser` role. As mentioned previously, `postgres` is the default value in the Amazon RDS console's **Create database** page. If you chose another name, that name is shown in the list of roles instead.

## Controlling user access to the PostgreSQL database

New databases in PostgreSQL are always created with a default set of privileges in the database's `public` schema that allow all database users and roles to create objects. These privileges allow database users to connect to the database, for example, and create temporary tables while connected.

To better control user access to the databases instances that you create on your RDS for PostgreSQL DB instance, we recommend that you revoke these default `public` privileges. After doing so, you then grant specific privileges for database users on a more granular basis, as shown in the following procedure.

### To set up roles and privileges for a new database instance

Suppose you're setting up a database on a newly created RDS for PostgreSQL DB instance for use by several researchers, all of whom need read-write access to the database.

1. Use `psql` (or `pgAdmin`) to connect to your RDS for PostgreSQL DB instance:

```
psql --host=your-db-instance.666666666666.aws-region.rds.amazonaws.com --port=5432
--username=postgres --password
```

When prompted, enter your password. The `psql` client connects and displays the default administrative connection database, `postgres=>`, as the prompt.

2. To prevent database users from creating objects in the `public` schema, do the following:

```
postgres=> REVOKE CREATE ON SCHEMA public FROM PUBLIC;
REVOKE
```

3. Next, you create a new database instance:

```
postgres=> CREATE DATABASE lab_db;
CREATE DATABASE
```

4. Revoke all privileges from the PUBLIC schema on this new database.

```
postgres=> REVOKE ALL ON DATABASE lab_db FROM public;
REVOKE
```

5. Create a role for database users.

```
postgres=> CREATE ROLE lab_tech;
CREATE ROLE
```

6. Give database users that have this role the ability to connect to the database.

```
postgres=> GRANT CONNECT ON DATABASE lab_db TO lab_tech;
GRANT
```

7. Grant all users with the lab\_tech role all privileges on this database.

```
postgres=> GRANT ALL PRIVILEGES ON DATABASE lab_db TO lab_tech;
GRANT
```

8. Create database users, as follows:

```
postgres=> CREATE ROLE lab_user1 LOGIN PASSWORD 'change_me';
CREATE ROLE
postgres=> CREATE ROLE lab_user2 LOGIN PASSWORD 'change_me';
CREATE ROLE
```

9. Grant these two users the privileges associated with the lab\_tech role:

```
postgres=> GRANT lab_tech TO lab_user1;
GRANT ROLE
postgres=> GRANT lab_tech TO lab_user2;
GRANT ROLE
```

At this point, `lab_user1` and `lab_user2` can connect to the `lab_db` database. This example doesn't follow best practices for enterprise usage, which might include creating multiple database instances, different schemas, and granting limited permissions. For more complete information and additional scenarios, see [Managing PostgreSQL Users and Roles](#).

For more information about privileges in PostgreSQL databases, see the [GRANT](#) command in the PostgreSQL documentation.

## Delegating and controlling user password management

As a DBA, you might want to delegate the management of user passwords. Or, you might want to prevent database users from changing their passwords or reconfiguring password constraints, such as password lifetime. To ensure that only the database users that you choose can change password settings, you can turn on the restricted password management feature. When you activate this feature, only those database users that have been granted the `rds_password` role can manage passwords.

### Note

To use restricted password management, your RDS for PostgreSQL DB instance must be running PostgreSQL 10.6 or higher.

By default, this feature is off, as shown in the following:

```
postgres=> SHOW rds.restrict_password_commands;
 rds.restrict_password_commands
-----
off
(1 row)
```

To turn on this feature, you use a custom parameter group and change the setting for `rds.restrict_password_commands` to 1. Be sure to reboot your RDS for PostgreSQL DB instance so that the setting takes effect.

With this feature active, `rds_password` privileges are needed for the following SQL commands:

```
CREATE ROLE myrole WITH PASSWORD 'mypassword';
CREATE ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2023-01-01';
ALTER ROLE myrole WITH PASSWORD 'mypassword' VALID UNTIL '2023-01-01';
```

```
ALTER ROLE myrole WITH PASSWORD 'mypassword';  
ALTER ROLE myrole VALID UNTIL '2023-01-01';  
ALTER ROLE myrole RENAME TO myrole2;
```

Renaming a role (`ALTER ROLE myrole RENAME TO newname`) is also restricted if the password uses the MD5 hashing algorithm.

With this feature active, attempting any of these SQL commands without the `rds_password` role permissions generates the following error:

```
ERROR: must be a member of rds_password to alter passwords
```

We recommend that you grant the `rds_password` to only a few roles that you use solely for password management. If you grant `rds_password` privileges to database users that don't have `rds_superuser` privileges, you need to also grant them the `CREATEROLE` attribute.

Make sure that you verify password requirements such as expiration and needed complexity on the client side. If you use your own client-side utility for password related changes, the utility needs to be a member of `rds_password` and have `CREATE ROLE` privileges.

## Using SCRAM for PostgreSQL password encryption

The *Salted Challenge Response Authentication Mechanism (SCRAM)* is an alternative to PostgreSQL's default message digest (MD5) algorithm for encrypting passwords. The SCRAM authentication mechanism is considered more secure than MD5. To learn more about these two different approaches to securing passwords, see [Password Authentication](#) in the PostgreSQL documentation.

We recommend that you use SCRAM rather than MD5 as the password encryption scheme for your RDS for PostgreSQL DB instance. It's a cryptographic challenge-response mechanism that uses the `scram-sha-256` algorithm for password authentication and encryption.

You might need to update libraries for your client applications to support SCRAM. For example, JDBC versions before 42.2.0 don't support SCRAM. For more information, see [PostgreSQL JDBC Driver](#) in the PostgreSQL JDBC Driver documentation. For a list of other PostgreSQL drivers and SCRAM support, see [List of drivers](#) in the PostgreSQL documentation.

### Note

RDS for PostgreSQL version 13.1 and higher support `scram-sha-256`. These versions also let you configure your DB instance to require SCRAM, as discussed in the following procedures.

## Setting up RDS for PostgreSQL DB instance to require SCRAM

you can require the RDS for PostgreSQL DB instance to accept only passwords that use the scram-sha-256 algorithm.

### Important

For existing RDS Proxies with PostgreSQL databases, if you modify the database authentication to use SCRAM only, the proxy becomes unavailable for up to 60 seconds. To avoid the issue, do one of the following:

- Ensure that the database allows both SCRAM and MD5 authentication.
- To use only SCRAM authentication, create a new proxy, migrate your application traffic to the new proxy, then delete the proxy previously associated with the database.

Before making changes to your system, be sure you understand the complete process, as follows:

- Get information about all roles and password encryption for all database users.
- Double-check the parameter settings for your RDS for PostgreSQL DB instance for the parameters that control password encryption.
- If your RDS for PostgreSQL DB instance uses a default parameter group, you need to create a custom DB parameter group and apply it to your RDS for PostgreSQL DB instance so that you can modify parameters when needed. If your RDS for PostgreSQL DB instance uses a custom parameter group, you can modify the necessary parameters later in the process, as needed.
- Change the `password_encryption` parameter to `scram-sha-256`.
- Notify all database users that they need to update their passwords. Do the same for your postgres account. The new passwords are encrypted and stored using the scram-sha-256 algorithm.
- Verify that all passwords are encrypted using as the type of encryption.
- If all passwords use scram-sha-256, you can change the `rds.accepted_password_auth_method` parameter from `md5+scram` to `scram-sha-256`.

**⚠ Warning**

After you change `rds.accepted_password_auth_method` to `scram-sha-256` alone, any users (roles) with `md5`-encrypted passwords can't connect.

**Getting ready to require SCRAM for your RDS for PostgreSQL DB instance**

Before making any changes to your RDS for PostgreSQL DB instance, check all existing database user accounts. Also, check the type of encryption used for passwords. You can do these tasks by using the `rds_tools` extension. This extension is supported on RDS for PostgreSQL 13.1 and higher releases.

**To get a list of database users (roles) and password encryption methods**

1. Use `psql` to connect to your RDS for PostgreSQL DB instance, as shown in the following.

```
psql --host=db-name.111122223333.aws-region.rds.amazonaws.com --port=5432 --  
username=postgres --password
```

2. Install the `rds_tools` extension.

```
postgres=> CREATE EXTENSION rds_tools;  
CREATE EXTENSION
```

3. Get a listing of roles and encryption.

```
postgres=> SELECT * FROM  
rds_tools.role_password_encryption_type();
```

You see output similar to the following.

rolname	encryption_type
pg_monitor	
pg_read_all_settings	
pg_read_all_stats	
pg_stat_scan_tables	
pg_signal_backend	
lab_tester	md5
user_465	md5

```
postgres          | md5
(8 rows)
```

## Creating a custom DB parameter group

### Note

If your RDS for PostgreSQL DB instance already uses a custom parameter group, you don't need to create a new one.

For an overview of parameter groups for Amazon RDS, see [Working with parameters on your RDS for PostgreSQL DB instance](#).

The password encryption type used for passwords is set in one parameter, `password_encryption`. The encryption that the RDS for PostgreSQL DB instance allows is set in another parameter, `rds.accepted_password_auth_method`. Changing either of these from the default values requires that you create a custom DB parameter group and apply it to your instance.

You can also use the AWS Management Console or the RDS API to create a custom DB parameter group. For more information, see

You can now associate the custom parameter group with your DB instance.

### To create a custom DB parameter group

1. Use the [create-db-parameter-group](#) CLI command to create the custom DB parameter group. This example uses `postgres13` as the source for this custom parameter group.

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group --db-parameter-group-name 'docs-lab-scam-
passwords' \
  --db-parameter-group-family postgres13 --description 'Custom parameter group for
SCRAM'
```

For Windows:

```
aws rds create-db-parameter-group --db-parameter-group-name "docs-lab-scam-
passwords" ^
```

```
--db-parameter-group-family postgres13 --description "Custom DB parameter group for SCRAM"
```

- Use the [modify-db-instance](#) CLI command to apply this custom parameter group to your RDS for PostgreSQL DB cluster.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance --db-instance-identifier 'your-instance-name' \
  --db-parameter-group-name "docs-lab-scram-passwords"
```

For Windows:

```
aws rds modify-db-instance --db-instance-identifier "your-instance-name" ^
  --db-parameter-group-name "docs-lab-scram-passwords"
```

To resynchronize your RDS for PostgreSQL DB instance with your custom DB parameter group, you need to reboot the primary and all other instances of the cluster. To minimize impact to your users, schedule this to occur during your regular maintenance window.

## Configuring password encryption to use SCRAM

The password encryption mechanism used by an RDS for PostgreSQL DB instance is set in the DB parameter group in the `password_encryption` parameter. Allowed values are `unset`, `md5`, or `scram-sha-256`. The default value depends on the RDS for PostgreSQL version, as follows:

- RDS for PostgreSQL 14 and above – Default is `scram-sha-256`
- RDS for PostgreSQL 13 – Default is `md5`

With a custom DB parameter group attached to your RDS for PostgreSQL DB instance, you can modify values for the password encryption parameter.

<input type="checkbox"/>	Name	Values	Allowed values	Modifiable	Source	Apply type
<input type="checkbox"/>	<code>password_encryption</code>	md5	md5, <code>scram-sha-256</code>	true	system	dynamic
<input type="checkbox"/>	<code>rds.accepted_password_auth_method</code>	md5+scram	md5+scram, scram	true	system	dynamic

## To change password encryption setting to scram-sha-256

- Change the value of password encryption to scram-sha-256, as shown following. The change can be applied immediately because the parameter is dynamic, so a restart isn't required for the change to take effect.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group --db-parameter-group-name \  
  'docs-lab-scram-passwords' --parameters  
  'ParameterName=password_encryption,ParameterValue=scram-  
sha-256,ApplyMethod=immediate'
```

For Windows:

```
aws rds modify-db-parameter-group --db-parameter-group-name ^  
  "docs-lab-scram-passwords" --parameters  
  "ParameterName=password_encryption,ParameterValue=scram-  
sha-256,ApplyMethod=immediate"
```

## Migrating passwords for user roles to SCRAM

You can migrate passwords for user roles to SCRAM as described following.

### To migrate database user (role) passwords from MD5 to SCRAM

- Log in as the administrator user (default user name, postgres) as shown following.

```
psql --host=db-name.111122223333.aws-region.rds.amazonaws.com --port=5432 --  
username=postgres --password
```

- Check the setting of the password\_encryption parameter on your RDS for PostgreSQL DB instance by using the following command.

```
postgres=> SHOW password_encryption;  
password_encryption  
-----  
md5  
(1 row)
```

3. Change the value of this parameter to `scram-sha-256`. This is a dynamic parameter, so you don't need to reboot the instance after making this change. Check the value again to make sure that it's now set to `scram-sha-256`, as follows.

```
postgres=> SHOW password_encryption;
password_encryption
-----
scram-sha-256
(1 row)
```

4. Notify all database users to change their passwords. Be sure to also change your own password for account `postgres` (the database user with `rds_superuser` privileges).

```
labdb=> ALTER ROLE postgres WITH LOGIN PASSWORD 'change_me';
ALTER ROLE
```

5. Repeat the process for all databases on your RDS for PostgreSQL DB instance.

## Changing parameter to require SCRAM

This is the final step in the process. After you make the change in the following procedure, any user accounts (roles) that still use `md5` encryption for passwords can't log in to the RDS for PostgreSQL DB instance.

The `rds.accepted_password_auth_method` specifies the encryption method that the RDS for PostgreSQL DB instance accepts for a user password during the login process. The default value is `md5+scram`, meaning that either method is accepted. In the following image, you can find the default setting for this parameter.

<input type="checkbox"/>	Name	Values	Allowed values	Modifiable	Source	Apply type
<input type="checkbox"/>	<code>password_encryption</code>	<code>scram-sha-256</code>	<code>md5, scram-sha-256</code>	true	system	dynamic
<input type="checkbox"/>	<code>rds.accepted_password_auth_method</code>	<code>md5+scram</code>	<code>md5+scram, scram</code>	true	system	dynamic

The allowed values for this parameter are `md5+scram` or `scram` alone. Changing this parameter value to `scram` makes this a requirement.

## To change the parameter value to require SCRAM authentication for passwords

1. Verify that all database user passwords for all databases on your RDS for PostgreSQL DB instance use `scram-sha-256` for password encryption. To do so, query `rds_tools` for the role (user) and encryption type, as follows.

```
postgres=> SELECT * FROM rds_tools.role_password_encryption_type();
rolname          | encryption_type
-----+-----
pg_monitor       |
pg_read_all_settings |
pg_read_all_stats |
pg_stat_scan_tables |
pg_signal_backend |
lab_tester       | scram-sha-256
user_465         | scram-sha-256
postgres        | scram-sha-256
( rows)
```

2. Repeat the query across all DB instances in your RDS for PostgreSQL DB instance.

If all passwords use `scram-sha-256`, you can proceed.

3. Change the value of the accepted password authentication to `scram-sha-256`, as follows.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group --db-parameter-group-name 'docs-lab-scam-
passwords' \
  --parameters
  'ParameterName=rds.accepted_password_auth_method,ParameterValue=scram,ApplyMethod=immediat
```

For Windows:

```
aws rds modify-db-parameter-group --db-parameter-group-name "docs-lab-scam-
passwords" ^
  --parameters
  "ParameterName=rds.accepted_password_auth_method,ParameterValue=scram,ApplyMethod=immediat
```

# Working with the PostgreSQL autovacuum on Amazon RDS for PostgreSQL

We strongly recommend that you use the autovacuum feature to maintain the health of your PostgreSQL DB instance. Autovacuum automates the start of the VACUUM and the ANALYZE commands. It checks for tables with a large number of inserted, updated, or deleted tuples. After this check, it reclaims storage by removing obsolete data or tuples from the PostgreSQL database.

By default, autovacuum is turned on for the Amazon RDS for PostgreSQL DB instances that you create using any of the default PostgreSQL DB parameter groups. These include `default.postgres10`, `default.postgres11`, and so on. All default PostgreSQL DB parameter groups have an `rds.adaptive_autovacuum` parameter that's set to 1, thus activating the feature. Other configuration parameters associated with the autovacuum feature are also set by default. Because these defaults are somewhat generic, you can benefit from tuning some of the parameters associated with the autovacuum feature for your specific workload.

Following, you can find more information about the autovacuum and how to tune some of its parameters on your RDS for PostgreSQL DB instance. For high-level information, see [Best practices for working with PostgreSQL](#).

## Topics

- [Allocating memory for autovacuum](#)
- [Reducing the likelihood of transaction ID wraparound](#)
- [Determining if the tables in your database need vacuuming](#)
- [Determining which tables are currently eligible for autovacuum](#)
- [Determining if autovacuum is currently running and for how long](#)

- [Other parameters that affect autovacuum](#)
- [Setting table-level autovacuum parameters](#)
- [Logging autovacuum and vacuum activities](#)
- [Understanding the behavior of autovacuum with invalid databases](#)

## Allocating memory for autovacuum

One of the most important parameters influencing autovacuum performance is the [maintenance\\_work\\_mem](#) parameter. This parameter determines how much memory that you allocate for autovacuum to use to scan a database table and to hold all the row IDs that are going to be vacuumed. If you set the value of the `maintenance_work_mem` parameter too low, the vacuum process might have to scan the table multiple times to complete its work. Such multiple scans can have a negative impact on performance.

When doing calculations to determine the `maintenance_work_mem` parameter value, keep in mind two things:

- The default unit is kilobytes (KB) for this parameter.
- The `maintenance_work_mem` parameter works in conjunction with the [autovacuum\\_max\\_workers](#) parameter. If you have many small tables, allocate more `autovacuum_max_workers` and less `maintenance_work_mem`. If you have large tables (say, larger than 100 GB), allocate more memory and fewer worker processes. You need to have enough memory allocated to succeed on your biggest table. Each `autovacuum_max_workers` can use the memory that you allocate. Thus, make sure that the combination of worker processes and memory equal the total memory that you want to allocate.

In general terms, for large hosts set the `maintenance_work_mem` parameter to a value between one and two gigabytes (between 1,048,576 and 2,097,152 KB). For extremely large hosts, set the parameter to a value between two and four gigabytes (between 2,097,152 and 4,194,304 KB). The value that you set for this parameter depends on the workload. Amazon RDS has updated its default for this parameter to be kilobytes calculated as follows.

```
GREATEST({DBInstanceClassMemory/63963136*1024}, 65536).
```

## Reducing the likelihood of transaction ID wraparound

In some cases, parameter group settings related to autovacuum might not be aggressive enough to prevent transaction ID wraparound. To address this, RDS for PostgreSQL provides a mechanism that adapts the autovacuum parameter values automatically. *Adaptive autovacuum parameter tuning* is a feature for RDS for PostgreSQL. A detailed explanation of [TransactionID wraparound](#) is found in the PostgreSQL documentation.

Adaptive autovacuum parameter tuning is turned on by default for RDS for PostgreSQL instances with the dynamic parameter `rds.adaptive_autovacuum` set to ON. We strongly recommend

that you keep this turned on. However, to turn off adaptive autovacuum parameter tuning, set the `rds.adaptive_autovacuum` parameter to 0 or OFF.

Transaction ID wraparound is still possible even when Amazon RDS tunes the autovacuum parameters. We encourage you to implement an Amazon CloudWatch alarm for transaction ID wraparound. For more information, see the post [Implement an early warning system for transaction ID wraparound in RDS for PostgreSQL](#) on the AWS Database Blog.

With adaptive autovacuum parameter tuning turned on, Amazon RDS begins adjusting autovacuum parameters when the CloudWatch metric `MaximumUsedTransactionIDs` reaches the value of the `autovacuum_freeze_max_age` parameter or 500,000,000, whichever is greater.

Amazon RDS continues to adjust parameters for autovacuum if a table continues to trend toward transaction ID wraparound. Each of these adjustments dedicates more resources to autovacuum to avoid wraparound. Amazon RDS updates the following autovacuum-related parameters:

- [autovacuum\\_vacuum\\_cost\\_delay](#)
- [autovacuum\\_vacuum\\_cost\\_limit](#)
- [autovacuum\\_work\\_mem](#)
- [autovacuum\\_naptime](#)

RDS modifies these parameters only if the new value makes autovacuum more aggressive. The parameters are modified in memory on the DB instance. The values in the parameter group aren't changed. To view the current in-memory settings, use the PostgreSQL [SHOW](#) SQL command.

When Amazon RDS modifies any of these autovacuum parameters, it generates an event for the affected DB instance. This event is visible on the AWS Management Console and through the Amazon RDS API. After the `MaximumUsedTransactionIDs` CloudWatch metric returns below the threshold, Amazon RDS resets the autovacuum-related parameters in memory back to the values specified in the parameter group. It then generates another event corresponding to this change.

## Determining if the tables in your database need vacuuming

You can use the following query to show the number of unvacuumed transactions in a database. The `datfrozenxid` column of a database's `pg_database` row is a lower bound on the normal transaction IDs appearing in that database. This column is the minimum of the per-table `relfrozenxid` values within the database.

```
SELECT datname, age(datfrozenxid) FROM pg_database ORDER BY age(datfrozenxid) desc
limit 20;
```

For example, the results of running the preceding query might be the following.

```
datname      | age
mydb         | 1771757888
template0    | 1721757888
template1    | 1721757888
rdsadmin     | 1694008527
postgres     | 1693881061
(5 rows)
```

When the age of a database reaches 2 billion transaction IDs, transaction ID (XID) wraparound occurs and the database becomes read-only. You can use this query to produce a metric and run a few times a day. By default, autovacuum is set to keep the age of transactions to no more than 200,000,000 ([autovacuum\\_freeze\\_max\\_age](#)).

A sample monitoring strategy might look like this:

- Set the `autovacuum_freeze_max_age` value to 200 million transactions.
- If a table reaches 500 million unvacuumed transactions, that triggers a low-severity alarm. This isn't an unreasonable value, but it can indicate that autovacuum isn't keeping up.
- If a table ages to 1 billion, this should be treated as an alarm to take action on. In general, you want to keep ages closer to `autovacuum_freeze_max_age` for performance reasons. We recommend that you investigate using the recommendations that follow.
- If a table reaches 1.5 billion unvacuumed transactions, that triggers a high-severity alarm. Depending on how quickly your database uses transaction IDs, this alarm can indicate that the system is running out of time to run autovacuum. In this case, we recommend that you resolve this immediately.

If a table is constantly breaching these thresholds, modify your autovacuum parameters further. By default, using `VACUUM` manually (which has cost-based delays disabled) is more aggressive than using the default autovacuum, but it is also more intrusive to the system as a whole.

We recommend the following:

- Be aware and turn on a monitoring mechanism so that you are aware of the age of your oldest transactions.

For information on creating a process that warns you about transaction ID wraparound, see the AWS Database Blog post [Implement an early warning system for transaction ID wraparound in Amazon RDS for PostgreSQL](#).

- For busier tables, perform a manual vacuum freeze regularly during a maintenance window, in addition to relying on autovacuum. For information on performing a manual vacuum freeze, see [Performing a manual vacuum freeze](#).

## Determining which tables are currently eligible for autovacuum

Often, it is one or two tables in need of vacuuming. Tables whose `relfrozenxid` value is greater than the number of transactions in `autovacuum_freeze_max_age` are always targeted by autovacuum. Otherwise, if the number of tuples made obsolete since the last `VACUUM` exceeds the vacuum threshold, the table is vacuumed.

The [autovacuum threshold](#) is defined as:

$$\text{Vacuum-threshold} = \text{vacuum-base-threshold} + \text{vacuum-scale-factor} * \text{number-of-tuples}$$

where the vacuum base threshold is `autovacuum_vacuum_threshold`, the vacuum scale factor is `autovacuum_vacuum_scale_factor`, and the number of tuples is `pg_class.reltuples`.

While you are connected to your database, run the following query to see a list of tables that autovacuum sees as eligible for vacuuming.

```
WITH vbt AS (SELECT setting AS autovacuum_vacuum_threshold FROM
pg_settings WHERE name = 'autovacuum_vacuum_threshold'),
vsf AS (SELECT setting AS autovacuum_vacuum_scale_factor FROM
pg_settings WHERE name = 'autovacuum_vacuum_scale_factor'),
fma AS (SELECT setting AS autovacuum_freeze_max_age FROM pg_settings WHERE name =
'autovacuum_freeze_max_age'),
sto AS (select opt_oid, split_part(setting, '=', 1) as param,
split_part(setting, '=', 2) as value from (select oid opt_oid, unnest(reloptions)
setting from pg_class) opt)
SELECT '''||ns.nspname||'.'||c.relname||''' as relation,
pg_size_pretty(pg_table_size(c.oid)) as table_size,
```

```

age(relfrozenxid) as xid_age,
coalesce(cfma.value::float, autovacuum_freeze_max_age::float)
  autovacuum_freeze_max_age,
(coalesce(cvbt.value::float, autovacuum_vacuum_threshold::float) +
coalesce(cvsf.value::float, autovacuum_vacuum_scale_factor::float) * c.reltuples)
AS autovacuum_vacuum_tuples, n_dead_tup as dead_tuples FROM
pg_class c join pg_namespace ns on ns.oid = c.relnamespace
join pg_stat_all_tables stat on stat.relid = c.oid join vbt on (1=1) join vsf on (1=1)
  join fma on (1=1)
left join sto cvbt on cvbt.param = 'autovacuum_vacuum_threshold' and c.oid =
  cvbt.opt_oid
left join sto cvsf on cvsf.param = 'autovacuum_vacuum_scale_factor' and c.oid =
  cvsf.opt_oid
left join sto cfma on cfma.param = 'autovacuum_freeze_max_age' and c.oid = cfma.opt_oid
WHERE c.relkind = 'r' and nsname <> 'pg_catalog'
AND (age(relfrozenxid) >= coalesce(cfma.value::float, autovacuum_freeze_max_age::float)
OR coalesce(cvbt.value::float, autovacuum_vacuum_threshold::float) +
coalesce(cvsf.value::float, autovacuum_vacuum_scale_factor::float) *
c.reltuples <= n_dead_tup)
ORDER BY age(relfrozenxid) DESC LIMIT 50;

```

## Determining if autovacuum is currently running and for how long

If you need to manually vacuum a table, make sure to determine if autovacuum is currently running. If it is, you might need to adjust parameters to make it run more efficiently, or turn off autovacuum temporarily so that you can manually run VACUUM.

Use the following query to determine if autovacuum is running, how long it has been running, and if it is waiting on another session.

```

SELECT datname, username, pid, state, wait_event, current_timestamp - xact_start AS
  xact_runtime, query
FROM pg_stat_activity
WHERE upper(query) LIKE '%VACUUM%'
ORDER BY xact_start;

```

After running the query, you should see output similar to the following.

```

datname | username | pid | state | wait_event |          xact_runtime          | query
-----+-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----+-----

```

```

mydb      | rdsadmin | 16473 | active |          | 33 days 16:32:11.600656 |
autovacuum: VACUUM ANALYZE public.mytable1 (to prevent wraparound)
mydb      | rdsadmin | 22553 | active |          | 14 days 09:15:34.073141 |
autovacuum: VACUUM ANALYZE public.mytable2 (to prevent wraparound)
mydb      | rdsadmin | 41909 | active |          | 3 days 02:43:54.203349 |
autovacuum: VACUUM ANALYZE public.mytable3
mydb      | rdsadmin | 618 | active |          | 00:00:00 |
SELECT datname, username, pid, state, wait_event, current_timestamp - xact_start AS
xact_runtime, query+
          |          |          |          |          |          | FROM
pg_stat_activity
          +
          |          |          |          |          |          | WHERE
query like '%VACUUM%'
          +
          |          |          |          |          |          | ORDER BY
xact_start;
          +

```

Several issues can cause a long-running autovacuum session (that is, multiple days long). The most common issue is that your [maintenance\\_work\\_mem](#) parameter value is set too low for the size of the table or rate of updates.

We recommend that you use the following formula to set the `maintenance_work_mem` parameter value.

```
GREATEST({DBInstanceClassMemory/63963136*1024},65536)
```

Short running autovacuum sessions can also indicate problems:

- It can indicate that there aren't enough `autovacuum_max_workers` for your workload. In this case, you need to indicate the number of workers.
- It can indicate that there is an index corruption (autovacuum crashes and restarts on the same relation but makes no progress). In this case, run a manual `vacuum freeze verbose table` to see the exact cause.

## Performing a manual vacuum freeze

You might want to perform a manual vacuum on a table that has a vacuum process already running. This is useful if you have identified a table with an age approaching 2 billion transactions (or above any threshold you are monitoring).

The following steps are guidelines, with several variations to the process. For example, during testing, suppose that you find that the [maintenance\\_work\\_mem](#) parameter value is set too small and that you need to take immediate action on a table. However, perhaps you don't want to bounce the instance at the moment. Using the queries in previous sections, you determine which table is the problem and notice a long running autovacuum session. You know that you need to change the `maintenance_work_mem` parameter setting, but you also need to take immediate action and vacuum the table in question. The following procedure shows what to do in this situation.

### To manually perform a vacuum freeze

1. Open two sessions to the database containing the table you want to vacuum. For the second session, use "screen" or another utility that maintains the session if your connection is dropped.
2. In session one, get the process ID (PID) of the autovacuum session running on the table.

Run the following query to get the PID of the autovacuum session.

```
SELECT datname, username, pid, current_timestamp - xact_start
AS xact_runtime, query
FROM pg_stat_activity WHERE upper(query) LIKE '%VACUUM%' ORDER BY
xact_start;
```

3. In session two, calculate the amount of memory that you need for this operation. In this example, we determine that we can afford to use up to 2 GB of memory for this operation, so we set [maintenance\\_work\\_mem](#) for the current session to 2 GB.

```
SET maintenance_work_mem='2 GB';
SET
```

4. In session two, issue a `vacuum freeze verbose` command for the table. The verbose setting is useful because, although there is no progress report for this in PostgreSQL currently, you can see activity.

```
\timing on
```

```
Timing is on.
```

```
vacuum freeze verbose pgbench_branches;
```

```
INFO:  vacuuming "public.pgbench_branches"
```

```
INFO:  index "pgbench_branches_pkey" now contains 50 row versions in 2 pages
```

```
DETAIL:  0 index row versions were removed.
```

```
0 index pages have been deleted, 0 are currently reusable.
```

```
CPU 0.00s/0.00u sec elapsed 0.00 sec.
```

```
INFO:  index "pgbench_branches_test_index" now contains 50 row versions in 2 pages
```

```
DETAIL:  0 index row versions were removed.
```

```
0 index pages have been deleted, 0 are currently reusable.
```

```
CPU 0.00s/0.00u sec elapsed 0.00 sec.
```

```
INFO:  "pgbench_branches": found 0 removable, 50 nonremovable row versions  
      in 43 out of 43 pages
```

```
DETAIL:  0 dead row versions cannot be removed yet.
```

```
There were 9347 unused item pointers.
```

```
0 pages are entirely empty.
```

```
CPU 0.00s/0.00u sec elapsed 0.00 sec.
```

```
VACUUM
```

```
Time: 2.765 ms
```

5. In session one, if autovacuum was blocking the vacuum session, you see in `pg_stat_activity` that waiting is "T" for your vacuum session. In this case, you need to end the autovacuum process as follows.

```
SELECT pg_terminate_backend('the_pid');
```

At this point, your session begins. It's important to note that autovacuum restarts immediately because this table is probably the highest on its list of work.

6. Initiate your `vacuum freeze verbose` command in session two, and then end the autovacuum process in session one.

## Reindexing a table when autovacuum is running

If an index has become corrupt, autovacuum continues to process the table and fails. If you attempt a manual vacuum in this situation, you receive an error message like the following.

```
postgres=> vacuum freeze pgbench_branches;
```

```
ERROR: index "pgbench_branches_test_index" contains unexpected
zero page at block 30521
HINT: Please REINDEX it.
```

When the index is corrupted and autovacuum is attempting to run on the table, you contend with an already running autovacuum session. When you issue a [REINDEX](#) command, you take out an exclusive lock on the table. Write operations are blocked, and also read operations that use that specific index.

### To reindex a table when autovacuum is running on the table

1. Open two sessions to the database containing the table that you want to vacuum. For the second session, use "screen" or another utility that maintains the session if your connection is dropped.
2. In session one, get the PID of the autovacuum session running on the table.

Run the following query to get the PID of the autovacuum session.

```
SELECT datname, username, pid, current_timestamp - xact_start
AS xact_runtime, query
FROM pg_stat_activity WHERE upper(query) like '%VACUUM%' ORDER BY
xact_start;
```

3. In session two, issue the reindex command.

```
\timing on
Timing is on.
reindex index pgbench_branches_test_index;
REINDEX
Time: 9.966 ms
```

4. In session one, if autovacuum was blocking the process, you see in `pg_stat_activity` that waiting is "T" for your vacuum session. In this case, you end the autovacuum process.

```
SELECT pg_terminate_backend('the_pid');
```

At this point, your session begins. It's important to note that autovacuum restarts immediately because this table is probably the highest on its list of work.

5. Initiate your command in session two, and then end the autovacuum process in session 1.

## Managing autovacuum with large indexes

As part of its operation, *autovacuum* performs several [vacuum phases](#) while running on a table. Before the table is cleaned up, all of its indexes are first vacuumed. When removing multiple large indexes, this phase consumes a significant amount of time and resources. Therefore, as a best practice, be sure to control the number of indexes on a table and eliminate unused indexes.

For this process, first check the overall index size. Then, determine if there are potentially unused indexes that can be removed as shown in the following examples.

### To check the size of the table and its indexes

```
postgres=> select pg_size_pretty(pg_relation_size('pgbench_accounts'));
pg_size_pretty
6404 MB
(1 row)
```

```
postgres=> select pg_size_pretty(pg_indexes_size('pgbench_accounts'));
pg_size_pretty
11 GB
(1 row)
```

In this example, the size of indexes is larger than the table. This difference can cause performance issues as the indexes are bloated or unused, which impacts the autovacuum as well as insert operations.

### To check for unused indexes

Using the [pg\\_stat\\_user\\_indexes](#) view, you can check how frequently an index is used with the `idx_scan` column. In the following example, the unused indexes have the `idx_scan` value of 0.

```
postgres=> select * from pg_stat_user_indexes where relname = 'pgbench_accounts' order
by idx_scan desc;
```

relid	indexrelid	schemaname	relname	indexrelname	idx_scan
idx_tup_read	idx_tup_fetch				
16433	16454	public	pgbench_accounts	index_f	6
6	0				

```

16433 | 16450      | public | pgbench_accounts | index_b          | 3
      | 199999    | 0
16433 | 16447      | public | pgbench_accounts | pgbench_accounts_pkey | 0
      | 0         | 0
16433 | 16452      | public | pgbench_accounts | index_d          | 0
      | 0         | 0
16433 | 16453      | public | pgbench_accounts | index_e          | 0
      | 0         | 0
16433 | 16451      | public | pgbench_accounts | index_c          | 0
      | 0         | 0
16433 | 16449      | public | pgbench_accounts | index_a          | 0
      | 0         | 0
(7 rows)

```

```

postgres=> select schemaname, relname, indexrelname, idx_scan from pg_stat_user_indexes
where relname = 'pgbench_accounts' order by idx_scan desc;

```

```

schemaname | relname          | indexrelname          | idx_scan
-----+-----+-----+-----
public     | pgbench_accounts | index_f               | 6
public     | pgbench_accounts | index_b               | 3
public     | pgbench_accounts | pgbench_accounts_pkey | 0
public     | pgbench_accounts | index_d               | 0
public     | pgbench_accounts | index_e               | 0
public     | pgbench_accounts | index_c               | 0
public     | pgbench_accounts | index_a               | 0
(7 rows)

```

### Note

These statistics are incremental from the time that the statistics are reset. Suppose you have an index that is only used at the end of a business quarter or just for a specific report. It's possible that this index hasn't been used since the statistics were reset. For more information, see [Statistics Functions](#). Indexes that are used to enforce uniqueness won't have scans performed and shouldn't be identified as unused indexes. To identify the unused indexes, you should have in-depth knowledge of the application and its queries.

To check when the stats were last reset for a database, use [pg\\_stat\\_database](#)

```
postgres=> select datname, stats_reset from pg_stat_database where datname =
'postgres';
```

```
datname | stats_reset
-----+-----
postgres | 2022-11-17 08:58:11.427224+00
(1 row)
```

## Vacuuming a table as quickly as possible

### RDS for PostgreSQL 12 and higher

If you have too many indexes in a large table, your DB instance could be nearing transaction ID wraparound (XID), which is when the XID counter wraps around to zero. Left unchecked, this situation could result in data loss. However, you can quickly vacuum the table without cleaning up the indexes. In RDS for PostgreSQL 12 and higher, you can use `VACUUM` with the [INDEX\\_CLEANUP](#) clause.

```
postgres=> VACUUM (INDEX_CLEANUP FALSE, VERBOSE TRUE) pgbench_accounts;

INFO: vacuuming "public.pgbench_accounts"
INFO: table "pgbench_accounts": found 0 removable, 8 nonremovable row versions in 1 out
of 819673 pages
DETAIL: 0 dead row versions cannot be removed yet, oldest xmin: 7517
Skipped 0 pages due to buffer pins, 0 frozen pages.
CPU: user: 0.01 s, system: 0.00 s, elapsed: 0.01 s.
```

If an autovacuum session is already running, you must terminate it to begin the manual `VACUUM`. For information on performing a manual vacuum freeze, see [Performing a manual vacuum freeze](#)

#### Note

Skipping index cleanup regularly might cause index bloat, which impacts the overall scan performance. As a best practice, use the preceding procedure only to prevent transaction ID wraparound.

### RDS for PostgreSQL 11 and older

However, in RDS for PostgreSQL 11 and lower versions, the only way to allow vacuum to complete faster is to reduce the number of indexes on a table. Dropping an index can affect query plans. We recommend that you drop unused indexes first, then drop the indexes when XID wraparound is very near. After the vacuum process completes, you can recreate these indexes.

## Other parameters that affect autovacuum

The following query shows the values of some of the parameters that directly affect autovacuum and its behavior. The [autovacuum parameters](#) are described fully in the PostgreSQL documentation.

```
SELECT name, setting, unit, short_desc
FROM pg_settings
WHERE name IN (
  'autovacuum_max_workers',
  'autovacuum_analyze_scale_factor',
  'autovacuum_naptime',
  'autovacuum_analyze_threshold',
  'autovacuum_analyze_scale_factor',
  'autovacuum_vacuum_threshold',
  'autovacuum_vacuum_scale_factor',
  'autovacuum_vacuum_threshold',
  'autovacuum_vacuum_cost_delay',
  'autovacuum_vacuum_cost_limit',
  'vacuum_cost_limit',
  'autovacuum_freeze_max_age',
  'maintenance_work_mem',
  'vacuum_freeze_min_age');
```

While these all affect autovacuum, some of the most important ones are:

- [maintenance\\_work\\_mem](#)
- [autovacuum\\_freeze\\_max\\_age](#)
- [autovacuum\\_max\\_workers](#)
- [autovacuum\\_vacuum\\_cost\\_delay](#)
- [autovacuum\\_vacuum\\_cost\\_limit](#)

## Setting table-level autovacuum parameters

You can set autovacuum-related [storage parameters](#) at a table level, which can be better than altering the behavior of the entire database. For large tables, you might need to set aggressive settings and you might not want to make autovacuum behave that way for all tables.

The following query shows which tables currently have table-level options in place.

```
SELECT relname, reloptions
FROM pg_class
WHERE reloptions IS NOT null;
```

An example where this might be useful is on tables that are much larger than the rest of your tables. Suppose that you have one 300-GB table and 30 other tables less than 1 GB. In this case, you might set some specific parameters for your large table so you don't alter the behavior of your entire system.

```
ALTER TABLE mytable set (autovacuum_vacuum_cost_delay=0);
```

Doing this turns off the cost-based autovacuum delay for this table at the expense of more resource usage on your system. Normally, autovacuum pauses for `autovacuum_vacuum_cost_delay` each time `autovacuum_cost_limit` is reached. For more details, see the PostgreSQL documentation about [cost-based vacuuming](#).

## Logging autovacuum and vacuum activities

Information about autovacuum activities is sent to the `postgresql.log` based on the level specified in the `rds.force_autovacuum_logging_level` parameter. Following are the values allowed for this parameter and the PostgreSQL versions for which that value is the default setting:

- `disabled` (PostgreSQL 10, PostgreSQL 9.6)
- `debug5`, `debug4`, `debug3`, `debug2`, `debug1`
- `info` (PostgreSQL 12, PostgreSQL 11)
- `notice`
- `warning` (PostgreSQL 13 and above)
- `error`, `log`, `fatal`, `panic`

The `rds.force_autovacuum_logging_level` works with the `log_autovacuum_min_duration` parameter. The `log_autovacuum_min_duration` parameter's value is the threshold (in milliseconds) above which autovacuum actions get logged. A setting of `-1` logs nothing, while a setting of `0` logs all actions. As with `rds.force_autovacuum_logging_level`, default values for `log_autovacuum_min_duration` are version dependent, as follows:

- `10000` ms – PostgreSQL 14, PostgreSQL 13, PostgreSQL 12, and PostgreSQL 11
- (empty) – No default value for PostgreSQL 10 and PostgreSQL 9.6

We recommend that you set `rds.force_autovacuum_logging_level` to `WARNING`. We also recommend that you set `log_autovacuum_min_duration` to a value from `1000` to `5000`. A setting of `5000` logs activity that takes longer than `5,000` milliseconds. Any setting other than `-1` also logs messages if the autovacuum action is skipped because of a conflicting lock or concurrently dropped relations. For more information, see [Automatic Vacuuming](#) in the PostgreSQL documentation.

To troubleshoot issues, you can change the `rds.force_autovacuum_logging_level` parameter to one of the debug levels, from `debug1` up to `debug5` for the most verbose information. We recommend that you use debug settings for short periods of time and for troubleshooting purposes only. To learn more, see [When to log](#) in the PostgreSQL documentation.

#### Note

PostgreSQL allows the `rds_superuser` account to view autovacuum sessions in `pg_stat_activity`. For example, you can identify and end an autovacuum session that is blocking a command from running, or running slower than a manually issued vacuum command.

## Understanding the behavior of autovacuum with invalid databases

A new value `-2` is introduced into the `datconnlimit` column in the `pg_database` catalog to indicate databases that have been interrupted in the middle of the `DROP DATABASE` operation as invalid.

This new value is available from the following RDS for PostgreSQL versions:

- 15.4 and all higher versions
- 14.9 and higher versions
- 13.12 and higher versions
- 12.16 and higher versions
- 11.21 and higher versions

Invalid databases do not affect autovacuum's ability to freeze functionality for valid databases. Autovacuum ignores invalid databases. Consequently, regular vacuum operations will continue to function properly and efficiently for all valid databases in your PostgreSQL environment.

## Topics

- [Monitoring transaction ID](#)
- [Adjusting the monitoring query](#)
- [Resolving invalid database issue](#)

## Monitoring transaction ID

The `age(datfrozenxid)` function is commonly used to monitor the transaction ID (XID) age of databases to prevent transaction ID wraparound.

Since invalid databases are excluded from autovacuum, their transaction ID (XID) counter can reach the maximum value of 2 billion, wrap around to - 2 billion, and continue this cycle indefinitely. A typical query to monitor Transaction ID wraparound might look like:

```
SELECT max(age(datfrozenxid)) FROM pg_database;
```

However, with the introduction of the -2 value for `datconnlimit`, invalid databases can skew the results of this query. Since these databases are not valid and should not be part of regular maintenance checks, they can cause false positives, leading you to believe that the `age(datfrozenxid)` is higher than it actually is.

## Adjusting the monitoring query

To ensure accurate monitoring, you should adjust your monitoring query to exclude invalid databases. Follow this recommended query:

```
SELECT
    max(age(datfrozenxid))
FROM
    pg_database
WHERE
    datconlimit <> -2;
```

This query ensures that only valid databases are considered in the `age(datfrozenxid)` calculation, providing a true reflection of the transaction ID age across your PostgreSQL environment.

### Resolving invalid database issue

When attempting to connect to an invalid database, you may encounter an error message similar to the following:

```
postgres=> \c db1
connection to server at "mydb.xxxxxxxxxx.us-west-2.rds.amazonaws.com" (xx.xx.xx.xxx),
port xxxx failed: FATAL: cannot connect to invalid database "db1"
HINT: Use DROP DATABASE to drop invalid databases.
Previous connection kept
```

Additionally, if the `log_min_messages` parameter is set to `DEBUG2` or higher, you may notice the following log entries indicating that the autovacuum process is skipping the invalid database:

```
2024-07-30 05:59:00 UTC::@[32000]:DEBUG: autovacuum: skipping invalid database "db6"
2024-07-30 05:59:00 UTC::@[32000]:DEBUG: autovacuum: skipping invalid database "db1"
```

To resolve the issue, follow the HINT provided during the connection attempt. Connect to any valid database using your RDS master account or a database account with the `rds_superuser` role, and drop invalid database(s).

```
SELECT
```

```
'DROP DATABASE ' || quote_ident(datname) || ';'
FROM
  pg_database
WHERE
  datconlimit = -2 \gexec
```

## Working with logging mechanisms supported by RDS for PostgreSQL

There are several parameters, extensions, and other configurable items that you can set to log activities that occur on your PostgreSQL DB instance. These include the following:

- The `log_statement` parameter can be used to log user activity in your PostgreSQL database. To learn more about RDS for PostgreSQL logging and how to monitor the logs, see [RDS for PostgreSQL database log files](#).
- The `rds.force_admin_logging_level` parameter logs actions by the Amazon RDS internal user (`rdsadmin`) in the databases on the DB instance. It writes the output to the PostgreSQL error log. Allowed values are `disabled`, `debug5`, `debug4`, `debug3`, `debug2`, `debug1`, `info`, `notice`, `warning`, `error`, `log`, `fatal`, and `panic`. The default value is `disabled`.
- The `rds.force_autovacuum_logging_level` parameter can be set to capture various autovacuum operations in the PostgreSQL error log. For more information, see [Logging autovacuum and vacuum activities](#).
- The PostgreSQL Audit (`pgAudit`) extension can be installed and configured to capture activities at the session level or at the object level. For more information, see [Using pgAudit to log database activity](#).
- The `log_fdw` extension makes it possible for you to access the database engine log using SQL. For more information, see [Using the log\\_fdw extension to access the DB log using SQL](#).
- The `pg_stat_statements` library is specified as the default for the `shared_preload_libraries` parameter in RDS for PostgreSQL version 10 and higher. It's this library that you can use to analyze running queries. Be sure that `pg_stat_statements` is set in your DB parameter group. For more information about monitoring your RDS for PostgreSQL DB instance using the information that this library provides, see [SQL statistics for RDS PostgreSQL](#).
- The `log_hostname` parameter captures to the log the hostname of each client connection. For RDS for PostgreSQL version 12 and higher versions, this parameter is set to `off` by default. If you turn it on, be sure to monitor session connection times. When turned on, the service uses the domain name system (DNS) reverse lookup request to get the hostname of the client that's making the connection and add it to the PostgreSQL log. This has a noticeable impact

during session connection. We recommend that you turn on this parameter for troubleshooting purposes only.

In general terms, the point of logging is so that the DBA can monitor, tune performance, and troubleshoot. Many of the logs are uploaded automatically to Amazon CloudWatch or Performance Insights. Here, they're sorted and grouped to provide complete metrics for your DB instance. To learn more about Amazon RDS monitoring and metrics, see [Monitoring metrics in an Amazon RDS instance](#).

## Managing temporary files with PostgreSQL

In PostgreSQL, a complex query might perform several sort or hash operations at the same time, with each operation using instance memory to store results up to the value specified in the [work\\_mem](#) parameter. When the instance memory is not sufficient, temporary files are created to store the results. These are written to disk to complete the query execution. Later, these files are automatically removed after the query completes. In RDS for PostgreSQL, these files are stored in Amazon EBS on the data volume. For more information, see [Amazon RDS DB instance storage](#). You can monitor the `FreeStorageSpace` metric published in CloudWatch to make sure that your DB instance has enough free storage space. For more information, see [FreeStorageSpace](#).

We recommend using Amazon RDS Optimized Read instances for the workloads involving multiple concurrent queries that increase the usage of temporary files. These instances use local Non-Volatile Memory Express (NVMe) based solid state drive (SSD) block-level storage to place the temporary files. For more information, see [Amazon RDS Optimized Reads](#).

You can use the following parameters and functions to manage the temporary files in your instance.

- [temp\\_file\\_limit](#) – This parameter cancels any query exceeding the size of `temp_files` in KB. This limit prevents any query from running endlessly and consuming disk space with temporary files. You can estimate the value using the results from the `log_temp_files` parameter. As a best practice, examine the workload behavior and set the limit according to the estimation. The following example shows how a query is canceled when it exceeds the limit.

```
postgres=>select * from pgbench_accounts, pg_class, big_table;
```

```
ERROR: temporary file size exceeds temp_file_limit (64kB)
```

- [log\\_temp\\_files](#) – This parameter sends messages to the postgresql.log when the temporary files of a session are removed. This parameter produces logs after a query successfully completes. Therefore, it might not help in troubleshooting active, long-running queries.

The following example shows that when the query successfully completes, the entries are logged in the postgresql.log file while the temporary files are cleaned up.

```
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:LOG:
temporary file: path "base/pgsql_tmp/pgsql_tmp31236.5", size 140353536
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:STATEMENT:
select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order by
a.bid limit 10;
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:LOG:
temporary file: path "base/pgsql_tmp/pgsql_tmp31236.4", size 180428800
2023-02-06 23:48:35 UTC:205.251.233.182(12456):adminuser@postgres:[31236]:STATEMENT:
select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order by
a.bid limit 10;
```

- [pg\\_ls\\_tmpdir](#) – This function that is available from RDS for PostgreSQL 13 and above provides visibility into the current temporary file usage. The completed query doesn't appear in the results of the function. In the following example, you can view the results of this function.

```
postgres=>select * from pg_ls_tmpdir();
```

name	size	modification
pgsql_tmp8355.1	1072250880	2023-02-06 22:54:56+00
pgsql_tmp8351.0	1072250880	2023-02-06 22:54:43+00
pgsql_tmp8327.0	1072250880	2023-02-06 22:54:56+00
pgsql_tmp8351.1	703168512	2023-02-06 22:54:56+00
pgsql_tmp8355.0	1072250880	2023-02-06 22:54:00+00
pgsql_tmp8328.1	835031040	2023-02-06 22:54:56+00
pgsql_tmp8328.0	1072250880	2023-02-06 22:54:40+00

(7 rows)

```
postgres=>select query from pg_stat_activity where pid = 8355;
```

```
query
```

```
-----
select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order by
a.bid
```

```
(1 row)
```

The file name includes the processing ID (PID) of the session that generated the temporary file. A more advanced query, such as in the following example, performs a sum of the temporary files for each PID.

```
postgres=>select replace(left(name, strpos(name, '.')-1), 'pgsql_tmp', '') as pid,
count(*), sum(size) from pg_ls_tmpdir() group by pid;
```

```
pid | count | sum
-----+-----
8355 |      2 | 2144501760
8351 |      2 | 2090770432
8327 |      1 | 1072250880
8328 |      2 | 2144501760
(4 rows)
```

- [pg\\_stat\\_statements](#) – If you activate the `pg_stat_statements` parameter, then you can view the average temporary file usage per call. You can identify the `query_id` of the query and use it to examine the temporary file usage as shown in the following example.

```
postgres=>select queryid from pg_stat_statements where query like 'select a.aid from
pgbench%';
```

```
queryid
```

```
-----
-7170349228837045701
(1 row)
```

```
postgres=>select queryid, substr(query,1,25), calls, temp_blks_read/calls
temp_blks_read_per_call, temp_blks_written/calls temp_blks_written_per_call from
pg_stat_statements where queryid = -7170349228837045701;
```

```

      queryid      |      substr      | calls | temp_blks_read_per_call |
temp_blks_written_per_call
-----+-----+-----+-----
-7170349228837045701 | select a.aid from pgbench |    50 |           239226 |
                    388678
(1 row)
```

- **Performance Insights** – In the Performance Insights dashboard, you can view temporary file usage by turning on the metrics **temp\_bytes** and **temp\_files**. Then, you can see the average of both of these metrics and see how they correspond to the query workload. The view within Performance Insights doesn't show specifically the queries that are generating the temporary files. However, when you combine Performance Insights with the query shown for `pg_ls_tmpdir`, you can troubleshoot, analyze, and determine the changes in your query workload.

For more information about how to analyze metrics and queries with Performance Insights, see [Analyzing metrics with the Performance Insights dashboard](#).

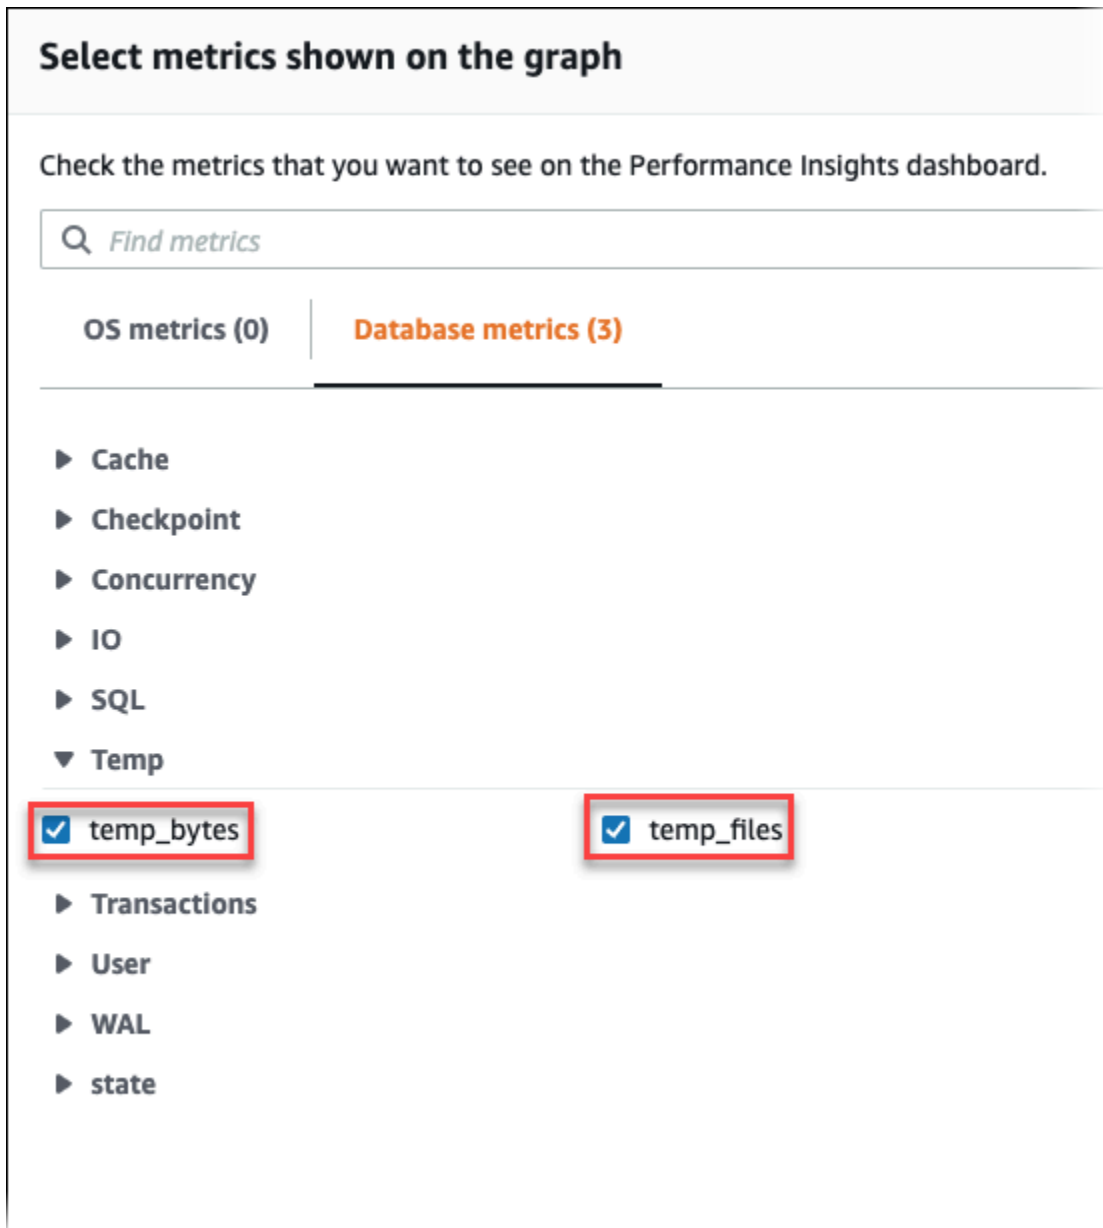

For an example of viewing temporary file usage with Performance Insights, see [Viewing temporary file usage with Performance Insights](#)

## Viewing temporary file usage with Performance Insights

You can use Performance Insights to view temporary file usage by turning on the metrics **temp\_bytes** and **temp\_files**. The view in Performance Insights doesn't show the specific queries that generate temporary files, however, when you combine Performance Insights with the query shown for `pg_ls_tmpdir`, you can troubleshoot, analyze, and determine the changes in your query workload.

1. In the Performance Insights dashboard, choose **Manage Metrics**.

2. Choose **Database metrics**, and select the **temp\_bytes** and **temp\_files** metrics as shown in the following image.

3. In the **Top SQL** tab, choose the **Preferences** icon.
4. In the **Preferences** window, turn on the following statistics to appear in the **Top SQL** tab and choose **Continue**.
  - Temp writes/sec
  - Temp reads/sec
  - Tmp blk write/call
  - Tmp blk read/call

5. The temporary file is broken out when combined with the query shown for `pg_ls_tmpdir`, as shown in the following example.

SQL statements	Calls/sec	Rows/sec	Temp wri...	Temp rea...	Tmp blk ...	Tmp blk r...
11.77 <code>select a.aid from pgbench_accounts a, pgbench_accounts b where a.bid=b.bid order...</code>	0.04	0.43	16589.14	10307.89	381550.15	237081.46

The `IO:BufFileRead` and `IO:BufFileWrite` events occur when the top queries in your workload often create temporary files. You can use Performance Insights to identify top queries waiting on `IO:BufFileRead` and `IO:BufFileWrite` by reviewing Average Active Session (AAS) in Database Load and Top SQL sections.

For more information on how to analyze top queries and load by wait event with Performance Insights, see [Overview of the Top SQL tab](#). You should identify and tune the queries that cause increase in temporary file usage and related wait events. For more information on these wait events and remediation, see [IO:BufFileRead and IO:BufFileWrite](#).

### Note

The `work_mem` parameter controls when the sort operation runs out of memory and results are written into temporary files. We recommend that you don't change the setting of this parameter higher than the default value because it would permit every database session to consume more memory. Also, a single session that performs complex joins and sorts can perform parallel operations in which each operation consumes memory.

As a best practice, when you have a large report with multiple joins and sorts, set this parameter at the session level by using the `SET work_mem` command. Then the change is only applied to the current session and doesn't change the value globally.

## Using pgBadger for log analysis with PostgreSQL

You can use a log analyzer such as [pgBadger](#) to analyze PostgreSQL logs. The pgBadger documentation states that the `%l` pattern (the log line for the session or process) should be a part of the prefix. However, if you provide the current RDS `log_line_prefix` as a parameter to pgBadger it should still produce a report.

For example, the following command correctly formats an Amazon RDS for PostgreSQL log file dated 2014-02-04 using pgBadger.

```
./pgbadger -f stderr -p '%t:%r:%u@%d:[%p]:' postgresql.log.2014-02-04-00
```

## Using PGSnapper for monitoring PostgreSQL

You can use PGSnapper to assist with periodic collection of Amazon RDS for PostgreSQL performance-related statistics and metrics. For more information, see [Monitor Amazon RDS for PostgreSQL performance using PGSnapper](#).

## Working with parameters on your RDS for PostgreSQL DB instance

In some cases, you might create an RDS for PostgreSQL DB instance without specifying a custom parameter group. If so, your DB instance is created using the default parameter group for the version of PostgreSQL that you choose. For example, suppose that you create an RDS for PostgreSQL DB instance using PostgreSQL 13.3. In this case, the DB instance is created using the values in the parameter group for PostgreSQL 13 releases, `default.postgres13`.

You can also create your own custom DB parameter group. You need to do this if you want to modify any settings for the RDS for PostgreSQL DB instance from their default values. To learn how, see [Parameter groups for Amazon RDS](#).

You can track the settings on your RDS for PostgreSQL DB instance in several different ways. You can use the AWS Management Console, the AWS CLI, or the Amazon RDS API. You can also query the values from the PostgreSQL `pg_settings` table of your instance, as shown following.

```
SELECT name, setting, boot_val, reset_val, unit
FROM pg_settings
ORDER BY name;
```

To learn more about the values returned from this query, see [pg\\_settings](#) in the PostgreSQL documentation.

Be especially careful when changing the settings for `max_connections` and `shared_buffers` on your RDS for PostgreSQL DB instance. For example, suppose that you modify settings for `max_connections` or `shared_buffers` and you use values that are too high for your actual workload. In this case, your RDS for PostgreSQL DB instance won't start. If this happens, you see an error such as the following in the `postgres.log`.

```
2018-09-18 21:13:15 UTC::@[8097]:FATAL:  could not map anonymous shared memory: Cannot
allocate memory
2018-09-18 21:13:15 UTC::@[8097]:HINT:  This error usually means that PostgreSQL's
request for a shared memory segment
exceeded available memory or swap space. To reduce the request size (currently
3514134274048 bytes), reduce
PostgreSQL's shared memory usage, perhaps by reducing shared_buffers or
max_connections.
```

However, you can't change any values of the settings contained in the default RDS for PostgreSQL DB parameter groups. To change settings for any parameters, first create a custom DB parameter group. Then change the settings in that custom group, and then apply the custom parameter group to your RDS for PostgreSQL DB instance. To learn more, see [Parameter groups for Amazon RDS](#).

There are two types of parameters in RDS for PostgreSQL.

- **Static parameters** – Static parameters require that the RDS for PostgreSQL DB instance be rebooted after a change so that the new value can take effect.
- **Dynamic parameters** – Dynamic parameters don't require a reboot after changing their settings.

**Note**

If your RDS for PostgreSQL DB instance is using your own custom DB parameter group, you can change the values of dynamic parameters on the running DB instance. You can do this by using the AWS Management Console, the AWS CLI, or the Amazon RDS API.

If you have privileges to do so, you can also change parameter values by using the ALTER DATABASE, ALTER ROLE, and SET commands.

## RDS for PostgreSQL DB instance parameter list

The following table lists some (but not all) parameters available in an RDS for PostgreSQL DB instance. To view all available parameters, you use the [describe-db-parameters](#) AWS CLI command. For example, to get the list of all parameters available in the default parameter group for RDS for PostgreSQL version 13, run the following.

```
aws rds describe-db-parameters --db-parameter-group-name default.postgres13
```

You can also use the Console. Choose **Parameter groups** from the Amazon RDS menu, and then choose the parameter group from those available in your AWS Region.

Parameter name	Apply_Type	Description
application_name	Dynamic	Sets the application name to be reported in statistics and logs.
archive_command	Dynamic	Sets the shell command that will be called to archive a WAL file.
array_nulls	Dynamic	Enables input of NULL elements in arrays.
authentication_timeout	Dynamic	Sets the maximum allowed time to complete client authentication.
autovacuum	Dynamic	Starts the autovacuum subprocess.
autovacuum_analyze_scale_factor	Dynamic	Number of tuple inserts, updates, or deletes before analyze as a fraction of reltuples.
autovacuum_analyze_threshold	Dynamic	Minimum number of tuple inserts, updates, or deletes before analyze.
autovacuum_freeze_max_age	Static	Age at which to autovacuum a table to prevent transaction ID wraparound.
autovacuum_naptime	Dynamic	Time to sleep between autovacuum runs.

Parameter name	Apply_Type	Description
autovacuum_max_workers	Static	Sets the maximum number of simultaneously running autovacuum worker processes.
autovacuum_vacuum_cost_delay	Dynamic	Vacuum cost delay, in milliseconds, for autovacuum.
autovacuum_vacuum_cost_limit	Dynamic	Vacuum cost amount available before napping, for autovacuum.
autovacuum_vacuum_scale_factor	Dynamic	Number of tuple updates or deletes before vacuum as a fraction of reltuples.
autovacuum_vacuum_threshold	Dynamic	Minimum number of tuple updates or deletes before vacuum.
backslash_quote	Dynamic	Sets whether a backslash (\) is allowed in string literals.
bgwriter_delay	Dynamic	Background writer sleep time between rounds.
bgwriter_lru_maxpages	Dynamic	Background writer maximum number of LRU pages to flush per round.
bgwriter_lru_multiplier	Dynamic	Multiple of the average buffer usage to free per round.
bytea_output	Dynamic	Sets the output format for bytes.
check_function_bodies	Dynamic	Checks function bodies during CREATE FUNCTION.
checkpoint_completion_target	Dynamic	Time spent flushing dirty buffers during checkpoint, as a fraction of the checkpoint interval.

Parameter name	Apply_Type	Description
checkpoint_segments	Dynamic	Sets the maximum distance in log segments between automatic write-ahead log (WAL) checkpoints.
checkpoint_timeout	Dynamic	Sets the maximum time between automatic WAL checkpoints.
checkpoint_warning	Dynamic	Enables warnings if checkpoint segments are filled more frequently than this.
client_connection_check_interval	Dynamic	Sets the time interval between checks for disconnection while running queries.
client_encoding	Dynamic	Sets the client's character set encoding.
client_min_messages	Dynamic	Sets the message levels that are sent to the client.
commit_delay	Dynamic	Sets the delay in microseconds between transaction commit and flushing WAL to disk.
commit_siblings	Dynamic	Sets the minimum concurrent open transactions before performing commit_delay.
constraint_exclusion	Dynamic	Enables the planner to use constraints to optimize queries.
cpu_index_tuple_cost	Dynamic	Sets the planner's estimate of the cost of processing each index entry during an index scan.
cpu_operator_cost	Dynamic	Sets the planner's estimate of the cost of processing each operator or function call.
cpu_tuple_cost	Dynamic	Sets the planner's estimate of the cost of processing each tuple (row).
cursor_tuple_fraction	Dynamic	Sets the planner's estimate of the fraction of a cursor's rows that will be retrieved.

Parameter name	Apply_Type	Description
datestyle	Dynamic	Sets the display format for date and time values.
deadlock_timeout	Dynamic	Sets the time to wait on a lock before checking for deadlock.
debug_pretty_print	Dynamic	Indents parse and plan tree displays.
debug_print_parse	Dynamic	Logs each query's parse tree.
debug_print_plan	Dynamic	Logs each query's execution plan.
debug_print_rewritten	Dynamic	Logs each query's rewritten parse tree.
default_statistics_target	Dynamic	Sets the default statistics target.
default_tablespace	Dynamic	Sets the default tablespace to create tables and indexes in.
default_transaction_deferrable	Dynamic	Sets the default deferrable status of new transactions.
default_transaction_isolation	Dynamic	Sets the transaction isolation level of each new transaction.
default_transaction_read_only	Dynamic	Sets the default read-only status of new transactions.
default_with_oids	Dynamic	Creates new tables with object IDs (OIDs) by default.
effective_cache_size	Dynamic	Sets the planner's assumption about the size of the disk cache.
effective_io_concurrency	Dynamic	Number of simultaneous requests that can be handled efficiently by the disk subsystem.

Parameter name	Apply_Type	Description
<code>enable_bitmapscan</code>	Dynamic	Enables the planner's use of bitmap-scan plans.
<code>enable_hashagg</code>	Dynamic	Enables the planner's use of hashed aggregation plans.
<code>enable_hashjoin</code>	Dynamic	Enables the planner's use of hash join plans.
<code>enable_indexscan</code>	Dynamic	Enables the planner's use of index-scan plans.
<code>enable_material</code>	Dynamic	Enables the planner's use of materialization.
<code>enable_mergejoin</code>	Dynamic	Enables the planner's use of merge join plans.
<code>enable_nestloop</code>	Dynamic	Enables the planner's use of nested-loop join plans.
<code>enable_seqscan</code>	Dynamic	Enables the planner's use of sequential-scan plans.
<code>enable_sort</code>	Dynamic	Enables the planner's use of explicit sort steps.
<code>enable_tidscan</code>	Dynamic	Enables the planner's use of TID scan plans.
<code>escape_string_warning</code>	Dynamic	Warns about backslash (\) escapes in ordinary string literals.
<code>extra_float_digits</code>	Dynamic	Sets the number of digits displayed for floating-point values.
<code>from_collapse_limit</code>	Dynamic	Sets the FROM-list size beyond which subqueries are not collapsed.
<code>fsync</code>	Dynamic	Forces synchronization of updates to disk.
<code>full_page_writes</code>	Dynamic	Writes full pages to WAL when first modified after a checkpoint.
<code>geqo</code>	Dynamic	Enables genetic query optimization.

Parameter name	Apply_Type	Description
geqo_effort	Dynamic	GEQO: effort is used to set the default for other GEQO parameters.
geqo_generations	Dynamic	GEQO: number of iterations of the algorithm.
geqo_pool_size	Dynamic	GEQO: number of individuals in the population.
geqo_seed	Dynamic	GEQO: seed for random path selection.
geqo_selection_bias	Dynamic	GEQO: selective pressure within the population.
geqo_threshold	Dynamic	Sets the threshold of FROM items beyond which GEQO is used.
gin_fuzzy_search_limit	Dynamic	Sets the maximum allowed result for exact search by GIN.
hot_standby_feedback	Dynamic	Determines whether a hot standby sends feedback messages to the primary or upstream standby.
intervalstyle	Dynamic	Sets the display format for interval values.
join_collapse_limit	Dynamic	Sets the FROM-list size beyond which JOIN constructs are not flattened.
lc_messages	Dynamic	Sets the language in which messages are displayed.
lc_monetary	Dynamic	Sets the locale for formatting monetary amounts.
lc_numeric	Dynamic	Sets the locale for formatting numbers.
lc_time	Dynamic	Sets the locale for formatting date and time values.

Parameter name	Apply_Type	Description
log_autovacuum_min_duration	Dynamic	Sets the minimum running time above which autovacuum actions will be logged.
log_checkpoints	Dynamic	Logs each checkpoint.
log_connections	Dynamic	Logs each successful connection.
log_disconnections	Dynamic	Logs end of a session, including duration.
log_duration	Dynamic	Logs the duration of each completed SQL statement.
log_error_verbosity	Dynamic	Sets the verbosity of logged messages.
log_executor_stats	Dynamic	Writes executor performance statistics to the server log.
log_filename	Dynamic	Sets the file name pattern for log files.
log_file_mode	Dynamic	Sets file permissions for log files. Default value is 0644.
log_hostname	Dynamic	Logs the host name in the connection logs. As of PostgreSQL 12 and later versions, this parameter is 'off' by default. When turned on, the connection uses DNS reverse-lookup to get the hostname that gets captured to the connection logs. If you turn on this parameter, you should monitor the impact that it has on the time it takes to establish connections.
log_line_prefix	Dynamic	Controls information prefixed to each log line.
log_lock_waits	Dynamic	Logs long lock waits.
log_min_duration_statement	Dynamic	Sets the minimum running time above which statements will be logged.

Parameter name	Apply_Type	Description
log_min_error_statement	Dynamic	Causes all statements generating an error at or above this level to be logged.
log_min_messages	Dynamic	Sets the message levels that are logged.
log_parser_stats	Dynamic	Writes parser performance statistics to the server log.
log_planner_stats	Dynamic	Writes planner performance statistics to the server log.
log_rotation_age	Dynamic	Automatic log file rotation will occur after N minutes.
log_rotation_size	Dynamic	Automatic log file rotation will occur after N kilobytes.
log_statement	Dynamic	Sets the type of statements logged.
log_statement_stats	Dynamic	Writes cumulative performance statistics to the server log.
log_temp_files	Dynamic	Logs the use of temporary files larger than this number of kilobytes.
log_timezone	Dynamic	Sets the time zone to use in log messages.
log_truncate_on_rotation	Dynamic	Truncate existing log files of same name during log rotation.
logging_collector	Static	Start a subprocess to capture stderr output and/or csvlogs into log files.
maintenance_work_mem	Dynamic	Sets the maximum memory to be used for maintenance operations.

Parameter name	Apply_Type	Description
<code>max_connections</code>	Static	Sets the maximum number of concurrent connections.
<code>max_files_per_process</code>	Static	Sets the maximum number of simultaneously open files for each server process.
<code>max_locks_per_transaction</code>	Static	Sets the maximum number of locks per transaction.
<code>max_pred_locks_per_transaction</code>	Static	Sets the maximum number of predicate locks per transaction.
<code>max_prepared_transactions</code>	Static	Sets the maximum number of simultaneously prepared transactions.
<code>max_stack_depth</code>	Dynamic	Sets the maximum stack depth, in kilobytes.
<code>max_standby_archive_delay</code>	Dynamic	Sets the maximum delay before canceling queries when a hot standby server is processing archived WAL data.
<code>max_standby_streaming_delay</code>	Dynamic	Sets the maximum delay before canceling queries when a hot standby server is processing streamed WAL data.
<code>max_wal_size</code>	Dynamic	Sets the WAL size (MB) that triggers a checkpoint. For all versions after RDS for PostgreSQL 10, the default is at least 1 GB (1024 MB). For example, <code>max_wal_size</code> setting for RDS for PostgreSQL 14 is 2 GB (2048 MB). Use the <code>SHOW max_wal_size;</code> command on your RDS for PostgreSQL DB instance to see its current value.

Parameter name	Apply_Type	Description
<code>min_wal_size</code>	Dynamic	Sets the minimum size to shrink the WAL to. For PostgreSQL version 9.6 and earlier, <code>min_wal_size</code> is in units of 16 MB. For PostgreSQL version 10 and later, <code>min_wal_size</code> is in units of 1 MB.
<code>quote_all_identifiers</code>	Dynamic	Adds quotes (") to all identifiers when generating SQL fragments.
<code>random_page_cost</code>	Dynamic	Sets the planner's estimate of the cost of a non-sequentially fetched disk page. This parameter has no value unless query plan management (QPM) is turned on. When QPM is on, the default value for this parameter 4.
<code>rds.adaptive_autovacuum</code>	Dynamic	Automatically tunes the autovacuum parameters whenever the transaction ID thresholds are exceeded.
<code>rds.force_ssl</code>	Dynamic	Requires the use of SSL connections. The default value is set to 1 (on) for RDS for PostgreSQL version 15. All other RDS for PostgreSQL major version 14 and older have the default value set to 0 (off).
<code>rds.local_volume_spill_enabled</code>	Static	Enables writing logical spill files to the local volume.
<code>rds.log_retention_period</code>	Dynamic	Sets log retention such that Amazon RDS deletes PostgreSQL logs that are older than <i>n</i> minutes.
<code>rds.rds_superuser_reserved_connections</code>	Static	Sets the number of connection slots reserved for <code>rds_superuser</code> s. This parameter is only available in versions 15 and earlier. For more information, see the PostgreSQL documentation <a href="#">reserved_connections</a> .

Parameter name	Apply_Type	Description
<code>rds.restrict_password_commands</code>	Static	Restricts who can manage passwords to users with the <code>rds_password</code> role. Set this parameter to 1 to enable password restriction. The default is 0.
<code>search_path</code>	Dynamic	Sets the schema search order for names that are not schema-qualified.
<code>seq_page_cost</code>	Dynamic	Sets the planner's estimate of the cost of a sequentially fetched disk page.
<code>session_replication_role</code>	Dynamic	Sets the sessions behavior for triggers and rewrite rules.
<code>shared_buffers</code>	Static	Sets the number of shared memory buffers used by the server.
<code>shared_preload_libraries</code>	Static	Lists the shared libraries to preload into the RDS for PostgreSQL DB instance. Supported values include <code>auto_explain</code> , <code>orafce</code> , <code>pgaudit</code> , <code>pglogical</code> , <code>pg_bigm</code> , <code>pg_cron</code> , <code>pg_hint_plan</code> , <code>pg_prewarm</code> , <code>pg_similarity</code> , <code>pg_stat_statements</code> , <code>pg_tle</code> , <code>pg_transport</code> , <code>plprofiler</code> , and <code>plrust</code> .
<code>ssl</code>	Dynamic	Enables SSL connections.
<code>sql_inheritance</code>	Dynamic	Causes subtables to be included by default in various commands.
<code>ssl_renegotiation_limit</code>	Dynamic	Sets the amount of traffic to send and receive before renegotiating the encryption keys.
<code>standard_conforming_strings</code>	Dynamic	Causes ... strings to treat backslashes literally.

Parameter name	Apply_Type	Description
statement_timeout	Dynamic	Sets the maximum allowed duration of any statement.
synchronize_seqscans	Dynamic	Enables synchronized sequential scans.
synchronous_commit	Dynamic	Sets the current transactions synchronization level.
tcp_keepalives_count	Dynamic	Maximum number of TCP keepalive retransmits.
tcp_keepalives_idle	Dynamic	Time between issuing TCP keepalives.
tcp_keepalives_interval	Dynamic	Time between TCP keepalive retransmits.
temp_buffers	Dynamic	Sets the maximum number of temporary buffers used by each session.
temp_file_limit	Dynamic	Sets the maximum size in KB to which the temporary files can grow.
temp_tablespaces	Dynamic	Sets the tablespaces to use for temporary tables and sort files.

Parameter name	Apply_Type	Description
timezone	Dynamic	<p>Sets the time zone for displaying and interpreting time stamps.</p> <p>The Internet Assigned Numbers Authority (IANA) publishes new time zones at <a href="https://www.iana.org/time-zones">https://www.iana.org/time-zones</a> several times a year. Every time RDS releases a new minor maintenance release of PostgreSQL, it ships with the latest time zone data at the time of the release. When you use the latest RDS for PostgreSQL versions, you have recent time zone data from RDS. To ensure that your DB instance has recent time zone data, we recommend upgrading to a higher DB engine version. You can't modify the time zone tables in PostgreSQL DB instances manually. RDS doesn't modify or reset the time zone data of running DB instances. New time zone data is installed only when you perform a database engine version upgrade.</p>
track_activities	Dynamic	Collects information about running commands.
track_activity_query_size	Static	Sets the size reserved for pg_stat_activity.current_query, in bytes.
track_counts	Dynamic	Collects statistics on database activity.
track_functions	Dynamic	Collects function-level statistics on database activity.
track_io_timing	Dynamic	Collects timing statistics on database I/O activity.
transaction_deferrable	Dynamic	Indicates whether to defer a read-only serializable transaction until it can be started with no possible serialization failures.

Parameter name	Apply_Type	Description
transaction_isolation	Dynamic	Sets the current transactions isolation level.
transaction_read_only	Dynamic	Sets the current transactions read-only status.
transform_null_equals	Dynamic	Treats expr=NULL as expr IS NULL.
update_process_title	Dynamic	Updates the process title to show the active SQL command.
vacuum_cost_delay	Dynamic	Vacuum cost delay in milliseconds.
vacuum_cost_limit	Dynamic	Vacuum cost amount available before napping.
vacuum_cost_page_dirty	Dynamic	Vacuum cost for a page dirtied by vacuum.
vacuum_cost_page_hit	Dynamic	Vacuum cost for a page found in the buffer cache.
vacuum_cost_page_miss	Dynamic	Vacuum cost for a page not found in the buffer cache.
vacuum_defer_cleanup_age	Dynamic	Number of transactions by which vacuum and hot cleanup should be deferred, if any.
vacuum_freeze_min_age	Dynamic	Minimum age at which vacuum should freeze a table row.
vacuum_freeze_table_age	Dynamic	Age at which vacuum should scan a whole table to freeze tuples.
wal_buffers	Static	Sets the number of disk-page buffers in shared memory for WAL.
wal_writer_delay	Dynamic	WAL writer sleep time between WAL flushes.

Parameter name	Apply_Type	Description
work_mem	Dynamic	Sets the maximum memory to be used for query workspaces.
xmlbinary	Dynamic	Sets how binary values are to be encoded in XML.
xmloption	Dynamic	Sets whether XML data in implicit parsing and serialization operations is to be considered as documents or content fragments.

Amazon RDS uses the default PostgreSQL units for all parameters. The following table shows the PostgreSQL default unit for each parameter.

Parameter name	Unit
archive_timeout	s
authentication_timeout	s
autovacuum_naptime	s
autovacuum_vacuum_cost_delay	ms
bgwriter_delay	ms
checkpoint_timeout	s
checkpoint_warning	s
deadlock_timeout	ms
effective_cache_size	8 KB
lock_timeout	ms
log_autovacuum_min_duration	ms

Parameter name	Unit
log_min_duration_statement	ms
log_rotation_age	minutes
log_rotation_size	KB
log_temp_files	KB
maintenance_work_mem	KB
max_stack_depth	KB
max_standby_archive_delay	ms
max_standby_streaming_delay	ms
post_auth_delay	s
pre_auth_delay	s
segment_size	8 KB
shared_buffers	8 KB
statement_timeout	ms
ssl_renegotiation_limit	KB
tcp_keepalives_idle	s
tcp_keepalives_interval	s
temp_file_limit	KB
work_mem	KB
temp_buffers	8 KB
vacuum_cost_delay	ms

Parameter name	Unit
wal_buffers	8 KB
wal_receiver_timeout	ms
wal_segment_size	B
wal_sender_timeout	ms
wal_writer_delay	ms
wal_receiver_status_interval	s

# Tuning with wait events for RDS for PostgreSQL

Wait events are an important tuning tool for RDS for PostgreSQL. When you can find out why sessions are waiting for resources and what they are doing, you're better able to reduce bottlenecks. You can use the information in this section to find possible causes and corrective actions. This section also discusses basic PostgreSQL tuning concepts.

The wait events in this section are specific to RDS for PostgreSQL.

## Essential concepts for RDS for PostgreSQL tuning

Before you tune your RDS for PostgreSQL database, make sure to learn what wait events are and why they occur. Also review the basic memory and disk architecture of RDS for PostgreSQL. For a helpful architecture diagram, see the [PostgreSQL](#) wikibook.

### Topics

- [RDS for PostgreSQL wait events](#)
- [RDS for PostgreSQL memory](#)
- [RDS for PostgreSQL processes](#)

### RDS for PostgreSQL wait events

A *wait event* is an indication that the session is waiting for a resource. For example, the wait event `Client:ClientRead` occurs when RDS for PostgreSQL is waiting to receive data from the client. Sessions typically wait for resources such as the following.

- Single-threaded access to a buffer, for example, when a session is attempting to modify a buffer
- A row that is currently locked by another session
- A data file read
- A log file write

For example, to satisfy a query, the session might perform a full table scan. If the data isn't already in memory, the session waits for the disk I/O to complete. When the buffers are read into memory, the session might need to wait because other sessions are accessing the same buffers. The database records the waits by using a predefined wait event. These events are grouped into categories.

By itself, a single wait event doesn't indicate a performance problem. For example, if requested data isn't in memory, reading data from disk is necessary. If one session locks a row for an update, another session waits for the row to be unlocked so that it can update it. A commit requires waiting for the write to a log file to complete. Waits are integral to the normal functioning of a database.

On the other hand, large numbers of wait events typically show a performance problem. In such cases, you can use wait event data to determine where sessions are spending time. For example, if a report that typically runs in minutes now takes hours to run, you can identify the wait events that

contribute the most to total wait time. If you can determine the causes of the top wait events, you can sometimes make changes that improve performance. For example, if your session is waiting on a row that has been locked by another session, you can end the locking session.

## RDS for PostgreSQL memory

RDS for PostgreSQL memory is divided into shared and local.

### Topics

- [Shared memory in RDS for PostgreSQL](#)
- [Local memory in RDS for PostgreSQL](#)

## Shared memory in RDS for PostgreSQL

RDS for PostgreSQL allocates shared memory when the instance starts. Shared memory is divided into multiple subareas. Following, you can find a description of the most important ones.

### Topics

- [Shared buffers](#)
- [Write ahead log \(WAL\) buffers](#)

## Shared buffers

The *shared buffer pool* is an RDS for PostgreSQL memory area that holds all pages that are or were being used by application connections. A *page* is the memory version of a disk block. The shared buffer pool caches the data blocks read from disk. The pool reduces the need to reread data from disk, making the database operate more efficiently.

Every table and index is stored as an array of pages of a fixed size. Each block contains multiple tuples, which correspond to rows. A tuple can be stored in any page.

The shared buffer pool has finite memory. If a new request requires a page that isn't in memory, and no more memory exists, RDS for PostgreSQL evicts a less frequently used page to accommodate the request. The eviction policy is implemented by a clock sweep algorithm.

The `shared_buffers` parameter determines how much memory the server dedicates to caching data.

## Write ahead log (WAL) buffers

A *write-ahead log (WAL) buffer* holds transaction data that RDS for PostgreSQL later writes to persistent storage. Using the WAL mechanism, RDS for PostgreSQL can do the following:

- Recover data after a failure
- Reduce disk I/O by avoiding frequent writes to disk

When a client changes data, RDS for PostgreSQL writes the changes to the WAL buffer. When the client issues a COMMIT, the WAL writer process writes transaction data to the WAL file.

The `wal_level` parameter determines how much information is written to the WAL.

## Local memory in RDS for PostgreSQL

Every backend process allocates local memory for query processing.

### Topics

- [Work memory area](#)
- [Maintenance work memory area](#)
- [Temporary buffer area](#)

### Work memory area

The *work memory area* holds temporary data for queries that performs sorts and hashes. For example, a query with an ORDER BY clause performs a sort. Queries use hash tables in hash joins and aggregations.

The `work_mem` parameter the amount of memory to be used by internal sort operations and hash tables before writing to temporary disk files. The default value is 4 MB. Multiple sessions can run simultaneously, and each session can run maintenance operations in parallel. For this reason, the total work memory used can be multiples of the `work_mem` setting.

### Maintenance work memory area

The *maintenance work memory area* caches data for maintenance operations. These operations include vacuuming, creating an index, and adding foreign keys.

The `maintenance_work_mem` parameter specifies the maximum amount of memory to be used by maintenance operations. The default value is 64 MB. A database session can only run one maintenance operation at a time.

## Temporary buffer area

The *temporary buffer area* caches temporary tables for each database session.

Each session allocates temporary buffers as needed up to the limit you specify. When the session ends, the server clears the buffers.

The `temp_buffers` parameter sets the maximum number of temporary buffers used by each session. Before the first use of temporary tables within a session, you can change the `temp_buffers` value.

## RDS for PostgreSQL processes

RDS for PostgreSQL uses multiple processes.

### Topics

- [Postmaster process](#)
- [Backend processes](#)
- [Background processes](#)

### Postmaster process

The *postmaster process* is the first process started when you start RDS for PostgreSQL. The postmaster process has the following primary responsibilities:

- Fork and monitor background processes
- Receive authentication requests from client processes, and authenticate them before allowing the database to service requests

### Backend processes

If the postmaster authenticates a client request, the postmaster forks a new backend process, also called a postgres process. One client process connects to exactly one backend process. The client process and the backend process communicate directly without intervention by the postmaster process.

## Background processes

The postmaster process forks several processes that perform different backend tasks. Some of the more important include the following:

- WAL writer

RDS for PostgreSQL writes data in the WAL (write ahead logging) buffer to the log files. The principle of write ahead logging is that the database can't write changes to the data files until after the database writes log records describing those changes to disk. The WAL mechanism reduces disk I/O, and allows RDS for PostgreSQL to use the logs to recover the database after a failure.

- Background writer

This process periodically write dirty (modified) pages from the memory buffers to the data files. A page becomes dirty when a backend process modifies it in memory.

- Autovacuum daemon

The daemon consists of the following:

- The autovacuum launcher
- The autovacuum worker processes

When autovacuum is turned on, it checks for tables that have had a large number of inserted, updated, or deleted tuples. The daemon has the following responsibilities:

- Recover or reuse disk space occupied by updated or deleted rows
- Update statistics used by the planner
- Protect against loss of old data because of transaction ID wraparound

The autovacuum feature automates the execution of VACUUM and ANALYZE commands. VACUUM has the following variants: standard and full. Standard vacuum runs in parallel with other database operations. VACUUM FULL requires an exclusive lock on the table it is working on. Thus, it can't run in parallel with operations that access the same table. VACUUM creates a substantial amount of I/O traffic, which can cause poor performance for other active sessions.

## RDS for PostgreSQL wait events

The following table lists the wait events for RDS for PostgreSQL that most commonly indicate performance problems, and summarizes the most common causes and corrective actions..

Wait event	Definition
<a href="#">Client:ClientRead</a>	This event occurs when RDS for PostgreSQL is waiting to receive data from the client.
<a href="#">Client:ClientWrite</a>	This event occurs when RDS for PostgreSQL is waiting to write data to the client.
<a href="#">CPU</a>	This event occurs when a thread is active in CPU or is waiting for CPU.
<a href="#">IO:BufFileRead and IO:BufFileWrite</a>	These events occur when RDS for PostgreSQL creates temporary files.
<a href="#">IO:DataFileRead</a>	This event occurs when a connection waits on a backend process to read a required page from storage because the page isn't available in shared memory.
<a href="#">IO:WALWrite</a>	This event occurs when RDS for PostgreSQL is waiting for the write-ahead log (WAL) buffers to be written to a WAL file.
<a href="#">Lock:advisory</a>	This event occurs when a PostgreSQL application uses a lock to coordinate activity across multiple sessions.
<a href="#">Lock:extend</a>	This event occurs when a backend process is waiting to lock a relation to extend it while another process has a lock on that relation for the same purpose.

Wait event	Definition
<a href="#">Lock:Relation</a>	This event occurs when a query is waiting to acquire a lock on a table or view that's currently locked by another transaction.
<a href="#">Lock:transactionid</a>	This event occurs when a transaction is waiting for a row-level lock.
<a href="#">Lock:tuple</a>	This event occurs when a backend process is waiting to acquire a lock on a tuple.
<a href="#">LWLock:BufferMapping (LWLock:buffer_mapping)</a>	This event occurs when a session is waiting to associate a data block with a buffer in the shared buffer pool.
<a href="#">LWLock:BufferIO (IPC:BufferIO)</a>	This event occurs when RDS for PostgreSQL is waiting for other processes to finish their input/output (I/O) operations when concurrently trying to access a page.
<a href="#">LWLock:buffer_content (BufferContent)</a>	This event occurs when a session is waiting to read or write a data page in memory while another session has that page locked for writing.
<a href="#">LWLock:lock_manager (LWLock:lockmanager)</a>	This event occurs when the RDS for PostgreSQL engine maintains the shared lock's memory area to allocate, check, and deallocate a lock when a fast path lock isn't possible.
<a href="#">Timeout:PgSleep</a>	This event occurs when a server process has called the <code>pg_sleep</code> function and is waiting for the sleep timeout to expire.
<a href="#">Timeout:VacuumDelay</a>	This event indicates that the vacuum process is sleeping because the estimated cost limit has been reached.

## Client:ClientRead

The `Client:ClientRead` event occurs when RDS for PostgreSQL is waiting to receive data from the client.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

### Supported engine versions

This wait event information is supported for RDS for PostgreSQL version 10 and higher.

### Context

An RDS for PostgreSQL DB instance is waiting to receive data from the client. The RDS for PostgreSQL DB instance must receive the data from the client before it can send more data to the client. The time that the instance waits before receiving data from the client is a `Client:ClientRead` event.

### Likely causes of increased waits

Common causes for the `Client:ClientRead` event to appear in top waits include the following:

#### Increased network latency

There might be increased network latency between the RDS for PostgreSQL DB instance and client. Higher network latency increases the time required for DB instance to receive data from the client.

#### Increased load on the client

There might be CPU pressure or network saturation on the client. An increase in load on the client can delay transmission of data from the client to the RDS for PostgreSQL DB instance.

#### Excessive network round trips

A large number of network round trips between the RDS for PostgreSQL DB instance and the client can delay transmission of data from the client to the RDS for PostgreSQL DB instance.

## Large copy operation

During a copy operation, the data is transferred from the client's file system to the RDS for PostgreSQL DB instance. Sending a large amount of data to the DB instance can delay transmission of data from the client to the DB instance.

## Idle client connection

When a client connects to the RDS for PostgreSQL DB instance in an `idle in transaction` state, the DB instance might wait for the client to send more data or issue a command. A connection in this state can lead to an increase in `Client:ClientRead` events.

## PgBouncer used for connection pooling

PgBouncer has a low-level network configuration setting called `pkt_buf`, which is set to 4,096 by default. If the workload is sending query packets larger than 4,096 bytes through PgBouncer, we recommend increasing the `pkt_buf` setting to 8,192. If the new setting doesn't decrease the number of `Client:ClientRead` events, we recommend increasing the `pkt_buf` setting to larger values, such as 16,384 or 32,768. If the query text is large, the larger setting can be particularly helpful.

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Place the clients in the same Availability Zone and VPC subnet as the instance](#)
- [Scale your client](#)
- [Use current generation instances](#)
- [Increase network bandwidth](#)
- [Monitor maximums for network performance](#)
- [Monitor for transactions in the "idle in transaction" state](#)

## Place the clients in the same Availability Zone and VPC subnet as the instance

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the RDS for PostgreSQL DB instance. Make sure that the clients are as geographically close to the DB instance as possible.

## Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

### Use current generation instances

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This technique might reduce the number of network round trips and increase network throughput. For more information, see [Jumbo frames \(9001 MTU\)](#) in the *Amazon EC2 User Guide*.

For information about DB instance classes, see [DB instance classes](#). To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place `db.` before the Amazon EC2 instance type name. For example, the `r5.8xlarge` Amazon EC2 instance is equivalent to the `db.r5.8xlarge` DB instance class.

### Increase network bandwidth

Use `NetworkReceiveThroughput` and `NetworkTransmitThroughput` Amazon CloudWatch metrics to monitor incoming and outgoing network traffic on the DB instance. These metrics can help you to determine if network bandwidth is sufficient for your workload.

If your network bandwidth isn't enough, increase it. If the AWS client or your DB instance is reaching the network bandwidth limits, the only way to increase the bandwidth is to increase your DB instance size. For more information, see [DB instance class types](#).

For more information about CloudWatch metrics, see [Amazon CloudWatch metrics for Amazon RDS](#).

### Monitor maximums for network performance

If you are using Amazon EC2 clients, Amazon EC2 provides maximums for network performance metrics, including aggregate inbound and outbound network bandwidth. It also provides connection tracking to ensure that packets are returned as expected and link-local services access for services such as the Domain Name System (DNS). To monitor these maximums, use a current enhanced networking driver and monitor network performance for your client.

For more information, see [Monitor network performance for your Amazon EC2 instance](#) in the *Amazon EC2 User Guide* and [Monitor network performance for your Amazon EC2 instance](#) in the *Amazon EC2 User Guide*.

## Monitor for transactions in the "idle in transaction" state

Check whether you have an increasing number of `idle in transaction` connections. To do this, monitor the `state` column in the `pg_stat_activity` table. You might be able to identify the connection source by running a query similar to the following.

```
select client_addr, state, count(1) from pg_stat_activity
where state like 'idle in transaction%'
group by 1,2
order by 3 desc
```

## Client:ClientWrite

The `Client:ClientWrite` event occurs when RDS for PostgreSQL is waiting to write data to the client.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is supported for RDS for PostgreSQL version 10 and higher.

## Context

A client process must read all of the data received from an RDS for PostgreSQL DB cluster before the cluster can send more data. The time that the cluster waits before sending more data to the client is a `Client:ClientWrite` event.

Reduced network throughput between the RDS for PostgreSQL DB instance and the client can cause this event. CPU pressure and network saturation on the client can also cause this event. *CPU pressure* is when the CPU is fully utilized and there are tasks waiting for CPU time. *Network saturation* is when the network between the database and client is carrying more data than it can handle.

## Likely causes of increased waits

Common causes for the `Client:ClientWrite` event to appear in top waits include the following:

### Increased network latency

There might be increased network latency between the RDS for PostgreSQL DB instance and client. Higher network latency increases the time required for the client to receive the data.

### Increased load on the client

There might be CPU pressure or network saturation on the client. An increase in load on the client delays the reception of data from the RDS for PostgreSQL DB instance.

### Large volume of data sent to the client

The RDS for PostgreSQL DB instance might be sending a large amount of data to the client. A client might not be able to receive the data as fast as the cluster is sending it. Activities such as a copy of a large table can result in an increase in `Client:ClientWrite` events.

## Actions

We recommend different actions depending on the causes of your wait event.

### Topics

- [Place the clients in the same Availability Zone and VPC subnet as the cluster](#)
- [Use current generation instances](#)
- [Reduce the amount of data sent to the client](#)
- [Scale your client](#)

### Place the clients in the same Availability Zone and VPC subnet as the cluster

To reduce network latency and increase network throughput, place clients in the same Availability Zone and virtual private cloud (VPC) subnet as the RDS for PostgreSQL DB instance.

### Use current generation instances

In some cases, you might not be using a DB instance class that supports jumbo frames. If you're running your application on Amazon EC2, consider using a current generation instance for the client. Also, configure the maximum transmission unit (MTU) on the client operating system. This

technique might reduce the number of network round trips and increase network throughput. For more information, see [Jumbo frames \(9001 MTU\)](#) in the *Amazon EC2 User Guide*.

For information about DB instance classes, see [DB instance classes](#). To determine the DB instance class that is equivalent to an Amazon EC2 instance type, place `db.` before the Amazon EC2 instance type name. For example, the `r5.8xlarge` Amazon EC2 instance is equivalent to the `db.r5.8xlarge` DB instance class.

## Reduce the amount of data sent to the client

When possible, adjust your application to reduce the amount of data that the RDS for PostgreSQL DB instance sends to the client. Making such adjustments relieves CPU and network contention on the client.

## Scale your client

Using Amazon CloudWatch or other host metrics, determine if your client is currently constrained by CPU or network bandwidth, or both. If the client is constrained, scale your client accordingly.

## CPU

This event occurs when a thread is active in CPU or is waiting for CPU.

### Topics

- [Supported engine versions](#)
- [Context](#)
- [Likely causes of increased waits](#)
- [Actions](#)

## Supported engine versions

This wait event information is relevant for all all versions of RDS for PostgreSQL.

## Context

The *central processing unit (CPU)* is the component of a computer that runs instructions. For example, CPU instructions perform arithmetic operations and exchange data in memory. If a query increases the number of instructions that it performs through the database engine, the time

spent running the query increases. *CPU scheduling* is giving CPU time to a process. Scheduling is orchestrated by the kernel of the operating system.

## Topics

- [How to tell when this wait occurs](#)
- [DBLoadCPU metric](#)
- [os.cpuUtilization metrics](#)
- [Likely cause of CPU scheduling](#)

## How to tell when this wait occurs

This CPU wait event indicates that a backend process is active in CPU or is waiting for CPU. You know that it's occurring when a query shows the following information:

- The `pg_stat_activity.state` column has the value `active`.
- The `wait_event_type` and `wait_event` columns in `pg_stat_activity` are both `null`.

To see the backend processes that are using or waiting on CPU, run the following query.

```
SELECT *
FROM   pg_stat_activity
WHERE  state = 'active'
AND    wait_event_type IS NULL
AND    wait_event IS NULL;
```

## DBLoadCPU metric

The Performance Insights metric for CPU is `DBLoadCPU`. The value for `DBLoadCPU` can differ from the value for the Amazon CloudWatch metric `CPUUtilization`. The latter metric is collected from the Hypervisor for a database instance.

## os.cpuUtilization metrics

Performance Insights operating-system metrics provide detailed information about CPU utilization. For example, you can display the following metrics:

- `os.cpuUtilization.nice.avg`
- `os.cpuUtilization.total.avg`

- `os.cpuUtilization.wait.avg`
- `os.cpuUtilization.idle.avg`

Performance Insights reports the CPU usage by the database engine as `os.cpuUtilization.nice.avg`.

### Likely cause of CPU scheduling

The operating system (OS) kernel handles scheduling for the CPU. When the CPU is *active*, a process might need to wait to get scheduled. The CPU is active while it's performing computations. It's also active while it has an idle thread that it's not running, that is, an idle thread that's waiting on memory I/O. This type of I/O dominates the typical database workload.

Processes are likely to wait to get scheduled on a CPU when the following conditions are met:

- The CloudWatch `CPUUtilization` metric is near 100 percent.
- The average load is greater than the number of vCPUs, indicating a heavy load. You can find the `LoadAverageMinute` metric in the OS metrics section in Performance Insights.

### Likely causes of increased waits

When the CPU wait event occurs more than normal, possibly indicating a performance problem, typical causes include the following.

#### Topics

- [Likely causes of sudden spikes](#)
- [Likely causes of long-term high frequency](#)
- [Corner cases](#)

### Likely causes of sudden spikes

The most likely causes of sudden spikes are as follows:

- Your application has opened too many simultaneous connections to the database. This scenario is known as a "connection storm."
- Your application workload changed in any of the following ways:
  - New queries

- An increase in the size of your dataset
- Index maintenance or creation
- New functions
- New operators
- An increase in parallel query execution
- Your query execution plans have changed. In some cases, a change can cause an increase in buffers. For example, the query is now using a sequential scan when it previously used an index. In this case, the queries need more CPU to accomplish the same goal.

## Likely causes of long-term high frequency

The most likely causes of events that recur over a long period:

- Too many backend processes are running concurrently on CPU. These processes can be parallel workers.
- Queries are performing suboptimally because they need a large number of buffers.

## Corner cases

If none of the likely causes turn out to be actual causes, the following situations might be occurring:

- The CPU is swapping processes in and out.
- The CPU might be managing page table entries if the *huge pages* feature has been turned off. This memory management feature is turned on by default for all DB instance classes other than micro, small, and medium DB instance classes. For more information, see [Huge pages for RDS for PostgreSQL](#).

## Actions

If the CPU wait event dominates database activity, it doesn't necessarily indicate a performance problem. Respond to this event only when performance degrades.

## Topics

- [Investigate whether the database is causing the CPU increase](#)
- [Determine whether the number of connections increased](#)

- [Respond to workload changes](#)

## Investigate whether the database is causing the CPU increase

Examine the `os.cpuUtilization.nice.avg` metric in Performance Insights. If this value is far less than the CPU usage, nondatabase processes are the main contributor to CPU.

## Determine whether the number of connections increased

Examine the `DatabaseConnections` metric in Amazon CloudWatch. Your action depends on whether the number increased or decreased during the period of increased CPU wait events.

### The connections increased

If the number of connections went up, compare the number of backend processes consuming CPU to the number of vCPUs. The following scenarios are possible:

- The number of backend processes consuming CPU is less than the number of vCPUs.

In this case, the number of connections isn't an issue. However, you might still try to reduce CPU utilization.

- The number of backend processes consuming CPU is greater than the number of vCPUs.

In this case, consider the following options:

- Decrease the number of backend processes connected to your database. For example, implement a connection pooling solution such as RDS Proxy. To learn more, see [Using Amazon RDS Proxy](#).
- Upgrade your instance size to get a higher number of vCPUs.
- Redirect some read-only workloads to reader nodes, if applicable.

### The connections didn't increase

Examine the `blks_hit` metrics in Performance Insights. Look for a correlation between an increase in `blks_hit` and CPU usage. The following scenarios are possible:

- CPU usage and `blks_hit` are correlated.

In this case, find the top SQL statements that are linked to the CPU usage, and look for plan changes. You can use either of the following techniques:

- Explain the plans manually and compare them to the expected execution plan.
- Look for an increase in block hits per second and local block hits per second. In the **Top SQL** section of Performance Insights dashboard, choose **Preferences**.
- CPU usage and `blks_hit` aren't correlated.

In this case, determine whether any of the following occurs:

- The application is rapidly connecting to and disconnecting from the database.

Diagnose this behavior by turning on `log_connections` and `log_disconnections`, then analyzing the PostgreSQL logs. Consider using the `pgbadger` log analyzer. For more information, see <https://github.com/darold/pgbadger>.

- The OS is overloaded.

In this case, Performance Insights shows that backend processes are consuming CPU for a longer time than usual. Look for evidence in the Performance Insights `os.cpuUtilization` metrics or the CloudWatch `CPUUtilization` metric. If the operating system is overloaded, look at Enhanced Monitoring metrics to diagnose further. Specifically, look at the process list and the percentage of CPU consumed by each process.

- Top SQL statements are consuming too much CPU.

Examine statements that are linked to the CPU usage to see whether they can use less CPU. Run an `EXPLAIN` command, and focus on the plan nodes that have the most impact. Consider using a PostgreSQL execution plan visualizer. To try out this tool, see <http://explain.dalibo.com/>.

## Respond to workload changes

If your workload has changed, look for the following types of changes:

### New queries

Check whether the new queries are expected. If so, ensure that their execution plans and the number of executions per second are expected.

### An increase in the size of the data set

Determine whether partitioning, if it's not already implemented, might help. This strategy might reduce the number of pages that a query needs to retrieve.

## Index maintenance or creation

Check whether the schedule for the maintenance is expected. A best practice is to schedule maintenance activities outside of peak activities.

## New functions

Check whether these functions perform as expected during testing. Specifically, check whether the number of executions per second is expected.

## New operators

Check whether they perform as expected during the testing.

## An increase in running parallel queries

Determine whether any of the following situations has occurred:
