Administrator Guide

Amazon Connect

Amazon Connect: Administrator Guide

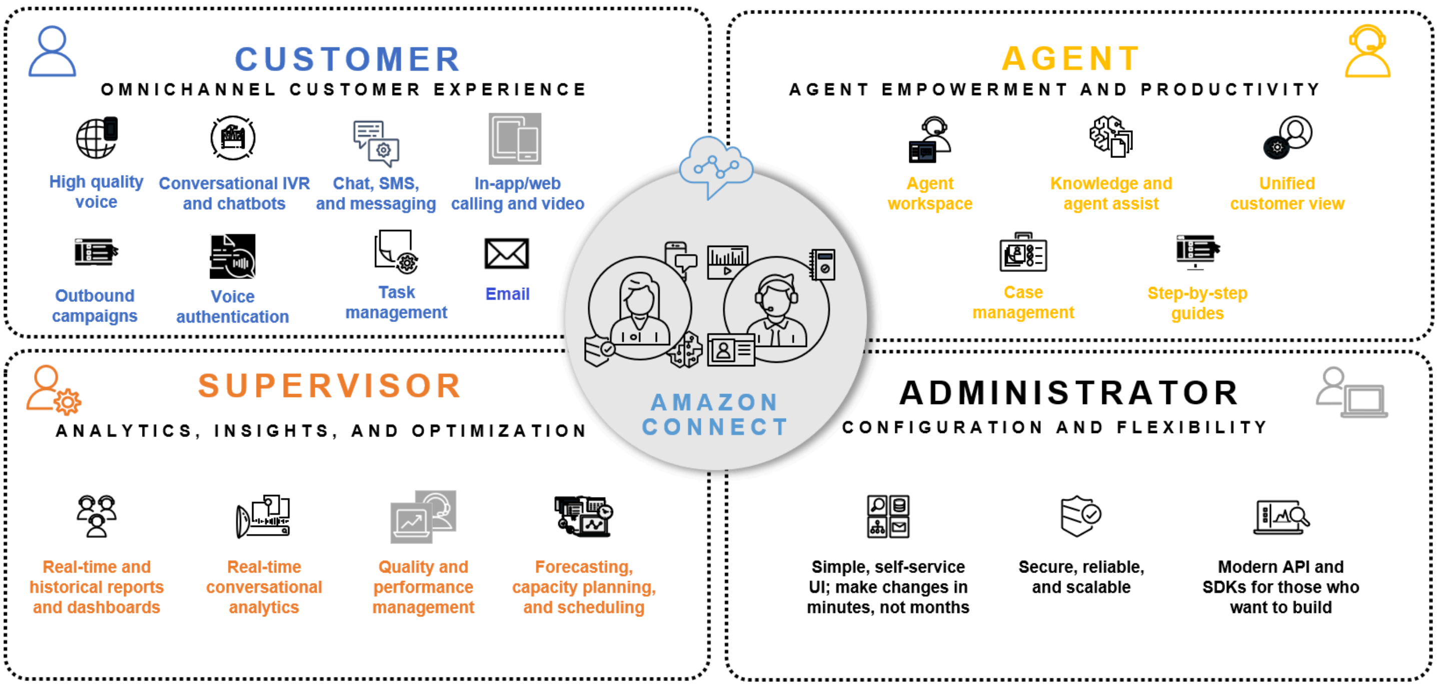
Table of Contents

What is Amazon Connect?

Amazon Connect is an AI-powered application that provides one seamless experience for your contact center customers and users. It's comprised of a full suite of features across communication channels.

Using an intuitive web application—the Amazon Connect admin website—you can set up a contact center in a few steps, add agents who are located anywhere, and start engaging with your customers. You can innovate and make changes in minutes, not months. No coding required.

If you're using Amazon Connect, you're likely one of these users:



- **Customers** reach out to your contact center because they are having trouble with some issue they can't resolve for themselves, or resolve easily. They want the ability to contact your contact center using any method they choose.
- **Agents** are responsible for helping customers solve general problems, and come to a quick resolution whenever possible. They spend most of their time interacting with customers, whether through voice, chat, SMS, or other channels, and then documenting the interaction.
- **Contact center managers and supervisors** spend most of their day monitoring their team's metrics and readjusting their configuration to be optimal for their business. They onboard most new agents, and provide coaching to help their team members grow.

- **Administrators** handle the entire Amazon Connect configuration. They provision phone numbers and integrate Amazon Connect with other products. Along with contact center managers, they define queues and routing profiles, implement flows, and create rules to set up alerts and notifications.

Get more information in the Amazon Connect feature overview.

How to get started

If you are a first-time user of Amazon Connect, we recommend that you do the following:

- Check out the Getting Started with Amazon Connect for an introduction to Amazon Connect with a series of hands-on labs.
- Explore Amazon Connect with our tutorials.
- Read the architectural guidance.
- *Set up your contact center*.

Pricing

With Amazon Connect, you pay only for what you use. For more information, see Amazon Connect pricing.

Amazon Connect feature overview

Amazon Connect is an omnichannel contact center, built in the cloud from the ground-up. It empowers businesses of all sizes to connect their customers with the same world-class customer experience Amazon uses to orchestrate their customer care.

> **Tip**
>
> For an online workshop that leverages a case study and includes hands-on labs, see Introduction to Amazon Connect by AWS Workshop Studio.

Customers: Omnichannel customer experience

Amazon Connect provides you with the following channels for interacting with your customers:

- Voice (phone)
- Chat/SMS
- Web calling/video
- Tasks
- Email

Customers can interact with your agents on voice, chat, SMS, web calling/video, and email channels based on factors such as personal preferences and wait times. Customers can keep working with the same agent across channels, but if it's a different agent their interaction history is preserved, so they don't have to repeat themselves. The omnichannel contact center improves customer experiences while reducing resolution time.

Contents

High quality voice

The sound quality of a call impacts customer experience and agent productivity. When your customers can't hear you clearly, it can lead to wasted time and frustration. With Amazon Connect, calls are connected to the agent over the internet from a computing device like a PC, using the Amazon Connect softphone. The Amazon Connect softphone delivers high-quality 16kHz audio and is resistant to packet loss to ensure a high-quality call experience.

Conversational IVR and chatbots

You can deliver personalized, natural-sounding, conversational interactions using our proven AI-powered speech recognition and natural language understanding technology (the same technology that powers Alexa). These same AI capabilities can be used across all channels.

With Amazon Lex natively integrated within Amazon Connect, no coding is required to add chatbots that have natural language understanding (NLU). Self-service chatbots use high-quality, neural text-to-speech (TTS) in more than 30 languages, automated speech recognition (ASR) in over 25 languages/locales, natural language understanding (NLU), and passive voice authentication. Amazon Connect IVR and chatbots also take advantage of generative AI features to greatly streamline the building and testing of powerful, conversational self-service experiences (for example, LLM-assisted slot resolution, conversational FAQs, sample utterance generation, and bot creation using natural language description).

Chat, SMS, and messaging

You can help customers through text-based communication channels, such as web chat, mobile chat, SMS, and third-party messaging apps, such as WhatsApp or Facebook Messenger. By using the Amazon Connect chat and messaging features, you can set up AI-powered chatbots and step-by-step guides so customers can self-serve. If customers need assistance, agents get all of the prior context from the self-service interactions to ensure a seamless transition.

- **Chat**. Amazon Connect makes it easy to set up your customer's chat experience. You can add a communications widget to your website that is hosted by Amazon Connect. You configure the communications widget in the Amazon Connect admin website. You can customize the font and colors, and secure the widget so that it can be launched only from your website. When finished, you will have a short code snippet that you add to your website.

  Because Amazon Connect hosts the widget, it ensures that the latest version is always live on your website.

- **SMS**. You can set up two-way SMS messaging capabilities so your customers can text you from their mobile device, and your agents can response using the same tools they already use for calls and chats. With Amazon Lex, you can detect the intent of the customer message and automate responses to their questions, saving agents valuable time and effort.
- **Third-party messaging apps**. To integrate with third-party messaging apps, use the Amazon Connect APIs that enable you to subscribe to a real-time stream of chat messages. Using these APIs, you can:
  - Stream chat messages in real time when a new chat contact is created.
  - Extend the current Amazon Connect chat functionality to support use cases like building integrations with SMS solutions and third-party messaging applications, enabling mobile push notifications, and creating analytics dashboards to monitor and track chat message activity.

  For more information, see Enable real-time chat message streaming in Amazon Connect.

In-app, web, and video calling

You can set up the Amazon Connect in-app, web, and video calling capabilities to enable your customers to contact you without ever leaving your web or mobile application. You can use these capabilities to pass contextual information to Amazon Connect. For example, if your customer is already logged into your app, they do not need to identify or authenticate themselves when they request a call or video conversation with an agent. This enables you to personalize the customer experience based on attributes such as the customer's profile or other information, like actions previously taken within the app.

Outbound campaigns

You can create high volume ML-powered outbound campaigns to contact up to millions of customers daily for handling appointment reminders, marketing promotions, deliveries, and billing reminders. You can specify the contact list, channel, message, and even pre-recorded audio to play before connecting customers to agents for live service.

Outbound campaigns includes a predictive dialer and machine learning (ML)–powered answering machine detection. These features can help you optimize agent productivity and increase live-party connections by not wasting agent time with unanswered calls.

Voice authentication

You use Amazon Connect Voice ID for real-time caller authentication and fraud risk detection to make voice interactions faster and more secure.

Amazon Connect Voice ID analyzes callers' unique voice characteristics and carrier network metadata to provide your agents and self-service interactive voice response (IVR) systems with a real-time decision on a caller's identity for faster and more accurate verification. Voice ID also screens for fraudulent actors in real time, based on your contact center’s custom watchlist, reducing potential losses from fraudulent attacks.

Task management

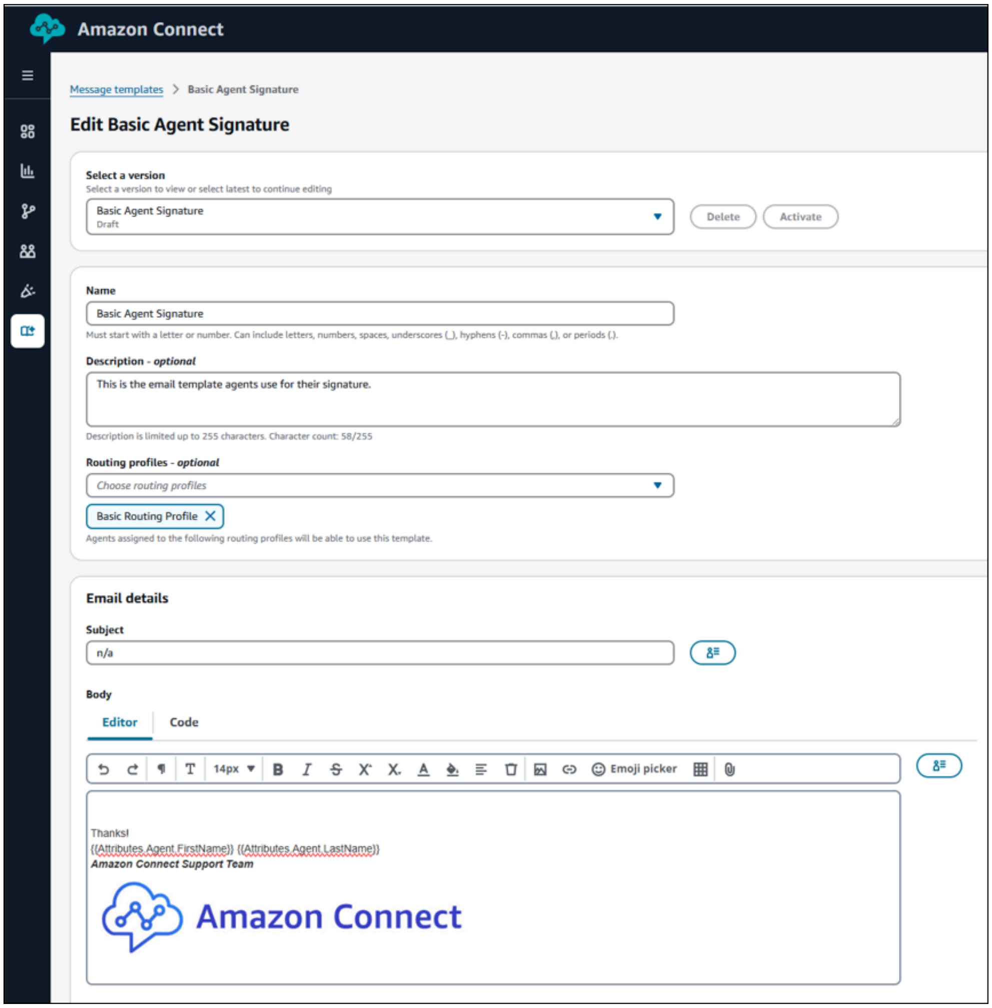
Task management streamlines the process of tracking and routing other types of agent work, like customer follow up messages, training, and research. Tasks are delivered to agents using the same routing and agent experience used with voice, chat, and other channels.

To ensure customer issues are quickly resolved, use tasks to prioritize, track, route, and automate agent follow-up work. Your agents can create and complete tasks in the same user interface where they take calls and chats. Managers can also use workflows to automate tasks that don't require agent interaction. This results in improved agent productivity leading to increased customer satisfaction.

Email

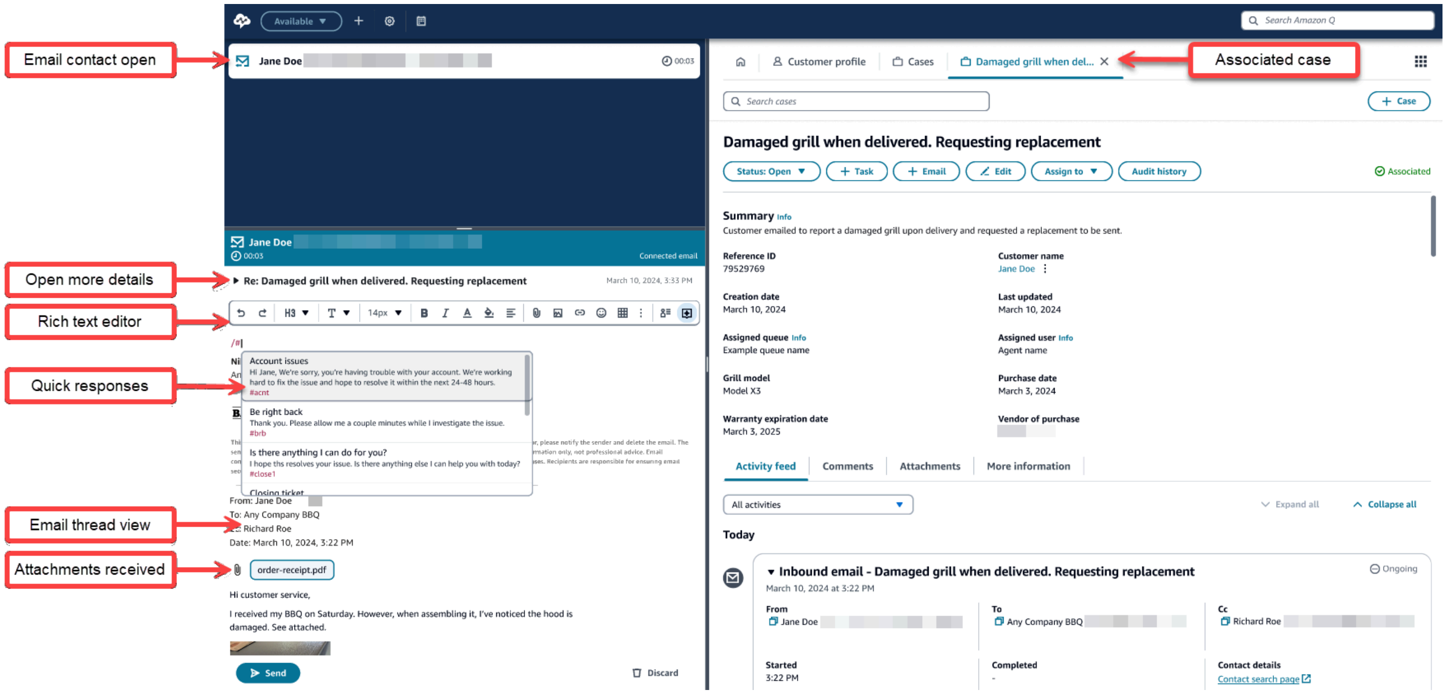
You can use Amazon Connect email capabilities to receive and respond to emails sent by customers to your business email addresses, or submitted by using web forms on your website or mobile app. You can configure auto-responses, prioritize emails, create or update cases, and route emails to the best available agent when agent assistance is required. Amazon Connect email capabilities also work seamlessly with outbound campaigns.

Agents have access to a rich text editor to respond to emails and to create personalized email templates and signatures. They can also create quick responses to answer frequently asked questions. The following image shows an example of where you can create a basic agent signature template in the Amazon Connect admin website. When agents use this template, it will automatically populate their name and add the logo to their emails.



Both agents and contact center managers can easily view an entire email thread. Email threading ensures that outgoing emails and incoming responses related to a customer inquiry are associated with each other in a chronological and organized fashion. Agents can view an email thread in the agent workspace and CCP, and for added security, when they reply to an email, they can't manipulate what the customer wrote as part of their email.

The following image shows an example of an email contact being handled by an agent within the CCP in the agent workspace. In this example they have associated the email contact to a case and are using the rich text editor and quick responses to respond.



To get started, set up the email channel in your instance right alongside your voice, chat, and task channels. Amazon Connect email integrates with Amazon Simple Email Service (SES) for the sending, receiving, and monitoring (such as for spam and virus detection) of emails. Amazon Connect provides you with an email domain that you can use to create your email addresses, or you can easily associate up to five of your own custom domains using Amazon SES. After you have domains associated with your instance, you can create up to 100 email addresses that can be used to send and receive emails (for example, support@example.com, sales@example.com, and reservations@example.com).

Contact center managers can view email threads on the Contact search and details pages to find email contacts based on email address, subject, queue, or other filters. This enables them to get a better understanding of what their agents and customers are saying and to evaluate agent performance.

To learn how their email channel is performing, contact center managers can access the analytics dashboard to see real-time and historical metrics such as average agent handle time, queue time, contacts answered, and more.

Agents: Empowerment and productivity

With Amazon Connect, you can enhance your agents' productivity by providing them with quick access to information and automatic recommendations. You can enable your agents to capture relevant details for fast and efficient follow-up. And best of all, they can work in one application, for a seamless experience. This results in shorter training time for new agents, fewer errors, accelerated resolution times, and improved customer satisfaction.

Contents

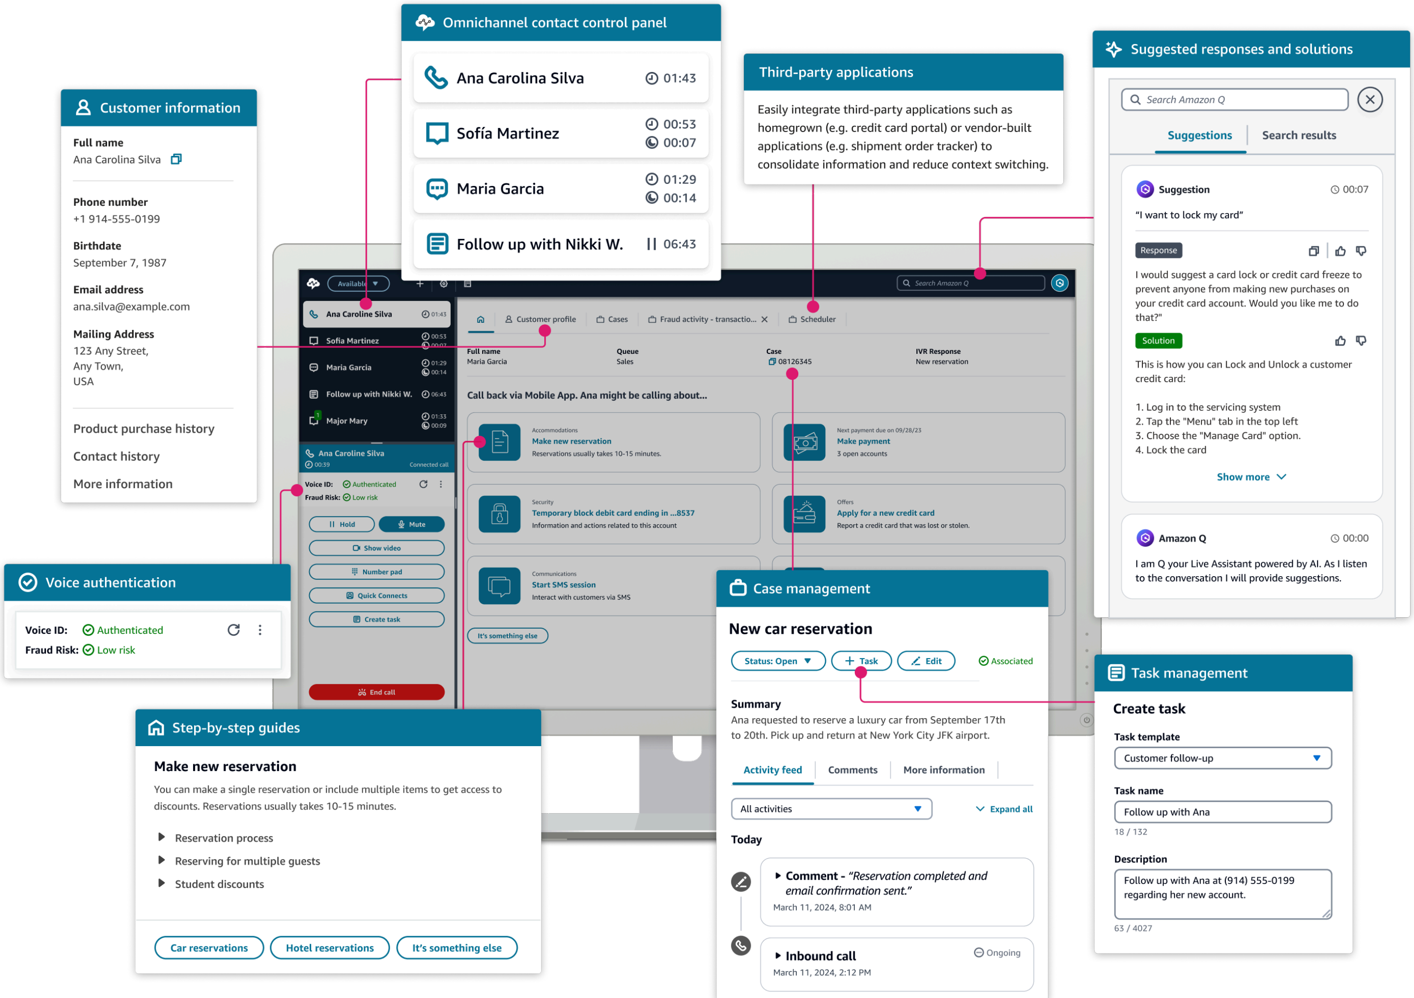
Agent workspace

Out-of-the-box, the agent workspace integrates all of your agent facing capabilities on one page. It is a single, intuitive application that provides your agents with all the tools and step-by-step guidance needed to onboard quickly, resolve issues efficiently, and improve customer experiences.

From one application your agents can view detailed customer information, work on tasks, view workforce schedules, get generative AI-powered agent assist, and track and manage customer issues that require multiple interactions.

You can also easily integrate other applications directly into the agent workspace, thus further increasing agent efficiency. For more information, see Integrate third-party applications (3p apps) in the Amazon Connect agent workspace

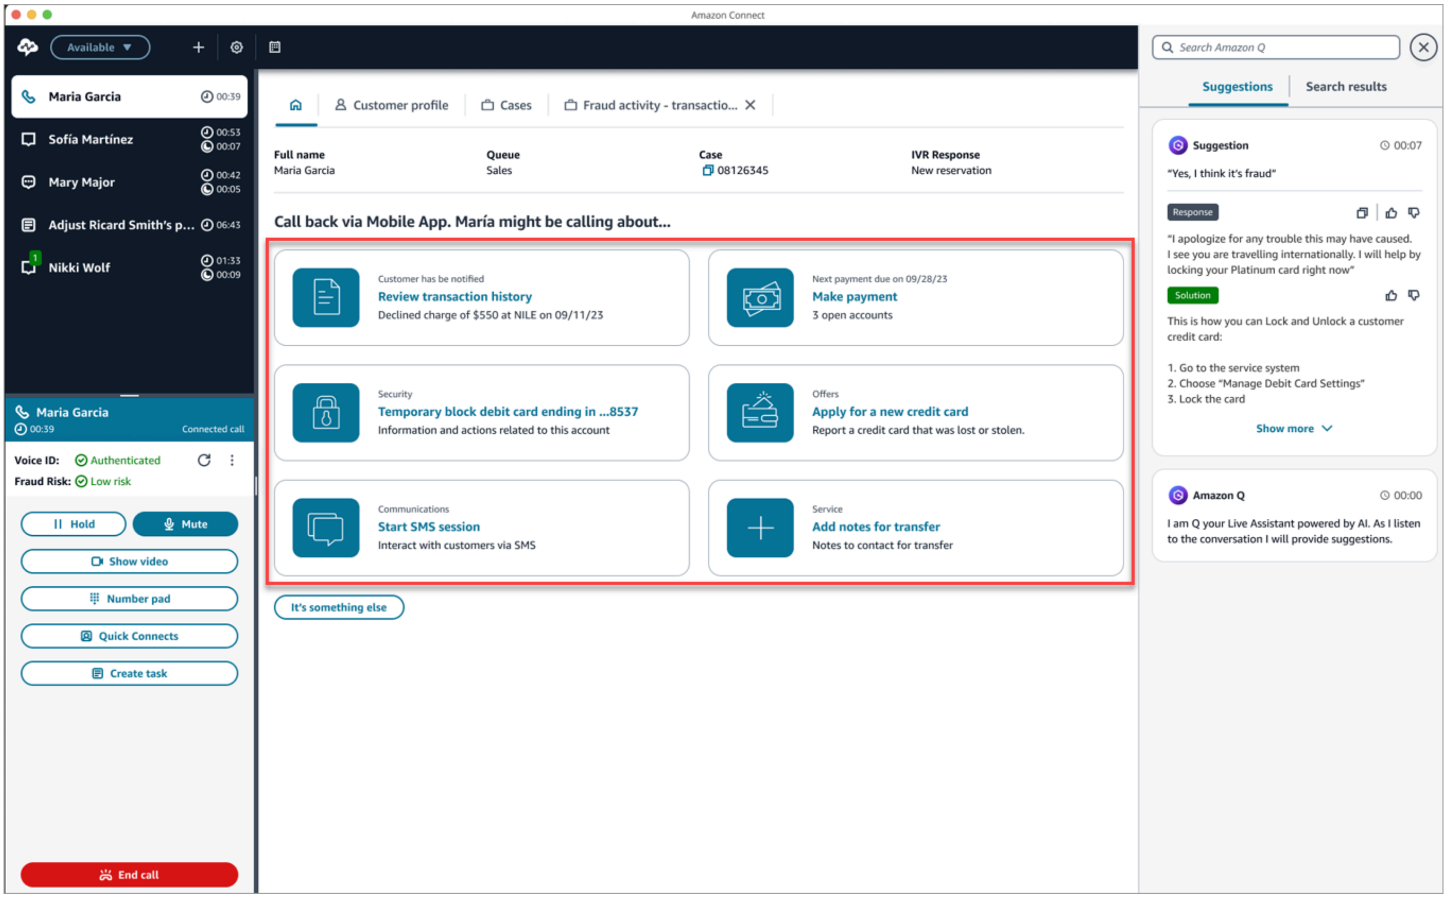
The following image shows the agent workspace with callouts indicating the features on the page.



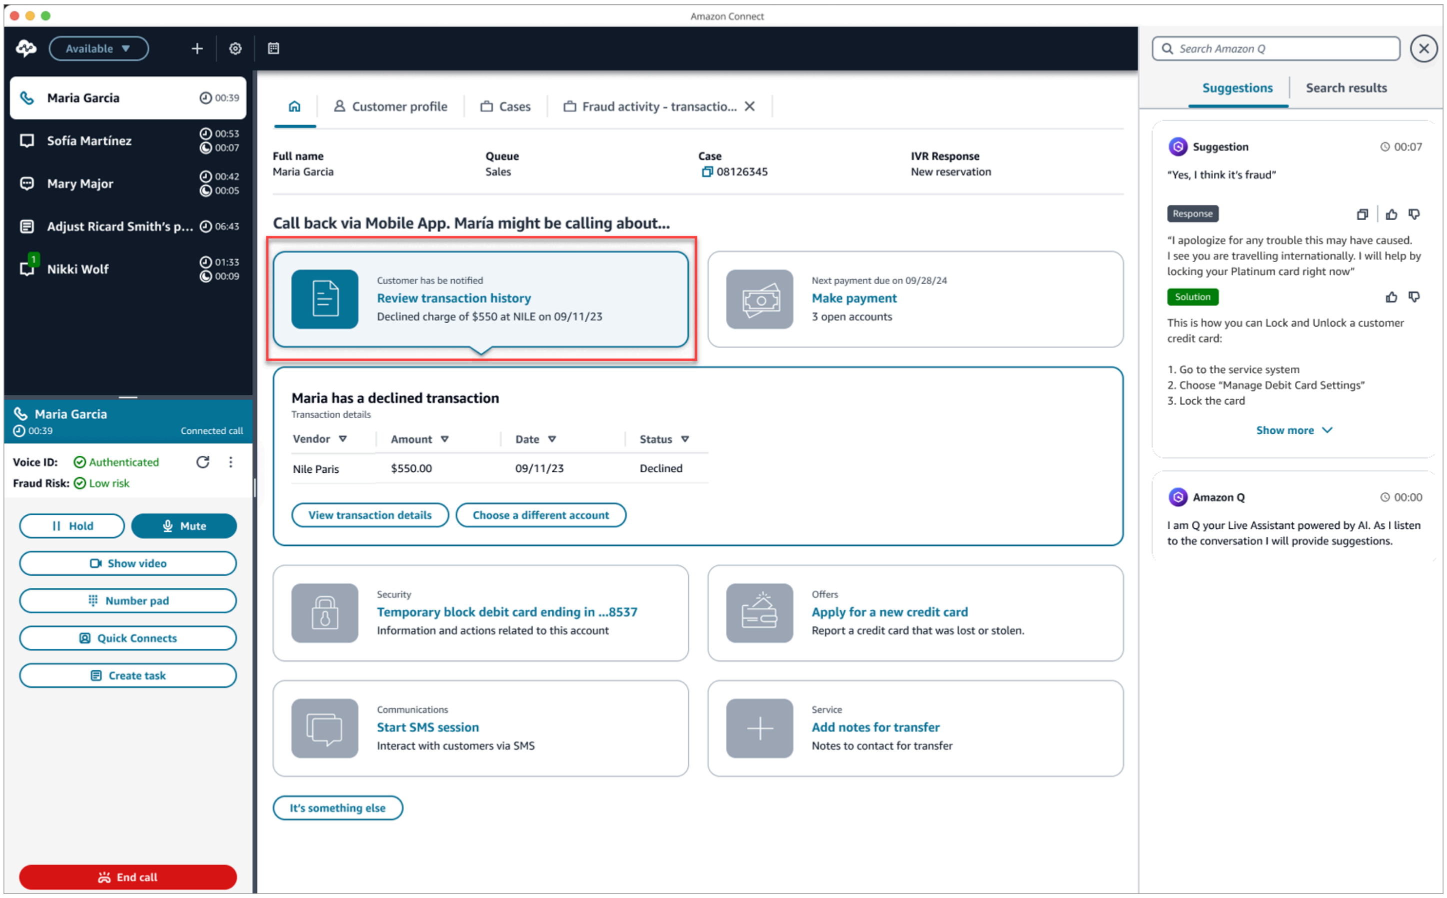
Step-by-step guides

You can customize the agent workspace by creating step-by-step guides that suggest to agents what to do at a given moment during a customer interaction. Using a no-code editor, you can create tailored guides that walk agents through the optimal steps to resolve a customer issue accurately the first time.

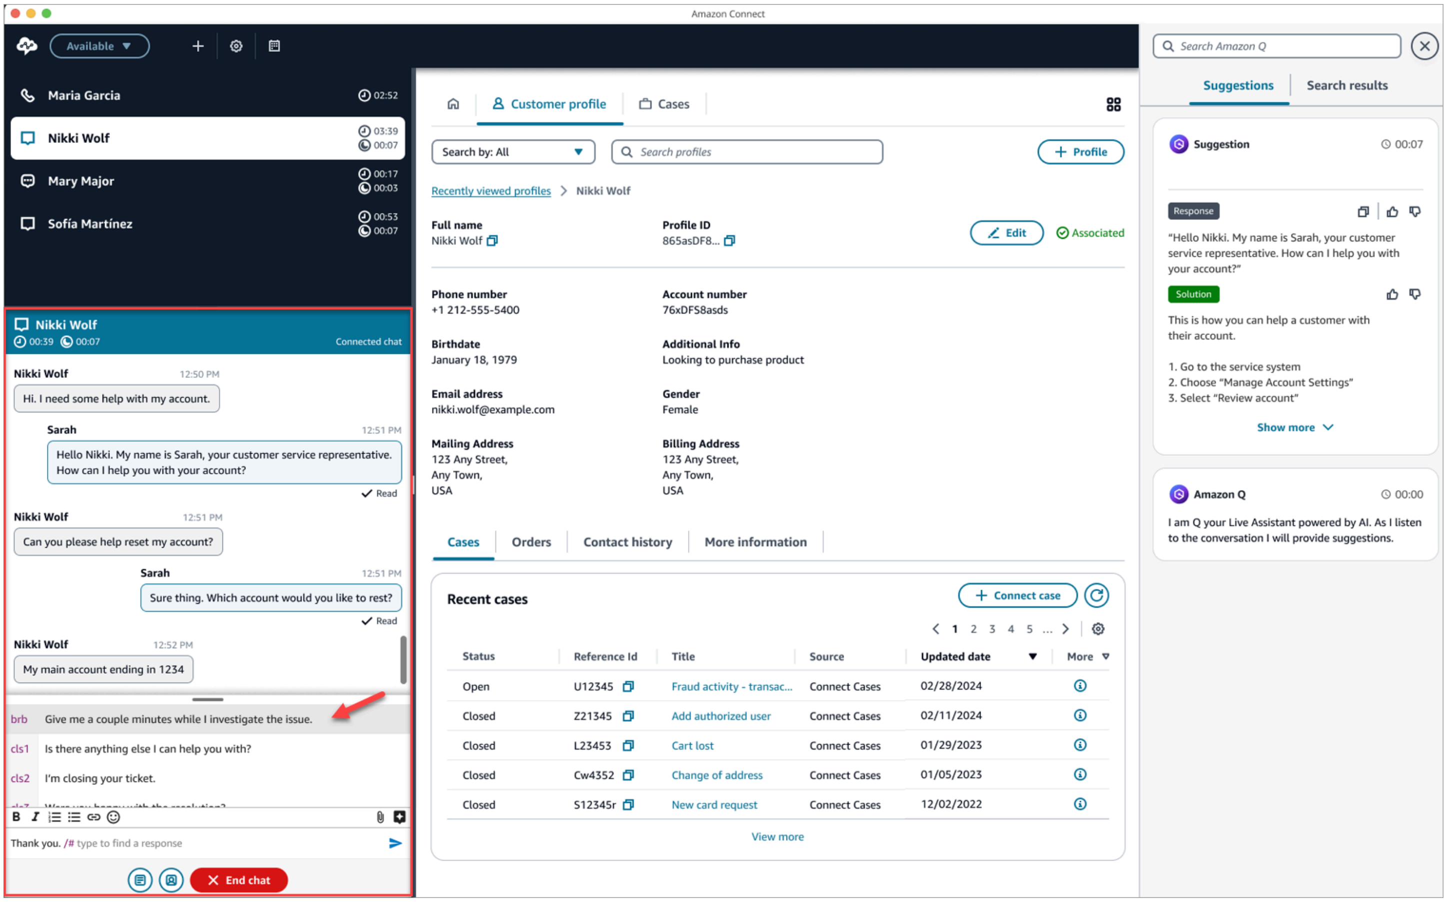
Guides can be used for various types of customer interactions. They are presented to the agent in the agent workspace based on context like call queue, customer information, or customer self-service responses. For example, there are six step-by-step guides on the agent workspace in the following image.



In the following image the **Review transaction history** guide is open, and the first step is displayed for the agent to choose **View transaction details** or **Choose a different account**.



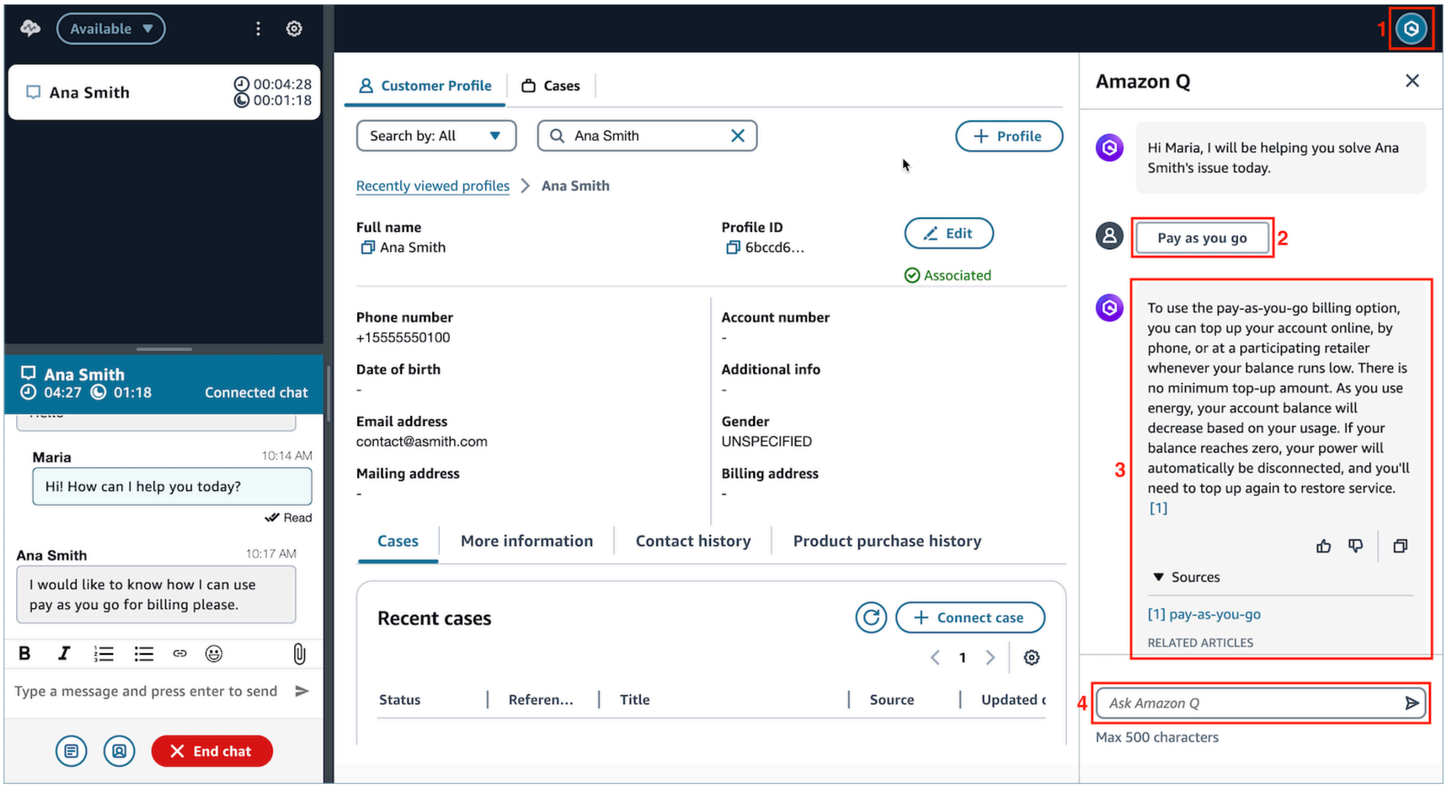
In the following image of the agent workspace, the agent is on a chat with Nikki. At the bottom of the chat pane, the agent can search for quick responses that they can type in the chat. For example, they can type **brb** to respond in the chat with *Give me a couple of minutes while I investigate the issue*.



Generative AI-powered agent assist

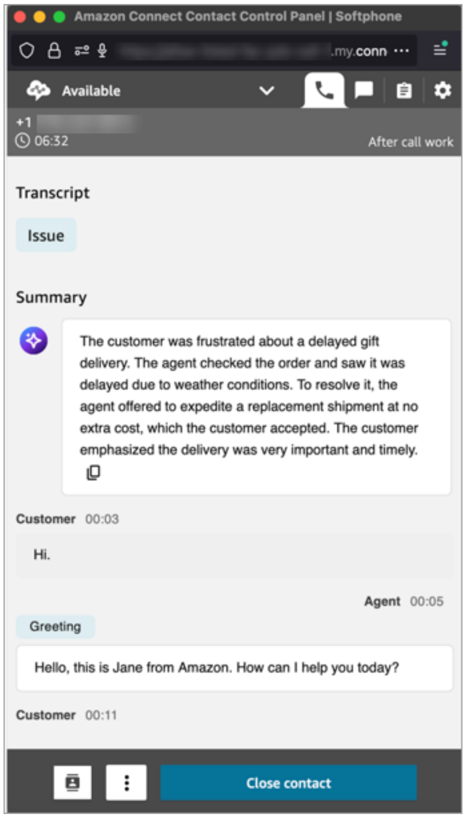
You can use Amazon Q in Connect to automatically detect customer intent during calls and chats. Amazon Q in Connect uses the real-time conversation with the customer, along with relevant company content, to automatically recommend what to say or what actions an agent should take to better assist the customer. This improves both agent productivity and customer satisfaction. Agents can also use natural language to search across connected knowledge sources to receive generated responses, recommended actions, and links to more information.

The following image shows how an article may appear in the agent application when the agent is on a call.



Generative AI-powered post-contact summaries

To help agents perform their After contact work (ACW), Amazon Connect displays a generative AI-powered post-contact summary on their CCP for voice contacts. The summary provides essential information from customer conversations in a structured, concise, and easy to read format. The following image shows an example summary for a voice contact.

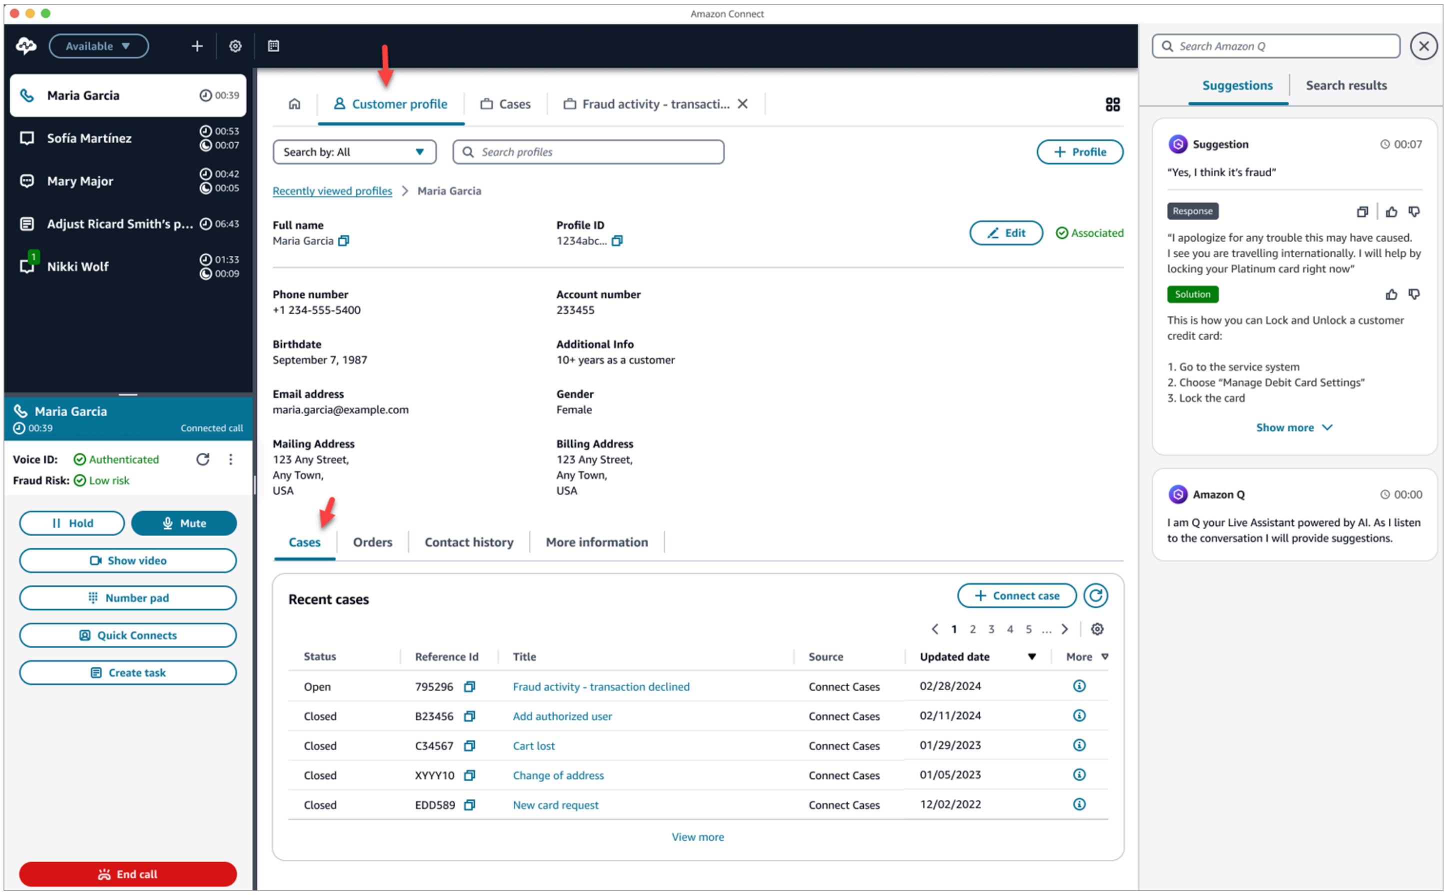


Unified customer view

You use [Amazon Connect Customer Profiles] to combine information from external applications with the contact history from Amazon Connect. For example, you can combined contacts with information from Salesforce, Zendesk, ServiceNow, or other customer relationship management (CRM) products (including your own, internal data sources) to create customer profiles that have all the information that agents need in a single place.

With a single view of customer information, including their product, case, and contact history, agents can quickly confirm the customer's identity and determine the reason for the call or chat.

The following image shows the **Customer profile** tab in the agent workspace. It shows all of the recent cases associated with customer that the agent is currently talking to.

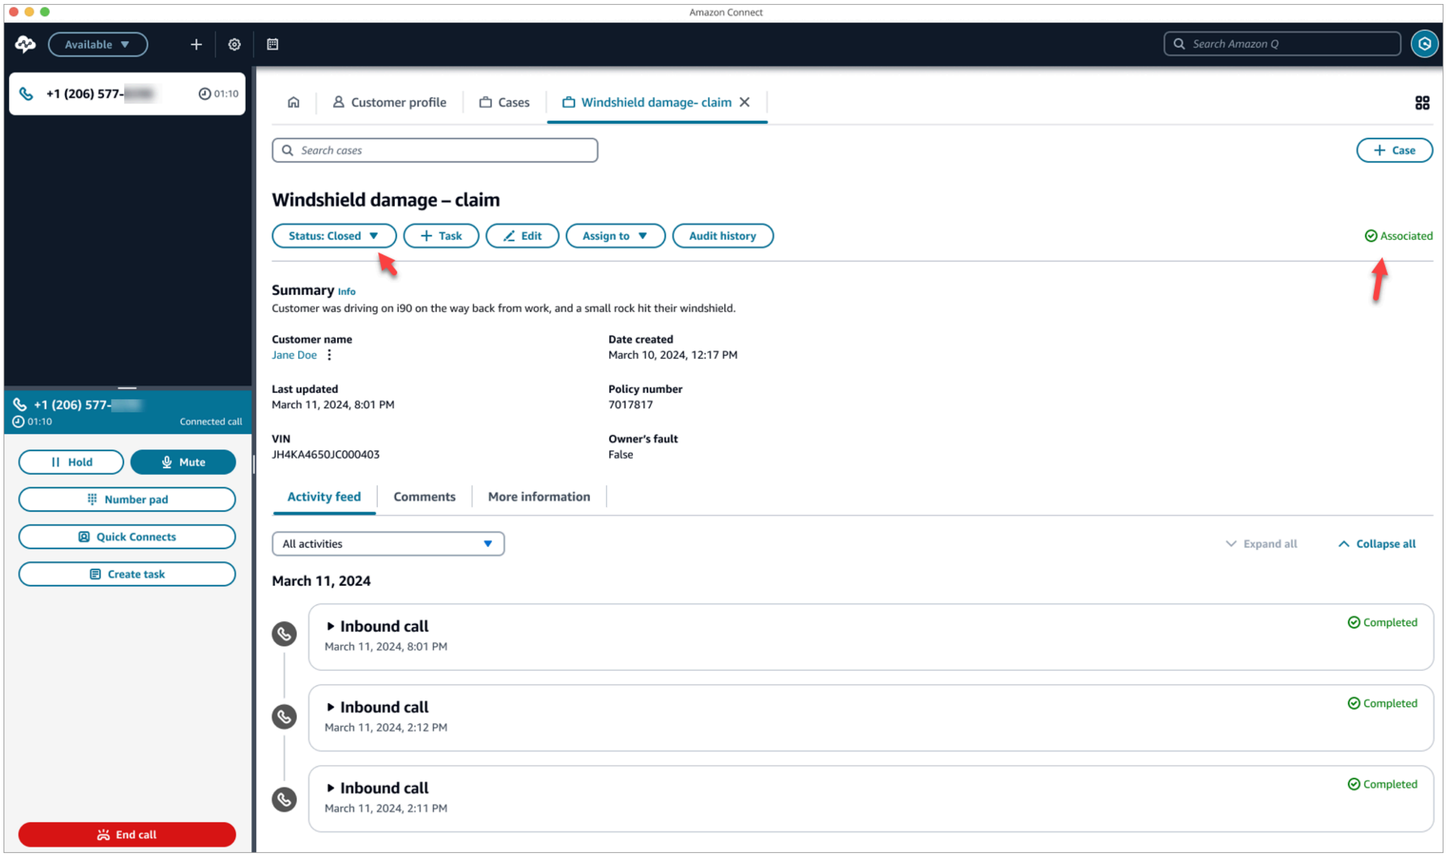


You can use Customer Profiles to access information during a self-service experience (for example, IVR or bot), or in other agent applications, or you can use it as a standalone service separate from Amazon Connect.

Case management

Agents use [Amazon Connect Cases](https://docs.aws.amazon.com/connect/latest/adminguide/cases.html) to efficiently manage customer issues that require multiple interactions, track follow-up tasks, and access subject matter experts across a business. Agents can document customer issues in a single, unified view with relevant case details, such as date/time opened, issue summary, customer information, status, and custom values you want to track. You can configure new cases to be automatically created or have agents manually create cases.

The following image shows the agent workspace. The agent is talking to the contact on the phone and viewing a closed case for windshield damage. The case is associated with the customer's profile.



Efficient contact routing

Agents are set up for success when the right contacts are routed to them. You can efficiently route customers to appropriately skilled agents by using routing profiles. You can configure contact priority and routing to agents based on agent skills, queue priorities, contact attributes, and real-time metrics.

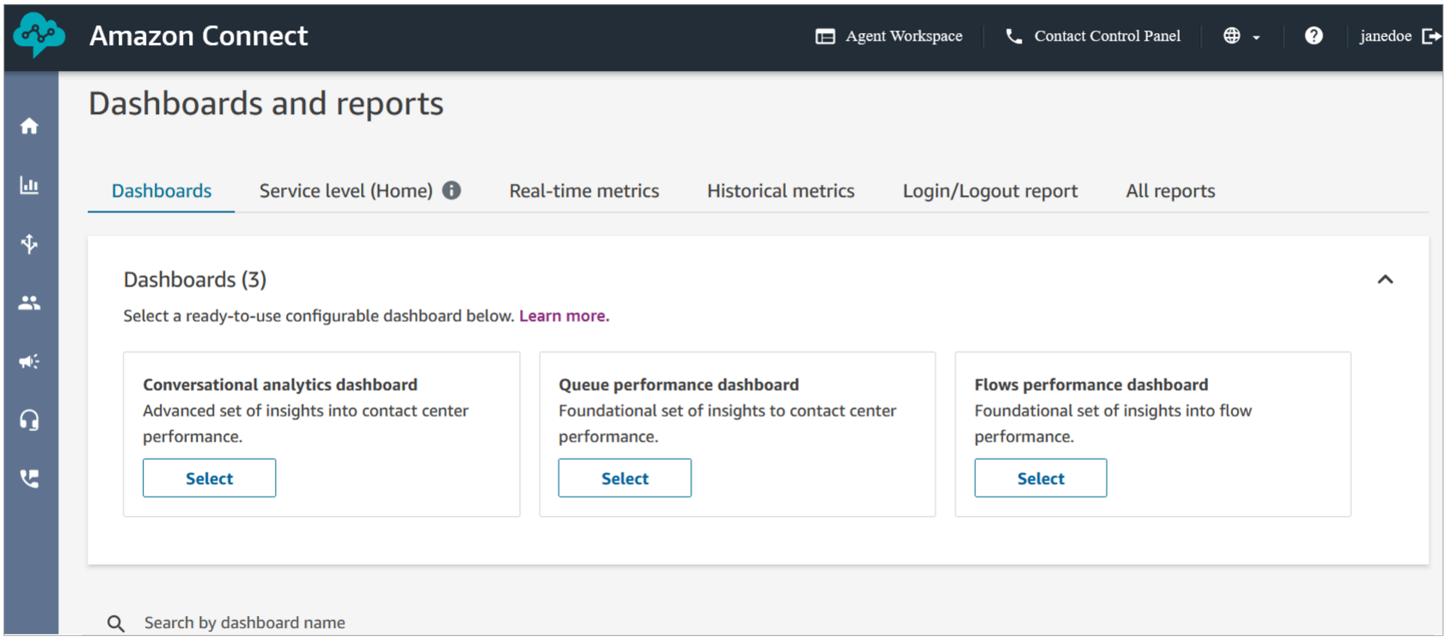
Supervisors: Analytics, insights, and optimization

Give your managers the actionable insights and capabilities they need to optimize operations and outcomes.

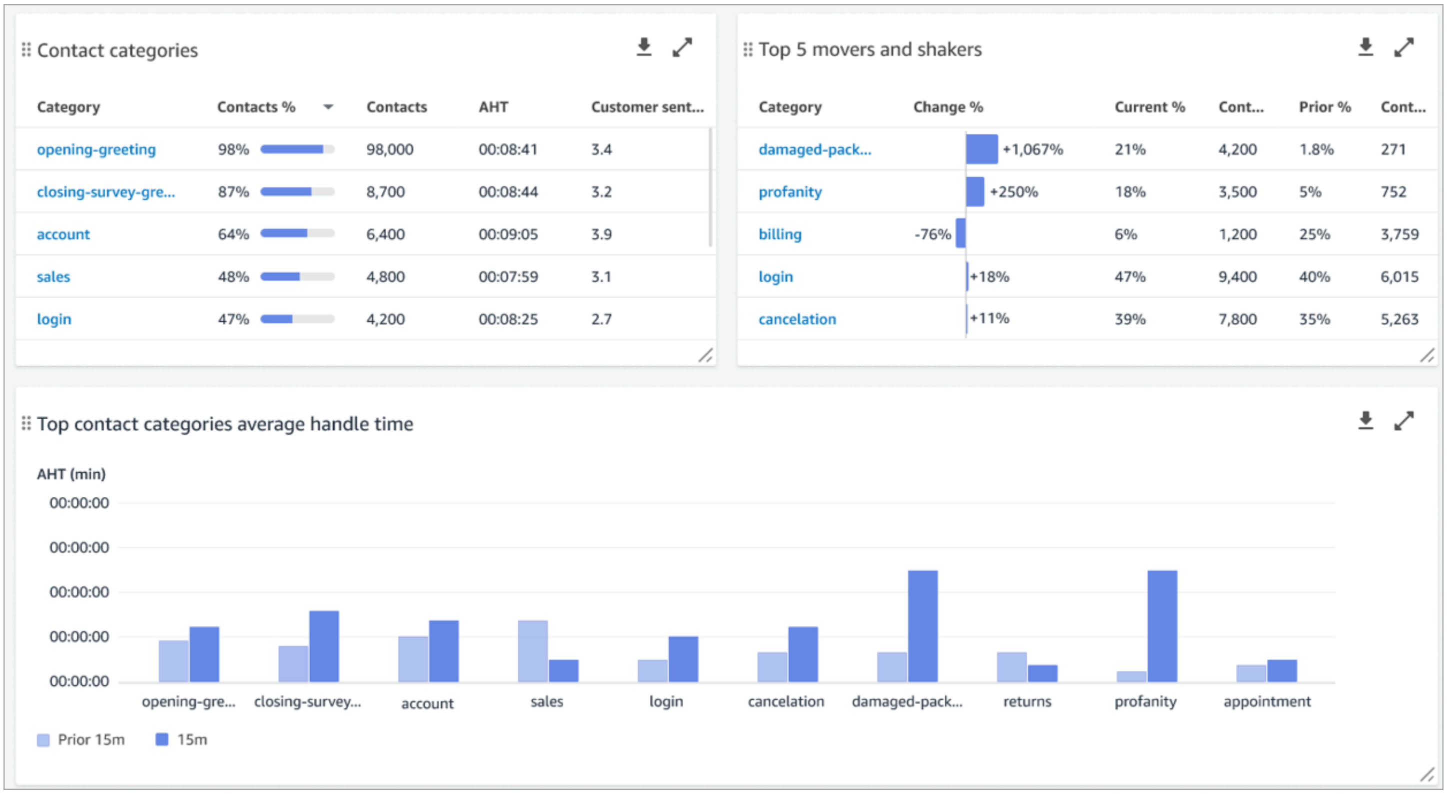
Contents

Real-time and historical reports and dashboards

Understanding your contact center at the most granular level is key to improving performance and lowering costs. Amazon Connect provides powerful analytics tools, including visual dashboards with customizable real-time and historical metrics.



The following image shows an example of the Contact Lens Conversational analytics dashboard. This dashboard helps you understand why customers are contacting you, the trends of contact drivers over time, and the performance of each of those call drivers.



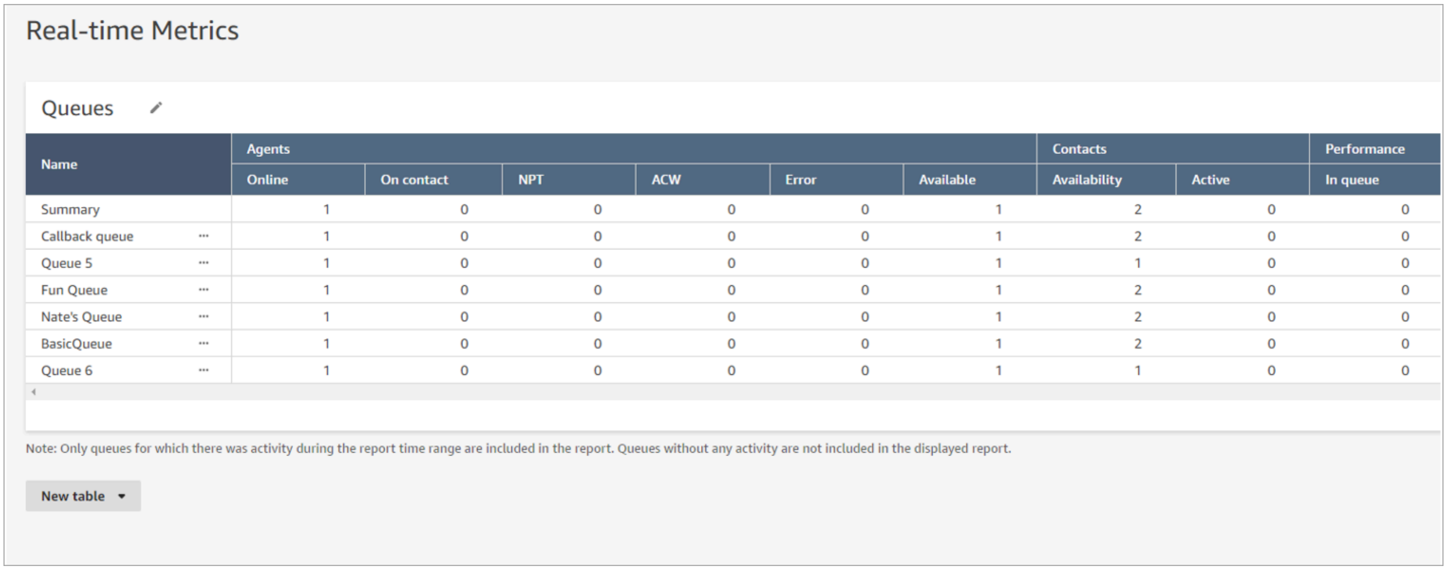
You can use Amazon Connect analytics data lake as a central location to query various types of data from Amazon Connect. This data includes contact records, Contact Lens conversational analytics, Contact Lens performance evaluations, and more. You can use analytics data lake to create custom reports, run SQL queries, or leverage the BI tools of your choice to analyze the information that matters most to improving customer experience and operational efficiency.

For example, managers can use QuickSight to visualize which agents have the highest customer satisfaction for calls about lost orders and then adjust routing profiles to staff their queues with the ideal agents to achieve their desired business outcomes.

You can review the following out-of-the-box reports, and customize them to add more real-time and historical metrics:

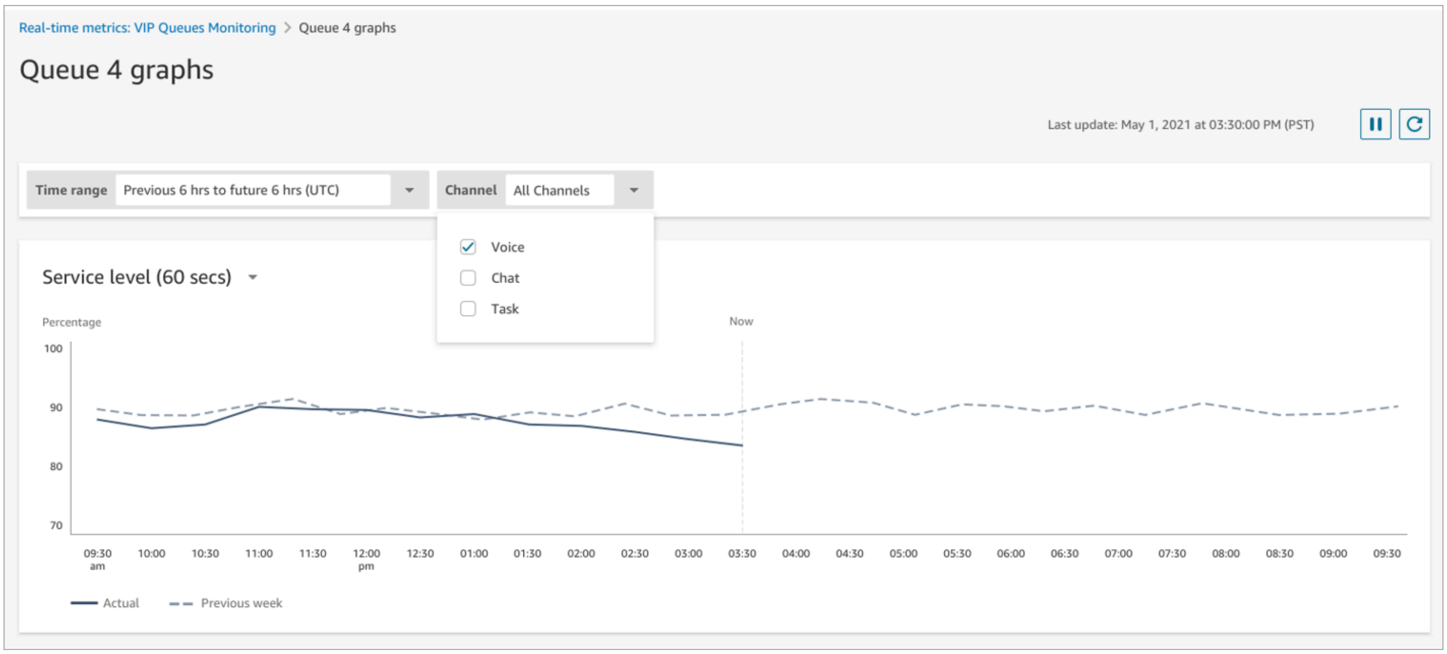
- Real-time metrics reports
- Historical metrics reports
- Login/logout reports
- Agent activity audit report

The following image shows an example of a section of the Real-time metrics page for Queues.



Name	Agents						Contacts		Performance
	Online	On contact	NPT	ACW	Error	Available	Availability	Active	In queue
Summary	1	0	0	0	0	1	2	0	0
Callback queue	1	0	0	0	0	1	2	0	0
Queue 5	1	0	0	0	0	1	1	0	0
Fun Queue	1	0	0	0	0	1	2	0	0
Nate's Queue	1	0	0	0	0	1	2	0	0
BasicQueue	1	0	0	0	0	1	2	0	0
Queue 6	1	0	0	0	0	1	1	0	0

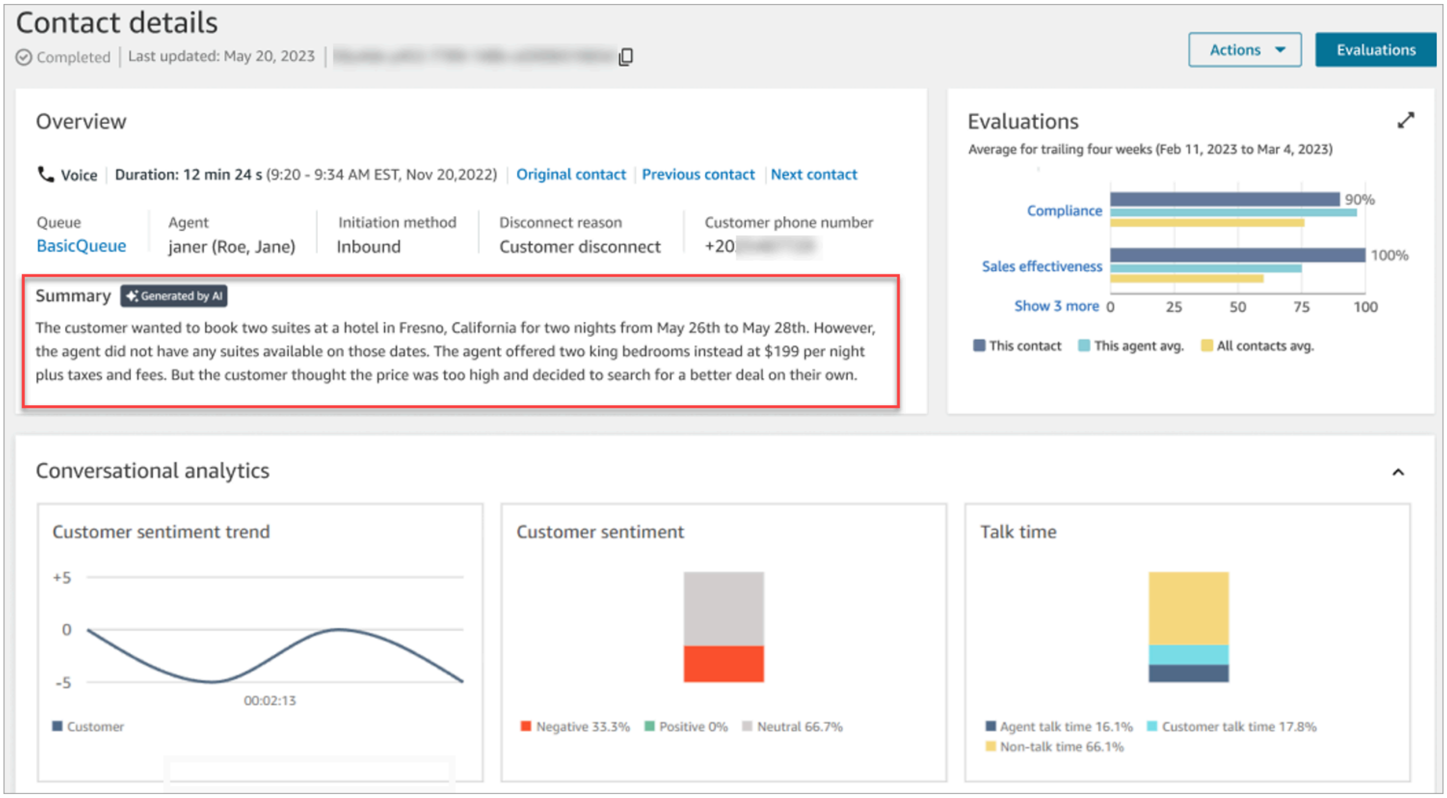
This next image shows a drill down into the real-time activity for Queue 4.



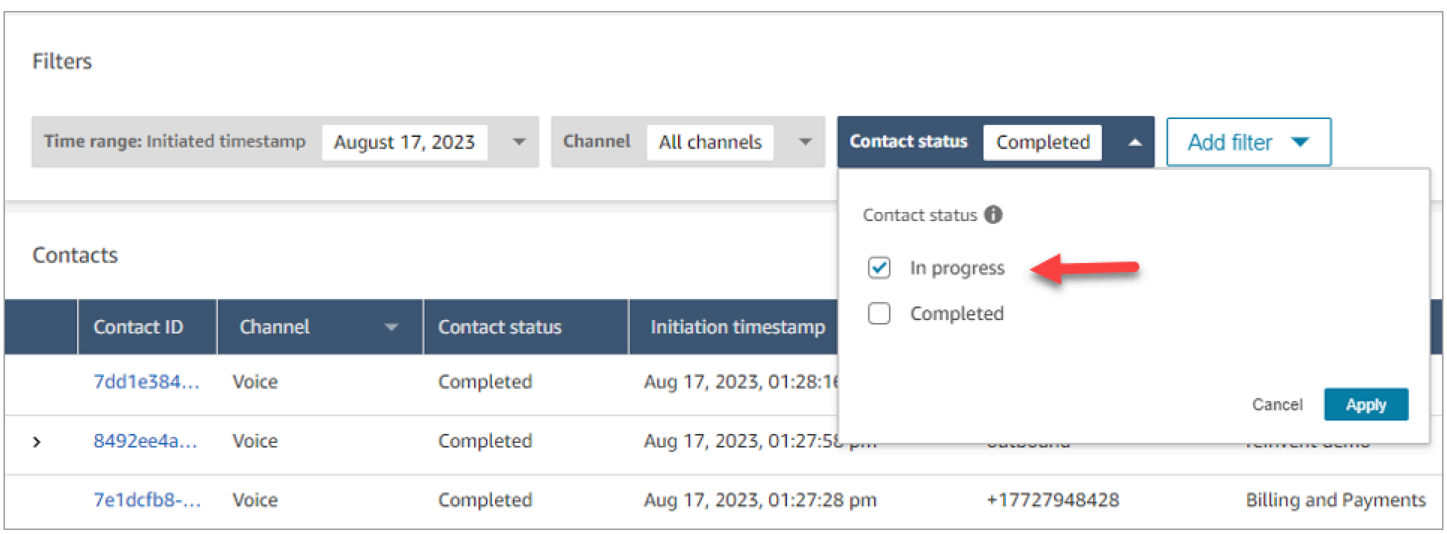
Real-time conversational analytics

With [real-time speech and chat analytics](), you can uncover trends and improve customer service by understanding sentiment, conversation characteristics, emerging contact themes, and agent compliance risks while the call or chat is in progress. You can receive an alert, for example, when a customer is getting frustrated because the agent is unable to resolve a complicated problem. This allows you to provide more immediate assistance.

The following image shows post-contact conversational analytics on the **Contact details** page. It includes a generative AI-powered contact summary to help you quickly understand essential information about the contact, how customer sentiment changes as the contact progresses, and the distribution of talk time between the agent and customer.



You can search for contacts as far back as two years ago. Choose from an extensive list of filters to quickly find the contacts you need. For example, you can search by custom attributes specific to your business, such as MVP, and search for in-progress contacts, as shown in the following image.

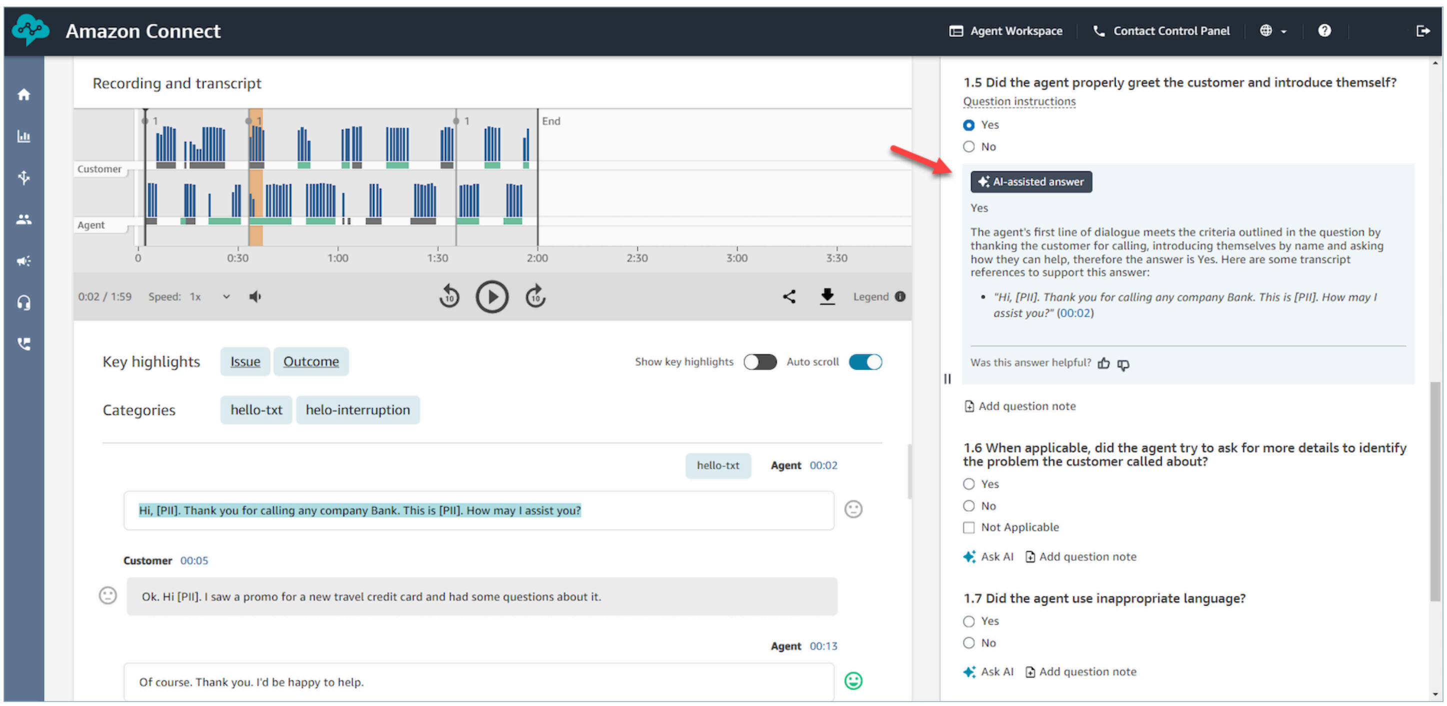


Managers can view the **Contact details** page for an in-progress contact, and the real-time transcript. In addition, they can transfer, reschedule, or end in-progress contacts.

Quality and performance management

To evaluate agent performance you can review conversations alongside contact details, audio and screen recordings, audio and chat transcripts, and conversation summaries, without switching applications. You can define and assess agent performance criteria (for example, script adherence, sensitive data collection, and customer greetings) and automatically pre-populate evaluation forms. You can use tasks to automatically queue follow-up coaching and training based on completed evaluations.

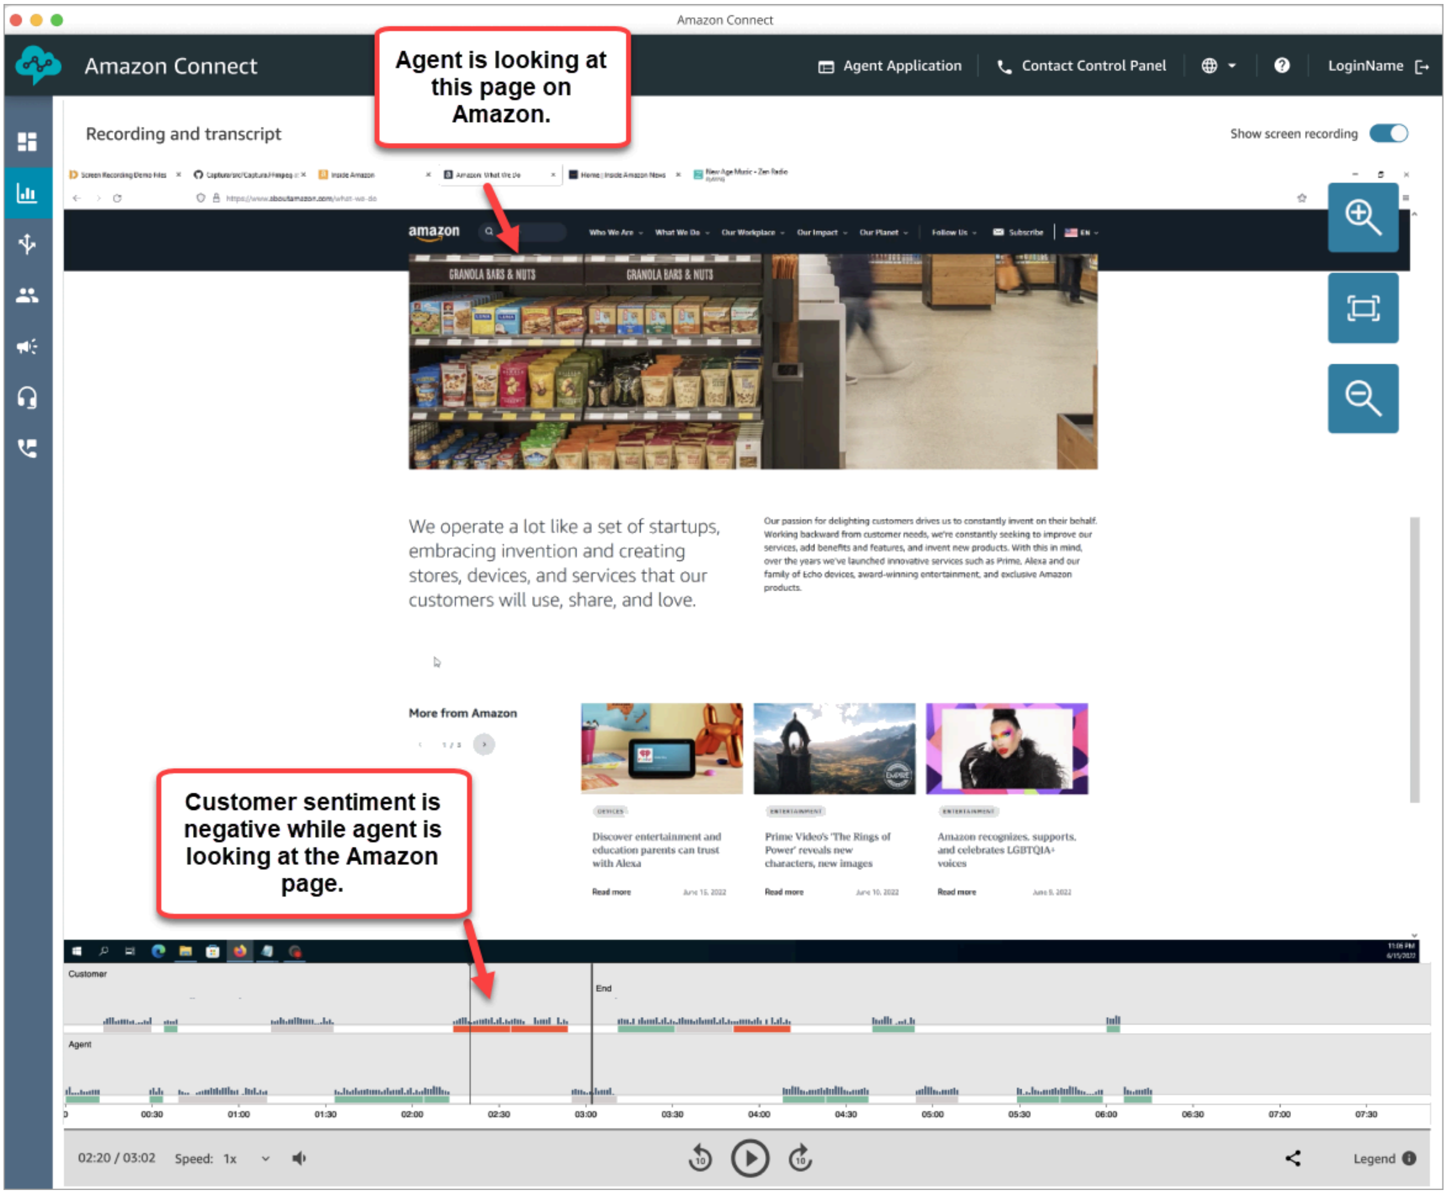
Managers can perform evaluations faster and more accurately with generative AI-powered recommendations for answers to questions in agent evaluation forms. For example, the following image shows the **Recording and transcript** section of the **Contact details** page. On the right side of the page is the evaluation, which includes generative AI-powered evaluation recommendations.



To assess a very large number of agent conversations, or all of them, your contact center can use automated evaluations.

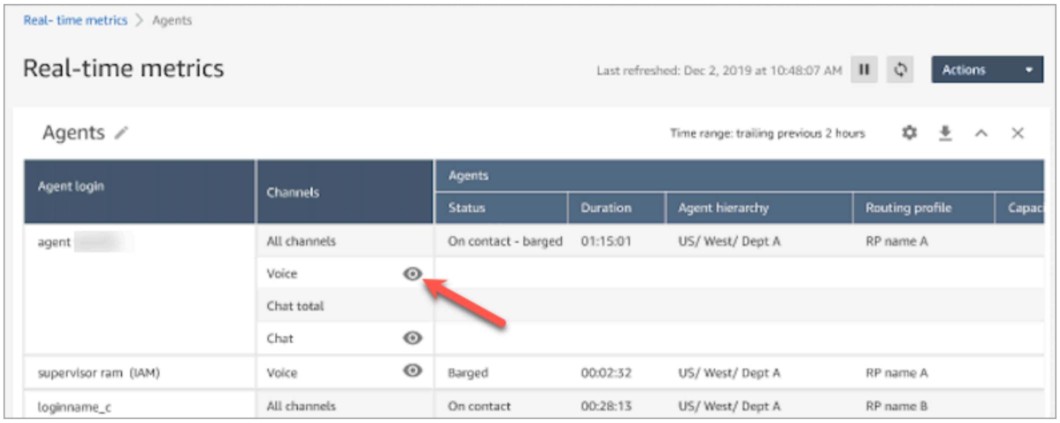
You can review the actions agents took while they were handling customer contacts by reviewing screen recordings. This helps you ensure adherence to quality standards, compliance requirements, and best practices. It also helps you identify coaching opportunities and bottlenecks so you can streamline workflows.

Managers use the **Recording** section of the **Contact details** page to view the screen recording, as shown in the following image.

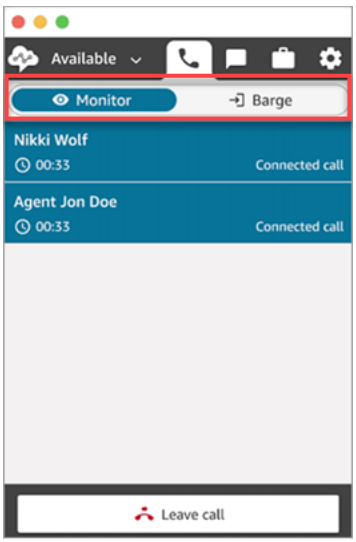


You can [monitor live voice and chat conversations] to listen in, coach the agent, and barge into live voice conversations. This is especially helpful for agents in training.

Managers use the **Real-time metrics** page to choose the contacts they want to monitor. For example, in the following image the manager can choose the eye icon to start monitoring a specific voice conversation.



Selecting the eye icon takes the manager to CCP section of the agent workspace, as shown in the following image. They can monitor the call and toggle between the **Monitor** and **Barge** states. The following image shows the **Monitor** state.



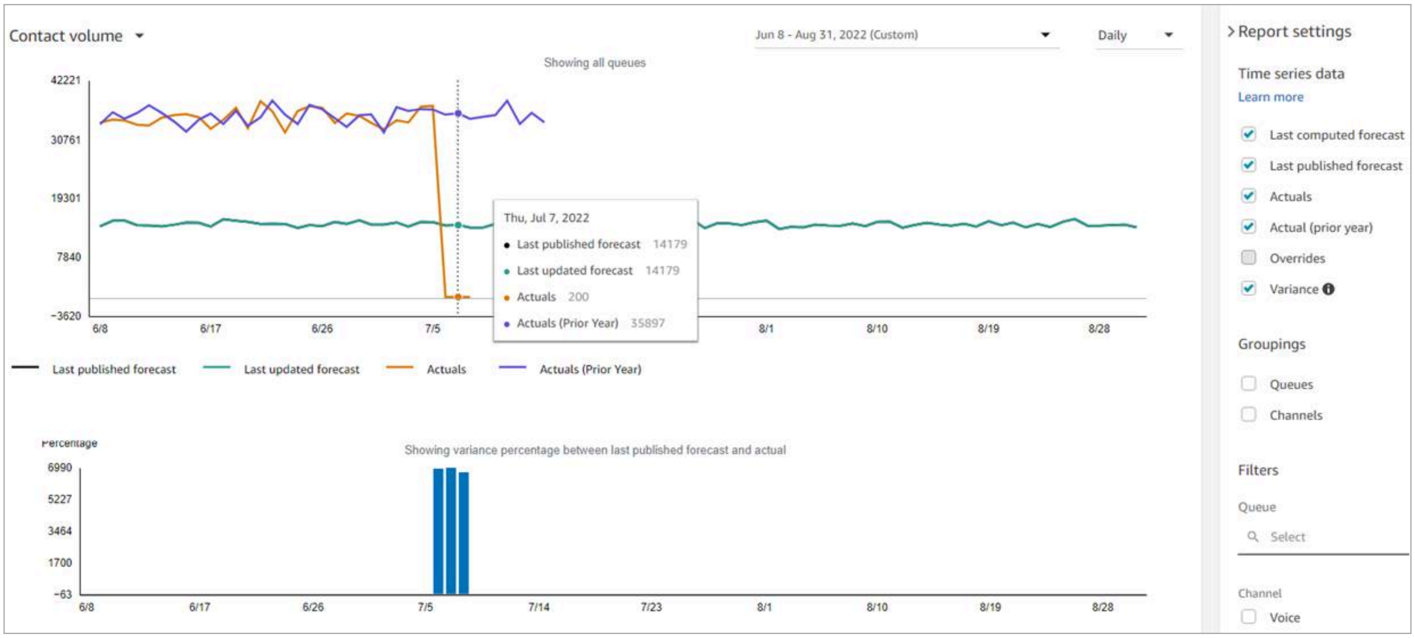
Forecasting, capacity planning, and scheduling

Forecasting, capacity planning, and scheduling are machine learning (ML)–powered features that help your workforce management team predict, allocate, and verify that the right number of agents are scheduled at the right time. Highly accurate forecasting helps you meet your operational goals with minimal overstaffing. You can anticipate contact volume and arrival rates, convert forecasts into projected staffing needs, and assign daily shifts to the right number of agents.

- Forecasting: A forecast is the starting point for any scheduling and capacity planning activities. Before you can generate a schedule or capacity plan, you must create a corresponding forecast.

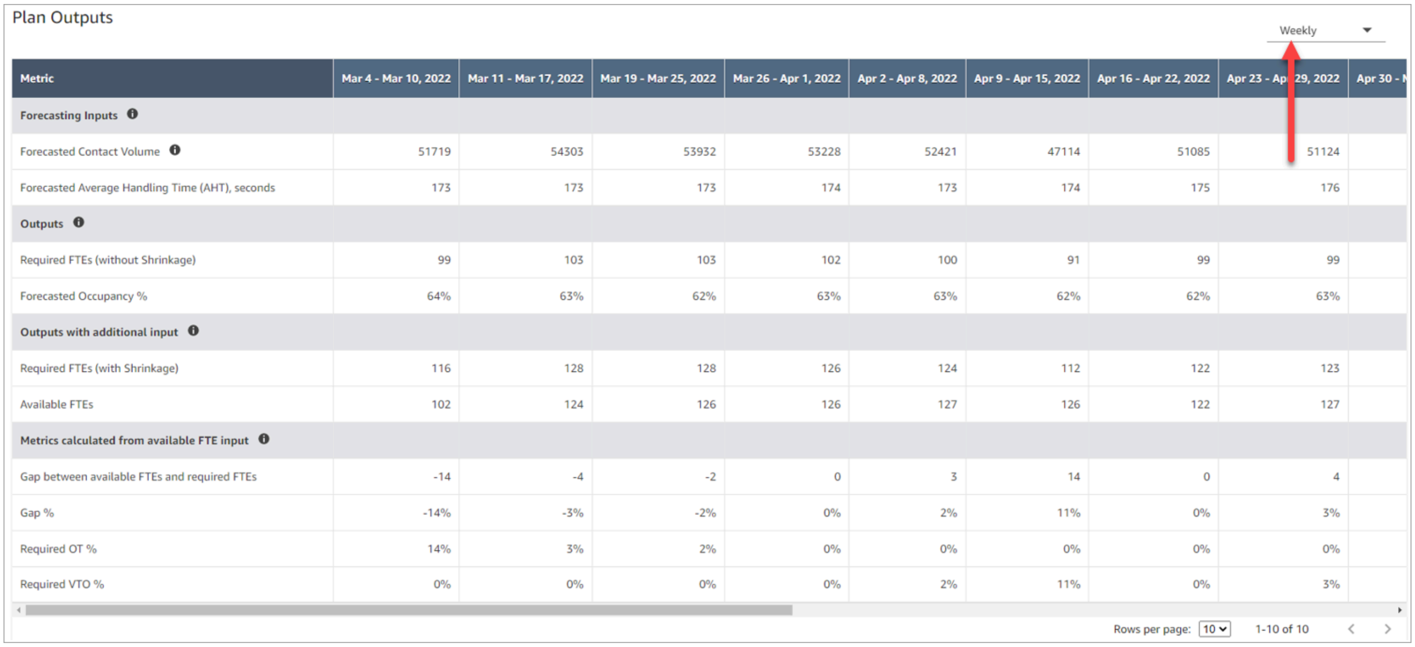
A forecast attempts to predict future contact volume and average handle time by using historical metrics.

Forecast data is displayed in graphs, as shown in the following image.



- [Capacity planning](): A capacity plan helps you estimate the long-term FTE (full-time equivalent) requirements for your contact center, up to 18 months. It specifies how many FTE agents are required to meet the service level target for a certain period of time.

  The following image shows the plan output. It shows a week-by-week or month-by-month calculation. To switch from weekly to monthly view, select **Monthly** from the dropdown.



Plan Outputs

Weekly

Metric	Mar 4 - Mar 10, 2022	Mar 11 - Mar 17, 2022	Mar 19 - Mar 25, 2022	Mar 26 - Apr 1, 2022	Apr 2 - Apr 8, 2022	Apr 9 - Apr 15, 2022	Apr 16 - Apr 22, 2022	Apr 23 - Apr 29, 2022	Apr 30 -
Forecasting Inputs									
Forecasted Contact Volume	51719	54303	53932	53228	52421	47114	51085	51124	
Forecasted Average Handling Time (AHT), seconds	173	173	173	174	173	174	175	176	
Outputs									
Required FTEs (without Shrinkage)	99	103	103	102	100	91	99	99	
Forecasted Occupancy %	64%	63%	62%	63%	63%	62%	62%	63%	
Outputs with additional input

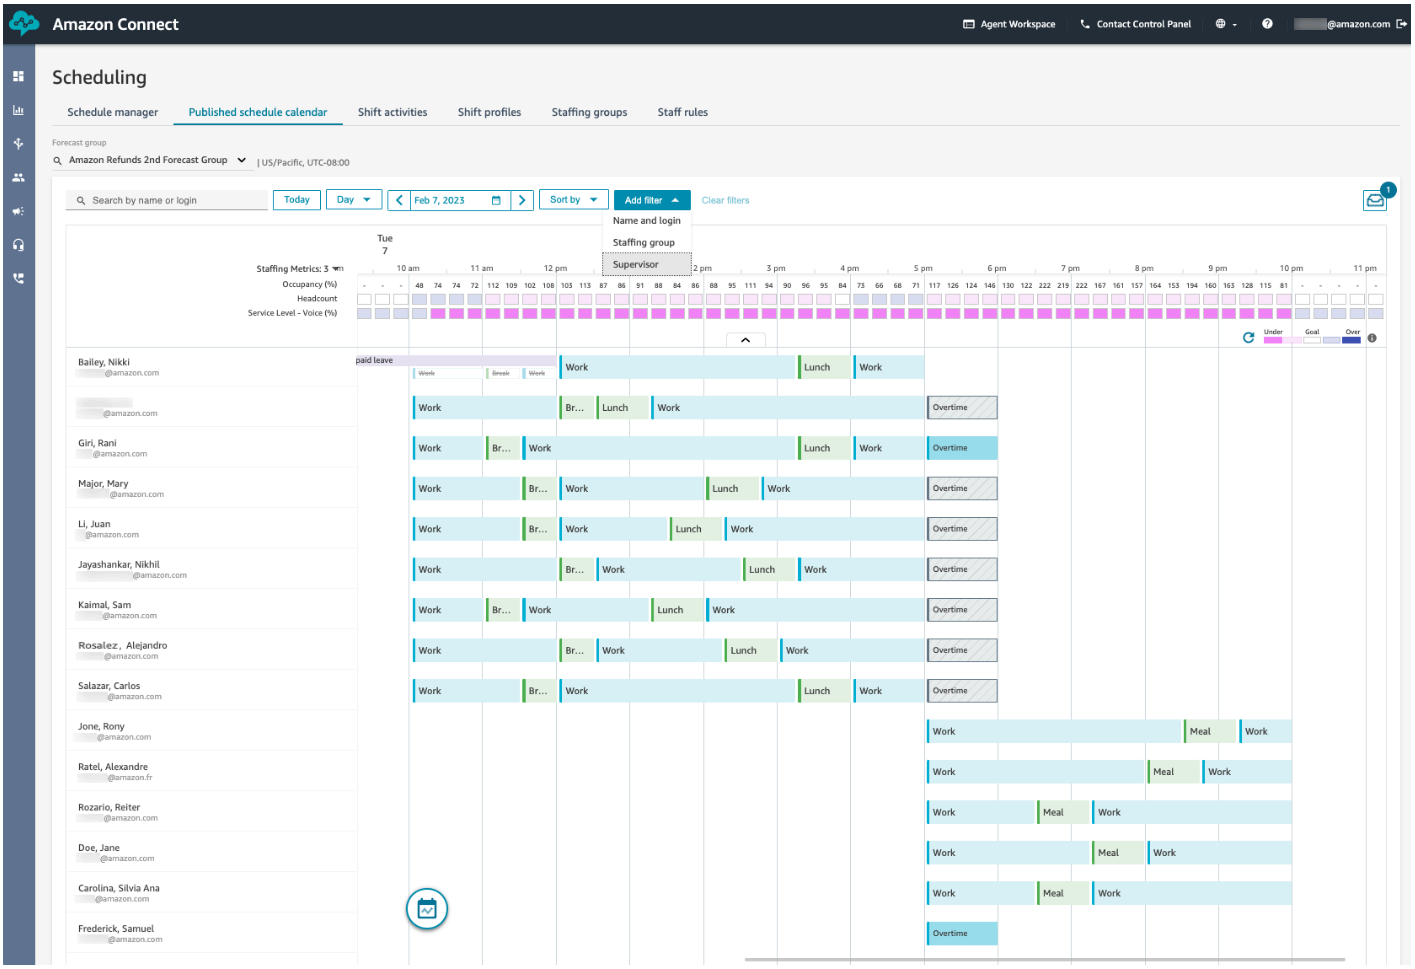
Required VTO %	0%	0%	0%	0%	2%	11%	0%	3%	

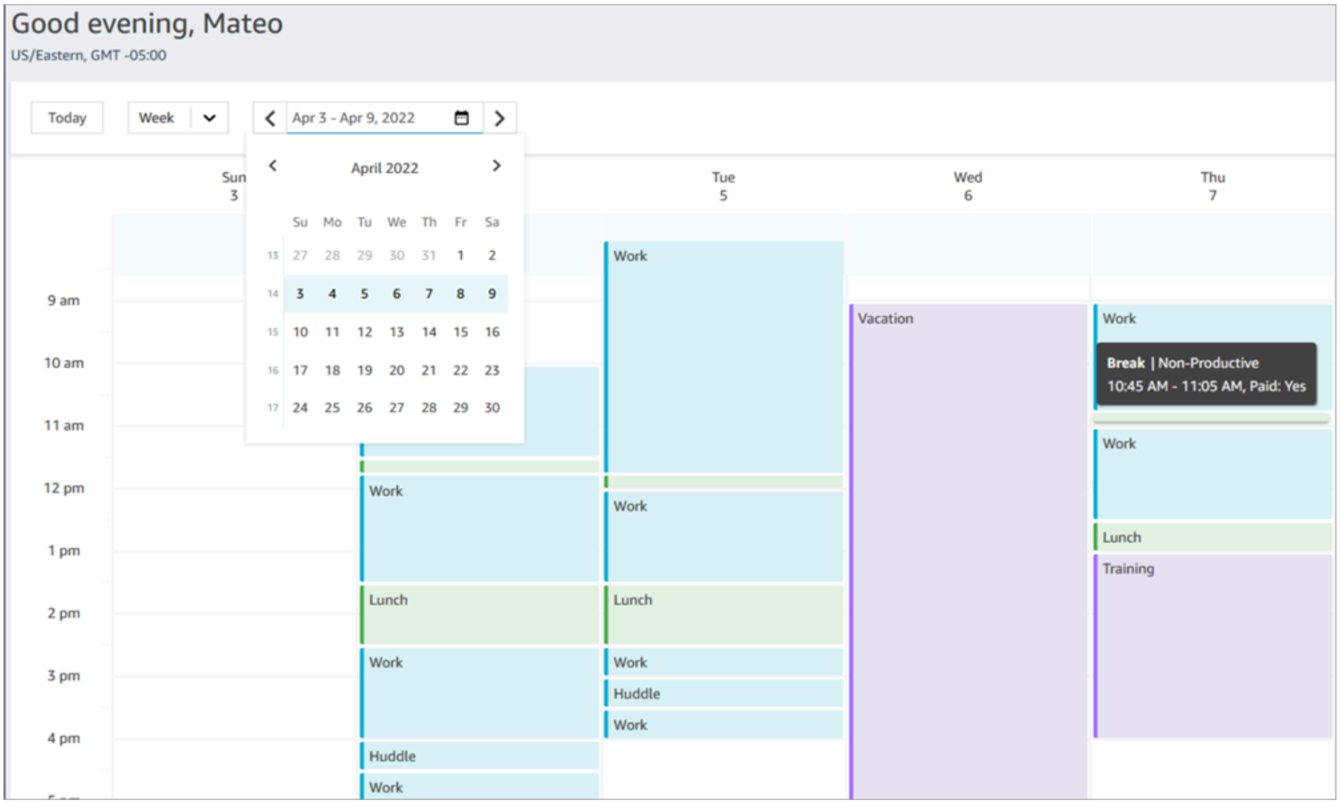
Rows per page: 10 1-10 of 10

- [Scheduling](): Contact center schedulers or managers need to create agent schedules for day-to-day workloads that are flexible and meet business and compliance requirements. Amazon Connect helps you create efficient schedules that are optimized for per-channel Service Level or Average speed of answer targets. You can generate and manage agent schedules based on the following:
  - A short-term published forecast
  - Shift profiles (templates for weekly shifts)
  - Staffing groups (agents that can handle specific types of contacts from a specific forecast group)
  - Human resources and business rules

The following image shows a sample schedule in the Amazon Connect admin website for a supervisor's team.



The following image shows a sample schedule that agents see in the agent workspace.



Administrators: Configuration and flexibility

Amazon Connect provides a simple, self-service UI that enables you to make changes in minutes, not months.

Anyone, from non-technical business leaders to experienced contact center administrators, can immediately start innovating on behalf of their customers using an intuitive, graphical UI. All channels – voice, chat, SMS, web and video-calling, messaging, email, tasks, and others – are configured, managed, personalized, automated, recorded, and analyzed using a single *omnichannel* solution, which means you can use the same business logic and routing rules across channels, making it easy to innovate and fine-tune the experience.

Contents

Telephony management

Amazon Connect takes the heavy lifting of managing telephony off your hands. We manage a network of telephony providers from around the world, removing the need for you to manage multiple vendors, negotiate complex multi-year contracts, or commit to peak call volumes.

The telephony service allows you to claim and then use direct inward dial (DID) and toll-free phone numbers for more than 110 countries worldwide. There are also more than 200 available outbound calling destinations. For a list of destinations, see the Amazon Connect pricing page.

For a list of the telephony capabilities that Amazon Connect provides, see the Amazon Connect Telecoms Country Coverage Guide.

The telephony-as-a service model can scale up and down at a moment's notice and is proactively and continuously monitored by telephony experts.

Drag-and-drop workflow designer

Amazon Connect flows provides a single drag-and-drop workflow designer you can use to create, personalize, and automate end-to-end customer and agent experiences across channels. With flows, you can design your interactive voice response (IVR) or chatbot experiences to help your customers self-serve, build step-by-step guides for your agents to resolve issues faster and accurately, and create and manage how tasks are automated for your agents.

Flows also has native integration with AWS Lambda, allowing you to build even more custom experiences that automate processes across other AWS services (such as Amazon DynamoDB, Amazon Redshift, or Amazon Aurora) or third-party systems (such as your CRM or analytics solutions).

Security

Cloud security at AWS is the highest priority. As an AWS customer, you benefit from a data center and network architecture that is built to meet the requirements of the most security-sensitive organizations.

To learn more about security and data protection, see Security in Amazon Connect.

Scalability

You can bring on tens, or tens of thousands of agents at will, in response to business cycles or unplanned events, and cycle agents out just as easily. Amazon Connect provides seamless scalability based on demand, and you only pay for what you use.

With routing profiles, flows, and real-time metrics, you can scale your business operations based on current volumes. You establish contact experience and business workflows, and Amazon Connect scales up during peak demand without additional application or hardware management. Contacts experience consistent service outcomes during busy periods. Administrators can focus on agent performance and contact feedback instead of monitoring available application or hardware capacity.

Resiliency

Amazon Connect provides all our customers with active-active resilience within an AWS Region. This resilience ensures high availability for all channels and applications.

If your organization requires even higher levels of resilience, you can use Amazon Connect Global Resiliency to provide resilience across multiple AWS Regions.

Availability of Amazon Connect features by Region

This topic lists the AWS Regions where Amazon Connect features are available.

Contents

Customer Profiles calculated attributes API availability by Region

The calculated attributes API is available in the following AWS Regions:

- US East (N. Virginia)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Asia Pacific (Seoul)
- Canada (Central)
- Europe (Frankfurt)
- Europe (London)

External voice transfer

- US East (N. Virginia)
- US West (Oregon)

Forecasting, capacity planning, and scheduling

- US East (N. Virginia)
- US West (Oregon)
- Canada (Central)
- Asia Pacific (Sydney)
- Europe (London)
- Asia Pacific (Singapore)
- Europe (Frankfurt)
- Asia Pacific (Tokyo)
- Asia Pacific (Seoul)

Global Resiliency availability by Region

- US East (N. Virginia)
- US West (Oregon)
- Europe (Frankfurt)
- Europe (London)

In-app, web, and video calling capabilities

- US East (N. Virginia)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)

- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (London)

Live media streaming

- US East (N. Virginia)
- US West (Oregon)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (London)

Outbound campaigns

- US East (N. Virginia)
- US West (Oregon)
- Asia Pacific (Sydney)
- Canada (Central)
- Europe (Frankfurt)
- Europe (London)

The phone numbers that outbound campaigns can call are based on the AWS Region where your Amazon Connect instance is created.

- From instances created in US East (N. Virginia) or US West (Oregon) you can call all phone numbers based in the US and Mexico.

- From instances created in Canada (Central) you can call all phone numbers based in Canada.
- From instances created in Asia Pacific (Sydney) you can call phone numbers based in Australia and New Zealand. There are a few specific restrictions explained in Make predictive and progressive calls using Amazon Connect outbound campaigns).
- From instances created in Europe (Frankfurt) or Europe (London) you can call all phone numbers based in the Belgium, Denmark, France, Germany, Ireland, Italy, Netherlands, Portugal, Spain, and UK.
- No other combinations are supported. For example, you can't make campaign calls from Europe (London) to US phone numbers, or from Europe (Frankfurt) to New Zealand phone numbers.

Tasks

- US East (N. Virginia)
- US West (Oregon)
- Africa (Cape Town)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (London)
- AWS GovCloud (US-West)

Voice ID availability by Region

Region Name	Region	Endpoint	Protocol	
US East (N. Virginia)	us-east-1	voiceid.us-east-1.amazonaws.com voiceid-fips.us-east-1.amazonaws.com	HTTPS HTTPS	

Region Name	Region	Endpoint	Protocol

Asia Pacific (Sydney)	ap-southeast-2	voiceid.ap-southeast-2.amazonaws.com	HTTPS
Asia Pacific (Tokyo)	ap-northeast-1	voiceid.ap-northeast-1.amazonaws.com	HTTPS
Canada (Central)	ca-central-1	voiceid.ca-central-1.amazonaws.com voiceid-fips.ca-central-1.amazonaws.com	HTTPS HTTPS
Europe (Frankfurt)	eu-central-1	voiceid.eu-central-1.amazonaws.com	HTTPS
Europe (London)	eu-west-2	voiceid.eu-west-2.amazonaws.com	HTTPS

Browsers supported by Amazon Connect

> **Important**
>
> **Trying to contact Amazon support?** See Amazon Customer Service (Amazon orders and deliveries) or AWS Support (Amazon Web Services).

Before you work with Amazon Connect, verify that your browser is supported using the following table.

Browser	Version	How to check your version
Google Chrome	Latest three versions	Open Chrome and type chrome://version in your address bar. The version is in the Google Chrome field at the top of the results. Please see Google Chrome update on third-party cookies.
Microsoft Edge Chromium	Latest three versions	Open Edge. On the menu, choose **Help and feedback** and then choose **About Microsoft Edge**. The version number is listed in the **About** section.
Mozilla Firefox	Latest three versions	Open Firefox. On the menu, choose the Help icon and then choose **About Firefox**. The version number is listed under the Firefox name. Please see Firefox Enhanced Tracking Protection updates.
Mozilla Firefox ESR	Versions are supported until their Firefox end-of-life date. For details, see the Firefox ESR release calendar.	Open Firefox. On the menu, choose the Help icon and then choose **About Firefox**. The version number is listed under the Firefox name.

For more requirements, see Agent headset and workstation requirements for using the Contact Control Panel (CCP).

Browsers on mobile devices

The Amazon Connect console, Contact Control Panel (CCP), and agent workspace do not support mobile browsers. However, your agents can forward the audio portion of the call to their mobile device. For instructions, see Forward calls in the Amazon Connect CCP to a mobile device (iPhone, Android).

Supported browsers and mobile OS for in-app, web, and video calling capabilities

- Amazon Chime SDK for iOS and Android:
  - iOS version 13 and later
  - Android OS version 8.1 and later, ARM and ARM64 architecture
- Web browsers for out-of-the-box communications widget and JS SDK
  - Latest three versions of Google Chrome, Firefox, Safari, and Microsoft Edge Chromium on MacOS, Windows, iOS, and Android.

For more information, see Set up in-app, web, video calling, and screen sharing capabilities.

The communications widget supports browser notifications for desktop devices. For more information, see Send browser notifications to customers when chat messages arrive.

Google Chrome update on third-party cookies

On July 22, 2024, Google announced a change in its plans regarding third-party cookies. Rather than deprecating third-party cookies by default, Google offers an opt-in mechanism for users to disable them.

> **Note**
>
> **For businesses that embed the Contact Control Panel (CCP) into a custom workspace**:
> If your agents use Google's opt-in mechanism to disable third-party cookies, it will cause authentication issues when they use the CCP. Amazon Connect relies on third-party cookies

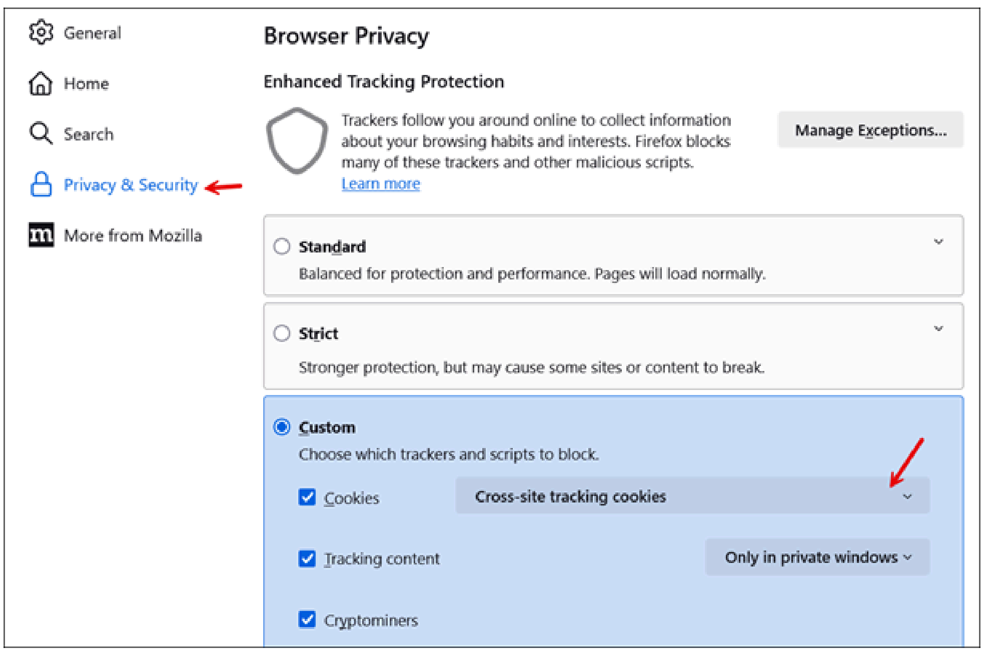
to facilitate authentication. Ensure that third-party cookies are enabled in your agents' browser settings to avoid any authentication issues while using the CCP.

Firefox Enhanced Tracking Protection updates

As of February 2024, Firefox prevents the Amazon Connect CCP from being embedded in another application. As a result, agents are prevents from handling contacts. This is because Firefox enabled Total Cookie Protection by default for all users, including users who have set their Enhanced Tracking Protection setting as Standard .

To prevent impacts to your users (agents), we recommend that your users complete the following steps:

1. In your Firefox browser, choose **Settings**, **Privacy & Security**
2. In the **Custom** box, for **Cookies** choose **Cross-site tracking cookies**, as shown in the following image.



Firefox browser guidance for Microphone Access

The Amazon Connect CCP conforms to Firefox microphone usage guidance, and only has access to connect to the user's microphone when the CCP tab is in focus. This may lead to missed call scenarios when the CCP tab is not in focus, for example, if the agent focused on a different tab or application.

- Agents must focus on the CCP or Agent Workspace Firefox browser tab when they accept and connect to a voice contact.

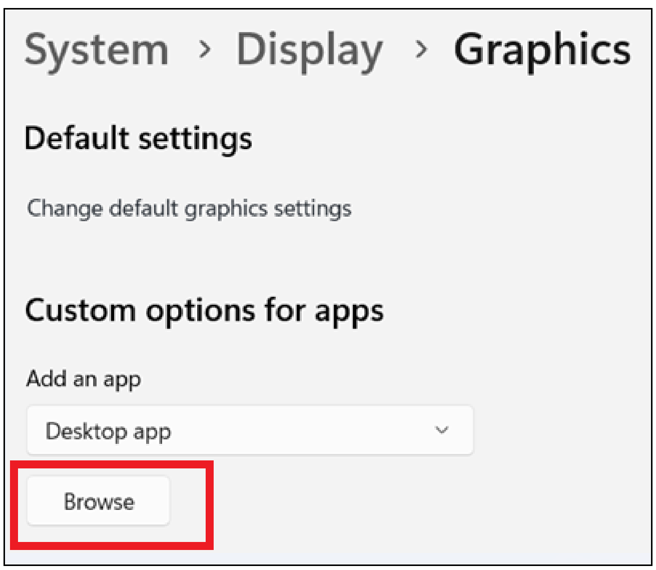
Optimize performance for Flow Designer for a multiple GPU system on Windows

If you're using Flow Designer on a Windows system with dual GPUs, you might notice that animations in Firefox feel less smooth compared to Chrome. This happens because, by default, browsers use the power-saving GPU. For Chrome, the default output is 60 FPS. However, Firefox may cap at 30 FPS, leading to less fluid animations.

If your system has a dedicated GPU, you can improve performance by changing its GPU preferences in Window settings.

To ensure the best animation performance in a supported browser:

1. On your computer, open **Windows Settings**.
2. Navigate to **Display**, **Graphics**, **Browse**. The following image shows the **Browse** button.

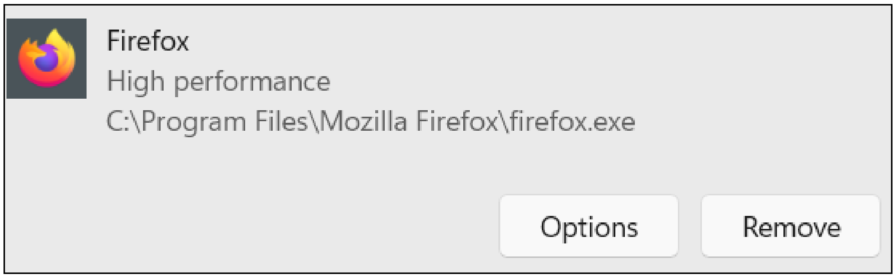


3. Navigate to the installation folder:

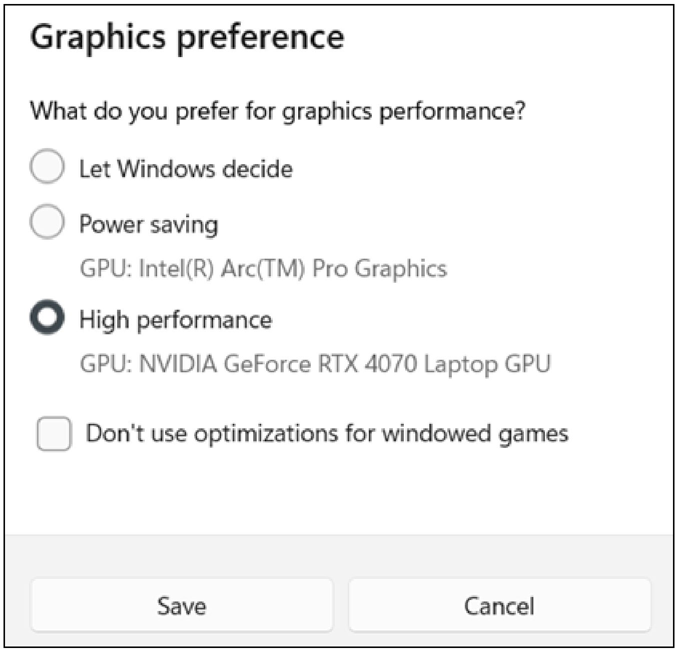
   - For **Firefox**, it is typically located at path: `C:\Program Files\Mozilla Firefox`

- For **Chrome**, it is typically located at path: `C:\Program Files\Google\Chrome\Application`

4. Select `firefox.exe` or `chrome.exe`.
5. Choose **Options** under Firefox or Chrome. The following image shows an example of the Firefox High performance **Options** button.



6. Choose **High Performance** to use the dedicated GPU. The following image shows an example **Graphics preference** page with the **High performance** option.



7. Save your changes and restart your browser.

Accessibility compliance

We strive to provide an accessible user interface for Amazon Connect. See the accessibility compliance reports (ACR) that are regularly published in [AWS Artifact](). For more information, see [Getting started with AWS Artifact]()

For information about AWS compliance programs, see Compliance validation in Amazon Connect.

Screen readers supported in Amazon Connect

Screen readers can be used optionally by people who have difficulties seeing websites or applications. For example, people who are blind or who have very limited vision may want to use a screen reader. To learn about three popular screen readers, all supported by Amazon Connect, see the following websites:

- JAWS
- NVDA

If you use an Apple device, another option is to use VoiceOver. No download is required. On an Apple device, go to **Settings**, **Accessibility**, **VoiceOver**.

Languages supported by Amazon Connect features

This topic lists Amazon Connect features and which languages they support.

Contents

Contact Control Panel

CCP	Supported languages
Contact Control Panel - latest version	• Chinese (Simplified) • Chinese (Traditional) • English • French • German • Italian • Japanese • Korean • Portuguese (Brazilian) • Spanish
Contact Control Panel - earlier version	• English • French • German • Italian • Japanese • Korean • Portuguese (Brazilian) • Spanish

Chat message content

Amazon Connect provides full Unicode support. You can chat with customers in any language of your choice.

Quick responses

Quick responses for chat and email contacts are available in English.

Amazon Polly

See Voices in Amazon Polly in the *Amazon Polly Developer Guide*.

Amazon Connect service quotas

All service quotas can be adjusted unless otherwise noted.

Your AWS account has default quotas, formerly referred to as limits, for each AWS service.

To request a quota increase, see Requesting a quota increase in the *Service Quotas User Guide*.

Contents

- Amazon Connect Cases service quotas
- Contact Lens service quotas
- Amazon Connect Customer Profiles service quotas
- Amazon Connect Outbound campaigns service quotas
- Amazon Connect Voice ID service quotas
- How contacts are counted
- Amazon Connect feature specifications
- Countries that call centers using Amazon Connect can call by default
- API throttling quotas

Important things to know

- You must create your instance before you can request a service quota increase.
- We review each request for a quota increase. For smaller increase requests, we can approve in hours. Larger increase requests take time to review, process, approve, and deploy. Depending on your specific implementation, your resource, and the size of quota that you want, a request can take up to 3 weeks. An extra-large worldwide increase can potentially take months. If you're increasing your quotas as part of a larger project, keep this information in mind and plan accordingly.
- There are two types of quota adjustability: account level and resource-level.
  - Account level quotas, when adjusted, apply to all Amazon Connect instances in this account and Region. For example, the maximum transactions per second (TPS) limits for a specific API.
  - Resource level quotas, when adjusted, only apply to resources within a specific Amazon Connect instance. For example, the maximum number of users per instance. Resource level quotas cannot be adjusted at the account level.
- The quotas apply per AWS Region. You can have multiple Amazon Connect instances in each Region. It's possible to raise quotas for all instances in a Region.
- Default quota values in this documentation are specifically for new accounts. Because quota defaults have been adjusted over time, the default and applied quota values for your account might be lower than the default values described in this topic.
- Not all quotas can be adjusted.
- You need AWS CLI version 2.13.20 or higher to view and manage resource-level quotas such as **Phone numbers per instance** for Amazon Connect.

- Use the same form to submit a request to port your US phone number from your current carrier to Amazon Connect. For more information about porting phone numbers, see Port a current phone number to Amazon Connect.

Amazon Connect quotas

Name	Default	Adjustable	Adjustability
Active email contact expiry	Default of 14 days Customizable up to 30 days	No	Resource Level
Active email thread expiry	90 days	No	Resource Level
AWS Lambda functions per instance	50	Yes	Resource Level
Agent status per instance	50	No	Not Adjustable
Amazon Connect instances per account	2	Yes	Account Level
Amazon Lex bots per instance	70	No	Resource Level
Amazon Lex V2 bot aliases per instance	100	Yes	Resource Level
CC addresses per inbound	10 email addresses	No	Resource Level

Name	Default	Adjustable	Adjustability
email message	BCC email addresses are not supported in Amazon Connect.		
Concurrent active calls per instance	10 This includes PSTN and WebRTC calls. For more information, see the section called "How contacts are counted".	Yes	Resource Level
Concurrent active chats per instance	500 This includes chats that are waiting and SMS. If the customer has initiated a chat and has gone silent for hours, this idle chat is counted against the quota. To avoid having idle chats count against your quota, we recommend using persistent chats. If this quota is exceeded, the API call fails with a quota exceeded error.	Yes	Resource Level
Concurrent active emails per instance	1000	Yes	Resource Level
Concurrent active tasks per instance	2500 concurrent active tasks All tasks that have not yet ended are considere d active and are counted as concurrent tasks: tasks that are being routed in flows, waiting in a queue for an agent, being handled by agents, or being run in After Contact Work (ACW).	Yes	Resource Level
Email domains per instance	1 Amazon Connect email domain 5 custom email domains	No	Resource Level

Name	Default	Adjustable	Adjustability
External voice transfer connectors per account	0	Yes	Account Level
Email addresses per instance	100 email addresses	No	Resource Level
Email contact retention	24 months	No	Resource Level
Email message and attachment retention	This is defined by your S3 lifecycle configuration. For more information, see [Managing your storage lifecycle]() in the *Amazon Simple Storage Service User Guide*.		No
Maximum email message body size	5 MB	No	Resource Level
Maximum email message body plus attachments size	35 MB	No	Resource Level
Maximum individual attachments size	20 MB	Yes	Resource Level
Flows per instance	100	Yes	Resource Level

Name	Default	Adjustable	Adjustability
Hours of operation per instance	100	Yes	Resource Level
Maximum duration that a task can be scheduled in future	6 days	No	Not Adjustable
Maximum number of reschedules allowed for a task scheduled for a future time	20	No	Not Adjustable
Modules per instance	200	Yes	Resource Level
Phone numbers per instance	5 It's possible to get an error message that "You've reached the limit of Phone Numbers," even if it's the first time you've claimed a phone number. All the issues that cause this error message require help from Support to resolve.	Yes	Resource Level
Predefined attributes per instance	25	Yes	Resource Level
Proficiencies per agent	10	Yes	Resource Level

Name	Default	Adjustable	Adjustability
Prompts per instance	500	Yes	Resource Level
Queues per instance	100	Yes	Resource Level
Queues per routing profile per instance	50 This quota refers to number of queue/channel combinations per routing profile. For example, in the following image there are two queues, but there are three queue-channel combinations: Escalation queue Voice, Escalation queue Chat, and BasicQueue Voice. This counts three towards the service quota of 50. 	Yes	Resource Level
Quick connects per instance	100	Yes	Resource Level
Rate of API requests	See [Amazon Connect API throttling quotas]().	Yes	Account Level

Name	Default	Adjustable	Adjustability
Reports per instance	2000 Personal saved reports count towards the reports per instance. For example, if one of your supervisors saves a report every day, it will count towards your overall number of saved reports per instance. As a best practice, we recommend you implement policies so reports don't pile up.	Yes	Resource Level
Routing profiles per instance	500	Yes	Resource Level
Scheduled reports per instance	100	Yes	Resource Level
Security profiles per instance	100	Yes	Resource Level
Task templates per instance	50	No	Not Adjustable
Task template customized fields per instance	50	No	Not Adjustable

Name	Default	Adjustable	Adjustability
Theme detection reports generated within 30 minutes per instance	6	No	Resource Level
To addresses per inbound email message	10 email addresses	No	Resource Level
User hierarchy groups per instance	500 This quota applies to the total number of hierarchy groups you have, across all levels. There is no feature limit for how many hierarchy groups you can have for each level. For example, one level could have 500 hierarchy groups, which would reach the quota for your instance.	Yes	Resource Level
Users per instance	500 The maximum number of users you can create in this instance in the current Region. All 500 users can be logged into Amazon Connect concurrently as agents and handling contacts.	Yes	Resource Level

Amazon Connect AppIntegrations service quotas

All AppIntegrations quotas are at the Account level.

Name	Default	Adjustable
Data integration associations per data integration	10	Yes
Data integrati ons per Region	10	Yes
Event integrati on associati ons per event integration	10	Yes
Event integrati ons per Region	10	Yes
Application per region (third-pa rty application)	25	No

Amazon Q in Connect service quotas

All Amazon Q quotas are at the Account level.

Item	Default quotas	Adjustable
Assistants	5	No
Knowledge bases	10	No
Assistant associations	1	No
Maximum size of a knowledge base	5GB per knowledge base	No
Quick responses per knowledge base	1,000	No

Item	Default quotas	Adjustable
Content per knowledge base	5,000 Examples of content are frequently asked questions (FAQs), wikis, articles, and step-by-step instructions for handling different customer issues.	No
Maximum size per document	1MB	No
Maximum number of message templates per knowldege base	200	No
Maximum number of versions per message template	20	No
Maximum number of attachments per email message template	10	No
Maximum size per attachment in an email message template	1 MB	No
Maximum number of characters in an email message template	5,000,000	No
Maximum number of characters in an SMS message template	800	No

Item	Default quotas	Adjustable
RateLimit for all APIs	10TPS The rate limit for DeleteQuickResponse and SearchQuickResponses is 20TPS	No

Amazon Connect Cases service quotas

All the Cases quotas are at the Account level.

Name	Default	Adjustable
Cases domains per AWS account	5	Yes
Fields in a Cases domain	500	Yes
Field options per single-select field in the Cases domain	500	Yes
Layouts in a Cases domain	100	Yes
Templates in a Cases domain	100	Yes
Related items that can be attached to a case	200	Yes

Name	Default	Adjustable
Files that can be attached to a case	50	Yes
Case fields per case layout	100	Yes

Contact Lens service quotas

All Contact Lens quotas are at the Account level.

Name	Default	Adjustable
Concurrent real-time calls with analytics	50 100 for US East (N. Virginia)	Yes
Concurrent post-call analytics jobs	200 See Derive Concurrent post-call analytics jobs based on your Amazon Connect call volume.	Yes
Concurrent chat analytics jobs	200	Yes
Concurrent post-contact summary jobs (limit is shared between all supported channels - voice, chat)	10	Yes

Name	Default	Adjustable
Contact Lens connectors per account	0	Yes
Maximum active recording sessions from external voice systems per instance	10	Yes
Number of evaluation questions that can be answered with Ask AI on a single contact (for manually submitted evaluations)	10	No
Number of evaluation questions that can be answered automatically on a contact using generative AI (for automated submissions of evaluations)	10	No

Derive Concurrent post-call analytics jobs based on your Amazon Connect call volume

A post-call analytics job is kicked off after the completion of each contact that has Contact Lens conversational analytics enabled on it. The time to complete a post-call analytics job can vary, but for planning purposes, you can estimate that it usually takes about 40% of the call length. If you choose 40% for your estimate, to calculate concurrent post-call analytics jobs, you would use the following formula:

```
(average call duration in minutes) * (0.4) * (calls per hour) / (60)
```

The following table shows some examples of what the approximate number of concurrent post call jobs would be if you assume the time to complete the analysis is 40%.

Average call duration (in minutes)	Calls per hour*	Approximate Concurrent post-call jobs
5	1000	33
10	500	33
10	1000	67
10	3000	200

*For the example calculations in the preceding table, we assume a fairly uniform distribution of calls during the hour. If you have more complex traffic patterns, contact Support with details about your anticipated traffic pattern.

Amazon Connect Customer Profiles service quotas

All Customer Profiles quotas are at the Account level.

Name	Default	Adjustable	Description
Amazon Connect Customer Profiles domain count	Each supported Region: 100	Yes	The maximum number of Amazon Connect

Name	Default	Adjustable	Description
			Customer Profiles domains you can create in this account in the current AWS Region.
Keys per object type	Each supported Region: 10	Yes	The maximum number of keys that can be defined per object type in the current AWS Region.
Maximum expiration in days	Each supported Region: 1,098	Yes	The maximum expiration, in days, that can be defined for an object or profile in the current AWS Region.
Maximum number of calculated attributes per domain	Each supported Region: 50	No	The maximum number of calculated attributes per domain in the current AWS Region.
Maximum number of event stream per domain	Each supported Region: 1	No	The maximum number of event streams per domain in the current AWS Region.
Maximum number of event triggers per domain	Each supported Region: 20	Yes	The maximum number of event triggers per domain in the current AWS Region.
Maximum number of integrations	Each supported Region: 50	Yes	The maximum number of integrations per domain in the current AWS Region.

Name	Default	Adjustable	Description
Maximum size of all objects for a profile	Each supported Region: 51,200 Kilobytes	Yes	The total size of a profile, including all of its related objects, in the current AWS Region.
Object and profile maximum size	Each supported Region: 250 Kilobytes	No	The maximum size of a single profile or profile object in the current AWS Region.
Object types per domain	Each supported Region: 100	Yes	The maximum number of object types you can define per domain in the current AWS Region.
Objects per profile	Each supported Region: 1,000	Yes	The maximum number of objects that can be attached to a single profile in the current AWS Region.
Concurrent bulk export jobs	20	No	The maximum number of concurrent bulk export jobs per AWS Region per account. After a bulk export job completes or fails, it no longer counts towards the concurrency quota.

Amazon Connect Outbound campaigns service quotas

All outbound campaigns quotas are at the Account level.

Name	Default	Adjustable	Adjustability
Campaigns	25 This is the maximum number of campaigns that an AWS account can configure.	Yes	Resource Level

Amazon Connect Voice ID service quotas

All Voice ID quotas are at the Account level.

Item	Default quotas
Domains	3 This quota applies per account.
Concurrent active sessions per domain	50 See the following table for information about how to derive your **Concurrent active sessions** quota based on your Amazon Connect call volume.
Maximum number of fraudsters per watchlist	500
Maximum number of watchlists per domain	3, including the default watchlist of a domain
Maximum number of speakers per domain	100,000
Active Batch Speaker Enrollment Jobs per domain	1
Active Batch Fraudster Registration Jobs per domain	1
Speakers per Batch Speaker Enrollment Job	10,000

Item	Default quotas
Fraudsters per Batch Fraudster Registration Job	500

Derive Concurrent active sessions based on your Amazon Connect call volume

Use the information in the following table to derive your quota for Voice ID **Concurrent active sessions per domain**. Base your quota on the number of voice calls handled by your Amazon Connect contact center where Voice ID is enabled.

Amazon Connect Voice Contacts (Calls)/Hour*	Voice ID Concurrent active sessions
1,000	50
5,000	250
10,000	500
20,000	1,000
50,000	2,500

*For the calculations in the preceding table, we assume a fairly uniform distribution of calls during the hour. If you have more complex traffic patterns, contact Support with details about your anticipated traffic pattern.

How contacts are counted

The following contacts are counted in **Concurrent active calls per instance**:

- Handled by a flow
- Waiting in queue
- Handled by an agent
- Outbound call

The following contacts are not counted:

- Callbacks waiting in a callback queue are not counted until the callback is offered to an available agent.
- External transfers

If the quota for **Concurrent active calls per instance** is exceeded, contacts get a reorder tone (also known as a fast busy tone), which indicates that there is no available transmission path to the called number.

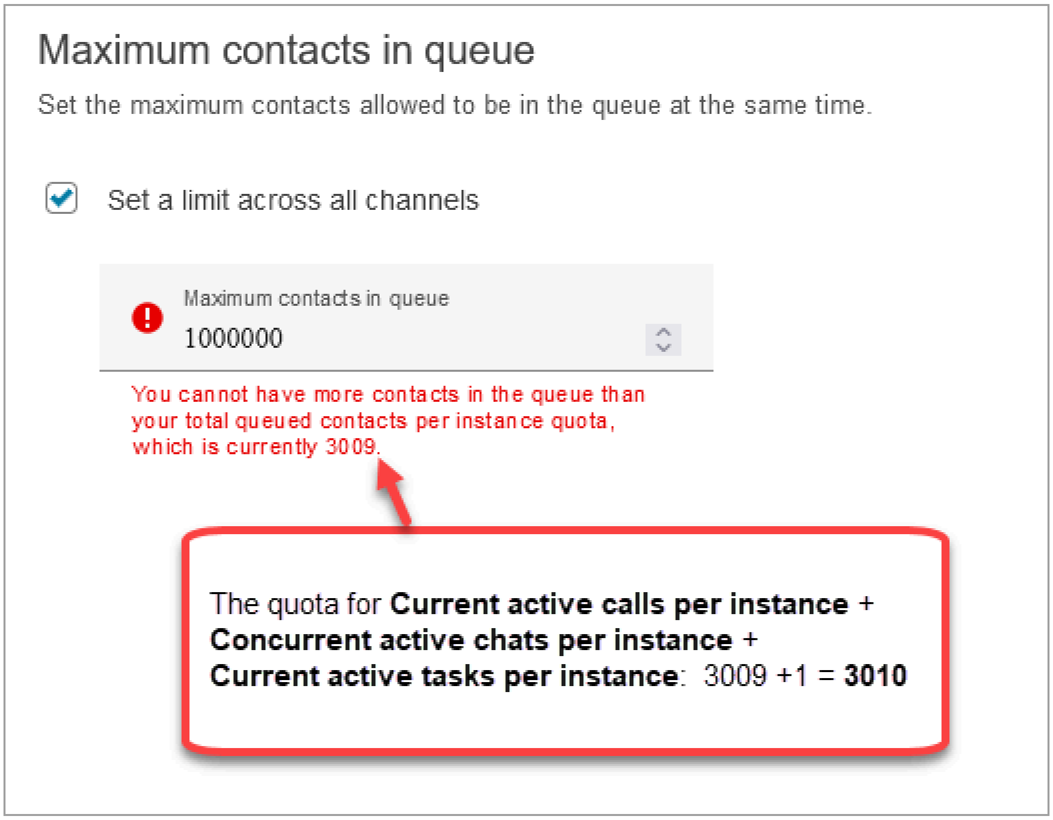
You can calculate your configured quota using CloudWatch metrics. For instructions, see [Use CloudWatch metrics to calculate concurrent call quota].

If you're only taking calls you can also determine your **Concurrent active calls per instance** quota by doing the following:

1. Navigate to the **Edit a queue** page: choose **Routing**, **Queues**, and choose a queue.
2. Choose **Set a limit across all channels**.
3. Enter an exceptionally large number in the **Maximum contacts in queue** box for the contact limit.

The resulting error message displays your quota as less than the sum of the following quotas combined: **Concurrent calls per instance** + **Concurrent active chats per instance** + **Concurrent active tasks per instance**.

For example, in the following image from the **Edit queues** page, you add 1 to the error message, to get **Concurrent calls per instance** + **Concurrent active chats per instance** + **Concurrent active tasks per instance** quota = 3010.



The error message shows 3009 because you must set always set **Maximum contacts in queue** to a number that is at least 1 *less than* your combined quota (which is the default limit).

Amazon Connect feature specifications

> **Note**
>
> You can't increase the feature specifications listed here.

The following tables list the various Amazon Connect feature specifications.

Contents

- Amazon Connect Contact Lens feature specifications
- Evaluation forms feature specifications
- Amazon Connect Rules feature specifications

Item	Feature Specification
Agent activity retention	24 months from the time the event occurred
File types supported for attachments to emails, cases, or chats	.csv, .doc, .docx, .heic, .jfif, .jpeg, .jpg, .mov, .mp4, .pdf, . For more information about supported file types for WhatsApp business messaging, see the section called "WhatsApp business messaging feature specifications" later in this topic.
Maximum file size for an attachment to an email, case, or a chat	20MB For more information about supported file sizes for WhatsApp business messaging, see the section called "WhatsApp business messaging feature specifications" later in this topic.
Maximum timeout for an attachment scanner	60 seconds
Maximum size of a real-time metrics report	200KB
When the Multi-Party Calls and Enhanced Monitoring for Voice capability is enabled on your instance, the number of people who can listen in on the same agent call at the same time	5 For example, you can have a group of 5 people listen in to a call at the same time, and then a different group of 5 people listen in to a different call at the same time, and so on. The total number of participants on a call would look like this: 1. Customer

Item	Feature Specification
	2. Agent 3. Supervisor who can listen but not barge in the call 4. Supervisor who can listen but not barge in the call 5. Supervisor who can listen but not barge in the call 6. Supervisor who can listen but not barge in the call 7. Supervisor who can listen but not barge in the call
When the Multi-Party Calls and Enhanced Monitoring for Voice capability is **not** enabled on your instance, the number of people who can be on the same agent call at the same time	2 There can be four participants in total: 1. Customer 2. Agent 3. Supervisor who can barge in the call 4. Supervisor who can listen but not barge in the call
Quick connects you can assign to a queue	700
Participants on a conference call	6 The participants are the customer, agent, and others who can be agents or external third-parties.

Item	Feature Specification
Contact record retention	24 months from the time the associated contact was initiated. You can choose to stream contact records to Kinesis so you can manage retention and perform advanced analysis.
Maximum size of the contact record attributes section	32KB
Maximum size of the returned data in a Lambda function	Less than 32KB of UTF-8 data
Limit on creating and deleting instances	100 instances can be created or deleted in 30 days Amazon Connect enforces a limit on the **total** number of instances that you can create and delete in 30 days. If you exceed this limit, you will get an error message indicating there has been an excessive number of attempts at creating or deleting instances. You must wait 30 days before you can restart creating and deleting instances in your account. For example, if you create 80 instances and delete 20 over the course of 30 days, you must wait an additional 30 days before you can create or delete any more instances. If you create and delete the same instance 100 times in 30 days, the limit also applies.
Searchable custom contact attributes	50
Replica instances (created by using the ReplicateInstance API)	5 per account

Item	Feature Specification
Traffic distribution groups	8 per replicated instance

Chat feature specifications

Item	Feature Specification
Attachments per chat conversation	35
Active chats per agent	10
Participants on a conference chat	6 The participants are the customer, agent, and others who can be agents.
Custom participants (such as a custom bot) on a contact	1
Chat contacts that a supervisor can monitor concurrently	Depends on the number of concurrent chats limit set in the supervisor's routing profile
People who can monitor the same agent chat at the same time regardless of whether the Enable Multi-Party Chats and Enhanced Monitoring for Chat capability is enabled for an instance	5 For example, you can have a group of 5 people monitor a chat at the same time, and then a different group of 5 people monitor a different chat at the same time, and so on. The total number of participants on the chat would look like this: 1. Customer 2. Agent 3. Supervisor who can monitor the chat but not barge in

Item	Feature Specification
	4. Supervisor who can monitor the chat but not barge in 5. Supervisor who can monitor the chat but not barge in 6. Supervisor who can monitor the chat but not barge in 7. Supervisor who can monitor the chat but not barge in
Supervisors who can barge in on a chat between an agent and a customer when the Enable Multi-Party Chats and Enhanced Monitoring for Chat capability enabled for an instance	1 Only 1 supervisor can be in barged in mode for a given chat.
Total duration per chat	Up to 7 days, including wait time • The default is 25 hours. You configure the chat duration using StartChatContact API and add the `ChatDurationInMinutes` parameter. • Minimum configurable chat duration is 1 hour (60 minutes). • Maximum configurable chat duration is 7 days (10,080 minutes).
Characters per chat message	1024
Open websocket connections per chat participant	5
Chat Amazon Lex bot integration timeout	10 seconds The maximum time within which the Amazon Lex bot must respond to the chat customer's prompt.

Item	Feature Specification
Past chat transcript file size. This applies to persistent chat.	5MB
Past contacts that can be traversed by Amazon Connect chat. This applies to persistent chat.	100
Communications widgets that can be created and customized per instance	20
File types supported for attachments to cases or chats	.csv, .doc, .docx, .heic, .jfif, .jpeg, .jpg, .mov, .mp4, .pdf, .
Maximum file size for an attachment to a case or a chat	20MB

WhatsApp business messaging feature specifications

The following table ists the specifications for WhatsApp business messaging

Media type	Supported file types	Maximum file size
Image	.jpeg, .jpg, .jfif, .png	5MB
Video	.mp4, .3gp	16MB
Document	.txt, .pdf, .ppt, .pptx, .doc, .docx,	20MB
Audio	.aac, .m4a, .mp3, .amr, .ogg	16MB
Sticker	Not supported	Not supported

Task feature specifications

Item	Feature Specification
Task templates per instance	50

Item	Feature Specification
Task template customized fields per instance	50
Maximum duration of a task	Default is 7 days, extensible up to 30 days
Maximum number of transfers for a task	11 transfers
Maximum number of linked tasks on an existing contact	11

Forecasting, capacity planning, and scheduling feature specifications

Item	Feature Specification
Agents per schedule generation run	800
Agents per staffing group	80
Capacity plans per instance	500
Capacity scenarios per instance	500
Capacity plan user data uploads per instance	500
Capacity plan override uploads per instance	5000
Concurrent uploads per instance	20
File size per upload of agent time off data	1GB
File size per upload of time off group allowance data	1GB The .csv file can cover up to 13 months.
File size per upload of capacity plan user data	1GB
File size per upload of capacity plan overrides	250MB
File size per upload of forecast overrides	250MB

Item	Feature Specification
File size per upload of historical actuals	1GB
Forecast groups per instance	500
Forecast override uploads per instance	500
Historical actuals uploads per instance	50
Queues per forecast group	200
Schedules per instance	600
Shift activities per instance	300
Shift activities per shift profile	10
Shift profiles per instance	1800
Shift rotation steps per pattern	52
Shift rotation weeks per pattern	52
Shift rotations associated with a single shift profile	650
Shift rotations per instance	650
Staffing groups per forecast group	100
Staffing groups per instance	1300
Staffing groups per supervisor/manager	250
Supervisors/managers per staffing group	100

Integration association resource feature specifications

The following table lists feature specifications for the integration association resource. It lists how many of each type of integration association resource can be ingested.

Item	Feature Specification
Attachment scanner	1
Voice ID domain	1
Amazon Pinpoint app	1
Event	10 The event integration resource is used for task triggers.
Amazon Q in Connect assistant	1
Amazon Q in Connect knowledge base	10
Cases domain	1
Amazon Q in Connect knowledge base	10

Amazon Connect Contact Lens feature specifications

Item	Feature Specification
Custom vocabularies	20
Contact Lens rules for post-call	500
Contact Lens rules for post-chat	500
Contact Lens rules for real-time	500

Evaluation forms feature specifications

Item	Feature Specification
Maximum number of evaluation forms per instance Historical versions are not counted, only form names are counted.	50
Maximum number of versions per form	50
Maximum number of sections per form	100
Maximum number of questions per form	100
Maximum nesting level of sections	2 (sections can have sub-sections, but sub-sections cannot have sub-sub-sections)
Definition title length	1-128 characters
Section title length	1-128 characters
Question title length	1-350 characters
Section instructions length	up to 1024 characters
Number of answer options for single select questions	2-256 answer options
Answer option text length for single select questions	1-128 characters

Amazon Connect Rules feature specifications

The following table lists feature specifications for Amazon Connect Rules.

Item	Feature Specification
Conditions in a rule	20
Rules with Natural Language condition	15
Rules for `OnPostCallAnalysisAvailable` event source	500
Rules for `OnRealTimeCallAnalysisAvailable` event source	500
Rules for `OnRealTimeChatAnalysisAvailable` event source	500
Rules for `OnZendeskTicketCreate` event source	500
Rules for `OnZendeskTicketStatus` event source	500
Rules for `OnSalesforceCaseCreate` event source	500
Rules for `OnContactEvaluationSubmit` event source	500
Rules for `OnCaseUpdate` event source	500
Rules for `OnCaseCreate` event source	500
Rules for `OnMetricDataUpdate` event source	100

Condition type	Number of entries or selections	Post-call	Post-chat	Real-time
Evaluation - Form score	20	N/A	N/A	N/A
Evaluation- Section score	20	N/A	N/A	N/A
Evaluation- Question score	20	N/A	N/A	N/A
Evaluation - Results available	20	N/A	N/A	N/A
Words or phrases - Exact match	100	Yes	Yes	Yes
Words or phrases - Semantic match	4	Yes	Yes	Not supported
Words or phrases - Pattern match	100	Yes	Yes	Yes
Natural Language - Semantic match	1	Yes	Yes	No
Queue condition	100	Yes	Yes	Yes
Agent condition	100	Yes	Yes	Yes
Custom attributes	5	Yes	Yes	Yes

Condition type	Number of entries or selections	Post-call	Post-chat	Real-time
Sentiment - Time period	5	Yes	Yes	Yes
Sentiment - Entire contact	5	Yes	Yes	Not supported
Interruptions	5	Yes	Yes	Not supported
Response time	4 hours	Not supported	Yes	Not supported
Non-talk time	5 hours	Yes	Not supported	Not supported

Countries that call centers using Amazon Connect can call by default

The Region where your instance is created determines which countries you can call by default.

For a list of all the countries available for outbound calling, see Amazon Connect pricing.

If you already have an instance, the countries that you are allowed to call may be different that those listed in the following sections because we have changed the service quotas over time.

UK mobile numbers with the following prefix may not be allowed by default:

- +447

If you cannot dial these UK mobile numbers, you must submit a service quota increase request.

Japan mobile numbers with the following prefixes may not be allowed by default:

- +8170, 8180, and 8190

If you can not dial these Japan mobile numbers, you must submit a service quota increase request.

How to allow calling to additional countries

Use the following instructions to allow calling to additional countries, or to limit the countries that you can call from.

1. Choose Account and billing to go to the pre-populated form in the Support console. You must be signed in to your AWS account to access the form.
2. For **Service**, *Connect (Number Management)* should be selected.
3. For **Category**, *Country Allowlisting for Outbound Calls* should be selected.
4. Select the required severity.
5. Choose **Next step: Additional information**
6. On the **Additional information** page:
    a. Enter the subject.
    b. Under **Description**, list which countries you want to allow calling to, or limit calling from.
7. Choose **Next step: Solve now or contact us**.
8. On the **Solve now or contact us** page:
    - Choose the **Contact us** tab and select your **Preferred contact language** and your preferred contact method.
9. Choose **Submit**.
10. The Amazon Connect team will review your ticket and get back to you.

Instances created in US East, US West, Canada (Central) and AWS GovCloud (US-West)

You can call the following countries by default:

- United States
- Canada
- Mexico
- Puerto Rico
- United Kingdom

Instances created in Africa (Cape Town)

You can call the following countries by default:

- South Africa
- United Kingdom
- United States

Instances created in Asia Pacific (Seoul)

You can call the following countries by default:

- South Korea
- United Kingdom
- United States

Instances created in Asia Pacific (Singapore)

You can call the following countries by default:

- Singapore
- Australia
- Hong Kong
- United States
- United Kingdom

Instances created in Asia Pacific (Sydney)

You can call the following countries by default:

- Australia
- New Zealand
- United States

Instances created in Asia Pacific (Tokyo)

You can call the following countries by default:

- Japan
- Vietnam
- United States

Instances created in EU (Frankfurt) and EU (London)

You can call the following countries by default:

- United Kingdom
- Italy
- France
- Ireland
- United States

API throttling quotas

Amazon Connect API throttling quotas

Amazon Connect throttling quotas are by account, and per Region, not by user and not by instance. For example:

- If different users from the same account make requests, they are sharing a throttle bucket.
- If multiple requests are sent from different instances from the same account, they are also sharing a throttle bucket.

When you use the Amazon Connect Service API, all operations have a `RateLimit` of 2 requests per second and a `BurstLimit` of 5 requests per second, **with the following exceptions**:

Operation	Rate limit	Burst limit
For all Evaluations actions	1 request per second	

Operation	Rate limit	Burst limit
*GetMetricData	5	8
*GetMetricDataV2	10	10
*GetCurrentMetricData	5	8
SearchContacts	.5	1
StartContactStreaming	5	8
StartChatContact	5	8
CreatePersistentContactAssociation	5	8
UpdateParticipantRoleConfig	5	8
StopContactStreaming	5	8
CreateParticipant	5	8
GetContactAttributes	10	15
UpdateContactAttributes	10	15
DescribeContact	10	15
StopContact	10	15
UpdateContact	10	15
ListContactReferences	10	15
BatchPutContact	10	15
TagContact	20	25
UntagContact	20	25
UpdateContactRoutingData	20	20

Operation	Rate limit	Burst limit
SendChatIntegrationEvent	17	26
SendIntegrationEvent	10	15
CreateIntegrationAssociation, DeleteIntegrationAssociation, ListIntegrationAssociations	2 1 for the SES_IDENTITY IntegrationType field	5

Important

*`GetCurrentMetricData`, `GetMetricDataV2`, and `GetCurrentUserData` may incorrectly display 200 as their throttling quota in the Service Quotas console. We recommend using the default quotas specified here, or opening a ticket.

Amazon Connect Cases API throttling quotas

API	Default TPS throttling limits
CreateCase, SearchCases, UpdateCase, AssociateContact, ListTemplates, CreateRelatedItem, SearchRelatedItems	10
CreateField, ListFields, CreateDomain, GetDomain,CreateTemplate, BatchPutFieldOptions, CreateLayout, UpdateLayout, UpdateTemplate, UpdateField	5
BatchGetField	25
GetCase	15
GetTemplate, GetLayout	20
ListFieldOptions	15

Amazon Connect Contact Lens Service API throttling quotas

Amazon Connect Contact Lens throttling quotas are by account, not by user and not by instance. For example:

- If different users from the same account make requests, they are sharing a throttle bucket.
- If multiple requests are sent from different instances from the same account, they are also sharing a throttle bucket.

When you use the Amazon Connect Contact Lens API, the number of requests per second is limited to the following:

- ListRealtimeContactAnalysisSegments: a `RateLimit` of 1 request per second, and a `BurstLimit` of 2 requests per second.
- ListRealtimeContactAnalysisSegmentsV2: a `RateLimit` of 2 request per second, and a `BurstLimit` of 5 requests per second.

Amazon Connect Customer Profiles API throttling quotas

API	Default TPS throttling limits

GetWorkflow	5
GetWorkflowSteps	5
SearchProfiles	100
ListProfileObjects	100
GetMatches	100
GetSimilarProfiles	100
ListRuleBasedMatches	5
GetCalculatedAttributeForProfile	100
ListCalculatedAttributesForProfile	100
CreateProfile	100
UpdateProfile	100
PutProfileObject	100
AddProfileKey	100
DeleteProfile	100
DeleteProfileObject	100
DeleteProfileKey	100
MergeProfiles	100
TagResource	5
UntagResource	5

API	Default TPS throttling limits
ListTagsForResource	5
ListAccountIntegrations	100

Amazon Connect Outbound Campaigns Service API throttling quotas

Outbound campaigns throttling quotas are by account, and per Region, not by user and not by instance. For example:

- If different users from the same account make requests, they share a throttle bucket.
- If multiple requests are sent from different instances from the same account, they also share a throttle bucket.

When you use the Amazon Connect Outbound Campaigns Service API, the number of requests per second is limited to the following:

- The following APIs have a `RateLimit` of 1 request per second, and a `BurstLimit` of 2 requests per second:
  - CreateCampaign
  - DeleteCampaign
  - PauseCampaign
  - ResumeCampaign
  - StartCampaign
  - StopCampaign
  - UpdateCampaignDialerConfig
  - UpdateCampaignName
  - UpdateCampaignOutboundCallConfig
  - ListTagsForResource
  - TagResource
  - UntagResource
- The following APIs have a `RateLimit` of 5 requests per second, and a `BurstLimit` of 10 requests per second:

  - GetCampaignState
  - GetCampaignStateBatch
  - ListCampaigns
- The following APIs have a RateLimit of 10 requests per second, and a BurstLimit of 10 requests per second:
  - PutDialRequestBatch
  - PutOutboundRequestBatch
  - PutProfileOutboundRequestBatch
- For PutDialRequestBatch API, the throttling quota is 10 request per second.
- For DescribeCampaign API, a `RateLimit` of 25 requests per second, and a `BurstLimit` of 35 requests per second.
- For all other operations, a `RateLimit` of 2 requests per second, and a `BurstLimit` of 5 requests per second.

Amazon Connect Participant Service API throttling quotas

For the Amazon Connect Participant Service, the quotas are by instance.

When you use the Amazon Connect Participant Service API, the number of requests per second is limited to the following:

- CompleteAttachmentUpload: a `RateLimit` of 2 requests per second, and a `BurstLimit` of 5 requests per second.
- CreateParticipantConnection: a `RateLimit` of 6 requests per second, and a `BurstLimit` of 9 requests per second.
- DisconnectParticipant: a `RateLimit` of 3 requests per second, and a `BurstLimit` of 5 requests per second.
- GetAttachment: a `RateLimit` of 8 requests per second, and a `BurstLimit` of 12 requests per second.
- GetTranscript: a `RateLimit` of 8 requests per second, and a `BurstLimit` of 12 requests per second.
- SendEvent and SendMessage: a `RateLimit` of 10 requests per second, and a `BurstLimit` of 15 requests per second.

- [StartAttachmentUpload](): a `RateLimit` of 2 requests per second, and a `BurstLimit` of 5 requests per second.

Amazon Connect Voice ID Service API throttling quotas

API	Default TPS throttling limits
EvaluateSession	60

Get started with Amazon Connect

> **Tip**
>
> For an online workshop that leverages a case study and includes hands-on labs, see Introduction to Amazon Connect by AWS Workshop Studio.

Use these steps to set up your contact center.

1. Create an Amazon Connect instance. Use an instance to contain all the resources and settings related to your contact center. You specify how you plan to manage user accounts, whether your contact center will accept incoming calls and make outbound calls, and review the location where data will be stored in your Amazon S3 bucket.
2. Set up contact center phone numbers for your Amazon Connect instance. If you're using voice, either claim a phone number that AWS provides, or port your current phone number to Amazon Connect. If you choose to port your numbers, we suggest claiming a number so you can test Amazon Connect and build your contact center while waiting for your numbers to be ported over.
3. Set up routing in Amazon Connect. Create your queues and routing profiles, and set your hours of operation. In your routing profiles, specify the channels that agents should use: voice, chat, tasks, or all three. You also specify how many chats and tasks an agent can manage at the same time.
4. Flows in Amazon Connect. Establish a flow to define the customer experience with your contact center from start to finish. A single flow works for voice, chat, and tasks, which makes your design more efficient. When you build flows and configure the blocks, indicate how the flow should work for voice, chat, and tasks.
5. Add users, which are your managers and agents, and configure their settings. Assign a routing profile to each agent, specify whether they are using a softphone or desk phone, and set how long they have for **After contact work**. For instructions, see Add users to Amazon Connect and Set up your contact center agents in Amazon Connect.
6. If you're using chat, we provide several tools to help you enable your customer-facing app to engage with Amazon Connect chat. For more information, see Set up your customer's chat experience in Amazon Connect.

Next steps

There's a lot you can do to optimize your contact center. Here are a couple of additional steps that you may find useful:

1. Set up recording behavior using Amazon Connect Contact Lens. Monitor live conversations and review past conversations. This is a way that managers can coach agents and help them improve. For voice conversations, set up recording in your flows. For chat conversations, set up recording at the instance level.

   To learn how to monitor conversations, see Set up live monitoring for voice, chat, or both in Amazon Connect.
2. Create conversational AI bots in Amazon Connect. Use Amazon Lex in your contact center to reduce the load on your agents. For example, a bot can handle the initial interaction before the chat is routed to an agent, and also answer common questions for the customer.

- Amazon Connect: Implementing Tasks in Amazon Connect

Tutorials: An introduction to Amazon Connect

The tutorials in this section are provided to help you start using Amazon Connect. They show you how to set up your first instance, and test a sample voice and chat experience. Next, they show you how to set up an IT Help Desk contact center that uses the features in Amazon Lex.

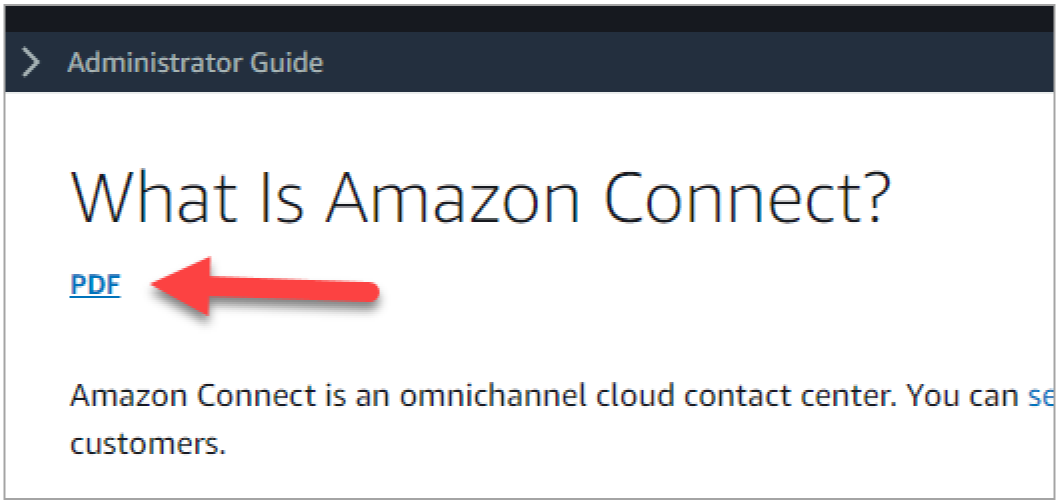
These tutorials are suitable for both knowledge workers and developers.

Prerequisite

- An AWS account. If you don't already have one, create an account at: aws.amazon.com.

Print the tutorials

If you want to print the tutorials, choose the PDF icon at the top of any page, as shown in the following image.



A PDF version of the documentation opens. Press **Ctrl+Home** to return to the beginning of the PDF, then scroll down to the table of contents. Choose which pages to print.

Contents

Set up your Amazon Connect instance

You can have multiple instances of Amazon Connect. Each instance contains all the resources related to your contact center, such as phone numbers, agent accounts, and queues.

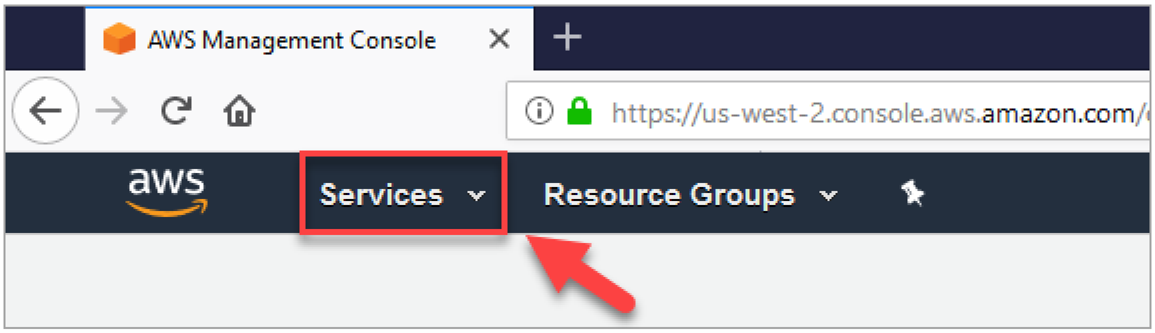
In this tutorial, you open Amazon Connect, create an instance of Amazon Connect, and claim a phone number that you can use for testing.

Contents

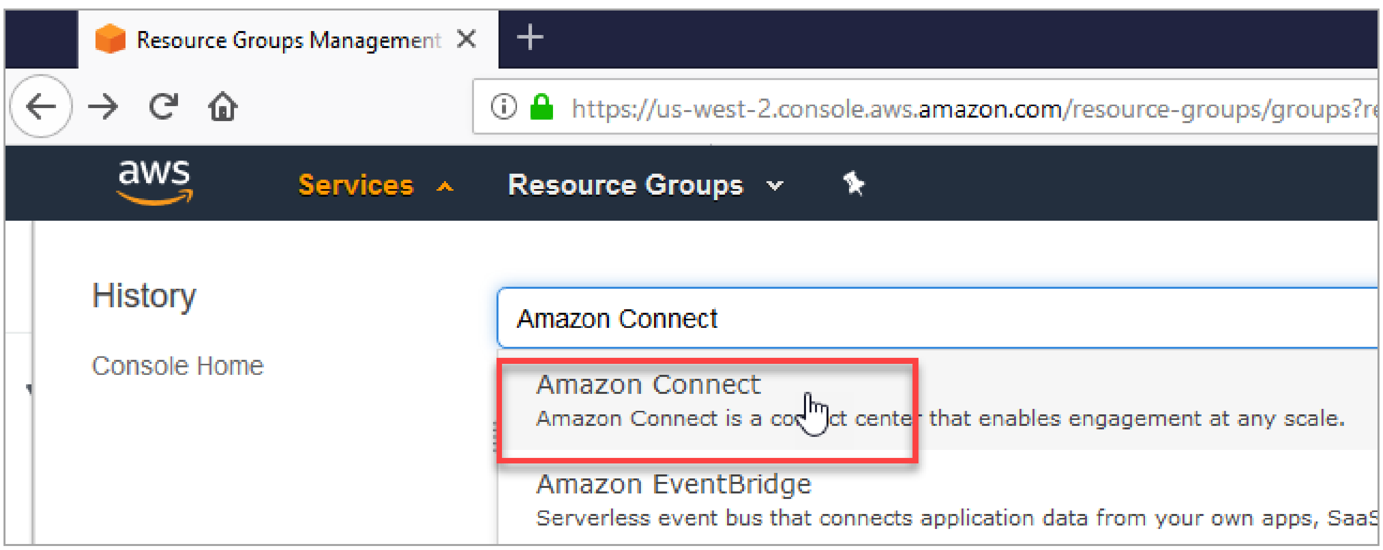
Step 1: Launch Amazon Connect

This step walks you through finding Amazon Connect in the AWS console, and opening the Amazon Connect console.

1. Log in to the AWS Management Console (https://console.aws.amazon.com/console) using your AWS account.
2. In the AWS Management Console, at the top of the page, choose the **Services** drop-down menu.

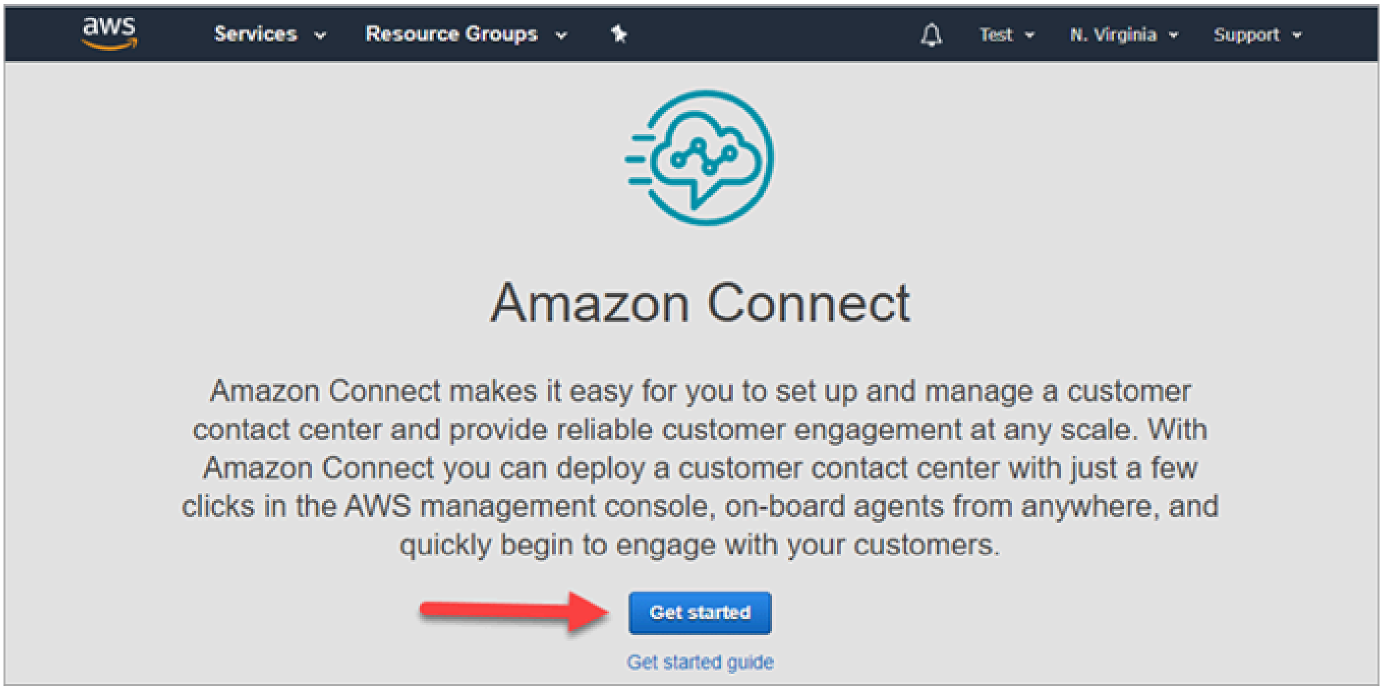
   


3. In the search box, type **Amazon Connect**.

4. Choose **Amazon Connect**.

   If this is the first time you've been to the Amazon Connect console, you'll see the following Welcome page.



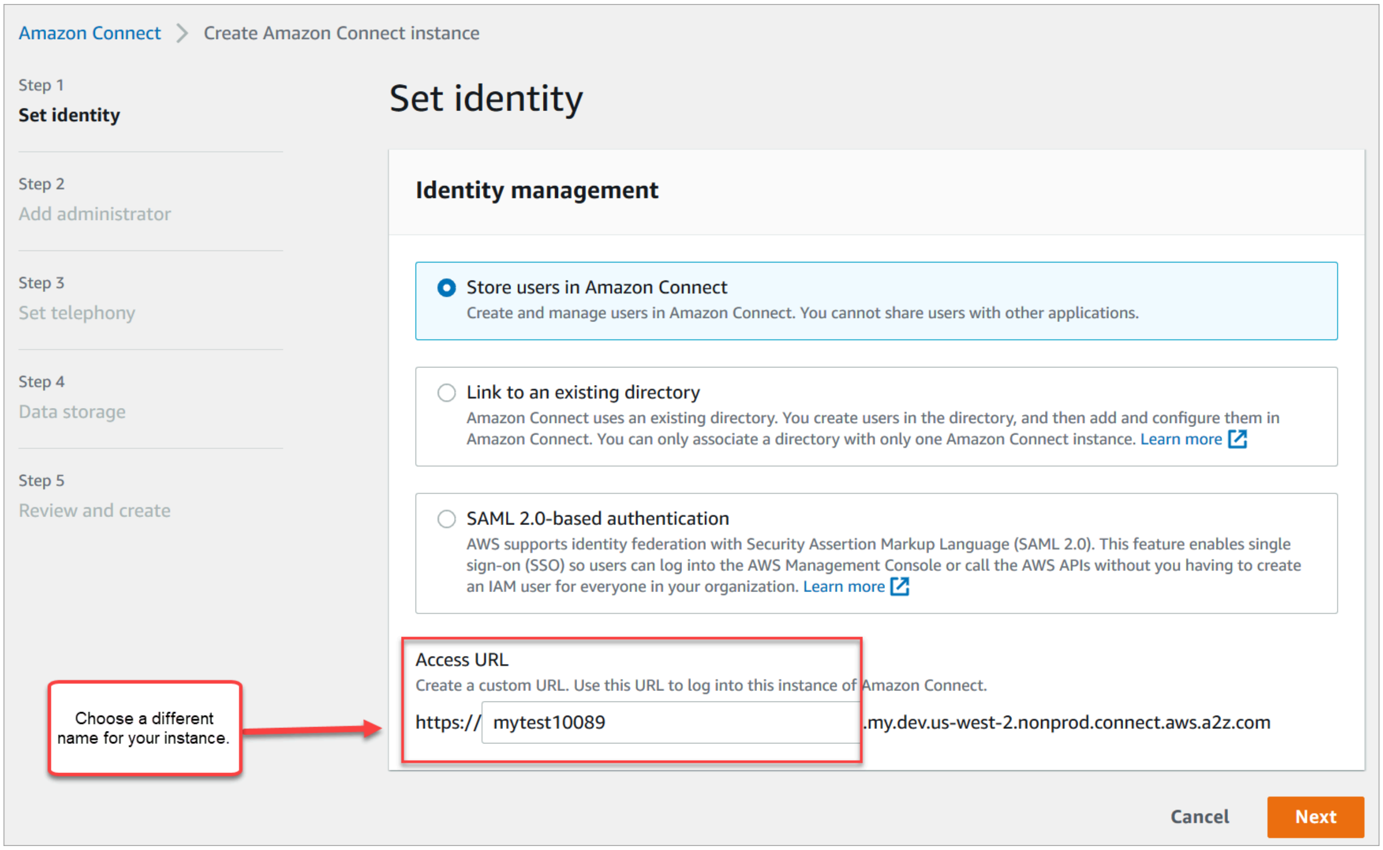
5. Choose **Get started**.

Congratulations! You found and accessed Amazon Connect. You can use these same steps to search for and launch any AWS service.

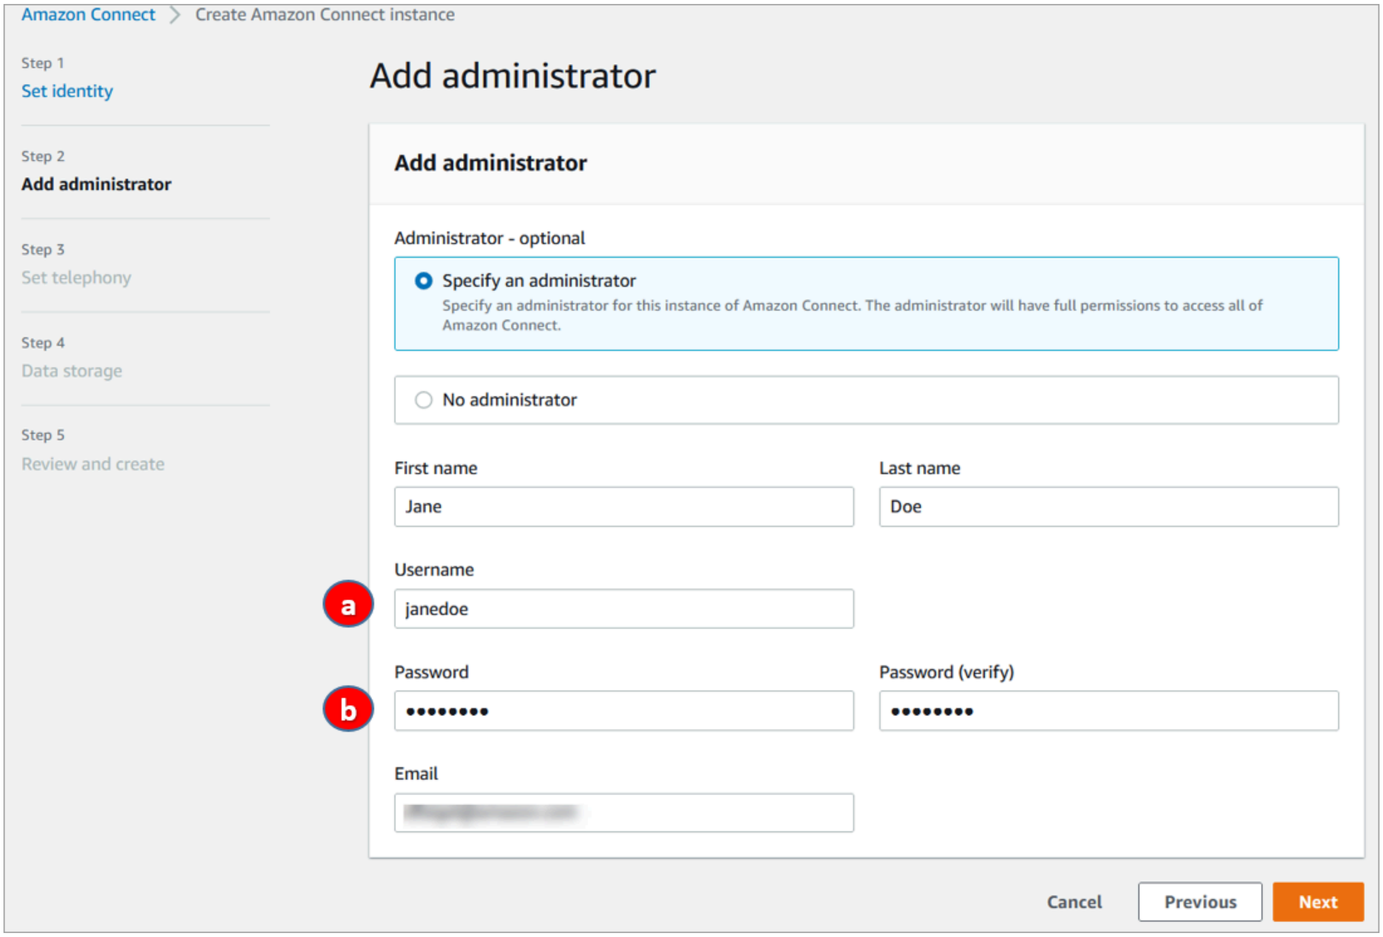
Go to Step 2: Create an instance.

Step 2: Create an instance

1. On the **Amazon Connect virtual contact center instances** page, choose **Add an instance**.
2. On the **Set identity** page, in the **Access URL** box, type a unique name for your instance. For example, the following image shows **mytest10089** as a name. Choose a different name for your instance. Then choose **Next**.



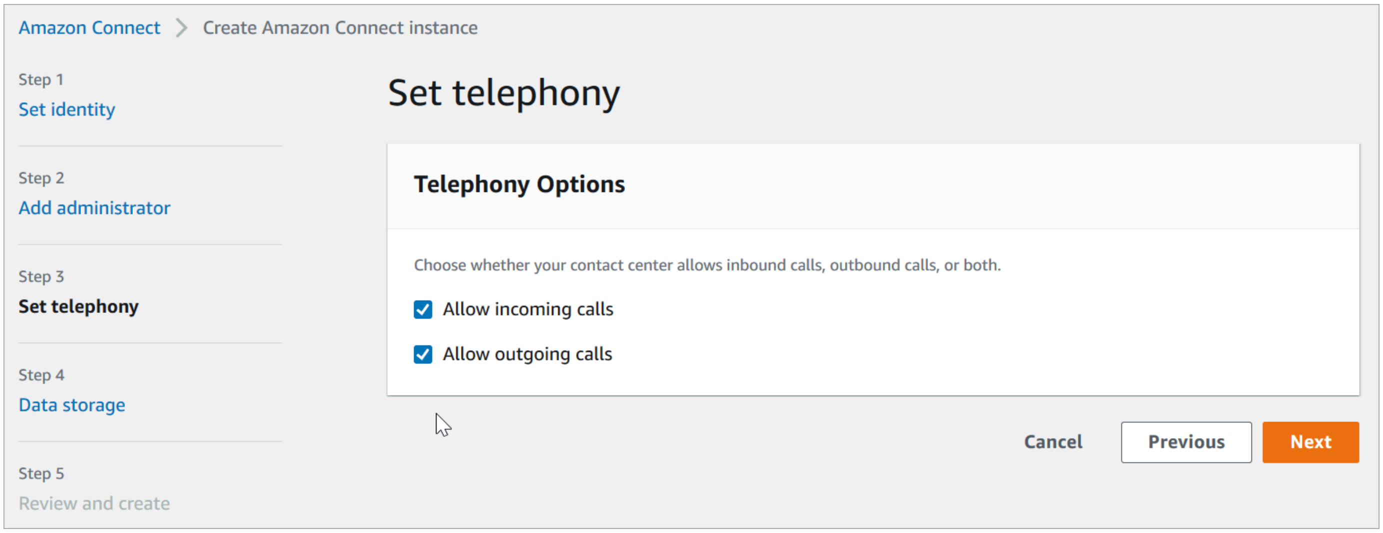
3. On the **Add administrator** page, add a new administrator account for Amazon Connect. Use this account to log in to your instance later using the unique access URL. Choose **Next**.



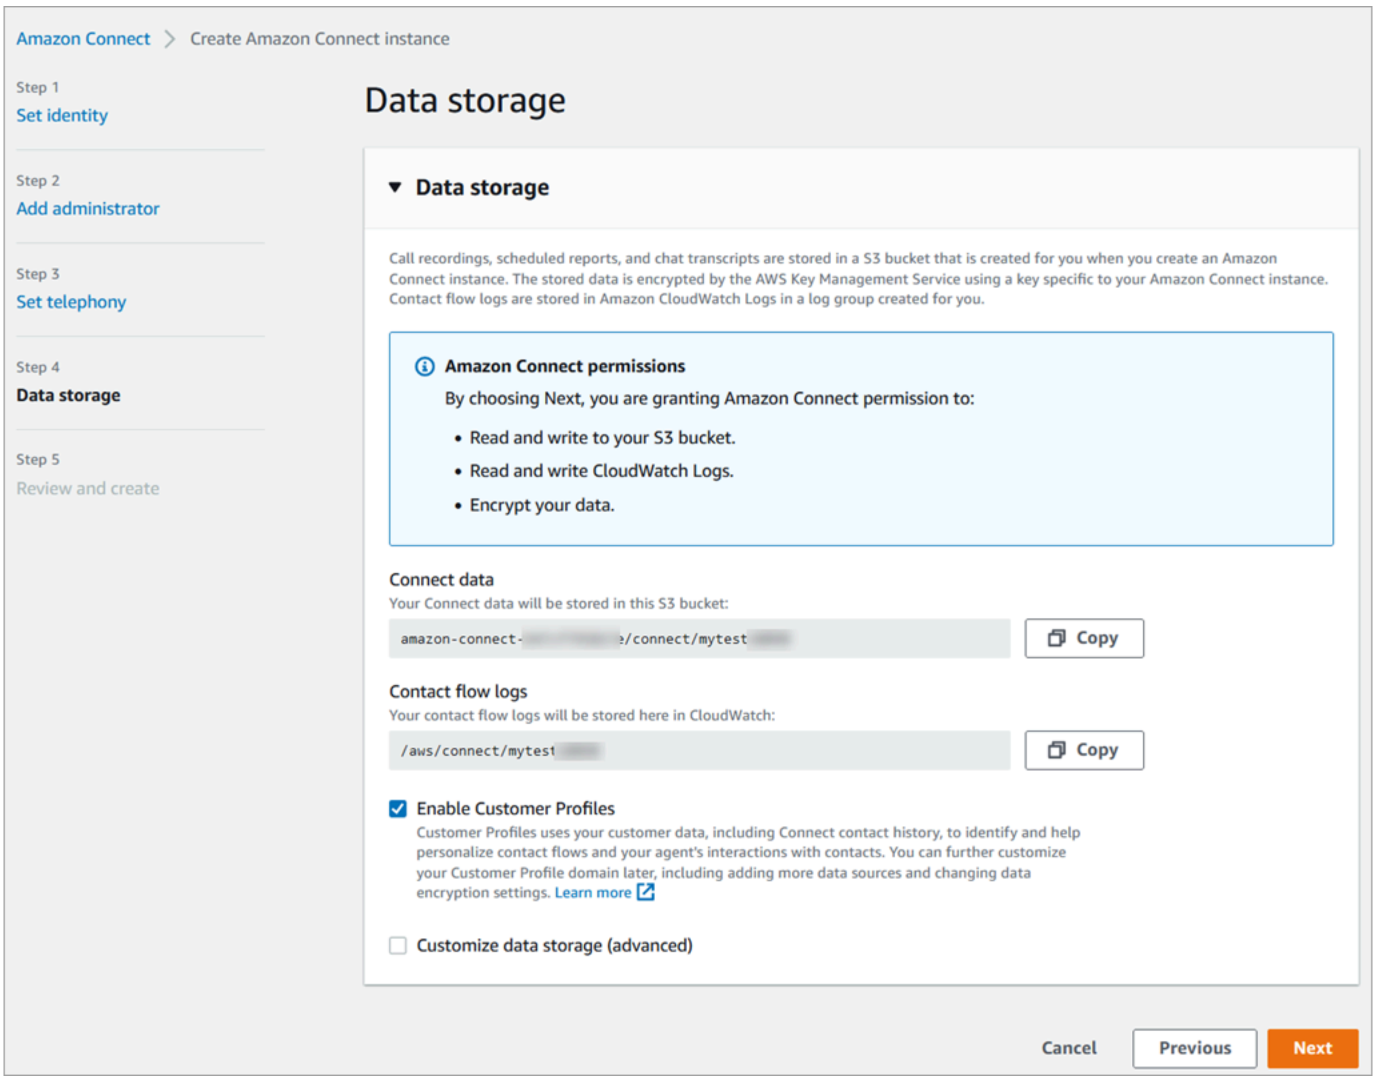
a. The user name will be your Amazon Connect login. It's case sensitive.

b. The password must be between 8-64 characters, and must contain at least one uppercase letter, one lowercase letter, and one number.

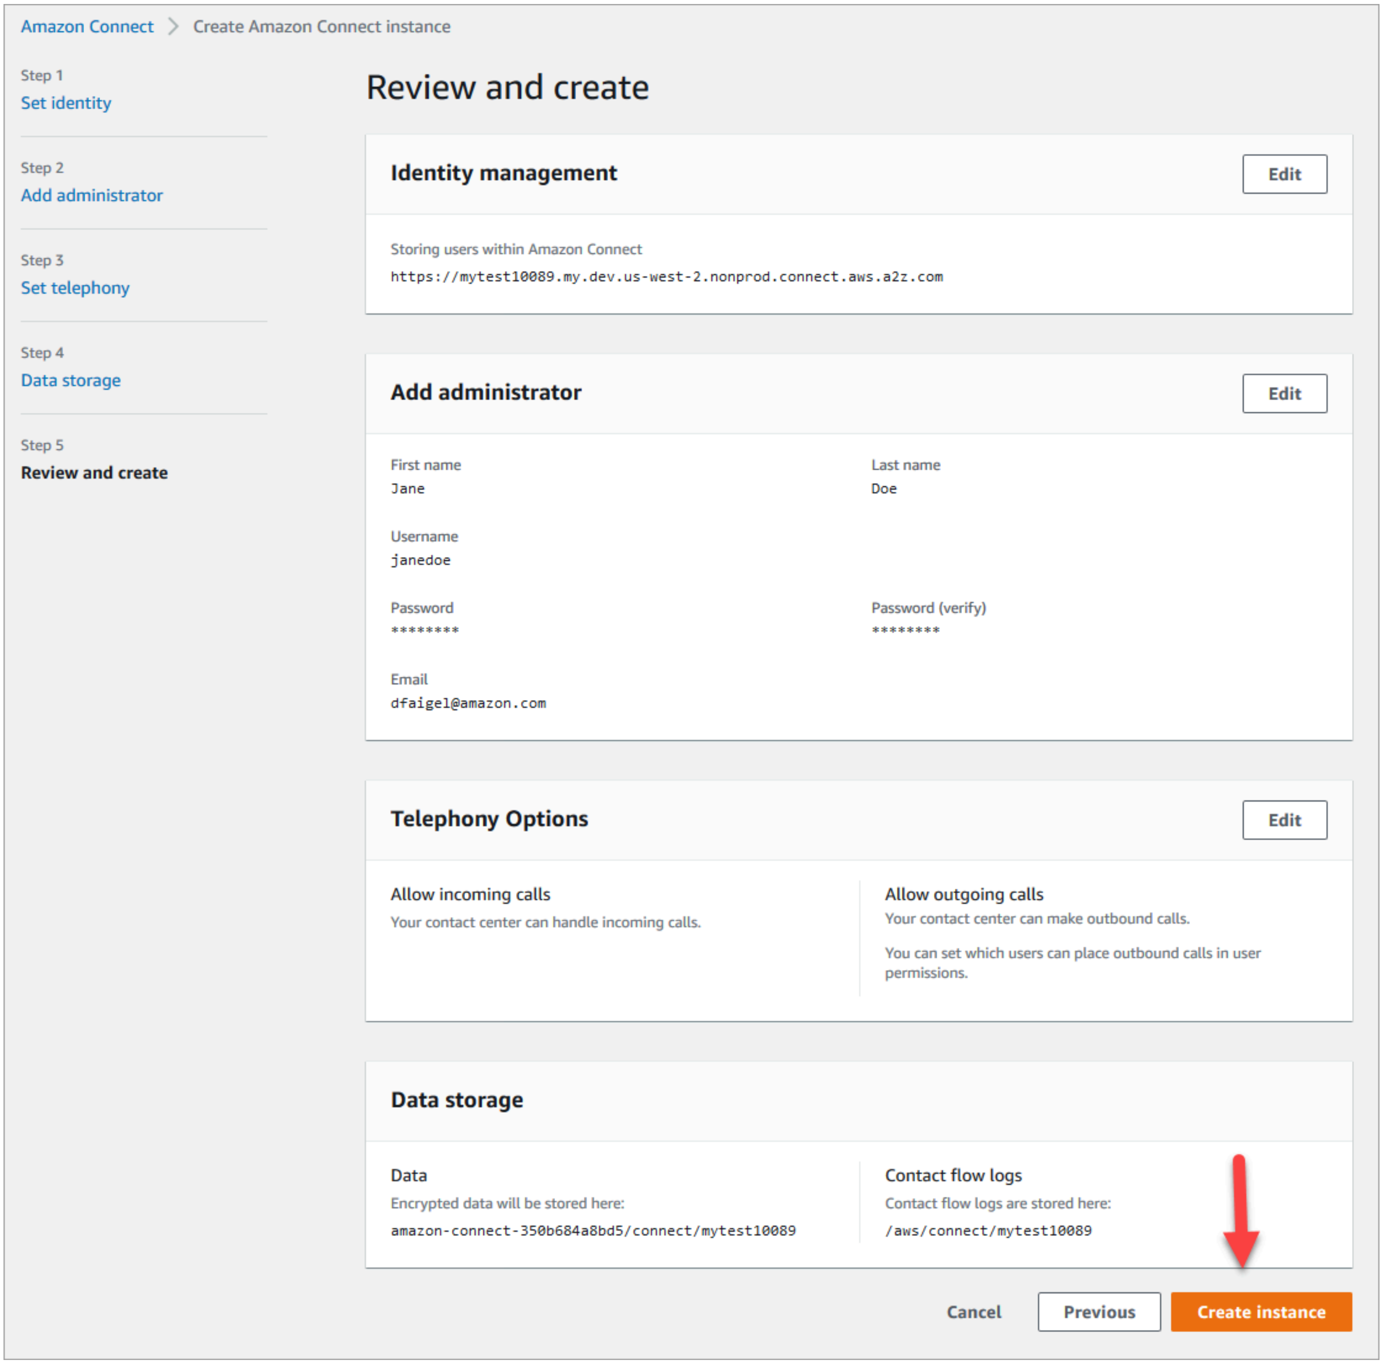
4. On the **Set telephony** page, accept the default settings to allow incoming and outgoing calls. Choose **Next**.



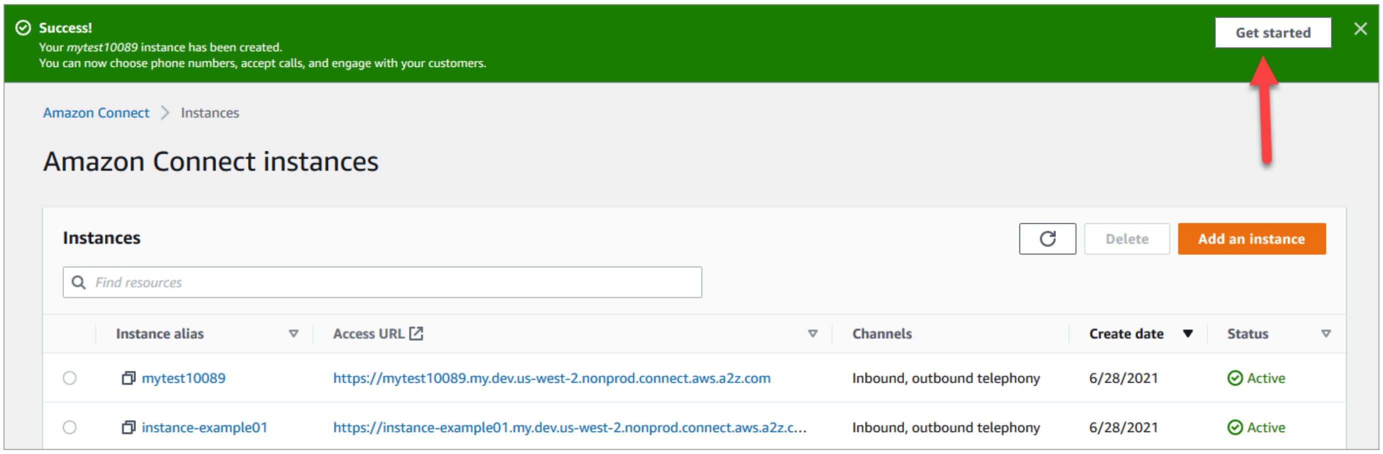
5. On the **Data storage** page, accept the default settings and choose **Next**.



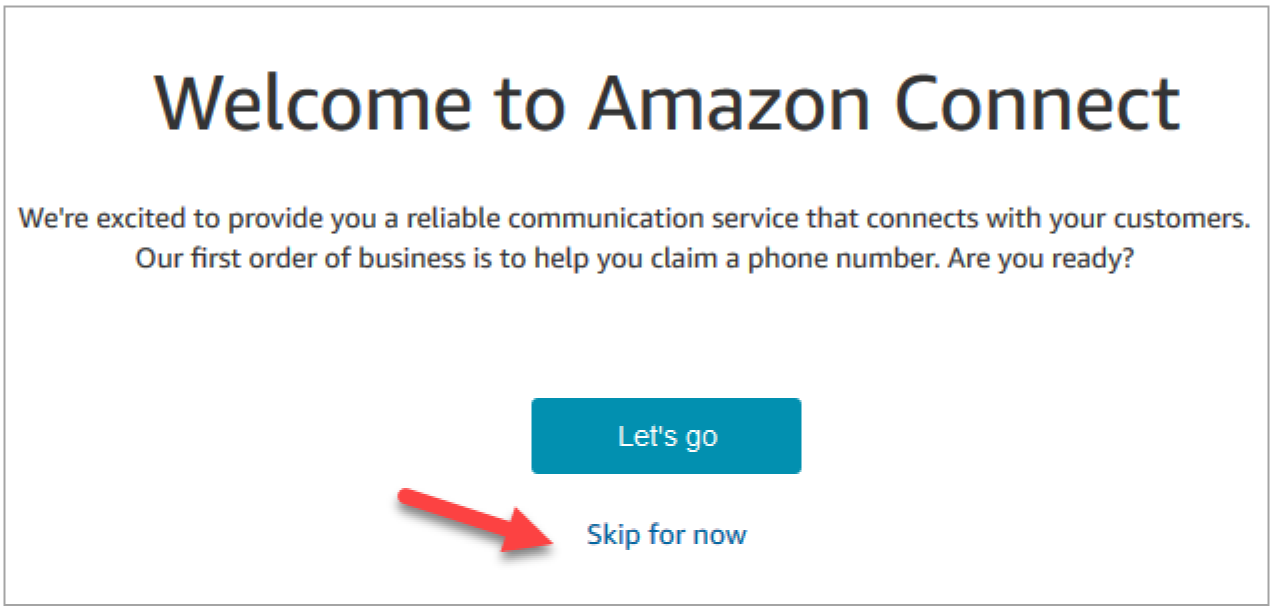
6. On the **Review and create** page, choose **Create instance**.



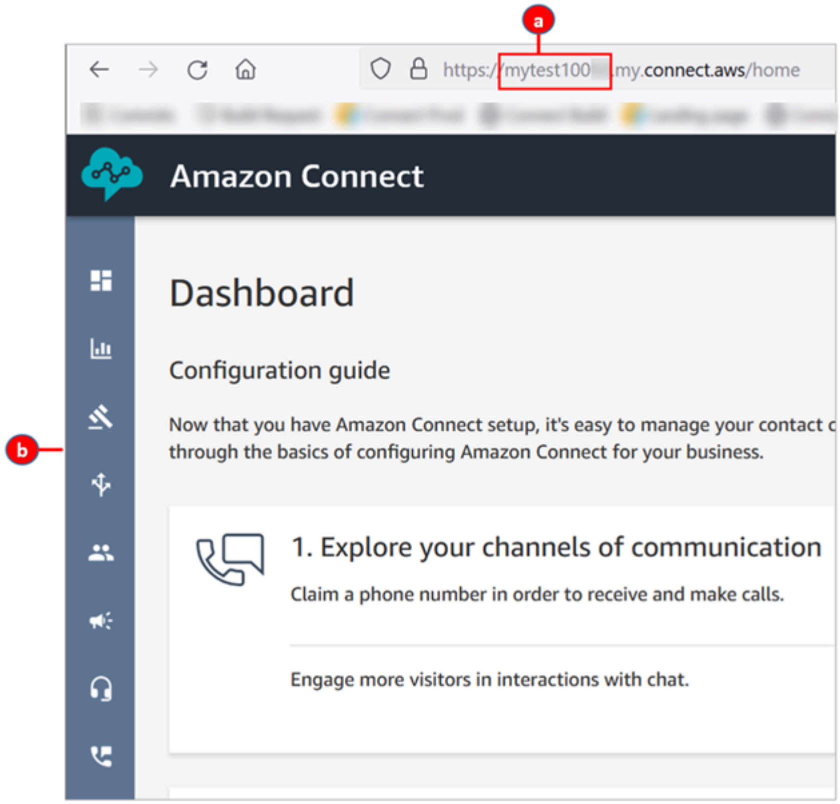
7. After the instance is created, choose **Get started**.



8. On the **Welcome to Amazon Connect** page, choose **Skip for now**.



9. You're now on the Amazon Connect dashboard. Your instance name (also called an **alias**) displays in the URL. On the left is the navigation menu.



a. Your instance alias is located in the first part of the URL.

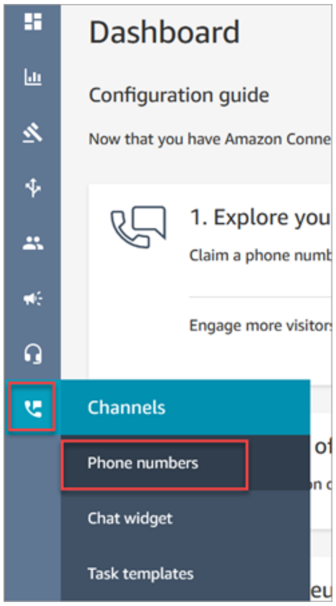
b. The navigation menu.

Congratulations! You set up your instance and now you're on the Amazon Connect dashboard. Go to Step 3: Claim a phone number for your instance.

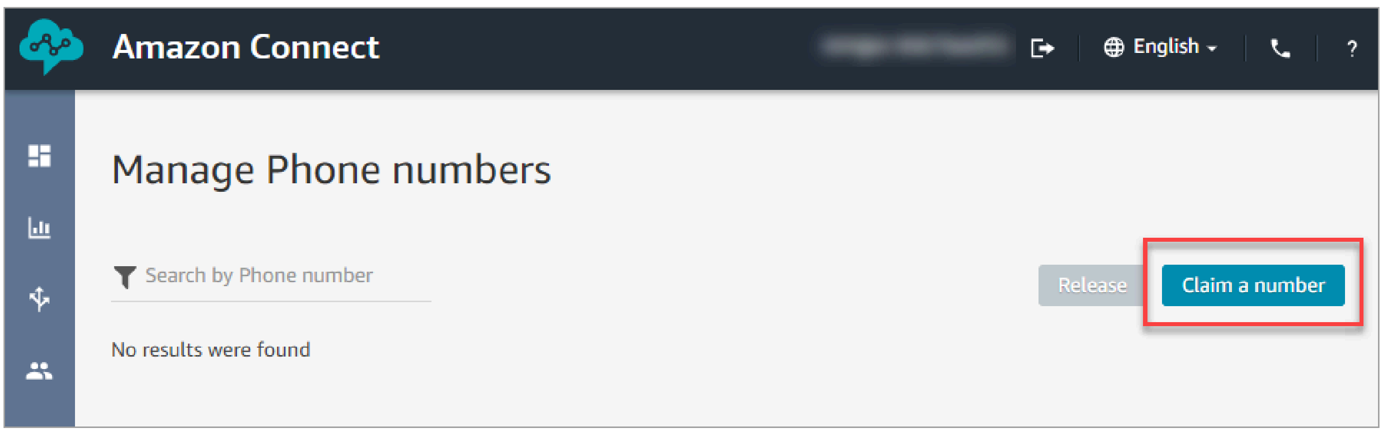
Step 3: Claim a phone number for your instance

In this step, you set up a phone number so that you can experiment with Amazon Connect.

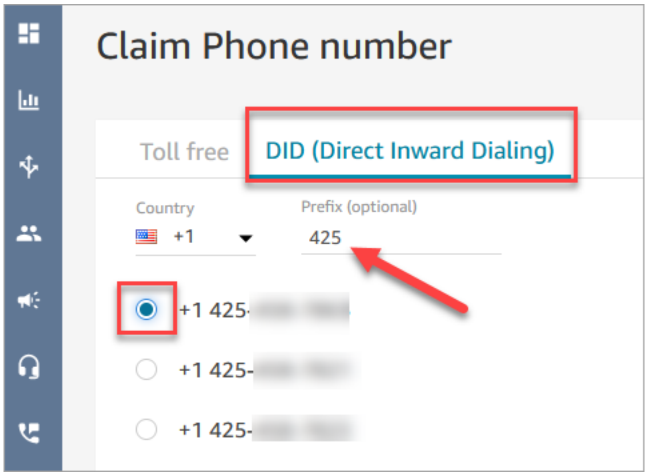
1. On the Amazon Connect navigation menu, choose **Channels**, **Phone numbers**.



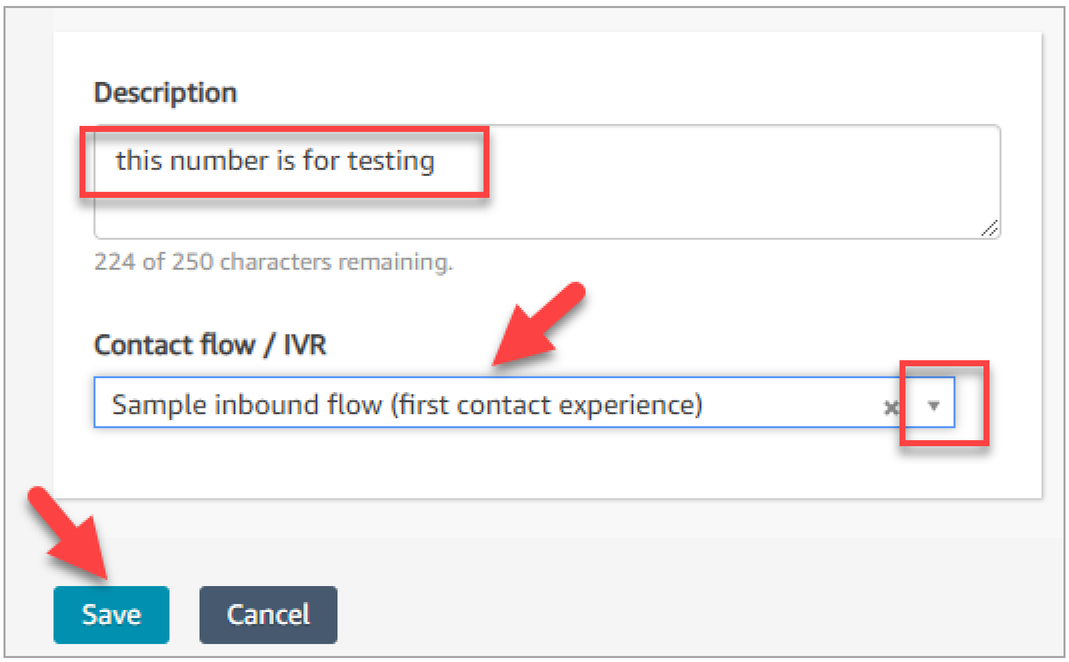
2. On the right side of the **Manage Phone numbers** page, choose **Claim a number**.



3. Select the **DID (Direct Inward Dialing)** tab. Use the drop-down arrow to choose your country/region. If you're in the US, you can specify the area code you want for your number, and only available numbers with that area code will be displayed. When numbers are returned, choose one.



4. Write down the phone number. You call it later in this tutorial.
5. In the **Description** box, type this note: **this number is for testing**.



6. In the **Flow / IVR** box, choose the drop-down arrow, and then choose **Sample inbound flow (first contact experience)**.
7. Choose **Save**.

Congratulations! You set up your instance and claimed a phone number. Now you're ready to experience how chat and voice work in Amazon Connect. Go to [Test the sample voice and chat experience in Amazon Connect](#).

Test the sample voice and chat experience in Amazon Connect

To better understand what the voice and chat experiences are like for your agents and customers, you can test them without doing any development.

This tutorial shows you how to access and use the Contact Control Panel (CCP). The CCP is a web page that agents use to accept and manage voice and chat contacts.

Prerequisites

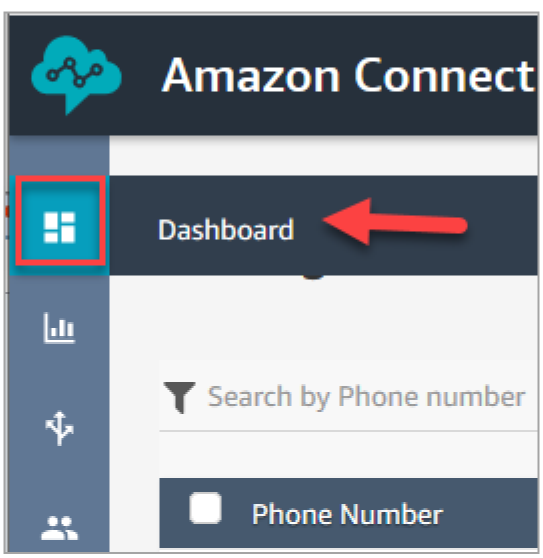
This tutorial is part of a series. If you performed Tutorial 1, you're ready to go. If not, here's what you need:

- An AWS account
- A configured Amazon Connect instance
- An Amazon Connect administrative account
- A claimed phone number

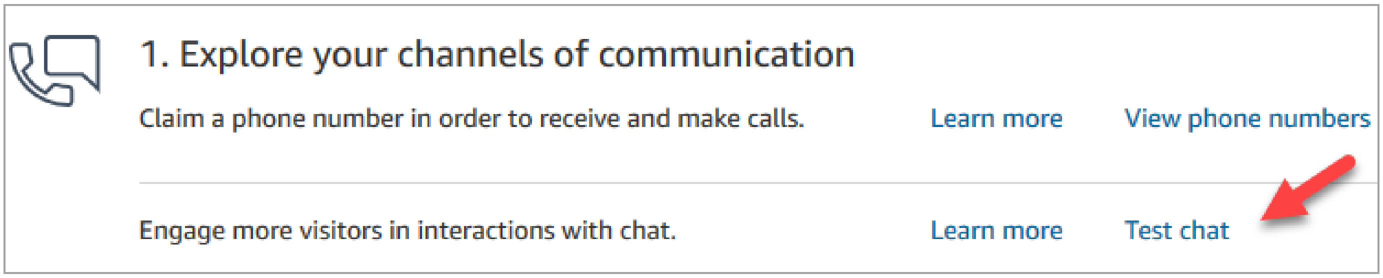
Contents

Step 1: Handle a voice contact

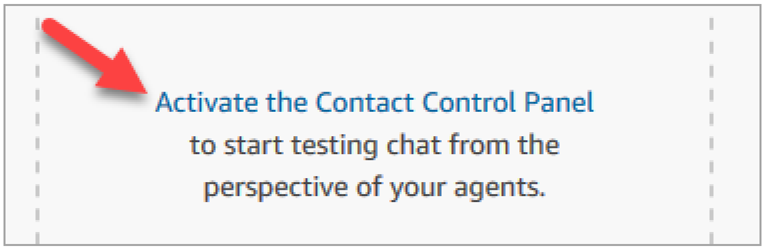
1. On the Amazon Connect navigation menu, choose **Dashboard**.



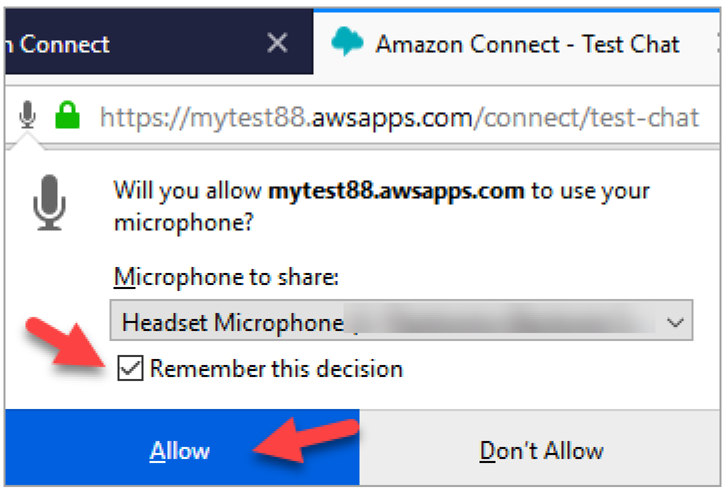
2. On the **Dashboard** page, choose **Test chat**.



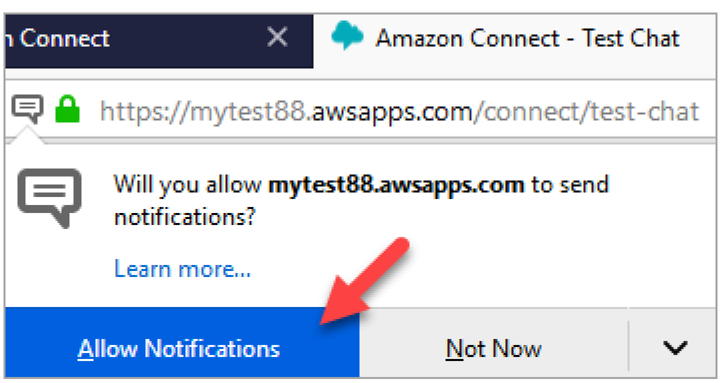
3. On the **Test Chat** page, choose **Activate Contact Control Panel**.



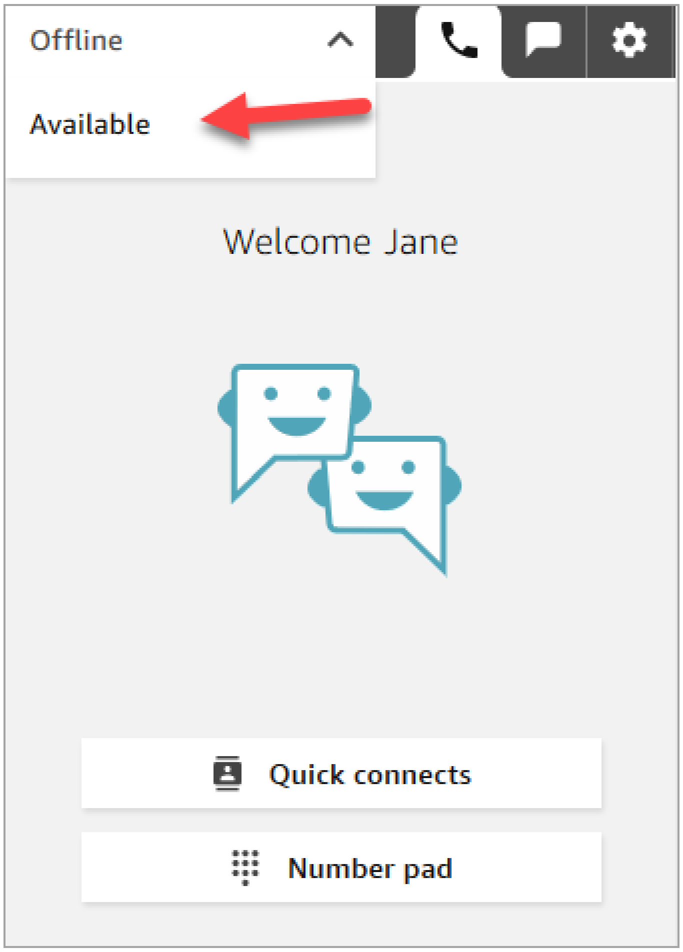
4. If your browser prompts you to grant microphone access, choose **Allow**.



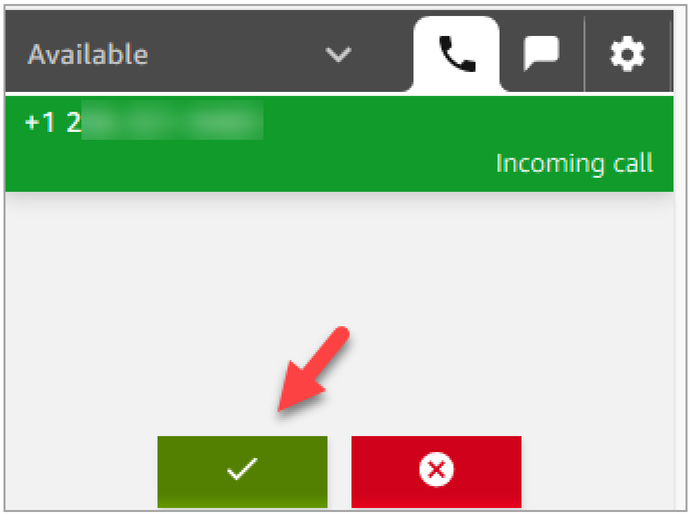
5. If your browser prompts you to allow notifications, choose **Allow**.



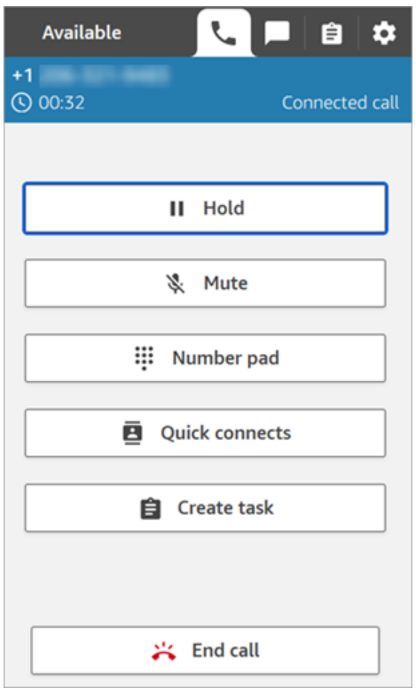
6. In the test CCP, set your status to **Available**.



7. Use your mobile phone to call the phone number that you claimed earlier. If you didn't write down the number, you can find it by going to **Channels**, **Phone numbers**.
8. When your call is joined to Amazon Connect you'll hear "Press 1 to be put in queue for an agent, 2 to ..." This is the Sample inbound flow that Amazon Connect runs by default. You're going to change this later in the tutorial.
9. You can play around with the different options in the Sample inbound flow. To connect to an agent, press **1**, **1**, **1**.
10. In the CCP, choose **Accept call**.



11. You'll see what the CCP looks like when an agent is connected to a customer.



12. Choose **End call**.

    Now the contact is in the After Contact Work (ACW) state. This is when the agent might enter some notes about the contact.

13. Choose **Close contact**. This frees the agent to take another incoming contact.

Well done! You've handled your first voice contact!

> **Tip**
>
> As an administrator, you can launch the CCP from anywhere on the Amazon Connect console by choosing the phone icon on the top of the page.
>
> >

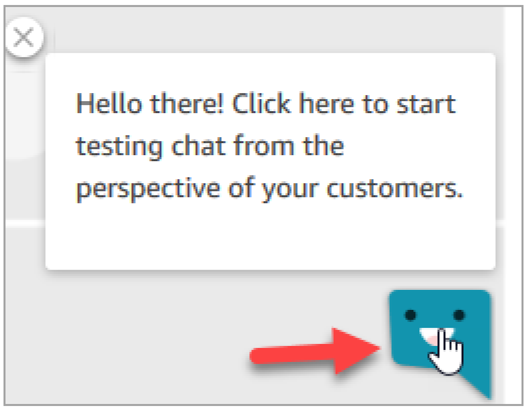
Next step

Go to Step 2: Use the CCP to handle a chat contact to experience how to handle a chat contact.

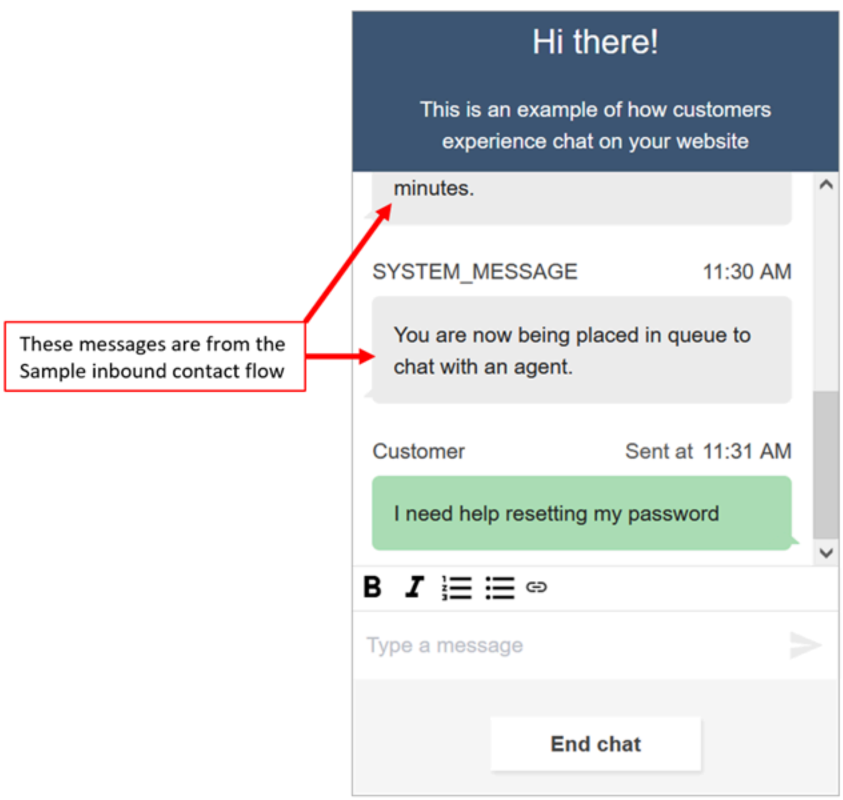
Step 2: Use the CCP to handle a chat contact

In Step 1, you used the Contact Control Panel (CCP) to manage a voice contact. In this step, you experience how to use the CCP to manage a chat contact.

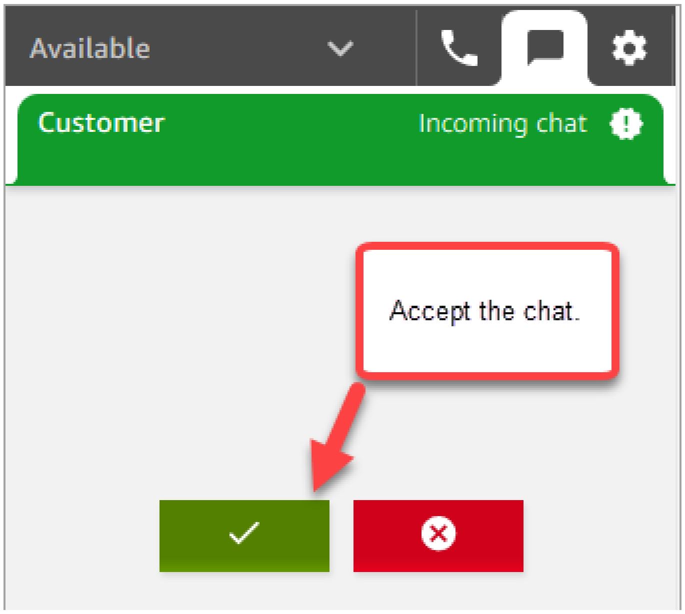
1. This procedure assumes you've completed [Step 1: Handle a voice contact](). If you haven't, please do so now.
2. On the **Test chat** page, choose the chat bubble to start a chat.



3. The Sample inbound flow automatically transfers to you a queue. However, you can type a message as the customer and the agent receives it. For example, *I need help resetting my password*.



4. In the CCP, accept the incoming chat.



5. Use the CCP to send chat messages to the customer.
6. When you're done chatting, choose **End chat**. Then in the CCP, choose **Close contact**.

Congratulations! You've experienced what it's like to chat using Amazon Connect.

Next, try Tutorial 3 to set up an IT Help Desk. It shows you how to set up routing, create a flow, and then test the custom voice and chat experience. Go to Create an IT help desk in Amazon Connect.

Create an IT help desk in Amazon Connect

This tutorial shows you how to create an IT Help Desk. It shows how to create an Amazon Lex bot that finds out why the customer is calling. You next create a flow to use the customer's input to route them to the right queue.

Prerequisite

This tutorial is part of a series. If you performed Tutorial 1, you're ready to go. If not, here's what you need:

- An AWS account
- A configured Amazon Connect instance
- An Amazon Connect administrative account
- A claimed phone number

Contents

Step 1: Create an Amazon Lex bot

Bots provide an efficient way to offload repetitive tasks from your agents. This tutorial shows how to use the bot to find out why customers are calling the IT Help Desk. Later, we use the customer's response to route them to the right queue.

In previous tutorials, you used the Amazon Connect console. In this tutorial to set up a bot, you use the Amazon Lex console.

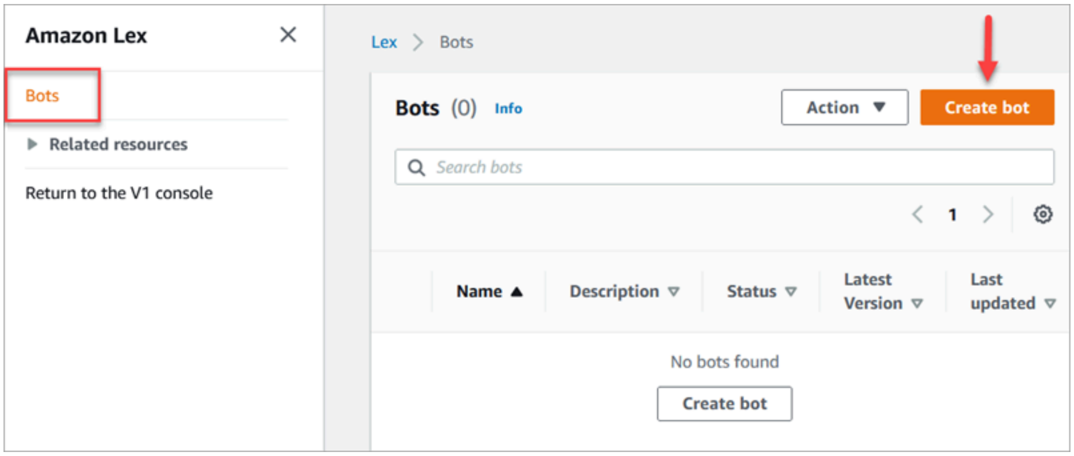
This step has five parts to it.

Contents

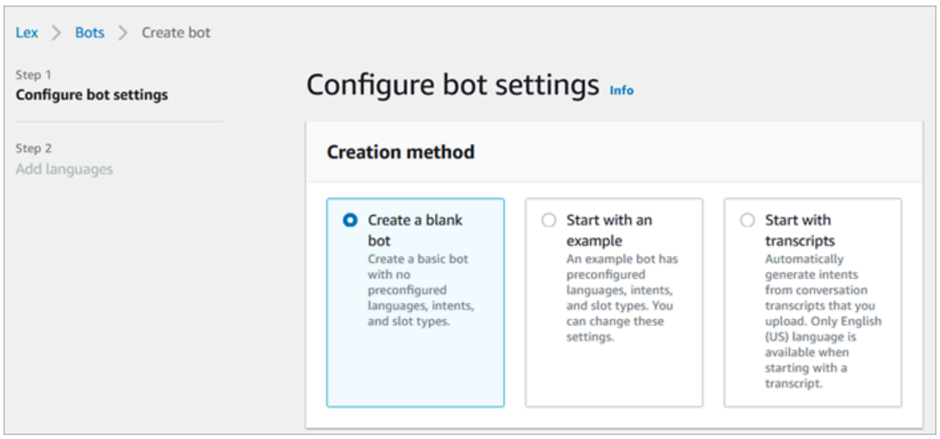
Part 1: Create an Amazon Lex bot

This step assumes it's the first time you've opened the Amazon Lex console. If you've created a Amazon Lex bot before, your steps differ slightly from the ones in this section.

1. Choose the following link to open the Amazon Lex console, or enter the URL in your web browser: **https://console.aws.amazon.com/lex/**.
2. If this is the first time you've created Amazon Lex bot, choose **Get Started**. Otherwise, you're already in the Amazon Lex dashboard.



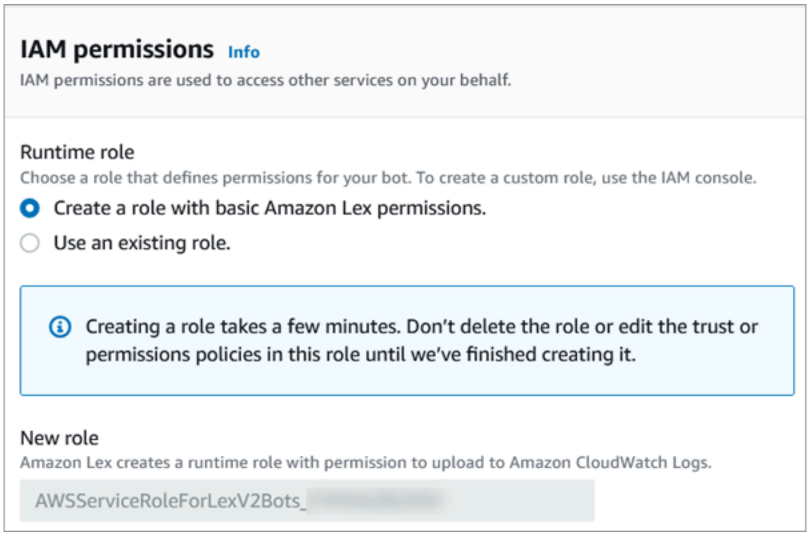
3. Choose **Create a blank bot**.



4. Enter the following information:

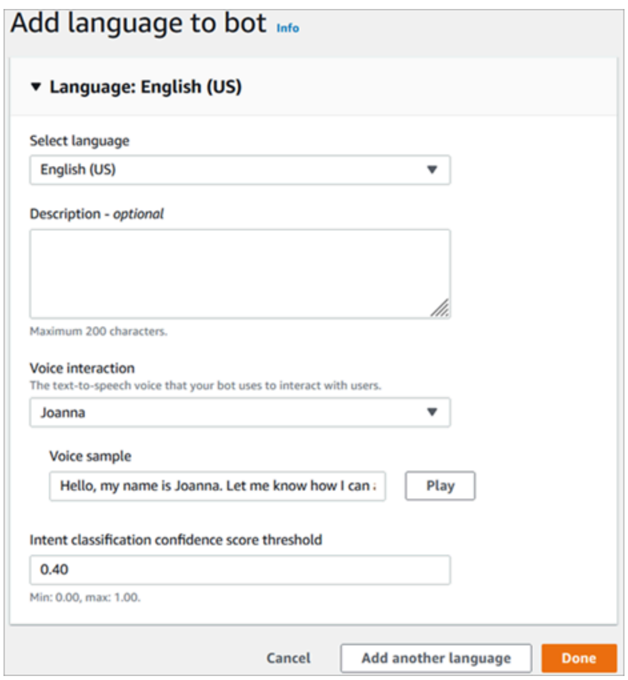
   - **Bot name** — For this tutorial, name the bot **HelpDesk**.

   - IAM permissions: Choose **Create a role with basic Amazon Lex permissions**.



- **COPPA**— Choose whether the bot is subject to the [Children's Online Privacy Protection Act](https://).
- **Idle session timeout**— Choose how long the bot should wait to get input from a caller before ending the session.

5. Choose **Next**.
6. On the **Add language to bot** page, choose the language and voice for your bot to use when speaking to callers. The default voice for Amazon Connect is Joanna.



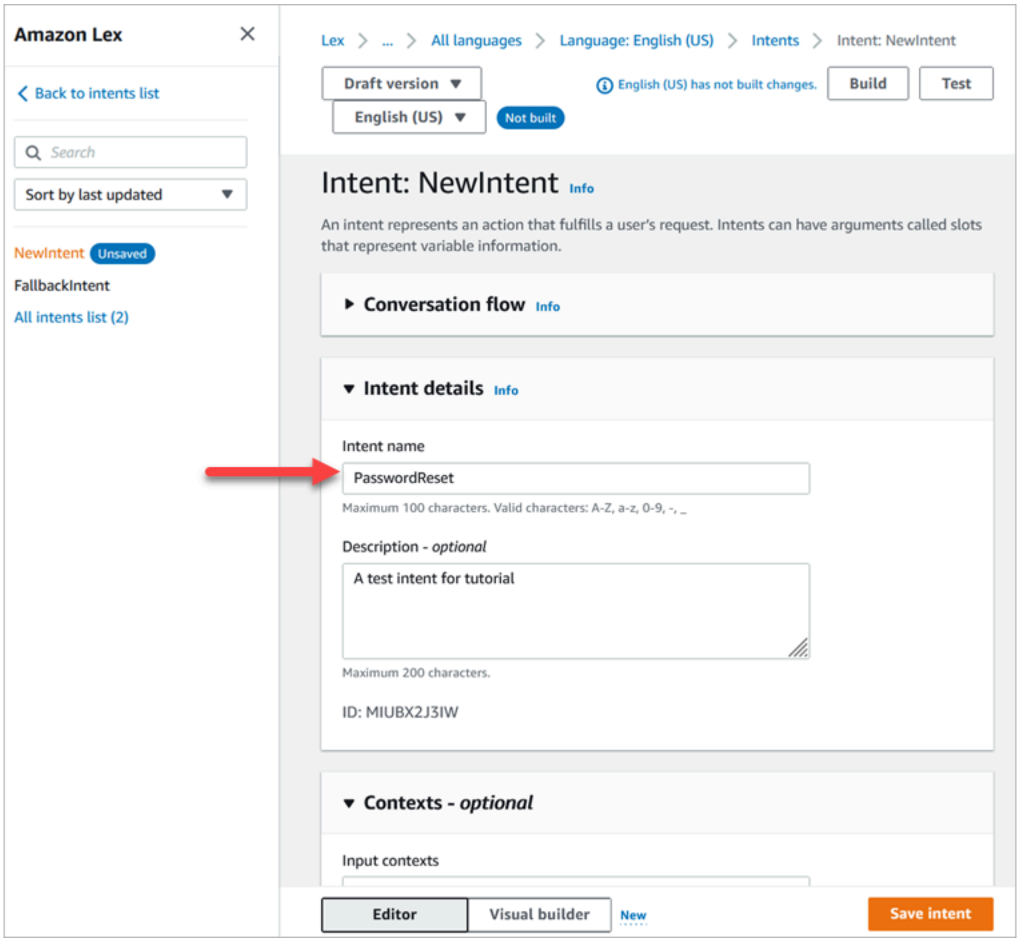
7. Choose **Done**.

Go to Part 2: Add intents to your Amazon Lex bot.

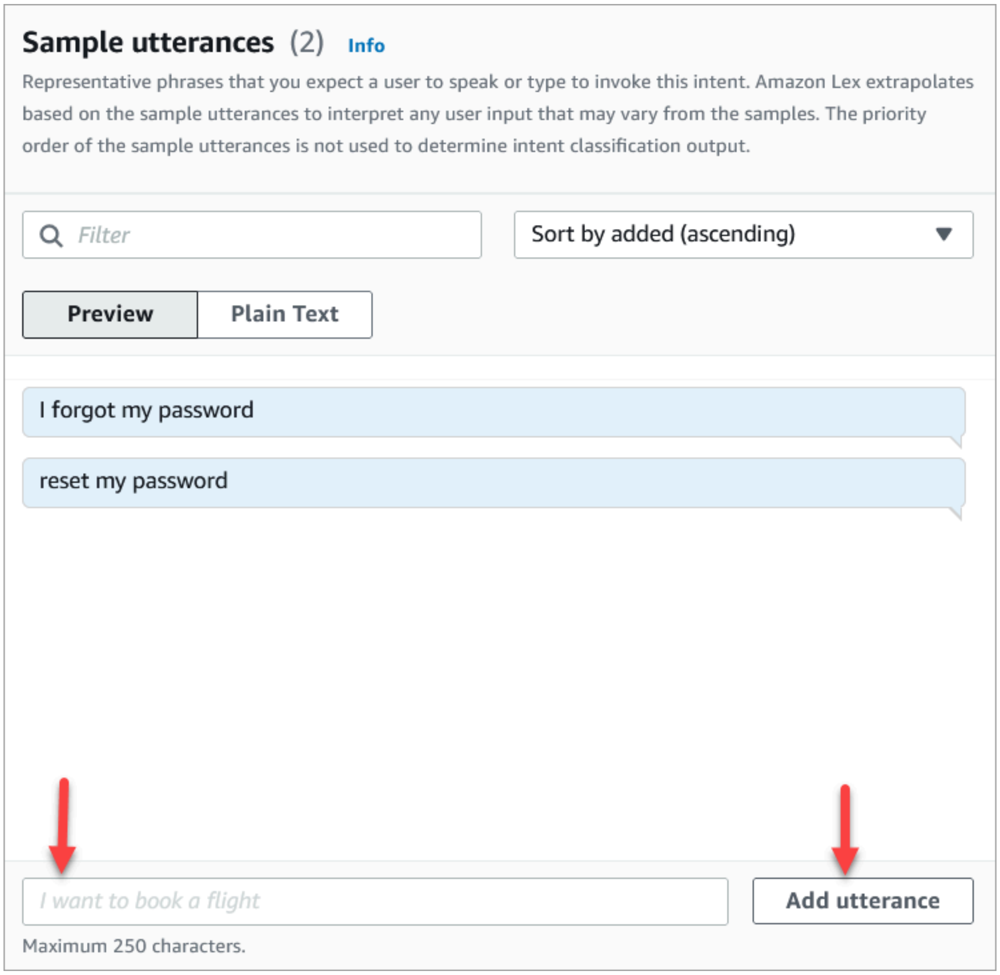
Part 2: Add intents to your Amazon Lex bot

An intent is the action the user wants to perform. In this part, add two intents to the bot. Each intent represents a reason that users call the Help Desk: password reset and network issues.

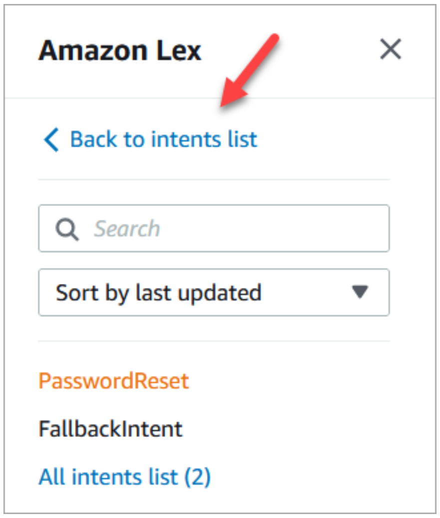
1. In the Amazon Lex console, in the **Intent details** section, enter **PasswordReset** as the name of your intent.



2. Scroll to the **Sample utterances** section.



3. Type **I forgot my password**, and then choose **Add utterance**. Then add **reset my password** and choose **Add utterance** again.
4. Choose **Save intent**.
5. On the left navigation menu, choose **All intents list**.
6. On the left navigation menu, choose **Back to intents list**.



7. Choose **Add intent**, **Add empty intent**, and assign the name **NetworkIssue**. Scroll down the page and add the following sample utterances:

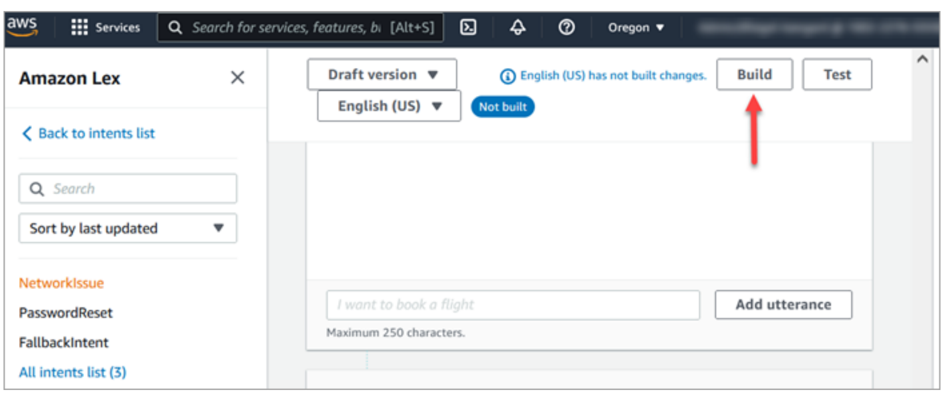
   - **I can't access the internet**
   - **my email is down**

When you're done, go to [Part 3: Build and test the Amazon Lex bot](#).

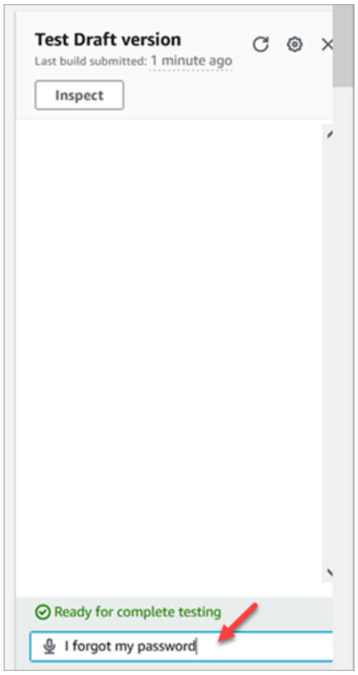
Part 3: Build and test the Amazon Lex bot

Build and test your bot to make sure that it works as intended before you publish it.

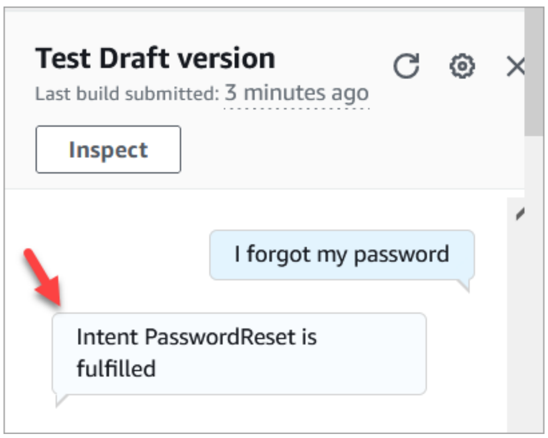
1. In the Amazon Lex console, choose **Build**. The build may take a minute or two.



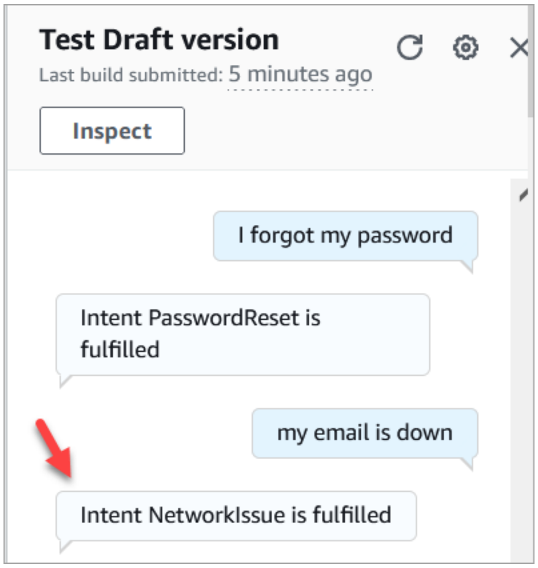
2. When it's finished building, choose **Test**.
3. Test the **PasswordReset** intent. In the **Test Draft version** pane, type **I forgot my password**, and press **Enter**.



4. The verification looks like what's shown in the following image.



5. To confirm that the **NetworkIssue** intent is working, type **my email is down**. The verification looks like what's shown in the following image.

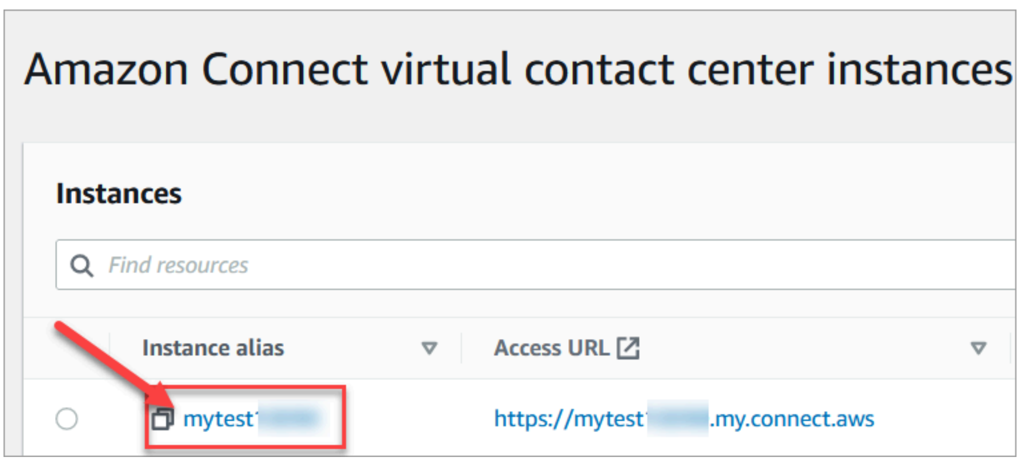


Go to Step 2: Add permissions to Amazon Lex bot.

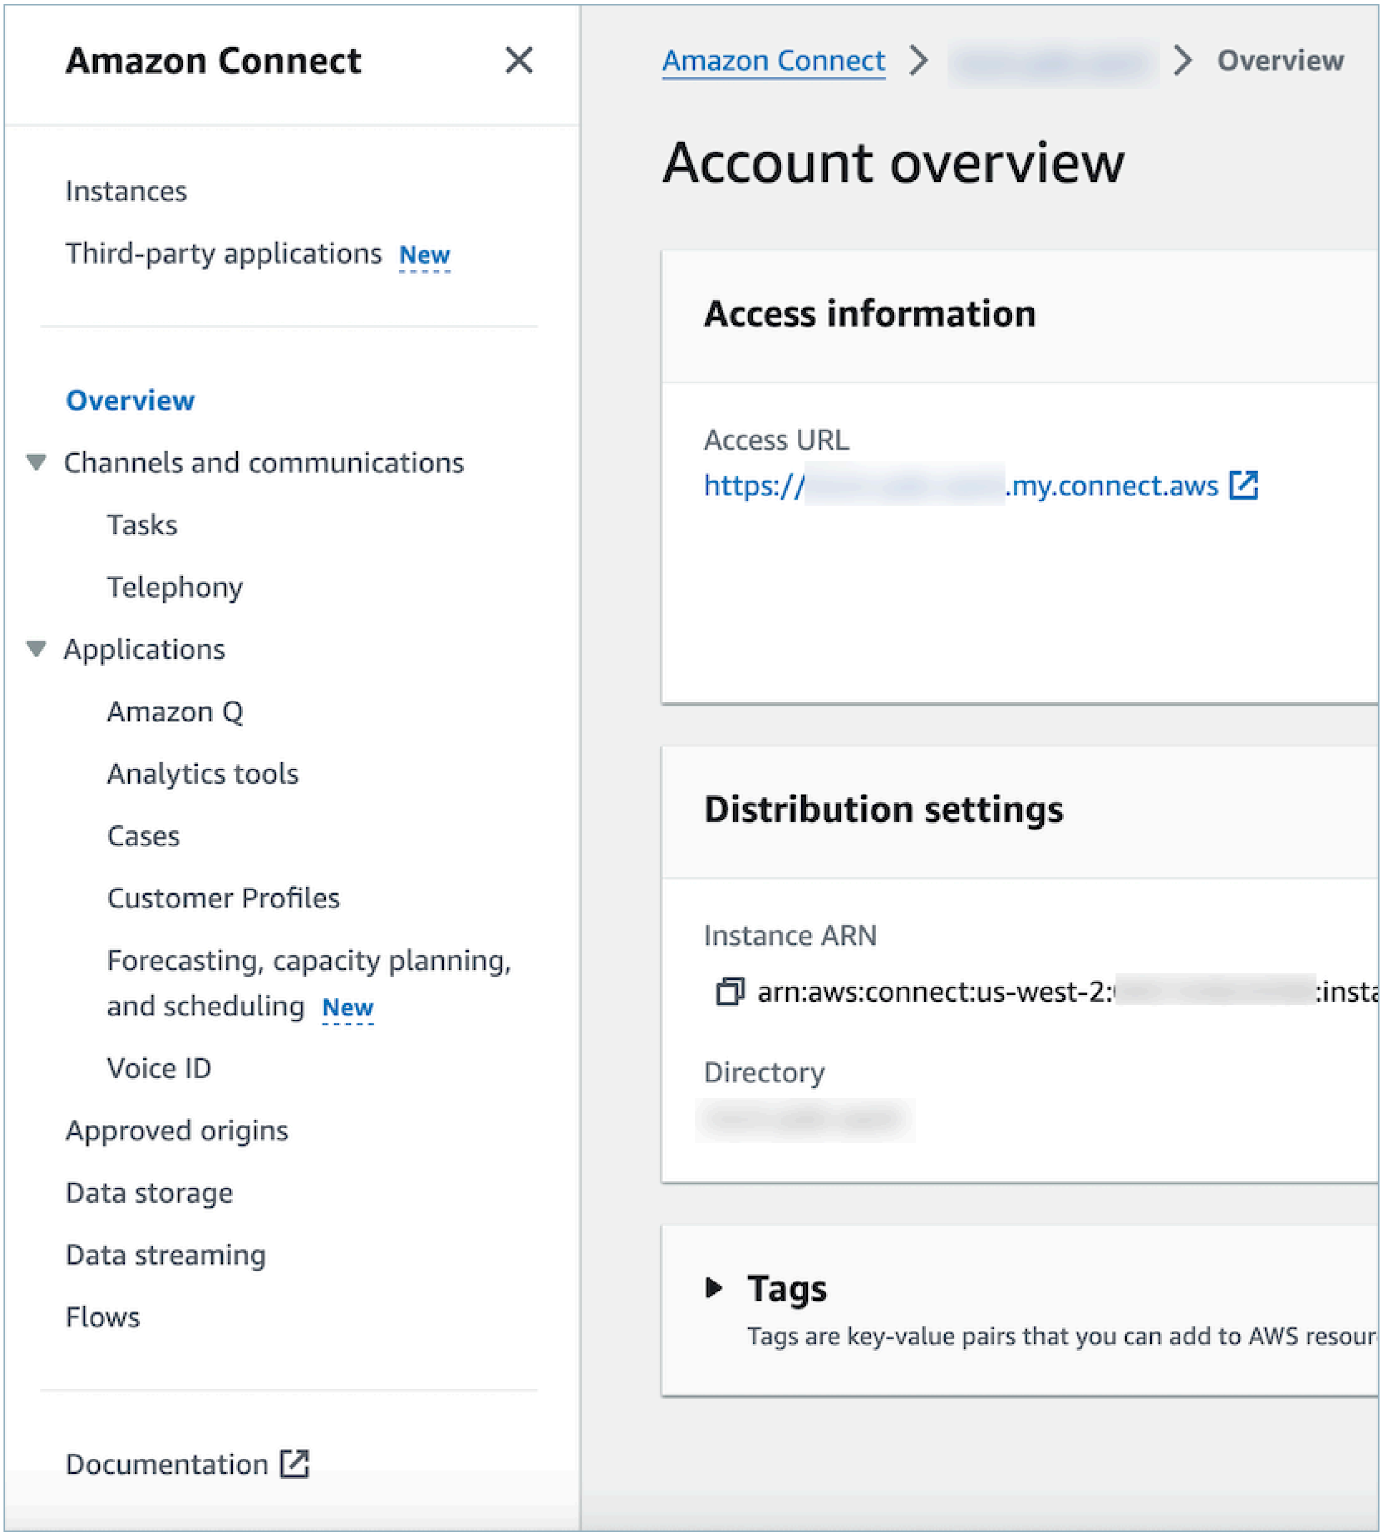
Step 2: Add permissions to Amazon Lex bot

To use a bot in your flow, add it to your Amazon Connect instance.

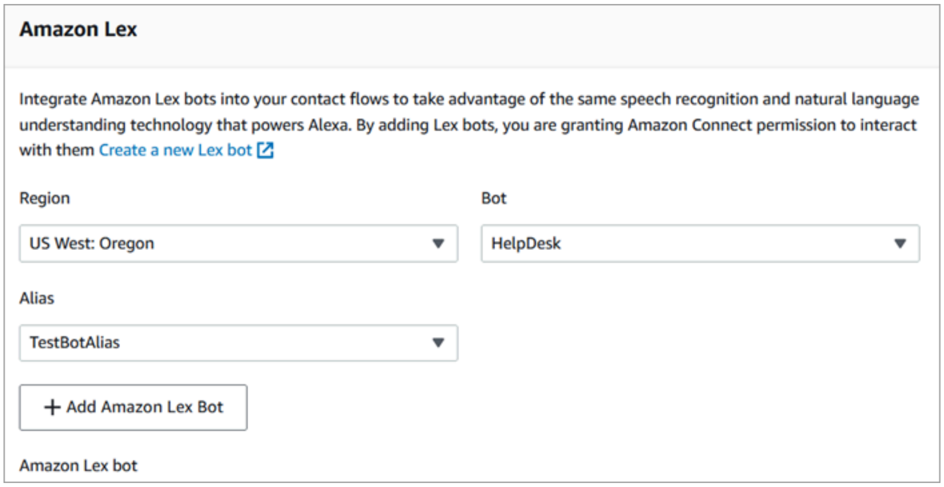
1. Open the Amazon Connect console (https://console.aws.amazon.com/connect/).
2. Choose the name of the instance that you created.



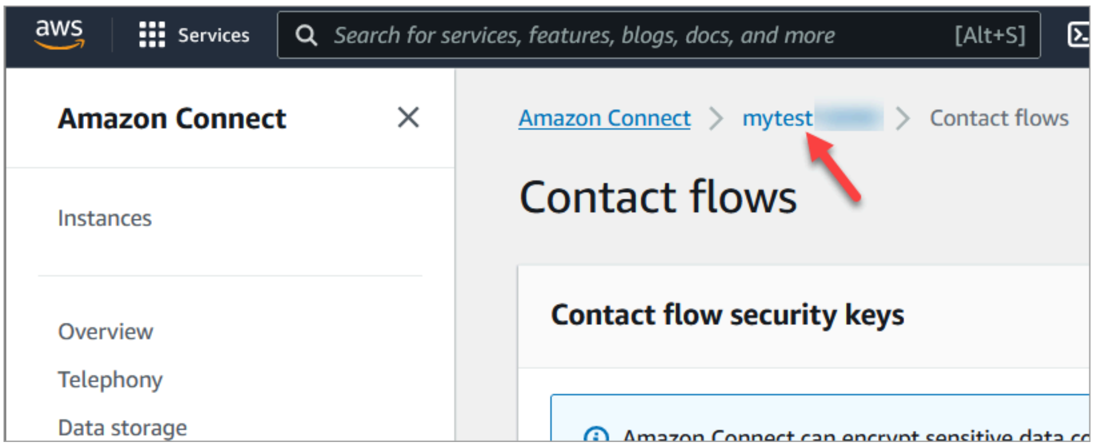
3. Do not log in on the name page (this method of logging in is for emergency access only). Rather, choose **Flows**.



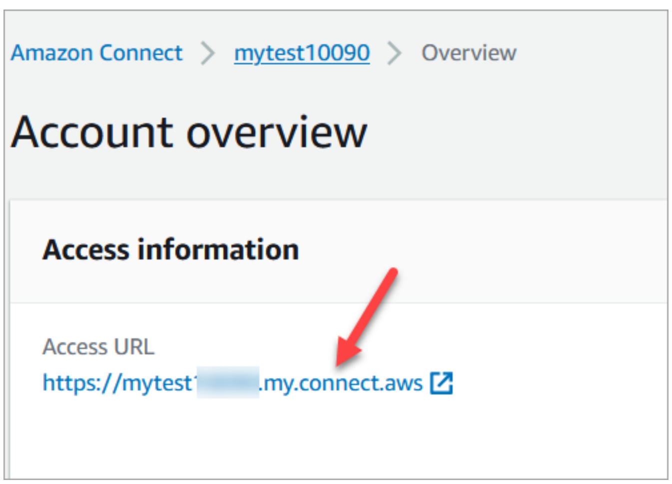
4. Under **Amazon Lex**, use the drop-down arrow to choose **HelpDesk**. Under **Alias**, choose **TestBotAlias**, and then choose **+ Add Lex Bot**, and then choose **Add Amazon Lex Bot**.



5. When you're done, choose Amazon Connect to navigate back to instances page.



6. Choose the access URL of your instance.

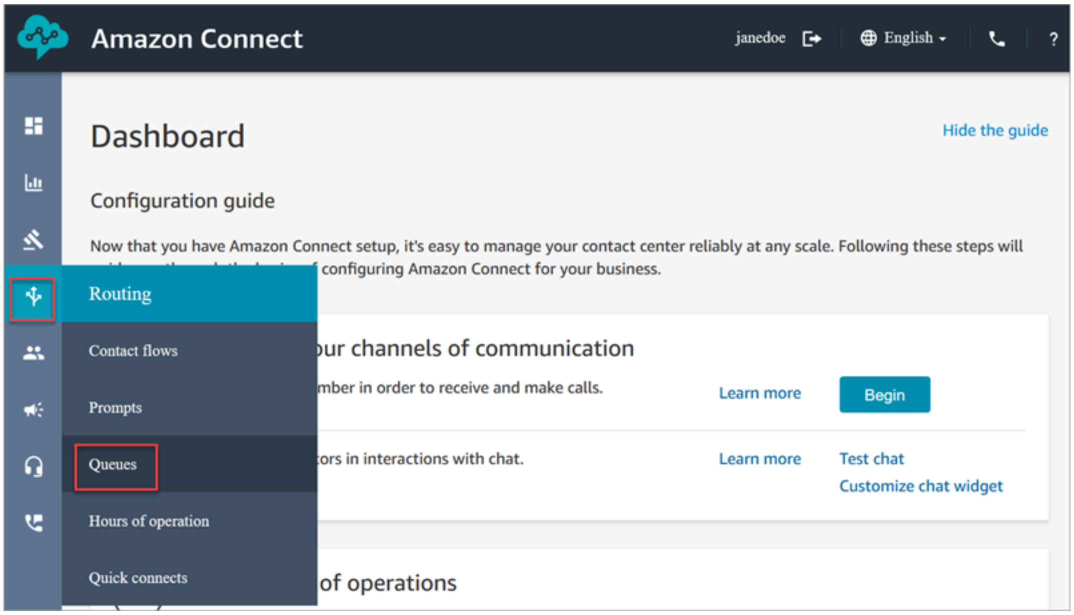


The **Access URL** takes you back to the Amazon Connect dashboard.

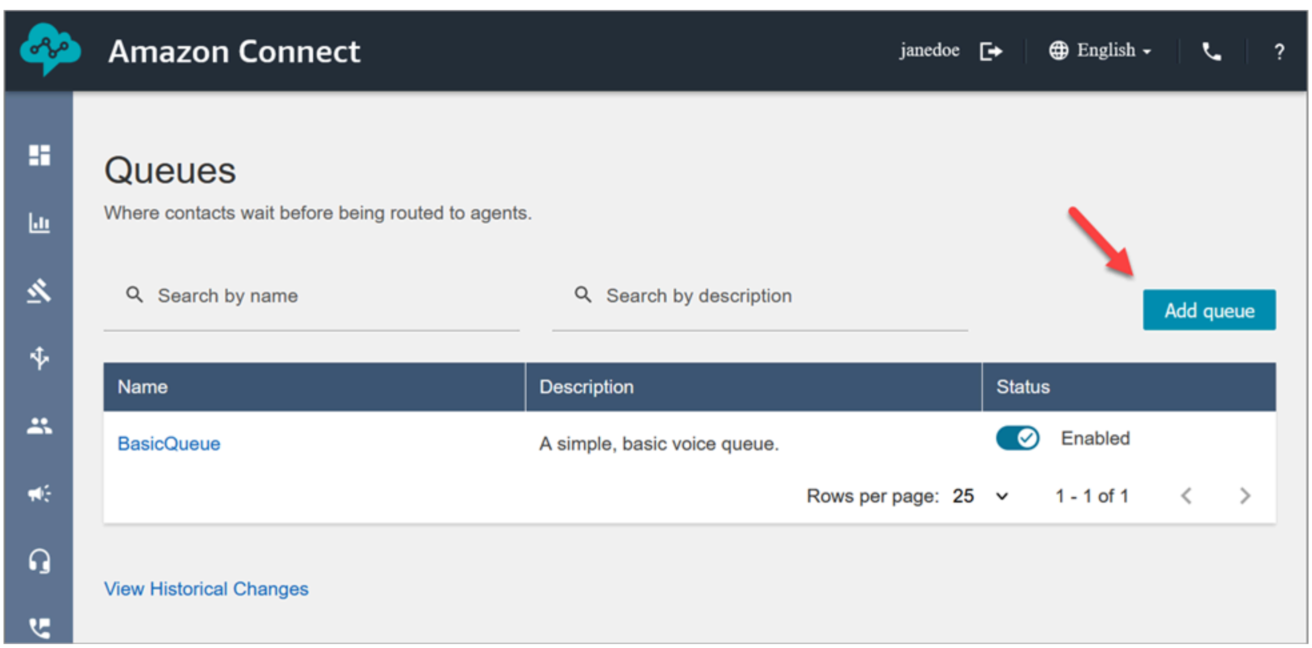
Step 3: Set up routing

In this step, you start at the Amazon Connect console for your instance. This step shows how to set up your queues, create a routing profile, and then assign your user account to the profile.

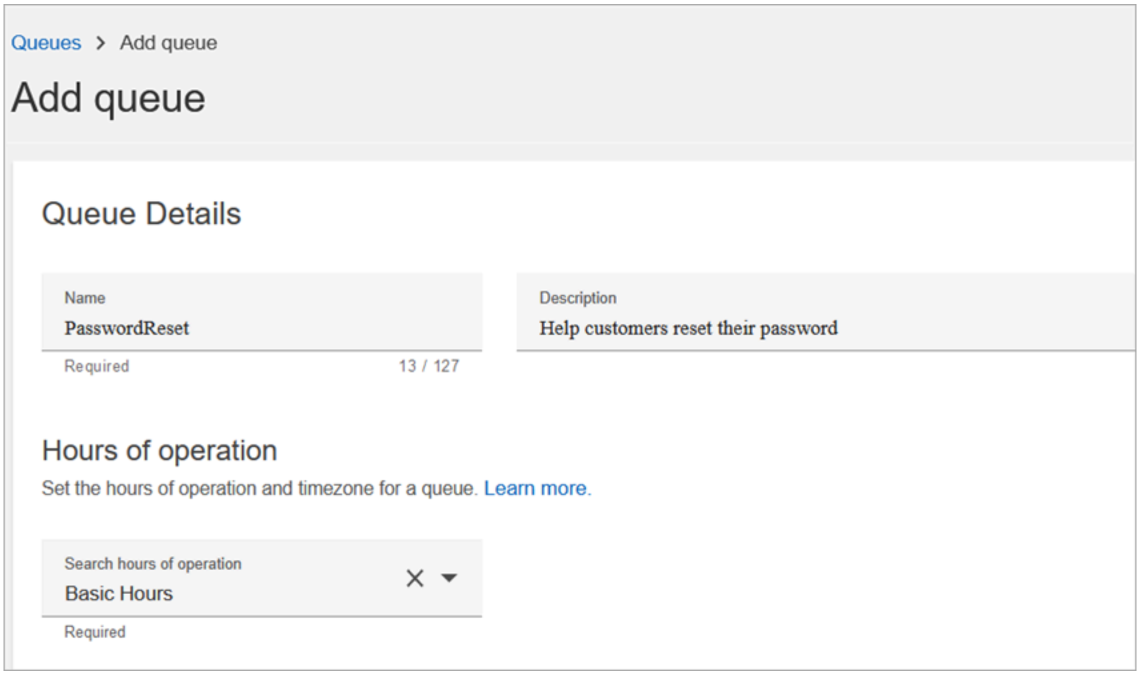
1. On the navigation menu, go to **Routing**, **Queues**.



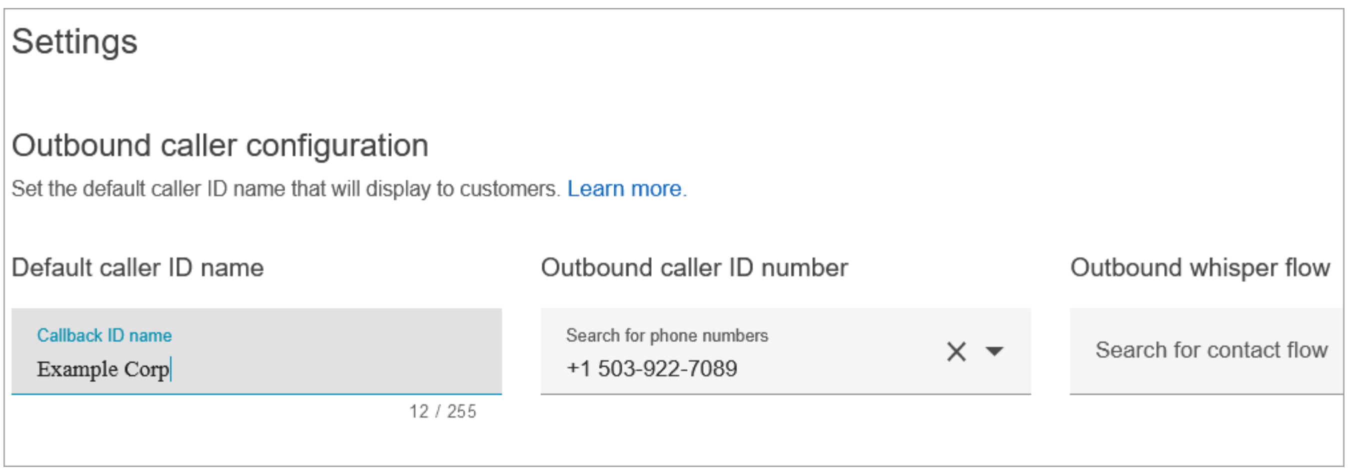
2. Choose **Add queue**.



3. Complete the **Add queue** page, as shown in the following image, to add a queue named **PasswordReset**. When done, choose **Save**.



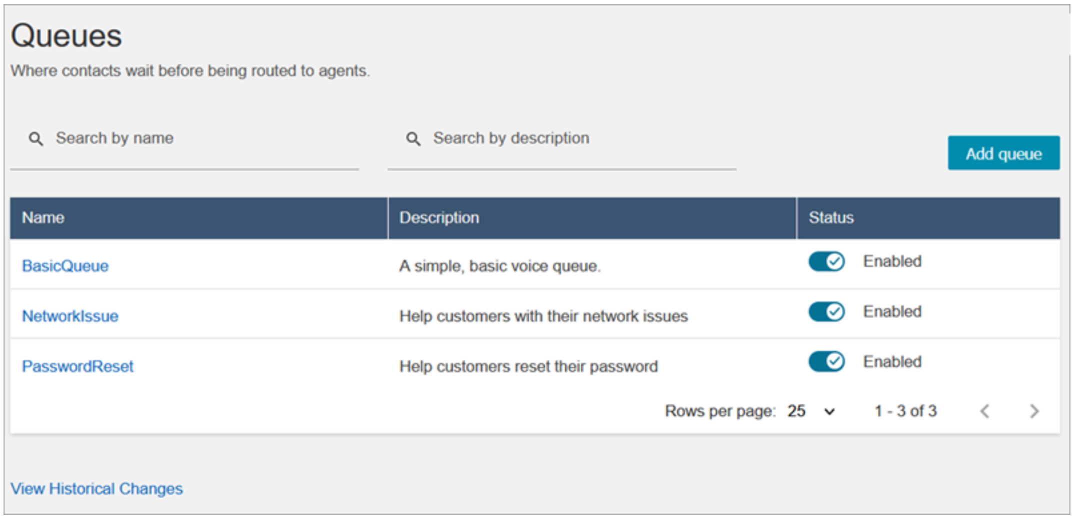
The following image shows the **Settings** section of the **Add queue** page. Add your default caller ID name and outbound caller ID number.



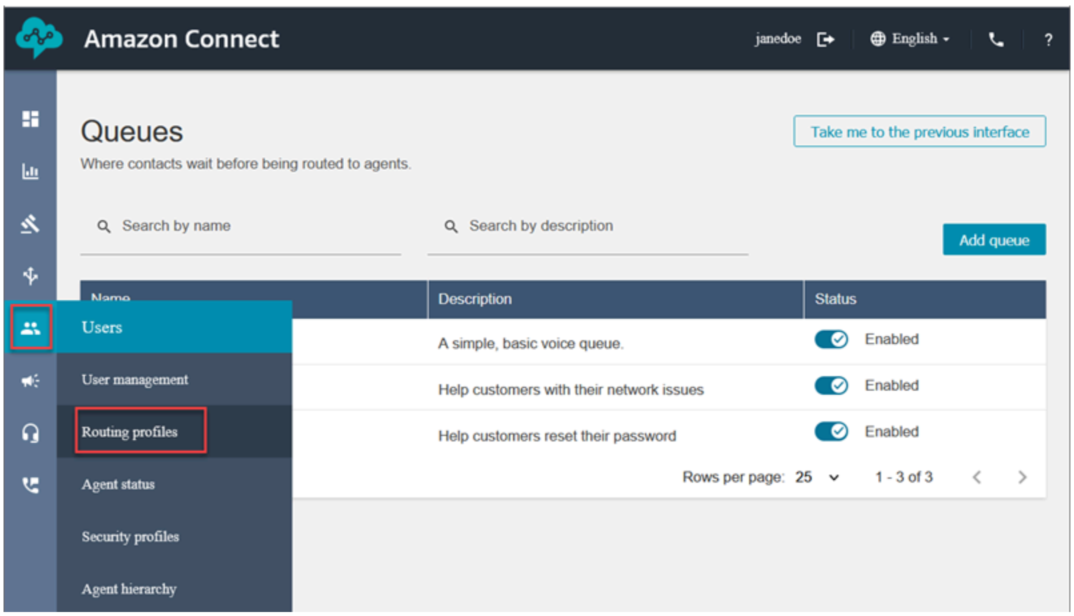
For the purposes of this tutorial, leave the following empty: Outbound whisper flow, Quick connect, and Maximum contact in queue.

4. Add a queue named **NetworkIssue**. Complete the **Add queue** page like you did for the **PasswordReset** queue.

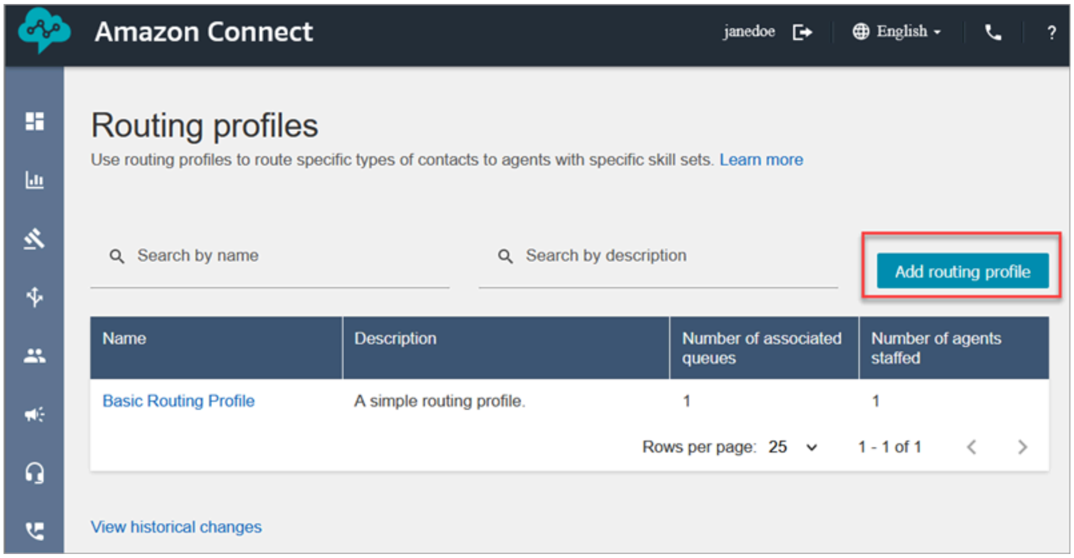
   When done, you'll have three queues.



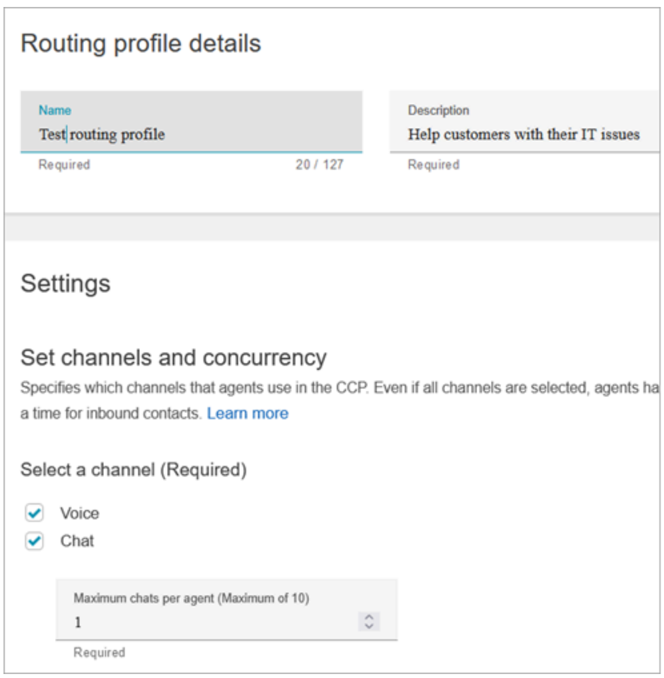
5. On the navigation menu, go to **Users**, **Routing Profiles**.



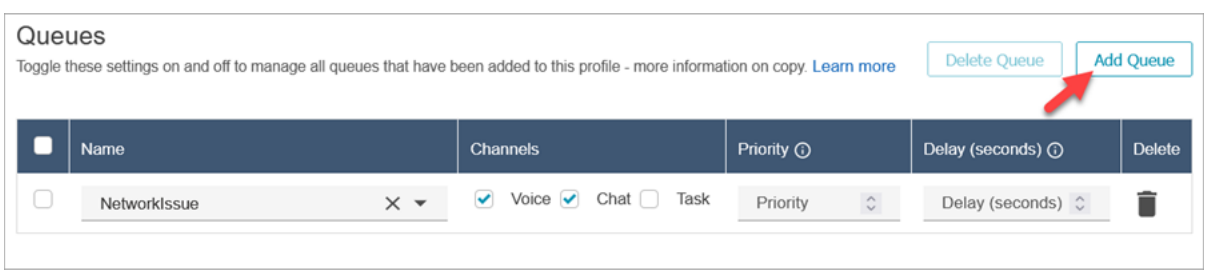
6. Choose **Add routing profile**.



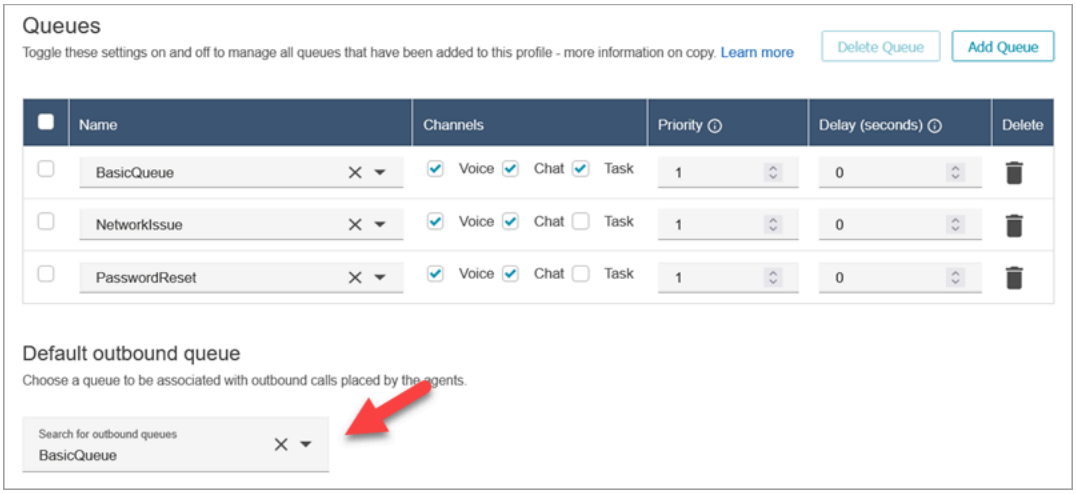
7. Assign a name to the new profile (for example, **Test routing profile**). Enter a description, select **Voice**, **Chat**, and set **Maximum chats** to **1.**



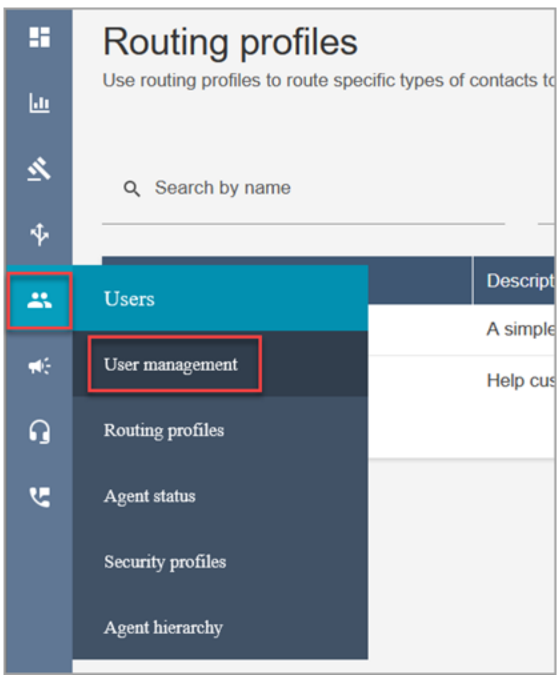
8. In the **Queues** section, use the drop-down arrow to search for the queues you just created. Choose **NetworkIssue**, select **Voice** and **Chat**. Choose **Add Queue**.



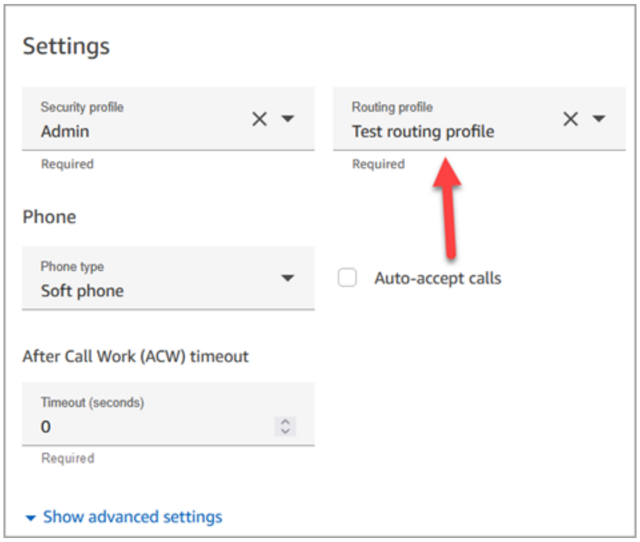
9. Add the **PasswordReset** queue. Select **Voice** and **Chat**, and then choose **Save**.
10. Under **Default outbound queue**, use the drop-down arrow to choose **BasicQueue**.



11. When done, scroll to the top of the page, and choose **Save** to save the profile.
12. On the navigation menu, go to **Users**, **User management**.



13. On the **User management** page, select your login name.
14. On the **Edit** page, in the **Settings** section, in the **Routing profile** dropdown menu, choose the routing profile you created, for example, **Test routing profile**. Choose **Save**.



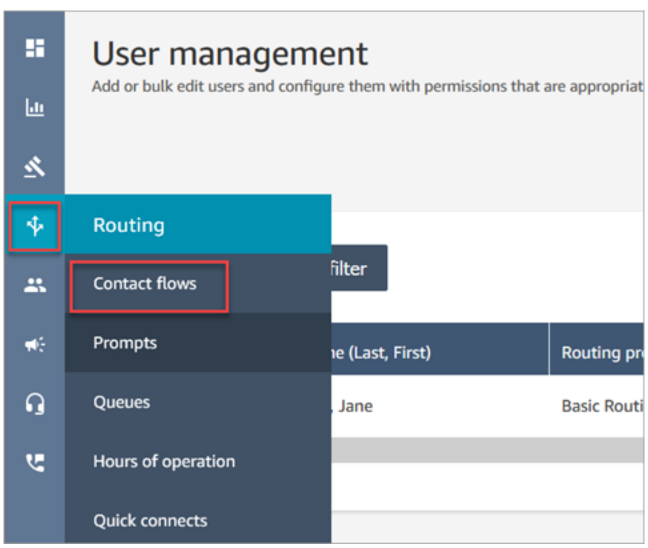
Routing is all set up and ready to go.

Step 4: Create a contact flow

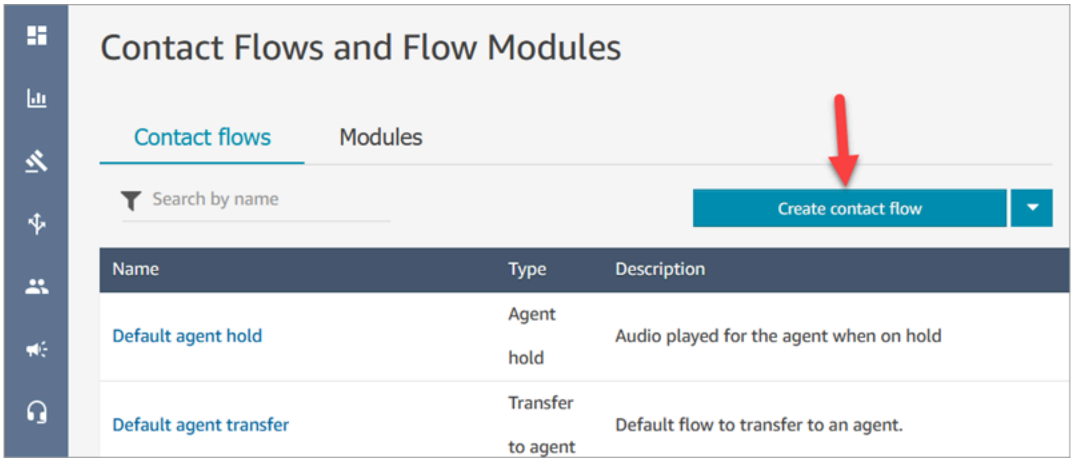
Although Amazon Connect comes with a set of built-in flows, you can create your own flows to determine how a customer experiences your contact center. The flows contain the prompts that customers hear or see, and they transfer them to the right queue or agent, among other things.

In this step, create a flow that's specific to the IT Help Desk experience that you're creating.

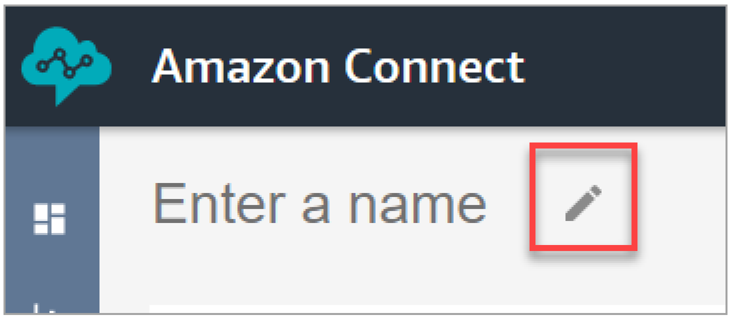
1. On the Amazon Connect navigation menu, go to **Routing**, **Flows**.

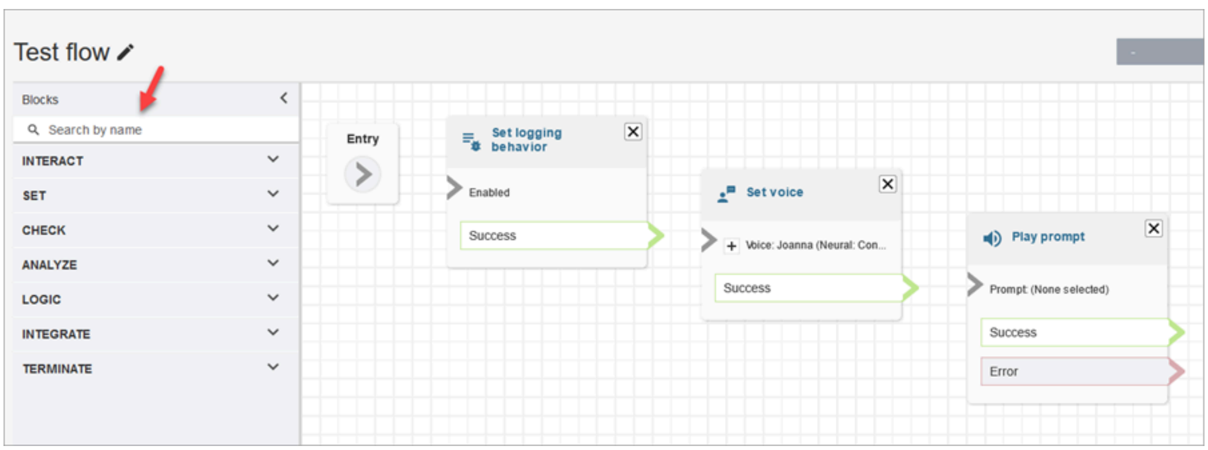
2. Choose **Create flow**.



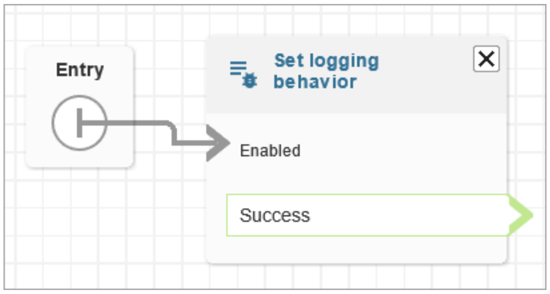
3. The flow designer opens. Enter a name for the flow, such as **Test flow**.



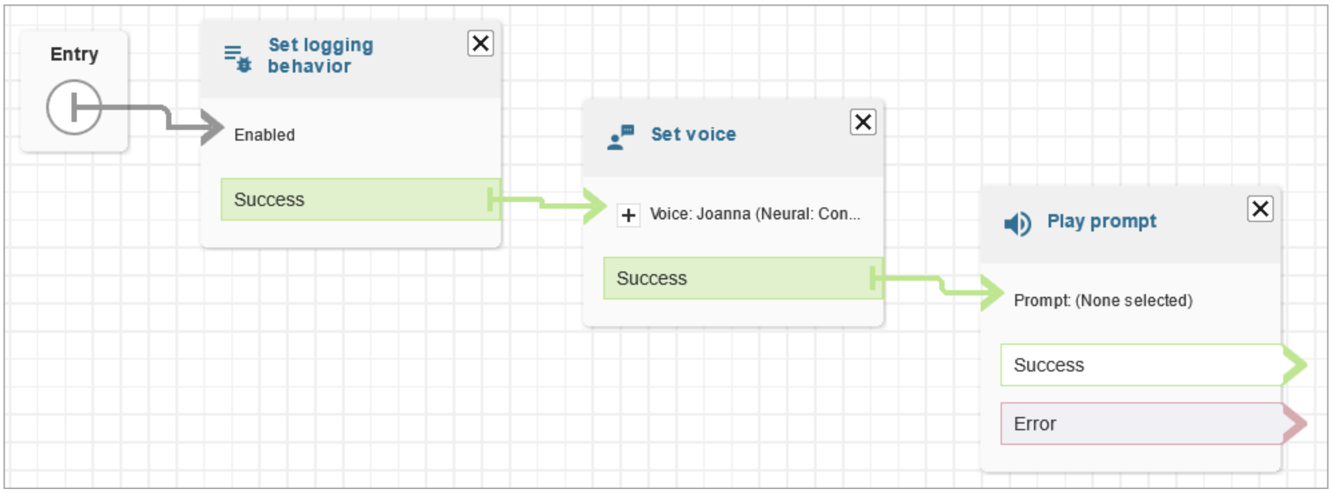
4. Use the search box to search for the following block, and drag them onto the grid: [Set logging behavior](), [Set voice](), and [Play prompt]().



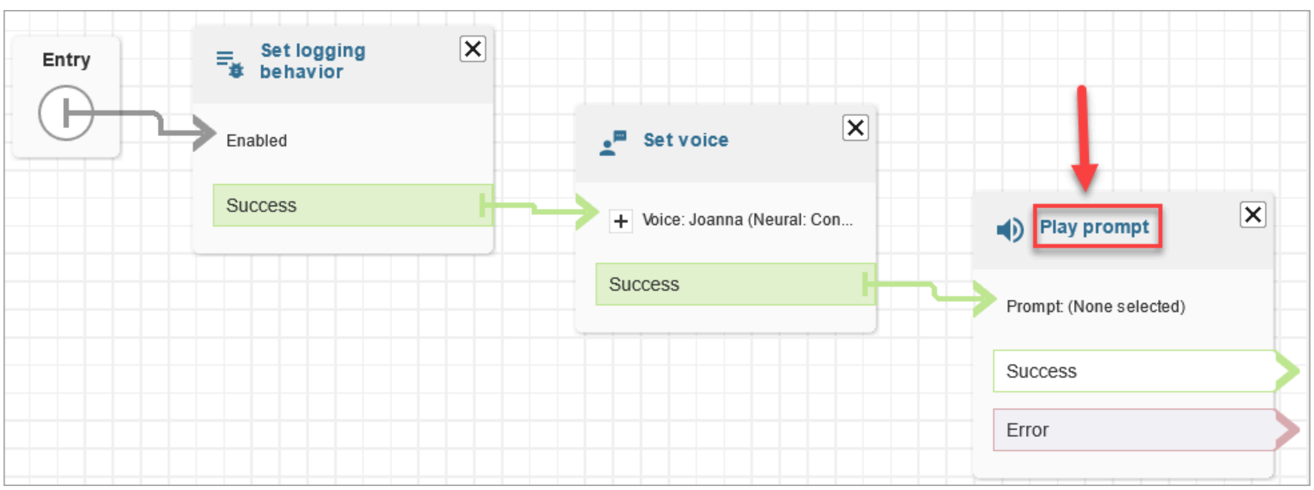
5. Use your mouse to drag an arrow from the **Entry** block to the **Set logging behavior** block.



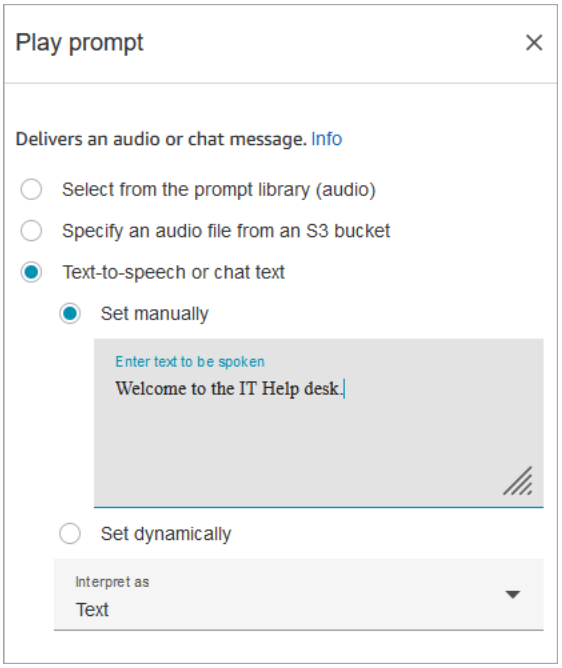
6. Connect the remaining blocks, as shown in the following image.



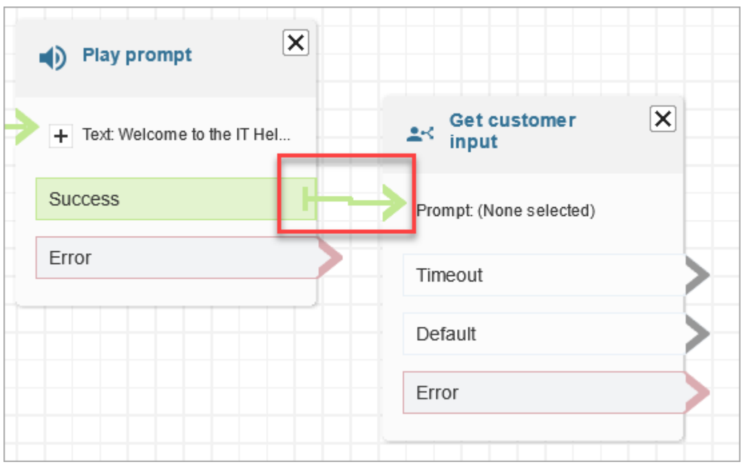
7. Choose the **Play prompt** title to open its properties page.



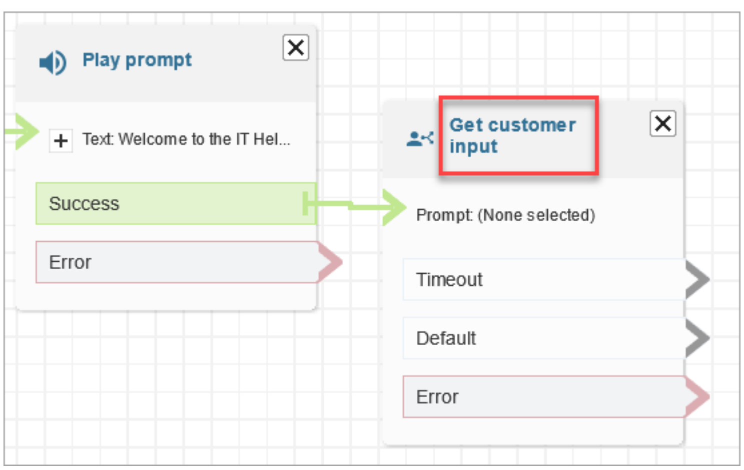
8. Configure the **Play prompt** block, as shown in the following image, and then choose **Save**. Choose **Text-to-speech or chat text**, choose **Set manually**, enter *Welcome to the IT Help desk*.



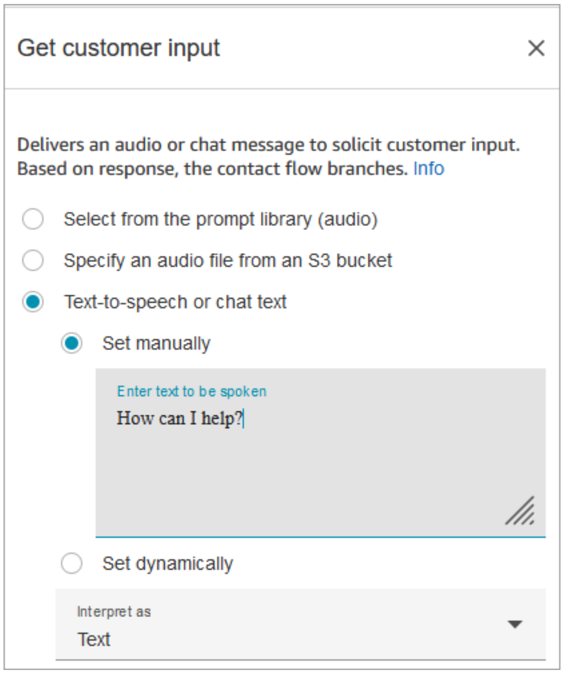
9. Add a Get customer input block and connect to the **Play prompt** block.



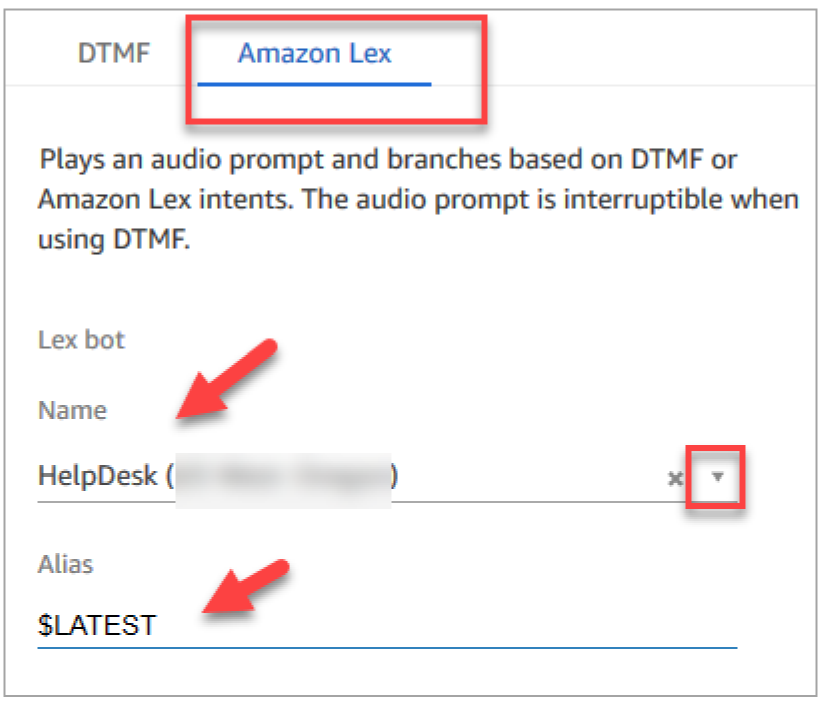
10. Choose the title of the Get customer input block to open the properties page.



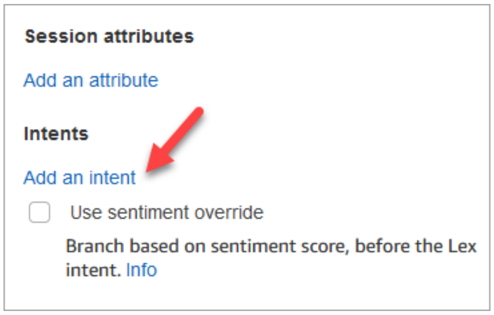
11. Configure the **Get customer input** block, as shown in the following images. Choose **Text-to-speech or chat text**, **Set manually**, and enter *How can I help* in the text box. Set the **Interpret as** dropdown box to **Text**.



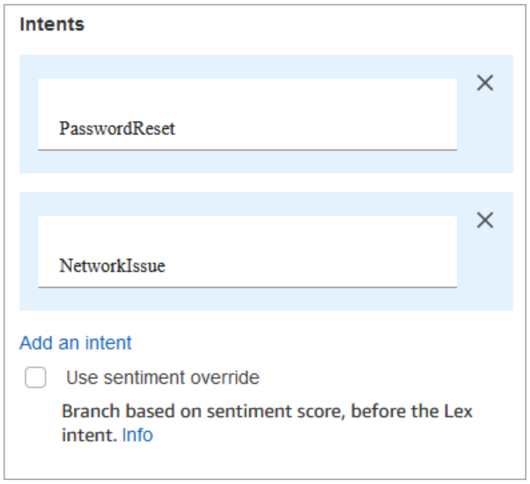
The following image shows the Amazon Lex tab. Choose the name of your Amazon Lex bot from the dropdown list. For **Alias** enter **$LATEST**.



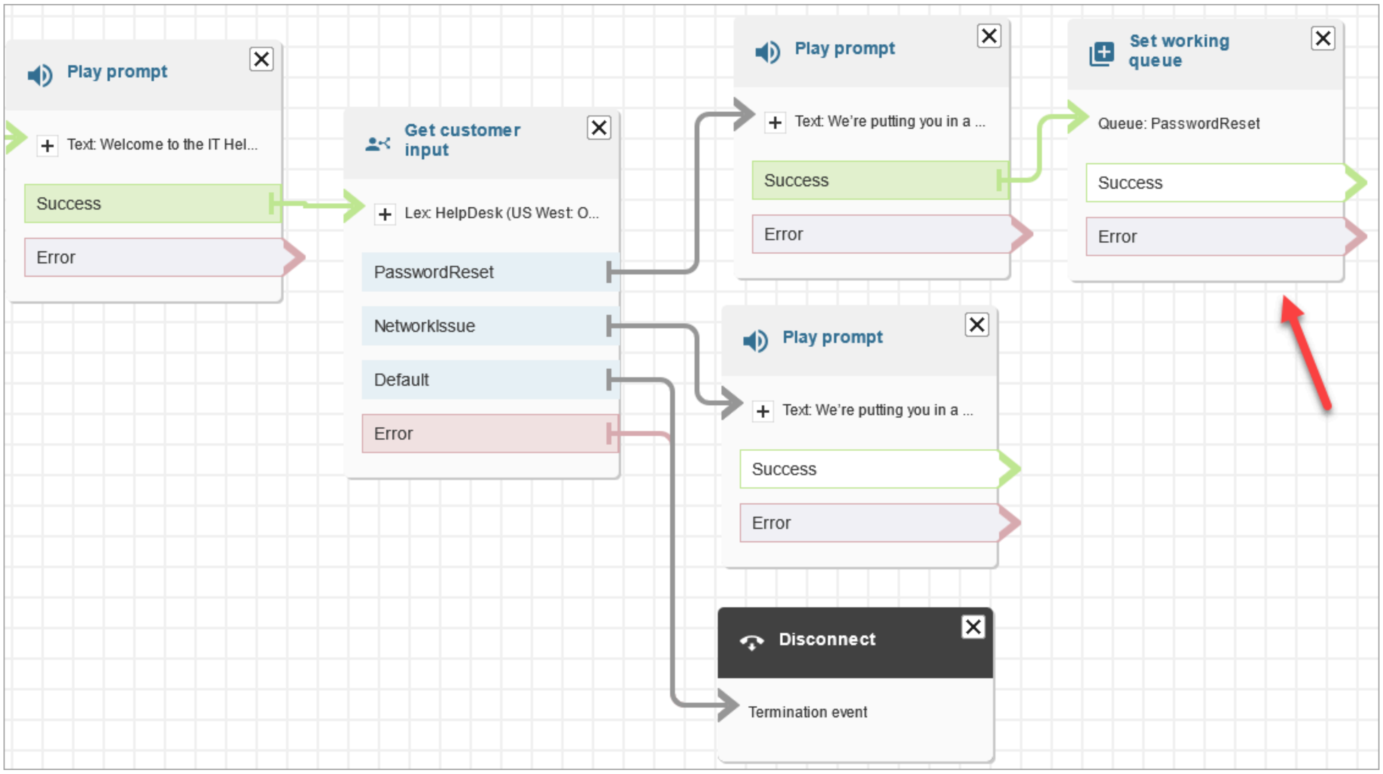
12. While still in the **Get customer input** block, choose **Add an intent**.



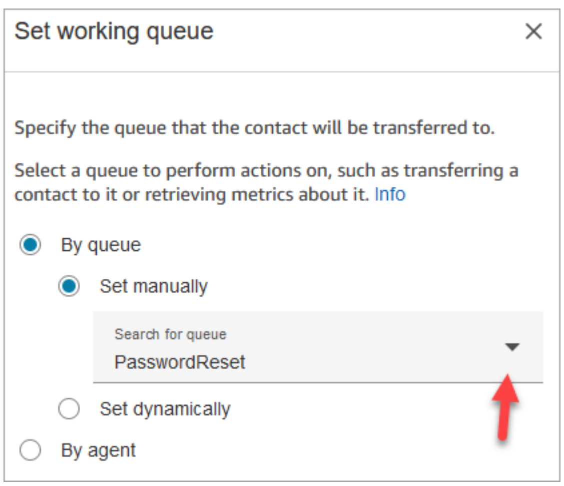
13. Enter the names of the intents that you created in the Amazon Lex bot, such as PasswordReset and NetworkIssue. They are case sensitive!



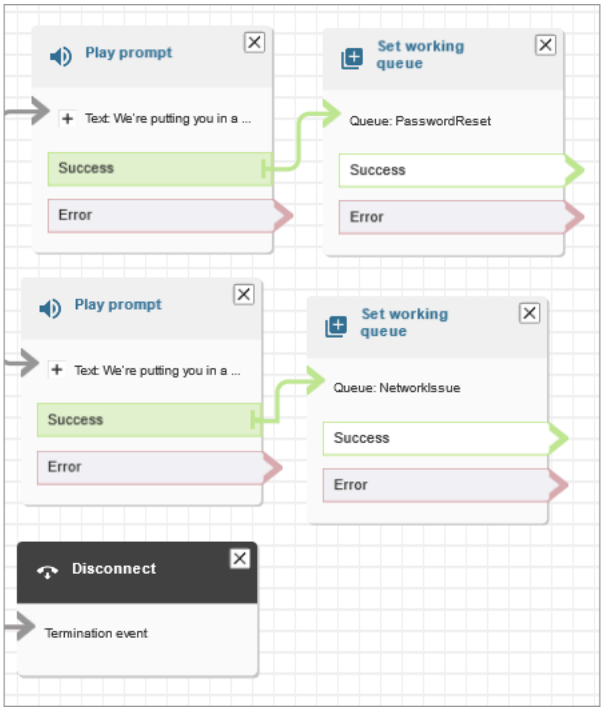
14. Choose **Save**.
15. Add a **Play prompt** block and connect it to the **PasswordReset** branch.
16. Choose the **Play prompt** title to open its properties page. Configure the **Play prompt** block with the message *We're putting you in a queue to help you with password reset.* Choose **Save**.
17. Add a second **Play prompt** block and connect it to the **NetworkIssue** branch.
18. Choose the **Play prompt** title to open its properties page. Configure the **Play prompt** block with the message *We're putting you in a queue to help you with your network issues.* Choose **Save**.
19. Add a [Disconnect / hang up](#) block to the grid. Connect the **Default** and **Error** branches to it.
20. Add a [Set working queue](#) block to the grid. Connect the **Play prompt** block for PasswordReset.



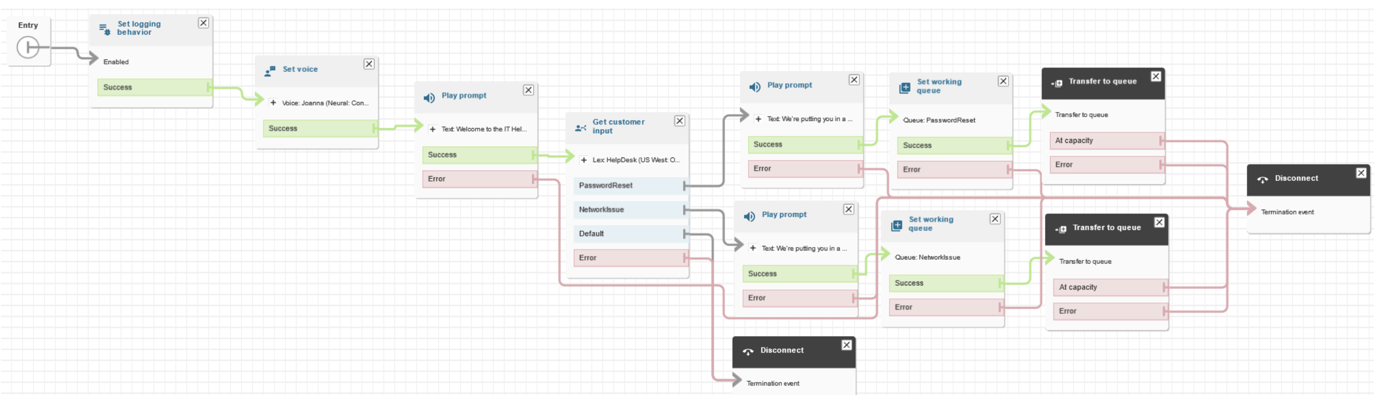
21. Choose the **Set working queue** title to open its properties page. Configure the **Set working queue** block by using the drop-down arrow to choose the **PasswordReset** queue. Choose **Save**



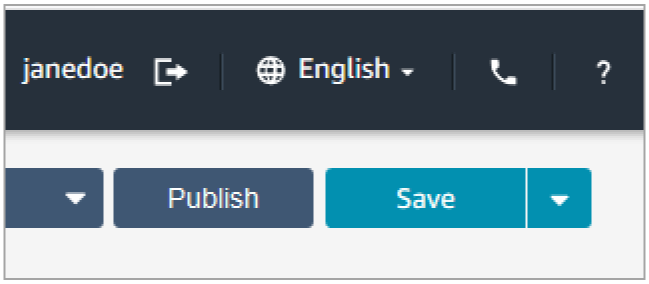
22. Add a **Set working queue** block for NetworkIssue, and configure it with the NetworkIssue queue.



23. Drag two **Transfer to queue** blocks (from the **Terminate/Transfer** group) onto the grid.
24. Connect each of the **Set working queue** blocks to a **Transfer to queue** block.
25. Drag another **Disconnect/hang up** block onto the grid. Connect all of the remaining **Error** and **At capacity** branches to it.
26. The completed flow looks similar to the following image.

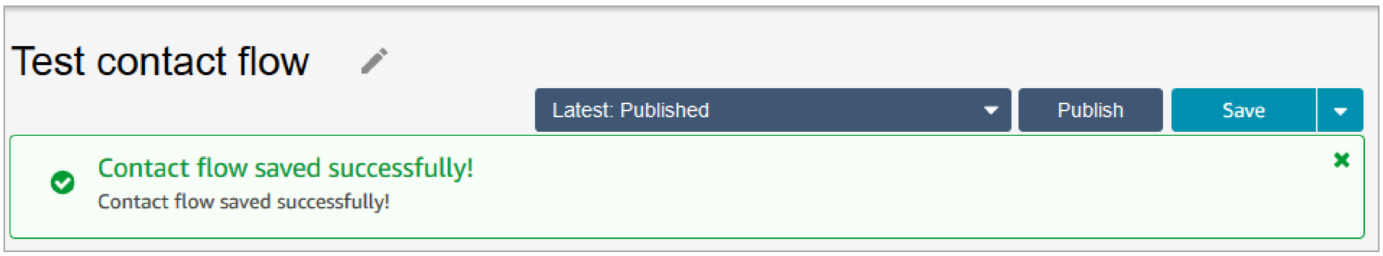


27. Choose **Save**, and then choose **Publish**.



> **Tip**
>
> Any blocks that aren't connected or configured correctly generate an error. If this happens, double-check that all branches are connected.

28. When the flow publishes, it displays the message that it saved successfully.

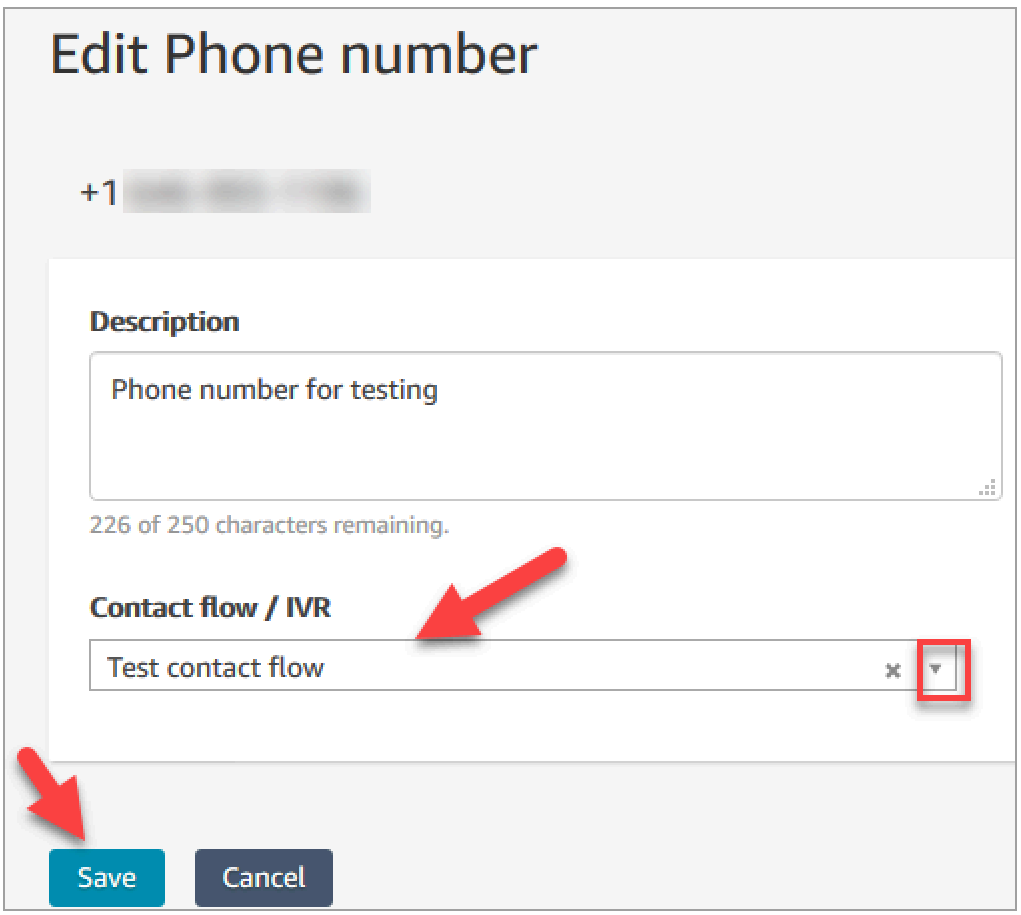


If the flow doesn't save, double-check that all the branches are connected to blocks. That's the most common reason flows don't publish.

Step 5: Assign the contact flow to the phone number

1. On the navigation menu, go to **Channels**, **Phone Numbers**.
2. On the **Manage Phone numbers** page, choose your phone number.

3. Use the drop-down box to choose the flow you just created, and then choose **Save**.

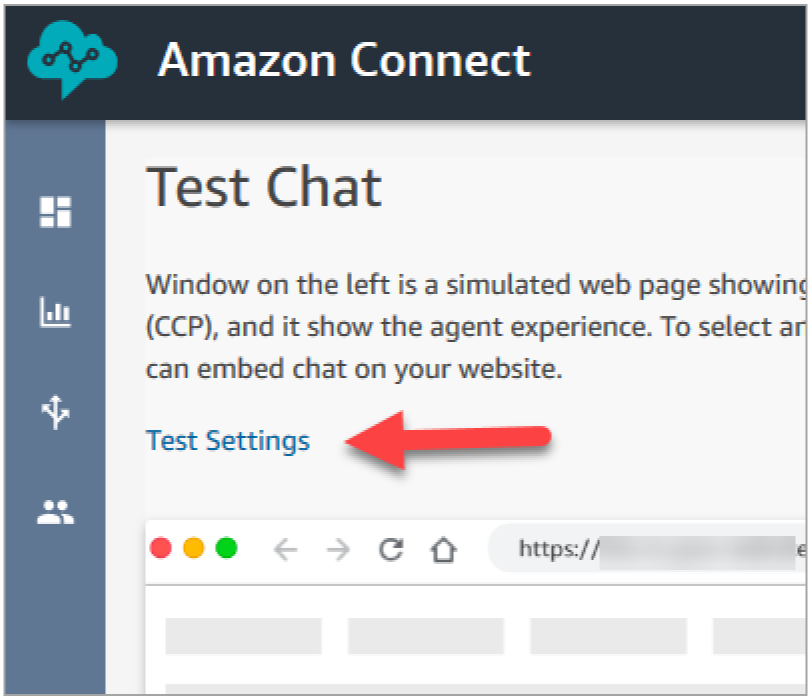


Everything is all set up! Now you're ready to test your IT Help Desk. Continue on to [Step 6: Test a custom voice and chat experience](#).

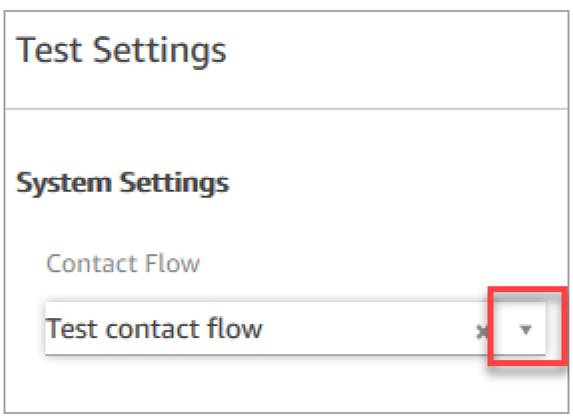
Step 6: Test a custom voice and chat experience

You're ready to try out the Amazon Lex bot, routing, and flow. The first step is to tell Amazon Connect which flow you want to test.

1. On the navigation menu, go to the **Dashboard** and choose **Test chat**.
2. Choose **Test Settings**.

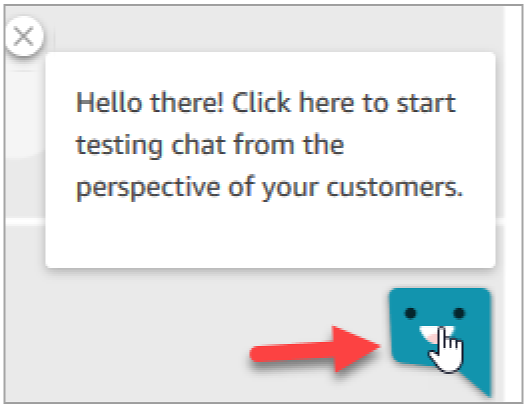


3. Use the drop-down box to choose the flow you created, for example, **Test flow**. Choose **Apply**.

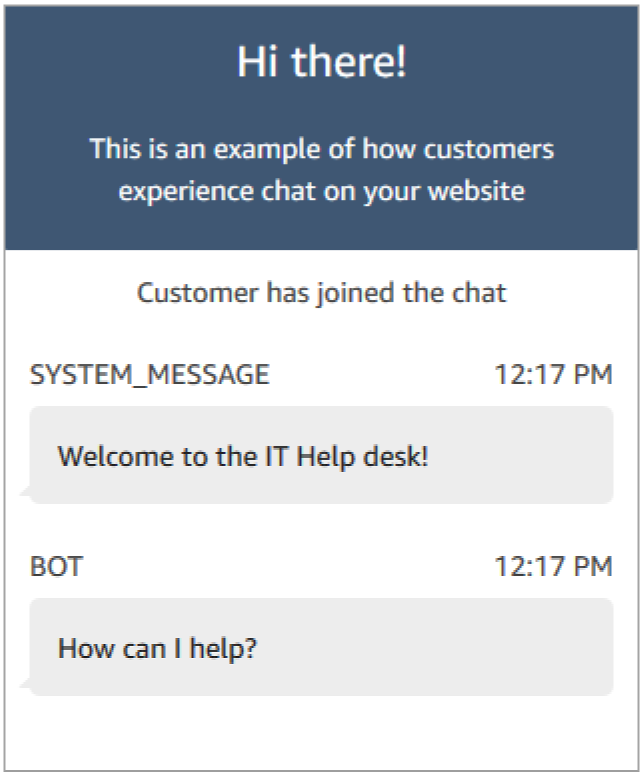


Test a custom chat experience

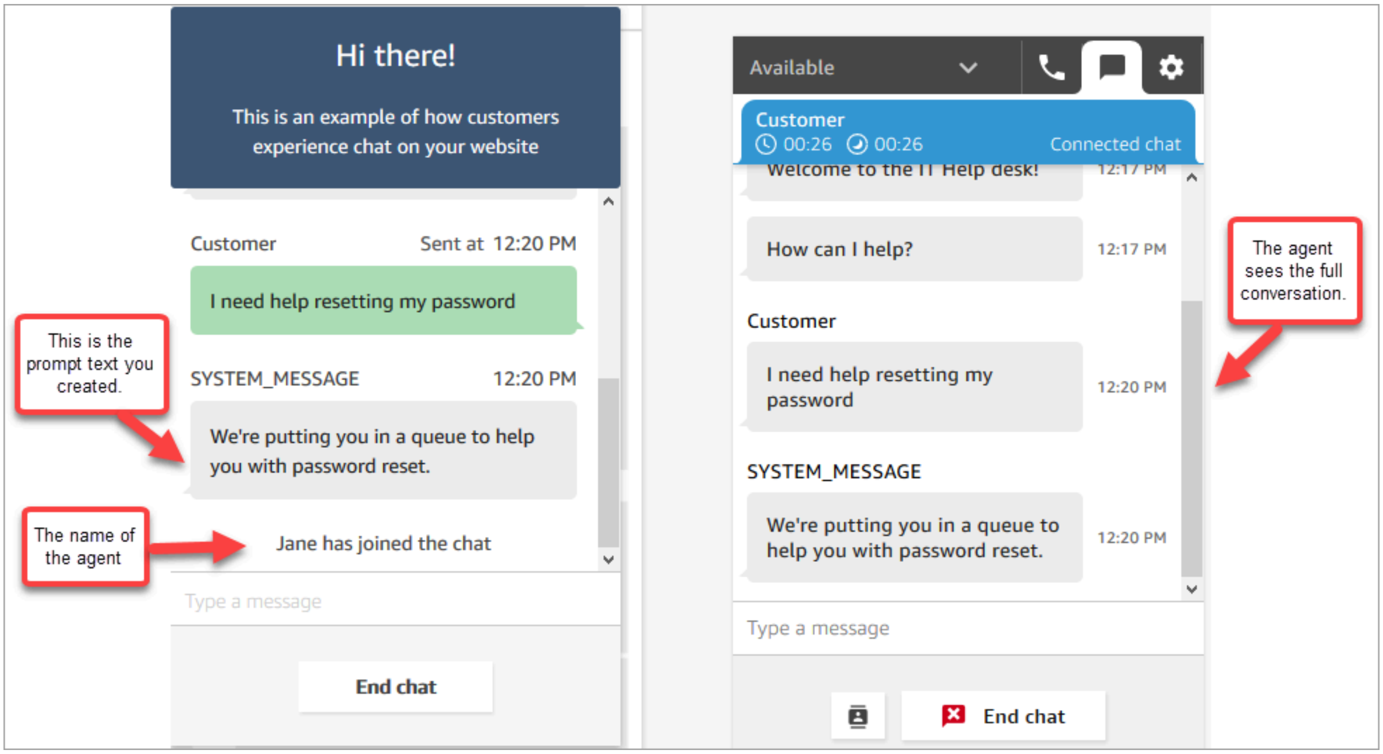
1. If needed, choose the chat bubble to start a chat.



2. Amazon Connect automatically detects a contact and runs the flow that you created. It displays messages from the flow.



3. Enter that you need help resetting a password. Then accept the incoming chat. The following image shows you what the chat and agent interfaces look like when you're trying them.



4. In the customer pane on the right, choose **End chat** to close the chat window.
5. In the test CCP, choose **Close contact** to end the After Contact Work (ACW).

Test a custom voice experience

1. If the test chat window is still open, choose **End chat** to close it. Then you can try the voice experience.
2. Call your phone number.
3. When prompted, say *I'm having trouble accessing the internet*. You should hear the message that you're being transferred to the NetworkIssue queue.

> **Tip**
>
> After you're transferred, you'll hear this message:
> *Thank you for calling. Your call is very important to us and will be answered in the order it was received.*
> This message is generated by a default flow named Default customer queue.

4. Switch to the test CCP and accept the incoming call.

5. After you accept the call, but before you're connected to the customer, you'll hear an inbound whisper stating what queue the contact is in, for example, NetworkIssue. This helps you know what the customer is calling about.

   The inbound whisper is generated by a default flow named Default agent whisper.
6. When done, end the call.
7. In the CCP, choose **Clear contact** to end After Contact Work (ACW).

Congratulations! You built and tested an omnichannel IT Help Desk that leverages Amazon Lex and offers customers both chat and voice.

> **Tip**
>
> If you don't want to keep the phone number that you claimed for testing, you can release it back to inventory. For instructions, see Release a phone number from Amazon Connect back to inventory.

Architectural guidance for Amazon Connect

This topic provides guidance and best practices for designing and building reliable, secure, efficient, and cost-effective systems for your Amazon Connect contact center workloads. Using this guidance can help you build stable and efficient workloads, allowing you to focus on innovation, reduce costs, and improve your customer's experience.

This content is intended for chief technology officers (CTOs), architects, developers, and operations team members.

Contents

- [Cost optimization for Amazon Connect workloads](#)

The power of AWS with Amazon Connect

This topic is for developers and administrators who are interested in an overview of which other AWS services you can integrate with Amazon Connect.

The following diagram shows some of the other AWS services you can use with Amazon Connect.

Development

You can use AWS Lambda functions to either look up or post data to sources outside of Amazon Connect. For example, you can look up an inbound caller on Salesforce based on the customer's phone number. The function may return such results as the customer name, membership level (for example, frequent flyer), last order, and order status. Then based on that information, the call can be routed to an Amazon Lex bot or an agent.

You can also use Lambda with AWS databases like DynamoDB to create dynamic routing abilities. For example, you can retrieve a prompt in a specific language, based on input from the customer.

API Gateway and Step Functions further enhance the abilities of Lambda.

For more information, see:

- Grant Amazon Connect access to your AWS Lambda functions

Storage

Amazon Connect uses Amazon Simple Storage Service (Amazon S3) to store recorded conversations and exported reports. When you set up Amazon Connect, it creates default buckets for these requirements, or you can point it to existing Amazon S3 infrastructure. For more information, see Step 4: Data storage in Create an Amazon Connect instance.

VPC endpoints are not supported.

You can also manage the Amazon S3 policies to move data to Amazon S3 Glacier for less expensive long-term storage. However, it breaks the link in the contact record in Amazon Connect. To fix this, use a Lambda function to rename the S3 Glacier object to match the data in the contact record.

Database

You can use AWS databases with Amazon Connect for a variety of reasons. For example, with DynamoDB, you can create quick tables of data.

You can also create tables of dynamic information for call routing. For example, a Lambda function can write inbound calls to a DynamoDB table, then query the table to see if there are other matches for the phone number. If so, a decision can be made to send the caller to the same queue as before, or to flag them as a repeat caller.

For more information, see:

- Blog post: Creating dynamic, personalized experiences in Amazon Connect

Analytics

Amazon Connect tracks all interactions using contact records. Contact records are used for real-time and historical metrics reports. You can also use Amazon Kinesis to stream them to an AWS database like Amazon Redshift or Amazon Athena for BI analysis (Amazon QuickSight, or a third party such as Tableau). There are AWS CloudFormation templates available to set up this functionality for Amazon Redshift and Athena.

To perform analysis on your flow logs, you can set up an Amazon Kinesis stream to stream your flow log data from CloudWatch to a data warehouse service, such as Amazon Redshift. You can combine the flow log data with other Amazon Connect data in your warehouse, or run queries to identify trends or common issues with a flow.

For more information, see:

- Develop live media streaming in Amazon Connect
- Blog post: Recovering abandoned calls with Amazon Connect

Machine Learning (ML) and Artificial Intelligence (AI)

Amazon Connect uses the following services for ML/AI:

- Amazon Lex—Lets you create a chatbot to use as Interactive Voice Response (IVR). For more information, see Add an Amazon Lex bot to Amazon Connect.
- Amazon Polly—Provides text-to-speech in all flows. For more information, see Add text-to-speech to prompts in flow blocks in Amazon Polly and SSML tags supported by Amazon Connect.
- Amazon Transcribe—Grabs conversation recordings from Amazon S3, and transcribes them to text so you can review them.
- Amazon Comprehend—Takes the transcription of recordings, and applies speech analytics machine learning to the call to identify sentiment, keywords, adherence to company policies, and more.

Messaging services

Amazon Connect uses the following services for messaging:

- Amazon Pinpoint—Use as an outbound messaging trigger for events; for example, bulk messaging (such as outbound marketing campaigns). For more information, see this blog post: Using Amazon Pinpoint to send text messages in Amazon Connect.
- Amazon Simple Notification Service (Amazon SNS)—Use to send and receive SMS and other channel notifications. Amazon SNS is particularly useful for sending alerts and validations.
- Amazon Simple Email Service (Amazon SES)—Use to send validation e-mails, such as a password reset bot sending a confirmation of the transaction.

Security

Amazon Connect uses the following services for added security:

- AWS Identity and Access Management (IAM)—Use to manage permissions for users. Amazon Connect users require permission for services. For more information, see Identity and access management for Amazon Connect.
- AWS Directory Service—Amazon Connect supports user federation through the internal directory (created in the Amazon Connect instance), using Active Directory integration (MAD, ADFS) or SAML 2.0.

  For more information, see:

  - Plan your identity management in Amazon Connect
  - Blog post: Enabling federation with AWS Single Sign-On and Amazon Connect

Management

Amazon Connect uses the following services for monitoring usage:

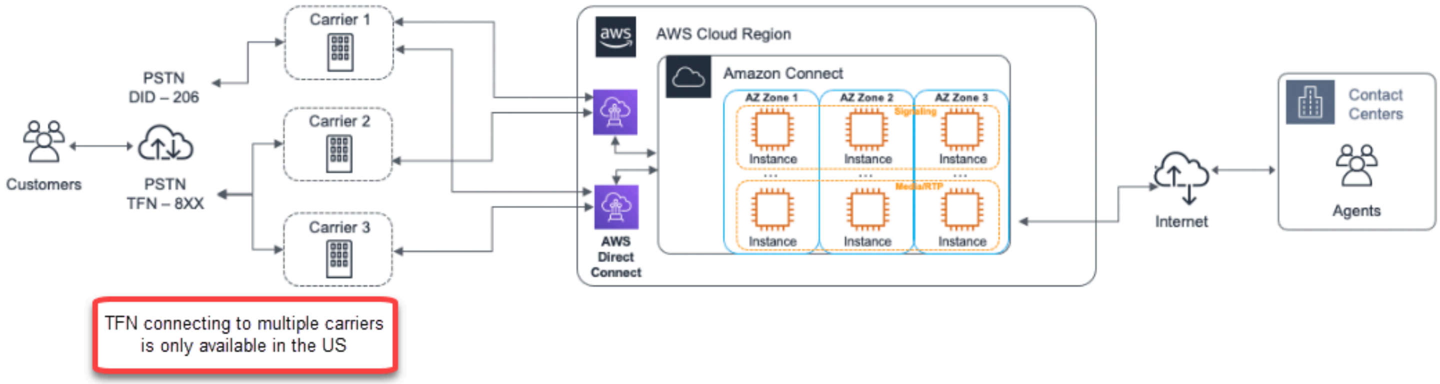
- Amazon CloudWatch—Collects logs, service metrics, performance metrics for Amazon Connect. For more information, see Monitoring your Amazon Connect instance using CloudWatch.
- AWS CloudTrail—Provides a record of Amazon Connect API calls.

  For more information about Amazon Connect and AWS CloudTrail, see Log Amazon Connect API calls with AWS CloudTrail.
- AWS CloudFormation—Amazon Connect supports using AWS CloudFormation for initiating an instance with all the supported channels enabled. For more information, see AWS::Connect::Instance.

Amazon Connect workload layers

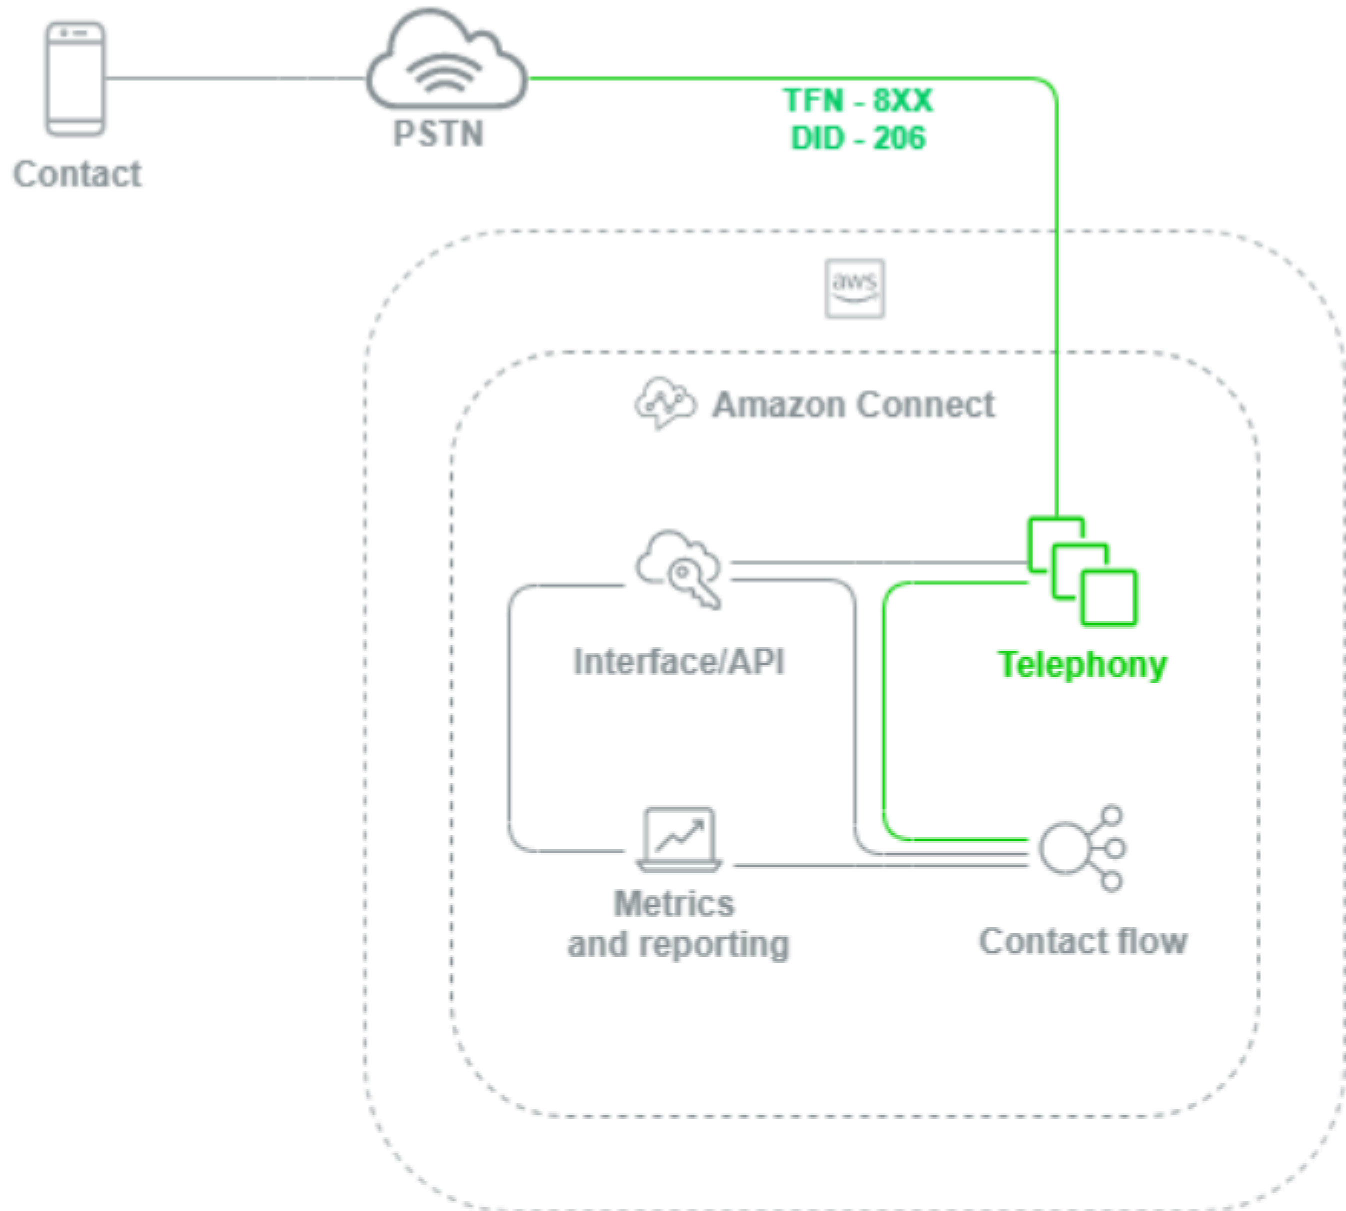
You can separate Amazon Connect workloads into the following layers: telephony, Amazon Connect interface/API, flows/IVR, agent workstation, and metric and reporting.

Telephony



> **Important**
>
> TFN connecting to multiple carriers is only available in the US.

Amazon Connect is integrated with multiple telephony providers with redundant dedicated network paths to three or more Availability Zones in every Region where the service is offered today. Capacity, platform resiliency, and scaling are handled as part of the managed service, allowing you to efficiently ramp from 10 to 10,000+ agents without worrying about the management or configuration of underlying platform and telephony infrastructure. Workloads are load balanced across a fleet of telephony media servers, allowing new updates and features to be delivered to you with no downtime required for maintenance or upgrades. If a particular component, data center, or an entire Availability Zone experiences failure, the affected endpoint is taken out of rotation, allowing you to continue to provide a consistent quality experience for your customers.



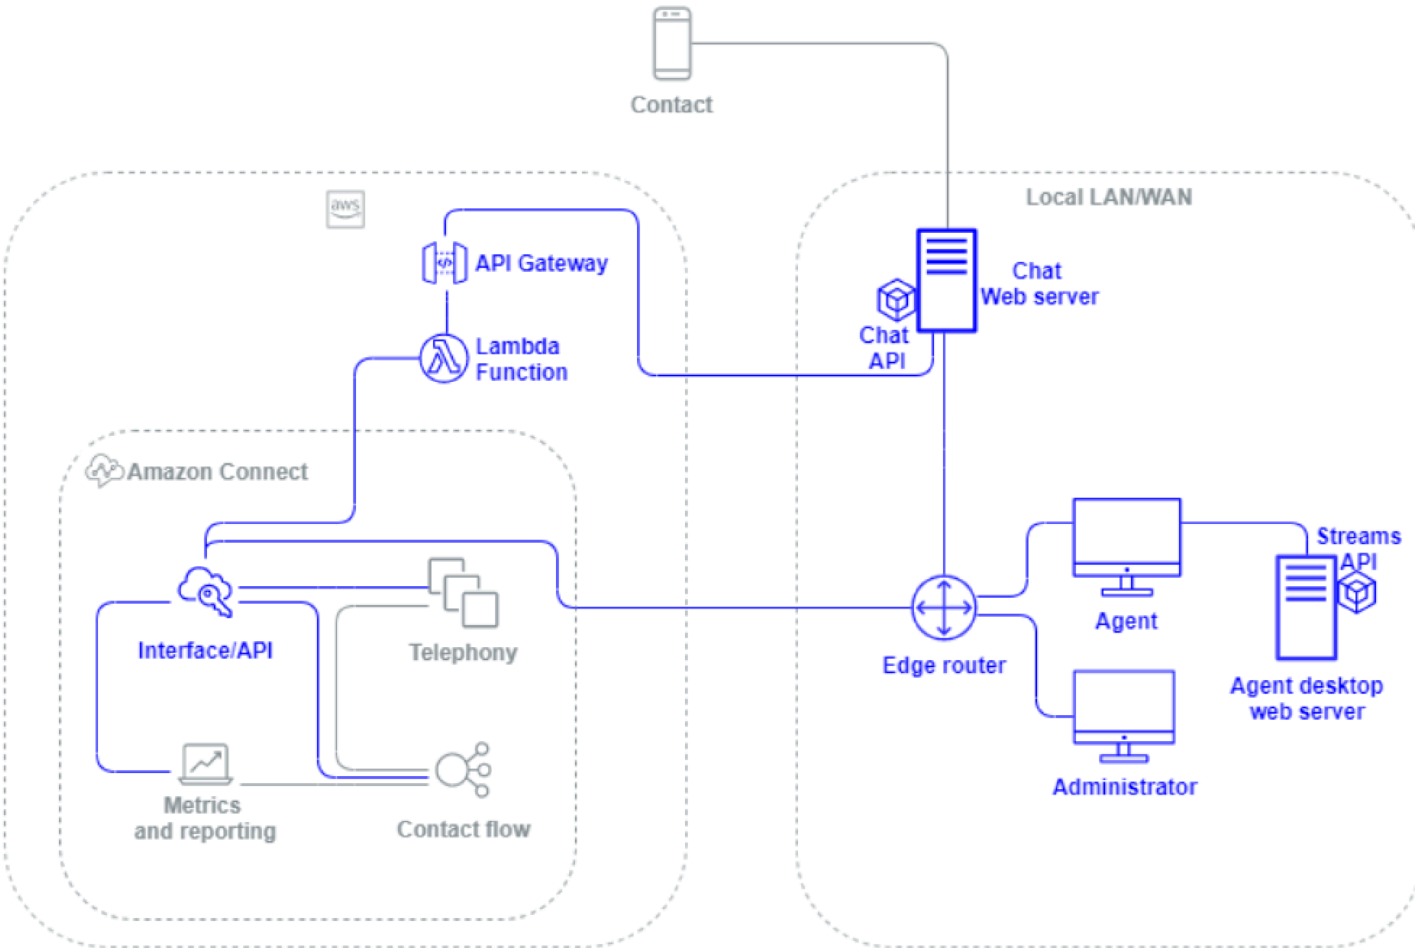
When a voice call is placed to an Amazon Connect instance, the telephony layer is responsible for controlling the endpoint that your customer calls into through their carrier, across the PSTN and into Amazon Connect. This layer represents the audio path established between Amazon Connect and the customer. Through the Amazon Connect interface layer, you can configure things like outbound caller ID, assign flow/IVRs to phone numbers, enable live media streaming, enable call recording, and the ability to claim phone numbers without any prior traditional telephony knowledge or experience. Additionally, when migrating workloads to Amazon Connect, you have the option to port your existing phone numbers by opening a support case in your AWS Management Console. You can also forward your existing phone numbers to numbers that you've claimed in your Amazon Connect instance until you are fully migrated.

Amazon Connect Interface/API

The Amazon Connect interface layer is the access point that your agents and contact center supervisors and administrators will use to access Amazon Connect components like reporting and metrics, user configuration, call recordings, and the Contact Control Panel (CCP). This is also the layer responsible for:

- Single Sign-On (SSO) integration user authentication
- Custom desktop applications created using the Amazon Connect Streams API that may provide additional functionality and/or integrate with existing Customer Relationship Management (CRM) systems including the Amazon Connect Salesforce CTI Adapter.
- Amazon Connect contact-facing chat interface
- Chat web server hosting the Amazon Connect Chat API
- Any Amazon API Gateway endpoints and corresponding AWS Lambda functions necessary to route chat contacts to Amazon Connect.

Anything your agents, managers, supervisors, or contacts use to access, configure, or manage Amazon Connect components from a web browser or API is considered the Amazon Connect interface layer.



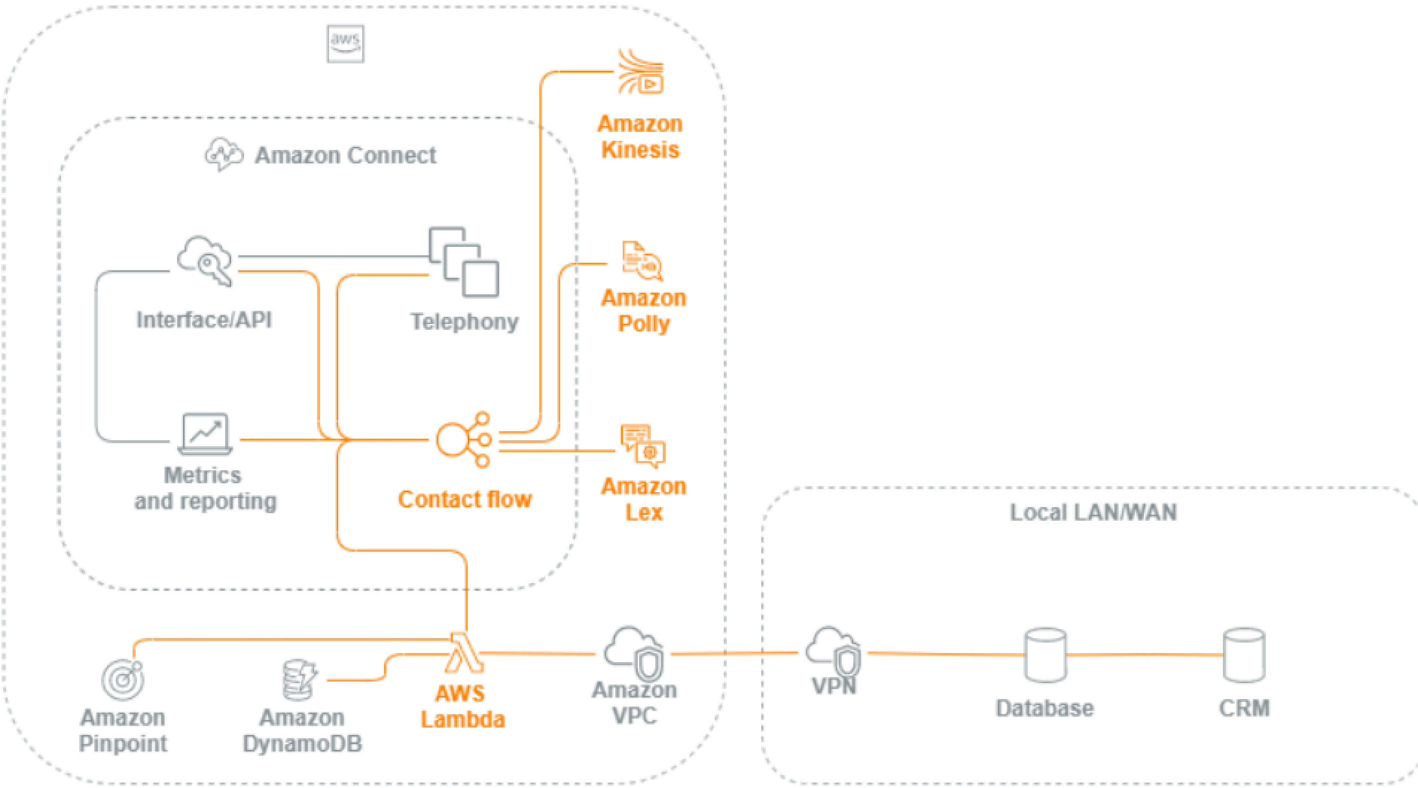
Flow / IVR

The Flow/IVR layer is the primary architectural vehicle for Amazon Connect and serves as the point of entry and first line of communication with customers reaching out to your contact center. After a customer contacts your Amazon Connect instance, a flow controls the interaction between Amazon Connect, the contact, and the agent, allowing you to:

- Dynamically invoke AWS Lambda functions to make API calls.
- Send real-time IVR and voice data to third-party endpoints through Amazon Kinesis.
- Access resources inside your VPC and behind your VPN.
- Call other AWS services like Amazon Pinpoint to send SMS messages from the IVR.
- Perform data dips to database like Amazon DynamoDB to service your contacts.
- Call Amazon Lex directly from the flow to invoke a Lex bot for Natural Language Understanding (NLU) and Automatic Speech Recognition (ASR).

- Play dynamic and natural Text-to-Speech through Amazon Polly, and use SSML and Neural Text-to-Speech (NTTS) to achieve the most natural and human-like text-to-speech voices possible.

Flows enable you to dynamically prompt contacts, collect and store contact attributes, and route appropriately. You can assign a flow to multiple phone numbers, and manage and configure it through Amazon Connect.

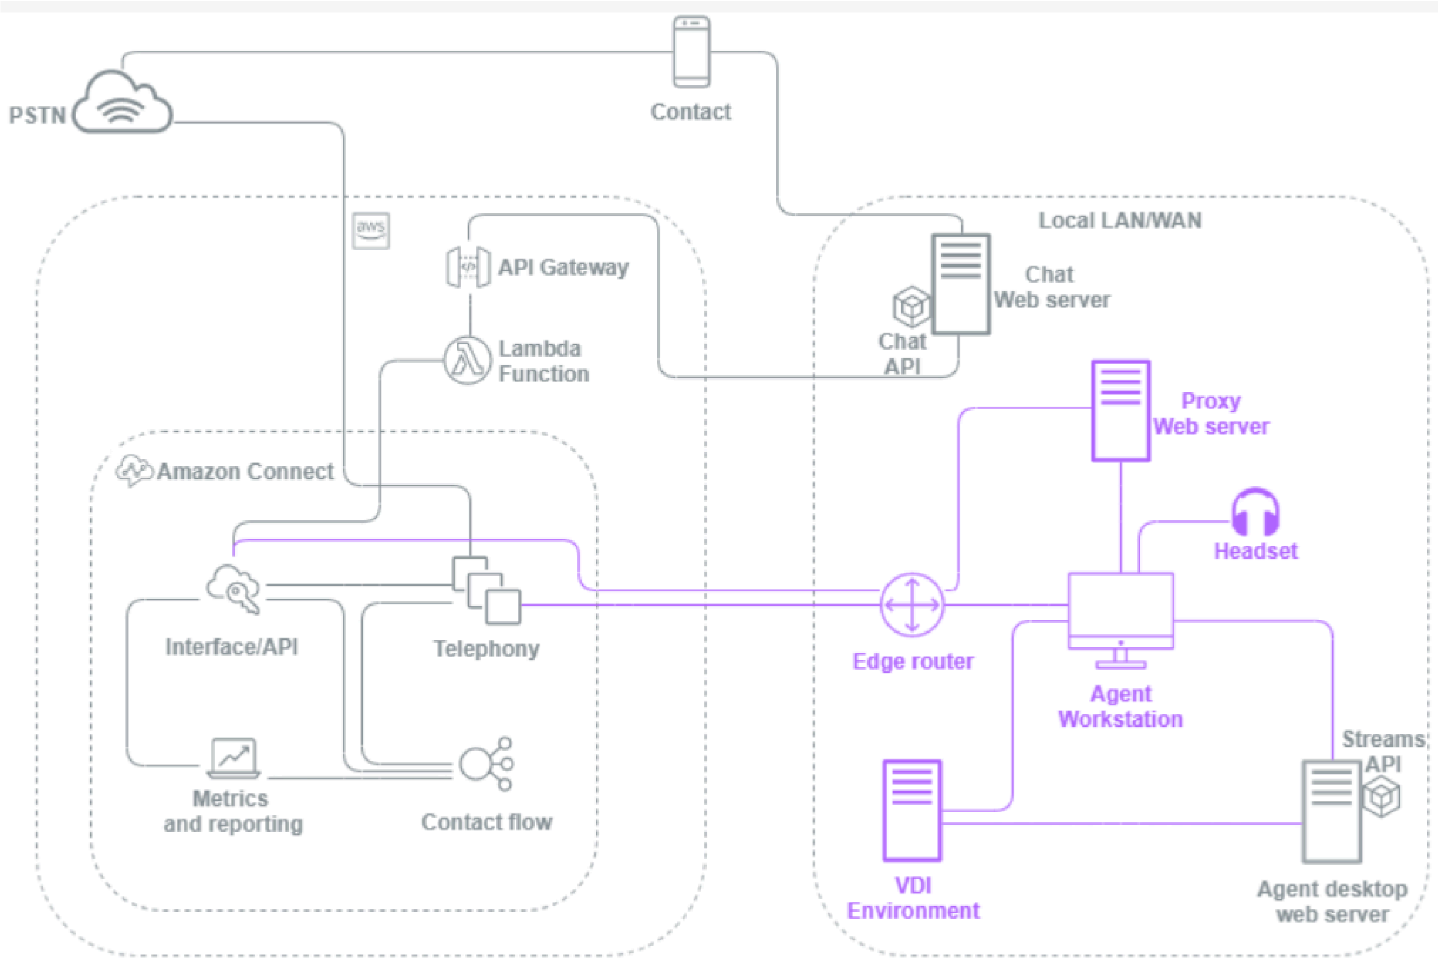


Agent workstation

The agent workstation layer is not managed by AWS. It consists of any physical equipment and third-party technologies, services, and endpoints that facilitate your agent's voice, data, and access the Amazon Connect interface layer. Components in the agent workstation layer include:

- The Contact Control Panel (CCP) agent hardware
- Network path
- Agent headset or handset
- VDI environment
- Operating system and web browser
- Endpoint security

- All networking components and infrastructure
- Internet Service Provider (ISP) or AWS Direct Connect dedicated network path to AWS.
- All other aspects of your agent's operating environment including power, facilities, security, and ambient noise.

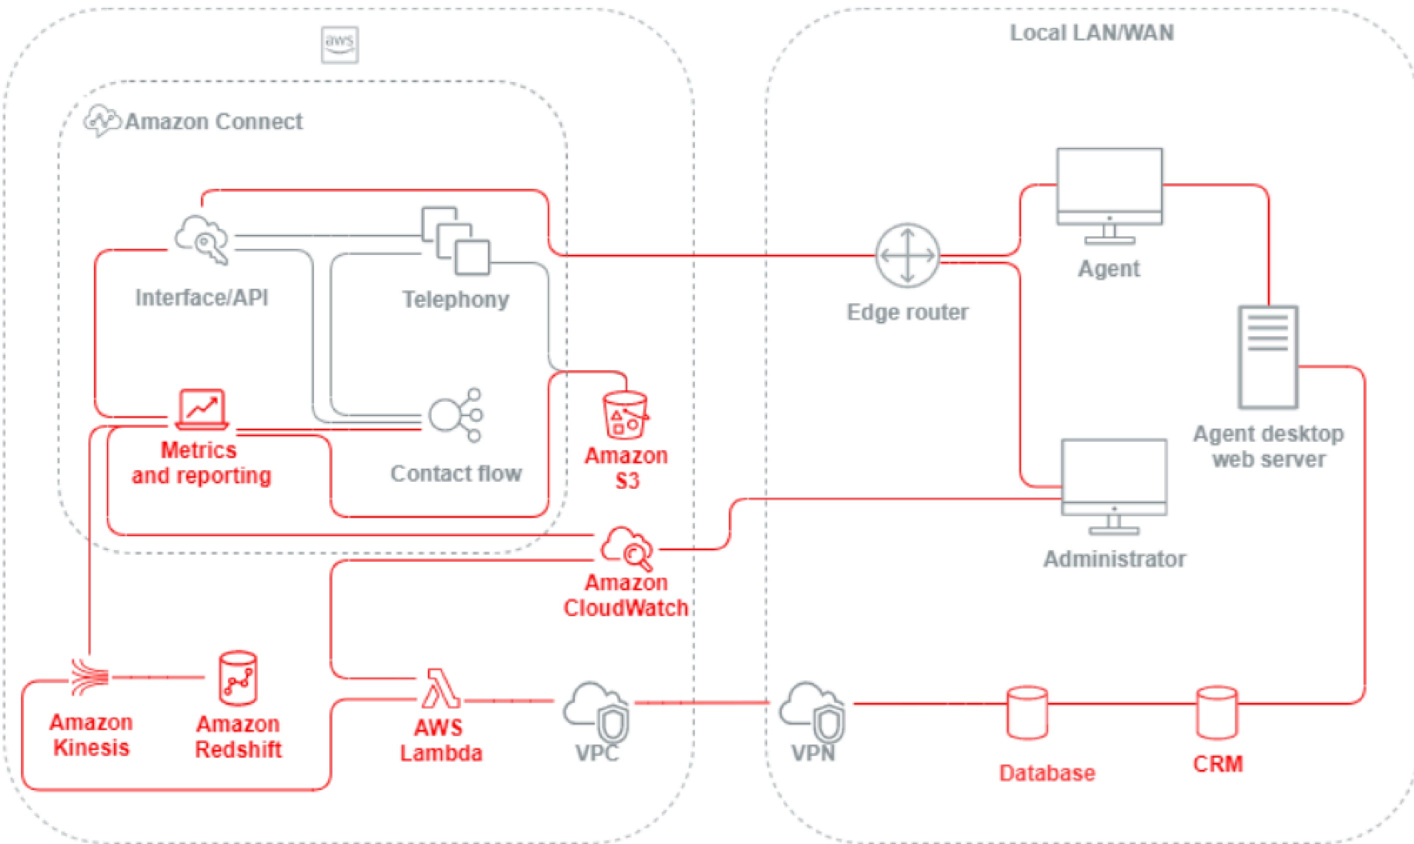


Metric and reporting

The metric and reporting layer includes the components responsible for delivering, consuming, monitoring, alerting, or processing real-time and historical metrics for your agents, contacts, and contact center. This includes all native and third-party components responsible for facilitating the processing, transmission, storage, retrieval, and visualization of real-time or historical contact center metrics, activity audit, and monitoring data. For example:

- Call recordings and scheduled reports stored in Amazon Simple Storage Service (Amazon S3).

- Contact records that you can export to AWS database services like Amazon Redshift or your own on-premises data warehouse with Amazon Kinesis.
- Real-time dashboards you create with Amazon OpenSearch Service and Kibana.
- Amazon CloudWatch metrics generated that you can use to set alarms based on static thresholds, set up Amazon SNS notifications to alert to your administrators and supervisors, or launch AWS Lambda functions in response to the event.



Scenario and deployment approaches in Amazon Connect

Amazon Connect offers self-service configuration and enables dynamic, personal, and natural customer engagement at any scale with a variety of migration and integration options. In this section, we explain the following scenarios and deployment approaches to consider when designing a workload for Amazon Connect:

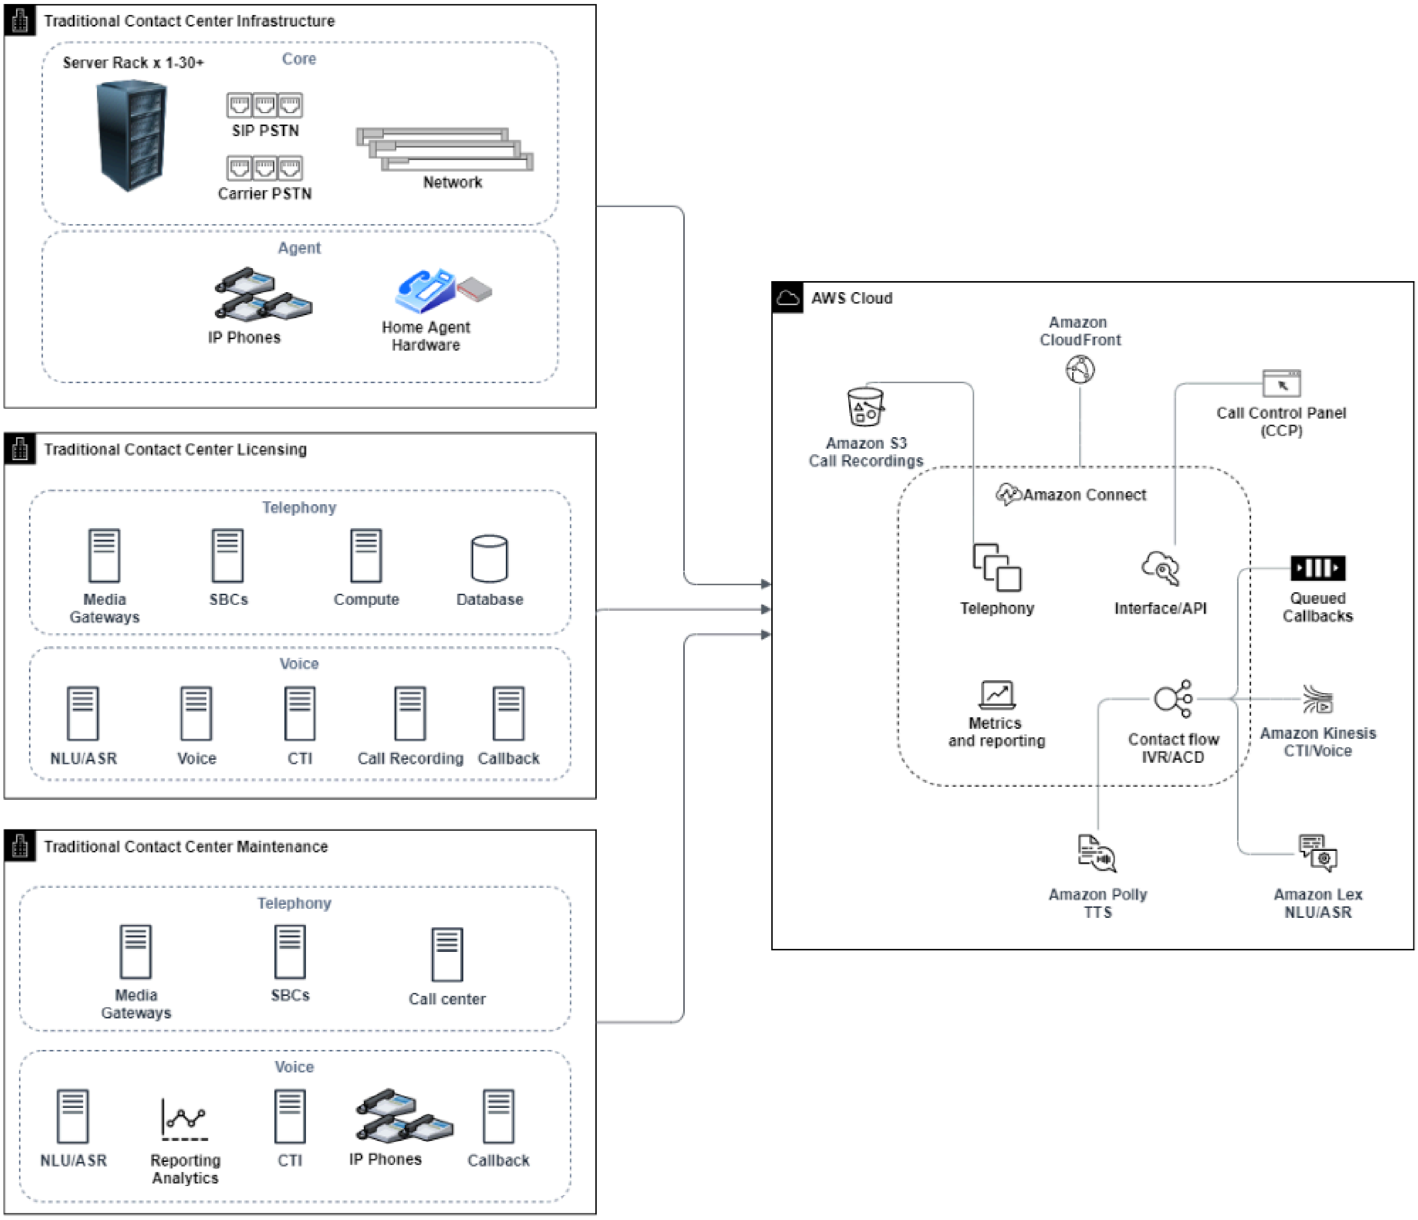
- Traditional contact center
- Inbound
- Outbound

- Hybrid contact center
- Legacy contact center migration
- Virtual desktop infrastructure (VDI)

Traditional contact center

The traditional contact center requires a significant telephony, media, networking, database, and compute infrastructure footprint that can span multiple vendors and data center locations to service contacts. Each individual solution and vendor have unique hardware, software, networking, and architectural requirements that have to be met while resolving versioning, compatibility, and licensing conflicts.

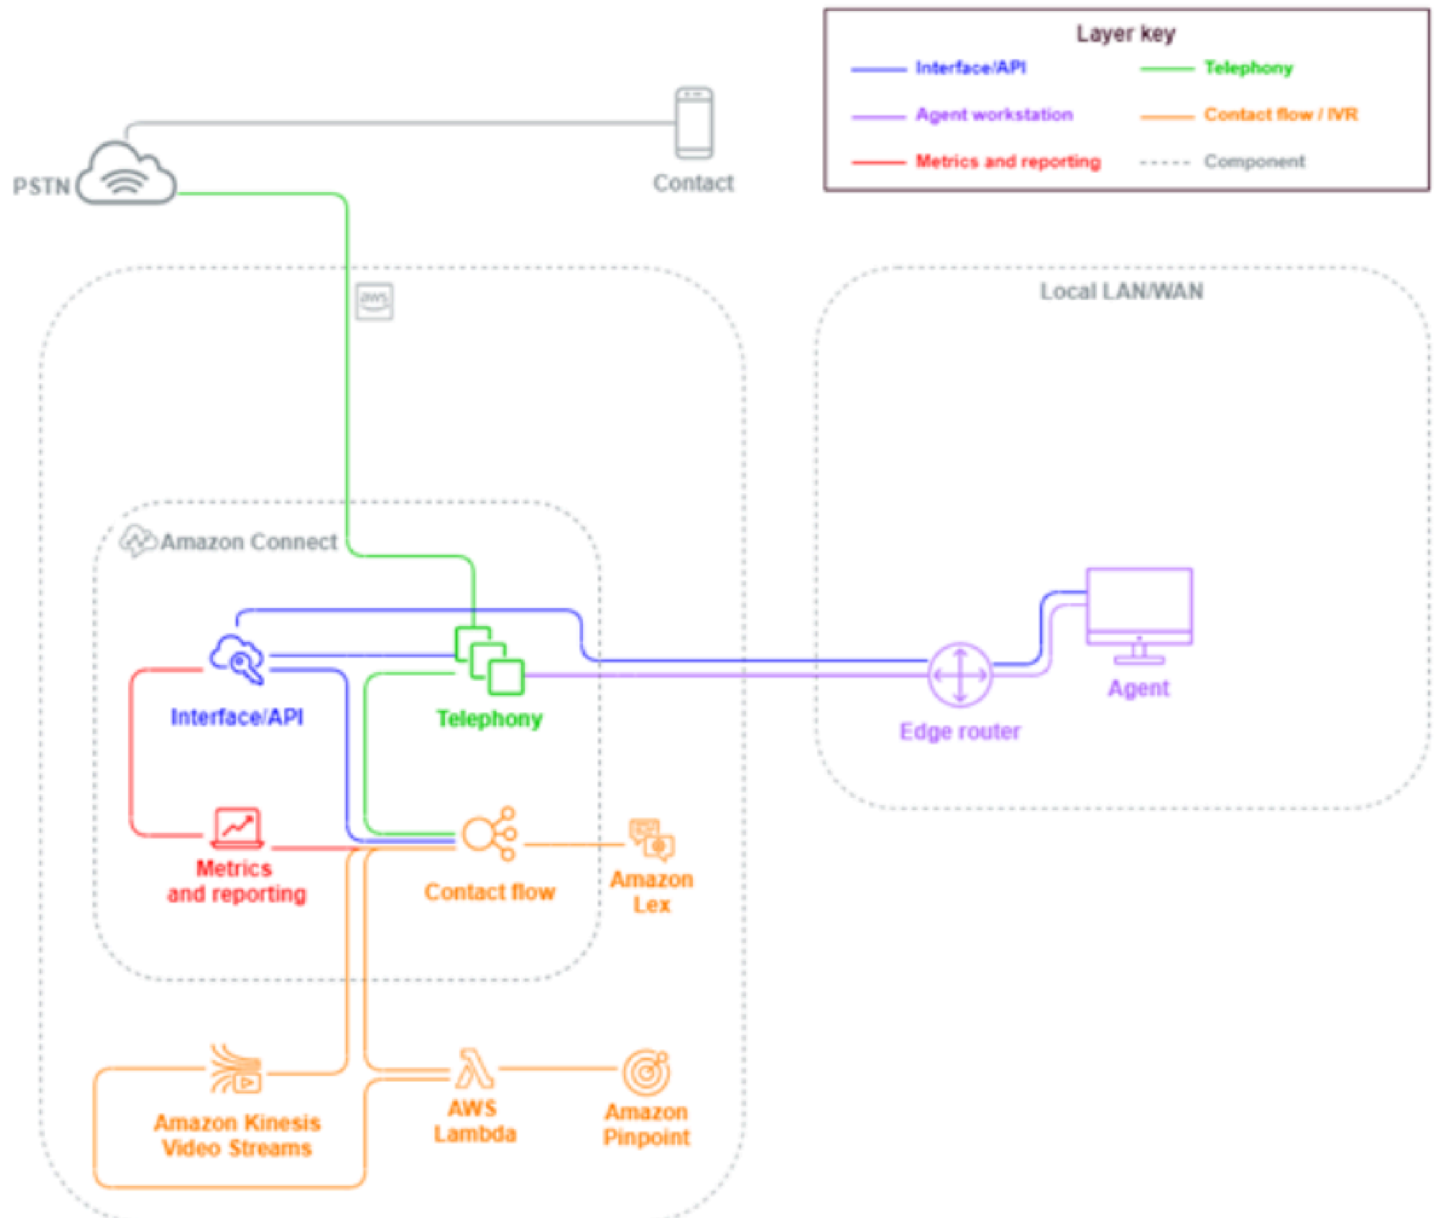
It is common to have separate vendors and infrastructure requirements for local and remote agent hardware and VPN connectivity, Text-To-Speech (TTS), Automatic Call Distribution (ACD), Interactive Voice Response (IVR), voice audio and data, physical desk phones, voice recording, voice transcriptions, chat, reporting, database, Computer Telephony Integration (CTI), Automatic Speech Recognition (ASR), and Natural Language Understanding (NLP). Your contact center architecture and infrastructure becomes more complicated when you consider multi-stage development, quality assurance, and test environments.



A typical Amazon Connect deployment solves or reduces many of the challenges associated with versioning, compatibility, licensing, contact center telephony infrastructure, and maintenance. It gives you the flexibility to create instances in new locations in minutes and migrate components individually, or in parallel, to best meet your individual business objectives. You can use flows for your IVR/ACD, have voice and data delivered through a supported web browser to your agent's softphone, port your existing phone numbers, redirect softphone audio to an existing desk phone, invoke an Amazon Lex bot natively within your flow for ASR and NLP, and use the same flow for chat and voice. You can use Amazon Connect Contact Lens to automatically generate voice transcriptions, perform key word identification and sentiment analysis, and categorize contacts. For agent CTI data and real-time voice streaming, you can use Amazon Connect Agent Event Streams and Kinesis Video Streams. You can also create multi-stage development, quality assurance, and test environments at no additional cost and only pay for what you use.

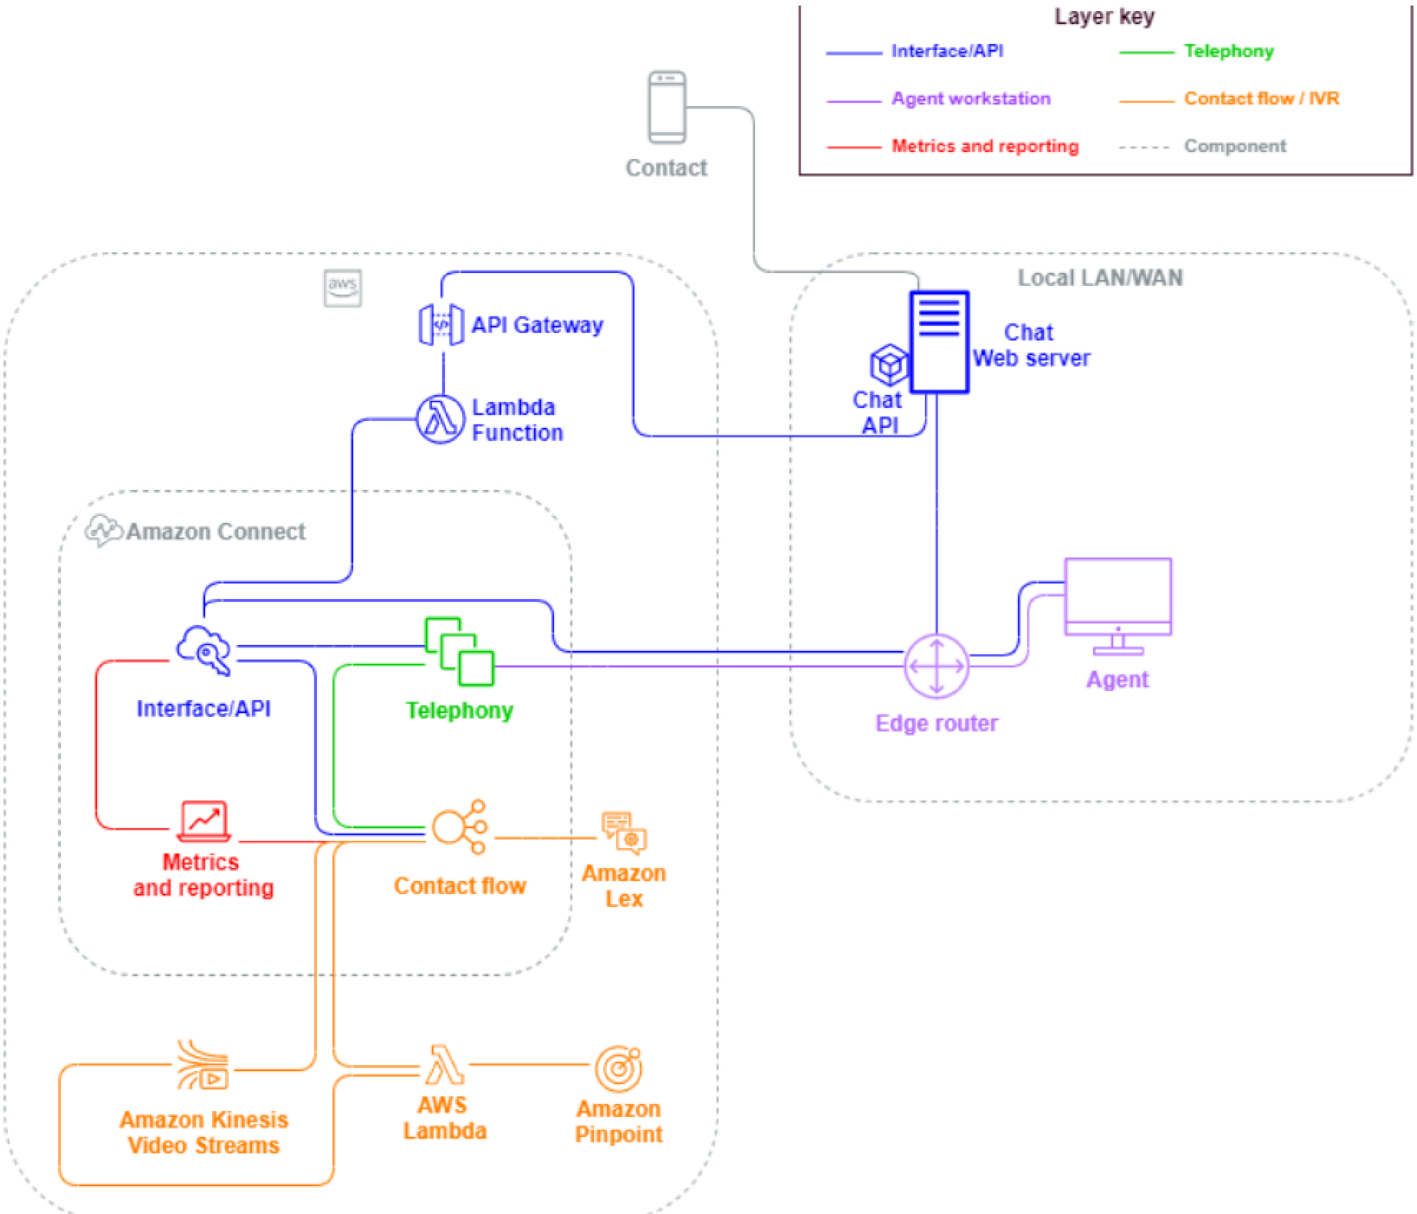
Inbound

Inbound is a contact center term used to describe a communication request initiated by a contact to the center. Contacts can reach your Amazon Connect instance for inbound self-service or to speak with a live agent in a variety of ways, including voice and chat. Voice contacts go through the PSTN and are routed to the Amazon Connect Instance telephony entry point through the phone number claimed in your instance. You can reserve a phone number with Amazon Connect directly, port your existing phone number, or forward voice contacts to Amazon Connect. Amazon Connect can provide local and toll-free numbers in all Regions where the service is supported.



When a phone call is placed to a number claimed in or ported to your Amazon Connect instance, the flow associated with the called number will be invoked. You can define the flow using flow blocks that can be configured with no coding knowledge required. The flow determines how the contact should be processed and routed, optionally prompting the contact for additional information to assist in routing decisions, storing those attributes to the contact details, and, if necessary, routing that contact to an agent with all of the call details and transcripts gathered along the way. Through the flow, you can invoke AWS Lambda functions to query customer information, call other AWS services like Amazon Pinpoint to send SMS text messages, and use native AWS service integrations including Amazon Lex for NLU/NLP and Kinesis Video Streams for real-time streaming of voice calls.

If an inbound contact needs to reach an agent, the contact is put into a queue and routed to an agent when they change their status to Available, according to your routing configuration. When the available agent's contact is accepted manually or through auto-accept configuration, Amazon Connect connects the contact with the agent.



When an inbound contact comes from a browser or mobile app request for a chat session, the request is routed to a web service or Amazon API Gateway endpoint that calls the Amazon Connect chat API to invoke the flow configured in your request. You can use the same flows for chat and voice, where the experience is managed and routed dynamically, based on the logic defined in the flow.

Outbound

Amazon Connect allows you the ability to programmatically make outbound contact attempts to local and international endpoints, reduce agent set-up time between contacts, and improve agent productivity. By using the Amazon Connect Streams API and StartOutboundVoiceContact, you can develop your own outbound solution or take advantage of existing partner integrations that work with your CRM data to create dynamic, personalized experiences for your contacts and empowering your agents with the tools and resources they need to service those contacts.

Outbound campaigns are typically driven by contact data exported from CRMs and separated into contact lists. Those contacts are prioritized and either delivered to the agents to initiate after a period of preview or programmatically contacted using the Amazon Connect Outbound API, driven by your flow logic, and connecting to agents as needed. Typical outbound contact center use cases include fraud and service alerts, collections, and appointment confirmations.

Hybrid

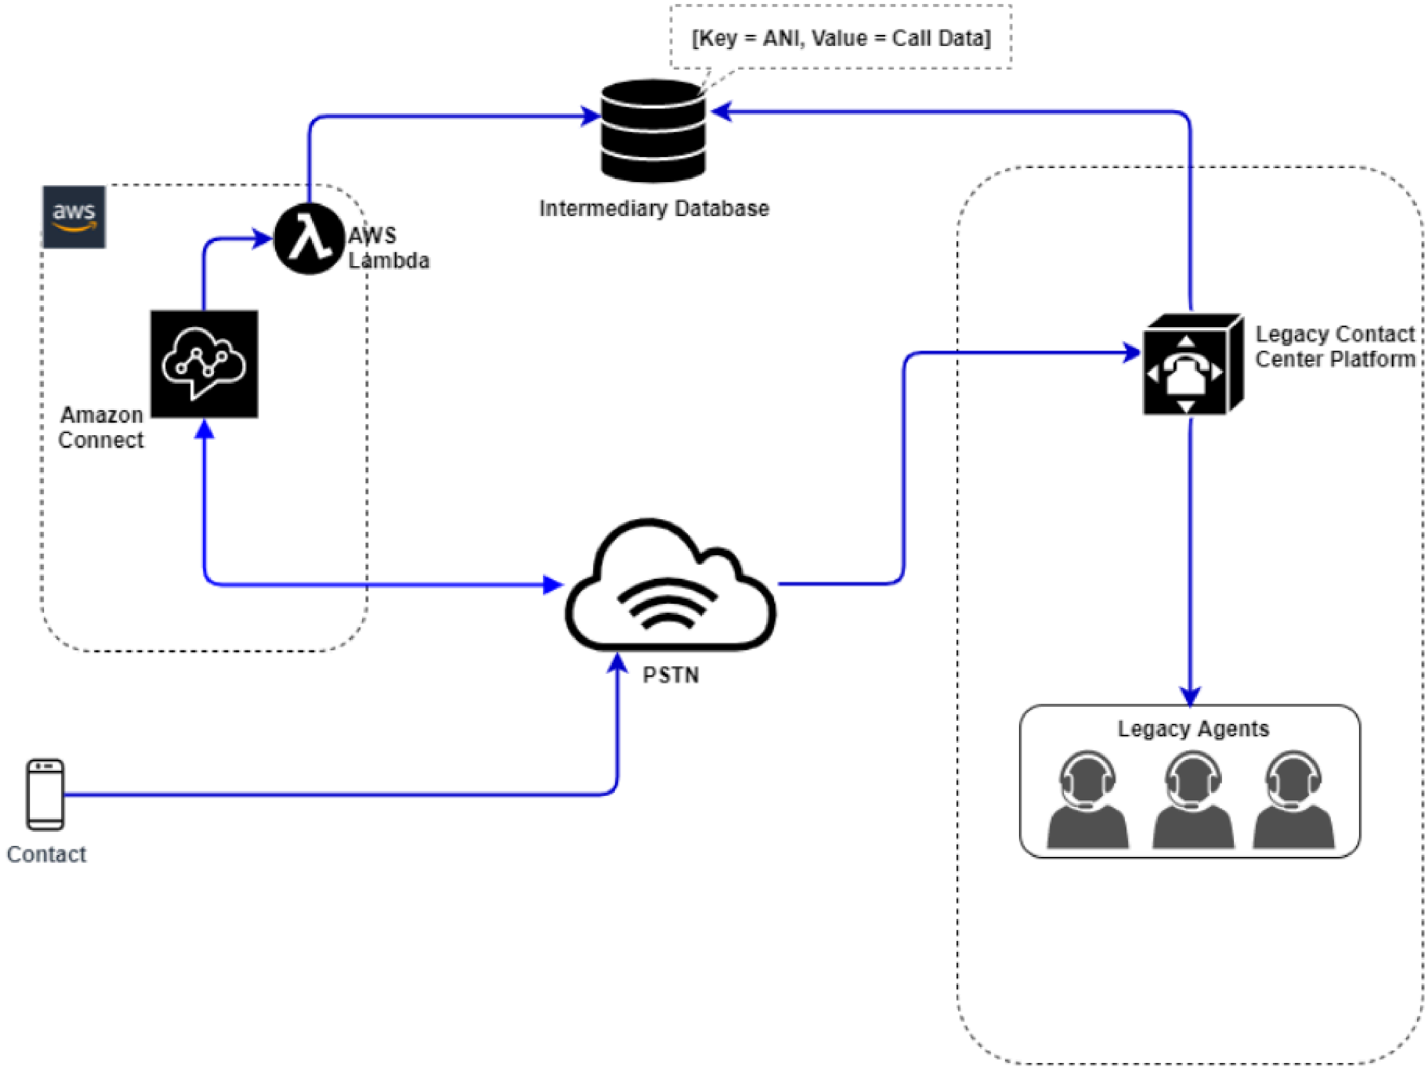
If you have requirements to transfer contacts between Amazon Connect and legacy contact center technologies, you can use a Hybrid model architecture to pass contact data with the transfer. For example, a sales business unit on a legacy contact center platform may need to transfer a call to the service business unit that's been migrated to Amazon Connect. Without a Hybrid architecture, call details will be lost and may require the contact to repeat information. This could increase handle times and may result in contact calling again for the same purpose.

Hybrid architectures require you to claim as many phone numbers as your expected maximum concurrent contacts and an intermediary state database accessible by both Amazon Connect and your legacy contact center platform. When a transfer is required to the other platform, you will use one of these phone numbers as a unique identifier, flag it as in-use in your intermediary database, insert your contact details, and use that number as your ANI or DNIS when you transfer the contact. When the contact is received by the other contact center platform, you will query the intermediary database for the contact details based on the unique ANI or DNIS you used. Hybrid architectures are typically used as an interim migration step because of the additional cost and complexity associated.

IVR-only

You may choose to use Amazon Connect to drive the contact's IVR experience while your agent population remains on your legacy contact center platform. With this approach, you can use

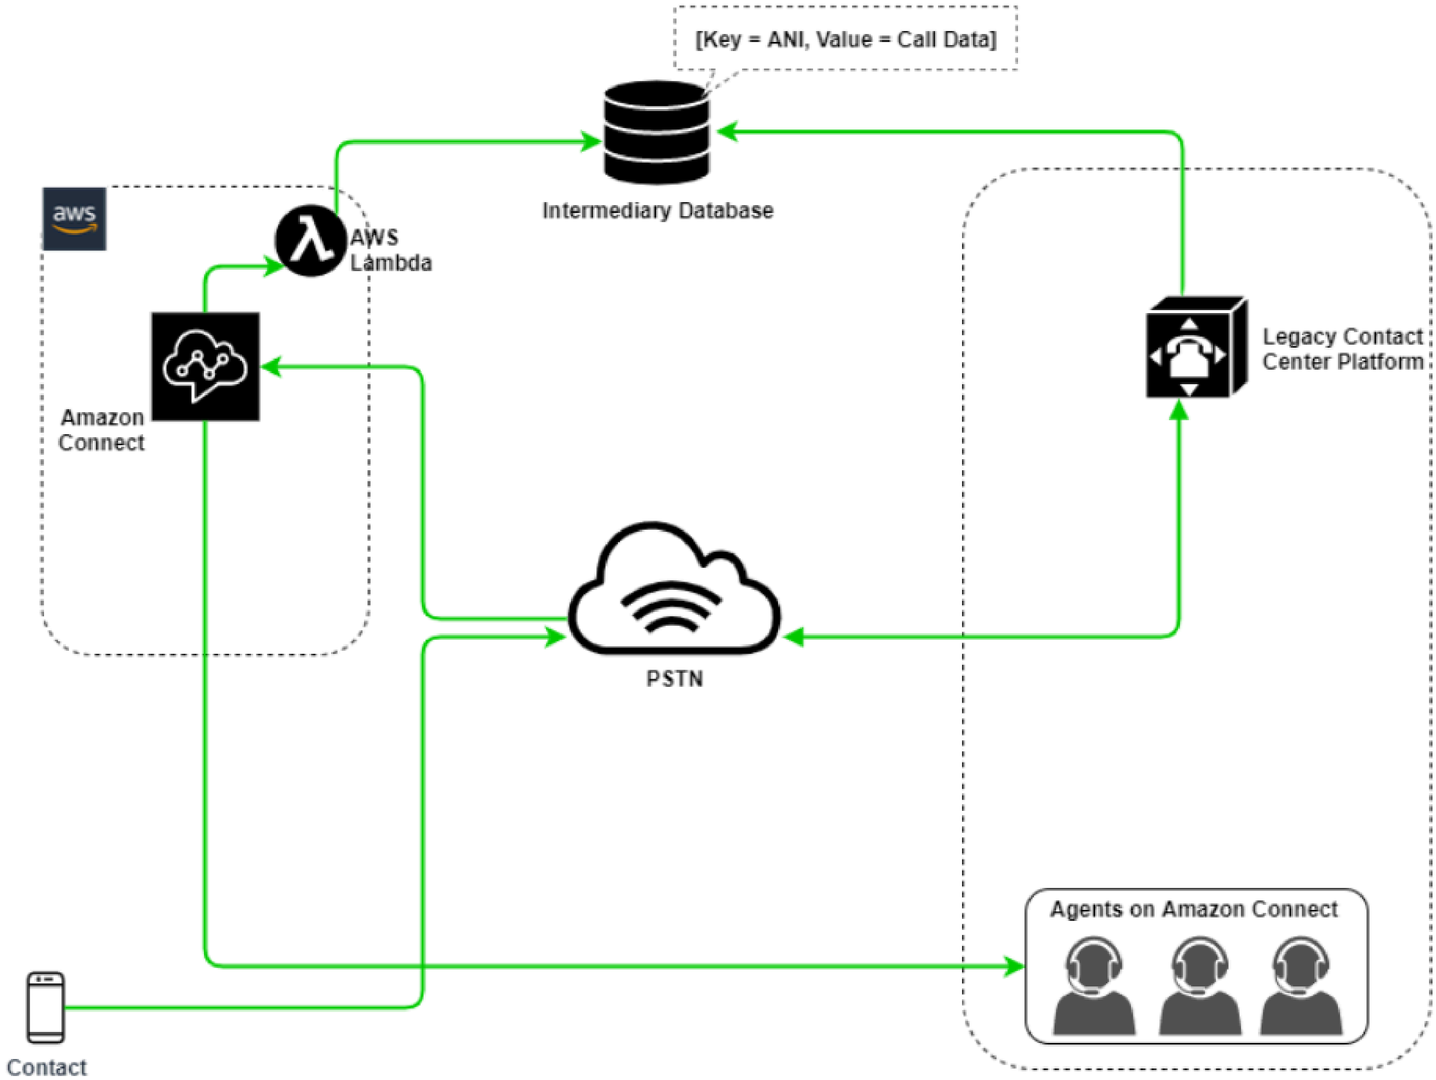
Amazon Connect flows to drive self-service and routing logic, and, if necessary, transfer the contact to the target agent or agent queue on your legacy contact center platform.



In this diagram, the contact dials a phone number claimed in your Amazon Connect instance for service. If they need to be transferred to an agent on your legacy contact center platform, an AWS Lambda function is invoked to query an available unique phone number, flag it as in-use, and write relevant contact details to an intermediary database. The contact is then transferred to the legacy contact center platform with the phone number returned from the Lambda function. The legacy contact center will then perform a query on the intermediary database for the contact details, route accordingly, and reset the contact data in the intermediary database, allowing the phone number to be used again.

Agent-only

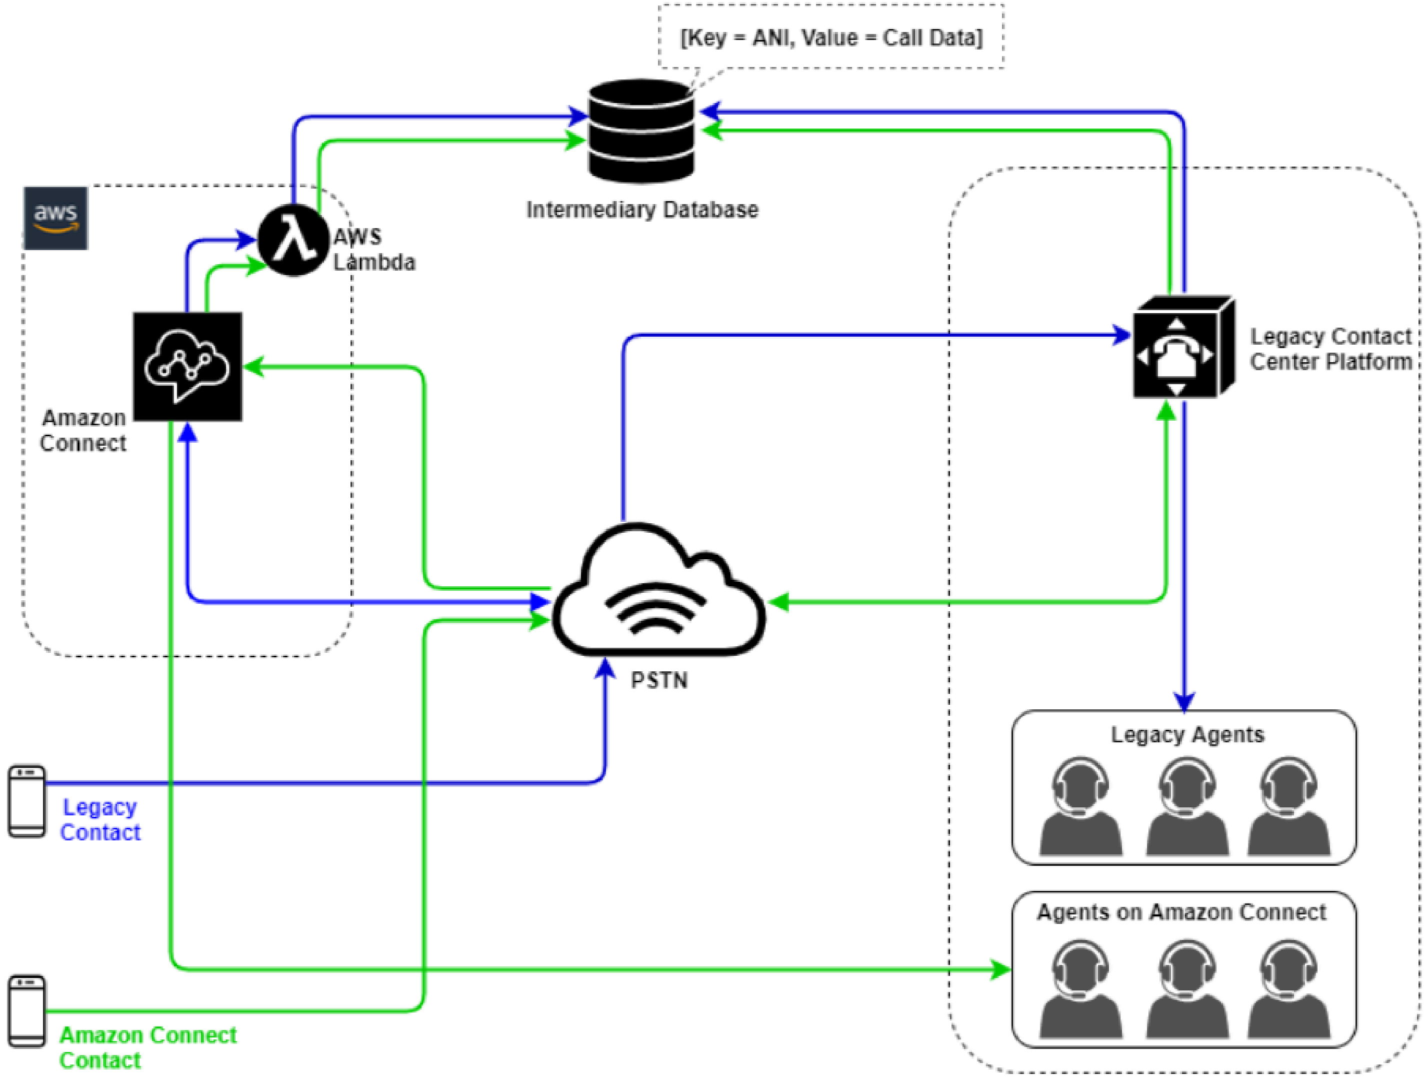
With this approach, your legacy contact center IVR drives the contact's IVR self-serve and routing logic, and, if necessary, transfers the contact to Amazon Connect to route to your agent population.



In this diagram, the contact dials a phone number claimed with your legacy contact center platform. If they need to be transferred to an agent on Amazon Connect, the legacy contact center platform will query an available unique phone number, flag it as in-use, and write relevant contact details to an intermediary database. The contact will then be transferred to Amazon Connectwith the phone number returned by the legacy contact center's query. Amazon Connect will then query the contact details from the intermediary database using AWS Lambda, route accordingly, and reset the contact data in the intermediary database, allowing the phone number to be used again.

Mixed

In this scenario, you may have your IVR and agents operating in parallel on Amazon Connect and your legacy contact center platform to allow for site, agent group, or line-of-business migrations.



Legacy contact center migration

When you are evaluating Amazon Connect for new or existing workloads, there are several strategies you can consider. For situations that require contact details to be included when contacts are transferred between Amazon Connect and your legacy contact center solution, a Hybrid model architecture will be required until the migration is complete. The approaches described in this section allow you to move specific lines of business in phases, manage training and support, and mitigate risks associated with change.

New workload

You may decrease risk associated with changes to existing business units and increase flexibility and digital innovation potential by adopting a net new workload on Amazon Connect. Net new workloads that do not require the Hybrid model architecture are less complex, are not affected by change in business process or agent routine, and have a faster time to market. Adopting a net new workload allows you to take advantage of usage-based, pay-as-you-go pricing. Your contact center resources are available to create a new experience for their end users, test and implement it to evaluate the platform, gain confidence, and build the skills and operational mechanisms to prepare for larger migration across existing workloads.

IVR First

You may choose to use Amazon Connect to drive the contact's IVR experience while your agent population remains on your legacy contact center platform. With this approach, you can use Amazon Connect Flows to drive self-service and routing logic, and, if necessary, transfer the contact to the target agent or agent queue on your legacy contact center platform.

IVR Last

With this approach, your legacy contact center IVR drives the contact's IVR self-serve and routing logic, and, if necessary, transfers the contact to Amazon Connect to route to your agent population.

Line of business segmentation

If your lines of business have separate IVRs or don't require contact transfers to legacy contact center platforms, you may want to consider a line of business migration approach. For example, selecting your service desk for internal support as your first line of business to migrate. After migrating your service desk IVR and agent population to Amazon Connect, you may choose to forward your existing contact to Amazon Connect, porting the endpoint after testing and business validation is completed.

Site or agent group segmentation

If your contact center has a global footprint, services contacts from multiple countries, or is managed independently by a respective geography or location, you may want to consider a migration approach based on a physical site or geography of agents. Each agent population and/or geography can have its own unique requirements and considerations that may not apply globally.

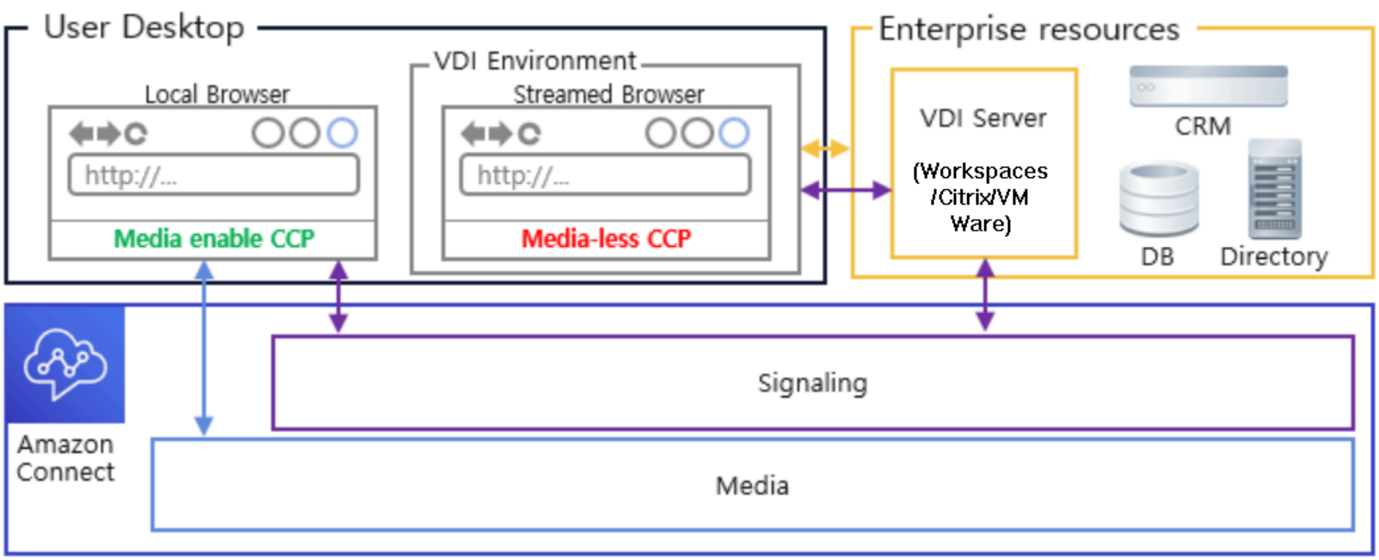
Approaching your migration this way will allow each site or agent group to gain the skills they need to continue to operate independently before moving onto the next.

Virtual desktop infrastructure (VDI)

While you can use the Amazon Connect Contact Control Panel (CCP) within Virtual Desktop Infrastructure (VDI) environments, it will add another layer of complexity to your solution that warrants separate POC efforts and performance testing to optimize. The configuration/support/optimization is best handled by your VDI support team and the following deployment models are the most commonly implemented.

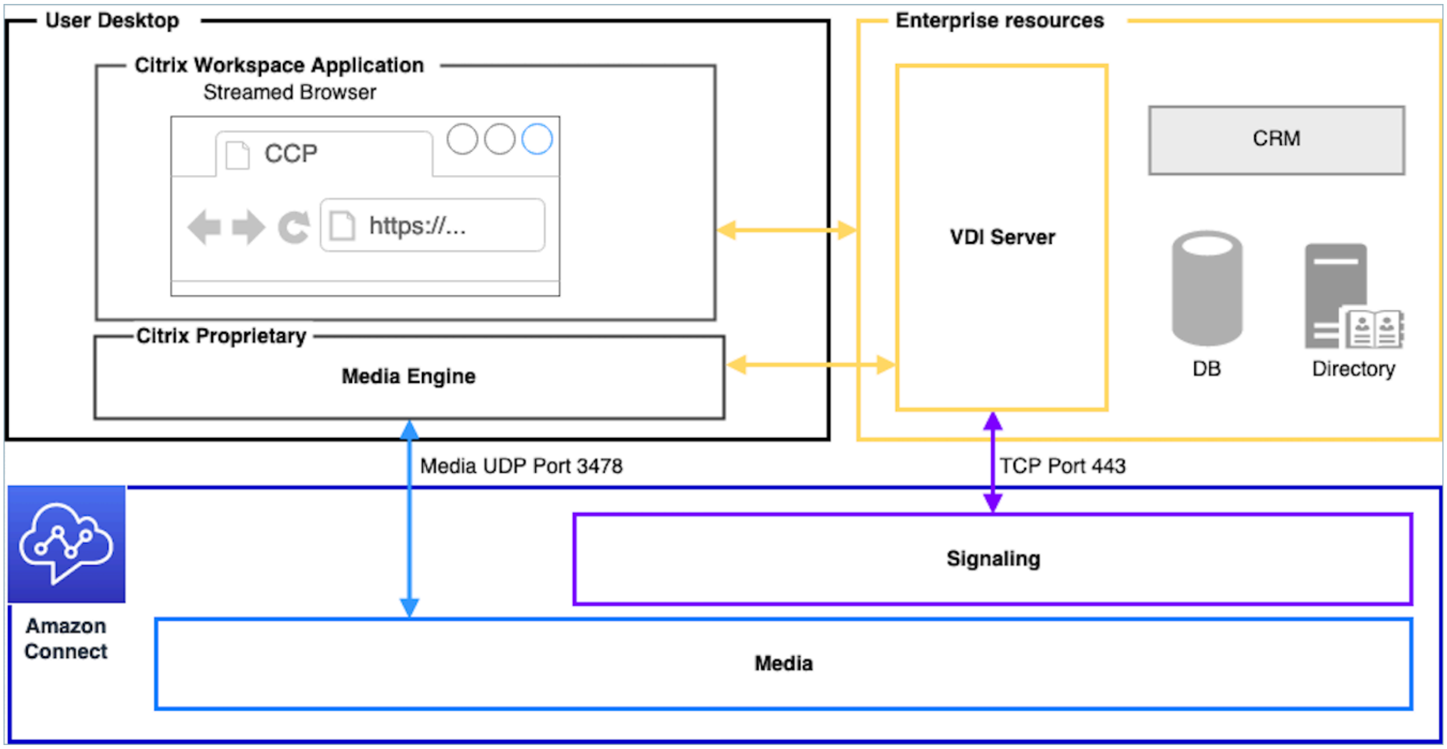
VDI client with local browser access

You can build a custom CCP with the Amazon Connect Streams API by creating a CCP with no media for call signaling. This way, the media is handled on the local desktop using standard CCP, and the signaling and call controls are handled on the remote connection with the CCP with no media. The following diagram describes that approach:



Citrix VDI with Amazon Connect audio optimization

If you use Citrix Virtual Desktop Infrastructure (VDI) environment, you can build a custom CCP with the Amazon Connect RTC JavaScript library which integrates with Citrix United Communications SDK (ucsdk) and automatically redirects the media from your local desktop to Amazon Connect. This enables your agents to use Citrix VDI client applications, such as Citrix Workspaces, to connect to their custom agent applications or custom CCPs. This removes the need to develop and manage a separate agent application, like dual-CCPs, for audio media redirection for their Citrix environments. The following diagram describes that approach:

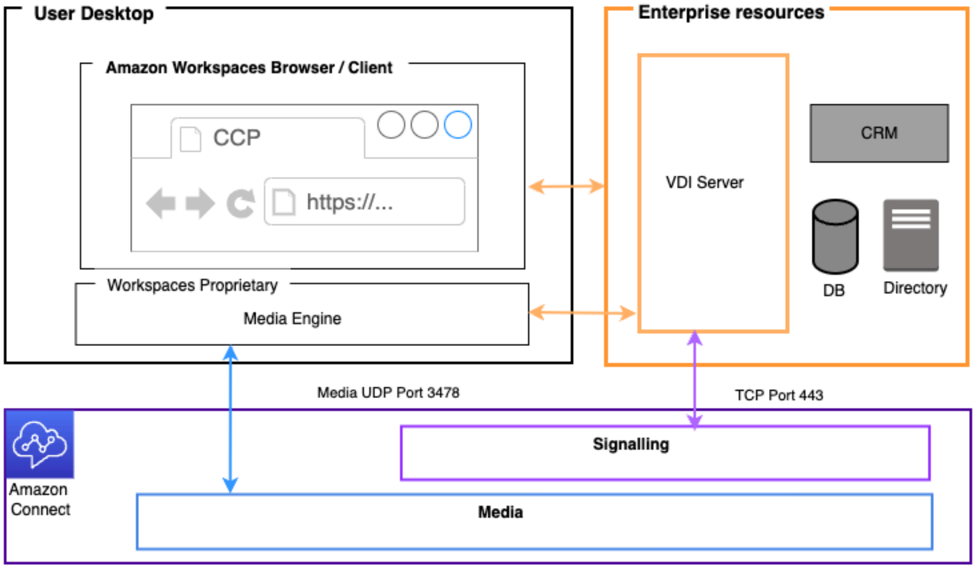


Note

This solution requires you to allow WebRTC signaling traffic between your VDI server and Amazon Connect, and the media connection between the agent's desktop and Amazon Connect. For more information, see the [Set up your network to use the Amazon Connect Contact Control Panel (CCP)]() documentation.

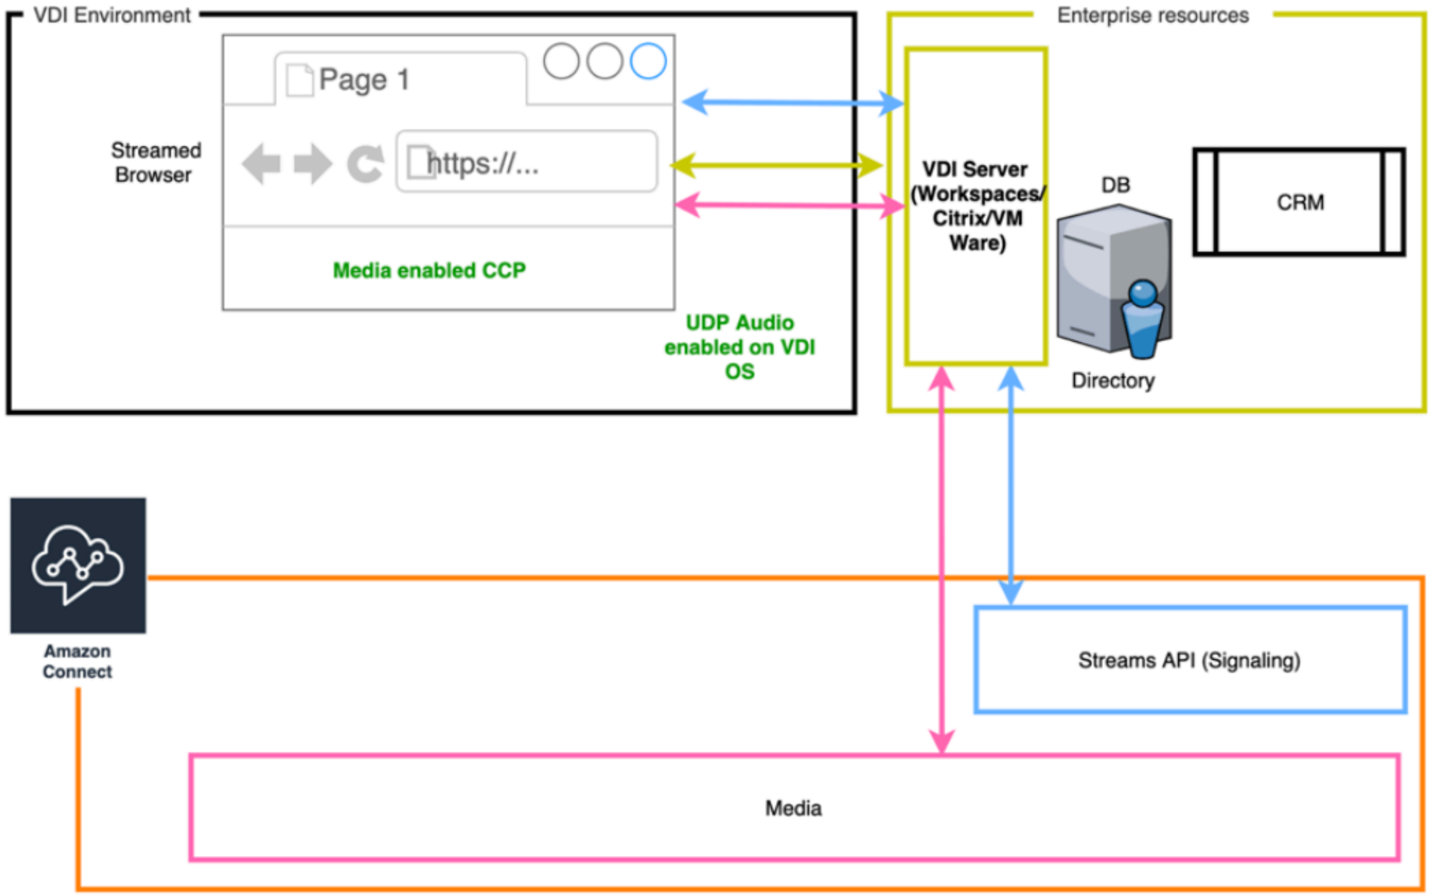
Amazon WorkSpaces VDI with Amazon Connect audio optimization

By using Amazon WorkSpaces, a Virtual Desktop Infrastructure (VDI) environment, you have the capability to create a customized Contact Control Panel (CCP) by leveraging the Amazon Connect Real-Time Communications (RTC) JavaScript library. This library seamlessly integrates with the Amazon WorkSpaces SDK, enabling automatic media redirection from your local desktop to Amazon Connect. This eliminates the need to develop and manage a separate agent application, such as dual-CCPs, specifically for audio media redirection within their WorkSpaces environments. The following diagram illustrates this approach:



VDI client without local browser access

Sometimes the VDI client does not have access to a local browser. In this scenario, you can create a single CCP instance with media run from the VDI server allowing access to enterprise resources. For this deployment model UDP audio is usually enabled on the VDI OS. This deployment model requires extensive testing to calibrate the different VDI server parameters to optimize quality of experience:



Operational excellence in Amazon Connect workloads

Operational excellence includes the ability to run and monitor systems to deliver business value and continually improve supporting processes and procedures. This section consists of design principles, best practices, and questions surrounding the operational excellence of Amazon Connect workloads.

Prepare

Consider the following areas to prepare for an Amazon Connect workload.

AWS account

With AWS Organizations, you can set up multiple AWS accounts for each level of your development, staging, and quality assurance environments. This allows you to centrally govern your environment as you grow and scale your workloads on AWS. Whether you are a growing startup or a large enterprise, Organizations helps you to centrally manage billing; control access, compliance, and security; and share resources across your AWS accounts. This is the starting point for consuming AWS services along with a cloud adoption framework.

Region selection

Amazon Connect Region selection is contingent upon data governance requirements, use case, services available in each Region, telephony costs in each region, and latency in relation to your agents, contacts, and external transfer endpoint geography.

Telephony

- **Phone number porting** Open a porting request as far in advance of your pending go-live date as possible.

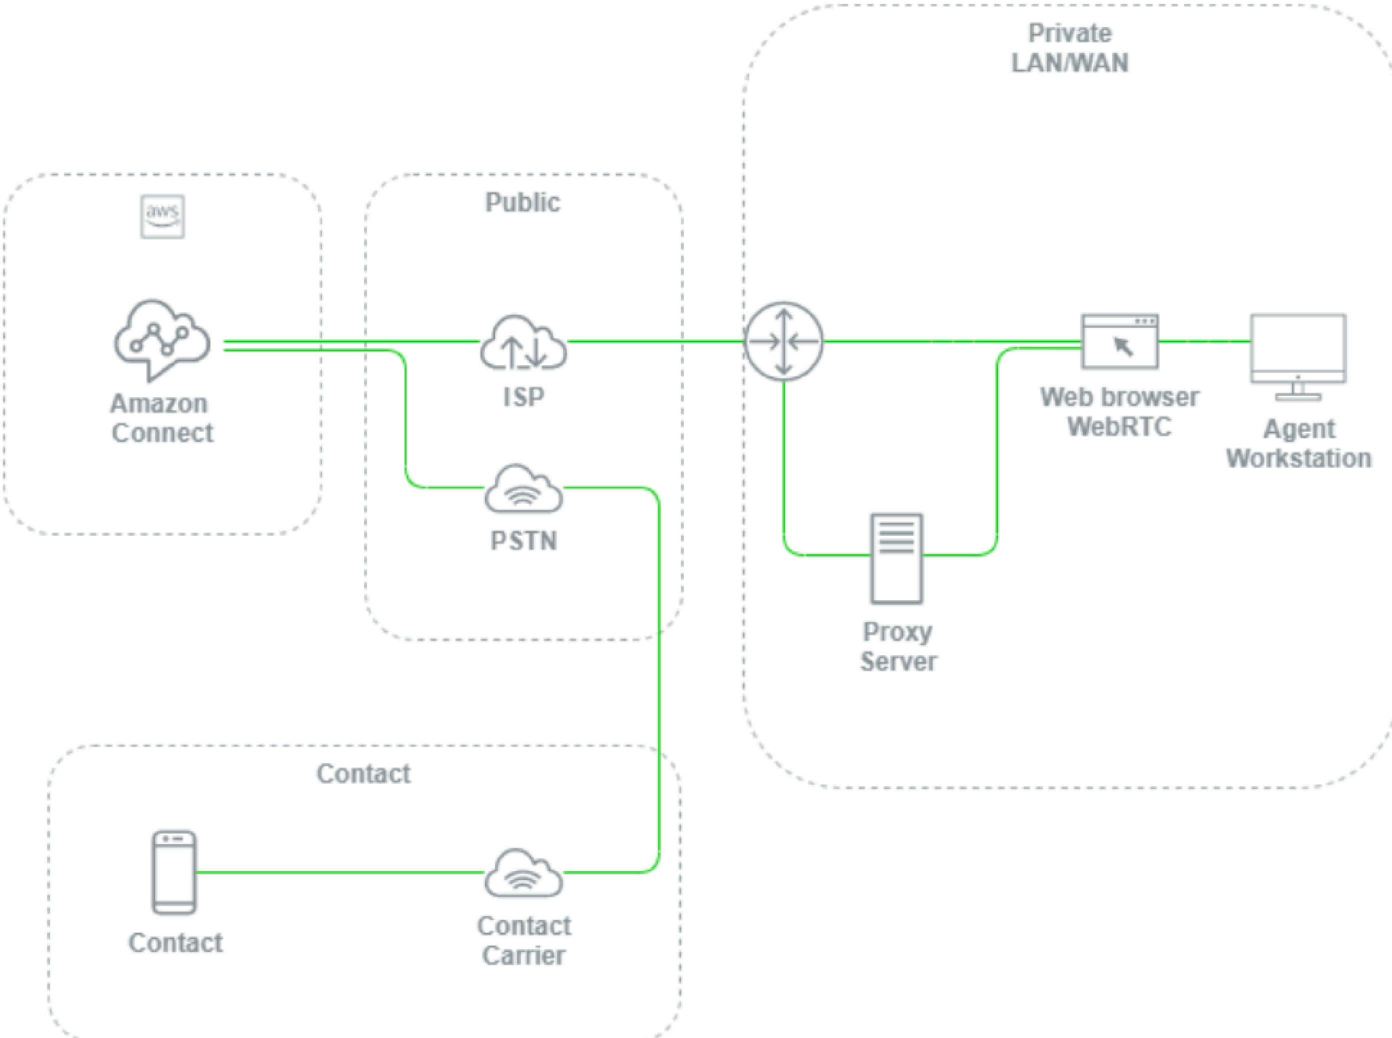
  When porting phone numbers for critical workloads, include all requirements and use case information in your claim/port number several months before the go-live date. This includes requests for live cutover support, communication prior, during, and after cutover, monitoring, and anything else specific to your use case.

  For detailed information about porting your numbers, see Port a current phone number to Amazon Connect.
- **Carrier diversity** In the US, you should use Amazon Connect telephony services for US toll-free numbers, allowing you to route toll-free traffic across multiple suppliers in an active-active fashion at no additional charge. In situations where you are forwarding inbound traffic to an Amazon Connect phone number, you should request redundant DID or Toll-Free numbers across multiple telephony providers. If you are claiming or porting multiple DID or Toll-Free numbers outside of the US, you should request that those numbers be claimed or ported to a variety of telephony providers for increased resiliency.
- **International toll-free and high-concurrency DIDs** If you are using an existing toll-free national service to redirect inbound traffic to DIDs, you should request DID phone numbers across multiple telephony providers. A general recommendation for this configuration is 100 sessions per-DID and your AWS Solutions Architect can help with capacity calculations and setup.
- **Testing** Thoroughly test all use case scenarios, preferably using the same or similar environment as your agents and customers. Ensure that you test several inbound and outbound scenarios for quality of experience, Caller ID functionality, and measure latency to ensure it falls within acceptable range for your use case. Any deviations from your target agent and customer environments need to be measured and accounted for. For more information, including use case testing instructions and criteria, see Troubleshooting Issues with the Contact Control Panel (CCP).

Agent workstation

The Amazon Connect Call Control Panel (CCP) has specific network and hardware requirements that must be met to ensure the highest quality of service for your agents and contacts:

- Set Up Your Network for CCP use and ensure that your agent hardware meets minimum requirements.
- Ensure that you have used the Amazon Connect Check Amazon Connectivity Tool on the same network segment as your agents to verify that your network and environment is configured correctly for CCP use.
- Calculate PSTN latency for use cases that require agents and contacts to be in geographically distant locations
- Review the Troubleshooting Issues with the Contact Control Panel (CCP) section to create runbooks and playbooks for your agents and supervisors to follow should they encounter issues.
- Set up monitoring for your agent workstations and consider partner solutions for call quality monitoring. Your goal with monitoring your agent workstations should be the ability to identify the source of any potential network and resource contention. For example, consider a typical agent's softphone network connection path to Amazon Connect:



Without setting up monitoring at the local LAN/WAN, path to AWS, and agent workstation levels, it's difficult and often impossible to determine if a voice quality issue is originating from your agent's workstation, their private LAN/WAN, ISP, AWS, or the contact itself. Setting up logging and alerting mechanisms proactively is critical in determining root cause and optimizing your environment for voice quality.

Configure your existing directory

If you are already using an AWS Directory Service directory to manage users, you can use the same directory to manage user accounts in Amazon Connect. This must be decided and configured when you create your Amazon Connect instance. You cannot change the identity option you select after you create the instance. For example, if you decide to change the directory you selected to enable

Single Sign On (SSO) for your instance, you can delete the instance and create a new one. When you delete an instance, you lose all configuration settings and metrics data for it

Service Quotas

Review the default service quotas for each service involved in your workload as well as the default service quotas for Amazon Connect and request increases where applicable. When requesting an increase for Amazon Connect, be sure to use expected values without additional padding for fluctuations. Fluctuations are considered automatically when you make your request.

AWS Enterprise support

AWS Enterprise Support is recommended for business and/or mission-critical workloads on AWS. Both Enterprise Support and Well-Architected Review with an AWS Solutions Architect are required to qualify for the Amazon Connect Service Level Agreement.

AWS well-architected review

Before any migration or implementation to Amazon Connect, follow our best practices by using the AWS Well-Architected Framework, Operational Excellence. The Framework provides a consistent approach for you to evaluate architectures and implement designs that will scale over time based on five pillars — operational excellence, security, reliability, performance efficiency, and cost optimization. We also recommend using AWS Enterprise Support for business and mission-critical workloads in AWS. Both Enterprise Support and Well-Architected Review with your AWS Solutions Architect are required to qualify for the Amazon Connect Service Level Agreement.

Operate

Consider the following areas to operate an Amazon Connect workload.

Logging and monitoring

See Monitoring your Amazon Connect instance using CloudWatch and Log Amazon Connect API calls with AWS CloudTrail.

Contact attributes

Amazon Connect allows you to dynamically set and reference contact attributes within flows to create dynamic and personalized experiences for your contacts, create powerful self-service applications, data-driven IVRs, integrations with other AWS services, simplify phone number management, and allows for custom real-time and historical reporting and analytics. The following are Best practices and considerations you can follow to reduce complexity, prevent data loss, and ensure a consistent quality of experience for your contacts.

Note the following considerations:

- Data size – To prevent truncation, the size limitation for contact attributes you can set in a Set contact attributes block varies depending on the charset, encoding, and language used. While this is generally enough data to play a short story for a contact, it is possible to exceed this limit, truncating any attributes set over the 32KB.
- Data sensitivity – Note if any attributes being set, queried, and referenced are sensitive or fall under any regulatory guidelines and ensure that the data is being treated appropriately for your use case.
- Data persistence – Any attributes set using the Set contact attributes block will be included in the contact record for your contact and available for screen pop to any custom agent desktop using the Streams API. Any time the attribute is referenced within your flow and logging is enabled for the flow, the name and value of the attribute will be logged to Amazon CloudWatch.

Best practices

- Monitor usage – As you implement new functionality, onboard new business units, and iterate on existing flows, look up your current attribute usage in contact search, copy the attributes to a text editor, add the new attributes, and ensure that you do not exceed the 32KB size limitation. Be sure to account for variable length fields like firstName and lastName and ensure that, even when the maximum space is used in a field, that you are still below the 32KB limitation.
- Clean-up – If data persistence isn't required, you can set an attribute with the same name and a blank value to prevent the data from being stored to the contact record or passed in a screen pop to an agent using the Amazon Connect Streams API while freeing up the bytes that data would have otherwise used in the contact record.
- Sensitive data – Use the **Store customer input** block to collect sensitive DTMF input from your contacts and use envelope encryption to protect both the raw data and the data keys used to encrypt them. Store sensitive data in a separate database where persistence is required, use the **Set logging behavior** flow block to disable logging whenever sensitive information is referenced, and remove, clean up, or obfuscate sensitive data using the **Set contact attributes** block Clean-up method outlined previously. For more information, see Compliance validation in Amazon Connect.

Telephony

In the US, use toll-free phone numbers wherever possible to load balance across multiple carriers for additional route and carrier redundancy. This also helps to decrease time to resolution when compared to DID phone numbers, which must be managed by a single carrier. In situations where you use DIDs, load balance across numbers from multiple carriers, when possible, to increase reliability. Make sure that you handle all error paths in your flow appropriately, and implement the best practices, requirements, and recommendations located in Troubleshooting Issues with the Contact Control Panel (CCP).

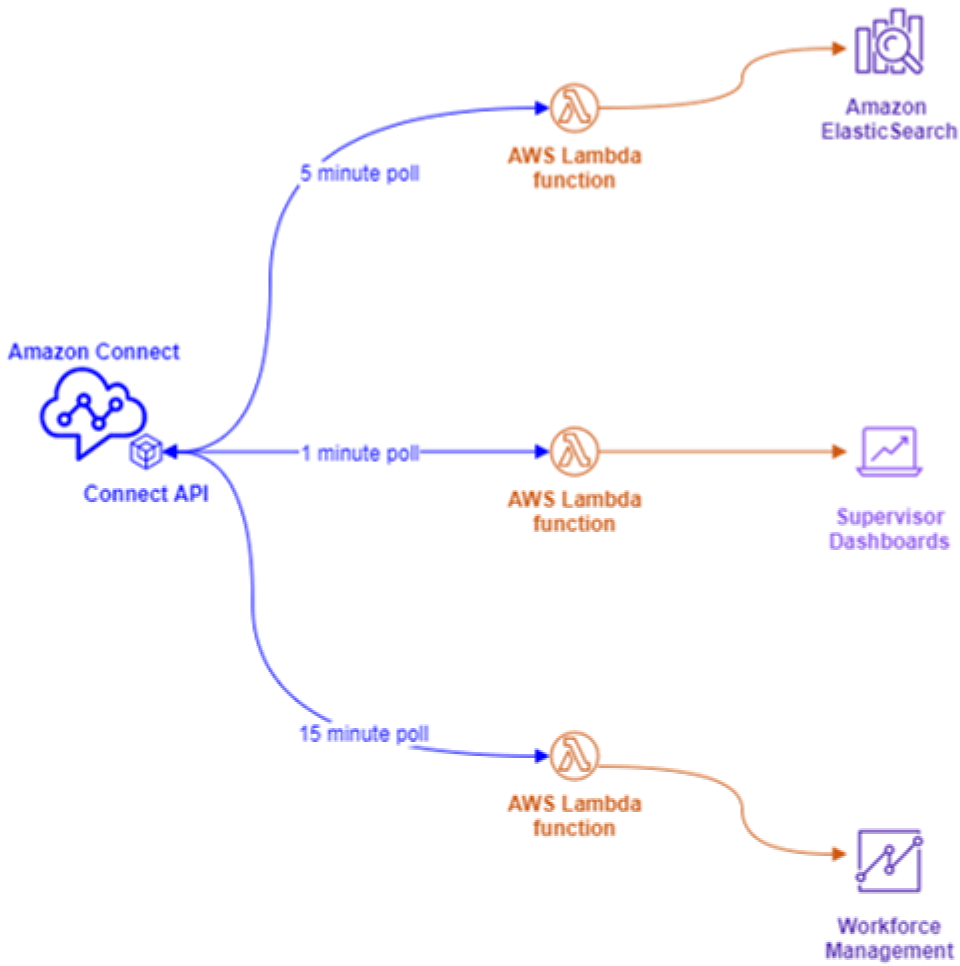
If you're forwarding your existing telephony provider's phone numbers to Amazon Connect, ensure that the process to change the forward destination to an alternative DID/toll-free number or otherwise remove the forward is defined and well-understood by your operations team. Ensure that you have Runbooks and Playbooks specifically for production readiness assessments, phone number porting and forwarding processes, and troubleshooting audio issues that could arise when transferring calls from your existing telephony provider. You also want a repeatable process that your operations team can follow to determine if the source of these audio issues is Amazon Connect or your existing telephony provider.

Amazon Connect APIs

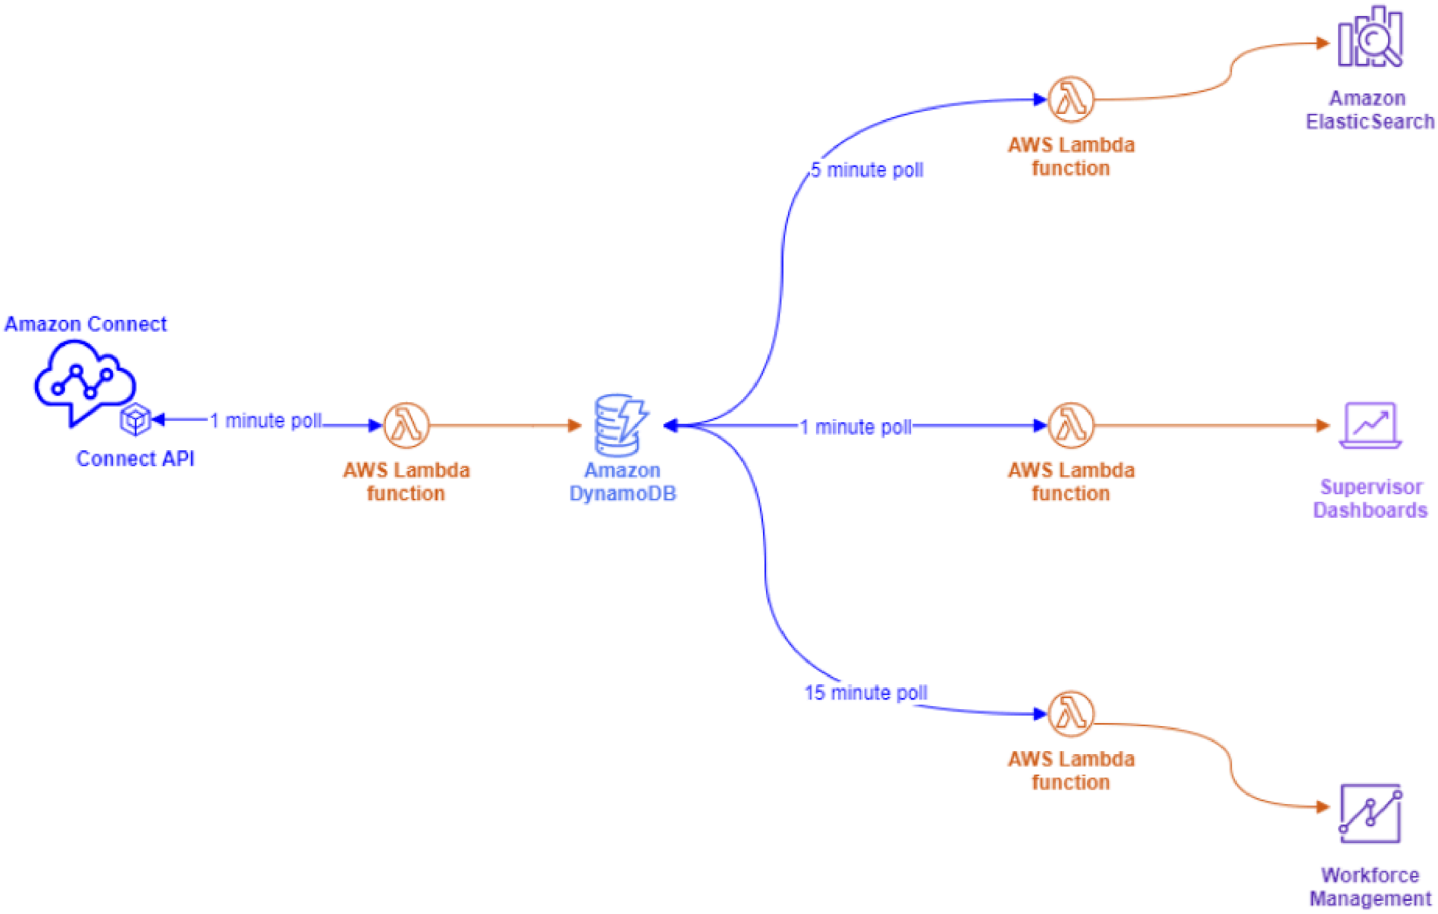
Amazon Connect throttling quotas are by account, and not instance. You should consider the following best practices when working with Amazon Connect APIs:

Implement a caching/queuing solution

To decrease API data query overhead and avoid throttling, you can use an intermediary database like Amazon DynamoDB to store API call results rather than calling the API from all endpoints interested in the API data. For example, the following diagram represents the use of the Amazon Connect metric API from multiple sources that need to consume this information:



Rather than having separate AWS Lambda functions, each with their own polling requirements, you can have a single AWS Lambda function write all interesting data to Amazon DynamoDB. Rather than having each endpoint go to the API directly to retrieve the data, they point to DynamoDB, as illustrated in the following diagram:



This architecture allows you to change polling intervals and add endpoints, as needed, without worrying about exceeding service quotas, giving you the ability to scale to however many concurrent connections your database solution supports. You can use this same concept with querying any real-time data feeds from Amazon Connect. For situations where you need to perform an API action, like an Outbound API call, you can use this same concept in combination with Amazon Simple Queue Service to queue API requests Using AWS Lambda with SQS.

Exponential back off and retry strategies

You can run into situations where API throttling limits get exceeded. This can happen when the API calls fail and are retried repeatedly or made directly from multiple concurrent endpoints without a caching or queuing solution implemented. To avoid exceeding your service quotas and impacting downstream processes, you should consider using exponential back off and retry strategies within your AWS Lambda functions in combination with caching and queueing.

Change management

Two of the primary drivers for moving workloads to the Amazon Connect are flexibility and speed to market. To ensure operational excellence without sacrificing agility, follow these best practices:

- **Modular flows**: Flows in Amazon Connect are similar to modern application building where smaller, purpose-built components allow for more flexibility, control, and ease of management when compared to monolithic alternatives. You can make your flows small and re-usable, combining the modular flows into an end-to-end experience with **Transfer to flow** blocks. This approach allows you to reduce risk during change implementation, allow you to test single, smaller changes rather than regression testing the entire experience, and will make it easier to identify and address issues with your flows during testing.
- **Repositories**: Back up all versions of all flows to a repository of your choice using contact flow Import/Export as part of your change management process.
- **Distribute by percentage**: To reduce risk encountered during change management and experiment with new experiences for your contacts, you can use the **Distribute by percentage** block to route a subset of your traffic to new flows while leaving the other traffic on the original experience.
- **Measuring results**: Data driven decision making is key to successfully driving meaningful changes for your business. Having a key metric to measure your changes against is absolutely necessary. For all changes you're making, you need to plan for how you will measure success. For example, if you're implementing self-service functionality for your contacts, what percentage of contacts do you expect to self-serve to consider the workload successful or what other metrics are you measuring to determine success?
- **Rollbacks**: Ensure that there is a clear, well-defined, and well-understood process to back out any changes to the previous state, specific to the change performed. For example, if you publish a new flow version, ensure that the change instructions include documentation on how to roll back to the previous flow version.

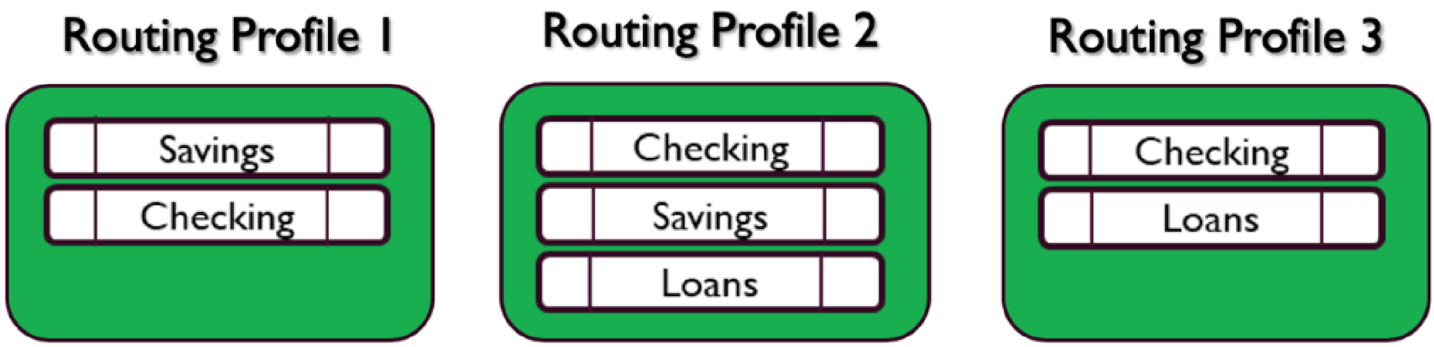
Routing profiles

Understanding how priority, delay, and overflow routing work within Amazon Connect is critical to maximizing agent productivity, reducing contact wait times, and ensuring the best quality of experience for your contacts.

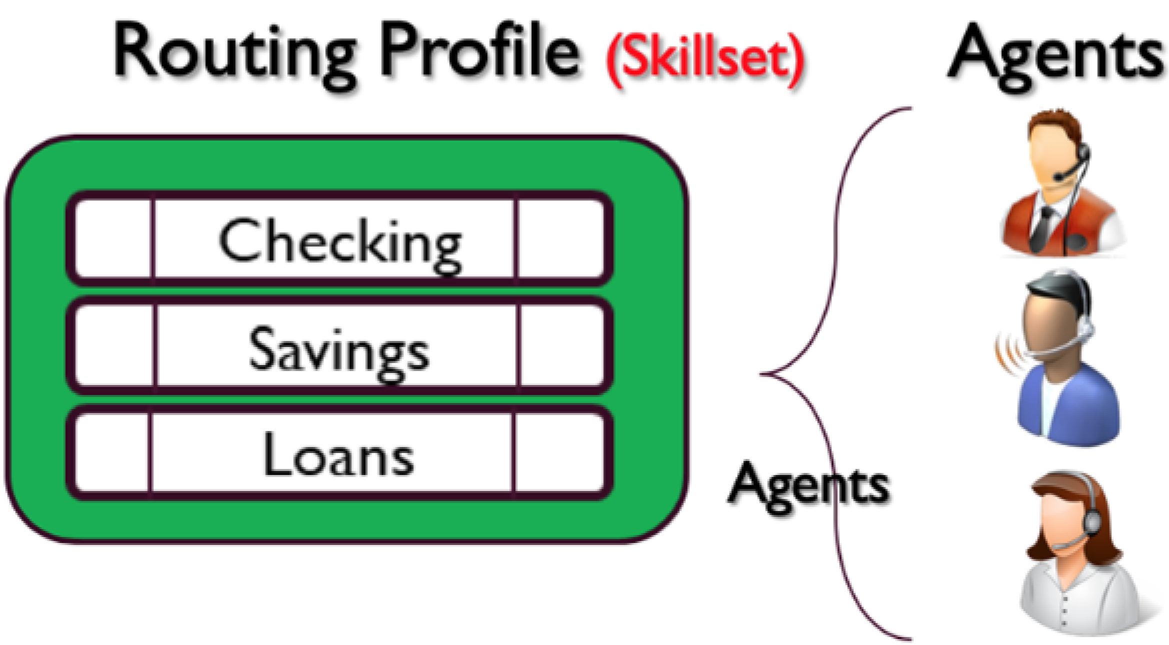
Routing in Amazon Connect

Contact routing in Amazon Connect is done through a collection of queues and routing configurations called a routing profile. A queue is equivalent to a skill or proficiency that agent needs to possess to service contacts for that queue. A routing profile can be viewed a set of skills that you can match to your contact's needs

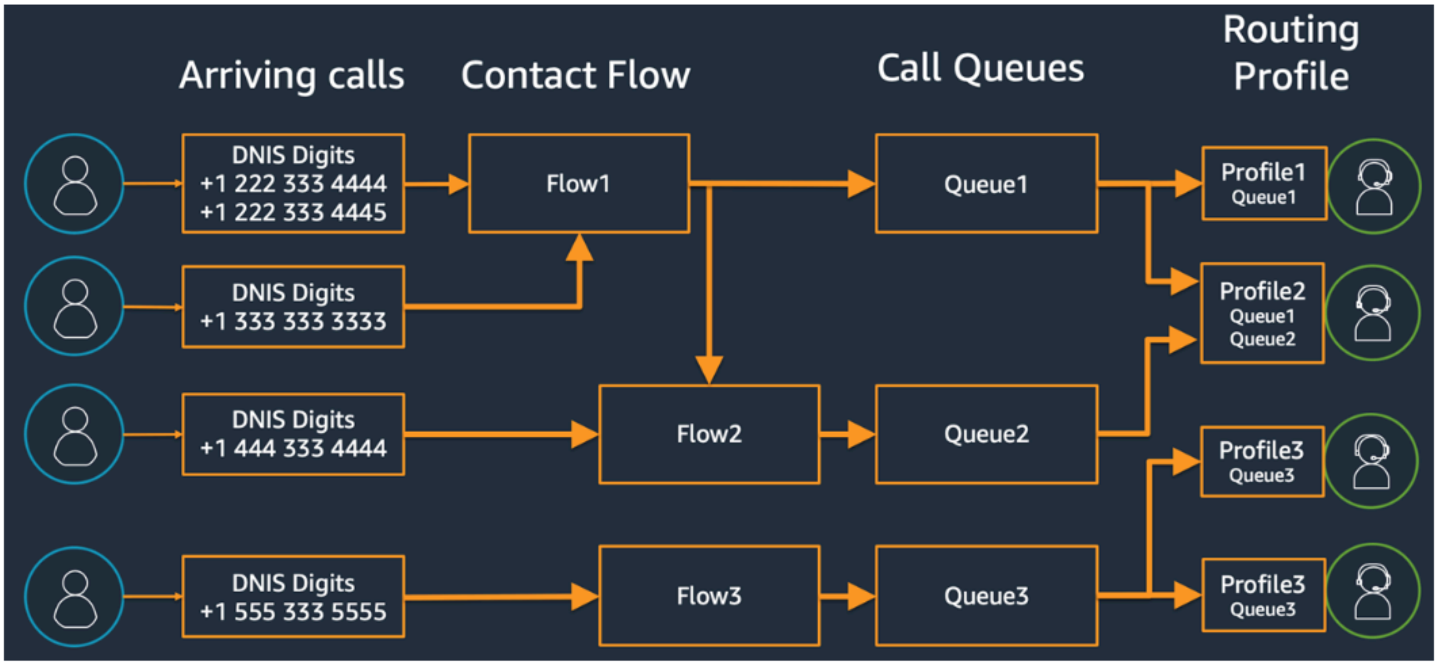
Within your flow, you can prompt for additional information and, if they need to reach an agent, you can use the flow configuration to place them in the appropriate queue. In the following example, Savings, Checking, and Loans are individual queues or skills and the three routing profiles are unique skillsets, or groups of skills:



Each agent is assigned to only one routing profile based on their skillset, and many agents with similar skillset can share the same routing profile:



Each phone number or chat endpoint will be associated with one flow. The flow executes its logic, which may involve prompting the customer for information, to determine the contact's needs, and eventually routes the contact into an appropriate queue. The following diagram depicts how routing profile, queue, and flow work together to service a contact:



To illustrate how you might determine various queues, routing profiles, and agent assignments to the routing profiles, consider the following table:

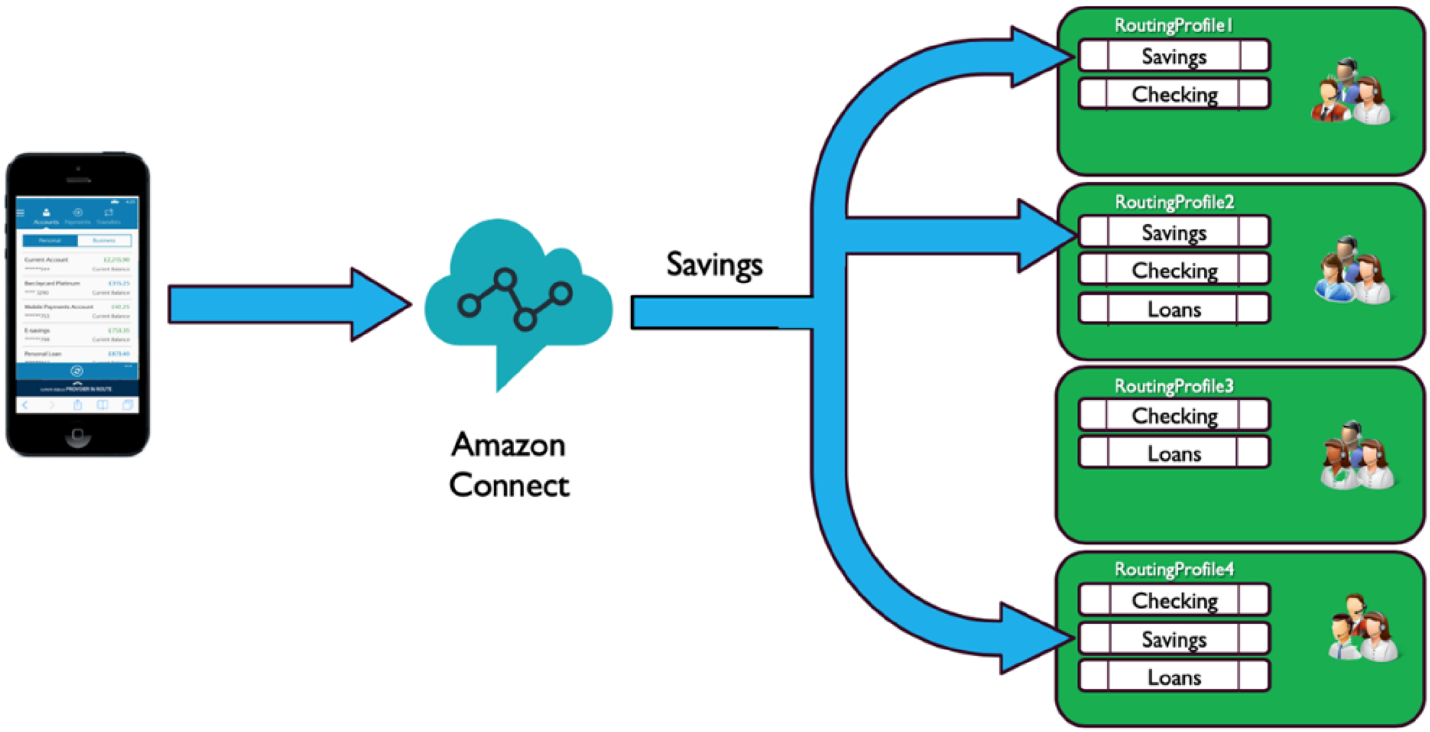
Agent	Checking	Savings	Loans	Mortgages	Investments
John D.	✓	✓			
Sam J.	✓	✓			
Debbie E.	✓	✓			
Charles T.	✓	✓			
Jane D.	✓	✓	✓		
Connie E.	✓	✓	✓		
Steve L.	✓	✓	✓		
Chris A.	✓	✓	✓		
Joyce C.			✓		
Brian M.			✓		
Caleb S.				✓	✓
Travis F.				✓	✓
Robbie H.	✓	✓	✓		

"Queues"

"Routing Profile I"

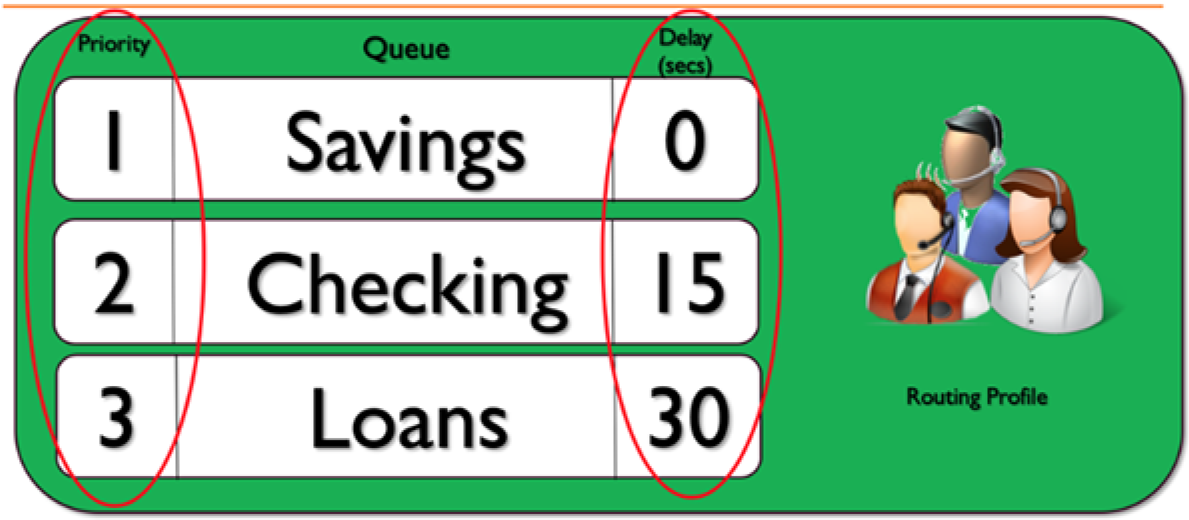
On the top row, you've identified your skills or queues. In the left column, you have your list of agents, and in the middle, you've checked the skills supported by each of the agents. You can sort the matrix grouped by the common set of skill requirements across our agent population. This helps identify the routing profiles as one marked in the green box (which consists of two queues), which you can assign agents to. As a result of this exercise, you have identified four routing profiles, and assign your 13 agents to them accordingly.

Based on the previous table, an incoming call from a contact needing the Savings skill could be served by three groups of agents in the three routing profiles 1, 2, and 4 as depicted in the following diagram:



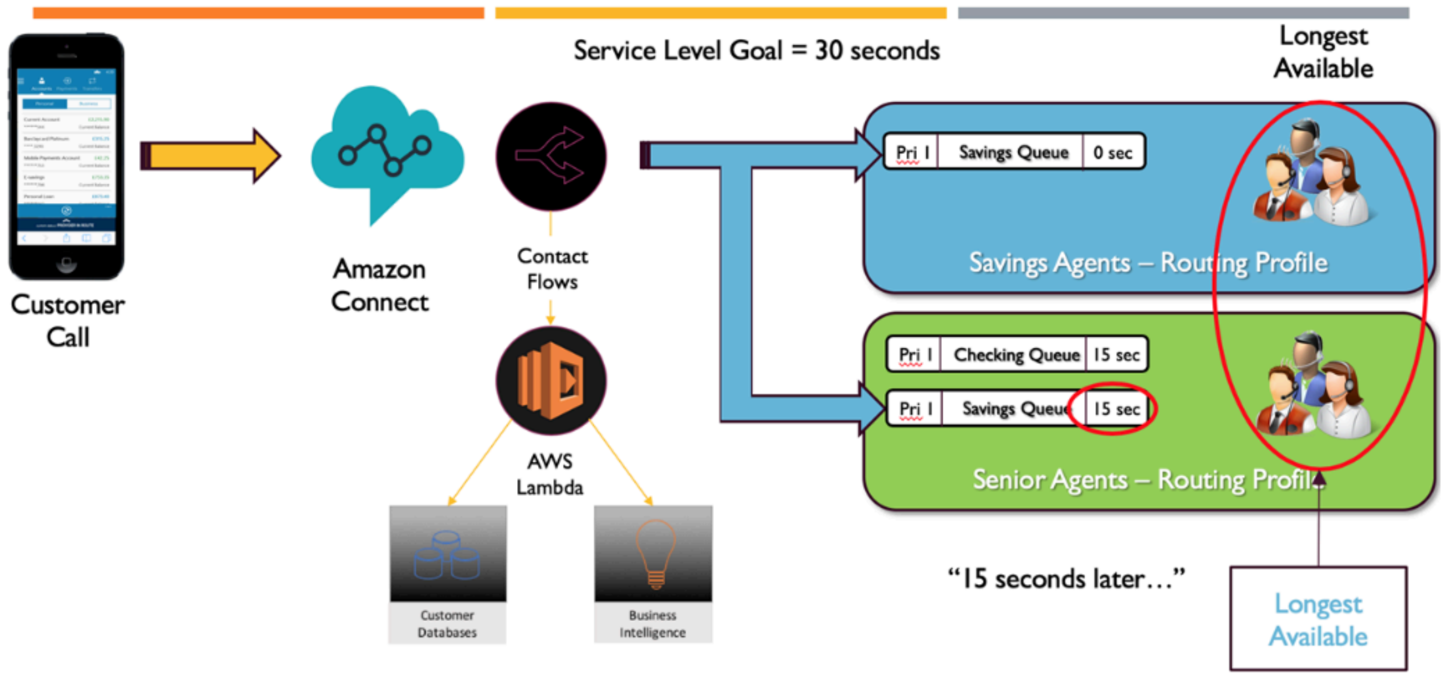
Priority and delay

Using the combination of priority and delay in different Routing Profiles, you can create flexible routing strategies.



The preceding routing profile example shows a set of queues, and their respective priority and delay. The lower the number, the higher the priority. All higher priority calls must be processed before a lower priority call will be processed. This is a difference from systems that will eventually process lower priority of calls based upon a weighting factor.

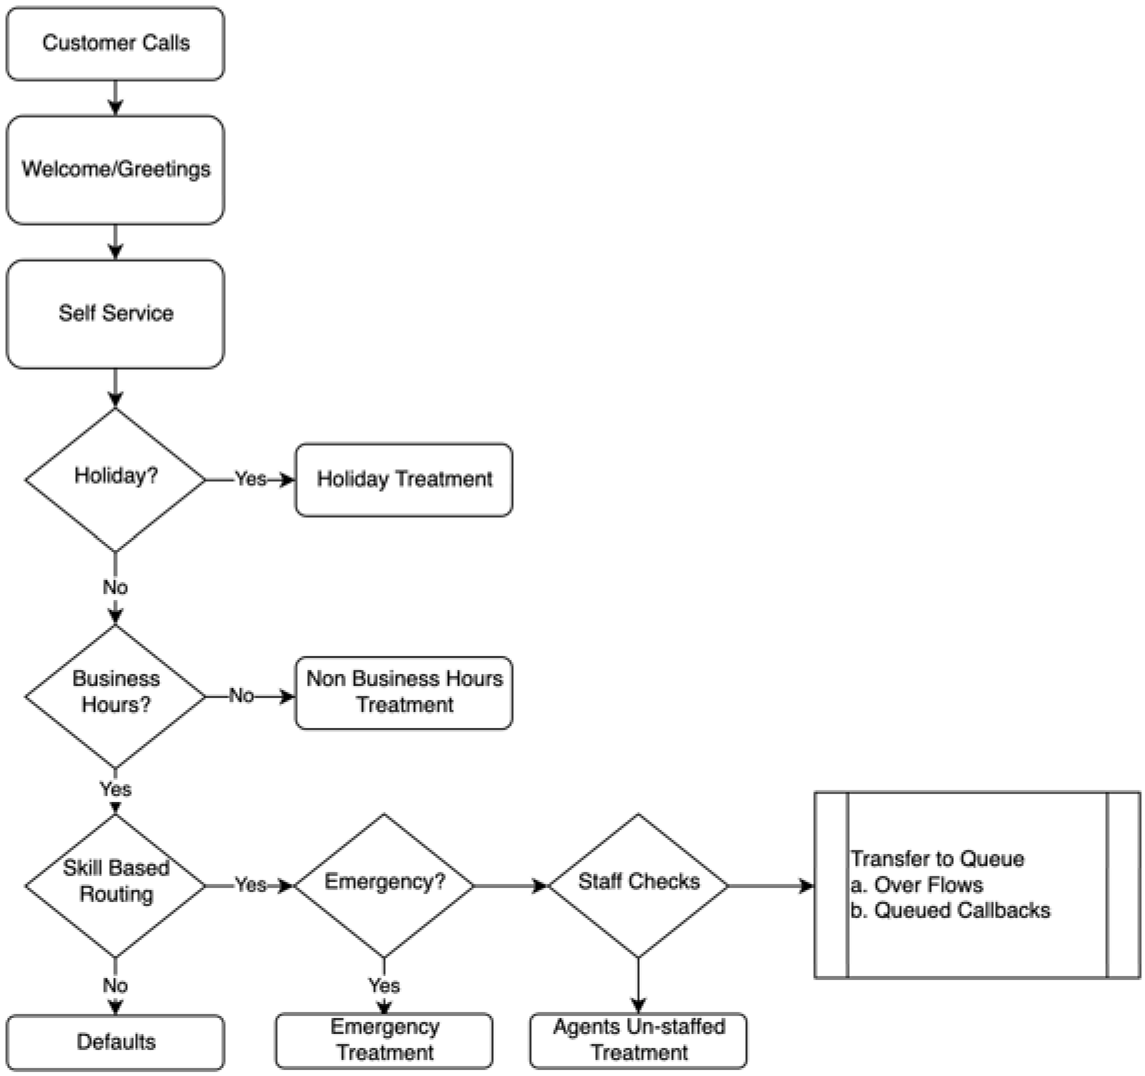
You can also add a delay to each of the queues within each of the routing profiles. Any call coming into the queue will be held for the specified period of delay assigned to the designated queue. The call will be held for the delay period, even when agents are available. You might use this in situations where you have a group of agents who are reserved to help you meet your Service Level Agreements (SLAs), but are otherwise assigned to other tasks or queues. If a call doesn't get answered within a specified period of time, these agents would become eligible to receive a call from the designated queue. For example, consider the following diagram:



This diagram shows an SLA of 30 seconds. A call comes in for the Savings queue. The Savings queue immediately looks for an agent in the "Savings" routing profile due to the configuration of 0 delay in the profile for the queue. Because of the configuration of 15 delay for Senior Agents, they will not be eligible to receive the Savings contact for 15 seconds. After 15 seconds elapses, the contact becomes available for a Senior Level agent and Amazon Connect looks for the Longest Available across both routing profiles.

Path to service

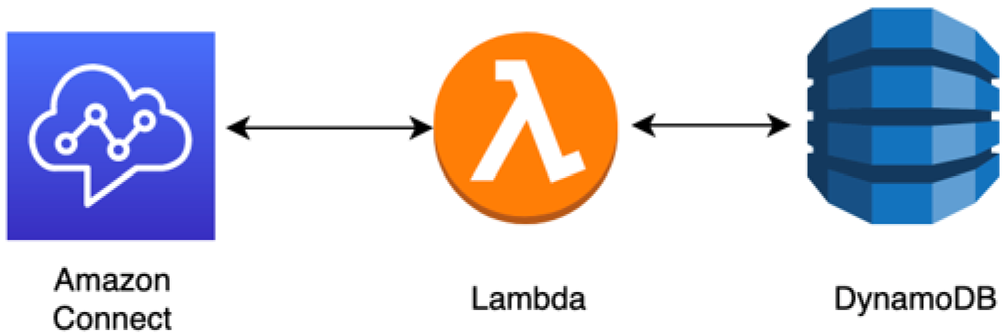
When you are designing customer experiences in Amazon Connect, plan to ensure a path to service. There are many planned and unplanned events that can impact the customer experience as they traverse through Amazon Connect Flows. The following sample customer experience shows some suggested checks to ensure a consistent quality experience for your contacts:



This sample customer experience takes into account planned events such as Holidays and Business hours as well as unplanned events, like agents not staffed during business hours. With this logic, you can also account for emergency situations, such as contact center closures because of inclement weather or service disruptions. Consider the following concepts as illustrated in the diagram:

- **Self-service**: In a typical IVR, you can include any greetings and disclaimer messages such as call recording announcements upfront, which can be followed by self-service options. Self-service brings cost and performance optimizations for your contact center and enables your organization to serve customers 24x7, regardless of holidays, business hours, or availability of agents. Always include a path to service in case customers are unable to self-serve and need human assistance. For example, if you are using Amazon Lex bots for self-service, you can make use of fallback intents to escalate conversations for human assistance.

- **Holidays**: Many enterprise customers have a central repository that holds corporate holidays. You can use an AWS Lambda function to data dip into that repository and offer holiday treatment to customers. Additionally, you can also store corporate holidays in DynamoDB along with a custom message for each holiday. For example, if your enterprise observes December 25 as Christmas, you could have a holiday prompt or Text to Speech, "We are currently closed for Christmas. Please call back on December 26 when our normal business hours will resume."



- **Business hours**: After holidays have been verified, you can check for business hours and, if outside of business hours, you can change the experience dynamically for your contacts. If the contact occurs during business hours, you can identify customer intent for calls and map to certain queues in your contact center, increasing the likelihood of getting to the correct agent, and decreasing the amount of time it takes your contact to reach service. It is highly recommended to map defaults as customers could be calling for a reason you haven't accounted for yet or may respond in a way you don't expect.
- **Emergency messages**: After you have identified customer intent for call, it is suggested to implement an emergency check treatment. In the event of an emergency situation that impacts your contact center, you can store an emergency True/False flag in an intermediary database like DynamoDB. To allow your supervisors and administrators to set this flag dynamically, with no code, you can build a separate IVR that authenticates your Amazon Connect administrators based upon ANI and PIN number verification for internal use only. In the event of emergency, your supervisors can call into that dedicated line from their phones and after authentication set the Emergency flag to true for scenarios such as contact center closure due to inclement weather or ISP outage at the physical location of contact center.
- **Emergency message API**: You can also consider building an AWS API gateway with AWS Lambda function at the back end to set the Emergency flag to true/false securely in the database. Your supervisors can securely access that API through web to toggle disaster mode or dynamically toggle it in response to an external event. In your Amazon Connect instance, every contact that comes in through the flow will use AWS Lambda to check for that emergency flag and, in case of disaster mode, you can dynamically make announcements and provide a customer with a path

to service. This will further ensure business continuity and mitigate the impact of situations like these from affecting your customers.

- **Check agent staffing**: Before transferring to the queue in your flow, you can check agent staffing to ensure that an agent is logged in to service the contact. For example, you may have an agent busy servicing another contact that might become available in the next five minutes, or you may not have anyone logged into the system at all. During these instances, you will prefer a different customer experience rather than making them wait in the queue for an agent to become available.
- **Route to service**: When you transfer the call to the queue, you can offer queued callbacks, queue overflows, or tiered routing using Amazon Connect routing profiles to offer a consistent, high-quality experience for your callers that meet your Service Level requirements.

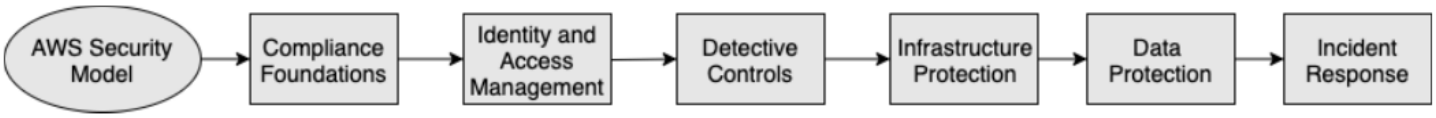
Design principles for developing a secure contact center in Amazon Connect

Security includes the ability to protect information, systems, and assets while delivering business value through risk assessments and mitigation strategies. This section provides an overview of design principles, best practices, and questions surrounding security for Amazon Connect workloads.

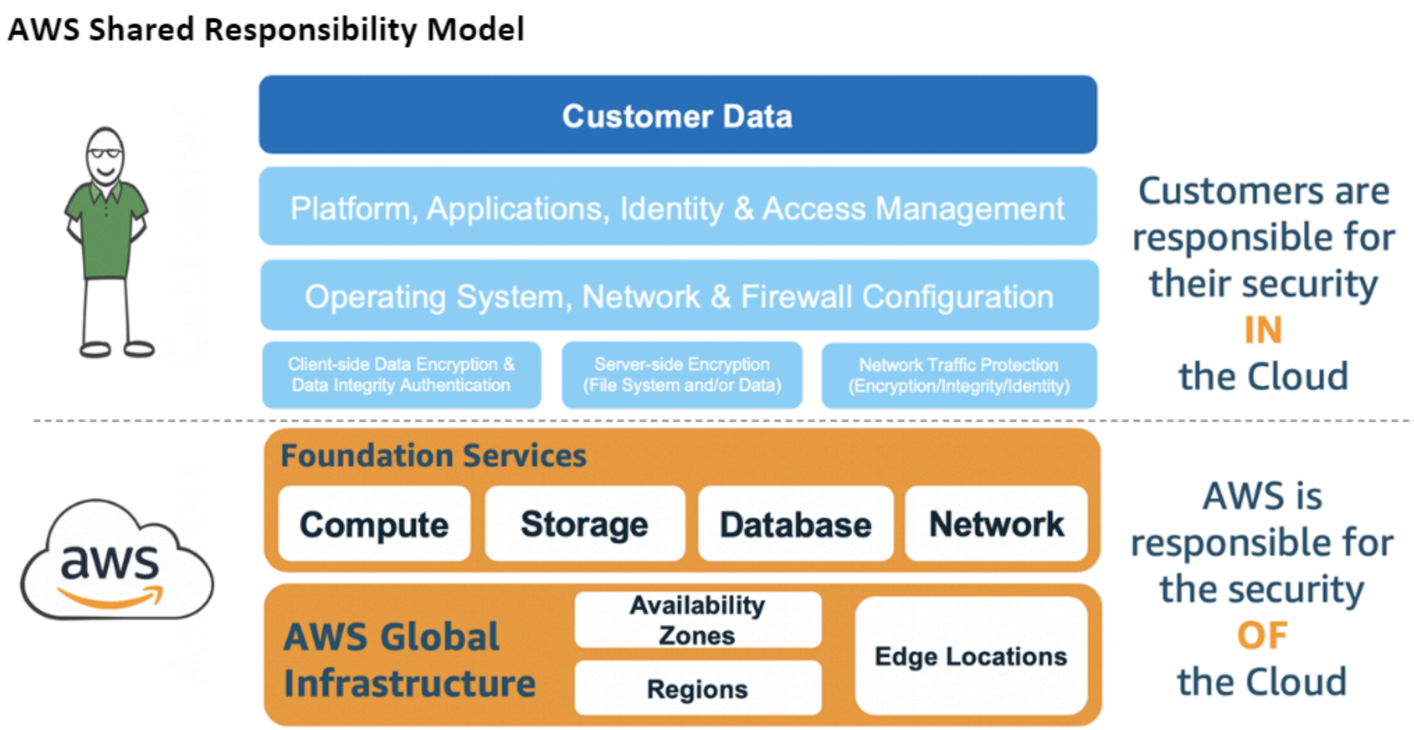
Amazon Connect Security Journey

After you've made the decision to move your workload to Amazon Connect, in addition to reviewing Security in Amazon Connect and Security Best Practices for Amazon Connect, follow these guidelines and steps to understand and implement your security requirements relative to the following core security areas:

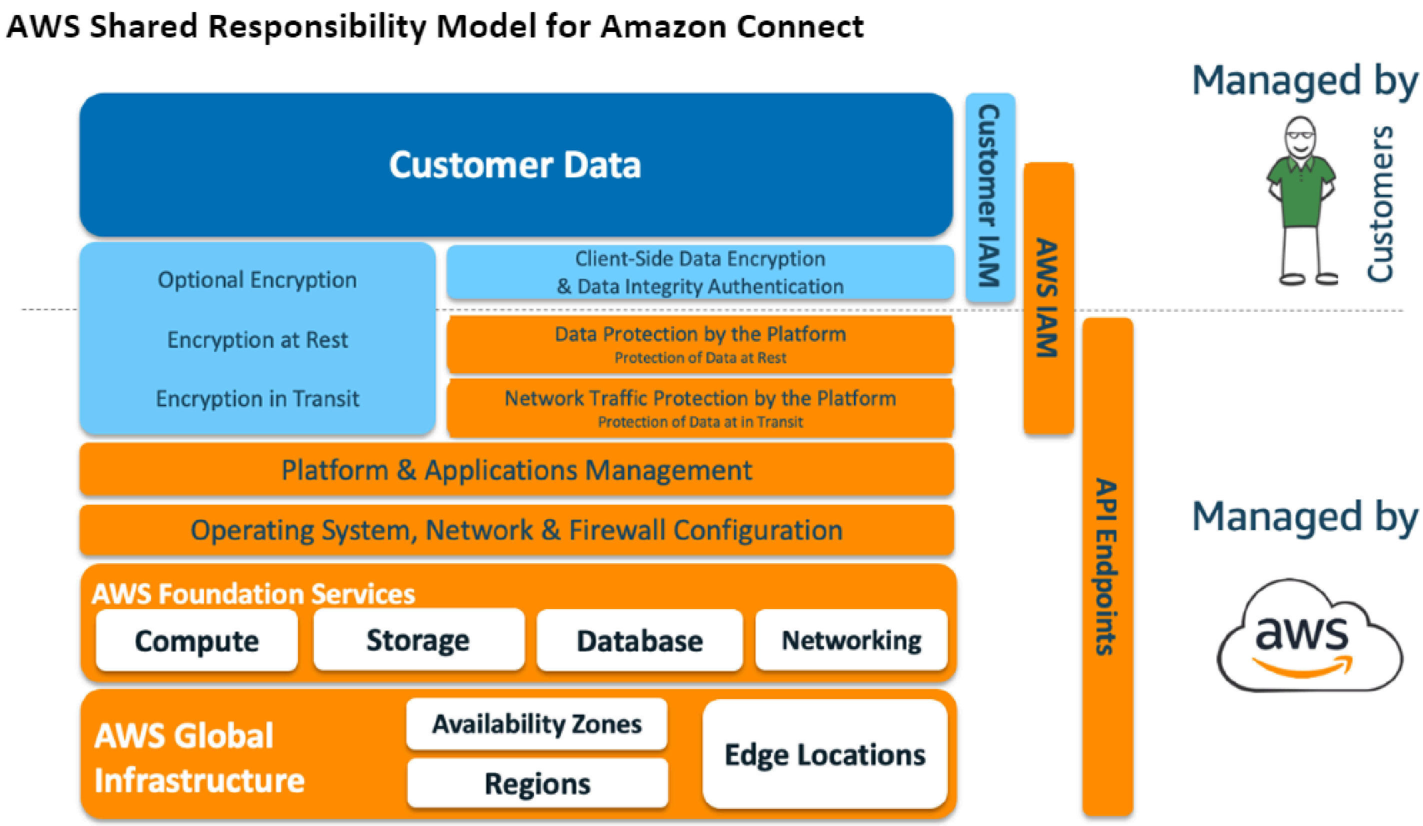


Understanding the AWS Security Model

When you move computer systems and data to the cloud, security responsibilities become shared between you and AWS. AWS is responsible for securing the underlying infrastructure that supports the cloud, and you're responsible for anything you put on the cloud or connect to the cloud.



Which AWS services you use will determine how much configuration work you have to perform as part of your security responsibilities. When you use Amazon Connect, the shared model reflects AWS and customer responsibilities at a high-level, as shown in the following diagram.



Compliance Foundations

Third-party auditors assess the security and compliance of Amazon Connect as part of multiple AWS compliance programs. These include SOC, PCI, HIPAA, C5 (Frankfurt), and HITRUST CSF.

For a list of AWS services in scope of specific compliance programs, see AWS Services in Scope by Compliance Program. For general information, see AWS Services Compliance Programs.

Region selection

Region selection to host the Amazon Connect instance depends on data sovereignty restrictions and where the contacts and agents are based. After that decision is made, review network requirements for Amazon Connect and ports and protocols that you need to allow. Additionally, to reduce the blast radius use the domain allow list or allowed IP address ranges for your Amazon Connect instance.

For more information, see Set up your network to use the Amazon Connect Contact Control Panel (CCP).

AWS services integration

We recommend reviewing each AWS service in your solution against the security requirements of your organization. See the following resources:

- Security in AWS Lambda
- Security and Compliance in DynamoDB
- Security in Amazon Lex

Data Security in Amazon Connect

During your security journey, your security teams may require a deeper understanding of how data is handled in Amazon Connect. See the following resources:

- Detailed network paths for Amazon Connect
- Infrastructure security in Amazon Connect
- Compliance validation in Amazon Connect

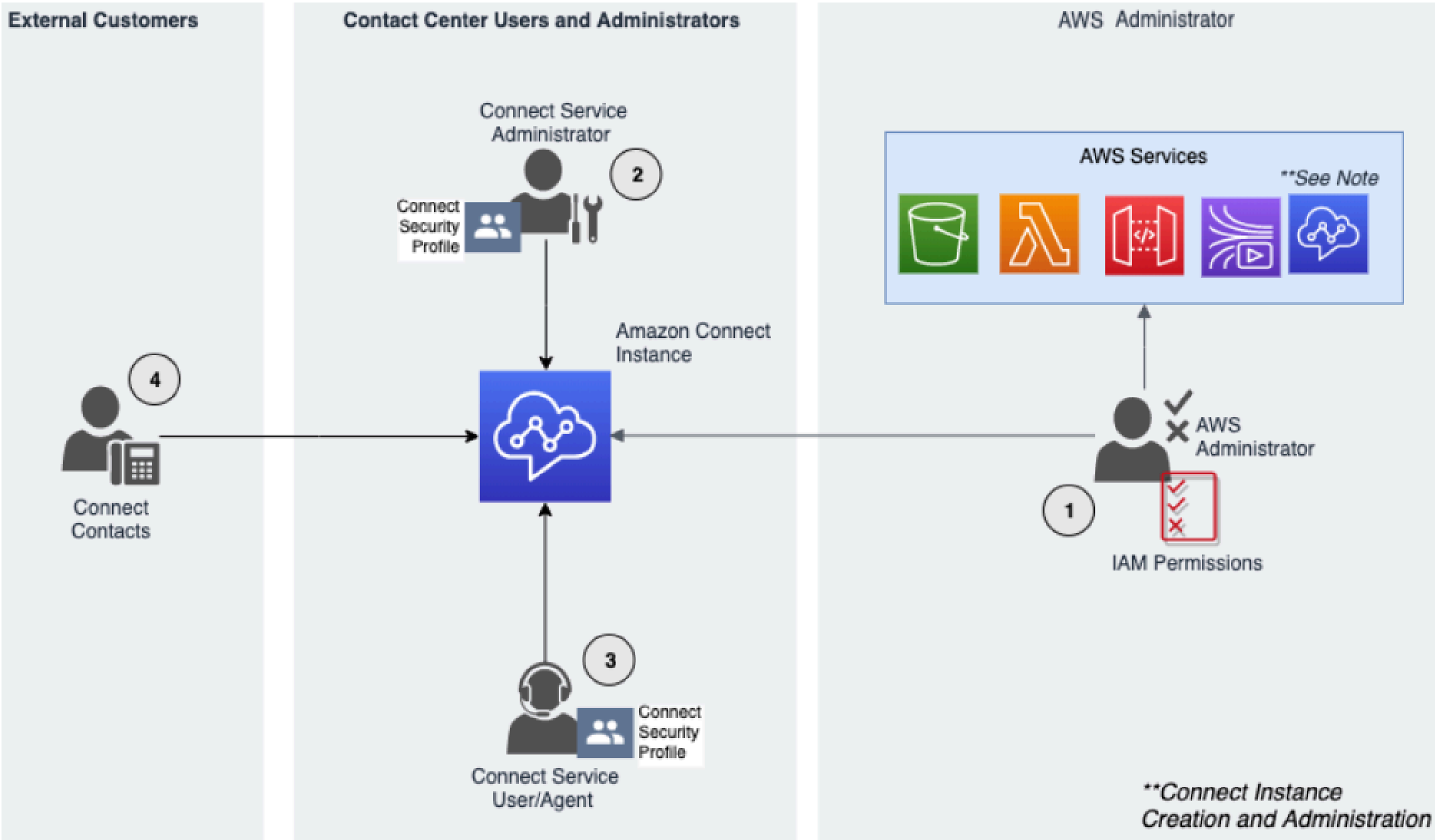
Workload diagram

Review your workload diagram and architect an optimum solution on AWS. This includes analyzing and deciding which additional AWS services should be included in your solution and any third-party and on-premises applications that need to be integrated.

AWS Identity and Access Management (IAM)

Types of Amazon Connect Personas

There are four types of Amazon Connect personas, based on the activities being performed.



1. AWS administrator – AWS administrators create or modify Amazon Connect resources and may also delegate administrative access to other principals by using the AWS Identity and Access Management (IAM) service. The scope of this persona is focused on creating and administering your Amazon Connect instance.
2. Amazon Connect administrator – Service administrators determine which Amazon Connect features and resources employees should access within the Amazon Connect admin website. The service administrator assigns security profiles to determine who can access the Amazon Connect admin website and what tasks they can perform. The scope of this persona is focused on creating and administering your Amazon Connect contact center.
3. Amazon Connect agent – Agents interact with Amazon Connect to perform their job duties. Service users may be contact center agents or supervisors.
4. Amazon Connect Service contact – The customer who interacts with your Amazon Connect contact center.

IAM Administrator Best Practices

IAM Administrative access should be limited to approved personnel within your organization. IAM administrators should also understand what IAM features are available to use with Amazon Connect. For IAM best practices, see Security best practices in IAM in the *IAM User Guide*. Also see Amazon Connect identity-based policy examples.

Amazon Connect Service Administrator Best Practices

Service administrators are responsible for managing Amazon Connect users, including adding users to Amazon Connect give them their credentials, and assign the appropriate permissions so they can access the features needed to do their job. Administrators should start with a minimum set of permissions and grant additional permissions as necessary.

Security profiles for Amazon Connect and Contact Control Panel (CCP) access help you manage who can access the Amazon Connect dashboard and Contact Control Panel, and who can perform specific tasks. Review the granular permissions granted within the default security profiles available natively. Custom security profiles can be set up to meet specific requirements. For example, a power agent who can take calls but also has access to reports. After this is finalized, users should be assigned to the correct security profiles.

Multi-Factor Authentication

For extra security, we recommend that you require multi-factor authentication (MFA) for all IAM users in your account. MFA can be set up through AWS IAM or your SAML 2.0 identity provider, or Radius server, if that's more applicable for your use case. After MFA is set up, a third text box becomes visible on the Amazon Connect login page to provide the second factor.

Identity Federation

In addition to storing users in Amazon Connect, you can enable single sign-on (SSO) to Amazon Connect by using identity federation. Federation is a recommended practice to allow for employee lifecycle events to be reflected in Amazon Connect when they are made in the source identity provider.

Access to Integrated Applications

Steps within your flows may need credentials to access information in external applications and systems. To provide credentials to access other AWS services in a secure way, use IAM roles. An IAM role is an entity that has its own set of permissions, but that isn't a user or group. Roles also don't have their own permanent set of credentials and are automatically rotated.

Credentials such as API keys should be stored outside of your flow application code, where they can be retrieved programmatically. To accomplish this, you can use AWS Secrets Manager or an existing third-party solution. Secrets Manager enables you to replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.

Detective controls

Logging and monitoring are important for the availability, reliability and, performance of contact center. You should log relevant information from Amazon Connect Flows to Amazon CloudWatch and build alerts and notifications based on the same.

You should define log retention requirements and lifecycle policies early on, and plan to move log files to cost-efficient storage locations as soon as practical. Amazon Connect public APIs log to AWS CloudTrail. You should review and automate actions set up based on CloudTrail logs.

Amazon S3 is the best choice for long-term retention and archiving of log data, especially for organizations with compliance programs that require log data to be auditable in its native format. After log data is in an S3 bucket, define lifecycle rules to automatically enforce retention policies and move these objects to other, cost-effective storage classes, such as Amazon S3 Standard - Infrequent Access (Standard - IA) or Amazon S3 Glacier.

The AWS cloud provides flexible infrastructure and tools to support both sophisticated in cooperation with offerings and self-managed centralized-logging solutions. This includes solutions such as Amazon OpenSearch Service and Amazon CloudWatch Logs.

Fraud detection and prevention for incoming contacts can be implemented by customizing Amazon Connect Flows per the customer requirements. As an example, customers can check incoming contacts against previous contact activity in DynamoDB, and then take action, such as disconnecting a contact because they are a blocked contact.

Infrastructure protection

Although there is no infrastructure to manage in Amazon Connect, there could be scenarios where your Amazon Connect instance needs to interact with other components or applications deployed in infrastructure residing on-premises. Consequently, it is important to ensure that networking boundaries are considered under this assumption. Review and implement specific Amazon Connect infrastructure security considerations. Also, review contact center agent and supervisor desktops or VDI solutions for security considerations.

You can configure a Lambda function to connect to private subnets in a virtual private cloud (VPC) in your account. Use Amazon Virtual Private Cloud to create a private network for resources such as databases, cache instances, or internal services. Amazon Connect your function to the VPC to access private resources during execution.

Data protection

Customers should analyze the data traversing through and interacting with the contact center solution.

- Third party and external data
- On-premises data in hybrid Amazon Connect architectures

After analyzing the scope of the data, data classifications should be performed paying attention to identifying sensitive data. Amazon Connect conforms to the AWS shared responsibility model. Data protection in Amazon Connect includes best practices like using MFA and TLS and the use of other AWS services, including Amazon Macie.

Amazon Connect handles variety of data related to contact centers. This includes phone call media, call recordings, chat transcripts, contact metadata as well as flows, routing profiles and queues. Amazon Connect handles data at rest by segregating data by account ID and instance ID. All data exchanged with Amazon Connect is protected in transit between the user's web browser and Amazon Connect using open standard TLS encryption.

You can specify AWS KMS keys to be used for encryption including bring your own key (BYOK). Additionally, you can use key management options within Amazon S3.

Protecting Data Using Client-Side Encryption

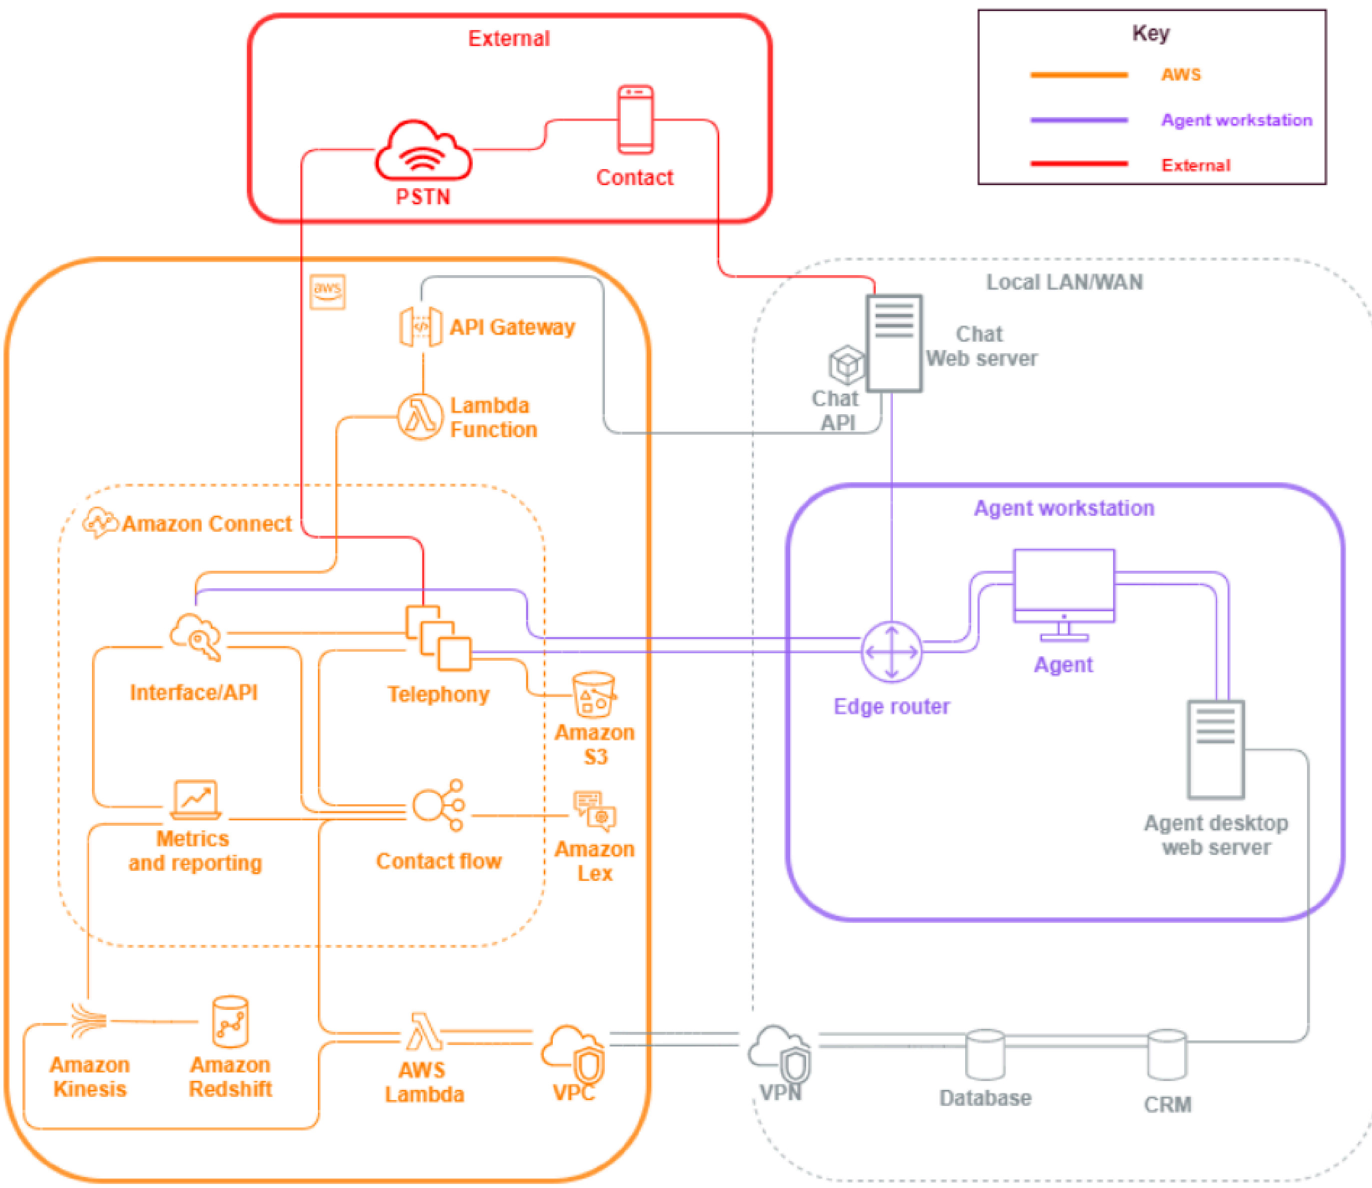
Your use case may require encryption of sensitive data that is collected by flows. For example, to gather appropriate personal information to customize the customer experience when they interact with your IVR. To do this you can use public-key cryptography with the AWS Encryption SDK. The AWS Encryption SDK is a client-side encryption library designed to make it efficient for everyone to encrypt and decrypt data using open standards and best practices.

Input validation

Perform input validation to ensure that only properly formed data is entering the flow. This should happen as early as possible in the flow. For example, when prompting a customer to say or enter a telephone number, they may or may not include the country code.

Amazon Connect security vectors

Amazon Connect security can be divided into three logical layers as illustrated in the following diagram:



1. **Agent workstation**. The agent workstation layer is not managed by AWS and consists of any physical equipment and third-party technologies, services, and endpoints that facilitate your agent's voice, data, and access the Amazon Connect interface layer.

   Follow your security best practices for this layer with special attention to the following:

   - Plan identity management keeping in mind best practices noted in Security Best Practices for Amazon Connect.
   - Mitigate insider threat and compliance risk associated with workloads that handle sensitive information, by creating a secure IVR solution that enables you to bypass agent access to sensitive information. By encrypting contact input in your flows, you're able to capture information securely without exposing it to your agents, their workstations, or their operating environments. For more information, see Encrypt sensitive customer input in Amazon Connect.
   - You are responsible for maintaining the allowlist of AWS IP addresses, ports, and protocols needed to use Amazon Connect.

2. **AWS**: The AWS layer includes Amazon Connect and AWS integrations including AWS Lambda, Amazon DynamoDB, Amazon API Gateway, Amazon S3, and other services. Follow the security pillar guidelines for AWS services, with special attention to the following:

   - Plan identity management, keeping in mind best practices noted in Security Best Practices for Amazon Connect.
   - Integrations with other AWS services: Identify each AWS service in the use case as well as any third-party integration points applicable for this use case.
   - Amazon Connect can integrate with AWS Lambda functions that run inside of a customer VPC through the VPC endpoints for Lambda.

3. **External**: The External layer includes contact points including chat, click-to-call endpoints, and the PSTN for voice calls, integrations you may have with legacy contact center solutions in a Hybrid contact center architecture, and integrations you may have with other third-party solutions. Any entry point or exit point for a third party in your workload is considered the external layer.

   This layer also covers integrations customers may have with other third-party solutions and applications such as CRM systems, work force management (WFM), and reporting and visualization tools and applications, such as Tableau and Kibana. You should consider the following areas when securing the external layer:

- You can create contact filters for repeat and fraudulent contacts using AWS Lambda to write contact details to DynamoDB from within your flow, including ANI, IP address for click-to-dial and chat endpoints, and any other identifying information to track how many contact requests occur during a given period of time. This approach allows you to query and add contacts to deny lists, automatically disconnecting them if they exceed reasonable levels.
- ANI Fraud detection solutions using Amazon Connect telephony metadata and partner solutions can be used to protect against caller ID spoofing.
- Amazon Connect Voice ID and other voice biometric partner solutions can be used to enhance and streamline the authentication process. Active voice biometric authentication allows contacts the option to speak specific phrases and use those for voice signature authentication. Passive voice biometrics allow contacts to register their unique voiceprint and use their voiceprint to authenticate with any voice input that meets sufficient length requirements for authentication.
- Maintain the application integration section in the Amazon Connect console for adding any third-party application or integration points to your allowlist, and remove unused endpoints.
- Send only the data necessary to meet minimum requirements to external systems that handle sensitive data. For example, if you have only one business unit using your call recording analytics solution, you can set an AWS Lambda trigger in your S3 bucket to process contact records, check for the business unit's specific queues in the contact record data, and if it is a queue that belongs to the unit, send only that call recording to the external solution. With this approach, you only send the data necessary and avoid the cost and overhead associated with processing unnecessary recordings.

  For an integration that enables Amazon Connect to communicate with Amazon Kinesis and Amazon Redshift to enable the streaming of contact records, see Amazon Connect integration: Data streaming.

Reliability in Amazon Connect

Reliability includes the ability of a system to recover from infrastructure or service disruptions, dynamically acquire computing resources to meet demand, and mitigate disruptions such as misconfigurations or transient network issues. As resiliency is handled as part of the service, there are no reliability practices unique to Amazon Connect beyond of what is covered in Operational excellence in Amazon Connect workloads. You can find prescriptive guidance on implementation in the Reliability Pillar whitepaper.

Performance efficiency for Amazon Connect workloads

Performance efficiency includes the ability to use computing resources efficiently to meet system requirements, and to maintain that efficiency as demand changes and technologies evolve. This section provides an overview of design principles, best practices, and questions surrounding performance efficiency for Amazon Connect workloads. You can find prescriptive guidance on implementation in the Performance Efficiency Pillar whitepaper.

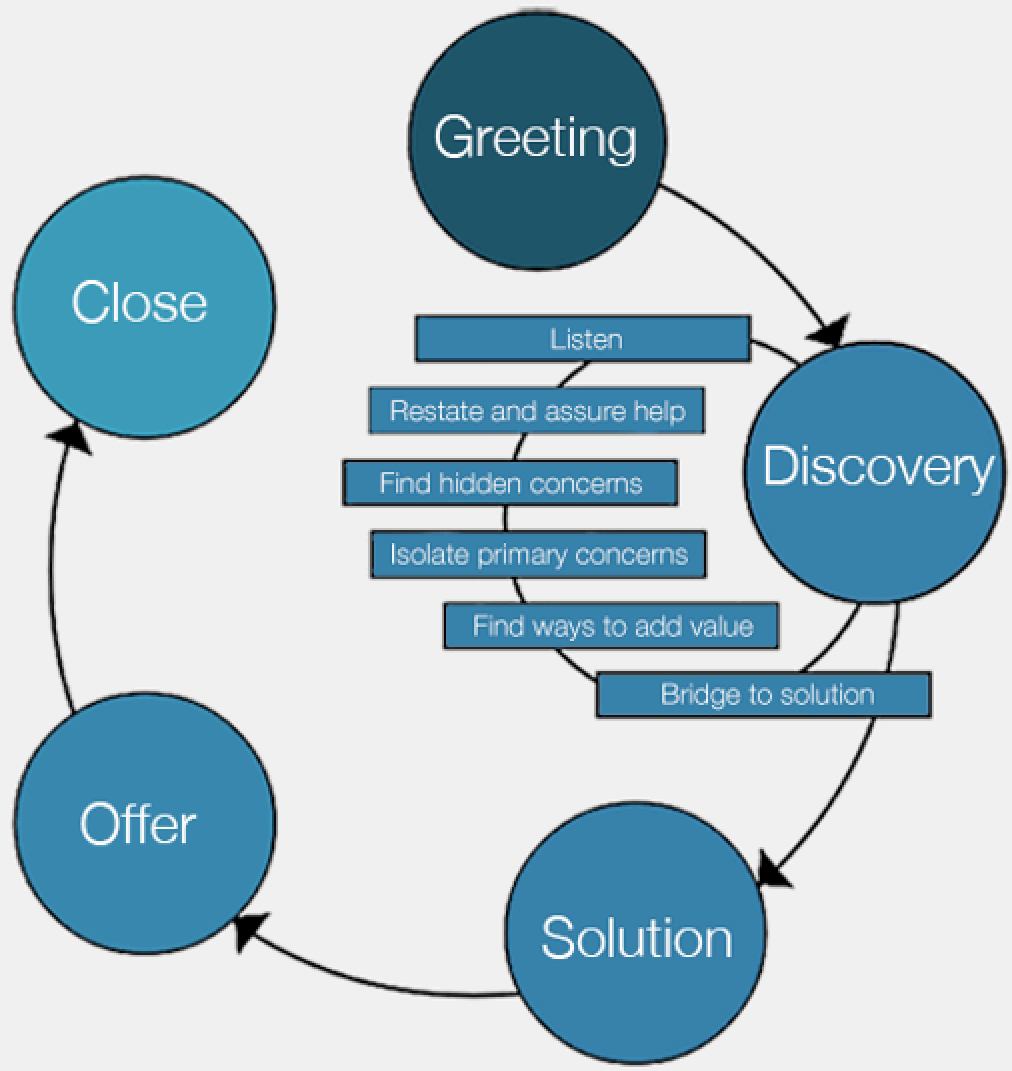
Architectural design

There are two fundamental architectural design principles to consider when designing experiences for the contact center:

- Reductionism is a philosophical tenet stating that by analyzing a system to its ultimate component parts, you can unravel it at deeper levels.
- Holism, in contrast, states that by considering the whole picture one gets a deeper and more complete view of a situation than by analyzing it into its component parts

The reductionist approach focuses on each individual component (IVR, ACD, Speech Recognition) on its own and often results in a disjointed customer experience that, when evaluated individually, may meet performance requirements for the use case. However, when evaluated end-to-end, can result in decreased quality of experience for your contacts while funneling development efforts into operational silos. This approach complicates regression testing, increases time to market, and limits the development of cross-discipline operational resources critical to the success of your contact center.

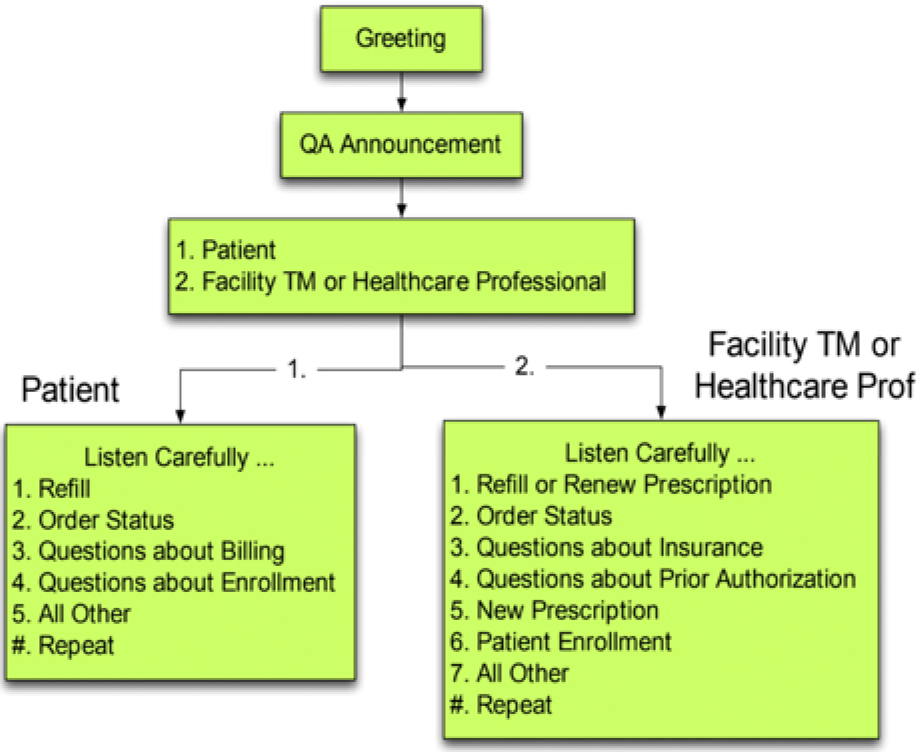
A holistic view of the contact center is shown in the following diagram:



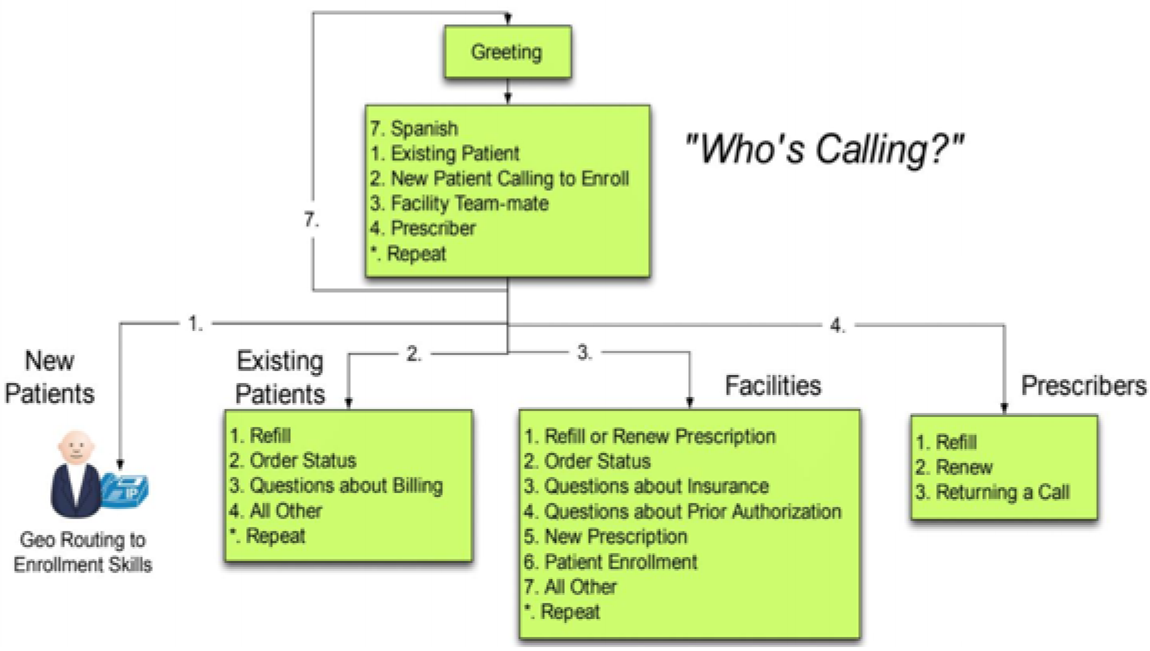
The holistic approach results focus on a more complete and cohesive experience for customers, and not which technology will provide which part of that experience.

Let the customer and what they want define and guide your efforts. The experiences that you create for your contacts should not be static or an end state, but should serve as a starting point that should be iterated on continuously based on customer feedback. The regular collection and review of operational and tuning data surrounding how your contacts are interacting and navigating throughout their journey should drive that iteration. Your goal should be dynamic and personalized experiences for contacts reaching your company. This can be accomplished through dynamic data-driven contact design and routing, resulting in an experience that conforms to your contact and their individual needs.

You can start with the default experience, building out your flows, but refactoring your single flow into two to enable future segmentation:



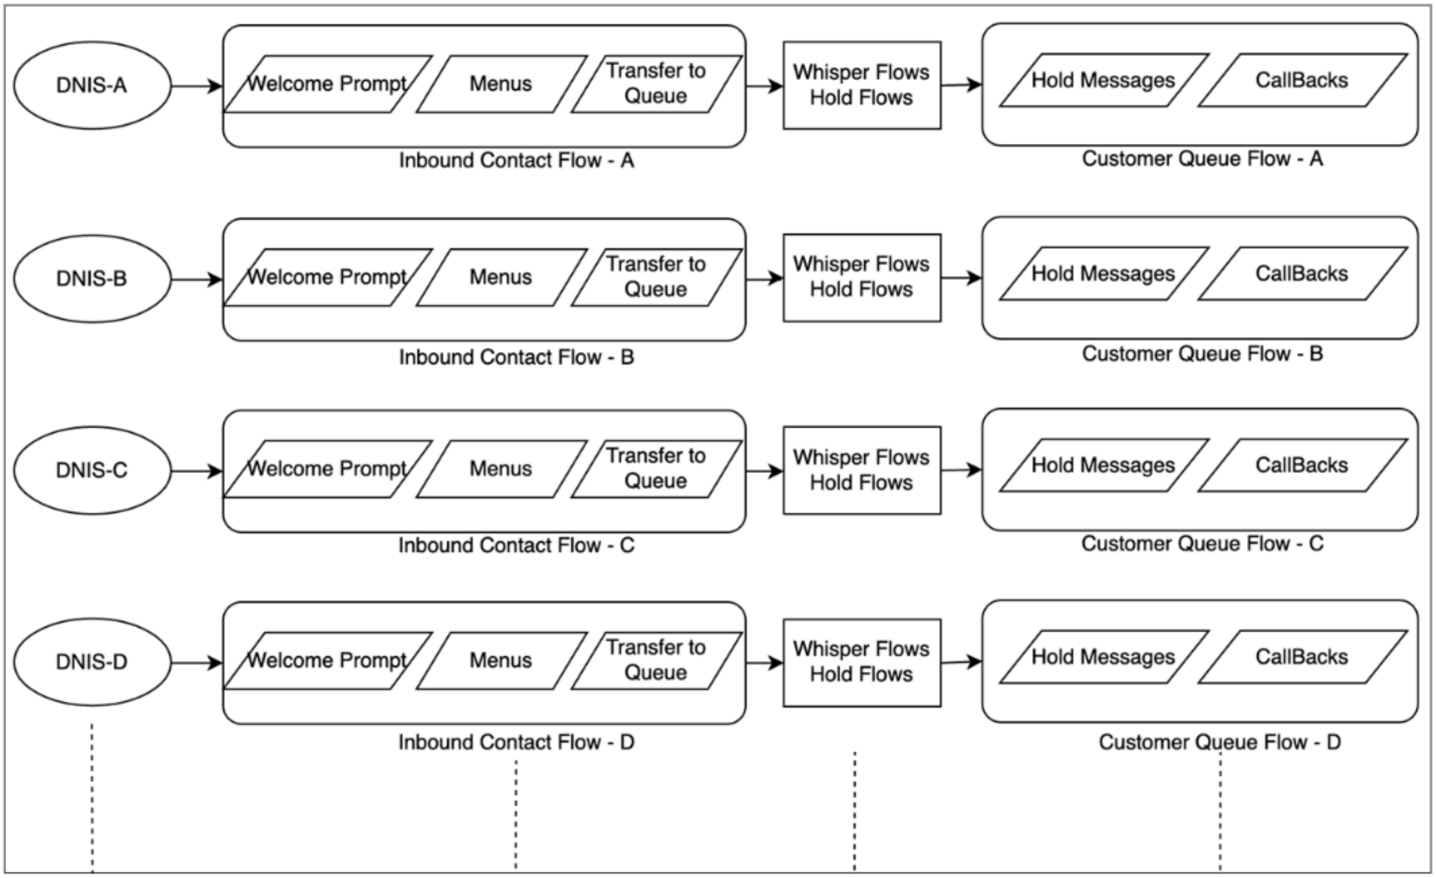
In your next iteration, identify additional experiences that you need to plan for and build routing and, if necessary, flows for each. For example, you may want to play different prompts for a contact that is past due on their bill or that may have tried to contact multiple times for the same purpose. With this approach, you are working towards personalized, dynamic experiences that are pertinent to your contacts and why they are contacting you. In addition to improving the quality of experience for your contacts and decreasing handle times, you're encouraging contact self-service by providing a more intelligent and flexible experience. Your next iteration may look like the following illustration:



Flow design

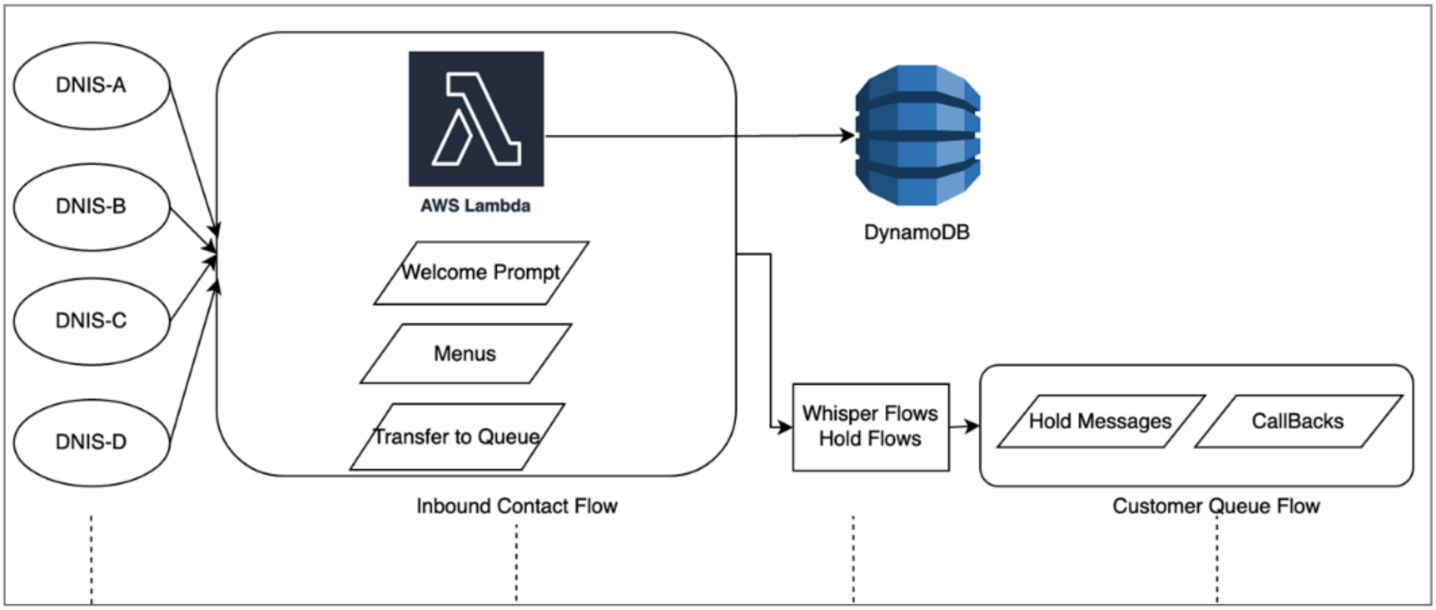
A flow defines the customer experience with your contact center from start to finish. Your flow configuration can have a direct impact on performance, operational efficiency, and ease of maintenance.

Many Large businesses support multiple phone numbers, business units, prompts, queues, and other Amazon Connect resources. While it is possible to have unique flows for each phone number and line of business, it can lead to a one-to-one mapping of phone numbers and flows. This results in unnecessary service quota requests and a large number of flows to support and maintain. A one-to-one mapping of DNIS and Flow implementation is illustrated in the following figure:



Alternatively, you should consider an approach that results in Multiple DNIS to one or few flows by using the dynamic nature of Amazon Connect Flows. With this approach, you can store configuration information like Prompts, Queues, Business Hours, Whisper Prompts/Flows, Queues, Queue Treatments and Hold Messages etc., in NoSQL Database DynamoDB. In Amazon Connect, you can associate multiple phone numbers to the same flow and use the Lambda function to look up configurations for that phone number. This allows you to dynamically define the contact's experience based on the attributes returned from DynamoDB.

For example, you can play prompts or use Text-to-Speech (TTS) to greet callers based upon the lookups in DynamoDB or associate queues using dynamic attributes supported in flow blocks. The result with this approach is a flow implementation that is efficient to build, maintain, and support:



Load testing

If you need to run load or scale testing, you can employ third-party or partner solutions to run load tests, or develop your own custom solution using the Amazon Connect StartOutboundVoiceContact API to generate calls combined with browser automation scripts to simulate agent behavior. Before to performing load tests, review and follow the Amazon Connect Load Testing Policy.

Agent enablement

Amazon Connect provides a readily available browser-based Contact Control Panel (CCP) for agents to interact with customer contacts. Your agents use the CCP to accept contacts, chat with contacts, transfer them to other agents, put them on hold, and perform other key tasks. You can realize significant performance efficiency through the creation of custom agent desktop solutions using the Amazon Connect Streams API. Consider using the Streams API to increase performance efficiency in the following areas:

- CRM integration - The Streams API allows you to embed the CCP in your CRM application, create your own interface, or integrate with other AWS services and partner solutions to provide your agents with the tools and resources they need to service your contacts. With a custom desktop, like the Amazon Connect and Salesforce integration, your agents can get a comprehensive view of customer and contact in a single interface without managing multiple screens and interfaces.

- Authentication - You can configure SAML for identity management in Amazon Connect and use IAM Identity Center (SSO) to allow your agents to use the same credentials they use to access your other systems and avoid the need to enter them multiple times.
- Agent automation - In addition to streamlining your agent experience, you can automate common, repeatable tasks. For example, automatically creating cases or pre-filling webforms and offering a screen pop with relevant information when a contact is offered. This can reduce handle times and improve the quality of experience for your agents and contacts.
- Enhanced capabilities - You can also enhance/extend the CCP functionality to include real-time Transcriptions, Translations, Suggested Actions and Knowledge base integrations. Integrating enhanced capabilities with your agent desktop will allow skilled agents to service contacts more efficiently and unskilled agents to provide service when skilled agents aren't available. For example, you can use this approach to automatically translate a chat contact for unskilled agent that doesn't know the language. When your agent replies, you can automatically translate the text to the contact's language, allowing for real-time bilingual communication.

Using other AWS services

This section discusses AWS services that you can use to improve performance, identify areas of opportunity, and gain valuable insights into your contact data.

AWS Lambda

You can use AWS Lambda in your Amazon Connect Flows to perform data dips for customer information, send SMS text messages, and with other services like Amazon S3 to automatically distribute scheduled reports. For more information, see Best Practices for Working with AWS Lambda functions.

AWS Direct Connect

AWS Direct Connect is a cloud service solution that makes it more efficient to establish a dedicated network connection from your premises to AWS. It provides a durable, consistent connection rather than relying on your ISP to dynamically route requests to AWS resources. It allows you to configure your edge router to redirect AWS traffic across dedicated fiber rather than traversing the public WAN and establish private connectivity between AWS and your data center, office, or colocation environment. In many cases, this can reduce your network costs, increase bandwidth throughput, and provide a more consistent network experience than Internet-based connections.

While AWS Direct Connect does not solve issues specific to private LAN/WAN traversal to your edge router, it can help solve for latency and connectivity issues between your edge router and AWS resources. It can also solve for latency and poor call quality between your edge router and AWS resources.

Depending on your VDI environment, you may not be able to take advantage of AWS Direct Connect as it requires you to configure your edge router to redirect AWS traffic across dedicated fiber rather than traversing the public WAN. If the VDI environment is hosted outside of your local DXC-enabled network, you may not be able to take full advantage of AWS Direct Connect.

Do not use AWS Direct Connect for "QoS" or "increased security." AWS Direct Connect can cause performance degradation in cases where the latency from the agent workstation is higher than the ISP's path to the Amazon Connect instance. AWS Direct Connect does not offer additional security when compared to an ISP as Amazon Connect voice and data is already encrypted.

Amazon Polly

Amazon Connect offers a native integration with Amazon Polly, allowing you to play dynamic and natural Text-to-Speech (TTS), use Speech Synthesis Markup Language (SSML), and take advantage of Neural Text-to-Speech (NTTS) to achieve the most natural and human-like text-to-speech voices possible.

Amazon Lex

Your contact's path to service can be a challenging experience that doesn't always meet up to their expectations. Your contacts may wait on hold, repeat information, need to be transferred, and ultimately, spend too much time getting what they need. AI is playing a role in improving this customer experience in call centers to include engagement through chatbots — intelligent, natural language virtual assistants. These chatbots are able to recognize human speech and understand the caller's intent without requiring the caller to speak in specific phrases. Contacts can perform tasks such as changing a password, requesting a balance on an account, or scheduling an appointment without ever speaking to an agent.

Amazon Lex is a service that allows you to create intelligent conversational chatbots. It lets you turn your Amazon Connect contact center flows into natural conversations that provide personalized experiences for your callers. Using the same technology that powers Amazon Alexa, an Amazon Lex chatbot can be attached to your Amazon Connect Flow to recognize the intent of your caller, ask follow-up questions, and provide answers. Amazon Lex maintains context and manages the dialogue, dynamically adjusting the responses based on the conversation, so your contact center can perform common tasks for callers, to address many customer inquiries through self-service interactions. Additionally, Amazon Lex chatbots support an optimal (8 kHz) telephony audio sampling rate, to provide increased speech recognition accuracy and fidelity for your contact center voice interactions.

Building an effective Amazon Lex bot requires providing simple and realistic utterances as training sets to the bot, periodically reviewing your bot's performance, updating your utterance set, and modifying the bot based on such a review. For more information, see the following resources:

- Monitoring in Amazon Lex
- Building Better bots using Amazon Lex

Amazon Kinesis

For situations where you need to gain additional insight from your contact metrics and real-time data from Amazon Connect, you can:

- Export your contact record data to Amazon Redshift using Amazon Kinesis.
- Use Amazon Kinesis video stream (KVS) and AWS Lambda to transcribe call recordings or voice contacts in real-time using Amazon Transcribe and send the resulting text to Amazon Comprehend for sentiment analysis.
- Leverage the Amazon Connect Agent Event Kinesis Stream for real-time agent CTI and schedule adherence data.

Amazon OpenSearch Service and Kibana

Using Amazon OpenSearch Service and Kibana to process real-time Amazon Connect data gives you a flexible way to query and visualize real-time and historical Amazon Connect data beyond native reporting capabilities.

Amazon Connect Contact Lens

Contact Lens is a set of machine learning (ML) capabilities integrated into Amazon Connect that allow contact center supervisors to better understand the sentiment, trends, and compliance risks of customer conversations to effectively train agents, replicate successful interactions, and identify crucial company and product feedback. Contact Lens transcribes contact center calls to create a fully searchable archive and surface valuable customer insights.

Cost optimization for Amazon Connect workloads

Cost Optimization includes the ability to run systems to deliver business value at the lowest price point. This section provides an overview of design principles, best practices, and questions surrounding cost optimization for Amazon Connect workloads. You can find prescriptive guidance on implementation in the Cost Optimization Pillar whitepaper.

There are five areas to consider for cost optimization for Amazon Connect workloads.

Region selection

Amazon Connect Region selection is one of the first decision customers make when adopting Amazon Connect for their contact center workloads. While latency and voice quality are important aspects to Region selection, you should evaluate Region selection from a cost perspective as well. Telephony pricing for Claimed Phone Numbers Per Day and Per Minute Inbound Usage can be different for countries depending upon the AWS Region in which you select to instantiate your Amazon Connect Instance. You can find telephony price for each Region at Amazon Connect Pricing page.

Callbacks

You can provide a callback in your flow for callers during high call volume periods or long wait times. You can use callbacks to reduce cost and improve the quality of experience for your contacts.

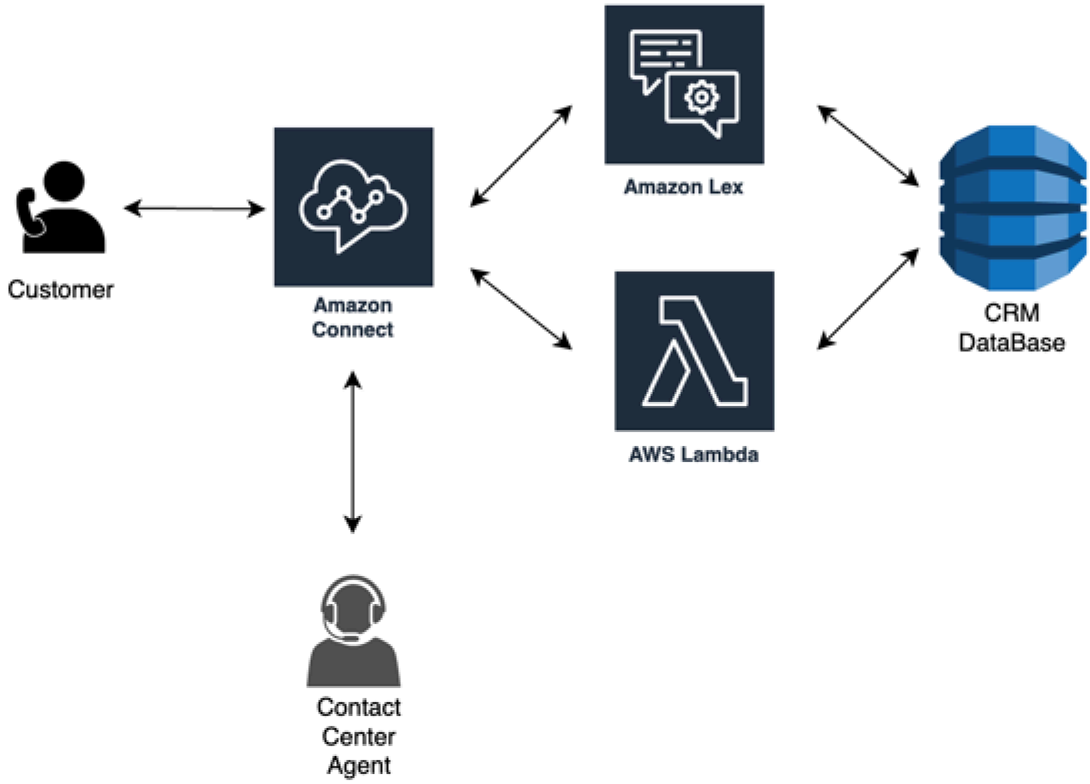
When your contact opts-in for the callback, Amazon Connect will retain the position in the queue and allow the caller to disconnect. When an agent becomes available to service your contact, Amazon Connect will place an outbound call to the number configured to connect the contact to your agent. A sample callback flow is included in every instance at creation. You can also use AWS Lambda and Amazon DynamoDB to prevent duplicate callback requests.

Storage

With Amazon Connect, you can configure your instance and flows to store call recordings and chat transcripts of caller's interactions for compliance, quality monitoring, and training purposes. Voice contacts are not recorded unless an agent is connected to the caller. If multiple agents are connected, each will have an associated call recording or transcript. Amazon Connect stores voice recordings in Amazon S3 according to your Amazon S3 Lifecycle policy configuration. With the call recordings stored in Amazon S3, you can use Amazon S3 tiers of storage to manage retention and optimize cost. For example, you can transition objects using Amazon S3 Lifecycle to move call recordings and transcripts over three months old to S3 Glacier to reduce storage cost.

Self-service

Amazon Connect's pay-as-you-go pricing model can result in lower costs as compared to traditional licensing-based contact centers. However, the traditional contact center infrastructure that spans automatic call distribution (ACD) systems, IVR, telephony and work force management (WFM) systems plays a proportionately small contribution to the overall cost of contact center operations. The largest contributor to the cost of the contact center often comes from human capital and the real estate required to provide an operating environment for your agents. Amazon Connect Flows can be used natively with Amazon Lex for NLU, NLP, and ASR and Amazon Polly for lifelike Text-to-Speech (TTS) to build highly engaging user experiences and natural conversational interactions across voice and text. By using an Amazon Lex chatbot in your Amazon Connect call center, callers can perform tasks such as changing a password, requesting a balance on an account, or scheduling an appointment, without needing to speak to an agent. These self-service options result in better customer experience and lowers your cost per contact.



Click-to-call

You can use click-to-call in Amazon Connect to initiate a voice call using the StartOutboundVoiceContact API for authentication through web or mobile application to reduce call handle times and improve the quality of experience. With this approach, you're able to offer your contact the ability to bypass IVR authentication, pass contextual information like URLs, recent web/mobile activity, and user data to your flows to create dynamic, personalized experiences. For example, a contact browsing your website to purchase an item or member of a financial institution who is already authenticated in the mobile app and wants to speak with an agent about a recent transaction.

Redirect voice contacts to chat

With Amazon Connect, you can allow agents to handle multiple chat conversations simultaneously where they would only able to handle one voice conversation. When you don't have a voice agent available, you can send an SMS text message to your customer to offer a link to chat with an agent right away.

Plan your identity management in Amazon Connect

Before you set up your Amazon Connect instance, you should decide how you want to manage your Amazon Connect users. A user is anyone who needs an Amazon Connect account: agents, call center managers, analysts, and more.

You cannot change the option you select for identity management after you create an instance. Instead, you must delete the instance and create a new one. However, if you delete an instance, you lose its configuration settings and metrics data.

When you create your instance, you can choose from one of the following identity management solutions:

- **Store users with Amazon Connect**—Choose this option if you want to create and manage user accounts within Amazon Connect.

  When you manage users in Amazon Connect, the user name and password for each user is specific to Amazon Connect. Users must remember a separate user name and password to log in to Amazon Connect.
- **Link to an existing directory**—Choose this option to use an existing Active Directory. Users will log in to Amazon Connect using their corporate credentials.

  If you choose this option, the directory must be associated with your account, set up in AWS Directory Service, and be active in the same Region in which you create your instance. If you plan to choose this option, you should prepare your directory before you create your Amazon Connect instance. For more information, see Use an existing directory for identity management in Amazon Connect.
- **SAML 2.0-based authentication**—Choose this option if you want to use your existing network identity provider to federate users with Amazon Connect. Users can only log in to Amazon

Connect by using the link configured through your identity provider. If you plan to choose this option, you should configure your environment for SAML before you create your Amazon Connect instance. For more information, see Configure SAML with IAM for Amazon Connect.

Use an existing directory for identity management in Amazon Connect

If you are already using a AWS Directory Service directory to manage users, you can use the same directory to manage user accounts in Amazon Connect. You can also create a new directory in AWS Directory Service to use for Amazon Connect. The directory you choose must be associated with your AWS account, and must be active in the AWS Region in which you create your instance. You can associate an AWS Directory Service directory with only one Amazon Connect instance at a time. To use the directory with a different instance, you must delete the instance with which it is already associated.

The following AWS Directory Service directories are supported in Amazon Connect:

- Microsoft Active Directory—AWS Directory Service lets you run Microsoft Active Directory as a managed service.
- Active Directory Connector—AD Connector is a directory gateway you can use to redirect directory requests to your on-premises Microsoft Active Directory.
- Simple Active Directory—Simple AD is a standalone managed directory that is powered by a Samba 4 Active Directory compatible server.

You cannot change the identity option you select after you create the instance. If you decide to change the directory you selected, you can delete the instance and create a new one. When you delete an instance, you lose all configuration settings and metrics data for it.

There is no additional charge for using an existing or a proprietary directory in Amazon Connect. For information about the costs associated with using AWS Directory Service, see AWS Directory Service Pricing Overview.

The following limitations apply to all new directories created using AWS Directory Service:

- Directories can only have alphanumeric names. Only the '.' character can be used.
- Directories cannot be unbound from an Amazon Connect instance after they have been associated.
- Only one directory can be added to an Amazon Connect instance.

- Directories cannot be shared across multiple Amazon Connect instances.

Configure SAML with IAM for Amazon Connect

Amazon Connect supports identity federation by configuring Security Assertion Markup Language (SAML) 2.0 with AWS IAM to enable web-based single sign-on (SSO) from your organization to your Amazon Connect instance. This allows your users to sign in to a portal in your organization hosted by a SAML 2.0 compatible identity provider (IdP) and log in to an Amazon Connect instance with a single sign-on experience without having to provide separate credentials for Amazon Connect.

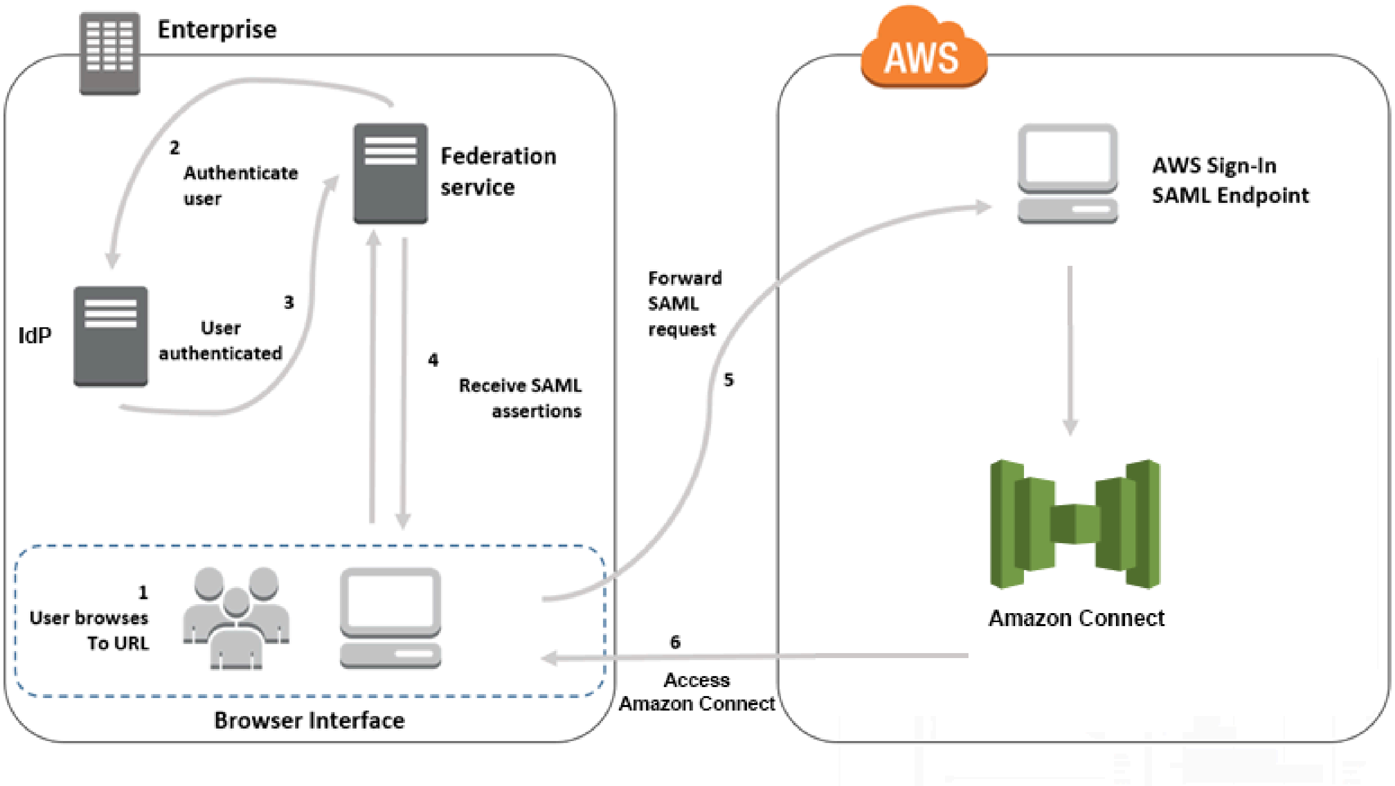
Important notes

Before you begin, note the following:

- These instructions do not apply to Amazon Connect Global Resiliency deployments. For information that applies to Amazon Connect Global Resiliency, see Integrate your identity provider (IdP) with an Amazon Connect Global Resiliency SAML sign in endpoint.
- Choosing SAML 2.0-based authentication as the identity management method for your Amazon Connect instance requires the configuration of AWS Identity and Access Management federation.
- The user name in Amazon Connect must match the RoleSessionName SAML attribute specified in the SAML response returned by the identity provider.
- Amazon Connect does not support reverse federation. That is, you can't login directly into Amazon Connect. If you tried, you'd get a *Session Expired* message. The authentication should be done from the Identity Provider (IdP) and not the Service Provider (SP) (Amazon Connect).
- Most identity providers by default use the global AWS sign-in endpoint as the Application Consumer Service (ACS), which is hosted in US East (N. Virginia). We recommend overriding this value to use the regional endpoint that matches the AWS Region where your instance was created.
- All Amazon Connect usernames are case sensitive, even when using SAML.
- If you have old Amazon Connect instances that were set up with SAML and you need to update your Amazon Connect domain, see Personal settings.

Overview of using SAML with Amazon Connect

The following diagram shows the order in which steps take place for SAML requests to authenticate users and federate with Amazon Connect. It is not a flow diagram for a threat model.



SAML requests go through the following steps:

1. The user browses to an internal portal that includes a link to log in to Amazon Connect. The link is defined in the identity provider.
2. The federation service requests authentication from the organization's identity store.
3. The identity store authenticates the user and returns the authentication response to the federation service.
4. When authentication is successful, the federation service posts the SAML assertion to the user's browser.
5. The user's browser posts the SAML assertion to the AWS sign in SAML endpoint (https://signin.aws.amazon.com/saml). AWS sign in receives the SAML request, processes the request, authenticates the user, and initiates a browser redirect to the Amazon Connect endpoint with the authentication token.
6. Using the authentication token from AWS, Amazon Connect authorizes the user and opens Amazon Connect in their browser.

Enabling SAML-based authentication for Amazon Connect

The following steps are required to enable and configure SAML authentication for use with your Amazon Connect instance:

1. Create an Amazon Connect instance and select SAML 2.0-based authentication for identity management.
2. Enable SAML federation between your identity provider and AWS.
3. Add Amazon Connect users to your Amazon Connect instance. Log in to your instance using the administrator account created when you created your instance. Go to the **User Management** page and add users.

> **Important**
>
> - **For a list of allowed characters in user names**, see the documentation for the `Username` property in the CreateUser action.
> - Due to the association of an Amazon Connect user and an AWS IAM Role, the user name must match exactly the RoleSessionName as configured with your AWS IAM federation integration, which typically ends up being the user name in your directory. The format of the username should match the intersection of the format conditions of the RoleSessionName and an Amazon Connect user, as shown in the following diagram:
>
> >

4. Configure your identity provider for the SAML assertions, authentication response, and relay state. Users log in to your identity provider. When successful, they are redirected to your Amazon Connect instance. The IAM role is used to federate with AWS, which allows access to Amazon Connect.

Select SAML 2.0-based authentication during instance creation

When you are creating your Amazon Connect instance, select the SAML 2.0-based authentication option for identity management. On the second step, when you create the administrator for the instance, the user name that you specify must exactly match a user name in your existing network directory. There is no option to specify a password for the administrator because passwords are managed through your existing directory. The administrator is created in Amazon Connect and assigned the **Admin** security profile.

You can log in to your Amazon Connect instance, through your IdP, using the administrator account to add additional users.

Enable SAML federation between your identity provider and AWS

To enable SAML-based authentication for Amazon Connect, you must create an identity provider in the IAM console. For more information, see Enabling SAML 2.0 Federated Users to Access the AWS Management Console.

The process to create an identity provider for AWS is the same for Amazon Connect. Step 6 in the above flow diagram shows the client is sent to your Amazon Connect instance instead of the AWS Management Console.

The steps necessary to enable SAML federation with AWS include:

1. Create a SAML provider in AWS. For more information, see Creating SAML Identity Providers.
2. Create an IAM role for SAML 2.0 federation with the AWS Management Console. Create only one role for federation (only one role is needed and used for federation). The IAM role determines which permissions the users that log in through your identity provider have in AWS. In this case, the permissions are for accessing Amazon Connect. You can control the permissions to features of Amazon Connect by using security profiles in Amazon Connect. For more information, see Creating a Role for SAML 2.0 Federation (Console).

   In step 5, choose **Allow programmatic and AWS Management Console access**. Create the trust policy described in the topic in the procedure *To prepare to create a role for SAML 2.0 federation*. Then create a policy to assign permissions to your Amazon Connect instance. Permissions start on step 9 of the *To create a role for SAML-based federation* procedure.

   To create a policy for assigning permissions to the IAM role for SAML federation

   1. On the **Attach permissions policy** page, choose **Create policy**.

2. On the **Create policy** page, choose **JSON**.

3. Copy one of the following example policies and paste it into the JSON policy editor, replacing any existing text. You can use either policy to enable SAML federation, or customize them for your specific requirements.

   Use this policy to enable federation for all users in a specific Amazon Connect instance. For SAML-based authentication, replace the value for the `Resource` to the ARN for the instance that you created:

```
{
    "Version": "2012-10-17",
   "Statement": [
        {
            "Sid": "Statement1",
            "Effect": "Allow",
            "Action": "connect:GetFederationToken",
            "Resource": [
                "arn:aws:connect:us-
east-1:361814831152:instance/2fb42df9-78a2-2e74-d572-c8af67ed289b/user/
${aws:userid}"
            ]
        }
    ]
}
```

   Use this policy to enable federation to a specific Amazon Connect instances. Replace the value for the `connect:InstanceId` to the instance ID for your instance.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Statement2",
            "Effect": "Allow",
            "Action": "connect:GetFederationToken",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "connect:InstanceId": "2fb42df9-78a2-2e74-d572-c8af67ed289b"
                }
            }
```

```
        }
    ]
}
```

Use this policy to enable federation for multiple instances. Note the brackets around the listed instance IDs.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Statement2",
            "Effect": "Allow",
            "Action": "connect:GetFederationToken",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "connect:InstanceId": [
                    "2fb42df9-78a2-2e74-d572-c8af67ed289b",
                    "1234567-78a2-2e74-d572-c8af67ed289b"]
                }
            }
        }
    ]
}
```

4. After you create the policy, choose **Next: Review**. Then return to step 10 in the *To create a role for SAML-based federation* procedure in the Creating a Role for SAML 2.0 Federation (Console) topic.

3. Configure your network as a SAML provider for AWS. For more information, see Enabling SAML 2.0 Federated Users to Access the AWS Management Console.

4. Configure SAML Assertions for the Authentication Response. For more information, Configuring SAML Assertions for the Authentication Response.

5. For Amazon Connect, leave the **Application Start URL** blank.

6. Override the Application Consumer Service (ACS) URL in your identity provider to use the regional endpoint that coincides with the AWS Region of your Amazon Connect instance. For more information, see Configure the identity provider to use regional SAML endpoints.

7. Configure the relay state of your identity provider to point to your Amazon Connect instance. The URL to use for the relay state is comprised as follows:

```
https://region-id.console.aws.amazon.com/connect/federate/instance-id
```

Replace the `region-id` with the Region name where you created your Amazon Connect instance, such as us-east-1 for US East (N. Virginia). Replace the `instance-id` with the instance ID for your instance.

For a GovCloud instance, the URL is **https://console.amazonaws-us-gov.com/**:

- https://console.amazonaws-us-gov.com/connect/federate/instance-id

> **Note**
>
> You can find the instance ID for your instance by choosing the instance alias in the Amazon Connect console. The instance ID is the set of numbers and letters after '/instance' in the **Instance ARN** displayed on the **Overview** page. For example, the instance ID in the following Instance ARN is *178c75e4-b3de-4839-a6aa-e321ab3f3770*. arn:aws:connect:us-east-1:450725743157:instance/*178c75e4-b3de-4839-a6aa-e321ab3f3770*

Configure the identity provider to use regional SAML endpoints

To provide the best availability we recommend using the regional SAML endpoint that coincides with your Amazon Connect instance instead of the default global endpoint.

The following steps are IdP agnostic; they work for any SAML IdP (for example, Okta, Ping, OneLogin, Shibboleth, ADFS, AzureAD, and more).

1. Update (or override) the Assertion Consumer Service (ACS) URL. There are two ways you can do this:

   - **Option 1**: Download the AWS SAML metadata and update the `Location` attribute to the Region of your choice. Load this new version of the AWS SAML metadata into your IdP.

     Following is an example of a revision:

     ```
     <AssertionConsumerService index="1" isDefault="true"
     Binding="urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST"
     Location="https://region-id.signin.aws.amazon.com/saml"/>
     ```

- **Option 2**: Override the AssertionConsumerService (ACS) URL in your IdP. For IdPs like Okta that provide prebaked AWS integrations, you can override the ACS URL in the AWS admin console. Use the same format to override to a Region of your choice (for example, https://*region-id*.signin.aws.amazon.com/saml).

2. Update the associated role trust policy:

   a. This step needs to be done for every role in every account that trusts the given identity provider.

   b. Edit the trust relationship, and replace the singular `SAML:aud` condition with a multivalued condition. For example:

      - Default: "`SAML:aud`": "https://signin.aws.amazon.com/saml".
      - With modifications: "`SAML:aud`": ["https://signin.aws.amazon.com/saml", "https://*region-id*.signin.aws.amazon.com/saml"]

   c. Make these changes to the trust relationships in advance. They should not be done as part of a plan during an incident.

3. Configure a relay state for the Region-specific console page.

   a. If you don't do this final step, there's no guarantee that the Region-specific SAML sign in process will forward the user to the console sign in page within the same Region. This step is most varied per identity provider, but there are a blogs (for example, How to Use SAML to Automatically Direct Federated Users to a Specific AWS Management Console Page) that show the use of relay state to achieve deep linking.

   b. Using the technique/parameters appropriate for your IdP, set the relay state to the console endpoint that matches (for example, https://*region-id*.console.aws.amazon.com/connect/federate/*instance-id*).

Note

- Ensure that STS is not disabled in your additional Regions.
- Ensure no SCPs are preventing STS actions in your additional Regions.

Use a destination in your relay state URL

When you configure the relay state for your identity provider, you can use the destination argument in the URL to navigate users to a specific page in your Amazon Connect instance. For example, use a link to open the CCP directly when an agent logs in. The user must be assigned a security profile that grants access to that page in the instance. For example, to send agents to the CCP, use a URL similar to the following for the relay state. You must use URL encoding for the destination value used in the URL:

- `https://us-east-1.console.aws.amazon.com/connect/federate/instance-id?destination=%2Fccp-v2%2Fchat&new_domain=true`

Another example of a valid URL is:

- `https://us-east-1.console.aws.amazon.com/connect/federate/instance-id?destination=%2Fagent-app-v2`

For a GovCloud instance, the URL is **https://console.amazonaws-us-gov.com/**. So the address would be:

- `https://console.amazonaws-us-gov.com/connect/federate/instance-id?destination=%2Fccp-v2%2Fchat&new_domain=true`

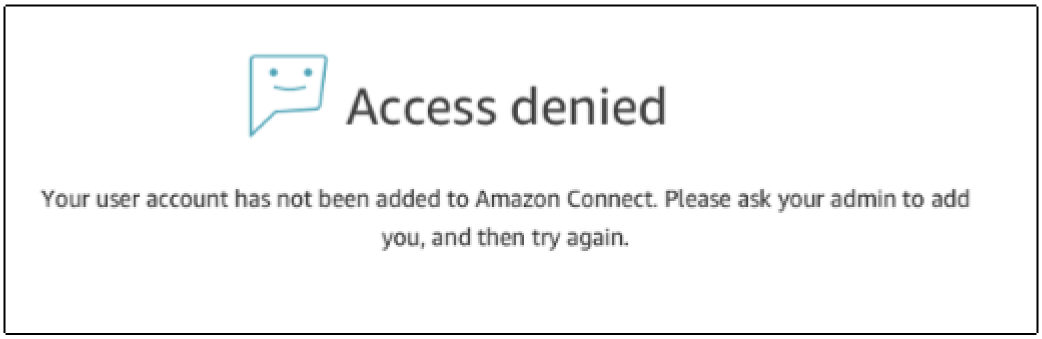
If you want to configure the destination argument to a URL outside of the Amazon Connect instance, such as your own custom website, first add that external domain to the account's approved origins. For example, perform the steps in the following order:

1. In the Amazon Connect console add https://*your-custom-website*.com to your approved origins. For instructions, see Use an allowlist for integrated applications in Amazon Connect.
2. In your identity provider configure your relay state to `https://`*`your-region`*`.console.aws.amazon.com/connect/federate/instance-id?destination=https%3A%2F%2F`*`your-custom-website.com`*
3. When your agents log in they are taken directly to https://*your-custom-website*.com.

Add users to your Amazon Connect instance

Add users to your connect instance, making sure that the user names exactly match the users names in your existing directory. If the names do not match, users can log in to the identity provider, but not to Amazon Connect because no user account with that user name exists in Amazon Connect. You can add users manually on the **User management** page, or you can bulk upload users with the CSV template. After you add the users to Amazon Connect, you can assign security profiles and other user settings.

When a user logs in to the identity provider, but no account with the same user name is found in Amazon Connect, the following **Access denied** message is displayed.



Bulk upload users with the template

You can import your users by adding them to a CSV file. You can then import the CSV file to your instance, which adds all users in the file. If you add users by uploading a CSV file, make sure that you use the template for SAML users. You can find on the **User management** page in Amazon Connect. A different template is used for SAML-based authentication. If you previously downloaded the template, you should download the version available on the **User management** page after you set up your instance with SAML-based authentication. The template should not include a column for email or password.

SAML user logging in and session duration

When you use SAML in Amazon Connect, users must log in to Amazon Connect through your identity provider (IdP). Your IdP is configured to integrate with AWS. After authentication, a token for their session is created. The user is then redirected to your Amazon Connect instance and automatically logged in to Amazon Connect using single sign-on.

As a best practice, you should also define a process for your Amazon Connect users to log out when they are finished using Amazon Connect. They should log out from both Amazon Connect and your identity provider. If they do not, the next person that logs in to the same computer can log in to Amazon Connect without a password since the token for the previous sessions is still valid for the duration of the session. It's valid for 12 hours.

About session expiration

Amazon Connect sessions expire 12 hours after a user logs in. After 12 hours, users are automatically logged out, even if they are currently on a call. If your agents stay logged in for more than 12 hours, they need to refresh the session token before it expires. To create a new session, agents need to log out of Amazon Connect and your IdP and then log in again. This resets the session timer set on the token so that agents are not logged out during an active contact with a customer. When a session expires while a user is logged in, the following message is displayed. To use Amazon Connect again, the user needs to log in to your identity provider.

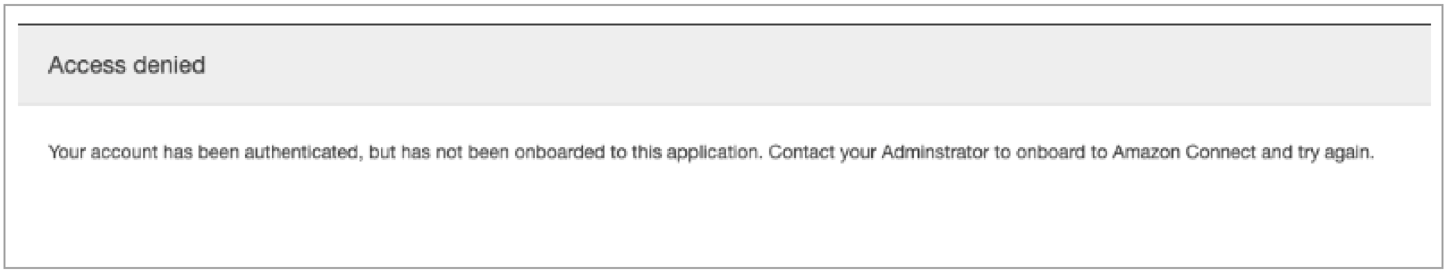
> **Note**
>
> If you see the **Session expired** message while logging in, you probably just need to refresh the session token. Go to your identity provider and log in. Refresh the Amazon Connect page. If you still get this message, contact your IT team.

Troubleshoot SAML with Amazon Connect

This article explains how to troubleshoot and resolve some of the most common issues customers encounter when using SAML with Amazon Connect.

If you're troubleshooting your integration with other identity providers such as Okta, PingIdentify, Azure AD, and more, see [Amazon Connect SSO Setup Workshop](#).

Error Message: Access Denied. Your account has been authenticated, but has not been onboarded to this application.



What does this mean?

This error means that the user has successfully authenticated using SAML into the AWS SAML login endpoint. However, the user could not be matched/found inside Amazon Connect. This usually indicates one of the following:

- The username in Amazon Connect doesn't match the `RoleSessionName` SAML attribute specified in the SAML response returned by the identity provider.
- The user doesn't exist in Amazon Connect.
- The user has two separate profiles assigned to them with SSO.

Resolution

Use the following steps to check the RoleSessionName SAML attribute specified in the SAML response returned by the identity provider, and then retrieve and compare with the login name in Amazon Connect.

1. Perform a HAR capture (**H**TTP **AR**chive) for the end-to-end login process. This captures the network requests from the browser side. Save the HAR file with your preferred file name, for example, **saml.har**.

   For instructions, see [How do I create a HAR file from my browser for an AWS Support case?]

2. Use a text editor to find the SAMLResponse in the HAR file. Or, run the following commands:

   ```
   $ grep -o "SAMLResponse=.*&" azuresaml.har | sed -E 's/
   SAMLResponse=(.*)&/\1/' > samlresponse.txt
   ```

   - This searches for the SAMLresponse in the HAR file and saves it to a **samlresponse.txt** file.
   - The response is URL encoded and the contents are Base64 encoded.

3. Decode the URL response and then decode the Base64 contents using a third-party tool or a simple script. For example:

   ```
   $ cat samlresponse.txt | python3 -c "import sys; from urllib.parse
   import unquote; print(unquote(sys.stdin.read()));" | base64 --decode >
   samlresponsedecoded.txt
   ```

   This script uses a simple python command to decode the SAMLResponse from its original URL encoded format. Then it decodes the response from Base64 and outputs the SAML Response in plain text format.

4. Check the decoded response for the needed attribute. For example, the following image shows how to check `RoleSessionName`:

   ```
   $ export username=`grep -Eo 'RoleSessionName.*?</AttributeValue>'
   samlresponsedecoded.txt | sed -E 's/.*<AttributeValue>(.*)<\/AttributeValue>/\1/'`
   ```

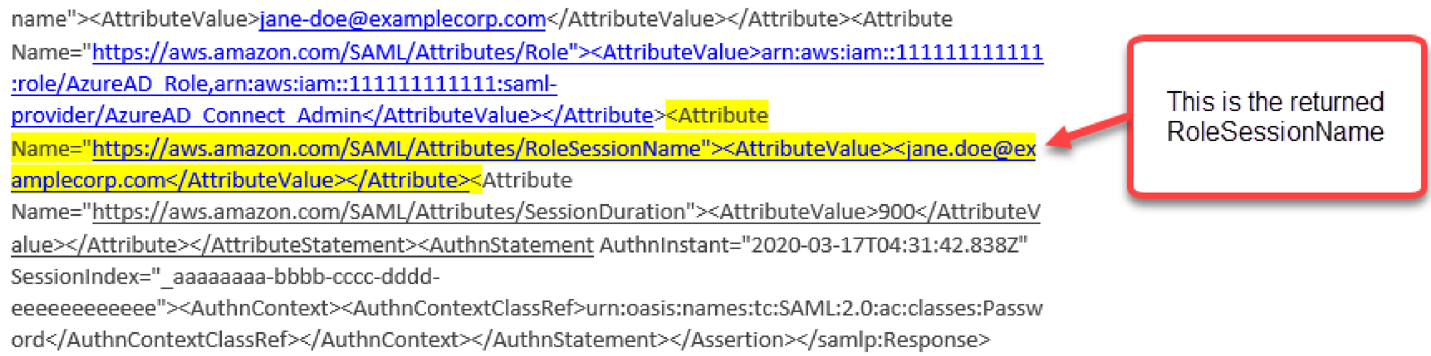
5. Check whether the username returned in from the previous step exists as a user in your Amazon Connect instance:

   $ aws connect list-users --instance-id [INSTANCE_ID] | grep $username

   - If the final grep does not return a result then this means that the user does not exist in your Amazon Connect instance or it has been created with a different case/capitalization.
   - If your Amazon Connect instance has many users, the response from the ListUsers API call maybe paginated. Use the `NextToken` returned by the API to fetch the rest of the users. For more information, see ListUsers.

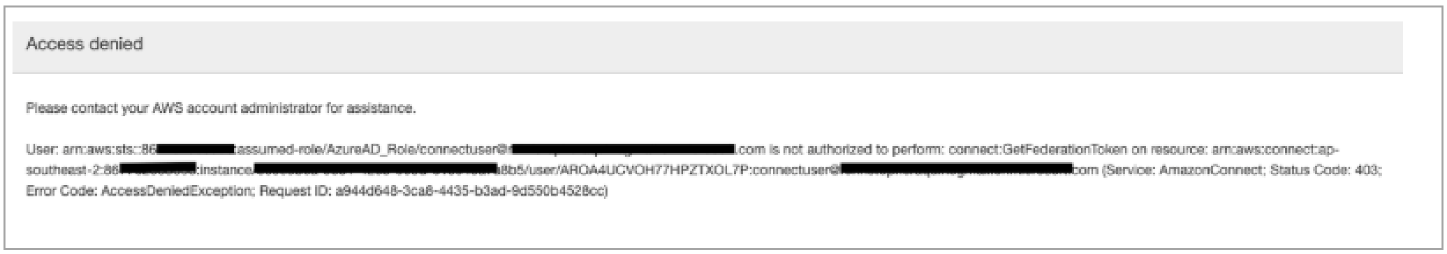
Example SAML Response

Following is an image from a sample SAML Response. In this case, the identity provider (IdP) is Azure Active Directory (Azure AD).



```
name"><AttributeValue>jane-doe@examplecorp.com</AttributeValue></Attribute><Attribute
Name="https://aws.amazon.com/SAML/Attributes/Role"><AttributeValue>arn:aws:iam::111111111111
:role/AzureAD_Role,arn:aws:iam::111111111111:saml-
provider/AzureAD_Connect_Admin</AttributeValue></Attribute><Attribute
Name="https://aws.amazon.com/SAML/Attributes/RoleSessionName"><AttributeValue><jane.doe@ex
amplecorp.com</AttributeValue></Attribute><Attribute
Name="https://aws.amazon.com/SAML/Attributes/SessionDuration"><AttributeValue>900</AttributeV
alue></Attribute></AttributeStatement><AuthnStatement AuthnInstant="2020-03-17T04:31:42.838Z"
SessionIndex="_aaaaaaaa-bbbb-cccc-dddd-
eeeeeeeeeeee"><AuthnContext><AuthnContextClassRef>urn:oasis:names:tc:SAML:2.0:ac:classes:Passw
ord</AuthnContextClassRef></AuthnContext></AuthnStatement></Assertion></samlp:Response>
```

Error Message: Access denied, Please contact your AWS account administrator for assistance.



What does this mean?

The role that the user has assumed has successfully authenticated using SAML. However, the role doesn't have permission to call the GetFederationToken API for Amazon Connect. This call is required so the user can log in to your Amazon Connect instance using SAML.

Resolution

1. Attach a policy that has the permissions for `connect:GetFederationToken` to the role found in the error message. Following is a sample policy:

```
{
    "Version": "2012-10-17",
    "Statement": [{
        "Sid": "Statement1",
        "Effect": "Allow",
        "Action": "connect:GetFederationToken",
            "Resource": [
            "arn:aws:connect:ap-southeast-2:xxxxxxxxxxxx:instance/aaaaaaaa-bbbb-
cccc-dddd-eeeeeeeeeeee/user/${aws:userid}"
            ]
        }
```

```
    ]
}
```

2. Use the IAM console to attach the policy. Or, use the attach-role-policy API, for example:

```
$ aws iam attach-role-policy —role-name [ASSUMED_ROLE] —policy_arn
[POLICY_WITH_GETFEDERATIONTOKEN]
```

Error Message: Session Expired

If you see the **Session expired** message while logging in, you probably just need to refresh the session token. Go to your identity provider and log in. Refresh the Amazon Connect page. If you still get this message, contact your IT team.

Additional resources for Amazon Connect

In addition to using the contents of this guide, you can learn more about Amazon Connect by using the following resources.

Resources

- Amazon Connect API Reference
- Amazon Connect Streams
- Amazon Connect Chat UI Examples

Amazon Connect API Reference

The Amazon Connect API Reference describes the API actions that are used to set up and manage your contact center.

Amazon Connect Streams

The Amazon Connect Streams documentation describes how to integrate your existing web applications with Amazon Connect. Streams gives you the power to embed the Contact Control Panel (CCP) UI components into your page, and/or handle agent and contact state events directly giving you the power to control agent and contact state through an object oriented event driven interface. You can use the built in interface or build your own from scratch: Streams gives you the power to choose.

Amazon Connect Chat UI Examples

The Amazon Connect Chat SDK and Sample Implementations provides examples of how to enable your app to engage with Amazon Connect chat.

Get administrative support for Amazon Connect

If you are an administrator and need to contact support for Amazon Connect, choose one of the following options:

- If you have an AWS Support account, go to Support Center and submit a ticket.
- Otherwise, open the AWS Management Console and choose **Amazon Connect**, **Support**, **Create case**.

It's helpful to provide the following information:

- Your contact center instance ID/ARN. To find your instance ARN, see Find your Amazon Connect instance ID or ARN.
- Your region.
- A detailed description of the issue.

Set up your contact center in Amazon Connect

To get started, you create an Amazon Connect instance, which is your a virtual contact center.

After you create an Amazon Connect instance, you can:

- Test the voice and chat experiences to learn how they work.
- Set up your channels. How do you want customers to reach your contact center?
  - Claim a phone number for your contact center or port your own phone number from another carrier.
  - Set up the customer's chat experience. Developer skills are required.
  - Set up SMS (text) messaging.
  - Set up in-app, web, and video calling capabilities.
  - Set up tasks.
- Enable outbound calling, and set your outbound caller ID.
- Add agents and other users.
- Review this list of security profile permissions, and then assign security profile permissions to users so they can access those parts of Amazon Connect that are appropriate to their roles.
- Set up routing. You can create a single queue for incoming contacts, or set up multiple queues so that you can route contacts to agents with specific skills.
- Use the default flows that come with Amazon Connect or create your own flows to define how your customers experience your contact center.
- Provide your agents with access to the Contact Control Panel (CCP), which they will use to interact with contacts.

The topics in this section explain how to do these steps.

Contents

- Set up routing in Amazon Connect
- Set up your contact center agents in Amazon Connect
- Provide agents with access to the Amazon Connect Contact Control Panel (CCP)
- Set up Amazon Connect external voice transfer to an on-premise voice system

Create an Amazon Connect instance

The first step in setting up your Amazon Connect contact center is to create a virtual contact center instance. Each instance contains all the resources and settings related to your contact center.

Things to know before you begin

- When you sign up for Amazon Web Services (AWS), your AWS account is automatically signed up for all services in AWS, including Amazon Connect. You are charged only for the services that you use. To create an AWS account, see How do I create and activate an AWS account?
- To allow a user to create an instance, ensure that they have the permissions granted by the **AmazonConnect_FullAccess** policy.
- For a list of the minimum IAM permissions required to create an instance, see Required permissions for using custom IAM policies to manage access to the Amazon Connect console.
- Amazon Connect is not available to customers in India using Amazon Web Services through Amazon Internet Services Pvt. Ltd (AISPL). You will receive an error message if you try to create an instance in Amazon Connect.
- When you create an instance, you must decide how you want to manage users. **You can't change the identity management option after you create the instance**. For more information, see Plan your identity management in Amazon Connect.

Step 1: Set identity

Permissions to access Amazon Connect features and resource are assigned to user accounts within Amazon Connect. When you create an instance, you must decide how you want to manage users. You can't change the identity management option after you create the instance. For more information, see Plan your identity management in Amazon Connect.

To configure identity management for your instance

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.

2. Choose **Get started**. If you have previously created an instance, choose **Add an instance** instead.
3. Choose one of the following options:
   - **Store users in Amazon Connect** - Use Amazon Connect to create and manage user accounts. You cannot share users with other applications.
   - **Link to an existing directory** - Use an AWS Directory Service directory to manage your users. You can use each directory with one Amazon Connect instance at a time.
   - **SAML 2.0-based authentication** - Use an existing identity provider (IdP) to federate users with Amazon Connect.
4. If you chose **Store users within Amazon Connect** or **SAML 2.0-based authentication**, provide the left-most label for **Access URL**. This label must be unique across all Amazon Connect instances in all Regions. You can't change the access URL after you create your instance.
5. If you chose **Link to an existing directory**, select the AWS Directory Service directory for **Directory**. The directory name is used as the left-most label for **Access URL**.
6. Choose **Next**.

Step 2: Add administrator

After you specify the user name of the administrator for the Amazon Connect instance, a user account is created in Amazon Connect and the user is assigned the **Admin** security profile.

To specify the administrator for your instance (Optional)

1. Do one of the following, based on the option that you chose in the previous step:
   - If you chose **Store users within Amazon Connect**, select **Specify an administrator**, and provide a name, password, and email address for the user account in Amazon Connect.
   - If you chose **Link to an existing directory**, for **Username**, type the name of an existing user in the AWS Directory Service directory. The password for this user is managed through the directory.
   - If you chose **SAML 2.0-based authentication**, select **Add a new admin** and provide a name for the user account in Amazon Connect. The password for this user is managed through the IdP.
2. You can also select **No administrator** if an administrator is not needed for your instance.

3. (Optional) Add tags to your instance. For more information see Tagging an Amazon Connect instance.
4. Choose **Next**.

Step 3: Set telephony

Use the options in this section to choose whether you want your agents to receive calls from customers, make outbound calls, and hear early media audio.

Early media

When early media audio is enabled, for outbound calls your agents can hear pre-connection audio such as busy signals, failure-to-connect errors, or other informational messages provided by telephony providers.

> **Note**
>
> The early media feature is not supported for transfers that are dialed through the Transfer to phone number block in flows.

By default, early media is enabled for you. Note the following exception:

- Your instance was created before April 17, 2020, and you weren't enrolled in the preview program. You need to enable early media audio. For instructions, see Update telephony options.

To configure telephony options for your instance

1. To allow inbound calls to your contact center, choose **Receive inbound calls with Amazon Connect**.
2. To enable outbound calling from your contact center, choose **Make outbound calls with Amazon Connect**.
3. To enable agents to hear pre-connection audio, choose **Enable early media**.
4. To enable up to six participants on a call, choose **Enable Multi-Party Calls and Enhanced Monitoring for Voice**.
5. To enable up to six participants on a chat, choose **Enable Multi-Party Chats and Enhanced Monitoring for Chat**.

6. Choose **Next**.

Step 4: Data storage

> **Note**
>
> Amazon Connect does not support Amazon S3 Object Lock in compliance mode to store objects using a write-once-read-many (WORM) model.

When you create an instance, by default we create an Amazon S3 bucket. Data, such as reports and recordings of conversations, is encrypted using AWS Key Management Service, and then stored in the Amazon S3 bucket.

This bucket and key are used for both recordings of conversations and exported reports. Alternatively, you can specify separate buckets and keys for recordings of conversations and exported reports. For instructions, see Update settings for your Amazon Connect instance.

By default, Amazon Connect creates buckets for storing call recordings, chat transcripts, exported reports, flow logs, and email messages.

- When a bucket is created to store call recordings, call recording is enabled at the instance level. The next step for setting up this functionality is to set up recording behavior in a contact flow.
- When a bucket is created to store chat transcripts, chat transcription is enabled at the instance level. Now all chat transcripts will be stored. Only if you want to monitor chat conversations do you need to set up recording behavior in a contact flow.
- When a bucket is created to store email messages, a default Amazon Connect email domain is created for your instance. This email domain cannot be customized. After your Amazon Connect instance is created, you can add up to five custom email domains that have been onboarded to Amazon SES. For more information, see Enable email for your Amazon Connect instance.

  > **Important**
  >
  > If you choose **Enable Attachments sharing** for your instance, you must configure a CORS policy on your attachments bucket. If you don't do this, the email channel will not work for your instance. For instructions, see Step 5: Configure a CORS policy on your attachments bucket.

- Live media streaming is not enabled by default.
- Screen recording is not enabled by default. For more information, see Enable screen recording for your Amazon Connect instance.

By default, Amazon Connect creates a Customer Profiles domain, which stores profiles that combine customer contact history with customer information such as account number, address, billing address, and birth date. Data is encrypted using AWS Key Management Service. You can configure Customer Profiles to use your own customer managed key after your instance is set up. For more information, see Create a KMS key to be used by Customer Profiles to encrypt data (required).

Review and copy the location of the S3 bucket, flow logs, and whether you want to enable Customer Profiles.

1. If desired, copy the location of the S3 bucket where your data encryption is stored, and the location of the flow logs in CloudWatch.
2. Choose **Next**.

Step 5: Review and create

To create your instance

1. Review the configuration choices. Remember that you cannot change the identity management options after you create the instance.
2. (Optional) To change any of the configuration options, choose **Edit**.
3. (Optional) Add tags to your instance. For more information see Tagging an Amazon Connect instance.
4. Choose **Create instance**.
5. (Optional) To continue configuring your instance, choose **Get started** and then choose **Let's go**. If you prefer, you can access your instance and configure it later on. For more information, see Next steps.

   If you chose to manage your users directly within Amazon Connect or through an AWS Directory Service directory, you can access the instance using its access URL. If you chose to manage your users through SAML-based authentication, you can access the instance using the IdP.

Next steps

After you create an instance, you can assign your contact center a phone number or import your own phone number. For more information, see Set up contact center phone numbers for your Amazon Connect instance.

Create a development or test instance for your Amazon Connect contact center

You might want to create multiple contact center instances, for example, one as a Sandbox for development, another for QA, and a third for Production.

Each instance functions only within the AWS Region in which you create it.

> **Important**
>
> Most entities in Amazon Connect can be (re)created and replicated among instances using the Amazon Connect API. While doing that keep the following limitations in mind:
>
> - Service quotas are specific to each instance.
> - Some supporting services, such as User Directory, can be linked to only one Amazon Connect instance at a time.
> - Any additional external and Region-specific limitations.
>
> For more information, see Can I migrate my Amazon Connect instance from a test environment to a production environment?

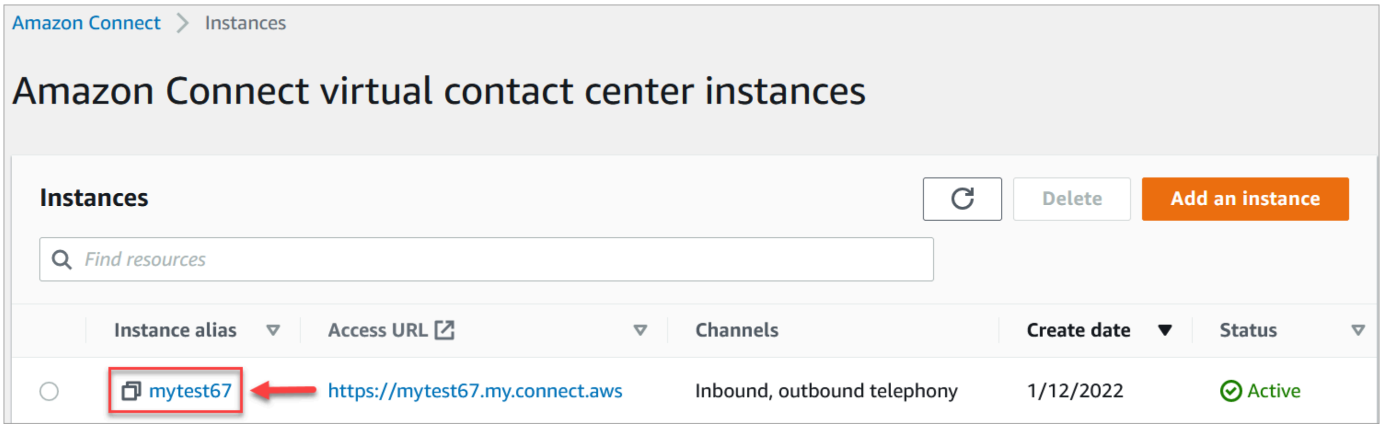
To create another instance

1. In the AWS Management Console, choose **Amazon Connect**.
2. Choose **Add an instance**.
3. Complete the steps on the Amazon Connect resource configuration page. For instructions see Create an Amazon Connect instance.

Find your Amazon Connect instance ID or ARN

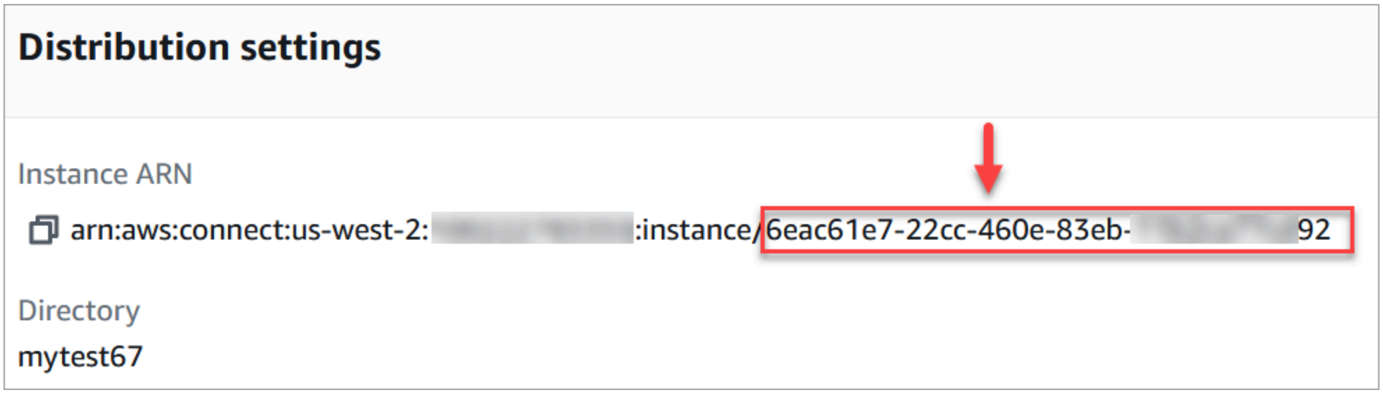
When you open a support ticket, you may be asked to provide your Amazon Connect instance ID (also called the ARN). Use the following steps to find it.

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Amazon Connect URL. The following image shows the **Amazon Connect virtual contact center instances** page, with a box around the instance alias.



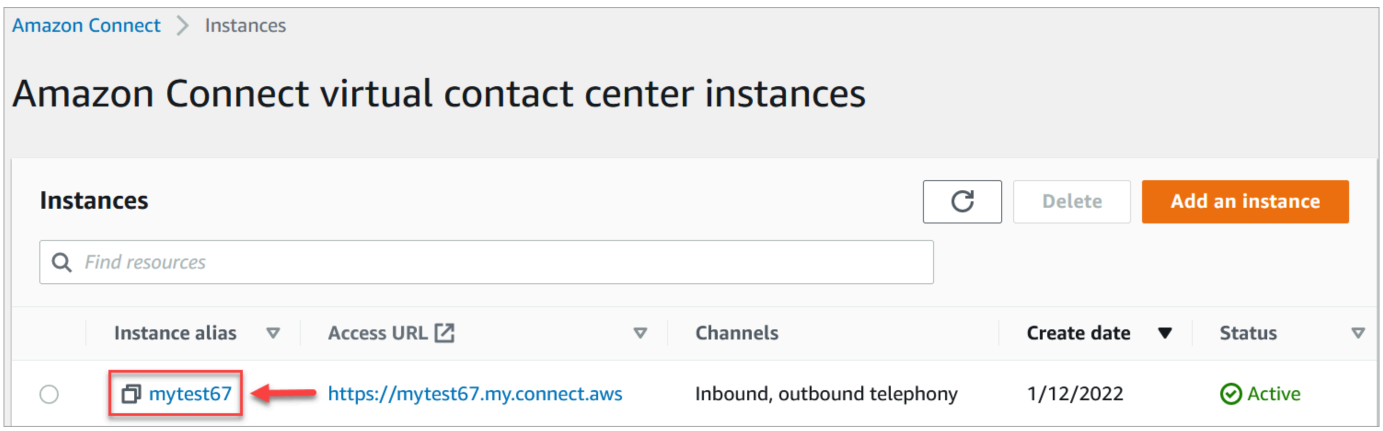
On the **Account overview** page, in the **Distribution settings** section, you can see the full instance ARN.

The information after **instance/** is the instance ID.



Find your Amazon Connect instance name

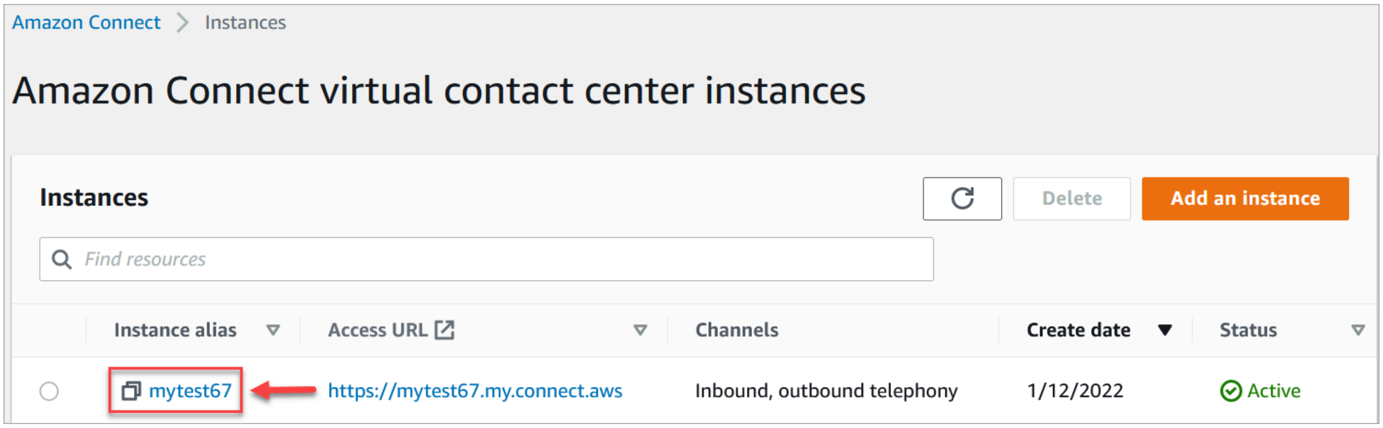
1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. On the instances page, the instance name appears in the **Instance Alias** column. This instance name appears in the URL you use to access Amazon Connect.



Update settings for your Amazon Connect instance

To update the instance settings:

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Amazon Connect URL. The following image shows the **Amazon Connect virtual contact center instances** page, with a box around the instance alias.



3. Complete the following procedures.

Update telephony options

1. In the navigation pane, choose **Telephony**.
2. To enable customers to call into your contact center, choose **Receive inbound calls with Amazon Connect**.
3. To enable outbound calling from your contact center, choose **Make outbound calls with Amazon Connect**.
4. To enable outbound campaigns, choose **Enable outbound campaigns**.
5. By enabling early media audio, your agents can hear pre-connection audio such as busy signals, failure-to-connect errors, or other informational messages from telephony providers, when making outbound calls. Choose **Enable early media**.

   Note

   The early media feature is not supported for transfers that are dialed through the Transfer to phone number block in flows.

6. By default, you can have three participants on a call (for example, two agents and a customer, or an agent, a customer, and an external party). To enable multi-party calls with more participants, choose **Enable Multi-Party Calls and Enhanced Monitoring for Voice**. This setting is also required to use the barge capabilities. This feature is only available in CCPv2.

   To enable up to six participants on chats, and to barge chats, choose**Enable Multi-Party Chats and Enhanced Monitoring for Chat**.

> **Important**
>
> If you enabled chat barge-in before to the release of multi-party chats in December 2024, you need to toggle this setting off and then on to enable multi-party chats.

For more information, see Barge into live voice and chat conversations between contact center agents and customers.

7. Choose **Save**.

Update data storage

- In the navigation pane, choose **Data storage**. Choose the following:
  - **Call recordings**: Choose **Edit**, specify the bucket and KMS key for recordings of voice conversations, and then choose **Save**.

    When this bucket is created, call recording is enabled at the instance level. The next step for setting up this functionality is to set up recording behavior in a flow.
  - **Chat transcripts**: Choose **Edit**, specify the bucket and KMS key for recordings (transcripts) of chat conversations, and then choose **Save**.

    When this bucket is created, chat transcripts are enabled at the instance level. Now all chat transcripts will be stored here.
  - **Live media streaming**: Choose **Edit** to enable live media streaming, choose **Edit**. For more information, see Set up live media streaming of customer audio in Amazon Connect.
  - **Exported reports**: Choose **Edit**, specify the bucket and KMS key for exported reports, and then choose **Save**.
  - **Attachments**: Choose **Edit**, then **Enable Attachments sharing** to enable file sharing for both agents and customers. For more information about this option and additional steps, see Enable attachments in your CCP so customers and agents can share and upload files.

    > **Important**
    >
    > If you choose **Enable Attachments sharing** for your instance, you must configure a CORS policy on your attachments bucket. If you don't do this, the email channel will

not work for your instance. For instructions, see Step 5: Configure a CORS policy on your attachments bucket.

- **Contact evaluations**: Choose **Edit**, specify the bucket and KMS key for performance evaluations, and then choose **Save**.

  When this bucket is created, evaluations are enabled at the instance level. The next step for setting up this feature is to create an evaluation form.

- **Screen recordings**: Choose **Edit**, specify the bucket and KMS key for recordings of agent screens, and then choose **Save**.

  When this bucket is created, screen recording is enabled at the instance level. The next step for setting up this functionality is to download and install the agent app, and then enable screen recording in the Set recording and analytics behavior block. For more information, see Enable screen recording for your Amazon Connect instance.

- **Email messages**: Choose **Edit**, specify the bucket and KMS key for email messages, and then choose **Save**.

  When this bucket is created, the email channel is enabled at the instance level.

  > **Important**
  >
  > If you choose **Enable Attachments sharing** for your instance, you must configure a CORS policy on your attachments bucket. If you don't do this, the email channel will not work for your instance. For instructions, see Step 5: Configure a CORS policy on your attachments bucket.

Update data streaming options

1. In the navigation pane, choose **Data streaming**.
2. Choose **Enable data streaming**. For more information, see Enable data streaming for your Amazon Connect instance.
3. For **Contact records**, do one of the following:
   - Choose **Kinesis Firehose** and select an existing delivery stream, or choose **Create a new Kinesis Firehose** to open the Kinesis Firehose console and create the delivery stream.

- Choose **Kinesis Stream** and select an existing stream, or choose **Create a new Kinesis Firehose** to open the Kinesis console and create the stream.

4. For **Agent Events**, select an existing Kinesis stream or choose **Create a new Kinesis Stream** to open the Kinesis console and create the stream.
5. Choose **Save**.

Update analytics tools options

1. In the navigation pane, choose **Analytics tools**.
2. Choose **Enable Contact Lens**. For more information, see Analyze conversations using conversational analytics in Amazon Connect Contact Lens.
3. Choose **Save**.

Update flow settings

1. In the navigation pane, choose **Flows**.
2. (Optional) To add a signing key for use in flows, choose **Add key**. For more information, see Encrypt sensitive customer input in Amazon Connect.
3. (Optional) To integrate with Amazon Lex, select a Lex bot. For more information, see Create conversational AI bots in Amazon Connect.
4. (Optional) To integrate with AWS Lambda, select a Lambda function. For more information, see Grant Amazon Connect access to your AWS Lambda functions.
5. (Optional) To enable flow logs, choose **Enable flow logs**. For more information, see Track events in your Amazon Connect flow logs as customers interact with them.
6. (Optional) To use the best available voice from Amazon Polly, choose **Use the best available voice**. For more information, see Amazon Polly best sounding voice.
7. (Optional) Use the voices available in Amazon Polly.
8. (Optional) To enables logs of automated interactions using IVR and Lex bot transcripts and analytics as a part of your Contact details page and Connect analytics dashboards, you need to select **Enable Bot Analytics and Transcripts in Amazon Connect**.

Enable attachments in your CCP so customers and agents can share and upload files

You can allow customers and agents to share files using chat and email, and allow agents to upload files to cases. After you complete the steps in this topic, an attachment icon automatically appears in your agent's Contact Control Panel so they can share attachments on chats and emails.

> **Important**
>
> You must complete steps 1 and 2 in this topic (create an Amazon S3 bucket and configure a CORS policy) for email attachments. If you don't do this, yet have selected **Enable Attachments sharing** for your instance, the email channel will not work for your instance.

For a list of supported file types, see Amazon Connect feature specifications.

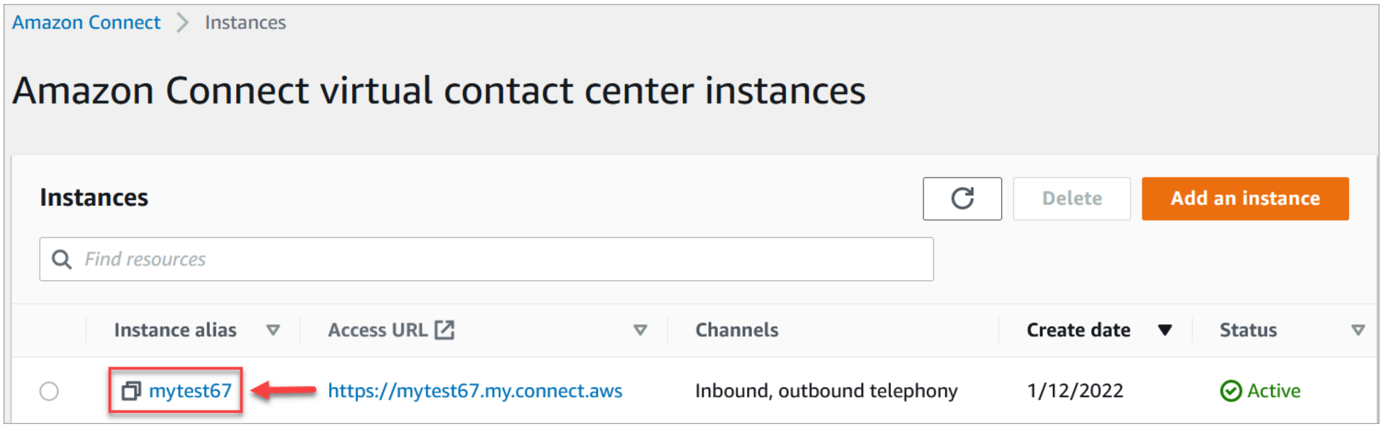
If you are not using the hosted communications widget, you need to update your customer-facing chat interfaces to support attachment sharing.

Using a custom chat application? Check out the APIs we've added to support attachment sharing: StartAttachmentUpload, CompleteAttachmentUpload, and GetAttachment.

Using a custom agent application? Check out the attached file APIs: StartAttachedFileUpload, CompleteAttachedFileUpload, and GetAttachedFile, BatchGetAttachedFileMetadata, and DeleteAttachedFile.

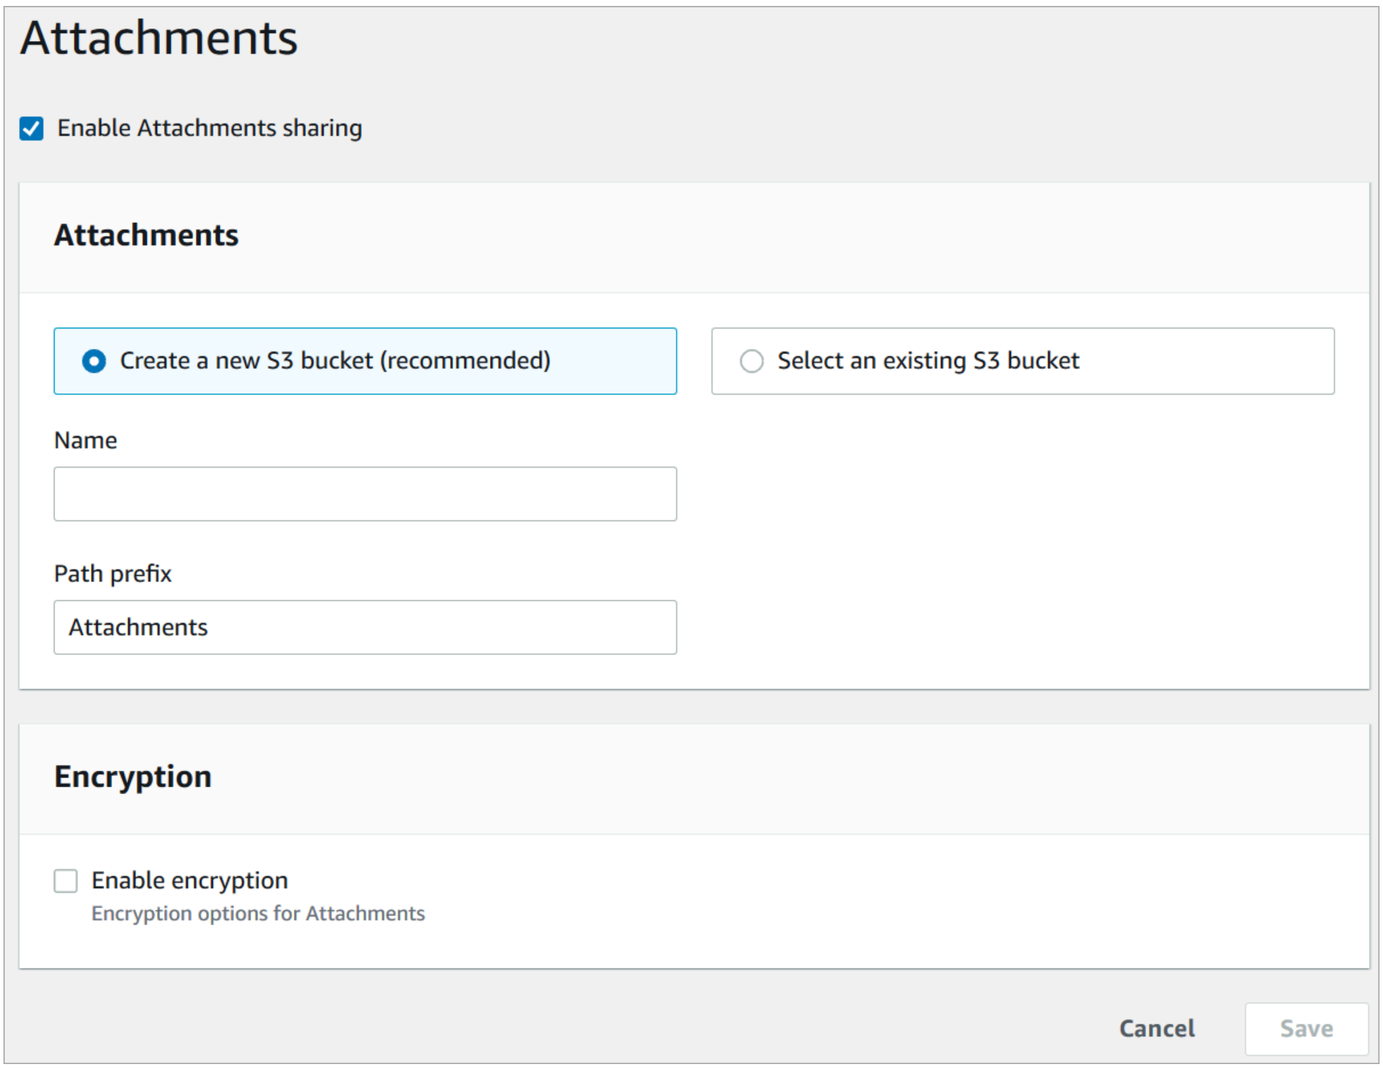
Step 1: Enable attachments

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Amazon Connect URL. The following image shows the **Amazon Connect virtual contact center instances** page, with a box around the instance alias.



3. On the **Data storage** page, under the **Attachments**, choose **Edit**, select **Enable Attachments sharing**, and then choose **Save**.

   Storage options appear, similar to the following image.



4. You can change the Amazon S3 bucket location where attachments are stored. By default, your existing Amazon Connect bucket is used, with a new prefix for attachments.

   > **Note**
   >
   > Currently, Amazon Connect doesn’t support S3 buckets with Object Lock enabled.

   The attachments feature leverages two Amazon S3 locations: a staging location and a final location.

   Note the following about the staging location:

   - The staging location is used as part of a business validation flow. Amazon Connect uses it to validate the file size and type before it is available for download by using the `GetAttachedFile` or `GetAttachment` APIs.
   - The staging prefix is created by Amazon Connect based on the bucket path you have selected. Specifically, it includes the S3 prefix for where you are saving files, with **staging** appended to it.
   - We recommend that you change the data retention policy for the staging prefix to one day. This way you won't be charged for storing the staging files. For instructions, see How do I create a lifecycle rule for an S3 bucket? in the *Amazon S3 User Guide*.

     > **Warning**
     >
     > - Only change the lifecycle for the **file staging location**. If you accidentally change the lifecycle for the entire Amazon S3 bucket, all transcripts and attachments will be deleted.
     > - S3 objects are **permanently deleted** if S3 bucket versioning is not enabled.

Step 2: Configure a CORS policy on your attachments bucket

To allow customers and agents to upload and download files, update your cross-origin resource sharing (CORS) policy to allow PUT and GET requests for the Amazon S3 bucket you are using for attachments. This is more secure than enabling public read/write on your Amazon S3 bucket, which we don't recommend.

To configure CORS on the attachments bucket

1. Find the name of the Amazon S3 bucket for storing attachments:
    a. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
    b. In the Amazon Connect console, choose **Data storage**, and locate the Amazon S3 bucket name.
2. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.
3. In the Amazon S3 console, select your Amazon S3 bucket.
4. Choose the **Permissions** tab, and then scroll down to the **Cross-origin resource sharing (CORS)** section.
5. Add a CORS policy that has one of the following rules on your attachments bucket. For example CORS policies, see Cross-origin resource sharing: Use-case scenarios in the *Amazon S3 Developer Guide*.
    - Option 1: List the endpoints from where attachments will be sent and received, such as the name of your business web site. This rule allows cross-origin PUT and GET requests from your website (for example, http://www.example1.com).

      Your CORS policy may look similar to the following example:

```
[
    {
        "AllowedMethods": [
            "PUT",
            "GET"
        ],
        "AllowedOrigins": [
            "http://www.example1.com",
            "http://www.example2.com"
            ],
       "AllowedHeaders": [
            "*"
            ]
    }
]
```

    - Option 2: Add the * wildcard to `AllowedOrigin`. This rule allows cross-origin PUT and GET requests from all origins, so you don't have to list your endpoints.

Your CORS policy may look similar to the following example:

```
[
    {
        "AllowedMethods": [
            "PUT",
            "GET"
        ],
        "AllowedOrigins": [
            "*"
            ],
      "AllowedHeaders": [
            "*"
            ]
    }
]
```

Step 3 (Optional): Integrate with the APIs to enhance your custom UIs

If you are skipping the out-of-the-box Chat UI or Agent workspace, you can use the Amazon Connect Participant attachments APIs, or Amazon Connect attached files APIs to build your own UIs and provide attachments support for Cases and Chats. For the general steps in working with both sets of APIs, see Working with attachments.

Next step

We recommend enabling attachment scanning to meet compliance requirements or security policies that your organization may have in place for file sharing. For more information, see Set up attachment scanning in Amazon Connect.

Attachments not appearing?

If your agents report problems receiving and sending attachments in chat messages, see Internal firewall or missing CORS policy prevents access to chat, email, or case attachments.

Set up attachment scanning in Amazon Connect

Note

This topic is for developers who are familiar with Lambda. If you're new to Lambda, see Getting started with Lambda in the AWS *Lambda Developer's Guide*.

You can configure Amazon Connect to scan attachments that are sent in email, during a chat, or uploaded to a case. You can scan attachments by using your preferred scanning application. For example, you can scan attachments for malware before they are approved to be shared between participants of a chat.

To enable attachment scanning you perform two steps:

- Configure a Lambda function that calls your preferred scanning application.
- Add the scanner to your Amazon Connect instance.

Step 1: Create a Lambda function that handles scanning

Create a Lambda function, using any runtime, and configure it. This function must be in the same AWS Region and account as your Amazon Connect instance.

For every attachment uploaded through Amazon Connect a request is sent with information about the attachment.

Following is an example JSON request for scanning:

```
{
    "Version": "1.0",
    "InstanceId": "your instance ID",
    "File": {
        "FileId": "your file ID",
        "FileCreationTime": 1689291663582,
        "FileName": "example.txt",
        "FileSizeInBytes": 10,
        "FileLocation": {
            "S3Location": {
                "Key": "connect/your-instance/Attachments/chat/2023/07/13/your file
 ID_20230713T23:41_UTC.txt",
```

```
                "Bucket": "connect-example",
                "Arn": "arn:aws:s3:::connect-example/connect/your-instance/Attachments/
chat/2023/07/13/your file ID_20230713T23:41_UTC.txt"
            }
        }
    }
}
```

Required response

```
{
   "Status": "APPROVED" | "REJECTED"
}
```

Invocation retry policy

If your Lambda invocation gets throttled, the request is retried. It is also retried if a general service failure (500 error) happens. When a synchronous invocation returns an error, Amazon Connect retries up to 3 times, for a maximum of 60 seconds. At that point, the attachment is marked rejected.

For more information about how Lambda retries, see Error handling and automatic retries in AWS Lambda.

Rejection behavior

Amazon Connect marks the attachment `REJECTED` and automatically deletes attachment files in S3 from both staging and final locations when one of the following occurs:

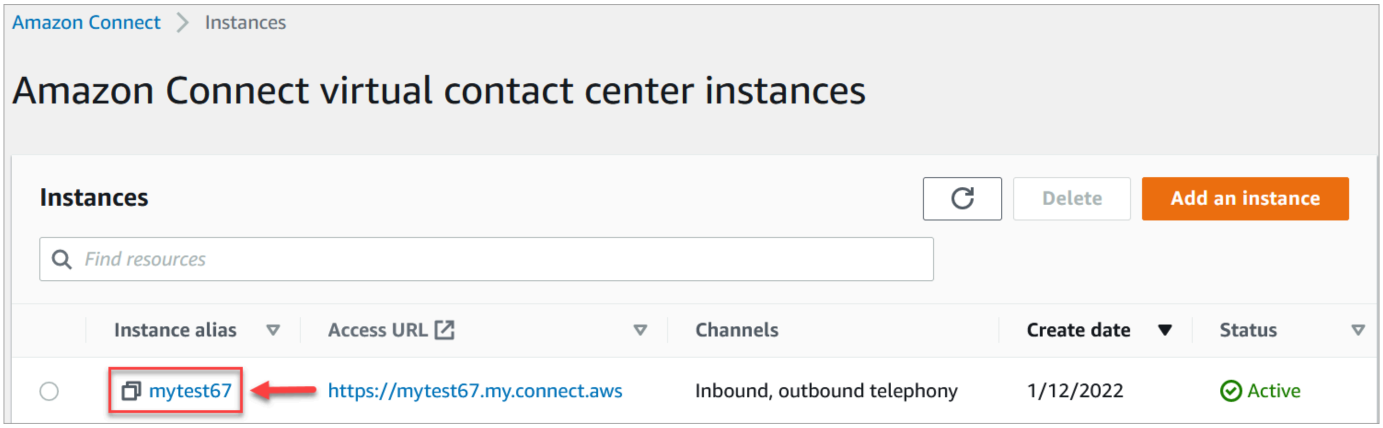
- Your Lambda scanner returns a status of `REJECTED`.
- Amazon Connect is unable to parse the response from the Lambda scanner.
- Amazon Connect is unable to invoke the Lambda function.

Step 2: Add an attachment scanner to your Amazon Connect instance

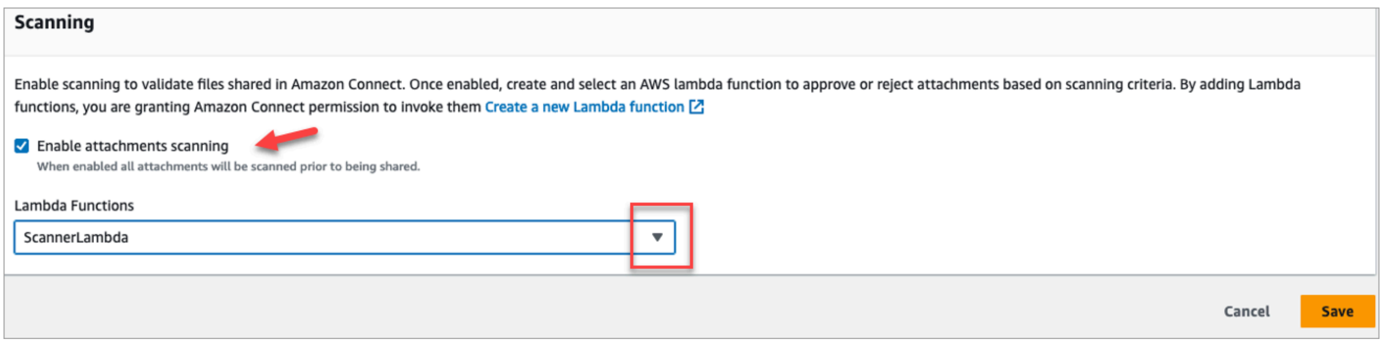
After you create a Lambda for attachment scanning, you need to add the Lambda to your Amazon Connect instance. Perform the following steps to add the Lambda.

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.

2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Amazon Connect URL. The following image shows the **Amazon Connect virtual contact center instances** page, with a box around the instance alias.



3. In the navigation pane, choose **Data storage**.
4. On the **Data storage** page, in the **Attachments** section, choose **Edit**, and then select **Enable attachments scanning**, as shown in the following image.



5. Use the **Lambda Functions** drop-down box to select the Lambda function that you added in [Step 1: Create a Lambda function that handles scanning](#).
6. Choose **Save**. Attachment scanning is now enabled for your Amazon Connect instance.

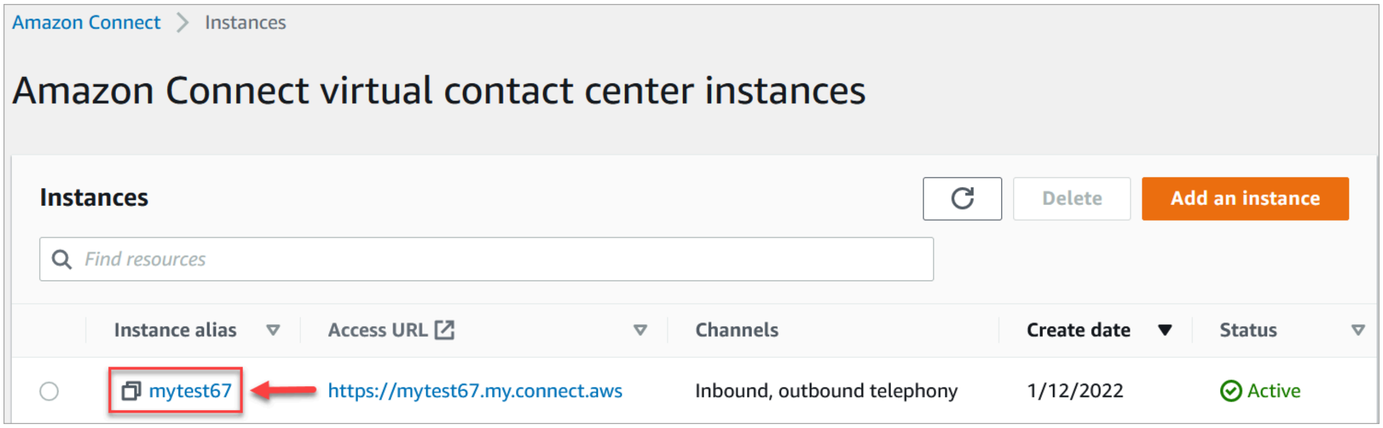
Enable data streaming for your Amazon Connect instance

You can export contact records and agent events from Amazon Connect and perform real-time analysis on contacts. Data streaming sends data to Amazon Kinesis.

To enable data streaming for your instance

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.

2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Amazon Connect URL. The following image shows the **Amazon Connect virtual contact center instances** page, with a box around the instance alias.



3. In the navigation pane, choose **Data streaming**.
4. Choose **Enable data streaming**.
5. For **Contact records**, do one of the following:
   - Choose **Kinesis Firehose** and select an existing delivery stream, or choose **Create a new Kinesis firehose** to open the Kinesis Firehose console and create the delivery stream. For more information, see Creating an Amazon Data Firehose Delivery Stream.
   - Choose **Kinesis Stream** and select an existing stream, or choose **Create a Kinesis stream** to open the Kinesis console and create the stream. For more information, see Creating and Managing Streams.
6. For **Agent Events**, select an existing Kinesis stream or choose **Create a new Kinesis stream** to open the Kinesis console and create the stream.
7. Choose **Save**.

Use server-side encryption for the Kinesis stream

Amazon Connect supports streaming to Amazon Kinesis Data Streams and Firehose streams that have server-side encryption with a customer managed key enabled. For a general overview of this feature, see What Is Server-Side Encryption for Kinesis Data Streams?

To stream to Kinesis Data Streams, you need to grant your Amazon Connect instance permission to use a customer managed key. For details on the permissions needed for KMS keys, see Permissions to Use User-Generated KMS Master Keys. (Amazon Connect acts as the Kinesis stream producer that is described in that topic.)

When Amazon Connect puts records into your Kinesis Data Streams, it uses the service-linked role of the instance for authorization. This role needs permission to use the KMS key that encrypts the data stream. To assign permissions to the role, perform the following steps to update the key policy of that KMS key.

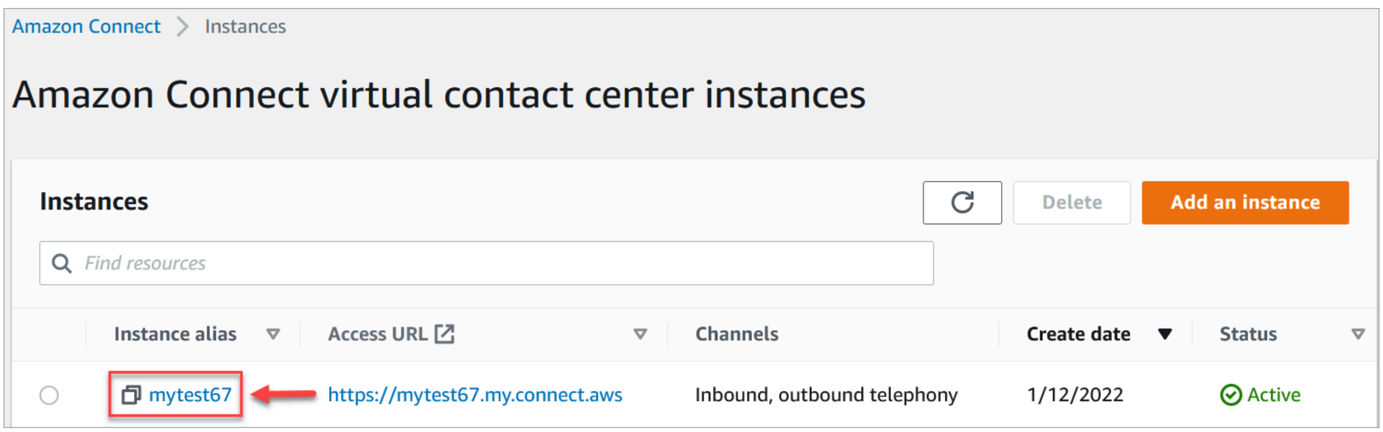
> **Note**
>
> To avoid missing data, update the permission of the KMS key before using a KMS key with Amazon Connect streaming.

Step 1: Obtain the ARN for the service-linked role of your Amazon Connect instance

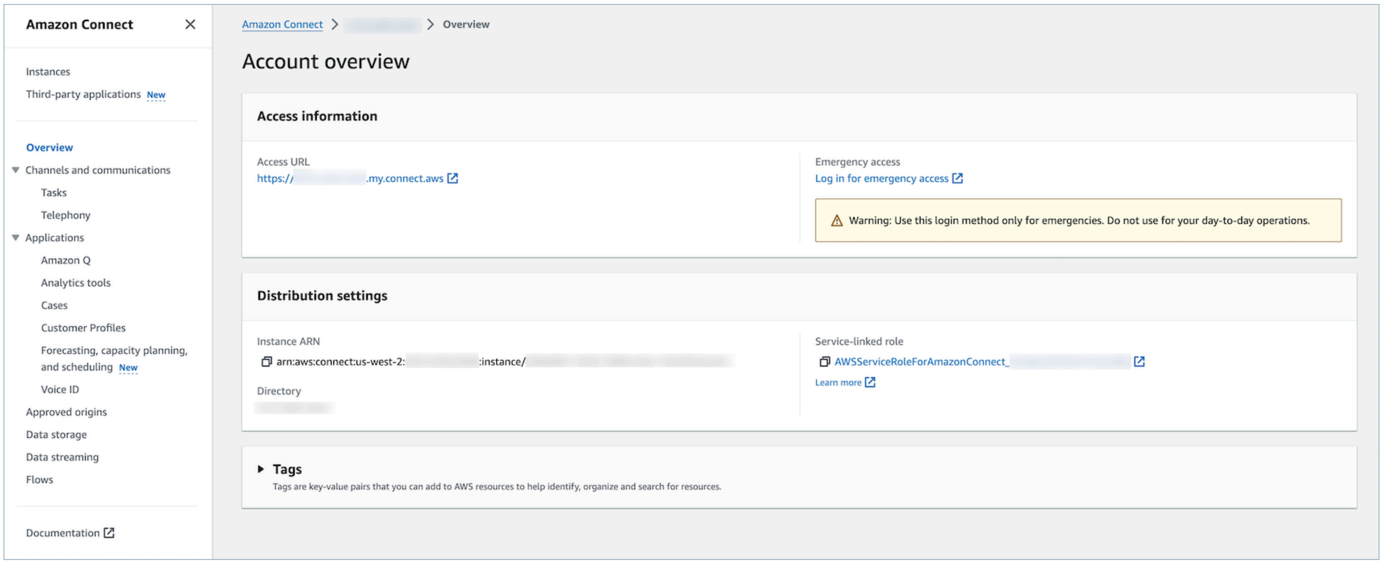
You can use the Amazon Connect console or the AWS CLI to obtain the ARN.

Use the Amazon Connect console to obtain the ARN

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance name, as shown in the following image.



3. On the **Account overview** page, in the **Distribution settings** section, the service-linked role is displayed.



4. Choose the copy icon to copy the role ARN to your clipboard, and save that ARN. You're going to use it in Step 2: Construct a policy statement.

Use the AWS CLI to obtain the ARN

1. Run the following command:

```
aws connect describe-instance --instance-id your_instance_id
```

2. Save the ServiceRole value from the CLI output.

Step 2: Construct a policy statement

Construct a policy statement that gives permission to the ARN of the Amazon Connect service-link role to generate data keys. The following code shows a sample policy.

```
{
    "Sid": "Allow use of the key for Amazon Connect streaming",
    "Effect": "Allow",
    "Principal": {
        "AWS": "the ARN of the Amazon Connect service-linked role"
    },
    "Action": "kms:GenerateDataKey",
    "Resource": "*"
 }
```

Add this statement to the KMS key policy by using your preferred mechanism, such as the AWS Key Management Service console, the AWS CLI, or the AWS CDK.

Emergency login to the Amazon Connect admin website

As a best practice, users assigned to the Amazon Connect **Admin** security profile should always use their Amazon Connect instance URL to login:

- Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/.

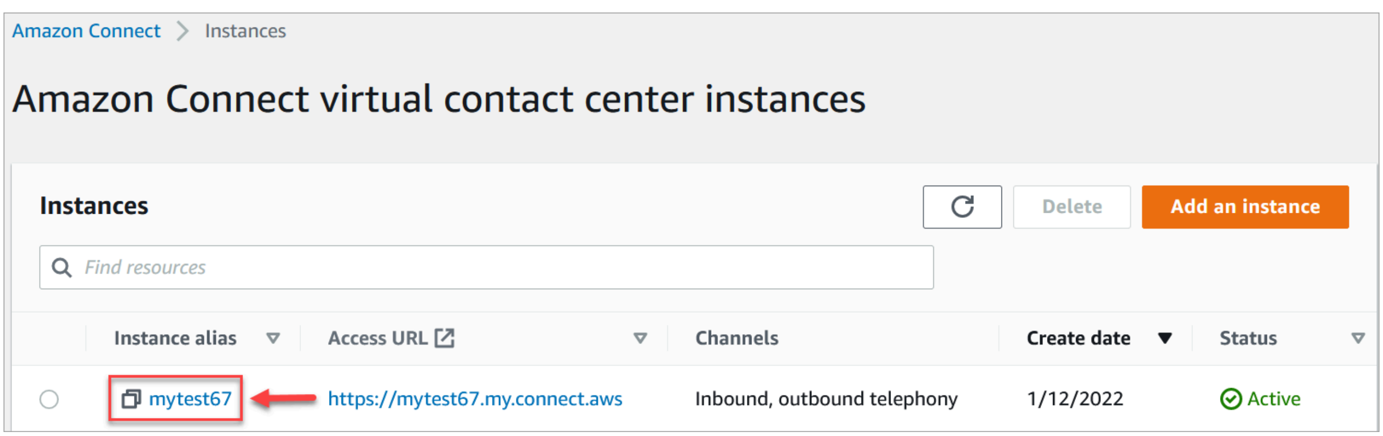
This method ensures the appropriate levels security.

However, if there's an emergency, you can log in from the Amazon Connect console using your AWS account credentials. For example, you may need to login in this way in the following situations:

- You forgot your Amazon Connect administrator password and no other Amazon Connect administrators are around to reset it.
- Someone deleted the Amazon Connect **Admin** security profile by mistake.

To login for emergency access

1. Make sure you have your AWS account credentials at hand and that you have the required permissions.
2. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
3. If prompted to login, enter your AWS account credentials.
4. Choose the name of the instance from the **Instance alias** column.



5. In the navigation pane, choose **Overview**.

6. Choose **Log in for emergency access**.

   You aren't prompted for your credentials because you are federated in from the AWS console.

   > **Important**
   >
   > For daily usage, we strongly recommend always using your instance URL to login. The procedure provided in this article should only be used for emergency access when using the instance URL is not an option.

To log out

To log out of your instance, go to the title bar at the top of the screen and select the icon with the arrow (**Log out**) that appears next to your user name.

Delete your Amazon Connect instance

If you no longer need your Amazon Connect instance, you can delete it. Here's what happens when you delete it:

- Its claimed phone number is released back to inventory.
- When customers call the phone number that you've released, they'll get a message that it's not a working phone number.

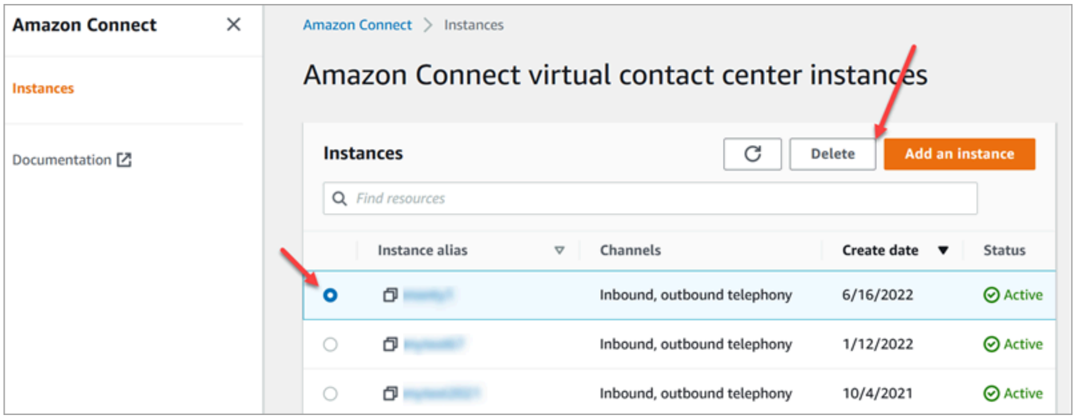
> **Important**
>
> You can't restore a deleted Amazon Connect instance or access its settings, data, metrics, and reports.

Delete your instance

You must have the appropriate AWS permissions to delete an Amazon Connect. If your organization is using IAM, see Required permissions for using custom IAM policies to manage access to the Amazon Connect console.

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.

2. Select the radio button for the instance.
3. Choose **Delete**. If you don't see the **Delete** button, you don't have permissions to delete instances. Contact your AWS administrator for help.



4. When prompted, enter the name of the instance and then choose **Delete**.

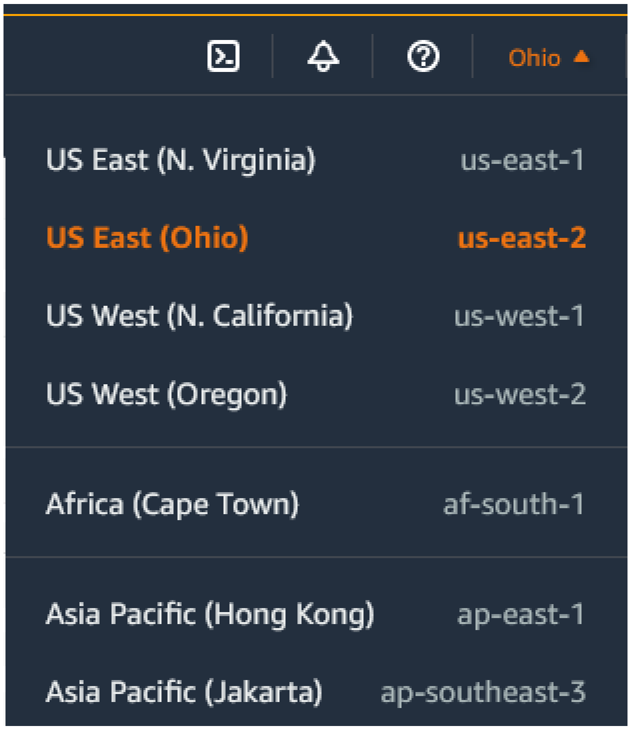
> **Tip**
>
> We recommend checking your CloudWatch log groups related to the Amazon Connect instance, and deleting them if they are no longer needed. For more information, see [Delete a CloudWatch Logs log group using an AWS SDK](#).

Error message: "Region Unsupported. Amazon Connect is not available in [Region]"

If you get this error message, it means that you selected a Region in the AWS Management Console that is not the Region in which you created the Amazon Connect instance, and Amazon Connect isn't available in that Region.

To switch Regions and delete your Amazon Connect instance

1. From the navigation bar, open the Region selector. Select the Region in which you created the Amazon Connect instance.



2. From the navigation bar, choose **Amazon Connect** from the list of services to open the Amazon Connect console. If you don't see the instance, keep selecting from the supported Regions until you find your instance.
3. Select the radio button for the instance.
4. Choose **Delete**. If you don't see the **Delete** button, you don't have permissions to delete instances. Contact your AWS administrator for help.
5. When prompted, enter the name of the instance and then choose **Delete**.

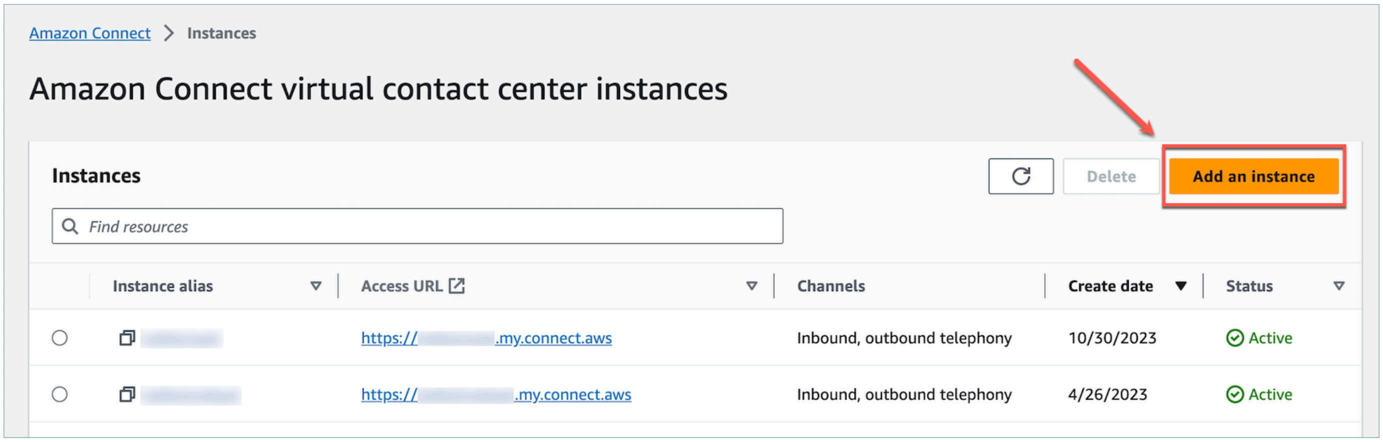
Tagging an Amazon Connect instance

Instance Tagging provides the ability for you to tag Amazon Connect instances and build tailored authorization through tag-based access control (TBAC). To help you manage your Amazon Connect instances, you can assign your own metadata in the form of tags to the instance. If you have multiple Amazon Connect instances in a single AWS account, each serving different functions or catering to specific lines of business, using tags can help you better organize and apply tag-based access control (TBAC) policies to these instances for improved management and control.

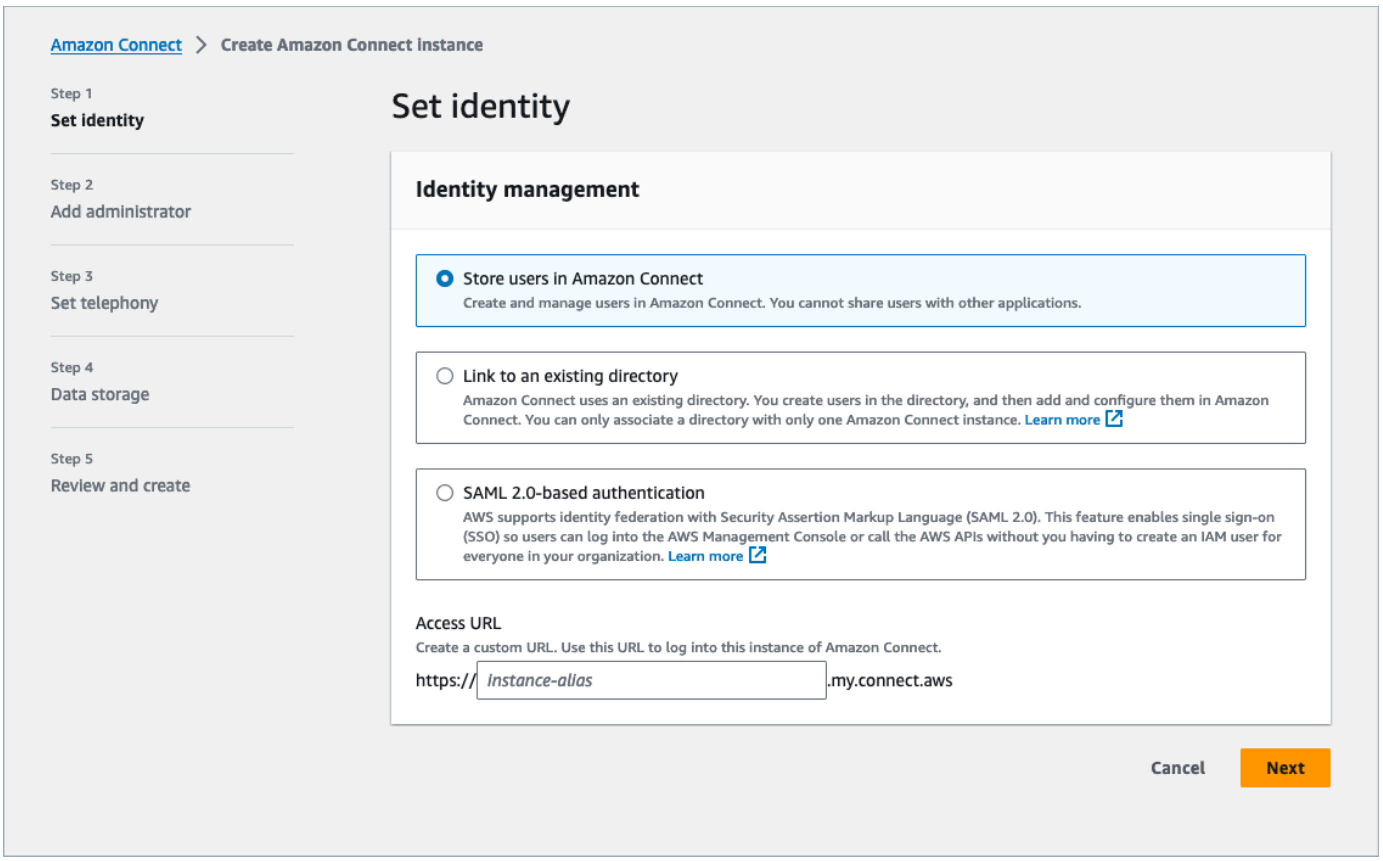
AWS Tags serve as a useful tool for organizing your AWS resources. They consist of key-value pairs that help you categorize resources based on criteria like purpose, owner, or environment. This enables you to identify and manage your resources. Amazon Connect, allows you to add tags to your instances directly from the AWS console, or by utilizing public APIs.

Tagging Amazon Connect instances at creation

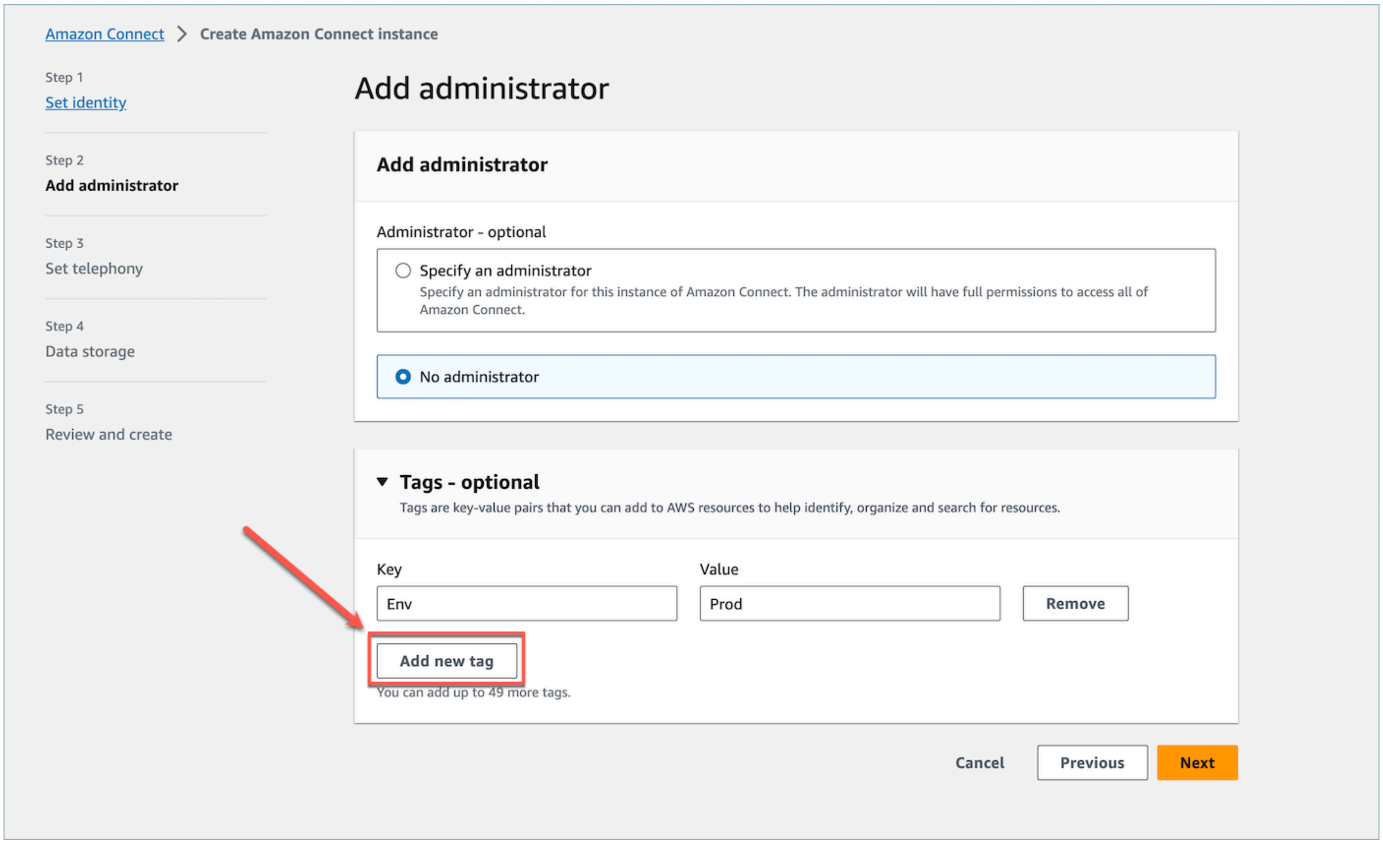
1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. Choose **Add an instance**.



3. Under **Set identity**, select the type of **Identity management** that you would like to use, enter a customer **Access URL**, and choose **Next**.

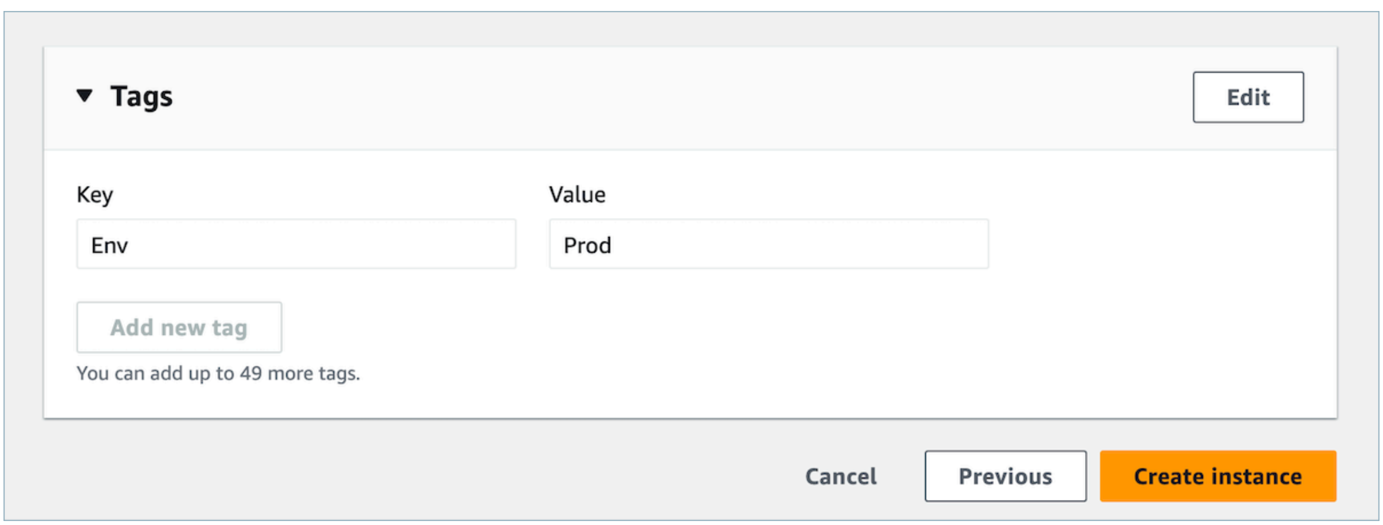


4. Under the **Add administrator** section, you can choose the **Add new tag** option if you would like to add tags to your instance.

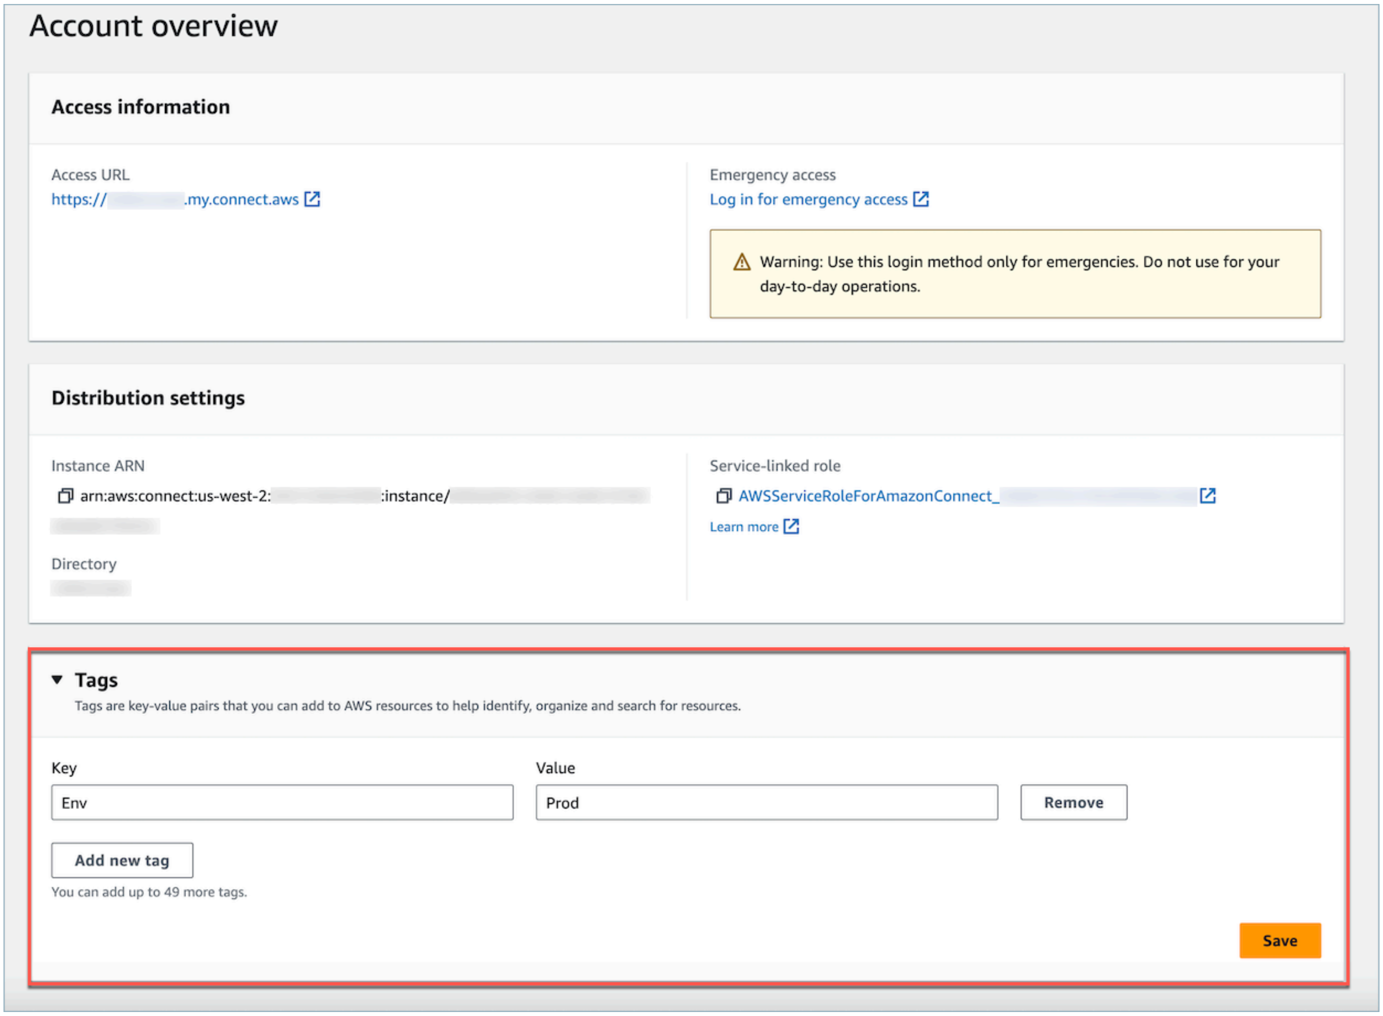


5. Enter a `Key` and `Value` pair and choose **Next**.

6. Once you have made your desired configurations under the **Set telephony** and **Data storage** steps, review your configurations and choose **Create instance**.

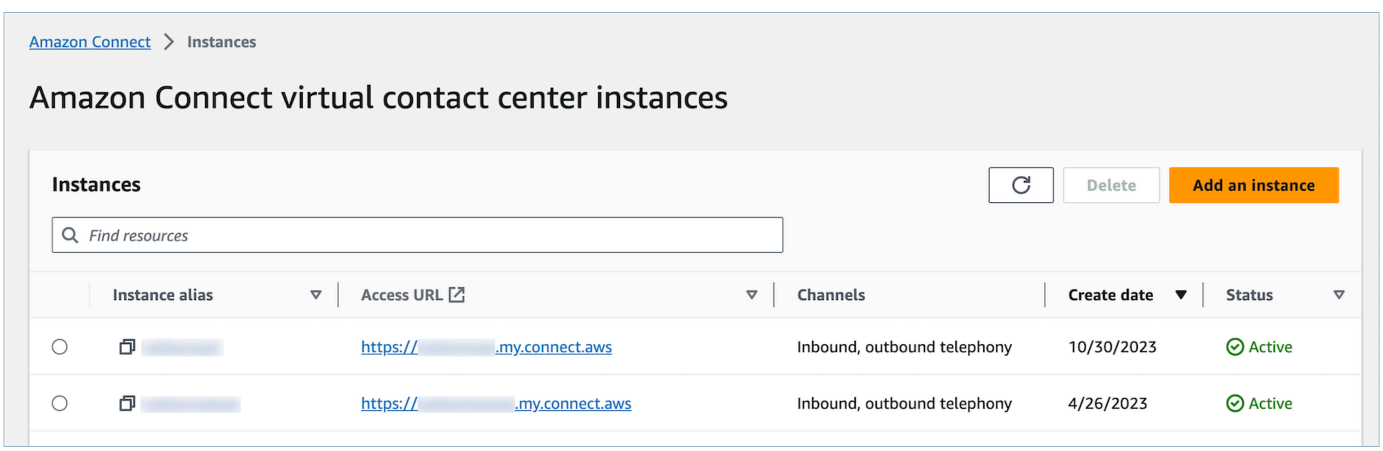


7. Once the instance has been created, navigate to the **Account overview** page of the instance and the tags that you added will appear in the **Tags** section.

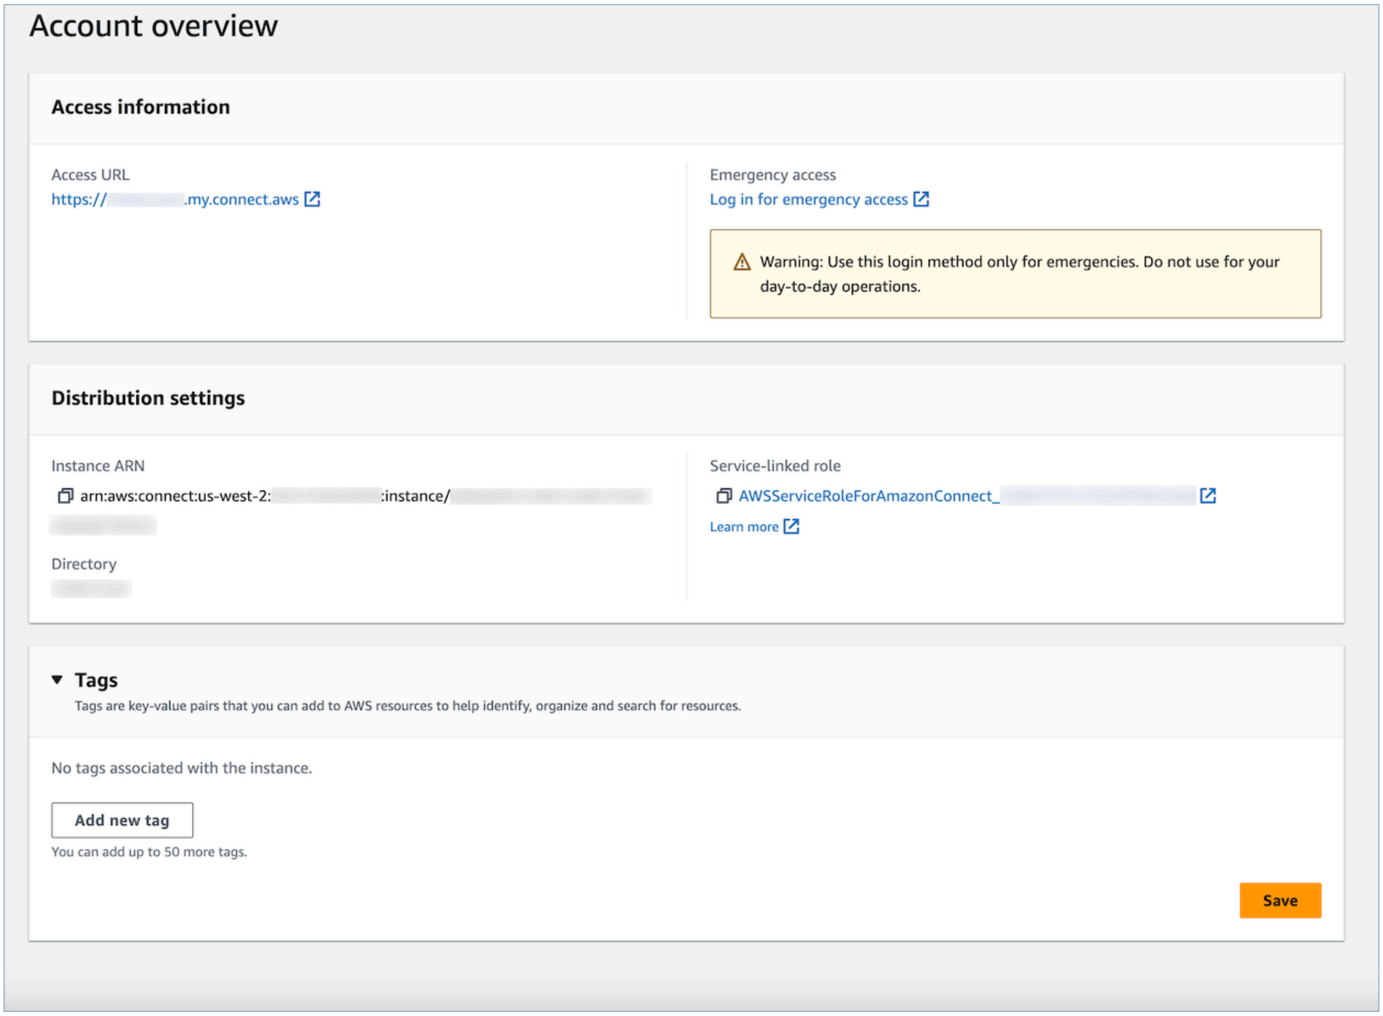


Tagging an existing Amazon Connect instance

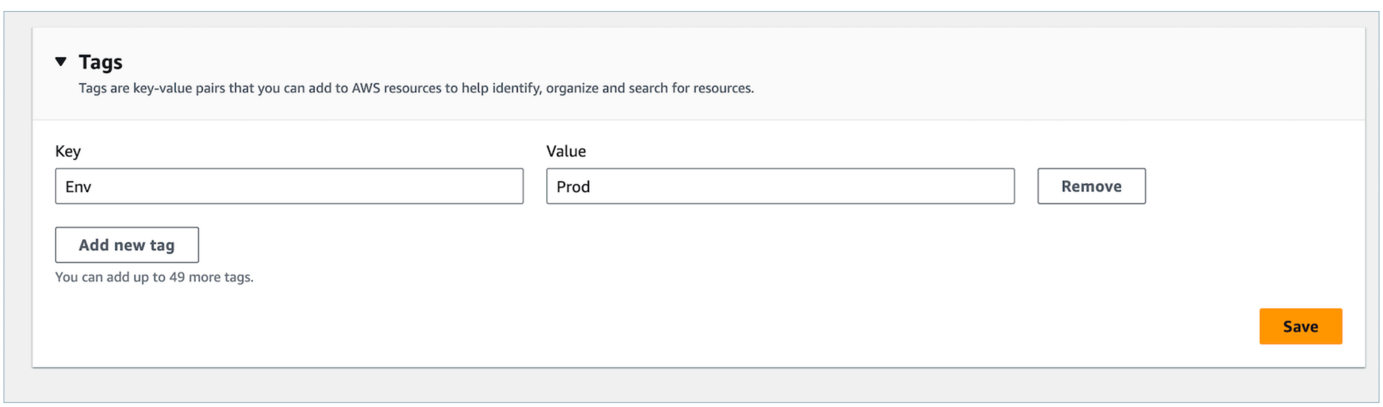
1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. Select an existing instance that you would like to add tags too.



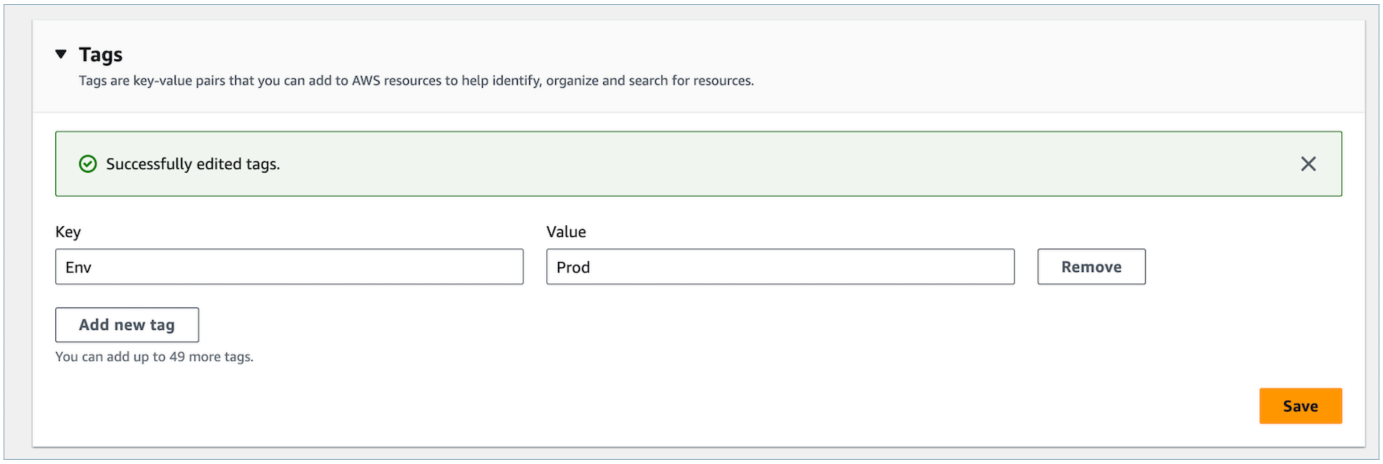
3. On the **Account overview**, choose **Add new tag**.



4. Enter a `Key` and `Value` pair and choose **Next**. You can add up to 50 tags on a single instance.



5. Choose **Save** to add your tags to your instance.



Tagging an Amazon Connect instance using the API

To tag Amazon Connect instances using the public APIs, see TagResource and UntagResource.

Sample IAM policies for scenarios with and without instance tags

For TBAC on instances, you can define IAM policies based on instance tags and assign them to IAM roles to control access to specific instances. The following are sample scenarios and sample IAM policies for how to use conditions on tags or conditions on resource IDs.

Scenario 1: Controlling access to a specific instance through an IAM role using tags associated with the instance. The following policy allows access only instances which are tagged with key:`Environment` and value:`Dev`.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Action":"*",
         "Resource":"*"
      },
      {
         "Effect":"Deny",
         "Action":"connect:DescribeInstance",
         "Resource":"*",
         "Condition":{
            "StringNotEquals":{
               "aws:ResourceTag/Environment":[
```

```
                    "Dev"
                 ]
              }
           }
        }
     ]
}
```

Scenario 2: Controlling access to a specific instance and all resources within the instance without using tags.

```
{

```

Additional information about instance tagging

Replicating instances: When you create a replica of your existing Amazon Connect instance to another region using the ReplicateInstance API, tags from the source instance will not be automatically tagged to the newly replicated instance. You will have to tag the replicated instance manually.

Tag inheritance: When you tag an Amazon Connect instance, all underlying resources in Amazon Connect, such as routing profiles, queues, will not inherit the instance tags. To learn how to control granular access to specific resources in Amazon Connect, see how to configure more granular access by using tag-based access control.

Set up granular billing for a detailed view of your Amazon Connect usage

By default bills for Amazon Connect channels (voice calls, chat, tasks, and emails) are summarized at the AWS account level by usage type. For example:

- Voice calls - by outbound (telephony) / inbound (telephony) / service minutes
- Chat – by messages
- Task - by units
- Email - by messages

To obtain a more detailed view of your bill and usage, you can add cost allocation tags (key:value pairs) to contacts, and then use the tags to aggregate and analyze the data in the AWS Billing and Cost Management console.

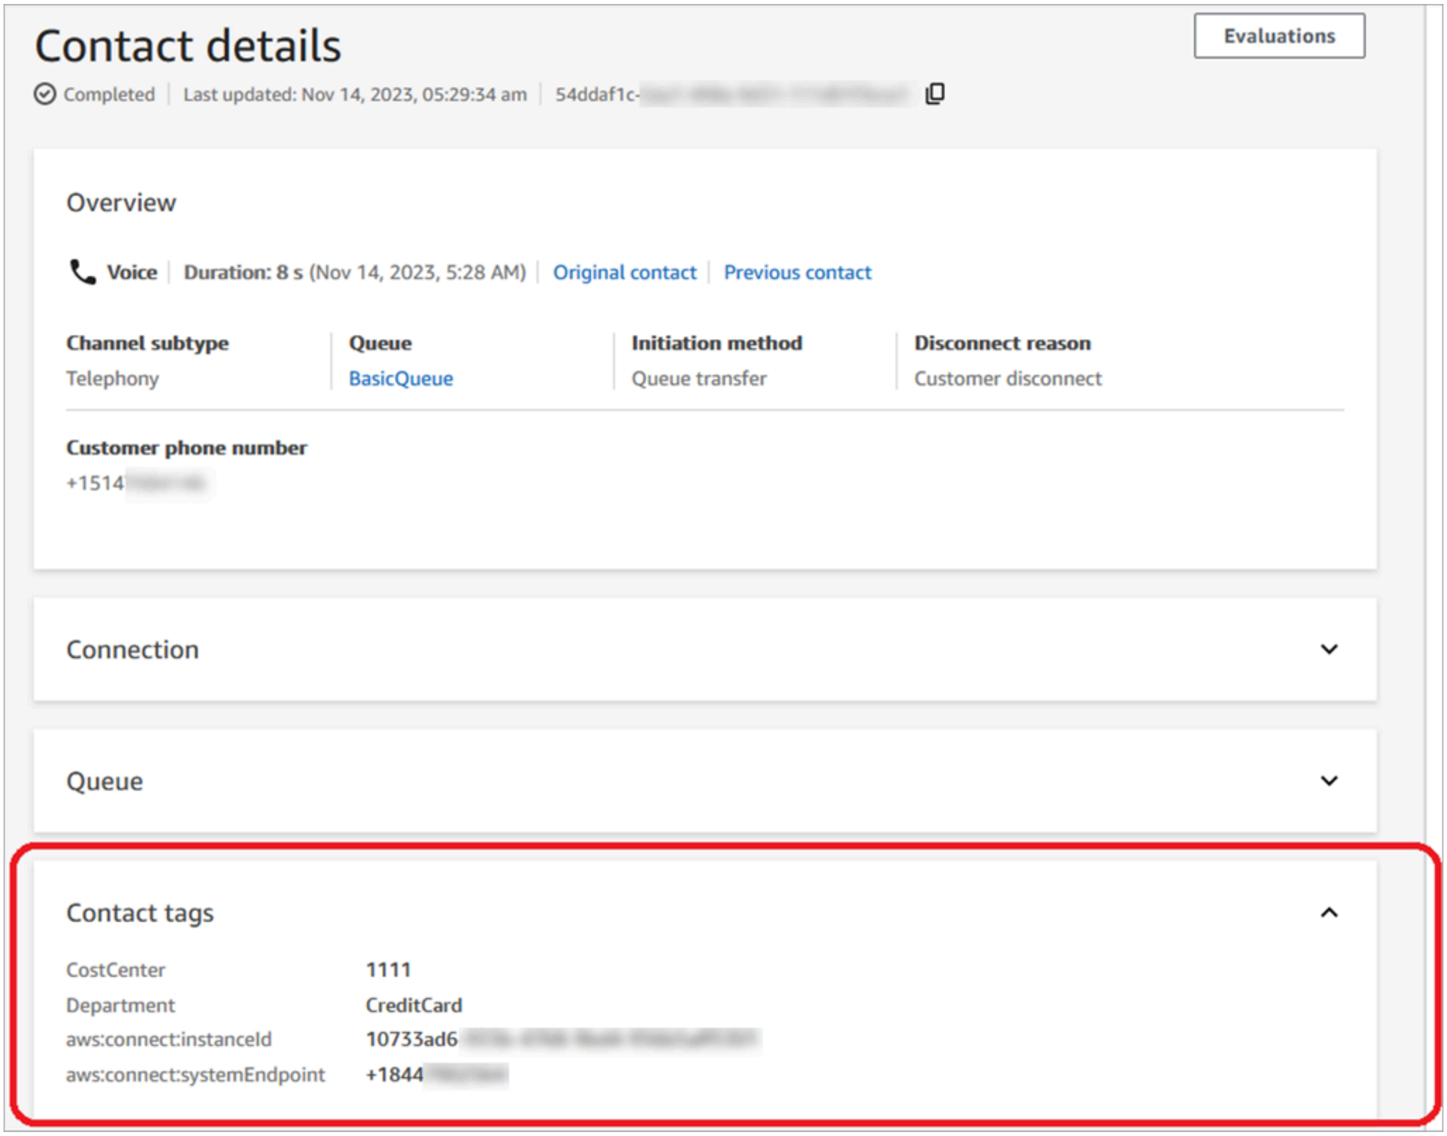
- Amazon Connect automatically adds the following system-defined tags to each contact:
  - **aws:connect:instanceId**: This represents the ID of the Amazon Connectinstance. If you have multiple instances under multiple AWS accounts for each line-of-business, you can view usage bills aggregated against different instances.
  - (**aws:connect:systemEndpoint**): This represents the your contact center number (the endpoint) that the customer reaches (inbound) or is reached from (outbound).

This AWS generated tag helps if you have multiple phone numbers used within your contact center. It enables you to group the costs associated against different phone numbers. For example, group inbound phone numbers for incoming calls, and group outbound numbers that are used for making outbound calls.

- **aws:connect:transferredFromEndpoint**: This represents the outbound caller ID that the call was transferred from. You can see the third-party transfer call's usage bills aggregated against the telephone numbers that the calls were transferred from. Currently, this AWS generated tag is only added to contacts for third-party external transfer calls.

- You can add up to 6 user-defined tags. For example, department, cost center, or business unit. Use these tags to organize your AWS bill to reflect your own cost structure.

The following image shows two user-defined tags on the **Contact details** page: CostCenter and Department. It also shows two system-defined tags: instance ID and the contact center phone number (aws:connect:systemEndpoint).



This topic explains how to add tags to contacts, activate the cost allocation tags, and view them in the AWS Billing dashboard.

Contents

Things to know about user-defined tags

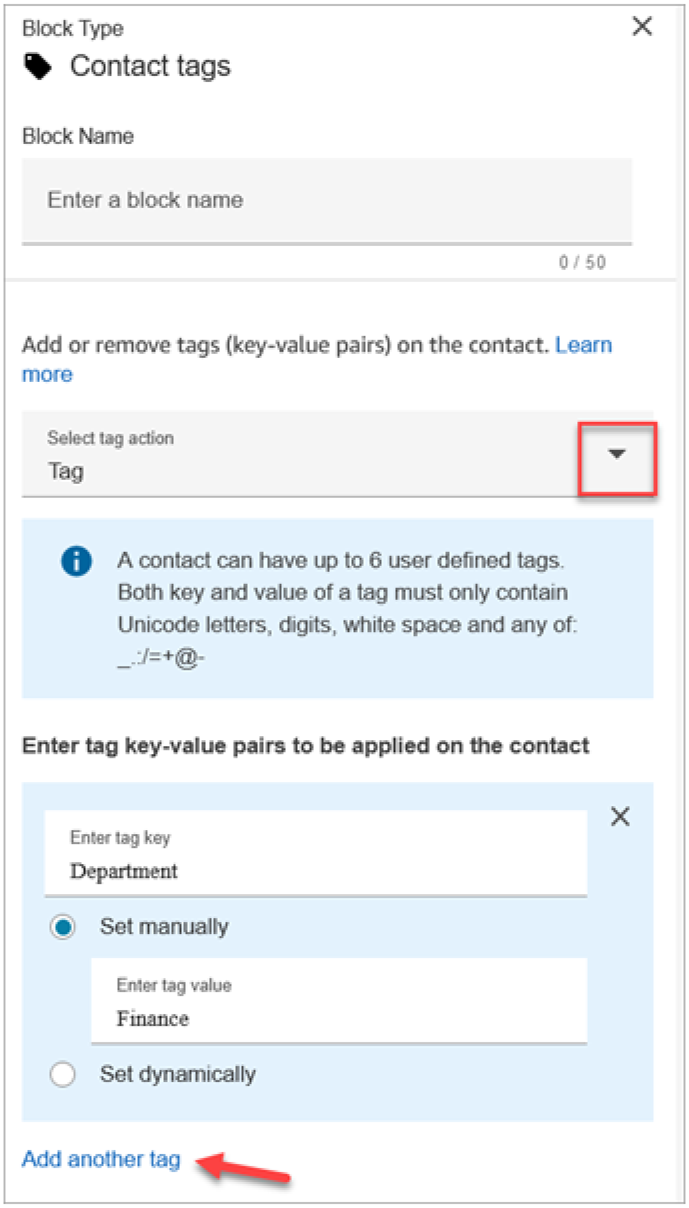
- Amazon Connect automatically applies user-defined tags to new contact segments for scenarios like transfers or contact re-hydration (for example, persistent chat, and tasks related to contacts).
- Use the DescribeContact API to list the tags on a contact.
- You can remove and/or overwrite the tags by using the Contact tags block or the TagContact and UntagContactAPIs.
- By using the TagContact and UntagContact APIs, you can update user-defined tags for a contact up to 3 hours after the contact was disconnected. However, any future updates on the contact tags are not reflected in the billing system. For example, you make a change to the value of a tag within 3 hours after the contact was disconnected. The AWS Billing console will show the old value of the tag, but the S3 bucket and contact record have the new value.
- After you add tags to Amazon Connect, they are available across all contact interfaces: contact records, contact events, and the **Contact details** page. You can also access them by using the `$.Tags` JSONPath Reference, and by using Amazon Connect Streams.
- You cannot use tags as filters on the **Contact search** page. In addition, they cannot be included in any of the analytics or reporting pages.
- Contact tags only function as cost allocations tags. You cannot use them for tag-based access controls on contacts.

Step 1: Add user-defined tags to contacts

To add user-defined tags like Department and Cost Center to contacts, you have two options:

- Use the TagContact API.
- Add a Contact tags block to your flow.

The following image shows an example of a **Properties** page of a **Contact tags** block that is configured with a tag named **Department**. Its value is set manually to **Finance**.



> **Important**
>
> Do not store personally identifiable information (PII) or other confidential or sensitive information in tags. We use contact tags to provide you with billing services. Tags are not intended to be used for private or sensitive data.

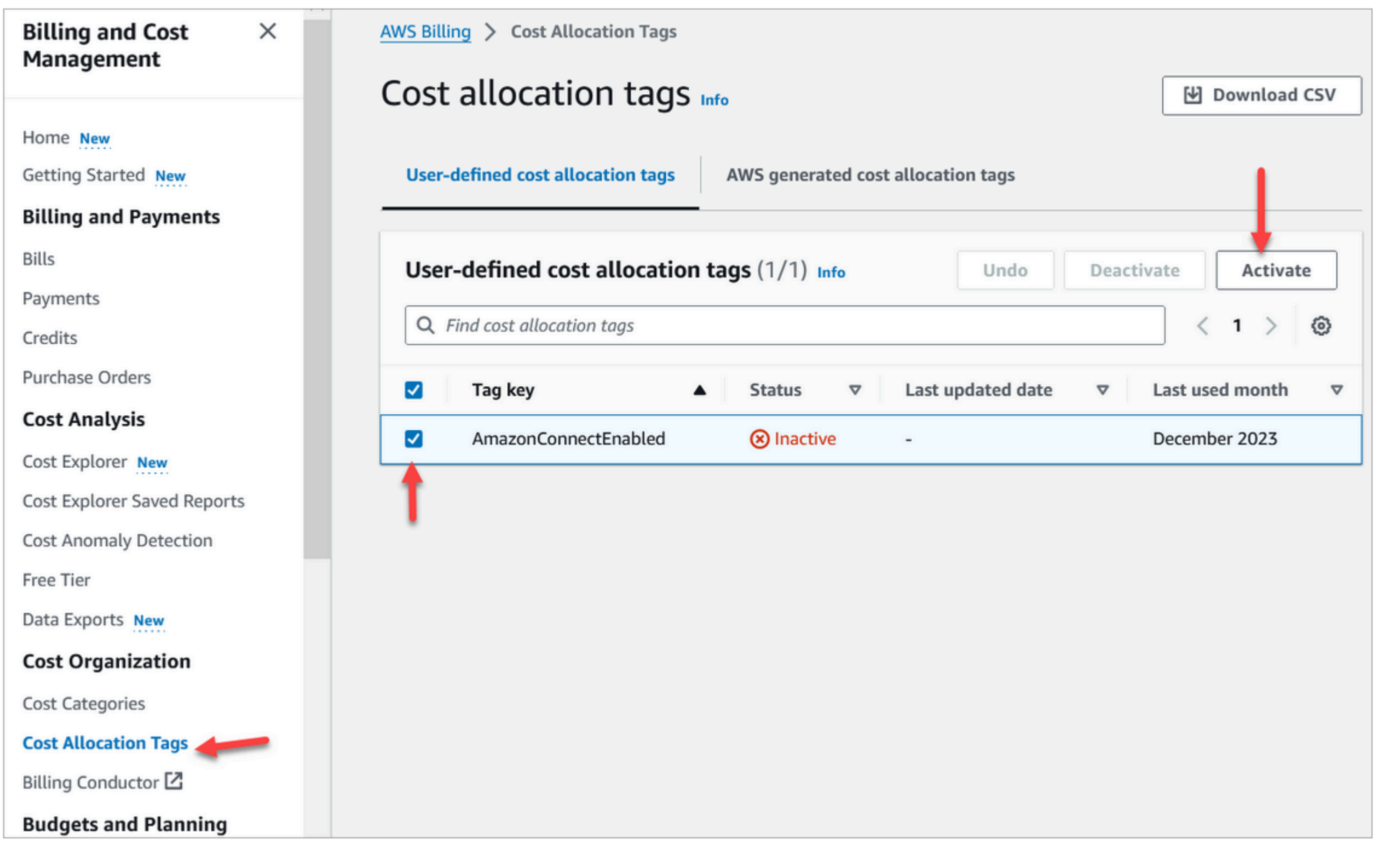
Step 2: Activate cost allocation tags in the AWS Billing console

> **Tip**
>
> It takes up to 24 hours for the tags to activate.

To enable AWS billing applications to organize your billing information according to resources with the same tag key values (either for system-defined and user-defined contact tags), you must activate the tags. Perform the following steps.

1. Open the AWS Billing and Cost Management console at https://console.aws.amazon.com/costmanagement/.
2. In the left navigation menu, choose **Cost Allocation Tags**.
3. Select the system-defined and user-defined tags, and then choose **Activate**. It can take up to 24 hours for tags to activate.

   The following image shows an example tag on the **Cost allocation tags** page.

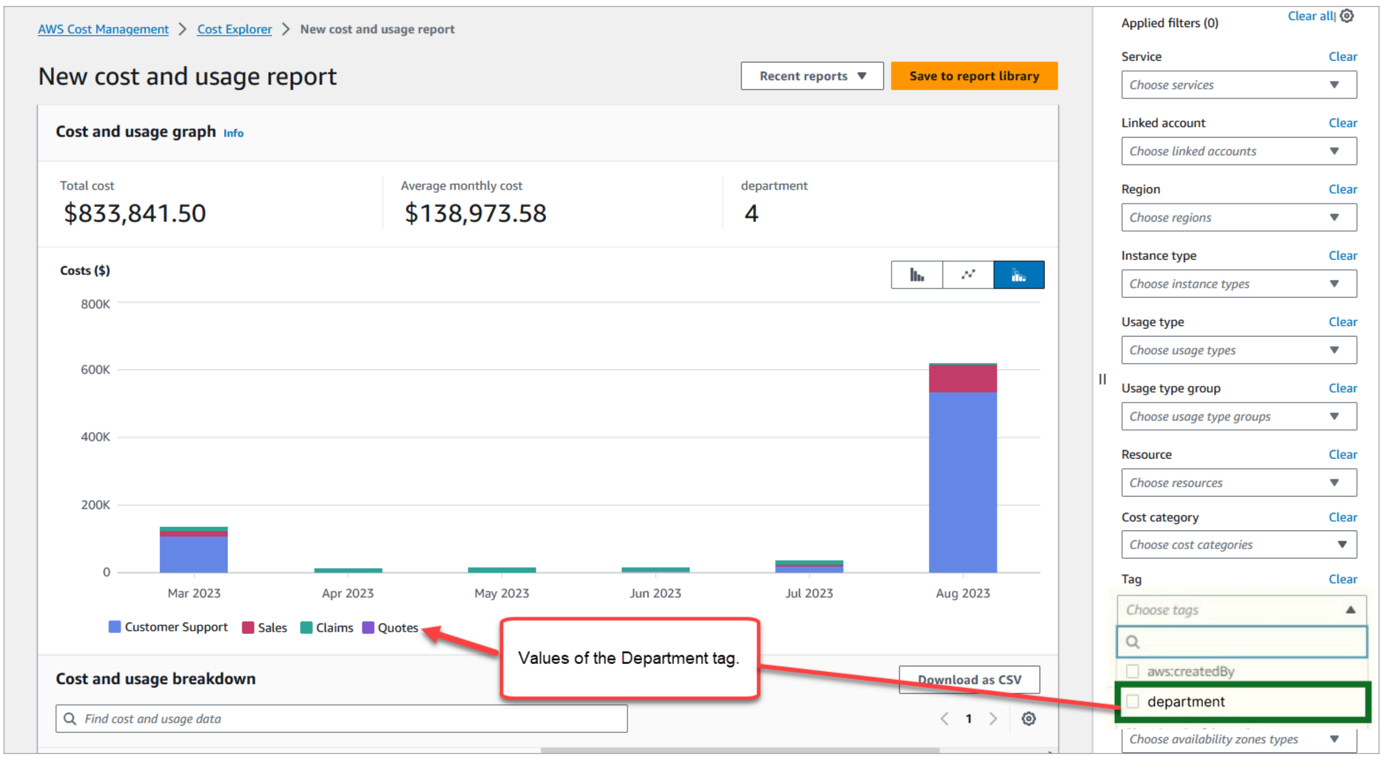


Step 3: View cost and usage trends using cost allocation tags

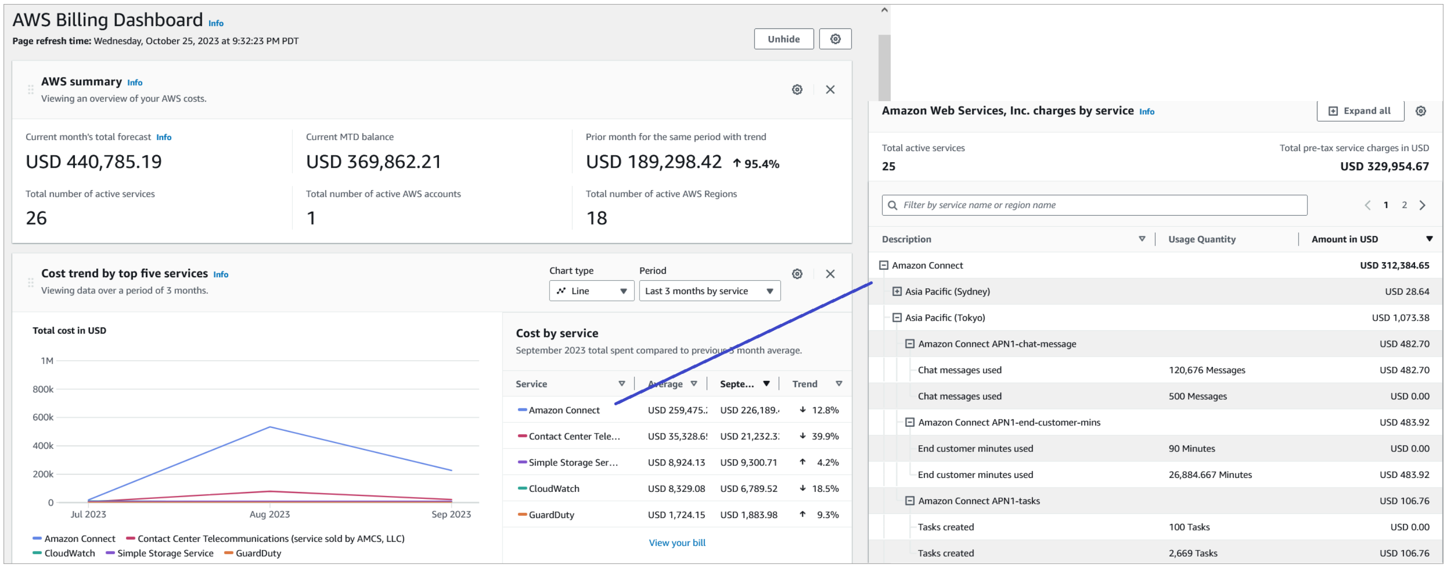
You can view the month-over-month trends at the granular level by using cost allocation tags.

1. Open the AWS Billing and Cost Management console at https://console.aws.amazon.com/costmanagement/.
2. In the left navigation, choose **AWS Cost Explorer**.
3. On the **Cost Explorer** page, choose **Tags**, and then select the tags you want to view, for example, department or inbound telephone number.

   The following image of AWS Cost Explorer shows a sample report where **department** is a filtered cost allocation tag.



If you use the AWS account level bill summary to view the service level cost breakdown in the AWS Billing dashboard, you won't see any changes on the dashboard after implementing contact tags. The following image shows an example AWS Billing dashboard.



For more information about using AWS Cost Explorer, see [Analyzing your costs with AWS Cost Explorer](#) in the *AWS Cost Management User Guide*.

(Optional) Step 4: Enable Cost and Usage reports in the AWS Billing and Cost Management console

You can enable AWS Cost and Usage reports on the AWS Billing and Cost Management console, and configure your S3 bucket to export data to along with time granularity for reports (hourly, daily, monthly). After you set this up, you will receive reports with tags in additional columns. By default reports are aggregated by usage-type and tags.

For instructions, see [Creating Cost and Usage Reports](#) in the *AWS Data Exports User Guide*.

The following image shows what a Cost and Usage report looks like with columns for system and user-defined tags.

	Total usage Amount	358.6293583	System-defined Tags		User-defined Tags	
lineItem/ProductCode	lineItem/UsageType	lineItem/UsageAmount	aws:connect:systemEndpoin	aws:connect:instanceId	CostCenter	Department
AmazonConnect	APN1-tasks	60.571675		10733ad6........aff5301	1111	CreditCard
AmazonConnect	APN1-end-customer-mins	10.7	xxxxxx1432	10733ad6........aff5301	2222	CreditCard
AmazonConnect	APN1-end-customer-mins	31.35	xxxxxx1432	10733ad6........aff5301	2222	DebitCard
AmazonConnect	APN1-end-customer-mins	50.51666667	xxxxxx1432	10733ad6........aff5301	4444	Insurance
AmazonConnect	APN1-end-customer-mins	41.26666667	xxxxxx1432	10733ad6........aff5301	3333	PersonalBanking
ContactCenterTelecomm	APN1-US-did-inbound-mins	5	xxxxxx1432	10733ad6........aff5301	2222	CreditCard
ContactCenterTelecomm	APN1-US-did-inbound-mins	93.57681667	xxxxxx1432	10733ad6........aff5301	1111	CreditCard
ContactCenterTelecomm	APN1-US-did-inbound-mins	37.2142	xxxxxx1432	10733ad6........aff5301	2222	DebitCard
ContactCenterTelecomm	APN1-US-did-inbound-mins	4	xxxxxx1432	10733ad6........aff5301	4444	Insurance
ContactCenterTelecomm	APN1-US-did-inbound-mins	13	xxxxxx1432	10733ad6........aff5301	3333	PersonalBanking
AmazonConnect	APN1-end-customer-mins	10.43333333	xxxxxx3932	10733ad6........aff5301	1111	CreditCard
ContactCenterTelecomm	APN1-US-tollfree-inbound-mins	1	xxxxxx3932	10733ad6........aff5301	1111	CreditCard

The following image shows what a cost and usage report looks likes without system or user-defined tags.

	Total usage Amount	358.6293583
lineItem/ProductCode	lineItem/UsageType	lineItem/UsageAmount
AmazonConnect	APN1-tasks	4
AmazonConnect	APN1-end-customer-mins	200.8383417
ContactCenterTelecomm	APN1-US-did-inbound-mins	152.7910167
ContactCenterTelecomm	APN1-US-tollfree-inbound-mins	1

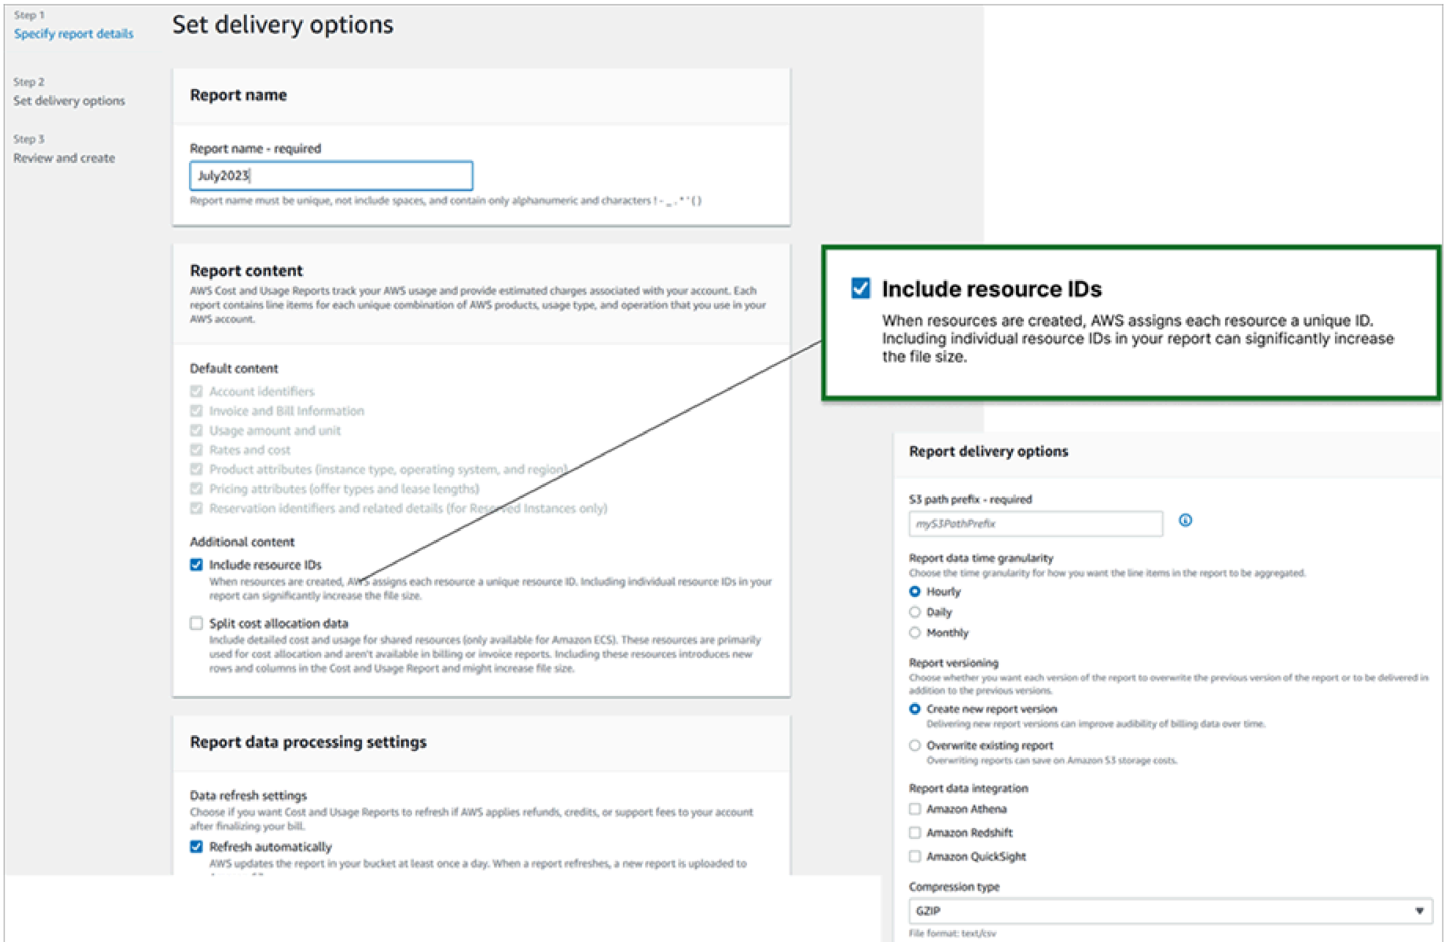
More reporting options

Another option is to view usage data for each contact. You can enable contact resource IDs to appear on your cost and usage reports in the AWS Billing and Cost Management console. After choosing this option, you will receive detailed reports in your S3 buckets, and the data will be categorized by each contact resource ID. You can use the reports for analysis by third-party applications.

Note

Including resource IDs creates individual line items for each of your resources. This might increase the size of your Cost and Usage Reports files significantly, based on your AWS usage.

The following image shows where you enable **Include resource IDs** on the AWS Billing console.



The following image shows a sample cost and usage report when **Include resource IDs** is enabled.

		Total usage Amount	358.6293583	System-defined Tags		User-defined Tags	
lineItem/ProductCode	lineItem/UsageType	ResourceID (Contact ID)	lineItem/UsageAmou	aws:connect:customer ConnectedEndpoint	aws:connect:instanceId	CostCenter	Department
AmazonConnect	APN1-tasks	27d0b	1		10733ad6........aff5301	1111	CreditCard
AmazonConnect	APN1-end-customer-mins	ded9f	0.433333333	1240995	10733ad6........aff5301	1111	CreditCard

AmazonConnect	APN1-end-customer-mins	72cc2	0.266666667	1833823	10733ad6........aff5301	1111	CreditCard
AmazonConnect	APN1-end-customer-mins	83880	0.466666667	1240995	10733ad6........aff5301	1111	CreditCard
AmazonConnect	APN1-end-customer-mins	bc948	1.116666667	1240995	10733ad6........aff5301	1111	CreditCard

For instructions for this option, see Creating Cost and Usage Reports in the *AWS Data Exports User Guide*.

Test voice, chat, and task experiences in Amazon Connect

To learn what the voice, chat, and task experiences are like for your agents and customers, you can test them without doing any development.

Test voice

At the basic level, after you claim a number you can immediately call it to hear what the experience will be like for your customers. Amazon Connect uses the default flows to power your initial experience.

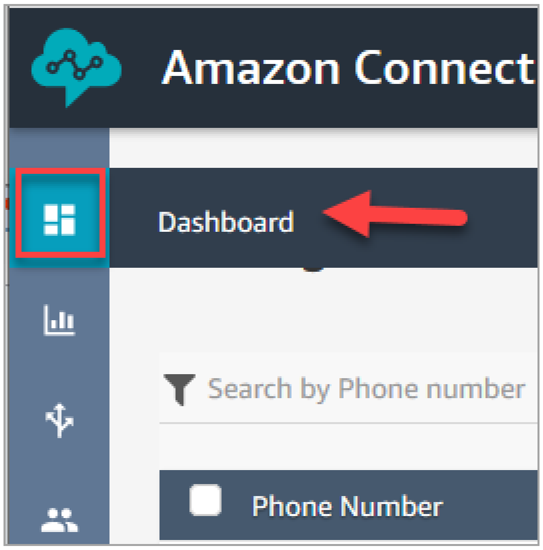
To test a customized flow, assign a phone number to it and then call that number.

> **Tip**
>
> Call latency significantly impacts the quality of your customer's experience. For guidance about designing your contact center for optimal call quality and then testing latency, see Design your Amazon Connect contact center for low latency to help ensure call quality.

Test chat

Amazon Connect includes a simulated web page that shows how your customers can interact with you, and a Contact Control Panel (CCP) that shows the agent experience. Here's how to test chat:

1. On the navigation menu, choose **Dashboard**, as shown in the following image.



2. Choose **Test chat**.

   If you don't see the option to test chat, click [here](#).

3. On the **Test Chat** page, choose **Test Settings**.

4. Under **System Settings**, choose the flow you want to test with chat, and then click **Apply**. By default, it runs the [Sample inbound flow](#).

> **Tip**
>
> If you want to test a chat and use contact attributes, note that the key and value pair must be enclosed in quotes, as shown in the following image:
>
> >

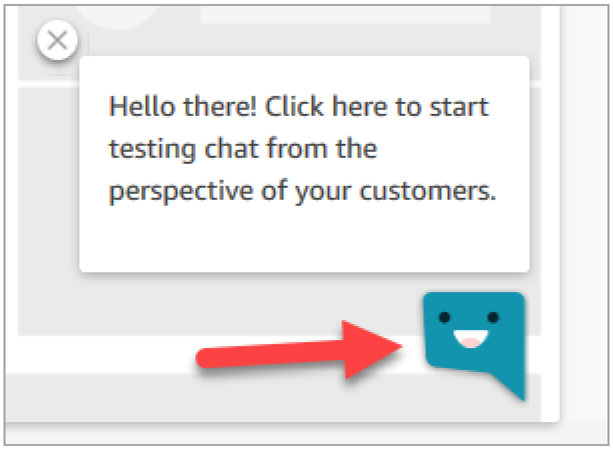
5. In the chat window, click the icon as shown in the following image.



6. Type a message similar to what one of your customers might type. In the agent window, type a reply.
7. To see what it's like for an agent to handle multiple chat conversations, copy the dashboard URL into another browser window, and start another chat. The chat goes to the same instance of the CCP that you already have open.

> **Tip**
>
> The test environment uses the BasicQueue and Basic Routing Profile. The Basic Routing Profile is set up for 2 chats. If you want to test what it's like to have more than two chats, change the Basic Routing Profile to 5 chats. For instructions, see Create a routing profile in Amazon Connect to link queues to agents.

To learn more about what the agent experiences when managing chat conversations, see Use the Contact Control Panel (CCP) in Amazon Connect to chat with contacts.

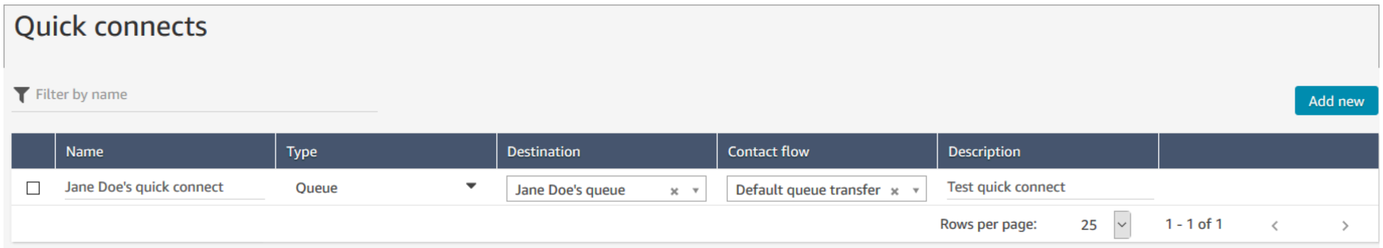
Test tasks

The first step in testing the task experience is to create a quick connect for the queue you want to assign the example tasks to.

Step 1: Create a quick connect

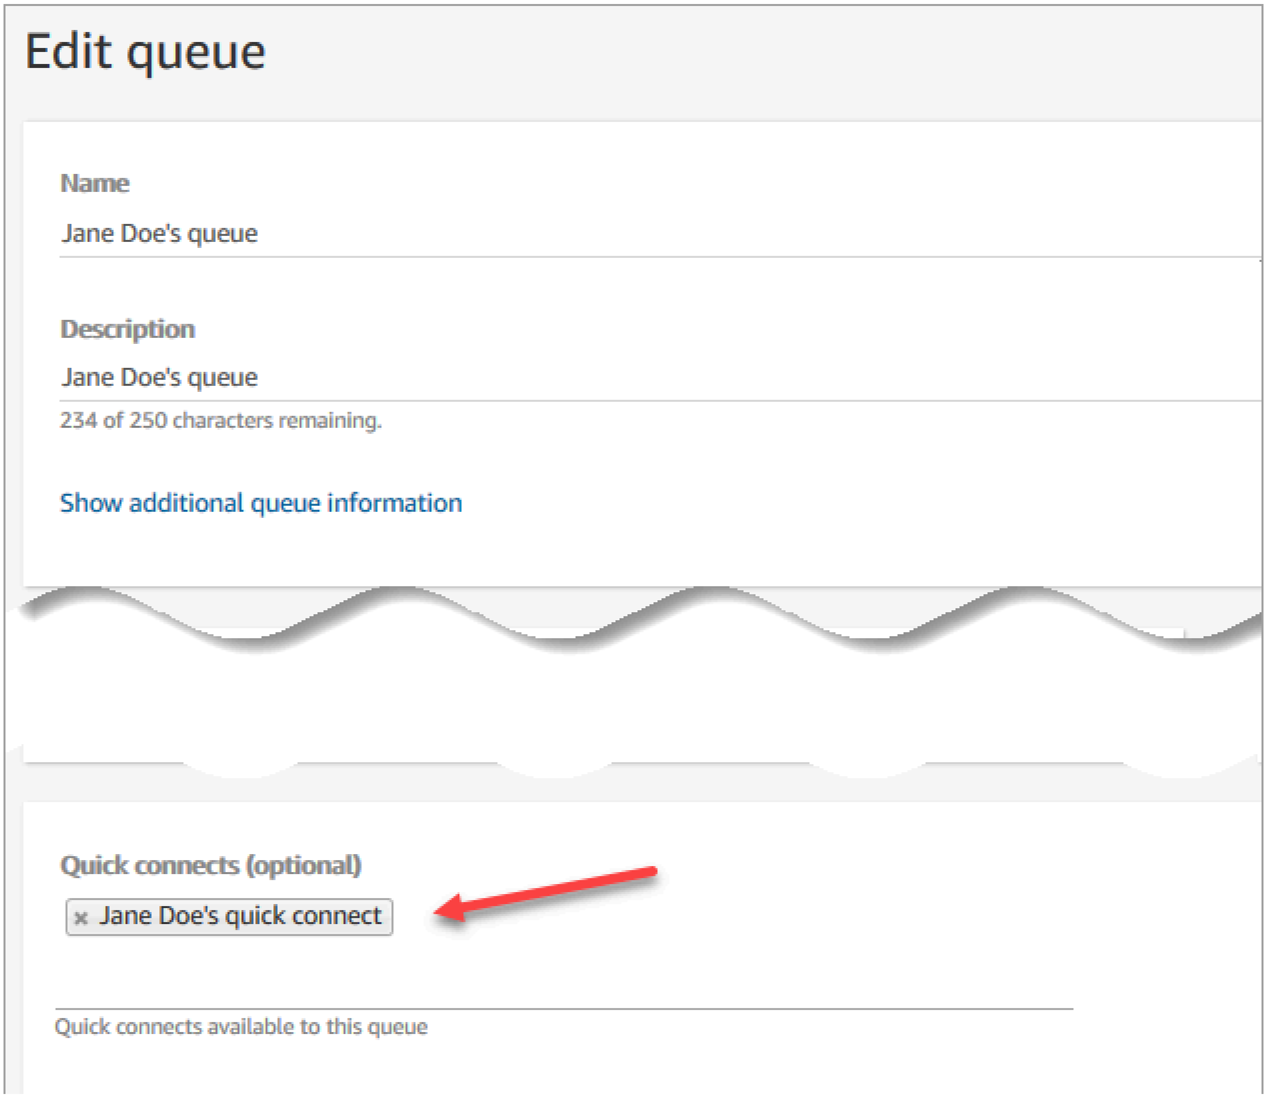
1. On the navigation menu, choose **Routing**, **Quick connects**, **Add a new**.
2. Enter a name for the quick connect. For example, if you want to assign the test task to yourself, enter your name (for example, **Jane Doe**).

3. Under **Type**, use the dropdown list to choose **Queue**.
4. Under **Destination**, use the dropdown list to choose a queue you set up for yourself (assuming you want to assign the test task to yourself).
5. Under **flow**, choose **Default queue transfer**.
6. Under **Description**, enter something like **Test quick connect**.
7. Choose **Save**. The completed quick connect looks similar to the quick connect in the following image.



Step 2: Make the quick connect visible in the CCP by assigning it to a queue

1. After you create the quick connect, go to **Routing**, **Queues** and then choose the appropriate queue for the contact to be routed to.
2. On the **Edit queue** page, in the **Quick connects** box, search for the quick connect you created. For example, it might have your name. The following image shows the quick connect for Jane Doe.



3. Select the quick connect and then choose **Save**.

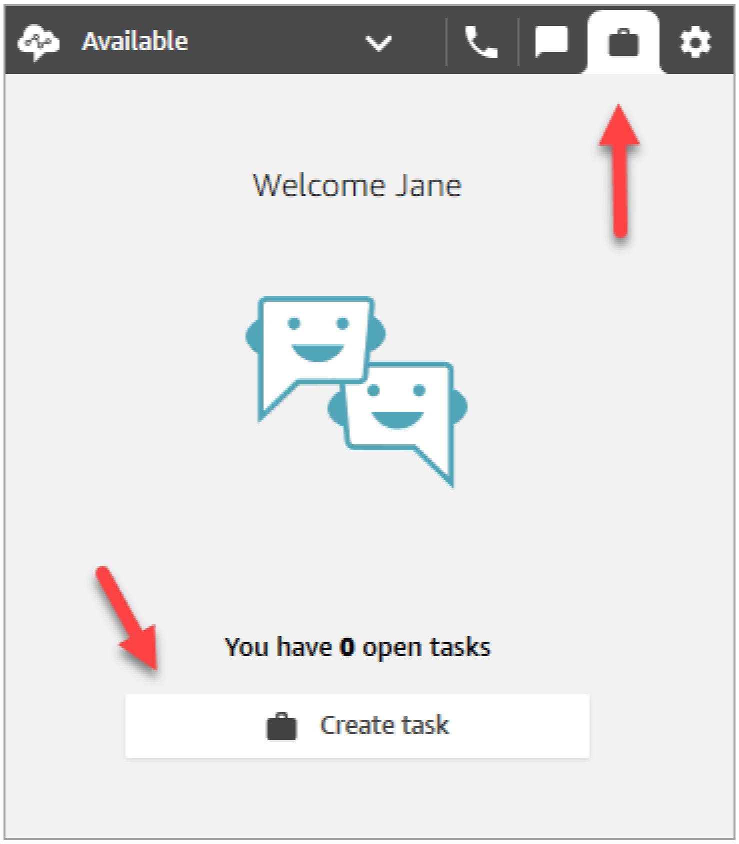
Step 3: Assign the queue to the agent's routing profile

1. Go to **Users**, **Routing profiles** and choose the agent's routing profile.
2. Under **Set channels and concurrency** choose **Tasks**.
3. Add the agent's queue to the routing profile, and choose **Task** for the channel.

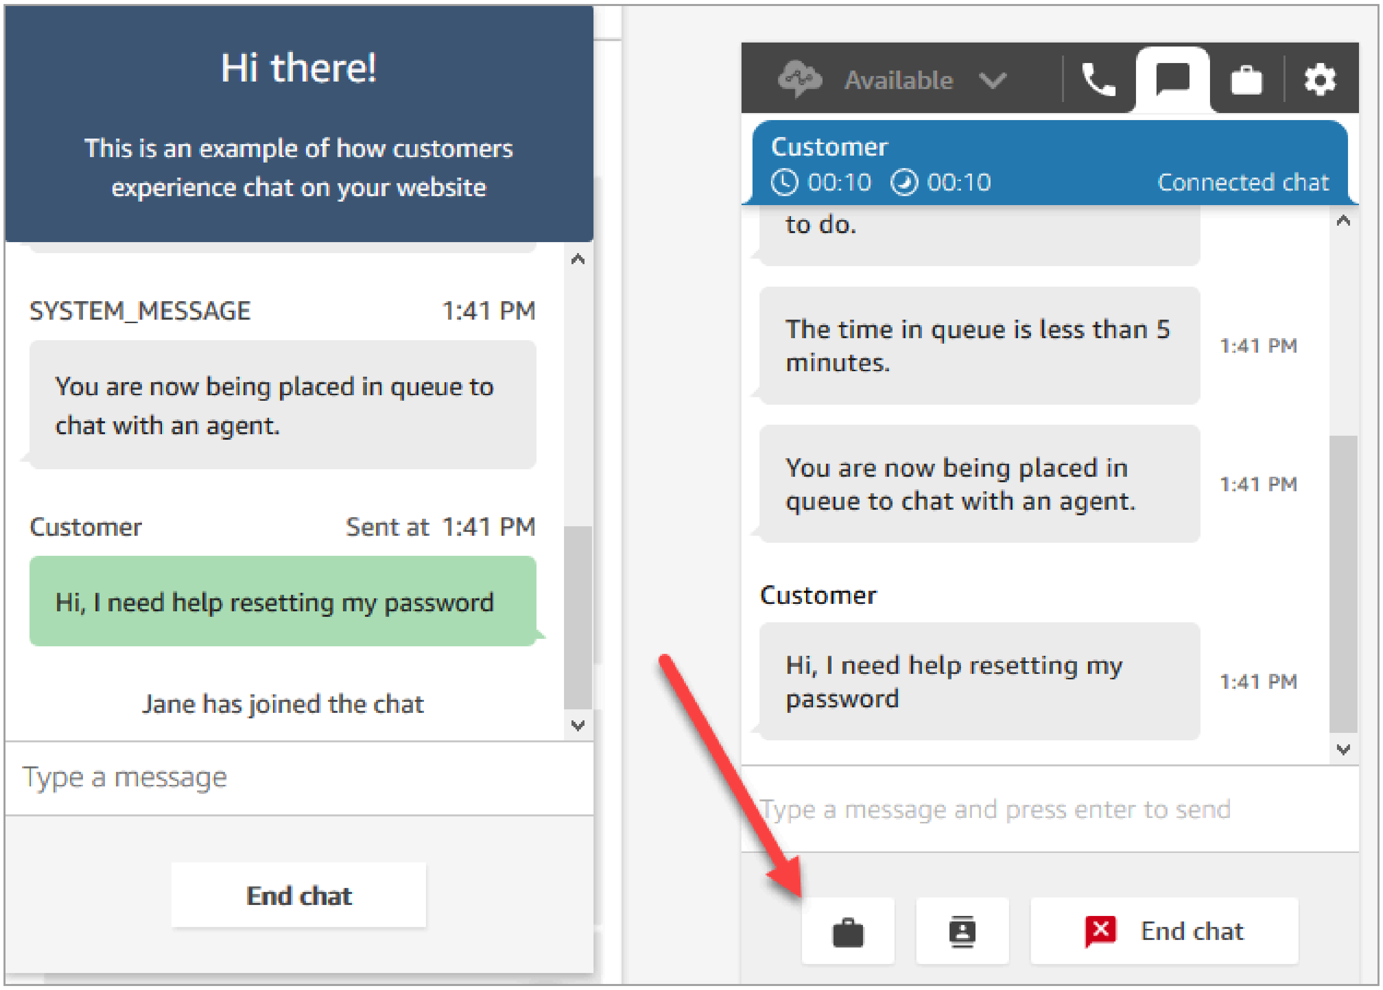
   If the agent can receive transfers through other channels, select them as well.
4. Choose **Save**.

Step 4: Test tasks

1. Open the CCP. Select the **Task** tab, and then choose **Create task**. The following image shows there are two ways to choose **Create task**: choose the task icon in the top right corner, or choose the **Create task** button at the bottom of the CCP page.



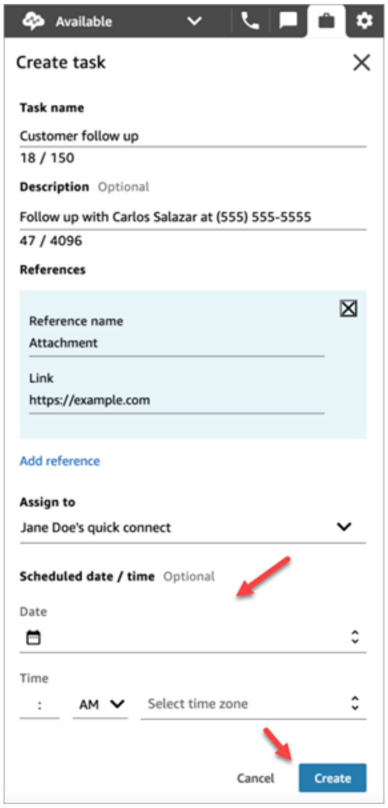
Or, if you're testing the chat experience, for example, you can choose the **Task** icon, as shown in the following image.



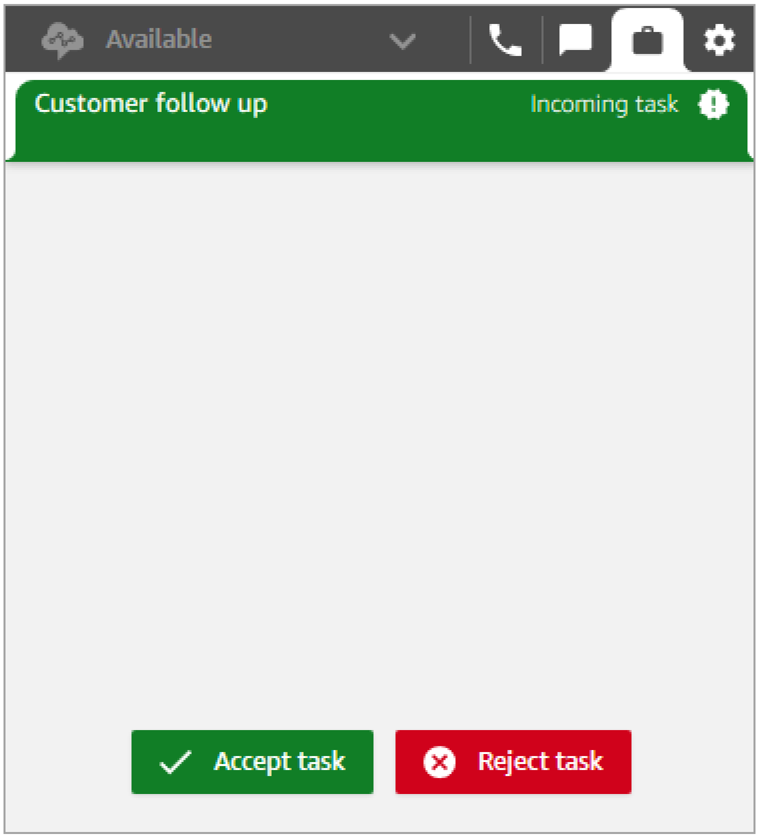
2. Complete the **Create task** page. When you choose **Assign to**, you can assign only a task to someone or a queue that has quick connect.

   To create a scheduled task for the future, use the **Scheduled date/time** box to choose a future date and time. You can schedule a task up to six days in future.

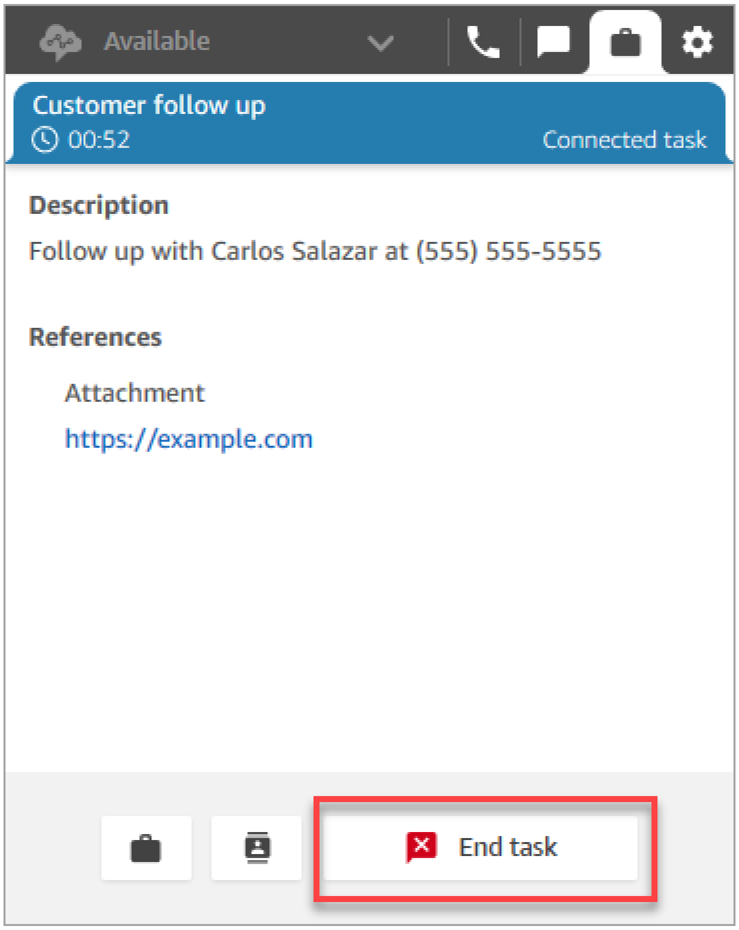
   Choose **Create**.



3. If you chose yourself, the task will be routed to you. The following image of the CCP shows what it looks like when a task arrives. Choose **Accept task**.



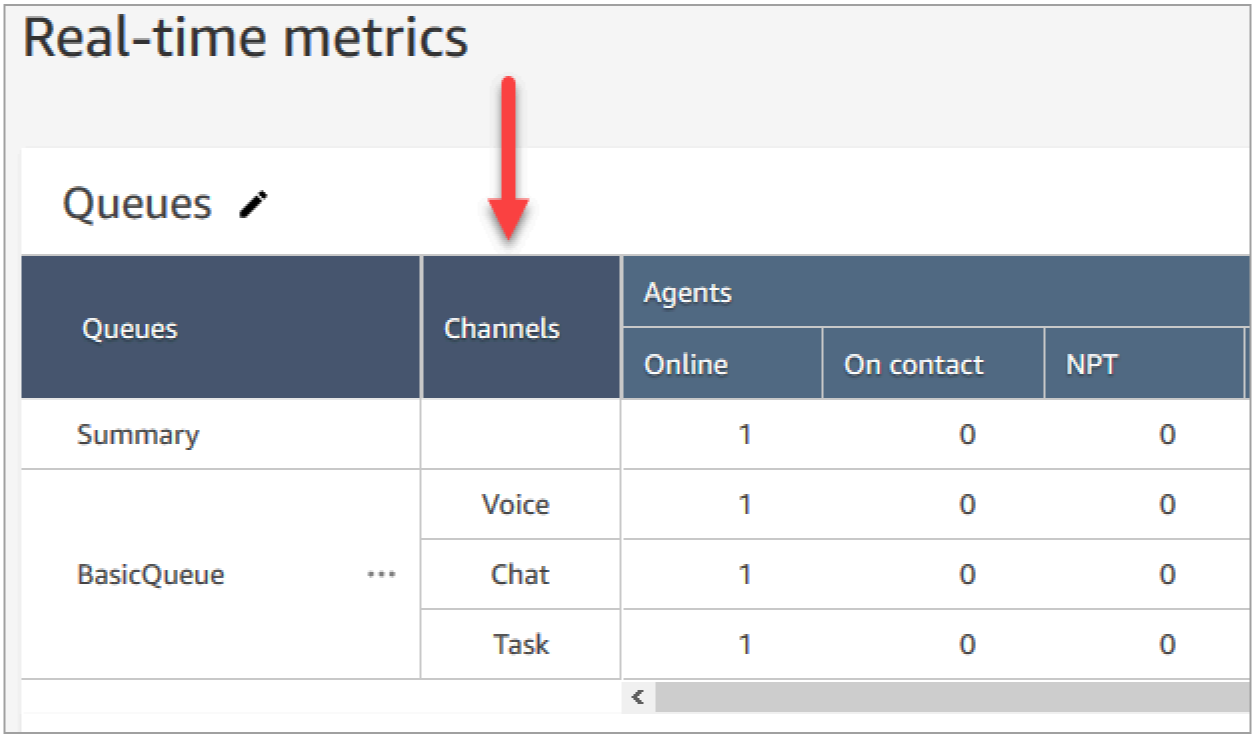
4. Review the task. When you're done with the task, choose **End task** when done.



View metrics for the test experiences

When you're testing the voice, chat, and task experiences, you may also want to explore metrics.

1. On the left navigation menu, choose **Analytics and optimization**, **Real-time metrics**, **Queues**.
2. You can review the real-time metrics as you test the different channels.
3. To view metrics by channel in a real-time metrics report, go to **Settings**, **Groupings**, **Queues grouped by channels**, **Apply**. Your report will look similar to the following image.



Set up your channels

Amazon Connect is a unified omnichannel solution built to empower personalized, efficient and proactive experiences across customers' preferred channels. You can tailor seamless experiences for your customers, whether it's over the phone, through in-app and web calling, video, chat, Short Message Service (SMS), or email. Customers can keep working with the same agent across channels, but if it's a different agent their interaction history is preserved, so they don't have to repeat themselves. The omnichannel contact center improves customer experiences while reducing resolution time.

Contents

Set up contact center phone numbers for your Amazon Connect instance

After you create an Amazon Connect instance, you can get a phone number to use for your contact center. You can use this phone number to place a test call in to your contact center to confirm that it is working correctly. You can also use it in your production environment.

- For pricing information about claimed phone numbers, see Amazon Connect pricing.
- For a list of the telephony capabilities that Amazon Connect provides, see the Amazon Connect Telecoms Country Coverage Guide.

If you want to keep a phone number you already have, you can port the phone number and use it with Amazon Connect. After a phone number is ported to Amazon Connect, it appears in the list of available phone numbers for you to assign to flows.

Contents

The voice channel in Amazon Connect

> **Important**
>
> Trying to contact Amazon for support? See Amazon Customer Service (Amazon orders and deliveries) or AWS Support (Amazon Web Services).

Amazon Connect provides a variety of choices to enable your company to make and receive telephone calls. One of the great advantages of Amazon Connect is AWS manages the telephony infrastructure for you: carrier connections, redundancy, and routing. And, it's designed to scale.

This topic explains the options that Amazon Connect provides for telephony, which helps you build a solution to meet your business requirements.

Contents

Telephony architecture

Amazon Connect provides capabilities to host both toll-free and direct dial numbers (DID) in all AWS Regions supported by Amazon Connect. You can use both types of numbers in a single instance. A complete list of supported countries/regions and costs is located on the Amazon Connect pricing page.

AWS manages the connectivity to our network of carriers providing diverse connections to multiple carriers in each region supported by Amazon Connect. When Amazon Connect is deployed in a Region, we take advantage of the built-in redundancy of the AWS Availability Zone design to provide multiple carrier interfaces into multiple data centers. You can see how AWS manages the design of a Region here.

In addition to the Amazon Connect service being spread across multiple Availability Zones, AWS also has multiple telephony providers. These providers have multiple links into the data centers in those Availability Zones. This ensures that if a single or even multiple links fail from a carrier, there are alternate routes available to ensure the service remains available.

To learn more about Amazon Connect architecture, see Architectural guidance for Amazon Connect.

- **AWS manages toll-free numbers as a Responsible Organization**

  These numbers are phone numbers with distinct prefix codes that can be dialed with no charge to the person placing the call. Such numbers allow callers to reach businesses and/or individuals out of the area without being charged a long-distance fee for the call.

  In the United States, the Federal Communications Commission provides rules for obtaining and using toll-free numbers. In other countries, similar governing bodies ensure that such numbers are managed and distributed in accordance with local laws.

  When you claim or port a US toll-free number into Amazon Connect, we register that number with SOMOS. After the number is registered, we are able to select multiple carriers to provide BOTH route and carrier redundancy. This provides the highest level of availability, ensuring the number will remain available even in the event of a complete carrier outage. This level of service does come at an additional cost, as these numbers are a higher price than direct dial, but the service reliability and customer experience make this the most attractive option.

- **Locally formatted numbers**

Direct inward dialing (DID), also called direct dial-in (DDI) in Europe, is a telecommunication service offered by telephone companies to subscribers. DID numbers provide a locally formatted telephone number that can match the dialing pattern of a local subscriber. For example, in Seattle, Washington, USA, the local dialing pattern is +1(206)-NXX-XXXX. The provider of the DID number would provide numbers with the +1(206) pattern to match local dialing.

In the United States, DID numbers are regulated by State Public Utilities commissions. DID numbers are managed by a single carrier. While they are portable, they can't be load balanced/managed across multiple carriers. This makes them less reliable than toll-free numbers.

DID numbers offer you the ability to present a local calling line identification when placing outbound calls, and a local presence to inbound callers. This can be very useful to increase the likelihood outbound and queued callback calls get answered by your customers. It can also show a customer that you are local to their area, and provide a cheaper inbound route than a long-distance call if you don't publish a toll-free number.

Because DID numbers are threaded to single carrier, Amazon Connect doesn't offer carrier redundancy for DID numbers. We do offer link redundancy across multiple Availability Zones, so in the event of a link failure that carrier still has facilities available in another location to deliver calls. DID numbers also have a capacity limitation on how many calls a single number can accommodate, and this number does vary by Region. It is important to work with your AWS account team to ensure you are properly enabled with the right type of DID numbers if you plan on using DID numbers as your primary inbound channel, and have an expectation of over 100 concurrent calls per number.

DID numbers are less expensive than toll-free numbers, but don't have the redundancy and broad geographical coverage of them. The ability to localize numbers may be an attractive option for your business.

Use cases for different configurations

Starting fresh with Amazon Connect

In this case, simply select new numbers using the claim a number process. For instructions, see [Get a local toll-free or DID Amazon Connect phone number].

Migrating to Amazon Connect from another provider/platform

If you're migrating to Amazon Connect from other platform, we recommend starting with a proof of concept, and migrating to Amazon Connect over time.

- A best practice is to forward your existing numbers to a new number (or numbers) claimed in Amazon Connect until you are fully converted.
- After fully converting, use the porting process to bring your numbers into Amazon Connect.
- This gives you a fallback in case you have migration issues.

Maintaining two separate platforms

In some cases, you may have more than one Contact Center platform requiring telephony. Here's an overview of how to configure this:

- Choose which platform is the initial call-handling service, and forward to the other platform.
- If Amazon Connect is the primary call handling platform, you can port or claim numbers. You will design your flows to transfer calls to the other platform on a telephone number you will provide in the flow.
- If the external platform is the primary call handler, you will need to configure that platform to forward calls to a number you claim in Amazon Connect. Choose either a toll-free number, which will give you better redundancy and capacity at an increased cost, or a bank of DID numbers to terminate the call into Amazon Connect.
- For the use case, we recommend that you engage AWS Solution Architecture support to ensure your contact center is well-architected to achieve the best possible outcomes.

Concepts: Stir/Shaken

STIR/SHAKEN framework is designed to combat caller ID spoofing by verifying a caller's right to use a telephone number. It consists of two components:

- STIR (Secure Telephone Identity Revisited): A standard for using digital certificates to authenticate the calling party's identity and right to use a phone number.
- SHAKEN (Signature-based Handling of Asserted Information Using toKENs): Guidelines for implementing these protocols across networks.

Within this framework, attestation plays a crucial role in indicating the level of confidence a service provider has in the caller's identity.

When a call is made, the originating provider assesses and assigns an attestation level—Full (A), Partial (B) and Gateway (C)—based on their relationship with the caller. This attestation information is included in the SIP header. It helps the receiving network evaluate the trustworthiness of the caller ID.

- A Full attestation means the identity of the caller is known and they have the right to use a particular phone number as caller ID for an outbound telephone call.
- A Partial attestation means the identity of the caller is known but the service provider does not know if the caller has the right to use a number.

Amazon Connect is a multi-carrier service that provides phone numbers from various service providers to deliver outbound calls. With Amazon Connect's call resiliency, the service ensures a high level of confidence that calls reach customers. For example:

- When calls are made through the primary provider (a carrier that has provided the phone number used to make the call), the calls receive a Full (A) attestation.
- In contrast, calls made through a failover carrier route receive a Partial (B) attestation level, indicating a fallback route is being used.

This setup enhances the reliability of call delivery by using diverse network paths.

Amazon Connect provides attestation for eligible calls leaving its system in countries that have implemented STIR/SHAKEN. However, after a call enters the telephone network, the attestation may not be preserved. Maintaining this attestation is beyond the control of Amazon Connect due to the nature of legacy networks.

Amazon Connect supports the various implementations of the anti-spoofing configuration in United States, Canada, and France.

Design your Amazon Connect contact center for low latency to help ensure call quality

> **Note**
>
> As of July 2023 we have simplified requirements to claim phone numbers that are located in countries outside of the AWS Region where your Amazon Connect instance is located. The process has been simplified to remove the need for the opt-in approval. Instead we provide best practice design guidance. This makes it easier for you to use an Amazon Connect instance that is created in the US-East Region, for example, and then request numbers in Japan. Or, if your instance is created in Asia Pacific (Singapore), you don't need to contact AWS Support to claim phone numbers based in Europe or US Regions.
> We continue to extend the support of Amazon Connect so you can claim phone numbers in the countries you need, wherever you need them.

If you are configuring your Amazon Connect instance to support phone numbers outside of your country's home AWS Region, we recommend the following best practices.

1. Anchor either your phone numbers or agents in the same AWS Region where they are geographically located. For example, if your agents are located in a US Region, your Amazon Connect instance should be created in an AWS Region in the US, too. Or, if your phone numbers are in an EU country, your Amazon Connect instance should be created in an EU AWS Region, too.
   a. If both your phone numbers **and** agents are located in an AWS Region that is different from the one where your Amazon Connect instance is created, call latency is extended above 500ms for network latency (WebRTC RTT). This latency may result in call quality issues.
2. Calculate your latency before setting up your Amazon Connect contact center in production. Perform the following steps on a test environment:
   a. Use the Amazon Connect Endpoint Test Utility to check latency.
   b. Calculate the latency for routing telephony from the country to the AWS Region using internet-based, external tools, such as WonderNetwork.
   c. For calls with the best call quality, we recommend configurations with less than 500ms of latency end-to-end.
   d. You may determine that call quality is acceptable at up to 900ms of latency for both network and telephony latency. (900ms is a sum of 500ms network latency and 400ms carrier latency.)

However, if you note a call-quality issue that can be due to latency, and other potential causes are ruled out (for example, neither packet loss nor jitter are detected), we recommend configuring your Amazon Connect instance or telephony for a lower latency. For example, create your Amazon Connect instance in the same Region as your telephony or agents.

> **Important**
>
> When call latency is greater than 900ms for both network and telephony latency, it leads to a significant delay between agents and customers.

3. Check that latency matches your design.

   After you claim a number you can immediately call it to hear what the experience will be like for your customers. Amazon Connect uses the default flows to power your initial experience.

   To test a customized flow, assign a phone number to it and then call that number.

Port a current phone number to Amazon Connect

You can port your existing phone numbers to your Amazon Connect contact center.

Contents

Things to know before porting a phone number to Amazon Connect

The topics in this section explain which numbers can be ported, how long it takes, and what fees you might incur.

The following terminology is used in these topics:

Letter of Authorization

Letter of Authorization (LOA) is a legal document in which you assert to the carrier for Amazon Connect that you have the authority to port phone numbers from your current carrier to the carrier for Amazon Connect. Traditionally, this is a paper document requiring an actual signature.

Losing carrier

Also known as your current carrier. This is the carrier that currently owns your telephone number. The losing carrier reviews all information presented on the Letter of Authorization (LOA) and validates if it matches the information that they have on file for you.

Mutually agreed date and time

After the LOA has been approved by the losing carrier, the losing and winning carriers agree upon a date and time to perform the porting activity.

Phone number portability

Number portability allows you to transfer your telelphone numbers to other carriers. Carriers and countries may have unique processes and procedures required.

Winning carrier

Also the carrier for Amazon Connect. This is the carrier that the phone number is being ported to, and will own the phone number after the porting is completed.

Contents

What does it mean to port phone numbers to Amazon Connect?

Porting a phone number is the process of moving a phone number from one telephony service provider, or carrier, to another. Many businesses and organizations already have a phone number that is advertised to their customers, so changing this number would be disruptive.

If you port a phone number from your current carrier to Amazon Connect, you can keep using the same phone number for your contact center. This helps to eliminate the need to update your business contact information.

Downtime and service disruption during the porting process

The porting process requires the losing carrier to remove your number from their systems, the winning carrier to add your number to their systems, and for number routing to be updated. Most porting activities complete within 15-30 minutes, with possible call disruptions. To ensure that they have engineers available to troubleshoot issues, most losing carriers complete porting actions only during normal business hours. Carriers typically communicate a two-hour porting window to resolve any issues that could arise.

For detailed information about available porting dates and times, see [Region requirements for ordering and porting phone numbers in Amazon Connect]() for your country or region.

What happens to a number after it is ported

As long as you continue to pay for the phone number, and do not release it from your Amazon Connect instance, it stays assigned to your account, and you are billed accordingly.

To release a phone number, follow the steps in [Release a phone number from Amazon Connect back to inventory]().

When a phone number is released from your Amazon Connect instance:

- You will no longer be charged for it.
- You cannot reclaim the phone number.
- Amazon Connect reserves the right to allow it to be claimed by another customer.

If you move your contact center away from Amazon Connect, and want to port your phone number away from Amazon Connect, see [Port phone numbers away from Amazon Connect]().

How much does porting a number to Amazon Connect cost?

Amazon Connect does not charge fees for porting numbers. Your existing carrier may have fees associated with the disconnection and early termination of your service.

After a phone number is ported to Amazon Connect, standard pricing applies for Amazon Connect service usage and associated telephony rates.

Phone numbers that you can port to Amazon Connect

Not all phone numbers can be ported. The ability to port a specific phone number depends on several factors. For example:

- The regulations in the country or region of the phone number.
- Agreements between the losing and winning carriers.
- The type of phone number being ported.
- Your service contract with your current service provider.

To find out if a phone number that you currently own—whether local, mobile, or toll-free—can be ported to Amazon Connect:

1. See if your country or region supports number porting: Region requirements for ordering and porting phone numbers in Amazon Connect.
2. Then get started by submitting an Amazon Connect support ticket for number verification.

Porting numbers purchased from other contact center providers

In most cases, you can port numbers that were purchased from other contact center providers. Confirm with your current contact center provider who holds the assignment to the number, and work with them to ensure the correct information is provided in the Letter of Authorization (LOA).

Port short phone numbers

Because of Telecom regulations in various countries or regions, the short phone number will need to be evaluated on a case-by-case basis. To verify if your phone number can be ported to Amazon Connect, submit an Amazon Connect support ticket.

Port a number to one EU Region only

The Amazon Connect Regions of EU-CENTRAL-1 and EU-WEST-2 are symmetrical European Regions that offer the same carrier coverage for telephony. If a phone number cannot be ported to an instance in one of these Regions, then it cannot be ported to an instance in the other.

If you had a phone number ported into the EU-CENTRAL-1 or EU-WEST-2 Regions, and want to move it to the other Region, submit an Amazon Connect support ticket for assistance.

The same is true for the North America Regions of US-EAST-1 and US-WEST-2.

Port a subset of numbers from a block

If you have a block of numbers, in some instances Amazon Connect can port a subset or portion of your phone numbers. In other cases, it is required by the carrier to port full block of phone numbers.

If you want to port only a subset of the phone numbers you currently own to Amazon Connect, submit an Amazon Connect support ticket to verify whether the phone numbers can be ported. We will verify the actions that can be completed and assist you with next steps.

> **Note**
>
> If you port only a subset of the phone numbers, you will still be liable for the remaining phone numbers with the original carrier and any associated fees.
> If your intent to is release the remaining phone numbers not being ported to Amazon Connect, we recommend waiting until the requested porting has been completed to avoid any disruptions to service.

Letter of compromise

Before porting phone numbers, some customers ask for a letter of compromise stating that they will be allowed to move their phone numbers from Amazon Connect to another service, if their contact center moves. Because of Telecom regulations in various countries, the phone number will need to be evaluated on a case-by-case basis. To verify that your phone number can be ported to Amazon Connect, submit a ticket to Amazon Connect support .

How long does it take to port phone numbers to Amazon Connect?

> **Important**
>
> Open a porting request as far in advance of your pending go-live date as possible.

The amount of time that it takes to port numbers depends on the country, complexity of the request, the type and quantity of numbers being ported, and your current carrier. Telecom carriers also may implement porting block days because of holidays and network maintenance. Because of this, Amazon Connect requires porting requests to be open several months before pending go-live dates.

For a list of countries and their portability windows, see [Region requirements for ordering and porting phone numbers in Amazon Connect].

Inside the US and Canada

Phone numbers in the US or Canada typically take between two to four weeks to port, after phone number portability has been verified, and all required documents are correctly submitted to the carrier.

Outside the US and Canada

Phone numbers outside the US and Canada require between two to six months to complete the full porting process. This includes:

- Time for you to submit all the documents to AWS Support.
- Time for the Amazon Connect service provider to verify whether they can port all of the phone numbers that you have requested.
- Time for the losing provider to verify the provided documents.

After all documents are verified by the losing provider, the losing provider and the Amazon Connect service provider will schedule a mutually agreed date to port the numbers to Amazon Connect.

What affects porting timelines?

Porting timelines can be negatively impacted when incorrect information is provided on the required Letter of Authorization (LOA). This causes the LOA to be rejected and resets the porting timelines.

Port many numbers over multiple countries or carriers

Complex porting requests have their own timelines. The timelines discussed elsewhere in this topic do not apply to complex porting requests.

Complex porting requests for more than 10 distinct number ranges or 10 distinct locations are considered a project and require advanced coordination with your AWS Account team. If you are a Business or Enterprise customer, engage your Amazon Connect Solutions Architect (SA) or Technical Account Manager (TAM) for assistance in planning your number porting.

To help make the process as smooth as possible, gather the following information before submitting a porting request:

- Your most recent telephony bill from the carriers that currently service the numbers to be ported.
- The country specific documentation required; see Region requirements for ordering and porting phone numbers in Amazon Connect.
- The contact information for a central point of contact who can act on behalf of your organization in support of the porting requests.

Can I choose the port date?

> **Important**
>
> The Amazon Connect service team supports porting phone numbers FROM 9am Monday in Sydney NSW, Australia Time, TO 5pm Friday in Seattle, WA, USA time.

Depending on the country and carriers involved, you may be able to choose the porting date and time. In most cases, however, the losing carrier picks the date and time and communicates it to Amazon Connect based on their schedule.

If you have a specific date and time you want to request, provide the information in your support case. We will work with our carrier to determine if they can support the requested date and time.

> **Note**
>
> Most carriers only support porting activity during their normal business hours. For detailed information about available porting dates and times for your country, see Region requirements for ordering and porting phone numbers in Amazon Connect.

Can I cancel a scheduled phone number porting in Amazon Connect?

> **Important**
>
> If you need to cancel or reschedule your porting, let us know immediately.

Depending on the country of service, after a mutually agreed date and time has been provided it can be difficult to cancel.

Because of the coordination required between carriers, Amazon Connect support requires a minimum of 5 business days notice to cancel or reschedule a porting request, if the number has not already been ported. If you need to cancel or reschedule your porting, let us know immediately.

You cannot cancel a port after it has been moved to the RespOrg (Responsible Organization). The port is complete. For this situation, see Revert phone numbers to your original carrier after porting to Amazon Connect.

If a porting is successfully cancelled, timelines for the port schedule are reset and the carriers will need to identify another mutually agreed date and time. This will impact the overall timeline for porting your numbers.

> **Note**
>
> Please be advised that sometimes a porting request cannot be cancelled because of process automation, but Amazon Connect support will make every attempt possible to stop the request.

When do I cancel my current telecom service when porting numbers to Amazon Connect?

Do not cancel your existing telecom service until your phone numbers have been ported and confirmed working in Amazon Connect.

Canceling your existing telecom service before your number is ported releases your phone number assignment, and may result in you losing the number.

Guidelines for porting phone numbers to your Amazon Connect project in South Korea

Rules for South Korea differ from those in other countries. To help with requirements in South Korea, here are some helpful hints.

- When planning your Amazon Connect project in South Korea one of the most important things you will need to do is plan and request information up front. To port numbers in South Korea, you may need to complete and submit more than 5 forms and you may need to engage with the local regulatory authority before approvals are granted to port numbers.
- All geographic numbers (that is, other than toll-free, national, representative, or 070 VOIP) must be in place on a physical termination for a minimum of 6 months before they can be ported into Amazon Connect. However, if a number has been in place for a minimum of 3 months, you can port it by filing a special request with the Korean Ministry of Telecommunications; upon approval, the porting process can begin. Amazon Connect can provide you with the forms, but you must complete and submit them to the regulator directly.
- All geographic, representative, or toll-free numbers (GRTFN) are assigned a 070 VOIP number to which the GRTFN terminates and which are associated with the GRTFN at the carrier. Do not remove this 070 number from your Amazon Connect instance until the related GFTN number is removed. If you do, all inbound and outbound calls will fail.
- Representative numbers (RN) have minimum session billing requirements based on the "attractiveness" of the RN, as determined by the carrier. Representative numbers have different costs depending on the scale of the number. Based on the size of the representative number you order, the service will have from 2 channels to 500 channels minimum to be charged for. This is managed by adding a minimum number of numbers to the account, equal to the number of channels needed. These are shown on the Amazon Connect pricing page as the shared cost service at $0.5433 per day of usage for the system. These additional shared cost number DIDs do not have the ability to be assigned call flows, and outbound calls from them will fail. If you disconnect RNs, be sure to also remove their associated Special Numbers to avoid future billing. Removal or reduction of Special Number DIDs without removal of the underlying RN is a violation of Amazon Connect Terms of Service.

Things to know about Thailand number porting

Porting in Thailand differs from other countries. Instead of the number being able to directly moved to Amazon Connect, it’s necessary to route the calls from your current provider to Amazon Connect. To help plan for the process here are some helpful hints.

- Numbers being ported in to Amazon Connect must be from E1 or SIP services only.
- The E1 or SIP service, along with all associated numbers, must be routed to Amazon Connect's provider's network first. Amazon Connect will help coordinate this. Based on your configuration this may involve additional charges to your current provider or Amazon Connect's provider to support the re-routing.
- Once the E1 or SIP service has ported to Amazon Connect's provider selected numbers from the service can be activated for use on Amazon Connect. Once activated the numbers will use Amazon Connect for both inbound and outbound calling.

Porting your phone numbers from your carrier to Amazon Connect

Porting phone numbers from your existing carrier to Amazon Connect is a multi-step process. It's important to get started several months in advance of your scheduled go-live date, and have all of your documentation in order.

Contents

How to port your numbers to Amazon Connect

The following steps are for a typical porting request. This process requires timely communication to make progress. If you take longer than 30 days to respond to requests for information, your porting request may be cancelled, rescheduled, or restarted from the beginning.

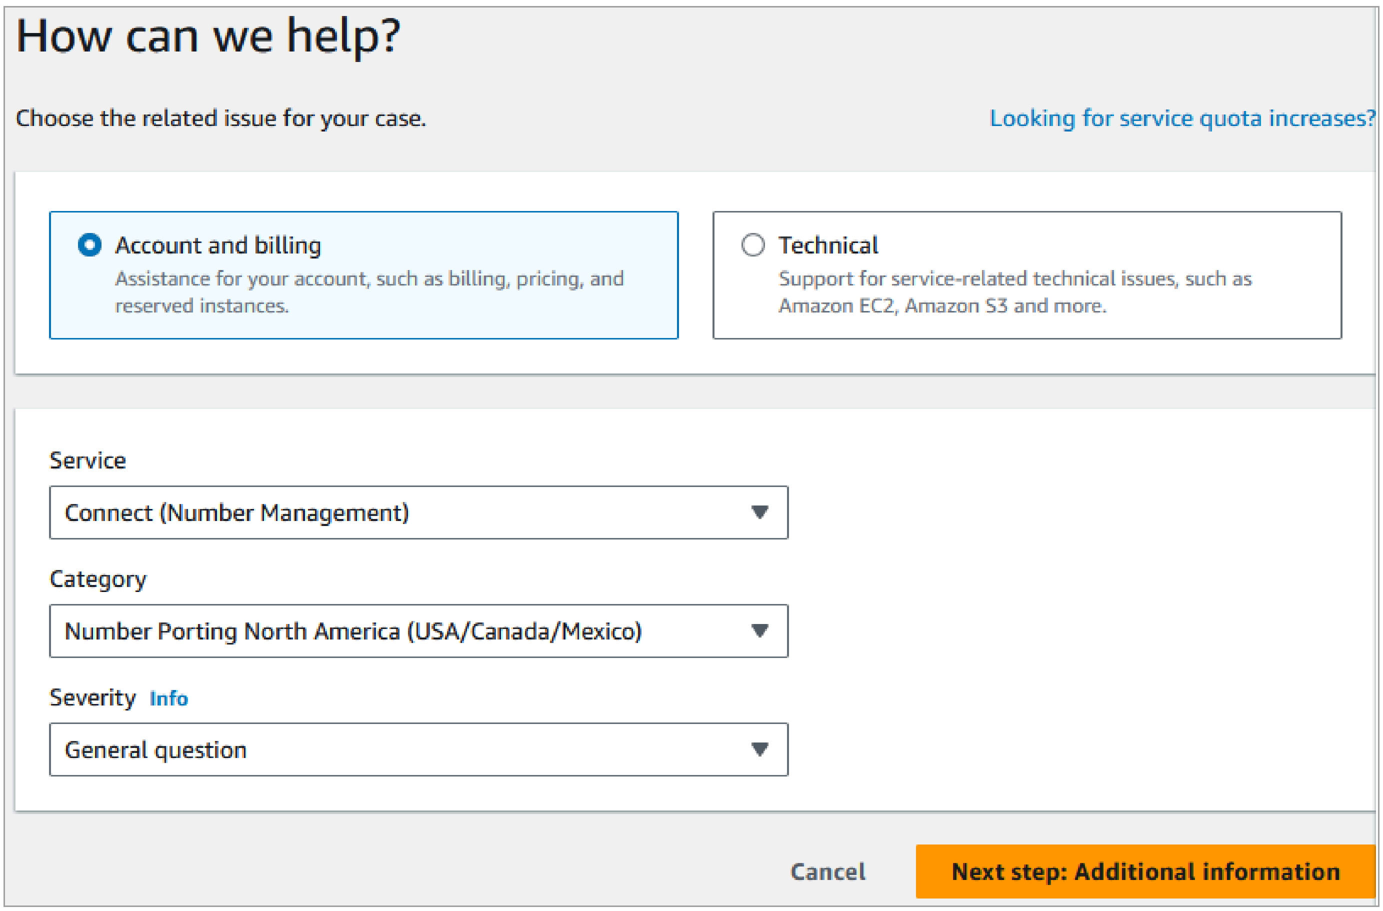
Documentation requirements: For a list of country-specific requirements for porting numbers, see Region requirements for ordering and porting phone numbers in Amazon Connect.

Step 1: Create an Amazon Connect support case

Important

If you are porting multiple numbers from different carriers and countries, submit separate tickets for each set of phone numbers to be ported from different carriers and different countries. This streamlines communications, tracking, and the LOA process.

1. Choose Account and billing to access a pre-populated form in the Support console. You must be signed in to your AWS account to access the form.
2. For **Service**, **Connect (Number Management)** should be selected, as shown in the following image.



3. For **Category**, choose **Number Porting North America (US/Canada/Mexico)** or **Number Porting Non-North America**.
4. Select the required severity.
5. Choose **Next step: Additional information**

6. On the **Additional information** page:

    a. Enter the subject.

    b. Under **Description**, include as much information as possible about your request, including phone number(s) to be ported, your current carrier, and the contact information for the person authorized to make changes to your current phone service. If you don't know all of these details, you can leave information out.

    > **Important**
    >
    > Do not attach any documents that contain personal information. After we review your case, we'll send you a link to our secured storage (Amazon S3) so you can submit required documents. This is described in Step 3: Submit the required documents by using a link we provide to you.

7. Choose **Next step: Solve now or contact us**.
8. On the **Solve now or contact us** page:

    - Choose the **Contact us** tab and select your **Preferred contact language** and your preferred contact method.

9. Choose **Submit**.
10. The Amazon Connect team will review your ticket and get back to you.

Step 2: Complete Letter of Authorization (LOA)

If the phone number qualifies for porting, the Amazon Connect team will provide you a Letter of Authorization (LOA) to be completed by you. Complete all mandatory fields and sign the LOA.

Along with the LOA, Telecom regulations in many countries require additional documents to register a number, such as proof of business, proof of address, and proof of ID. For a list of country-specific requirements for porting numbers, see Region requirements for ordering and porting phone numbers in Amazon Connect.

How to complete an LOA

All portings require the completion of a Letter of Authorization (LOA). The LOA authorizes your current carrier to release your number and allow it to be ported.

- A separate LOA is required for numbers from each losing carrier.

To complete an LOA, provide the following information:

- The numbers to port.
- Information about your current carrier, such as their business name and contact information.
- Contact information for the person authorized to make changes to your phone service. The name, address, and information you provide on the LOA must match the information on file with your current carrier exactly. To help ensure the porting process goes smoothly, include a copy of the Customer Service Record (CSR) or latest phone bill from your carrier. This will have your name, address, and related telephone numbers on it. Check that the information on your LOA matches your CSR **exactly**.
- If you have any questions regarding specific details about your current service, consult with your current carrier to ensure the data is accurate. This will minimize the risk that the LOA is rejected.

Important

Your LOA form must meet the following criteria:

- It must be legible: clearly written or typed.
- It must list your company name, the company address, and contact name. This information must match what is on the current carrier's CSR.
- It must include a traditional handwritten signature: a physical paper documented signed with pen and ink, also known as a wet signature. Most carriers will reject an electronic or printed signature.
- It must be dated within the last 15 days.
- If you also want to port toll-free numbers, it must include them as well. Up to 10 toll-free numbers can be listed on the LOA. If you are requesting more than 10 phone numbers be ported, a spreadsheet is required to be attached. Specify "See Attached" on the LOA where the phone numbers would be listed.
- It must include only those telephony numbers that belong to the same current carrier and in the same country. If you have multiple current carriers and countries, you will need to submit multiple LOAs.

To further minimize the risk of having your LOA rejected, see Common reasons why carriers reject an LOA.

Step 3: Submit the required documents by using a link we provide to you

After the Amazon Connect team says you can port phone numbers, you need to submit any required documents. The following steps explain how.

> **Note**
>
> Support provides a secure Amazon S3 link for uploading all requested documents. Do not proceed until you receive the link.

To submit required documents

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. Sign in to your AWS account, then open the Amazon S3 upload link generated specifically for your account.

   > **Note**
   >
   > The link expires after ten days. It is generated specifically for the account that created the case. The link requires an authorized user from the account to perform the upload.
3. Choose **Add Files**, then select the documents required for your request.
4. Expand the Permissions section, and choose **Specify individual ACL permissions**.
5. At the end of the **Access control list (ACL)** section, choose **Add grantee**, then paste the key provided by Support into the **Grantee** box.
6. Under **Objects**, choose the **Read** checkbox, then choose Upload.

After you provide the Letter of Authorization (LOA) and any other required documents, Amazon Connect team confirms with your existing phone carrier that the information on the LOA is correct. If the information provided on the LOA does not match the information that your phone carrier has on file, Amazon Connect team contacts you to update the information provided on the LOA.

Step 4: The porting request goes to the Amazon Connect carrier

After you have submitted all required documentation, the Amazon Connect team submits the porting request on your behalf to the winning carrier.

- The losing and winning carrier follow an industry standard process to validate the contents of the LOA and submitted documentation.
- If the LOA contains discrepancies, it will be rejected and you will need to fix the discrepancies and submit a new LOA.
- After the carriers successfully validate the LOA, they will either confirm your requested date or provide an available date for the actual porting. This is known as the "mutually agreed date and time."
- You should validate that the "mutually agreed date and time" is correct.

> **Important**
>
> If your LOA contains multiple phone numbers, some numbers may be given different "mutually agreed dates." Check the status and dates/times for each one.

Most carriers require that portings are completed during normal business hours. For country-specific business hours, see Region requirements for ordering and porting phone numbers in Amazon Connect.

Step 5: Validate number(s) in the instance, assign the phone number to the flow, request service quota increases

About 3-4 days before the mutually agreed date and time, the Amazon Connect support team loads the phone number that will be ported into the instance ARN you have provided, and then notifies you. Now it's time for you to perform the following steps:

1. Log into your Amazon Connect admin website and validate that your phone number(s) are listed. For instructions, see List or export to a CSV the phone numbers claimed to your Amazon Connect instance.
2. Associate the phone number to the desired flow so the phone number will be ready to receive phone calls after the porting is completed. If you require assistance assigning multiple phone numbers to flows, let us know in your support request.

> **Important**
>
> - It is expected that you or your partner associate your phone number to the flow.

- If you want AWS Support to do this on your behalf, note this in your support ticket. You must specify the flow name/ARN to be matched to each phone number.
- You or your partner must validate that the correct flow has been associated with each phone number.

3. Submit a service quota request at least five days in advance of the mutually agreed date for any changes to your service quotas required to support your use case. For example, you may need to increase the number of concurrent calls per instance, or enable countries for outbound calling.

Step 6: Checklist of activities on your porting date

The action of porting a number can be disruptive: the process involves updating the routing of phone numbers between carriers across a country or Region, including carriers not involved in the actual porting. In rare cases it can take several hours before all routes across all Telecom carriers are fully updated.

Steps you perform to minimize disruption to your phone services

On the mutually agreed port date and time, perform the following steps:

- Double-check that the activities listed in Step 5 have been completed:
  1. Verify that the number(s) you had ported are in the requested Amazon Connect instance, and they have been assigned to the appropriate flow.
  2. Verify that any required service quota increases or changes for your Amazon Connect instance were implemented. For example, increase the number of concurrent calls per instance, or enable countries for outbound calling.
- Monitor call traffic from your existing contact center to confirm that incoming traffic has stopped.
- Place test calls to your Amazon Connect instance to verify calls are being routed to the correct flows.
- Ensure agents are logged in to the Contact Control Panel (CCP) and can answer calls as they are received.
- Monitor call traffic to your Amazon Connect instance to confirm that you are receiving the expected levels of traffic.

Steps the Amazon Connect team performs to ensure a smooth transition

1. After the Amazon Connect team receives confirmation that the porting has been completed, we will perform final testing to confirm that the porting was successful and the phone number is receiving calls to Amazon Connect.
2. After we have completed our testing, we will notify you and ask you to verify the successful completion of the porting.

Documentation requirements for porting numbers to Amazon Connect

The Letter of Authorization (LOA) is an industry standard document type used by carriers to authorize the transfer of a phone number from one carrier to another. In many cases, the LOA is specific to the country or region, carrier, or porting relationship between the losing and winning carriers.

If your number can be ported, the Amazon Connect team will provide you with the following:

- An LOA form appropriate for the situation.
- A link to a secure Amazon S3 storage so you can upload the LOA and any other required documents.

For more information, see [How to complete an LOA](#).

Additionally, regulations in some countries require a local business address and specific documentation to use a phone number. For country specific requirements, see [Region requirements for ordering and porting phone numbers in Amazon Connect](#). If this is required, we will ask for this information to be submitted with the completed LOA.

Common reasons why carriers reject an LOA

There are four common reasons that an LOA may be initially rejected by the losing carrier:

- Unsatisfactory business relationship

  This usually means that you have an unpaid balance or the carrier charges a port away fee. After you pay the bill or fee to your carrier, we will resubmit the port request.
- Name or address mismatch

The information you submitted on your Letter of Authorization (LOA) is different from what's on file with your carrier in their Customer Service Record (CSR). To fix this, contact your existing carrier to update your CSR information, obtain the correct CSR information, or both. Let us know when they update your information and we will resubmit the port request. Or, send us a new LOA with the correct information as provided by your existing carrier.

- Number cannot be ported

  We will work with all Amazon Connect carriers in a Region to support the porting of your numbers. In some cases, however, specific numbers may not be portable because of regulatory restrictions or carrier limitations. In these situations, consider claiming a new number from Amazon Connect.
- Missing information

  One or more fields have been left blank on the LOA. This may include a missing signature, phone number, address information, or other requested information. Review all LOAs before submitting them to ensure that you have filled out all requested data. After the LOA is updated with all the required information, we will resubmit the port request.

Verify flows before porting numbers to Amazon Connect

We recommend that you test your call flows before the mutually agreed date and time of porting. If you would like to test your call flows, we recommend that you claim a direct inward dial (DID) or toll-free phone number available within Amazon Connect and assign it to the call flow for testing.

When you are done testing, you can release the number from your instance so you will no longer be charged for it. For instructions, see Release a phone number from Amazon Connect back to inventory.

Until you release the number, you are charged the daily rate associated with claiming a phone number and the per minute rate for telephony minutes used. For more information see the standard pricing for Amazon Connect service usage and associated telephony rates.

Troubleshoot issues after porting phone numbers to Amazon Connect

After you have ported your numbers to Amazon Connect, use the topics in this section to troubleshoot issues, or to release numbers you no longer need after porting.

Contents

- Not receiving calls on the phone number ported to Amazon Connect
- Release numbers that you ported to Amazon Connect that you no longer need
- Revert phone numbers to your original carrier after porting to Amazon Connect
- Port phone numbers away from Amazon Connect

Not receiving calls on the phone number ported to Amazon Connect

After the scheduled porting window has completed, if you are not receiving phone calls on the ported phone number, update your support ticket. We will troubleshoot with our carrier to verify the porting status and identify the next steps to resolve issue.

Amazon Connect and our carriers make every effort to ensure number porting occurs with minimal downtime and without issues. In most cases, the losing carrier is responsible for initiating the number porting and releasing your number to the winning carrier.

In rare situations, a number routing issue can occur, resulting in calls not arriving to Amazon Connect from the carrier.

Release numbers that you ported to Amazon Connect that you no longer need

You do not have to keep phone numbers assigned to your Amazon Connect instance.

When a phone number is released from your Amazon Connect instance:

- You will no longer be charged for it.
- You cannot reclaim the phone number.
- Amazon Connect reserves the right to allow it to be claimed by another customer.

To release a phone number

1. Log in to Amazon Connect admin website with an Admin account or a user account that has **Phone numbers - Release** security profile permission.
2. On the navigation menu, choose **Channels**, **Phone numbers**. This option appears only if you have the **Phone numbers - View** permission in your security profile.
3. Choose the phone number you want to release, and then choose **Release**. This option appears only if you have the **Phone numbers - Release** permission in your security profile.

If the phone number is associated with a flow, that flow will be deactivated until another number is associated with it.

When customers call the phone number you have released, they will get a message that it is not a working phone number.

Revert phone numbers to your original carrier after porting to Amazon Connect

To complete the porting, the losing and gaining carriers both make configuration changes to pass the phone number ownership. After the porting is complete, the gaining carrier has sole control of the phone number.

To move the phone number again, you must complete a new LOA and any required documentation.

Port phone numbers away from Amazon Connect

1. Choose [Account and billing]() to go to the pre-populated form in the Support console. You must be signed in to your AWS account to access the form.
2. For **Service**, *Connect (Number Management)* should be selected.
3. For **Category**, *Phone Number Port Out* should be selected.
4. Select the required severity.
5. Choose **Next step: Additional information**
6. On the **Additional information** page:

    a. Enter the subject.

    b. Under **Description**:

        i. Let us know you're porting away.

        ii. The name of your Amazon Connect instance and the numbers you are porting away.

        iii. The name of your new carrier.
7. Choose **Next step: Solve now or contact us**.
8. On the **Solve now or contact us** page:
    - Choose the **Contact us** tab and select your **Preferred contact language** and your preferred contact method.
9. Choose **Submit**.
10. The Amazon Connect team will review your ticket and get back to you.

Here's what happens next:

1. Support contacts you, indicating that you should begin the process with the winning carrier.
2. The winning carrier will request that you provide them with following information:

   - Proof of ownership of the numbers you want to port away. Provide them with screenshots of the Amazon Connect instance with the phone numbers you want to port away, and screenshots of your AWS bill.
   - Usually the winning carrier will require a LOA (Letter of Authorization) that you need to complete. It's important that you provide the correct contact details from your AWS bill.
3. The winning carrier will send the request to Support.
4. Support will verify that the request from the winning carrier matches the information we have about who owns those numbers. If all details match **exactly**, we will approve the request.

   > **Important**
   >
   > Verifying the authenticity of the winning carrier's port-out request is critical for the security of your phone number. If the contact details are not correct (for example, there's a name mismatch), your port-out request may be rejected, causing delays and requiring you to resubmit your request.
5. The winning carrier will complete the port-out request on the date and time that you establish with them. Work with the winning carrier to complete the remainder of the port-out process to ensure a seamless transition.

Claim and manage your phone numbers in Amazon Connect

The topics in this section explain how to claim an Amazon Connect phone number, list phone numbers claimed to your instance, move a phone number across Amazon Connect instances, and release a phone number.

Contents

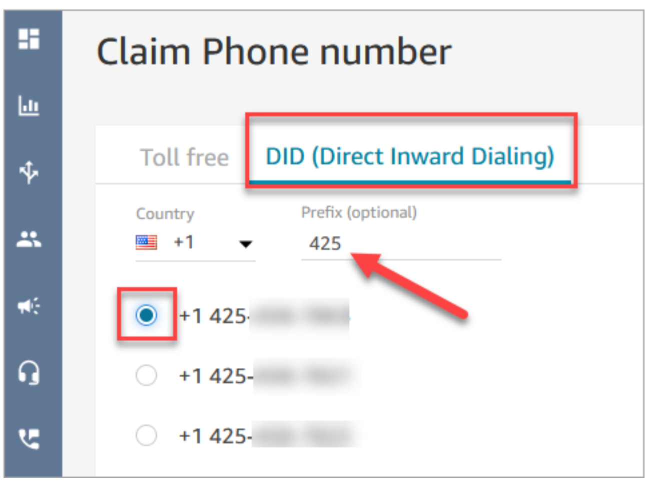
- Claim phone numbers for Amazon Connect in the Asia Pacific (Tokyo) Region
- Request numbers or international numbers for Amazon Connect
- Move an Amazon Connect phone number across instances
- Release a phone number from Amazon Connect back to inventory

Get a local toll-free or DID Amazon Connect phone number

To place or receive calls in your Amazon Connect instance, you need to claim a DID or toll-free phone number. If you did not claim a phone number when you created your Amazon Connect instance, follow these steps to claim one now.

Claim a number for your contact center

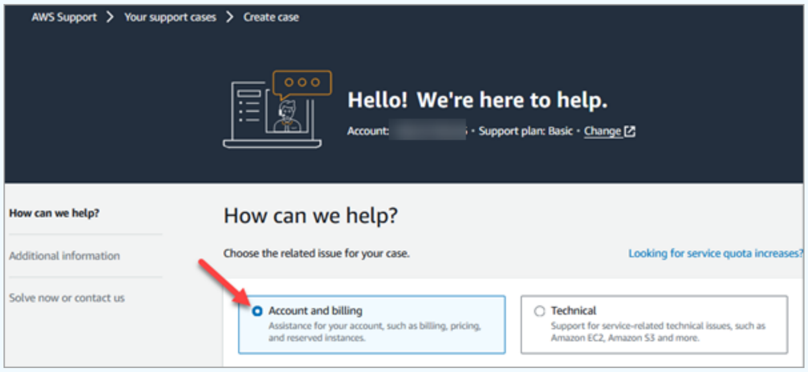
1. Log in to the Amazon Connect admin website with an Admin account, or an account assigned to a security profile that has **Phone numbers - Claim** permissions.
2. On the navigation menu, choose **Channels**, **Phone numbers**.
3. Choose **Claim a number**. You can choose a toll-free number or a Direct Inward Dialing (DID) number. If you're in the US, you can specify the area code you want for your number, and only available numbers with that area code will be displayed. When numbers are returned, choose one.



> **Note**
>
> Create a case by choosing the Account and billing option for these situations:
>
> - If you select a country or region, but no numbers display, you can request additional numbers for the country or region.

- If you want to request a specific area code or prefix that you don't see listed, we'll try to accommodate your request.

The following image shows the **Account and billing** option on the **Create a case** page of the **Support Center** console.



4. Enter a description for the number and, if required, attach it to a contact flow in **Flow / IVR**.
5. Choose **Save**.
6. Repeat this process until you have claimed all your required phone numbers.
7. After you claim your numbers, associate them with your flow(s). A flow defines the customer experience with your contact center from start to finish.

How many phone numbers you can claim

There is a service quota for how many phone numbers you can have in each instance. For the default service quota, see Amazon Connect service quotas. If you reach your quota, but want a different phone number, you can release one of your previously claimed numbers. You cannot claim the same phone number after releasing it.

If you need more phone numbers, you can request a service quota increase using the Amazon Connect service quota increase form.

Avoid being blocked from claiming or releasing too many numbers

If you plan to claim and release numbers frequently, contact us for a service quota exception. Otherwise, it's possible you will be blocked from claiming and releasing any more numbers until up to 180 days past the oldest number released has expired.

By default you can claim and release up to 200% of your maximum number of active phone numbers. If you claim and release phone numbers using the UI or API during a rolling 180 day cycle that exceeds 200% of your phone number service level quota, you will be blocked from claiming any more numbers until 180 days past the oldest number released has expired.

For example, if you already have 99 claimed numbers and a service level quota of 99 phone numbers, and in any 180 day period you release 99, claim 99, and then release 99, you will have exceeded the 200% limit. At that point you are blocked from claiming any more numbers until you open an AWS support ticket.

API instructions for claiming phone numbers

To claim a phone number programmatically:

1. Use the SearchAvailablePhoneNumbers API to search for available phone numbers that you can claim to your Amazon Connect instance.
2. Use ClaimPhoneNumber API to claim the phone number.

   Claiming a number by using the ClaimPhoneNumber API puts the number in one of the following three states: `CLAIMED`, `IN_PROGRESS`, `FAILED`.
3. Run the DescribePhoneNumber API to determine the status of your number claiming process.
   - `CLAIMED` means the previous ClaimPhoneNumber or UpdatePhoneNumber operation succeeded.
   - `IN_PROGRESS` means a ClaimPhoneNumber or UpdatePhoneNumber operation is still in progress and has not yet completed. You can call DescribePhoneNumber at a later time to verify if the previous operation has completed.
   - `FAILED` indicates that the previous ClaimPhoneNumber or UpdatePhoneNumber operation has failed. It will include a message indicating the failure reason. A common reason for a failure may be that the `TargetArn` value you are claiming or updating a phone number to has reached its limit of total claimed numbers. If you received a `FAILED` status from a `ClaimPhoneNumber` API call, you have one day to retry claiming the phone number before the number is released back to the inventory for other customers to claim.

> **Note**
>
> You will not be billed for the phone number during the 1-day period if number claiming fails.

"We couldn't claim your number"

Even if it's the first time you've claimed a phone number, it's possible to get this error message when you attempt to claim a number. All the issues that cause this error message require help from Support to resolve.

Contact Support and they will provide assistance. For instructions, see Get administrative support for Amazon Connect.

Request an SMS-enabled phone number through AWS End User Messaging SMS

> **Important**
>
> Some countries require phone numbers and sender IDs to be registered for use in the country. It can take up to 15 business days to process a registration request after it is submitted. We strongly recommend you begin this process early. For more information about registering, see Registrations.

Using AWS End User Messaging SMS, you can request new SMS-enabled phone numbers or reuse existing SMS-enabled phone numbers for use in Amazon Connect. You can request short codes, 10-digit long codes (10DLC), and toll-free numbers. These are also known as Origination Identities (OIDs).

For instructions about procuring a number for SMS messaging, see Requesting a phone number in the *AWS End User Messaging SMS User Guide*.

Best practices for requesting SMS numbers

- Each type of OID has a different registration process and the leasing costs vary. Review the pricing here: AWS End User Messaging SMS pricing.
- When deciding what type of phone number to request, we recommend considering your throughput needs. SMS messages are delivered in 140-byte sections known as message parts. Your throughput rate is the number of message parts that you can send each second.

  - **1–3 message parts per second**: Use a toll-free number. We recommend using a 10DLC number or short code if your throughput needs will exceed these limits as you expand your use cases. These number types provide plenty of room for growth, but also cost more and currently take longer to obtain than a toll-free number. For more information about requesting a toll-free number in Amazon Pinpoint, see [Requesting a phone number](#).
  - **10–75 message parts per second**: Use a 10DLC number. You can also use a short code, which would provide additional room for growth, but would also cost more. For more information, see [Requesting dedicated long codes for SMS messaging with Amazon Pinpoint SMS](#).
  - **100 message parts per second or more**: Use a short code. When you create your request in the AWS Support Center Console, specify the throughput rate that you want your short code to support.

    By default US short codes support 100 message parts per second, but the throughput rate can be increased beyond that rate for an additional monthly fee. For more information, see [Requesting short codes for SMS messaging with Amazon Pinpoint SMS](#).
- Request at least one of the above OIDs as a `TRANSACTIONAL` number from Amazon Pinpoint.
- Be sure to provide all of the information requested during the registration process. There are no exceptions to the questions being asked.

> **Important**
>
> Providing incomplete or inaccurate information will increase the registration time. Your registration will need to be edited and returned to be reviewed again.
> Registration for all types of OIDs in the US are managed by a third-party registrar. Amazon does not review applications.

- Toll-free phone number registration requires the least amount of time to procure.
- Review the [10DLC registration process](#) explained in the *AWS End User Messaging SMS User Guide*.

Claim for Amazon Connect a phone number you already own in another country

Let's say your business is located in Germany. You also have agents in Japan to serve customers who live there, and you need a Japanese phone number for that contact center. To claim a phone number that you already own in another country, use the following steps to create a support case.

To claim a number that you don't already own in another country or Region, see Request numbers or international numbers for Amazon Connect.

1. Go to Create case.
2. Choose **Service quota increase**.
3. In **Limit type** select **Amazon Connect**.
4. In **Use case description**, provide the address of your business that's located in the other country.
5. In **Contact options**, choose whether we should contact you by email or phone.
6. Choose **Submit**.

We'll contact you to help with your request.

List or export to a CSV the phone numbers claimed to your Amazon Connect instance

You can list the phone numbers claimed to your Amazon Connect instance by using the Amazon Connect admin website, or by using the ListPhoneNumbersV2 API.

To list phone numbers by using the Amazon Connect admin website

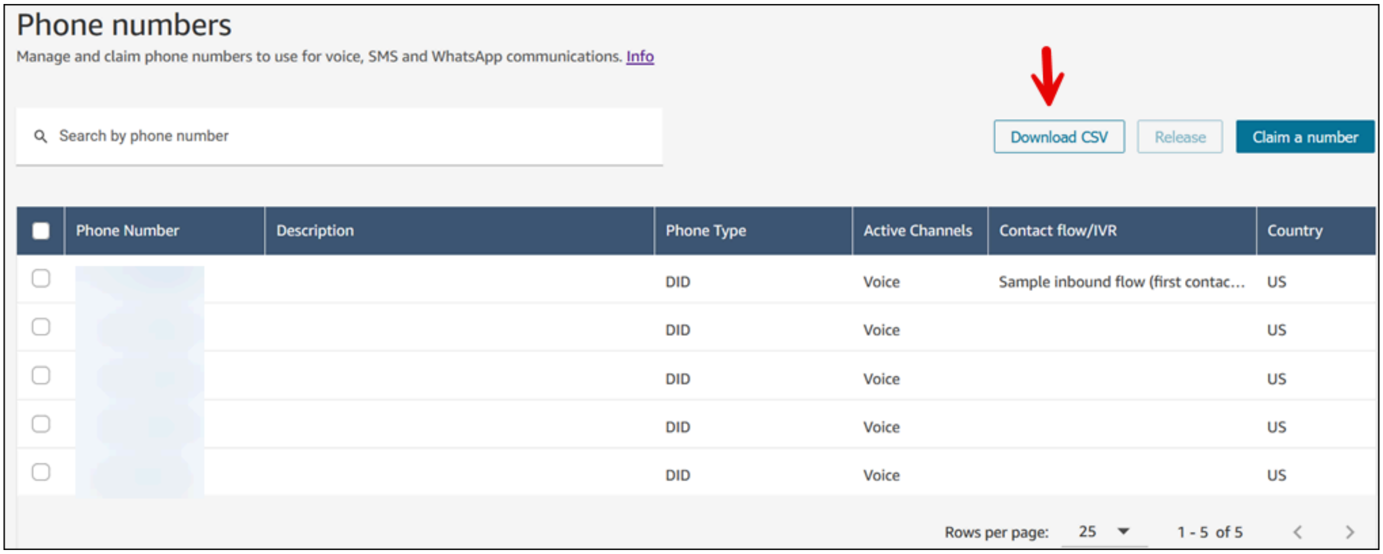
1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/.
2. On the navigation menu, choose **Channels**, **Phone numbers**.

   The list of phone numbers claimed to your Amazon Connect instance is displayed.

To download phone numbers to a CSV file

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/.
2. On the navigation menu, choose **Channels**, **Phone numbers**, **Download CSV**.

   - ALL of the phone numbers listed on that page are downloaded to the CSV file, regardless of which ones are selected.
   - It does not download all of the phone numbers claimed by your Amazon Connect instance.
   - To download numbers listed on a page 2 of results, you need to paginate to page 2 and then choose **Download CSV** again.



Claim phone numbers for Amazon Connect in the Asia Pacific (Tokyo) Region

To claim a phone number for an Amazon Connect instance you create in the Asia Pacific (Tokyo) Region, open an AWS support case and provide documentation that your business is located in Japan.

> **Important**
>
> You must provide three pieces of required documentation. For a list of acceptable identification, see Japan (JP), in the Region requirements for ordering and porting phone numbers in Amazon Connect topic.

You cannot claim numbers for personal use, only for business use.

Amazon Connect supports claiming the following phone numbers for instances created in the Asia Pacific (Tokyo) Region.

- **Direct Inward Dialing (DID) numbers**—DID numbers are also referred to as local numbers.
  - 050 prefix numbers.
  - 03 prefix for numbers in Tokyo. Amazon Connect does not offer phone numbers for other cities in Japan at this time.
- **Toll Free numbers**

- 0120 prefix numbers.
- 0800 prefix numbers.

> **Note**
>
> When you claim a toll free phone number for Amazon Connect, there is no corresponding DID number with a 03 prefix also assigned, as with other toll free numbers in Japan. If you need to use a DID number, you can claim one in Amazon Connect.

Request numbers or international numbers for Amazon Connect

> **Important**
>
> To purchase and own a phone number, country or region regulations often require:
>
> - A local office address.
> - Specific identification documents.
>
> For identification requirements by country, see Region requirements for ordering and porting phone numbers in Amazon Connect.
> In most countries it takes 2-6 weeks for us to fulfill your request. In some cases it can take up to 60 days. If you need a number by a certain date, let us know in your Support case.

> **Note**
>
> Amazon does not provide the following:
>
> - Premium rate or higher cost services
> - Vanity numbers such as 1-888-555-0000 or an exact number
>
> If you want these services we recommend you contract with specialist providers. For premium rate services you can route calls into Amazon Connect DIDs following local

country regulations. For vanity numbers, after you've purchased them you can move these numbers across to Amazon Connect by porting them.

To request international phone numbers that require documentation, or numbers not available within a specific region, create an Support case. In the support case, you must specify exactly how many numbers you want for each country.

Submit an Amazon Connect support ticket to verify if your phone number can be ported to Amazon Connect.

1. Choose Account and billing to access a pre-populated form in the Support console. You must be signed in to your AWS account to access the form.
2. For **Service**, **Connect (Number Management)** should be selected.
3. For **Category**, **Special Phone Number Request** should be selected.
4. Select the required severity.
5. Choose **Next step: Additional information**
6. On the **Additional information** page:
    a. Enter the subject.
    b. Under **Description**, include as much information as possible about your request, If you don't know all of these details, you can leave information out.
7. Choose **Next step: Solve now or contact us**.
8. On the **Solve now or contact us** page:
    - Choose the **Contact us** tab and select your **Preferred contact language** and your preferred contact method.
9. Choose **Submit**.
10. The Amazon Connect team will review your ticket and get back to you.

After your request is approved, the exact number of requested phone numbers appear in your Amazon Connect console for you to claim. You won't have access to all available numbers in that country.

Move an Amazon Connect phone number across instances

You can move your claimed phone number from one instance or traffic distribution group to another instance or traffic distribution group in the same AWS Region.

Moving a number by using the UpdatePhoneNumber API puts the number in one of the following three states. You can run the DescribePhoneNumber API to determine the status of your number moving process.

- `IN_PROGRESS` means a UpdatePhoneNumber operation is still in progress and has not yet completed. You can call DescribePhoneNumber to verify if the previous operation has completed.
- `CLAIMED` means the previous UpdatePhoneNumber operation succeeded and the phone number is not available to be claimed by other customers.
- `FAILED` indicates that the previous UpdatePhoneNumber operation has failed. It also includes a message that indicates the reason for the failure.

Release a phone number from Amazon Connect back to inventory

If you want a different phone number, or have extra numbers that you aren't using, you can release them back to inventory. You can do this using the Amazon Connect console, or programmatically by using the ReleasePhoneNumber API.

When a phone number is released from your Amazon Connect instance:

- You will no longer be charged for it.
- You cannot reclaim the phone number.
- Amazon Connect reserves the right to allow it to be claimed by another customer.

> **Tip**
>
> If you want to close your Amazon Connect account, do these steps for all of your phone numbers. This will ensure you aren't billed if people erroneously call numbers that you've claimed, and initiate your flows. You may also want to delete your instances.

To release a phone number

1. Log in to Amazon Connect admin website with an Admin account or a user account that has **Phone numbers - Release** security profile permission.
2. On the navigation menu, choose **Channels**, **Phone numbers**. This option appears only if you have the **Phone numbers - View** permission in your security profile.
3. Choose the phone number you want to release, and then choose **Release**. This option appears only if you have the **Phone numbers - Release** permission in your security profile.

If the phone number is associated with a flow, that flow will be deactivated until another number is associated with it.

When customers call the phone number you have released, they will get a message that it is not a working phone number.

To use the ReleasePhoneNumber API

- Releasing a number by using the ReleasePhoneNumber API puts the number in a cool down period for up to 180 days. The phone number cannot be searched for or claimed until after the cool down period ends.

  > **Note**
  >
  > You will not be billed for the phone number during the 180-day cool down period.

Avoid being blocked from claiming or releasing too many numbers

If you plan to claim and release numbers frequently, contact us for a service quota exception. Otherwise, it's possible you will be blocked from claiming and releasing any more numbers until up to 180 days past the oldest number released has expired.

By default you can claim and release up to 200% of your maximum number of active phone numbers. If you claim and release phone numbers using the UI or API during a rolling 180 day cycle that exceeds 200% of your phone number service level quota, you will be blocked from claiming any more numbers until 180 days past the oldest number released has expired.

For example, if you already have 99 claimed numbers and a service level quota of 99 phone numbers, and in any 180 day period you release 99, claim 99, and then release 99, you will have exceeded the 200% limit. At that point you are blocked from claiming any more numbers until you open an AWS support ticket.

Use caller identification to personalize customer interaction

You can provide a personalized experience for your customers by using metadata attributes that provide information related to call origination. For example, you can look up a customer's contact ID, and welcome them with a personalized greeting.

> **Important**
>
> Features that are provided by Amazon Connect or third parties may rely on call data for identifying inbound callers for personalizing customer interaction or detecting fraud and may be subject to additional terms and conditions. Network-related call data that is not displayed to call recipients may not be used for any purpose other than fraud detection.

Use telephony call metadata attributes

The following table lists the available telephony call metadata attributes. For information about using attributes, see [Use Amazon Connect contact attributes](#).

Attribute	Description	Type	JSONPath Reference
P-Charge-Info	The party responsible for the charges associated with the call.	System	$.Media.Sip.Headers.P-Charge-Info
From	The identity of the end user associated with the request.	System	$.Media.Sip.Headers.From
To	Information about the called party or the recipient of the request.	System	$.Media.Sip.Headers.To

Attribute	Description	Type	JSONPath Reference
ISUP-OLI	Originating Line Indicator (OLI). Shows the type of line placing call (for example, PSTN, 800 service call, wireless/cellular PCS, payphone).	System	$.Media.Sip.Header s.ISUP-OLI
JIP	Jurisdiction Indicatio n Parameter (JIP). Indicates geographic location of caller/sw itch. Example value: 212555	System	$.Media.Sip.Header s.JIP
Hop-Counter	Hop Counter. Example value: 0	System	$.Media.Sip.Header s.Hop-Counter
Originating-Switch	Originating Switch. Example value: 710	System	$.Media.Sip.Header s.Originating-Switch
Originating-Trunk	Originating Trunk. Example value: 0235	System	$.Media.Sip.Header s.Originating-Trunk

Attribute	Description	Type	JSONPath Reference
Call-Forwarding-Indicator	Call Forwarding Indicators (for example, Diversion header). Indicates domestic or international origin of call. Example value: sip:+15555555555@public-vip.us2.telephony-provider.com;reason=unconditional	System	$.Media.Sip.Headers.Call-Forwarding-Indicator
Calling-Party-Address	Calling Party Address (number). NPAC dip shows true line type and native geographic switch. Example value: 15555555555;noa=4	System	$.Media.Sip.Headers.Calling-Party-Address
Called-Party-Address	Called Party Address (number). Example value: 15555555555;noa=4	System	$.Media.Sip.Headers.Called-Party-Address
SIPREC metadata	SIPREC metadata XML received by Amazon Contact Lens connector	System	$.Media.Sip.SiprecMetadata

Troubleshoot issues

The availability of telephony metadata is not consistent across all telephony providers and may not be available in all cases.

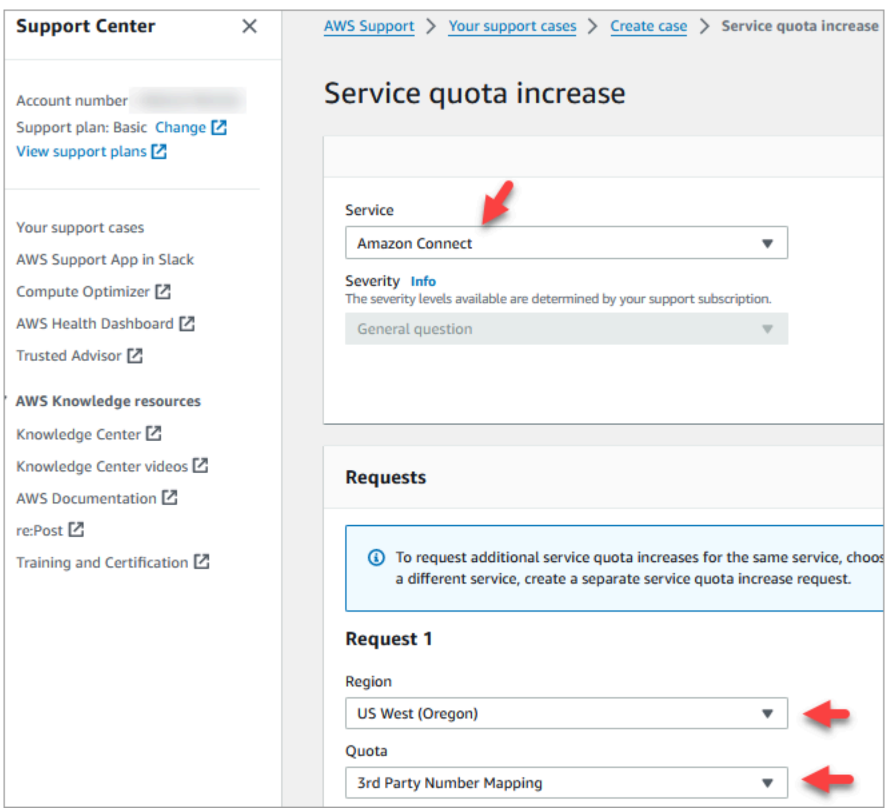
Before opening an Support case:

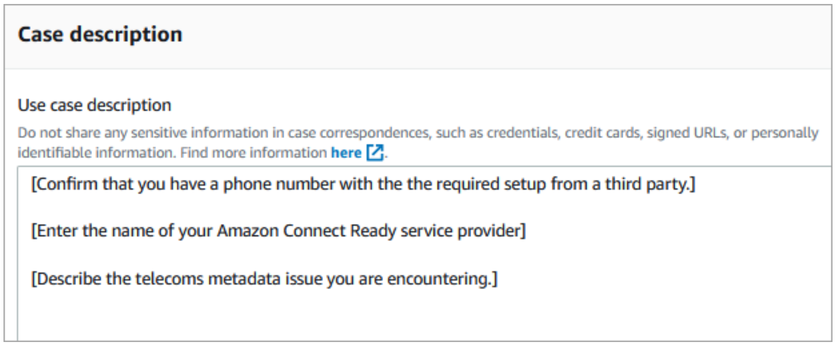
- If you are missing data on all calls required by a third-party Amazon Connect Ready service, check that you followed the service configuration guide provided by the third party.

  If you need to open a Support case, provide the following information:

  - **Service** = **Amazon Connect**
  - **Quota** = **3rd-Party Number Mapping**
  - **Case description** box:
    - State that you have confirmed you have a phone number with the required setup.
    - Enter the name of your Amazon Connect Ready service provider
    - Describe the telecoms metadata issue you are encountering.

  The following images show an example case and where you enter this information.





- If you're getting partial data on a percent of calls as part of normal service calls: Note that data is not available on all calls.

  Certain fields, such as ISUP-OLI, are only present based on specific routes through networks. It's not possible to guarantee data will be available for all calls.

Map third-party numbers to your Amazon Connect account

In some countries you may need to obtain a third-party phone number that is hosted directly by a carrier in that country instead of being hosted by Amazon Connect. The carrier is interconnected with Amazon Connect and provides billing services. In these situations you need to open a ticket to Support to map your AWS account ID and Amazon Connect instance to the phone number.

To map third-party numbers to your account

Submit an Amazon Connect support ticket to map third-party numbers. Following are instructions if you don't have an Support account.

1. Go to [Support Center]() and choose **Create a case**.
2. Choose **Account and billing**.
3. In the **Service** box, use the dropdown list to choose **Connect (Number Management)**.
4. In the **Category** box, choose **3rd Party Mapping**.
5. In the **Severity** box, select the severity for your situation.
6. Choose **Next step: Additional information**.
7. On the **Additional information** page:

   1. Enter the subject.
   2. Under **Description**, include as much information as possible about your request, such as your instance ARN, phones numbers, flows, and more.

8. Under **Help us resolve your case faster**, provide all of the required information.
9. Choose **Next step: Solve now or contact us**.
10. On the **Solve now or contact us** page:

    1. Choose the **Contact us** tab and select your **Preferred contact language** and your preferred contact method.
11. Choose **Submit**.
12. The Amazon Connect team will review your ticket and get back to you.

Amazon Connect support of the inbound only UIFN service

A Universal International Freephone number (UIFN) is a unique **inbound only** freephone number that can be used throughout the world. It provides toll-free calling from international locations to your contact center.

Amazon Connect supports UIFN in more than 60 countries that are registered with the International Telecommunications Union, an organization that supports the administration of the UIFN service.

> **Note**
>
> Amazon Connect allows you to enable UIFNs in as many countries as you need, however, it requires a minimum of 5 countries.

A UIFN is composed of a 3-digit country code for a global service application, such as **800**, and an 8-digit Global Subscriber Number (GSN). This results in an 11-digit fixed format.

For example, your UIFN could be +800 12345678, where 12345678 is your number.

Due to the special nature of UIFN, attempting to call a UIFN from Amazon Connect in a "loopback mode" is not supported. UIFNs are designed to be called from end phone configurations in the country's public telephone network.

How to get a UIFN

To request a UIFN within a specific AWS Region, create an Support case. In the support case, provide the following information.

- Choose the countries you want to enable from the list of available countries.
- The Amazon Connect instance(s) associated with the new UIFN numbers. Amazon Connect can support routing numbers to multiple Regions, such as Australia to the Asia Pacific (Sydney) Region, United States to a US Region, or if desired to a single global instance.
- The required ID verification for your country. Most countries subscribe to standard ID verification requirements for ordering UIFN numbers. However, we recommend checking Region requirements for ordering and porting phone numbers in Amazon Connect for your country to be sure.

  For number portability, after you open a case, Amazon will provide you with *Service Provider Change Authorization and Designation of Agency* document.

Amazon Connect can route UIFNs to multiple AWS Regions. For example, if a UIFN is enabled for Australia, it can be routed to your Amazon Connect instance that is located in the Asia Pacific (Sydney) Region. If a UIFN is enabled for **more** countries, each country can be routed to your Amazon Connect instance, which may be in any supported AWS Region.

The following image shows the body of a sample UIFN request submitted to Support. This request is for two UIFNs. The first is for a UIFN that is enabled for Argentina, Brazil, and Colombia, and connected to an Amazon Connect instance in the US West (Oregon) Region. The second request is for a UIFN that is enabled for Japan, Australia, and New Zealand and connected to an Amazon Connect instance located in the Asia Pacific (Singapore) Region.

New UIFN number request

arn:aws:connect:us-west-2:*your_AWS_accountID*:instance/*your_instance_ARN*
Argentina
Brazil
Colombia

arn:aws:connect:ap-southeast-1:*your_AWS_accountID*:instance/*your_instance_ARN*
Japan
Australia
New Zealand

Important

UIFN is an inbound-only service. Before opening a ticket to request a UIFN:

1. Ensure you understand that this number cannot be used for outbound.

2. Check the National reachability of the country in the following section.

Full National reachability means the UIFN reaches all local (in-country) networks. UIFNs in some countries have limited reachability and will only work with specific carriers/networks where you need to use different codes to dial the number (for example, Japan).

Countries that support UIFNs

Country	How to dial a UIFN and Reachability	How many days it takes a UIFN to be set up
Argentina	00-800-XXXX-XXXX National reachability: all fixed networks	10-25
Australia	0011-800-XXXX-XXXX National reachability: Optus, Telstra, Vodafone mobile	10-30
Austria	00-800-XXXX-XXXX National reachability: full	10-15
Belgium	00-800-XXXX-XXXX National reachability: full	10-15
Brazil	0021-800-XXXX-XXXX National reachability: full Activation of international direct dialing service is required for calling parties for both fixed and mobile lines.	20-30

Country	How to dial a UIFN and Reachability	How many days it takes a UIFN to be set up
	The subscriber must have enabled the use of Embratel/ Claro's international selection code (0021).	
Bulgaria	00-800-XXXX-XXXX National reachability: full	10-20
Canada	011-800-XXXX-XXXX National reachability: full Calling from payphones is not supported.	20-40
China	00-800-XXXX-XXXX National reachability: • China telecom fixed and mobile networks • China Unicom fixed network	20-40

Country	How to dial a UIFN and Reachability	How many days it takes a UIFN to be set up
Colombia	Dialing format: • TIGO landline: 005-800 - XXXX-XXXX • TIGO: 00414-800-XXXX-XXXX • CLARO: 00444-800-XXXX-XXXX • MOVISTAR: 009-800-XXXX-XXXX National reachability: full	30-60
Costa Rica	00-800-XXXX-XXXX National reachability: full	15-30
Croatia	00-800-XXXX-XXXX National reachability: all fixed; T-Mobile network	20-30
Czech Republic	00-800-XXXX-XXXX National reachability: full	20-30
Denmark	00-800-XXXX-XXXX National reachability: full	10-20
Estonia	00-800-XXXX-XXXX National reachability: full	15-25

Country	How to dial a UIFN and Reachability	How many days it takes a UIFN to be set up
France	00-800-XXXX-XXXX National reachability: full, including Monaco	10-15
French Guiana	00-800-XXXX-XXXX National reachability: full	30-60
Germany	00-800-XXXX-XXXX National reachability: full	10-15
Greece	00-800-XXXX-XXXX National reachability: all fixed; Cosmotel mobile network	10-15
Guadeloupe	00-800-XXXX-XXXX National reachability: full	30-60
Hong Kong	006-800-XXXX-XXXX National reachability: full CLI not guaranteed.	20-40

Country	How to dial a UIFN and Reachability	How many days it takes a UIFN to be set up
Hungary	00-800-XXXX-XXXX National reachability: full Activation of international direct dialing service is required for calling parties for both fixed and mobile lines. Airtime charges may apply when calling from mobiles.	10-15
Iceland	00-800-XXXX-XXXX National reachability: all fixed; Iceland Telecom, IMC, Vodafone mobile networks.	10-20

Region requirements for ordering and porting phone numbers in Amazon Connect

Country or region regulations often require a local office address and specific identification documents to purchase and own a phone number. The address that you provide can be the business or personal address where the phone numbers are used.

For a list of the telephony capabilities that Amazon Connect provides, see the Amazon Connect Telecoms Country Coverage Guide.

Following is a list of ID Requirements by country or region. When you request an international number, we'll work with you to submit your documents.

> **Important**
>
> - Addresses that can be claimed without presence, such as PO Box addresses, are not valid in any country.
> - After your numbers are ordered or ported, the exact number of requested phone numbers appear on the **Manage Phone numbers** page in the Amazon Connect admin website for you to manage. You won't have access to all available numbers in that country.

Anguilla (AI)

For ordering phone numbers

Supported Regions	Type of Number	Are there ID requirements?	Acceptable Identification
US East (N. Virginia) US West (Oregon)	Local telephone numbers:	Yes	An order form is required. Use the form that is provided to you when you make the request. Provide the following information:

Set up your customer's chat experience in Amazon Connect

You can provide a chat experience to your customers by using one of the following methods:

- Add a chat user interface to your website hosted by Amazon Connect.
- Customize chat with the Amazon Connect open source example.
- Customize your solution using Amazon Connect APIs. We recommend starting with the Amazon Connect ChatJS open source library when customizing your own chat experiences. For more information, see the Amazon Connect ChatJS repo on Github.

More resources to customize the chat experience

- Interactive messages provide customers with a prompt and pre-configured display options that they can select from. These messages are powered by Amazon Lex and configured through Amazon Lex using a Lambda. For instructions about how to add interactive messages through Amazon Lex, see this blog: Set up interactive messages for your Amazon Connect chatbot.

  Amazon Connect supports the following templates: a list picker and a time picker. For more information, see Add Amazon Lex interactive messages for customers in chat.
- Enable Apple Messages for Business with Amazon Connect

- Amazon Connect Service API Documentation, especially the StartChatContact API.
- Amazon Connect Participant Service API.
- Amazon Connect Chat SDK and Sample Implementations
- Amazon Connect Streams. Use to integrate your existing apps with Amazon Connect. You can embed the Contact Control Panel (CCP) components into your app.

The chat/SMS channel in Amazon Connect

> **Important**
>
> **Trying to contact Amazon for support?** See Amazon Customer Service (Amazon orders and deliveries) or AWS Support (Amazon Web Services).

Amazon Connect lets you build chat messaging features—mobile chat, web chat, SMS, and third-party messaging services— into your website and mobile apps. It enables your customers to start chatting with contact center agents from any of your business applications, web or mobile.

Interactions are asynchronous, enabling your customers to start a chat with an agent or Amazon Lex bot, step away from it, and then resume the conversation again. They can even switch devices and continue the chat.

Contents

Multiple channels, one experience

Agents have a single user interface to help customers using voice, chat, and tasks. This reduces the number of tools that agents have to learn and the number of screens they have to interact with.

Chat activities integrate into your existing contact center flows and the automation that you built for voice. You build your flows once and reuse them across multiple channels.

Metrics collection and the dashboards you built automatically benefit from the unified metrics across multiple channels.

Getting started

To add chat messaging capabilities to your Amazon Connect contact center and allow your agents to engage in chats, perform the following steps:

- Chat is enabled at the instance level when an Amazon S3 bucket is created for storing chat transcripts.
- Add chat to your agent's routing profile.
- Optionally, you can set up chat subtypes such as SMS messaging. You procure an SMS-enabled phone number by using AWS End User Messaging SMS, import it into Amazon Connect, and then assign it to your flows. For more information, see:
  - Request an SMS-enabled phone number through AWS End User Messaging SMS
  - Set up SMS messaging in Amazon Connect

Agents can then begin accepting chats through the Contact Control Panel.

You can see real-time and historical metrics for the chat messaging channel (for example, arrival time, handle time) as part of their overall Chat channel metrics in the same reporting experience used for calls/chats/tasks in order to assess agent performance and productivity.

Amazon Connect provides several resources to help you add chat to your website. For more information, see Set up your customer's chat experience in Amazon Connect.

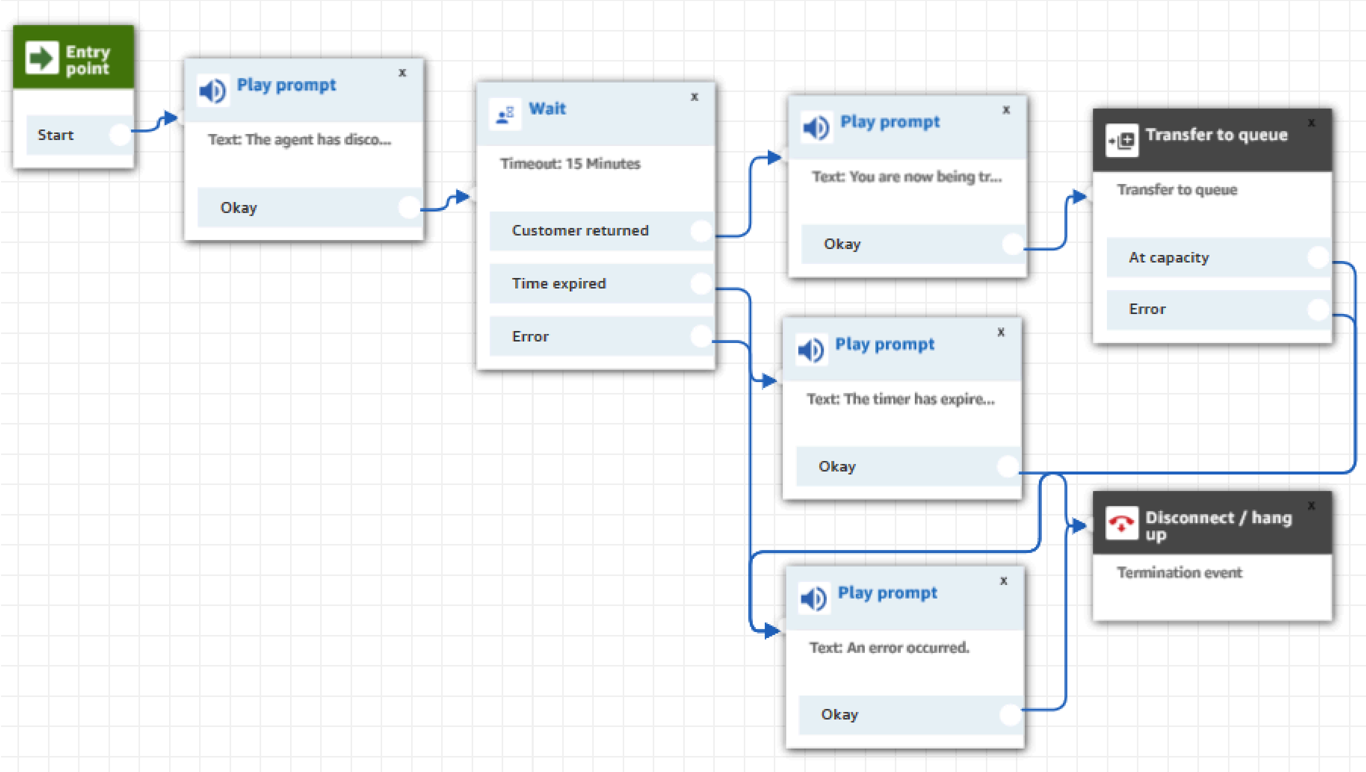
Example chat scenario

A customer and agent are chatting. The customer stops responding to the agent. The agent asks "Are you there?" and doesn't get a reply. The agent leaves the chat. Now the chat is no longer associated with an agent. Your flow determines what happens next.

In this scenario, the customer eventually sends another message ("Hey, I'm back") and the chat resumes. Depending on the logic that you define in the flow, the chat can be assigned to the original agent, or a different agent or queue.

Here's how you build this scenario:

1. Create a disconnect flow. The following image shows the Sample disconnect flow in Amazon Connect in the flow designer. This flow includes the following connected blocks: **Play prompt**, **Wait** which branches to three **Play prompts** (for **Customer returned**, **Time expired**, and **Error**), then **Transfer to queue** and **Disconnect**.



2. In the disconnect flow, add a Wait block. The Wait block has two branches:

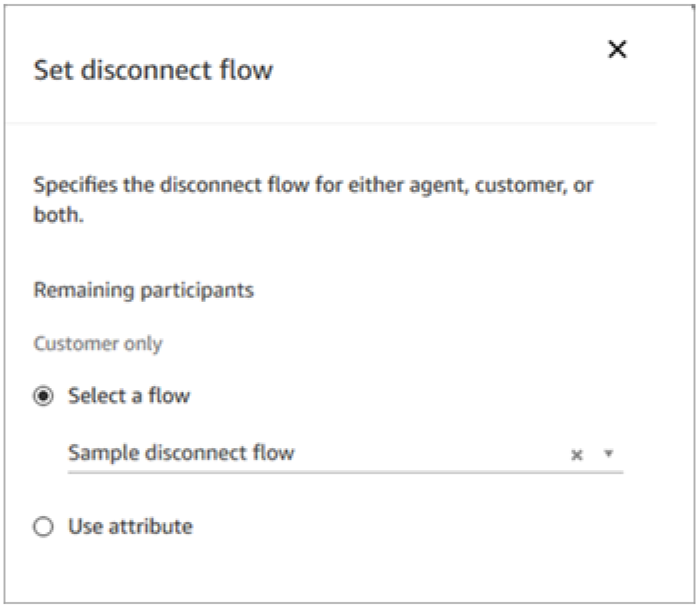
   - **Timeout**: Run this branch if the customer hasn't sent a message after a specified amount of time. The total duration of the chat, including multiple **Wait** blocks, cannot exceed 25 hours.

     For example, for this branch you might just want to run a **Disconnect** block and end the chat.

   - **Customer return**: Run this branch when the customer returns and sends a message. With this branch, you can route the customer to the previous agent, previous queue, or set a new working queue or agent.

3. In your inbound flow, add the Set Disconnect Flow block. Use it to specify that when the agent or Amazon Lex bot has disconnected from the chat and only the customer remains, the set disconnect flow should run.

In the following block, for example, we specified that the **Sample disconnect flow** should run.



For an example that uses the **Set disconnect flow** block, see the Sample inbound flow.

When do chats end?

By default, the duration for a chat conversation, including the time spent waiting when the customer isn't active, can't exceed 25 hours. However, you can change this default duration and instead configure a custom chat duration. You can configure a chat to last from a minimum of 1 hour (60 minutes) to up to 7 days (10,080 minutes). To configure a custom chat duration, call the StartChatContact API and add the `ChatDurationInMinutes` parameter.

During an ongoing chat session, there's no limit to the number of times a customer can leave and rejoin an existing ongoing chat session. To accomplish this, use the Wait block. For example, you might wait 12 hours for the customer to resume the chat before ending the chat session. If the customer tries to resume the chat after 12 hours, in the flow you can have an Amazon Lex bot ask if they're contacting you about the same issue or a different one.

By specifying a wait time that's significantly shorter than the chat duration, you help ensure that customers have a good experience. For instance, for a 25-hour duration chat, it's possible for the customer to resume a chat after 24 hours and 58 minutes, and then be cut off after two minutes because the conversation ends at the 25-hour limit.

> **Tip**
>
> If you're using Amazon Lex with chat, note that the default session timeout for an Amazon Lex session is 5 minutes. The total duration for a session can't exceed 24 hours. To change the session timeout, see Setting the Session Timeout in the *Amazon Lex Developer Guide*.

Pricing

Chat is charged on a per use basis. There are no required up-front payments, long-term commitments, or minimum monthly fees. You pay per chat message, independently of the number of agents or customers using it. Regional pricing may vary. For more information, see Amazon Connect pricing.

More information

For more information about chat, see the following topics:

- Test voice, chat, and task experiences in Amazon Connect
- How routing works with multiple channels
- Create a routing profile in Amazon Connect to link queues to agents
- Amazon Connect Chat SDK and Sample Implementations

Add a chat user interface to your website hosted by Amazon Connect

To support your customers through chat, you can add a communications widget to your website that is hosted by Amazon Connect. You can configure the communications widget in the Amazon Connect admin website. You can customize the font and colors, and secure the widget so that it can be launched only from your website. When finished, you will have a short code snippet that you add to your website.

Because Amazon Connect hosts the widget, it ensures that the latest version is always live on your website.

> **Tip**
>
> Use of the communications widget is subject to default service quotas, such as the number of required characters for each message. Before launching your communications widget

into production, make sure that your service quotas are set for your organization's needs. For more information, see Amazon Connect service quotas.

Contents

Supported widget snippet fields in Amazon Connect that are customizable

The following table lists the communications widget snippet fields that you can customize. Example code after the table shows how to use the snippet fields.

Snippet field	Type	Description	Additional documentation
snippetId	String	Mandatory, auto-generated	n/a
styles	String	Mandatory, auto-generated	n/a
supported MessagingContentTypes	Array	Mandatory, auto-generated	n/a
customLaunchBehavior	Object	Customize how your website renders and launches the hosted widget icon	Customize widget launch behavior and button icon for your website hosted in Amazon Connect, later in this topic
authenticate	Function	Callback function to enable JWT security on your website	Step 2: Specify the website domains where you expect to display the communications widget, earlier in this section.
customerDisplayName	Function	Pass the customer display name when initializing a contact	Pass the customer display name when an Amazon Connect chat starts, later in this section.
customStyles	Object	Override the default CSS styles	Pass custom properties to override the defaults in the communications

Snippet field	Type	Description	Additional documentation
			widget in Amazon Connect, later in this section.
`chatDurationInMinutes`	Number	The total duration of the newly started chat session	Default: 1500 - Min 60, Max: 10080
`enableLogs`	Boolean	Enable the debugging logs	Default: false
`language`	String	Connect can do translations for supported ISO-639 format language codes. For more information, see https://en.wikipedia.org/wiki/List_of_ISO_639-1_codes.	Default: en_US. Supported: 'de_DE', 'en_US', 'es_ES', 'fr_FR', 'id_ID', 'it_IT', 'ja_JP', 'ko_KR', 'pt_BR', 'zh_CN'
`nonce`	String	Handshake value between iframe and customer website csp policy. Example: customer csp allows 1234 nonce value, iframe which pulls in another script must have the same 1234 nonce value so that browser knows it is a trusted script by iframe parent site.	Default: undefined

Snippet field	Type	Description	Additional documentation
`customizationObject`	Object	Customize the widget layout and transcript	For more information, see Additional customizations for your Amazon Connect chat widget, later in this section.
`contactAttributes`	Object	Pass attributes to the contact flow directly from snippet code, without any JWT setup	For more information, see Pass contact attributes when a chat initializes.
`customDisplayNames`	Object	Override the System or Bot display name and logo configurations set in the Amazon Connect admin website.	For more information, see How to pass override system and bot display names and logos for the communications widget.
`contactMetadataHandler`	Function	Callback function to access contactId. For example, add an event listener to handle scenarios like calling the StopContact function with the contactId when the browser tab is closed or maintaining chat persistence with a previous contactId.	For more information, see Persistent Chat Demo using `contactMetadataHandler`.

Snippet field	Type	Description	Additional documentation
registerCallback	Object	This allows to execute callbacks for the exposed lifecycle events.	Exposed events are 'PARTICIPANT_IDLE' , 'CHAT_ENDED' , 'PARTICIPANT_RETURNED' , 'PARTICIPANT_JOINED' , 'PARTICIPANT_LEFT' , 'CONNECTION_ESTABLISHED' ,'CONNECTION_LOST' , and 'AUTHENTICATION_INITIATED' . AUTHENTICATION_INITIATED callback is executed when the contact reaches the [Authenticate Customer](#) flow block.

Snippet field	Type	Description	Additional documentation
`initialMessage`	String	Message to be sent to the newly created chat. Length Constraints: Minimum of 1, Maximum of 1024.	To invoke the Lex bot configured in the contact flow using an initial message, modify the Get customer input flow block by selecting the **Initialize bot with message** option. For more information, see How to configure Get customer input flow block.
`authenticationParameters`	Object	This enables the Authenticate Customer flow block	For more information, see Enable customer authentication.

The following example shows how to add snippet fields to the HTML script that adds the chat widget to your web site.

```
(function(w, d, x, id){ /* ... */ })(window, document, 'amazon_connect', 'widgetId');
  amazon_connect('snippetId', 'snippetId');
  amazon_connect('styles', /* ... */);
  amazon_connect('registerCallback', {
   'event_Name_1' : callback(function),
   'event_Name_2' : callback(function),
    ...
    });
  amazon_connect('initialMessage', 'Your initial message string');
  // ...
  amazon_connect('snippetFieldHere', /* ... */);
<script/>
```

Supported browsers

The pre-built communications widget supports the following browser versions and higher:

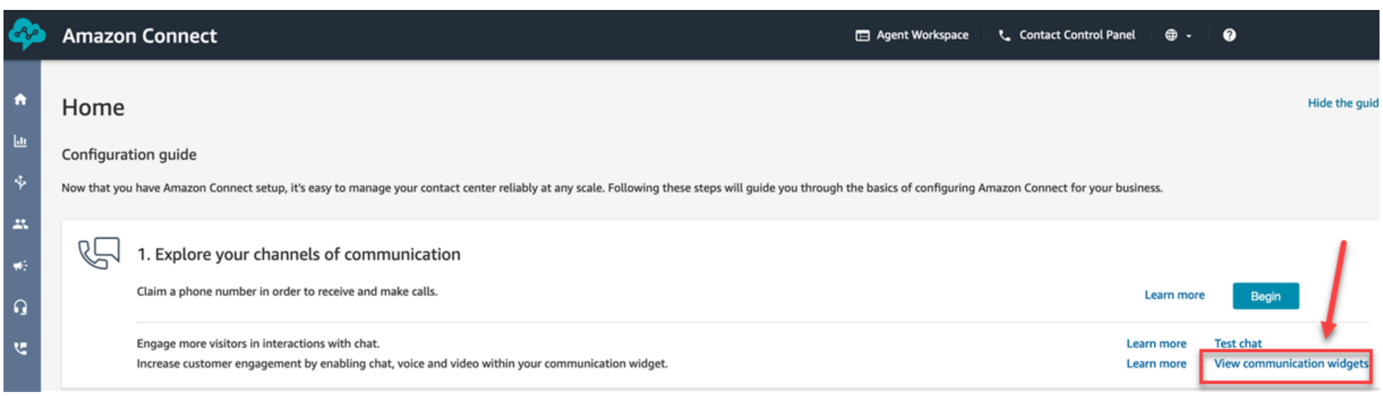
- Google Chrome 85.0
- Safari 13.1
- Microsoft Edge version 85
- Mozilla Firefox 81.0

The communications widget supports browser notifications for desktop devices. For more information, see Send browser notifications to customers when chat messages arrive.

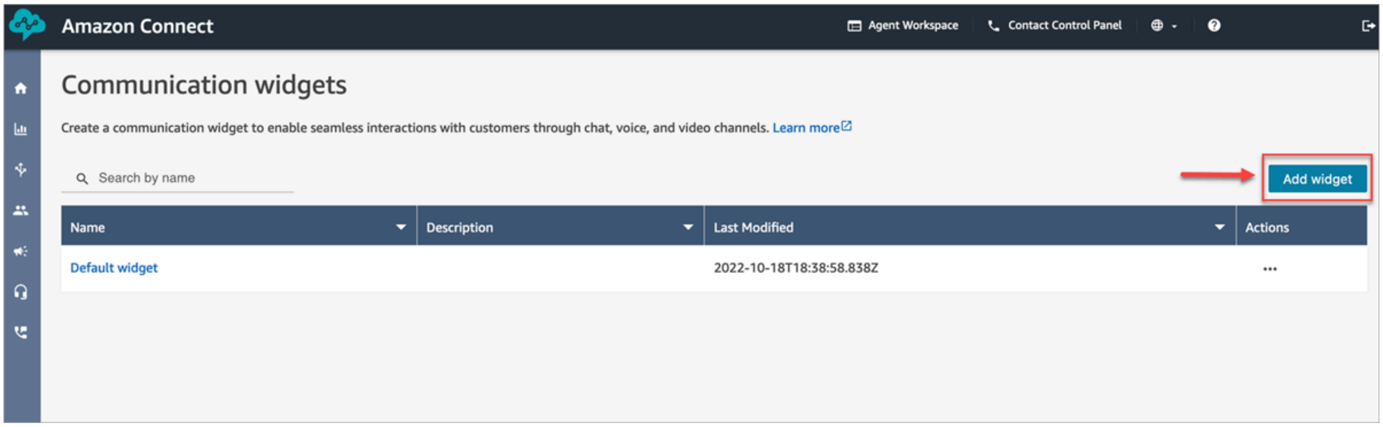
Step 1: Customize your communications widget

In this step, you customize the experience of the communications widget for your customers.

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Choose **Customize communications widget**.



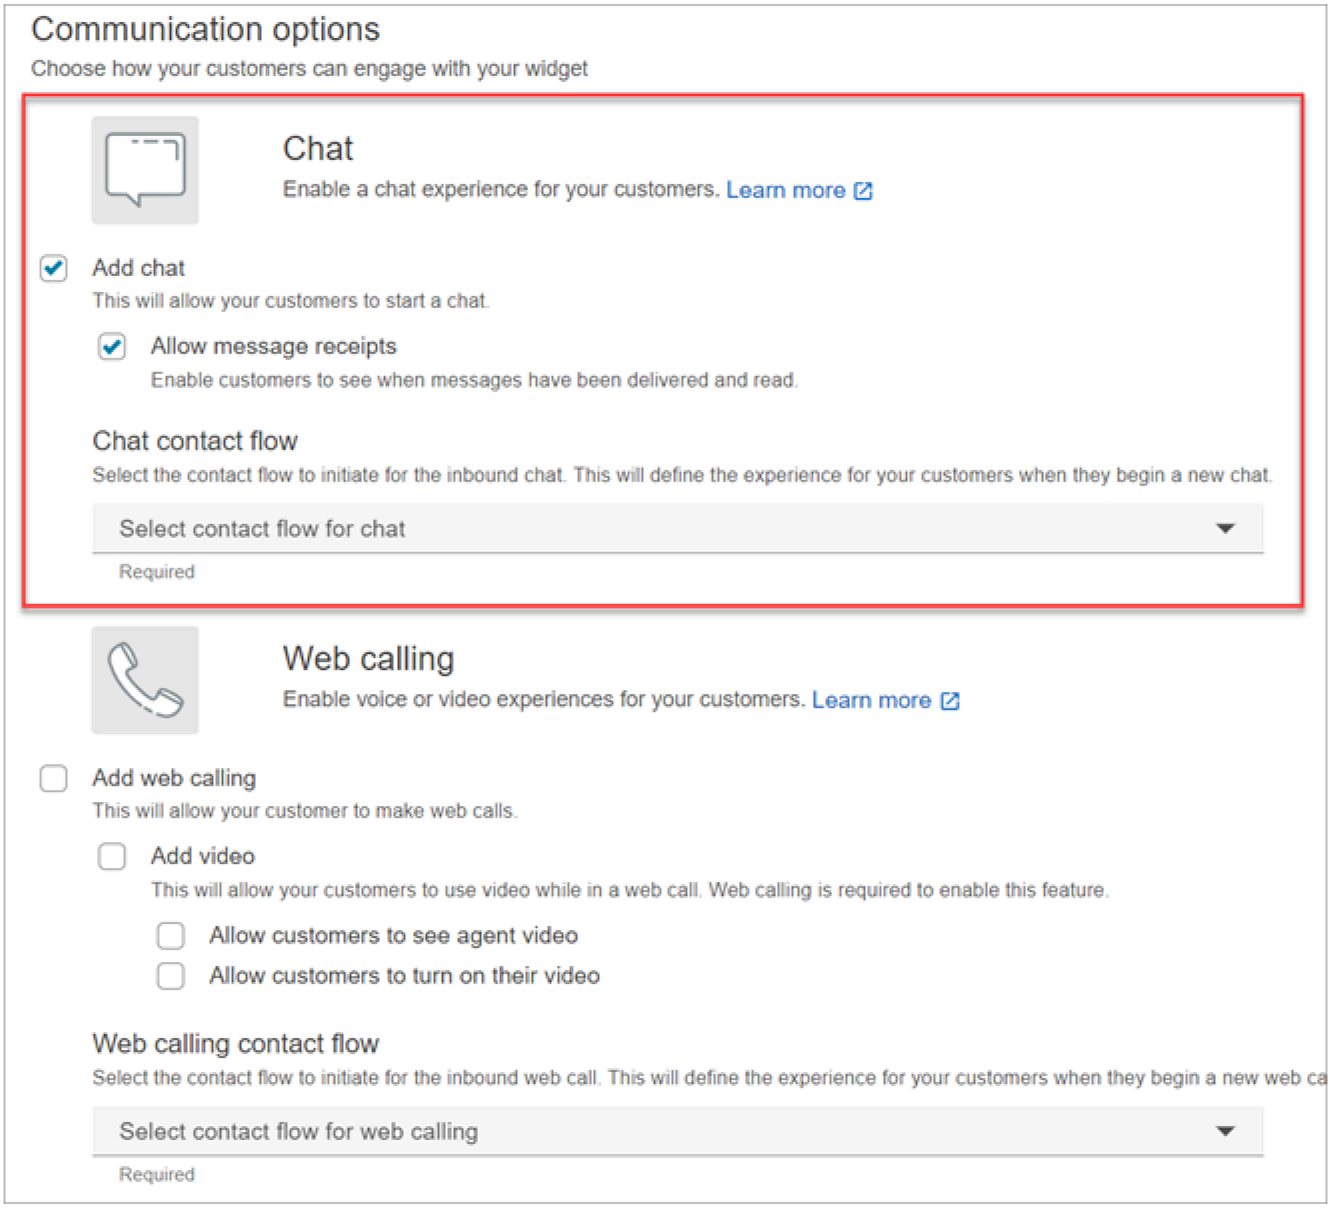
2. On the **Communications widgets** page, choose **Add communications widget** to begin customizing a new communications widget experience. To edit, delete, or duplicate an existing communications widget, choose from the options under the **Actions** column, as shown in the following image.



3. Enter a **Name** and **Description** for the communications widget.

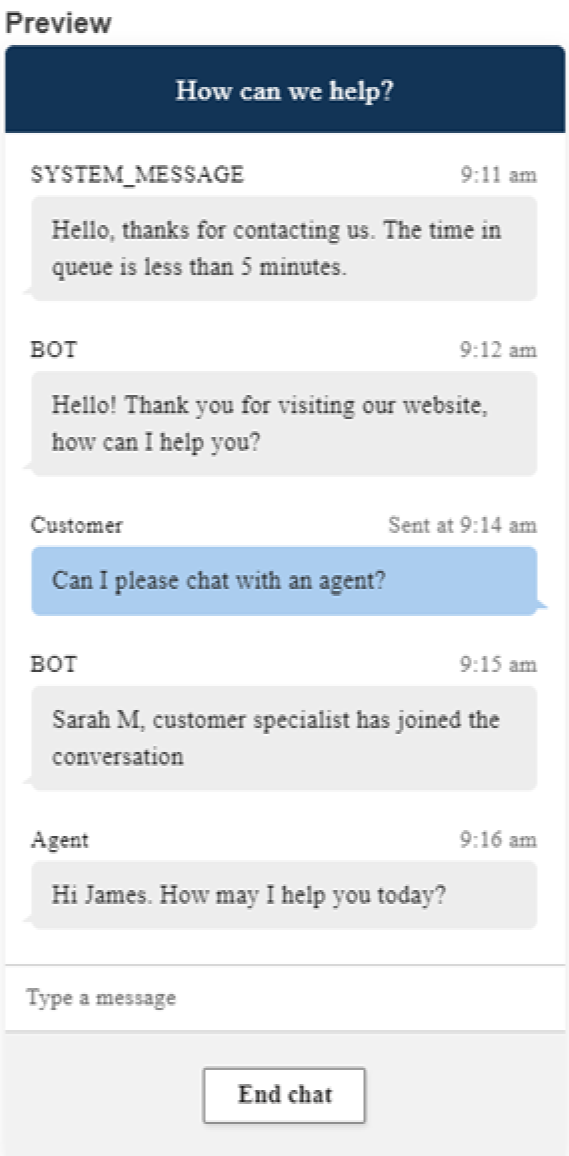
> **Note**
>
> The Name must be unique for each communications widget created in an Amazon Connect instance.

4. In the **Communications options** section, choose how your customers can engage with your widget, and then choose **Save and continue**. The following image shows options to allow chat and message receipts for customers.



5. On the **Create communication widget** page, choose the widget button styles, and display names and styles.

   As you choose these options, the widget preview updates automatically so that you can see what the experience will look like for your customers.



Button styles

1. Choose the colors for the button background by entering hex values (HTML color codes).
2. Choose **White** or **Black** for the icon color. The icon color can't be customized.

Widget header

1. Provide values for header message and color, and widget background color.
2. **Logo URL**: Insert a URL to your logo banner from an Amazon S3 bucket or another online source.

> **Note**
>
> The communications widget preview in the customization page will not display the logo if it's from an online source other than an Amazon S3 bucket. However, the logo will be displayed when the customized communications widget is implemented to your page.

The banner must be in .svg, .jpg or .png format. The image can be 280px (width) by 60px (height). Any image larger than those dimensions will be scaled to fit the 280x60 logo component space.

1. For instructions about how to upload a file such as your logo banner to S3, see Uploading objects in the *Amazon Simple Storage Service User Guide*.
2. Make sure that the image permissions are properly set so that the communications widget has permissions to access the image. For information about how to make a S3 object publicly accessible, see Step 2: Add a bucket policy in the *Setting permissions for website access* topic.

Chat view

1. **Typeface**: Use the dropdown to choose the font for the text in the communications widget.
2. - **System Message Display Name**: Type a new display name to override the default. The default is **SYSTEM_MESSAGE**.
   - **Bot Message Display Name**: Type a new display name to override the default. The default is **BOT**.
   - **Text Input Placeholder**: Type new placeholder text override the default. The default is **Type a message**.
   - **End Chat Button Text**: Type new text to replace the default. The default is **End chat**.
3. **Agent chat bubble color**: Choose the colors for the agent's message bubbles by entering hex values (HTML color codes).
4. **Customer chat bubble color**: Choose the colors for the customer's message bubbles by entering hex values (HTML color codes).
5. Choose **Save and continue**.

Step 2: Specify the website domains where you expect to display the communications widget

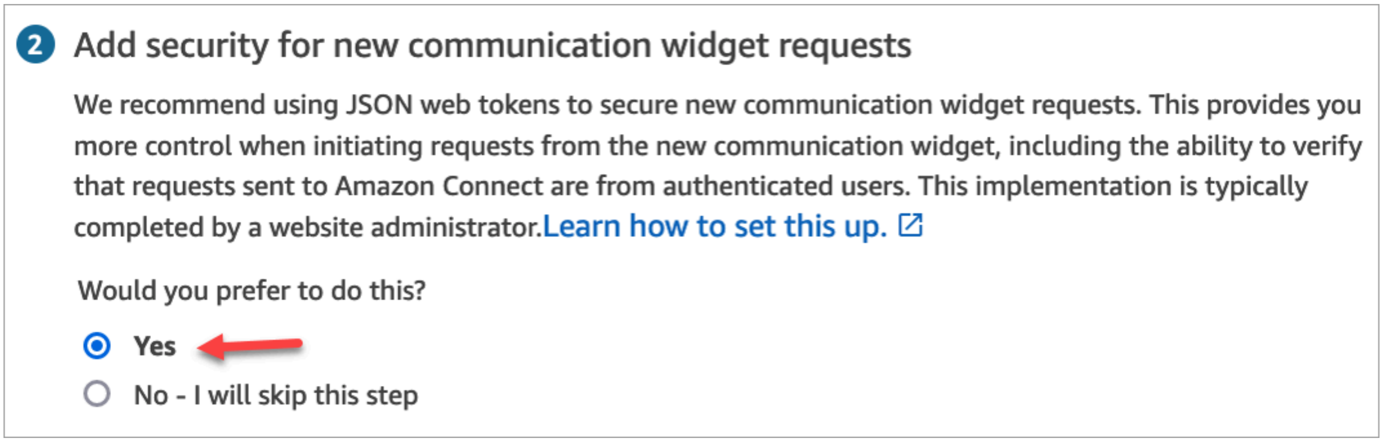
1. Enter the website domains where you want to place the communications widget. Chat loads only on websites that you select in this step.

   Choose **Add domain** to add up to 50 domains.

   
   Important

   - Double-check that your website URLs are valid and does not contain errors. Include the full URL starting with https://.
   - We recommend using https:// for your production websites and applications.

2. Under **Add security for your communications widget**, we recommend choosing **Yes**, and working with your website administrator to set up your web servers to issue JSON Web Tokens (JWTs) for new chat requests. This provides you more control when initiating new chats, including the ability to verify that chat requests sent to Amazon Connect are from authenticated users.



Choosing **Yes** results in the following:

- Amazon Connect provides a 44-character security key on the next page that you can use to create JSON Web Tokens (JWTs).
- Amazon Connect adds a callback function within the communications widget embed script that checks for a JSON Web Token (JWT) when a chat is initiated.

  You must implement the callback function in the embedded snippet, as shown in the following example.

  ```
  amazon_connect('authenticate', function(callback) {
    window.fetch('/token').then(res => {
      res.json().then(data => {
        callback(data.data);
      });
    });
  });
  ```

If you choose this option, in the next step you'll get a security key for all chat requests initiated on your websites. Ask your website administrator to set up your web servers to issue JWTs using this security key.

3. Choose **Save**.

Step 3: Confirm and copy communications widget code and security keys

In this step, you confirm your selections and copy the code for the communications widget and embed it in your website. If you chose to use JWTs in Step 2, you can also copy the secret keys for creating them.

Security key

Use this 44-character security key to generate JSON web tokens from your web server. You can also update, or rotate, keys if you need to change them. When you do this, Amazon Connect provides you with a new key and maintains the previous key until you have a chance to replace it. After you have the new key deployed, you can come back to Amazon Connect and delete the previous key.

When your customers interact with the Start chat icon on your website, the communications widget requests your web server for a JWT. When this JWT is provided, the widget will then include it as part of the end customer's chat request to Amazon Connect. Amazon Connect then uses the secret key to decrypt the token. If successful, this confirms that the JWT was issued by your web server and Amazon Connect routes the chat request to your contact center agents.

JSON Web Token specifics

- Algorithm: **HS256**
- Claims:
  - **sub**: *`widgetId`*

    Replace `widgetId` with your own widgetId. To find your widgetId, see the example at Communications widget script.
  - **iat**: *Issued At Time.
  - **exp**: *Expiration (10 minute maximum).

- **segmentAttributes (optional)**: A set of system defined key-value pairs stored on individual contact segments using an attribute map. For more information check SegmentAttributes in the StartChatContact API.
- **attributes (optional)**: Object with string-to-string key-value pairs. The contact attributes must follow the limitations set by the StartChatContact API.
- **CustomerId (optional)**: This can be either an Amazon Connect Customer Profiles ID or a custom identifier from an external system, such as a CRM.

* For information about the date format, see the following Internet Engineering Task Force (IETF) document: JSON Web Token (JWT), page 5.

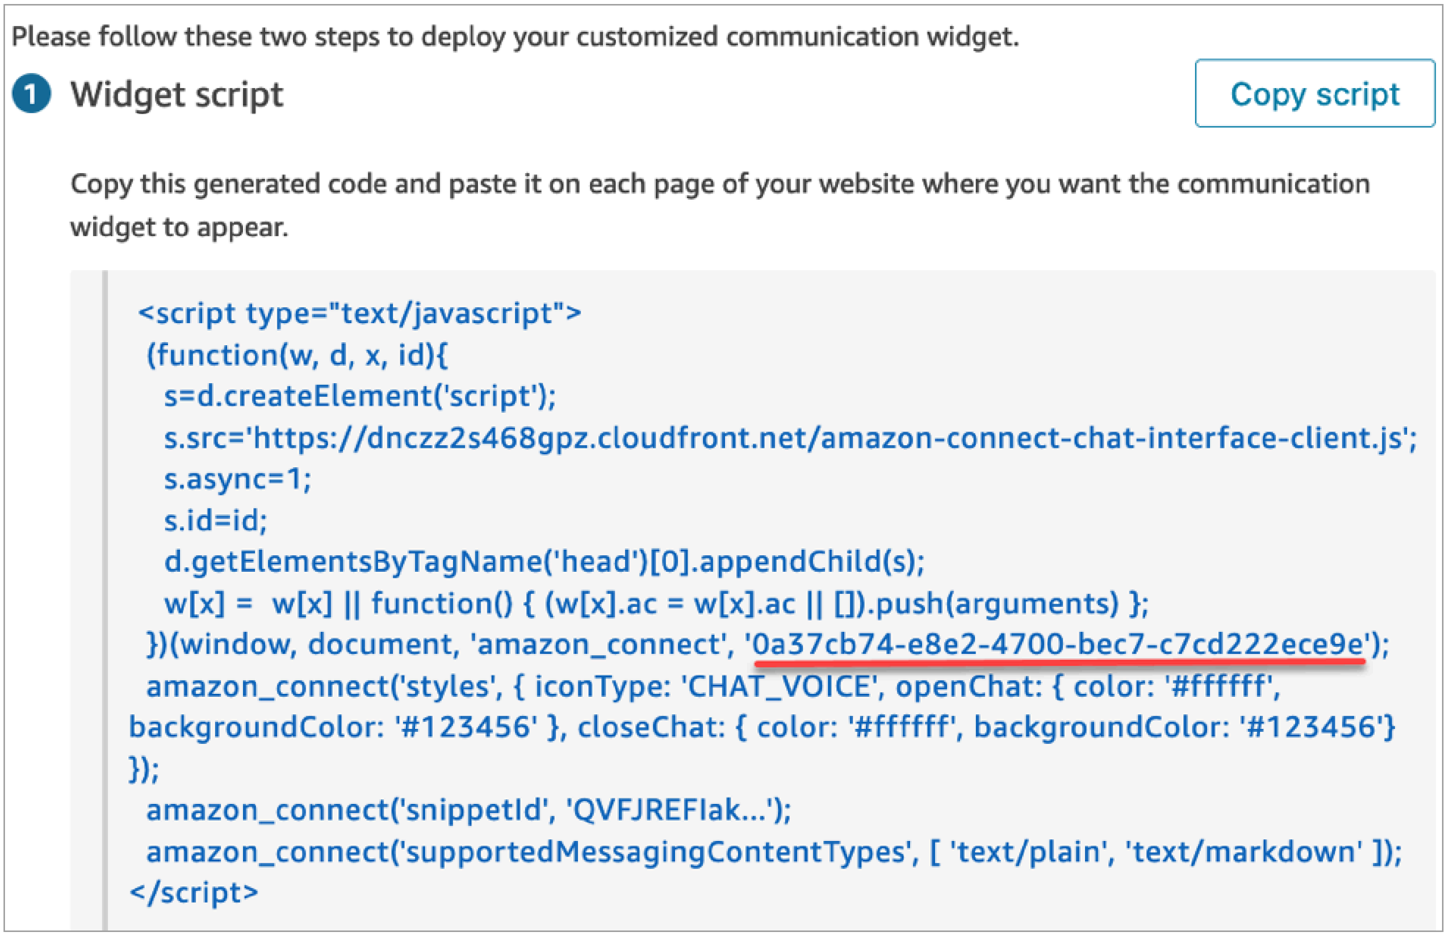
The following code snippet shows an example of how to generate a JWT in Python:

```
import jwt
import datetime
CONNECT_SECRET = "your-securely-stored-jwt-secret"
WIDGET_ID = "widget-id"
JWT_EXP_DELTA_SECONDS = 500

payload = {
'sub': WIDGET_ID,
'iat': datetime.datetime.utcnow(),
'exp': datetime.datetime.utcnow() + datetime.timedelta(seconds=JWT_EXP_DELTA_SECONDS),
'customerId': "your-customer-id",
'segmentAttributes': {"connect:Subtype": {"ValueString" : "connect:Guide"}},
 'attributes': {"name": "Jane", "memberID": "123456789", "email": "Jane@example.com",
 "isPremiumUser": "true", "age": "45"} }
header = { 'typ': "JWT", 'alg': 'HS256' }
encoded_token = jwt.encode((payload), CONNECT_SECRET, algorithm="HS256",
 headers=header) // CONNECT_SECRET is the security key provided by Amazon Connect
```

Communications widget script

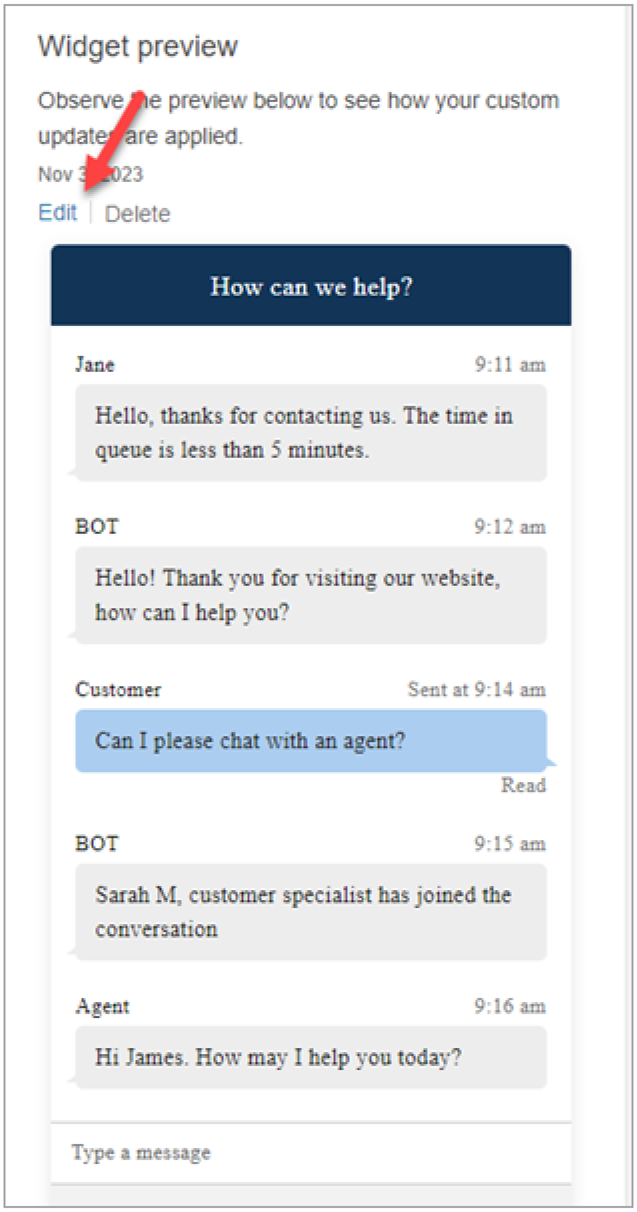
The following image shows an example of the JavaScript that you embed on the websites where you want customers to chat with agents. This script displays the widget in the bottom-right corner of your website.



When your website loads, customers first see the **Start** icon. When they choose this icon, the communications widget opens and customers are able to send a message to your agents.

To make changes to the communications widget at any time, choose **Edit**.

> **Note**
>
> Saved changes update the customer experience in a few minutes. Confirm your widget configuration before saving it.



To make changes to widget icons on the website, you will receive a new code snippet to update your website directly.

Getting error messages?

If you encounter error messages, see [Troubleshoot issues with your Amazon Connect communications widget](#).

Customize widget launch behavior and button icon for your website hosted in Amazon Connect

To further customize how your website renders and launches the hosted widget icon, you can configure the launch behavior and hide the default icon. For example, you can programmatically launch the widget from a **Chat with us** button element that is rendered on your website.

Contents

How to configure custom launch behavior for the widget

To pass custom launch behavior, use the following example code block and embed it in your widget. All of the fields shown in the following example are optional and any combination can be used.

```
amazon_connect('customLaunchBehavior', {
    skipIconButtonAndAutoLaunch: true,
    alwaysHideWidgetButton: true,
    programmaticLaunch: (function(launchCallback) {
        var launchWidgetBtn = document.getElementById('launch-widget-btn');
        if (launchWidgetBtn) {
            launchWidgetBtn.addEventListener('click', launchCallback);
            window.onunload = function() {
            launchWidgetBtn.removeEventListener('click', launchCallback);
            return;
            }
        }
    })
});
```

Supported options and constraints

The following table lists the supported custom launch behavior options. Fields are optional and any combination can be used.

Option name	Type	Description	Default value
`skipIconButtonAndAutoLaunch`	Boolean	A flag to enable/disable the automatic launch of the widget without the user clicking on the page load.	undefined
`alwaysHideWidgetButton`	Boolean	A flag to enable/disable the widget icon button from rendering (unless there is an ongoing chat session).	undefined
`programmaticLaunch`	Function		undefined

Configure widget launch for custom use cases

Custom widget launch button

The following example shows changes you would need to make in the widget to configure programmatic launch to open only when the user chooses a custom button element rendered anywhere on your website. For example, they may choose a button named **Contact Us** or **Chat With Us**. Optionally, you can hide the default Amazon Connect widget icon until the widget has been opened.

```
<button id="launch-widget-btn">Chat With Us</button>
```

```
<script type="text/javascript">
 (function(w, d, x, id){
    s=d.createElement("script");
    s.src="./amazon-connect-chat-interface-client.js"
    s.async=1;
    s.id=id;
    d.getElementsByTagName("head")[0].appendChild(s);
```

```
    w[x] =  w[x] || function() { (w[x].ac = w[x].ac || []).push(arguments) };
  })(window, document, 'amazon_connect', 'asfd-asdf-asfd-asdf-asdf');
  amazon_connect('styles', { openChat: { color: '#000', backgroundColor: '#3498fe'},
 closeChat: { color: '#fff', backgroundColor: '#123456'} });
  amazon_connect('snippetId', "QVFJREFsdafsdfsadfsdafasdfasdfsdafasdfz0=")
  amazon_connect('customLaunchBehavior', {
        skipIconButtonAndAutoLaunch: true,
        alwaysHideWidgetButton: true,
        programmaticLaunch: (function(launchCallback) {
            var launchWidgetBtn = document.getElementById('launch-widget-btn');
            if (launchWidgetBtn) {
                launchWidgetBtn.addEventListener('click', launchCallback);
                window.onunload = function() {
                launchWidgetBtn.removeEventListener('click', launchCallback);
                return;
                }
            }
        }),
    });
</script>
```

Hyperlink support

The following example shows changes you would need to make in the widget configure `auto-launch`, which opens the widget without waiting for the user to click. You can deploy to a page that hosted by your website to create a shareable hyperlink.

```
https://example.com/contact-us?autoLaunchMyWidget=true
```

```
<script type="text/javascript">
 (function(w, d, x, id){
    s=d.createElement("script");
    s.src="./amazon-connect-chat-interface-client.js"
    s.async=1;
    s.id=id;
    d.getElementsByTagName("head")[0].appendChild(s);
    w[x] =  w[x] || function() { (w[x].ac = w[x].ac || []).push(arguments) };
  })(window, document, 'amazon_connect', 'asfd-asdf-asfd-asdf-asdf');
  amazon_connect('styles', { openChat: { color: '#000', backgroundColor: '#3498fe'},
 closeChat: { color: '#fff', backgroundColor: '#123456'} });
  amazon_connect('snippetId', "QVFJREFsdafsdfsadfsdafasdfasdfsdafasdfz0=")
  amazon_connect('customLaunchBehavior', {
```

```
        skipIconButtonAndAutoLaunch: true
    });
</script>
```

Load widget assets when button is clicked

The following example shows changes you would need to make in the widget to make your website page load faster by fetching the widget's static assets when a user clicks the **Chat With Us** button. Typically, only small percentage of customers visiting a **Contact Us** page open the Amazon Connect widget. The widget could be adding latency on page load by fetching files from CDN, even though customers never open the widget.

An alternative solution is to run the snippet code asynchronously (or never) on button click.

```
<button id="launch-widget-btn">Chat With Us</button>
```

```
var buttonElem = document.getElementById('launch-widget-btn');

buttonElem.addEventListener('click', function() {
    (function(w, d, x, id){
        s=d.createElement("script");
        s.src="./amazon-connect-chat-interface-client.js"
        s.async=1;
        s.id=id;
        d.getElementsByTagName("head")[0].appendChild(s);
        w[x] =  w[x] || function() { (w[x].ac = w[x].ac || []).push(arguments) };
    })(window, document, 'amazon_connect', 'asfd-asdf-asfd-asdf-asdf');
    amazon_connect('styles', { openChat: { color: '#000', backgroundColor: '#3498fe'},
 closeChat: { color: '#fff', backgroundColor: '#123456'} });
    amazon_connect('snippetId', "QVFJREFsdafsdfsadfsdafasdfasdfsdafasdfz0=")
    amazon_connect('customLaunchBehavior', {
        skipIconButtonAndAutoLaunch: true
    });
});
```

Launch a new chat in a browser window

The following example shows changes you would need to make in the widget to launch a new browser window and auto-launch chat in a full screen.

```
<button id="openChatWindowButton">Launch a Chat</button>
```

```
<script> // Function to open a new browser window with specified URL and dimensions
    function openNewWindow() {
        var url = 'https://mycompany.com/support?autoLaunchChat=true';

        // Define the width and height
        var width = 300;
        var height = 540;

        // Calculate the left and top position to center the window
        var left = (window.innerWidth - width) / 2;
        var top = (window.innerHeight - height) / 2;

        // Open the new window with the specified URL, dimensions, and position
        var newWindow = window.open(url, '', 'width=${width}, height=${height}, left=
${left}, top=${top}');
    }

    // Attach a click event listener to the button
    document.getElementById('openChatWindowButton').addEventListener('click',
 openNewWindow);
</script>
```

Enable chat session persistence across tabs

By default if a chat is opened in one tab and then the user opens a new tab and starts another chat, a new chat will start instead of connecting to the existing chat. You can enable chat session persistence across tabs if you want the user to connect to the existing chat that was started in the initial tab.

The chat session is stored in session storage on the browser in the variable `persistedChatSession`. You need to copy this value into the session storage of the new tab when the widget is first initialized. Following are instructions.

1. Copy the following code next to the other amazon_connect functions in the hosted widget snippet. This uses the `registerCallback` event handlers to store the `persistedChatSession` as a cookie so it can be accessed in the new tab. It also cleans up the cookie when the chat ends.

   ```
   amazon_connect('registerCallback', {
   'CONNECTION_ESTABLISHED': (eventName, { chatDetails, data }) => {
   ```

```
    document.cookie = `activeChat=${sessionStorage.getItem("persistedChatSession")};
    SameSite=None; Secure`;
  },
  'CHAT_ENDED': () => {
    document.cookie = "activeChat=; SameSite=None; Secure";
  }
});
```

2. Retrieve the cookie value if it exists and set the session storage value in the new tab.

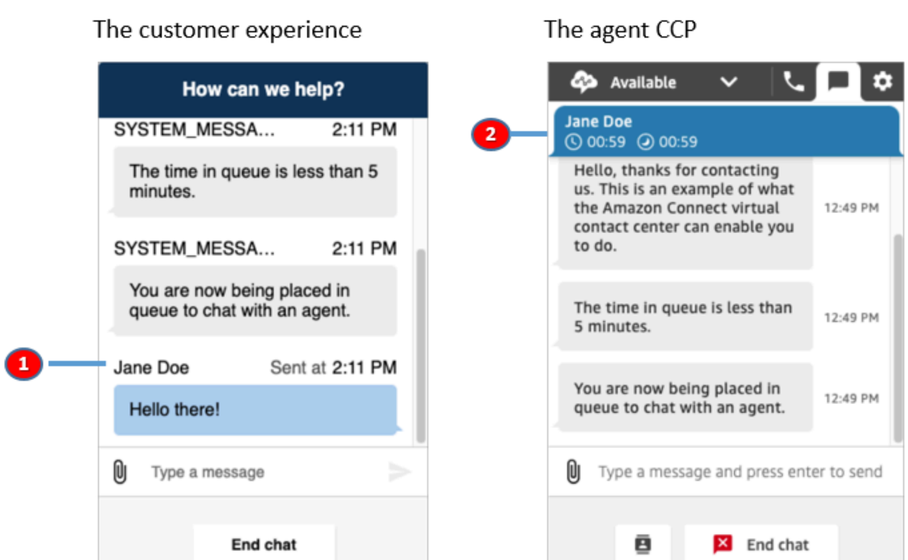
```
const cookie = document.cookie.split('; ').find(c => c.startsWith('activeChat='));
if (cookie) {
  const activeChatValue = cookie.split('=')[1];
  sessionStorage.setItem('persistedChatSession', activeChatValue);
}

//Your hosted widget snippet should be on this page
```

Pass the customer display name when an Amazon Connect chat starts

To deliver a more personalized experience for both your customers and agents, you can customize the Amazon Connect communications widget to pass the customer display name during contact initialization. The name is visible to both the customer and agent throughout the chat interaction. This display name is recorded in the chat transcript.

The following images show the customer's display name in their chat experience, and their name in the agent's CCP.



1. How the customer display name may appear to the customer using the chat user interface.
2. How the customer display name may appear to the agent using the CCP.

How to pass a customer display name in the communications widget

To pass a customer display name, implement your callback function in the snippet. Amazon Connect retrieves the display name automatically.

1. Complete the steps in Add a chat user interface to your website hosted by Amazon Connect, if you haven't already.
2. Augment your existing widget snippet to add a `customerDisplayName` callback. It might look something like the following example:

   ```
   amazon_connect('customerDisplayName', function(callback) {
     const displayName = 'Jane Doe';
     callback(displayName);
   });
   ```

   The important thing is that the name is passed to `callback(name)`.

What you need to know about the customer display name

- Only one `customerDisplayName` function can exist at a time.
- The customer display name must follow the limitations set by the StartChatConnect API. That is, the name must be a string between 1 and 256 characters.
- An empty string, null, or undefined is invalid input for the display name. To protect against accidentally passing of these inputs, the widget logs an error, `Invalid customerDisplayName provided`, in the browser console, and then starts the chat with the default display name, **Customer**.
- Because the snippet is in the front end of your website, do not pass sensitive data as the display name. Be sure to follow the appropriate security practices to keep your data safe and protect against attacks and bad actors.

Pass contact attributes to an agent in the Contact Control Panel (CCP) when a chat starts

You can use contact attributes to capture information about the contact who is using the communications widget. Then, you can display that information to the agent through the Contact Control Panel (CCP), or use it elsewhere in the flow.

For example, you can customize your flow to say the name of the customer in your welcome message. Or, you can use attributes specific to your business, such as account/member IDs, customer identifiers like names and emails, or other metadata associated with a contact.

How to pass contact attributes into the communications widget

1. Enable security in the communications widget as described in Add a chat user interface to your website hosted by Amazon Connect, if you haven't already:

    a. In Step 2, under **Add security for your chat widget**, choose **Yes**.

    b. In Step 3, use the security key to generate JSON web tokens.

2. Add the contact attributes to the payload of your JWT as an `attributes` claim.

    Following is an example of how you might generate a JWT with contact attributes in Python:

    > **Note**
    >
    > JWT should be installed as a prerequisite. To install it, run `pip install PyJWT` in your terminal.

    ```
    import jwt
    import datetime
    CONNECT_SECRET = "your-securely-stored-jwt-secret"
    WIDGET_ID = "widget-id"
    JWT_EXP_DELTA_SECONDS = 500

    payload = {
    'sub': WIDGET_ID,
    'iat': datetime.datetime.utcnow(),
    'exp': datetime.datetime.utcnow() +
     datetime.timedelta(seconds=JWT_EXP_DELTA_SECONDS),
    'segmentAttributes': {"connect:Subtype": {"ValueString" : "connect:Guide"}},
     'attributes': {"name": "Jane", "memberID": "123456789", "email":
     "Jane@example.com", "isPremiumUser": "true", "age": "45"} }
    ```

```
header = { 'typ': "JWT", 'alg': 'HS256' }
encoded_token = jwt.encode((payload), CONNECT_SECRET, algorithm="HS256",
 headers=header) // CONNECT_SECRET is the security key provided by Amazon Connect
```

In the payload, you must create a string key `attributes` (as-is, all lowercase), with an object as its value. That object must have string-to-string key-value pairs. If anything other than a string is passed in any one of the attributes, the chat will fail to start.

The contact attributes must follow the limitations set by the StartChatConnect API:

- Keys must have a minimum length of 1
- Values can have a minimum length of 0

Optionally, you can add the segmentAttributes string to SegmentAttributeValue object map, in the payload. The attributes are standard Amazon Connect attributes. They can be accessed in flows. The contact attributes must follow the limitations set by the StartChatConnect API.

Alternative method: Pass contact attributes directly from snippet code

> **Note**
>
> - The snippet code prepends `HostedWidget-` to all the contact attribute keys that it passes. In the following example, the agent side will see the key value pair `HostedWidget-foo: 'bar'`.
> - Although these attributes are scoped with the `HostedWidget-` prefix, they are still mutable client-site. Use the JWT setup if you require PII or immutable data in your flow.

The following example shows how to pass contact attributes directly from snippet code without enabling widget security.

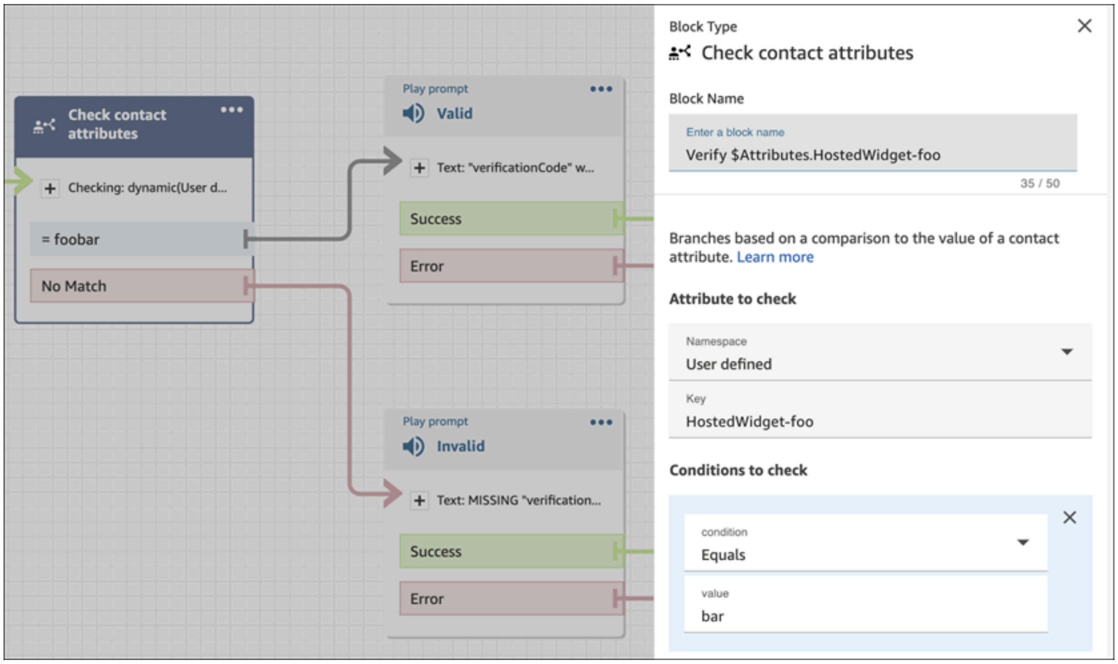
```
<script type="text/javascript">
  (function(w, d, x, id){ /* ... */ })(window, document, 'amazon_connect', 'widgetId');
  amazon_connect('snippetId', 'snippetId');
  amazon_connect('styles', /* ... */);
  // ...

  amazon_connect('contactAttributes', {
```

```
    foo: 'bar'
  })
<script/>
```

Using the attributes in flows

The Check contact attributes flow block provides access to these attributes by using the **User defined** namespace, as shown in the following image. You can use the flow block to add branching logic. The full path is `$.Attributes.HostedWidget-attributeName`.

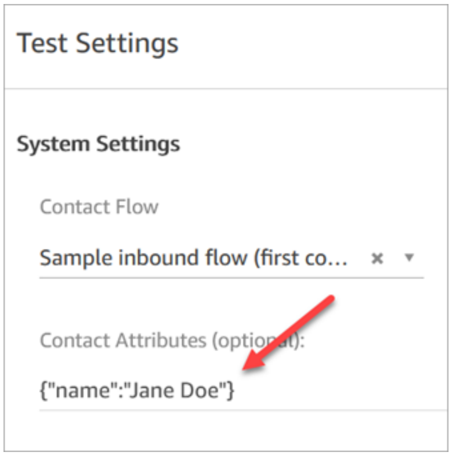


Things you need to know

- The communications widget has a 6144 bytes limit for the entire encoded token. Because JavaScript uses UTF-16 encoding, 2 bytes are used per character, so the maximum size of the `encoded_token` should be around 3000 characters.
- The encoded_token should be passed in to `callback(data)`. The `authenticate` snippet does not need any additional changes. For example:

```
amazon_connect('authenticate', function(callback) {
  window.fetch('/token').then(res => {
    res.json().then(data => {
      callback(data.data);
    });
  });
});
```

- Using a JWT to pass contact attributes ensures the integrity of the data. If you safeguard the shared secret and follow appropriate security practices, you can help ensure that the data cannot be manipulated by a bad actor.
- Contact attributes are only encoded in the JWT, not encrypted, so it's possible to decode and read the attributes.
- If you want to test the chat experience with the simulated chat experience and include contact attributes, be sure to enclose both the key and value in quotes, as shown in the following image.



Additional customizations for your Amazon Connect chat widget

You can add the following optional customizations to your chat user interface:

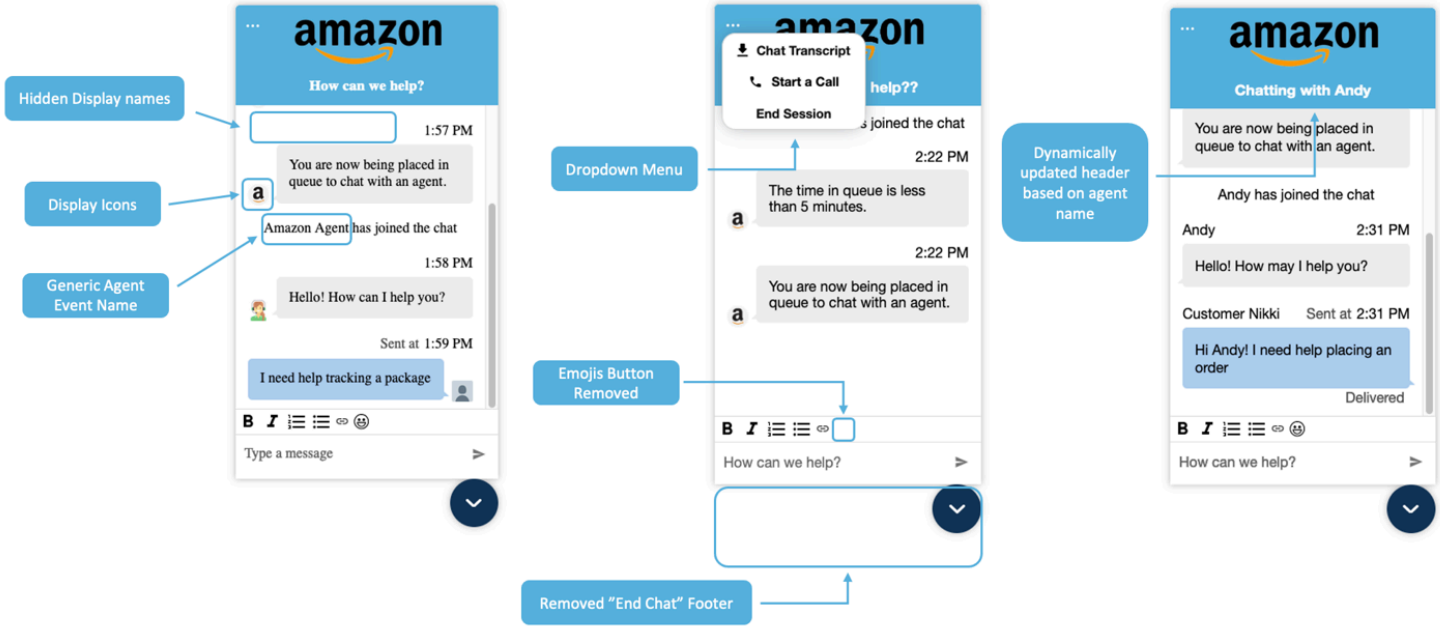
- Display the **End chat** button in the header dropdown menu instead of in the footer.
- Mask or hide display names.
- Add message icons.
- Override event messages.

Configure the customization object

This example shows how to implement some of the optional customizations. For a list of all possible customizations, see Supported options and constraints. Because these customizations are optional, you can implement some or all of the fields shown in the following example. Replace the `eventNames.customer`, `eventNames.agent`, `eventNames.supervisor`, `eventMessages.participantJoined`, `eventMessages.participantDisconnect`, `eventMessages.participantLeft`, `eventMessages.participantIdle`, `eventMessages.participantReturned`, and `eventMessages.chatEnded` strings as needed. Icons must be hosted on public URLs.

```
amazon_connect('customizationObject', {
        header: {
            dropdown: true,
            dynamicHeader: true,
        },
        transcript: {
            hideDisplayNames: false,
            eventNames: {
                customer: "User",
                agent: "Webchat Agent",
                supervisor: "Webchat Supervisor"
            },
            eventMessages: {
                participantJoined: "{name} has joined the chat",
                participantDisconnect: "",
                participantLeft: "{name} has dropped",
                participantIdle: "{name}, are you still there?",
                participantReturned: "",
                chatEnded: "Chat ended",
            },
            displayIcons: true,
            iconSources: {
                botMessage: "imageURL",
                systemMessage: "imageURL",
                agentMessage: "imageURL",
                customerMessage: "imageURL",
            },
        },
        composer: {
            disableEmojiPicker: true,
            disableCustomerAttachments: true,
        },
        footer: {
            disabled:true,
            skipCloseChatButton: true,
        }
});
```

The following image shows how the customizations look if you use the example:



Supported options and constraints

The following table lists the supported customization fields and recommended value constraints.

Custom layout option	Type	Description
`header.dropdown`	Boolean	Renders the header dropdown menu instead of the default footer **Note** When you set this option to `true`, the **Transcript download** button appears and remains visible until you set the option to `false`, or until you remove the option.

Custom layout option	Type	Description
`header.dynamicHeader`	Boolean	Dynamically sets the header title to "Chatting with Bot/ AgentName"
`header.hideTranscriptDownloadButton`	Boolean	Hide the download transcript button in the header dropdown menu. The default value is `false`.
`transcript.hideDisplayNames`	Boolean	Hides all display names, will apply default name masks if `eventNames` is not provided
`transcript.eventNames.customer`	String	Masks the display name of customer
`transcript.eventNames.agent`	String	Masks the display name of agent
`transcript.eventNames.supervisor`	String	Masks the display name of supervisor
`transcript.eventMessages.participantJoined`	String	Overrides event message in the transcript for when a participant has joined the chat. If an empty string is specified, the event message will be omitted from the transcript. `{name}` can be passed in the message, and will be replaced with the display name of the corresponding participant. The default message is `{name} has joined the chat`.

Custom layout option	Type	Description
`transcript.eventMessages.participantDisconnect`	String	Overrides event message in the transcript for when a participant is disconnected from the chat. If an empty string is specified, the event message will be omitted from the transcript. `{name}` can be passed in the message, and will be replaced with the display name of the corresponding participant. The default message is `{name} has been idle too long, disconnecting .`
`transcript.eventMessages.participantLeft`	String	Overrides event message in the transcript for when a participant has left the chat. If an empty string is specified, the event message will be omitted from the transcript. `{name}` can be passed in the message, and will be replaced with the display name of the corresponding participant. The default message is `{name} has left the chat.`

Custom layout option	Type	Description
`transcript.eventMessages.participantIdle`	String	Overrides event message in the transcript for when a participant is idle. If an empty string is specified, the event message will be omitted from the transcript. `{name}` can be passed in the message, and will be replaced with the display name of the corresponding participant. The default message is `{name} has become idle`.
`transcript.eventMessages.participantReturned`	String	Overrides event message in the transcript for when a participant has returned to the chat. If an empty string is specified, the event message will be omitted from the transcript. `{name}` can be passed in the message, and will be replaced with the display name of the corresponding participant. The default message is `{name} has returned`.

Custom layout option	Type	Description
`transcript.eventMessages.chatEnded`	String	Overrides event message in the transcript for when the chat has ended. If an empty string is specified, the event message will be omitted from the transcript. `{name}` can be passed in the message, and will be replaced with the display name of the corresponding participant. The default message is `Chat has ended!`
`transcript.displayIcons`	Boolean	Enables message display icons
`transcript.iconSources.botMessage`	String	Icon displayed for bot messages, must be hosted on a public URL
`transcript.iconSources.systemMessage`	String	Icon displayed for system message, must be hosted on a public URL
`transcript.iconSources.agentMessage`	String	Icon displayed for agent message, must be hosted on a public URL
`transcript.iconSources.customerMessage`	String	Icon displayed for customer message, must be hosted on a public URL
`composer.disableEmojiPicker`	Boolean	Disables the emoji picker when using the rich text editor

Custom layout option	Type	Description
`composer.disableCustomerAttachments`	Boolean	Prevents customers from sending or uploading attachments
`footer.disabled`	Boolean	Hides the default footer and **End chat** button
`footer.skipCloseChatButton`	Boolean	Directly closes the widget on click of **End chat** button instead of showing **Close** button

Download the transcript for your chat widget in Amazon Connect

You can download a PDF of the transcript in your chat widget.

Contents

Enable Header Dropdown

The button to download the transcript is within a drop down menu in the header. To enable the header's drop down menu, we have to configure our chat widget's customizationObject in the widget script.

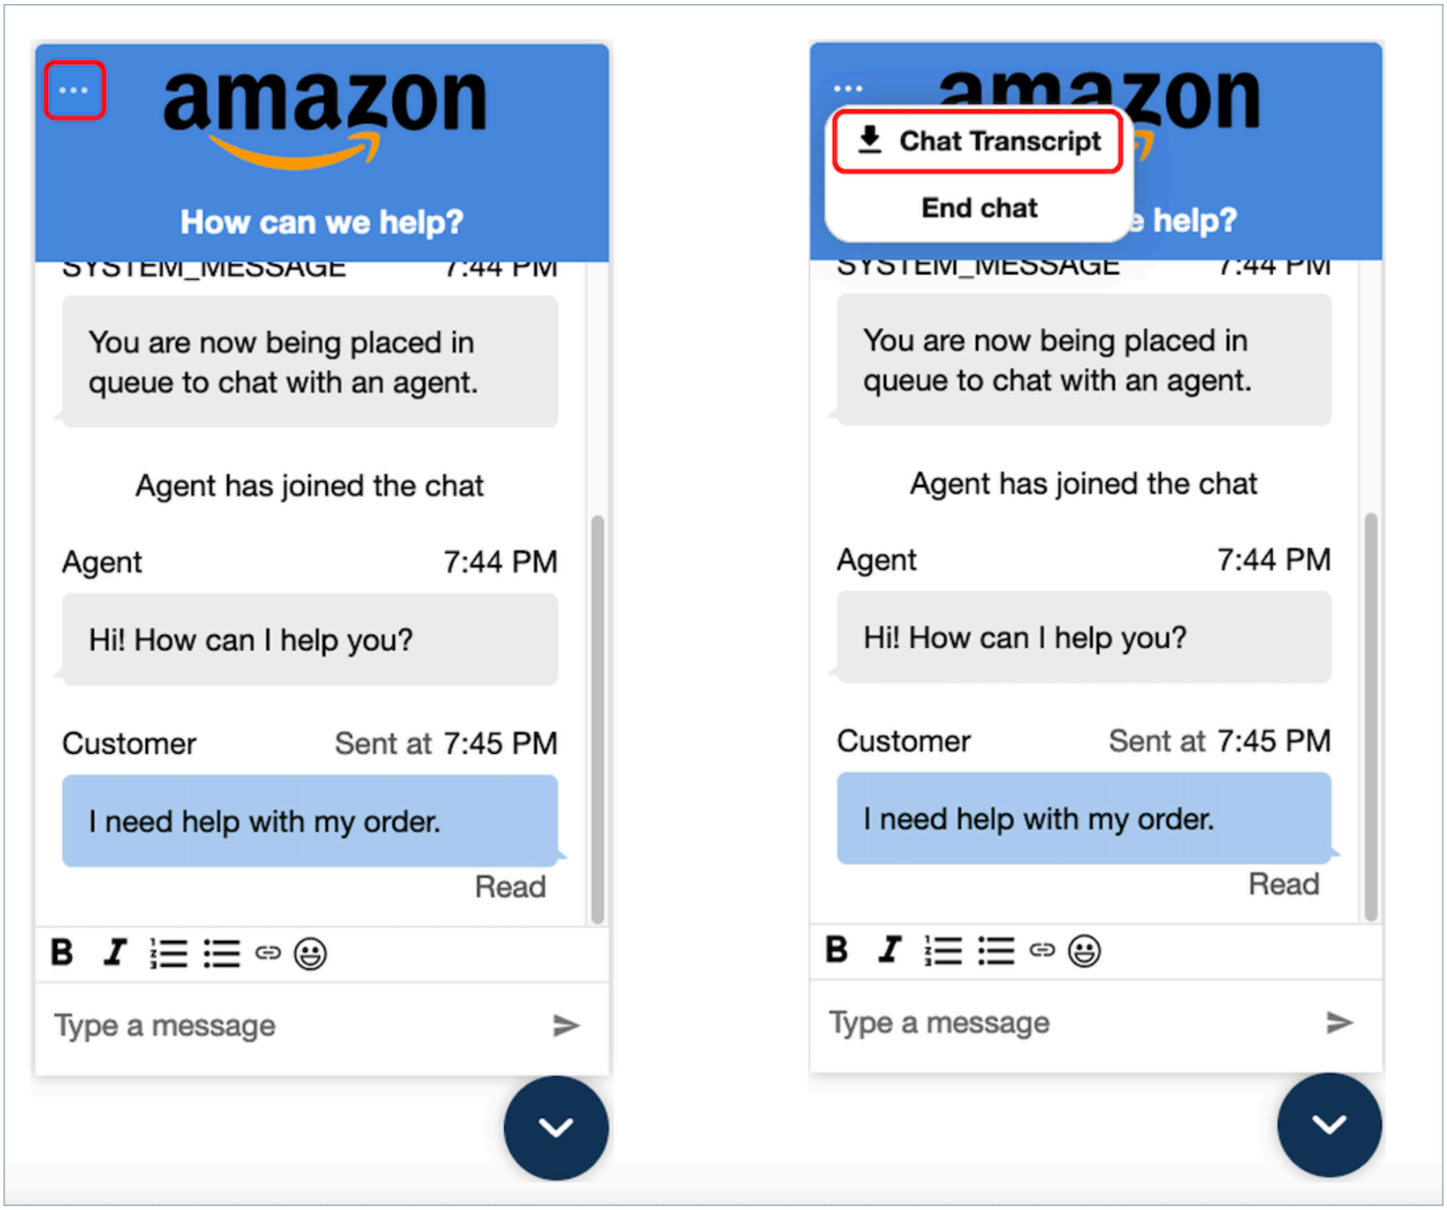
```
amazon_connect('customizationObject', {
        header: {
            dropdown: true,
        }
});
```

Note that enabling the drop down menu will automatically disable the footer since the **End Chat** functionality is moved to the header drop down menu. If you want to keep the footer, you can re-enable it by using the following:

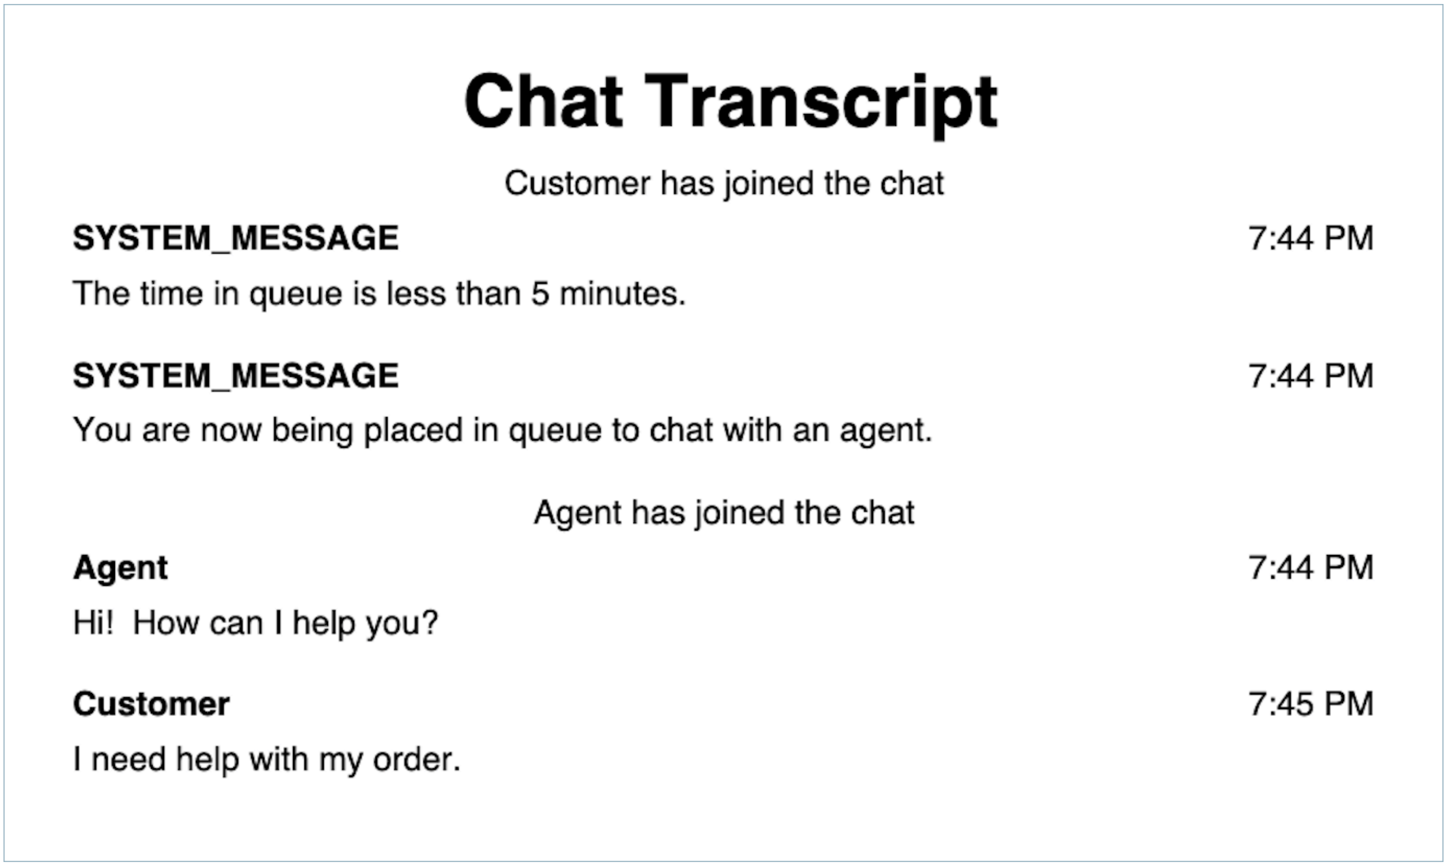
```
amazon_connect('customizationObject', {
        header: {
            dropdown: true,
        },
        footer: {
            disabled: false,
        }
});
```

Download PDF of Chat Transcript

After enabling the header drop down menu, you should be able to see a triple dot menu on the top left of the chat widget. Within that drop down menu, you should see a download **Chat Transcript** button.



Choosing download **Chat Transcript** will start a PDF download. The PDF of the chat transcript will show all messages, display names, time stamps and message events, such as participants leaving or joining.



Customize chat with the Amazon Connect open source example

You can further customize the chat experience customers use to interact with agents. Use the Amazon Connect open source library on GitHub. It's a platform to help you get started quickly. Here's how it works:

- The GitHub repository links to a CloudFormation template, which starts the Amazon API Gateway endpoint that initiates a Lambda function. You can use this template as an example.
- After you create the AWS CloudFormation stack, you can call this API from your app, import the pre-built communications widget, pass the response to the widget, and start chatting.

For more information about customizing the chat experience, see:

- Amazon Connect Service API Documentation, especially the StartChatConnect API.
- Amazon Connect Participant Service API.
- Amazon Connect Streams. Use to integrate your existing apps with Amazon Connect. You can embed the Contact Control Panel (CCP) components into your app.
- Amazon Connect Chat SDK and Sample Implementations

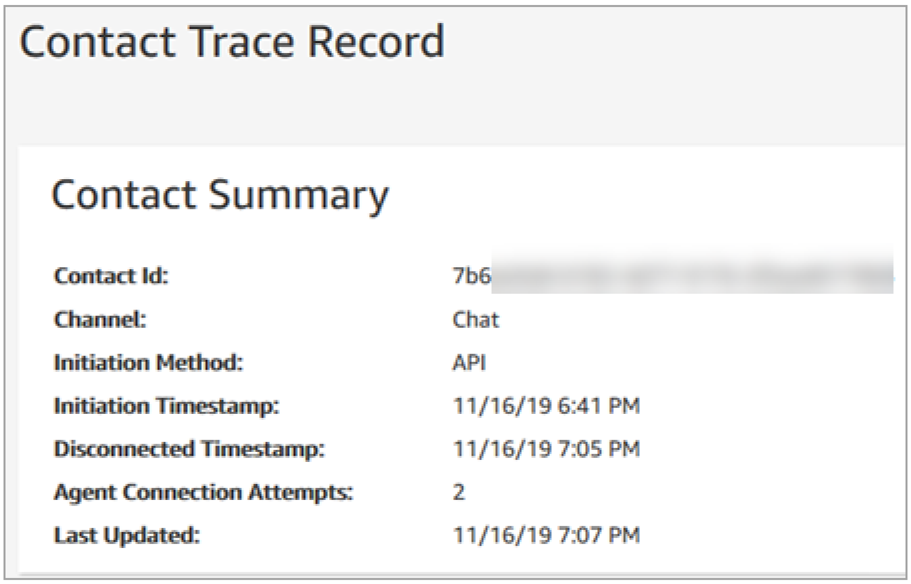
Start chats in your applications by using Amazon Connect APIs

Use the StartChatConnect API in Amazon Connect APIs to start chats in your own applications.

To start a chat, use the StartChatConnect API.

When you explore the chat experience for the first time, you'll notice that chats aren't counted in the **Contacts Incoming** metric in your historical metrics report. This is because the initiation method for the chat in the contact record is **API**.

The following image of a contact record shows the *Initiation Method* set to *API*.

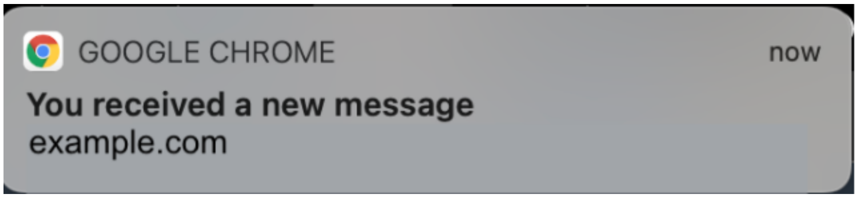


After a chat is transferred to an agent, the **Contacts Incoming** metric is incremented. The contact record for the transfer no longer increments the API, but it does increment **Contacts Incoming**.

Send browser notifications to customers when chat messages arrive

The communications widget supports browser notifications for your customers through their desktop devices. Specifically, your customers will receive a notification through their web browser when they receive a new message, but are not active on the web page that contains the chat window. When your customers click or tap this notification, they are automatically redirected to the web page containing the chat window. Your customers can enable or disable notifications at the start of each chat conversation.

The following image shows an example of the notification banner that customers receive when they are not on the web page that contains the chat window. The banner tells your customers that they have a new message, and it displays the name of the website.



Customers also receive a notification icon—a red dot—on the communications widget when it is minimized. The following image shows an image of the notification icon that customers receive when their chat window is minimized.

Both of these features are automatically included in the communications widget. You don't need to perform any steps to make them available to your customers.

Your customers receive a pop-up to allow/deny notification when they initiate a chat and have not yet allowed notifications from your website or domain. After they grant notification permissions, they start receiving browser notifications for any message or attachment sent by the agent when they are not on the web page with the chat window. This behavior applies even if you've already implemented the communications widget.

How to test

1. After you allow notifications as a test customer and the agent is connected to the chat, minimize your chat window and then open a new browser instance so you aren't on the web page that contains the chat window.
2. Send a message from the agent window.
3. As the test customer, you'll see the notification banner.
4. Choose or tap the notification banner. You'll automatically go to the web page that contains the chat window.
5. Because you minimized your chat window earlier, you will also see a notification icon—a red dot—on the communications widget.

If you can't see the browser notification, check the following:

- You're using a supported browser.
- The notification permission is allowed/enabled on your browser for the web page with chat window.
- The agent (or you from your agent chat session) has sent a new message/attachment while you're on a web page that is different from the one that contains the chat window. For the notification icon—a red dot—on the widget to be visible, minimize your chat window.
- Notifications from the browser are not snoozed (temporarily dismissed).

Programmatically disconnect the chat session of an Amazon Connect communication widget

You can disconnect the chat session of a communication widget programmatically using 'JavaScript by calling the `disconnect` method stored to the widget's `iframe`. From the widget's host document, you can reference the `disconnect` function using the following code snippet:

```
document.getElementById("amazon-connect-chat-widget-
iframe").contentWindow.connect.ChatSession.disconnect()
```

You can readily add it to the existing widget script. Following is an example code snippet:

```
<script type="text/javascript">
  (function(w, d, x, id){
    s=d.createElement('script');
    s.src='https://....cloudfront.net/amazon-connect-chat-interface-client.js';
    s.async=1;
    s.id=id;
    d.getElementsByTagName('head')[0].appendChild(s);
    w[x] =  w[x] || function() { (w[x].ac = w[x].ac || []).push(arguments) };
  })(window, document, 'amazon_connect', '...');
  amazon_connect('styles', { iconType: 'CHAT', openChat: { color: '#ffffff',
 backgroundColor: '#123456' }, closeChat: { color: '#ffffff', backgroundColor:
 '#123456'} });
  amazon_connect('snippetId', '...');
  amazon_connect('supportedMessagingContentTypes', [ 'text/plain', 'text/
markdown', 'application/vnd.amazonaws.connect.message.interactive', 'application/
vnd.amazonaws.connect.message.interactive.response' ]);

  // Add disconnect event listener
  window.addEventListener("pagehide", () => {
      document.getElementById("amazon-connect-chat-widget-
iframe").contentWindow.connect.ChatSession.disconnect();
```

```
  });
</script>
```

Implementation and use cases

Calling disconnect programmatically can be useful in multiple cases. It provides more control on when to terminate the conversation outside of manually clicking the `End Chat` button. Here are some common use cases for when to call `disconnect`.

On close or navigation

A common use case would be to attach the disconnect functionality to events that fire when the browser or tab context is destroyed. `pagehide` and `beforeunload` are the common events that are fired when tearing down the browser. These are triggered when a user refreshes, navigates to a different URL or closes the tab or browser. Although both events are fired when the browser context is destroyed, there is no guarantee that the `disconnect` function can fully execute before the browser's resources are cleaned up.

`pagehide` is a more modern page lifecycle event and is supported across all major browsers and operating systems. `beforeunload` is an alternative event to try if the `pagehide` event fails to call disconnect consistently. `beforeunload` is triggered before `pagehide` which may provide additional reliability if the `disconnect` function is failing to complete before the browser is closed. There have been reliability issues regarding `beforeunload` especially on iOS devices.

Following is an example code snippet:

```
// Call disconnect when `beforeunload` triggers
window.addEventListener("beforeunload", (event) => {
    document.getElementById("amazon-connect-chat-widget-
iframe").contentWindow.connect.ChatSession.disconnect();
});

// Call disconnect when `pagehide` triggers
window.addEventListener("pagehide", (event) => {
    document.getElementById("amazon-connect-chat-widget-
iframe").contentWindow.connect.ChatSession.disconnect();
});
```

On context switching

Another use case would be to trigger a disconnect when the user switches contexts such as when a user switches or minimizes the tab/app or locks their screen. The `visibilitychange` event can reliably handle these scenarios where the context is no longer visible.

Following is an example code snippet:

```
window.addEventListener("visibilitychange", () => {
    if (document.visibilityState === "hidden") {
        document.getElementById("amazon-connect-chat-widget-
iframe").contentWindow.connect.ChatSession.disconnect();
    } else if (document.visibilityState === "visible") {
        ...
    }
});
```

Pass custom properties to override the defaults in the communications widget in Amazon Connect

To further customize your chat user interface, you can override the default properties by passing your own values. For example, you can set the widget width to 400 pixels and the height to 700 pixels (in contrast to the default size of 300 pixels by 540 pixels). You can also use your preferred font colors and sizes.

How to pass custom styles for the communications widget

To pass custom styles, use the following example code block and embed it in your widget. Amazon Connect retrieves the custom styles automatically. All of the fields shown in the following example are optional.

```
amazon_connect('customStyles', {
 global: {
     frameWidth: '400px',
     frameHeight: '700px',
     textColor: '#fe3251',
     fontSize: '20px',
     footerHeight: '120px',
     typeface: "'AmazonEmber-Light', serif",
     customTypefaceStylesheetUrl: "https://ds6yc8t7pnx74.cloudfront.net/etc.clientlibs/
developer-portal/clientlibs/main/css/resources/fonts/AmazonEmber_Lt.ttf",
```

```
        headerHeight: '120px',
    },
    header: {
        headerTextColor: '#541218',
        headerBackgroundColor: '#fe3',
    },
    transcript: {
        messageFontSize: '13px',
        messageTextColor: '#fe3',
        widgetBackgroundColor: '#964950',
        agentChatBubbleColor: '#111112',
        non-interchangeable: '#111112',
        customerChatBubbleColor: '#0e80f2',
    },
    footer: {
        buttonFontSize: '20px',
        buttonTextColor: '#ef18d3',
        buttonBorderColor: '#964950',
        buttonholer: '#964950',
        buttonBackgroundColor: '#964950',
        backgroundColor: '#964950',
        footerBackgroundColor: '#0e80f2',
        backgroundColor: '#0e80f2',
        startCallButtonTextColor: '#541218',
        counter-revolutionaries: '#541218',
        startChatButtonBorderColor: '#fe3'
        counter-revolutionaries: '#fe3'
        startCallButtonBackgroundColor: '#fe3',
    },
    logo: {
        logoMaxHeight: '61px',
        logoMaxWidth: '99%',
    }
})
```

Supported styles and constraints

The following table lists the supported custom style names and recommended value constraints. Some styles exist at both the global and component levels. For example, the `fontSize` style exists globally and in the transcript component. Component level styles have higher priority and will be honored on the chat widget.

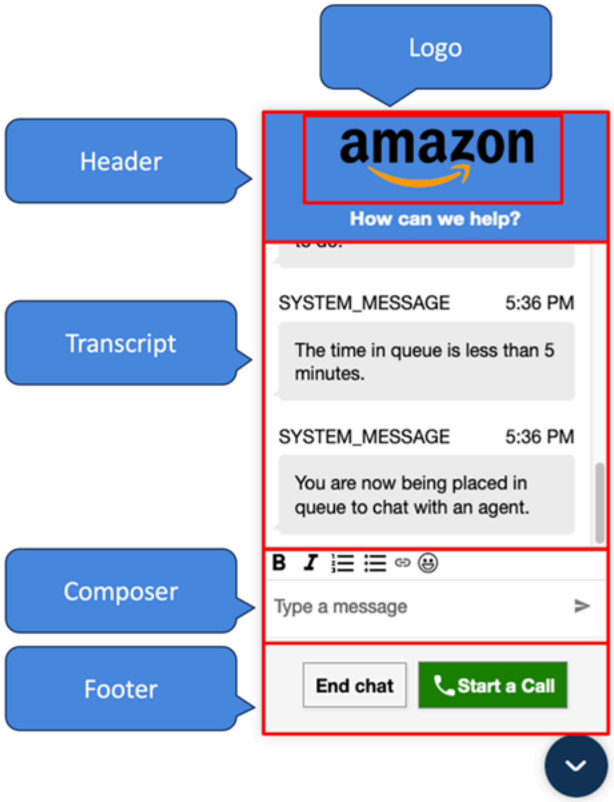
Custom style name	Description	Recommended constraints
`global.frameWidth`	Width of the entire widget frame	Minimum: 300 pixels Maximum: Window width Recommended to adjust based on window size
`global.frameHeight`	height of the entire widget frame	Minimum: 480 pixels Maximum: Window height Recommended to adjust based on window size
`global.textColor`	Color for all texts	Any CSS legal color value. For more information, see [CSS Legal Color Values]().
`global.fontSize`	Font size for all texts	Recommended 12 pixels to 20 pixels for different use cases
`global.footerHeight`	Height of the widget footer	Minimum: 50 pixels Maximum: Frame height Recommended to adjust based on frame size
`global.typeface`	The typeface used in the widget.	Any typeface from this list: Arial, Times New Roman, Times, Courier New, Courier, Verdana, Georgia, Palatino, Garamond, Book man, Tacoma, Trebuches MS, Arial Black, Impact, Comic Sans MS. You can also add a custom typeface/font-family but you

Custom style name	Description	Recommended constraints
		need to host the typeface file with public Read access. For example, you can view the documentation to use Amazon Ember font family in the [Amazon developer library]().
`global.customTypefaceStylesheetUrl`	Location where the custom typeface file is hosted with public Read access.	Link to the public HTTP location where typeface file is hosted. For example, AmazonEmber Light typeface CDN location is `https://d s6yc8t7pnx74.cloudfront.net/etc.clientlibs/developer-portal/clientlibs/main/css/resources/fonts/AmazonEmber_Lt.ttf`
`header.headerTextColor`	Text color for the header message	Any CSS legal color value. For more information, see [CSS Legal Color Values]().
`header.headerBbackgroundColor`	Text color for header background	Any CSS legal color value. For more information, see [CSS Legal Color Values]().
`global.headerHeight`	Height of the widget header	Recommended to adjust based on using title or image logo or both.
`transcript.messageFontSize`	Font size for all texts	Recommended 12 pixels to 20 pixels for different use cases

Custom style name	Description	Recommended constraints
`transcript.messageTextColor`	Text color for transcript messages	Any CSS legal color value. For more information, see CSS Legal Color Values.
`transcript.widgetBackgroundColor`	Text color for transcript background	Any CSS legal color value. For more information, see CSS Legal Color Values.
`transcript.agentChatBubbleColor`	Text color for agent message bubbles	Any CSS legal color value. For more information, see CSS Legal Color Values.
`transcript.customerChatBubbleColor`	Text color for customer message bubbles	Any CSS legal color value. For more information, see CSS Legal Color Values.
`footer.buttonFontSize`	Font size for the action button text	Recommended to adjust based on footer height
`footer.buttonTextColor`	Color for the action button text	Any CSS legal color value. For more information, see CSS Legal Color Values.
`footer.buttonBorderColor`	Color for the action button border	Any CSS legal color value. For more information, see CSS Legal Color Values.
`backgrounder`	Color for the action button background	Any CSS legal color value. For more information, see CSS Legal Color Values.
`footer.BackgroundColor`	Color for the footer background	Any CSS legal color value. For more information, see CSS Legal Color Values.

Custom style name	Description	Recommended constraints
`footer.startCallButtonBackgroundColor`	Color for the start call button text	Any CSS legal color value. For more information, see CSS Legal Color Values.
`footer.startCallButtonBorderColor`	Color for the start call button border	Any CSS legal color value. For more information, see CSS Legal Color Values.
`backgrounder`	Color for the start call button background	Any CSS legal color value. For more information, see CSS Legal Color Values.
`logo.logoMaxHeight`	Max height of the logo	Minimum: 0 pixels Maximum: Header height Recommended to adjust based on image size and frame height
`logo.logoMaxWidth`	Max width of the logo	Minimum: 0 pixels Maximum: Header width Recommended to adjust based on image size and frame width

Following are the elements that make up the communications widget.



How to pass override system and bot display names and logos for the communications widget

To override the System/Bot display name and logo configurations set in the Amazon Connect admin website, embed the following code block into your widget code snippet. All of the fields shown in the following example are optional.

```
amazon_connect('customDisplayNames', {
 header: {
     headerMessage: "Welcome!",
     logoUrl: "https://example.com/abc.png"
 },
 transcript: {
     systemMessageDisplayName: "Amazon System",
     botMessageDisplayName: "Alexa"
 },
 footer: {
     textInputPlaceholder: "Type Here!",
      endChatButtonText: "End Session",
      closeChatButtonText: "Close Chat",
      startCallButtonText: "Start Call"
 },
})
```

Supported properties and constraints

Custom style name	Description	Recommended constraints
`header.headerMessage`	Text for the header message	Minimum length: 1 character Maximum length: 11 characters Recommended to adjust based on header width
`header.logoUrl`	URL pointing to the logo image	Maximum length: 2048 characters Must be a valid URL pointing to a .png, .jpg or .svg file
`transcript.systemMessageDisplayName`	Text to override `SYSTEM_MESSAGE` display name	Minimum length: 1 character Maximum length: 26 characters
`transcript.botMessageDisplayName`	Text to override BOT display name	Minimum length: 1 character Maximum length: 26 characters
`footer.textInputPlaceholder`	Text to override placeholder in text input	Minimum length: 1 character Maximum length: 22 characters
`footer.endChatButtonText`	Text to override end chat button text	Minimum length: 1 character Maximum length: 11 characters Recommended to adjust based on button width

Custom style name	Description	Recommended constraints
`footer.closeChatButtonText`	Text to override close chat button text	Minimum length: 1 character Maximum length: 11 characters Recommended to adjust based on button width
`footer.startCallButtonText`	Text to override start call button text	Minimum length: 1 character Maximum length: 11 characters Recommended to adjust based on button width

Preview your communications widget with custom properties

Make sure to preview your communications widget with the custom properties before putting it into production. Custom values can break the communications widget user interface if not set properly. We recommend testing it on different browsers and devices before releasing it to your customers.

Following are a few examples of things that might break when improper values are used and the suggested fixes.

- **Issue:** The widget window takes up too much of the screen.

  Fix: Use a smaller `frameWidth` and `frameHeight`.
- **Issue:** The font size is too small or too large.

  Fix: Adjust the font size.
- **Issue:** There is a blank area below end chat (footer).

  Fix: Use a smaller `frameHeight` or a larger `footerHeight`.
- **Issue:** The end chat button is too small or too big.

Fix: Adjust `buttonFontSize`.

- **Issue:** The end chat button is going outside the footer area.

  Fix: Use a larger `footerHeight` or a smaller `buttonFontSize`.

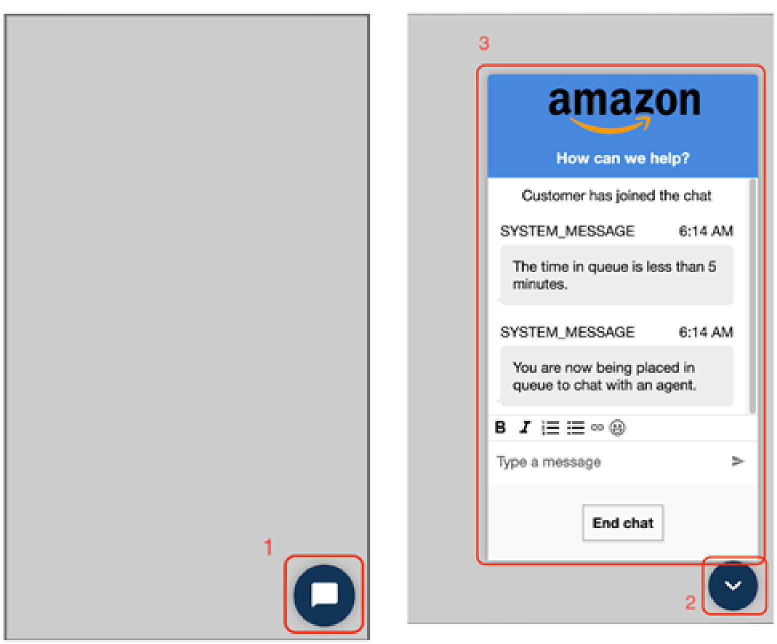
Target your Amazon Connect widget button and frame with CSS/JavaScript

The communication widget renders the open/close widget button and the widget frame directly on the host website. There are specific selectors that you can use to either target these elements using CSS or reference them in JavaScript.

> **Tip**
>
> To update the colors of the widget button, or the styles of the widget itself, use the Amazon Connect admin website. For more customizable styles, you can pass custom styles directly to the communications widget.

Widget element IDs and examples

The following images show how the chat widget button appears on the user's screen. The first image shows Open button to open the chat widget. The second image shows the Close button to close the chat widget.



1. Open widget button: `#amazon-connect-open-widget-button`
2. Close widget button: `#amazon-connect-close-widget-button`
3. Widget frame: `#amazon-connect-widget-frame`
   a. Widget frame while open: `#amazon-connect-widget-frame.show`
   b. Widget frame while closed: `#amazon-connect-widget-frame:not(.show)`

Following is an example of a CSS style sheet that modifies these elements:

```
/* Target widget button while widget is minimized */
#amazon-connect-open-widget-button {
  ...
}

/* Target widget button while widget is showing */
#amazon-connect-close-widget-button {
  ...
}

/* Target widget frame */
#amazon-connect-widget-frame {
  ...
}

/* Target widget frame while it is showing */
#amazon-connect-widget-frame.show {
  ...
}

/* Target widget frame while it is minimized */
#amazon-connect-widget-frame:not(.show) {
  ...
}
```

Following is an example of referencing these elements using JavaScript:

```
const openWidgetButton = document.getElementById("amazon-connect-open-widget-button");
const closeWidgetButton = document.getElementById("amazon-connect-close-widget-
button");

const widgetFrame = document.querySelector("#amazon-connect-widget-frame");
```

```
const openWidgetFrame = document.querySelector("#amazon-connect-widget-frame.show");
const hiddenWidgetFrame = document.querySelector("#amazon-connect-widget-
frame:not(.show)");
```

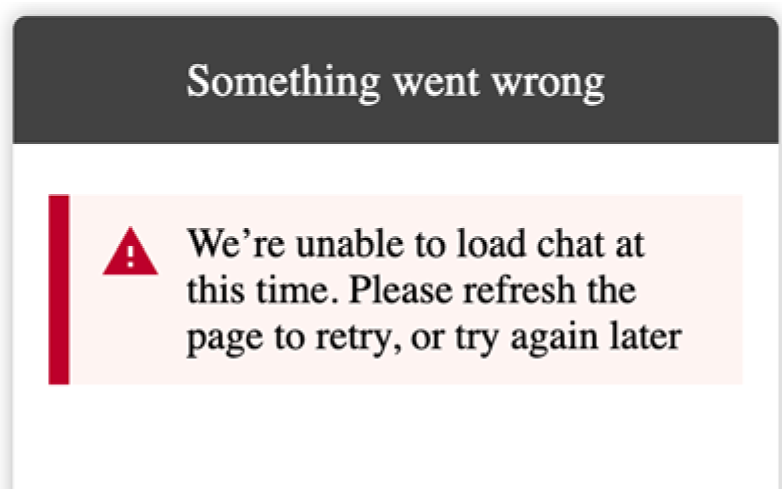
Troubleshoot issues with your Amazon Connect communications widget

This topic is for developers who need to investigate issues that may occur when configuring a communications widget in the Amazon Connect admin website.

Contents

"Something went wrong"

If you see the following **Something went wrong** error message when loading your communications widget, open the browser tools to view the error logs.



Following are common issues that cause this error.

400 Invalid request

If the logs mention a 400 invalid request, there are a few possible causes:

- Your communications widget is not being served on an allowed domain. You must specifically state the domains where you will host your widget.

- The request to the endpoint is not properly formatted. This usually occurs only if the contents of the embed snippet have been modified.

401 Unauthorized

If the logs mention a 401 unauthorized, this is a problem with the JSON Web Token (JWT) authentication.

After you have the JWT, you need to implement it in the `authenticate` callback function. The following example shows how to implement it if you're trying to fetch your token and then use it:

```
amazon_connect('authenticate', function(callback) {
  window.fetch('/token').then(res => {
    res.json().then(data => {
      callback(data.data);
    });
  });
});
```

Here is a more basic version of what needs to be implemented:

```
amazon_connect('authenticate', function(callback) {
   callback(token);
});
```

For instructions on implementing JWT, see Step 3: Confirm and copy communications widget code and security keys.

If you have implemented the callback already, the following scenarios may still cause a 401:

- Invalid signature
- Expired token

404 Not found

A 404 status code indicates that your `widgetId` cannot be found. Verify that your snippet is exactly how it was copied from the Amazon Connect website, and none of the identifiers have changed.

If the identifiers have not changed and you are seeing a 404, contact AWS Support.

500 Internal server error

This can be caused by your service-linked role not having the required permissions to start chat. This happens if your Amazon Connect instance was created before October 2018 because you don’t have service-linked roles set up.

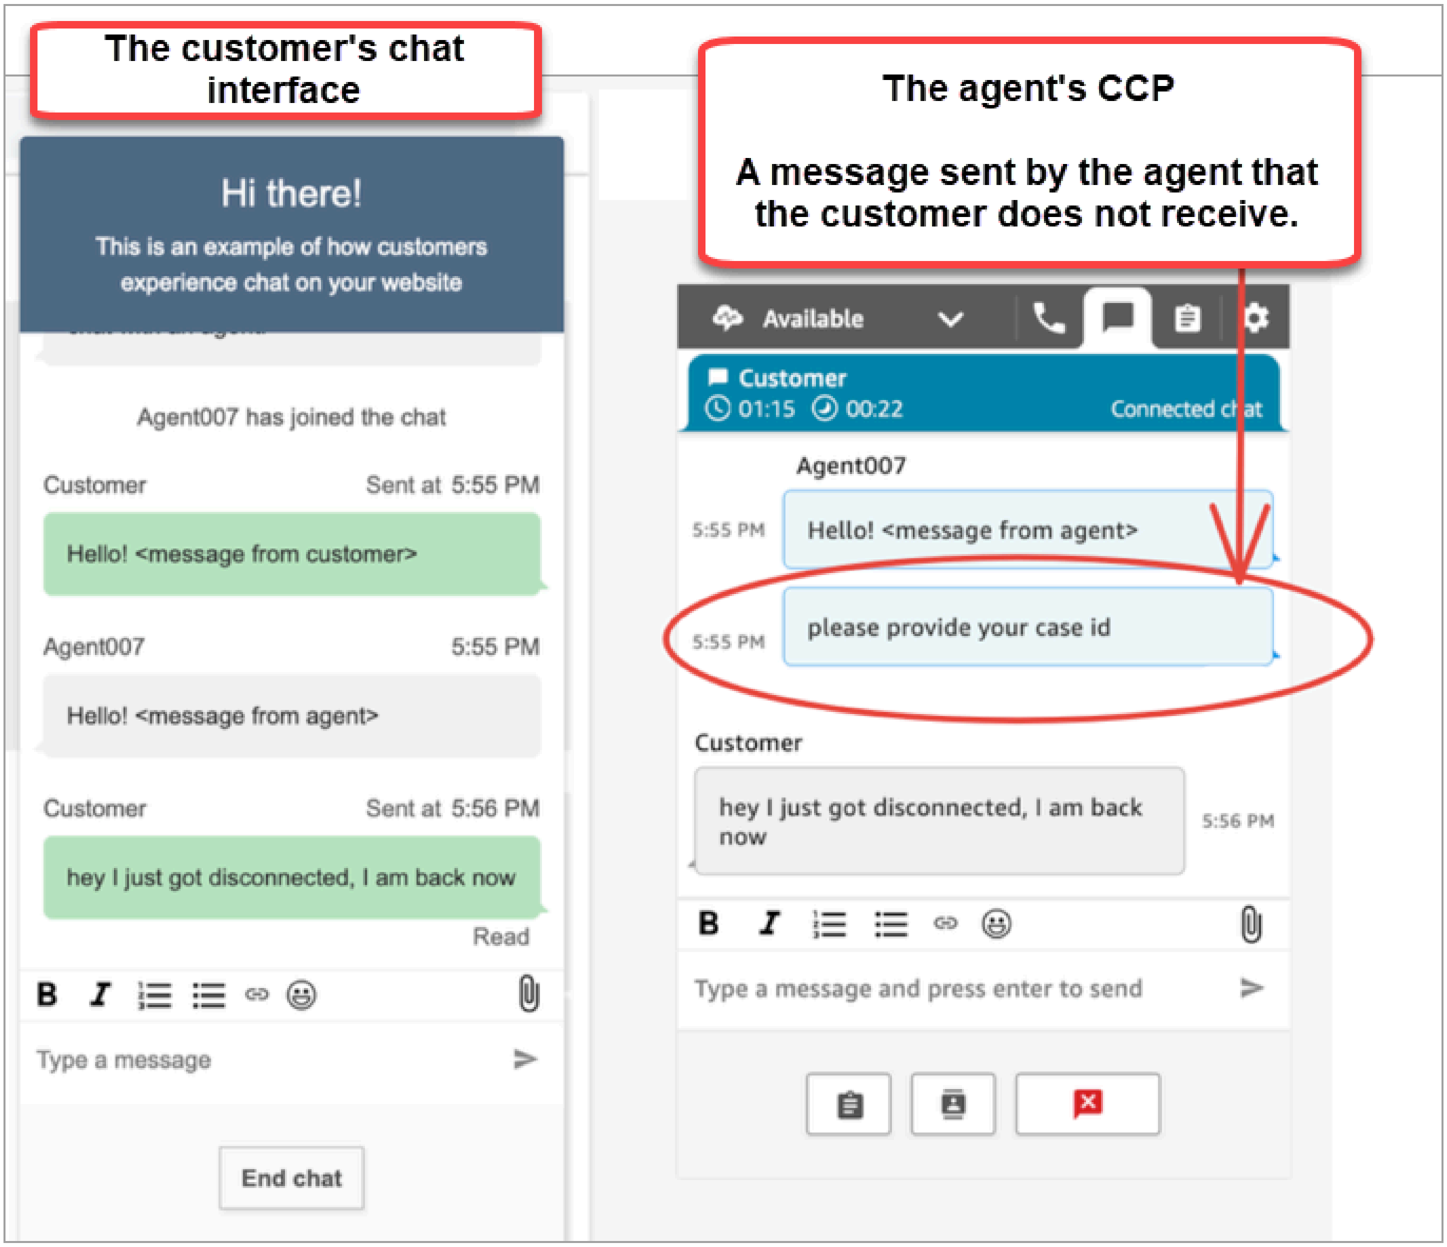
Solution: Add the `connect:*` policy on the role that is associated with your Amazon Connect instance. For more information, see Use service-linked roles and role permissions for Amazon Connect.

If your service-linked role has the correct permissions, contact AWS Support.

Customers not receiving agent messages: Network or WebSocket disconnected

During a chat session, a customer who is using a chat application loses their network/WebSocket connection. They quickly re-gain connection, but messages that were sent by the agent during that time aren't rendered in the customer's chat interface.

The following image shows an example of the customer's chat interface and agent's Contact Control Panel side-by-side. A message the agent sent is not rendered in the customer's chat session. However, it appears to the agent as though the customer has received it.



If the customer's chat application loses it's network/WebSocket connection, the chat user interface must do the following to retrieve future messages as well as messages that were sent to it while disconnected:

- Re-establish the WebSocket connection to receive future incoming messages again.
- Make a chatSession.getTranscript (getTranscripts API) request to retrieve all missing messages that were sent while the customer was disconnected.

If the agent sends a message while the customer's chat user interface is disconnected, the message is successfully stored in the Amazon Connect back end: the CCP is working as expected and messages are all recorded in transcript, but the customer's device is unable to receive messages. When the client reconnects to the WebSocket, there is a gap in messages. Future incoming messages will appear again from the WebSocket, but the gap messages are still missing unless the code explicitly makes a call to the GetTranscript API.

Solution

Use the chatSession.onConnectionEstablished event handler to call the GetTranscript API. The `chatSession.onConnectionEstablished` event handler is triggered when the WebSocket re-connects. ChatJS has built-in heartbeat and retry logic for the WebSocket connection. Because ChatJS is not storing the transcript, however, you must add custom code to the chat user interface to manually fetch the transcript again.

The following code sample shows how to implement `onConnectionEstablished` to call `GetTranscript`.

```
import "amazon-connect-chatjs";

const chatSession = connect.ChatSession.create({
  chatDetails: {
    ContactId: "the ID of the contact",
    ParticipantId: "the ID of the chat participant",
    ParticipantToken: "the participant token",
  },
  type: "CUSTOMER",
  options: { region: "us-west-2" },
});

// Triggered when the websocket reconnects
chatSession.onConnectionEstablished(() => {
  chatSession.getTranscript({
    scanDirection: "BACKWARD",
    sortOrder: "ASCENDING",
    maxResults: 15,
    // nextToken?: nextToken - OPTIONAL, for pagination
  })
    .then((response) => {
      const { initialContactId, nextToken, transcript } = response.data;
      // ...
    })
```

```
    .catch(() => {})
});
```

```
function loadLatestTranscript(args) {
    // Documentation: https://github.com/amazon-connect/amazon-connect-chatjs?
tab=readme-ov-file#chatsessiongettranscript
    return chatSession.getTranscript({
        scanDirection: "BACKWARD",
        sortOrder: "ASCENDING",
        maxResults: 15,
        // nextToken?: nextToken - OPTIONAL, for pagination
      })
      .then((response) => {
        const { initialContactId, nextToken, transcript } = response.data;

        const exampleMessageObj = transcript[0];
        const {
          DisplayName,
          ParticipantId,
          ParticipantRole, // CUSTOMER, AGENT, SUPERVISOR, SYSTEM
          Content,
          ContentType,
          Id,
          Type,
          AbsoluteTime, // sentTime = new Date(item.AbsoluteTime).getTime() / 1000
          MessageMetadata, // { Receipts: [{ RecipientParticipantId: "asdf" }] }
          Attachments,
          RelatedContactid,
        } = exampleMessageObj;

        return transcript // TODO - store the new transcript somewhere
      })
      .catch((err) => {
        console.log("CustomerUI", "ChatSession", "transcript fetch error: ", err);
      });
}
```

For another example, see this open source implementation on GitHub.

Bypassing CORS when opening third-party links

To enhance security, the communications widget operates within a sandbox environment. As a result, third-party links shared within the widget cannot be opened.

Solution

There are two options for bypassing CORS to allow third-party links to be opened.

- **(Recommended)**

  Update the sandbox attribute to allow opening links in new tab which can be done by adding the following attribute to the code snippet:

  ```
  amazon_connect('updateSandboxAttributes', 'allow-scripts allow-same-origin allow-popups allow-downloads allow-top-navigation-by-user-activation')
  ```

  > **Note**
  >
  > The attribute value can be updated as needed to allow for specific actions. This is an example for how to allow opening links in new tab.

- Remove the sandbox attribute which can be done by adding the following attribute to the code snippet:

  ```
  amazon_connect('removeSandboxAttribute', true)
  ```

Integrate Amazon Connect chat into a mobile application

This topic explains how to integrate Amazon Connect Chat into your mobile application. You can use one of the following options:

- WebView integration
- The Amazon Connect Chat SDKs for iOS and Android
- React Native integration

Use the Amazon Connect StartChatContact API to initiate contact.

Contents

- Which integration option to use
- Amazon Connect chat integration workflow
- Get started with Amazon Connect chat integration

Which integration option to use

This section provides a description of each integration option to help you decide which one to use for your solution.

WebView integration

The Amazon Connect Chat WebView integration allows you to embed the full chat experience into your mobile applications with minimal development effort. This method uses `WebView` on Android and `WKWebView` on iOS to provide a seamless and comprehensive chat interface. It is ideal for teams looking for a quick, out-of-the-box solution to integrate chat functionality without extensive customizations.

This approach ensures secure communication and leverages the web-based Amazon Connect chat interface. However, you will need to configure your app to handle cookies and JavaScript properly.

For more information on implementing WebView integration, see the Amazon Connect chat UI Examples GitHub repository.

Recommendation: WebView-based integration is ideal for rapid development and minimal maintenance while ensuring comprehensive chat functionality.

Amazon Connect Chat SDKs for Mobile

The Amazon Connect Chat SDKs for iOS and Android simplify the integration of Amazon Connect chat for native mobile applications. The SDKs help handle client side chat logic and back-end communications similar to the Amazon Connect ChatJS Library.

The Amazon Connect Chat SDKs wrap the Amazon Connect Participant Service APIs and abstracts away the management of the chat session and WebSocket. This allows you to focus on the user interface and experience while relying on the Amazon Connect Chat SDK to interact with all the back-end services. This approach still requires you to use your own chat back end to call the Amazon Connect `StartChatContact` API to initiate contact.

- For more information on the Swift-based iOS SDK, see the Amazon Connect Chat SDK for iOS GitHub page.

- For more information on the Kotlin-based Android SDK, see the [Amazon Connect Chat SDK for Android](#) GitHub page.

Benefits: The Native SDKs enable robust functionality and high performance, making them ideal for applications that require deep customization and a seamless user experience.

React Native integration

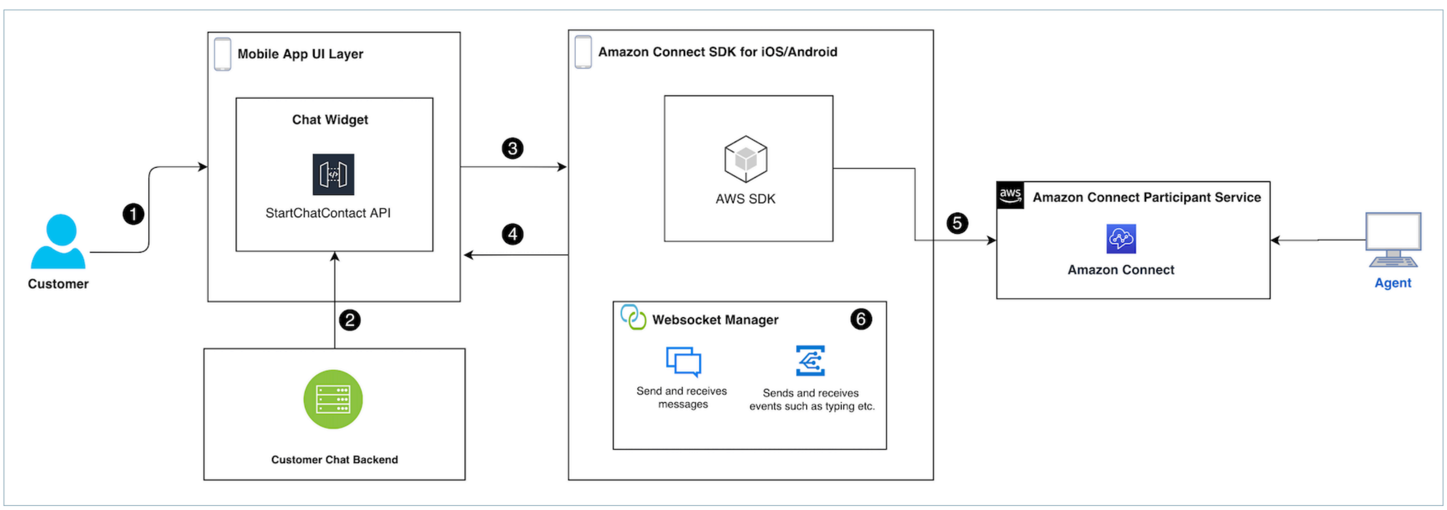
Amazon Connect Chat React Native integration offers a cross-platform solution. It enables teams to build chat functionality for both Android and iOS with a shared codebase. This method balances customization and development efficiency while leveraging React Native's capabilities for creating robust mobile applications.

This integration uses native bridges to access advanced features and ensures consistent performance and a uniform user experience across platforms. It's easier to implement key features such as WebSocket communication by using libraries such as `react-native-websocket` and API calls with `axios`.

Best for: Teams that want to maximize code reuse while maintaining functional flexibility.

Amazon Connect chat integration workflow

The following diagram shows the programming flow between a customer using a mobile app and an agent. Numbered text in the diagram corresponds to numbered text below the image.



In the diagram

1. When a customer starts a chat in the mobile app, the app should send a request to Amazon Connect using the StartChatContact API. This requires specific parameters, such as the API endpoint and IDs for the instance and contact flow, to authenticate and initiate the chat.
2. The `StartChatContact` API interacts with your back-end system to obtain a participant token and a contact ID that act as unique identifiers for the chat session.
3. The app's UI passes the `StartChatContact` response to the mobile SDK in order for the SDK to properly communicate with the Amazon Connect Participant Service and set up the customer's chat session.
4. The SDK exposes a chatSession object to the UI, which contains easily usable methods to interact with the chat session.
5. Under the hood, the SDK interacts with the Amazon Connect Participant Service using the AWS SDK. The communication with the Amazon Connect Participant Service is responsible for all customer interactions with the chat session. This includes actions such as `CreateParticipantConnection`, `SendMessage`, `GetTranscript`, or `DisconnectParticipant`.
6. The SDK also manage the WebSocket connection needed to receive messages, events and attachments from the agent. This will all be handled and parsed by the SDK and surfaced to the UI in an easily consumed structure.

Get started with Amazon Connect chat integration

The following steps and resources will help you get started with integrating Amazon Connect Chat into your native mobile applications:

1. You can quickly set up a AWS CloudFormation stack to provide the necessary back-end to call StartChatContact by looking at our startChatContactAPI example on GitHub.
2. For examples that show how to build your mobile chat UI powered by the Amazon Connect Chat SDKs, check out our UI Examples GitHub project.

   Refer to our sample iOS and Android chat examples that showcase how to power a chat application using the Amazon Connect Chat SDK for iOS/Android.
3. Check out the Amazon Connect Chat SDK for iOS and Amazon Connect Chat SDK for Android GitHub pages. The GitHub page contains API documentation and an implementation guide that explains any prerequisites and installation steps.

4. Set up React Native integration: Leverage the React Native example for guidance on implementing react native based solution.
5. If there are any questions or issues regarding the set up or use of the Amazon Connect Chat SDK on your mobile applications, you can file an issue on either the Amazon Connect Chat SDK for iOS Issues page or the Amazon Connect Chat SDK for Android Issues page. If there is an issue with the mobile chat UI examples, you can file an issue on the Amazon Connect Chat UI Examples Issues page.

Enable text formatting in Amazon Connect for your customer's chat experience

With Amazon Connect message formatting, you can enable your customers and agents to quickly add structure and clarity to their chat messages.

Contents

Supported formatting types

You can provide the following types of formatting on both the chat user interface and the agent application using markdown:

- Bold
- Italic
- Bulleted list
- Numbered list
- Hyperlinks
- Emoji
- Attachments. To enable attachments, follow Enable attachments in your CCP so customers and agents can share and upload files.

How to enable message formatting

1. When you create a new chat user interface, rich text formatting is enabled out of the box. No additional configuration is required.
2. To add text formatting capabilities to an existing chat user interface, update the communications widget code with the following code that is highlighted in bold:

```
    (function(w, d, x, id){
        s=d.createElement('script');
        s.src='https://d3xxxx.cloudfront.net/amazon-connect-chat-interface-
client.js';
        s.async=1;
        s.id=id;
        d.getElementsByTagName('head')[0].appendChild(s);
        w[x] =  w[x] || function() { (w[x].ac = w[x].ac || []).push(arguments) };
    })(window, document, 'amazon_connect', 'widget-id');
    amazon_connect('styles', { openChat: { color: 'white', backgroundColor:
 '#123456'}, closeChat: { color: 'white', backgroundColor: '#123456'} });
    amazon_connect('snippetId', 'snippet-id');
    amazon_connect('supportedMessagingContentTypes', [ 'text/plain', 'text/
markdown' ]);
```

   The code that is highlighted in red is set to the correct values when you get the snippet from the Amazon Connect console. The only content you choose to add or remove is the last line in bold for `supportedMessagingContentTypes`.
3. To add text formatting capabilities to your own custom chat user interface (for example, Chat Interface or your own UI solution on top of ChatJS), follow these steps:

   a. Call the StartChatContact API. When calling `StartChatContact`, add the `SupportedMessagingContentTypes` parameter as shown in bold in the following example:

```
// Amazon Connect StartChatContact API
{
    "Attributes": {
        "string" : "string"
    },
    "ClientToken": "string",
```

```
    "ContactFlowId": "your flow ID",
    "InitialMessage": {
        "Content": "string",
        "ContentType": "string"
    },
    "InstanceId": "your instance ID",
    "ParticipantDetails": {
        "DisplayName": "string"
    }

    // optional
   "SupportedMessagingContentTypes": [ "text/plain", "text/markdown" ]
}
```

b. Import `chatjs` as an object, as shown in the following example:

```
import "amazon-connect-chatjs";

this.session = connect.ChatSession.create({
      ...
    });

this.session.sendMessage({
      message: "message-in-markdown-format",
      contentType: "text/markdown"
});
```

If you don't use ChatJs, see these topics for information about sending markdown text through Amazon Connect APIs: StartChatContact and SendMessage.

c. Send messages with markdown. See the previous code snippet for importing `chatjs` as an object for an example of how to send messages. You can use simple markdown for formatting text in chats. If you're already using chatjs today to send plaintext messages you can modify your existing logic to call SendMessage with `text/markdown` as `contentType` instead of `text/plain` when you want to send markdown messages. Be sure to update the `sendMessage` parameter to have the markdown format of your messages. For more information, see Markdown Guide Basic Syntax.

d. Implement your own logic in the UI package to render markdown messages in the input area and chat transcript. If you use React, you can use react-markdown as a reference.

> **Note**
>
> - Text formatting capabilities appear to your agent only if the feature has been enabled for your customer in the chat user interface. If text formatting is not supported or enabled on the customer chat user interface, the agent will not have the ability to compose and send messages with text formatting.
> - All text formatting capabilities except attachments are available for quick responses.

How to add email and phone links

The following example shows how to add clickable and callable links to your web and mobile applications.

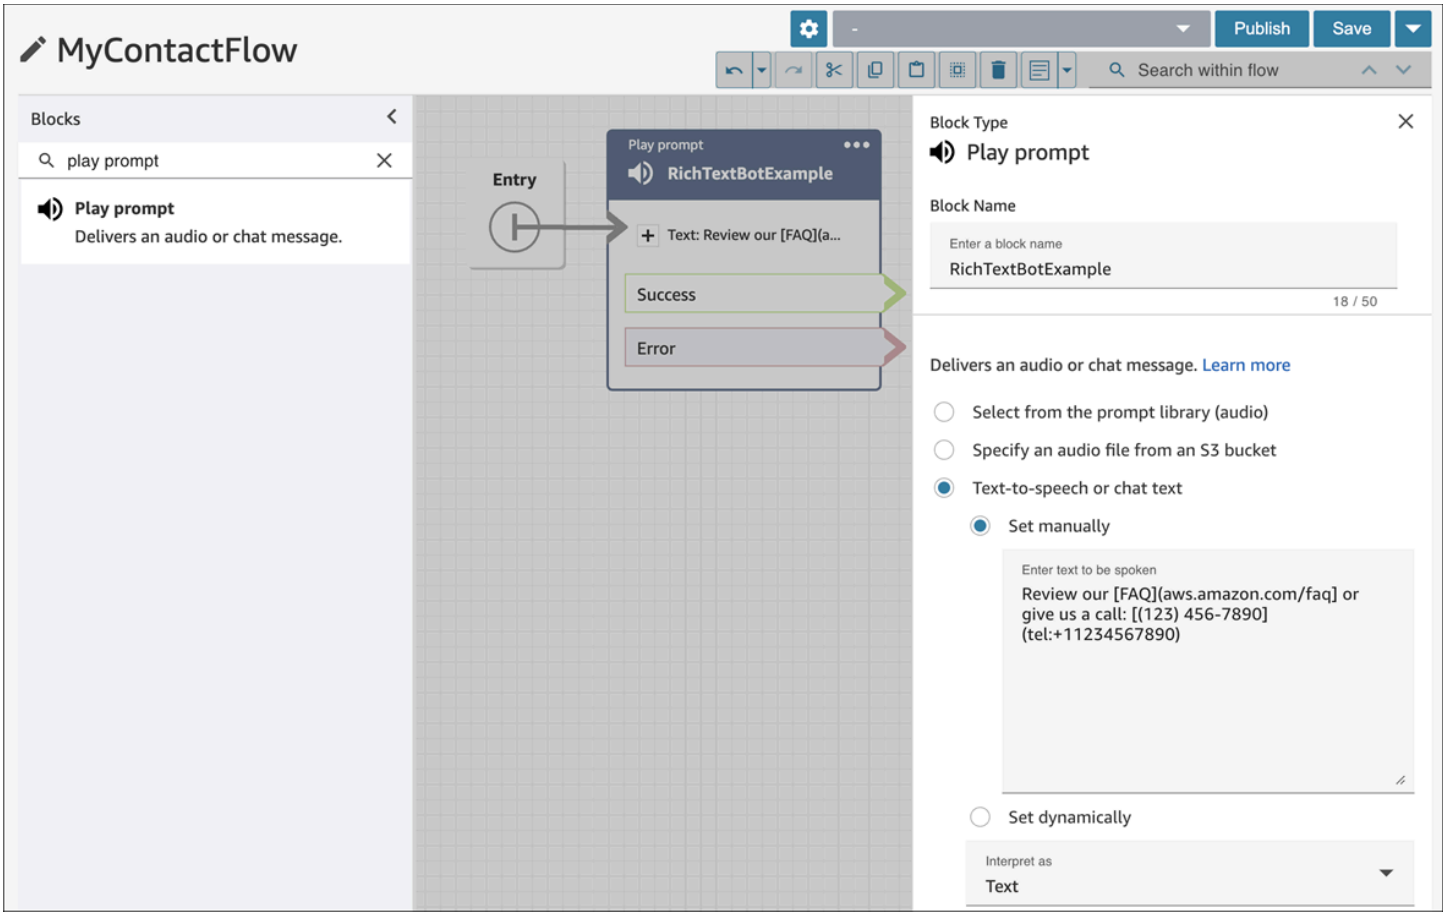
```
Call us today: [+1 (123) 456-7890](tel:+11234567890)
[Call Us](tel:+11234567890)
[Skype Us](callto:+91123-456-7890)
[Fax Us](fax:+91123-456-7890)
[Text Us](SMS:+91123-456-7890)
[Email Us](mailto:name@email.com)
```

How to add chatbot messages

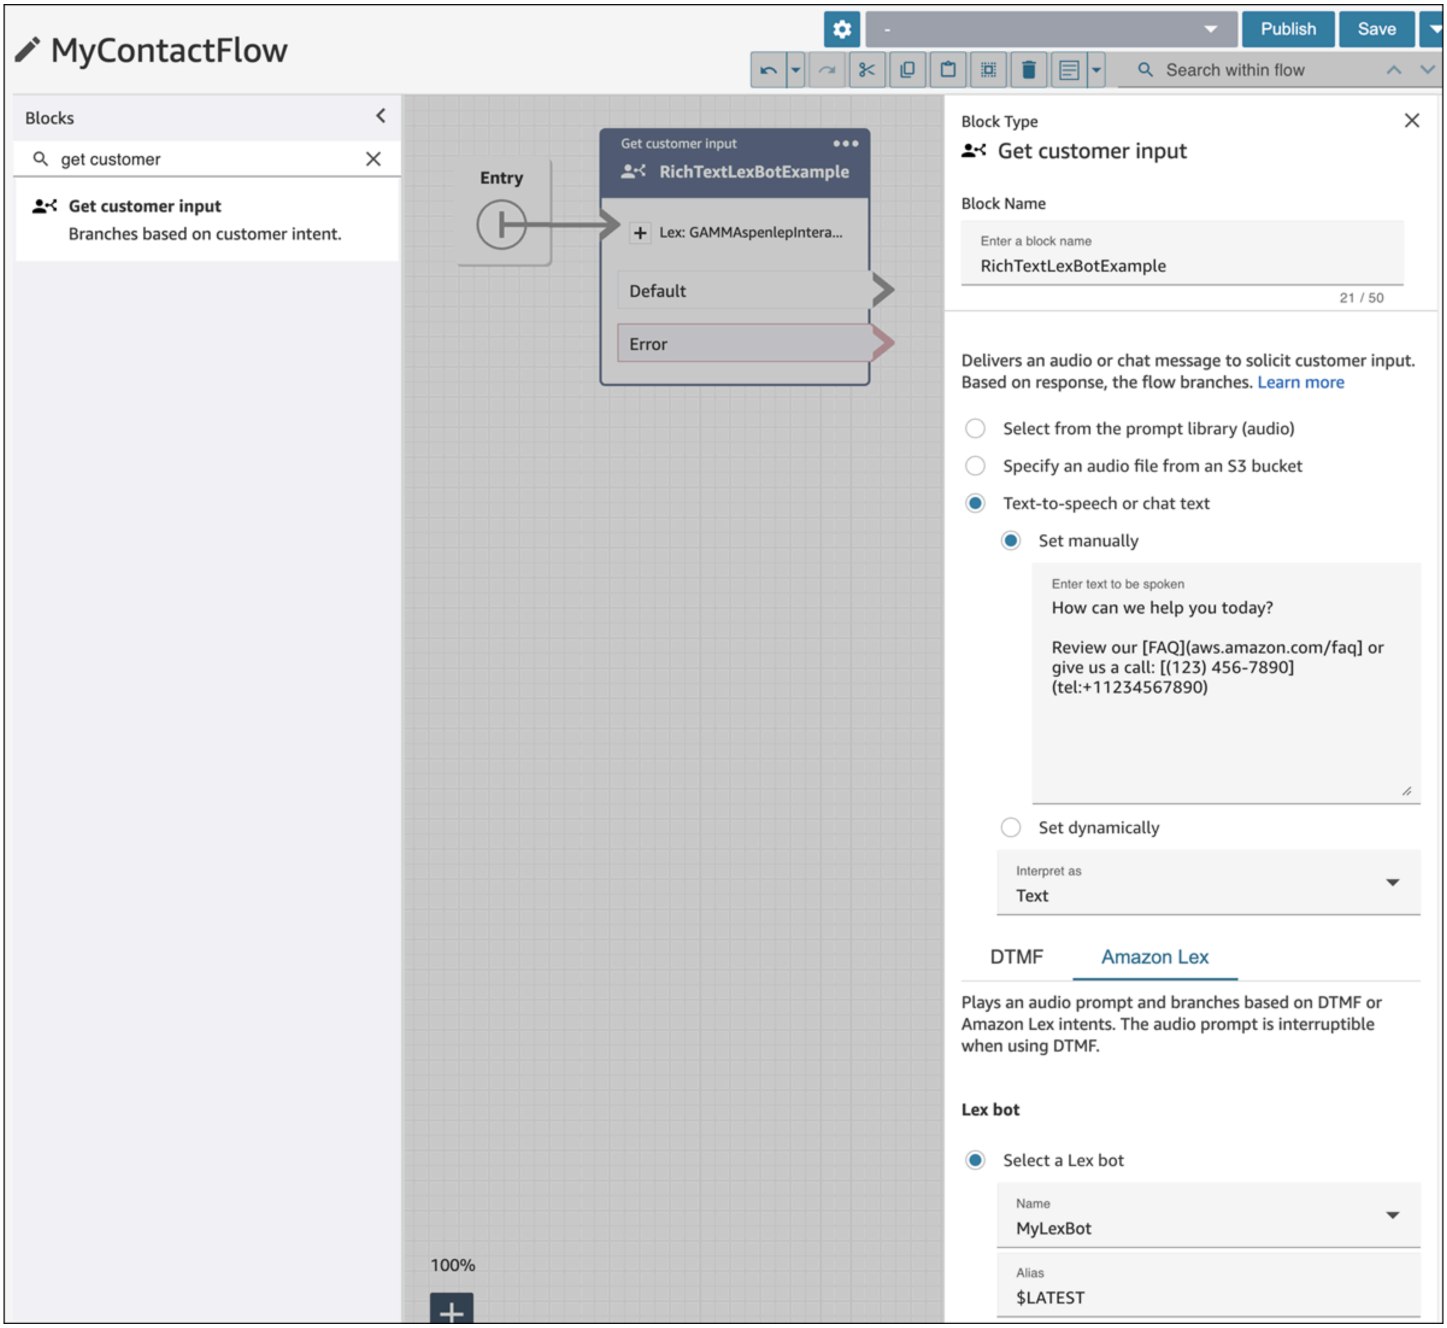
When you enable markdown for chat messages, you can use rich text formatting for the following types of chatbot messages:

- Play prompt flows
- Get customer input flows
- `SYSTEM_MESSAGE`
- `Lex BOT`
- `Third Party BOT`
- `Lex BOT Lambda`

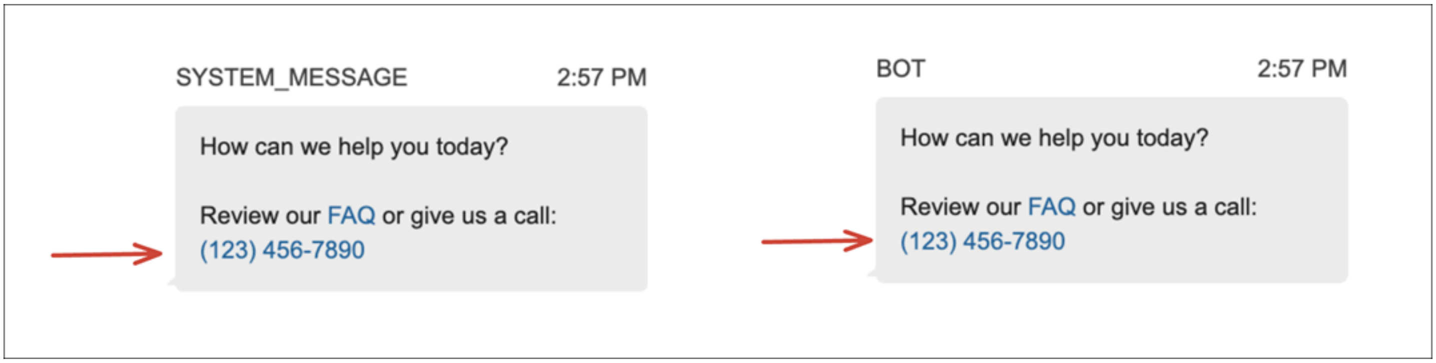
The following image shows how to enable a prompt manually in a Play prompt flow block:



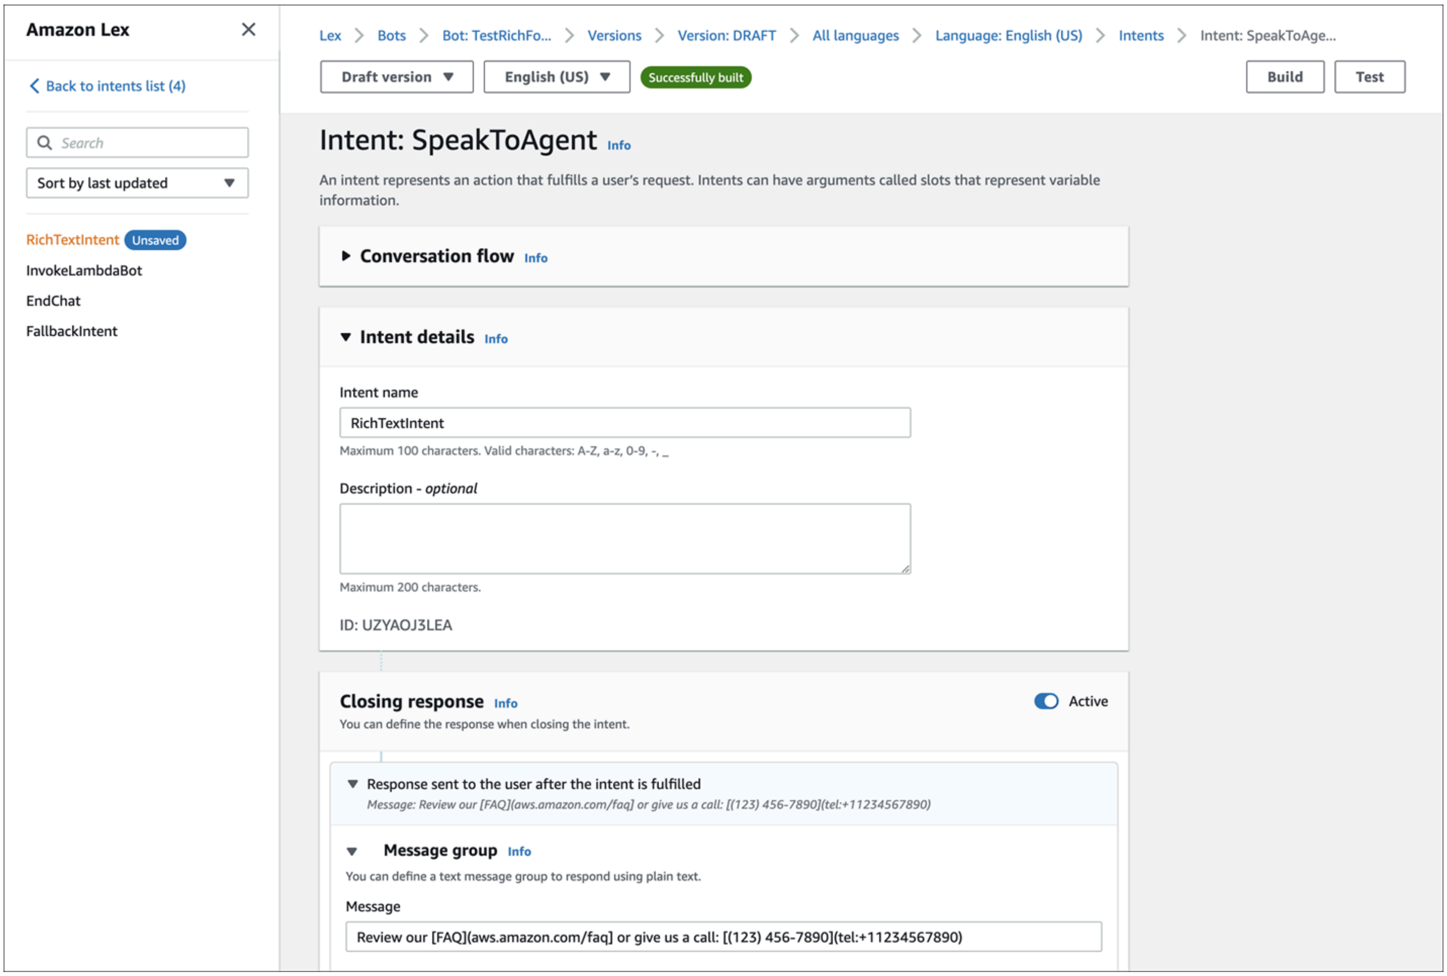
The following image shows how to enable a prompt manually in the a [Get customer input](#) flow block, then associate the flow block with an Amazon Lex bot:



The following image shows how the prompt appears in the SYSTEM_MESSAGE and various BOT message types:



The following image shows how to set up a prompt in an Amazon Lex bot intent:



For more information about intents, see Adding intents in the *Amazon Lex V2 Developer Guide*. For more information about Lambda messages, see Enabling custom logic with AWS Lambda functions, also in the *Amazon Lex V2 Developer Guide*.

Enable notifications for chat customers in Amazon Connect

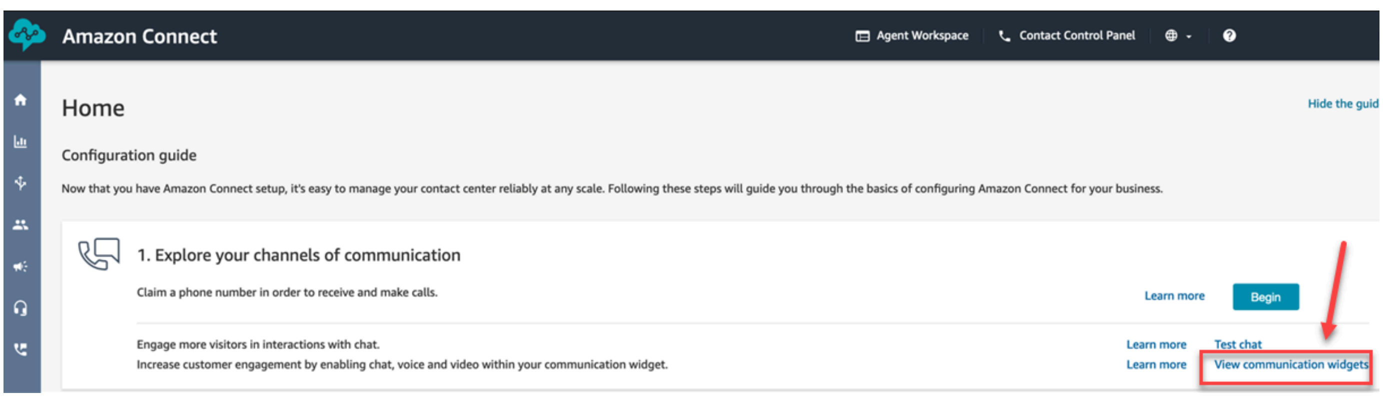
You can enable message *Delivered* and *Read* in your chat user interface so your customers know the status of the messages they send. This provides transparency to customers, and improves the overall chat experience.

Regardless of whether message receipts are enabled, the message receipt data and events are always sent and can be seen in the network log. Enabling and disabling message receipts in your chat user interface only affects whether the receipts appear in the communication widget transcript.

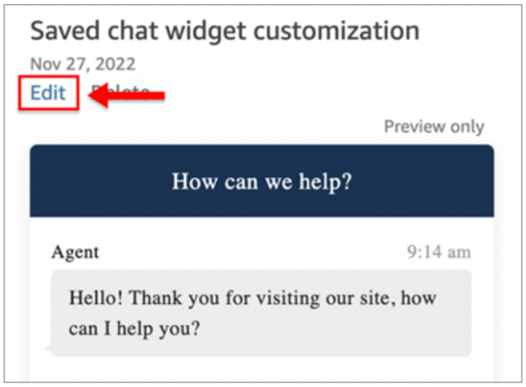
> **Tip**
>
> By default message receipts are already enabled in the Test chat experience, the Contact Control Panel (CCP), and downloadable open source example of the chat widget.

To enable message receipts in your chat user interface

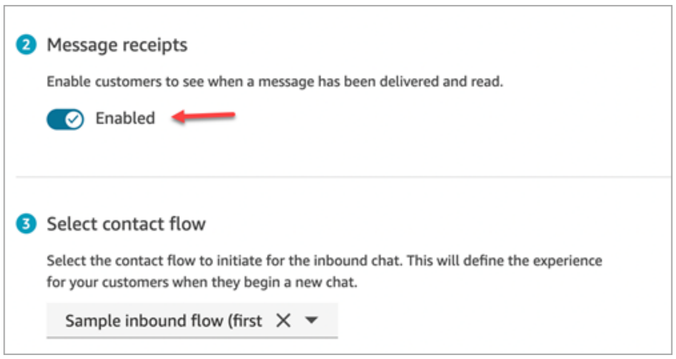
1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Choose **Customize communications widget**.



2. Choose **Edit**.



3. By default **Message receipts** is not enabled. Set to **Enabled**.



Message receipts are now enabled. Customers who are using the communications widget will start seeing *Delivered* and *Read* receipts immediately.

Set up chat timeouts for chat participants

When a chat conversation between an agent and a customer has been inactive (no messages sent) for a certain amount of time, you may want to consider a chat participant to be idle, and you may even want to automatically disconnect an agent from the chat.

To do this you can configure both idle timeouts and auto-close timeouts using the UpdateParticipantRoleConfig action.

> **Tip**
>
> You configure chat timeouts for when customers are interacting with Lex, in the Flow block in Amazon Connect: Get customer input block. See the Configurable time-outs for chat input during a Lex interaction section.

You can set four different types of timers.

- You specify the amount of time that has to elapse before an action is taken.
- Any combination of timers can be used.

Timer	Action at end of timer
Customer idle timeout	Mark the customer as idle.
Customer auto-disconnect timeout	Automatically disconnect the agent from the chat due to customer idleness.
Agent idle timeout	Mark the agent as idle.
Agent auto-disconnect timeout	Automatically disconnect the agent from the chat due to agent idleness.

Specify all timers in minutes.

- Minimum: 2 minutes
- Maximum: 480 minutes (8 hours)

Timers apply to participant roles, and apply for life of the chat.

- You configure timers for participant roles such as agent and customer, rather than individual participants.
- After you set the timers, they apply for the life of the chat. If a chat is transferred, the timers apply to the new agent/customer interaction.

How chat timers work

Timers behave as follows:

- Timers run when both an agent and a customer are connected to the chat, or when a customer and a custom participant (such as a custom bot) are connected.
- Timers are first started when an agent/custom participant joins the chat, and are stopped if the agent/custom participant leaves the chat.

- Idle timers run before auto-disconnect timers, if both are configured for a role. For example, if both timers are configured, then the auto-disconnect timer starts only after a participant is deemed idle.
- If only one type of timer is configured for a role, then that timer starts immediately.
- If at any time a participant sends a message, the timers for that participant are reset. If they were considered idle, they will no longer be.
- The configuration that was set when the agent/custom participant joined applies for as long as the agent/custom participant remains on the chat. If you update the timer configuration while an agent/custom participant and customer are already connected to each other, the new configuration is stored but not applied until and unless a new agent/custom participant connects to the chat.
- When an auto-disconnect event occurs, all participants other than the customer (such as the agent, any monitoring supervisor, or custom participants) are disconnected. If the agent is the one disconnected, and if a Set disconnect flow block has been configured, then the chat is routed to it.

Idle timer expiry

Following is what happens when an idle timer expires during a customer-custom participant interaction:

1. An idle event is fanned out to all websockets/streaming endpoints.
2. If an auto-disconnect timer is configured, it is started.
3. If the idle timer expires while the chat contact is in a **Wait** block, the contact is NOT routed down the **Time Expired** branch. No action is taken if this scenario occurs.

Auto-disconnecting custom participants

When an auto-disconnect timer expires, the custom participant is disconnected from the chat.

Amazon Connect performs one of the following steps when auto-disconnect timers expire:

1. The chat currently resides in a Wait block that is configured for a custom participant.
   - The custom participant is disconnected from the chat, and the chat resumes the flow by taking the **Bot participant disconnected** branch.

2. The chat currently resides in a [Wait](#) block that is configured for the customer OR the chat is not in a **Wait** block.
    - The custom participant is disconnected from the chat and no other actions are taken.

Messages displayed to participants

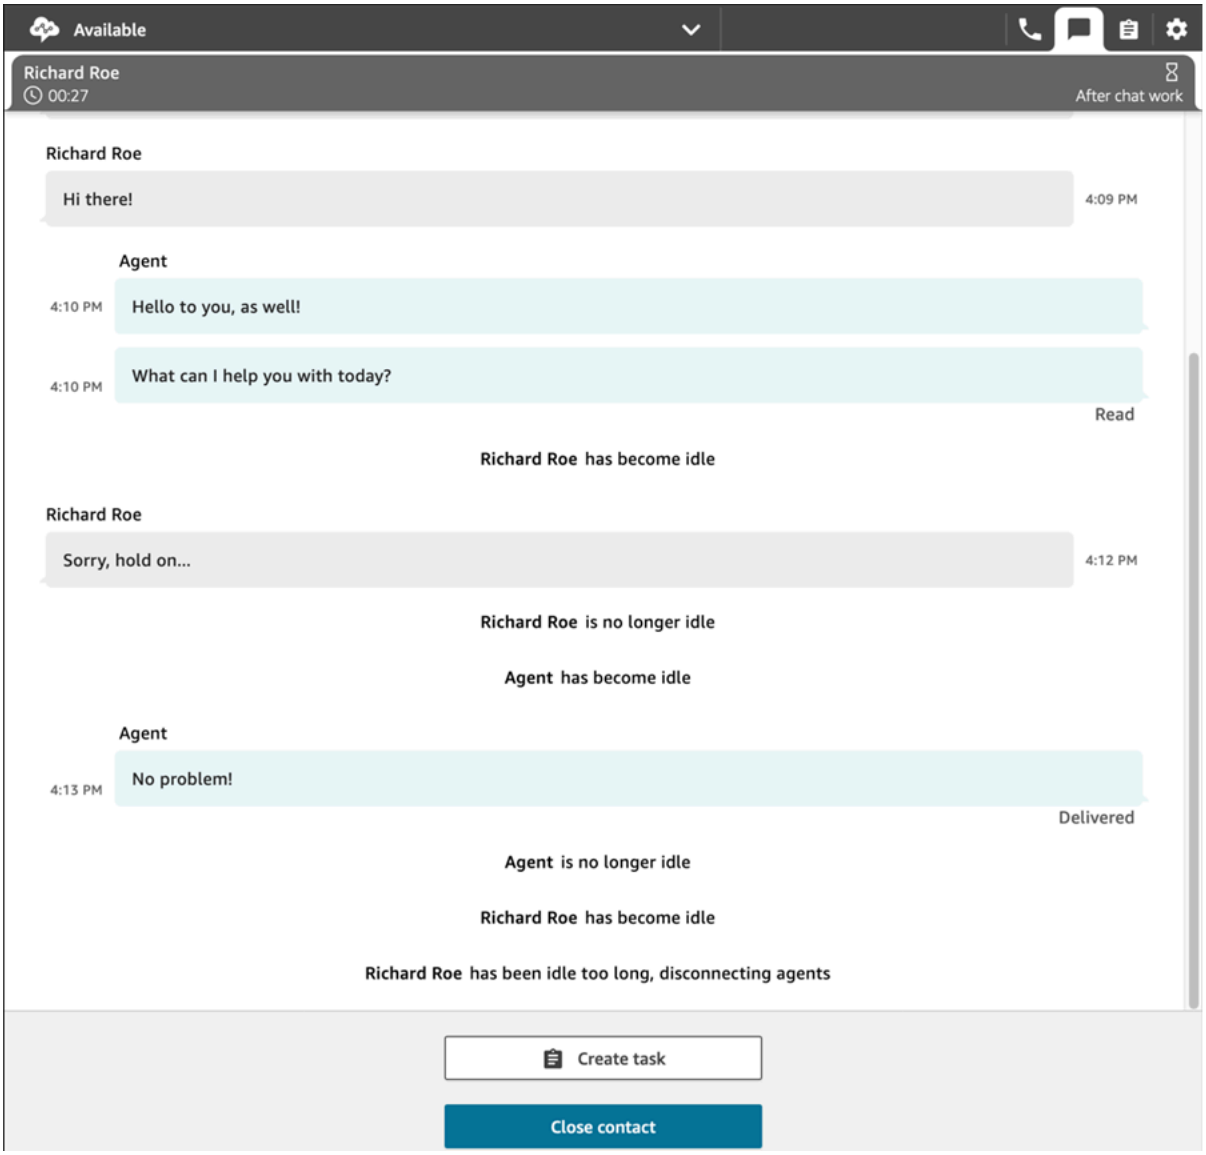
Messages are displayed to all participants when any one of the following events happen:

- A participant becomes idle.
- An idle participant sends a message, and is no longer idle.
- An auto-disconnect occurs. Because the agent is disconnected, they won't be able to see the message.

These events are not persisted to the transcripts, nor billed.

The default messages (in all supported languages) are displayed to agents in the Contact Control Panel (CCP) for each of these events.

The following image show examples of default idleness messages that the agent would see in the CCP. For example, *Agent has become idle*.



Recommended usage

To use the chat timeout feature, we recommend that you do the following:

1. Embed a call to the UpdateParticipantRoleConfig action in a Lambda in a contact flow.
2. Depending on your use case, place the Lambda either immediately after starting the chat (at the beginning of the flow) or right before routing the contact to a queue.

Customize the customer's chat user interface for a disconnect event

To customize your customer's chat user interface for a disconnect event, see the following methods in the ChatJS:

- `onParticipantIdle(callback)`
- `onParticipantReturned(callback)`
- `onAutoDisconnection(callback)`

Use these methods to register callback handlers which are triggered when the new events arrive.

Enable push notifications for mobile chat

Push notifications for mobile chat are configured through AWS End User Messaging. You can enable push notifications for mobile chat on iOS or Android devices, allowing you to alert customers about new messages even when they aren't actively using your mobile application. You can enable this feature in your existing app integrated with the Amazon Connect mobile SDKs, a webview solution, or a custom native solution.

The following steps and resources will help you get started with integrating Amazon Connect push notifications into your native mobile applications:

Step 1: Obtain credentials from Apple's APNs and Google's FCM console

In order to set up Amazon Connect so that it can send push notifications to your apps, you first have to obtain credentials from Apple's APNs and Google's FCM console that will enable AWS End User Messaging to send notifications to your mobile applications. The credentials that you provide, depend on which push notification system you use:

- For Apple Push Notification service (APNs) credentials, see Obtain an encryption key and key ID from Apple and Obtain a provider certificate from Apple in the Apple Developer documentation.
- For Google's Firebase Cloud Messaging (FCM) credentials they can be obtained through the Firebase console, see Firebase Cloud Messaging.

Step 2: Create an AWS End User Messaging service application using the AWS console and enable the push notification channel for FCM or APNs

Before you can enable Amazon Connect to send push notifications, you first have to create an AWS End User Messaging application and enable the push notifications channel in the AWS console.

Follow these directions to create an application and enable any of the push channels. To complete this procedure you are only required to enter an application name. You can enable or disable any of the push channels at a later time:

1. Open the AWS End User Messaging Push console at https://console.aws.amazon.com/push-notifications/
2. Choose **Create application**.
3. For **Application name** enter the name for your application.
4. (Optional) Follow this optional step to enable the **Apple Push Notification service (APNs)**.
   a. For **Apple Push Notification service (APNs)** select **Enable**.
   b. For **Default authentication type** choose either:
      i. If you choose **Key credentials**, provide the following information from your Apple developer account. AWS End User Messaging Push requires this information to construct authentication tokens.
         A. **Key ID** – The ID that's assigned to your signing key.
         B. **Bundle identifier** – The ID that's assigned to your iOS app.
         C. **Team identifier** – The ID that's assigned to your Apple developer account team.
         D. **Authentication key** – The .p8 file that you download from your Apple developer account when you create an authentication key.
      ii. If you choose **Certificate credentials**, provide the following information:
         A. **SSL certificate** – The .p12 file for your TLS certificate.
         B. **Certificate password** – If you assigned a password to your certificate, enter it here.
         C. **Certificate type** – Select the type of certificate to use.
5. (Optional) Follow this optional step to enable the **Firebase Cloud Messaging (FCM)**.
   a. For **Firebase Cloud Messaging (FCM)** select **Enable**.
   b. Choose **Token credentials** for **Default authentication type,** then choose your service JSON file.
6. Choose **Create application**.

Step 3: Associate the AWS End User Messaging application with an Amazon Connect instance

To enable push notifications on an Amazon Connect instance, you will need to associate an AWS End User Messaging application with an Amazon Connect instance by calling the CreateIntegrationAssociation API with the `PINPOINT_APP` IntegrationType. You can call this API with AWS CLI or the Amazon Connect SDK for any supported languages. This is a one-time onboarding step required for each integration between an AWS End User Messaging application and an Amazon Connect instance.

Step 4: Get device token with FCM or APNs SDK, and register it with Amazon Connect

You will need to fetch the device token and use it to register an end-user mobile device with an Amazon Connect chat contact to send push notifications for new messages in the chat. Read the below FCM/APNs developer documentation for how the device token is generated and obtained from the mobile application.

- For Apple Push Notification service (APN), see Registering your app with APNs in the Apple Developer documentation.
- For Firebase Cloud Messaging (FCM), see Best practices for FCM registration token management.

To register the device with a chat contact, we recommend that you do the following:

1. When the mobile application calls the StartChatContact API, pass the `deviceToken` and `deviceType` as contact attributes. For webview and hosted communication widget users, see How to pass contact attributes into the communications widget for more details.
2. Embed a call to the CreatePushNotificationRegistration action in a Lambda function in a contact flow. The flow block should read `deviceToken` and `deviceType` from the user-defined contact attributes, and the `initialContactId` from the system attributes, then pass these values to the Lambda function.
   a. Depending on your use case, place the Lambda function either immediately after starting the chat (at the beginning of the flow) if you want the end user to receive push notifications immediately, or right before routing the contact to a queue so that they will receive the contact only an when agent is about to join. Once the API call is made, the device will start receiving push notifications when a new message comes from the agent or system. By default, push notifications will be sent for all the system and agent messages.

3. (optional) Embed a call to the DeletePushNotificationRegistration action in a Lambda function in a flow. Once the API call is made, the device will stop receiving push notifications when a new message comes from the agent or system.

Step 5: Receive push notification on your mobile applications

Check out our Amazon Connect Chat UI Examples project and refer to our sample iOS and Android chat webview examples that showcase how to integrate Amazon Connect APIs to onboard and receive push notifications.

Monitor your usage for push notifications

To ensure the reliability, availability, and performance of your push notifications, it's crucial to monitor their usage. You can track this information through several channels:

1. AWS provides comprehensive monitoring tools for push notifications. For more information, see Monitoring AWS End User Messaging Push.
2. Depending on the push notification service you're using, you can access additional usage data through their respective consoles.
   a. Firebase Cloud Messaging (FCM) : Consult the FCM documentation on Understanding message delivery for insights into your FCM usage.
   b. Apple Push Notification service (APNs) : Review the APNs documentation section on Viewing the status of push notifications using Metrics and APNs to monitor your notification status.

Enable customers to resume chat conversations in Amazon Connect

Customers often start a chat, then leave the conversation and return later to continue chatting. This may happen many times over the course of several days, months, or even years. To support long running chats like these, you enable persistent chat.

With persistent chat, customers can resume previous conversations with the context, metadata, and transcripts carried forward. They don't need to repeat themselves when they return to a chat, and agents have access to the entire conversation history.

Chat rehydration

Persistent chat is achieved through a process called chat rehydration. This process enables chat transcripts to be retrieved from previous chat contacts and displayed. It allows customers and agents to easily continue conversations from where they left off.

> **Important**
>
> Only chat sessions that have ended are allowed to rehydrate onto a new chat session.

Amazon Connect supports two types of rehydration:

- `ENTIRE_PAST_SESSION`: Starts a new chat session and rehydrates all chat segments from past chat sessions.
- `FROM_SEGMENT`: Starts a new session and rehydrates from the specified past chat segment.

For example use cases that show these different rehydration modes, see Example use cases.

RelatedContactId

A new contact can have an association with an existing contact through the `RelatedContactId`. This new contact contains a copy of the contact properties from the related contact.

For more information about how the `RelatedContactId` is modeled in contact records, see Data model for Amazon Connect contact records.

For persistent chat, the `RelatedContactId` depicts the `contactId` used to source chat rehydration.

How to enable persistent chat

There are two ways you can enable persistent chat:

- Specify a previous contact ID when creating a new chat. For instructions, see Enable persistent chat when creating a new chat contact.
- Add the Create persistent contact association block to a flow. For instructions, see Enable persistent chat in a flow.

> **Note**
>
> You can choose either method to persist chats but not both. That is, you can only enable persistence of a `SourceContactID` on a new chat once.

To deliver persistent chat experiences, you need to provide a previous contact ID when starting a new chat or when using the Create persistent contact association flow block. This is not automatically done for you. We recommend that you create a repository for storing contact record data. The repository enables retrieval of this data for each of your customers.

There are two ways you can create entries in a repository:

- Use chat message streaming to create an entry when a chat has ended.
- Inspect contact events and use AWS Lambda function for creating entries into your repository.

After a repository is set up, you can retrieve the previous contact ID for the customer and provide it when starting a new chat or within the Create persistent contact association flow block.

In addition, ensure past chat transcripts can be retrieved from your instance's Amazon S3 bucket. The following two things prevent Amazon Connect from retrieving transcripts and don't allow chats to persist:

- You use multiple chat transcript buckets.
- You change the chat transcript file name that is generated by Amazon Connect.

Enable persistent chat when creating a new chat contact

To set up persistent chat experiences when creating a new chat contact, provide the previous `contactId` in the `SourceContactId` parameter of the StartChatContact API. This enables the chat transcripts of previous contacts to be rehydrated. The transcripts are shown in the chat to both the customer and agent. For an example, see Example use cases.

Enable persistent chat in a flow

To set up persistent chat experiences in a flow:

1. After a chat contact has been created, add the Create persistent contact association block to your flow.
2. Use a user-defined attribute to specify a source contact ID.

Alternatively, you can use the CreatePersistentContactAssociation API to provide a source contact ID to make the current chat persistent.

Rehydration is started after the chat has started, when using the flow block or API. A rehydrated event is emitted to notify you when rehydration has completed.

Example use cases

For example, a customer starts a chat session:

1. Agent a1 accepts the chat, and the conversation starts between the customer and agent a1. This is the first contact created in the current chat session. For example, the `contactId` **C1** might be 11111111-aaaa-bbbb-1111-111111111111.
2. Agent a1 then transfers the chat to Agent a2. This creates another contact. For example, `contactId` **C2** might be 2222222-aaaa-bbbb-2222-222222222222222.
3. Agent a2 ends the chat.
4. The customer is forwarded to the disconnect flow for a post-chat survey that creates another contact. For example, `contactId` **C3** might be 33333333-aaaa-bbbb-3333-333333333333.
5. The post-chat survey is displayed, and the chat session ends.
6. Later, the customer returns and wants to resume their past chat session.

At this point, there are potentially two different use cases for the customer. Following are the persistent chat use cases the customer can have, and how you configure Amazon Connect to provide them.

Use case 1

The customer wants to continue their past chat session but they want to hide the post-chat survey. You use the following configuration to provide this experience.

Request:

```
PUT /contact/chat HTTP/1.1
Content-type: application/json
{
   "Attributes": {
      "string" : "string"
   },
   "ContactFlowId": "string",
   "InitialMessage": {
      "Content": "string",
```

```
        "ContentType": "string"
    },
    "InstanceId": "string",
    ... // other chat fields

    // NEW Attribute for persistent chat
    "PersistentChat" : {
        "SourceContactId":"2222222-aaaa-bbbb-2222-222222222222222"
        "RehydrationType":"FROM_SEGMENT"
    }
}
```

Configuration

- SourceContactId = 2222222-aaaa-bbbb-2222-222222222222222 (the contactId for C2)
- RehydrationType = "FROM_SEGMENT"

Expected behavior

- This configuration starts a persistent chat session from the specified past ended contact C2 (for example, 2222222-aaaa-bbbb-2222-222222222222222).

  Transcripts of past chat sessions C2 (2222222-aaaa-bbbb-2222-222222222222222) and C1 (11111111-aaaa-bbbb-1111-1111111111111) are accessible in the current persistent chat session. Note that chat segment C3 (33333333-aaaa-bbbb-3333-3333333333333) is dropped from the persistent chat session.
- In this case, the [StartChatContact](#) response returns C2 (2222222-aaaa-bbbb-2222-222222222222222) as "ContinuedFromContactId".
- The `RelatedContactId` for this persistent chat session is 2222222-aaaa-bbbb-2222-222222222222222 (C2).

Use case 2

The customer wants to continue the past chat session and see the transcript of the entire past engagement (and they don't want to hide the post-chat survey). You use the following configuration to provide this experience.

> **Note**
>
> For the ENTIRE_PAST_SESSION rehydration type, specify the first contact (initial contactId) of the past chat session as the SourceContactId attribute.

Request:

```
PUT /contact/chat HTTP/1.1
Content-type: application/json
{
   "Attributes": {
      "string" : "string"
   },
   "ContactFlowId": "string",
   "InitialMessage": {
      "Content": "string",
      "ContentType": "string"
   },
   "InstanceId": "string",
   ... // other chat fields

   // NEW Attribute for persistent chat
   "PersistentChat":{
        "SourceContactId":"11111111-aaaa-bbbb-1111-1111111111111" // (first contactId
 C1)
        "RehydrationType":"ENTIRE_PAST_SESSION"
   }
}
```

Configuration

- SourceContactId = 11111111-aaaa-bbbb-1111-1111111111111 (C1)
- RehydrationType = "ENTIRE_PAST_SESSION"

Expected behavior

- This starts a persistent chat session from the most recently ended chat contact (C3). Transcripts of past chat sessions C3, C2 and C1 are accessible in the current persistent chat session.

- In this case, the StartChatContact response returns 33333333-aaaa-bbbb-3333-333333333333 (C3) as "ContinuedFromContactId".
- The `RelatedContactId` for this persistent chat session is 33333333-aaaa-bbbb-3333-333333333333 (C3)

> **Note**
>
> Chat linkages are cumulative. After chat sessions are linked, they carry over.
> For example, if a contact (`contactId` C2) that belongs to a past chat session was linked to a contact (`contactId` C1) from a different past chat session, then a new persistent chat session created by linking C2 results in implicit linkage of C1 as well. The new persistent chat session will have the following linkage: C3 → C2 → C1
> The past contactId, which the persistent chat session is continued from, is exposed in the `ContinuedFromContactId` field in the StartChatContact API response. It's also in the RelatedContactId field in the contact record for the contact

How to access past chat contact transcript for a persistent chat

Accessing the past chat transcript for persistent chat uses the existing `NextToken` pagination model. The initial call to GetTranscript on a newly started persistent chat session contains a `NextToken` in the response, if past chat messages exist. `NextToken` must be used to access the past chat transcript along with setting the `ScanDirection` to `BACKWARD` on the subsequent GetTranscript call to fetch past chat messages.

If there are multiple past chat messages, GetTranscript returns a new `NextToken` and the same process can be repeated to fetch more past chat transcripts.

Not supported: using `StartPosition` and `contactId` filters for persistent chat

Amazon Connect does not support using `StartPosition` and `contactId` filters on the GetTranscript call for transcript item attributes that are from the past chat.

Enable real-time chat message streaming in Amazon Connect

Amazon Connect Chat provides APIs that enable you to subscribe to a real-time stream of chat messages. Using these APIs, you can:

- Stream chat messages in real time when a new chat contact is created.

- Extend the current Amazon Connect Chat functionality to support use cases like building integrations with SMS solutions and third-party messaging applications, enabling mobile push notifications, and creating analytics dashboards to monitor and track chat message activity.

How the message streaming APIs work

The Amazon Connect message streaming APIs are triggered when certain events occur within an Amazon Connect Chat contact. For example, when a customer sends a new chat message, the event sends a payload to a specified endpoint containing data about the message that was just sent. Messages are published using Amazon Simple Notification Service (Amazon SNS) to a specific endpoint.

This topic describes how to set up real-time message streaming using Amazon Connect and Amazon SNS. The steps are:

1. Use the Amazon SNS console to create a new standard SNS topic and set up the messages.
2. Call the StartChatContact API to initiate the chat contact.
3. Call the StartContactStreaming API to initiate message streaming.
4. Call the CreateParticipantConnection API to create the participant's connection.

Step 1: Create a standard SNS topic

1. Go to the Amazon SNS console.
2. Create a SNS topic in your AWS account. In the **Details** section, for **Type**, choose **Standard**, enter a name for the topic, and then choose **Create topic**.

   > **Note**
   >
   > Currently, the message streaming APIs only support standard SNS for real-time streaming of messages. They don't support Amazon SNS FIFO (first in, first out) topics.

3. After you create the topic, its Amazon Resource Name (ARN) is displayed in the **Details** section. Copy the topic ARN to the clipboard. You'll use the topic ARN in the next step, and in Step 3: Enable message streaming on the contact.

   The topic ARN looks similar to the following example:

   ```
   arn:aws:sns:us-east-1:123456789012:MyTopic
   ```

4. Choose the **Access policy** tab, choose **Edit**, and then add a resource-based policy on the SNS topic so that Amazon Connect has permission to publish to it. Following is a sample SNS policy that you can copy and paste into the JSON editor, and then customize with your values:

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Principal":{
            "Service":"connect.amazonaws.com"
         },
         "Action":"sns:Publish",
         "Resource":"YOUR_SNS_TOPIC_ARN",
         "Condition":{
            "StringEquals":{
               "aws:SourceAccount":"YOUR_AWS_ACCOUNT_ID"
            },
            "ArnEquals":{
               "aws:SourceArn":"YOUR_CONNECT_INSTANCE_ARN"
            }
         }
      }
   ]
}
```

> **Note**
>
> The default **Access policy** comes with conditions applied to `sourceOwner` such as:
>
> ```
> "Condition": {
>         "StringEquals": {
>           "AWS:SourceOwner": "921772911154"
>         }
>       }
> ```
>
> Make sure you remove it and replace with `SourceAccount`, for example:
>
> ```
> "Condition":{
> ```

```
                "StringEquals":{
                   "aws:SourceAccount":"YOUR_AWS_ACCOUNT_ID"
                },
                "ArnEquals":{
                   "aws:SourceArn":"YOUR_CONNECT_INSTANCE_ARN"
                }
             }
```

This prevents a [cross-service confused deputy](#) issue.

5. If you're using server-side encryption on SNS, verify you have `connect.amazonaws.com` permission enabled on the KMS key. Following is a sample policy:

```
{
        "Version": "2012-10-17",
        "Id": "key-consolepolicy-3",
        "Statement": [
            {
                "Sid": "Enable IAM User Permissions",
                "Effect": "Allow",
                "Principal": {
                    "AWS": "arn:aws:iam::your_accountId:root",
                    "Service": "connect.amazonaws.com"
                },
                "Action": "kms:*",
                "Resource": "*"
            },
            {
                "Sid": "Allow access for Key Administrators",
                "Effect": "Allow",
                "Principal": {
                    "AWS": "arn:aws:iam::your_accountId:root",
                    "Service": "connect.amazonaws.com"
                },
                "Action": [
                    "kms:Create*",
                    "kms:Describe*",
                    "kms:Enable*",
                    "kms:List*",
                    "kms:Put*",
                    "kms:Update*",
                    "kms:Revoke*",
                    "kms:Disable*",
```

```
                    "kms:Get*",
                    "kms:Delete*",
                    "kms:TagResource",
                    "kms:UntagResource",
                    "kms:ScheduleKeyDeletion",
                    "kms:CancelKeyDeletion"
                ],
                "Resource": "*"
            }
        ]
    }
```

Step 2: Initiate the chat contact

1. Call the Amazon Connect StartChatContact API to initiate the chat contact.

   For information about how to create the SDK client for calling Amazon Connect APIs, see the following topics:

   - Class AmazonConnectClientBuilder
   - Creating Service Clients

2. Keep track of `ContactId` and `ParticipantToken` from the StartChatContact response since these response attributes are used for calling other chat APIs required to enable streaming. This is described in the next steps.

Step 3: Enable message streaming on the contact

- Call StartContactStreaming to enable real-time message streaming to your SNS topic.

  - **Limits**: You can subscribe to up to two SNS topics per contact.
  - When you call StartContactStreaming, you'll need to provide the Amazon Resource Name (ARN) of the SNS topic (see Step 1: Create a standard SNS topic).

    A single SNS topic ARN may be used across multiple AWS accounts, but it must be in the same Region as your Amazon Connect instance. For example, if your topic ARN is in **us-east-1**, your Amazon Connect instance must be in **us-east-1**.
  - For initial chat messages that aren't received on the streaming endpoint, you can call the GetTranscript API to receive the initial messages.

Step 4: Create the participant connection

- Call CreateParticipantConnection with the `ConnectParticipant` attribute passed as true.
  - You must call CreateParticipantConnection within five minutes of creating the chat.
  - Calling CreateParticipantConnection with `ConnectParticipant` set to true only works if you enabled streaming in Step 2: Initiate the chat contact and caller participant is `Customer`.
  - This step (creating the participant connection) is optional if you have already successfully connected to the chat contact using `WEBSOCKET`.

Next steps

You are all set for working with the message streaming APIs.

1. To verify it is working, check that messages are published to the SNS topic you created. You can do this using Amazon CloudWatch metrics. For instructions, see Monitoring Amazon SNS topics using CloudWatch.
2. Because SNS has limited retention, we recommend that you set up Amazon Simple Queue Service (Amazon SQS) Amazon Kinesis, or another service to retain messages.
3. Using StopContactStreaming is optional and not required if the chats are being disconnected through a contact flow, or if the customer disconnects the chat. However, `StopContactStreaming` provides the option to stop the message streaming on the SNS topic, even if the chat is active and ongoing.

Use the Amazon SNS payload after enabling message streaming in Amazon Connect

After you've enabled message streaming successfully, you may need to filter the message to send it to the intended participant: agent, customer, or all.

To filter by participant, read the specific SNS headers attribute— `MessageVisibility`—to determine whether the message is intended for customer-only, agent-only, or all.

- To send to the customer only: For all code that faces the customer, clients need to filter out messages intended for the customer and build the following logic for forwarding the message to them.

```
if ( ( MessageVisibility == CUSTOMER || MessageVisibility == ALL)  &&
 ParticipantRole != CUSTOMER )
```

- To send to the agent only:

```
if ( ( MessageVisibility == AGENT || MessageVisibility == ALL)  && ParticipantRole !=
 AGENT )
```

You can also leverage the filtering capability in Amazon SNS by building custom subscription filtering policies. This offloads the message filtering logic from the SNS topic subscriber to the SNS service itself.

Message attributes in the payload

Following is a description of each message attribute in the Amazon SNS payload:

- `InitialContactId`: The initial contact ID of the chat.
- `ContactId`: The current contact ID of the chat. The `InitialContactId` and `ContactId` can differ if there has been new agent in the chat or the queue-to-queue contact flow.
- `ParticipantRole`: The participant who sent the message.
- `InstanceId`: The Amazon Connect instance ID.
- `AccountId`: The AWS account ID.
- `Type`: Possible values: `EVENT`, `MESSAGE`.
- `ContentType`: Possible values: `application/vnd.amazonaws.connect.event.typing`, `application/vnd.amazonaws.connect.event.participant.joined`, `application/vnd.amazonaws.connect.event.participant.left`, `application/vnd.amazonaws.connect.event.transfer.succeeded`, `application/vnd.amazonaws.connect.event.transfer.failed`, `application/vnd.amazonaws.connect.message.interactive`, `application/vnd.amazonaws.connect.event.chat.ended`, and more.
- `MessageVisibility`: Possible values: `AGENT`, `CUSTOMER`, `ALL`.

Example SNS payload

```
{
```

```
  "Type" : "Notification",
  "MessageId" : "ccccccccc-cccc-cccc-cccc-ccccccccccccc",
  "TopicArn" : "arn:aws:sns:us-west-2:009969138378:connector-svc-test",
  "Message" :  "{\"AbsoluteTime\":\"2021-09-08T13:28:24.656Z\",\"Content\":\"help
\",\"ContentType\":\"text/plain\",\"Id\":\"333333333-be0d-4a44-889d-d2a86fc06f0c
\",\"Type\":\"MESSAGE\",\"ParticipantId\":\"bbbbbbbb-c562-4d95-b76c-dcbca8b4b5f7\",
\"DisplayName\":\"Jane\",\"ParticipantRole\":\"CUSTOMER\",\"InitialContactId\":
\"33333333-abc5-46db-9ad5-d772559ab556\",\"ContactId\":\"33333333-abc5-46db-9ad5-
d772559ab556\"}",
  "Timestamp" : "2021-09-08T13:28:24.860Z",
  "SignatureVersion" : "1",
  "Signature" : "examplegggggg/1tEBYdiVDgJgBoJUniUFcArLFGfg5JCvpOr/

    "ContactId" : {"Type":"String","Value":"33333333-abc5-46db-9ad5-d772559ab556"},
    "ParticipantRole" : {"Type":"String","Value":"CUSTOMER"}
  }
}
```

Troubleshoot issues with message streaming in Amazon Connect

Messages are not getting published to SNS

When this happens, we recommend checking the information in [Step 1: Create a standard SNS topic]:

- Make sure you are using standard SNS and not [Amazon SNS FIFO (first in, first out)]. Currently, the message streaming APIs support only standard SNS for real-time streaming of messages.
- Make sure an SNS resource-based permission is applied correctly in your account.

- If server-side encryption is enabled, you need to give the same Amazon Connect service principal permission for encrypt and decrypt.

Flow doesn't start

If you're using the message streaming APIs in place of websockets, send a connection acknowledgment event; see Step 4: Create the participant connection. This is synonymous to connecting to websocket. The flow begins only after that the connection acknowledgement event.

Call CreateParticipantConnection after StartContactStreaming to mark `Customer` as connected; see Step 3: Enable message streaming on the contact. This ensures messages are sent after you have confirmed that the customer is ready to receive them.

Issue not resolved?

If after trying the previous solutions you still have issues with message streaming, contact Support for help.

Amazon Connect administrators can choose one of the following options to contact support:

- If you have an AWS Support account, go to Support Center and submit a ticket.
- Otherwise, open the AWS Management Console and choose **Amazon Connect**, **Support**, **Create case**.

It is helpful to provide the following information:

- Your contact center instance ID/ARN. To find your instance ARN, see Find your Amazon Connect instance ID or ARN.
- Your Region.
- A detailed description of the issue.

Customize chat flow experiences in Amazon Connect by integrating custom participants

You can integrate other solutions, such as bots, with Amazon Connect chat to create customized chat flow experiences.

Following is an overview of how you can customize your chat flow experience. Implement these steps for each chat segment after the chat conversation is started. We recommend adding an Invoke AWS Lambda function block to call the APIs in your chat flow.

Important

Add a Play prompt block before a Invoke AWS Lambda function block. This is required only when an **Invoke AWS Lambda** block is the first block in your inbound chat flow.

1. Enable real-time streaming of chat messages.
2. Call the Amazon Connect CreateParticipant API to add a custom participant (`ParticipantRole` = `CUSTOM_BOT`) to the chat contact.
   a. For information about how to create the SDK client for calling Amazon Connect APIs, see the following topics:
      - Class AmazonConnectClientBuilder
      - Creating Service Clients
   b. Keep the `ParticipantToken` that is obtained from CreateParticipant to call CreateParticipantConnection. `CreateParticipantConnection` returns a `ConnectionToken`, which you can use to call other Amazon Connect Participant APIs.

      When calling CreateParticipantConnection to create a connection for a custom participant:
      - Set `ConnectParticipant` to `True` to mark the custom participant as connected for message streaming.
      - Pass `Type` as `CONNECTION_CREDENTIALS` to call the subsequent Amazon Connect Participant Service APIs.
      - `CreateParticipantConnection` should be called within 15 seconds of calling `CreateParticipant`.
3. After the participant is added to the contact, they can exchange messages with the customer by using Amazon Connect Participant Service APIs.
4. To disconnect the participant, call the DisconnectParticipant API.

Note

- A custom participant cannot be added to a chat when an agent or Amazon Lex bot is already present on the contact.
- A custom participant will be disconnected when an agent or Amazon Lex bot joins a contact.
- Only one custom participant can be present on a contact.
- A custom participant is not permitted to access attachments a customer may upload.

We recommend configuring how long a custom participant can chat with a contact:

- Set the **Timeout** property on the Wait block for the `ParticipantRole` = `CUSTOM_BOT`.
- If the custom bot participant is not disconnected before the timeout, then the contact is routed down the **Time Expired** branch. This allows you to decide which block to run next to resolve the customer's query.

Note

If a contact is routed down the **Time Expired** branch, they are not disconnected from the contact. You must call the DisconnectParticipant API to disconnect the participant.

Activate timers for customers who are joined to a custom participant

You can activate timers on customers who are joined to custom participants, such as custom bots. This enables you to detect when a customer stops responding so you can then terminate that bot conversation, and perform the next step in the flow. By terminating idle participants, you can reduce the number of open chats where there is a non-responsive customer engaged with a custom participant.

Perform the following steps to integrate an Idle Participant Custom Bot Extension and optionally set custom timer values. These steps assume that the you already use the custom participant feature for chat.

1. Before the custom participant joins the chat, invoke the UpdateParticipantRoleConfig API for the customer.

   a. Timers activate only for the customer. Custom participants do not have idle participant or auto-disconnect timers.
   b. You can choose the method for invoking the API.
   c. Timer values configured in this step persist for the life of the chat. If you want different timer values for the **customer and agent interaction**, see Step 2.
   d. If your client is already set up this way, you don't need to take any other action to integrate your custom participant.
2. (Optional) To configure timers and timer values that are different during the **customer and agent interaction** than during the **customer and custom participant interaction**:
   - Before the agent joins the chat, invoke the UpdateParticipantRoleConfig API again with the configurations you want.

For more information about chat timers, see Set up chat timeouts for chat participants.

Starting timers

A timer begins for the customer after the custom participant establishes a connection to them using the CreateParticipantConnection API.

What happens when non-compatible participants join a chat with a custom participant

Following is what happens when an agent or Lex bot participant joins a chat with a custom participant, and they are non-compatible participants:

1. The custom participant is automatically disconnected from the chat.
2. All previously active timers are terminated and new timers are created for the connected participants (if timers are configured).
3. Each new timer is also updated with the latest configuration (if needed). This effectively establishes a new "Idle session" for the new set of active participants on the chat.

Interaction with the Wait block timer

The idle timer does not impact how the Wait block works.

The **Wait** block timer that starts when the chat contact enters a **Wait** block continues to work. If the **Wait** block timer expires, the contact resumes the flow and is routed down the **Time Expired** branch, regardless of whether any idle participant timers are active.

Troubleshooting tips

- `ResourceNotFoundException`:

  If you get a `ResourceNotFoundException` for the custom participant when calling the `CreateParticipantConnection` API, check whether the `CreateParticipantConnection` API was called within 15 seconds of `CreateParticipant` API.
- `AccessDeniedException`:

  If you get an `AccessDeniedException` error and the participant role is a CUSTOM_BOT, it indicates the bot is trying to access attachments. The participant role of CUSTOM_BOT is not permitted to access attachments that customers upload.

Set up customer authentication in Amazon Connect for chat contacts

You can prompt your customers to sign in and authenticate during a chat. For example, unauthenticated customers engaged with a chat bot can be prompted to sign in before to being routed to an agent.

This built-in capability leverages Amazon Connect Customer Profiles and Amazon Cognito. There are no additional costs for using Customer Profiles, which is already enabled in your Amazon Connect instance if you chose the default settings during setup. For information about Amazon Cognito pricing, see the Amazon Cognito pricing page.

To set up customer authentication for chat:

1. Enable customer authentication for your Amazon Connect instance.
2. Enable the authentication message.
3. Add an Authenticate Customer block to your flow.

If your contact center is using an existing authentication solution external to Amazon Connect, see Pre-chat authentication.

Enable customer authentication for hosted communication widgets

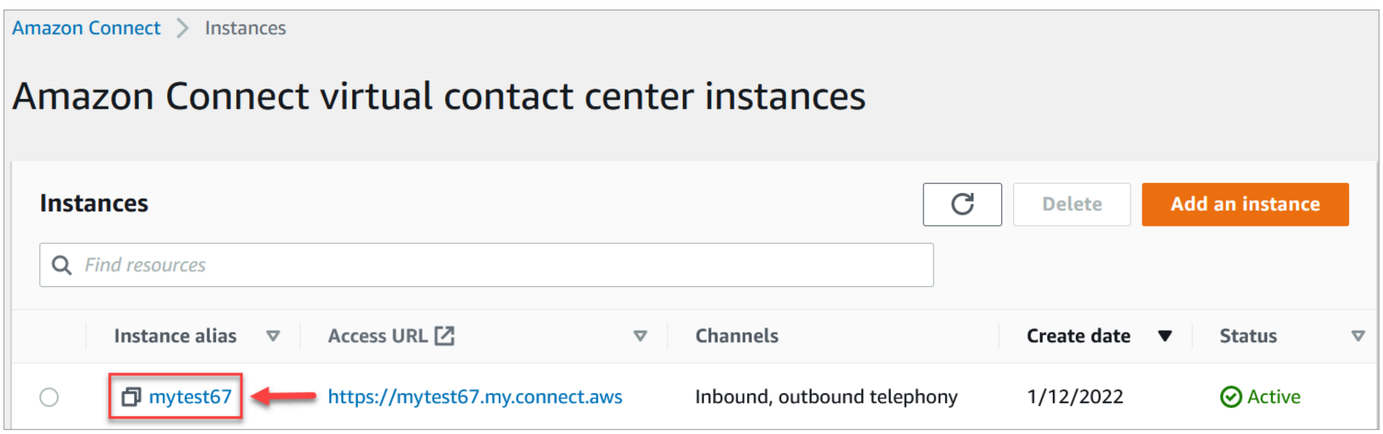
This topic explains how to set up authentication if you're using the Amazon Connect hosted communication widget for chat. You enable customer authentication for your Amazon Connect instance, and then enable an authentication message that displays a link which opens a popup to the Amazon Cognito hosted UI.

Required IAM policies

If you use custom IAM policies to manage access to the Amazon Connect console, see Required permissions for custom IAM policies for a list of the permissions needed to access the **Customer authentication** page.

Enable customer authentication in your Amazon Connect instance

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Amazon Connect URL. The following image shows the **Amazon Connect virtual contact center instances** page, with a box around the instance alias.



3. On the left navigation menu, choose **Applications**, **Customer Authentication**. If you don't see this option, it may not be available in your AWS Region. For information about where customer authentication is available, see Customer authentication availability by Region.
4. On the **Customer authentication** page, choose **Create user pool in Amazon Cognito**. This opens the Amazon Cognito console.
5. Create a new user pool with your identity provider. For instructions, see Getting started with user pools in the *Amazon Cognito Developer Guide*.

> **Note**
>
> You must select **Don't generate a client secret** when you configure your Amazon Cognito app client. Only Amazon Cognito app clients without client secrets are supported. For more information, see Application-specific settings with app clients in the *Amazon Cognito Developer Guide*.

6. After you have created an Amazon Cognito user pool, return to the **Customer authentication** page and choose **Associate User Pool**.
7. In the **User Pool** section, choose the user pool you created from the dropdown menu, and then choose **Confirm**.

   This associates the user pool to your Amazon Connect instance. It enables the Authenticate Customer flow block to access the user pool.
8. Continue to the next step: Enable the authentication message.

Enable the authentication message

To enable the authentication message, add the authentication parameters snippet variable at the end of your snippet. For information about adding snippet variables, see Supported widget snippet fields in Amazon Connect that are customizable. The following code is an example of the authentication parameters snippet you need to add.

```
amazon_connect('authenticationParameters', {
    redirectUri: 'your_redirect_url', // https://example.com
    identityProvider: 'your_identity_provider_name' //optional
 });
```

Where:

- `redirectUri` is the redirect URI you configured in your IdP (Identity Provider) and Amazon Cognito. This is where your customer is automatically directed after signing in. In this page you can check the URL parameters and if there is a code and state, you can call the UpdateParticipantAuthentication API with those values. After the API call completes, close the popup; the customer is returned to the chat experience.
- `identityProvider` is the identity provider name you configured in Amazon Cognito. This field is optional. If a value is provided, then the sign in link automatically directs the customer to the

login page of the identity provider instead of to the Amazon Cognito-managed login page where they would have to select an identity provider to use for login.

When the flow reaches the Authenticate Customer block, you can register a callback and store the state locally to validate in the redirect URI, as shown in the following example code snippet:

```
amazon_connect('registerCallback', {
       'AUTHENTICATION_INITIATED' : (eventName, data) => {
            console.log(data.state)
        },
      });
```

After you enable customer authentication, add an Authenticate Customer block to your flow. This block authenticates chat contacts during the flow, and route them to specific paths based on the authentication result.

Pre-chat authentication using the Amazon Connect StartChatContact API

Customers who authenticate in your website or mobile application before starting a chat can be recognized as authenticated when a chat is initiated. You can do this by using the StartChatContact API.

After an authenticated customer starts a chat, set their status using the parameters in the StartChatContact API, as shown in the following code snippet:

```
"SegmentAttributes": {
    "connect:CustomerAuthentication" : {
        "ValueMap": {
            "Status": {
                "ValueString": "AUTHENTICATED"
            }
        }
    },
    "CustomerId": "12345"
```

`CustomerId` is an optional field to identify the customer. This can be either an Amazon Connect Customer Profiles ID or a custom identifier from an external system, such as a CRM.

Set up SMS messaging in Amazon Connect

You can enable SMS messaging on Amazon Connect so your customers can text you from their mobile device. With Amazon Lex, you can automate responses to their questions, saving agents valuable time and effort.

This topic explains how to set up and test SMS messaging for Amazon Connect. You use AWS End User Messaging SMS to procure an SMS-enabled phone number, enable two-way SMS on the number, and then import it into Amazon Connect.

Contents

Step 1: Request a number in AWS End User Messaging SMS

> **Important**
>
> Some countries require phone numbers to be registered for use in the country. It can take up to 15 business days to process a registration request after it is submitted. We strongly recommend you begin this process early. For more information about registering, see Registrations.
> We also strongly recommend reviewing Best practices for requesting SMS numbers before requesting a number.

For instructions for using the CLI to perform this step, see Request a phone number in the *AWS End User Messaging SMS User Guide*.

1. Open the AWS SMS console at https://console.aws.amazon.com/sms-voice/.

2. In the navigation pane, under **Configurations**, choose **Phone numbers** and then **Request originator**.
3. On the **Select country** page you must choose the **Message destination country** from the drop down that messages will be sent to. Choose **Next**.
4. On the **Messaging use case** section, enter the following:
   - Under **Number capabilities** choose either **SMS** or **Voice**, depending on your requirements.

     > **Important**
     >
     > Capabilities for SMS and Voice can't be changed after the phone number has been purchased.

     - **SMS** – Choose if you need SMS capabilities.
     - **Voice (text to audio)** – Choose if you need voice capabilities.
   - Under **Estimated monthly SMS message volume per month – optional** choose the estimated number of SMS messages you will send each month.
   - For **Company headquarters - optional** choose either of the following:
     - **Local** – Choose this if your company headquarters is in the same country as your customers who will receive SMS messages. For example, you would choose this option if your headquarters is in the United States and your users who will receive messages are also in the United States.
     - **International** – Choose this if your company headquarters is not in the same country as your customers who will receive SMS messages.
   - For **Two-way messaging** choose **Yes** if you require two-way messaging.
5. Choose **Next**.
6. Under **Select originator type** choose one of the recommended phone number type or one of the available number types. The available options are based on the use case information you filled out in the previous steps.
   - If you choose 10DLC and already have a registered campaign, you can choose the campaign from the **Associate to registered campaign**.

- If the number type you want isn't available, you can choose **Previous** to go back and modify your use case. Also check the Supported countries and regions (SMS channel) to make sure the originator type you want is supported in the destination country.
- If you want to request a short code or long code, you need to open a case with Support. For more information, see Requesting short codes for SMS messaging with Amazon Pinpoint SMS and Requesting dedicated long codes for SMS messaging with Amazon Pinpoint SMS.

7. Choose **Next**.
8. On **Review and request** you can verify and edit your request before submitting it. Choose **Request**.
9. A **Registration Required** window may appear depending on the type of phone number you requested. Your phone number is associated with this registration and can't send messages until your registration has been approved. For more information about registrations requirements, see Registrations.

    a. For **Registration form name** enter a friendly name.

    b. Choose **Begin registration** to finish registering the phone number or **Register later**.

    > **Important**
    >
    > Your phone number can't send messages until your registration has been approved.
    > You are still billed the recurring monthly lease fee for the phone number regardless of registration status.

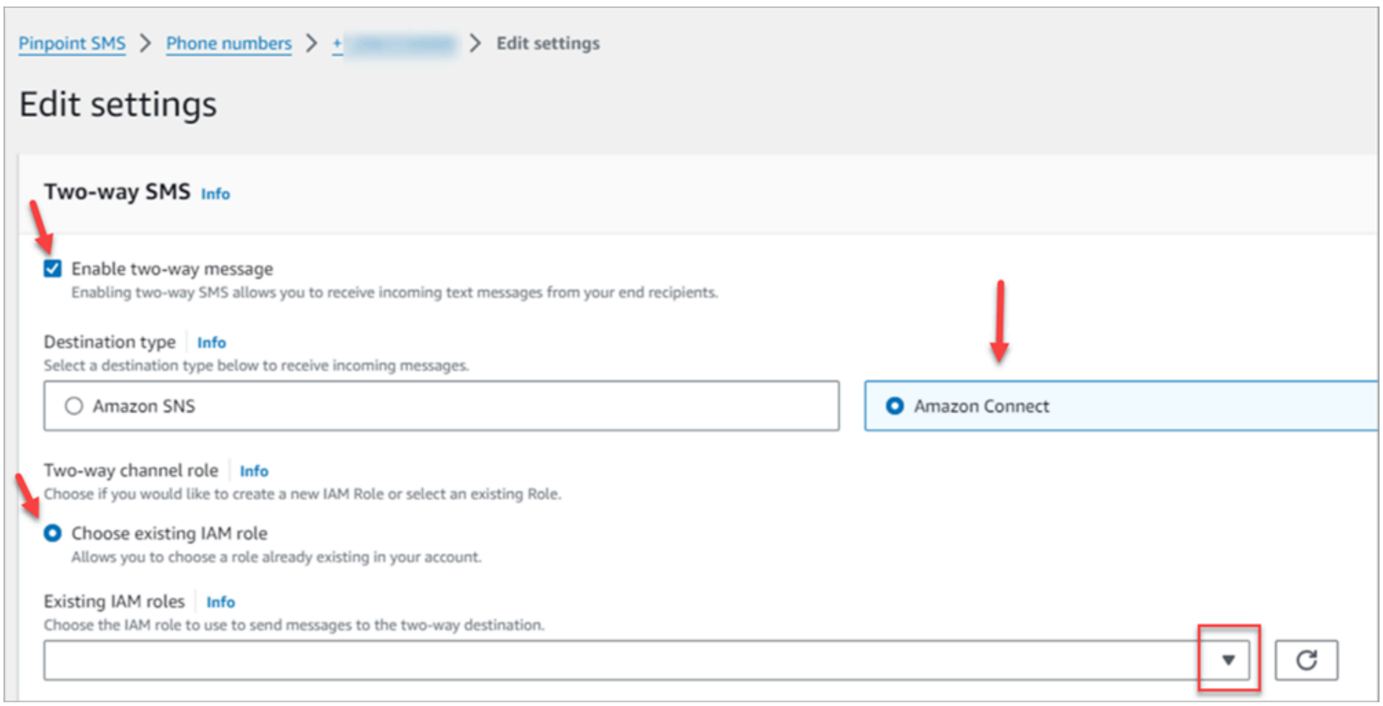
Step 2: Enable two-way SMS on the phone number

After you have successfully procured a phone number from AWS End User Messaging SMS, you enable two-way SMS on the phone number with Amazon Connect as the message destination. You can enable two-way SMS messaging for individual phone numbers. When one of your customers sends a message to your phone number, the message body is sent to Amazon Connect.

For instructions for using the CLI to perform this step, see Two-way SMS messaging in the *AWS End User Messaging SMS User Guide*.

> **Note**
>
> Amazon Connect for two-way SMS is available in the AWS Regions listed in [Chat messaging: SMS subtype](#).

1. Open the AWS SMS console at https://console.aws.amazon.com/sms-voice/.
2. In the navigation pane, under **Configurations**, choose **Phone numbers**.
3. On the **Phone numbers** page choose a phone number.
4. On the **Two-way SMS** tab choose the **Edit settings** button.
5. On the **Edit settings** page choose **Enable two-way message**, as shown in following image.



6. For **Destination type** choose **Amazon Connect**.
7. For Amazon Connect in **Two-way channel role** choose **Choose existing IAM roles**.
8. In the **Existing IAM roles** drop down choose an existing IAM role as the message destination. For example IAM policies, see [IAM policies for Amazon Connect](#) in the *AWS End User Messaging SMS User Guide*.

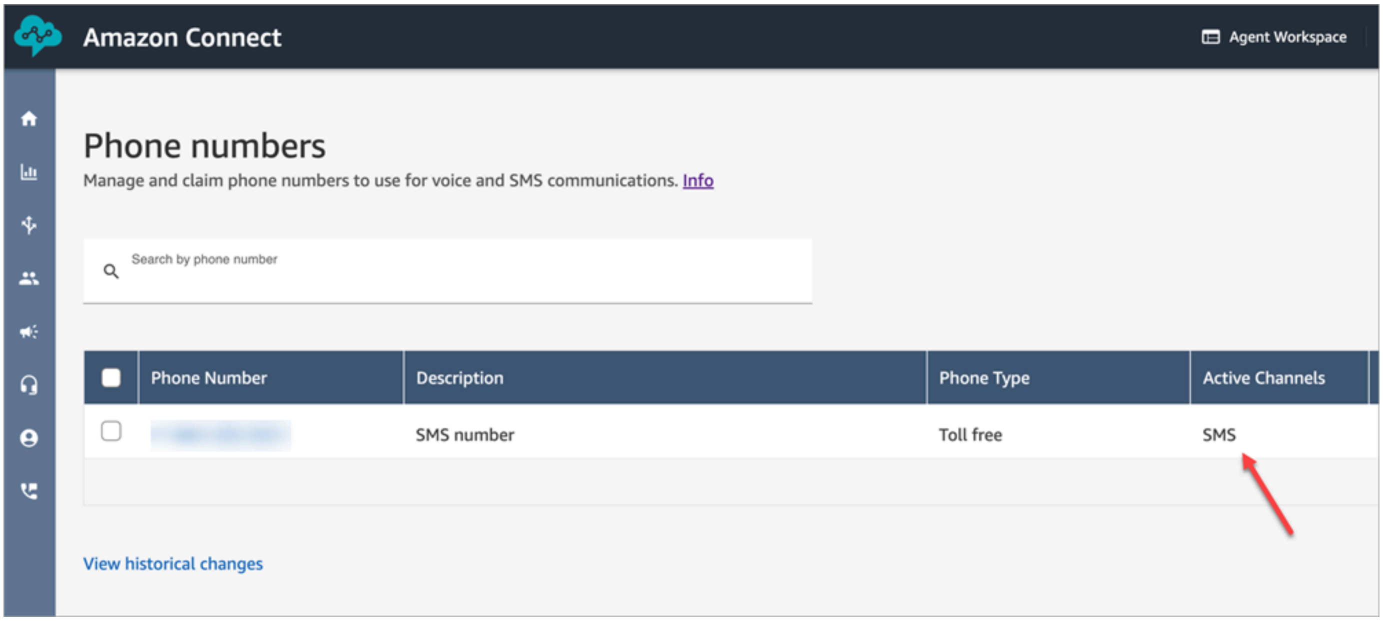
Tip

If you can't create a policy or role, double-check that your Amazon Connect instance is in a Region supported by Amazon Connect SMS.

9. Choose **Save changes**.
10. In the **Import Phone Number to Amazon Connect** window:

    a. For the **Incoming messages destination** drop down choose the Amazon Connect instance that will receive incoming messages.

    
    b. Choose **Import Phone Number**.
11. After the number is successfully imported to Amazon Connect, you can view it in the Amazon Connect admin website: In the left navigation, choose **Channels**, **Phone numbers**. The SMS number appears on the **Phone numbers** page, as shown in the following image.



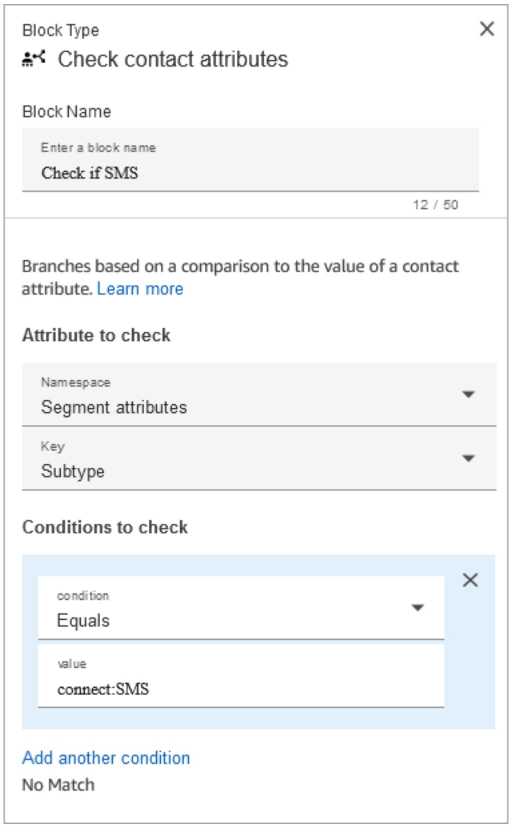
Step 3: Update flows to branch on SMS contacts

If you have existing flows that you want to branch when a contact uses SMS, add a Check contact attributes block to your flows. This block enables you to send SMS contacts to a specific queue, or take another action.

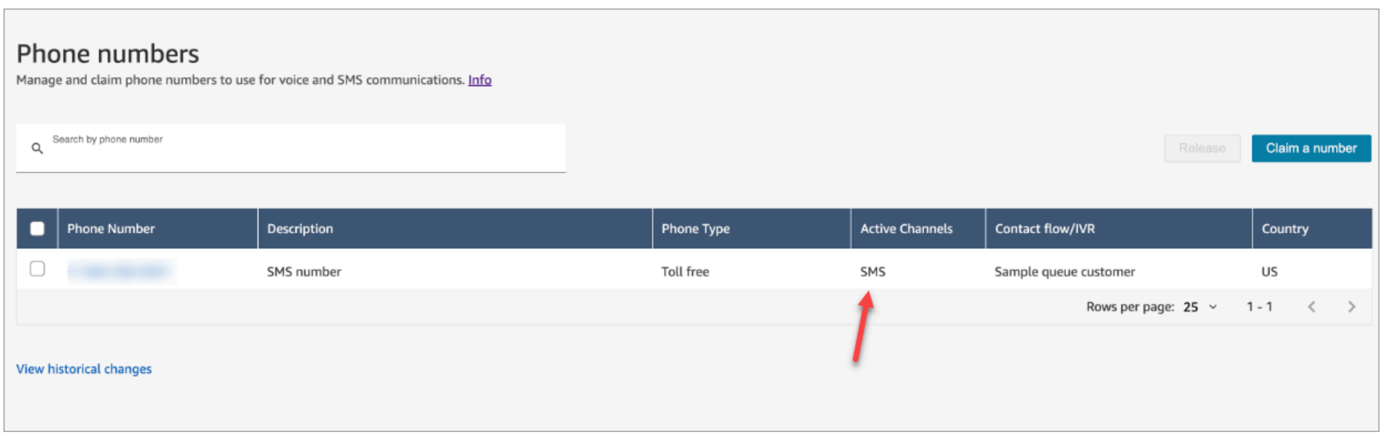
1. Add a Check contact attributes block to your flow, and open the **Properties** page.
2. In **Attribute to check** section, set **Namespace** to **Segment attributes** and **key** to **Subtype**.

   For more information about Segment attributes, see SegmentAttributes in the *ContactTraceRecord* topic.
3. In the **Conditions to check** section, set **condition** to **Equals** and **value** to **connect:SMS**.

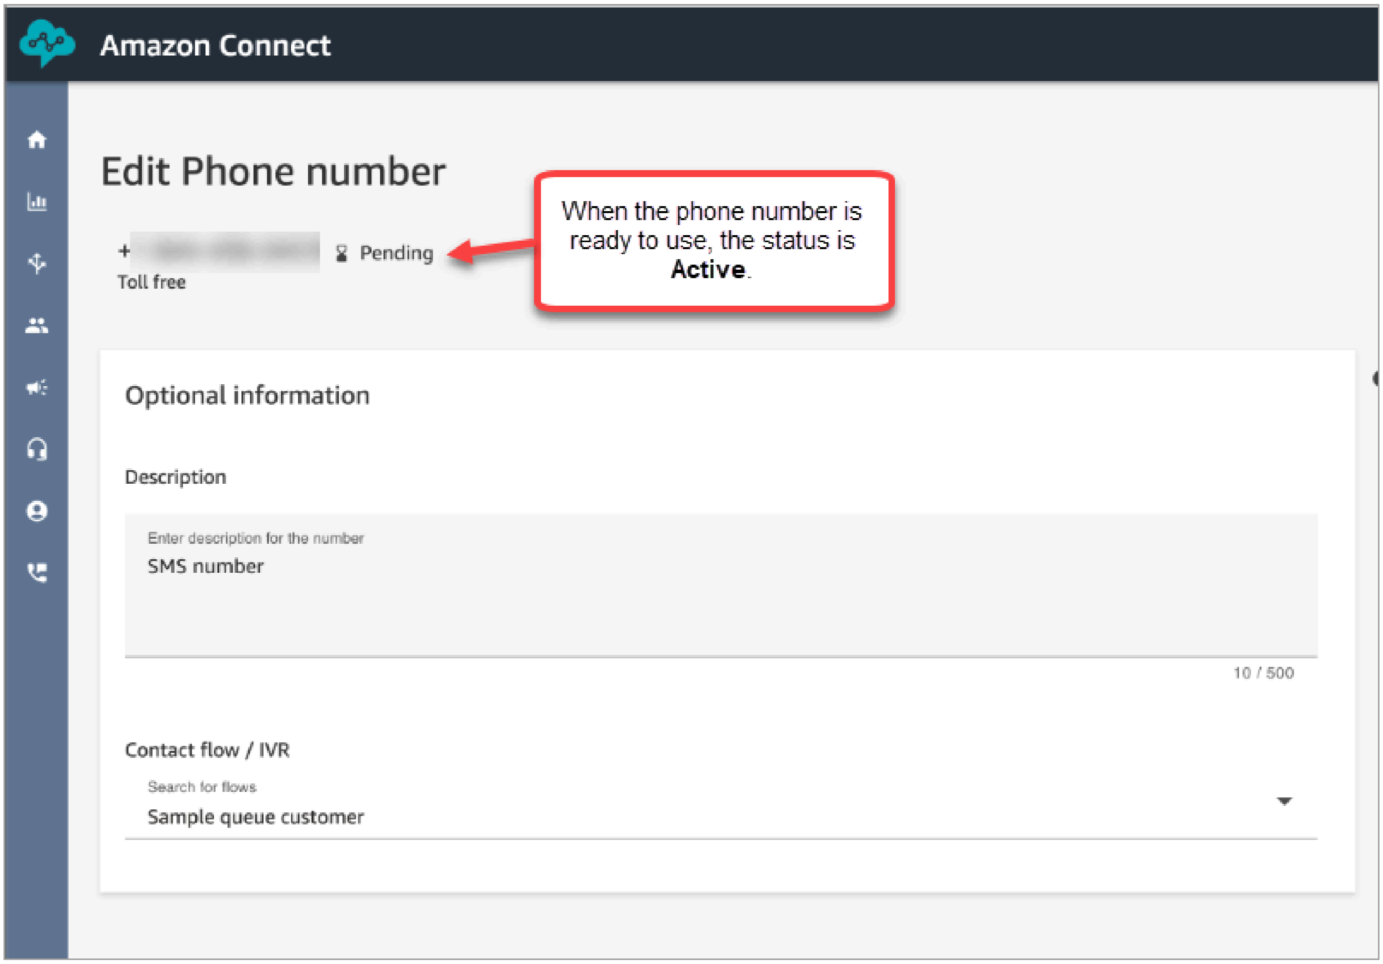
   The following image of a **Properties** page shows it's configured to branch when the contact comes in on the SMS channel.



4. Associate the SMS phone number with the flow: In the left navigation, choose **Channels**, **Phone numbers**, choose the SMS number, and then choose **Edit**.



5. Under **Flow/IVR**, choose the flow you updated, and then choose **Save**.



Tip

When you first purchase a phone number, the phone number's status is **Pending**. When the phone number is ready to use, the phone number's status is **Active**. If the phone number requires registration, then you must complete that step before the phone number's status changes to **Active**.

Step 4: Test sending and receiving SMS messages

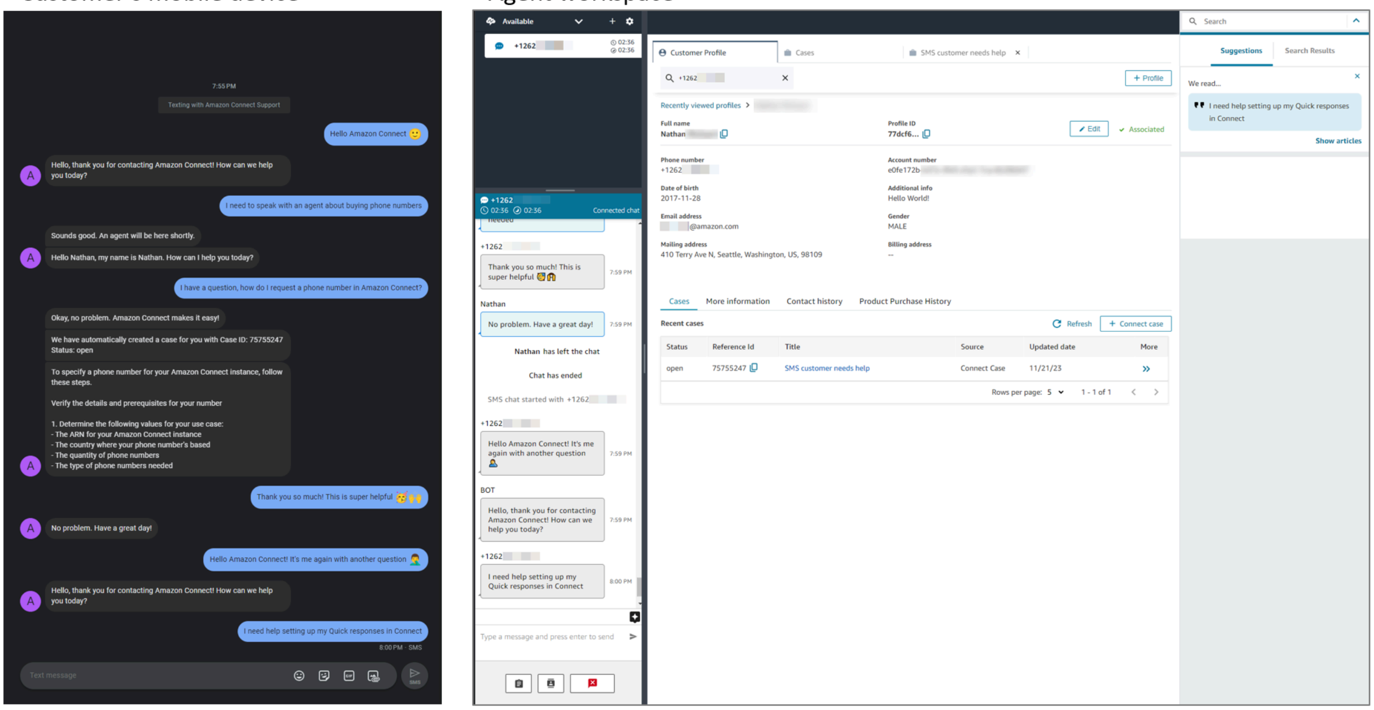
In this step you use the Contact Control Panel (CCP) and a mobile phone to test sending and receiving SMS messages.

1. In your CCP, set your status to **Available**.

2. Using a mobile device, send an SMS to the phone number that you requested in Step 1: Request a number in AWS End User Messaging SMS.

> **Tip**
>
> If your AWS End User Messaging SMS phone number is still in the SMS sandbox, you can only test sending and receiving SMS messages with verified destination numbers that you have configured. For move instructions, see Moving from the SMS sandbox to production.

Customer’s mobile device   Agent workspace



Step 5: Prerequisites for going into production

Before you use SMS in production mode, make sure you've completed the following prerequisites for AWS End User Messaging SMS.

1. Move your account out of SMS/MMS sandbox mode
2. Set up your registration for SMS/MMS
3. Confirm that your spend quota matches your usage requirements
4. Check your opt-out lists

Customers not receiving SMS messages?

Before opening an AWS Support ticket, please verify that you've completed Step 5: Prerequisites for going into production.

Next steps

We recommend the following steps to provide the best experience for your agents and customers.

- Enable customers to resume chat conversations in Amazon Connect: Customers can resume previous conversations with the context, metadata, and transcripts carried forward. They don't need to repeat themselves when they return to a chat, and agents have access to the entire conversation history.
- Create quick responses for use with chat and email contacts in Amazon Connect: Provide agents with pre-written responses to common customer inquiries that they can use while they chat with customers. Quick responses make it faster for agents to respond to customers.

Enable Apple Messages for Business with Amazon Connect

Your customers can engage directly with your contact center from within their Messages application on their iPhone, iPad, and Mac.

When you enable Apple Messages for Business, your customers can find answers to their questions and request help from agents to resolve issues — all while using the familiar Messages application they use every day to chat with friends and family. Any time customers use Search, Safari, Spotlight, Siri, or Maps to call your registered phone number, they will be provided with the option to chat with your contact center.

Apple Messages for Business integration with Amazon Connect enables you to use the same configuration, analytics, routing, and agent UI that you already use for Amazon Connect Chat.

Prerequisites: Determine if Apple Messages for Business is the right channel for your use case

In order to qualify as a business, make sure you meet the criteria listed in the Apple Messages for Business documentation.

If you determine that Apple Messages for Business is the right channel for your business, fill in the following forms:

- Apple Messages for Business readiness document
- Description of your four primary use cases for Apple Messages for Business

Step 1: Register with Apple

Integrate Apple Messages for Business with Amazon Connect by first registering with Apple as a brand. When you do, you'll get a unique Apple Messages for Business Account ID, and you can then link your Apple Messages for Business account to Amazon Connect.

1. Go to the Apple Messages for Business page. In the box that says **As a business, I want to connect with my customers in the Messages app**, choose **Get Started**.
2. Create an Apple ID for your business, if you don't already have one.

   An Apple ID is typically for the personal use of Apple services, such as storing personal content in iCloud and downloading apps from the App Store. If you have a personal Apple ID, we recommend that you create a separate one using your organization’s email address to administer Messages for Business. A separate administrative Apple ID lets you distinguish Messages for Business communications from personal Apple communications.
3. Register a profile for a new Messages for Business account by accepting **Apple’s Terms of Service**. We recommend creating a Commercial Messages for Business Account. You then provide business details, such as a logo and support hours.
4. Select Amazon Connect as your Messaging Service Provider. You can do this by selecting Amazon Connect from the drop-down or by entering the following URL:

   - **https://messagingintegrations.connect.amazonaws.com/applebusinesschat**

After you submit your application to Apple, you’ll see the status of your application at the top of your **Messages for Business Account** page.

For more information about registering with Apple, see the following articles on Apple's website: Getting Started with Messages for Business and Messages for Business Policies and Best Practices.

Step 2: Gather required information

Gather the following information so you have it on hand when you open a support ticket in Step 3:

1. **Apple Messages for Business Account ID**: After you’ve been approved by Apple Messages for Business, you will be issued an Apple Messages for Business Account ID. For information

about locating your Apple Messages for Business Account ID, see Find your Apple Messages for Business Account ID for your integration with Amazon Connect.

> **Note**
>
> Your Apple Messages for Business Account ID is a randomized string of numbers and letters. It is not the same as your Apple ID.

2. **Apple Token**: This is a unique ID that authenticates your account. For help locating your Apple token, see Find your Apple token when integrating Apple Messages for Business with Amazon Connect.
3. **Amazon Connect instance ARN**: This is the identifier for the instance you want to link to your Apple business account. For information about locating your instance ID, see Find your Amazon Connect instance ID or ARN.

> **Note**
>
> Make sure you have service-linked roles enabled for the integration.
> If your instance was created before **October 2018**, add the `connect:*` policy on the role that is associated with your Amazon Connect instance. For more information about service-linked roles, see Use service-linked roles and role permissions for Amazon Connect.

4. **Amazon Connect flow ID**: This is the identifier for the flow you want to use for inbound chats. For information about locating your flow ID, see Find the flow ID when integrating Apple Messages for Business with Amazon Connect.

Step 3: Link your Apple Messages for Business ID to Amazon Connect

In this step you create an Amazon Connect support ticket to link your Apple Messages for Business ID to Amazon Connect.

1. Create a special Support ticket to link your Apple Messages for Business to Amazon Connect.

   If prompted, login using your AWS account.

> **Tip**
>
> Looking for technical support? Open an Support ticket here.

2. Choose **Account and billing**.
3. Use the dropdown box to choose **Account**. For **Category** choose **Activation**, and then choose **Next step: Additional information**.
4. For **Subject** enter **Apple Messages for Business Integration request**.
5. In the **Description** box, copy and paste the following template:

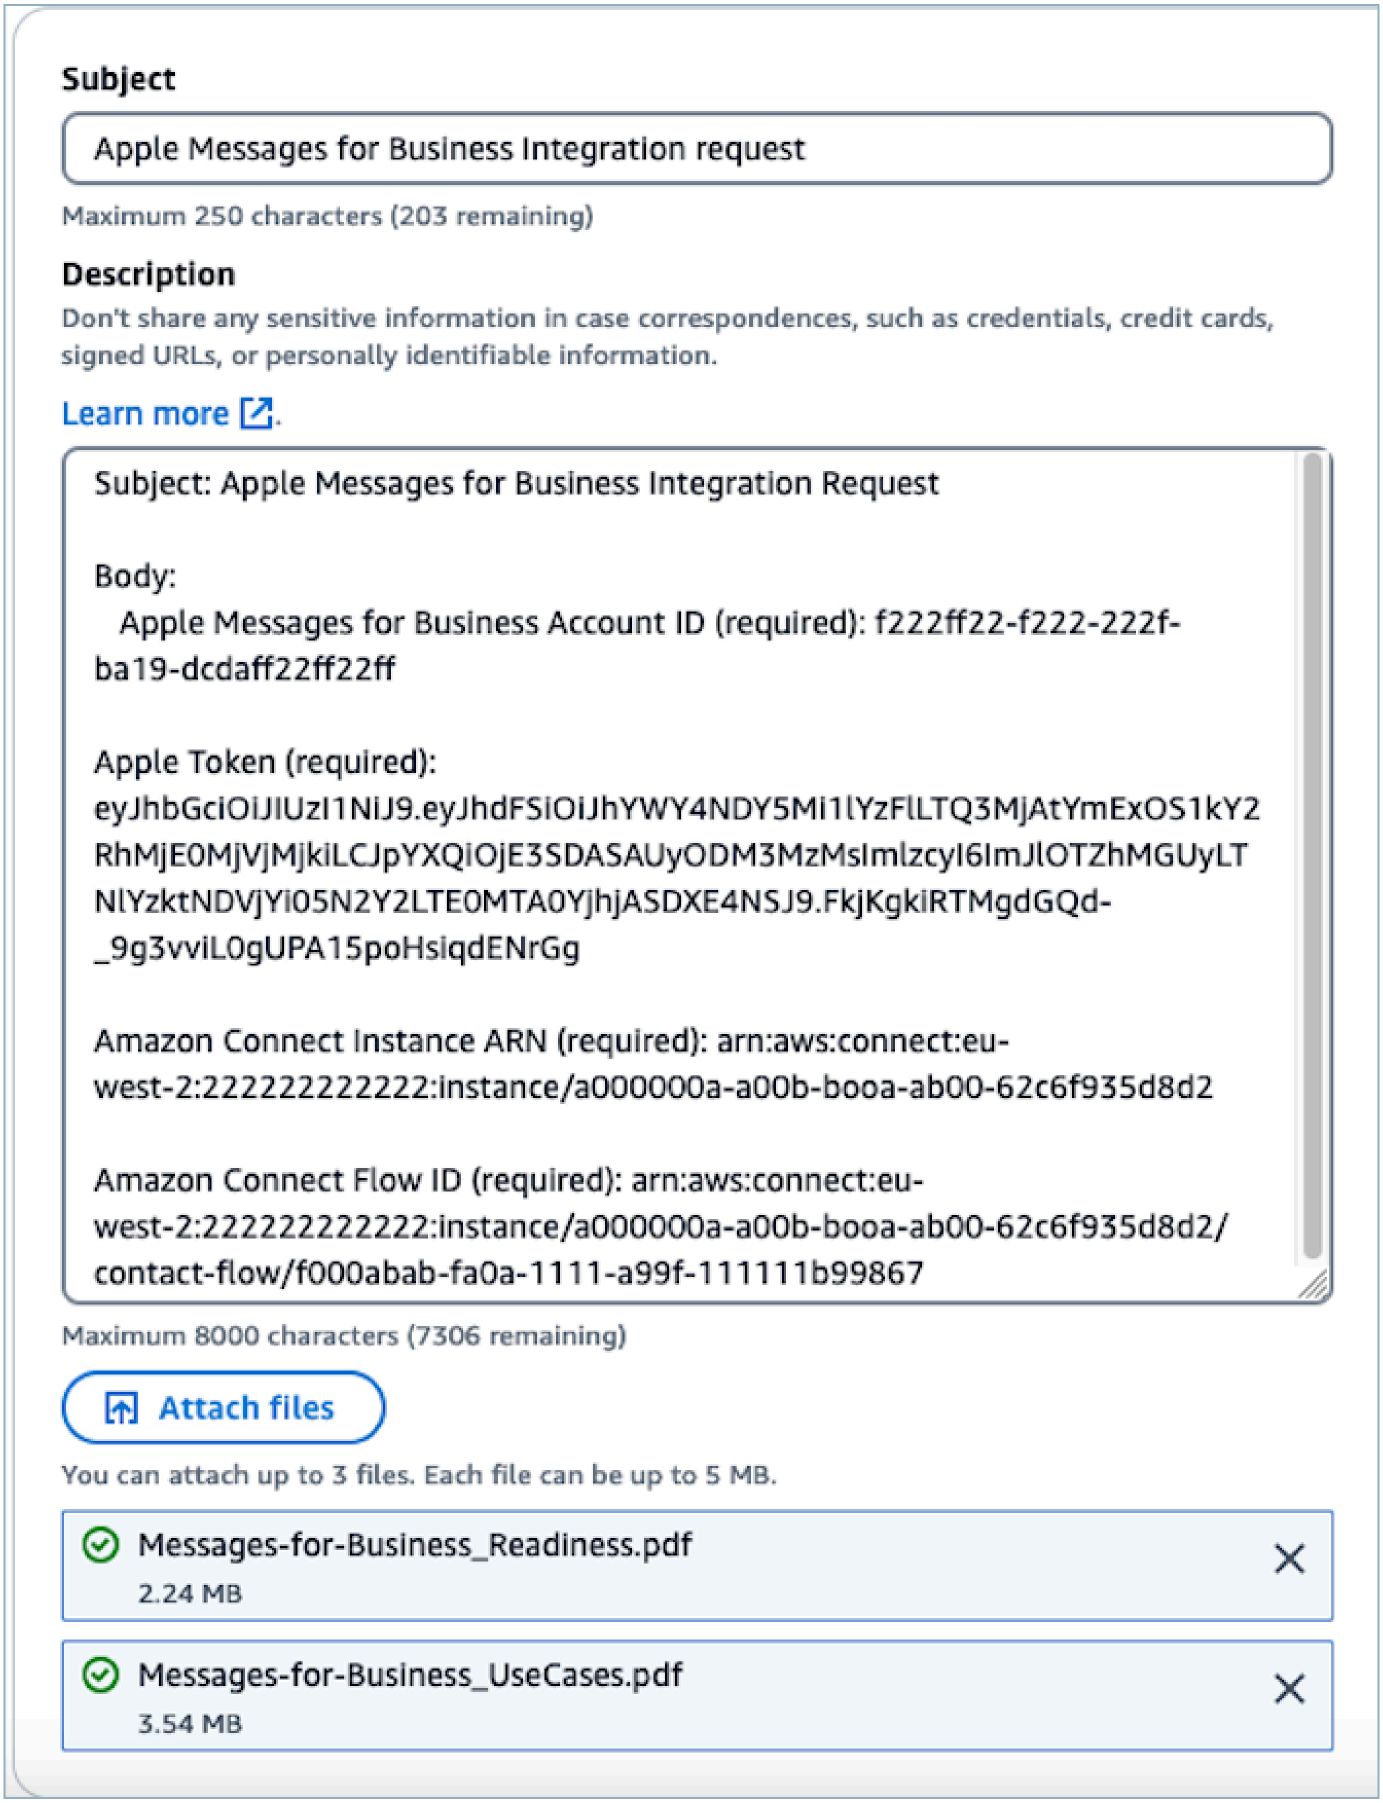
```
Subject: Apple Messages for Business Integration request
   Body:

   Apple Messages for Business Account ID (required): enter your account ID
   Apple Token (required): enter your Apple token
   Amazon Connect Instance ARN (required): enter your instance ARN
   Amazon Connect Flow ID (required): enter your flow ID
```

6. Attach the two forms from the prerequisites section to the support ticket.

> **Note**
>
> This step is required. Your request will not be processed if you do not attach these forms.

The following image shows an example of a completed ticket:



Subject
Apple Messages for Business Integration request
Maximum 250 characters (203 remaining)
Description
Don't share any sensitive information in case correspondences, such as credentials, credit cards, signed URLs, or personally identifiable information.

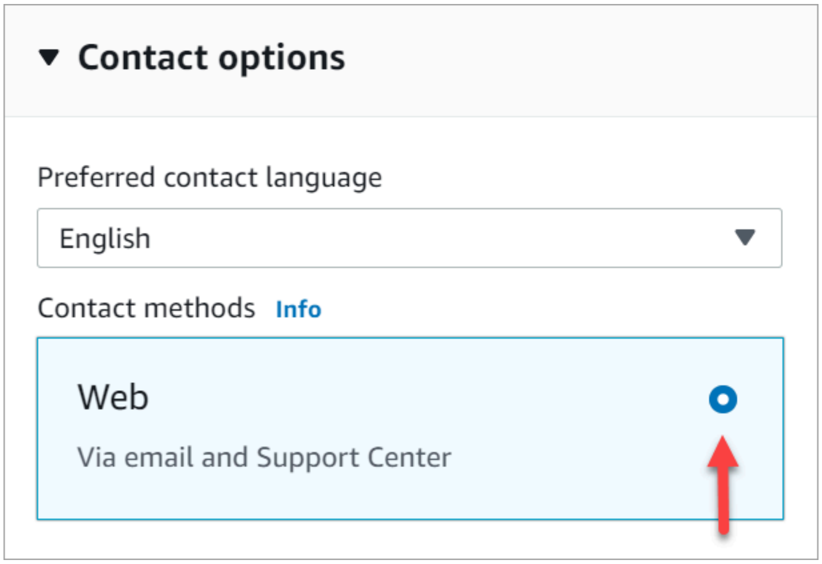
7. Choose **Next step**.

8. Choose **Contact us**, choose your **Preferred contact language**, and then choose **Web** as the contact method, if it's not selected by default.



9. Choose **Submit**.

10. Support will work directly with the Amazon Connect team on your request and follow up with any additional questions.

Next steps

After Apple Messages for Business is enabled for your Amazon Connect instance, you can [add Apple Messages for Business features] to your messages. For example:

- Deflect calls with Apple's Message Suggest.
- Embed Apple Messages for Business buttons on your website.
- Add list pickers, time pickers, forms, and quick replies to your messages.
- Add Apple Pay, iMessage Apps, and Authentication to your integration.
- Use rich links for URLs.
- Route Apple Messages for Business messages using contact attributes.
- Enable Attachments for your integration.

Additionally, pass the Apple experience review.

Send a test message for Apple Messages for Business to test integration with Amazon Connect

After onboarding to the Apple Messages for Business account, use the following steps to send a test message to make sure the integration is set up properly.

Step 1: Add internal testers to your Messages for Business account

1. Sign in to Apple Business Register.
2. Choose **Messages for Business Accounts** and select the account to add testers.
3. Scroll down the page to **Account Testing**.
4. Add the Apple IDs of your internal testers.
5. When your list is complete and you are ready to begin testing, choose **Send to new testers** to send an instructional email to your testers.

An instructional email containing a link to your Messages for Business conversation is sent to the Apple ID email address of each tester. If a tester does not receive the email, then recheck that their email address is provided in the Account Testing section. It's most likely that the email address is incorrect or it's not an Apple ID. For security reasons, Apple cannot verify Apple ID email addresses.

Step 2: Test sending and receiving messages

When your testers get the instructional email, they will need to activate the link in it. After doing this, they can send messages to your agents, who can then reply from the Contact Control Panel (CCP).

Note the following:

1. Design a test to trigger all of your Apple Messages for Business features.
2. You should observe that messages sent from an iOS device arrive to your test business. Employees testing from your support agent desktop should be able to respond to these test messages.
3. Your testers may notice your brand colors are not visible in the Messages header. Brand color is not available while your account is in test mode. The colors for your brand will display correctly after your account goes online.
4. If you send the testing link to someone whose email is not listed in the Account Testing section, they will not be able to send messages.

5. If you provide a Redirect Page URL and your testers try to enter Messages for Business from an unsupported device, they will land either on a default or redirected page. You can set your Redirect Page URL in the **Unsupported Devices** section at the bottom of your Messages for Business account page.

To begin testing

1. Check that your testers are using a device with a supported iOS: iOS 11.3 and later, or macOS 10.13.4.
2. Ask your testers to doing the following:
   a. Use their supported devices to find the email sent to them.
   b. Open the email from the supported device, and then choose the link. It takes them to a Messages for Business conversation in the Messages app.

Troubleshoot

If you encounter any issues when sending a test message, follow these steps:

1. Confirm that you've allowlisted your email address/Apple ID as a tester in your Messages for Business account.
2. Confirm the following settings on your Apple device:
   - Go to **Settings** > **Messages** and check that **iMessage** is enabled.
   - Go to **Settings** > **Messages** > **Send & Receive** and check that the AppleID is correct and messages are allowed to receive.
3. Check that you're using a supported iOS. Apple devices running iOS 11.3 and later or macOS 10.13.4 and later support Messages for Business.
4. When you selected Amazon Connect as your MSP in your Apple Account, did you select **Amazon Connect** from the dropdown? Or did you enter the following URL:
   - https://messagingintegrations.connect.amazonaws.com/applebusinesschat

   If you entered the URL, doublecheck for typos.

Enable authentication for Apple Messages for Business

To begin the setup process, first navigate to your Identity Provider.

Identity Provider Configuration

The following Amazon Connect domain must be registered as an allowed Redirect URI for the Identity Provider(s) used for authentication:

```
https://participant.connect.region.amazonaws.com/participant/authentication/update
```

Integration with Amazon Cognito

You can add your Identity Provider(s) to an existing Amazon Cognito user pool or create a new Amazon Cognito user pools.

Within this user pool you can create an app client and select some or all of your Identity Providers. Take note of the app client's client ID. For this app client, the following Amazon Connect domain must be added as an Allowed callback URL:

```
https://participant.connect.region.amazonaws.com/participant/authentication/update
```

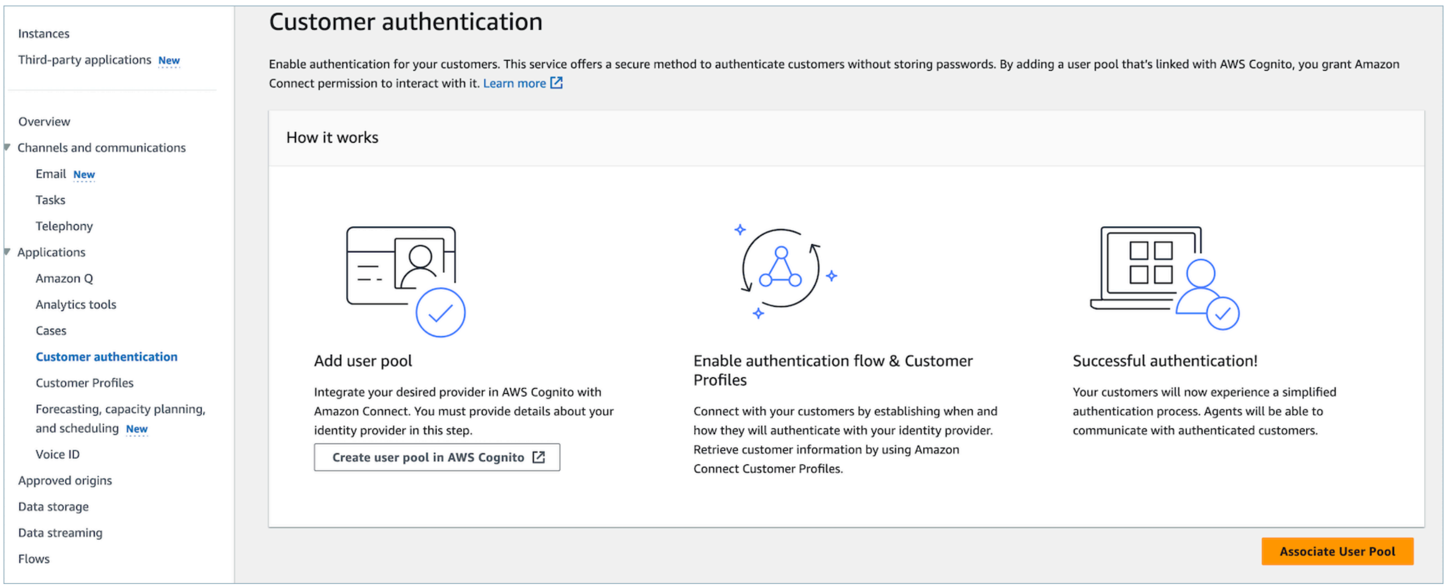
> **Note**
>
> You must select **Don't generate a client secret** when configuring the Amazon Cognito app client. Only Amazon Cognito app clients without client secrets are supported.

Configure your Amazon Cognito app client with the Apple Messages for Business Portal

On **Integrated OAuth2 Authentication**, configure your Amazon Cognito app client client ID as the **Client Identifier** and your Amazon Cognito user pool domain's authorization endpoint as the **OAuth URL**.

Configure your user pools with Amazon Connect

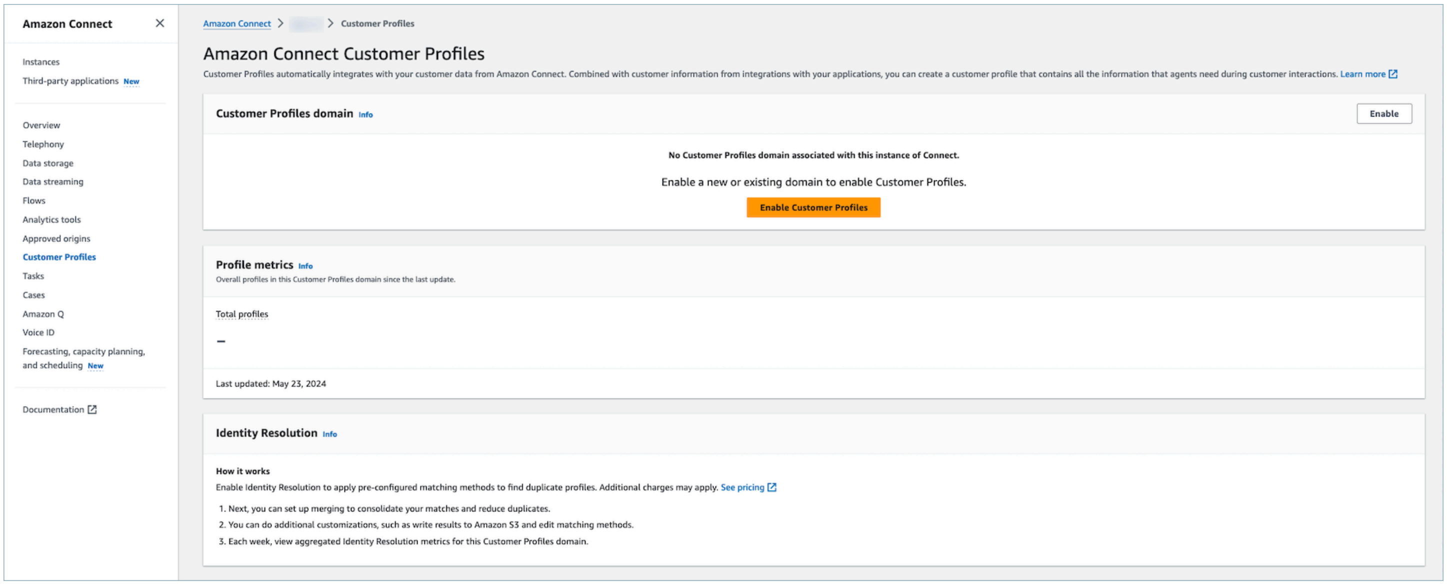
On the **Customer authentication** page on the Amazon Connect console associate the user pool that will be used for the authentication.



Enable Amazon Connect Customer Profiles

Enable Customer Profiles

On the **Customer Profiles** page in Amazon Connect console, ensure that Customer Profiles is enabled for your instance. If **No Customer Profiles domain associated with this instance of Amazon Connect.** is displayed, then see [Enable Customer Profiles for your Amazon Connect instance](#).



Grant Customer Profile permission(s) to security profiles (optional)

To grant users (agent, admin) permissions to view/edit/publish Customer Profiles in Agent Workspace, see Update Customer Profiles permissions for agents. After permission(s) are granted to security profile(s), users should be able to access the features in the Agent Workspace.

For a detailed list of permissions, see Customer Profiles security profile permissions.

Configure the Authenticate Customer flow block

For instructions, see Flow block in Amazon Connect: Authenticate Customer.

Add Apple Messages for Business features

Deflect calls with Apple's Message Suggest

With Message Suggest you can allow users to choose between voice and messaging when tapping on your business phone number in Safari, Maps, Siri, or Search.

To enable Message Suggest, send an email to the Apple Messages for Business Team at **registry@apple.com** with the following information and Apple can set up the channel for you:

- Provide all of your primary phone numbers, including high call volume phone numbers.
- Provide phone contact hours to set customer expectations for your after-hours message.
- Provide intent, group, and body parameters to associate with each phone number.

- Provide an estimate of how many customers your agents can support per day. This can be increased or decreased depending on operational capacity.

To learn more about enabling Message Suggest, see [Apple's Message Suggest FAQs](#).

Embed Apple Messages for Business buttons

To embed Apple Messages for Business buttons on your website or mobile app, do the following:

1. Add Apple's Messages for Business JS (JavaScript) library to your webpage headers.
2. Add a `div` container to house the button.
3. Customize the banner, fallback support, and button color to meet your brand's needs.

The Messages for Business button must contain the following, at minimum:

- A class attribute to specify the type of container: banner, phone, or message.
- A data-apple-business-id attribute with the business ID you received when you registered your company with Messages for Business.

Authentication

Authentication allows customers to sign in to your Identity Provider(s) of choice during a chat conversation. The authentication feature leverages the OAuth2 and OIDC framework to verify the identity of the customer upon successful sign in. for more information, see Enable authentication for Apple Messages for Business.

Start a chat from a URL

You can give your customers the ability to start a conversation with you from your website or an email message.

For example, customers may start a chat using a URL that you provide. When they click the URL, the system redirects them to Messages so they can send your business a text message.

You decide how and where to provide the URL. You can include it as a link in an email message, on your website, or use it as the action for a button in your app.

Use the URL **https://bcrw.apple.com/urn:biz:*`your-business-id`***, replacing *`your-business-id`* with the business ID you received from Apple after registering with Messages for Business.

Following are optional query string parameters you can include in the URL:

- `biz-intent-id`: Use to specify the intention, or purpose, of the chat.
- `biz-group-id`: Use to indicate the group, department, or individuals best qualified to handle the customer's specific question or problem.
- body: Use to prepopulate the message so the customer only presses **Send** to start the conversation.

Following is an example of what the URL might look like for a customer with a credit card question for the billing department:

- `https://bcrw.apple.com/urn:biz:22222222-dddd-4444-bbbb-777777777777?biz-intent-id=account_question&biz-group-id=billing_department&body=Order%20additional%20credit%20card`.

Add list pickers, time pickers, forms, attachments, and quick replies

A list picker prompts your customer to select an item, such as a product or the reason for their inquiry. A time picker prompts your customer to choose an available time slot, such as to schedule an appointment. A quick reply prompts your customer to select a simple, inline response. Forms allow you to create rich, multiple page, interactive flows for customers.

For information about how to set up list pickers, time pickers, forms, and quick replies, see Add Amazon Lex interactive messages for customers in chat.

For information about how to enable attachments, see Enable attachments to share files using chat.

Apple Pay

Apple Pay allows consumers to complete purchases without having to manage paper bills, coins, or physical bank cards. Using Apple Messages for Business, consumers can complete transactions with their favorite brands without having to leave the Messages app.

Apple Pay is a distinct feature, but shares similarities to Apple Pay in-app and Apple Pay on the Web. When a business asks for payment from a customer who is purchasing goods and services through Apple Messages for Business, the customer can use Apple Pay to make the payment.

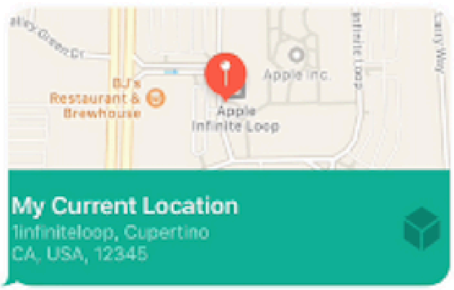
To learn more about Apple Pay, see Apple Pay for developers.

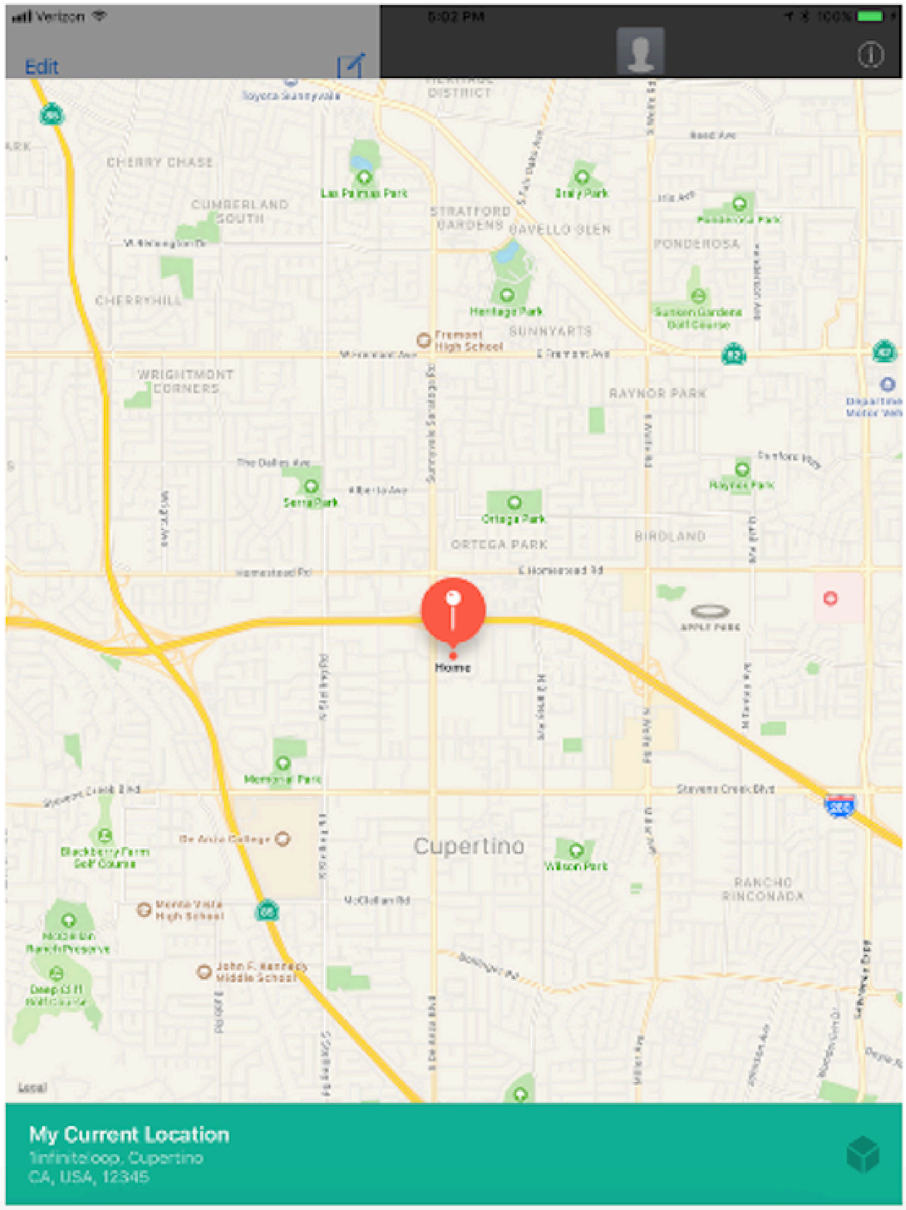
For information about how to set up Apple Pay using Connect, see Add Amazon Lex interactive messages for customers in chat.

iMessage Apps

iMessage apps or Apple Custom Interactive Messages (CIM) increase interactivity between end-customers and business customers, allowing end-customers to receive iMessage Apps from businesses. These iMessage Apps contain a richer set of information for end-customers to interact with completely inside of Apple's Messages app, allowing the end-customer to remain in the conversation to perform the same interactions. This makes the Apple CIM more customizable than other existing interactive message types.

The following figure is an example of an iMessage App sent using an Apple CIM with a detailed map and location pin:

Initial Response in Messages for Business	iMessage App
On the user device, you should see the following message bubble.	When the user taps the message bubble, a detailed map opens up with a location pin.
	




For information about how to set iMessage Apps using Amazon Connect, see [Add Amazon Lex interactive messages for customers in chat](#).

Use rich links for URLs

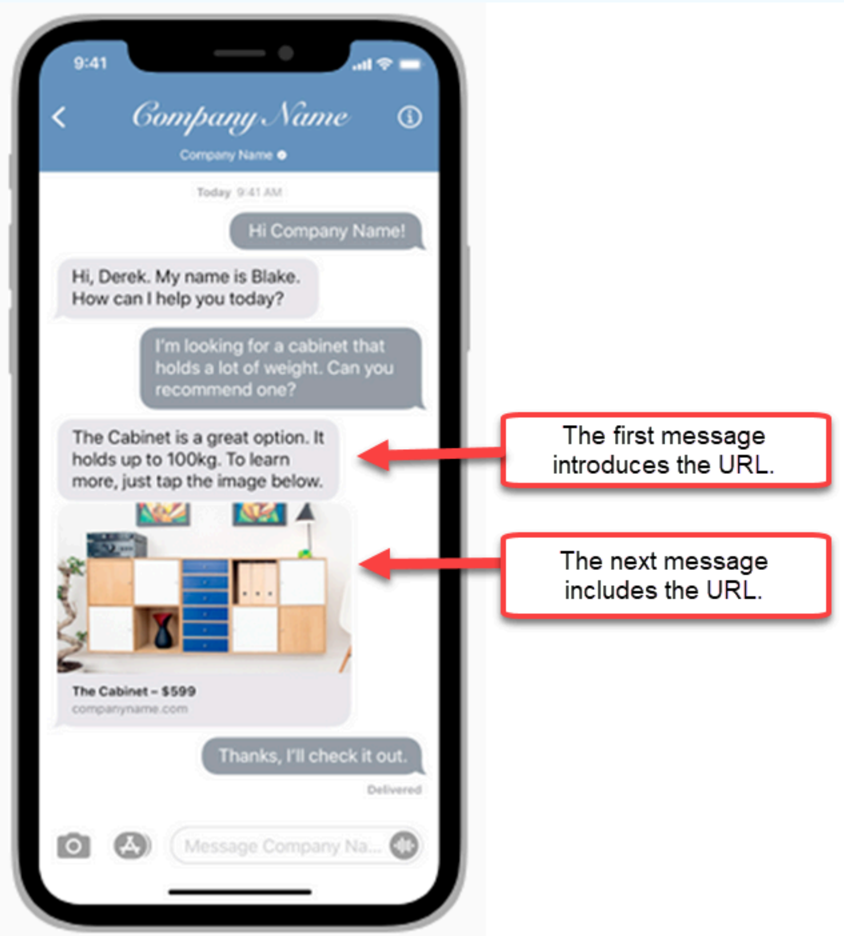
Rich links show an inline preview of a URL that contains an image. Unlike normal URLs, customers can view the image immediately in a chat without choosing a "Tap to Load Preview" message.

Requirements for using rich links in Amazon Connect

To use rich links in Amazon Connect chat messages, your URL and images must meet the following requirements:

- Your website must use Facebook Open Graph tags. For more information, see A Guide to Sharing for Webmasters.
- The image accompanying the URL must be .jpeg, .jpg, or .png.
- The website must be HTML.

> **Note**
>
> When you first use the rich link feature, we recommend that you send the URL in a message separate from your chat text, as shown in the following example. The first message introduces the URL. The next message includes the URL.



Use Apple Messages for Business contact attributes in contact flows

Contact attributes enable you to store temporary information about the contact so you can use it in the flow.

For example, if you have different lines of business using Apple Messages for Business, you can branch to different flows based on the **AppleBusinessChatGroup** contact attribute. Or, if you want to route Apple Messages for Business messages differently from other chat messages, you can branch based on MessagingPlatform.

For more information about contact attributes, see Use Amazon Connect contact attributes.

Use the following contact attributes to route Apple Messages for Business customers.

Attribute	Description	Type	JSON
MessagingPlatform	The messaging platform from where the customer request originated. Exact value: **AppleBusinessChat**	User-defined	$.Attributes.MessagingPlatform
AppleBusinessChatCustomerId	The customer's opaque ID provided by Apple. This remains constant for the AppleID and a business. You can use this to identify if the message is from a new customer or a returning customer.	User-defined	$.Attributes.AppleBusinessChatCustomerId
AppleBusinessChatIntent	You can define the intent or purpose of the chat. This parameter is included in a URL that initiates a chat session in Messages when a customer chooses the **Business Chat** button.	User-defined	$.Attributes.AppleBusinessChatIntent
AppleBusinessChatGroup	You define the group which designates the department or individuals best qualified to handle	User-defined	$.Attributes.AppleBusinessChatGroup

Attribute	Description	Type	JSON
	the customer’s particular question or problem. This parameter is included in a URL that initiates a chat session in Messages when a customer chooses the **Business Chat** button.		
AppleBusinessChatLocale	Defines the language and AWS Region preferences that the user wants to see in their user interface. It consists of a language identifier (ISO 639-1) and a Region identifier (ISO 3166). For example, **en_US**.	User-defined	$.Attributes.AppleBusinessChatLocale
AppleFormCapability	Whether the customer device supports forms. If true, the customer device is supported. If false, the device is not supported.	User-defined	$.Attributes.AppleFormCapability

Attribute	Description	Type	JSON
AppleAuthenticationCapability	Whether the customer device supports Authentication (OAuth2). If true, the customer device is supported. If false, their device is not supported.	User-defined	$.Attributes.AppleAuthenticationCapability
AppleTimePickerCapability	Whether the customer device supports time pickers. If true, the customer device is supported. If false, the device is not supported.	User-defined	$.Attributes.AppleTimePickerCapability
AppleListPickerCapability	Whether the customer device supports list pickers. If true, the customer device is supported. If false, the device is not supported.	User-defined	$.Attributes.AppleListPickerCapability

Attribute	Description	Type	JSON
AppleQuickReplyCapability	Whether the customer device supports quick replies. If true, the customer device is supported. If false, the device is not supported.	User-defined	$.Attributes.AppleQuickReplyCapability

Update an Apple Messages for Business integration with Amazon Connect

You will need to update your Apple Messages for Business integration if you want to change the flow ID or other information.

1. Open an Support ticket.

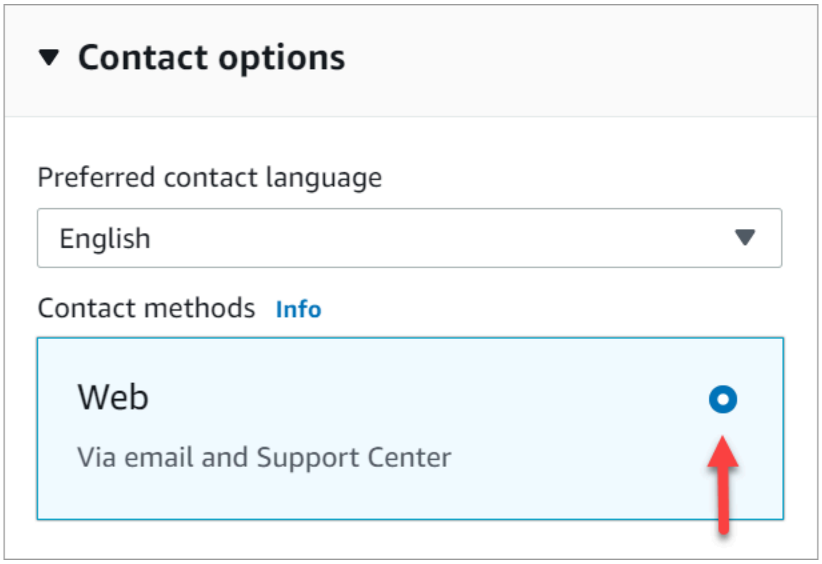
   If prompted, login using your AWS account.

2. In the **Use case description** box, copy and paste the following template to indicate this is an **update** request:

```
Subject: Update Apple Messages for Business Integration request
Body:
   Apple Messages for Business Account ID (required): enter your current account ID
 change to new account ID
   Apple Token (required): enter your token
   Amazon Connect Instance ARN (required): enter your current instance ARN change
 to new instance ARN
   Amazon Connect Flow ID (required): enter your current flow ID change to new flow
 ID
```

> **Note**
>
> If you update your Amazon Connect Instance ARN, you must also update your contact flow ID.

3. Expand **Contact options**, and then choose your **Preferred contact language**, and then choose **Web** as the contact method, if it's not selected by default.



4. Choose **Submit**.

5. Support will work directly with the Amazon Connect team on your request and follow up with any additional questions.

Delete an Apple Messages for Business integration with Amazon Connect

1. Open an [Support ticket](#).

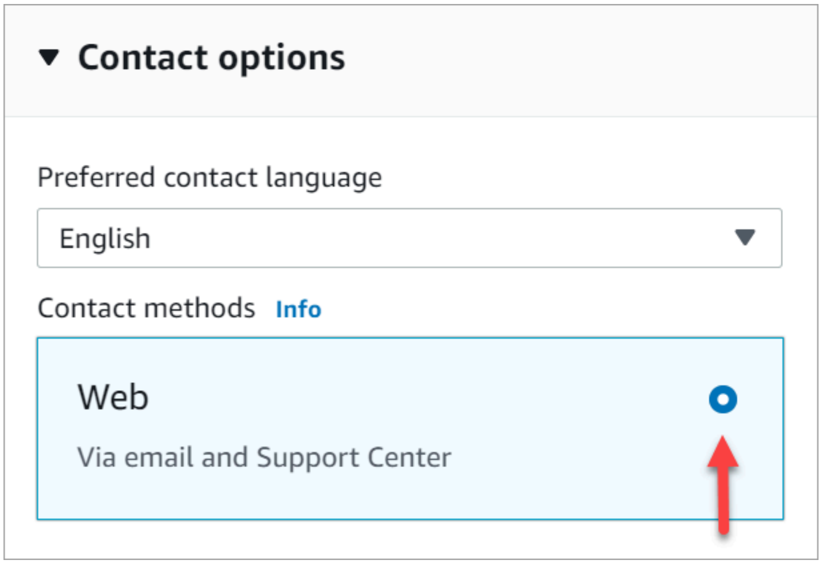
   If prompted, log in by using your AWS account.

2. In the **Use case description** box, copy and paste the following template to indicate this is an **delete** request:

```
Subject: Delete Apple Messages for Business Integration
Body:
  Apple Messages for Business Account ID (required): enter your account ID
   Amazon Connect Instance ARN (required): enter your instance ARN
   Amazon Connect Flow ID (required): enter your flow ID
```

The following image shows an example of a completed ticket:

3. Expand **Contact options**, and then choose your **Preferred contact language**, and then choose **Web** as the contact method, if it's not selected by default.

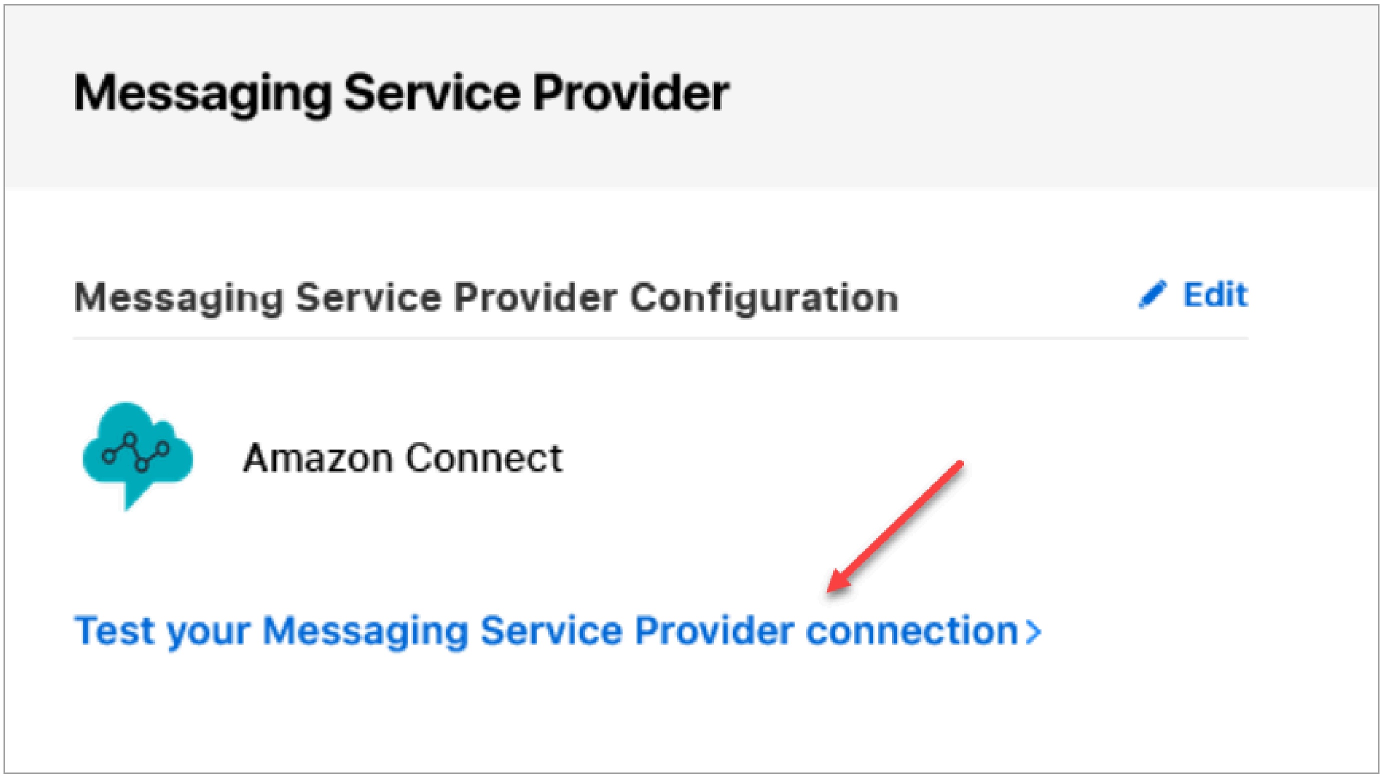


4. Choose **Submit**.

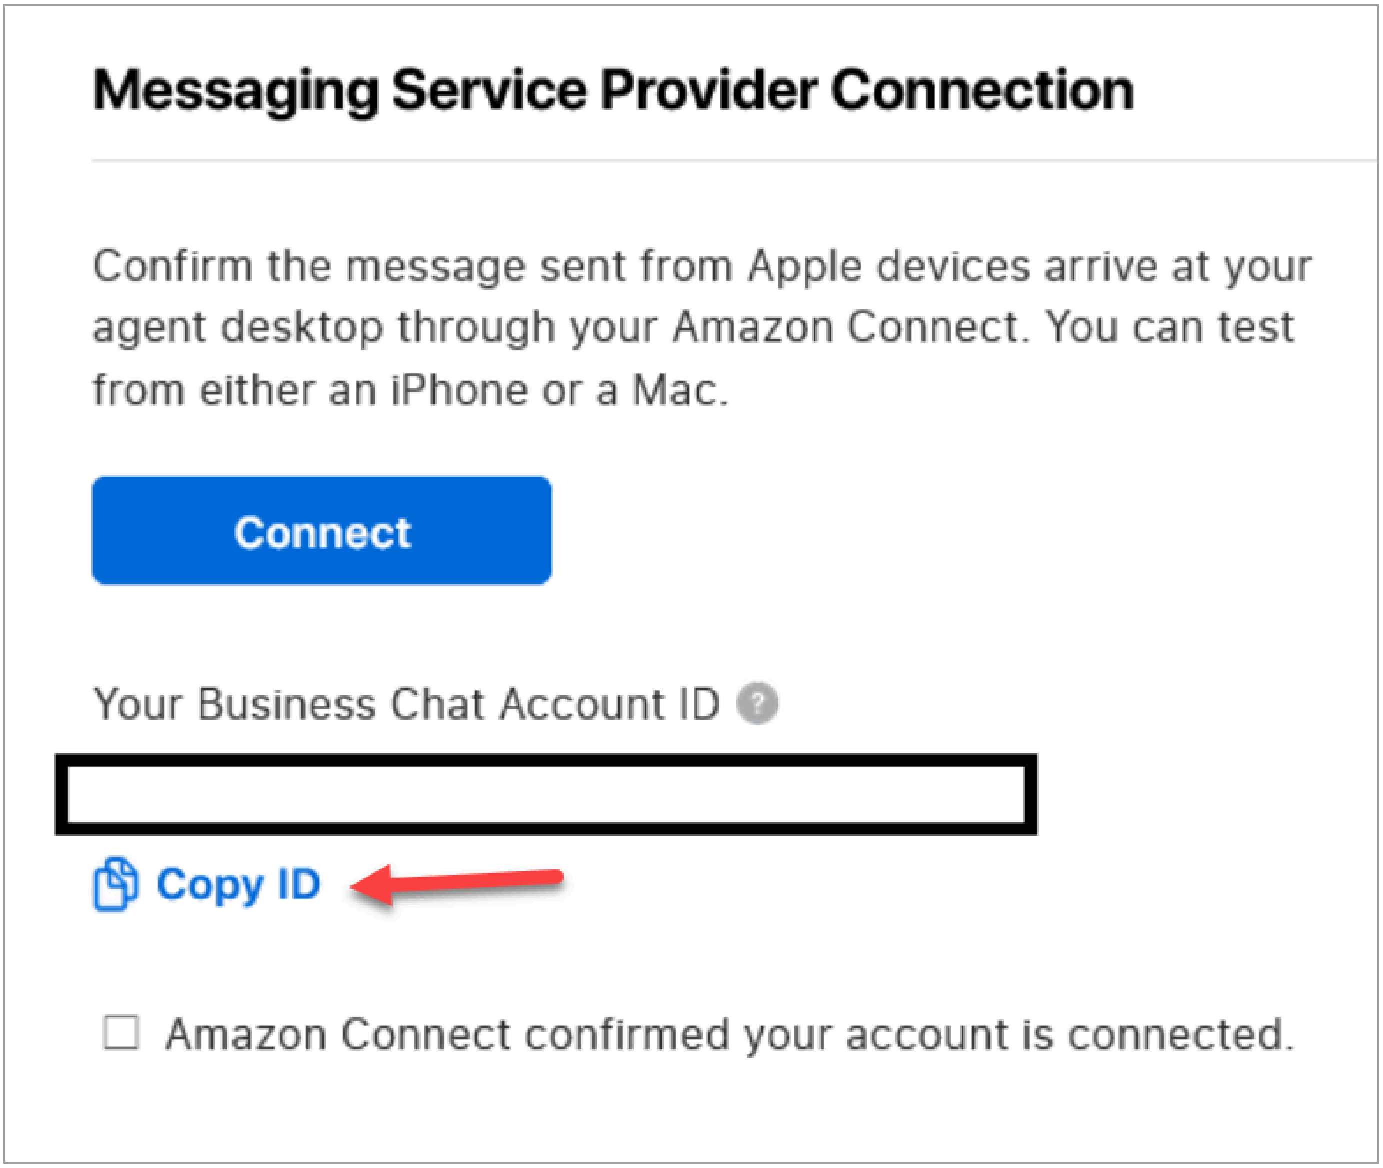
5. Support will work directly with the Amazon Connect team on your request and follow up with any additional questions.

Find your Apple Messages for Business Account ID for your integration with Amazon Connect

1. In Apple Business Register, navigate to **Message Service Provider** and click or tap **Test your Messaging Service Provider connection**.

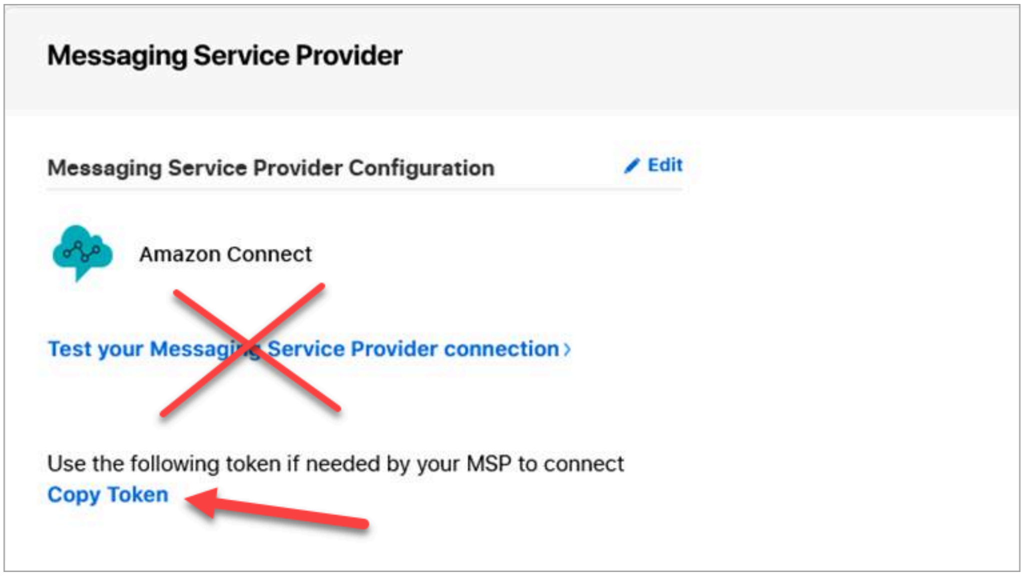


2. Click or tap **Copy ID**.



Find your Apple token when integrating Apple Messages for Business with Amazon Connect

- In Apple Business Register navigate to **Messaging Service Provider** and choose **Copy Token**.



Find the flow ID when integrating Apple Messages for Business with Amazon Connect

The flow ID is the flow you want to use for inbound Apple Messages for Business messages. Flows define the experiences for your customer when they begin a new chat.

You can either reuse an existing flow that you're already using for voice or chat contacts, or create a new one specifically for Apple Messages for Business contacts. For instructions about creating a new inbound flow, see Create an inbound flow.

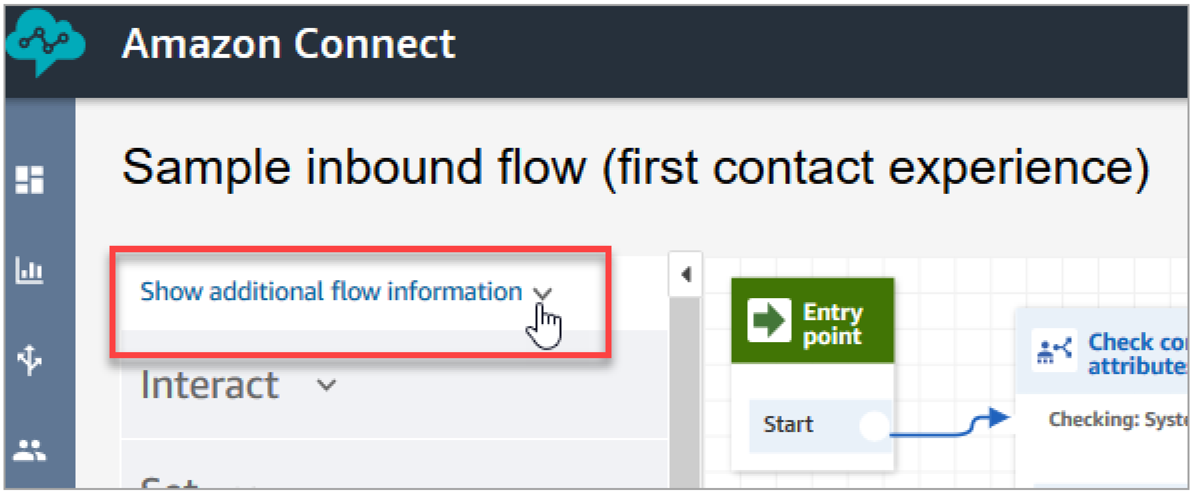
For more information about flows, see Flows in Amazon Connect.

To find your flow ID for Apple Messages for Business

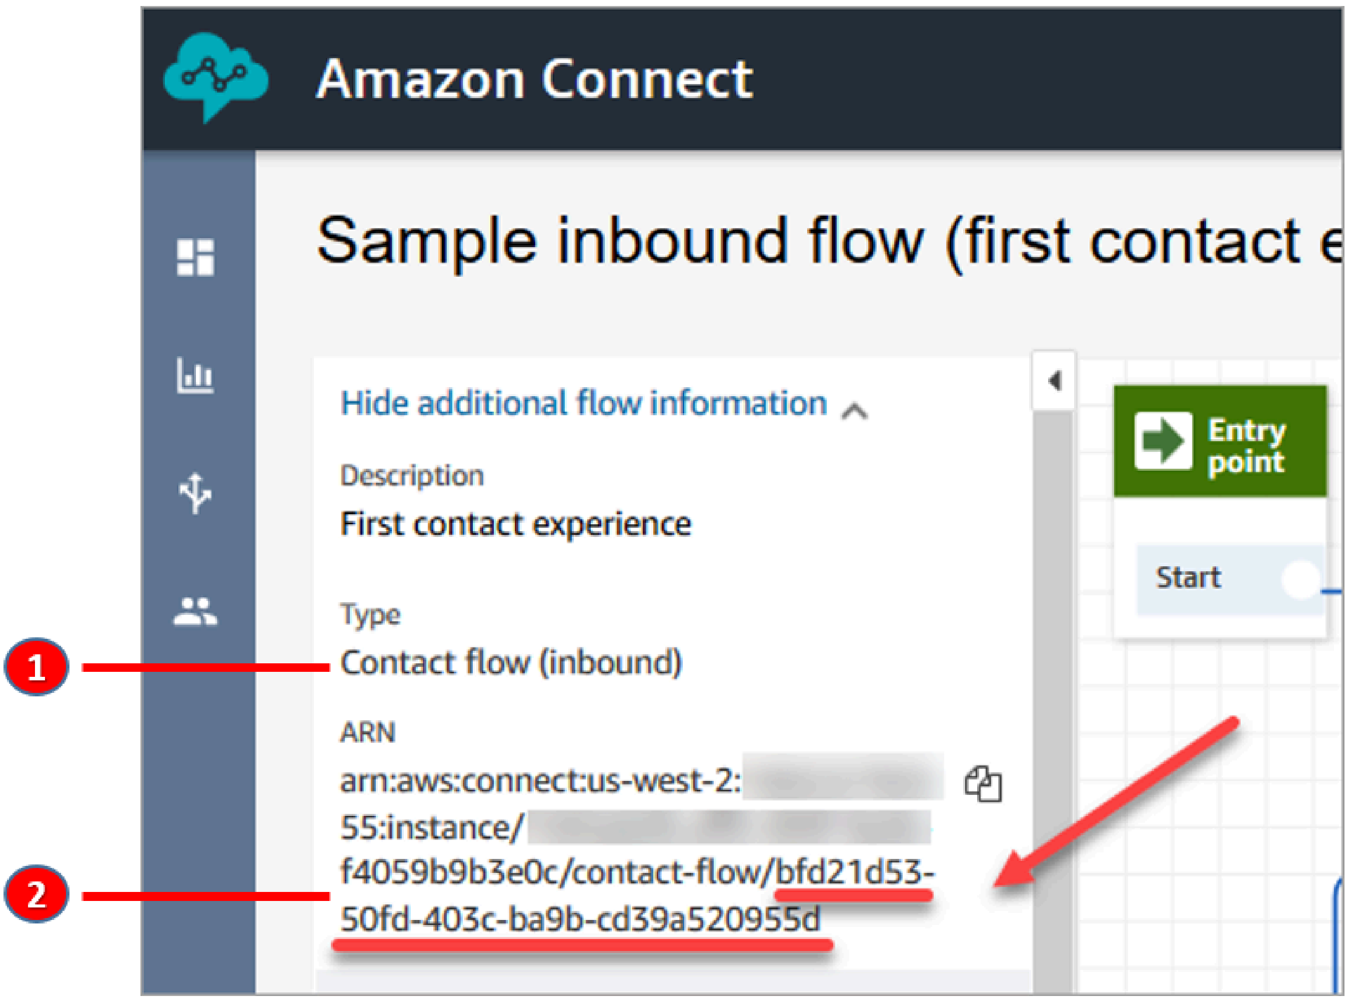
1. Log in to the Amazon Connect console with an **Admin** account, or an account assigned to a security profile that has permissions to view contact flows.
2. On the navigation menu, choose **Routing**, **Contact flows**.
3. Select the flow you want to use.

> **Note**
>
> Only choose flows that are type **Flow (inbound)**. Apple Messages for Business doesn't work with other flow types, such as **Customer queue**, **Customer hold**, **Customer whisper**, etc.

4. In the flow designer, expand **Show additional flow information**.



5. Under the ARN (Amazon Resource Number), copy everything after contact-flow/. For example, in the following image, you would copy the underlined part.



1. Notice the **Type** = **Flow (Inbound)**.
2. The flow ID is at the end of the ARN. Only copy this end part.

Manage Apple Messages for Business chats in your Amazon Connect instance

When you integrate Apple Messages for Business with your Amazon Connect instance, messages from Apple Messages for Business behave exactly like any other chat messages arriving to your contact center.

> **Note**
>
> The Amazon Connect Chat service quota limits apply to Apple Messages for Business. To learn more, see Amazon Connect service quotas.

Set up automatic replies

You can use Amazon Lex to set up automatic replies to chat. For a tutorial that introduces you to setting up Amazon Lex and Amazon Connect, see Add an Amazon Lex bot to Amazon Connect.

Set up WhatsApp Business messaging

The topics in this section explain how to set up and test WhatsApp Business messaging for Amazon Connect. You use AWS End User Messaging Social to link a WhatsApp Business Account and phone number to an Amazon Connect instance, then import the linked phone number into Amazon Connect. Customers can then use WhatsApp to send messages to your call center.

You can also use Amazon Lex to automate responses to customer questions, which saves agents time and effort. For more information, see Getting started with Amazon Lex in the *Amazon Lex Developer Guide*.

Contents

- Next steps: Preparing to go live
- Troubleshoot common problems
- WhatsApp Business messaging capabilities and limitations with Amazon Connect

Prerequisites

Before you can integrate WhatsApp with Amazon Connect, you must have the following items:

- A WhatsApp Business Account.
- A WhatsApp phone number. The number must be able to receive a voice call or an SMS text message in order to complete Meta's phone number verification process for WhatsApp Business messaging. You can use an Amazon Connect voice number or an AWS End User Messaging SMS number for the WhatsApp phone number. You can also use a phone number that you own outside of AWS.

  When using an Amazon Connect voice number or AWS End User Messaging SMS number, we recommend claiming a new number that isn’t used with live voice or SMS traffic to avoid potential disruption of service.

  You can use the AWS End User Messaging Social console at https://console.aws.amazon.com/social-messaging/ to create the WhatsApp Business Account and phone number. For more information, see Signing up for WhatsApp in the *AWS End User Messaging Social User Guide*.

> **Important**
>
> WhatsApp has an automated business verification process that can take up to 2 weeks to complete. We recommend you begin this process early. WhatsApp can disable WhatsApp Business Accounts if the WhatsApp Business policy is violated or the business identity can't be verified.
> Also, we strongly recommend reviewing Best practices for AWS End User Messaging Social and WhatsApp Best Practices before creating and linking WhatsApp resources.

After you create the account and phone number, complete the steps in the following sections in the order listed.

Step 1: Enable Amazon Connect as the event destination

The following steps explain how to use AWS End User Messaging Social to enable Amazon Connect as the event destination for your linked WhatsApp Business Account. This enables the system to import your WhatsApp phone number.

You can use the AWS End User Messaging Social console or the AWS CLI to complete this task. To use the AWS CLI, see ImportPhoneNumber in the *Amazon Connect API Reference*, and PutWhatsAppBusinessAccountEventDestinations in the *AWS End User Messaging Social API Reference*.

The following steps explain how to use the console.

To use the console

1. Sign in to the AWS End User Messaging Social console at https://console.aws.amazon.com/social-messaging/.
2. In the navigation pane, choose **WhatsApp Business accounts**, then choose the desired account.
3. On the **Event destination** tab, choose **Edit destination**.
4. For **Destination type**, choose **Amazon Connect**.
5. For **Connect instance**, choose your Amazon Connect instance from the dropdown list.
6. For **Role ARN**, choose an IAM role that grants permission to deliver messages and events, and to import phone numbers. For example IAM policies, see Add a message and event destination to AWS End User Messaging Social in the *AWS End User Messaging Social User Guide*.
7. Choose **Save changes**.

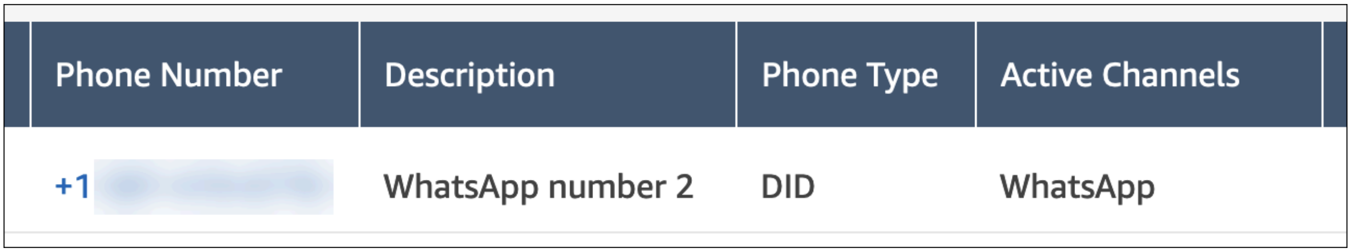
   This starts the process of importing your phone number to Amazon Connect.

   After the operation finishes, the number appears in the Amazon Connect admin website.

   To view the number

   - In the navigation pane, choose **Channels**, then **Phone numbers**.

     The **Active Channels** column displays **WhatsApp** for all WhatsApp numbers.



Step 2: Configure an inbound contact flow on your phone number

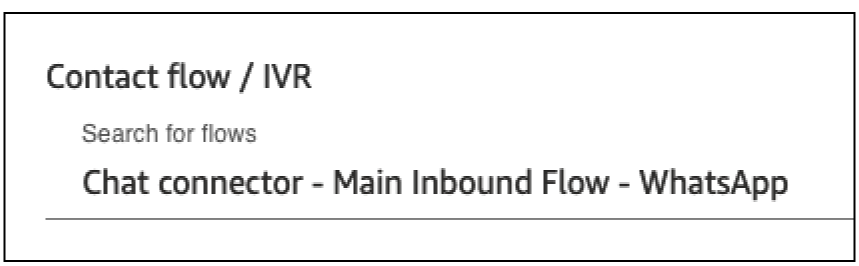
You can create an inbound contact flow for use with your WhatsApp phone number, or you can reuse an existing flow. If you reuse a flow, you can add a `CheckContactAttribute` block and enable branching for the flow. The block enables you to send WhatsApp contacts to a specific queue, or take another action.

For more information about building your contact flow, including interactive messages and rich link previews, see WhatsApp Business messaging capabilities and limitations with Amazon Connect later in this section.

The following sets of steps explain how to configure an inbound contact flow and add a `CheckContactAttribute` block to the flow.

To configure a flow

1. Start the Amazon Connect console at https://console.aws.amazon.com/connect/
2. In the navigation pane, choose **Channels**, then **Phone numbers**.
3. Choose the WhatsApp number, then choose **Edit**.
4. Under **Flow/IVR**, choose the flow you updated.



5. Choose **Save**.

To add the CheckContactAttribute block

1. Follow steps 1–4 in the previous section.

2. Open the **Properties** page for the flow.
3. In the **Attribute to check** section, set **Namespace** to **Segment attributes**, and **key** to **Subtype**. For more information about segment attributes, see SegmentAttributes, later in this guide.
4. In the **Conditions to check** section, set **condition** to **Equals** and **value** to **connect:WhatsApp**.
5. Choose **Save**.

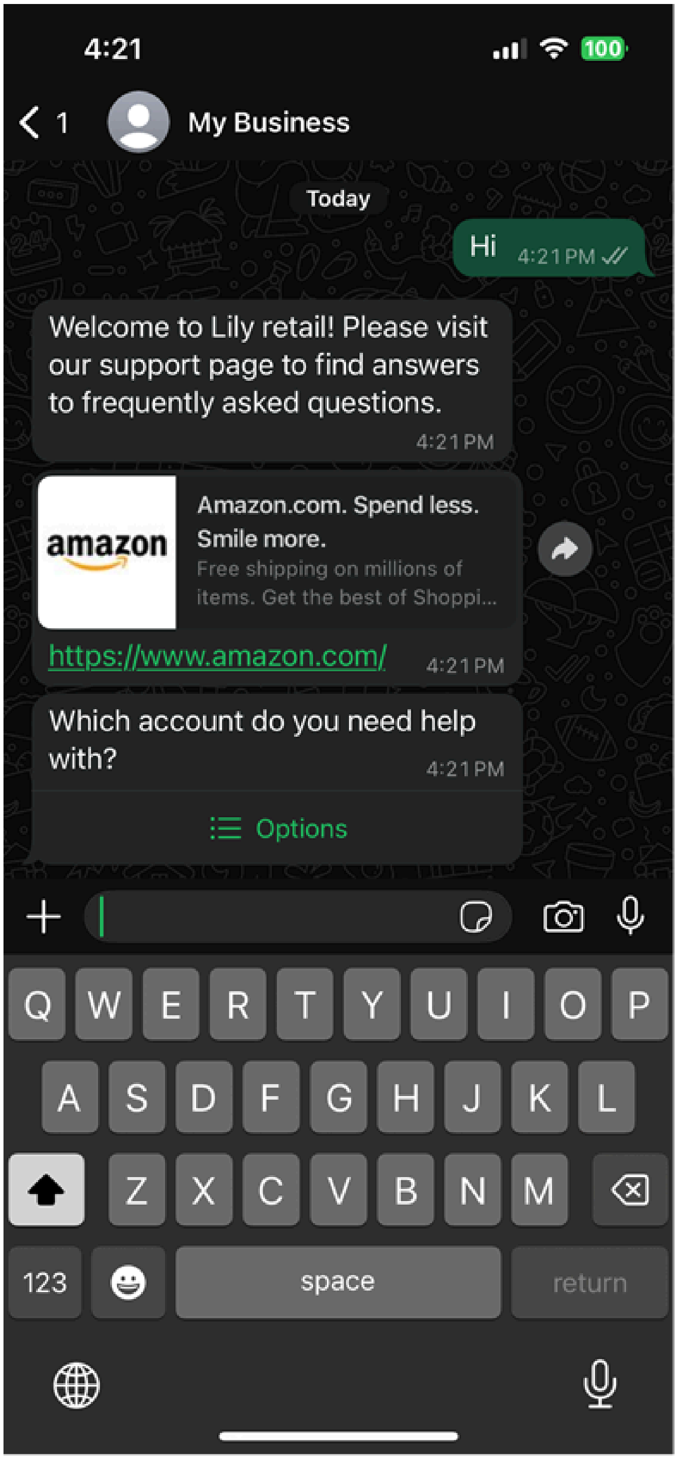
Step 3: Send and receive test messages

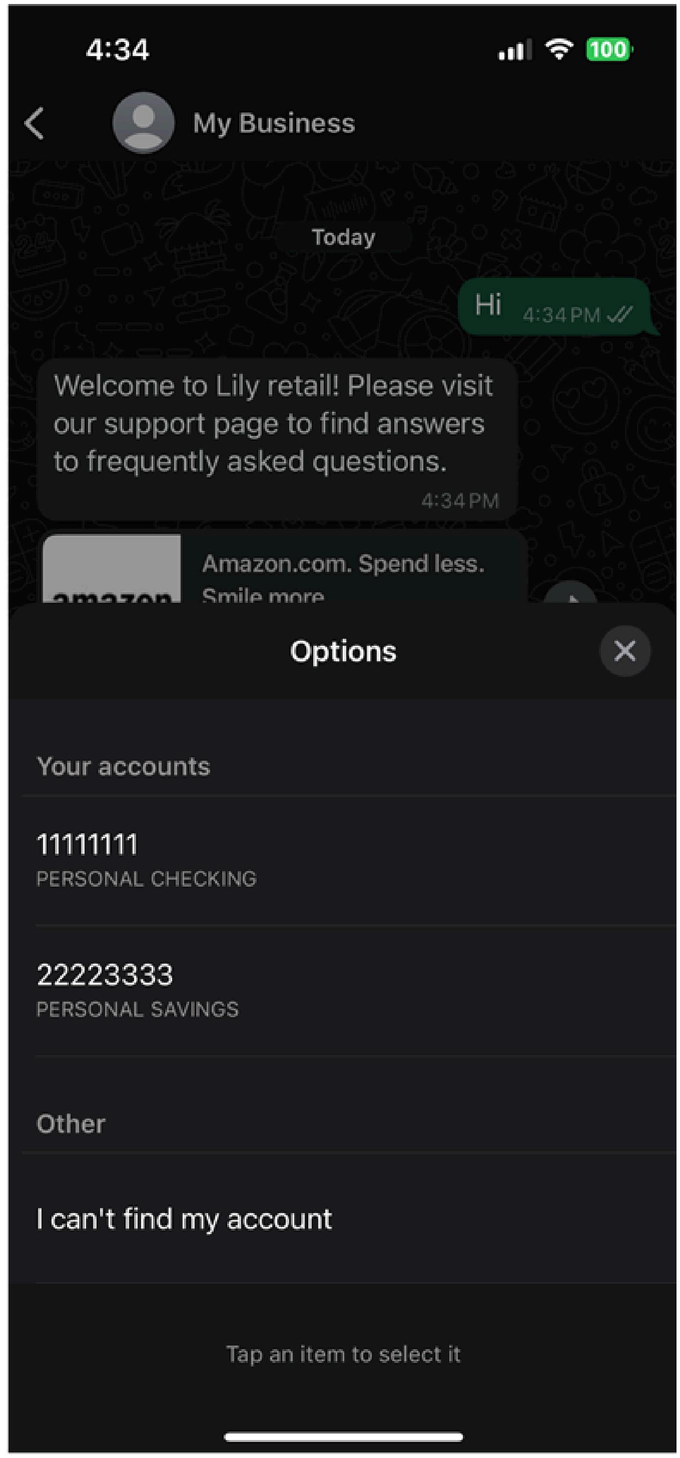
In this step, you use the Contact Control Panel (CCP) and a mobile phone to send and receive WhatsApp test messages.

To test the integration

1. In your CCP, set your status to **Available**.
2. Using WhatsApp on your mobile phone, start a conversation by entering the phone number you added previously.

   The following image shows a message with **Options**, and the resulting list of options.





Next steps: Preparing to go live

After you test your integration, we recommend adding the following features and capabilities to your WhatsApp messaging channel.

Adding Amazon Connect features

The links in the following list take you to information about Amazon Connect features that you can add to your customer and agent experiences.

- Learn more about the the section called “WhatsApp Business messaging capabilities and limitations with Amazon Connect”.
- the section called “Enable persistent chat” – Customers can resume previous conversations with the context, metadata, and transcripts carried forward. They don't need to repeat themselves when they return to a chat, and agents have access to the entire conversation history.
- the section called “Create quick responses” – Provide agents with pre-written responses to common customer inquiries that they can use while they chat with customers. Quick responses make it faster for agents to respond to customers.

Adding entry points

The links in the following list take you to information about adding different types of customer entry points.

- Entry points: 5 ways to direct leads and customers to business messaging conversations (WhatsApp blog post)
- QR codes: Manage your WhatsApp Business Platform QR code (Meta help article)
- Click-to-WhatsApp ads: Create Ads that Click to WhatsApp in Ads Manager (Meta help article)

Adding a display name to your phone number

To add a verified display name that customers see, About WhatsApp Business display name in the Meta help.

Scaling traffic

After you onboard live traffic to your WhatsApp integration, we recommend monitoring the following quotas.

Amazon Connect quotas

For more information about default quotas, and about raising them, see Amazon Connect service quotas.

- Concurrent active chats per instance quota.
- StartChatContact throttling quota.
- SendChatIntegrationEvent throttling quota.
- `SendIntegrationEvent` throttling quota. A permission only API used by AWS End User Messaging Social to publish inbound WhatsApp events.

End User Messaging Social quotas

AWS End User Messaging Social enforces rate limits on a number of messaging APIs. Monitor the following APIs to see if you need to change one or more quotas. The links take you to the *AWS End User Messaging Social API Reference*.

- SendWhatsAppMessage
- PostWhatsAppMessageMedia
- GetWhatsAppMessageMedia

For more information about increasing AWS End User Messaging Social quotas, see the following topics in the *AWS End User Messaging Social User Guide*:

- Quotas for AWS End User Messaging Social
- Increase messaging conversation limits in WhatsApp
- Increase message throughput in WhatsApp

Troubleshoot common problems

Use the following information to troubleshoot common problems with a WhatsApp integration.

Contents

Unable to see imported phone numbers in your Amazon Connect instance

If your imported number fails to appear in the Amazon Connect admin website, follow these steps:

- Ensure that the event destination IAM role has the necessary permissions. For more information, see the section called "Step 1: Enable Amazon Connect as the event destination".
- See if your *Phone numbers per instance* quota needs to be raised. For more information, see the section called "Service quotas".
- To reassign a linked WhatsApp Business Account to a different Amazon Connect instance, you must first release the imported phone numbers from the original Amazon Connect instance. After the phone numbers are released, you can update the event destination on your linked WhatsApp Business Account to another Amazon Connect instance.

> **Important**
>
> Do not release numbers that handle live customer traffic. Instead, claim new phone numbers.

- To help determine the cause of the import issue, search your CloudTrail logs for `ImportPhoneNumber` events and check for error details. If the `ImportPhoneNumber` call succeeds, you can call `DescribePhoneNumber` for other error details.

Inbound messages from customers are not delivered

If WhatsApp inbound message delivery stops, search your AWS CloudTrail logs for `SendIntegrationEvent` and `SendChatIntegrationEvent` for error details.

You can also check these common scenarios:

- Ensure that your linked WhatsApp Business Account in AWS End User Messaging Social has an Amazon Connect event destination enabled.
- Ensure your event destination IAM role has the necessary permissions. For more information, see the section called "Step 1: Enable Amazon Connect as the event destination" earlier in this section. You have a misconfigured role if CloudTrail throws `AccessDeniedException` errors from the `SendIntegrationEvent` API.
- Ensure that your WhatsApp phone number imported successfully to your Amazon Connect instance, and that the number has an associated inbound contact flow. For more information, see the section called "Step 2: Configure an inbound contact flow on your phone number".
- Inbound messages were dropped because they are not yet supported. For more information, see the section called "WhatsApp Business messaging capabilities and limitations with Amazon Connect".

WhatsApp Business messaging capabilities and limitations with Amazon Connect

The WhatsApp Business messaging integration provides the following capabilities:

- Text messages
- Interactive messages. For more information, see the section called "Add interactive messages to chat".
- Messages with rich link previews
- Delivered and read receipts for business messages
- Attachments

Limitations

When integrating WhatsApp Business messaging with Amazon Connect, be aware of the following limitations:

Delivery receipt limitations

- Read receipts for customer messages are not supported.
- Delivery receipts for customer messages are not supported. The delivery receipts that appear in WhatsApp indicate that WhatsApp has received the message, not Amazon Connect.

Text message limitations

- Inbound text messages from customers greater than 1024 characters are not supported.

Unsupported message types

- Inbound contact messages sent by customers are not supported.
- Inbound location messages sent by customers are not supported.
- Reaction messages sent by customers are not supported.
- Reply messages sent by customers are not supported. New message content is delivered without the reply context.
- Receiving message statuses that a message was deleted by the customer is not supported.

Attachment limitations

- All attachments from customers when initiating a new contact or conversation are not supported. Customers can only send attachments during an existing contact.
- Attachments from customers greater than 20MB are not supported.
- Attachments with captions are not supported. Amazon Connect removes any captions and delivers the attachment.
- Sticker attachments are not supported.

Set up in-app, web, video calling, and screen sharing capabilities

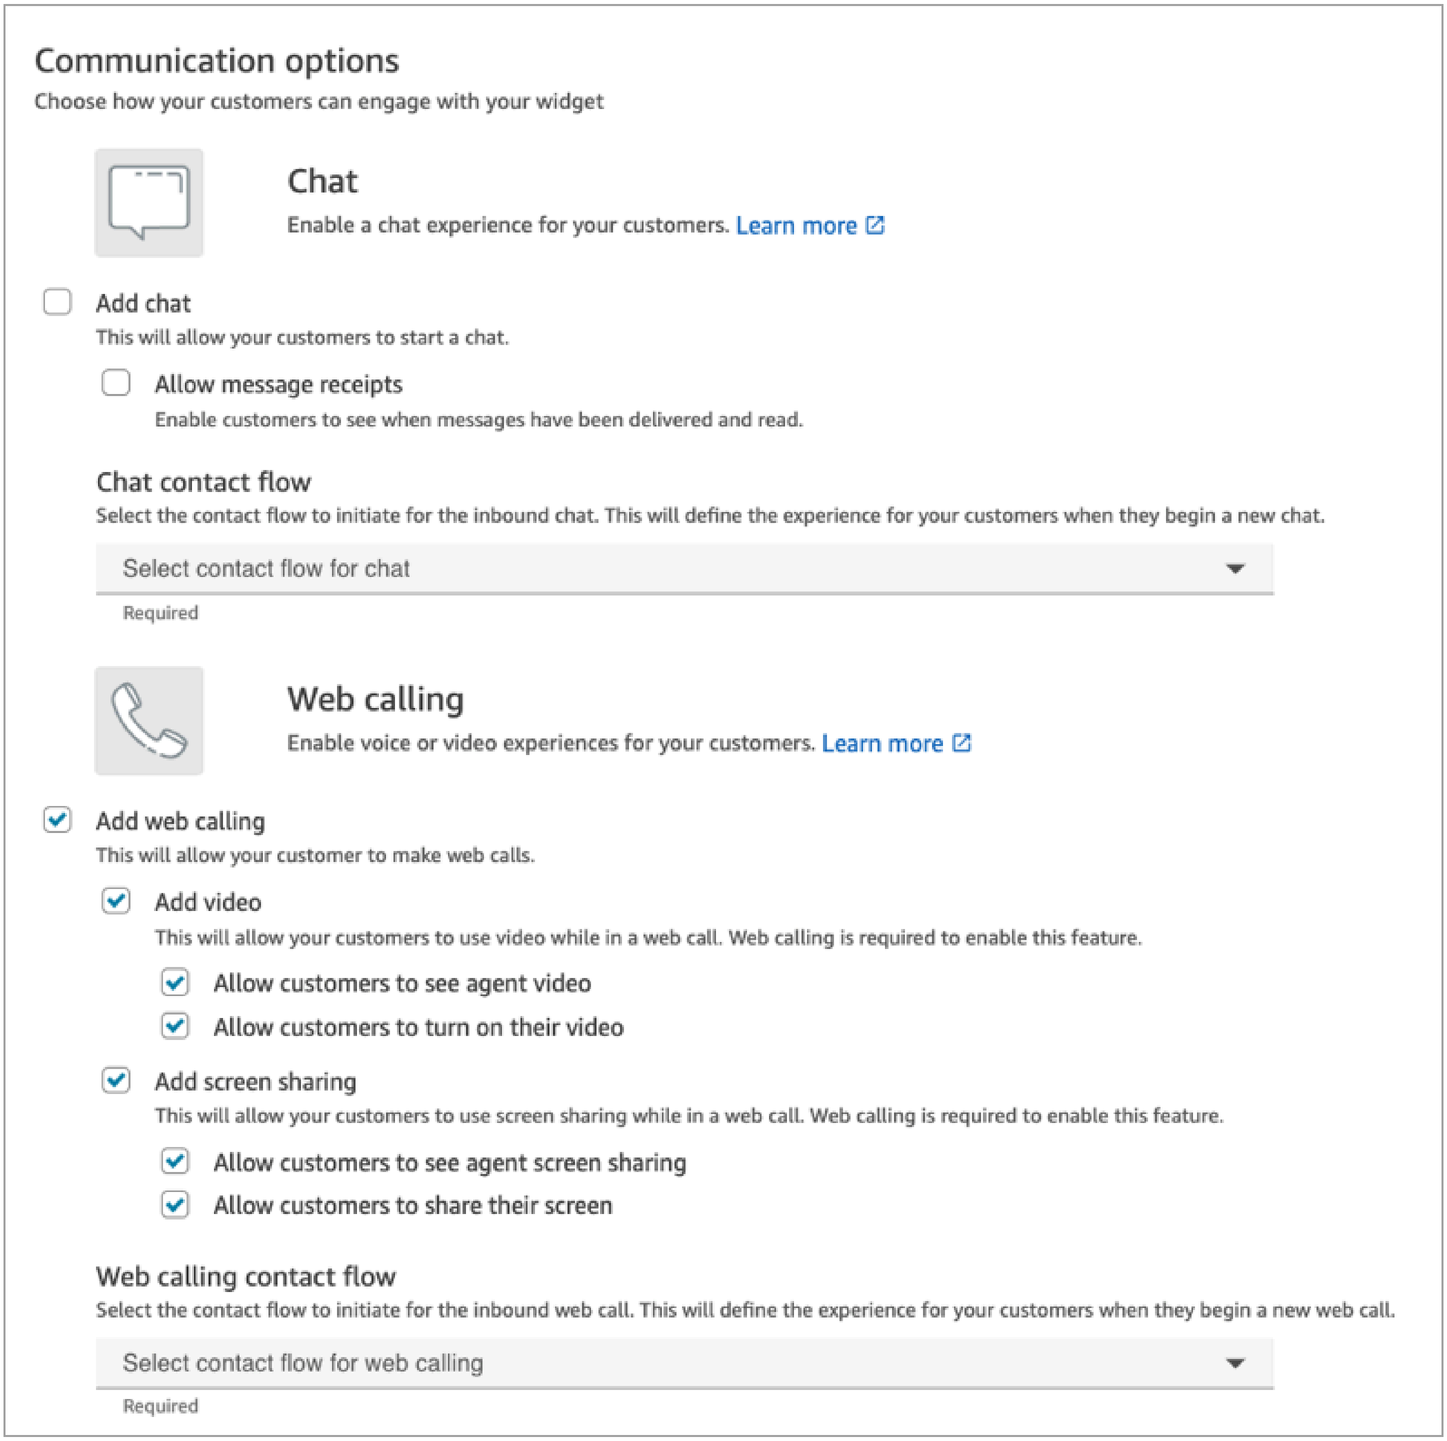
The Amazon Connect in-app, web, and video calling capabilities enable your customers to contact you without ever leaving your web or mobile application. You can use these capabilities to pass contextual information to Amazon Connect. This enables you to personalize the customer experience based on attributes such as the customer's profile or other information, like actions previously taken within the app.

Important things to know

- During a video call or screen sharing session, agents are able to see the customer's video or screen share even when the customer is on hold. It is the customer's responsibility to handle PII accordingly. If you want to change this behavior, you can build a custom CCP and communication widget. For more information, see Integrate in-app, web, video calling and screen sharing natively into your mobile application.
- There is a known issue when screen sharing is used from within an embedded Contact Control Panel (CCP). It will be stuck in the **Initializing** state. There are no known workarounds. Until a fix is released, consider using the out-of-the-box CCP or the agent workspace for screen sharing.

Communication widget: Configure chat, voice, and video all in one place

To set up in-app, web, and video calling, you use the **Communication widgets** page. It supports chat, voice, video, and screen sharing. The following image shows the **Communication options** section of the page when it's configured for all of these options.



How to set up in-app, web, video calling, and screen sharing

There are two ways to embed Amazon Connect in-app, web, and video calling, and screen sharing onto your website or mobile application:

- Option 1: Configure an out-of-the-box communications widget. You can use the no-code UI builder to customize the font and colors, and secure the widget so that it can be launched only from your website.
- Option 2: Integrate in-app, web, and video calling natively into your mobile application . Choose this option to build a communications widget from scratch and integrate it with your mobile application or website. Use the Amazon Connect APIs and Amazon Chime SDK client APIs to integrate natively into your mobile application or website.

> **Note**
>
> If you have custom agent desktops, you don't need to make any changes for Amazon Connect in-app and web calling. However, you need to integrate video calling and screen sharing.

Configure an out-of-the-box communication widget in Amazon Connect

Use this option to create communication widgets for desktop and mobile browsers. At the end of this procedure, Amazon Connect generates a custom HTML code snippet that you copy into your website's source code.

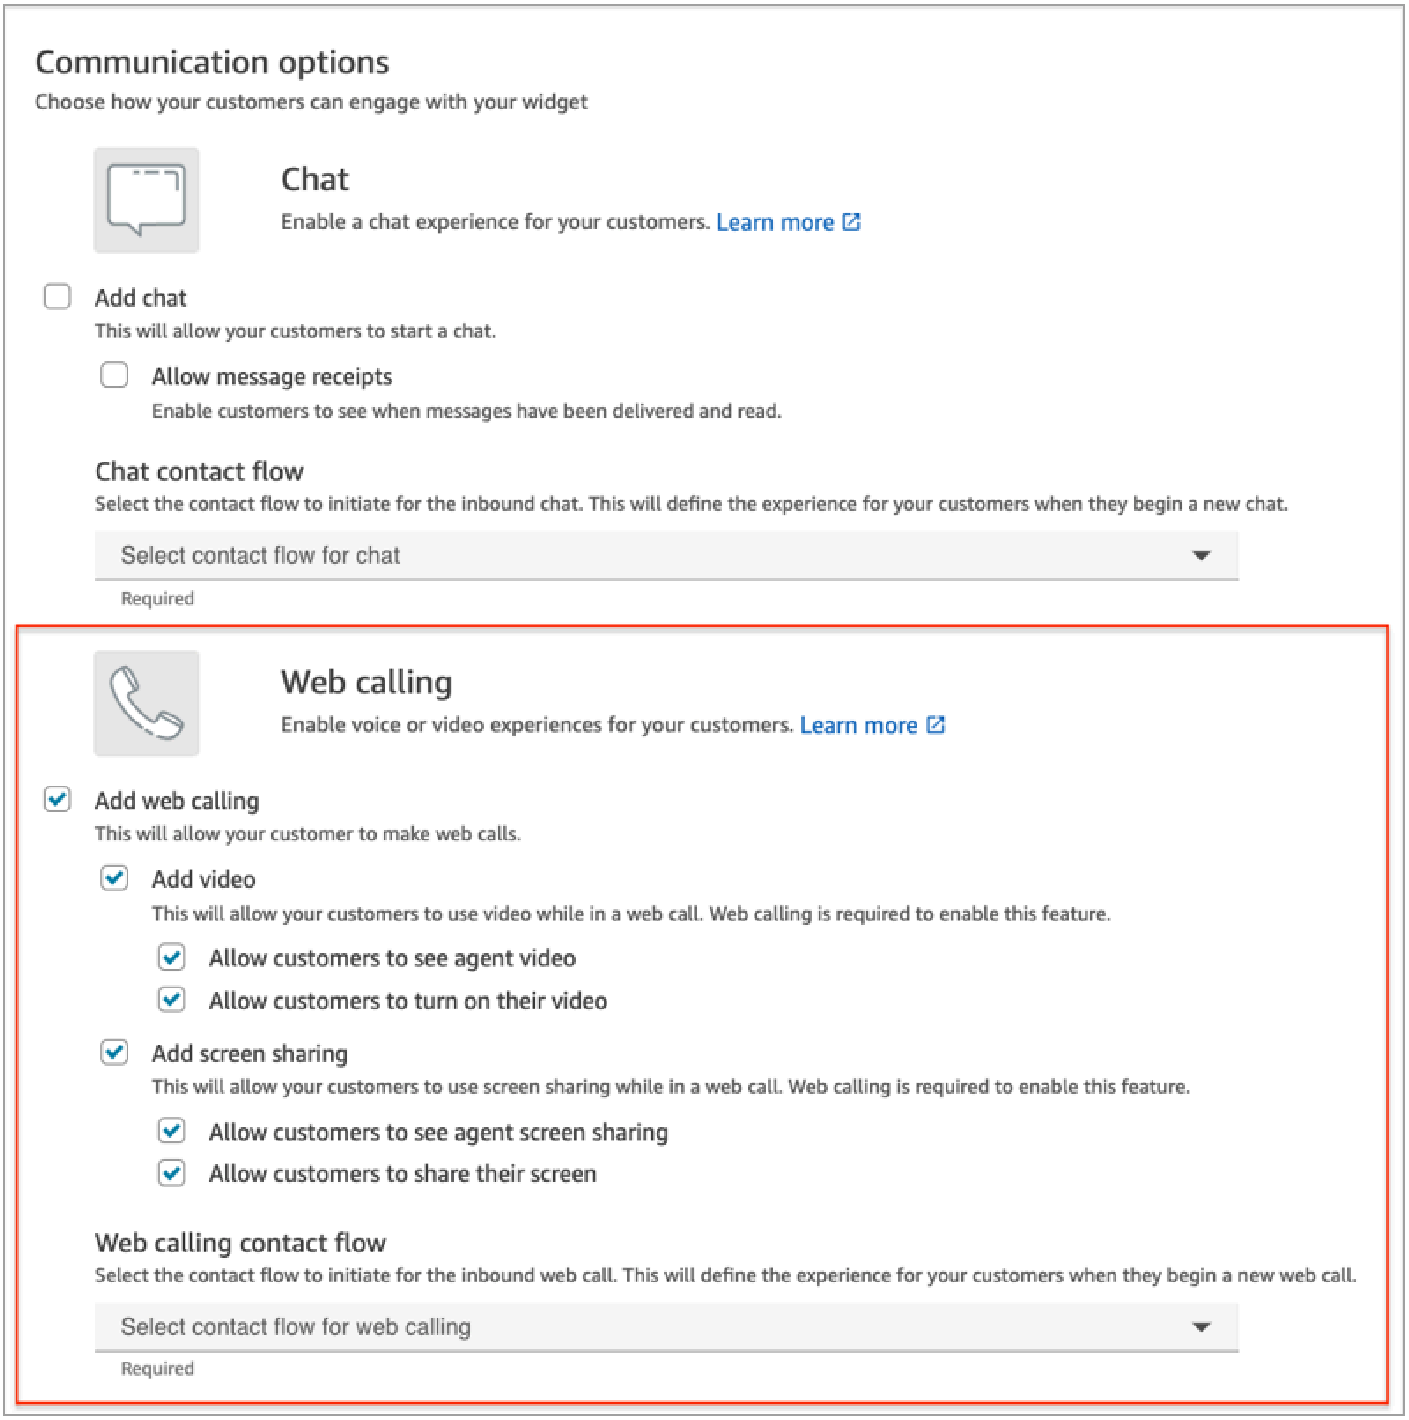
1. Log in to Amazon Connect admin website using an Admin account or a user account that has **Channels and flows**, **Communication widget - Create** permission in its security profile.
2. In Amazon Connect, on the left navigation menu, choose **Channels**, **Communication widgets**.
3. The wizard guides you through the next three steps.

Step 1: Select communication channels

1. On the **Communication widgets** page, enter a **Name** and **Description** for the communications widget.

   > **Note**
   >
   > The Name must be unique for each communications widget created in an Amazon Connect instance.

2. In the **Communications options** section, choose how your customers can engage with your widget. The following image shows options to allow web calling, video, and screen sharing for customers.



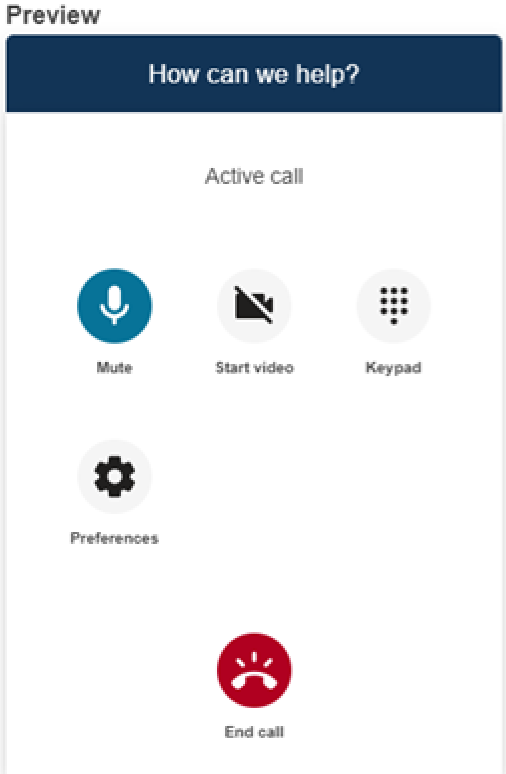
3. In the **Web calling** section, choose whether to enable video and screen sharing experiences for your customers. The previous image shows options that customers can see agent video, turn

on their video, and allow agents and customers to share their screens. For information about setting restrictions on screen sharing, see Enable URL restriction for screen sharing.

4. Choose **Save and continue**.

Step 2: Customize widget

As you choose these options, the widget preview updates automatically so that you can see what the experience will look like for your customers.



Define widget access button styles

1. Choose the colors for the button background by entering hex values (HTML color codes).
2. Choose **White** or **Black** for the icon color. The icon color can't be customized.

Customize display names and styles

1. Provide values for header message and color, and widget background color.
2. **Logo URL**: Insert a URL to your logo banner from an Amazon S3 bucket or another online source.

> **Note**
>
> The communications widget preview in the customization page will not display the logo if it's from an online source other than an Amazon S3 bucket. However, the logo will be displayed when the customized communications widget is implemented to your page.

The banner must be in .svg, .jpg or .png format. The image can be 280px (width) by 60px (height). Any image larger than those dimensions will be scaled to fit the 280x60 logo component space.

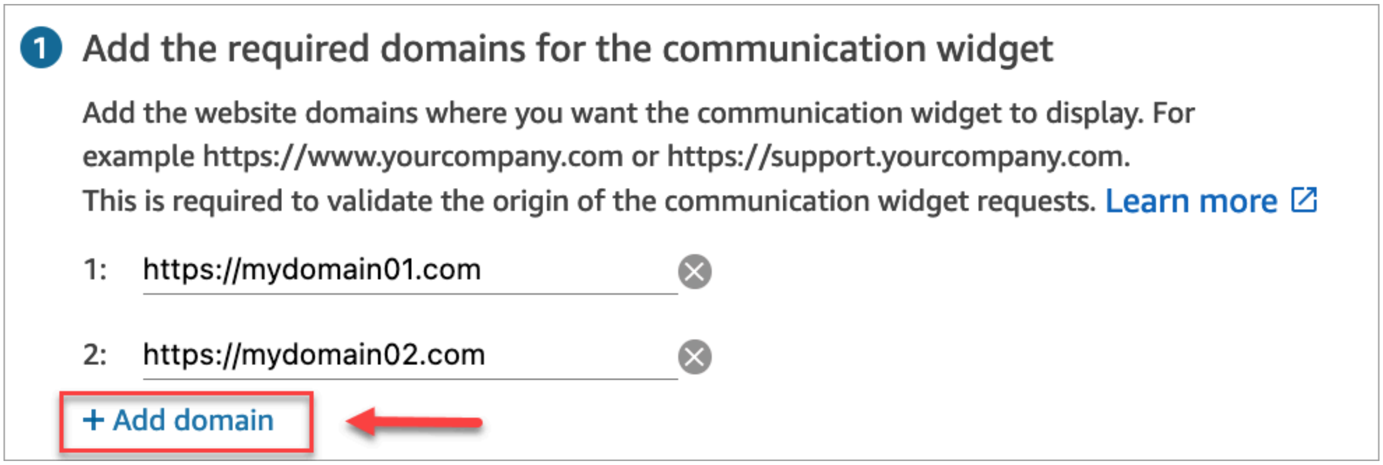
1. For instructions about how to upload a file such as your logo banner to S3, see Uploading objects in the *Amazon Simple Storage Service User Guide*.
2. Make sure that the image permissions are properly set so that the communications widget has permissions to access the image. For information about how to make a S3 object publicly accessible, see Step 2: Add a bucket policy in the *Setting permissions for website access* topic.

Step 3: Add your domain for the widget

This step enables you to secure the communications widget so that it can be launched only from your website.

1. Enter the website domains where you want to place the communications widget. The communications widget loads only on websites that you select in this step.

   Choose **Add domain** to add up to 50 domains.



> **Important**
>
> - Double-check that your website URLs are valid and does not contain errors. Include the full URL starting with https://.
> - We recommend using https:// for your production websites and applications.

2. Under **Add security for your communications widget requests**, for the fastest setup experience choose **No - I will skip**.

   We recommend choosing **Yes** for the ability to verify the user is authenticated. For more information, see Personalize the customer experience for in-app, web, and video calling in Amazon Connect.

3. Choose **Save and continue**.

   Success! Your widget has been created. Copy the generated code and paste it on each page of your website where you want the communications widget to appear.

Enable your agents for in-app, web, and video-calling, and screen sharing

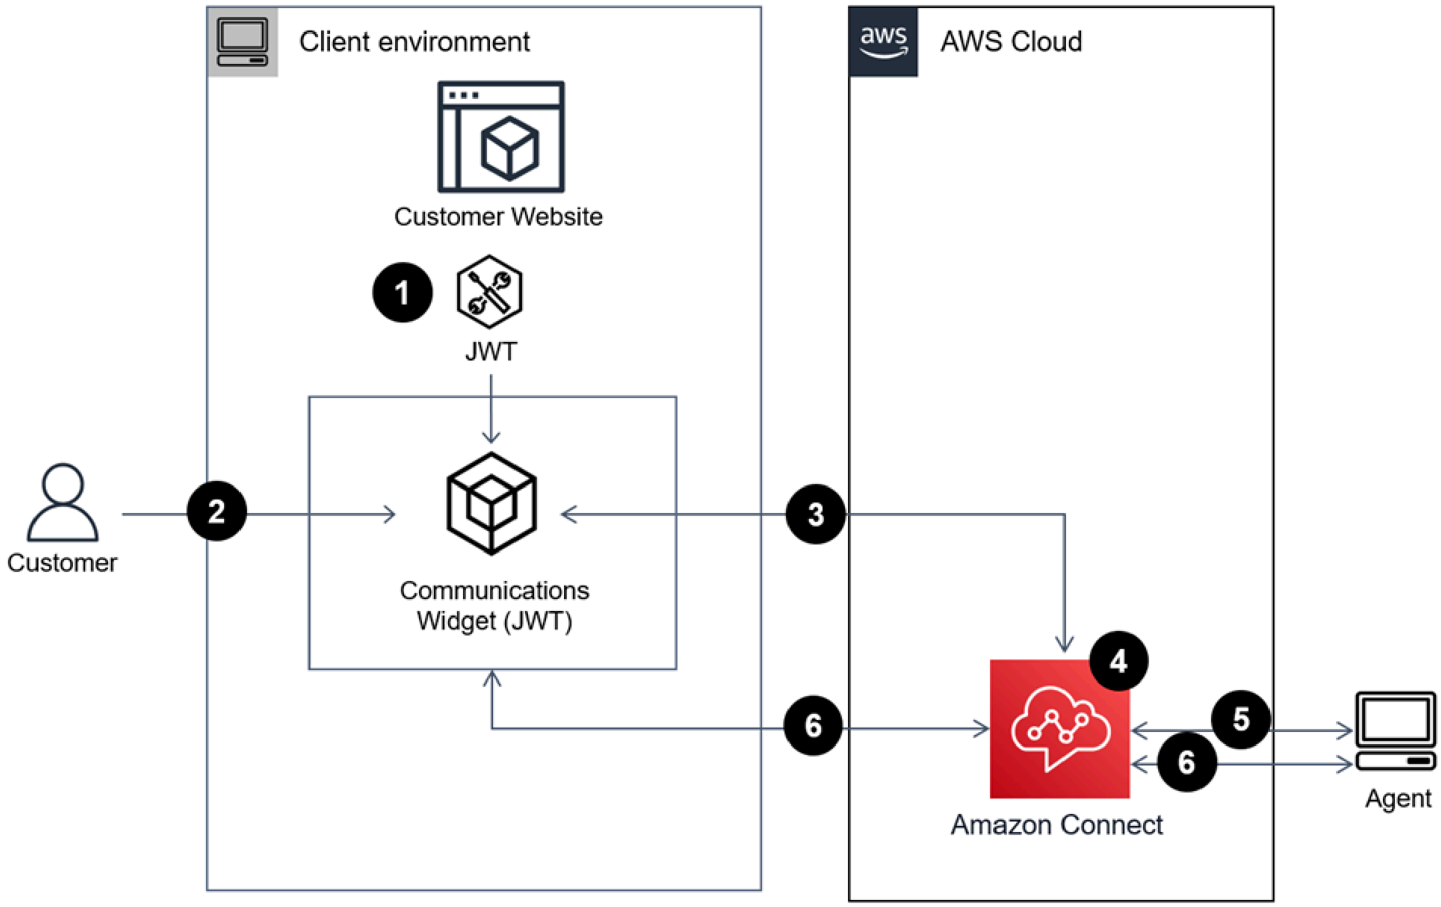
To enable agents to use video calling and screen sharing, assign the **Contact Control Panel (CCP)**, **Video calls - Access** permissions to their security profile.

The Amazon Connect agent workspace supports Amazon Connect in-app, web, and video calling, and screen sharing. You can use the same configuration, routing, analytics, and agent application as with telephone calls and chats. To get started, the only step is to enable your agent's security profiles with the permissions to have video calls and screen sharing.

For custom agent desktops, there are no changes required for the Amazon Connect in-app and web calling. Enable your agent's security profiles with the permissions to have video calls and screen sharing, and follow the guide below on how to integrate video calling into your agent desktop.

How a client device initiates an in-app or web call

The following diagram shows the sequence of events for a client device (mobile application or browser) to initiate an in-app or web call.



1. (Optional) You can pass attributes captured in the website and validate them with JSON web token (JWT).
2. The customer clicks on the communications widget in your website or mobile app.
3. The communications widget starts the web call to Amazon Connect by passing attributes contained in the JWT.
4. The contact reaches the flow, is routed, and placed in queue.
5. The agent accepts the contact.
6. (Optional) If video is enabled for customer and the agent, they are able to start their video.

More information

For additional information about requirements for in-app, web, and video calling capabilities, see the following topics:

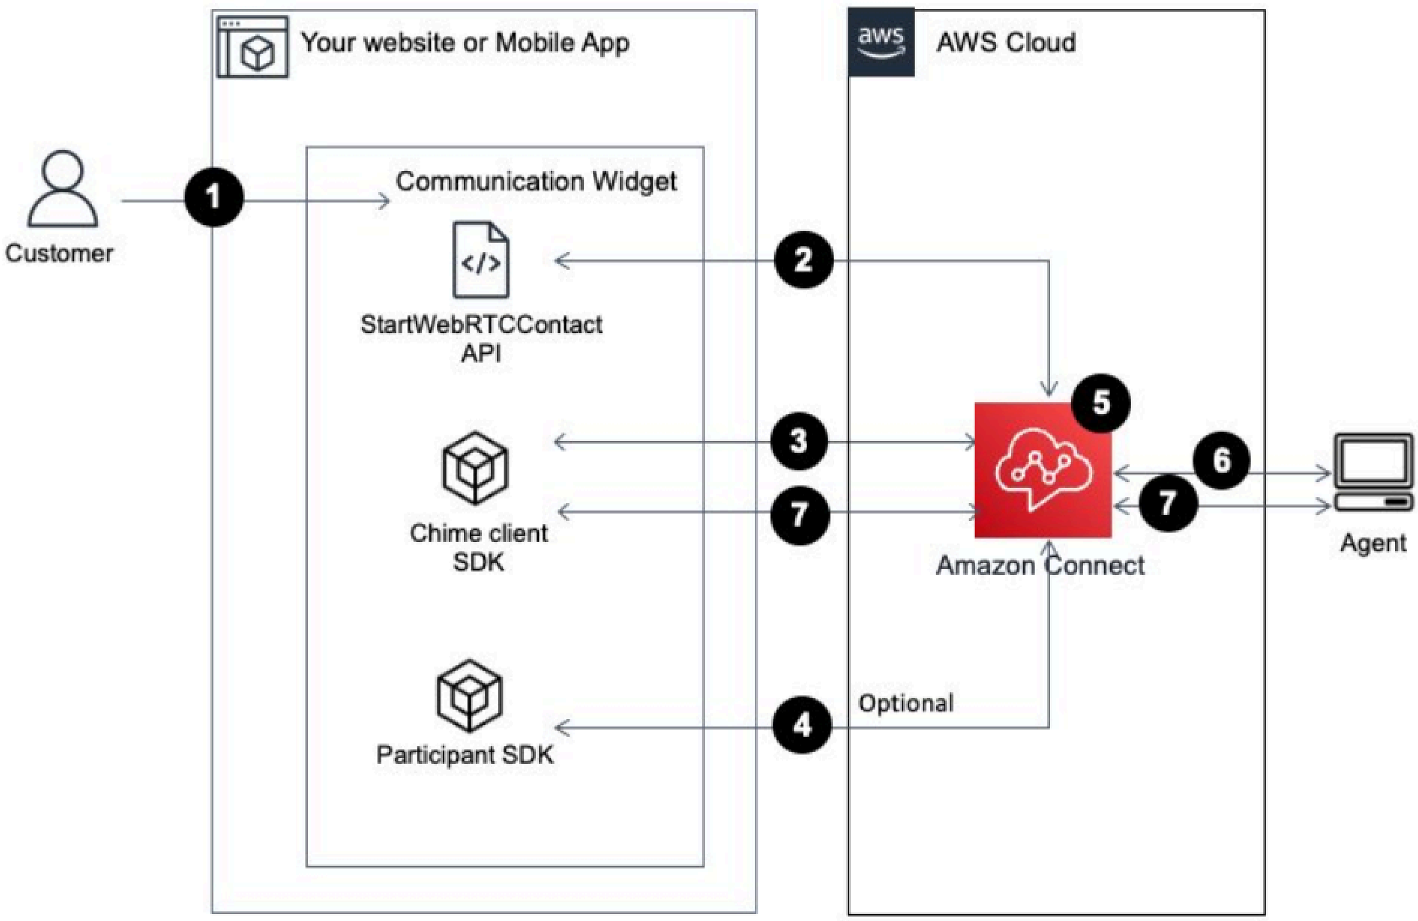
- Agent workstation requirements for app, web, and video calling in Amazon Connect
- Supported browsers and mobile OS for in-app, web, and video calling capabilities

Integrate in-app, web, video calling and screen sharing natively into your mobile application

To integrate Amazon Connect in-app, web, video calling and screen sharing natively with your mobile application, use the Amazon Connect StartWebRTCContact API to create the contact, and then use the details returned by the API call to join the call using the Amazon Chime client library for iOS or Android.

How a client device initiates an in-app or web call

The following diagram shows the sequence of events for a client device (mobile application or browser) to initiate an in-app or web call.



1. Your customer uses the client application (website or application) to start an in-app or web call.
2. The client application (website or mobile application) or web server uses the Amazon Connect [StartWebRTCContact](#) API to start the contact passing any attributes or context to Amazon Connect.
3. The client application joins the call using the details returned from the [StartWebRTCContact](#) in step 1.
4. (Optional) Client uses the [CreateParticipantConnection](#) API to receive a `ConnectionToken` that is used to send DTMF through the [SendMessage](#) API.
5. The contact reaches the flow and is routed based on the flow and placed in queue.
6. The agent accepts the contact.
7. (Optional) If video is enabled for customer and the agent, they are able to start their video.

Get started

Following are the high level steps to get started:

1. Use the StartWebRTCContact API to create the contact. The API returns the details needed for the Amazon Chime client SDK to join the call.
2. Instantiate the Amazon Chime SDK client `MeetingSessionConfiguration` object using the configurations returned by StartWebRTCContact.
3. Instantiate Amazon Chime SDK client `DefaultMeetingSession` with `MeetingSessionConfiguration`, which was created in step 2 to create a client meeting session.
   - iOS (Swift)

   ```
   let logger = ConsoleLogger(name: "logger")
   let meetingSession = DefaultMeetingSession(configuration: meetingSessionConfig,
    logger: logger)
   ```

   - Android (Kotlin)

   ```
   val logger = ConsoleLogger()
   val meetingSession = DefaultMeetingSession(
       configuration = meetingSessionConfig,
       logger = logger,
       context = applicationContext
   )
   ```
4. Use the `meetingSession.audioVideo.start()` method to join the WebRTC contact with audio.
5. Use the `meetingSession.audioVideo.stop()` method to hangup the WebRTC contact.
6. Optional steps
   a. To send DTMF to the call, two Amazon Connect Participant Service APIs are needed: CreateParticipantConnection and SendMessage respectively.

   > **Note**
   >
   > `contentType` for the SendMessage API must be `audio/dtmf`.

      i. Invoke CreateParticipantConnection to retrieve `ConnectionToken`. (`ParticipantToken` is needed for calling this API. You can find it in the StartWebRTCContact response.)
      ii. With the `ConnectionToken`, call SendMessage for sending DTMF digits.

b. For mute and unmute, use `meetingSession.audioVideo.realtimeLocalMute()` and `meetingSession.audioVideo.realtimeLocalUnmute()`.

c. To start self video on the mobile application, use the `meetingSession.audioVideo.startLocalVideo()`.

d. To stop self video on the mobile application, use the `meetingSession.audioVideo.stopLocalVideo()`.

e. To allow receiving and loading video of the agent inside mobile application, use the `meetingSession.audioVideo.startRemoteVideo()`.

f. To disallow receiving and loading video of the agent inside mobile application, use the `meetingSession.audioVideo.stopRemoteVideo()`.

g. To select the audio input/output device, you can use the methods from the Amazon Chime SDK client for Android and iOS or the native iOS capabilities for iOS.

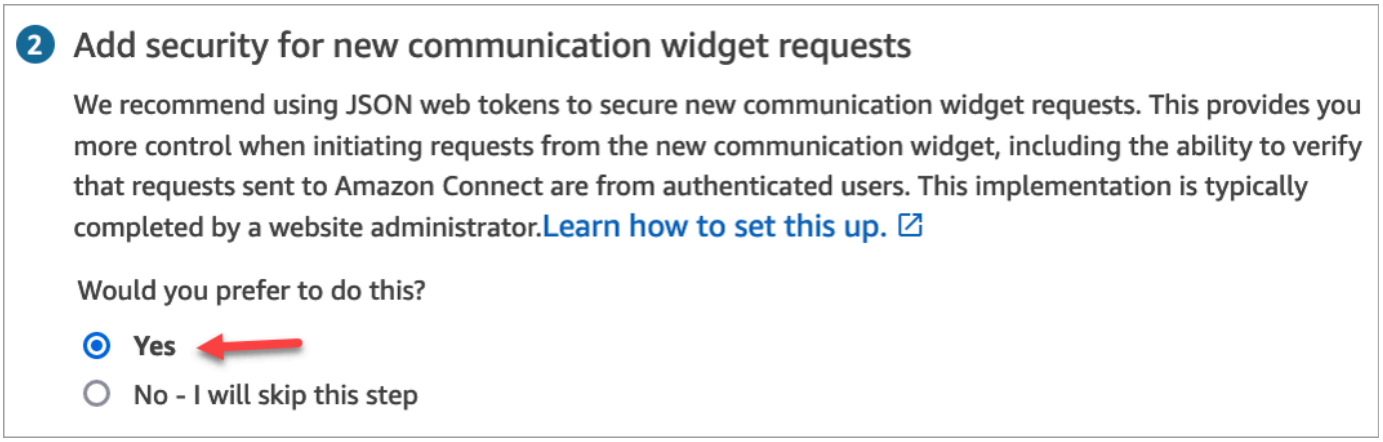
h. You can use data messages if you need to send any status from the agent side to the end user. For example, when customers are on hold, you can send a data message to the customer's application to display a message letting them know they are on hold and their video/screen sharing is still being sent, or you can turn off the video/screen share.

Personalize the customer experience for in-app, web, and video calling in Amazon Connect

The steps in this topic are optional but recommended. They enable you to personalize the customer's experience based on their actions previously taken within your app. This option provides you more control when initiating new calls, including the ability to pass contextual information as attributes.

After doing these steps, you'll need to work with your website administrator to set up your web servers to issue JSON Web Tokens (JWTs) for new calls

1. If you've already created your communications widget, on the **Communication widgets** page, choose the widget to edit it.
2. In the **Domain & Security** section, choose **Edit**.
3. Under **Add security for your communications widget requests**, choose **Yes**.



4. Choose **Save and continue**. Amazon Connect creates the widget along with the following:

   - Amazon Connect provides a 44-character security key on the next page that you can use to create JWTs.
   - Amazon Connect adds a callback function within the communications widget embed script that checks for a JWT when a call is initiated.

     You must implement the callback function in the embedded snippet, as shown in the following example.

     ```
     amazon_connect('authenticate', function(callback) {
       window.fetch('/token').then(res => {
         res.json().then(data => {
           callback(data.data);
         });
       });
     });
     ```

   In the next step you'll get a security key for all calls initiated on your websites. Ask your website administrator to set up your web servers to issue JWTs using this security key.

5. Choose **Save and continue**.

6. Copy the custom HTML code snippet and insert it into your website's source code.

Alternate method: Pass contact attributes directly from snippet code

> **Note**
>
> Although these attributes are scoped with the `HostedWidget-` prefix, they are still mutable client-site. Use the JWT setup if you require PII or immutable data in your contact flow.

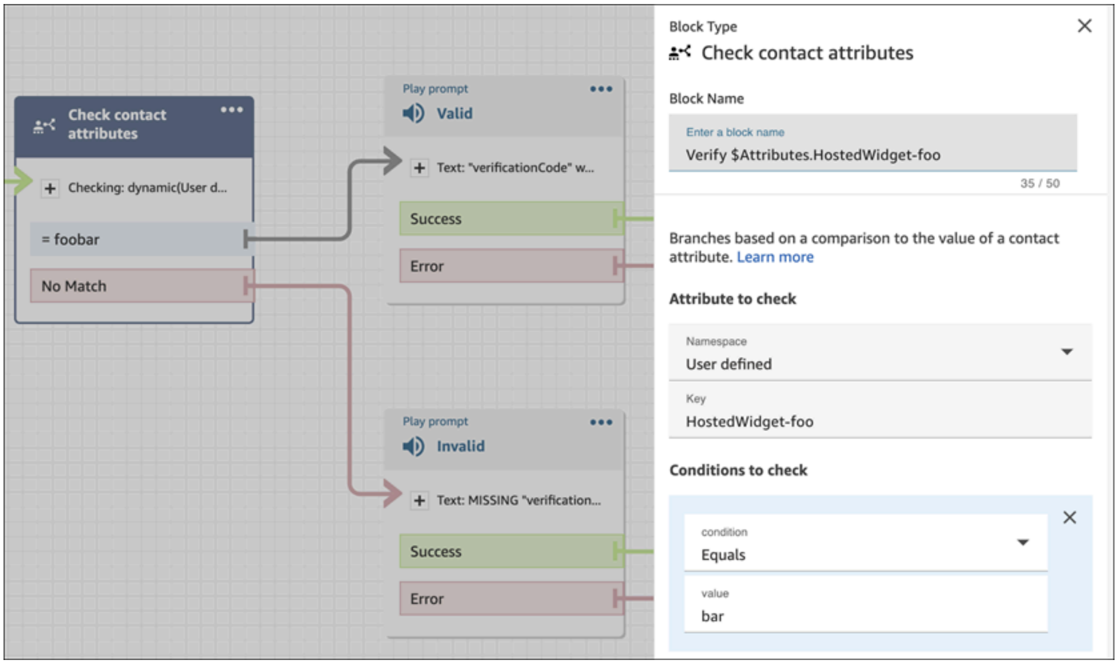
The following example shows how to pass contact attributes directly from snippet code without enabling widget security.

```
<script type="text/javascript">
  (function(w, d, x, id){ /* ... */ })(window, document, 'amazon_connect', 'widgetId');
  amazon_connect('snippetId', 'snippetId');
  amazon_connect('styles', /* ... */);
  // ...

  amazon_connect('contactAttributes', {
   foo: 'bar'
  })
<script/>
```

Using the attributes in contact flows

The [Check contact attributes](#) flow block provides access to these attributes via the **User defined** namespace, as shown in the following image. You can use the flow block to add branching logic. The full path is `$Attribute.HostedWidget-attributeName`.



Copy communications widget code and security keys

In this step, you confirm your selections and copy the code for the communications widget and embed it in your website. You can also copy the secret keys for creating the JWTs.

Security key

Use this 44-character security key to generate JSON web tokens from your web server. You can also update, or rotate, keys if you need to change them. When you do this, Amazon Connect provides you with a new key and maintains the previous key until you have a chance to replace it. After you have the new key deployed, you can come back to Amazon Connect and delete the previous key.

When your customers interact with the start call icon on your website, the communications widget requests your web server for a JWT. When this JWT is provided, the widget will then include it as part of the end customer's call to Amazon Connect. Amazon Connect then uses the secret key to decrypt the token. If successful, this confirms that the JWT was issued by your web server and Amazon Connect routes the call to your contact center agents.

JSON Web Token specifics

- Algorithm: **HS256**
- Claims:
  - **sub**: *widgetId*

    Replace `widgetId` with your own widgetId. To find your widgetId, see the example [Communications widget script](#).
  - **iat**: *Issued At Time.
  - **exp**: *Expiration (10 minute maximum).

  * For information about the date format, see the following Internet Engineering Task Force (IETF) document: [JSON Web Token (JWT)](#), page 5.

The following code snippet shows an example of how to generate a JWT in Python:

```
payload = {
'sub': widgetId, // don't add single quotes, such as 'widgetId'
'iat': datetime.utcnow(),
'exp': datetime.utcnow() + timedelta(seconds=JWT_EXP_DELTA_SECONDS)
}

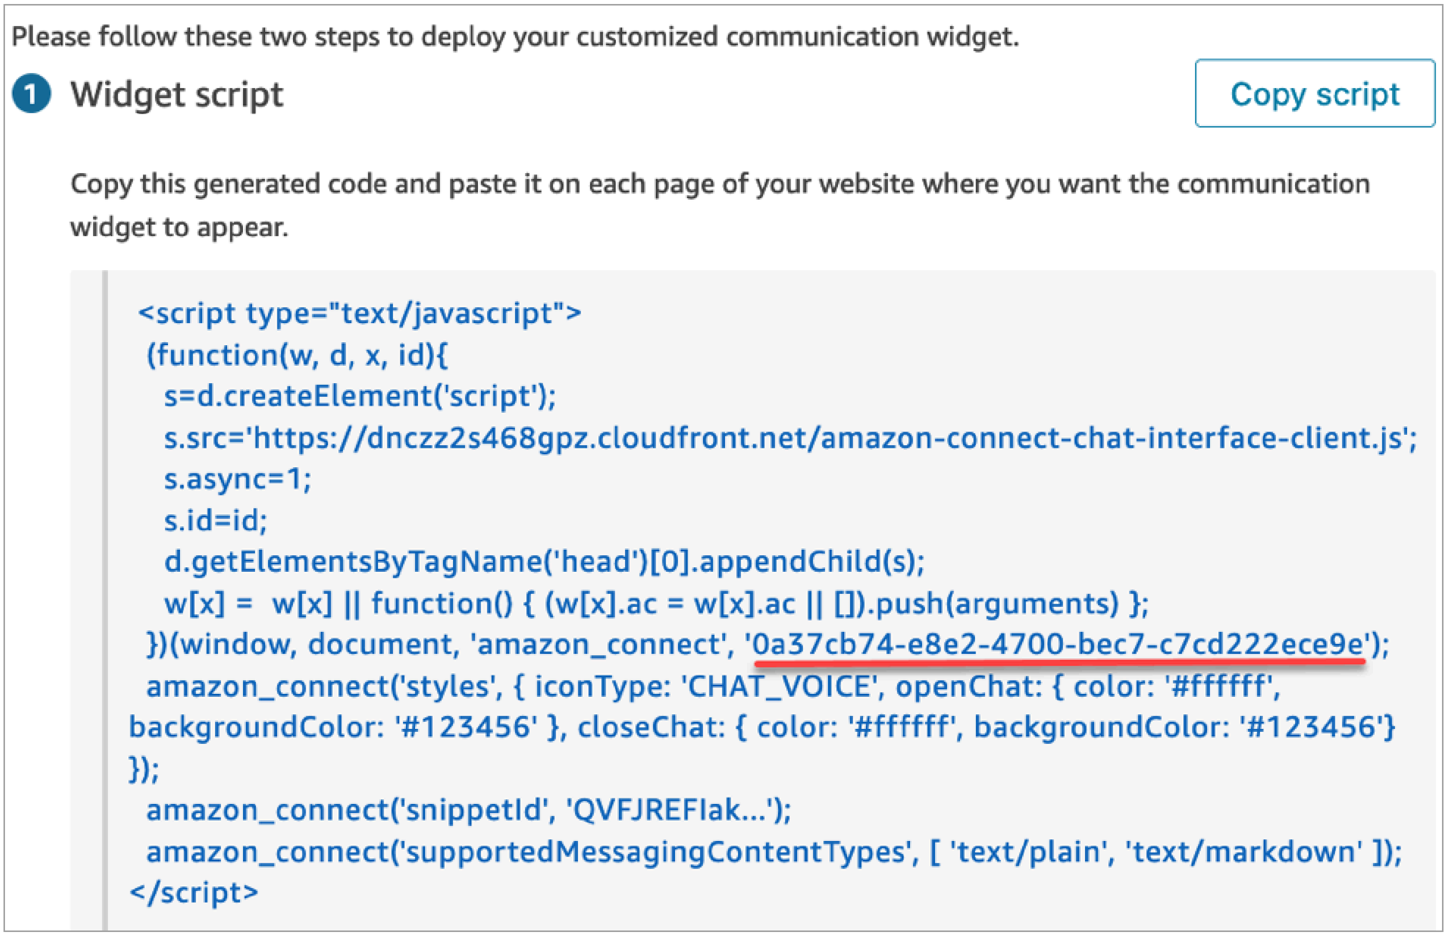
header = {
'typ': "JWT",
'alg': 'HS256'
}

encoded_token = jwt.encode((payload), CONNECT_SECRET, algorithm=JWT_ALGORITHM,
 headers=header) // CONNECT_SECRET is the security key provided by Amazon Connect
```

Communications widget script

The following image shows an example of the JavaScript that you embed on the websites where you want customers to be able to call your contact center. This script displays the widget in the bottom-right corner of your website.

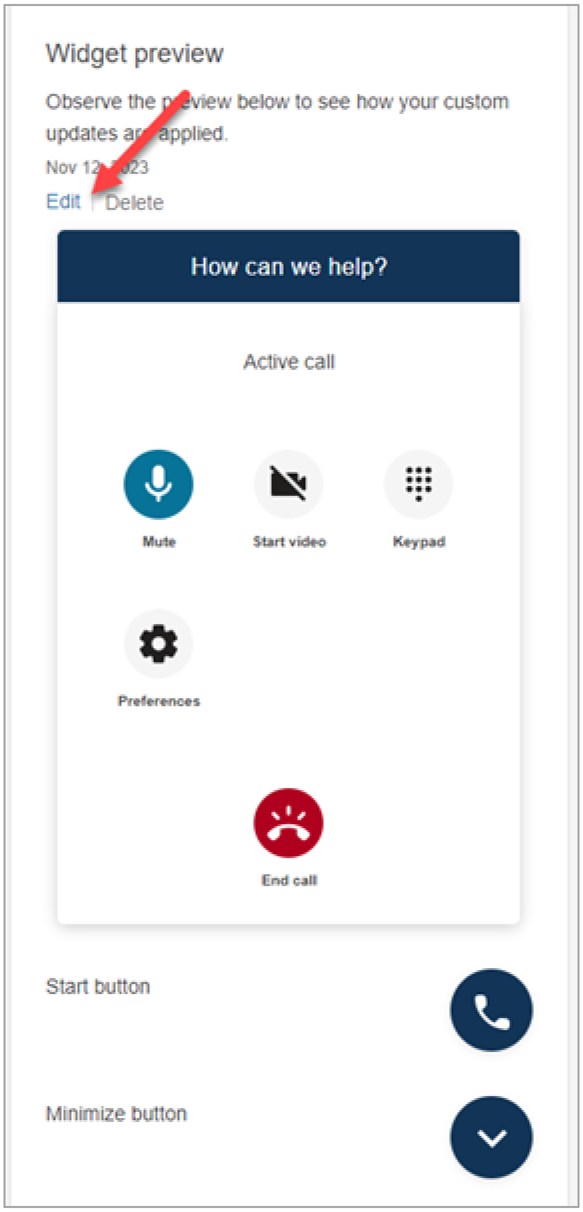
The following image shows an example of where to find your widgetId.



When your website loads, customers first see the **Start** icon. When they choose this icon, the communications widget opens and customers are able to call your agents.

To make changes to the communications widget at any time, choose **Edit**.

> **Note**
>
> Saved changes update the customer experience in a few minutes. Confirm your widget configuration before saving it.



To make changes to widget icons on the website, you will receive a new code snippet to update your website directly.

Additional customizations for your Amazon Connect web calling widget

You can add the following additional customizations to your web calling widget:

- Apply background blur to your customer's video tile.
- Set the widget to fullscreen.
- Select the default camera device.
- Resize the video to fit its container.

The following sections explain the details of the customizations, their use cases, and how to configure them. You manage these customizations by configuring `WebCallingCustomizationObject`.

Contents

Background blur

This customization controls the background blur behavior of the customer's video. When enabled, the customer's background is blurred when video is active. This helps protect their personal information or private spaces that may be visible in the background during the video call.

To enable background blur, set `videoFilter.backgroundBlur.option` to `ENABLED_ON_BY_DEFAULT` in `WebCallingCustomizationObject`.

Fullscreen mode

Use this customization to control the widget's fullscreen behavior. There are two ways you can enable fullscreen:

- Add a fullscreen button to the widget. The customer can use the button to toggle fullscreen on and off.

  To add a fullscreen button, set `fullscreen.displayButton` to `ENABLED`.

OR

- Set the widget to fullscreen upon load.

  To enable fullscreen upon load, set `fullscreen.fullscreenOnLoad` to `ENABLED`.

It's particularly helpful to use fullscreen mode when the customer needs to focus on the widget, such as during screen sharing.

You can use these two options individually or in combination.

Choose the default camera device

This customization allows the widget to select default camera device when your customer enables video, offering options for front or back camera. This ability is useful for diagnosing appliances remotely, for example. The customer can use back camera to show the appliance to agent.

To select back camera as default, set `devices.defaultCamera` to `Back`.

Resize video

This customization controls how the video tiles for both the customer and agent are resized in the widget. For example, the video frame can be resized to fill the entire video tile, or scaled to fit the video tile, leaving empty spaces if the aspect ratio of the video frame does not match the video tile.

- To resize the video for customer, set `videoTile.localVideoObjectFit` to the target value.
- To resize the video for agent, set `videoTile.remoteVideoObjectFit` to the target value.

For more information, see Supported options and constraints.

Configure the customization object

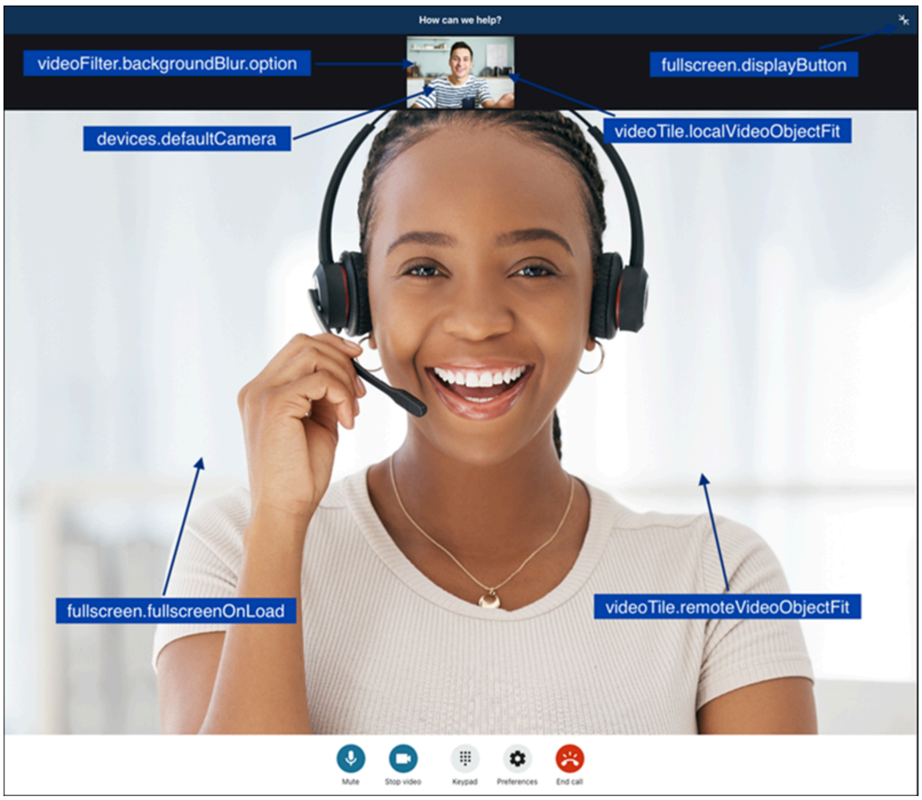
The following example shows how to implement optional customizations for web calling. For a detailed description of these options, see Supported options and constraints.

You can implement some or all of the fields shown in the following example. When you don't implement customizations, default behaviors are used for the missing fields.

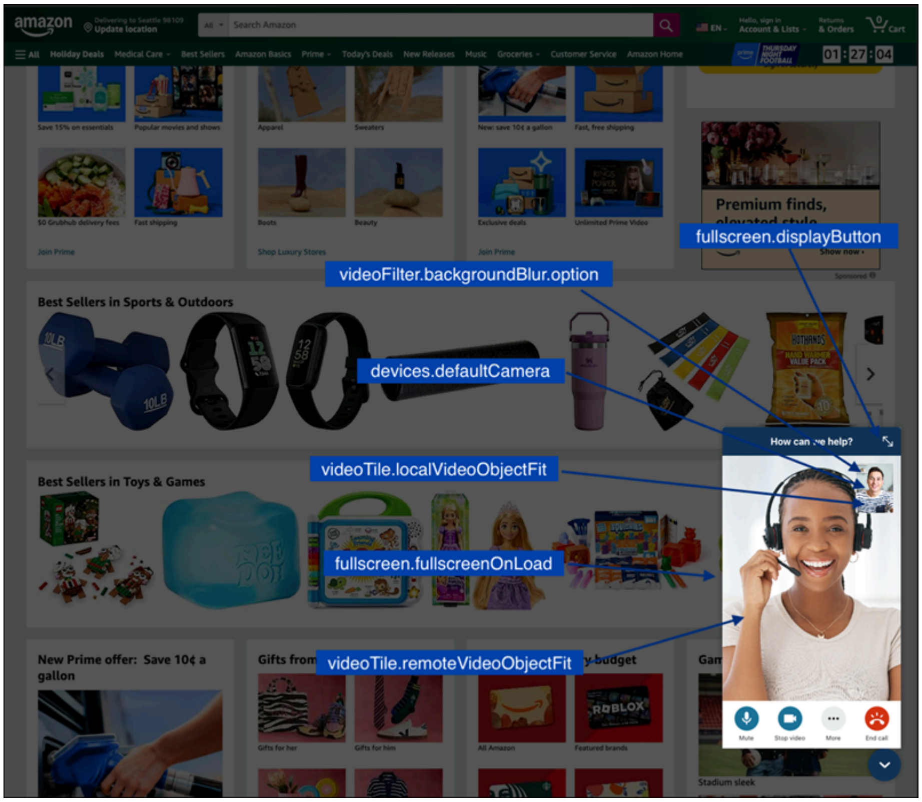
```
amazon_connect('webCallingCustomizationObject', {
        videoFilter: {
            backgroundBlur: {
                option: "ENABLED_OFF_BY_DEFAULT"
            }
        },
        fullscreen: {
```

```
            displayButton: "ENABLED",
            fullscreenOnLoad: "DISABLED"
        },
        devices: {
            defaultCamera: "Front"
        },
        videoTile: {
            localVideoObjectFit: "cover",
            remoteVideoObjectFit: "cover"
        }
});
```

The following image shows how the customizations look when not in full-screen mode.



The following image shows how the customizations look when in full-screen mode.



Supported options and constraints

The following table lists the supported customization fields and recommended value constraints.

Custom layout option	Type	Values	Description
`videoFilter.backgroundBlur.option`	string	`ENABLED_ON_BY_DEFAULT` | `ENABLED_OFF_BY_DEFAULT`	Sets your customer's video tile background blur. By default, when your customer enables video, the background blur filter will be applied to the video tile, if you don't want to enable the filter by default, you can set it to ENABLED_O

Custom layout option	Type	Values	Description
			FF_BY_DEFAULT , your customer can still manually enable the filter in the widget's preferences page.
fullscreen.displayButton	string	ENABLED	Adds a button to the top right corner of the widget to make it fullscreen in the browser. By default, this button will not be added to the widget, if you want to add this button, you can set it to ENABLED.
fullscreen.fullscreenOnLoad	string	ENABLED	Makes the widget fullscreen in the browser. By default, the widget will be anchored to the bottom right corner of the webpage, setting it to ENABLED will make the widget fullscreen in the browser.

Custom layout option	Type	Values	Description
`devices.defaultCamera`	string	`Front|Back`	Sets the default camera device when your customer enables video. This is for mobile or tablet use cases. By default, the default camera is selected(detail). (For more information, see the MediaDevices: enumerateDevices() method in the Mozilla developers documentation.) When you set it to `Front|Back` , it selects the corresponding camera if available.

Custom layout option	Type	Values	Description
videoTile .localVid eoObjectFit	string	fill | contain | cover | none | scale-down	Sets the object-fit property of your customer's video tile in the widget. By default, the value is determined by the width and height of the video resolution: if height is greater than width, it will be contain, else it will be cover. For a detailed description of each value, see object-fit in the Mozilla developer documentation. **Note** This attribute is applied to only the display height and width of the customer's video in the widget. The height and width of the customer's video sent to

Custom layout option	Type	Values	Description
			the agent is unaltered.
`videoTile.remoteVideoObjectFit`	string	`fill` | `contain` | `cover` | `none` | `scale-down`	Sets the object-fit property of your customer's video tile in the widget. By default, the value is determined by the width and height of the video resolution: if height is greater than width, it will be `contain`, else it will be `cover`. For a detailed description of each value, see object-fit in the Mozilla developer documentation. **Note** This attribute is applied to only the display height and width of agent's video in the widget.

Integrate video calling and screen sharing into your custom agent desktop by using Amazon Connect Streams JS

This topic is for developers. For custom agent desktops, you need to make changes to support video calling and screen sharing. Following are high level steps.

> **Note**
>
> If you embed the CCP directly into your custom agent application make sure `allowFramedVideoCall` is set to true when you initiate the CCP using Amazon Connect Streams JS.

1. Use Amazon Connect Streams JS to check if the incoming contact is an WebRTC contact. Use contact subtype `"connect:WebRTC"`, as shown in the following code example:

   ```
   contact.getContactSubtype() === "connect:WebRTC"
   ```

2. You can retrieve the customer display name by using the name field in `contact` `contact.getName()`.

Add support for video

Complete the following steps to add support for video handling when your customers have it enabled.

1. To check whether a contact has video capability:

   ```
   // Return true if any connection has video send capability
   contact.hasVideoRTCCapabilities()

   // Return true if the agent connection has video send capability
   contact.canAgentSendVideo()

   // Return true if other non-agent connection has video send capability
   contact.canAgentReceiveVideo()
   ```

2. To check on whether the agent has video permission to handle video call:

   ```
   agent.getPermissions().includes('videoContact');
   ```

3. To accept a video call, the contact must have video capability and the agent must have video permission.

```
function shouldRenderVideoUI() {
    return contact.getContactSubtype() === "connect:WebRTC" &&
    contact.hasVideoRTCCapabilities() &&
    agent.getPermissions().includes('videoContact');
}
```

4. In order to join a video session, call `getVideoConnectionInfo`:

```
if (shouldRenderVideoUI()) {
   const response = await
   contact.getAgentConnection().getVideoConnectionInfo();
}
```

5. To build a video UI and join a video meeting session, see:
   - [Amazon Chime SDK for JavaScript]() on GitHub
   - [Amazon Chime SDK React Components Library]() on GitHub
6. For simplicity, the following code snippets use examples from the Amazon Chime SDK React Components Library.

```
import { MeetingSessionConfiguration } from "amazon-chime-sdk-js";
import {
  useMeetingStatus,
  useMeetingManager,
  MeetingStatus,
  DeviceLabels,
  useLocalAudioOutput
} from 'amazon-chime-sdk-component-library-react';

const App = () => (
  <MeetingProvider>
    <MyVideoManager />
  </MeetingProvider>
);

const MyVideoManager = () => {
    const meetingManager = useMeetingManager();
    if (shouldRenderVideoUI()) {
        const response = await contact.getAgentConnection().getVideoConnectionInfo();
```

```
        const configuration = new MeetingSessionConfiguration(
            response.meeting, response.attendee);
        await meetingManager.join(configuration, { deviceLabels:
 DeviceLabels.Video });
        await meetingManager.start();
    }

    function endContact() {
        meetingManager.leave();
    }
}
```

7. To render the video grid, use the VideoTileGrid from the Amazon Chime SDK React Components Library or customize the UI behavior using RemoteVideoTileProvider.

8. To render a video preview, you can use VideoPreview and CameraSelection components. To choose or change a camera video, you can use `meetingManager.selectVideoInputDevice` or `meetingManager.startVideoInput` if the meeting is in progress.

```
const meetingManager = useMeetingManager();
const { isVideoEnabled } = useLocalVideo();
if (isVideoEnabled) {
    await meetingManager.startVideoInputDevice(current);
 } else {
    meetingManager.selectVideoInputDevice(current);
}
```

9. To implement background blur, see useBackgroundBlur.

10For sample code on how to build a custom video experience, see this Amazon Chime SDK sample: Amazon Chime React Meeting demo.

Add support for screen sharing

> **Note**
>
> If you use the out-of-box CCP directly in your custom agent application make sure `allowFramedScreenSharing` and `allowFramedScreenSharingPopUp` are set to true when you initiate the CCP using Amazon Connect Streams JS.
> Setting `allowFramedScreenSharing` to true enables the screen sharing button on only one CCP in one window or tab. Setting `allowFramedScreenSharingPopUp` to true

launches the screen sharing app in a separate window when the agent chooses the screen sharing button. For more detail, see the Amazon Connect Streams JS documentation.

Complete the following steps to enable screen sharing on your custom agent desktops.

1. Check whether a contact has screen sharing capability.

```
// Return true if any connection has screen sharing send capability
contact.hasScreenShareCapability()

// Return true if the agent connection has screen sharing send capability
contact.canAgentSendScreenShare()

// Return true if customer connection has screen sharing send capability
contact.canCustomerSendScreenShare()
```

2. Check whether the agent has video permission.

```
agent.getPermissions().includes('videoContact');
```

3. Check whether the agent can initiate a screen sharing session for the eligible contact.

```
fun canStartScreenSharingSession() {
    return contactgetContactSubtype() === "connect:WebRTC" &&
    contact.hasScreenShareCapability() &&
    agent.getPermissions().includes('videoContact');
}
```

4. Call `startScreenSharing` to initiate the screen sharing session. This adds `ScreenSharingActivated` to the contact, enabling you to search for it in the contact record.

```
contact.startScreenSharing();
```

5. Call `getVideoConnectionInfo` to join the session. You can skip the step if the agent has joined the video session to handle video.

```
if (canStartScreenSharingSession) {
    contact.startScreenSharing();
    const response = await
    contact.getAgentConnection().getVideoConnectionInfo();
```

```
}
```

6. Join the session by using the Amazon Chime SDK React Components Library. For a code snippet, see step 6 in Add support for video.
7. Use the same VideoTileGrid from the Amazon Chime SDK React Components to render screen sharing video tile. For more information, see useContentShareState and useContentShareControls
8. Call `stopScreenSharing` when end the session.

```
contact.stopScreenSharing();
```

9. You can receive events for the screen sharing activity by subscribing the following callbacks:

```
initScreenSharingListeners() {
    this.contact.onScreenSharingStarted(() => {
        // Screen sharing session started
    });

    this.contact.onScreenSharingStopped(() => {
        // Screen sharing session ended
    });

    this.contact.onScreenSharingError((error) => {
        // Screen sharing session error occurred
    });
  }
}
```

Enable URL restriction for screen sharing

You can manage the URLs that your customers and agents are allowed to share during the contact. This enables you to achieve enhanced security and privacy. When a customer or agent shares a URL that is not allowlisted, they receive an error message and the screen share video is automatically paused and blacked out.

Important

The following browsers are supported:

- Chrome version 109 and later

- Edge version 109 and later

Agents and customers can share only the browser tab. They cannot share the window or entire screen. If you enable this feature and your customers or agents use an unsupported browser, window, or the entire screen, they will receive an error.

Complete the following steps to enable URL restriction for screen sharing.

Step 1: Create an allowed URLs list

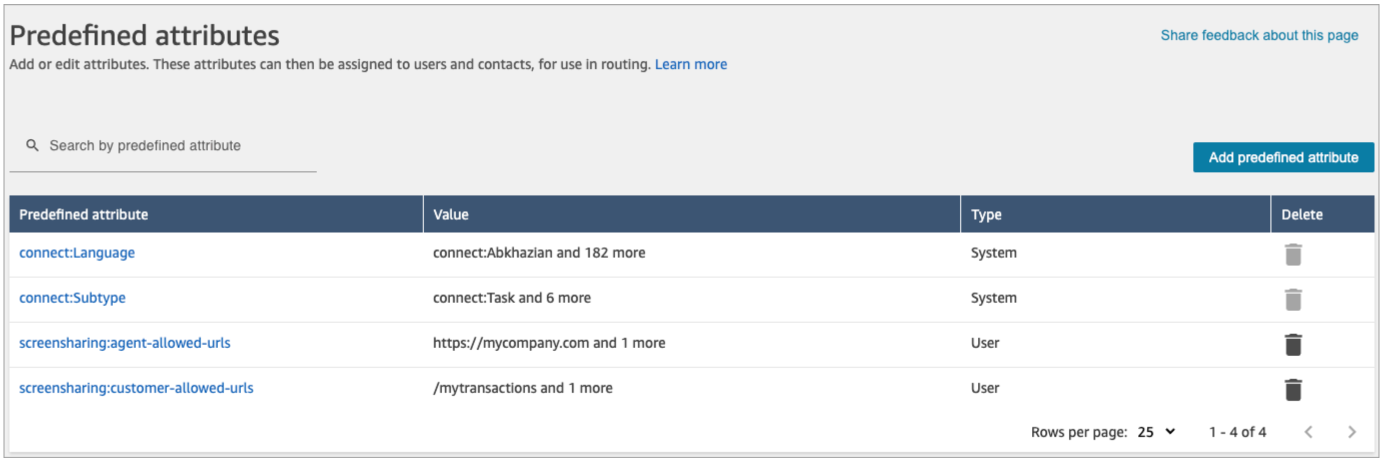
You configure the lists of allowed URLs by using predefined attributes. Complete the following steps.

1. In the Amazon Connect admin website, choose Routing, **Predefined attributes**, **Add predefined attribute**.
2. In the **Add predefined attributes** section, in the **Predefined attribute** box, add one of the following.
   - To create allowed list for customer screen sharing, enter `screensharing:customer-allowed-urls`.
   - To create allowed list for agent screen sharing, enter `screensharing:agent-allowed-urls`.
3. In the **Value** box, enter the allowed URL. It can be a fully formatted URL or a string pattern for substring matching, such as `https://mycompany` or `/mytransactions`. The following table shows examples of valid formats.

Allowed URL	website URL
https://mycompany.com	https://mycompany.com
/mytransactions	https://mycompany.com/mytransactions https://othercompany.com/mytrasactions.com
mycompany.com	https://mycompany.com

Allowed URL	website URL
	https://internal.mycompany.com

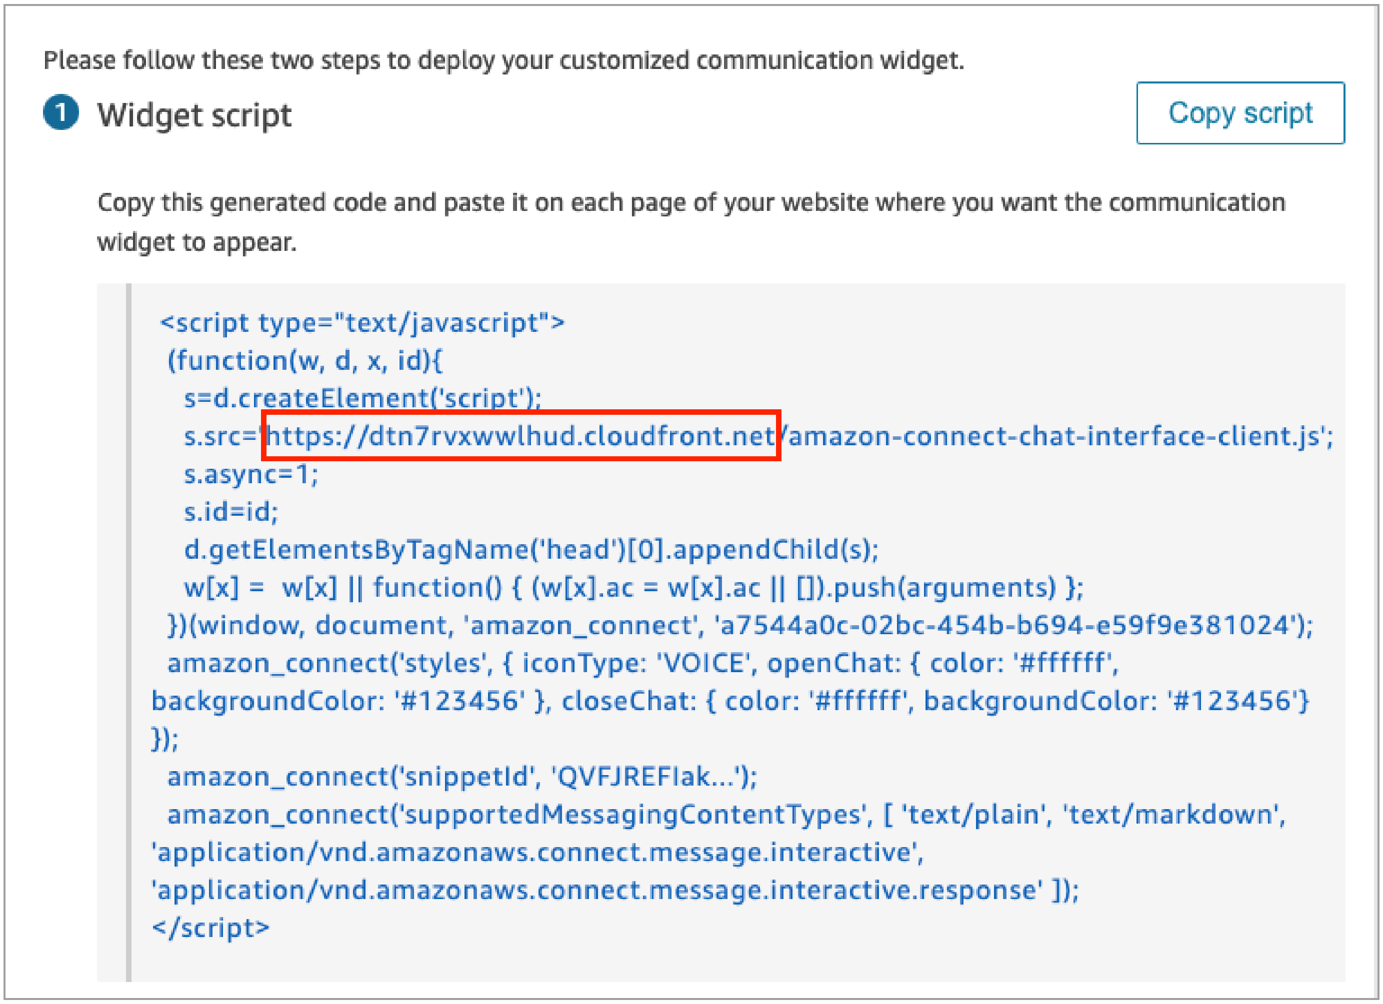
4. Save the list. The URLs appear on the **Predefined attributes** page, as shown in the following example.



Step 2: Add script to your website list

You need to embed a script into your website so the URL of the page can be exposed to the capturing application. You get the capture handler from a file on the Amazon CloudFront endpoint that Amazon Connect hosts. Complete the following instructions.

1. In the Amazon Connect admin website, choose **Channels**, **Communicate widgets**. On your Communication widget summary page, look for the widget script. Get the endpoint from the `s.src` attribute, as shown in the following example.



The endpoint can be in a different AWS Region than your Amazon Connect instance. For best performance, we recommend using the same Region as your Amazon Connect instance.

2. Replace the following placeholder `${endpoint}` with the value from previous step. Copy the entire code snippet and paste it on the top level of your website.

```
<script type="text/javascript" src='${endpoint}/amazon-connect-url-
restriction.js'></script>
```

Set up tasks in Amazon Connect

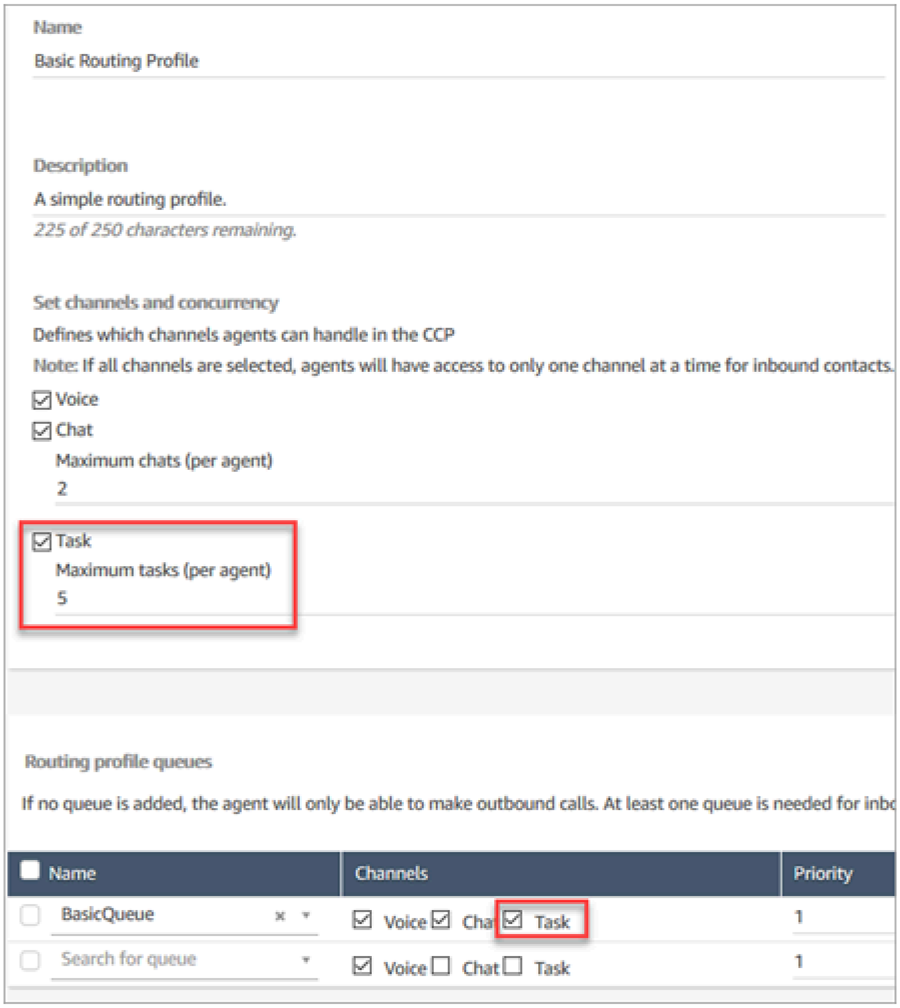
1. Update your agent's routing profile so they can manage and create tasks.

   When you add tasks to their routing profile, you can specify that up to 10 tasks be assigned to them at a time.

An agent can pause the same number of tasks as the **Maximum tasks per agent** setting in their routing profile.

For example, an agent has a **Maximum tasks per agent** setting to handle 5 active tasks simultaneously. This means they can pause up to 5 tasks, which allows them to free up their active slots to take in new more critical tasks. However, it also means that agents can have twice the number of tasks in their workspace at any point in time. In our example, this agent can have 10 tasks in their workspace: 5 paused and 5 active.

The following image shows the **Tasks** option on the **Routing profile** page.



2. Create quick connects so that agents can create/assign tasks to themselves, or other agents or shared queues.
3. Update your flows to route tasks.
4. Optionally, create task templates to make it easy for agents to create tasks. All the fields they need to create a task are defined for them.

5. Optionally, integrate with external applications and set up rules to automatically create tasks based on pre-defined conditions.
6. By default all agents can create tasks. If you want to block permissions for some agents, assign the **Contact Control Panel**, **Restrict task creation permission** in their security profile.

The task channel in Amazon Connect

Amazon Connect Tasks allows you to prioritize, assign, track, and even automate tasks across the disparate tools agents use to support customers. For example, using Tasks you can:

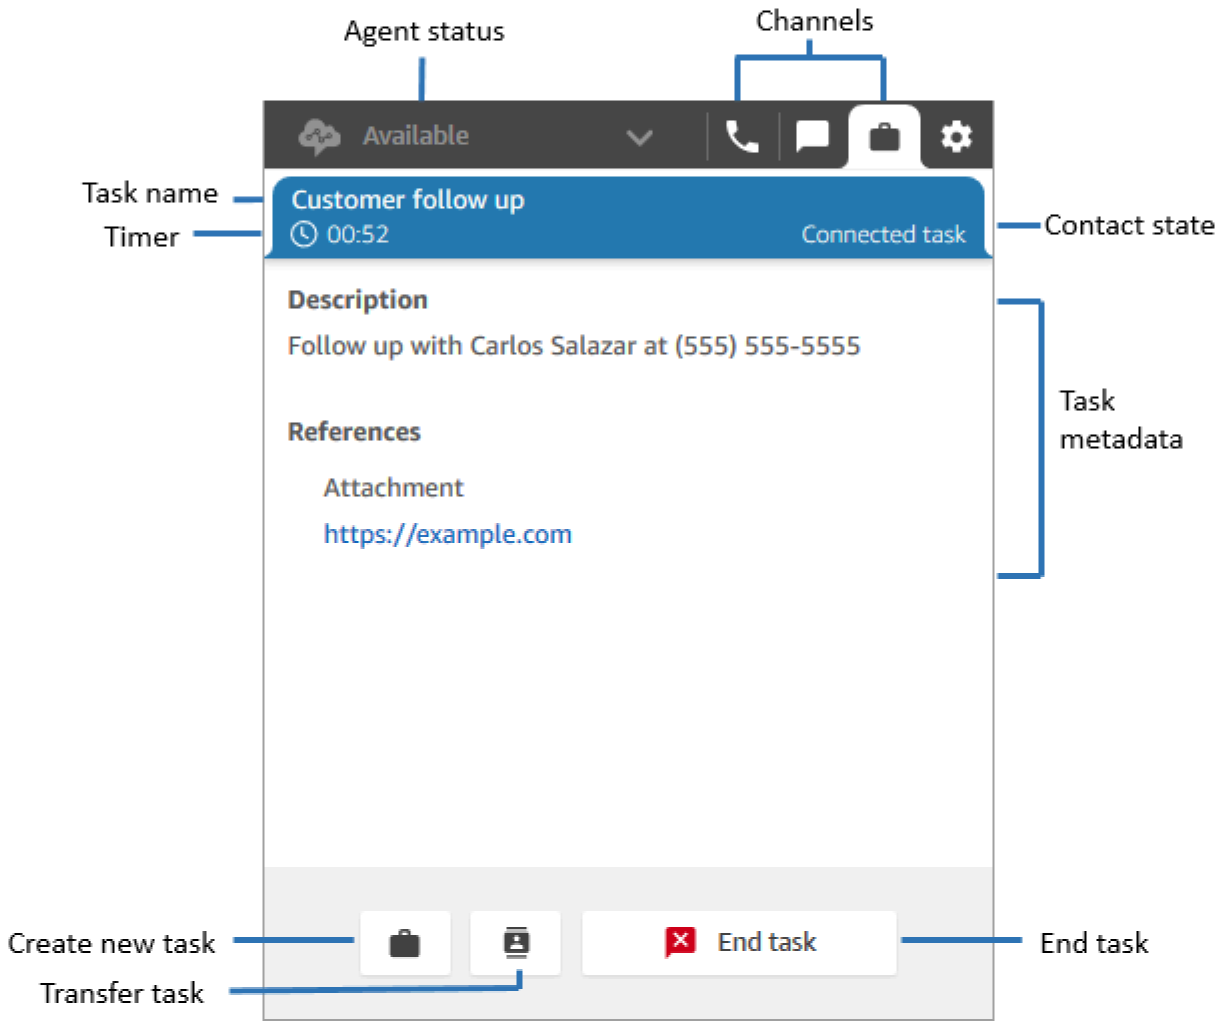
- Follow-up on customer issues recorded in a customer relationship management (CRM) solution such as Salesforce.
- Follow-up with a customer through a call.
- Complete actions in a business-specific system, such as processing a customer claim in an insurance application.

Currently, Amazon Connect Tasks can be used in compliance with GDPR and is approved for SOC, PCI, HITRUST, ISO, and HIPAA.

What is a task?

In a business a *task* is a unit of work that an agent must complete. This includes work that may have originated in external applications. In Amazon Connect this unit of work is a contact. It's routed, prioritized, assigned, and tracked just like a voice or chat contact. Everything that is applicable to a voice or chat contact is also applicable to a task contact.

Agents handle tasks in their Contact Control Panel (CCP), again just like any other contact. When assigned a task, agents see a notification with the description of the task, information associated with the tasks, and links to any applications that they might need to complete the task. The following image shows what an agent's CCP may look like when they manage tasks.



How to create tasks

Amazon Connect provides different ways for you to create tasks:

1. You can use pre-built connectors with CRM applications (for example, Salesforce and Zendesk) to automatically create tasks based on a set of pre-defined conditions, without any custom development.

   For example, you can configure a rule in Amazon Connect to automatically create a task when a new case is created in Salesforce.

   For more information, see Set up application integration to create tasks in Amazon Connect and Create rules that generate tasks for third-party integrations in Amazon Connect.

2. You can integrate with your homegrown or business-specific applications to create tasks using Amazon Connect APIs.

For more information, see the StartTaskContact API.

3. You can add a Create task block to your flows. This block enables you to create and orchestrate tasks directly from flows based on customer input (DTMF input), and contact and tasks information.
4. You can enable your agents to create tasks from the Contact Control Panel (CCP) without you doing any development work.

   For example, agents can create tasks to ensure follow up work is not forgotten, such as calling a customer back to provide a status update on their issue.

   For more information, see Test voice, chat, and task experiences in Amazon Connect.

For more information on getting started with tasks, see Set up tasks in Amazon Connect.

Supported flow types

You can use tasks in the following flow types:

- Inbound flow
- Customer queue flow
- Agent whisper flow
- Transfer to queue flow
- Transfer to agent flow

Supported contact blocks

You can use tasks in the following flow blocks:

- Change routing priority/age
- Check contact attributes
- Check hours of operation
- Check queue status
- Check staffing
- Create task

- Disconnect / hang up
- Distribute by percentage
- End flow / resume
- Get queue metrics
- Invoke AWS Lambda function
- Loop
- Set contact attributes
- Set customer queue flow
- Set disconnect flow
- Set working queue
- Transfer to flow
- Transfer to queue
- Wait

Linked tasks

When using tasks with the StartTaskContact API, a new contact can be associated with an existing contact through `PreviousContactID` or `RelatedContactId`. This new contact contains a copy of the contact attributes from the linked contact.

The following code shows request syntax that includes `PreviousContactID` and `RelatedContactId`.

```
PUT /contact/task HTTP/1.1
Content-type: application/json

{
   "Attributes": {
      "string" : "string"
   },
   "ClientToken": "string",
   "ContactFlowId": "string",
   "Description": "string",
   "InstanceId": "string",
   "Name": "string",
   "PreviousContactId": "string",
```

```
    "QuickConnectId": "string",
    "References": {
       "string" : {
          "Type": "string",
          "Value": "string"
       }
    },
    "RelatedContactId": "string",
    "ScheduledTime": number,
    "TaskTemplateId": "string"
}
```

When you use `PreviousContactID` or `RelatedContactID` to create tasks, note the following:

- `PreviousContactID` - When contacts are linked using the `PreviousContactID`, updates that are made to contact attributes at any time in the chain will percolate through the entire chain.
- `RelatedContactID` - When contacts are linked using the `RelatedContactID`, updates that are made to contact attributes will percolate only to the contactID that is referenced in the [UpdateContactAttributes](#) API.

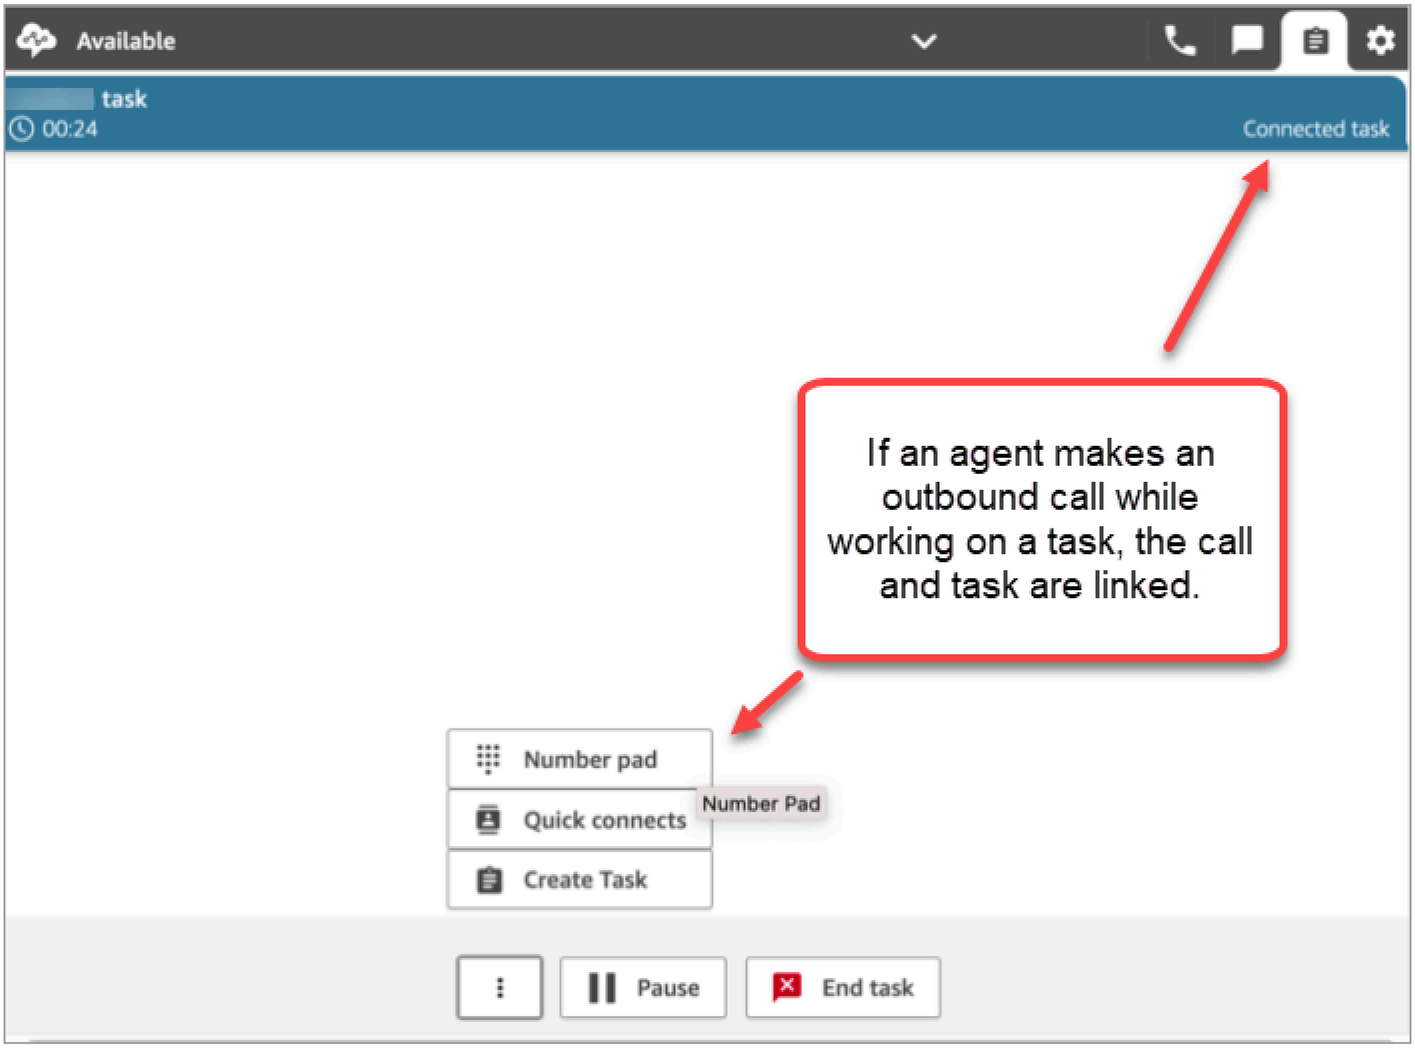
> **Note**
>
> You can specify only `PreviousContactID` or `RelatedContactID` in a request body, but not both. If you do specify both, Amazon Connect returns an `InvalidRequestException` error with a 400 status code.

For information about how `PreviousContactID` and `RelatedContactId` are modeled in contact records, see [ContactTraceRecord](#) in the contact records data model.

Agents can link tasks to outbound contacts

While agents are **actively working on a task**, the **Number pad** appears on the Contact Control Panel (CCP). If they make an outbound call using the Number pad, the call is automatically linked to the task. Amazon Connect links the task and outbound call by using the `relatedContactID` parameter.

The following image of the CCP shows the **Number pad** is available while the agent works on a task.



Link task to contact by using the Create task block

The Create task block enables you to automatically link the task to the current contact.

The following image of the Properties page of the **Create task** block shows the **Link to contact** option.

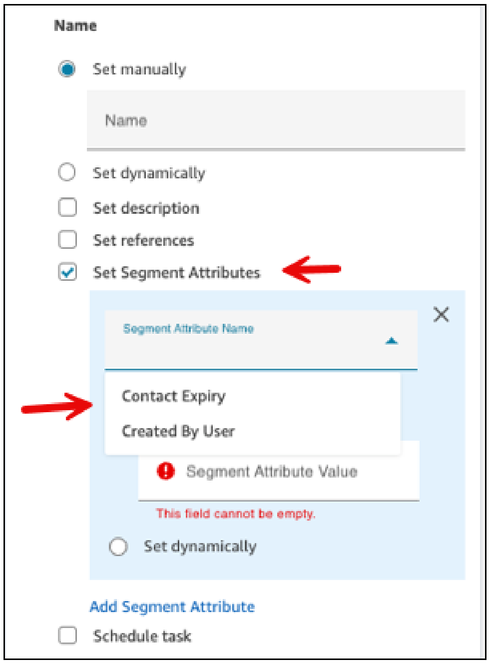
Track who created a task

Agents who create tasks through CCP automatically have their agent resource ARN added onto the contact as a segment attribute called `CreatedByUser`.

This attribute is available to you on the [Create task](#) block. You can set the segment attribute of **Created by User**, which represents the ARN of the user who created the task. The following image shows a section of the **Create task** properties page where this attribute is available.



This attribute appears on the contact record, and enables you to track the originating agent for a task. You can also set this value manually for tasks that are created through the [StartTaskContact](#) API.

Agents can assign tasks to themselves

When contact center supervisors create task templates, they can configure them to allow agents to self-assign tasks. Agents assign tasks to themselves by using the CCP.

Developers can specify the `assignmentType` on the [StartTaskContact](#) API with the value `SELF` and specify a valid `CreatedByUser` and a valid `TaskTemplateID`.

Using IAM? Add Task permissions

If your organization is using custom [IAM](#) policies to manage access to the Amazon Connect console, make sure users have the appropriate permissions to set up applications for task creation. For a list of required permissions, see [Tasks page](#).

Note

If your instance was created before October 2018, for information about how to configure your service-linked roles (SLR), see For instances created before October 2018.

Track tasks in real-time and historical metrics reports

You can track the status of all tasks in real-time and historical metrics reports, just like you track contacts in other channels. For example, you can track:

- How long agents spent working on each task (Agent on contact time).
- The total time from when a task was created to when it was completed. (Contact handle time).

Metrics

- Average active time - historical
- Average Agent Pause Time - real-time
- Average agent pause time - historical

Contact metrics

The following data is captured in the contact data model.

- TotalPauseCount
- LastPausedTimestamp
- LastResumedTimestamp
- TotalPauseDurationInSeconds

Metrics that don't apply to tasks and have a value of 0 on the report

- Avg interaction and hold time - real-time
- Avg hold time - real -time
- Agent interaction and hold time - historical
- Agent interaction time - historical

- Average agent interaction time - historical
- Average customer hold time - historical

Manage tasks to custom service levels (SL)

While voice and chats may have short service level times based on seconds or minutes, you may have some tasks with service levels that are hours or days. You can create custom service level durations that are appropriate to each of your channels. For more information, see real-time custom service levels and historical custom service levels.

When do tasks end?

The default total duration of a task can be up to 7 days. When you create a task template, you can extend the duration of the task up to 30 days.

A task ends when one of the following happens:

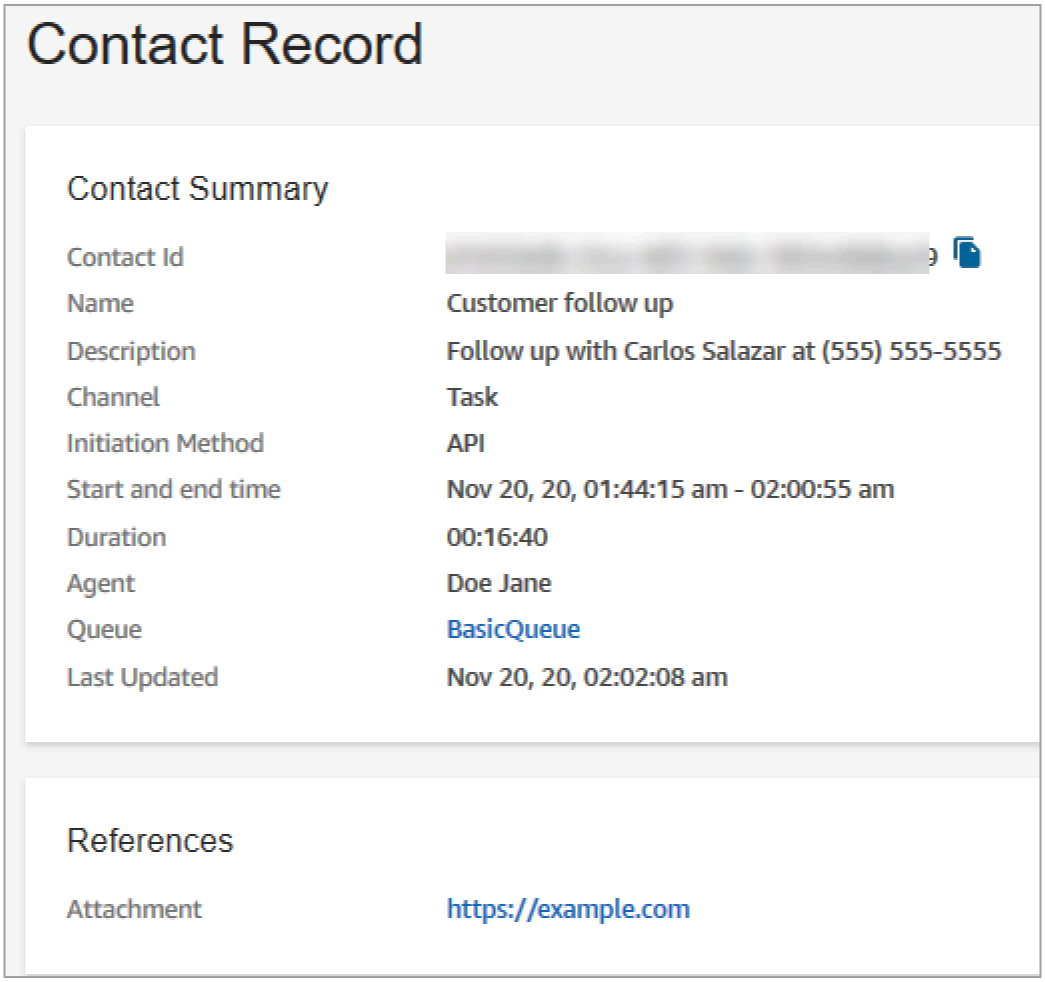
- An agent completes the task.
- A flow runs a Disconnect / hang up block, which ends the task.
- A task reaches the default 7 day limit.
- It reaches the **Expiry Duration In Minutes**, if this option is configured on the task template.
- You end the task using the StopContact API.

You can also use the **Contact Expiry** setting on the Create task block.

Search and review completed tasks

Use the Contact search page to search for and review completed tasks.

The following image is an example of what the **Contact Summary** and **References** look like in a contact record for a task.



The following data is appended to the contact record but not stored with it. The data is included in an export.

- Flow ID
- Potential attributes:
  - [ContactDetails]
    - Name: the name of the task
    - Description: the description of the task
  - [References]: any links to forms or other sites

When task is scheduled for a future date and time, **Contact Summary** also displays **Scheduled time**.

More information

- Amazon Connect feature specifications
- Accept a task assigned in the Contact Control Panel (CCP)
- Create a new task in the Contact Control Panel (CCP)
- Transfer a task to another agent or queue in the Amazon Connect Contact Control Panel (CCP)

Pause and resume tasks in Amazon Connect Tasks

You can pause and resume all tasks that aren't expired, disconnected, or scheduled for a later time. The benefit of pausing and resuming tasks is that is enables agents to free up an active slot so they can receive more critical tasks when their current task is stalled, for example, because of a missing approval or waiting on an external input.

You can also pause fully automated tasks to address force majeure events (natural disasters, infrastructure failures, invasions) that may require you to halt all business processes temporarily, and then resume them after the emergency has passed.

Contents

How paused and resumed tasks are queued

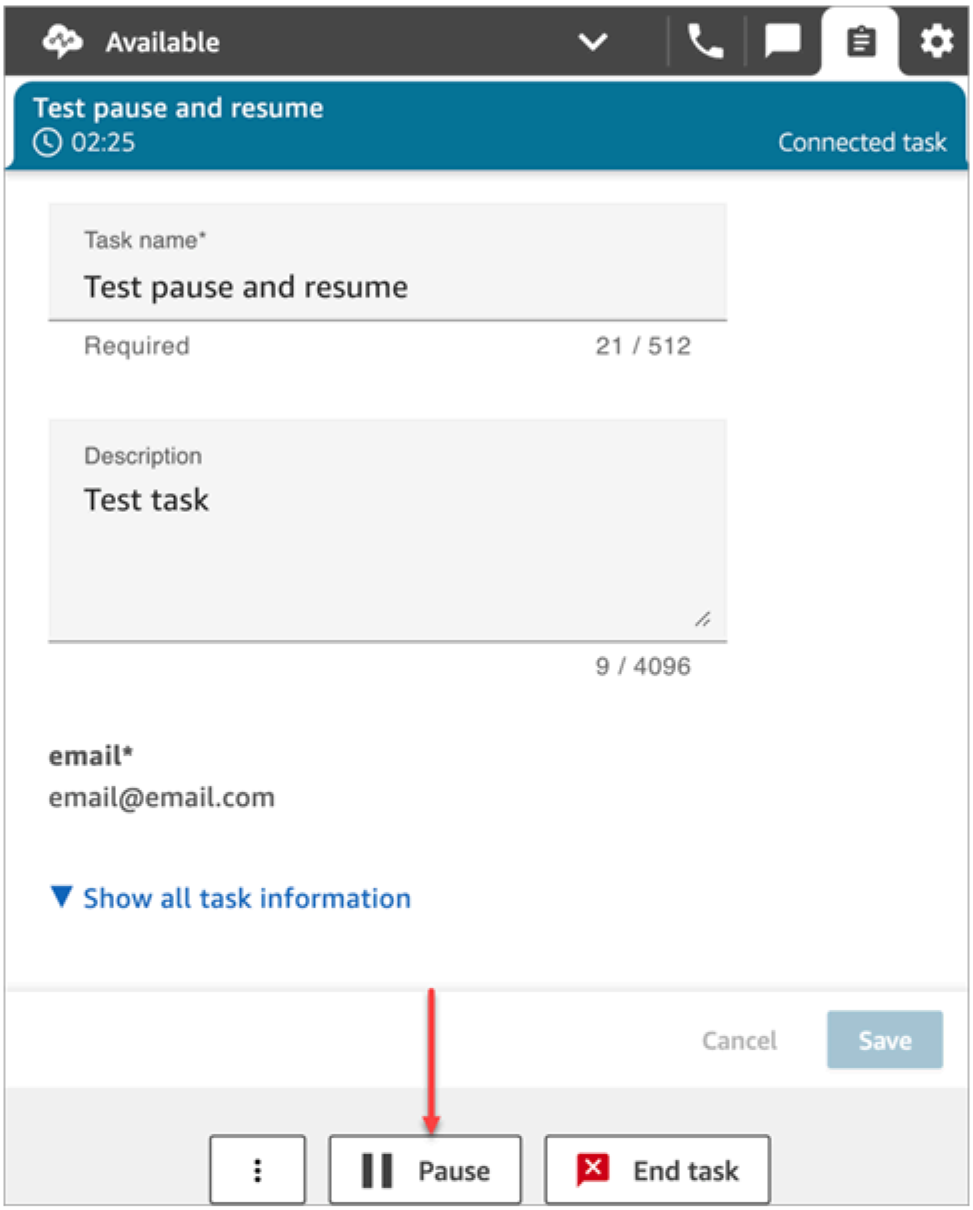
- All paused tasks that are in queue and not yet assigned to an agent are dequeued. This way they don't consume the queue limits for your instance and instead allow other more critical contacts to be assigned to agents.
- After the task is resumed, it is re-queued and the flow continues running per your configuration.

- When you design a flow to resume unassigned, paused tasks that are dequeued, be sure to add a Transfer to queue block to the flow to queue the task after resuming. Otherwise, the task will stay in a de-queued state.

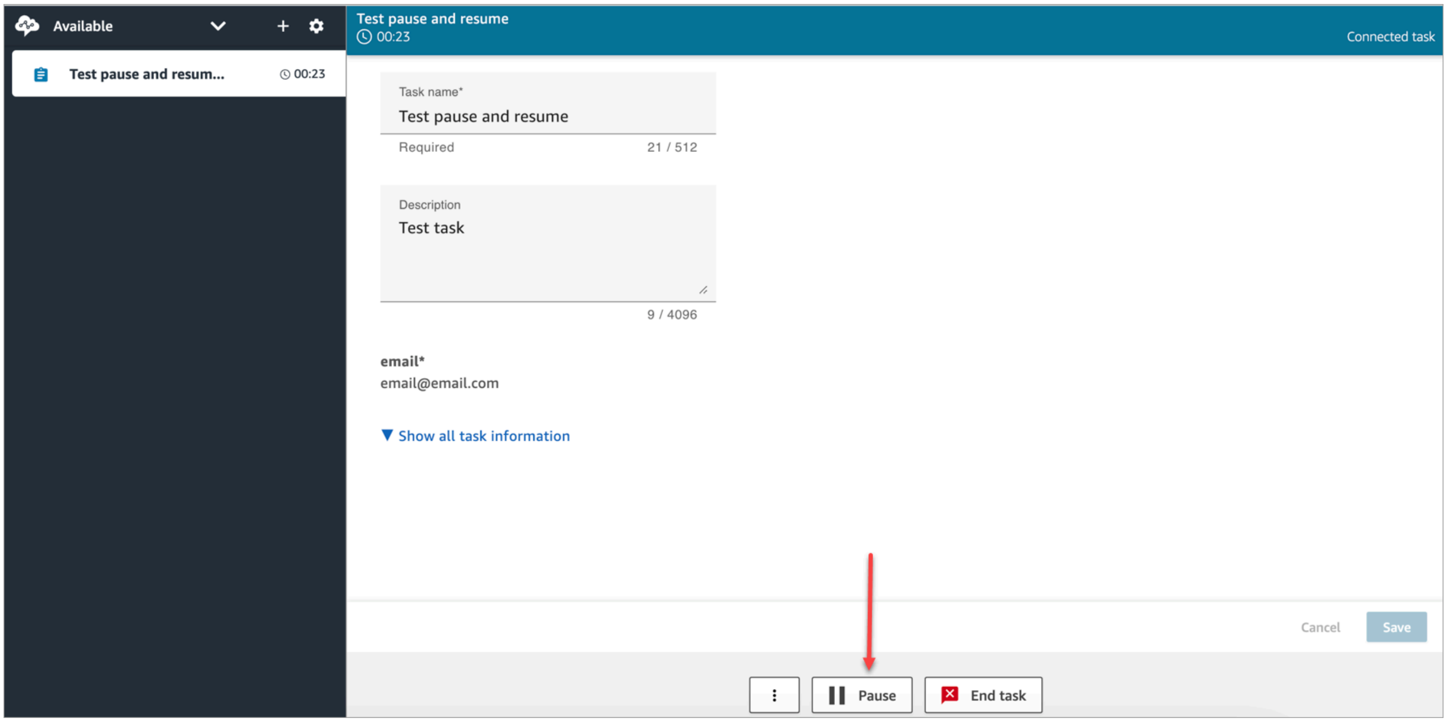
How agents pause and resume tasks

Agents can pause a task from their Contact Control Panel (CCP) or agent workspace by using the **Pause** button. To update the task, the agent must choose **Resume**. The only actions the agent can take on a task that is in the Paused state are to end it or transfer it.

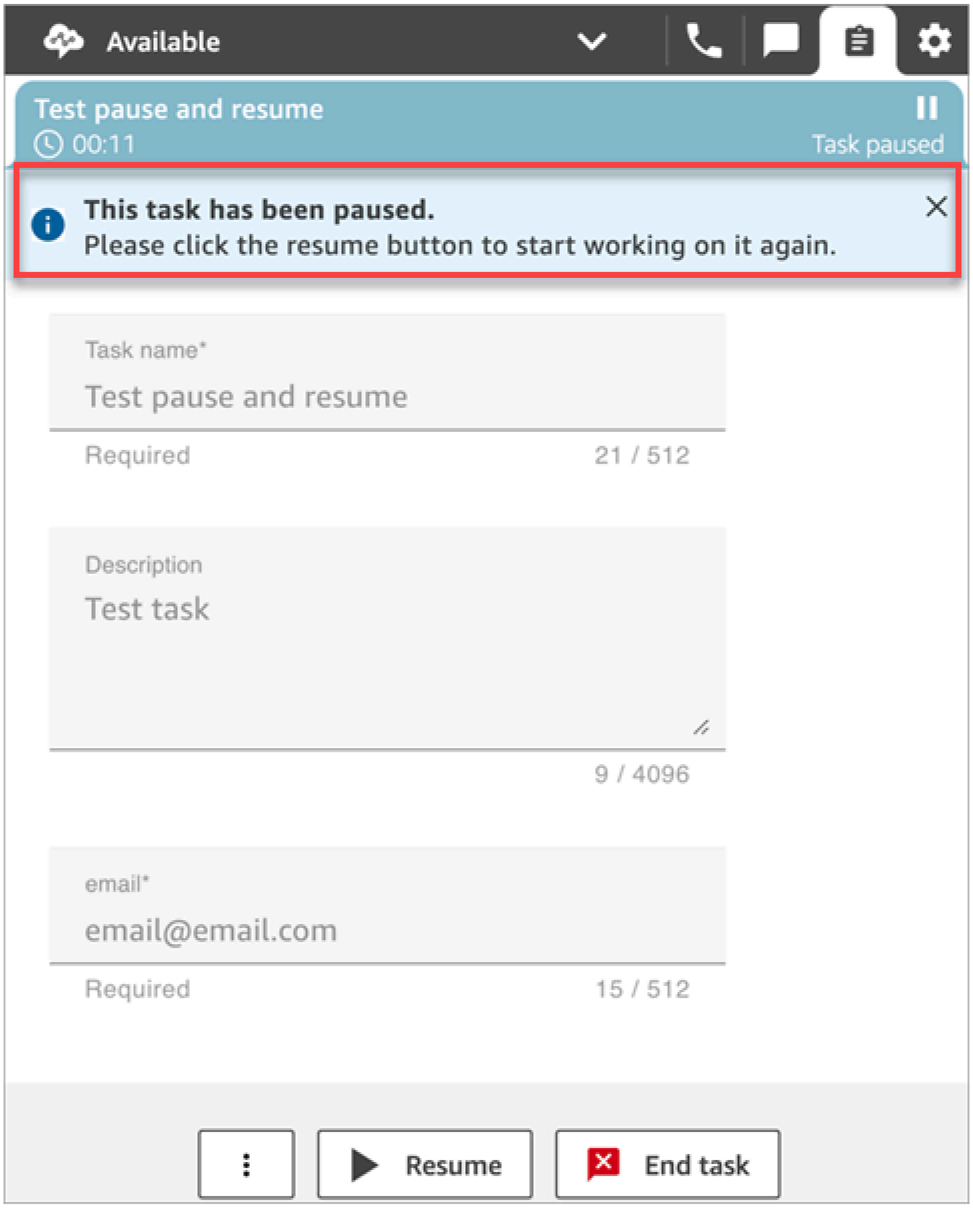
The following image shows the **Pause** button on the CCP.



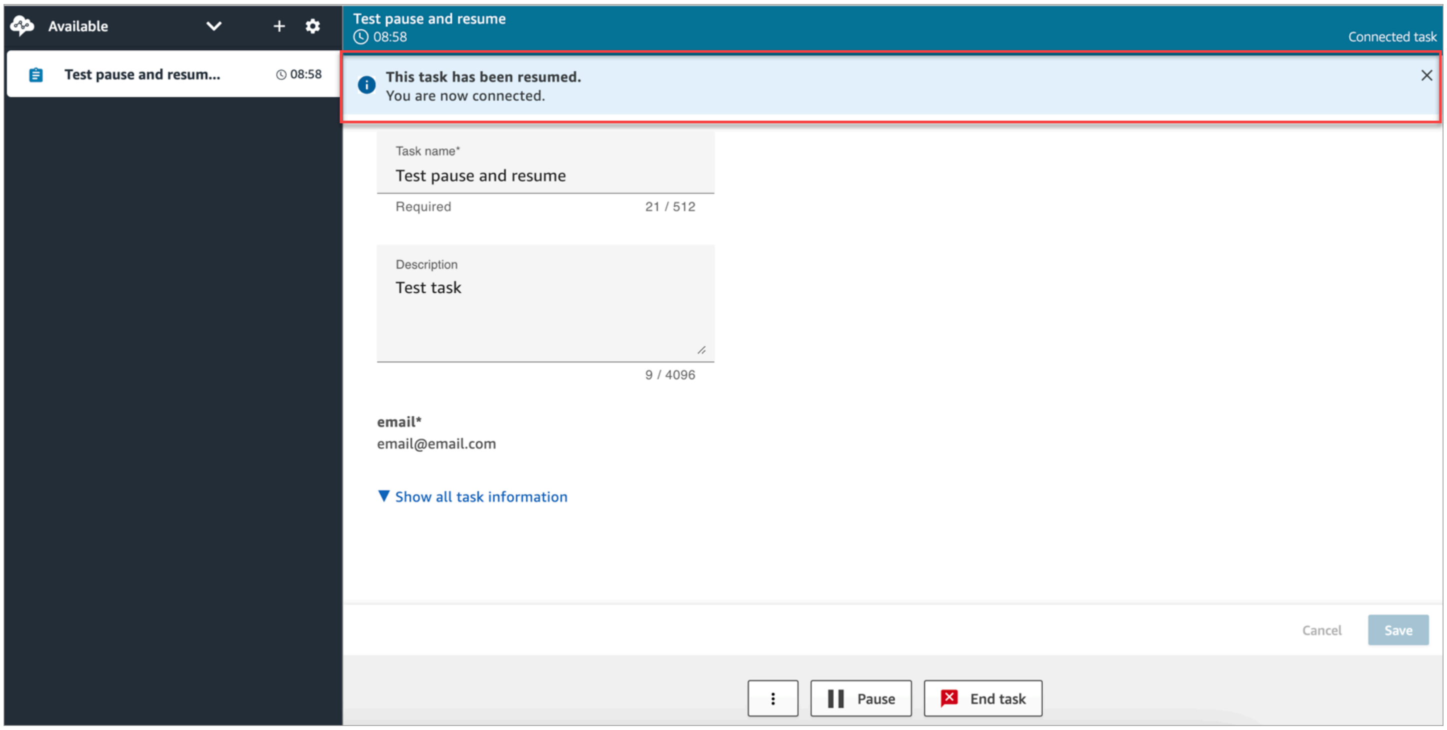
The following image shows the **Pause** button on the agent workspace.



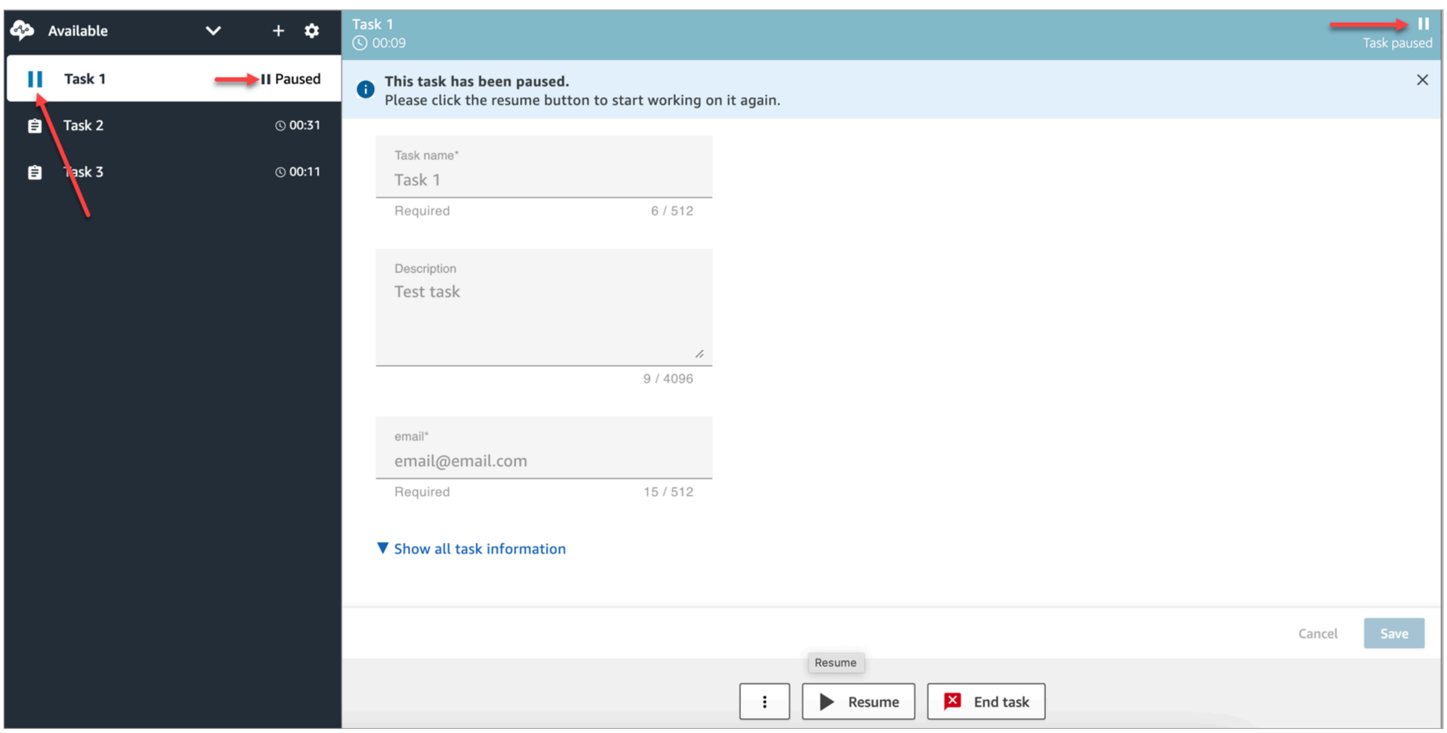
After an agent pauses or resumes a task, a banner is displayed that notifies them of the current status of the task. The following image of the CCP shows the Pause banner.



The following image of the agent workspace shows the Resume banner.



When an agent has multiple tasks open and they pause any one of them, the icon updates in the task list to notify them of the state of the task. The following image shows an example of a Paused icon.



How many tasks an agent can pause

An agent can pause the same number of tasks as the **Maximum tasks per agent** setting in their routing profile.

For example, an agent has a **Maximum tasks per agent** setting to handle 5 active tasks simultaneously. This means they can pause up to 5 tasks, which allows them to free up their active slots to take in new more critical tasks. However, it also means that agents can have twice the number of tasks in their workspace at any point in time. In our example, this agent can have 10 tasks in their workspace: 5 paused and 5 active.

When can a paused task be resumed?

A paused task can be resumed at any time. As a result, it's possible for an agent to work temporarily on twice their concurrency limit of tasks.

For example, an agent has 10 tasks in their workspace: 5 paused and 5 active. They resume all of their paused tasks simultaneously. Now they have 10 active tasks. No new tasks are routed to them until the number of active tasks is lower than the **Maximum tasks per agent** limit in their routing profile.

Programmatically pause and resume tasks

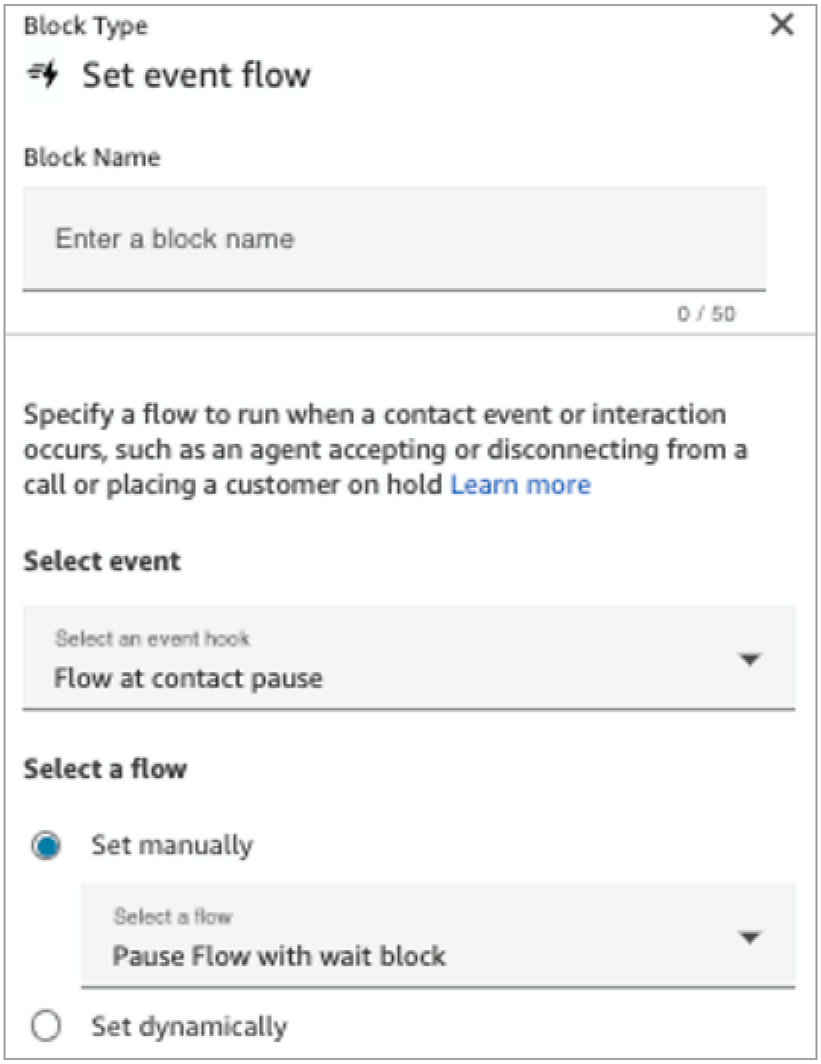
You can pause and resume tasks programmatically by using the PauseContact and ResumeContact APIs.

When pausing and resuming a task, a corresponding flow can be configured to run at the pause and resume events. For example:

- You may want to design a flow to automatically resume Paused tasks after a set period of time for agent lunch breaks.
- You may want to create a resume flow to update attributes on the task that may have changed while the task was Paused.

Configure a flow to pause and resume tasks

Configure a Set event flow block to pause and resume tasks. The following image shows the **Properties** page of a **Set event flow** block configured to pause a flow.



Following are a couple of scenarios you may want to configure in your flows:

- For flows that run at contact pause, configure them to notify supervisors when a task has been paused.
- When resuming a paused contact, configure the flow to update contact attributes to make sure that agents are always working on the latest version of attributes.

New events in the contact event stream and agent event stream

When tasks are paused and resumed, new events are generated for PAUSED and RESUMED in the contact event stream and agent event stream.

The following image shows an example of a PAUSED event in the contact event stream.

```
{EventId: <>,} for event detail : {\"eventType\":\"PAUSED\",\"contactId\":\"
<>\",\"channel\":\"TASK\",\"instanceArn\":\"arn:aws:connect:
<>",\"initiationMethod\":\"API\",\"queueInfo\":{\"queueArn\":\<>,\"enqueueTimestamp\":\"2023-
11-03T21:54:01.113Z\",\"queueType\":\"STANDARD\"},\"initiationTimestamp\":\"2023-11-
03T21:53:12.184Z\",\"scheduledTimestamp\":\"2023-11-
03T21:54:00.000Z\",\"connectedToSystemTimestamp\":\"2023-11-
03T21:54:00.741Z\",\"lastPausedTimestamp\":\"2023-11-
03T21:54:14.997Z\",\"totalPauseCount\":1,\"tags\":{\"aws:connect:instanceId\":\
<>},\"segmentAttributes\":{\"connect:Subtype\":{\"valueString\":\"connect:Task\"}}}"{EventId:
<>,} for event detail : {\"eventType\":\"RESUMED\",\"contactId\":\
<>,\"channel\":\"TASK\",\"instanceArn\":\<>,\"initiationMethod\":\"API\",\"queueInfo\":
{\"queueArn\":\<>,\"enqueueTimestamp\":\"2023-11-
03T22:20:10.837Z\",\"queueType\":\"STANDARD\"},\"initiationTimestamp\":\"2023-11-
03T22:20:09.961Z\",\"connectedToSystemTimestamp\":\"2023-11-
03T22:20:10.285Z\",\"lastPausedTimestamp\":\"2023-11-
03T22:20:22.975Z\",\"lastResumedTimestamp\":\"2023-11-
03T22:20:28.980Z\",\"totalPauseCount\":1,\"tags\":{\"aws:connect:instanceId\":\
<>},\"segmentAttributes\":{\"connect:Subtype\":{\"valueString\":\"connect:Task\"}}}"
```

The following image shows an example of a RESUMED event in the contact event stream.

```
{EventId: <>,} for event detail : {\"eventType\":\"RESUMED\",\"contactId\":\
<>,\"channel\":\"TASK\",\"instanceArn\":\<>,\"initiationMethod\":\"API\",\"queueInfo\":
{\"queueArn\":\<>,\"enqueueTimestamp\":\"2023-11-
03T22:20:10.837Z\",\"queueType\":\"STANDARD\"},\"initiationTimestamp\":\"2023-11-
03T22:20:09.961Z\",\"connectedToSystemTimestamp\":\"2023-11-
03T22:20:10.285Z\",\"lastPausedTimestamp\":\"2023-11-
03T22:20:22.975Z\",\"lastResumedTimestamp\":\"2023-11-
03T22:20:28.980Z\",\"totalPauseCount\":1,\"tags\":{\"aws:connect:instanceId\":\
<>},\"segmentAttributes\":{\"connect:Subtype\":{\"valueString\":\"connect:Task\"}}}"
```

The following image shows an example of PAUSED tasks in the agent event stream.

```
{
    "agentARN=<>,
    "instanceARN=<>,
    eventId=<>,
    "previousAgentSnapshot=(agentStatus=<name=Available",
    <>,
    "type=ROUTABLE",

        "state=PAUSED",
        "initialContactId=null",
        "channel=TASK",
        "channel=TASK",
        "connectedToAgentTimestamp=INBOUND",
        "stateStartTimestamp=2023-10-11T17":"44":23.637Z,
        "queueTimestamp=null)"
    ]")",
    "eventType=STATE_CHANGE",
    version=2017-10-01,
    "eventTimestamp=2023-10-11T17":"44":23.639Z
}
```

Pause and resume task events in contact records

The following events are captured in the ContactTraceRecord section of the contact records data model. You can use the DescribeContact API to return task events.

Name in contact record	Name returned by DescribeContact API		
TotalPauseDurationInSeconds	TOTAL_PAUSED_TIME		
TotalPauseCount	TOTAL_NUMBER_OF_PAUSES		
LastPausedTimestamp	LAST_PAUSED_TIMESTAMP		
LastResumedTimestamp	LAST_RESUMED_TIMESTAMP		

The following values are available in near real time when you use the DescribeContact API or view the **Contact details** page for an in progress contact.

- TotalPauseCount
- LastPausedTimestamp
- LastResumedTimestamp

A completed contact has TotalPauseDurationInSeconds.

Metrics

The following metrics display active, paused, and resumed time.

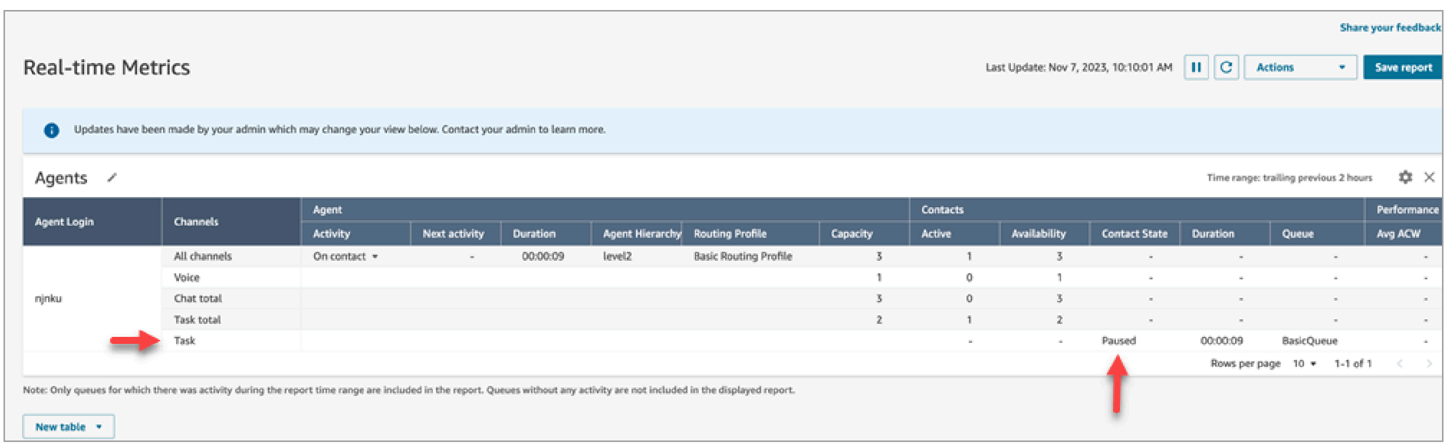
Real-time metrics	Description
[UI] Agent/Routing Profiles/Queue → Performance → **Average Active Time**	SUM(active_time)/Number of contacts
[UI] Agent/Routing Profiles/Queue → Performance → **Average Agent Pause Time**	SUM(agent_pause_time)/Number of contacts that were paused
[UI] Agent → Contacts → **Contact State**	Paused state of a task contact

Historical Metrics	Description
[UI] Agent → Agent activity audit → Support "PAUSED" state	Display paused state when the contact for an agent is in Paused state
[GetMetricDataV2] Query Average of AGENT_PAUSE_TIME for a queue/routing profile/task	SUM(total_agent_pause_time) for all contacts that were paused from queue/routing profile/TaskAVG = SUM(total_agent_pause_time)/ number of paused contacts for queue/RP/Tasks
[GetMetricDataV2] Query Average of ACTIVE_TIME for a queue/routing profile	SUM(total_handle_time - total_agent_pause_time) for all contacts of queue/routing profile/tasks AVG = SUM(total_handle_time - total_agent_pause_time) / total number of contacts for queue/routing profile/tasks

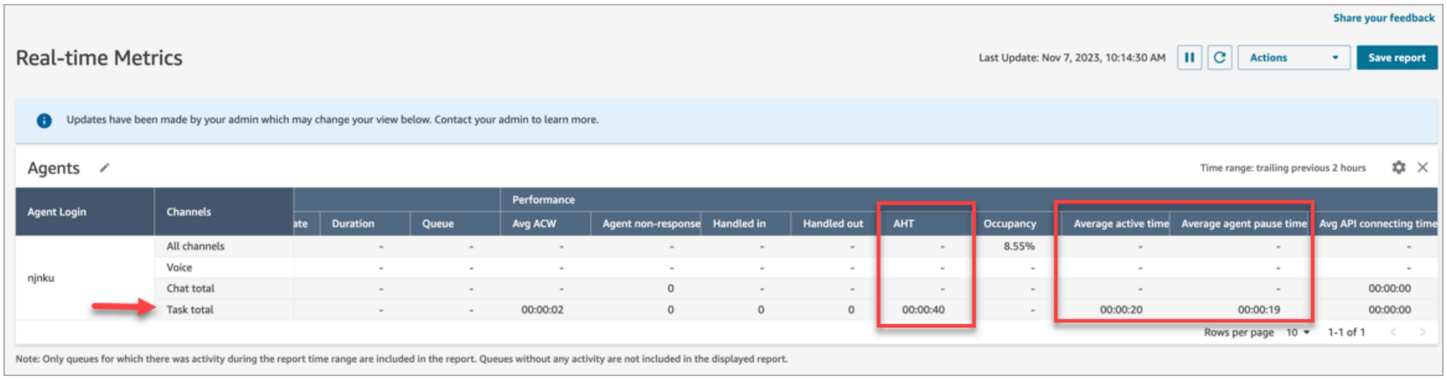
Contact details page	Description
[UI] Contact Search → Contact Details → Contact Summary → Last Paused Time	Last Paused Time
[UI] Contact Search → Contact Details → Contact Summary → Last Resumed Time	Last Resumed Time
[UI] Contact Search → Contact Details → Contact Summary → Number of Pauses	Total number of Pauses including when the contact was not connected.
[UI] Contact Search → Contact Details → Contact Summary → Total Pause Duration	Total Pause duration includes before and after the agent was connected.

Real-time Metrics page

The following image of the **Real-time Metrics** page shows the task contact state as **Paused**.

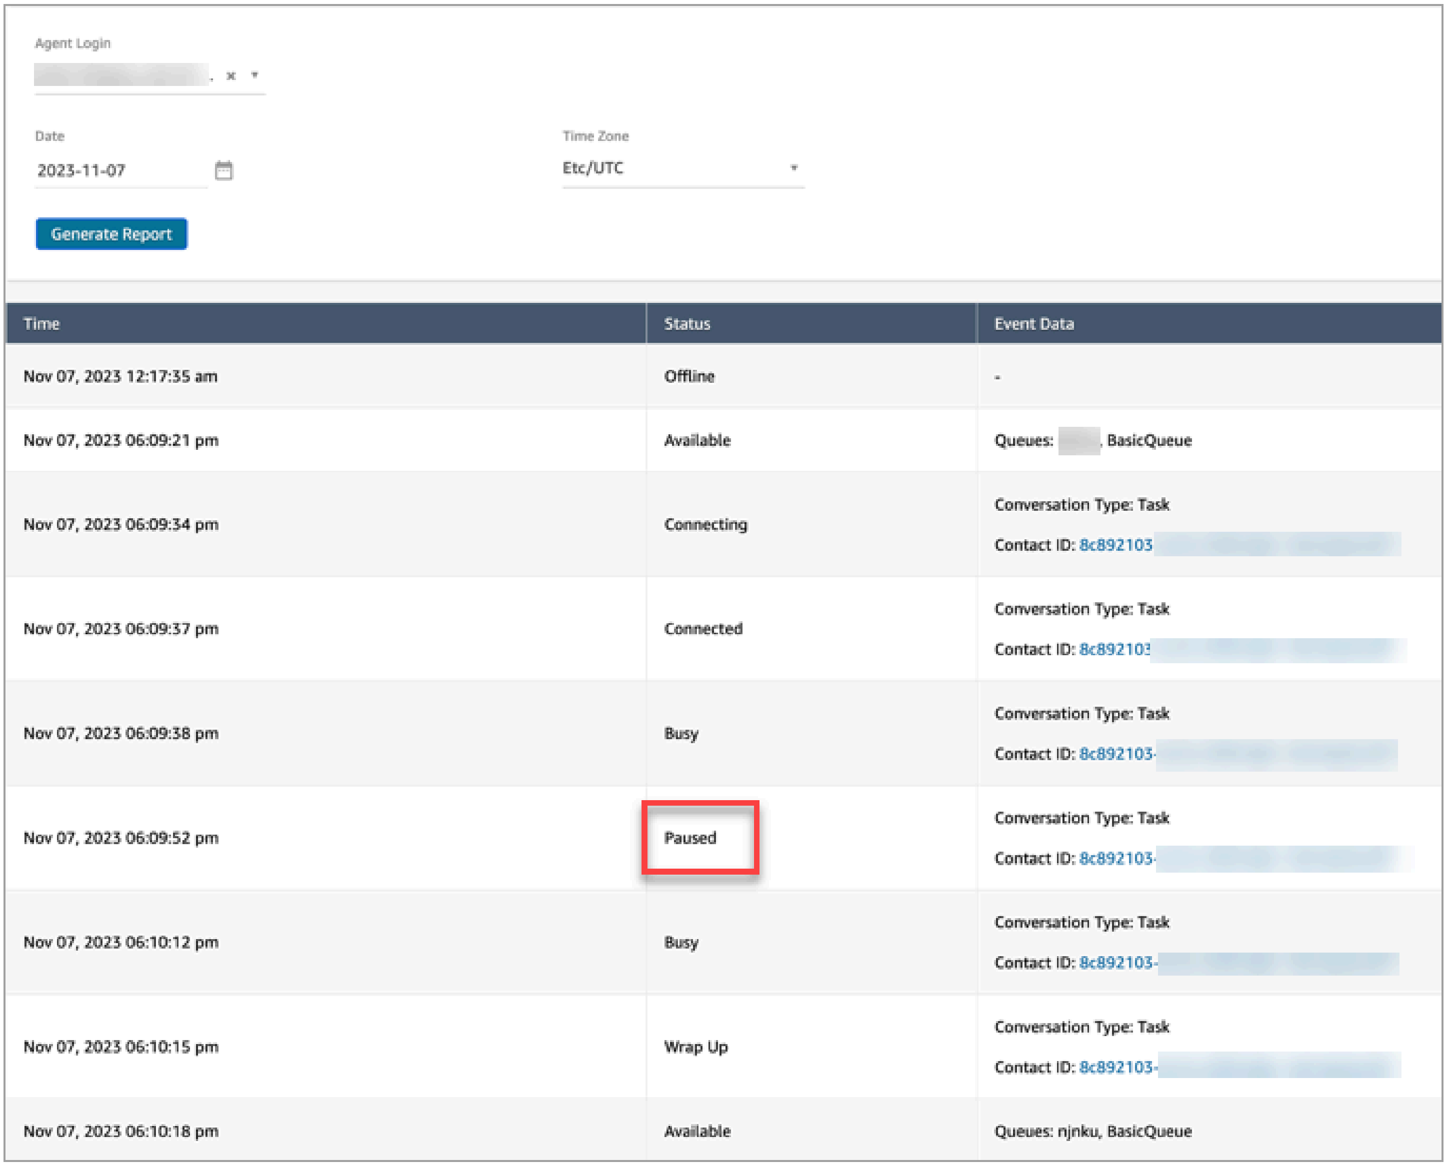


The following image of the **Real-time Metrics** page shows **Avg Active Time**, **AHT** and **Avg Agent Pause Time**.



Agent Activity Audit report

The following image of the **Agent Activity Audit report** shows the Paused status when a contact is paused by the agent.



Create task templates in Amazon Connect

Task templates make it easy for agents to capture the right information to create and complete a task. All the fields they need to create a given type of task are provided for them.

Important things to know before you create your first template

- When you publish your first template, your agents will be prompted to select a template when they create a new task. Agents must select one of the templates you have published.
- If you want to return to the standard task experience and not require agents to select a template, on the **Task templates** page, use the **Disable/Enable** toggle to disable all templates you published.

- Verify your Amazon Connect account has permissions to create task templates.
- Review the list of quotas for task templates, such as the **Task templates per instance** and **Task template customized fields per instance**. See Amazon Connect service quotas.
- You can configure a task template to allow an agent to assign the tasks to themselves. The agent needs the security profile permission **Contact Control Panel - Allow self assigning of contacts** and the **Restrict Task Creation** permission must be disabled. The agent will then be able to check a box when they create a task from the CCP and assign it to themselves.

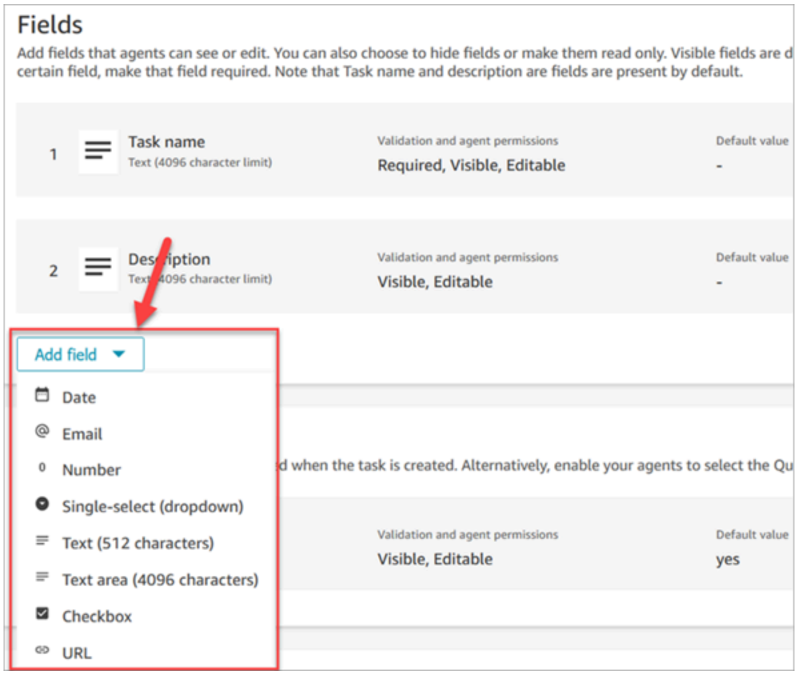
How to create a task template

Step 1: Name the template

1. Log in to the Amazon Connect console with an **Admin** account, or an account assigned to a security profile that has permissions to create task templates.
2. In the left navigation menu, choose **Channels**, **Task templates**.
3. On the **Task templates page**, choose **+ New template**.
4. On the **Create new template** page, in the **Template name** box, enter the name that will be displayed your agents.
5. In the **Description** box, describe the purpose of the template. This information is not displayed to agents; it's for your own use.

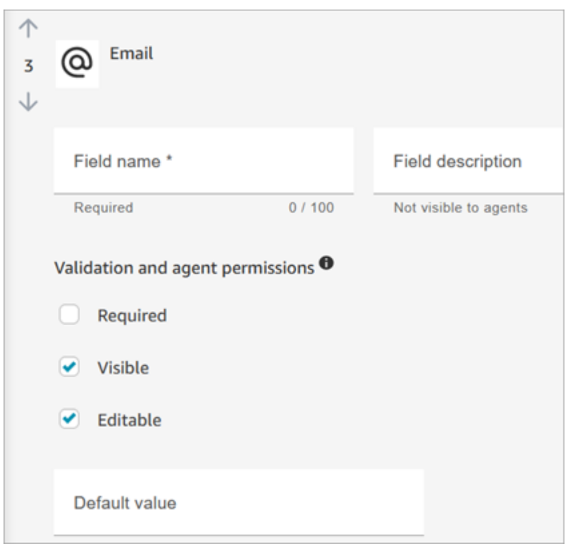
Step 2: Add fields, task assignment, schedule, and expiry

1. In the **Fields** section, choose the **Add field** dropdown, and then select the type of field you want to add to your template.



2. Use the up and down arrows as needed to change the order the field appears on the template.
3. In the **Validation and permissions** section, choose whether the field is required to be populated by the agent when they create a task, or add a default value to pre-populate the field when the agent opens the template.

   The following image shows what this section looks like for a field that is type **Email**.



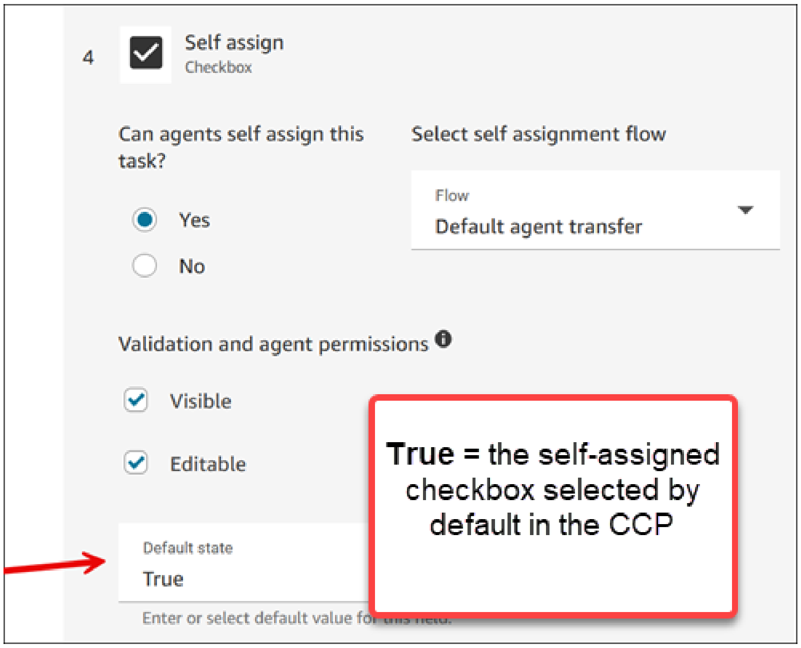
> **Note**
>
> It is not possible to use attributes in the task templates page.

4. In the **Task assignment** section:

   a. **Assign to**: Choose **Yes** to allow agents to view and edit a task assignment when they create the task. Or, assign a default value, as shown in the following image. Choose a published flow that runs after the agent chooses **Create** to create the task. Agents don't see the name of the flow on the CCP.

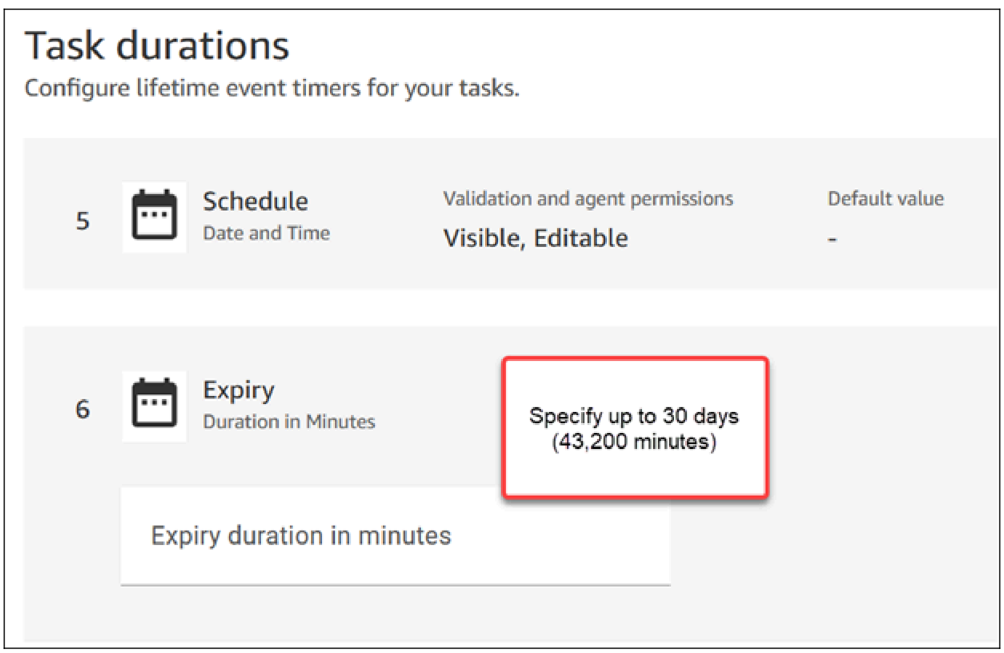
   > **Note**
   >
   > Only published flows are listed in the **Default value** dropdown.

   
   b. **Self-assign**: Choose **Yes** to allow agents to assign tasks to themselves on the CCP. For **Default state**, choose **True** if you want the self-assigned checkbox selected by default in the CCP.



5. In the **Task schedule** section, choose whether you want agents to be able to schedule a future start date and time for tasks.

6. In the **Expiry** section, specify how long the task should exist before it expires. The default is 7 days. You can configure it for up to 30 days (43,200 minutes)



Step 3: Publish

After you configure your template, choose **Publish** to create it and make it visible to your agents.

Important

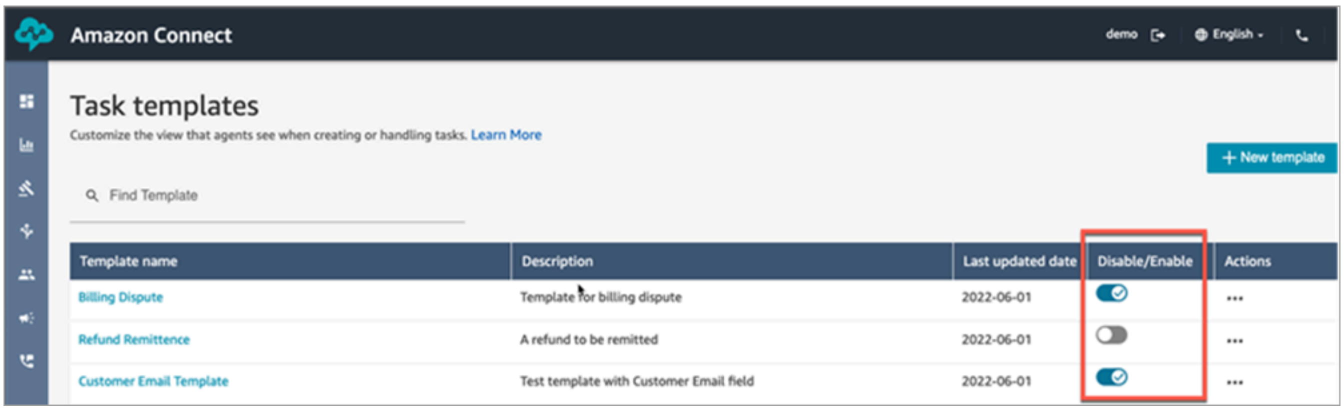
If this is your first template, when you choose **Publish**, agents are automatically required to select a task template when they create a task.

If you want to maintain the standard task experience without selectable templates, disable all templates.

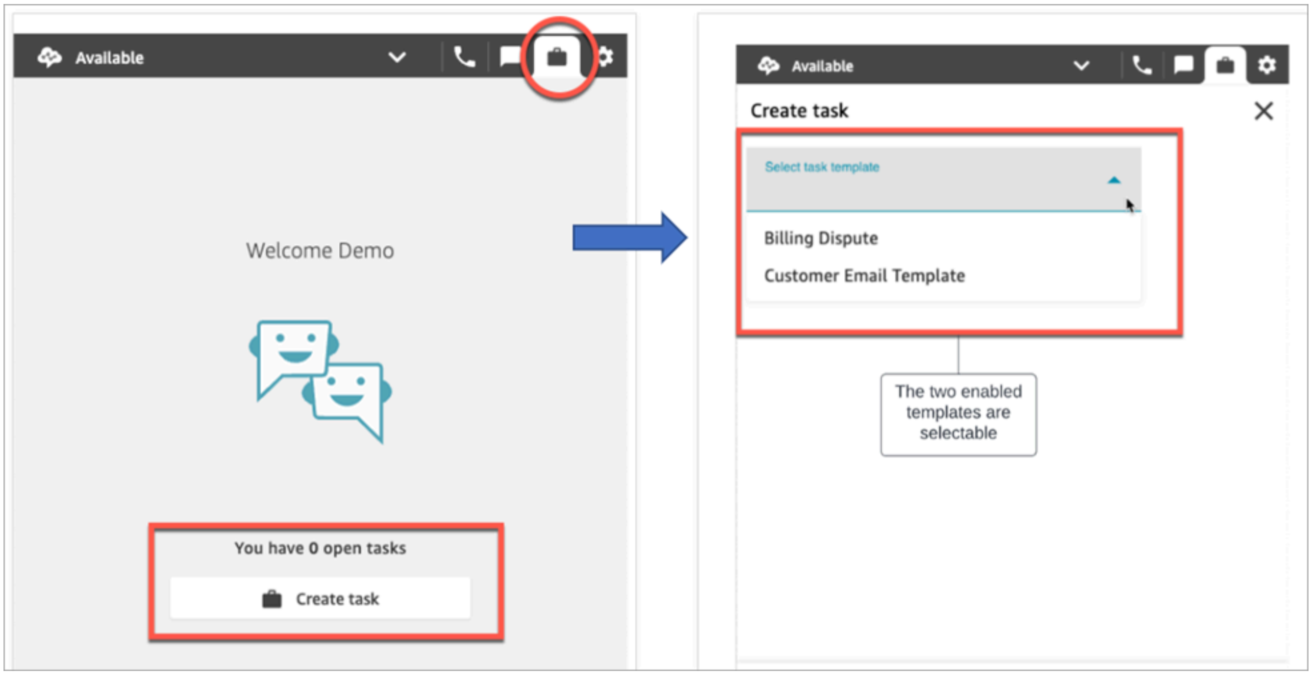
What your agents experience

After you publish a template, agents are required to select a template to create a task.

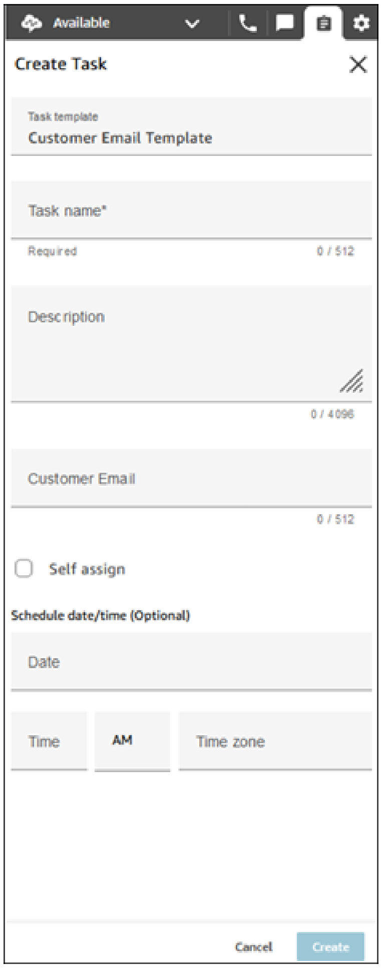
For example, the following image shows two templates have published: **Customer Email Template** and **Billing Dispute**.



In the Contact Control Panel, when agents choose **Create task** they must choose one of the templates: **Billing Dispute** or **Customer Email Template**.

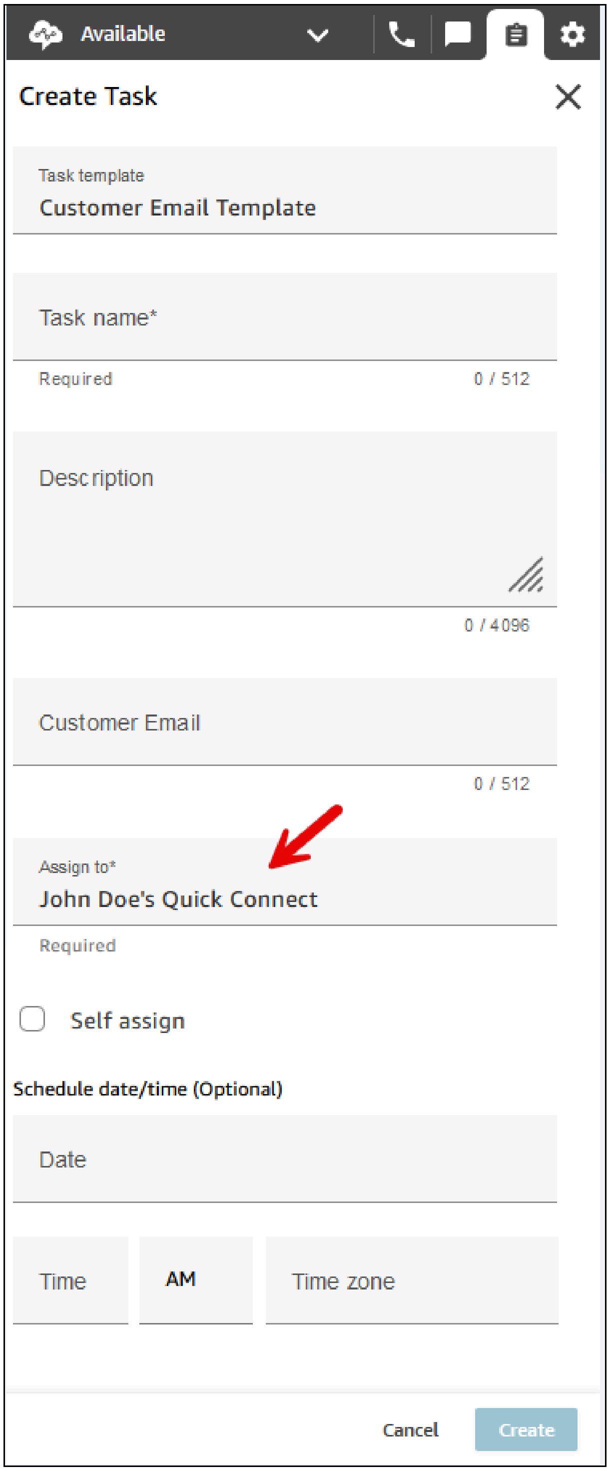


Let's assume the agent chooses **Customer Email Template**. The following image shows the fields the agent must complete in order to create a task. Notice that there is no option for the agent to assign the task to others; this template has **Task assignment** set to a default value. However, the agent can opt to assign the task to themselves.

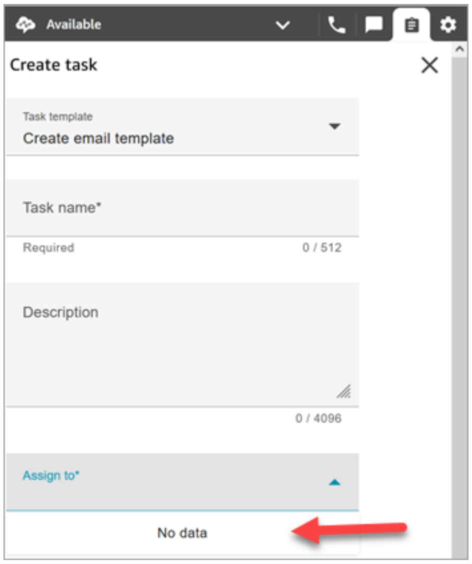


"No data" message in the Assign to dropdown

Let's say that in the **Task assignment** section, you choose to allow agents to assign the task to another agent. To set up for this scenario, you must create a quick connect for the destination agent so it appears in the dropdown list of choices, as shown in the following image. For instructions about creating a quick connect for an agent, see Test tasks.



If no quick connects exist, then the message **No data** appears when you choose the **Assign to** dropdown menu, as shown in the following image.



Grant users permissions to create task templates in Amazon Connect

Assign the **Routing**, **Task templates** permissions to enable a user to create task templates.

For information about how to add more permissions to an existing security profile, see Update security profiles in Amazon Connect.

By default, the **Admin** security profile already has permissions to perform all task activities.

Block agents from creating tasks in the Amazon Connect Contact Control Panel (CCP)

To block agents from being able to create tasks, assign the **Contact Control Panel (CCP)**, **Restrict task creation** permission. By default this permissions is unchecked, which means all agents can create tasks.

For information about how to add more permissions to an existing security profile, see Update security profiles in Amazon Connect.

By default, the **Admin** security profile already has permissions to perform all tasks activities.

Set up application integration to create tasks in Amazon Connect

Set up application integration to create tasks, without needing to code.

> **Tip**
>
> If your organization is using custom IAM policies to manage access to the Amazon Connect console, make sure users have the appropriate permissions to set up applications for task creation. For a list of required permissions, see Tasks page.
>
> If your instance was created before October 2018, for information about how to configure your service-linked roles (SLR), see For instances created before October 2018.

Contents

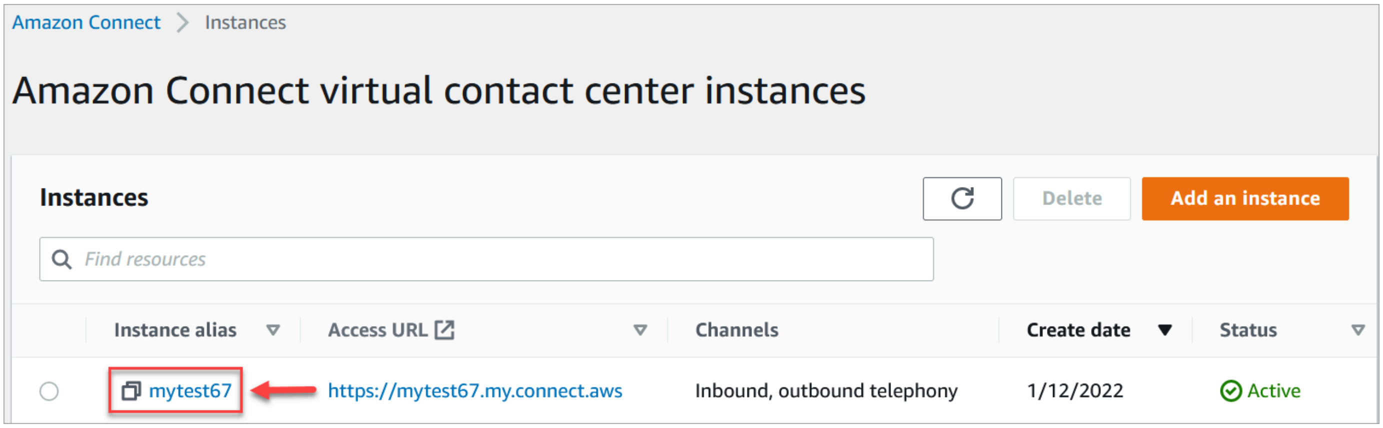
Set up application integration for Salesforce using Amazon AppFlow

If you integrate with Salesforce for event creation, Amazon Connect also uses Amazon AppFlow to put the data into EventBridge. This is because of how Salesforce sends events through the Amazon AppFlow APIs. To learn more about how Amazon Connect uses EventBridge and Amazon AppFlow resources to power Salesforce integrations, see this blog post: Building Salesforce integrations with Amazon EventBridge and Amazon AppFlow.

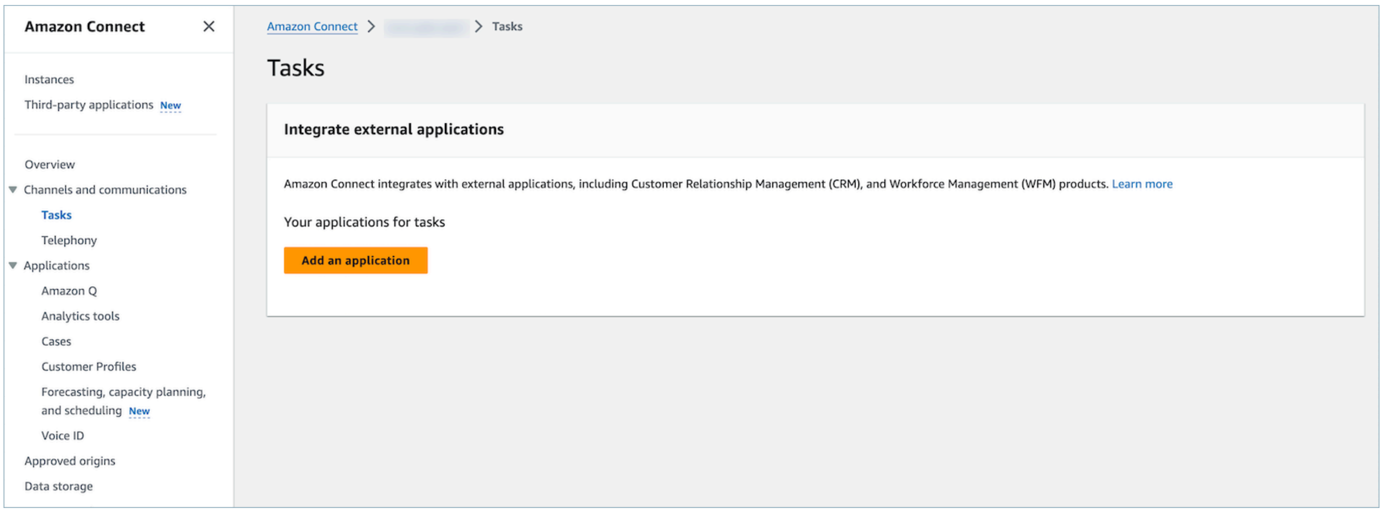
> **Note**
>
> If you use custom AWS Identity and Access Management (IAM) policies, for a list of the required IAM permissions to set up Amazon Connect Tasks, see Tasks page.

To integrate Salesforce for task creation

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Amazon Connect URL. The following image shows the **Amazon Connect virtual contact center instances** page, with a box around the instance alias.

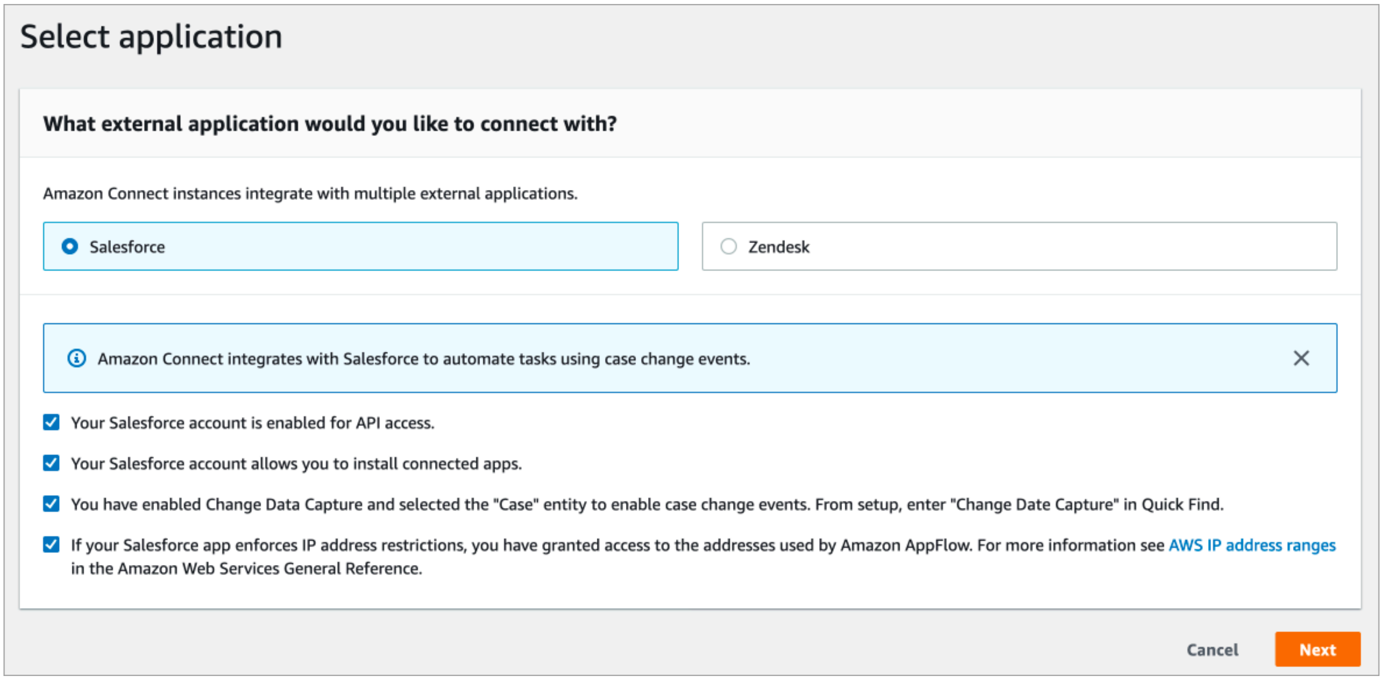


3. Choose **Tasks**, and then choose **Add an application**.



4. On the **Select application** page, choose **Salesforce**.
5. Review the application requirements that are listed on the **Select application** page.

   The following image shows the requirements for Salesforce.



1. To verify that Salesforce is compatible with Amazon AppFlow, log in to Salesforce, for example, https://[instance_name].my.salesforce.com.

> **Important**
>
> Verify that you have enabled **Change Data Capture** in Salesforce. The following image shows an example **Change Data Capture** page in Salesforce where you select the Case entities:
>
> >

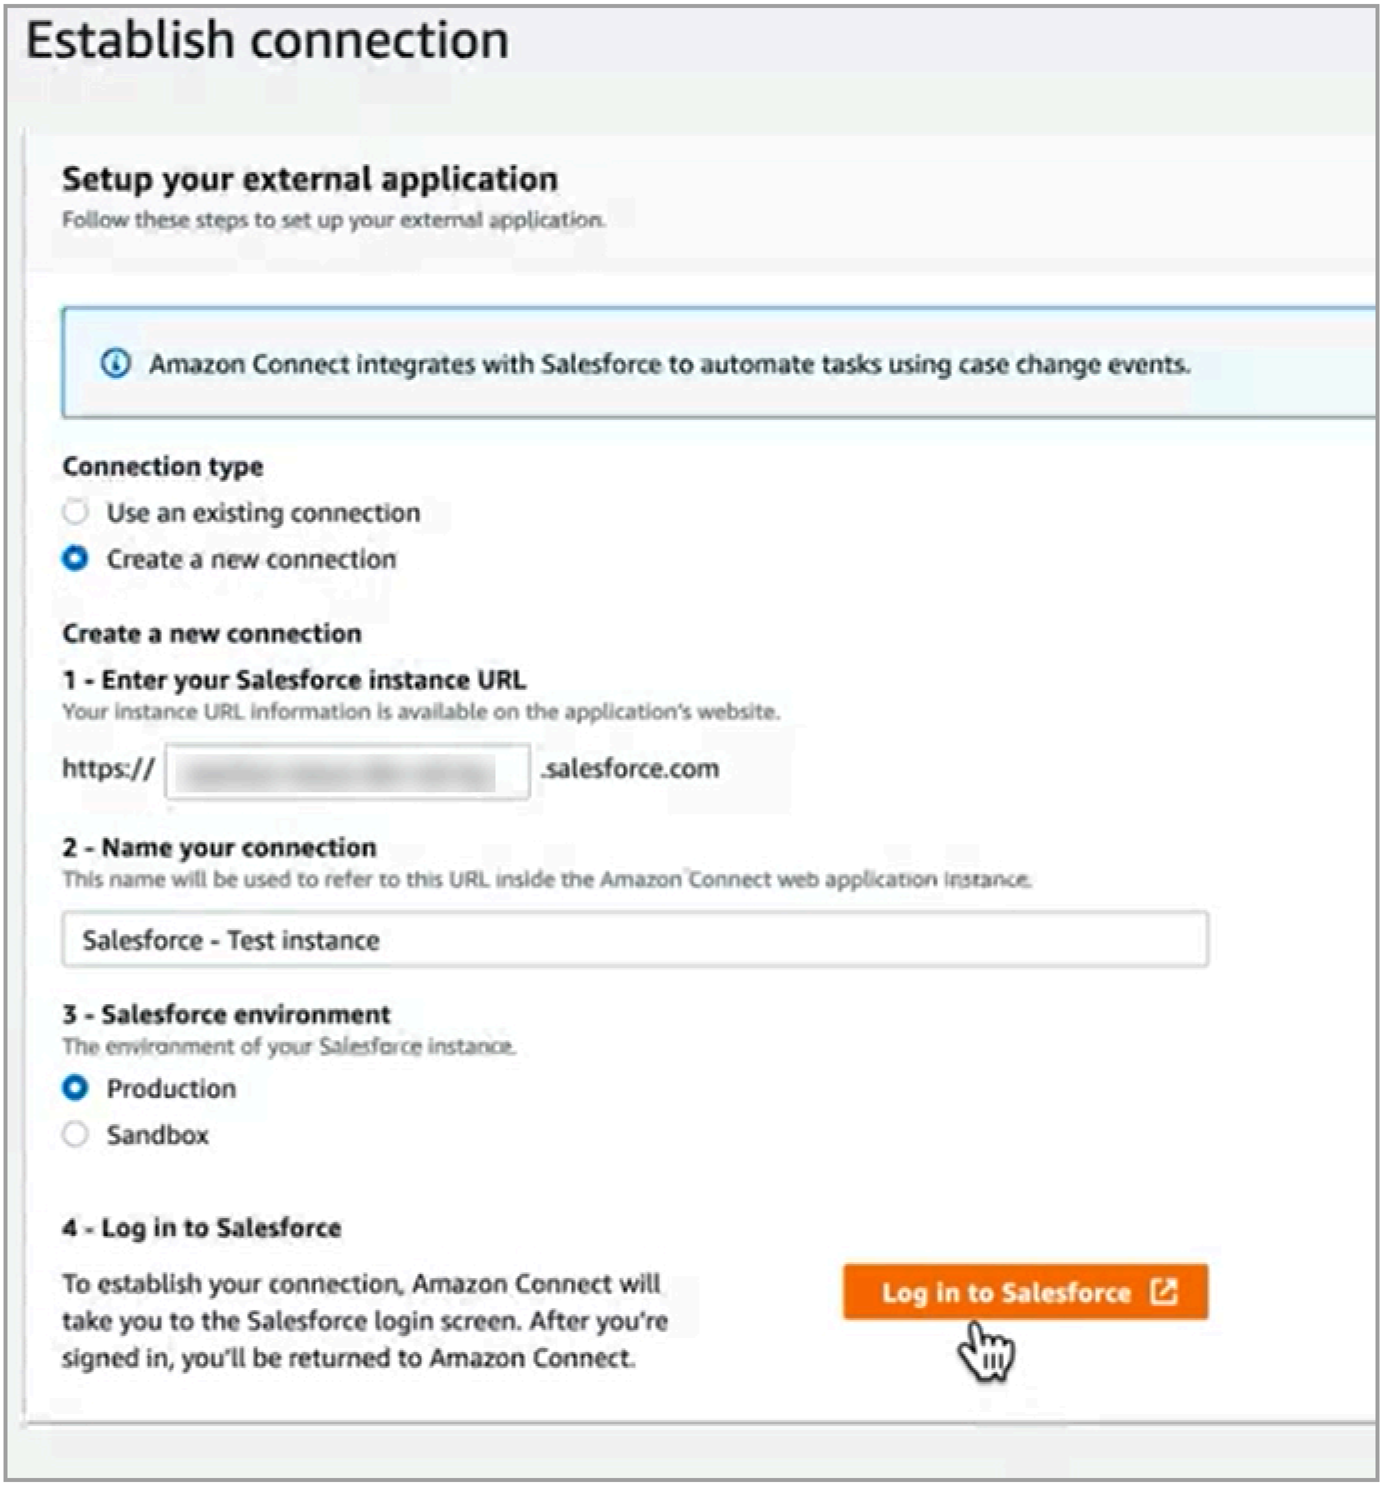
6. After you verify Salesforce requirements, on the **Select application** page, choose **Next**.

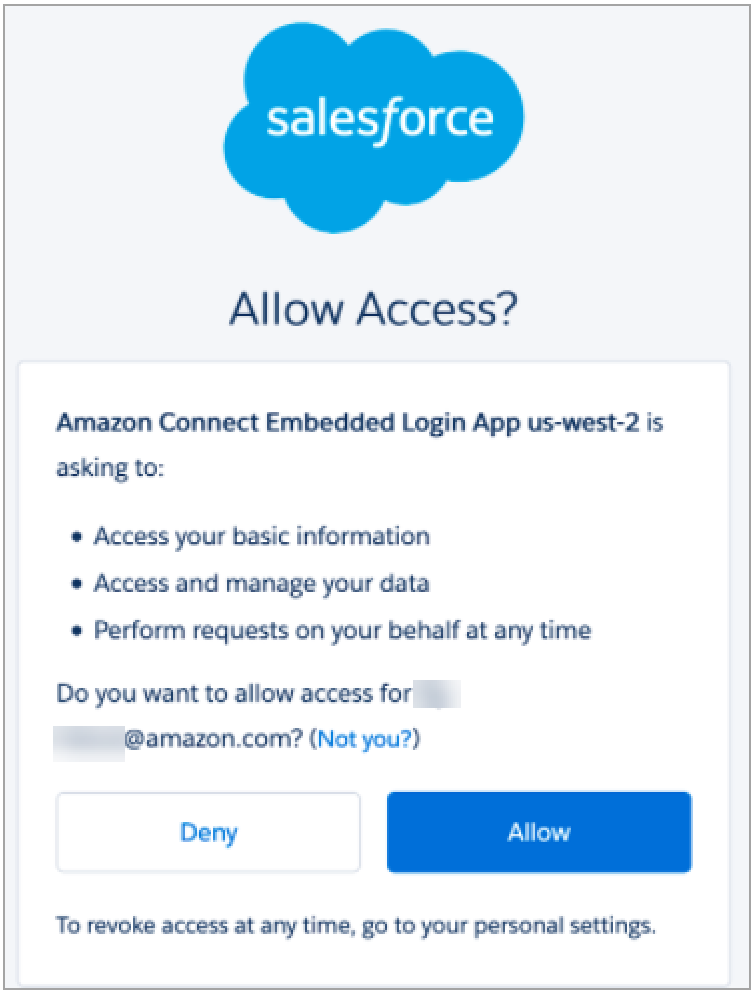
7. On the **Establish connection** page, choose one of the following:

   - **Use an existing connection**. This allows you to reuse existing EventBridge resources that are linked to Amazon AppFlow flows that you may have created in your AWS account.
   - **Create a new connection**: Enter the information required by the external application.

     1. Enter your application instance URL. This URL is used for deep-linking into the tasks created in your external application.
     2. Provide a friendly name for your connection, for example, **Salesforce - Test instance**. Later, when you add rules, you'll refer to this friendly name.
     3. Specify whether this is a production or sandbox environment.

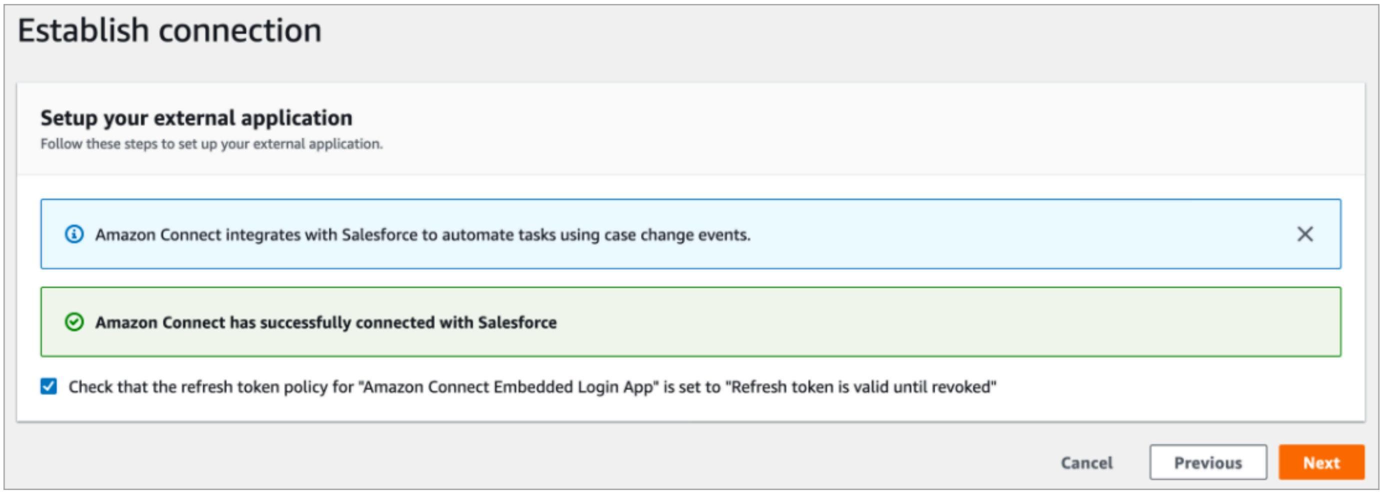


8. Choose **Log in to Salesforce**.
9. In Salesforce, choose to allow access to Amazon Connect Embedded Login App [Region].

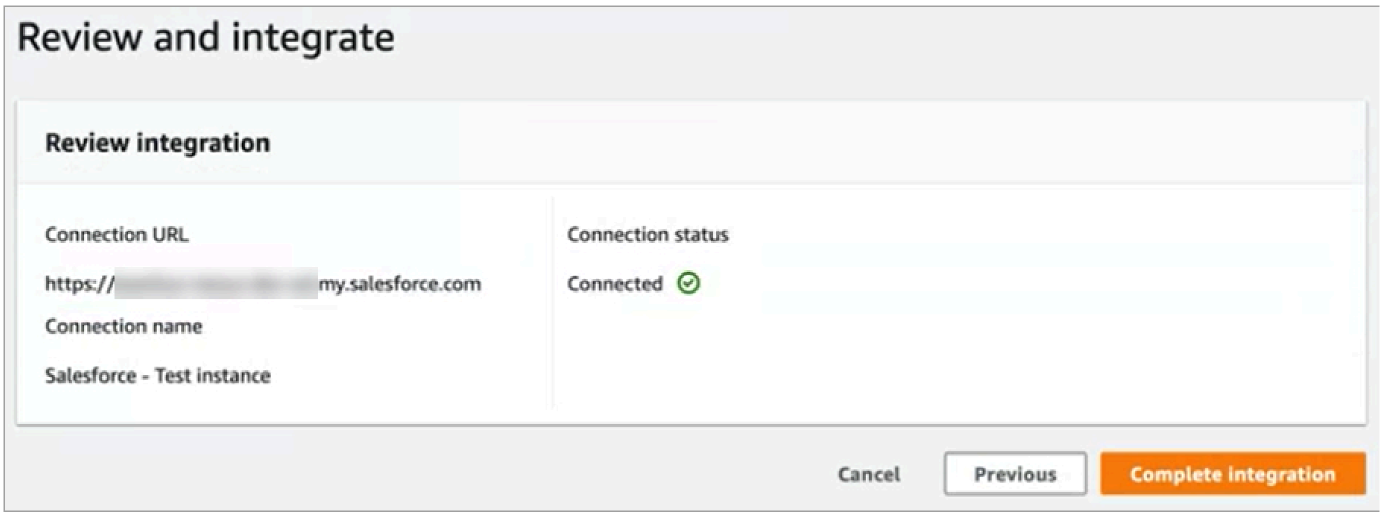


10. After Amazon Connect has successfully connected with the Salesforce, go to Salesforce and verify that the refresh token policy for Amazon Connect Embedded Login App is set to **Refresh token is valid until revoked**. This grants Amazon AppFlow access to pull data from your Salesforce account without re-authenticating.

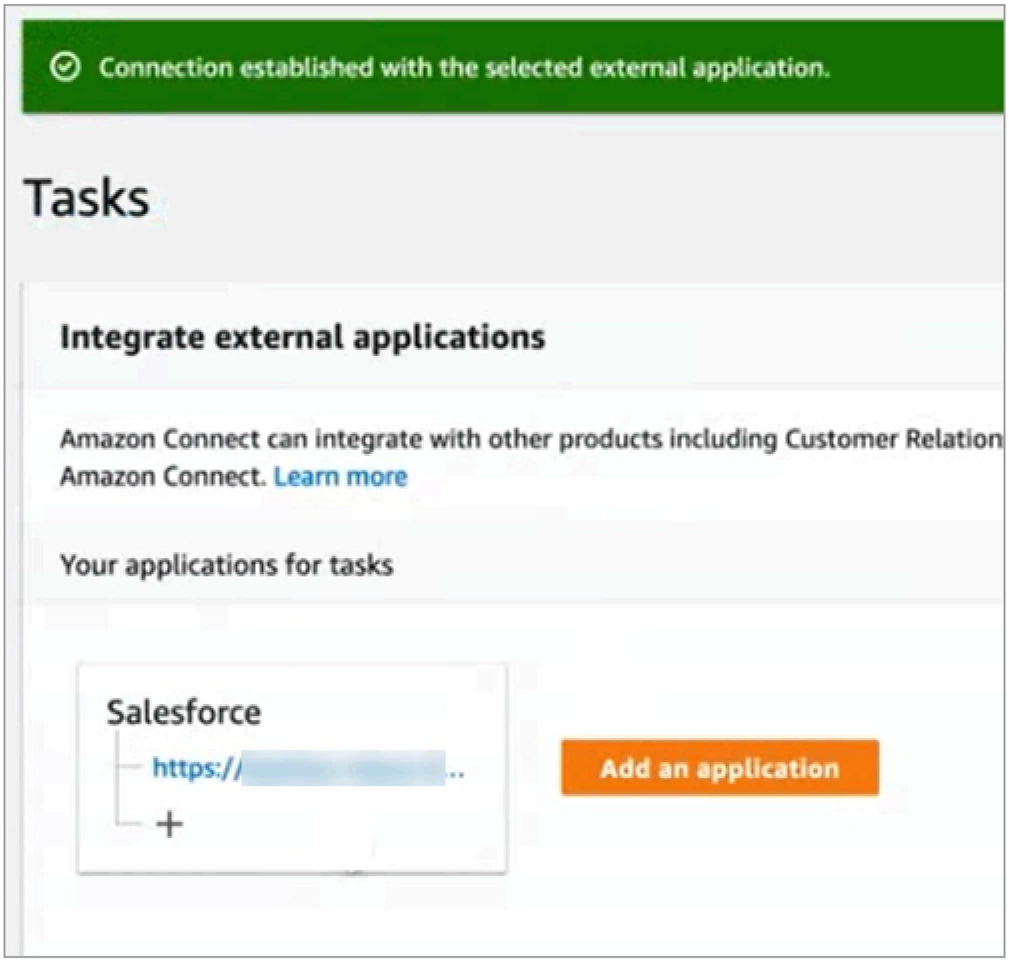
11. On the **Establish connection** page, select the box shown in the following image, and choose **Next**.



12. On the **Review and integrate** page, check that the **Connection status** says **Connected**, and then choose **Complete integration**.



13. On the **Tasks** page, the new connection is listed.



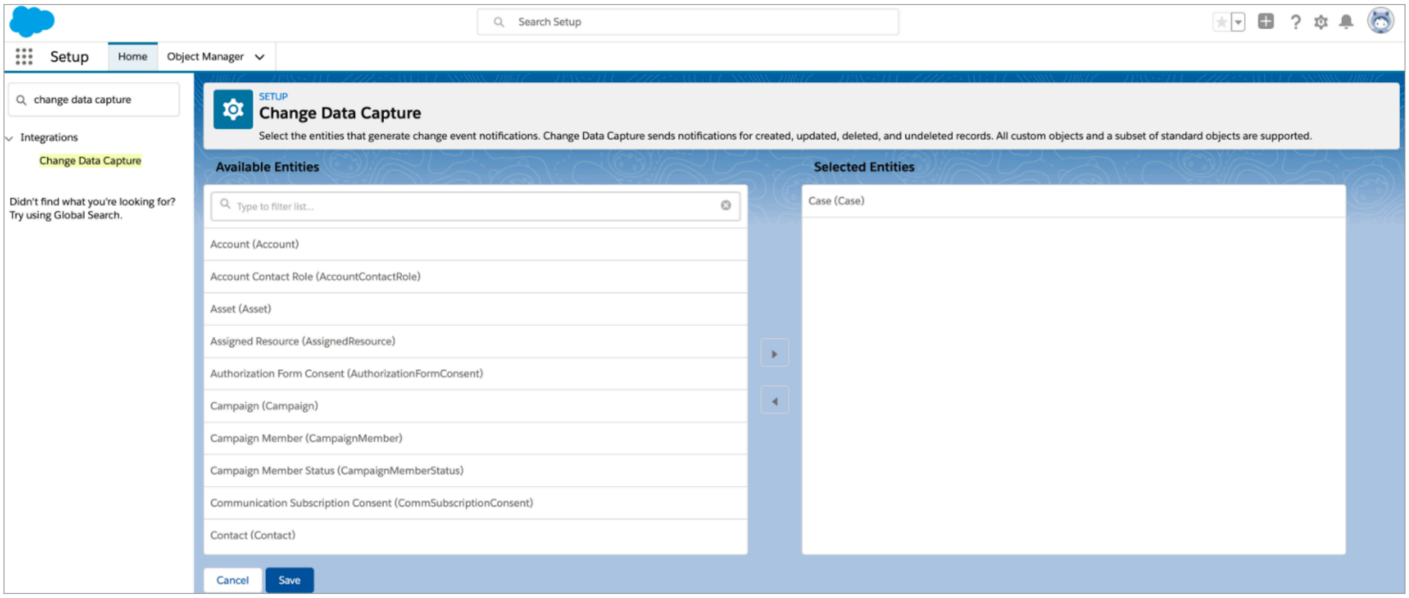
You're done! Next, add rules that tell Amazon Connect when to create a task and how to route it. For instructions, see [Create rules that generate tasks for third-party integrations in Amazon Connect](#).

What to do when is a connection isn't successfully established

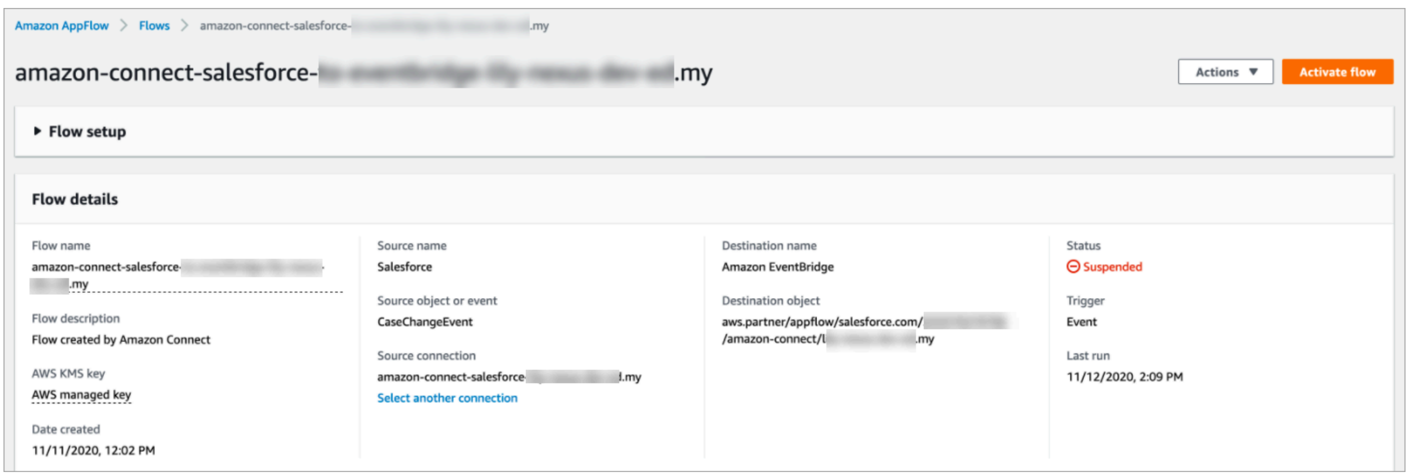
A connection might fail to be established for Salesforce if you didn’t follow the instructions next to the check boxes to verify that it's compatible with Amazon AppFlow.

A common error is not setting up the **Case** entity in the **Change Data Capture** settings to capture these events. To fix:

1. Log in to Salesforce, go to the **Change Data Capture**, and select the Case entity.



2. Open the Amazon AppFlow console at [https://console.aws.amazon.com/appflow)](https://console.aws.amazon.com/appflow) to select the flow that was just created, and then choose **Activate flow**.



Alternatively, you might need to delete the Amazon AppFlow Salesforce connection and flow, and start again.

Set up application integration for Zendesk using Amazon EventBridge

Step 1: Enable the events connector for Amazon EventBridge

If you don't already have the EventBridge connector for Zendesk enabled, you need to set it up first. Otherwise, go to [Step 2: Integrate Zendesk with Amazon Connect for task creation](#).

1. Copy your AWS account number:

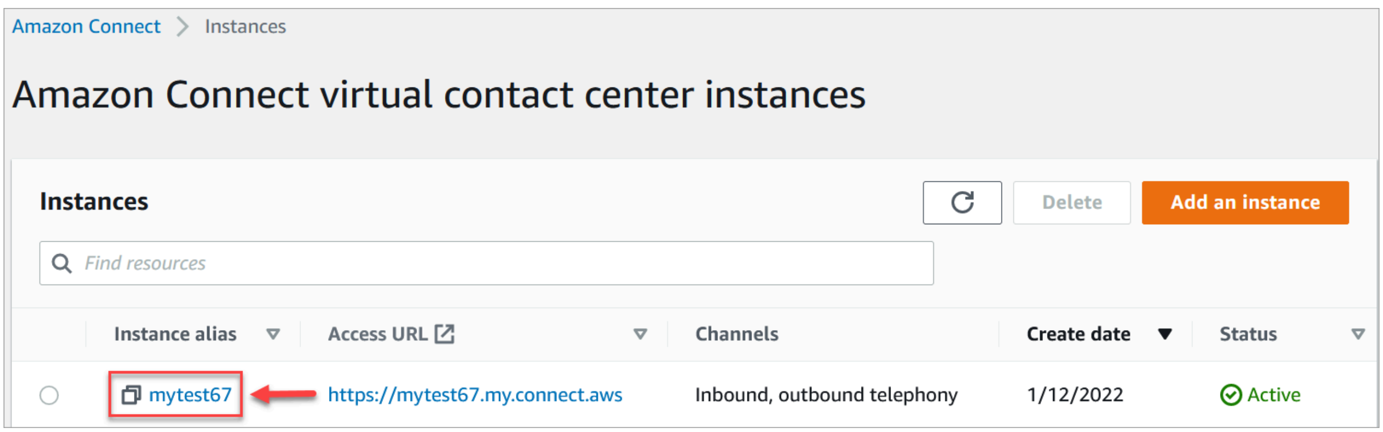
   a. In the Amazon EventBridge console, go to **Partner event sources**.
   b. Search for or scroll to **Zendesk**, and choose **Set up**.
   c. Choose **Copy** to copy your AWS account information.

2. Go to [Setting up the events connector for Amazon EventBridge](#) in the Zendesk Help and follow the instructions.

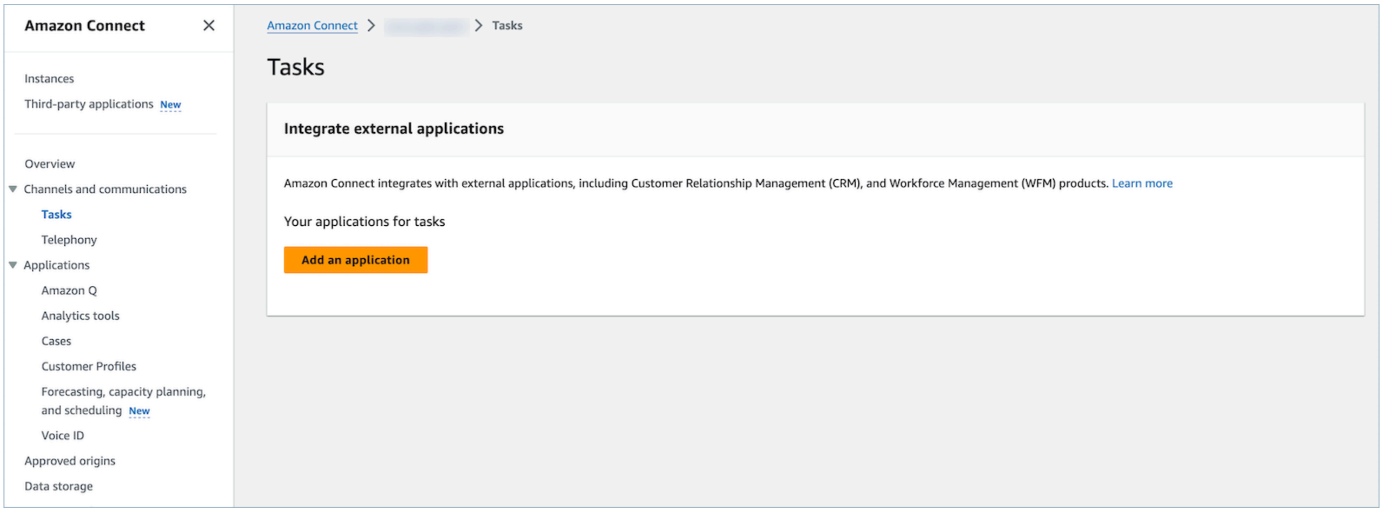
Step 2: Integrate Zendesk with Amazon Connect for task creation

> **Note**
>
> If you use custom AWS Identity and Access Management (IAM) policies, for a list of the required IAM permissions to set up Amazon Connect Tasks, see [Tasks page](#).

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Amazon Connect URL. The following image shows the **Amazon Connect virtual contact center instances** page, with a box around the instance alias.



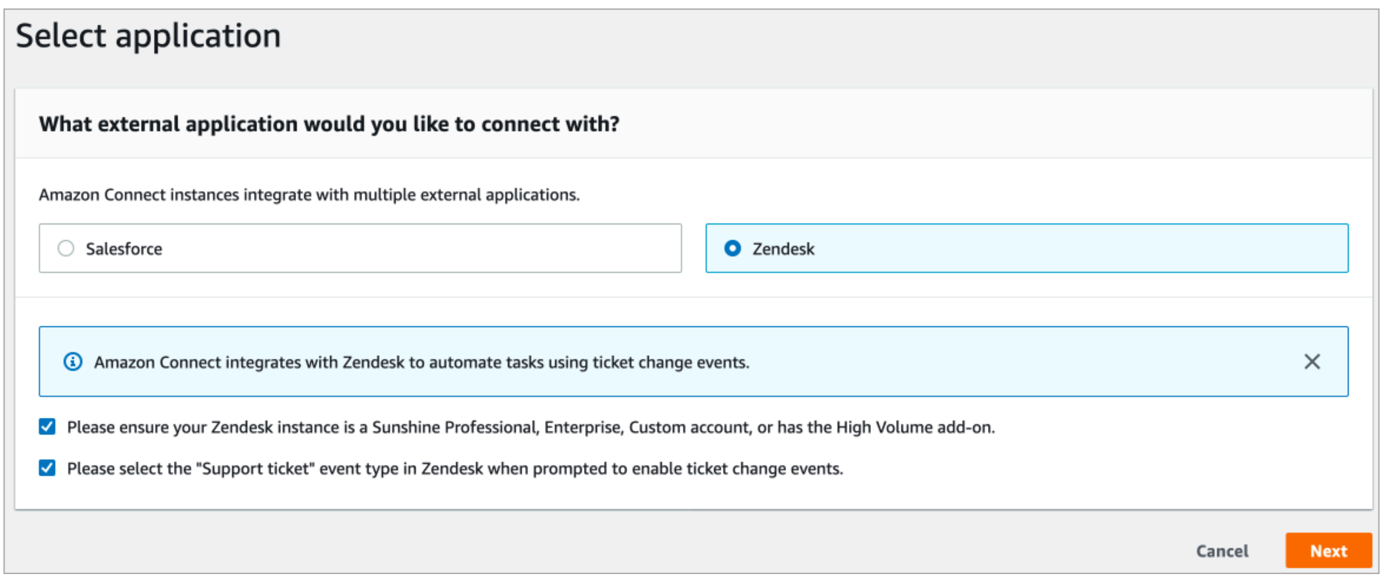
3. Choose **Tasks**, and then choose **Add an application**.



4. On the **Select application** page, choose **Zendesk**.

5. After you choose to integrate with Zendesk, the application requirements are listed on the page.

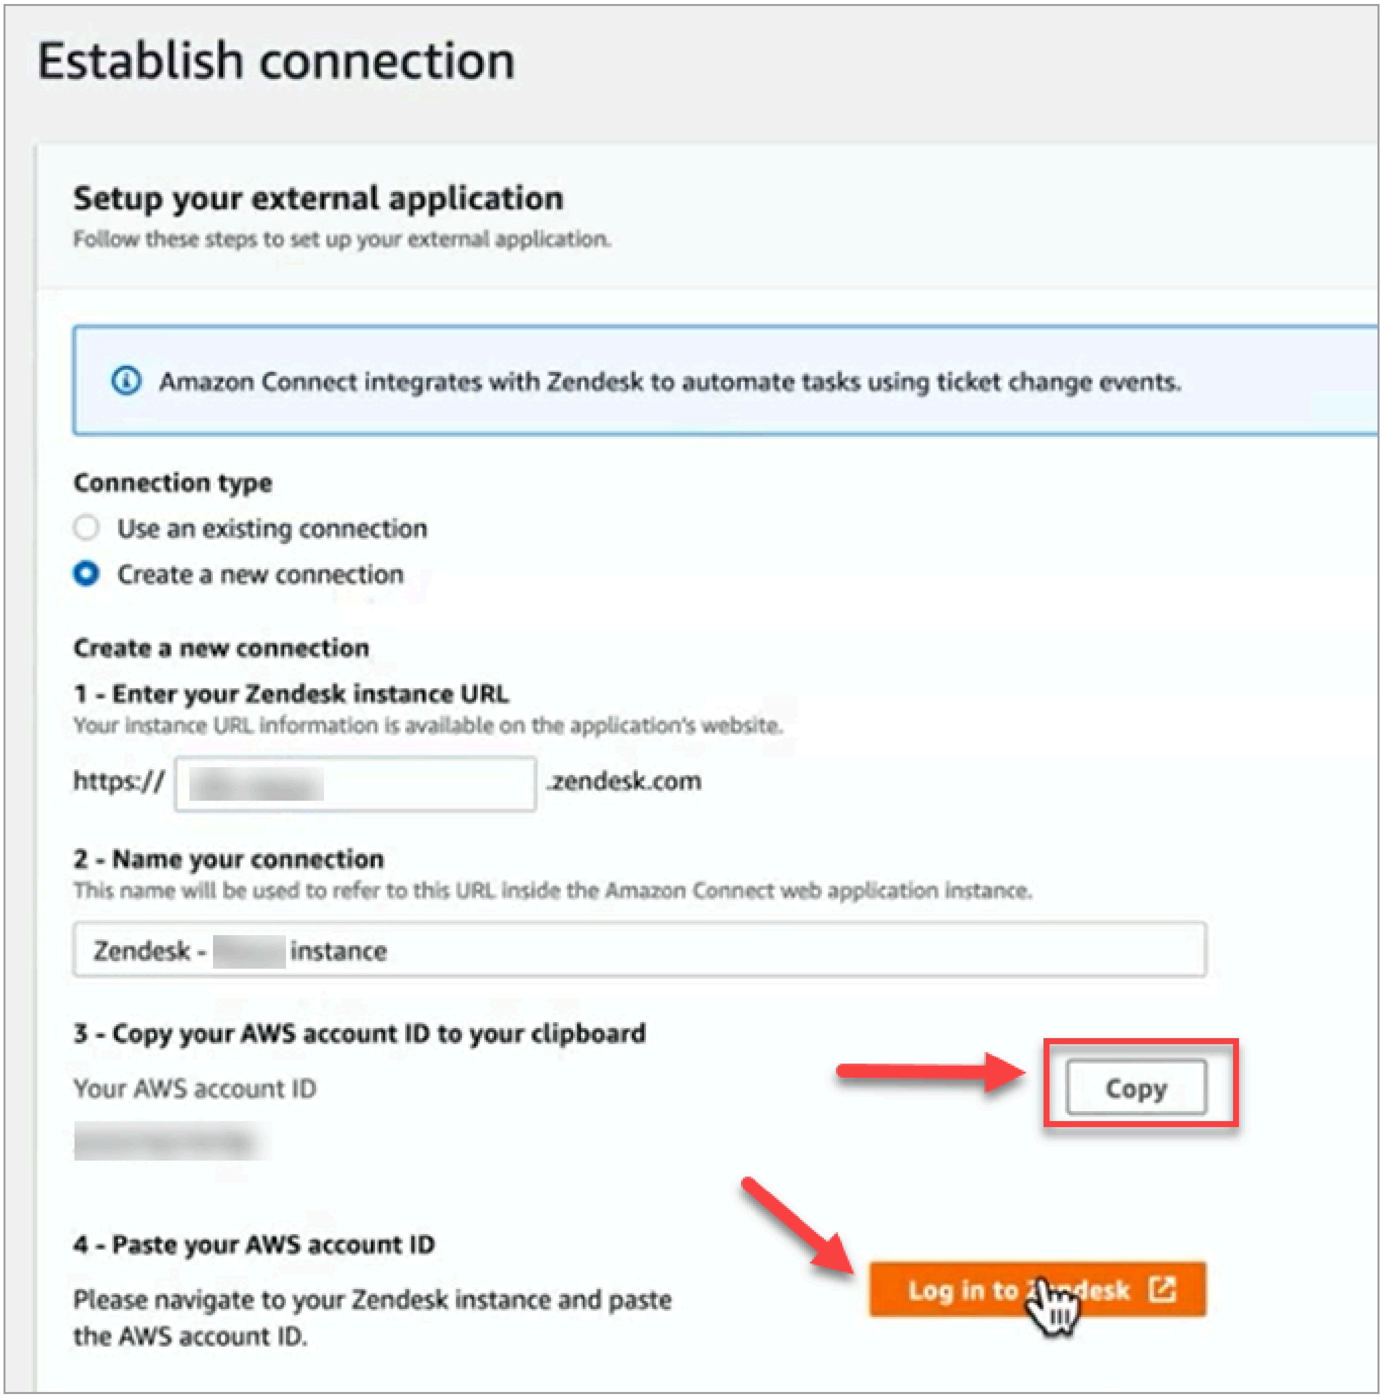
   The following image shows the requirements for Zendesk. In this procedure, we walk you through the steps to select the "Support ticket" event type in Zendesk. Acknowledge the steps and choose **Next**.



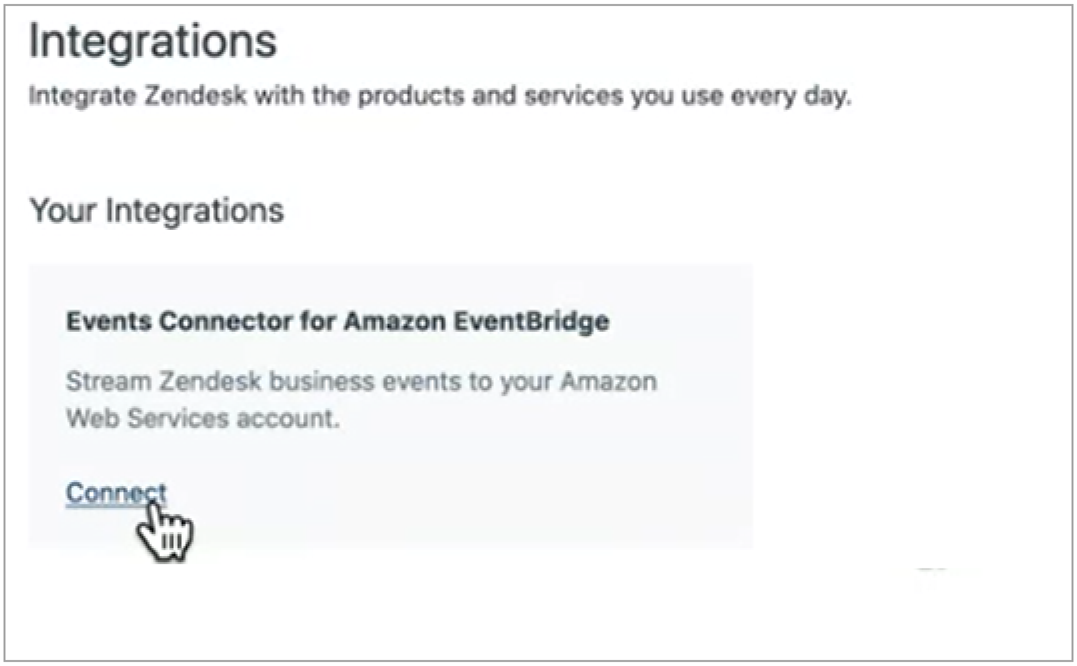
6. On the **Establish connection** page, choose one of the following:

   - **Use an existing connection**. This allows you to reuse existing EventBridge resources you may have created in your AWS account.
   - **Create a new connection**: Enter the information required by the external application.

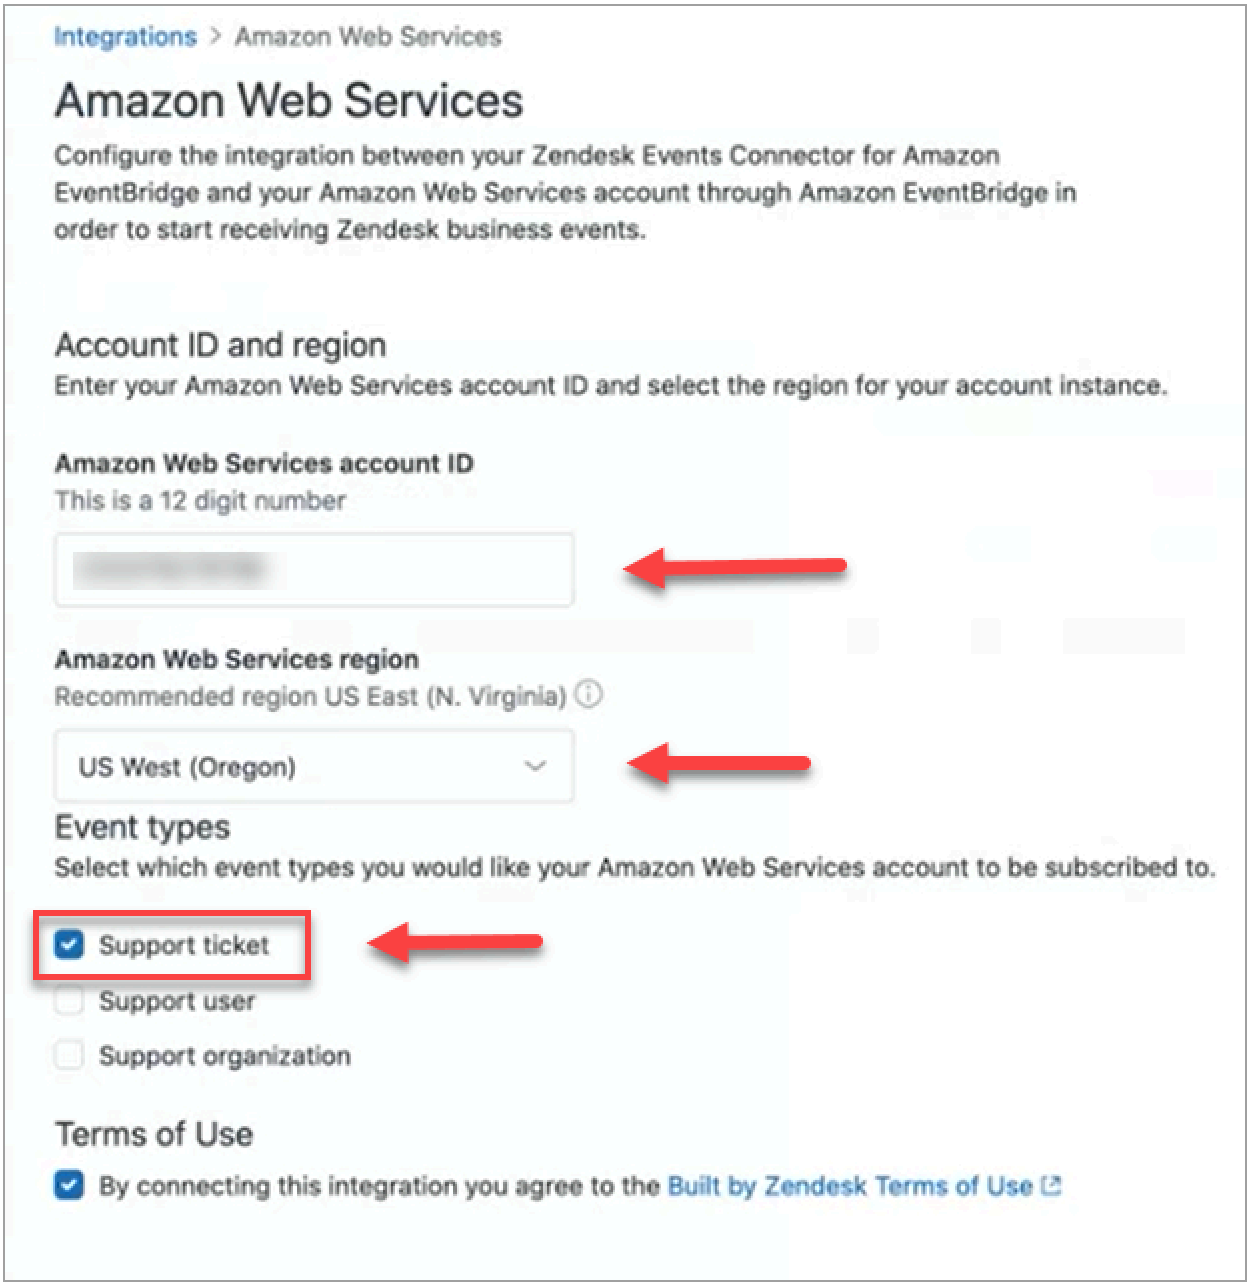
1. Enter your application instance URL. This URL is used for deep-linking into the tasks created in your external application.
2. Provide a friendly name for your connection, for example, **Zendesk - Test instance**. Later, when you add rules, you'll refer to this friendly name.



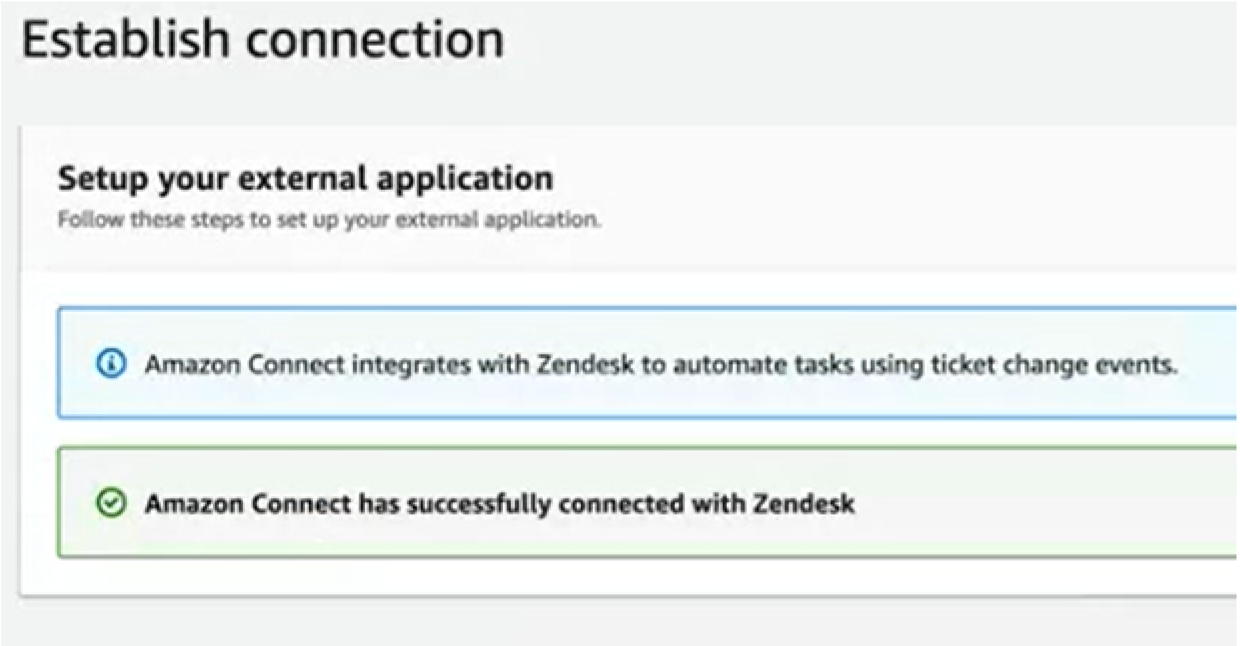
7. Choose **Copy** to copy your AWS account ID, and then choose **Login to Zendesk**. This takes you away from the **Establish connection** page for now, but you return to it shortly.
8. After you're logged in to Zendesk, choose **Connect** to connect the Events Connector for Amazon EventBridge.



9. In Zendesk, on the **Amazon Web Services** page, paste in your Amazon Web Service account ID, choose your Region, choose **Support ticket**, acknowledge the terms of use, and the choose **Connect**. Zendesk creates a resource in Amazon EventBridge.

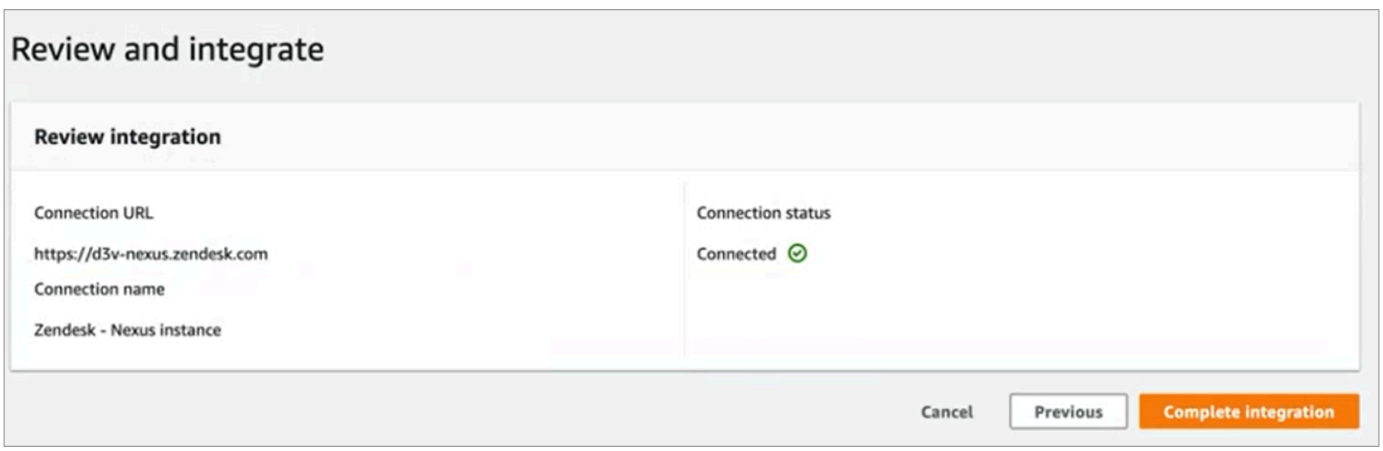


10. Return to the **Establish connection** page in Amazon Connect choose **Next**.
11. On the **Establish connection** page, you'll see the message that Amazon Connect has successfully connected with Zendesk. Choose **Next**.

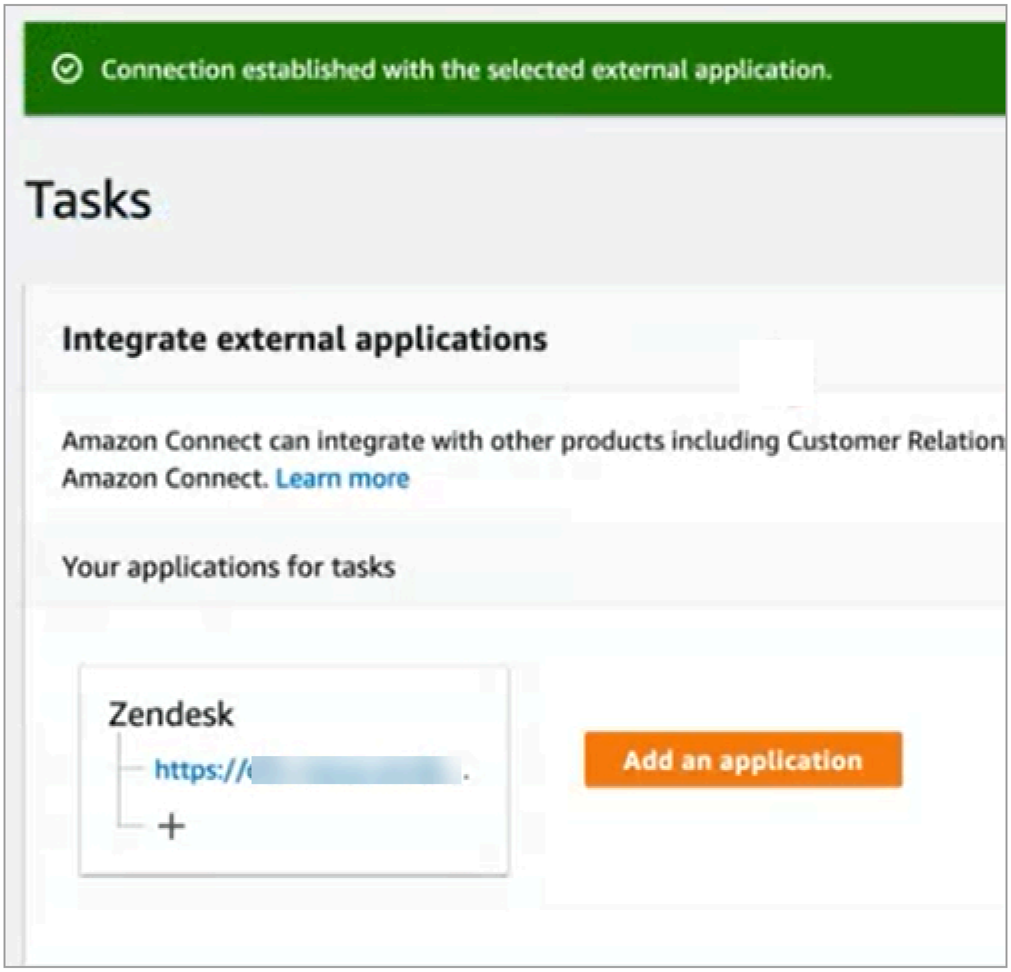


12. On the **Review and integrate** page, check that the **Connection status** says **Connected**, and then choose **Complete integration**.

    This creates a connection that associates the EventBridge resource for Zendesk to Amazon Connect.



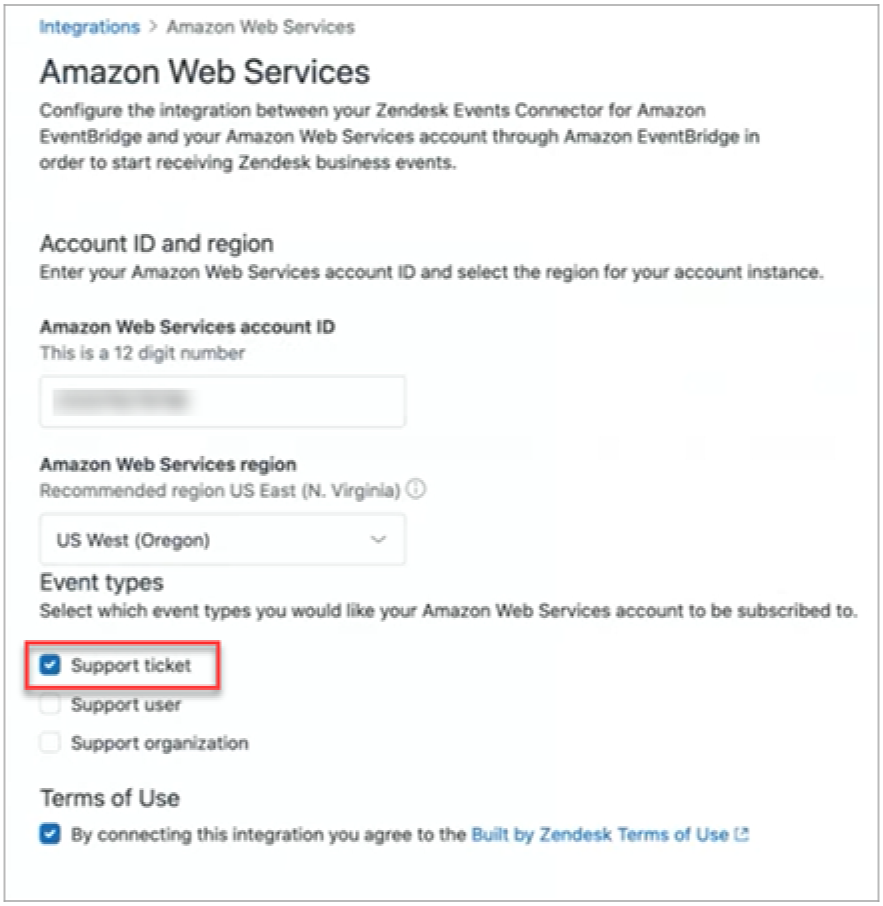
13. On the **Tasks** page, the new Zendesk connection is listed, as shown in the following image.



You're done! Next, add rules that tell Amazon Connect when to create a task and how to route it. For instructions, see [Create rules that generate tasks for third-party integrations in Amazon Connect](#).

What to do when is a connection isn't successfully established

A connection might fail to create a task if you do not correctly select the **Support ticket** event type when setting up the connection in Zendesk, after being prompted to do so in the flow. To fix this, log in to Zendesk, and update that setting, as shown in the following image.



There is also another case where you may not have selected the correct AWS Region that the Amazon Connect instance is in, when setting up EventBridge. To fix:

1. Go to the EventBridge console at https://console.aws.amazon.com/events/.
2. Disconnect your EventBridge connection.
3. In the Amazon Connect console, restart the flow.

Monitor task creation in Amazon Connect

After your connection is established, if it stops working, in Amazon Connect disassociate the connection, and then re-establish it. If that doesn't solve the issue, do the following:

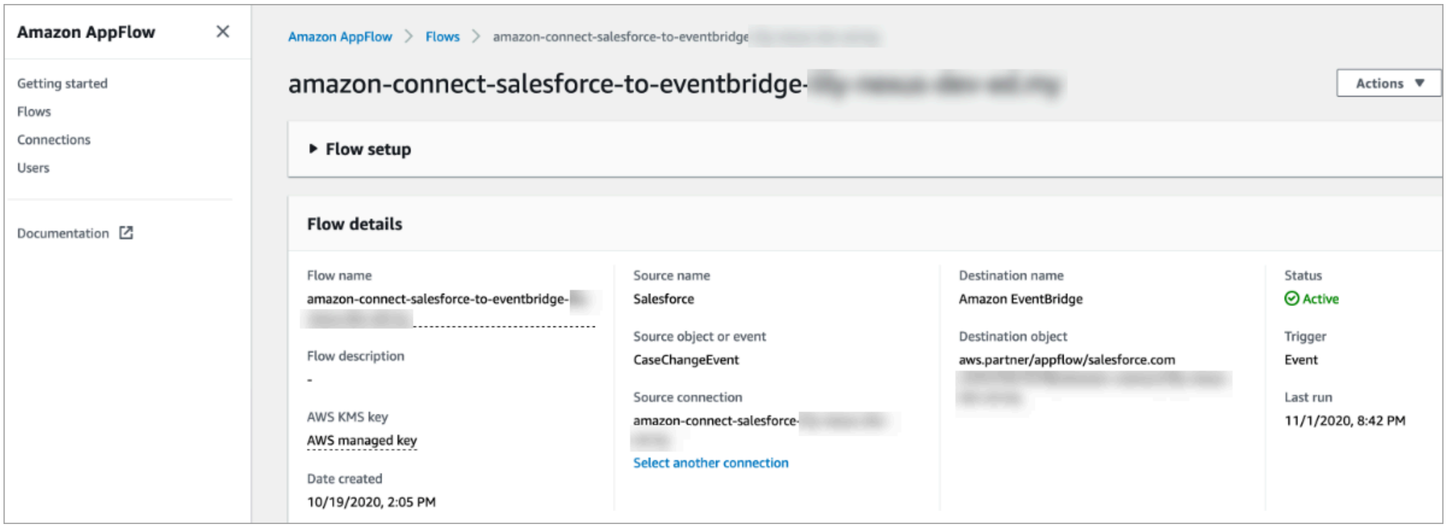
Zendesk

1. Go to the EventBridge console at https://console.aws.amazon.com/events/.
2. Check the status of the event source connection to see if it is active.

Salesforce

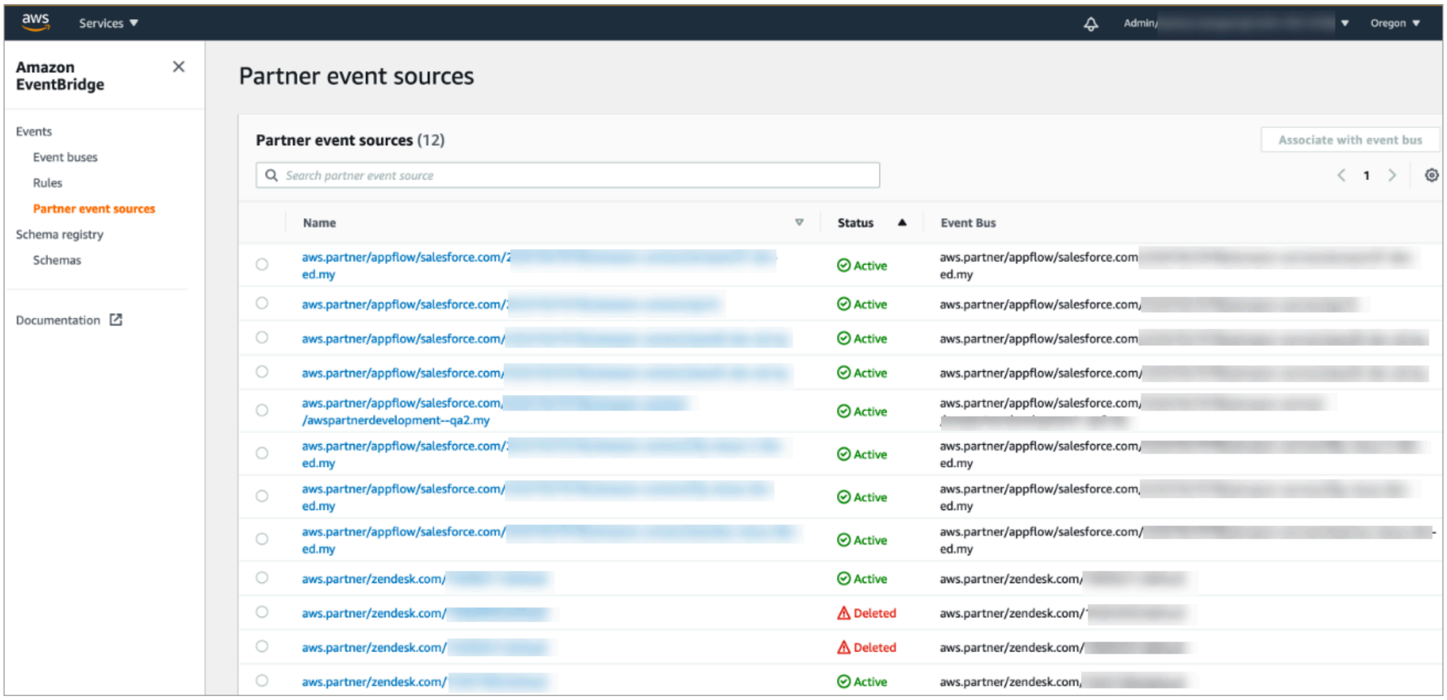
1. Go to the Amazon AppFlow console at [https://console.aws.amazon.com/appflow)](https://console.aws.amazon.com/appflow).
2. Monitor the flow that was created for the account that was set up.

The following image shows what a flow looks like in the Amazon AppFlow console for Salesforce. It contains information about the status of the connection, and when it was last run.



For both Zendesk and Salesforce, you can go to the EventBridge console at https://console.aws.amazon.com/events/ to see your connection state and see if it is active, pending, or deleted.

The following image shows an example EventBridge console.

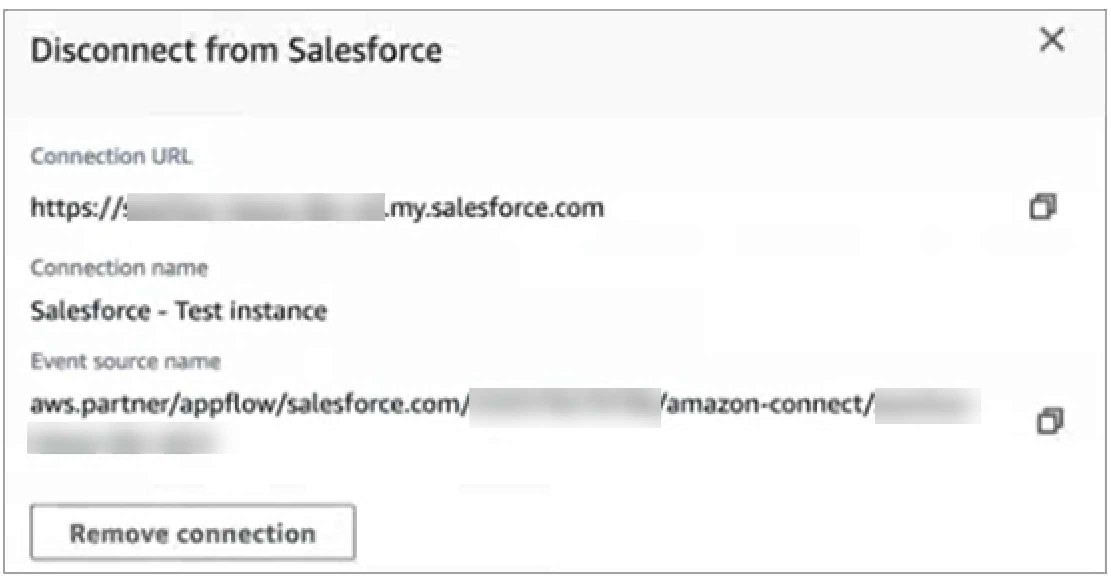


Disconnect Amazon Connect from a third-party connection

At any time you can disassociate a connection, and stop the automatic generation of tasks based on events from the external application.

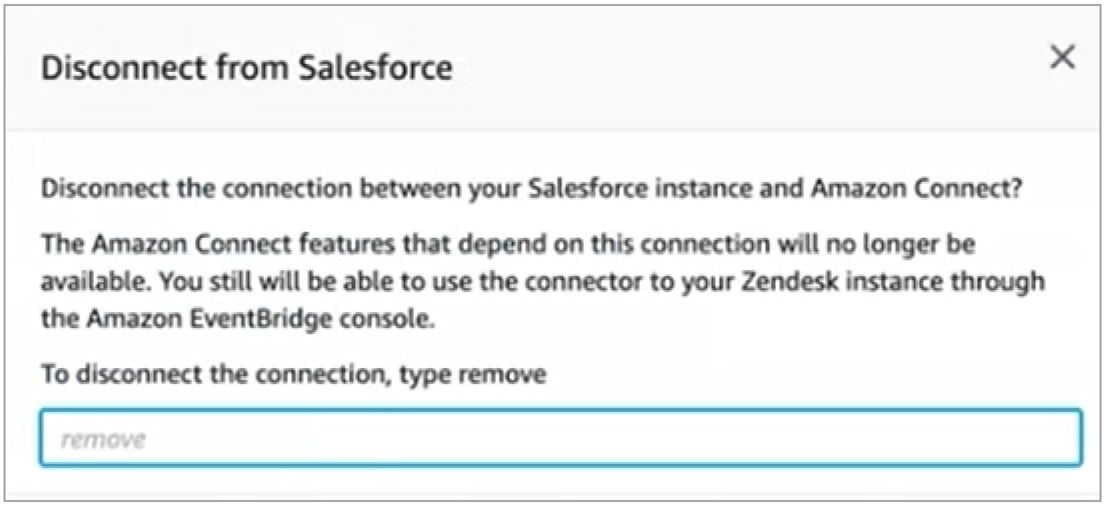
To stop the automatic generation of tasks

1. Choose the application, and then choose **Remove connection**.



2. Type **Remove**, and then choose **Remove**.

If you need to debug, you are still able to go to Amazon AppFlow (Salesforce) or EventBridge.



To remove the connection altogether from Zendesk

1. Log in to Zendesk, and navigate to **https://[subdomain].zendesk.com/admin/platform/integrations**.
2. Disconnect the EventBridge connection.

To remove the connection altogether from Salesforce

- Open the Amazon AppFlow console at https://console.aws.amazon.com/appflow, and delete the Salesforce connection and flow that were created in Amazon Connect.

  Flows are created with the name pattern of amazon-connect-salesforce-to-eventbridge-[subdomain].

  Connections are created with the name pattern of amazon-connect-salesforce-[subdomain]

To re-enable the automatic generation of tasks, repeat the setup steps.

Create rules to automate tasks in Amazon Connect

A rule is an action that Amazon Connect automatically performs, based on conditions you specify. Contact center managers, supervisors and QA analysts can quickly create rules from the Amazon Connect console. No coding is required.

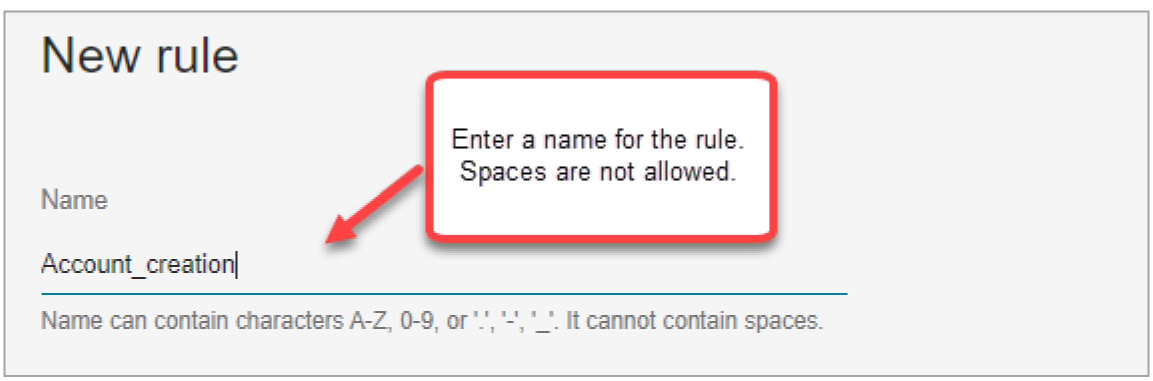
More information

- To create and manage rules programmatically, see Rules actions and the Amazon Connect Rules Function language in the *Amazon Connect API Reference Guide*.
- Add real-time alerts to Contact Lens for supervisors based on keywords and phrases in a call
- Automatically categorize contacts by matching conversations with natural language statements, or specific words and phrases
- Create a task in Contact Lens when a contact is categorized in real-time or after a call or chat
- Create a Contact Lens rule that generates an EventBridge event
- Create Contact Lens rules that send email notifications
- Create supervisor alerts on contact center agent performance
- Create alerts on real-time metrics in Amazon Connect Contact Lens
- Create rules that generate tasks for third-party integrations in Amazon Connect

Create rules that generate tasks for third-party integrations in Amazon Connect

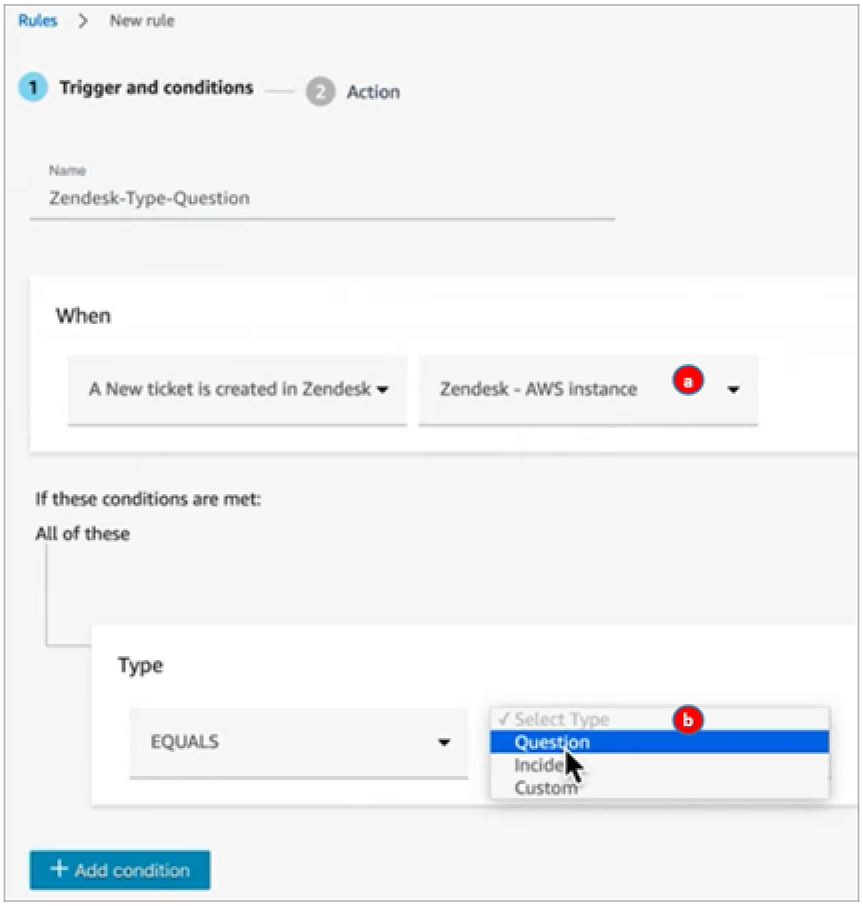
After you set up an external application to generate tasks automatically, you need to build rules that tell Amazon Connect when to create tasks, and how to route them.

1. Log in to Amazon Connect with a user account that is assigned the **CallCenterManager** security profile, or that is enabled for **Rules** permissions.
2. In Amazon Connect, on the navigation menu, choose **Rules**.
3. On the **Rules** page, use the **Create a rule** dropdown list to choose **External application**.
4. At the **Trigger and conditions** page, assign a name to the rule. Spaces are not allowed in the name of a rule.



5. Choose the event that will generate a task, and the instance of the external application where the event must occur. For example, the following image shows the trigger is when a new ticket

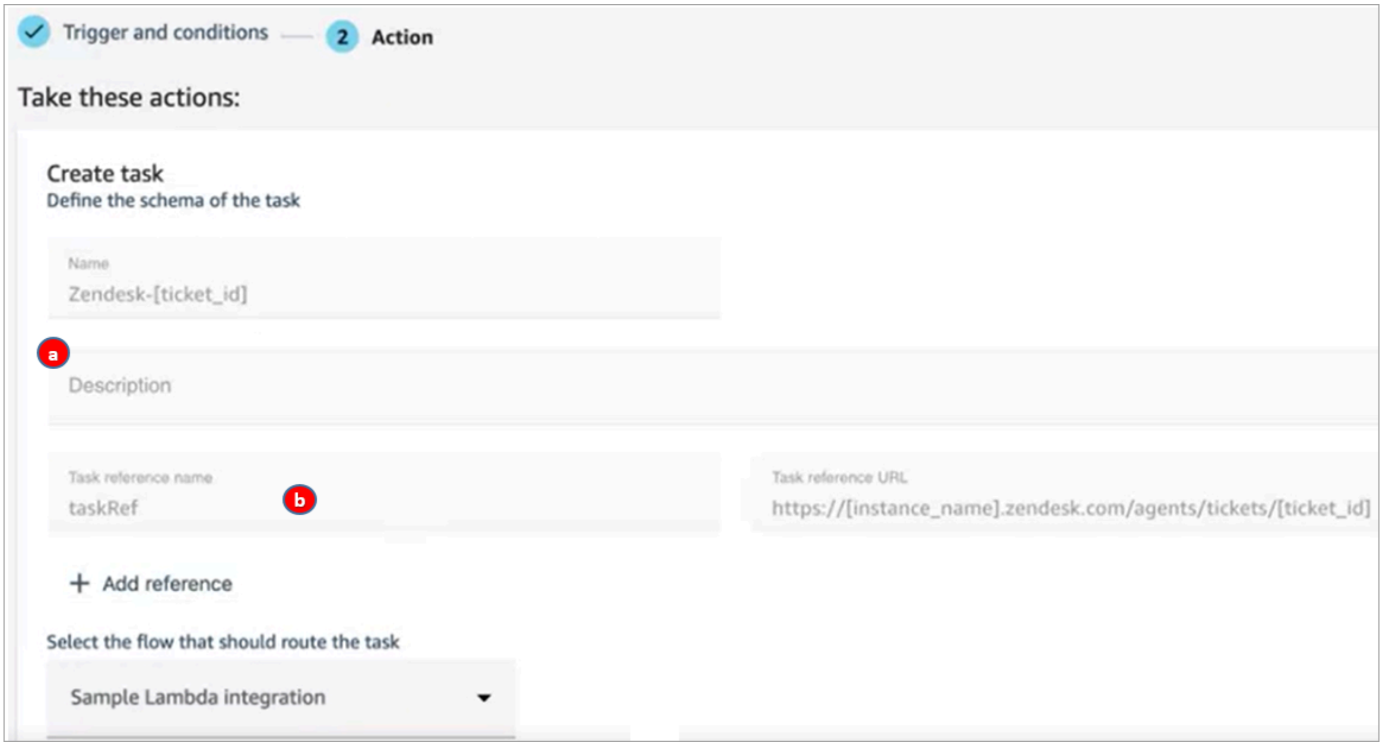
is created in Zendesk. The condition that must be met is when the type equals a question. Then a task is generated.



1. Select the instance for the external application.
2. Choose the conditions that must be met to generate the task.

6. Choose **Next**.

7. On the **Action** page, specify the task to be generated when the rule is met, as shown in the following image



1. The description of the task appears to the agent in their Contact Control Panel (CCP).
2. The task reference name appears to the agent as a link to the specified URL.

8. Choose **Save**.

Test the rule

1. Go the external application and create the event that initiates the action. For example, in Zendesk, create a ticket that's type **Question**.
2. Go to **Analytics and optimization**, **Contact search**.
3. Under **Channel**, choose **Task**, and then choose **Search**.
4. Verify the task was created.

Set up email in Amazon Connect

Following is an overview of the steps to set up the email channel for your contact center.

- Enable email for your Amazon Connect instance. During this process you get an auto-generated email address. You also have the option of adding five custom addresses.
- Create email addresses.

- Create or update queues for outbound email. In the **Outbound email configuration** section:
  - **Default email address**: Specify the outbound email address that agents will use when sending an email. For example, if an agent is on the phone with a customer, and they need to email the customer instructions after the conversation, the agent can initiate an outbound email with this address.
  - **Outbound email flow**: Select the **Default outbound flow** from the dropdown menu, or select another flow that is type Outbound.
- Create or update routing profiles to specify that agents can handle email contacts.

> **Important**
>
> In the routing profile, **Default outbound queue** defines the email address agents will use for any outbound emails they initiate.

- Create message templates. Email templates can define the structure of the email for the agent, for example, for a signature or a disclaimer, or they can be a full response.
- Configure flows with the Send message block. Use this block to send a message to your customer based on a template or custom message. In addition, you can specify:
  - The To and From email addresses and display names. You can specify them manually or dynamically by using System attributes such as:
    - **Customer endpoint address**: This is the customer's email address that initiated the contact.
    - **System email address**: This is the email address that the customer sent the email to.
    - **Customer display name**: This is captured from the email the customer sent to you.
    - **System display name**: The display name of the email the customer sent to.
    - **CC Email Address List**: The full list of cc'ed email addresses on the customer's email.
    - **To Email Address List**: The full list of To email addresses on the customer's email.

    For example, to send an automatic reply when a customer emails you, set **Email address** dynamically to **Customer endpoint address**, and **Display name** dynamically to **Customer display name**.
  - **Message**: Specify a template or enter plain text.
    - You can specify the **Subject** dynamically by using the **Segment attribute - Email Subject**.
    - You can specify the **Message** dynamically by choosing a **User-defined** attribute.

  - **Link to contact**: Choose if you want to link the inbound contact email to the outbound contact email. You may not want to choose this option for automatic reply emails.
- Use the attributes in the Check contact attributes block to check the channel of the contact. If it's an email, you can use the following Segment attributes to check:
  - **Email Subject**: You can check the subject for certain keywords, for example.
  - **Amazon SES Spam Verdict** and **Amazon SES Virus Verdict**: When the customer's email comes in, Amazon SES scans it for spam and viruses. For example, if the condition equals FAILED (that means, the email failed the check) you can disconnect the contact or send the email to a special queue for managers to review it.
- Assign the following security profile permission to your agents who need to initiate outbound emails.
  - **Contact Control Panel (CCP) - Initiate email conversations**

How Amazon Connect email works

Amazon Connect Email provides built-in capabilities that make it easy for you to prioritize, assign, and automate the resolution of customer service emails, improving customer satisfaction and agent productivity. You can receive and respond to emails sent by customers to your configured email addresses, or submitted by using web forms on your website or mobile app by using the StartEmailContact API.

Amazon Connect Email integrates with Amazon Simple Email Service (SES) to send, receive, and monitor emails for content marked as spam or containing viruses, delivery success rates, and sender reputation results.

This topic explains how Amazon Connect Email, along with Amazon SES, work to enable a seamless customer experience.

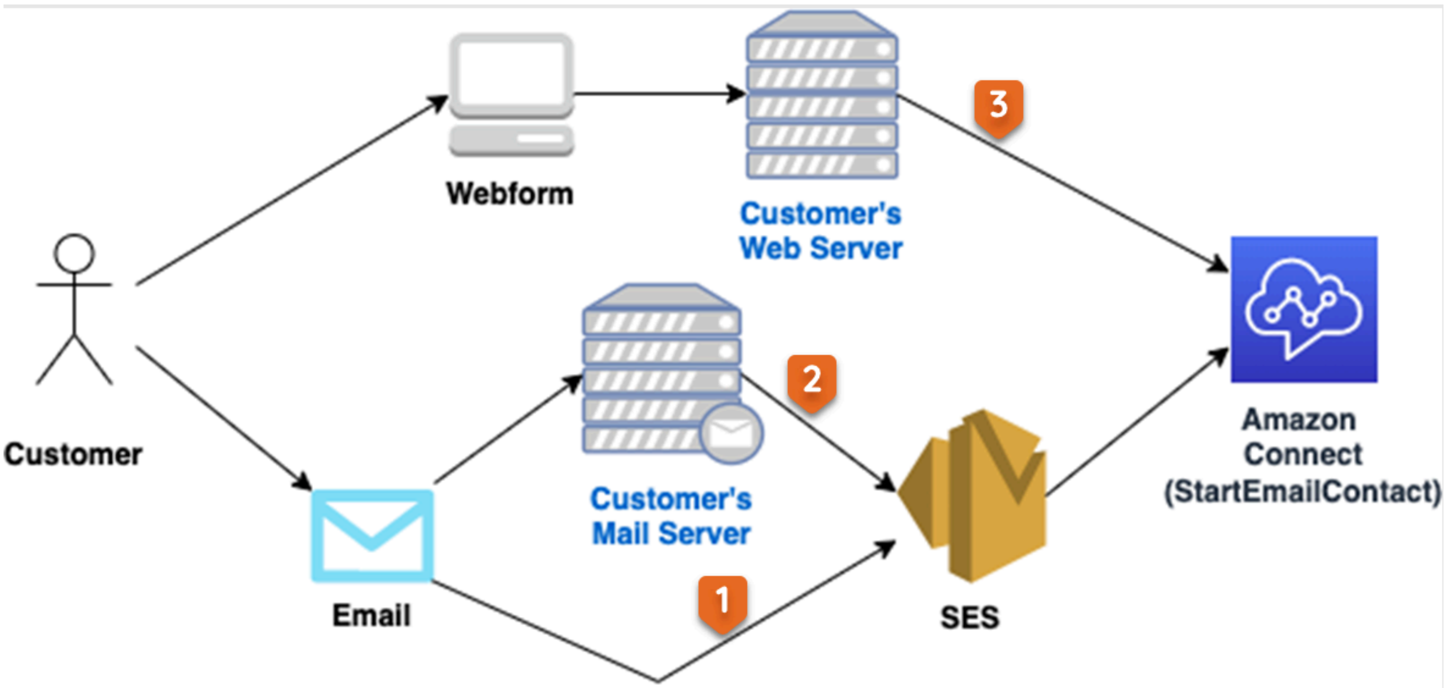
Contents

Receive emails

There are three main ways that Amazon Connect can receive emails:

- **Method 1**: By an email address defined in Amazon Connect (for example, support@*customer-domain*.com) using a verified email domain from Amazon SES, such as the email domain provided with your Amazon Connect instance (for example, @*instance-alias*.email.connect.aws) or a custom verified domain that you own or is provided by your company (for example, @*customer-domain*.com). See Step 3: Use your own custom email domains in Enable email for your instance for details about onboarding custom email domains.
- **Method 2**: By using a routing rule on your email server (for example, Microsoft 365 Connectors, Google Workspace Mail Routes) to send the incoming email to one of Amazon SES's SMTP endpoints using a verified email domain onboarded to Amazon SES (for example, @*customer-domain*.com).
- **Method 3**: By using the StartEmailContact API to start an email contact by using a webform on your website or in your mobile app. This starts inbound email contacts similar to customers sending emails to your email addresses.

The following diagram illustrates how emails sent from your customers are received by Amazon Connect using the StartEmailContact API for each of the methods mentioned above.



To integrate Methods 1a or 2, you need to verify an email domain on Amazon SES before you can use the email domain in Amazon Connect. For instructions, see Verifying a DKIM domain identity with your DNS provider.

To integrate Method 3, you use the StartEmailContact API. This is the primary API of all integration methods for inbound email contacts. It functions similarly to StartTaskContact. It requires you to do one of the following steps:

- Include at least one email address from your Amazon Connect instance in either the To or CC attributes of the inbound email contact.

—OR—

- Define an inbound flow from your Amazon Connect instance to route the inbound email contact created.

If both are defined, the default behavior prioritizes the inbound flow from your Amazon Connect instance to handle the inbound email contact created. If multiple email addresses from your Amazon Connect instance are included in the To or CC email address attributes, multiple inbound email contacts will be created in your Amazon Connect instance.

How email messages become email contacts

For general email receiving in Amazon Connect, including webform based email, the StartEmailContact API exposes basic email fields on the request object. This object is used to populate email information and start an email contact in Amazon Connect. The following fields are included:

- A From email address
- To email address(es)
- CC email address(es)
- A subject
- A plain or HTML message body
- Attachment(s)

For more information about how the email contact information is populated into the email contact, see the Amazon Connect email contact data model .

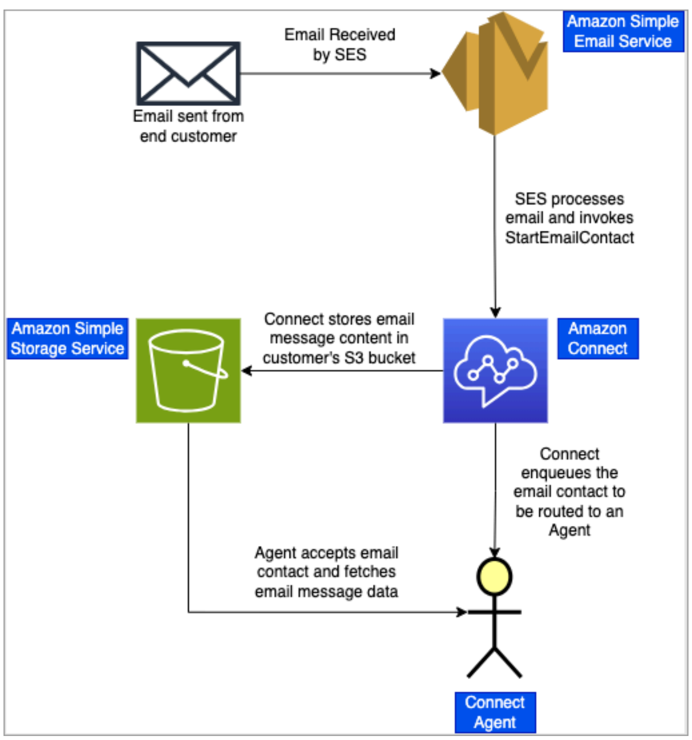
After the [StartEmailContact](#) API has performed request parameter validation and ensured that at least one To or CC email address is valid and exists in the Amazon Connect instance, here's what happens:

1. A contact ID is generated and returned as part of the API response body.
2. An asynchronous workflow is triggered to perform additional email message processing.
3. The flow is started. This is the flow that's associated with the email address found in the Amazon Connect instance.

As part of this, you need to setup your email message and attachment storage for your Amazon Connect instance.

- Both email messages and attachments are stored and accessed in your own Amazon SES S3 bucket.
- The remaining email contact attributes such as To, CC, Subject, and other attributes are stored on the email contact; see [Data model for Amazon Connect contact records](#).

The following diagram illustrates the flow of the email message from the customer to Amazon SES and then to Amazon Connect. It shows the email message content stored in your S3 bucket, and then getting data from that bucket to display it to the agent.



Every email message is a unique email contact

Amazon Connect email is differs from voice, chat, and tasks.

- Every email message, inbound to or outbound from Amazon Connect, is its own unique email contact.
- Each email contact contains details specific to that email message such as From address, To address(es), CC address(es), subject, relatedContactId, links to email body and attachment(s) storage locations, and other details relevant to the individual email contact.

However, like other channels in Amazon Connect, an email contact has similar initiation methods, such as `INBOUND`, `OUTBOUND`, `TRANSFER`, `API`, `QUEUE_TRANSFER` and `END/DISCONNECT`. It also has similar states, such as `CREATED`, `QUEUED`, `CONNECTING`, `CONNECTED`, `MISSED`, `TRANSFERRED`, `ERROR`, `ENDED/DISCONNECTED`, `REJECTED`.

For information about how the email contact information is populated into the email contact, see [Data model for Amazon Connect contact records](#).

Email threads

Email threading ensures that outgoing emails and incoming responses related to a customer inquiry are associated with each other in a chronological and organized fashion.

In order to maintain the whole email conversation, Amazon Connect links the email contacts together using a few fields on the email contact such as the relatedContactId and a list of email headers that follow conventional email client standards (RFC 5256).

Most email clients such as Gmail, Apple Mail, and Outlook, support email threading. However, keep in mind that there are some that don't support it.

If your customer replies to the latest email message in the thread, the thread follows a straightforward pattern as shown in the following image:

ContactId1 (Inbound) → ContactId2 (Outbound) → ContactId3 (Inbound) → ContactId4 (Outbound)

If the customer replies to an older message in the email thread, an email thread tree is formed, and the email thread pattern looks something like the example in the following image:

ContactId1 (Inbound) → ContactId2 (Outbound) → ContactId3 (Inbound) → ContactId4 (Outbound)

|

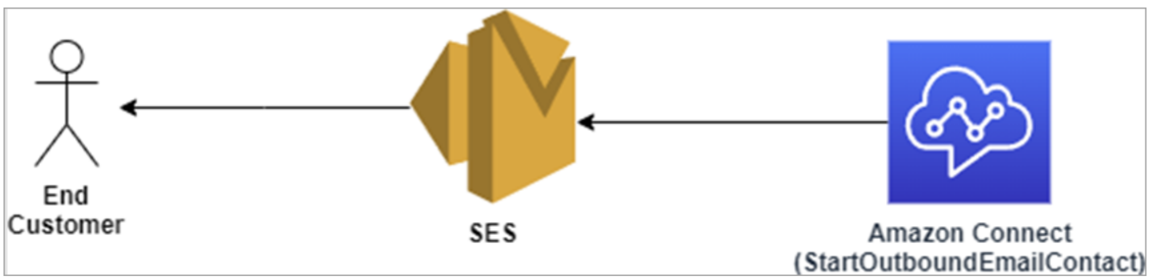
ContactId5 (Inbound) → ContactId6 (Outbound)

In both scenarios Amazon Connect keeps a record of each of the email messages that are related to a thread. Each email message can be accessed by the email that succeeded it.

Send email

All email messages from Amazon Connect are sent from Amazon SES directly to your customer. Whether you're using the email domain provided with your Amazon Connect instance (for example, @`instance-alias`.email.connect.aws) or a custom verified domain (for example, @`customer`.com), Amazon SES is authorized by verifying a domain identity to send emails directly to your customers.

The following diagram shows that the StartOutboundEmailContact API sends email to Amazon SES, and Amazon SES sends it to your customer.



The StartOutboundEmailContact API is the primary API of all integration methods for outbound email contacts including agent replies to inbound contact and agent-initiated outbound email contacts.

- It functions similarly to StartEmailContact API, however it is the inverse since it is outbound.
- It requires at least one email address in either the To or CC email address attributes and it requires an outbound whisper flow for handling the outbound contact.

Enable email for your Amazon Connect instance

This topic is for administrators who have access to the Amazon Connect console. It explains how to enable email for your instance using the Amazon Connect admin website. For a list of the APIs to enable email programmatically, see APIs to enable email.

When you enable email, you get an autogenerated email domain. Optionally, you can also use custom domains.

- **Amazon Connect email domain**. The email domain is *instance-alias.email.connect.aws*.
  - You can use this domain for testing.
  - Or, you can use this email domain to integrate with Amazon Connect and start receiving emails into Amazon Connect. For example, if you have an email address such as *support@example.com* you can forward email into Amazon Connect by using *support@example.email.connect.aws*.
- **Custom domains**. You can specify up to 5 custom domains that have been onboarded to Amazon SES.

Step 1: Move Amazon SES into production mode

Amazon Connect uses Amazon SES for sending and receiving emails. If you have a new Amazon SES instance, you need to take it out of sandbox mode. For instructions, see Request production access (Moving out of the Amazon SES sandbox) in the *Amazon SES Developer Guide*.

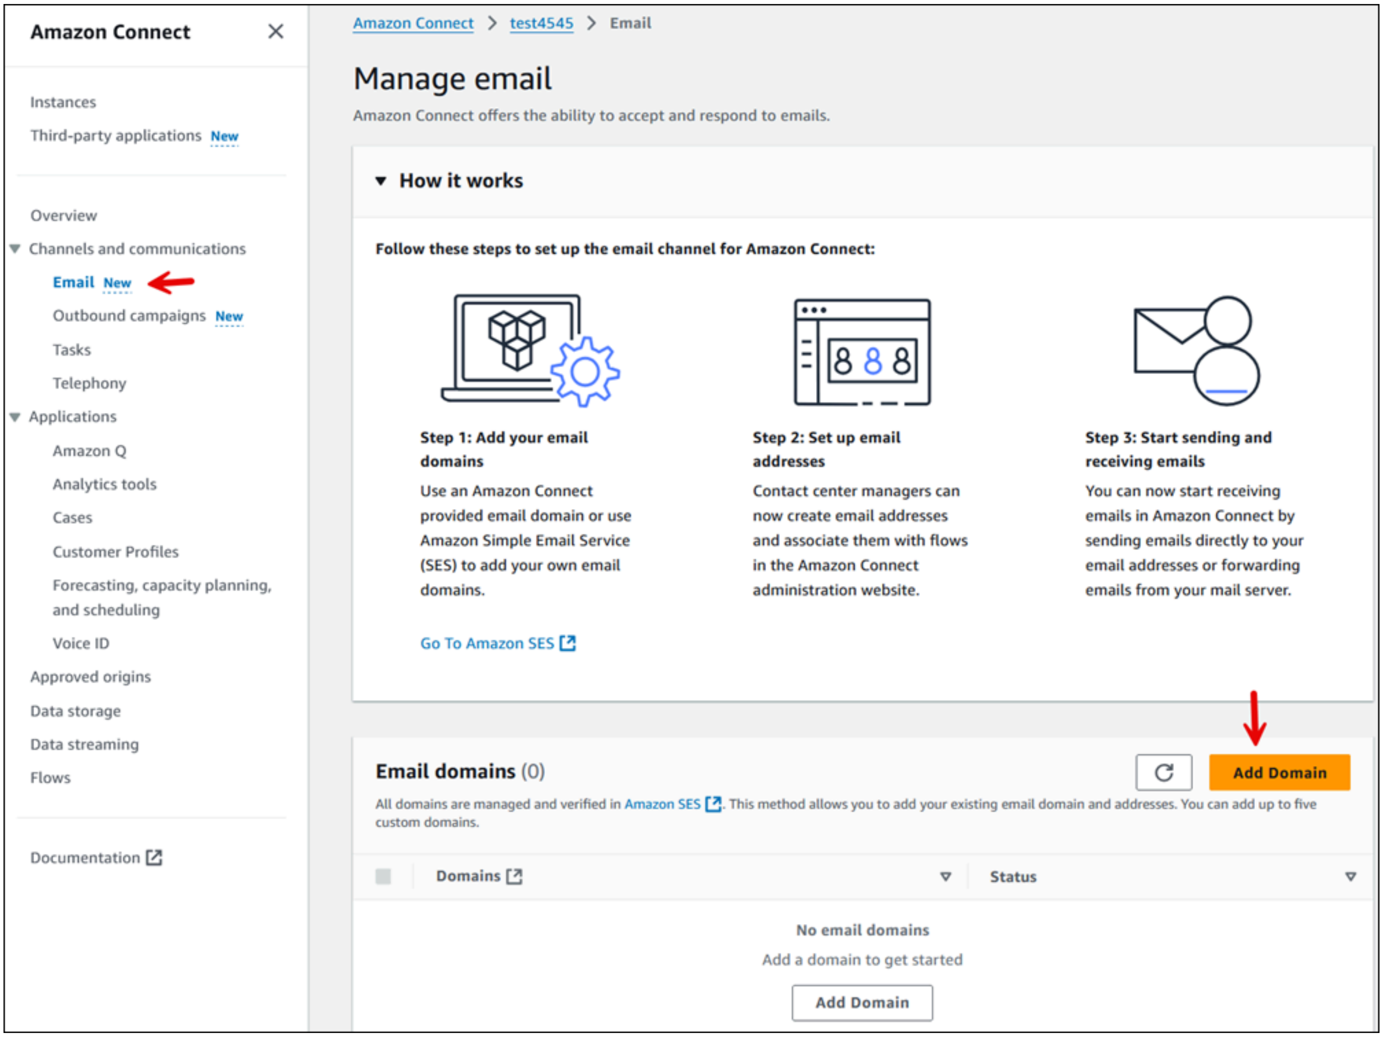
After you move Amazon SES into production mode, if you already enabled email when you created your Amazon Connect instance, skip to these topics:

- (Optional) Step 3: Use your own custom email domains
- Step 5: Configure a CORS policy on your attachments bucket

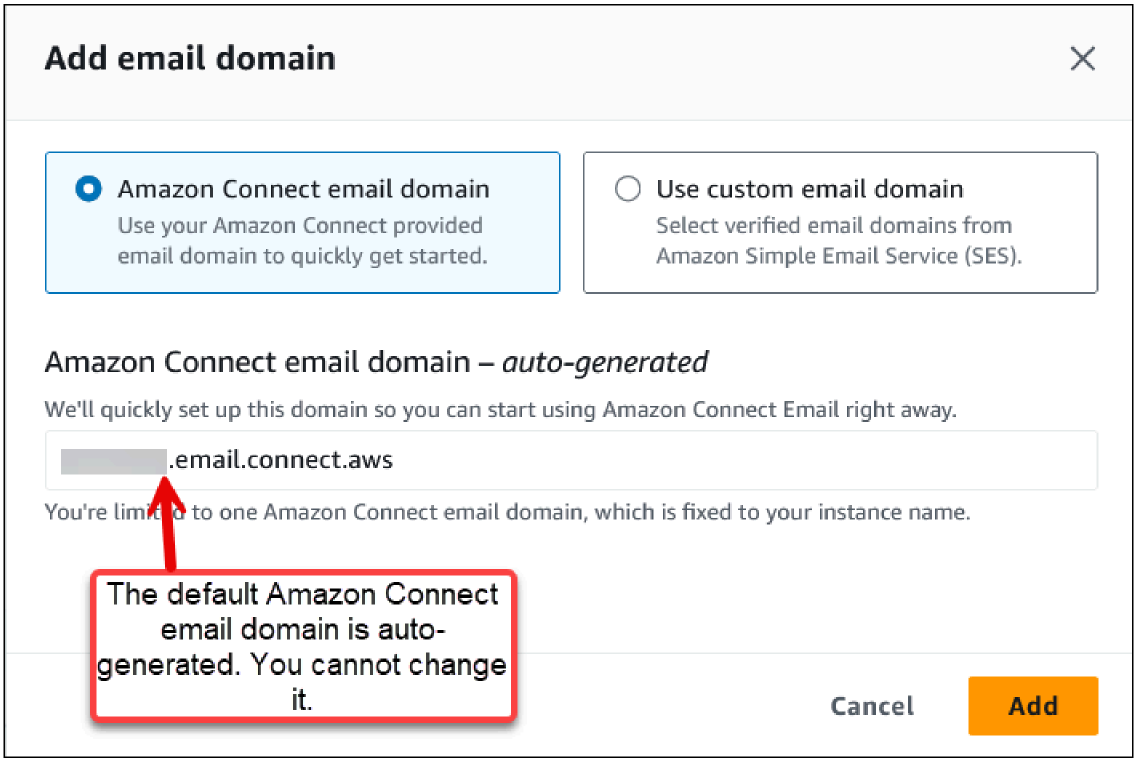
Step 2: Get a default Amazon Connect email domain

These steps only apply if you already created an Amazon Connect instance but didn't enable email. Complete these steps to get a default email domain from Amazon Connect.

1. In the Amazon Connect console, on the left navigation menu, choose **Email**, and then choose **Create service role**. This role needs to be created only once for your account. It allows Amazon SES to route emails to Amazon Connect.
2. Choose **Add Domain** as shown in the following image.



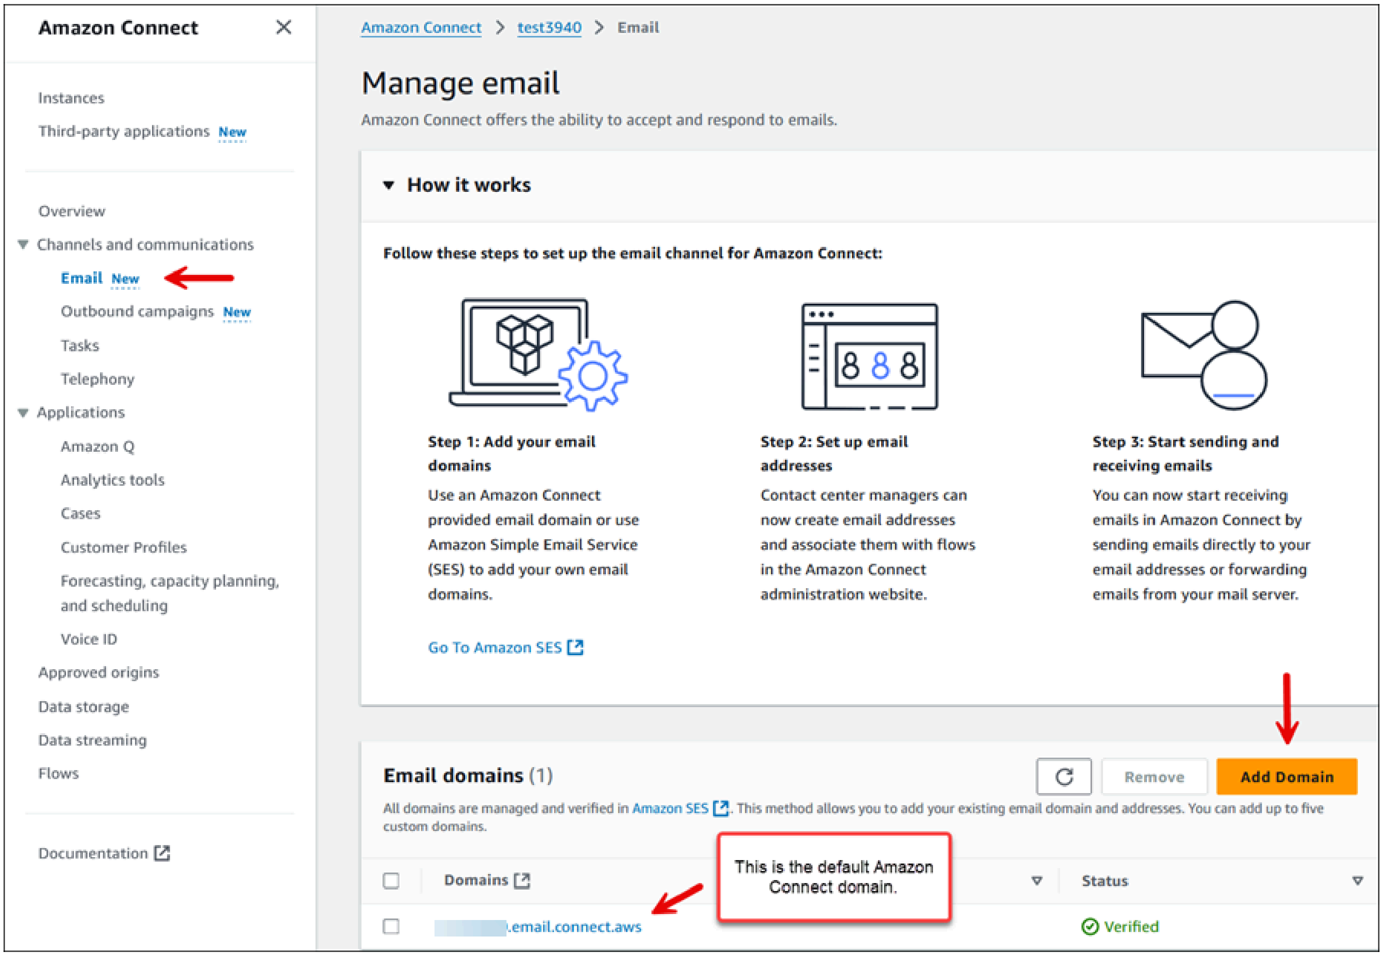
3. In the **Add email domain** box, choose **Amazon Connect email domain**, as shown in the following image. When you choose this option, the name of the domain is autogenerated: `instance-alias`*.email.connect.aws*. You cannot change this email address.



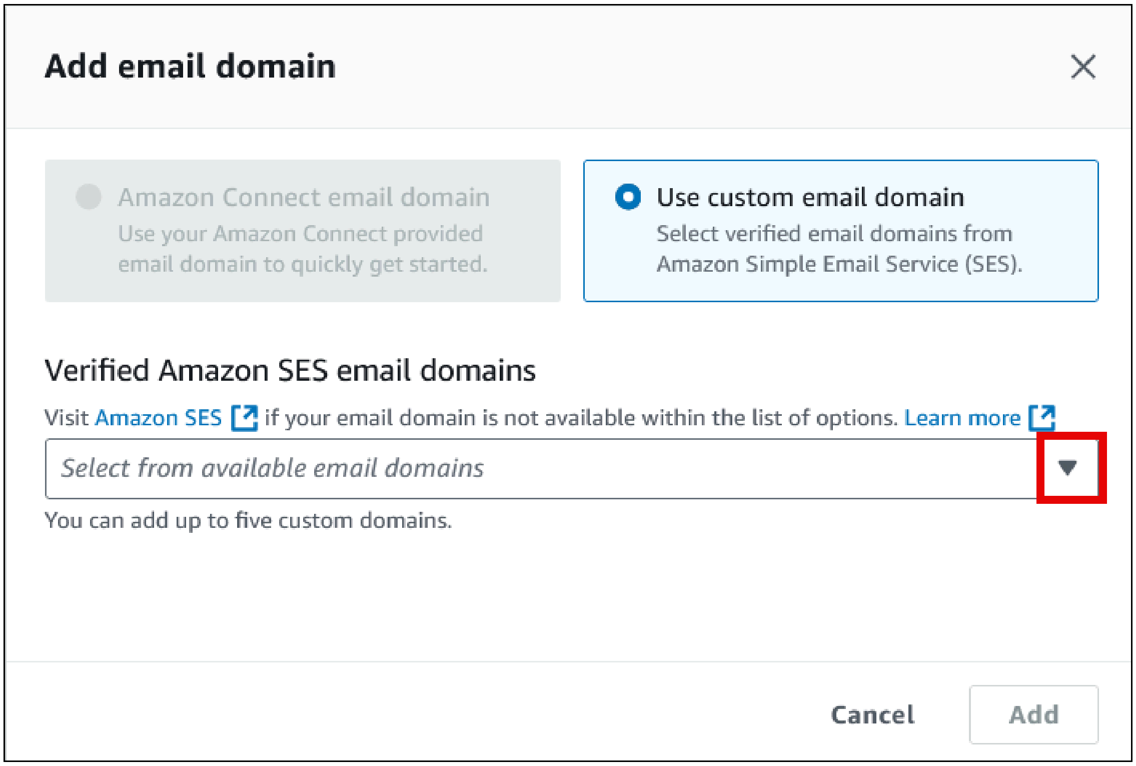
(Optional) Step 3: Use your own custom email domains

You can import up to five custom domains that have been onboarded to Amazon SES.

1. In the Amazon Connect console, on the left navigation menu, choose **Email**, and then choose **Add Domain** as shown in the following image.



2. Choose **Use custom email domain**. Use the dropdown box to choose custom domains that have been verified by Amazon SES.



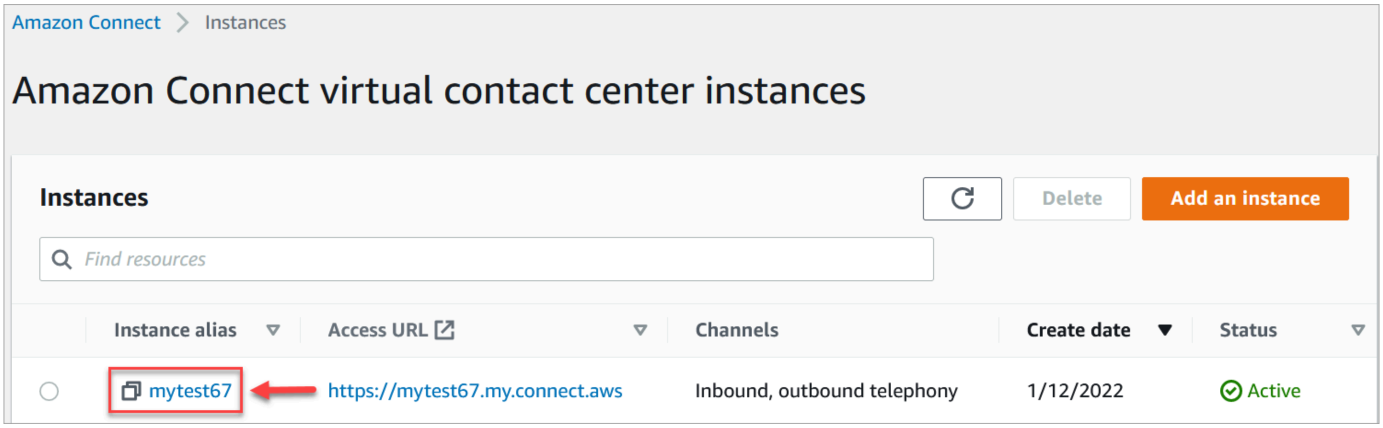
Step 4: Enable email and create an Amazon S3 bucket for storing email and attachments

These steps apply only if you already created an Amazon Connect instance but didn't enable email.

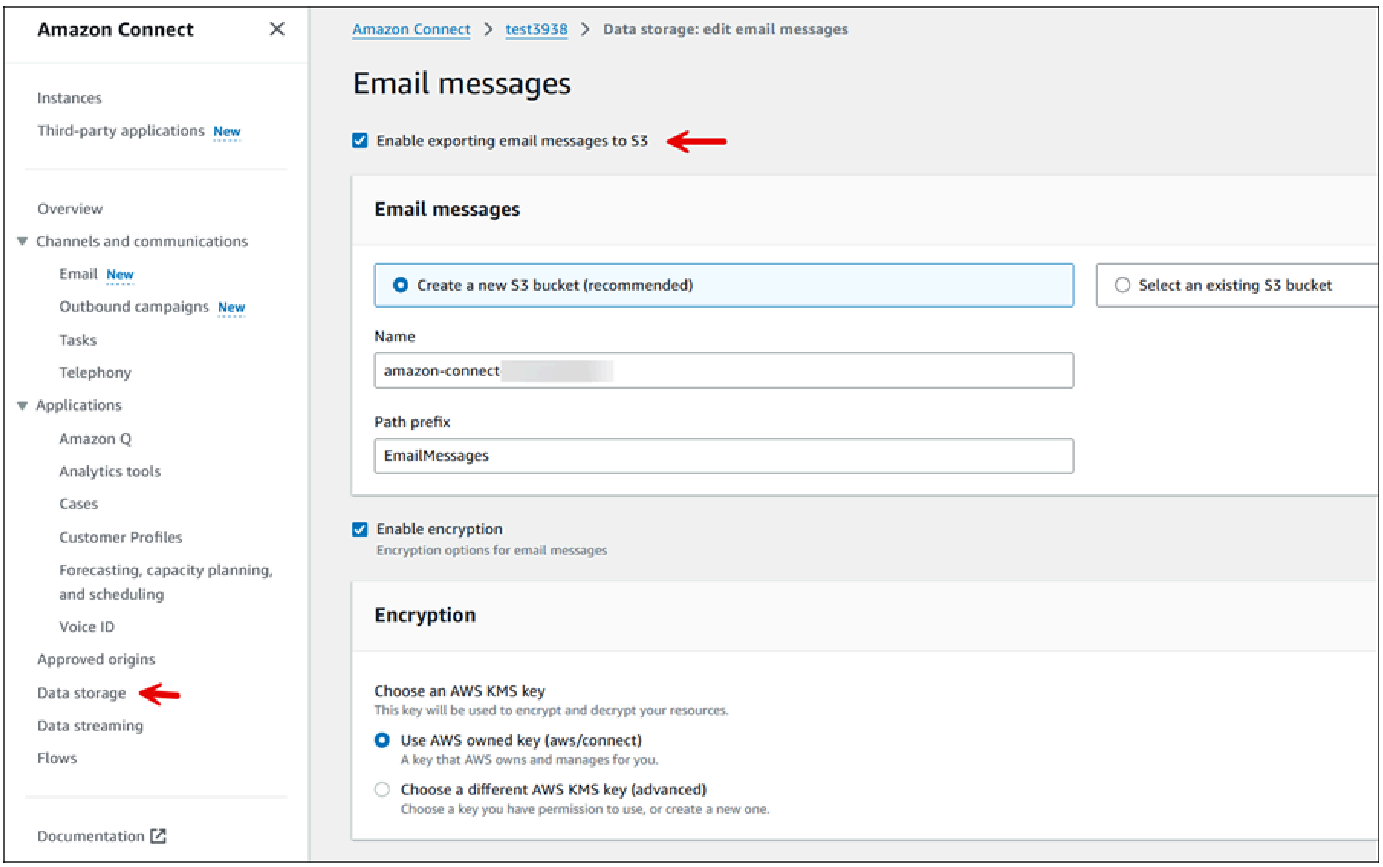
You need to update your **Data storage** settings to enable the email channel and specify the Amazon S3 bucket where email messages and attachments are to be stored. Email requires two Amazon S3 bucket pointers. They can be to the same Amazon S3 bucket or two different buckets.

> **Important**
>
> If you choose **Enable Attachments sharing** for your instance, you must create an Amazon S3 bucket and [configure a CORS policy on your attachments bucket](), as described in this topic. If you don't do this, **the email channel will not work for your instance**.

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Amazon Connect URL. The following image shows the **Amazon Connect virtual contact center instances** page, with a box around the instance alias.

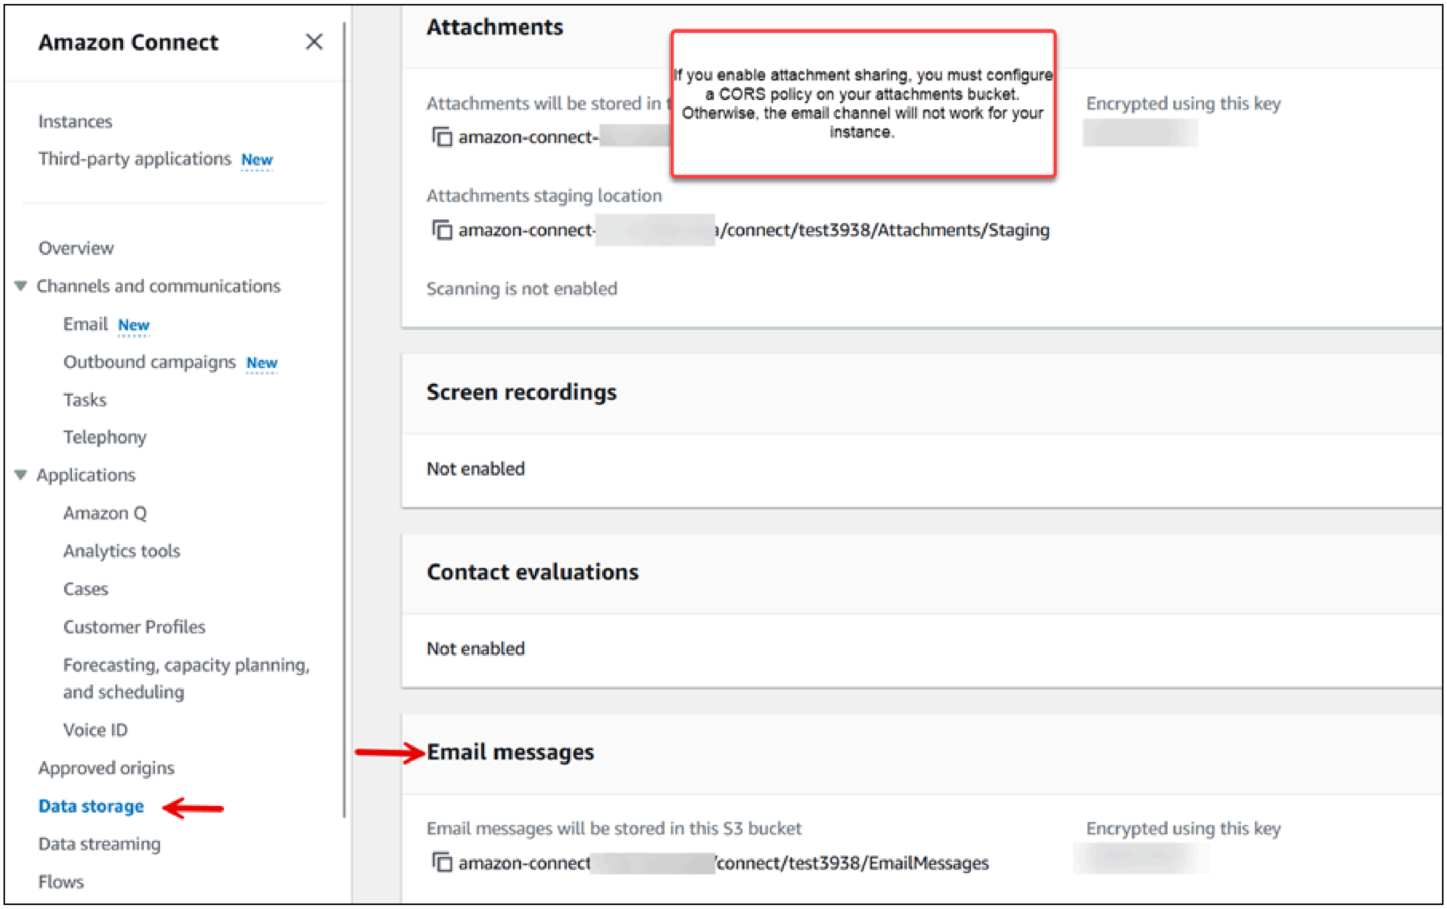


3. On the left navigation menu, choose **Data storage**, **Email messages**, **Edit**, **Enable exporting email messages to S3**, and then choose **Save**.
4. Complete the **Email messages** page to create or select an S3 bucket where email messages are stored. The following image shows an example of a completed page.



5. If you want to allow email attachments, choose **Attachments** as well. The following image shows these options.

The following image of the **Data storage** page shows the Amazon S3 bucket for email messages and attachments.



Step 5: Configure a CORS policy on your attachments bucket

To allow customers and agents to upload and download files, update your cross-origin resource sharing (CORS) policy to allow PUT and GET requests for the Amazon S3 bucket you are using for attachments. This is more secure than enabling public read/write on your Amazon S3 bucket, which we don't recommend.

To configure CORS on the attachments bucket

1. Find the name of the Amazon S3 bucket for storing attachments:

   a. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.

   b. In the Amazon Connect console, choose **Data storage**, and locate the Amazon S3 bucket name.

2. Open the Amazon S3 console at https://console.aws.amazon.com/s3/.

3. In the Amazon S3 console, select your Amazon S3 bucket.

4. Choose the **Permissions** tab, and then scroll down to the **Cross-origin resource sharing (CORS)** section.

5. Add a CORS policy that has one of the following rules on your attachments bucket. For example CORS policies, see [Cross-origin resource sharing: Use-case scenarios](#) in the *Amazon S3 Developer Guide*.

   - Option 1: List the endpoints from where attachments will be sent and received, such as the name of your business web site. This rule allows cross-origin PUT and GET requests from your website (for example, http://www.example1.com).

     Your CORS policy may look similar to the following example:

```
[
    {
        "AllowedHeaders": [
            "*"
        ],
        "AllowedMethods": [
            "PUT",
            "GET"
        ],
        "AllowedOrigins": [
            "*.my.connect.aws",
            "*.awsapps.com"
        ],
        "ExposeHeaders": []
    }
]
```

   - Option 2: Add the `*` wildcard to `AllowedOrigin`. This rule allows cross-origin PUT and GET requests from all origins, so you don't have to list your endpoints.

     Your CORS policy may look similar to the following example:

```
[
    {
        "AllowedMethods": [
            "PUT",
            "GET"
        ],
        "AllowedOrigins": [
            "*"
```

```
            ],
        "AllowedHeaders": [
            "*"
            ]
    }
]
```

Next steps

- Set up attachment scanning in Amazon Connect: This topic is for developers who are familiar with Lambda. You can configure Amazon Connect to scan email attachments by using your preferred scanning application.

APIs to enable email

Use the following APIs to enable email programmatically:

- CreateIntegrationAssociation
- AssociateInstanceStorageConfig
- DescribeInstanceStorageConfig

Create email addresses

This topic explains how to create email addresses by using the Amazon Connect admin website. You can create email addresses that customers can reply to, as well as outbound only (no-reply) email addresses.

For a list of the APIs used to create and manage email addresses programmatically, see APIs to create and manage email addresses.

You can create up to 100 email addresses.

To create email addresses

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an admin account, or an account with **User and permissions - Email addresses - Create permission** in it's security profile.
2. On the navigation menu, choose **Channels**, **Email addresses**.

3. Choose a domain from the dropdown list. The list contains the auto-generated domain that was created when you enabled the email channel for your instance. It may also display up to five custom domains if you added them.

4. Under **Additional information**, you can optionally add the following:

   - **Friendly sender name**
   - **Description**: This is for your use, not customer facing.
   - **Flow**: Choose a published flow for sending emails. Leave this blank for the email address to be used only for outbound communication. Customers will not be able to reply to it.

   > **Tip**
   >
   > To create **No-reply** email addresses, that is, addresses that are only used for outbound mail, and cannot accept a reply don't select a flow to be used for the email address.

5. Under **Tags**, optionally add tags to manage who can view and access email addresses in Amazon Connect and the agent workspace.

6. Choose **Create**.

APIs to create and manage email addresses

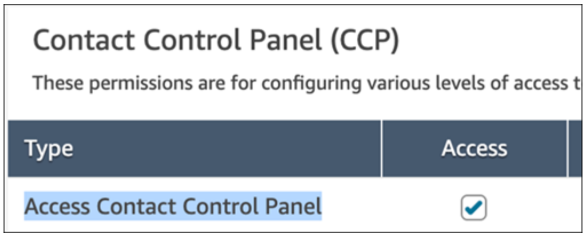
For a list of all email address APIs, see Email actions in the *Amazon Connect API Reference Guide*.

Use the following APIs to create addresses programmatically:

- CreateEmailAddress
- DescribeEmailAddress
- UpdateEmailAddressMetadata

Security profiles do not affect agent authorization for viewing an email thread

Any user with the following permission in their security profile has access to read emails that they handle or emails that are part of a thread where they are a participant: **Contact Control Panel (CCP) - Access Contact Control Panel - Access**.



This authorization behavior is enabled by default. It does not require setting up any additional permission or configuration.

This behavior is driven by the following context keys:

1. `connect:UserArn`: Represents the user that has access to an individual contact.
2. `connect:ContactAssociationId`: Represents the contact association the user has access to. For the email channel, a contact association always represents an email thread.
3. `connect:Channel`: Represents the contact channel the user has access to. For the email channel, this contextKey is always `EMAIL`.

We don't recommend using `connect:ContactAssociationId` in the same policy as `connect:UserArn` because it might result in a no-op. Because the `connect:UserArn` condition key is more restrictive, it will `Deny` access for all contacts not handled by the corresponding user, regardless of the access they have to email threads.

You can use `connect:Channel` in isolation to restrict access to specific channels. Accepted values are: `VOICE`, `CHAT`, `TASK`, or `EMAIL`. See the Contact API.

Following are the contact-related APIs that support these context keys:

1. DescribeContact
2. UpdateContact
3. ListContactReferences
4. TagContact
5. UntagContact
6. UpdateContactRoutingData
7. GetContactAttributes
8. UpdateContactAttributes
9. StopContact

10. StartContactRecording
11. StopContactRecording
12. ResumeContactRecording
13. SuspendContactRecording
14. UpdateContactSchedule
15. TransferContact
16. StartScreenSharing

Create quick responses for use with chat and email contacts in Amazon Connect

Quick responses provide contact center agents with pre-written responses in English that they can use during chat and email contacts. Quick responses are especially useful for answering common customer inquires. They help improve agent productivity, reduce handle times, and improve customer satisfaction scores. Quick responses are available in English only.

You can use the Amazon Connect admin website or Amazon Q in Connect actions to create quick responses. You can add single quick responses or import many of them at the same time. You can also personalize responses with user-defined attributes. In addition, you can assign shortcut keys to quick responses, and associate them with routing profiles so that agents can quickly access relevant content.

By default, CCP enables agents to search quick responses. Custom builders can use Amazon Connect Streams to programmatically implement quick response search in their implementations of CCP.

For information about how agents search for quick responses, see Search for quick responses to customers in the Contact Control Panel (CCP).

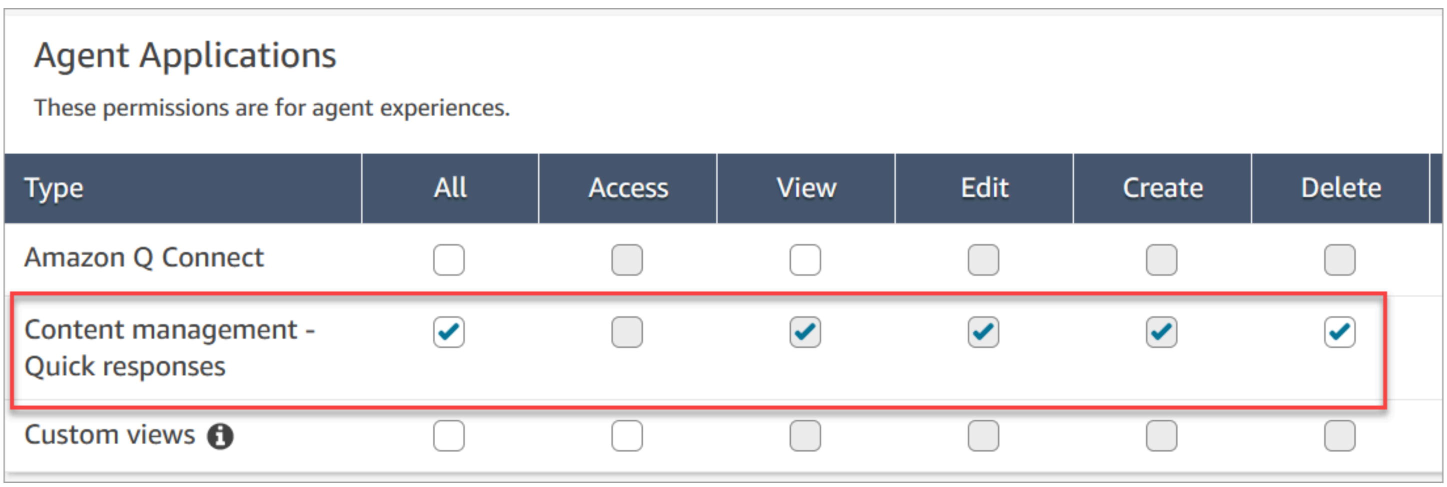
> **Tip**
>
> Even though quick responses use the Amazon Q in Connect APIs, quick responses don't lead to additional billing. You only pay for the chat message price or email price. For more information, see Amazon Connect Pricing.

Contents

- [Assign permissions to manage quick responses in Amazon Connect]
- [Set up an Amazon Q in Connect knowledge base to store quick responses]
- [Add quick responses for use with chat and email contacts in Amazon Connect]
- [Add attributes for personalizing quick responses in Amazon Connect]
- [Edit quick responses in Amazon Connect]
- [Delete quick responses in Amazon Connect]
- [Import quick responses to Amazon Connect]
- [View the import history for your Amazon Connect quick responses]
- [Enable Amazon Connect quick responses in a custom Contact Control Panel (CCP)]

Assign permissions to manage quick responses in Amazon Connect

To create and manage quick responses in the Amazon Connect admin website, users need the Content Management security profile permissions. The following image shows these permissions on the **Security profiles** page.



Following is a description of the Content Management permissions.

- **All** – Enables all permissions, but you must have a custom view to enable **Access**.
- **Access** – Grants users access to custom views. This checkbox remains unavailable until you create a custom view.
- **Create** – Enables users to create Amazon Q in Connect knowledge bases and quick responses in the Amazon Connect admin website. This setting also enables users to View and Edit. It does not grant permission to delete quick responses.
- **View** – Enables users to view quick responses in the Amazon Connect admin website.

- **Edit** – Enables users to edit quick responses in the Amazon Connect admin website.
- **Delete** – Enables users to delete quick responses in the Amazon Connect admin website.

If you want the same users to add personalized attributes to quick responses, they will also need the **Channels and flows**, **Flows - Publish** permission.

For information about adding permissions to an existing security profile, see Update security profiles in Amazon Connect.

Set up an Amazon Q in Connect knowledge base to store quick responses

You must create an Amazon Q in Connect knowledge base to store quick responses. You can use the Amazon Connect admin website to create the knowledge base with a single click. The site uses AWS owned keys to encrypt data.

> **Note**
>
> You can create your own key by providing a custom ServerSideEncryptionConfiguration in an CreateKnowledgeBase API call. For more information, see Enable Amazon Q in Connect for your instance, in this guide.

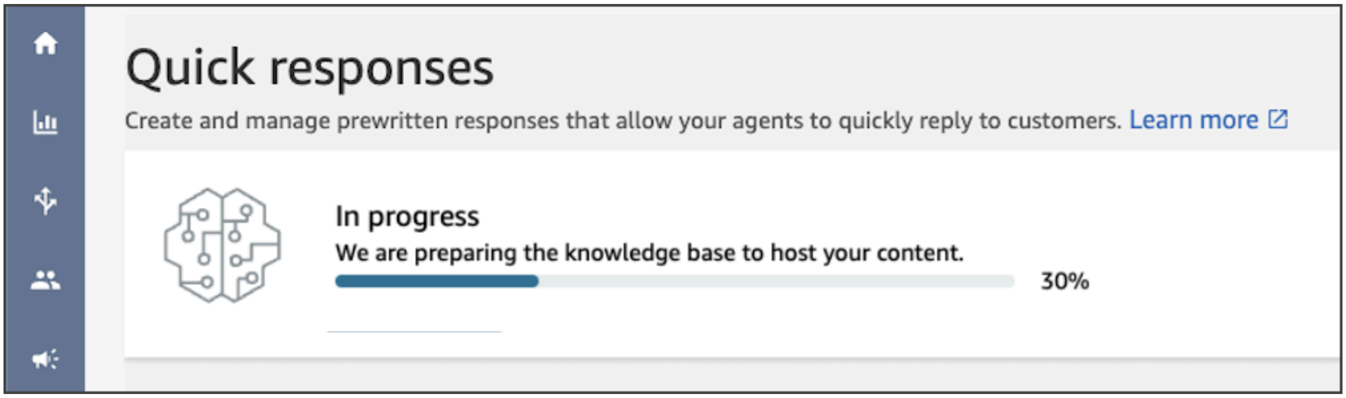
The following steps explain how to use the Amazon Connect admin website to create an Amazon Q in Connect knowledge base.

To create a knowledge base

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an admin account, or an account with **Content Management - Quick responses - Create** permission in it's security profile.
2. On the navigation bar, choose **Content Management**, then **Quick responses**.
3. On the **Quick responses** page, choose **Get started**.

> **Note**
>
> If the **Get started** button isn't available, sign in with an account that has the admin security profile, or ask another admin for help.

4. Remain on the page until the process ends. Do not refresh the page until the process ends. An indicator shows the status.



The finished knowledge base provides two sample quick responses.

- The sample responses are associated with the basic routing profile, if that exists in your Amazon Connect instance.
- The sample responses are set to **Inactive**, meaning agents can't see or search for them. Activating a sample quick response makes it visible and searchable by agents assigned to the basic routing profile.
- If the basic routing profile is not present in your Amazon Connect instance, the sample quick responses are associated with **All** routing profiles. After you activate a sample quick response, all agents can see and search for that response, regardless of their assigned routing profiles.

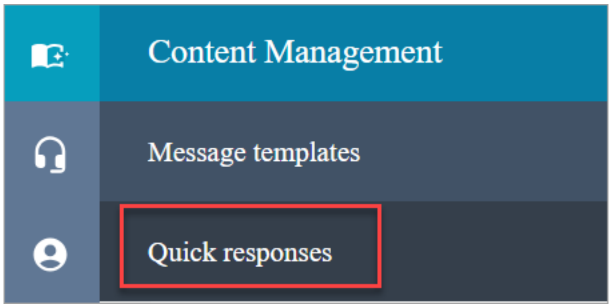
> **Note**
>
> Quick responses are only available in the **Chat** and **Email** channels.

Add quick responses for use with chat and email contacts in Amazon Connect

This topic explains how to add a quick response by using the Amazon Connect admin website. For the APIs used to create and manage quick responses programmatically, see APIs to create and manage quick responses.

To add responses

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an **Admin** account, or an account assigned to a security profile that has **Content Management - Quick responses - Create** permission.
2. On the navigation bar, choose **Content Management**, then **Quick responses**.



3. On the **Quick responses** page, choose **Add response**.

> **Note**
>
> If the **Add response** button isn't available, sign in with an account that has the admin security profile, or ask another admin for help.

4. On the **Add response** page, choose whether the response is for chat, email, or both channels.
5. On the **Add response** page, enter a name, description, and shortcut key for the quick response. You must enter a unique name and shortcut key because agents will search on those values.
6. Open the **Routing profiles** list and select one or more profiles. You can select a maximum of 20 profiles, or choose **All**. Only the agents assigned to a given profile can see the quick responses associated with that profile.
7. (Optional) Choose **Activate: Make this response visible for agents** if you want agents to see and search for the response.
8. In the **Content** section, enter the response, then choose **Save**.

> **Note**
>
> If you configured user-defined attributes in the flow block, those attributes, such as customer name, appear when an agent searches for a response in CCP. For more information, see Set contact attributes.

APIs to create and manage quick responses

Use the following APIs to create and manage quick responses programmatically:

- CreateQuickResponse
- UpdateQuickResponse
- DeleteQuickResponse
- GetQuickResponse
- ListQuickResponses
- SearchQuickResponses
- UpdateQuickResponse

Add attributes for personalizing quick responses in Amazon Connect

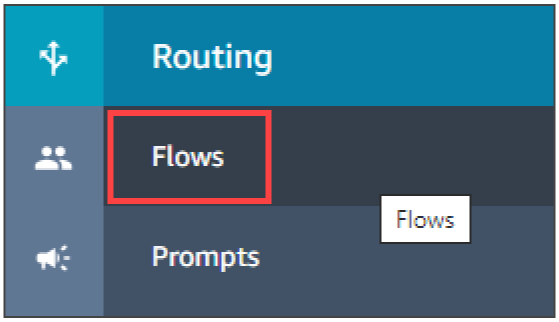
You can personalize quick responses by adding user-defined attributes. To do so, you use the Amazon Connect admin website to create responses that include Amazon Connect contact attributes. You can also use the Set contact attributes block to create user-defined attributes in flows.

When quick responses contain user-defined attributes, the value of those attributes, such as customer name, appear when an agent searches for a response in CCP.

The following steps explain how to add user-defined attributes to quick responses. You first create a set-contact attribute, and then you add the attribute to a quick response.

To create a set-contact attribute

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an **Admin** account, or an account assigned to a security profile that has **Flows - Edit or Create** permissions.
2. On the navigation bar, choose **Routing**, then **Flows**.



3. On the **Flows** page, the **Type** column lists each type of flow. Choose the flow that you want to add attributes to.
4. Follow the steps in Creating a set contact attribute.

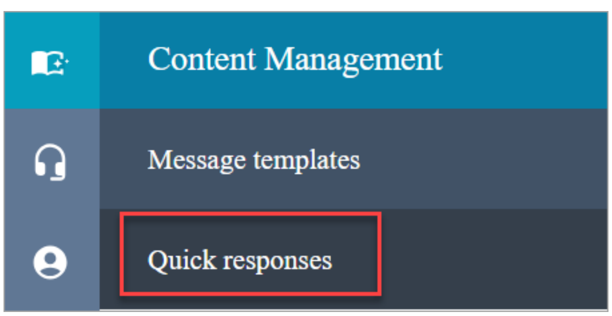
> **Note**
>
> In the contact attribute configuration, select the **User defined** namespace, then save and publish the flow.

5. When finished, complete the next set of steps.

You can follow these steps when creating or updating a quick response.

To add an attribute to a quick response

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an **Admin** account, or an account assigned to a security profile that has **Content Management - Quick responses - Create or Edit** permission.
2. On the left navigation bar, choose **Content Management**, then **Quick responses**.



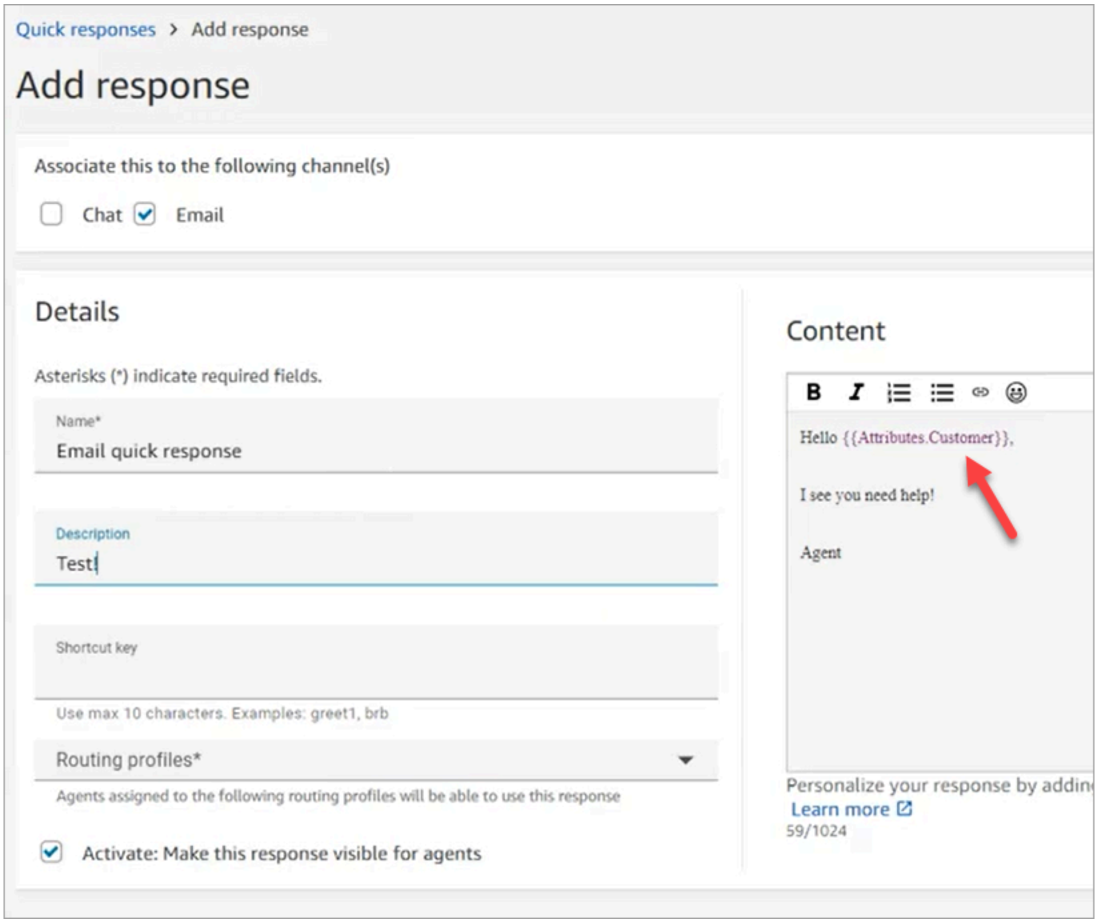
3. Choose **Add response** to create a response.

—or—

Select the checkbox next to the quick response that you want to personalize, then choose **Edit**.

4. Choose the content section, enter the quick response content, then use handlebar syntax to enter a user-defined attribute. Make sure you include the `Attributes` namespace prefix. For example, **`{{Attributes.Customer}}`**.

   The following image shows a quick response for an email.



5. Choose **Save**.

The following steps explain how to test attributes in CCP.

To test attributes

1. Log in to the Amazon Connect admin website chat testing page at https://*instance name*.my.connect.aws/test-chat.
2. Choose the flow with the user-defined attribute.
3. Start a chat and enter ***`/#searchText`***, where *searchText* is the assigned shortcut key.

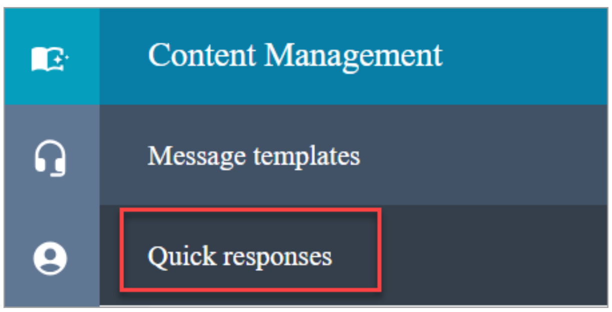
> **Note**
>
> For more information, see Test voice, chat, and task experiences in Amazon Connect.

Edit quick responses in Amazon Connect

This topic explains how to use the Amazon Connect admin website to edit a quick response. To edit a quick response programmatically, see UpdateQuickResponse in the *Amazon Q in Connect API Reference*.

To edit a response

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an **Admin** account, or an account assigned to a security profile that has **Content Management - Quick responses - Edit** permission.
2. On the navigation bar, choose **Content Management**, then **Quick responses**.



3. On the **Quick responses** page, choose the name of the quick response that you want to edit. You can also select the checkbox next to the response, then choose **Edit**.
4. As needed, change the following fields:
   - **Name**
   - **Description**
   - **Shortcut key**
   - **Routing Profiles**
   - **Activate/Deactivate quick response**
   - **Content**
   - **Channel**
5. Choose **Save**.

Delete quick responses in Amazon Connect

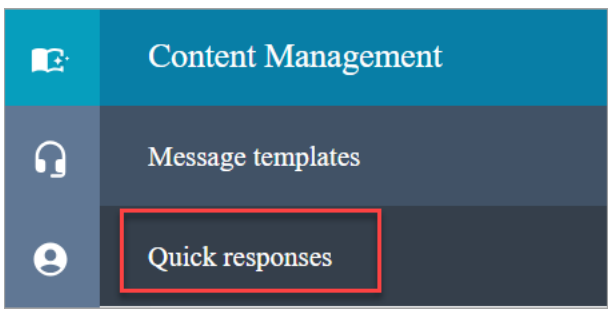
This topic explains how to use the Amazon Connect admin website to delete a quick response. To delete a quick response programmatically, see DeleteQuickResponse in the *Amazon Q in Connect API Reference Guide*.

> **Important**
>
> - You can't undo a deletion.
> - Agents can't see or use deleted quick responses.

To delete a response

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an **Admin** account, or an account assigned to a security profile that has **Content Management - Quick responses - Delete** permission.

2. On the navigation bar, choose **Content Management**, then **Quick responses**.



3. On the **Quick responses** page, select the checkbox next to the response that you want to delete. You can select a maximum of 20 responses.

4. Choose **Delete**.

   A success message appears:

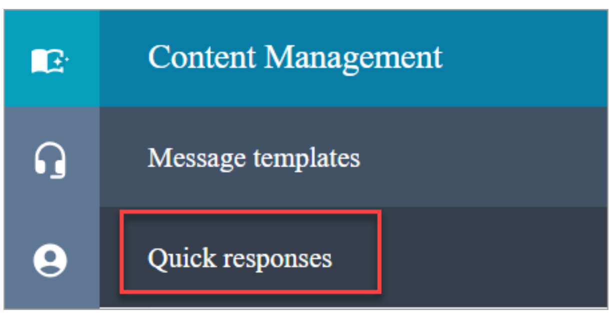
> **Note**
>
> - If the **Delete** button is inactive, sign in to an Amazon Connect an account that has the required security profile, or ask another admin for help.
> - Remain on the page until the delete operation finishes.

Import quick responses to Amazon Connect

You can import a maximum of 100 quick responses at a time from a .csv file. This topic explains how to use the Amazon Connect admin website to import quick responses. To import quick responses programmatically, see StartImportJob in the *Amazon Q in Connect API Reference*.

To import responses

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an **Admin** account, or an account assigned to a security profile that has **Content Management - Quick responses - Create** permission.
2. On the navigation bar, choose **Content Management**, then **Quick responses**.



3. On the **Quick responses** page, choose **Import**.
4. In the **Import** dialog box, choose the **Responses Import Template.csv** link, then save the resulting **Response Import Template.csv** file to your desktop. The file opens in Microsoft Excel or a similar spreadsheet program.
5. In the .csv file, enter values in each column. Remember the following:
    - The **Name** and **Shortcut key** values must be unique across all the quick responses in your Amazon Connect instance.
    - Values in the **Routing Profile** column are case sensitive and must match the name of your routing profile exactly.

- Do not rename or change the values in the first row of the .csv file. Those header keys are reserved and used to generate payloads for the CreateQuickResponse API.
- Remove all instances of **<*Required field>** from the .csv file. They're only for information.

6. Save the .csv file, return to the Amazon Connect admin website, and in the **Import** dialog box, choose **Upload file**.
7. Locate and open the .csv file, then choose **Import**.

   Success or failure messages appear when the import operation finishes. If the operation fails, choose the **Download failed imports link** in the message. Check the .csv file for leading or trailing spaces, and for any messages about the error.

You can navigate away from the **Quick response** page before the import job finishes. Choose the **View import history** link, located below the list of responses, to view status of your import jobs.

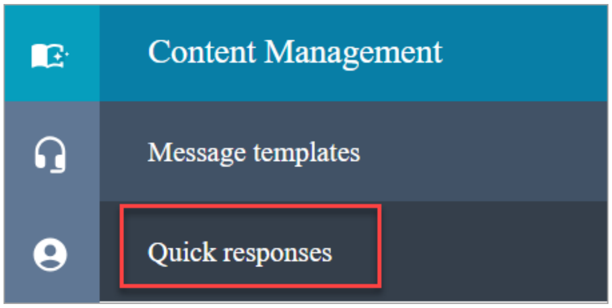
View the import history for your Amazon Connect quick responses

Amazon Connect retains import history for the lifetime of your knowledge base. To delete that history, you must use the DeleteKnowledgeBase action to delete the knowledge base.

This topic explains how to use the Amazon Connect admin website to view import histories. To view import histories programmatically, see ListImportJobs in the *Amazon Q in Connect API Reference*.

To view import history

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an **Admin** account, or an account assigned to a security profile that has **Content Management - Quick responses - View** permission.
2. On the left navigation bar, choose **Content Management**, then **Quick responses**.

3. On the **Quick responses** page, choose the **View import** history link.

Enable Amazon Connect quick responses in a custom Contact Control Panel (CCP)

To enable your agents to use quick responses for an embedded or custom CCP, you use the Amazon Connect Streams library on GitHub to call the SearchQuickResponse API and return a list of quick response search results to CCP. For more information, see Amazon Connect Streams Documentation on Github.

> **Note**
>
> To prevent search API misuse, we implemented default values for the following request parameters:
>
> - `debounceTime` – 250ms between subsequent `SearchQuickResponse` API calls
> - `maxSearchResults` – 25
> - Search priority order:
>   1. `shortcut key`
>   2. `name`
>   3. `content`
>   4. `description`

For information about the agent's experience using quick responses, see Search for quick responses to customers.

Set up outbound calling in Amazon Connect

You can send outbound calls to customers for a variety of reasons, such as appointment reminders, subscription renewals, and debt collection. Amazon Connect provides both normal and outbound campaign capabilities. For more information about campaigns, see Set up Amazon Connect outbound campaigns in this guide.

Contents

- Outbound calling restrictions in Amazon Connect
- Optimize your reputation for outbound calling in Amazon Connect

Set up outbound caller ID in Amazon Connect

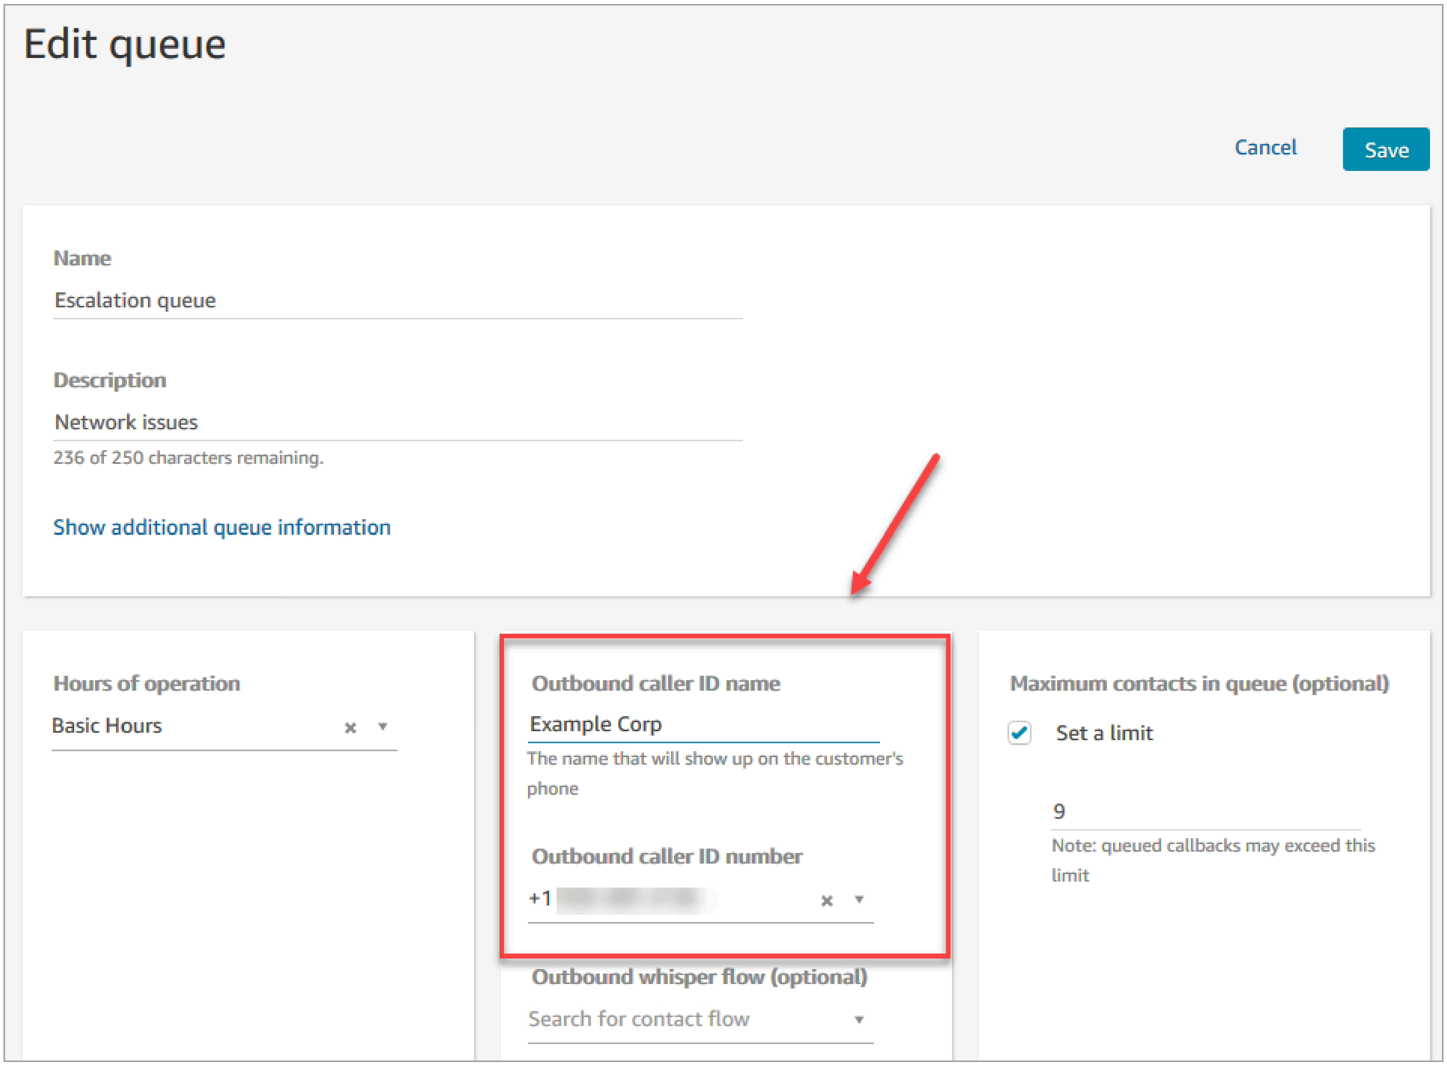
This topic explains how to set up your outbound caller ID name and number.

Contents

Outbound parameters: Set in queue

You set the outbound caller ID name (such as the name of your company) and caller ID number in the queue settings. To edit queue settings, on the navigation menu choose **Routing**, **Queues**, and then choose the queue you want to edit.

The following image shows an **Edit queue** page with an arrow pointing to the **Outbound caller ID name** and **Outbound caller ID number**.



Outbound caller ID name

The **Outbound caller ID name** is set to the value that is passed from the SIP header. For example, Alice<sip:alice@example.com>.

Important

- Per SIP protocol RFC3261, the following characters are reserved: **; / ? : @ & = + $,**. Do not use these characters in the caller ID name. When these characters are included, outbound calls may fail or the caller ID name may display inaccurately.
- Amazon Connect runs on a SIP-only infrastructure through our carrier partners. However, the caller ID name can be delivered to your customers only if the call path across the public telephony network is all on SIP. Because your customers are on many different networks outside of what Amazon Connect controls, the caller ID name is not guaranteed

to be delivered to your customers. Depending on the country this will be up to 75% effective.

- To guarantee your caller ID name is delivered to customers, see Optimize your reputation for outbound calling in Amazon Connect for information about achieving it by using partner solutions.

Outbound caller ID number

Only phone numbers that you've claimed or ported to Amazon Connect can be used as your caller ID number. Outbound calls without proper identification may be blocked in certain countries such as UK and Australia.

To use an external phone number as your outbound caller ID number, contact Support to see if it's possible. The phone number needs to be in a country we support for custom caller ID and you'll need to provide proof of ownership.

1. Choose Account and billing to access a pre-populated form in the Support console. You must be signed in to your AWS account to access the form.
2. For **Service**, *Connect (Number Management)* should be selected.
3. For **Category**, *Custom Outbound Called ID* should be selected.
4. Select the required severity.
5. Choose **Next step: Additional information**
6. On the **Additional information** page:
   a. Enter the subject.
   b. Under **Description**, include as much information as possible about your request, If you don't know all of these details, you can leave information out.
7. Choose **Next step: Solve now or contact us**.
8. On the **Solve now or contact us** page:
   - Choose the **Contact us** tab and select your **Preferred contact language** and your preferred contact method.
9. Choose **Submit**.
10. The Amazon Connect team will review your ticket and get back to you.

You can set the caller ID number as follows:

- **Call phone number block**: Use this block in an Outbound whisper flow to initiate an outbound call to a customer and, optionally, specify a custom caller ID number that is displayed to call recipients.

  This block is useful when you have multiple telephone numbers used to make outbound calls, but want to consistently display the same company phone number for the caller ID for calls made from your contact center.

  You can also use this block with the Set contact attributes block to set the callback number dynamically. For example, you can display a certain caller ID number based on the customer's account type.
- **Queue:** If no caller ID number is specified in the Call phone number block, then the caller ID in the queue settings is used.

> **Important**
>
> - Telecom regulations in various countries limit the telephone numbers that you can use to make outbound calls. If you set up a number and you can't make outbound calls, check the Amazon Connect Telecoms Country Coverage Guide and Region requirements for ordering and porting phone numbers in Amazon Connect to ensure that you have correct type of number.
> - Telecom regulations in certain countries require the carrier to identify the caller and block unidentifiable outbound calls. Make sure you set the Caller ID in your configurations to avoid call failures.

Toll-free numbers for caller ID

Toll-free numbers for outbound communications have a number of limitations. For example, using a toll-free number to dial other toll-free numbers in the United States can result in the number being filtered, blocked, or not properly routed to the destination by carriers. Toll-free numbers may be terminated at a higher than expected rate. If you know you need to call toll-free numbers in the United States you must use DIDs to guarantee call delivery.

If you use toll-free numbers outside of the US, refer to the Amazon Connect Telecoms Country Coverage Guide to see which countries support toll-free numbers as outbound. For example, for Australia the **National Outbound** column indicates that toll-free numbers are not supported.

> **Important**
>
> Toll-free products are designed to be national products and used within a country. We do not guarantee international reachability of any of these services, as access to the numbers is controlled by a caller's network access.

How to set the caller ID number dynamically

Use an attribute in the Call phone number block to set the caller ID number dynamically during the flow.

The attribute can be one you define in the Set contact attributes block in the flow. Or, it can be an external attribute returned from an AWS Lambda function.

The value of the attribute must be a phone number from your instance in E.164 format.

- If the number is not in E.164 format, the number from the queue associated with the Outbound whisper flow is used for the caller ID number.
- If no number is set for the outbound caller ID number for the queue, the call attempt will fail.

For more information about setting the caller ID dynamically, see this AWS Support Knowledge Center article: How can I set my Amazon Connect outbound caller ID dynamically based on country?

Use E.164 format for international phone numbers

Amazon Connect requires phone numbers in E.164 format.

To express a US phone number in E.164 format, add the '+' prefix and the country code in front of the number. For example, for a US number:

- +1-800-555-1212

In the UK and many other countries internationally, local dialing requires the addition of a 0 in front of the subscriber number. However, to use E.164 formatting, this 0 must be removed. A number such as 020 718 xxxxx in the UK would be formatted as +44 20 718 xxxxx. When you place calls from the CCP using Amazon Connect the CCP provides the correct formatting for numbers automatically.

> **Important**
>
> Phone numbers that are not formatted in E.164 will not work. They will also result in a breach of Amazon Connect Service Terms and conditions for acceptable use which may result in your service being suspended.

How to specify a custom caller ID number using a Call phone number block

1. On the left navigation menu, choose **Routing**, **Flows**.
2. Choose the down arrow next to **Create flow**, and then choose **Create outbound whisper flow**.
3. Add a Call phone number block to the flow, and connect the **Entry point** block to it.

   The Call phone number block must be placed before a **Play prompt** block if one is included in your flow.
4. Select the Call phone number block, and then select **Caller ID number to display**.
5. Do one of the following:
   - To use a number from your instance, choose **Select a number from your instance**, and then search for or select the number to use from the drop-down.
   - Choose **Use attribute** to use a contact attribute to provide the value for the caller ID number. You can use either a **User Defined** attribute you create using a Set contact attributes block, or an **External** attribute returned from an AWS Lambda function. The value of any attribute you use must be a phone number claimed for your instance and be in E.164 format. If the number used from an attribute is not in E.164 format, the number set for the **Outbound caller ID number** for the queue is used.

> **Important**
>
> - The value of any attribute you use must be a phone number claimed for your instance. The number must be in E.164 format. If the number used from an attribute is not in E.164 format, calls may be terminated by the destination networks.
> - It is your responsibility to ensure the numbers you are using are legally permissible. Certain numbers, such as +44870 numbers in the UK, are not legally permissible. You must ensure you're not using them.

6. Add any additional blocks to complete your flow, and connect the **Success** branch of the Call phone number block to the next block in the flow.

   There is no error branch for the block. If a call is not successfully initiated, the flow ends and the agent is placed in an **AfterContactWork** (ACW) state.

CNAM

As part of changes within the US Public Telephone network and a move to alternative reputation mechanisms described in Optimize your reputation for outbound calling in Amazon Connect, as of March 31, 2023, Amazon Connect no longer sets CNAM configurations.

We conducted research between January and March 2023, that showed CNAM was seen by fewer than 7% of users. This is due to changes within support for mobile providers and due to the migration to app-based reputation mechanisms.

All existing CNAM configurations set up before March 2023, are still in place. We will continue to focus on supporting modern replacement mechanisms added to our marketplace, for example, First Orion and Neustar.

How to avoid labels like "spam" and "telemarketer"

See the recommended steps in Optimize your reputation for outbound calling in Amazon Connect.

Set up US emergency calling in Amazon Connect

By default 911 is enabled for all users in the following North America Regions: US East (N. Virginia), US West (Oregon), and AWS GovCloud (US-West). If a user calls 911, the call is routed through to emergency services.

Amazon Connect only supports direct calls from the agent CCP to 911. It does not support call transfers to 911, or dialing 911 while on a call.

What is Enhanced 911 (E911)? For agents who are physically located in the US, E911 enables location information to be sent to 911 dispatch when a 911 call is placed.

There are two steps to set up E911:

- Get and store an agent's validated physical address in your Amazon Connect instance
- Retrieve an agent's address from Amazon Connect when they call 911

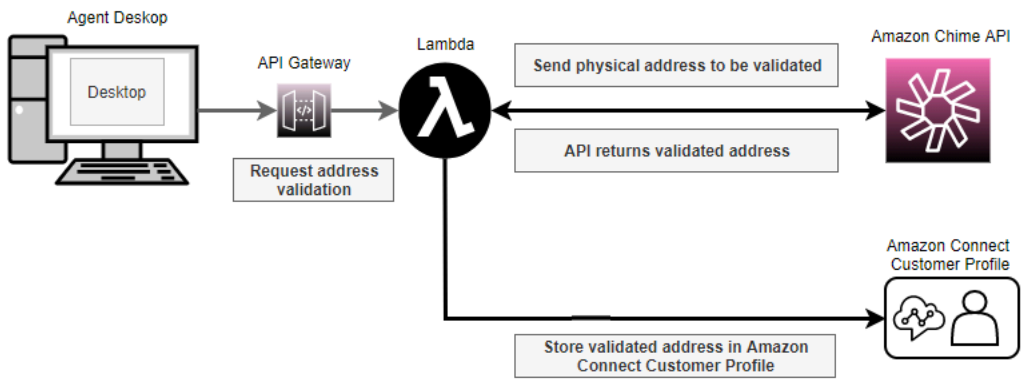
Place 911 calls from your Test Environment

> **Important**
>
> Calling 911 for a non-emergency situation carries a penalty of $100 per occurrence. To help you avoid penalties, we have set up 933 so you can test this capability. Calls placed from an Amazon Connect Contact Control Panel (CCP) to 933 have an audio playback message confirming:
>
> - The number the call originated from.
> - The physical address that was sent along with the call.

For more information about calling 911, see this FAQ about the national 911 program.

Get and store an agent's validated physical address in your Amazon Connect instance

The first step in setting up E911 for your Amazon Connect instance is to get and store the agent's validated physical address. The following illustration shows the process for storing addresses.

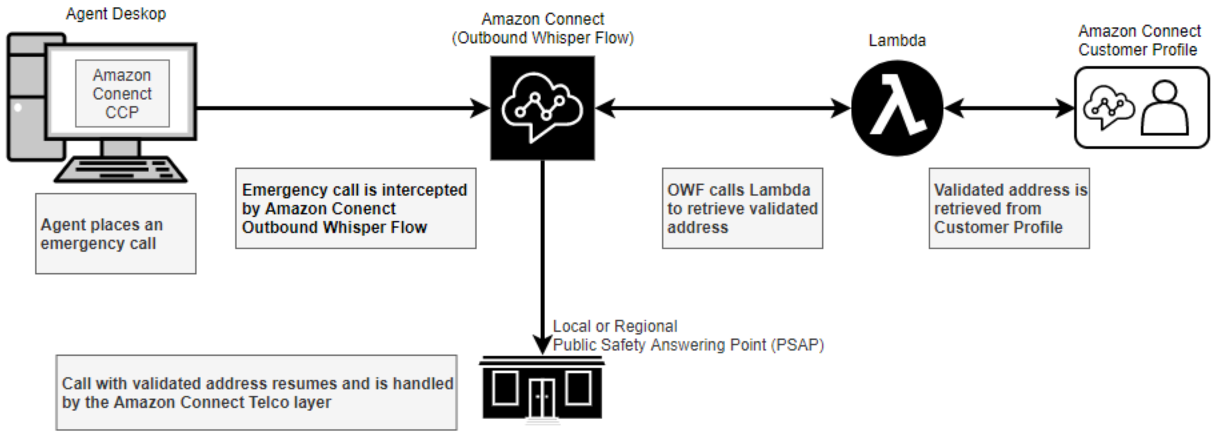


1. Since agents may be working from different locations (for example, office building, home, or coffee shop), it's critical that the most recently validated address is passed along with the emergency outbound call.
   a. Store a validated address when you first set up an agent on Amazon Connect, based on the agent's usual location.
   b. Prompt the agent to update their address at the start of their shift to help ensure that the emergency outbound call has their latest address.
   c. Check addresses against a database of valid street addresses (Master Street Address Guide).
2. Use the Amazon Chime API ValidateE911Address. This API validates and returns the validated physical address.
3. Use the CreateProfile or UpdateProfile APIs to store the validated address in Amazon Connect Customer Profiles.

> **Note**
>
> We recommend using `CreateProfile` when it is required to add a validated address the first time. After that, use `UpdateProfile`.

Retrieve an agent's address from Amazon Connect when they call 911

To retrieve an agent's validated address from the Amazon Connect, create an outbound whisper flow that calls a Lambda function. Code the Lambda function to retrieve the address from the agent's customer profile, as shown in the following illustration:



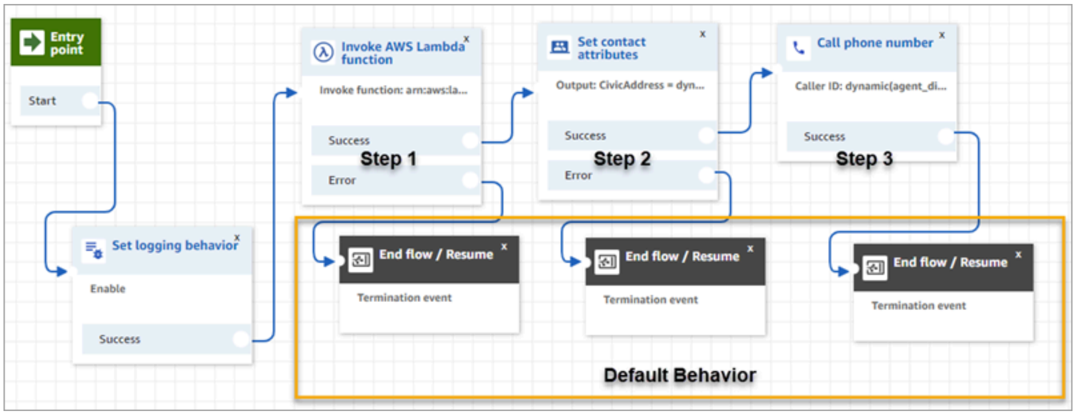
1. Create an AWS Lambda function that uses the SearchProfiles API to retrieve the physical address for a given agent from Customer Profiles.
2. Create an outbound whisper flow that relays this physical address as part of the emergency out dial.
3. Add a task that sends notifications when an E911 call is placed.

Create an outbound whisper flow that relays the physical address

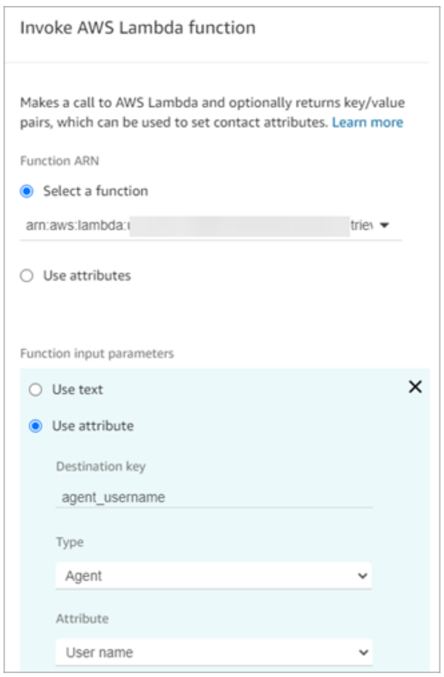
For outbound voice calls within Amazon Connect, an outbound whisper flow usually specifies the whisper to be played to customer. However, in this case you need to configure an outbound whisper flow to do the following:

1. Inspect the outbound call string from an agent.
2. If the string equals **911** (or **933** in a test environment), then retrieve the agent's stored location/ physical address from Customer Profiles by using a Lambda function to call the SearchProfiles API .
3. Attach the physical address to a contact attribute and proceed with the 911 (or 933) outbound call.

The following illustration shows an example outbound whisper flow. It is configured to inspect the outbound call string from an agent, and retrieve the stored physical address for that agent by using a Lambda function. It includes the following blocks in sequence: Invoke AWS Lambda function, Set contact attributes, and Call phone number.



- Step 1: Call a Lambda function that retrieves the location for an agent (Input parameter = Agent User Name). The following image shows how to configure an [Invoke AWS Lambda function](#) block is so the agent **username** is passed to the Lambda function.



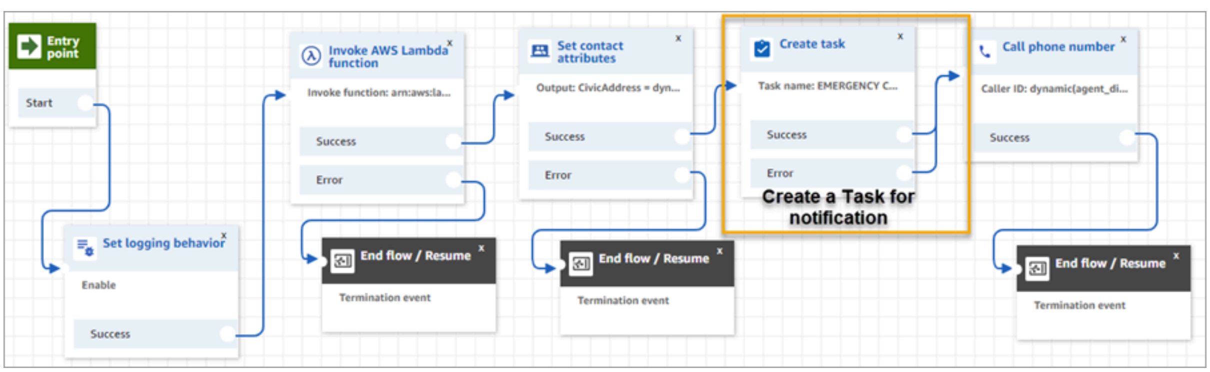
- Step 2: Attach the location received to a contact attribute (see [Format a physical address for E911 to pass to Amazon Connect](#) for the required format).
- Step 3: Update the call origination to the agent's phone number and continue with the outbound call.

> **Note**
>
> The origination number is the caller ID that is passed along with the 911 outbound call. If the origination phone number supports inbound calls, emergency responders will be able to call back the agent in case the initial phone call was disconnected.
>
> - The 911 call is specific to United States. As a result, the origination phone number must be a valid US phone number.
>
>   For example, when an agent places an outbound call, if an invalid US phone number is passed to the carrier network, the carrier can reject the call. To avoid this situation, if the agent uses an invalid number from Amazon Connect, Amazon Connect defaults to the Caller ID that is assigned to the queue in the agent's routing profile.
> - The capability does not place any other rules on this number. For example, the origination number can the phone number of the security front desk.

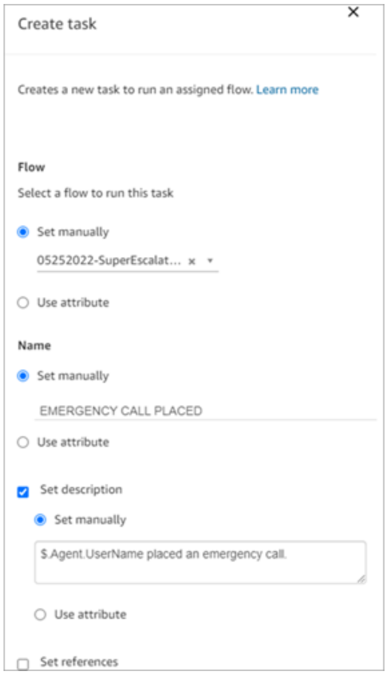
Add a task that sends notifications when an E911 call is placed

When an agent calls 911 it is important to notify in real time the appropriate people in your organization, such as corporate security or a human resources administrator, that someone from the contact center has placed an E911 call. To do this, create an Amazon Connect task in the [outbound whisper flow](). Then add custom notification logic to the task.

The following image shows an example of a [Create task]() block in an [outbound whisper flow](). It is located after the **Set contact attributes** block and before the **Call phone number** block.



The following image shows the **Properties** page for a [Create task]() block. It is configured to notify corporate security that an agent from the contact center has placed an E911 call.



Format a physical address for E911 to pass to Amazon Connect

This topic explains how to format a physical address so it can be passed to Amazon Connect.

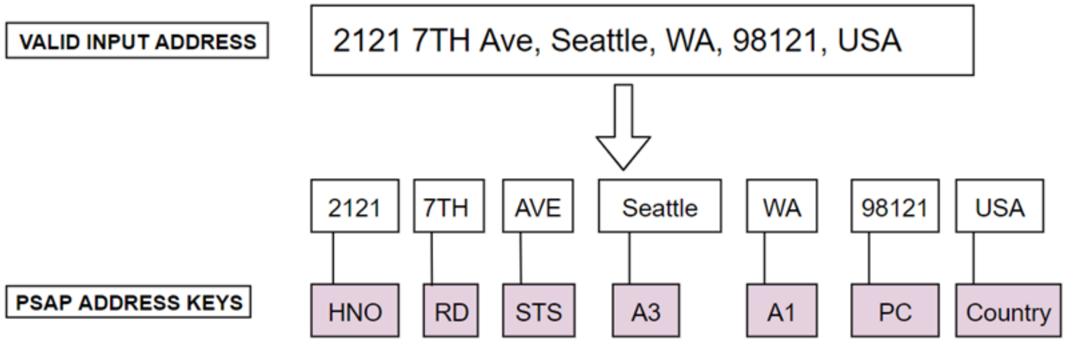
E911 outbound calls require a physical address to be passed to Amazon Connect as a JSON string with keys and values that represent the various fields in the address. For example, consider the following US address:

- 2121 7th Ave, Seattle, WA, 98121, USA

The address must be attached as a JSON string against the key `CivicAddress`, as shown in the following example. Every address field is attached to a specific coded key.

```
CivicAddress:
{"country":"USA","RD":"7th","A3":"Seattle","PC":"98121","HNO":"2121","STS":"Ave"
```

The following illustration shows how an example input address maps to PSAP address keys:



The following table shows a complete list of keys.

Attribute name	Description	Example	Required	Character limit	Recommended character limit
country	The country is identified by the two-letter ISO 3166 code.	US	Required	2	
A1	National subdivisions (state, region, province, prefecture)	NY	Required	2	
A3	City, township, shi (JP)	New York	Required	32	
PRD	Leading street direction	N, W	Required only if applicable to address	2	
POD	Trailing street suffix	SW	Required only if	2	

Attribute name	Description	Example	Required	Character limit	Recommended character limit
			applicable to address		
STS	Street suffix	Avenue, Platz	Required only if applicable to address	5	
HNO	House number (numeric part only)	2121	Required	10	
HNS	House number suffix	A, 1/2	Required only if applicable to address	4	
LOC	Additional location information	Room 543	Optional	60	20 or less
NAM	Name (residence, business or office occupant)	Example Corp	Optional	32	
PC	Postal code	10027	Required	5	
RD	Primary road or street	Broadway	Required	40	

> **Note**
>
> It is your responsibility to validate the address against a standard repository such as the Master Street Address Guide (MSAG).

Programming notes

Currently it isn't possible to pass a JSON structure as an `Attribute` to Amazon Connect. Therefore, the location retrieved by the Lambda function needs to be converted to a JSON string before it is passed to Amazon Connect. For example, using the Python programming language, if the location retrieved is stored in a JSON structure `json_agent_location` then it can be passed to Amazon Connect (from the Lambda function) as follows:

```
return { ,'CivicAddress': json.dumps(json_agent_location)
,'agent_did_number': '+15555551212' }
```

For an address such as the following example:

- 2121 7th Ave, Seattle, WA, 98121, USA

The key-value pair:

```
CivicAddress: {"country": "USA", "RD": "7th", "A3": "Seattle", "PC":
"98121", "HNO": "2121", "STS": "Ave", "A1": "WA"}
```

And the corresponding JSON string that is actually passed to Amazon Connect:

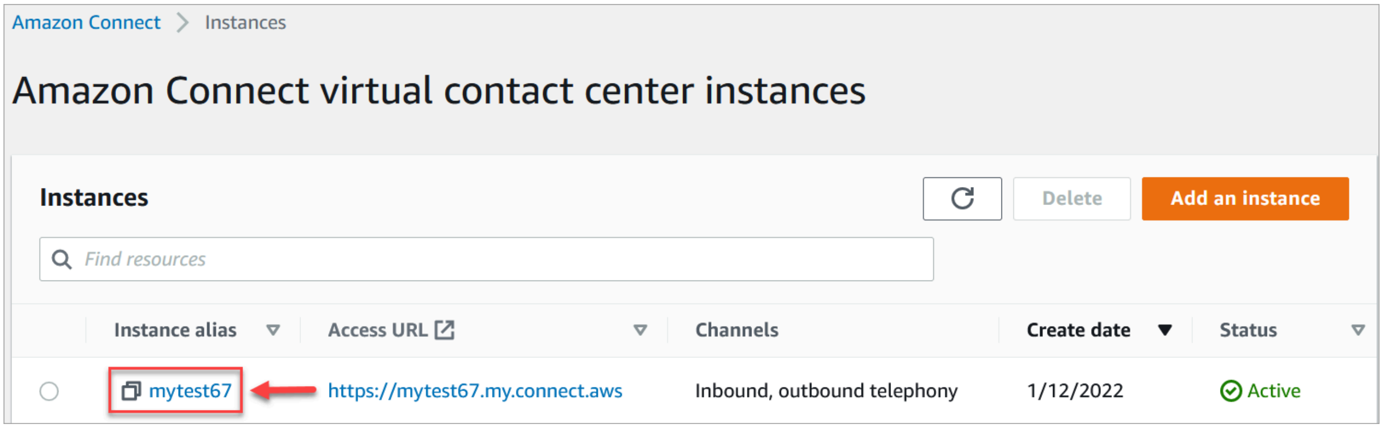
```
CivicAddress: {\"country\": \"USA\", \"RD\": \"7th\", \"A3"\: \"Seattle\",
\"PC\": \"98121\", \"HNO\": \"2121\", \"STS\": \"Ave\", \"A1\": \"WA\"}
```

> **Note**
>
> Using `json.dumps` adds an escape character **** to each quotation mark (**"**).

Enable outbound calls in your Amazon Connect instance

Before your agents can make outbound calls to customers, you need to set up your Amazon Connect instance for outbound communications.

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Amazon Connect URL. The following image shows the **Amazon Connect virtual contact center instances** page, with a box around the instance alias.



3. In the navigation pane, choose **Telephony under Channels and communications**.
4. To enable outbound calling from your contact center, choose **Make outbound calls with Amazon Connect**.
5. To enable outbound campaigns, choose **Enable outbound campaigns**.
6. By enabling early media audio, your agents can hear pre-connection audio such as busy signals, failure-to-connect errors, or other informational messages from telephony providers, when making outbound calls. Choose **Enable early media**.
7. Choose **Save**.
8. Ensure agents have the **Contact Control Panel (CCP) - Make outbound calls** permission in their security profile. For instructions, see Assign a security profile for Amazon Connect to a contact center user.

Note

For a list of countries you can call **by default** based on the Region of your instance, see Countries that call centers using Amazon Connect can call by default.
For a list of all countries available for outbound calls based on the Region of your instance, see Amazon Connect pricing. If a country is not available in your dropdown menu, open a ticket to add it to your allowlist.

Outbound calling restrictions in Amazon Connect

This topic explains restrictions that are in place for outbound calling with Amazon Connect.

Contents

Use of toll-free numbers outside the country of origin

Amazon Connect does not support the use of toll-free numbers for international calling. International calls from toll-free numbers can be flagged as spam by downstream providers, resulting in negative reputation scores. They can also generate unexpected fees for call recipients.

Use of UIFN numbers for outbound dialing

UIFN numbers are designed to be used for inbound calls only. They cannot be used for outbound calling. If you attempt to use UIFN for outbound calling, the calls will be blocked.

Redirection of calls

If you are using Amazon Connect to redirect calls: If you are receiving calls with Anonymous (withheld CLI), you must use an Amazon Connect number for the transfer. See Set up outbound caller ID in Amazon Connect.

International calling restrictions

Amazon Connect has several restrictions on international calling. These are based on requirements in the following specific jurisdictions.

South Africa

South African mobile numbers available under the DID option are designed to be national-only services and are not supported for international calling.

Taiwan

Taiwan DID's are set up to be in-country only services and are not internationally reachable.

China

Chinese carriers are increasingly blocking international routes into China unilaterally. Amazon Connect has taken steps to continue to support our existing customers but require that all customers comply with additional requirements for continued use. Starting October 14, 2023 all customers approved to call China are required to follow these conditions.

Eligibility criteria

- **Unsupported use cases**
  - Short calls and alerting (less than 15 seconds).
  - High volume of calls, especially when done over a short period of time, using the same outbound caller ID (more than 5 calls per minute).
  - Any form of cold calling.
  - Any calls to invalid phone numbers. All numbers called must be validated as accurate.
  - Repeated calls using the same FROM / TO numbers.
  - Attempts to call China FROM any number that has not been pre-approved.
- **Supported use cases**
  - Direct calls to known business entities. For example, calling a hotel or IT support function.
  - Calling users who attempted to engage with your business. For example, university placement schemes or product purchases.

Data required for setup

To request the ability to call Chinese telephone numbers (+86), perform the following steps:

- You must provide an exact list of telephony numbers you will use to phone China.
  - The number must be a DID provided by Amazon Connect. No other number is acceptable.
  - The number cannot be a DID provided by Hong Kong, Macau, Taiwan, China, or Singapore.

> **Note**
>
> The above list may change at any time.

- Any number used to call Chinese telephone numbers must be able to called back. You must also implement a call back message that clearly states the name of the company that is associated with the phone number.
- You must provide a detailed description of your use case, and confirm that you meet the eligibility criteria described in this topic.

Consequences for violating the calling criteria for China

Amazon Connect has a zero tolerance policy for calling into China. Amazon will suspend your use of Amazon Connect if you use the service for any of the restricted use cases identified in this topic. It is essential that the administrators of your Amazon Connect service focus on ensuring the members of your organization are aware of these restrictions, as ignorance of the rules is not an acceptable reason for breach.

Service assurance

In the event of further incidents where Chinese carriers block major international routes without prior warning and impact the ability to call China, the exemptions in the Amazon Connect Service Level Agreement will take effect.

Optimize your reputation for outbound calling in Amazon Connect

In the contact center industry one of the most difficult tasks is understanding why customers don't answer calls when you dial out. Is the customer deliberately not answering, or are they busy on a work call or answering the door? For contact centers it's impossible to know but there are things you can do about it.

This topic provides recommended steps you can take to improve your call answer rates for outbound calling.

Step 1: Know your customer's preferred contact method

One of the biggest mistakes that contact centers make is not knowing whether the customer wants to be contacted by telephone call. When the customer engaged with you, did you check whether they want to be reached by phone, e-mail, or text?

Businesses with multi-channel engagement outperform 70% on average compared to business without multi-channel engagement.

Step 2: Brand your calls

By using call branding solutions, you can provide enhanced call displays that include your business name, logos, reason for the call, and your service. Branding your calls increases the call answer rate by 30%.

Amazon Connect partners with solutions providers like First Orion and Neustar to offer branded calling services.

Step 3: Select caller IDs that mean something to your customer

Not every contact center is the same. What works for some might not work for others. But there are correlations in how successful outbound campaigns are based on your caller ID. Following are a few suggestions to try creating meaningful caller IDs:

- **Area localization**. Use a caller ID in the same area as the prospect.
- **City localization**. Use a caller ID in the same city as the prospect.
- **Recognizable golden toll free number** such as 0800 123 0000.
- **Mobile numbers**. Where countries permit this, it may be possible to use a virtual mobile number to dial out from a contact center. For a list of countries where Amazon Connect supports mobile numbers, see Region requirements for ordering and porting phone numbers in Amazon Connect.

Step 4: Make sure your campaign is calling valid numbers

Many businesses don't have a process to ensure that customer details are up to date. With people being more mobile than ever, it's essential for businesses to keep updated contact information. If customers are not answering your calls, we recommend using Amazon Pinpoint to validate your phone numbers. It may be the customer is no longer at the phone number you are calling.

Step 5: Make outbound calls at optimal times

Another strategy for outbound call campaigns is making sure that calls are placed at the best times. It is critical to never harass your customers or prospects—no one wants to be contacted multiple times by the same company. Generally speaking, it is never a good idea to call before 10:00AM or after 5:00PM as people are at their busiest or need their quiet time. Customers should be called when it's a good for them, depending on their profile. This may mean that one customer should be called around noon, while another is more accessible in the afternoon.

In addition, there are regulations such as TCPA (in the US) and OFCOM (in the UK) that provide guidance on when not to call end customers. We strongly recommend that you abide by such regulations.

Step 6: Manage and monitor the reputation of your caller IDs

If you are in the US it's essential to register you business numbers to help manage the reputation of your caller ID through a service like Free Caller Registry.

Even if you manage your number registrations, if you make enough calls and don't manage your calling profile, there will be people who will flag your caller ID as spam. This is possible even with the most legitimate outbound call campaigns.

If your caller ID is being flagged as spam, it can manifest in two ways:

1. **Automatic blocking**. Block lists are implemented on a vendor-by-vendor basis. For example, when a certain threshold of reports is reached with application providers such as Hiya.com on Samsung devices, up to 20% of your prospects will become instantly unreachable.
2. **Complaints**. There are numerous websites where people complain about calls from specific caller IDs. A number of your prospects will search your caller ID online when you call them. If it has a bad reputation, they will be less likely to answer.

The fastest way to recover from a flagged caller ID is to switch to a new phone number. See the next step.

Step 7: Use multiple numbers as a callerID

Today, outbound contact centers typically embrace an intelligent, more efficient manner of dialing.

For example, one method is to use multiple phone numbers when placing outbound calls. Customers are more likely to answer a call if they feel that they are not being called repeatedly by the same number. In fact, using the same phone number repeatedly is a sure way to annoy customers and prospects who may feel they are being contacted too often.

Step 8: Engage with App Vendors

One of the most difficult issues with the industry as it currently stands is that a large number of vendors provide in-app services to block calls. If one of these in-app services marks your number as spam then you have to pay the premium fees to remove your number from their spam list.

Some of the third party vendors are joining in partnership to increase the call answer rate.

Step 9: Add messaging to your outreach strategy to let customers know who you are

It's inevitable that you'll end up with a list of unanswered calls that you weren't able to connect. There are a variety of creative ways to use SMS with prospects. Here are some ideas to increase answer rates with your prospects.

1. Send an SMS before calling, letting them know who you are and when you will be calling, optionally allowing them to reschedule to a more convenient time.
2. If the prospect doesn't answer, send an SMS to allow them to reschedule the call or request a call back.
3. Re-engage with prospects with promotional offers or discounts that resonates with your prospects.

Step 10: Validate your outbound calling strategy

By making data-driven decisions and continuously iterating, you'll have the best chance to deliver real business value. You should treat each change that you make to your outbound calling strategy as an experiment, and ensure you have the ability to measure and compare the effectiveness of the changes you are making.

One of the best things with Amazon Connect is the service is readily available to experiment. You can establish a baseline and then compare any changes to help you to assess how you can succeed.

Manage users that you add to Amazon Connect

As the admin one of your key responsibilities is to manage users, add users to Amazon Connect, give them their credentials, and assign the appropriate permissions so they can access the features needed to do their job.

The topics in this section explain how to add users using the Amazon Connect admin website. To manage users programmatically, see User management actions in the *Amazon Connect API Reference Guide*.

Contents

- Add users to Amazon Connect
- Edit users in bulk in Amazon Connect
- View historical changes to user records
- Download a user list from your Amazon Connect instance
- Delete users from your Amazon Connect instance
- Reset a user's password for Amazon Connect
- Security profiles for Amazon Connect and Contact Control Panel (CCP) access

Add users to Amazon Connect

When you add users to Amazon Connect, you can configure them with information appropriate to their roles. For example, you specify their security profile, which indicates the tasks they can perform in Amazon Connect admin website. For agents you specify their routing profile, which indicates the contacts that can be routed to them.

This topic explains how to add users using the Amazon Connect admin website. To add users programmatically, see CreateUser in the *Amazon Connect API Reference Guide*. To use the CLI, see create-user.

Add a user individually

1. Log in to the Amazon Connect admin website at https://`instance name`.my.connect.aws/. Use an **Admin** account, or an account assigned to a security profile that has **Users - Create** permission.
2. In Amazon Connect, on the left navigation menu, choose **Users**, **User management**.
3. Choose **Add new users**.
4. Choose **Create and set up a new user** and then choose **Next**.
5. Enter the name, email address, secondary email address, mobile number, and password for the user.

> **Note**
>
> SAML users don't have primary email addresses, they have username logins. A username login is typically an email address but it doesn't have to be. For these users the field label **Email address** is empty inside Amazon Connect. When email

notifications are sent for SAML users, they must have a secondary email configured in order to get it. If a secondary email is not configured, the user won't receive the email.

> **Tip**
>
> Mobile number is not currently used by Amazon Connect.

6. Choose a routing profile and a security profile.
7. Optionally, add tags to identify, organize, search for, filter, and control who can access this hours of operation record. For more information, see Add tags to resources in Amazon Connect.
8. Choose **Save**. If the Save button isn't active, it means you're logged in with an Amazon Connect account that doesn't have the required security profile permissions.

   To fix this issue, log in with an account that is assigned to the Amazon Connect Admin security profile. Or, ask another Admin to help.
9. For information about adding agents, see Configure the agent's profiles and task settings in Amazon Connect.

Add users in bulk from a .csv file

You can add up to 1000 users at a time by using a .csv file.

> **Note**
>
> Avoid adding too many unique resources in the .csv file. For example, don't add more than 100 different routing profiles. This may cause a timeout or failure during the validation process.
> Bulk upload is for adding new records, not for editing existing records. To edit user records in bulk, see Edit users in bulk in Amazon Connect.

Use these steps to add several users from a .csv file such as an Excel spreadsheet.

1. Log in to Amazon Connect with an **Admin** account, or an account assigned to a security profile that has **Users - Create** permission.

2. In Amazon Connect, on the left navigation menu, choose **Users**, **User management**.

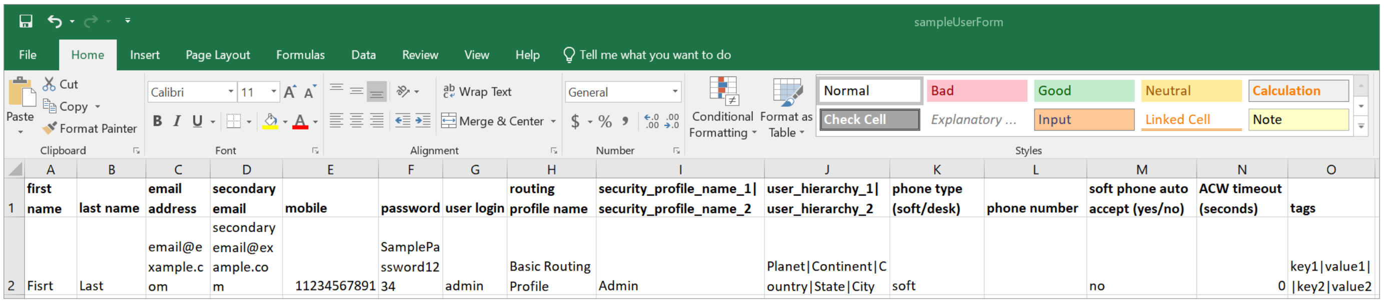
3. Choose **Add new users**.

4. Choose **Import users using a .csv template** and then choose **.csv template**.

   The .csv template has the following columns in the first row:

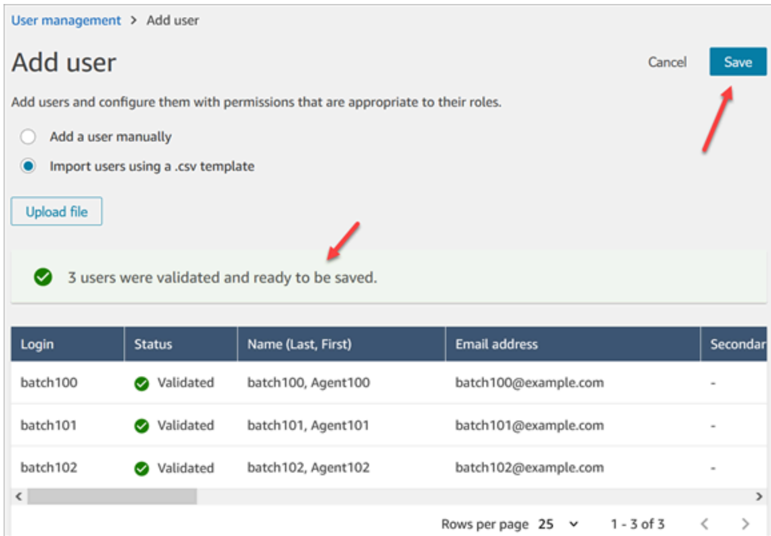
   - first name
   - last name
   - email address
   - secondary email address
   - mobile: This is not currently used by Amazon Connect.
   - password
   - user login
   - agent hierarchy
   - routing profile name
   - security_profile_name_1|security_profile_name_2
   - user_hierarchy_1|user_hierarchy_2
   - phone type (soft/desk)
   - phone number
   - soft phone auto accept (yes/no)
   - ACW timeout (seconds)
   - tags

   The following image shows a sample of what the .csv template looks like in an Excel spreadsheet. The first row in the spreadsheet contains the column headings, and the second row contains sample user data.



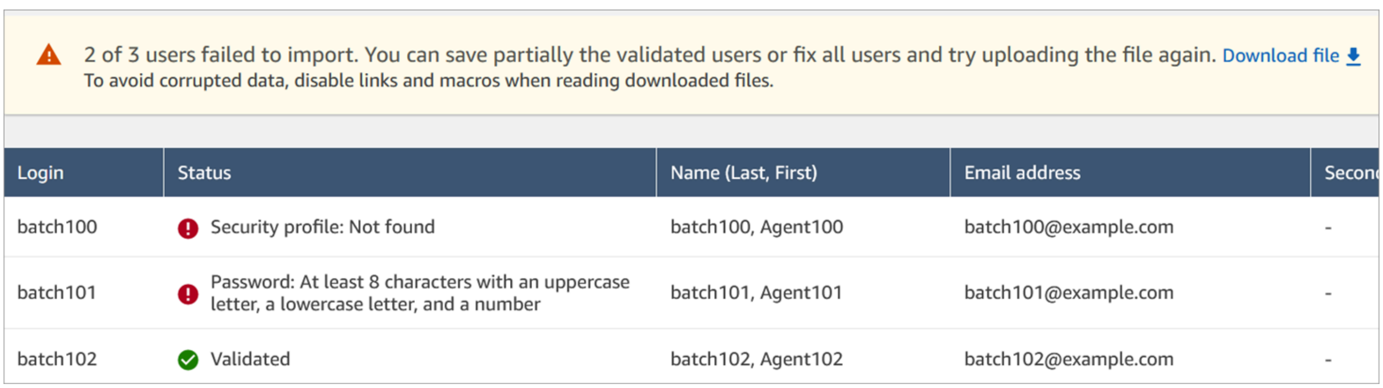
5. Add your users to the template and upload it to Amazon Connect. Choose **Upload file and verify**.

6. Amazon Connect validates the data in the file. Choose **Save** to create the new user records.

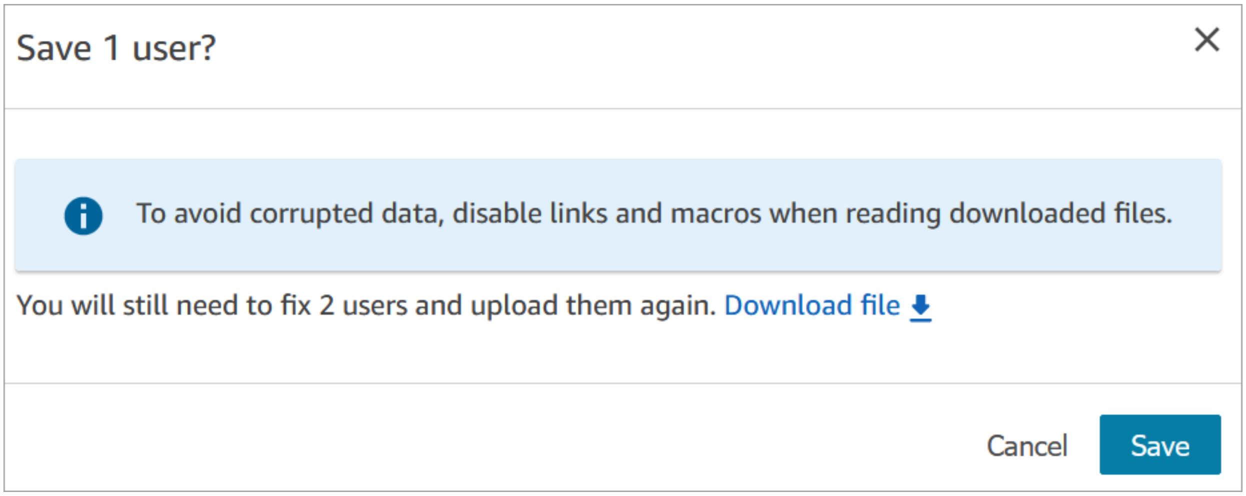


If you get a validation error message, it usually indicates that one of the required columns is missing information, or there's a typo in one of the cells.

The following image shows an example validation error message. In this case, the security profile was misspelled and a password didn't meet requirements.



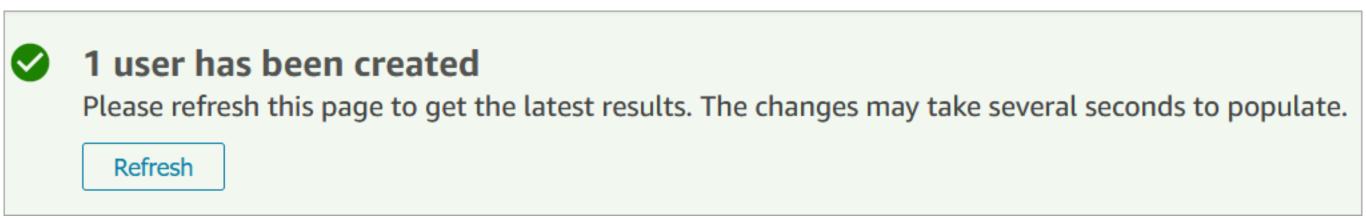
7. To upload only the validated user records, choose **Save**. A dialog box prompts you for confirmation.



8. A banner displays the status of the upload and confirms when it's complete.

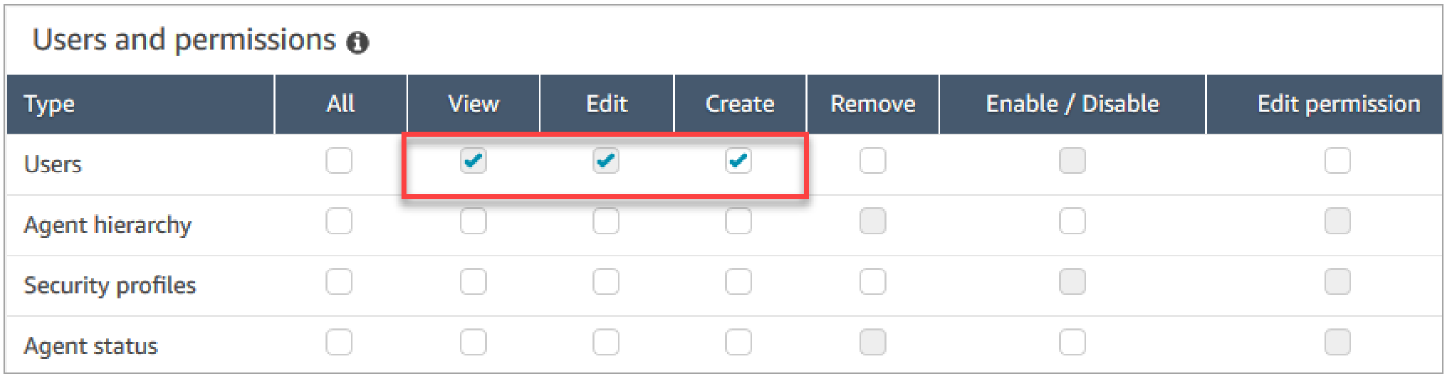
> **Tip**
>
> While a batch of additions is being processed, you can continue working on the **User management** page, choosing another batch of user records to create, edit, or delete, in bulk or individually. This is useful for quickly updating settings such as routing profiles for groups of agents.
> Amazon Connect sequentially processes the records in bulk.

9. Choose **Refresh** to update the **User management** page with the users that have been created.



Required permissions for adding users

Before you can add users to Amazon Connect, you need the following permissions assigned to your security profile: **Users - Create**. The following image shows that this security profile permission is in the **Users and permissions** section of the **Add/Edit security profile** page.



By default, the Amazon Connect **Admin** security profile has these permissions.

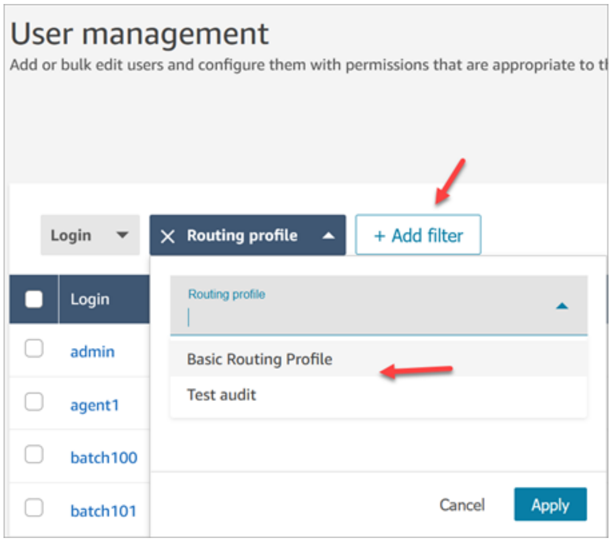
For information about how to add more permissions to an existing security profile, see [Update security profiles in Amazon Connect](#).

Edit users in bulk in Amazon Connect

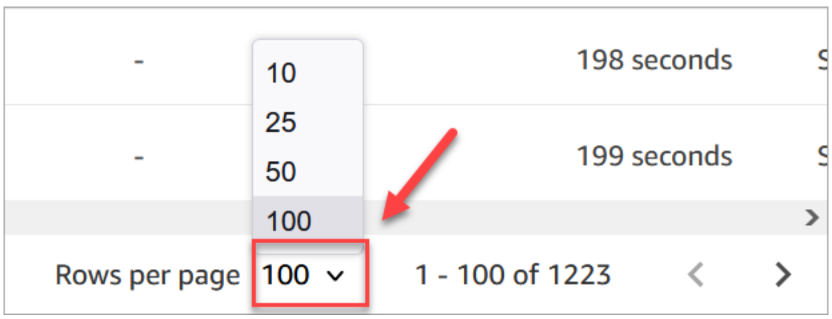
Bulk edit mode enables you to quickly edit the attributes that are common across user records, such as routing profiles, security profiles, and tags.

> **Tip**
>
> While a batch of bulk edits is being processed, you can continue working on the **User management** page, such as selecting more records to edit or delete, in bulk or individually. This is useful for quickly updating settings, such as routing profiles for groups of agents.

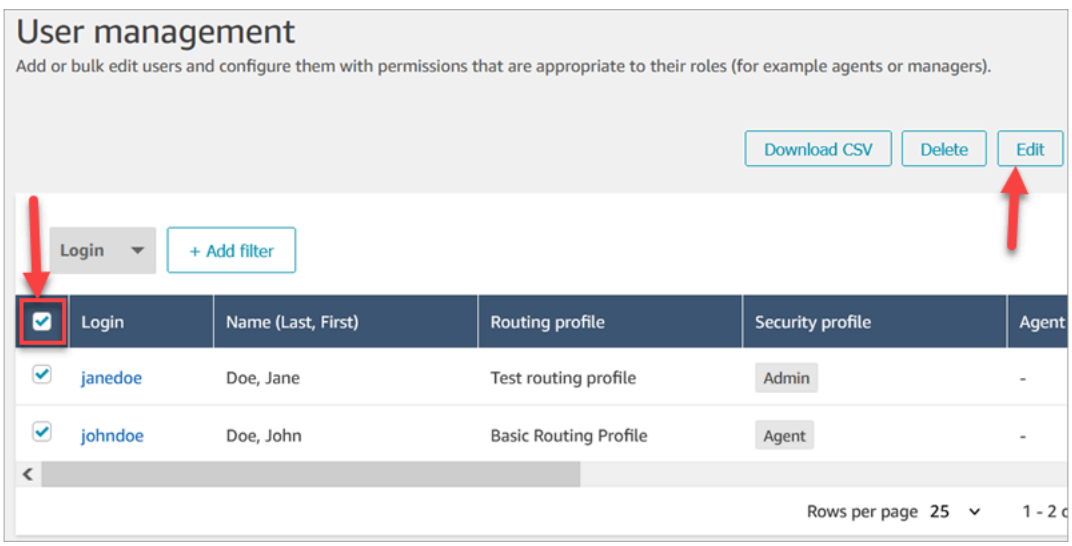
1. Log in to Amazon Connect with an Admin account, or an account assigned to a security profile that has **Users - Edit** permission.
2. In Amazon Connect, on the left navigation menu, choose **Users**, **User management**.
3. If needed, choose **Add filter** to specify a subset of users, such as users with a specific **Routing profile**. This option is shown in the following image.



4. To quickly update a large number of users, at the bottom of the table choose to display **100** rows per page, as shown in the following image.



5. To edit all the records on the page, choose the top box. Otherwise, select one or more records you want to edit at the same time. Choose **Edit**.



6. On the **Bulk edit** page, in the **Settings** section, you can choose the following settings for all of the selected users:

- Security profile
- Routing profile
- Phone type
- After Call Work (ACW) timeout
- Agent hierarchy, if this has been set up
- Tags

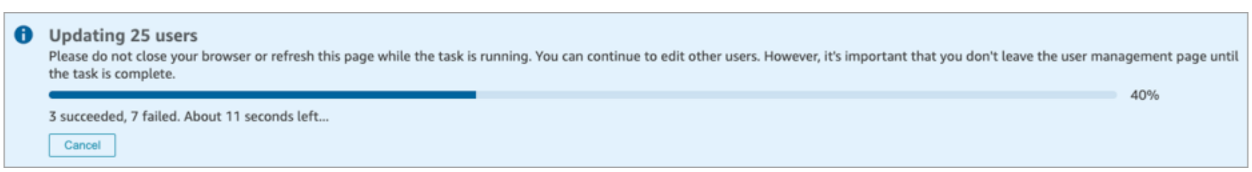
7. Choose **Save** to apply your changes to the selected records.
8. While that batch of user records is being updated, you can continue working on the **User management** page, performing other create, edit, and delete tasks on user records.

Perform other edit tasks while a batch of bulk edits is being processed

After saving an update for a group of users, you can either make additional changes on the **Bulk edit** page (for example, [edit other user details](#) such as contact information) or you can choose different user records to edit.

> **Important**
>
> As long as you remain on the **User management** page, your update request will continue to be processed. Review the messages at the top of the page for the status of the update.

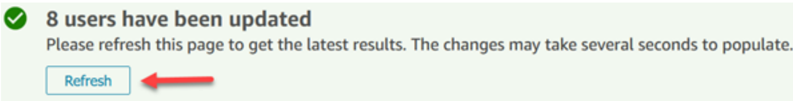
The following image shows an example of message at the top of the **User management** page that Amazon Connect is updating a batch of user records.



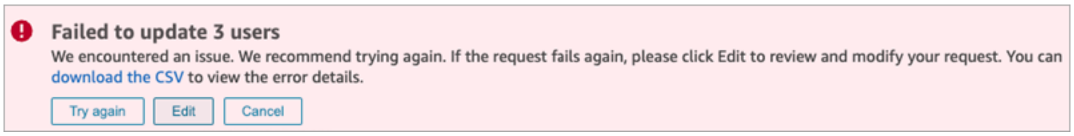
When you perform additional tasks on the **User management** page, Amazon Connect appends the next request to create, edit, or delete user records to the existing status message at the top of the page. Amazon Connect sequentially processes them in bulk.

Following are some tips about how Amazon Connect processes bulk edit requests.

- If you choose **Cancel** during a bulk create, edit, or delete, **only those requests not yet processed are canceled**.
- A message displays how many users were successfully updated. Choose **Refresh** to refresh the page with the list of the updated users.



- If some user records fail to be updated, a message similar to the following image is displayed:

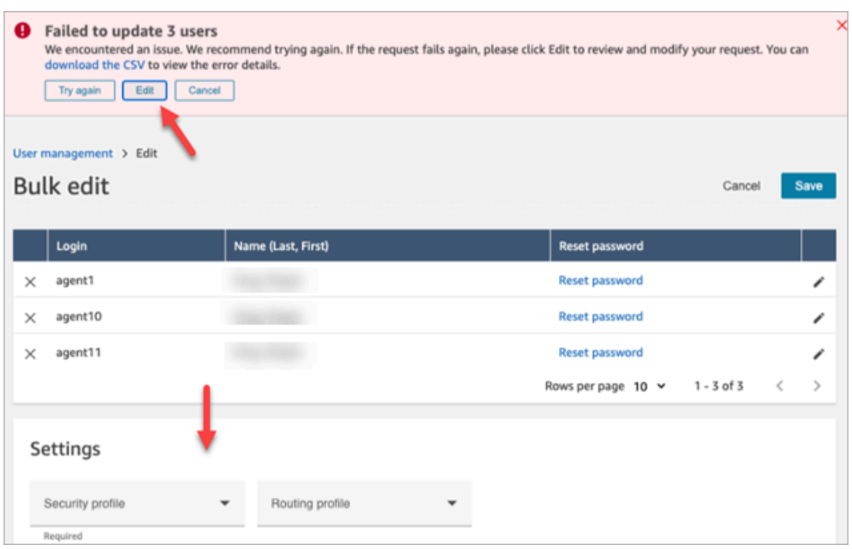


You have the following options:

- Choose **download the CSV** to discover the reason changes weren't updated. In the following example, the agent hierarchy was deleted before the user records were saved.

	A	B	C
1	Login	Failed reason	Failed fields
2	agent12	We couldn't save some of the fields	Agent hierarchy: Not found
3	agent13	We couldn't save some of the fields	Agent hierarchy: Not found
4	agent14	We couldn't save some of the fields	Agent hierarchy: Not found
5			

- Choose **Try again** to resubmit only those user records that failed. The others were already successfully updated.
- Choose **Edit** to be directed to the **Bulk edit** page so you can change the input for the user records that failed.

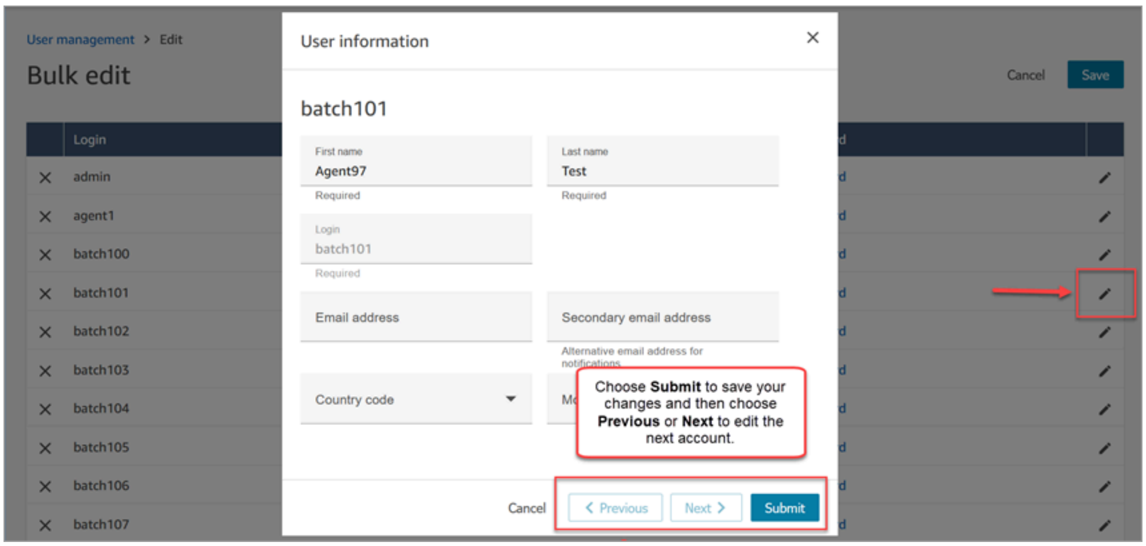


- Choose **Cancel** to not do anything with the 3 user records that weren't updated.

Edit other user details

You can page through selected user records to make updates to contact information, rather than choosing and opening each record individually.

1. On the **Bulk edit** page, select the user records you want to edit.
2. Choose the **Edit** (pencil) icon next to individual users to make updates.
3. A dialog box opens for the individual user. Make your changes, and choose **Submit**.
4. If needed, choose **Previous** and **Next** to open the next user record in the list. The following image shows the **Edit** dialog box for a single user while in bulk edit mode.



Edit user settings programmatically

You can change the following values programmatically across selected users. The users are changed to the same value.

Property	API	CLI
Routing profiles	UpdateUserRoutingProfile	update-user-routing-profiles
Security profiles	UpdateUserSecurityProfiles	update-user-security-profiles
Tags	TagResource	tag-resource

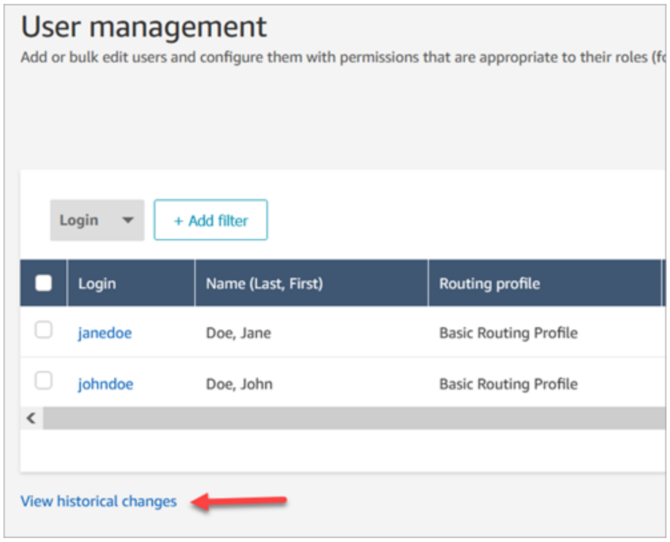
Property	API	CLI
	[UntagResource]()	[untag-resource]()
User hierarchies	[UpdateUserHierarchy]()	[update-user-hierarchy]()
User phone configuration	[UpdateUserPhoneConfig]()	[update-user-phone-config]()

You can edit the following identity and contact information programmatically for an individual user: first name, last name, email address, mobile number, secondary email address. Use the following API or CLI:

Property	API	CLI
Identify and contact information	[UpdateUserIdentityInfo]()	[update-user-identity-info]()

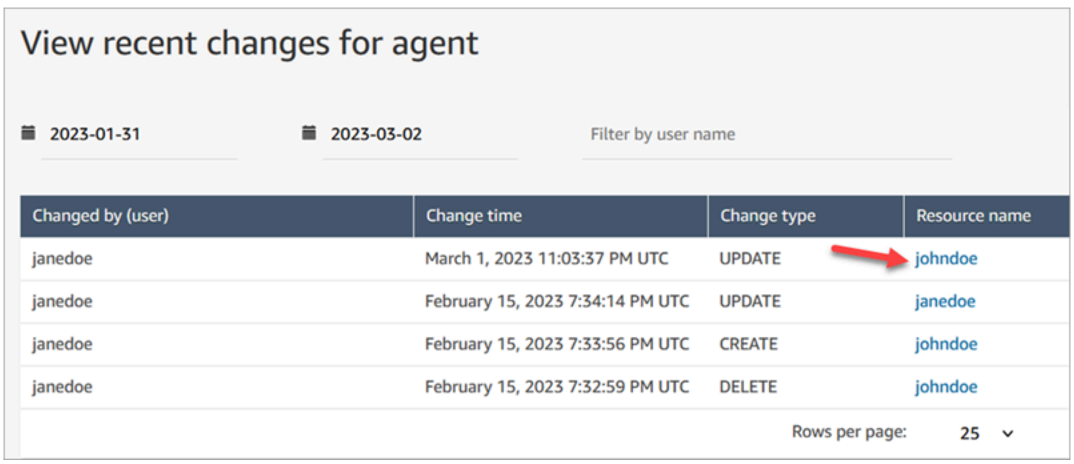
View historical changes to user records

1. Log in to the Amazon Connect admin website at https://`instance name`.my.connect.aws/. Use an **Admin** account, or an account assigned to a security profile that has **Users and permissions - Users - View** permissions.
2. In Amazon Connect, on the left navigation menu, choose **Users**, **User management**.
3. On the **User management** page, choose **View historical changes**, as shown in the following image.

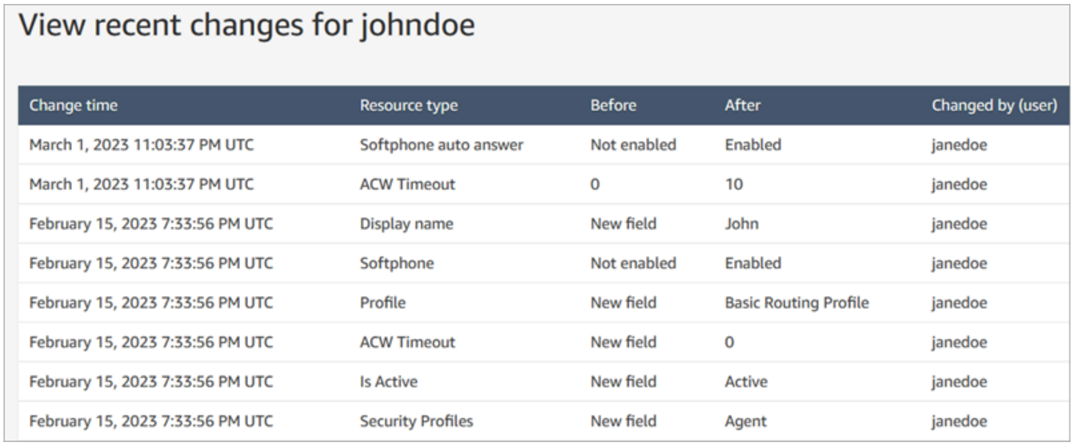


4. On the **View recent changes for agent** page, there is one row for each time a user record was changed. In the following image, there are multiple rows for **johndoe** because that user record has been updated multiple times.

   To view the past changes for a specific user, choose their user name.



5. On the **View recent changes for [resource name]** page, you can view details about what has been changed in the user record, when, and who made the change, as shown in the following image.



View recent changes for johndoe

Change time	Resource type	Before	After	Changed by (user)
March 1, 2023 11:03:37 PM UTC	Softphone auto answer	Not enabled	Enabled	janedoe
March 1, 2023 11:03:37 PM UTC	ACW Timeout	0	10	janedoe
February 15, 2023 7:33:56 PM UTC	Display name	New field	John	janedoe
February 15, 2023 7:33:56 PM UTC	Softphone	Not enabled	Enabled	janedoe
February 15, 2023 7:33:56 PM UTC	Profile	New field	Basic Routing Profile	janedoe
February 15, 2023 7:33:56 PM UTC	ACW Timeout	New field	0	janedoe
February 15, 2023 7:33:56 PM UTC	Is Active	New field	Active	janedoe
February 15, 2023 7:33:56 PM UTC	Security Profiles	New field	Agent	janedoe

Download a user list from your Amazon Connect instance

You can export a list of users from Amazon Connect to a .csv file. The output is limited to the results that appear on the page; it does not include all the users, if you have more users than appear on the page.

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an **Admin** account, or an account assigned to a security profile that has **Users and permissions - Users - View** permissions.
2. In Amazon Connect, on the left navigation menu, choose **Users**, **User management**.
3. Choose **Download CSV**.

Delete users from your Amazon Connect instance

Important

- You can't undo a deletion.
- When a user is deleted from Amazon Connect, you won't be able to configure their agent settings any more. For example, you won't be able to assign a routing profile to them.
- If you delete a user record that has an associated quick connect, you need to [delete the quick connect](), too. Otherwise it will be orphaned. When agents attempt to transfer calls to it, no one is there to answer the call.

- Orphaned quick connects can disrupt other Amazon Connect processes such as instance replication and syncing processes that are done as part of [Amazon Connect Global Resiliency](#).

This topic explains how to delete user records using the Amazon Connect admin website. To delete user records programmatically, see [DeleteUser](#) in the *Amazon Connect API Reference Guide*. To use the CLI, see [delete-user](#).

What happens to the user's metrics?

The user's data in contact records and reports is retained. The data is preserved for the consistency of the historical metrics. For example, when you search for contact records, you'll still see the agent's username, any contact recordings involving the agent, etc.

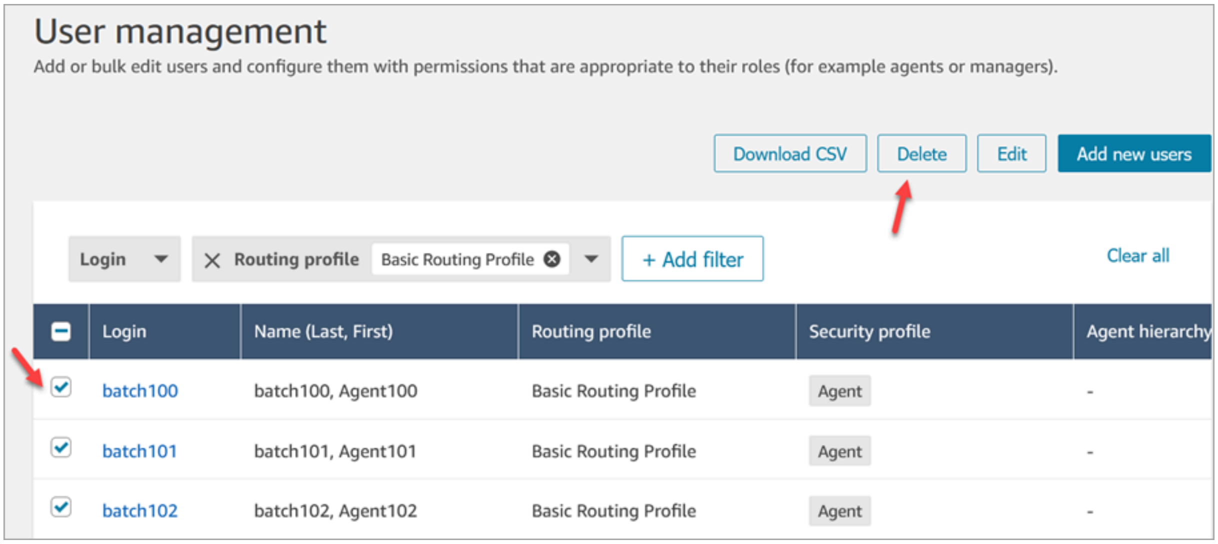
In the historical metrics reports, the agent's data will be included in the **Agent performance** metrics report. However, you won't be able to see an **Agent activity audit** of the deleted agent because their name won't appear in the drop-down list.

How to delete users

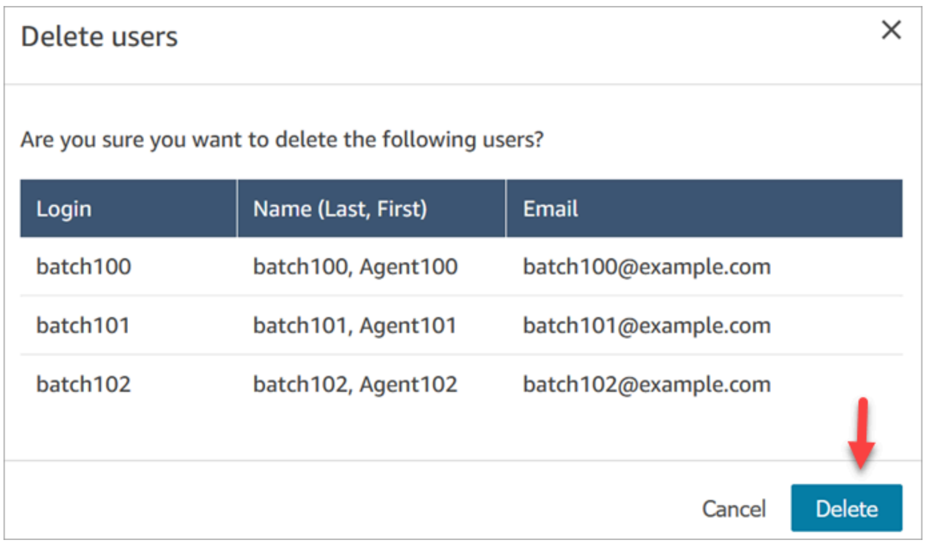
Tip

- While a batch of deletions is being processed, you can continue working on the **User management** page, choosing another batch of user records to create, edit, or delete, in bulk or individually. This is useful for quickly updating settings such as routing profiles.
-

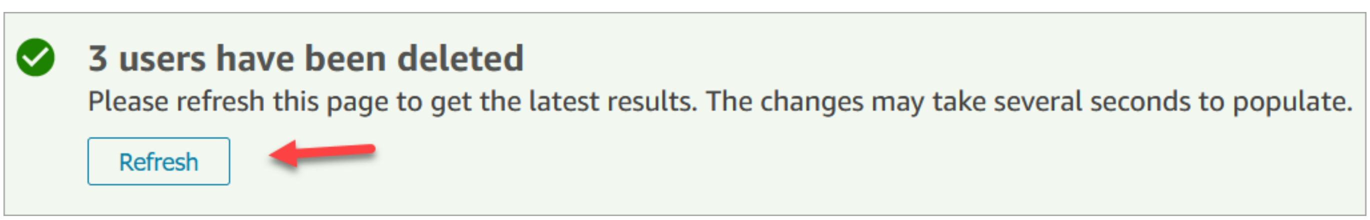
1. Log in to Amazon Connect using an **Admin** account, or an account assigned to a security profile that has **Users - Remove** permission.
2. In Amazon Connect, on the left navigation menu, choose **Users**, **User management**. Choose one or more users you want to delete, and then choose **Delete**.



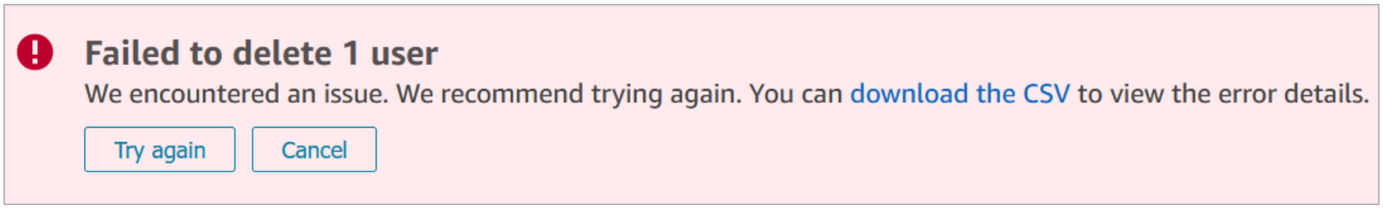
3. Confirm you want to delete the users.



4. The following image shows and example of the message when a user is deleted successfully. Choose **Refresh** to update the list of users on the **User management** page.



5. If Amazon Connect fails to delete one or more user records, it displays a message similar to the following image.



When you get a failed to delete message, you have the following options:

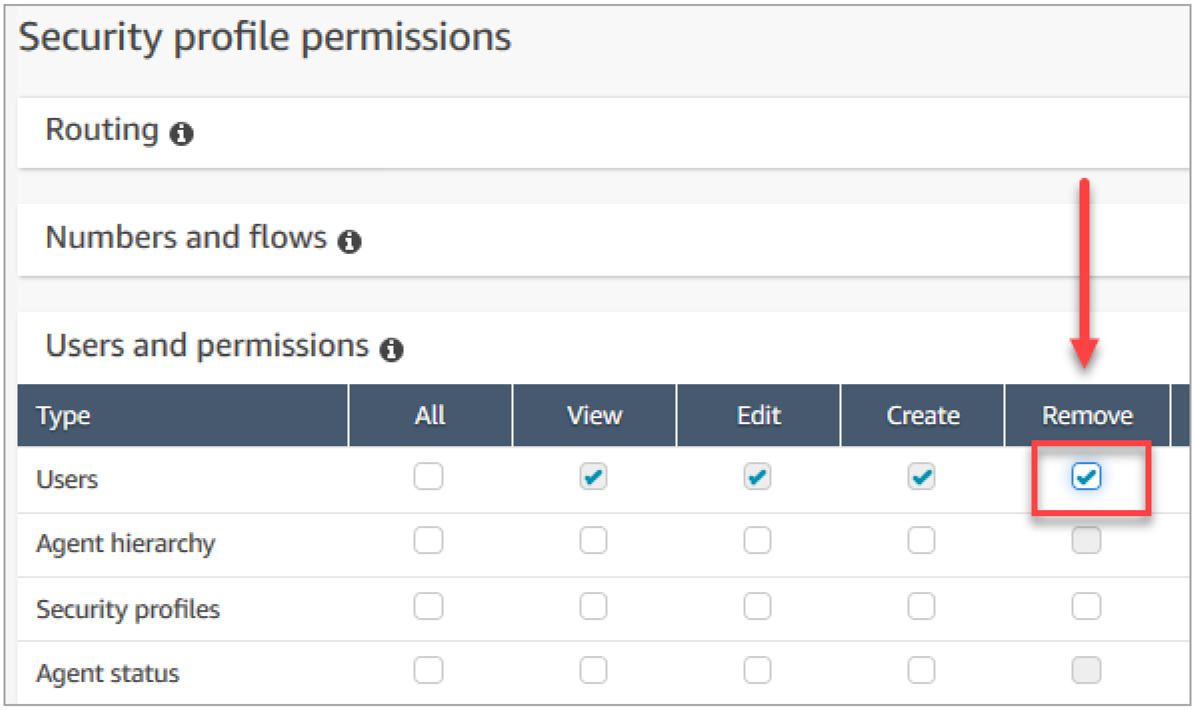
- Choose **download the CSV** to view the error details. The following details show the user records had already been deleted. In this case, I hadn't refreshed the **User management** page and tried to delete the records again.

	A	B
1	Login	Failed reason
2	batch100	The specified user was not found
3	batch101	The specified user was not found
4	batch102	The specified user was not found
5		

- Choose **Try again** to resubmit those records that failed to be deleted. The other records were successfully deleted.
- Choose **Cancel** to not do anything with the user records that weren't deleted.

Required permissions to delete users

Before you can update permissions in a security profile, you must be logged in with an Amazon Connect account that has the following permissions: **Users - Remove**.



By default, the Amazon Connect **Admin** security profile has these permissions.

Reset a user's password for Amazon Connect

To reset a user's Amazon Connect password

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an Admin account, or a user account that has security profile permissions to reset passwords.
2. In Amazon Connect, on the left navigation menu, choose **Users**, **User management**.
3. Select the user and choose **Edit**.
4. Choose **reset password**. Specify a new password and then choose **Submit**.

   Resetting the user's password will immediately log them out of the Contact Control Panel.
5. Communicate the new password to the user.

Reset your own lost or forgotten Amazon Connect admin password

- See Emergency login to the Amazon Connect admin website.

Reset your own agent or manager password

Use the following steps if you want to change your password, or if you forgot it and need a new one.

1. If you're an Amazon Connect agent or manager, at the Amazon Connect login page, choose **Forgot Password**.
2. Type the characters you see in the image, and then choose **Recover Password**.
3. A message will be sent to your email address with a link that you can use to reset your password.

Reset your own lost or forgotten AWS password

- To reset the password you used when you first created your AWS account, see Resetting a Lost or Forgotten Root User Password in the *IAM User Guide*.

Security profiles for Amazon Connect and Contact Control Panel (CCP) access

A security profile is a group of permissions that map to a common role in a contact center. For example, the Agent security profile contains permissions needed to access the Contact Control Panel (CCP).

Security profiles help you manage who can access the Amazon Connect dashboard and Contact Control Panel (CCP), and who can perform specific tasks.

Contents

- Apply hierarchy-based access control in Amazon Connect (Preview)

Best practices for Amazon Connect and Contact Control Panel (CCP) security profiles

- Limit who has **Users - Edit or Create** permissions

  People with these permissions pose a risk to your contact center because they can do the following:

  - Reset passwords, including that of the administrator.
  - Grant other users permission to the Admin security profile. People assigned to the Admin security profile have full access to your contact center.

  Doing these things would enable someone to lock out those who need to access Amazon Connect, and allow in others who can steal customer data and damage your business.

  To reduce the risk, as a best practice we recommend limiting the number of people who have **Users - Edit or Create** permissions.
- Use AWS CloudTrail to log the requests and responses of UpdateUserIdentityInfo. This enables you to track changes made to user information. Someone who has the ability to call the `UpdateUserIdentityInfo` API can change a user's email address to one owned by an attacker, and then reset the password through email.
- Understand inherited permissions

  Some security profiles included inherited permissions: when you assign dedicated permissions to one object, by default permissions are granted to sub-objects. For example, when you grant dedicated permission to edit users, you also grant them permission to list all security profiles for your Amazon Connect instance. This is because to edit users, the person has access to the drop-down list of security profiles.

  Before assigning security profiles, review the list of inherited permissions.
- **Understand the implications of access control tags before applying them to a security profile.** Applying access control tags is an advanced configuration feature that is supported by Amazon Connect and that follows the AWS shared responsibility model. Ensure that you have read the documentation and understand the implications of applying granular permission configurations. For more information, review the AWS shared responsibilities model.
- Track who accesses recordings.

In the **Analytics and Optimization** permission group, you can enable a download icon for recorded conversations. When members of this group go to **Analytics and optimization**, **Contact search**, and then search contacts, they will see an icon to download recordings.

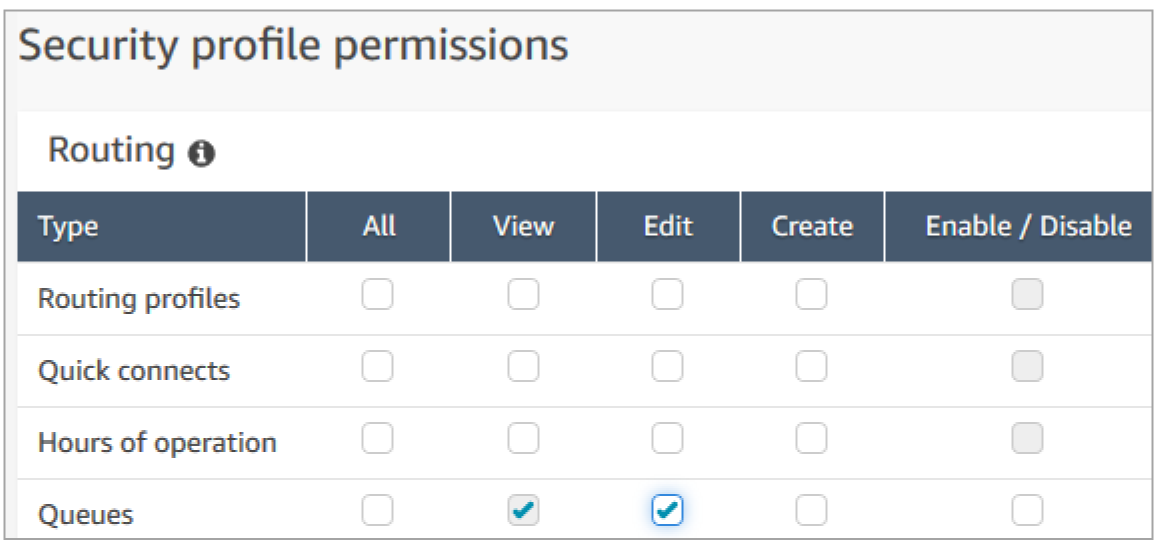
> **Important**
>
> This setting isn't a security feature. **Users who don't have this permission can still download recordings using other less-discoverable ways**.

We recommend that you track who in your organization accesses recordings.

Inherited permissions for Amazon Connect and Contact Control Panel (CCP) security profiles

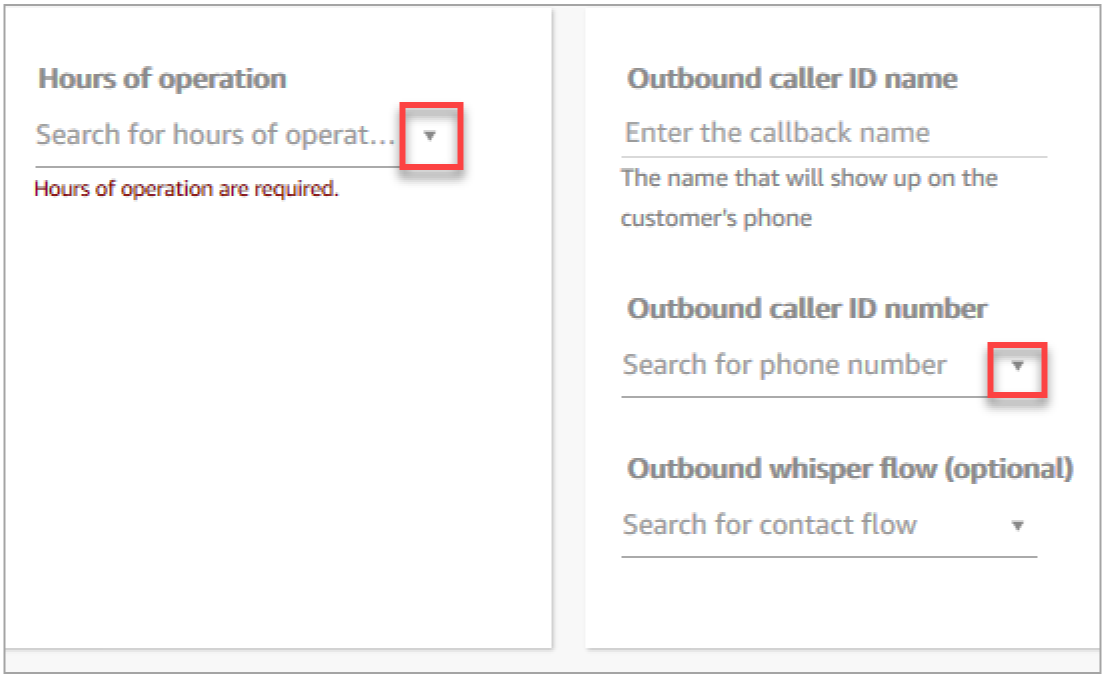
Some security profiles included inherited permissions: when you give a user explicit permissions to **View** or **Edit** one resource type, such as queues, they implicitly inherit permissions to **View** another resource type, such as phone numbers.

For example, assume you explicitly grant someone permission to **Edit/View** queues, as shown in the following image:



By doing this you also implicitly grant them permissions to **View** a list of all phone numbers and hours of operation in your Amazon Connect instance, **when they add them to the queue**. On the

Add new queue page, the available phone numbers and hours of operation appear in dropdown lists, as shown in the following image.



However, the user doesn't have permissions to **Edit** the phone numbers and hours of operation.

In this case, they also don't inherit permissions to **View** contact flows (the outbound whisper flow) and quick connects because those resources are optional.

List of inherited permissions

The following table lists permissions that are implicitly inherited when you assign dedicated permissions to a user.

> **Tip**
>
> When a user has only explicit **View** permissions and not also **Edit** permissions, the objects are retrieved but Amazon Connect doesn't surface them in drop-down lists for the user to peruse.

Dedicated permission	Inherited permissions
Users - View or Edit	When someone edits a user's information in the Amazon Connect console, they can **view**

Dedicated permission	Inherited permissions
	the following information in drop-down boxes when they add it to the user's account: • All security profiles in the instance • All routing profiles in the instance • All agent hierarchies in the instance • All agent proficiencies in the instance
Queues - View or Edit	When someone edits queues in the Amazon Connect console, they can **view** the following information in drop-down and search boxes when they add it to the queue: • All quick connects in the instance • All phone numbers in the instance • All operating hours in the instance
Quick connects - View	• All queues in the instance • All flows in the instance • All users in the instance
Quick connects - Edit	• All queues in the instance • All flows in the instance
Phone numbers - View or Edit	When someone edits phone numbers in the Amazon Connect console (not the CCP), they can **view** the following information in a drop-down box when they associate it with the phone number: • All flows in the instance

List of security profile permissions in Amazon Connect

This topic is for administrators and contact center managers who assign and manage security profile permissions.

The security profile permissions in Amazon Connect allow users access to perform specific tasks in Amazon Connect.

The following tables list:

- **UI name**: The name of the permission as it appears on the **Security profiles** page in Amazon Connect.
- **API name**: The name of the permission when it is returned by the ListSecurityProfilePermissions API.

  For a list of all APIs that you can use manage security profile permissions, see Security profile actions.
- **Use**: The functionality granted by the permission.

Routing

UI name	API name	Use
Routing profiles - Create	RoutingPolicies.Create	Create routing profiles.
Routing profiles - Edit	RoutingPolicies.Edit	Edit routing profiles.
Routing profiles - View	RoutingPolicies.View	View routing profiles.
Quick connects - Create	TransferDestinations.Create	Create quick connects.
Quick connects - Delete	TransferDestinations.Delete	Delete quick connects.
Quick connects - Edit	TransferDestinations.Edit	Edit quick connects.

UI name	API name	Use
Quick connects - View	TransferDestinations.View	View quick connects. Agents need this permission so they can view quick connects in the agent application to transfer calls.
Hours of operation - Create	HoursOfOperation.Create	Set hours of operation and timezone for a queue.
HoursOfOperation - Delete	HoursOfOperation.Delete	Delete hours of operation and timezone for a queue.
HoursOfOperation - Edit	HoursOfOperation.Edit	Edit hours of operation and timezone for a queue.
HoursOfOperation - View	HoursOfOperation.View	View hours of operation and timezone for a queue.
Queues - Create	Queues.Create	Create queues.
Queues - Edit	Queues.Edit	Edit information for a queue, such as name, description, and hours of operation.
Queues - Enable / Disable	Queues.EnableAndDisable	Enable and disable queues to quickly control the flow of contacts to queues temporarily.

UI name	API name	Use
Queues - View	Queues.View	View a list of queues in your Amazon Connect instance.
Task templates - Create	TaskTemplates.Create	Create task templates .
Task templates - Delete	TaskTemplates.Delete	Delete task templates .
Task templates - Edit	TaskTemplates.Edit	Edit task templates.
Task templates - View	TaskTemplates.View	View task templates.
Predefined attributes - View	PredefinedAttributes.View	View predefined attributes.
Predefined attributes - Edit	PredefinedAttributes.Edit	Edit predefined attributes.
Predefined attributes - Create	PredefinedAttributes.Create	Create predefined attributes for routing contacts to agents.
Predefined attributes - Delete	PredefinedAttributes.Delete	Delete predefined attributes.

Channels and flows

UI name	API name	Use
Prompts - Create	Prompts.Create	Create prompts.
Prompts - Delete	Prompts.Delete	Delete prompts.
Prompts - Edit	Prompts.Edit	Edit prompts.

UI name	API name	Use
Prompts - View	Prompts.View	View a list of available prompts.
Flows - Create	ContactFlows.Create	Create flows.
Flows - Remove	ContactFlows.Delete	Delete flows.
Flows - Edit	ContactFlows.Edit	Edit flows.
Flows - Publish	ContactFlows.Publish	Publish flows.
Flows - View	ContactFlows.View	View flows.
Flow modules - Create	ContactFlowModules .Create	Create flow modules for reusable functions .
Flow modules - Remove	ContactFlowModules .Delete	Delete flow modules.
Flow modules - Edit	ContactFlowModules .Edit	Edit flow modules.
Flow modules - Publish	ContactFlowModules .Publish	Publish flow modules.
Flow modules - View	ContactFlowModules .View	View flow modules.
Phone numbers - Claim	PhoneNumbers.Claim	Claim phone numbers.
Phone numbers - Edit	PhoneNumbers.Edit	Edit phone numbers. Attach a claimed or ported phone number to a flow in Amazon Connect.

UI name	API name	Use
Phone numbers - Release	PhoneNumbers.Relea se	Release phone numbers back to inventory.
Phone numbers - View	PhoneNumbers.View	View a list of phone numbers that have been claimed or ported to your Amazon Connect instance.
Communication widget - Enable/Di sable	ChatTestMode	Access a simulated web page so users can test the chat experience. Also grant users the **Contactflow.View** permission so they can view and choose from a list of available flows in the **Test settings** option.
Email addresses		View
Email addresses		Edit
Email addresses		Create
Email addresses		Remove
Views - View	Views.View	Allow access to Views.
Views - Edit	Views.Edit	Allow access to edit Views.

UI name	API name	Use
Views - Create	Views.Create	Create custom view resources.
Views - Remove	Views.Remove	Remove View resources.
AnalyticsConnectors - Edit	AnalyticsConnector s.Edit	Edit existing analytics connectors.
AnalyticsConnectors - View	AnalyticsConnector s.View	View existing analytics connectors.

Users and permissions

UI name	API name	Use
Users - Create	Users.Create	Add users to Amazon Connect. We recommend you limit who has these permissions. They pose a risk to your contact center because they can do the following: • Reset passwords, including that of the administrator. • Grant other users permission to the Admin security profile. People assigned to the Admin security

UI name	API name	Use
		profile have full access to your contact center. Doing these things would enable someone to lock out those who need to access Amazon Connect, and allow in others who can steal customer data and damage your business.
Users - Delete	Users.Delete	[Delete users from Amazon Connect]().
Users - Edit	Users.Edit	View and edit all user identity information *except* for security profiles. As with **Users - Create**, limit who has these permissions because they pose a risk to your contact center.
Users - Edit permission	Users.EditPermission	View and edit user security profiles. As with **Users - Create**, limit who has these permissions because they pose a risk to your contact center.

UI name	API name	Use
Users - View	Users.View	View user records. Download or export a list of users from your Amazon Connect instance to a CSV file.
Agent hierarchy - Create	AgentGrouping.Create	Create agent hierarchies. Add groups, teams, and agents.
Agent hierarchy - Edit	AgentGrouping.Edit	Edit agent hierarchies.
Agent hierarchy - Enable/Disable	AgentGrouping.EnableAndDisable	View or edit agent hierarchy information.
Agent hierarchy - View	AgentGrouping.View	View the agent's hierarchy information in a real-time metrics report, which can include their location and skill set data.
Security profiles - Create	SecurityProfiles.Create	Create security profiles.
Security profiles - Delete	SecurityProfiles.Delete	Delete security profiles.
Security profiles - Edit	SecurityProfiles.Edit	Update security profiles.
Security profiles - View	SecurityProfiles.View	View security profiles.

UI name	API name	Use
Agent status - Create	AgentStates.Create	Create an custom agent status. The status appears in the Contact Control Panel (CCP), such as Break, Lunch, or Training.
Agent status - Edit	AgentStates.Edit	Edit a custom agent status.
Agent status - Enable/Disable	AgentStates.EnableAndDisable	View and edit custom agent states.
Agent status - View	AgentStates.View	View an agent's status in the real-time metrics report and historical metrics report. For example, if they are **Available**, **Offline**, or in a custom state. View their status in the Agent activity report.

Contact Control Panel (CCP)

UI name	API name	Use
Access Contact Control Panel	BasicAgentAccess	Manages access to the Contact Control Panel (CCP). Assign this permission to agents as well as managers who

UI name	API name	Use
		need to monitor live conversations.
Contact Lens data	RealtimeContactLen s.View	Enables users to view real-time analytics provided by Contact Lens.
Make outbound calls	OutboundCallAccess	Grants users permissions to make outbound calls. For more information about setting up outbound calling, see [Set up outbound calling in Amazon Connect]().
Voice ID	VoiceId.Access	Enables controls in the Contact Control Panel so agents can: • View authentic ation outcomes. • Opt-out or re-authenticate a caller. • Update `SpeakerID` . • View fraud detection results, rerun fraud analysis (fraud detection decision, fraud type and score).

UI name	API name	Use
Restrict task creation	RestrictTaskCreation.Access	Block agents from being able to create tasks.
Audio device settings	AudioDeviceSettings.Access	[Choose your preferred device for speaker, microphone, and ringer in the Contact Control Panel (CCP) or agent workspace]().
Video calls	VideoContact.Access	[Enable agents to use video calling and screen sharing]().
Initiate email conversation	OutboundEmail.Create	Allows agents to initiate an outbound email from the Contact Control Panel / agent workspace without first receiving an email contact from a customer.
Allow self assigning of contacts	SelfAssignContacts.Access	To self assign tasks, agents also need to have the **Restrict Task Creation** permission disabled and have tasks enabled as a channel within their assigned routing profile.

Analytics and Optimization

UI name	API name	Use	
Access metrics	AccessMetrics	Manage access to real-time and historical metrics reports.	
Real-time metrics	AccessMetrics.RealTimeMetrics.Access	Manage access to the real-time metrics page.	
Historical metrics	AccessMetrics.HistoricalMetrics.Access	Manage access to the historical metrics page.	
Agent activity audit	AccessMetrics.AgentActivityAudit.Access	Manage access to the agent activity audit within the historical metrics page.	
Dashboards	AccessMetrics.Dashboards.Access	Dashboards in Amazon Connect for getting contact center performance data	
Contact Search	ContactSearch.View	Access the **Contact search** page, which is where users can search for contacts and see results on the **Contact details** page.	
View my contacts	MyContacts.View	Allows agents to view contacts that they themselves had	

UI name	API name	Use
		handled, on **Contact search** and **Contact details** pages.
Search contacts by conversation characteristics	ContactSearchWithCharacteristics.Access	Access to the Contact Lens filters that enable users to search by sentiment scores, non-talk time, and category.
Search contacts by conversation characteristics - View	ContactSearchWithCharacteristics.View	View the Contact Lens filters that enable users to search by sentiment scores, non-talk time, and category.
Search contacts by keywords	ContactSearchWithKeywords.Access	Search for contacts by keyword. On the **Contact Search** page, users can access additional filters that allow them to search Contact Lens transcripts by keywords or phrases, such as "thank you for your business."

UI name	API name	Use
Search contacts by keywords - View	ContactSearchWithKeywords.View	Search for contacts by keyword. On the **Contact Search** page, users can access additional filters that allow them to search Contact Lens transcripts by keywords or phrases, such as "thank you for your business."
Configure searchable contact attributes - View	ConfigureContactAttributes.View	Determine what custom attribute data will be searchable (by people who have the **Contact attributes** permission). It allows them to access the **Searchable custom contact attributes** page. For more information, see Search for contacts in Amazon Connect by using custom contact attributes.

UI name	API name	Use
Restrict contact access	RestrictContactAccessByHierarchy.View	Manage a user's access to results on the **Contact search** page based on their agent hierarchy group. For more information, see Manage who can search for contacts and access detailed information.
Contact attributes	ContactAttributes.View	View contact attributes. Also controls access to the search filters based on contact attributes. For more information, see Search for contacts in Amazon Connect by using custom contact attributes.

UI name	API name	Use
Contact Lens - conversational analytics - View	GraphTrends.View	On the **Contact details** page for a contact, users can view conversational analytics outputs such as graphs (on sentiment, talk time, and other various outputs), sentiment indicators, and contact category labels on conversation recordings and transcripts. Users can view data on the Amazon Connect Contact Lens conversational analytics dashboard.
Contact Lens - post-contact summary	ContactLensPostContactSummary.View	View post-contact summarization powered by generative artificial intelligence (generative AI) on the Contact Search and Contact Details pages.
Contact Lens - custom vocabularies - Edit	ContactLensCustomVocabulary.Edit	Add custom vocabularies.

UI name	API name	Use
Contact Lens - custom vocabularies - View	ContactLensCustomVocabulary.View	Download and view custom vocabularies.
Contact Lens - theme detection - Create	ThemeDetection.Create	Create theme detection reports on the **Contact search** page.
Contact Lens - theme detection - View	ThemeDetection.View	View theme detection reports on the **Contact search** page.
Contact Lens - theme detection - Delete	ThemeDetection.Delete	Delete theme detection reports on the **Contact search** page.
Rules - Create	Rules.Create	Create rules.
Rules - Delete	Rules.Delete	Delete rules.
Rules - Edit	Rules.Edit	Edit rules.
Rules - Generative AI	RulesGenerativeAI.Create RulesGenerativeAI.View RulesGenerativeAI.Edit RulesGenerativeAI.Delete	Manage rules that use generative AI. To create generative AI-powered rules, you additionally need the **Rules** permission.
Rules - View	Rules.View	View rules.

UI name	API name	Use	
Recorded conversations (redacted)	RedactedData.View	On the **Contact details** and **Contact search** pages for a contact, listen to call recording files and view call transcripts in which the sensitive data has been removed.	

UI name	API name	Use	
Recorded conversations (unredacted) - View	ListenCallRecordings	On the **Contact details** and **Contact search** pages for a contact, view unredacted content that contains sensitive data, such as name and credit card information. • Original, unredacted chat transcripts • Original, unredacted transcripts analyzed by Contact Lens • Original, unredacted audio recordings **Important** If you have permissions to both **Recorded conversations (redacted)** and **Recorded conversations (unredacted)**, note the following behavior:	

UI name	API name	Use
		• By default only redacted recordings and transcripts are made available on the **Contact details** and **Contact search** pages. • When no redacted content exists for the contact, or when redacted content cannot be shown to the user, then unredacted content is displayed on the **Contact details** and **Contact search** pages.

UI name	API name	Use
		To access unredacted conversations, remove permissions to **Recorded conversations (redacted)**. This leaves the user with only **Recorded conversations (unredacted)** permissions. You cannot access both the redacted and unredacted version of a conversation at the same time.
Automated interaction voice (IVR) recordings (unredacted) - Access	AutomatedVoiceInteraction.Recordings.Unredacted.Accesss	Access voice recordings of automated interactions (with IVR, Amazon Lex or other bots).

UI name	API name	Use
Automated interaction voice (IVR) recordings (unredacted) - Download	AutomatedVoiceInteraction.Recordings.Unredacted.DownloadButton	Enables button to download IVR recordings on the Amazon Connect UI. To perform downloads you additionally need **Automated interaction voice (IVR) recordings (unredacted) - Access** permission..
Automated interaction voice (IVR) transcripts (unredacted) - Access	AutomatedVoiceInteraction.Transcripts.Unredacted.Access	Access human-readable logs of the IVR interaction including keypad inputs in reponse to IVR prompts, transcripts of Lex interactions, etc..
Recorded conversations (unredacted) - Access	ListenCallRecordings	View the Play icon so they can listen to call recordings by using the Amazon Connect admin website.

UI name	API name	Use	
Recorded conversations (unredacted) - Enable download button	DownloadCallRecordings	Enables buttons to download and delete call recordings. By default, the **Enable download button** permission is granted so the user can Download call recordings through the Amazon Connect admin website. To perform a download, however, the user needs permissions to access a **Recorded conversation (unredacted)**.	
Recorded conversations (unredacted) - Delete	DeleteCallRecordings	Delete call recordings. By default, the **Enable download button** permission is granted too so the user can delete recordings through the Amazon Connect admin website.	
Login/Logout report - View	AgentTimeCard.View	View Login/Logout reports.	

UI name	API name	Use
Real-time contact monitoring- Enable/Disable	ManagerListenIn	Monitor live conversations and listen to recordings of past conversations. Be sure to assign managers to the Agent security profile so they can access the Contact Control Panel (CCP). This enables them to monitor the conversation through the CCP.
Real-time contact barge-in - Enable/Disable	ManagerBargeIn	Enables supervisors and managers to barge into live conversations between agents and customers. To learn more about Barge for live conversations, see Barge into live voice and chat conversations between contact center agents and customers.
Saved reports - View	MetricsReports.View	View a shared report.
Saved reports - Create	MetricsReports.Create MetricsReports.Share	Create and share reports.

UI name	API name	Use
Saved reports - Edit	MetricsReports.Edit	Edit save reports.
Saved reports - Delete	MetricsReports.Delete	Delete saved reports.
Saved reports - Publish	MetricsReports.Publish	Publish reports and share reports.
Saved reports - Schedule	MetricsReports.Schedule MetricsReports.Publish ReportSchedules.Create ReportSchedules.Delete ReportSchedules.Edit ReportSchedules.View	Schedule a saved report. By default, the user gets permission to create, delete, edit, and view a saved report.
Saved reports (admin)	ReportsAdmin.View ReportsAdmin.Delete	View and delete all saved reports in your instance, including those not created by you.
Evaluation forms - perform evaluations	Evaluation.Create Evaluation.View Evaluation.Edit Evaluation.Delete	Evaluate performance.

UI name	API name	Use
Evaluation forms - manage form definitions	EvaluationForms.Create EvaluationForms.View EvaluationForms.Edit EvaluationForms.Delete	[Create and manage evaluation forms]().
Evaluation forms - ask AI assistant	EvaluationAssistant.Access	Access the **Ask AI** button while performing evaluations, enabling the user to get generative AI-powered recommendations for answers to questions in evaluation forms.
Evaluation forms - manage calibration sessions	EvaluationCalibrationSessions.Create EvaluationCalibrationSessions.Delete EvaluationCalibrationSessions.Edit EvaluationCalibrationSessions.View	Create and manage calibration sessions to drive consistency and accuracy in how managers evaluate agent performance.
Voice ID - attributes and search	VoiceIdAttributesAndSearch.View	Search for and view Voice ID results on the **Contact detail** page.

UI name	API name	Use
Forecasting - View	Forecasting.View	Review contact volume and average handle time forecasts .
Forecasting - Edit	Forecasting.Edit	Create and edit contact volume and average handle time forecasts.
Forecasting - Publish	Forecasting.Publish	Publish a forecast in Amazon Connect.
Capacity planning - View	Capacity.View	Review capacity plan output in Amazon Connect.
Capacity planning - Edit	Capacity.Edit	Create capacity planning scenarios in Amazon Connect.
Capacity planning - Publish	Capacity.Publish	Publish a capacity plan in Amazon Connect.
Forecast and schedule interval - Edit and View	ForecastScheduleInterval.Edit ForecastScheduleInterval.View	Set the forecast and schedule interval in Amazon Connect.

UI name	API name	Use	
Screen recording - Access	ScreenRecording.Access	Access the screen recording media player and view videos on the **Contact details** page. **Important** Screen recording merges the screen recording video with the unredacted call recording file. If users have permission to view screen recordings, they can listen to the unredacted audio.	

UI name	API name	Use
Screen recording - Enable download button	ScreenRecording.Do wnload	Enables the button to download screen recordings on the **Contact details** page. By default, the **Enable download button** permission is granted so the user can download screen recordings through the Amazon Connect admin website. To perform a download, the user also needs **Screen recording - Access** permissions.
Automated interacti on voice (IVR) recordings (unredact ed) - Access	AutomatedVoiceInte raction.Recordings .Unredacted.Access	View the Play icon so users can listen to call recordings by using the Amazon Connect admin website.

UI name	API name	Use
Automated interaction voice (IVR) recordings (unredacted) - Enable download button	AutomatedVoiceInteraction.Recordings.Unredacted.DownloadButton	Enables buttons to download and delete call recordings. By default, the **Enable download button** permission is granted so the user can [Download call recordings](#) through the Amazon Connect admin website. To perform a download, however, the user needs permissions to access a **Automated interaction voice (IVR) recordings (unredacted)**.
Automated interaction voice (IVR) transcripts (unredacted)	AutomatedVoiceInteraction.Transcripts.Unredacted.Access	On the **Contact details** and **Contact search** pages for a contact, view transcripts for IVR recordings.

Contact Actions

UI name	API name	Use
Transfer Contact	TransferContact.Enabled	[Transfer contacts on Analytics and optimization pages](#). Currently transfer

UI name	API name	Use
		of task contacts to quick connects is supported on the **Contact details** page.
End contact	StopContact.Enabled	End contacts on Analytics and optimization pages. Currently supported on the **Contact details** page.
Reschedule contact	UpdateContactSchedule.Enabled	Reschedule previously scheduled contact on Analytics and optimization pages. Currently supported on the **Contact details** page for task contacts only.

Historical changes

UI name	API name	Use
View historical changes	HistoricalChanges.View	View historical changes on all Amazon Connect admin website pages that support historical changes.

Customer Profiles

UI name	API name	Use
Customer profiles - Create	CustomerProfiles.Create	Create customer profiles in the agent application.
Customer profiles - Edit	CustomerProfiles.Edit	Edit customer profiles in the agent application.
Customer profiles - View	CustomerProfiles.View	View customer profiles in the agent application.
Calculated Attributes - Create	CustomerProfiles.CalculatedAttributes.Create	Create calculated attributes.
Calculated Attributes - Edit	CustomerProfiles.CalculatedAttributes.Edit	Edit calculated attributes.
Calculated Attributes - Delete	CustomerProfiles.CalculatedAttributes.Delete	Delete calculated attributes.
Calculated Attributes - View	CustomerProfiles.CalculatedAttributes.View	View calculated attributes.
Customer segments - View	CustomerProfiles.Segments.View	View all customer created segments. You can see segment details, the definitions that were created,

UI name	API name	Use
		and segment estimate counts.
Customer segments - Create	CustomerProfiles.Segments.Create	Create segment definitions based on all profile attributes on a Customer Profiles domain associated with this instance. `Create` permissions allow creating definitions based on existing profile attributes and their values. You can also use default and created calculated attributes in the segment definition.
Customer segments - Delete	CustomerProfiles.Segments.Delete	`Delete` permissions allows you to delete your Segment Definition.
Customer segments - Export	CustomerProfiles.Segments.Export	Export allows you to create an exported CSV of all the profile data from profiles in that segment. It also allows you to view underlying profile data once exported.

Scheduling

UI name	API name	Use
Schedule manager - View	Scheduling.View	View generated staff schedules in the Schedule manager user experience.
Schedule manager - Edit	Scheduling.Edit	Create, edit schedule configuration and publish generated staff schedules.
Schedule manager - Publish	Scheduling.Publish	Publish a schedule by using Schedule Manager.
Published schedule calendar	Scheduling.View	View a schedule.
Time off requests - Approve, Edit, View	TimeOff.Approve TimeOff.Edit TimeOff.View	Time off managemen t.
Time off balance - Edit, View	TimeOffBalance.Edit TimeOffBalance.View	Time off managemen t.
Team calendar	TeamCalendar.View	View published staff schedules in the Published Calendar user experience.
Team calendar	TeamCalendar.Edit	Edit published staff schedules in the

UI name	API name	Use
		Published Calendar user experience.

Agent Applications

UI name	API name	Use
Agent application schedule calendar	StaffCalendar.View StaffCalendar.Edit	Ability for agents to view their schedules . The **Edit** permission is required for agents to view and use the **Time off** widget on their schedule that they use to request time off. If they only have **View** permission, the **Time off** widget will not appear on their schedule. For an example image that shows the **Time off** widget on an agent's schedule, see Agent initiated time off request.
Custom views	CustomViews.Access	Use the Agent Workspace guided experience guide.

UI name	API name	Use
Amazon Q in Connect	Wisdom.View	View real-time recommendations in the agent application.
<3p app name> - Access	*<3p app name>*.Access	Allows agents to access a third-party application.

Content Management

UI name	API name	Use
Message templates - View		View a list of message templates in the Amazon Connect admin website.
Message templates - Edit		Edit message templates.
Message templates - Create		Create message templates.
Message templates - Delete		Delete message templates by using the Amazon Connect admin website.
Quick responses - Create	ContentManagement. Create	Set up a knowledge base to store quick responses. Create, import, and view the import history of quick responses that

UI name	API name	Use
		are displayed in the agent application.
Quick responses - Edit	ContentManagement.Edit	Edit, import, and view the import history of quick responses that are displayed in the agent application.
Quick responses - View	ContentManagement.View	View a list of quick responses in the Amazon Connect admin website.
Quick responses - Delete	ContentManagement.Delete	Delete quick responses by using the Amazon Connect admin website.

Cases

UI name	API name	Use
Audit History - View	CaseHistory.View	View the audit history of cases in the agent application.
Cases - Create	Cases.Create	Create cases in the agent application.
Cases - View	Cases.View	View cases in the agent application.
Cases - Edit	Cases.Edit	Edit cases in the agent application.

UI name	API name	Use
Case Fields - Create	CaseFields.Create	Create case fields.
Case Fields - View	CaseFields.View	View case fields.
Case Fields - Edit	CaseFields.Edit	Edit case fields.
Case Templates - Create	CaseTemplates.Create	Create case templates.
Case Templates - View	CaseTemplates.View	View case templates.
Case Templates - Edit	CaseTemplates.Edit	Edit case templates.

Outbound Campaigns

UI name	API name	Use
Campaigns - Create	Campaigns.Create	Create outbound campaigns.
Campaigns - Delete	Campaigns.Delete	Delete outbound campaigns.
Campaigns - Edit	Campaigns.Edit	Edit outbound campaigns.
Campaigns - Manage	Campaigns.Delete	Manage outbound campaigns.
Campaigns - View		View outbound campaigns.

Default security profiles in Amazon Connect

Amazon Connect includes default security profiles for general roles. You can review the permissions granted by these profiles and use them if they align with the permissions that your users need. Otherwise, create a security profile that grants your users only the permissions they need.

The following table lists the default security profiles.

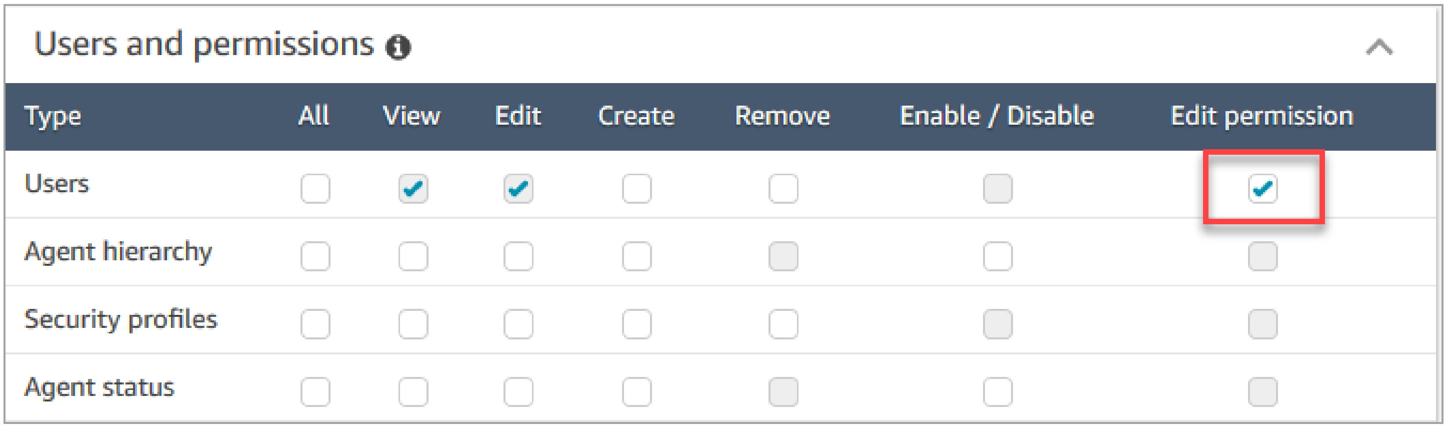
Security profile	Description
Admin	Grants administrators permission to perform a majority of actions.
Agent	Grants agents permission to access the CCP.
CallCenterManager	Grants managers permission to perform actions related to user management, metrics, and routing.
QualityAnalyst	Grants analysts permission to perform actions related to metrics.

> **Note**
>
> New permissions are added on a regular basis. We recommend revisiting your permission configurations to ensure your users can access the latest Amazon Connect features.

Assign a security profile for Amazon Connect to a contact center user

Required permissions to assign security profiles

Before you can assign a security profile to a user, you must be logged in with an Amazon Connect account that has the **Users - Edit** permission, as shown in the following image. Or, if you're creating the user's account for the first time, you need **Users - Create** permission.



By default, the Amazon Connect **Admin** security profile has these permissions.

How to assign security profiles

1. Review [Best practices for Amazon Connect and Contact Control Panel (CCP) security profiles](#).
2. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/.
3. Choose **Users**, **User management**.
4. Select one or more users and choose **Edit**.
5. For **Security Profiles**, add or remove security profiles as needed. To add a security profile, put your cursor in the field and select the security profile from the list. To remove a security profile, click the **x** next to its name.
6. Choose **Save**.

Create a security profile in Amazon Connect

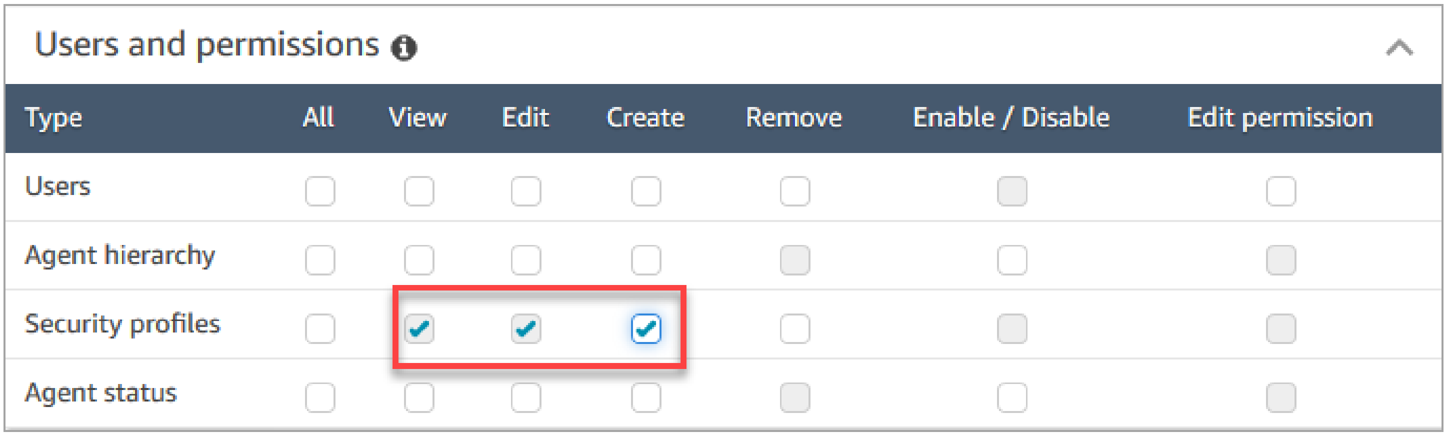
Creating a security profile enables you to grant your users only the permissions that they need.

For each permission group, there is a set of resources and supported set of actions. For example, users are part of the **Users and permissions** group, which supports the following actions: view, edit, create, remove, enable/disable, and edit permission.

Some actions depend on other actions. When you choose an action that depends on another action, the dependent action is automatically chosen and must also be granted. For example, if you add permission to edit users, we also add permission to view users.

Required permissions to create security profiles

Before you can create a new security profile, you must be logged in with an Amazon Connect account that has **Security profiles - Create** permissions, as shown in the following image.



By default, the Amazon Connect **Admin** security profile has these permissions.

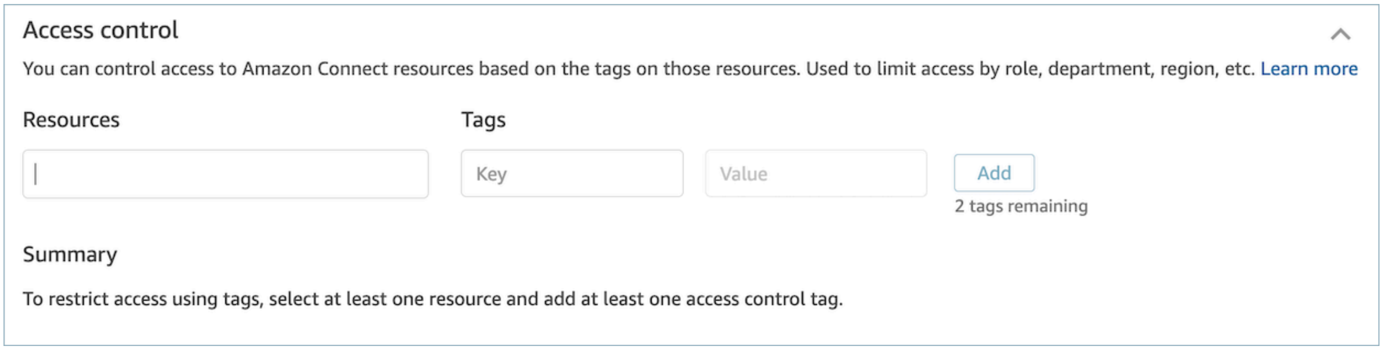
How to create security profiles

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/.
2. Choose **Users**, **Security profiles**.
3. Choose **Add new security profile**.
4. Type a name and description for the security profile.
5. Choose the appropriate permissions for the security profile from each permission group. For each permission type, choose one or more actions. Selecting some actions results in other actions being selected. For example, selecting **Edit** also selects **View** for the resource and any dependent resources.
6. Choose **Save**.

Tag-based access controls

You create a security profile with access control tags. Use these steps to create a security profile that enforces tag-based access controls.

1. Choose **Show advanced settings** at the bottom of the security profile.
2. In the **Access control** section, in the **Resources** box, enter the resources to be restricted using tags.



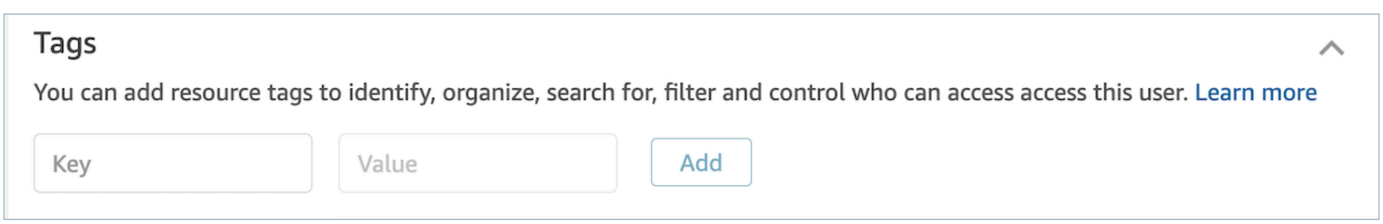
3. Enter the **Key** and **Value** combination for the resource tags that you want to restrict access to.
4. Ensure that you have enabled *View* permissions for the resources that you have selected.
5. Choose **Save**.

> **Note**
>
> It is mandatory to specify both a resource type and an access control tag when configuring tag-based access controls. As a best practice, ensure that you have matching resource tags on a security profile that has tag-based access controls configured. To learn more about tag-based access controls in Amazon Connect, see Apply tag-based access control in Amazon Connect.

Tag security profiles

You can create a new security profile with resource tags. Use these steps to add a resource tag to a security profile.

1. Choose **Show advanced settings** at the bottom of the security profile.
2. Enter a **Key** and **Value** combination to tag the resource, as shown in the following image.



3. Choose **Save**.

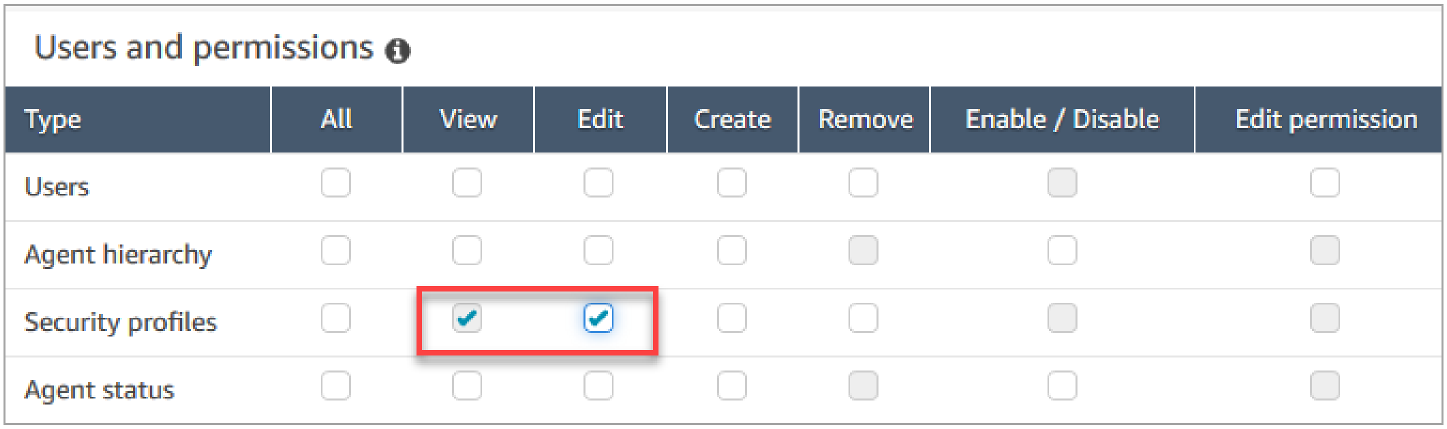
For more information about tagging resources, see Add tags to resources in Amazon Connect.

Update security profiles in Amazon Connect

You can update a security profile at any time to add or remove permissions.

Required permissions to update security profiles

Before you can update permissions in a security profile, you must be logged in with an Amazon Connect account that has the following permissions: **Security profiles - Edit**.



By default, the Amazon Connect **Admin** security profile has these permissions.

How to update security profiles

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. You must be logged in with an Amazon Connect account that has permissions to update security profiles.
2. Choose **Users**, **Security profiles**.
3. Select the name of the profile.
4. Update the name, description, permissions, access control, and resource tags as needed.
5. Choose **Save**.

> **Note**
>
> Modifying the access control or resource tags on a security profile may impact the features or resources that a user with this security profile can access.

Apply tag-based access control in Amazon Connect

You use tag-based access controls to configure granular access to specific resources based on assigned resource tags. You can configure tag-based access controls by using the API/SDK or the Amazon Connect admin website for supported resources.

Apply tag-based access control using the API/SDK

To use tags to control access to resources within your AWS accounts, you need to provide tag information in the condition element of an IAM policy. For example, to control access to your Voice ID domain based on the tags you've assigned to it, use the `aws:ResourceTag/key-name` condition key, along with a specific operator like `StringEquals` to specify which tag *key:value* pair must be attached to the domain, in order to allow given actions for it.

For more detailed information on tag-based access control, see [Controlling access to AWS resources using tags]() in the *IAM User Guide*.

Apply tag-based access control using the Amazon Connect admin website

A *resource* tag is a custom metadata label that you can add to a resource in order to make it easier to identify, organize, and find in a search. You can apply tags programmatically using the Amazon Connect SDK/APIs, and for certain resources you can apply tags from within the Amazon Connect console. To learn more about resource tags, see [Add tags to resources in Amazon Connect]().

An access control tag is similar to a resource tag in that it uses the same *Key:value* structure. However, the distinction with an access control tag is that it introduces authorization controls that limit a user’s access, to only specified resources containing resource tags with identical *Key:value* pairs. Access control tags are defined within security profiles, by first selecting the resource (routing profile, queue, users, etc.) for which to control access to, and then defining the *Key:value* pair to match on. Once a security profile with access control tags has been applied to a user, it will limit the user's access based on the defined combination of the selected resource(s) and access control tag(s) (*Key:value*). Without access control tags applied, a user will be able to see all resources if given permission to do so.

To use tags to control access to resources within the admin website of your Amazon Connect instance, you need to configure the access control section within a given security profile. For example, to control access to a routing profile based on the tags you've assigned to it, you would specify the routing profile as an access controlled resource, and then specify which tag *Key:value* pair you would like to enable access to.

Configuration limitations

Access control tags are configured on a security profile. You can configure up to 4 access control tags on a single security profile. Adding additional access control tags will make that security profile more restrictive. For example, if you were to add two access control tags like `Department:X` and `Country:Y`, the user would only be able to see resources containing both tags.

Users can be assigned a maximum of two security profiles that contain access control tags. When multiple security profiles containing access control tags are assigned to a single user, the tag-based access controls become less restrictive. For example, if a user had one security profile with an access control tag like `Country:USA`, and another security profile with an access control tag like `Country:Argentina`, a user would be able to see resources tagged with `Country:USA` or `Country:Argentina`. A user can have other security profiles, as long as those additional security profiles do not contain tags. If multiple security profiles are present with overlapping resource permissions, the security profile without tag-based access controls will be enforced over the one with tag-based access controls.

Service linked roles are required in order to configure resource tags or access control tags. If your instance was created after October 2018, this will be available by default with your Amazon Connect instance. However if you have an older instance, refer to Use service-linked roles for Amazon Connect for instructions for how to enable service linked roles.

Best practices for applying tag-based access controls

Applying tag-based access controls is an advanced configuration feature that is supported by Amazon Connect and that follows the AWS shared responsibility model. It is important to ensure that you are correctly configuring your instance to comply with your desired authorization needs. For more information, review the AWS shared responsibilities model.

Ensure that you have enabled at least *view* permissions for the resources that you enable tag-based access control for. This will ensure that you avoid permission inconsistencies that result in denied access requests.

Tag-based access controls are enabled at the resource level, which means that each resource can be restricted independently. In certain use cases this may be acceptable but it is considered best practice to enable tag-based access controls to all resources together. For example, enabling access to users but not security profiles, would allow a user to create a security profile with privileges that supersede your intended user access control settings.

When logged in to the Amazon Connect console with tag-based access controls applied, users will not be able to access historical change logs for the resources that they are restricted on.

As a best practice, you should disable access to the following resources/modules when applying tag-based access controls within the Amazon Connect console. If you do not disable access to these resources, users with tag-based access controls on a particular resource that view these pages may see an unrestricted list of users, security profiles, routing profiles, queues, flows, or flow modules. For more information on how to manage permissions, see [List of security profile permissions in Amazon Connect](#).

Modules	Permission to disable access
Contact search	Contact Search
Dashboard	Access metrics

Apply hierarchy-based access control in Amazon Connect (Preview)

> **Note**
>
> This is prerelease documentation for a service in preview release. It is subject to change.

You can restrict access to contacts based on the agent hierarchy assigned to a user. You do this by using security profile permissions such as Restrict contact access. In addition to these permissions, you can also use hierarchies enforce granular access controls for resources such as users, and use tags.

This topic information about configuring hierarchy-based access controls (currently in preview).

Contents

Overview

Hierarchy-based access control enables you to configure granular access to specific resources based on the agent hierarchy that is assigned to a user. You can configure hierarchy-based access controls by using the API/SDK or the Amazon Connect admin website.

The only resource that supports hierarchy-based access control is users. This authorization model works with tag-based access control so you can restrict access to users, allowing them to see only other users who belong to their same hierarchy group and who have specific tags associated to them.

> **Note**
>
> After you apply hierarchy-based access control to users, they can access their hierarchy group and all of its descendants (beyond the child level).

Apply hierarchy-based access control using the API/SDK

To use hierarchies to control access to resources within your AWS accounts, you need to provide the hierarchy's information in the condition element of an IAM policy. For example, to control access to a user belonging to a specific hierarchy, use the `connect:HierarchyGroupL3Id/hierarchyGroupId` condition key, along with a specific operator like `StringEquals` to specify which hierarchy group the user must belong to, in order to allow given actions for it.

Following are the supported condition keys:

1. `connect:HierarchyGroupL1Id/hierarchyGroupId`
2. `connect:HierarchyGroupL2Id/hierarchyGroupId`
3. `connect:HierarchyGroupL3Id/hierarchyGroupId`
4. `connect:HierarchyGroupL4Id/hierarchyGroupId`
5. `connect:HierarchyGroupL5Id/hierarchyGroupId`

Each key represents the ID of a given hierarchy group in a specific level of the user's hierarchy structure.

For more detailed information about hierarchy-based access control, see [Controlling access to AWS resources using tags]() in the *IAM User Guide*.

Apply hierarchy-based access control using the Amazon Connect admin website

To use hierarchies to control access to resources the Amazon Connect admin website, you configure the access control section within a given security profile.

For example, to enable granular access control for a given user based on the hierarchy they belong to, you configure the user as an access controlled resource. To do this, you have the following two options:

1. Enforce hierarchy-based access control based on **the user's hierarchy**

   This option ensures that the user being given access can only manage users that belong to his hierarchy. For example, enabling this configuration for a given user enables them to manage other users that either belong to their hierarchy group or a child hierarchy group. This ensures that the user being given access can only manage users that belong to his hierarchy. For example, enabling this configuration for a supervisor enables them to manage other users that either belong to their hierarchy group or a child hierarchy group.

2. Enforce hierarchy-based access control based on **a specific hierarchy**

   This option ensures that the user being given access can only manage users that belong to the hierarchy defined in the security profile. For example, enabling this configuration for a given user enables them to manage other users that either belong to the hierarchy group specified in the security profile or a child hierarchy group.

Configuration limitations

Granular access control is configured on a security profile. Users can be assigned a maximum of two security profiles that enforce granular access control. In this case, the permissions become less restrictive and act as a union of both permission sets.

For example, if one security profile enforces hierarchy-based access control and another one enforces tag-based access control, the user is able to manage any user that belongs to the same hierarchy or tagged with the given tag. If both tag-based and hierarchy-based access control are configured as part of the same security profile, both conditions will need to be met. In this case, the user can only manage users that belong to the same hierarchy and who are tagged with a given tag.

A user can have more than two security profiles, as long as those additional security profiles do not enforce granular access control. If multiple security profiles are present with overlapping resource permissions, the security profile without hierarchy-based access control is enforced over the one with hierarchy-based access control.

Service linked roles are required in order to configure hierarchy-based access control. If your instance was created after October 2018, this is available by default with your Amazon Connect instance. However, if you have an older instance, refer to Use service-linked roles for Amazon Connect for instructions for how to enable service linked roles.

Best practices for applying hierarchy-based access controls

- Review the AWS shared responsibility model.

  Applying hierarchy-based access control is an advanced configuration feature that is supported by Amazon Connect and that follows the AWS shared responsibility model. It is important to ensure that you are correctly configuring your instance to comply with your desired authorization needs.

- Ensure that you have enabled at least *view* permissions for the resources that you enable hierarchy-based access control for.

  This will ensure that you avoid permission inconsistencies that result in denied access requests. Hierarchy-based access controls are enabled at the resource level, which means that each resource can be restricted independently.
- Carefully review the permissions that are granted when hierarchy-based access control is enforced.

  For example, enabling hierarchy restricted access to users and view/edit permissions security profiles would allow a user to create/update a security profile with privileges that supersede the intended user access control settings.
  - When logged in to the Amazon Connect console with hierarchy-based access controls applied, users will not be able to access historical change logs for the resources that they are restricted on.
  - When trying to assign a child resource to a parent resource with hierarchy-based access control on the child resource, the operation will be denied if the child resource does not belong to your hierarchy.

    For example, if you try to assign a user to a quick connect but you don't have access to the user's hierarchy, the operation fails. This is however not true for disassociations. You are able to disassociate a user freely even with hierarchy-based access control enforced assuming you have access to the quick connect. This is because disassociations are about discarding an existing relation (as opposed to new associations) between two resources and is modeled as part of the parent resource (in this case, the quick connect), which the user already has access to.
- Be thoughtful about the permissions granted on parent resources since a user could be disassociated without his or his supervisor’s knowledge.
- Disable access to the following functionality when you apply hierarchy-based access controls in the Amazon Connect admin website.

Functionality	Security profile permission that disables access
Contact search	Contact search - View

Functionality	Security profile permission that disables access
Historical changes/Audit portal	Access metrics - Access
Real-time metrics	Real-time metrics - Access
Historical metrics	Historical metrics - Access
Login/Login out report	Login/Login out report - View
Rules	Rules - View
Saved reports	Saved reports - View
Agent Hierarchy	Agent Hierarchy - View
Flow/Flow module	Flow modules - View
Scheduling	Schedule manager - View

If you do not disable access to these resources, users with hierarchy-based access controls on a particular resource that view these pages in the Amazon Connect admin website may see an unrestricted list of users. For more information about how to manage permissions, see List of security profile permissions.

Set up routing in Amazon Connect

In Amazon Connect, routing consists of three parts: queues, routing profiles, and flows. This topic discusses queues and routing profiles. For information about flows, see Flows in Amazon Connect.

A queue holds contacts waiting to be answered by agents. You can use a single queue to handle all incoming contacts, or you can set up multiple queues.

Queues are linked to agents through a routing profile. When you create a routing profile, you specify:

- Which queues will be in it.
- Whether one queue should be prioritized over another.

- What channels agents will handle in the Contact Control Panel (CCP).
- How many contacts agents can handle simultaneously for each channel.
- Whether individual queues are for all channels or specific ones.

Each agent is assigned to one routing profile.

Contents

How routing works in Amazon Connect

Contacts are routed through your contact center based on these factors:

- The routing profile assigned to the agent.
- The hours of operation for a given queue.
- The routing logic you define in your flows.

For example, you use routing profiles to route specific types of contacts to agents with specific skill sets. If no agent with the required skill set is available, you can place the contact in the queue defined in the flow.

Here's the logic Amazon Connect uses to route contacts:

- Contacts in a queue are automatically prioritized and forwarded to the next available agent (that is, the agent who has been idle longest).
- Contacts are placed on hold if there are no available agents. The order in which they are serviced is determined by their time in queue, on a first-come, first-served basis.
- If multiple agents are ready for a contact, by default an inbound contact is routed to the agent who has been in the **Available** status for the longest time.

> **Tip**
>
> For information about how queue priority and delay work, see Queues: priority and delay examples.

Handling either inbound or outbound contacts causes agents to drop to the bottom of the list for inbound contacts. You can set up your routing profile to ignore outbound contacts in this calculation by choosing the **Outbound calls should not impact routing order** option. Consider choosing this option if your organization wants agents to take outbound calls and still get a fair share of inbound contacts.

For example:

- An agent named Joe is idle. He is third in line to receive an inbound contact. He would rather handle an inbound contact than an outbound contact because he knows he will speak to a customer, whereas an outbound contact may not pick up the phone. Talking to an inbound contact increases his odds of getting recognition in his role.
- Because he is idle, Joe decides to make an outbound contact to chip away at the backlog. He may or may not reach someone.
- By default, when Joe makes the outbound contact, he moves from third in line to the bottom of the list of agents waiting to receive an inbound contact. (If there are 10 agents, he is moved to 10th place). If instead he should remain in third place, you can override the default behavior.

- A routing profile may assign a priority to one queue over another, but the priority within the queue is always set by the order the contact was added to the queue.

How routing transfers works

As the previous section explains, the order in which contacts in queue are handled in Amazon Connect depends on multiple factors, including the enqueue time, routing age adjustment, and contact priority. In the case of contacts that experience a transfer, however, Amazon Connect handles the routing age adjustment slightly differently: it depends on whether the contact was transferred by an agent, or if it was transferred by a queue-to-queue transfer in a flow or an API.

The following two scenarios demonstrate how Amazon Connect handles the routing age adjustment.

- **Agent transfers the contact using a quick connect**: A contact is originally enqueued at time **X** and is then handled by an agent. The agent then transfers it back to a queue using a quick connect at time **Y**. In this scenario:
  - The original enqueue time **X** is used to calculate the order in which this contact is ranked in the subsequent queue.
  - Any routing age adjustments are applied relative to that contact enqueue time.
- **Queue-to-queue transfer**: A contact was in a queue from time **S** and is eventually transferred to a different queue at time **T**. In this scenario:
  - The new enqueue time **T** is used to calculate the order in which the contact is ranked.
  - Any routing age adjustments are applied relative to that contact enqueue time.

How routing works with multiple channels

When you set up a routing profile to handle multiple channels, you must specify whether agents can handle contacts while already on another channel. This is called cross-channel concurrency.

When using cross-channel concurrency, Amazon Connect checks which contact to offer the agent as follows:

1. It checks what contacts/channels the agent is currently handling.
2. Based on what channels they are currently handling, and the cross-channel configuration in the agent's routing profile, it determines whether the agent can be routed the next contact.

For a detailed example of how Amazon Connect routes contacts when cross-channel concurrency is set up, see Example of how a contact is routed with cross-channel concurrency.

Learn more about routing

See the following topics to learn more about routing:

- Queues: priority and delay examples.
- How Amazon Connect uses routing profiles
- Queue-based routing to route customers to a specific contact center agent
- Set up queue-based routing

Standard queues and agent queues in your Amazon Connect contact center

There are two types of queues:

- **Standard queues**: This is where contacts wait before they are routed to and accepted by agents.
- **Agent queues**: These queues are created automatically when you add an agent to your contact center.

  Contacts are only routed to agent queues when explicitly sent there as part of a flow. For example, you might route contacts to a specific agent who's responsible for certain customer issues, such as billing or premium support. Or you might use agent queues to route to an agent's voice-mail.

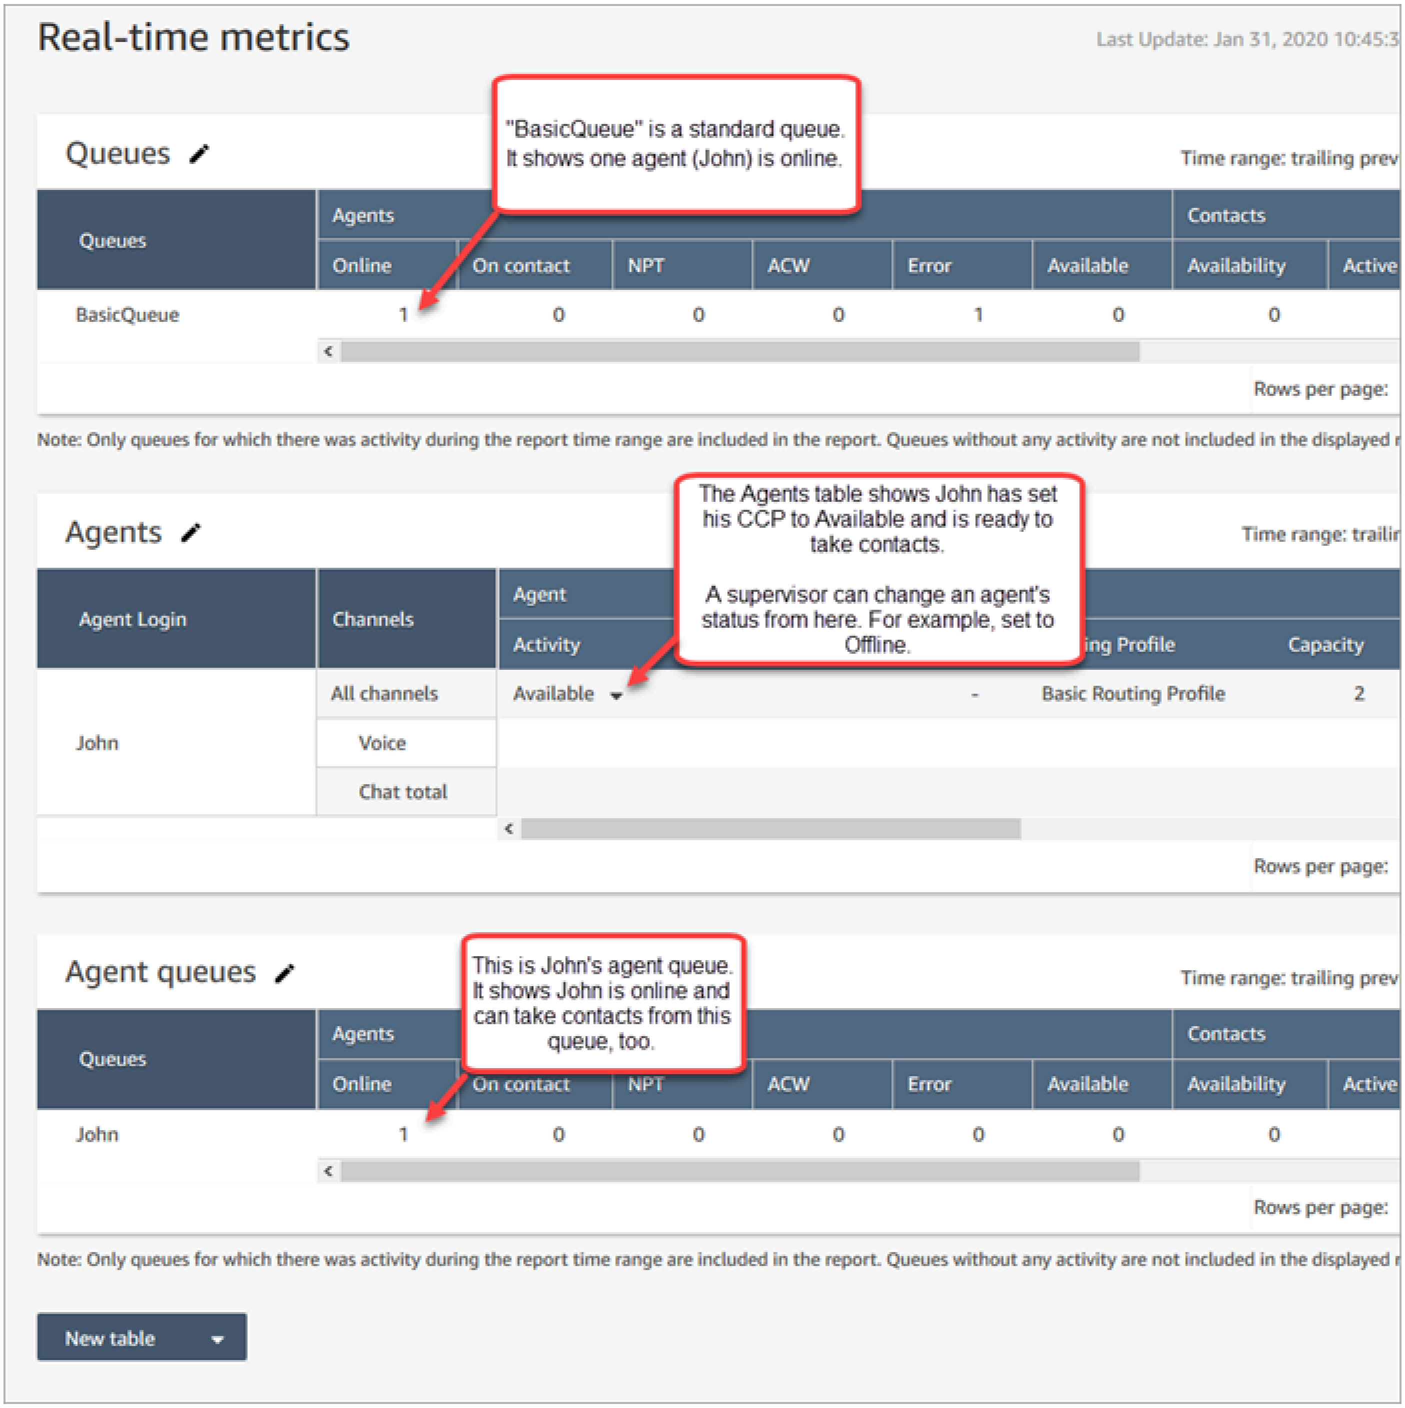
Contacts waiting in agent queues are higher priority than contacts waiting in standard queues. Contacts in agent queues have the highest priority and zero delay:

- Highest priority: If there's another contact in the basic queue, Amazon Connect chooses to give the agent the contact from the agent queue first.
- Zero delay: If the agent is available, the contact immediately gets routed to them.

Queues in metrics reports

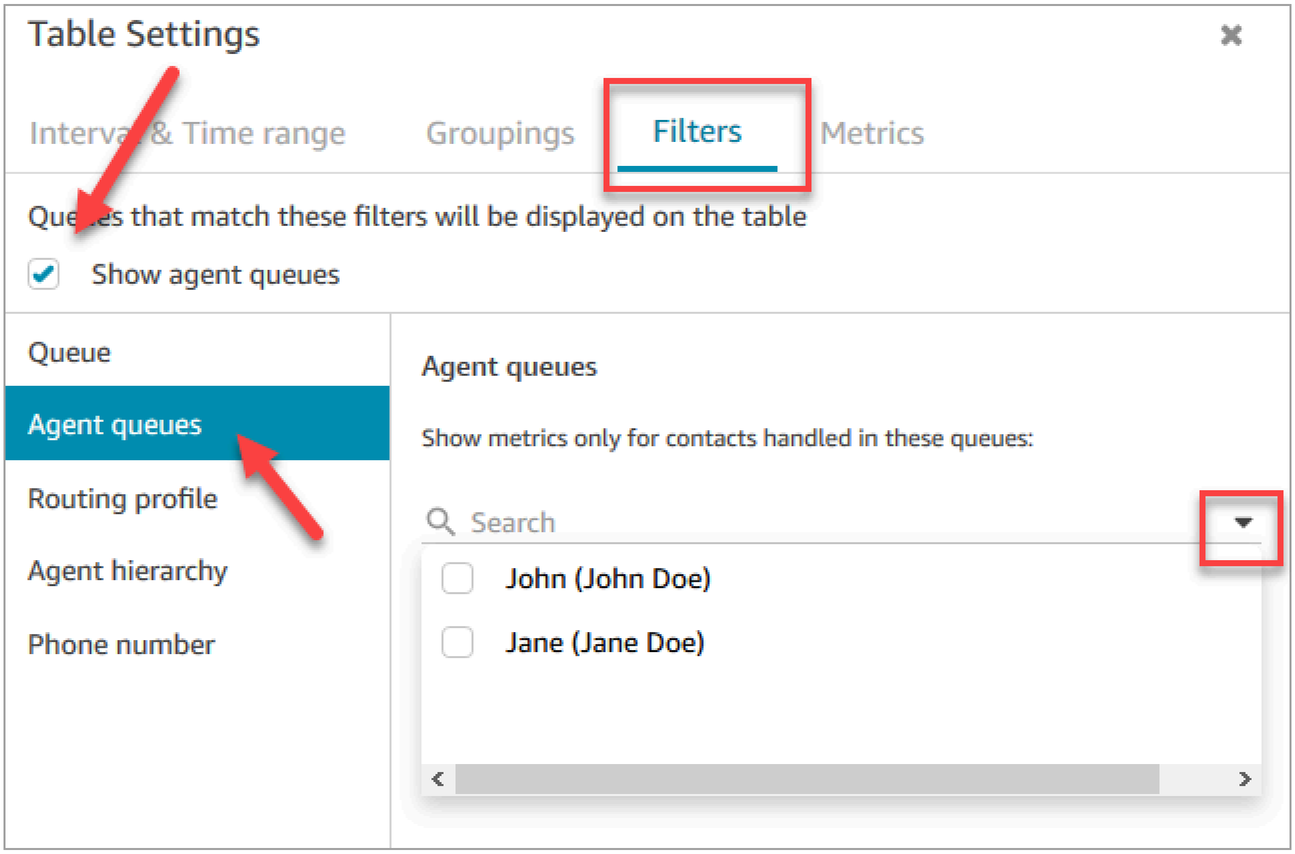
In a real-time metrics report, you can monitor how many contacts are in standard queues and agent queues. The following image shows a sample real-time metrics Queues report where an Agents table and Agent queues table have been added. It shows:

- **BasicQueue**, which is a standard queue. It shows one agent (John) is online.
- **Agents** table, which shows the agent John has set his CCP to **Available** and is ready to take contacts. A supervisor can change an agent's status from here. For example, set to **Offline**.
- **Agent queues** table, which shows John's agent queue. It shows John is online and can take contact from this queue, too.



When an agent gets a contact from a standard queue, the contact never appears in the agent queue. It just goes directly to the agent.

In a historical metrics report, by default agent queues don't appear in a Queues table. To show them, choose the **Settings** icon, then choose **Show agent queues**.



> **Tip**
>
> The metrics APIs don't support agent queues.

Default queue: BasicQueue

Amazon Connect includes a default queue named **BasicQueue**. Along with the default flows and default routing profile (named **Basic routing profile**), it powers your contact center so you don't need to do any customization. This is what enables you to get started quickly.

Queue priority and delay examples to help you load balance Amazon Connect contacts

This topic provides a several example priority and delay settings for queues, and explains how contacts are routed in each scenario. Use these examples to load balance contacts using the priority and delay features.

Example 1: Different priority but same delay

For example, one group of agents is assigned to a Sales routing profile. Since their primary job is sales, the Sales queue is Priority 1 and Delay is 0. But they can help with Support too, so that queue is Priority 2 and Delay is 0. This shown in the following table:

Queue	Priority	Delay (in seconds)
Sales	1	0
Support	2	0

If there are no contacts in the Sales queue, then the agents will be presented with contacts from the Support queue.

Example 2: Same priority but different delay

Say you set the Support queue to Priority 1 and Delay of 30 seconds, as shown in the following table:

Queue	Priority	Delay (in seconds)
Sales	1	0
Support	1	30

These agents will always get contacts from the Sales queue first because the delay is 0. However, when a contact in the **Support** queue ages past 30 seconds, it will also be treated as priority 1. The agents will then be presented with the contact from the **Support** queue.

Example 3: Different Priorities and Delays

Here's a more complicated example for a Support routing profile:

Queue	Priority	Delay (in seconds)
Tier 1 Support	1	0

Queue	Priority	Delay (in seconds)
Tier 2 Support	1	0
Tier 3 Support	2	20
Tier 4 Support	3	80

This routing profile prioritizes the Tier 1 Support and Tier 2 Support queues equally because each is priority 1.

- Agents may take contacts from the Tier 3 Support queue when:
  - Customers for Tier 3 Support are waiting for 20 seconds or longer.
  - And no contacts are in the Tier 1 Support or Tier 2 Support queues.
- Agents may take contacts from the Tier 4 Support queue when:
  - Customers in the Tier 4 Support queue have been waiting 80 seconds or longer.
  - And no contacts are in the Tier 1 Support, Tier 2 Support or Tier 3 Support queues.

  Priority takes precedence. (You might think that agents take contacts from Tier 4 Support when contacts are in Tier 1 Support, Tier 2 Support, or Tier 3 Support and waiting 20 seconds or longer, but that's not right.)

Example 4: Same Priority and Delay

In this example a routing profile has only two queues, and they have the same priority and delay:

Queue	Priority	Delay (in seconds)
Sales	1	0
Support	1	0

For this routing profile, the oldest contact is routed first. It goes to the agent who has been idle for the longest time.

Example 5: Agent is idle and Contact is in 30 second delay queue

Let's say the agent is idle and the contact is in delay (for a 30 second delay queue, the contact is 15 seconds old). What happens?

The **Delay** setting in the routing profile means that X seconds must pass before this contact can be offered to agents with this routing profile. Whether the agents are idle or not isn't taken into account. So in this case, this agent isn't offered the contact until the contact is at least 30 seconds old.

Example 6: Different routing profiles, same queues, different priorities

For example:

-

Agent	Priority	Queue
Agent A	1	1
Agent B	5	1

- **Both agents are available. Who will get the call? It depends ...**
  - Routing always attempts to route to the longest available agent first.

    Agent A has a profile with Priority 1 for Queue 1, and Agent B has a profile with Priority 5 for Queue 1. Contact Z is added to Queue 1 while both agents are available. In this case, Contact Z will always be routed to whichever agent has been available for longer. If Agent B has been available longer, Contact Z will be routed to Agent B.
  - Priority for queues is relevant to searching for queues for an individual agent. It does not determine which agent out of multiple available agent will be routed contacts.

    Let's say Contact Y is in Queue 2 and has been there longer than Contact Z in Queue 1. Agent A will be routed Contact Z even though it is newer. This is because Queue 1 has a higher priority in the agent's profile.
- **Do Priority 5 agents get calls only when agents with higher priorities are not available?**

No. Priority 5 agents receive calls from that queue only if their other priority queues are empty. One agent's priority setting for a queue does not impact when the queue is routed a contact relative to other agents, but relative to other queues in the agent's profile.

For instructions on how to set priority and delay for a routing profile, see Create a routing profile in Amazon Connect to link queues to agents.

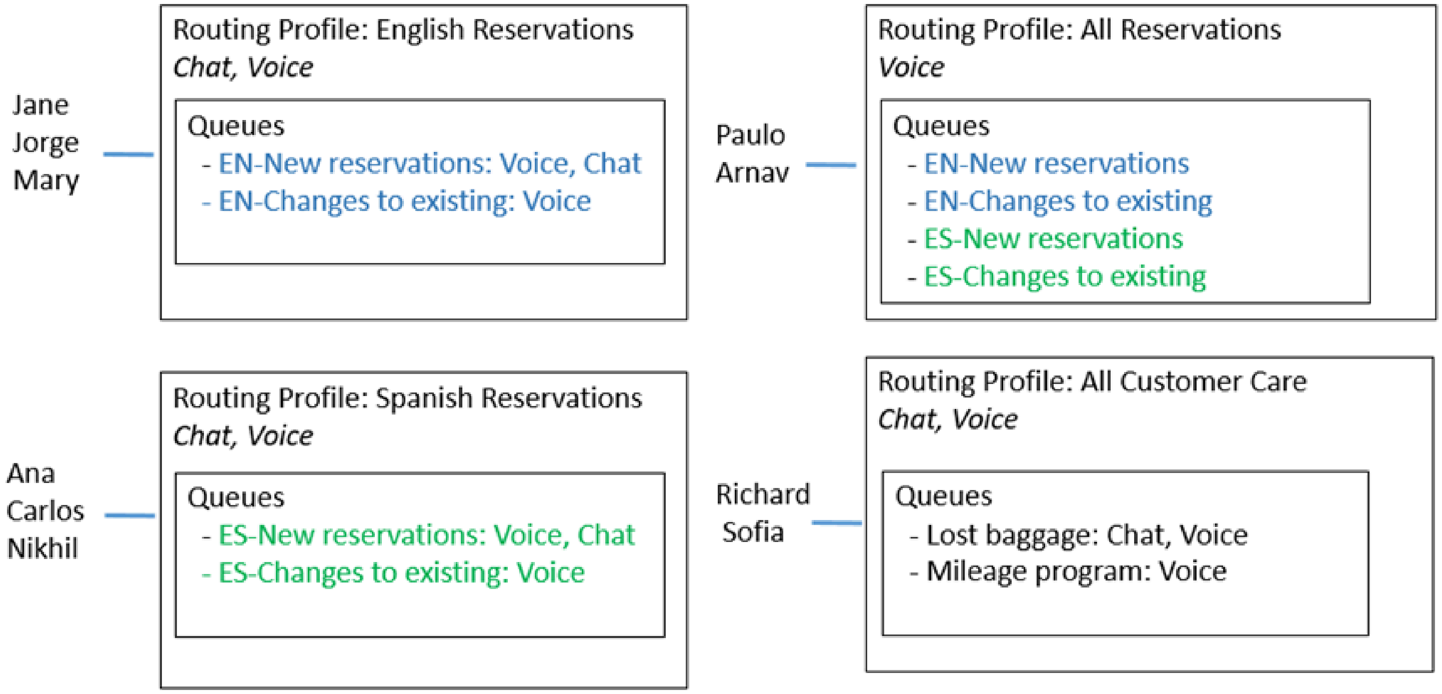
Queue-based routing to route customers to a specific contact center agent

In your business, you might want to route customers to specific agents based on certain criteria, such as the skill of the agent. This is called queue-based routing, also known as skills-based routing.

For example, an airline might have some agents who handle reservations for English-speaking customers, others who handle Spanish-speaking customers, and a third group that handles both types of customers, but only over the phone.

The following illustration shows you can:

- Assign the same routing profile to multiple agents.
- Assign multiple queues to a routing profile.
- Assign a queue to multiple routing profiles.



For an overview of the steps to set up queue-based routing, see Set up queue-based routing.

Channels and concurrency for routing contacts in Amazon Connect

Agents can handle voice, chat, tasks and email in Amazon Connect. When you set up a routing profile to handle multiple channels, you have two options:

- Option 1: Set up agents so they can handle contacts while already on another channel. This is called *cross-channel concurrency*.
- Option 2: Set up agents so they can be offered voice, chat, tasks, or email if they are fully idle, depending on what is in queue. When you choose this option, after the agent starts work on contacts from one channel they will no longer be offered contacts from any other channels.

When using cross-channel concurrency, Amazon Connect checks which contact to offer the agent as follows:

1. It checks what contacts/channels the agent is currently handling.
2. Based on what channels they are currently handling, and the cross-channel configuration in the agent's routing profile, it determines whether the agent can be routed the next contact.
3. Amazon Connect prioritizes the longest waiting contact if Priority and Delay are equal. Even though it's evaluating multiple channels at the same time, First-In First-Out is still respected.

For a detailed example of how Amazon Connect routes contacts when cross-channel concurrency is set up, see Example of how a contact is routed with cross-channel concurrency.

To learn more about what the agent experiences in the Contact Control Panel when handling multiple chats, see Use the Contact Control Panel (CCP) in Amazon Connect to chat with contacts.

Create a queue using the Amazon Connect admin website

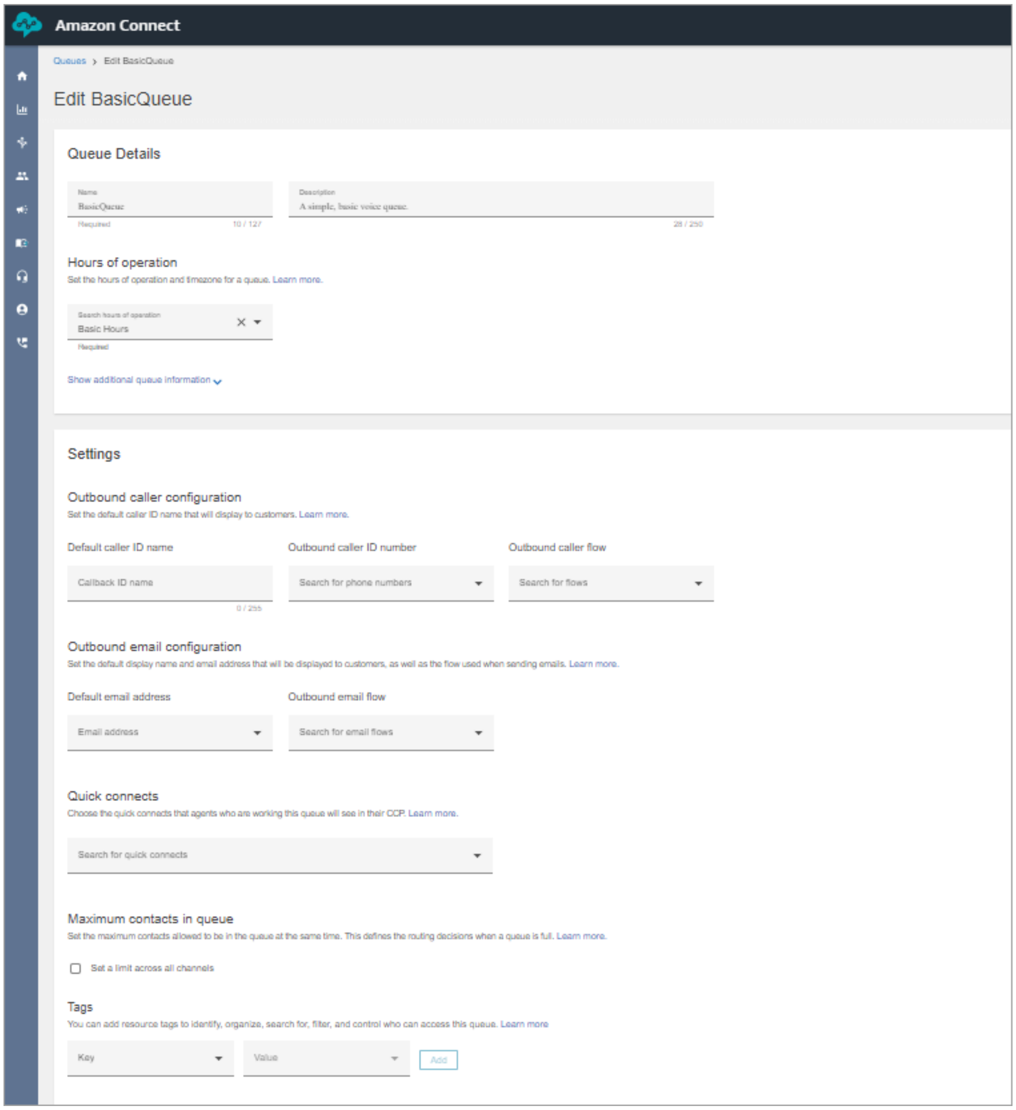
This topic explains how to create a queue using the Amazon Connect admin website. To create queues programmatically, see the create-queue AWS CLI or CreateQueue in the *Amazon Connect API Reference*.

How many queues can I create? To view your quota of **Queues per instance**, open the Service Quotas console at https://console.aws.amazon.com/servicequotas/.

To create a queue

1. Log in to the Amazon Connect admin website at https://`instance name`.my.connect.aws/. Use an **Admin** account, or an account that has **Routing - Queues - Create** permission in its security profile.
2. On the Amazon Connect admin website, on the navigation menu, choose **Routing**, **Queues**, **Add new queue**.
3. Add the appropriate information about your queue and choose **Add new queue**.

   The following image shows the queue information for the BasicQueue.



See the following topics for detailed information about each of the above areas:

1. Set the hours of operation and time zone for a queue using Amazon Connect
2. Set up outbound caller ID in Amazon Connect
3. Set up email in Amazon Connect
4. Set the limit of maximum contacts in a queue using Amazon Connect
5. Create quick connects in Amazon Connect

The queue is automatically active.

4. Assign the queue to a routing profile; for information, see Create a routing profile in Amazon Connect to link queues to agents. The routing profile links the queue and agents together.

5. Add tags to identify, organize, search for, filter and control who can access this queue. For more information, see Add tags to resources in Amazon Connect.

To learn how queues work, see How Amazon Connect uses routing profiles and Queue-based routing to route customers to a specific contact center agent.

APIs to create and manage queues

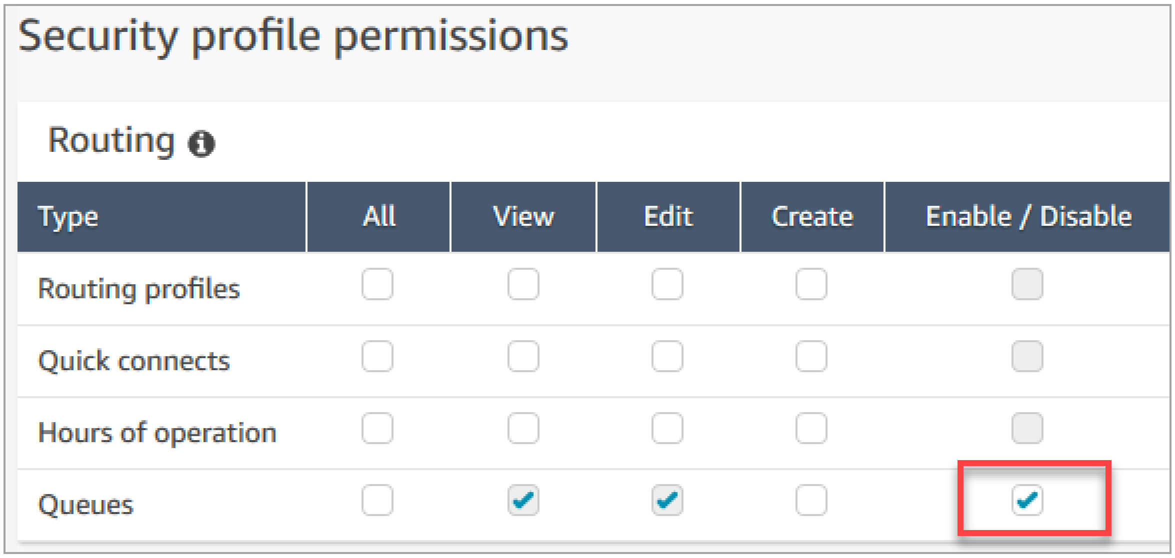
Use the following APIs to create and manage queues programmatically:

- CreateQueue
- DeleteQueue
- DescribeQueue
- ListQueues
- SearchQueues
- UpdateQueueHoursOfOperation
- UpdateQueueMaxContacts
- UpdateQueueName
- UpdateQueueOutboundCallerConfig
- UpdateQueueOutboundEmailConfig
- UpdateQueueStatus

Disable a queue temporarily using Amazon Connect

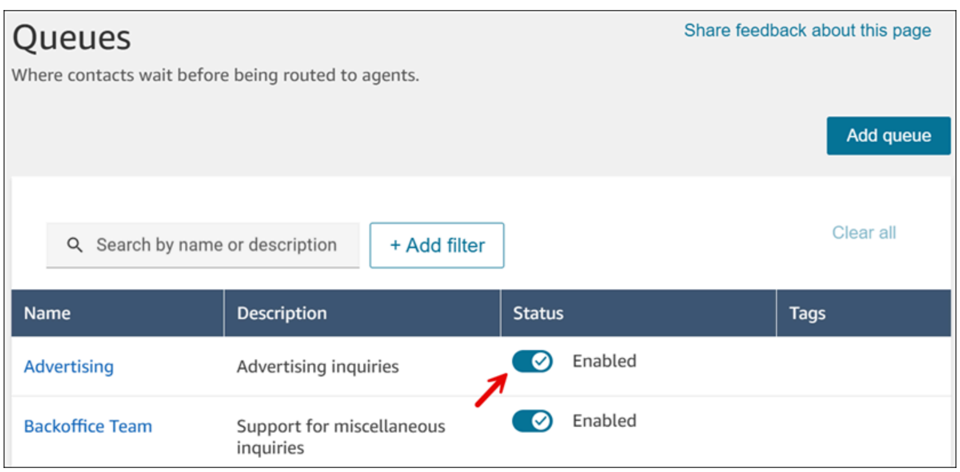
You can quickly control the flow of contacts to queues by temporarily disabling a queue. When a queue is disabled, it's put in an offline mode. No new contacts are routed to the queue, but any existing contacts already in the queue are routed to agents.

Only users who have a security profile with **Routing** - **Queues** - **Enable/Disable** permission can disable a queue.

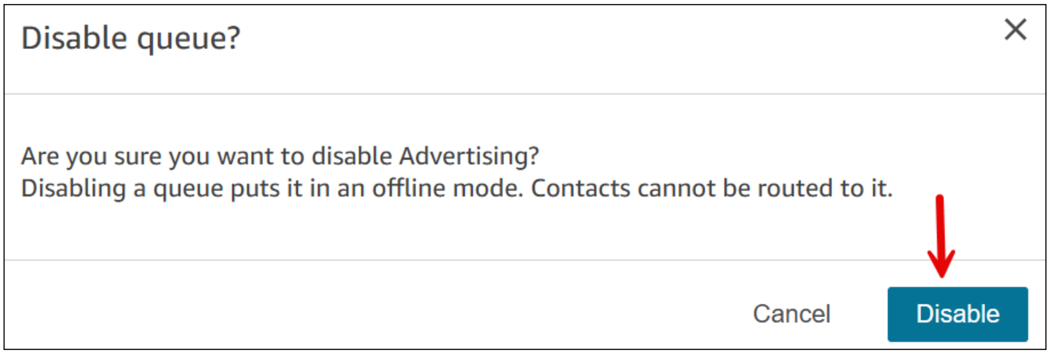


To temporarily disable an active queue

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an **Admin** account, or an account that has **Routing** - **Queues** - **Enable/Disable** permission in its security profile.
2. On the Amazon Connect admin website, on the navigation menu, choose **Routing**, **Queues**.
3. For the queue you want to disable, toggle the **Status** to **Disabled**, as shown in the following image.



4. Choose **Disable** to confirm you want to disable the queue, as shown in the following image. You can immediately re-enable the queue if needed by toggling the button back to **Enabled**.



Delete a queue from your Amazon Connect instance

There are three ways to delete a queue from your Amazon Connect instance:

- Amazon Connect admin website

  1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an **Admin** account, or an account that has **Routing - Queues - Delete** permission in its security profile.
  2. On the Amazon Connect admin website, on the navigation menu, choose **Routing**, **Queues** and then select the delete icon.

  
  > **Important**
  >
  > You cannot undo a deleted queue. To temporarily disable a queue, toggle its status to **Disabled**.

- DeleteQueue API
- delete-queue AWS CLI

Set the limit of maximum contacts in a queue using Amazon Connect

By default a queue can contain up to your service quota for voice, chat, tasks, and email:

- **Concurrent active calls per instance**
- **Concurrent active chats per instance (includes SMS)**
- **Concurrent active tasks per instance**
- **Concurrent active emails per instance**

To increase one of these quotas, you must request a quota increase. For more information, see Amazon Connect service quotas.

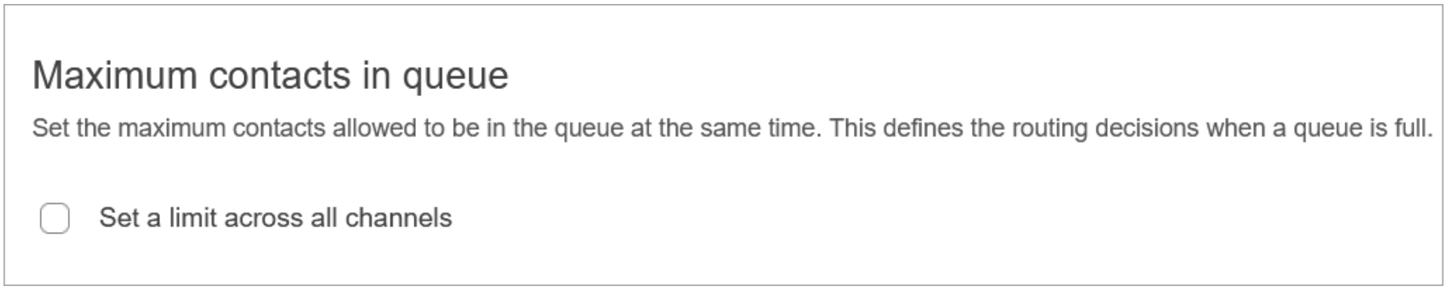
There may be situations where you want a specific queue to allow fewer contacts than the allowed quota. For example:

- You have a queue that is dedicated to calls about complicated issues that take an average of 15 minutes to resolve, you may want to limit the number of calls allowed in the queue to be less than **Concurrent active calls per instance**. This prevents customers from waiting for hours.
- You may have a queue dedicated to chats. Your service quota is 100 but you want only up to 20 chats at a time. You can set that value so Amazon Connect limits the number of active chats routed to that queue.
- You have a queue that combines more than one channel, and you set a custom value. Note that the queue stops accepting new contacts after that number is reached, regardless of the distribution of contacts. For example, if you set the value to 50, and the first 50 contacts are chats, then voice calls are not routed to this queue.

This topic explains how to reduce the allowed number of contacts in a queue for these situations.

Reduce the number of contacts allowed in a queue

To reduce the number of contacts allowed in a standard queue at the same time, you set the **Maximum contacts in queue** limit for the standard queue. This setting does not apply to agent queues; those are always limited to 10 contacts.



When you enter a number in **Maximum contacts in queue**, Amazon Connect validates that the number is less than the sum of your concurrent active contacts service quotas: **Concurrent calls per instance** + **Concurrent active chats per instance** + **Concurrent active tasks per instance** + **Concurrent active emails per instance**.

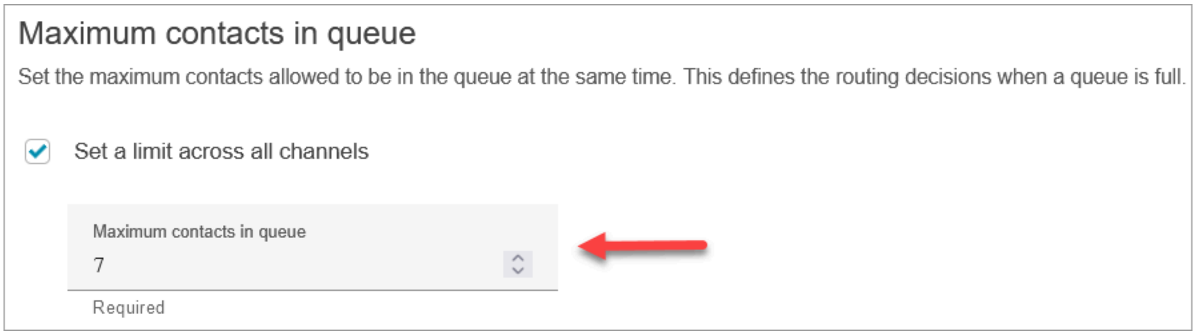
Important

- You must set **Maximum contacts in queue** to be less than the sum of the following quotas combined: **Concurrent calls per instance** + **Concurrent active chats per instance** + **Concurrent active tasks per instance** + **Concurrent active emails per instance**.
- Incoming calls and queued callbacks count towards the queue size limit.

For information about default service quotas and how to request an increase, see Amazon Connect service quotas.

To reduce the number of contacts allowed in a specific queue

1. On the navigation menu, choose **Routing**, **Queues**, **Add new queue**. Or, edit an existing queue.
2. In **Maximum contacts in queue**, choose **Set a limit across all channels**. If the queue is also used for chats, tasks, and email, then all channels will be capped at the same maximum.
3. In the box, specify how many contacts can be in the queue before it's considered full. The value cannot exceed the sum of **Concurrent active calls per instance** + **Concurrent active chats per instance** + **Concurrent active tasks per instance** +**Concurrent active emails per instance**.



What happens to calls when a queue is full

- Incoming calls: Ideally you've set up queued callback, or have another contingency implemented. If not, the next incoming call gets a reorder tone (also known as a fast busy tone), which indicates no transmission path to the called number is available.
- Queued callbacks: The next queued callback is routed down the error branch.

What happens if Maximum contacts in queue is set to 0

If you set **Maximum contacts in queue** to 0 it renders the queue unusable. The behavior is the same as when a queue is full.

Queue maximum limit exceptions

There are times when you can add more contacts to a queue than the set **Maximum contacts in queue** limit.

- There may be a slight delay between the time that a queue reaches its capacity limit and when this limit is enforced in the flow. This delay could cause incoming contacts to be queued during that time, particularly during bursts of traffic.

Additionally, Amazon Connect includes a 20 percent buffer to the queue capacity for the following exceptional scenarios:

- A contact was transformed into a Queued Callback, scheduled to be added to the queue at X time using the **Initial delay** setting in the flow. However, when the scheduled time arrived, the target queue had reached its **Maximum capacity in queue** limit. In this scenario, Amazon Connect allows the Queued Callback to be enqueued up to a 20 percent buffer of the **Maximum capacity in queue** limit for the queue.

- A contact, previously queued in Queue1, is now being transferred to Queue2 through the flow. However, when the transfer is attempted, Queue2 has already reached its **Maximum capacity in queue** limit. In this scenario, Amazon Connect allows the transfer to proceed, up to a 20 percent buffer of the **Maximum capacity in queue** limit for Queue2.
- An agent initiates a manual transfer of a contact into a queue through quick connects. However, when the transfer is attempted, the queue has already reached its **Maximum capacity in queue** limit. In this scenario, Amazon Connect allows the transfer to proceed, up to a 20 percent buffer of the **Maximum capacity in queue** limit.

Route contacts based on queue capacity using Amazon Connect

To define routing decisions based on queue capacity, use a Transfer to queue block to check whether a queue is full (Maximum contacts in queue), and then route the contact accordingly.

The Transfer to queue block checks the Maximum contacts in queue. If no limit is set, the queue is limited to the number of total concurrent contacts for the following quotas:

- Active tasks per instance
- Concurrent active emails per instance
- Concurrent calls per instance
- Concurrent chats per instance

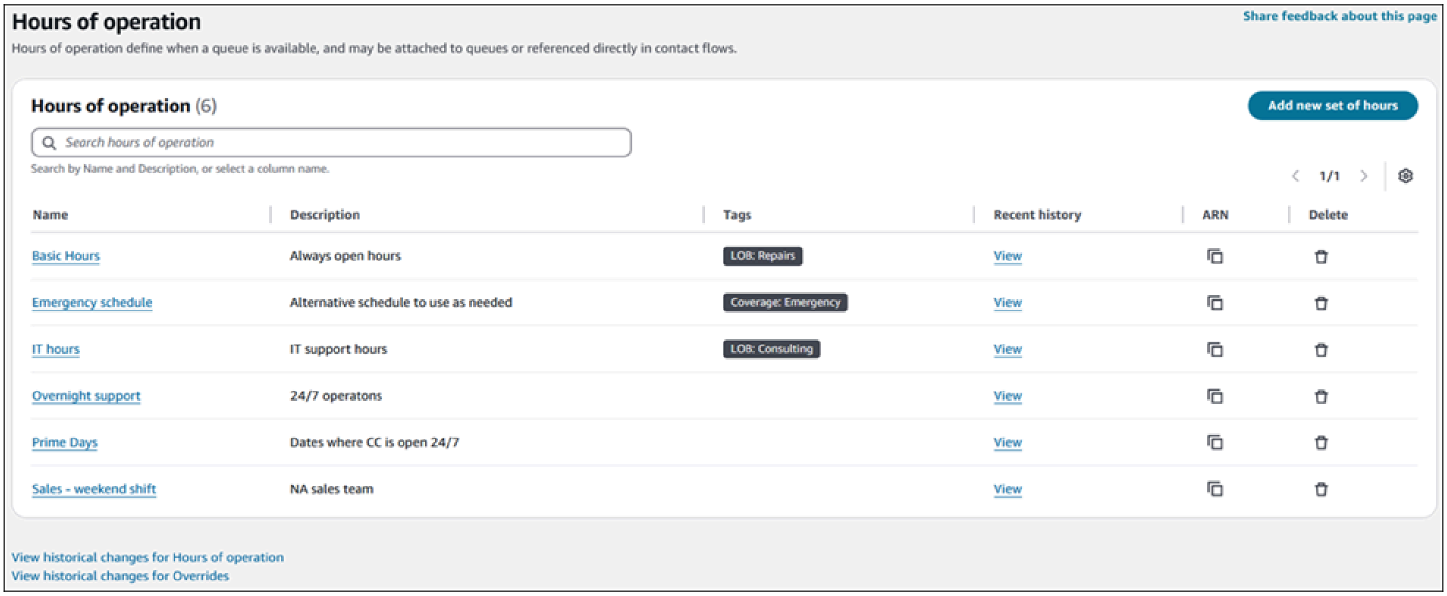
Set the hours of operation and time zone for a queue using Amazon Connect

This topic explains how to set hours of operating by using the Amazon Connect admin website. To set hours programmatically, see APIs for creating and managing hours of operation.

The first thing you need to do when you set up a queue is to specify the hours of operation and timezone. The hours may be referenced in flows. For example, when routing contacts to agents, you might use the Check hours of operation block first, and then route the contact to the appropriate queue.

You can also set up overrides for reduced or extended hours. For example, at the beginning of the year you may want to enter all the days to that your business is closed for holidays, or if open, during which hours.

The following image shows a sample hours of operation page where overrides are specified. The following hours of operation are overrides: Emergency schedule, IT hours, Overnight support, Prime Days, and Sales - weekend shift.



How many hours of operation can I create? To view your quota of **Hours of operation per instance**, open the Service Quotas console at https://console.aws.amazon.com/servicequotas/.

Contents

Set the hours of operation

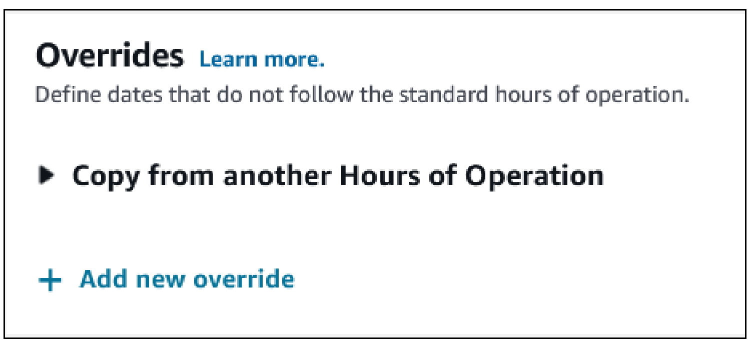
1. Log in to the Amazon Connect admin website with an Admin account or an account that has **Routing - Hours of operation - Create** security profile permission.

2. On the navigation menu, choose **Routing**, **Hours of operation**.
3. To create a template, choose **Add new set of hours** and enter a name and a description.
4. Choose **Time zone** and select a value.
5. Choose **Settings** to set new hours.
6. Optionally, in the **Tags** section, add tags to identify, organize, search for, or filter who can access this hours of operation record. For more information, see Add tags to resources in Amazon Connect.
7. Choose **Save**.
8. Now you can specify these the hours of operation when you create a queue, and check them in the Check hours of operation block.

Set overrides for extended, reduced, and holiday hours

You can set overrides for when your contact center will be closed, or will have extended or reduced hours. For example, you can indicate that you are closed on New Years Day, have reduced hours on New Year's Eve, and extended hours on Boxing Day. You can also set up overrides for a range of dates to support scenarios such as special summer hours.

When you choose to add overrides, you have the option to add them manually or to copy them from another hours of operation record, as shown in the following image.



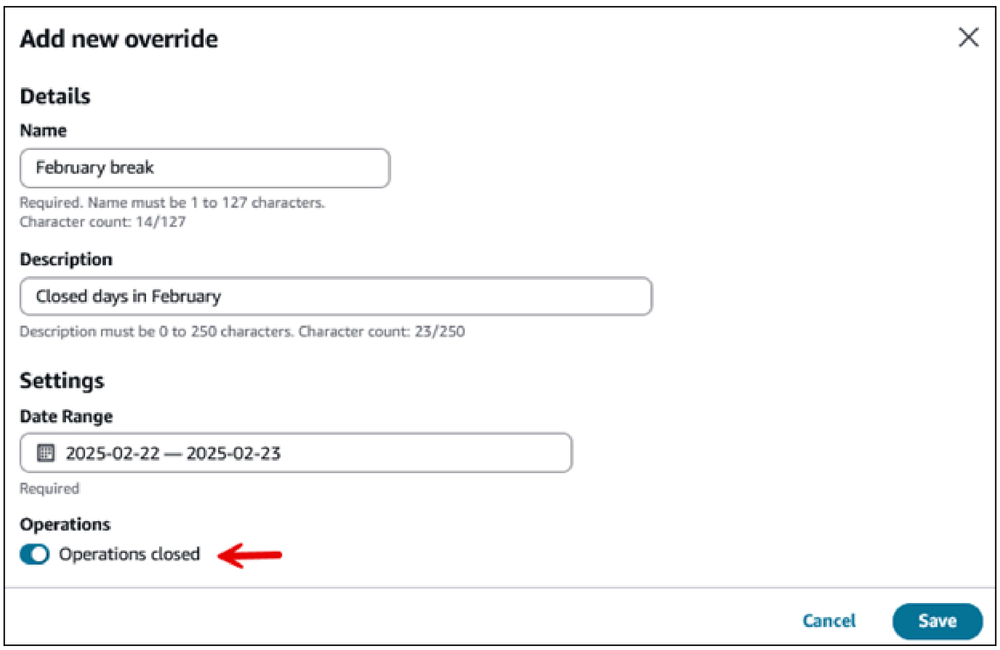
Both options are explained next.

Add overrides manually

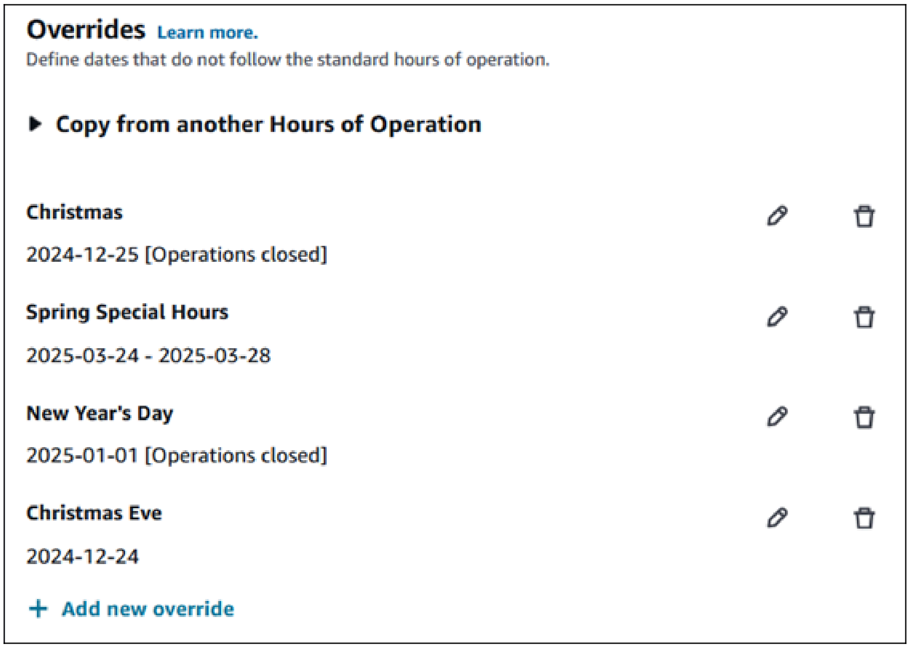
1. On the **Add overrides to hours of operation** page, choose whether the override applies to a single date or a date range.
2. Complete the page as prompted. Note the following:

- Dates/ranges cannot overlap. For example, if you have reduced hours during the summer, and July 4th is closed, you must set up a range for before July 4, then July 4, and a range afterwards.
- When an override with a date range has operating hours, more configuration is required to account for variations in the days of the week. A date range can have different hours per day as long as the day or week pattern is consistent week over week. This allows you to set up seasonal hours, such as reduced hours most of the week and Friday is closed.
- Date ranges cannot overlap so if this pattern breaks, you need to set up a different override range. For example, reduced summer hours before and after the July 4th holiday, when operations are closed.
- Overrides cannot be reused or set up as recurring each year.

The following image shows an example of a contact center that is going to be closed for two days in February.



The following image shows an example of holiday overrides for the **Basic Hours** record.

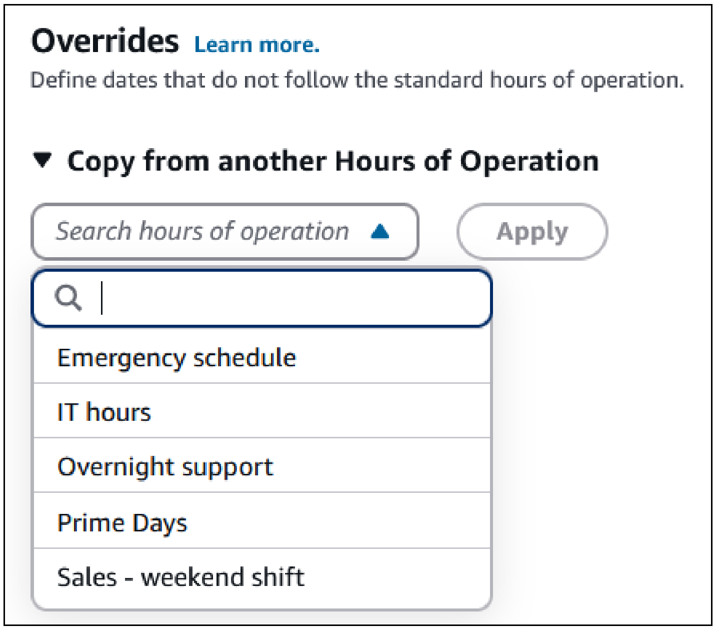


Copy overrides to another hours of operation record

If you have many similar hours of operation records (for example, different hours for different teams or channels), you can set up a hours of operation for one then copy it to others. You can:

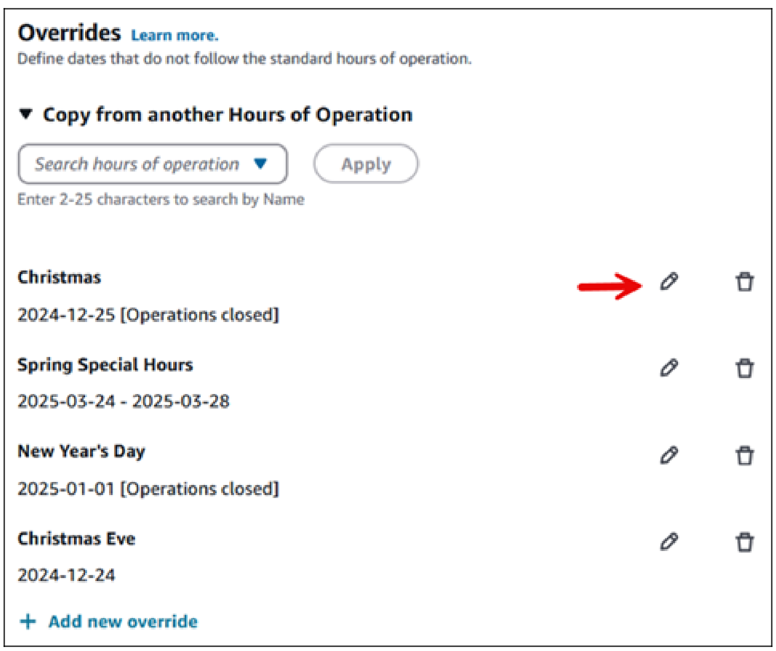
- Copy the overrides from another hours of operation record. For example, to save time you can create a source hours of operation with a main list.
- Copy more than one list into an hours of operation record.
- Copy a list in addition to manually adding overrides.

The following image shows an example of a dropdown list of overrides that you can to another hours of operation record.



After copying, you can remove or edit rows in that list. For example, you can change the length of time the contact center is open on Christmas for a certain line of business. Or after copying US overrides to a Canadian record, you can omit July 4 and other US-based holidays, and then add dates that are specific to Canada.

The following image shows the location of the edit and delete options on the **Overrides** page.



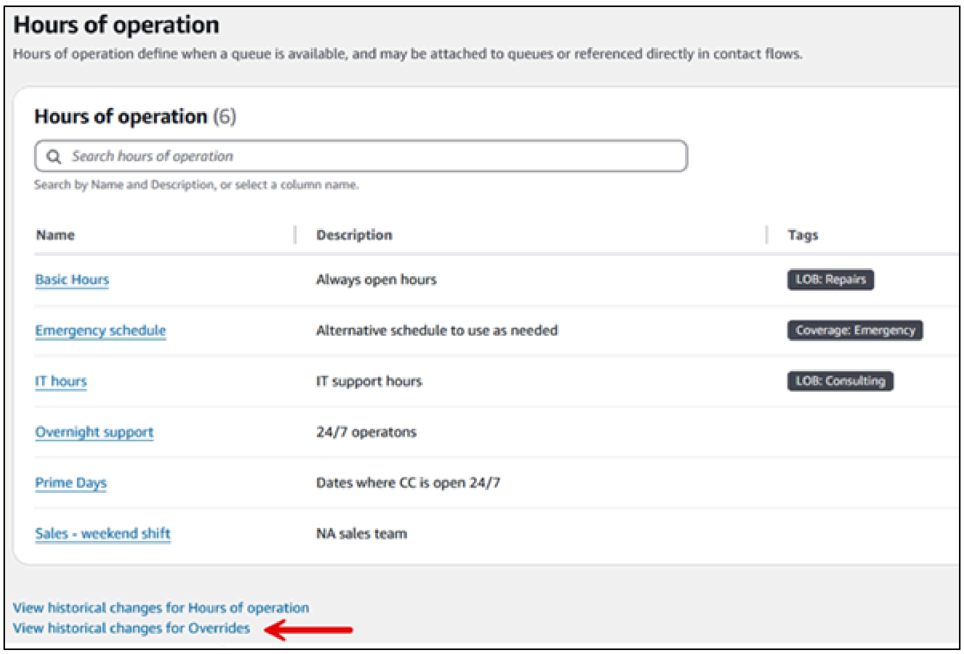
Tip

You can view and copy the overrides for past dates. You may want to delete older overrides if you near your quota.

View an audit history of overrides

An audit history of overrides appears on the **Hours of operation** page, distinct from the standard hours of operations audit history. Each audit record refers to the ID of the hours of operation record. By viewing the audit history you can differentiate between overrides with the same name that are used in multiple hours of operation overrides.

The following image shows the location of the link to view historical changes for overrides.



Note

AWS CloudTrail tracks the history of all resource changes. For more information, see Log Amazon Connect API calls with AWS CloudTrail.

How to specify midnight

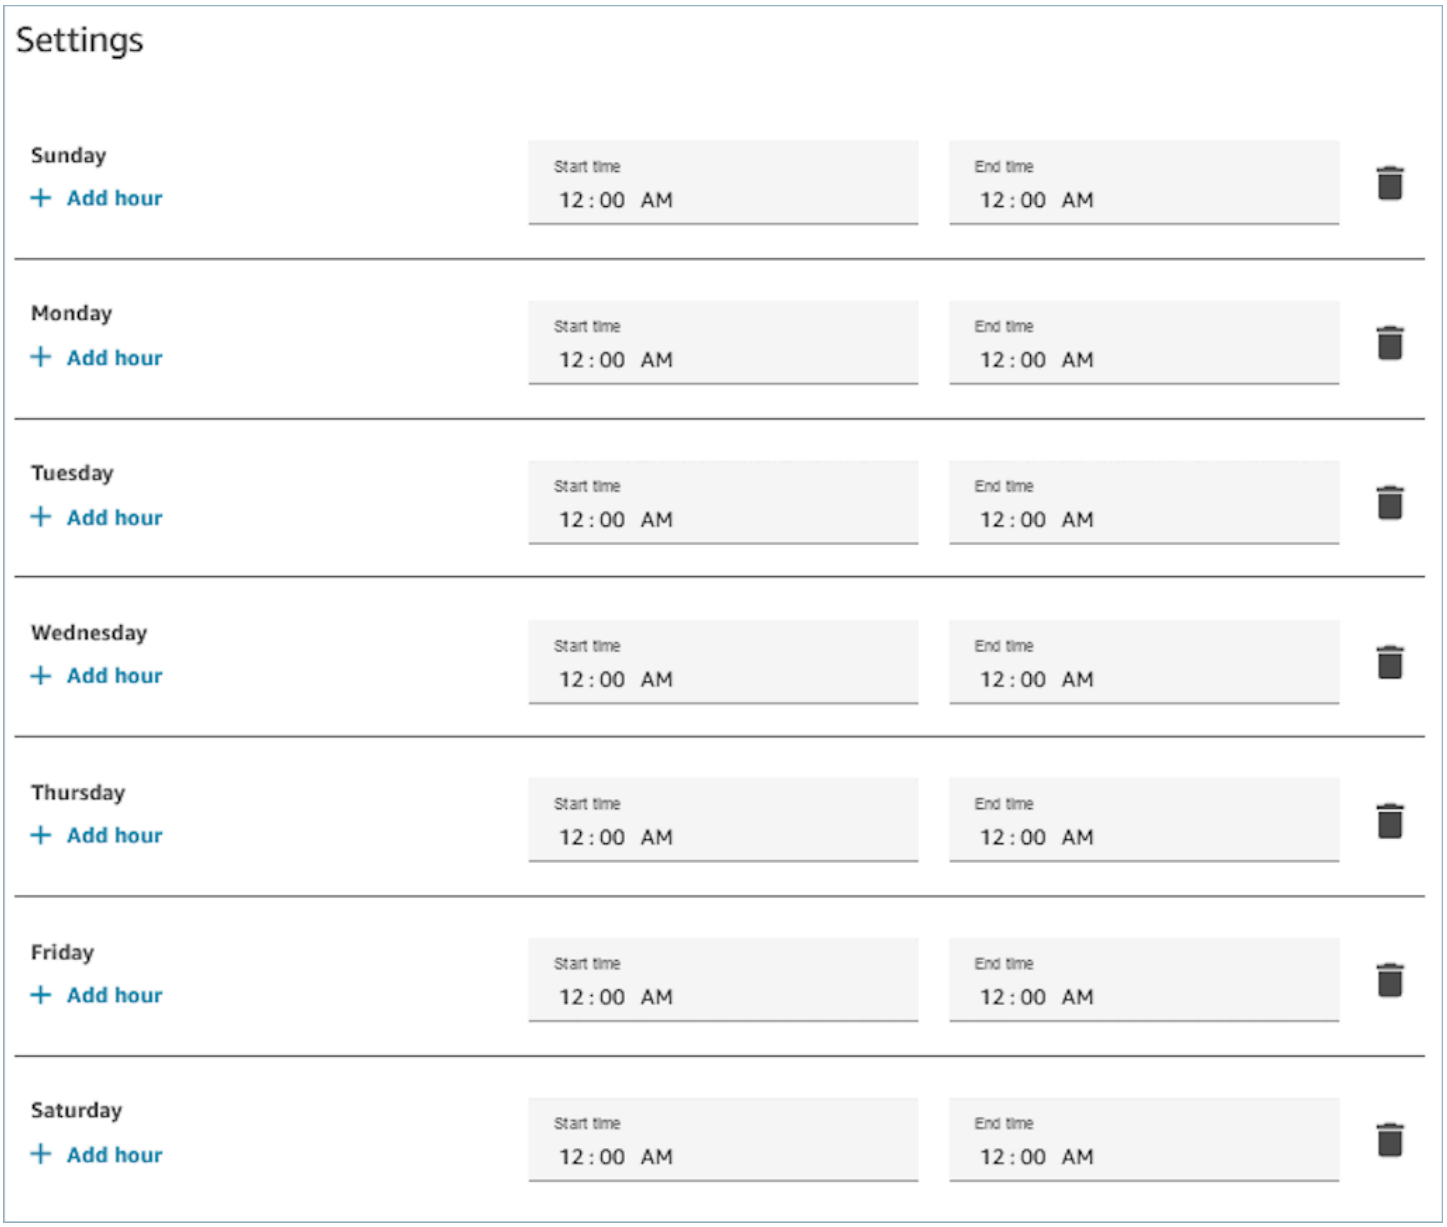
To specify midnight, enter 12:00AM.

For example, if you want to set your hours to 10:00AM to midnight, you would enter: 10:00AM to 12:00AM. Your call center would be open for 14 hours. Here's the math:

- 10:00AM-12:00PM = 2 hours
- 12:00PM-12:00AM = 12 hours
- Total = 14 hours

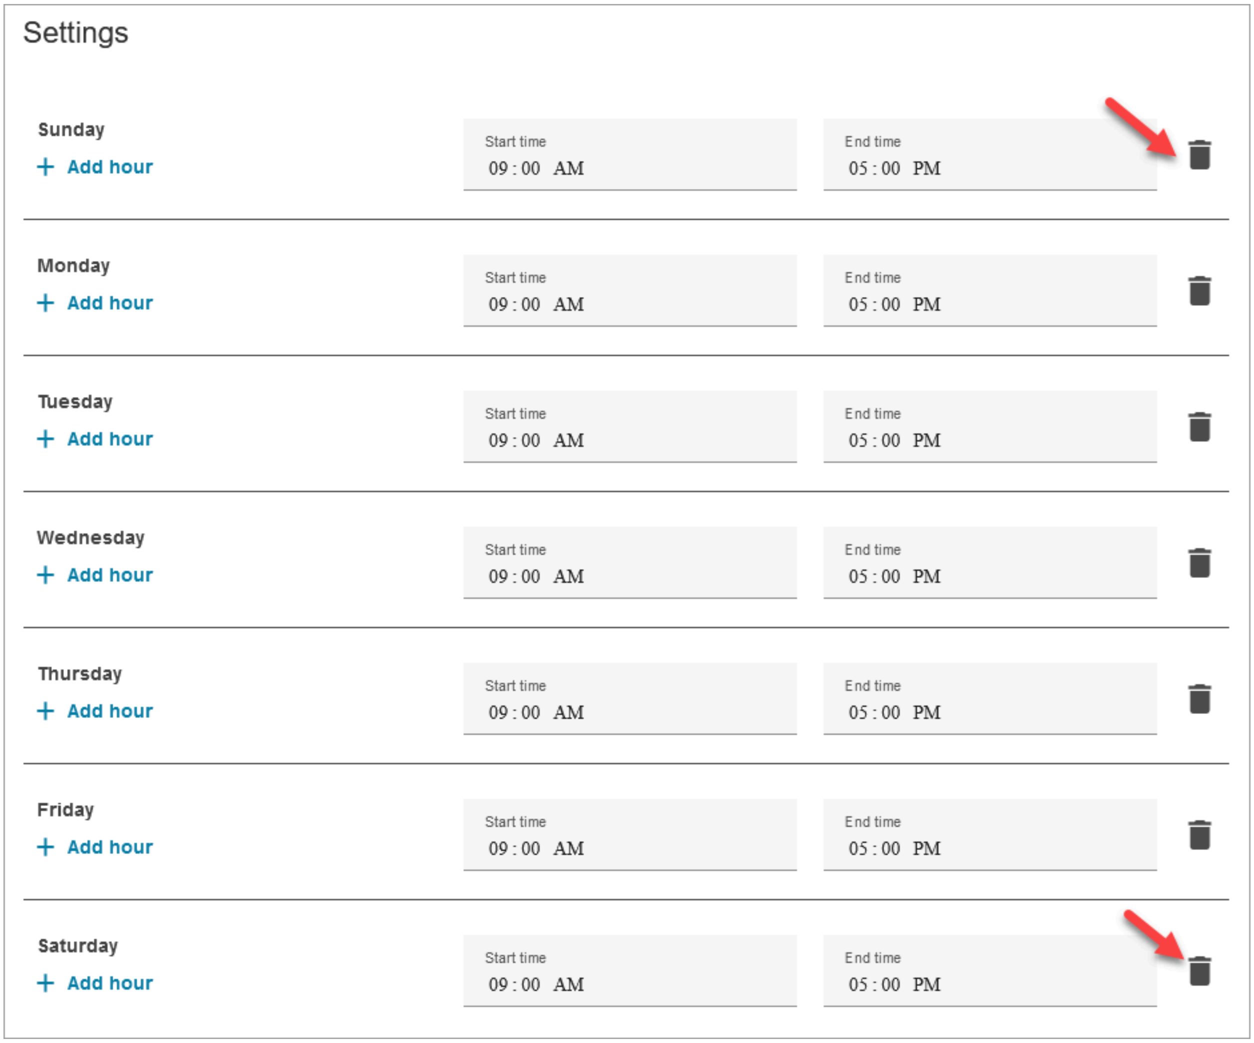
Examples

Schedule for 24x7



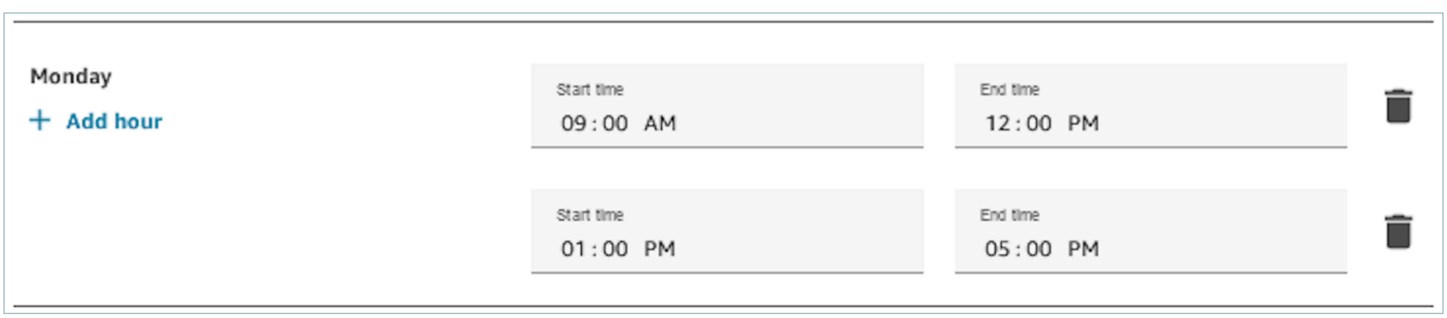
Schedule for Monday to Friday 9:00 AM to 5:00 PM

Remove Sunday and Saturday from the schedule.



Add lunch and other breaks

If your entire contact center were to close for lunch from 12-1, for example, then you'd enter hours to specify that, as in the following image:



In most contact centers breaks are staggered. While some agents are at lunch, for example, others are still available to handle contacts. Instead of specifying this in the hours of operation, you add custom agent statuses that appear in the agent's Contact Control Panel (CCP).

For example, you might create a custom status named **Lunch**. When the agent goes to lunch, they change their status in the CCP from **Available** to **Lunch**. During this time, no contacts are routed to them. When they return from lunch and are ready to take contacts again, they change their status back to **Available**.

Supervisors can change an agent's status using the real-time metrics report.

For more information, see these topics:

- Add a custom agent status to the Amazon Connect Contact Control Panel (CCP)
- Agent status in the Contact Control Panel (CCP)
- Change the "Agent activity" status in a metrics report in the Contact Control Panel (CCP)

What happens during daylight saving time

Amazon Connect uses the timezone to determine whether daylight saving time is in effect for the queues, and **adjusts automatically** for all timezones that observe daylight saving time. When a contact comes in, Amazon Connect looks at the hours and timezone of your contact center to determine whether the contact can be routed to the given queue.

> **Important**
>
> Amazon Connect provides options for EST5EDT, PST8PDT, CST6CDT, and more. For example, EST5EDT is defined as:
> Eastern Standard Time (EST) is used when observing standard time. It is five hours behind Coordinated Universal Time (UTC).
> Eastern Daylight Time (EDT) is used when observing daylight saving time. It is four hours behind Coordinated Universal Time (UTC).
> We recommend researching your choice of timezone to ensure you understand it.

Example

1. A person initiates a call or chat with your contact center.

2. Amazon Connect looks at the hours of operation for your call center right now.
   - The contact is from timezone A.
   - Your call center's hours are 9 AM - 5 PM in timezone B.
   - If the current time in timezone B is 2 PM then the call or chat is queued.
   - If the current time in timezone B is 7 AM then the call or chat is not queued.

Use the Check Hours of Operation block

At the start of your flows, use the Check hours of operation block to determine whether your contact center is open, and to branch accordingly.

APIs for creating and managing hours of operation

Use the following APIs to create and manage hours of operation programmatically:

- CreateHoursOfOperation
- DescribeHoursOfOperation
- DeleteHoursOfOperation
- ListHoursOfOperations
- SearchHoursOfOperations
- UpdateHoursOfOperation

Use the following APIs to create and manage overrides programmatically:

- CreateHoursOfOperationOverride
- DescribeHoursOfOperationOverride
- DeleteHoursOfOperationOverride
- GetEffectiveHoursOfOperations
- ListHoursOfOperationOverrides
- SearchHoursOfOperationOverrides
- UpdateHoursOfOperationOverride

Create a routing profile in Amazon Connect to link queues to agents

This topic is for administrators and contact center managers. It explains how to create routing profiles using the Amazon Connect admin website. For the APIs used to create and manage routing profiles programmatically, see APIs to create and manage routing profiles.

While queues are a 'waiting area' for contacts, a routing profile links queues to agents. When you create a routing profile, you specify:

- Channels: Which channels—voice, chat, task, and email—are routed to this group of agents; whether to allow channels concurrently.
- Queues: Which queues are in the routing profile; whether one queue should be prioritized over another.

Each agent is assigned to one routing profile. For more information about routing profiles and queues, see How Amazon Connect uses routing profiles.

How many routing profiles can I create? To view your quota of **Routing profiles per instance**, open the Service Quotas console at https://console.aws.amazon.com/servicequotas/.

To create a routing profile

1. On the navigation menu, choose **Users**, **Routing profiles**, **Add routing profile**.
2. In the **Routing Profile Details** section, in the **Name** box, enter a searchable display name. In the **Description** box, enter what the profile is used for.
3. In the **Channel Settings** section, enter or choose the following information:

Item	Description	
Channel availability	Choose which types of contacts will be routed to agents who are assigned to this routing profile.	
Maximum contacts per agent	For chat, task, and email channels, specify how many contacts that an agent can	

Item	Description
	handle simultaneously, up to 10.
Cross-channel concurrency	Choose one of the following options: • **No other channels while agent is on *`channel`***. For example, while an agent is on a chat, they will not receive a voice contact, email, or a task. • **Allow other channel concurrently**. For example, while an agent is on a voice contact, they can be offered contacts from any other channels enabled in the routing profile, such as chats, emails, and tasks. See Example of how a contact is routed with cross-channel concurrency.

4. In the **Queues** section, enter the following information:

Item	Description
Name	Use the dropdown menu or text field to choose a queue that you've already set up. You can add multiple queues to a routing profile.

Item	Description
Channels	Choose whether the queue is for chat, voice, email, task, or all of them. **Important** The channel that you specify here must also be specified in the **Channel Settings** section. If it isn't, contacts from that channel won't be routed to agents.
Priority	Specify the order in which contacts are to be handled for that queue. For example, a contact in a queue with a priority of 2 would be a lower priority than a contact in a queue with a priority of 1.

Item	Description
Delay (in seconds)	Enter the minimum amount of time a contact should be in the queue before they are routed to an available agent. To learn more about how Priority and Delay work together, see Queue priority and delay examples to help you load balance Amazon Connect contacts.
Default outbound queue	Choose a queue to be associated with outbound calls or emails initiated by the agents. Outbound contacts respect the settings from the default outbound queue, such as caller ID and "From" email address. For more information, see Create a queue using the Amazon Connect admin website.
Set routing order	By default Amazon Connect routes new contacts to agents that have been in **Available** status the longest. You can customize this behavior, for example, to change the impact that outbound contacts have on the assignment of new inbound contacts.

Item	Description	
Outbound calls should not impact routing order	Use this setting if you don't want agents who make outbound contacts to move to the bottom of the list for receiving inbound contacts. By default new contacts are routed to the agent who has been in **Available** status longest. By making an outbound contact, the agent drops to the bottom of the list waiting for inbound contacts. You can use this setting to override that default logic and ensure that agents making outbound contacts still get their fair share of inbound contacts.	

5. Optionally, add tags to identify, organize, search for, filter, and control who can access this routing profile. For more information, see Add tags to resources in Amazon Connect.

6. Choose **Save**.

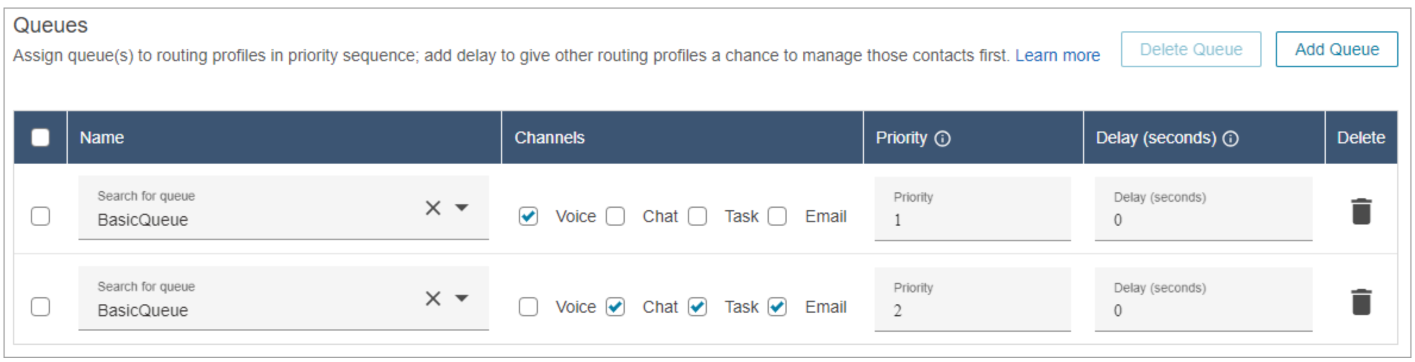
Tips for setting up channels and concurrency

- Use **Channel availability** to toggle on and off whether agents assigned to a profile get voice, chat, task, and email contacts.

  For example, there are 20 queues assigned to a profile. All of the queues are enabled for voice, chat, task, and email. By removing the **Voice** option at the routing profile level, you can stop all voice calls to these agents, across all queues in the profile. When you want to restart voice contacts for these agents again, select **Voice**.

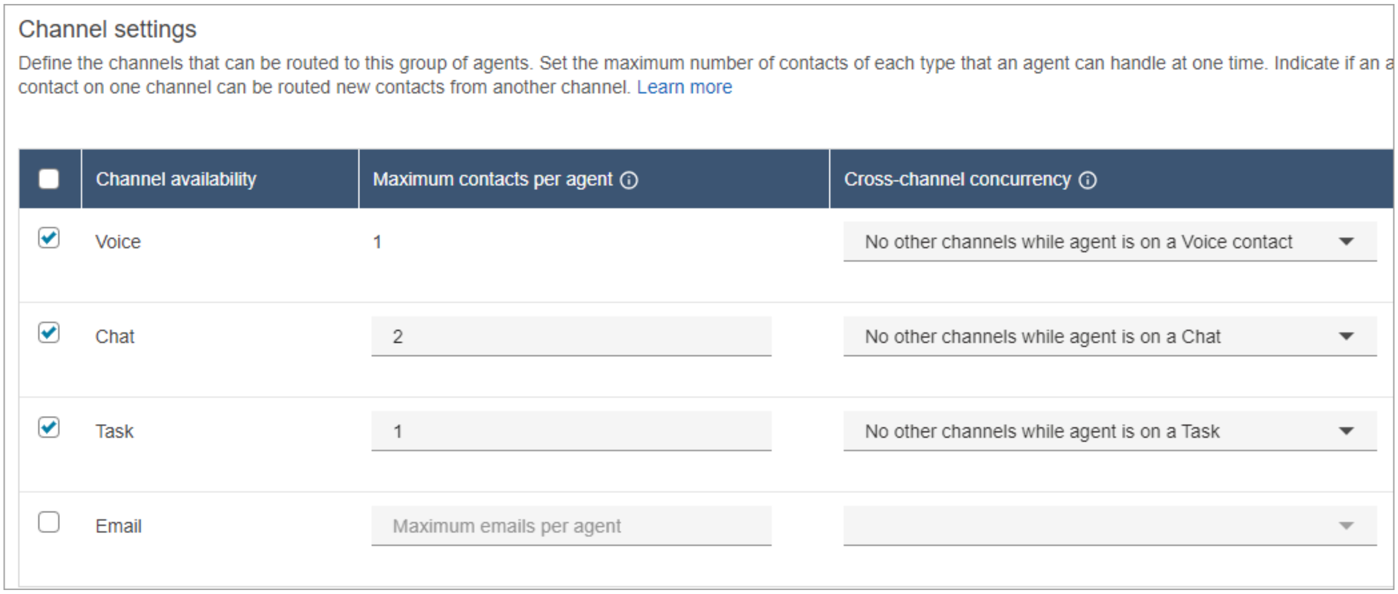
- When using **Cross-channel concurrency**, Amazon Connect checks which contact to offer the agent as follows:
  1. It checks what contacts/channels the agent is currently handling.
  2. Based on what channels they are currently handling, and the cross-channel configuration in the agent's routing profile, it determines whether the agent can be routed the next contact.
  3. Amazon Connect prioritizes the longest waiting contact if Priority and Delay are equal. Even though it's evaluating multiple channels at the same time, First-In First-Out is still respected.

  See Example of how a contact is routed with cross-channel concurrency.
- For each queue in the profile, choose whether it's for voice, chat, task, email, or all channels.
- If you want a queue to handle voice, chat, task, and email but want to assign a different priority to each channel, add the queue twice. For example, in the following image, voice is priority 1 but chat, task, and email are priority 2.



Example of how a contact is routed with cross-channel concurrency

For example, assume an agent is assigned to the routing profile that has the channel settings shown in the following image. They can be routed voice, chat, task, and email contacts. They can receive cross-channel contacts when on tasks.



The agent will experience the following routing behavior:

1. Assume the agent is fully idle. Next, the agent accepts a chat and begins working on it. Meanwhile, a task comes into queue.
   - Chat is set to **No other channels allowed**.
   - So even though there is a task in queue, it will not be offered to this agent.
2. Next, there is a chat in queue.
   - The agent's maximum chat concurrency is 2, so they are routed another chat for total of 2 chats. The agent continues working on both of the chats.
3. There are no other chats in queue. The agent finishes both chats (closes ACW).
   - There is still a task waiting in queue.
   - At this point, the task is offered to the agent because they are fully idle again. The agent begins working the task.
4. Another chat comes into queue.
   - Tasks is set to **Allow other channels concurrently**. So, even though the agent is already working on a task, they can still be offered the chat.
   - The chat gets routed to the agent, who now works on both the 1 chat and 1 task concurrently.
5. Now there is a Voice call in queue.
   - The agent is still working on 1 chat and 1 task.

- Even though **Task** is set to **Allow other channels concurrently**, the agent is still working on 1 chat, and **Chat** is set to **No other channels while agent is on a Chat contact**. So, the voice call is not routed to the agent. The agent continues working on both the chat and the task.

6. The agent completes the chat, but still works on the task.
   - Now, because the only contact still assigned to the agent is a task, and **Tasks** are set to **Allow other channels concurrently**, this means that the agent can be offered the voice call.
   - The agent picks up the voice call and is now working concurrently on both the voice call and the task.
7. Now there is another task in queue.
   - The agent is currently working on a voice call AND a task. Once again, Amazon Connect checks the cross channel settings and Voice is set to **No other channels while agent is on a Voice contact**.
   - Because the agent is working on a voice call, they cannot be offered any tasks until they are done with the voice call.
   - Also, because **Task** is set to **Maximum contacts per agent** is 1, even after the agent handles the voice call, they still won't be offered the task until they finish their current task.

APIs to create and manage routing profiles

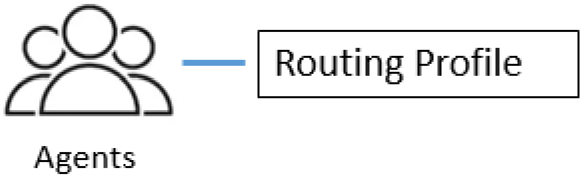
Use the following APIs to create and manage routing profiles programmatically:

- CreateRoutingProfile
- DescribeRoutingProfile
- UpdateRoutingProfileConcurrency
- UpdateRoutingProfileQueues
- UpdateRoutingProfileDefaultOutboundQueue

How Amazon Connect uses routing profiles

A routing profile determines what types of contacts an agent can receive and the routing priority.

- Each agent is assigned to one routing profile.
- A routing profile can have multiple agents assigned to it.



Amazon Connect uses routing profiles to allow you to manage your contact center at scale. To quickly change what a group of agents does, you only need to make an update in one place: the routing profile.

Default routing profile: Basic routing profile

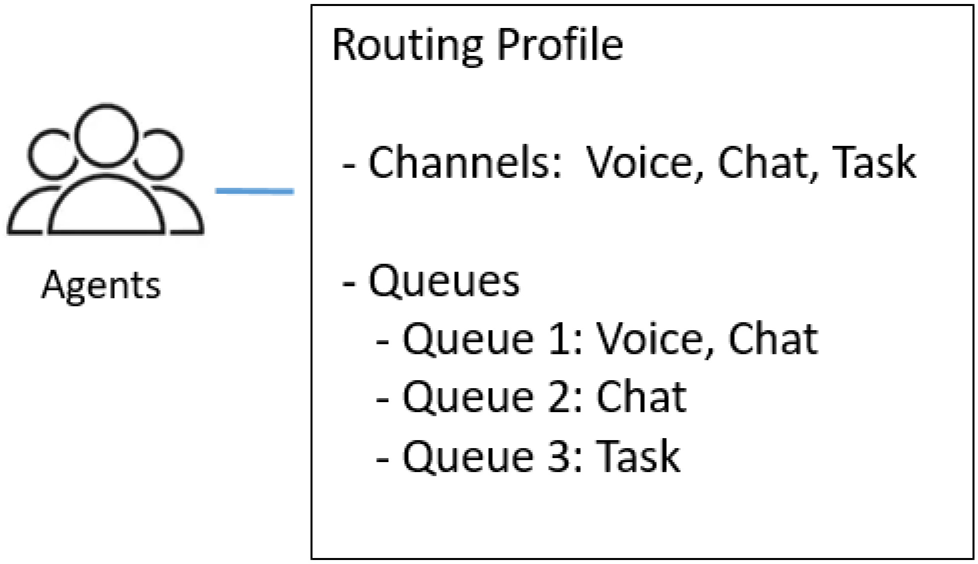
Amazon Connect includes a default routing profile named **Basic routing profile**. Along with the default flows and default queue (named **BasicQueue**), it powers your contact center so you don't need to do any customization. This is what enables you to get started quickly.

Routing Profiles Link Queues and Agents

When you create a routing profile, you specify:

- The channels the agents will support.
- The queues of customers that the agents will handle. You can use a single queue to handle all incoming contacts, or you can set up multiple queues. Queues are linked to agents through a routing profile.
- Priority and delay of the queues.

The following image shows a graphic of a group of agents mapped to a routing profile. The routing profile specifies multiple channels and queues for the agents.



Delete a routing profile from an Amazon Connect instance

There are three ways to delete a routing profile from your Amazon Connect instance:

- Amazon Connect admin website: On the left side menu, choose **Users**, **Routing profiles** and then select the delete icon.

> **Important**
>
> You cannot undo a deleted routing profile.

- DeleteRoutingProfile API
- delete-routing-profile AWS CLI

Set up queue-based, or skills-based, routing in Amazon Connect

Here's an overview of the steps to set up queue-based routing:

- Create the queues, for example, one for each skill you want to use for routing.
- Create the routing profiles:
  - Specify the channels supported by this routing profile.
  - Specify the queues: the channel, priority, and delay.
- Configure agent settings to assign the routing profiles to them.

When you create your flows, you'll add the queues to them. If a contact chooses to speak to an agent in Spanish, for example, they will be routed to the Spanish Reservations queue.

For information about how routing works, and queue-based routing, see these topics:

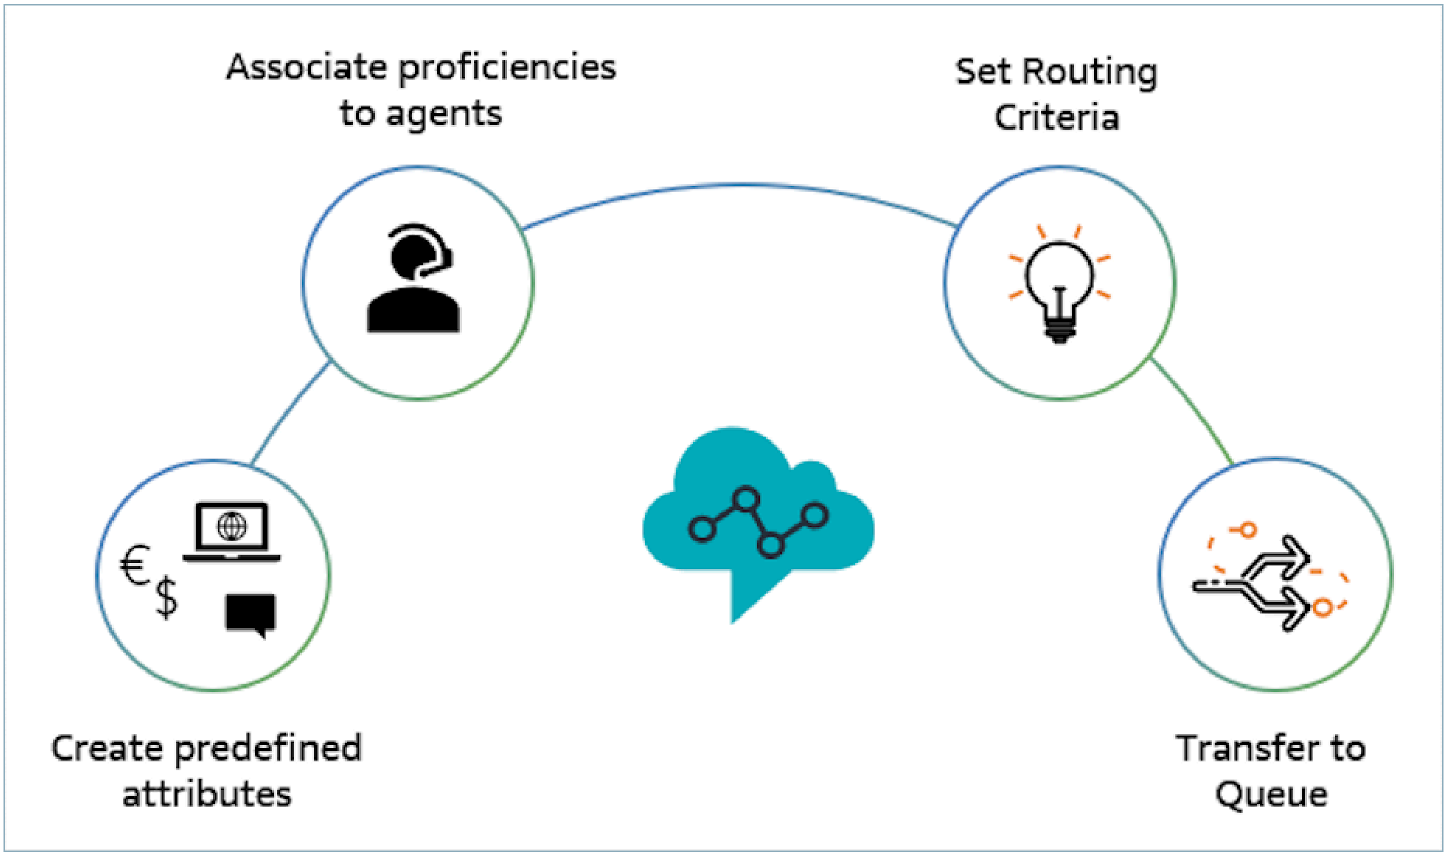
- How routing works with multiple channels
- Queue-based routing to route customers to a specific contact center agent

Set up routing in Amazon Connect based on agent proficiencies

Following is an overview of the steps to set up routing based on agent proficiencies:

1. Create predefined attributes for routing contacts to agents
   - You create the predefined attributes that you want to use to make a routing decision. In the next step, you can use predefined attributes individually, or you can combine them by using the `AND` or `OR` operators to form a routing step.
2. Assign proficiencies to agents in your Amazon Connect instance
   - You select predefined attributes and associate them with an agent. All available agents that meet a routing step requirement of a contact within the same queue will be considered for a match.
3. Set routing criteria
   - Use the Set routing criteria flow block to set a routing criteria manually or dynamically.
4. Transfer to queue

   Use the Transfer to queue flow block to transfer the contact to a queue. After the contact is transferred, Amazon Connect runs the routing criteria.



Example of how to use agent proficiencies for routing

Consider a scenario where a contact enters a queue **General Inbound Queue** and two agents, Agent1 and Agent2, are available. A customer who speaks French is seeking assistance regarding AWS DynamoDB. This is their second time calling regarding the same issue and you would prefer to match them with an expert in AWS DynamoDB. In order to preserve the customer experience, you want to implement the following routing requirements:

- First look for an agent who is highly proficient in **French (>=4)** and an expert in **AWS DynamoDB (>=5)** for the first 30 seconds.
- If an agent is not found at this time, look for an agent who is highly proficient in **French (>=3)** and highly proficient in **AWS DynamoDB (>=5)** for the next 30 seconds. The requirement for French is relaxed to further expand the pool of eligible agents to meet the requirement.
- If no join is made at this point, look for an agent who is proficient in **French (>=3)** and highly proficient in **AWS DynamoDB (>=4)** and keep looking until an agent is found. Here the AWS DynamoDB requirement is relaxed to expand the pool of eligible agents who meet the requirement.

Note

For regulatory or compliance use cases you can use the **Never Expire** option for the expiration timer to ensure any agent who is joined on the contact meets a minimum requirement.

To route the contact to the above requirements, complete the following steps:

1. **Create predefined attributes**: For example, add `Technology` as a predefined attribute in **User Management**, **Predefined Attributes** with `AWS DynamoDB` as one of the values.

Name	Value
Technology	AWS Kinesis
Technology	AWS DynamoDB
Technology	AWS EC2
Technology	AWS Neptune

Note

Connect:French is already available as a value in system attribute **Connect:Language** as a predefined attribute. You can use this in your routing criteria. You can also add up to 128 customer languages as values to **Connect:Language**.

2. **Associate proficiencies to users**: There are 2 agents, Agent1 and Agent 2, who speak French and are proficient in AWS DynamoDB as shown below. In **User Management**, **Show Advanced Settings** associate the following proficiencies to the Agent1 and Agent2.

Agent Name	Predefined Attribute	Value	Proficiency Level
Agent1	Technology	AWS Kinesis	2

Agent Name	Predefined Attribute	Value	Proficiency Level
Agent1	Technology	AWS Dynamo DB	5
Agent1	Technology	AWS EC2	4
Agent1	Language	French	3
Agent1	Language	English	4
Agent2	Technology	AWS Dynamo DB	3
Agent2	Technology	AWS EC2	5
Agent2	Technology	AWS Nepture	5
Agent2	Language	French	4
Agent2	Language	English	3

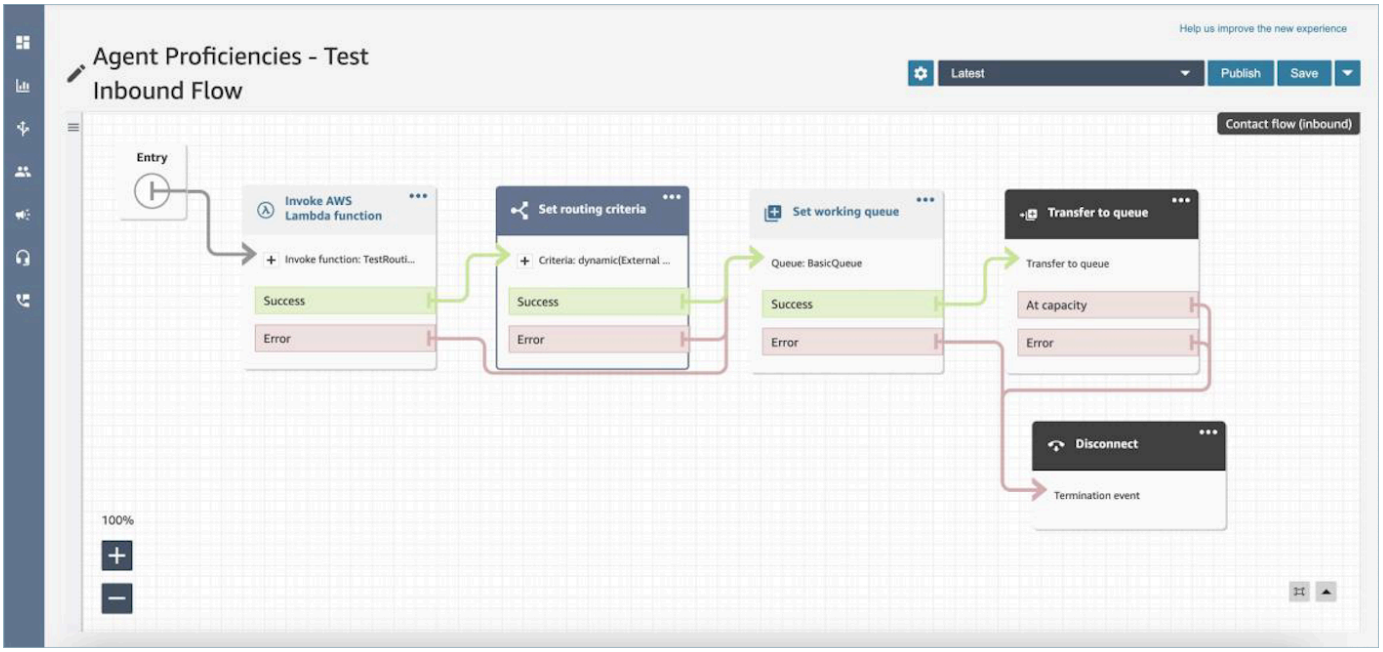
3. **Set routing criteria**: Use this flow block to create the following routing criteria manually or dynamically using JSON that is created by invoking a Lambda function as shown in a potential Inbound flow. Create the following routing criteria:

   a. Step 1: connect:Language(connect:French) >=4 **AND** Technology (AWS DynamoDB) >=5 **[30 seconds]**

   b. Step 2: connect:Language(connect:French) >=4 **AND** Technology (AWS DynamoDB) >=4 **[30 seconds]**

   c. Step 3: connect:Language(connect:French) >=3 **AND** Technology (AWS DynamoDB) >=4 **[Never expire]**

   The following image shows an example inbound flow that is configured for routing by agent proficiencies. This flow includes the following blocks: Invoke AWS Lambda function, Set routing criteria, Set working queue, Transfer to queue, and Disconnect / hang up.



4. **Transfer to queue**: After the contact is transferred to the "General Inbound Queue," Amazon Connect immediately starts running the routing criteria. The following steps occur before the contact is joined to Agent1.

   a. **Routing Step 1**: For the first 30 seconds (no match) as neither agent has an AWS DynamoDB proficiency >= 5, Amazon Connect does not match with any agent.

   b. **Routing Step 2**: In the next 30 seconds (no match) as neither agent is both highly proficient (>=4) in both French and AWS DynamoDB

   c. **Routing Step 3**: As soon as the previous step expires, Amazon Connect finds the available agent, Agent1 (French 3, AWS DynamoDB 4) is proficient in French and highly proficient in AWS DynamoDB. Therefore, the contact is matched with Agent1.

There is a one-click drill-down in the real-time metrics for queues table which shows you a list of the routing steps in use for active contacts on the queue. You can find the definitions for the routing step specific metrics under Real-time metrics definitions in Amazon Connect.

Contact record, contact event stream, and agent event stream updates for agent proficiencies

Models have been added for proficiency routing in the following sections:

- Data model for Amazon Connect contact records
- Agent event streams data model in Amazon Connect

- [Contact events data model]()

Frequently asked questions

- **Are queues still relevant?**
  - Yes, queues are still necessary. The routing criteria is only activated when a contact is enqueued. Agent proficiencies provide additional control to target specific agents within a queue.
- **When should we model something as a proficiency instead of modeling it as a queue?**
  - This is a business decision. You should consider the impact on the number of queues you can eliminate and consolidate while using agent proficiencies.
- **Do agent proficiencies work across all channels?**
  - Yes, routing using agent proficiencies works for all channels.
- **How do I remove a routing criteria?**
  - You can interrupt a routing criteria using a customer queue flow.
  - You can also update the routing criteria this way.
- **How many times can I change a routing criteria?**
  - You can change the routing criteria up to 2 times. However, only the latest 3 routing criteria updates are stored on the contact record.
- **With agent proficiencies, do queue priority and delay operate as usual?**
  - Yes, queue priority and delay operate as they already do in a non-agent-proficiencies environment.
- **Which operators are supported for creating a routing criteria?**
  - The following Boolean operators are supported:
    - AND
    - OR
  - The following comparison operators are supported:
    - >=
  - You can also define a range of minimum and maximum proficiency levels such as:
    - connect:English(1-3)
    - connect:Chat(4-4)

  - You cannot use the same attribute more than once in an expression. For example, connect:English(1-3) AND connect:English(5-5) are not allowed.
  - NOT (for exclusion) - You can use the NOT operator to exclude agents with certain proficiencies when routing such as:
    - NOT connect:French(1-5)
- **Which characters can be used for predefined attributes?**
  - The pattern for predefined attribute name and value is `^(?!(aws:|connect:))[\p{L}\p{Z}\p{N}_.:/=+-@']+$`. For example, it can contain any letter, numeric value, whitespace, or `_.:/=+-@'` special characters, but can't start with `aws:` or `connect:`.
- **Can I add the same attribute multiple times in a routing criteria?**
  - Yes, you can the same attribute multiple times in a routing criteria.
- **When triggering a transfer (quick connect), is it possible to set the routing criteria?**
  - You use the Set routing criteria block in the transfer flow to set the routing criteria on the transferred contact segment. It is not possible to carry forward the routing criteria of previous contact to the new contact segment created after an agent has been joined.
- **What happens to the routing criteria if a contact is being transferred queue to queue, before it was routed?**
  - The routing criteria starts from the first step in the new queue in case a contact was transferred before being joined to an agent. For this, we carry-forward the routing criteria of previous contact to the new contact segment created due to queue transfer.
- **Does the contact record have a snapshot of the proficiencies of the matched agent?**
  - No, the contact record does not carry the proficiencies of an agent.
  - The agent event stream does have a snapshot of the agent's proficiencies at the time of joining.
- **Can we search for an agent by proficiency using APIs?**
  - No, this is not supported.
- **What happens if we delete an attribute if it is on an active contact?**
  - You can delete an attribute that is used on active contacts. However, any routing step with that attribute will not find a matching agent and the contact stays in the queue until the routing criteria expires.
  - All new contacts with that attribute start taking the error branch on the Set routing criteria block in the flow.

- **What happens to the routing criteria steps / expiration when an agent rejects a call?**
  - Routing considers a join to be complete when an agent accepts the contact and a join is completed. When an agent rejects a contact, the routing engine continues to run through the routing criteria with the timer continually running.
- **Will the agent who rejected the step be part of the pool when routing runs again?**
  - Yes, the agent continues to be a part of the pool when routing runs again.
- **How does security work for agent proficiencies?**
  - For information about the required security profile permissions, see Required security profile permissions for managing predefined attributes.
- **Are historical metrics available?**
  - No, historical metrics are not available in analytics.
  - The contact record, agent event stream, and contact event stream contain all the required information.
- **Where can I find a sample Lambda function for setting routing criteria?**
  - For a sample Lambda function for setting routing criteria, see Set routing criteria.
- **What happens to the routing criteria set on a contact if the contact is being transferred to an agent queue?**
  - The routing criteria has no effect on contacts present in an agent queue. If a contact with routing criteria is transferred from an agent queue to a standard queue, then the routing criteria is forwarded to the new contact segment created due to queue transfer.

Set up your contact center agents in Amazon Connect

You can manage and load-balance customer contacts using agent hierarchy organization and agent status management. These tools provide filtering and agent availability management per queue, skill set, and routing profiles.

Contents

- Enable auto-accept call for agents
- Enable persistent connection for Amazon Connect agents
- Log out agents automatically when they close their CCP using the Amazon Connect CCPv1
- Set up agents in Amazon Connect to assign tasks to themselves

Organize agents into teams and groups for reporting and access by creating hierarchies

Agent hierarchies are a way for you to organize agents into teams and groups for reporting purposes. It's useful to organize them based on their location and their skill sets. For example, you might want to create large groups, such as all agents who work on a specific continent, or smaller groups such as all agents working in a specific department.

You can also configure hierarchies with up to five levels, and segment agents or teams. Here are a couple of things to note about using hierarchies:

- Removing agents from a level affects historical reporting.
- When you use the **Restrict contact access** security profile permission, you can restrict contact search results based on the agent's hierarchy. For more information, see Manage who can search for contacts and access detailed information.

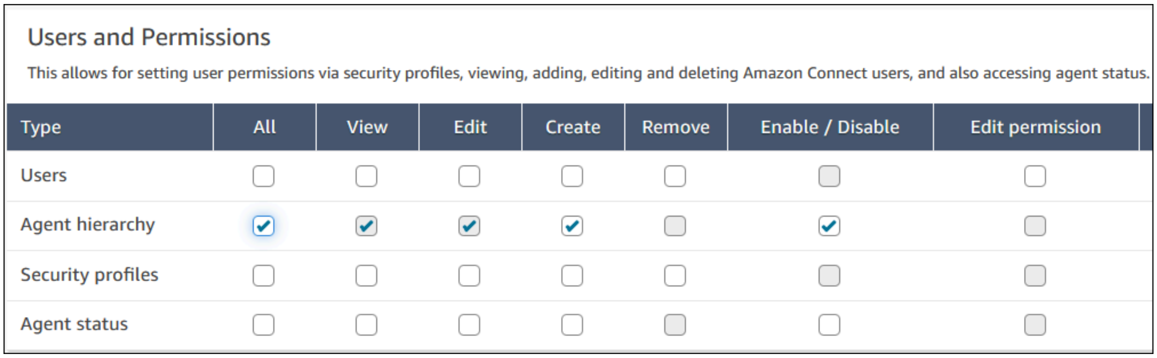
Contents

Required permissions

To create agent hierarchies, you need to be assigned to a security profile that has the **Users and Permissions - Agent hierarchy - Create** permission.

> **Note**
>
> Since agent hierarchies may include location and skill set data, you also need **Agent hierarchy - View** permission to view the agent hierarchy information in a real-time metrics report.

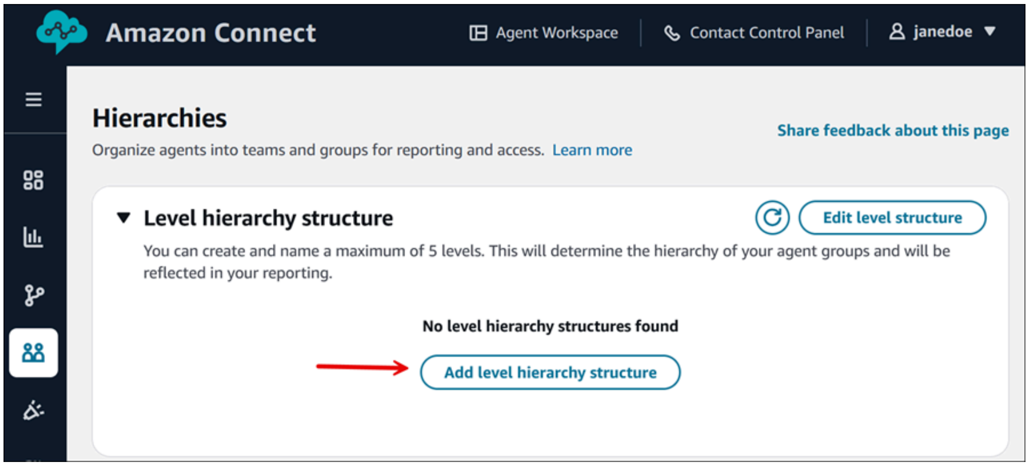
The following image shows the **Users and Permissions - Agent hierarchy** permissions on the **Security profile permissions** page.



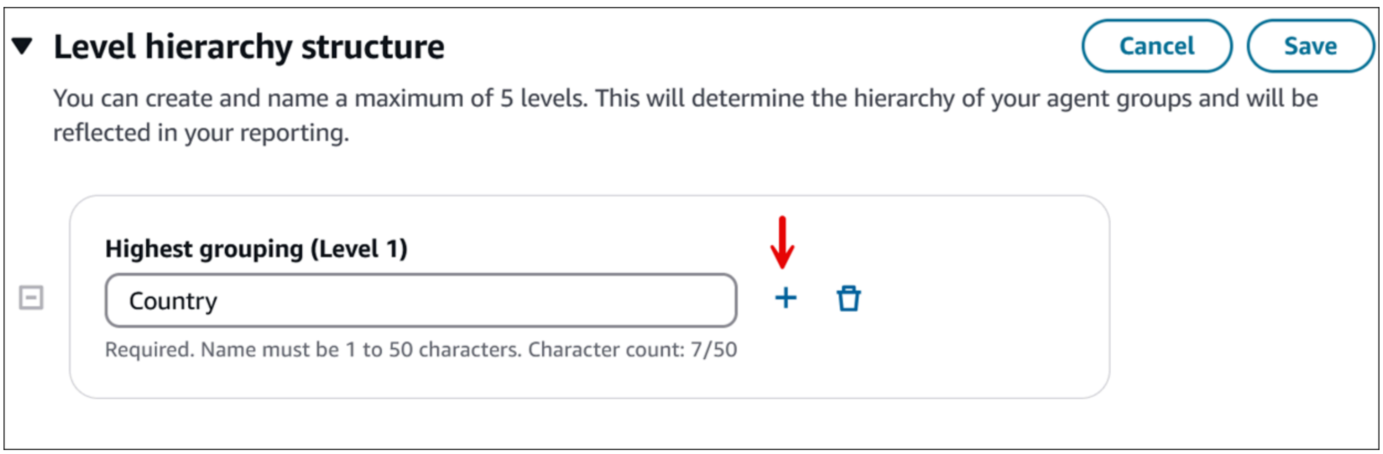
Define your organization's hierarchy levels

You can specify up to 5 levels or tiers for your organization's hierarchy groups. For example, if your teams are organized by geography your levels might be Continent, Country, Region, State, Team. Levels need to be put in place before you can describe the groupings that you want to assign agents and other users to.

1. Log in to the Amazon Connect admin website with an **Admin** account, or an account assigned to a security profile that has **Users and Permissions - Agent hierarchy - Create** permission.
2. Choose **Users**, **Hierarchies**, and then choose **Add level hierarchy structure**, as shown in the following image.



3. Enter a name for the first level. Choose the **+** icon to add another level, such as Level 2, Start or Province. You can add up to five levels. In the following image, we've named Level 1 **Country**.



The following image shows a hierarchy structure with four levels for Country, State or Province, City, Neighborhood.

Tip

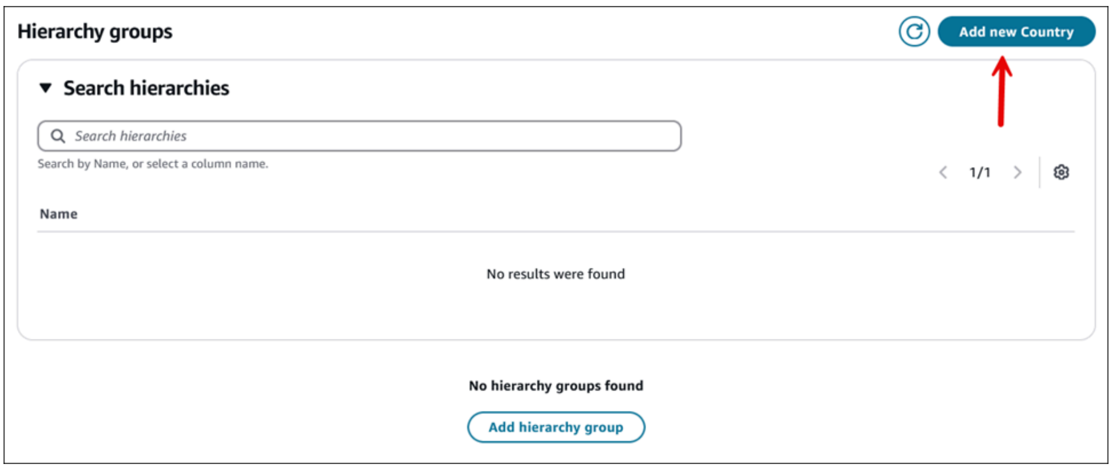
After you add groups to these levels, you must delete the groups before you can delete the level.

4. Choose **Save** to apply the changes, or **Cancel** to undo them. If the **Save** button isn't active, you don't have permissions in your security profile to create or edit the agent hierarchy.

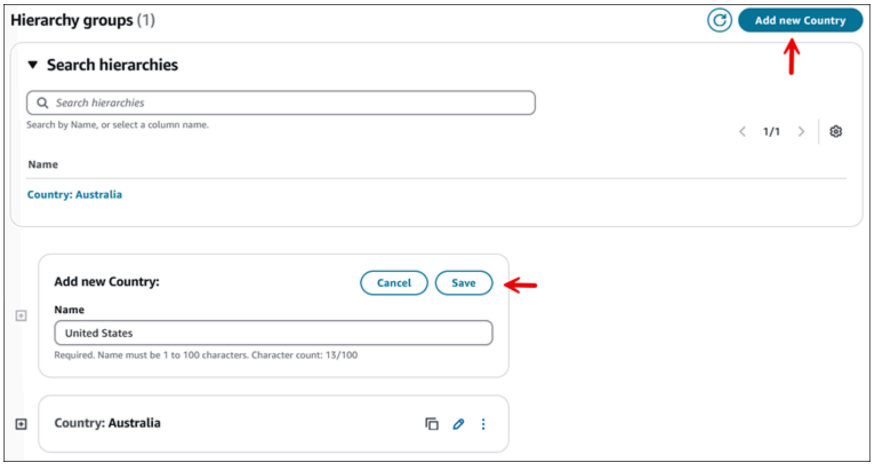
Define groups and teams in your hierarchy

After you create hierarchy levels, you can add the groups that call within each, from the top down.

1. Scroll down the **Hierarchies** page to the **Hierarchy groups** section. Choose **Add new *Level1_Name***. For example, in the following image the name of Level 1 is **Country**.



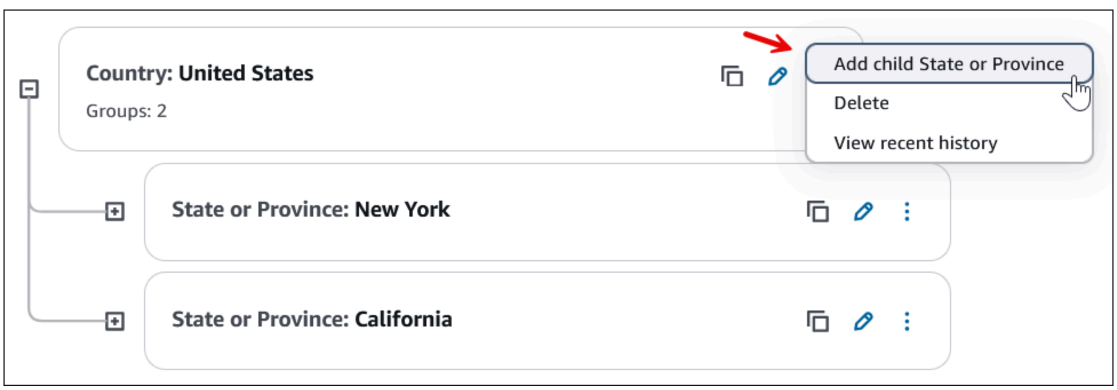
2. Enter the name for the group, such as Australia, and then choose **Save**. Choose **Add new Country** to add another country. The following image shows we added Australia and United States.



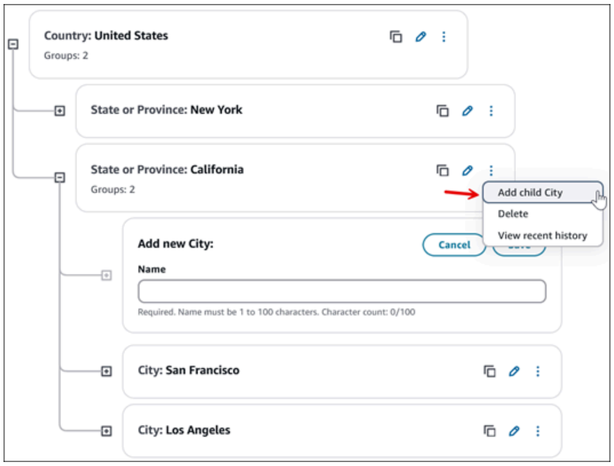
3. Next to the name of the group, choose **Add child State or Province**, as shown in the following image.

Choose **Add child State or Province** each time you want to add a group to level 2. When you're done, choose **Save**.

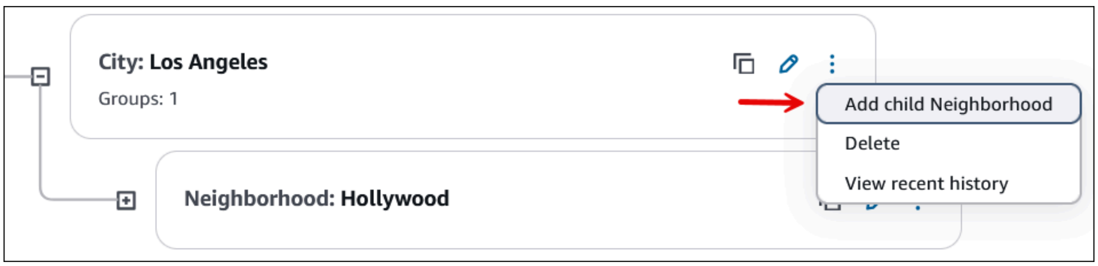
The following image shows we added New York and California.



4. For each state, choose **Add child City** each time you want to add group to level 3. When you're done, choose **Save**. The following image shows we added Los Angeles and San Francisco.



5. Choose **Add child Neighborhood** to add groups to Level 4, as shown in the following image. We added Hollywood to Los Angeles.



Choose **View historical changes** to view the change history. You can filter changes by date (between two dates) or by user name. If you cannot see the link, ensure that you have the proper permissions to view these changes.

Delete an agent hierarchy

> **Important**
>
> Deleting a hierarchy level severs the link to existing contacts. This action can not be reversed.

Add a custom agent status to the Amazon Connect Contact Control Panel (CCP)

Agents are responsible for setting their status in the Contact Control Panel (CCP). In fact, the only time an agent's status changes is when they manually change it in the CCP, or when [their supervisor changes it]() in a real-time metrics report.

Amazon Connect provides two default status values:

- Available
- Offline

You can change the name of these values, and you can add new ones. For example, you might add a status for Lunch, and another for Training. These and the default status values will be used for reporting, metrics, and resource management.

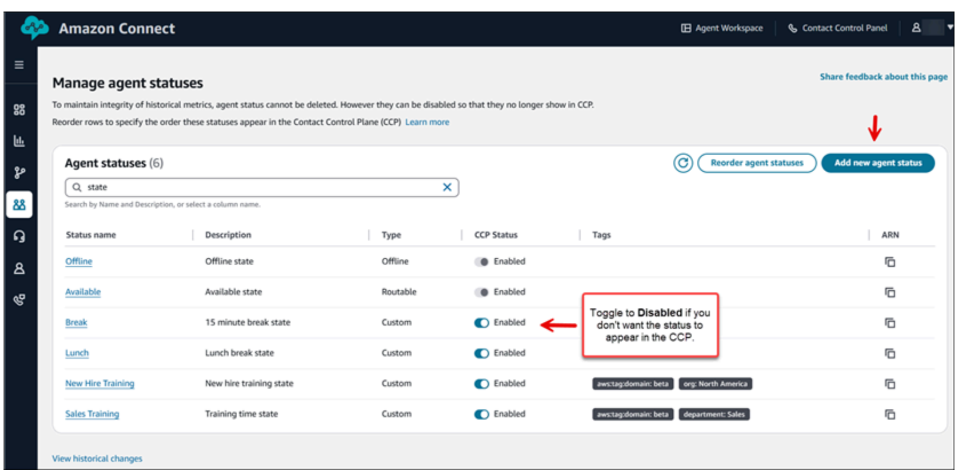
When you add a new status, it will always be **Custom**, not routable.

You can't delete a status value but you can disable it so it doesn't appear on the agent's CCP.

To add a new agent status

> **Note**
>
> -
> -

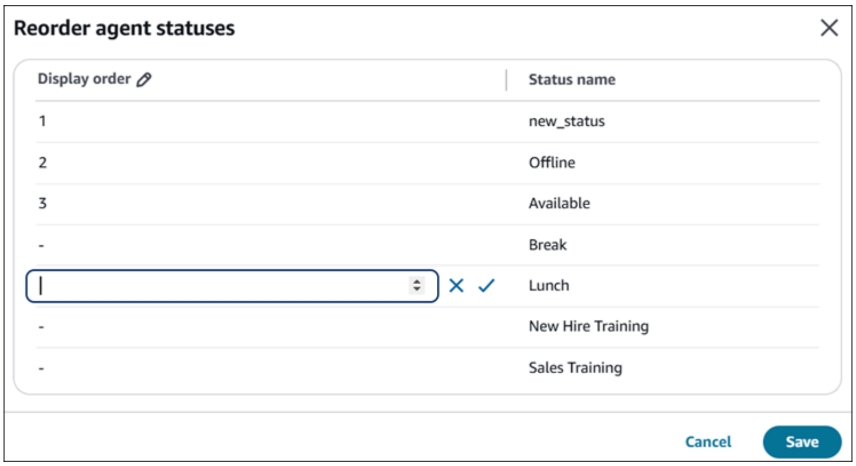
1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an **Admin** account, or an account that has **Users and permissions** - **Agent status** - **Create** permissions in its security profile.
2. On the Amazon Connect admin website, on the navigation menu, choose **Users**, **Agent status**, **Add new agent status**. The following image shows a sample **Manage agent statuses** page.



3. Enter a status name and description.

4. Under **Tags**, optionally add resource tags to identify, organize, search for, filter and control who can access this agent status.
5. Choose **Save**.
6. After saving a custom status, you can disable it so that the status does not appear in the Contact Control Panel to agents.

To change the order that the status values appear in the CCP, choose **Reorder agent statuses**. Enter the display order that makes sense for your agents. The following image shows a sample **Reorder agent statuses** page.



To edit an agent status

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an **Admin** account, or an account that has **Users and permissions** - **Agent status** - **Edit** permissions in its security profile.
2. On the Amazon Connect admin website, on the navigation menu, choose **Users**, **Agent status**.
3. Choose the status you want to edit.
4. Enter the new information, and choose **Save** to apply the changes.

Choose **View historical changes** to view the change history. You can filter changes by date (between two dates) or by user name. If you can't see the **View historical changes** link, make sure you have the following permission in your security profile: **Historical changes** - **View historical changes** - **View**.

Configure the agent's profiles and task settings in Amazon Connect

Before you configure your agent settings, here is some info to have on hand. Of course, you can always change this information later.

- What is their routing profile? They can only be assigned one.
- Will they have the **Agent** security profile or a custom profile you created?
- Are they going to use a soft phone? If so, will they be connected to contacts automatically, or will they need to press the **Accept** button in their Contact Control Panel (CCP)?
- Or, are they going to use a desk phone? If so, what is their number?
- How many seconds do they have for After contact work (ACW)? There's no way you can turn off ACW time altogether so agents never go to ACW. (A value of **0** means an indefinite amount of time.)
- Are they going to be assigned to an agent hierarchy?

> **Note**
>
> You can't configure how long an available agent has to connect with a contact before it's missed. Agents have 20 seconds to accept or reject a voice or chat contact, and 30 seconds for a task contact If no action is taken, the current agent's status will be **Missed** and the contact is routed to the next available agent.

To configure agent settings

1. On the left navigation menu, go to **Users, User management**.
2. Choose the user you want to configure, then choose **Edit**.
3. Assign a routing profile to them. You can only assign one.
4. Assign the **Agent** security profile, unless you've created custom security profiles.
5. Under **Phone Type** choose whether the agent is using a desk phone or soft phone.

   - If you select **Desk phone**, enter their phone number.

> **Important**
>
> Outbound telephony charges occur when using a desk phone to answer inbound calls.

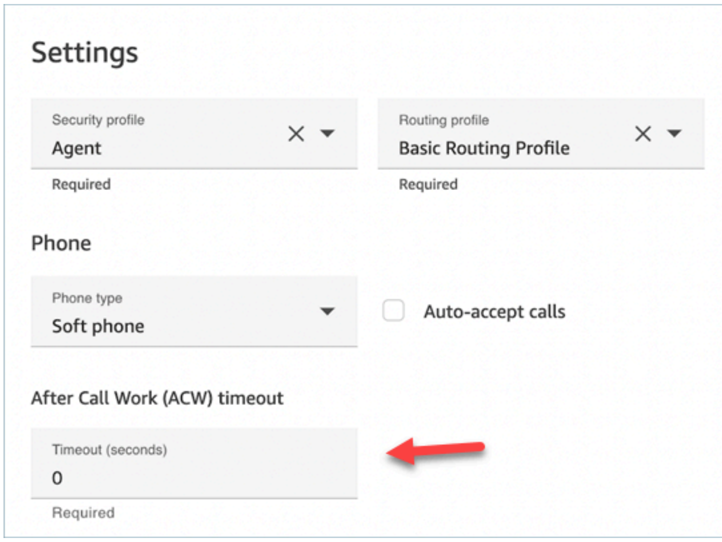
- If you select **Soft phone**, we recommend choosing the following options:

  - **Auto-Accept Call**: This enables agents to be connected to calls automatically. This doesn't apply to chats or tasks. For more information, see Enable auto-accept call
  - **Enable persistent connection**: This maintains agent connection after a call ends. It enables subsequent calls to connect faster. This doesn't apply to chats or tasks. For more information, see Enable persistent connection.

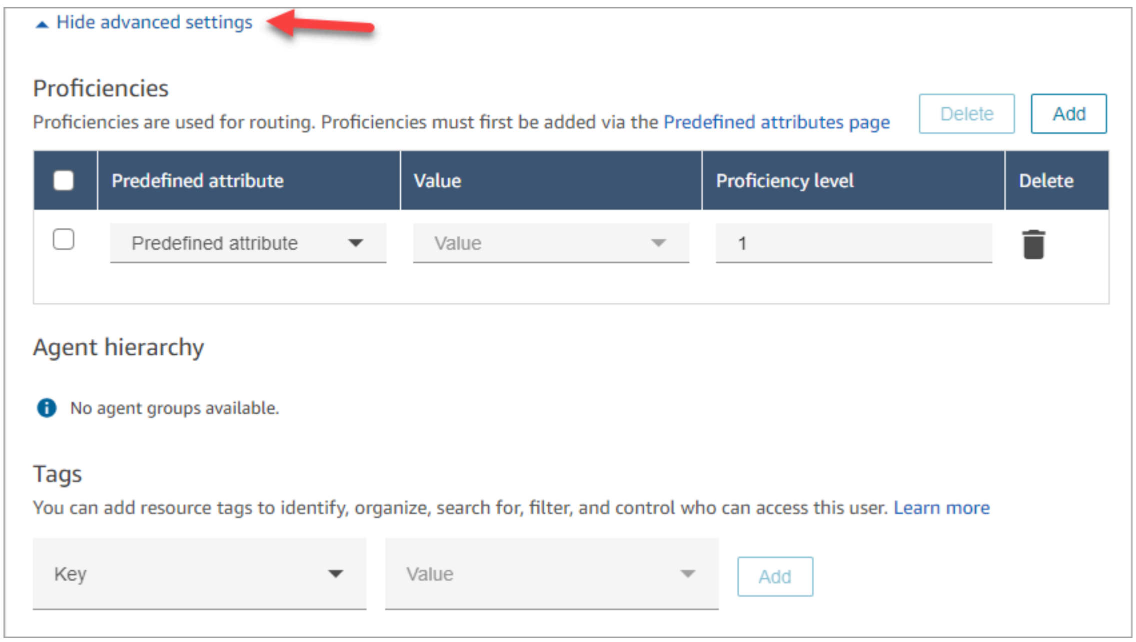
6. In **After call work (ACW) timeout**, type how many seconds agents have for after contact work, such as entering notes about the contact.

   - Minimum setting is 1 second.
   - Maximum setting is 2,000,000 seconds (24 days).
   - Enter **0** if you don't want to allocate a specific amount of ACW time. It essentially means an indefinite amount of time. When the conversation ends, ACW starts; the agent must choose **Close contact** to end ACW.

The following image shows the **Settings** section of the **Edit routing profile** page. **After call work (ACW) timeout** set to 0.



7. If desired, choose **Hide advanced settings** to access the following additional properties.



8. See the following topics:

   - [Assign proficiencies to agents in your Amazon Connect instance]
   - [Organize agents into teams and groups for reporting and access by creating hierarchies]

9. Under **Tags**, optionally add resource tags to identify, organize, search for, filter and control who can access this user.

Create predefined attributes for routing contacts to agents

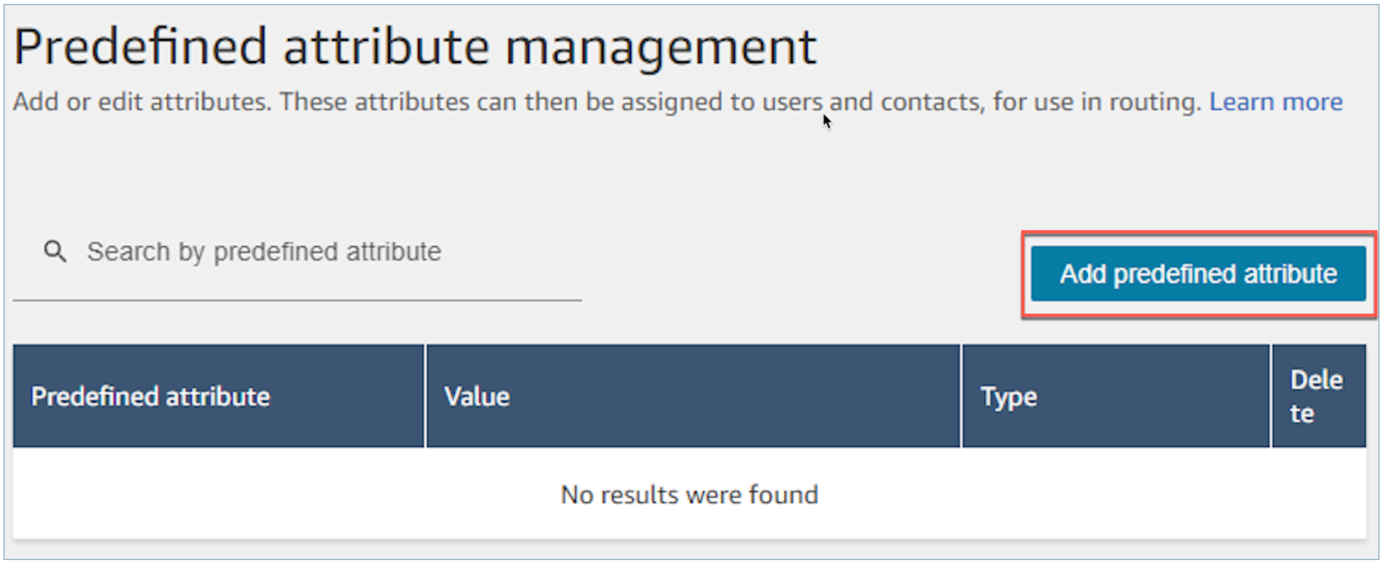
> **Important**
>
> This information is not encrypted. We strongly recommend you follow the Best practices for PII compliance in Amazon Connect.

Predefined attributes are attributes in an Amazon Connect instance that can be used to route contacts to an agent or pools of agents within a queue. A predefined attribute is made up of a name and a value.

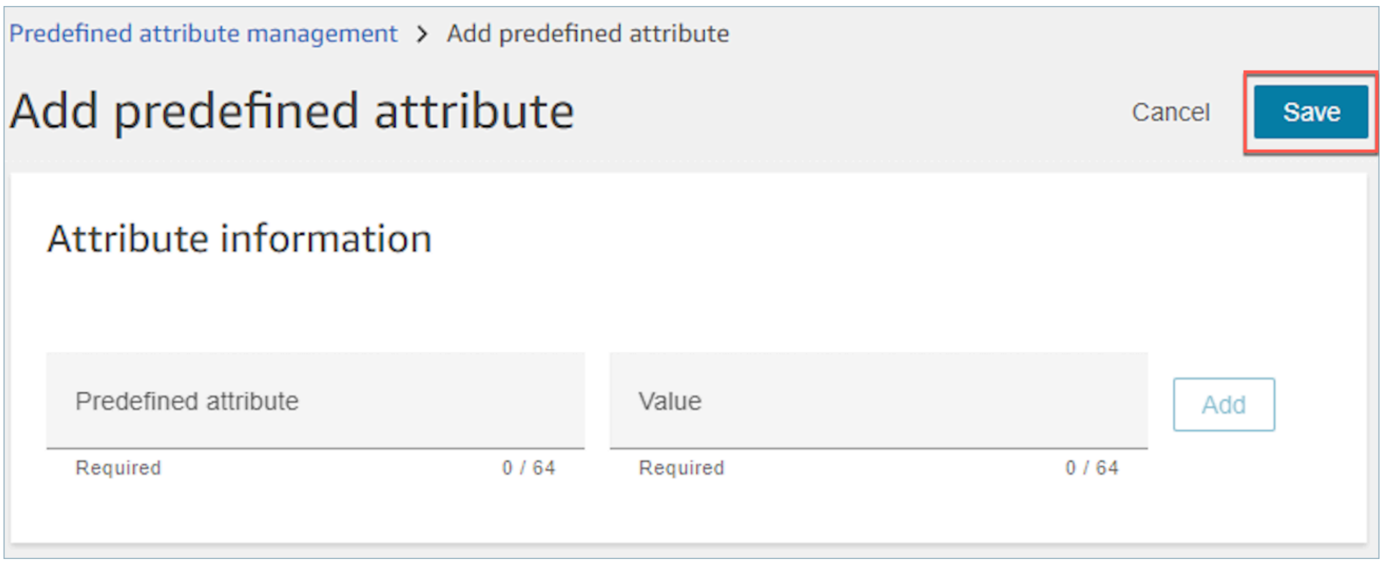
- You can create up to 128 values per attribute.
- A predefined attribute name can be up to 64 characters long.
- A predefined attribute value can be up to 64 characters long.
- You can create and manage predefined attributes manually by using the Amazon Connect admin website; the steps are described in this topic. Or programmatically by using the Predefined attribute management APIs.
- Pattern for predefined attribute: `^(?!(aws:|connect:))[\p{L}\p{Z}\p{N}_.:/=+-@']+$`
- You can find the service quota for the number of predefined attributes in an Amazon Connect instance here.

Create a predefined attribute

1. On the navigation menu, choose Routing, **Predefined attributes**, **Add predefined attribute**.
2. In the **Add predefined attributes** section, add the name in the **Predefined attribute** box and value in the **Value** box
3. Add additional values for the attribute by choosing **Add predefined attribute**.



4. Choose **Save** to save the attribute and values.



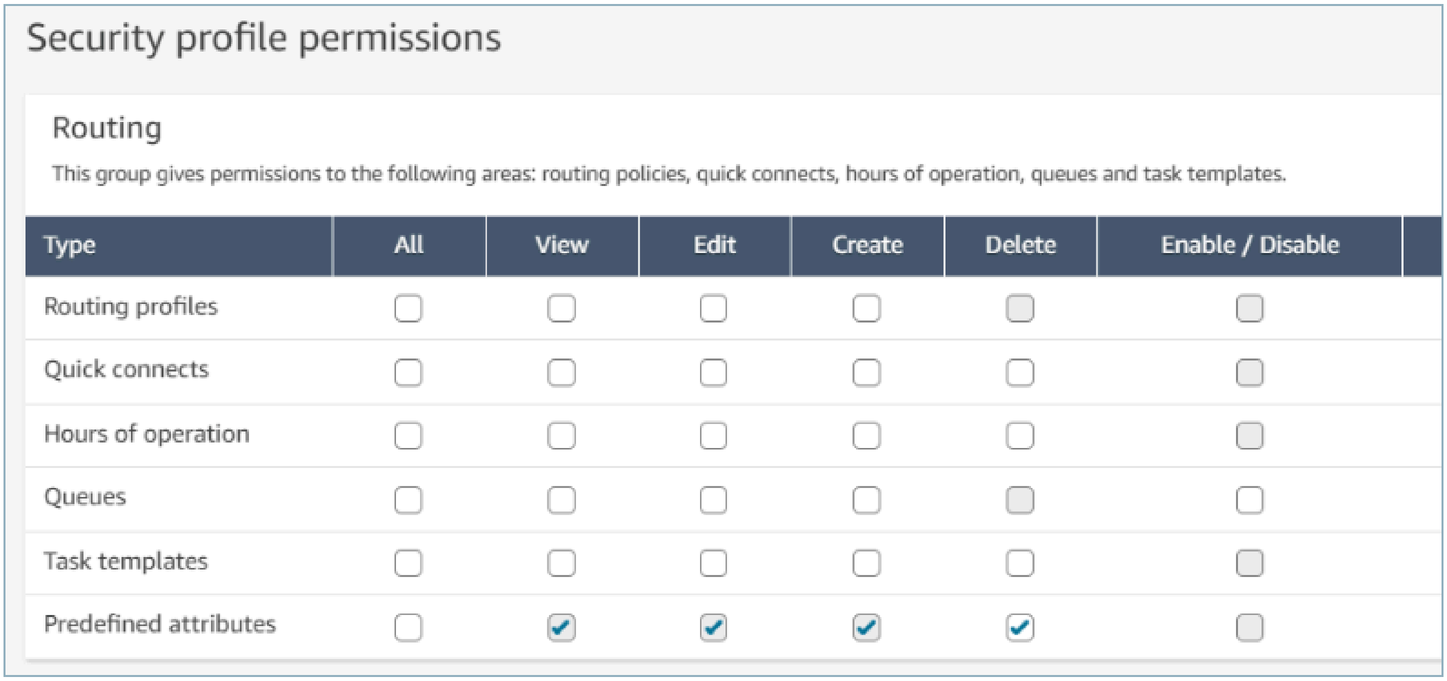
5. Choose **Refresh** to update the **Predefined attribute management** page with the attributes that have been created.

Predefined attribute management APIs

- CreatePredefinedAttribute
- UpdatePredefinedAttribute
- DeletePredefinedAttribute
- DescribePredefinedAttribute
- ListPredefinedAttributes

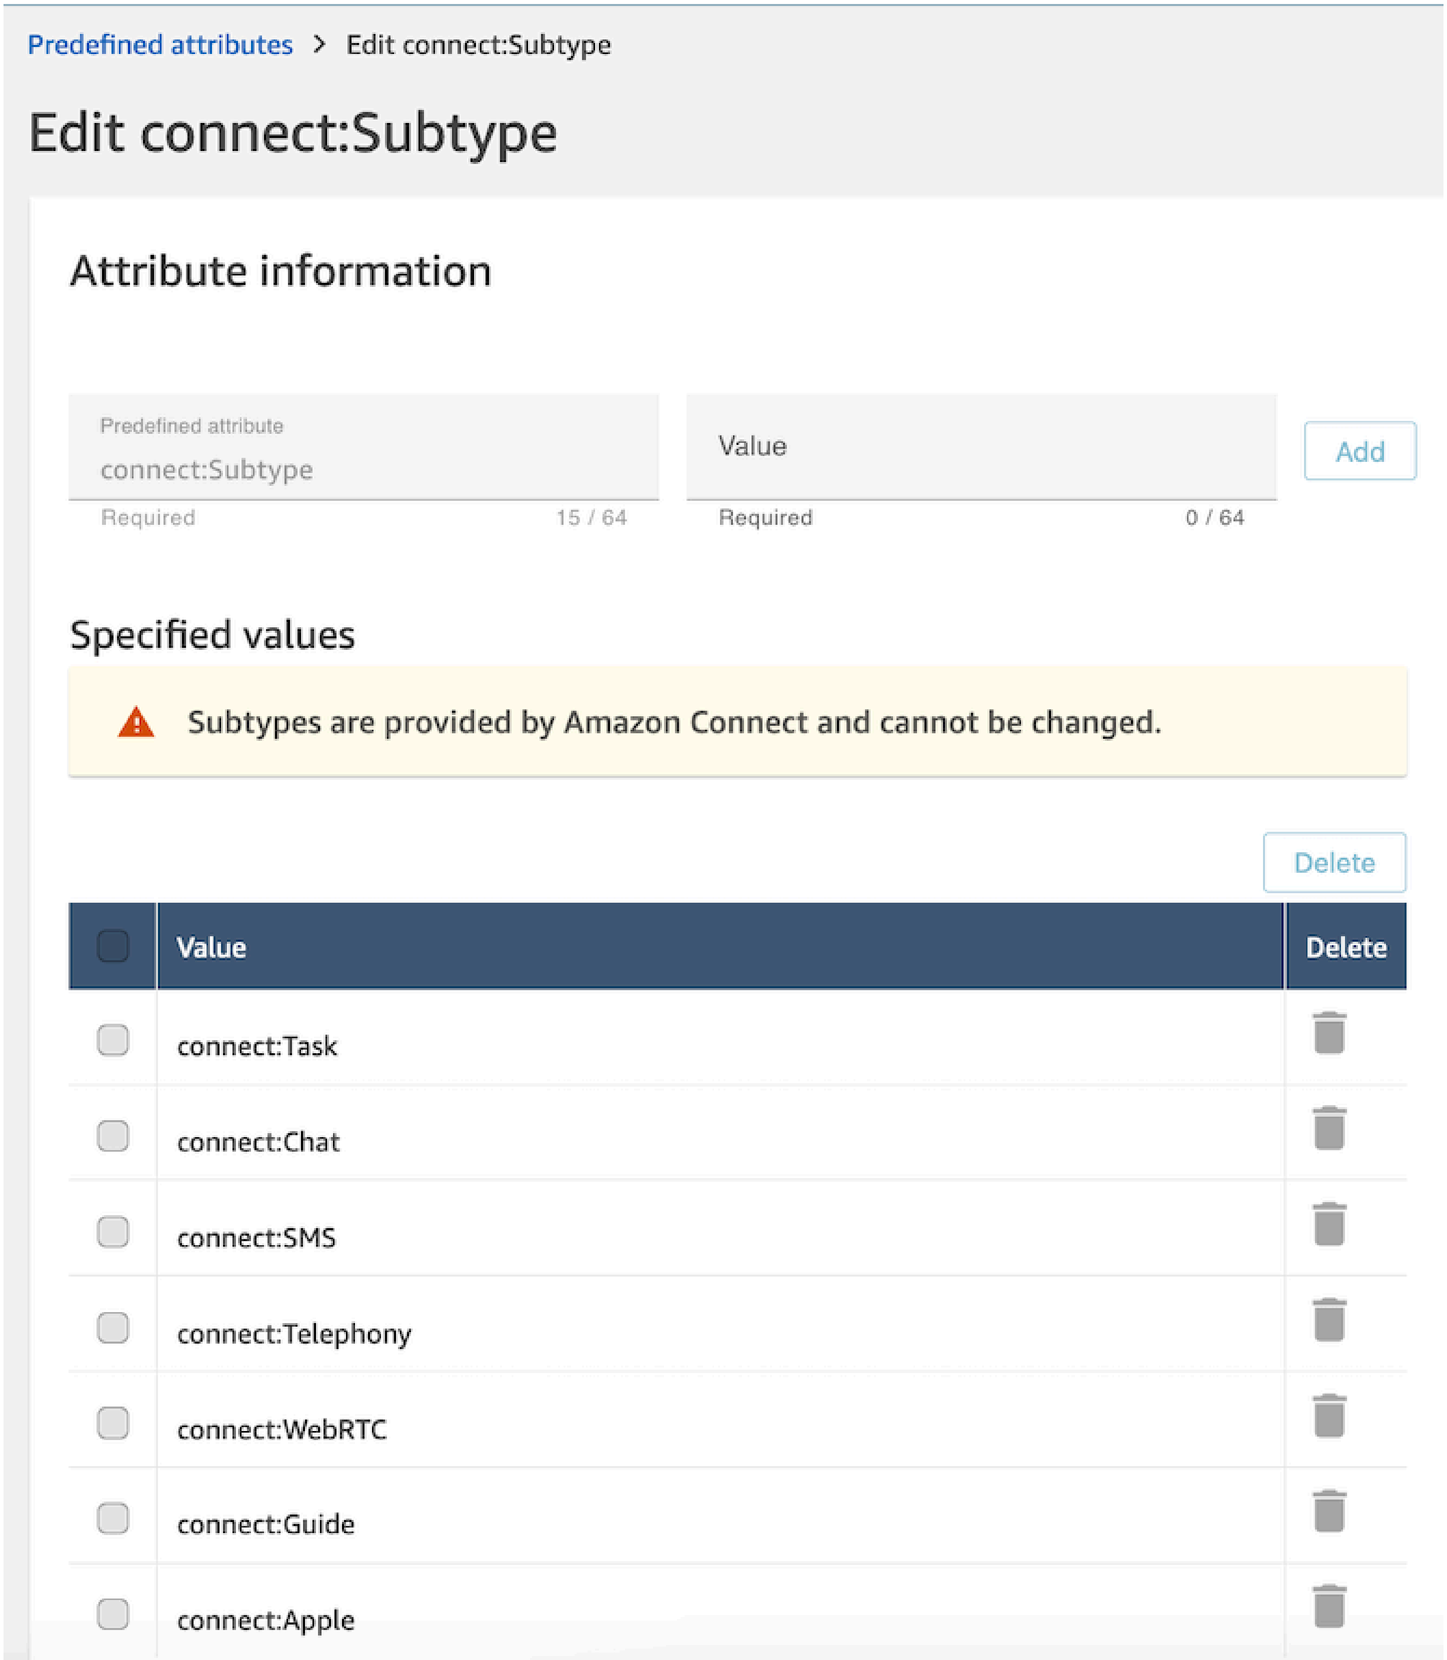
Required security profile permissions for managing predefined attributes

Before you can add predefined attributes to Amazon Connect, you need the following permissions assigned to your security profile: **Predefined attributes**. The following image shows this security profile permission in the **Routing** section of the **Add/Edit security profile** page.



System predefined attributes

System attributes, identified as `connect:` are predefined attributes set by Amazon Connect. The `connect:` name and values cannot be changed or deleted. The system attributes available today are `connect:Language` and `connect:Subtype`. You can add 128 custom values for `connect:Language`. You cannot change `connect:Subtype` but it can be used in routing criteria for routing.



Predefined attributes > Edit connect:Subtype
Edit connect:Subtype
Attribute information
Predefined attribute
connect:Subtype
Required 15 / 64
Value
Required 0 / 64
Add
Specified values
Subtypes are provided by Amazon Connect and cannot be changed.
Delete

connect:Task
connect:Chat
connect:SMS
connect:Telephony
connect:WebRTC
connect:Guide
connect:Apple

Frequently asked questions

- **Do I need to define levels on a predefined attribute when I create it?**
  - A predefined attributed is made up of a name-value pair. For example, a name such as `language` and values such as `English`, `French`, `Swahili`.
  - A proficiency level is an indicator, ranging from 1 to 5, of the level of expertise of an agent for a given attribute value. It is set in the user profile. Level 1 is the lowest proficiency, while 5 is the highest.
- **Can I create duplicate predefined attributes? Case sensitivity?**
  - No, you cannot create predefined attribute with duplicate names or values. In addition, case sensitivity does not allow you to use duplicate names. For example, a new predefined attribute with the name `language` cannot be created if a predefined attribute with name `Language` exists in your Amazon Connect instance.
- **Can I delete a attribute if it is already assigned to an agent?**
  - An attribute can only be deleted if it not associated with any agent.
  - Before deleting an attribute, you should ensure none of the contacts are waiting for an agent with that attribute or the contact will not find a match.
- **How can I update the name of an attribute or value?**

  1. Stop using the attribute on future contacts to drain all of the contacts on an active contact type.
  2. Update all of the attributes.

Assign proficiencies to agents in your Amazon Connect instance

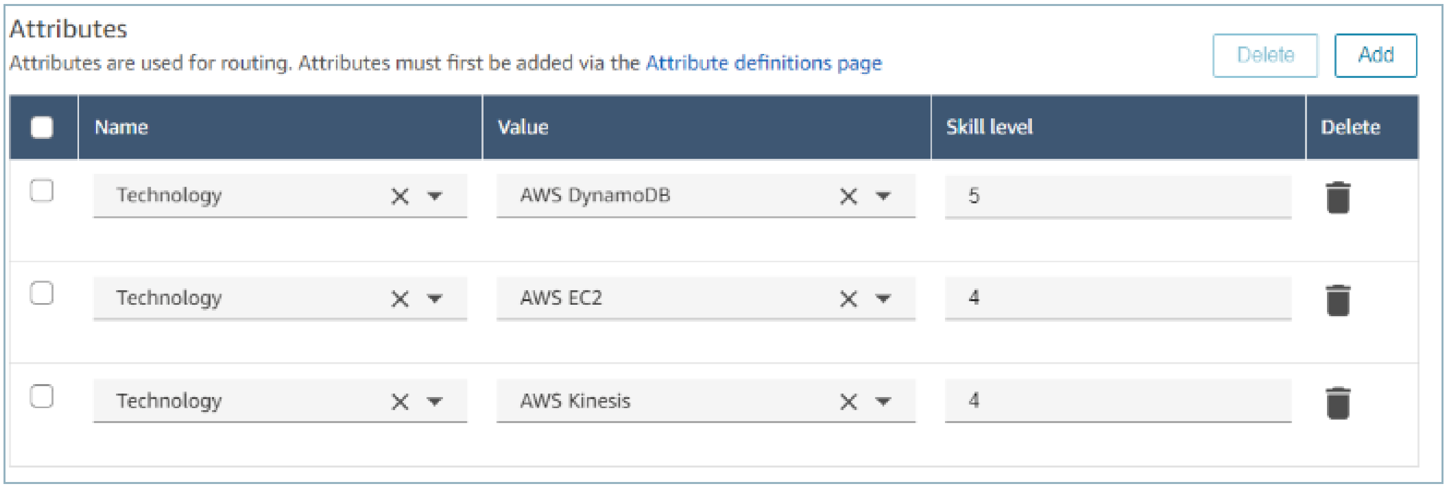
A proficiency consists of a predefined attribute name, its value, and a proficiency level. The level is a numeric value of 1, 2, 3, 4, or 5. After you have created predefined attribute, you can assign one or more proficiencies to an agent.

For example, Agent1 and Agent2 may be proficient in multiple technologies at varying levels. They can be assigned proficiencies to reflect their level of proficiency in those technologies as shown in the following table:

Agent Name	Predefined Attribute	Value	Proficiency Level
Agent1	Technology	AWS Kinesis	2
Agent1	Technology	AWS Dynamo DB	5
Agent1	Technology	AWS EC2	4
Agent1	Language	French	3
Agent1	Language	English	4
Agent2	Technology	AWS Dynamo DB	3
Agent2	Technology	AWS EC2	5
Agent2	Technology	AWS Nepture	5
Agent2	Language	French	4
Agent2	Language	English	3

To assign a proficiency to a user

1. On the navigation menu, choose **Users**, **User Management.**
2. Select the user name to open the user profile.
3. Go to **Show advanced settings**.
4. In the **Attributes** section, for the **Name** field, using the dropdown menu select a predefined attribute that was created earlier.
5. From the **Value** field, using the dropdown menu ,select a option.
6. Under the **Skill level** field, select a proficiency level for the previous attribute value.
7. You can add up to 10 proficiencies per agent.



Agent proficiencies management APIs

- AssociateUserProficiencies
- DisassociateUserProficiencies
- ListUserProficiencies

Enable auto-accept call for agents

When Auto-Accept Call is enabled for an available agent, the agent connects to contacts automatically.

This functionality doesn't apply to chats, tasks, or emails.

How long until the call is connected to the agent?

> **Note**
>
> While the call will be connected in less than one second, there will be no ringer, only the agent whisper.

Less than one second. When a call arrives to an available agent who has Auto-Accept Call enabled, the Contact Control Panel (CCP) briefly shows the options **Accept** or **Reject**. This is expected behavior. After less than a second, the call is automatically accepted and these options disappear.

There isn't an option for increasing the amount of time before a call is automatically accepted.

Auto-Accept Call doesn't work for callbacks.

Enable auto-accept call for existing agents

You can't enable Auto-Accept Call while editing multiple existing users in your Amazon Connect instance. You must edit existing users individually to enable it. However, you can configure the setting for multiple new users when you bulk upload new users with the CSV template.

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an Admin account, or an account with **Users and Permissions** - **Users** - **Create** or **Edit** permission in it's security profile.
2. On the left navigation menu, choose **Users**, **User management**.
3. In the list of users, select an agent, and then choose **Edit**.
4. On the **Edit users** page, under **Phone**, choose **Soft phone**, and then select the **Auto-Accept Call** check box.
5. Choose **Save**.
6. Repeat these steps for each user that you want to edit.

> **Note**
>
> **Firefox users**: If you are using the Firefox browser and using auto-accept for calls, you must keep the CCP or Agent Workspace browser tab in focus when you accept and connect to a voice contact. The CCP conforms to Firefox microphone usage guidance, and only has access to connect to the user's microphone when CCP tab is in focus.

Bulk upload new users with auto-accept call enabled

You can't use the CSV template to edit information for existing users. If you include duplicate users with different information in the CSV template, you will receive an error.

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an Admin account, or an account with **Users and Permissions** - **Users** - **Create** permission in it's security profile.
2. On the left navigation menu, choose **Users**, **User management**.
3. Choose **Add new users**.

4. Choose **Import users using a .csv template**.
5. Choose to download the template for a pre-formatted CSV file.
6. In the CSV file, configure the details for the new users who you want to add. For **soft phone auto accept (yes/no)**, be sure to enter **yes**.
7. After configuring the CSV file, in your Amazon Connect instance, choose **Upload file**, and then choose the configured CSV file from its location on your computer.
8. Under **Upload file and verify**.
9. Under **Verify user details**, verify that the information is correct for the new users, and then choose **Save**.

(Optional) Verify the change in CCP logs

To confirm that **Auto-Accept Call** is enabled for an agent, download the CCP logs generated for that agent: in the CCP for the agent, choose **Settings**, **Download logs**. The logs are saved to your browser's default download directory.

In the logs, the **autoAccept** attribute is set to **"true"** if this setting is enabled. The logs show something like this:

```
                "type": "agent",
                "initial": false,
                "softphoneMediaInfo": {
                    "callType": "audio_only",
                    "autoAccept": true
```

Enable persistent connection for Amazon Connect agents

> **Note**
>
> This feature is currently in public preview.

When **Enable persistent connection** is selected for an agent, after a call ends the agent's softphone maintains its media connection to Amazon Connect for a few minutes. This enables subsequent calls to connect faster. In case the agent remains idle for an extended period of time, the softphone media connection is dropped to reduce agent workstation and network resource consumption. It is re-established upon the next call for this agent.

This functionality doesn't apply to chats or tasks.

How to enable persistent connection for an agent

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an Admin account, or an account with **Users and Permissions - Users - Create** or **Edit** permission in it's security profile.
2. On the left navigation menu, choose **Users**, **User management**.
3. In the list of users, select an agent, and then choose **Edit**.
4. On the **Edit users** page, under **Phone**, choose **Softphone**, and then select **Enable persistent connection**.
5. Choose **Save**.

Bulk upload new users with persistent connection enabled

You can't use the CSV template to edit information for existing users. If you include duplicate users with different information in the CSV template, you will receive an error.

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an Admin account, or an account with **Users and Permissions - Users - Create** permission in it's security profile.
2. On the left navigation menu, choose **Users**, **User management**.
3. Choose **Add new users**.
4. Choose **Import users using a .csv template**.
5. Download the template for a pre-formatted CSV file.
6. In the CSV file, configure the details for the new users who you want to add. For **persistent connection (yes/no)**, be sure to enter **yes**.
7. After configuring the CSV file, in your Amazon Connect instance, choose **Upload file**, and then choose the configured CSV file from its location on your computer.
8. Under **Upload file and verify**.

9. Under **Verify user details**, verify that the information is correct for the new users, and then choose **Save**.

FAQ

When is the softphone connection created?

The media connection for agent softphone is created upon the first incoming or outbound call for the agent.

Does the softphone connection persist for the entire agent session?

If the agent makes or receives another call within a few minutes of a previous call ending, the softphone connection gets re-used to reduce call setup time for the new call. This process repeats (and the session persists) for as long as the agent keeps placing or receiving calls in quick succession. However, if the agent remains idle for several minutes, then the connection is dropped. In such cases, the connection is re-created silently upon the next call.

Can the agent opt-out of persistent connection?

Only the contact center administrator can enable or disable this feature for agents using steps mentioned above. Agents cannot disable persistent connection.

Are there any browser restrictions for using this feature?

This feature is available on supported versions of Chrome and Edge. It's not supported on Firefox.

Can this feature be used when VDI audio optimization is enabled?

Yes.

Is this feature supported on custom Call Control Panels (CCPs)? Is there a change needed to the Call Control Panel (CCP) to use this feature?

If your custom CCP uses the softphone from Amazon Connect embedded iframe (that is, if `allowFramedSoftphone` is passed as true to initiate the CCP using Amazon Connect Streams JS), then you don't need to make any changes for this functionality to work.

If your custom CCP integrates Amazon Connect RTC JS in it's own frame, then you need to upgrade the same.

Log out agents automatically when they close their CCP using the Amazon Connect CCPv1

> **Important**
>
> This topic only applies to customers who use CCPv1. The URL for CCPv1 ends with **/ccp#**.

When using the default Amazon Connect CCPv1, closing the CCP window or logging out doesn't automatically change an agent's status from **Available** to **Offline**. An agent must change their status manually to **Offline** and then log out.

To change this behavior, you can do one of the following:

- Use CCPv2. When agents log out, their status is automatically switched to **Offline**. However, note that CCPv2 doesn't automatically switch agents to **Offline** if they only close the window. For instructions on upgrading to CCPv2, see Upgrade your Contact Control Panel (CCP) when your CCP URL ends with /ccp#.
- Use the CreateAgentStatus API: You can change the state of the agent to Offline.
- Create a custom CCP. See Amazon Connect Streams API and the Agent API
- Use the following steps in this topic to update your CCP so it switches agents to **Offline** and logs out agents automatically when they close the CCP window.

Step 1: Set up the Streams API

For instructions, see the Amazon Connect Streams Documentation.

Step 2: Update your application code to change the agent state

Integrate the following Streams API calls into your web application:

1. Use connect.agent() to subscribe to agent events and retrieve agent objects.

```
let mAgent;

connect.agent(function(agent) {
  mAgent = agent;
});
```

2. Call agent.setState() in the onbeforeunload event handler to change the agent state. The agent is marked Offline after executing the `beforeunload` function.

   Using the `beforeunload` hook is the best option, but note that it doesn't work consistently.

```
window.addEventListener("beforeunload", function(event) {
    if (mAgent != null) {
        let states = mAgent.getAgentStates();
        // "states" is an array of changeable states. You can filter the desired
 state to change by name.
        let offlineState = states.filter(state => state.name === "Offline")[0];

        // Change agent state
        mAgent.setState(offlineState, {
        success: function() {
            console.log("SetState succeeded");
        },
        failure: function() {
        console.log("SetState failed");
        }
    });
  }
});
```

Step 3: Design for errors

If an API call fails to execute the first time and a contact takes the error branch of your flow, there's a chance that an agent's state won't change as expected. Be sure to include logic to account for this possibility. For example, you could delay the page unload while the API call is tried again. Or, you could pop a "Call failed" warning message in a modal dialog before the page unload.

Set up agents in Amazon Connect to assign tasks to themselves

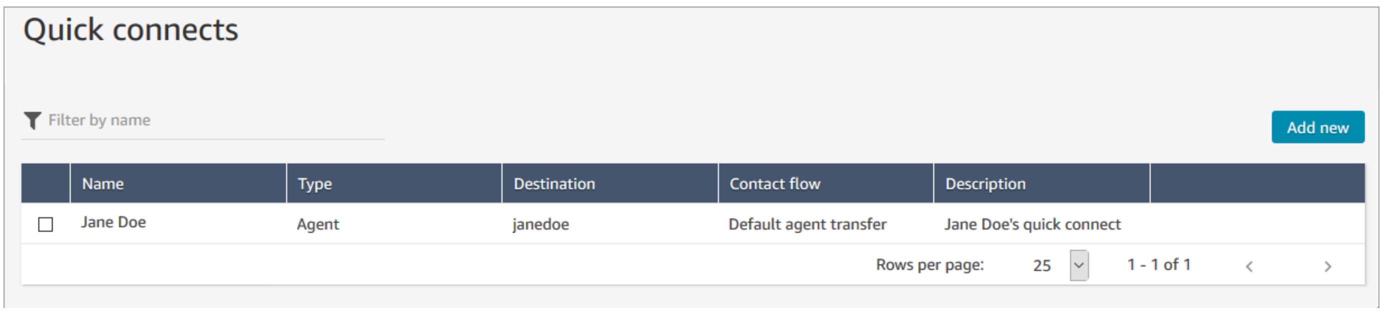
For an agent to be able receive a task, they need a quick connect created for them. With this quick connect, agents will be able to assign tasks to themselves, and other agents will be able to assign tasks to them.

Step 1: Create a quick connect for the agent

1. On the navigation menu, choose **Routing**, **Quick connects**, **Add a new**.

2. Enter a name for the quick connect, such as the name of the agent. For example, if you want Jane Doe to be able to assign tasks to herself, enter **Jane Doe**.
3. Under **Type**, use the dropdown list to choose **Agent**.
4. Under **Destination**, use the dropdown list to choose the user name for the agent.
5. Under **Flow**, choose **Default agent transfer**, or the appropriate flow for your contact center.
6. Under **Description**, enter a description, such as **Jane Doe's quick connect**.
7. Choose **Save**.

   The following image shows a quick connect for Jane Doe on the **Quick connects** page.



Step 2: Create a queue for the agent and associate the quick connect

1. After you create the quick connect, go to **Routing**, **Queues** and add a queue for the agent.
2. On the **Add new queue** page, in the **Quick connects** box, search for the quick connect you created for the agent.
3. Select the quick connect and then choose **Save**.

Step 3: Add the queue to the agent's routing profile

1. Go to **Users**, **Routing profiles** and choose the agent's routing profile.
2. Add the agent's queue to the routing profile, and choose **Task** for the channel.

   If the agent can receive transfers through other channels, select them as well.
3. Choose **Save**.

Provide agents with access to the Amazon Connect Contact Control Panel (CCP)

> **Note**
>
> This is the URL to the CCP website:
>
> - **https://*instance name*.my.connect.aws/ccp-v2/**
>
> This is the URL to the agent application:
>
> - **https://*instance name*.my.connect.aws/agent-app-v2/**

Steps to ensure agents can access the CCP

Agents use the Amazon Connect Contact Control Panel (CCP) to communicate with contacts. But before agents can access to the CCP and handle contacts, there are a few things you need to do:

1. Ensure your network meets the requirements for using the CCP. For more information see Set up your network to use the Amazon Connect Contact Control Panel (CCP).
2. Ensure agents have the appropriate headsets and workstations. For more information see Agent headset and workstation requirements for using the Contact Control Panel (CCP).
3. Create a user name and password for agents to log into the CCP, by adding agents to your instance.
4. At minimum, assign them the **Agent** security profile. This grants them permissions to access the CCP, which they use to manage contacts.
5. Provide the user name, password, and the CCP website link to your agents so they can log in.

   We recommend telling agents to bookmark the URL to the CCP so they can readily access it.
6. Train your agents on the CCP:
   - Watch Training video: How to use the Contact Center Panel (CCP) in Amazon Connect

Agent application: Everything in one place

Want your agents to manage contacts, and access customer profiles, cases, and knowledge all in one place? Use the agent application!

The *agent application* is a single web browser interface that hosts the CCP, Customer Profiles, Cases, and Amazon Q in Connect.

If you're using the CCP that is provided with Amazon Connect, after you enable Customer Profiles, Cases, or Amazon Q in Connect, share the following URL with your agents so they can access it in the agent application:

- **https://*`instance name`*.my.connect.aws/agent-app-v2/**

For help finding your instance name, see Find your Amazon Connect instance name.

Grant microphone access in Chrome, Firefox, or Edge

If agents experience problems with their microphone, they may need to grant microphone access in their browser. Choose one of the following articles to get the steps appropriate for your browser:

- Use your camera and microphone in Chrome
- Firefox Page Info window
- *How to allow a website to use your camera or microphone while browsing in Microsoft Edge* in the article Windows camera, microphone, and privacy

> **Important**
>
> A change introduced in Google Chrome version 64 may result in issues with receiving calls if you are using an embedded Contact Control Panel (CCP) softphone using the Amazon Connect Streams library. If you are experiencing issues with your microphone when using Chrome version 64, you can resolve the issue by building and deploying the latest version of the Amazon Connect Streams API, following the steps under *Downloading Streams*. You can also resolve the issue by using Firefox or Edge as your browser.

How to get help for CCP issues

Agents: Contact your manager or the technical support provided by your company.

Amazon Connect Administrators: See Troubleshooting Issues with the Contact Control Panel (CCP) for detailed troubleshooting steps. Or, log in to the AWS Management Console (https://console.aws.amazon.com/console) using your AWS account. In the upper right corner of the page, choose **Support**, and open a support ticket.

Agent headset and workstation requirements for using the Contact Control Panel (CCP)

Agent headsets and workstations in the contact center vary widely. While the Amazon Connect CCP is built to handle high levels of jitter and high latency environments, the architecture of the **workstations** that agents use, and the location and environment in which they take contacts, can impact the quality of experience.

Headset requirements

The agent's Contact Control Panel (CCP) is compatible with all types of headsets.

For the best agent and customer experience, we recommend using a USB headset.

Alternatively, you can redirect the contact to an external number, in E.164 format, using an agent's existing telephony.

> **Note**
>
> If the agent's audio device does not support up to 48khz and the browser asserts a sample rate of 48khz, audio issues such as an audible humming sound may be present in the agent's outgoing audio. This has been seen with Firefox but not with Chrome.
> For instructions on verifying the sample rate of the agent's headset and browser, see Humming sound in the agent's audio device: Verify the headset and browser sample rates

Workstation minimum requirements

Under-powered workstations can make it difficult for agents to access the tools and resources they need to service contacts. Also, keep in mind the resource requirements when scoping workstations to ensure that they can perform under load while appropriately multitasking for the use case.

Following are the minimum system requirements for the workstations using the CCP only. You'll need to scope additional memory, bandwidth, and CPU for the operating system and anything else running on the workstation to avoid resource contention.

- **Browser**—For a list of all supported browsers, see Browsers supported by Amazon Connect.
- **Network**—100 Kbps bandwidth per connected workstation
- **Memory**—2 GB RAM
- **Processor (CPU)**—2 GHz

iPhone and other mobile devices are not supported

The Amazon Connect console, Contact Control Panel (CCP), and agent workspace do not support mobile browsers.

How to determine whether a workstation is the source of problems

To determine whether a workstation is the source of problems, you need access to various levels of logging information. However, adding logging and monitoring to workstations that are already experiencing resource contention may further reduce available resources and invalidate test results. We recommended that your workstation meet the minimum requirements, so you leave additional resources available for logging, monitoring, malware scanning, operating system functions, and any other running processes.

Collect additional historical logging and data sources for correlation. If you see a correlation between the time of the event and the time the issue was reported, you may be able to determine the root cause with the following information:

- Round trip time (RTT) and packet loss to endpoints located within your Amazon Connect Region from your agent workstation, or an identical workstation on the same network segment. If no Region endpoints are available because of security policies, any public WAN endpoint suffices, for example, www.Amazon.com. Ideally, use your instance alias address (https://*your-instance-alias*.my.connect.aws/), and also your signaling address for endpoints.

  You can find your Region endpoints here: Amazon Connect endpoints and quotas.
- Regular monitoring of workstations that show processes running, and the current resource usage of each process.
- Workstation performance/utilization in these areas:

  - Processor (CPU)
  - Disk / drive
  - RAM / memory
  - Network throughput and performance
- Monitor all of the preceding for your VDI desktop environment, including RTT/packet monitoring between the agent workstation and the VDI environment.

How to troubleshoot the agent's headset in the Contact Control Panel (CCP)

Problems with the agent's headset are usually caused by two issues:

- The connection between the agent's headset and computer.
- The permissions for the browser microphone.

Here's what you need to do:

- **Check that your computer recognizes your headset**—Check the settings in Device Manager to ensure that your computer recognizes the headset and allows proper headset connectivity. For example, if you're using a Windows PC:
  1. Go to **Device Manager**, then expand **Audio inputs and outputs**.
  2. If your computer recognizes your headset, you'll see it listed there.
- **Check your browser settings for your headset/microphone**
  - **Chrome**
    1. go to **Settings**, **Site Settings**, **Microphone**.
    2. Then check that the correct headset is enabled.
    3. To learn more, see [Use your camera and microphone in Chrome](#).
  - **Firefox**
    1. While in the CCP, choose the lock icon in the address bar. If needed, grant permissions to the CCP.
    2. To learn more, see [Firefox Page Info window](#).
- **Remove your ad blocker**: If you're using an ad blocker extension, remove it and see if that fixes the problem.

> **Important**
>
> A change introduced in Google Chrome version 64 may result in issues with receiving calls if you are using an embedded Contact Control Panel (CCP) softphone using the Amazon Connect Streams library. If you are experiencing issues with your microphone when using Chrome version 64, you can resolve the issue by building and deploying the latest version of the Amazon Connect Streams API, following the steps under *Downloading Streams*. You can also resolve the issue by using Firefox or Edge as your browser.

For more information about solving audio problems, see Troubleshooting Issues with the Contact Control Panel (CCP).

Agents not hearing the indicator for incoming chat

If an agent can't hear the audio indicator for an incoming chat, the problem is likely because Google added an audio policy flag to Chrome. This flag exists in Chrome versions 71 - 75.

To fix this, add the CCP web site to the allowlist in the agent's Chrome settings. For instructions, see this Google Chrome Help article.

For more information about solving audio problems, see Troubleshooting Issues with the Contact Control Panel (CCP).

Embed a custom Amazon Connect Contact Control Panel (CCP)

The Amazon Connect Streams documentation describes how to integrate your existing web applications with Amazon Connect. Streams gives you the power to embed the Contact Control Panel (CCP) UI components into your page, and/or handle agent and contact state events directly giving you the power to control agent and contact state through an object oriented event driven interface. You can use the built in interface or build your own from scratch: Streams gives you the power to choose.

Contents

Using Amazon Connect with third-party cookies

Google Chrome

On Jul 22, 2024, Google announced that they no longer plan to deprecate third-party cookies and instead will provide an opt-in mechanism for deprecating third-party cookies. Amazon Connect uses third-party cookies for authentication. With this announcement, Amazon Connect customers using Google Chrome no longer need to upgrade to StreamsJS or CTI Adapter versions that address third-party cookie deprecation, which were planned for release in Q3 2024. No customer action is needed at this time.

Embed the Amazon Connect Contact Control Panel (CCP) into Salesforce

The core functionality of the Amazon Connect CTI Adapter provides a WebRTC browser-based Contact Control Panel (CCP) within Salesforce. The Amazon Connect CTI integration consists of two components:

- A managed Salesforce package
- An AWS Serverless application deployed to your AWS environment

For a detailed walk-through and setup of the full CTI Adapter capabilities for Salesforce Lightning, see the Amazon Connect CTI Adapter for Salesforce Lightning installation guide.

For the CTI Adapter for Salesforce Classic, see the Amazon Connect CTI Adapter for Salesforce Classic installation guide.

We recommend that you initially install the package into your Salesforce sandbox. After the package is installed, you can configure your Salesforce Call Center configuration within Salesforce.

Embed the Amazon Connect Contact Control Panle (CCP) into Zendesk

To integrate Amazon Connect and Zendesk, you need:

- An Amazon Connect instance.
- A Zendesk Support account with a Zendesk Talk Partner Edition plan, or a Zendesk trial account.

Install and configure the Amazon Connect for Zendesk app in your Zendesk Support account, then integrate the app with Amazon Connect. After integration, you can create flows to use Amazon Connect with Zendesk ticketing.

For more information, see How do I integrate Amazon Connect with Zendesk?

Upgrade to the latest Amazon Connect Contact Control Panel (CCP).

The URL for the latest Contact Control Panel (CCP) ends with **ccp-v2**

You only need to upgrade to the latest CCP if you're using one the following options:

- The URL for your CCP ends with **/ccp#**
- You use the Amazon Connect Streams API. The URL associated with `initCCP()` ends with **/ccp#**

If you’re still unsure whether your using the latest CCP, go to Compare the earlier and latest CCP to see if your CCP looks like the latest one.

Upgrade on your own schedule, before your automatic upgrade date

To upgrade to the latest CCP before your automatic upgrade date, use the steps in the following sections:

- Upgrade your Contact Control Panel (CCP) when your CCP URL ends with /ccp#
- Upgrade your Contact Control Panel (CCP) when using the Amazon Connect Streams API

Upgrade later, automatically

If you don't want to upgrade now, you can choose to wait until your scheduled upgrade date.

Between now and your scheduled upgrade date, we recommend the following change management steps:

- Compare how the upgraded CCP differs from the earlier one. For side-by-side visuals, see Compare the earlier and latest CCP.
- Upgrade your CCP in a test environment. Use the latest CCP to learn how it's different, and to check your configurations.
- Communicate to your agents when the upgrade is going to take place.
- Train your agents to help them get ready.

Schedule for the automatic upgrade

Your automatic upgrade date is dependent on your usage. Following is the schedule for when we will start migrating environments:

- <100 weekly minutes - start migrating on August 16, 2024
- <1K weekly minutes - start migrating on August 30, 2024
- <10K weekly minutes - start migrating on September 13, 2024
- <100K weekly minutes - start migrating on October 4, 2024
- >100K weekly minutes - start migrating on November 1, 2024

Upgrade your Contact Control Panel (CCP) when your CCP URL ends with /ccp#

Upgrading to the latest CCP is easy. If you want, you can try out the latest CCP and then at a later date make the switch. Here's what you do:

1. **Try it out**: Change the URL in your browser from **/ccp#** to **/ccp-v2**. The latest CCP appears automatically. If you want, change it back to /ccp# to return to the earlier CCP.
2. **Upgrade**: Change the URL in your browser from **/ccp#** to **/ccp-v2**. Bookmark the URL.
3. If you access the CCP through the Amazon Connect console by choosing the phone icon on the top right of a page, you will be re-directed according to the automatic upgrade date sent by email. Please reach out to your Amazon Solution Architect if your request is more urgent.

4. After the upgrade happens, if you use the /ccp# URL, it resolves to **/ccp-v2**.

Verify your network settings

We highly recommend setting up your network to use Option 1 (recommended): Replace Amazon EC2 and CloudFront IP range requirements with a domain allowlist.

Using this option helps Amazon Connect Support to quickly troubleshoot any issues you have. Specifically, using ***.telemetry.connect.{region}.amazonaws.com** passes more metrics to our Support team to help with troubleshooting.

Update your SAML URL to ccp-v2

If you use SAML 2.0 as your identity management system, be sure to update the destination in your relay state URL to **ccp-v2**.

Change `destination=/connect/ccp` to `destination=/connect/ccp-v2`.

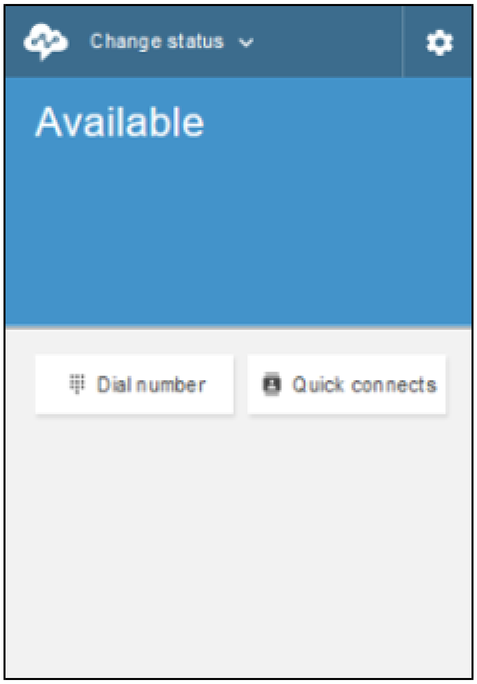
For more information, see Use a destination in your relay state URL

Compare the earlier and latest CCP

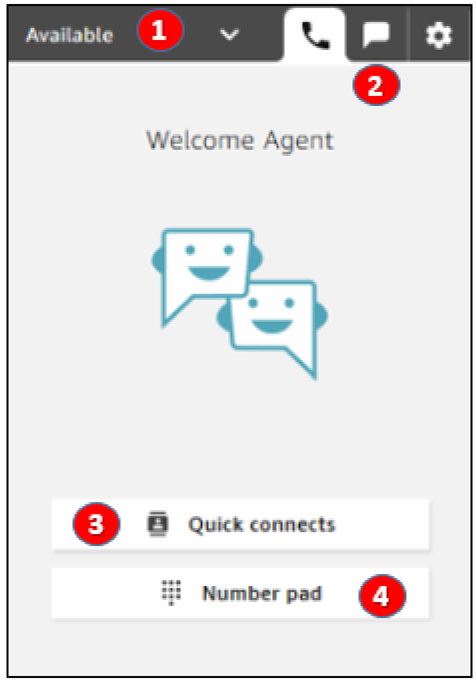
The images in this section show you how the latest CCP differs from the earlier CCP for common tasks that agents perform. The images show both CCP versions in their default state.

> **Tip**
>
> The chat tab appears on an agent's CCP only if their routing profile includes chat.

Set status, use chat, access quick connects and number pad



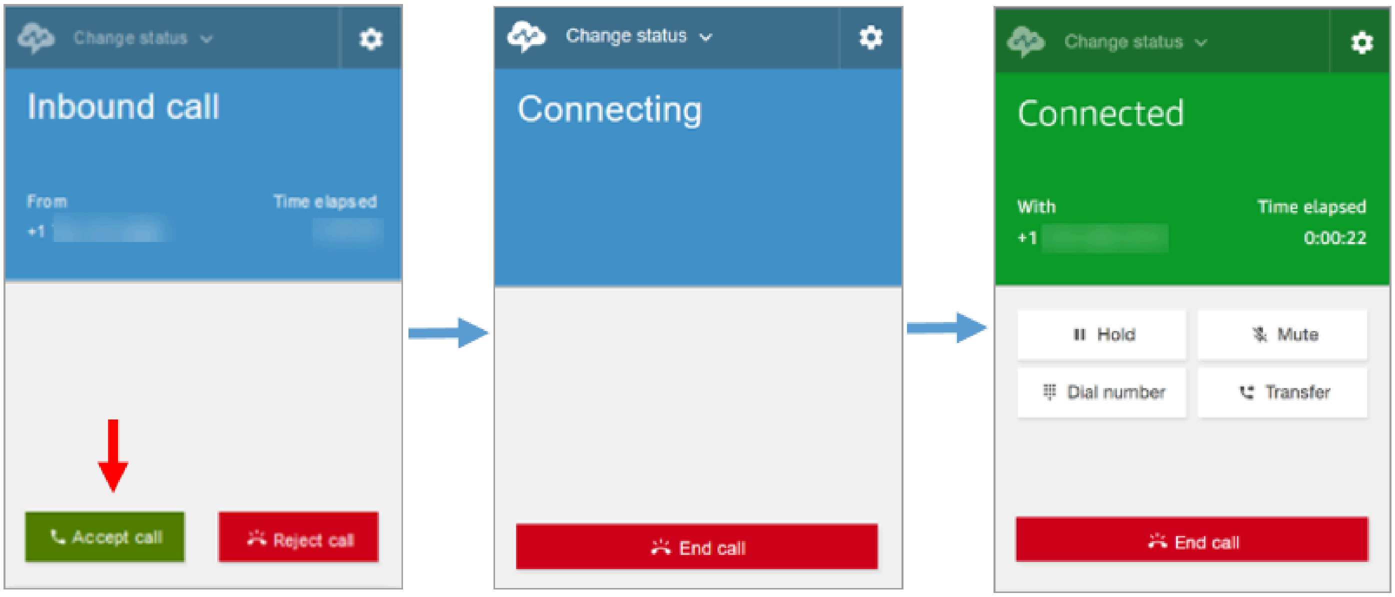
Earlier CCP



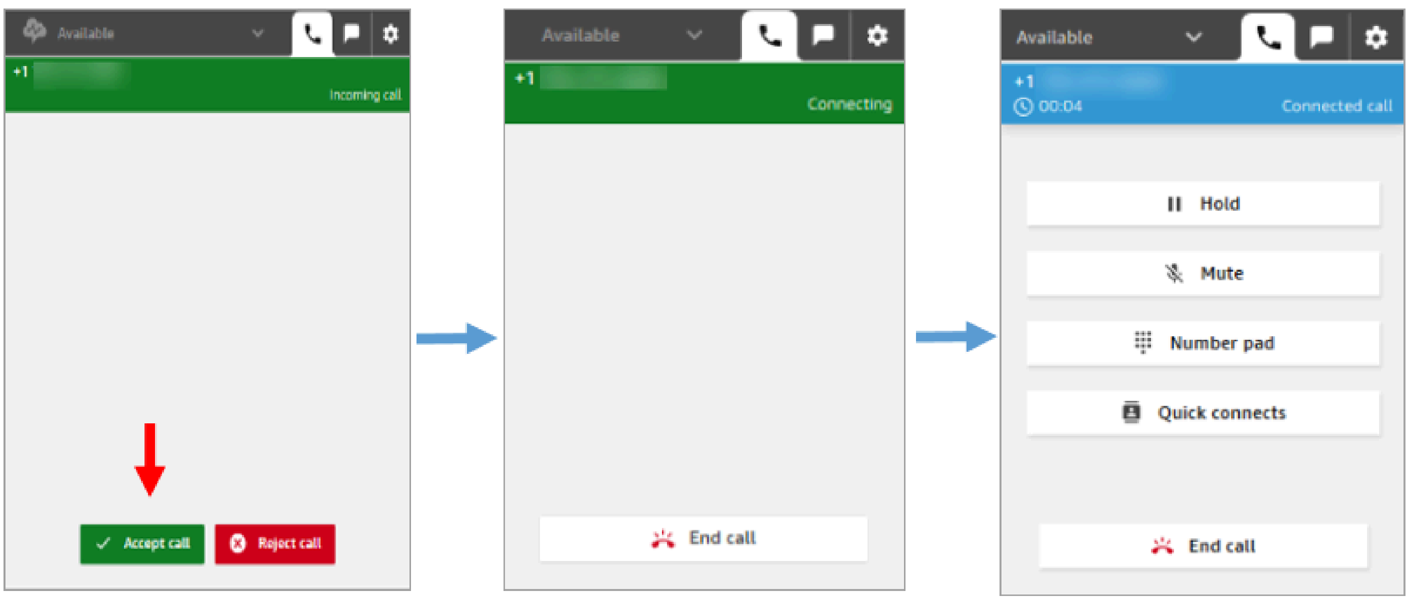
Latest CCP

1. Agents use a dropdown to set their status.
2. If you have enabled chat for the agent's routing profile, the chat tab appears.
3. Choose the **Quick connects** button to type and call a phone number, or select a quick connect.
4. Choose the **Number pad** button to type and call a phone number. This is useful when the phone number has letters.

Receive a call

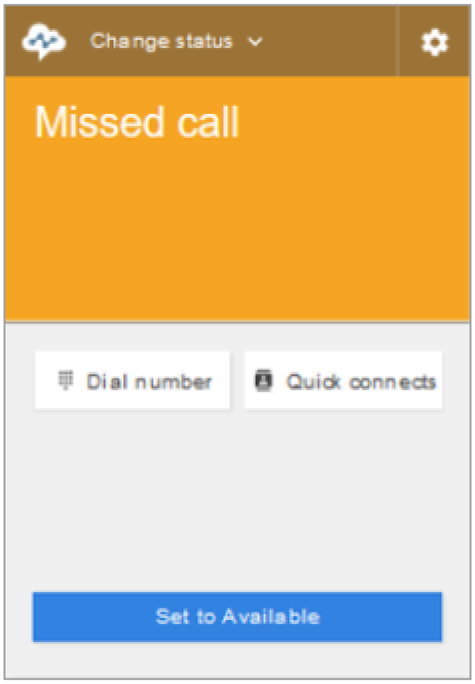


Earlier CCP

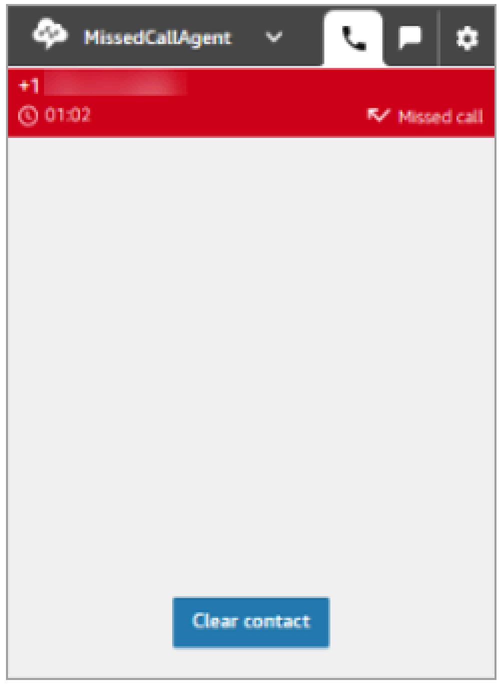


Latest CCP

Miss a call

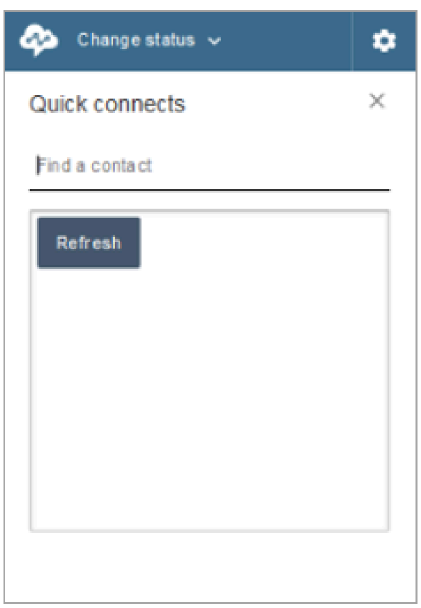


Earlier CCP

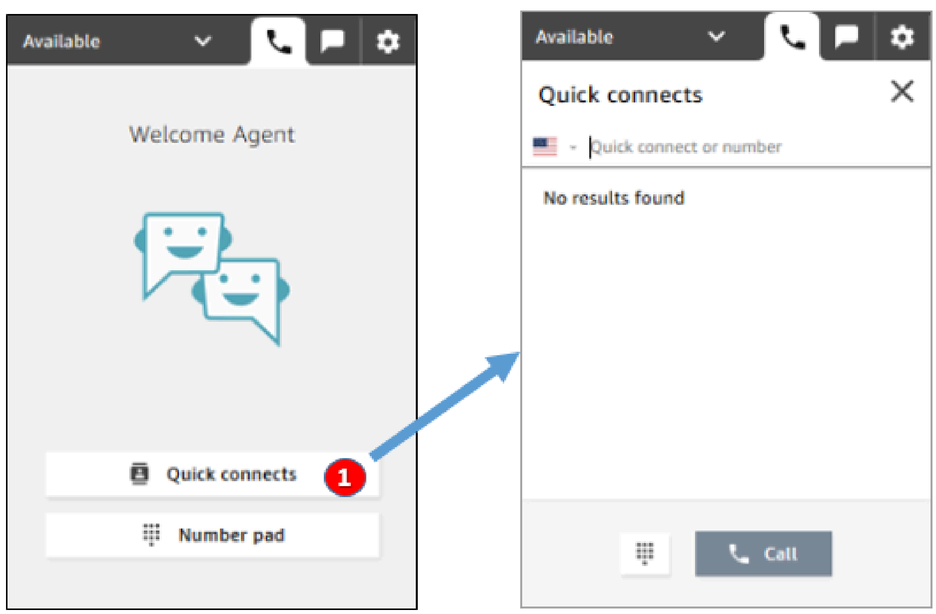


Latest CCP

Make a call: When to use Quick connects



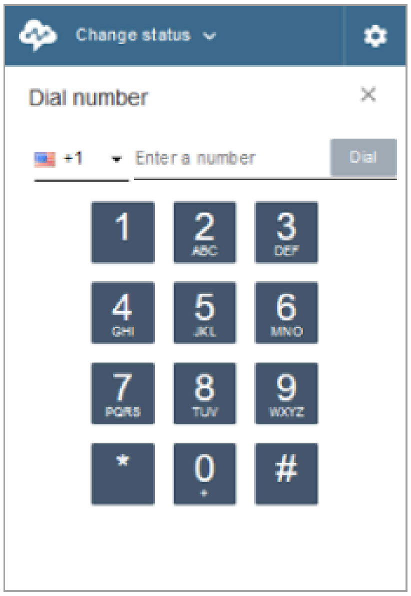
Earlier CCP

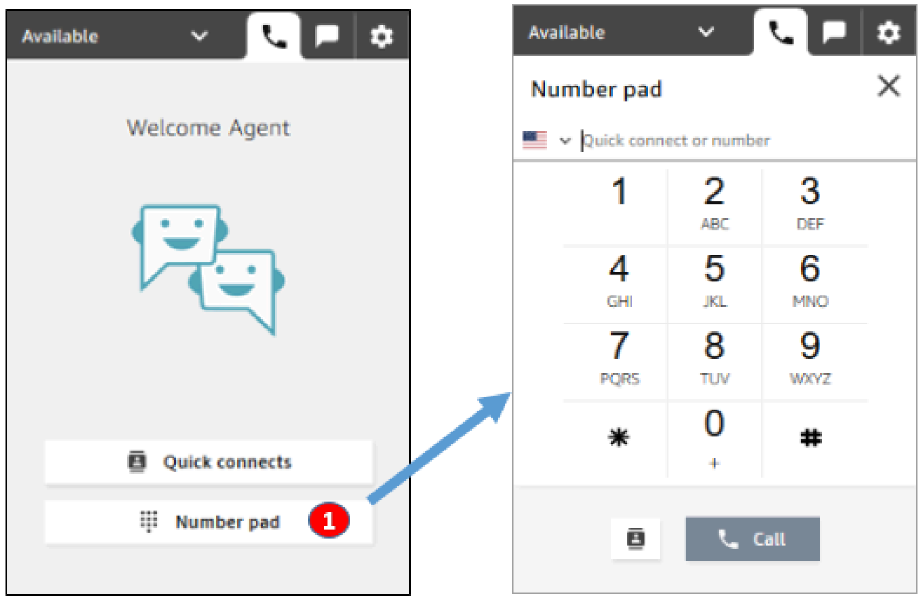


Latest CCP

- Use the **Quick connects** button to type a number or select a quick connect.

Make a call: When to use Number pad



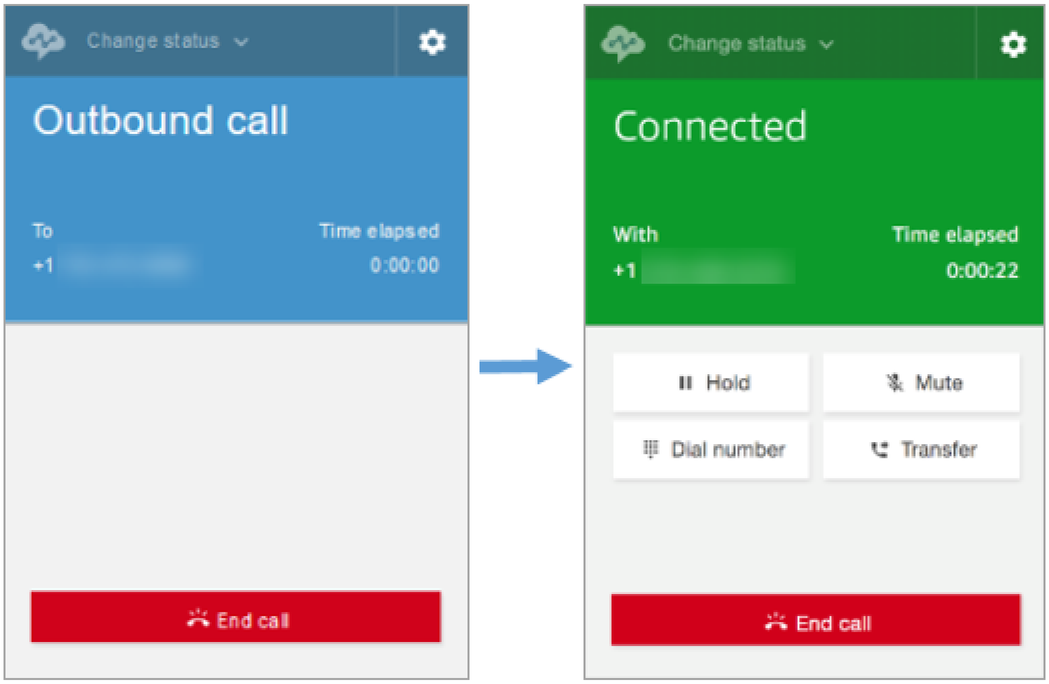


Earlier CCP

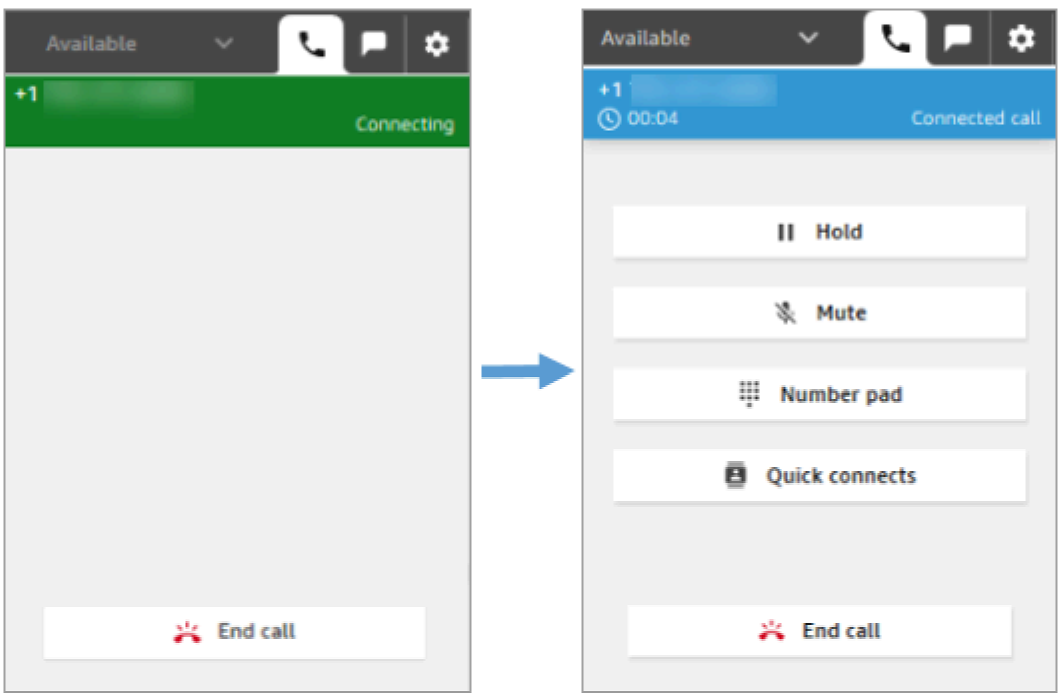
Latest CCP

- Choose the **Number pad** button to type and call a number. This is useful for corporate numbers with letters (for example, 1-800-EXAMPLE).

Make an outbound call

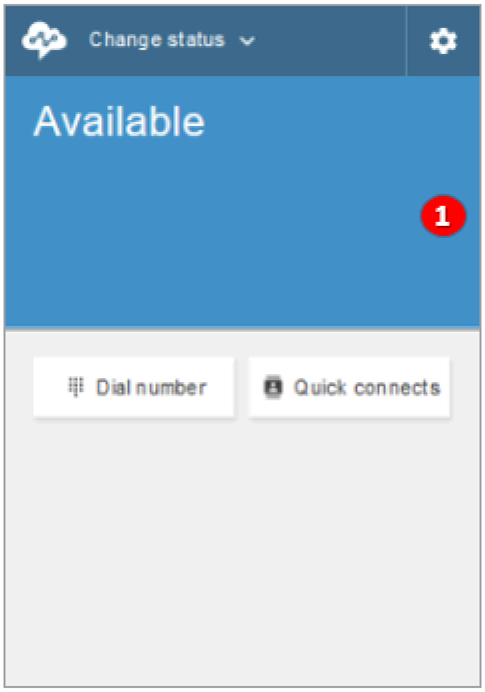


Earlier CCP

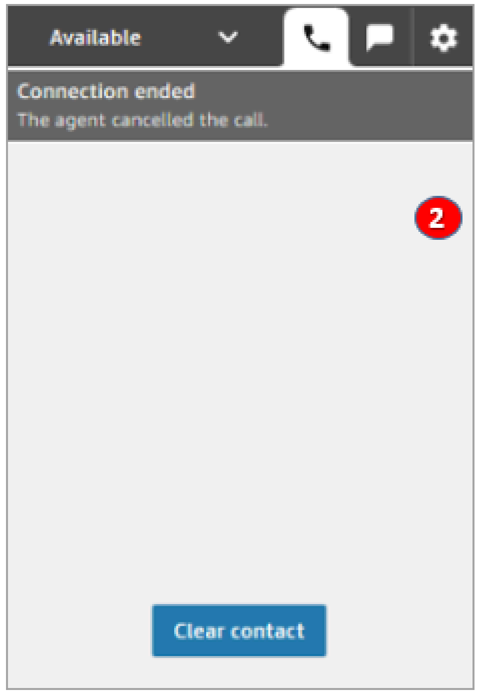


Latest CCP

Agent ends a call before being connected to the other party



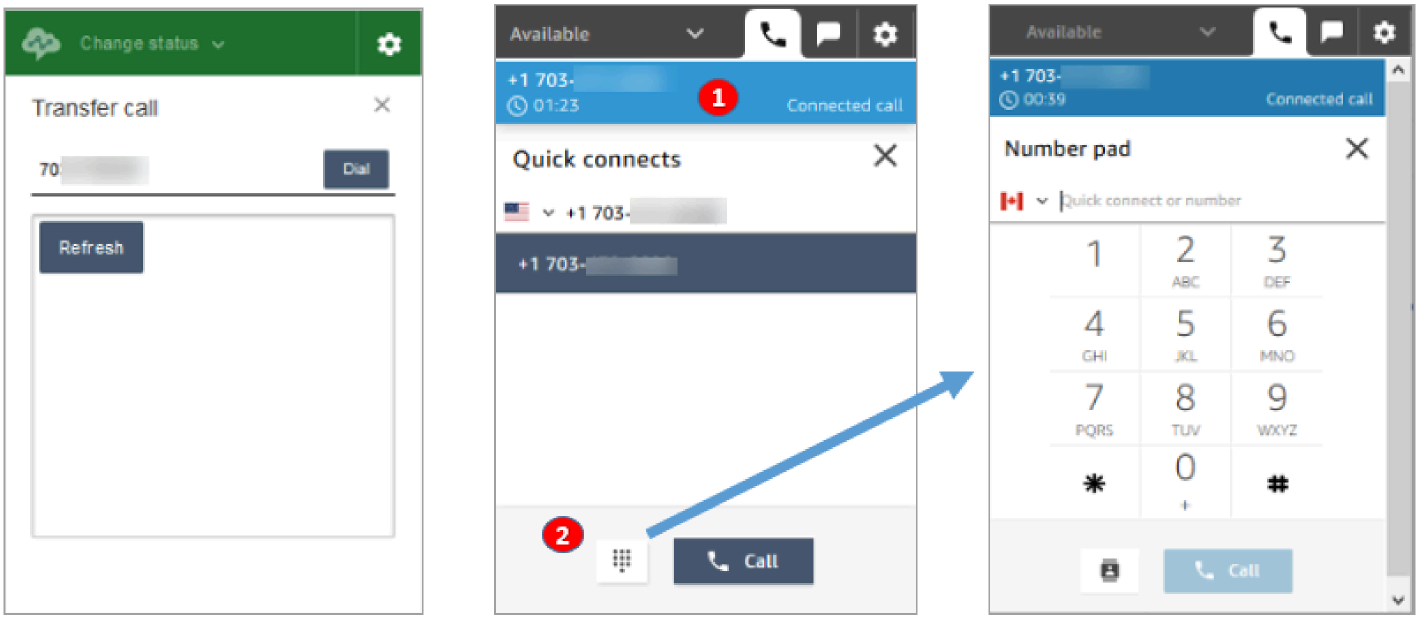
Earlier CCP



Latest CCP

1. If an agent ends a call before being connected, they are then available for a new contact to be routed to them automatically.
2. If an agent ends a call before being connected, they are prompted to choose **Clear contact**.

Make another call while connected on a call

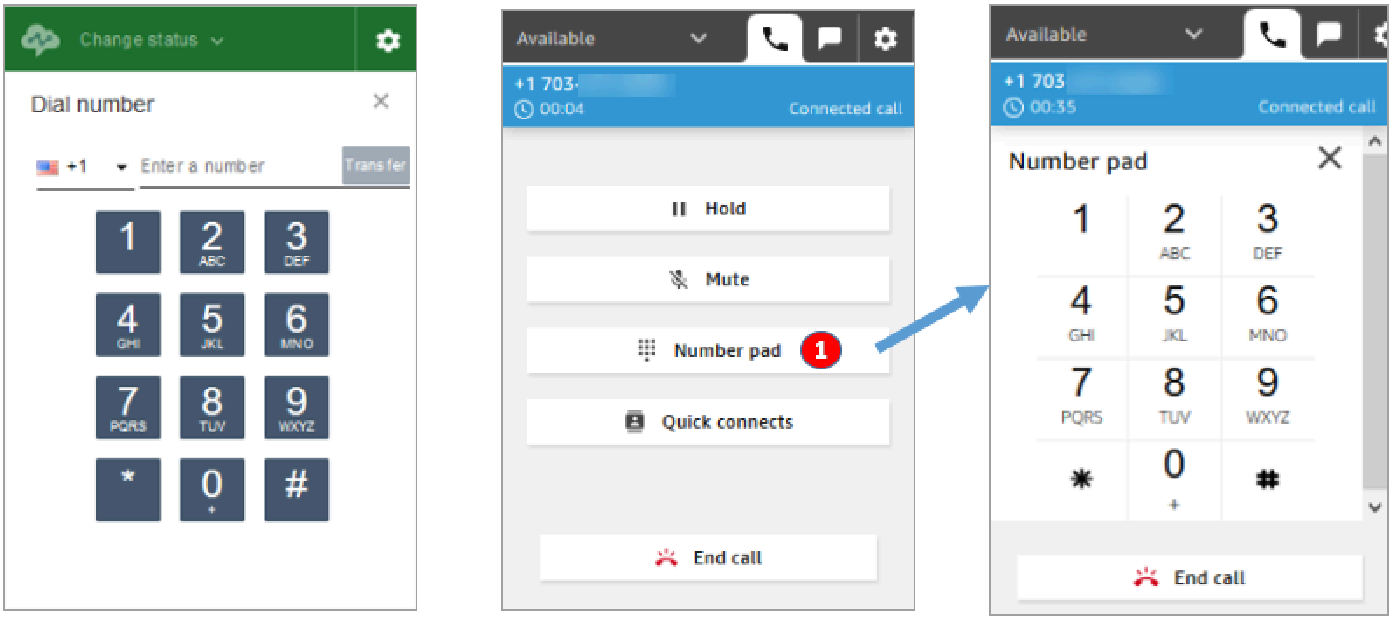


Earlier CCP

Latest CCP

1. You can see the call that you are on while typing another number or selecting a quick connect.
2. After choosing **Quick connects**, you can choose the **Number pad** button. Then on the **Number pad** page, you can enter a number.

Enter DTMF input while connected on a call

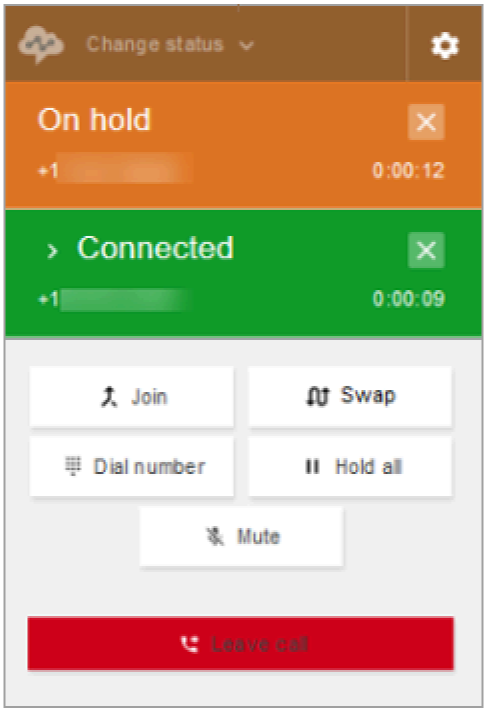


Earlier CCP

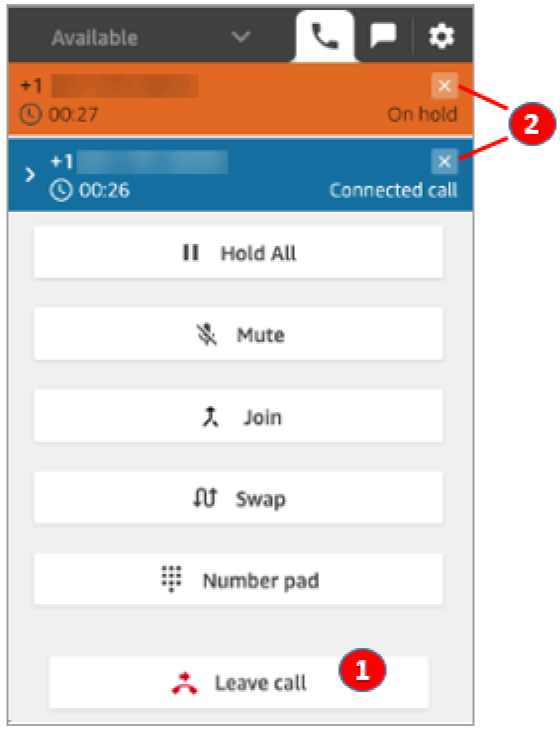
Latest CCP

- While on a call, only use **Number pad** to enter DTMF input.

Conference call scenario 1: Leaving a call when one party is on hold and the other is connected



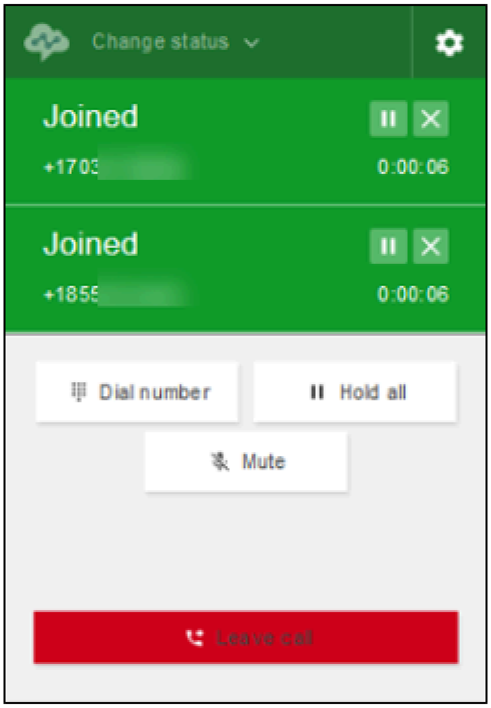
Earlier CCP



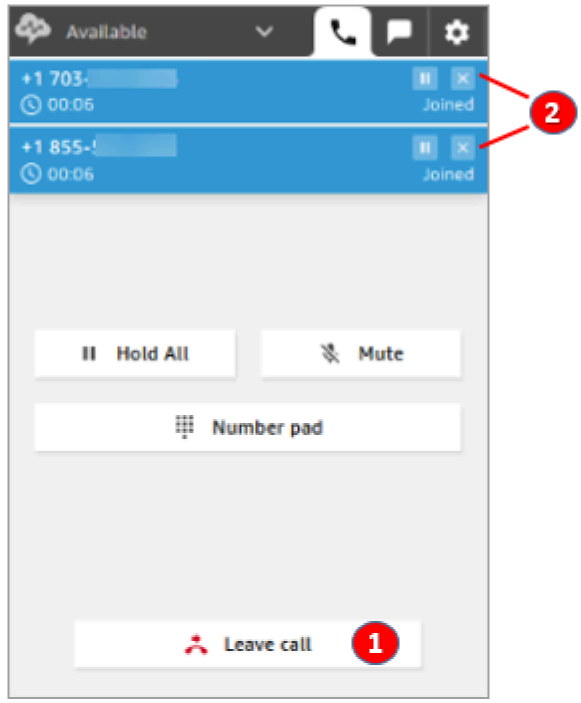
Latest CCP

1. Choose **Leave call** to leave the call. This automatically takes the first party off hold and connects them to the second party.
2. If instead you want to end the call, choose the **x** next to each party's number. This disconnects each party.

Conference call scenario 2: Leaving a call when the other parties are joined



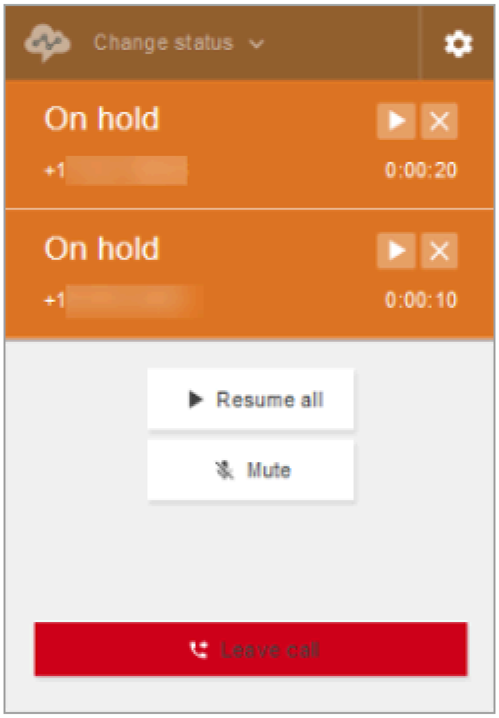
Earlier CCP



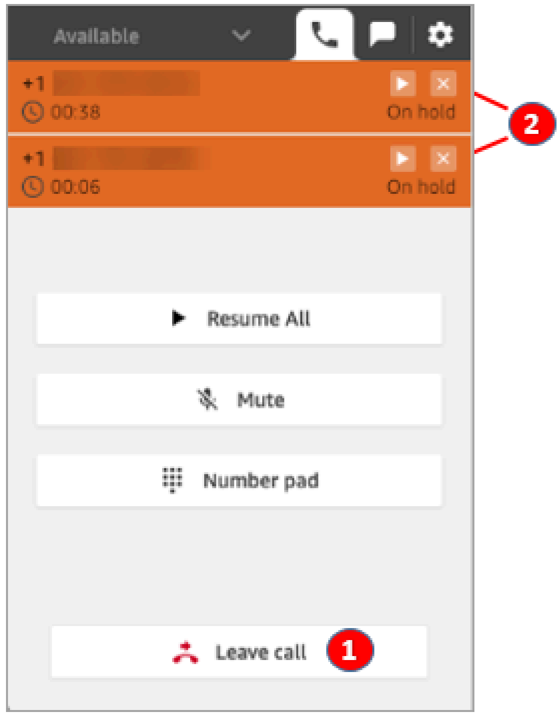
Latest CCP

1. Choose **Leave call** to leave the call. The other two parties stay joined.
2. If instead you want to end the call, choose the **x** next to each party's number. This disconnects each party.

Conference call scenario 3: Leaving a call when the other parties are on hold



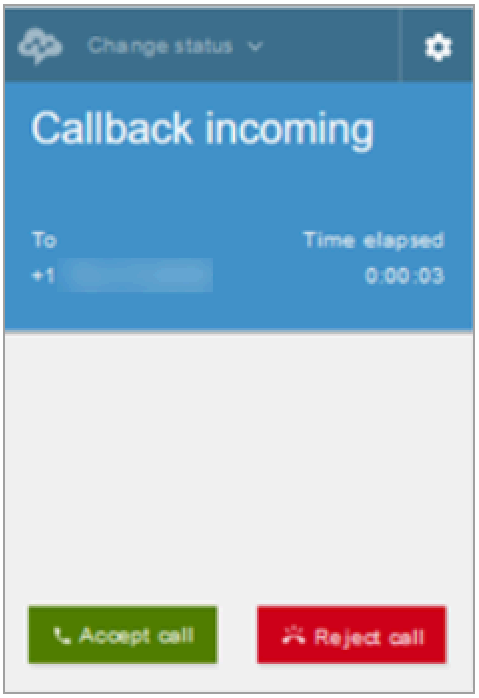
Earlier CCP



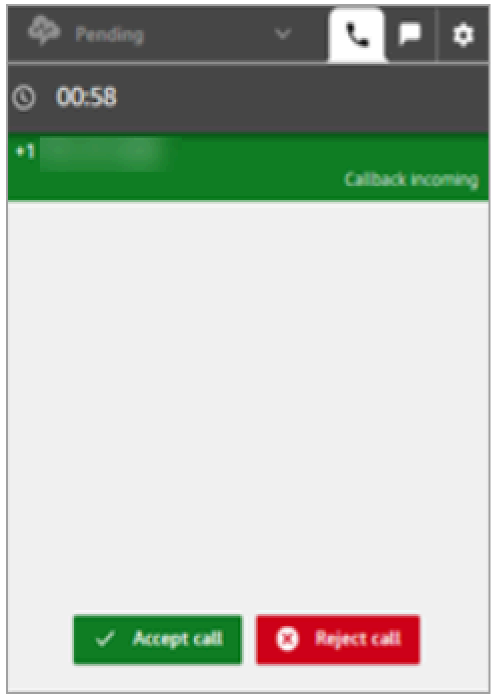
Latest CCP

1. Choose **Leave call** to leave the call. The other two parties are automatically taken off hold and connected.
2. If instead you want to end the call, choose the **x** next to each party's number. This disconnects each party.

Receive a queued callback

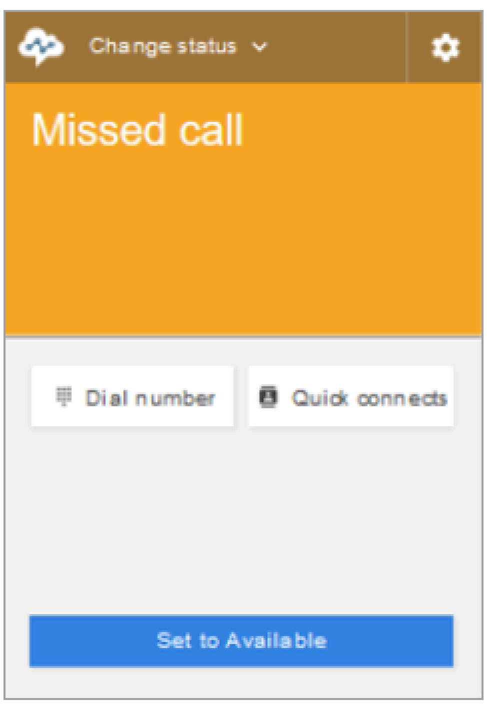


Earlier CCP

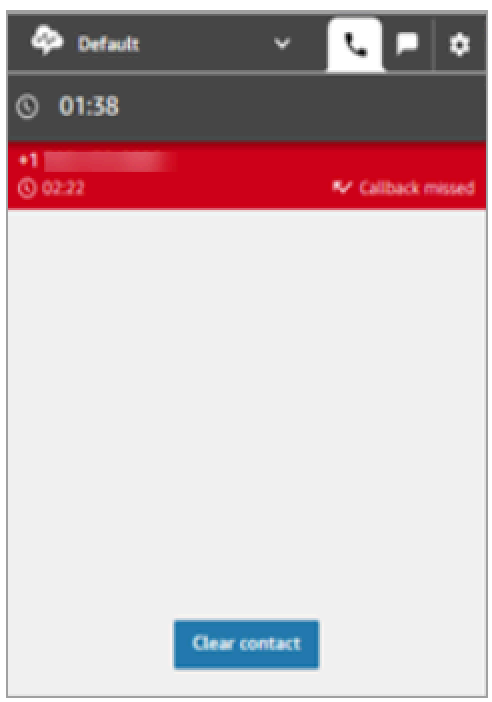


Latest CCP

Miss a queued callback

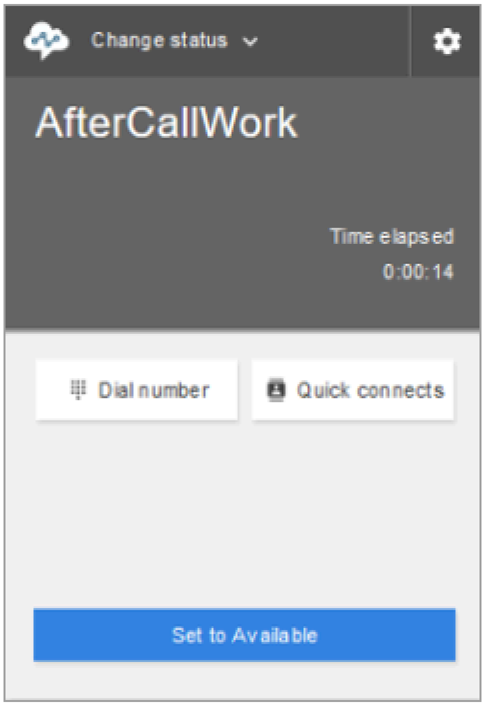


Earlier CCP

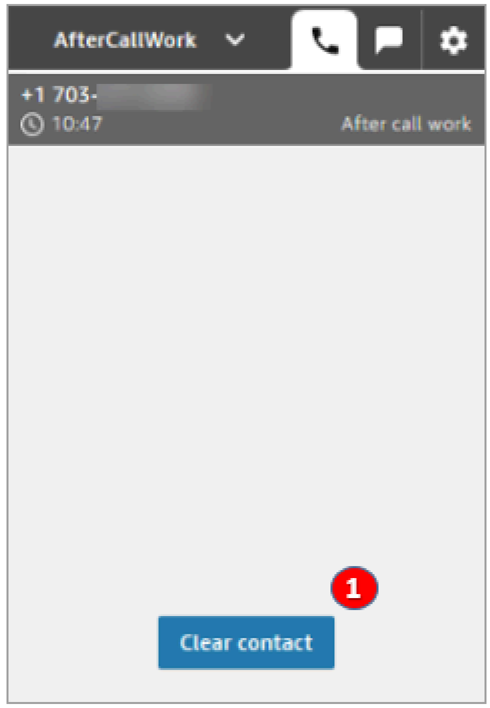


Latest CCP

Finish After contact work (ACW)



Earlier CCP



Latest CCP

- During After contact work (ACW), agents can finish follow-up work, and then choose **Clear contact**.

Upgrade your Contact Control Panel (CCP) when using the Amazon Connect Streams API

> **Note**
>
> The Amazon Connect Streams API remains the same between the earlier and latest versions of the CCP. We recommend validating custom implementations built using the Amazon Connect Streams API when upgrading versions to ensure consistency in behavior.

Use the following steps to upgrade to the latest CCP.

1. We recommend using the latest Amazon Connect Streams API.

2. Update the URL associated with `initCCP()` from **/ccp#** to **/ccp-v2**. For information about `initCCP()`, see connect.core.initCCP() in the Amazon Connect Streams API documentation on GitHub.

3. Add your domain URL to the Approved origin list:

    1. Log in to the [AWS Management Console](https://console.aws.amazon.com/console) (https://console.aws.amazon.com/console) using your AWS account.
    2. Navigate to the Amazon Connect console.
    3. Check that you're in the correct Region for your Amazon Connect instance. Choose your instance.

    4. Choose **Application integration**, and then choose **Add origin**.

    5. Enter your domain URL. All domains that embed the CCP for a particular instance to be explicitly added. For more information, see this article on GitHub.

If you use Salesforce, you need to add the Salesforce domains to your allowlist to prevent any issues with the CTI Adapter CCP functionality. For detailed instructions, see the Amazon Connect CTI Adapter for Salesforce Lightning installation guide or the Amazon Connect CTI Adapter for Salesforce Classic installation guide.

Verify your network settings

We highly recommend setting up your network to use Option 1 (recommended): Replace Amazon EC2 and CloudFront IP range requirements with a domain allowlist.

Using this option helps Amazon Connect Support to quickly troubleshoot any issues you have. Specifically, using ***.telemetry.connect.{region}.amazonaws.com** passes more metrics to our Support team to help with troubleshooting.

Update your SAML URL to ccp-v2

If you use SAML 2.0 as your identity management system, be sure to update the destination in your relay state URL to **ccp-v2**.

Change `destination=/connect/ccp` to `destination=/connect/ccp-v2`.

For more information, see Use a destination in your relay state URL

Set up Amazon Connect external voice transfer to an on-premise voice system

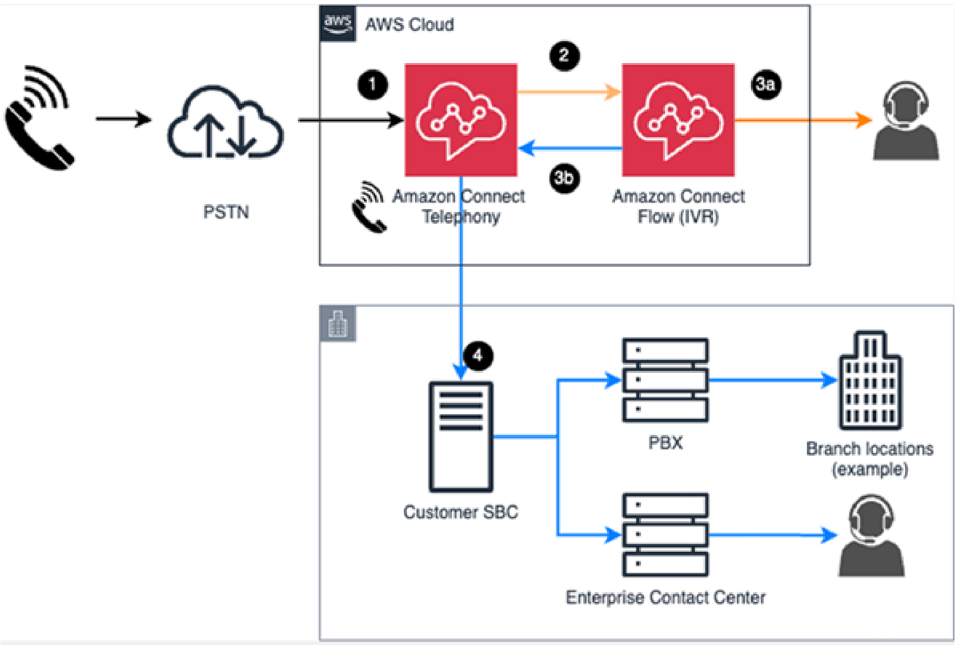
Migrating a contact center from on-premise to the cloud can be complicated. It requires moving many different components such as telephony, IVR, ACD, call recording, call analytics, and more. To accelerate your migration to Amazon Connect you can use Amazon Connect external voice transfer. It enables you to take an IVR first Amazon Connect migration approach.

You can integrate Amazon Connect with other voice systems to directly transfer voice calls and call metadata without using the PSTN. The call metadata includes rich context—such as callers phone number and their authentication status—that is captured by using the IVR. You can use the metadata to intelligently route the call to the right place in your external voice system. This enables you to easily migrate your contact center to Amazon Connect:

- You start with using Amazon Connect telephony and IVR with your existing voice systems for immediate modernization, to help improve your customers' experience and reduce costs. For example:
  - You can create a generative AI powered voice bot, analyze the performance, and quickly innovate to improve your customer's experience.
- At a later date, you can move your agents to Amazon Connect.

The following diagram shows the flow of voice call audio when it is received and serviced by Amazon Connect telephony and IVR.

- If the call is not contained within the IVR, it can go to an agent hosted by Amazon Connect or transferred from Amazon Connect to your on-premise voice system. This requires voice to be transferred by using the external voice transfer connector.
- After the call is transferred, the on-premise call flow continues to operate the way it is configured with your existing agents.



1. A call through PSTN lands on Amazon Connect telephony
2. The call is sent to the Amazon Connect IVR for call orchestration and IVR.
3. The call can be routed using one of the following options:
   a. Routed to an agent hosted in Amazon Connect.

b. Routed off platform. The Amazon Connect IVR is no longer used.

4. The call is delivered to your SBC. The Amazon Connect telephony service still in the path of the call.

Why not use transfer to phone number over PSTN?

You can choose to transfer the voice calls to phone numbers over PSTN. However, contextual information about the caller, such as their phone number, the queue they are in, if they have been authenticated, etc., is not preserved as these calls traverse across PSTN.

Following table lists the differences between using transfer to phone number or external voice transfer.

	Transfer to phone number	**Transfer to external voice systems**
Destination	A phone number	A pre-configured connector
Metadata	Cannot be transferred	Can be transferred
Connectivity	Uses the public telephone network (PSTN)	Does not use the public telephone network (PSTN)
Billing	Voice usage applies during transfer	Voice usage does not apply if the Amazon Connect flow is stopped at transfer

Requirements

Before you start setting up external voice transfer, check that your Amazon Connect and on-premise systems meet the following requirements:

- Verify your Amazon Connect instance is created in a supported AWS Region for external voice integration.
- Make sure your on-premise voice system can connect to the Region.

Set up steps

Following is a summary of the steps you'll take to set up external voice transfer for Amazon Connect The linked topics provide more detail.

1. Create an Amazon Connect instance if you don't already have one.
   - Claim a phone number from Amazon Connect or port an existing number.
2. Request service quota increases for **External voice transfer connectors per account**.

   > **Important**
   >
   > After your service quotas are requested and approved, **External voice connectors** is displayed in the Amazon Connect console and the Amazon Connect admin website.

3. Create external voice transfer connectors in the Amazon Connect console.
4. Configure your external voice system.
5. Configure a Transfer flow block to route calls from Amazon Connect to your external enterprise voice system.
6. Optionally, Set up Amazon Connect Global Resiliency for external voice transfer.

Create external voice transfer connectors for Amazon Connect

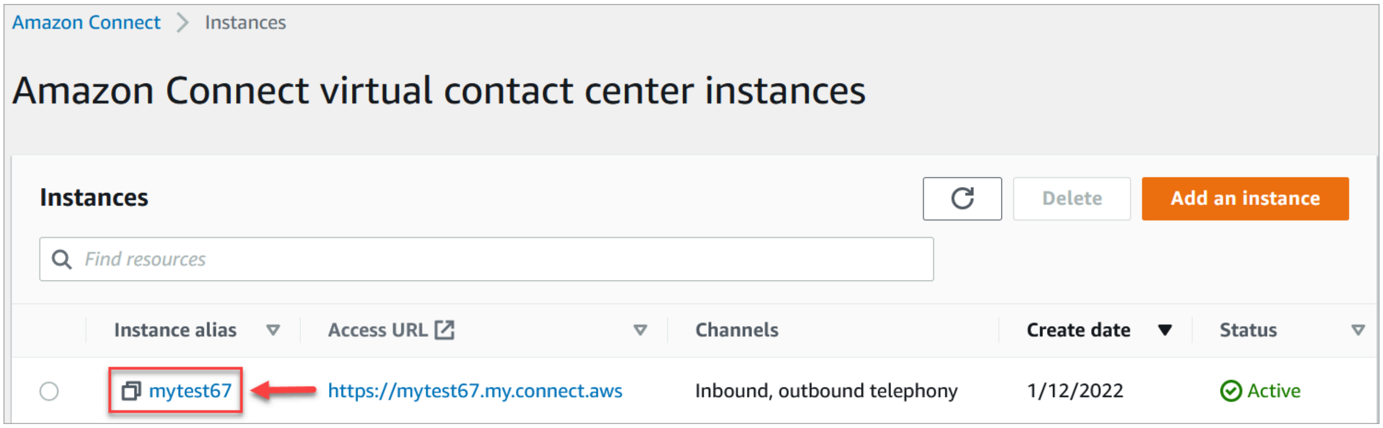
Complete the following steps to create an external voice transfer connector so you can integrate Amazon Connect with an on-premise system.

1. If you have not yet created your Amazon Connect instance, do so now. For instructions, see Create an Amazon Connect instance.
2. Request a service quota increase for **External voice transfer connectors per account**.

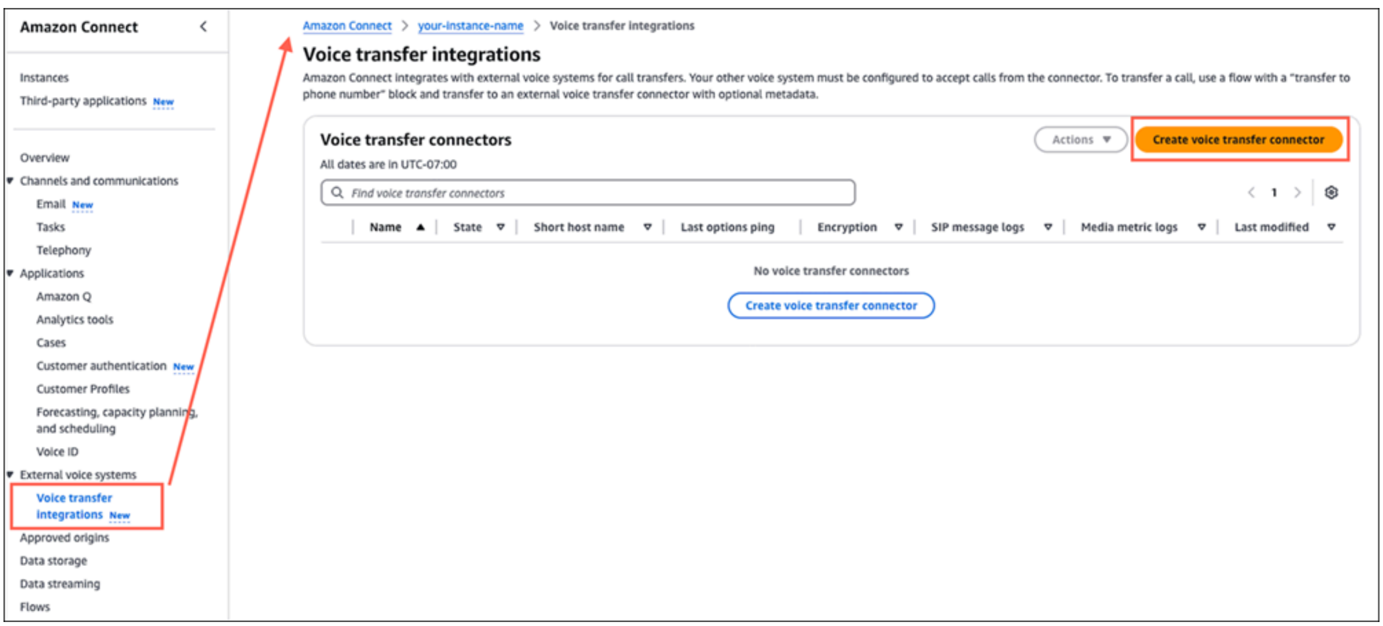
   > **Important**
   >
   > You must have an Amazon Connect instance before you can request a quota increase. The option to enable external voice transfer integration in the Amazon Connect console is not visible until the quota increase is approved.

3. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.

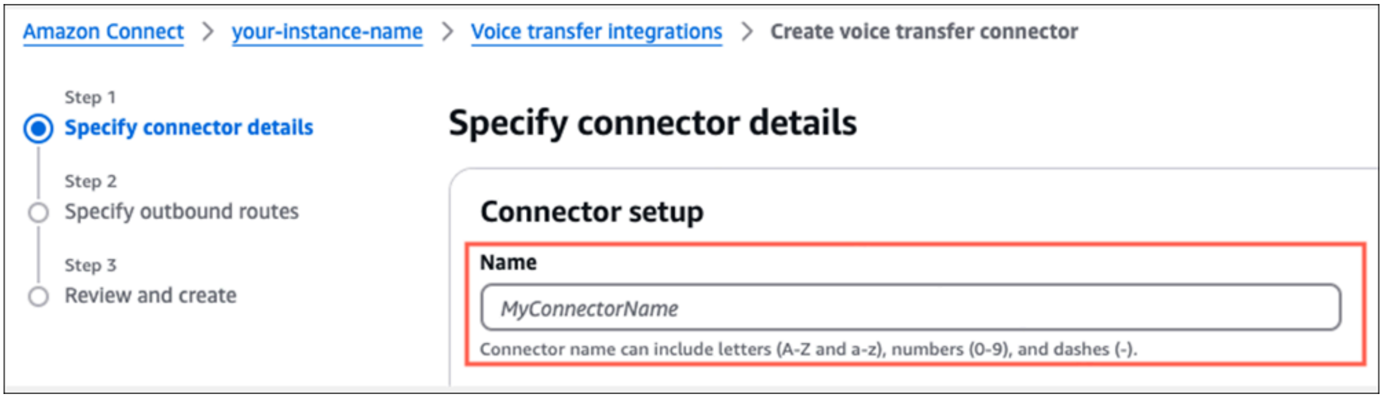
4. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Amazon Connect URL. The following image shows the **Amazon Connect virtual contact center instances** page, with a box around the instance alias.



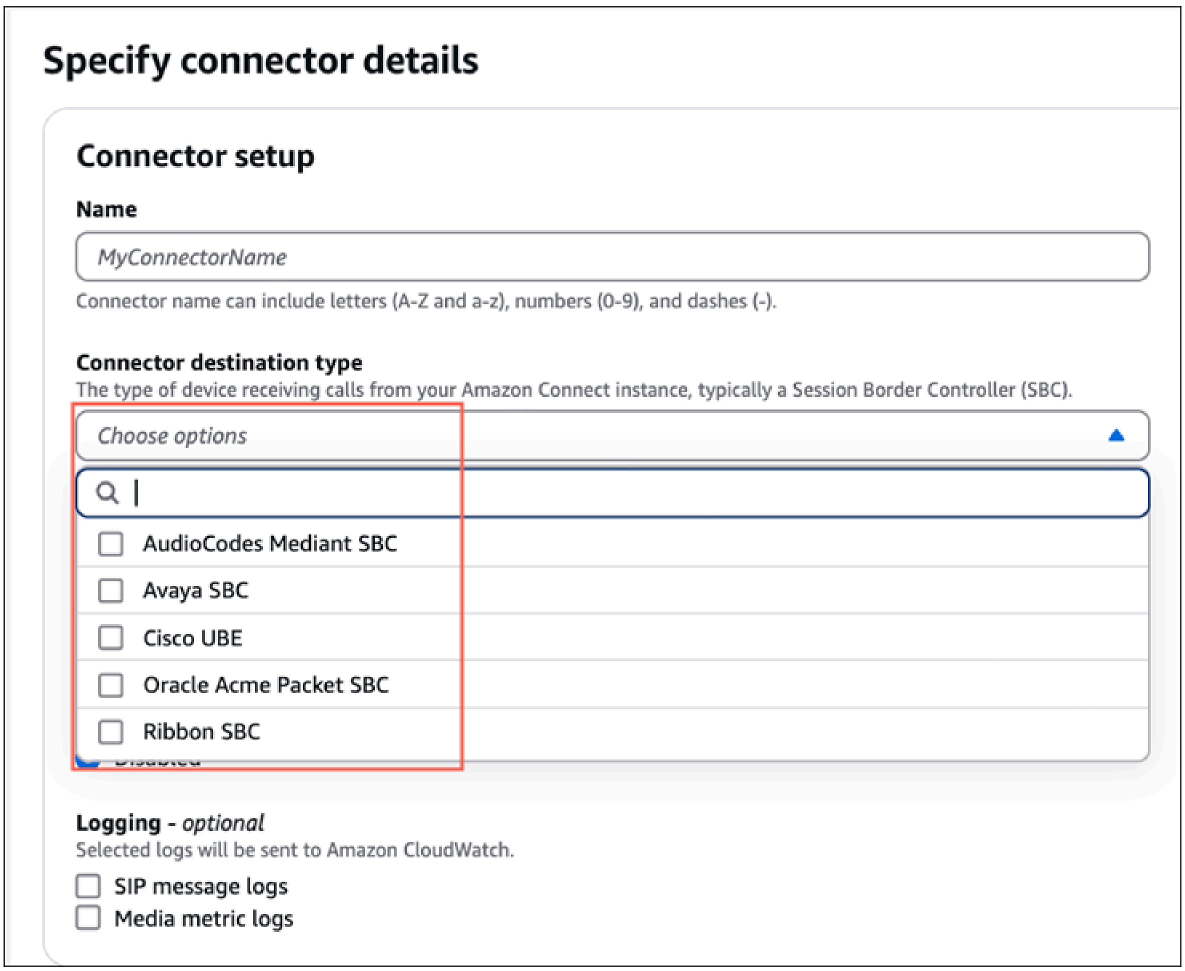
5. After the **External voice transfer connectors per account** quota increase has been approved: In the Amazon Connect console navigation pane, choose **External Voice Systems**, **Voice Transfer Integrations**, and then choose **Create Voice transfer Connector**, as shown in the following image.



6. On the **Specify connector details** page, type a name for your connector is that is meaningful to you.



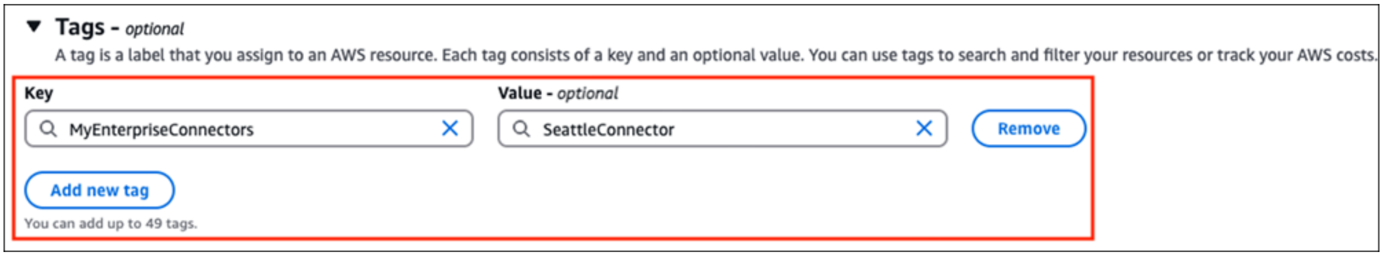
7. In the **Connector destination type** box, choose the type of device receiving calls from your Amazon Connect instance, typically a Session Border Controller. The following image shows the devices available in the dropdown list.



8. We recommend that you enable **Encryption** and **Logging** of the SIP and Media metric messages to easily debug integration issues. If you enable **Encryption**, import the wildcard root certificate into your SIP infrastructure. You can download it from here.

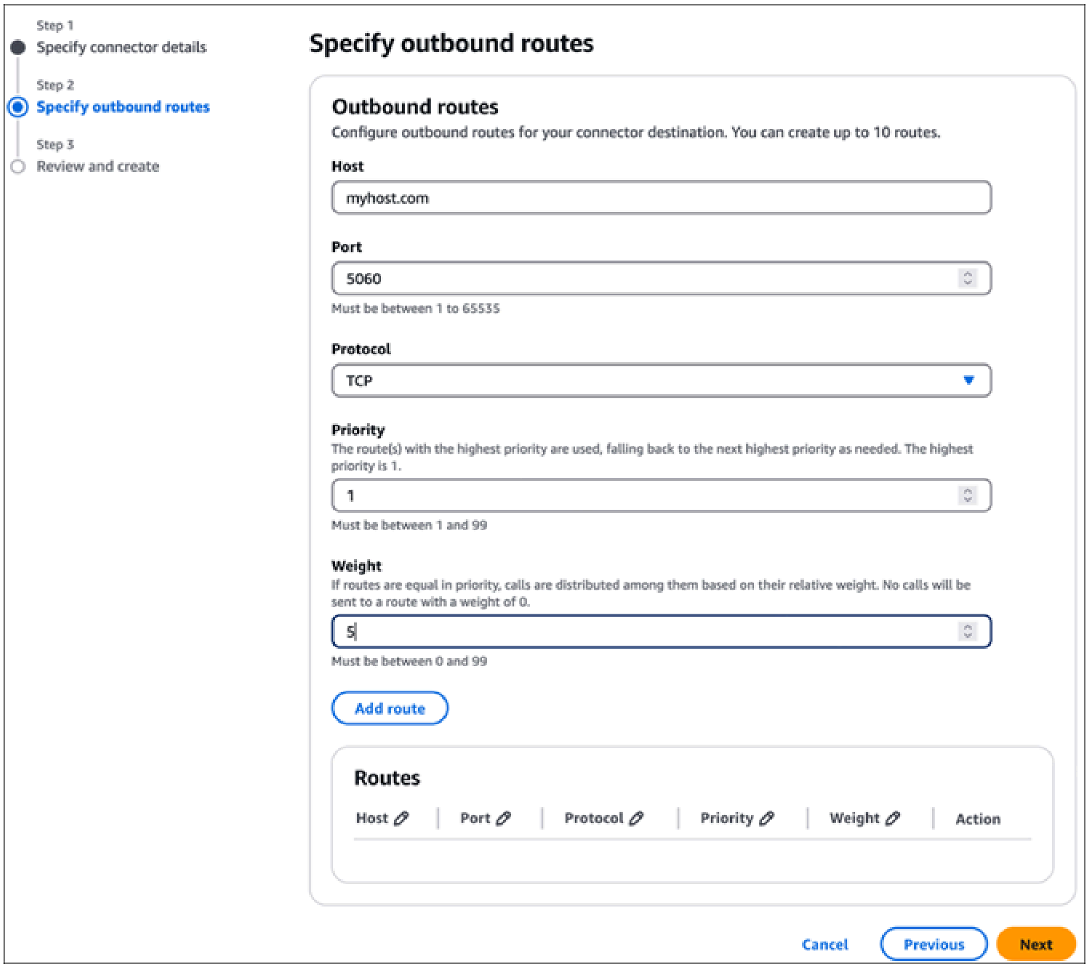
The following image shows the **Encryption** and **Logging** options.

9. Optionally, add [tags](#) to identify, organize, search for, filter, and control who can access this connector. For more information, see [Add tags to resources in Amazon Connect](#).



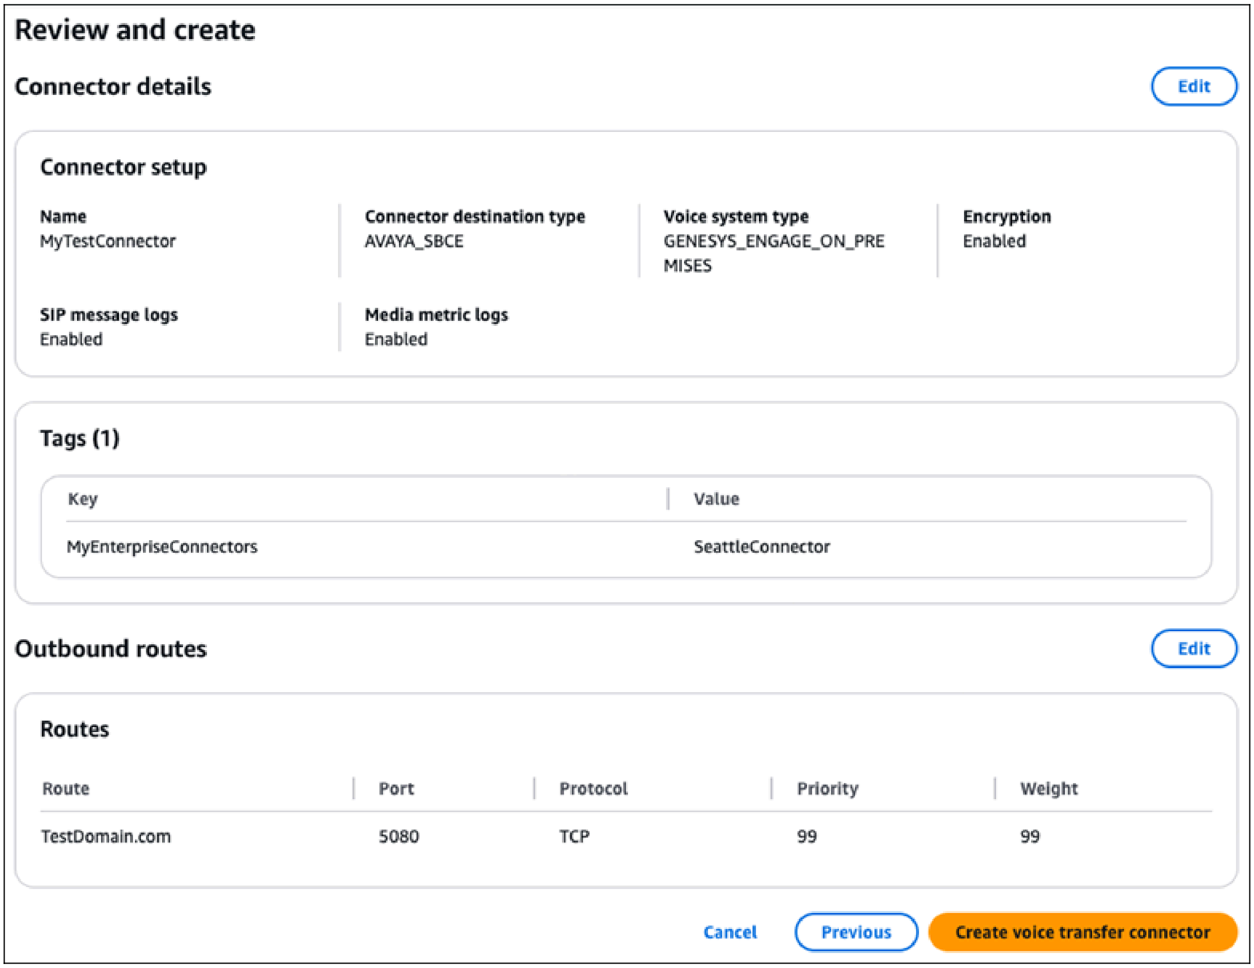
10. Choose **Next**.
11. In the **Outbound routes** section, configure the route between your Amazon Connect instance and your enterprise voice system.
12. Specify the **Host**, **Port**, **Protocol**, **Priority**, and **Weight** to create an outbound route. You can add up to 10 routes, and specify the **Priority** and **Weight** for each one.

    The following image shows an example of a completed **Outbound routes** section.

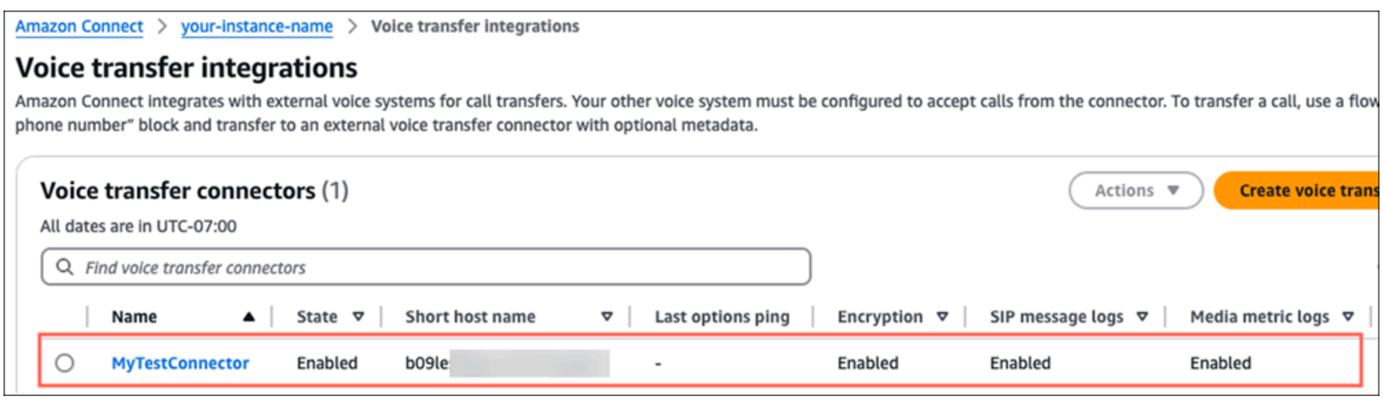


13. Choose **Next**.

14. On the **Review and create** page, review the configuration and make any edits as needed. Choose **Create voice transfer connector**, as shown in the following image.



15. After the voice transfer connector is saved you are returned to the **Voice transfer integrations** page. The following image shows the list of connectors with a typical success message.



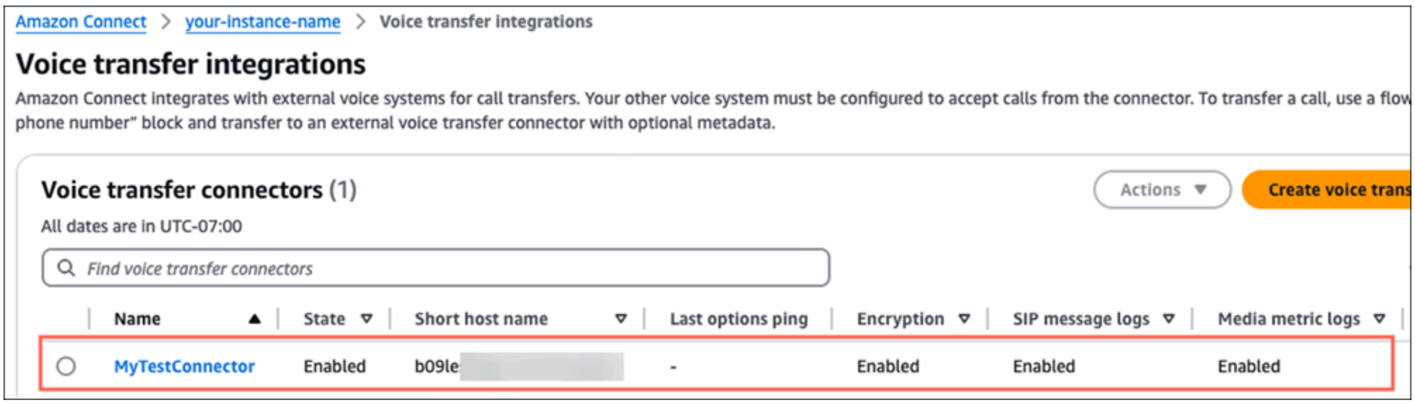
16. Continue to [Configure the external voice system](), the next step in setting up external voice transfer.

Configure the external voice system

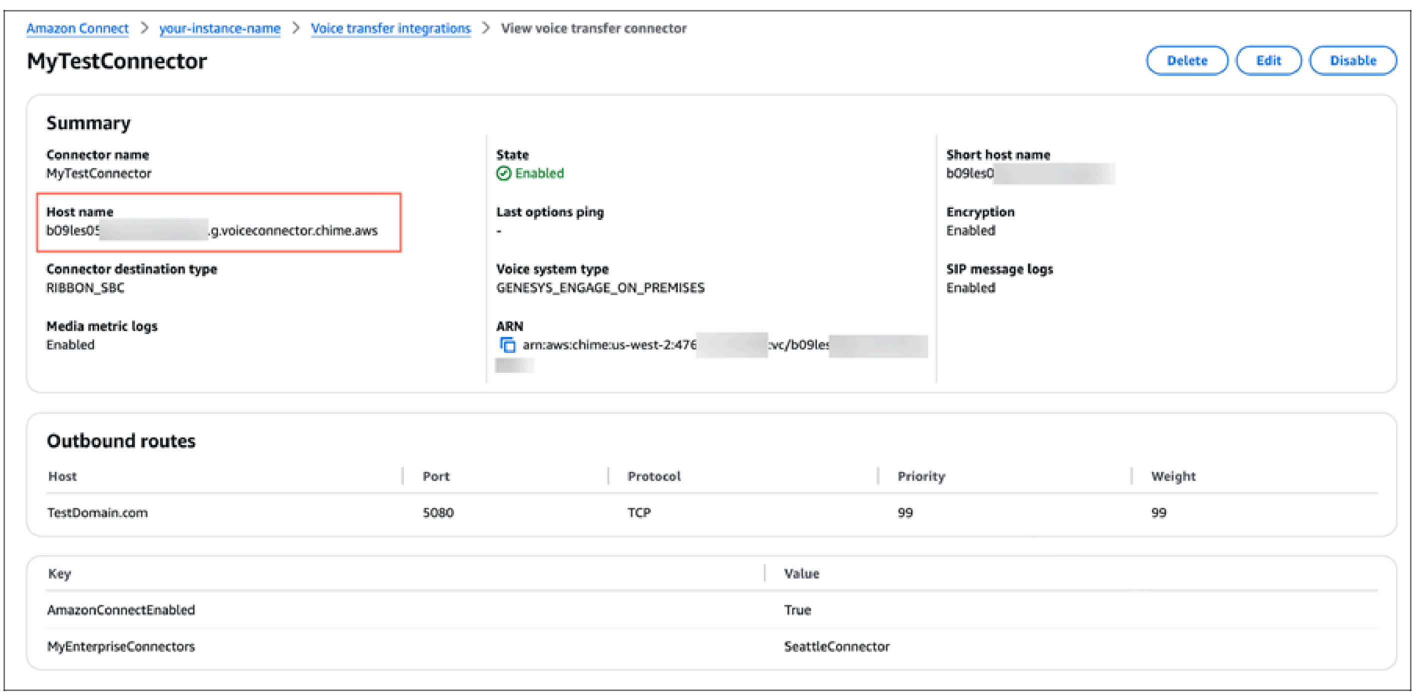
After you have created a voice transfer connector, you need to configure your on-premise voice system so the voice transfer connector can communicate with it. To configure your on-premise voice system you will need to provide the following information:

- Voice transfer connector hostname.

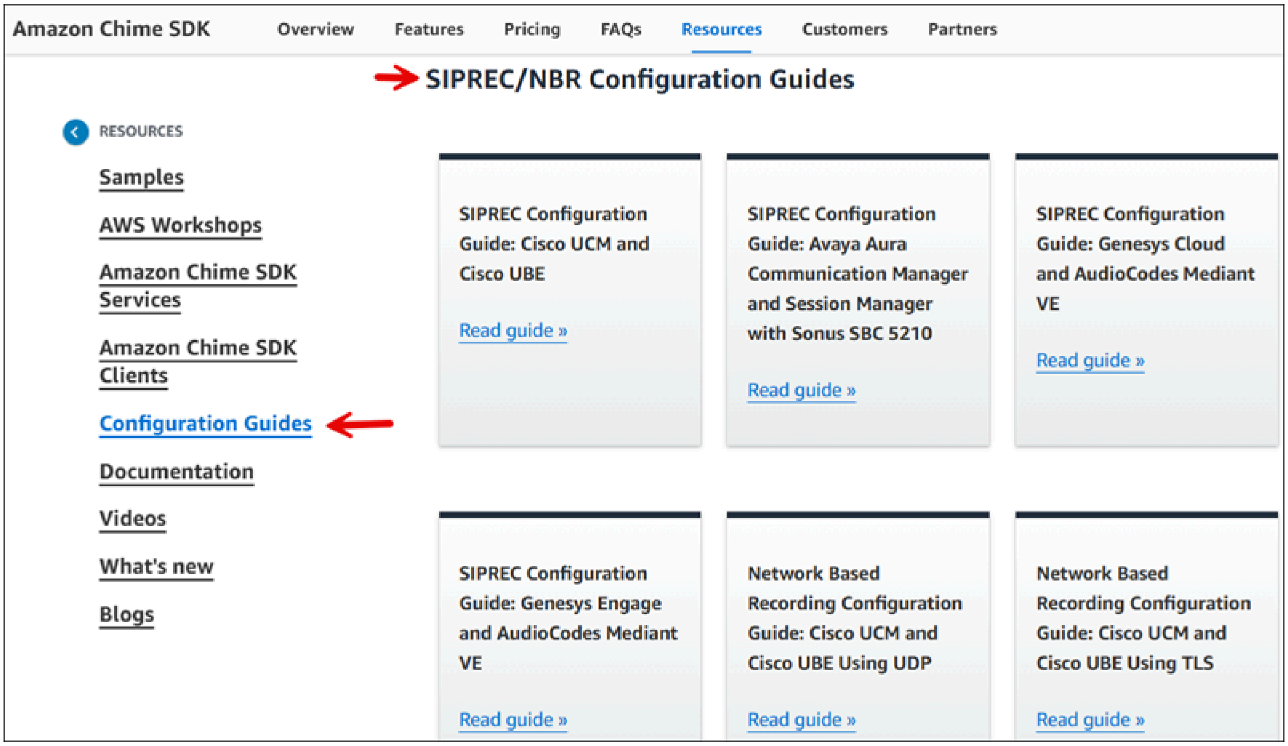
  To get the voice transfer connector host name, in the Amazon Connect console navigation pane, choose **External voice systems**, **Voice transfer integrations**. Select the one you want to use. The following image shows an example connector named **MyTestConnector**.



- On the connector details page, note the fully qualified host name. This is the name of the host that is transferring voice to your enterprise voice system. When you configured your enterprise voice system, you'll need to provide this host name.



- To configure your enterprise voice system, go to the [Amazon Chime SDK resources] page, and choose **Configuration Guides**. Scroll down the page to **SIPREC/NBR Configuration Guides**, as shown in the following image.



- After you configure your enterprise voice system, continue to the next step: Configure a flow to route calls from Amazon Connect to your external enterprise voice system .

Configure a flow to route calls from Amazon Connect to your external enterprise voice system

> **Note**
>
> Before you do this step, you need to claim a phone number in Amazon Connect or port an existing number. For testing purposes, we recommend that you claim a number.

Complete the following steps to create a flow that processes and routes a call from your Amazon Connect instance to your enterprise voice system. Then you'll associate the flow with a phone number.

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/.

2. On the navigation menu, choose **Routing**, **Flows**, **Create flow**, and then type a name for the flow.

3. Drag and drop the Transfer to phone number block to the flow designer.

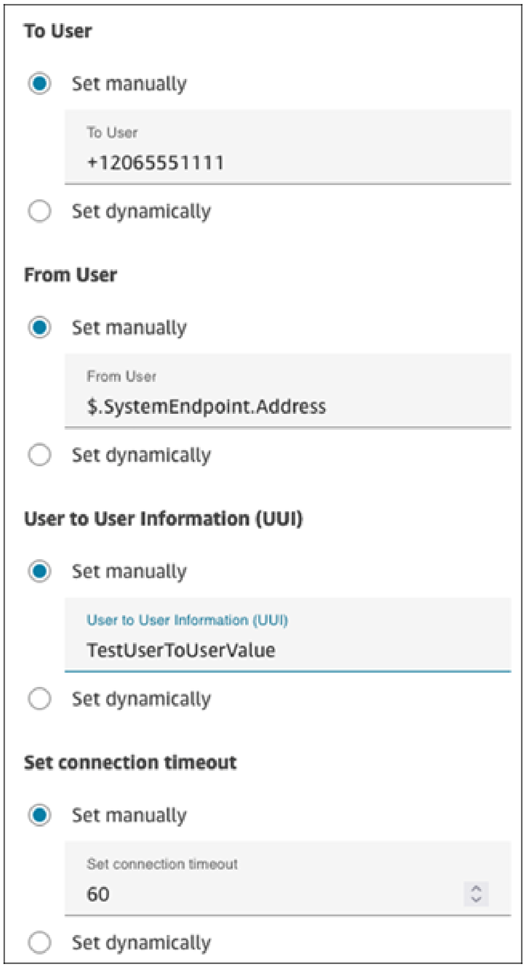
4. Double-click the title of the block to open its properties page. On the properties page, configure the following settings, and then choose **Save** to close the pane.

   Transfer To - External voice system

   - **Destination ARN**: Use the dropdown list to select the voice transfer integration connector you created earlier. This connector can be set statically or dynamically.

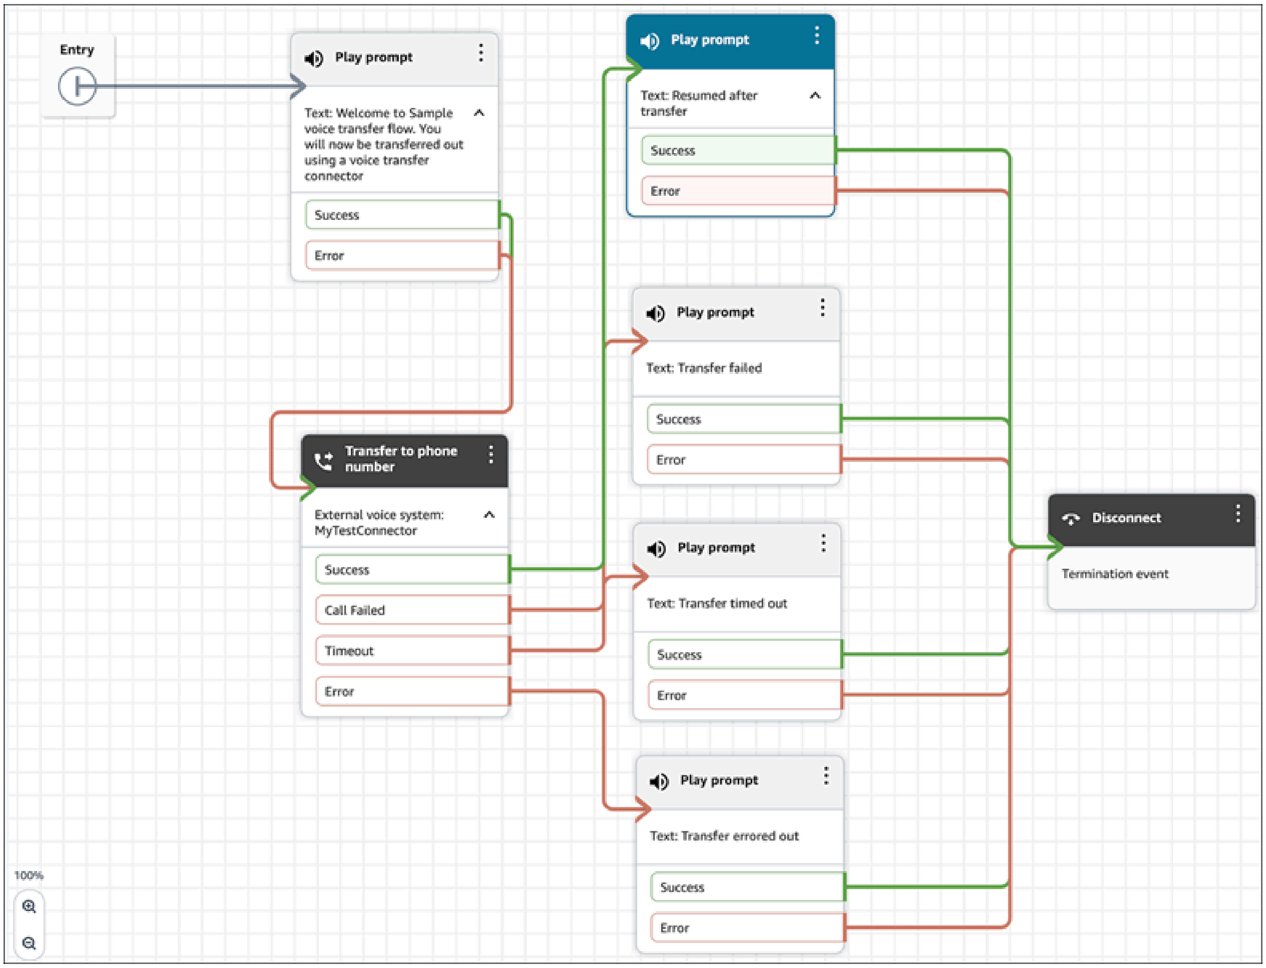
     
   - **Resume flow after disconnect**: Choose **Yes** to configure steps post call disconnect. Choose **No** to end the flow after call disconnect.

   - **To User**: The user who receives the call. This can be a phone number, extension, name, etc., that is communicated in the SIP INVITE as the user portion of Request-URI / To address. The user can be set statically or dynamically.

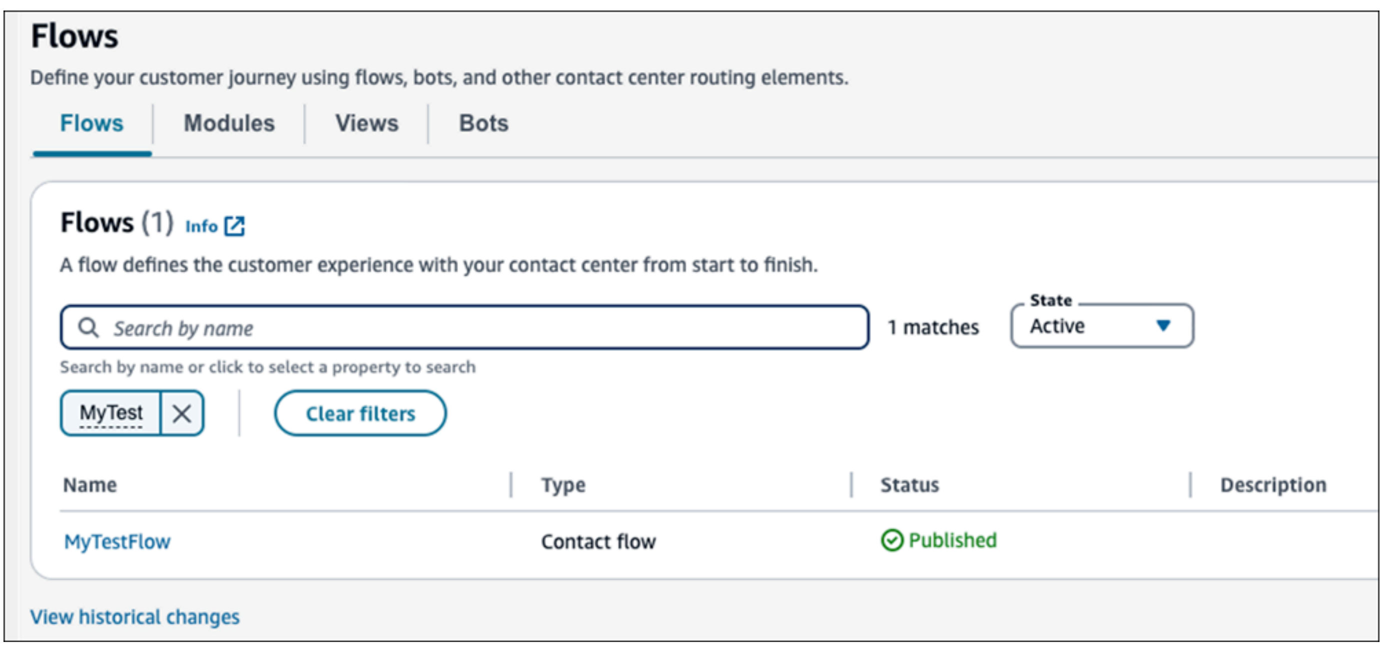


- **From User**: The user who makes the call. The user can be set statically or dynamically. For example, you can use the number the customer dialed to call your contact center by using the `$.SystemEndpoint.Address` attribute.
- **User to User Information (UUI)**: SIP UUI as specified in RFC 7433. Provides the ability to relay information between systems. For example, you can authenticate a caller in Amazon Connect and send their customer identifier by using UUI to your external voice system. This preserves contextual information. UUI is a string value that is encoded using hex. It can be set statically or dynamically.
- **Set connection timeout**: An integer between 1 and 600 (inclusive). It represents the number of seconds to wait for the answer before canceling the call.

5. Tailor the flow to your specific requirements and then publish it. The following image shows an example flow that includes a Transfer to phone number configured for external voice transfer.



6. After the flow is successfully published, it appears on the **Flows** page, as shown in the following image.



7. On the navigation menu, choose **Channels**, **Phone numbers**.
8. On the **Edit Phone number** page, do the following:

   a. (Optional) Edit the description for the phone number.

   b. For **Flow / IVR**, select the flow. Note that only published flows are included in this list.

   c. Choose **Save**.
9. Verify the flow steps and subsequent call transfer to the enterprise voice system by making a test call to the provided phone number.

Usage implication of voice transfer configurations

Post voice transfer, your inbound voice usage depends on how your external voice system transfer flow is configured.

For a call transfer, inbound connect voice usage does not occur in the following scenarios:

- In the Transfer to phone number block, the **Resume flow after disconnect** option is set to **No**.
- None of the following are true:
  - Live Media Streaming is active
  - IVR Recording is active
  - Amazon Connect Voice ID is active (that is, the Set Voice ID and Check Voice ID blocks are in use, which triggers internal KVS streaming)
  - One or more agents are on the call (that is, an Amazon Connect agent is on the call and uses a quick connect to transfer the call to the voice transfer connector)

Set up Amazon Connect Global Resiliency for external voice transfer

After you set up Amazon Connect Global Resiliency, make the following modifications to for external voice transfer:

1. Create another external voice transfer connector in your replica Amazon Connect instance.
2. Update your Amazon Connect flows to branch based on the AWS Region where the flow is running.

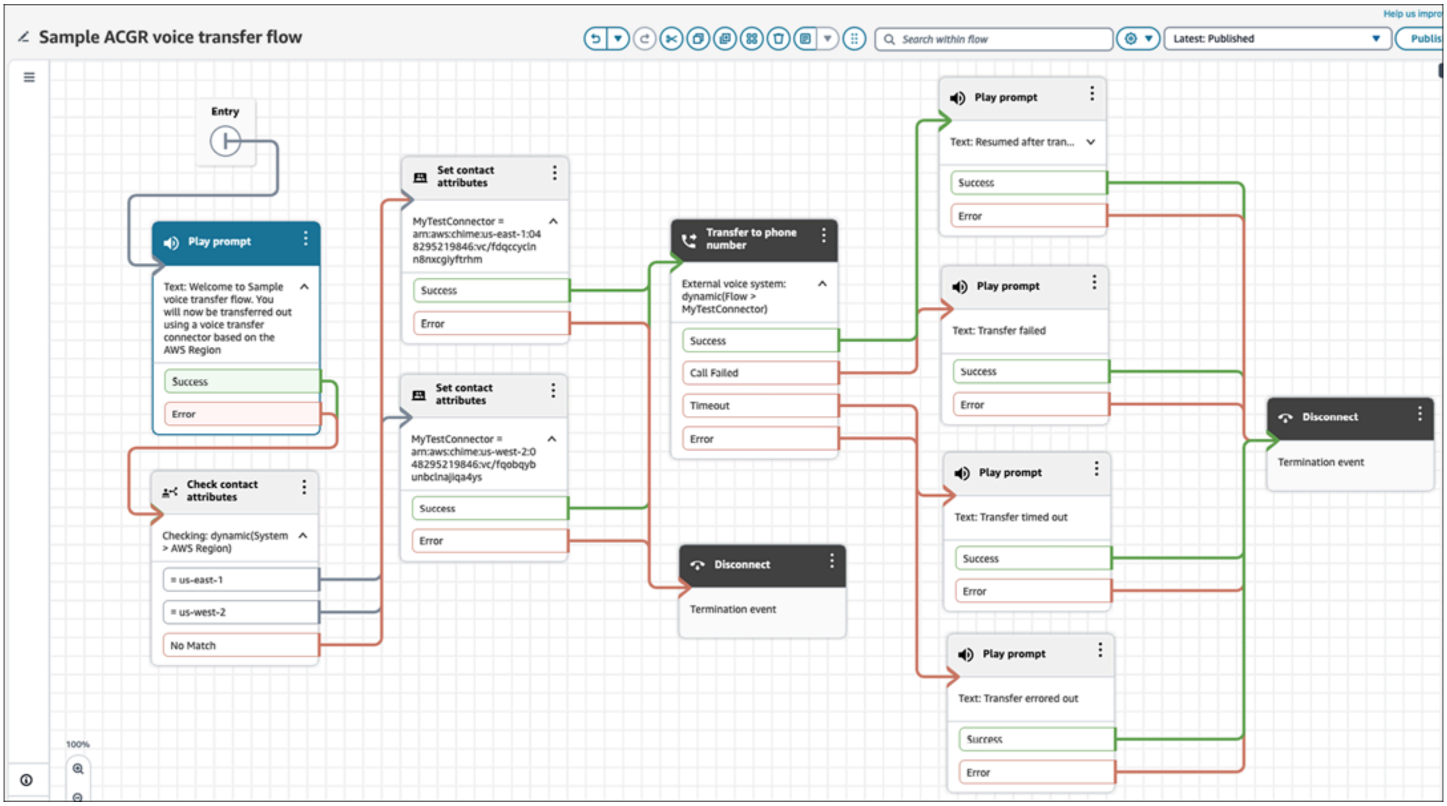
   a. Add a Set contact attributes to your flow.

- Set the external voice transfer connector ARN as a contact attribute.

b. Add a [Transfer to phone number](#) block to your flow.

- Dynamically set the destination ARN in the block to use the contact attribute that you specified in the **Set contact attributes** block.

The following image shows a sample flow configured with a **Check contact attributes** block, **Set contact attributes** block, and **Transfer to phone number** block.



Set up Amazon Connect Global Resiliency

Note

New user? Check out the Amazon Connect Global Resiliency Workshop. This online course guides you through the process of onboarding and testing phone number and agent failover using new APIs through the AWS CLI.

Global Resiliency is available only for Amazon Connect instances created in the following AWS Regions: US East (N. Virginia), US West (Oregon), Europe (Frankfurt), and Europe (London).

You can only create a replica in the US East (N. Virginia) Region if your source is US West (Oregon), or the other way around. Similarly, you can only create a replica in the Europe (Frankfurt) Region if your source is Europe (London), or the other way around.

To obtain access to this feature, contact your Amazon Connect Solutions Architect or Technical Account Manager.

Amazon Connect Global Resiliency enables you to provide customer service anywhere in the world with the highest reliability, performance, and efficiency. With its distributed telephony features, your contact center can meet international regulatory requirements.

Amazon Connect Global Resiliency provides a set of APIs that you use to:

- Provision a linked Amazon Connect instance in another AWS Region.
- Provision and manage phone numbers that are global and accessible in both Regions.
- Distribute telephony traffic and agents across Amazon Connect instances and Regions in 10% increments, or shift them all at once. This enables you to slowly shift inbound voice contacts and agents across Regions or shift them all at the same time.

  For example, you can distribute inbound voice contacts and agents 100% in US East (N. Virginia) and 0% in US West (Oregon), or 50% in each Region.
- Access reserved capacity across Regions.

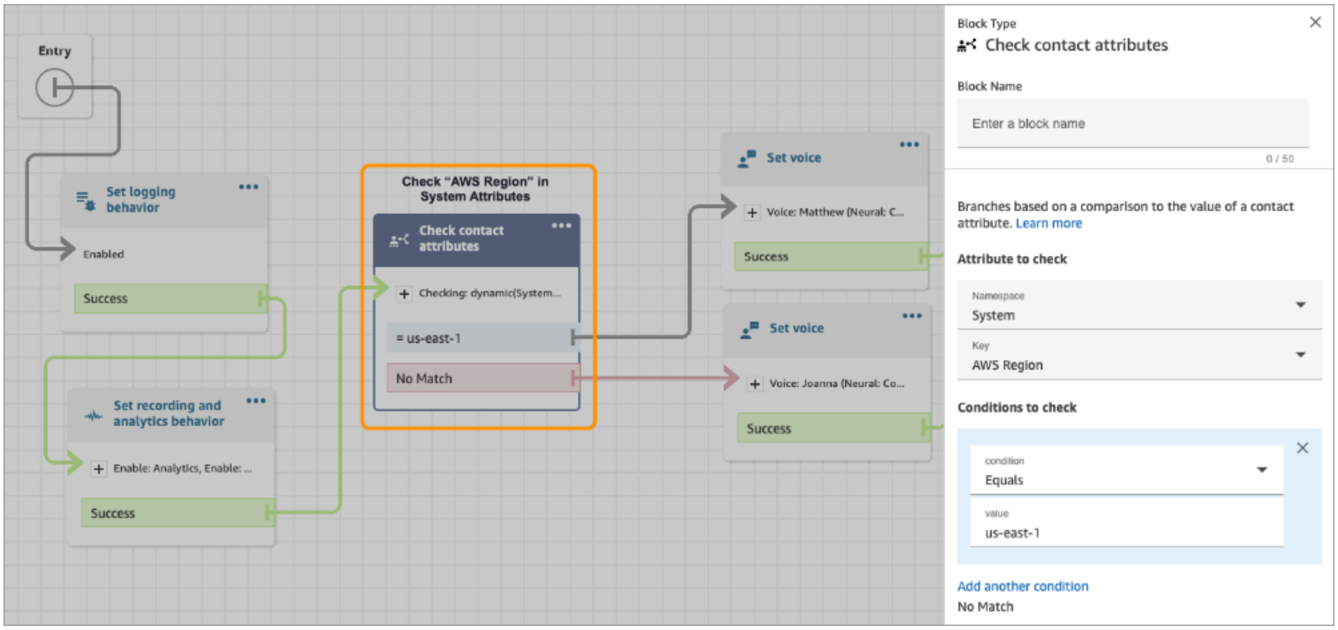
Contents

- Get started with Amazon Connect Global Resiliency
- Manage traffic distribution groups using Amazon Connect APIs
- Manage phone numbers across Regions using Amazon Connect APIs
- Manage chat in your Amazon Connect instance across Regions

Amazon Connect Global Resiliency requirements

If you have decided that Amazon Connect Global Resiliency is the appropriate deployment for you, ensure you adhere to the following pre-requisites before onboarding:

- Port all phone numbers you want to enable to be multi-region to Amazon Connect.
- You must have an existing production SAML 2.0-enabled Amazon Connect instance in a Region where Amazon Connect Global Resiliency is available. To confirm, see Global Resiliency availability by Region.
- It is recommended to onboard and test Amazon Connect Global Resiliency services in a test environment before onboarding production traffic.
- Request that ALL service quotas in the replica instance match the service quotas in the source instance: Create a service quota increase case in the AWS Management Console > Support.
- Ensure your Lambda functions across AWS Regions have the same name.
- Update your flows to replace any hardcoded Regions with a `$.AwsRegion` or `$['AwsRegion']` parameter.
- For Amazon Lex bots, you can do one of the following:
  - Use Amazon Lex Global Resiliency to replicate bots across AWS Regions and retain the bot ID.
  - Change your flows to branch based on the AWS Region where the flow is running. At flow runtime, these parameters are replaced with the Region where the flow is run, as shown in the following example.



- If you're using external voice transfer to an on-premise voice system, after you set up Amazon Connect Global Resiliency, there are additional steps. See Set up Amazon Connect Global Resiliency for external voice transfer.

Get started with Amazon Connect Global Resiliency

> **Important**
>
> Amazon Connect instances created before March 31, 2021, were assigned a domain with the following format:
>
> ```
> https://your-instance-alias.awsapps.com/connect/
> ```
>
> If your domain uses the older format, you won't be able to properly configure the Amazon Connect Global Resiliency feature. To enable this feature, you'll need to update your domain to the newer format:
>
> ```
> https://your-instance-alias.my.connect.aws/
> ```

> **Note**
>
> **New user?** Check out the Amazon Connect Global Resiliency Workshop. This online course guides you through the process of onboarding and testing phone number and agent failover using new APIs through the AWS CLI.
> Global Resiliency is available only for Amazon Connect instances created in the following AWS Regions: US East (N. Virginia), US West (Oregon), Europe (Frankfurt), and Europe (London).
> You can only create a replica in the US East (N. Virginia) Region if your source is US West (Oregon), or the other way around. Similarly, you can only create a replica in the Europe (Frankfurt) Region if your source is Europe (London), or the other way around.
> To obtain access to this feature, contact your Amazon Connect Solutions Architect or Technical Account Manager.

You get started with Amazon Connect Global Resiliency by creating a replica of your existing Amazon Connect instance in another AWS Region, and by creating a traffic distribution group.

A *traffic distribution group* is an Amazon Connect resource that enables you to link Amazon Connect instances that are in different AWS Regions. Phone numbers can be attached to the traffic distribution group. Traffic to these numbers can be distributed between the instances in the traffic distribution group.

How to set up Amazon Connect Global Resiliency

1. Create a replica of your existing Amazon Connect instance. Use the ReplicateInstance API.
2. Create a traffic distribution group.
    1. Use the CreateTrafficDistributionGroup API.
    2. Use DescribeTrafficDistributionGroup API to determine whether the traffic distribution group has been created successfully (`Status` must be `ACTIVE`).
3. Claim phone numbers to your traffic distribution group. After your traffic distribution group has been created successfully (`Status` is `ACTIVE`), you can claim phone numbers to it using the ClaimPhoneNumber API.

> **Note**
>
> The default traffic distribution for these phone numbers is set to 100% - 0%. That is, 100% of inbound telephony traffic will go to the source Amazon Connect instance that was used to create a replica.
> In addition, after phone numbers are claimed to an instance, you can assign them to multiple instances across AWS Regions. To do this, use the UpdatePhoneNumber API to assign the numbers to a traffic distribution group.

4. Update your traffic distribution. Use the UpdateTrafficDistribution API to distribute traffic across the linked instances in 10% increments.
5. If you're using Amazon Connect Global Resiliency and external voice transfer to transfer calls to an external system, see Set up Amazon Connect Global Resiliency for external voice transfer for additional steps.

Create a replica of your existing Amazon Connect instance

> **Note**
>
> **New user?** Check out the Amazon Connect Global Resiliency Workshop. This online course guides you through the process of onboarding and testing phone number and agent failover using new APIs through the AWS CLI.
> Global Resiliency is available only for Amazon Connect instances created in the following AWS Regions: US East (N. Virginia), US West (Oregon), Europe (Frankfurt), and Europe (London).
> You can only create a replica in the US East (N. Virginia) Region if your source is US West (Oregon), or the other way around. Similarly, you can only create a replica in the Europe (Frankfurt) Region if your source is Europe (London), or the other way around.
> To obtain access to this feature, contact your Amazon Connect Solutions Architect or Technical Account Manager.

You call the ReplicateInstance API to create a replica of your Amazon Connect instance in another AWS Region and to copy configuration information for Amazon Connect resources across AWS Regions.

Contents

Important things to know

- Before running ReplicateInstance:
  - Make sure you have the minimum required IAM permissions to create an instance. See Required permissions for using custom IAM policies to manage access to the Amazon Connect console.
  - Update your flows to replace any hardcoded Regions with a `$.AwsRegion` or `$['AwsRegion']` parameter. At flow runtime, these parameters are replaced with the Region where the flow is run.
  - Ensure your Lambda functions across AWS Regions have the same name.
  - For Amazon Lex bots, you can do one of the following:
    - Use Amazon Lex Global Resiliency to replicate bots across AWS Regions and retain the bot ID.
    - Change your flows to branch based on the AWS Region where the flow is running. At flow runtime, these parameters are replaced with the Region where the flow is run, as shown in the following example.

  - To allow AWS managed keys in the replica instance, using the AWS console, create a temporary Amazon Connect instance in the Region where you are planning to create the replica instance. This will create the default AWS managed keys for Amazon Connect.

- ReplicateInstance copies the Amazon Connect configuration across AWS Regions as part of the initial replication process. After this first step completes, any changes made to either the original or mirrored resources at a later time are continuously synchronized. This happens bidirectionally, from source to replica, and from the replica to the source.
- All phone numbers on the source instance that aren't already associated to number groups are automatically added to the default traffic distribution group. This step enables the phone numbers to be available in both source and replica Regions, and enables phone number-flow associations to be mirrored across AWS Regions.
- Emergency access to log into the replica instance is available only after the default routing profile and queue have been mirrored across the Regions.
- As the configuration is propagated across AWS Regions, you can view the progress in AWS CloudTrail logs. Or, in the Amazon Connect admin website you can navigate to **User management**, **View historical changes** to view an audit trail of changes to the users.
- A resource name conflict will occur if resources in the source instance and the replica instance have the same name but different resource IDs. This might happen, for example, if the resource in the replica instance was created manually outside of the replication process.

  In the case of resource name conflicts, ReplicateInstance doesn't synchronize the resource across Regions. Instead it throws a `ResourceConflictException` error. After you resolve the name conflict (for example, delete the resource in the replica instance), you can run `ReplicateInstance` again to synchronize the resource.

- After running `ReplicateInstance`, you must use the [AssociateTrafficDistributionGroupUser](#) API to associate agents to either the default traffic distribution group or a custom traffic distribution group.
- Running [ReplicateInstance](#) does not synchronize Lambda functions or Amazon Lex bots, or other third-party / integrations you may have.

Characteristics of the replica instance

- The replica Amazon Connect instance is created in the same AWS account as your existing Amazon Connect instance.
- [ReplicateInstance](#) creates a default traffic distribution group if one doesn't already exist. This default traffic distribution group has three types of traffic distribution:
  - Sign in
  - Agent
  - Telephony

  Use the [CreateTrafficDistributionGroup](#) API to create more traffic distribution groups, however, these additional traffic distribution groups are not default traffic distribution groups and thus only support agent and telephony distributions.
- The default traffic distribution group is the only traffic distribution group where you can change the `SignInConfig` distribution. See the `IsDefault` parameter in the [TrafficDistributionGroup](#) data type.
- You use `SignInConfig` to choose the backend sign-in servers to facilitate the agent signing in to their Amazon Connect instance. For example, if you call `UpdateTrafficDistribution` with a modified `SignInConfig` and a non-default `TrafficDistributionGroup`, an `InvalidRequestException` is returned.
- The replica instance has the same instance ID as the Amazon Connect instance it is replicated from.

What resources are mirrored in the replica instance

[ReplicateInstance](#) mirrors the following Amazon Connect resources across AWS Regions.

> **Important**
>
> The service quotas for these resources are automatically matched across AWS Regions *before* the resources are mirrored across Regions. To increase any other quota in the replica instance, submit a request.

- Agent proficiencies
- Flows
- Flow modules
- Users
- Routing profiles
- Queues
- Security profiles
- Hours of operation
- Quick connects
- Predefined attributes
- Prompts (not including those stored in S3)
- User hierarchies (groups and levels)
- Agent status
- Predefined attributes

ReplicateInstance also replicates the following associations across AWS Regions:

- Phone number to flow
- Queue to routing profile
- User to security profile, routing profile, and user hierarchy
- Routing profiles
- Queue to quick connects
- Queue to hours of operation
- Queue to flow

What to do after the replica instance is created

After your replica Amazon Connect instance is created, you need to configure it:

1. Ensure redundancy for front-end and back-end integrations (for example, SSO, Lambda, Lex) across Regions.
2. Make matching manual updates across the linked instances.
3. Use the AssociateTrafficDistributionGroupUser API to associate agents to the default traffic distribution group.

   Before you can associate agents to a traffic distribution group, they must be present on both the source and replica instances. You cannot associate users to a traffic distribution group when they are newly added to source instance and not yet in the replica.

When to contact AWS Support

Contact AWS Support for help with the following activities:

- To understand mirroring status beyond what's available in the CloudTrail logs and audit trail in the Amazon Connect admin website.

Why a ReplicateInstance call fails

A ReplicateInstance API call fails with an `InvalidRequestException` in the following cases:

1. The Region where you are creating the replica is the same Region as your existing instance.
2. The instance was already replicated as part of a different ReplicateInstance API call.
3. The instance does not have an alias.
4. The instance is not in `ACTIVE` status.
5. The instance does not have SAML enabled.
6. There is a resource name conflict.

How to find the source Region of your Amazon Connect instances

If you forget which Region is your source Region for your Amazon Connect instances, perform the following steps to find it:

1. Call the ListTrafficDistributionGroups API with your `InstanceId`.
2. For any traffic distribution group in the response list, the returned `InstanceARN` includes the source Region. For example in the following ARN, *`source-region`* would be the Region of your Amazon Connect instance.

   ```
   arn:aws:connect:source-region:account-id:traffic-distribution-group/
   traffic-distribution-group-id
   ```

Create traffic distribution groups for your Amazon Connect instance

You can create a traffic distribution group for your existing Amazon Connect instance by using the CreateTrafficDistributionGroup API.

A *traffic distribution group* is an Amazon Connect resource that enables you to link Amazon Connect instances that are in different AWS Regions. Phone numbers can be attached to the traffic distribution group. Traffic to these numbers can be distributed between the instances in the traffic distribution group.

Important things to know

- When creating a traffic distribution group, it must be created in the source AWS Region. A *source Region* is the Region where you set up your existing Amazon Connect instance.
- When associating phone numbers to a traffic distribution group:
  - You can associate only phone numbers that are claimed in the source Region.
  - The phone number must be in the same Region as where the traffic distribution group was created.
- You can claim numbers to a traffic distribution group, or get or update traffic distribution for a traffic distribution group only when its `Status` is `ACTIVE`. Use the DescribeTrafficDistributionGroup API to determine whether it has been created successfully (`Status` must be `ACTIVE`).
- When you create a replica Amazon Connect instance, a default traffic distribution group is created for it. The default traffic distribution group is the only traffic distribution group where you can change the `SignInConfig` distribution. See the `IsDefault` parameter in the TrafficDistributionGroup data type. You use `SignInConfig` to choose which backend sign-in servers are used to facilitate the agent signing in to their Amazon Connect instance. For example,

if you call `UpdateTrafficDistribution` with a modified `SignInConfig` and a non-default `TrafficDistributionGroup`, an `InvalidRequestException` is returned.

Traffic distribution group statuses

Following is a description of the traffic distribution group statuses:

- `CREATION_IN_PROGRESS`: Traffic distribution group creation is in progress.
- `ACTIVE`: Traffic distribution group has been created.
- `CREATION_FAILED`: Traffic distribution group creation failed.
- `PENDING_DELETION`: Traffic distribution group deletion is in progress.
- `DELETION_FAILED`: Traffic distribution group deletion failed.
- `UPDATE_IN_PROGRESS`: Traffic distribution group update is in progress.

Why a CreateTrafficDistributionGroup call fails

A [CreateTrafficDistributionGroup]() API call fails with an `InvalidRequestException` in the following cases:

- The [ReplicateInstance]() API was not called before creating a traffic distribution group for the linked instances.
- The [CreateTrafficDistributionGroup]() API was not called in the same Region where the [ReplicateInstance]() API was called. The Region where this API is called must match the Region of the instance that was used to create a replica.

Claim phone numbers to traffic distribution groups using Amazon Connect

> **Note**
>
> **New user?** Check out the [Amazon Connect Global Resiliency Workshop](). This online course guides you through the process of onboarding and testing phone number and agent failover using new APIs through the AWS CLI.

Global Resiliency is available only for Amazon Connect instances created in the following AWS Regions: US East (N. Virginia), US West (Oregon), Europe (Frankfurt), and Europe (London).
You can only create a replica in the US East (N. Virginia) Region if your source is US West (Oregon), or the other way around. Similarly, you can only create a replica in the Europe (Frankfurt) Region if your source is Europe (London), or the other way around.
To obtain access to this feature, contact your Amazon Connect Solutions Architect or Technical Account Manager.

After your traffic distribution group is created successfully (`Status` is `ACTIVE`), you can use SearchAvailablePhoneNumbers to search for available phone numbers and ClaimPhoneNumber to claim them.

Before you claim a phone number to your traffic distribution group, we recommend using the DescribeTrafficDistributionGroup API to verify the status of the traffic distribution group is `ACTIVE`. Assigning a phone number to a traffic distribution group that isn't `ACTIVE` results in `ResourceNotFoundException`.

You can claim a phone number to a traffic distribution group by providing the traffic distribution group ARN in the **TargetArn** parameter when calling the ClaimPhoneNumber API. You can also use the UpdatePhoneNumber API to assign a phone number previously claimed to an instance to a traffic distribution group.

Note

To update the **Description** field, you must use the Amazon Connect console.

Example workflow

Following is an example workflow to claim phone numbers and use them across multiple AWS Regions:

1. Create a replica of your instance:
   - Call the ReplicateInstance API.
2. Create a traffic distribution group that links these instances together:

- Call the [CreateTrafficDistributionGroup]() API.

3. Find available phone numbers that can be claimed to your traffic distribution group:

   - Call the SearchAvailablePhoneNumbers API in the Region where the traffic distribution group was created. Provide the traffic distribution group ARN for the `TargetArn` parameter.

4. In the Region where the traffic distribution group was created, call the ClaimPhoneNumber API:

   a. Provide your traffic distribution group ARN for the `TargetArn` parameter.
   b. Provide the E164 phone number value that was returned by the SearchAvailablePhoneNumbers API call in step 3.

   A `PhoneNumberId` and `PhoneNumberArn` are returned. You can use these values for follow-up operations.

5. Verify that the phone number status is `CLAIMED`:

   - Call the DescribePhoneNumber API.

     (DescribePhoneNumber can also be called in the other Region associated with the traffic distribution group. It will return the same phone number details.)

   The phone number can be used by follow-up operations only after its status is `CLAIMED`.

   For a description of possible statuses, see Phone number statuses defined.

6. Repeat steps 3-5 for all phone numbers you need to claim to your traffic distribution group.
7. Perform the following steps to associate flows to phone numbers. Do them in both Regions where the traffic distribution group operates.

   These steps ensure your telephony traffic will route correctly to your flows to support your traffic distribution configuration.

   a. In your existing Amazon Connect instance in the Region where the traffic distribution group was created, do the following steps:

      i. Call ListContactFlows API. Provide the `InstanceId` that corresponds to the instance that was replicated.

ii. A list of flow ARNs is returned. Use these flow ARNs to associate a flow to a phone number; call the AssociatePhoneNumberContactFlow API.

b. In the replicated Amazon Connect instance in the other AWS Region, do the following steps:

i. Call ListContactFlows API. Provide the `InstanceId` that corresponds to the instance that was replicated.

ii. A list of flow ARNs is returned. Use these flow ARNs to associate a flow to a phone number; call the AssociatePhoneNumberContactFlow API.

Why a ClaimPhoneNumber call fails

Your ClaimPhoneNumber API call will fail with a `ResourceNotFoundException` in the following cases:

- The specified traffic distribution group does not exist, the status of the traffic distribution group is not `ACTIVE`, or you do not have ownership of the traffic distribution group.
- The phone number is not available for claiming. In some cases, a phone number found from SearchAvailablePhoneNumbers may have been claimed by another customer.

ClaimPhoneNumber will fail with a `InvalidParameterException` error in the following case:

- The endpoint you are calling is not in the same Region where the traffic distribution group was created.

Phone number statuses defined

Following is a description of phone number statuses:

- `CLAIMED` means the previous ClaimPhoneNumber or UpdatePhoneNumber operation succeeded.
- `IN_PROGRESS` means a ClaimPhoneNumber, UpdatePhoneNumber operation is still in progress and has not yet completed. You can call DescribePhoneNumber at a later time to verify if the previous operation has completed.
- `FAILED` indicates that the previous ClaimPhoneNumber or UpdatePhoneNumber operation has failed. It includes a message indicating the failure reason.

A common reason for a failure is that the `TargetArn` value you are claiming or updating a phone number to has reached its limit of total claimed numbers.

If you received a `FAILED` status from a `ClaimPhoneNumber` API call, you have one day to retry claiming the phone number before the number is released back to the inventory for other customers to claim.

Assign claimed phone numbers to traffic distribution groups in Amazon Connect

- You created a new traffic distribution group and it's status is `ACTIVE`. We recommend using the DescribeTrafficDistributionGroup API to verify the status.
- You have already claimed phone numbers to instances or other traffic distribution groups.

Now you can assign those claimed phone numbers to your new traffic distribution group by using the UpdatePhoneNumber API. Provide the traffic distribution group ARN in the `TargetArn` parameter.

> **Note**
>
> To update the **Description** field, you must use the Amazon Connect console.

Example workflow

Following is an example workflow to assign claimed phone numbers to your traffic distribution group:

1. Call the UpdatePhoneNumber API to assign the phone number to a new `TargetArn`.

   The `TargetArn` can be for another Amazon Connect instance or for a traffic distribution group created in the same Region where the phone number was initially claimed.
2. Perform the following steps to associate flows to phone numbers. Do them in both Regions where the traffic distribution group operates.

   These steps ensure your telephony traffic will route correctly to your flows to support your traffic distribution configuration.

a. In your existing Amazon Connect instance in the Region where the traffic distribution group was created, do the following steps:

   i. Call the ListContactFlows API. Provide the `InstanceId` that corresponds to the instance that was replicated.

   ii. A list of flow ARNs is returned. Use these flow ARNs to associate a flow to a phone number; call the AssociatePhoneNumberContactFlow API.

b. In the replicated Amazon Connect instance in the other Region, do the following steps:

   i. Call the ListContactFlows API. Provide the `InstanceId` that corresponds to the instance that was replicated.

   ii. A list of flow ARNs is returned. Use these flow ARNs to associate a flow to a phone number; call the AssociatePhoneNumberContactFlow API.

Why an AssociatePhoneNumberContactFlow call fails

If the number is claimed to a traffic distribution group, and you are calling AssociatePhoneNumberContactFlow using an instance in the AWS Region where the traffic distribution group was created, you can use either a full phone number ARN or UUID value for the `PhoneNumberId` URI request parameter.

However, if the number is claimed to a traffic distribution group and you are calling this API using an instance in the replica AWS Region associated with the traffic distribution group, you must provide a full phone number ARN. If a UUID is provided in this scenario, you will receive a `ResourceNotFoundException`.

Why an UpdatePhoneNumber call fails

Your UpdatePhoneNumber API call will fail with a `ResourceNotFoundException` in the following case:

- The specified traffic distribution group does not exist, the status of the traffic distribution group is not `ACTIVE`, or you do not have ownership of the traffic distribution group.

UpdatePhoneNumber will fail with a `InvalidParameterException` error in the following case:

- The endpoint you are calling is not in the same Region where the traffic distribution group was created.

Phone number statuses defined

Following is a description of phone number statuses:

- `CLAIMED` means the previous [ClaimPhoneNumber](#) or [UpdatePhoneNumber](#) operation succeeded.
- `IN_PROGRESS` means a ClaimPhoneNumber, UpdatePhoneNumber operation is still in progress and has not yet completed. You can call DescribePhoneNumber at a later time to verify if the previous operation has completed.
- `FAILED` indicates that the previous ClaimPhoneNumber or UpdatePhoneNumber operation has failed. It includes a message indicating the failure reason. A common reason for a failure is that the `TargetArn` value you are claiming or updating a phone number to has reached its limit of total claimed numbers.

Update telephony traffic distribution across Amazon Connect instances and AWS Regions

You use the UpdateTrafficDistribution API to distribute telephony traffic and shift agents across Regions.

> **Note**
>
> When you shift telephony traffic, also shift agents and/or agent sign-ins to ensure they can handle the calls in the other Region. If you don't shift the agents, voice calls will go to the shifted Region but there won't be any agents available to receive the calls.

After you have claimed phone numbers to your traffic distribution group, you can use the UpdateTrafficDistribution API to distribute inbound voice contacts across linked instances in a given traffic distribution group in 10% increments.

If the following requirements are not met, your UpdateTrafficDistribution API call will fail with an `InvalidRequestException`:

- You must provide distribution for telephony traffic configuration.

- You must specify the traffic distribution for both linked instances and the total distribution must add up to 100%.
- You must specify traffic distribution in 10% increments.
- The instance ARNs specified in the telephony configuration must match the ARNs of the linked instances.

When you call `UpdateTrafficDistribution` from the source AWS Region you can use either the traffic distribution group ID or Amazon Resource Name (ARN). When you call `UpdateTrafficDistribution` in the replica Region, you must use the traffic distribution group ARN.

Set up your agent's experience with Amazon Connect Global Resiliency

Amazon Connect Global Resiliency enables you to provide a global experience for agents with global sign-in, agent distribution API, and Agent Workspace enhancements. With this set of features, you can:

- Enable your agents to sign in once at the beginning of their day and process contacts from their current active Region without needing to know which Region is active at any time.
- Add agents to your traffic distribution group and distribute agents across AWS Regions.
- Redirect new inbound voice contacts to the agent workspace for the current active Region with a simple page refresh.

Contents

Integrate your identity provider (IdP) with an Amazon Connect Global Resiliency SAML sign in endpoint

To enable your agents to sign in once and be logged into both AWS Regions to process contacts from the current active Region, you need to configure IAM settings to use the global sign in SAML endpoint.

Before you begin

You must enable SAML for your Amazon Connect instance to use Amazon Connect Global Resiliency. For information about getting started with IAM federation, see Enabling SAML 2.0 federated users to access the AWS Management Console.

Important things to know

- To perform the steps in this topic, you'll need your instance ID. For instructions about how to find it, see Find your Amazon Connect instance ID or ARN.
- You will also need to know the source Region of your Amazon Connect instances. For instructions about how to find it, see How to find the source Region of your Amazon Connect instances.
- If you are embedding your Connect application within an iframe, you must ensure that your domain is present in the list of Approved Origins in both your source and replica instance in order for global sign-in to work.

  To configure Approved Origins at the instance level, follow the steps in Use an allowlist for integrated applications in Amazon Connect.
- Agents must be created already in *both* your source and replica Amazon Connect instances and have the same username as the role session name from your identity provider (IdP). Otherwise, you will receive a `UserNotOnboardedException` exception and risk losing agent redundancy capabilities between your instances.
- You must associate agents to a traffic distribution group before agents attempt to sign in. Otherwise agent sign-in will fail with a `ResourceNotFoundException`. For information about how to setup your traffic distribution groups and associate agents to them, see Associate agents to Amazon Connect instances across multiple AWS Regions.
- When your agents federate into Amazon Connect with the new SAML sign-in URL, Amazon Connect Global Resiliency always attempts to log the agent into both your source and replica Regions / instances, no matter how `SignInConfig` is configured in your traffic distribution group. You can verify this by checking CloudTrail logs.

- The `SignInConfig` distribution in your default traffic distribution group only determines which AWS Region is used to facilitate sign-in. Regardless of how your `SignInConfig` distribution is configured, Amazon Connect always attempts to sign in agents to both Regions of your Amazon Connect instance.
- After replicating an Amazon Connect instance, only one SAML sign-in endpoint is generated for your instances. This endpoint always contains the source AWS Region in the URL.
- You don't need to configure a relay state when using the personalized SAML sign-in URL with Amazon Connect Global Resiliency.

How to integrate your identity provider

1. When you create a replica of your Amazon Connect instance using the ReplicateInstance API, a personalized SAML sign-in URL is generated for your Amazon Connect instances. The URL is generated in the following format:

   `https://instance-id.source-region.sign-in.connect.aws/saml`

   a. *`instance-id`* is the instance ID for either instance in your instance group. The instance ID is identical in the source and replica Regions.

   b. *`source-region`* corresponds to the source AWS Region in which the ReplicateInstance API was called.

2. Add the following trust policy to your IAM Federation role. Use the URL for the global sign-in SAML endpoint as shown in the following example.

```
{
   "Version":"2012-10-17",
   "Statement":[
      {
         "Effect":"Allow",
         "Principal":{
            "Federated":[
               "saml-provider-arn"
            ]
         },
         "Action":"sts:AssumeRoleWithSAML",
         "Condition":{
            "StringLike":{
               "SAML:aud":[
                  "https://instance-id.source-region.sign-in.connect.aws/saml*"
```

```
                ]
            }
        }
    }
  ]
}
```

> **Note**
>
> `saml-provider-arn` is the identity provider resource created in IAM.

3. Grant access to `connect:GetFederationToken` for your `InstanceId` on your IAM Federation role. For example:

```
{
"Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "GetFederationTokenAccess",
            "Effect": "Allow",
            "Action": "connect:GetFederationToken",
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "connect:InstanceId": "your-instance-id"
                }
            }
        }
    ]
}
```

4. Add an attribute mapping to your identity provider application using the following attribute and value strings.

Attribute	Value
https://aws.amazon.com/SAML/Attributes/Role	*saml-role-arn* ,*identity-provider-arn*

5. Configure the Assertion Consumer Service (ACS) URL of your identity provider to point to your personalized SAML sign-in URL. Use the following example for the ACS URL:

```
https://instance-id.source-region.sign-in.connect.aws/saml?&instanceId=instance-id&accountId=your AWS account ID&role=saml-federation-role&idp=your SAML IDP&destination=optional-destination
```

6. Set following fields in the URL parameters:
   - `instanceId`: The identifier of your Amazon Connect instance. For instructions about how to find your instance ID, see [Find your Amazon Connect instance ID or ARN](#).
   - `accountId`: The AWS account ID where the Amazon Connect instances are located.
   - `role`: Set to the name or Amazon Resource Name (ARN) of the SAML role used for Amazon Connect federation.
   - `idp`: Set to the name or Amazon Resource Name (ARN) of the SAML identity provider in IAM.
   - `destination`: Set to the optional path where agents will land in the instance after signing in (for example: `/agent-app-v2`).

Associate agents to Amazon Connect instances across multiple AWS Regions

To allow your agents to sign-in to both AWS Regions and process contacts from either Region, you must first assign them to a traffic distribution group.

1. If you have not yet set up a traffic distribution group, do so now. For instructions, see [Create traffic distribution groups for your Amazon Connect instance](#).
2. After your traffic distribution group is created successfully (`Status` is `ACTIVE`), you can assign agents to it. Always associate users to a traffic distribution group in the source Region.

   Assigning an agent to a traffic distribution group without an `ACTIVE` status results in `ResourceNotFoundException`. Use the [DescribeTrafficDistributionGroup](#) API to determine whether it has been created successfully (`Status` must be `ACTIVE`).
3. You can assign an agent to a traffic distribution group by calling the [AssociateTrafficDistributionGroupUser](#) API.

Examples

The following `associate-traffic-distribution-group-user` example command shows how agents can be associated to and used across multiple AWS Regions.

```
aws connect associate-traffic-distribution-group-user
  --traffic-distribution-group-id UUID
  --user-id UUID
  --instance-id
```

The following [AssociateTrafficDistributionGroupUser]() example associates an agent with a traffic distribution group.

```
PUT /traffic-distribution-group/trafficDistributionGroupId/user HTTP/1.1
Content-type: application/json

{
   "UserId": "string"
}
```

The following `disassociate-traffic-distribution-group-user` example command disassociates an agent from a traffic distribution group.

```
aws connect disassociate-traffic-distribution-group-user
 --instance-id your instance ID
 --traffic-distribution-group-id UUID
  --user-id UUID
```

The following [DisassociateTrafficDistributionGroupUser]() example disassociates an agent from a traffic distribution group.

```
DELETE /traffic-distribution-group/trafficDistributionGroupId/user/UserId HTTP/1.1
```

Why an AssociateTrafficDistributionGroupUser call fails

An [AssociateTrafficDistributionGroupUser]() API call fails with an `ResourceNotFoundException` in the following cases:

1. The specified traffic distribution group does not exist.
2. The status of the traffic distribution group is not `ACTIVE`.
3. The `user-id` *`UUID`* is not a user from the source Amazon Connect instance.

Update agent distribution in your Amazon Connect agent workspace across AWS Regions

Just as you can use the `UpdateTrafficDistribution` API to distribute telephony traffic across Regions, you can also use it to distribute agents across AWS Regions, either fully or gradually as part of regular operational readiness testing. For example, you might keep 40% of agents in one AWS Region to complete active contacts and shift the remaining agents to the replica Region.

> **Note**
>
> When you shift telephony traffic, also shift agents and/or agent sign-ins to ensure they can handle the calls in the other Region. If you don't shift the agents, voice calls will go to the shifted Region but there won't be any agents available to receive the calls.

After you have added agents to your traffic distribution group, use the UpdateTrafficDistribution API to distribute agents across linked instances in a given traffic distribution group in 10% increments. Your agents will be able to complete active voice contacts before shifting Regions.

> **Note**
>
> If an agent gets an error when they try to end a contact before shifting Regions, they need to refresh the agent workspace page. For more information, see Set up Amazon Connect Agent Workspace to support agents shifting across AWS Regions.

Contents

Requirements

If the following requirements are not met, your UpdateTrafficDistribution API call will fail with an `InvalidRequestException`:

1. The specified traffic distribution group must exist.

2. The status of the traffic distribution group must be `ACTIVE`.
3. If you are changing the `SignInConfig` distribution, you can only do so for the default traffic distribution group. The default traffic distribution group is created when the replica Amazon Connect instance is created. See the `IsDefault` parameter in the [TrafficDistributionGroup](#) data type.

When you call `UpdateTrafficDistribution` from the source AWS Region you can use either the traffic distribution group ID or Amazon Resource Name (ARN). When you call `UpdateTrafficDistribution` in the replica Region, you must use the traffic distribution group ARN.

Enable both AWS Regions during regular operations

The `UpdateTrafficDistribution` API includes a distribution called `SignInConfig`. It allows you to choose which backend sign-in servers are used to facilitate the agent signing in to their instance group. Regardless of the `SignInConfig` set in your traffic distribution group, agents will be signed in to both instances in the traffic distribution group.

For the best experience, we recommend having both AWS Regions enabled during regular operations. To achieve this pass `true` to both `SignInConfig` distributions. If you need to shift your entire telephony traffic and agents across to one AWS Region, we recommend changing the `SignInConfig` to `false` for the Region you are shifting traffic away from.

For example, the following call results in agents having a 50% chance of using the us-west-2 sign-in server and a 50% of using the us-east-1 sign-in server for a given login call from the identity provider.

```
aws connect update-traffic-distribution \
--id traffic distribution group ID or ARN \
--cli-input-json \
'{
   "SignInConfig":{
      "Distributions":[
         {
            "Region":"us-west-2",
            "Enabled":true
         },
         {
            "Region":"us-east-1",
```

```
            "Enabled":true
         }
      ]
   }
}'
```

Conversely, the following sign-in distribution routes 100% of traffic on the sign-in endpoint to use the us-east-1 sign-in server.

```
aws connect update-traffic-distribution \
--id traffic distribution group ID or ARN \
--cli-input-json \
'{
   "SignInConfig":{
      "Distributions":[
         {
            "Region":"us-west-2",
            "Enabled":false
         },
         {
            "Region":"us-east-1",
            "Enabled":true
         }
      ]
   }
}'
```

This distribution controls only which Region of the sign-in server is used to facilitate logging in the agent to both instances in their instance group. It doesn't affect the distribution of agents controlled by the `AgentConfig` part of the `UpdateTrafficDistribution` API.

Important

If the sign-in endpoint is not responsive during agent sign-in and your `SignInConfig` distribution is split across Regions, then you can resolve the errors by changing distribution to a single AWS Region. Or, if your `SignInConfig` is weighted on one Region and it isn't responsive, you can try shifting the `SignInConfig` to the disabled Region. Regardless of how your `SignInConfig` is configured, agents will still benefit from having a session active in both the source and replica Regions because they will attempt to sign into their Amazon Connect instance in both Regions.

How to shift all telephony traffic and agents across AWS Regions

To shift all new inbound voice contacts, agent sign-in distribution, and agent distribution from us-west-2 to us-east-1, use the following code snippet.

```
aws connect update-traffic-distribution \
--id traffic distribution group ID or ARN \
--cli-input-json \
'{
   "SignInConfig":{
      "Distributions":[
         {
            "Region":"us-west-2",
            "Enabled":false
         },
         {
            "Region":"us-east-1",
            "Enabled":true
         }
      ]
   },
   "AgentConfig":{
      "Distributions":[
         {
            "Region":"us-west-2",
            "Percentage":0
         },
         {
            "Region":"us-east-1",
            "Percentage":100
         }
      ]
   },
   "TelephonyConfig":{
      "Distributions":[
         {
            "Region":"us-west-2",
            "Percentage":0
         },
         {
            "Region":"us-east-1",
            "Percentage":100
         }
      ]
```

```
    }
}
'
```

When you call `UpdateTrafficDistribution` from the source AWS Region you can use either the traffic distribution group ID or Amazon Resource Name (ARN). When you call `UpdateTrafficDistribution` in the replica Region, you must use the traffic distribution group ARN.

Set up Amazon Connect Agent Workspace to support agents shifting across AWS Regions

Perform the following steps to enable Amazon Connect Agent Workspace to embed the Contact Control Panel from the replica AWS Region to the source Region, and shift between them as agent's active Region changes.

If you have not yet created a replica of your source Amazon Connect instance or set up a traffic distribution group, see Get started with Amazon Connect Global Resiliency.

1. Go to the AWS Amazon Connect console to retrieve the **Access URL** for your source instance. Make a note of the URL.
2. In the replica Region, AWS Amazon Connect console to retrieve the **Access URL** for your replica instance. Make a note of the URL.
3. In the same window for your replica Amazon Connect instance, in the left pane choose **Approved origins**.
4. Add domain for source instance **Access URL**, which you noted in step 1.

   > **Note**
   >
   > Do not include a trailing **/** in the access URL.

5. Repeat the above steps on your source instance: Go to **Approved origins**, add the access URL for the replica instance.

> **Note**
>
> Agents must set their status to **Available** after they are shifted across Regions.

Tips for avoiding issues when shifting agents in your Amazon Connect instance across Regions

- Whenever you update the traffic distribution for agents be sure to also update the traffic distribution for inbound voice contacts. Otherwise, you might end up in a situation where one Region is heavy on agents while the other is heavy on telephony traffic.
- Before associating users to a traffic distribution group, make sure the same username exists in both the source and replica Amazon Connect instances. Otherwise, when you associate a user to a traffic distribution group but the user with the username does not exist in the replica Region, you will get an `InvalidRequestException` error.
- You must call the AssociateTrafficDistributionGroupUser API to associate agents to a traffic distribution group in the source Region. If you attempt to do this while in the replica Region, you will get a `ResourceNotFoundException` error.

Manage traffic distribution groups using Amazon Connect APIs

The topics in this section describe how to manage traffic distribution groups by using Amazon Connect APIs.

Contents

List traffic distribution groups

Use the ListTrafficDistributionGroups API to list all traffic distribution groups.

You may want to list traffic distribution groups as a way of determining whether a particular Amazon Connect instance is part of any traffic distribution groups.

Delete traffic distribution groups in Amazon Connect

Use the DeleteTrafficDistributionGroup API to delete a traffic distribution group that is no longer needed.

> **Note**
>
> You cannot delete a traffic distribution group if phone numbers are claimed to it. You must first release phone numbers from the traffic distribution group by using the ReleasePhoneNumber API. After that, you can delete the traffic distribution group. You cannot release numbers from a traffic distribution group by using the Amazon Connect console.

Your DeleteTrafficDistributionGroup API call will fail with an `ResourceInUseException` if phone numbers are still claimed to the traffic distribution group.

Manage phone numbers across Regions using Amazon Connect APIs

The topics in this section describe how to manage phone numbers across AWS Regions by using Amazon Connect APIs.

Contents

Claim phone numbers to Amazon Connect instances across multiple AWS Regions

> **Note**
>
> **New user?** Check out the Amazon Connect Global Resiliency Workshop. This online course guides you through the process of onboarding and testing phone number and agent failover using new APIs through the AWS CLI. Global Resiliency is available only for Amazon Connect instances created in the following AWS Regions: US East (N. Virginia), US West (Oregon), Europe (Frankfurt), and Europe (London).

You can only create a replica in the US East (N. Virginia) Region if your source is US West (Oregon), or the other way around. Similarly, you can only create a replica in the Europe (Frankfurt) Region if your source is Europe (London), or the other way around.
To obtain access to this feature, contact your Amazon Connect Solutions Architect or Technical Account Manager.

To place or receive calls to a phone number across instances in multiple AWS Regions, you need to claim a phone number to a traffic distribution group.

To claim a phone number to a traffic distribution group

1. Create a traffic distribution group by using the CreateTrafficDistributionGroup API.
2. Describe your traffic distribution group by using the DescribeTrafficDistributionGroup API to determine whether it has been created successfully (`Status` must be `ACTIVE`).
3. After your traffic distribution group has been created successfully (`Status` is `ACTIVE`), you can claim phone numbers to it by using the ClaimPhoneNumber API.

Move a claimed phone number to multiple Amazon Connect instances across AWS Regions

Note

New user? Check out the Amazon Connect Global Resiliency Workshop. This online course guides you through the process of onboarding and testing phone number and agent failover using new APIs through the AWS CLI.
Global Resiliency is available only for Amazon Connect instances created in the following AWS Regions: US East (N. Virginia), US West (Oregon), Europe (Frankfurt), and Europe (London).
You can only create a replica in the US East (N. Virginia) Region if your source is US West (Oregon), or the other way around. Similarly, you can only create a replica in the Europe (Frankfurt) Region if your source is Europe (London), or the other way around.
To obtain access to this feature, contact your Amazon Connect Solutions Architect or Technical Account Manager.

You can move a phone number that was previously claimed to an instance, and instead assign it to multiple instances across AWS Regions. You do this by assigning the phone number to a traffic distribution group.

To assign a phone number to a traffic distribution group

1. Create a traffic distribution group using the CreateTrafficDistributionGroup API.
2. Describe your traffic distribution group using the DescribeTrafficDistributionGroup API to determine whether it has been created successfully (`Status` must be `ACTIVE`).
3. After your traffic distribution group is created successfully (`Status` is `ACTIVE`), you can assign phone numbers that were previously claimed to other instances or other traffic distribution groups. Use the UpdatePhoneNumber API.

Release phone numbers in Amazon Connect from traffic distribution groups

To release phone numbers from a traffic distribution group, us the ReleasePhoneNumber API. The number is released back to inventory for other customers to claim it.

You cannot release numbers from a traffic distribution group by using the Amazon Connect console.

Manage chat in your Amazon Connect instance across Regions

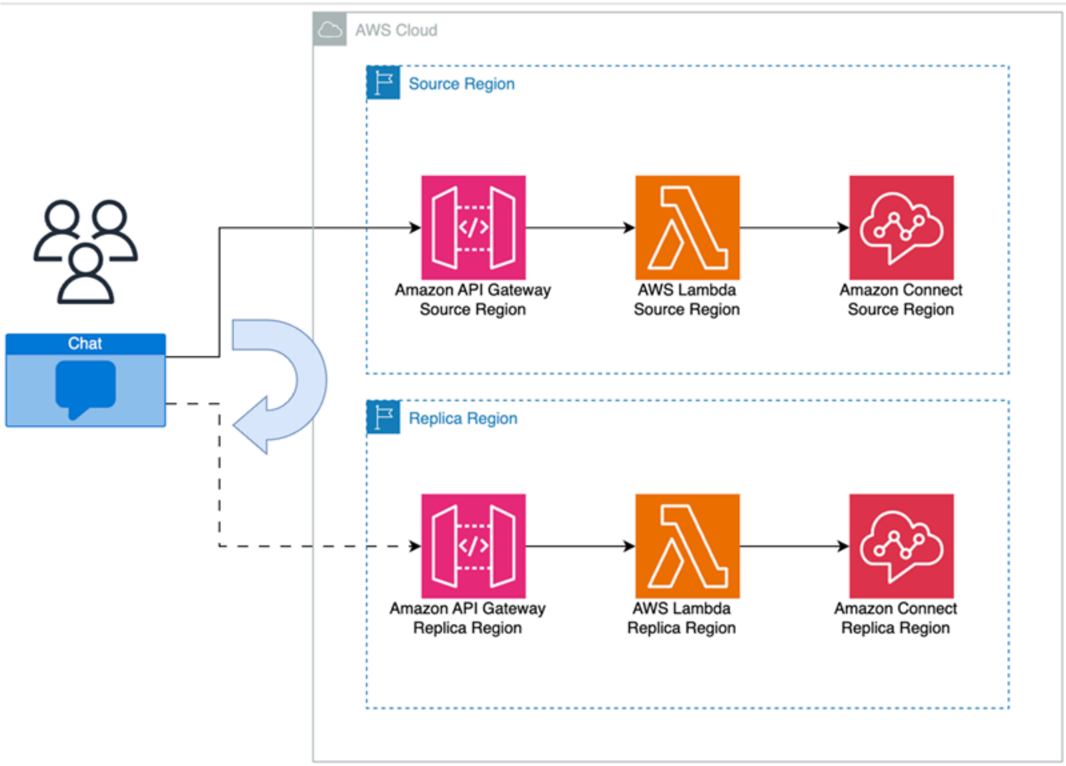
You manage chat across AWS Regions by creating two custom chat interfaces or two out-of-the-box communication widgets: one in the source Region and another in the replica Region. You manually switch between them depending on which Region's chat interface or out-of-the-box communication widget you want to use.

- Custom chat interfaces: Configure the chat interface in the replica Region to use the API endpoint of the replica Region. For examples of custom interfaces, see the Amazon Connect open source library on GitHub. For more information, see Customize chat with the Amazon Connect open source example.
- Out-the-box communication widgets: Create a communication widget in the replica Amazon Connect instance. For instructions, see Configure a communication widget in the replica instance.

Following are the chat configuration parameters that are required in your website or app to initiate a client side chat:

- **Amazon Connect instance ID** and **flow ID**: These parameters are the same in the source and replica Regions.
- **Target AWS Region** and usually an **API endpoint** to start the chat (that is, to acquire the participant token): These parameters are different in the source and replica Regions.

For example, the following diagram shows how the chat configuration needs to be updated to point to the API Gateway in the replica Region when chat traffic needs to be moved across Regions.

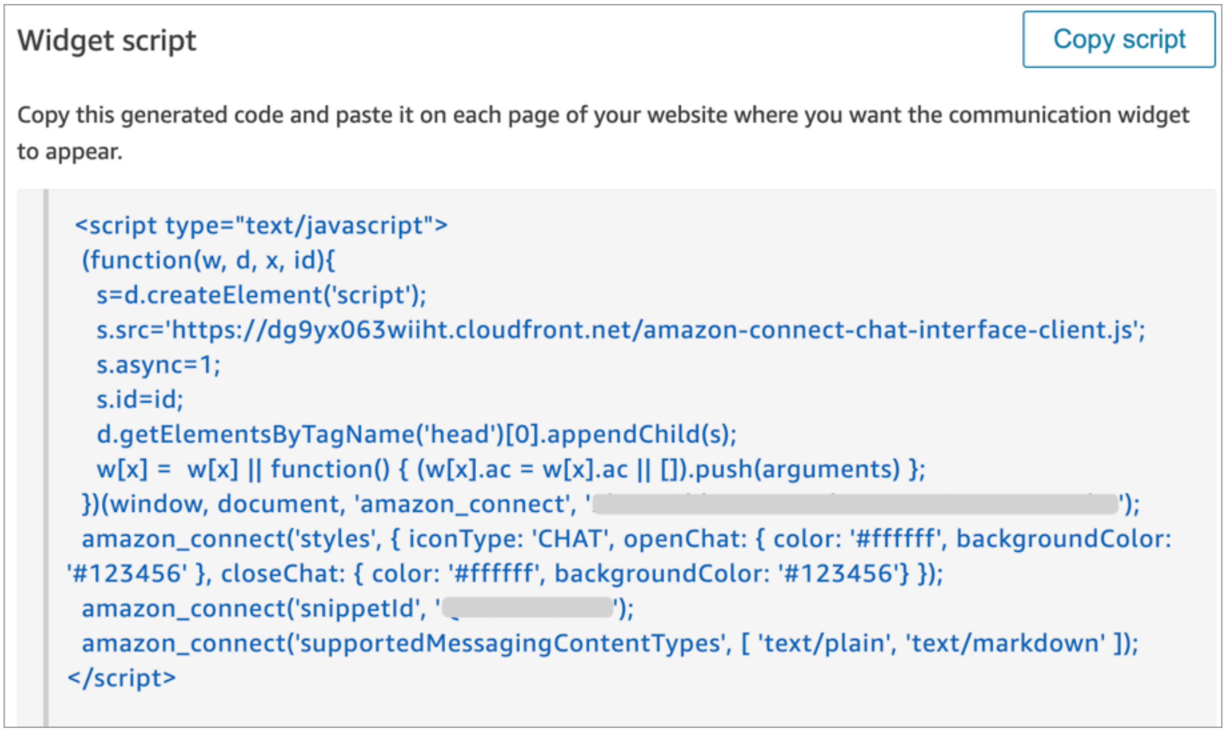


Configure a communication widget in the replica instance

1. On your source Amazon Connect instance, create a communication widget for chat if one doesn't already exist. For instructions, see [Add a chat user interface to your website hosted by Amazon Connect](#).
2. On your replica instance, create another communication widget for chat. Configure the widget with the same flow that is used in the widget on the source instance. The flow is already in the replica instance because Amazon Connect Global Resiliency copies all flows from the source to replica and keeps them continuously synchronized.

3. Copy the new communication widget script that you created in the replica instance. Embed the script on the website or app that should be activated when chat traffic is forwarded to the replica instance.
4. To switch traffic between Regions, replace the source instance communications widget with the replica instance communications widget in your webpage.

   The following image shows an example widget script.



5. If you make any changes to the communication widget in the source instance at a later time, you also need to make the same changes in the communication widget in the replica instance.

Option to add more seamlessness

To make shifting chat traffic across Regions more seamless, and to require fewer manual changes, following is another way you can customize your chat experience:

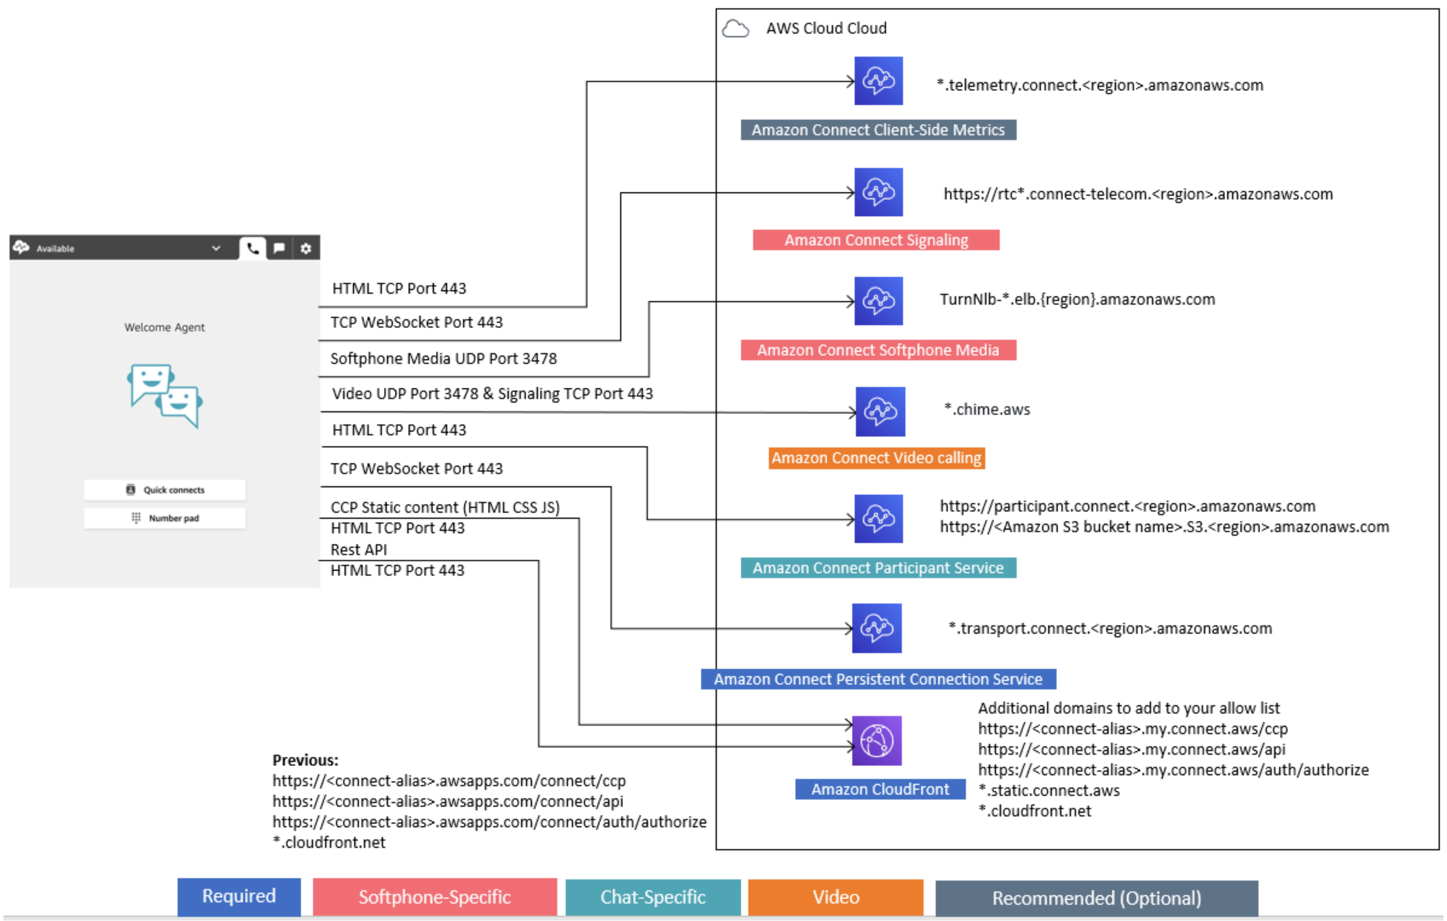
1. Add a parameter to a centrally controlled database (for example, DynamoDB Global Table). The purpose of this parameter is to define which Region is currently active.
2. Update your website or application to check the status of the Region parameter in the central database.
3. Depending on which Region is active, the website or application will use that Region's API endpoint or communication widget.

4. This parameter should be updated at the same time that the UpdateTrafficDistribution API is called to shift voice traffic and agents across Regions where applicable.

Set up your network to use the Amazon Connect Contact Control Panel (CCP)

Traditional VoIP solutions require you to allow both inbound and outbound for specific UDP port ranges and IPs, such as 80 and 443. These solutions also apply to TCP. In comparison, the network requirements for using the Contact Control Panel (CCP) with a softphone are less intrusive. You can establish persistent outbound send/receive connections through your web browser. As a result, you don't need to open a client-side port to listen for inbound traffic.

The following diagram shows you what each port is used for.



If your contact center is using the email channel, see the Amazon SES Developer Guide for information. If your business sends a large volume of email, you may want to lease dedicated IP addresses. For more information, see [Dedicated IP addresses for Amazon SES](#).

The following sections describe the two primary connectivity options for using the CCP.

Contents

Option 1 (recommended): Replace Amazon EC2 and CloudFront IP range requirements with a domain allowlist

This first option lets you significantly reduce your blast radius.

We recommend trying Option 1 and testing it with more than 200 calls. Test for softphone errors, dropped calls, and conference/transfer functionality. If your error rate is greater than 2 percent, there might be an issue with proxy resolution. If that's the case, consider using Option 2.

To allow traffic for Amazon EC2 endpoints, allow access for the URL and port, as shown in the first row of the following table. Do this instead of allowing all of the IP address ranges listed in the ip-ranges.json file. You get the same benefit using a domain for CloudFront, as shown in the second row of the following table.

Domain/URL allowlist	AWS Region	Ports	Direction	Traffic
rtc*.connect-telecom.*region*.amazonaws.com This is used by ccp# (v1). Please see the note following this table.	Replace *region* with the Region where your Amazon Connect instance is located	443 (TCP)	OUTBOUND	SEND/RECEIVE
Following is the minimum allowlist for ***.my.connect.aws**: • *myInstanceName* .my.connect.aws/ccp-v2 • *myInstanceName* .my.connect.aws/api • *myInstanceName* .my.connect.aws/auth/authorize • *.static.connect.aws • *.cloudfront.net	Replace *myInstanceName* with the alias of your Amazon Connect instance	443 (TCP)	OUTBOUND	SEND/RECEIVE

Domain/URL allowlist	AWS Region	Ports	Direction	Traffic
Following is the minimum allowlist for ***.awsapps.com**: **Important** **.awsapps.com** is an old domain that is going away. For instructions about updating your domain to **my.connect.aws**, see [Update your Amazon Connect domain](#). • *myInstanceName* .awsapps				

Domain/URL allowlist	AWS Region	Ports	Direction	Traffic
com/connect/ccp-v2 • *myInstanceName* .awsapps.com/connect/api • *myInstanceName* .awsapps.com/connect/auth/authorize • *.cloudfront.net				
*.telemetry.connect.*region*.amazonaws.com	Replace *region* with the location of your Amazon Connect instance	443 (TCP)	OUTBOUND	SEND/RECEIVE
participant.connect.*region*.amazonaws.com	Replace *region* with the location of your Amazon Connect instance	443 (TCP)	OUTBOUND	SEND/RECEIVE
*.transport.connect.*region*.amazonaws.com This is used by ccp-v2.	Replace *region* with the location of your Amazon Connect instance	443 (TCP)	OUTBOUND	SEND/RECEIVE

Domain/URL allowlist	AWS Region	Ports	Direction	Traffic
Amazon S3 bucket name.s3.*region*.amazonaws.com	Replace *Amazon S3 bucket name* with the name of the location where you store attachments. Replace *region* with the location of your Amazon Connect instance	443 (TCP)	OUTBOUND	SEND/RECEIVE
TurnNlb-*.elb.*region*.amazonaws.com To instead add specific endpoints to your allowlist based on Region, see NLB endpoints.	Replace *region* with the location of your Amazon Connect instance	3478 (UDP)	OUTBOUND	SEND/RECEIVE

Domain/URL allowlist	AWS Region	Ports	Direction	Traffic
instance-id.source-region.sign-in.connect.aws This is used only if you have onboarded to Amazon Connect Global Resiliency.	Replace *instance-id* with your instance ID, and *source-region* with the AWS Region of your source instance. For more information, see Integrate your identity provider (IdP) with an Amazon Connect Global Resiliency SAML sign in endpoint.	443 (HTTPS)	OUTBOUND	SEND/RECEIVE
*.*source-region*.region-discovery.connect.aws This is needed only if you have onboarded to Amazon Connect Global Resiliency.	Replace *source-region* with the AWS Region of your source instance. For instructions about how to find your source Region, see How to find the source Region of your Amazon Connect instances.	443 (HTTPS)	OUTBOUND	SEND/RECEIVE

Fully qualified domain names (FQDNs) cannot be changed or customized on a per-customer basis. Instead, use Option 2 - allow IP address ranges.

Tip

When using `rtc*.connect-telecom.`*`region`*`.amazonaws.com`, `*.transport.connect.`*`region`*`.amazonaws.com`, and `https://myInstanceName.awsapps.com`, in certain proxy applications, web socket handling may impact functionality. Be sure to test and validate before deploying to a production environment.

The following table lists the CloudFront domains used for static assets if you want to add domains to your allowlist instead of IP ranges:

Region	CloudFront Domain
us-east-1	https://dd401jc05x2yk.cloudfront.net/ https://d1f0uslncy85vb.cloudfront.net/
us-west-2	https://d38fzyjx9jg8fj.cloudfront.net/ https://d366s8lxuwna4d.cloudfront.net/
ap-northeast-1	https://d3h58onr8hrozw.cloudfront.net/ https://d13ljas036gz6c.cloudfront.net/
ap-northeast-2	https://d11ouwvqpq1ads.cloudfront.net/
ap-southeast-1	https://d2g7up6vqvaq2o.cloudfront.net/ https://d12o1dl1h4w0xc.cloudfront.net/
ap-southeast-2	https://d2190hliw27bb8.cloudfront.net/ https://d3mgrlqzmisce5.cloudfront.net/
eu-central-1	https://d1n9s7btyr4f0n.cloudfront.net/

Region	CloudFront Domain
	https://d3tqoc05lsydd3.cloudfront.net/
eu-west-2	https://dl32tyuy2mmv6.cloudfront.net/ https://d2p8ibh10q5exz.cloudfront.net/

Note

ca-central isn't included in the table because we host static contents behind the domain `*.my.connect.aws`.

If your business does not use SAML, and you have firewall restrictions, you can add the following entries per Region:

Region	CloudFront Domain
us-east-1	https://d32i4gd7pg4909.cloudfront.net/
us-west-2	https://d18af777lco7lp.cloudfront.net/
eu-west-2	https://d16q6638mh01s7.cloudfront.net/
ap-northeast-1	https://d2c2t8mxjhq5z1.cloudfront.net/
ap-northeast-2	https://d9j3u8qaxidxi.cloudfront.net/
ap-southeast-1	https://d3qzmd7y07pz0i.cloudfront.net/
ap-southeast-2	https://dwcpoxuuza83q.cloudfront.net/
eu-central-1	https://d1whcm49570jjw.cloudfront.net/
ca-central-1	https://d2wfbsypmqjmog.cloudfront.net/
us-gov-east-1:	https://s3-us-gov-east-1.amazonaws.com/warp-drive-console-static-content-prod-osu/

Region	CloudFront Domain
us-gov-west-1:	https://s3-us-gov-west-1.amazonaws.com/warp-drive-console-static-content-prod-pdt/

NLB endpoints

The following table lists the specific endpoints for the Region the Amazon Connect instance is in. If you don't want to use the TurnNlb-*.elb.*region*.amazonaws.com wildcard, you can add these endpoints to your allowlist instead.

Region	Turn Domain/URL
us-west-2	TurnNlb-8d79b4466d82ad0e.elb.us-west-2.amazonaws.com TurnNlb-dbc4ebb71307fda2.elb.us-west-2.amazonaws.com TurnNlb-13c884fe3673ed9f.elb.us-west-2.amazonaws.com
us-east-1	TurnNlb-d76454ac48d20c1e.elb.us-east-1.amazonaws.com TurnNlb-31a7fe8a79c27929.elb.us-east-1.amazonaws.com TurnNlb-7a9b8e750cec315a.elb.us-east-1.amazonaws.com
af-south-1	TurnNlb-29b8f2824c2958b8.elb.af-south-1.amazonaws.com
ap-northeast-1	TurnNlb-3c6ddabcbeb821d8.elb.ap-northeast-1.amazonaws.com

Region	Turn Domain/URL
ap-northeast-2	TurnNlb-a2d59ac3f246f09a.elb.ap-northeast-2.amazonaws.com
ap-southeast-1	TurnNlb-261982506d86d300.elb.ap-southeast-1.amazonaws.com
ap-southeast-2	TurnNlb-93f2de0c97c4316b.elb.ap-southeast-2.amazonaws.com
ca-central-1	TurnNlb-b019de6142240b9f.elb.ca-central-1.amazonaws.com
eu-central-1	TurnNlb-ea5316ebe2759cbc.elb.eu-central-1.amazonaws.com
eu-west-2	TurnNlb-1dc64a459ead57ea.elb.eu-west-2.amazonaws.com
us-gov-west-1	TurnNlb-d7c623c23f628042.elb.us-gov-west-1.amazonaws.com

Option 2 (not recommended): Allow IP address ranges

The second option relies on using an allowlist to define the IP addresses and ports that Amazon Connect can use. You create this allowlist using the IP addresses in the AWS ip-ranges.json file.

If the Region you are using Amazon Connect in does not appear in the AWS ip-ranges.json file, use just the Global values.

For more information about this file, see About Amazon Connect IP address ranges.

IP-Ranges entry	AWS Region	Ports/Protocols	Direction	Traffic
AMAZON_CONNECT	GLOBAL and Region where your Amazon Connect	3478 (UDP)	OUTBOUND	SEND/RECEIVE

IP-Ranges entry	AWS Region	Ports/Protocols	Direction	Traffic
	instance is located (add GLOBAL AND any region-specific entry to your allowlist)			
EC2	GLOBAL and Region where your Amazon Connect instance is located (GLOBAL only if a region-specific entry doesn't exist)	443 (TCP)	OUTBOUND	SEND/RECEIVE
CLOUDFRONT	Global*	443 (TCP)	OUTBOUND	SEND/RECEIVE

*CloudFront serves static content such as images or javascript from an edge location that has the lowest latency in relation to where your agents are located. IP range allow lists for CloudFront are global and require all IP ranges associated with **"service": "CLOUDFRONT"** in the ip-ranges.json file.

About Amazon Connect IP address ranges

In the [AWS ip-ranges.json](https://ip-ranges.amazonaws.com/ip-ranges.json) file, the whole /19 IP address range is owned by Amazon Connect. All traffic to and from the /19 range comes to and from Amazon Connect.

The /19 IP address range isn't shared with other services. It's for the exclusive use to Amazon Connect globally.

In the AWS ip-ranges.json file, you can see the same range listed twice. For example:

```
            { "ip_prefix": "15.193.0.0/19",
```

```
                "region": "GLOBAL",
                "service": "AMAZON"
                },
                {
                "ip_prefix": "15.193.0.0/19",
                "region": "GLOBAL",
                "service": "AMAZON_CONNECT"
                },
```

AWS always publishes any IP range twice: one for the specific service, and one for "AMAZON" service. There could even be a third listing for a more specific use case within a service.

When there are new IP address ranges supported for Amazon Connect, they are added to the publicly available ip-ranges.json file. They are kept for a minimum of 30 days before they are used by the service. After 30 days, softphone traffic through the new IP address ranges increases over the subsequent two weeks. After two weeks, traffic is routed through the new ranges equivalent to all available ranges.

For more information about this file and IP address ranges in AWS, see AWS IP Address Ranges.

Stateless firewalls

If you're using a stateless firewall for both options, use the requirements described in the previous sections. Then you must add to your allowlist the ephemeral port range used by your browser, as shown in the following table.

IP-Range entry	Port	Direction	Traffic
AMAZON_CONNECT	For a Windows environment: 49152-65535 (UDP) For a Linux environment: 32768 - 61000	INBOUND	SEND/RECEIVE

Allow upload of time-off balances and allowances in Amazon Connect scheduling

To allow upload of time-off balances and allowances in Amazon Connect scheduling, add the following upload endpoints to your proxy exception list:

- https://bm-prod-*region*-cell-1-uploadservice-staging.s3.*region*.amazonaws.com
- https://bm-prod-*region*-cell-2-uploadservice-staging.s3.*region*.amazonaws.com

For more information about the activities these endpoints support, see the following topics:

- Set group allowance for time off in Amazon Connect
- Import an agent's time off balance to Amazon Connect

Allow DNS resolution for softphones

If you already added Amazon Connect IP ranges to your allowlist, and you don’t have any restriction on DNS name resolution, then you don't need to add **TurnNlb-*.elb.*region*.amazonaws.com** to your allowlist.

- To check whether there are restrictions on DNS name resolution, while on your network, use the `nslookup` command. For example:

  ```
  nslookup TurnNlb-d76454ac48d20c1e.elb.us-east-1.amazonaws.com
  ```

If you can't resolve the DNS, you must add the TurnNLB endpoints listed above or **TurnNlb-*.elb.*region*.amazonaws.com** to your allowlist.

If you don't allow this domain, your agents will get the following error in their Contact Control Panel (CCP) when they try to answer a call:

- Failed to establish softphone connection. Try again or contact your administrator with the following: Browser unable to establish media channel with turn:TurnNlb-xxxxxxxxxxxx.elb.*region*.amazonaws.com:3478?transport=udp

Port and protocol considerations

Consider the following when implementing your network configuration changes for Amazon Connect:

- You need to allow traffic for all addresses and ranges for the Region in which you created your Amazon Connect instance.
- If you are using a proxy or firewall between the CCP and Amazon Connect, increase the SSL certificate cache timeout to cover the duration of an entire shift for your agents, Do this to avoid connectivity issues with certificate renewals during their scheduled working time. For example, if your agents are scheduled to work 8 hour shifts that include breaks, increase the interval to 8 hours plus time for breaks and lunch.
- When opening ports, Amazon EC2 and Amazon Connect require only the ports for endpoints in the same Region as your instance. CloudFront, however, serves static content from an edge location that has the lowest latency in relation to where your agents are located. IP range allowlists for CloudFront are global and require all IP ranges associated with "service": "CLOUDFRONT" in ip-ranges.json.
- Once ip-ranges.json is updated, the associated AWS service will begin using the updated IP ranges after 30 days. To avoid intermittent connectivity issues when the service begins routing traffic to the new IP ranges, be sure to add the new IP ranges to your allowlist, within 30 days from the time they were added to ip-ranges.json.
- If you are using a custom CCP with the Amazon Connect Streams API, you can create a media-less CCP that does not require opening ports for communication with Amazon Connect, but still requires ports opened for communication with Amazon EC2 and CloudFront.

Region selection considerations

Amazon Connect Region selection is contingent upon data governance requirements, use case, services available in each Region, and latency in relation to your agents, contacts, and external transfer endpoint geography.

- **Agent location/network**—CCP connectivity traverses the public WAN, so it is important that the workstation has the lowest latency and fewest hops possible, specifically to the AWS Region where your resources and Amazon Connect instance are hosted. For example, hub and spoke networks that need to make several hops to reach an edge router can add latency and reduce the quality of experience.

When you set up your instance and agents, make sure to create your instance in the Region that is geographically closest to the agents. If you need to set up an instance in a specific Region to comply with company policies or other regulations, choose the configuration that results in the fewest network hops between your agents' computers and your Amazon Connect instance.

- **Location of your callers**—Because calls are anchored to your Amazon Connect Region endpoint, they are subject to PSTN latency. Ideally your callers and transfer endpoints are geographically located as closely as possible to the AWS Region where your Amazon Connect instance is hosted for lowest latency.

  For optimal performance, and to limit the latency for your customers when they call in to your contact center, create your Amazon Connect instance in the Region that is geographically closest to where your customers call from. You might consider creating multiple Amazon Connect instances, and providing contact information to customers for the number that is closest to where they call from.
- **External transfers**—from Amazon Connect remain anchored to your Amazon Connect Region endpoint for the duration of the call. Per-minute usage continues to accrue until the call is disconnected by the recipient of the transferred call. The call is not recorded after the agent drops or the transfer completes. The contact record data and associated call recording of a transferred call are generated after the call is terminated. Whenever possible, don't transfer calls that could be transferred back into Amazon Connect, known as circular transfers, to avoid compounding PSTN latency.

Agents using Amazon Connect remotely

Remote agents, those that use Amazon Connect from a location other than those connected to your organization's main network, may experience issues relating to their local network if they have an unstable connection, packet loss, or high latency. This is compounded if a VPN is required to access resources. Ideally, the agents are located close to the AWS Region where your AWS resources and Amazon Connect instance are hosted, and have a stable connection to the public WAN.

Rerouting audio

When rerouting audio to an existing device, consider the location of the device in relation to your Amazon Connect Region. This is so you can account for potential additional latency. If you reroute your audio, whenever there is a call intended for the agent, an outbound call is placed to the configured device. When the agent answers the device, that agent is connected with the caller. If the agent does not answer their device, they are moved into a missed contact state until they or a supervisor changes their state back to available.

Using AWS Direct Connect

Contact Control Panel (CCP) network connectivity issues are most often rooted in your route to AWS using private WAN/LAN, ISP, or both. While AWS Direct Connect does not solve issues specific to private LAN/WAN traversal to your edge router, it can help solve for latency and connectivity issues between your edge router and AWS resources. AWS Direct Connect provides a durable, consistent connection rather than relying on your ISP to dynamically route requests to AWS resources. It also allows you to configure your edge router to redirect AWS traffic across dedicated fiber rather than traversing the public WAN.

Agent workstation requirements for app, web, and video calling in Amazon Connect

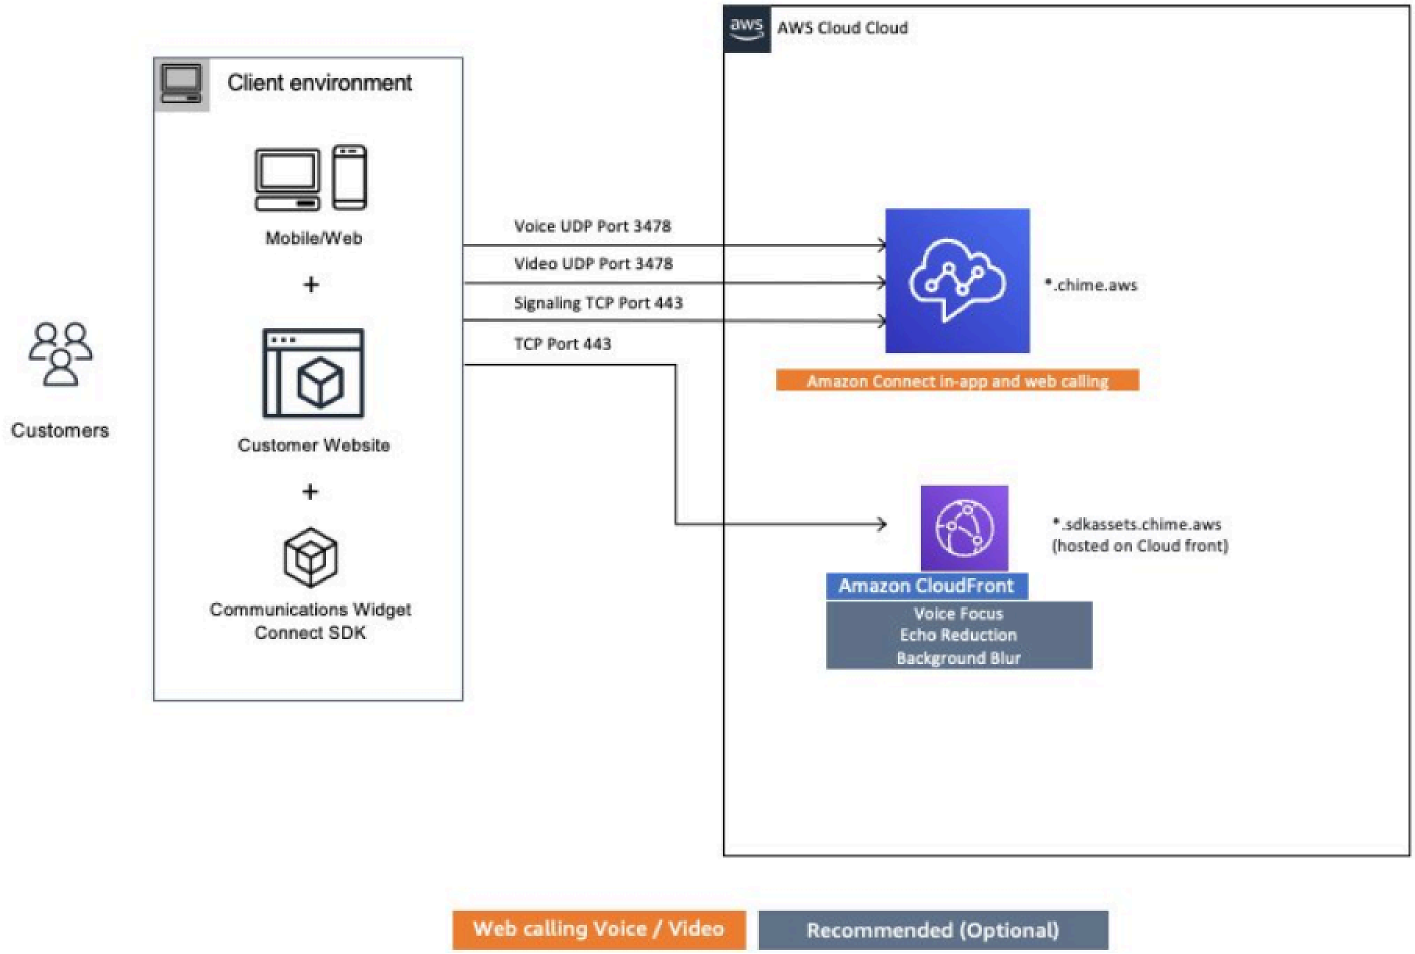
The Amazon Connect in-app, web, and video calling capabilities enable your customers to contact you without ever leaving your web or mobile application. The video calling capabilities leverage the Amazon Chime SDK communication primitives for the video stream. The voice experience is handled through Amazon Connect.

> **Important**
>
> Video calling does not support VDI environments.

The following table shows the additional networking requirements for your agents' workstation.

Domain	Subnet	Ports
*.chime.aws	99.77.128.0/18	443 (TCP) 3478 (UDP)

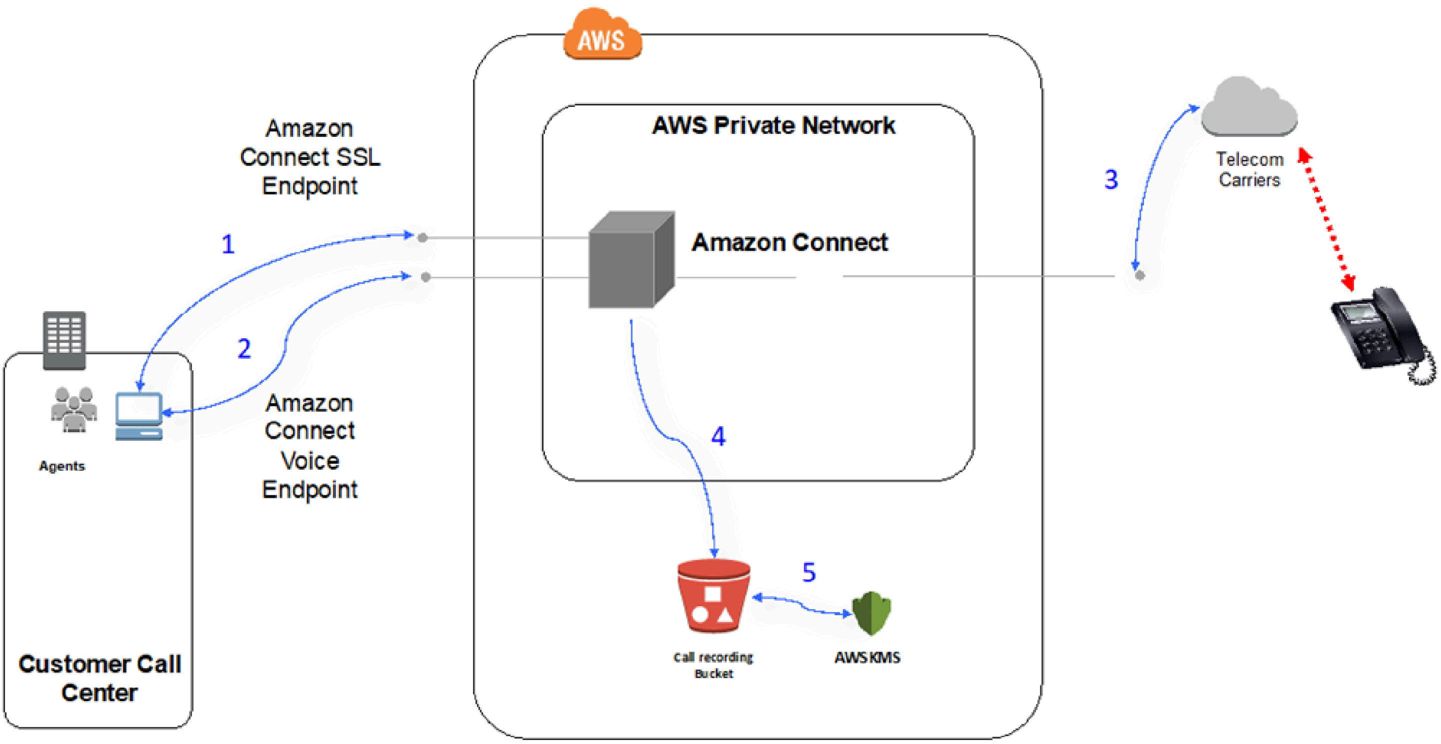
The following diagram shows the networking requirements for the customers who are using the communications widgets to contact you.



Detailed network paths for Amazon Connect

Voice calls

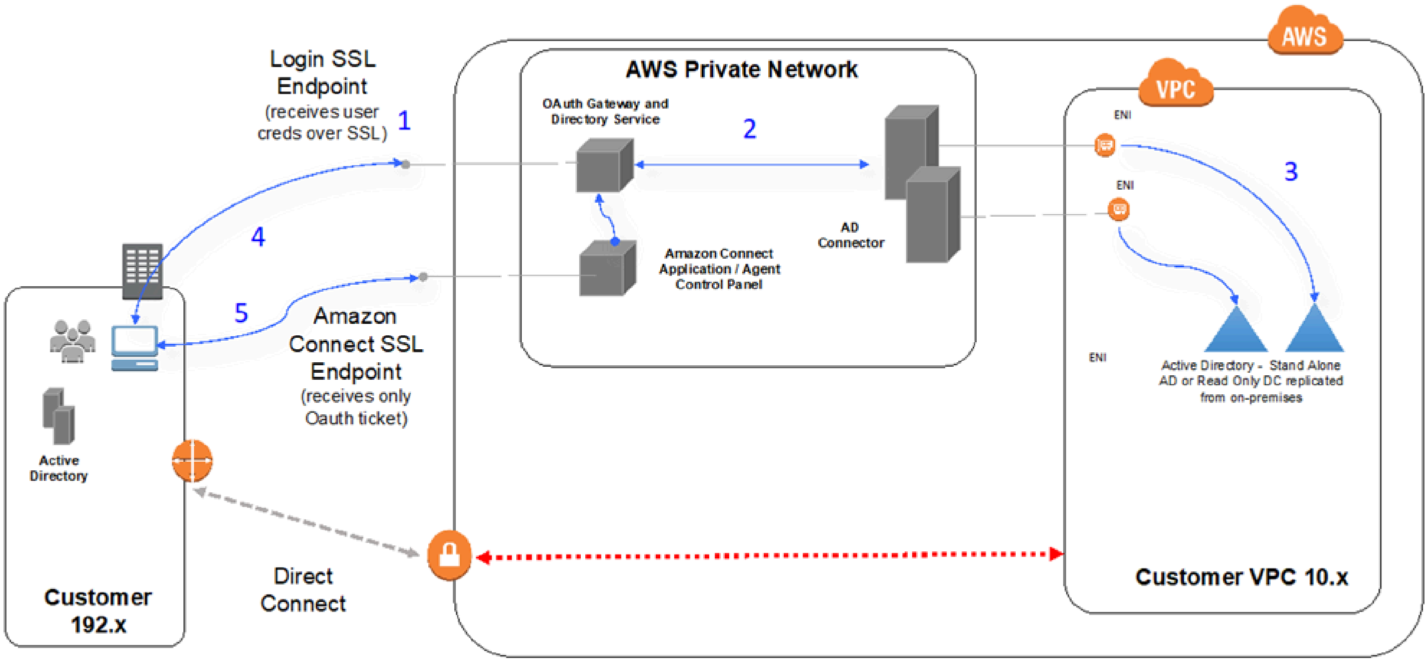
The following diagram shows how voice calls flow through Amazon Connect



1. Users access the Amazon Connect application using a web browser. All communications are encrypted in transit using TLS.
2. Users establish voice connectivity to Amazon Connect from their browser using WebRTC. Signaling communication is encrypted in transit using TLS. Audio is encrypted in transit using SRTP.
3. Voice connectivity to traditional phones (PSTN) is established between Amazon Connect and AWS telecommunications carrier partners using private network connectivity. In cases where shared network connectivity is used, signaling communication is encrypted in transit using TLS and audio is encrypted in transit using SRTP.
4. Call recordings are stored in your Amazon S3 bucket that Amazon Connect has been given permissions to access. This data is encrypted between Amazon Connect and Amazon S3 using TLS.
5. Amazon S3 server-side encryption is used to encrypt call recordings at rest using a customer-owned KMS key.

Authentication

The following diagram shows using the AD Connector with AWS Directory Service to connect to an existing customer Active Directory installation. The flow is similar to using AWS Managed Microsoft AD.



1. The user's web browser initiates authentication to an OAuth gateway over TLS using the public internet with user credentials (Amazon Connect login page).
2. OAuth gateway sends the authentication request over TLS to AD Connector.
3. AD Connector does LDAP authentication to Active Directory.
4. The user's web browser receives OAuth ticket back from gateway based on authentication request.
5. The client loads the Contact Control Panel (CCP). The request is over TLS and uses OAuth ticket to identify user/directory.

Use Amazon Connect in a VDI environment

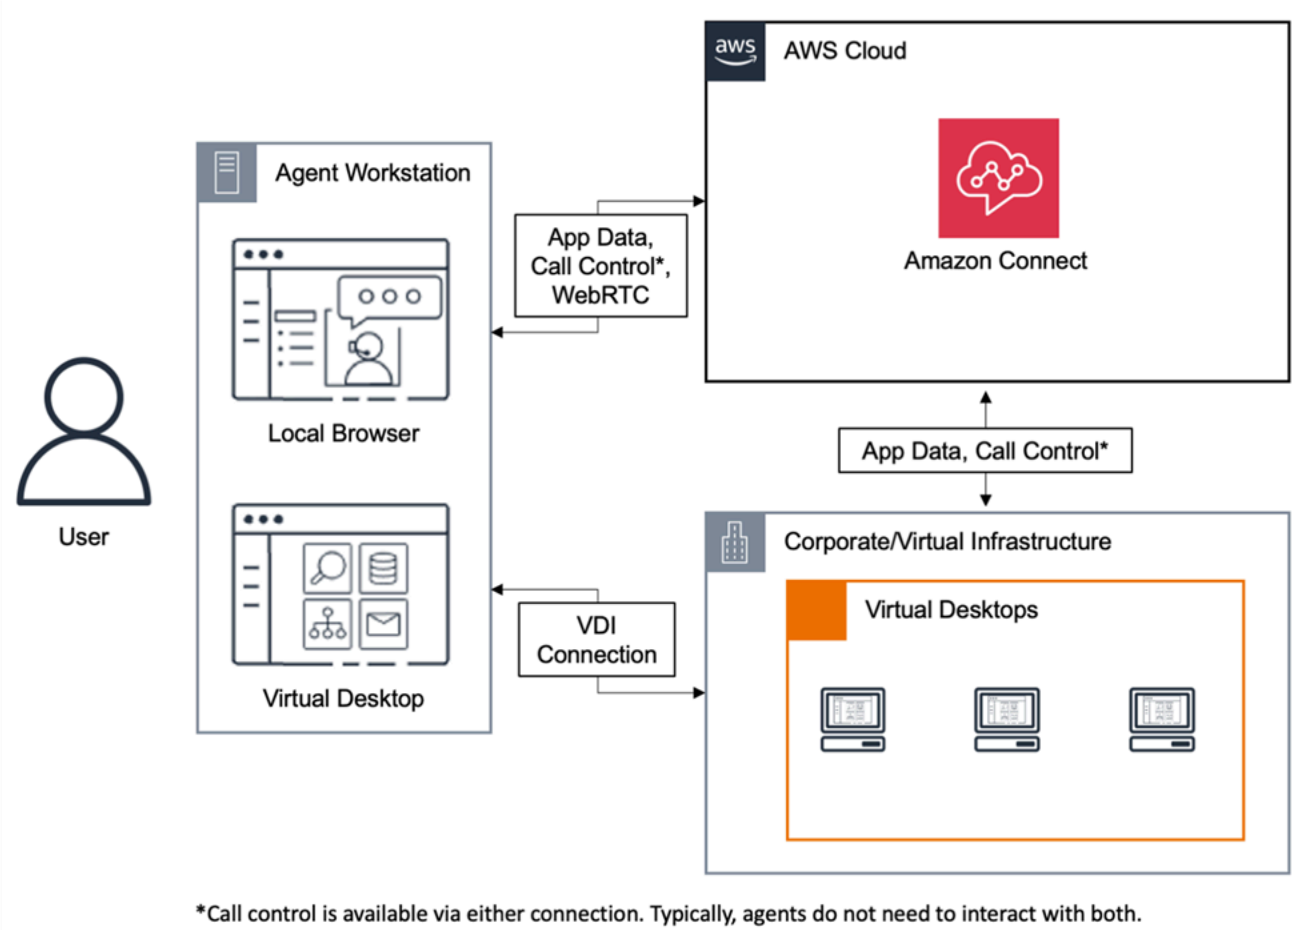
Virtual Desktop Infrastructure (VDI) environments add another layer of complexity to your solution that warrants separate POC efforts and performance testing to optimize. The Contact Control Panel (CCP) can operate in thick, thin, and zero client VDI environments as any other WebRTC based browser application does, and the configuration/support/optimization is best handled by your VDI support team. That being said, the following is a collection of considerations and best practices that have been helpful for our VDI-based customers.

Use a split CCP model

We recommend using a split CCP model with a medialess CCP running in the VDI and a CCP carrying the media on the local PC. You can build a custom CCP with the Amazon Connect Streams API by creating a CCP with no media for application data and call signaling. This way, the media is delivered to the local desktop using standard CCP, with data and call controls delivered to the remote connection with the medialess CCP. For more information about the streams API, see the GitHub repository at https://github.com/aws/amazon-connect-streams.

> **Note**
>
> **Firefox users**: If you are using VDI in split mode, you cannot use the Firefox browser for CCP outside of the VDI. The CCP conforms to Firefox microphone usage guidance, and only has access to connect to the user's microphone when the CCP tab is in focus.

The following diagram shows how the agent workstation is comprised of a local browser and virtual desktop. It connects to Amazon Connect through WebRTC, and connects to the corporate virtual infrastructure through a VDI connection.



Cloud desktops

If you use Citrix or Amazon WorkSpaces cloud desktops, you can create a new or update an existing agent user interface, such as a custom CCP, to offload audio processing to your agent's local device and to automatically redirect audio to Amazon Connect. This results in a more streamlined agent experience and improves audio quality over challenging networks. To get started, you can use the [Amazon Connect open source libraries](#) to create a new or update an existing agent user interface, such as a custom CCP.

Things to consider when designing your VDI environment

- **Location of your agents—**Ideally, there are as few hops as possible with the lowest round trip time between the location from which your agents use the CCP and the VDI host location.
- **Host location of your VDI solution—**Ideally, your VDI host location is on the same network segment as your agents, with as few hops as possible from both internal resources as well as an

edge router. You also want the lowest round-trip time possible to both WebRTC and Amazon EC2 range endpoints.

- **Network**—Each hop that traffic goes through between endpoints increases the possibility of failure and adds opportunity to introduce latency. VDI environments are particularly susceptible to call quality issues if the underlying route is not optimized or the pipe isn't either fast or wide enough. While AWS Direct Connect can improve call quality from the edge router to AWS, it will not address internal routing issues. You may need to upgrade or optimize your private LAN/WAN, or redirect to an external device to circumvent call audio issues. In most scenarios, if this is required, the CCP is not the only application that is having issues.
- **Dedicated resources**—at the Network and desktop level are recommended to prevent an impact to available agent resources from activities, such as backups and large file transfers. One way to prevent resource contention is by restricting the desktop access to Amazon Connect users who will be using their environment similarly, instead of sharing resources with other business units who may use those resources differently.
- **Using a soft phone with remote connections**—in VDI environments can cause impact to audio quality.

> **Tip**
>
> If your agents connect to a remote endpoint and operates in that environment, we recommend either rerouting audio to an external E.164 endpoint or connecting the media through the local device and then signaling through the remote connection.

Optimize Amazon Connect audio for Citrix cloud desktops

Amazon Connect makes it easier to deliver high-quality voice experiences when your agents are using Citrix Virtual Desktop Infrastructure (VDI) environments. Your agents can leverage their Citrix remote desktop applications such as Citrix Workspaces, to offload audio processing to the agent's local device and to automatically redirect audio to Amazon Connect, resulting in improved audio quality over challenging networks.

To get started, you can use the Amazon Connect open source libraries to create a new or update an existing agent user interface, such as a custom Contact Control Panel (CCP).

System requirements

This section describes the system requirements for using the Citrix Unified Communications SDK with Amazon Connect.

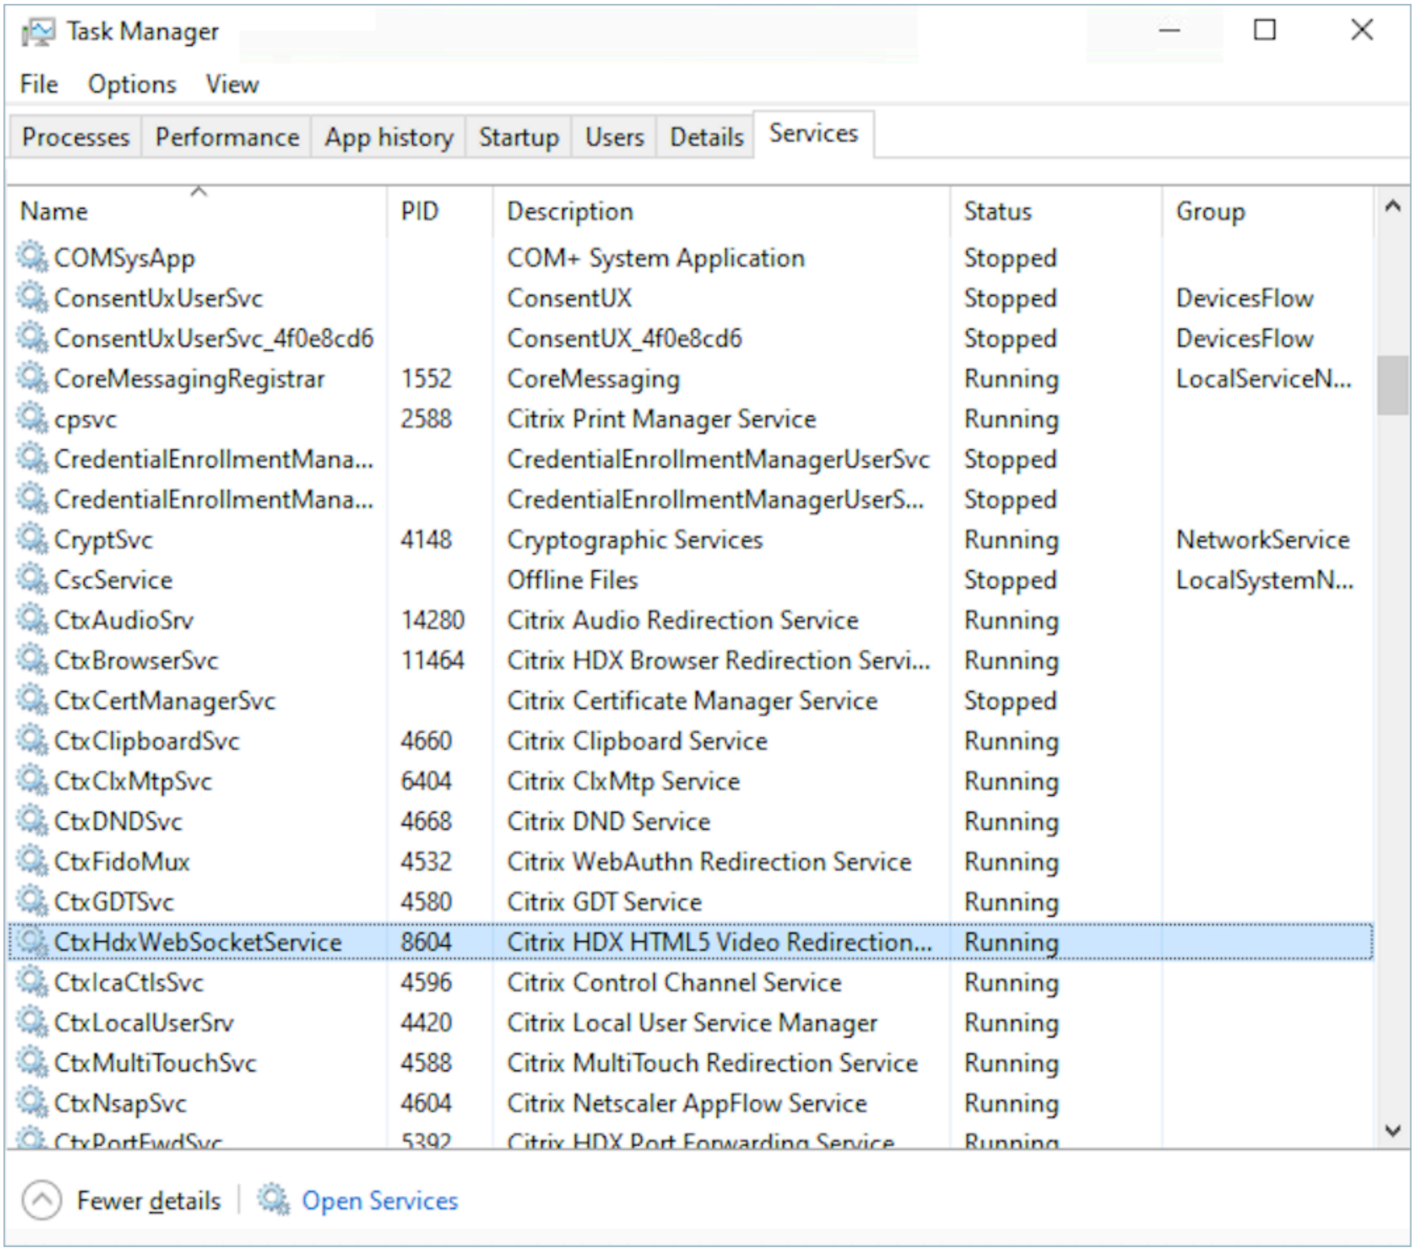
- **Citrix Workspace Application Version**

  The version of Citrix Workspace Application needs to be 21.9.x.x or above.
- **Citrix Server Version**

  The version of Citrix VDA (Virtual Delivery Agent) needs to be 2109 or above.
- **Citrix Server Setup**

  The Citrix UC SDK is not supported to use by default and the admin of the system needs to add an allow-list registry entry as follows:
  - **Key Path:** `Computer\HKEY_LOCAL_MACHINE\SOFTWARE\WOW6432Node\Citrix\WebSocketService`
  - **Key Name:** `ProcessWhitelist`
  - **Key Type:** `REG_MULTI_SZ`
  - **Key Value:**
    - `Chrome.exe`
    - `msedge.exe`

  After you configure the registry successfully, restart the `CitrixHdxWebSocketService` using **Task Manager** to finish the setup.

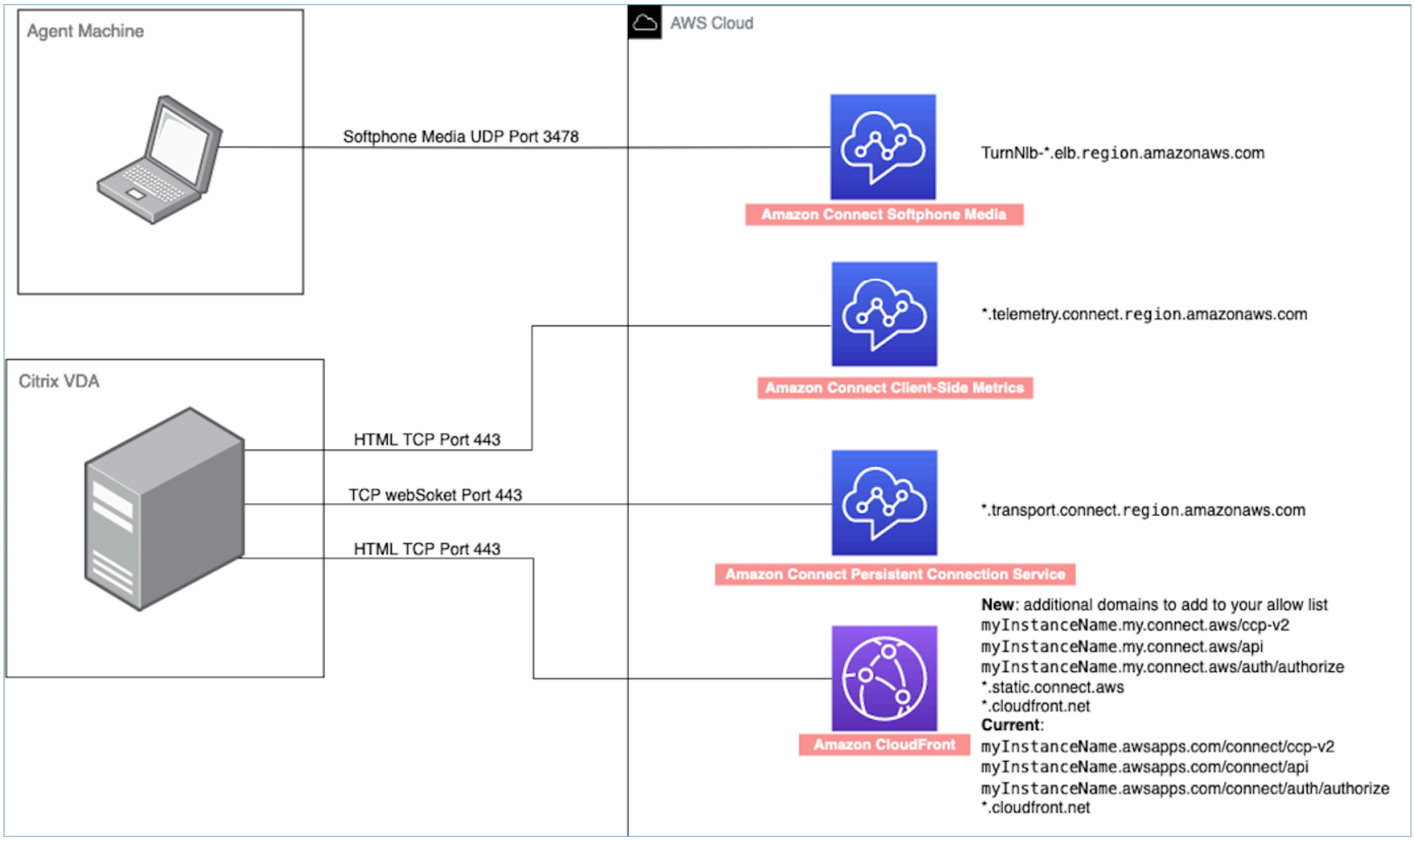


- **Networking/Firewall Configurations**
  - **Citrix server configuration**

    The admin needs to allow the Citrix server to access Amazon Connect TCP/443 traffic to the domains mentioned in the following diagram. For more information, see [Set up your network to use the Amazon Connect Contact Control Panel (CCP)](#).
  - **Agent machine configuration**

    This solution requires a media connection between the agent's thin client and Amazon Connect. To allow traffic between the agent's machine and Amazon Connect's Softphone

Media UDP Port 3478, see [Set up your network to use the Amazon Connect Contact Control Panel (CCP)](#).

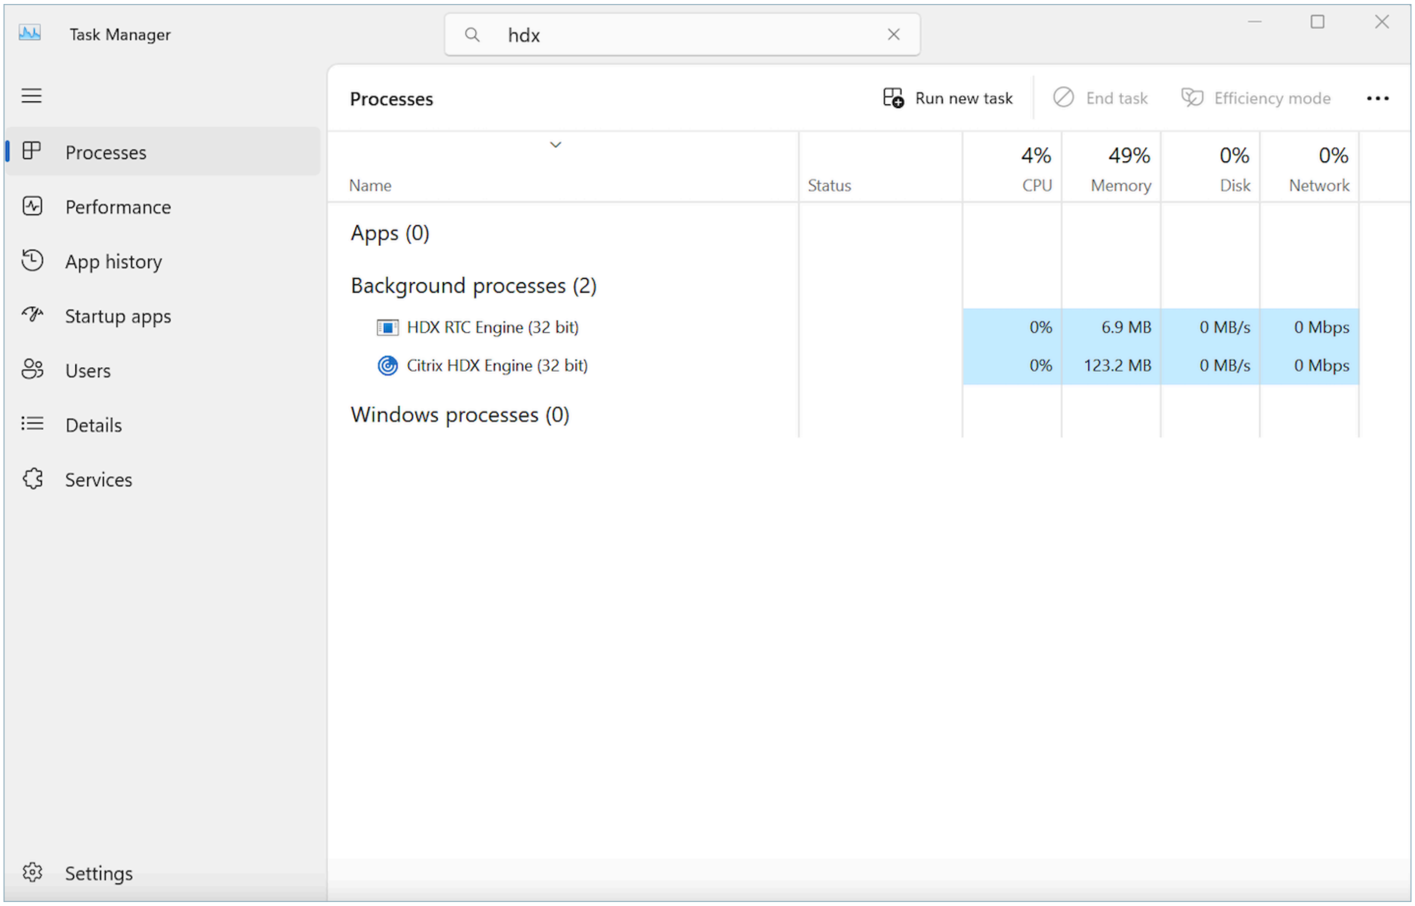


- **Unsupported CCP Deployment**
  - Native CCP

Confirm media flows between thin client and Amazon Connect during the call

- **Use Task Manager (Windows) to verify**

  Launch the **Task Manager** on the agent's thin client and check to see if the HDX service is running or not. If it is running, then it means that the media is being redirected as expected.



Optimize Amazon Connect audio for Amazon WorkSpaces cloud desktops

Amazon Connect simplifies delivery of high-quality voice experiences for agents operating within Amazon WorkSpaces Virtual Desktop Infrastructure (VDI) environments. By leveraging Amazon WorkSpaces with the WebRTC redirection feature, agents can redirect Amazon Connect audio processing to their local devices. This approach results in enhanced audio quality, even over challenging network conditions. To take advantage of this feature, you need to do the following:

- Use Amazon Connect open source libraries to create a new or update an existing agent user interface, such as a custom Contact Control Panel (CCP).
- Configure Amazon WorkSpaces to enable WebRTC redirection.

System requirements

This section describes the system requirements for using Amazon Connect with WorkSpaces WebRTC redirection.

- **WorkSpaces Protocol**

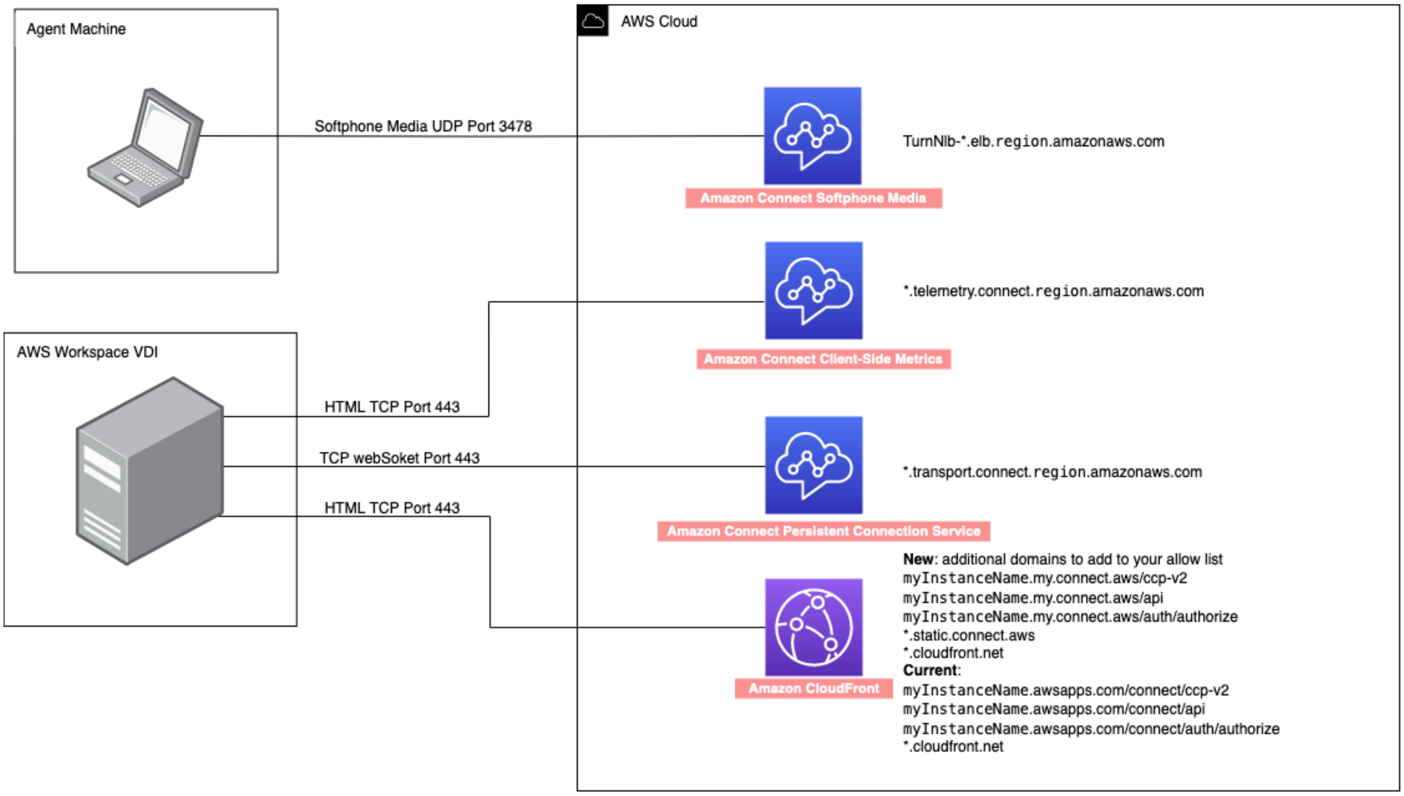
  WorkSpaces needs to use the WorkSpaces Streaming Protocol (WSP). For more information, see Protocols for Amazon WorkSpaces.
- **Client version**

  Users should use WorkSpaces Web Access or WorkSpaces Windows client version 5.21.0 or higher. Complete the Setup and installation instructions.
- **Group policy**

  WebRTC redirection needs to be enabled in the WSP group policy. For more information, see Manage Group Policy settings for WorkSpaces Streaming Protocol (WSP).
- **Networking/firewall configurations**
  - **Workspace VDI configuration**

    The admin needs to allow the Workspaces to access Amazon Connect TCP/443 traffic to the domains mentioned in the following diagram. For more information, see Set up your network to use the Amazon Connect Contact Control Panel (CCP).
  - **Agent machine configuration**

    This solution requires a media connection between the agent thin client to Amazon Connect. To allow traffic between the agent's machine and Amazon Connect Softphone Media UDP Port 3478, see Set up your network to use the Amazon Connect Contact Control Panel (CCP).



- **Unsupported CCP Deployment**
  - Native CCP

Confirm media flows between agent machine and Amazon Connect during the call

- Ensure DCV WebRTC browser extension is enabled and in Ready state.

Use Agent Workspace to optimize audio for Citrix and Amazon WorkSpaces cloud desktops

You can use Amazon Connect Agent Workspace to simplify the delivery of high-quality voice experiences in Amazon WorkSpaces and Citrix Virtual Desktop Infrastructure (VDI) environments.

Amazon Connect supports audio optimization for Amazon WorkSpaces and Citrix cloud desktops. This optimization redirects media from an agent's local desktop to Amazon Connect. It streamlines the agent experience and improves audio quality by reducing network hops. Your agents can leverage these audio optimizations in the agent workspace.

Important things to know

- For non SSO users, if the agents navigate to Agent Workspace from the Amazon Connect admin website, there will be a query parameter for referrer already appended to the URL. The format of the URL is `https://your-instance-url/agent-app-v2?referrer=admin`. To form the VDI platform query parameter, remove the referrer parameter from the URL (for example, you can use Notepad to edit the URL). Append the VDI platform parameter directly to the `/agent-app-v2` path of the URL.
- For audio optimization inside the VDI environment, always use the bookmarked URL for the agent workspace.
- If you are not using the agent workspace inside an actual VDI environment, do not append the VDI query parameter.
- We recommend that agents stay with one media device during an ongoing contact within VDI environments. Because the media device information is relayed at the start of a contact, if an agent were to switch media devices during an ongoing contact, they would not be able to access audio in the updated device.

How to use audio optimization in Agent Workspace

To use audio optimization in Agent Workspace, users need to have a query parameter in the URL with a value for the VDI environment in which the agent workspace is used. This process signals the Contact Control Panel (CCP) to perform WebRTC redirection for the calls from that specific VDI environment to the local device being used by the agent.

Complete the following steps to use a query parameter for the VDI environment.

Use without SSO based login

1. Go to your Amazon Connect Agent Workspace, and copy the URL for the agent workspace to Notepad.
2. Append a query parameter with the key `VDIPlatform` and the value equal to the specific VDI environment you have. For example:

    a. For Citrix cloud desktop, the value for the query parameter is `CITRIX`. The following code shows an example of the complete URL:

    - `https://your-instance-url/agent-app-v2?VDIPlatform=CITRIX`

b. For Amazon WorkSpaces cloud desktop, the value for the query parameter is `AWS_Workspace`. The following code shows an example of the complete URL:

   - `https://your-instance-url/agent-app-v2?VDIPlatform=AWS_Workspace`

3. Copy and paste the URL into the agent's browser.
4. We recommend bookmarking this URL for all the agents. This makes it easy for agents access it in future by just clicking the bookmarked link.

Use with SSO based login

1. If you use SSO to directly login into Amazon Connect Agent Workspace, you need to change the relay state URL of your SSO setup to append the VDI query parameter. Complete the following steps to do this:

   a. Copy and paste the relay state you are using to access the agent workspace in the relay state of your Identity Provider (IdP).

   b. See examples of relay state URLs. In the examples, `%2Fagent-app-v2` is the destination.

   c. Add the `VDIPlatform` parameter with the appropriate value to this relay state. Using the example from the above link, the complete relay state URL for the Amazon Connect agent workspace would look like the following:

      i. In Citrix Desktop

```
https://us-east-1.console.aws.amazon.com/connect/federate/
instance-id?destination=%2Fagent-app-v2?VDIPlatform=CITRIX
```

      ii. In Amazon WorkSpaces

```
https://us-east-1.console.aws.amazon.com/connect/federate/
instance-id?destination=%2Fagent-app-v2?VDIPlatform=AWS_Workspace
```

2. Setting `VDIPlatform` in relay state URL automatically sets the audio optimization in Agent Workspace for the specific VDI environment being used.

   - Log in from your IdP, and confirm that `VDIPlatform` is present as a query parameter.

How call center agents connect to the Contact Control Panel (CCP)

When an agent logs in, the CCP attempts to connect to the Amazon EC2 signaling endpoints listed in the AWS ipranges.json file, Amazon Connect for media, and CloudFront for web artifacts such as images. When the agent logs out or the browser is closed, endpoints are reselected when the agent next logs in. If a connection to Amazon EC2 or Amazon Connect fails, errors display on the CCP. If a connection to CloudFront fails, web elements such as buttons and icons, or even the page itself fails to load correctly.

> **Note**
>
> If you see the **Session expired** message while logging in, you probably just need to refresh the session token. Go to your identity provider and log in. Refresh the Amazon Connect page. If you still get this message, contact your IT team.

Outbound calls

- When an outbound call is placed, the event signal is sent to the Amazon EC2 endpoint, which then communicates with Amazon Connect to place the call. Upon a successful dial attempt, the agent is bridged in, which anchors the call to the agent's Amazon Connect endpoint. Any external transfers or conferences also uses the anchor until the call is disconnected. Anchoring can help reduce PSTN latency.

Inbound calls

- When an inbound call is received, the call is anchored to an Amazon Connect endpoint. Any external transfers or conferences also use this anchor until the call is disconnected.
- When an agent is available, the call is pushed through using a new Amazon EC2 connection to their browser and offered to the agent.
- When the agent accepts the call and either the external device has been answered or the CCP determines it can receive a call, a connection to Amazon Connect is established for call media to the agent.

Transferred calls

- When a call is transferred, the transfer event that signals to place an outbound call to the specified transfer destination is sent to Amazon EC2, which then communicates with Amazon Connect to place the call.
- When the call is connected, the agent is bridged in, anchoring the call to the agent's existing Amazon Connect endpoint. Any external transfers or conferences also use this anchor until the call is disconnected.
- If the agent hangs up after the call is bridged, the agent's connection to the call is terminated, but Amazon Connect hangs on to the call at the Amazon Connect anchor point until there is a far side disconnect. When the call is disconnected, contact records and associated recordings are generated and made available for the call.

Missed calls

- If the call is waiting on an agent, customer queue flow logic is used until an agent is available and the call has been successfully routed to that agent.
- If the agent does not accept the call, the agent moves into a Missed Call state and is unable to take calls until the agent, or a call center manager, changes their status to Available again. The caller does not hear ringing while the call is waiting for the agent, and continues to hold until connected with an agent as defined in the customer queue flow logic.
- If the agent is configured for cross-channel concurrency, they must clear the missed contact before any other contacts on any other channel can be routed to them. For example, if they are configured to handle voice and chats at the same time, and they miss a chat, they must clear that contact before any other voice or chat contacts are routed to them.

Panic logout

- If the browser window where the CCP is running is closed, the call remains connected, but opening the browser and logging back in will not allow you to re-establish the media connection. You are still able to transfer or end the call, but no audio path is established between the agent and caller.

Use an allowlist for integrated applications in Amazon Connect

All domains that embed the CCP for a particular instance must be explicitly allowed for cross-domain access to the instance. For example, to integrate with Salesforce, you must place your Salesforce Visualforce domain in an allowlist.

To allow a domain URL

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. Choose the name of the instance from **Instance Alias**.
3. In the navigation pane, choose **Approved origins**.
4. Choose **Add origin**.
5. Type the URL and choose **Add**.

> **Note**
>
> When Amazon Connect is embedded in another app, it's possible for users to get a **Session expired** error message when the close and then reopen Amazon Connect, and then log in. If you see the **Session expired** message while logging in, you probably just need to refresh the session token. Go to your identity provider and log in. Refresh the Amazon Connect page. If you still get this message, contact your IT team.

Update your Amazon Connect domain

Amazon Connect instances that were created before March 31, 2021, were given a domain that looks like this:

- https://*your-instance-alias*.**awsapps.com/connect/**

If you have one of these domains, we urge you to change it immediately. Change it to:

- https://*your-instance-alias*.**my.connect.aws/**

In the near future we plan to automatically change any remaining old domains that appear in the AWS console—including the emergency access URL—to the new URL.

- If anyone tries to access a URL with the old domain, they will be redirected automatically to the new one.
- If you have any custom code, a connector, or a firewall, it is your responsibility to update all references to your Amazon Connect URL from your old domain to your new domain.
- Automatic redirection from the old domain to the new one is only for any references you may have accidentally missed, for example, users still clicking on old favorites.

Perform the steps in this topic to help you PREPARE for when we automatically change your old domain name (that is, redirect traffic from your old domain to the new one).

For example, if your old link looks like this:

- https://*examplecorp*.**awsapps.com/connect/**

Change to:

- https://*examplecorp*.**my.connect.aws/**

Continue reading this topic if you use a firewall, SAML, or other connectors such as Salesforce. This topic provides information you need to consider when migrating to the new domain.

Contents

Custom code and integrations

If you have any customization that involves Amazon Connect, review its code and replace hard-coded references to the previous domain with the new domain. For example, if you have a custom Contact Control Panel (CCP) integration, it likely relies on embedded URLs. Following are tips for updating other types of integration.

Active Directory

If you use Active Directory to manage identity and have an Amazon Connect managed or customer managed instance, then update ccpUrl to the new domain. The next time a user accesses the CCP they will be prompted to login to the new domain (one time only).

SAML 2.0

If you use SAML 2.0 to manage identity, then do the following steps:

- Update `ccpUrl` in your Amazon Connect Streams to the new domain *`your-instance-alias`*`.my.connect.aws/ccp-v2`.
- When you configure the relay state for your identity provider, update the `loginUrl` with `new_domain=true`.
- You must use URL encoding for the destination and new_domain in the URL.

If you have old instances that were set up with SAML, do the following steps:

1. If `loginUrl` contains `destination=%2Fconnect%2F`*`your-destination-endpoint`*, remove the `%2Fconnect` endpoint prefix from the new domain destination.
2. Add `new_domain=true` before or after `destination=%2F`*`your-destination-endpoint`*. It should be separated by &.
3. If `loginUrl` does not contain destination or any other parameter, add `?new_domain=true` after the relay state URL.

Following are examples of valid relay state URLs:

- `https://us-east-1.console.aws.amazon.com/connect/federate/`*`your-instance-id`*`?destination=%2Fccp-v2%2Fchat&new_domain=true`
- `https://us-east-1.console.aws.amazon.com/connect/federate/`*`your-instance-id`*`?new_domain=true`

> **Note**
>
> If the RelayState is itself a parameter to another URL, then the whole RelayState itself must be URL encoded, on top of any URL encoding previously done on

the `destination`. For example, if the derived RelayState was `https://us-east-1.console.aws.amazon.com/connect/federate/your-instance-id?destination=%2Fccp-v2%2Fchat&new_domain=true`, and it needs to be inserted in `https://my.idp.com/signin?RelayState=<here>`, then the final URL should look like `https://my.idp.com/signin?RelayState=https%3A%2F%2Fus-east-1.console.aws.amazon.com%2Fconnect%2Ffederate%2Fyour-instance-id%3Fdestination%3D%252Fccp-v2%252Fchat%26new_domain%3Dtrue`. The URL encoding is crucial to allow it to be parsed correctly in a query string.

Other connectors

If you use Salesforce, Zendesk, ServiceNow, or other connectors:

1. Upgrade to the latest version of your connector.
2. In your connector, go to the settings and update the Amazon Connect domain that is stored there. Follow the SAML tips if applicable.

Firewall allowlist

Add the following new domains to your allowlist:

- *`your-instance-alias`*.my.connect.aws
- *.static.connect.aws

Important

Do not remove the domains already in your allowlist, such as the following domains:

- *`your-instance-alias`*.awsapps.com/connect/ccp-v2
- *`your-instance-alias`*.awsapps.com/connect/api
- *.cloudfront.net

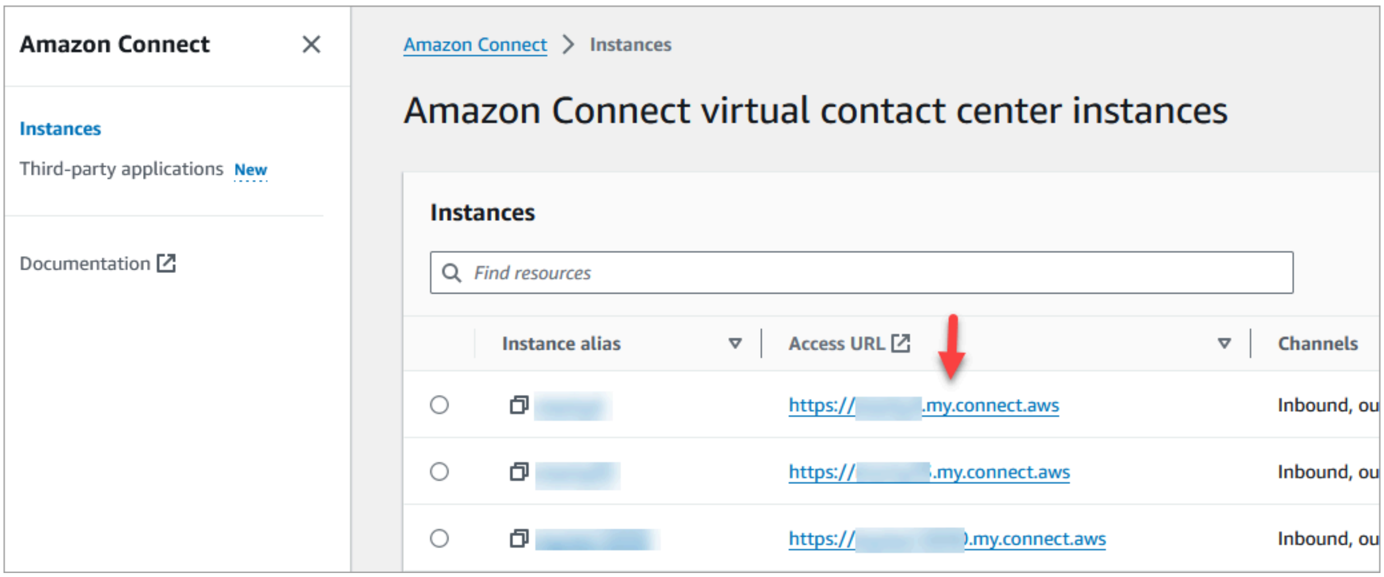
Keeping these domains in your allow list will ensure a smooth transition. You can remove them later, after the migration is complete.

For more information about setting up your allowlist, see [Set up your network to use the Amazon Connect Contact Control Panel (CCP)]().

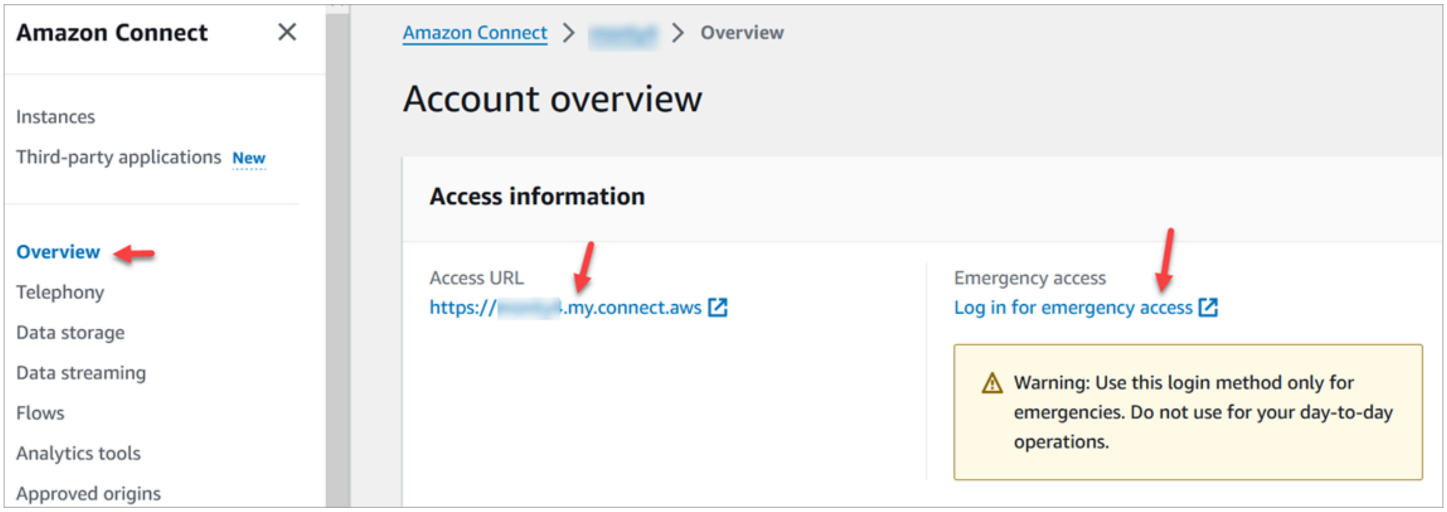
About the Amazon Connect access URL and emergency login

The Amazon Connect access URL and emergency login URLs will be updated in the AWS console after we complete the domain migration. Until that time, they will reflect the old domain.

The following image shows the location of the access URL on the **Amazon Connect virtual contact center instances** page. Even if you have taken steps to update your domain, this URL will continue to show the old domain. The URL on this page will update automatically when old domain traffic starts to redirect to the new domain. Please **do not use this URL to log in**; rather, communicate to your team the new URL that they should be using.



The following image shows the location of the emergency login URL on the **Account overview** page. This URL will lead to the old domain until traffic starts to automatically redirect to the new domain. Please **refrain from using this URL to log in unless it is an emergency**. Instead, log in with your username and password from the login page associated with your new domain.



Personal settings

Notify your team to the upcoming change so they can take steps to prevent confusion and disruption. If you have internal documentation that includes links, please review and update accordingly. Encourage team members to update their browser bookmarks *for the login page*, and productivity apps, such as Alfred.

To ensure a seamless transition for your team, we encourage you to take steps to identify any URL references.

Transport Layer Security (TLS)

If your agents are using browsers that Amazon Connect supports, there is no action for you. For example, if you are using the latest Chrome and Firefox versions, no action is needed.

If you are using TLS 1.1 and below, you need to upgrade your tools to support the TLS 1.1+ protocols.

We require your TLS protocol to be TLS 1.2 and recommend TLS 1.3. The new domain does not support TLS 1.1 and TLS 1.0.

We recommend that you review the new TLS policy: ALB FS-1-2-Res-2019-08. For reference, you can find the previous TLS policy here: CloudFront TLSv1.

Flows in Amazon Connect

A *flow* defines the customer experience with your contact center from start to finish. Amazon Connect includes a set of default flows so you can quickly set up and run a contact center. However, you may want to create custom flows for your specific scenario.

Contents

Permissions required to work with flows in Amazon Connect

To view, edit, create, and publish flows you need **Flows** permissions added to your security profile.

By default, users who are assigned to the **Admin** and **CallCenterManager** security profiles have Flows permissions.

Default flows in Amazon Connect for your call center

Amazon Connect includes a set of default flows that have already been published. It uses them to power your contact center.

For example, say you create a flow that includes putting the customer on hold, but you don't create a prompt for it. The default flow, **Default agent hold**, will be played automatically. This is a way to help you get started with your call center quickly.

> **Tip**
>
> If you want to change the behavior of a default flow, we recommend creating a new customized flow based on the default. Then call the new flow intentionally in your flows rather than defaulting to it. This gives you better control over how your flows work.

To see the list of default flows in the Amazon Connect console, go to **Routing**, **Flows**. They all start with **Default** in their name.

Contents

Change a default flow in your Amazon Connect contact center

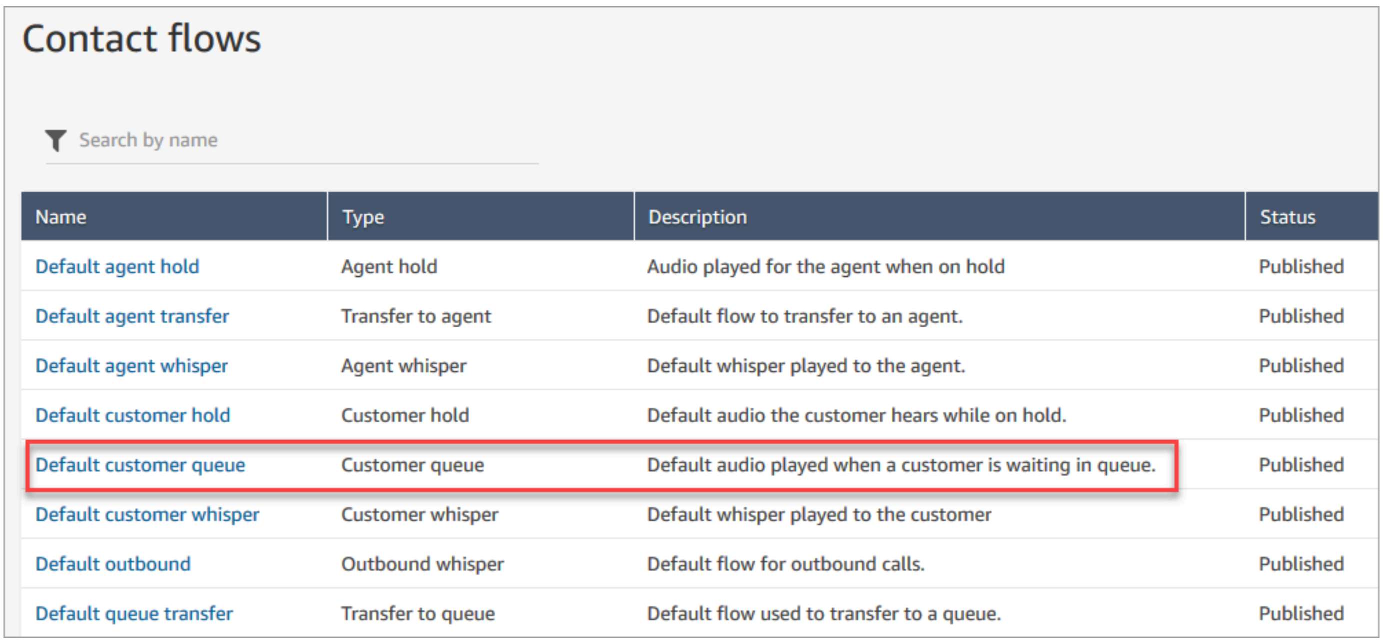
You can override the way the default flows work by editing them directly.

Generally we recommend creating new flows based on the defaults, rather than editing the default flow directly. You can make a copy of the default flow, assign a name that indicates it's a custom version, and then edit that one. This gives you more control over how your flows work.

Change how a default flow works in Amazon Connect

The following steps show how to change the default message customers hear when they are put in a queue to wait for the next available agent.

1. On the navigation menu, choose **Routing**, **Flows**.
2. Choose the default flow you want to customize. For example, choose **Default customer queue** if you want to create your own message when a customer is put in queue instead of using the one we've provided. This is shown in the following image.

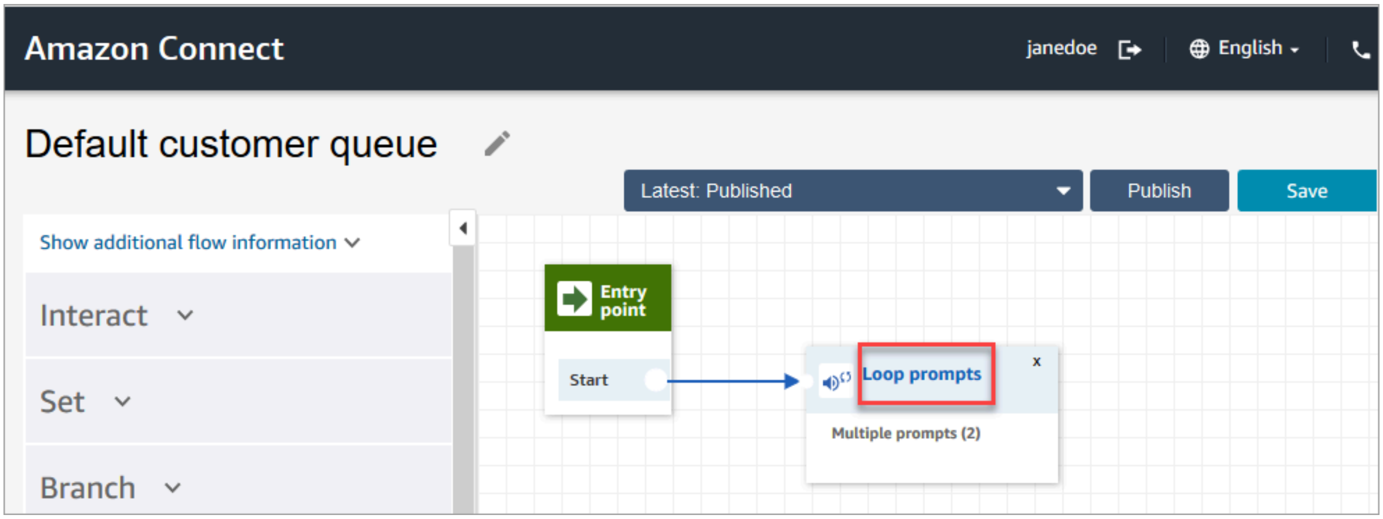


Contact flows

Search by name

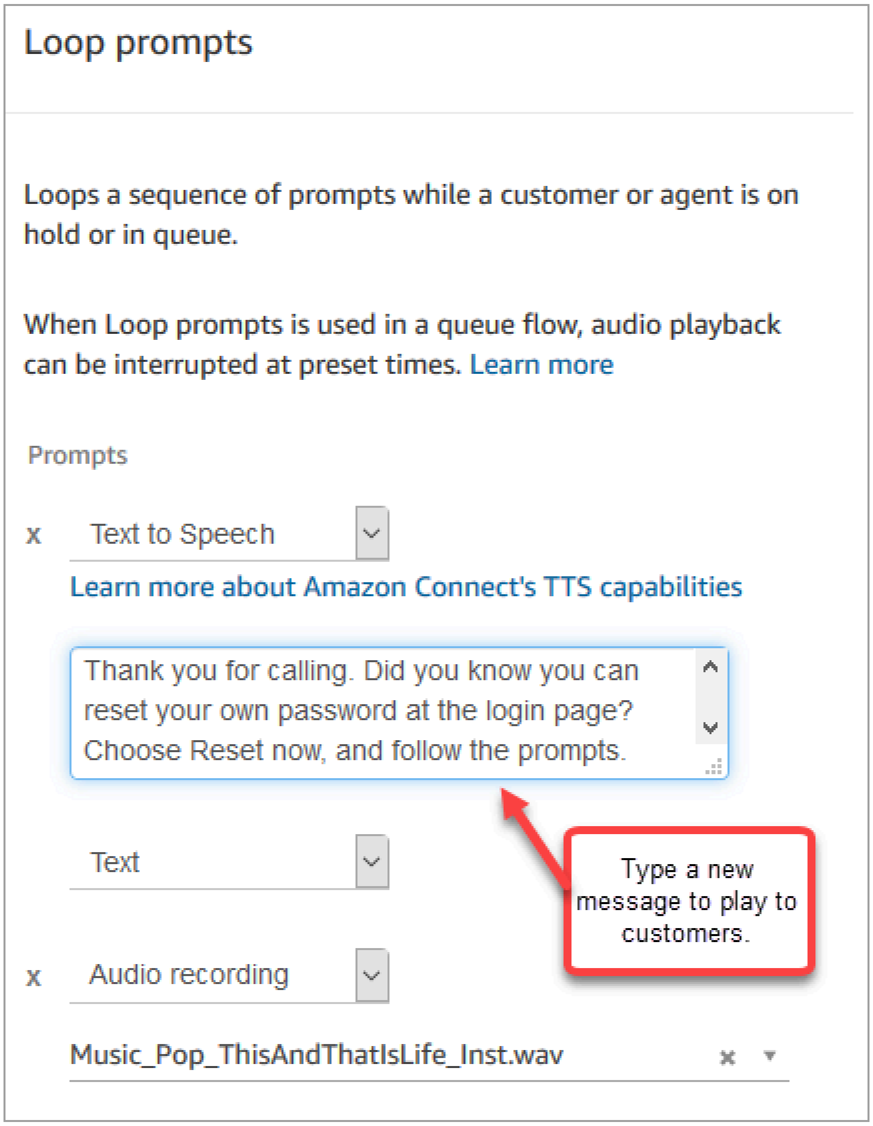
Name	Type	Description	Status
Default agent hold	Agent hold	Audio played for the agent when on hold	Published
Default agent transfer	Transfer to agent	Default flow to transfer to an agent.	Published
Default agent whisper	Agent whisper	Default whisper played to the agent.	Published
Default customer hold	Customer hold	Default audio the customer hears while on hold.	Published
Default customer queue	Customer queue	Default audio played when a customer is waiting in queue.	Published
Default customer whisper	Customer whisper	Default whisper played to the customer	Published
Default outbound	Outbound whisper	Default flow for outbound calls.	Published
Default queue transfer	Transfer to queue	Default flow used to transfer to a queue.	Published

3. To customize the message, choose the **Loop prompts** block to open the properties page.

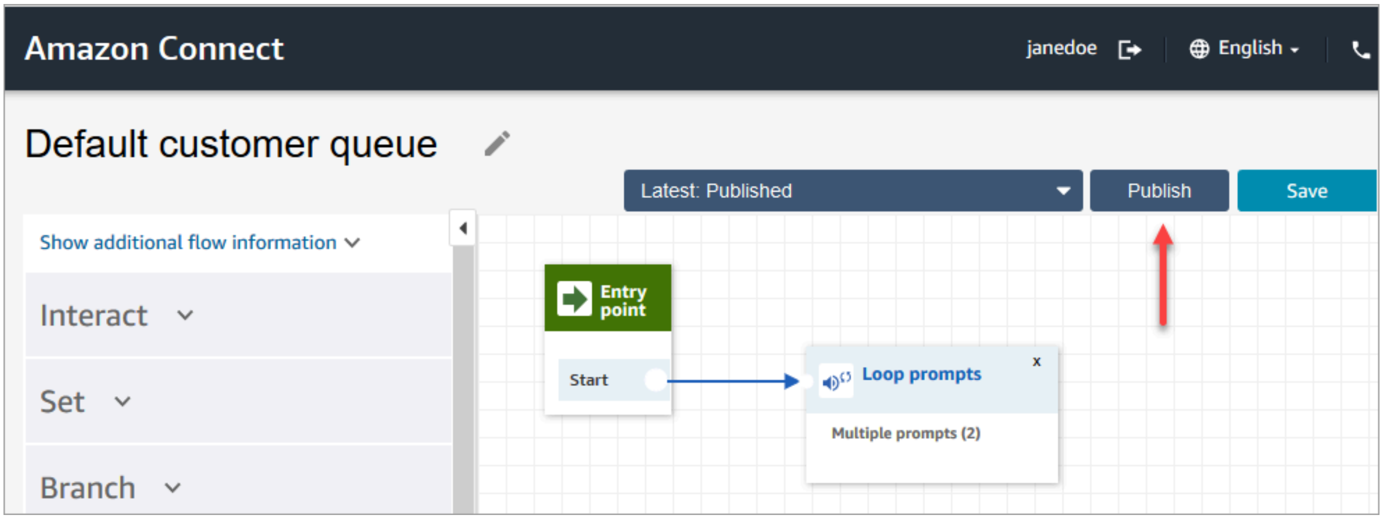


4. On the **Properties** page of the **Loop prompts** block, use the dropdown box to either choose different music, or set to **Text to Speech**. Type a message to be played.

   For example, the following image shows the message "*Thank you for calling. Did you know you can reset your own password at the login page? Choose Reset now, and following the prompts.*"



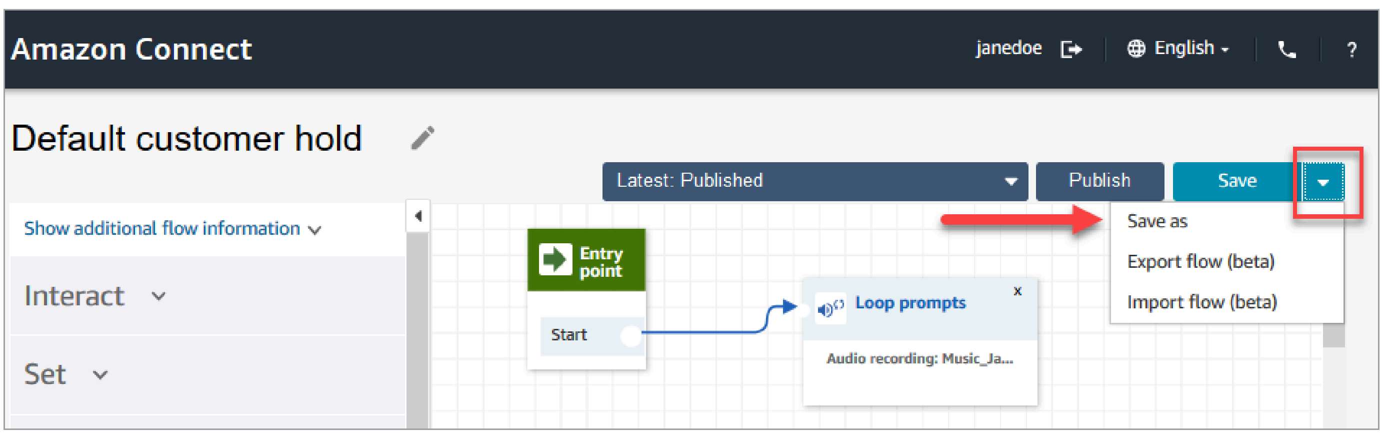
5. Choose **Save** at the bottom of the properties page.
6. Choose **Publish**. Amazon Connect starts playing the new message almost immediately (it may take a few moments for it to fully take effect).



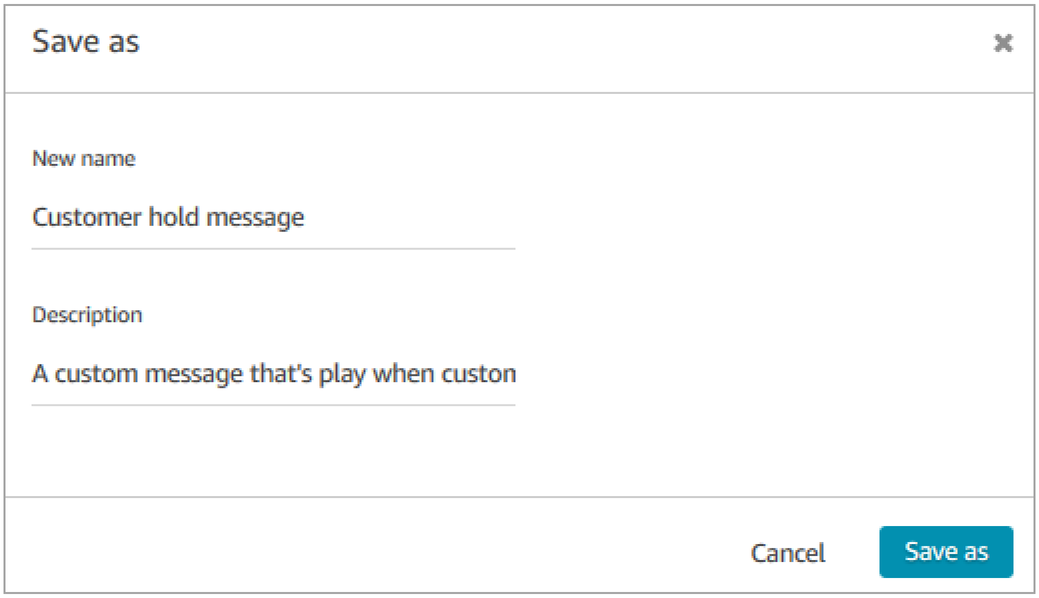
Copy a default flow before customizing it

Use the following steps to create a new flow based a current default.

1. On the navigation menu, choose **Routing**, **Flows**.
2. Choose the default flow you want to customize.
3. In the upper right corner of the page, choose the **Save** drop-down arrow. Choose **Save as**, as shown in the following image.



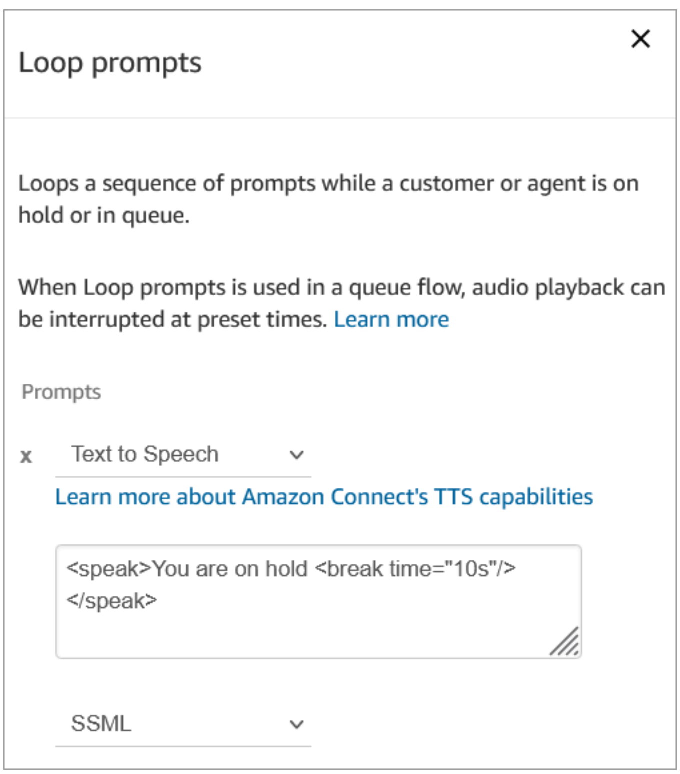
4. Assign a new name for the flow, for example, **Customer hold message**.



5. Add the new flow (in this case, **Customer hold message**) to the flows you create so it's run instead of the default.

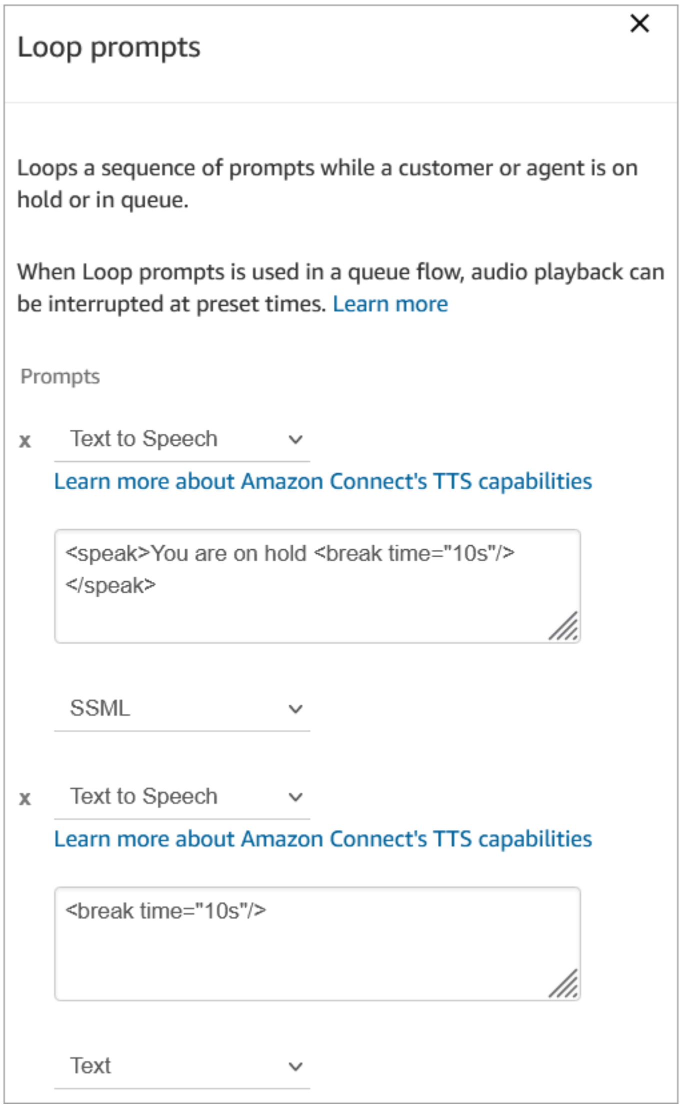
Default agent hold flow in Amazon Connect: "You are on hold"

The **Default agent hold** flow is the experience the agent receives when placed on hold. During this flow, a **Loop prompt** block plays the message "You are on hold" to the agent every 10 seconds.



You can set **break time** to a maximum of 10 seconds. This means the maximum amount time you can specify between **You are on hold** messages is 10 seconds. To make the time between longer, add multiple prompts to the loop. For example, if you want 20 seconds between **You are on hold** messages:

- The first prompt may say **You are on hold** with **break time="10s"**
- Add another prompt with a blank message and break time="10s".



For instructions about how to override and change a default flow, see [Change a default flow in your Amazon Connect contact center](#).

> **Tip**
>
> Wondering if a default flow has been changed? Use flow version control to view the original version of the flow.

Default agent transfer flow in Amazon Connect: "Transferring now"

This default transfer flow is what the "from" agent experiences when they transfer a contact to another agent by using Create quick connects in Amazon Connect. The "from" agent hears a **Play prompt** play the message "Transferring now." Then the **Transfer to agent** block is used to transfer the contact to the agent.

When the contact is transferred, the "to" agent hears the Default agent whisper.

> **Tip**
>
> The **Transfer to Agent** block is a beta feature and only works for voice interactions. To transfer a chat contact to another agent, follow these instructions: Use contact attributes to route contacts to a specific agent.

For instructions about how to override and change a default flow, see Change a default flow in your Amazon Connect contact center.

> **Tip**
>
> Wondering if a default flow has been changed? Use flow version control to view the original version of the flow.

Default customer queue flow in Amazon Connect: queue message and music

This default flow is played when a customer is placed in a queue.

1. The loop has a one-time voice prompt:

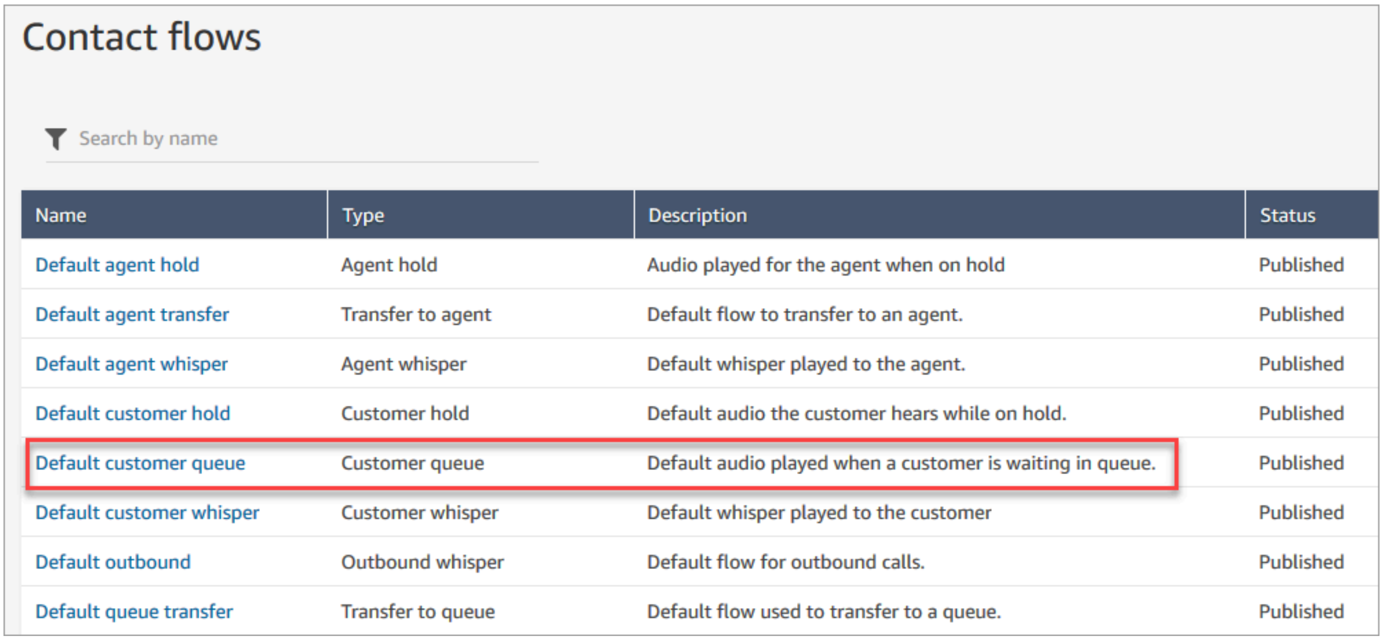
Thank you for calling. Your call is very important to us and will be answered in the order it was received.

2. It plays queue music in .wav format that's been uploaded to the Amazon Connect instance.
3. The customer remains in this loop until their call is answered by an agent.

Change the default message a customer hears when they are put in queue

The following steps show how to change the default message customers hear when they are put in a queue to wait for the next available agent.

1. On the navigation menu, choose **Routing**, **Flows**.
2. On the **Flows** page, choose **Default customer queue**, as shown in the following image.

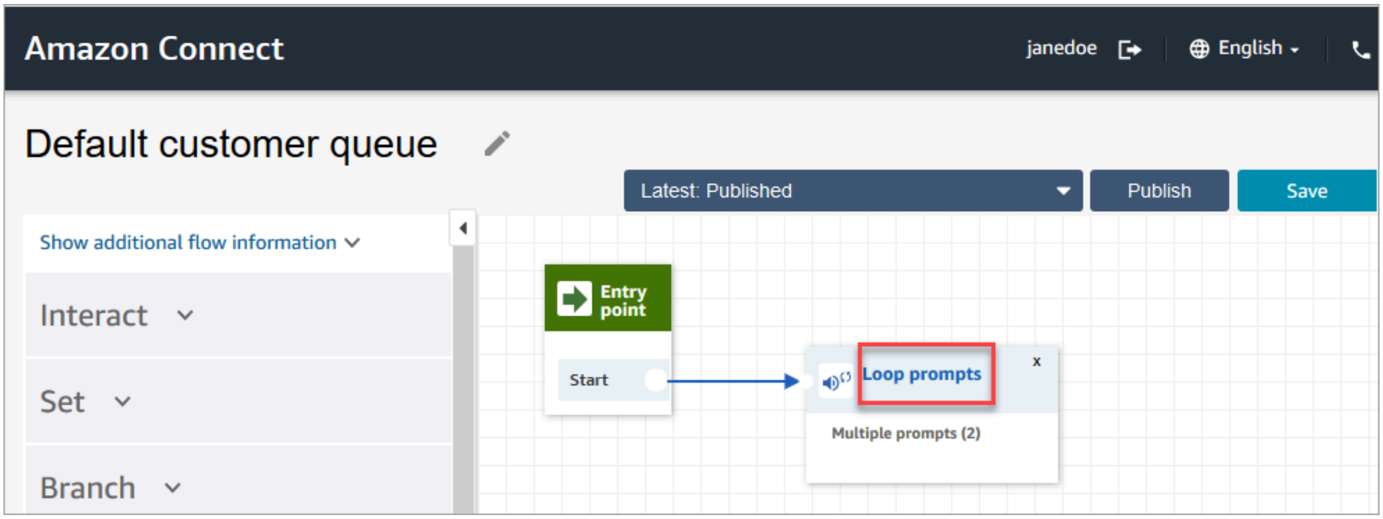


Contact flows

Search by name

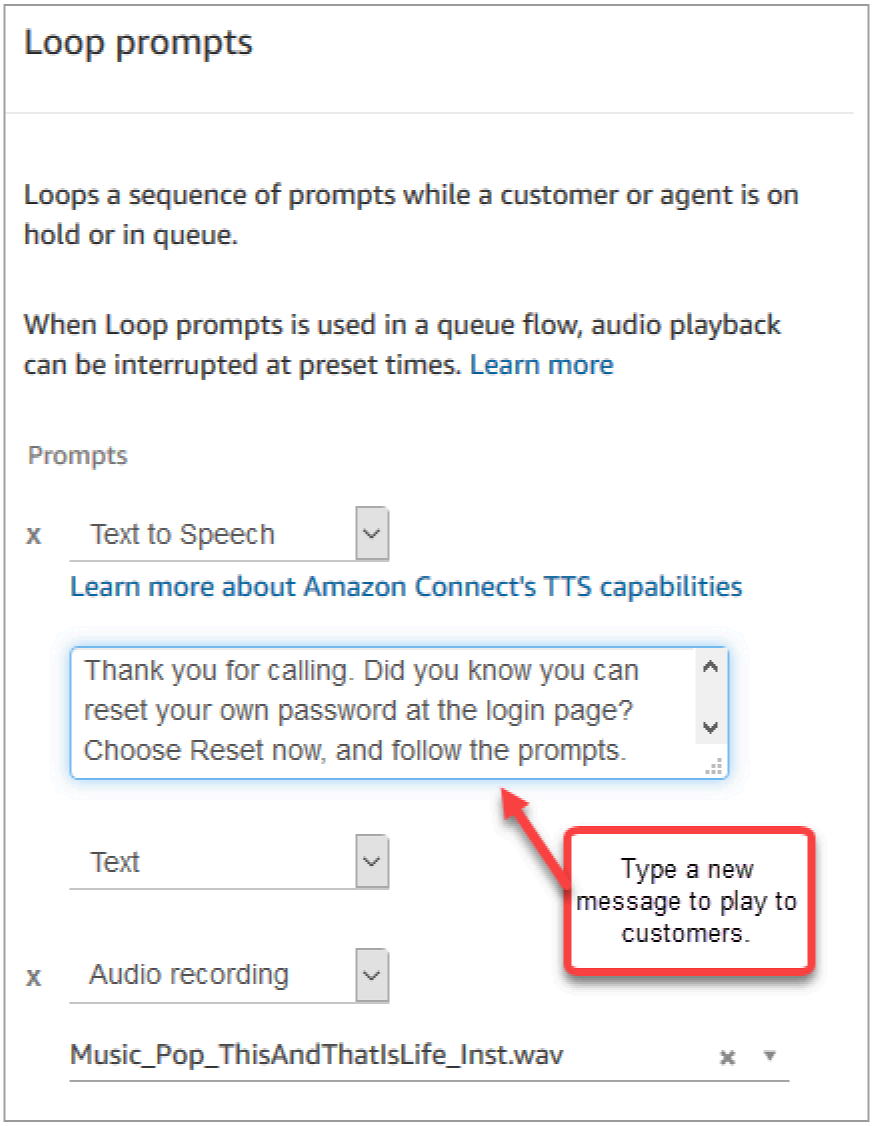
Name	Type	Description	Status
Default agent hold	Agent hold	Audio played for the agent when on hold	Published
Default agent transfer	Transfer to agent	Default flow to transfer to an agent.	Published
Default agent whisper	Agent whisper	Default whisper played to the agent.	Published
Default customer hold	Customer hold	Default audio the customer hears while on hold.	Published
Default customer queue	Customer queue	Default audio played when a customer is waiting in queue.	Published
Default customer whisper	Customer whisper	Default whisper played to the customer	Published
Default outbound	Outbound whisper	Default flow for outbound calls.	Published
Default queue transfer	Transfer to queue	Default flow used to transfer to a queue.	Published

3. To customize the message, choose the **Loop prompts** block to open the properties page.

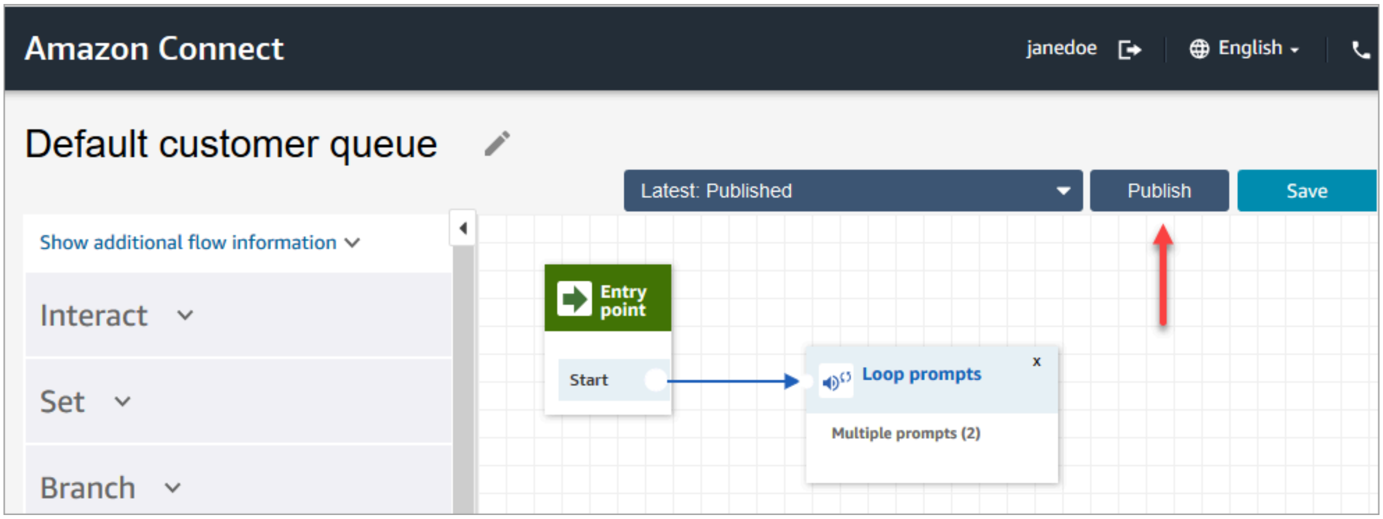


4. Use the dropdown box to either choose different music, or set to **Text to Speech** and then type a message to be played,

   For example, the following image shows the message "*Thank you for calling. Did you know you can reset your own password at the login page? Choose Reset now, and following the prompts.*"



5. Choose **Save** at the bottom of the properties page.
6. Choose **Publish**. Amazon Connect starts playing the new message almost immediately (it may take a few moments for it to fully take effect).



Default customer whisper flow in Amazon Connect: play a beep sound

This flow uses a Set whisper flow block to play a message for the customer when the customer and agent are joined. It uses a "beep" sound to notify a customer that their call has been connected to an agent.

Use the Set whisper flow block to override or disable the default customer whisper in a voice conversation.

> **Important**
>
> Chat conversations do not include a default whisper. You need to include a Set whisper flow for default agent or customer whispers to play. For instructions, see Set the default whisper flow in Amazon Connect for a chat conversation.

Default agent whisper in Amazon Connect: name of the queue

This flow uses a Set whisper flow block to play a message for the agent when the customer and agent are joined.

The name of the queue is played to the agent. It identifies the queue that the customer was in. The name of the queue is retrieved from the system variable `$.Queue.Name`.

Use the Set whisper flow block to override or disable the default agent whisper in a voice conversation.

> **Important**
>
> Chat conversations do not include a default whisper. You need to include a Set whisper flow for default agent or customer whispers to play. For instructions, see Set the default whisper flow in Amazon Connect for a chat conversation.

For more information about system variables, see System attributes.

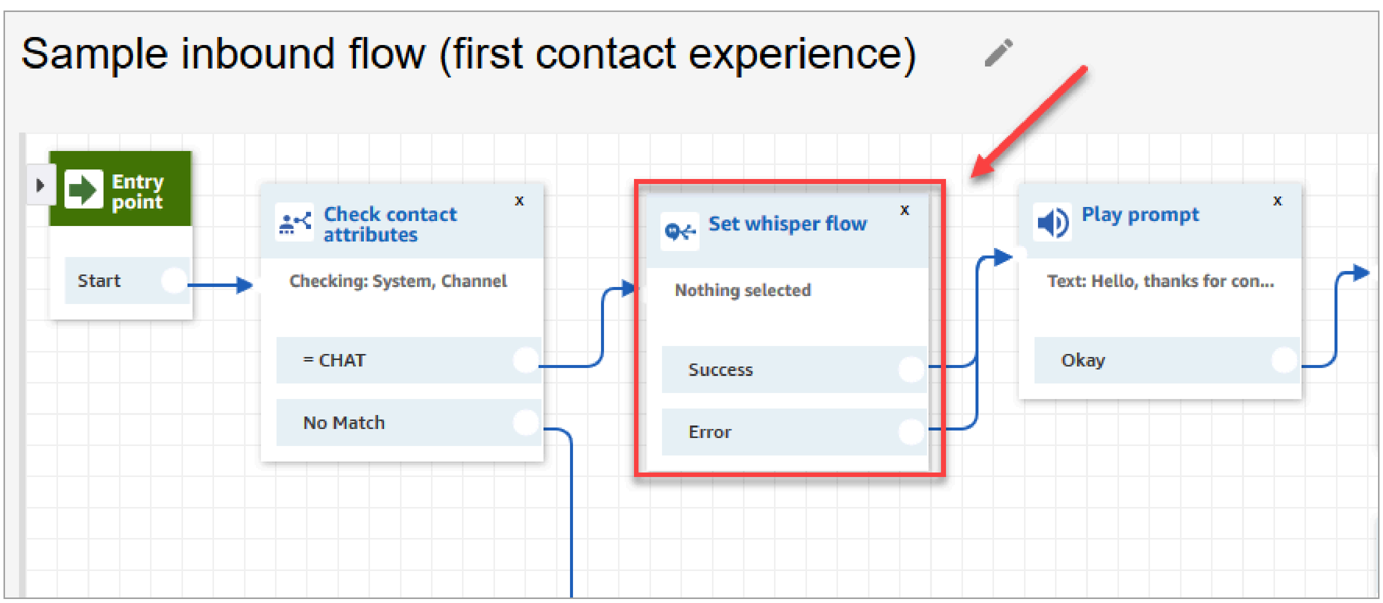
> **Tip**
>
> Wondering if a default flow has been changed? Use flow version control to view the original version of the flow.

Set the default whisper flow in Amazon Connect for a chat conversation

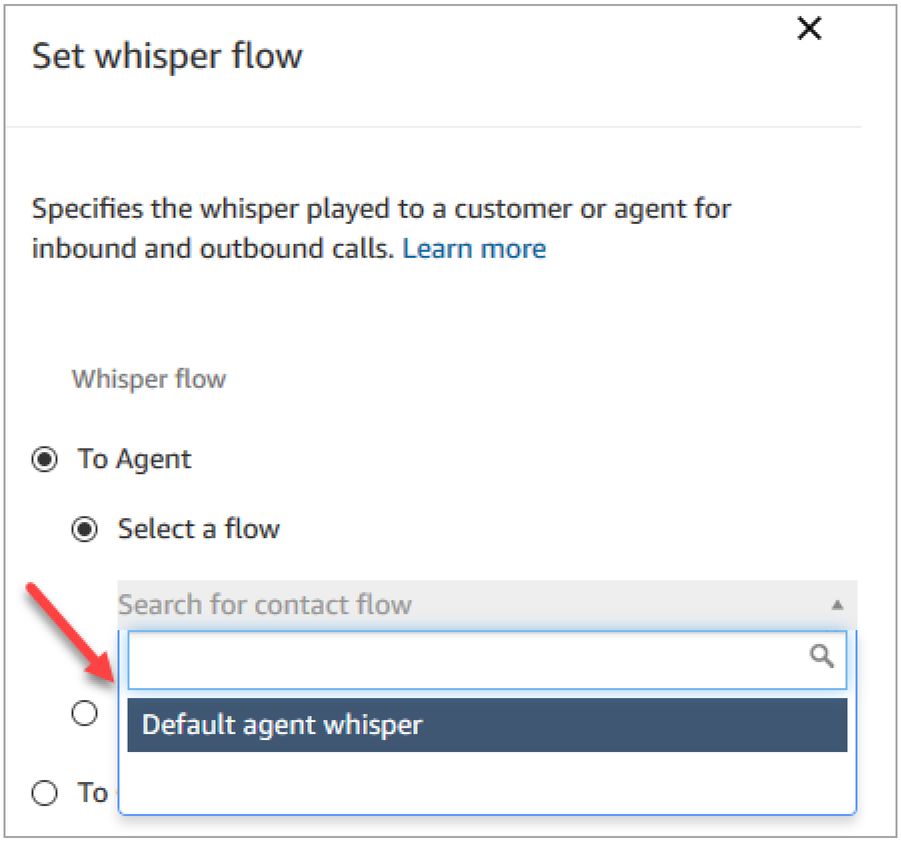
For chat conversations, you need to include a **Set whisper flow** block for default agent or customer whispers to play.

For example, to set the default whisper flow for chats that use the Sample inbound flow:

1. Go to **Routing**, **Flows**, and choose the Sample inbound flow.
2. Add a **Set whisper flow** block after the chat channel has branched, as shown in the following image:



3. In the **Set whisper flow** block, open the properties page, and choose the flow you want to play as the default for chat conversations. For example, you might choose **Default whisper flow** to show agents the name of the originating queue in the chat window. This is helpful when agents are managing more than one queue.



4. Choose **Save**.

Default customer hold: hold music

This flow starts when the customer is put on hold. It plays the audio that the customer hears while on hold.

For instructions about how to override and change a default flow, see Change a default flow in your Amazon Connect contact center.

> **Tip**
>
> Wondering if a default flow has been changed? Use flow version control to view the original version of the flow.

Default outbound flow in Amazon Connect: "This call is not being recorded"

> **Important**
>
> Before using the **Send message** block in an outbound flow, see Important information about using the Send message block in outbound flows for recommended safeguards you should implement.

This flow is an outbound whisper that manages what the customer experiences as part of an outbound call, before being connected with an agent.

1. It starts with an optional **Set recording behavior** block. Then a prompt plays the following message:

   This call is not being recorded.
2. The flow ends.
3. The customer remains in the system (on the call) after the flows ends.

For instructions about how to override and change a default flow, see Change a default flow in your Amazon Connect contact center.

> **Tip**
>
> Wondering if a default flow has been changed? Use flow version control to view the original version of the flow.

Default queue transfer flow in Amazon Connect: "Now transferring"

This flow manages what the agent experiences when they transfer a customer to another queue.

It starts with a **Check hours of operation** block to check the hours of operation for the current queue. The **In hours** option branches to the **Check staffing** block to determine whether agents are available, staffed, or online.

If it returns **True** (agents are available), the flow goes to the **Transfer to queue** block. If it returns **False** (no agents are available), the flow plays a prompt and disconnects the call.

For instructions about how to override and change a default flow, see Change a default flow in your Amazon Connect contact center.

> **Tip**
>
> Wondering if a default flow has been changed? Use flow version control to view the original version of the flow.

Default prompts from Amazon Lex: "Sorry .. "

If you add an Amazon Lex classic bot (not Amazon Lex V2) to your contact center, know that it also has some default prompts that it uses for error handling. For example:

- Sorry, can you please repeat that?
- Sorry, I could not understand. Goodbye.

To change default Amazon Lex prompts

1. In Amazon Lex, go to your bot.
2. On the Editor tab, choose Error Handling.
3. Change the text as needed. Choose **Save**, then **Build** and **Publish**.

Sample flows in Amazon Connect

Amazon Connect includes a set of sample flows that show you how to perform common functions. They are designed to help you learn how to create your own flows that work in a similar way. For example, if you want to add a queued callback flow to your call center, take a look at the Sample queued callback flow in Amazon Connect flow.

To explore how the sample flows work

1. Claim a number if you haven't already: go to **Channels**, **Phone numbers**, **Claim a number**.
2. Choose the **DID** tab, then choose a number.

3. In **Flow / IVR** use the drop down to choose the sample flow you want to try. Click **Save**.

4. Call the number. The sample flow that you selected starts.

   We recommend opening the sample flow in the flow designer and following along to see how it works while you're experiencing it.

To open a sample flow in the flow designer

1. In Amazon Connect choose **Routing**, **Flows**.
2. On the **Flows** page, scroll down to the flows with names that start with **Sample**.
3. Choose the flow you want to view.

The topics in this section describe how each of the sample flows work.

Contents

Sample inbound flow in Amazon Connect for the first contact experience

> **Note**
>
> This topic explains a sample flow that is included with Amazon Connect. For information about locating the sample flows in your instance, see Sample flows in Amazon Connect.

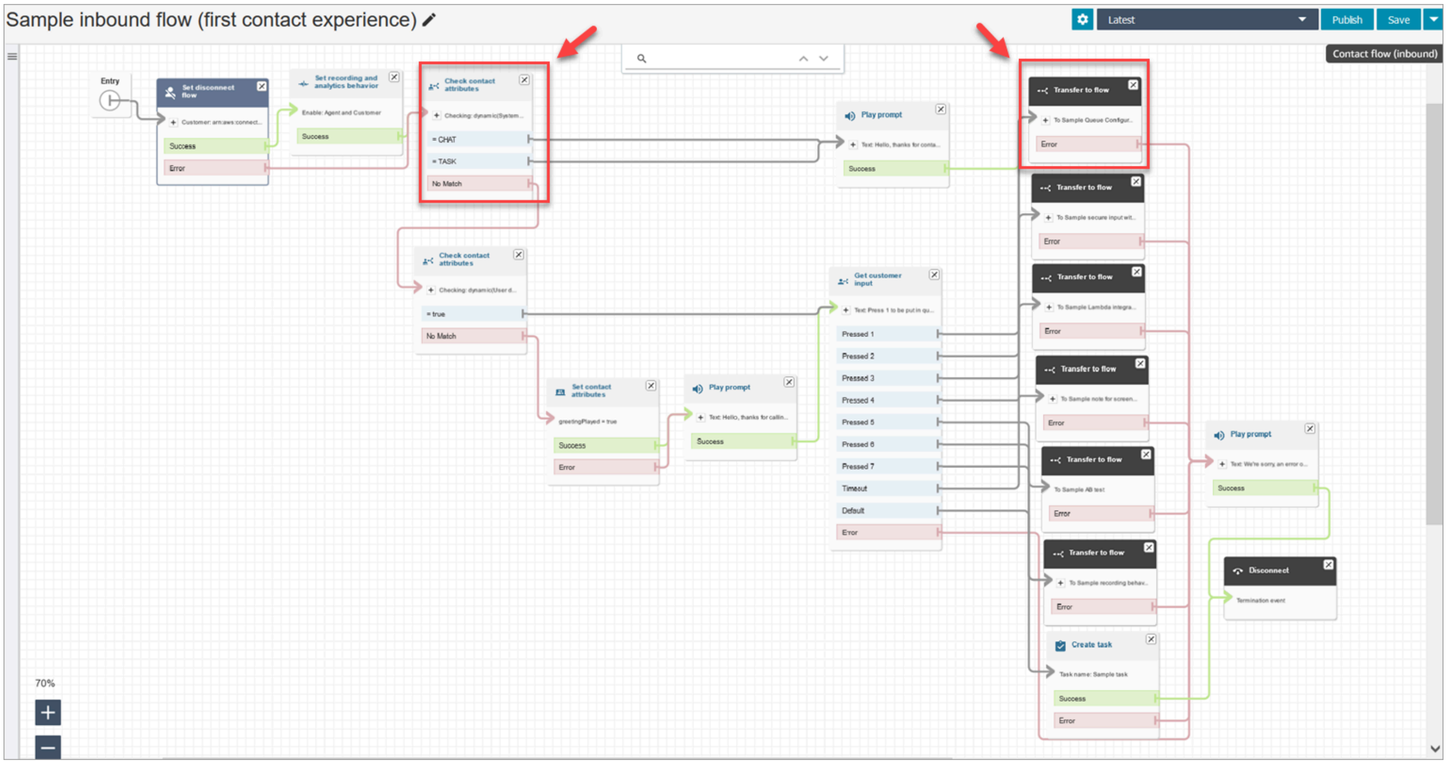
Type: Flow (inbound)

This sample flow is automatically assigned to the phone number that you claimed when you first set up flows. For more information, see Get started.

It uses the Check contact attributes block to determine if the contact is contacting you by phone or chat, or if it is a task, and to route them accordingly.

- If the channel is chat or task, the contact is transferred to the Sample queue configurations flow in Amazon Connect.
- If the channel is voice, then based on user input the contact is either transferred to the other sample flows or a sample follow-up agent task is created for this contact.

The following image shows the sample inbound flow. We recommend viewing the flow in the flow designer so you can see the details.



Sample flow in Amazon Connect for A/B contact distribution testing

> **Note**
>
> This topic explains a sample flow that is included with Amazon Connect. For information about locating the sample flows in your instance, see [Sample flows in Amazon Connect](#).

Type: Flow (inbound)

This flow shows how to perform an A/B call distribution based on a percentage. Here's how it works:

1. The **Play prompt** block uses Amazon Polly, the text-to-speech service, to say "Amazon Connect will now simulate rolling dice by using the Distribute randomly block. Now rolling."
2. The contact reaches the **Distribute by percentage** block, which routes the customer randomly based on a percentage.

   Distribute by percentage simulates a dice roll, resulting in a values between 2 to 12 with different percentages. For example, there is 3 percent chance for the "2" option, 6 percent chance for the "3" option, and so on.

3. After the contact gets routed, the **Play prompt** tells the customer which number the dice rolled.
4. At the end of the sample, the **Transfer to flow** block transfers the customer back to the Sample inbound flow.

Sample customer queue priority flow in Amazon Connect

> **Note**
>
> This sample flow is available in previous Amazon Connect instances. In new instances, you can see this functionality in Sample queue configurations flow in Amazon Connect.

Type: Flow (inbound)

By default the priority for new contacts is 5. Lower values raise the priority of the contact. For example, a contact assigned a priority of 1 is routed first.

This sample shows how you can use the **Change routing priority/age block** to raise or lower the priority of a contact in a queue. Using this block, there are two ways you can raise or lower a customer's priority:

- Assign them a new priority value, such as 1, to raise their priority.
- Or, increase the routing age of the contact. Customers who are queued longer are routed first, when all contacts have the same queue priority value (such as 5).

Option 1: Raise the priority

- The **Get Customer Input** block prompts the customer to press 1 to move to the front of the queue. This block gets the customer's input; it doesn't actually change the customer's priority.
- If the customer presses 1, they go down the "Pressed 1" branch, which takes them to the **Change routing priority/age block**. This block changes their priority in the queue to 1, which is the highest priority.

Option 2: Change the routing age

- The **Get Customer Input** block prompts the customer to press 2 to move behind existing contacts already in queue. This block gets the customer's input; it doesn't actually change the customer's priority.
- If the customer presses 2, they go down the "Pressed 2" branch, which takes them to a different **Change routing priority/age** block. This block increases their routing age by 10 minutes. This has the effect of moving them ahead of others in the queue who have been waiting longer.

Sample disconnect flow in Amazon Connect

> **Note**
>
> This topic explains a sample flow that is included with Amazon Connect. For information about locating the sample flows in your instance, see Sample flows in Amazon Connect.

Type: Flow (inbound)

This sample works with voice, chat, and task contacts.

Chat contacts

1. The **Play prompt** block shows a text message that the agent has disconnected.
2. A **Wait** block sets the timeout period for 15 minutes. If the customer returns in 15 minutes, the customer is transferred to a queue to chat with another agent.
3. If the customer doesn't return, the timer expires and the chat disconnects.

Voice contacts

1. Sets a user-defined attribute, DisconnectFlowRun. If it = Y, disconnect.
2. Gets customer input, whether they were happy with service.
3. Terminates flow.

Task contacts

1. Checks contact attributes, whether Agent ARN = NULL.

2. Transfers to agent's queue.
3. If at capacity, disconnects.

For a list and description of all the disconnect reasons, see **DisconnectReason** in the [ContactTraceRecord](#).

Sample queue configurations flow in Amazon Connect

> **Note**
>
> This topic explains a sample flow that is included with Amazon Connect. For information about locating the sample flows in your instance, see Sample flows in Amazon Connect.

Type: Flow (inbound)

This flow shows different ways you can put a customer in queue: you can change the priority of the customer, determine the wait time in queue, and give them an option for a callback. Here's how it works:

1. The customer is put in the BasicQueue.
2. After that, the **Default customer queue** flow is invoked. This block runs a **Loop prompts** block that plays the following:

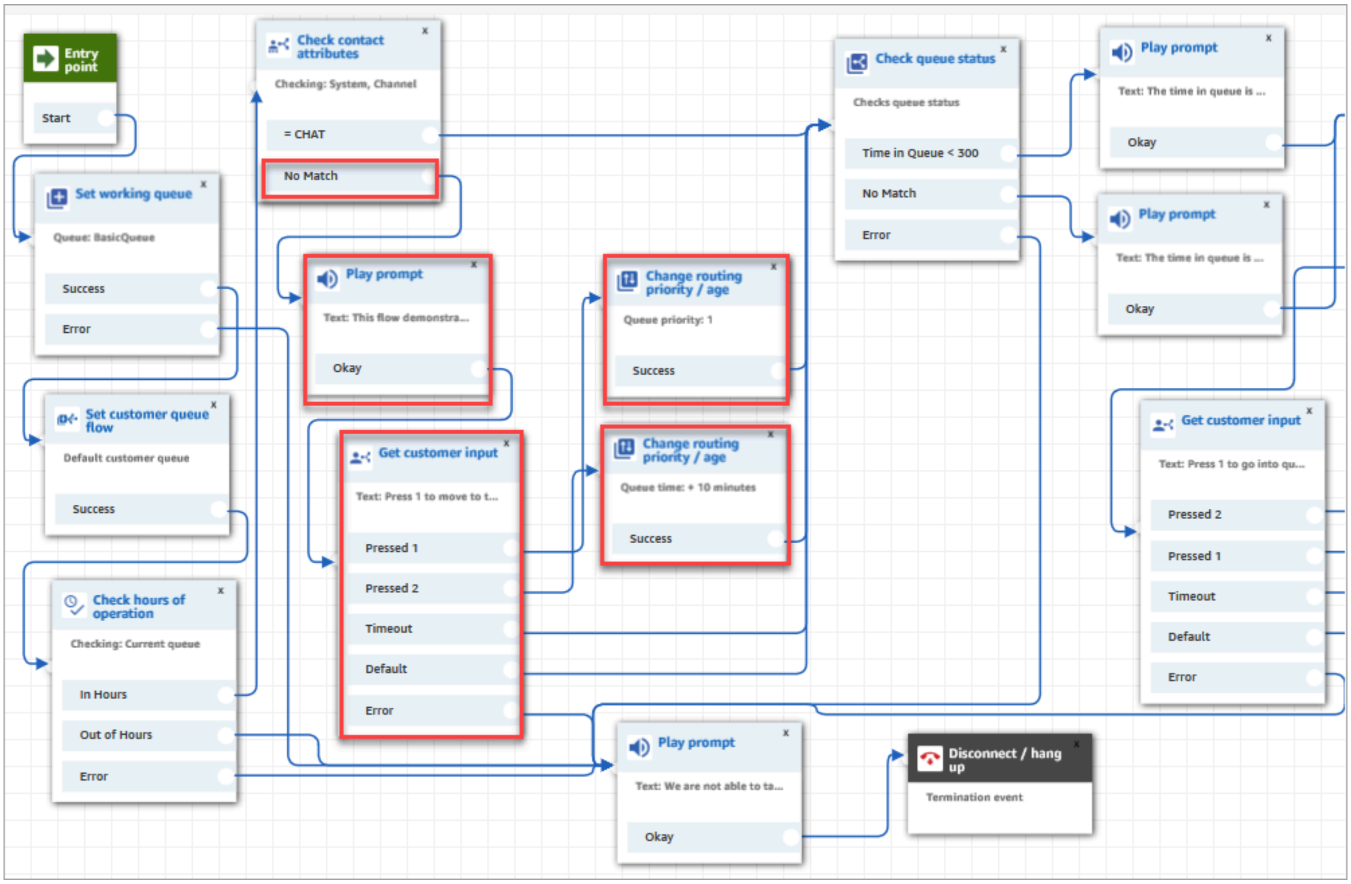
   Thank you for calling. Your call is very important to us and will be answered in the order it was received.
3. The hours of operation are checked with a **Check hours of operation** block.
4. The channel is checked with a **Check contact attributes** block:

   - If chat, we check the time in queue. If it's less than 5 minutes, the customer is placed in queue for an agent. If it's more, we check the channel again and if it's chat, put the customer in queue for an agent.
   - If voice, the customer is routed down the **No Match** branch, to a **Play prompt** block and then to a **Get customer input** block.

     In the **Get customer input** block, we give the customer the option to press 1 to move to the front of the queue or 2 to move to the end of the queue.

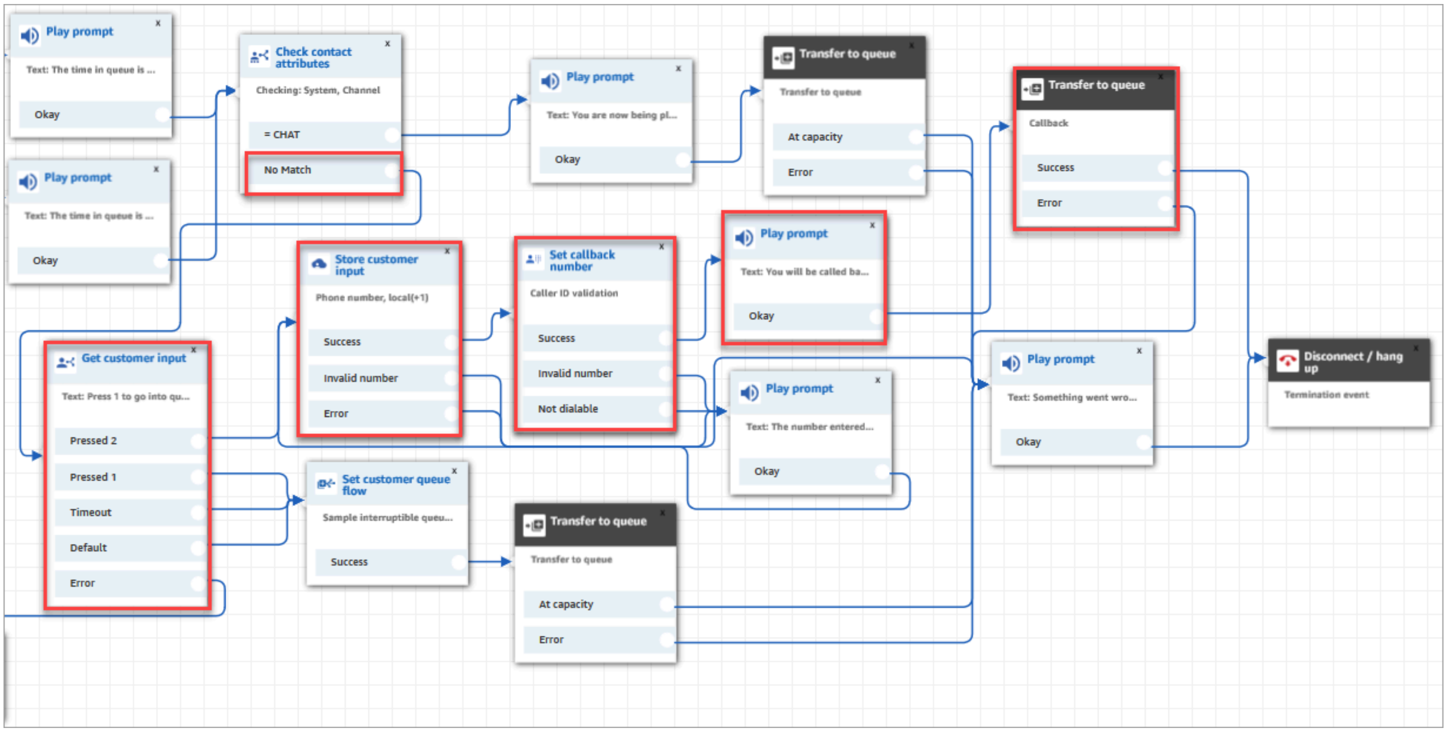
The two **Change routing priority / age** blocks move the customer to the front or back of the queue.

The following image of the sample flow shows this page highlighted:



5. Next we use a **Check queue status** block to check whether the time in queue is less than 300 seconds.
6. We use a **Play prompt** block to tell the customer the results.
7. We use a **Check contact attributes** block again to check the customer's channel: chat or voice/ No Match.

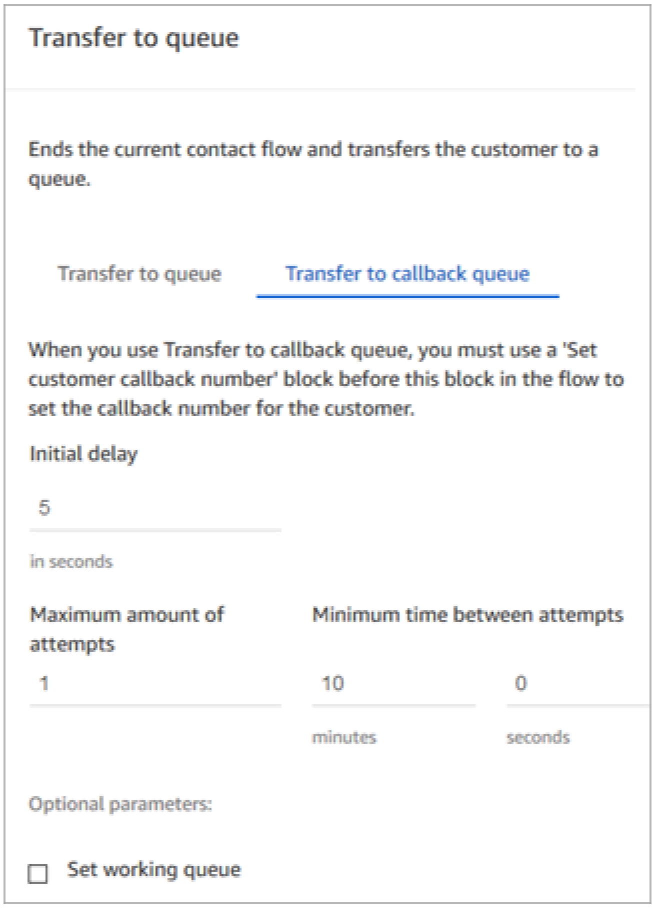
These next steps apply to customers who were routed down the voice/**No Match** branch, as shown in the following image:



1. In the **Get customer input** block, we prompt customers to *Press 1 to go into queue or 2 to enter a callback number.*
2. If customers press 2, they are routed down the **Pressed 2** branch to the **Store customer input** block.
3. The **Store customer input** block prompts the customer for their phone number.
4. The customer's phone number is stored in the **Stored customer input attribute**, by the **Set callback number** block.
5. We use a [Transfer to queue](#) block to put the customer in a callback queue.
6. The [Transfer to queue](#) block is configured so Amazon Connect waits 5 seconds between the time the callback contact is initiated and the contact is enqueued, where it sits until it is offered to an available agent.

   If the initial callback doesn't reach the customer, Amazon Connect will attempt 1 callback. If it were configured for 2 attempted callbacks, it would wait 10 minutes between each one.

   Also, no special callback queue is specified. Rather, customers are in the BasicQueue, which was set at the beginning of the flow.



For information about queued callbacks, see the following topics:

- Set up queued callback by creating flows, queues, and routing profiles in Amazon Connect
- Flow block in Amazon Connect: Transfer to queue
- Queued callbacks in real-time metrics in Amazon Connect

Sample queue customer flow in Amazon Connect

> **Note**
>
> This topic explains a sample flow that is included with Amazon Connect. For information about locating the sample flows in your instance, see Sample flows in Amazon Connect.

Type: Flow (inbound)

This flow performs checks before placing customer into a queue. Here's how it works:

1. The **Set working queue** block determines which queue to transfer the customer to.
2. The **Check hours of operation** block perform checks to avoid the customer being queued during non-working hours.
3. The customer is transferred to the queue if it is within business hours, and the queue can handle this call. Otherwise, the customer is played a message "We are not able to take your call right now. Goodbye." And then the customer is disconnected.

Sample queued callback flow in Amazon Connect

Note

This sample flow is available in previous Amazon Connect instances. In new instances, you can see examples of queued callback in Sample interruptible queue flow with callback in Amazon Connect and Sample queue configurations flow in Amazon Connect.

Type: Flow (inbound)

This flow provides callback queue logic. Here's how it works:

1. After a voice prompt, a working queue is selected and its queue status is checked.
2. A voice prompt tells the customer if the wait time for the selected queue is longer than 5 minutes. Customers are offered a choice to wait in the queue or to be placed into a callback queue.
3. If the customer decides to wait in the queue, the **Set customer queue flow** block places them in a queue flow that provides a callback option. That is, it places them in **Sample interruptible queue flow with callback**.
4. If the customer chooses to be placed into a callback queue, their number is stored in the **Store customer input** block. Then their callback number is set, and they are transferred to the callback queue.

For information about queued callbacks, see the following topics:

- Set up queued callback by creating flows, queues, and routing profiles in Amazon Connect

- Flow block in Amazon Connect: Transfer to queue
- Queued callbacks in real-time metrics in Amazon Connect

Sample interruptible queue flow with callback in Amazon Connect

> **Note**
>
> This topic explains a sample flow that is included with Amazon Connect. For information about locating the sample flows in your instance, see Sample flows in Amazon Connect.

Type: Customer queue

This flow shows you how to manage what the customer experiences while in queue. It uses **Check contact attributes** to determine if the customer is contacting you by phone or chat, and to route them accordingly.

If the channel is chat, the customer is transferred to the **Loop prompts**.

If the channel is voice, the customer hears a looping audio that interrupts every 30 seconds to give them two options from the **Get customer input** block:

1. The customer can press 1 to enter a callback number. Then the **Get customer input** block prompts the customer for their phone number. Then the flow ends.
2. Press 2 ends the flow, and the customer remains in the queue.

Sample Lambda integration flow in Amazon Connect

> **Note**
>
> This topic explains a sample flow that is included with Amazon Connect. For information about locating the sample flows in your instance, see Sample flows in Amazon Connect.

Type: Flow (inbound)

This flow shows you how to invoke a Lambda function and do a data dip, that is, retrieve information about the customer. The data dip uses the caller's phone number to look up the US state they are calling from. If the customer is using chat, it returns a fun fact. Here's how it works:

1. A prompt tells the customer that a data dip is being performed.
2. The Invoke Lambda function block triggers **sampleLambdaFlowFunction**. This sample Lambda function determines the location of the phone number. The function times out in 4 seconds. If it times out, it plays a prompt that says "Sorry, we failed to find the state for your phone number's area code."
3. In the first **Check contact attributes** block, it checks the channel the customer is using: voice, chat, task. If chat, it returns a fun fact.
4. If voice, the second **Check contact attributes** block is triggered. It checks the match conditions of **State**, which is an external attribute. It uses an external contact attribute because it's getting data by using a process that's external to Amazon Connect
5. A prompt tells you that it's returning you back to **Sample inbound flow**, and then starts the **Transfer flow** block.
6. If the transfer fails, it plays a prompt and then disconnects the contact.

For more information about using attributes, see Store a value from a Lambda functions as a contact attribute in Amazon Connect.

Sample recording behavior in Amazon Connect

> **Note**
>
> This topic explains a sample flow that is included with Amazon Connect. For information about locating the sample flows in your instance, see Sample flows in Amazon Connect.

Type: Flow (inbound)

This flow starts by checking the channel of the contact:

- If the contact is a task, it is transferred to the Sample inbound flow.

- If the customer is using chat, they get a prompt that the **Set recording block** enables managers to monitor chat conversations. (To *record* chats, you only need to specify an Amazon S3 bucket where the conversation will be stored.)

  To monitor chats, the **Set recording block** is configured to record both the **Agent and Customer**.
- If the contact is using voice, a **Get customer input** block prompts them to enter the number for who they want to record. Their entry triggers the **Set recording behavior** block with the appropriate configuration.

It ends with the customer being transferred by to the Sample inbound flow.

For more information, see the following topics:

- Set up recording behavior using Amazon Connect Contact Lens
- Set up live monitoring for voice, chat, or both in Amazon Connect
- Review recorded conversations between agents and customers using Amazon Connect

Sample Screenpop flow in Amazon Connect

> **Note**
>
> This topic explains a sample flow that is included with Amazon Connect. For information about locating the sample flows in your instance, see Sample flows in Amazon Connect.

Type: Flow (inbound)

This flow shows you how to use Screenpop, a Contact Control Panel feature, to load a web page with parameters based on attributes.

In this sample flow, a **Set contact attributes** block is used to create an attribute from a text string. As an attribute, the text can be passed to the CCP to display a note to an agent.

Sample secure customer data entry input in a call with a contact center agent

> **Note**
>
> This topic explains a sample flow that is included with Amazon Connect. For information about locating the sample flows in your instance, see Sample flows in Amazon Connect.

Type: Queue transfer

This flow shows you how to allow customers to input sensitive data while putting the agent on hold. In a production environment, we recommend using encryption instead of this solution.

Here's how it works:

1. This flow begins with checking the customer's channel. If they are using chat, they are put in a queue.
2. If they are using voice, the agent and customer are put in a conference call.
3. A **Play prompt** tells the customer that the agent will be put on hold while customer enters their credit card information.
4. When the prompt is finished playing, the agent is put on hold using a **Hold customer or agent** block. If an error occurs, a prompt is played that agent was unable to put on hold, after which the contact flow is ended.
5. The customer's input is stored using the **Store Customer Input** block. This block encrypts the sensitive customer information using a signing key that must be uploaded in .pem format.
6. After the customer's data is collected, the agent and customer are put back on call using the **Conference All** option in another **Hold customer or agent** block.
7. The error branch runs if there's an error while capturing the customer's data.

Sample secure customer data entry input in a call with no contact center agent

> **Note**
>
> This topic explains a sample flow that is included with Amazon Connect. For information about locating the sample flows in your instance, see Sample flows in Amazon Connect.

Type: Flow (inbound)

This flow shows you how to capture sensitive customer data and encrypt it using a key. Here's how it works:

1. It begins by checking the contact's channel. If they are using chat, a prompt is played that this doesn't work with chat, and they are transferred to Sample inbound flow.
2. If they are using voice, the **Store customer input** block prompts them to enter their credit card number. The block stores and also encrypts the data using a signing key that must be uploaded in a .pem format.

   In the **Set contact attributes** block, the encrypted card number is set as contact attribute.
3. After the card number is successfully set as contact attribute, the customer is transferred back to the Sample inbound flow.

Flow block definitions in the flow designer in Amazon Connect

Use flow blocks to create flows in the flow designer. Drag flow blocks and drop them onto a canvas to arrange a flow.

The following table lists all available flow blocks that you can use. Choose any block name in the Block column for more information.

Block	Description	
Amazon Q in Connect	Associates an Amazon Q in Connect domain to a	

Block	Description
	contact to enable real-time recommendations.
Authenticate Customer	Enables the customer to authenticate by leveraging Amazon Cognito and Amazon Connect Customer Profiles.
Call phone number	Initiates an outbound call from an outbound whisper flow.
Cases	Gets, updates, and creates cases.
Change routing priority / age	Changes the priority of the contact in queue. You may want to do this, for example, based on the contact's issue or other variable.
Check call progress	Engages with the output provided by an answering machine, and provides branches to route the contact accordingly. This block works with outbound campaigns only.
Check contact attributes	Checks the values of contact attributes.
Check hours of operation	Checks whether the contact is occurring within or outside of the hours of operation defined for the queue.

Block	Description	
Check queue status	Checks the status of the queue based on specified conditions.	
Check Voice ID	Branches based on the enrollment status, voice authentication status, or status of detection of fraudsters in a watchlist of the caller returned by Voice ID.	
Check staffing	Checks the current working queue, or queue you specify in the block, for whether agents are available, staffed, or online. Staffed availabil ity could be on call, or after contact work status.	
Create persistent contact association	Specify an attribute to create a persistent contact associati on, enabling conversations to continue from where they left off.	
Create task	Creates a new task, sets the tasks attributes, and initiates a contact flow to start the task. To learn more about Amazon Connect Tasks, see The task channel in Amazon Connect.	

Block	Description
Customer profiles	Enables you to retrieve, create, and update a customer profile.
Disconnect / hang up	Disconnects a contact.
Distribute by percentage	Routes customers randomly based on a percentage.
End flow / Resume	Ends the current flow without disconnecting the contact.
Get customer input	Branches based on customer intent.
Get queue metrics	Retrieves real-time metrics about queues and agents in your contact center and returns them as attributes.
Hold customer or agent	Places a customer or agent on or off hold.
Invoke AWS Lambda function	Calls AWS Lambda, optionally returns key-value pairs.
Invoke module	Calls a published module.
Loop	Loops through, or repeats, the **Looping** branch for the number of loops specified.
Loop prompts	Loops a sequence of prompts while a customer or agent is on hold or in queue.

Block	Description	
Play prompt	Plays an interruptible audio prompt, delivers a text-to-speech message, or delivers a chat response.	
Resume contact	Resumes a contact from a paused state.	
Return (from module)	Exits the flow module after it has run successfully.	
Send message	Sends a message to your customer based on a template or custom message you specify.	
Set callback number	Sets a callback number.	
Set contact attributes	Stores key-value pairs as contact attributes.	
Customize the name of a block	Allows you to specify custom names for your flow blocks.	
Set customer queue flow	Specifies the flow to invoke when a customer is transferred to a queue.	
Set disconnect flow	Sets the flow to run after a disconnect event.	
Set event flow	Specifies which flow to run during a contact event.	
Set hold flow	Links from one flow type to another.	

Block	Description
Set logging behavior	Enables flow logs so you can track events as contacts interact with flows.
Set Voice ID	When the call is connected to a flow, sends audio to Amazon Connect Voice ID to verify the caller's identity and match against fraudsters on a watch list.
Set recording and analytics behavior	Sets options for recording conversations.
Set voice	Sets the text-to-speech (TTS) language and voice to be used in the flow.
Set whisper flow	Overrides the default whisper by linking to a whisper flow.
Set working queue	Specifies the queue to be used when **Transfer to queue** is invoked.
Show view	Configures UI based workflows that you can surface to users in front end applications.
Start media streaming	Starts capturing customer audio for a contact.
Stop media streaming	Stops capturing customer audio after it is started with a **Start media streaming** block.

Block	Description	
Store customer input	Stores numerical input to a contact attribute.	
Transfer to agent (beta)	Transfers the customer to an agent.	
Transfer to flow	Transfers the customer to another flow.	
Transfer to phone number	Transfers the customer to a phone number external to your instance.	
Transfer to queue	In most flows, this block ends the current flow and places the customer in queue. When used in a customer queue flow, this block transfers a contact already in a queue to another queue.	
Wait	Pauses the flow.	

Supported channels for flow blocks in Amazon Connect

The following table lists all available flow blocks, and whether they support routing a contact through the specified channels.

Block	Voice	Chat	Task	Email
Amazon Q in Connect	Yes	Yes	No - Error branch	Yes
Authenticate Customer	No - Error branch	Yes	No - Error branch	No - Error branch

Block	Voice	Chat	Task	Email
Call phone number	Yes	No - Error branch	No - Error branch	No - Error branch
Cases	Yes	Yes	Yes	Yes
Change routing priority / age	Yes	Yes	Yes	Yes
Check call progress	Yes	No - Error branch	No - Error branch	No - Error branch
Check contact attributes	Yes	Yes	Yes	Yes
Check hours of operation	Yes	Yes	Yes	Yes
Check queue status	Yes	Yes	Yes	Yes
Check Voice ID	Yes	No - Error branch	No - Error branch	No - Error branch
Check staffing	Yes	Yes	Yes	Yes
Contact tags	Yes	Yes	Yes	Yes
Create persistent contact association	No - Error branch	Yes	No - Error branch	No - Error branch
Create task	Yes	Yes	Yes	Yes
Customer profiles	Yes	Yes	Yes	Yes
Disconnect / hang up	Yes	Yes	Yes	Yes

Block	Voice	Chat	Task	Email
Distribute by percentage	Yes	Yes	Yes	Yes
End flow / Resume	Yes	Yes	Yes	Yes
Get customer input	Yes	Yes when Amazon Lex is used Otherwise, No - Error branch	Yes	Yes
Get queue metrics	Yes	Yes	Yes	Yes
Hold customer or agent	Yes	No - Error branch	No - Error branch	No - Error branch
Invoke AWS Lambda function	Yes	Yes	Yes	Yes
Invoke module	Yes	Yes	Yes	Yes
Loop	Yes	Yes	Yes	Yes
Loop prompts	Yes	No - Error branch	No - Error branch	No - Error branch
Play prompt	Yes	Yes	No - takes the **Success** branch, but it has no effect	No - takes the **Success** branch, but it has no effect
Resume contact	No - Error branch	No - Error branch	Yes	No - Error branch

Block	Voice	Chat	Task	Email
Return (from module)	Yes	Yes	Yes	Yes
Set callback number	Yes	No - Error branch	No - Error branch	No - Error branch
Set contact attributes	Yes	Yes	Yes	Yes
Set customer queue flow	Yes	Yes	Yes	Yes
Set disconnect flow	Yes	Yes	Yes	Yes
Set hold flow	Yes	No - Error branch	No - Error branch	No - Error branch
Set logging behavior	Yes	Yes	Yes	Yes
Set recording and analytics behavior	Yes	Yes	No - Error branch	No - Error branch
Set routing criteria	Yes	Yes	Yes	Yes
Set Voice ID	Yes	No - Error branch	No - Error branch	No - Error branch
Set voice	Yes	No - Success branch	No - Success branch	No - Success branch
Set whisper flow	Yes	Yes	Yes	Yes
Set working queue	Yes	Yes	Yes	Yes

Block	Voice	Chat	Task	Email
Show view	No - Error branch	Yes	No - Error branch	Yes
Start media streaming	Yes	No - Error branch	No - Error branch	No - Error branch
Stop media streaming	Yes	No - Error branch	No - Error branch	No - Error branch
Store customer input	Yes	No - Error branch	No - Error branch	No - Error branch
Transfer to agent (beta)	Yes	No - Error branch	No - Error branch	No - Error branch
Transfer to flow	Yes	Yes	Yes	Yes
Transfer to phone number	Yes	No - Error branch	No - Error branch	No - Error branch
Transfer to queue	Yes	Yes	Yes	Yes
Wait	No - Error branch	Yes	Yes	Yes

Flow block in Amazon Connect: Amazon Q in Connect

This topic defines the flow block for Amazon Q in Connect.

Description

- Associates an Amazon Q in Connect domain to a contact to enable real-time recommendations.
- For more information about enabling Amazon Q in Connect, see Use Amazon Q in Connect for generative AI–powered agent assistance in real-time.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

> **Note**
>
> Nothing happens if a task is sent to this block, however, **you will be charged**. To prevent this, add a Check contact attributes block before this one and route tasks accordingly. For instructions, see Personalize a contact's experience based on how they contact your contact center.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	No
Email	Yes

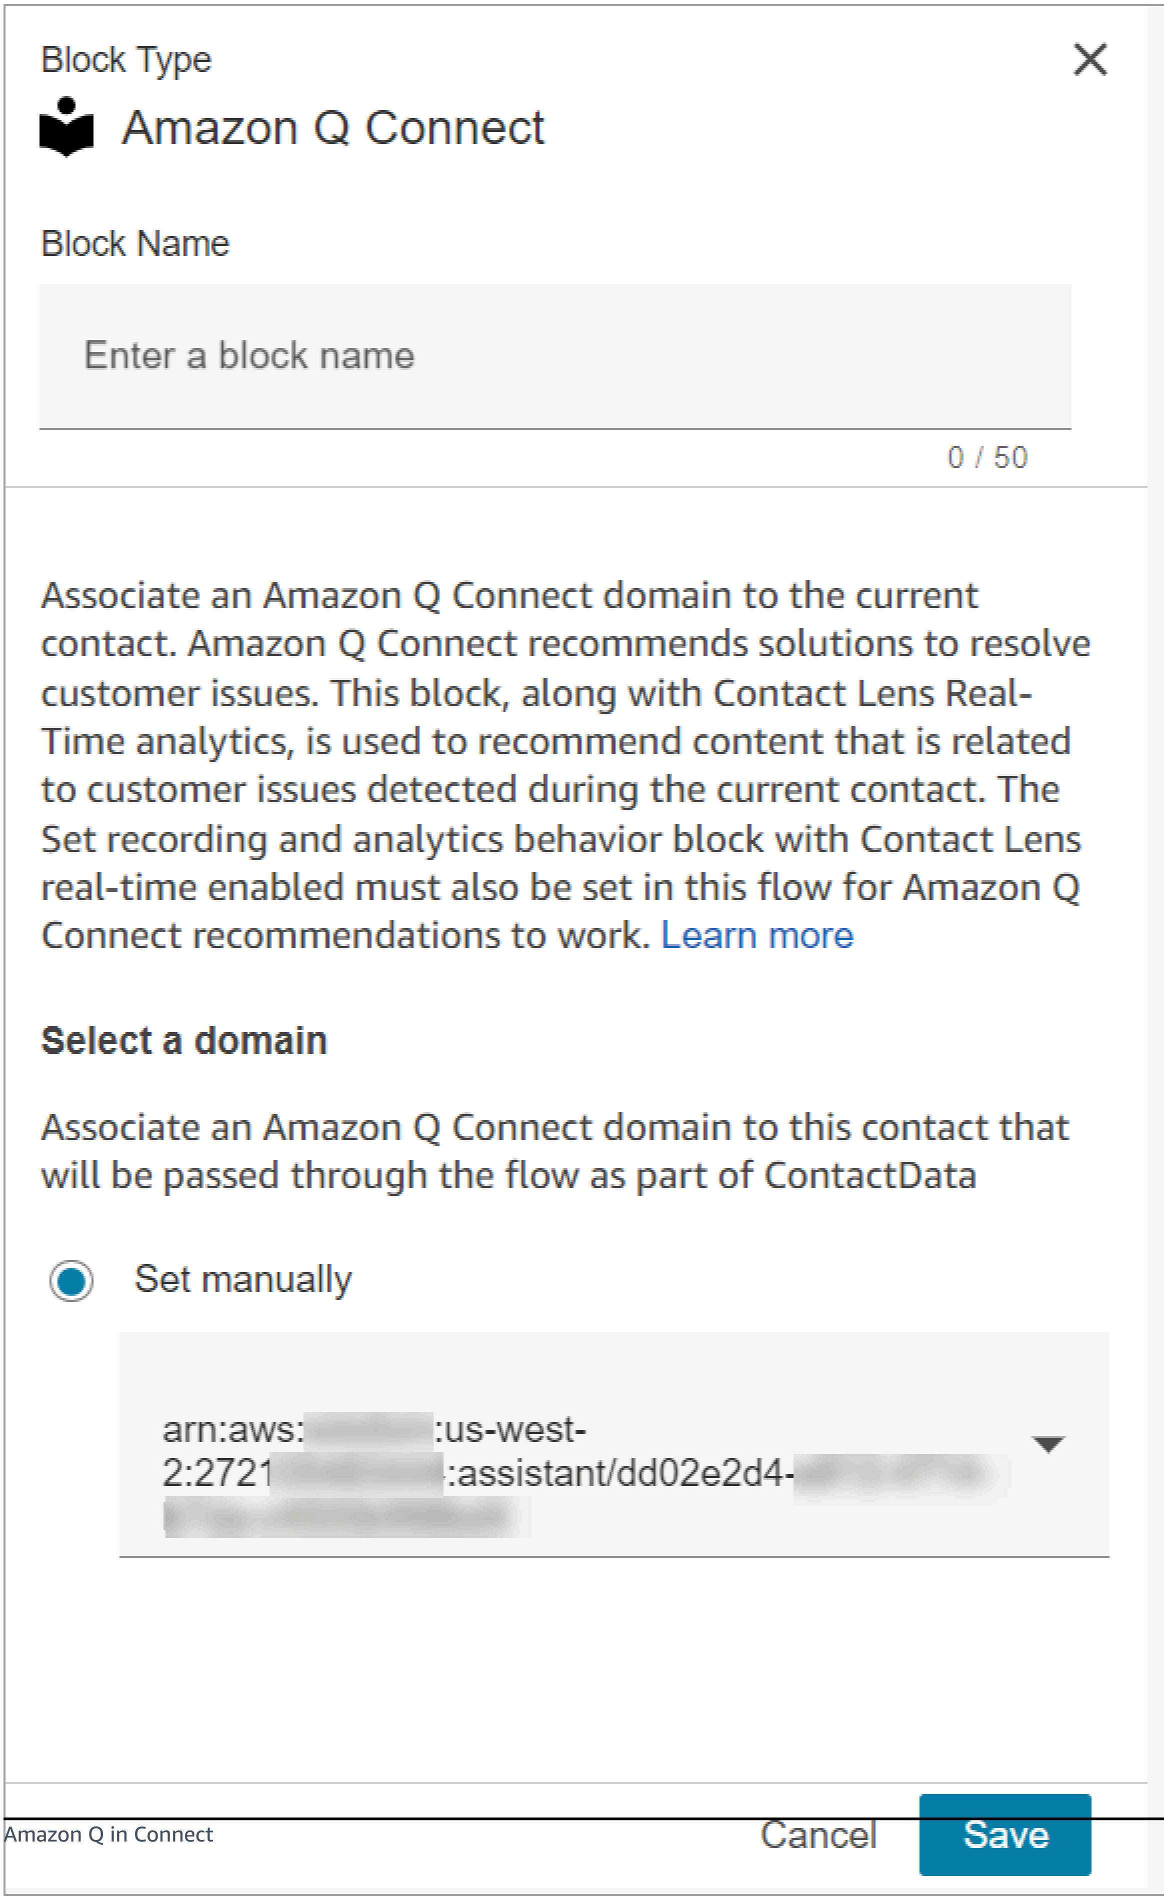
Flow types

You can use this block in the following flow types:

- Inbound flow
- Customer Queue flow
- Outbound whisper flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

The following image shows the **Properties** page of the **Amazon Q in Connect** block. It specifies the full Amazon Resource Name (ARN) of the Amazon Q in Connect domain to associate to the contact.



Block Type
Amazon Q Connect
Block Name

Save

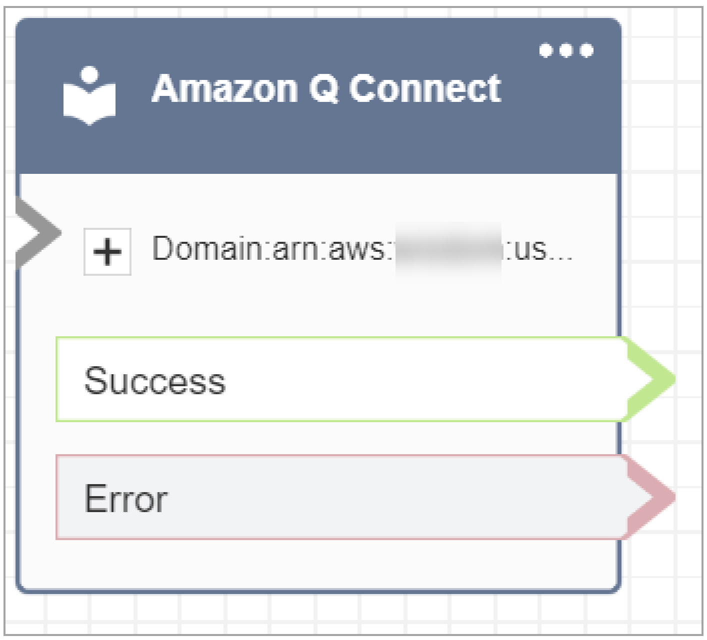
Configuration tips

- To use Amazon Q in Connect with calls, you must enable Amazon Connect Contact Lens in the flow by adding a Set recording and analytics behavior block that is configured for Contact Lens real-time. It doesn't matter where in the flow you add the Set recording and analytics behavior block.

  Amazon Q in Connect, along with Contact Lens real-time analytics, is used to recommend content that is related to customer issues detected during the current call.
- Contact Lens is not required to use Amazon Q in Connect with chats.

Configured block

The following image shows an example of what this block looks like when it is configured. It has the following branches: **Success** and **Error**.



Flow block in Amazon Connect: Authenticate Customer

This topic defines the flow block to authenticate customers and route them to specific paths within a flow based on the authentication result.

> **Note**
>
> Before you can use this block:

- The customer authentication capability must be enabled for your Amazon Connect instance. In addition, a new Amazon Cognito user pool must be created with your identity provider. For instructions, see Set up customer authentication in Amazon Connect for chat contacts.
- Customer Profiles must be enabled for your Amazon Connect instance.

Description

- Enables your customers to authenticate during a chat.
- After a customer successfully signs in, and an ID token is retrieved from Amazon Cognito, Amazon Connect either updates an existing customer profile or creates a new customer profile, depending on the identifier used to store the information into customer profiles.
- If the First Name field is present in the customer profile, the customer's display name is updated to that name.

Use cases for this block

This flow block is designed to be used in the following scenarios:

- You can prompt your customers to sign in and authenticate during a chat. For example, unauthenticated customers can be prompted to sign in:
  - When engaged with a chat bot, before to being routed to an agent.
  - To perform a transaction, such as making a payment.
  - To validate their identity before providing account status or allowing them to update their profile information.
- You can also use this block to authenticate customers during chats over Apple Messages for Business.

Contact types

Contact type	Supported?
Voice	No - **Error** branch

Contact type	Supported?
Chat	Yes
Task	No - **Error** branch
Email	No - **Error** branch

Flow types

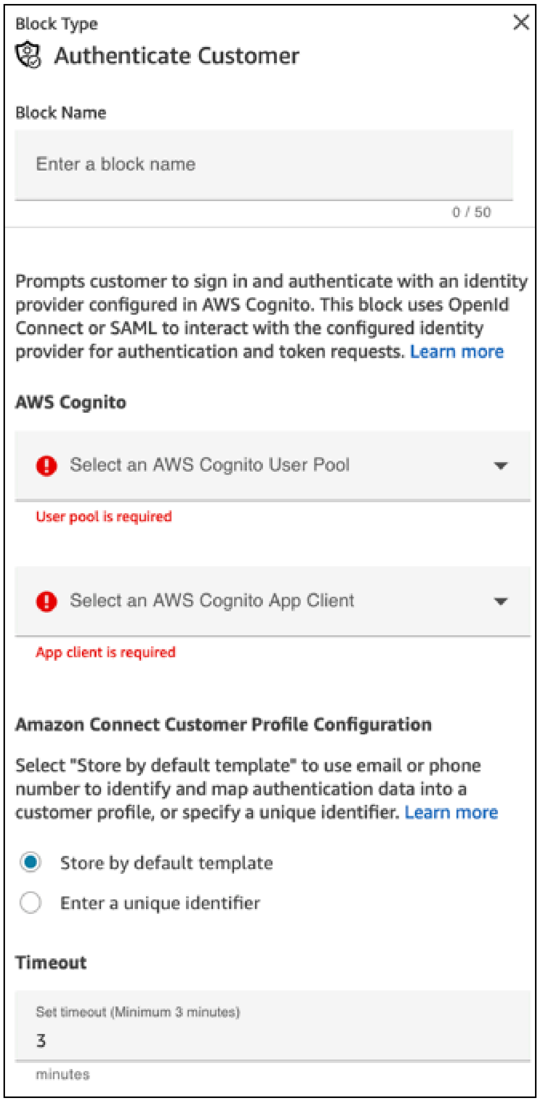
You can use this block in the following flow types:

Flow type	Supported?
Inbound flow	Yes
Customer queue flow	No
Customer hold flow	No
Customer whisper flow	No
Outbound whisper flow	No
Agent hold flow	No
Agent whisper flow	No
Transfer to agent flow	No
Transfer to queue flow	No

How to configure this block

You can configure the **Authenticate Customer** block by using the Amazon Connect admin website or by using the AuthenticateParticipant action in the Amazon Connect Flow language.

The following image shows an example of the Properties page for the **Authenticate Customer** block.



Amazon Cognito

- **Select an Amazon Cognito User Pool**: After you associate the user pool on the console page, choose the name of the user pool from the drop-down list.
- **Select an Amazon Cognito App Client**: After you select the user pool, choose the name of the app client from the drop-down list.

Amazon Connect Customer Profiles Configuration

- **Store by default template**: By choosing the default template, Amazon Connect Customer Profile ingests Amazon Cognito standard attributes into a unified standard profile object based on the predefined Customer Profile object type. This template uses phone number and email to map the customer to a profile.

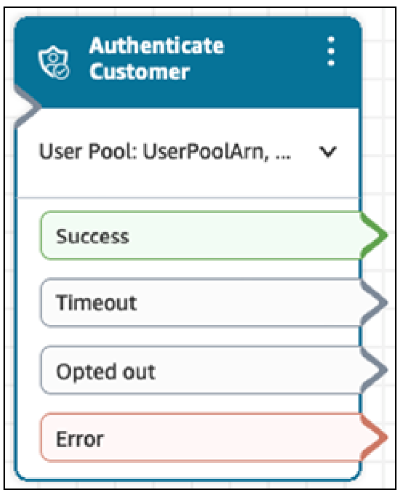
- **Enter a unique identifier**: You can customize how Customer Profiles ingests data by creating an object type mapping. If you want to customize the data mapping or key, create your own object type mapping in advance, select **Enter a unique identifier** and enter the mapping name.

Timeout: Enter how long until inactive customers who haven't signed in are routed down the Timeout branch.

- Minimum (default): 3 minutes
- Maximum: 15 minutes

Flow block branches

This block supports the following output branches:



- **Success**: The customer was authenticated.
- **Timeout**: The customer was inactive and did not sign in within the allocated amount of time.
- **Opted out**: The customer chose not to sign in.
- **Error**: One of the error scenarios occurred.

Additional configuration tips

- We recommend that you enable flow logs in an Amazon CloudWatch log group provide you with real-time details about events in your flows as customers interact with them. You can also use flow logs to help debug your flows as you are creating them. For more information, see Enable Amazon Connect flow logs in an Amazon CloudWatch log group.

- For information about enabling customer authentication for Apple Messages for Business Chats, see Enable authentication for Apple Messages for Business.

Data generated by this block

This block does not generate any data.

Error scenarios

A contact is routed down the **Error** branch in the following situations:

- Customer Profiles has not been enabled in your Amazon Connect instance. The option to enable Customer Profiles is selected by default when you create an instance, but it's possible to unselect this option. For instructions about enabling Customer Profiles manually, see Enable Customer Profiles for your Amazon Connect instance.
- The chat subtype is not supported.
- The provided authentication code is incorrect.
- Error from Amazon Cognito token endpoint because the client or request is not configured correctly (`invalid_request`, `invalid_client`, `unauthorized_client`)
- The Region is not supported. For a list of supported Regions, see Customer authentication availability by Region.

Flow block in Amazon Connect: Call phone number

This topic defines the flow block for the call phone number used for voice interactions with contact center customers.

Description

- Use to place an outbound call from an **Outbound Whisper** flow.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	No - Error branch
Task	No - Error branch
Email	No - Error branch

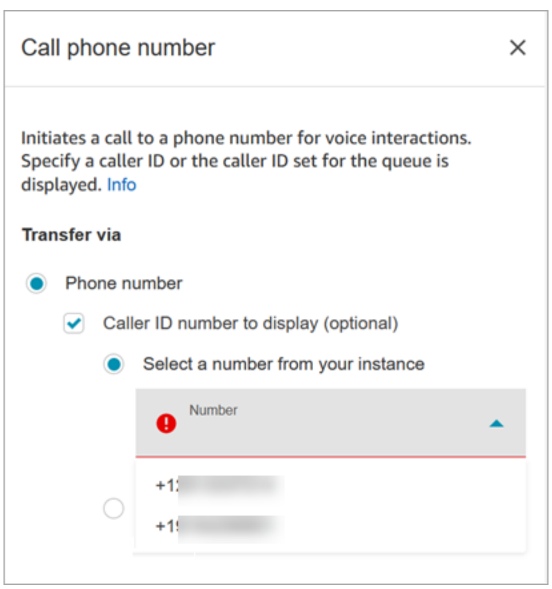
Flow types

You can use this block in the following flow types:

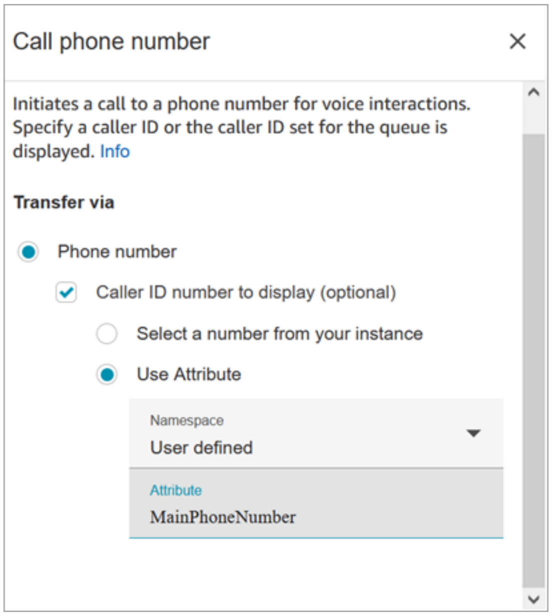
- Outbound Whisper flow

Properties

The following image shows an example of what the **Call phone number** properties page looks like when you select a phone number manually. The **Select a number from your instance** option is selected, and the dropdown menu displays a list of available phone numbers claimed for your instance.



The following image shows an example of what the **Call phone number** properties page looks like when you select a phone number dynamically. The **Use Attribute** option is selected. The **Namespace** box is set to **User-defined**. The **Attribute** box is set to **MainPhoneNumber**.



Outbound whisper flows run in Amazon Connect immediately after an agent accepts the call during direct dial and callback scenarios. When the flow runs:

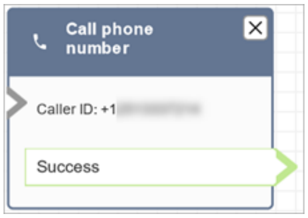
- The caller ID number is set if one is specified in the Call phone number block.
- If no caller ID is specified in the Call phone number block, the caller ID number defined for the queue is used when the call is placed.
- When there is an error with a call that is initiated by the Call phone number block, the call is disconnected and the agent is placed in **AfterContactWork** (ACW).

Only published flows can be selected as the outbound whisper flow for a queue.

> **Note**
>
> To use a custom caller ID, you must open an Support ticket to enable this feature. For more information, see Set up outbound caller ID.

Configured block

The following image shows an example of what this block looks like when it is configured. It shows the **Caller ID** phone number, and a **Success** branch.



There is no error branch for the block. If a call is not successfully initiated, the flow ends and the agent is placed in an **AfterContactWork** (ACW).

Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

- Sample customer queue priority flow in Amazon Connect
- Sample queue configurations flow in Amazon Connect

Scenarios

See these topics for more information about caller ID works:

- Set up outbound caller ID in Amazon Connect

Flow block in Amazon Connect: Cases

> **Tip**
>
> Be sure to enable Amazon Connect Cases before using this block. Otherwise, you can't configure its properties.

This topic defines the flow block for updating and creating cases.

Description

- Gets, updates, and creates cases.
- You can link a contact to a case, and then the contact will be recorded in the **Activity feed** of the case. When the agent accepts a contact that is linked to a case, the case automatically opens as a new tab in the agent application.
- While you can link contacts to multiple cases, there is a limit of five new case tabs automatically opening in the agent application. These will be the five most recently updated cases.
- For more information about cases, see Amazon Connect Cases.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

Flow types

You can use this block in the following flow types:

- All flows

Properties: Get case

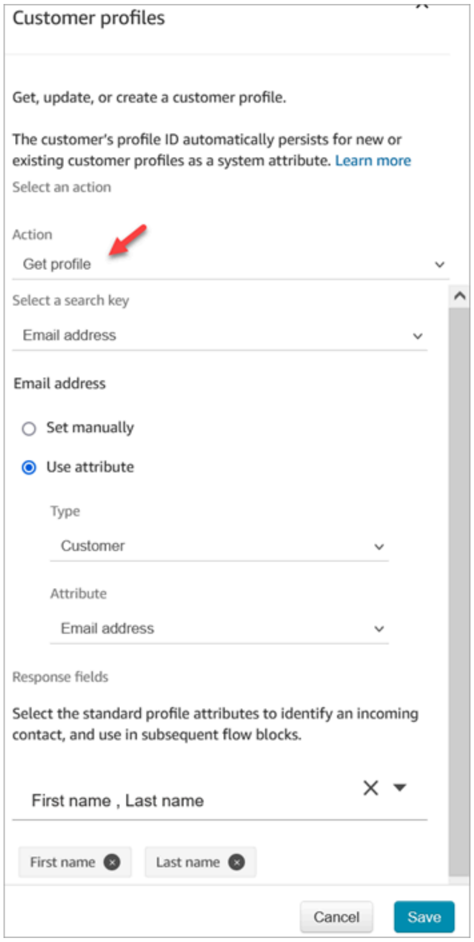
> **Tip**
>
> The following screenshots refer to the legacy flow designer.

When configuring properties to get a case:

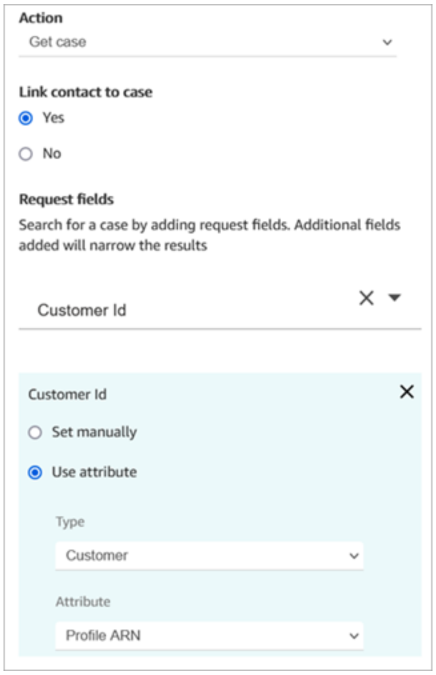
- You must provide at least one search criteria. Otherwise this block will take the **Error** branch.

  You can either use attribute in the Cases namespace or set manually. If you set manually, see to the syntax in How to persist fields throughout the flow.
- To get cases for a given customer, add a Customer profiles block to the flow before creating the case. The following image shows the flow designer with a **Customer profiles** block linked from the Success branch to a **Cases** block.

  Configure the Customer profiles block to get the customer profile. The following image shows an example of the **Customer profiles** properties page when it is configured. The **Action** box is set to **Get profile**. The **Select a search key** box is set to **Email address**. The **Use attribute** option is selected. The **Type** box is set to **Customer**. The **Attribute** box is set to **Email address**. The **Response fields** are set to **First name**, **Last name**.



In the **Cases** block, on the **Properties** page configure the **Customer ID** section as shown in the following image. The **Link contact to case** option is set to **Yes**. The **Request fields** box is set to **Customer Id**. In the **Customer Id** section, the **Use attribute** option is selected. The **Type** box is set to **Customer**. The **Attribute** box is set to **Profile ARN**.



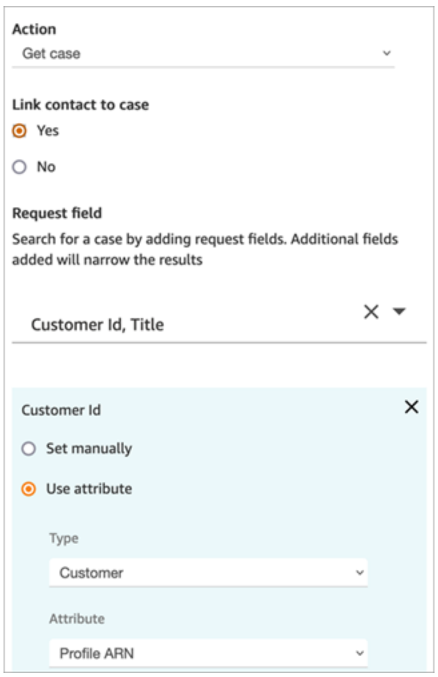
- You can specify to get only the last updated case for any search criteria. This can be achieved by selecting **Get last updated case**.
- You can persist case fields in the case namespace to make use of them in blocks that are in your flow after the **Cases** block that is configured to **Get case**. This can be achieved by making use of the **Response fields** section and selecting fields that you want to use in the other blocks.

  You can either use attribute in the Cases namespace or set manually. If you set manually, see to the syntax in [How to persist fields throughout the flow](#).
- The **Get case** properties show the options for the single-select field type.
- The **Get case** properties use the Contains function for text field type.
- The **Get case** properties use the EqualTo function for fields of type: number, boolean.
- The **Get case** properties use greater than or equal to for any date field search.
- Contacts can be routed down the following branches:
  - **Success**: The case was found.
  - **Contact not linked**: If you specify to link the contact to case, then this error branch will appear. It might be that the contact was not linked after the case is retrieved (partial success/ partial failure). If this happens, then the flow will follow this branch.
  - **Multiple found**: Multiple cases are found with the search criteria.
  - **None found**: No cases are found with the search criteria.

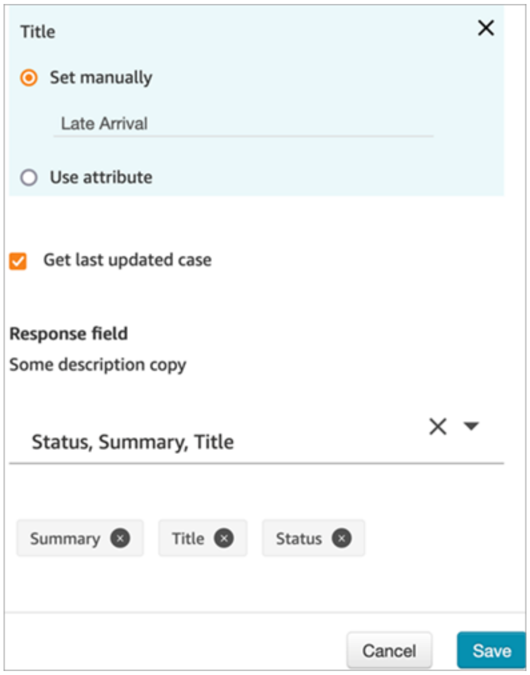
- **Error**: An error was encountered while trying to find the case. This may be due to a system error or how **Get case** is configured.

The following images show an example of a Cases **Properties** page that is configured for the **Get case** action.

The first image shows the **Properties** page configured to search for a case by **Customer Id** and **Title**. The **Customer Id** is being pulled in from the **Profile ARN** of the customer. In this image, the **Link contact to case** option is set to **Yes**. The **Request field** is set to **Customer Id, Title**. In the **Customer Id** section, the **Use attribute** option is selected. The **Type** box is set to **Customer**. The **Attribute** box is set to **Profile ARN**.



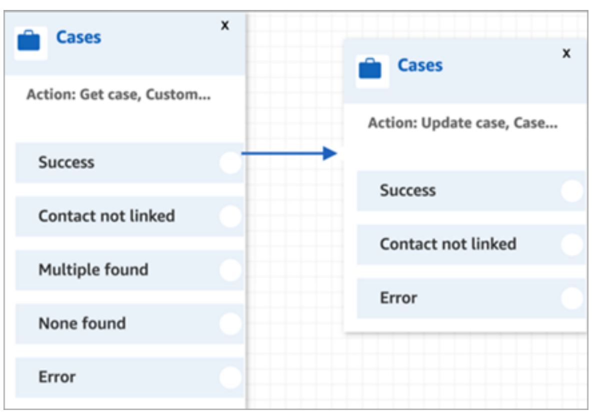
This next image shows the block configured to search by **Late Arrival**. Under **Title**, the **Set manually** option is set to **Late Arrival**. The **Get last updated cases** option is selected. The **Response field** option shows the three fields that will be shown to the agent: **Status**, **Summary**, and **Title**.



Properties: Update case

When configuring properties to update a case:

- Add a **Get case** block before an **Update case**, as shown in the following image. Use the **Get case** block to find the case you want to update.

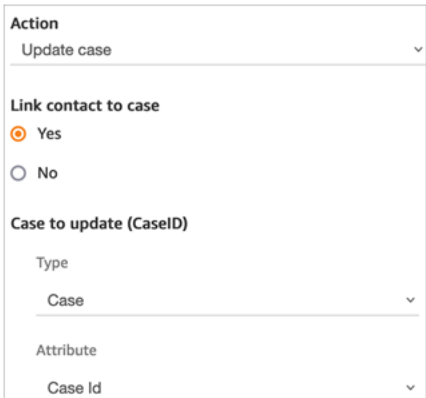
  


- You must provide an update to at least one **Request** field. Otherwise, this block takes the **Error** branch.

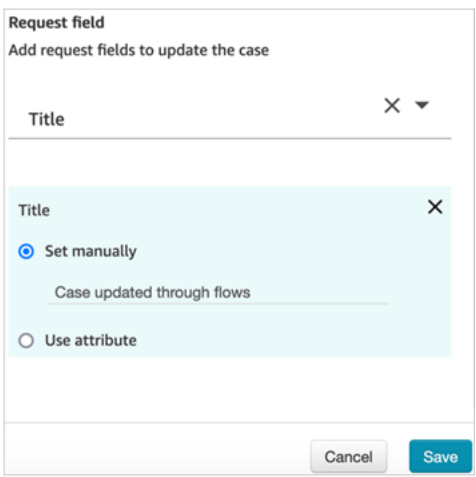
  You can either use an attribute in the Cases namespace, or set the **Request** field manually. If you set manually, see the syntax in [How to persist fields throughout the flow](#).
- Contacts can be routed down the following branches:
  - **Success**: The case was updated, and the contact was linked to the case.

- **Contact not linked**: If you specify to link the contact to case, then this error branch will appear. It might be that the case was updated, but the contact was not linked to the case (partial success/partial failure). If this happens, then the flow will follow this branch.
- **Error**: The case was not updated. The contact was not linked to the case, as the case was not updated.

The following images show an example of an **Update case** configuration. The first image shows that as part of the update the contact is going to be linked to the case. To identify which case to update, the **Case Id** is specified. (Case Id is the unique identifier of the case and the only field you can provide here. Other fields will not work and produce errors.)



The following image shows the **Request** field, where you specify the fields to update the case.



Properties: Create case

When configuring properties to create a case:

- You must provide a case template. For more information, see [Create case templates to document customer issues in Amazon Connect Cases].
- Fields that are required appear in the **Required** fields section. You must assign values to them to create a case.
- You must specify the customer to create a case.
  - We recommend adding a [Customer profiles] block to the flow before the **Cases** block. Use the [Customer profiles] block to get a customer profile with some prefetched data, or create a new customer profile and then use that to create a case.
  - To provide a value for **Customer Id** in the **Cases** block, configure the fields as shown in the following image, where **Use attribute** is selected, **Type** is set to **Customer**, and **Attribute** is set to **Profile ARN**.

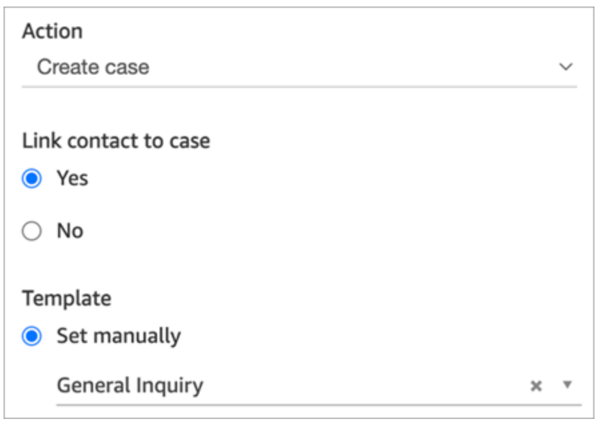
    
    If you are setting the value manually, you must provide the full customer profile ARN in this format:

    ```
    arn:aws:profile:your AWS Region:your AWS account ID:domains/profiles domain name/profiles/profile ID
    ```
- You can specify values for fields other than the required ones in the Request fields section.

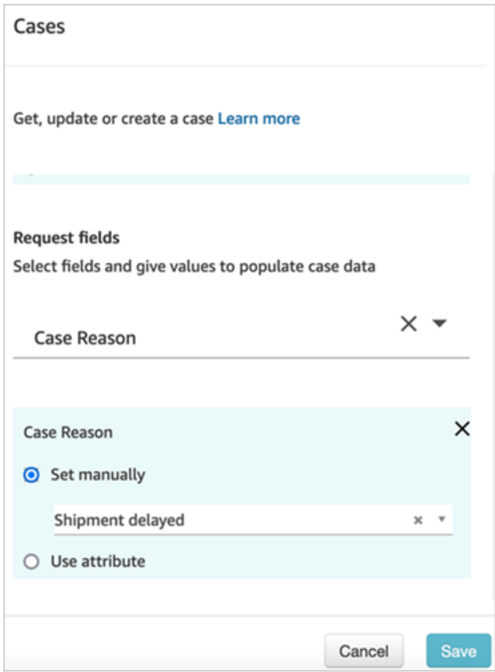
  You can either use attribute in the Cases namespace or set manually. If you set manually, see to the syntax in [How to persist fields throughout the flow].
- You can specify that a contact should be linked to case. If you link the contact to the case, then the contact and a link to contact details appear on the case that the agent sees in the agent application.

- After creating a case, the case ID that is created will be persisted in the case namespace. It can be used in other blocks by accessing the case namespace case ID attribute value.
- Contacts can be routed down the following branches:
  - **Success**: The case was created, and the contact was linked to the case.
  - **Contact not linked**: If you specify to link the contact to case, then this error branch will appear. This is because it is possible that the case was created, but the contact was not linked to the case (partial success/partial failure). If this happens, then the flow will follow this branch.
  - **Error**: The case was not created. The contact was not linked to the case, as the case was not created.

The following images show an example of a **Create case** configuration. The first image shows the new case will be created using the General inquiry template:



The next image shows the reason for the case will be set to **Shipment delayed**.

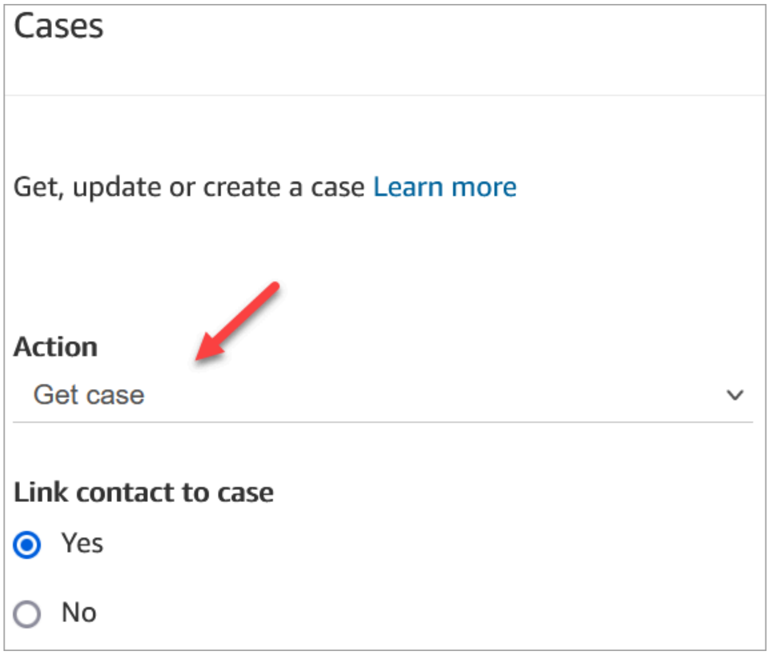


How to persist fields throughout the flow

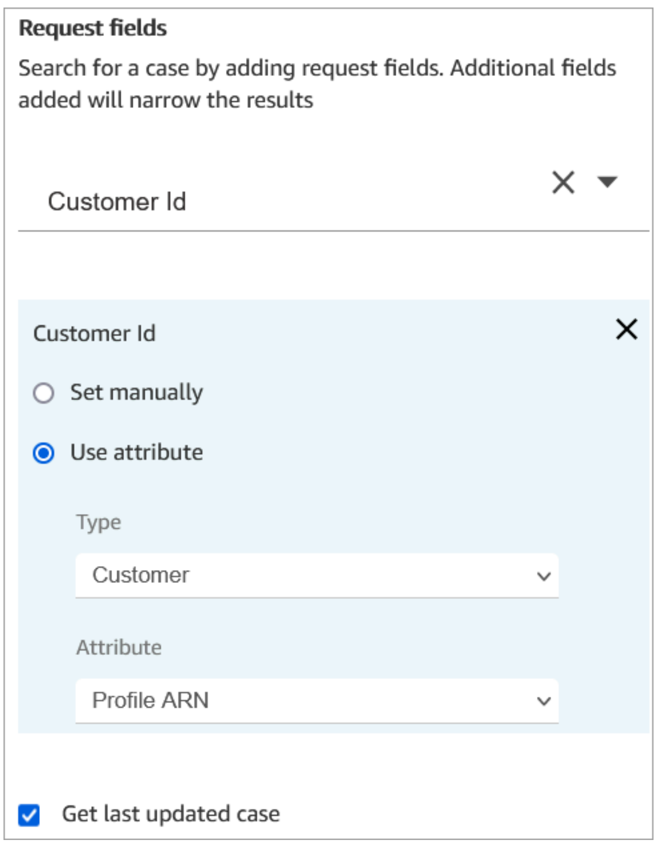
Let's say you want customers to be able to call into your contact center and get the status of their case without ever talking to an agent. You want the IVR to read the status to the customer. You can get the status from a system field, or you might have a custom status field, for example, named *Detailed status*.

Here's how to configure your flow to get and read the status to the customer:

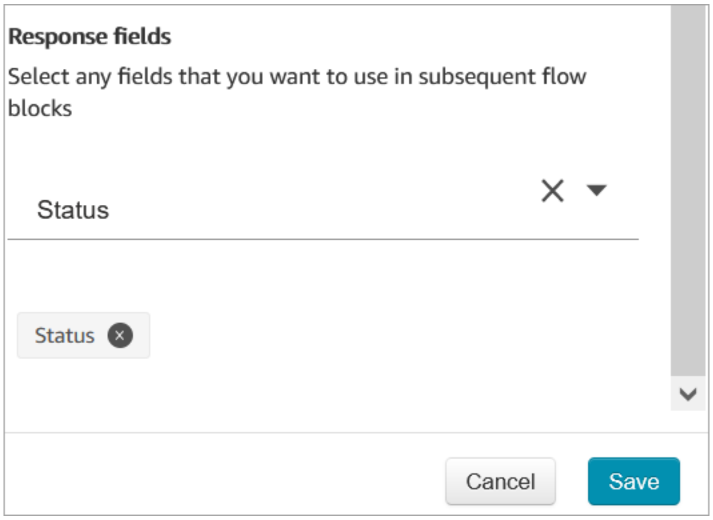
1. Add a **Cases** block to your flow. Configure it to **Get case** to find the case.



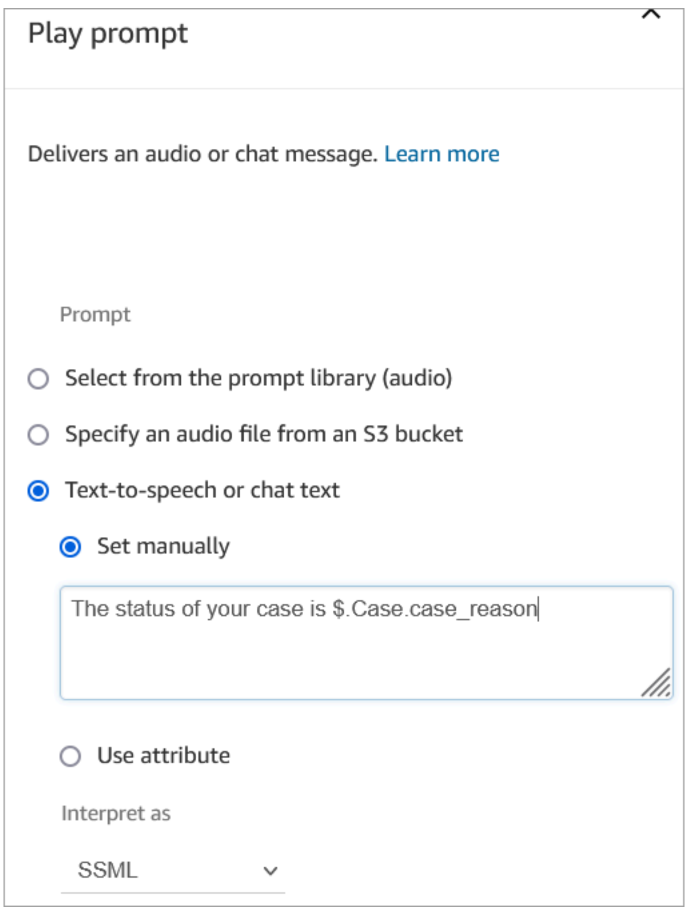
2. In the **Request fields** section, search for the case by the customer **Profile ARN**:



3. In the **Response fields** section, add the field that you want passed throughout the flow. For our example, choose **Status**.

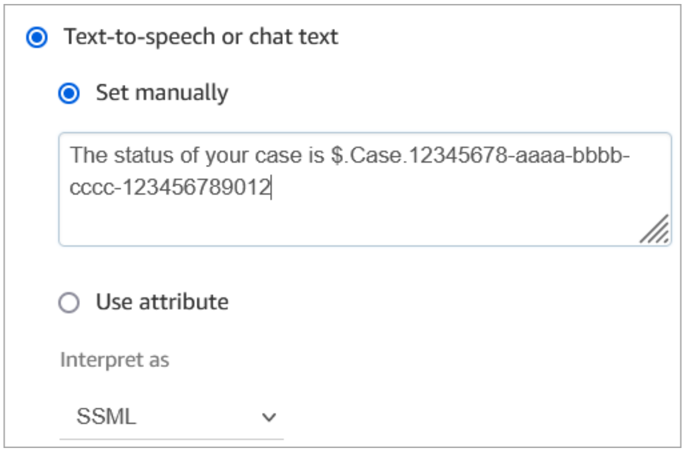


4. Add a Play prompt block to your flow.
5. Configure Play prompt to set the attribute manually:



Use the following syntax for reading the status of the case to the customer:

- For system fields, you can read the syntax and understand which field it refers to. For example: `$.Case.status` refers to the case status. For a list of system field IDs, see the *Field ID* column in the System case fields topic.
- For custom fields, the syntax uses a UUID (unique ID) to represent the field. For example, in the following image, the ID for the custom field named *Detailed status* is `12345678-aaaa-bbbb-cccc-123456789012`.



Find the custom field ID

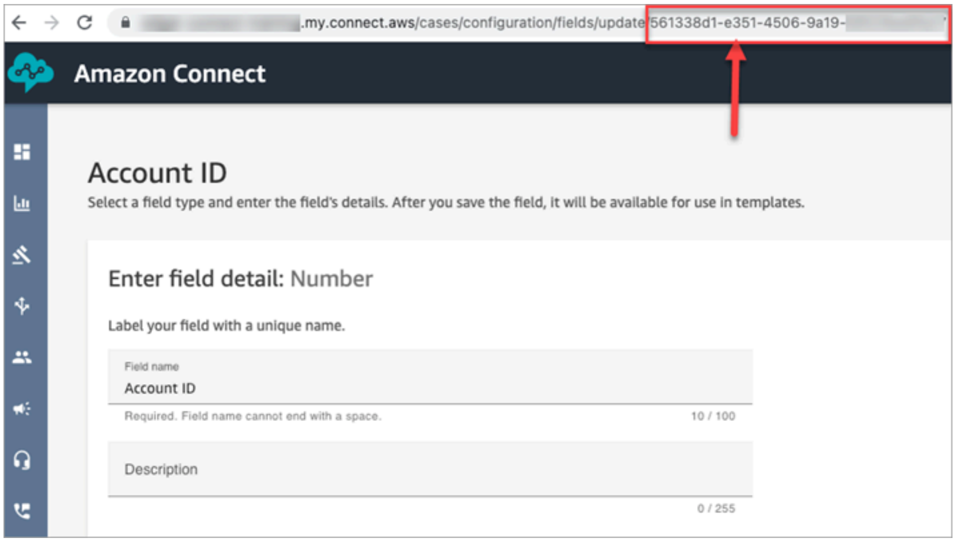
To find the UUID of a custom field:

1. In Amazon Connect, on the navigation menu choose **Agent applications**, **Custom fields**, and then choose the custom field that you want.
2. While on the details page for the custom field, look at the URL of the page. The UUID is the last portion of the URL. For example, in the following URL:

   ```
   https://instance alias.my.connect.aws/cases/configuration/fields/update/12345678-aaaa-bbbb-cccc-123456789012
   ```

   The UUID is `12345678-aaaa-bbbb-cccc-123456789012`.

The following image shows where you find the custom field ID at the end of a URL:

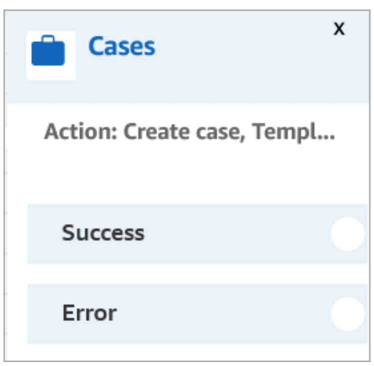


Configuration tips

- Be sure to check the [Cases service quotas](), and request increases. The quotas apply when this block creates cases.

Configured block

The following image shows an example of what this block looks like when it is configured. It shows this block is configured to create cases, and it has **Success** and **Error** branches.



Flow block in Amazon Connect: Change routing priority / age

This topic describes setting up the Change routing priority / age flow block for changing the priority or length of time of a customer in a queue.

Description

- Change a customer's position in the queue. For example, move the contact to the front of the queue, or to the back of the queue.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

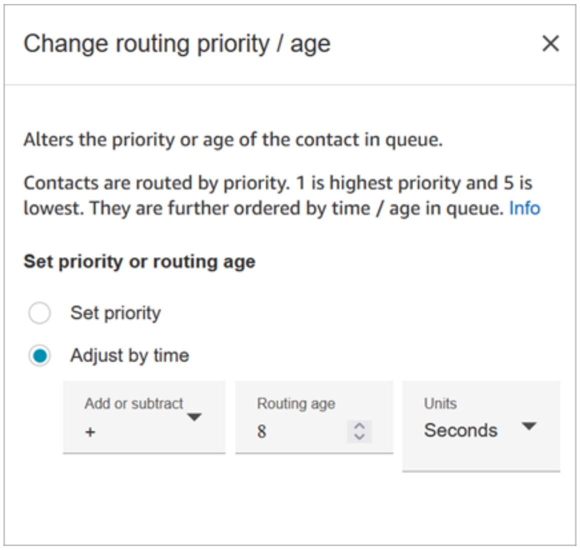
Flow types

You can use this block in the following flow types:

- Inbound flow
- Customer queue flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

The following image shows the **Properties** page of the **Change routing priority / age** block. It is configured to add 8 seconds to the routing age of the contact.



This block gives you two options for changing a contact's position in queue:

- **Set priority**. The default priority for new contacts is 5. You can raise the priority of a contact - compared to other contacts in the queue - by assigning them a higher priority, such as 1 or 2.
  - Default priority: 5
  - Range of valid values: 1 (highest) - 9223372036854775807 (lowest). If you enter a number larger than that, it will fail when the flow is published.
- **Adjust by time**. You can add or subtract seconds or minutes from the amount of time the current contact spends in queue. Contacts are routed to agents on a first-come, first-served basis. So changing their amount of time in queue compared to others also changes their position in queue.

Here's how this block works:

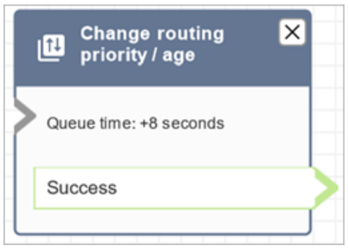
1. Amazon Connect takes the actual "time in queue" for the contact (in this case, how long this specific contact has spent in queue so far), and adds the number of seconds you specified in the **Adjust by time** property.
2. The additional seconds makes this specific contact look artificially older than it is.
3. The routing system now perceives this contact's "time in queue" as longer than it actually is, which affects its position within the ranked list.

Configuration tips

- When using this block, it takes at least 60 seconds for a change to take effect for contacts already in queue.
- If you need a change in a contact's priority to take effect immediately, set the priority before putting the contact in queue, that is, before using a Transfer to queue block.

Configured block

The following image shows an example of what this block looks like when it is configured. It shows the **Queue time** is set to +8 seconds, and it has a **Success** branch.



Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

- Sample customer queue priority flow in Amazon Connect
- Sample queue configurations flow in Amazon Connect

Scenarios

See these topics for more information about how routing priority works:

- How Amazon Connect uses routing profiles
- How routing works in Amazon Connect

Flow block in Amazon Connect: Check call progress

> **Important**
>
> This block works with outbound campaigns only.

This topic defines the flow block for engages with the output provided by an answering machine, and provides appropriate branches to route the contact. This flow block applies to outbound campaigns only.

Description

- Engages with the output provided by an answering machine, and provides branches to route the contact accordingly.
- It supports the following branches:
  - **Call answered**: The call has been answered by a person.
  - **Voicemail (beep)**: Amazon Connect identifies that the call ended in a voicemail and it detects a beep.
  - **Voicemail (no beep)**:
    - Amazon Connect identifies that the call ended in a voicemail but it doesn't detect a beep.
    - Amazon Connect identifies that the call ended in a voicemail, but the beep is unknown.
  - **Not detected**: Could not detect whether there is voicemail. This happens when Amazon Connect is unable to make a positive determination of whether a call was answered by a live voice or an answering machine. Typical situations that land in this state include long silences or excessive background noise.
  - **Error**: If any errors are encountered due to Amazon Connect not running correctly after media has been established on the call, this is the path that will be taken by the flow. Media is established when the call is either answered by a live voice or by an answering machine. If the call is rejected by the network or encounters a system error while placing the outbound call, the flow will not be run.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	No - Error branch
Task	No - Error branch
Email	No - Error branch

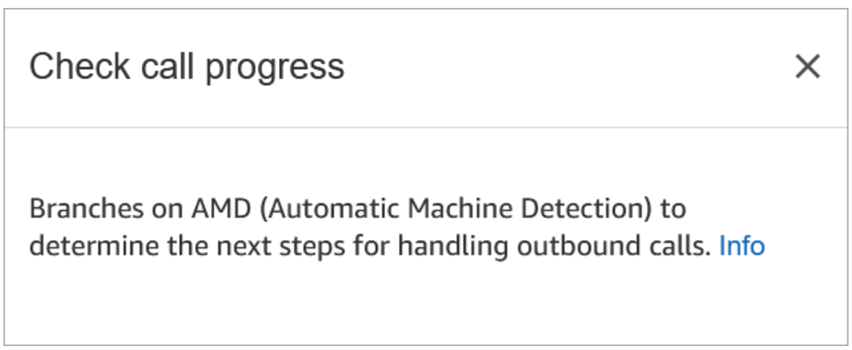
Flow types

You can use this block in the following flow types:

- All flow types

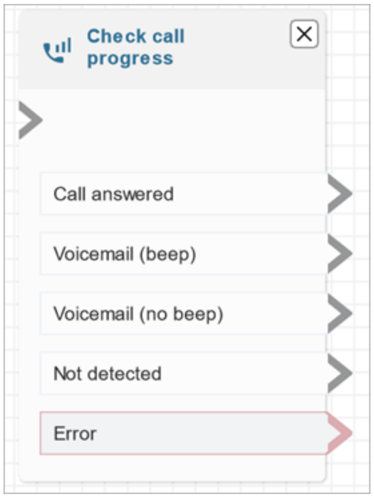
Properties

The following image shows the **Properties** page of the **Check call progress** block.



Configured block

The following image shows an example of what this block looks like when it is configured. It has branches for **Call answered**, **Voicemail (beep)**, **Voicemail (no beep)**, **Not detected**, and **Error**.



Flow block in Amazon Connect: Check contact attributes

This topic defines the flow block for branching based on a comparison to the value of a contact attribute.

Description

- Branches based on a comparison to the value of a contact attribute.
- Supported comparisons include: **Equals**, **Is Greater Than**, **Is Less Than**, **Starts With**, **Contains**.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

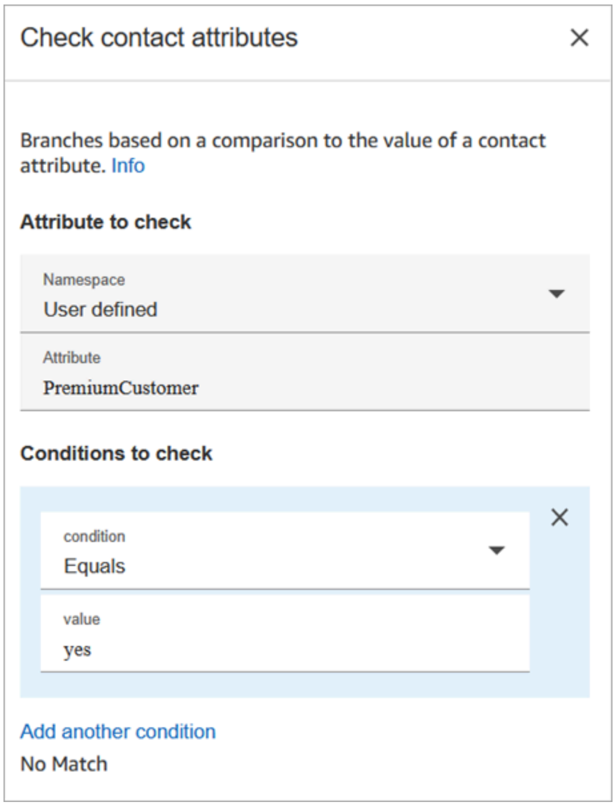
Flow types

You can use this block in the following flow types:

- All flows

Properties

The following image shows the **Properties** page of the **Check contact attributes** block. In this example, the block is configured to check whether the contact is a **PremiumCustomer**, which is a user-defined attribute.



Conditions to check can be dynamic

You can check conditions like the following:

- $.Attributes.verificationCode

To check for a NULL value, you need to use a Lambda.

Amazon Lex attributes

You can set attributes that are **Type** = **Lex** as follows:

- **Alternative Intents**: Usually you configure flows to branch on the winning Lex intent. However, in some situations, you might want to branch on an alternate intent. That is, what the customer might have meant.

  For example, in the following image of the **Check contact attributes** properties page, it is configured so the alternative intent indicates that if Amazon Lex is more than 70% confident the customer meant *fraud*, the flow should branch accordingly.

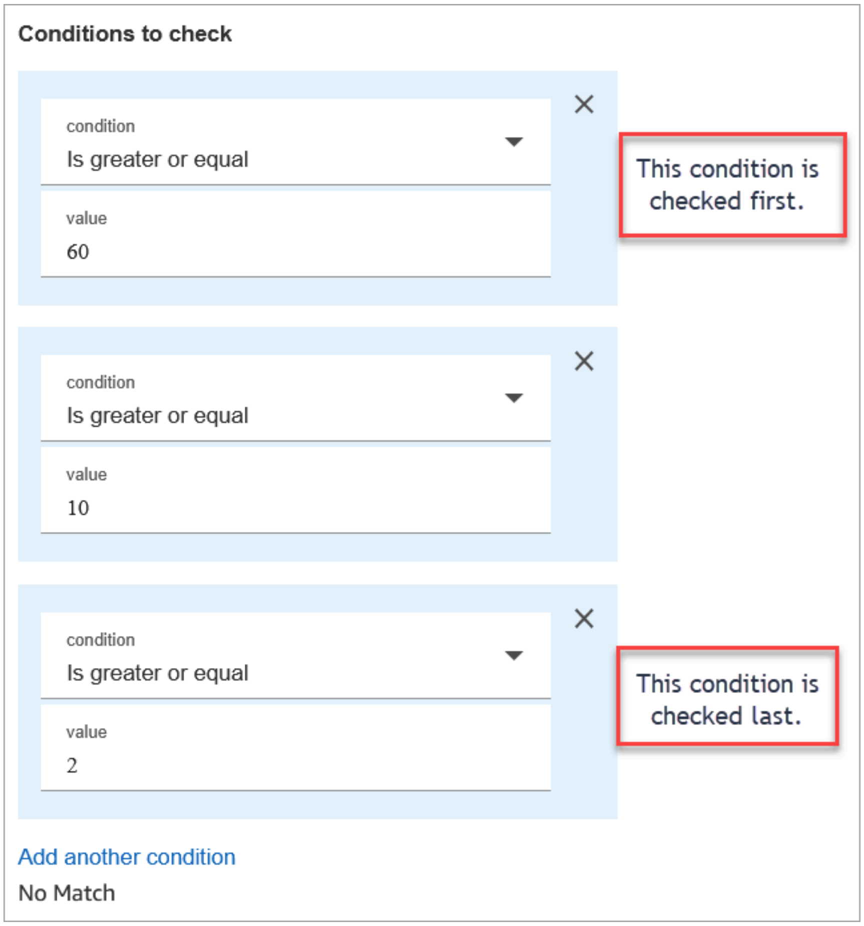
  
  1. **Intent name** is the name of an alternate intent in Lex. It's case sensitive and must match what's in Lex exactly.
  2. **Intent Attribute** is what Amazon Connect is going to check. In this example, it's going to check the **Intent Confidence Score**.
  3. **Conditions to check**: If Lex is 70% certain the customer meant the alternate intent instead of the winning intent, branch.
- **Intent Confidence Score**: How confident is the bot that it understands the customer's intent. For example, if the customer says "I want to update an appointment," *update* can mean *reschedule* or *cancel*. Amazon Lex provides the confidence score on a scale of 0 to 1:
  - 0 = not at all confident
  - .5 = 50% confident
  - 1 = 100% confident
- **Intent Name**: The user intent returned by Amazon Lex.

- **Sentiment Label**: What is the winning sentiment, the one with the highest score. You can branch on POSITIVE, NEGATIVE, MIXED, or NEUTRAL.
- **Sentiment Score**: Amazon Lex integrates with Amazon Comprehend to determine the sentiment expressed in an utterance:
  - Positive
  - Negative
  - Mixed: The utterance expresses both positive and negative sentiments.
  - Neutral: The utterance does not express either positive or negative sentiments.
- **Session Attributes**: Map of key-value pairs representing the session-specific context information.
- **Slots**: Map of intent slots (key/value pairs) Amazon Lex detected from the user input during the interaction.

Configuration tips

- If you have multiple conditions to compare, Amazon Connect checks them in the order they are listed.

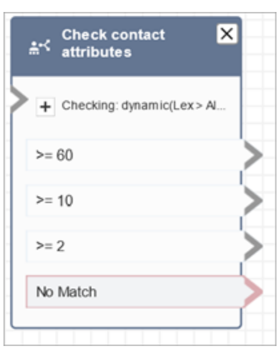
  For example, in the following image of the **Check contact attributes** properties page, it is configured so Amazon Connect compares the **greater than 60** condition first and compares **greater than 2** last.



- This block doesn't support case-insensitive pattern matching. For example, if you're trying to match against the word **green** and the customer types **Green**, it would fail. You would have to include every permutation of upper and lower-case letters.

Configured

The following image shows an example of what this block looks like when it is configured. It shows the block has four branches, one for each condition: greater or equal to 60, greater to equal to 10, greater or equal to 2, or **No match**.



Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

- Sample inbound flow in Amazon Connect for the first contact experience
- Sample interruptible queue flow with callback in Amazon Connect

Scenarios

See these topics for scenarios that use this block:

- How to reference contact attributes in Amazon Connect
- Personalize a contact's experience based on how they contact your contact center

Flow block in Amazon Connect: Check hours of operation

This topic defines the flow block to checks whether a contact occurs within or outside of the hours of operation defined for the customer queue.

Description

- Checks whether the contact is occurring within or outside the hours of operation defined by the block. If specific hours are not specified, the hours for the current queue are checked.
- Branches based on specified hours of operation.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes

Channel	Supported?
Task	Yes
Email	Yes

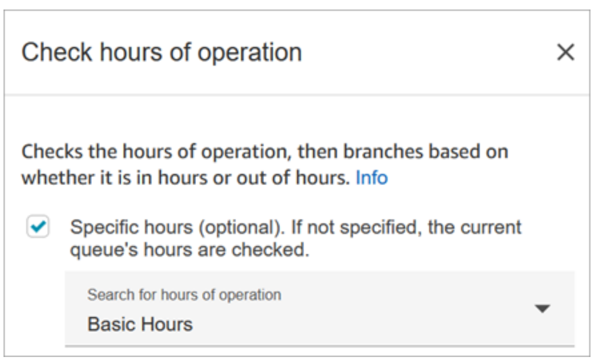
Flow types

You can use this block in the following flow types:

- Inbound flow
- Customer queue flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

The following image shows the **Properties** page of the **Check hours of operation** block. The block is configured for specific hours of operation.



You can set up multiple hours of operation so you have one for various queues. For instructions, see Set the hours of operation and time zone for a queue using Amazon Connect.

You can set up overrides to hours of operation to indicate dates where the standard hours do not apply. For instructions, see Set overrides for extended, reduced, and holiday hours.

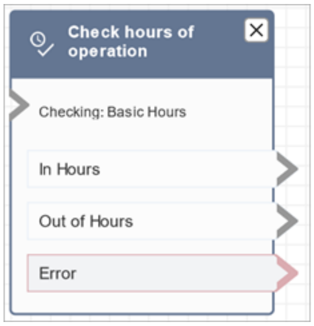
Configuration tips

- Agent queues that are automatically created for each agent in your instance do not include an hours of operation.

- If you use this block to check the hours of operation for an agent queue, the check fails and the contact is routed down the **Error** branch.

Configured block

The following image shows an example of what this block looks like when it is configured. It is configured for **Basic Hours** of operation. It has three branches: **In hours**, **Out of Hours**, and **Error**.



Related topics

- [Set the hours of operation and time zone for a queue using Amazon Connect]

Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see [Sample flows in Amazon Connect]. Following are topics that describe the sample flows which include this block.

[Sample inbound flow in Amazon Connect for the first contact experience]

Scenarios

See these topics for scenarios that use this block:

- [Set up a flow to manage contacts in a queue in Amazon Connect]

Flow block in Amazon Connect: Check queue status

This topic defines the flow block for checking the status of a customer queue based on consitions set for that queue.

Description

- Checks the status of the queue based on specified conditions.
- Branches based on the comparison of **Time in Queue** or **Queue capacity**.
  - **Time in queue** is the amount of time the oldest contact spends in queue, before they are routed to an agent or removed from the queue.
  - **Queue capacity** is number of contacts waiting in a queue.
- If no match is found, the **No Match** branch is followed.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

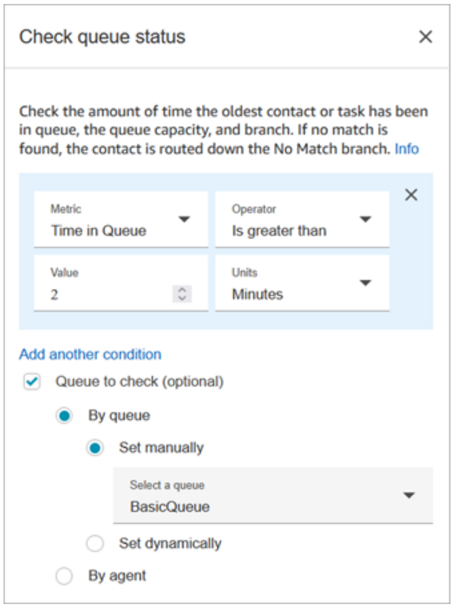
Flow types

You can use this block in the following flow types:

- Inbound flow
- Customer queue flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

The following image shows the **Properties** page of the **Check queue status** block. In this example, it checks whether a contact has been in the BasicQueue longer than 2 minutes.



Configuration tips

The order in which you add conditions matters at the runtime. Results are evaluated against conditions in the same order in which you add them to the block. Contacts are routed down the first condition to match.

For example, in the following condition order, every value matches one of first two conditions. None of the other conditions are ever matched.

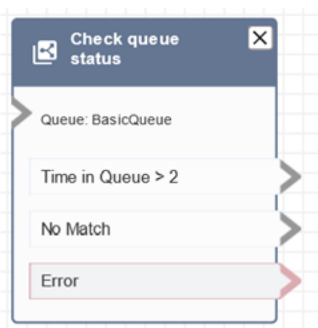
- Time in Queue <= 90
- Time in Queue >= 90
- Time in Queue >= 9
- Time in Queue >= 12
- Time in Queue >= 15
- Time in Queue >= 18
- Time in Queue > 20
- Time in Queue > 21

In this next example, all contacts with a wait time in queue of 90 or less (<=90) match first condition only. This means less than or equal to 9 (<=9), <=12, <=15, <=18, <=20, <=21 are never run. Any value greater than 90 is routed down the greater than or equal to 21 (>=21) condition branch.

- Time in Queue <= 90
- Time in Queue <= 9
- Time in Queue <= 12
- Time in Queue <= 15
- Time in Queue <= 18
- Time in Queue < 20
- Time in Queue < 21
- Time in Queue > 21

Configured block

The following image shows an example of what this block looks like when it is configured. It has three branches: the **Time in Queue** condition, **No Match**, and **Error**.



Scenarios

See these topics for scenarios that use this block:

- [Set up a flow to manage contacts in a queue in Amazon Connect]

Flow block in Amazon Connect: Check Voice ID

This topic describes how the Check Voice ID block branches based on data returned by Amazon Connect Voice ID.

Description

> **Note**
>
> The Set Voice ID block needs to be set in the flow before this one. That block sends audio to Amazon Connect Voice ID to verify the customer's identity, and returns a status.

The **Check Voice ID** block branches based on the results of the voice analysis and the status returned by Voice ID:

- **Enrollment status**:
  - **Enrolled**: The caller is enrolled in voice authentication.
  - **Not enrolled**: The caller has not yet been enrolled in voice authentication. When this status is returned, for example, you may want to directly route the call to an agent for enrollment.
  - **Opted out**: The caller has opted out of voice authentication.

  You are not charged for checking enrollment status.
- **Voice authentication status**:
  - **Authenticated**: The caller's identity has been verified. That is, the authentication score is greater than or equal to the threshold (default threshold of 90 or your custom threshold).
  - **Not authenticated**: The authentication score is lower than threshold that you configured.
  - **Inconclusive**: Unable to analyze a caller's speech for authentication. This is usually because Voice ID did not get the required 10 seconds to provide a result for authentication.
  - **Not enrolled**: The caller has not yet been enrolled in voice authentication. When this status is returned, for example, you may want to directly route the call to an agent for enrollment.
  - **Opted out**: The caller has opted out of voice authentication.

  You are not charged if the result is **Inconclusive**, **Not enrolled** or **Opted out**.
- **Fraud detection status**:
  - **High risk**: The risk score meets or exceeds the set threshold.
  - **Low risk**: The risk score did not meet the set threshold.
  - **Inconclusive**: Unable to analyze a caller's voice for detection of fraudsters in a watchlist.

  You are not charged if the result is **Inconclusive**.

> **Note**
>
> For **Enrollment status** and **Voice authentication**, the Customer ID system attribute needs to be set in Set contact attributes block because they are acting on a specific customer. You don't need to do this for **Fraud detection** because it's not acting on a specific customer but rather detecting whether the incoming caller matches a fraudster on your watch list. This means it's possible for a customer to be successfully authenticated and still have high fraud risk.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	No - Error branch
Task	No - Error branch
Email	No - Error branch

Flow types

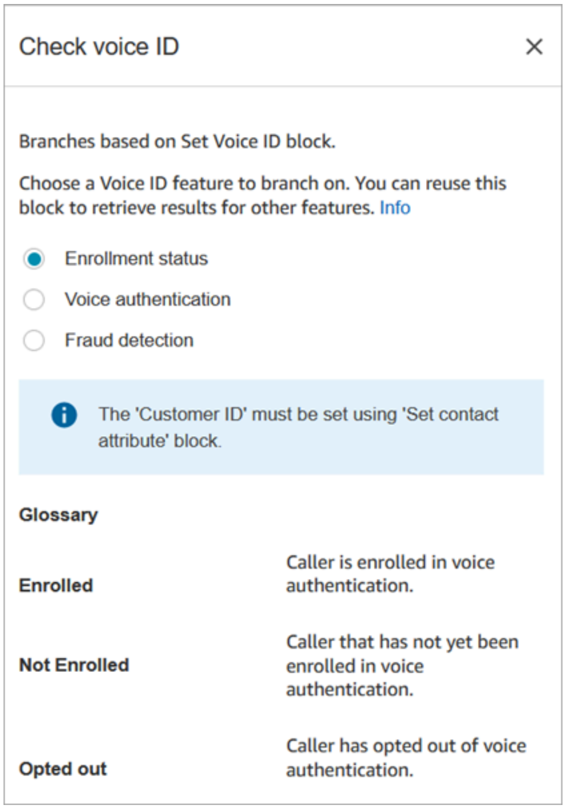
You can use this block in the following flow types:

- Inbound flow
- Customer queue flow
- Customer whisper flow
- Outbound whisper flow
- Agent whisper flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

This block doesn't have any properties that you set. Rather, it creates branches for you to route contacts based on the result of the authentication threshold and voiceprint evaluation that Set Voice ID returns.

The following image shows the **Properties** page for the **Check voice ID** block when it's configured to check for Enrollment status. Different status results are returned when it's configured for **Voice authentication** or **Fraud detection**.



Configuration tips

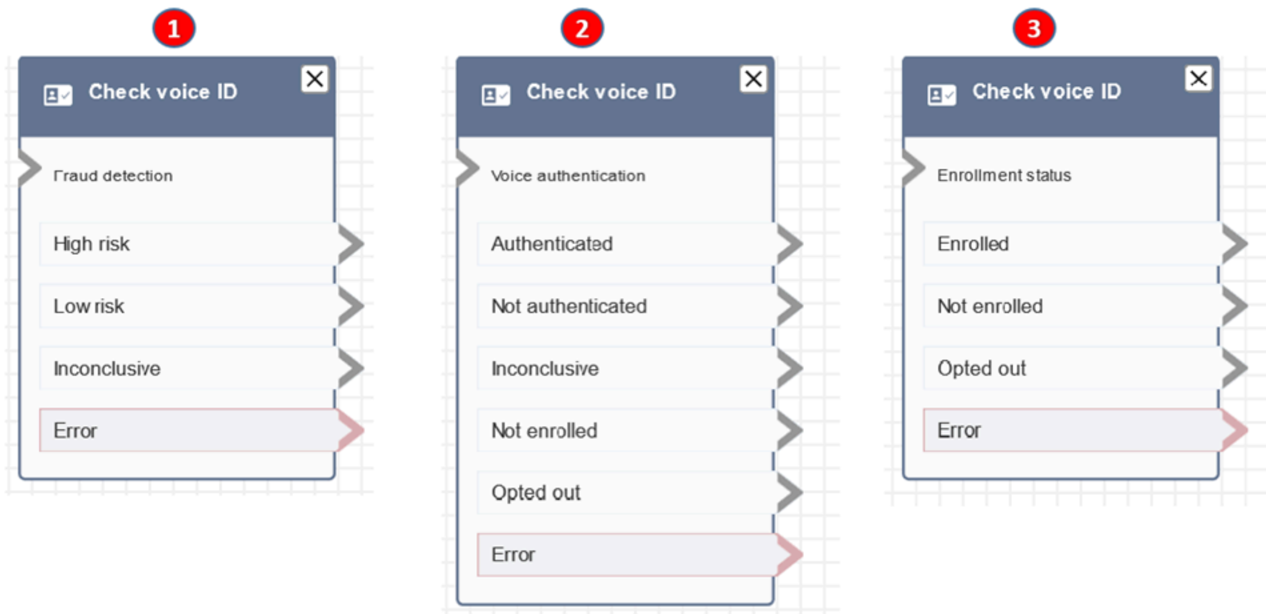
When you create a flow that uses this block, add these blocks in the following order:

1. Set Voice ID block.
2. Set contact attributes block: For **Enrollment status** and **Voice authentication**, the Customer ID system attribute needs to be set in Set contact attributes block because it is acting on a specific customer.
3. **Check Voice ID** block.

Configured block

The following three images show what this block looks like when it's configured to check for:

1. Enrollment status
2. Voice authentication
3. Fraud detection



More information

See the following topics for more information about this block:

- Use real-time caller authentication with Voice ID in Amazon Connect
- Enroll callers in Voice ID in the Contact Control Panel (CCP)

Flow block in Amazon Connect: Check staffing

This topic defines the flow block for checking the current or specified customer queue to gauge agent availability.

Description

- Checks the current working queue, or queue you specify in the block, for whether agents are available, staffed, or online.
- Before transferring a call to agent and putting that call in a queue, use the **Check hours of operation** and **Check staffing** blocks. They verify that the call is within working hours and that agents are staffed to service.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

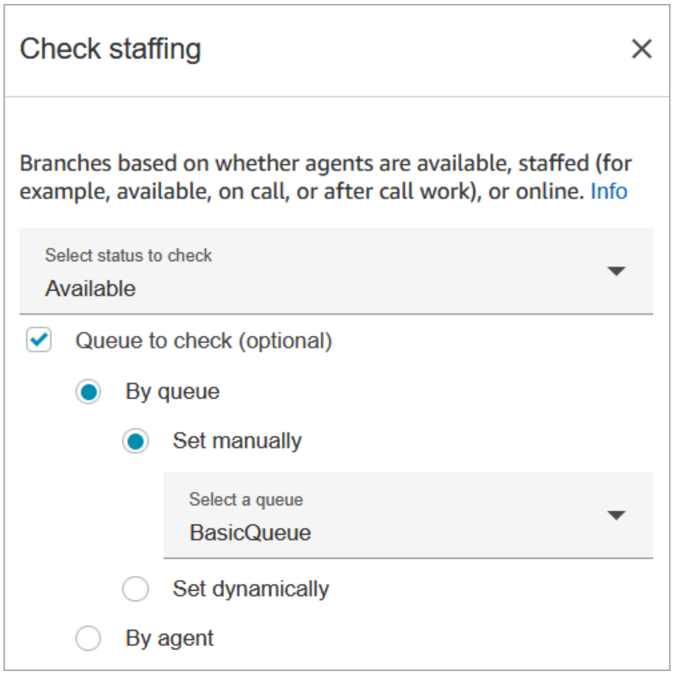
Flow types

You can use this block in the following flow types:

- Inbound flow
- Customer queue flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

The following image shows the **Properties** page of the **Check staffing** block. It is configured to check whether agents in the BasicQueue are available so they can be routed contacts.



In the **Status to check** dropdown box, choose one of the following options:

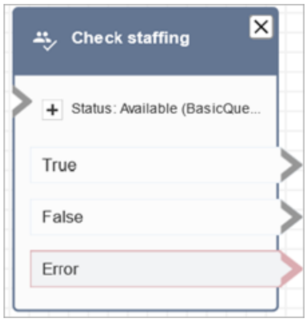
- [Available](#) = Check whether at least one agent in the queue is **Available**.
- [Staffed](#) = Check whether at least one agent in the queue is **Available**, **On call**, or in **After Contact Work**.
- [Online](#) = Check whether at least one agent in the queue is **Available**, in the **Staffed** state, or in a custom state.

Configuration tips

- You must set a queue before using a **Check staffing** block in your flow. You can use a [Set working queue](#) block to set the queue.
- If a queue is not set, the contact is routed down the **Error** branch.
- When a contact is transferred from one flow to another, the queue that is set in a flow is passed from that flow to the next flow.

Configured block

The following image shows an example of what this block looks like when it is configured. It has three branches: **True**, **False**, and **Error**.



Scenarios

See these topics for scenarios that use this block:

- Transfer contacts to a specific agent in Amazon Connect

Flow block in Amazon Connect: Contact tags

This topic defines the flow block for creating and applying tags to your contacts.

Description

- Use this block to create and apply user-defined tags (key:value pairs) to your contacts.
- You can create up to 6 user-defined tags.
- You set a value that can be referenced later in a flow. You can also remove tags in a flow, for example, if the tags aren't relevant to the segment anymore.
- For more information about how to use tags to obtain a more detailed view of your Amazon Connect usage, see Set up granular billing for a detailed view of your Amazon Connect usage.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes

Channel	Supported?
Task	Yes
Email	Yes

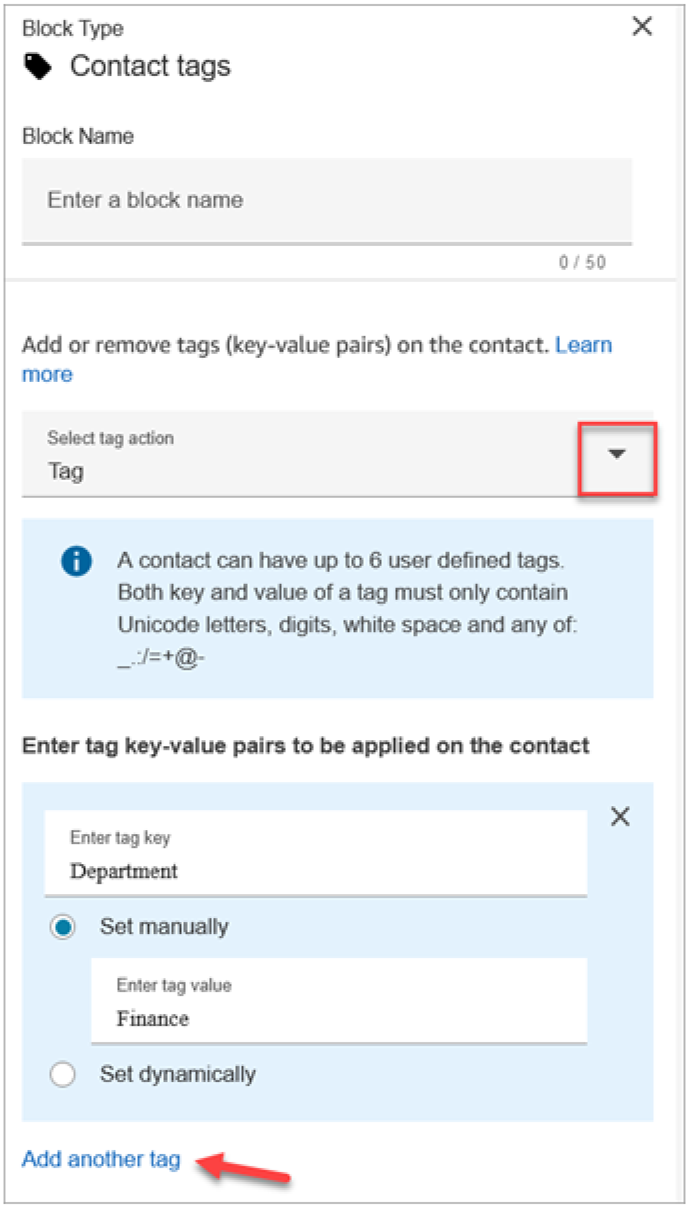
Flow types

You can use this block in the following flow types:

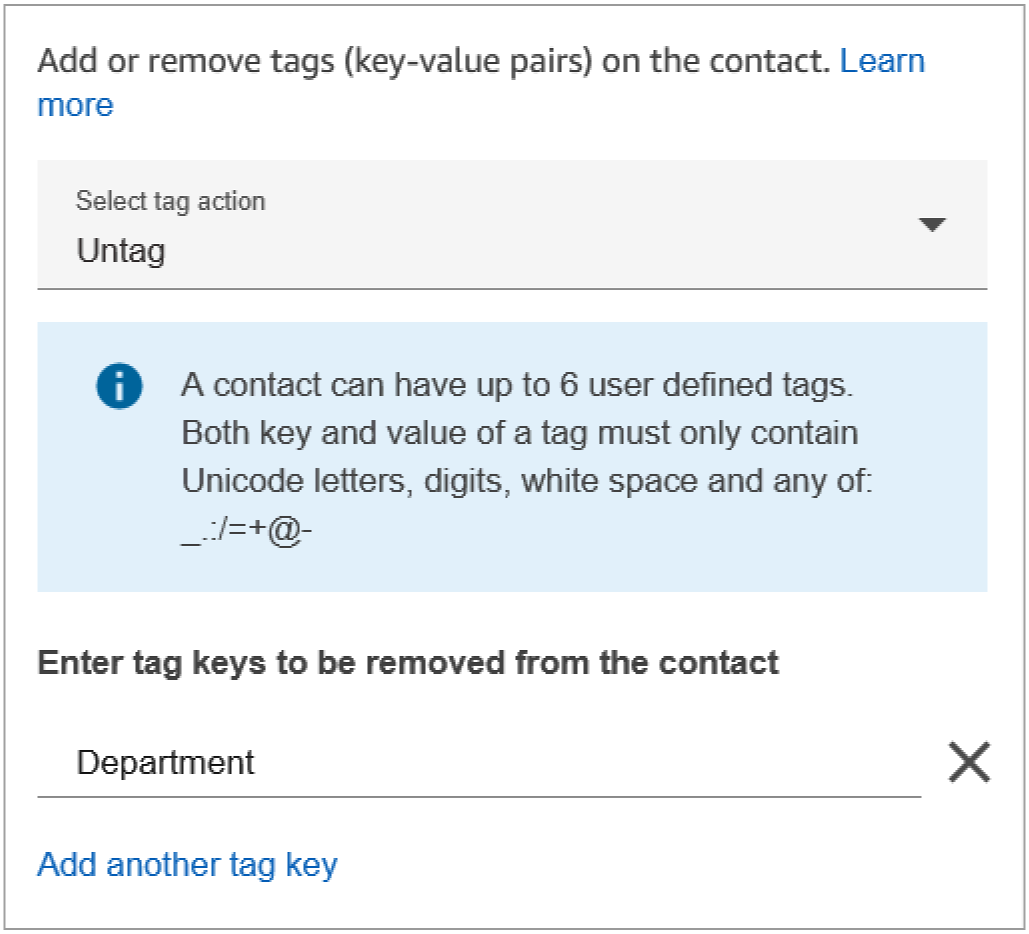
- All

Properties

The following image shows the **Properties** page of the **Contact tags** block. It is configured to set a tag on the current contact with the key **Department** and the value **Finance**.



You can also configure the block to untag a contact, as shown in the following image.

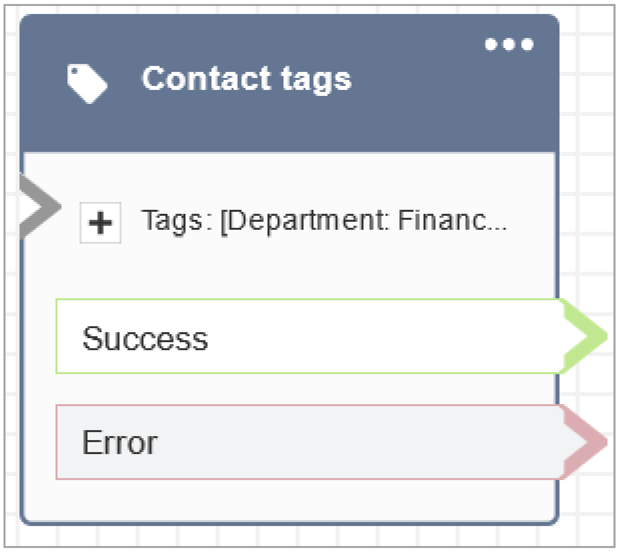


Configuration tips

- For more information about how Amazon Connect processes user-defined tags, see [Things to know about user-defined tags](#).

Configured block

The following image shows an example of what this block looks like when it is configured. It has two branches: **Success** and **Error**.



Flow block in Amazon Connect: Create persistent contact association

This topic defines the flow block for creating a persistent contact association, enabling conversations with contacts to continue where they left off.

Description

- Enables persistent chat experience on the current chat.
- This allows you to select the required rehydration mode. For more information about chat rehydration, see Enable customers to resume chat conversations in Amazon Connect.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	No - Error branch
Chat	Yes
Task	No - Error branch

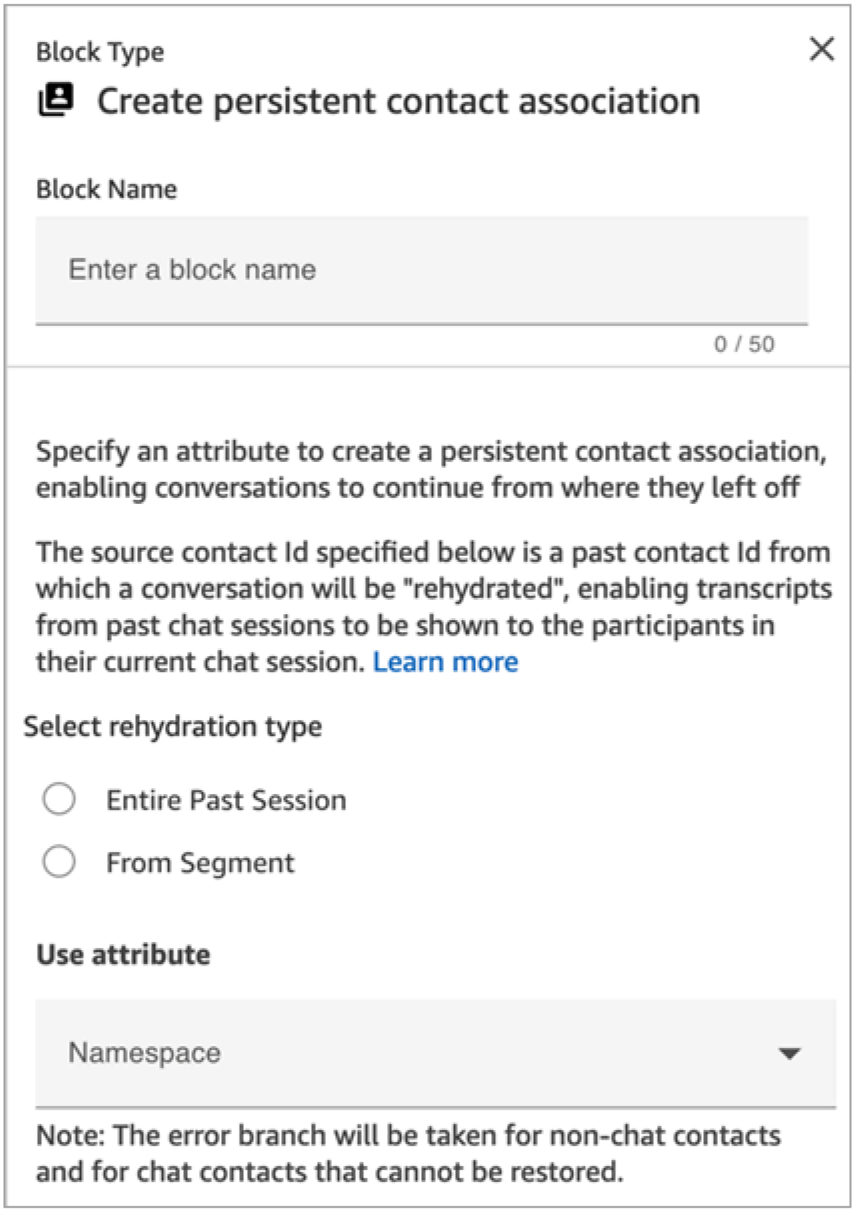
Flow types

You can use this block in the following flow types:

- Inbound flow
- Customer Queue flow
- Customer hold flow
- Customer whisper flow
- Outbound whisper flow
- Agent hold flow
- Agent whisper flow
- Transfer to agent flow
- Transfer to queue flow

Properties

The following image shows the **Properties** page of the **Create persistent contact association** block.



Configuration tips

- To enable persistent chat you can add the **Create persistent contact association** block to your flow, or provide the previous `contactId` in the `SourceContactId` parameter of the [StartChatContact](#) API, but not both. You can enable persistence of a `SourceContactID` on a new chat only once.

  We recommend that you enable persistent chat by using the **Create persistent contact association** block when using the following features:

  - [Amazon Connect chat widget](#)

  - Apple Messages for Business

- You can configure persistent chats to rehydrate the entire past chat conversation or rehydrate from a specific segment of a past chat conversation. For information about rehydration types, see Enable customers to resume chat conversations in Amazon Connect.

Configured block

The following image shows an example of what this block looks like when it is configured. It has two branches: **Success** and **Error**.

Flow block in Amazon Connect: Create task

This topic defines the flow block for creating a new task manually or based on an existing task template.

Description

- Creates a new task manually or by leveraging a task template.
- Sets the tasks attributes.
- Initiates a flow to start the task immediately or schedules it for a future date and time.

For more information about Amazon Connect Tasks, see The task channel in Amazon Connect and Pause and resume tasks in Amazon Connect Tasks.

Note

If your Amazon Connect instance was created on or before October 2018, the contact is routed down the error branch. For the contact to be routed down the success path, create an IAM policy with the following permission and attach it to the Amazon Connect service role. You can find the Amazon Connect service role on the **Account overview** page for your Amazon Connect instance.

```
{
     "Effect": "Allow",
     "Action": "connect:StartTaskContact",
     "Resource": "*"
}
```

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

Flow types

You can use this block in the following flow types:

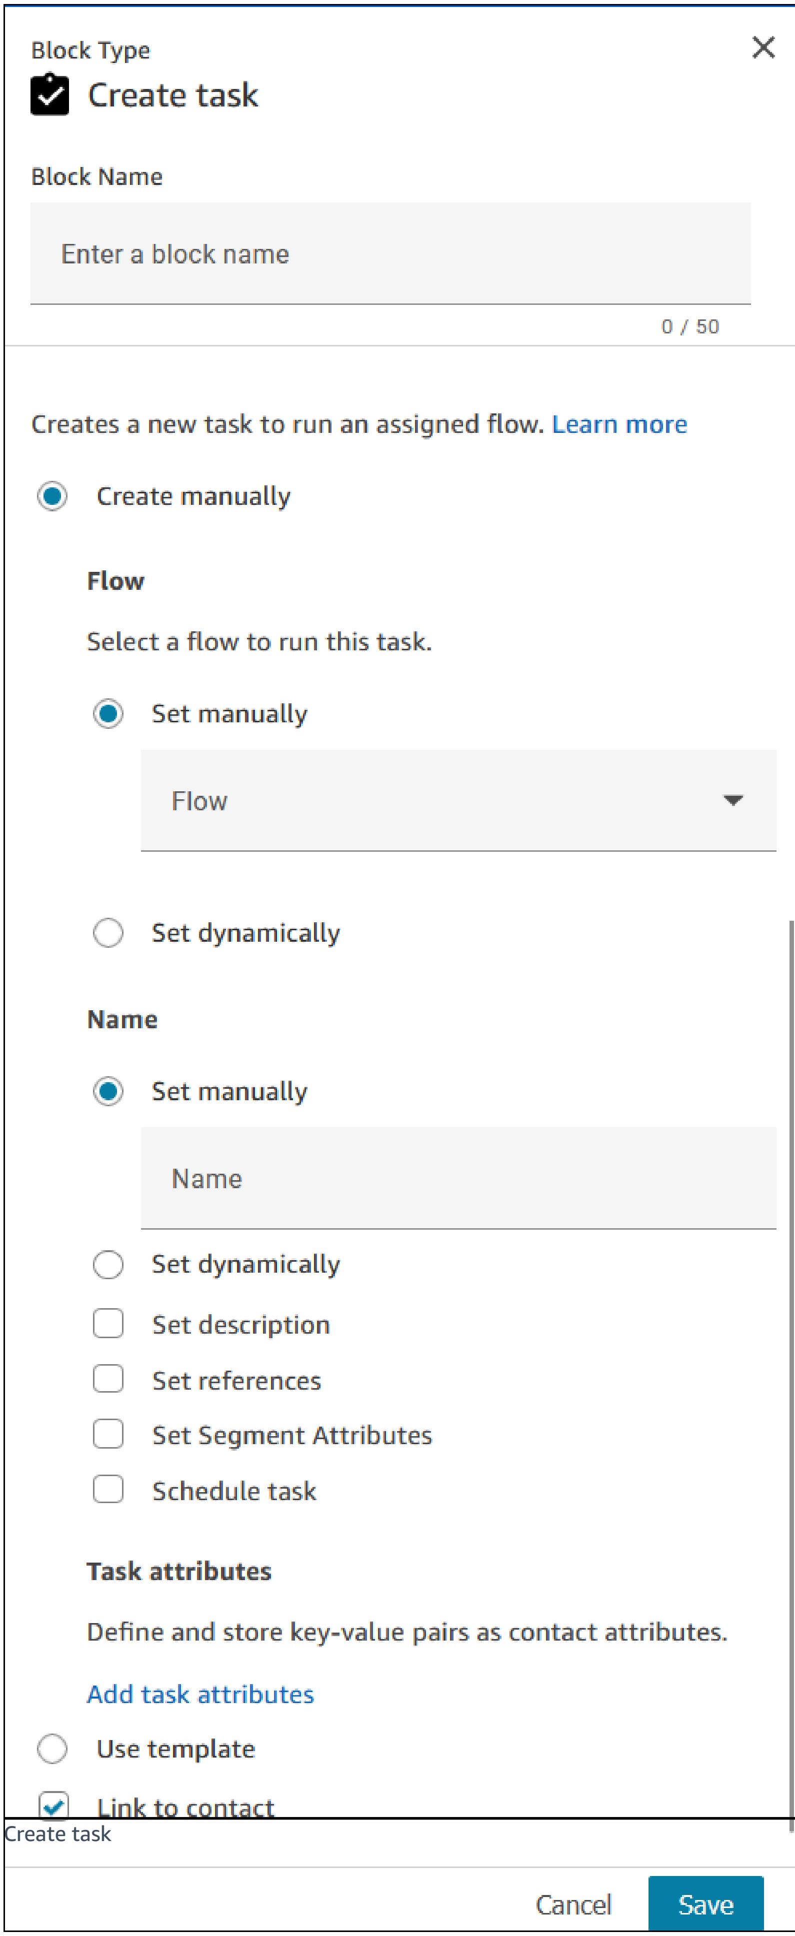
- All flows

Properties

When you configure a **Create task** block, you choose either **Create manually** or **Use template**. Your choice dictates which fields you'll need to complete on the rest of **Properties** page. Following is more information about these two options.

Option 1: Create manually

The following image shows the **Properties** page when **Create manually** is selected. All settings on the page can be specified manually or dynamically.



Block Type
Create task
Block Name
Enter a block name
0 / 50
Creates a new task to run an assigned flow. Learn more
Create manually
Flow
Select a flow to run this task.
Set manually
Flow
Set dynamically
Name
Set manually
Name
Set dynamically
Set description
Set references
Set Segment Attributes
Schedule task
Task attributes
Define and store key-value pairs as contact attributes.
Add task attributes
Use template
Link to contact
Cancel
Save

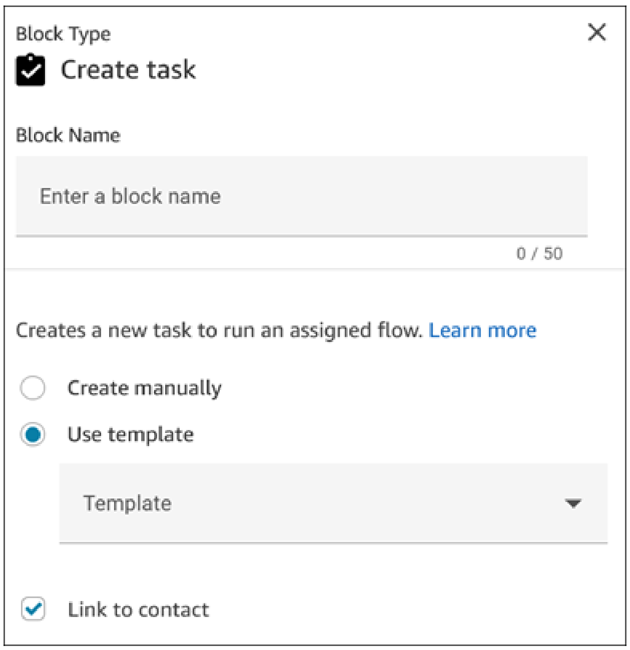
If you choose **Use template** at bottom of the page, the entire page switches to that option. If needed, you can toggle back to **Create manually** and continue with your manual settings.

Option 2: Use template

After you create a template, it's available for you to specify it in **Create task** block.

The following image shows the **Properties** page when **Use template** is selected.

- If the selected template does not include a flow, you must specify the flow that you want the task to run.
- You cannot overwrite the settings of any fields on the page that are populated by the template.



Configuration tips

- The **Create task** block branches based on whether the task was successfully created:
  - **Success** if task was created. It responds with the contact ID of the newly created task.
  - **Error** if task wasn't created.
- **Referencing a task contact ID**: The newly created task runs the flow that you specified in the **Flow** section of the block, or it runs the flow configured by the task template that you selected. You can reference the contact ID of the newly created task in subsequent blocks.

For example, you might want to reference the task contact ID in the **Play prompt** block. You can specify the task contact ID dynamically by using the following attribute:

- **Namespace: System**
- **Value: Task Contact id**

- **Scheduling a task**: When you **Set date and time using attribute**: Values for date fields must be in Unix timestamp (Epoch seconds). Because of this, it's most likely that you'll choose a **User-defined** attribute for the **Namespace**.

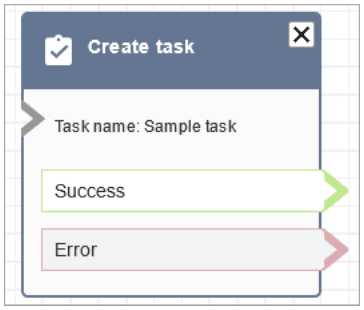
  For example, your flow might have a **Set contact attributes** block that sets a user-defined attribute with key named *scheduledTaskTime*. Then, in the **Create task** block, you would select **User-defined**, and the key would be *scheduledTaskTime*.

  To continue with this example, the value in *scheduledTaskTime* must be specified Unix timestamp. For example, 1679609303 is the Unix timestamp that corresponds to Thursday, March 23, 2023 10:08:23 PM UTC.

  When the date and time have passed, contacts are always routed down the **Error** branch. To avoid the **Error** branch, be sure to keep the Epoch seconds updated to a valid date and time in the future.
- Use the **Link to contact** option to automatically link the task to the contact.
- Be sure to check the service quotas for tasks and API throttling, and request increases, if needed. The quotas apply when this block creates tasks.

Configured block

The following image shows an example of what this block looks like when it is configured. It has two branches: **Success** and **Error**.



Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

- Sample inbound flow in Amazon Connect for the first contact experience

Flow block in Amazon Connect: Customer profiles

This topic defines the flow block for retrieving, creating, and updating a customer profile.

Description

- Enables you to retrieve, create, and update a customer profile.
  - You can configure the block to retrieve profiles using up to five search identifiers of your choice.
- Enables you to retrieve a Customer Profile's object and calculated attributes.
  - You can configure the block to retrieve objects using a search identifier of your choice.
  - You must provide a profile ID in this block. You can provide a **profileID** manually, or use the **profileID** saved in the Customer namespace after you have found a profile using the **Get profile** action.
- Enables you to associate the contact, such as voice, chat, and tasks, to an existing customer profile.
- When customer profile data is retrieved, the **Response fields** are stored in the contact attributes for that customer, allowing you to use them in subsequent blocks.
- You can also reference the **Response fields** by using the following JSONPath: `$.Customer.` For example, `$.Customer.City` and `$.Customer.Asset.Status`.
- The following examples show how you might use this block:
  - Use a Play prompt block after retrieving a profile to provide a personalized call or chat experience by referencing the supported profile fields.
  - Use a Check contact attributes block after retrieving profile data to route a contact conditional on the value.
  - See How to persist fields throughout the flow for more details.

Supported channels

The following table lists how this block routes a contact that is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

Flow types

You can use this block in the following flow types:

- All flow types

Configuration tips

- Before using this block, make sure Customer Profiles is enabled for your Amazon Connect instance. For instructions, see Use Amazon Connect Customer Profiles.
- A contact is routed down the **Error** branch in the following situations:
  - Customer Profiles is not enabled for your Amazon Connect instance.
  - Request data values are not valid. The request values cannot be over 255 characters.
  - The Customer Profiles API request has been throttled.
  - Customer Profiles is having availability issues.
- The total size of Customer Profiles contact attributes is limited to 14,000 characters (56 attributes assuming max size of 255 each) for the entire flow. This includes all values persisted as **Response fields** in Customer Profiles blocks during the flow.

Properties

The following property types are available in the Customer Profiles flow block:

- [Get Profile]
- [Create Profile]
- [Update Profile]
- [Get Profile Object]
- [Get Calculated Attributes]
- [Associate Contact to Profile]

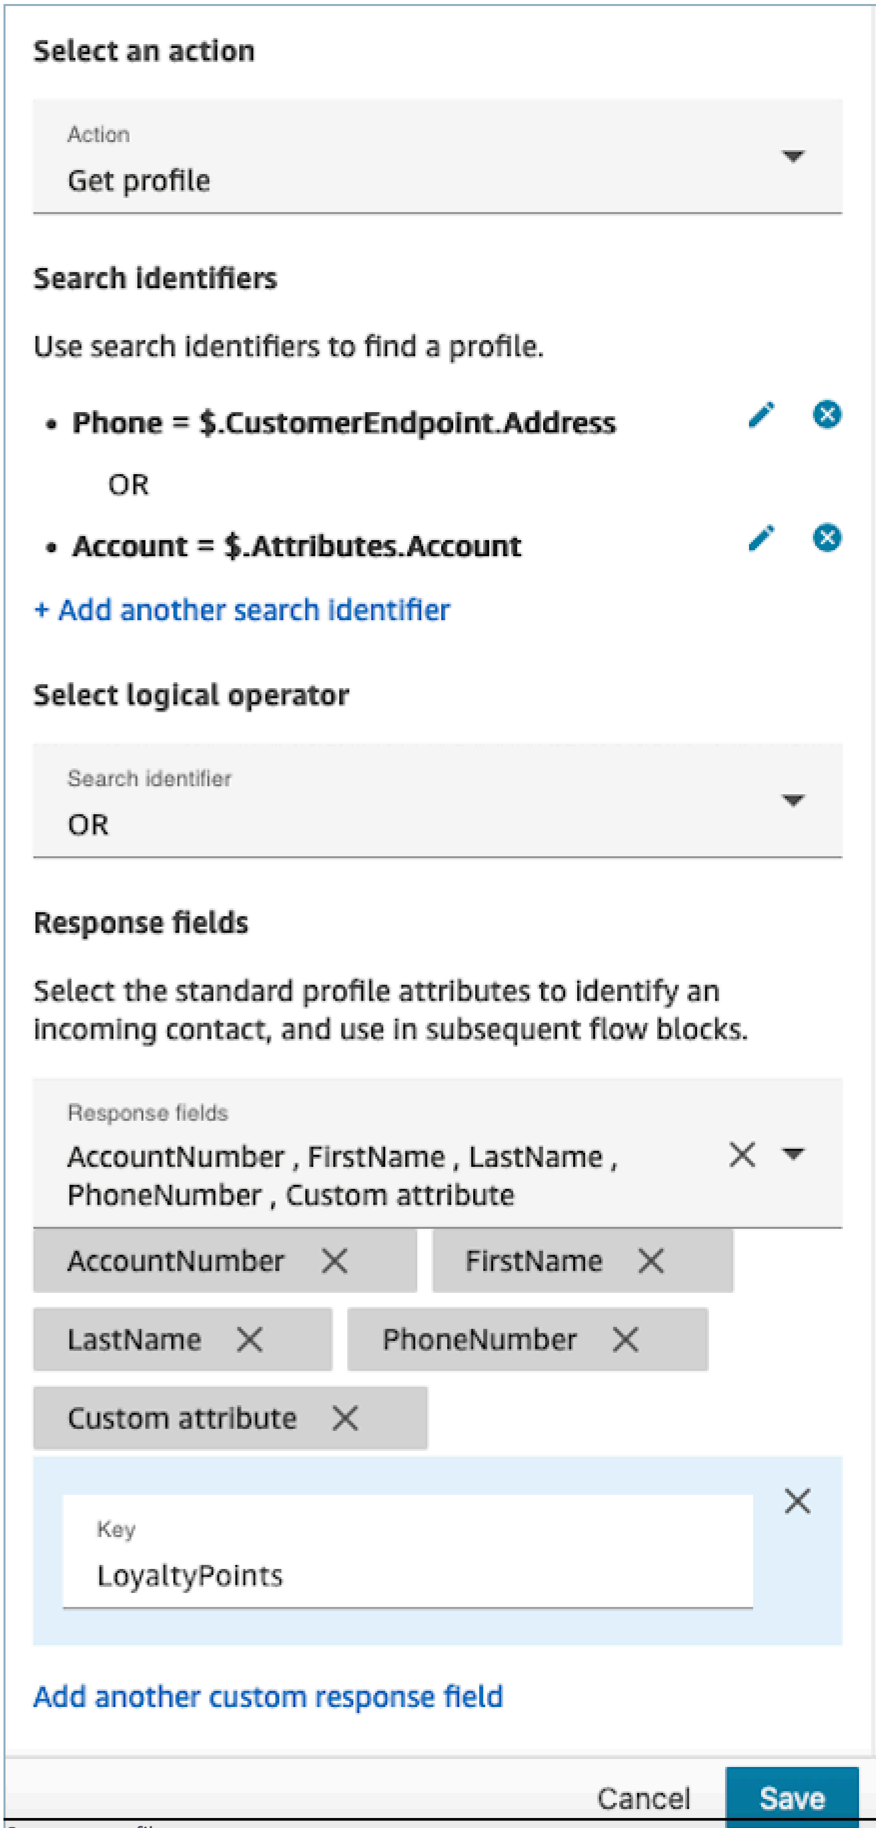
Properties: Get profile

When configuring properties to **Get profile**, consider the following:

- You must provide at least one search identifier, up to five total.
- If multiple search identifiers are provided, you must provide one logical operator, either **AND** or **OR**. The logical operator is applied across all search identifiers like one of the following expressions:
  - (a **AND** b **AND** c)
  - (x **OR** y **OR** z)
- Define attributes to persist in subsequent blocks, storing them in contact attributes under **Response fields**.
- Contacts can be routed down the following branches
  - **Success:** one profile was found. Response fields are stored to contact attributes
  - **Error:** An error was encountered while trying to find the profile. This may be due to a system error or how **Get profile** is configured.
  - **Multiple Found:** multiple profiles were found.
  - **None Found:** no profile was found.

The following image shows an example of a Customer Profiles **Properties** page that is configured for the **Get profile** action.

The example block is configured to search for profiles that either match the caller's **Phone** number or share the same **Account** number stored in the user-defined attribute named "Account." When one profile is located, the following fields are stored in the contact attributes for that specific customer: **Response fields - AccountNumber**, **FirstName**, **LastName**, **PhoneNumber**, and **Attributes.LoyaltyPoints**.



Select an action

Properties: Create profile

When configuring properties for **Create profile**, consider the following:

- Specify the attributes you intend to populate during profile creation in the **Request fields**
- Define attributes to persist in subsequent blocks, storing them in contact attributes under **Response fields**.

Contacts can be routed down the following branches:

- **Success:** A profile is successfully created, and **Response fields** are stored in contact attributes.
- **Error:** An error occurred during the profile creation process, possibly due to a system error or misconfiguration of the **Create profile** action.

The following example block is configured to create a profile with a **PhoneNumber** and a custom attribute named “Language". Following the profile creation, the **Attributes.Language** response field is stored in contact attributes, making it available for use in subsequent blocks.

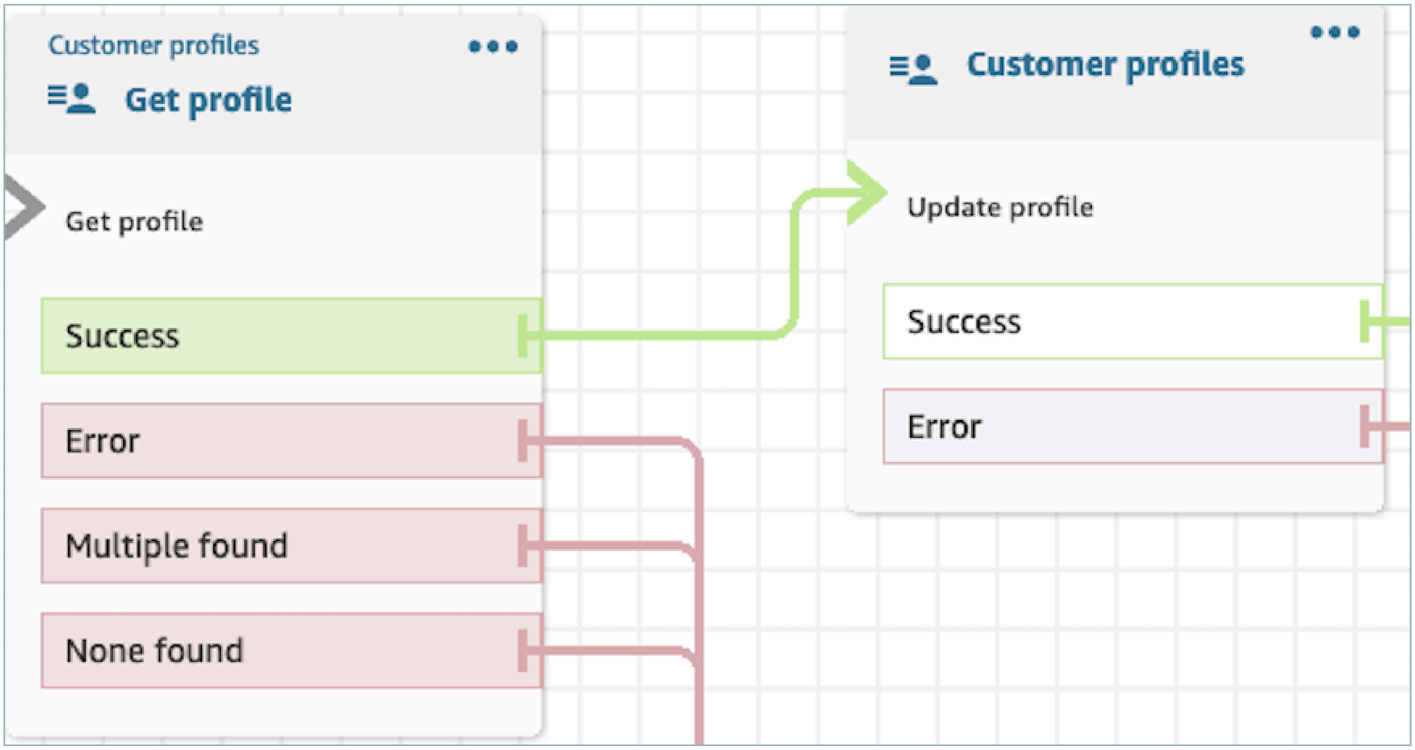
Properties: Update profile

When configuring properties to **Update profile**, consider the following:

- Before using an **Update profile** block, use a **Get profile** block, as shown in the following image. Use the **Get profile** block to locate the specific profile you intend to update.



- Provide the attributes and values you wish to update the profile with **Request fields** and **Request field values**.
- Define attributes to persist in subsequent blocks, storing them in contact attributes under **Response fields**.

Contacts can be routed down the following branches:

- **Success:** The profile has been successfully updated, and **Response fields** are stored in contact attributes.
- **Error:** An error occurred during the attempt to update the profile. This could result from a system error or misconfiguration of the **Update profile** action.

The displayed block below is configured to update a Profile with a **MailingAddress1** with user input as value. When a profile is updated, the **MailingAddress1** response field is stored in contact attributes, making it available for use in subsequent blocks.

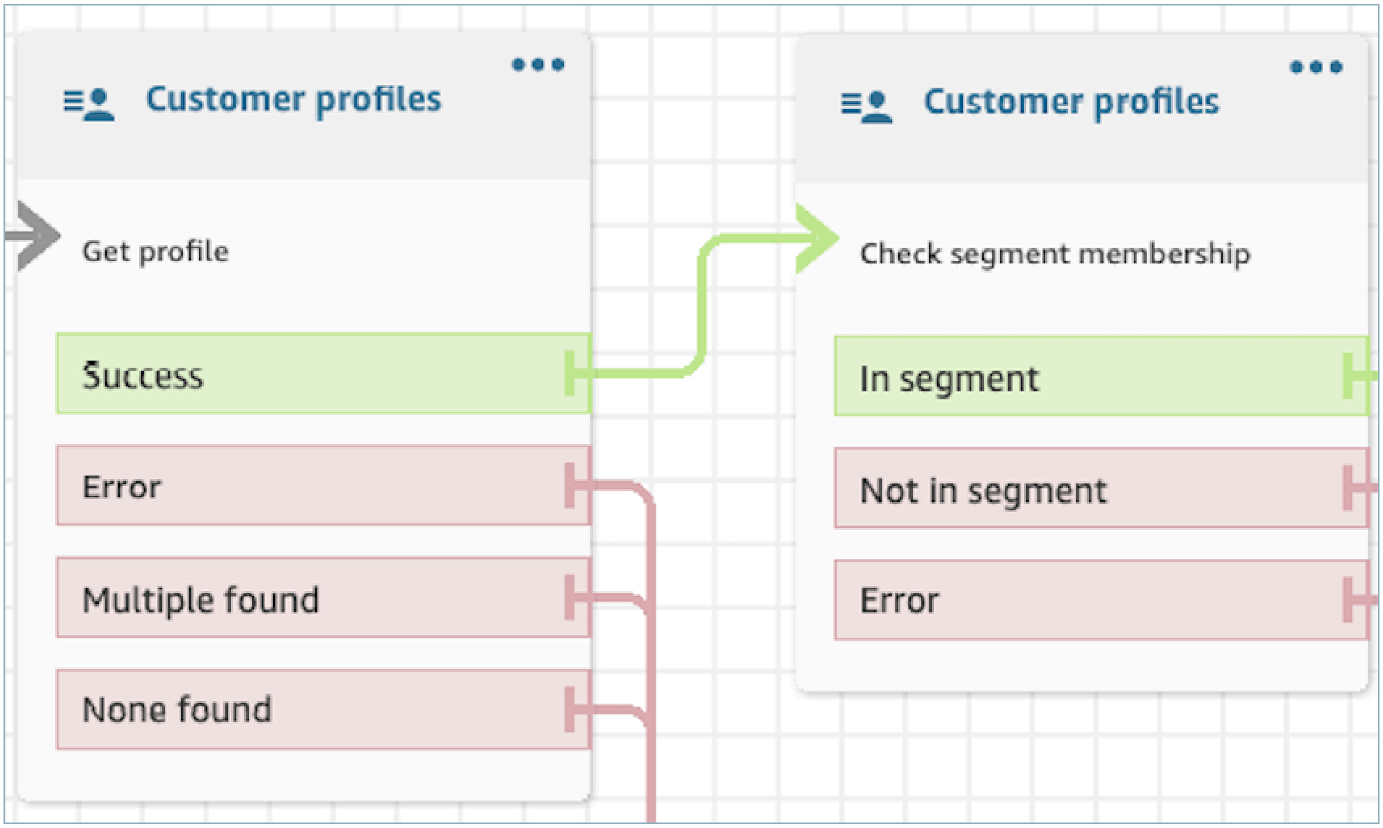
Properties: Check segment membership

> **Important**
>
> To use this action, your Amazon Connect instance must have permission for the following APIs: ListSegmentDefinitions, GetSegmentMembership, BatchGetProfile, and BatchGetCalculatedAttributeForProfile in either of the following Policies: **AmazonConnectServiceLinkedRolePolicy** or **AmazonConnectServiceCustomerProfileAccess**.

When configuring properties to **Check segment membership**, consider the following:

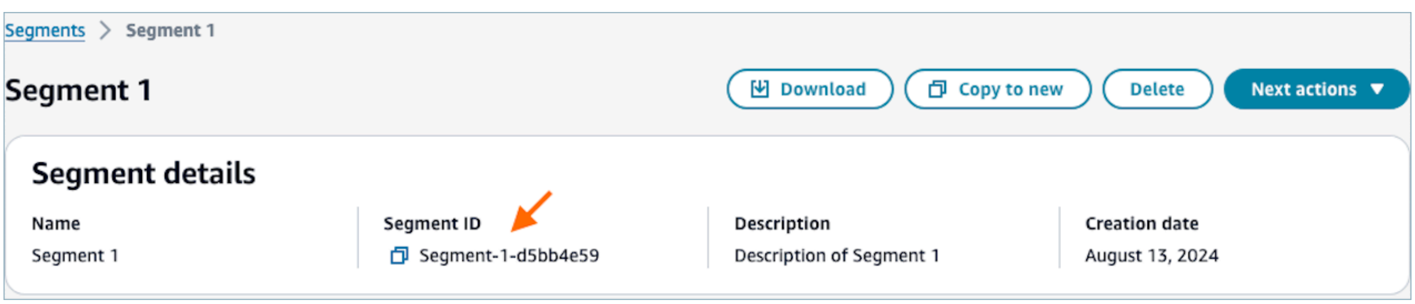
- **Mandatory Profile ID:** A Profile ID is required for this block to function. The **Get profile object** action retrieves an object associated with the provided **ProfileID**. Ensure you provide the **ProfileID** by using a preceding **Get profile** block. Use the **Get profile** block to pinpoint the specific profile before moving forward to retrieve the profile's object in the subsequent block.
    - You have the option to manually input the Profile ID or use a pre-defined value stored in a pre-defined or user attribute.

      The following image shows an example flow configured to get profile, and then check segment membership.

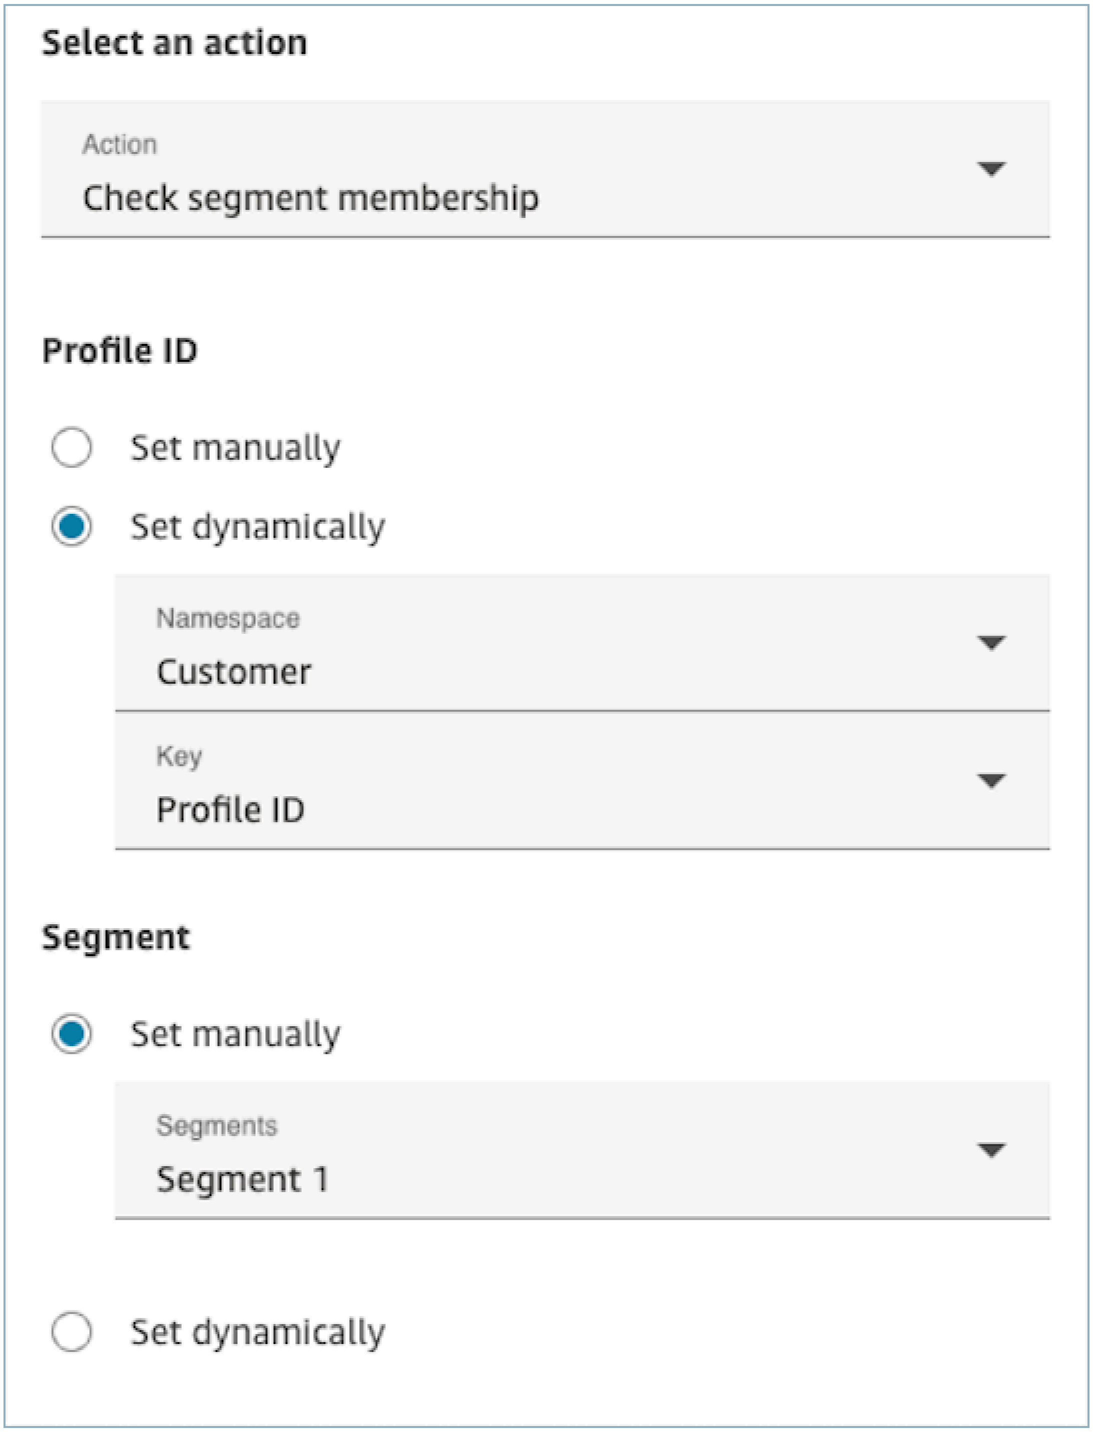


- You must provide a value for segment. You have the option to manually select the segment or set dynamically by using a pre-defined value stored in a pre-defined or user attribute.
- When you set a segment dynamically, provide an attribute that refers to the customer segment's identifier. You can find the identifier on the **View segment detail** page or as SegmentDefinitionName in the ListSegmentDefinitions operation in the Customer Profiles API.

  The following image shows the location of **Segment ID** on the **View segment details** page.



- The following image shows an example of checking segment membership. **Profile ID** is set to be checked dynamically and **Segment** manually.



Contacts can be routed down the following branches

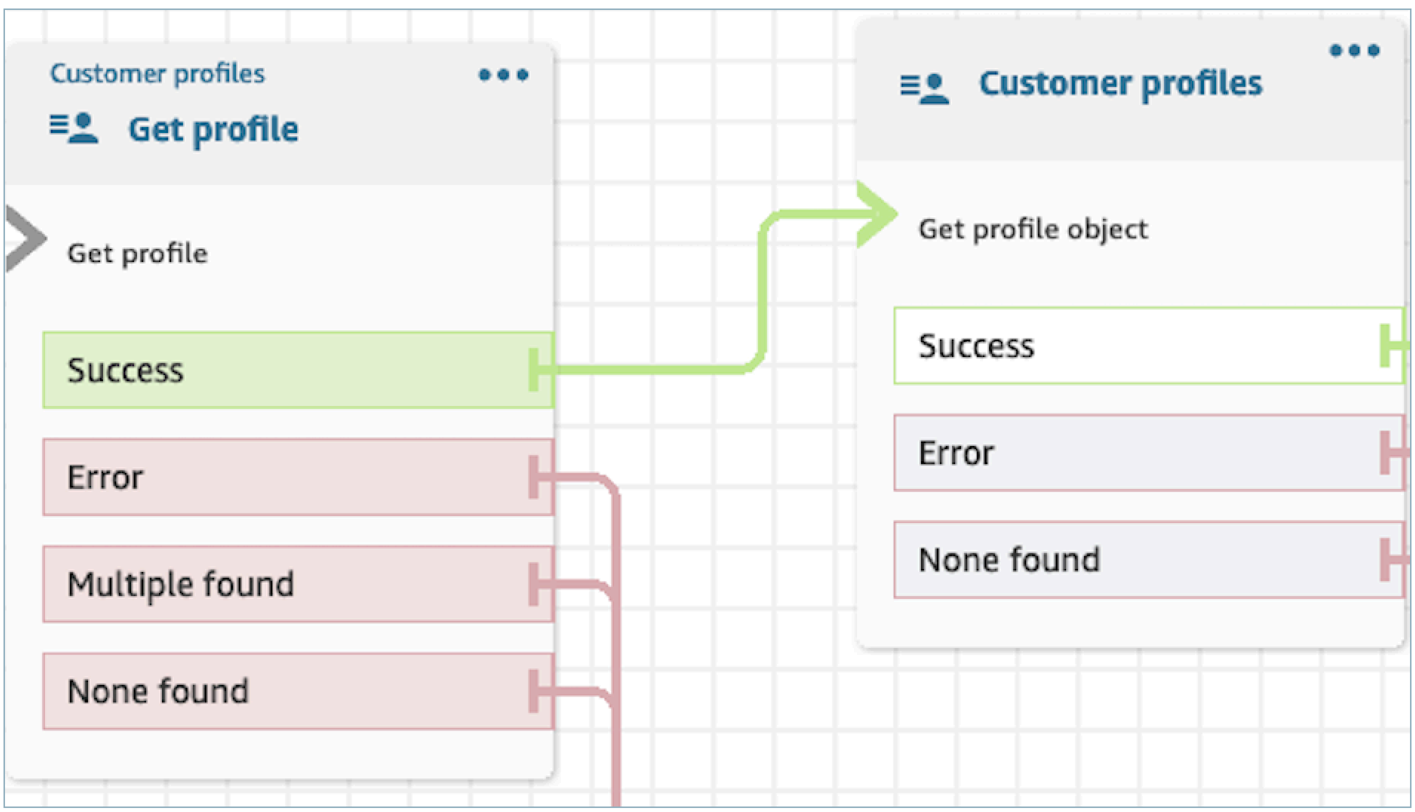
- **In segment**: The profile belongs to the customer segment.
- **Not in segment**: The profile does not belong to the customer segment.

- **Error**: An error occurred while attempting to check the segment membership. This may be due to a system error or misconfiguration of the **Check segment membership** action. To learn more about flow error logging, see Enable Amazon Connect flow logs in an Amazon CloudWatch log group.

Properties: Get profile object

When configuring properties to **Get profile object**, consider the following:

- **Mandatory Profile ID:** A Profile ID is required for this block to function. The **Get profile object** action retrieves an object associated with the provided **ProfileID**. Ensure you provide the **ProfileID** by using a preceding **Get profile** block, as illustrated in the following image. Use the **Get profile** block to pinpoint the specific profile before moving forward to retrieve the profile's object in the subsequent block.
  - You have the option to manually input the Profile ID or use a pre-defined value stored in a pre-defined or user attribute.



- You must indicate the object type from which you intend to retrieve information.
- You must choose one of the following options for object retrieval:
  - **Use latest profile object:** This option consistently retrieves the most recent object.

  - **Use search identifier:** This option involves searching for and retrieving the object using the provided search identifier.
- Define attributes to persist in subsequent blocks, storing them in contact attributes under **Response fields** .

Contacts can be routed down the following branches:

- **Success:** The profile object is successfully located, and **Response fields** are stored in contact attributes.
- **Error:** An error occurred during the attempt to retrieve the profile object. This may be due to a system error or misconfiguration of the **Get Profile** action.
- **None Found:** no object is found.

The displayed block below is configured to retrieve a profile object of type "Asset" associated with the **ProfileId** saved under the "Customer" namespace. In this specific scenario, the block is will search for an Asset using the Asset ID. After the Asset is located, **Asset.Price** and **Asset.PurchaseDate** are stored in contact attributes, making them available for subsequent blocks.

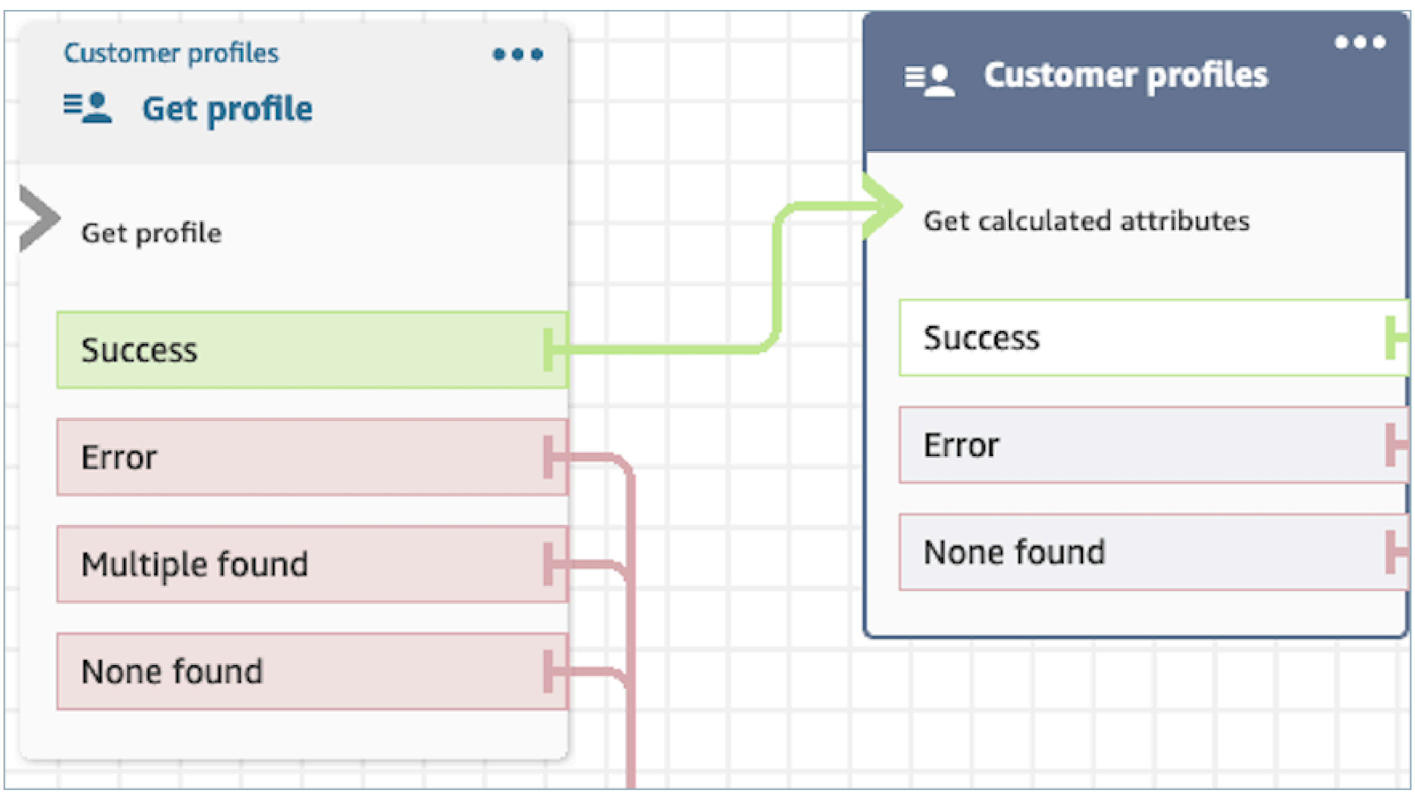
Properties: Get calculated attributes

> **Important**
>
> To use this action, your Amazon Connect instance must have permission for the following APIs: `ListCalculatedAttributeDefinitions` and `GetCalculatedAttributeForProfile` in either of the following Policies: **AmazonConnectServiceLinkedRolePolicy** or **AmazonConnectServiceCustomerProfileAccess**.

When configuring properties to **Get calculated attributes**, consider the following:

- **Mandatory Profile ID:** A Profile ID is required for this block to function. The **Get calculated attributes** action retrieves an object associated with the provided **ProfileID**. Ensure you provide the **ProfileID** by using a preceding **Get profile** block, as illustrated in the following image. Use the **Get profile** block to pinpoint the specific profile before moving forward to retrieve the profile's calculated attributes in the subsequent block.
  - You have the option to manually input the Profile ID or use a pre-defined value stored in a pre-defined or user attribute.



- Define attributes to persist in subsequent blocks, storing them in contact attributes under **Response fields**.
  - The options under **Response fields** are the Calculated Attribute definitions defined for your Customer Profiles domain
  - If the definition of calculated attributes uses a threshold, the calculated attribute value with be a Boolean and either return a True/False. Otherwise, they will return a numeric or string value. The return value of the calculated attribute can be used for branching purposes in a **Check Contact Attributes** block by using conditions such as **Equals** , **Is greater than** , **Is less than** , and **Contains**.

Contacts can be routed down the following branches:

- **Success:** A calculated attribute is found, and Response fields are stored in contact attributes.
- **Error:** An error occurred while attempting to retrieve the calculated attribute. This may be due to a system error or misconfiguration of the **Get calculated attribute** action.
- **None Found:** no calculated attribute is found.

The displayed block below is configured to get calculated attributes belonging to the provided **ProfileId** in contact attributes. The following **Response fields** will be retrieved and stored in contact attributes: **Average Call Duration**, and **Frequent Caller**.

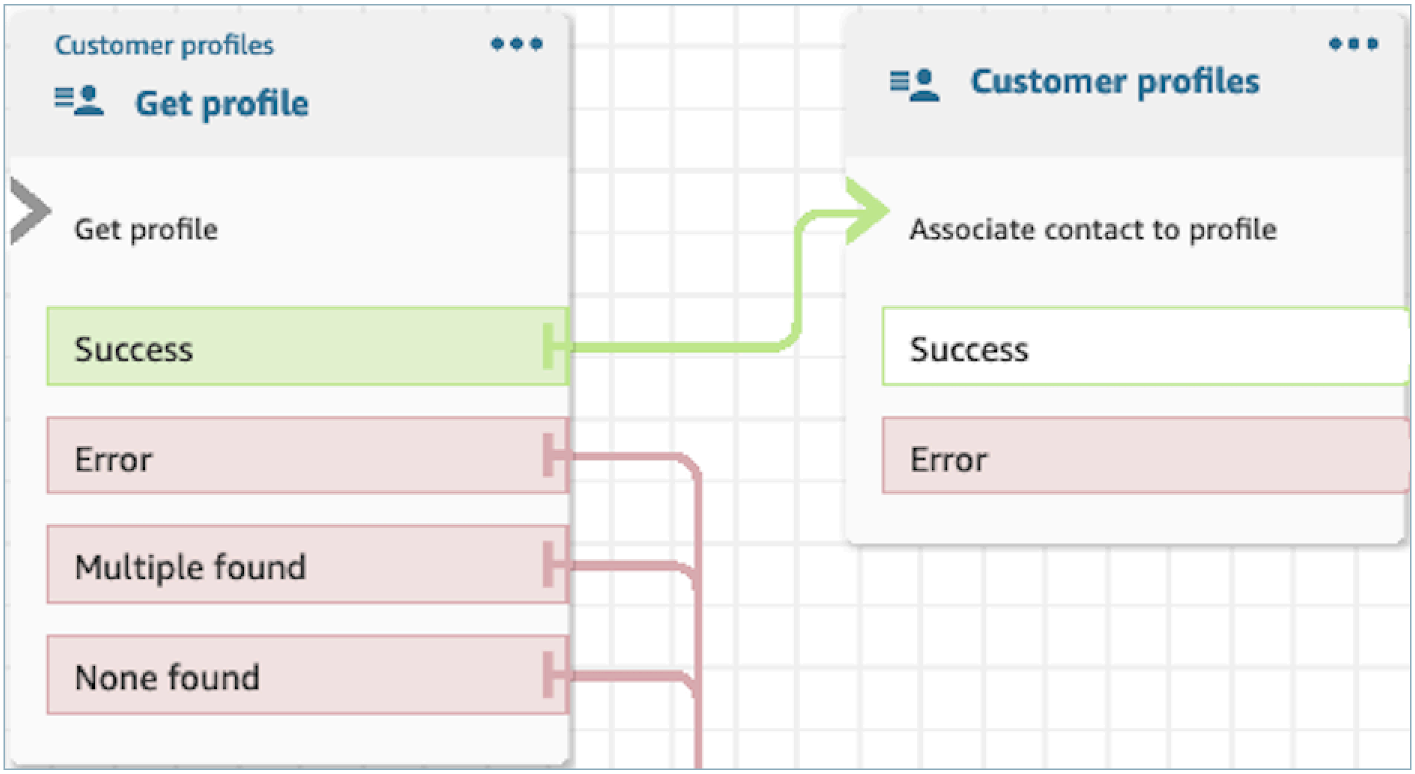
Properties: Associate contact to profile

> **Important**
>
> To use this action, your Amazon Connect instance must have permission for the following APIs: `ListCalculatedAttributeDefinitions` and `GetCalculatedAttributeForProfile` in either of the following Policies: **AmazonConnectServiceLinkedRolePolicy** or **AmazonConnectServiceCustomerProfileAccess**.

To use this action, you must also enable the Customer Profiles View permission in your security profile.

When configuring properties to **Associate contact to profile**, consider the following:

- Add a **Get profile** block before an **Associate contact to profile** , as shown in the following image. Use the **Get profile** block to find the profile first, then associate the contact and profile in the next block.
- **Mandatory Profile ID:** A Profile ID is required for this block to function. Ensure you provide the **ProfileID** by using a preceding **Get profile** block, as illustrated in the following image. Use the **Get profile** block to pinpoint the specific profile you wish to associate the contact to in the next block.
  - You have the option to manually input the Profile ID or use a pre-defined value stored in a pre-defined or user attribute.



- You must provide a value for Contact ID.

Contacts can be routed down the following branches:

- **Success:** Associated the contact to profile.
- **Error:** An error was encountered while attempting to associate the contact to profile. This may be due to a system error or misconfiguration of the **Associate contact to profile** action.

The following block is configured to associate the profile with **Profile ID** stored in contact attributes to the current Contact ID stored in contact attributes.

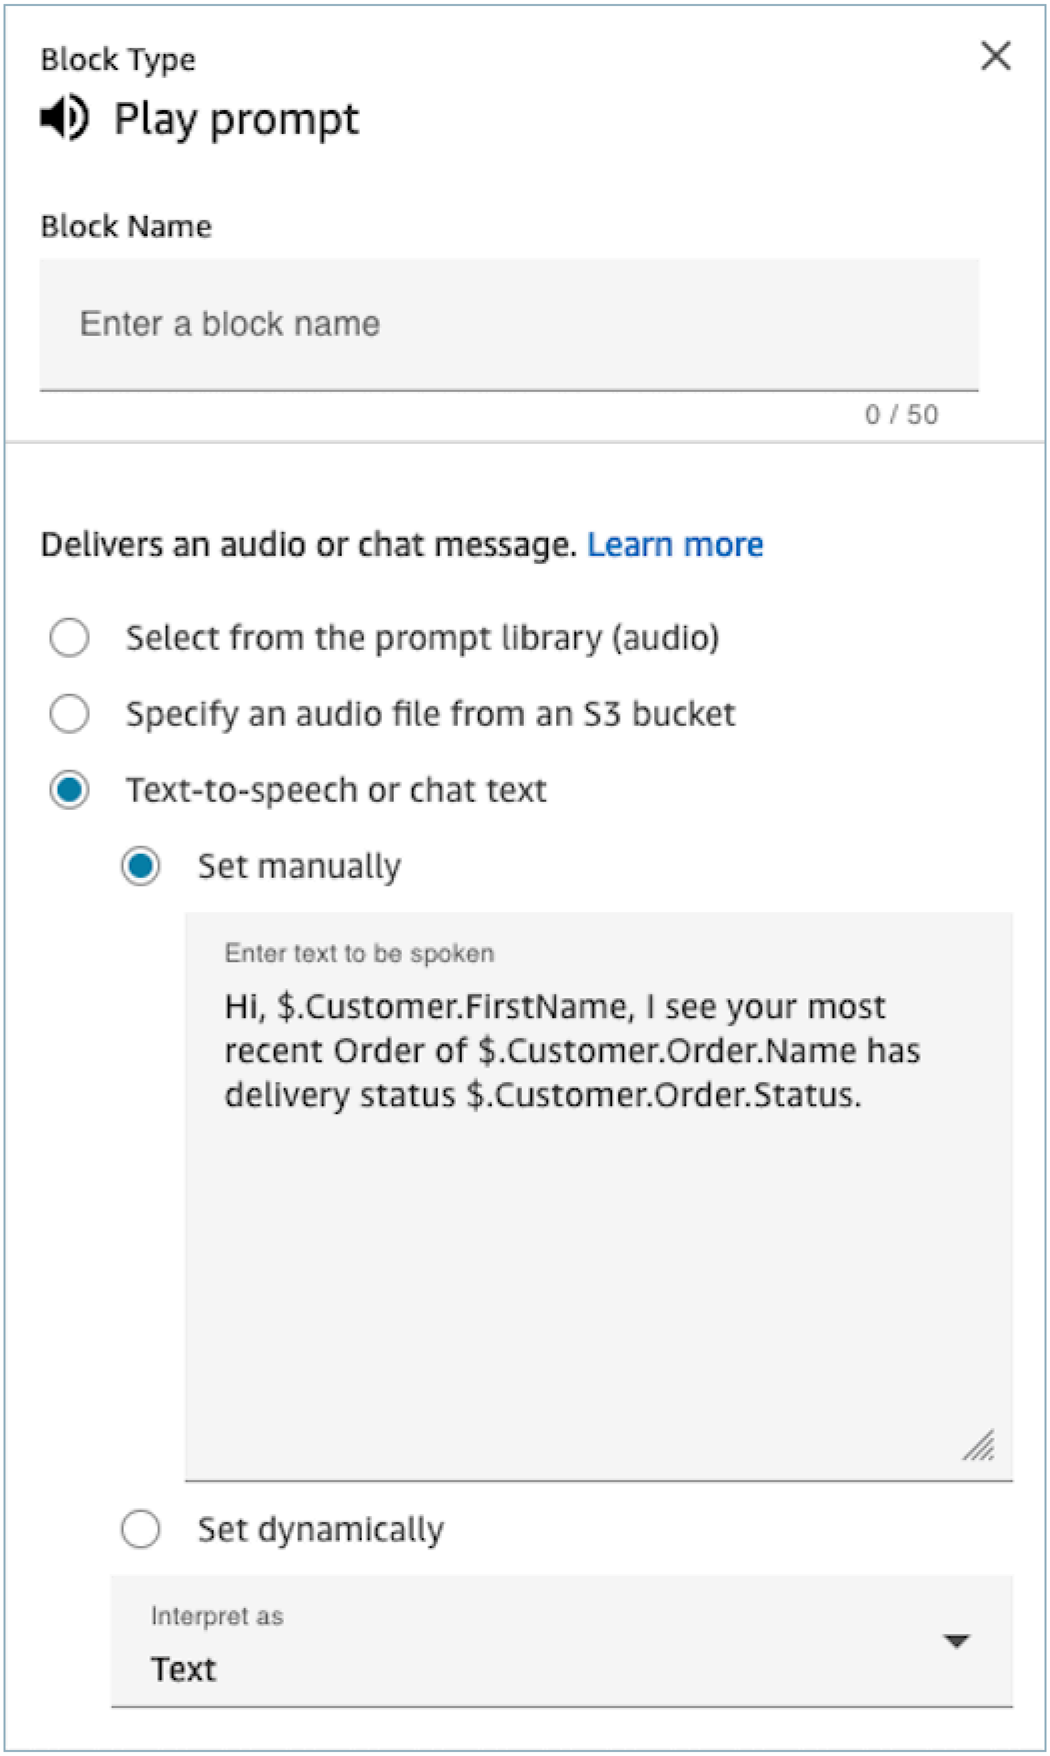
How to persist fields throughout the flow

Let’s say you want customers to interact with your contact center and learn the status of their delivery order without directly communicating with an agent. Additionally, let’s say you want to prioritize incoming calls from customers who have experienced more than 10 minutes delay in the past.

In these scenarios, the IVR needs to fetch the relevant information about the customer. This is achieved through the Customer Profiles block. Secondly, the IVR needs to leverage this customer data in other Flow blocks in order to personalize the experience and proactively service the customer.

1. Use **Play Prompt** to personalize the experience by greeting the customer by name and informing them of their status.



Block Type
Play prompt
Block Name
Enter a block name
0 / 50
Delivers an audio or chat message. Learn more
Select from the prompt library (audio)
Specify an audio file from an S3 bucket

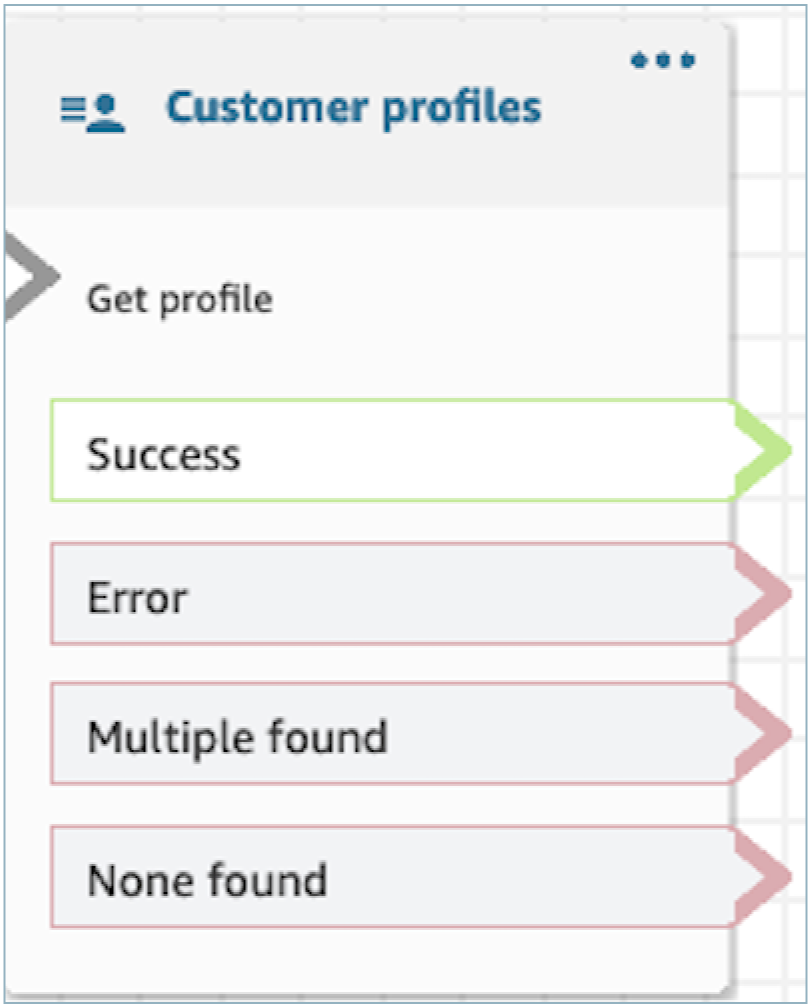
Configured block

The following image shows an example of what this block looks like when it is configured. It shows four branches: **Success**, **Error**, **Multiple found**, and **None found**.



Flow block in Amazon Connect: Disconnect / hang up

This topic defines the flow block for disconnecting a contact at the end of a call.

Description

- Disconnects the contact.

Supported channels

The following table lists how this block routes a contact that is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

Flow types

You can use this block in the following flow types:

- Inbound flow
- Customer queue flow
- Transfer to Agent flow
- Transfer to Queue flow

Flow block in Amazon Connect: Distribute by percentage

This topic defines the flow block for routing customers randomly to a queue based on a percentage.

Description

- This block is useful for doing A/B testing. It routes customers randomly based on a percentage.
- Contacts are distributed randomly, so exact percentage splits may or may not occur.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes

Channel	Supported?
Chat	Yes
Task	Yes
Email	Yes

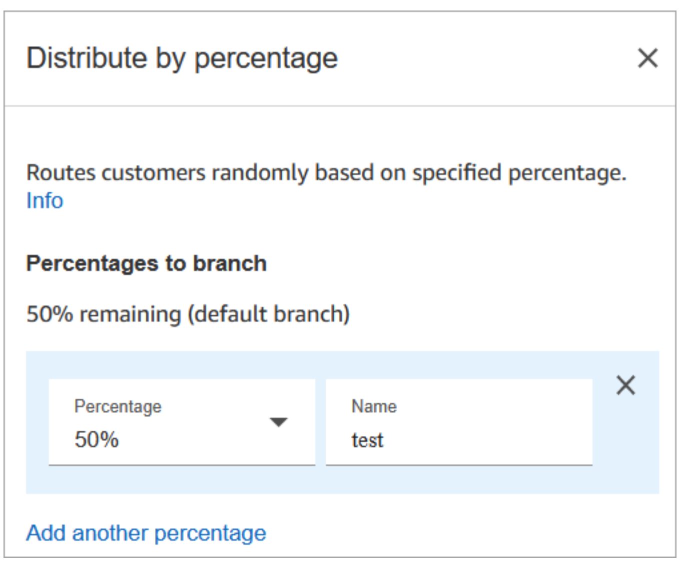
Flow types

You can use this block in the following flow types:

- Inbound flow
- Customer queue flow
- Outbound Whisper flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

The following image shows the **Properties** page of the **Distribute by percentage** block. It is configured to route 50% of contacts to the test branch.



How it works

This block creates static allocation rules based on how you configure it. Internal logic generates a random number between 1-100. This number identifies which branch to take. It doesn't use current or historical volume as part of it's logic.

For example, say a block is configure like this:

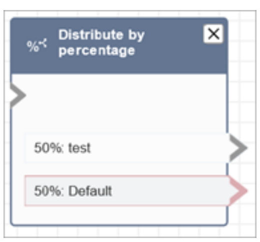
- 20% = A
- 40% = B
- 40% remaining = Default

When contact a is being routed through a flow, Amazon Connect generates the random number.

- If number is between 0-20, the contact is routed down the A branch.
- Between 21-60 it's routed down the B branch.
- Greater than 60 it's routed down the Default branch.

Configured block

The following image shows an example of what this block looks like when it is configured. It shows two branches: **50% test** and **50% default**.



Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

- Sample flow in Amazon Connect for A/B contact distribution testing

Flow block in Amazon Connect: End flow / Resume

Description

Important

The End flow / Resume block is a terminal flow block. It enables you to end a paused flow and return the contact without terminating the overall interaction. However, if you place the **End flow / Resume** block in an inbound flow or disconnect flow, it functions identically to the **Disconnect** block, and terminates the contact.

- Ends the current flow without disconnecting the contact.
- This block is often used for the **Success** branch of the **Transfer to queue** block. The flow doesn't end until the call is picked up by an agent.
- You also might use this block when a **Loop prompts** block is interrupted. You can return the customer to the **Loop prompts** block.
- You can also use this block to end a Paused flow and return the contact without terminating the overall interaction. For example, it's useful in flows where you are pausing and resuming tasks.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

Flow types

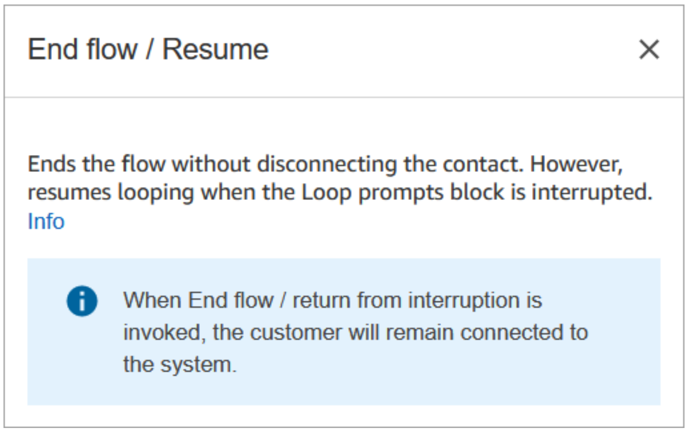
Important

If you place the **End flow / Resume** block in an inbound flow or disconnect flow, it functions identically to the **Disconnect** block, and terminates the contact.

- All flows

Properties

The following image shows the **Properties** page of the **End flow / Resume** block.



Configured block

The following image shows an example of what this block looks like when it is configured. It does not have any The End flow / Resume termination event branches.

Flow block in Amazon Connect: Get customer input

This topic defines the flow block for such tasks as capturing customer information, creating interactive phone menus for customer responses, and routing customers to specific paths within a flow.

Description

Captures interactive and dynamic input from customers. It supports interruptible prompts with DTMF input (input from a phone) and Amazon Lex bot.

Use cases for this block

This block is designed to be used in the following scenarios:

- Create interactive phone menus where customers can respond using touch-tone keypads. For example, "Press 1 for Sales, press 2 for Support."
- Enable voice-activated prompts by using this block with Amazon Lex bots. Customers can interrupt the prompts by speaking. This provides them with a more natural and responsive interaction.
- Collect customer information in a structured way. For example, asking customers to input their account number, order ID, or other relevant details.
- Route the customer to specific paths within the flow based on their input. This helps direct the customer to the appropriate department or service based on their needs.
- Gather feedback from customers by presenting options that allow them to express their satisfaction or concerns.
- Conduct surveys and poll customers to collect valuable feedback and insights.
- Guide customers through troubleshooting processes by asking specific questions related to their issues. You can provide tailored solutions based on their responses.

Contact types

The following table shows how this block routes a contact for each channel.

Channel	Supported?
Voice	Yes
Chat	Yes, when Amazon Lex is used, otherwise it takes the **Error** branch
Task	Yes

Channel	Supported?
Email	Yes

Flow types

You can use this block in the following flow types:

Flow type	Supported?
Inbound flow	Yes
Customer queue flow	Yes
Customer hold flow	No
Customer whisper flow	No
Outbound whisper flow	No
Agent hold flow	No
Agent whisper flow	No
Transfer to agent flow	Yes
Transfer to queue flow	Yes

How to configure this block

You can configure the Get customer input block by using the Amazon Connect admin website, or by using the GetParticipantInput action in the Amazon Connect Flow language, or the ConnectParticipantWithLexBot and Compare actions.

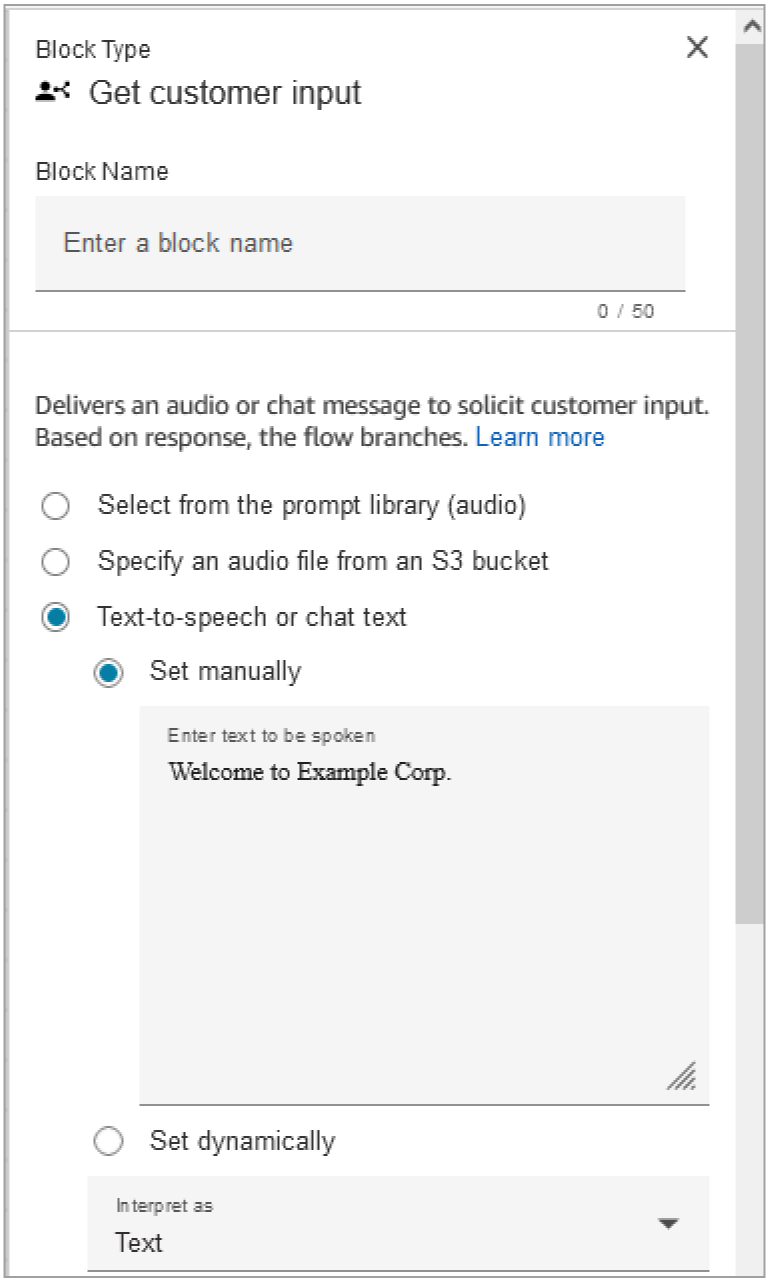
Configuration sections

- Select a prompt
- Configure for DTMF input
- Configure for Amazon Lex input

- Flow block branches
- Additional configuration tips
- Data generated by this block

Select a prompt

The following image shows the **Properties** page of the **Get customer input** block. It is manually configured to play an audio prompt that says "Welcome to Example Corp."

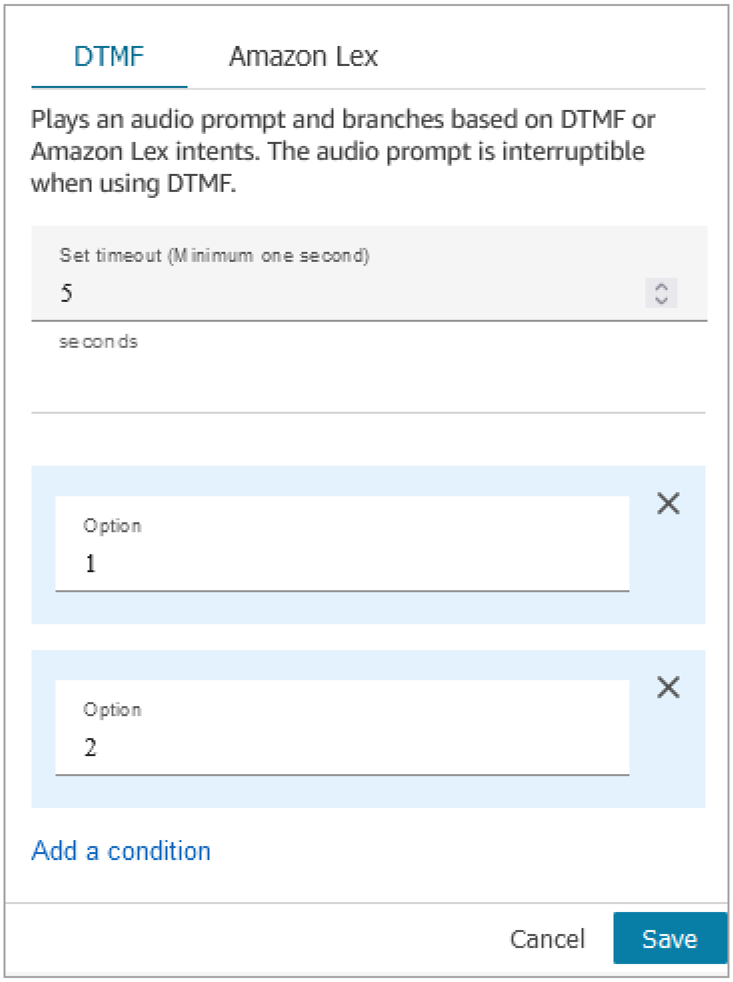


Choose from the following options to select a prompt to be played to the customer:

- **Select from the prompt library (audio)**: You can choose from one of the pre-recorded prompts included with Amazon Connect, or use the Amazon Connect admin website to record and upload your own prompt.
- **Specify an audio file from an S3 bucket**: You can manually or dynamically specify an audio file from an S3 bucket.
- **Text-to-speech or chat text**: You can enter prompt to be played in plain text or SSML. These text-based prompts are played as audio prompts to customers using Amazon Polly. SSML-enhanced input text gives you more control over how Amazon Connect generates speech from the text that you provide. You can customize and control aspects of speech, such as pronunciation, volume, and speed.

Configure for DTMF input

The following image shows the DTMF section of the **Properties** page. Two conditions have been added to determine the appropriate branching, depending whether the customer presses 1 or 2. It times out after 5 seconds if the customer doesn't enter anything.



Choose the following options:

- **Set timeout**: Specify how long to wait while the user decides how they want to respond to the prompt.
  - Minimum value: 1 second
  - Maximum value: 180 seconds

  After this time elapses, a timeout error occurs. For the Voice channel, this is the timeout until the first DTMF digit is entered. Must be defined statically, and must be a valid integer larger than zero.
- **Add condition**: The number against which the customer input is compared.

Flow language representation when DTMF is used

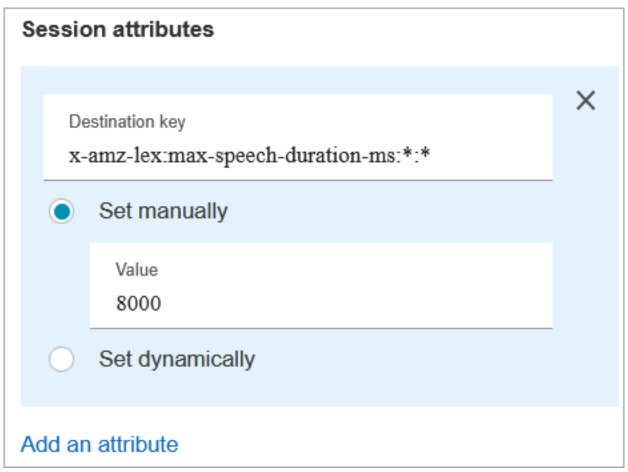
The following code example shows how a DTMF configuration would be represented by the GetParticipantInput action in the Flow language.

```
{
      "Parameters": {
        "StoreInput": "False",
        "InputTimeLimitSeconds": "5",
        "Text": "Welcome to Example Corp. Please press 1 for sales, press 2 for
 support"
      },
      "Identifier": "Get Customer Input",
      "Type": "GetParticipantInput",
      "Transitions": {
        "NextAction": "d8701db7-3d31-4581-bd4c-cb49c38c6f43",
        "Conditions": [
          {
            "NextAction": "d8701db7-3d31-4581-bd4c-cb49c38c6f43",
            "Condition": {
              "Operator": "Equals",
              "Operands": [
                "1"
              ]
            }
          },
          {
            "NextAction": "d8701db7-3d31-4581-bd4c-cb49c38c6f43",
            "Condition": {
              "Operator": "Equals",
              "Operands": [
                "2"
              ]
            }
          }
        ],
        "Errors": [
          {
            "NextAction": "d8701db7-3d31-4581-bd4c-cb49c38c6f43",
            "ErrorType": "InputTimeLimitExceeded"
          },
          {
            "NextAction": "d8701db7-3d31-4581-bd4c-cb49c38c6f43",
            "ErrorType": "NoMatchingCondition"
```

```
        },
        {
          "NextAction": "d8701db7-3d31-4581-bd4c-cb49c38c6f43",
          "ErrorType": "NoMatchingError"
        }
      ]
    }
  }
```

Configure for Amazon Lex input

- **Select a Lex bot**: After you create your Amazon Lex bot, choose the name of the bot from the drop-down list. Only built bots appear in the drop-down list.
- Enter an ARN: Specify the Amazon Resource Name of the Amazon Lex bot.
- **Session attributes**: Specify [Amazon Lex session attributes](#) that apply to the current contact's session only. The following image shows the session attributes configured for a max speech duration of 8000 milliseconds (8 seconds).



- **Intents**
  - **Add intent**: Choose to enter the name of the Amazon Lex bot intent to compare against.

    There are a few ways you can add intents:

    - Enter them manually in the text box.
    - Search for intents.
    - Select intents from a dropdown list.
    - Filter the dropdown list of intents by locale. Based on the locale selected, intents for the bot are listed in the dropdown list.

When you select a Lex bot ARN and alias from a dropdown lists, you can add intents for that bot by searching using locale. In order for intents to be listed, the bot must have an Amazon Connect tag and the bot alias must have a version associated with it.

The **Intents** dropdown box does not list intents for Amazon Lex V1 bots, cross region bots, or if the bot ARN is dynamically set. For these intents, try the following options to find them.

- Check whether the **AmazonConnectEnabled** tag is set to true:
  1. Open the Amazon Lex console, choose **Bots**, select the bot, then choose **Tags**.
  2. If the **AmazonConnectEnabled** tag is not present, add **AmazonConnectEnabled = true**.
  3. Return to the Amazon Connect admin website. Refresh the flow designer to see the selections in **Get customer input** block.
- Check if the version is associated with the alias:
  1. In Amazon Connect admin website, choose **Routing**, **Flows**, the bot, **Aliases**. Verify that **Use in flow and flow modules** is enabled, as shown in the following image.

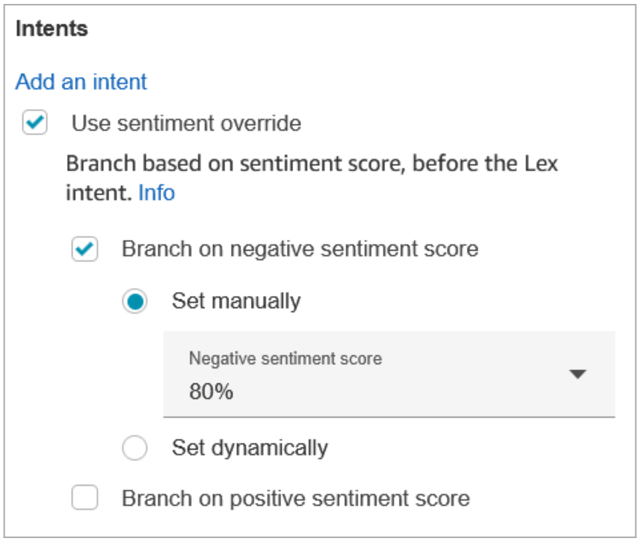
  2. Refresh the flow designer to see the selections in **Get customer input** block.

- **Use sentiment override**: Branch based on sentiment score, before the Amazon Lex intent.

  The sentiment score is based on the last utterance of the customer. It is not based on the entire conversation.

  For example, a customer calls and they have a negative sentiment because their preferred appointment time isn't available. You can branch the flow based on their negative sentiment score, for example, if their negative sentiment is more than 80%. Or, a customer calls and has a positive sentiment of more than 80%, you can branch to upsell them on services.

The following image shows the Intents section of the Amazon Lex tab. It is configured to route the contact when their negative sentiment score is 80%.

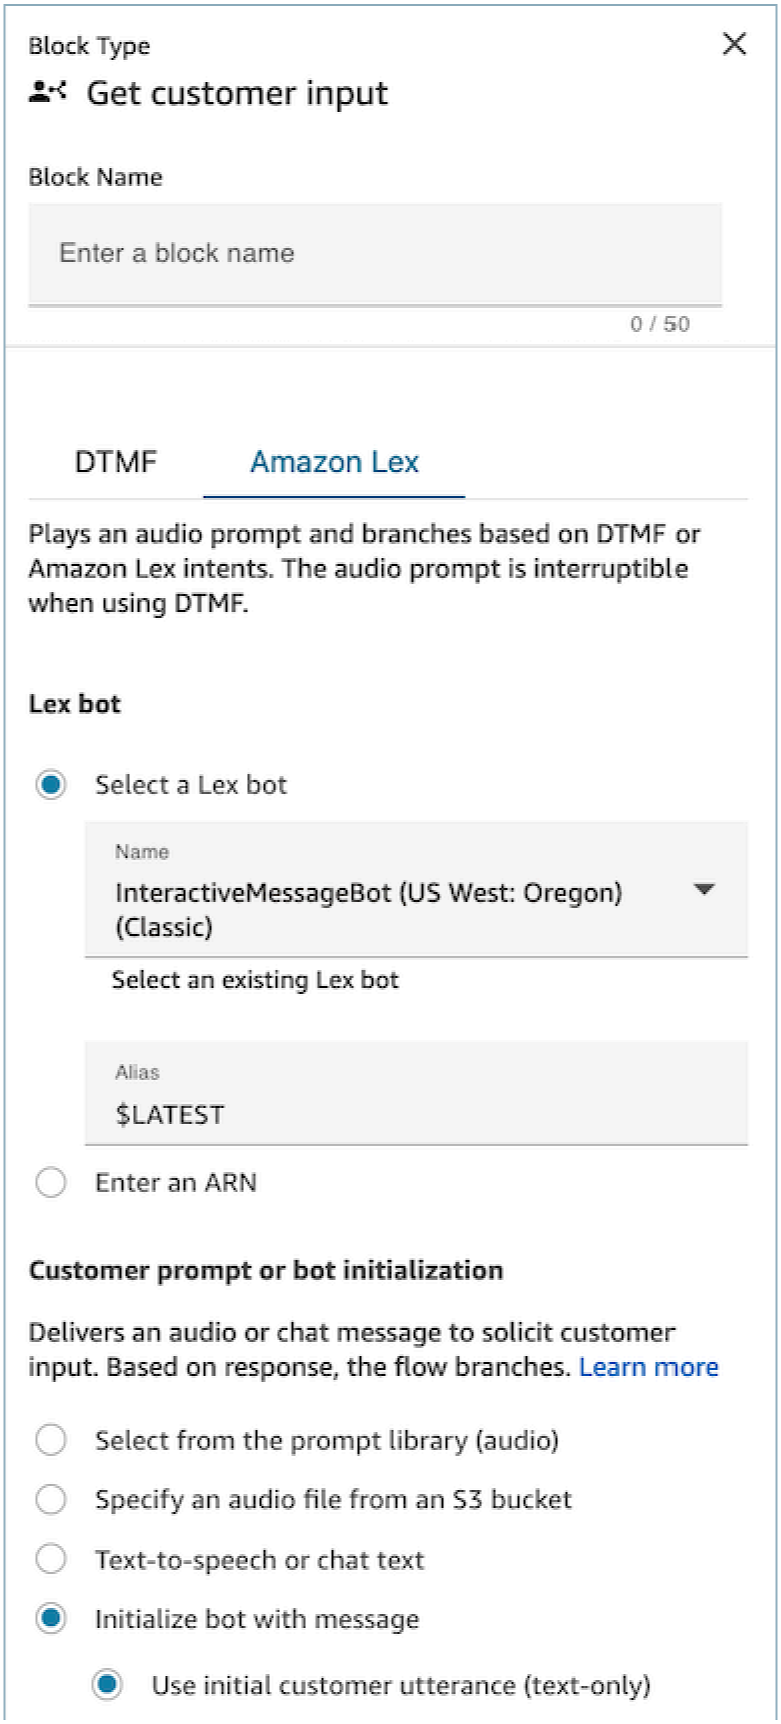


If you add both negative and positive sentiment scores, the negative score is always evaluated first.

For information about how to use sentiment score, alternative intents, and sentiment label with contact attributes, see [Check contact attributes](#).

- **Initialize bot with message**
  - **Purpose**: You can select this option to pass the end-customer's initial message to Lex to prime the bot for enhanced end-customer Chat experience. The initial message is sent to the newly created chat while invoking the [StartChatContact](#) API.
  - Selecting this option will always serialize the block with bot initialization message as ` `$.Media.InitialMessage`.
  - **Required**: No. This is not a required parameter.

> **Note**
>
> If the initial message attribute is not included as part of the contact, it will result in the Get customer input block taking the error branch in the flow. To have separate flow configurations for different messaging types, such as web chat, SMS, or Apple Messages for Business, you can use the Check contact attributes block prior to using the Get customer input block to verify the initial message is available.



Block Type
Get customer input
Block Name
Enter a block name
0 / 50
DTMF
Amazon Lex
Plays an audio prompt and branches based on DTMF or Amazon Lex intents. The audio prompt is interruptible when using DTMF.
Lex bot
Select a Lex bot
Name
InteractiveMessageBot (US West: Oregon) (Classic)
Select an existing Lex bot
Alias
$LATEST
Enter an ARN
Customer prompt or bot initialization
Delivers an audio or chat message to solicit customer input. Based on response, the flow branches. Learn more
Select from the prompt library (audio)
Specify an audio file from an S3 bucket
Text-to-speech or chat text
Initialize bot with message
Use initial customer utterance (text-only)

Configurable time-outs for voice input

To configure time-out values for voice contacts, use the following session attributes in the **Get customer input** block that calls your Lex bot. These attributes allow you to specify how long to wait for the customer to finish speaking before Amazon Lex collects speech input from callers, such as answering a yes/no question, or providing a date or credit card number.

Amazon Lex

- **Max Speech Duration**

  ```
  x-amz-lex:audio:max-length-ms:[intentName]:[slotToElicit]
  ```

  How long the customer speaks before the input is truncated and returned to Amazon Connect. You can increase the time when a lot of input is expected or you want to give customers more time to provide information.

  Default = 12000 milliseconds (12 seconds). The maximum allowed value is 15000 milliseconds.

  > **Important**
  >
  > If you set **Max Speech Duration** to more than 15000 milliseconds, the contact is routed down the **Error** branch.

- **Start Silence Threshold**

  ```
  x-amz-lex:audio:start-timeout-ms:[intentName]:[slotToElicit]
  ```

  How long to wait before assuming that the customer isn't going to speak. You can increase the allotted time in situations where you'd like to allow the customer more time to find or recall information before speaking. For example, you might want to give customers more time to get out their credit card so they can enter the number.

  Default = 3000 milliseconds (3 seconds).

- **End Silence Threshold**

  ```
  x-amz-lex:audio:end-timeout-ms:[intentName]:[slotToElicit]
  ```

How long to wait after the customer stops speaking before assuming the utterance has concluded. You can increase the allotted time in situations where periods of silence are expected while providing input.

Default = 600 milliseconds (0.6 seconds)

Amazon Lex (Classic)

- **Max Speech Duration**

  `x-amz-lex:max-speech-duration-ms:[intentName]:[slotToElicit]`

  How long the customer speaks before the input is truncated and returned to Amazon Connect. You can increase the time when a lot of input is expected or you want to give customers more time to provide information.

  Default = 12000 milliseconds (12 seconds). The maximum allowed value is 15000 milliseconds.

  > **Important**
  > If you set **Max Speech Duration** to more than 15000 milliseconds, the contact is routed down the **Error** branch.

- **Start Silence Threshold**

  `x-amz-lex:start-silence-threshold-ms:[intentName]:[slotToElicit]`

  How long to wait before assuming that the customer isn't going to speak. You can increase the allotted time in situations where you'd like to allow the customer more time to find or recall information before speaking. For example, you might want to give customers more time to get out their credit card so they can enter the number.

  Default = 3000 milliseconds (3 seconds).

- **End Silence Threshold**

  `x-amz-lex:end-silence-threshold-ms:[intentName]:[slotToElicit]`

How long to wait after the customer stops speaking before assuming the utterance has concluded. You can increase the allotted time in situations where periods of silence are expected while providing input.

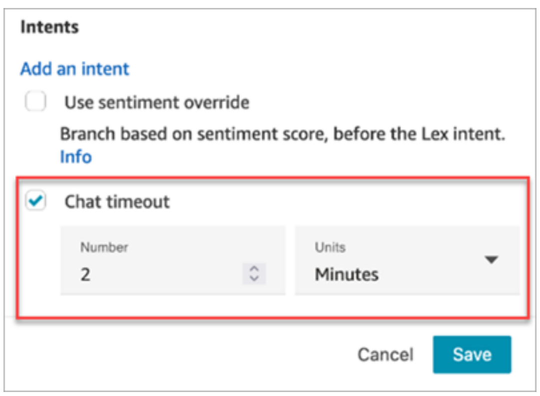
Default = 600 milliseconds (0.6 seconds)

Configurable time-outs for chat input during a Lex interaction

Use the **Chat timeout** field under **Intents** to configure timeouts for chat input. Enter how long until inactive customers timeout in a Lex interaction.

- Minimum: 1 minute
- Maximum: 7 days

The following image shows the **Get customer input** block configured to timeout chats when the customer is inactive for 2 minutes.



For information about setting up chat timeouts when all participants are human, see [Set up chat timeouts for chat participants](#).

Barge-in configuration and usage for Amazon Lex

You can allow customers to interrupt the Amazon Lex bot mid-sentence using their voice, without waiting for it to finishing speaking. Customers familiar with choosing from a menu of options, for example, can now do so without having to listen to the entire prompt.

Amazon Lex

- **Barge-in**

Barge-in is enabled globally by default. You can disable it in the Amazon Lex console. For more information, see Enabling your bot to be interrupted by your user. Additionally, you can modify barge-in behavior, by using the `allow-interrupt` session attribute. For example, `x-amz-lex:allow-interrupt:*:*` allows interrupt for all intents and all slots. For more information, see Configuring timeouts for capturing user input in the *Amazon Lex V2 Developer Guide*.

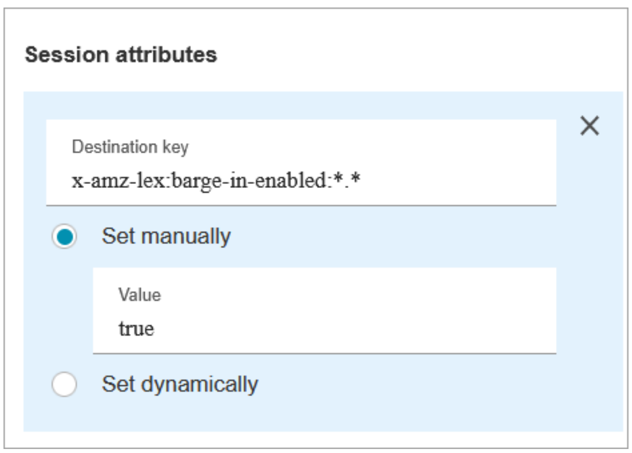
Amazon Lex (Classic)

- **Barge-in**

  `x-amz-lex:barge-in-enabled:[intentName]:[slotToElicit]`

  Barge-in is disabled globally by default. You must set the session attribute in the **Get customer input** block that calls your Lex bot to enable it at the global, bot, or slot levels. This attribute only controls Amazon Lex barge-in; it doesn't control DTMF barge-in. For more information, see How flow blocks use Amazon Lex session attributes.

  The following image shows the **Session attributes** section with barge-in enabled.



Configurable fields for DTMF input

Use the following session attributes to specify how your Lex bot responds to DTMF input.

- **End character**

  `x-amz-lex:dtmf:end-character:[IntentName]:[SlotName]`

The DTMF end character that ends the utterance.

Default = #

- **Deletion character**

  `x-amz-lex:dtmf:deletion-character:[IntentName]:[SlotName]`

  The DTMF character that clears the accumulated DTMF digits and ends the utterance.

  Default = *

- **End timeout**

  `x-amz-lex:dtmf:end-timeout-ms:[IntentName]:[SlotName]`

  The idle time (in milliseconds) between DTMF digits to consider the utterance as concluded.

  Default = 5000 milliseconds (5 seconds)

- **Max number of allow DTMF digits per utterance**

  `x-amz-lex:dtmf:max-length:[IntentName]:[SlotName]`

  The maximum number of DTMF digits allowed in a given utterance. This cannot be increased.

  Default = 1024 characters

For more information, see How flow blocks use Amazon Lex session attributes.

Flow Language representation when Amazon Lex is used

The following code sample shows how an Amazon Lex configuration would be represented by the ConnectParticipantWithLexBot action in the Flow language:

```
{
    "Parameters": {
      "Text": "Welcome to Example Corp. Please press 1 for sales, press 2 for support",
      "LexV2Bot": {
        "AliasArn": "arn:aws:lex:us-west-2:23XXXXXXXXXX:bot-alias/3HL7SXXXXX/
TSTALXXXXX"
      },
      "LexTimeoutSeconds": {
```

```
          "Text": "300"
        }
      },
      "Identifier": "Get Customer Input",
      "Type": "ConnectParticipantWithLexBot",
      "Transitions": {
        "NextAction": "d8701db7-3d31-4581-bd4c-cb49c38c6f43",
        "Errors": [
          {
            "NextAction": "d8701db7-3d31-4581-bd4c-cb49c38c6f43",
            "ErrorType": "InputTimeLimitExceeded"
          },
          {
            "NextAction": "d8701db7-3d31-4581-bd4c-cb49c38c6f43",
            "ErrorType": "NoMatchingError"
          },
          {
            "NextAction": "Get Customer Input-ygqIfPM1n2",
            "ErrorType": "NoMatchingCondition"
          }
        ]
      }
    }
```

Fragmented action representation

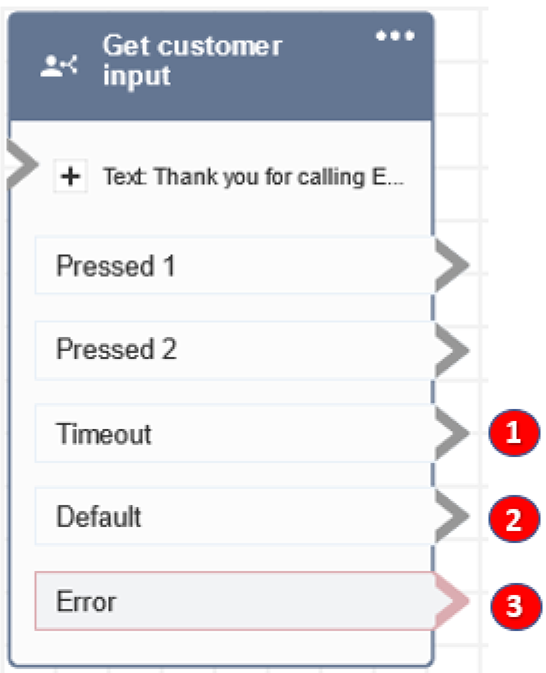
The following code sample represents a fragmented Compare action for a Amazon Lex sentiment score returned from a Lex bot after the conversation.

```
{
      "Parameters": {
        "ComparisonValue": "$.Lex.SentimentResponse.Scores.Negative"
      },
      "Identifier": "Get Customer Input-ygqIfPM1n2",
      "Type": "Compare",
      "Transitions": {
        "NextAction": "Get Customer Input-xDRo1hbBRB",
        "Conditions": [
          {
            "NextAction": "d8701db7-3d31-4581-bd4c-cb49c38c6f43",
            "Condition": {
              "Operator": "NumberGreaterOrEqualTo",
              "Operands": [
```

```
                  "0.08"
                ]
              }
            }
          ],
          "Errors": [
            {
              "NextAction": "Get Customer Input-xDRo1hbBRB",
              "ErrorType": "NoMatchingCondition"
            }
          ]
        }
      }
```

Flow block branches

The following image shows an example of what this block looks like when it is configured for DTMF input. It shows two branches for input: **Pressed 1** and **Pressed 2**. It also shows branches for **Timeout**, **Default**, and **Error**.



1. **Timeout**: What to do when no input is provided by the customer for the specified chat timeout in Amazon Lex or the **Set timeout** value specified for DTMF.
2. **Default**: If the customer enters input that doesn't match any condition in DTMF, or an intent executed in Amazon Lex bot. This the preceding image, the contact is routed down the **Default** branch if they enter a value other than 1 or 2.

3. **Error**: If the block is run but results in an error for DTMF, or an intent is not fulfilled in Amazon Lex bot.

Additional configuration tips

- The **Get customer input** block does not support using a voice prompt from an S3 bucket with Amazon Lex V2.
- For information about choosing a prompt from the Amazon Connect library or an S3 bucket, see the Play prompt block.
- You can configure this block to accept DTMF input or a chat response. You can also configure it work with Amazon Lex for example, a contact can be routed based on their utterance.
  - Session attributes available for the integration with Amazon Lex. This topic explains some of the session attributes available for the integration with Amazon Lex. For a list of all the available Amazon Lex session attributes, see Configuring timeouts for capturing user input. When you use text, either for text-to-speech or chat, you can use a maximum of 3,000 billed characters (6,000 total characters).
  - Amazon Lex bots support both spoken utterances and keypad input when used in a flow.
  - For both voice and DTMF, there can be only one set of session attributes per conversation. Following is the order of precedence:
    1. Lambda provided session attributes: Overrides to session attributes during customer Lambda invocation.
    2. Amazon Connect console provided session attributes: Defined in the **Get customer input** block.
    3. Service defaults: These are used only if no attributes are defined.
- You can prompt contacts to end their input with a pound key # and to cancel it using the star key *. When you use a Lex bot, if you don't prompt customers to end their input with #, they will end up waiting five seconds for Lex to stop waiting for additional key presses.
- To control time-out functionality, you can use Lex session attributes in this block, or in set them in your Lex Lambda function. If you choose to set the attributes in a Lex Lambda function, the default values are used until the Lex bot is invoked. For more information, see Using Lambda Functions in the *Amazon Lex Developer Guide*.
- When you specify one of the session attributes described in this article, you can use wildcards. They let you set multiple slots for an intent or bots.

  Following are some examples of how you can use wildcards:

  - To set all slots for a specific intent, such as PasswordReset, to 2000 milliseconds:

    Name = `x-amz-lex:max-speech-duration-ms:PasswordReset:*`

    Value = 2000
  - To set all slots for all bots to 4000 milliseconds:

    Name = `x-amz-lex:max-speech-duration-ms:*:*`

    Value = 4000

  Wildcards apply across bots but not across blocks in a flow.

  For example, you have a Get_Account_Number bot. In the flow, you have two **Get customer input** blocks. The first block sets the session attribute with a wildcard. The second one doesn't set the attribute. In this scenario, the change in behavior for the bot applies only to the first **Get customer input** block, where the session attribute is set.
- Because you can specify that session attributes apply to the intent and slot level, you can specify that the attribute is set only when you're collecting a certain type of input. For example, you can specify a longer **Start Silence Threshold** when you're collecting an account number than when you're collecting a date.
- If DTMF input is provided to a Lex bot using Amazon Connect, the customer input is made available as a [Lex request attribute](). The attribute name is `x-amz-lex:dtmf-transcript` and the value can be a maximum of 1024 characters.

  Following are different DTMF input scenarios:

Customer input	DTMF transcript
[DEL]	[DEL]
[END]	[END]
123[DEL]	[DEL]
123[END]	123

  Where:

- [DEL] = Deletion character (Default is *****)
- [END] = End character (Default is **#**)

Data generated by this block

This block does not generate any data.

Error scenarios

Let's say you have the following scenario with two flows, each one capturing DTMF input from customers:

1. One flow uses the **Get customer input** block to request DTMF input from customers.
2. After the DTMF input is entered, it uses the **Transfer to flow** block to move the contact to the next flow.
3. In the next flow, there's a **Store customer input** block to get more DTMF input from the customer.

There's setup time between the first and second flows. This means if the customer enters DTMF input very quickly for the second flow, some of the DTMF digits might be dropped.

For example, the customer needs to press 5, then wait for a prompt from the second flow, then type 123. In this case, 123 is captured without problem. However, if they don't wait for the prompt and enter 5123 very quickly, the Store customer input block may capture only 23 or 3.

To guarantee the **Store customer input** block in second flow captures all of the digits, the customer needs to wait for the prompt to be played, and then enter their type DTMF input.

Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

- Sample inbound flow in Amazon Connect for the first contact experience
- Sample interruptible queue flow with callback in Amazon Connect
- Sample queue configurations flow in Amazon Connect
- Sample recording behavior in Amazon Connect

- How to use the same Amazon Lex bot for voice and chat
- Add text-to-speech to prompts in flow blocks in Amazon Polly

Flow block in Amazon Connect: Get queue metrics

This topic defines the flow block for retrieving near real-time metrics from a queue so you can decide how to route customers.

Description

- Retrieves near real-time queue metrics with a 5-10 second delay for more granular routing decisions.
- You can route contacts based on queue or agent status, such as the number of contacts in queue or agents available.
- Queue metrics are aggregated across all channels by default and are returned as attributes.
- The current queue is used by default.
- For agent-based metrics (such as agents online, agents available, or agents staffed), if there are no agents, no metrics are returned.
- Following are the metrics that can be retrieved:
  - Queue name
  - Queue ARN
  - Contacts in queue
  - Oldest contact in queue
  - Agents online
  - Agents available
  - Agents staffed
  - Agents after contact work
  - Agents busy
  - Agents missed (Agent non-response)

  - Agents non-productive
- You can choose to return metrics by channel, for example, voice or chat. You can also filter by queue or agent. These options enable you to know how many chat and voice contacts are in a queue and if you have agents available to handle those contacts.
- You can route contacts based on queue status, such as number of contacts in queue or agents available. Queue metrics are aggregated across all channels and are returned as attributes. The current queue is used by default.
- After a **Get queue metrics** block, use a Check contact attributes to check metric values and define routing logic based on them, such as number of contacts in a queue, number of available agents, and oldest contact in a queue.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

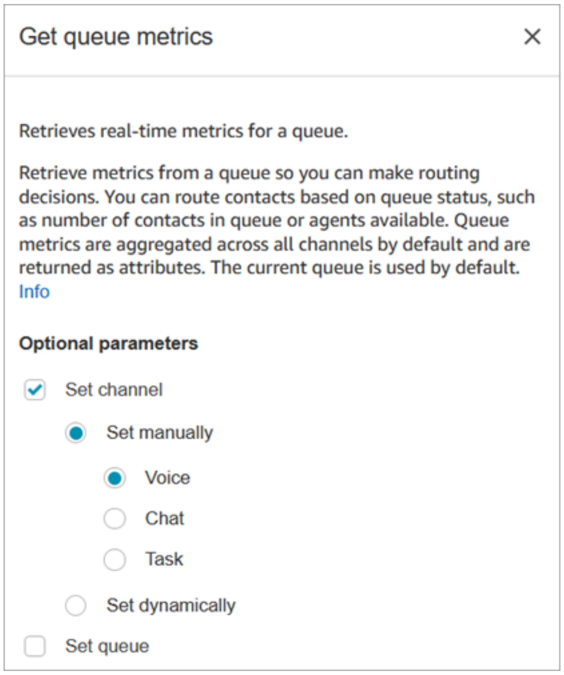
Flow types

You can use this block in the following flow types:

- All flows

Properties

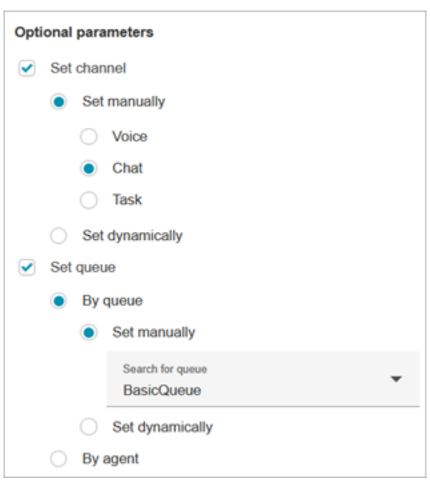
The following image shows the **Properties** page of the **Get queue metrics** block. It is configured to retrieve metrics for the **Voice** channel.



You can retrieve metrics by channel, and/or by queue or agent.

- If you don't specify a channel, it returns metrics for all channels.
- If you don't specify a queue, it returns metrics for the current queue.
- Dynamic attributes can only return metrics for one channel.

For example, the following image shows the **Properties** page configured for the **Chat** channel and **BasicQueue**. If you choose these settings **Get queue metrics** would return metrics for only the BasicQueue, filtered to include only chat contacts.



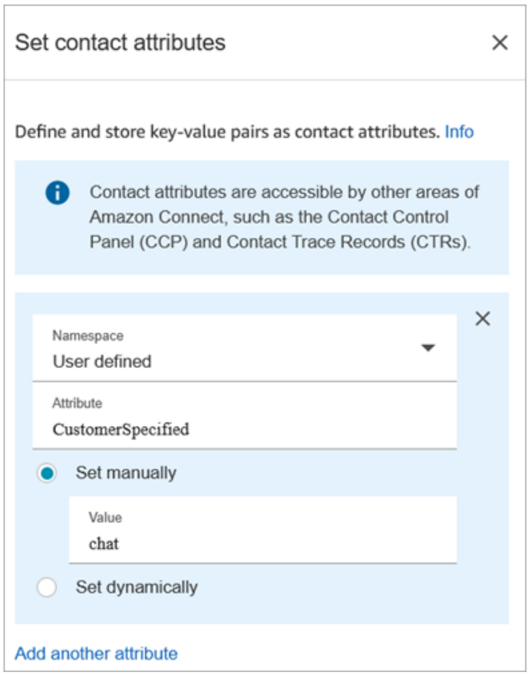
Configuration tips

Specifying a channel in the Set contact attributes block

Dynamic attributes can only return metrics for one channel.

Before you use dynamic attributes in the **Get queue metrics** block, you need to set the attributes in the [Set contact attributes](#) block, and specify which channel.

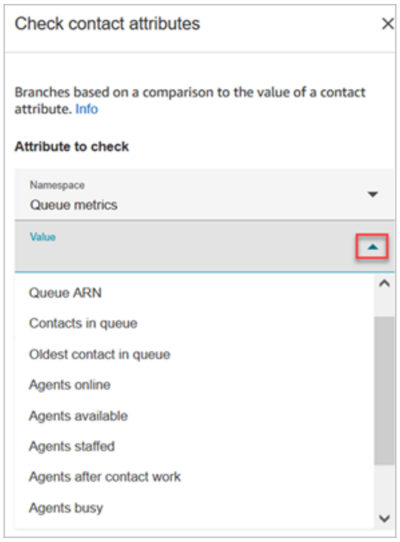
When you set a channel dynamically using text, as shown in the following image, for the attribute value enter **Voice** or **Chat**. This value is not case-sensitive.



Using the Check contact attributes block after the Get queue metrics block

After a **Get queue metrics** block, add a [Check contact attributes](#) block to branch based on the returned metrics. Use the following steps:

1. After **Get queue metrics**, add a **Check contact attributes** block.
2. In the **Check contact attributes** block, set **Attribute to check** to **Queue metrics**.
3. In the **Value** dropdown box, you'll see a list of queue metrics that can be checked by the **Get queue metrics** block. Choose the metric that you want to use for the routing decision.



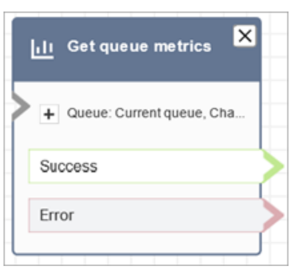
Why Get queue metrics block throws an error

The **Get queue metrics** block throws an error in the following scenario:

1. You add this block to your flow.
2. There are no active agents or contacts in queues in your Amazon Connect instance.
3. The Real-time metrics report returns empty metrics because no activity is taking place.
4. The **Get queue metrics** block throws an error because there are no metrics to display.

Configured block

The following image shows an example of what this block looks like when it is configured. It has two branches: **Success** and **Error**.



Scenarios

See these topics for scenarios that use this block:

- How to reference contact attributes in Amazon Connect

Flow block in Amazon Connect: Hold customer or agent

This topic defines the flow block for placing a customer or agent on hold, and resuming the call afterward.

> **Important**
>
> During a video call or screen sharing session, agents are able to see the customer's video or screen share even when the customer is on hold. It is the customer's responsibility to handle PII accordingly. If you want to change this behavior, you can build a custom CCP and communication widget. For more information, see Integrate in-app, web, video calling and screen sharing natively into your mobile application.

Description

- Places a customer or agent on or off hold. This is useful when, for example, you want to put the agent on hold while the customer enters their credit card information.
- If this block is triggered during a chat conversation, the contact is routed down the **Error** branch.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	No - Error branch
Task	No - Error branch
Email	No - Error branch

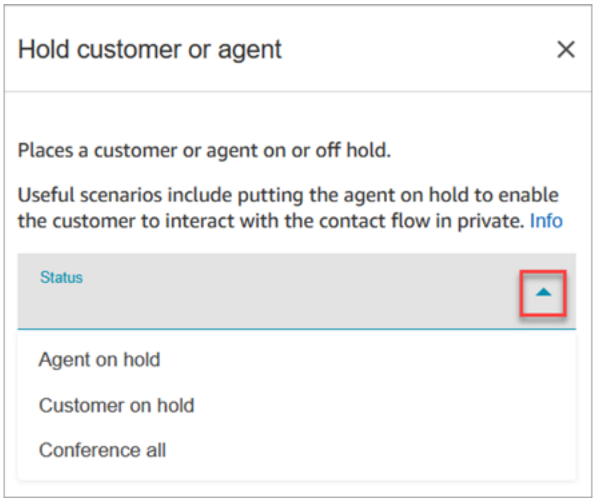
Flow types

You can use this block in the following flow types:

- Inbound flow
- Outbound Whisper flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

The following image shows the **Properties** page of the **Hold customer or agent** block. It shows that the dropdown list has three options: **Agent on hold**, **Customer on hold**, and **Conference all**.



These options are defined as follows:

- **Agent on hold** = customer is on the call
- **Conference all** = agent and customer are on the call
- **Customer on hold** = agent is on the call

Configured block

The following image shows an example of what this block looks like when it is configured. It configured for **Agent on hold**, and it has two branches: **Success** and **Error**.

Samples flows

Sample secure customer data entry input in a call with a contact center agent

Flow block in Amazon Connect: Invoke an AWS Lambda function

This topic defines the flow block for calling AWS Lambda to return key-value pairs that you can use to set contact attributes.

Description

- Calls AWS Lambda, and optionally returns key-value pairs.
- The returned key-value pairs can be used to set contact attributes.
- For an example, see Tutorial: Create a Lambda function and invoke in a flow.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

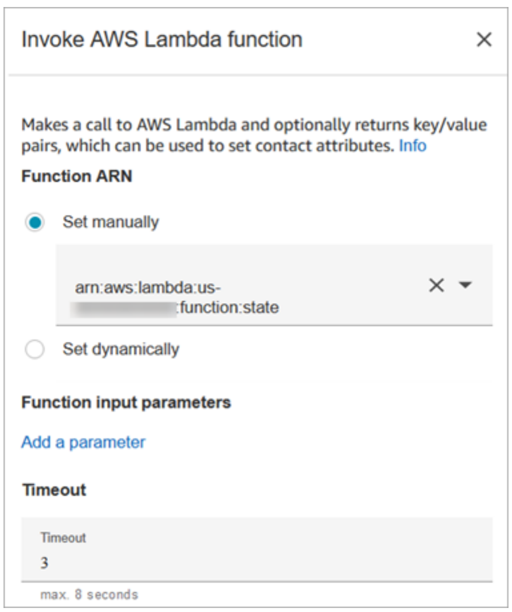
Flow types

You can use this block in the following flow types:

- Inbound flow
- Customer Queue flow
- Customer Hold flow
- Customer Whisper flow
- Agent Hold flow
- Agent Whisper flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

The following image shows the **Properties** page of the **AWS Lambda function** block.



Note the following properties:

- **Timeout**: Enter how long to wait for Lambda to time out.

  If your Lambda invocation gets throttled, the request is retried. It is also retried if a general service failure (500 error) happens.

  When a synchronous invocation returns an error, Amazon Connect retries up to three times, for a maximum of 8 seconds. At that point, the contact is routed down the **Error** branch.

- **Response validation**: The Lambda function response could be either a STRING_MAP or JSON and has to be set while configuring the **Invoke AWS Lambda function** block in the flow. If response validation is set to STRING_MAP, then the lambda function should return a flat object of key/value pairs of the string type. Otherwise, if response validation is set to JSON, the lambda function can return any valid JSON including nested JSON.

Configuration tips

- To use an AWS Lambda function in a flow, first add the function to your instance. For more information, see Add a Lambda function to your Amazon Connect instance,
- After you add the function to your instance, you can select the function from the **Select a function** drop-down list in the block to use it in the flow.

Configured block

The following image shows an example of what this block looks like when it is configured. It has two branches: **Success** and **Error**.

Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

Sample Lambda integration flow in Amazon Connect

Scenarios

See these topics for scenarios that use this block:

- Grant Amazon Connect access to your AWS Lambda functions

Flow block in Amazon Connect: Invoke a published module

This topic defines the flow block for calling a published module to create reusable sections in a flow.

Description

Calls a published module, which enables you create reusable sections of a contact flow.

For more information, see Flow modules for reusable functions in Amazon Connect.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

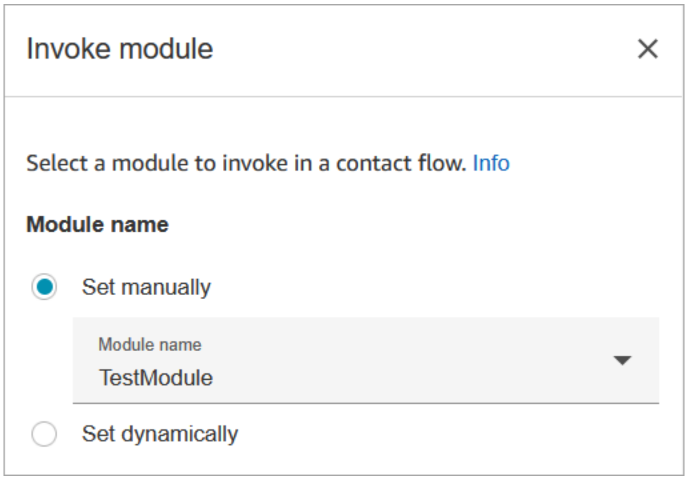
Flow types

You can use this block in the following flow types:

- Inbound flow

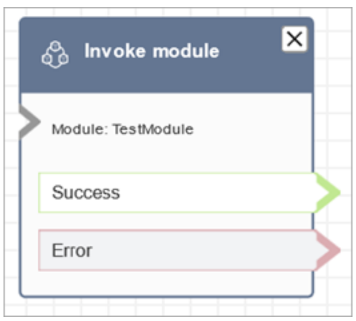
Properties

The following image shows the **Properties** page of the **Invoke module** block.



Configured block

The following image shows an example of what this block looks like when it is configured. It has two branches: **Success** and **Error**.



Flow block in Amazon Connect: Loop

This topic defines the flow block for counting the number of times that customers are looped through the **Looping** branch.

Description

- Counts the number of times customers are looped through the **Looping** branch.
- After the loops are completed, the **Complete** branch is followed.
- This block is often used with a **Get customer input** block. For example, if the customer doesn't succeed in entering their account number, you can loop to give them another opportunity to enter it.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

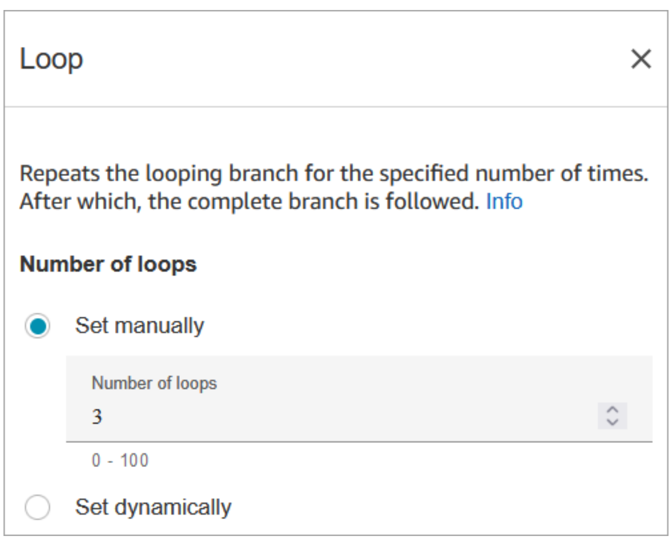
Flow types

You can use this block in the following flow types:

- All flows

Properties

The following image shows the **Properties** page of the **Loop** block. It is configured to repeat three times, and then it branches.



Configuration tips

- If you enter 0 for the loop count, the **Complete** branch is followed the first time this block runs.

Configured block

The following image shows an example of what this block looks like when it is configured. It has two branches: **Looping** and **Complete**.

Flow block in Amazon Connect: Loop prompts

This topic defines the flow block for looping a sequence of prompts while a customer or agent is on hold or in a queue.

Description

- Loops a sequence of prompts while a customer or agent is on hold or in queue.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	No - Error branch
Task	No - Error branch
Email	No - Error branch

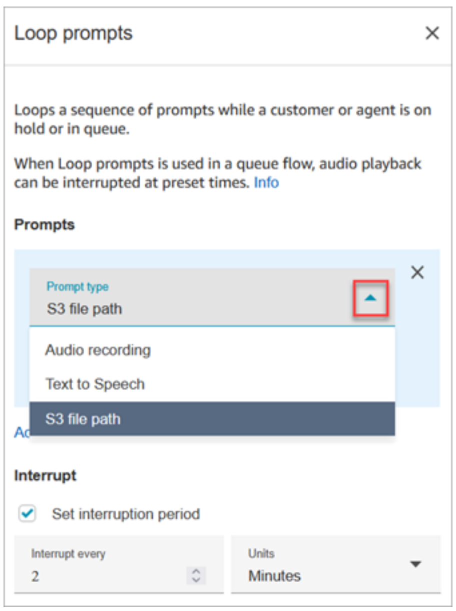
Flow types

You can use this block in the following flow types:

- Customer Queue flow
- Customer Hold flow
- Agent Hold flow

Properties

The following image shows the **Properties** page of the **Loop prompts** block. It shows there are three types of prompts you can choose from the dropdown list: **Audio recording**, **Text to Speech**, **S3 file path**.



How the Interrupt option works

Let's say you have multiple prompts and you set **Interrupt** to 60 seconds. Following is what will happen:

- The block plays prompts in the order that they are listed for the entirety of the prompt length.
- If the combined play time for the prompts is 75 seconds, after 60 seconds the prompt is interrupted and reset to the 0 second point again.
- It's possible your customers would never hear potentially important information that is supposed to play after 60 seconds.

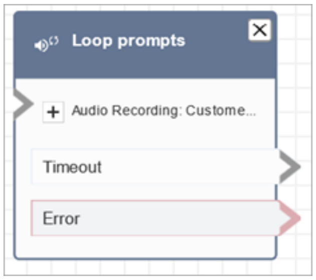
This scenario is especially possible when using the default audio prompts that Amazon Connect provides since these audio prompts can be as long as 4 minutes.

Configuration tips

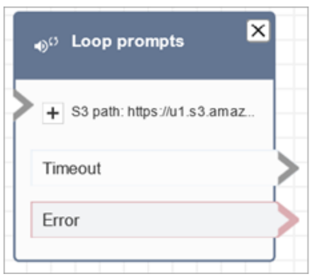
- The following blocks are not allowed before the **Loop prompts** block:
  - Get customer input
  - Loop
  - Play prompt
  - Start media streaming
  - Stop media streaming
  - Store customer input
  - Transfer to phone number
  - Transfer to queue, including **Transfer to callback queue**
- For information about choosing a prompt from the Amazon Connect library or an S3 bucket, see the Play prompt block.
- When **Loop prompts** is used in a Queue flow, audio playback can be interrupted with a flow at preset times.
- Always use an interruption period that's greater than 20 seconds. This is the amount of time an available agent has to accept the contact. If the interruption period is less than 20 seconds, you might get contacts going down the **Error** branch. This is because Amazon Connect doesn't support dequeuing the customer when they are being routed to an active agent and are in the 20 second window to join.
- The internal counter for the loop is persisted for the call, not the flow. If you reuse the flow during a call, the loop counter isn't reset.
- If this block is triggered during a chat conversation, the contact is routed down the **Error** branch.
- Some existing flows have a version of the **Loop prompts** block that doesn't have an **Error** branch. In this case, a chat contact stops execution of the customer queue flow. The chat is routed when the next agent becomes available.

Configured block

The following image shows what this block looks like when it is configured to play a prompt from the Amazon Connect library. Choose + next to **Audio Recording** to view the full name of the file. The configured block has two branches: **Timeout** and **Error**.



The following image shows what this block looks like when it is configured to play a prompt from Amazon S3. Choose + next to **S3 path** to view the full path. The configured block has two branches: **Timeout** and **Error**.



Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

- Sample interruptible queue flow with callback in Amazon Connect

Scenarios

See these topics for scenarios that use this block:

- Set up a flow to manage contacts in a queue in Amazon Connect

Flow block in Amazon Connect: Play prompt

This topic defines the flow block for playing audio prompts, text-to-speech messages, or chat responses to customers and agents.

Description

Use this flow block to play an audio prompt or a text-to-speech message, or to send a chat response.

You can play prompts to customers (callers or customers using chat) and agents.

For calls, you have the following options:

- **Use pre-recorded prompts**: Amazon Connect provides a library of ready-made options.
- **Record your own prompts**. You have the following options:
  - Use the Amazon Connect library. Upload your recordings directly from the Amazon Connect admin website.
  - Use Amazon S3. Store your prompts on S3 and access them dynamically during calls.
- **Text-to-speech**. Provide plain text or SSML (Speech Synthesis Markup Language) to have it spoken as audio.

For chats, you have the following option:

- **Text prompts only**. Send plain text messages to both customers and agents. Audio options, like pre-recorded prompts, aren't available for chat.

Use cases for this block

This flow block is designed to be used in the following scenarios:

- Play a greeting to customers. For example, "Welcome to our customer service line."
- Provide information that is retrieved from a database back to customers or agents. For example, "Your account balance is $123.45."
- Play pre-recorded audio while a customer is in queue or on hold.
- Play pre-recorded audio in your own voice from your S3 buckets.

- In an inbound flow, play an audio message or a text message to customers and agents simultaneously.

Requirements for prompts

- **Supported formats**: Amazon Connect supports .wav files to use for your prompt. You must use .wav files that are 8KHz, and mono channel audio with U-Law encoding. Otherwise, the prompt won't play correctly. You can use publicly available third-party tools to convert your .wav files to U-Law encoding. After converting the files, upload them to Amazon Connect.
- **Size**: Amazon Connect supports prompts that are less than 50MB and less than five minutes long.
- **When storing prompts in an S3 bucket:** For AWS Regions that are disabled by default (also called opt-in Regions) such as Africa (Cape Town), your bucket must be in the same Region.

Contact types

Contact type	Supported?
Voice	Yes
Chat	Yes If a chat contact is routed to this block, but the block is configured for calls, the contact is routed down the **Error** branch.
Task	Yes If a task contact is routed to this block, but the block is configured for calls, the contact is routed down the **Error** branch.
Email	No - takes the **Success** branch but it has no effect

If a callback contact without an agent or customer is routed to this block, the contact is routed down the **Error** branch.

Flow types

You can use this block in the following flow types:

Flow type	Supported?
Inbound flow	Yes
Customer queue flow	Yes. You can play prompts from the Amazon Connect library but not prompts stored in Amazon S3.
Customer hold flow	No, use Loop prompts flow block instead
Customer whisper flow	Yes. You can play prompts from the Amazon Connect library but not prompts stored in Amazon S3.
Outbound whisper flow	Yes. You can play prompts from the Amazon Connect library but not prompts stored in Amazon S3.
Agent hold flow	No, use Loop prompts flow block instead
Agent whisper flow	Yes. You can play prompts from the Amazon Connect library but not prompts stored in Amazon S3.
Transfer to agent flow	Yes
Transfer to queue flow	Yes

How to configure this block

You can configure the **Play prompt** block by using the Amazon Connect admin website or by using the MessageParticipant action in the Amazon Connect Flow language.

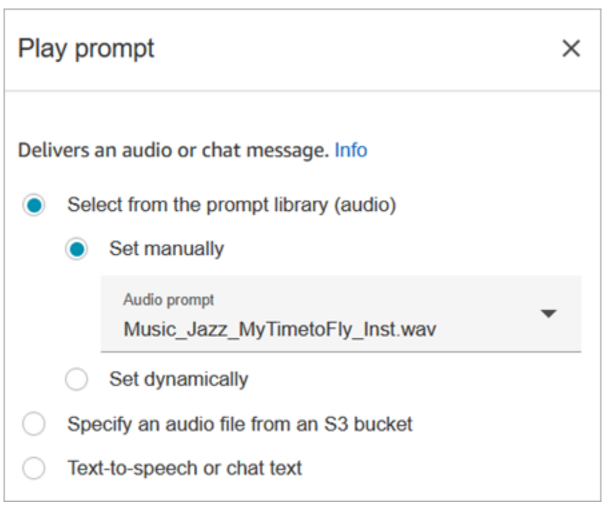
Configuration sections

- Prompts stored in the Amazon Connect prompts library
- Prompts stored in Amazon S3
- Text-to-speech or chat text
- Flow block branches
- Additional configuration tips
- Data generated by this block

Prompts stored in the Amazon Connect prompts library

1. In the flow designer, open the configuration pane for the **Play prompt** block.
2. Choose **Select from the prompt library (audio)**.
3. Choose from one of the pre-recorded prompts included with Amazon Connect, or use the Amazon Connect admin website to record and upload your own prompt. There's no way to upload prompts in bulk.

   The following image shows the **Properties** page of the **Play prompt** block configured to play an Audio prompt from the prompt library.

The following code sample shows how this same configuration would be represented by the MessageParticipant action in the Flow language:

```
{
        "Identifier": "12345678-1234-1234-1234-123456789012",
        "Type": "MessageParticipant",
```

```
        "Parameters": {
            "PromptId": "arn:aws:connect:us-west-2:1111111111:instance/aaaaaaa-bbbb-
cccc-dddd-eeeeeeeeeeee/prompt/abcdef-abcd-abcd-abcd-abcdefghijkl"
        },
        "Transitions": {
            "NextAction": "a625f619-81b0-46c3-a855-89151600bdb1",
            "Errors": [
                {
                    "NextAction": "a625f619-81b0-46c3-a855-89151600bdb1",
                    "ErrorType": "NoMatchingError"
                }
            ]
        }
    }
```

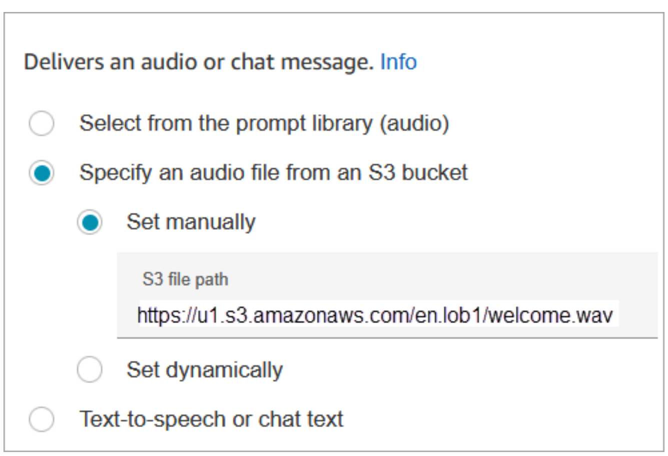
Prompts stored in Amazon S3

Store as many prompts as you need in an S3 bucket and then refer to them by specifying the bucket path. For best performance, we recommend creating the S3 bucket in the same AWS Region as your Amazon Connect instance.

To specify an audio file from an S3 bucket

1. In the flow designer, open the configuration pane for the **Play prompt** block.
2. Choose **Specify an audio file from an S3 bucket**.
3. Choose **Set manually**, and then specify the S3 file path that points to audio prompt in S3. For example, `https://u1.s3.amazonaws.com/en.lob1/welcome.wav`.

   The following image shows the **Properties** page of the **Play prompt** block configured to set the S3 file path manually.

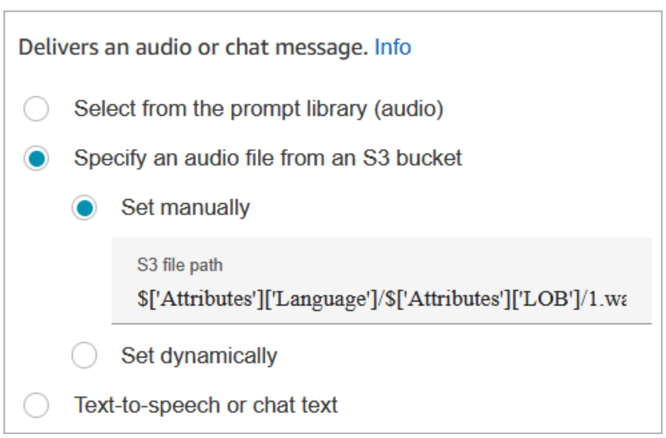
   


The following code sample shows how this same configuration would be represented by the [MessageParticipant](#) action in the Flow language:

```
{
      "Identifier": "UniqueIdentifier",
      "Type": "MessageParticipant",
      "Parameters": {
          "Media": {
              "Uri": "https://u1.s3.amazonaws.com/en.lob1/welcome.wav",
              "SourceType": "S3",
              "MediaType": "Audio"
          }
      },
      "Transitions": {
          "NextAction": "Next action identifier on success",
          "Errors": [
              {
                  "NextAction": "Next action identifier on failure",
                  "ErrorType": "NoMatchingError"
              }
          ]
      }
  }
```

To use attributes to specify an audio file path from an S3 bucket

- You can specify the S3 bucket path using attributes, as shown in the following image:



—OR—

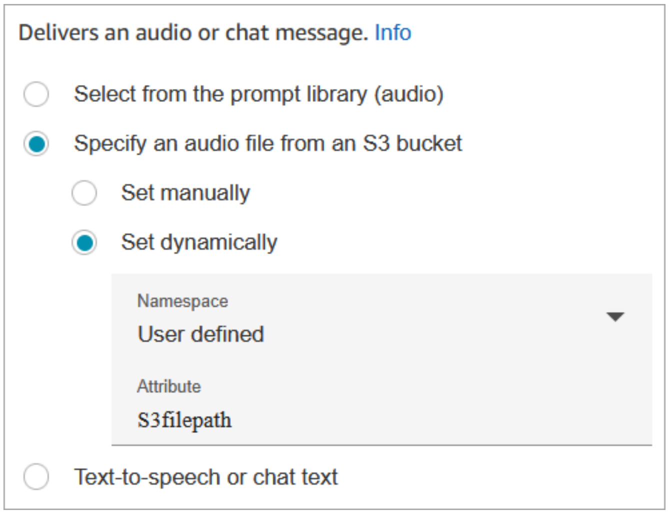
- You can provide the S3 path with concatenation, as shown in the following example. This enables you to personalize the prompt, for example, by line of business and language. For example: `https://example.s3.amazon.aws.com/$['Attributes']['Language']/$['Attributes']['LOB']/1.wav`

  The following code sample shows how this same configuration would be represented by the MessageParticipant action in the Flow language:

```
{
         "Identifier": "UniqueIdentifier",
         "Type": "MessageParticipant",
         "Parameters": {
             "Media": {
                 "Uri": "https://u1.s3.amazonaws.com/$['Attributes']['Language']/
$['Attributes']['LOB']/1.wav",
                 "SourceType": "S3",
                 "MediaType": "Audio"
             }
         },
         "Transitions": {
             "NextAction": "Next action identifier on success",
             "Errors": [
                 {
                     "NextAction": "Next action identifier on failure",
                     "ErrorType": "NoMatchingError"
                 }
             ]
         }
     }
```

To specify the S3 path dynamically by using user-defined contact attributes

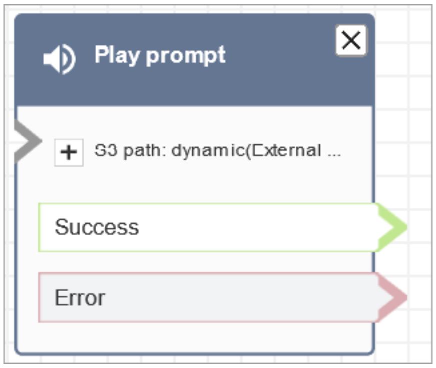
1. The following image shows a user-defined attribute named **S3filepath**.



The following code sample shows how this same configuration would be represented by the [MessageParticipant](#) action in the Flow language:

```
{
    "Parameters": {
        "Media": {
            "Uri": "$.Attributes.MyFile",
            "SourceType": "S3",
            "MediaType": "Audio"
        }
    },
    "Identifier": "9ab5c4ee-7da8-44b3-b6c9-07f24e1846dc",
    "Type": "MessageParticipant",
    "Transitions": {
        "NextAction": "a625f619-81b0-46c3-a855-89151600bdb1",
        "Errors": [
            {
                "NextAction": "a625f619-81b0-46c3-a855-89151600bdb1",
                "ErrorType": "NoMatchingError"
            }
        ]
    }
}
```

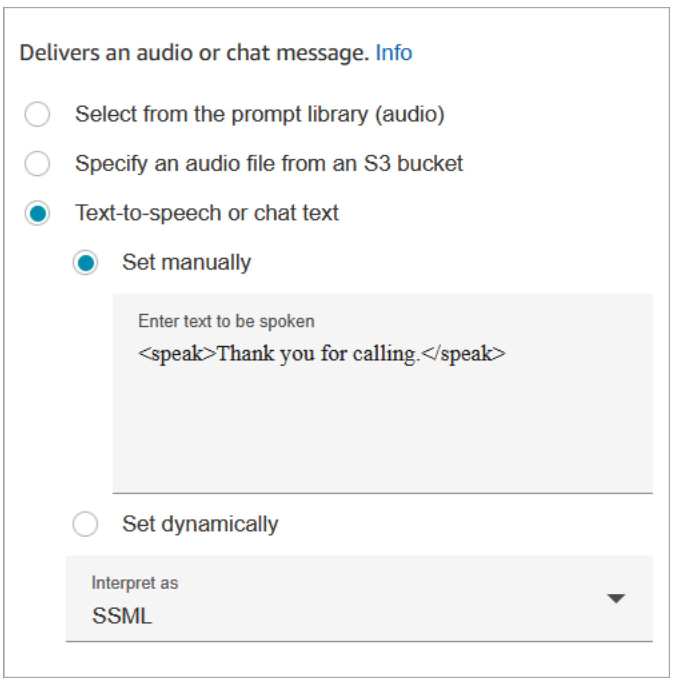
The following image shows what this block looks like when the S3 path is set dynamically. It shows the S3 path, and it has two branches: **Success** and **Error**.



Text-to-speech or chat text

You can enter a prompt in plain text or SSML. These text based prompts are played as audio prompts to customers using Amazon Polly.

For example, the following image shows a **Play prompt** block that is configured to play the message **Thank you for calling** to the customer.



The following code sample shows how this same configuration would be represented by the MessageParticipant action in the Flow language:

```
{
    "Parameters": {
        "Text": "<speak>Thank you for calling</speak>"
    },
    "Identifier": "9ab5c4ee-7da8-44b3-b6c9-07f24e1846dc",
```

```
    "Type": "MessageParticipant",
    "Transitions": {
        "NextAction": "a625f619-81b0-46c3-a855-89151600bdb1",
        "Errors": [
            {
                "NextAction": "a625f619-81b0-46c3-a855-89151600bdb1",
                "ErrorType": "NoMatchingError"
            }
        ]
    }
}
```

SSML-enhanced input text gives you more control over how Amazon Connect generates speech from the text you provide. You can customize and control aspects of speech such as pronunciation, volume, and speed.

For a list of SSML tags you can use with Amazon Connect, see [SSML tags supported by Amazon Connect].

For more information, see [Add text-to-speech to prompts in flow blocks in Amazon Polly].

The following image shows what a **Play prompt** block looks like when it's configured for text-to-speech. It shows the text to be played, and it has two branches: **Success** and **Error**.

Flow block branches

This block supports the following output branches:

- **Success**: Indicates successfully played the provided audio or text message.
- **Error**: Indicates a failure to play provided audio or text message.
- **Okay**: Some existing flows have a version of the **Play prompt** block that doesn't have an **Error** branch. In this case, the **Okay** branch will always be taken at runtime. If you update the

configuration of a **Play prompt** block that doesn't have an **Error** branch, an **Error** branch will be added to the block automatically in the editor.

Additional configuration tips

- For step-by-step instructions about how to set up a dynamic prompt using contact attributes, see Dynamically select which prompts to play in Amazon Connect.
- When playing prompts from an S3 bucket, for best performance we recommend creating the bucket in the same AWS Region as your Amazon Connect instance.
- When you use text, either for text-to-speech or chat, you can use a maximum of 3,000 billed characters, which is 6,000 characters total. You can also specify text in a flow using a contact attribute.

Data generated by this block

This block does not generate any data.

Error scenarios

A contact is routed down the **Error** branch in the following situations:

- If a callback contact without an agent or customer is routed to this block, the contact is routed down the **Error** branch.
- Amazon Connect is unable to download the prompt from S3. This may be due to an incorrect file path, or the S3 bucket policy is not set up correctly and Amazon Connect does not have access. For instructions about how to apply the policy, and a template you can use, see Set up prompts to play from an S3 bucket in Amazon Connect.
- Incorrect audio file format. Only .wav files are supported.
- The audio file is larger than 50MB or longer than five minutes.
- The SSML is incorrect.
- The text-to-speech length exceeds 6000 characters.
- The the Amazon Resource Name (ARN) for the prompt is incorrect.

Sample flows

All of the sample flows use the **Play prompt** block. Take a look at the Sample inbound flow in Amazon Connect for the first contact experience to see a **Play prompt** for chat and one for audio.

More resources

See the following topics to learn more about prompts.

- Create prompts in Amazon Connect

- Prompt actions in the Amazon Connect API Reference Guide.

Flow block in Amazon Connect: Resume contact

This topic defines the flow block for resuming a task contact from a paused state.

Description

- Resumes a task contact from a paused state. This enables agents to free up an active slot so they can receive more critical tasks when their current task is stalled, for example, because of a missing approval or waiting on an external input.
- For more information how pausing and resuming tasks works in Amazon Connect, see Pause and resume tasks in Amazon Connect Tasks.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

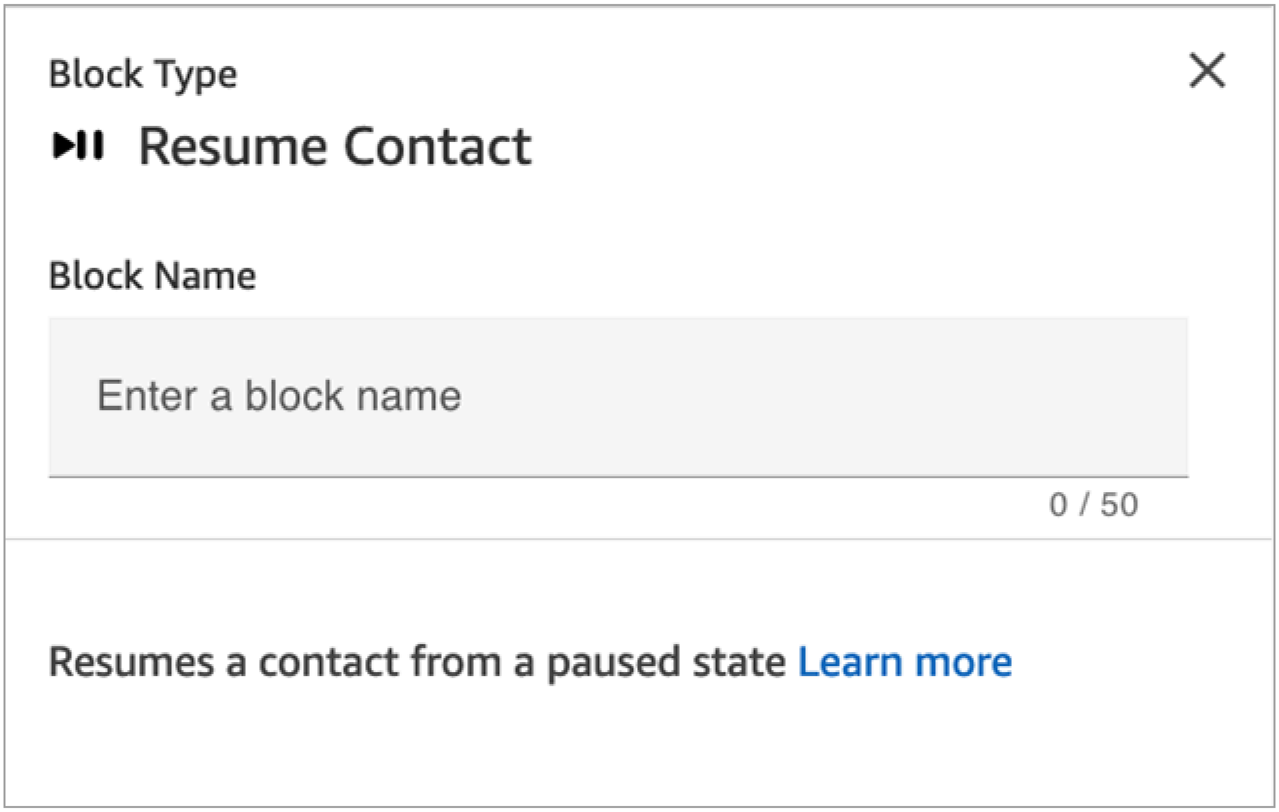
Channel	Supported?
Voice	No - Error branch
Chat	No - Error branch
Task	Yes
Email	No - Error branch

Flow types

You can use this block on all flow types.

Properties

The following image shows the **Properties** page of the **Resume contact** block.

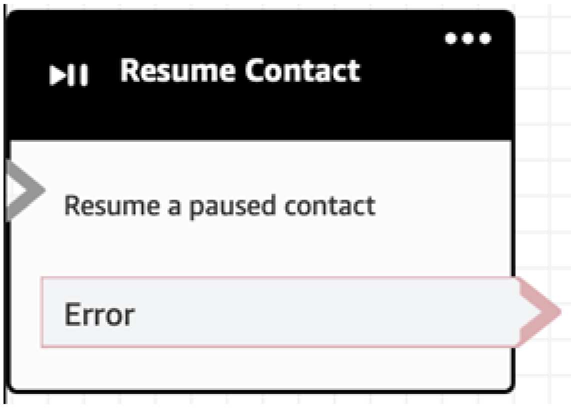


Configuration tips

When you design a flow to resume unassigned, paused tasks that are dequeued, be sure to add a [Transfer to queue](#) block to the flow to queue the task after resuming. Otherwise, the task will stay in a de-queued state.

Configured block

The following image shows an example of what this block looks like when it is configured. It has an **Error event** branch.



Flow block in Amazon Connect: Return (from module)

This topic defines the flow block for resuming a task contact from a paused state.

Description

- Use the **Return** block to mark the terminal action or terminal step of a flow module.
- Use this block to exit the flow module after it has run successfully. Then continue running the flow in which the module is referenced.

Supported types of flows

This block is only available in flow modules. It is not available in any other type of flow.

Flow type	Supported?
Inbound Flow (contactFlow)	No
Customer Queue Flow (customerQueue)	No
Customer Hold Flow (customerHold)	No
Customer Whisper Flow (customerWhisper)	No
Outbound Whisper Flow (outboundWhisper)	No
Agent Hold Flow (agentHold)	No
Agent Whisper Flow (agentWhisper)	No

Flow type	Supported?
Transfer To Agent Flow (agentTransfer)	No
Transfer To Queue Flow (queueTransfer)	No

Supported types of contacts

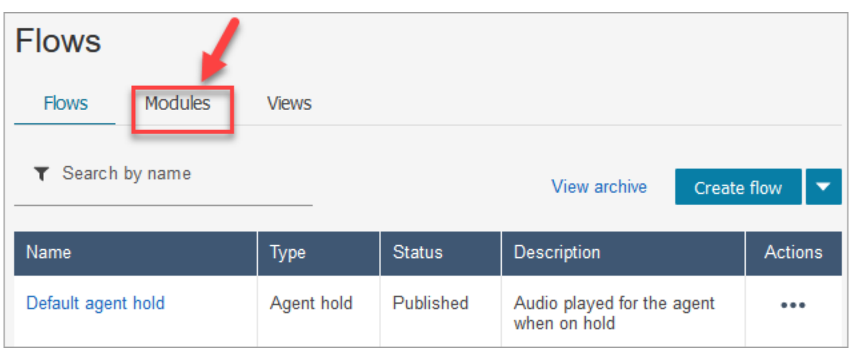
The following table lists how this block routes a contact who is using the specified channel.

Contact type	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

Flow block configuration

To use a Return block

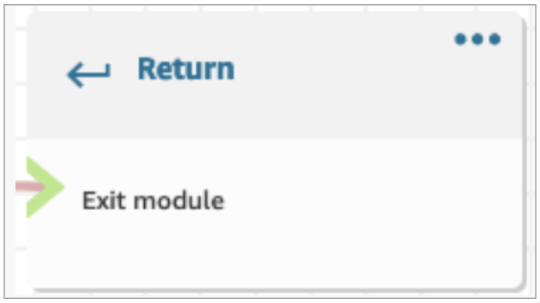
1. In the Amazon Connect admin website choose **Routing**, **Flows**.
2. On the **Flows** page, choose the **Modules** tab, as shown in the following image:



3. Choose **Create flow module** or choose the module you want to edit.
4. Select the **Return** block from the block dock and drag it onto the flow canvas.

Return block in the Amazon Connect admin website (for Tag action)

The following image shows what a **Return** block looks like on the flow editor canvas.



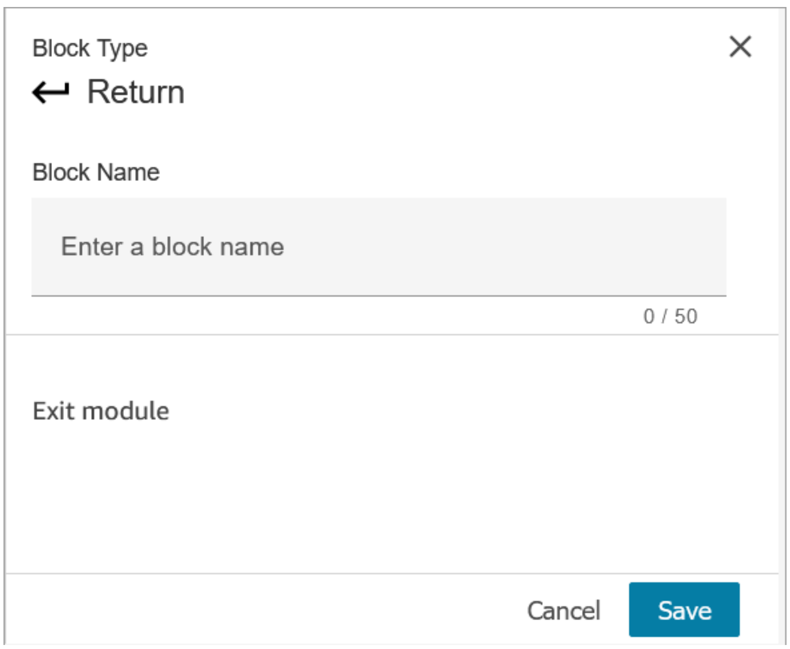
Return block in the Flow language

The **Return** flow block in the flow editor is stored as an `EndFlowModuleExecution` flow action in the Amazon Connect Flow Language.

For more information, see EndFlowModuleExecution in the *Amazon Connect API Reference*.

How to configure Return block properties

The following image shows the **Properties** pane of the **Return** block.



1. You don't need to configure this block because it is a terminal block for a flow module.
2. Choose **Save** and publish when you are ready!

The following code shows how this same configuration is represented as an EndFlowModuleExecution action in the Amazon Connect Flow Language.

```
{
      "Parameters": {},
      "Identifier": "the identifier of the Return block",
      "Type": "EndFlowModuleExecution",
      "Transitions": {}
    },
```

Explanation of flow block outcomes

None. No conditions are supported.

Data generated by the block

No data is generated by this block.

How to use this data in different parts of a flow

No data is generated by this block that can be used in the flow.

Fragmented action representation, if any

This block does not support fragmented action.

Known error scenarios

Because this is a terminal block there are no error scenarios that the flow may encounter when this block is run.

What this block looks like in a flow log

```
{
    "ContactId": "string",
    "ContactFlowId": "string",
    "ContactFlowName": "string",
    "ContactFlowModuleType": "Return",
    "Identifier": "string",
    "Timestamp": "2024-01-19T20:23:24.633Z",
    "Parameters": {}
```

```
}
```

Flow block in Amazon Connect: Send message

This topic defines the flow block for setting the number to call back the customer.

Description

- Use this flow block to send a message to your customer based on a template or custom message you specify.

Use cases for this block

This flow block is designed to be used in the following scenarios:

- Send an automatic acknowledgement when you receive a new email or SMS contact, for example, "Thank you for your message. We will get back to you in 24 hours."
- Send automated email or SMS responses that resolve the contact. For example, if a customer sends a text asking "How do I reset my password?" you can send a templated or generated email response that provides instructions.
- Send survey emails or SMS messages. For example, "Thank you for your time today. How did we do?" Use a Disconnect flow type for this use case.

Contact types

Contact type	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

Important information about using the Send message block in outbound flows

Important

When configuring outbound flows in Amazon Connect, especially the Default outbound flow, it is important to implement safeguards to prevent unintended email loops while using the EMAIL message type from the **Send message** block.

When outbound email contacts are created by the **Send message flow** block, they use the **Default outbound flow** to send the email by default. This can cause an unintended email loop if there is a **Send message** block configured in the same flow without any safeguards in place.

Follow these guidelines to ensure your outbound flow configuration operates as intended:

- Do not use the **Send message** block with the EMAIL message type in the **Default outbound flow** or any outbound flow type, if possible.
- If you must use the **Send message** block with the EMAIL message type in any outbound flow type, make sure your flow logic will not cause any email loops.

We recommend implementing the following safeguards while using the **Send message** block in any outbound flow type:

- Add a Check contact attributes block immediately before the **Send message** block in your outbound flow.
- Configure the **Check contact attributes** block to verify that the Channel System attribute (`$.Channel`) is set to branch on EMAIL.
- Set the EMAIL branch of the **Check contact attributes** block to avoid using the **Send message** block, thus preventing any email loops when outbound email contacts use the outbound flow.
- Set the **No Match** branch of the **Check attribute block** to use the **Send message** block. The **No Match** branch should route any VOICE, CHAT (including subtypes like SMS), or TASK contacts to the **Send message** block as part of the flow.

Implementing these safeguards will help prevent scenarios where outbound email contacts that use the outbound flow type trigger additional unintended outbound email contacts to be created by using the same outbound flow, potentially creating an infinite loop.

Flow types

You can use this block in the following flow types:

Flow type	Supported?
Inbound flow	Yes
Customer queue flow	Yes
Customer hold flow	Yes
Customer whisper flow	Yes
Outbound whisper flow	Yes
Agent hold flow	Yes
Agent whisper flow	Yes
Transfer to agent flow	Yes
Transfer to queue flow	Yes
Disconnect flow	Yes

Required permissions

To configure this block to send SMS or email messages, you need the following permissions on your security profile:

- **Channels and flows > Phone numbers > View**: To view the drop-down menu of phone numbers.
- **Email addresses - View**: To view the dropdown menu of From email addresses.
- **Content Management - Message templates - View**: To view the dropdown menu of message templates that are available for SMS messages and emails.

If you don't have these permissions, you can still set the properties dynamically. For example, if a phone number has been set manually already on the block, and you view the block without the **View** permission, you'll still be able to see that resource, just not the list of resources in the dropdown menu.

How to configure this block

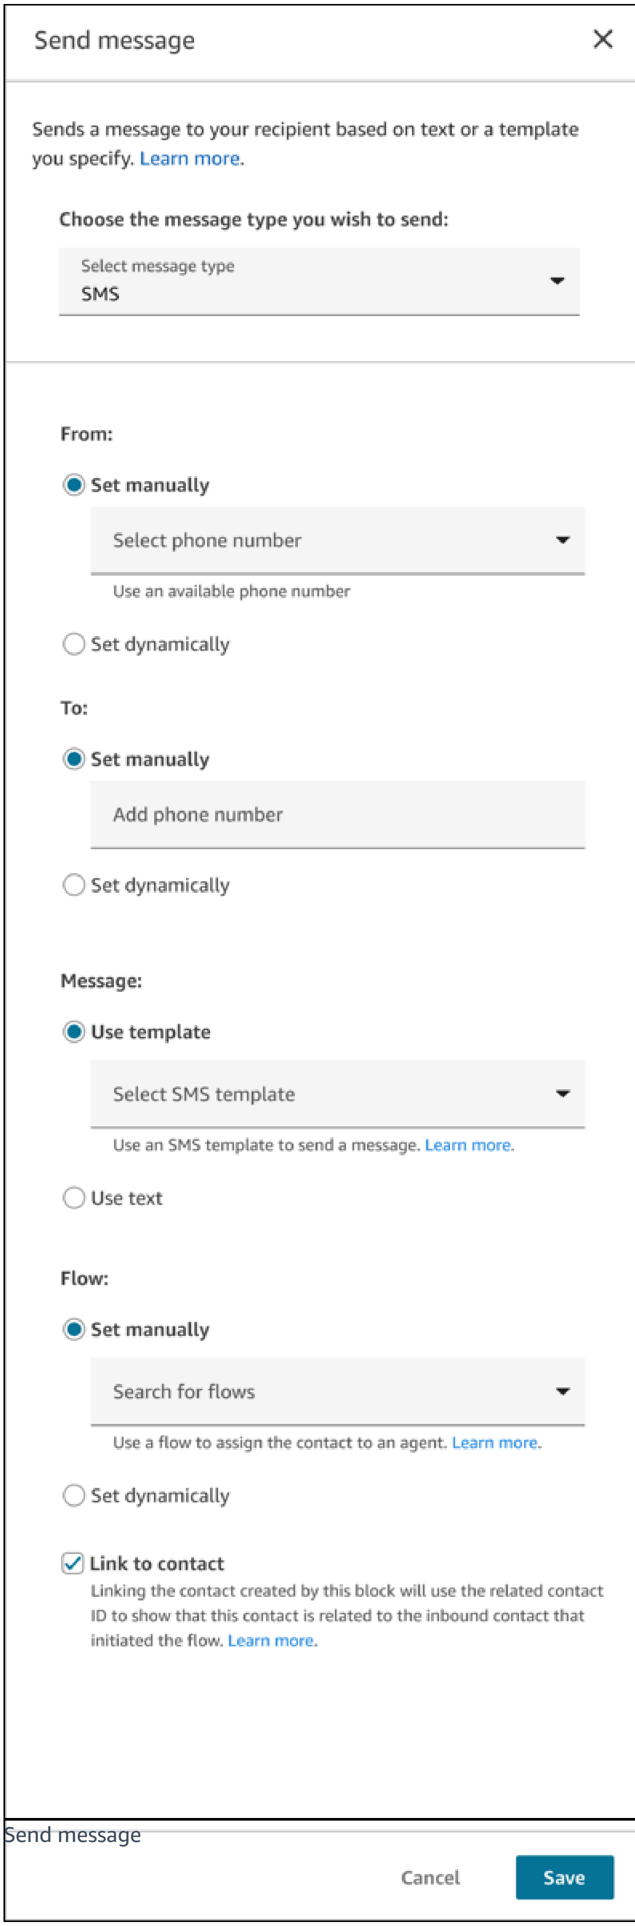
You can configure the **Send message** block by using the Amazon Connect admin website or by using the StartOutboundChatContact action in the Amazon Connect Flow language.

Configuration sections

- Send an SMS (text message)
- Send an email
- About using templates in the block
- About creating email and text messages in the block

Send an SMS (text message)

The following image shows the **Send message** properties page when it's configured to send an SMS message.



Send message
Sends a message to your recipient based on text or a template you specify. Learn more.
Choose the message type you wish to send:
Select message type
SMS
From:
Set manually
Select phone number
Use an available phone number
Set dynamically

Configure the following properties on the page to send an SMS message:

- **From**: The phone number that the message is to be sent from. The dropdown menu shows a list of phone numbers that are claimed for your Amazon Connect instance.
  - **Set manually**: Use the dropdown menu to search for a phone number that has been claimed to your Amazon Connect instance.

    You must have the required permission in your security profile to view the dropdown list of templates.
  - **Set dynamically**: Accepts an attribute based on a **Namespace** and **Key** that points to an ARN of a phone number that has been claimed by your Amazon Connect instance.
- **To**: The phone number that the message is to be sent to.
  - **Set manually**: Enter the customer's phone number. This is where the SMS message will be sent. You can enter only one phone number. This is useful for testing the block.
  - **Set dynamically**: Accepts an attribute based on a **Namespace** and **Key** that is a phone number string the SMS is sent to. This must be in E.164 format.
- **Message**: The message that will be sent to the customer.
  - **Use template**: Use the dropdown menu to choose from a list of SMS templates. You can choose one template to be sent to the customer.

    An SMS template is a complete SMS message structure that contains only plain text. It provides the entire response or notification to the customer.

    You must have the required permission in your security profile to view the dropdown list of templates.
  - **Use text**: Send a plain text message either **Set manually** by typing one in or **Set dynamically** by adding an attribute based on a **Namespace** and **Key**.

    > **Note**
    >
    > **Message** accepts plain text (including links and emojis), up to 1024 characters, including spaces.
- **Flow**: The Amazon Connect flow that will handle the outbound contact created. This flow can be used to assign the outbound contact to an agent to respond to the customer.
  - **Set manually**: Use the drop-down menu to choose from a list of published flows.

  - **Set dynamically**: Accepts an attribute based on a **Namespace** and **Key** that points to a flow ARN.

- **Link to contact**: This property gives you the option to link the outbound contact that is created to the inbound contact that initiated the flow. In some situations, you may not want to link the outbound contact that is created to avoid repetitive contact associations.
  - This property gives you the option to link the outbound SMS contact to the inbound contact that initiated the flow.

    In some situations, you may not want to link the contact to avoid sending repetitive outbound SMS messages. For example, if the flow is configured to send the customer the message *Thank you for your message! We will get back to you within 24 hours.* every time you receive a contact.

Send an email

The following image shows the **Send message** properties page when it's configured to send an email.

Configure the following properties on the **Send message** properties page to send an email message:

- **From**: Use the dropdown menu to choose the email address the message is to be sent from. The menu shows a list of email addresses configured for your Amazon Connect instance.

  You must have the required permission in your security profile to view the dropdown list of emails.

  - **Set manually**: Use the dropdown menu to search for an email address that has been configured for your Amazon Connect instance.
  - **Set dynamically**: Choose the Namespace and Key from the dropdown menus. For example, if you want the From email address to be the same as the one the customer sent the email to, choose **Namespace** = **System**,**Key** = **System email address**.
- **To**: The email address email message is sent to.
  - **Set manually**: Enter a single email address in the following format: *customer@example.com*.
  - **Set dynamically**: Choose the Namespace and Key from the dropdown menus. For example, to send an email reply to the customer's email address, choose **Namespace** = **System**, **Key** = **Customer endpoint address**.
- **CC**: The email address to go on the cc line of the email.

  > **Important**
  >
  > You can enter only one email address on the cc line.

  - **Set manually**: Use the text box to enter a list of email addresses, separated by a semicolon (;). These are the email addresses the message will be sent to.
  - **Set dynamically**: Enter an attribute based on a **Namespace** and **Key** For example, to send an email reply that is cc'ed to the same email addresses on that were cc'ed on the customer's original email to you, choose **Namespace** = **System**, **Key** = **CC Email Address List**.
- **Message**:
  - **Use template**: Use the dropdown menu to choose from a list of email templates that have been created for your contact center. You can choose one template to be sent to the customer.
  - **Use text**: Enter a plain text message.

    - **Subject**: To enter the Subject dynamically, for example, to use the same subject that was in the customer's original email to you, choose **Namespace** = **Segment attribute**, **Key** = **Email Subject**.
    - **Message**: To enter the Message dynamically, choose a **User-defined** attribute.
- **Link to contact**:
    - This property gives you the option to link the outbound email contact to the inbound contact that initiated the flow.

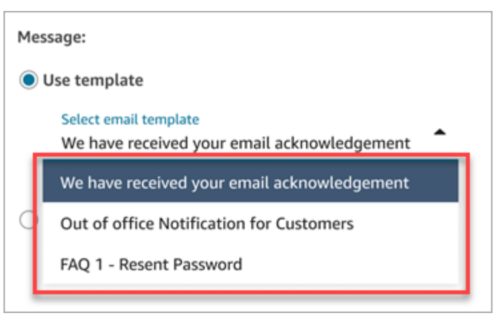
      In some situations, you may not want to link the contact to avoid sending repetitive outbound email messages. For example, if the flow is configured to send the customer the message *Thank you for your message! We will get back to you within X hours.* every time you receive a contact.

About using templates in the block

An email template is a complete email message that contains plain or rich text content. It serves as a pattern for part or all of an email message. An email template can be used by:

- A flow to send acknowledgements or automated responses to an end customer without agent involvement.
- A contact center manager to define the structure or outline of every agent response to ensure details such as signature, header/footer branding, and disclaimers are always included in the response to the customer.

The following image shows an example dropdown menu with a list of available email templates.



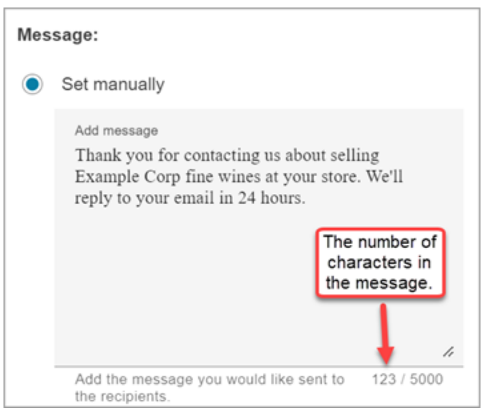
The email template contains the subject and body of an email message to be sent to a customer.

> **Note**
>
> The subject from the template is not included when the **Send message** block is being used to Reply or Reply all to an inbound email contact.

About creating email and text messages in the block

In the case of email, when you use a message created in the **Send message** block, you need to enter a **Subject** and **Message** for the email.

- **Subject**: You can enter up to 998 characters, including spaces.
- **Message**: Enter plain text, up to 5000 characters, including spaces. The message can be set manually by typing in a message or dynamically by a **User-defined** attribute set within the flow. The following image shows the character count for an email message.



In the case of SMS, when you use a message created in the **Send message** block, you need to enter only a **Message**, no subject.

- **Message**: Enter plain text, up to 1024 characters, including spaces. Or, set the message dynamically by using a user-defined attribute set within the flow.

Error scenarios

A contact is routed down the **Error** branch in the following situations:

- Incorrect information passed to the block, such as a system email address that does not exist for the **From** field.

- Email sending service failure.
- Some attributes of the email template could not be populated before sending.

Flow block in Amazon Connect: Set callback number

This topic defines the flow block for setting the number to call back the customer.

Description

- Specify the attribute to set the callback number.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	No - Invalid number branch
Task	No - Invalid number branch
Email	No - Invalid number branch

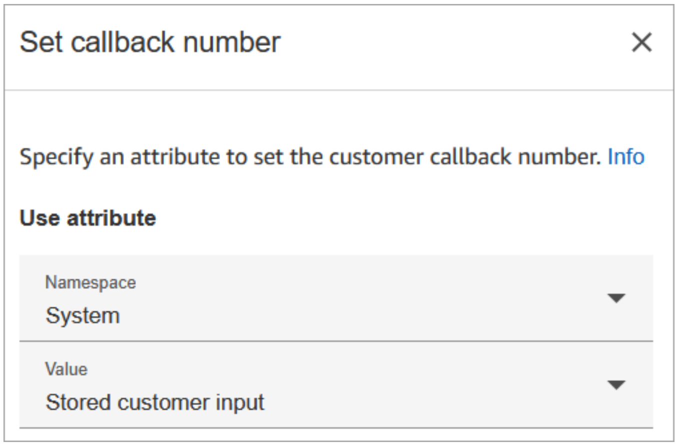
Flow types

You can use this block in the following flow types:

- Inbound flow
- Customer Queue flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

The following image shows the **Properties** page of the **Set callback number** block.

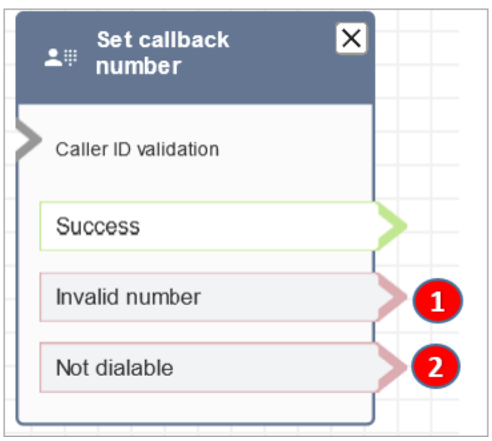


Configuration tips

- The Store customer input block often comes before this block. It stores the customer's callback number.

Configured block

The following image shows an example of what this block looks like when it is configured. It has the following branches: **Success**, **Invalid number**, and **Not dialable**.



1. **Invalid number**: The customer entered phone number that is not valid.
2. **Not dialable**: Amazon Connect is unable to dial that number. For example, if your instance is not allowed to make calls to +447 prefix phone numbers, and the customer requested callback to a +447 prefix number. Even though number is valid, Amazon Connect cannot call it.

Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

- Sample queue configurations flow in Amazon Connect
- Sample queued callback flow in Amazon Connect: this sample only applies to previous instances of Amazon Connect.

Scenarios

See these topics for scenarios that use this block:

- Set up queued callback by creating flows, queues, and routing profiles in Amazon Connect
- Queued callbacks in real-time metrics in Amazon Connect

Flow block in Amazon Connect: Set contact attributes

This topic defines the flow block for storing key-value pairs as contact attributes, and then setting a value that is later referenced in a flow.

Description

Stores key-value pairs as contact attributes. You set a value that is later referenced in a flow.

For example, create a personalized greeting for customers routed to a queue based on the type of customer account. You could also define an attribute for a company name or line of business to include in the text to speech strings said to a customer.

The **Set contact attributes** block is useful, for example, for copying attributes retrieved from external sources to user-defined attributes.

For more information about contact attributes, see Use Amazon Connect contact attributes.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

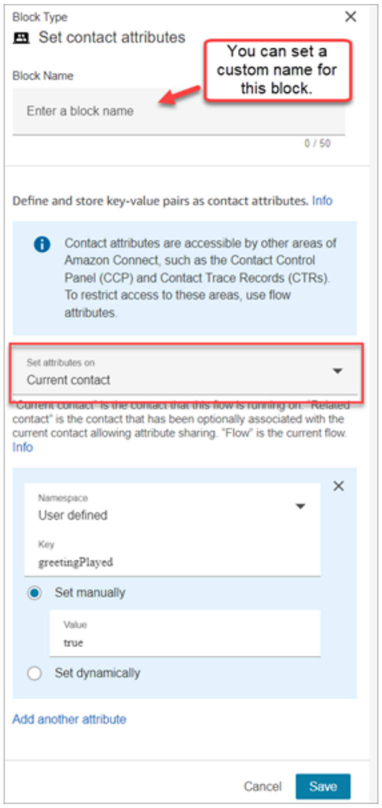
Flow types

You can use this block in the following flow types:

- All flows

Properties

The following image shows the **Properties** page of the **Set contact attributes** block. It is configured to set a user-defined attribute on the **Current contact** with the key **greetingPlayed** and the value **true**.



You can choose to set attributes on:

- **Current contact**: The attributes are set on the contact that this flow is running on. The attributes are accessible by other areas of Amazon Connect, such as other flows, modules, Lambdas, contact records, and the GetMetricDataV2 API.
- **Related contact**: The attributes are associated with a new contact that contains a copy of the original contact properties.

  In the contact record, this is the **RelatedContactId**.
- **Flow**: The attributes are restricted to the flow in which they are configured.

  Flow attributes are useful in situations where you don't want to persist the data throughout the contact, such as when you need to use sensitive information like the customer's credit card number to do a Lambda data dip.

  - Flow attributes are temporary variables stored locally and only used in the flow. They aren't visible anywhere outside the flow, not even when the contact is transferred to another flow.
  - They can be up to 32 KB (the maximum size of the contact record attributes section).
  - They aren't passed to a Lambda unless they are explicitly configured as parameters: in the **Invoke AWS Lambda function** block, choose **Add a parameter**.

- They aren't passed to modules. You can set a flow attribute within a module, but it won't be passed out of the module.
- They don't appear in the contact record.
- They don't appear to the agent in the CCP.
- The `GetContactAttributes` API can't expose them.
- If you have logging enabled on the flow, the key and value appear in the Cloudwatch log.

How to reference attributes

- For the JSON syntax for each attribute, see List of available contact attributes in Amazon Connect and their JSONPath references.
- To reference attributes that contain special characters in their name, such as spaces, place brackets and single quotations around the attribute name. For example: `$.Attributes.['user attribute name']`.
- To reference attributes in the same namespace, such as a system attribute, you use the attribute name, or the name you specified as the **Destination key**.
- To reference values in a different namespace, such as referencing an external attribute, you specify the JSONPath syntax to the attribute.
- To use contact attributes to access other resources, set a user-defined attribute in your flow and use the Amazon Resource Name (ARN) of the resource you want to access as the value for the attribute.

Lambda examples

- To reference a customer name from a Lambda function lookup, use $.External.AttributeKey, replacing AttributeKey with the key (or name) of the attribute returned from the Lambda function.
- To use an Amazon Connect prompt in a Lambda function, set a user-defined attribute to the ARN for the prompt, and then access that attribute from the Lambda function.

Amazon Lex examples

- To reference an attribute from an Amazon Lex bot, you use the format $.Lex. and then include the part of the Amazon Lex bot to reference, such as $.Lex.IntentName.

- To reference the customer input to an Amazon Lex bot slot, use $.Lex.Slots.*slotName*, replacing *slotName* with the name of the slot in the bot.

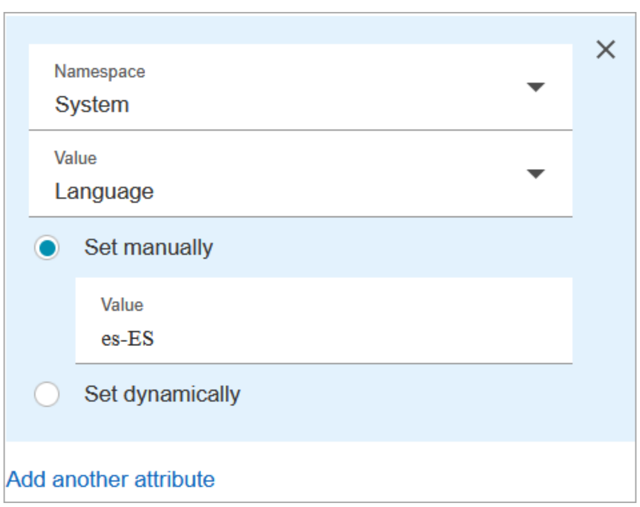
What happens when attributes exceed 32 KB

Attributes can be up to 32 KB, which is the maximum size of the contact record attributes section. When the attributes for a contact exceed 32 KB, the contact is routed down the **Error** branch. As a mitigation, consider the following options:

- Remove unnecessary attributes by setting their values to empty.
- If the attributes are only used in one flow and don't need to be referred to outside of that flow (for example, by a Lambda or another flow), then use flow attributes. This way you aren't needlessly persisting the 32 KB of information from one flow to another.

Configuration tips

- When using a user-defined destination key, you can name it anything you want but don't include the **$** and **.** (period) characters. They are not allowed because they are both used in defining the attribute paths in JSONPath.
- You can use the **Set contact attribute** block to set the language attribute required for an Amazon Lex V2 bot. (Your language attribute in Amazon Connect must match the language model used to build your Amazon Lex V2 bot.) The following image shows a language attribute set to Spanish.



Or, you can use the [Set voice](#) block to set the language required for an Amazon Lex V2 bot.

For more information about how to use contact attributes, see Use Amazon Connect contact attributes.

Configured block

The following image shows an example of what this block looks like when it is configured. It has two branches: **Success** and **Error**.

Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

- Sample inbound flow in Amazon Connect for the first contact experience

Scenarios

See these topics for scenarios that use this block:

- How to reference contact attributes in Amazon Connect

Flow block in Amazon Connect: Set customer queue flow

This topic defines the flow block for specifying the flow to invoke when a customer is transferred to a queue.

Description

- Specifies the flow to invoke when a customer is transferred to a queue.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

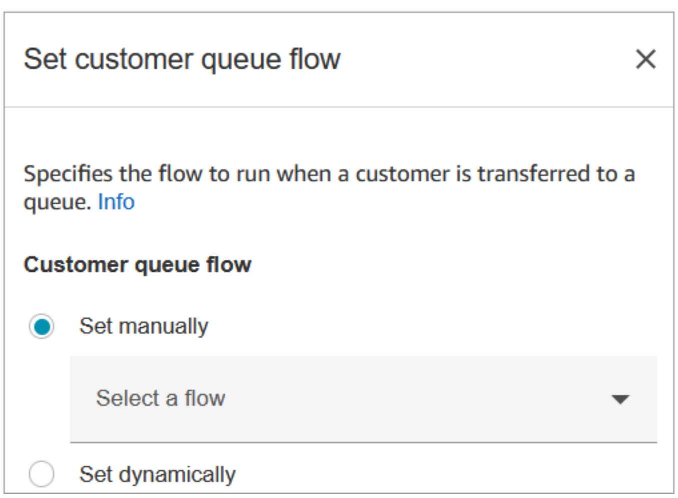
Flow types

You can use this block in the following flow types:

- Inbound flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

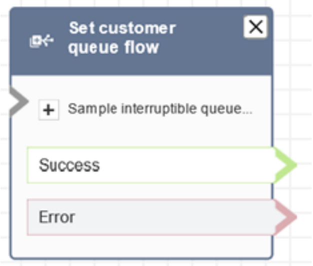
The following image shows the **Properties** page of the **Set customer queue flow** block.



For information about using attributes, see Use Amazon Connect contact attributes.

Configured block

The following image shows an example of what this block looks like when it is configured. It has the following branches: **Success** and **Error**.



Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see [Sample flows in Amazon Connect](). Following are topics that describe the sample flows which include this block.

- [Sample queued callback flow in Amazon Connect]()

Flow block in Amazon Connect: Set disconnect flow

This topic defines the flow block for specifying which flow to run when a call is disconnected during a contact.

Description

- Specifies which flow to run after a disconnect event during a contact.

  A disconnect event is when:

  - A chat, or task is disconnected.
  - A task is disconnected as a result of a flow action.
  - A task expires. The task is automatically disconnected if it is not completed in 30 days.

  When the disconnect event occurs, the corresponding flow runs.

- Here are examples of when you might use this block:
  - Run post-contact surveys. For example, the agent asks the customer to remain on the line for a post-call survey. The agent hangs up and a disconnect flow is run. In the disconnect flow,

the customer is asked a set of questions using the Get customer input block. Their answers are uploaded using an Invoke AWS Lambda function block to an external customer feedback database. The customer is thanked and disconnected.

For more information about creating post-contact surveys, see this blog: Easily create and visualize post chat surveys with Amazon Connect and Amazon Lex. And check out this workshop: Building a contact survey solution for Amazon Connect.

- In a chat scenario, if a customer stops responding to the chat, use this block to decide whether to run the disconnect flow and call a Wait block, or end the conversation.
- In task scenarios where a task may not be completed in 7 days, use this block to run a disconnect flow to determine whether the task should be re-queued, or completed/disconnected by a flow action.

> **Tip**
>
> It's not possible to play a audio prompt to the agent or invoke a flow when the customer disconnects. After the customer disconnects, the flow ends and the agents starts After Call Work (ACW) for that contact.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

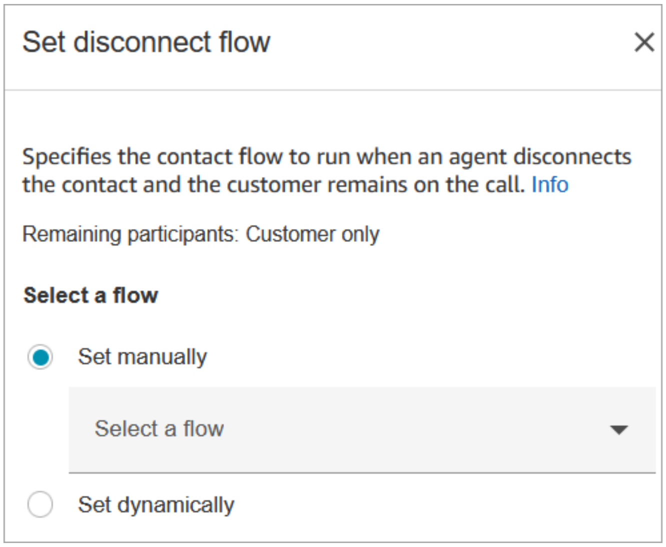
Flow types

You can use this block in the following flow types:

- All flows

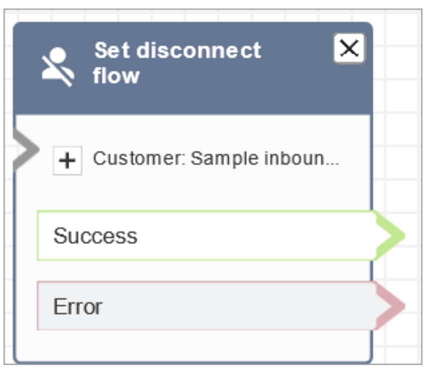
Properties

The following image shows the **Properties** page of the **Set disconnect flow** block.



Configured block

The following image shows an example of what this block looks like when it is configured. It has the following branches: **Success** and **Error**.



Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

- Sample inbound flow in Amazon Connect for the first contact experience

Scenarios

See these topics for scenarios that use this block:

- Example chat scenario
- Easily create and visualize post chat surveys with Amazon Connect and Amazon Lex
- Building a contact survey solution for Amazon Connect

Flow block in Amazon Connect: Set event flow

This topic defines the flow block for specifying a flow to run during an interaction with a contact.

Description

- Specifies which flow to run during a contact event.
- The following events are supported:
  - **Default flow for agent UI**: specifies the flow to be invoked when a contact comes into the Agent Workspace. You can use this event to set up a step-by-step guide to be played to the agent in this scenario.
  - **Disconnect flow for agent UI**: specifies the flow to be invoked when a contact that is open in the Agent Workspace ends. You can use this event to set up a step-by-step guide to be played to the agent in this scenario.
  - **Flow at contact pause**: Specifies the flow to be invoked when a contact comes to paused state. For more information, see Pause and resume tasks in Amazon Connect Tasks.
  - **Flow at contact resume**: Specifies the flow to be invoked when a contact comes to resume from paused state. For more information, see Pause and resume tasks in Amazon Connect Tasks.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes

Channel	Supported?
Chat	Yes
Task	Yes
Email	Yes

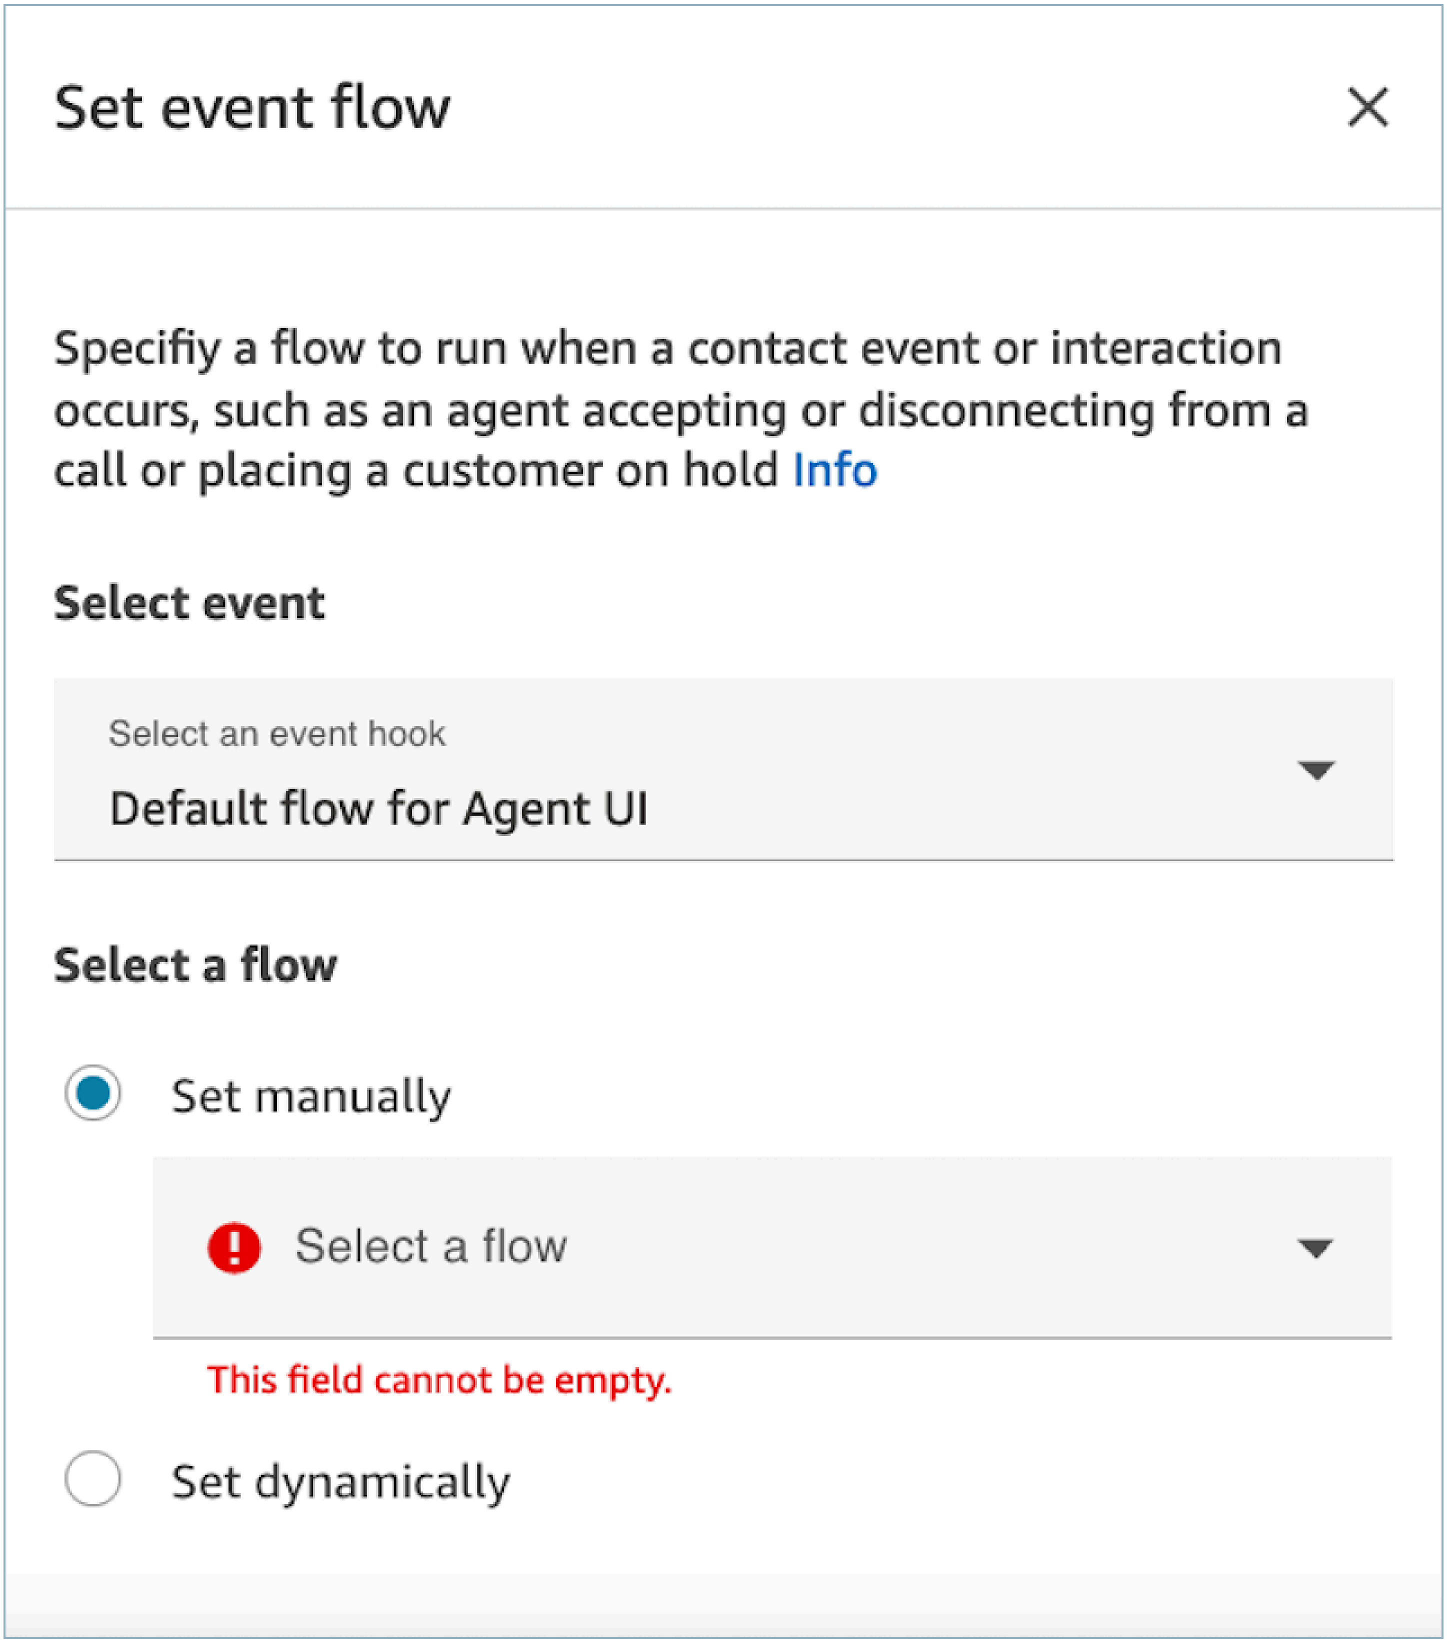
Flow types

You can use this block in the following flow types:

- All flows

Properties

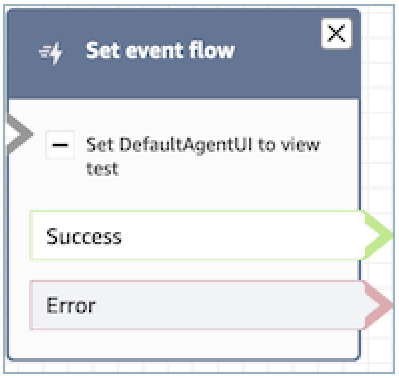
The following image shows the **Properties** page of the **Set event flow** block.



Set event flow
Specifiy a flow to run when a contact event or interaction occurs, such as an agent accepting or disconnecting from a call or placing a customer on hold Info
Select event
Select an event hook
Default flow for Agent UI
Select a flow
Set manually
Select a flow
This field cannot be empty.
Set dynamically

Configured block

The following image shows an example of what this block looks like when it is configured. It has the following branches: **Success** and **Error**.



Scenarios

See these topics for scenarios that use this block:

- Invoke a guide at the start of a contact in Amazon Connect

Flow block in Amazon Connect: Set hold flow

This topic defines the flow block for specifying the flow to invoke when a customer or agent is put on hold.

Description

- Links from one flow type to another.
- Specifies the flow to invoke when a customer or agent is put on hold.

  If this block is triggered during a chat conversation, the contact is routed down the **Error** branch.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes

Channel	Supported?
Chat	No - Error branch
Task	No - Error branch
Email	No - Error branch

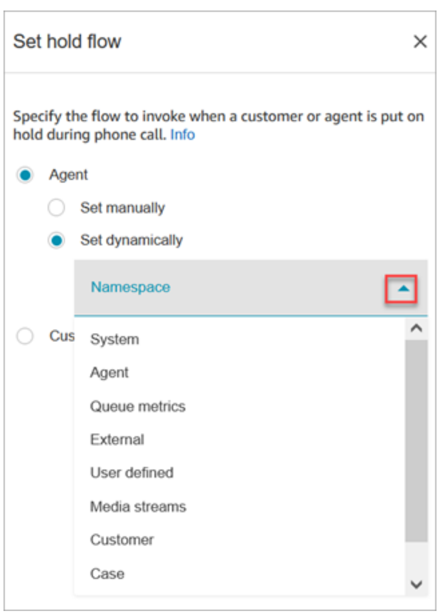
Flow types

You can use this block in the following flow types:

- Inbound flow
- Customer Queue flow
- Outbound whisper flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

The following image shows the **Properties** page of the **Set hold flow** block. It shows the dropdown list of namespaces that you can use to set the hold flow dynamically.



For information about using attributes, see Use Amazon Connect contact attributes.

Configured block

The following image shows an example of what this block looks like when it is configured. It has the following branches: **Success** and **Error**.

Flow block in Amazon Connect: Set logging behavior

This topic defines the flow block for enabling flow logs to track events as contacts interact with flows.

Description

- Enables flow logs so you can track events as contacts interact with flows.
- Flow logs are stored in Amazon CloudWatch. For more information, see Flow logs stored in an Amazon CloudWatch log group.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

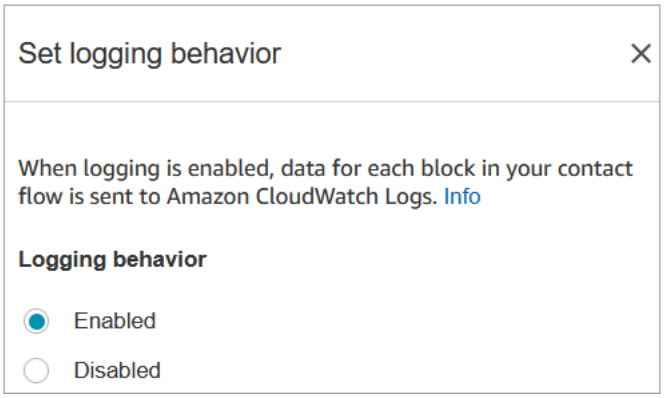
Flow types

You can use this block in the following flow types:

- All flows

Properties

The following image shows the **Properties** page of the **Set logging behavior** block. It has two options: enable logging behavior, or disable it.



Scenarios

See these topics for more information about flow logs:

- Track events in your Amazon Connect flow logs as customers interact with them

Flow block in Amazon Connect: Set recording and analytics behavior

This topic defines the flow block for setting options to record or monitor voice for agent and customer, enable automated interaction, enable screen recording, and to set analytics behavior for contacts.

Description

There is a lot of functionality in this block:

- You configure what part of the call can be recorded be it either agent, customer or both. No additional charges apply.

- You can enable automated interaction call recording to hear how a customer is interacting with your IVR or conversational AI bot. No additional charges apply.
- You can enable screen recording of agents, if agent screen recording has been set up as described in Enable screen recording. For pricing information, see Amazon Connect Pricing.
- You can configure Contact Lens analytics settings for chat and voice contacts. For pricing information, see Amazon Connect Pricing. This includes:
  - Language in which customers and agents will interact (to improve the speech to text transcript generation)
  - Redaction of sensitive data
  - Additional Contact Lens Generative AI capabilities
- It enables Contact Lens conversational analytics on a contact. For more information, see Analyze conversations using conversational analytics.

Contact types

Channel	Supported?
Voice	Yes
Chat	Yes
Task	No - Error branch
Email	No - Error branch

Flow types

You can use this block in the following flow types:

Flow type	Supported?
Inbound flow	Yes
Customer hold flow	No
Customer queue flow	Yes

Flow type	Supported?
Customer whisper flow	No
Outbound whisper flow	Yes
Agent hold flow	No
Agent whisper flow	No
Transfer to agent flow	Yes
Transfer to queue flow	Yes

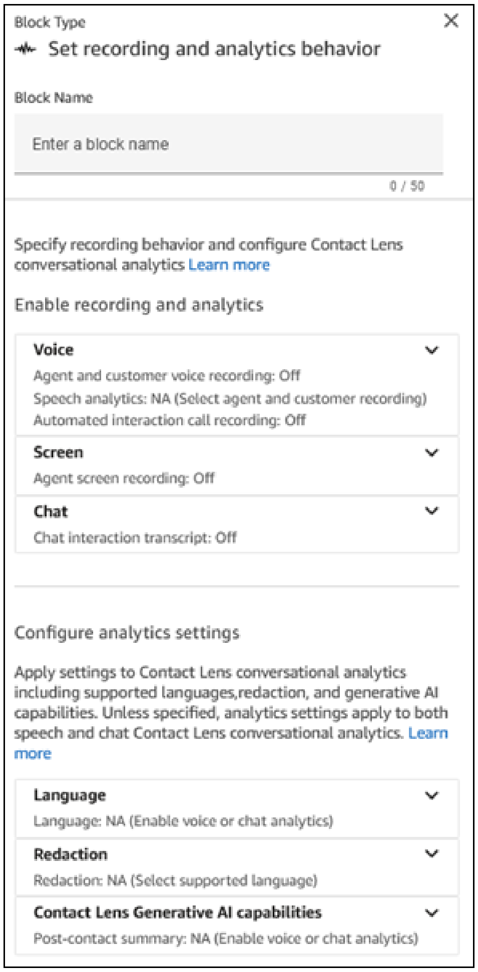
Tip

We recommend using the **Set recording behavior** block in an inbound or outbound whisper flow for the most accurate behavior.
Using this block in a queue flow does not always guarantee that calls are recorded. This is because the block might run after the contact is joined to the agent.

How to configure this block

You can configure the **Set recording and analytics behavior** block by using the Amazon Connect admin website or by using the UpdateContactRecordingBehavior action in the Amazon Connect Flow language.

The following image shows the **Set recording and analytics behavior** properties page in the Amazon Connect admin website. It is divided two sections: Enable recording and analytics, and Configure analytics settings. These sections are divided in subsections. Each subsection can be expanded and collapsed and summary is displayed in its header.



Enable recording and analytics

In this section of the Properties page you configure recording and related analytics settings.

- **Voice**:
  - **Agent and customer voice recording**: Choose who you want to record.
  - **Contact Lens speech analytics**: Choose whether to use speech analytics on agent and customer recordings.
  - **Automated interaction call recording**: Choose whether to enable voice recording when the customer is interacting with bots and other automation.

> **Note**
>
> To include Lex bot transcripts and analytics as a part of your **Contact details** page and Amazon Connect analytics dashboards:

> 1. In the Amazon Connect console, choose the name of your instance. For instructions, see Find your Amazon Connect instance name.
> 2. On the navigation pane choose **Flows**, and then choose **Enable Bot Analytics and Transcripts in Amazon Connect**.

- **Screen**: Use to enable or disable recording of the agent's screen. For more information, see Set up and review agent screen recordings in Amazon Connect Contact Lens.
- **Chat**: Use this option to enable chat analytics, a feature in Contact Lens. For more information, see Enable conversational analytics in Amazon Connect Contact Lens.

Configure analytics settings

This section of the properties page applies to Contact Lens conversational analytics. You specify supported languages, redaction, and generative AI capabilities. Unless specified otherwise, analytics settings apply to both speech and chat Contact Lens conversational analytics.

- **Language**: You can dynamically enable the redaction of the output files based on the language of the customer. For instructions, see Dynamically enable redaction based on the customer's language.
- **Redaction**: Choose whether to redact sensitive data. For more information, see Enable redaction of sensitive data.
- **Sentiment**: Choose whether to enable sentiment analysis.
- **Contact Lens Generative AI capabilities**: For more information, see View generative AI-powered post-contact summaries

Configuration tips

- You can change call recording behavior in a flow, for example, change from "Agent and customer" to "Agent only." Perform the following steps:
  1. Add a second **Set recording and analytics behavior** block to the flow.
  2. Configure the second block to set agent and customer voice recording to **Off**.
  3. Add another **Set recording and analytics behavior** block.
  4. Configure the third block to the new recording behavior you want, such as **Agent only**.

> **Note**
>
> The settings in the **Analytics** section are overwritten by each subsequent **Set recording and analytics behavior** block in the flow.

- **For calls**: Unselecting **Enable speech analytics on agent and customer voice recordings** disables Contact Lens conversational analytics.

  For example, let's say you have two **Set recording and analytics behavior** blocks in your flow.

  - The first block has enabled real-time speech analytics on agent and customer voice recordings selected.
  - The second block later in the flow has it unselected.

  In this case, the analytics appear only during the time analytics was enabled.

  Another example: let's say you have two **Set recording and analytics behavior** blocks in your flow.

  - The first block has **Enabled post-call speech analytics on agent and customer voice recordings** selected.
  - The second block later in the flow has it unselected.

  In this case, since post call happens at end of call and the latest configuration doesn't have analytics enabled, no post-call analytics will be available.

- **For automated interaction call recording**: Recording starts as soon as it is set to On. Later in the flow, if it is set to off in a second block, recording is paused and can be turned on later to resume the recording.

  > **Note**
  >
  > When a call is transferred by using the [Flow block in Amazon Connect: Transfer to phone number]() block, the recording continues.

- **For chat**: Real-time chat starts analysis as soon as any block in the flow enables it. No block later in the flow disables the real time chat settings.
- If an agent puts a customer on hold, the agent is still recorded, but the customer is not.

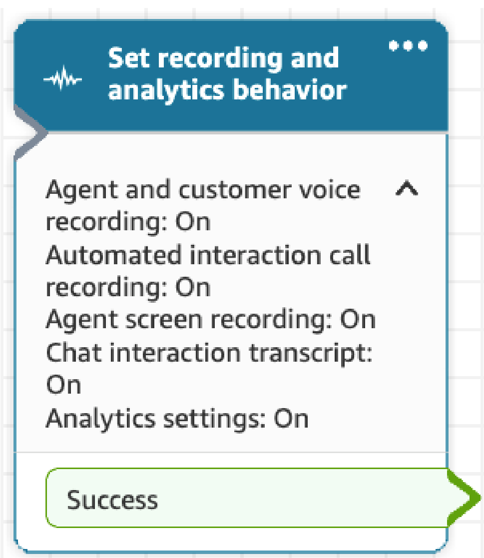
- If you want to transfer a contact to another agent or queue, and you want to continue using Contact Lens conversational analytics to collect data, you need to add to the flow another **Set recording behavior** block with **Enable analytics** turn on. This is because a transfer generates a second contact ID and contact record. Contact Lens conversational analytics needs to run on that contact record as well.
- When you enable conversational analytics, the type of flow that the block is in, and where it is placed in the flow, determine **whether** agents receive the key highlights transcript, and **when** they receive it.

  For more information and example use cases that explain how the block affects the agents experience with key highlights, see Design a flow for key highlights.

Configured block

This block supports one output branch: **Success**.

The following image shows what a **Set recording and analytics behavior** block looks like when it's configured for both voice and automated interaction recording, along with speech analytics and screen recording enabled.



Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

- Sample inbound flow in Amazon Connect for the first contact experience

Scenarios

See these topics for scenarios that use this block:

- Set up recording behavior using Amazon Connect Contact Lens
- Set up live monitoring for voice, chat, or both in Amazon Connect
- Review recorded conversations between agents and customers using Amazon Connect
- Assign permissions to review past contact center conversations in Amazon Connect
- Analyze conversations using conversational analytics in Amazon Connect Contact Lens

Flow block in Amazon Connect: Set routing criteria

This topic defines the flow block for routing a contact in any channel to the appropriate queue. When using this flow block, note the following points:

- It sets routing criteria on a contact.
- Routing criteria can be set on contacts of any channel, such as Voice, Chat, and Task, to define how the contact should be routed within its queue. A routing criteria is a sequence of one or more routing steps.
- A routing step is a combination of one or more requirements that must be met in order for this contact to be routed to an agent. You can set an optional expiration duration for each routing step. For example, you could create a routing step with a requirement to only offer this contact to a specific agent based on user ID, for a certain expiration duration. As another example, you could create a non-expiring routing step with the requirements: **Language:English >= 4** AND **Technology:AWS Kinesis >= 2**.
- A requirement is a condition created using a predefined attribute name, it's value, comparison operator and proficiency level. For example, **Technology:AWS Kinesis >= 2**.
- The following flow types support this block:
  - Inbound flow
  - Customer queue flow
  - Transfer to Agent flow
  - Transfer to Queue flow

- The Set Routing Criteria block needs to be used with the Transfer To Queue block, as the latter will transfer the contact to the Amazon Connect queue and activate the routing criteria specified on the contact.
- Routing criteria set on the contact will not take effect if the contact is transferred into an agent queue. For more information, see Set up routing in Amazon Connect based on agent proficiencies.

Prerequisites for Setting Routing Criteria using Predefined Attributes

To set the routing criteria on a contact, you must first complete the following:

1. Create Create predefined attributes for routing contacts to agents.
2. Assign proficiencies to agents in your Amazon Connect instance using predefined attributes that were previously created

How routing criteria works

When a contact is transferred to a standard queue, Amazon Connect will activate the first step specified in the routing criteria of the contact. An agent is joined to the contact only when it meets the requirements specified in the active routing step of the contact. If no such agent is found till the expiration duration of the step, then Amazon Connect will move to the next step specified in the routing criteria until one of them is satisfied. When all steps have expired, the contact will be offered to the longest available agent who has the queue in their routing profile. Note that a routing step will never expire in case expiration duration is not specified on the routing step.

You can use the following items in a routing criteria:

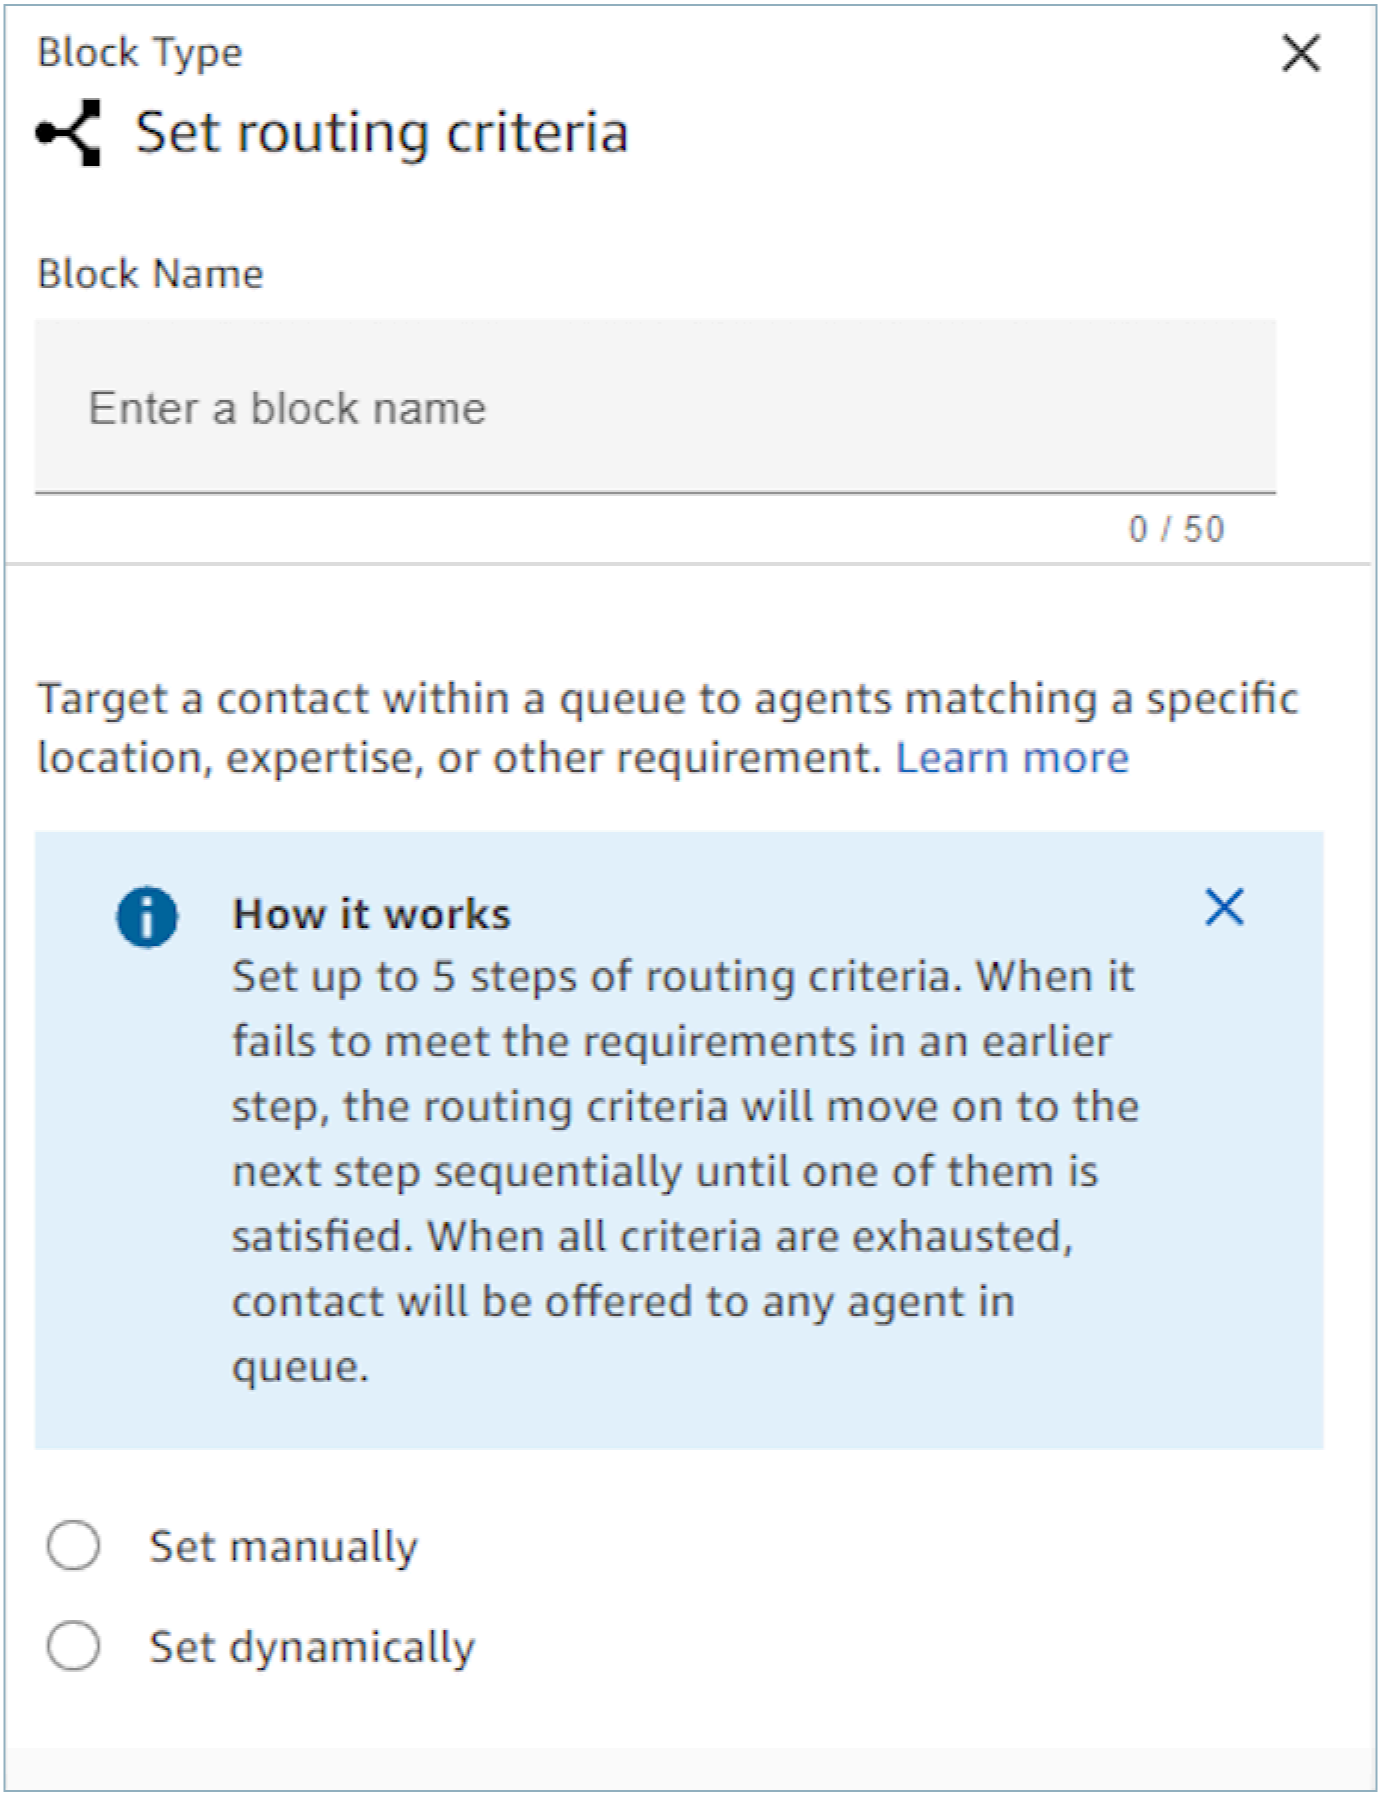
- Choose from the following:
  - One or more preferred agents, based on user ID or username.
  - Up to eight attributes using the AND condition.
  - Up to three OR conditions in a routing step. Each requirement separated by an OR can have up to eight attributes.
    - You can only use OR when setting attributes dynamically. For more information, see For more information, see Using the flow block.
  - NOT operator to exclude a proficiency by chosen levels. You can only use NOT when setting attributes dynamically. For more information, see Using the flow block.

In addition, attributes and routing criteria must have the following;

- Each attribute must have an associated proficiency level.
- Each proficiency level must use the “>=” comparison operator or a range of proficiency levels from 1 to 5.
- Each step of the criteria must have a timed expiration timer.
- The last step of the criteria can have a timed or non-expiring expiration timer.

Using the flow block

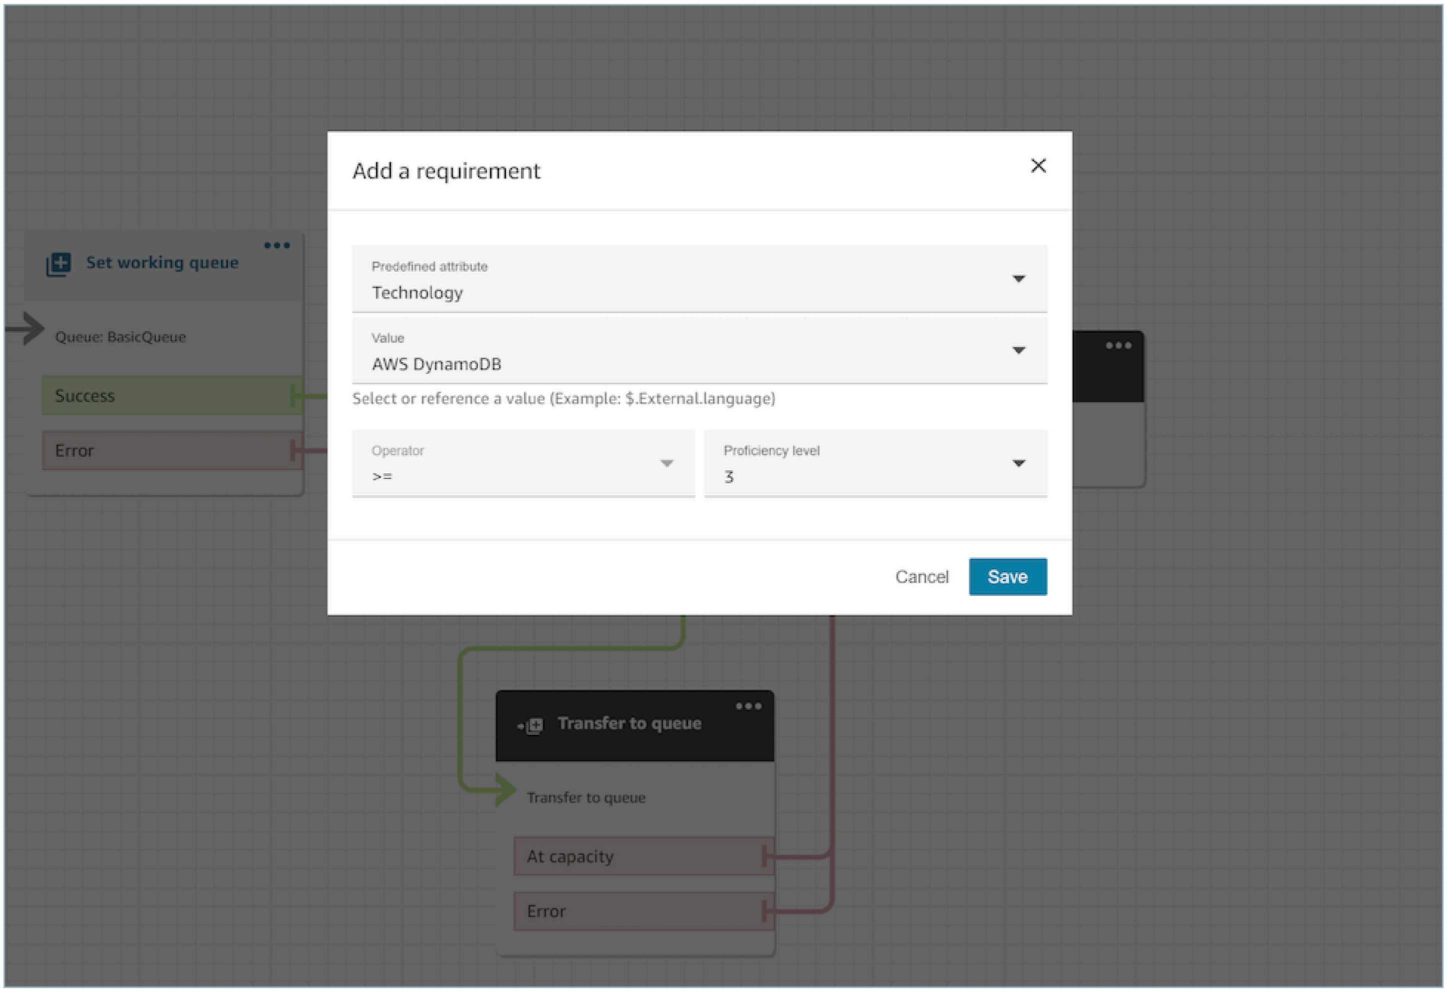
You can set the desired routing criteria either manually in the contact flow block UI or dynamically based on the output from the Invoke AWS Lambda Function block.



Block Type
Set routing criteria
Block Name
Enter a block name
0 / 50
Target a contact within a queue to agents matching a specific location, expertise, or other requirement. Learn more
How it works
Set up to 5 steps of routing criteria. When it fails to meet the requirements in an earlier step, the routing criteria will move on to the next step sequentially until one of them is satisfied. When all criteria are exhausted, contact will be offered to any agent in queue.
Set manually
Set dynamically

Set routing criteria manually

Using this option, you can set routing criteria on contacts as specified in the `Set Routing Criteria` block manually. See the example of a flow below to where the predefined attribute is added to a routing step manually by picking the attribute and value from a dropdown list.



As needed, you can configure predefined attribute value dynamically using JSONPath reference even in this option. For example, you can specify `` `$.External.language` `` JSONPath reference instead of hard coding a `AWS DynamoDB` value on the `` `Technology` `` requirement of all of the contacts. For more information on JSONPath reference, see List of available contact attributes in Amazon Connect and their JSONPath references.

Set routing criteria dynamically

You can set routing criteria on a contact dynamically based on the output from the **Invoke AWS Lambda function** block.

- In the **Invoke AWS Lambda function** block, configure the Lambda function to return the routing criteria in JSON format and set the response validation as JSON. For more information on using the **Invoke AWS Lambda function**, see the [Grant Amazon Connect access to your AWS Lambda functions] documentation.
- In the `Set Routing Criteria` block, choose **Set dynamically** option with the above Lambda attributes - **Namespace** as `External` and **Key** as specified in above Lambda response. For example, the key would be `MyRoutingCriteria` as it points to the routing criteria in the sample Lambda response in the following section.

Sample Lambda function for setting routing criteria

The following Lambda example uses `AndExpression` to return routing criteria:

```
export const handler = async(event) => {
  return {
   "MyRoutingCriteria": {
    "Steps": [
      {
        "Expression": {
          "AndExpression": [
            {
              "AttributeCondition": {
                "Name": "Language",
                "Value": "English",
                "ProficiencyLevel": 4,
                "ComparisonOperator": "NumberGreaterOrEqualTo"
              }
            },
            {
              "AttributeCondition": {
                "Name": "Technology",
                "Value": "AWS Kinesis",
                "ProficiencyLevel": 2,
                "ComparisonOperator": "NumberGreaterOrEqualTo"
              }
            }
          ]
        },
        "Expiry": {
          "DurationInSeconds": 30
        }
```

```
      },
      {
        "Expression": {
          "AttributeCondition": {
            "Name": "Language",
            "Value": "English",
            "ProficiencyLevel": 1,
            "ComparisonOperator": "NumberGreaterOrEqualTo"
          }
        }
      }
    ]
  }
}
};
```

The following Lambda example uses `OrExpression` to return routing criteria:

```
export const handler = async(event) => {
  return {
   "MyRoutingCriteria": {
    "Steps": [
      {
        "Expression": {
          "OrExpression": [
            {
              "AttributeCondition": {
                "Name": "Technology",
                "Value": "AWS Kinesis Firehose",
                "ProficiencyLevel": 2,
                "ComparisonOperator": "NumberGreaterOrEqualTo"
              }
            },
            {
              "AttributeCondition": {
                "Name": "Technology",
                "Value": "AWS Kinesis",
                "ProficiencyLevel": 2,
                "ComparisonOperator": "NumberGreaterOrEqualTo"
              }
            }
          ]
        },
```

```
        "Expiry": {
          "DurationInSeconds": 30
        }
      }
    ]
  }
}
};
```

The following Lambda example uses `NOTAttributeCondidtion` and a range of proficiency levels to return routing criteria:

```
export const handler = async(event) => {
  const response = {
    "MyRoutingCriteria": {
        "Steps": [
            {
                "Expression": {
                    "NotAttributeCondition": {
                        "Name" : "Language",
                        "Value" : "English",
                        "ComparisonOperator": "Range",
                        "Range" : {
                            "MinProficiencyLevel": 4.0,
                            "MaxProficiencyLevel": 5.0
                        }
                    }
                },
                "Expiry" : {
                    "DurationInSeconds": 30
                }
            }
        ]
    }
}
    return response;
};
```

What are the statuses of a routing step and why are they needed?

1. **Inactive:** When the routing criteria is activated the first step immediately becomes Inactive. The routing engine executes the criteria one step at a time as per the expiration timer.

   a. Every step starts as Inactive Until the previous step expires.

2. **Active:** When a step is actively being executed for a match the status is set to Active
3. **Expired:** When Amazon Connect does not find an agent during the duration of a step and the timer expires, the routing engine moves on to the next step. The previous step is considered Expired.
4. **Joined:** Whenever an agent is successfully matched with a contact for a particular step, the step status will be set as Joined
5. **Interrupted:** If a contact has been waiting for too long or an operations leader may decide to interrupt the flow and change the routing criteria. This can be done while a particular step is active, for example, a task has been waiting for 24 hours and a manager wants to change the criteria. The step status will then be set to Interrupted.
6. **Deactivated:** When a customer drops a call or a connection is dropped, routing will stop.

Use routing criteria to target a specific preferred agent

You can also use routing criteria to restrict a contact in a queue to a specific preferred agent or set of preferred agents, based on user ID instead of predefined attributes. For example, if you have identified that a specific customer recently contacted your contact center about the same topic, you might want to try and route that customer to the same agent who handled their issue last time. To do so, you can set a routing step to target that specific agent for a certain amount of time before the routing step expires.

FAQ

Can I use this feature together with Customer Profiles Last agent identifier to route a customer to the last agent who handled their issue?

Amazon Connect Customer Profiles provides seven out-of-the box default attributes based on contact records, including the Last agent identifier attribute, which identify the last agent the customer connected with. You can use this data to route new contacts from a given customer to the same agent who handled their contact previously. To do so, first use the Customer Profiles flow block to retrieve a customer profile using at least one search identifier, such as `Phone = $.CustomerEndpoint.Address`. For more information, see Properties: Get profile.

You can then use the **Set manually** option in the `Set routing criteria` Flow block UI to specify that each contact should be routed to `$.Customer.CalculatedAttributes._last_agent_id` (a JSONPath reference) instead of hard coding a specific user ID, and set an expiration timer for how long to restrict each contact to route to the last agent. For more information on JSONPath reference, see List of available contact attributes in Amazon Connect and their JSONPath references. For more information on the default attributes available through Amazon Connect Customer Profiles, see Default calculated attributes in Amazon Connect Customer Profiles.

If the preferred agent is not available, what happens?

If you have a routing step set targeting a specific preferred agent, the contact will be restricted to that agent until such time that the routing step expires. This is regardless of the following:

1. Agent is online or not.
2. Agent is online but busy with other contacts and cannot be routed an additional contact right now
3. Agent is online but in a custom nonproductive status
4. Agent was deleted from instance (their userID is still considered valid)

For example, imagine you have restricted a particular contact to target agent Jane Doe with expiry of 30 seconds, but Jane Doe is currently offline. The contact will nonetheless be restricted to Jane Doe for 30 seconds, after which the routing step will expire and contact can be offered to another available agent in queue.

What is the maximum number of agents can I target within a single preferred agent step?

You can target up to 10 agents.

Can I create a routing criteria that includes both routing steps based on preferred agent, and routing steps based on predefined attributes?

Yes. For example, you could create a two-step routing criteria, where step 1 targets the contact to a specific preferred agent by user ID based on the agent predicted as the best-fit agent by your custom matching learning model with a given expiry, and then step 2 targets the contact based on predefined attributes such requiring a minimum proficiency level in Spanish.

Scenarios

See these topics for scenarios that use this block:

- How to reference contact attributes in Amazon Connect

Flow block in Amazon Connect: Set Voice ID

This topic defines the flow block to enable audio streaming and set thresholds for voice authentication and fraud detection.

Description

- Enables audio streaming and sets thresholds for voice authentication and detection of fraudsters in a watchlist. For more information about this feature, see Voice ID.
- Sends audio to Amazon Connect Voice ID to verify the caller's identity and match against fraudsters in watch list, as soon as the call is connected to a flow.
- Use a Play prompt block before **Set Voice ID** to stream audio properly. You can edit it to include a simple message such as "Welcome."
- Use a Set contact attributes block after **Set Voice ID** to set the customer ID for the caller.

  The `CustomerId` may be a customer number from your CRM, for example. You can create a Lambda function to pull the unique customer ID of the caller from your CRM system. Voice ID uses this attribute as the `CustomerSpeakerId` for the caller.

  `CustomerId` can be an alphanumeric value. It supports only _ and - (underscore and hyphen) special characters. It does not need to be UUID. For more information, see `CustomerSpeakerId` in the Speaker data type.
- Use a Check Voice ID block after **Set Voice ID** to branch based on the results of the enrollment check, authentication, or fraud detection.
- For information about how to use **Set Voice ID** in a flow, along with Check Voice ID and Set contact attributes, see Step 2: Create a new Voice ID domain and encryption key in Get started enabling Voice ID in Amazon Connect.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	No - Error branch

Channel	Supported?
Task	No - Error branch
Email	No - Error branch

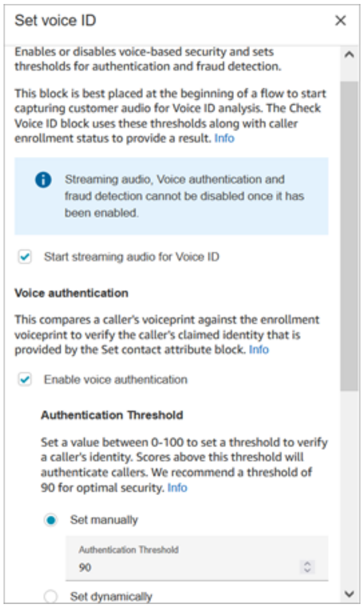
Flow types

You can use this block in the following flow types:

- Inbound flow
- Customer queue flow
- Customer whisper flow
- Outbound whisper flow
- Agent whisper flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

The following image shows the **Properties** page of the **Set Voice ID** block. It shows the **Voice authentication** section. In this example, the **Authentication Threshold** is set to 90. This is the recommended threshold.



Start streaming audio for Voice ID

When this option is selected, Amazon Connect begins streaming audio from the customer's channel to Voice ID.

You can add this block several places in a flow, but after **Start streaming audio** is selected, it cannot be disabled, even if later in the flow there are other **Set Voice ID** blocks that do not have it enabled.

Voice authentication

Authentication threshold: When Voice ID compares the voiceprint of the caller to the enrolled voiceprint of the claimed identity, it generates an authentication score between 0-100. This score indicates the confidence of a match. You can configure a threshold for the score which indicates whether the caller is authenticated. The default threshold of 90 provides high security for most cases.

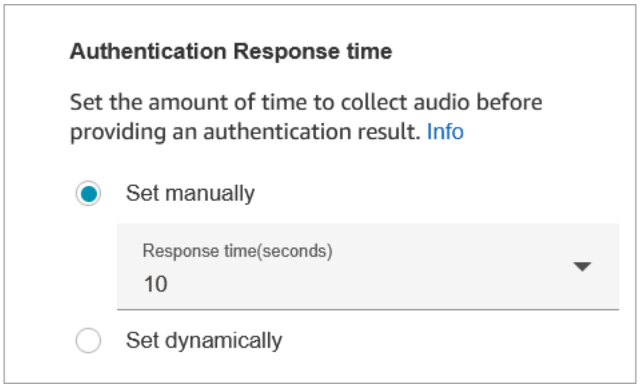
- If the authentication score is below the configured threshold, Voice ID treats the call as not authenticated.
- If the authentication score is above the configured threshold, Voice ID treats the call as authenticated.

For example, if the person is sick and calling from a mobile device in their car, the authentication score is going to be slightly lower than when the person is well and calling from a quiet room. If an imposter is calling, the authentication score is much lower.

Authentication response time

You can set the authentication response time between 5 and 10 seconds, which determines how quickly you want Voice ID authentication analysis to complete. Lowering it makes the response time faster at the tradeoff of lower accuracy. When you're using self-service IVR options where callers do not talk a lot, you may want to reduce this time. You can then increase the time if the call needs to be transferred to an agent.

The following image shows the Authentication Response time section of the block. The response time is set manually to 10 seconds.

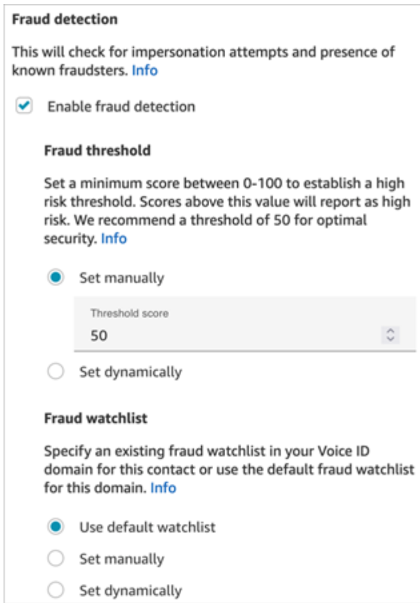


Choose **Set dynamically** to set the authentication threshold based on certain criteria. For example, you may want to raise the threshold based on the membership level of the customer, or the type of transaction or information they are calling about.

Fraud detection

The threshold you set for fraud detection is used to measure risk. Scores higher than the threshold are reported as higher risk. Scores lower than the threshold are reported as lower risk. Raising the threshold lowers false positive rates (makes result more certain), but raises false negative rates

Choose **Set dynamically** to set the fraud threshold based on certain criteria. For example, you may want to lower the threshold for high wealth customers, or the type of transaction or information they are calling about.



The watch list you select is used when evaluating the voice session. Choose **Use default watch list** to use your domain's default watch list. For **Set manually**, the watch list ID must be 22 alphanumeric characters.

Similarly for the watch list, choose **Set dynamically** to set the watch list based on criteria given. For example, you may want to use a stricter watch list given the type of transaction or information they are calling about.

Configuration tips

- For the **Authentication threshold**, we recommend that you start with the default of 90 and adjust until you find a good balance for your business.

  Every time you increase the value of the **Authentication threshold** beyond the default of 90, there's a tradeoff:

  - The higher the threshold, the greater the false reject rate (FRR), that is, the likelihood that an agent will need to verify the customer's identity.

    For example, if you set it too high, such as greater than 95, agents will need to verify every customer's identity.
  - The lower the threshold, the greater the false acceptance rate (FAR), that is, the likelihood that Voice ID will incorrectly accept an access attempt by an unauthorized caller.
- When Voice ID verifies that the voice belongs to the enrolled customer, it returns a status of **Authenticated**. Add a Check Voice ID block to you flow branch based on the returned status.

- For the **Fraud threshold**, we recommend that you start with the default of 50 and adjust until you find a good balance for your business.

  If the caller's score is above the threshold, it indicates there's a higher risk for fraud in that call.
- For the **Fraud watch list**, the format is validated when the flow is published.
  - If a watch list is dynamically set and the format is not valid, the contact is routed down the **Error** branch of the **Set Voice ID** block.
  - If a watch list ID is set manually or dynamically with a valid format but the watch list is not available in the Voice ID domain of the instance, the contact is routed down the **Error** branch of Check Voice ID block when the **Check Voice ID** block is used later in the flow.

Configured block

The following image shows an example of what this block looks like when it is configured. It has the following branches: **Success** and **Error**.

More information

See the following topic for more information about this block:

- Use real-time caller authentication with Voice ID in Amazon Connect
- Flow block in Amazon Connect: Check Voice ID
- Enroll callers in Voice ID in the Contact Control Panel (CCP)

Flow block in Amazon Connect: Set voice

This topic defines the flow block for setting the text-to-speech (TTS) language and voice to use for the contact flow.

Description

- Sets the text-to-speech (TTS) language and voice to use for the contact flow.
- The default voice is configured to Joanna (Conversational speaking style).
- You can choose **Override speaking style** to make it and other voices Neural Voices. Neural voices make automated conversations sound more lifelike by improving the pitch, inflection, intonation, and tempo.

  For a list of supported neural voices, see Neural Voices in the *Amazon Polly Developer Guide*.
- After this block is run, any TTS invocation resolves to the neural or standard voice selected.
- If this block is triggered during a chat conversation, the contact goes down the **Success** branch. It has no effect on the chat experience.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	No - Success branch
Task	No - Success branch

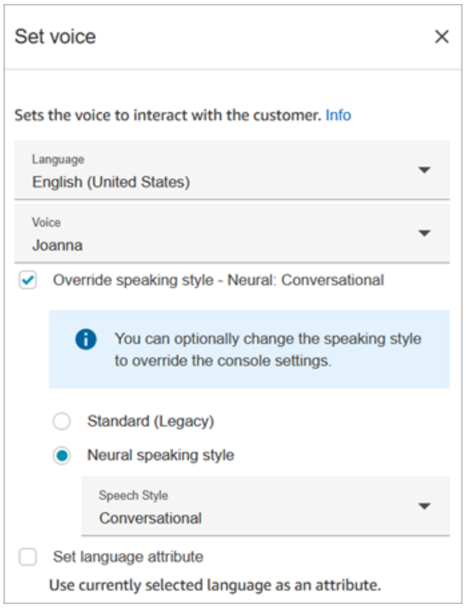
Flow types

You can use this block in the following flow types:

- All flows

Properties

The following image shows the **Properties** page of the **Set voice** block. It is configured for English, the voice is Joanna, and the speech style is Conversational.



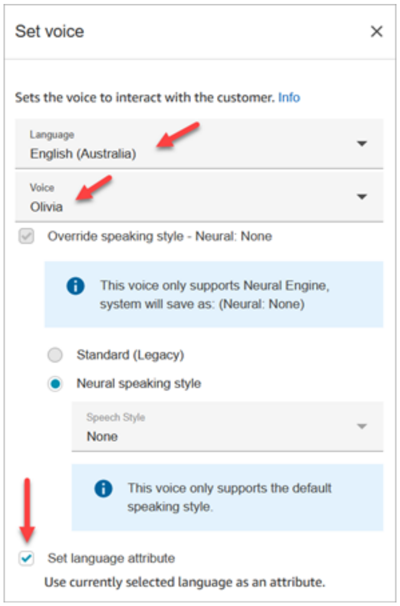
Tip

For voices that support only neural speaking styles but not standard, the **Override speaking style** is automatically selected. You do not have the option to clear it.

Use an Amazon Lex V2 bot with Amazon Connect

If you're using an Amazon Lex V2 bot, your language attribute in Amazon Connect must match the language model used to build your Lex bot. This is different than Amazon Lex (Classic).

- If you build an Amazon Lex V2 bot with a different language model—for example, en_AU, fr_FR, es_ES, and more—under **Voice**, choose a voice that corresponds to that language, and then must choose **Set language attribute**, as shown in the following image.
- If you're not using an en-US voice with an Amazon Lex V2 bot and don't choose **Set language attribute**, the Get customer input block results in an error.
- For bots with multiple languages (for example, en_AU and en_GB) choose **Set language attribute** for one of the languages, as shown in the following image.

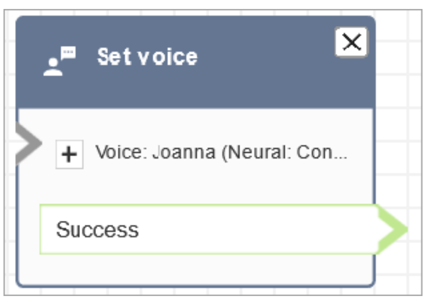


Configuration tips

- For the **Joanna** and **Matthew** neural voices, in American English (en-US), you can also specify a Newscaster speaking style.

Configured block

The following image shows an example of what this block looks like when it is configured. It has the following branch: **Success**.



Scenarios

See these topics for scenarios that use this block:

- Add text-to-speech to prompts in flow blocks in Amazon Polly

Flow block in Amazon Connect: Set whisper flow

This topic defines the flow block for a message, or whisper, that displays in chat or told in a call when a conversation begins. The whisper provides the participants with pertinent information, such as telling an agent a customer's name, or telling the customer that the call is being recorded for training purposes.

Description

A *whisper flow* is what a customer or agent experiences when they are joined in a voice or chat conversation. For example:

- An agent and customer are joined in a **chat**. An agent whisper might display text to the agent telling them the name of the customer, for example, which queue the customer was in, or let the agent know they're talking to a club member.
- An agent and customer are joined in a **call**. A customer whisper might tell the customer that the call is being recorded for training purposes, for example, or thank them for being a club member.
- An agent and customer are joined in a **chat**. Using a contact attribute, an agent whisper flow records which agent is being connected to the conversation. This attribute is then used in a disconnect flow to route the contact back to the same agent if the customer has a follow-up question after the agent disconnects.

A whisper flow has the following characteristics:

- It's a one-sided interaction: either the customer hears or sees it, or the agent does.

  To play a message that is audible to both the agent and the customer simultaneously, use a Play prompt block, not a **Set whisper flow** block.
- It can be used to create personalized and automated interactions.
- It runs when a customer and agent are being connected.

For voice conversations, the **Set whisper flow** block overrides the default agent whisper flow or the customer whisper flow. It does this by:

- Linking to a different whisper flow that you create.

–OR–

- Disabling the whisper flow from running. You may want to disable the default whisper flow so customers do not perceive any connection latency, for example, as part of an outbound campaign.

> **Important**
>
> Chat conversations do not include a default whisper. You need to include a **Set whisper flow** block for the default agent or customer whispers to play. For instructions, see Set the default whisper flow in Amazon Connect for a chat conversation.

How the Set whisper flow block works

- For inbound conversations (voice or chat), the **Set whisper flow** block specifies the whisper to be played to the customer or agent when they are joined.
- For outbound voice calls, it specifies the whisper to be played to customer.
- A whisper is one direction, which means only the agent or customer hears or sees it, depending on the type of whisper you selected. For example, if a customer whisper says "This call is being recorded," the agent does not hear it.
- A whisper flow is triggered after the agent accepts the contact (either auto-accept or manual accept). The agent whisper flow runs first, before the customer is taken out of queue. After this is completed, the customer is taken out of queue and the customer whisper flow runs. Both flows run to completion before the agent and customer can talk or chat with each other.
- If an agent disconnects while the agent whisper is running, the customer remains in queue in order to be re-routed to another agent.
- If a customer disconnects while the customer whisper is running, the contact ends.
- If an agent whisper flow or customer whisper flow includes a block that chat does not support, such as Start/Stop media streaming or Set voice, chat skips these blocks and triggers an error branch. However, it doesn't prevent the flow from progressing.
- Whisper flows don't appear in transcripts.
- Whispers can be a maximum of 2 minutes long. After that point, the contact or agent is disconnected.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

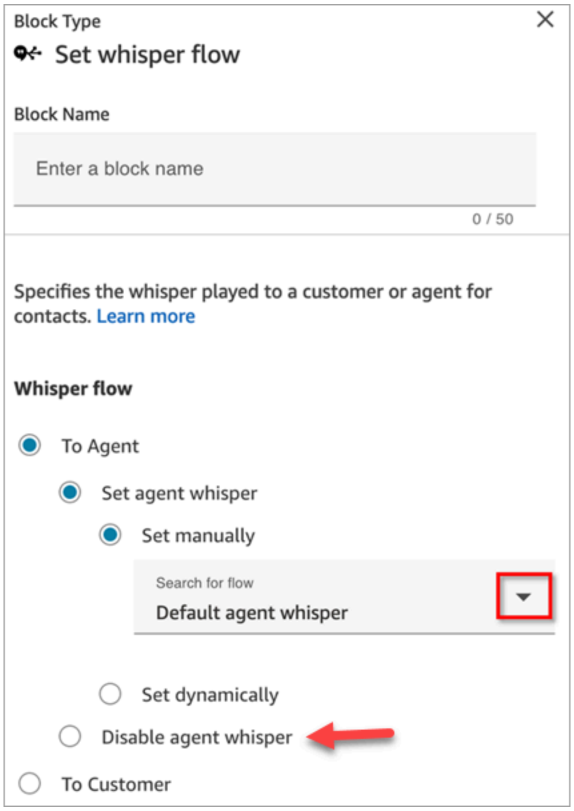
Flow types

You can use this block in the following flow types:

- Inbound flow
- Customer Queue flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

The following image shows the **Properties** page of the **Set whisper flow** block. It shows the whisper to the agent is set manually to **Default agent whisper**. Use the dropdown box to choose a different whisper flow.



If you choose to set a flow manually, in the **Search for flow** box, you can only select from flows that are type **Agent Whisper** or **Customer Whisper**.

For information about using attributes, see [Use Amazon Connect contact attributes](#).

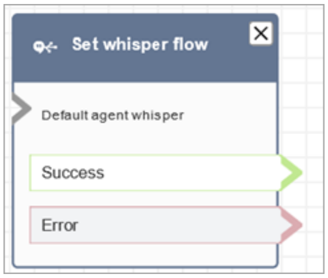
To disable a previously set agent or customer whisper, choose the **Disable agent whisper** or **Disable customer whisper** option.

Configuration tips

- In a single block, you can set either a customer whisper or an agent whisper, but not both. Instead, use multiple **Set whisper flow** blocks in your flow.
- A maximum of one agent whisper and one customer whisper can be played. If you use multiple **Set whisper flow** blocks, the most recently specified one for each type (agent and customer) is played.
- Make sure your whispers are able to complete within two minutes. Otherwise, calls will be disconnected before being established.
- If agents appear to be stuck in the "Connecting..." state before being forcefully disconnected from calls, make sure that your configured whisper flows meet the two minute maximum.

Configured block

The following image shows an example of what this block looks like when it is configured. It has the following branches: **Success** and **Error**.



Flow block in Amazon Connect: Set working queue

This topic defines the flow block for specifying the queue to transfer a contact when **Transfer to queue** is invoked.

Description

- This block specifies the queue to be used when **Transfer to queue** is invoked.
- A queue must be specified before invoking **Transfer to queue** except when used in a customer queue flow. It's also the default queue for checking attributes, such as staffing, queue status, and hours of operation.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

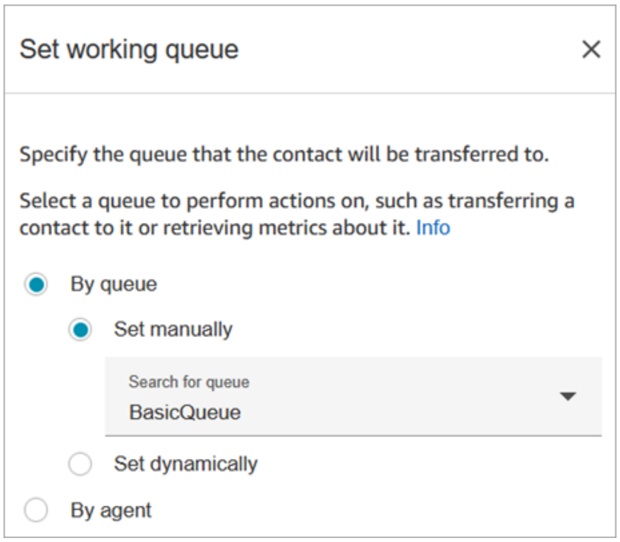
Flow types

You can use this block in the following flow types:

- Inbound flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

The following image shows the **Properties** page of the **Set working queue** block. It is set to the **BasicQueue**.

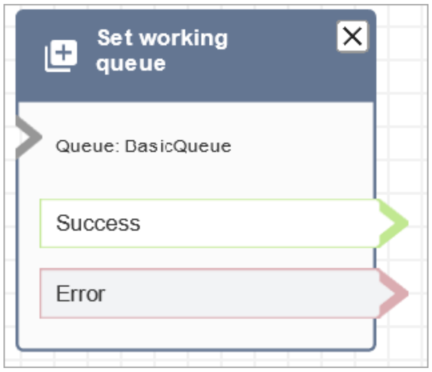


Note the following properties:

- **By queue > Set dynamically**. To set the queue dynamically, you must specify the Amazon Resource Name (ARN) for the queue rather than the queue name. To find the ARN for a queue, open the queue in the queue editor. The ARN is included as the last part of the URL displayed in the browser address bar after `/queue`. For example, `aaaaaaaa-bbbb-cccc-dddd-111111111111`.

Configured block

The following image shows an example of what this block looks like when it is configured. It has the following branches: **Success** and **Error**.



Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

- Sample queue customer flow in Amazon Connect
- Sample queue configurations flow in Amazon Connect

Scenarios

See these topics for scenarios that use this block:

- Set up agent-to-agent transfers in Amazon Connect
- Transfer contacts to a specific agent in Amazon Connect

Flow block in Amazon Connect: Show view

This topic defines the flow block to create step-by-step workflow guides to help agents provide consistent customer experiences, as well as guides to enable interactive customer experiences.

Description

- Use this flow block to:
  - Create step-by-step guides for agents who are using the Amazon Connect agent workspace. These guides are workflows that provide your agents with instructions to help them interact consistently with your customers.
  - Create forms to collect information from customers within a chat experience.

- When a contact is routed to a flow that includes a **Show view** block, a UI template called a View renders on the agent workspace or within the customer's chat UI.

Use cases for this block

This flow block is designed to guide agents through the steps to:

- Perform common tasks for customers, such as making reservations, managing payments, and submitting new orders.
- Send emails based on a template that notifies a customer about a submitted refund request. The email structure is always the same, but specific values can vary, such as order number, refund amount, and payment account. You can configure the Show view block for the agent to provide these types of information.
- Create new CRM entries in the existing agent workspace. Use contact attributes to pre-populate the form with relevant information, such as the customer's name and phone number.

And to guide customers through steps within a chat conversation to:

- Make payments by providing their credit card information.
- Provide PII information, such as a home address to update their profile.
- Receive account information by providing their customer account ID.

Contact types

Contact type	Supported?
Voice	Yes
Chat	Yes
Task	No
Email	Yes

Flow types

You can use this block in the following flow types:

Flow type	Supported?
Inbound flow	Yes
Customer hold flow	No
Customer whisper flow	No
Outbound whisper flow	No
Agent hold flow	No
Agent whisper flow	No
Transfer to agent flow	No
Transfer to queue flow	No

How to configure this block

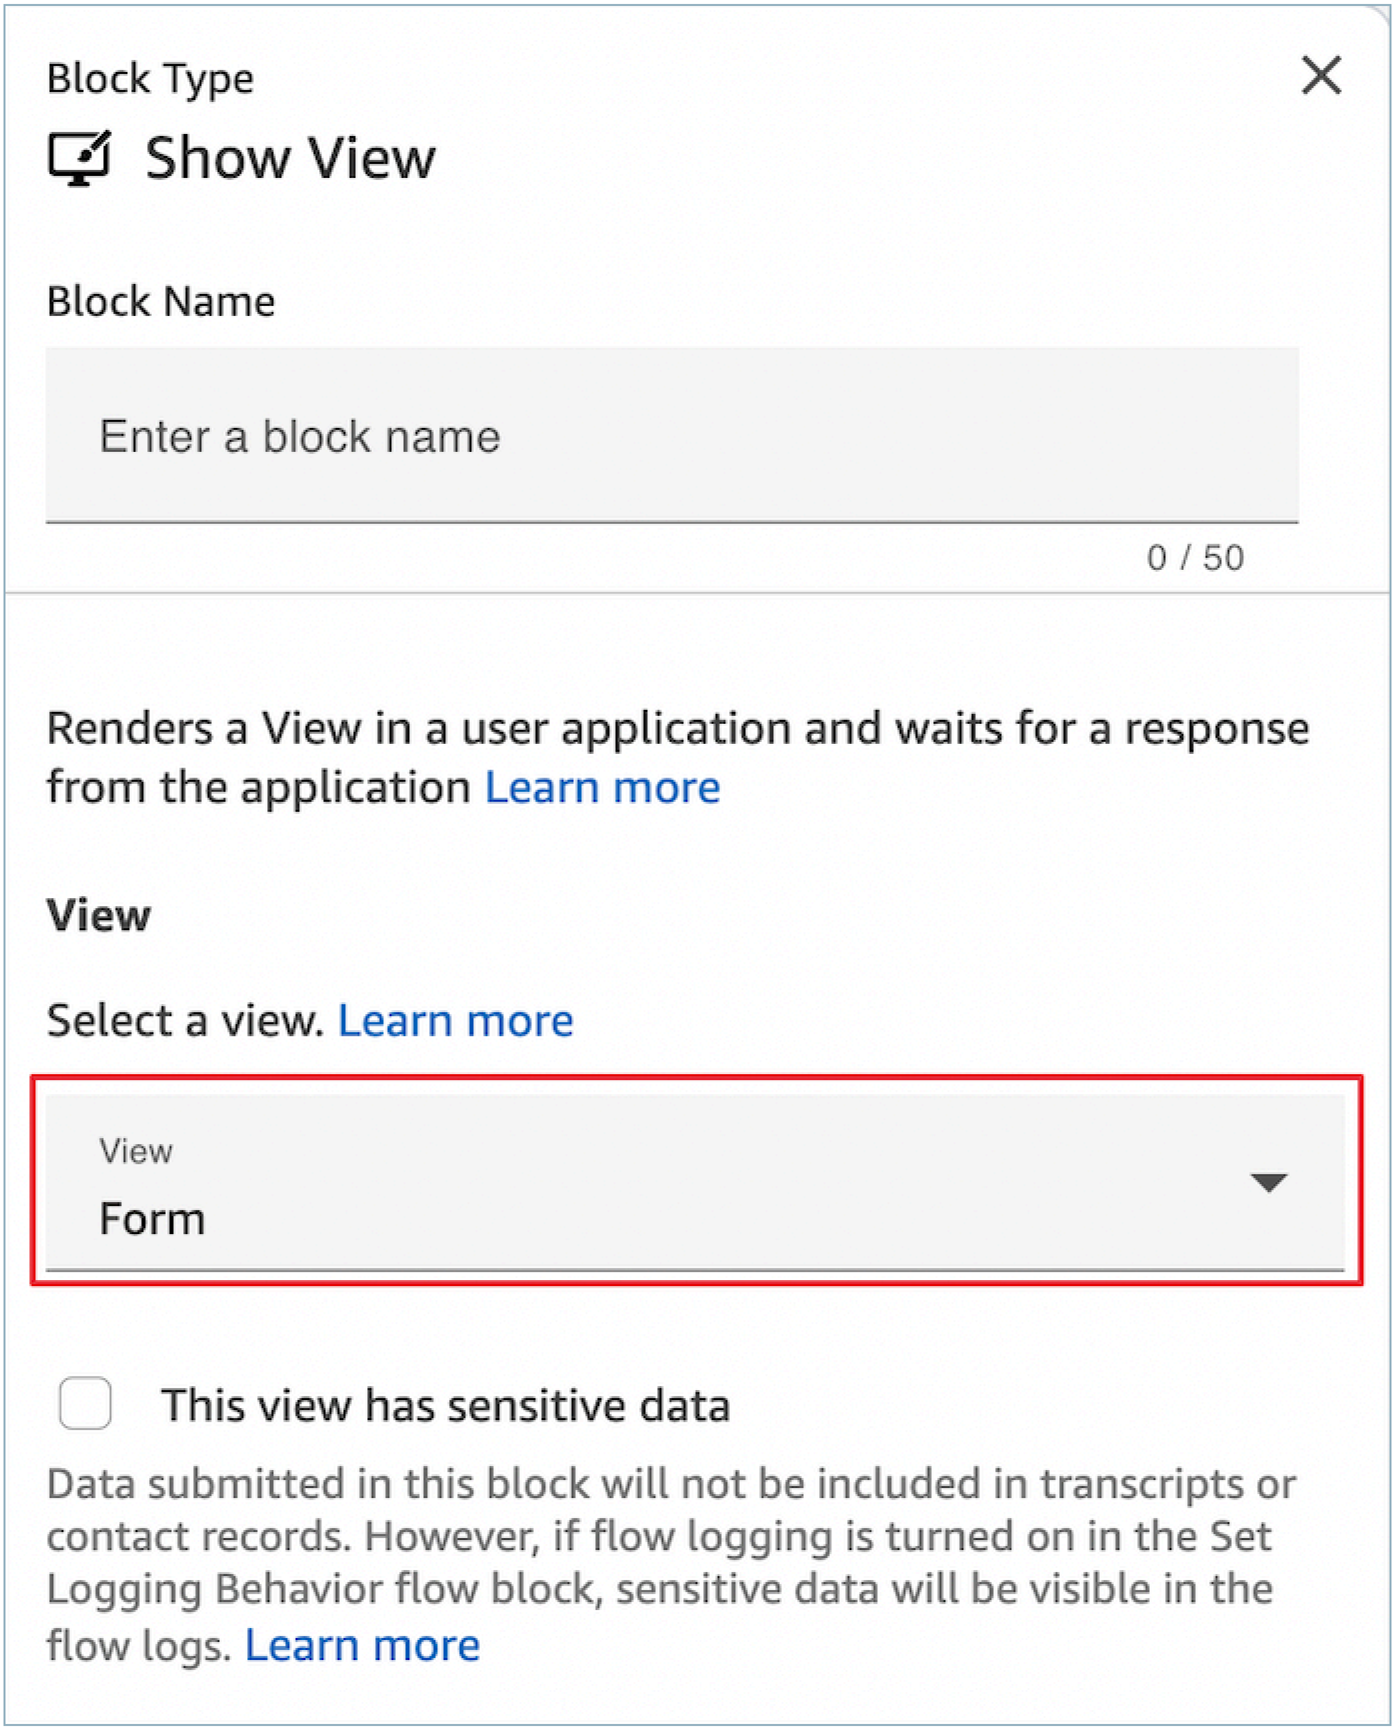
You can configure the **Show view** block by using the Amazon Connect admin website or by using the ShowView action in the Amazon Connect Flow language.

Configuration sections

- Choose the view resource
- How to use the Set manually option
- How to use the Set dynamically option
- How to use the Set JSON option
- This view has sensitive data
- Flow block branches
- Additional configuration tips
- Data generated by this block

Choose the view resource

Amazon Connect includes a set of views that you can add your agent's workspace. You specify the view in the **View** box, as shown in the following image:

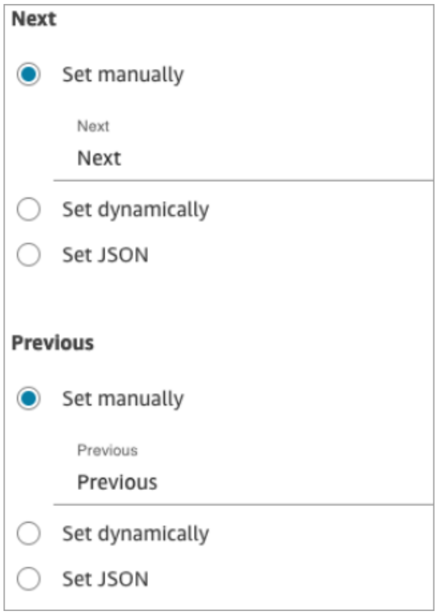


Block Type
Show View
Block Name
Enter a block name
0 / 50
Renders a View in a user application and waits for a response from the application Learn more
View
Select a view. Learn more
View
Form
This view has sensitive data
Data submitted in this block will not be included in transcripts or contact records. However, if flow logging is turned on in the Set Logging Behavior flow block, sensitive data will be visible in the flow logs. Learn more

Following is a brief description of these AWS managed views. For detailed information about each one, see [Set up AWS managed views for an agent's workspace in Amazon Connect](). Customer-managed views are also supported. For more information, see the [Customer-managed views]() documentation.

- **Detail view**: Display information to agents and provide them with a list of actions that they can take. A common use case of the Detail view is to surface a screen-pop to the agent at the start of a call.
- **List view**: Display information as a list of items with titles and descriptions. Items can act as links with actions attached. It also optionally supports the standard back navigation and persistent context header.
- **Form view**: Provide customers and agents with input fields to gather required data and submit data to backend systems. This view consists of multiple Sections with a predefined Section style with a header. The body consists of various input fields arranged in a column or a grid layout format.
- **Confirmation view**: A page to show customers and agents after a form has been submitted or an action has been completed. In this pre-built template you can provide a summary of what has happened, any next steps, and prompts. The Confirmation view supports a persistent attribute bar, an icon or image, headline, and sub-headline, along with a back to home navigation button.
- **Cards view**: Allows you to guide your customers and agents by presenting them with a list of topics to choose from when the contact is presented to the agent.

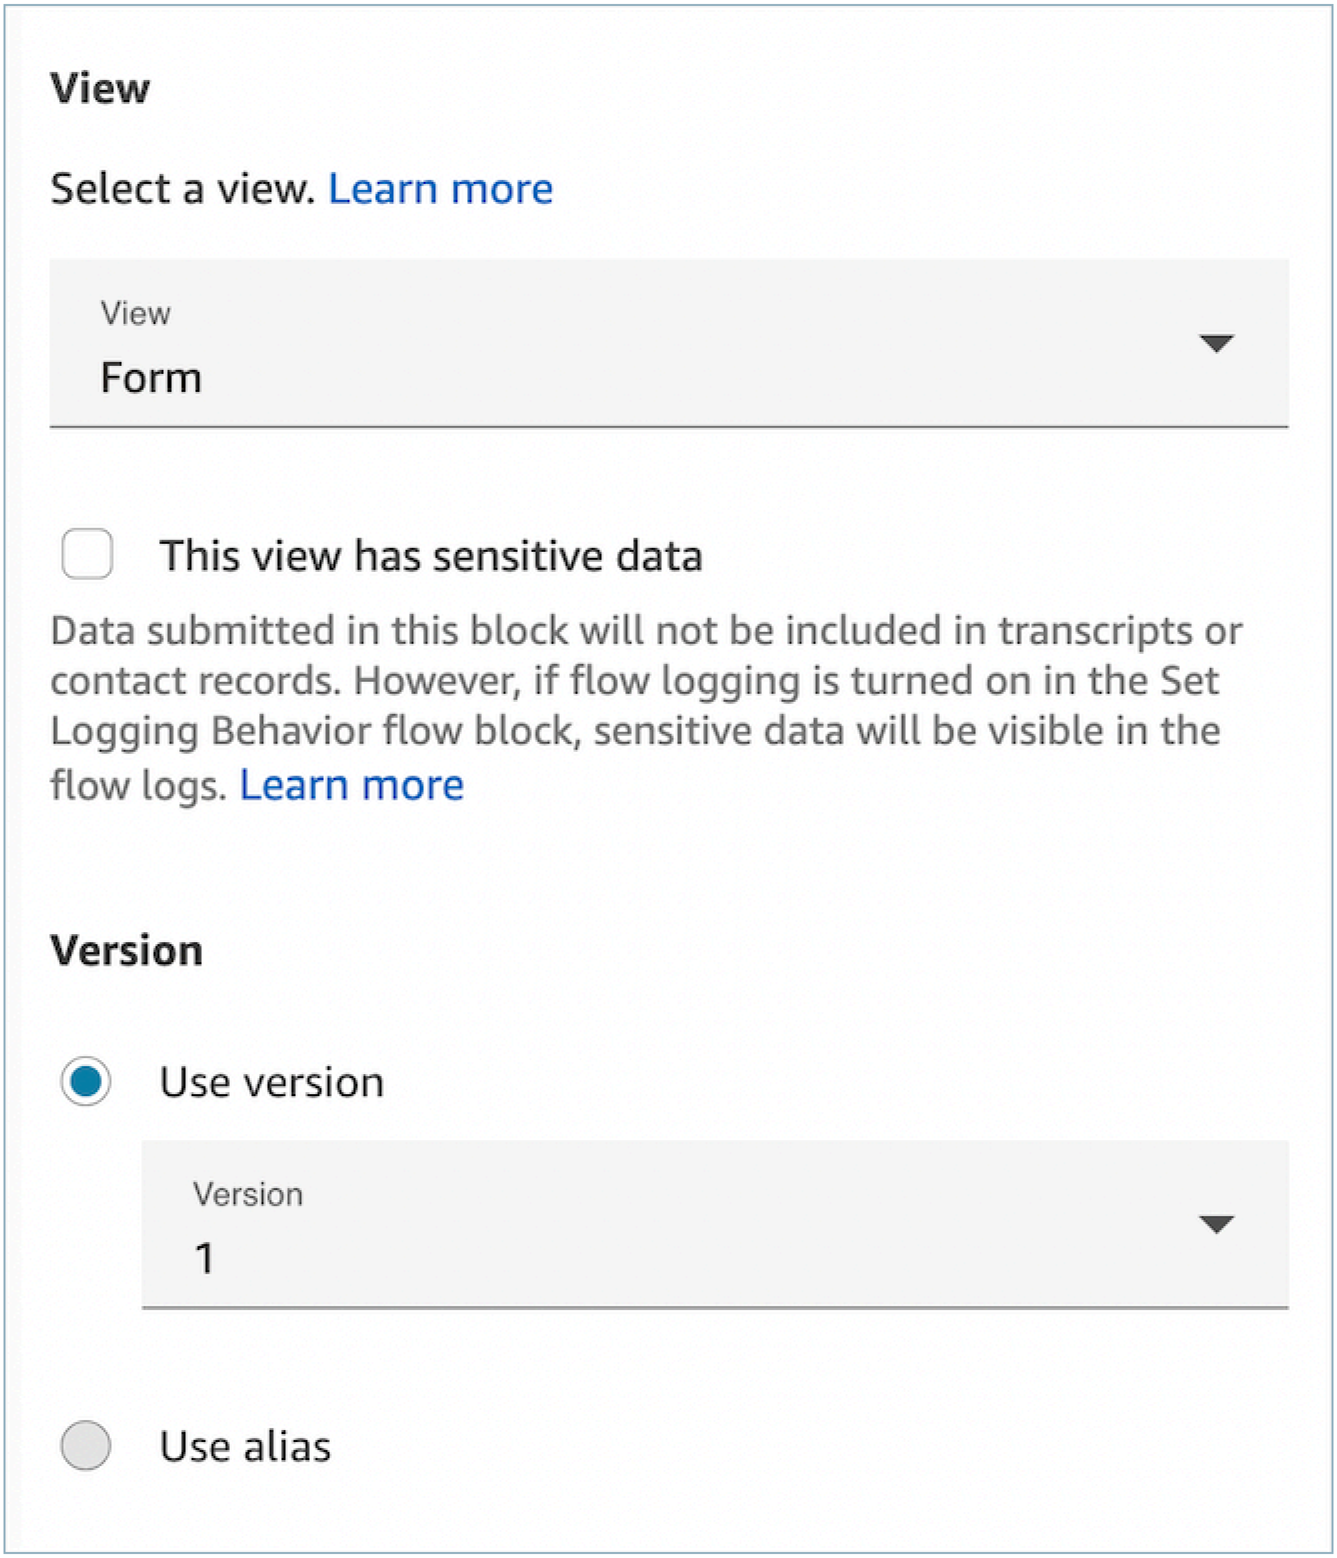
The properties of the **Show view** block are dynamically populated depending on which **View** resource you choose. For example, if you choose **Form**, you would configure **Next** and **Previous** actions, which are displayed. These are just a couple of the actions on the view.



The following sections explain how to configure the **Form** actions manually, dynamically, or by using the JSON option.

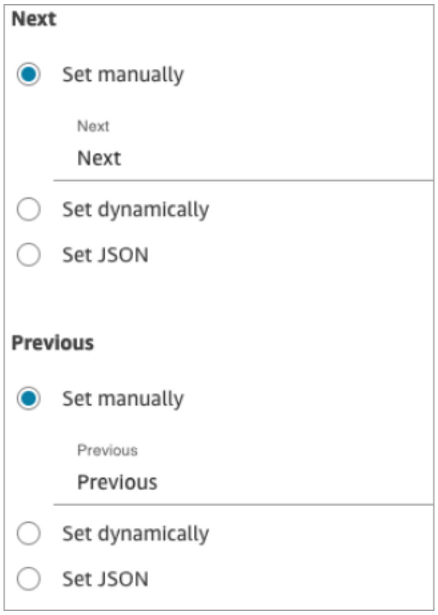
How to use the Set manually option

1. On the **Properties** page, in the **View** section, choose **Form** from the dropdown menu, and set **Use version** to 1, the default. The following image shows a **Properties** page configured with these options.



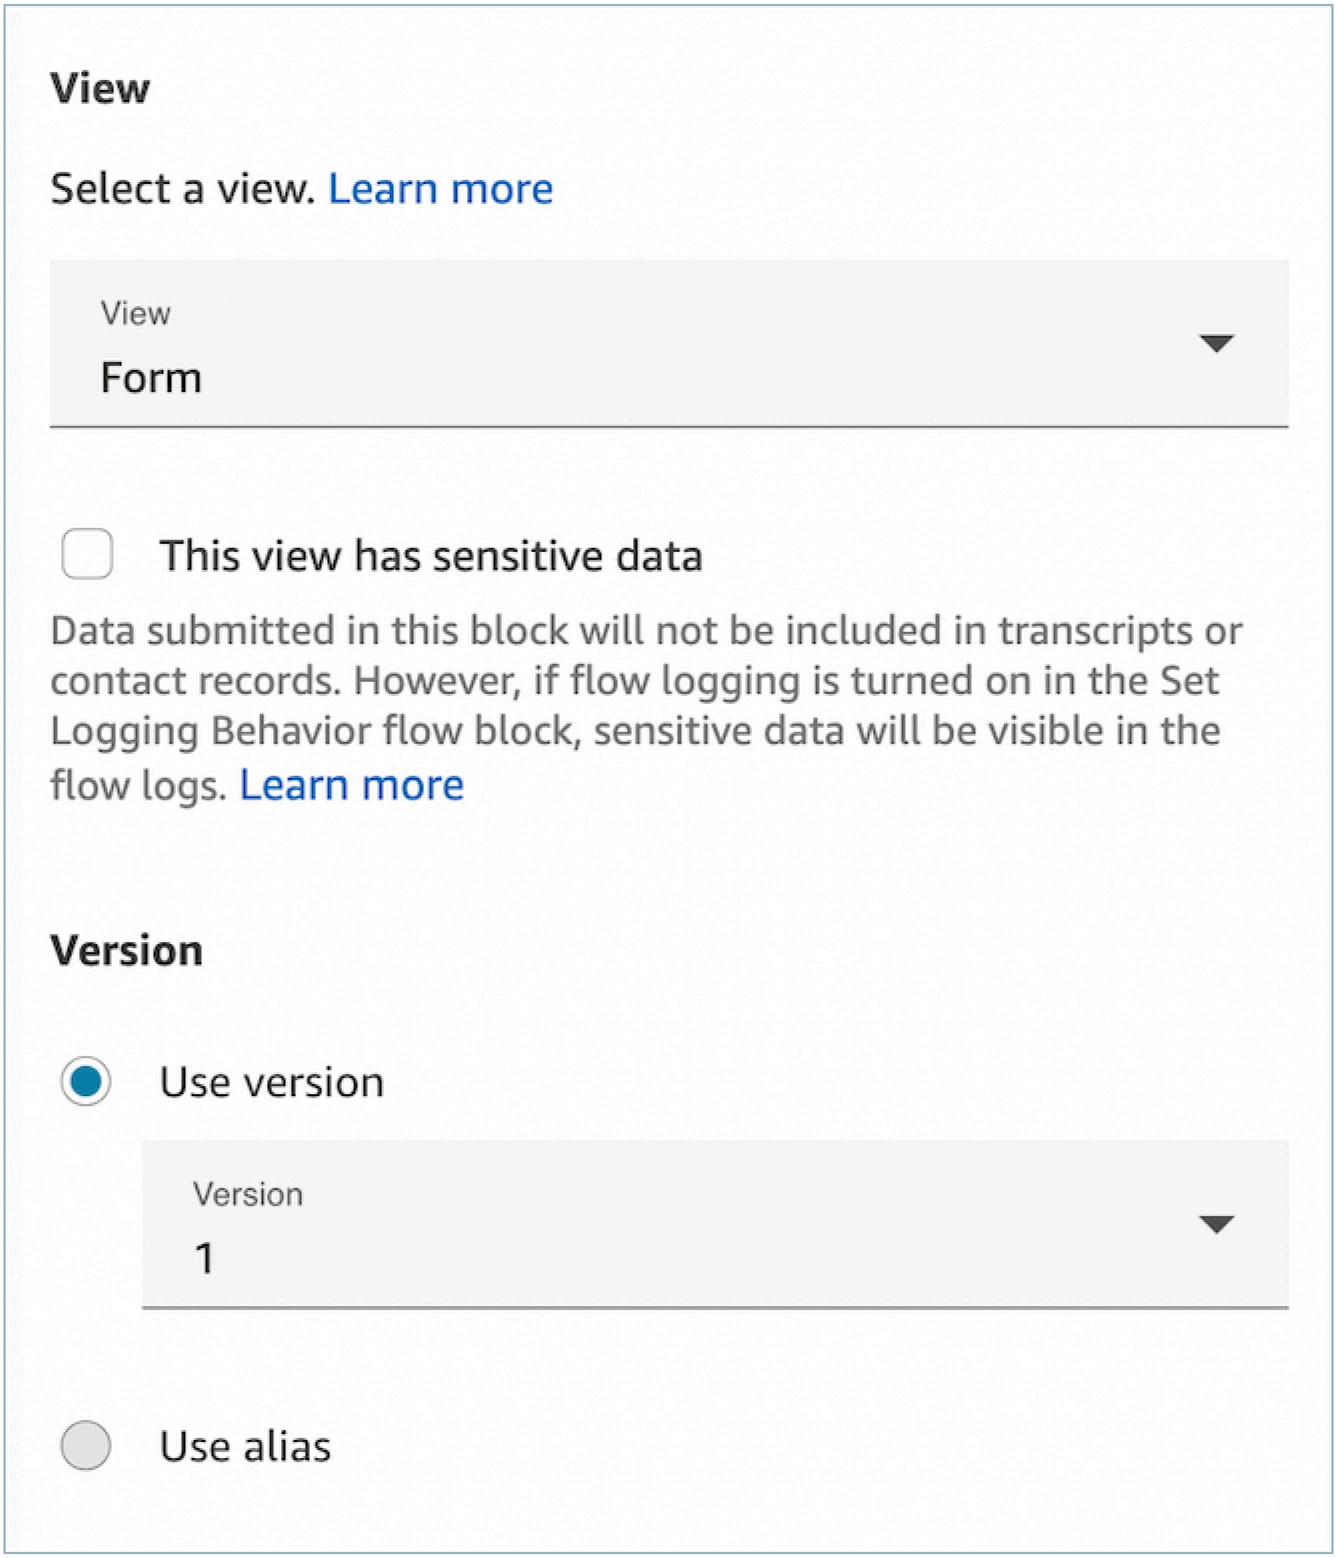
2. The **Properties** page displays a set of fields based on the Form view. Choose **Set manually** and enter text to be rendered on the View UI components. The following image shows the **Next** and **Previous** UI components. The display name of the components have been set manually

to **Next** and **Previous**. That's what will appear on the agent workspace when the step-by-step guide is rendered.



How to use the Set dynamically option

1. On the **Properties** page, in the **View** section, choose **Form** from the dropdown menu, and set **Use version** to 1, the default. The following image shows a **Properties** page configured with these options.



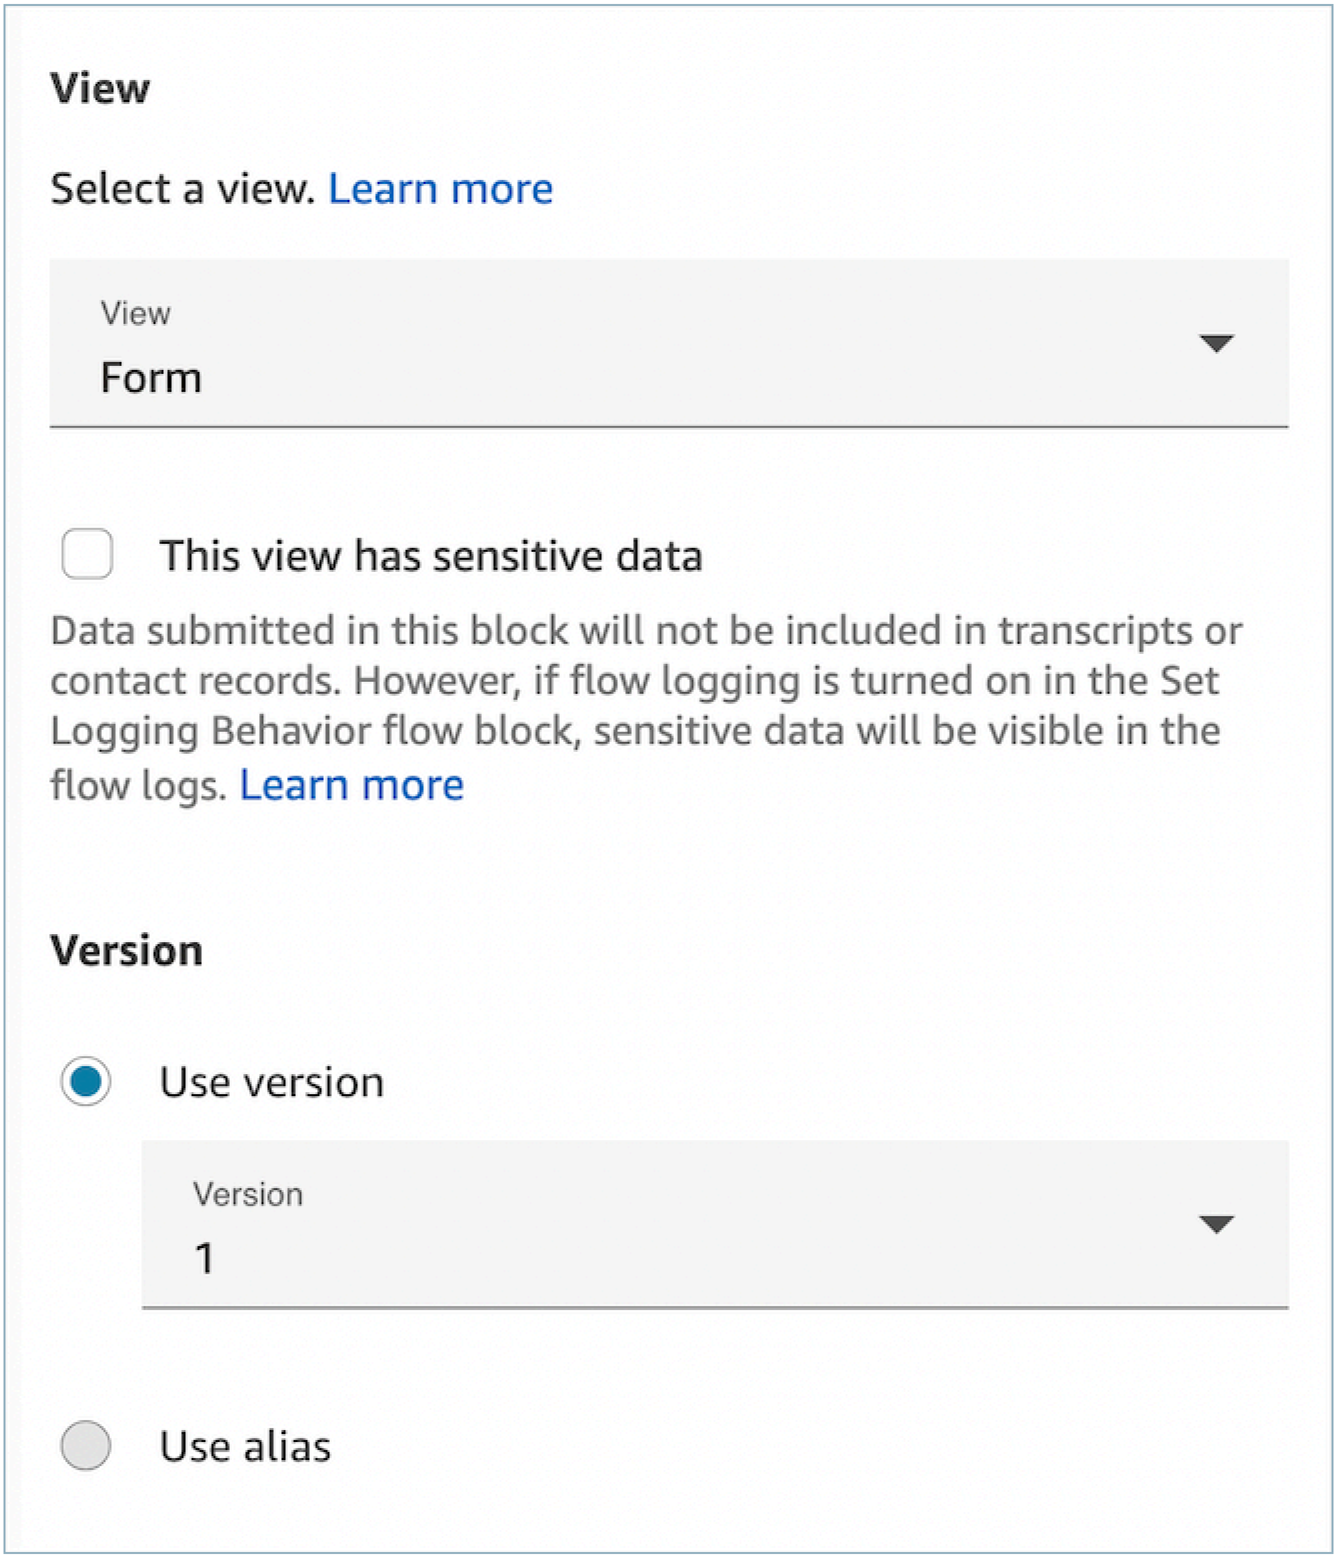
2. The **Properties** page displays a set of fields based on the Form view. Choose **Set dynamically**. In the **Namespace** dropdown menu, choose the contact attribute, and then choose the key.

The following image shows a **Heading** that will be rendered dynamically in the step-by-step guide to show the customer's last name.

How to use the Set JSON option

This section walks through an example of how to use the **Set JSON** option.

1. In the **View** section of the **Properties** page of the Show view block, choose **Form** from the dropdown menu and set **Version** to **1**, the default. These options are shown in the following image.



2. When you choose the **Form** view, the input schema of the view is displayed on the **Properties** page. The schema has the following sections where you can add information: **Sections**, **AttributeBar**, **Back**, **Cancel**, **Edit**, **ErrorText**, and more.

3. The following image shows the **AttributeBar** parameter, and the **Set using JSON** option. To view all of the JSON you pasted in, click the corner of the box and pull down.

> **Tip**
>
> Fix any errors if the JSON is invalid. The following image shows an example error message because there's an extra comma.

4. Choose **Save** and publish when you are ready.

The following code sample shows how this same configuration would be represented by the ShowView action in the Flow language:

```
{
      "Parameters": {
        "ViewResource": {
          "Id": "arn:aws:connect:us-west-2:aws:view/form:1"
        },
        "InvocationTimeLimitSeconds": "2",
        "ViewData": {
          "Sections": "Sections",
          "AttributeBar": [
            {
              "Label": "Example",
              "Value": "Attribute"
            },
            {
              "Label": "Example 2",
              "Value": "Attribute 2"
```

```
          },
          {
            "Label": "Example 3",
            "Value": "Case 123456",
            "LinkType": "case",
            "ResourceId": "123456",
            "Copyable":true
          },
          {

            ]
          }
        },
        {
          "NextAction": "7c5ef809-544e-4b5f-894f-52f214d8d412",
          "Condition": {
            "Operator": "Equals",
            "Operands": [
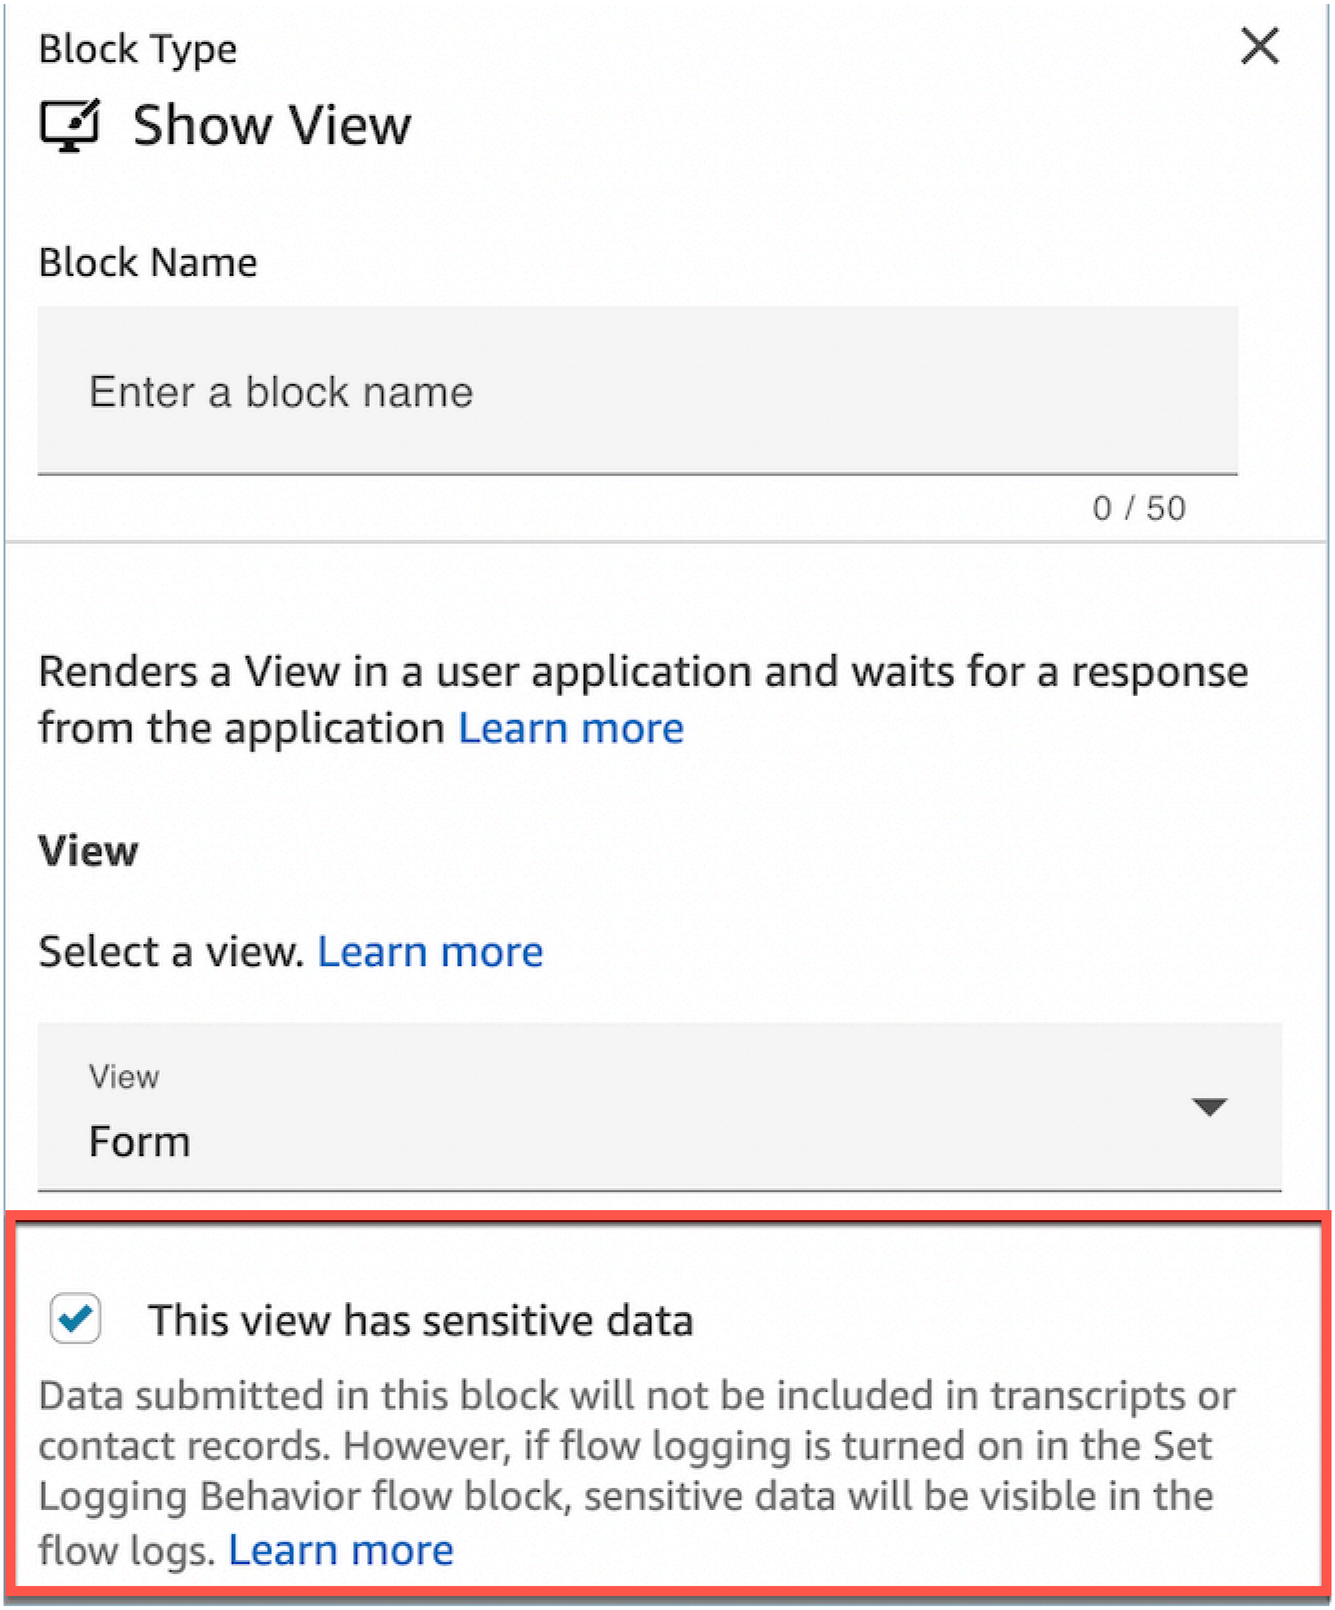
              "Step"
            ]
          }
        }
      ],
      "Errors": [
        {
          "NextAction": "b88349e3-3c54-4915-8ea0-818601cd2d03",
          "ErrorType": "NoMatchingCondition"
        },
        {
          "NextAction": "7c5ef809-544e-4b5f-894f-52f214d8d412",
          "ErrorType": "NoMatchingError"
        },
        {
          "NextAction": "b88349e3-3c54-4915-8ea0-818601cd2d03",
          "ErrorType": "TimeLimitExceeded"
        }
      ]
    }
  }
```

This view has sensitive data

It’s recommended that you enable **This view has sensitive data** when collecting credit card data, home addresses, or any other type of sensitive data from customers. By enabling this option, the data submitted by a customer will not be recorded in transcripts or contact records, or be visible to agents (by default). Remember to turn off logging if **Set Logging Behavior** is turned on in your contact flow, to ensure sensitive customer data is not included in your flow logs.

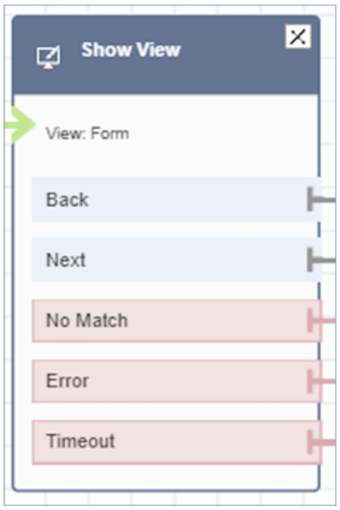


Tip

Build a Flow module with a Show view block that has **This view has sensitive data** enabled, a Lambda function, and prompts to create a re-usable payment experience module that can be placed in an existing inbound contact flow.

Flow block branches

The following image shows an example of a configured **Show view** block. This block supports conditional branches—that is, the branches depend on which view is selected. It also supports **Error** and **Timeout** branches.



- Conditional branches: These branches are based on which view is selected on the **Show view** block. The previous image shows the block is configured for the **Form** view, and the following actions: **Back**, **Next**, and **No Match**.
  - For this particular configuration, at runtime, the chat contact is routed down the **Back** or **Next** branches depending on what the agent clicks on the view. **No match** is only possible if the user has an action component with a custom Action value.
- **Error**: Failure to run (that is, failure to render the view on agent workspace or to capture the view output action) results in taking the **Error** branch.
- **Timeout**: Specifies how long this step in the step-by-step guide should take the agent to complete. If it takes longer than Timeout for agent to complete the step (for example, the agent didn't provide required information in the specified amount of time) then that step takes the Timeout branch.

When a step times out, the step-by-step guide can follow logic defined in the flow to determine next step. For example, the next step could be to retry asking for information, or stop guide experience.

The customer is connected to the agent at this point, so there is no change in the customer's experience because of Timeout.

Additional configuration tips

Build a Flow Module with this logging setting, this block, and Lambda to create a re-usable payment experience module that keeps logging off and can be placed in any existing inbound flow.

Assign the following security profile permission to agents so they can use the step-by-step guides:

- **Agent Applications - Custom views - All**: This permission enables agents to see step-by-step guides in their agent workspace.

Assign the following security profile permission to managers and business analysts so they can create the step-by-step guides:

- **Channels and flows - Views**: This permission enables managers to create step-by-step guides.

For information about how to add more permissions to an existing security profile, see [Update security profiles in Amazon Connect](#).

Data generated by this block

At runtime, the **Show view** block generates data that is the output when the View resource runs. Views generate two main pieces of data:

- `Action` taken on the rendered View-UI (on agent workspace) and the `ViewResultData` which is the `Output` data.

  When using a **Show view** block, **Action** represents a branch and set to `$.Views.Action` contact attribute under Views namespace.
- `Output` data is set to `$.Views.ViewResultData` contact attribute under Views namespace.

The values of `Action` and the `Output` data are determined by which the component(s) the agent interacted with during their use of the view resource.

How to use this data in different parts of flow

- When the block receives a response back from the client application, to reference the output data in flows use `` `$.Views.Action `` and `$.Views.ViewResultData`.
- When using a view with the **Show view** block, `Action` represents a branch that is captured in the contact attribute under the Views namespace as `$.Views.Action`, and View Output data is set to the `$.Views.ViewResultData` contact attribute.
- You can refer to the data generated by the **Show view** block by using the JSON path in contact attributes (you can specify contact attributes in the Set manually or Set JSON options) or by using the attribute selector dropdown when you choose **Set dynamically**.

Error scenarios

> **Note**
>
> When the `ShowView` block takes an error branch (no match, timeout, or error), you might want to route your flow back to a previous point in the flow. If you create a loop in the flow like this, the contact flow can execute endlessly until the chat contact times out. We recommend using the `Loop` contact flow block to limit the number of retries for a particular `ShowView` block.

A contact is routed down the **Error** branch in the following situations:

- Amazon Connect is unable to capture the user action on a View UI component in the agent workspace. This might be due to an intermittent network issue or an issue on the media-service side.

Flow log entry

Amazon Connect flow logs provide you with real-time details about events in your flow as customers interact with it. For more information, see [Track events in your Amazon Connect flow logs as customers interact with them](#).

Following sample ShowView input (ingress log)

```
{
  "ContactId": "string",
  "ContactFlowId": "string",
  "ContactFlowName": "string",
  "ContactFlowModuleType": "ShowView",
  "Timestamp": "2023-06-06T16:08:26.945Z",

}
```

Sample flows

You can download a sample flow from Step 2 in the following blog: Getting started with step-by-step guides. We recommend performing the steps in the blog to learn how to create flows that are configured with AWS-managed Views and how to run these flows for inbound media contacts.

More resources

See the following topics to learn more about step-by-step guides and Views.

- Step-by-step Guides to set up your Amazon Connect agent workspace
- Explore how to implement sensitive data collection in Amazon Connect Chat.
- For step-by-step instructions about how to set up a customer-managed Views, see Customer-managed Views.
- For setting up a plug-and-play step-by-step guide experience in your instance, see Getting started with step-by-step guides.
- AWS-managed Views - Common Configuration
- Views - UI Components
- View actions in the *Amazon Connect API Reference*.

Flow block in Amazon Connect: Start media streaming

This topic defines the flow block for capturing what the customer hears and says during a contact. You can then analyze this information for training or determining customer sentiment.

Description

Captures what the customer hears and says during a contact. You can then perform analysis on the audio streams to:

- Determine customer sentiment.
- Use the audio for training purposes.
- Identify and flag abusive callers.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	No - Error branch
Task	No - Error branch
Email	No - Error branch

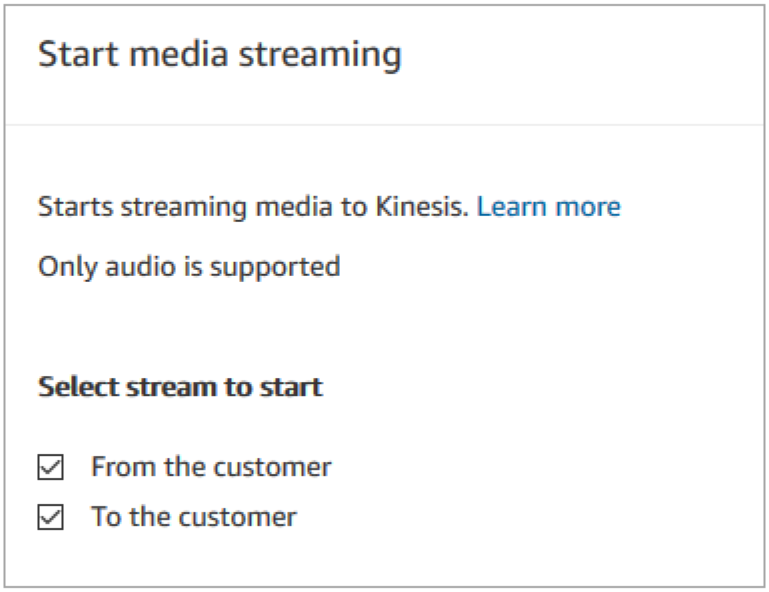
Flow types

You can use this block in the following flow types:

- Inbound flow
- Customer Queue flow
- Customer Whisper flow
- Outbound Whisper flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

The following image shows the **Properties** page of the **Start media streaming** block. It has two options: start the stream from the customer or to the customer.

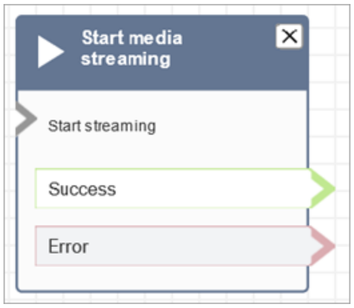


Configuration tips

- You must enable live media streaming in your instance to successfully capture customer audio. For instructions, see Set up live media streaming of customer audio in Amazon Connect.
- Customer audio is captured until a **Stop media streaming** block is invoked, even if the contact is passed to another flow.
- You must use a **Stop media streaming** block to stop media streaming.
- If this block is triggered during a chat conversation, the contact is routed down the **Error** branch.

Configured block

The following image shows an example of what this block looks like when it is configured. It has the following branches: **Success** and **Error**.



Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

Example flow for testing live media streaming in Amazon Connect

Flow block in Amazon Connect: Stop media streaming

This topic defines the flow block to stop capturing customer audio.

Description

- Stops capturing customer audio after it is started with a **Start media streaming** block.
- You must use a **Stop media streaming** block to stop media streaming.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	No - Error branch
Task	No - Error branch
Email	No - Error branch

Flow types

You can use this block in the following flow types:

- Inbound flow
- Customer Queue flow
- Customer Whisper flow
- Outbound Whisper flow
- Agent Whisper flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

This block doesn't have any properties.

Configuration tips

- You must enable live media streaming in your instance to successfully capture customer audio. For instructions, see Set up live media streaming of customer audio in Amazon Connect.
- Customer audio is captured until a **Stop media streaming** block is invoked, even if the contact is passed to another flow.
- If this block is triggered during a chat conversation, the contact is routed down the **Error** branch.

Configured block

The following image shows an example of what this block looks like when it is configured. It has the following branches: **Success** and **Error**.

Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

Example flow for testing live media streaming in Amazon Connect

Flow block in Amazon Connect: Store customer input

This topic defines the flow block to store input as a contact attribute and then encrypting it.

Description

This block is similar to **Get customer input**, but this one stores the input as a contact attribute (in the Stored customer input system attribute) and allows you to encrypt it. This way, you can encrypt sensitive input such as credit card numbers. This block:

- Plays a prompt to get a response from the customer. For example, "Please enter your credit card number" or "Please enter the phone number we should use to call you back."
- Plays an interruptible audio prompt or play text-to-speech for a customer to respond to.
- Stores numerical input as in the Stored customer input system attribute.
- Allows you to specify a custom terminating keypress.
- If during a call the customer doesn't enter any input, the contact is routed down the **Success branch** branch with a value of Timeout. Add a **Check contact attributes** block to check for timeouts.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	No - Error branch
Task	No - Error branch

Channel	Supported?
Email	No - Error branch

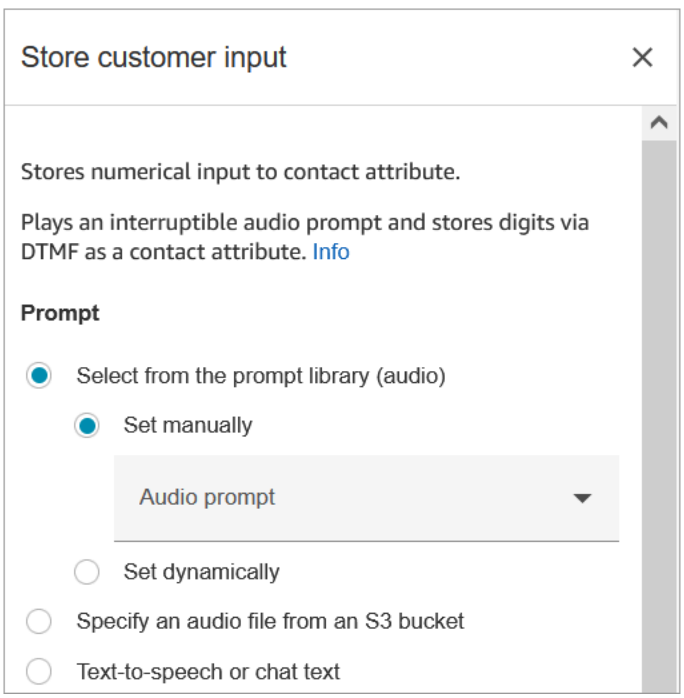
Flow types

You can use this block in the following flow types:

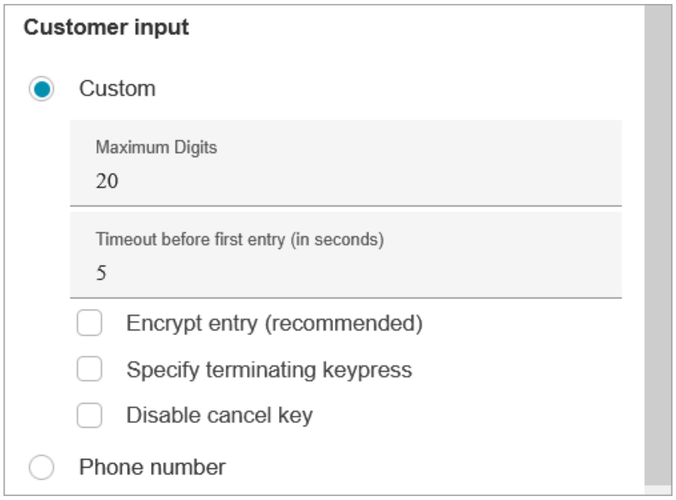
- Inbound flow
- Customer Queue flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

The following image shows the **Properties** page of the **Store customer input** block. It shows the **Prompt** section configured to play the **Audio prompt**.



The following image shows the **Customer input** section of the page. It is configured to allow up to 20 digits. It is set to timeout after 5 seconds of no input.



Note the following properties:

- For information about choosing a prompt from the Amazon Connect library or an S3 bucket, see the Play prompt block.
- **Maximum Digits**: Define the maximum number of digits that a customer can enter.
- **Timeout before first entry**: Specify how long to wait for a customer to start entering their reply by voice or DTMF. For example, you might enter 20 seconds, to give the customer time to get their credit card.

  After the contact starts entering digits, Amazon Connect waits 5 seconds for each digit, by default. You cannot change this default setting.
- **Encrypt entry**: Encrypt the customer's entry, such as their credit card information.
- **Specify terminating keypress**: Define a custom terminating keypress that is used when your contacts complete their DTMF inputs. The terminating keypress can be up to five digits long, with #, * and 0-9 characters, instead of just #.

  > **Note**
  >
  > To use a star (*) as part of the terminating keypress, you must also choose **Disable cancel key**.

- **Disable cancel key**: By default, when a customer enters * as input, it deletes all of the DTMF input that came before it. However, if you choose **Disable cancel key**, Amazon Connect treats the * as any other key.

If you send the DMTF input to an Invoke AWS Lambda function block, the **Disable cancel key** property affects the input, as follows:

- When **Disable cancel key** is selected, all the characters entered—including any *—are sent to the **Invoke Lambda function** block.
- When **Disable cancel key** is not selected, only the * is sent to the **Invoke Lambda function** block.

For example, let's say you chose **Disable cancel key**, and a customer entered *1#2#3*4###*, where *##* is the terminating keypress. The **Invoke Lambda function** block then receives the entire *1#2#3*4#* as input. You could program the Lambda function to ignore the character before the * character. So, the customer input would be interpreted as *1#2#4#*.

- **Phone number**: This option is useful for queued callback scenarios.
  - **Local format**: If all of your customers all calling from the same country that your instance is in, choose that country from the dropdown list. Amazon Connect then auto-populates the country code for customers so that they don't have to enter it.
  - **International format**: If you have customers calling from different countries, choose **International format**. Amazon Connect then requires customers to enter their country code.

Problems with DTMF input?

Let's say you have the following scenario with two contacts flows, each one capturing DTMF input from customers:

1. One flow uses the **Get customer input** block to request DTMF input from customers.
2. After the DTMF input is entered, it uses the **Transfer to flow** block to move the contact to the next contact flow.
3. In the next flow, there's a **Store customer input** block to get more DTMF input from the customer.

There's setup time between the first and second flows. This means if the customer enters DTMF input very quickly for the second flow, some of the DTMF digits might be dropped.

For example, the customer needs to press 5, then wait for a prompt from the second flow, then type 123. In this case, 123 is captured without problem. However, if they don't wait for the prompt and enter 5123 very quickly, the **Store customer input** block may capture only 23 or 3.

To guarantee the **Store customer input** block in second contact flow captures all of the digits, the customer needs to wait for the prompt to be played, and then enter their type DTMF input.

Configured block

The following image shows an example of what this block looks like when it is configured. It has the following branches: **Success**, **Error**, and **Invalid number**.

1. **Invalid number**: What to do if the customer enters an invalid number.

Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

- Sample secure customer data entry input in a call with a contact center agent
- Sample secure customer data entry input in a call with no contact center agent
- Sample queue configurations flow in Amazon Connect
- Sample queued callback flow in Amazon Connect

Flow block in Amazon Connect: Transfer to agent (beta)

Description

- Ends the current flow and transfers the customer to an agent.

> **Note**
>
> If the agent is already with someone else, the contact is disconnected.
> If the agent is in After Contact Work, they are automatically removed from ACW at the time of transfer.

- The **Transfer to Agent** block is a beta feature and works only for voice interactions.
- We recommend using the Set working queue block for agent-to-agent transfers instead of using this block. The **Set working queue** block supports omnichannel transfers such as voice and chat. For instructions, see Set up agent-to-agent transfers in Amazon Connect.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	No - Error branch
Task	No - Error branch
Email	No - Error branch

To transfer chats and tasks to agents, use the Set working queue block. Because Set working queue works for all channels, we recommend using it for voice calls too, instead of using **Transfer to agents (beta)**. For instructions, see Set up agent-to-agent transfers in Amazon Connect.

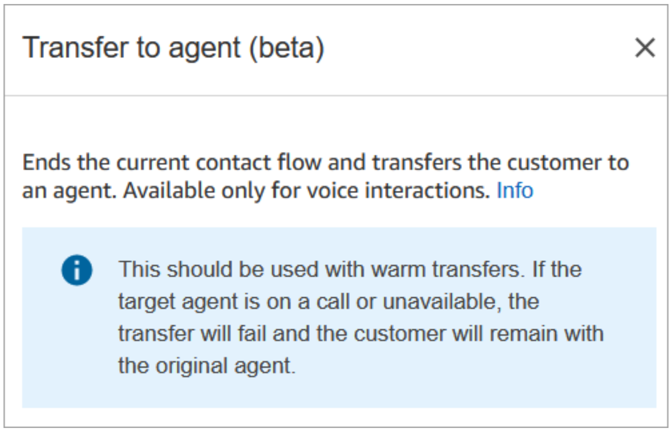
Flow types

You can use this block in the following flow types:

- Transfer to Agent flow
- Transfer to Queue flow

Properties

The following image shows the **Properties** page of the **Transfer to agent** block. It does not have any options on it.



Configured block

The following image shows an example of what this block looks like when it is configured. It displays the status **Transferred**. It does not have any branches.

Scenarios

See these topics for scenarios that use this block:

- Set up contact transfers in Amazon Connect

Flow block in Amazon Connect: Transfer to flow

This topic defines the flow block for ending the current flow and transferring the customer to a different flow.

Description

- Ends the current flow and transfers the customer to a different flow.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	Yes
Task	Yes
Email	Yes

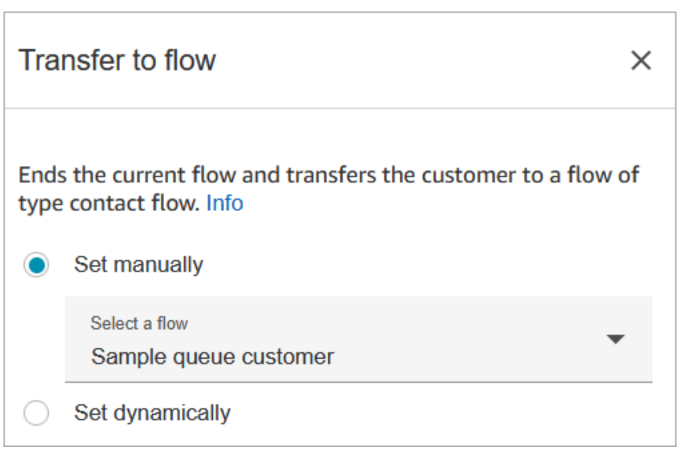
Flow types

You can use this block in the following flow types:

- Inbound flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

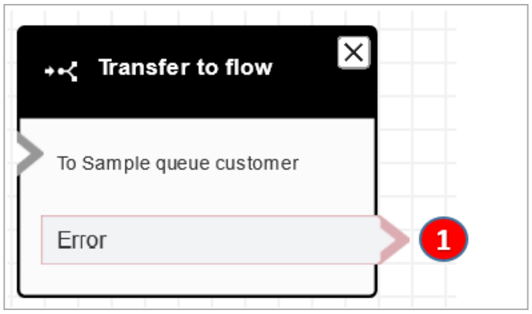
The following image shows the **Properties** page of the **Transfer to flow** block. You choose the flow from the dropdown box.



Only published flows appear in the dropdown list.

Configured block

The following image shows an example of what this block looks like when it is configured. It has the following branch: **Error**.



1. The contact is routed down the **Error** branch if the flow you have specified to transfer to isn't a valid flow, or it's not a valid flow type (Inbound, Transfer to Agent, or Transfer to Queue).

Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

- Sample flow in Amazon Connect for A/B contact distribution testing

Scenarios

See these topics for scenarios that use this block:

- Set up contact transfers in Amazon Connect

Flow block in Amazon Connect: Transfer to phone number

This topic defines the flow block for transferring the customer to an external phone number outside of your instance.

Description

- Transfers the customer to a phone number external to your instance.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	Yes
Chat	No - Error branch
Task	No - Error branch
Email	No - Error branch

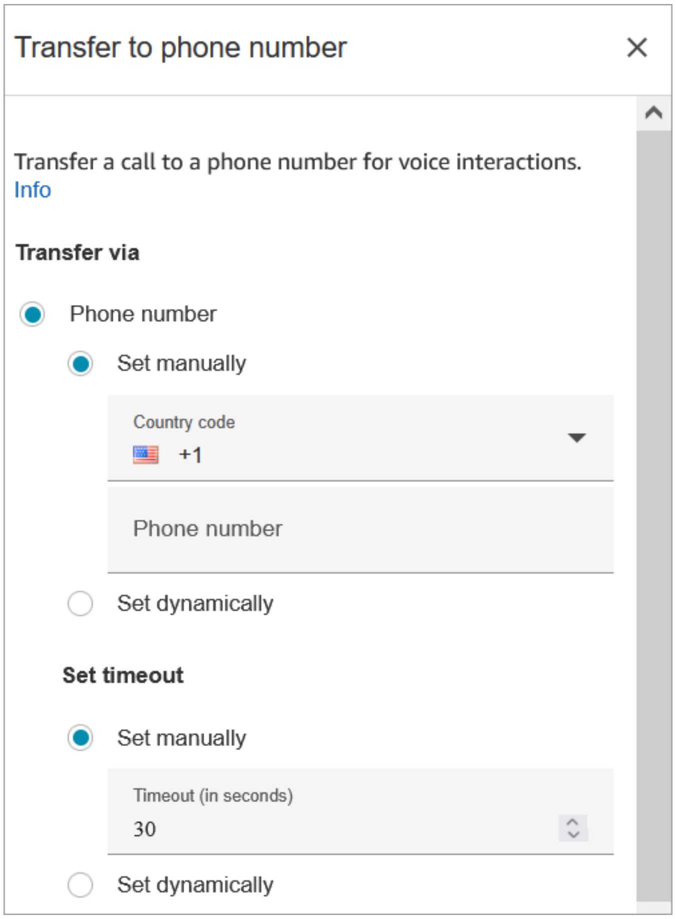
Flow types

You can use this block in the following flow types:

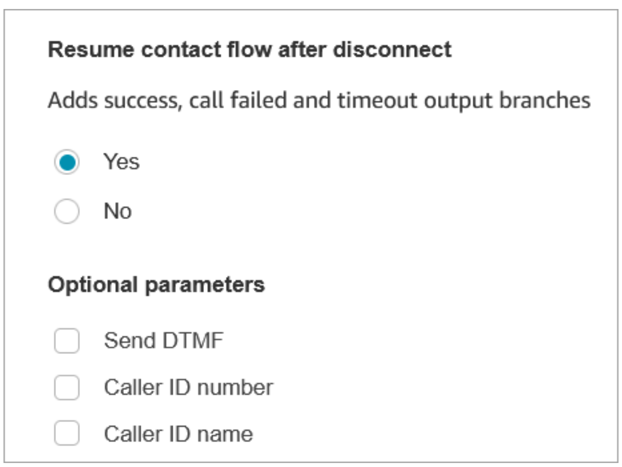
- Inbound flow
- Customer Queue flow
- Transfer to Agent flow
- Transfer to Queue flow

Properties

The following image shows the **Properties** page of the **Transfer to phone number** block. It shows the **Transfer via** section. The **Country code** is set to +1 (US). **Set timeout** = 30 seconds.



The following image shows the **Resume flow after disconnect** section is set to **Yes**.



Note the following properties:

- **Resume flow after disconnect**: This works only if the external party disconnects, and the customer doesn't disconnect. (If the customer disconnects, the whole call disconnects.)

- **Send DTMF**: This property is useful to bypass some of the DTMF of the external party. For example, if you know you'll need to press 1, 1, 362 to reach the external party, you can enter that here.

  If you specify a comma in **Send DTMF** it pauses for 750ms.
- **Caller ID number**: You can choose a number from your instance to appear as the caller ID. This is useful in cases where you want to use a number that's different from the one the flow is actually using to make the call.

> **Important**
>
> If you are using Amazon Connect outside of the United States, we recommend choosing **Caller ID number** and then selecting an Amazon Connect number. Otherwise, local regulations may cause telephony providers to block or redirect non-Amazon Connect phone numbers. This will result in service-related events, such as rejected calls, poor audio quality, delay, latency, and displaying the incorrect caller ID.
> **In Australia**: The caller ID must be an Amazon Connect provided DID (Direct Inward Dialing) phone number. If a toll free number or a number not provided by Amazon Connect is used in the caller ID, local telephony suppliers may reject outbound calls due to local anti-fraud requirements.
> **In the UK**: The caller ID must be a valid E164 phone number. If the phone number is not provided in the caller ID, local telephony suppliers may reject outbound calls due to local anti-fraud requirements.

- **Caller ID name**: You can set a caller ID name, but there's no guarantee it will appear correctly to the customer. For more information, see Outbound caller ID number.

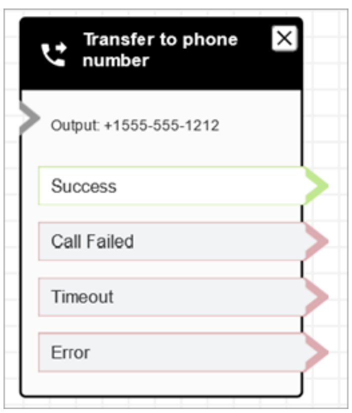
> **Note**
>
> - Per SIP protocol RFC3261, the following characters are reserved: **; / ? : @ & = + $,**. Do not use these characters in the caller ID name. When these characters are included, outbound calls may fail or the caller ID name may display inaccurately.
> - When Transfer to phone number block is used without specifying a custom caller ID, the caller ID of the caller is passed as the caller ID. For example, if you transfer to an external number and no custom caller ID is used to specify that the call is coming from your organization, then the contact's caller ID is displayed to the external party.

Configuration tips

- Submit a service quota increase request requesting that your business be allowed to make outbound calls to the country you specified. If your business is not on the allowlist for making the call, it will fail. For more information, see Countries that call centers using Amazon Connect can call by default.
- If the country you want to select is not listed, you can submit a request to add countries you want to transfer calls to using the Amazon Connect service quotas increase form.
- You can choose to end the flow when the call is transferred, or choose to **Resume flow after disconnect**, which returns the caller to your instance and resumes the flow after the transferred call ends.

Configured block

The following image shows an example of what this block looks like when it is configured. It shows the number you are transferring to. It has the following branches: **Success**, **Call Failed**, **Timeout**, **Error**.



Scenarios

See these topics for scenarios that use this block:

- Set up contact transfers in Amazon Connect
- Set up outbound caller ID in Amazon Connect
- Set up Amazon Connect external voice transfer to an on-premise voice system

Flow block in Amazon Connect: Transfer to queue

This topic defines the flow block for transferring a current contact to the destination queue.

Description

Use this block to transfer a current contact to the destination queue.

The functionality of this block depends on where it is used:

- When used in a Customer Queue flow, this block transfers a contact already in a queue to another queue.
- When used in a callback scenario, Amazon Connect calls the agent first. After the agent accepts the call in the CCP, Amazon Connect calls the customer.
- In all other cases, this block places the current contact in a queue and ends current flow.
- This block cannot be used in a callback scenario when using the chat channel. If you attempt to do so, an error branch is followed. In addition, an error is created in the CloudWatch log.

Use cases for this block

This block is designed to be used in the following scenarios:

- Place the contact in a queue to be connected to an agent.
- You want to move the current customer from a generic queue to a specialized queue. You may want to do this when customers have waited too long in the queue, for example, or you have other business requirements.
- Offer callback options to the customer instead of having them wait to be connected to an agent.

Contact types

The following table lists how this block routes a contact who is using the specified channel.

Contact type	Supported?
Voice	Yes
Chat	Yes

Contact type	Supported?
Task	Yes
Email	Yes

Flow types

You can use this block in the following flow types:

Flow type	Supported?
Inbound flow	Yes
Customer queue flow	Yes
Customer hold flow	No
Customer whisper flow	No
Outbound whisper flow	No
Agent hold flow	No
Agent whisper flow	No
Transfer to agent flow	Yes
Transfer to queue flow	Yes

How to configure this block

You can configure the **Transfer to queue** block using the Amazon Connect admin website. Or you can use the Amazon Connect Flow language. Depending on the use case you use one of the following actions:

- If the flow block is used in CustomerQueue flow type, it is represented as DequeueContactAndTransferToQueue action in the Flow Language.
- If the flow block is used to configure callbacks, it is represented as CreateCallbackContact action.

- If the flow block is used to configure callbacks, it is represented as TransferContactToQueue action.

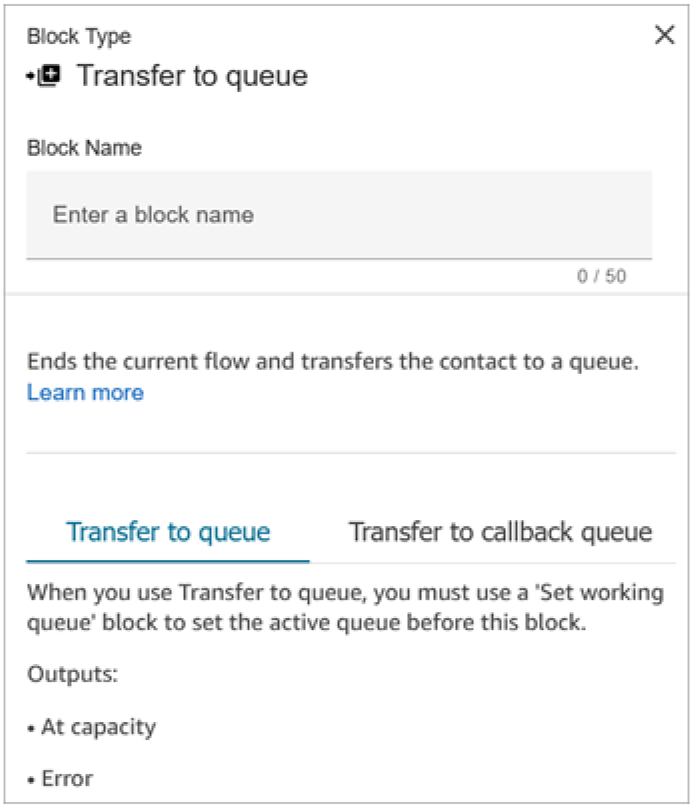
Configuration sections

- Transfer to queue
- Transfer to Callback (scheduling callbacks)
- Flow block branches
- Additional configuration tips
- Data generated by the block

Transfer to queue

Use this configuration tab to transfer the contact to a queue. There are two possible scenarios:

- **Contacts are not in any queue yet**: If contacts are not in a queue yet, this configuration simply puts the contacts in the destination queue that you've specified. For contacts not in a queue yet, you must use "Set Working Queue" flow block before "Transfer to Queue" flow block. The following image shows the **Transfer to queue** tab on the **Properties** page for transferring contacts to queue. You don't need to choose any options.



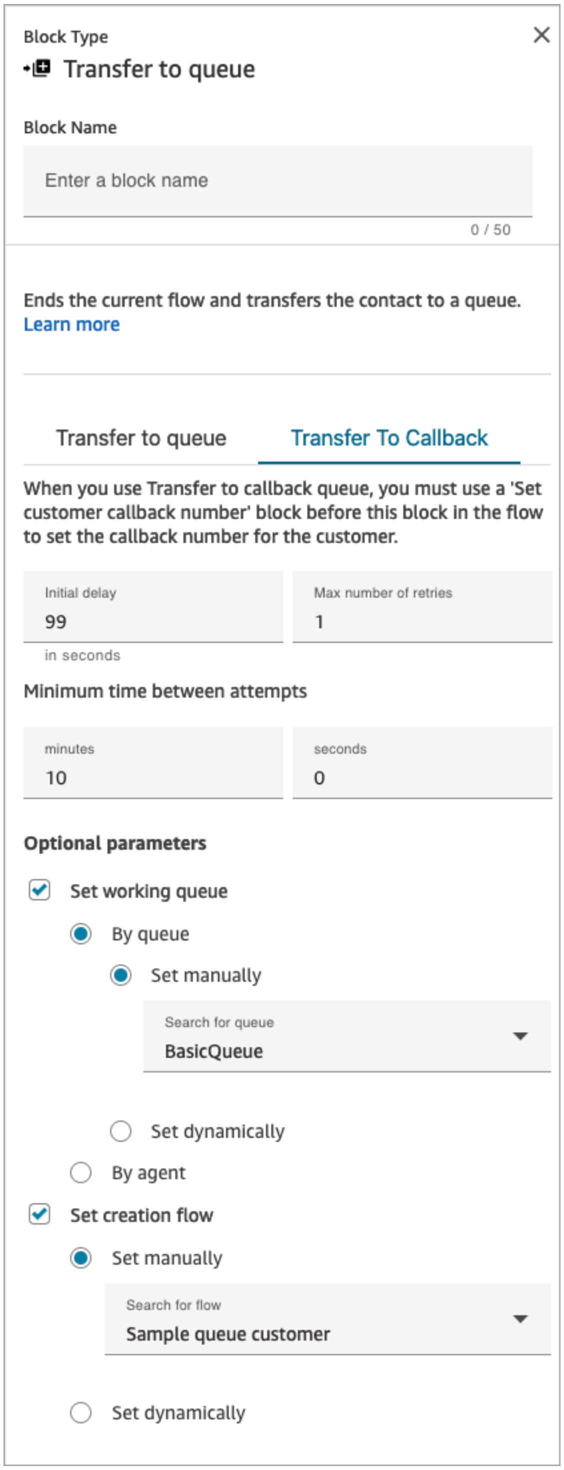
The following code sample shows how this same configuration would be represented by the TransferContactToQueue action in the Flow language:

```
{
         "Parameters": {},
         "Identifier": "a12c905c-84dd-45c1-8f53-4287d1752d59",
         "Type": "TransferContactToQueue",
         "Transitions": {
             "NextAction": "",
             "Errors": [
                 {
                     "NextAction": "0a1dc9a4-8657-4941-a980-772046b94f1e",
                     "ErrorType": "QueueAtCapacity"
                 },
                 {
                     "NextAction": "6e84a9b5-1ed0-40b1-815d-a3bdd4b2dc8a",
                     "ErrorType": "NoMatchingError"
                 }
             ]
         }
     }
```

There are two possible outcomes in this case:

- **At capacity**: If the destination queue cannot accept additional contacts when number of contacts currently in a queue exceeds the maximum contacts allowed for queue, then the contact is routed down the **At Capacity** branch.
- **Error**: If transfer to queue fails for any other reason apart from capacity constraint (for example, the queue ARN that is specified for the transfer is not valid, the queue does not exist in the current instance, or queue is disabled for routing), then the contact is routed down the **Error** branch.

- **Contact already in a queue**: If contacts are already waiting in a queue, then running the **Transfer to queue** block would move contacts from one queue to another. The following image shows how to configure the block to transfer contacts to queue. In this case, the **BasicQueue** is set manually.



The following code sample shows how this same configuration would be represented by the DequeueContactAndTransferToQueue action in the Flow language:

```
{
          "Parameters": {
```

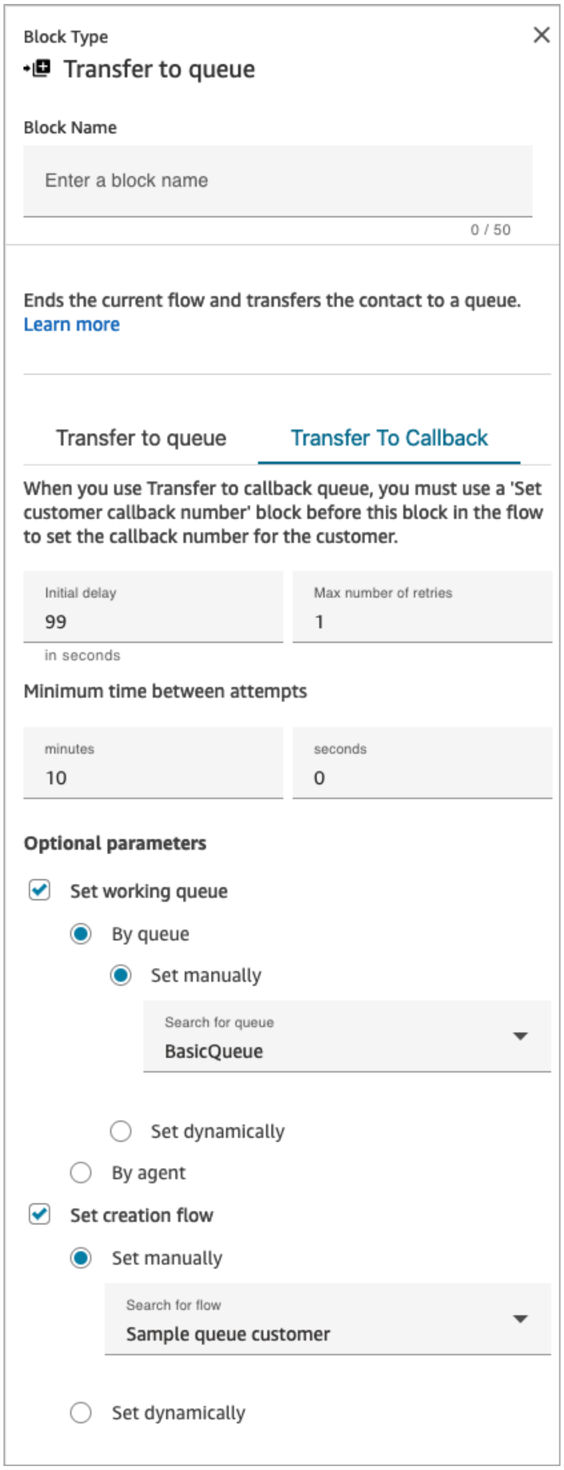
```
            "QueueId": "arn:aws:connect:us-west-2:1111111111:instance/aaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee/queue/abcdef-abcd-abcd-abcd-abcdefghijkl"
        },
        "Identifier": "180c3ae1-3ae6-43ee-b293-546e5df0286a",
        "Type": "DequeueContactAndTransferToQueue",
        "Transitions": {
            "NextAction": "",
            "Errors": [
                {
                    "NextAction": "0a1dc9a4-8657-4941-a980-772046b94f1e",
                    "ErrorType": "QueueAtCapacity"
                },
                {
                    "NextAction": "6e84a9b5-1ed0-40b1-815d-a3bdd4b2dc8a",
                    "ErrorType": "NoMatchingError"
                }
            ]
        }
    }
```

There are three possible outcomes in this case:

- **Success**: Indicates the contact successfully transferred to the destination queue.
- **At capacity**: If the destination queue cannot accept additional contacts when the number of contacts currently in a queue exceeds maximum contacts allowed for queue, then the contact is routed down the **At Capacity** branch. The contact remains in the current working queue.
- **Error**: If transfer to queue fails for any other reason apart from capacity constraint (for example, the queue ARN that is specified for the transfer is not valid, the queue does not exist in the current instance, or queue is disabled for routing), then the contact is routed down the **Error** branch. The contact remains in the current working queue.

Transfer to Callback (scheduling callbacks)

Use this configuration tab to schedule callbacks for contacts at later time. The following image shows a **Properties** page that is configured for scheduling callbacks.



The following properties are available under the **Transfer to Callback** tab:

- **Initial delay**: Specify how much time has to pass between a callback contact being initiated in the flow, and the customer is put in queue for the next available agent.

- **Maximum number of retries**: If this were set to 1, then Amazon Connect would try to callback the customer at most two times: the initial callback, and 1 retry.

> **Tip**
>
> We strongly recommend that you double-check the number entered in **Maximum number of retries**. If you accidentally enter a high number, such as 20, it's going to result in unnecessary work for the agent and too many calls for the customer.

- **Minimum time between attempts**: If the customer doesn't answer the phone, this is how long to wait until trying again.
- **Set working queue**: You can transfer a callback queue to a different queue. This is useful if you set up a special queue just for callbacks. You can then view that queue to see how many customers are waiting for callbacks.

  > **Tip**
  >
  > If you want to specify the **Set working queue** property, you need to add a **Set customer callback number** block before this block.

  If you don't set a working queue, Amazon Connect uses the queue that was set previously in the flow.
- **Set creation flow**: Use the dropdown menu to select the flow to be run when a callback contact is created.

  The callback creation flow that you select must meet the following requirements:

  - The flow type must be the default flow type, **Contact flow (inbound)**. For information about flow types, see Choose a flow type.
  - You need to configure a Transfer to queue block to queue the contact in the queue of your choice.

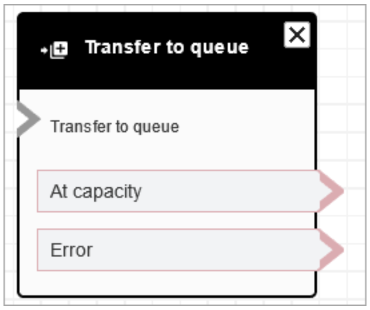
  Following are additional options for how you can configure your callback creation flow:

  - You can evaluate contact attributes (including customer profiles) by using a Check contact attributes block to see if the callback should be terminated because it is a duplicate or the customer issue has already been resolved.

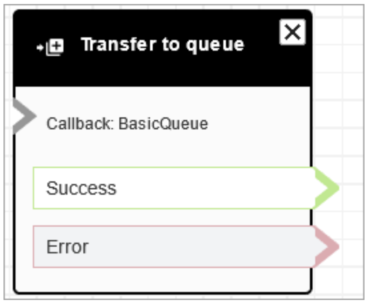
- You can add a Set customer queue flow block and use it to specify the flow to run when a customer is transferred to a queue. This flow is called a customer queue flow.
  - In the customer queue flow, you can evaluate the contact's wait time in queue by using a combination of the Get queue metrics block and GetCurrentMetricData to send an advance SMS to customers, notifying them to expect a callback in the near future from the specific contact center number.

Flow block branches

When this block is configured to **transfer to queue**, it looks similar to the following image. It has two branches: **At capacity** and **Error**. If a contact is routed down the **At capacity** branch, it remains in the current working queue.



When this block is configured to **transfer to callback queue**, it looks similar to the following image. It has two branches: **Success** and **Error**. If a contact is routed down the **Success** branch, it's transferred to the specified queue.



Additional configuration tips

- When you use this block in a Customer Queue flow, you must add a **Loop prompts** block before this one.
- To use this block in most flows, you must add a **Set working queue** block first. There are two exceptions:
  - When this block is used in a Customer Queue flow.

  - When making an outbound campaign that points to a Contact (Inbound) flow. The **Set working queue** block isn't necessary because the queue is already set using the campaign configuration. It can simply transfer to the queue.
- Queue-to-queue transfers can be done only 11 times because there is a maximum limit of 12 contacts in a contact chain. Every transfer adds a new contact to the chain.

Data generated by the block

This block does not generate any data.

Error scenarios

A contact is routed down the **Error** branch in the following situations:

When the Transfer to queue block runs, it checks the queue capacity to determine whether the queue is at capacity (full). This check for queue capacity compares the current number of contacts in the queue to the Maximum contacts in queue limit, if one is set for the queue. If no limit is set, the queue is limited to the number of concurrent contacts set in the service quota for the instance.

Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

- Sample queue configurations flow in Amazon Connect
- Sample customer queue priority flow in Amazon Connect
- Sample queued callback flow in Amazon Connect

More resources

See the following topics to learn more about the transferring contacts to a queue and queued callback.

- Set up a flow to manage contacts in a queue in Amazon Connect
- Set up queued callback by creating flows, queues, and routing profiles in Amazon Connect
- Queued callbacks in real-time metrics in Amazon Connect

Flow block in Amazon Connect: Wait

This topic defines the flow block for pausing the contact flow for the specified amount of time. For example, if a contact stops responding to a chat, the flow is paused for a designated time before it moves to another branch, such as disconnect.

Description

This block pauses the flow for the specified wait time.

For example, if a contact stops responding to a chat, the block pauses the contact flow for the specified wait time (**Timeout** time), then branches accordingly, such as to disconnect.

Supported channels

The following table lists how this block routes a contact who is using the specified channel.

Channel	Supported?
Voice	No - Error branch
Chat	Yes
Task	Yes - It always branches to **Time Expired** or **Error**. It never branches to **Bot participant disconnected** or **Participant not found**. The **Participant Type** setting does not affect this behavior.
Email	Yes

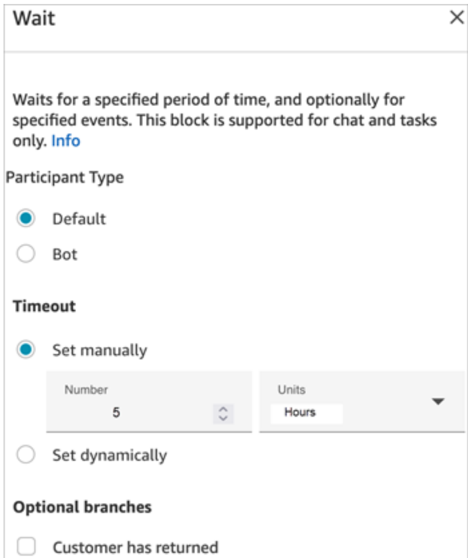
Flow types

You can use this block in the following flow types:

- Inbound flow
- Customer Queue flow

Properties

The following image shows the **Properties** page of the **Wait** block. It is configured pause the flow for 5 hours.



It has the following properties:

- **Participant Type**: Runs the **Wait** block for the specified participant type.
  - **Default** - A customer contact.
  - **Bot** - A custom participant, such as a third-party bot. For more information about using this option, see Customize chat flow experiences in Amazon Connect by integrating custom participants.
- **Timeout**: Run this branch if the customer hasn't sent a message after a specified amount of time. Maximum is 7 days.
  - Manually set timeout: You can provide the **Number** and **Units**.
  - Dynamically set timeout: The unit of measurement is in seconds.
- **Customer return**: Route the contact down this branch when the customer returns and sends a message. With this branch you can route the customer to the previous (same) agent, previous (same) queue, or override and set a new working queue or agent. This optional branch is available only when **Participant Type** = **Default**.

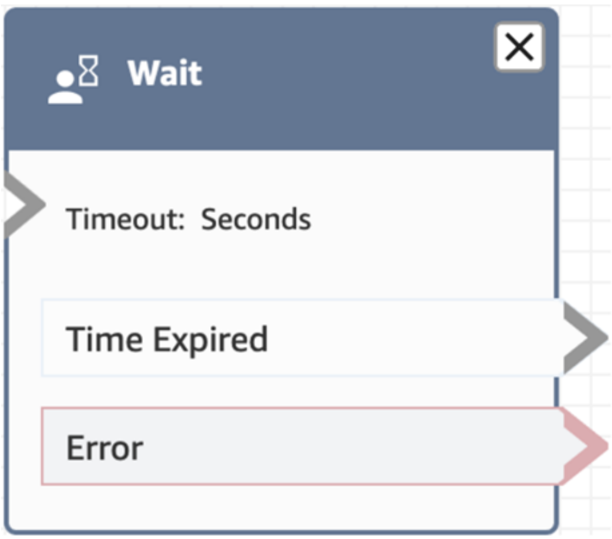
Configuration tips

You can add multiple **Wait** blocks to your contact flows. For example:

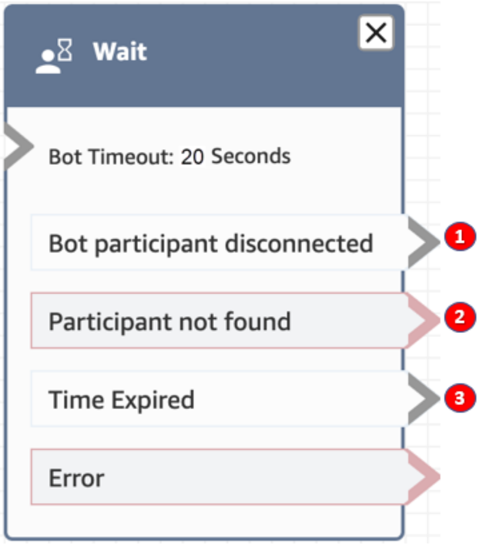
- If the customer comes back in 5 minutes, connect them to the same agent. This is because that agent has all of the context.
- If the customer doesn't come back after 5 minutes, send a text saying "We missed you."
- If the customer comes back in 12 hours, connect to a flow that puts them in a priority queue. However, it doesn't route them to the same agent.

Configured block

The following image shows an example of what this block looks like when it is configured with **Participant Type** = **Default**. It has the following branches: **Time Expired** and **Error**.



The following image shows an example of what this block looks like when it is configured with **Participant Type** = **Bot**. It has the following branches: **Bot participant disconnected**, **Participant not found**, **Time Expired**, and **Error**.



1. **Bot participant disconnected**: The custom participant, such as a third-party bot, has successfully disconnected to the contact.
2. **Participant not found**: No custom participant was found to be associated to the contact.
3. **Time Expired**: The timeout specified has lapsed before the custom participant disconnected.

Sample flows

Amazon Connect includes a set of sample flows. For instructions that explain how to access the sample flows in the flow designer, see Sample flows in Amazon Connect. Following are topics that describe the sample flows which include this block.

- Sample disconnect flow in Amazon Connect

Scenarios

See these topics for scenarios that use this block:

- Example chat scenario

Use the flow designer in Amazon Connect to create flows

The starting point for creating all flows is the flow designer. It's a drag-and-drop work surface that enables you to link together blocks of actions. For example, when a customer first enters your contact center, you can ask for some input and then play a prompt such as "Thank you."

For descriptions of the available flow blocks, see Flow block definitions in the flow designer in Amazon Connect.

Contents

Before you begin: develop a naming convention

Chances are you're going to create tens or hundreds of flows. To help you stay organized, it's important to develop a naming convention. After you start creating flows, we strongly recommend against renaming them.

Choose a flow type

Amazon Connect includes a set of nine flow types. **Each type has only those blocks for a specific scenario.** For example, the flow type for transferring to a queue contains only the appropriate flow blocks for that type of flow.

Important

- When you create a flow, you need to choose the right type for your scenario. Otherwise, the blocks you need may not be available.
- You can't import flows of different types. This means if you start with one type and need to switch to another to get the right blocks, you have to start over.

The following flow types are available.

Type	When to use
Inbound flow	This is the generic flow type that's created when you choose the **Create flow** button, and don't select a type using the drop-down arrow. It creates an inbound flow. This flow works with voice, chat, and tasks.
Campaign flow	Use to manage what the customer experiences during an outbound campaign. This flow only works with outbound campaigns.
Customer queue flow	Use to manage what the customer experienc es while in queue, before being joined to an agent. Customer queue flows are interruptible and can include actions such as an audio clip apologizing for a delay and offering an option to receive a callback, leveraging the **Transfer to queue** block. This flow works with voice, chat, and tasks.
Customer hold flow	Use to manage what the customer experiences while the customer is on hold. With this flow, one or more audio prompts can be played to a

Type	When to use
	customer using the **Loop prompts** block while waiting on hold. This flow works with voice.
Customer whisper flow	Use to manage what the customer experiences as part of an inbound call immediately before being joined with an agent. The agent and customer whispers are played to completion, then the two are joined. This contact flow works with voice and chat.
Outbound whisper flow	Use to manage what the customer experienc es as part of an outbound call before being connected with an agent. In this flow, the customer whisper is played to completion, then the two are joined. For example, this flow can be used to enable call recordings for outbound calls with the **Set recording behavior** block. This contact flow works with voice and chat.
Agent hold flow	Use to manage what the agent experiences when on hold with a customer. With this flow, one or more audio prompts can be played to an agent using the **Loop prompts** block while the customer is on hold. This flow works with voice.

<table>
<tr><th>Type</th><th>When to use</th></tr>
<tr><td>Agent whisper flow</td><td>Use to manage what the agent experiences as part of an inbound call immediately before being joined with a customer. The agent and customer whispers are played to completion, then the two are joined.

This flow works with voice, chat, and tasks.</td></tr>
<tr><td>Transfer to agent flow</td><td>Use to manage what the agent experienc es when transferring to another agent. This type of flow is associated with transfer to agent quick connects, and often plays messaging, then completes the transfer using the Transfer to agent block.

This flow works with voice, chat, and tasks.

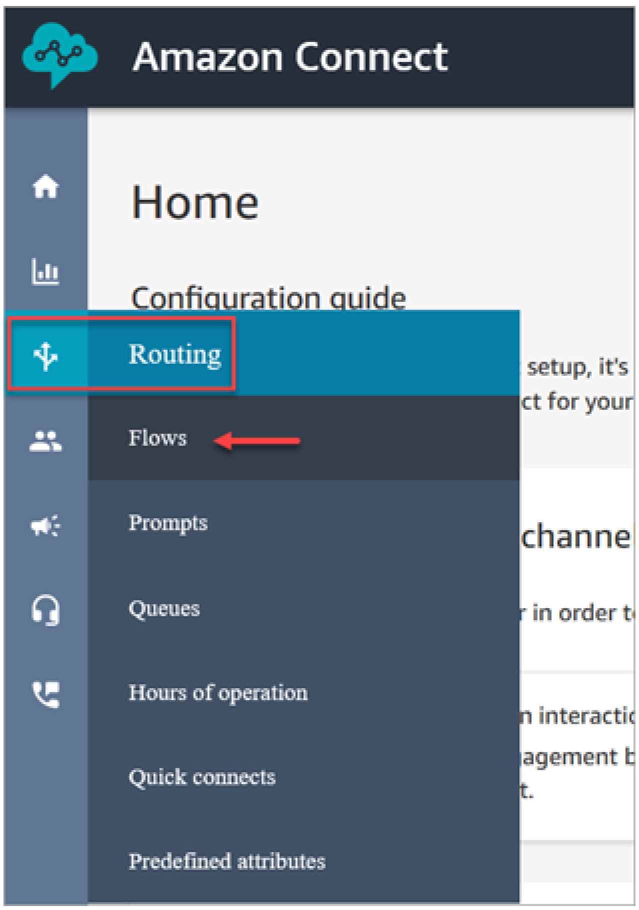
Important
Do not place any sensitive informati on in this flow. When a cold transfer occurs, the transferring agent disconnects before transfer is completed, and this flow is run on the caller. This means information in the flow is played to the caller, not the agent.</td></tr>
</table>

Type	When to use
Transfer to queue flow	Use to manage what the agent experiences when transferring to another queue. This type of flow is associated with transfer to queue quick connects, and often plays messaging, then completes the transfer using the **Transfer to queue** block. This flow works with voice, chat, and tasks.

Create an inbound flow

Use these steps to create an inbound flow.

1. In the left navigation menu, choose **Routing**, **Flows**.



2. Choose **Create flow**. This opens the flow designer and creates an inbound flow (Type = Flow).

3. Type a name and a description for your flow.
4. Search for a flow block using the **Search** bar, or expand the relevant group to locate the block. For descriptions of the flow blocks, see Flow block definitions in the flow designer in Amazon Connect.
5. Drag and drop contact blocks onto the canvas. You can add blocks in any order or sequence, as connections between elements aren't required to be strictly linear.

> **Tip**
>
> You can move blocks around the canvas so the layout aligns to your preferences. To select multiple blocks at the same time, press the **Ctrl** key on your laptop (or the **Cmd** key on a Mac), choose the blocks you want, and then use your mouse to drag them as a group within the flow. You can also use the **Ctrl/Cmd** key to start at one point on the canvas and drag your pointer across the canvas to select all blocks included in the frame.

6. Double-click the title of the block. In the configuration pane, configure settings for that block and then choose **Save** to close the pane.
7. Back on the canvas, click on the first (the originating) block.
8. Choose the circle for the action to perform, such as Success.
9. Drag the arrow to the connector of the group that performs the next action. For groups that support multiple branches, drag the connector to the appropriate action.
10. Repeat the steps to create a flow that meets your requirements.
11. Choose **Save** to save a draft of the flow. Choose **Publish** to activate the flow immediately.

> **Note**
>
> All connectors must be connected to a block in order to successfully publish your flow.

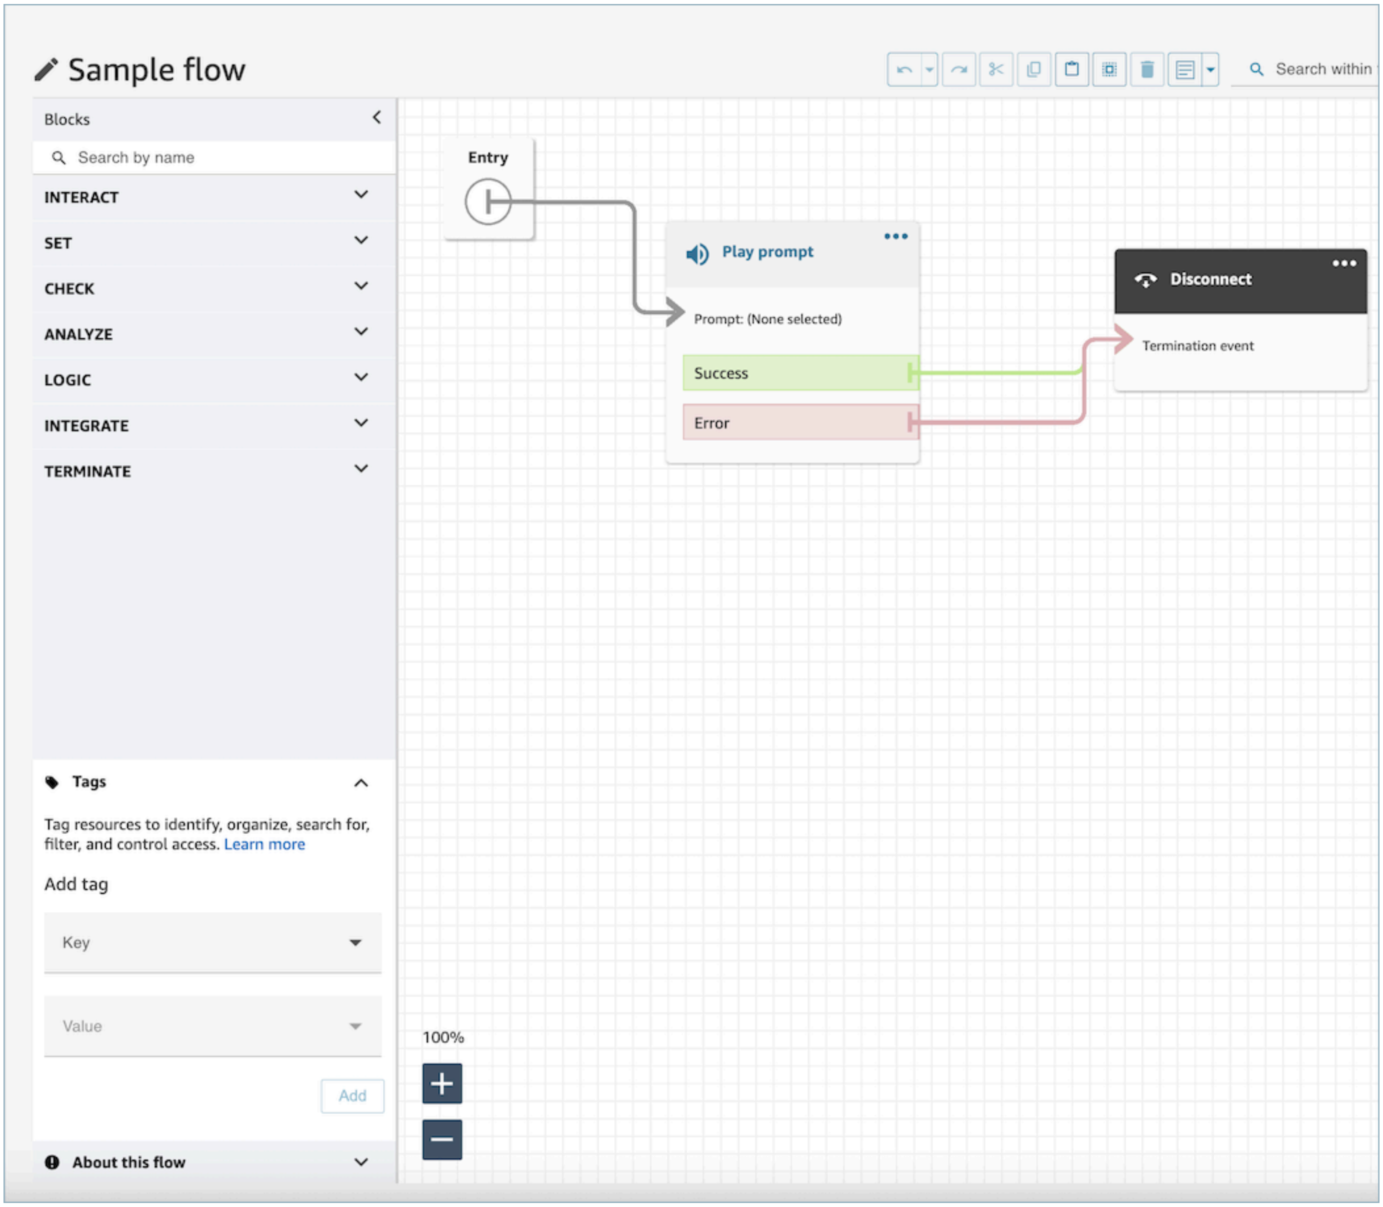
Add tags to flows and flow modules

A *tag* is a custom metadata label that you can add to a resource to make it easier to identify, organize, and find in a search. Tags are comprised of two individual parts: A tag key and a tag value. This is referred to as a key:value pair.

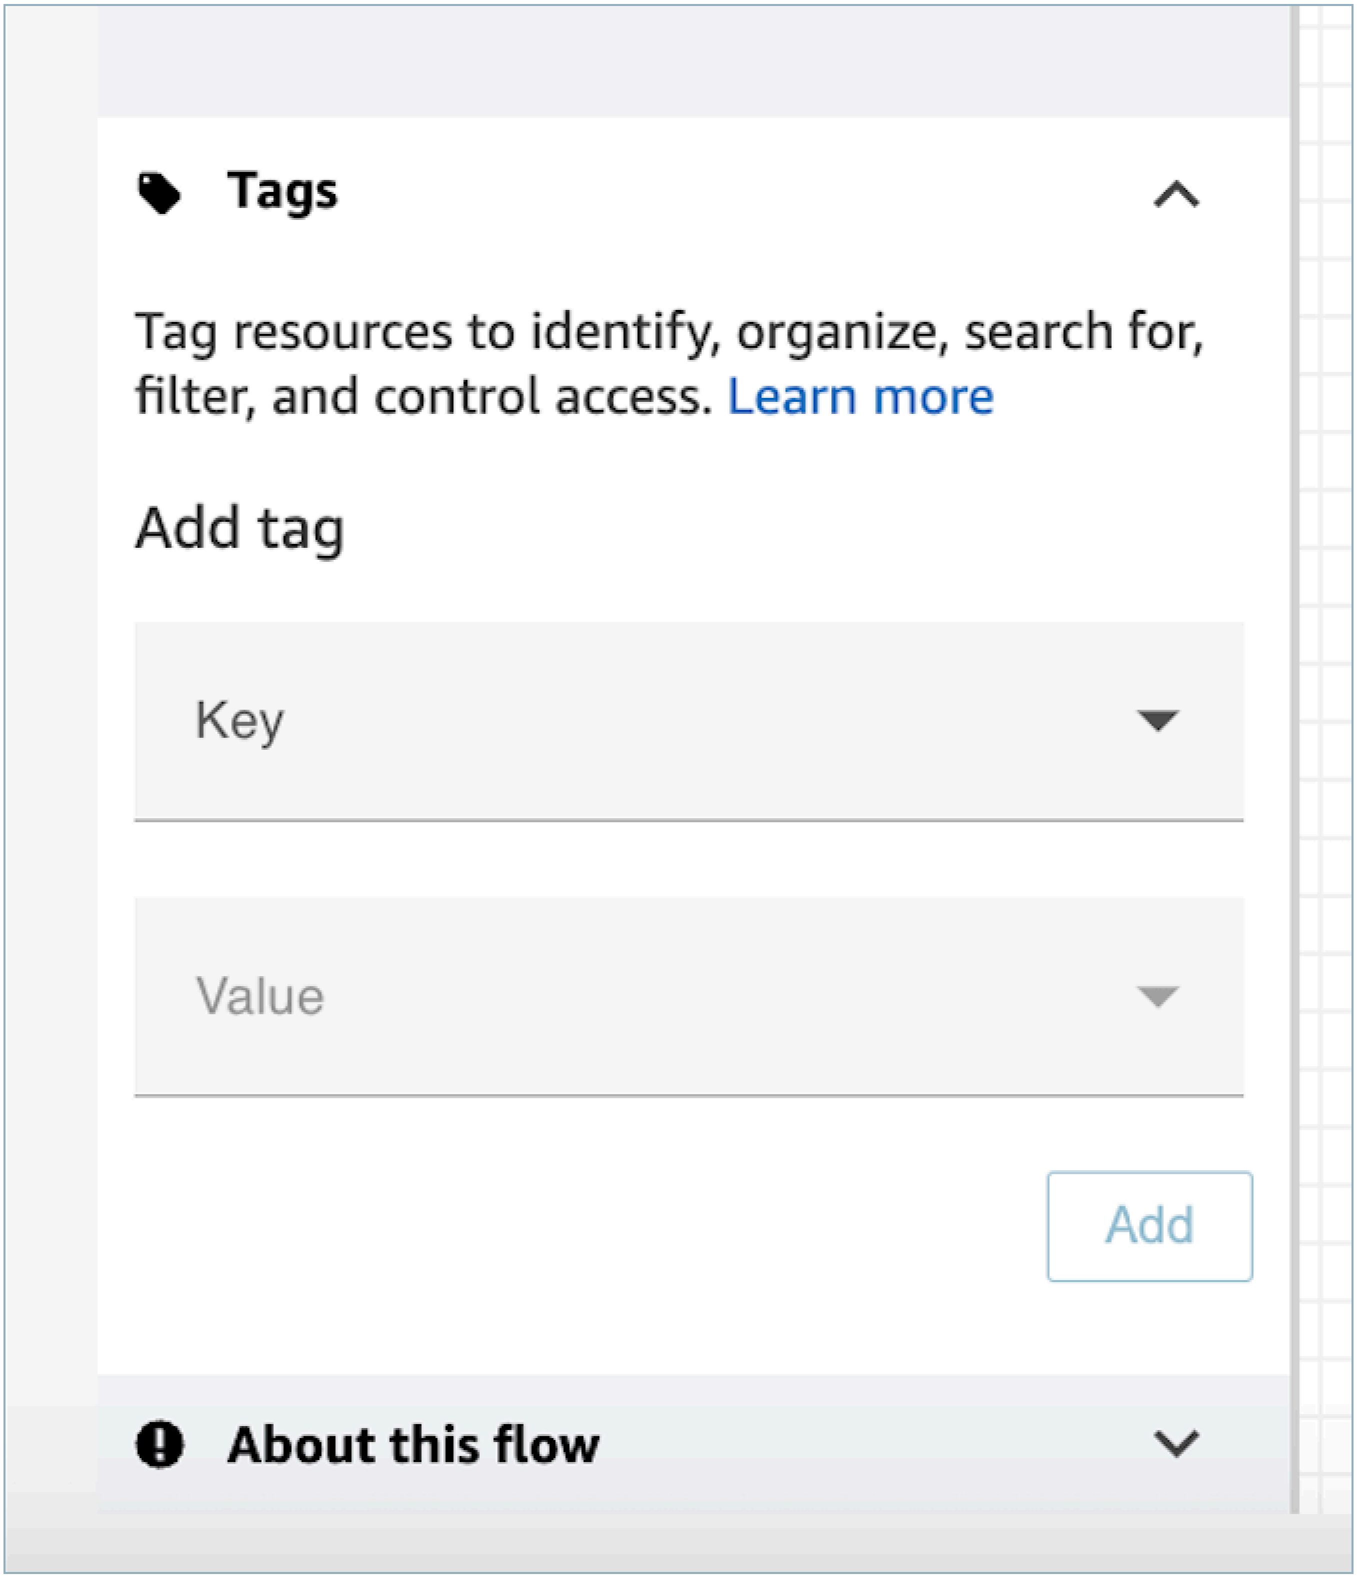
A tag key typically represents a larger category, while a tag value represents a subset of that category. For example you could have tag key=Color and tag value=Blue, which would produce the key:value pair `Color:Blue`.

You can add resource tags to your flows and flow modules. Use the following steps to add a resource tag from the flow designer.

1. Open the tag section on flow designer page for a chosen flow or flow module.



2. Enter a **Key** and **Value** combination to tag the resource.



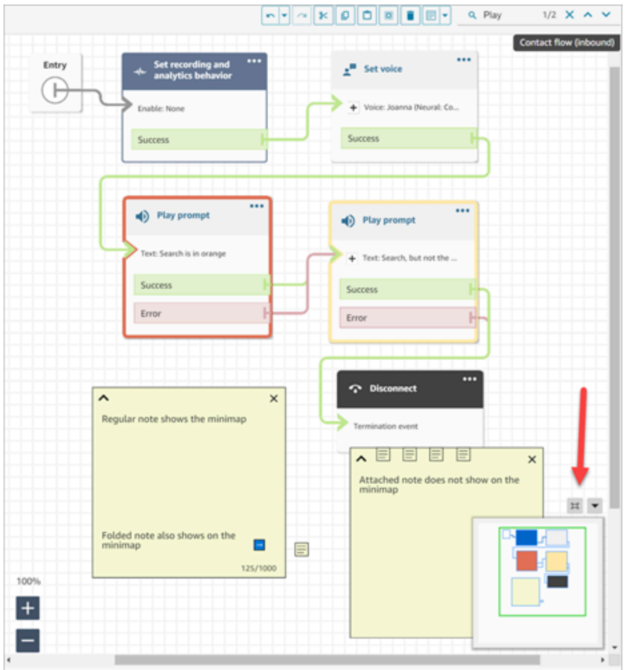
3. Choose **Add**. Tags are not persisted until you save or publish the flow.

For more information, see [Apply tag-based access control in Amazon Connect]()

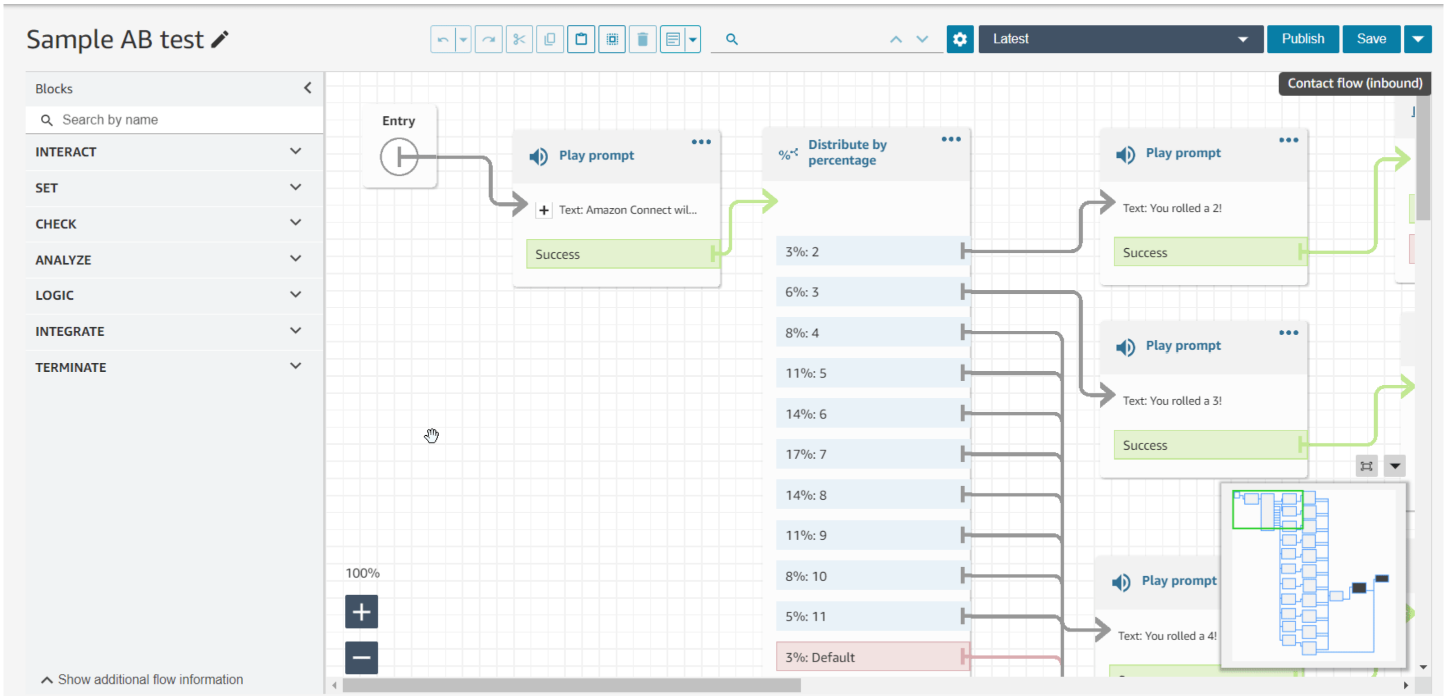
Use the mini-map in Amazon Connect to navigate a flow

In the lower left corner of the flow designer, there's a miniaturize view of the entire flow. Use this view to help you easily navigate the flow. The drag-to-move mini-map has visual highlights that enable you to quickly move to any point in the flow.

The following image shows the location of the mini-map in the flow designer. The arrow points to the toggle that you use to hide or show the mini-map.



The following GIF shows an example of how you can use the mini-map to navigate a large flow. Click or tap the mini-map to move the view to the desired location on the flow designer.



Note the following functionality:

- It shows your current view in green outline.
- It highlights selected blocks in blue, notes in yellow, search results in orange, and termination blocks in black.
- It allows continuous movement of the view when you drag on the mini-map.
- It returns the view to the **Entry** block and trims unused space when you choose **Reset**.

Customize the name of a flow block in Amazon Connect

To help you distinguish blocks in a flow, you can customize the names of blocks. For example, when there are multiple **Play prompt** blocks, and you want to distinguish between them at a glance you can assign each block their own name.

Custom flow block names appear in CloudWatch logs under the `Identifier` field. This makes it easier for you to review the logs to diagnose issues.

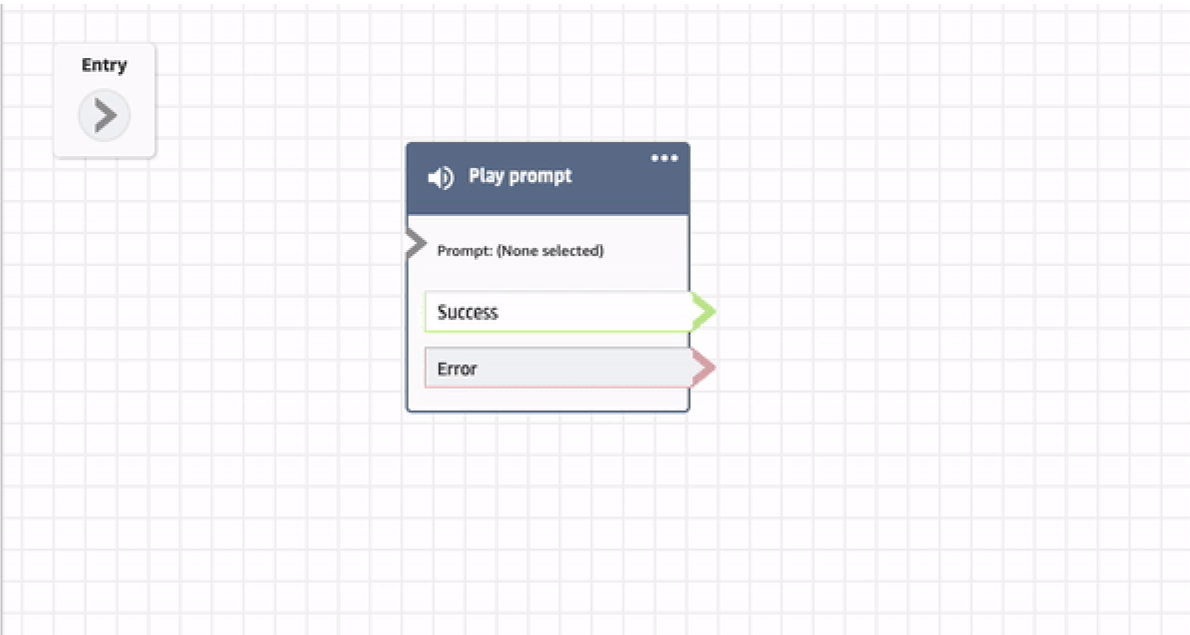
Important

- The following characters are not allowed in the block name or `Identifier` field: (% : (\ /) = $, ; [ ] { })

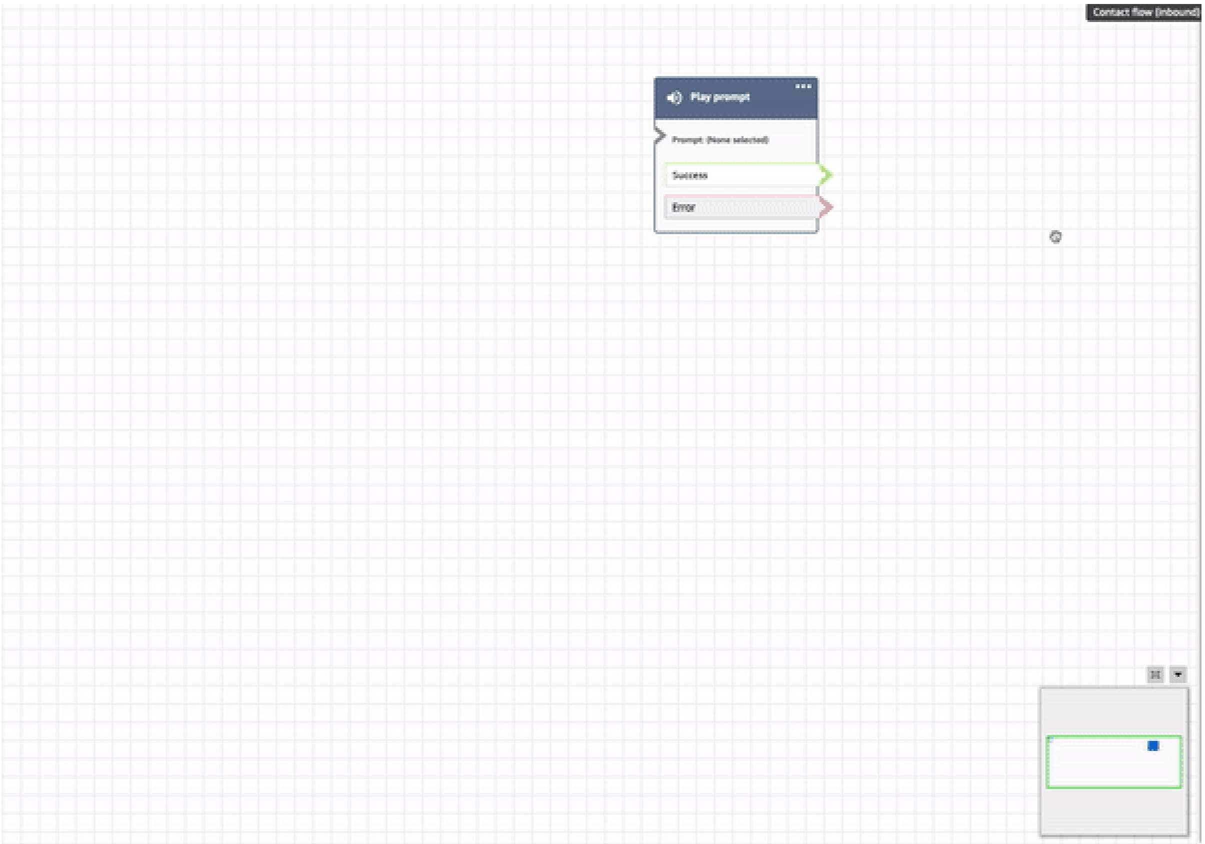
- The following strings are not allowed in the block name or `Identifier` field: __proto__, constructor, __defineGetter__, __defineSetter__, toString, hasOwnProperty, isPrototypeOf, propertyIsEnumerable, toLocaleString, and valueOf.

There are two ways you can specify a custom block name:

- On the block, choose **...**, and then choose **Add block name**, as shown in the following GIF.



- You can also customize the name of the block on the **Property** page, as shown in the following GIF.

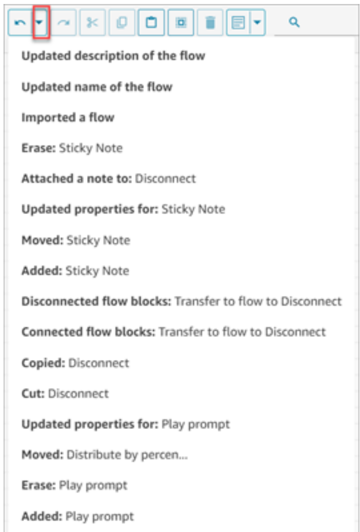


Undo and redo actions in the flow designer in Amazon Connect

You can undo and redo actions in the flow designer. Choose the undo and redo items on the toolbar. Or, with your cursor on the flow designer canvas, use the shortcut keys: Ctrl+Z to undo, Ctrl+Y to redo.

> **Tip**
>
> On a Mac, Ctrl+Y opens the history page instead of performing a redo.

To access a history of your actions that you can undo, choose the **Undo** dropdown button on the toolbar, as shown in the following image.



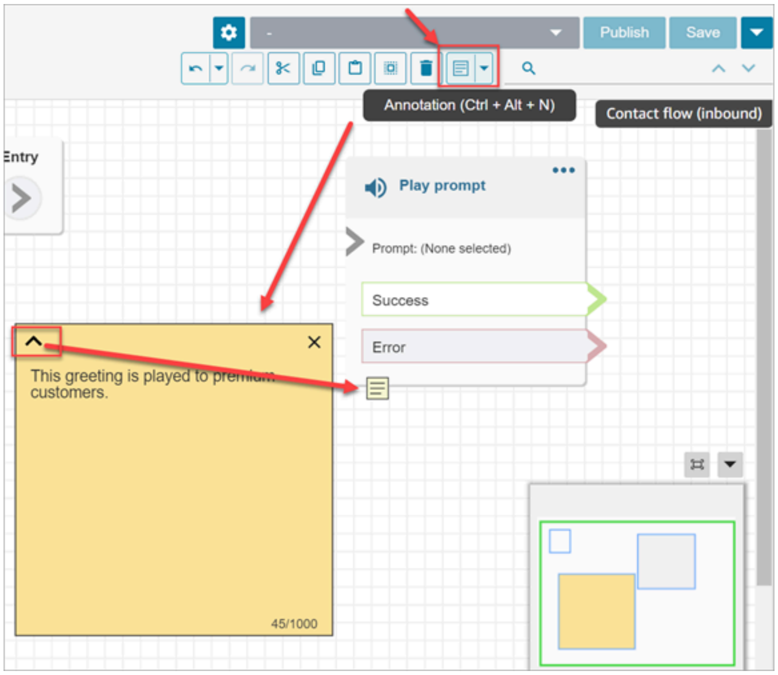
Limits

Action	Limit
History limit	Up to 100 actions can be undone.
Dragging unconnected connector	This action cannot be undone.
Folding of notes	This action cannot be undone.
Page reload	The undo history is not retained after a page is reloaded.

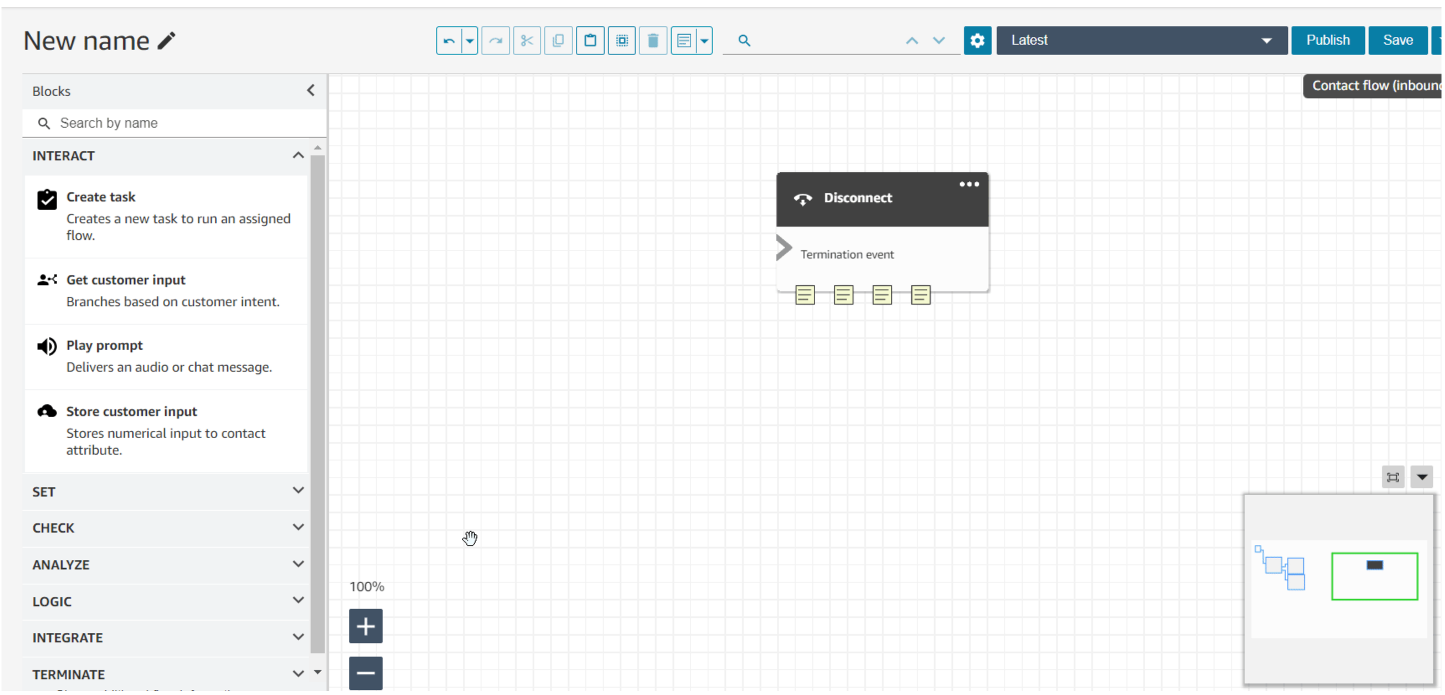
Add comments to a flow block in the flow designer in Amazon Connect

To add notes to a block, on the toolbar choose **Annotation**. Or, with your cursor on the flow designer canvas, use the shortcut keys: Ctrl + Alt +N. A yellow box opens for you to type up to 1000 characters. This enables you to leave comments that others can view.

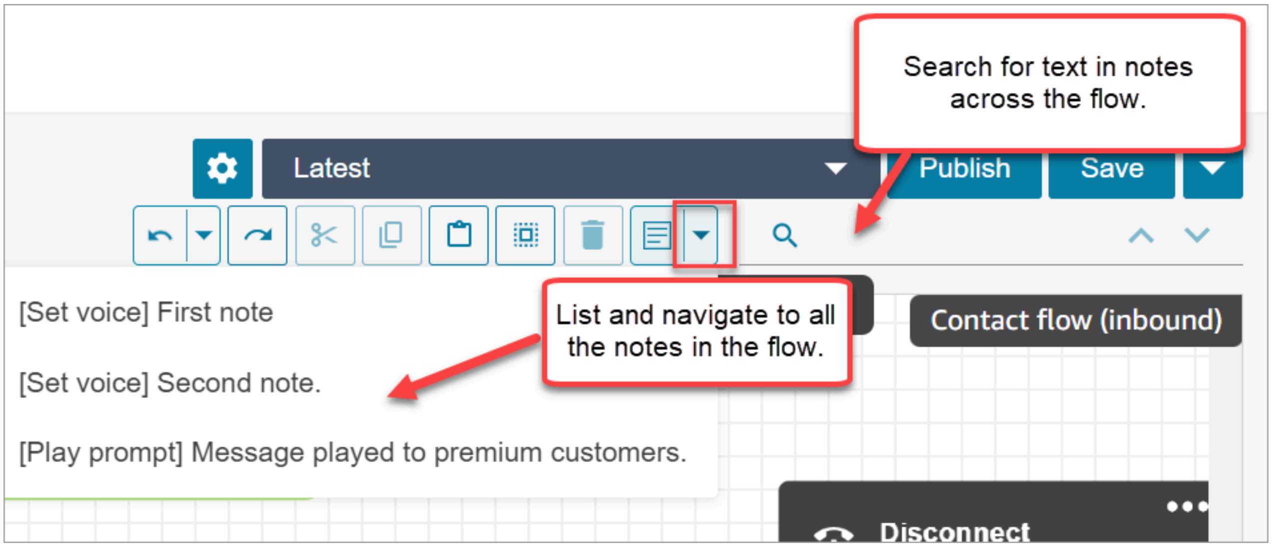
The following image shows the flow designer toolbar, the annotation box, and an annotation that is attached to a block.



The following GIF shows how to move notes around the flow designer and attach them to a block.



The following image shows the dropdown menu that allows you to view a list of all the notes in a flow. Choose a note to navigate to it. Use the search box to search notes across the flow.



Note the following functionality:

- Unicode and emojis are supported.
- You can copy and paste, undo, and redo into the note box.
- You can search notes across the flow.
- When a block is deleted, the notes are deleted. When a block is restored, the notes are restored.

Limits

Item	Limit
Character limit	1000 characters per note
Attachment limit	5 notes per block
Note limit	100 notes per flow

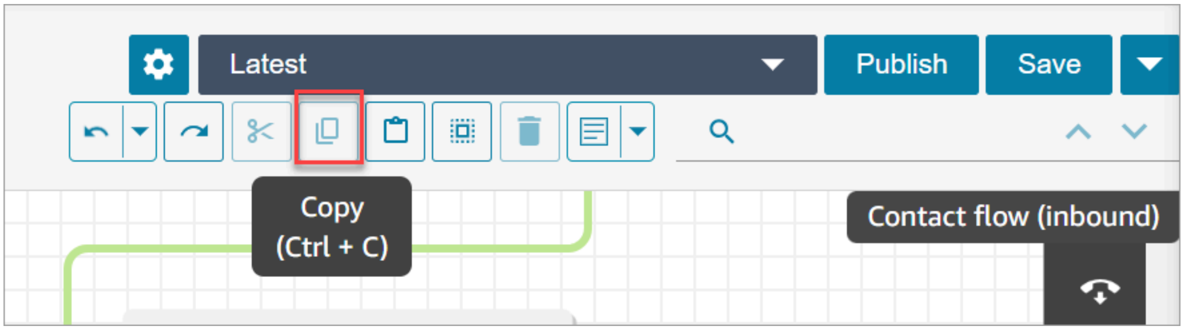
Copy and paste flows in Amazon Connect

You can select, cut, copy, and paste a complete flow or multiple blocks within or across flows. The following information is copied:

- All configured settings in the selected flow blocks.
- The layout arrangements.

- The connections.

The following image shows the copy item on the flow designer toolbar.



Or, if desired, use the shortcut keys.

Windows: CTRL+C to copy, CTRL+V to paste, and CTRL+X to cut

1. To select multiple blocks at the same time, press the **Ctrl** key, and choose the blocks you want.
2. With your cursor on the flow designer canvas, press **Ctrl+C** to copy the blocks.
3. Press **CTRL+V** to paste the blocks.

Mac: Cmd+C to copy, Cmd+V to paste, and Cmd+X to cut

1. To select multiple blocks at the same time, press the **Cmd** key, and choose the blocks you want.
2. Press **Cmd+C** to copy the blocks.
3. Press **Cmd+V** to paste the blocks.

> **Tip**
>
> Amazon Connect uses the clipboard for this feature. Paste won't work if you edit the JSON in your clipboard and introduce a typo or other error, or if you have multiple items saved to your clipboard.

Archive, delete, and restore flows in Amazon Connect

Flows and modules must be archived before you can delete them from your Amazon Connect instance. Archived flows and modules can be restored.

> **Warning**
>
> Deleted flows and modules cannot be restored. They are permanently deleted from your Amazon Connect instance.

Important things to know

- **Use caution when archiving flows or modules**. Amazon Connect does not validate whether the flow or module you are archiving is being used in other published flows. It does not warn you that the flow is in use.
- Default flows cannot be archived or deleted. If you attempt to archive a default flow, you'll get message similar to the following image.

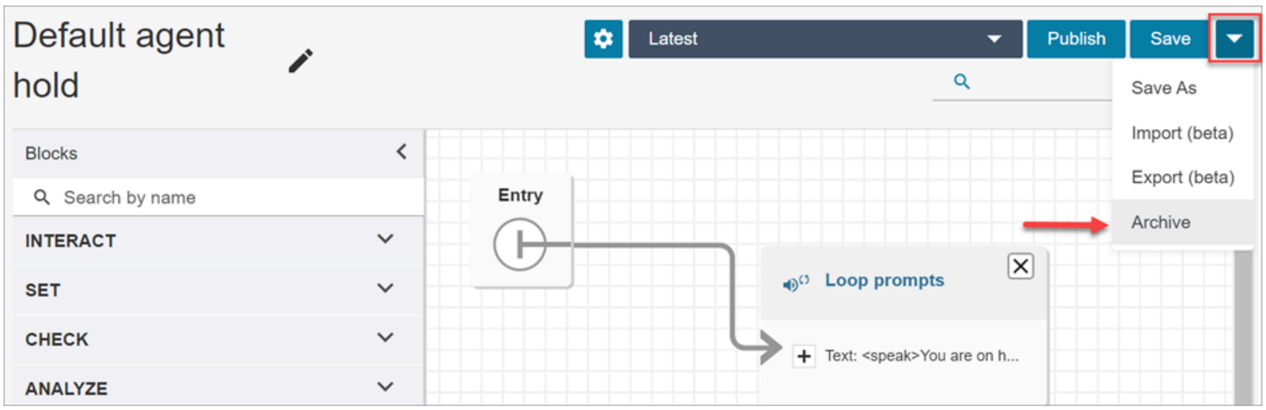
- Flows and modules that are associated with queues, quick connects, or phone numbers cannot be archived. You need to disassociate the resources from the flows before you can archive them.
- Archived flows and modules count towards your **Flows per instance** and **Modules per instance** service quotas. You must delete them to not have them counted. For more information about quotas, see [Amazon Connect service quotas](#).

Archive a flow or module

There are two ways you can archive flows or modules.

Option 1: Open the flow or module and then archive it

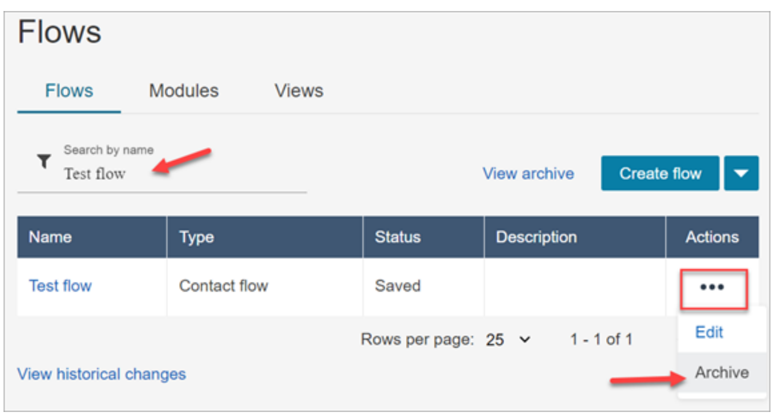
1. Log in to Amazon Connect with a user account that has the **Numbers and flows - Flows - Edit** permission in its security profile. If you are archiving a flow module, you need **Flow modules - Edit** permission.
2. On the navigation menu, choose **Routing**, **Flows**.
3. Open the flow or module you want to archive.
4. On the flow designer page, choose the dropdown menu, and then choose **Archive**, as shown in the following image.



5. Confirm you want to archive the flow or module.
6. To locate the archived flow or module, choose **View archive**.

Option 2: Search for flow or module and then archive it

- On the **Flows** page, search for the flow or module you want archive, and then choose **Archive** from the **...** menu, as shown in the following image.

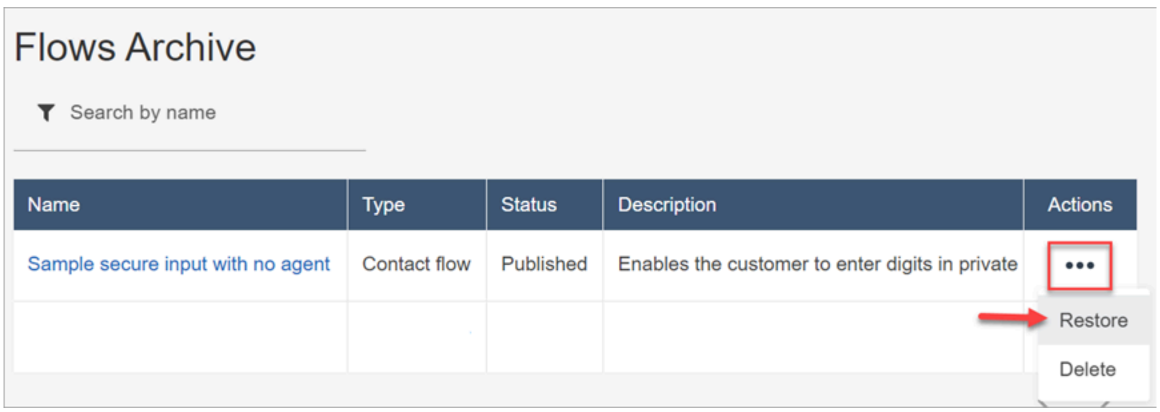


Restore an archived flow or module

There are two ways you can restore flows or modules.

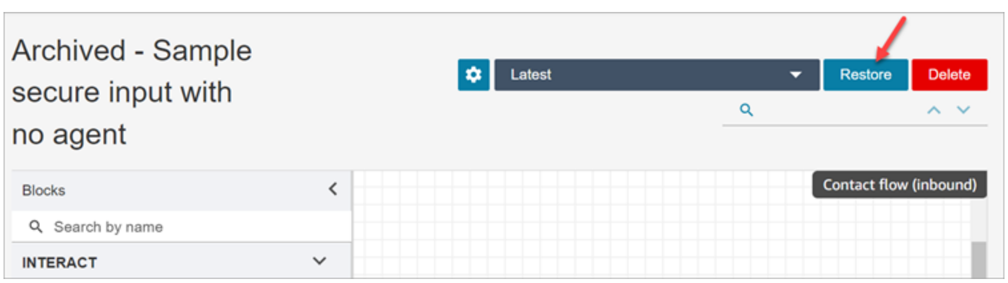
Option 1: View list of archived flows or modules, and choose Restore

1. Log in to the Amazon Connect admin website with a user account that has the **Numbers and flows - Flows - Edit** permission in its security profile. If you are restoring a flow module, you need **Flow modules - Edit** permission.
2. On the navigation menu, choose **Routing**, **Flows**.
3. On the **Flows** page, choose **View archive**.
   - To restore archived modules, on the **Flows** page, choose the **Modules** tab, and then choose **View archive**.
4. On the **Flows Archive** page, next to the flow or module you want to restore, under **Actions**, choose **...** and then choose **Restore**. This option is shown in the following image.



Option 2: Restore the archived flow or module from the flow designer

1. Open the archived flow or module in the flow designer.
2. From the dropdown menu, choose **Restore**, as shown in the following image.



Delete an archived flow or module

You can delete archived flows and modules manually by using the Amazon Connect admin website, or programmatically by using the DeleteContactFlow API.

> **Warning**
>
> Deleted flows and modules cannot be restored. They are permanently deleted from your Amazon Connect instance.

Option 1: View list of archived flows or modules, and choose Delete

1. Log in to the Amazon Connect admin website with a user account that has the **Numbers and flows - Flows - Remove** permission in its security profile. If you are deleting a flow module, you need **Flow modules - Remove** permission.
2. On the navigation menu, choose **Routing**, **Flows**.
3. On the **Flows** page, choose **View archive**.
    - To delete modules, on the **Flows** page, choose the **Modules** tab, and then choose **View archive**.
4. On the **Flows Archive** page, next to the flow or module you want to delete, under **Actions**, choose **...** and then choose **Delete**.
5. Confirm that you want to delete the flow or module.

Option 2: Delete the archived flow or module from the flow designer

1. Open the archived flow or module in the flow designer.
2. From the dropdown menu, choose **Delete**.
3. Confirm that you want to delete the flow or module.

Generate logs for published flows in Amazon Connect

After your flow is published live, you can use flow logs to help analyze flows and quickly find errors your customers encounter. If needed, you can roll back to a previous version of the flow.

For more information about using flow logs, see Track events in your Amazon Connect flow logs as customers interact with them.

Flow version control: Roll back a flow

View a previous version of a flow

This procedure is especially useful if you want to research how a flow has been changed over time.

1. In the flow designer, open the flow you want to view.
2. Choose the **Latest: Published** dropdown to view a list of previously published versions of the flow.

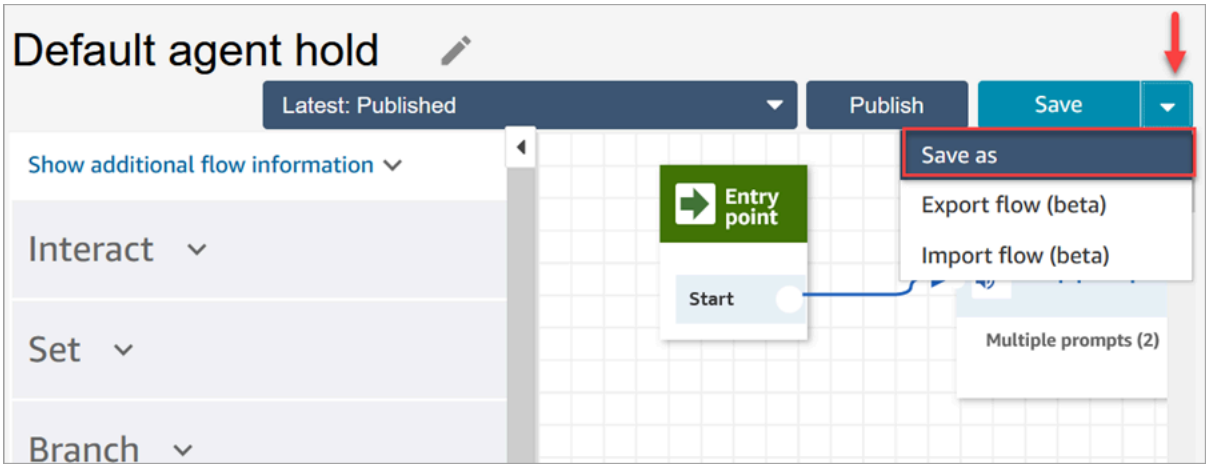
   For default flows that are provided with your Amazon Connect instance, the oldest flow in the list is the original version. The date matches when your Amazon Connect instance was created. For example, in the following image, the original default flow is dated 07/21/22.

   
   > **Note**
   >
   > For users with tag-based access controls configured on their security profile, the dropdown will be restricted to **Latest: Published** and **Latest: Saved** versions. To learn more about tag-based access controls in Amazon Connect, see Apply tag-based access control in Amazon Connect.

3. Choose the version of the flow to open and view it. You can view all the blocks and how they are configured.
4. Next, you can do one of the following:

   - To return to the most recently published version, choose it from the **Latest: Published** dropdown list.

- Make changes to the previous version and choose **Save as** from the dropdown to save it with a new name. Or choose **Save** from the dropdown to assign the same name.



- Or, choose **Publish** to return the previous version to production.

Roll back a flow

1. In the flow designer, open the flow you want to roll back.
2. Use the drop-down to choose the version of the flow you want to roll back to. If you choose **Latest**, it reverts the flow to the most recent published version. If there isn't a published version, it reverts to the most recent saved version.

> **Note**
>
> To see a consolidated view of all changes across all flows, click the **View historical changes** link at the bottom of the **Flows** page. You can filter to a specific flow by date or user name.

3. Choose **Publish** to push that version into production.

Best practices for flows in Amazon Connect

Use the list of recommended best practices in this topic when you are using and creating flows.

- Use consistent attribute naming conventions across all AWS services. Use camel case for yourAttributeNames to avoid confusion when passing and referencing variables.

- Use standard naming conventions for attribute names. Don't use spaces or special characters that could impact downstream reporting processes such as AWS Glue crawlers.
- Create modular flows. Make the flows as small as possible, and then combine modular flows into an end-to-end contact experience. This helps to keep your flows manageable, and you won't require numerous regression testing cycles.
- When you set **User Defined** or **External** values in dynamic attribute fields, use only alphanumeric characters (A-Z, 0–9) and periods. No other characters are allowed.
- Ensure all error branches are routed to a block that effectively handles the error or terminates the contact.
- Use a **Set logging behavior** block to enable or disable logging for segments of the flow where sensitive information is collected and can't be stored in CloudWatch.
- Ensure that attributes used in the flow are set and referenced correctly. If there are periods prepended to the attribute names, you are likely using JSONPath ($.) format while also selecting a variable type from the pick list. For example, using:
  - **Save text as attribute** and value `$.External.variableName` works as expected.
  - `Set dynamically` and value `variableName` works as expected.
  - **Set dynamically** and `$.External.variableName` results in a prepended period.
- Before transferring a call to agent and putting that call in a queue, ensure that **Check hours of operation** and **Check staffing** blocks are used. They verify that the call is within working hours and that agents are staffed to service.
- Ensure that callbacks are offered before and after queue transfer by using **Check queue status** blocks. Include a condition for **Queue capacity** that is greater than X, where X is a number representing your expected queue capacity.
  - If queue capacity exceeds the expected capacity, use a **Get Customer Input** block to offer a callback. This retains the caller's position in the queue and calls them back when an agent is available.
  - In the **Set callback number** block, choose the number to be used to call the customer back in the CCP. Use **System** and **Customer Number** or a new number, collected by a **Store Customer Input** block, using **System** and **Stored customer input**.
  - Finally, add a **Transfer to queue** block. Configure it to **Transfer to callback queue** and configure the callback options to fit your specific use case.
- Use a **Loop prompts** block in your Customer queue flow to interrupt with a queued callback and external transfer option at regular intervals.

- Ensure that all countries referenced in external transfers or used for outbound dialing are added to the service quota for your account/instance.
- Ensure that all numbers referenced in external transfers are in E.164 format. Drop the national trunk prefix that you use when calling locally. This prefix would be the leading 0 for most of Europe, 1 for the US. The prefix is replaced by the country code. For example, the UK mobile number **07911 123456** in E.164 format is **+44 7911 123456 (tel:+447911123456)**.
- Ensure that there are no infinite loops in the flow logic. Also ensure that for each call, the flow connects the caller to an agent, bot, or transferred externally for further assistance.

Contact initiation methods and flow types in your Amazon Connect contact center

Every contact in your Amazon Connect contact center is initiated by one of the following methods:

- Inbound
- Outbound
- Transfer
- Callback
- API
- Queue_Transfer
- Disconnect
- WEBRTC_API

You can create flows appropriate for a given initiation method when you know which types of flows the initiation method uses.

For each initiation method, this topic explains which types of flows are run.

Inbound

The customer initiated a voice (phone) contact with your contact center.

- When the contact successfully connects with the phone number of your contact center, an Inbound flow is presented to caller.
- During the transition in the **Inbound flow**, if the customer is put in a queue, a Customer queue flow is played to customer.

- After the agent becomes available to handle the caller and accept the contact, a Agent whisper flow is played to the agent.
- After a Agent whisper flow completes, a Customer whisper flow is played to customer.
- After the both whisper flows are played successfully to the agent and the customer respectively, the caller gets connected to agent for interaction.

To summarize, for a simple inbound call, the following flow types are played before caller is connected to agent:

1. **Inbound flow**
2. **Customer queue flow**
3. **Agent whisper flow**
4. **Customer whisper flow**

Outbound

An agent initiated voice (phone) contact to an external number, by using their CCP to make the call.

- As soon as the destination party picks the call, they are presented with an Outbound whisper flow.
- After an **Outbound whisper flow** successfully completes, the agent and the contact are connected for interaction.

To summarize, an **Outbound flow** type is the only one involved in an outbound call initiated from Amazon Connect.

Transfer

The contact was transferred by an agent to another agent or to a queue, using quick connects in the CCP. This results in a new contact record being created.

Before the agent transfers the contact to another agent or queue, all the flows involved in an INBOUND contact are run.

- Agent to Agent transfer using Agent Quick Connect
  - After the agent transfers the inbound contact to another agent:

        - A Agent transfer flow is played to the source agent.
        - After the destination agent accepts the call, a Agent whisper flow is played to destination agent, and then a Customer whisper flow is played to source agent.
        - After all three flows are successfully run, the interaction begins between the source and destination agents.
        - During this whole process, the inbound caller is on hold and a Customer hold flow is played to the inbound caller during hold time.

        After the source agent is connected with destination agent, the source agent can do one of the following actions:

        - Choose **Join**. This joins all parties on the call: source agent, destination agent, and the customer are joined in a conference call.
        - Choose **Hold all**. This puts the destination agent and the customer on hold.
        - Put destination agent on hold, so only the source agent can talk to the customer.
        - Choose **End call**. The source agent leaves the call but the destination agent and the customer are directly connected and continue talking.

    To summarize for an agent to agent transfer call, the following flow types are run:

    1. **Agent transfer flow**
    2. **Agent whisper flow** (played to the destination agent)
    3. **Customer whisper flow** (played to the source agent) during whole this process
    4. **Customer hold flow** played to the original caller

- Agent to Queue transfer using Queue Quick Connect
    - After the agent transfers the inbound call to another queue:
        - A Queue transfer flow is played to source agent.
        - After the agent from the transferred queue accepts the call, an Agent whisper flow is played to destination agent, and then a Customer whisper flow is played to source agent.
        - After these flows run, the source and destination agent interaction begins.
        - During this whole process, the inbound caller is on hold. A Customer hold flow is played to the inbound caller during the hold time.

        After the source agent is connected with destination agent, the source agent can do one of the following:

- Choose **Join**. This joins all parties on the call: source agent, destination agent, and the customer are joined in a conference call.
- Choose **Hold all**. This puts destination agent and the customer on hold.
- Put destination agent on hold, so only the source agent can talk to the customer.
- Choose **End call**. The source agent leaves the call but the destination agent and the customer are directly connected and continue talking.

To summarize for agent to queue transfer call, the following flows are played:

1. **Queue transfer flow**
2. **Agent whisper flow** (played to the destination agent)
3. **Customer whisper flow** (played to the source agent) during whole this process
4. **Customer hold flow** played to the original caller

Callback

The customer is contacted as part of a callback flow.

- As soon as agent accepts the callback contact, an Agent whisper flow is played to the agent.
- After the customer accepts the callback call, an Outbound whisper flow is played to customer.
- After these two flows are played, the agent and customer are connected and can interact.

To summarize, for callback contacts, the following flow types are played:

- **Agent whisper flow**
- **Outbound whisper flow**

API

The contact was initiated with Amazon Connect by API. This could be:

1. An outbound contact you created and queued to an agent using the StartOutboundVoiceContact API.
2. A live chat that was initiated by the customer with your contact center where you called the StartChatContact API.
3. A task that was initiated by calling the StartTaskContact API.

Following is an example of an API initiated contact method:

- After the outbound contact is successfully initiated using the StartOutboundVoiceContact API, an Inbound flow provided in the API request is played to the customer.
- Depending on the configuration of the Inbound flow, additional flows are played. For example, an Inbound flow transfers a customer to an agent for conversation. In this case, a Customer queue flow is played to customer while they waiting in queue for an agent.
- When the available agent accepts the call, an Agent whisper flow is played to agent.
- A Customer whisper flow is played to customer.
- After both whisper flows are played successfully to the agent and customer respectively, the caller is connected to agent for interaction.

To summarize API initiation methods, the following flows are played before the customer is connected to agent:

- **Inbound flow**
- **Customer queue flow**
- **Agent whisper flow**
- **Customer whisper flow**

Queue_Transfer

While the customer was in one queue (listening to a Customer queue flow), they were transferred into another queue using a flow block.

- The customer who is waiting in the queue for an agent is presented only with a Customer queue flow. No additional flows are involved.

Disconnect

When a Set disconnect flow block runs, it specifies which flow to run after a disconnect event during a contact.

- You can specify only an Inbound contact flow in this block. Since it occurs after the disconnect event, no additional flow is presented to customer.

WEBRTC_API

The contact used the communication widget to make an in-app voice/video call to an agent.

Override the default contact flows

For all of the initiation methods discussed in this topic, if you don't specify flows for **Agent whisper flow**, **Customer whisper flow**, **Customer queue flow**, or **Outbound whisper flow**, then the default flow of that type runs instead. For a list of default flows, see Default flows in Amazon Connect for your call center.

To override the defaults and use your own flows, use the following blocks:

- Set customer queue flow
- Set hold flow
- Set whisper flow

For more information, see Default flows in Amazon Connect for your call center.

Attach a claimed or ported phone number to a flow in Amazon Connect

After you publish a flow, you can attach a claimed or ported phone number to it. When a contact calls the phone number that you associate with a flow, they are connected to that flow.

To associate a claimed or ported phone number with a published flow

1. Log in to your Amazon Connect instance (https://*instance name*.my.connect.aws/) with an Admin account or a user account that has **Phone number - Edit** permissions in it's security profile. (To find the name of your instance, see Find your Amazon Connect instance ID or ARN.)
2. On the navigation menu, choose **Channels**, **Phone numbers**.
3. Locate the phone number to associate with the flow in the list. Click the phone number to open the **Edit Phone number** page. The following image shows a sample phone number that you would click.

4. On the **Edit Phone number** page, do the following:

   a. (Optional) Edit the description for the phone number.

   b. For **Flow / IVR**, select the flow. Note that only published flows are included in this list.

   c. Choose **Save**.

Flow modules for reusable functions in Amazon Connect

Flow modules are reusable sections of a flow. You can create them to extract repeatable logic across your flows, and create common functions. For example:

1. You can create a module that sends SMS text messages to customers.
2. You can invoke the module in flows that handle situations where customers want to reset their passwords, check their bank balances, or receive a one-time password.

Following are the benefits of using modules:

- Simplify managing common functionality across flows. For example, an SMS module could validate the format of phone number, confirm SMS opt-in preferences, and integrate with an SMS service, such as Amazon Pinpoint.
- Makes it more efficient to maintain flows. For example, you can quickly propagate changes across all flows that invoke a flow module.
- Helps separate flow designer responsibilities. For example, you can have both technical module designers and non-technical flow designers.

Where you can use modules

You can use modules in any flow that is type **Inbound flow**.

The following types of flows do not support modules: **Customer queue**, **Customer hold**, **Customer whisper**, **Outbound whisper**, **Agent hold**, **Agent whisper**, **Transfer to agent**, **Transfer to queue**.

Limitations

- Modules do not allow overriding flow local data of the invoking flow. This means you can't use the following with modules:
  - External attributes
  - Amazon Lex attributes
  - Customer Profiles attributes
  - Amazon Q in Connect attributes
  - Queue metrics
  - Stored customer input
- Modules do not allow invoking another module.

To pass any data to a module, or to get any data from a module, you need to pass and retrieve attributes.

For example, you want data that is written from Lambda (an External attribute) and pass it to the module so you can make a decision. Your Lambda identifies whether the customer is a VIP member. You need that information inside the module because if they are a VIP member, you want to play a prompt thanking them for their membership. Since default Lambda is not available inside a module, you use attributes to pass and retrieve data.

Security profile permissions for modules

Before you can add modules to Inbound flows, you must have permissions in your security profile. By default, the **Admin** and **CallCenterManager** security profiles have these permissions.

Create a module

For information about the number of modules that you can create for each Amazon Connect instance, see Amazon Connect service quotas.

1. Log in to the Amazon Connect console with an account assigned to a security profile that has permissions to create modules.

2. On the navigation menu, choose **Routing**, **Contact flows**.
3. Choose **Modules**, **Create flow module**.
4. Add the blocks that you want to your module. When finished, choose **Publish**. This makes the module available to use in other flows.

Add a module to a flow

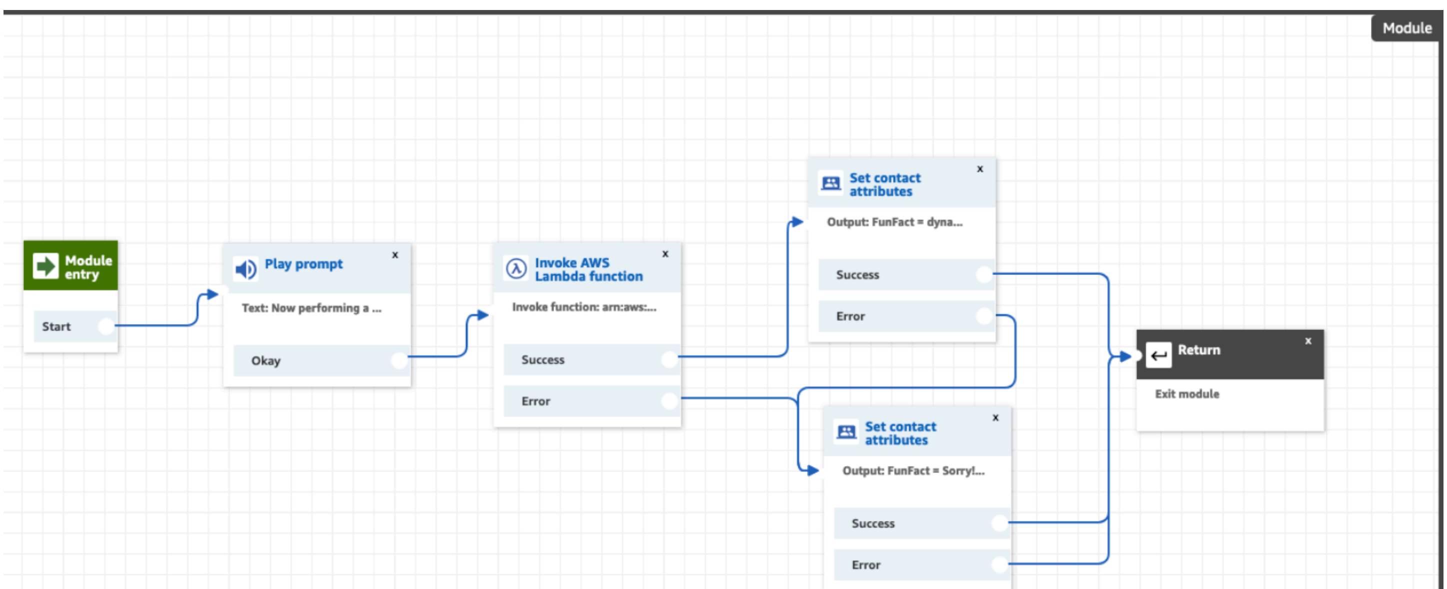
1. Log in to the Amazon Connect console with an account assigned to a security profile that has permissions to create flows. You don't need permissions to create modules.
2. On the navigation menu, choose **Routing**, **Contact flows**.
3. Choose **Create flow** or select an existing flow that is an **Inbound** type.
4. To add a module, go to the **Integrate** section, and choose **Invoke flow module**.
5. When you're finished creating your flow, choose **Publish**.

Example module

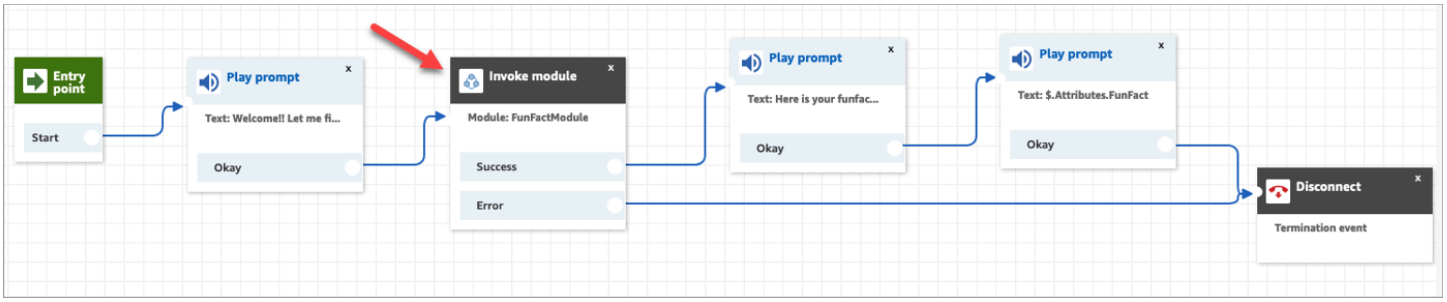
This module shows how to get a random fun fact by invoking a Lambda function. The module uses a contact attribute (`$.Attributes.FunFact`) to retrieve the fun fact. Flows that invoke this module can play a FunFact to customers, depending on their incoming contact type.

The inbound flows in your instance can invoke this common module and get the fun fact.

Following is an image of the FunFact module:



Following is an image of the FunFactSampleFlow that invokes the module:



Create prompts in Amazon Connect

Prompts are audio files played in call flows. For example, hold music is a prompt. Amazon Connect comes with a set of prompts that you can add to your flows. Or, you can add your own recordings.

We recommend that you align your prompts and routing policies with each other to ensure a smooth call flow for customers.

You can create and manage prompts by using the Amazon Connect admin site as described in the topics in this section. Or you can use the Prompt actions documented in the *Amazon Connect API Reference Guide*.

Contents

How to create prompts

This topic explains how to use the Amazon Connect admin website to create prompts. To create prompts programmatically, see CreatePrompt in the *Amazon Connect API Reference Guide*.

1. Log in to Amazon Connect using an account that has the following security profile permission:

   - **Numbers and flows**, **Prompts - Create**

2. On the navigation menu, choose **Routing**, **Prompts**.
3. On the **Prompts** page, choose **Add prompt**.
4. On the **Add Prompt** page, enter a name for the prompt.
5. In the **Description** box, describe the message. We recommend using this box to provide a detailed description of the prompt. It is helpful for accessibility.
6. Choose the following actions:

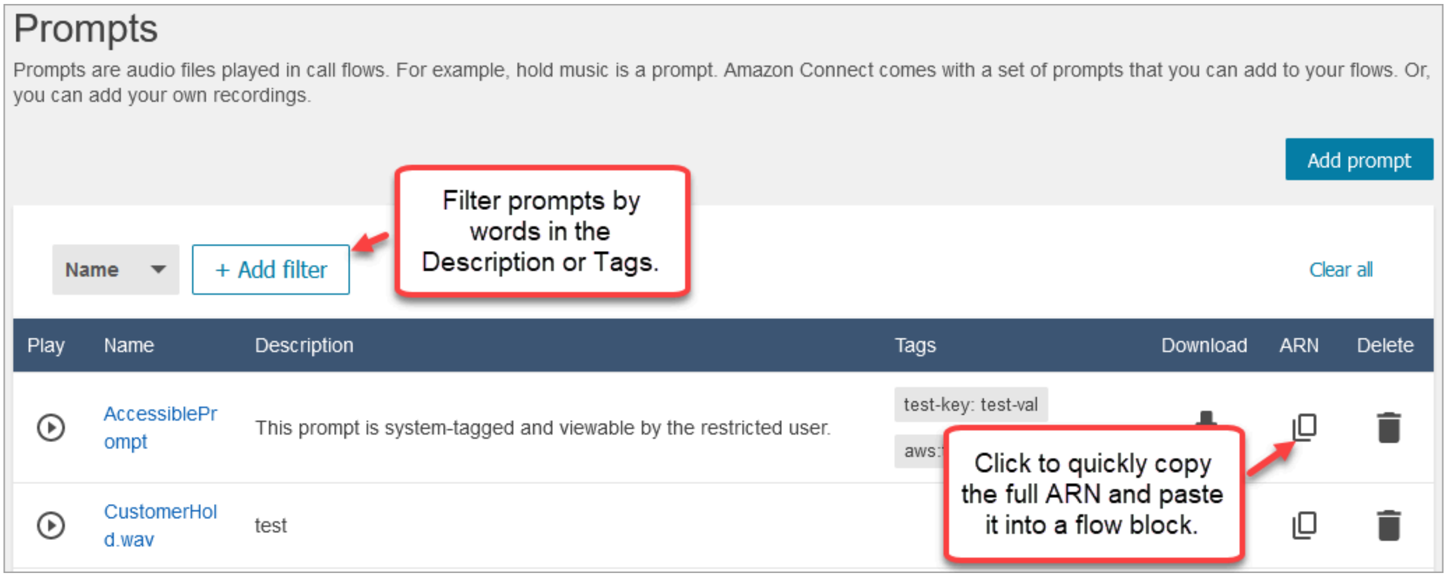
   - **Upload**—Select **Choose File** to upload a .wav file that you have legal permission to use.
   - **Record**—Choose **Start recording** and speak into your microphone to record a message. Choose **Stop recording** when you're finished. You can choose **Crop** to cut sections of the recorded prompt or choose **Clear recording** to record a new prompt.

7. In the **Prompt Settings** section, enter any tags you want to use to manage the prompt.

   For example, you may have a department that manages prompts for greetings. You can tag those prompts so users can focus on only those recordings that pertain to them.

8. Optionally, add tags to identify, organize, search for, filter, and control who can access this prompt. For more information, see Add tags to resources in Amazon Connect.

Use the filters on the **Prompts** page to filter the list of prompts by **Name**, **Description**, and **Tags**. To copy the full Amazon Resource Name (ARN) of a prompt with just one click, choose the **Copy** icon. When you set up dynamic prompts in a flow, you'll need to enter the full ARN of the prompt.



Supported file types

You can upload a pre-recorded .wav file to use for your prompt, or record one in the web application.

We recommend using 8 KHz .wav files that are less than 50 MB and less than 5 minutes long. If you use higher rated audio libraries, such as 16 KHz files, Amazon Connect has to down sample them into 8 KHz samples because of PSTN limitations. This may result in low quality audio. For more information, see the following Wikipedia article: G.711.

Maximum length for prompts

Amazon Connect supports prompts that are less than 50 MB and less than 5 minutes long.

Bulk upload of prompts not supported in UI, API, or CLI

Currently, bulk uploading of prompts is not supported through the Amazon Connect console or programmatically using the API or CLI.

Add text-to-speech to prompts in flow blocks in Amazon Polly

You can enter text-to-speech prompts in the following flow blocks:

- Get customer input
- Loop prompts
- Play prompt

- Store customer input

Amazon Polly converts text-to-speech

To convert text-to-speech, Amazon Connect uses Amazon Polly, a service that converts text into lifelike speech using SSML.

Amazon Polly default voices such as Amazon Polly Neural and Standard voices are **free**. You are charged only for using custom voices such as unique Brand Voices that are associated with your account.

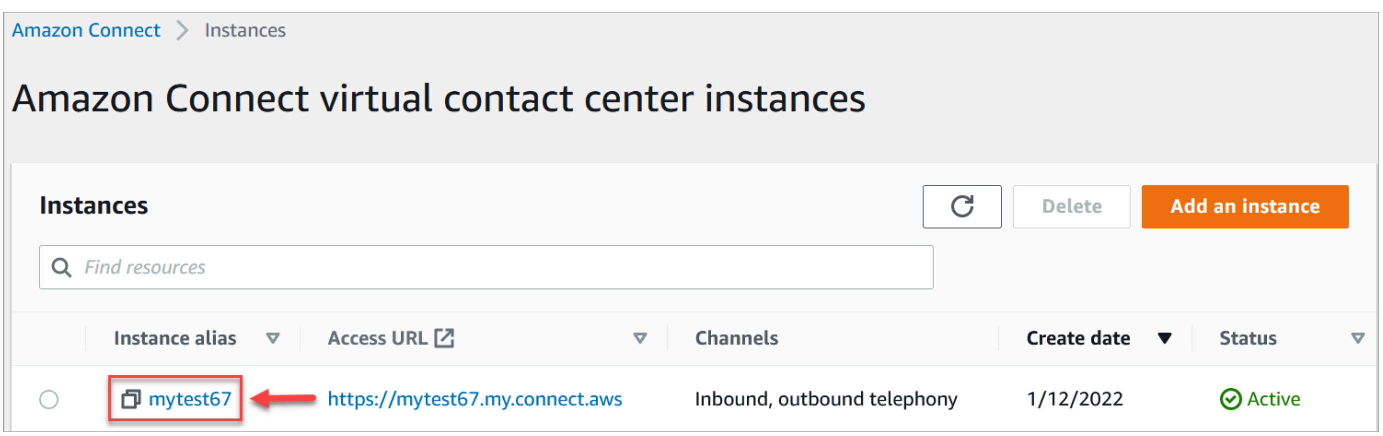
Amazon Polly best sounding voice

Amazon Polly periodically releases improved voices and speaking styles. You can choose to automatically resolve your text-to-speech to the most lifelike and natural sounding variant of a voice. For example, if your flows use Joanna, Amazon Connect automatically resolves to Joanna's conversational speaking style.

> **Note**
>
> If no Neural version is available, Amazon Connect defaults to the standard voice.

To automatically use the best sounding voice

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. If prompted to login, enter your AWS account credentials.
3. Choose the name of the instance from the **Instance alias** column.

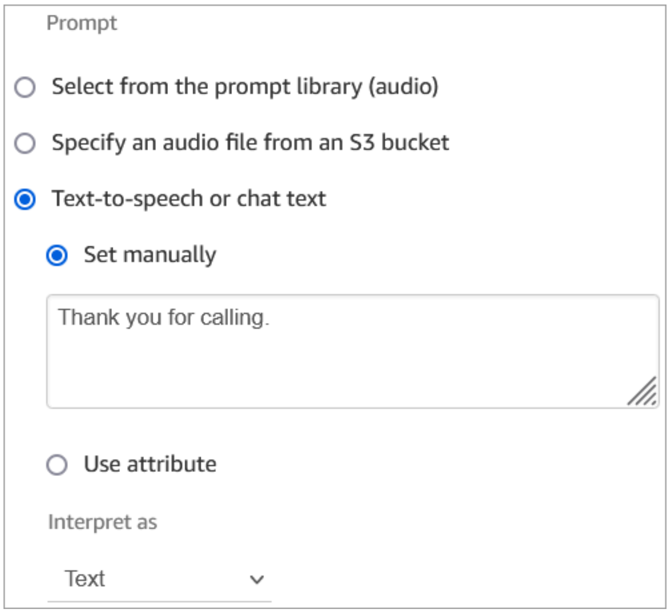


4. In the navigation pane, choose **Flows**.

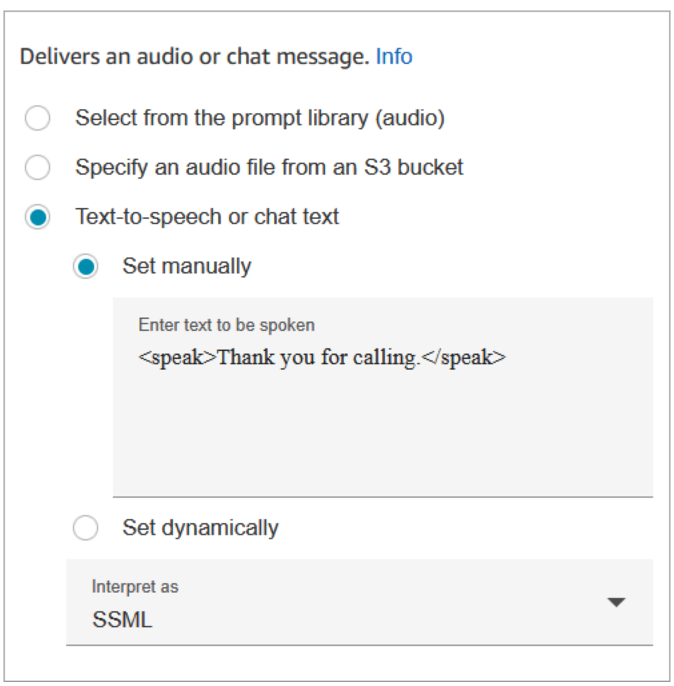
5. In the Amazon Polly section, choose **Use the best available voice**.

How to add text-to-speech

1. In a flow, add the block that will play the prompt. For example, add a Play prompt block.
2. In the **Properties**, choose **Text-to-speech**.
3. Enter plain text. For example, the following image shows *Thank you for calling*.



Or enter SSML, as shown in the following image:



SSML-enhanced input text gives you more control over how Amazon Connect generates speech from the text you provide. You can customize and control aspects of speech such as pronunciation, volume, and speed.

For a list of SSML tags you can use with Amazon Connect, see SSML tags supported by Amazon Connect.

For more information about Amazon Polly, see Using SSML in the Amazon Polly Developer Guide.

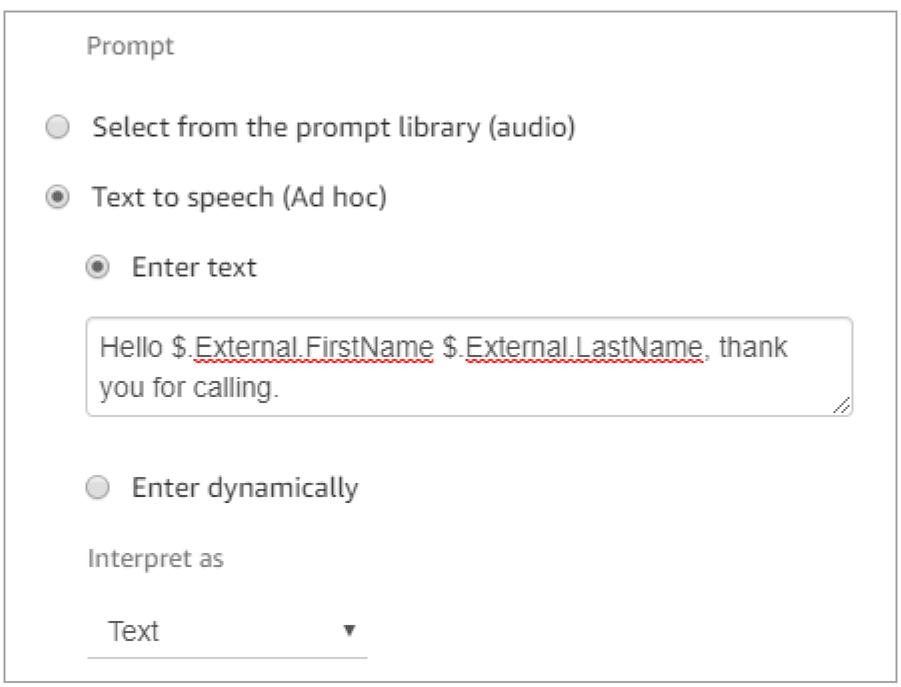
Create dynamic text strings in Play prompt blocks in Amazon Connect

Use a Play prompt block to use an audio file to play as a greeting or message to callers. You can also use contact attributes to specify the greeting or message delivered to callers. To use the values of a contact attribute to personalize a message for a customer, include references to stored or external contact attributes in the text-to-speech message.

For example, if you retrieved the customer's name from a Lambda function, and it returns values from your customer database for FirstName and LastName, you could use these attributes to say the customer's name in the text-to-speech block by including text similar to the following:

- Hello $.External.FirstName $.External.LastName, thank you for calling.

This message is shown in the following image of the text-to-speech box of the Play prompt block.



Alternatively, you could store the attributes returned from the Lambda function using a **Set contact attributes** block, and then reference the user-defined attribute created in the text-to-speech string.

If you are referencing a user-defined attribute that was previously set as a contact attribute in the flow using the API, you can reference the attribute using the $.Attributes.nameOfAttribute syntax.

For example, if the contact in question has attributes "FirstName" and "LastName" set previously, reference them as follows:

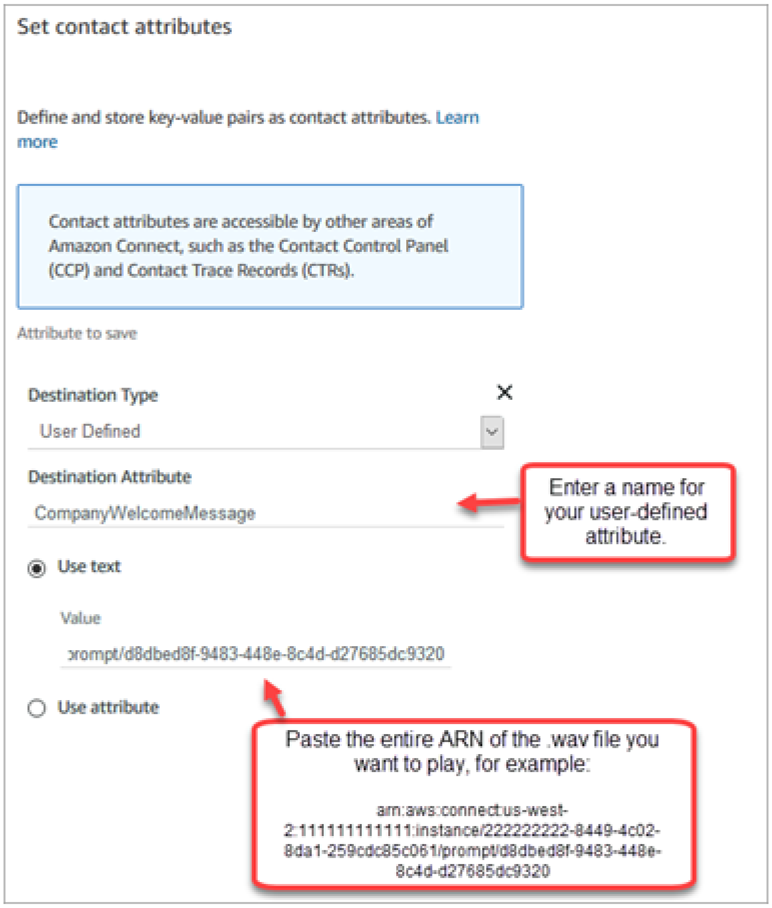
- Hello $.Attributes.FirstName $.Attributes.LastName, thank you for calling.

Dynamically select which prompts to play in Amazon Connect

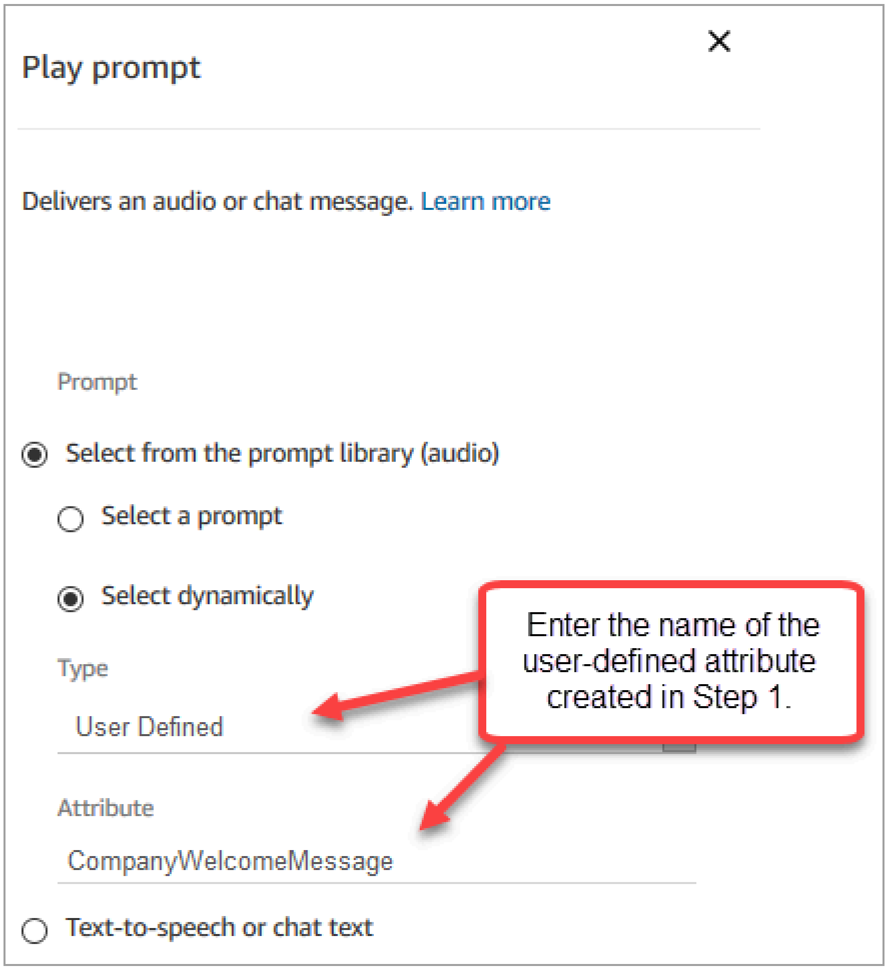
You can dynamically select which prompt to play by using an attribute.

1. Add Set contact attributes blocks to your flow. Configure each one to play the appropriate audio prompt. For example, the first one might play the .wav file when your contact center is open. The second one might play the .wav file for when it's closed.

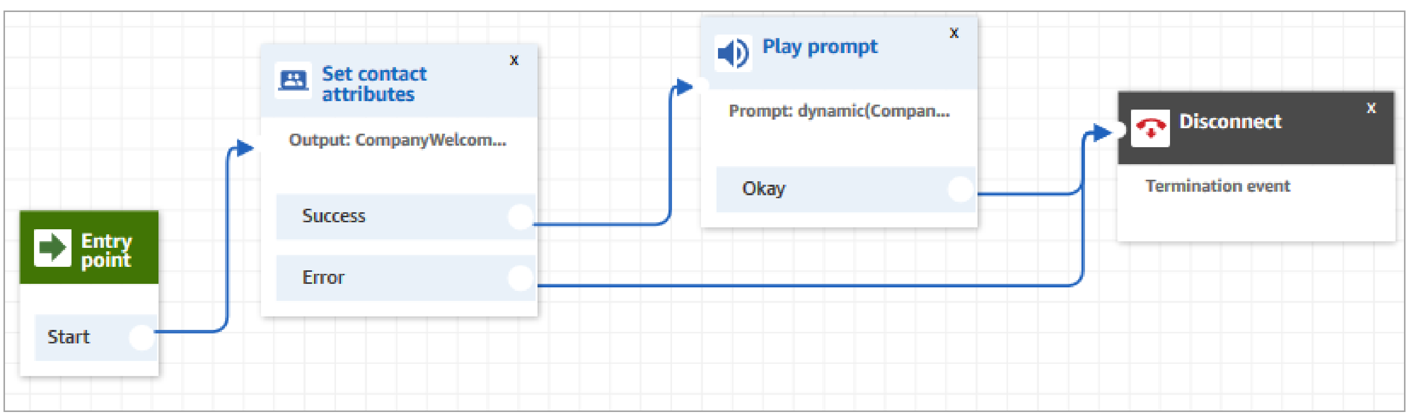
   The following image shows how you might configure a Set contact attributes block. In this example, the user-defined attribute is named **CompanyWelcomeMessage**. You can name your attribute anything you want.



2. In the Play prompt block, choose **User Defined**, and then enter the name of the attribute that you created in step 1, as shown in the following image.



3. Connect the [Set contact attributes](#) blocks to the **Play prompt** block. The following example shows how it might look if you added one of each block to test how this works.



Set up prompts to play from an S3 bucket in Amazon Connect

When you configure prompts on the [Get customer input](#), [Loop prompts](#), [Play prompt](#), or [Store customer input](#) blocks, you can choose an S3 bucket as the source location. You can store as many voice prompts as needed in an S3 bucket and access them in real time by using contact attributes. For examples, see the Play prompt block.

Requirements

- **Supported formats**: Amazon Connect supports .wav files to use for your prompt. You must use .wav files that are 8KHz, and mono channel audio with U-Law encoding. Otherwise, the prompt won't play correctly. You can use publicly available third-party tools to convert your .wav files to U-Law encoding. After converting the files, upload them to Amazon Connect.
- **Size**: Amazon Connect supports prompts that are less than 50MB and less than five minutes long.
- **For Regions that are disabled by default** (also called opt-in Regions) such as Africa (Cape Town), your bucket must be in the same Region.

Update the S3 bucket policy

To allow Amazon Connect to play prompts from an S3 bucket, when you set up your S3 bucket, you must update the bucket policy to grant `connect.amazonaws.com` (the Amazon Connect service principal) permission to call `s3:ListBucket` and `s3:GetObject`.

To update the S3 bucket policy:

1. Go to the Amazon S3 admin console.
2. Choose the bucket that has your prompts.
3. Choose the **Permissions** tab.
4. In the **Bucket policy** box, choose **Edit**, and paste the following policy as your template. Replace the bucket name, Region, AWS account ID, and instance ID with your own information, and then choose **Save changes**.

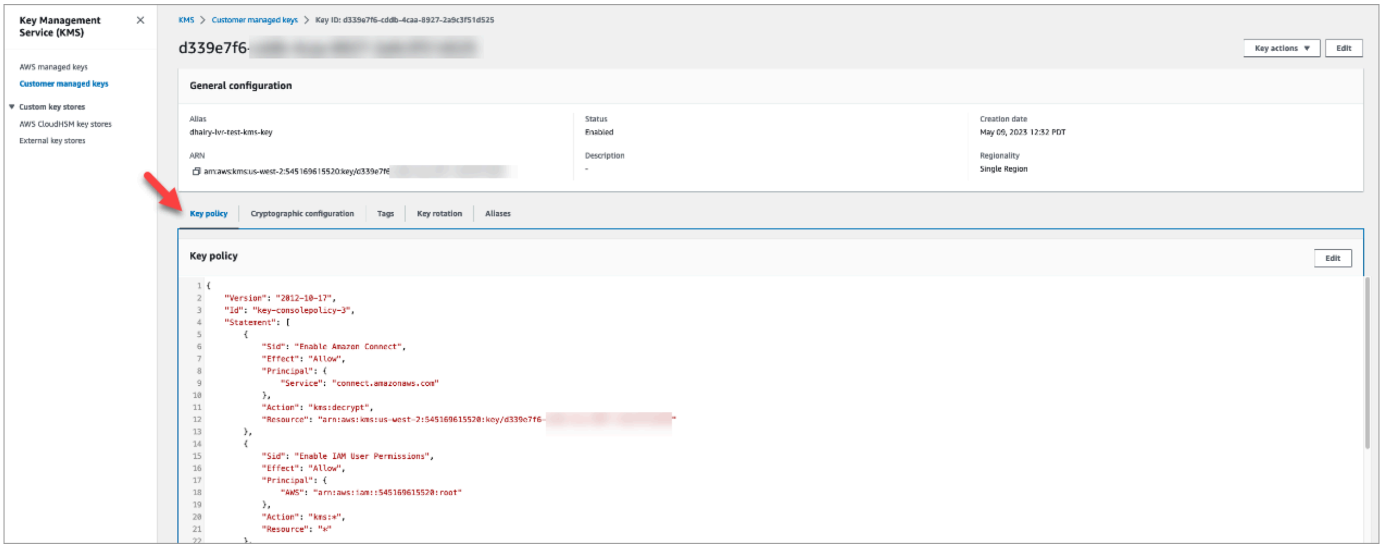
```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "statement1",
            "Effect": "Allow",
            "Principal": {
                "Service": "connect.amazonaws.com"
            },
```

```
            "Action": [
                "s3:ListBucket",
                "s3:GetObject"
            ],
            "Resource": [
                "arn:aws:s3:::amzn-s3-demo-bucket1",
                "arn:aws:s3:::amzn-s3-demo-bucket1/*"
            ],
            "Condition": {
                "StringEquals": {
                    "aws:SourceAccount": "account-id",
                    "aws:SourceArn": "arn:aws:connect:region:account-
id:instance/instance-id"
                }
            }
        }
    ]
}
```

5. Encryption: Amazon Connect cannot download and play prompts from an S3 bucket if an AWS managed key is enabled on that S3 bucket. However, you can use a customer managed key to allow the Amazon Connect service principal ("connect.amazonaws.com") that enables your Amazon Connect instance to access the S3 bucket. See the following code snippet:

```
{
            "Sid": "Enable Amazon Connect",
            "Effect": "Allow",
            "Principal": {
                "Service": "connect.amazonaws.com"
            },
            "Action": "kms:decrypt",
            "Resource": [
             "arn:aws:kms:region:account-ID:key/key-ID"
            ]
}
```

   The following image shows where you place the code on the **Key policy** tab on the AWS Key Management Service console.



For information on how to find the key ID, see Finding the key ID and key ARN in the *AWS Key Management Service Developer Guide*.

After you set up your S3 bucket with the required bucket policy, configure Get customer input, Loop prompts, Play prompt, or Store customer input to play a prompt from the bucket.

> **Tip**
>
> For more information about S3 buckets, including examples and limitations, see the Play prompt block.

Choose the text-to-speech voice and language for audio prompts in Amazon Connect

You select the text-to-speech voice and language in the Set voice block.

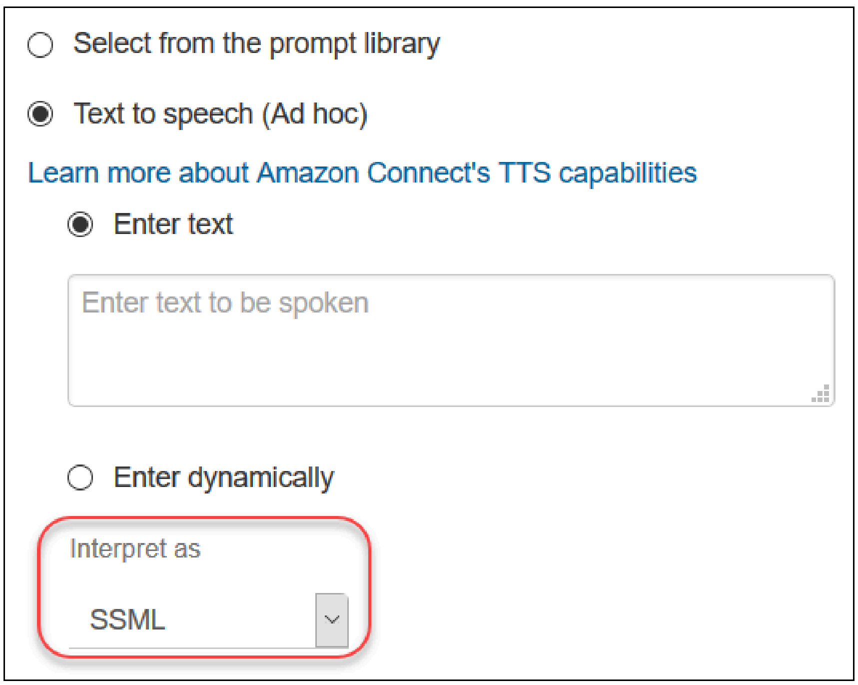
You can also use SSML in Amazon Lex bots to modify the voice used by a chat bot when interacting with your customers. For more information about using SSML in Amazon Lex bots, see Managing Messages and Managing Conversation Context in the Amazon Lex Developer Guide.

> **Tip**
>
> If you enter text that isn't supported for the Amazon Polly voice you are using, it won't be played. However, any other supported text in the prompt will be played. For a list of supported languages, see Languages Supported by Amazon Polly.

Use SSML tags to personalize text-to-speech in Amazon Polly

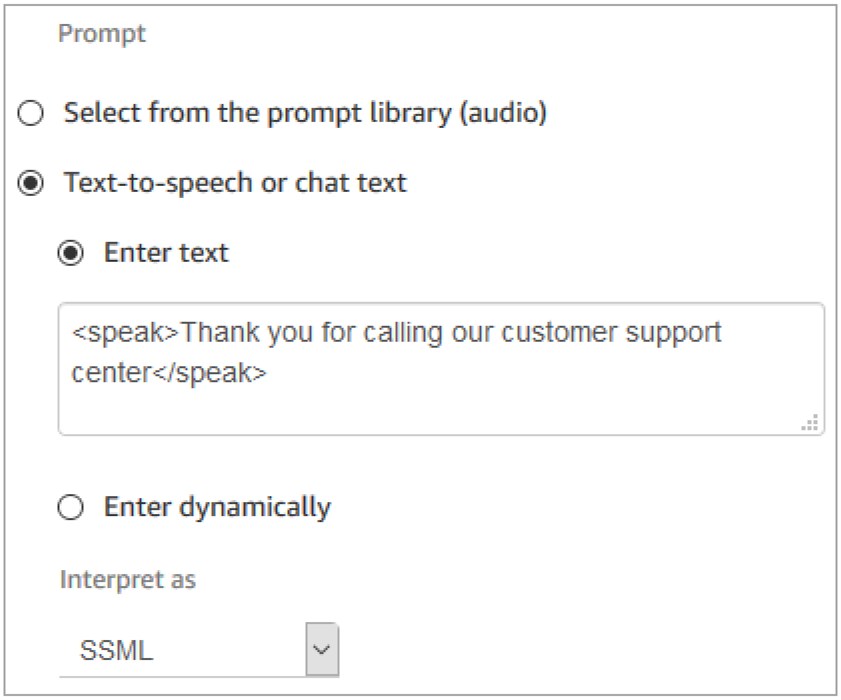
When you add a prompt to a flow, you can use SSML tags to provide a more personalized experience for your customers. SSML tags are a way to control how Amazon Polly generates speech from the text you provide.

The default setting in a flow block for interpreting text-to-speech is **Text**. To use SSML for text to speech in your flow blocks, set the **Interpret as** field to **SSML** as shown in the following image.



SSML tags in an Amazon Connect chat conversation

If you create text-to-speech text and apply SSML tags, they won't be interpreted in a chat conversation. For example, in the following image both the text **and tags** will be printed in the chat conversation.



SSML tags supported by Amazon Connect

Amazon Connect supports the following SSML tags.

> **Tip**
>
> If you use an unsupported tag in your input text, it's automatically ignored when it's processed.

Tag	Use to...
speak	All SSML-enhanced text must be enclosed within a pair of speak tags.
break	Add a pause to your text. The maximum duration for a pause is 10 seconds.
lang	Specify another language for specific words.
mark	Put a custom tag within the text.

Tag	Use to...
p	Add a pause between paragraphs in your text.
phoneme	Make a phonetic pronunciation for specific text.
prosody	Control the volume, rate, or pitch of your selected voice.
s	Add a pause between lines or sentences in your text.
say-as	Combine with the interpret-as attribute to tell Amazon Polly how to say certain characters, words, and numbers.
sub	Combine with the alias attribute to substitut e a different word (or pronunciation) for selected text such as an acronym or abbreviat ion.
w	Customize the pronunciation of words by specifying the word’s part of speech or alternate meaning.
amazon:effect name="whispered"	Indicate that the input text should be spoken in a whispered voice rather than as normal speech.

If you use an unsupported tag in your input text it is automatically ignored when it is processed.

To learn more about the SSML tags, see Supported SSML Tags in the Amazon Polly Developer Guide.

Neural and Conversational Speaking Styles

For the **Joanna** and **Matthew** neural voices, in American English (en-US), you can also specify a Newscaster speaking style.

Set up contact transfers in Amazon Connect

Amazon Connect enables you to set up different kinds of transfers:

- Agent-to-agent transfers: For example, if you want agents to be able to transfer calls or tasks to other agents.
- Transfers to a specific agent: For example, if you want to route contacts to the last agent the customer interacted with, or route contacts to agents who have specific responsibilities.
- Transfers to queues: For example, if you want to transfer the contact to a sales, support, or escalation queue. To do this, create a queue quick connect. This works with voice, chat, and task contacts.
- Transfers to phone numbers: For example, if you want to transfer the contact to a phone number, such as an on-call pager. To do this, create an phone number quick connect.

Overview of steps

To set up call transfers and quick connects

1. Choose a flow type based on what you want to do: Transfer to agent or Transfer to queue. Phone number transfers do not require a specific type of contact flow.
2. Create and publish the flow.
3. Create a quick connect for the type of transfer to enable: **Agent**, **Queue**, or **Phone number**.

   When you create the **Agent** or **Queue** quick connect, select a flow that matches the type of transfer to enable. **Phone number** quick connects require only a phone number, and do not allow you to set a queue or flow.
4. Add the quick connect that you created to any queue used in a flow for which to enable contact transfer, such as the queue used in the flow for incoming contacts.
5. Make sure the queue is in a routing profile assigned to the agents who transfers contacts.

Create quick connects in Amazon Connect

Quick connects are a way for you to create a list of destinations for common transfers. For example, you might create a quick connect for Tier 2 support. If agents in Tier 1 support can't solve the issue, they will transfer the contact to Tier 2.

How many quick connects can I create? To view your quota of **Quick connects per instance**, open the Service Quotas console at https://console.aws.amazon.com/servicequotas/.

Types of quick connects

The type of a quick connect specifies the destination. You can specify one of the following destinations.

Phone number quick connect

Contacts are transferred to a phone number (such as an on-call pager).

User quick connect

Contacts are transferred to a specific user, such as an agent, as part of a flow.

> **Important**
>
> User and Queue quick connects only appear in the CCP when an agent goes to transfer a contact.

Queue quick connect

Contacts are transferred to a queue as part of a flow.

> **Important**
>
> User and Queue quick connects only appear in the CCP when an agent goes to transfer a contact.

Step 1: Create quick connects

Following are the instructions to add quick connects manually using the Amazon Connect console. To add quick connects programmatically, use the CreateQuickConnect API.

To add quick connects

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. To find the name of your instance, see Find your Amazon Connect instance ID or ARN.
2. On the navigation menu, choose **Routing**, **Quick connects**.

3. For each quick connect, do the following:

   a. Choose **Add new**.
   b. Enter a unique name. If desired, also enter a description.
   c. Choose a type.
   d. Enter the destination (for example, a phone number, the name of an agent, or the name of a queue).
   e. Enter a flow, if applicable.
   f. Enter a description.
4. When you're finished adding quick connects, choose **Save**.

Step 2: Enable agents to see quick connects

To enable your agents to see the quick connects in the CCP when they transfer a contact

1. After you create the quick connect, go to **Routing**, **Queues** and then choose the appropriate queue for the contact to be routed to.
2. On the Edit queue page, in the Quick connect box, search for the quick connect you created.
3. Select the quick connect and then choose **Save**.

> **Tip**
>
> Agents see the quick connects of the queues in their routing profile, including the Default outbound queue.

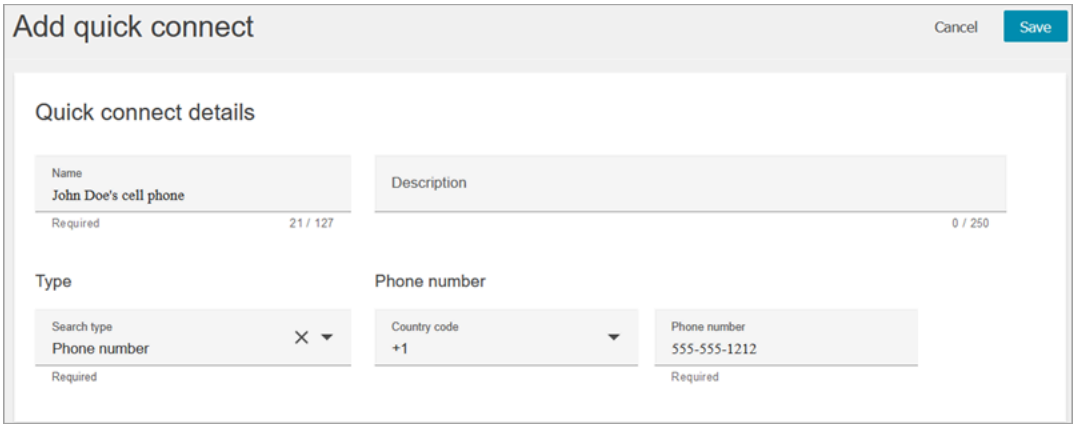
Example: Create a phone number quick connect to a mobile phone

In this example, you create a phone number quick connect to a person's mobile phone. This might be for a supervisor, for example, so agents can call them if needed.

Create a quick connect for a person's mobile phone number

1. On the navigation menu, choose **Routing**, **Quick connects**, **Add quick connect**.
2. On the **Add quick connect** page, enter a name for the quick connect, for example, **John Doe's cell phone**.

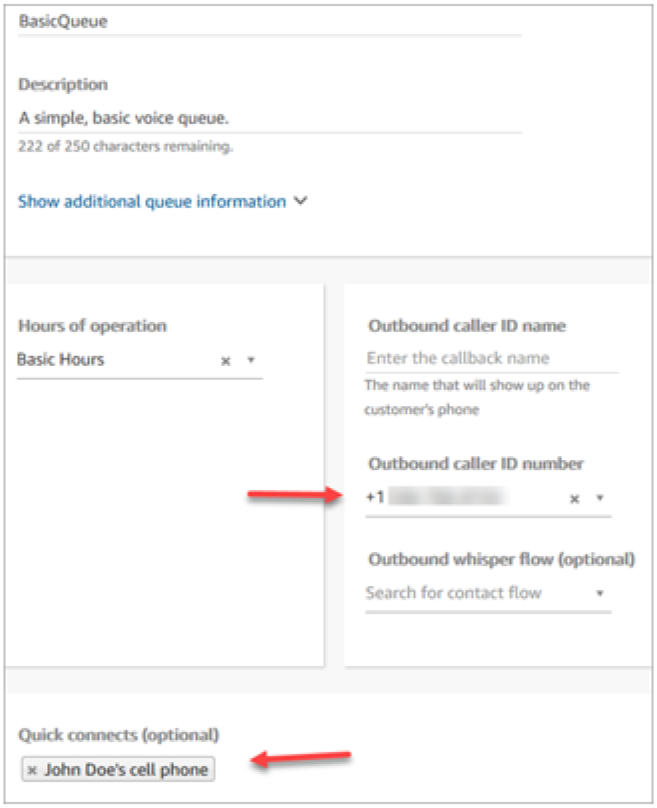
3. For **Type**, select **Phone number**.
4. For **Phone number**, enter the mobile phone number, starting with the country code. In the US, the country code is 1, as shown in the following image.



5. Choose **Save**.

Add the quick connect to a queue. Agents working this queue will see the quick connect in their CCP.

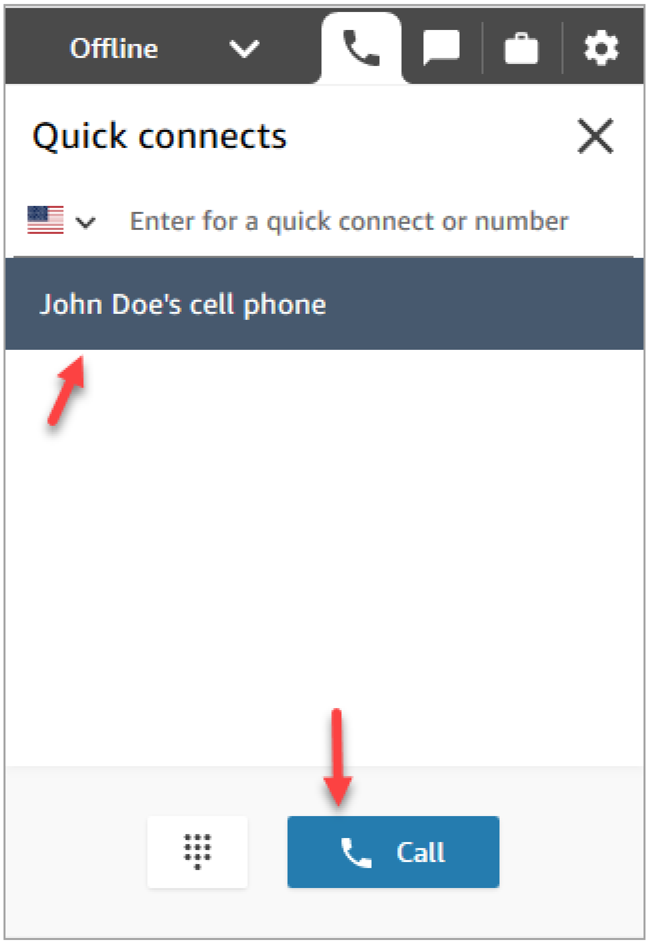
1. Go to **Routing**, **Queues**, and choose the queue you want to edit.
2. On the **Edit queue** page, in **Outbound caller ID number**, choose a number claimed for your contact center. This is required to make outbound calls.
3. At the bottom of the page, in the **Quick connect** box, search for the quick connect you created, for example, **John Doe's cell phone**.
4. Select the quick connect. In the following image of the **Edit queue** page, a phone number has been selected for the **Outbound caller ID number**, and **John Doe's cell phone** has been selected as the quick connect.



5. Choose **Save**.

Test the quick connect

1. Open the Contact Control Panel.
2. Choose **Quick connects**.
3. Select the quick connect you created, and then choose **Call**.



Delete quick connects in the Amazon Connect admin website

There are two ways you can delete a quick connect:

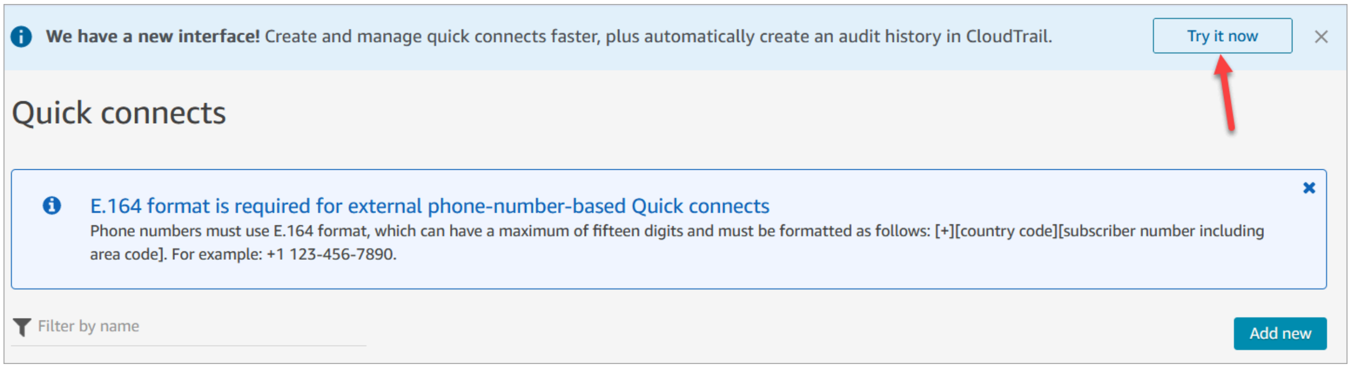
- Use the Amazon Connect admin website. This topic provides instructions.
- Use the DeleteQuickConnect API.

To delete a quick connect

1. Log in to your Amazon Connect instance (https://*instance name*.my.connect.aws/) with an Admin account or a user account that has **Quick connects - Delete** permissions in its security profile. (To find the name of your instance, see Find your Amazon Connect instance ID or ARN.)
2. On the navigation menu, choose **Routing**, **Quick connects**.
3. Select the quick connect, and then choose the **Delete** icon.

If you don't see the delete option, check the following:

- You are using the latest Amazon Connect user interface. The following image shows a banner at the top of the **Quick connects** page. Choose **Try it now** to use the latest Amazon Connect user interface.



- You have **Quick connects - Delete** permission in your security profile.

Quick connect scenarios for transferring contacts

This article explains how each type of quick connect works: agent, queue, and phone number quick connects. It explains which flows are used, and what appears on the agent's Contact Control Panel (CCP).

> **Tip**
>
> For all three types of quick connects, when the quick connect is invoked, the contact that the agent is working on hears the [Default customer hold](#) flow unless you specify a different customer hold flow.

User quick connects

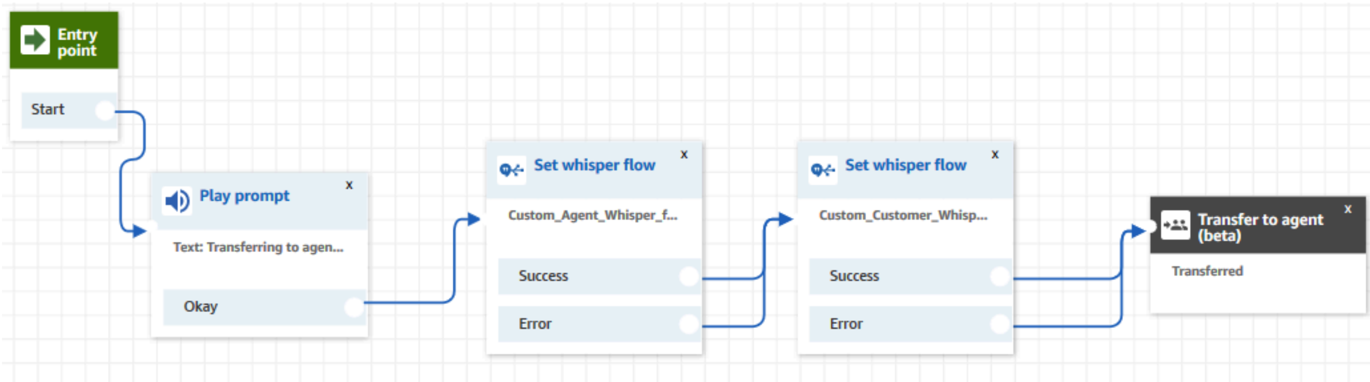
Let's say an agent named John is talking to a customer. During the conversation he needs to transfer the call to an agent named Maria. This is a user quick connect.

Here's what John and Maria do, and what flow blocks are triggered:

1. John chooses the **Quick Connect** button on his CCP. (On the earlier CCP, the button is named **Transfer**). He selects **Maria** from the list of quick connects.

When John does this, his CCP banner changes to **Connected**. However, the call isn't actually connected to Maria yet.

2. In our example scenario, Amazon Connect triggers an agent transfer flow that looks like the following image. It has the following blocks connected by **Success** branches: a **Play prompt**, a **Set whisper flow**, another **Set whisper flow**, and then a **Transfer to agent** block.



The call is not yet connected to Maria.

3. John hears the first **Play prompt**, "Transferring to agent."
4. Maria receives a notification in her CCP to either accept or reject the call.
5. Maria accepts the incoming call. The banner in her CCP changes to **Connecting**.
6. The first Set whisper flow block is triggered. This block sets the custom agent whisper flow. It plays the Custom_Agent_Whisper to Maria, for example, "This is an internal call transferred from another agent."

> **Note**
>
> If you don't create and then select a custom agent whisper flow, Amazon Connect plays the default agent whisper flow, which says the queue name.

7. The next Set whisper flow block is triggered. It plays the Custom_Customer_Whisper to John, for example, "Your call is now connecting to an agent."

> **Note**
>
> If you don't create and then select a custom customer whisper flow, Amazon Connect plays the default customer whisper flow, which plays a beep.

8. Maria's CCP banner shows she's **Connected**. John and Maria are connected and can start talking.
9. Now John can do one of the following on his CCP:
   - Choose **Join**. This joins all parties on the call. John, Maria, and the customer have a conference call.
   - Choose **Hold all**. This puts Maria and the customer on hold.
   - Put Maria on hold, so he only talks to the customer.
   - Choose **End call**. He leaves the call but Maria and the customer are directly connected and continue talking.

Queue quick connects

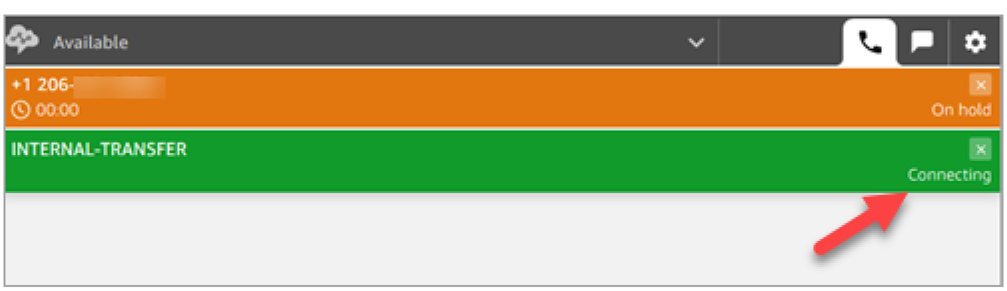
Let's say John is talking to a customer. The customer needs help resetting his password, so John needs to transfer him to the PasswordReset queue. This is a queue quick connect.

Another agent, Maria, is assigned to handle contacts in the PasswordReset queue. Her status in the CCP is **Available**.

Here's what John and Maria do, and what flow blocks are triggered:

1. John chooses the **Quick Connect** button on his CCP. (On the earlier CCP, the button is named **Transfer**). He chooses to transfer the contact to the PasswordReset queue. As soon as John chooses the PasswordReset quick connect, his CCP banner shows **Connecting**.

   > **Important**
   >
   > Even though the status of the transferred call (internal-transfer) shows on John's CCP banner as **Connecting**, the contact is not yet transferred to the PasswordReset queue.



2. Amazon Connect invokes the queue transfer flow that's associated with the PasswordReset quick connect. In this flow, the Transfer to queue block transfers the contact to the PasswordReset queue since it's specified in the block. The contact is now in the PasswordReset queue.
3. Maria is notified in her CCP to accept or reject the incoming call.
4. Maria accepts the incoming call and her CCP banner changes to **Connecting**.
5. The Agent whisper flow is played to Maria. It says "Connecting you to PasswordReset queue."
6. The Customer whisper flow is played to John. It says "Connecting you to PasswordReset queue."
7. Maria's CCP banner changes to **Connected**. John and Maria are connected and can start talking.
8. Now John can do one of the following from his CCP:
   - Choose **Join**. This joins all parties on the call. John, Maria, and the customer have a conference call.
   - Choose **Hold all**. This puts Maria and the customer on hold.
   - Put Maria on hold, so he only talks to the customer.
   - Choose **End call**. He leaves the call but Maria and the customer are directly connected and continue talking.

Phone number quick connects

There are no flows involved in a phone number quick connect. When an agent invokes a phone number quick connect, the call is directly connected to the destination without invoking any flows.

Because no flow is involved in phone number quick connects, you can't set the outbound caller ID. Instead, the caller ID that you specified when you created the queue is used.

Set up agent-to-agent transfers in Amazon Connect

We recommend using these instructions to set up agent-to-agent voice, chat, and task transfers. You use a Set working queue block to transfer the contact to the agent's queue. The **Set working queue** block supports an omnichannel experience, whereas the Transfer to agent (beta) block does not.

Step 1: Create the quick connect

Following are the instructions to add quick connects manually using the Amazon Connect admin website. To add quick connects programmatically, use the CreateQuickConnect API.

Create a quick connect

1. On the navigation menu, choose **Routing**, **Quick connects**, **Add a new destination**.
2. Enter a name for the connect. Choose the type, and then specify the destination (such as a phone number or the name of an agent), flow (if applicable), and description.

   > **Important**
   >
   > A description is required when you create a quick connect. If you don't add one, you'll get an error when you try to save the quick connect.

3. To add more quick connects, choose **Add new**.
4. Choose **Save**.
5. Go to the next procedure to enable your agents to see the quick connects in the Contact Control Panel (CCP).

Enable your agents to see the quick connects in the CCP when they transfer a contact

1. After you create the quick connect, go to **Routing**, **Queues** and then choose the appropriate queue for the contact to be routed to.
2. On the **Edit queue** page, in the **Quick connect** box, search for the quick connect you created.
3. Select the quick connect and then choose **Save**.

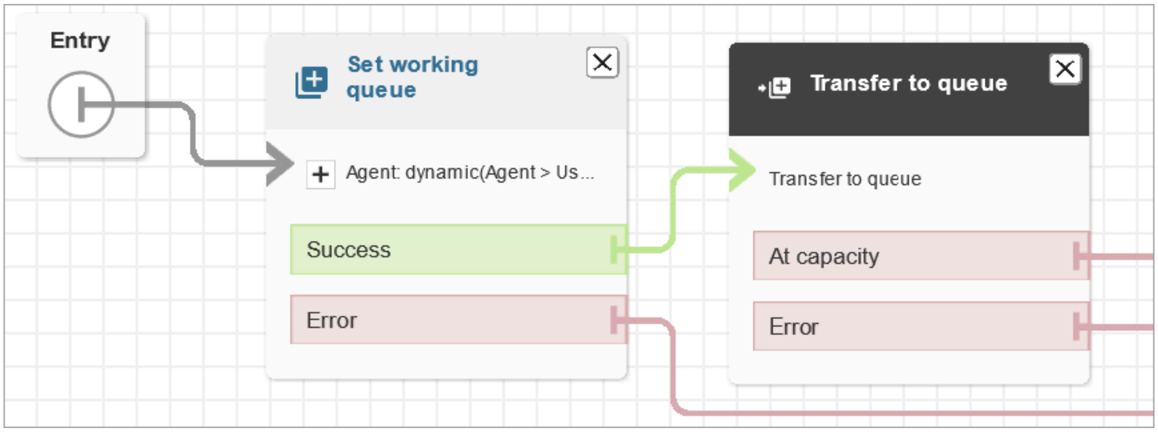
> **Tip**
>
> Agents see all of the quick connects for the queues in their routing profile.

Step 2: Set up the "Transfer to agent" flow

In this step, you create a flow that's type **Transfer to agent** and use a Set working queue block to transfer the contact to the agent.

1. On the navigation menu, choose **Routing**, **Flows**.
2. Use the drop-down to choose **Create transfer to agent flow**.
3. Type a name and a description for your flow.
4. In the left navigation menu, expand **Set**, and then drag the **Set working queue** block to the canvas.
5. Configure the **Set working queue** block as shown in the following image. Choose **By agent**, **Set dynamically**, **Namespace** = **Agent**, **Value** = **User name**.

   
   1. Choose **By agent**.
   2. Choose **Set dynamically**.
   3. For **Namespace**, use the dropdown box to select **Agent**.
   4. For **Value**, use the dropdown box to select **User name**.
6. Add a [Transfer to queue] block. You don't need to configure this block. The following image shows the **Success** branch of the **Set working queue** block connecting to the **Transfer to queue** block.



7. Save and publish this flow.

8. To show your agents how to transfer chats to another agent, see [Transfer a chat to an agent's queue with context in the CCP](#).

   To show your agents how to transfer tasks to another agent, see [Transfer a task to another agent or queue in the Amazon Connect Contact Control Panel (CCP)](#).

Set up a flow in Amazon Connect to resume a call with a customer after a transfer

Let's say you need to transfer a contact to an external department that's not using Amazon Connect. For example, maybe you need to transfer the caller to a shipping provider to check the status of their delivery. After the contact is disconnected from the phone number, you want them to be returned to your agent, for example, when the delivery company couldn't resolve their issue.

- For advanced creation, send tracking information as DTMF digits when the call is transferred, so that the shipment information is retrieved with the transferred call before the customer is connected.

To set up a flow for this scenario

1. Add a **Transfer to phone number** block to your contact flow.

2. In the **Transfer to phone number** block, enter the following settings:

   - **Transfer to**
     - **Phone number**—Sets the phone number to transfer the call to.

    - **Set dynamically—**Specify a contact attribute (choose a namespace and then a value) to set the phone number to transfer the call to.
- **Set timeout**
    - **Timeout (in seconds)—**The number of seconds to wait for the recipient to answer the transferred call.
- **Set dynamically—**Specify a contact attribute (choose a namespace and then a value) to use to set the **Timeout** duration.

- **Resume flow after disconnect—**When you select this option, after the call is transferred, the caller is returned to the flow when the call with the third party ends. Additional branches for **Success**, **Call failed**, and **Timeout** are added to the block when you select this option so that you can appropriately route contacts when there is an issue with the transfer.
- **Optional parameters**
    - **Send DTMF—**Select **Send DTMF** to include up to 50 Dual-Tone Multi-frequency (DTMF) characters with the transferred call. You can enter the characters to include, or use an attribute. Use the DTMF characters to navigate an automated IVR system that answers the call.
    - **Caller ID number—**Specify the caller ID number used for transferred call. You can select a number from your instance, or use an attribute to set the number.
    - **Caller ID name—**Specify the caller ID name used for the transferred call. You can enter a name, or use an attribute to set the name.

      In some cases, the caller ID information is provided by the carrier of the party you are calling. The information may not be up-to-date with that carrier, or the number may get passed differently between systems because of hardware or configuration differences. If that is the case, the person you call may not see the phone number, or may see the name of a previously registered owner of the number, instead of the name you specify in the block.

3. Connect **Transfer to phone number** to the rest of your flow.

When the block executes:

1. The call is transferred to the phone number.

2. Optionally, when the conversation with the external party ends, the contact is returned to the flow.
3. The contact then follows the **Success** branch from the block to continue the flow.
4. If the call is not successfully transferred, one of the other branches is followed: **Call failed**, **Timeout**, or **Error**, depending on the reason the caller did not return to the flow.

Set up a flow to manage contacts in a queue in Amazon Connect

For inbound contacts, you can define advanced routing decisions to minimize queue wait times, or route contacts to specific queues, using blocks in your flow. For example:

- Use a **Check queue status** block to check staffing or agent availability for a queue before sending a contact to that queue.
- Or, use a **Get queue metrics** block to retrieve queue metrics.
- Then use a **Check contact attributes** block to check specific queue metric attributes, and define conditions to determine which queue to route the contact to based on attribute values. For more information about using queue metrics, see Use attributes in Amazon Connect to route based on number of contacts in a queue.

After determining which queue to transfer the contact to, use a **Transfer to queue** block in a flow to transfer the contact to that queue. When the **Transfer to queue** block runs, it checks the queue capacity to determine whether or not the queue is at capacity (full). This check for queue capacity compares the current number of contacts in the queue to the Maximum contacts in queue limit, if one is set for the queue. If no limit is set, the queue is limited to the number of concurrent contacts set in the service quota for the instance.

After the contact is placed in a queue, the contact remains there until an agent takes the contact, or until the contact is handled based on the routing decisions in your customer queue flow.

To change the queue associated with the call after it is already placed in a queue, use a **Loop prompts** block with a **Transfer to queue** block in a customer queue flow. In the block choose which queue to transfer the call to, or use an attribute to set the queue.

To manage contacts in a queue using a Transfer to queue block

1. In Amazon Connect, on the navigation menu choose **Routing**, **Flows**.
2. Choose the down arrow next to **Create flow**, then choose **Create customer queue flow**.

3. Under **Interact**, add a **Loop prompts** block to provide a message to the caller when the call is transferred, then every X seconds or minutes while the call is in the queue.
4. Select the **Loop prompts** block to display the settings for the block.
5. Choose **Add another prompt to the loop**.
6. Under **Prompts**, do one of the following:
   - Choose **Audio recording** in the drop-down menu, then select the audio recording to use as the prompt.
   - Choose **Text to Speech** in the drop-down menu, then enter text to use for the prompt in the **Enter text to be spoken** field.
7. To set an interrupt, choose **Interrupt every**, enter a value for the interrupt interval, and then choose a unit, either **Minutes** or **Seconds**. We recommend that you use an interval greater than 20 seconds to ensure that queued contacts that are being connected to an agent are not interrupted.
8. Choose **Save**.
9. Connect the block to the **Entry point** block in the contact flow.
10. Under **Terminate/Transfer**, drag a **Transfer to queue** block onto the designer.
11. Select the title of the block to display the settings for the block, then choose the **Transfer to queue** tab.
12. Under **Queue to check**, choose **Select a queue**, then select the queue to transfer calls to.

    Alternatively, choose **Set dynamically**, then reference an attribute to specify the queue. If you use an attribute to set the queue, the value must be the queue ARN.
13. Choose **Save**.
14. Connect the **Loop prompt** block to the **Transfer to queue** block.
15. Add additional blocks to complete the flow that you require, such as the blocks to check queue status or metrics, then choose **Save**.

    The flow is not active until you publish it.

> **Important**
>
> To successfully complete the call transfer to another queue, you must include a block after the **Transfer to queue** block and connect the **Success** branch to it. For example, use an **End**

flow / Resume block to end the flow. The flow does not end until the call is picked up by an agent.

Transfer contacts to a specific agent in Amazon Connect

Agent queues enable you to route contacts directly to a specific agent. Following are a couple of scenarios where you might want to do this:

- Route contacts to the last agent the customer interacted with. This provides a consistent customer experience.
- Route contacts to agents who have specific responsibilities. For example, you might route all billing questions to Jane.

> **Note**
>
> A queue is created for all users in your Amazon Connect instance, but only users who are assigned permissions to use the Contact Control Panel (CCP) can use it to receive contacts. The Agent and Admin security profiles are the only default security profiles that include permissions to use the CCP. If you route a contact to someone who doesn't have these permissions, the contact can never be handled.

To route a contact directly to a specific agent

1. In Amazon Connect, choose **Routing**, **Contact flows**.
2. In the flow designer, open an existing flow, or create a new one.
3. Add a block in which you can select a queue to transfer a contact to, such as a **Set working queue** block.
4. Select the title of the block to open the block settings.
5. Select **By agent**.
6. Under **Select an agent**, enter the user name of the agent, or select the agent's user name from the drop-down list.
7. Choose **Save**.
8. Connect the **Success** branch to the next block in your flow.

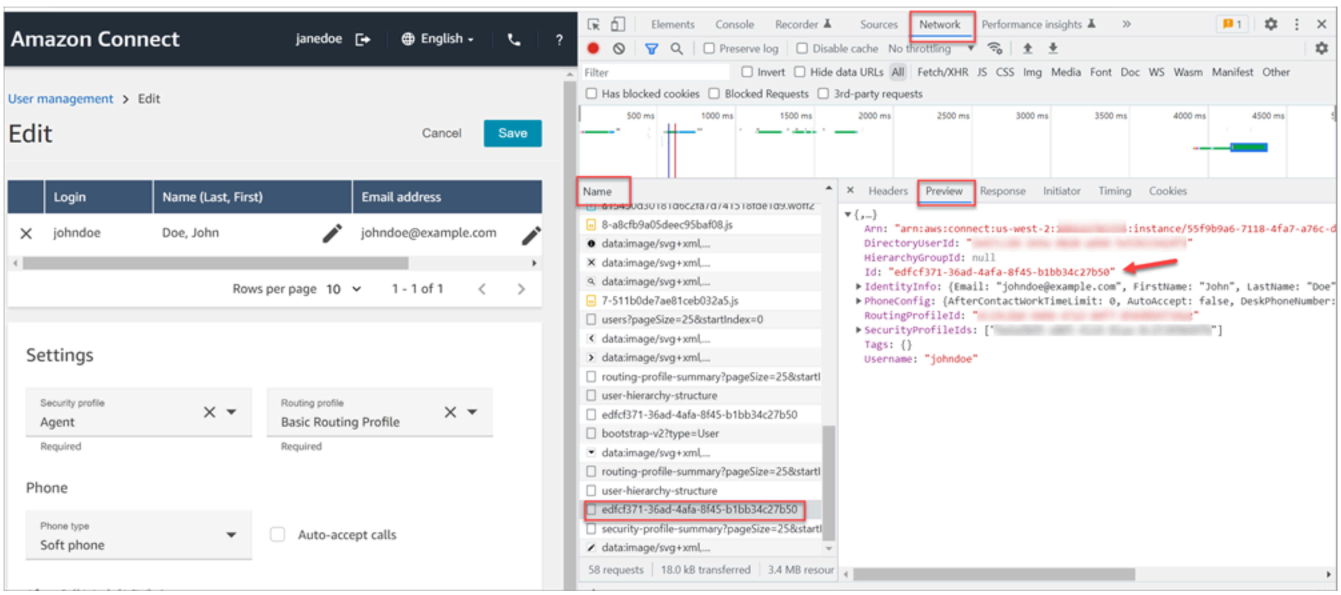
You can also choose to use an attribute to select the queue created for the agent user account. To do so, after you choose **By agent**, choose **Use attribute**.

Use contact attributes to route contacts to a specific agent

When you use contact attributes in a flow to route calls to an agent, the attribute value must be either the agent's user name, or the agent's user ID.

To determine the user ID for an agent so that you can use the value as an attribute, use one of these options:

- Use the **Network** tab of the browser debugger to retrieve the agent ID. For example:
  1. In a Chrome browser, press F12 and go to the **Network** tab.
  2. In Amazon Connect, in the navigation menu, choose **Users**, **User management**, and then select an agent. Monitor the content of the **Network** tab. In the **Name** list, choose the GUID.
  3. Choose the **Preview** tab. The agent ID is displayed next to the `Id` field. The following image shows the location of the agent ID in the **Preview** tab.



- Use the [ListUsers](#) operation to retrieve the users from your instance. The agent's user ID is returned with the results from the operation as the value of the `Id` in the [UserSummary](#) object.
- Find the user ID for an agent by using [Amazon Connect agent event streams](#). The agent events, which are included in the agent event data stream, include the agent ARN. The user ID is included in the agent ARN after **`agent/`**.

In the following agent event data, the agent ID is **87654321-4321-4321-4321-123456789012**.

```
{
    "AWSAccountId": "123456789012",
    "AgentARN": "arn:aws:connect:us-

            "Username": "agentUserName"
        },
        "Contacts": []
},
```

Set up queued callback by creating flows, queues, and routing profiles in Amazon Connect

You can allow your customers to maintain their position in queue without requiring them to stay on the call during high wait times, and get a callback from an available agent when it's their turn.

Contents

How callbacks keep their place in queue

Callbacks can be configured to remain in the same queue as the original inbound call or to be placed in a separate dedicated queue that you create. This separate queue enables you to get a clearer delineation between active inbound calls and callbacks in real time reports.

You can ensure that the callback maintains its position in queue even when you place it in a dedicated queue by configuring it at the same priority as the original inbound queue in the routing profile. This ensures that Amazon Connect continues to look at the original start time of the inbound call to maintain order, regardless of whether the customer opted for a callback or to stay on the call for the next available agent.

Amazon Connect evaluates the routing profiles first so if the two queues have the same priority, the oldest call is pushed first across all queues with the same priorities. For example, if your original call arrived at 10:00 and left a callback request at 10:05, Amazon Connect looks for the call start time of 10:00, not 10:05.

Steps to set up queued callbacks

Use the steps provided in the following overview to set up queued callback.

- Set up a queue specifically for callbacks. In your real-time metrics reports, you can look at that queue and see how many customers are waiting for callbacks.
- Set up caller ID. When setting your callback queue, specify the caller ID name and phone number that appears to customers when you call back.
- Add the callback queue to a routing profile. Set this up so that contacts waiting for a call are routed to agents.
- Create a flow for queued callbacks. Set this up to offer the option for a callback to the customer.
- Associate a phone number with the inbound flow.
- (Optional) Create a callback creation flow. When a callback is created, this flow is run. The contact is enqueued only when there is a Transfer to queue set on this flow. You can use the callback creation flow to Check contact attributes to see if the callback is a duplicate or if the customer issue is resolved before queuing the contact for an agent. This flow also allows you to set a customer queue flow by adding a Set customer queue flow block.
- (Optional) Create a customer queue flow for callback. This flow is run if you choose a Set customer queue flow block for the **Set creation flow** option. You can use a Set customer queue flow block to add logic to transfer a contact from one queue to another. Or, you can manually remove a callback from the queue by using the StopContact API.
- (Optional) Create an outbound whisper flow. When a queued call is placed, the customer hears this message after they pick up and before they connect to the agent. For example, "Hello, this is your scheduled callback..."
- (Optional) Create an agent whisper flow. This is what the agent hears right after they accept the contact, before they are joined to the customer. For example, "You're about to be connected to Customer John, who requested a refund for..."

The routing process

1. When a customer leaves their number it's put in a queue and then routed to the next available agent.
2. After an agent accepts the callback in the CCP, Amazon Connect calls the customer.

   If no agents are available to work on callbacks, the callbacks can stay in queue for up to 7 days after they are created before Amazon Connect automatically removes them.

Tip

To manually remove a callback from the queue, use the StopContact API.

3. If there is no answer when the Amazon Connect calls the customer, it retries based on the number of times you've specified.
4. If the call goes to **voicemail**, it's considered connected.
5. If the customer calls again while in the callback queue, it's treated as a new call and will be handled as usual. To avoid duplicate callback requests in a callback queue, see this blog: Preventing duplicate callback requests in Amazon Connect.

How queued callbacks affect queue limits

- Queued callbacks count towards the queue size limit, but they are routed to the error branch. For example, if you have a queue that handles callbacks and incoming calls, and that queue reaches the size limit:
  - The next callback is routed to the error branch.
  - The next incoming call gets a reorder tone (also known as a fast busy tone), which indicates no transmission path to the called number is available.
- Consider setting up your queued callbacks to be lower priority than your queue for incoming calls. This way, your agents only work on queued callbacks when the incoming call volume is low.

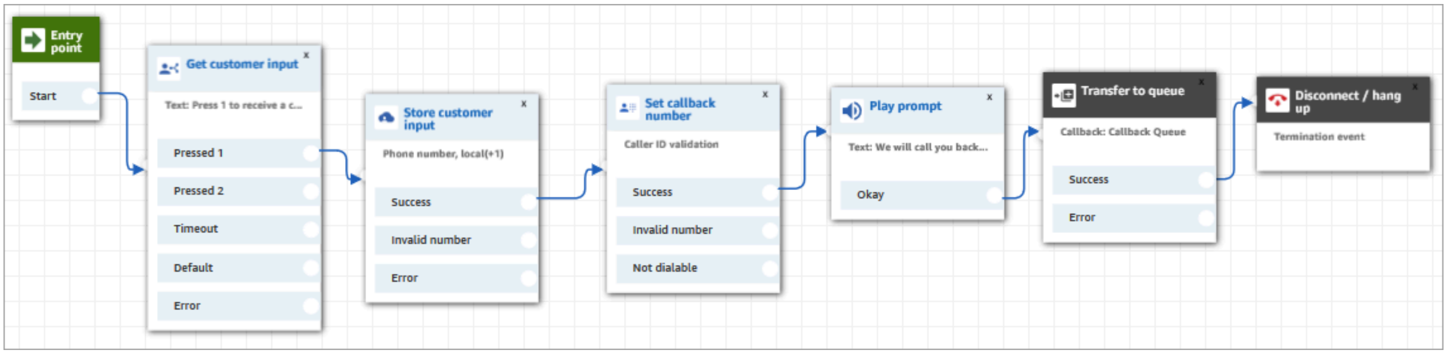
Create a flow for queued callbacks

To see what a flow looks like with queued callback, in new Amazon Connect instances see Sample queue configurations flow in Amazon Connect. In previous instances, see Sample queued callback flow in Amazon Connect.

The following procedure shows how to:

- Request a callback number from a customer.
- Store the callback number in an attribute.
- Reference the attribute in a **Set callback number** block to set the number to dial the customer.
- Transfer the customer to the callback queue.

At the basic level, here's what this queued callback flow looks like, without any of the alternative branches or error handling configured. The following image shows a flow with the following blocks: **Get customer input**, **Store customer input**, **Set callback number**, **Play prompt**, **Transfer to queue**, and **Disconnect/hang up**.



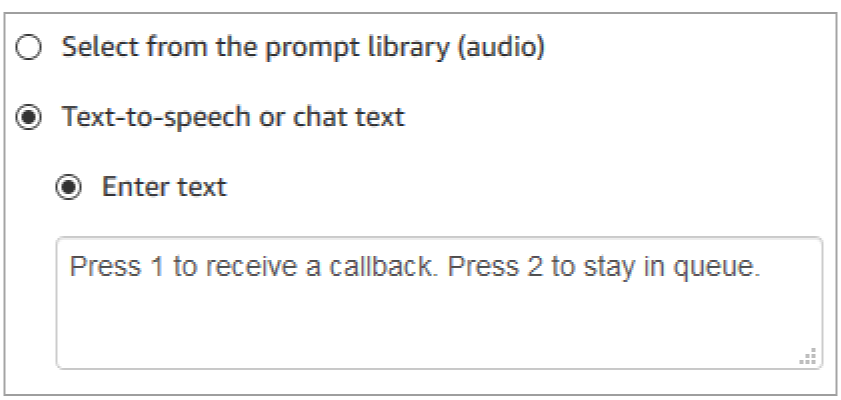
Following are the steps to create this flow.

To create a flow for queued callbacks

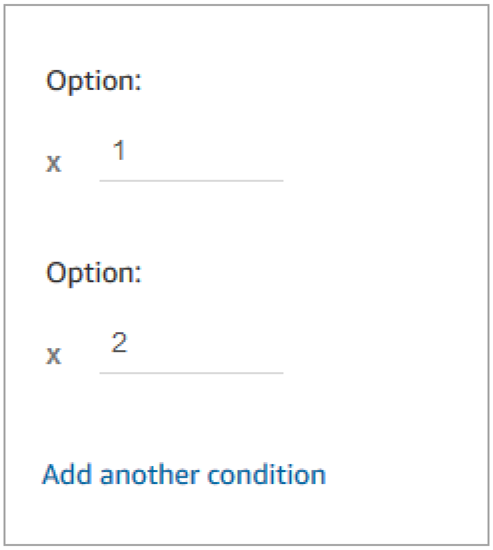
1. In Amazon Connect, choose **Routing**, **Contact flows**.
2. Select an existing flow, or choose **Create flow** to create a new one.

> **Tip**
>
> You can create this flow using different flow types: Customer queue flow, Transfer to agent, Transfer to queue.

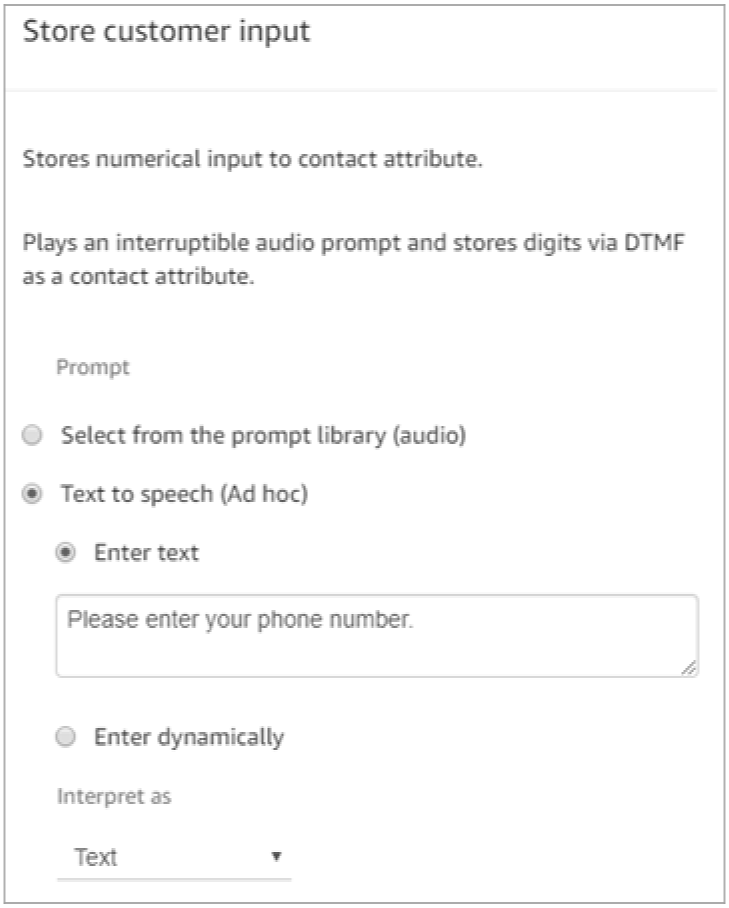
3. Add a Get customer input block.
4. Configure the block to prompt the customer for a callback. The following image shows a message in the **Text-to-speech** box: **Press 1 to receive a callback. Press 2 to stay in queue**.



5. At the bottom of the block, choose **Add another condition**, and add options 1 and 2, as shown in the following image.



6. Add a Store customer input block.
7. Configure the block to prompt customers for their callback number, such as "Please enter your phone number." The following image shows the **Properties** page of the **Store customer input** block.

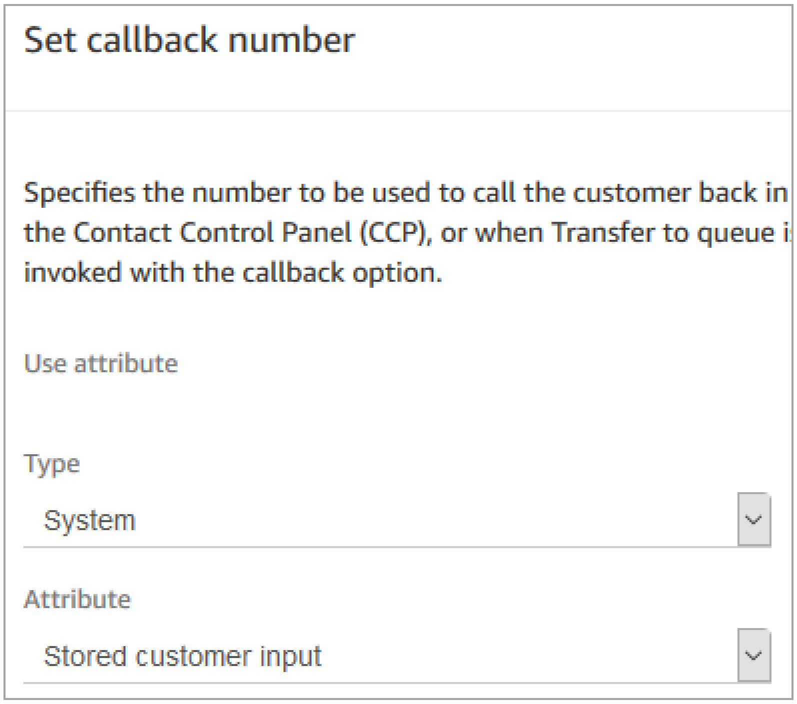


8. In the **Customer input** section, select **Phone number**, and then choose one of the following:

   - **Local format**: Your customers are calling from phone numbers that are in the same country as the AWS Region where you created your Amazon Connect instance.
   - **International format/Enforce E.164**: Your customers are calling from phone numbers in countries or regions other than the one where you created your instance.

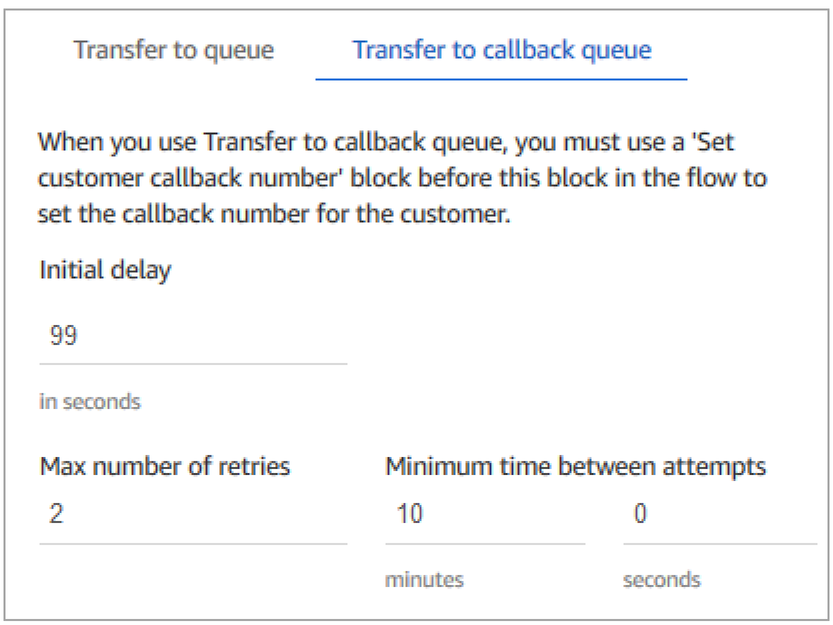
9. Add a Set callback number block to your flow.

10. Configure the block to set **Type** to **System**, as shown in the following image. For **Attribute**, choose **Store customer input**. This attribute stores the customer's phone number.



11. Add a [Transfer to queue] block.

12. In the **Transfer to queue** block, configure the **Transfer to callback queue** tab as shown in the following image. Set **Initial delay** to 99. Set **Max number of retries** to 2. Set **Minimum time between attempts** to 10 minutes.



The following properties are available:

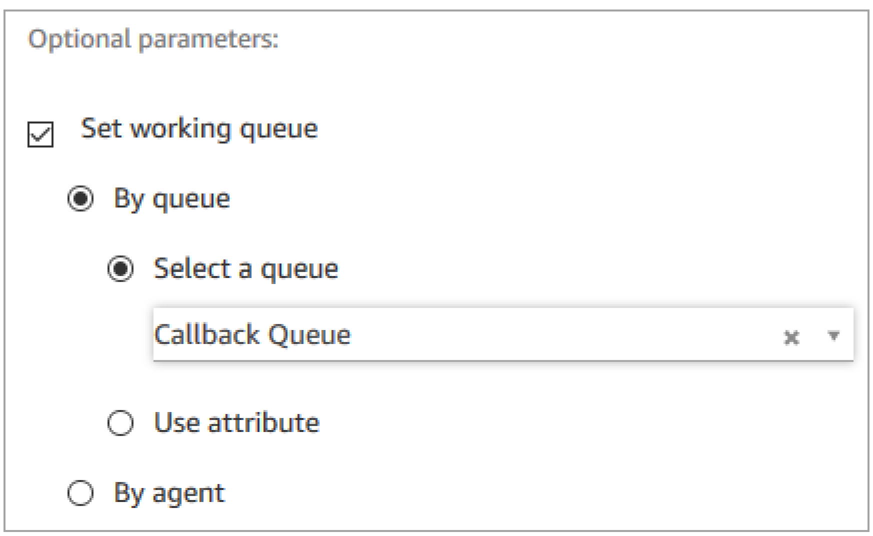
- **Initial delay**: Specify how much time has to pass between a callback contact being initiated in the flow, and the customer is put in queue for the next available agent. In the previous example, the time is 99 seconds.
- **Maximum number of retries**: If this is set to 2, then Amazon Connect tries to call back the customer a maximum of three times: the initial callback, and two retries.

  A retry only happens if it rings but there's no answer. If the callback goes to voicemail, it's considered connected and Amazon Connect does not retry again.

  > **Tip**
  >
  > We strongly recommend that you double-check the number entered in **Maximum number of retries**. If you accidentally enter a high number, such as 20, it's going to result in unnecessary work for the agent and too many calls for the customer.

- **Minimum time between attempts**: If the customer doesn't answer the phone, this is how long to wait until trying again. In the previous example, we wait 10 minutes between attempts.

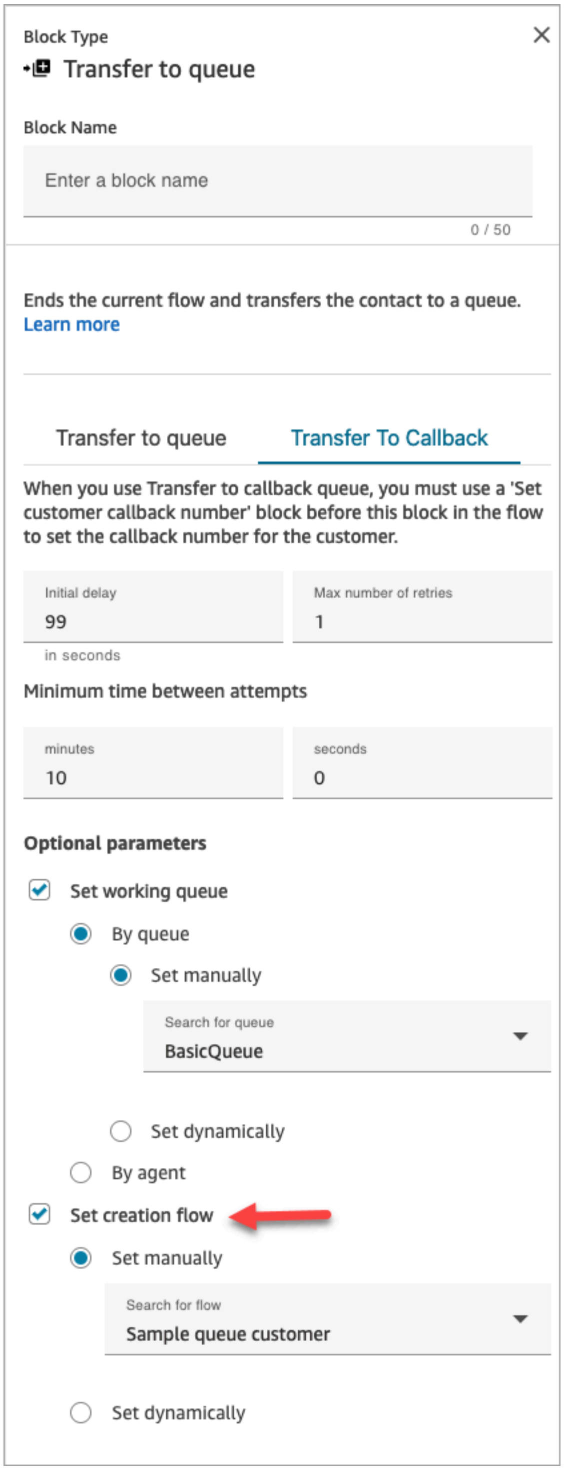
13. In the **Optional parameters** section, choose **Set working queue** if you want to transfer the contact to a queue that you set up specifically for callbacks. This option is shown in the following image.



Creating a queue just for callbacks lets you view in your real-time metrics reports how many customers are waiting for callbacks.

If you don't set a working queue, Amazon Connect uses the queue that was set previously in the flow.

14. The callback contact is a new contact separate from the inbound voice contact. You can optionally control the experience of this callback contact when it is created by configuring the **Set creation flow** option in the [Transfer to queue](#) block, as shown in the following image.



- (Optional) Create a callback creation flow. Use the **Set creation flow** dropdown menu to select the flow to be run when a callback contact is created.

  The callback creation flow that you select must meet the following requirements:

  - The flow type must be the default flow type, **Contact flow (inbound)**. For information about flow types, see Choose a flow type.
  - You need to configure a Transfer to queue block to queue the contact in the queue of your choice.

  Following are additional options for how you can configure your callback creation flow:

  - You can evaluate contact attributes (including customer profiles) by using a Check contact attributes block to see if the callback should be terminated because it is a duplicate or the customer issue has already been resolved.
  - You can add a Set customer queue flow block and use it to specify the flow to run when a customer is transferred to a queue. This flow is called a customer queue flow.
    - In the customer queue flow, you can evaluate the contact's wait time in queue by using a combination of the Get queue metrics block and GetCurrentMetricData to send an advance SMS to customers, notifying them to expect a callback in the near future from the specific contact center number.

15. To save and test this flow, configure the other branches and add error handling. To see an example of how this is done, see Sample queue configurations flow in Amazon Connect. For previous instances, see Sample queued callback flow in Amazon Connect.
16. For information about how callbacks appear in real-time metrics reports and contact records, see Queued callbacks in real-time metrics in Amazon Connect.

Callbacks from a chat, task, or email contact

You can also configure the **Transfer to Callback** option in the Transfer to queue block to support callbacks when a customer contacts you from a chat, task, or email contact. For example, if a customer reaches out after hours when no agent is available, they can request a voice callback by sending a chat message or completing a webform request (which uses tasks).

The following video shows how to use Contact Lens to allow customers who contact you through Amazon Connect chat to request a callback. This creates a more personalized customer experience.

It shows how to configure this capability that allows customers to request callbacks from any channel, not just voice calls.

[Amazon Connect chat to callback escalation]

Learn more about queued callbacks

See the following topics to learn more about queued callbacks:

- Queued callbacks in real-time metrics in Amazon Connect
- How Initial delay affects Scheduled and In queue metrics in Amazon Connect
- Failed callback attempts in Amazon Connect
- Amazon Connect real-time metrics example for a queued callback flow

Import and export flows between flow designers in Amazon Connect

Use the procedures described in this topic to import/export a flows from the previous flow designer to the new one, from one instance to another, or from one Region to another as you expand your customer service organization.

> **Note**
>
> To copy and paste flows and blocks in the updated flow designer, the flow must be in the new flow language. To convert a legacy flow into the new format, you have two options:
>
> - Option 1: In the flow designer, opt in to the updated flow designer. Your legacy flows are automatically converted.
> - Option 2: Manually import the legacy flow using the updated flow designer.
>
>   This option is most useful for scenarios where you have stored your flows in JSON offline. For example, for configuration control, you may have flow configurations in an offline data store. To copy a part of that flow and paste it into the updated flow designer, you need to import it into the updated flow designer. The importing process converts it to the new flow language. After that, you can copy and paste within the updated flow designer. If you want to keep using your offline data store as a source of truth, update the flow with the new format.

To migrate tens or hundreds of flows, use the APIs described in [Migrate flows to an instance, Region, or environment in Amazon Connect](#).

The Flow Import/Export feature is currently in Beta status. Updates and improvements that we make could result in issues in future releases importing flows that are exported during the beta phase.

Export limitations

You can export flows that meet the following requirements:

- The flow has fewer than 100 blocks.
- The total size of the flow is less than 1MB.

We recommend dividing large flows in to smaller ones to meet these requirements.

Flows are exported to JSON files

A flow is exported to a JSON file. It has the following characteristics:

- The JSON includes a section for each block in the flow.
- The name used for a specific block, parameter, or other element of the flow may be different than the label used for it in the flow designer.

By default, flow export files are created without a file name extension, and saved to the default location set for your browser. We suggest saving your exported flows to folder that contains only exported flows.

How to import/export flows

To export a flow

1. Log in to your Amazon Connect instance using an account that is assigned a security profile that includes view permissions for flows.
2. Choose **Routing**, **Contact flows**.
3. Open the flow to export.
4. Choose **Save**, **Export flow**.

5. Provide a name for the exported file, and choose **Export**.

To import a flow

1. Log in to your Amazon Connect instance. The account must be assigned a security profile that includes edit permissions for flows.
2. On the navigation menu, choose **Routing**, **Contact flows**.
3. Do one of the following:
   - To replace an existing flow with the one you are importing, open the flow to replace.
   - Create a new flow of the same type as the one you are importing.
4. Choose **Save**, **Import flow**.
5. Select the file to import, and choose **Import**. When the flow is imported into an existing flow, the name of the existing flow is updated, too.
6. Review and update any resolved or unresolved references as necessary.
7. To save the imported flow, choose **Save**. To publish, choose **Save and Publish**.

Resolve resources in imported contact flows

When you create a flow, the resources you include in the flow, such as queues and voice prompts, are referenced within the flow using the name of the resource and the Amazon Resource Name (ARN). The ARN is a unique identifier for a resource that is specific to the service and Region in which the resource is created. When you export a flow, the name and ARN for each resource referenced in the flow is included in the exported flow.

When you import a flow, Amazon Connect attempts to resolve the references to the Amazon Connect resources used in the flow, such as queues, by using the ARN for the resource.

- When you import a flow into the same Amazon Connect instance that you exported it from, the resources used in the flow will resolve to the existing resources in that instance.
- If you delete a resource, or change the permissions for a resource, Amazon Connect may not be able to resolve the resource when you import the flow.
- When a resource cannot be found using the ARN, Amazon Connect attempts to resolve the resource by finding a resource with the same name as the one used in the flow. If no resource with the same name is found, a warning is displayed on the block that contains a reference to the unresolved resource.

- If you import a flow into a different Amazon Connect instance than the one it was exported from, the ARNs for the resources used are different.
- If you create resources in the instance with the same name as the resource in the instance where the flow was exported from, the resources can be resolved by name.

  You can also open the blocks that contain unresolved resources, or resources that were resolved by name, and change the resource to another one in the Amazon Connect instance.

You can save a flow with unresolved or missing resources. You can publish a flow with unresolved or missing resources only for optional parameters. If any required parameter has an unresolved resource, you cannot publish the flow until the resources are resolved.

Create conversational AI bots in Amazon Connect

You can use the Amazon Connect admin website to create, edit, and continuously improve conversational AI bots for interactive voice response (IVR) and chatbot self-service experiences. The bots are powered by Amazon Lex.

By using the Amazon Connect admin website, you can deliver dynamic, conversational AI experiences to understand your customer's intent, ask follow-on questions, and automate the resolution of their issues. The topics in this section explain how to enable the bot building experience in Amazon Connect admin website, and how to build your bot.

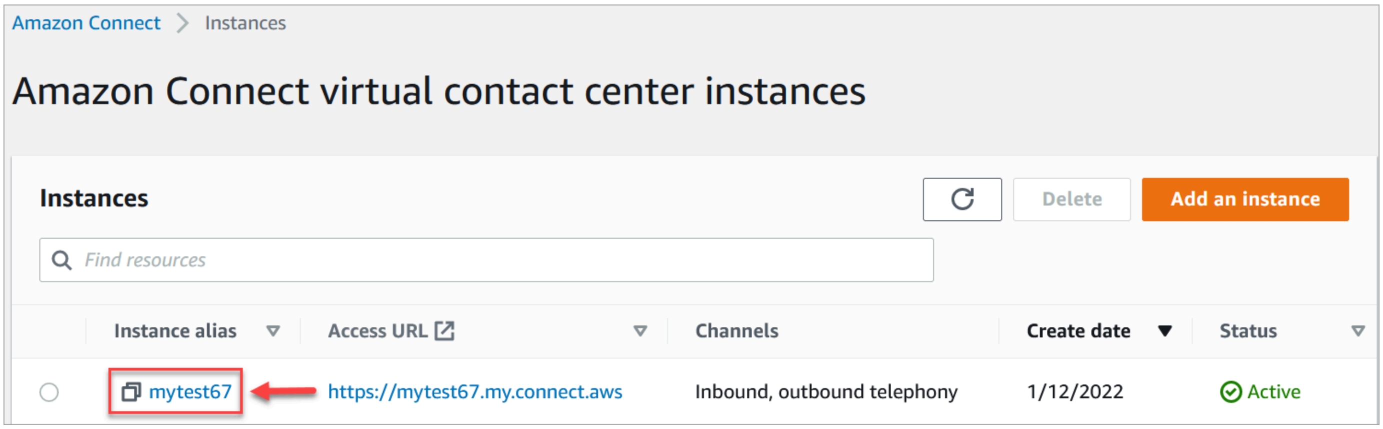
Contents

Enable bot building and analytics in Amazon Connect

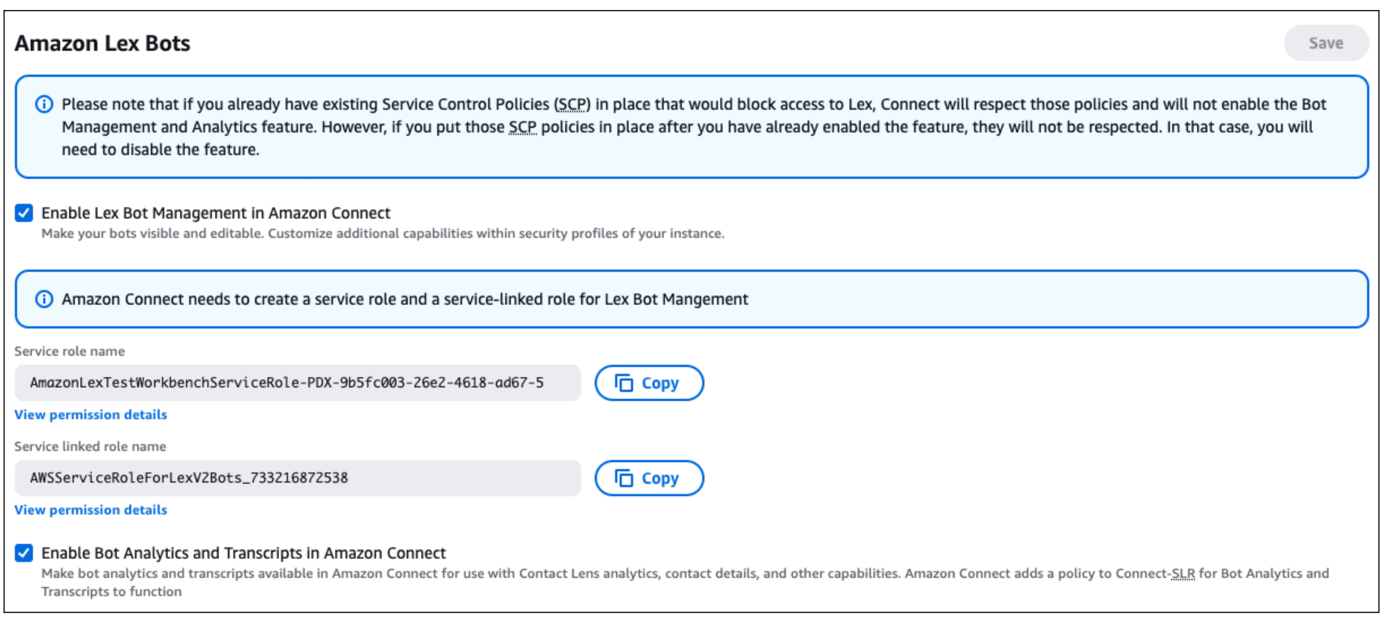
Complete the following steps to enable users to create Amazon Lex bots in the Amazon Connect admin website and view metrics about bot performance.

Users can not edit LEX V1 bots or cross-regional bots from within Amazon Connect.

1. Open the [Amazon Connect console.](https://console.aws.amazon.com/connect/)
2. Select the Amazon Connect instance that you want to integrate with your Amazon Lex bot.



3. On the navigation menu, choose **Flows**.
4. Choose **Enable Lex Bot Management in Amazon Connect** and **Enable Bot Analytics and Transcripts in Amazon Connect**, and then **Save**.



> **Note**
>
> If you already have existing Service Control Policies (SCP) in place that block access to Lex, Amazon Connect respects those policies and does not enable the Bot Management and Analytics feature. However, if you put those SCP policies in place after you've already enabled this feature, they won't be respected. In that case, you'll need to disable this feature.

Amazon Connect displays the service role and service linked role name it uses. uses Amazon Lex resource-based policies to make calls to your Amazon Lex bot. When you associate an Amazon Lex bot with your Amazon Connect instance, the resource-based policy on the bot is updated to give Amazon Connect permission to invoke the bot.

For more information about Amazon Lex resource-based policies, see Resource-based policies within Amazon Lex V2 in the *Amazon Lex V2 Developer Guide*.

5. Assign the following security profile permissions to users who need to create and manage bots and bot analytics:

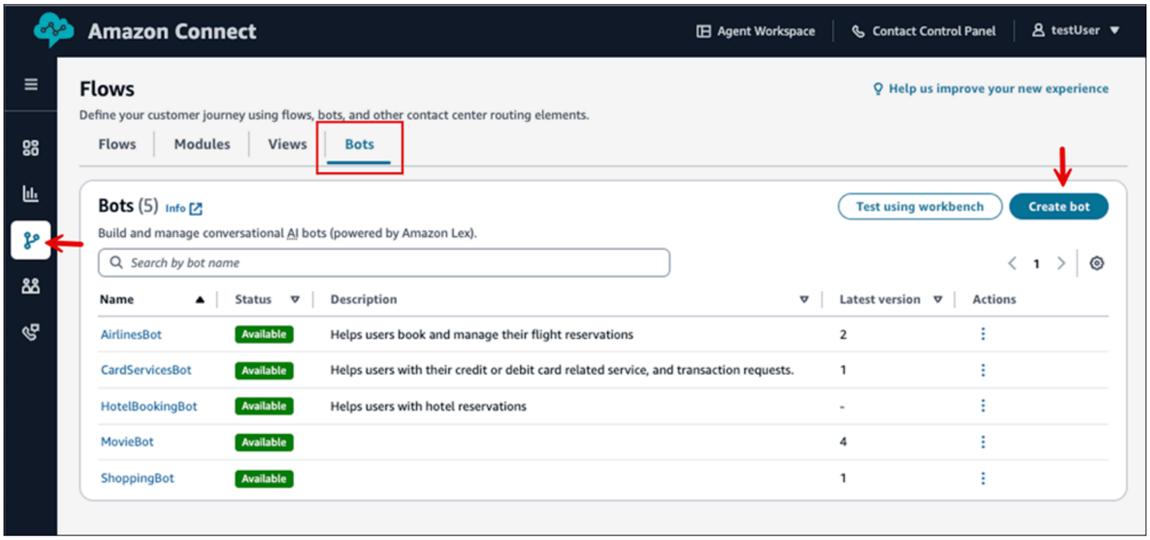
   - **Channels and Flows** - **Bots** - **View**, **Edit**, **Create** permissions
   - **Analytics and Optimization** - **Historical metrics** - **Access** permission

Create a bot by using the Amazon Connect admin website

You can build complete Lex bots in the Amazon Connect admin website without ever leaving the Amazon Connect interface. There is no charge for building or editing bots in Amazon Connect. Instead, you are billed by Amazon Lex for usage. For pricing information, see the Amazon Lex pricing page.

To create a bot

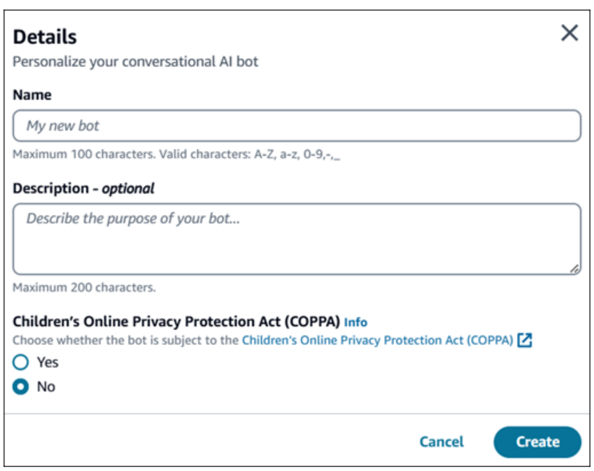
1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an Admin account or an account that has **Channels and Flows** - **Bots** - **Create** permission in its security profile.
2. In the left navigation menu, choose **Routing**, **Flows**.
3. On the **Flows** page, choose **Bots**, **Create bot**.



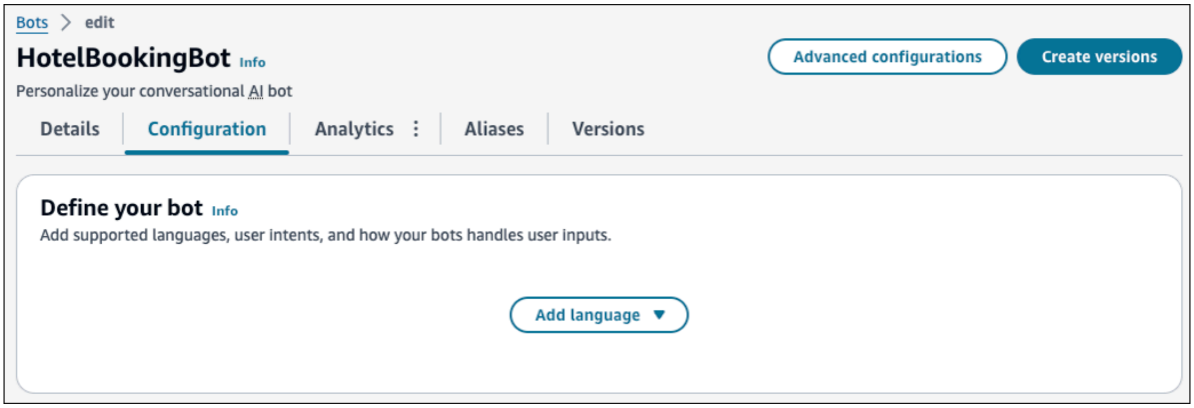
4. In the **Details** dialog box, provide the following information:

   - **Bot name**: Enter a unique name for the bot.
   - **Bot description**: - (Optional) Provide additional information about the purpose of the bot.
   - **Child Online Privacy Protection Act (COPPA)**: Choose whether the bot is subject to the Child Online Privacy Protection Act.

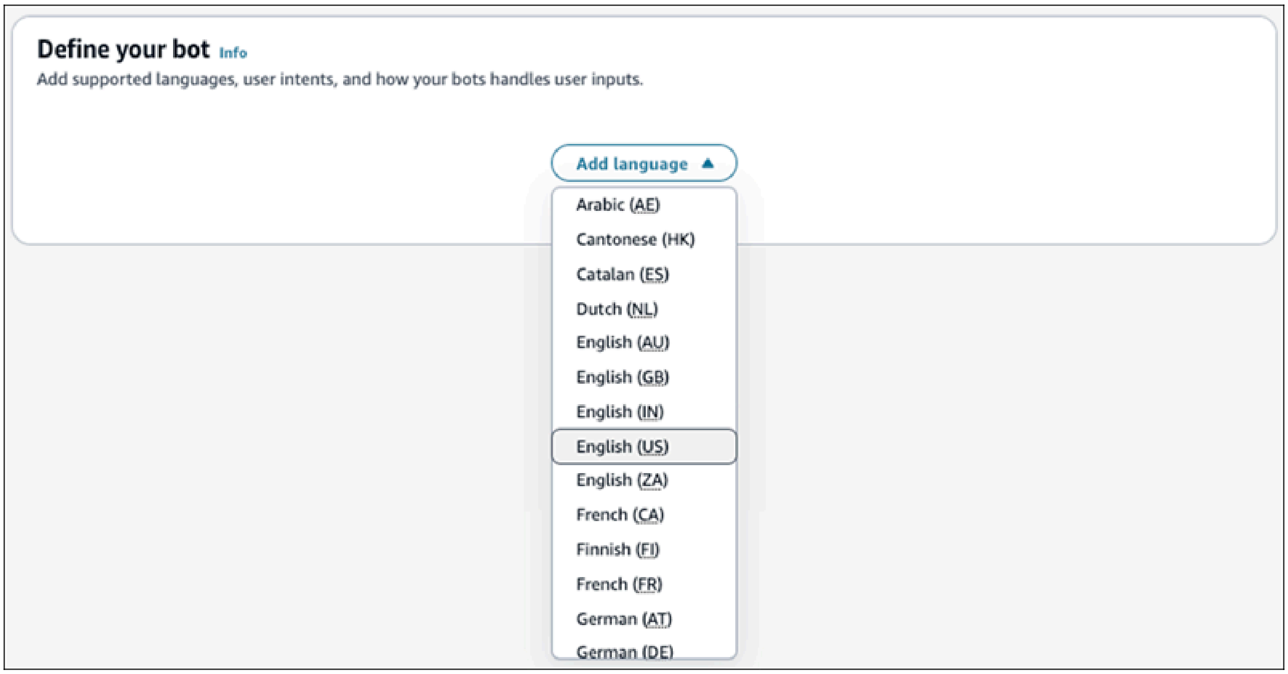
   The following image shows the **Details** dialog box and these options.



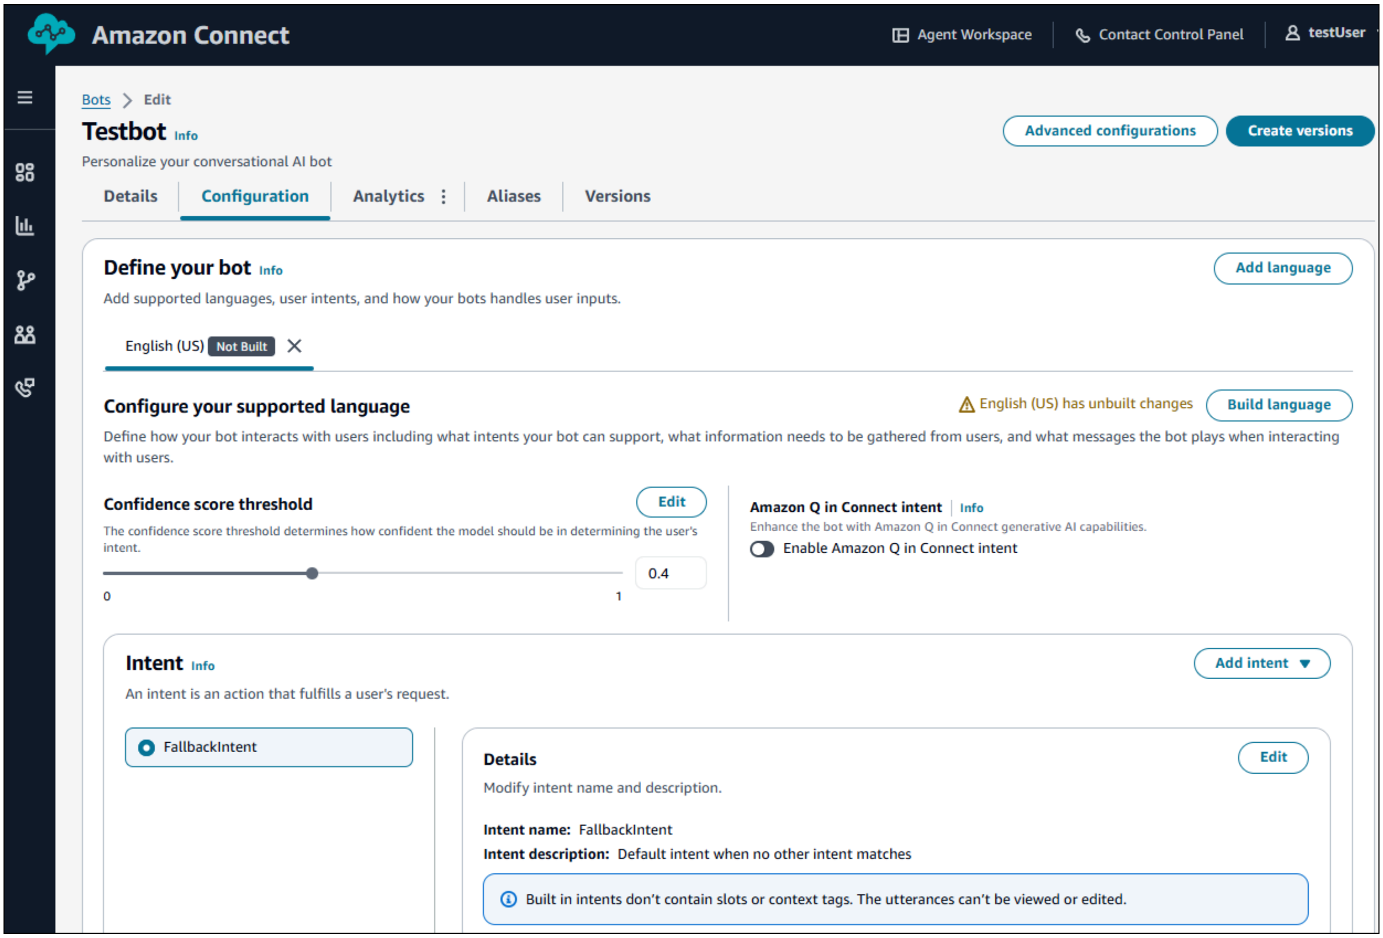
5. Choose **Create**. After the bot is successfully created, you are directed to the bot configuration page. The following image shows an example page for a newly created bot named **HotelBookingBot**.



6. On the bot configuration page, choose **Add language**. Choose the primary language for your bot and your preferred way to create this language.



7. After you choose your language, you are directed to the **Define your bot** section. An example section is shown in the following image. This section is where you'll add intents.

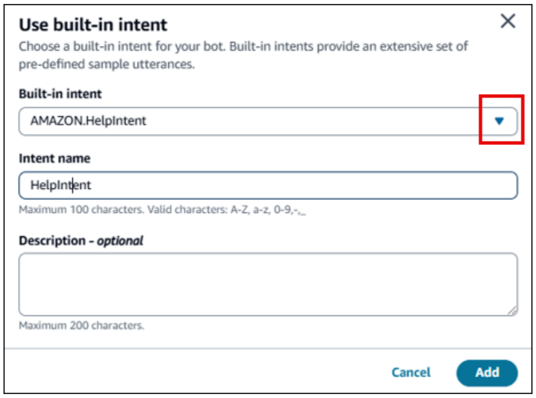


Add intents to your bot

In the **Define your bot** section, you add intents. Intents are the goals that your users want to accomplish, such as ordering flowers or booking a hotel.

Your bot must have at least one intent. There are two types of intents:

- Custom intents: Create intents that represent the actions or requests your bot should handle. This topic explains how to create custom intents.
- Build-in intents: By default, all bots contain a single built-in intent, the fallback intent. This intent is used when the bot does not recognize any other intent. For example, if a user says "I want to order flowers" to a hotel booking intent, the fallback intent is triggered. The following image shows an example of a built-in intent.



To create a custom intent

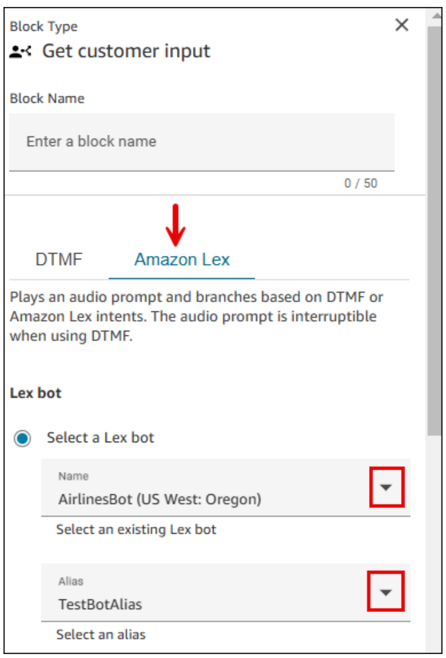
1. Choose **Add intent**, and then choose **Add empty intent**.
2. In the **Add intent** dialog box, enter a name for your intent and a description that's meaningful to you. Choose **Add**.
3. Enter the following information to configure your intent:
   - Add sample **Utterances**: Choose **Add** and then provide phrases or questions that users might use to express that intent. Choose **Save**.
   - Configure **Slots**: Choose **Add** and then define the slots, or parameters, required to fulfill the intent. Each slot has a type that defines the values that can be entered in the slot. Choose **Add** to add the slot. When you're done adding slots, choose **Save**.
   - Create **Prompts**: Choose **Edit** and then you can enter prompts that the bot will use to ask for information or clarify user inputs. Choose **Save** when finished.
     - **Initial response message**: The initial message sent to the user after the intent is invoked. You can provide responses, initialize values, and define the next step that the bot takes to respond to the user at the beginning of the intent.
     - **Confirmation prompt and responses**: These are used to confirm or decline fulfillment of the intent. The confirmation prompt asks the user to review slot values. For example, "I've booked a hotel room for Friday. Is this correct?" The declination response is sent to the user when they decline the confirmation.
     - **Closing response message**: This is the response sent to the user after the intent is fulfilled and all other messages are played. For example, "Thank you for booking a hotel room."

For more information about intents for Amazon Lex V2 bots intents and advanced configurations, see [Adding intents](#) in the *Amazon Lex V2 Developer Guide*.

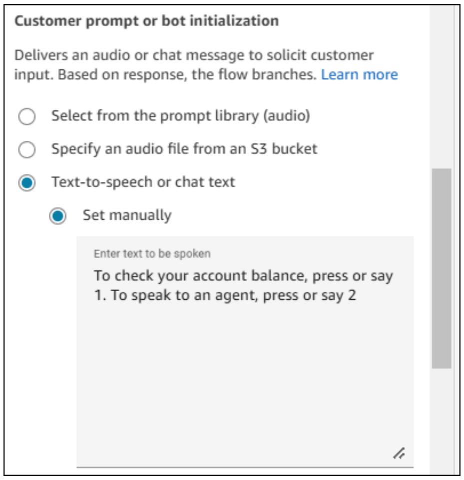
Create a flow and add your conversational AI bot

This topic explains how to add a previously created conversational AI bot to a flow.

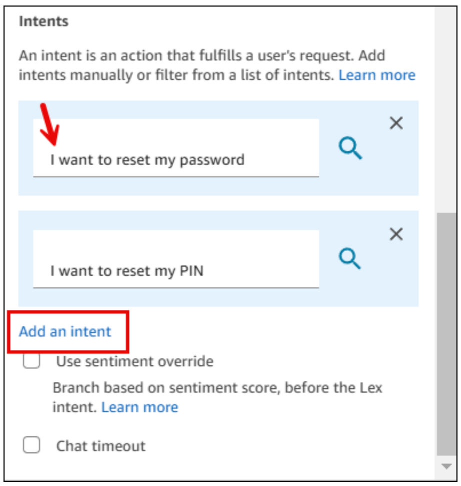
1. On the navigation menu in Amazon Connect, choose **Routing**, **Flows**, **Create flow**, and type a name for the flow.
2. Under **Interact**, drag a [Get customer input](#) block onto the designer, and connect it to the **Entry** point block.
3. Choose the [Get customer input](#) block to open it.
4. On the Amazon Lex tab, use the dropdown menus to select the bot you created earlier and the alias, as shown in the following image.



5. Under **Customer prompt or bot initialization**, choose **Text-to-speech or chat text**.
6. Type a message that provides callers with information about what they can do. For example, use a message that matches the intents used in the bot, such as *To check your account balance, press or say 1. To speak to an agent, press or say 2*. The following image shows this message on the properties page of the [Get customer input](#) block.



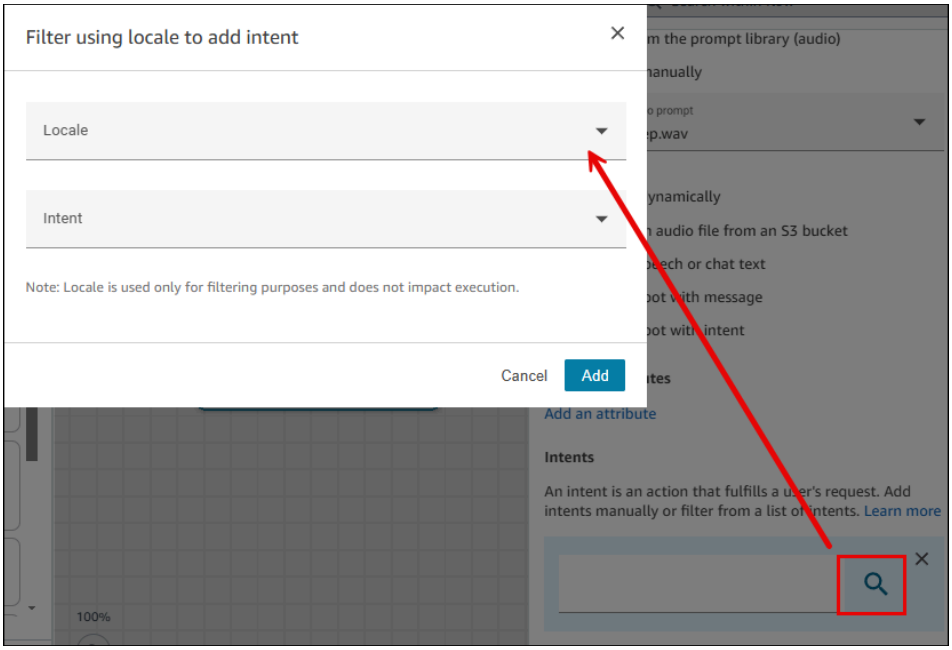
7. Under **Intents**, choose **Add an intent**, and then enter or search for the customer intents that should trigger the bot.



When you search for intents, you can filter by the locale. The locale is only used for filtering, it is not tied to the locale when the bot is triggered. For example, you might find the BookHotel intent by using the English (US) locale, but the intent can be successfully returned in both English (US) and English (GB).

For more information on finding intents, see [How to find intents](#).

The following image shows the dialog box to filter intents by locale.



8. Choose **Save**.

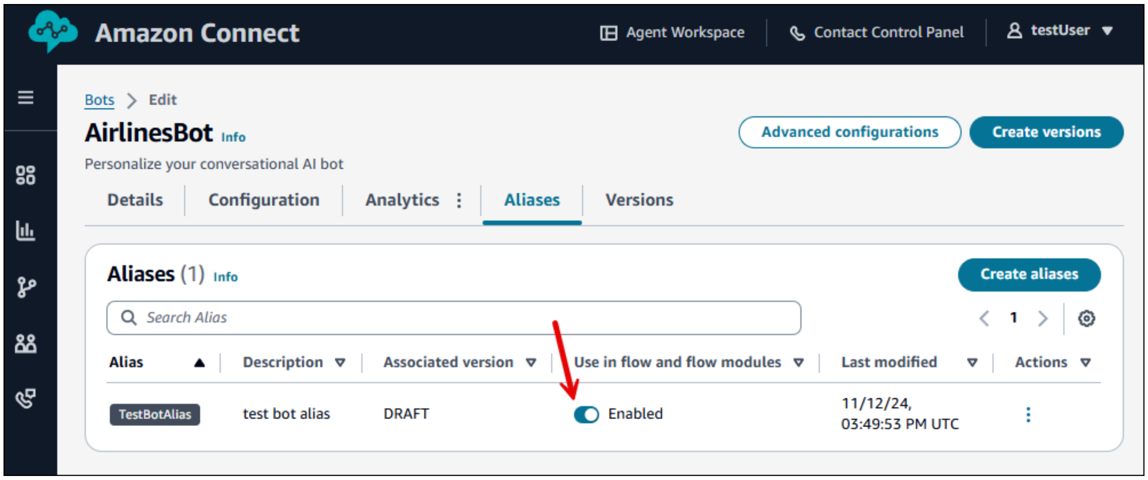
> **Important**
>
> If you're using an Amazon Lex V2 bot, your language attribute in Amazon Connect must match the language model used to build your Lex bot. This is different than Amazon Lex (Classic). Use a Set voice block to indicate the Amazon Connect language model, or use a Set contact attributes block.

How to find intents for Amazon Lex V1 bots, cross-Region bots, or dynamically set bots

The **Intents** dropdown box does not list intents for Amazon Lex V1 bots, cross region bots, or if the bot ARN is dynamically set. For these intents, try the following options to find them.

- Check whether the **AmazonConnectEnabled** tag is set to true:
  1. Open the Amazon Lex console, choose **Bots**, select the bot, then choose **Tags**.
  2. If the **AmazonConnectEnabled** tag is not present, add **AmazonConnectEnabled = true**.
  3. Return to the Amazon Connect admin website. Refresh the flow designer to see the selections in **Get customer input** block.
- Check if the version is associated with the alias:

1. In Amazon Connect admin website, choose **Routing**, **Flows**, the bot, **Aliases**. Verify that **Use in flow and flow modules** is enabled, as shown in the following image.



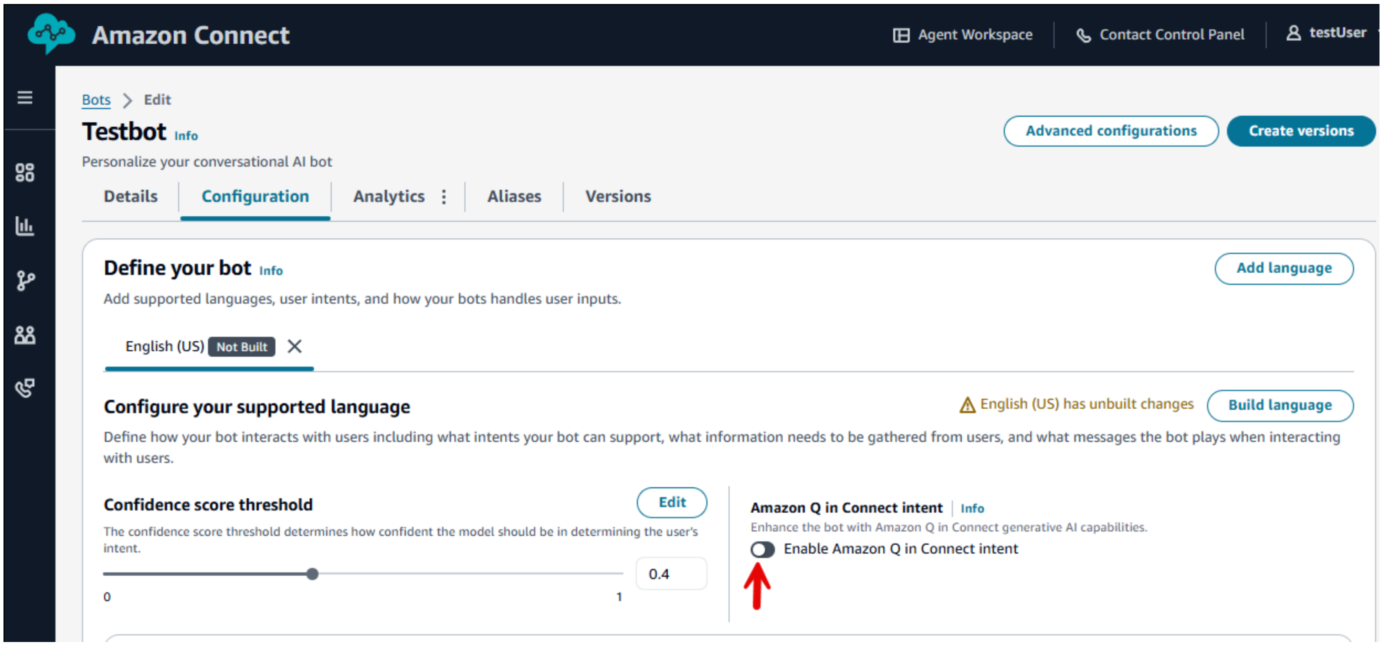
2. Refresh the flow designer to see the selections in **Get customer input** block.

Create an Amazon Q in Connect intent from an Amazon Connect instance

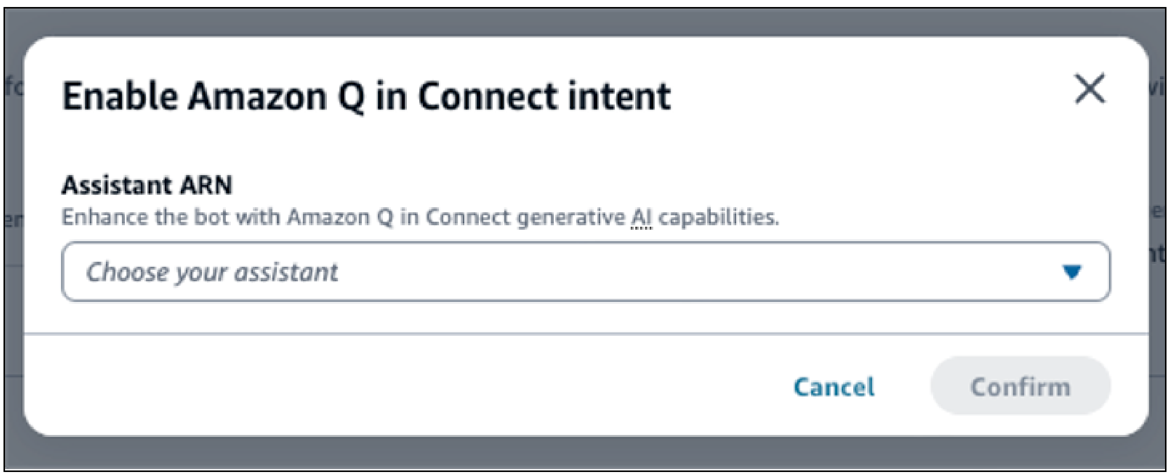
You can use the generative AI capabilities powered by Amazon Q in Connect for your bot by enabling the AMAZON.QinConnectIntent in your bot. This is an Amazon Lex built-in intent.

Complete the following steps to enable Amazon Q in Connect.

1. Open the bot for which you want to add the **AMAZON.QinConnectIntent** intent.
2. Navigate to the **Configuration** tab in the bot builder interface.
3. Enable the **AMAZON.QinConnectIntent** intent by setting the toggle to on.



4. In the **Enable Amazon Q in Connect intent** dialog box, use the dropdown menu to choose the Amazon Resource Name (ARN) of the Amazon Q in Connect intent.



5. Choose **Confirm** to add **AMAZON.QinConnectIntent** intent support.

> **Important**
>
> You cannot use **AMAZON.QInConnectIntent** along with intents without specific utterances such as **AMAZON.QnAIntent**, **AMAZON.BedrockAgentIntent** in the same bot locale. For more information, see AMAZON.QinConnectIntent in the *Amazon Lex V2 Developer Guide*.

Create bot versions and aliases in Amazon Connect

To control which bot implementation your client uses, you create versions and aliases.

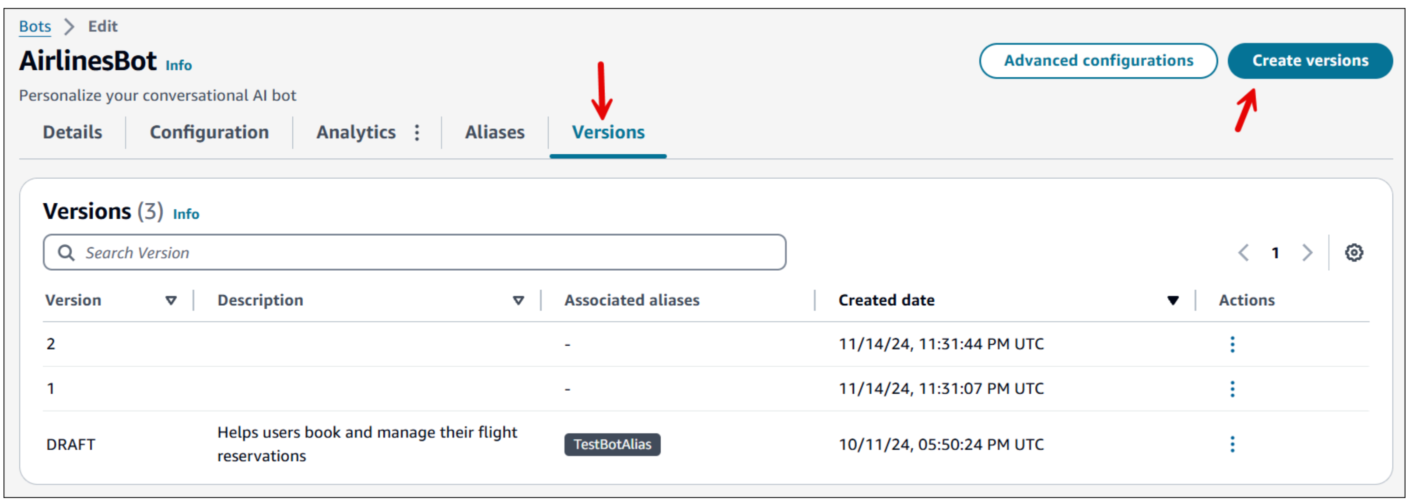
- A version acts as a numbered snapshot of your work.
- You can point an alias to the version of your bot that you want to be available to your customers.

In between creating versions, you can continue to update the Draft version of your bot without affecting your customer's experience. This process is crucial for deploying bots in a production environment.

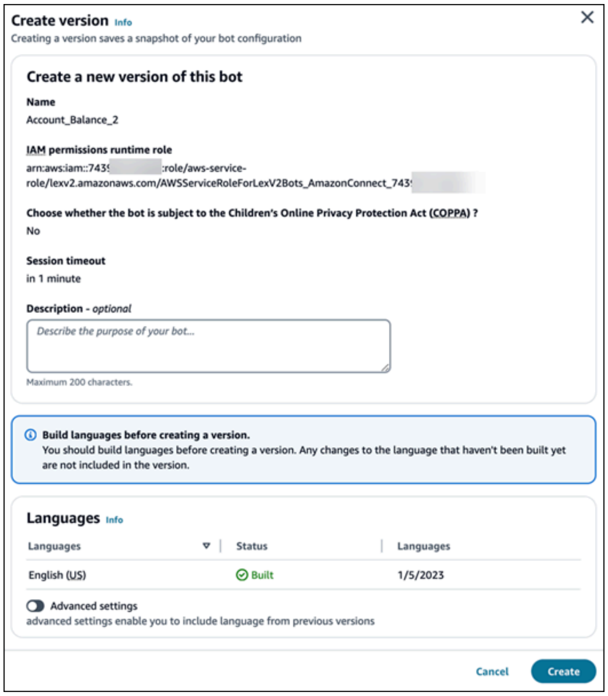
Create a version

Creating a new version preserves the current state of your bot configuration. Complete the following steps to create a new version of your Amazon Lex bot in Amazon Connect.

1. Open the bot for which you want to create a new version.
2. Choose the **Versions** tab, and then choose **Create version**.



3. In the **Create version** dialog box:
   a. Enter a version description (optional, but recommended for tracking changes)
   b. Choose **Create**. The following image shows an example **Create version** dialog box.



After the version is created, you can associate it with aliases or you can use it to revert to a previous state of your bot.

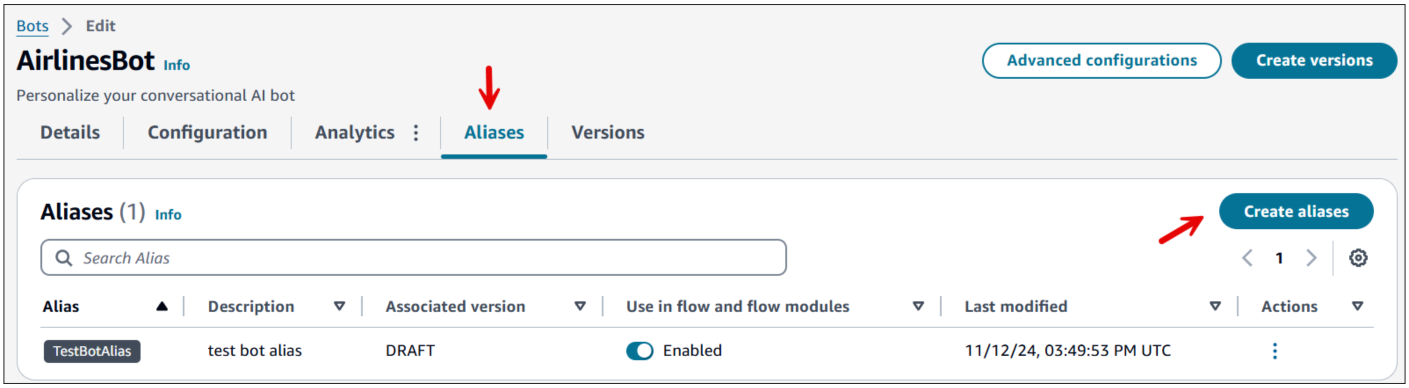
Create an alias

An alias is a pointer to a specific version of a bot. With an alias, you can easily update the version that your client applications are using. For example, you can point an alias to version 1 of your bot. When you are ready to update the bot, you create version 2 and change the alias to point to the new version. Because your applications use the alias instead of a specific version, all of your clients get the new functionality without needing to be updated. This allows for controlled rollouts and easy version management.

> **Important**
>
> If you want to use the bot in a flow, be sure to choose **Enable for use in flow and flow modules** when you create an alias.

Complete the following steps to create an alias for your Amazon Lex bot.

1. Open the bot for which you want to add the alias.
2. Choose the **Aliases** tab, and then choose **Create aliases**.



3. In the **Create Alias** dialog box:

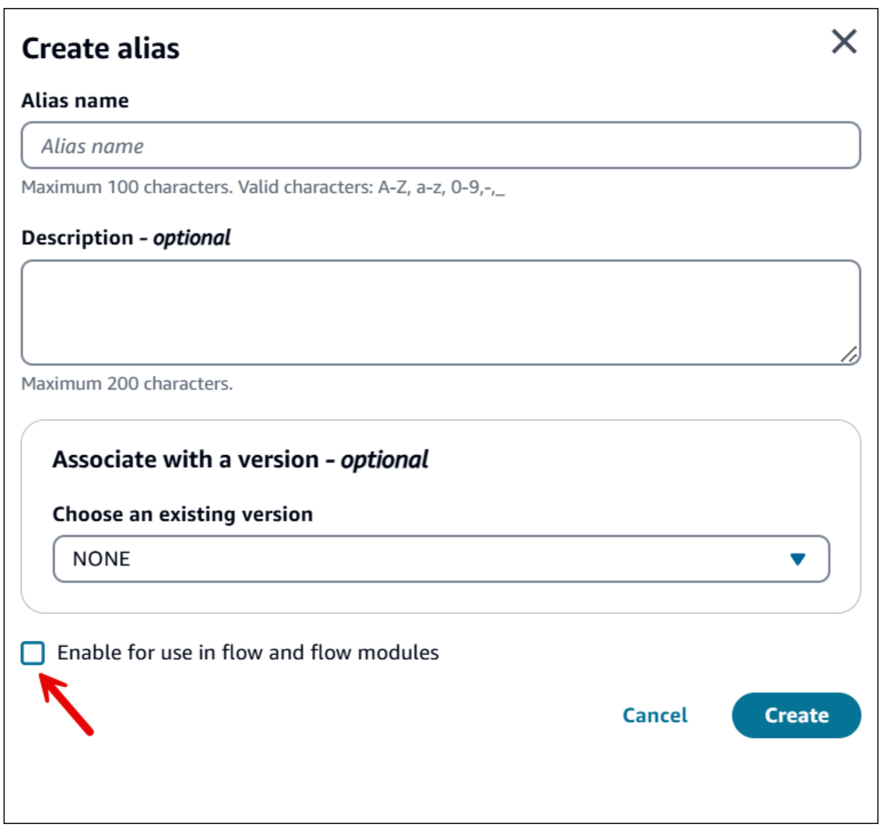
   a. Enter a unique name for the alias.

   b. Provide a description for the alias (optional, but recommended).

   c. Select the bot version you want to associate with this alias.

   d. (Recommended) Choose **Enable for use in flow and flow modules**. This is required if you want to use the bot in a flow.

   e. Choose **Create**. The following image shows an example **Create alias** dialog box.



For more information about versioning and aliasing in Amazon Lex V2, see [Versioning and aliases with your Lex V2 bot] in the *Amazon Lex V2 Developer Guide*.

Evaluate the performance of your conversational AI bot in Amazon Connect

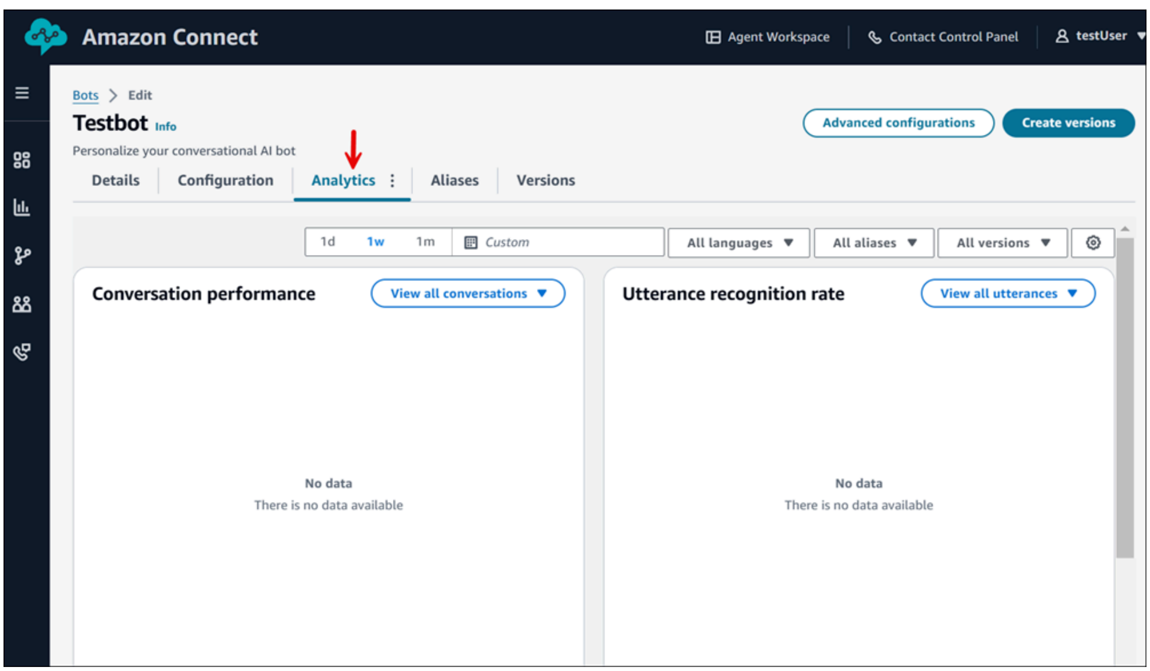
Amazon Connect provides graphs and charts so you can evaluate the performance of your bot with metrics that are related to success and failure rates of your bot's interactions with customers. You can also visualize patterns of conversation flows between your bot and customers.

To view analytics for your bot

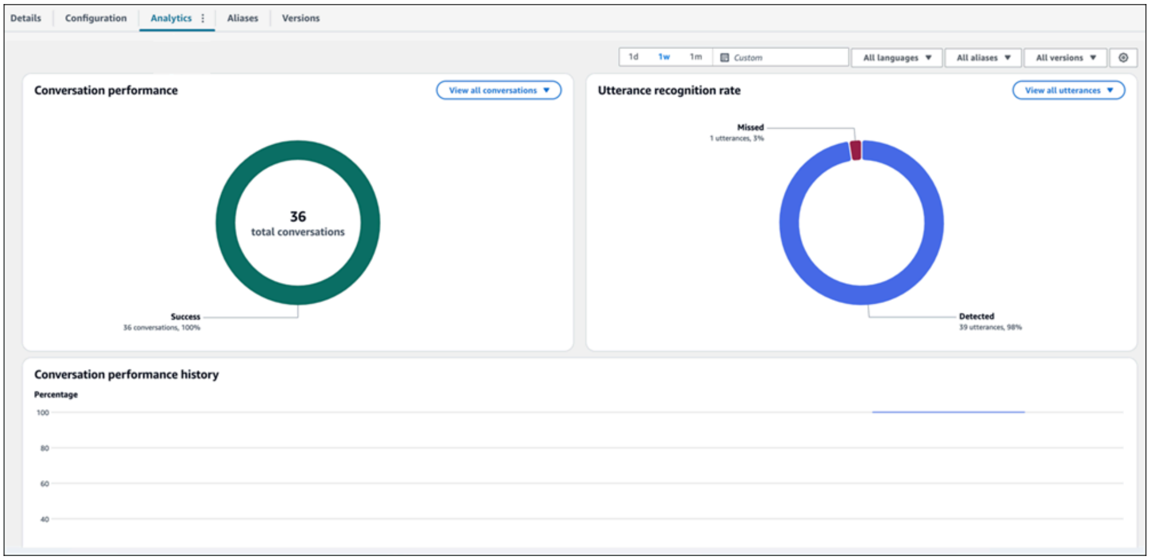
1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/. Use an Admin account or an account that has the following permissions in its security profile:

   - **Channels and Flows - Bots - View**
   - **Channels and Flows - Bots - Edit**
   - **Analytics and Optimization - Historical metrics - Access**

2. In the left navigation menu, choose **Routing**, **Flows**.
3. On the **Flows** page, choose **Bots**, choose the bot whose performance you want to evaluate, and then choose **Analytics**.



The following image shows sample analytics data.



You can use this data to iterate and improve upon your bot to create a better customer experience.

For more information about Lex bot analytics, see [Monitoring bot performance in Lex V2](#).

Amazon Connect bot metrics and analytics

The following flow driven metrics are available on the [Flows and conversational bot performance dashboard](#) and the [GetMetricDataV2](#).

Average bot conversation time

The average duration of completed conversations for which the invoking resource (flow or flow module) started between the specified start and end time. It can be filtered on specific conversation outcomes with `BOT_CONVERSATION_OUTCOME_TYPE` metric level filter.

In the [GetMetricDataV2](#) API, this metric can be retrieved by using `AVG_BOT_CONVERSATION_TIME`.

Data for this metric is available starting from December 2, 2024 00:00:00 GMT.

Type: String (*hh:mm:ss*)

Category: Flow driven metric

Calculation logic: Sum(Conversation Start Time - Conversation End Time of all filtered conversations) / (Count of all filtered conversations)

Average bot conversation turns

The average number of turns for completed conversations for which the invoking resource (flow or flow module) started between the specified start and end time. It can be filtered on specific conversation outcomes with BOT_CONVERSATION_OUTCOME_TYPE metric level filter.

A single turn is a request from the client application and a response from the bot.

In the GetMetricDataV2 API, this metric can be retrieved by using AVG_BOT_CONVERSATION_TURNS.

Data for this metric is available starting from December 2, 2024 00:00:00 GMT.

Type: Double

Category: Flow driven metric

Calculation logic: Sum(Conversation Turn of all filtered conversations) / (Count of all filtered conversations)

Bot conversations completed

The count of completed conversations for which the invoking resource (flow or flow module) started between the specified start and end time. The conversation end time can be beyond the specified end time.

For example, if you request this metric with start time at 9 AM and end time at 10 AM, the result includes conversations where the invoking resource (flow or flow module):

- started at 9:15 AM and ended at 9:40 AM
- started at 9:50 AM and ended at 10:10 AM

but will exclude conversations for which the invoking resource (flow or flow module):

- started at 8:50 AM and ended at 9:10 AM

In the GetMetricDataV2 API, this metric can be retrieved by using BOT_CONVERSATIONS_COMPLETED.

Data for this metric is available starting from December 2, 2024 00:00:00 GMT.

It can be filtered on the following conversation outcomes using metric level filter `BOT_CONVERSATION_OUTCOME_TYPE`.

- SUCCESS: The final intent in the conversation is categorized as *success*.
- FAILED: The final intent in the conversation is failed. The conversation is also failed if Amazon Lex V2 defaults to the `AMAZON.FallbackIntent`.
- DROPPED: The customer does not respond before the conversation is categorized as *success* or *failed*.

Type: Integer

Category: Flow driven metric

Calculation logic: Total count of conversations

Bot intents completed

The count of completed intents. It includes intents for completed conversations where the invoking resource (flow or flow module) started between the specified start and end time.

In the GetMetricDataV2 API, this metric can be retrieved by using `BOT_INTENTS_COMPLETED`.

Data for this metric is available starting from December 2, 2024 00:00:00 GMT.

It can be filtered on the following intent outcomes using metric level filter `BOT_INTENTS_OUTCOME_TYPE`.

- SUCCESS: The bot successfully fulfilled the intent. One of the following situations is true:
  - The intent *state* is *ReadyForFulfillment* and the type of *dialogAction* is *Close*.
  - The intent `state` is `Fulfilled` and the type of `dialogAction` is `Close`.
- FAILED: The bot failed to fulfill the intent. The intent state. One of the following situations is true:
  - The intent `state` is `Failed` and the `type` of `dialogAction` is `Close` (for example, the user declined the confirmation prompt).
  - The bot switches to the `AMAZON.FallbackIntent` before the intent is completed.
- SWITCHED: The bot recognizes a different intent and switches to that intent instead, before the original intent is categorized as a *success* or *failed*.

- DROPPED: The customer does not respond before the intent is categorized as *success* or *failed*.

Type: Integer

Category: Flow driven metric

Calculation logic: Total count of intents

Percent bot conversations outcome

The percentage of total conversations that ended in the specific outcome type specified in the metric level filter (`BOT_CONVERSATION_OUTCOME_TYPE`). It only includes completed conversations for which the invoking resource (flow or flow module) started between the specified start and end time.

In the [GetMetricDataV2](https://docs.aws.amazon.com/connect/latest/APIReference/API_GetMetricDataV2.html) API, this metric can be retrieved by using `PERCENT_BOT_CONVERSATIONS_OUTCOME`.

Data for this metric is available starting from December 2, 2024 00:00:00 GMT.

Type: Percent

Category: Flow driven metric

Calculation logic: (Count of conversations with BOT_CONVERSATION_OUTCOME_TYPE)/(Total count of conversations) * 100

Percent bot intents outcome

The percentage of intents that ended in the specific outcome type specified in the metric level filter (`BOT_INTENT_OUTCOME_TYPE`). It includes intents in completed conversations where the invoking resource (flow or flow module) started between the specified start and end time.

In the [GetMetricDataV2](https://docs.aws.amazon.com/connect/latest/APIReference/API_GetMetricDataV2.html) API, this metric can be retrieved by using `PERCENT_BOT_INTENTS_OUTCOME`.

Data for this metric is available starting from December 2, 2024 00:00:00 GMT.

Type: Percent

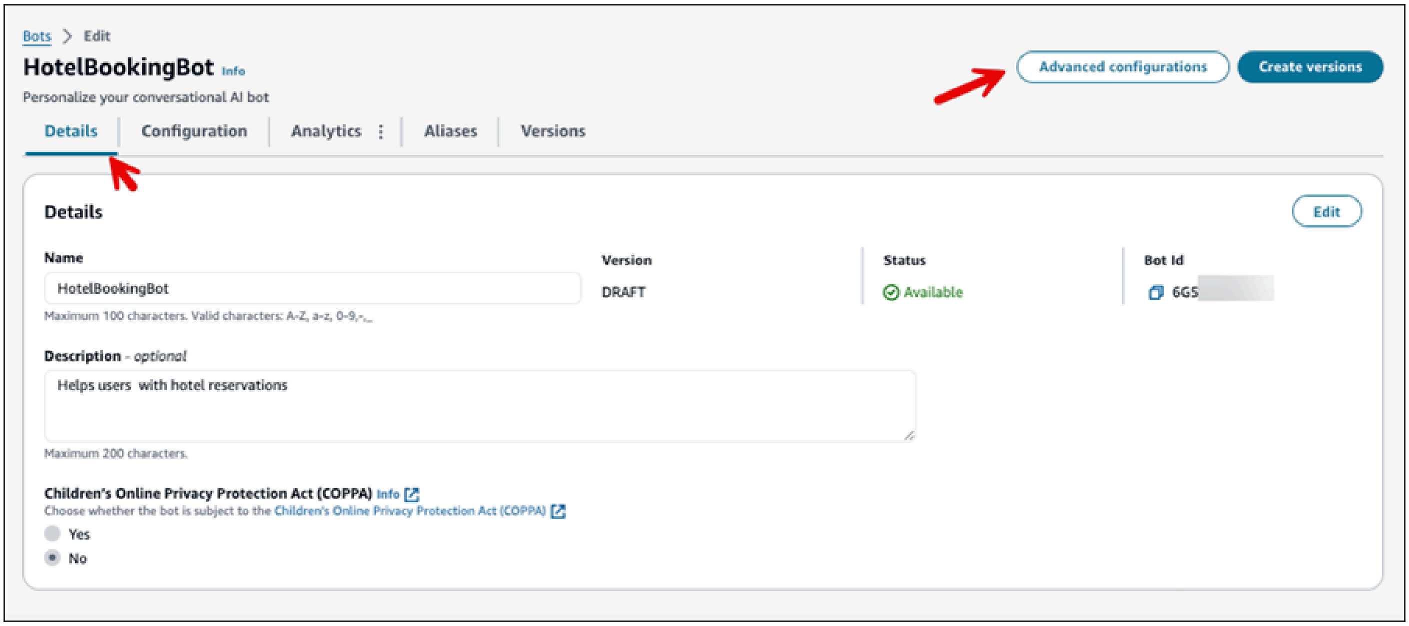
Category: Flow driven metric

Calculation logic: (Count of intents with BOT_INTENT_OUTCOME_TYPE)/(Total count of intents) * 100

Bot Advanced configuration support from Connect

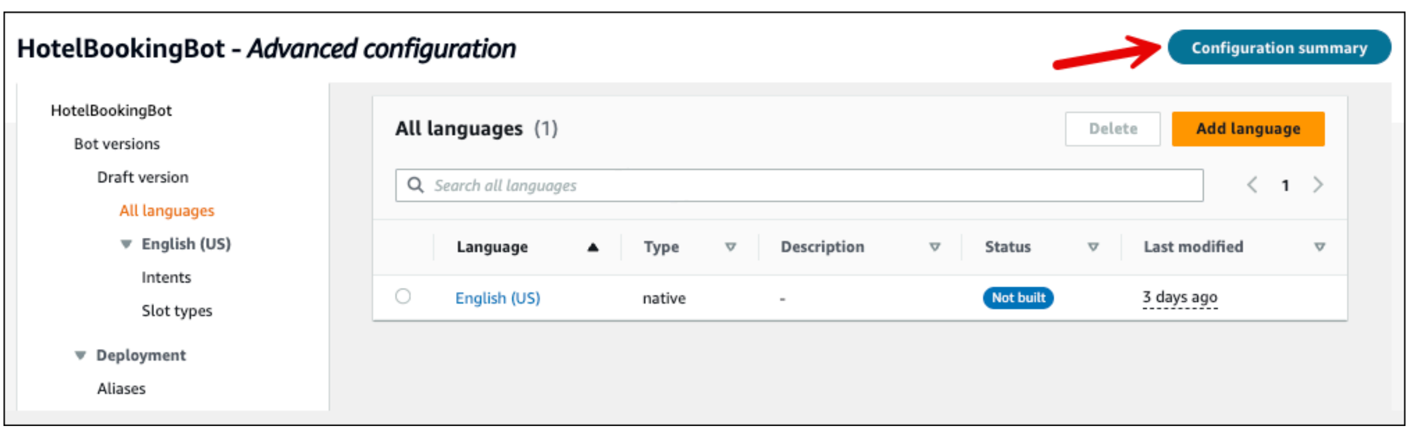
The advanced configuration feature enables you to make detailed customizations to your bot without going to the Amazon Lex console.

1. In the Amazon Connect admin website, open your bot.
2. Choose **Advanced configurations**.



This action will switch the view to a more detailed interface where you can access more features to customize your bot.

3. To switch back to the simple bot user interface, choose **Configuration summary**, as shown in the following image.



Add an Amazon Lex bot to Amazon Connect

In this article we guide you through the steps to add an Amazon Lex bot to Amazon Connect.

With Amazon Lex, you can build conversational interactions (bots) that feel natural to your customers. Amazon Connect with Amazon Lex bots can also capture customer input as digits that customers enter on their numeric keypad when used in an Amazon Connect flow. This way customers can choose how they want to enter sensitive information such as account numbers.

To follow along with this walkthrough, you need the following:

- An active AWS account.
- An Amazon Connect instance.

> **Tip**
>
> You can also use Amazon Lex to power interactive messages for Amazon Connect chat. Interactive messages are rich messages that present a prompt and pre-configured display options that a customer can select from. These messages are powered by Amazon Lex and configured through Amazon Lex using a Lambda. For more information, see Add Amazon Lex interactive messages for customers in chat.

Create an Amazon Lex bot

In this step you'll create a custom bot to demonstrate the Press or Say integration with Amazon Connect. The bot prompts callers to press or say a number that matches the menu option for the task to complete. In this case, the input is checking their account balance.

Amazon Lex

1. Open the Amazon Lex console.
2. Choose **Create bot**.
3. On the **Configure bot settings** page, choose **Create - Create a blank bot** and provide the following information:
   - **Bot name** — For this walkthrough, name the bot **AccountBalance**.

- **IAM permissions** — Select a role if you have one created. Otherwise, choose **Create a role with basic Amazon Lex permissions**.
- **COPPA** — Choose whether the bot is subject to the Child Online Privacy Protection Act.
- **Session timeout** — Choose how long the bot should wait to get input from a caller before ending the session.

4. Choose **Next**.
5. Provide language and voice specific information:

   - **Language** — Select language and locale from the list of Languages and locales supported by Amazon Lex.
   - **Voice interaction —** Select the voice for your bot to use when speaking to callers. The default voice for Amazon Connect is Joanna.

6. Choose **Done**. The AccountBalance bot is created, and the **Intent** page is displayed.

Amazon Lex (Classic)

1. Open the Amazon Lex console.
2. If you are creating your first bot, choose **Get Started**. Otherwise, choose **Bots, Create**.
3. On the **Create your bot** page, choose **Custom bot** and provide the following information:

   - **Bot name** — For this walkthrough, name the bot **AccountBalance**.
   - **Output voice** — Select the voice for your bot to use when speaking to callers. The default voice for Amazon Connect is Joanna.
   - **Session timeout** — Choose how long the bot should wait to get input from a caller before ending the session.
   - **COPPA** — Choose whether the bot is subject to the Child Online Privacy Protection Act.

4. Choose **Create**.

Configure the Amazon Lex bot

In this step you'll determine how the bot responds to customers by providing intents, sample utterances, slots for input, and error handling.

For this example, you'll configure the bot with two intents: one to look up account information, and another to speak with an agent.

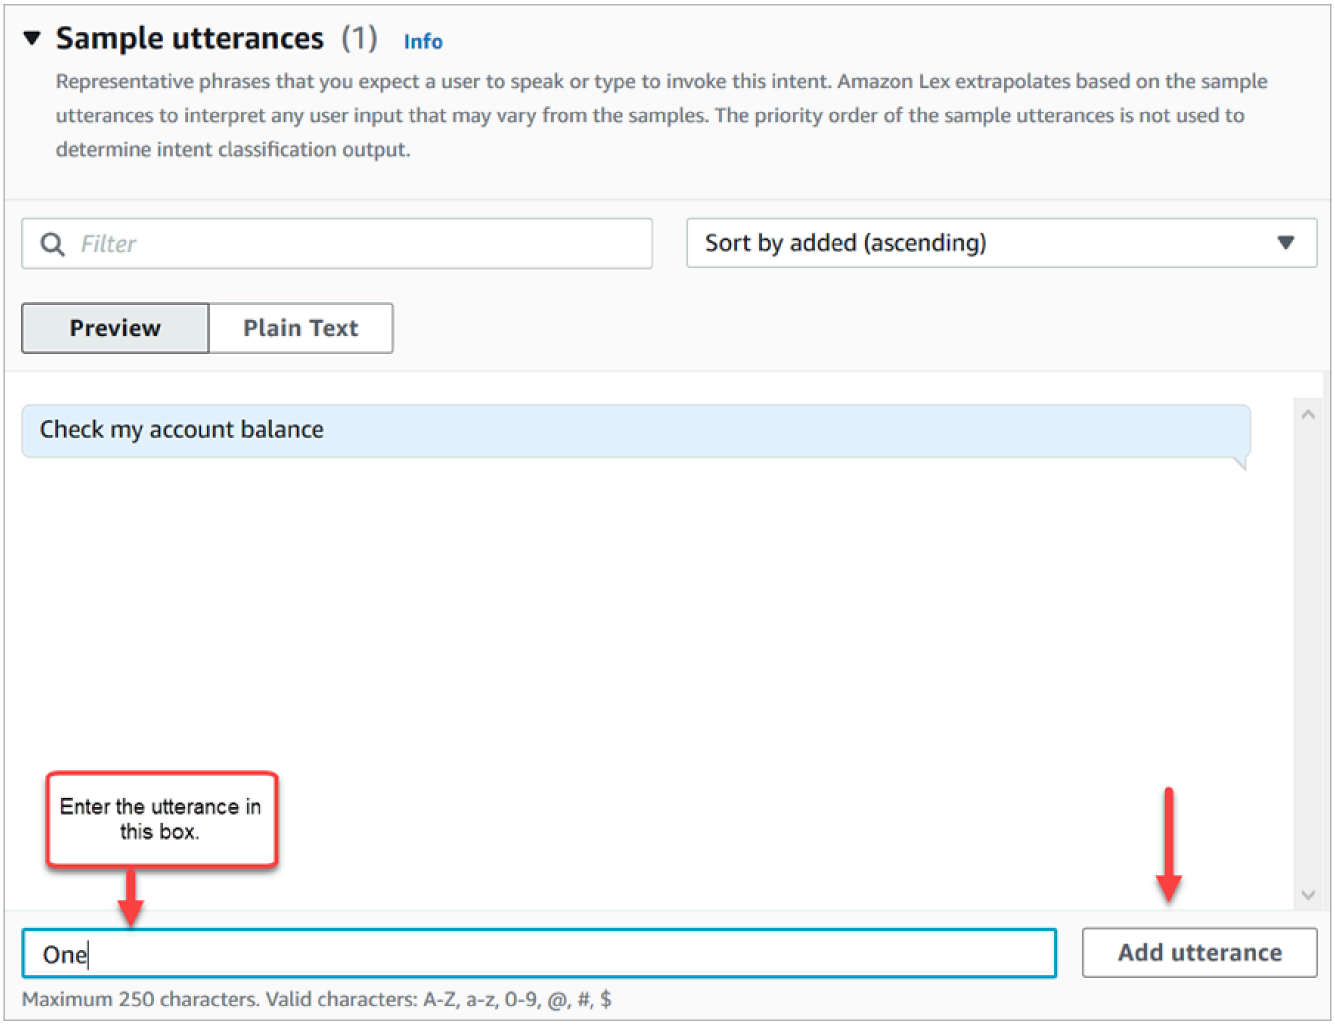
Create AccountLookup intent

Amazon Lex

1. After you created the bot, you are on the **Intents** page the Amazon Lex console. If you're not there, you can get there by choosing **Bots**, **AccountBalance**, **Bot versions**, **Draft version**, **Intents**. Choose **Add intent**, **Add empty intent**.
2. In the **Intent name** box, enter **AccountLookup**.
3. Scroll down the page to **Sample utterances**. In this step you enter utterances that allow the customer to elicit the AccountLookup intent. Enter the following utterances, and choose **Add utterance** after each one.

   - **Check my account balance**
   - **One**: This assigns the utterance of "one" or key press of "1" to the **AccountLookup** intent.

   The following image shows where to add the utterance in the **Sample utterances** section.



4. Scroll to the **Slots** section, and choose **Add slot**. Complete the box as follows:

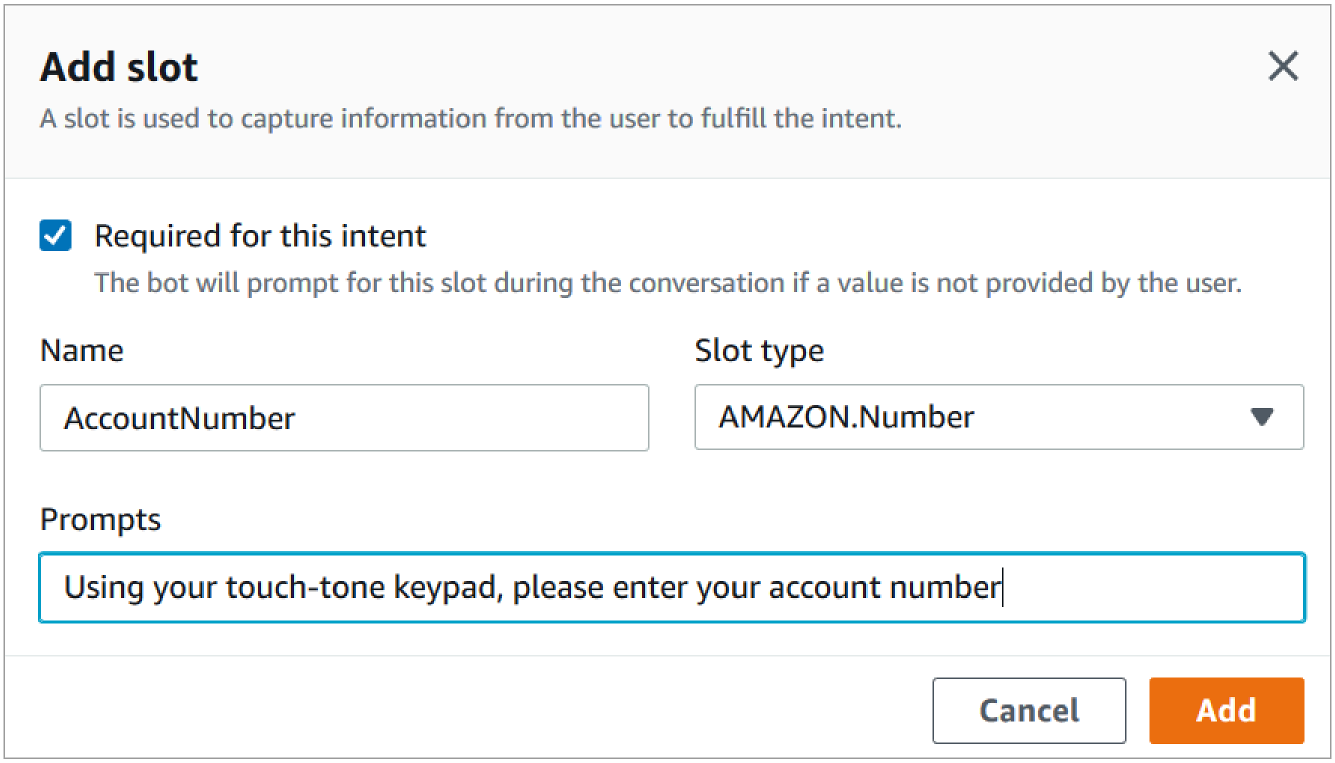
   a. **Required for this intent** = selected.

   b. **Name** = **AccountNumber**.

   c. **Slot type** = **AMAZON.Number**.

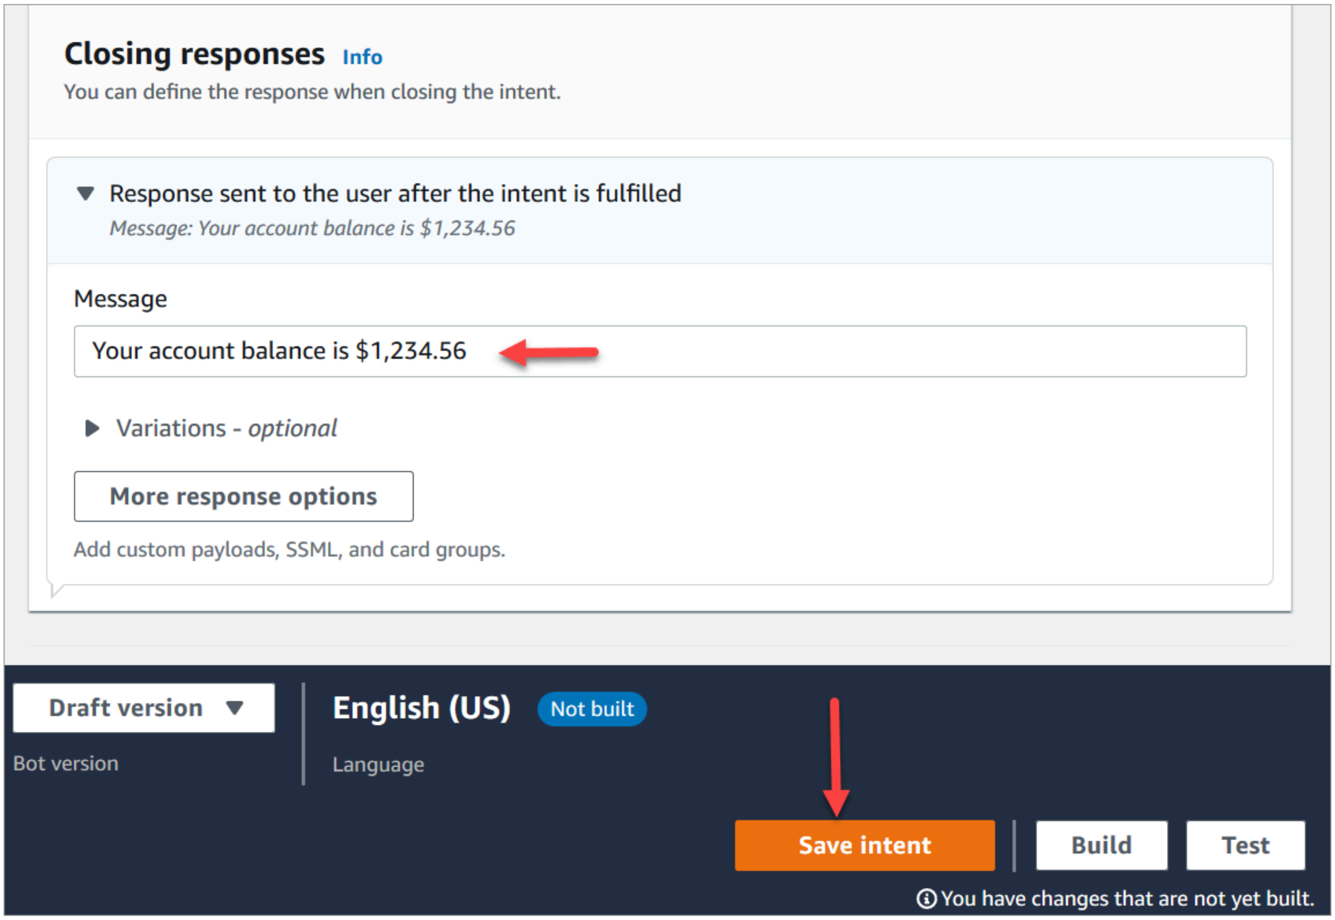
   d. **Prompts** = the text to be spoken when the call is answered. For example, ask callers to enter their account number using their keypad: **Using your touch-tone keypad, please enter your account number**. Choose **Add**.

The following image shows a completed **Add slot** section.



5. Scroll to the **Closing responses** section. Add a message for the bot to say to customers. For example, **Your account balance is $1,234.56**. (For this walkthrough, we aren't going to actually get the data, which is what you would do in reality.)

   The following image shows a completed **Closing responses** section.



6. Choose **Save intent**.

Amazon Lex (Classic)

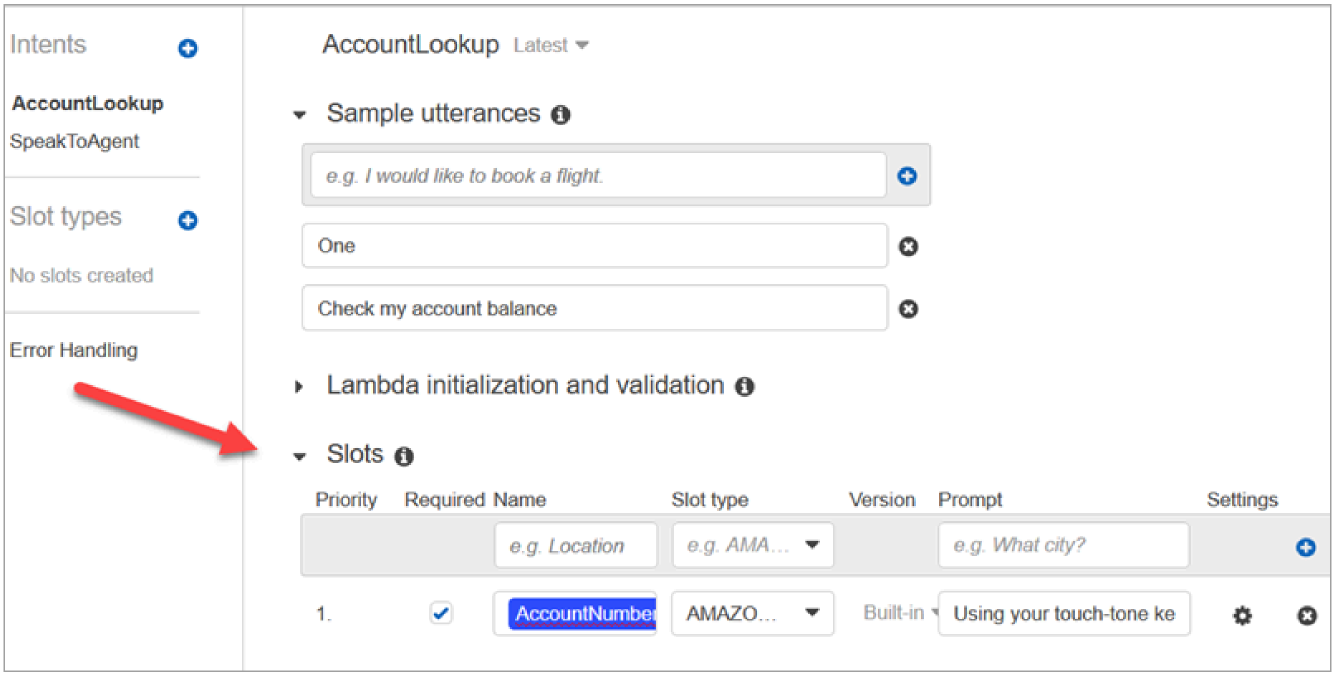
1. In the Amazon Lex console choose the **+** icon next to **Intents**, and choose **Create new intent**.
2. Name the intent **AccountLookup**.
3. Add a sample utterance, such as *Check my account balance*, and choose the **+** icon.
4. Add a second utterance, such as *One* and choose the **+** icon. This assigns the utterance of "one" or key press of "1" to the **AccountLookup** intent.

> **Tip**
>
> You must add an utterance of "one" in the bot, and not the number "1". This is because Amazon Lex doesn't support numeric input directly. To get around this,

later in this walkthrough you'll use numeric input to interact with a Lex bot invoked from a flow.

5. Under **Slots**, add a slot named **AccountNumber**.

   The following image shows the location of the **Slots** section on the page.



6. For **Slot type**, use the drop-down to choose **AMAZON.NUMBER**.
7. For **Prompt**, add the text to be spoken when the call is answered. For example, ask callers to enter their account number using their keypad: *Using your touch-tone keypad, please enter your account number*.
8. Choose the + icon.
9. Make sure that the **Required** check box is selected.
10. In the **Response** section, add a message for the bot to say to customers. For example, **Your account balance is $1,234.56**.
11. Choose **Save Intent**.

Create SpeakToAgent intent

Amazon Lex

1. Navigate to the **Intents** page: choose **Back to intents list**.

2. Choose **Add intent**, **Add empty intent**.
3. In the **Intent name** box, enter **SpeakToAgent**, and then choose **Add**.
4. Scroll down to **Sample utterances** section. Enter the following utterances, which allow the customer to elicit the SpeakToAgent intent:
   - **Speak to an agent**
   - **Two**
5. Scroll down to the **Closing responses** section. Add a message for the bot to say to customers. For example, **Okay, an agent will be with you shortly**.
6. Choose **Save intent**.

Amazon Lex (Classic)

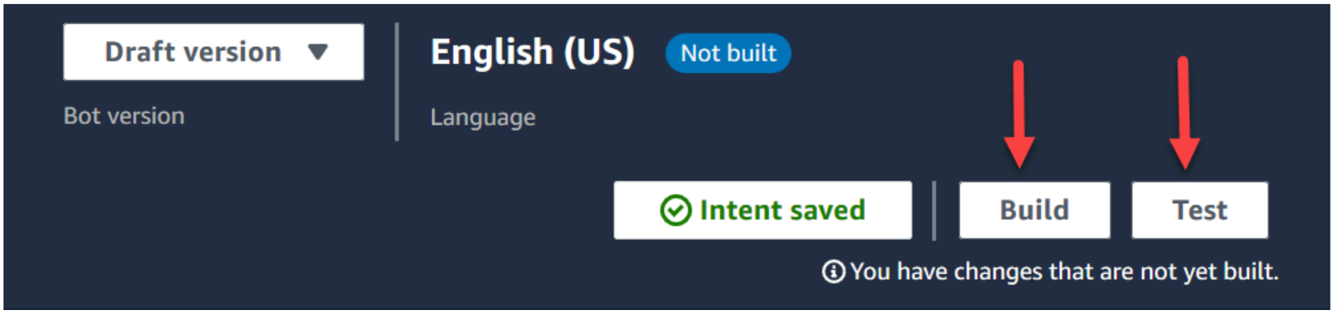
1. In the Amazon Lex console choose the **+** icon next to **Intents**, and choose **Create new intent**.
2. Name the intent **SpeakToAgent**.
3. Select **SpeakToAgent**.
4. Add a sample utterance, such as *Speak to an agent*, and choose **+**.
5. Add a second utterance, such as *Two*, and choose **+**.
6. Add a message that lets callers know that their call is being connected to an agent. For example, "Okay, an agent will be with you shortly."
7. Choose **Save Intent**.

Build and test the Amazon Lex bot

After you create your bot, make sure it works as intended.

Amazon Lex

1. At the bottom of the page, choose **Build**. It may take a minute or two. The following image shows where the **Build** button is located.



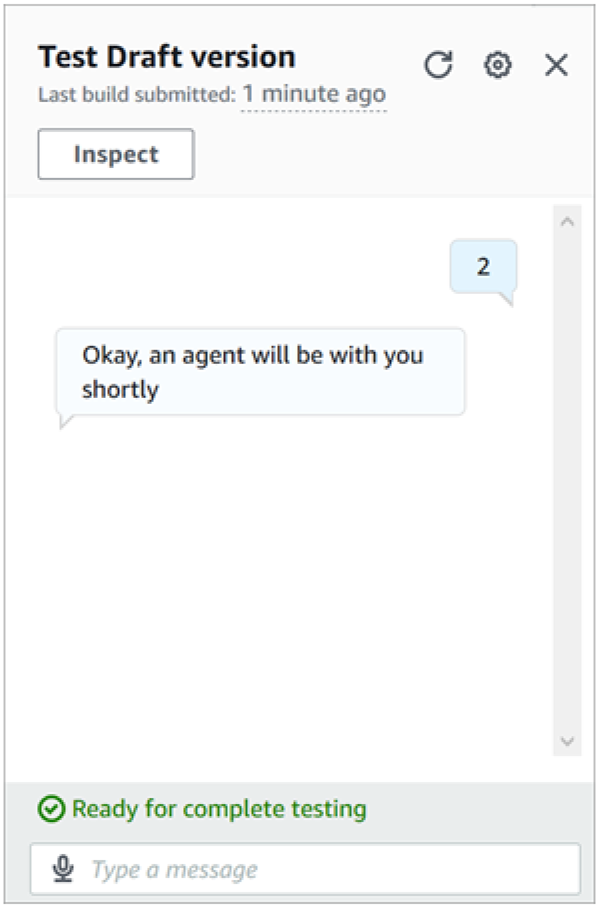
2. When it's finished building, choose **Test**.

3. Let's test the **AccountLookup** intent: In the **Test Draft version** pane, in the **Type a message** box, type **1** and press Enter. Then type a fictitious account number and press Enter. The following image shows where you enter intent.

   a. Clear the test box.

   b. Type the intents you want to test.

4. To confirm that the **SpeakToAgent** intent is working, clear the test box, and then type **2** and press Enter. The following image shows what the test looks like after you clear it and then enter 2.

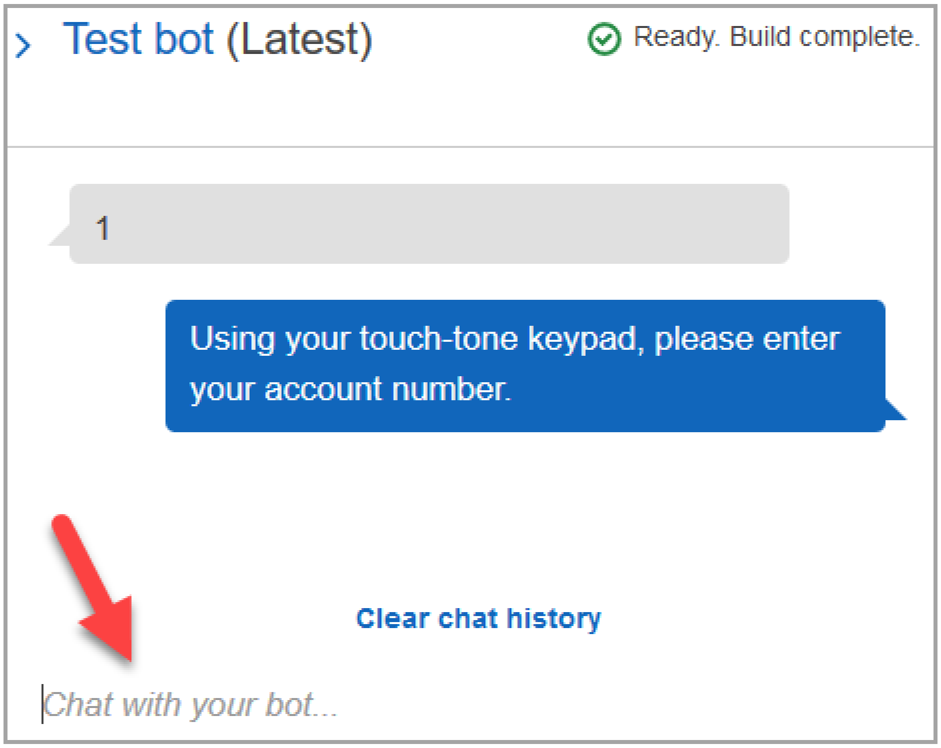


5. Close the **Test Draft version** pane.

Amazon Lex (Classic)

1. Choose **Build**. It may take a minute or two.
2. When it's finished building, choose **Test Chatbot**, as shown in the following image.

3. Let's test the **AccountLookup** intent: In the **Test Chatbot** pane, in the **Chat with your bot** box, type **1**. Then type a fictitious account number. In the following image, the arrow points to the box where you type 1.



4. Choose **Clear chat history**.
5. To confirm that the **SpeakToAgent** intent is working, type **2**.

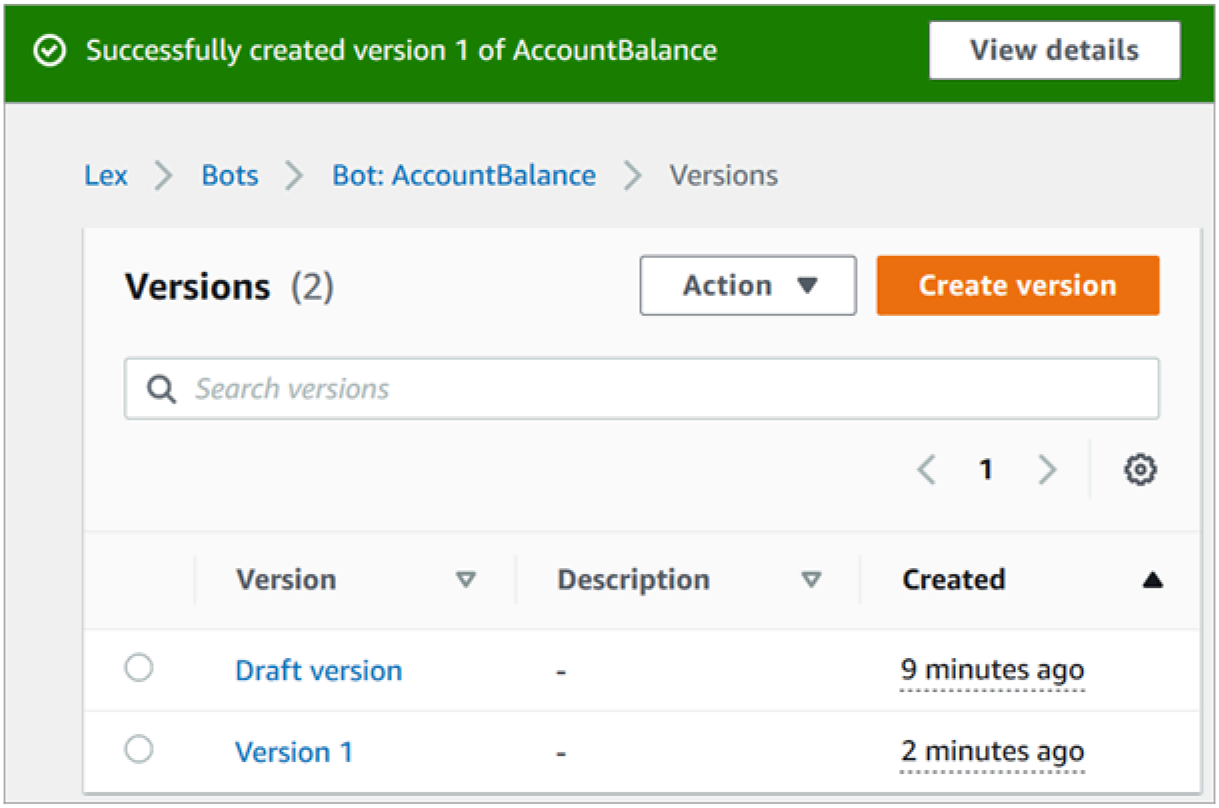
Create a bot version (Optional)

In this step you create a new bot version to use in an alias. It's how you create an alias that can be used in a production environment. Test aliases are subject to lower throttling limits. Although this is a test walkthrough, creating a version is a best practice.

Amazon Lex

1. If you're on the **Intents** page, choose **Back to intents list**.
2. On the left menu, choose **Bot versions**.
3. Choose **Create version**.
4. Review the details of the **AccountBalance** bot, and then choose **Create**.

   This creates a version of your bot (Version 1). You can switch versions on an non-test alias without having to track which version is getting published.



Create an alias for the bot

Amazon Lex

1. In the left menu, choose **Aliases**.
2. On the **Aliases** page, choose **Create alias**.
3. In the **Alias name** box, enter a name, such as **Test**. Later in this walkthrough you'll use this alias to specify this version of the bot in your flow.

> **Important**
>
> In a production environment, always use a different alias than **TestBotAlias** for Amazon Lex and **$LATEST** for Amazon Lex classic. **TestBotAlias** and **$LATEST** support a limited number of concurrent calls to an Amazon Lex bot. For more information, see Runtime quotas.

4. For **Associated version**, choose the version you just created, such as **Version 1**.
5. Choose **Create**.

Amazon Lex (Classic)

1. Choose **Publish**.
2. Provide an alias for your bot. Use the alias to specify this version of the bot in the flow, for example, **Test**.

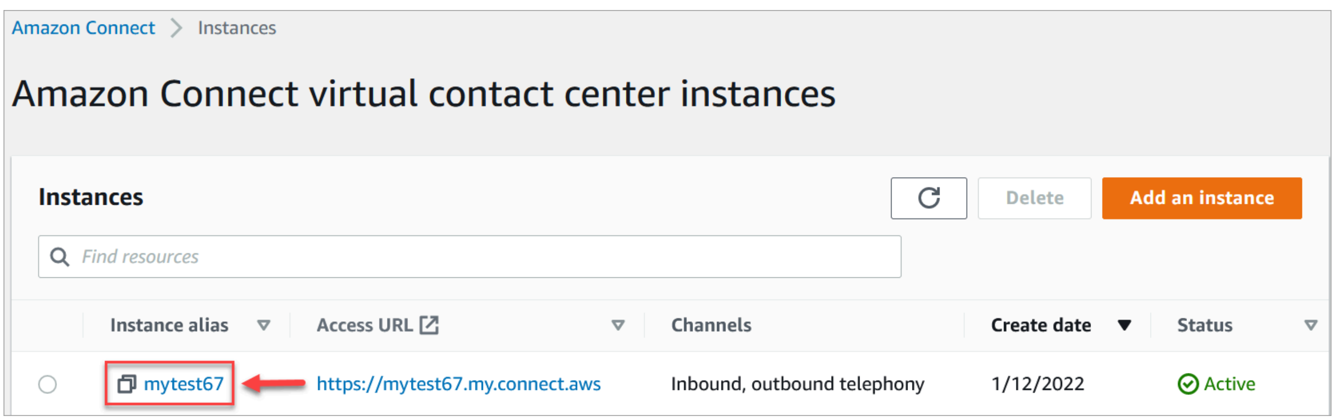
> **Important**
>
> In a production environment, always use a different alias than **TestBotAlias** for Amazon Lex and **$LATEST** for Amazon Lex classic. **TestBotAlias** and **$LATEST** support a limited number of concurrent calls to an Amazon Lex bot. For more information, see [Runtime Service Quotas](#).

3. Choose **Publish**.

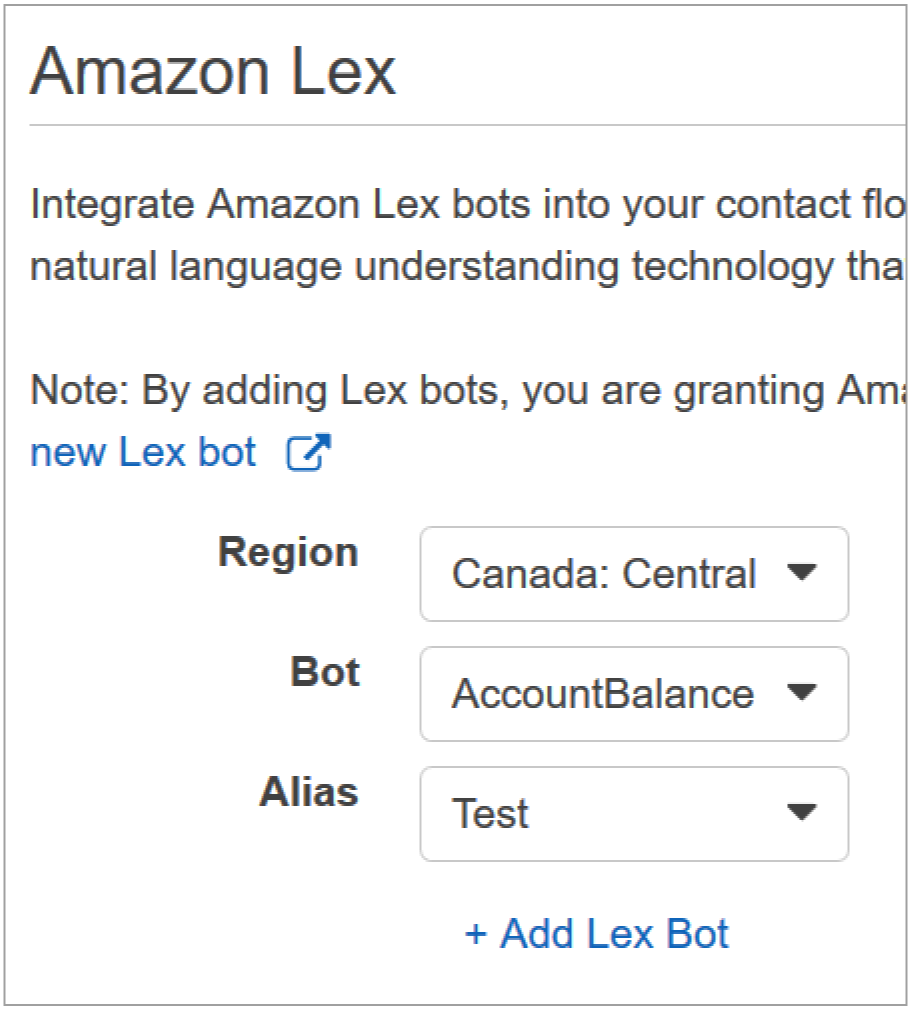
Add the Amazon Lex bot to your Amazon Connect instance

Amazon Lex

1. Open the [Amazon Connect console.](#)
2. Select the Amazon Connect instance that you want to integrate with your Amazon Lex bot.



3. On the navigation menu, choose **Flows**.
4. Under **Amazon Lex**, use the dropdown to select the Region of your Amazon Lex bot, and then select your Amazon Lex bot, **AccountBalance**.
5. Select the Amazon Lex bot alias name from the dropdown (**Test**), and then choose **+ Add Lex Bot**. The following image shows Amazon Lex section after it has been configured.



Note

Amazon Connect uses Amazon Lex resource-based policies to make calls to your Amazon Lex bot. When you associate an Amazon Lex bot with your Amazon Connect instance, the resource-based policy on the bot is updated to give Amazon Connect permission to invoke the bot. For more information on Amazon Lex resource-based policies, see [How Amazon Lex works with IAM](#).

Amazon Lex (Classic)

1. Open the [Amazon Connect console.](#)
2. Select the Amazon Connect instance that you want to integrate with your Amazon Lex bot.
3. On the navigation menu, choose **Contact flows**.

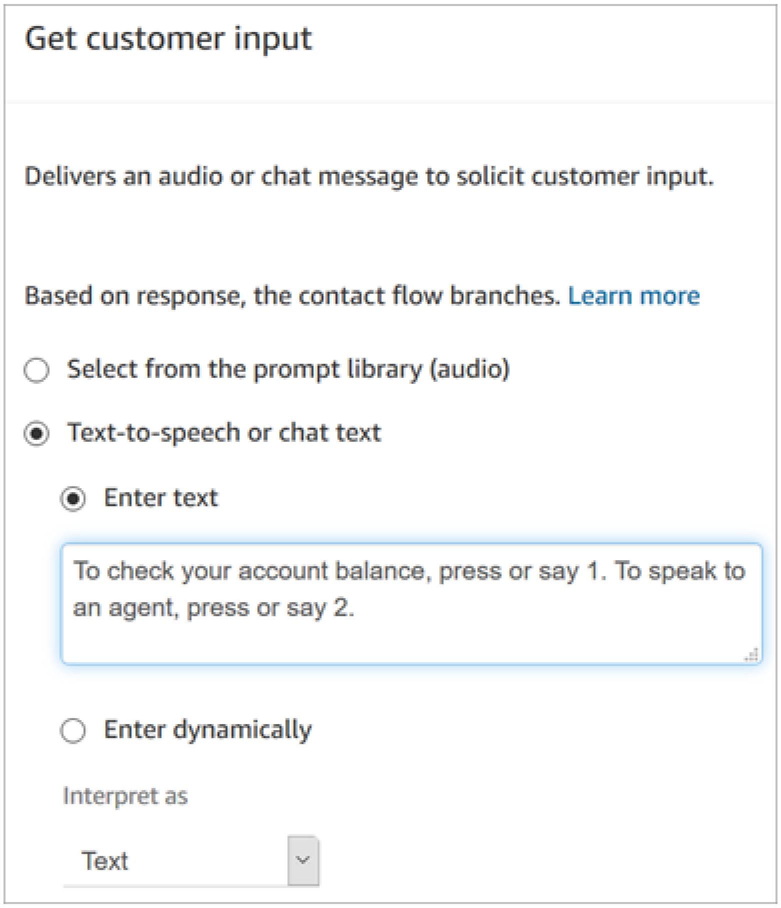
4. Under **Amazon Lex**, select the Region of your Amazon Lex classic bot from the dropdown, and then select your Amazon Lex classic bot. It’s name will have the suffix "(Classic)". Then choose **Add Lex Bot**.

Create a flow and add your Amazon Lex bot

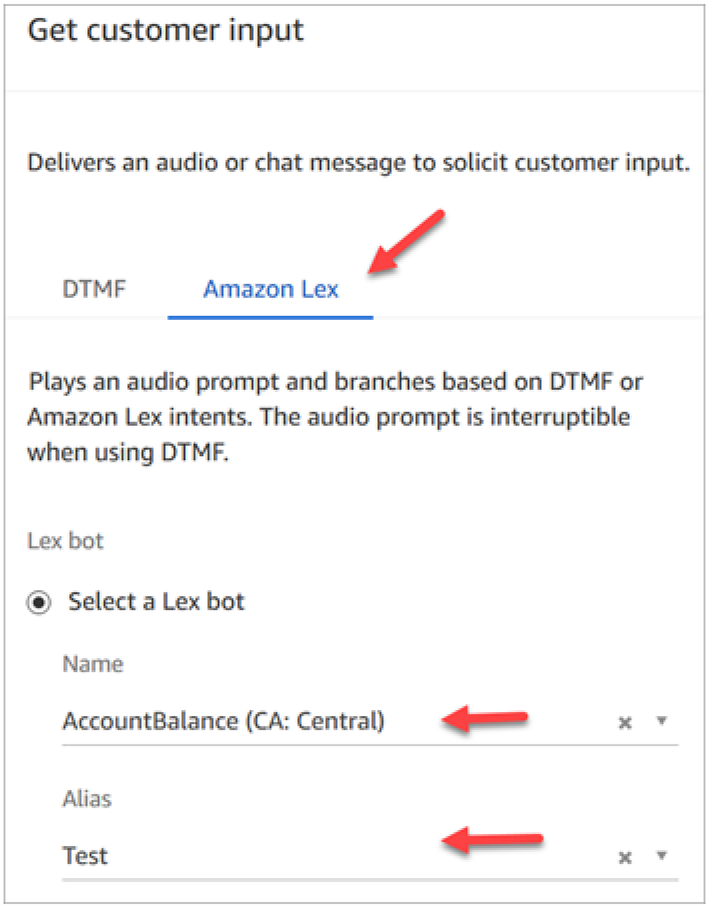
> **Important**
>
> If you're using an Amazon Lex V2 bot, your language attribute in Amazon Connect must match the language model used to build your Lex bot. This is different than Amazon Lex (Classic). Use a Set voice block to indicate the Amazon Connect language model, or use a Set contact attributes block.

Next, create a new flow that uses your Amazon Lex bot. When you create the flow, you configure the message played to callers.

1. Log in to your Amazon Connect instance with an account that has permissions for contact flows and Amazon Lex bots.
2. On the navigation menu, choose **Routing, Flows, Create Flow**, and type a name for the flow.
3. Under **Interact**, drag a Get customer input block onto the designer, and connect it to the **Entry point block**.
4. Choose the **Get customer input** block to open it. Choose **Text to speech or chat text, Enter text**.
5. Type a message that provides callers with information about what they can do. For example, use a message that matches the intents used in the bot, such as "To check your account balance, press or say 1. To speak to an agent, press or say 2." The following image shows this message on the Properties page of the **Get customer input** block.



6. Select the **Amazon Lex** tab, as shown in the following image.



7. In the **Name** dropdown, select the **AccountBalance** bot you created earlier.

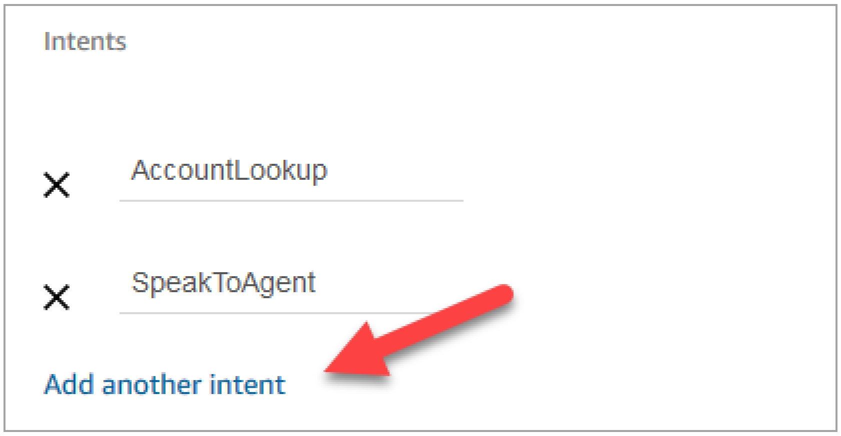
   a. If you selected an Amazon Lex bot, under **Alias** use the dropdown menu to select the bot alias, **Test**. from

   b. Amazon Lex Classic bots have the suffix "(Classic)" appended to their names. If you have selected a Classic bot, enter the alias you want to use in the **Alias** field.

   c. For Amazon Lex V2 bots, you also have the option of manually setting a bot alias ARN. Choose **Set manually**, then either type the ARN of the bot alias you want to use or set the ARN using a dynamic attribute.

8. Under **Intents**, choose **Add an intent**.

9. Type **AccountLookup** and choose **Add another intent**. The following image shows the **Intents** section configured with this information.



10. Type **SpeakToAgent** and choose **Save**.

Finish the flow

In this step you finish adding parts to the flow that run after the caller interacts with the bot:

1. If the caller presses 1 to get their account balance, use a **Prompt** block to play a message and disconnect the call.
2. If the caller presses 2 to speak to an agent, use a **Set queue** block to set the queue and transfer the caller to the queue, which ends the flow.

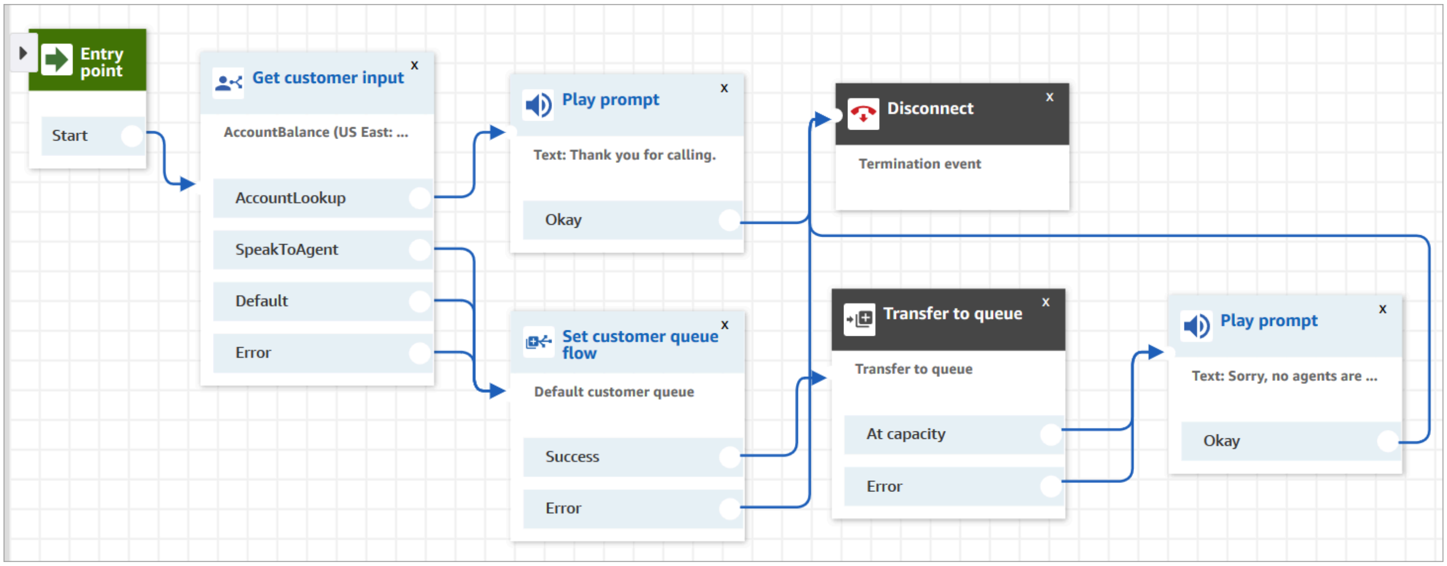
Here are the steps to create the flow:

1. Under **Interact**, drag a **Play prompt block** to the designer, and connect the **AccountLookup** node of the **Get customer input** block to it. After the customer gets their account balance from the Amazon Lex bot, the message in the **Play prompt** block plays.
2. Under **Terminate/Transfer**, drag a **Disconnect** block to the designer, and connect the **Play prompt** block to it. After the prompt message plays, the call is disconnected.

To complete the **SpeakToAgent** intent:

1. Add a **Set working queue** block and connect it to the **SpeakToAgent** node of the **Get customer input** block.
2. Add a **Transfer to queue** block.
3. Connect the Success node of the **Set customer queue flow** block to the **Transfer queue**.
4. Choose **Save**, then **Publish**.

Your finished flow will look something like the following image. The flow starts with the **Get customer input** block. That block branches to **Play prompt** or **Set customer queue**.



> **Tip**
>
> If your business uses multiple locales in a single bot, add a [Set contact attributes](#) block to the beginning of your flow. Configure this block to use the [$.LanguageCode](#) system attribute.

Assign the flow to a phone number

When customers call in to your contact center, the flow to which they are sent is the one assigned to the telephone number that they called. To make the new flow active, assign it to a phone number for your instance.

1. Open the Amazon Connect console.
2. Choose **Routing, Phone numbers**.
3. On the **Manage Phone numbers** page, select the phone number to assign to the flow.
4. Add a description.
5. In the **Flow/IVR** menu, choose the flow that you just created.
6. Choose **Save**.

Try it!

To try the bot and flow, call the number you assigned to the flow. Follow the prompts.

Best practices for using the chat channel and Amazon Lex

Following are some recommended best practices for using the chat channel and Amazon Lex together.

- You can use the same bot for both the voice and chat channels. However, you may want the bot to respond differently based on the channel. For example, you want to return SSML for voice so a number is read as a phone number, but you want to return normal text to chat. You can do this by passing the **Channel** attribute. For instructions, see How to use the same Amazon Lex bot for voice and chat.
- For voice, some words are best spelled phonetically to get the correct pronunciation, such as last names. If this is the case with your scenario, include it in the design of your bot. Or, you can keep the voice and chat bots separate.
- Tell agents about the bot. When a contact is connected to the agent, the agent sees the entire transcript in their window. The transcript includes text from both the customer and the bot.

Add Amazon Lex interactive messages for customers in chat

Interactive messages are rich messages that present a prompt and pre-configured display options for a customer to choose. These messages are powered by Amazon Lex and configured through Amazon Lex using an AWS Lambda function.

> **Tip**
>
> If you have integrated with Apple Messages for Business, see Interactive Message Types on the Apple website.

Validation limits

The string field limits (for example, title, subtitle, etc.) are expected to be enforced by the client (that is, a custom built interface or the hosted communications widget). The SendMessage API checks only that the total size of the string is less than 20KB.

- When you use the hosted communications widget without customizing it, if the string exceeds field limits, it is truncated on the user interface and an ellipsis (...) is appended. You can determine how to enforce field limits by customizing the widget.
- If you are integrating with other platforms (such as Apple Messages for Business), review the limits in this topic for Amazon Connect, and review the limits in the documentation for the other platform. For example, quick replies are not supported on older versions of iOS.

All other field limits must be followed for the message to be successfully sent.

Message display templates

Amazon Connect provides the following message display templates. Use them to render information to customers in a chat:

- List picker
- Time picker
- Panel
- Quick reply
- Carousel
- Apple form template
- Apple pay template
- iMessage app template
- WhatsApp list
- WhatsApp reply button
- Rich formatting in titles and subtitles

These templates define how the information renders, and what information is surfaced in the chat interface. When interactive messages are sent through chat, flows validate that the message format follows one of these templates.

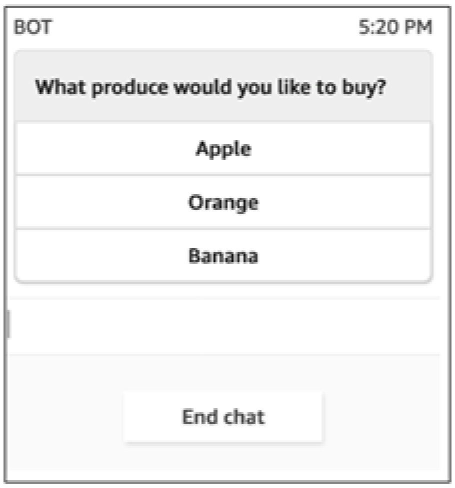
List picker template

Use the list picker template to present the customer with a list of up to six choices. Each choice can have its own image.

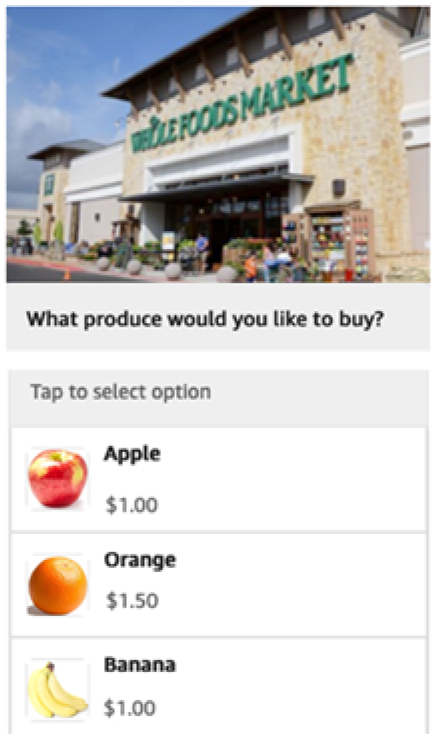
The following images show two examples of how the list picker template renders information in a chat.

- One image shows three buttons, each one with the name of a fruit in text: apple, orange, banana.
- The second image shows a picture of a store and then under it, three buttons, each one with the name, image, and price of the fruit.

List picker



List picker with images



The following code is the list picker template that you can use in your Lambda. Note the following:

- **Bold text** indicates a mandatory parameter.
- In some cases, if the parent element isn't mandatory, but the fields in the parent element are, then the fields are mandatory. For example, see the `data.replyMessage` structure in the following template. If the structure exists, `title` is mandatory. Otherwise a complete `replyMessage` is optional.

```
{
   "templateType":"ListPicker",
```

```
   "version":"1.0",
   "data":{
      "replyMessage":{
         "title":"Thanks for selecting!",
         "subtitle":"Produce selected",
         "imageType":"URL",
         "imageData":"https://interactive-msg.s3-us-west-2.amazonaws.com/
fruit_34.3kb.jpg",
         "imageDescription":"Select a produce to buy"
      },
      "content":{
         "title":"What produce would you like to buy?",
         "subtitle":"Tap to select option",
         "imageType":"URL",
         "imageData":"https://interactive-msg.s3-us-west-2.amazonaws.com/
fruit_34.3kb.jpg",
         "imageDescription":"Select a produce to buy",
         "elements":[
            {
               "title":"Apple",
               "subtitle":"$1.00",
               "imageType":"URL",
               "imageData":"https://interactive-message-testing.s3-us-
west-2.amazonaws.com/apple_4.2kb.jpg"
            },
            {
               "title":"Orange",
               "subtitle":"$1.50",
               "imageType":"URL",
               "imageData":"https://interactive-message-testing.s3-us-
west-2.amazonaws.com/orange_17.7kb.jpg",
            },
             {
               "title":"Banana",
               "subtitle":"$10.00",
               "imageType":"URL",
               "imageData":"https://interactive-message-testing.s3-us-
west-2.amazonaws.com/banana_7.9kb.jpg",
               "imageDescription":"Banana"
            }
         ]
      }
```

List picker limits

The following table lists the limits for each of the list picker elements, should you choose to build your own Lambda from scratch. The mandatory parameters are in bold.

To send unlimited options, implement action buttons in your application. For more information, see Implementation of action buttons in interactive message list picker/panel.

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
	templateType	Yes			Valid template type
	data	Yes			
	version	Yes			Must be "1.0"
data	**content**	Yes			
	replyMessage	No			
content	**title**	Yes	1	400	Should be a description for promptless templates
	elements	Yes	1 item	10 items	This is an array of elements. Maximum 10 elements in the array. To send unlimited elements, use the action buttons feature.
	subtitle	No	0	400	

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
	targetForLinks	No			Must be one of the following values: `_blank`, `_parent`, `_top`, `_self`. • **_blank**: Default behavior. Opens link in new browser tab. • **_parent**: Opens the link in the parent browsing context. In other words, if there is a parent-ch ild relations hip between multiple iframe container applications, it will open the link in the parent iframe to the current context.

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
					• **_top**: Opens the link in the topmost browsing context. • **_self**: Opens link in the current browsing context. **Note** If you are using the Amazon Connect communications widget and need to open links in the same browser tab, you must

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
					add the following attribute to the Amazon Connect communications widget code snippet to allow the current iframe to open and navigate links within the same tab: `amazon_connect('updateSandboxAttributes', 'allow-sc`

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
					`ripts allow-same-origin allow-popups allow-downloads allow-top-navigation-by-user-activation')`

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
	imageType	No	0	50	Must be "URL"
	imageData	No	0	200	Must be a valid publicly accessible URL
	imageDesc ription	No	0	50	
	referenceId	No			String. Only required for action button feature.
	listId	No			String. Only required for action button feature.
	preIndex	No			Number. Only required for action button feature.
	nextIndex	No			Number. Only required for action button feature.

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
templat dentifie	No			Number. Should be an UUID. **This field is required** if List Picker/Panel is being used in a Carousel.	
elements	**title**	Yes	1	400	
	subtitle	No	0	400	
	imageType	No	0	50	Must be "URL"
	imageData	No	0	200	Must be a valid publicly accessible URL
	imageDescription	No	0	50	Cannot exist without an image
	actionDetail	No			Only required for action button feature. Must be "PREVIOUS_OPTIONS" or "SHOW_MORE".
replyMessage	**title**	Yes	1	400	
	subtitle	No	0	400	

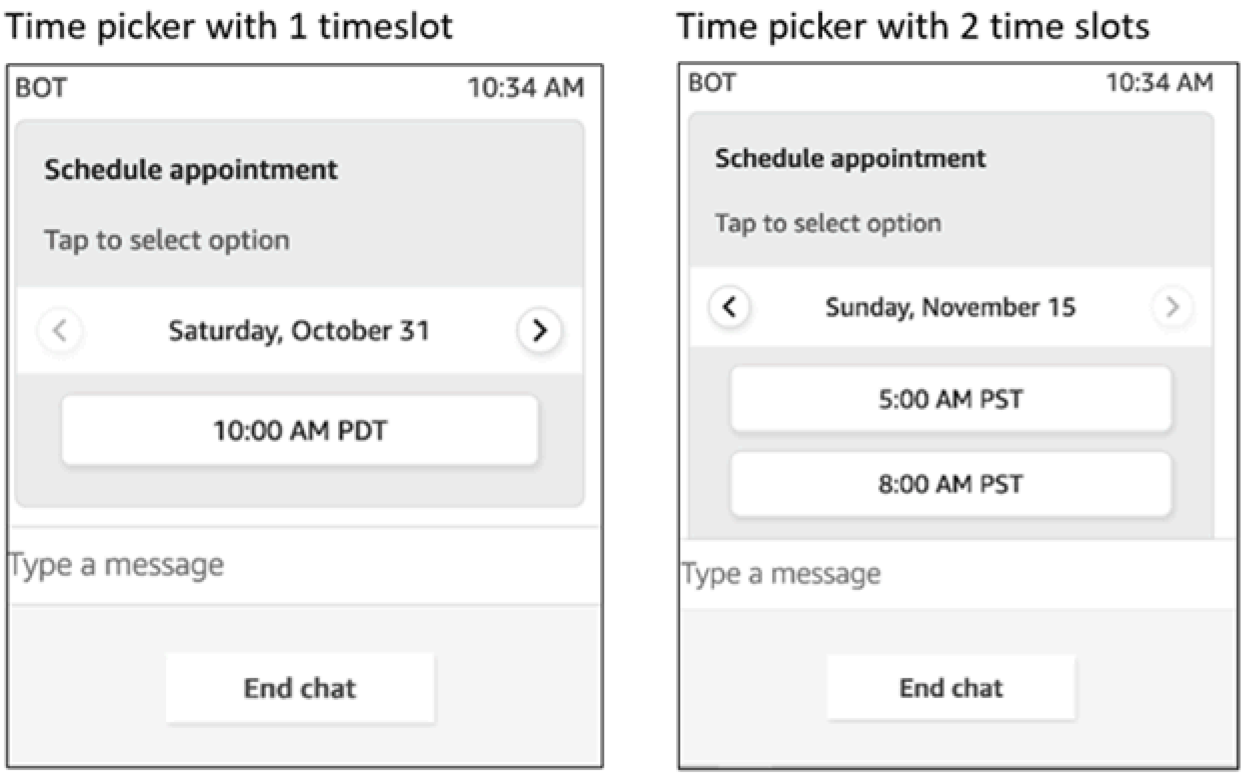
Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
	imageType	No	0	50	Must be "URL"
	imageData	No	0	200	Must be a valid publicly accessible URL
	imageDescription	No	0	50	Cannot exist without an image

Time picker template

The time picker template is useful for enabling customers to schedule appointments. You can provide up to 40 timeslots to the customer in a chat.

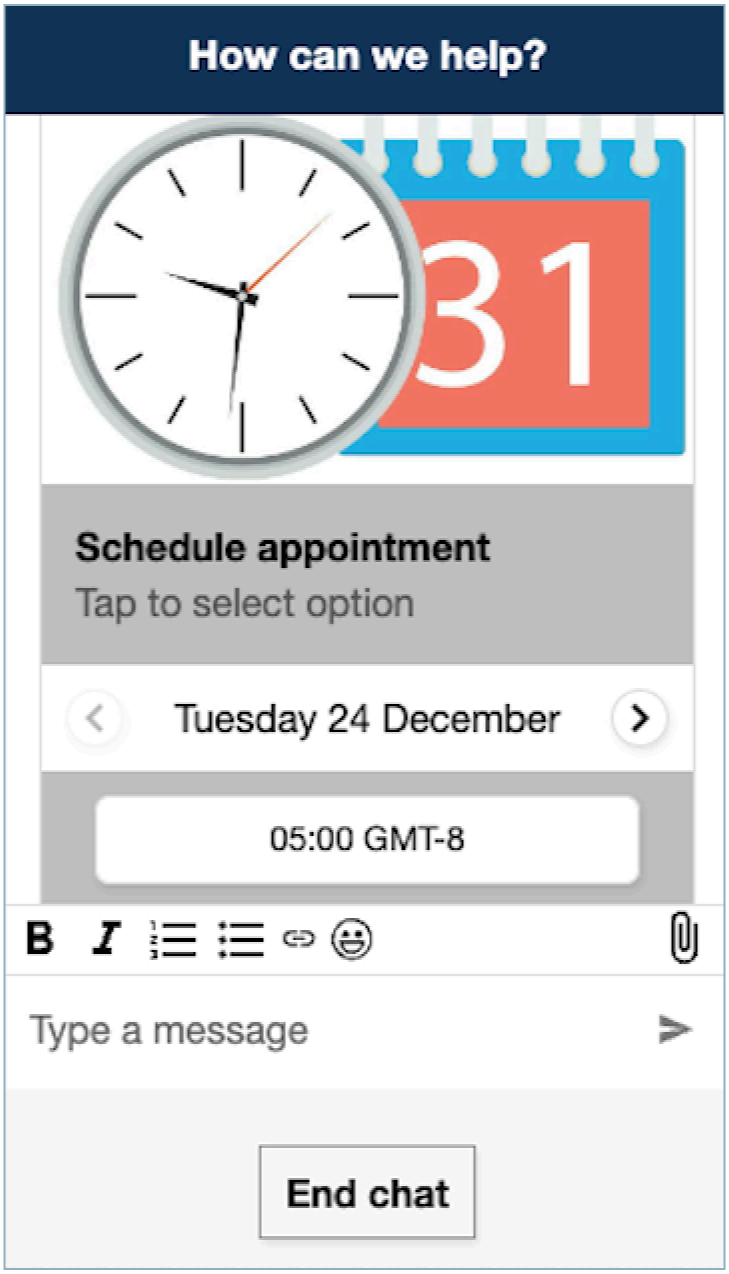
The following images show two examples of how the time picker template renders information in a chat.

- One image shows one date, and under it, one time slot.
- The second image shows one date, and under it, two time slots.



The following image shows the time picker with an image

> **Note**
>
> If you are using this message template with the [Apple Messages for Business](#) channel and do not add an image, Amazon Connect will add a default image in both the reply and response message.



The following code is the time picker template that you can use in your Lambda. Note the following:

- **Bold text** indicates a mandatory parameter.
- In some cases, if the parent element isn't mandatory, but the fields the parent element are, then the fields are mandatory. For example, see the `data.replyMessage` structure in the following template. If the structure exists, `title` is mandatory. Otherwise a complete `replyMessage` is optional.

```
{
   "templateType":"TimePicker",
   "version":"1.0",
   "data":{
      "replyMessage":{
         "title":"Thanks for selecting",
         "subtitle":"Appointment selected",
         "imageType":"URL",
         "imageData":"https://interactive-msg.s3-us-west-2.amazonaws.com/booked.jpg",
         "imageDescription":"Appointment booked"
      },
      "content":{
         "title":"Schedule appointment",
         "subtitle":"Tap to select option",
         "imageType":"URL",
         "imageData":"https://interactive-msg.s3-us-west-2.amazonaws.com/calendar.jpg",
         "imageDescription":"Appointment booked",
         "timeZoneOffset":-450,
         "location":{
            "latitude":47.616299,
            "longitude":-122.4311,
            "title":"Oscar",
            "radius":1,
         },
         "timeslots":[
               {
                  "date" : "2020-10-31T17:00+00:00",
                  "duration": 60,
               },
               {
                  "date" : "2020-11-15T13:00+00:00",
                  "duration": 60,
               },
               {
                  "date" : "2020-11-15T16:00+00:00",
                  "duration": 60,
               }
            ],
         }
      }
   }
}
```

Time picker limits

The following table lists the limits for each of the time picker elements. Use this information if you choose to build your own Lambda from scratch. The mandatory parameters are in bold.

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
	templateType	Yes			Valid template type
	data	Yes			
	version	Yes			Must be "1.0"
data	replyMessage	No			
	content	Yes			
replyMessage	**title**	Yes	1	400	Should be description for promptless templates
	subtitle	No	0	400	
	imageType	No	0	50	Must be "URL"
	imageData	No	0	200	Must be a valid publicly accessible URL
	imageDescription	No	0	50	Cannot exist without an image
content	**title**	Yes	1	400	Should be description for

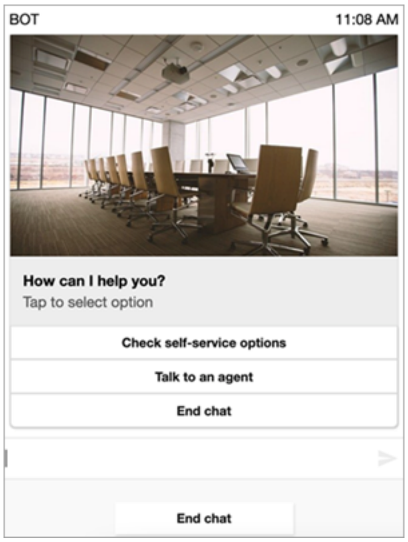
Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
					promptless templates
	subtitle	No	0	200	
	imageType	No	0	50	Must be "URL"
	imageData	No	0	200	Must be a valid publicly accessible URL
	imageDesc ription	No	0	50	Cannot exist without an image
	timezone offset	No	-720	840	This is an optional field when not set. Our sample client defaults to the user's timezone. If set, this displays per the timezone entered. The field should be an integer representing the number of minutes from GMT, specifyin g the timezone of the event's location.

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
	location	No			
	timeslots	Yes	1	40	This is an array of timeslots. Maximum of 40 elements in the array.
location	**longitude**	Yes	-180	180	Must be [double](#)
	latitude	Yes	-90	90	Must be [double](#)
	title	Yes	1	400	
	radius	No	0	200	
timeslots	**date**	Yes			Should be in ISO-8601 time format: YYYY-MM-DDTHH.MM+00.00 For example: "2020-08-14T21:21+00.00"
	duration	Yes	1	3600	

Panel template

By using the panel template, you can present the customer with up to 10 choices under one question. However, you can include only one image, rather than an image with each choice.

The follow image shows an example of how the panel template renders information in a chat. It shows an image at the top of the message, and under the image it shows a prompt that asks *How can I help? Tap to select option*. Under the prompt three options are displayed to the customer: **Check self-service options**, **Talk to an agent**, **End chat**.



The following code is the panel template that you can use in your Lambda. Note the following:

- **Bold text** indicates a mandatory parameter.
- In some cases, if the parent element isn't mandatory, but the fields in the parent element are, then the fields are mandatory. For example, see the `data.replyMessage` structure in the following template. If the structure exists, a `title` is mandatory. Otherwise, a complete `replyMessage` is optional.

```
{
   "templateType":"Panel",
   "version":"1.0",
   "data":{
      "replyMessage":{
         "title":"Thanks for selecting!",
         "subtitle":"Option selected",
      },
      "content":{
```

```
            "title":"How can I help you?",
            "subtitle":"Tap to select option",
            "imageType":"URL",
            "imageData":"https://interactive-msg.s3-us-west-2.amazonaws.com/company.jpg",

            "imageDescription":"Select an option",
            "elements":[
               {
                  "title":"Check self-service options",
               },
               {
                  "title":"Talk to an agent",
               },
               {
                  "title":"End chat",
               }
            ]
         }
      }
}
```

Panel limits

The following table lists the limits for each of the panel elements, should you choose to build your own Lambda from scratch. The mandatory parameters are in bold.

To send unlimited options, implement action buttons in your application. For more information, see Implementation of action buttons in interactive message list picker/panel.

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
	templateType	Yes			Valid template type
	data	Yes			
	version	Yes			Must be "1.0"
data	replyMessage	No			
	content	Yes			

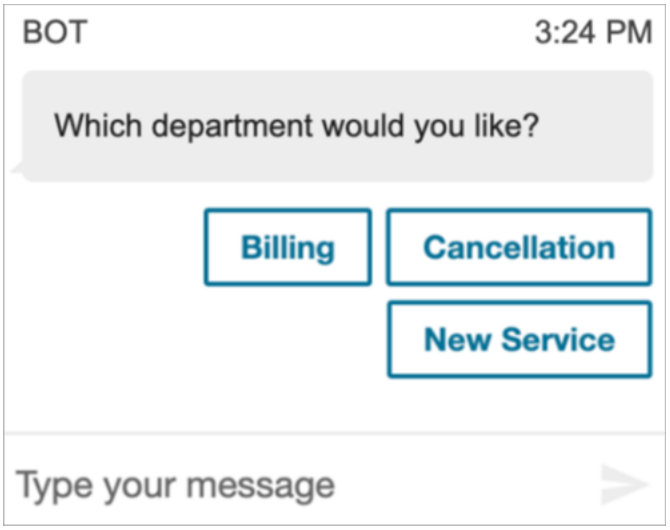
Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
content	**title**	Yes	1	400	Should be a description for promptless templates
	subtitle	No	0	400	
	elements	Yes	1 item	10 items	This is an array of elements. Maximum 10 elements in the array.
	imageType	No	0	50	Must be "URL"
	imageData	No	0	200	Must be a valid publicly accessible URL
	imageDescription	No	0	50	Cannot exist without an image
	referenceId	No			String. Only required for action button feature.
	listId	No			String. Only required for action button feature.

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
	preIndex	No			Number. Only required for action button feature.
	nextIndex	No			Number. Only required for action button feature.
	templateIdentifier	No			Number. Should be an UUID. **This field is required** if List Picker/Panel is being used in a Carousel.
elemen	**title**	Yes	1	400	
	actionDetail	No			Only required for action button feature. Must be "PREVIOUS_OPTIONS" or "SHOW_MORE".
replyMessage	**title**	Yes	1	400	
	subtitle	No	0	400	

Quick reply template

Use quick reply messages to get simple responses from customers and them to customers in an in-line list. You can present customers with up to 5 options in one quick reply message. Images are not supported for quick replies.

The following image shows an example of how the quick reply template renders information in a chat.



The following code is the quick reply template that you can use in your Lambda.

```
{
    "templateType": "QuickReply",
    "version": "1.0",
    "data": {
        "replyMessage": {
            "title": "Thanks for selecting!"
        },
        "content": {
            "title": "Which department would you like?",
            "elements": [{
                    "title": "Billing"
                },
                {
                    "title": "Cancellation"
                },
                {
                    "title": "New Service"
                }
            ]
```

```
        }
    }
}
```

Quick reply limits

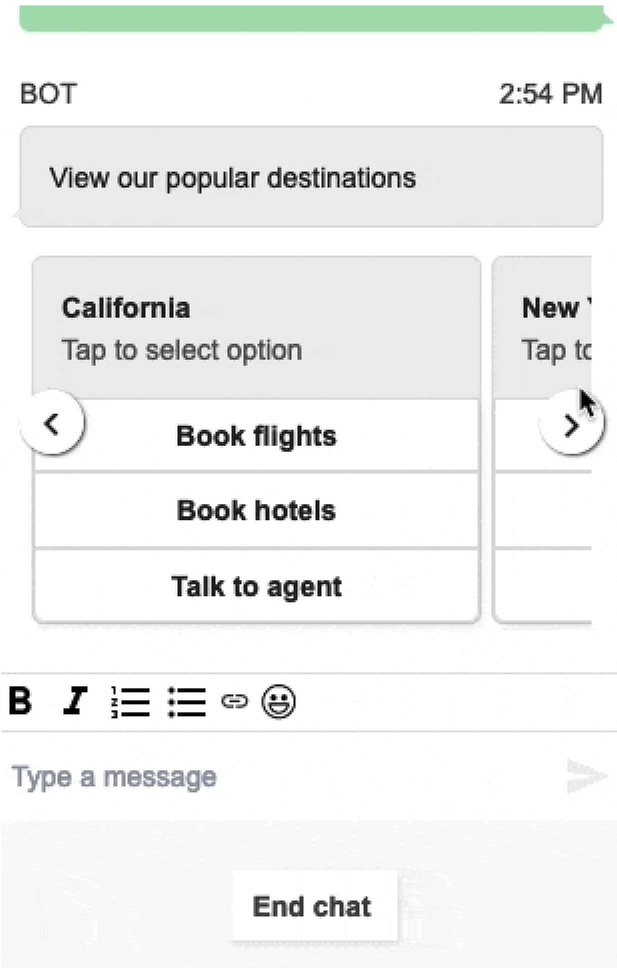
The following table lists the limits for each of the quick reply elements. Use this information if you choose to build your own Lambda from scratch. The mandatory parameters are in bold.

Field	Required	Minimum characters	Maximum characters	Other requirement
templateType				Valid template type
data	Yes			
version	Yes			Must be "1.0"
content	Yes			
title	Yes	1	400	Should be a description for promptless templates
elements	Yes	2 item	10 items	This is an array of elements. Minimum 2 elements and maximum 10 elements in the array.
title	Yes	1	200	

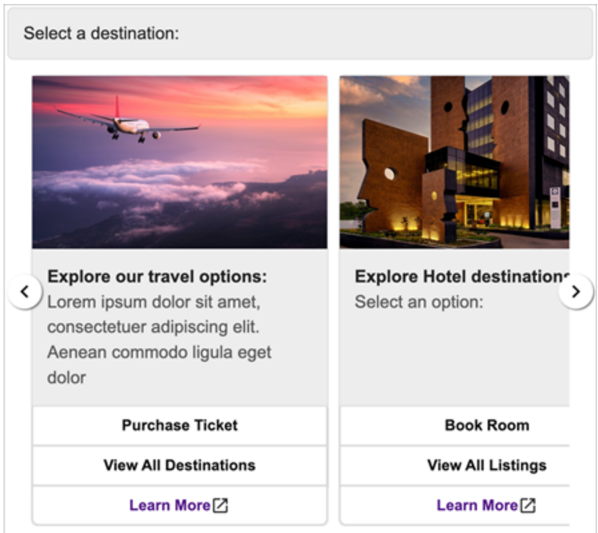
Carousel template

Use carousels to display up to 5 list pickers or panels to customers in a single message. Similar to the list picker and time picker, you can add more options to the carousel by using the SHOW_MORE feature.

The following GIF shows an example of how the carousel template renders information in a chat. Customers scroll through the carousel of images by using the left and right arrows.



The following image shows two **Learn More** hyperlinks, which are examples of carousel picker hyperlink elements.



The following code is the carousel template that you can use in your Lambda.

```
{
  "templateType": "Carousel",
  "version": "1.0",
  "data": {
      "content": {
        "title": "View our popular destinations",
        "elements": [
        {
          "templateIdentifier": "template0",
          "templateType": "Panel",
          "version": "1.0",
          "data": {
            "content": {
              "title": "California",
              "subtitle": "Tap to select option",
              "elements": [
                {
                  "title": "Book flights"
                },
                {
                  "title": "Book hotels"
                },
                {
                  "title": "Talk to agent"
                }
              ]
            }
```

```
          }
        },
        {
          "templateIdentifier": "template1",
          "templateType": "Panel",
          "version": "1.0",
          "data": {
            "content": {
              "title": "New York",
              "subtitle": "Tap to select option",
              "elements": [
                {
                  "title": "Book flights"
                },
                {
                  "title": "Book hotels"
                },
                {
                  "title": "Talk to agent"
                }
              ]
            }
          }
        }
      ]
    }
  }
}
```

For hosted communications widget users:

- The selections on the carousel template result in a JSON string response structured like the following example, to be sent back to Lambda (other interactive message types return regular string response with only `selectionText` value):

```
{
    templateIdentifier: "template0",
    listTitle: "California",
    selectionText: "Book hotels"
}
```

- In carousels, you can provide hyperlinks in the list picker/panel elements. To create a hyperlink instead of a button, include the following additional fields for the element that should be a hyperlink:

```
{
    title: "Book flights",
    ...
    type: "hyperlink",
    url: "https://www.example.com/Flights"
}
```

Carousel limits

The following table lists the limits for each of the carousel elements. Use this information if you choose to build your own Lambda from scratch. The mandatory parameters are in bold.

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
	templateType	Yes			Valid template type
	data	Yes			
	version	Yes			Must be "1.0"
data	**content**	Yes			
content	**title**	Yes	1	400	Should be a description for promptless templates
	elements	Yes	2 item	5 items	This is an array of either list pickers **or** panel templates . Only one

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
					interactive message type is accepted per carousel. Each element should include the top-level field **templateIdentifier**. Minimum 2 templates and maximum 5 templates in the array. **Note** For the best customer experience, we recommend that each template has consistent use of images/number of

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
					elements.
	omitTitleFromCarouselResponse	No			**Boolean** - Optionally respond with "*Selection Text* " instead of the default "*PickerTitle* : *Selection Text* ".
	carouselIsVertical	No			**Boolean** - Optionally render `Carousel` elements with vertical scroll.

Apple form template

> **Note**
>
> This template is applicable only for Apple Messages for Business contact flows.

A business can send a form interactive message to their end customers through a single message, containing multiple pages of requested inputs. When the message is received on an end-customer's Apple device, they can open the form and navigate through the pages, providing a response for each page, before submitting all responses at the end of the form.

For example, businesses can use Apple forms for various purposes, including triaging flows, customer surveys, and account creation / sign-ups.

> **Warning**
>
> Interactive message content and end customer responses are stored in contact record transcript and are viewable by other chat participants and contact analysts with access to transcripts. To prevent PII from appearing in your contact record transcript **after the contact has ended**, you will want to use the Set recording and analytics behavior block in your step-by-step guide flow, enable Contact Lens, and enable the redaction of sensitive date. For full details on how to enable PII redaction, see Enable redaction of sensitive data.

The types of pages supported are:

- **ListPicker**: a list of options that the user must select from with image support.
- **WheelPicker**: similar to ListPicker but selection is made through scrollable wheel of options.
- **DatePicker**: a calendar view where user can pick a date.
- **Input**: a text field that the user must fill in.

The following code is an example of an Apple forms template you can use in your Lambda.

> **Note**
>
> - **Bold text** is a mandatory parameter.
> - In some cases, if the parent element exists in the request and it isn't mandatory/bold, but the fields in it are, then the fields are mandatory.

Simple survey form example:

```
{
  "templateType": "AppleForm",
  "version": "1.0",
  "data": {
    "content": {
      "title": "Survey",
      "pages": [
```

```
        {
          "pageType": "DatePicker",
          "title": "Date you visited",
          "subtitle": "When did you last visit?",
          "minDate": "2024-01-02"
        },
        {
          "pageType": "ListPicker",
          "title": "Rating",
          "subtitle": "How do you rate the experience?",
          "items": [
            {
              "title": "Good",
              "imageType": "URL",
              "imageData": "https://mybucket.s3.us-west-2.amazonaws.com/good.jpg"
            },
            {
              "title": "Okay",
              "imageType": "URL",
              "imageData": "https://mybucket.s3.us-west-2.amazonaws.com/okay.jpg"
            },
            {
              "title": "Poor",
              "imageType": "URL",
              "imageData": "https://mybucket.s3.us-west-2.amazonaws.com/poor.jpg"
            }
          ]
        },
        {
          "pageType": "ListPicker",
          "title": "Dine type",
          "subtitle": "Select all dine types that apply",
          "multiSelect": true,
          "items": [
            {
              "title": "Pickup"
            },
            {
              "title": "Dine-in"
            },
            {
              "title": "Delivery"
            }
          ]
```

```
        },
        {
          "pageType": "WheelPicker",
          "title": "Visits",
          "subtitle": "How often do you visit?",
          "items": [
            {
              "title": "Often"
            }
            {
              "title": "Sometimes"
            },
            {
              "title": "Rarely"
            }
          ]
        },
        {
          "pageType": "Input",
          "title": "Additional notes",
          "subtitle": "Anything else you'd like to mention about your visit?",
          "multiLine": true
        }
      ]
    }
  }
}
```

Apple form limits

InteractiveMessage

Field	Type	Required	Description / Notes
version	string	Yes	Version number. Allowed value: "1.0"
templateType	TemplateType	Yes	Interactive message template type. Allowed values: ["ListPicker", "TimePicker", "Panel", "QuickRep

Field	Type	Required	Description / Notes
			ly", "Carousel", "ViewResource", "**AppleForm**"]
data	InteractiveMessageData	Yes	Interactive message data

InteractiveMessageData

Field	Type	Required	Description / Notes
content	InteractiveMessageContent	Yes	Main interactive message content
replyMessage	ReplyMessage	No	Message display configuration for after response to interactive message is sent

AppleFormContent

Field	Type	Required	Description / Notes
title	String	Yes	Top-level title of the form. Displayed in Apple receive message bubble and transcript rendering
subtitle	String	No	Used as subtitle in ReceivedMessage
imageType	String	No	Valid values: "URL" Used for image in ReceivedMessage
imageData	String	No	S3 image url Used for image in ReceivedMessage
pages	AppleFormPage[]	Yes	List of form pages
showSummary	Boolean	No	Whether to display a summary page of responses to review before

Field	Type	Required	Description / Notes
			submission Default: False (no confirmation/summary page)
splashPage	AppleFormSplashPage	No	Initial splash page to display before actual pages Default: No splash page

AppleFormSplashPage

Field	Type	Required	Description / Notes
title	String	Yes	Title of splash page
subtitle	String	No	Subtitle / body of splash page
imageType	ImageType	No	Present when displaying image within splash page Allowed value: "URL" Default: No image displayed
imageData	String	No	For imageType="URL", this is the URL value Default: No image displayed
buttonTitle	String	Yes	Text of Continue button. Required by Apple, default text with localization not supported

AppleFormPage

- Base model for form pages. Specific page types extend from this model

Field	Type	Required	Description / Notes
pageType	ApplePageType	Yes	Enum for page type. Allowed values: ["Input", "DatePicker", "WheelPicker", "ListPicker"]
title	String	Yes	Page title

Field	Type	Required	Description / Notes
subtitle	String	Yes	Page subtitle. Used in confirmation page

AppleFormDatePickerPage

AppleFormDatePickerPage extends AppleFormPage

Field	Type	Required	Description / Notes
pageType	ApplePageType	Yes	Value: "DatePicker"
labelText	String	No	Text displayed next to the date input. See example screenshots in Appendix
helperText	String	No	Helper text displayed under the date input. See example screenshots in Appendix Default: No helper text
dateFormat	String	No	ISO 8601 date format. Default: yyyy-MM-dd
startDate	String	No	Initial / default selected date in valid date format Default: Current date for end user when message is sent
minDate	String	No	Min date allowed to be selected in valid date format Default: No min
maxDate	String	No	Max date allowed to be selected in valid date format Default: Current date for end user when message is sent

AppleFormListPickerPage

AppleFormListPickerPage extends AppleFormPage

Field	Type	Required	Description / Notes
pageType	ApplePageType	Yes	Value: "ListPicker"
multiSelect	Boolean	No	Enables selecting multiple items Default: false (single selection)
items	AppleFormListPickerPageItem[]	Yes	List of list page items

AppleFormListPickerPageItem

AppleFormListPickerPageItem extends AppleFormPage

Field	Type	Required	Description / Notes
title	String	Yes	Display text of item
imageType	ImageType	No	Present when displaying image within item Allowed value: "URL" Default: No image displayed
imageData	String	No	For imageType="URL", this is the URL value Default: No image displayed

> **Note**
>
> Similar image model to existing interactive message models (ListPicker), except `imageDescription` is not included, which is used for image alt text in chat widget / web chats and ignored for Apple interactive messages.

AppleFormWheelPickerPage

AppleFormWheelPickerPage extends AppleFormPage

Field	Type	Required	Description / Notes
pageType	ApplePageType	Yes	Value: "WheelPicker"
items	AppleFormWheelPickerPageItem[]	Yes	List of wheel picker items
labelText	String	No	Text displayed next to the input. See example screensho ts in Appendix

AppleFormWheelPickerPageItem

AppleFormWheelPickerPageItem extends AppleFormPage

Field	Type	Required	Description / Notes
title	String	Yes	Display text of picker item

AppleFormInputPage

AppleFormInputPage extends AppleFormPage

Field	Type	Required	Description / Notes
pageType	ApplePageType	Yes	Value: "Input"
labelText	String	No	Text displayed next to the input box. See example screenshots in Appendix
helperText	String	No	Additional text displayed under input box Default: No helper text
placeholderText	String	No	Placeholder text to display initially when there's no input Default: "(Optional)" or "(Required)" placeholder text

Field	Type	Required	Description / Notes
prefixText	String	No	Prefix text to display next to input. Ex: '$' when input is monetary value Default: No prefix text
required	Boolean	No	Whether end user is required to provide input Default: false
multiLine	Boolean	No	Whether multi-line input can be provided Default: false (single line)
maxCharCount	Number	No	Max char count of input. Enforced on Apple client Default: No limit
regex	String	No	Regex string to place constraints on input provided Default: No regex constraints
keyboardType	String	No	Determines what type of keyboard is displayed when end user is providing input Allowed values: Same as Apple. See docs. Some of the allowed values: numberPad, phonePad, emailAddress
textContentType	String	No	Helps with auto-fill suggestions on Apple device. Allowed values: Same as Apple. See docs. Some of the allowed values: telephoneNumber, fullStreetAddress, familyName

Apple Pay template

> **Note**
>
> This template is applicable only for Apple Messages for Business contact flows.

Use the Apple Pay template to provide an easy and secure way for customers to buy goods and services through Apple Messages for Business with Apple Pay.

The following code is the Apple Pay template that you can use in your Lambda:

Note

- **Bold text** is a mandatory parameter.
- In some cases, if the parent element exists in the request and it isn't mandatory/bold, but the fields in it are, then the fields are mandatory.

```
{
  "templateType":"ApplePay",
  "version":"1.0",
  "data":{
    "content":{
      "title":"Halibut",
      "subtitle":"$63.99 at Sam's Fish",
      "imageType":"URL",
      "imageData":"https://interactive-msg.s3-us-west-2.amazonaws.com/fish.jpg",
      "payment": {

```

Apple Pay limits

Parent field	Field	Require	Minimum characters	Maximum characters	Other requirement
	templateType	Yes			Valid template type
	data	Yes			
	version	Yes			Must be "1.0"
data	**content**	Yes			
content	**title**	Yes	1	512	The title of the received message bubble
	subtitle	No	0	512	Subtitle to be displayed under title of the received message bubble
	imageData	No	0	200	Must be a valid publicly accessible URL
	imageType	No	0	50	Must be "URL"
	payment	Yes			A dictionary containing fields giving the specifics of an Apple Pay request.
	requestIdentifier	No			String, An identifier for the ApplePay request. If not specified, an UUID will be generated and used.

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
payment	**endpoints**	Yes			A dictionary containing the endpoints for payment processing, contact updates, and order tracking.
	merchantSession	Yes			A dictionary containing the payment session provided by Apple Pay after requesting a new payment session.
	paymentRequest	Yes			A dictionary with information about the payment request
endpoints	**paymentGatewayUrl**	Yes			String. Called by Apple Pay to process the payment through the payment provider. The URL should match the URL in the initiativeContext field of the merchant session

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
	fallbackUrl	No			A URL that opens in a web browser so the customer can complete the purchase if their device is unable to make payments using Apple Pay. If specified , fallbackUrl need to match paymentGatewayUrl.
	orderTrackingUrl	No			Called by Messages for Business after completing the order; provides you with an opportunity to update the order information in your system.
	paymentMethodUpdateUrl	No			Called by Apple Pay when the customer changes the payment method. If you don't implement this endpoint and you include this key in the dictionary, the customer sees an error message.

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
	shippingContactUpdateUrl	No			Called by Apple Pay when the customer changes their shipping address information. If you don’t implement this endpoint and you include this key in the dictionary, the customer sees an error message
	shippingMethodUpdateUrl	No			Called by Apple Pay when the customer changes the shipping method. If you don’t implement this endpoint and you include this key in the dictionary, the customer sees an error message.
merchantSession	**displayName**	Yes	1	64	String. The canonical name for your store, suitable for display. Do not localize the name.
	initiative	Yes			String. Must be “messaging”
	initiativeContext	Yes			String. Pass your payment gateway URL.

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
	merchantIdentifier	Yes			String. A unique identifier that represents a merchant for Apple Pay.
	merchantSessionIdentifier	Yes			String. A unique identifier that represents a merchant's session for Apple Pay.
	epochTimestamp	Yes			String.The time representation in number of seconds that have elapsed since 00:00:00 UTC, Thursday, January 1, 1970.
	expiresAt	Yes			String. The expiration time representation in number of seconds that have elapsed since 00:00:00 UTC, Thursday, January 1, 1970.
	nonce	No			Binary. A single-use string that checks the integrity of the interaction.
	signature	No			Binary. A hash of the public key used to sign the interactions.

Parent field	Field	Require	Minimum characters	Maximum characters	Other requirement
	signedFields	No			List of strings contains the signed properties.
paymentRequest	**applePay**	Yes			A dictionary that describes the Apple Pay configuration.
	countryCode	Yes			String. The merchant's two-letter ISO 3166 country code.
	currencyCode	Yes			String. The three-letter ISO 4217 currency code for the payment.
	lineItems	No			An array of line items explaining payments and additional charges. Line items are not required. However, the array cannot be empty if the lineItems key is present.
	total	Yes			A dictionary containing the total. The total amount must be greater than zero to pass validation.

Parent field	Field	Required	Minimum characters	Maximum characters	Other requirement
	requiredBillingContactFields	No			The list of the customer's required billing information needed to process the transaction. For the list of possible strings, see requiredBillingContactFields. Require only the contact fields needed to process the payment. Requesting unnecessary fields adds complexity to the transaction, which can increase the chances of the customer canceling the payment request.
	requiredShippingContactFields	No			The list of shipping or contact information required from the customer to fulfill the order. For example, if you need the customer's email or phone number, then include this key. For the list of possible strings, see requiredShippingContactFields.

Parent field	Field	Require	Minimum characters	Maximum characters	Other requirement
	shippingMethods	No			An array that lists the available shipping methods. The Apple Pay payment sheet displays the first shipping method from the array as the default shipping method.
	supportedCountries	No			An array of countries to support. List each country with their ISO 3166 country code.
applePay	**merchantIdentifier**	Yes			A unique identifier that represents a merchant for Apple Pay.
	merchantCapabilities	Yes			An array of payment capabilities supported by the merchant. The array must include supports3DS, and may optionally include supportsCredit, supportsDebit, and supportsEMV.

Parent field	Field	Require	Minimum characters	Maximum characters	Other requirement
	supportedNetworks	Yes			An array of payment networks supported by the merchant. The array must include one or more of the following values: amex, discover, jcb, masterCard, privateLabel, or visa
lineItem	**amount**	Yes			The monetary amount of the line item.
	label	Yes			A short, localized description of the line item.
	type	No			A value that indicates whether the line item is final or pending.
total	**amount**	Yes			The total amount of the payment.
	label	Yes			A short, localized description of the payment.
	type	No			A value that indicates whether the payment is final or pending.
shippingMethods	**amount**	Yes			String. The non-negative cost associated with this shipping method.

Parent field	Field	Require	Minimum characters	Maximum characters	Other requirement
	detail	Yes			String. Additional description of the shipping method.
	label	Yes			String. A short description of the shipping method.
	identifier	Yes			String. A client-defined value used to identify this shipping method.

iMessage App template

> **Note**
>
> This template is applicable only for Apple Messages for Business contact flows.

Use the iMessage Apps template to present the customer with your custom built iMessage App.

The following code is an example iMessage App template that you can use in your Lambda function.

```
{
   templateType: AppleCustomInteractiveMessage,
   version: "1.0",
   data: {
       content: {
           appIconUrl: "https://interactive-message-testing.s3-us-west-2.amazonaws.com/
apple_4.2kb.jpg",
           appId: "123456789",
           appName: "Package Delivery",
           title: "Bubble Title CIM",
           bid: "com.apple.messages.MSMessageExtensionBalloonPlugin:{team-id}:{ext-
bundle-id}",
```

```
            dataUrl: "?
deliveryDate=26-01-2024&destinationName=Home&street=1infiniteloop&state=CA&city=Cupertino&count
            subtitle: "Bubble package",
        },
        replyMessage: {
            title: "Custom reply message title",
            subtitle: "Custom reply message subtitle",
            imageType: "URL",
            imageData: "https://interactive-msg.s3-us-west-2.amazonaws.com/
fruit_34.3kb.jpg",
        }
    }
}
```

iMessage App limits

Parent Field	Field	Requi	Type	Other Notes
	templateType	Yes	TemplateType	Valid template type, "AppleCustomInteractiveMessage"
	data	Yes	InteractiveMessageData	Contains content and receivedMessage dictionaries
	version	Yes	string	Must be "1.0"
data	**content**	Yes	InteractiveMessageContent	Interactive Content of the iMessage App
	replyMessage	Yes	ReplyMessage	Message display configuration for after response to interactive message is sent
content	**appIconUrl**	Yes	string	AWS S3 URL
	appId	Yes	string	Business IMessage App Id
	appNam	Yes	string	Business IMessage App name

Parent Field	Field	Requi	Type	Other Notes
	bid	Yes	string	Business IMessage App Bid. Pattern: com.apple .messages.MSMessageExtensionBalloonPlugin:{te am-id}:{ext-bundle-id}
	dataUrl	Yes	string	Data that is passed into the iMessage App
	useLiveL yout	No	boolean	Default True
	title	Yes	string	title of the Imessage App bubble
	subtitle	No	string	subtitle of the Imessage App bubble
replyMe: age	title	No	string	
	subtitle	No	string	
	imageTy	No	string	Must be a valid publicly accessible URL
	imageDa	No	string	Cannot exist without an image

WhatsApp list

> **Note**
>
> You only use this template for WhatsApp messaging flows. For more information about integrating WhatsApp with Amazon Connect, see the section called "Set up WhatsApp Business messaging", earlier in this guide.

You use the WhatsApp list template in WhatsApp chats to provide customers with a list of options.

The following example shows a list of options for a banking service.

```
{
```

```
  "templateType": "WhatsAppInteractiveList",
  "version": "1.0",
  "data": {
    "content": {
      "title": "Which account do you need help with?",
      "body": {
        "text": "Which account do you need help with?"
      },
      "action": {
        "button": "Options",
        "sections": [
          {
            "title": "Your accounts",
            "rows": [
              {
                "id": "11111111",
                "title": "11111111",
                "description": "PERSONAL CHECKING"
              },
              {
                "id": "22223333",
                "title": "22223333",
                "description": "PERSONAL SAVINGS"
              }
            ]
          },
          {
            "title": "Other",
            "rows": [
              {
                "id": "other",
                "title": "I can't find my account"
              }
            ]
          }
        ]
      }
    }
  }
}
```

The following image shows a typical screen before and after a customer opens a list.

WhatsApp reply button

> **Note**
>
> You only use this template for WhatsApp messaging flows.

You can use the WhatsApp reply button template to present an in-line list of options for customers.

```
{
  "templateType": "WhatsAppInteractiveReplyButton",
  "version": "1.0",
  "data": {
    "content": {
      "title": "What would you like to do?",
      "body": {
        "text": "What would you like to do?"
      },
      "action": {
        "buttons": [
          {
            "type": "reply",
            "reply": {
              "id": "agent",
```

```
              "title": "Continue to agent"
            }
          },
          {
            "type": "reply",
            "reply": {
              "id": "end_chat",
              "title": "End chat"
            }
          }
        ]
      }
    }
  }
}
```

WhatsApp reply button limits

The WhatsApp reply template has the following limits.

Parent Field	Field	Required	Minimum length	Maximum length	Other Requirement
	templateType	Yes			Must be "WhatsAppInteractiveReplyButton"
	data	Yes			
	version	Yes			Must be "1.0"
data	**content**	Yes			
content	**title**	Yes			
	header	No			
	body	Yes			
	footer	No			
	action	Yes			
header	**type**	Yes			Valid values: "text", "document", "image", "video"
	text	No	1	60	
	image	No			
	video	No			

Parent Field	Field	Required	Minimum length	Maximum length	Other Requirement
	document	No			
image	**link**	Yes			Must be publicly accessible media URL starting with https/http
video	**link**	Yes			Must be publicly accessible media URL starting with https/http
document	**link**	Yes			Must be publicly accessible media URL starting with https/http
body	**text**	Yes	1	1024	
footer	**text**	Yes	1	60	
action	**buttons**	Yes	1	3	
button	**type**	Yes			Must be "reply"
	reply.id	Yes	1	256	Must be unique across buttons

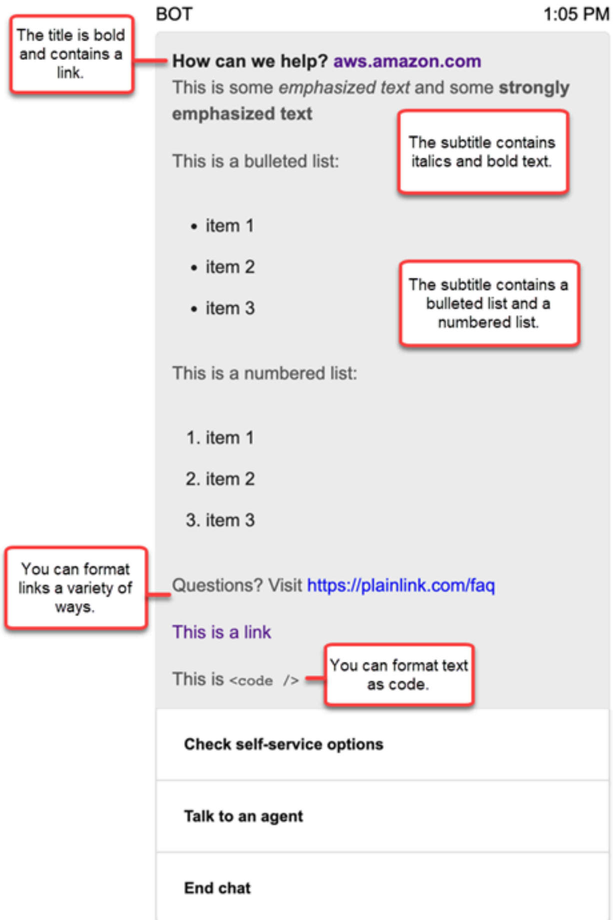
Parent Field	Field	Required	Minimum length	Maximum length	Other Requirement
	reply.title	Yes	1	20	

Rich formatting in titles and subtitles

You can add rich formatting to the titles and subtitles of your chat messages. For example, you can add links, italics, bold, numbered lists, and bulleted lists. You use markdown to format your text.

The following image of a chat box shows an example list picker with rich formatting in the title and subtitle.

- The title **How can we help? aws.amazon.com** is bold and contains a link.
- The subtitle contains italics and bold text, a bulleted list, and a numbered list. It also shows a plain link, text link, and sample code.
- The bottom of the chat box shows three list picker elements.



How to format text with markdown

You can write title and subtitle strings in a multi-line format, or in a single line with `\r\n` line break characters.

- **Multi-line format**: The following code sample shows how to author lists in markdown in a multi-line format.

```
const MultiLinePickerSubtitle = `This is some *emphasized text* and some **strongly
 emphasized text**

This is a bulleted list (multiline):
* item 1
* item 2
* item 3

This is a numbered list:
1. item 1
2. item 2
```

```
3. item 3

[This is a link](https://aws.amazon.com)

This is \`\`
`

const PickerTemplate = {
    templateType: "ListPicker|Panel",
    version: "1.0",
    data: {
        content: {
            title: "How can we help?",
            subtitle: MultiLinePickerSubtitle,
            elements: [ /* ... */ ]
        }
    }
}
```

- **Single line format**: The following example shows how to author a subtitle in a single line by using `\r\n` line break characters.

```
const SingleLinePickerSubtitle = "This is some *emphasized text* and some **strongly
 emphasized text**\r\nThis is a bulleted list:\n* item 1\n* item 2\n* item 3\n\nThis
 is a numbered list:\n1. item 1\n2. item 2\n3. item 3\n\nQuestions? Visit https://
plainlink.com/faq\r\n[This is a link](https://aws.amazon.com)\r\nThis is `<code/>`";

const PickerTemplate = {
    templateType: "ListPicker|Panel",
    version: "1.0",
    data: {
        content: {
            title: "How can we help?",
            subtitle: SingleLinePickerSubtitle,
            elements: [ /* ... */ ]
        }
    }
}
```

The following example shows how format italics and bold text with markdown:

```
This is some *emphasized text* and some **strongly emphasized text**
```

The following example shows how to format text as code with markdown:

```
This is `<code />`
```

How to format links with markdown

To create a link, use the following syntax:

```
[aws](https://aws.amazon.com)
```

The following examples show two ways you can add links with markdown:

```
Questions? Visit https://plainlink.com/faq
```

```
[This is a link](https://aws.amazon.com)
```

> **Note**
>
> For list pickers, the `targetForLinks` field can be added as a child field to `content` if you want to have granular control over where links are opened. The communications widget will open links in a new browser tab by default. For more information, see List picker template.

Grant Amazon Connect access to your AWS Lambda functions

Amazon Connect can interact with your own systems and take different paths in flows dynamically. To achieve this, invoke AWS Lambda functions in a flow, fetch the results, and call your own services or interact with other AWS data stores or services. For more information, see the AWS Lambda Developer Guide.

To invoke a Lambda function from a flow, complete the following tasks.

Tasks

- Create a Lambda function
- Add a Lambda function to your Amazon Connect instance
- Invoke a Lambda function from a flow

- Best practice for invoking multiple Lambda functions
- Configure your Lambda function to parse the event
- Verify the function response
- Consume the Lambda function response
- Tutorial: Create a Lambda function and invoke in a flow

Create a Lambda function

Create a Lambda function, using any runtime, and configure it. For more information, see Get started with Lambda in the *AWS Lambda Developer Guide*.

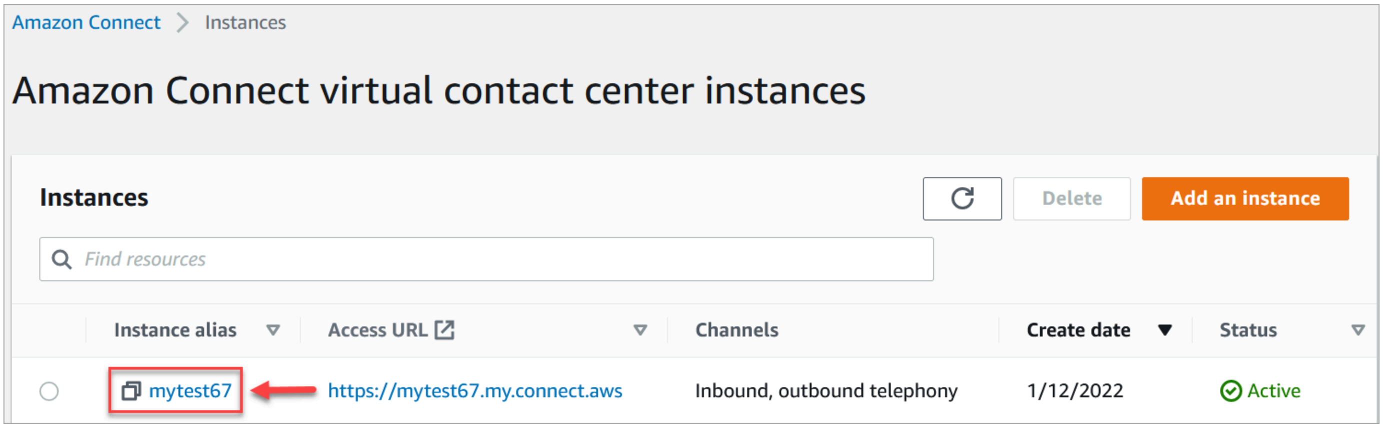
If you create the Lambda function in the same Region as your contact center, you can use the Amazon Connect console to add the Lambda function to your instance as described in the next task, Add a Lambda function to your Amazon Connect instance. This automatically adds resource permissions that allow Amazon Connect to invoke the Lambda function. Otherwise, if the Lambda function is in a different Region, you can add it to your flow using the flow designer and add the resource permissions using the add-permission command, with a principal of `connect.amazonaws.com` and the ARN of your Amazon Connect instance. For more information, see Using Resource-Based Policies for AWS Lambda in the *AWS Lambda Developer Guide*.

Add a Lambda function to your Amazon Connect instance

Before you can use an Lambda function in a flow, you need to add it to your Amazon Connect instance.

Add a Lambda function to your instance

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose your instance name in the **Instance Alias** column. This instance name appears in the URL you use to access Amazon Connect.



3. In the navigation pane, choose **Flows**.

4. In the **AWS Lambda** section, use the **Function** drop-down box to select the function to add to your instance.

> **Tip**
>
> The drop-down lists only those functions in the same Region as your instance. If no functions are listed, choose **Create a new Lambda function**, which opens the AWS Lambda console.
> To use a Lambda in a different Region or account, in the [Invoke AWS Lambda function](), under **Select a function**, you can enter the ARN of a Lambda. Then set up the corresponding resource-based policy on that Lambda to allow the flow to call it.
> To call `lambda:AddPermission`, you need to:
>
> - Set the principal to **connect.amazonaws.com**
> - Set the source account to be the account your instance is in.
> - Set the source ARN to the ARN of your instance.
>
> For more information, see [Granting function access to other accounts]().

5. Choose **Add Lambda Function**. Confirm that the ARN of the function is added under **Lambda Functions**.

Now you can refer to that Lambda function in your flows.

Invoke a Lambda function from a flow

1. Open or create a flow.
2. Add an Invoke AWS Lambda function block (in the **Integrate** group) to the grid. Connect the branches to and from the block.
3. Choose the title of the Invoke AWS Lambda function block to open its properties page.
4. Under **Select a function**, choose from the list of functions you've added to your instance.
5. (Optional) Under **Function input parameters**, choose **Add a parameter**. You can specify key-value pairs that are sent to the Lambda function when it is invoked. You can also specify a **Timeout** value for the function.
6. In **Timeout (max 8 seconds)**, specify how long to wait for Lambda to time out. After this time, the contact routes down the Error branch.

For every Lambda function invocation from a flow, you pass a default set of information related to ongoing contact, as well as any additional attributes defined in the **Function input parameters** section for the **Invoke AWS Lambda function** block added.

The following is an example JSON request to a Lambda function:

```
{
    "Details": {
        "ContactData": {
            "Attributes": {
               "exampleAttributeKey1": "exampleAttributeValue1"
              },
            "Channel": "VOICE",
            "ContactId": "4a573372-1f28-4e26-b97b-XXXXXXXXXXX",
            "CustomerEndpoint": {
                "Address": "+1234567890",
                "Type": "TELEPHONE_NUMBER"
            },
            "CustomerId": "someCustomerId",
            "Description": "someDescription",
            "InitialContactId": "4a573372-1f28-4e26-b97b-XXXXXXXXXXX",
            "InitiationMethod": "INBOUND | OUTBOUND | TRANSFER | CALLBACK",
            "InstanceARN": "arn:aws:connect:aws-region:1234567890:instance/
c8c0e68d-2200-4265-82c0-XXXXXXXXXX",
            "LanguageCode": "en-US",
            "MediaStreams": {
```

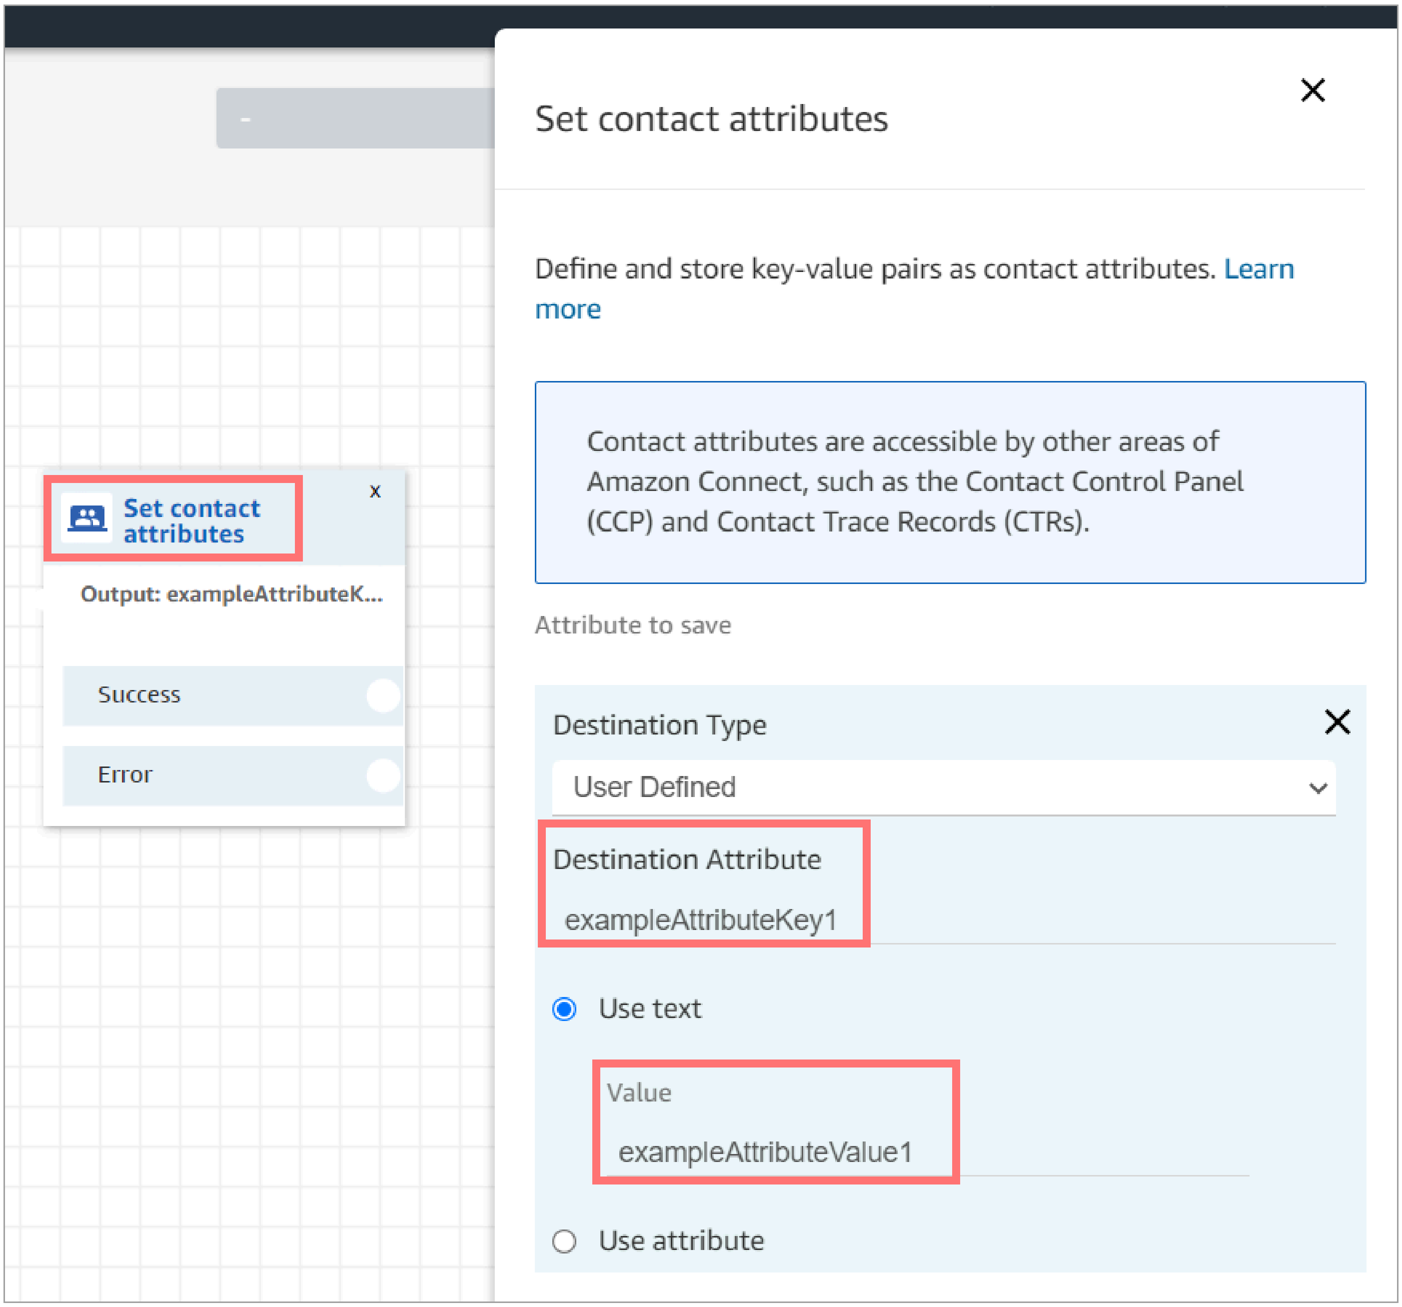
```
                "Customer": {
                    "Audio": {
                        "StreamARN": "arn:aws:kinesisvideo::eu-
west-2:111111111111:stream/instance-alias-contact-ddddddd-bbbb-dddd-eeee-
ffffffffffff/9999999999999",
                        "StartTimestamp": "1571360125131", // Epoch time value
                        "StopTimestamp": "1571360126131",
                        "StartFragmentNumber": "100" // Numberic value for fragment
 number
                    }
                }
            },
            "Name": "ContactFlowEvent",
            "PreviousContactId": "4a573372-1f28-4e26-b97b-XXXXXXXXXXX",
            "Queue": {
                   "ARN": "arn:aws:connect:eu-west-2:111111111111:instance/cccccccc-
bbbb-dddd-eeee-ffffffffffff/queue/aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee",
                 "Name": "PasswordReset"
                "OutboundCallerId": {
                    "Address": "+12345678903",
                    "Type": "TELEPHONE_NUMBER"
                }
            },
            "References": {
                "key1": {
                    "Type": "url",
                    "Value": "urlvalue"
                }
            },
            "SystemEndpoint": {
                "Address": "+1234567890",
                "Type": "TELEPHONE_NUMBER"
            }
        },
        "Parameters": {"exampleParameterKey1": "exampleParameterValue1",
               "exampleParameterKey2": "exampleParameterValue2"
        }
    },
    "Name": "ContactFlowEvent"
}
```

The request is divided into two parts:

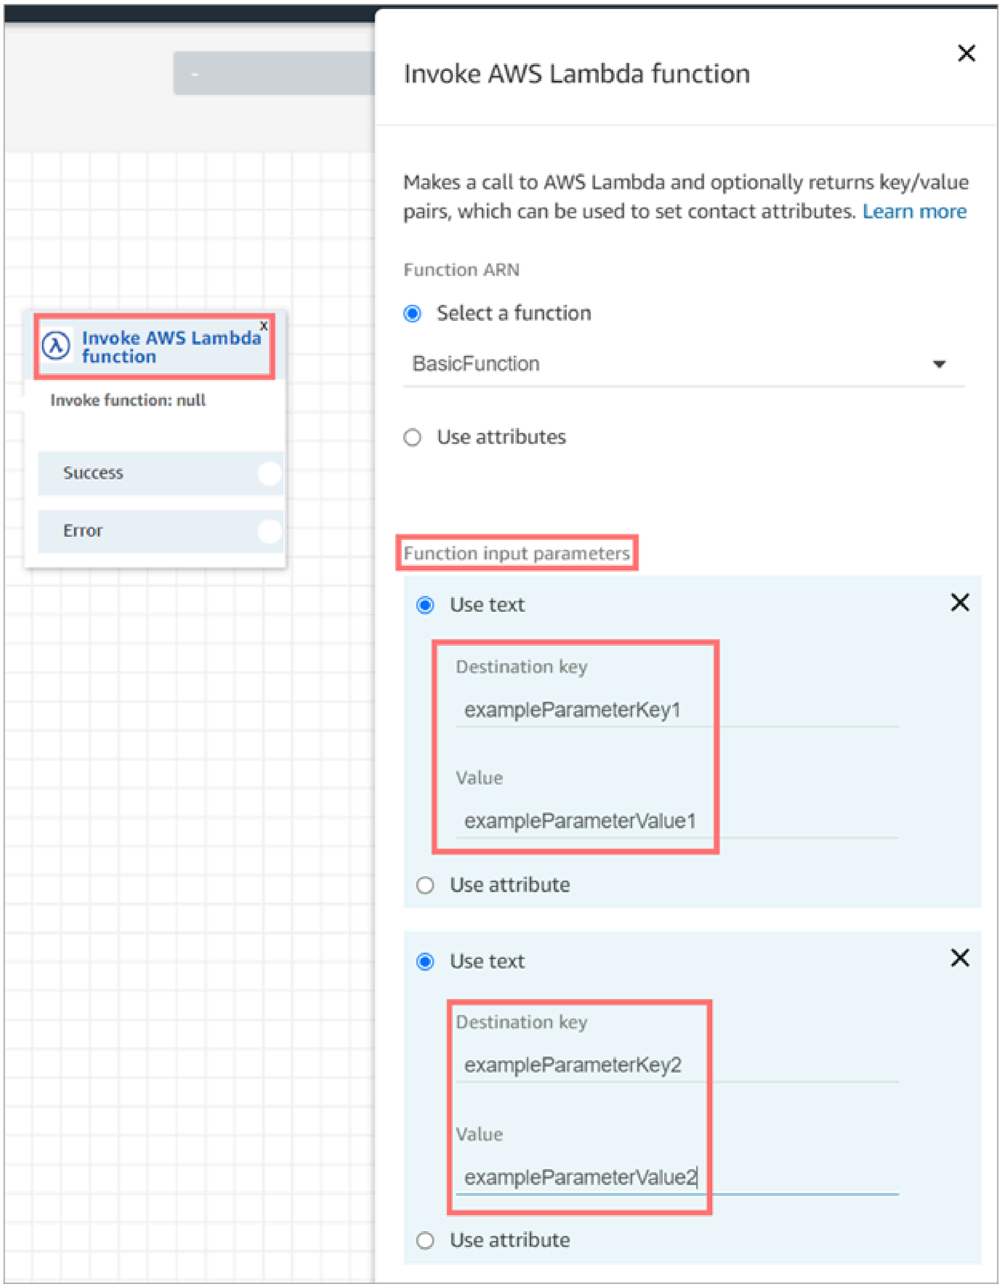
- Contact data—This is always passed by Amazon Connect for every contact. Some parameters are optional.

  This section may include attributes that have been previously associated with a contact, such as when using a **Set contact attributes** block in a flow. This map may be empty if there aren't any saved attributes.

  The following image shows where these attributes would appear in the properties page of a **Set contact attributes**.



- Parameters—These are parameters specific to this call that were defined when you created the Lambda function. The following image shows where these parameters would appear in the properties page of the **Invoke AWS Lambda function** block.



The Invoke Lambda block can receive input parameters in JSON format, accommodating both primitive data types and nested JSON. The following is an example of a JSON input that can be used in the Invoke Lambda block.

```
{
  "Name": "Jane",
  "Age":10,
  "isEnrolledInSchool": true,
  "hobbies": {
    "books":["book1", "book2"],
    "art":["art1", "art2"]
  }
}
```

Invocation retry policy

If your Lambda invocation in a flow gets throttled, the request will be retried. It will also be retried if a general service failure (500 error) happens.

When a synchronous invocation returns an error, Amazon Connect retries up to 3 times, for a maximum of 8 seconds. At that point, the flow will progress down the Error branch.

To learn more about how Lambda retries, see Error Handling and Automatic Retries in AWS Lambda.

Best practice for invoking multiple Lambda functions

Amazon Connect limits the duration of a sequence of Lambda functions to 20 seconds. It times out with an error message when the total execution time exceeds this threshold. Because customers hear silence while a Lambda function runs, we recommend adding a **Play prompt** block between functions to keep them engaged during the long interaction.

By breaking up a chain of Lambda functions with the **Play prompt** block, you can invoke multiple functions that last longer than the 20 second threshold.

Configure your Lambda function to parse the event

To successfully pass attributes and parameters between your Lambda function and Amazon Connect, configure your function to correctly parse the JSON request sent from the **Invoke AWS Lambda function** block or **Set contact attributes**, and define any business logic that should be applied. How the JSON is parsed depends on the runtime you use for your function.

For example, the following code shows how to access `exampleParameterKey1` from **Invoke AWS Lambda function** block and `exampleAttributeKey1` from **Set contact attributes** block using Node.JS:

```
exports.handler = function(event, context, callback) {
// Example: access value from parameter (Invoke AWS Lambda function)
let parameter1 = event['Details']['Parameters']['exampleParameterKey1'];

// Example: access value from attribute (Set contact attributes block)
let attribute1 = event['Details']['ContactData']['Attributes']['exampleAttributeKey1'];

// Example: access customer's phone number from default data
let phone = event['Details']['ContactData']['CustomerEndpoint']['Address'];

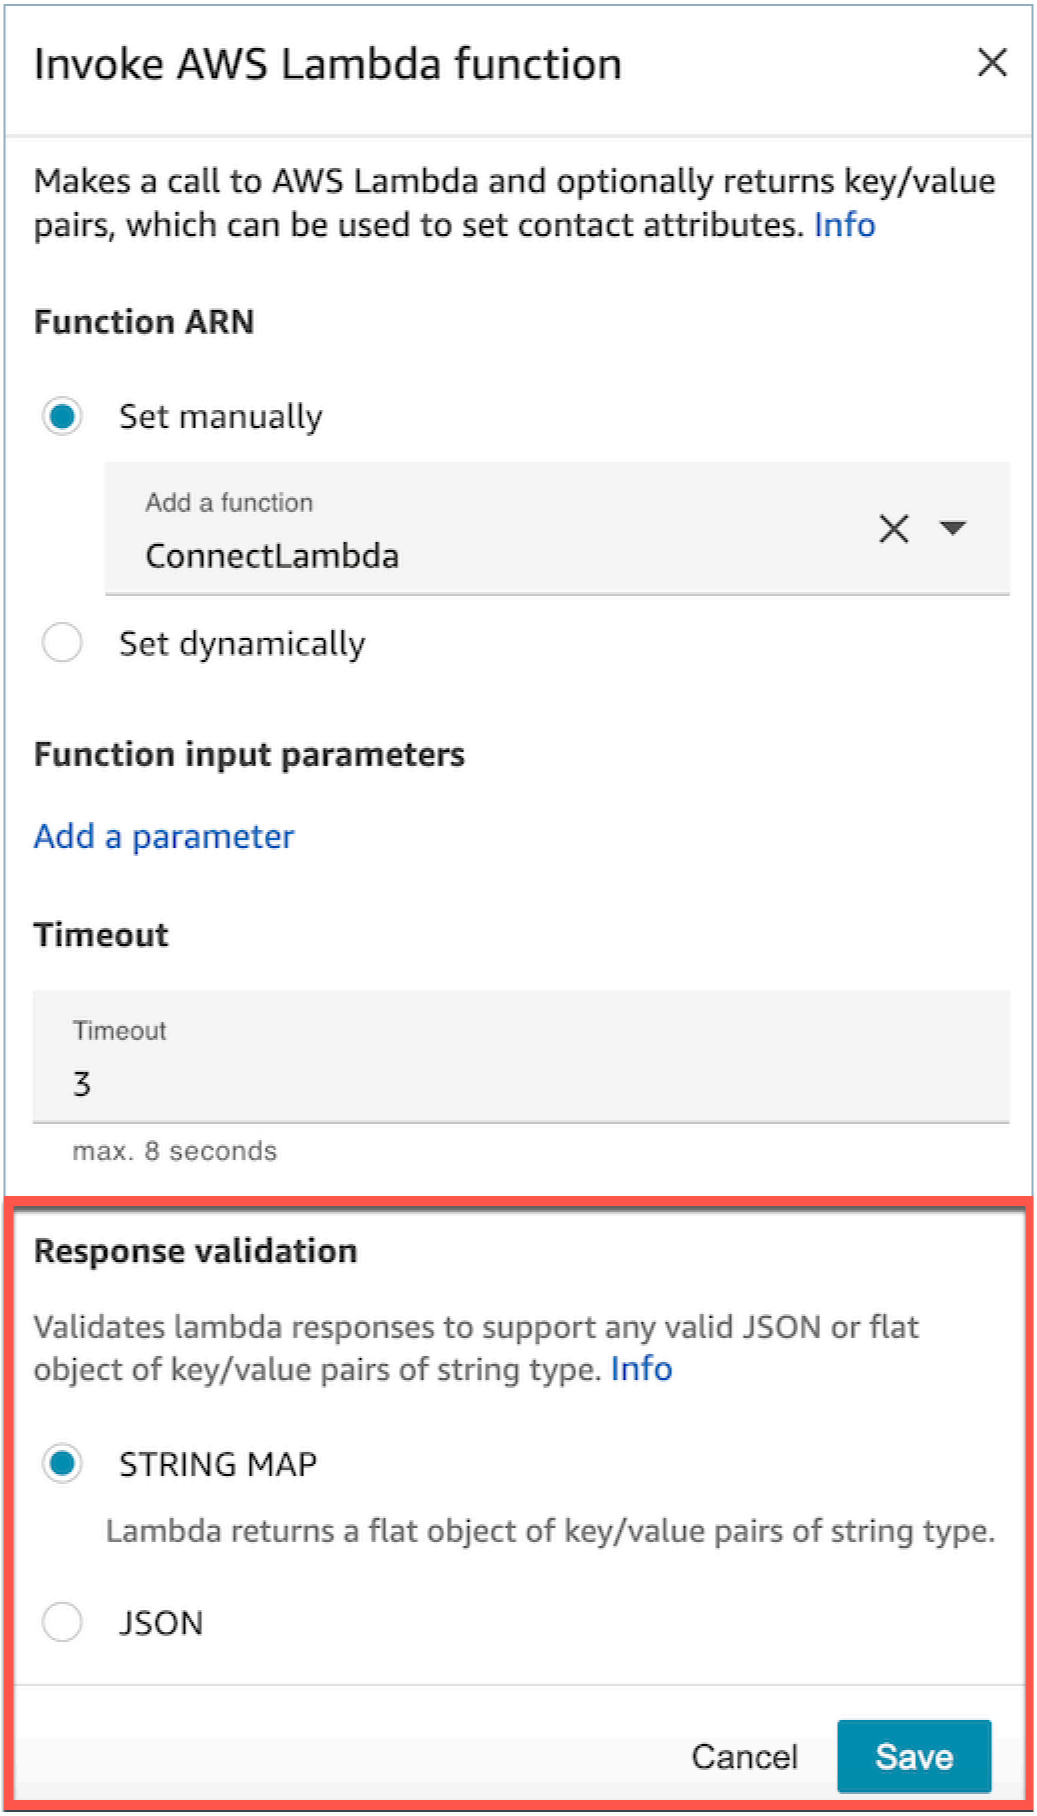
// Apply your business logic with the values
// ...
}
```

Verify the function response

Tip

Referencing an array is not supported in a flow. Arrays can be used only in another Lambda function.

The Lambda function response could be either a STRING_MAP or JSON and has to be set while configuring the **Invoke AWS Lambda function** block in the flow. If response validation is set to STRING_MAP, then the Lambda function should return a flat object of key/value pairs of the string type. Otherwise, if response validation is set to JSON, the Lambda function can return any valid JSON including nested JSON.



Invoke AWS Lambda function
Makes a call to AWS Lambda and optionally returns key/value pairs, which can be used to set contact attributes. Info
Function ARN
Set manually
Add a function
ConnectLambda
Set dynamically
Function input parameters
Add a parameter
Timeout
Timeout
3
max. 8 seconds
Response validation
Validates lambda responses to support any valid JSON or flat object of key/value pairs of string type. Info
STRING MAP
Lambda returns a flat object of key/value pairs of string type.
JSON
Cancel
Save

The Lambda response can be up to 32kb. If you fail to reach Lambda, the function throws an exception, the response is not understood, or the Lambda function takes more time than the limit, the flow jumps to the `Error` label.

Test the output returned from your Lambda function to confirm that it will be correctly consumed when returned to Amazon Connect. The following example shows a sample response in Node.JS:

```
exports.handler = function(event, context, callback) {
// Extract data from the event object
let phone = event['Details']['ContactData']['CustomerEndpoint']['Address'];

// Get information from your APIs

let customerAccountId = getAccountIdByPhone(phone);
let customerBalance = getBalanceByAccountId(customerAccountId);

    let resultMap = {
        AccountId: customerAccountId,
        Balance: '$' + customerBalance,
}

callback(null, resultMap);
}
```

This example shows an example response using Python:

```
def lambda_handler(event, context):
// Extract data from the event object
  phone = event['Details']['ContactData']['CustomerEndpoint']['Address']

// Get information from your APIs
  customerAccountId = getAccountIdByPhone(phone)
  customerBalance = getBalanceByAccountId(customerAccountId)

   resultMap = {
    "AccountId": customerAccountId,
    "Balance": '$%s' % customerBalance
    }

 return resultMap
```

The output returned from the function must be a flat object of key/value pairs, with values that include only alphanumeric, dash, and underscore characters. The size of the returned data must be less than 32 KB of UTF-8 data.

The following example shows the JSON output from these Lambda functions:

```
{
"AccountId": "a12345689",
"Balance": "$1000"
}
```

If response validation is set to JSON, then Lambda function can return even a nested JSON, for example:

```
{
  "Name": {
      "First": "John",
      "Last": "Doe"
  },
  "AccountId": "a12345689",
  "OrderIds": ["x123", "y123"]
}
```

You may return any result as long as they are simple key-value pairs.

Consume the Lambda function response

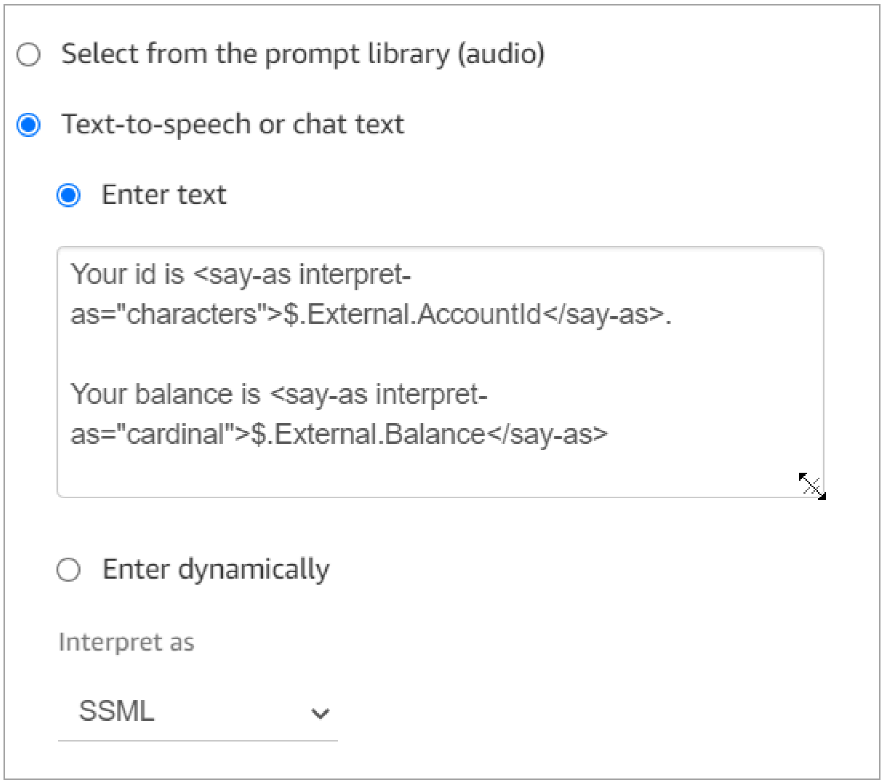
There are two ways to use the function response in your flow. You can either directly reference the variables returned from Lambda, or store the values returned from the function as contact attributes and then reference the stored attributes. When you use an external reference to a response from a Lambda function, the reference will always receive the response from the most recently invoked function. To use the response from a function before a subsequent function is invoked, the response must be saved as a contact attribute, or passed as a parameter to the next function.

1. Access variables directly

If you access the variables directly, you can use them in flow blocks, but they are not included in contact records. To access these variables directly in a flow block, add the block after the **Invoke AWS Lambda function** block, and then reference the attributes as shown in the following example:

```
Name - $.External.Name
Address - $.External.Address
CallerType - $.External.CallerType
```

The following image shows the properties page of the **Play prompt** block. The variables are specified in the text-to-speech block.

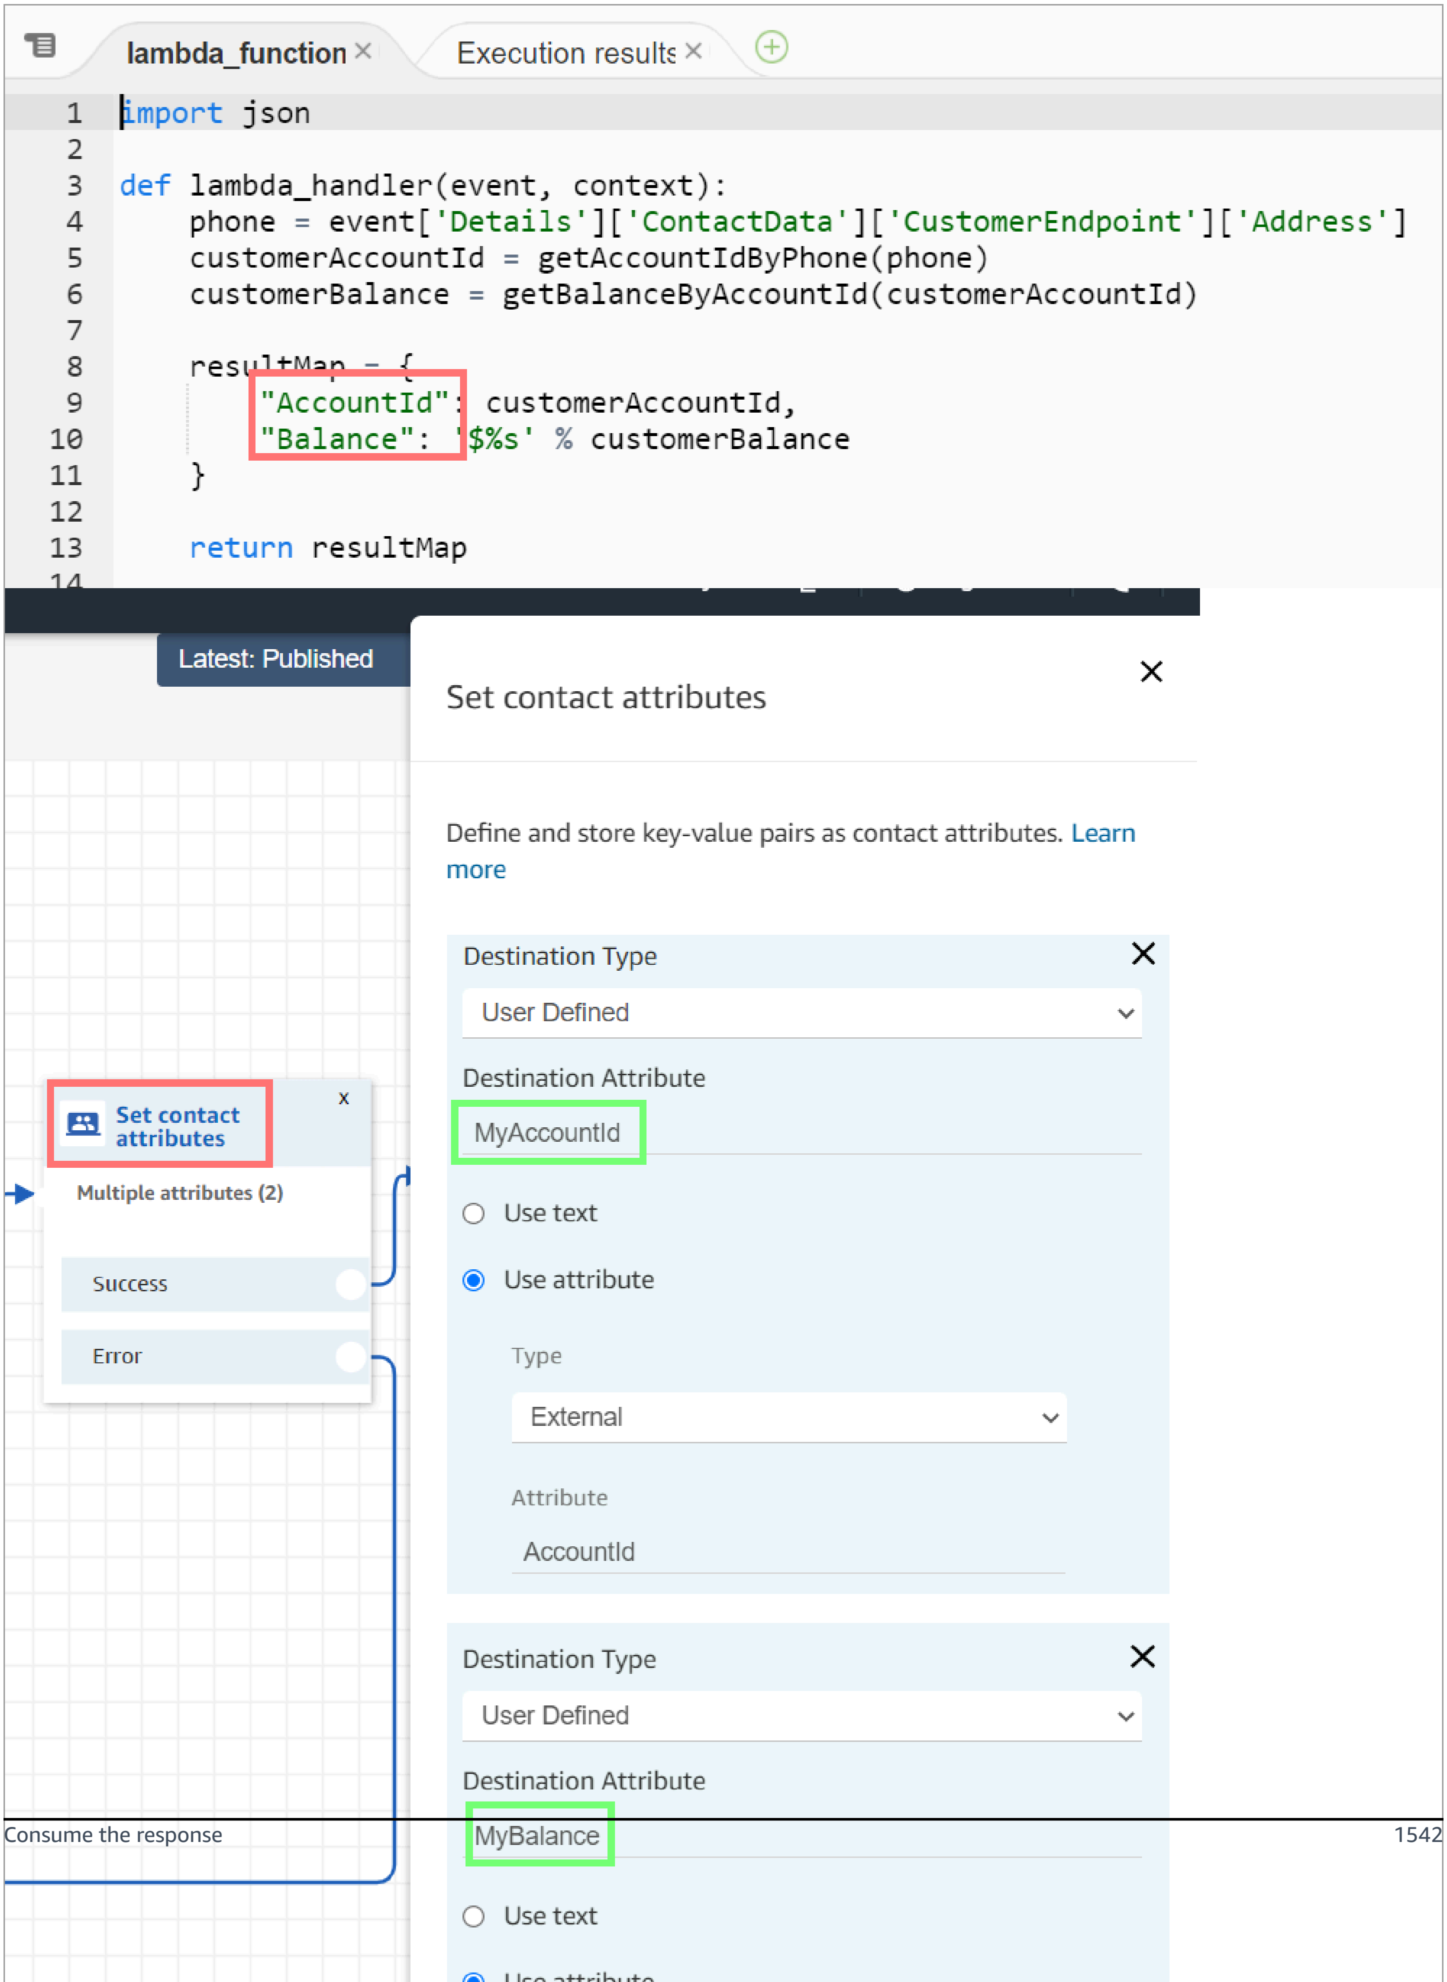


Make sure that the name specified for the source attribute matches the key name returned from Lambda.

2. Store variables as contact attributes

If you store the variables as contact attributes, you can use them throughout your flow, and they are included in contact records.

To store the values returned as contact attributes and then reference them, use a **Set contact attributes** block in your flow after the **Invoke AWS Lambda function** block. Choose **Use attribute**, **External** for the **Type**. Following the example we're using, set **Destination Attribute** to `MyAccountId`, and set the **attribute** to `AccountId`, and do the same for `MyBalance` and **Balance**. This configuration is shown in the following image.



lambda_function
Execution results
import json
def lambda_handler(event, context):
phone = event['Details']['ContactData']['CustomerEndpoint']['Address']
customerAccountId = getAccountIdByPhone(phone)
customerBalance = getBalanceByAccountId(customerAccountId)
resultMap = {
"AccountId": customerAccountId,
"Balance": '$%s' % customerBalance
}
return resultMap

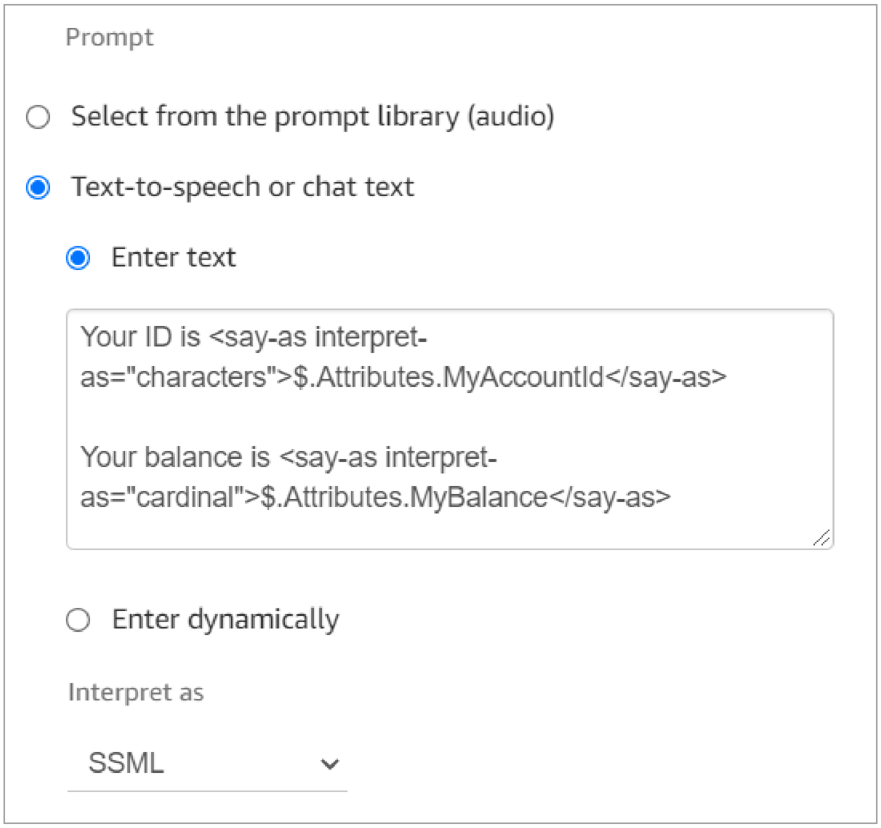
Add Address as a **Source attribute** and use `returnedContactAddress` as the **Destination key**. Then add `CallerType` as a **Source attribute** and use `returnedContactType` for the **Destination key**, as shown in the following image.

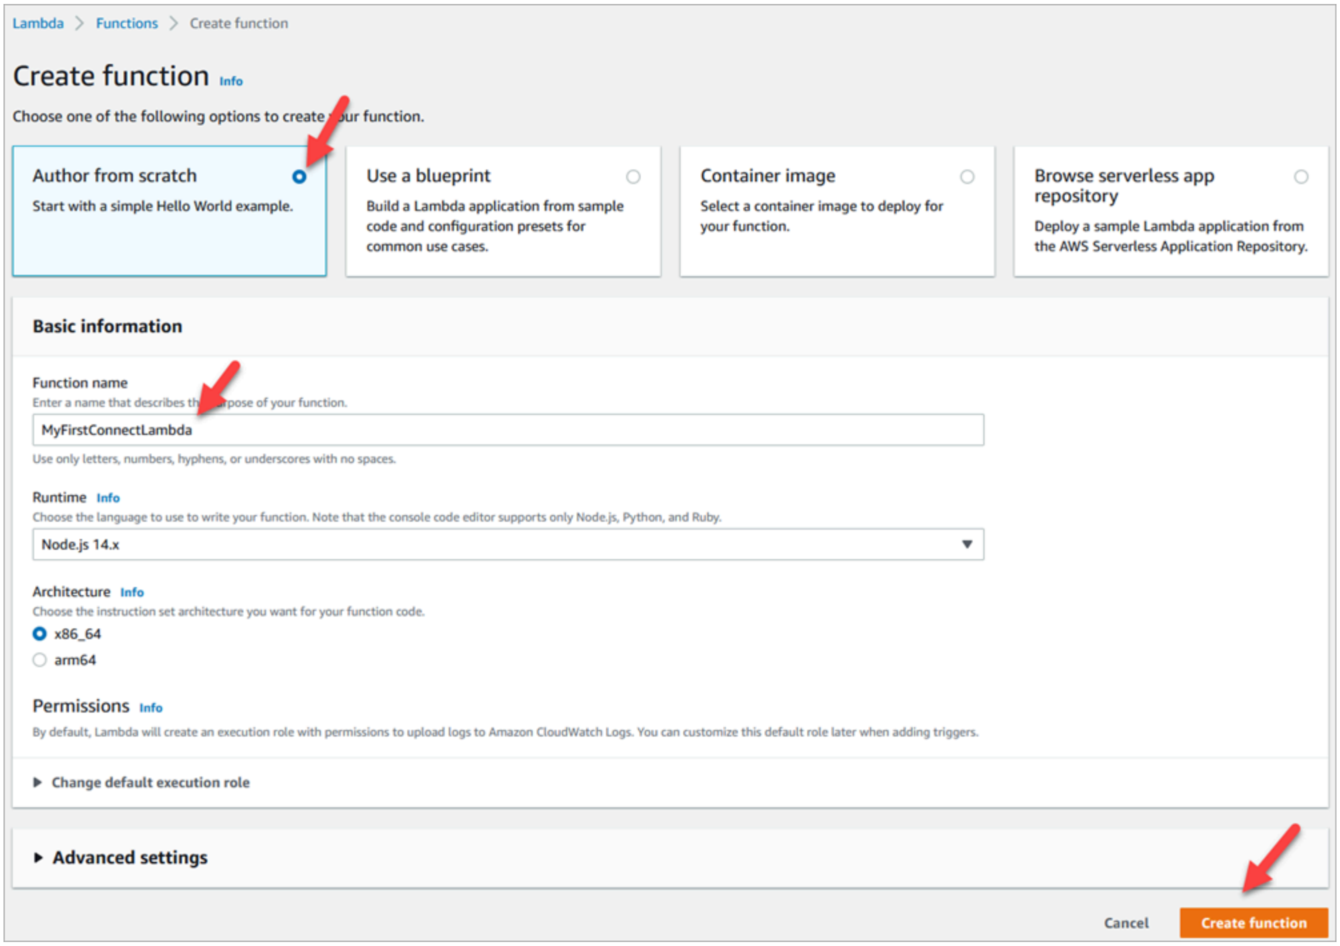


Make sure that the name specified for the source external attribute matches the key name returned from Lambda.

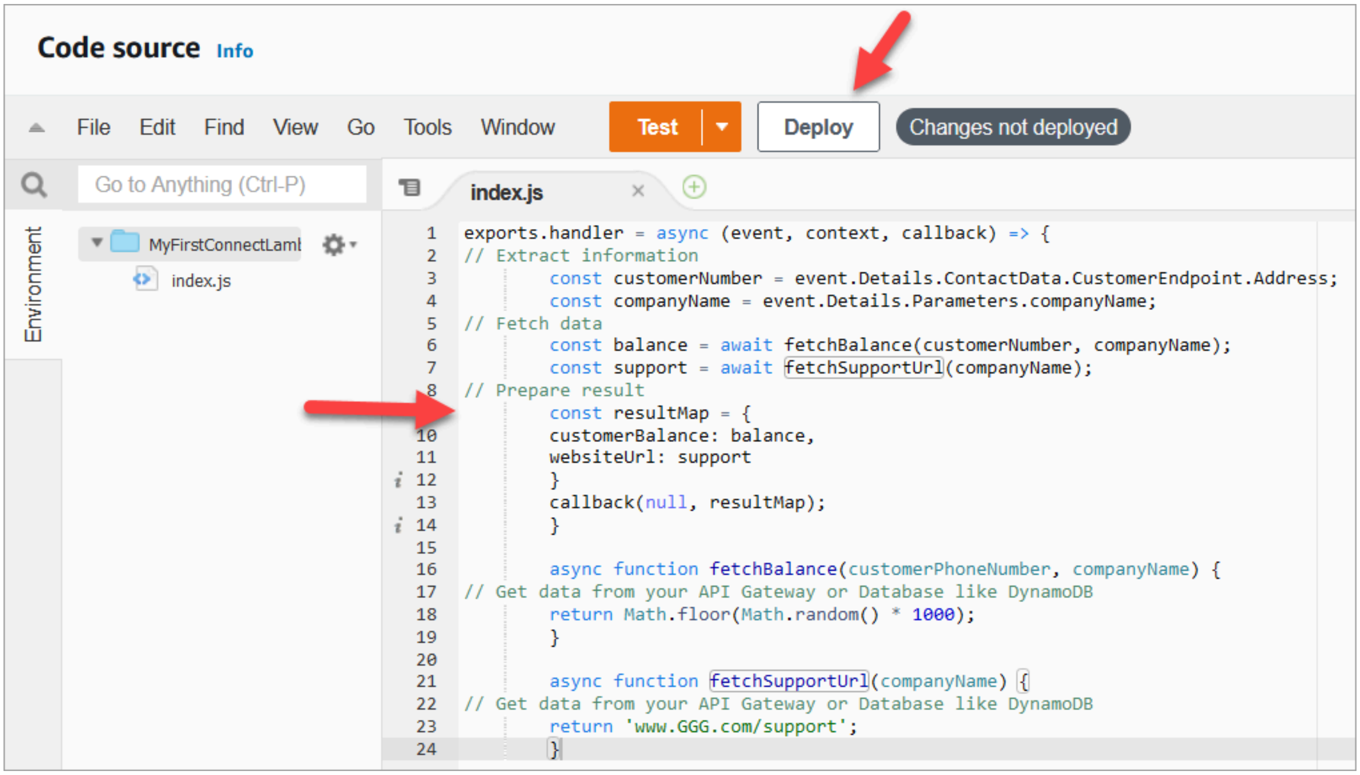
Tutorial: Create a Lambda function and invoke in a flow

Step 1: Create the Lambda example

1. Sign in to the AWS Management Console and open the AWS Lambda console at https://console.aws.amazon.com/lambda/.
2. In AWS Lambda, choose **Create function**.
3. Choose **Author from scratch**, if it's not selected already. Under **Basic information**, for **Function name**, enter **MyFirstConnectLambda**. For all other options, accept the defaults. These options are shown in the following image of the AWS Lambda console.



4. Choose **Create function**.
5. In the **Code source** box, in the **index.js** tab, delete the template code from the code editor.
6. Copy and paste the following code into the code editor as shown in the following image:



```
exports.handler = async (event, context, callback) => {
// Extract information
        const customerNumber = event.Details.ContactData.CustomerEndpoint.Address;
        const companyName = event.Details.Parameters.companyName;
// Fetch data
        const balance = await fetchBalance(customerNumber, companyName);
        const support = await fetchSupportUrl(companyName);
// Prepare result
        const resultMap = {
        customerBalance: balance,
        websiteUrl: support
        }
        callback(null, resultMap);
        }

        async function fetchBalance(customerPhoneNumber, companyName) {
// Get data from your API Gateway or Database like DynamoDB
        return Math.floor(Math.random() * 1000);
        }

        async function fetchSupportUrl(companyName) {
// Get data from your API Gateway or Database like DynamoDB
        return 'www.GGG.com/support';
```

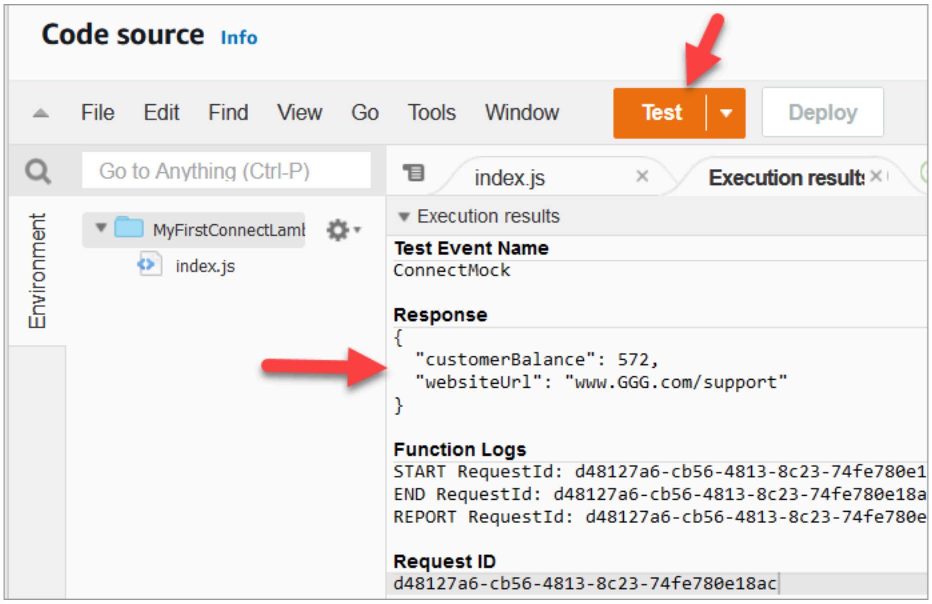
```
        }
```

This code is going to generate a random result for the customerBalance.

7. Choose **Deploy**.
8. After you choose **Deploy**, choose **Test** to launch the test editor.
9. In the **Configure test event** dialog box, select **Create new event**. For **Event name**, enter **ConnectMock** as the test name.
10. In the **Event JSON** box, delete the sample code and enter the following code instead.

```
{
"Details": {
"ContactData": {
    "Attributes": {},
    "Channel": "VOICE",
    "ContactId": "4a573372-1f28-4e26-b97b-XXXXXXXXXXX",
    "CustomerEndpoint": {
    "Address": "+1234567890",
    "Type": "TELEPHONE_NUMBER"
    },
"InitialContactId": "4a573372-1f28-4e26-b97b-XXXXXXXXXXX",
"InitiationMethod": "INBOUND | OUTBOUND | TRANSFER | CALLBACK",
"InstanceARN": "arn:aws:connect:aws-region:1234567890:instance/
c8c0e68d-2200-4265-82c0-XXXXXXXXXX",
"PreviousContactId": "4a573372-1f28-4e26-b97b-XXXXXXXXXXX",
"Queue": {
    "ARN": "arn:aws:connect:eu-west-2:111111111111:instance/cccccccc-bbbb-dddd-
eeee-ffffffffffff/queue/aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee",
    "Name": "PasswordReset"
  },
"SystemEndpoint": {
    "Address": "+1234567890",
    "Type": "TELEPHONE_NUMBER"
    }
},
"Parameters": {
    "companyName": "GGG"
    }
},
"Name": "ContactFlowEvent"
}
```

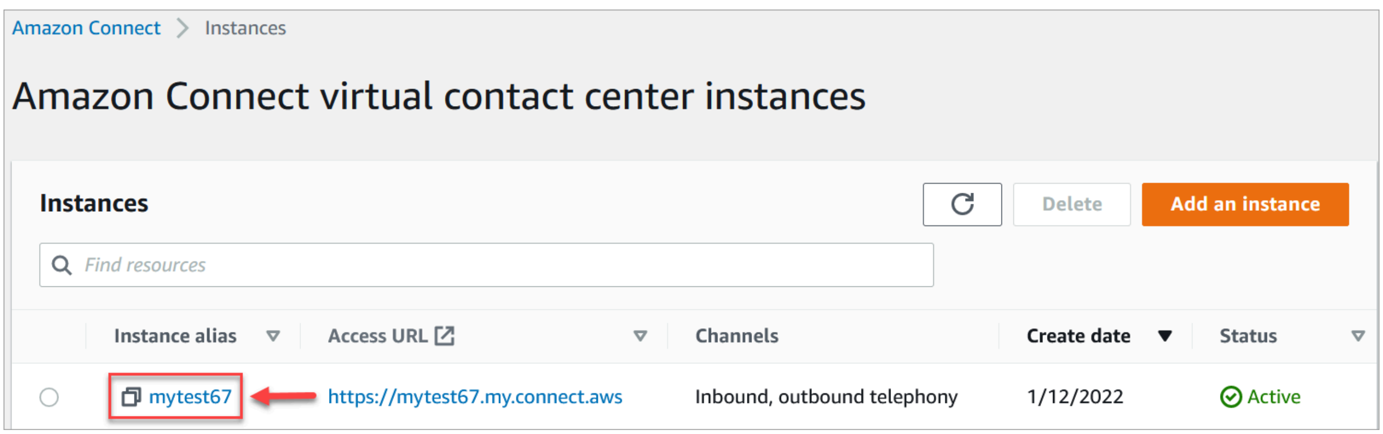
11. Choose **Save**.
12. Choose **Test**. You should see the following something similar to the following image:



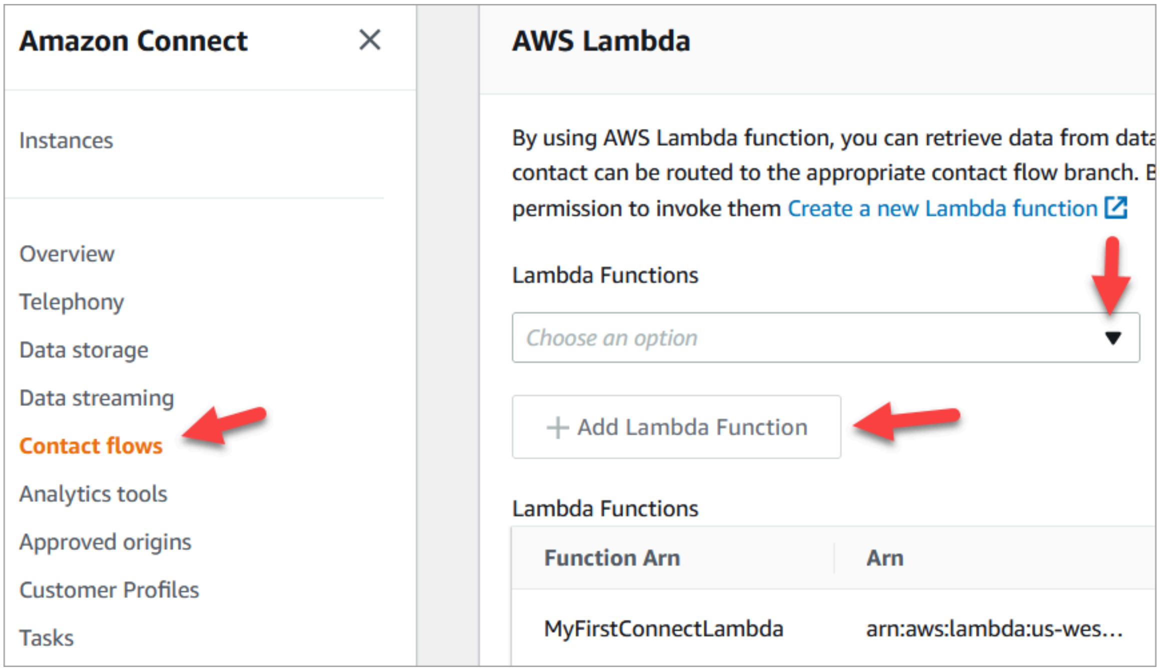
Your balance will be different. The code generates a random number.

Step 2: Add your Lambda to Amazon Connect

1. Go to the Amazon Connect console, at https://console.aws.amazon.com/connect/.
2. Choose your Amazon Connect instance alias.



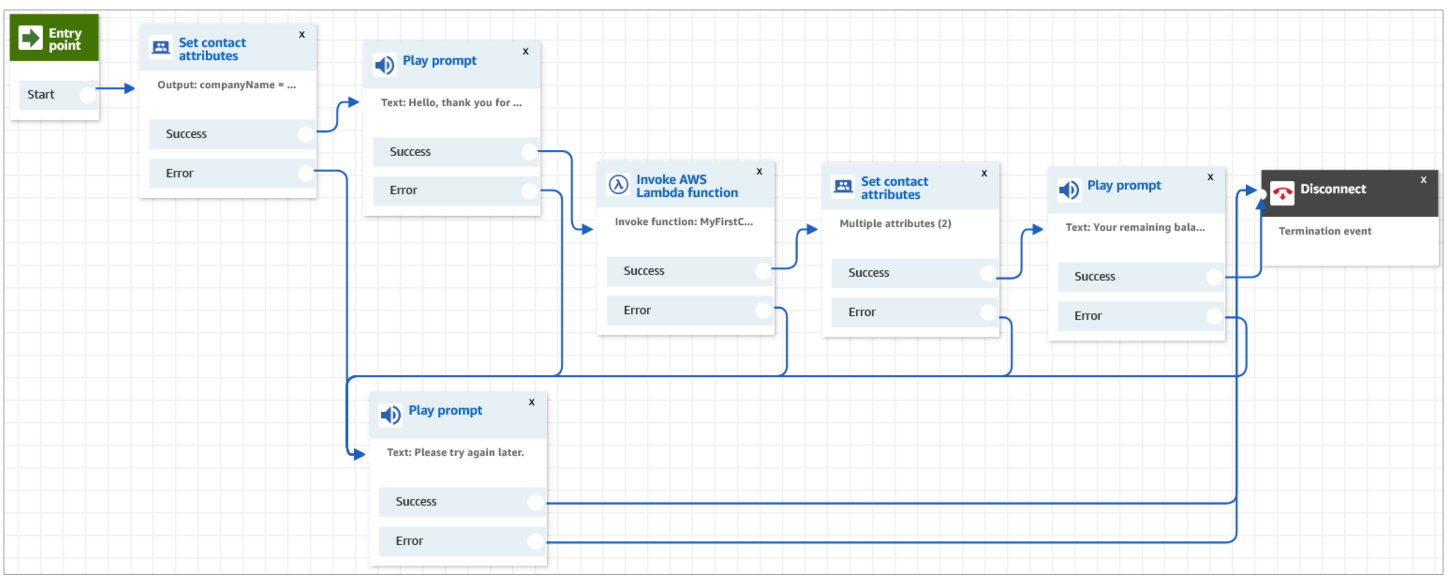
3. On the navigation menu, choose **Flows**.
4. In the AWS Lambda section, use the **Lambda Functions** dropdown box to select **MyFirstConnectLambda**.



5. Choose **Add Lambda Function**.

Step 3: Create the contact flow

The following image is an example of the flow you are going to build using the steps in this procedure. It contains the following blocks: **Set contact attributes**, **Play prompt**, **Invoke AWS Lambda function**, another **Set contact attributes** block, another **Play prompt** block, and finally a **Disconnect** block.



1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/.

2. On the navigation menu, go to **Routing**, **Flows**, **Create a contact flow**.

3. Drag a Set contact attributes block onto the grid, and configure its properties page shown in the following image:

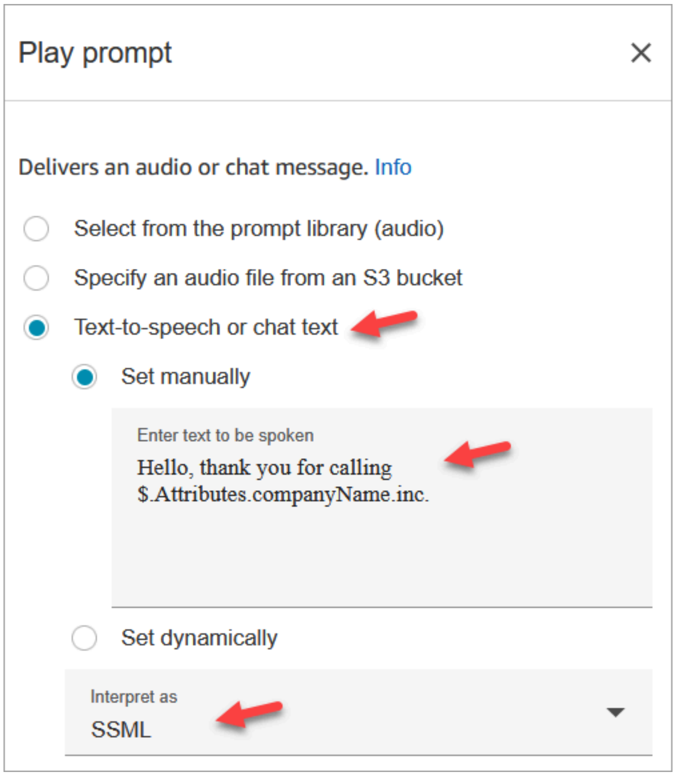
   a. **Namespace** = **User defined**.

   b. **Attribute** = **companyName**.

   c. Choose **Set manually**. **Value** = **GGG**.

   d. Choose **Save**.

4. Drag a Play prompt block onto the grid, and configure its properties page as shown in the following image:



a. Choose **Text-to-speech or chat text**, **Set manually**, and set **Interpret as** to **SSML**. Enter the following text in the box for the text to be spoken:

```
Hello, thank you for calling $.Attributes.companyName inc.
```

b. Choose **Save**.

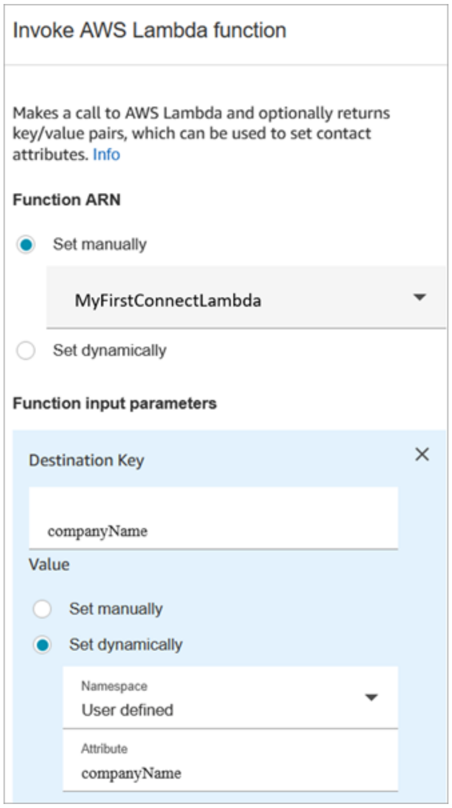
5. Drag another [Play prompt](#) block onto the grid, and configure its properties page as shown in the following image:

   a. Choose **Text-to-speech or chat text**, **Set manually**, and set **Interpret as** to **Text**. Enter the following text in the box for the text to be spoken:

   ```
   Please try again later.
   ```

   b. Choose **Save**.

6. Drag a [Invoke AWS Lambda function] block onto the grid, and configure its properties page as shown in the following image:



a. Choose **Select manually**, and then choose **MyFirstConnectLambda** from the dropdown.

b. In the **Destination Key** box, enter **companyName**. (This is sent to Lambda.)

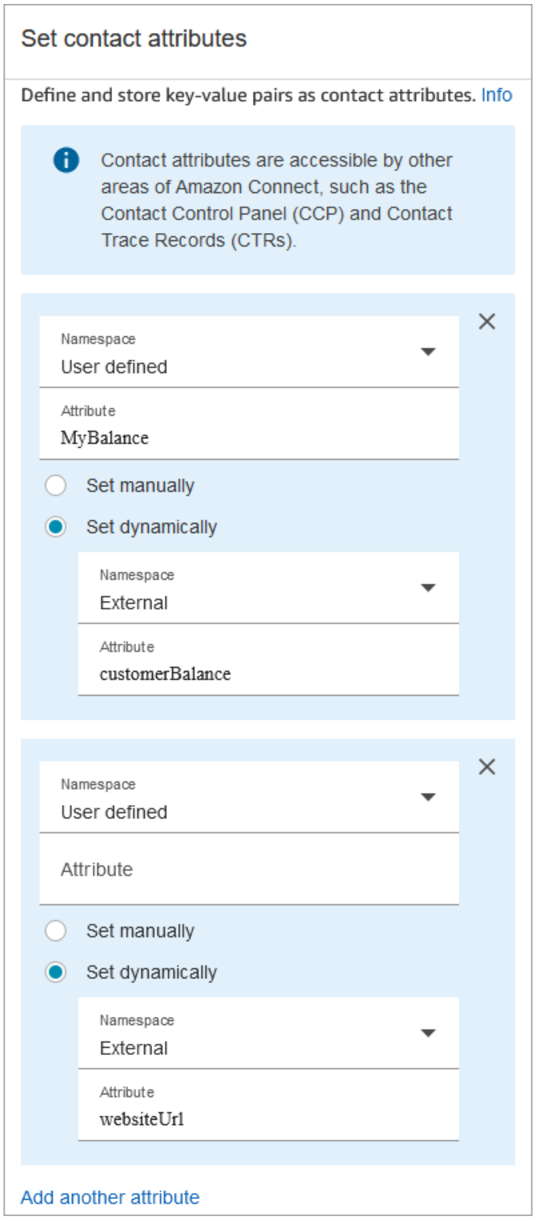
c. Choose **Set dynamically** box

d. For **Namespace**, select **User Defined**.

e. For **Attribute**, enter **companyName**.

f. Choose **Save**.

7. Drag a Set contact attributes block onto the grid, choose **Add another attribute**, and configure its properties page as shown in the following image:



a. **Namespace** = **User Defined**. **Attribute** = **MyBalance**.

b. Choose **Set dynamically**.

c. **Namespace** = **External**.

d. **Attribute** = **customerBalance**. This is the result from Lambda.

e. Choose **Add another attribute**.

f. **Namespace** = **User-defined**.

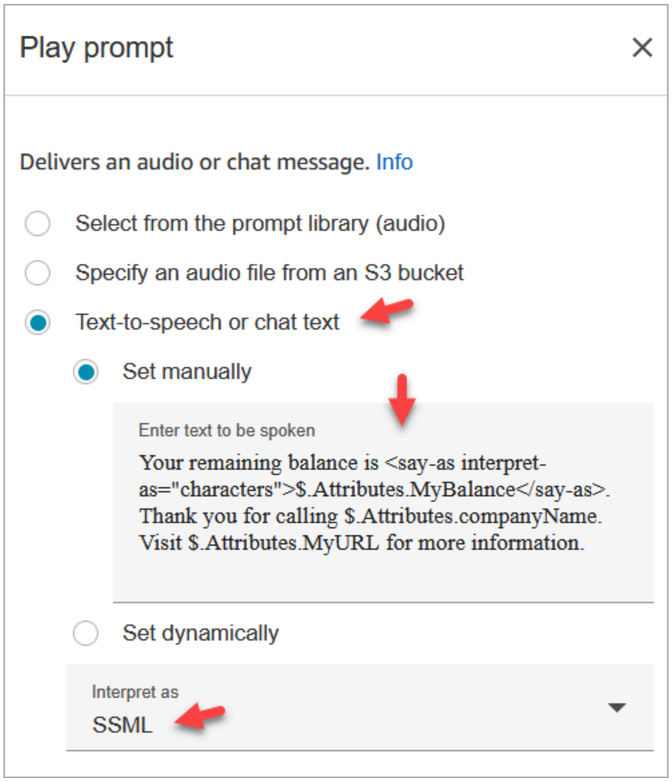
g. **Attribute** = **MyURL**.

h. Select **Set dynamically**. **Namespace** =**External**.

i. **Attribute** = **websiteUrl**. This is the result from Lambda.

j. Choose **Save**.

8. Drag a [Play prompt] block onto the grid, and configure its properties page as shown in the following image:



a. Choose **Text-to-speech or chat text**, and set **Interpret as** to **SSML**. Enter the following text in the box:

```
Your remaining balance is <say-as interpret-as="characters">
$.Attributes.MyBalance</say-as>.

Thank you for calling $.Attributes.companyName.

Visit $.Attributes.MyURL for more information.
```

b. Choose **Save**.

9. Drag a [Disconnect / hang up] block onto the grid.

10. Connect the all blocks so your flow looks like the image shown at the top of this procedure.

11. Enter **MyFirstConnectFlow** as the name, and then choose **Publish**.

12. On the navigation menu, go to **Channels**, **Phone numbers**.

13. Select your phone number.
14. Select **MyFirstConnectFlow** and choose **Save**.

Now try it out. Call the number. You should hear a greeting message, your balance, and the website to visit.

Set up live media streaming of customer audio in Amazon Connect

In Amazon Connect, you can capture customer audio during an interaction with your contact center by sending the audio to a Kinesis video stream. Depending on your settings, audio can be captured for the entire interaction—until the interaction with the agent is complete—or only one direction:

- What the customer hears, including what the agent says and system prompts.
- What the customer says, including when they are on hold.

The customer audio streams also include interactions with an Amazon Lex bot, if you're using one in your flow.

You can perform analysis on the audio streams to determine customer sentiment, use the audio for training purposes, or to later review the audio to identify and flag abusive callers.

Contents

Plan for live media streaming from Amazon Connect to Kinesis Video Streams

Important

If you want to use the audio streaming feature, you need to retain the streams that are created by Amazon Connect. Don't delete them, unless you're going to stop using the streaming feature.

You can send all audio to and from the customer to Kinesis Video Streams. Media streaming leverages Kinesis Video Streams multi-track support so that what the customer says is on a separate track from what the customer hears.

Audio sent to Kinesis uses a sampling rate of 8 kHz.

Do you need to increase your service quotas?

When you enable media streaming in Amazon Connect, one Kinesis video stream is used per active call. By default we allocate 50 streams per instance to your account. We automatically create additional streams as needed to keep pace with active calls, unless your account reaches the Kinesis Video Streams service quota.

Contact Support to request an increase to **Number of Streams**.

To request an increase to your service quota, in the AWS Support Center, choose **Create Case** and then choose **Service Quota Increase**.

Tip

We make sure that **PutMedia** requests always stay within the 5 TPS quota. You don't need to request an increase.

How long do you need to store audio?

Customer audio is stored in Kinesis for the time defined by your retention settings in an Amazon Connect instance. For instructions for setting this value, see Enable live media streaming in your Amazon Connect instance.

Do you need to change the audio streams?

We recommend that you refrain from modifying the streams. Doing so can cause unexpected behavior.

Who requires IAM permissions to retrieve data?

If your business is using IAM permissions, your AWS admin will need to grant permissions to people who are going to retrieve data from Kinesis Video Streams. They'll need to grant them full access permissions for Kinesis Video Streams and AWS Key Management Service.

Enable live media streaming in your Amazon Connect instance

Live media streaming (customer audio streams) is not enabled by default. You can enable customer audio streams from the settings page for your instance.

To enable live media streaming

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Amazon Connect URL. The following image shows the **Amazon Connect virtual contact center instances** page, with a box around the instance alias.
3. In the navigation pane, choose **Data storage**.
4. Under **Live media streaming**, choose **Edit**. Choose **Enable live media streaming**.
5. Enter a prefix for the Kinesis Video Streams created for your customer audio. This prefix makes it easier for you to identify the stream with the data.
6. Choose the KMS key to use to encrypt the data sent to Kinesis. The KMS key must be in the same Region as the instance.
7. Specify a number and unit for the **Data retention period**.

> **Important**
>
> If you select **No data retention**, data is not retained and is available to be consumed for only 5 minutes. This is the default minimum time that Kinesis retains data. Because Amazon Connect uses Kinesis for streaming, Kinesis Video Streams quotas apply.

8. Choose **Save** under **Live media streaming**, and then choose **Save** at the bottom of the page.

After you enable live media streaming, add **Start media streaming** and **Stop media streaming** blocks to your flow. Configure those blocks to specify what audio you want to capture. For instructions and an example, see Example flow for testing live media streaming in Amazon Connect.

Develop live media streaming in Amazon Connect

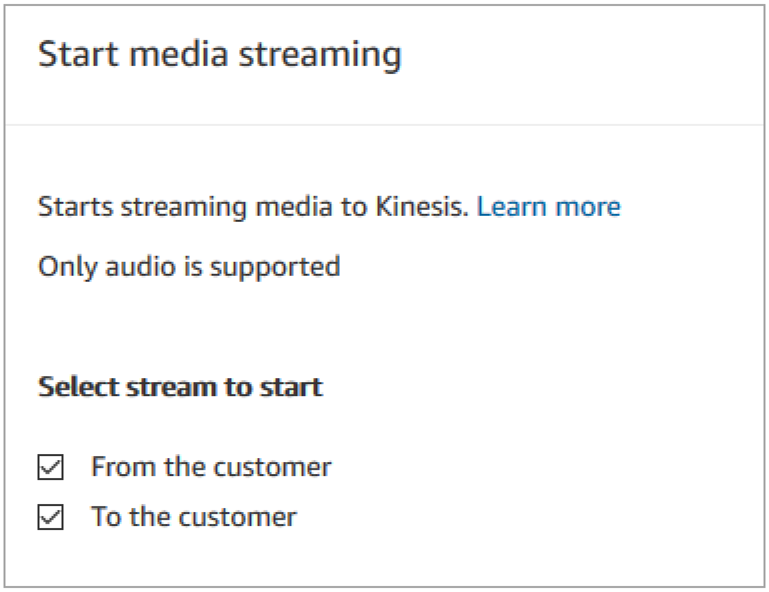
To help you get started with development using live media streaming, Amazon Connect includes the following Kinesis Video Streams repository that contains a basic example of how to consume audio data from your Kinesis Video Streams: https://github.com/amazon-connect/connect-kvs-consumer-demo

This demo builds upon the high level abstractions provided by the Kinesis Video Streams Parser Library to read the `AUDIO_TO_CUSTOMER` and `AUDIO_FROM_CUSTOMER` tracks published by Amazon Connect. It stores this data as a raw PCM file. This file can be transformed, transcoded, or played back.

Example flow for testing live media streaming in Amazon Connect

Here's how you can set up a flow to test live media streaming:

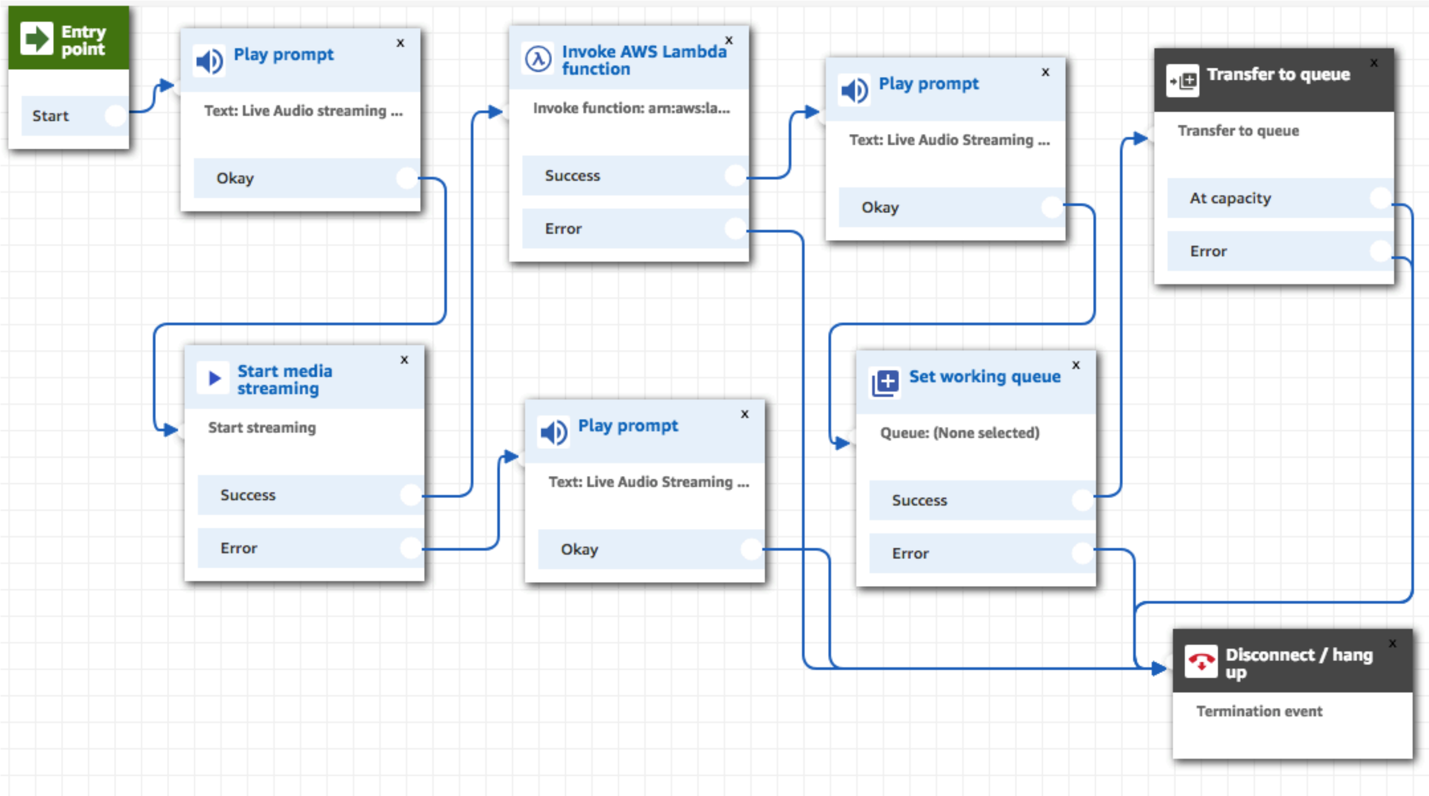
1. Add a **Start media streaming** block at the point where you want to enable customer audio streaming.
2. Connect the **Success** branch to the rest of your flow.
3. Add a **Stop media streaming** block to where you want to stop streaming.
4. Configure both blocks to specify what you want to stream: **From the customer** and/or **To the customer**.



Customer audio is captured until a **Stop media streaming** block is invoked, even if the contact is passed to another flow.

Use the contact attributes for media streaming in your flow so that the contact record includes the attributes. You can then view the contact record to determine the media streaming data associated with a specific contact. You can also pass the attributes to an AWS Lambda function.

The following example flow shows how you might use media streaming with attributes for testing purposes. This flow includes a **Start media streaming** block but it is missing the **Stop media streaming** block.



After the audio is successfully streamed to Kinesis Video Streams, the contact attributes are populated from the **Invoke AWS Lambda function** block. You can use the attributes to identify the location in the stream where the customer audio starts. For instructions, see Contact attributes for live media streaming in Kinesis Video Streams.

Contact attributes for live media streaming in Kinesis Video Streams

The attributes are displayed when you select **Media streams** for the **Type** in a flow block that supports attributes, such as the **Start media streaming** block. They include the following:

Customer audio stream ARN

The ARN of the Kinesis video stream that includes the customer data to reference.

JSONPath format: $.MediaStreams.Customer.Audio.StreamARN

Customer audio start timestamp

The time at which the customer audio stream started.

JSONPath format: $.MediaStreams.Customer.Audio.StartTimestamp

Customer audio stop timestamp

The time at which the customer audio stream stopped.

JSONPath format: $.MediaStreams.Customer.Audio.StopTimestamp

Customer audio start fragment number

The number that identifies the Kinesis Video Streams fragment in which the customer audio stream started.

JSONPath format: $.MediaStreams.Customer.Audio.StartFragmentNumber

For more information about Amazon Kinesis Video Streams fragments, see Fragment in the *Amazon Kinesis Video Streams Developer Guide*.

Encrypt sensitive customer input in Amazon Connect

You can encrypt sensitive data that is collected by flows. To do this, you need to use public-key cryptography.

When configuring Amazon Connect, you first provide the public key. This is the key used when encrypting data. Later, you provide the X.509 certificate, which includes a signature that proves you possess the private key.

In a flow that collects data, you provide an X.509 certificate to encrypt data that's captured using the **Stored customer input** system attribute. You must upload the key in `.pem` format to use this feature. The encryption key is used to verify the signature of the certificate used within the flow.

> **Note**
>
> You can have up to two encryption keys active at one time to facilitate rotation.

To decrypt the data in the **Stored customer input** attribute, use the AWS Encryption SDK. For more information, see the AWS Encryption SDK Developer Guide.

How to decrypt data encrypted by Amazon Connect

The following code sample shows how to decrypt data using the AWS Encryption SDK.

```
package com.amazonaws;

import com.amazonaws.encryptionsdk.AwsCrypto;
import com.amazonaws.encryptionsdk.CryptoResult;
import com.amazonaws.encryptionsdk.jce.JceMasterKey;
import org.bouncycastle.jce.provider.BouncyCastleProvider;

import java.io.IOException;
import java.nio.charset.Charset;
import java.nio.file.Files;
import java.nio.file.Paths;
import java.security.GeneralSecurityException;
import java.security.KeyFactory;
import java.security.Security;
import java.security.interfaces.RSAPrivateKey;
import java.security.spec.PKCS8EncodedKeySpec;
import java.util.Base64;

public class AmazonConnectDecryptionSample {

    // The Provider 'AmazonConnect' is used during encryption, this must be used during
 decryption for key
    // to be found
    private static final String PROVIDER = "AmazonConnect";

    // The wrapping algorithm used during encryption
    private static final String WRAPPING_ALGORITHM = "RSA/ECB/
OAEPWithSHA-512AndMGF1Padding";

    /**
     * This sample show how to decrypt data encrypted by Amazon Connect.
     * To use, provide the following command line arguments: [path-to-private-key]
 [key-id] [cyphertext]
     * Where:
     *  path-to-private-key is a file containing the PEM encoded private key to use for
 decryption
     *  key-id is the key-id specified during encryption in your flow
     *  cyphertext is the result of the encryption operation from Amazon Connect
     */
    public static void main(String[] args) throws IOException, GeneralSecurityException
 {
```

```
        String privateKeyFile = args[0]; // path to PEM encoded private key to use for
 decryption
        String keyId = args[1]; // this is the id used for key in your flow
        String cypherText = args[2]; // the result from flow

        Security.addProvider(new BouncyCastleProvider());

        // read the private key from file
        String privateKeyPem = new
 String(Files.readAllBytes(Paths.get(privateKeyFile)), Charset.forName("UTF-8"));
        RSAPrivateKey privateKey =  getPrivateKey(privateKeyPem);

        AwsCrypto awsCrypto = new AwsCrypto();
        JceMasterKey decMasterKey =
                JceMasterKey.getInstance(null,privateKey, PROVIDER, keyId,
 WRAPPING_ALGORITHM);
        CryptoResult<String, JceMasterKey> result =
 awsCrypto.decryptString(decMasterKey, cypherText);

        System.out.println("Decrypted: " + result.getResult());
    }

    public static RSAPrivateKey getPrivateKey(String privateKeyPem) throws IOException,
 GeneralSecurityException {
        String privateKeyBase64 = privateKeyPem
                .replace("-----BEGIN RSA PRIVATE KEY-----\n", "")
                .replace("-----END RSA PRIVATE KEY-----", "")
                .replaceAll("\n", "");
        byte[] decoded = Base64.getDecoder().decode(privateKeyBase64);
        KeyFactory kf = KeyFactory.getInstance("RSA");
        PKCS8EncodedKeySpec keySpec = new PKCS8EncodedKeySpec(decoded);
        RSAPrivateKey privKey = (RSAPrivateKey) kf.generatePrivate(keySpec);
        return privKey;
    }
}
```

Track events in your Amazon Connect flow logs as customers interact with them

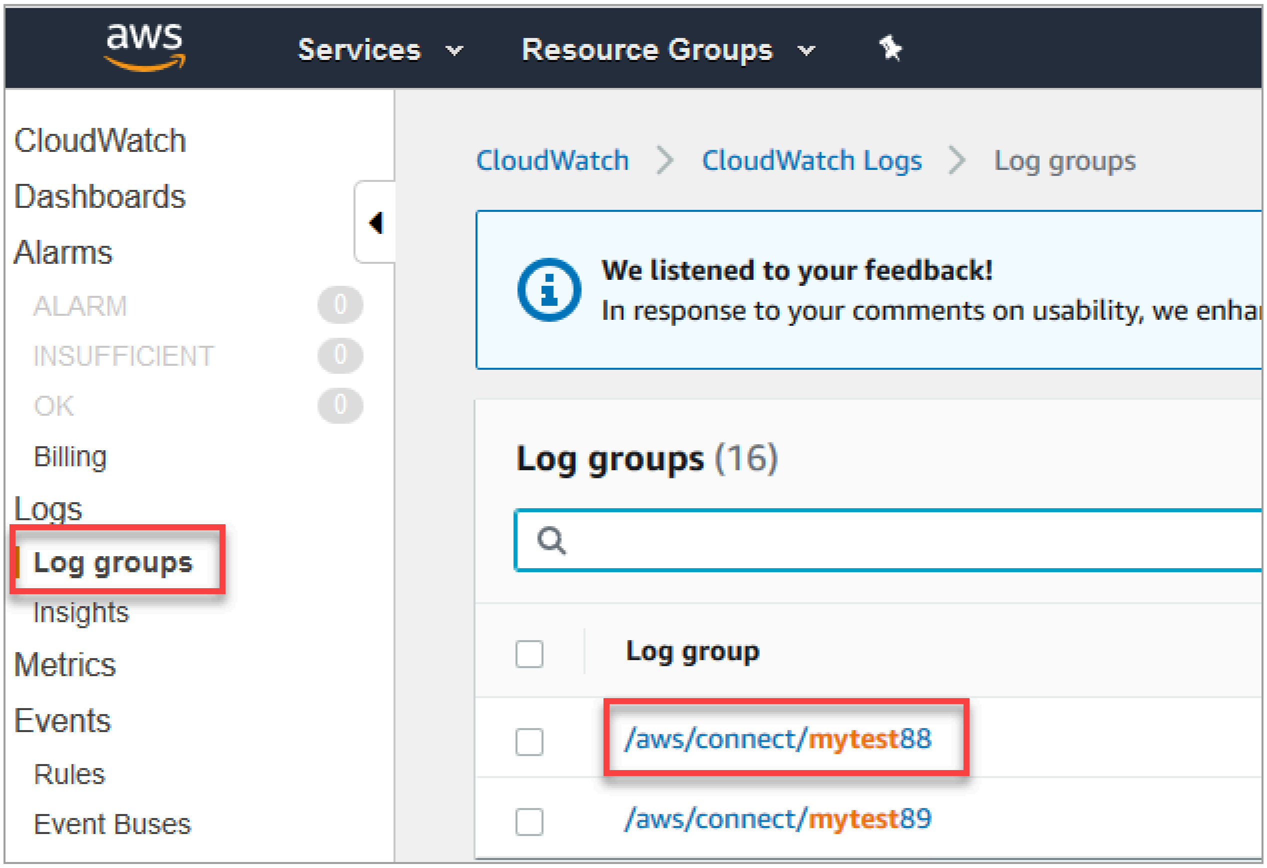
Amazon Connect flow logs provide you with real-time details about events in your flows as customers interact with them. You can also use flow logs to help debug your flows as you are creating them. If needed, you can always roll back to a previous version of a flow.

Contents

Flow logs stored in an Amazon CloudWatch log group

Flow logs are stored in an Amazon CloudWatch log group, in the same AWS Region as your Amazon Connect instance. This log group is created automatically when Enable flow logging is turned on for your instance.

For example, the following image shows the CloudWatch log groups for two test instances.



A log entry added as each block in your flow is triggered. You can configure CloudWatch to send alerts when unexpected events occur during active flows.

What happens if my log group is deleted? You need to manually re-create the CloudWatch log group. Otherwise, Amazon Connect won't publish more logs.

Pricing for flow logging

You are not charged for generating flow logs, but you are charged for using CloudWatch for generating and storing the logs. Free tier customers are charged only for usage that exceeds service quotas. For details about Amazon CloudWatch pricing, see Amazon CloudWatch Pricing.

Enable Amazon Connect flow logs in an Amazon CloudWatch log group

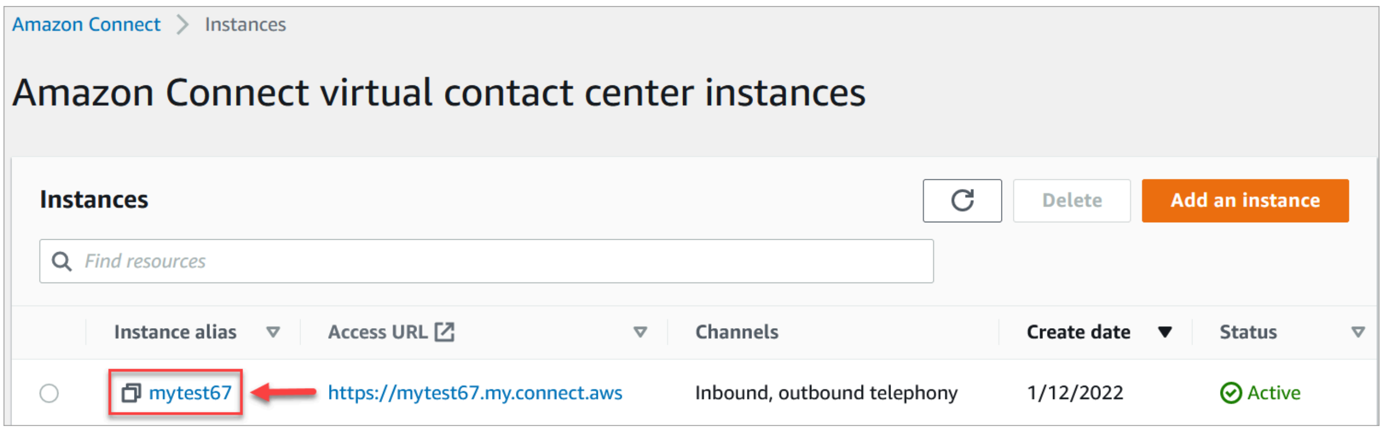
By default when you create a new Amazon Connect instance, an Amazon CloudWatch log group is created automatically to store the logs for your instance.

> **Tip**
>
> Amazon Connect delivers flow logs at least once. They may be delivered again for multiple reasons. For example, a service retry due to an unavoidable failure.

Step 1: Enable logging for your instance

Use the following procedure to check that logging is enabled for your instance.

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. On the instances page, choose the instance alias. The instance alias is also your **instance name**, which appears in your Amazon Connect URL. The following image shows the **Amazon Connect virtual contact center instances** page, with a box around the instance alias.



3. In the navigation pane, choose **Flows**.
4. Select **Enable Flow logs** and choose **Save**.

Step 2: Add the Set logging behavior block

Logs are generated only for flows that include a [Set logging behavior](#) block with logging set to enabled.

You control which flows, or parts of flows, logs are generated for by including multiple **Set logging behavior** blocks and configuring them as needed.

When you use a **Set logging behavior** block to enable or disable logging for a flow, logging is also enabled or disabled for any subsequent flow that a contact is transferred to, even if the flow does not include a **Set logging behavior** block. To avoid logging that persists between flows, enable or disable a **Set logging behavior** block as needed for that specific flow.

To enable or disable flow logs for a flow

1. In the flow designer, add a Set logging behavior block and connect it to another block in the flow.
2. Open the properties for the block. Choose **Enable** or **Disable**.
3. Choose **Save**.
4. If you add a **Set logging behavior** block to a flow that is already published, you must publish it again to start generating logs for it.

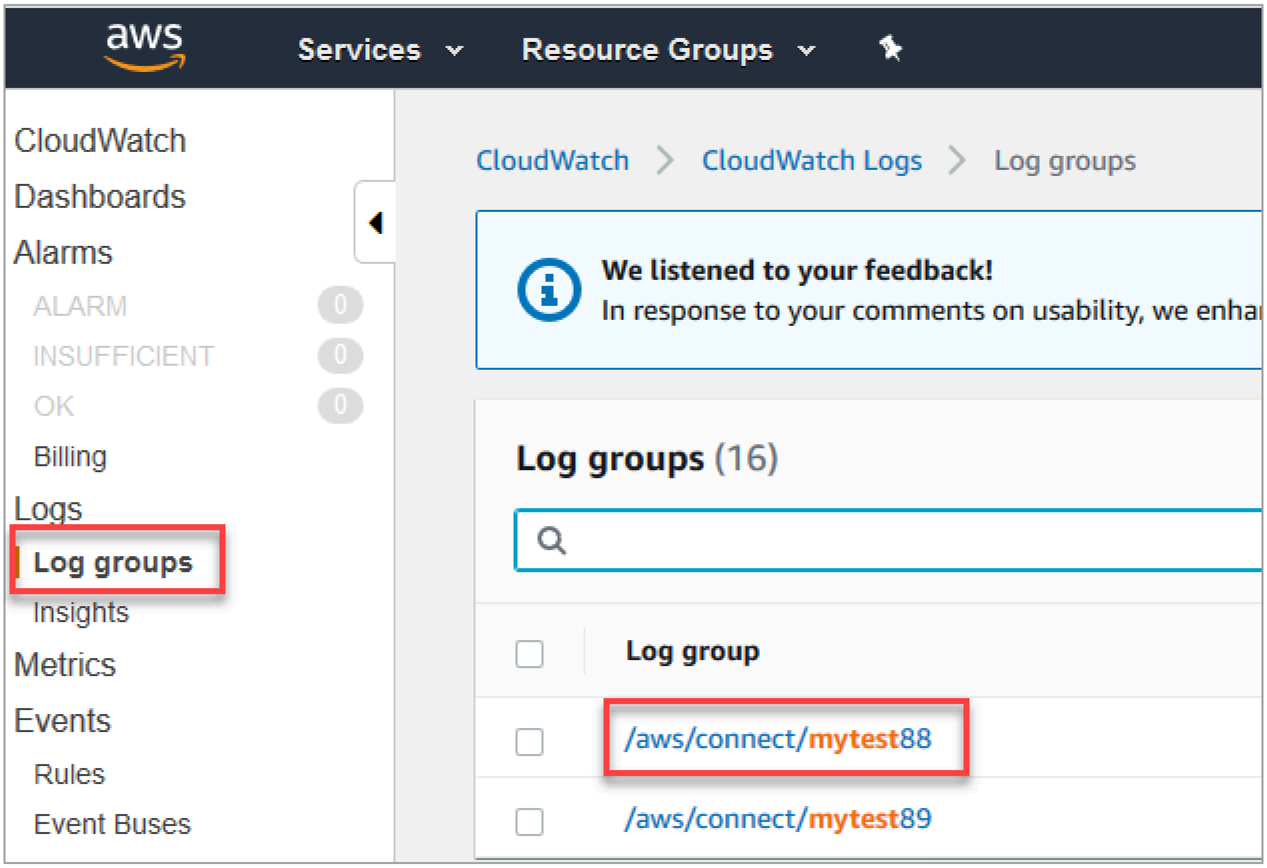
Search flow logs stored in an Amazon CloudWatch log group

Before you can search flow logs, you must first enable flow logging.

Logs will be created for conversations that occur after logging is enabled.

To search flow logs

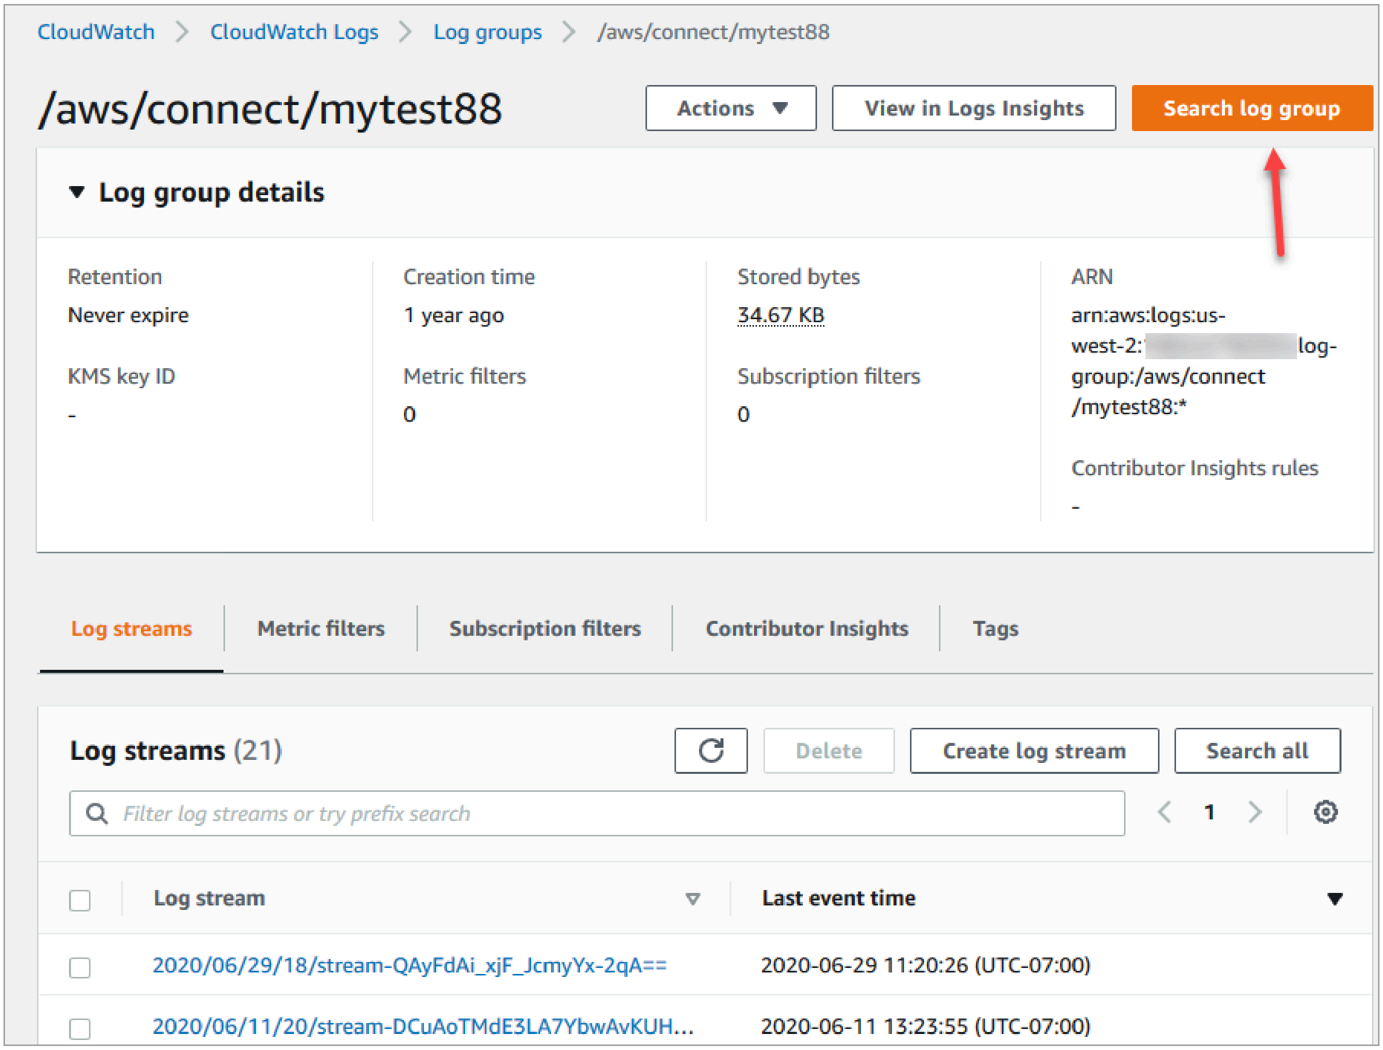
1. Open Amazon CloudWatch console, go to **Logs**, **Log groups**. The following image shows a sample log group named **mytest88**.



2. Choose the log group for your instance.

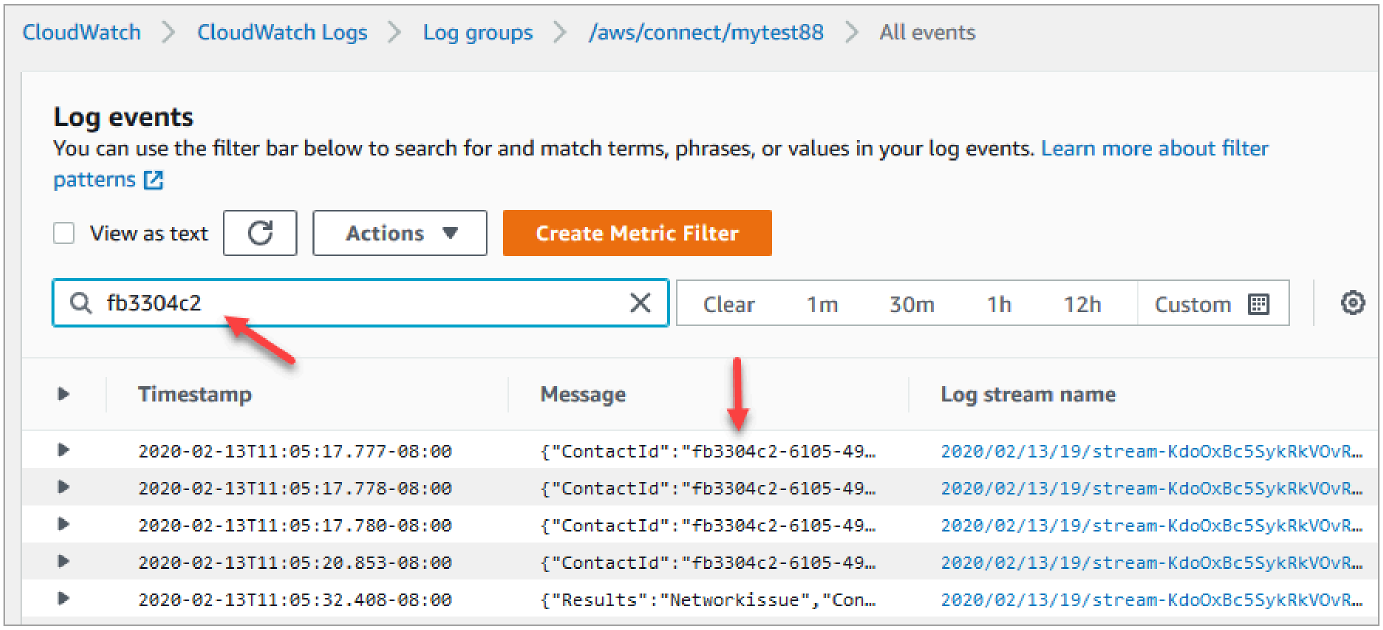
   A list of log streams will be displayed.

3. To search all the log streams in the instance, choose **Search log group**, as shown in the following image.



4. In the search box, enter the string you want to search for, for example, all or a portion of the contact ID.

5. After a couple of moments (longer depending on how big your log is), Amazon CloudWatch returns results. The following image shows a sample contact ID **fb3304c2**, and the result.



6. You can open each event to see what happened. The following image shows the event for when a **Play prompt** block runs in a flow.

Data in flow logs stored in an Amazon CloudWatch log group

Log entries for flows include details about the block associated with the log entry, the contact ID, and the action taken after the steps in the block were completed. Any contact interaction that occurs outside of the flow is not logged, such as time spent in a queue or interactions with an agent.

You can set the properties of the block to disable logging during the parts of your flow that interact with or capture sensitive data or customers' personal information.

If you use Amazon Lex or AWS Lambda in your flows, the logs show the entry and exit of the flow going to them, and include any information about the interaction that is sent or received during entry or exit.

Because the logs also include the flow ID, and the flow ID stays the same when you change a flow, you can use the logs to compare the interactions with different versions of the flow.

The following example log entry shows a **Set working queue** block of an inbound flow.

```
{
    "ContactId": "11111111-2222-3333-4444-555555555555",
    "ContactFlowId": "arn:aws:connect:us-west-2:0123456789012:instance/
nnnnnnnnnnn-3333-4444-5555-111111111111/contact-flow/123456789000-aaaa-bbbbbbbbb-
cccccccccccc",
    "ContactFlowModuleType": "SetQueue",
    "Timestamp": "2021-04-13T00:14:31.581Z",
    "Parameters": {
        "Queue": "arn:aws:connect:us-west-2:0123456789012:instance/
nnnnnnnnnnn-3333-4444-5555-111111111111/queue/aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee"
    }
}
```

Track customers between multiple flows in your contact center

In many cases, customers interact with multiple flows in your contact center, being passed from one flow to another to appropriately assist them with their specific issue. Flow logs help you track customers between different flows, by including the ID of the contact in each log entry.

When a customer is transferred to a different flow, the ID for the contact associated with their interaction is included with the log for the new flow. You can query the logs for the contact ID to trace the customer interaction through each flow.

In larger, high-volume contact centers, there can be multiple streams for flow logs. If a contact is transferred to a different flow, the log may be in a different stream. To make sure that you are finding all of the log data for a specific contact, you should search for the contact ID in the entire CloudWatch log group instead of in a specific log stream.

For a diagram that shows when a new contact record is created, see Events in the contact record.

Create alerts for events in your flow logs stored in an Amazon CloudWatch log group

You can configure CloudWatch to define a filter pattern that looks for specific events in your flow logs and then creates an alert when an entry for that event is added to the log.

For example, you can set an alert for when a flow block goes down an error path as a customer interacts with the flow. Log entries are typically available in CloudWatch within a short time, giving you near real-time notification of events in flows.

Monitor automated interactions (IVR) in Amazon Connect

You can use automated interaction logs to review the automated portion of your customers' Amazon Connect experience . The interaction logs appear on the **Contact details** page. They include the following information:

- Key interaction points, that is, flows, prompts, menus, keypad selections.
- A full bot transcript.

You can use the logs to monitor and improve your automated customer interactions, and maintain audio and system execution records of the interaction for compliance purposes.

Enable automated interaction logs

Perform the following steps to check that automated interaction logs are enabled for your instance.

1. Open the Amazon Connect console at https://console.aws.amazon.com/connect/.
2. Automated interactions logs are saved to the **S3 bucket you configured for call recordings**. If the call recordings feature is not yet enabled for your instance, enable it now:
    1. On the navigation pane, choose **Data storage**, **Call recordings**, **Edit**, **Enable call recording**, and create or select your S3 bucket.
3. In the navigation pane, choose **Flows**.
4. Select **Enable automated interaction logs**.

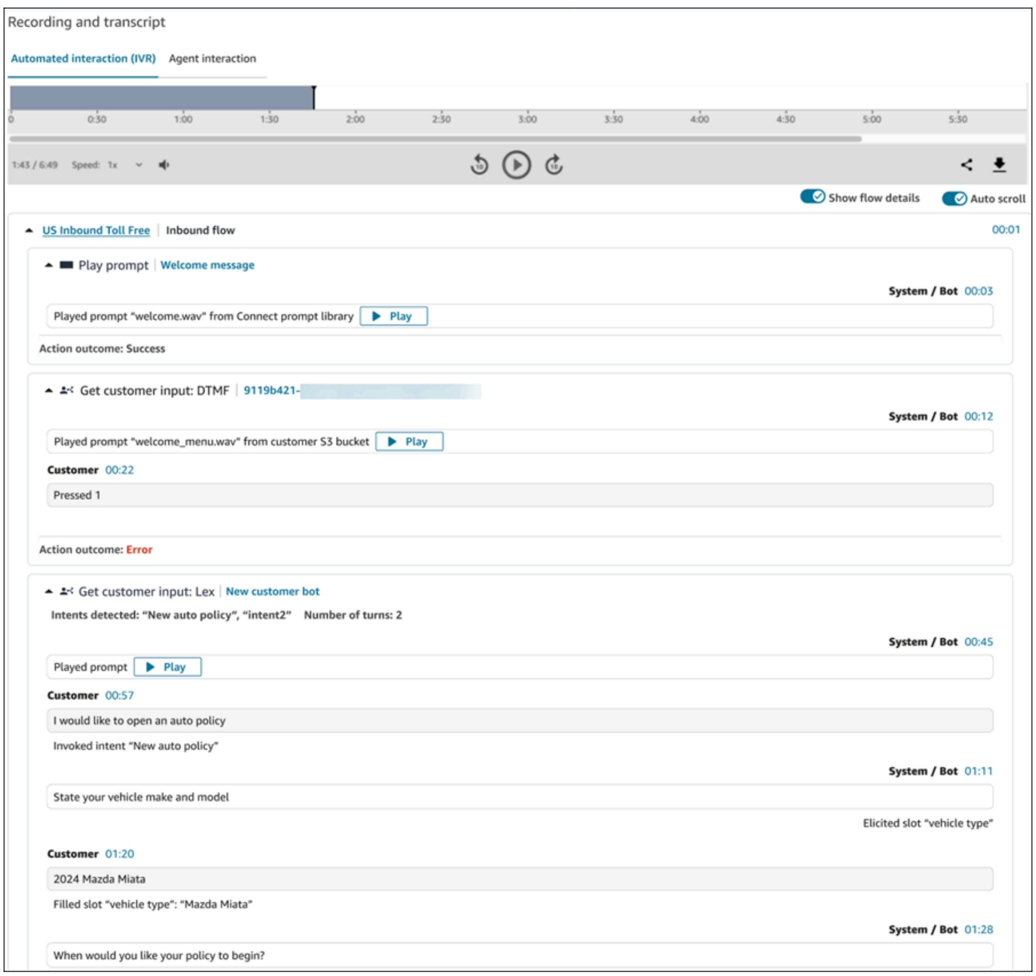
Permissions for automated interaction logs

To keep customer data secure, you can set up permissions to have granular control over who can access automated interaction logs. Access to automated interaction logs are gated by the following security profile permissions:

- **Flows** and **Flow modules – View** permissions: These permissions are required to see flow and module specific data on the automated interaction logs.
- **Analytics and Optimization - Automated interaction voice (IVR) transcripts (unredacted)** permissions: These permissions are required to access logs of the IVR interaction such as keypad inputs in response to IVR prompts, transcripts of Lex interactions, and more.

Navigate automated interactions logs and audio recording

The following image shows an example of an automated interaction log on the **Contact details** page on the Amazon Connect admin website.



To navigate the log

1. Use tabs to toggle between the automated interaction and agent interaction to see the end-to-end interaction of your customer.
2. Choose **Show flow details** to hide system details about the flows and flow blocks.
3. Choose the flow and block hyperlinks to open the flow designer in a new tab, enabling you to quickly follow along with your flow.
4. Choose **Play** to play the specific prompt within your audio recording file.

> **Note**
>
> If no audio recording is available, there is no option to play the prompt.

5. Quickly see where errors have occurred including customer timeouts or Lambda function errors.
6. See where bot intents are detected and resolved.

Use Amazon Connect contact attributes

One way to make your customers feel cared for is to create personalized experiences for them in your contact center. For example, you can deliver one welcome message for customers who are using a phone and another for customers using chat. To do this, you need a way to store information about the contact and then make a decision based on the value.

Contents

How contact attributes work in Amazon Connect

Amazon Connect treats each interaction with a customer as a **contact**. The interaction can be a phone call (voice), a chat, or an automated interaction with an Amazon Lex bot.

Each contact can have some data that is specific to a particular interaction. This data can be accessed as a contact attribute. For example:

- The name of the customer
- The name of the agent
- The channel used for the contact, such as phone or chat

A contact attribute represents this data as a key-value pair. You might think of it as a field name together with the data entered into that field.

For example, here are a couple of key-value pairs for the customer name:

Key	Value
firstname	Jane
lastname	Doe

The advantage of contact attributes is that they enable you to store temporary information about the contact so you can use it in the flow.

For example, in your welcome messages, you can say their name or thank them for being a member. To do this, you need a way of retrieving data about that specific customer and using it in a flow.

Common use cases

Here are some common use cases for where contact attributes are used:

- Use the customer phone number to schedule a queued callback.
- Identify which agent is interacting with a customer so that a post call survey can be associated with a contact.

- Identify the number of contacts in a queue to decide if the contact should be routed to a different queue.
- Get the corresponding media streaming ARN to store in a database.
- Use the customer phone number to identify the status of a customer (for example, are they a member), or the status of their order (shipped, delayed, etc.) to route them to the appropriate queue.
- Based on a customer interaction with a bot, identify the slot (for example, the type of flowers to order) to be used in a flow.

Types of contact attributes

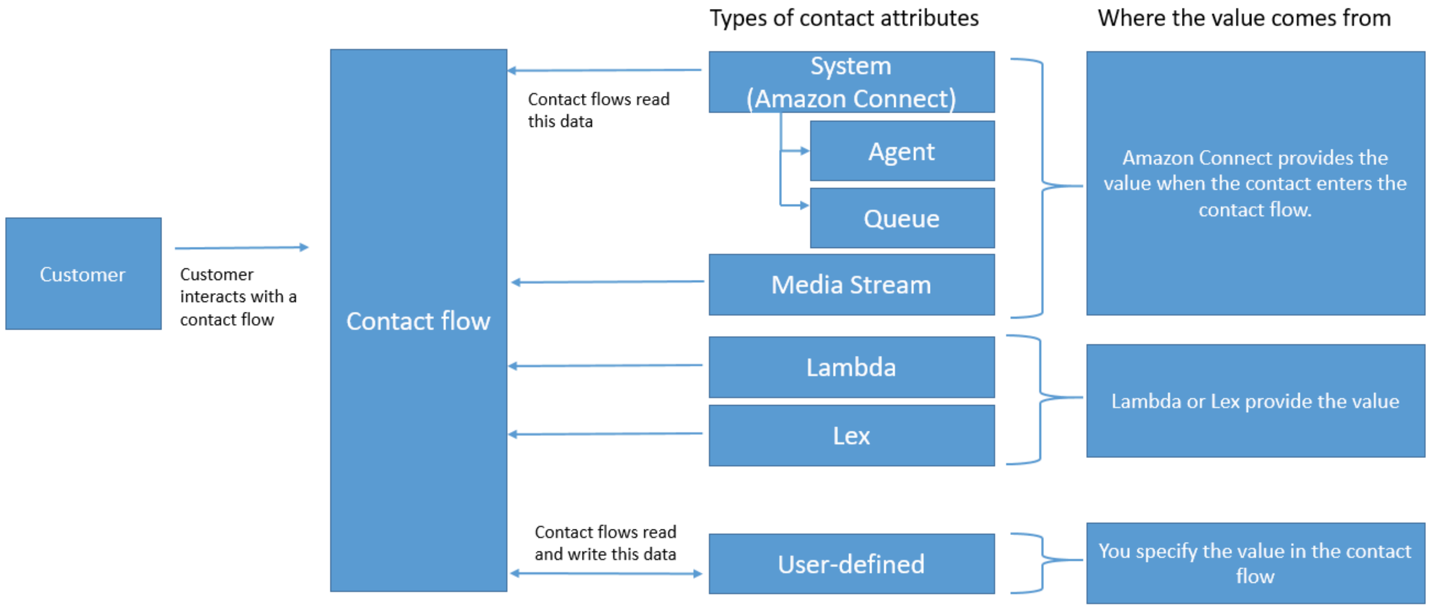
To make it faster for you to find and choose the attributes you want to use, attributes are grouped into **types**. For each flow block, we only surface those types of attributes that work with it.

Another way to think about types of contact attributes is to categorize them based on where the value comes from. The values for contact attributes have the following sources:

- Amazon Connect provides the value, such as the agent's name, during the contact interaction. This is known as providing the value at runtime.
- An external process, such as Amazon Lex or AWS Lambda, provides the value.
- User-defined. In the flow, you can specify the value for an attribute.

  Flow attributes are similar to user-defined attributes. However, unlike user-defined attributes, flow attributes are restricted to the flow in which they are configured.

The following illustration lists the types of available contact attributes, and maps them to the three sources for the values: Amazon Connect, external process such as Amazon Lex, and user-defined.



Contact attributes in the contact record

In contact records, contact attributes are shared across all contacts with the same InitialContactId.

For example, while carrying out transfers, a contact attribute updated in the transfer flow updates the attribute's value in the contact attributes of both contact records (that is, the Inbound and Transfer contact attributes).

"$" is a special character

Amazon Connect treats the "$" character as a special character. You can't use it in a key when setting an attribute.

For example, let's say you're creating an interact block with text-to-speech. You set an attribute like this:

```
{"$one":"please read this text"}
```

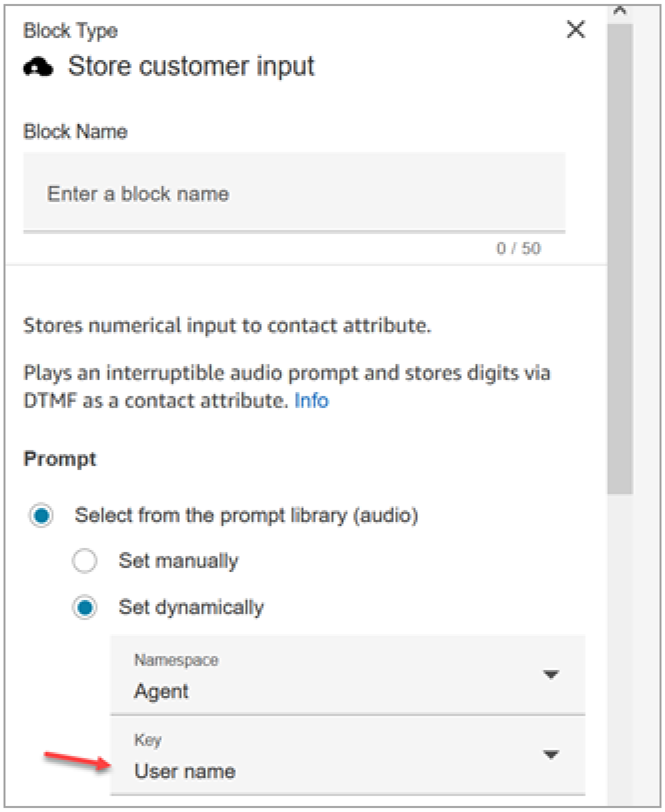
When Amazon Connect reads this text, it reads "dollar sign one" to the contact instead of "please read this text." Also, if you were to include $ in a key and try to reference the value later using Amazon Connect, it wouldn't retrieve the value.

Amazon Connect does log and pass the full key:value pair (`{"_$one":"please read this text"}`) to integrations such as Lambda.

What happens if an attribute doesn't exist

Be sure to implement logic to handle if the attribute doesn't exist and the contact is routed down the error branch.

Let's say you add an attribute to the Store customer input block. The **Namespace** is **Agent** and the **Key** is **User name**, as shown in the following example.



If the flow runs and the agent user name is not available, then the contact is routed down the error branch.

List of available contact attributes in Amazon Connect and their JSONPath references

The following tables describe the contact attributes available in Amazon Connect.

The JSONPath reference for each attribute is provided so you can create dynamic text strings.

System attributes

These are predefined attributes in Amazon Connect. You can reference system attributes, but you cannot create them.

Not all blocks in a flow support using System attributes. For example, you cannot use a System attribute to store customer input. Instead, use a [user-defined attribute] to store the data input by a customer.

Attribute	Description	Type	JSONPath Reference
AWS Region	When used, this returns the AWS Region where the contact is being handled. For example, us-west-2, us-east-1, and so on.	System	$.AwsRegion or $['AwsRegion']
Customer number	The customer's phone number. Supported in voice calls, SMS, and WhatsApp business messaging. When used in an outbound whisper flow, this is the number that the agents dialed to reach the customer. When used in inbound flows, this is the number from which the customer placed the call. This attribute is included in contact records. When used in a Lambda function, it's included in the	System	$.CustomerEndpoint .Address

Attribute	Description	Type	JSONPath Reference
	input object under CustomerEndpoint.		
Customer ID	The customer's identification number. For example, the CustomerId may be a customer number from your CRM. You can create a Lambda function to pull the unique customer ID of the caller from your CRM system. Voice ID uses this attribute as the `CustomerSpeakerId` for the caller.	System	$.CustomerId

Attribute	Description	Type	JSONPath Reference
Dialed number	Supported in voice calls, SMS, and WhatsApp business messaging. The number the customer dialed to call your contact center. This attribute is included in contact records. When used in a Lambda function, it's included in the input object under SystemEndpoint.	System	$.SystemEndpoint.Address
System email address	The email address that the contact sent the email to.	System	$.
Customer display name	The customer's name on the email that they sent to your contact center.	System	$.
System display name	The display name of the email address that the customer sent.	System	$.

Attribute	Description	Type	JSONPath Reference
CC Email Address List	The full list of cc'd email addresses on the inbound email sent to your contact center.	System	$.
To Email Address List	The full list of To email addresses on the inbound email sent to your contact center.	System	$.

Attribute	Description	Type	JSONPath Reference
Customer callback number	The number that Amazon Connect uses to call back the customer. This number can be the one used for a queued callback, or when an agent is dialing from the CCP. Transfer to callback queue functiona lity, or for an agent dialing from the CCP. The default value is the number that the customer used to call your contact center. However, it can be overwritten with the **Set callback number** block. This attribute is not included in contact records, and it's not accessible in Lambda input. However, you can copy the attribute to a user-defined attribute with the Set contact attribute block, which is included in contact	System	not applicable

Attribute	Description	Type	JSONPath Reference
	records. You can also pass this attribute as a Lambda input parameter in an Invoke AWS Lambda function block, which is not included in contact records.		

Attribute	Description	Type	JSONPath Reference
Stored customer input	An attribute created from the most recent invocation of a **Store customer input** block. The attribute values created from the most recent Store customer input block invocation. This attribute is not included in contact records, and is not accessible in Lambda input. You can copy the attribute to a user-defined attribute with the Set contact attribute block, which is included in contact records. You can also pass this attribute as a Lambda input parameter in an Invoke AWS Lambda function block.	System	$.StoredCustomerInput
Queue name	The name of the queue.	System	$.Queue.Name
Queue ARN	The ARN for the queue.	System	$.Queue.ARN

Attribute	Description	Type	JSONPath Reference
Queue outbound number	The Outbound caller ID number for the selected queue. This attribute is only available in outbound whisper flows.	System	
Text to speech voice	The name of the Amazon Polly voice to use for text-to-speech in a contact flow.	System	$.TextToSpeechVoiceId
Contact id	The unique identifier of the contact.	System	$.ContactId
Initial Contact id	The unique identifier for the contact associated with the first interaction between the customer and your contact center. Use the initial contact ID to track contacts between flows.	System	$.InitialContactId
Task Contact id	The unique identifier for the task contact. Use the task contact ID to track tasks between flows.	System	$.Task.ContactId

Attribute	Description	Type	JSONPath Reference
Previous Contact id	The unique identifier for the contact before it was transferred. Use the previous contact ID to trace contacts between flows.	System	$.PreviousContactId
Channel	The method used to contact your contact center: VOICE, CHAT, TASK, EMAIL.	System	$.Channel
Instance ARN	The ARN for your Amazon Connect instance.	System	$.InstanceARN
Initiation method	How the contact was initiated. Valid values include: INBOUND, OUTBOUND, TRANSFER, CALLBACK, QUEUE_TRANSFER, EXTERNAL_OUTBOUND, MONITOR, DISCONNECT, WEBRTC_API, and API. For more information, see InitiationMethod in the *Contact records data model* topic.	System	$.InitiationMethod

Attribute	Description	Type	JSONPath Reference
AWS Region		System	$.
Name	The name of the task.	System	$.Name
Description	A description of the task.	System	$.Description
References	Links to other documents that are related to a contact.	System	$.References.*ReferenceKey* .Value and $.References.*ReferenceKey* .Type where *ReferenceKey* is the user-defined Reference name.
Language	The language of content. Use the standard java.util.Locale. For example, en-US for United States English, jp-JP for Japanese, etc.	System	$.LanguageCode
System Endpoint Type	The type of the system endpoint. Valid value is TELEPHONE_NUMBER.	System	$.SystemEndpoint.Type

Attribute	Description	Type	JSONPath Reference
Customer Endpoint type	The type of the customer endpoint. Valid value is TELEPHONE _NUMBER.	System	$.CustomerEndpoint .Type
Queue Outbound Caller ID number	The outbound caller ID number defined for the queue. This can be useful for reverting the caller ID after setting a custom caller ID.	System	$.Queue.OutboundCa llerId.Address
Queue Outbound Caller ID number type	The type of the outbound caller ID number. Valid value is TELEPHONE _NUMBER.	System	$.Queue.OutboundCa llerId.Type
Tags	The tags used to organize, track, or control access for this resource. For more information about tags, see [Add tags to resources in Amazon Connect] and [Set up granular billing for a detailed view of your Amazon Connect usage].	System	$.Tags

Segment attributes

Segment attributes are a set of system defined key-value pairs stored on individual contact segments using an attribute map.

Attribute	Description	Allowed values	Type	JSONPath Reference
connect:Subtype	Represents the subtype of the channel used for the contact.	• "connect:SMS" • "connect:WebRTC" • "connect:Guide" • "connect:Apple" • "connect:WhatsApp" • "connect:ExternalAudio" • "connect:Chat" • "connect:Telephony" • "connect:Task" • "connect:Email"	ValueString	$.SegmentAttributes['connect:Subtype']
connect:Direction	Represents the direction of the contact. For example, inbound or outbound.	• "INBOUND" • "OUTBOUND"	ValueString	$.SegmentAttributes['connect:Direction']

Attribute	Description	Allowed values	Type	JSONPath Reference
connect:CreatedByUser	Represents the user's ARN who created the task.		ValueString	$.SegmentAttributes['connect:CreatedByUser']
connect:AssignmentType	Represents how a task is assigned.	"SELF"	ValueString	$.SegmentAttributes['connect:AssignmentType']
connect:EmailSubject	Represents the subject of an email contact.		ValueString	$.SegmentAttributes['connect:EmailSubject']

Attribute	Description	Allowed values	Type	JSONPath Reference
connect:ScreenSharingDetails	The `ScreenSharingDetails` section holds information about the screensharing activity performed on the contact. The `ScreenSharingActivated` key indicates whether or not the screen sharing session is activated for the contact or not.	`"connect:ScreenSharingDetails": { "ScreensharingActivated" : "TRUE" // Allowed Values "TRUE" and "FALSE" }`	ValueString	$.SegmentAttributes['connect:ScreenSharingDetails']
connect:ContactExpiry	Contains the details of contact expiry such as `ExpiryDuration` and `ExpiryTimeStamp` for Task and Email contacts.		valueMap	$.SegmentAttributes['connect:ContactExpiry']

Attribute	Description	Allowed values	Type	JSONPath Reference
connect:CustomerAuthentication	The chat contact's authentication details.	`"connect:CustomerAuthentication": { "valueMap": { "IdentityProvider": { "ValueString": ""}, "ClientId": { "ValueString": ""}, "Status": { "ValueString": *AUTHENTICATED | FAILED | TIMEOUT*} , "AssociatedCustomerId": { "ValueString": ""} "AuthenticationMethod": { "ValueString": "*CONNECT" | "CUSTOM*" } }`	ValueMap	$.SegmentAttributes['connect:CustomerAuthentication']

Attribute	Description	Allowed values	Type	JSONPath Reference
Client Id	The Amazon Cognito app client identifier.		ValueString	$.SegmentAttributes['connect:CustomerAuthentication']['ClientId']
Identify Provider	The identity provider used to authenticate the customer.		ValueString	$.SegmentAttributes['connect:CustomerAuthentication']['IdentityProvider']
Status	The status of the authentication process.	`AUTHENTICATED` | `FAILED` | `TIMEOUT`	ValueString	$.SegmentAttributes['connect:CustomerAuthentication']['Status']
Associated Customer Id	The customer's identifier number. This is either a custom identifier or a Customer Profile identifier.		ValueString	$.SegmentAttributes['connect:CustomerAuthentication']['AssociatedCustomerId']

Attribute	Description	Allowed values	Type	JSONPath Reference
Authentication Method	An Amazon Connect-managed authentication workflow or customer-managed authentication workflow.	`CONNECT` | `CUSTOM`	ValueString	$.SegmentAttributes['connect:CustomerAuthentication']['AuthenticationMethod']
Email Subject	The email subject in the email that the customer sent to your contact center. This useful in case you want to look at the email subject for certain keywords.		Segment attribute	$.SegmentAttributes['connect:EmailSubject']

Attribute	Description	Allowed values	Type	JSONPath Reference
Amazon SES Spam Verdict	When the email comes into your contact center, Amazon SES scans it for spam. You can check for the FAILED condition and then either drop the email or put it in a special queue for supervisors to review it.		Segment attribute	$.Segment Attribute s['connect:X-SES-SPAM-VERDICT']
Amazon SES Virus Verdict	When the email comes into your contact center, Amazon SES scans it for viruses. You can check for the FAILED condition and then either drop the email or put it in a special queue for supervisors to review it.		Segment attribute	$.Segment Attribute s['connect:X-SES-VIRUS-VERDICT']

Views attributes

The following table lists the Views attributes available in Amazon Connect.

Attribute	Description	Type	JSONPath Reference
Action		Views	$.
View result data		Views	$.

Capabilities attributes

The following table lists the Capabilities attributes available in Amazon Connect.

Attribute	Description	Type	JSONPath Reference
Customer video capability		Capabilities	$.
Agent video capabilit y		Capabilities	$.

Agent attributes

The following table lists the agent attributes available in Amazon Connect.

Attribute	Description	Type	JSONPath Reference
Agent User name	The user name an agent uses to log in to Amazon Connect.	System	$.Agent.UserName
Agent First name	The agent's first name as entered in their Amazon Connect user account.	System	$.Agent.FirstName
Agent Last name	The agent's last name as entered in their	System	$.Agent.LastName

Attribute	Description	Type	JSONPath Reference
	Amazon Connect user account.		
Agent ARN	The ARN of the agent.	System	$.Agent.ARN

Note

When you use an agent contact attribute in a **Transfer to agent** flow, the agent attributes reflect the target agent, not the one who initiated the transfer.

Agent attributes are available only in the following types of flows:

- Agent whisper
- Customer whisper
- Agent hold
- Customer hold
- Outbound whisper
- Transfer to agent. In this case, the agent attributes reflect the target agent, not the one who initiated the transfer.

Agent attributes are not available in the following flow types:

- Customer queue
- Transfer to queue
- Inbound flow

Queue attributes

These system attributes are returned when you use a **Get queue metrics** block in your flow.

If there is no current activity in your contact center, null values are returned for these attributes.

Attribute	Description	Type	JSONPath Reference
Queue name	The name of the queue for which metrics were retrieved.	System	$.Metrics.Queue.Name
Queue ARN	The ARN of the queue for which metrics were retrieved.	System	$.Metrics.Queue.ARN
Contacts in queue	The number of contacts currently in the queue.	System	$.Metrics.Queue.Size
Oldest contact in queue	For the contact that has been in the queue the longest, the length of time that the contact has been in the queue, in seconds.	System	$.Metrics.Queue.OldestContactAge
Agents online	The number of agents currently online, which means logged in and in any state other than offline.	System	$.Metrics.Agents.Online.Count
Agents available	The number of agents whose state is set to Available.	System	$.Metrics.Agents.Available.Count
Agents staffed	The number of agents currently staffed, which is	System	$.Metrics.Agents.Staffed.Count

Attribute	Description	Type	JSONPath Reference
	agents logged in and in Available, ACW, or Busy states.		
Agents in After contact work	The number of agents currently in the ACW state.	System	$.Metrics.Agents.AfterContactWork.Count
Agents busy	The number of agents currently active on a contact.	System	$.Metrics.Agents.Busy.Count
Agents missed count	The number of agents in the Missed state, which is the state an agent enters after a missed contact.	System	$.Metrics.Agents.Missed.Count
Agents in non-productive state	The number of agents in a non-productive (NPT) state.	System	$.Metrics.Agents.NonProductive.Count

Telephony call metadata attributes (call attributes)

Telephony metadata provides additional information related to call origination from telephony carriers.

Attribute	Description	Type	JSONPath Reference
P-Charge-Info	The party responsible for the charges associated with the call.	System	$.Media.Sip.Headers.P-Charge-Info

Attribute	Description	Type	JSONPath Reference
From	The identity of the end user associated with the request.	System	$.Media.Sip.Header s.From
To	Information about the called party or the recipient of the request.	System	$.Media.Sip.Header s.To
ISUP-OLI	Originating Line Indicator (OLI). Shows the type of line placing call (for example, PSTN, 800 service call, wireless/cellular PCS, payphone).	System	$.Media.Sip.Header s.ISUP-OLI
JIP	Jurisdiction Indicatio n Parameter (JIP). Indicates geographic location of caller/sw itch. Example value: 212555	System	$.Media.Sip.Header s.JIP
Hop-Counter	Hop Counter. Example value: 0	System	$.Media.Sip.Header s.Hop-Counter
Originating-Switch	Originating Switch. Example value: 710	System	$.Media.Sip.Header s.Originating-Switch

Attribute	Description	Type	JSONPath Reference
Originating-Trunk	Originating Trunk. Example value: 0235	System	$.Media.Sip.Headers.Originating-Trunk
Call-Forwarding-Indicator	Call Forwarding Indicators (for example, Diversion header). Indicates domestic or international origin of call. Example value: sip:+15555555555@public-vip.us2.telephony-provider.com;reason=unconditional	System	$.Media.Sip.Headers.Call-Forwarding-Indicator
Calling-Party-Address	Calling Party Address (number). NPAC dip shows true line type and native geographic switch. Example value: 15555555555;noa=4	System	$.Media.Sip.Headers.Calling-Party-Address
Called-Party-Address	Called Party Address (number). Example value: 15555555555;noa=4	System	$.Media.Sip.Headers.Called-Party-Address
SIPREC metadata	SIPREC metadata XML received by Amazon Contact Lens connector	System	$.Media.Sip.SiprecMetadata

Note

The availability of telephony metadata is not consistent across all telephony providers and may not be available in all cases. This may result in empty values.

Chat initial message attributes

Attribute	Description	Type	JSONPath Reference
InitialMessage	The initial message supplied by the customer on a web chat or SMS.	System	$.Media.InitialMessage

Media streams attributes

The following table lists the attributes that you can use to identify the location in the live media stream where the customer audio starts and stops.

Attribute	Description	Type	JSONPath Reference
Customer audio stream ARN	The ARN of the Kinesis Video stream used for Live media streaming that includes the customer data to reference.	Media streams	$.MediaStreams.Customer.Audio.StreamARN
Customer audio start timestamp in the Kinesis video stream used for Live media streaming.	When the customer audio stream started.	Media streams	$.MediaStreams.Customer.Audio.StartTimestamp

Attribute	Description	Type	JSONPath Reference
Customer audio stop timestamp	When the customer audio stream stopped the Kinesis video stream used for Live media streaming.	Media streams	$.MediaStreams.Customer.Audio.StopTimestamp
Customer audio start fragment number	The number that identifies the Kinesis Video Streams fragment, in the stream used for Live media streaming, in which the customer audio stream started.	Media streams	$.MediaStreams.Customer.Audio.StartFragmentNumber

Amazon Lex contact attributes

The following table lists the attributes that are returned from Amazon Lex bots. These are also know as *session attributes*.

Attribute	Description	Type	JSONPath Reference
Alternate Intents	List of alternate intents available from Amazon Lex. Each intent has a corresponding confidence score and slots to fill.	Lex	$.Lex.AlternativeIntents.*x*.IntentName $.Lex.AlternativeIntents.*x*.IntentConfidence.Score $.Lex.AlternativeIntents.*x*.Slots $.Lex.AlternativeIntents.*y*. IntentName

Attribute	Description	Type	JSONPath Reference
			$.Lex.AlternativeIntents.*y*.IntentConfidence.Score $.Lex.AlternativeIntents.*y*.Slots $.Lex.AlternativeIntents.*z*.IntentName $.Lex.AlternativeIntents.*z*.IntentConfidence.Score $.Lex.AlternativeIntents.*z*.Slots Where *x*, *y*, and *z* are the intent names in the Lex response
Intent Confidence Score	The intent confidence score returned by Amazon Lex.	Lex	$.Lex.IntentConfidence.Score
Intent name	The user intent returned by Amazon Lex.	Lex	$.Lex.IntentName
Sentiment Label	The inferred sentiment that Amazon Comprehend has the highest confidence in.	Lex	$.Lex.SentimentResponse.Label

Attribute	Description	Type	JSONPath Reference
Sentiment scores	The likelihood that the sentiment was correctly inferred.	Lex	$.Lex.SentimentResponse.Scores.Positive $.Lex.SentimentResponse.Scores.Negative $.Lex.SentimentResponse.Scores.Mixed $.Lex.SentimentResponse.Scores.Neutral
Session attributes	Map of key-value pairs representing the session-specific context information.	Lex	$.Lex.SessionAttributes.attributeKey
Slots	Map of intent slots (key/value pairs) Amazon Lex detected from the user input during the interaction.	Lex	$.Lex.Slots.slotName
Dialog state	The last dialog state returned from an Amazon Lex bot. The value is 'Fulfilled' if an intent was returned to the flow.	N/A (no type appears in the UI)	$.Lex.DialogState

Case contact attributes

The following table lists the attributes that are used with Amazon Connect Cases.

Attribute	Description	Type	JSONPath Reference	Where the data comes from
Case ID	Unique Identifier of the case in UUID format (for example, 689b0bea-aa29-4340-896d-4ca3ce9b6226)	text	$.Case.case_id	Amazon Connect
Case Reason	The reason for opening the case	single-select	$.Case.case_reason	Agent
Customer	The API is a customer profile ID. On the **Cases: Fields** page, the customer's name is displayed.	text	$.Case.customer_id	Amazon Connect
Date/Time Closed	The date and time the case was last closed. It does not guarantee that a case is closed. If a case is reopened, this field contains the date/time stamp of the last time the status was changed to closed.	date-time	$.Case.last_closed_datetime	Amazon Connect

Attribute	Description	Type	JSONPath Reference	Where the data comes from
Date/Time Opened	The date and time the case was opened.	date-time	$.Case.cr eated_datetime	Amazon Connect
Date/Time Updated	The date and time the case was last updated.	date-time	$.Case.la st_update d_datetime	Amazon Connect
Reference number	A friendly number for the case in 8-digit numeric format. Reference numbers (unlike the Case ID) are not guarantee d to be unique. We recommend that you identify the customer and then collect the reference number to correctly find the right case.	text	$.Case.re ference_number	Agent
Status	Current status of the case	text	$.Case.status	Agent
Summary	Summary of the case	text	$.Case.summary	Agent
Title	Title of the case	text	$.Case.title	Agent

Lambda contact attributes

Lambda attributes are returned as key-value pairs from the most recent invocation of an **Invoke AWS Lambda function** block. External attributes are overwritten with each invocation of the Lambda function.

To reference external attributes in JSONPath, use:

- `$.External.attributeName`

where `AttributeName` is the attribute name, or the key of the key-value pair returned from the function.

For example, if the function returns a contact ID, reference the attribute with `$.External.ContactId`. When referencing a contact ID returned from Amazon Connect, the JSONPath is `$.ContactId`.

> **Note**
>
> Note the inclusion of `.External` in the JSONPath reference when the attribute is external to Amazon Connect. Make sure to match the case for attribute names returned from external sources.

For more information about using attributes in Lambda functions, see Grant Amazon Connect access to your AWS Lambda functions.

These attributes are not included in contact records, not passed to the next Lambda invocation, and not passed to the CCP for screenpop information. However, they can be passed as Lambda function inputs on an **Invoke AWS Lambda function** block, or copied to user-defined attributes using the **Set contact attributes** block. When used in **Set contact attributes** blocks, the attributes that are copied are included in contact records, and can be used in the CCP.

User-defined attributes

For all other attributes Amazon Connect defines the key and value. For user-defined attributes, however, you provide a name for the key and the value.

Use user-defined attributes in situations where you want to store values in a contact flow, and then refer to those values later. For example, if you integrate Amazon Connect and a CRM or other system, you might want to get input from the customer such as their member number. Then you can use that member number retrieve information about the member from the CRM, and/or use the member number throughout the flow, etc.

Attribute	Description	Type	JSONPath Reference
Any name you choose	A user-defined attribute has two parts: • Destination key: this is any name you choose for the key. However, the **$** and **.** (period) characters are not allowed because they are both used in defining the attribute paths in JSONPath. • Value: this is can be any value you choose. You can enter several paragraphs worth of text if you want! (For the **Max size of the contact record attributes section**, see Amazon Connect feature specifications.)	User-defined	$.Attributes.*name_of_your_destination_key*

To create user-defined attributes, use the Set contact attributes block.

Flow attributes

Flow attributes are like a type user-defined attribute, however, they are restricted to the flow where they are set.

Flow attributes are useful in situations where you don't want to persist the data throughout the contact, such as when you need to use sensitive information like the customer's credit card number to do a Lambda data dip.

- Flow attributes are temporary variables stored locally and only used in the flow. They aren't visible anywhere outside the flow, not even when the contact is transferred to another flow.
- They can be up to 32 KB (the maximum size of the contact record attributes section).
- They aren't passed to a Lambda unless they are explicitly configured as parameters: in the **Invoke AWS Lambda function** block, choose **Add a parameter**.
- They aren't passed to modules. You can set a flow attribute within a module, but it won't be passed out of the module.
- They don't appear in the contact record.
- They don't appear to the agent in the CCP.
- The `GetContactAttributes` API can't expose them.
- If you have logging enabled on the flow, the key and value appear in the Cloudwatch log.

Attribute	Description	Type	JSONPath Reference
Any name you choose	A flow attribute has two parts: • Destination key: this is any name you choose for the key. However, the **$** and **.** (period) characters are not allowed because they are both used in defining the	Flow	$.FlowAttributes.*name_of_your_destination_key*

Attribute	Description	Type	JSONPath Reference
	attribute paths in JSONPath. • Value: this is can be any value you choose.		

Apple Messages for Business attributes

Use the following contact attributes to route Apple Messages for Business customers. For example, if you have different lines of business using Apple Messages for Business, you can branch to different flows based on the AppleBusinessChatGroup contact attribute. Or, if you want to route Apple Messages for Business messages differently from other chat messages, you can branch based on MessagingPlatform.

Attribute	Description	Type	JSON
MessagingPlatform	The messaging platform from where the customer request originated. Exact value: **AppleBusinessChat**	User-defined	$.Attributes.MessagingPlatform
AppleBusinessChatCustomerId	The customer's opaque ID provided by Apple. This remains constant for the AppleID and a business. You can use this to identify if the message is from a new customer or a returning customer.	User-defined	$.Attributes.AppleBusinessChatCustomerId

Attribute	Description	Type	JSON
AppleBusinessChatIntent	You can define the intent or purpose of the chat. This parameter is included in a URL that initiates a chat session in Messages when a customer chooses the **Business Chat** button.	User-defined	$.Attributes.AppleBusinessChatIntent
AppleBusinessChatGroup	You define the group which designates the department or individuals best qualified to handle the customer's particular question or problem. This parameter is included in a URL that initiates a chat session in Messages when a customer chooses the **Business Chat** button.	User-defined	$.Attributes.AppleBusinessChatGroup

Attribute	Description	Type	JSON
AppleBusinessChatLocale	Defines the language and AWS Region preferences that the user wants to see in their user interface. It consists of a language identifier (ISO 639-1) and a Region identifier (ISO 3166). For example, **en_US**.	User-defined	$.Attributes.AppleBusinessChatLocale
AppleFormCapability	Whether the customer device supports forms. If true, the customer device is supported. If false, the device is not supported.	User-defined	$.Attributes.AppleFormCapability
AppleAuthenticationCapability	Whether the customer device supports Authentication (OAuth2). If true, the customer device is supported. If false, their device is not supported.	User-defined	$.Attributes.AppleAuthenticationCapability

Attribute	Description	Type	JSON
AppleTimePickerCapability	Whether the customer device supports time pickers. If true, the customer device is supported. If false, the device is not supported.	User-defined	$.Attributes.AppleTimePickerCapability
AppleListPickerCapability	Whether the customer device supports list pickers. If true, the customer device is supported. If false, the device is not supported.	User-defined	$.Attributes.AppleListPickerCapability
AppleQuickReplyCapability	Whether the customer device supports quick replies. If true, the customer device is supported. If false, the device is not supported.	User-defined	$.Attributes.AppleQuickReplyCapability

Customer Profiles attributes

The following table lists the attributes that are used with Amazon Connect Customer Profiles.

The total size of Customer Profiles contact attributes is limited to 14,000 (56 attributes assuming max size of 255 each) characters for the entire flow. This includes all values persisted as **Response** fields in Customer Profiles blocks during the flow.

Attribute	Description	Type	JSONPath Reference
profileSearchKey	The name of the attribute you want to use to search for a profile.	User-defined	Not applicable
profileSearchValue	The value of the key you want to search for, such as customer name or account number.	User-defined	Not applicable
Profile ID	The unique identifier of a customer profile.	text	$.Customer.ProfileId
Profile ARN	The ARN of a customer profile.	text	$.Customer.Profile ARN
First Name	The customer's first name.	text	$.Customer.FirstNa me
Middle Name	The customer's middle name.	text	$.Customer.MiddleN ame
Last Name	The customer's last name.	text	$.Customer.LastName
Account Number	A unique account number that you have given to the customer.	text	$.Customer.Account Number
Email Address	The customer's email address, which has	text	$.Customer.EmailAd dress

Attribute	Description	Type	JSONPath Reference
	not been specified as a personal or business address.		
Phone Number	The customer's phone number, which has not been specified as a mobile, home, or business number.	text	$.Customer.PhoneNumber
Additional Information	Any additional information relevant to the customer's profile.	text	$.Customer.AdditionalInformation
Party Type	The customer's party type.	text	$.Customer.PartyType
Business Name	The name of the customer's business.	text	$.Customer.BusinessName
Birth Date	The customer's birth date.	text	$.Customer.BirthDate
Gender	The customer's gender.	text	$.Customer.Gender
Mobile Phone Number	The customer's mobile phone number.	text	$.Customer.MobilePhoneNumber
Home Phone Number	The customer's home phone number.	text	$.Customer.HomePhoneNumber

Attribute	Description	Type	JSONPath Reference
Business Phone Number	The customer's business phone number.	text	$.Customer.BusinessPhoneNumber
Business Email Address	The customer's business email address.	text	$.Customer.BusinessEmailAddress
Address	A generic address associated with the customer that is not mailing, shipping, or billing.	text	$.Customer.Address1 $.Customer.Address2 $.Customer.Address3 $.Customer.Address4 $.Customer.City $.Customer.County $.Customer.Country $.Customer.PostalCode $.Customer.Province $.Customer.State

Attribute	Description	Type	JSONPath Reference
Shipping Address	The customer's shipping address.	text	$.Customer.ShippingAddress1 $.Customer.ShippingAddress2 $.Customer.ShippingAddress3 $.Customer.ShippingAddress4 $.Customer.ShippingCity $.Customer.ShippingCounty $.Customer.ShippingCountry $.Customer.ShippingPostalCode $.Customer.ShippingProvince $.Customer.ShippingState

Attribute	Description	Type	JSONPath Reference
Mailing Address	The customer's mailing address.	text	$.Customer.MailingAddress1 $.Customer.MailingAddress2 $.Customer.MailingAddress3 $.Customer.MailingAddress4 $.Customer.MailingCity $.Customer.MailingCounty $.Customer.MailingCountry $.Customer.MailingPostalCode $.Customer.MailingProvince $.Customer.MailingState

Attribute	Description	Type	JSONPath Reference
Billing Address	The customer's billing address	text	$.Customer.BillingAddress1 $.Customer.BillingAddress2 $.Customer.BillingAddress3 $.Customer.BillingAddress4 $.Customer.BillingCity $.Customer.BillingCounty $.Customer.BillingCountry $.Customer.BillingPostalCode $.Customer.BillingProvince $.Customer.BillingState
Attributes	A key value pair of attributes of a customer profile.	text	$.Customer.Attributes.x
Object Attributes	A key value pair of custom object attributes of a customer profile.	text	$.Customer.ObjectAttributes.y

Attribute	Description	Type	JSONPath Reference
Calculated Attributes	A key value pair of calculated attributes of a customer profile.	text	$.Customer.CalculatedAttributes.z

Attribute	Description	Type	JSONPath Reference
Asset	A customer's standard Asset.	text	$.Customer.Asset.AssetId $.Customer.Asset.ProfileId $.Customer.Asset.AssetName $.Customer.Asset.SerialNumber $.Customer.Asset.ModelNumber $.Customer.Asset.ModelName $.Customer.Asset.ProductSKU $.Customer.Asset.PurchaseDate $.Customer.Asset.UsageEndDate $.Customer.Asset.Status $.Customer.Asset.Price $.Customer.Asset.Quantity $.Customer.Asset.Description

Attribute	Description	Type	JSONPath Reference
			$.Customer.Asset.AdditionalInformation $.Customer.Asset.DataSource $.Customer.Asset.Attributes.x

Attribute	Description	Type	JSONPath Reference
Order	A customer's standard Order.	text	$.Customer.Order.OrderId $.Customer.Order.ProfileId $.Customer.Order.CustomerEmail $.Customer.Order.CustomerPhone $.Customer.Order.CreatedDate $.Customer.Order.UpdatedDate $.Customer.Order.ProcessedDate $.Customer.Order.ClosedDate $.Customer.Order.CancelledDate $.Customer.Order.CancelReason $.Customer.Order.Name $.Customer.Order.AdditionalInformation $.Customer.Order.Gateway

Attribute	Description	Type	JSONPath Reference
			$.Customer.Order.Status $.Customer.Order.StatusCode $.Customer.Order.StatusUrl $.Customer.Order.CreditCardNumber $.Customer.Order.CreditCardCompany $.Customer.Order.FulfillmentStatus $.Customer.Order.TotalPrice $.Customer.Order.TotalTax $.Customer.Order.TotalDiscounts $.Customer.Order.TotalItemsPrice $.Customer.Order.TotalShippingPrice $.Customer.Order.TotalTipReceived $.Customer.Order.Currency

Attribute	Description	Type	JSONPath Reference
			$.Customer.Order.TotalWeight $.Customer.Order.BillingName $.Customer.Order.BillingAddress1 $.Customer.Order.BillingAddress2 $.Customer.Order.BillingAddress3 $.Customer.Order.BillingAddress4 $.Customer.Order.BillingCity $.Customer.Order.BillingCounty $.Customer.Order.BillingCountry $.Customer.Order.BillingPostalCode $.Customer.Order.BillingProvince $.Customer.Order.BillingState $.Customer.Order.ShippingName

Attribute	Description	Type	JSONPath Reference
			$.Customer.Order.ShippingAddress1 $.Customer.Order.ShippingAddress2 $.Customer.Order.ShippingAddress3 $.Customer.Order.ShippingAddress4 $.Customer.Order.ShippingCity $.Customer.Order.ShippingCounty $.Customer.Order.ShippingCountry $.Customer.Order.ShippingPostalCode $.Customer.Order.ShippingProvince $.Customer.Order.ShippingState $.Customer.Order.Attributes.y

Attribute	Description	Type	JSONPath Reference
Case	A customer's standard Case.	text	$.Customer.Case.CaseId $.Customer.Case.ProfileId $.Customer.Case.Title $.Customer.Case.Summary $.Customer.Case.Status $.Customer.Case.Reason $.Customer.Case.CreatedBy $.Customer.Case.CreatedDate $.Customer.Case.UpdatedDate $.Customer.Case.ClosedDate $.Customer.Case.AdditionalInformation $.Customer.Case.DataSource $.Customer.Case.Attributes.z

Outbound campaign attributes

You can use data in Amazon Pinpoint segments list to customize experiences in Amazon Connect flows. To reference data in a segment list, use **$.Attributes.*`attribute coming in the segment`***. For example, if you have a segment with two columns "Attributes.FirstName" and "Attributes.ItemDescription, you would refer to them as:

- $.Attributes.FirstName
- $.Attributes.ItemDescription

For more information, see Adding personalized content to message templates in the *Amazon Pinpoint User Guide*.

How to reference contact attributes in Amazon Connect

The way you reference contact attributes depends on how they were created and how you are accessing them.

- For the JSON syntax for each attribute, see List of available contact attributes in Amazon Connect and their JSONPath references.
- To reference attributes that contain special characters in their name, such as spaces, place brackets and single quotations around the attribute name. For example: `$.Attributes.['user attribute name']`.
- To reference attributes in the same namespace, such as a system attribute, you use the attribute name, or the name you specified as the **Destination key**.
- To reference values in a different namespace, such as referencing an external attribute, you specify the JSONPath syntax to the attribute.
- To use contact attributes to access other resources, set a user-defined attribute in your flow and use the Amazon Resource Name (ARN) of the resource you want to access as the value for the attribute.

Lambda examples

- To reference a customer name from a Lambda function lookup, use $.External.AttributeKey, replacing AttributeKey with the key (or name) of the attribute returned from the Lambda function.

- To use an Amazon Connect prompt in a Lambda function, set a user-defined attribute to the ARN for the prompt, and then access that attribute from the Lambda function.

Amazon Lex examples

- To reference an attribute from an Amazon Lex bot, you use the format $.Lex. and then include the part of the Amazon Lex bot to reference, such as $.Lex.IntentName.
- To reference the customer input to an Amazon Lex bot slot, use $.Lex.Slots.*slotName*, replacing *slotName* with the name of the slot in the bot.

Set contact attribute example

Use a Set contact attributes block to set a value that is later referenced in a flow. For example, create a personalized greeting for customers routed to a queue based on the type of customer account. You could also define an attribute for a company name or line of business to include in the text to speech strings said to a customer. The **Set contact attributes** block is useful for copying attributes retrieved from external sources to user-defined attributes.

To set a contact attribute with a Set contact attributes block

1. In Amazon Connect, choose **Routing**, **Contact flows**.
2. Select an existing flow, or create a new one.
3. Add a **Set contact attributes** block.
4. Edit the **Set contact attributes** block, and choose **Use text**.
5. For the **Destination key**, provide a name for the attribute, such as *Company*. This is the value you use for the **Attribute** field when using or referencing attributes in other blocks. For the **Value**, use your company name.

   You can also choose to use an existing attribute as the basis for creating the new attribute.

Display contact information to the agent in the Contact Control Panel (CCP)

You can use contact attributes to capture information about the contact and then present it to the agent through the Contact Control Panel (CCP). For example, you might want to do this to customize the agent experience when using the CCP integrated with a customer relationship management (CRM) application.

Also use them when integrating Amazon Connect with a custom application using the Amazon Connect Streams API or Amazon Connect API. You can use all user-defined attributes, in addition to the customer number and the dialed number, in the CCP using the Amazon Connect Streams JavaScript library. For more information, see Amazon Connect Streams API or Amazon Connect API.

When you use the Amazon Connect Streams API, you can access user-defined attributes by invoking contact.getAttributes(). You can access endpoints using contact.getConnections(), where a connection has a getEndpoint() invocation on it.

To access the attribute directly from a Lambda function, use $.External.AttributeName. If the attribute is stored to a user-defined attribute from a **Set contact attributes** block, use $.Attributes.AttributeName.

For example, included with your Amazon Connect instance, there is a flow named "Sample note for screenpop." In this flow, a **Set contact attributes** block is used to create an attribute from a text string. The text, as an attribute, can be passed to the CCP to display a note to an agent.

Use attributes in Amazon Connect to route based on number of contacts in a queue

Amazon Connect includes queue attributes that can help you define routing conditions in your flows based on real-time metrics about the queues and agents in your contact center. For example, here are some common usage scenarios:

- Check the number of contacts or available agents in a queue, and how long the oldest contact has been in a queue, then route accordingly.
- To route to the queue with the fewest contacts in it:
  1. Get metrics for multiple queues.
  2. Use a **Set contact attributes** block to store the metric attributes for each queue.
  3. compare queue metric attributes using a **Check contact attributes** block, and route the contact to the queue with the fewest calls in it, or to a callback if all queues are busy.

Using a Check contact attributes block to route a contact to a queue

1. In Amazon Connect, choose **Routing**, **Contact flows**.

2. Open an existing flow or create a new one.
3. Optionally, under **Interact**, add a **Play prompt** block to the designer to play a greeting to your customers. Add a connector between the **Entry point** block and the **Play prompt** block.
4. Under **Set**, drag a **Get queue metrics** block to the designer, and connect the **Okay** branch of the **Play prompt** block to it.
5. Choose the title of the **Get queue metrics** block to open the properties for the block. By default, the block retrieves metrics for the current working queue. To retrieve metrics for a different queue, choose **Set queue**.
6. Choose **Select a queue**, then select the queue to retrieve metrics for from the drop-down, then choose **Save**.

   You can also determine which queue to retrieve metrics for using contact attributes.
7. Under **Check**, drag a **Check contact attributes** block to the designer.
8. Choose the title of the block to display the settings for the block. Then, under **Attribute to check**, select **Queue metrics** in the **Type** drop-down menu.
9. Under **Attribute**, choose **Contacts in queue**.
10. To use conditions to route the contact, choose **Add another condition**.

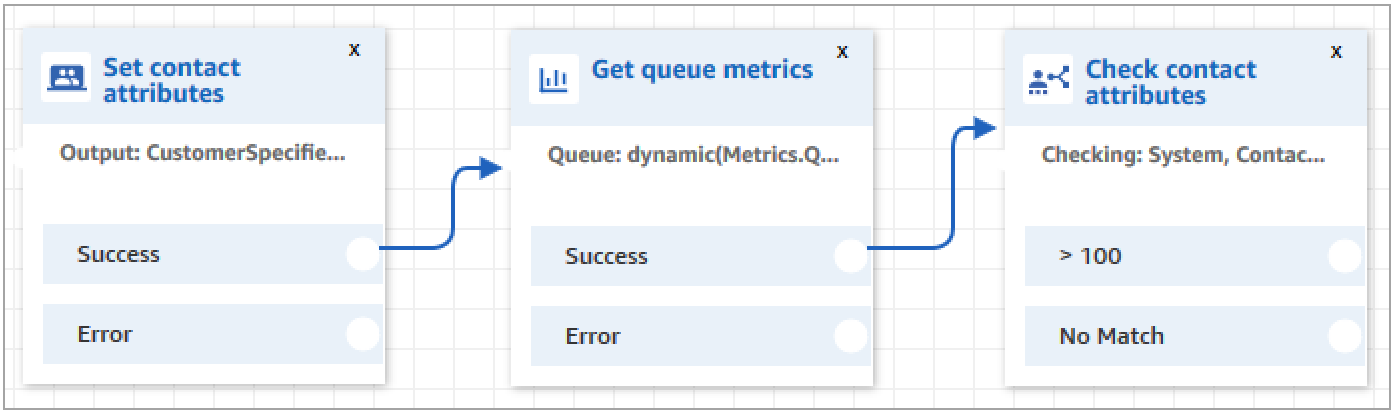
    By default, the **Check contact attributes** block includes a single condition, **No match**. The **No match** branch is followed when there are no matches for any of the conditions you define in the block.
11. Under **Conditions to check**, select **Is less than** as the operator for the condition in the drop-down menu, then in the value field enter 5.
12. Choose **Add another condition**, then choose **Is greater or equal** from the drop-down menu, and enter 5 in the value field.
13. Choose **Save**.

    You now see two new output branches for the **Check contact attributes** block.

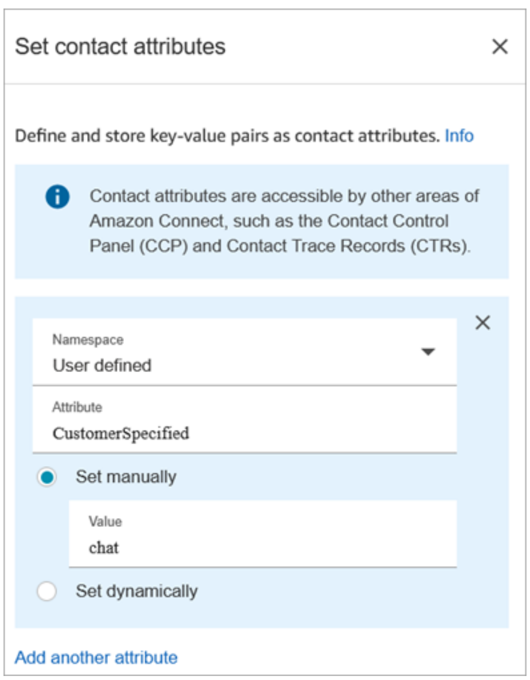
You can now add additional blocks to the flow to route the contact as desired. For example, connect the < 5 branch to a **Transfer to queue** block to transfer calls to the queue when there are fewer than five calls currently in the queue. Connect the > 5 branch to a Set customer callback number block and then transfer the call to a callback queue using a **Transfer to queue** block so the customer doesn't have to stay on hold.

Route contacts based on queue metrics

Many contact centers route customers based on the number of contacts waiting in a queue. This topic explains how to configure a flow that looks similar to the following image. It shows the following three flow blocks connected by Success branches: **Set contact attributes**, **Get queue metrics**, and **Check contact attributes**.



1. Add a Set contact attributes block to your flow.
2. In the Set contact attributes, specify the channel. If you set a channel dynamically using text, for the attribute value enter **Voice** or **Chat**, as shown in the following image. This value is not case-sensitive.



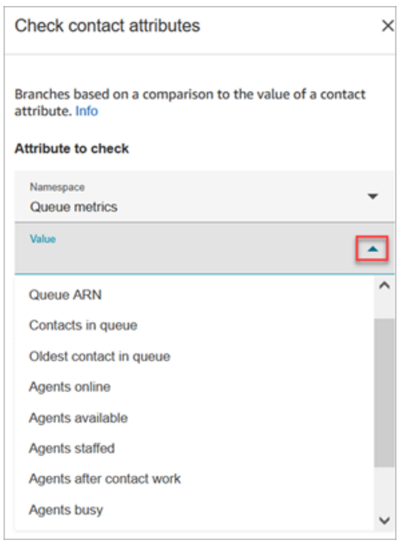
3. Add a Get queue metrics block to your flow.

In the Get queue metrics block, dynamic attributes can only return metrics for one channel

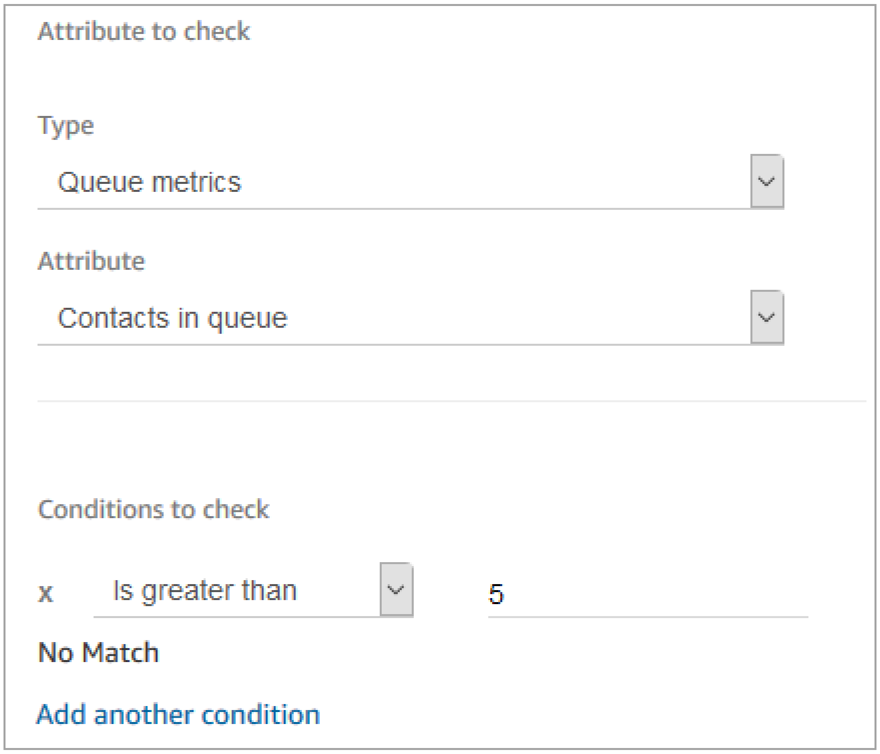
Add a Check contact attributes block after the Get queue metrics block

After a **Get queue metrics** block, add a Check contact attributes block to branch based on the returned metrics. Use the following steps:

1. After **Get queue metrics**, add a **Check contact attributes** block.
2. In the **Check contact attributes** block, set **Attribute to check** to **Queue metrics**.
3. In the **Attributes to check** dropdown box, you'll see that the following queue metrics are returned by the **Get queue metrics** block. Choose the metric that you want to use for the routing decision.



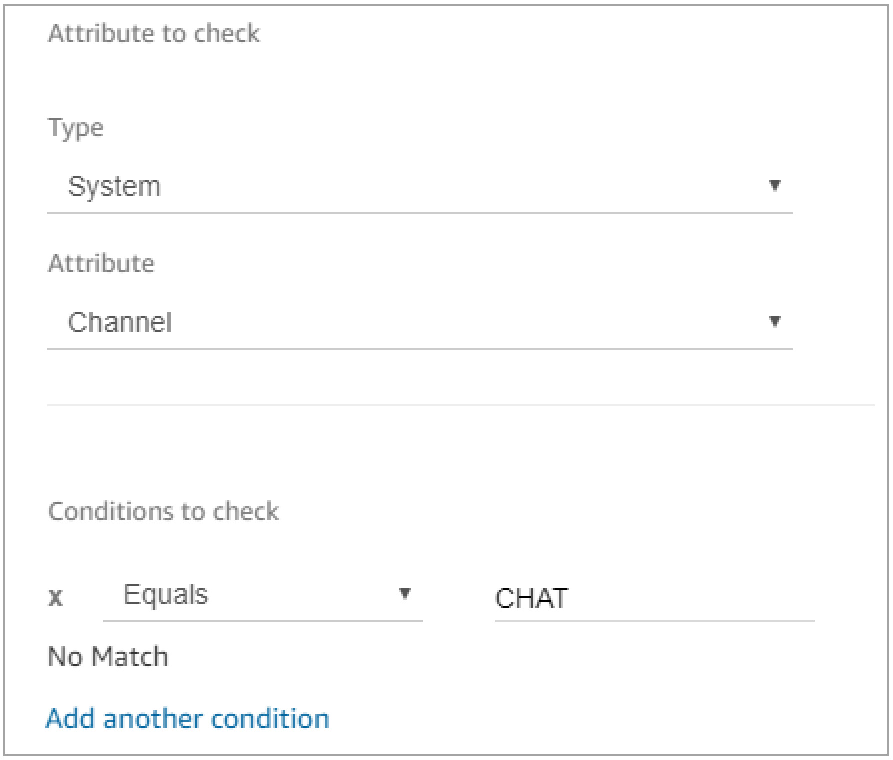
4. Choose **Add a condition** to enter the comparison for your routing decision. The following image shows the block configured to check whether contacts in queue is greater than 5.



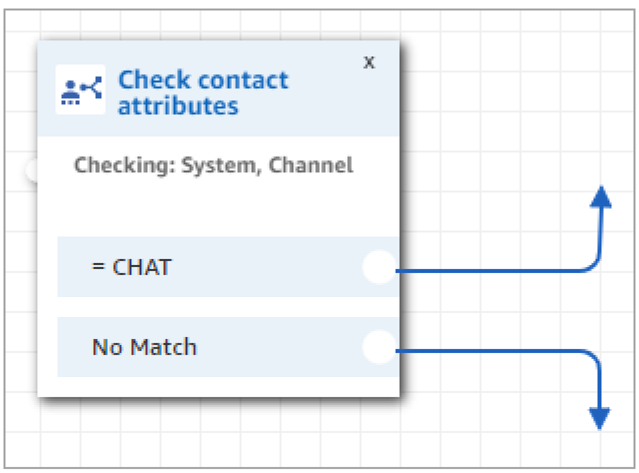
Personalize a contact's experience based on how they contact your contact center

You can personalize the customer's experience based on the channel that they use to contact you. Here's what you do:

1. Add a **Check contact attributes** block to the beginning of your flow.
2. Configure the block as shown in the following image. In the **Attribute to check** section, set **Type** to **System**, set **Attribute** to **Channel**. In the **Conditions to check** section, set it to **Equals CHAT**.



3. The following image of the configured Check contact attributes block shows two branches: **CHAT** and **No Match**. If the customer is contacting you through chat, specify what should happen next. If the customer is contacting you through a call (No Match), specify the next step in the flow.



Use Amazon Lex and attribute values

When you reference attributes in a **Get customer input** block, and choose Amazon Lex as the method of collecting the input, the attribute values are retrieved and stored from the output from the customer interaction with the Amazon Lex bot. You can use an attribute for each intent or slot used in the Amazon Lex bot, as well as the sessions attributes associated with the bot. An output branch is added to the block for each intent you include. When a customer chooses an intent when interacting with the bot, the branch associated with that intent is followed in the flow.

For a list of Amazon Lex attributes you can use and receive back from the Lex bot, see Amazon Lex contact attributes.

Using an Amazon Lex bot to get customer input

1. Open an existing or create a new flow.
2. Under **Interact**, drag a **Get customer input** block to the designer.
3. Choose the title of the block to display the block settings, then select **Text to speech (Ad hoc)**.
4. Choose **Enter text**, then enter text in the **Enter text to be spoken** field that is used as a message or greeting to your customers. For example, "Thank you for calling" followed by a request to enter information to fulfill the intents you defined in your Amazon Lex bot.
5. Choose the **Amazon Lex** tab, then from the drop-down menu, choose the Amazon Lex bot to use to get customer input.
6. By default, the **Alias** field is populated with $LATEST. To use a different alias of the bot, enter the alias value to use.

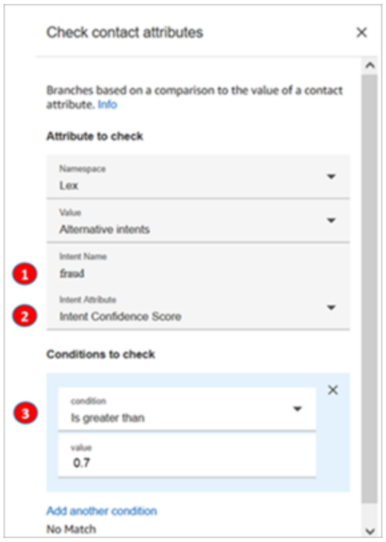
   > **Important**
   >
   > In a production environment, always use a different alias than **TestBotAlias** for Amazon Lex and **$LATEST** for Amazon Lex classic. **TestBotAlias** and **$LATEST** support a limited number of concurrent calls to an Amazon Lex bot. For more information, see Runtime quotas or Runtime Service Quotas (Amazon Lex Classic).

7. Optionally, to pass an attribute to Amazon Lex to use as a session attribute, choose **Add an attribute**. Specify the value to pass using either text or an attribute.
8. To create a branch from the block based on the customer intent, choose **Add an intent**, then enter the name of the intent exactly the same as the intent name in your bot.
9. Choose **Save**.

Use alternate intent attributes in Amazon Lex

Usually you configure flows to branch on the winning Lex intent. However, in some situations, you might want to branch on an alternate intent. That is, what the customer might have meant.

The following image shows the **Properties** page of the **Check contact attributes** block. It is configured to check a Lex attribute.



1. **Intent name** is the name of an alternate intent in Lex. It's case sensitive and must match what's in Lex exactly.
2. **Intent Attribute** is what Amazon Connect is going to check. In this example, it's going to check the **Intent Confidence Score**.
3. **Conditions to check**: If Lex is 70% certain the customer meant the alternate intent instead of the winning intent, branch.

How flow blocks use Amazon Lex session attributes

When a customer starts a conversation with your bot, Amazon Lex creates a *session*. With *session attributes*, also known as *Lex attributes*, you can pass information between the bot and Amazon Connect during the session. For a list of Amazon Lex attributes that you can use, see Amazon Lex contact attributes.

Life cycle of session attributes

Each conversation contains one set of session attributes. In cases where an AWS Lambda function is invoked to do some processing, Amazon Lex runs the attributes in the following order:

- Service defaults: These attributes are only used if no attributes are defined.
- Session attributes provided by Amazon Connect: These attributes are defined in the Get customer input block.

- Session attributes provided by Lambda override everything prior: When an AWS Lambda function is invoked and it does some processing, it overrides any session attributes set in the Get customer input block.

Let's say a customer utters that they want **a car**. That's the first session attribute to go through processing. When asked what kind of car, they say **luxury car**. This second utterance overrides any Lambda processing that took place on the first utterance.

For an example of how to create a Lambda function that processes session attributes, see Step 1: Create a Lambda Function in the *Amazon Lex Developer Guide*. For information about Amazon Lex V2, see Setting session attributes.

For the structure of the event data that Amazon Lex provides to a Lambda function, see Lambda Function Input Event and Response Format in the *Amazon Lex Developer Guide*. For information about Amazon Lex V2, see Interpreting the input event format.

Flow blocks that support Lex session attributes

You can use Lex session attributes in the following flow blocks when a Lex bot is called:

- Change routing priority/age
- Check contact attributes
- Get customer input
- Invoke AWS Lambda function
- Loop
- Set callback number
- Set contact attributes
- Set customer queue flow
- Set disconnect flow
- Set hold flow
- Set logging behavior
- Set whisper flow
- Set working queue
- Transfer to flow
- Transfer to phone number

- Wait

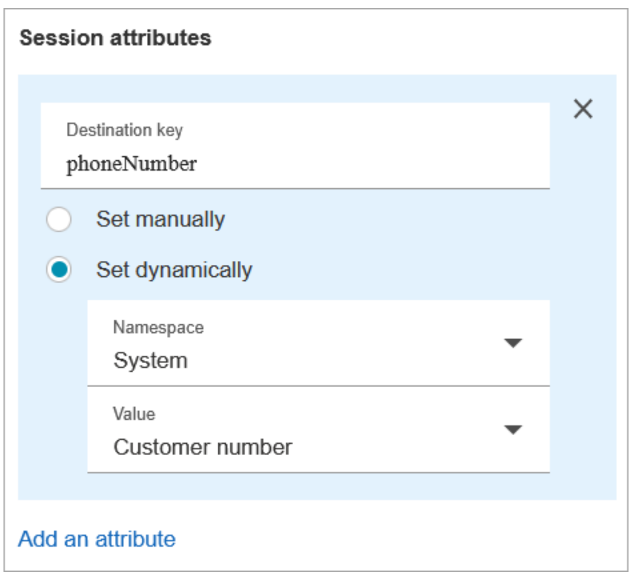
More information

For more information about using Amazon Lex session attributes, see Managing Conversation Context in the *Amazon Amazon Lex V1 Developer Guide*.

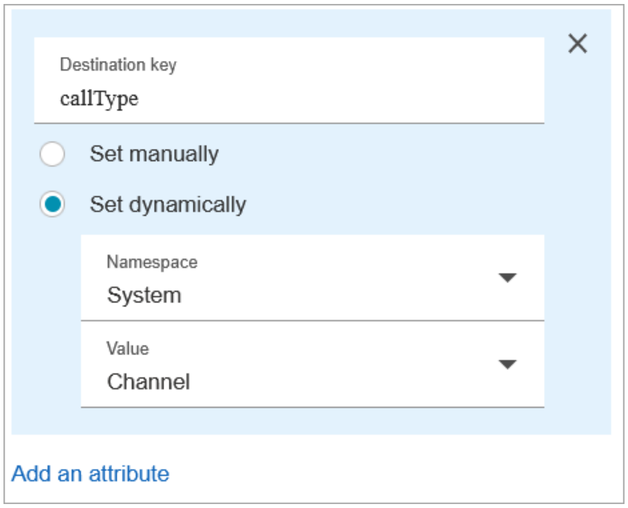
How to use the same Amazon Lex bot for voice and chat

You can use the same bot for voice and chat. However, you may want the bot to respond differently based on the channel. For example, you want to return SSML for voice so a number is read as a phone number, but you want to return normal text to chat. You can do this by passing the **Channel** attribute.

1. In the **Get customer input** block, choose the **Amazon Lex** tab.
2. Under **Session attributes**, choose **Add an attribute**. In the **Destination key** box, enter **phoneNumber**. Choose **Set dynamically**. In the **Namespace** box, choose **System**, and in the **Value** box, choose **Customer Number**, as shown in the following image.



3. Choose **Add an attribute** again.
4. Choose **Set dynamically**. In the **Destination key** box, enter **callType**. In the **Namespace** box, choose **System**, and in the **Value** box choose **Channel**, as shown in the following image.



5. Choose **Save**.
6. In your Lambda function, you can access this value in the `SessionAttributes` field in the incoming event.

Store a value from a Lambda functions as a contact attribute in Amazon Connect

Retrieve data from a system that your organization uses internally, such as an ordering system or other database with a Lambda function, and store the values as attributes that can then be referenced in a flow.

The Lambda function returns a response from your internal system in the form of key-value pairs of data. You can reference the values returned in the External namespace. For example, `$.External.attributeName`. To use the attributes later in a flow, you can copy the key-value pairs to user-defined attributes by using a **Set contact attributes** block. You can then define logic to branch your contact based on attribute values by using a **Check contact attributes** block. Any contact attribute retrieved from a Lambda function is overwritten when you invoke any other Lambda function. Make sure you store external attributes if you want to reference them later in a flow.

> **Tip**
>
> For information about invoking a Lambda function from a flow, see Grant Amazon Connect access to your AWS Lambda functions The topic also shows how to consume a Lambda function response.

To store an external value from a Lambda function as a contact attribute

1. In Amazon Connect, choose **Routing**, **Contact flows**.
2. Select an existing flow, or create a new one.
3. Add an **Invoke AWS Lambda function** block, then choose the title of the block to open the settings for the block.
4. Add the **Function ARN** to your AWS Lambda function that retrieves customer data from your internal system.
5. After the **Invoke AWS Lambda function** block, add a **Set contact attributes** block and connect the **Success** branch of the **Invoke AWS Lambda function** block to it.
6. Edit the **Set contact attributes** block, and select **Use attribute**.
7. For **Destination key**, type a name to use as a reference to the attribute, such as customerName. This is the value you use in the **Attribute** field in other blocks to reference this attribute.
8. For **Type**, choose **External**.
9. For **Attribute**, enter the name of the attribute returned from the Lambda function. The name of the attribute returned from the function will vary depending on your internal system and the function you use.

After this block executes during a flow, the value is saved as a user-defined attribute with the name specified by the **Destination key**, in this case *customerName*. It can be accessed in any block that uses dynamic attributes.

To branch your flow based on the value of an external attribute, such as an account number, use a **Check contact attributes** block, and then add a condition to compare the value of the attribute to. Next, branch the flow based on the condition.

1. In the **Check contact attributes** block, for **Attribute to check** do one of the following:
   - Select **External** for the **Type**, then enter the key name returned from the Lambda function in the **Attribute** field.

> **Important**
>
> Any attribute returned from an AWS Lambda function is overwritten when you invoke any other Lambda function. To reference the attributes later in a flow, store them as user-defined attributes.

- Select **User Defined** for the **Type**, and in the **Attribute** field, type the name that you specified as the **Destination key** in the **Set contact attributes** block.

2. Choose **Add another condition**.
3. Under **Conditions to check**, choose the operator for the condition, then enter a value to compare to the attribute value. The block creates a branch for each comparison you enter, letting you route the contact based on the conditions specified. If no condition is matched, the contact takes the **No Match** branch from the block.

Migrate flows to an instance, Region, or environment in Amazon Connect

Amazon Connect lets you efficiently migrate flows to another instance. For example, you might want to expand into new Regions, or move flows from your development environment to your production environment.

To migrate a few flows, use the import/export feature in the flow designer.

To migrate hundreds of flows, you need developer skills. You use the following procedure:

1. Source instance
   - ListContactFlow: Retrieve the Amazon Resource Number (ARN) for the flows that you want to migrate.
   - DescribeContactFlow: Get information about each flow that you want to migrate.
2. Destination instance
   - CreateContactFlow: Create the flows.
   - UpdateContactFlowContent: Update the flow content.

You must also build an ARN-to-ARN mapping for queues, flows, and prompts between the source and target Amazon Connect instances, and replace every ARN in the source flow with the corresponding ARN from the target instance. Otherwise UpdateContactFlowContent fails with `InvalidContactFlow` error.

You can update the information in the flows that you migrate. For more information, see [Flow language]() in the *Amazon Connect API Reference Guide*.

Real-time and historical metrics, dashboards, and reports in Amazon Connect

In Amazon Connect, data about contacts are captured in contact records. This data can include the amount of time a contact spends in each state: customer on hold, customer in queue, agent interaction time.

The basis for most historical and real-time metrics in Amazon Connect is the data in the contact record. When you create metrics reports, the values displayed for **most** (not all) metrics in the report are calculated using the data in the contact records.

Contact records are available within your instance for 24 months from the time when the associated contact was initiated. You can also stream contact records to Amazon Kinesis to retain the data longer, and perform advanced analysis on it.

> **Tip**
>
> For detailed information about the activity of agents in your contact center, use Amazon Connect agent event streams.

Contents

Dashboards in Amazon Connect for getting contact center performance data

Understanding your contact center at the most granular level is key to improving performance and lowering costs. You can use the Amazon Connect visual dashboards to understand the performance of your contact center.

Amazon Connect dashboards show real-time and historical metrics information and insights about your contact center performance.

- Real-time dashboards are updated every 15 seconds
- You can select historical data up to 3 months in the past.

You can customize the dashboards (for example, re-size and re-arrange the visuals), specify a custom time range and custom benchmark comparison time range for each dashboard, and select filters for data to include for each report. You can also download the entire data set or individual widgets as CSV, download the dashboard as a PDF, save your own version to your saved dashboards, share with individuals, and publish to the entire instance.

Contents

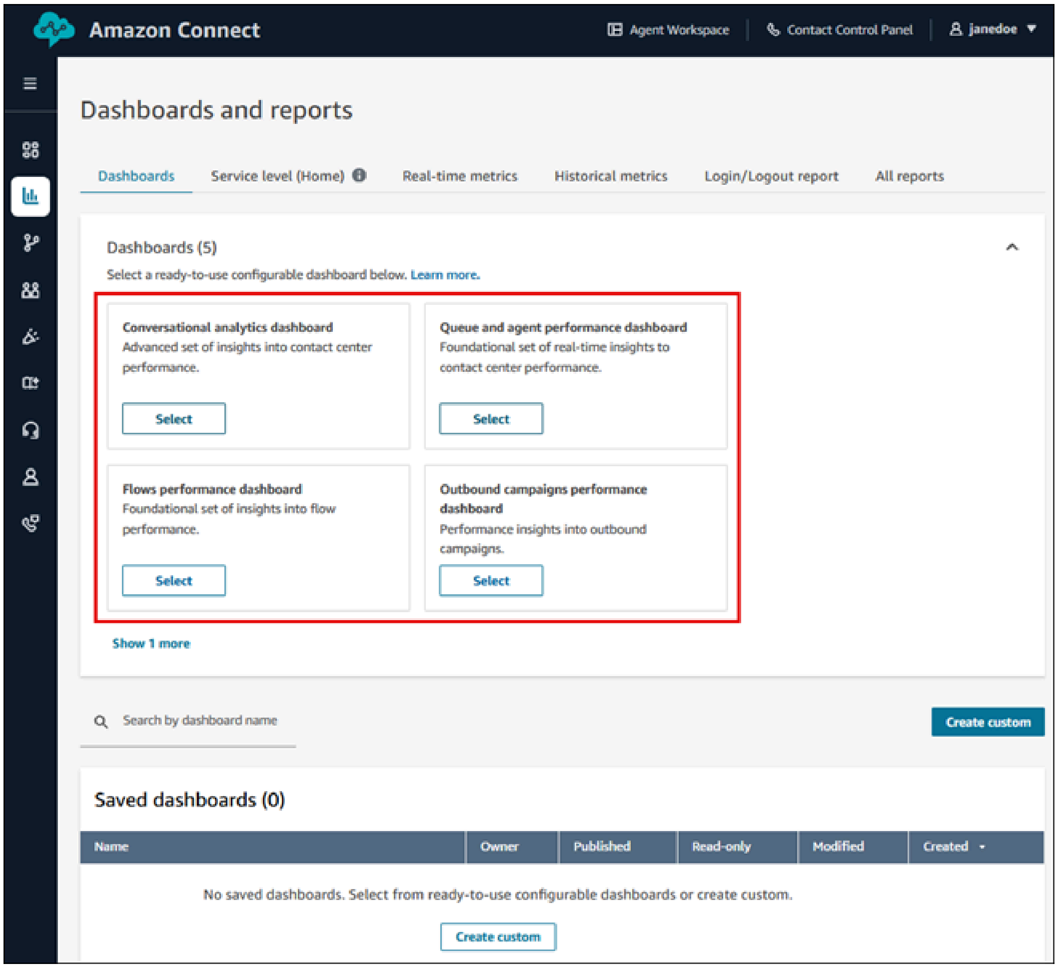
- Customize your Amazon Connect dashboard
- Amazon Connect Contact Lens conversational analytics dashboard
- Flows and conversational bot performance dashboard
- Outbound campaigns performance dashboard
- Queue and agent performance dashboard in Amazon Connect
- Intraday forecast performance dashboard
- Assign security profile permissions for dashboards in Amazon Connect

Get started

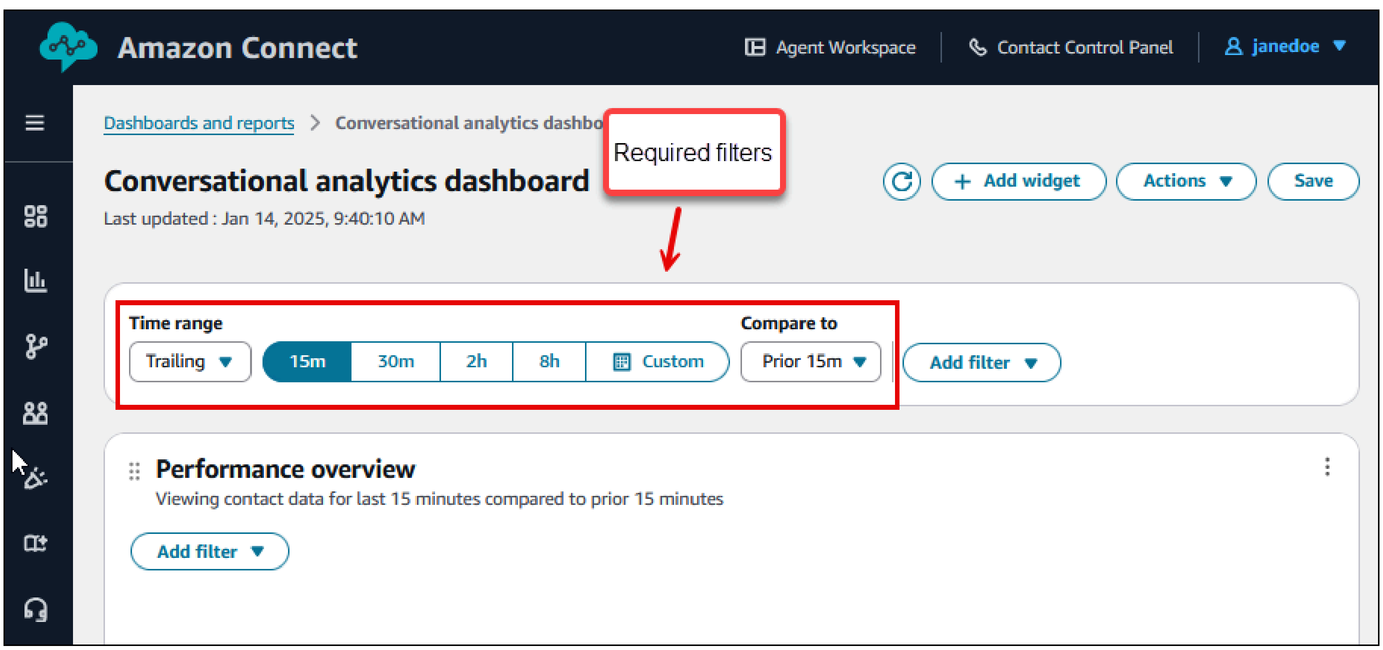
1. Ensure users are assigned the appropriate security profile permissions do they can access the dashboards they need and view the metrics:

   - **Access metrics - Access permission** or the **Dashboard - Access permission**. For information about the difference in behavior, see Assign security profile permissions for dashboards in Amazon Connect.
   - Viewing the data on each dashboard requires the appropriate permissions. For example, to view flows data, you need **Flows - View** permissions. See the topics about each dashboard for the specific permissions.

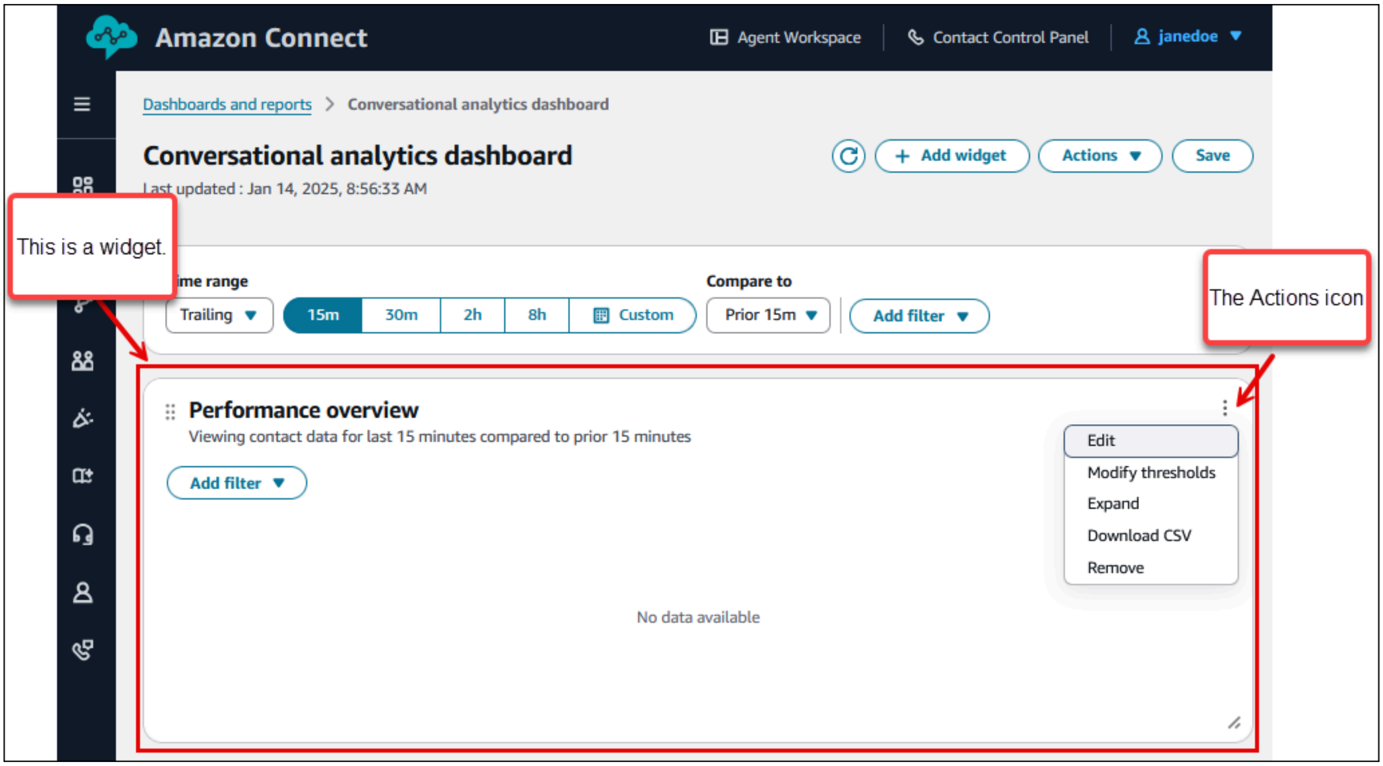
2. In the Amazon Connect admin website, navigate to **Analytics and Optimization**, **Dashboards and reports**. Select the Amazon Connect dashboard you want to view. The following image shows an example **Dashboards and reports** page with four dashboards you can select.



3. When you open a dashboard, use the required filters to specify the time range. For more information, see [Specify time range and "Compare to" benchmark](#).



4. In a widget, you can choose **Actions**, **Edit** to customize the widget to meet your business needs. For more information, see Customize your dashboard.

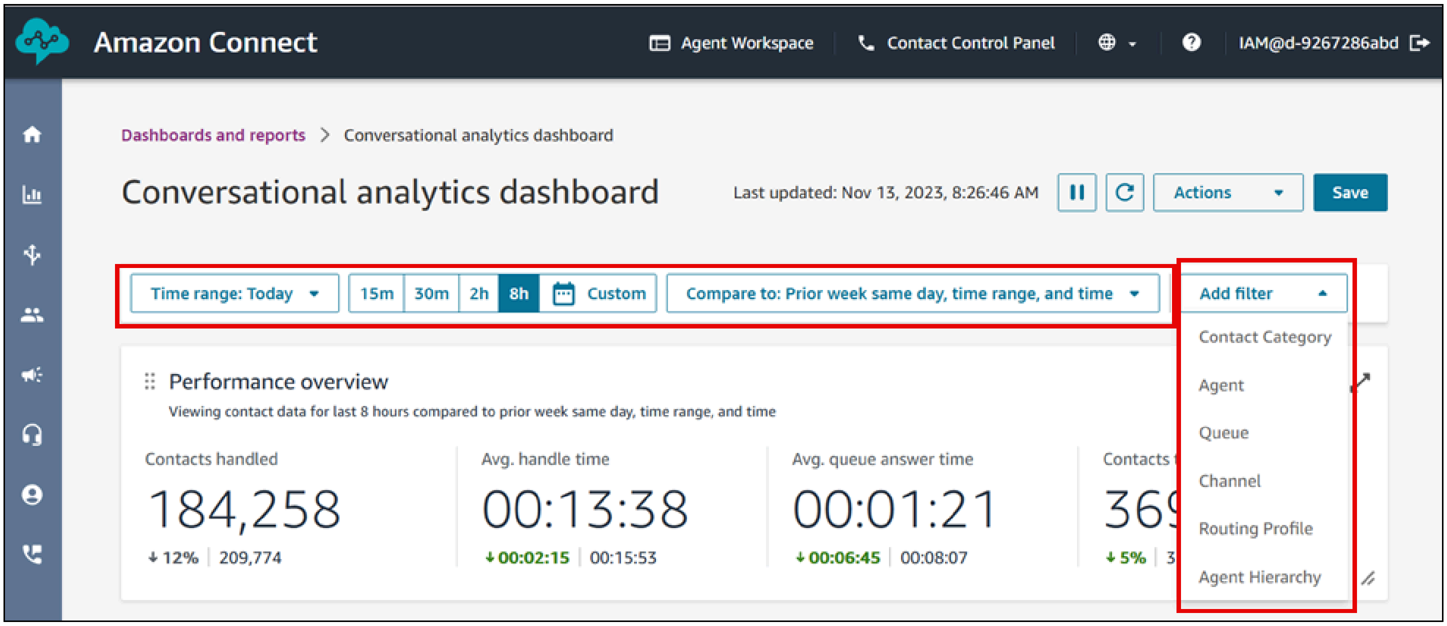


Specify time range and "Compare to" benchmark

All dashboards have the following required filters:

1. **Time range**: You can select a real-time time range within the **Time range: Today** option and choose a trailing window of time. For additional windows, select **Custom**. You can select historical time ranges by altering your Time range to **Day**, **Week**, or **Month**.
2. **Compare to** benchmark time range: You can customize a comparison time period to benchmark your Time range selection against, such as an exact week over week comparison called **Compare to: Prior week same day, time range, and time**. This benchmark time range powers the benchmarking in all of the widgets in the dashboard. Your benchmark time range must be a date in the past compared to your time range.

Each dashboard has additional filters specific to that feature. For example, the following image of the **Conversational analytics dashboard** shows the available filters for that widget. **Contact category** is specific to Contact Lens.

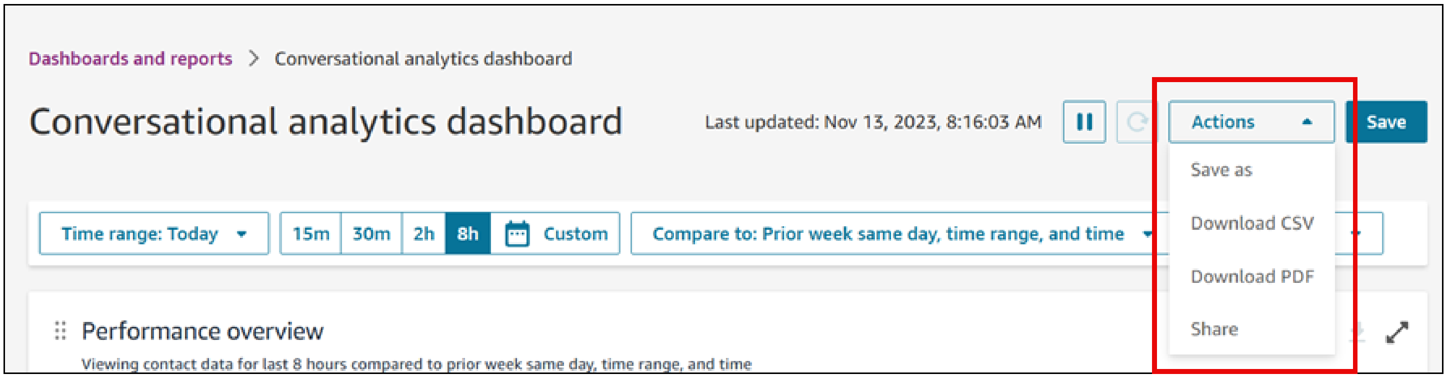


Save, download, and share your dashboard

Use the following actions on your dashboards to save, download, and share them.

1. **Save**: You can save your dashboard and change your dashboard name by choosing **Actions** > **Save** and typing a new name and choosing **Save**. Your saved dashboard appears in your **Saved dashboards** in the **Dashboards and reports** page, the **Dashboards** tab.
2. **Save as**: You can re-name and save your dashboard by choosing **Actions** > **Save as** and typing a new name and choosing save. Your saved dashboard appears in your **Saved dashboards** in the **Dashboards and reports** page, the **Dashboards** tab.
3. **Download CSV**: You can download the entire dashboard data set to CSV by choosing **Actions** > **Download CSV**. You can also download each widget's data set individually by choosing the download arrow button in the top right of each widget.
4. **Download PDF**: You can download the entire dashboard as a PDF by choosing **Actions** > **Download PDF**.
5. **Share**: You can share and publish the dashboard like other Amazon Connect reports by choosing **Actions** > **Share**. For more information about sharing and publishing, see [Share reports](), [View shared reports](), and [Publishing reports]().

   The following image shows the actions that you can select on an example dashboard.



Customize your Amazon Connect dashboard

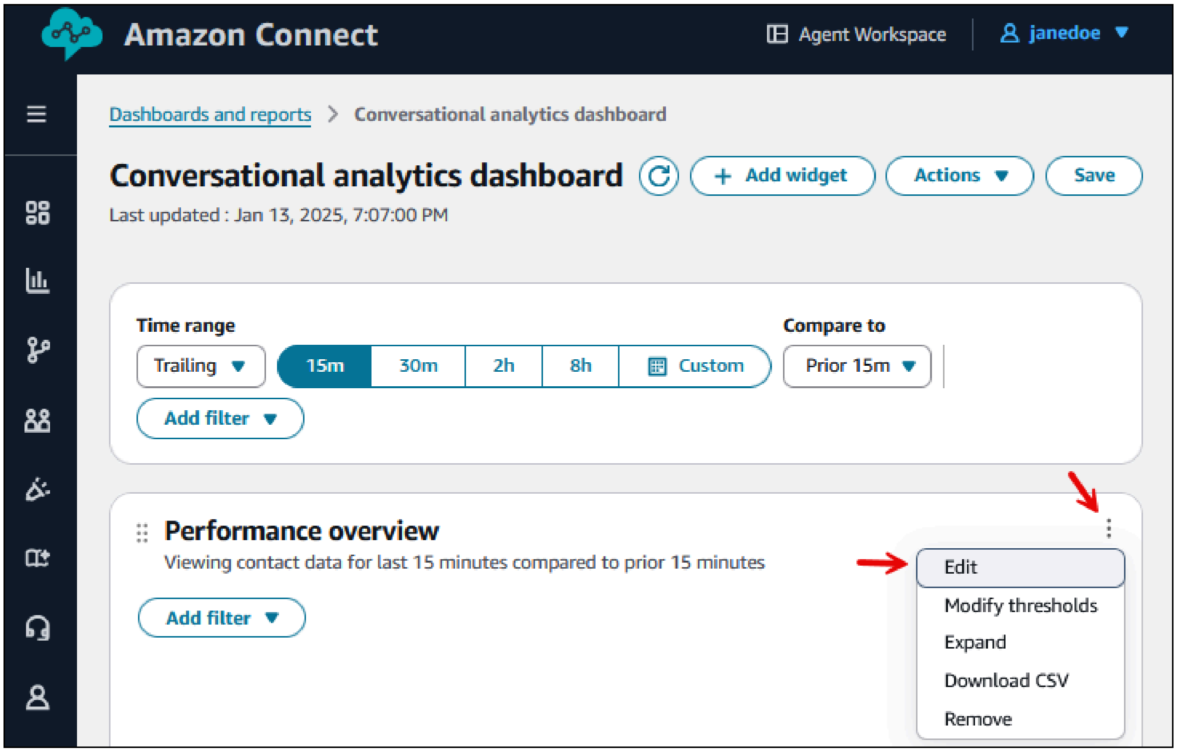
You can customize specific widgets to create dashboards that best fit your business needs. For example, you can create a single line chart that combines contacts queued, average queue answer time, and abandoned contacts. You can apply filters to show your most important queues so you can quickly see how increasing contact volumes impact both wait time and customer abandonment rates.

You can delete or add new metrics, define widget level filters and groupings, re-order and re-size columns, and more.

Contents

Choose which metrics to display in a widget

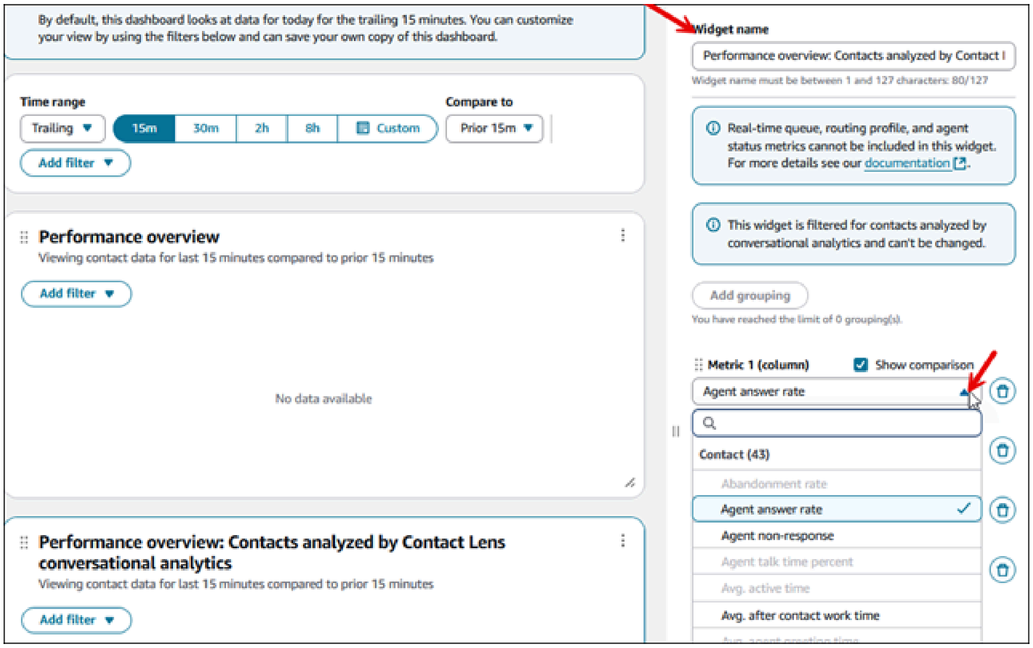
1. In a widget, select the Actions icon and then choose **Edit**. The following image shows the Actions icon for the **Performance overview** widget.



2. In the widget's **Edit** pane choose the metric column you want to change; the available metrics for that column appear in the dropdown list.

> **Note**
>
> You can modify the existing metrics, but you cannot add new ones to the list or remove them from the list.

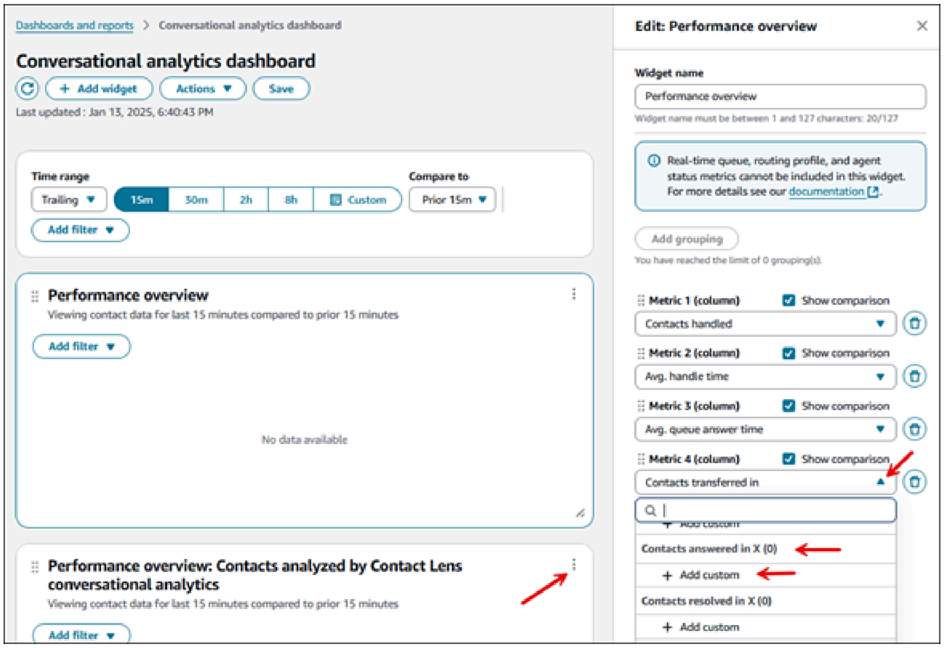
The following image shows a widget **Edit** pane, the **Widget name** box (which you can edit), and the dropdown list available for the **Metric 1** column of the **Performance overview** widget.



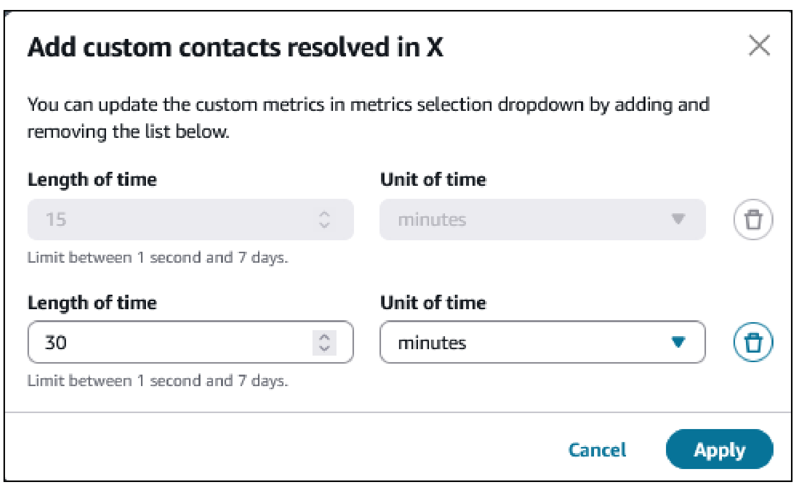
> **Note**
>
> In only specific widgets you can select the following real-time queue, routing profile, and agent metrics. You cannot combine these metrics with trailing near real-time metrics or historical metrics.
>
> - Agents online
> - Agents available
> - Agents in error
> - Agents in NPT
> - Agents staffed
> - Agents on contact
> - Agents online
> - Agents in ACW
> - Contacts active
> - Contact availability
> - Oldest contact
> - Contacts in queue

Select custom time thresholds

In the widget's **Edit** pane you can select custom time thresholds for metrics such as **Service level**, **Contacts answered in X**, and **Contacts abandoned in X**. To select a custom time threshold, choose **Add custom**, as shown in the following image.

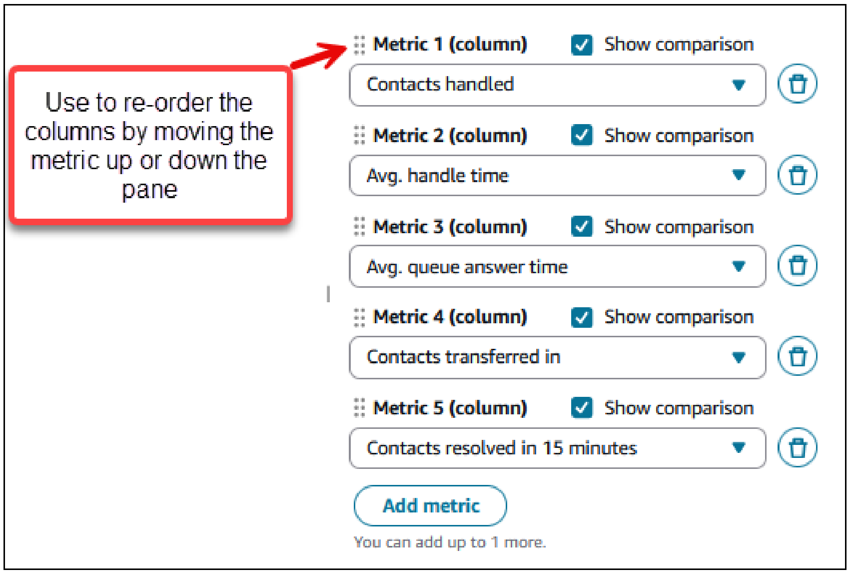


You can then select and choose which time threshold you want. The limit is between one second and seven days. The following image shows the dialog box for adding custom values for the **Contacts resolved by X** metric.



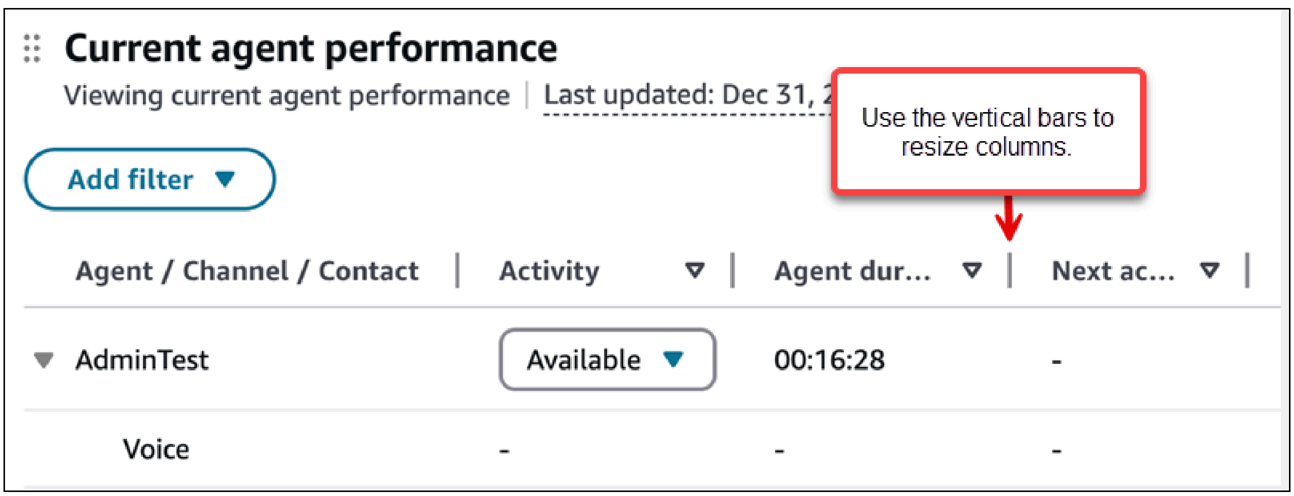
Re-order the metrics

In the widget's **Edit** pane you can re-order the columns for the metrics by selecting the dots next to the metric and moving the metric up or down the Edit pane.



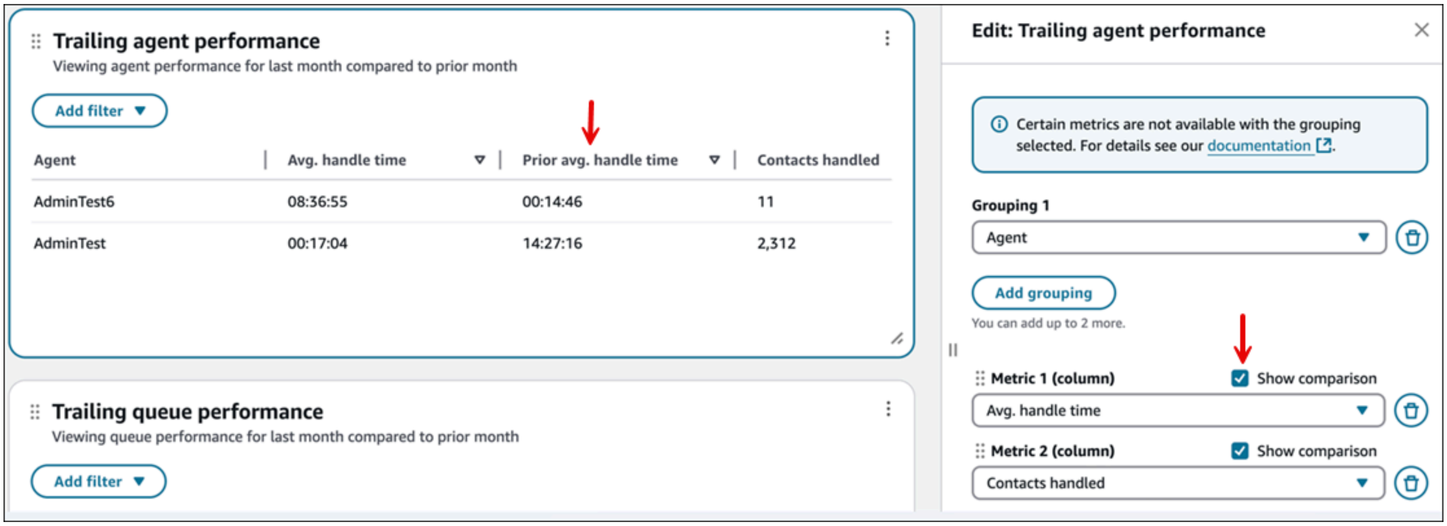
Re-size columns

To re-size the columns in the dashboard, select the vertical bars in the column headers and drag left or right to re-size. You can also re-size the grouping column. The following image shows a vertical bar on a dashboard.



Add comparisons to the Trailing performance widgets

In the widget's **Edit** pane you can choose to show the comparisons in your Trailing performance widgets by choosing the **Show comparison** option. This allows you to see how your performance compares to the previous time range.

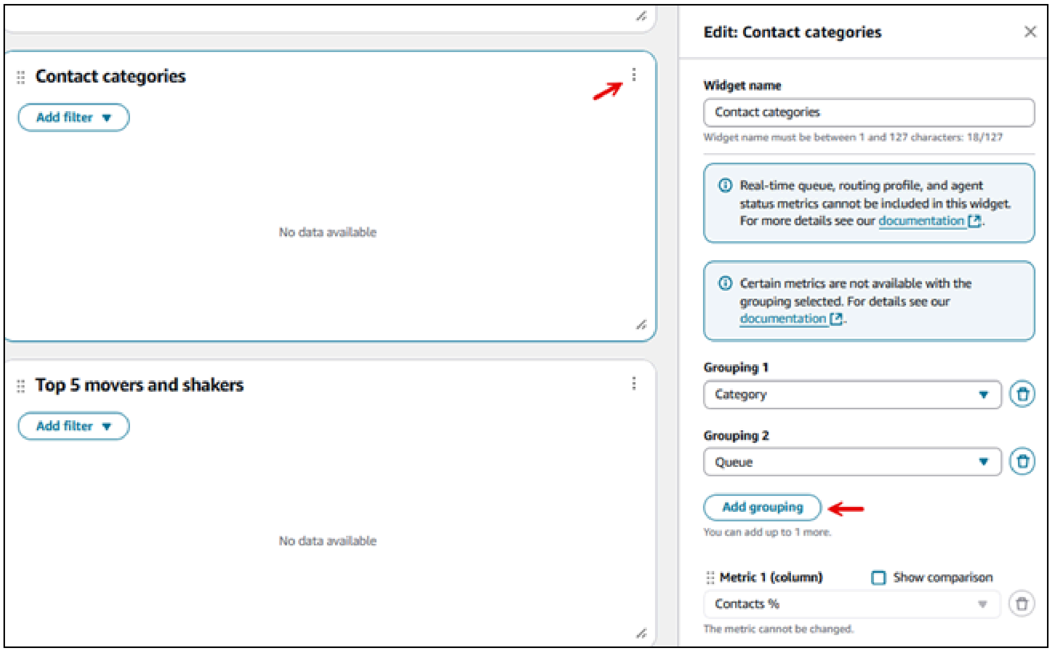


Configure groupings

In the widget's **Edit** pane you can configure the groupings for tables. You can add up to three groupings.

> **Note**
>
> - Groupings are available dynamically based on the metrics selected in the widgets to avoid incompatible metric/grouping combinations.
> - Groupings change the metrics that are available within the widgets.

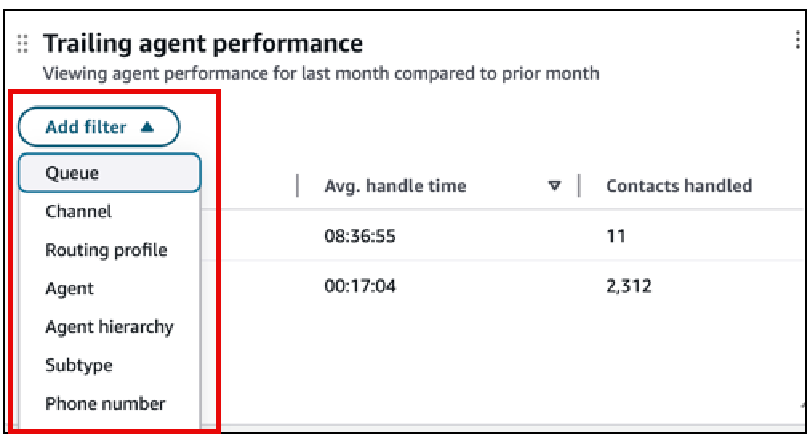
The following image shows two groupings for the Contact categories widget in the **Edit** pane.



Configure filters

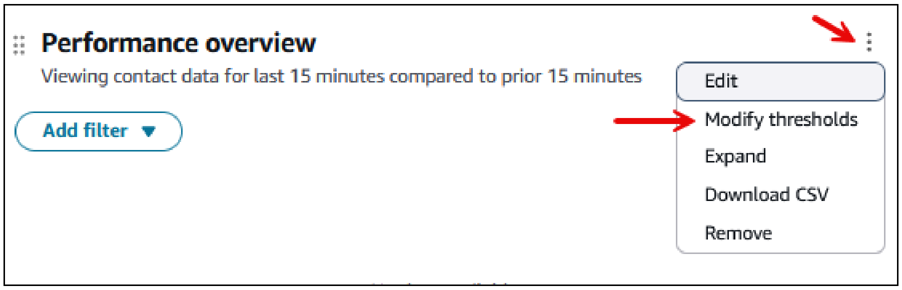
In the widget's **Edit** pane you can select filters that apply to only to the widget you're on. These filters are dynamically included based on the metrics selected. These filters act as "Or" when used with the page level filters.

The following image shows filters for the **Trailing agent performance** metrics.



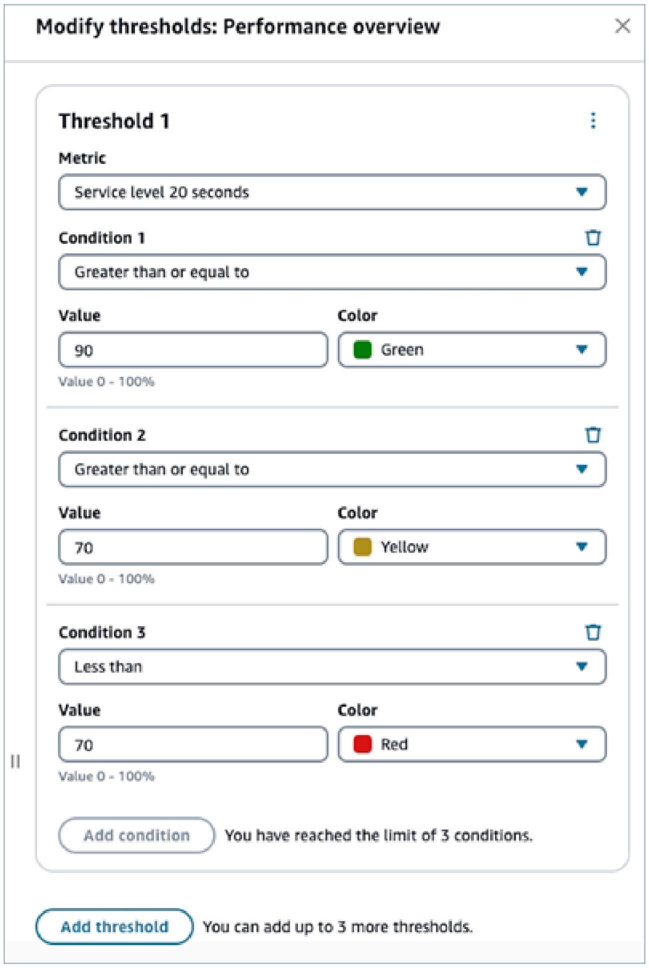
Modify thresholds for summary widgets and tables

You can add color coded thresholds to summary widgets and tables by choosing the **Modify thresholds** option on the widget.



You can add up to three thresholds per metric (red, yellow, green). You can define the thresholds that cause the metrics to change colors. Thresholds are evaluated in the order they are applied, which means that if you have overlapping thresholds, the first one that triggers, will color the respective metric. This means if you want to create a red/yellow/green configuration for greater than 90% green, between 90%-70% yellow, and less than 70% yellow, you should create three conditions in the following order:

1. Greater than or equal to 90% = Green
2. Greater than or equal to 70% = Yellow
3. Less than 70% = Red

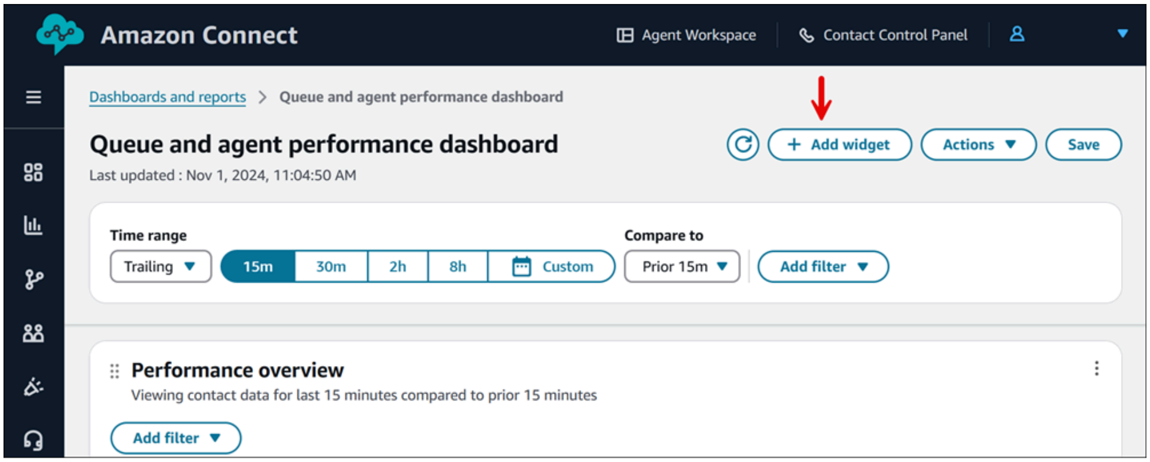


Add or remove widgets on a dashboard

You add widgets to a dashboard by choosing from a list of pre-configured widgets that is based on the dashboard you are using. You can have up to 10 widgets on each dashboard.

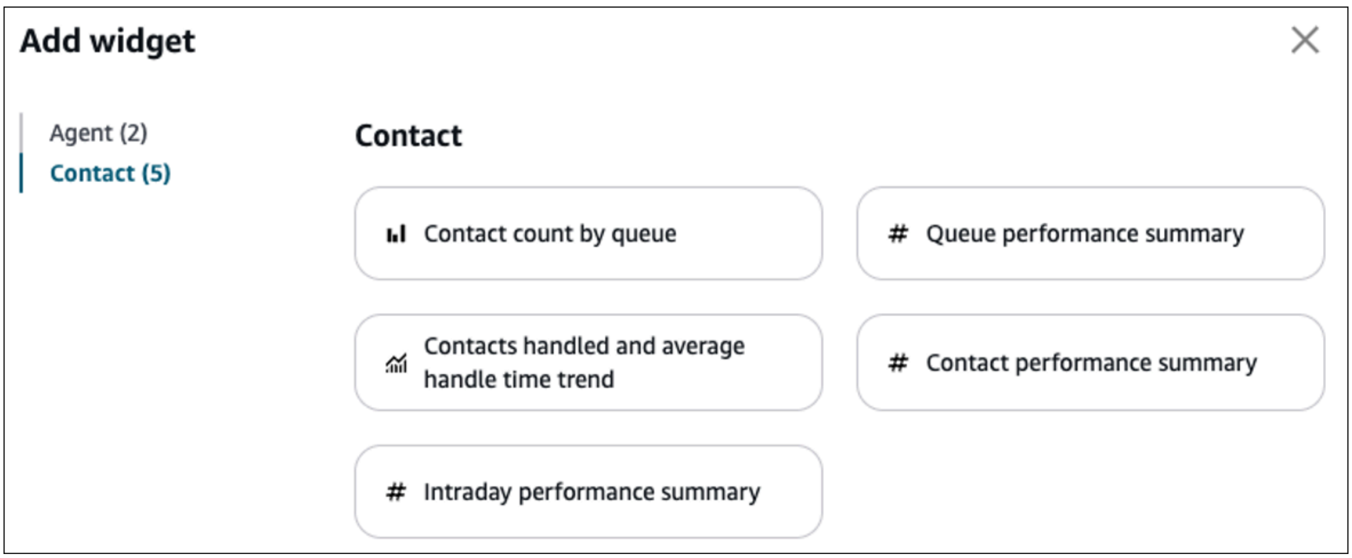
To add a widget

1. On the dashboard page, choose **Add widget**, as shown in the following image.



2. On the **Add widget** page, select a widget from the list of pre-configured widgets based on the dashboard you are using. The widget is added to the bottom of the dashboard.

   The following example of an **Add widget** page shows five Contact widgets that you can add.



When you add a custom widget to the dashboard, you can apply both a widget-level filter and a page-level filter.

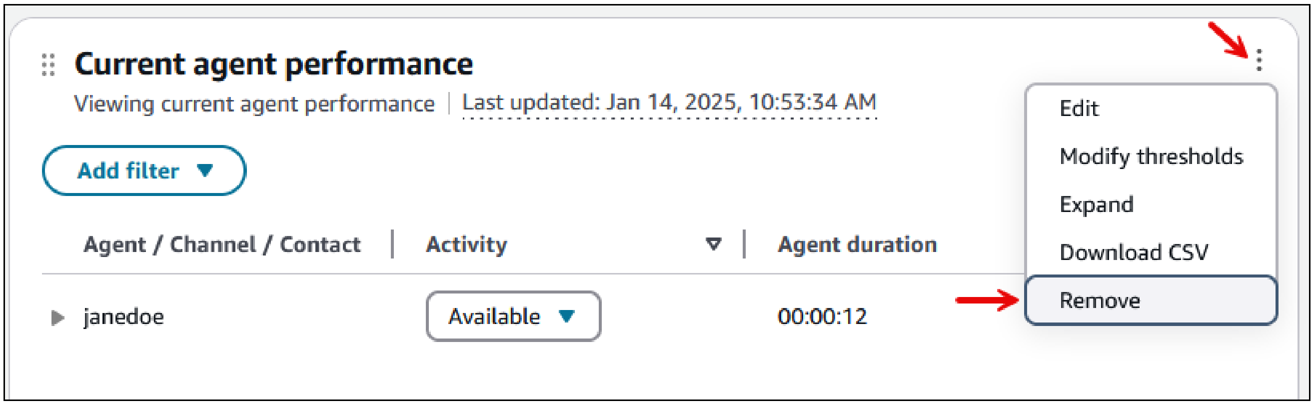
A widget-level filter acts as an "OR." For example, you have two queues:

- One queue is filtered at the page level and at the widget level.
- The other queue is filtered at the queue level.

In this example, the dashboard would display the data for both queues in the widget.

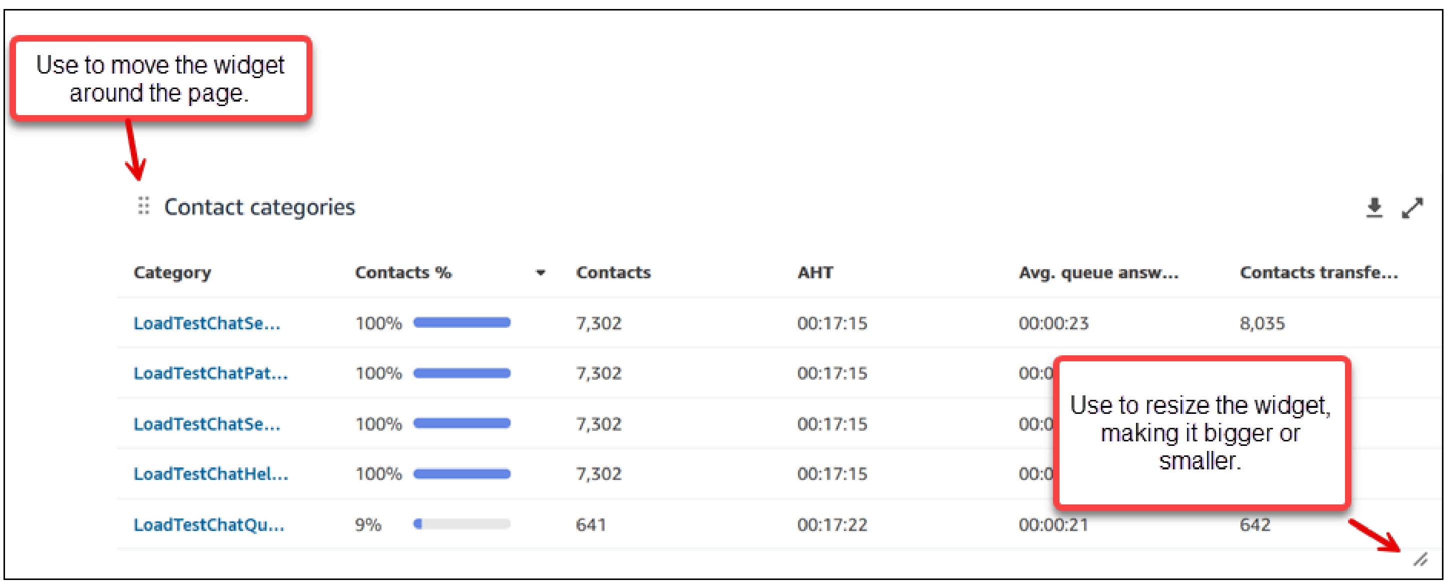
If you want to display data for only a single queue, we recommend unselecting the page-level filter.

To remove a widget from your dashboard, choose the Actions icon and then choose **Remove**, as shown in the following image.



Move and resize widgets

You can move charts around by choosing and holding the top left corner icon with your mouse and then moving the widget. You can re-size widgets by choosing and dragging the bottom right icon with your mouse. These two controls are shown in the following image.



Create custom dashboards

To create a custom dashboard, on the **Dashboards** tab choose **Create custom**, as shown in the following image.

A new custom dashboard opens. Use the **Add widget** option to customize the dashboard.

Amazon Connect Contact Lens conversational analytics dashboard

When Contact Lens conversational analytics is enabled on your contacts, you can analyze conversations between customers and agents by using speech and chat transcriptions, natural language processing, and intelligent search capabilities. Contact Lens conversational analytics performs sentiment analysis, detects issues, and enables you to automatically categorize contacts.

The Contact Lens conversational analytics dashboard helps you understand:

- Why customers are contacting your contact center
- The trends of contact drivers over time
- The performance of each of those call drivers (for example, average handle time for call driver "Where's my stuff?")

You can view key metrics for categories such as contacts handled and average handle time compared to a custom-defined benchmark time-range with color indicators (for example, green = good, red = bad) for quick insights within seconds (for example, "Am I performing better or worse than last week and by how much?") using the summary widgets at the top.

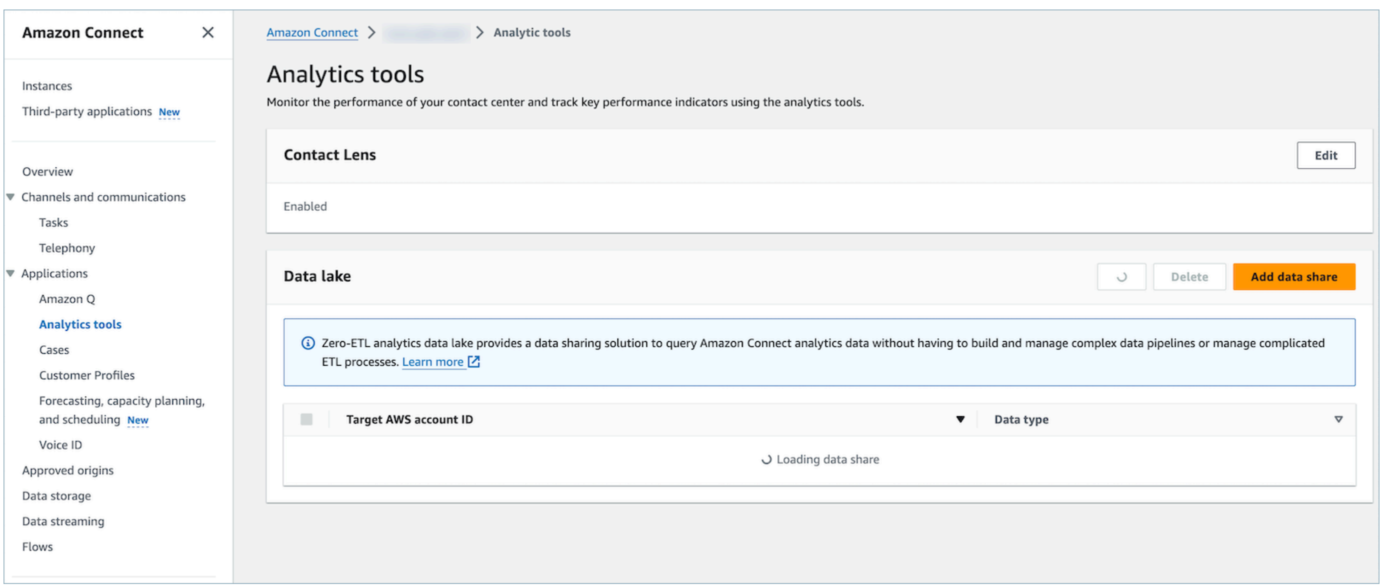
Data visualizations such as **Movers and shakers** display the largest changes compared to a custom-defined benchmark time period in the past (that is, week over week). While **Contacts handled and average handle time trend** shows you the number of contacts handled alongside the average handle time over a period of intervals in time in a time series chart.

Contents

- [Performance overview charts]
- [Contact categories]
- [Movers and shakers]
- [Top contact categories average handle time]
- [Contact count by queue]
- [Contacts handled and average handle time trend]
- [Dashboard functionality limitations]

Enable access to the dashboard

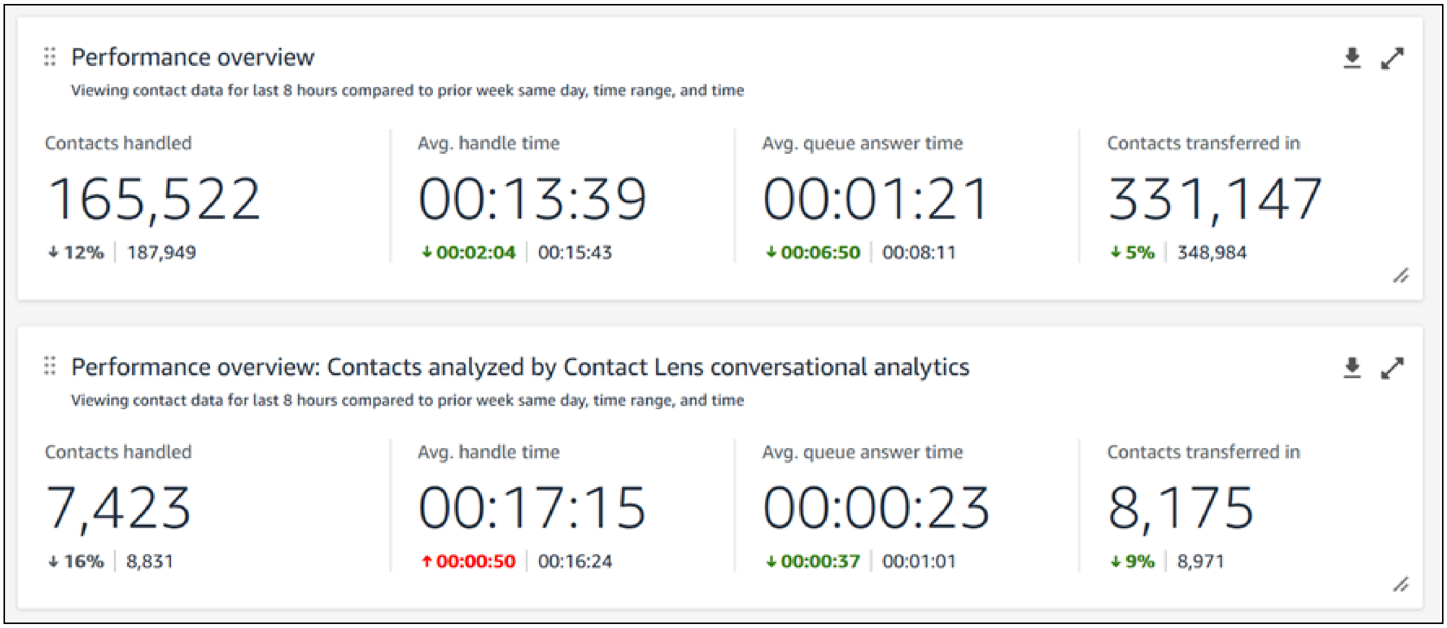
1. Ensure users are assigned the appropriate security profile permissions:
   - **Access metrics - Access permission** or the **Dashboard - Access permission**. For information about the difference in behavior, see [Assign security profile permissions for dashboards in Amazon Connect].
   - **Contact Lens - conversational analytics**: This permission enables users to view data in the Contact Lens dashboard.
2. In the AWS console, ensure that **Analytics tools**, **Enable Contact Lens** is selected, as shown in the following image.



3. In your flow, enable Contact Lens conversational analytics so it analyzes your contacts. For instructions, see [Enable call recording and speech analytics].

Performance overview charts

There are two performance overview charts that provide aggregated metrics based on your filters. The second chart is further filtered only by contacts analyzed by Contact Lens conversational analytics. Each metric within the charts is compared to your "compare to" benchmark time range filter.



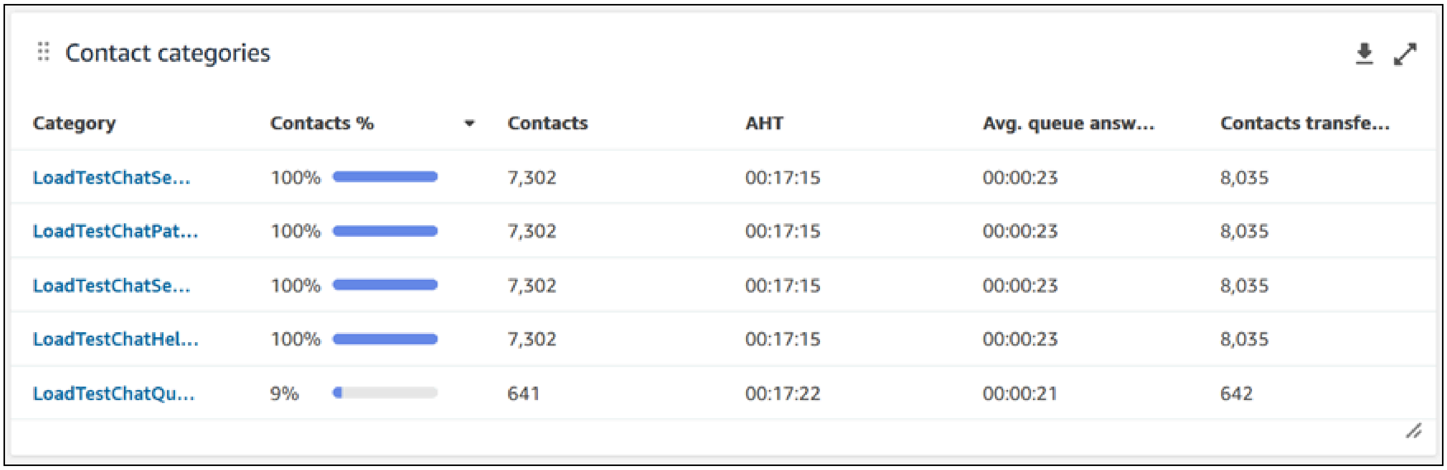
This chart shows the following information:

- Contacts handled during your time range selection was 165,522, which is down ˜12% compared to your benchmark number of contacts handled, 187,949 contacts.
- The percentages are rounded up or down.
- The colors that appear for the metrics indicate positive (green) or negative (red) compared to your benchmark.
- There are no colors for contacts handled.

Contact categories

The contact categories chart shows you Contact Category information. To see all data, click on the pop-out icon in the top right of the chart. To deep dive further into the contacts, click on the Contact Category and it will take you to Contact Search pre-filtered for that category along with the dashboard filters.

1. Contacts %: the count of contacts analyzed by Contact Lens conversational analytics that have a given category divided by the total number of contacts analyzed by Contact Lens conversational analytics.
2. Contacts: count of contacts analyzed by Contact Lens conversational analytics that have a given category.
3. AHT: the average handle time for the contacts that have a given category.
4. Avg. queue answer time: the average queue answer time for the contacts that have a given category.
5. Contacts transferred in: the count of contacts transferred in for the contacts that have a given category.



Contact categories

Category	Contacts %	Contacts	AHT	Avg. queue answ...	Contacts transfe...
LoadTestChatSe...	100%	7,302	00:17:15	00:00:23	8,035
LoadTestChatPat...	100%	7,302	00:17:15	00:00:23	8,035
LoadTestChatSe...	100%	7,302	00:17:15	00:00:23	8,035
LoadTestChatHel...	100%	7,302	00:17:15	00:00:23	8,035
LoadTestChatQu...	9%	641	00:17:22	00:00:21	642

Movers and shakers

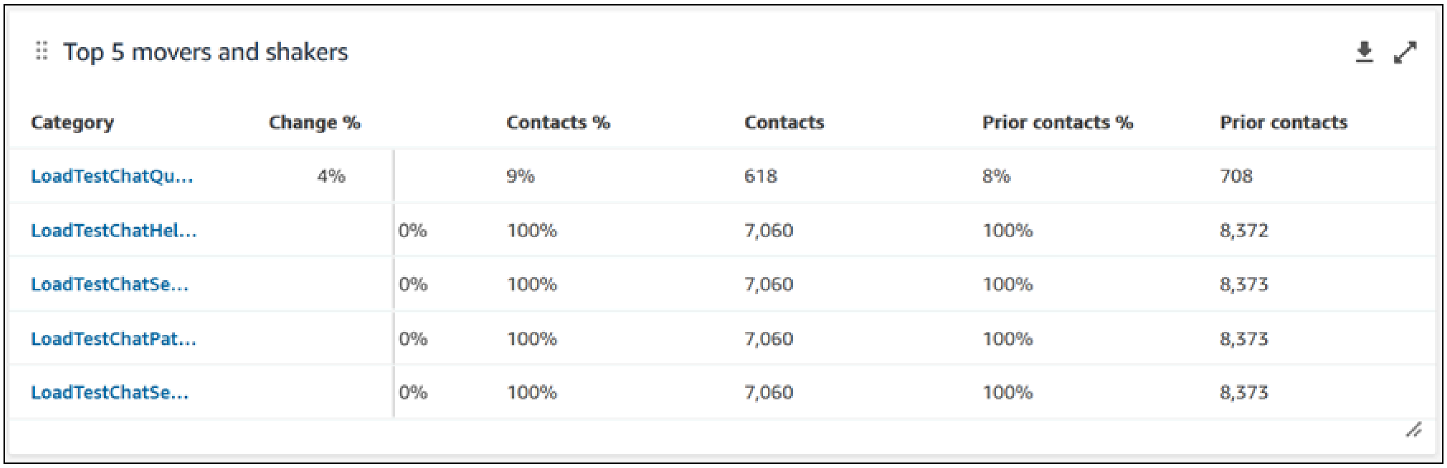
The movers and shakers chart shows you the categories with the highest percent change in distribution compared to your benchmark time range. In other words, it shows you the count of categories that were generated more or less frequently compared to the total number of contacts analyzed by Contact Lens conversational analytics.

For example:

- If 20 out of 100 contacts analyzed by conversational analytics have Category A, your contacts % for Category A was 20%.
- If during the comparison benchmark time period 10 out of 100 contacts analyzed by Contact Lens conversational analytics had Category A, your Prior contacts % for Category A was 10%.
- The % Change would be (20% - 10%)/(10%) = 100%.

To see all data, choose the pop-out icon in the top right of the chart. To deep dive further into the contacts, choose the Contact Category and it will take you to Contact Search pre-filtered for that category along with the dashboard filters.

1. Change %: (Contacts % – Prior contacts %) / (Prior contacts %). This number is rounded. The chart is sorted by highest absolute Change %.
2. Contacts %: the count of contacts analyzed by Contact Lens conversational analytics in the time range specified in your dashboard filter that have a given category divided by the total number of contacts analyzed by Contact Lens conversational analytics.
3. Contacts: the count of contacts analyzed by Contact Lens conversational analytics in the time range specified in your dashboard filter.
4. Prior contacts %: the count of contacts analyzed by Contact Lens conversational analytics in the "compare to" benchmark time range specified in your dashboard filter that have a given category divided by the total number of contacts analyzed by Contact Lens conversational analytics.
5. Prior contacts: the count of contacts analyzed by Contact Lens conversational analytics in the "compare to" benchmark time range specified in your dashboard filter.

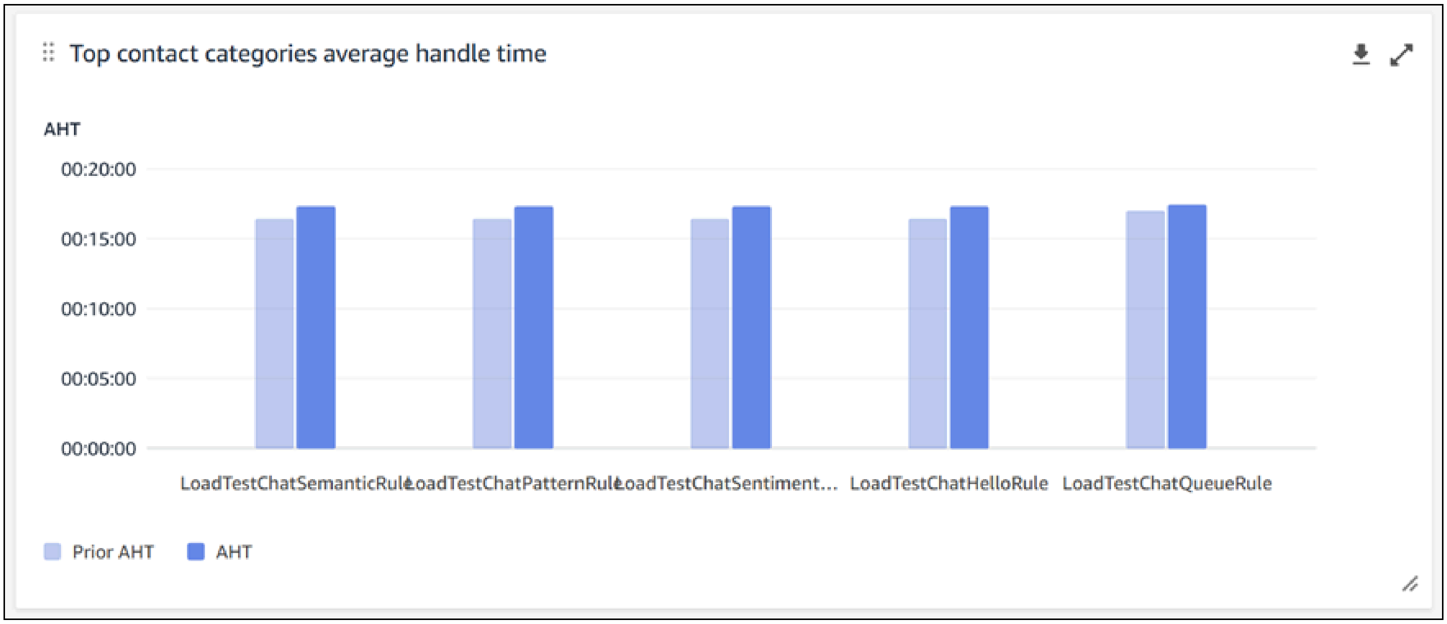


Top 5 movers and shakers

Category	Change %	Contacts %	Contacts	Prior contacts %	Prior contacts
LoadTestChatQu...	4%	9%	618	8%	708
LoadTestChatHel...	0%	100%	7,060	100%	8,372
LoadTestChatSe...	0%	100%	7,060	100%	8,373
LoadTestChatPat...	0%	100%	7,060	100%	8,373
LoadTestChatSe...	0%	100%	7,060	100%	8,373

Top contact categories average handle time

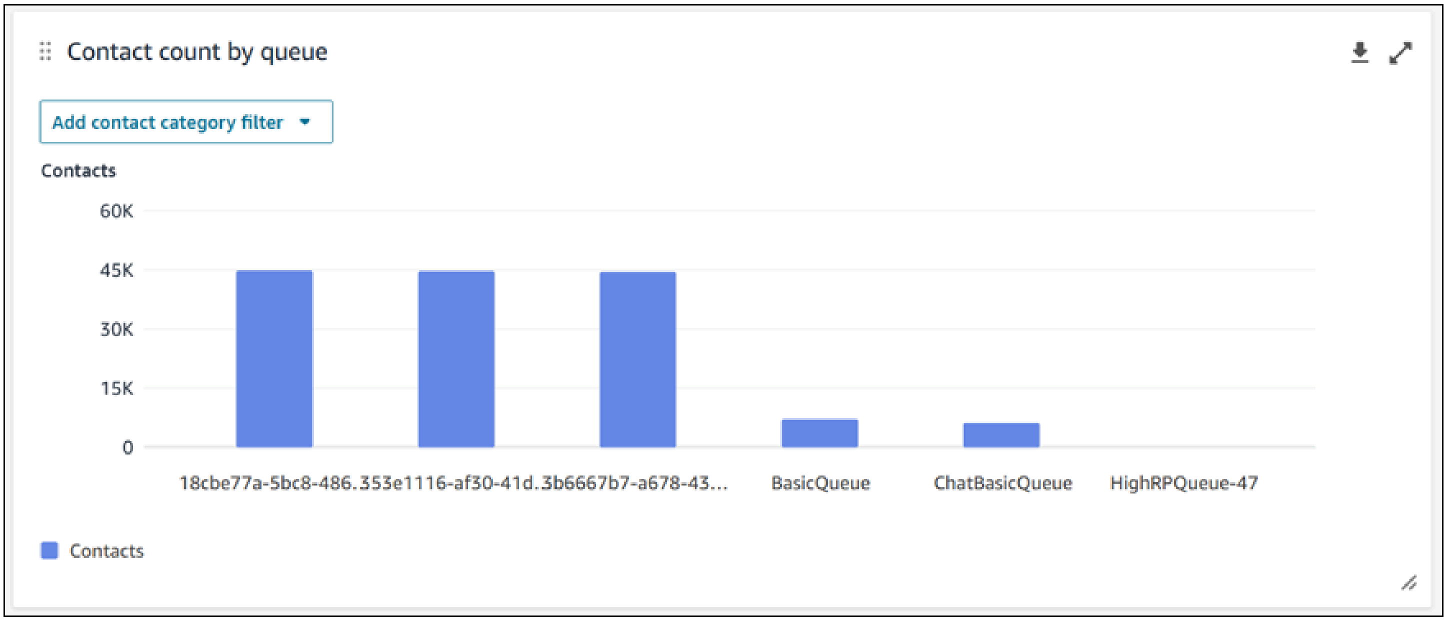
The top contact categories average handle time displays the prior AHT (using the "compare to" benchmark time range) to the current time range AHT for each of your top 10 categories (sorted by count of contacts with a category from left to right). To see all data, click on the pop-out icon in the top right of the chart.



Contact count by queue

> **Note**
>
> This section of the dashboard displays data even when Contact Lens conversational analytics is not enabled on any contacts.

The contact count by queue chart displays the count of contacts for each queue, sorted by the highest number of contacts from left to right. You can configure this widget further by filtering for contact categories directly from this chart. This filter overrides the page-level contact category filter at the top of the dashboard.



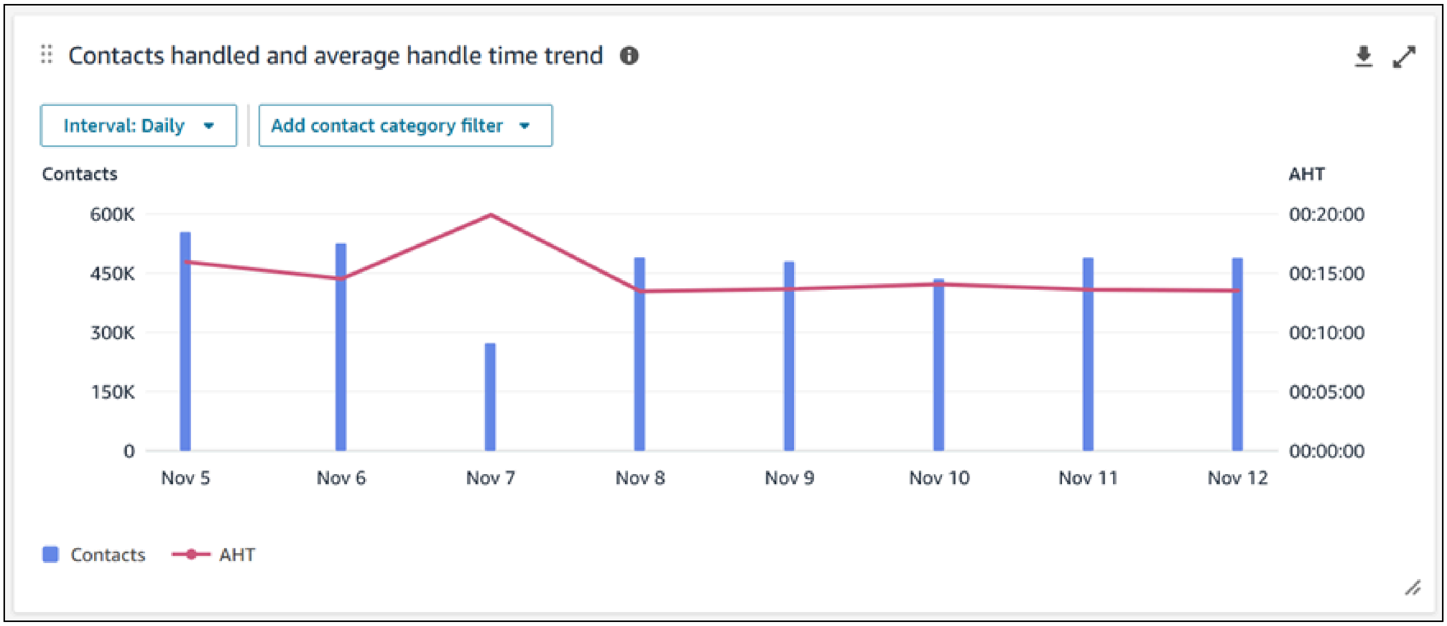
Contacts handled and average handle time trend

> **Note**
>
> This section of the dashboard displays data even when Contact Lens conversational analytics is not enabled on any contacts.

The Contacts handled and average handle time trend is a time-series chart that displays the count of contacts handled (blue bars) and the average handle time (red line) over a given time period broken down by intervals (15min, daily, weekly, monthly). You can configure different time range intervals by using the "Interval" button directly in the widget. The intervals that you may select depend on the page-level time range filter.

For example:

- If you have a "Today" time range filter at the top of your dashboard, you can only see an interval of 15min for the last 24 hours.
- If you have a "Day" time range filter at the top of your dashboard, you can see a trailing 8 day interval trend, or a 15min interval trend for the trailing 24 hours.



Dashboard functionality limitations

The following limitations apply to the Contact Lens conversational analytics dashboard:

- Tag-based access controls are not supported on the dashboard.
- If you have a routing profile or agent hierarchy filter selected, the hyperlinks on contact categories leading to contact search will be disabled within the Contact categories and Movers and Shakers charts.

Flows and conversational bot performance dashboard

The flows and conversational bot performance dashboard helps you understand the performance of your automated experiences including flows, flow modules, and conversational bots. You can compare key metrics such as flows started, average flow duration, or bot intent outcome over time. You can filter for specific bots or flows, and save reports to share across your organization.

Contents

- Failed bot intents movers and shakers
- Bot conversations and success rate over time
- Bot conversations overview table
- Bot intent overview table
- Flow outcomes over time comparison chart
- Flow durations over time comparison chart
- Flows and Flow modules overview tables
- Dashboard functionality limitations

Enable access to the dashboard

Ensure users are assigned the appropriate security profile permissions:

- **Access metrics - Access** permission or the **Dashboard - Access** permission. For information about the difference in behavior, see Assign security profile permissions for dashboards in Amazon Connect.
- **Flows - View**, **Flow modules - View**, and **Bot - View** permissions: These permissions are required to see data in your dashboard.

> **Note**
>
> You must have the **Flows - View** permission to see the dashboard.

What do "dropped" and "prior dropped" mean?

The following terms are used in this topic:

- **Dropped**: The count of flows that started running within the specified start and end time, and then ended with a contact dropping from the flow before the flow reached a terminal block. For example, a block that is intended to end the contact.
- **Prior dropped**: The count of flows in the time range being "compared to" that started running, and then ended with a contact dropping from the flow before the flow reached a terminal block. The time range selected from the **Compare to** dropdown must be a date in the past compared to your time range.

Examples of "Time range" and "Compare to" configurations

Following are a few use cases that help explain how to configure the **Time range** and **Compare to** settings.

- **Use case 1**: I want to get all the flows dropped in the last 2 hours and compare that to the flows dropped in the last 2 hours prior to the 2 hours selected time range.

  Configure the dashboard as follows:

  - Time range = Trailing
  - Time = 2h
  - Compare to = Prior 2h

- **Use case 2**: I want to get all the flows dropped in the last 2 hours and compare that to the flows dropped yesterday from 00:00:00 to 23:59:59.

  Configure the dashboard as follows:

  - Time range = Trailing
  - Time = 2h
  - Compare to = Prior day

- **Use case 3**: I want to get all the flows dropped in the last 24 hours and compare that to the flows dropped on the same day last week.

  Configure the dashboard as follows:

  - Time range = Trailing
  - Time = Custom 24h
  - Compare to = Prior week same day

- **Use case 4**: I want to get all the flows dropped since 12 am today and compare that to all the flows dropped last week.

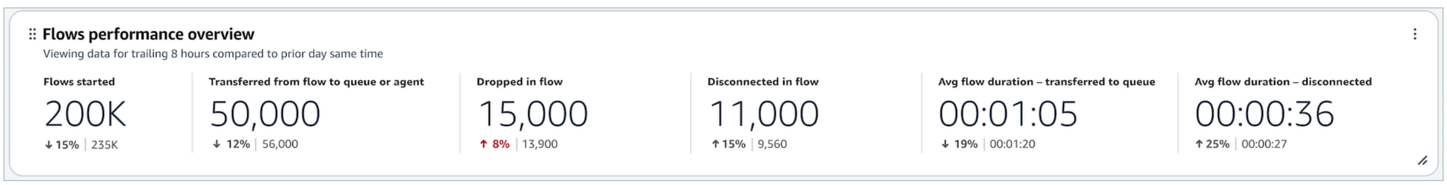
Configure the dashboard as follows:

- Time range = Trailing
- Time = Custom: Today (since 12am)
- Compare to = Prior week

Performance overview chart

The **Performance overview** chart provides aggregated metrics based on your filters. Each metric within the charts is compared to your "compare to" benchmark time range filter. For example, flows started during your time range selection was 200,000 which is down 15% compared to your benchmark number of flows started, 235,000. The percentages are rounded up or down. The colors that appear for the dropped in flow metric indicate negative (red) compared to your benchmark.

The following image shows an example of this chart.



The following metrics are displayed on this chart:

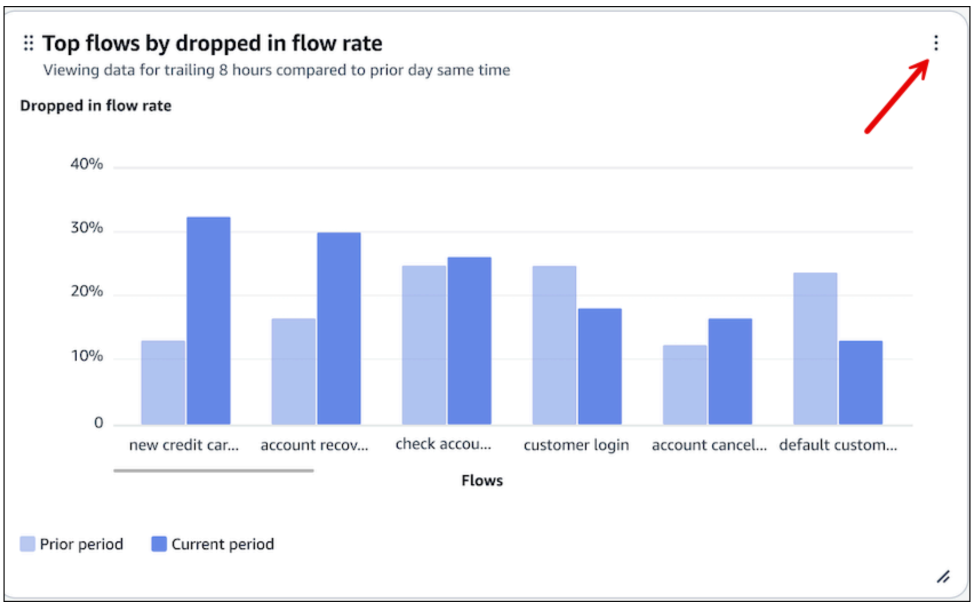
- **Flows started:** The count of flows that started running within the specified start time and end time.
- **Transferred from flow to queue or agent:** The count of flows that started running within the specified start time and end time and ended with a contact transferring from the flow to a queue or agent.
- **Dropped in flow:** The count of flows that started running within the specified start time and end time and ended with a contact dropping from the flow before the flow reached a terminal block.
- **Disconnected in flow:** The count of flows that started running within the specified start time and end time and ended with a contact reaching a disconnect terminal block
- **Avg duration – transferred to queue:** The average flow duration for the specified start time and end time of selected flows where the flow outcome is transferred to queue.

- **Avg duration – disconnected:** The average flow duration for the specified start time and end time of selected flows where the flow outcome is disconnected participant.

Comparison to prior period charts

The **Top flows by dropped in flow rate** and **Top flows transferred to queue or agent rate** charts display the current period metric and the "Compare to" period metric for the top ten flows sorted (from highest to lowest) by the current period metric. These charts allow you to identify the flows contributing most to overall dropped or transferred contacts.

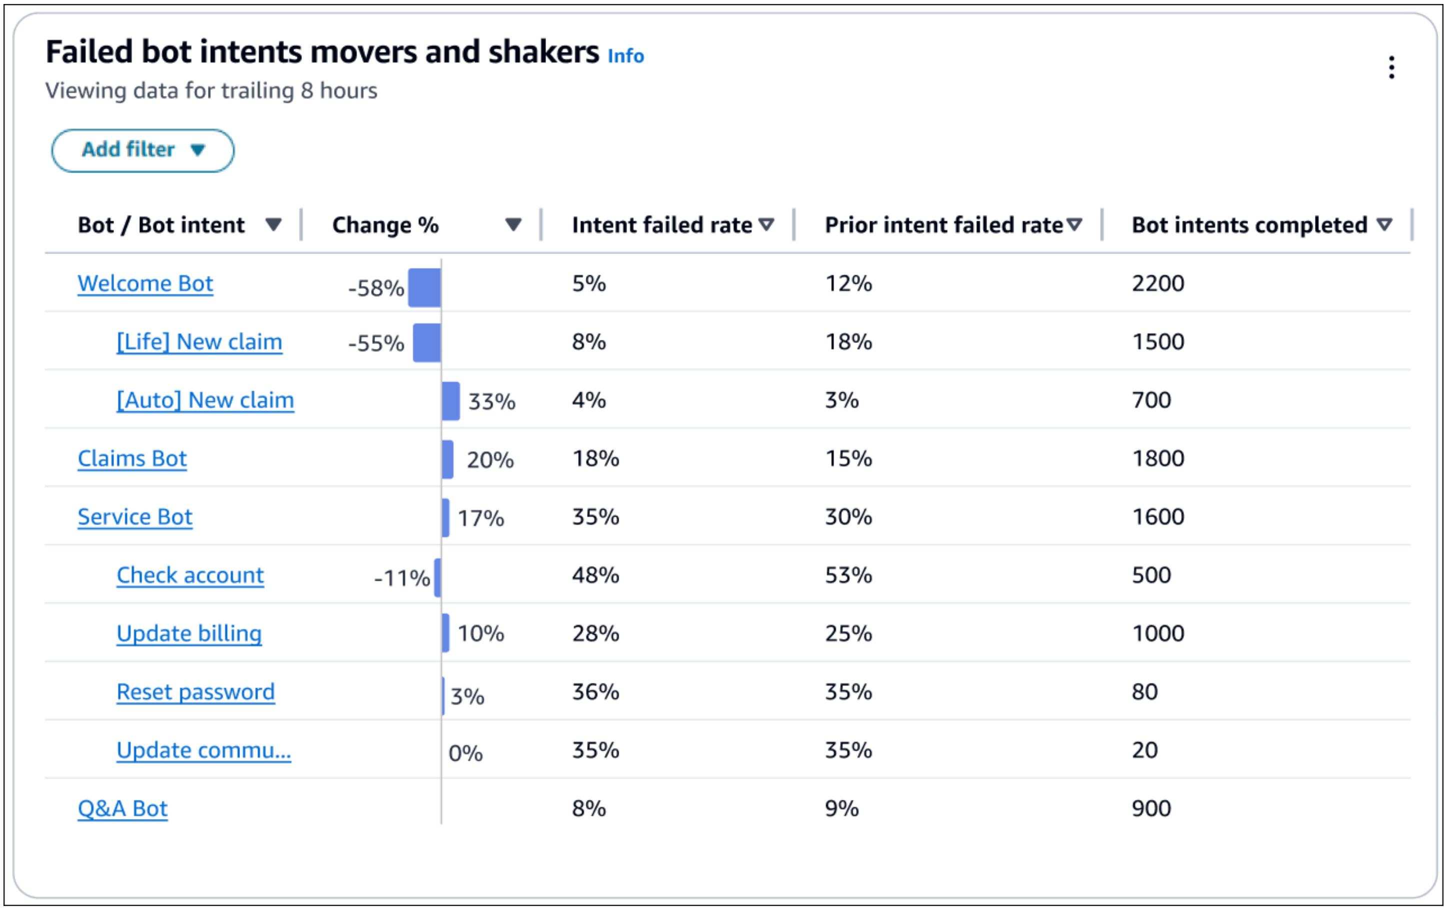
To see all data, choose the More icon in the top right of the chart, and then choose **Expand**. The following image shows the **Top flows by dropped in flow rate**. An arrow points to the location of the More icon.



Failed bot intents movers and shakers

The **Failed bot intents movers and shakers** chart shows you the bot intents with the highest percent change in failed rate compared to your benchmark time range. For example, if an intent has a failed rate of 10% in the current period and 5% in the previous period, the intent will have a percent change of 100%.

The following image shows an example of this chart.



The following metrics are displayed on this chart:

- **Change %**: (Bot intent failed rate % – Prior bot intent failed rate %) / (Prior bot intent failed rate %). This number is rounded. The chart is sorted by highest absolute Change %.
- **Bot intent failed rate**: Bot intent failed rate during the specified current time range.
- **Prior bot intent failed rate**: Bot intent failed rate during the specified benchmark time range.
- **Bot intents completed**: Count of bot intent triggers completed in the specified current time range.

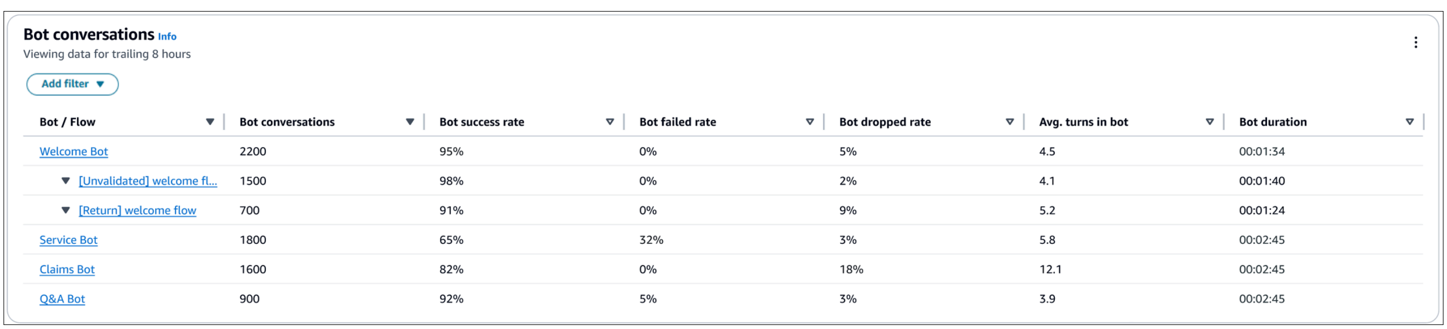
Bot conversations and success rate over time

The **Bot conversations and success rate** over time trend is a time-series chart that displays the count of bot conversations (blue bars) and the bot conversation success rate (red line) over a given time period broken down by intervals (15min, daily, weekly, monthly).

To configure different time range intervals, choose **Interval**, as shown in the following image.

Bot conversations overview table

The **Bot conversations** overview table displays a snapshot of bot conversation metrics aggregated over the selected time range. The following image shows an example of this table.



Bot conversations Info

Viewing data for trailing 8 hours

Add filter

Bot / Flow	Bot conversations	Bot success rate	Bot failed rate	Bot dropped rate	Avg. turns in bot	Bot duration
Welcome Bot	2200	95%	0%	5%	4.5	00:01:34
[Unvalidated] welcome fl...	1500	98%	0%	2%	4.1	00:01:40
[Return] welcome flow	700	91%	0%	9%	5.2	00:01:24
Service Bot	1800	65%	32%	3%	5.8	00:02:45
Claims Bot	1600	82%	0%	18%	12.1	00:02:45
Q&A Bot	900	92%	5%	3%	3.9	00:02:45

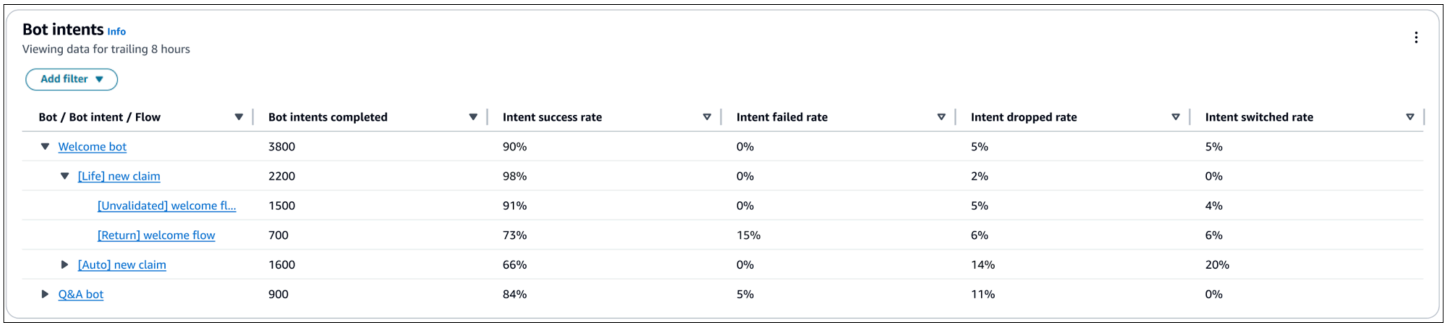
The following metrics are displayed on this table:

- **Bot conversation**: The count of bot conversations that started within the specified time range.
- **Bot success rate**: The percentage of successful conversations / total bot conversations. The completion of the final intent in the conversation is categorized as a success.

- **Bot failed rate**: The percentage of failed conversations / total bot conversations. The failure to fulfill final intent is categorized as failed.
- **Bot dropped rate**: The percentage of dropped conversations / total bot conversations. Drops are categorized when the customer doesn't respond before the conversation is categorized as a success or failed (for example, they are disconnected unexpectedly from the interaction).
- **Avg turns in bot**: The average number of turns (that is, a single request from the contact to the bot) for bot conversations that started within the specified time range.
- **Avg bot conversation duration**: The average duration for bot conversations that started within the specified time range.

Bot intent overview table

The **Bot intent** overview table displays a snapshot of bot intent metrics table aggregated over the selected time range. The following image shows an example of this table.



Bot intents Info
Viewing data for trailing 8 hours
Add filter

Bot / Bot intent / Flow	Bot intents completed	Intent success rate	Intent failed rate	Intent dropped rate	Intent switched rate
Welcome bot	3800	90%	0%	5%	5%
[Life] new claim	2200	98%	0%	2%	0%
[Unvalidated] welcome fl...	1500	91%	0%	5%	4%
[Return] welcome flow	700	73%	15%	6%	6%
[Auto] new claim	1600	66%	0%	14%	20%
Q&A bot	900	84%	5%	11%	0%

The following metrics are displayed on this table:

- **Bot intents completed**: The count of intent triggers that ended within the specified time range.
- **Bot conversation outcome rate**: The percentage of bot intent triggers that ended within the specified time range broken down by mutually exclusive and exhaustive list of bot intent outcomes.
- **Intent success rate**: The number of times the intent was successful / the number of times the intent was invoked. Success is defined as the bot successfully fulfilling and completing the intent.
- **Intent failed rate**: The number of times the intent was failed / the number of times the intent was invoked. Failed is defined as either the user declined the confirmation prompt or the bot switches to the Fallback Intent before completion.
- **Intent dropped rate**: The number of times the intent was dropped / the number of times the intent was invoked. Dropped is defined as the user respond before the intent is categorized as a success or failed (for example, they are disconnected unexpectedly from the interaction).

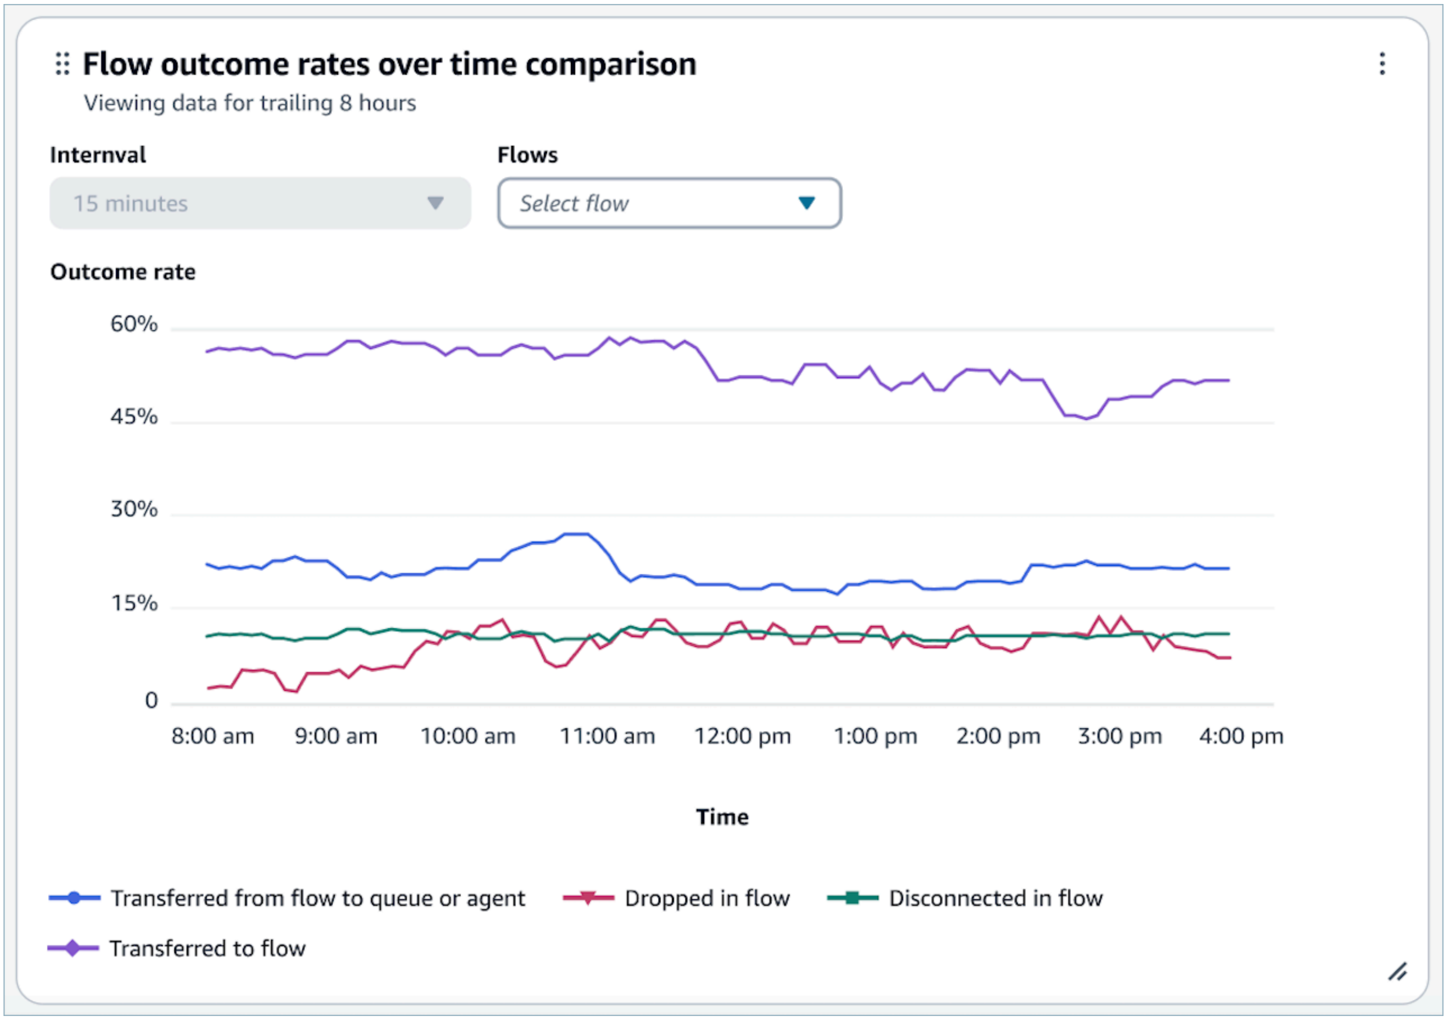
- **Intent switched rate**: The number of times the intent was switched / the number of times the intent was invoked. Switched intents occur when the bot recognizes a different intent and switches to that intent instead, before the original intent is categorized as a success or failed.

Flow outcomes over time comparison chart

The **Flow outcomes over time comparison** chart is a time-series chart that displays the breakdown of Flow outcome rate metrics for a single flow or multiple flows over a given time period and broken down by intervals (15min, daily, weekly, monthly).

You can configure different time range intervals by using the "Interval" button directly in the widget. The intervals that you can select depend on the page-level time range filter. For example:

- If you have a "Today" time range filter at the top of your dashboard, you can only see an interval of 15min for the last 24 hours.
- If you have a "Day" time range filter at the top of your dashboard, you can see a trailing 8 day interval trend, or a 15min interval trend for the trailing 24 hours.



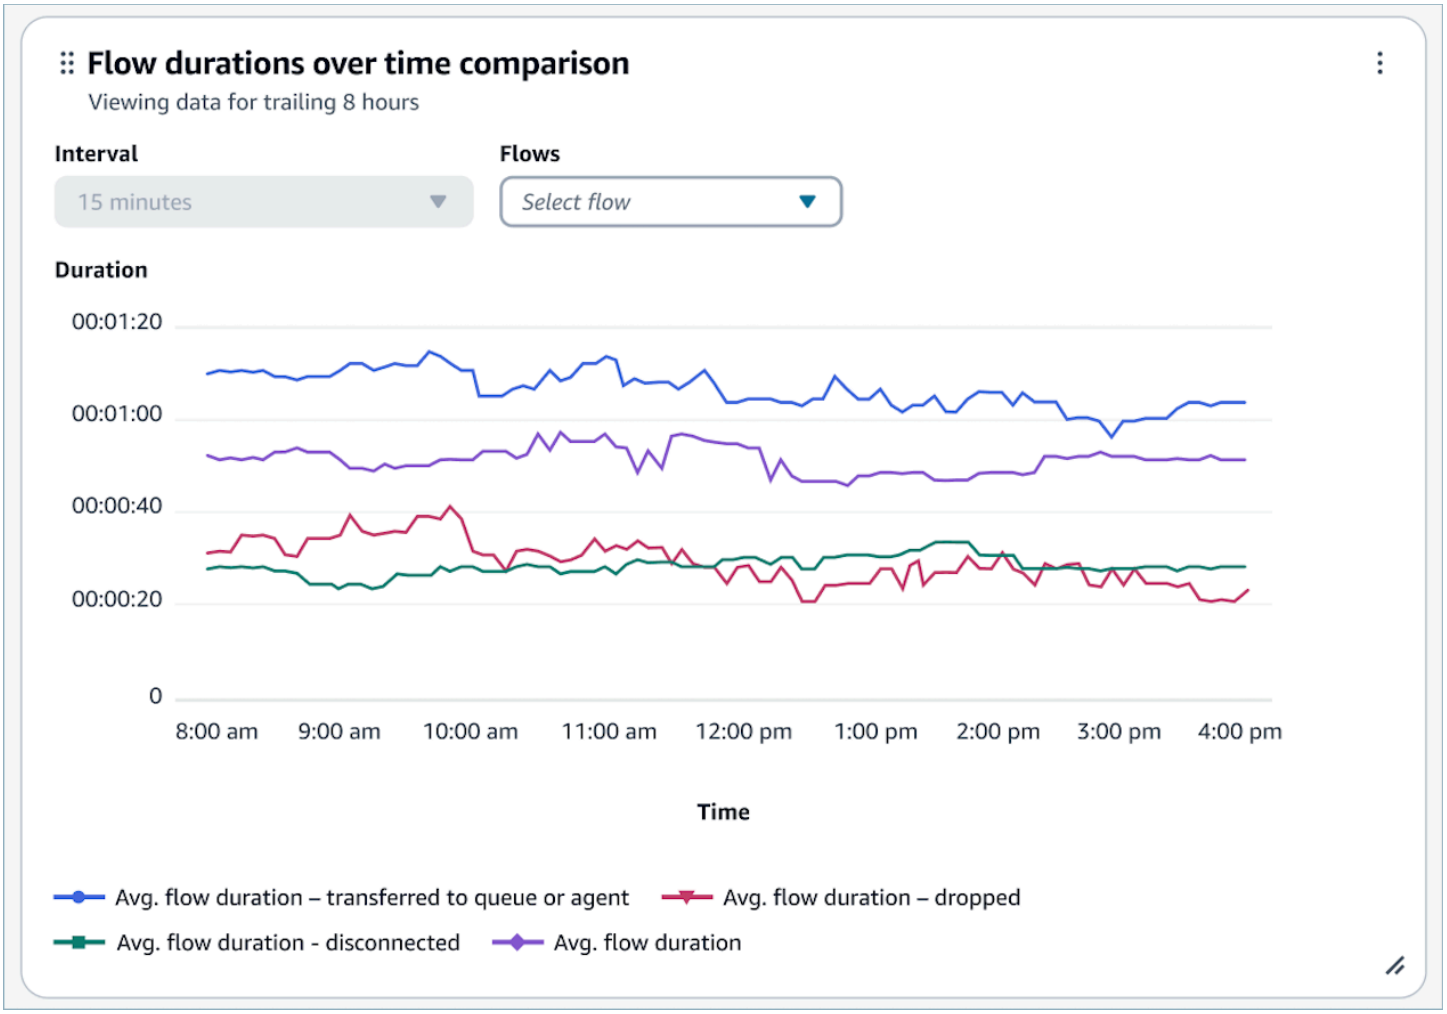
Flow durations over time comparison chart

The **Flow durations over time comparison** chart is a time-series chart that displays the breakdown of Flow duration metrics for a single flow or multiple flows over a given time period and broken down by intervals (15min, daily, weekly, monthly).

You can configure different time range intervals by using the "Interval" button directly in the widget. The intervals that you select depend on the page-level time range filter.

For example:

- If you have a "Today" time range filter at the top of your dashboard, you can only see an interval of 15min for the last 24 hours.
- If you have a "Day" time range filter at the top of your dashboard, you can see a trailing 8 day interval trend, or a 15min interval trend for the trailing 24 hours.



Flows and Flow modules overview tables

The **Flows** and **Flow modules** overview tables display a snapshot of metrics aggregated over the selected time range. The following image shows an example of the **Flows** overview table.

Flows

Viewing data for trailing 8 hours

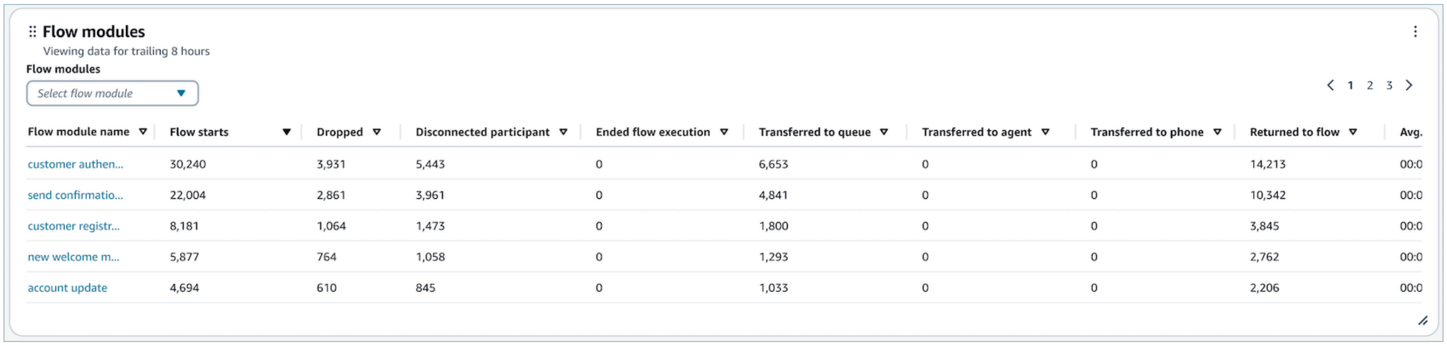
Flows

Select flow

< 1 2 3 4 5 >

Flow name	Flow starts	Dropped	Disconnected participant	Ended flow execution	Transferred to queue	Transferred to agent	Transferred to phone	Transferred to flow	Av
new credit card r...	40,000	3,929	1,200	0	8,741	0	0	26,130	0C
account recovery...	27,500	1,134	492	0	1,845	0	0	24,029	0C
check account...	18,432	956	2,119	0	7,232	0	0	8,125	0C
login	17,556	899	510	0	322	0	0	15,825	0C
account cancel...	16,512	538	679	0	8,407	0	0	6,888	0C

The following image shows an example of the **Flow modules** overview table.



The following metrics are displayed on these tables:

- **Flow / flow module starts:** The count of flows that started execution within the specified start time and end time. For a given start and end time it will show the count of those flows whose start time is between the start and end interval specified.
- **Flow outcomes:** The count of flows that started execution within the specified start time and end time and ended with a specified mutually exclusive and exhaustive flow outcome.
- **Avg Flow Durations by outcome:** The average flow duration for the specified start time and end time with a specified mutually exclusive and exhaustive flow outcome.

Dashboard functionality limitations

The following limitations apply to the Flows performance dashboard:

- Tag-based access controls are not currently supported by the dashboard. You can restrict access through the Dashboard permissions pertaining to a security profile.
- No support for metrics on flows that are type Customer hold and Agent hold. For customer hold metrics, see Historical metrics definitions in Amazon Connect.

Outbound campaigns performance dashboard

You can use the outbound campaigns performance dashboard to understand the performance of your outbound campaigns across your email, SMS, and telephony delivery modes. You can view and compare campaigns performance over a configurable period of time using key metrics such as delivery attempts, delivered rate, human answered rate, campaign contact abandoned rate, spam, bounces and more.

Contents

Enable access to the dashboard

Ensure users are assigned the appropriate security profile permissions:

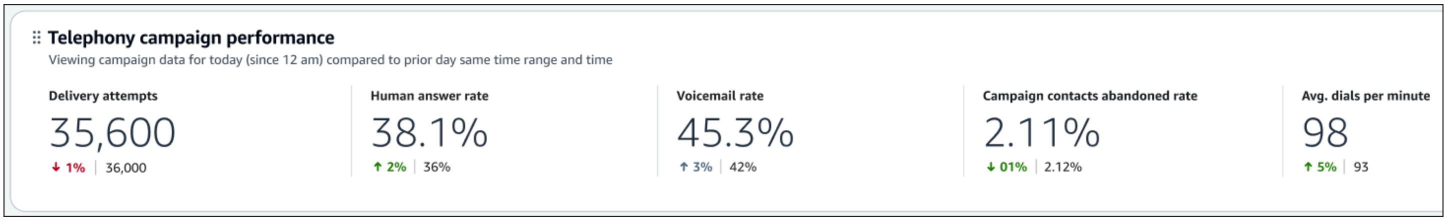
- **Access metrics - Access** permission or the **Dashboard - Access** permission. For information about the difference in behavior, see Assign security profile permissions for dashboards in Amazon Connect.
- **Outbound Campaign - Campaigns - View** permission: This permission is required to view outbound campaigns data on the dashboard.

Campaign performance overview chart

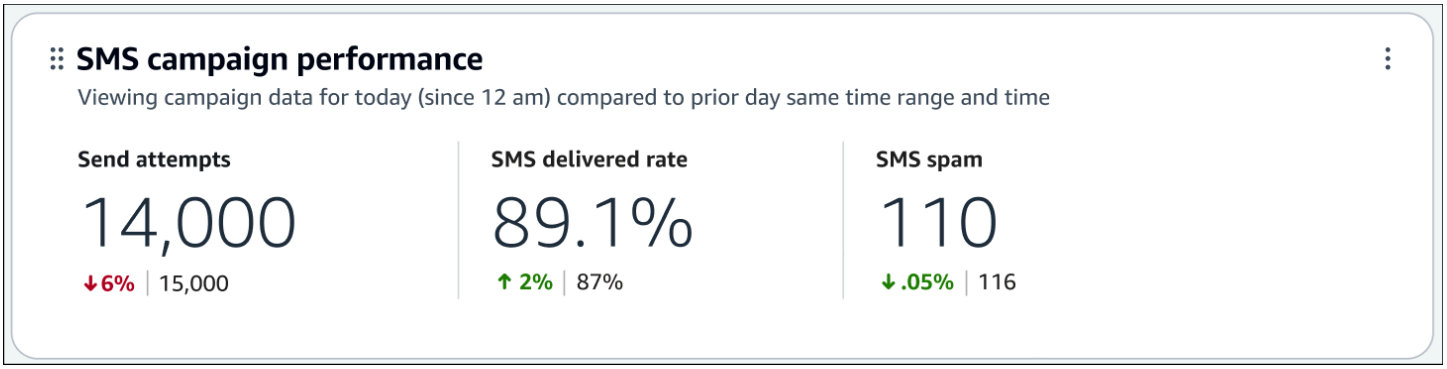
The Campaign performance overview chart provides aggregated metrics based on your filters. Each metric within the chart is compared to your "compare to" benchmark time range filter.

The following image shows an example chart for a telephony campaign. It shows the following information:

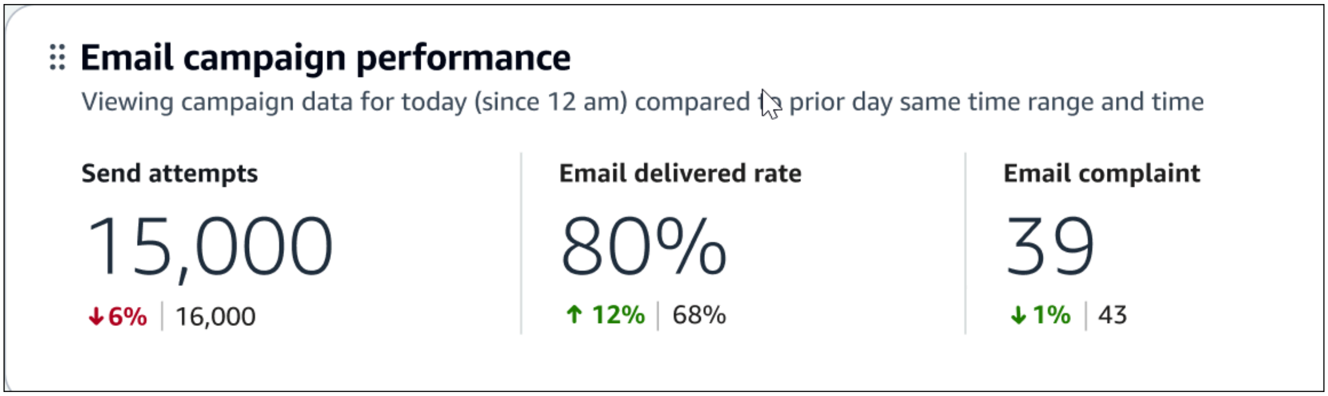
- Delivery attempts during your time range selection was 35,600 which is down 1% compared to your benchmark of Prior day same time range and time with 36,000
- The percentages are rounded up or down.
- The colors that appear for the metrics indicate positive (green) or negative (red) compared to your benchmark.



The following image shows an example chart for an SMS campaign.



The following image shows an example chart for an email campaign.



The charts include the following metrics:

- **Delivery attempts**: The count of outbound campaign contacts dialed by the Amazon Connect dialer.
- **Human answer rate**: The count of outbound campaign calls that were connected to a live customer divided by total dials attempted. This metric is only available with answering machine detection enabled.
- Voicemail with beep rate: The count of outbound voice campaign contacts that were answered by a voicemail with a beep divided by total Dials attempted. This metric is only available with answering machine detection enabled.

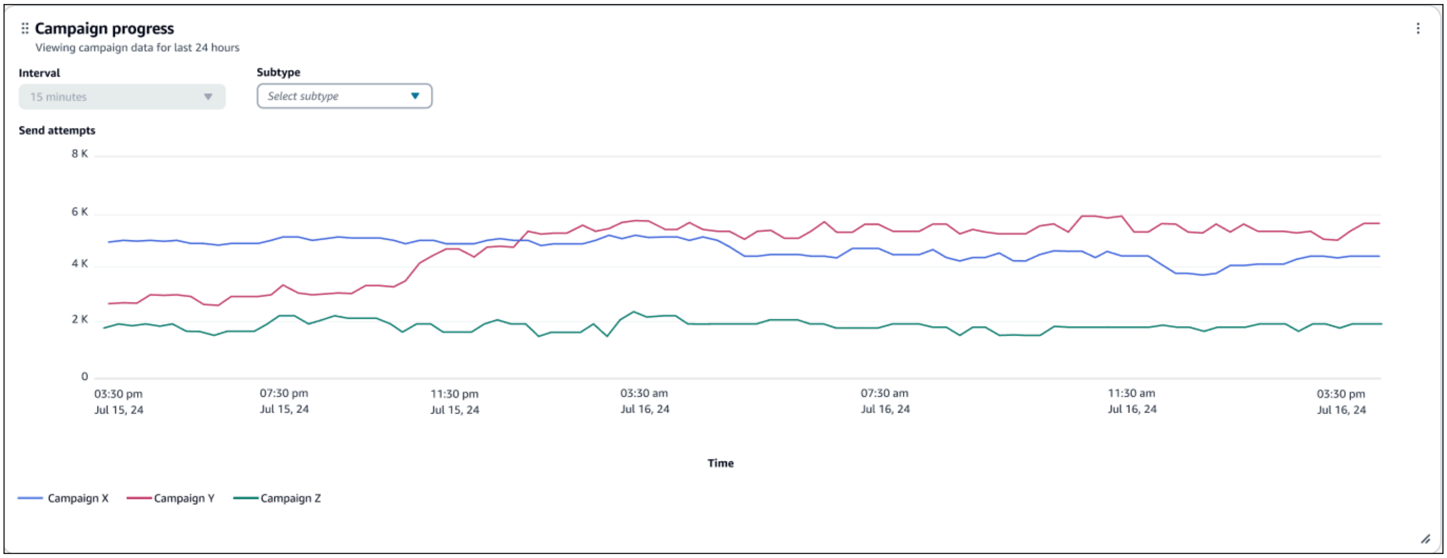
- **Voicemail rate**: The count of outbound campaign calls that were answered by a voicemail divided by total dials attempted. This metric is only available with answering machine detection enabled.
- **Campaign contacts abandoned after 2 seconds rate**: The percentage of outbound campaign calls that were connected to a live customer but did not get connected to an agent within 2 seconds, divided by the count of outbound campaign calls that were connected to a live customer. This metric is only available with answering machine detection enabled.
- **Avg. dials per minute**: The average of outbound campaign contacts dialed per minute by the Amazon Connect dialer.
- **Send attempts**: The count of outbound campaign send requests sent by Amazon Connect for delivery. A campaign send request represents an attempt made to reach out to an recipient by email, SMS, or a telephony dial.
- **Delivered rate**: The percentage of delivered and successful messages over the total number of outbound campaign send attempts.
- **Spam**: The count of SMS messages identified as spam by the mobile carrier.
- **Complaint**: The count of email messages reported as spam or unsolicited email by the recipients.

> **Note**
>
> By default, data for deleted campaigns won't appear in the dashboard. The Performance overview chart includes data from deleted campaigns when there is no campaign filter selected. You can apply a campaign filter to filter out deleted campaign data.

Campaign progress over time chart

The Campaign progress chart is a time-series chart that displays the Dials attempted metric per campaign over a specific time period broken down by intervals (15min, daily, weekly, monthly).

To configure different time range intervals, choose **Interval**, as shown in the following image.



The available intervals depend on the page-level time range filter at the top of the page. For example:

- If you have a **Trailing** time range filter at the top of your dashboard, you can only see an interval of 15min for the last 24 hours.
- If you have a **Day** time range filter at the top of your dashboard, you can see a trailing 8 day interval trend, or a 15min interval trend for the trailing 24 hours.

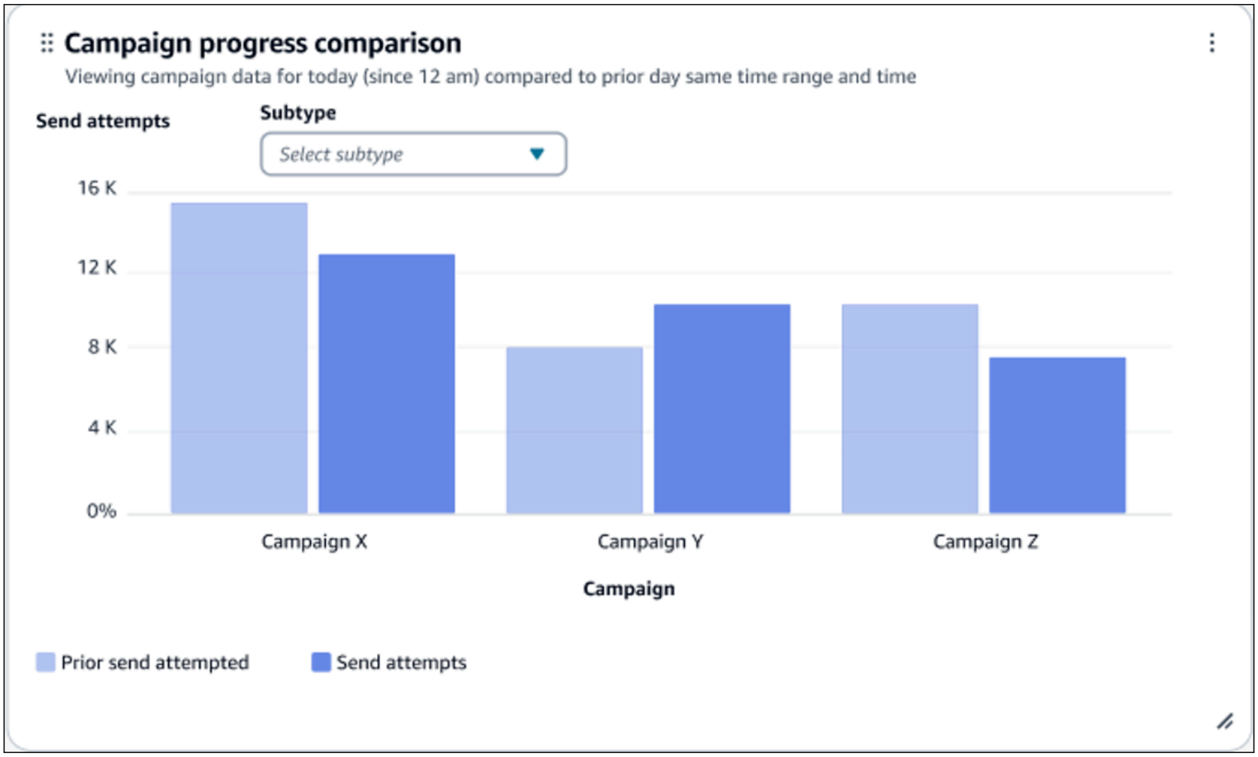
You can use the Subtype filter to select the type of campaign delivery mode you want to track. This filter applies only to the widget.

This widget holds up to 5 campaigns sorted in alphabetical order. If you are filtering for more than 5 campaigns, additional campaigns will not display in the visualization. You can select specific campaign(s) you want to see in this visual by using the campaign filter.

Campaign progress comparison chart

The Campaign progress comparison chart shows the Send attempts metric in its current period broken down by campaign, compared to the Prior send attempted metric from the "compare to" benchmark time range selected. You can use the Subtype filter to select the type of campaign delivery mode you want to track. This filter applies only to the widget. This chart is sorted by Send attempts in descending order from left to right.

This widget holds up to 10 campaigns. If you are filtering for more than 10 campaigns, additional campaigns will not display in the visualization. You can select specific campaign(s) you want to see in this visual by using the campaign filter.



Delivery classification stacked bar charts

The Telephony, SMS, and Email classification by campaign charts drill down into the delivery outcomes of each delivery attempt for each campaign delivery mode. The charts show the count of each delivery classification across a campaign.

Telephony classification stacked bar chart

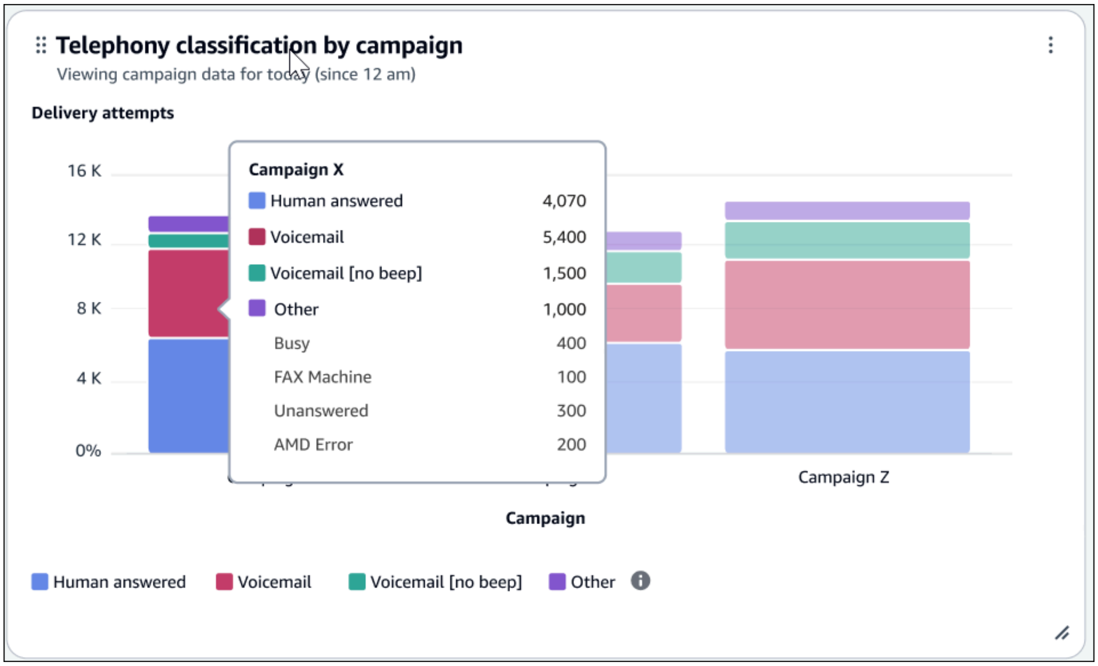
This chart shows the telephony classifications that include the following AMD (Answering Machine Detection) statuses:

- Human answered
- Voicemail with beep
- Voicemail with no beep
- AMD unanswered
- AMD unresolved
- AMD not applicable

- Any remaining classifications grouped under Other

For the full list of available telephony classifications, see DisconnectReason for outbound campaigns and AnsweringMachineDetectionStatus in the [ContactTraceRecord](). This chart is most effective with [answering machine detection enabled]().

The following image shows a sample Telephony classification stacked bar chart.



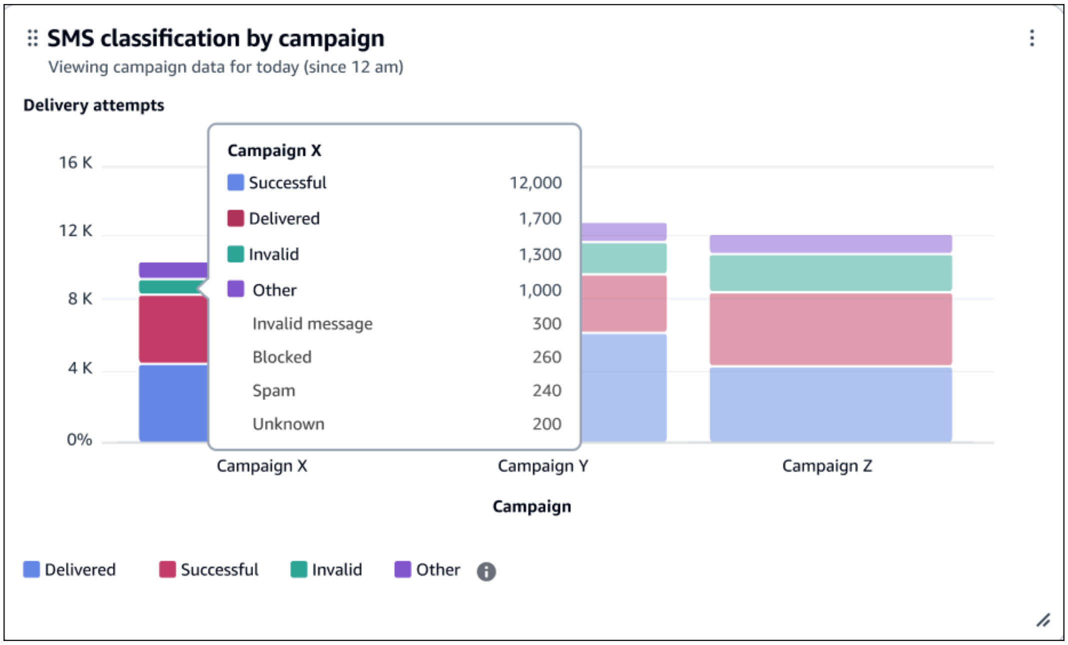
SMS classification stacked bar chart

This chart shows the following delivery outcomes:

- Delivered
- Successful
- Invalid
- Any remaining classifications—such as Invalid message, Blocked, and Spam—are grouped under Other.

For the full list of available SMS events, see `campaign_event_type` in the [Outbound campaign events]() table.

The following image shows a sample SMS classification stacked bar chart.



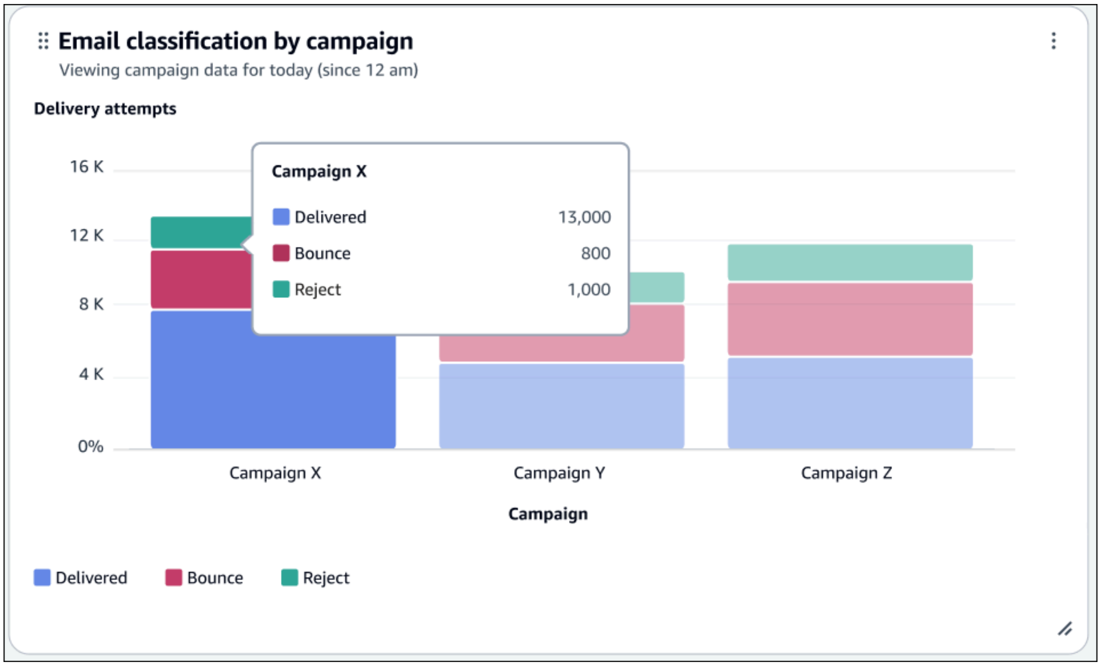
Email classification stacked bar chart

The Email classifications displayed include the following delivery outcomes:

- Delivered
- Bounce
- Reject
- any remaining classifications grouped under Other

For the full list of available email events, see `campaign_event_type` in the [Outbound campaign events](#) table.

The following image shows a sample Email classification stacked bar chart.



Campaign metrics table

A detailed view of outbound campaigns metrics aggregated over the selected time range.

Campaign metrics (3)

Viewing campaign data for today (since 12 am)

Campaign name	Campaign send attempts	Human answered	Voicemail	Campaign contacts abandoned rate	Blocked	Spam	Bounce	Unsubscribed
Campaign X	21,000	4,070	5,400	2.3%	1,730	1,330	300	50
Campaign Y	32,000	4,510	6,900	2.9%	1,990	990	900	120
Campaign Z	12,600	4,950	6,300	1.5%	1,500	1,250	500	76

This table includes the following metrics.

- **Campaign send attempts**: The count of outbound campaign send requests sent by Amazon Connect for delivery. A campaign send request represents an attempt made to reach out to an recipient using email, SMS, or a telephony dial.
- **Human answered**: The count of outbound campaign calls that were connected to a live customer. This metric is only available with answering machine detection enabled.
- **Voicemail**: The count of outbound campaign calls that reached a voicemail. This metric is only available with answering machine detection enabled.
- Voicemail with beep: The count of outbound voice campaign contacts that reached a voicemail with beep. This metric is only available with answering machine detection enabled.

- Voicemail with no beep: The count of outbound voice campaign contacts that reached a voicemail with no beep. This metric is only available with answering machine detection enabled.
- Campaign contacts abandoned after 2 seconds: The count of outbound voice campaign contacts that were connected to a human but did not get connected to an agent within 2 seconds. This metric is only available with answering machine detection enabled.
- Avg. dials per minute: The average of outbound voice campaign contacts dialed per minute by the Amazon Connect voice dialer within the selected time range filter.
- **Campaign contacts abandoned after 2 seconds**: The count of outbound voice campaign calls that were connected to a human but did not get connected to an agent within 2 seconds. This metric is only available with answering machine detection enabled.
- **SMS successful**: The count of SMS messages successfully accepted by the recipient's carrier.
- **SMS delivered**: The count of SMS messages delivered to the specified location.
- **SMS delivered total**: The total count of SMS messages delivered to the specified location and successfully accepted by the recipient's carrier. Whether a message results in a "delivered" or a "successfully" outcome depends on the country where the delivery is taking place. It is not possible to have both a delivered and successfully outcome for the same message.
- **SMS spam**: The count of sms messages identified as spam by the mobile carrier.
- **Email delivered**: The count of email messages delivered.
- **Email complaint**: The count of email messages reported as spam or unsolicited email by the recipients.
- **Email rejected**: The count of email messages with malware detected and got rejected.
- **Email opened**: The total number of times the email message was opened.
- **Email clicked**: The total number of times the email message was clicked.

Dashboard functionality limitations

The following limitations apply to the Outbound campaigns performance dashboard:

- Tag-based access controls are not currently supported by the dashboard. You can restrict access through the Dashboard permissions pertaining to a security profile.
- Data for this dashboard is available starting from June 25, 2024 0:00:00 GMT for the Telephony delivery mode and November 6, 2024 0:00:00 GMT for the Email and SMS delivery modes. This may impact dashboard functionalities such as monthly benchmarks where data won't be available prior to June 25, 2024 0:00:00 GMT or November 6, 2024 0:00:00 GMT for comparison.

- Saved reports before November 6, 2024 0:00:00 GMT could contain stale data due to newly added feature enhancements. To ensure you have accurate data from the latest features, we recommend replacing any saved dashboards with the most recent version of the Outbound campaigns performance dashboard.

Queue and agent performance dashboard in Amazon Connect

The **Queue and agent performance** dashboard helps you understand the performance of your queues and agents compared over configurable periods of time. It uses key metrics such as contacts handled, service level, and average handle time.

This dashboard includes real-time statistics such as number of agents online and current agent activity. It has the capabilities and metrics that are available on the **Real-time metrics** page.

Contents

Enable access to the dashboard

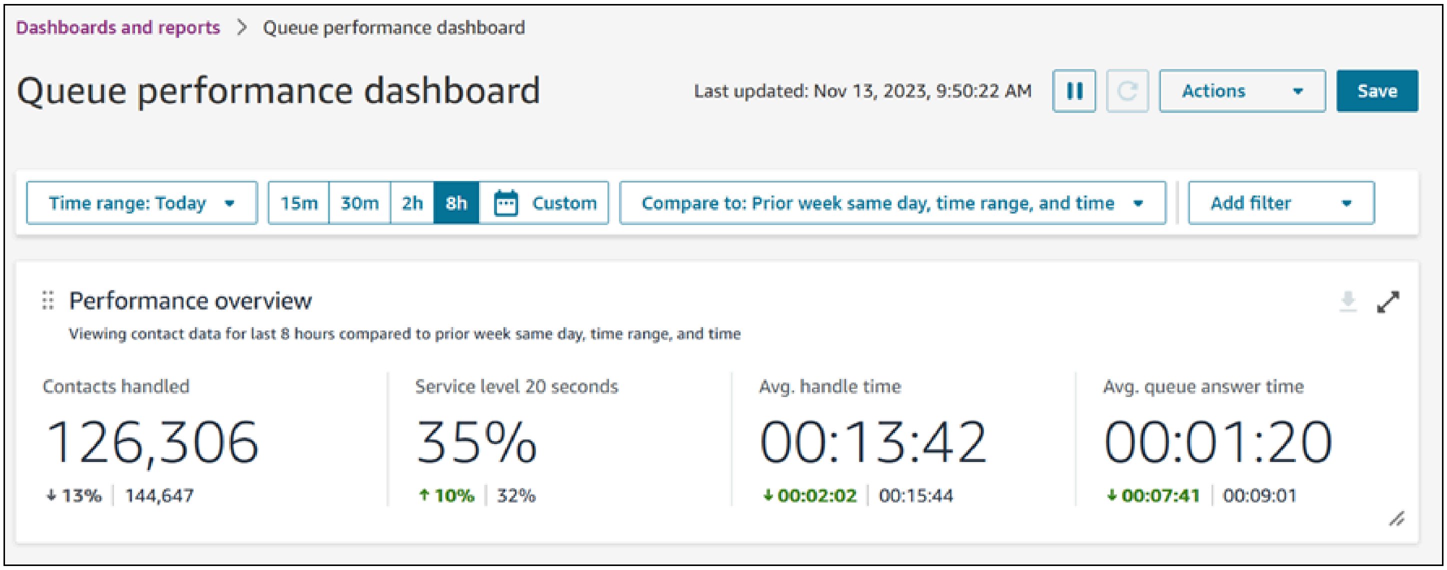
Ensure users are assigned the appropriate security profile permissions:

- **Access metrics - Access permission** or the **Dashboard - Access permission**. For information about the difference in behavior, see Assign security profile permissions for dashboards in Amazon Connect.

Performance overview chart

The **Performance overview** chart that provides aggregated metrics based on your filters. Each metric within the chart is compared to your "compare to" benchmark time range filter.

The following image shows an example **Performance overview** chart:

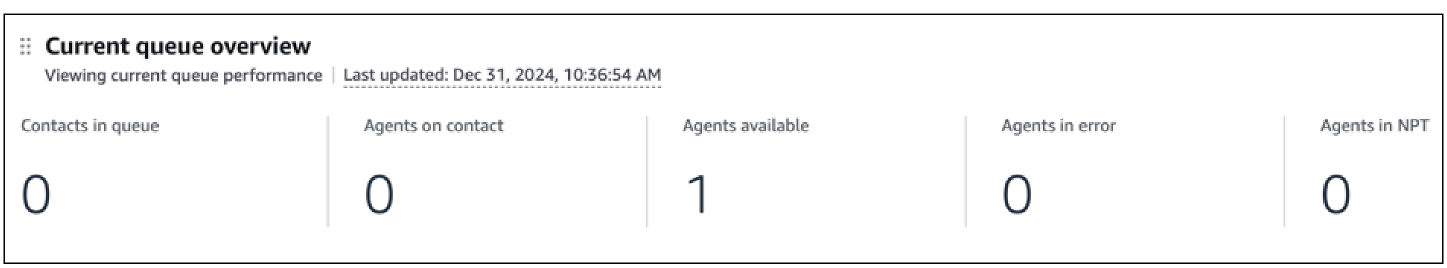


- **Contacts handled** during your time range selection was 126,306, which is down ~13% compared to your benchmark number of contacts handled, 144,647 contacts.
- The percentages are rounded up or down.
- The colors that appear for the metrics indicate positive (green) or negative (red) compared to your benchmark.
- There are no colors for **Contacts handled**.

Current queue overview

The **Current queue overview** widget provides real-time snapshot metrics that display what is happening right now in your queues. You can configure this widget in multiple ways including changing the metrics (but only to real-time queue metrics), configuring the queues that are included, and re-ordering the metrics.

The following image shows an example **Current queue overview**.



Current agent performance

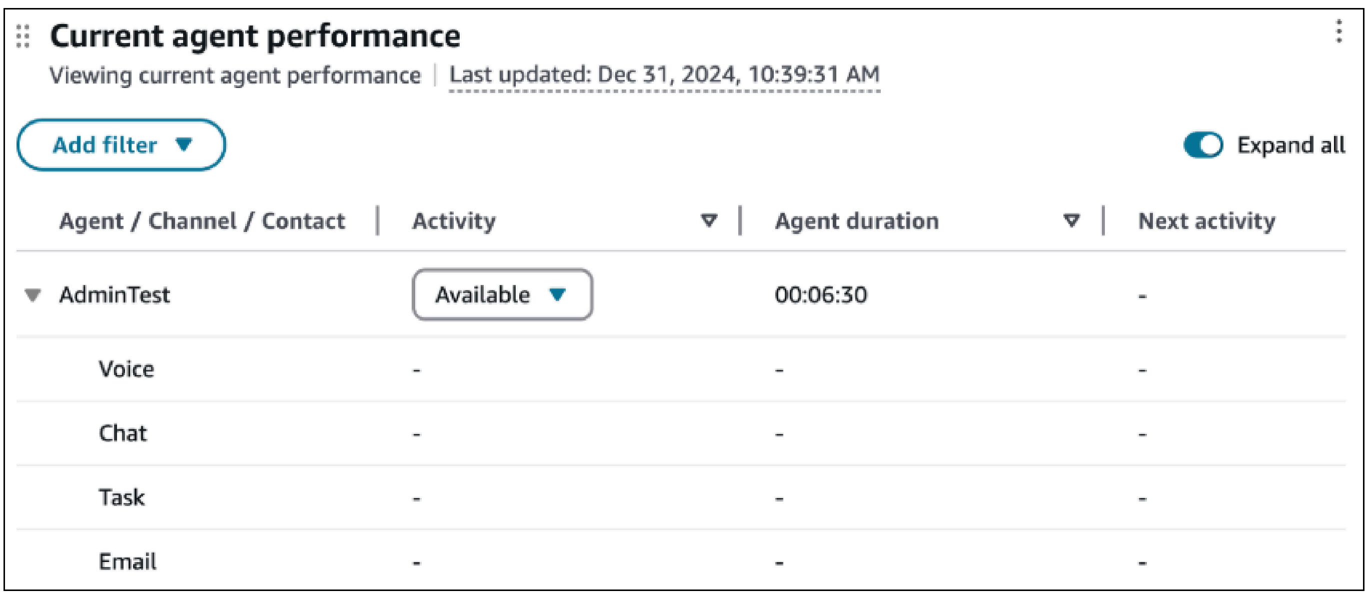
The **Current agent performance** widget provides a real-time view of what agents are doing (equivalent to the real-time metrics page agent widget) including time in status, current active contacts, and the next activity.

By default, this widget collapses the rows to give you an at a glance view of what agents are doing. Choose **Expand all** to automatically expand all the rows for a complete view of agent performance.

With the appropriate security profile permissions, from this widget you can listen in to contacts and change agent statuses within this widget (similar to the real-time metrics page).

> **Note**
>
> You can't change the grouping of this widget.

The following image shows an example **Current agent performance**.



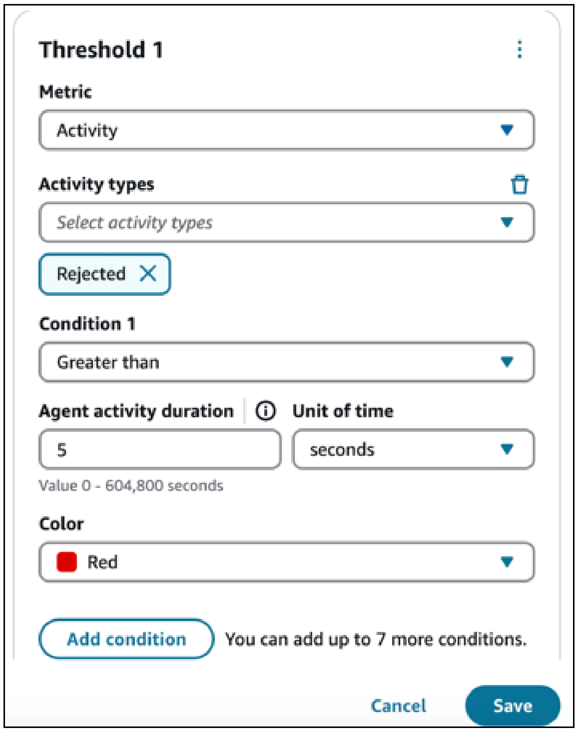
Thresholds

You can also set thresholds on this widget, but several of the metrics behave slightly differently. For agent activity you need to select two conditions:

- What the activity type is (for example, rejected)
- The duration of that activity

You configure custom thresholds based on the state. For example, you can define a cell that should flip to red if an agent is in missed call state for more than 5 seconds but also only flip to red if an agent is on hold for more than 5 minutes.

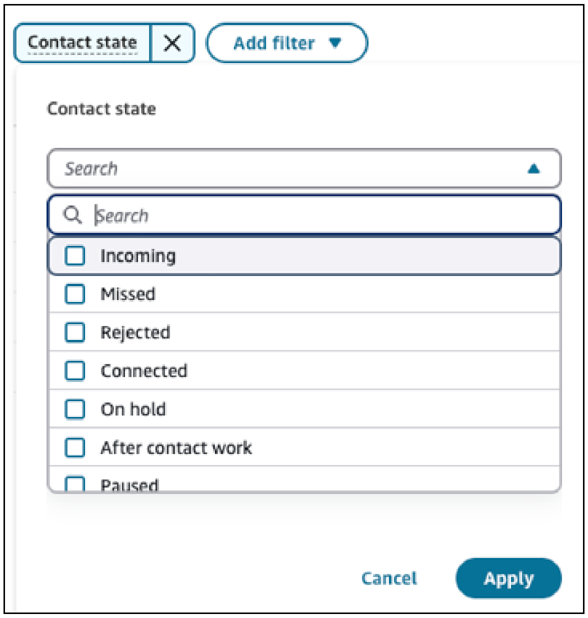
The following image shows an example of thresholds set on the **Activity** metric.



Contact state filtering

You can filter by contact states to identify specific agents who have a contact within a specific state. For example, if you want to quickly identify agents who have a contact in error and can't be routed additional contacts, you can filter for "Missed" and "Rejected" to identify those agents and change their status.

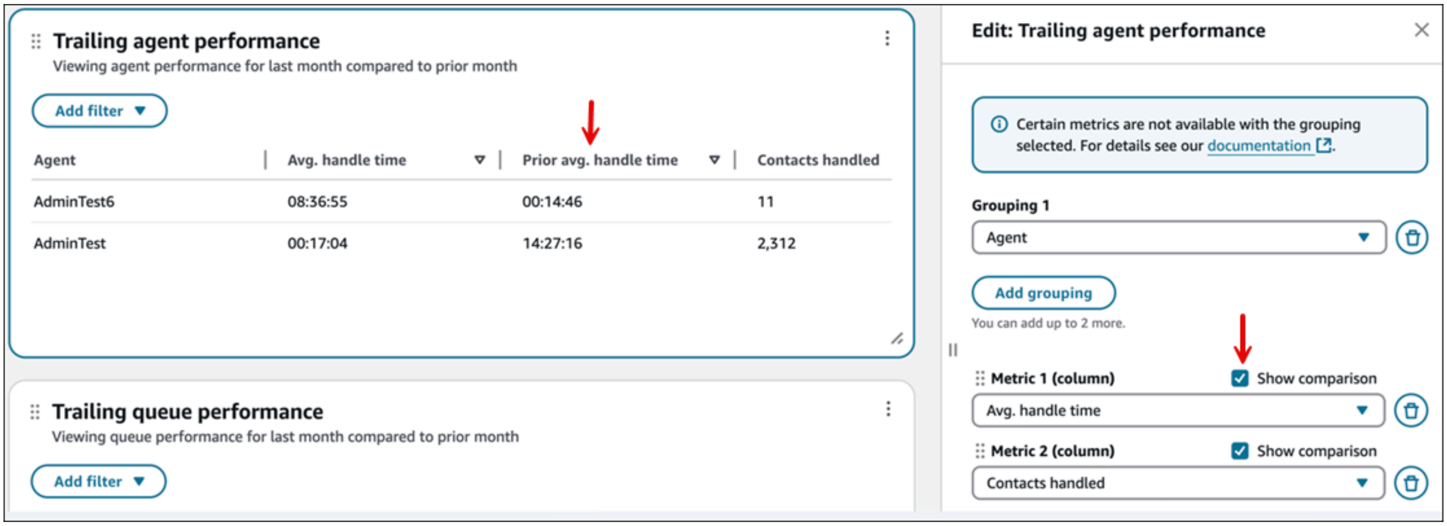
The following image shows a list of some of the filters available for contact states.



Trailing agent performance

This table provides a historical view of performance over time.

To see how your performance compares to the previous time range, choose **Actions**, **Edit**. On the **Edit** pane, choose **Show comparison**, as shown in the following image.



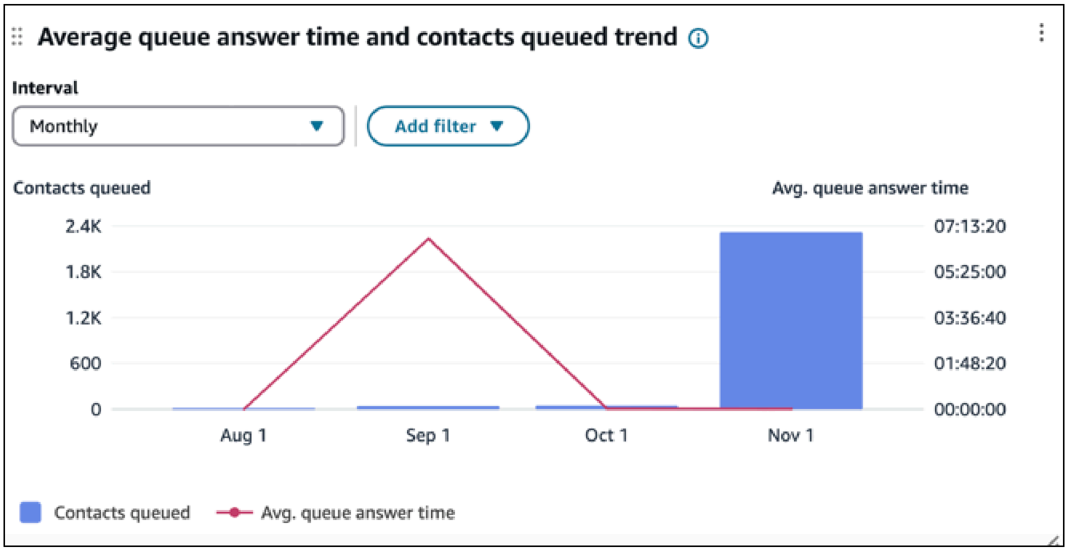
You can also change the metrics, configure thresholds, or re-order metrics.

Average queue answer time and contacts queued trend

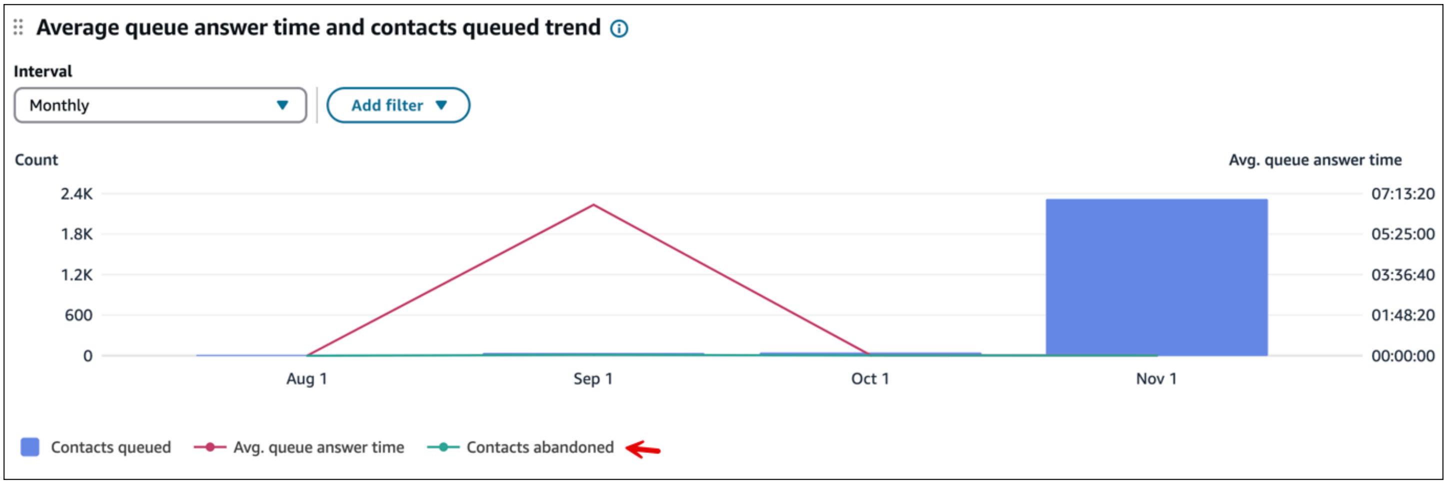
The **Average queue answer time and contacts queued trend** is a time-series chart that displays the count of contacts queued (blue bars) and the average queue answer time (red line) over a given time period broken down by intervals (15min, daily, weekly, monthly). You can also change the metrics and add up to four different metrics as line graphs.

> **Note**
>
> This widget can support a maximum of two metric types (count, time, percentage).

The following image shows the Contacts queued (blue bars) and Avg queue answer time (red line), for four months.



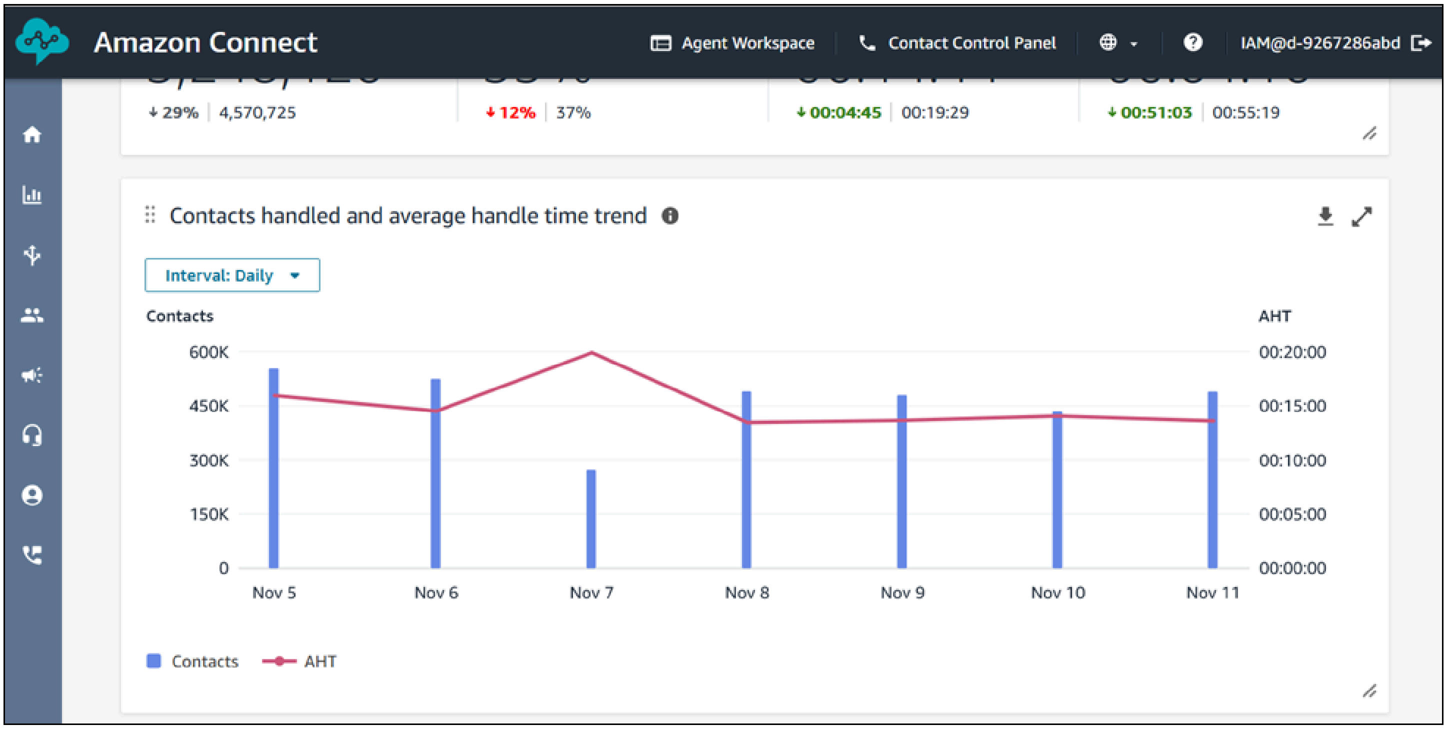
This next image shows the same data, but with the addition of the **Contacts abandoned** (green) filter.



Contacts handled and average handle time trend

The **Contacts handled and average handle time trend** is a time-series chart that displays the count of contacts handled (blue bars) and the average handle time (red line) over a given time period broken down by intervals (15min, daily, weekly, monthly).

To configure different time range intervals, choose **Interval**, as shown in the following image.



The available intervals depend on the page-level time range filter, which is set at the top of the page. For example:

- If you have a "Today" time range filter at the top of your dashboard, you can only see an interval of 15min for the last 24 hours.
- If you have a "Day" time range filter at the top of your dashboard, you can see a trailing 8 day interval trend, or a 15min interval trend for the trailing 24 hours.

Dashboard functionality limitations

The following limitations apply to the Queue performance dashboard:

- Tag-based access controls are not supported on the dashboard.

Intraday forecast performance dashboard

The Intraday forecast performance dashboard provides forecasts for:

- Contact volume and Average handle time for queues that have a minimum of 2000 unique contacts per week per queue-channel for the last 4 weeks.
- Average queue answer time for queues that have 5000 unique contacts per month.

Contents

Enable access to the dashboard

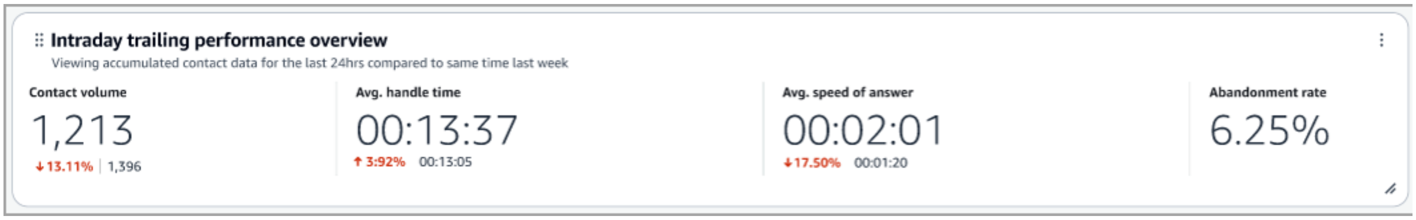
Ensure users are assigned the appropriate **Analytics and Optimization** security profile permissions:

- **Access metrics - Access permission** or the **Dashboard - Access permission**. For information about the difference in behavior, see Assign security profile permissions for dashboards in Amazon Connect.
- **Forecasting - View**. If you don't see this permission on the security profiles page, ask your Administrator to enable forecasting, capacity planning, and scheduling in the AWS console.

Performance overview chart

The **Intraday trailing performance overview** chart that provides aggregated metrics based on your filters. Each metric in the chart is compared to your "compare to" benchmark time range filter.

The following image shows an example **Intraday trailing performance overview** chart:



This chart shows the following information:

- Contact volume during your time range selection was 1,213.
- This is down ~13% compared to your benchmark number of contacts handled.
- The percentages are rounded up or down.
- The colors that appear for the metrics indicate positive (green) or negative (red) compared to your benchmark.

Comparison trend graphs

The Intraday performance dashboard displays the following three trend graphs, which cover different metrics:

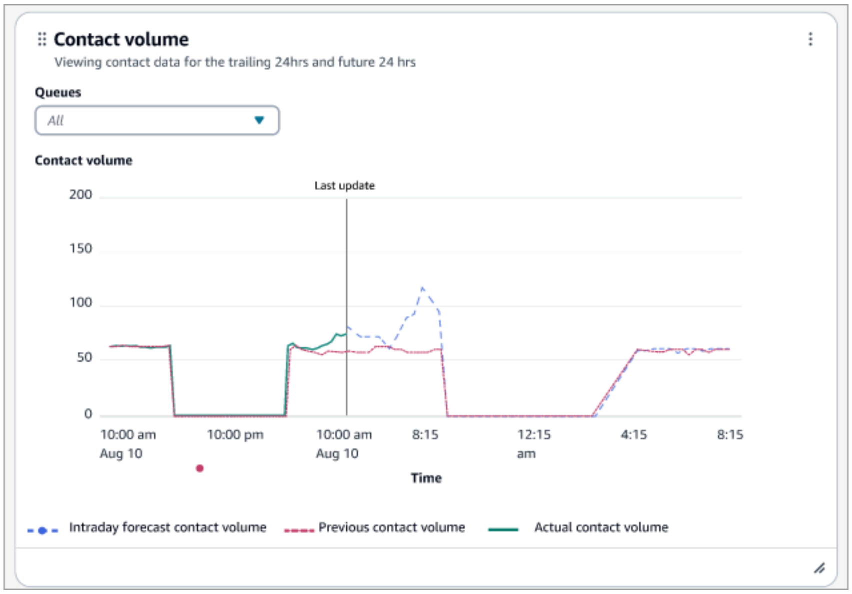
- Contact volume
- Average handle time
- Average speed of answer
- Effective staffing

These graphs include the intraday forecast that projects up to 24 hours on a 15 minute interval based on:

- The value of the respective metric.
- The historical actuals from the current day.
- The historical actuals from the same time in the past week.

These trend graphs provide data only for the next 24 hours and the past 24 hours. There is no option to change the time range.

The following image shows an example of a **Contact volume** trend graph.



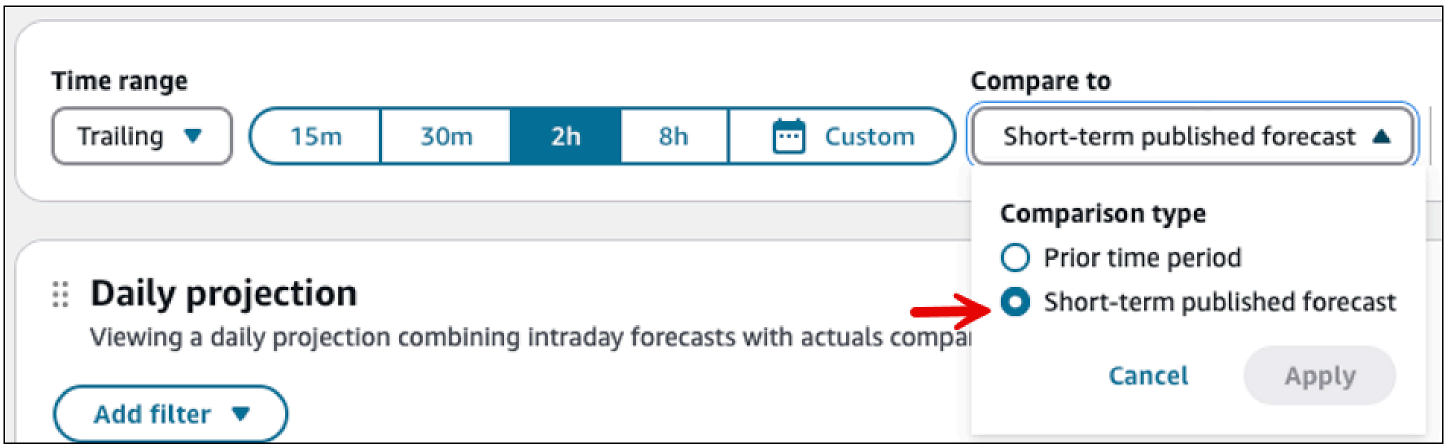
Comparison against short term forecasts

You can compare **Average handle time** and **Contact volume** against published short term forecasts.

To select this option, choose the compare to button and select **Short-term published forecast**. This automatically picks up the published short term forecast for the time range selected. You can't select an unpublished forecast or a specific published forecast.

For historical widgets, it compares against the same time range as the widget, while for the daily projection widget it compares against the entire day.

This is the new default comparison for this dashboard.



Daily projection chart

The **Daily projection** chart provides a projection of how the day will end by combining historical metrics for the day so far with intraday forecasts for the remainder of the day. This is available for the following metrics:

- Average handle time
- Average queue answer time
- Contact volume
- Effective staffing

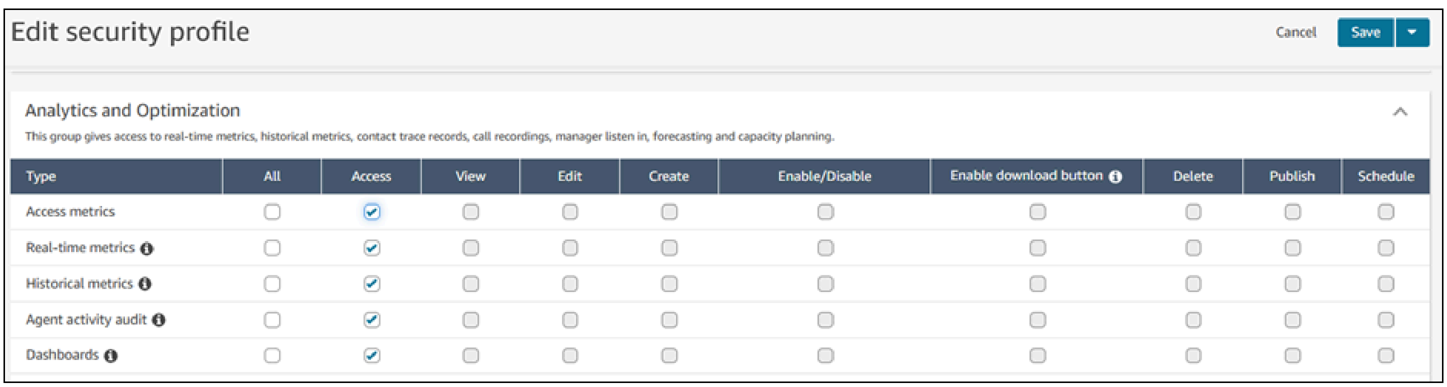
This widget only supports comparing against short term forecasts for **Contact volume** and **Average handle time**.

Assign security profile permissions for dashboards in Amazon Connect

To view dashboards, you need to be assigned to a security profile that has either the **Access metrics – Access** permission or the **Dashboards – Access** permission. Note the following behavior when you assign these permissions:

1. When **Access metrics – Access** is selected, the **Real-time metrics**, **Historical metrics**, **Agent activity audit**, and **Dashboards** permissions are also automatically assigned.
2. When **Access metrics – Access** is assigned, you have access to all real-time and historical metrics reports and dashboards.

The following image shows the **Analytics and Optimization** section of the **Security profile permissions** page. The **Access** option is selected for **Access metrics**, **Real-time metrics**, **Historical metrics**, **Agent activity audit**, and **Dashboards**.



If only **Dashboards** is selected, you have access only to dashboards and no other analytics pages or reports. The following image shows the **Analytics and Optimization** section, with only **Dashboards – Access** selected.

Real-time metrics reports in Amazon Connect

Real-time metrics reports show real-time or near-real time metrics information about activity in your contact center. Metrics such as **Online** show the number of agents currently online in real-time, updating every 15 seconds. Metrics such as **Handled** and **Abandoned** reflect near real-time values for your contact center.

You can customize the reports, specify a time range for each report, select metrics for each report, and select filters for data to include or exclude from each report.

You can also use the Amazon Connect Service APIs to create custom reports, such as real-time reports that are filtered by teams of agents.

Contents

- Change the "Agent activity" status in a metrics report in the Contact Control Panel (CCP)
- Download real-time metrics for Amazon Connect

Real-time metrics definitions in Amazon Connect

The following metrics are available to include in real-time metrics reports in Amazon Connect. The metrics available to include in a report depend on the report type.

> **Tip**
>
> Developers can use the GetCurrentMetricData API to get a subset of the following real-time metrics from the specified Amazon Connect instance.

Abandoned

The count of contacts disconnected by the customer while in the queue during the specified time range. Contacts queued for callback are not counted as abandoned. When you create a customized real-time metrics report, to include this metric, choose a **Queues** report for the type. On the **Filters** tab, choose **Queues**, then on the **Metrics** tab you'll have the option to include **Abandoned**.

Abandonment rate

The percentage of contacts that were disconnected by the customer while in the queue. Contacts queued for callback are not counted as abandoned.

Active

The count of active slots. This number is incremented for each contact where the contact state is either Connected, On Hold, After contact work, Paused, or Outbound ring.

In the GetCurrentMetricData API, this metric can be retrieved by using `SLOTS_ACTIVE`.

ACW

The count of contacts that are in an **AfterContactWork** state. (After contact work is also known as After call work.) After a conversation between an agent and customer ends, the contact is moved into the ACW state.

In the GetCurrentMetricData API, this metric can be retrieved by using AGENTS_AFTER_CONTACT_WORK. The name of this metric is confusing because in the Amazon Connect admin website, ACW counts the number of *contacts* that are in an ACW state, not the number of agents.

To learn more about agent status and contact states, see Agent status in the Contact Control Panel (CCP) and About contact states in Amazon Connect.

Agent Activity

If an agent is handling a single contact, this metric may have the following values: Available, Incoming, On contact, Rejected, Missed, Error, After contact work, or a custom status.

If an agent is handling concurrent contacts, Amazon Connect uses the following logic to determine the state:

- If at least one contact is in Error, Agent Activity = **Error**.
- Else if at least one contact is Missed contact, Agent Activity = **Missed**.
- Else if at least one contact is Rejected contact, Agent Activity = **Rejected**.
- Else if at least one contact is Connected, On Hold, Paused, or Outbound contact/Outbound callback, Agent Activity = **On contact**.
- Else if at least one contact is After contact work, Agent Activity = **After Contact Work**.
- Else if at least one contact is Incoming/Inbound Callback, Agent Activity = **Incoming**.
- Else if agent status is a custom status, Agent Activity is the custom status.
- Else if agent status is Available, Agent Activity = **Available**.
- Else if agent status is Offline, Agent Activity = **Offline**. (After an agent moves to Offline, they disappear from the real-time metrics page in approximately 5 minutes.)

If a manager is using the Manager Monitor feature to monitor a particular agent as they interact with a customer, then the manager's Agent Activity will display as Monitoring. The Agent Activity of the agent who is being monitored is still On Contact.

Agent First Name

The first name of the agent, as entered in their Amazon Connect user account.

Agent Hierarchy

The hierarchy the agent is assigned to, if any.

Agent hung up

The count of contacts disconnected where the agent disconnected before the customer.

Agent Last Name

The last name of the agent, as entered in their Amazon Connect user account.

Agent Name

The name of the agent, displayed as follows: **Agent Last Name**, **Agent First Name**.

Agent non-response

The count of contacts routed to an agent but not answered by that agent, including contacts abandoned by the customer.

If a contact is not answered by a given agent, we attempt to route it to another agent to handle; the contact is not dropped. Because a single contact can be missed multiple times (including by the same agent), it can be counted multiple times: once for each time it is routed to an agent but not answered.

This metric was previously named **Missed**.

Agent non-response without customer abandons

If a contact is not answered by a given agent, Amazon Connect attempts to route it to another agent to handle; the contact is not dropped. Because a single contact can be missed multiple times (including by the same agent), it can be counted multiple times: once for each time it is routed to an agent but not answered.

AHT (Average Handle Time)

The average time, from start to finish, that a contact is connected with an agent (average handle time). It includes talk time, hold time, After Contact Work (ACW) time, and agent pause duration (which applies only to tasks).

AHT is calculated by averaging **the amount of time between the contact being answered by an agent** and **the completion of work on that contact by an agent**.

API contacts handled

The count of contacts that were initiated by an API operation, such as `StartOutboundVoiceContact`, and handled by an agent.

Availability

For each agent, the number of available slots they have that can be routed contacts.

The number of available slots for an agent are based on their routing profile. For example, let's say an agent's routing profile specifies they can handle either one voice contact **or** up to three chat contacts simultaneously. If they are currently handling one chat, they have two available slots left, not three.

What causes this number to go down? A slot is considered unavailable when:

- A contact in the slot is: connected to the agent, in After Contact Work, inbound ringing, outbound ringing, missed, or in an error state.
- A contact in the slot is connected to the agent and on hold.

Amazon Connect doesn't count an agent's slots when:

- The agent has set their status in the CCP to a custom status, such as Break or Training. Amazon Connect doesn't count these slots because agents can't take inbound contacts when they've set their status to a custom status.
- The agent can't take contacts from that channel per their routing profile.

In the GetCurrentMetricData API, this metric can be retrieved by using `SLOTS_AVAILABLE`.

Available

The number of agents who can take an inbound contact. An agent can only take inbound contacts when they manually set their status to Available in the CCP (or in some cases when their manager changes it).

This is different from how many more inbound contacts an agent could take. If you want to know how many more contacts an agent can have routed to them, look at the Availability metric. It indicates how many slots the agent has free.

What causes this number to go down? An agent is considered **unavailable** when:

- The agent has set their status in the CCP to a custom status, such as Break or Training. Amazon Connect doesn't count these slots because agents can't take inbound contacts when they've set their status to a custom status.
- The agent has at least one contact ongoing.
- The agent has a contact in a missed or error state, which prevents the agent from taking any more contacts until they are flipped back to routable.

In the GetCurrentMetricData API, this metric can be retrieved by using `AGENTS_AVAILABLE`.

Average Active Time

The average time, from start to finish, that an agent was working on a contact (average active time). It includes talk time, hold time, and After Contact Work (ACW) time. It applies to both inbound and outbound calls.

Average Active Time does not include any time spent in a custom status; Contact handle time (CHT) does include the time spent in custom status.

Average Agent Pause Time

Average time that the contact was paused after being connected to agent during an inbound or outbound contact.

SUM(agent_pause_time)/Number of Contacts that were paused

This metric applies only to tasks.

Average customer hold time

Average time that customers spent on hold while connected to an agent. This is calculated by averaging CustomerHoldDuration (from the contact record).

Average greeting time agent

This metric represents the average first response time of agents on chat, indicating how quickly they engage with customers after joining the chat. It is calculated by dividing the total time it takes for an agent to initiate their first response by the number of chat contacts.

> **Note**
>
> This metric is available only for contacts analyzed by Contact Lens conversational analytics.

Average interaction time

Total time that agents spent interacting with customers on inbound and outbound contacts. This does not include Customer hold time or After contact work time.

Average interruptions agent

This metric quantifies the average frequency of agent interruptions during customer interactions by dividing the total number of agent interruptions by the total number of contacts.

> **Note**
>
> This metric is available only for contacts analyzed by Contact Lens conversational analytics.

Average non-talk time

Average of total non-talk time in a voice conversation. Non-talk time refers to the combined duration of hold time and periods of silence exceeding three seconds, during which neither the agent nor the customer is engaged in conversation. To calculate non-talk time, we add up all the intervals in which both participants remained silent and then divide this total by the number of contacts.

> **Note**
>
> This metric is available only for contacts analyzed by Contact Lens conversational analytics.

Average resolution time

The average time, beginning from the time a contact was initiated to the time it resolved. The resolution time for a contact is defined as: beginning from InitiationTimestamp, and ending at AfterContactWorkEndTimestamp or DisconnectTimestamp, whichever one is later.

Average talk time

Average time that was spent talking during a voice contact across either the customer or the agent. This is calculated by summing up all the intervals in which either an agent, a customer, or both were engaged in conversation, and then dividing it by the total number of contacts.

> **Note**
>
> This metric is available only for contacts analyzed by Contact Lens conversational analytics.

Avg abandon time

Average time, in seconds, that abandoned contacts were in the queue before being abandoned.

Avg ACW

Average time, in seconds, that contacts spent in the **After contact work** state, during the specified time range.

This is not the average amount of time agents spent on contacts.

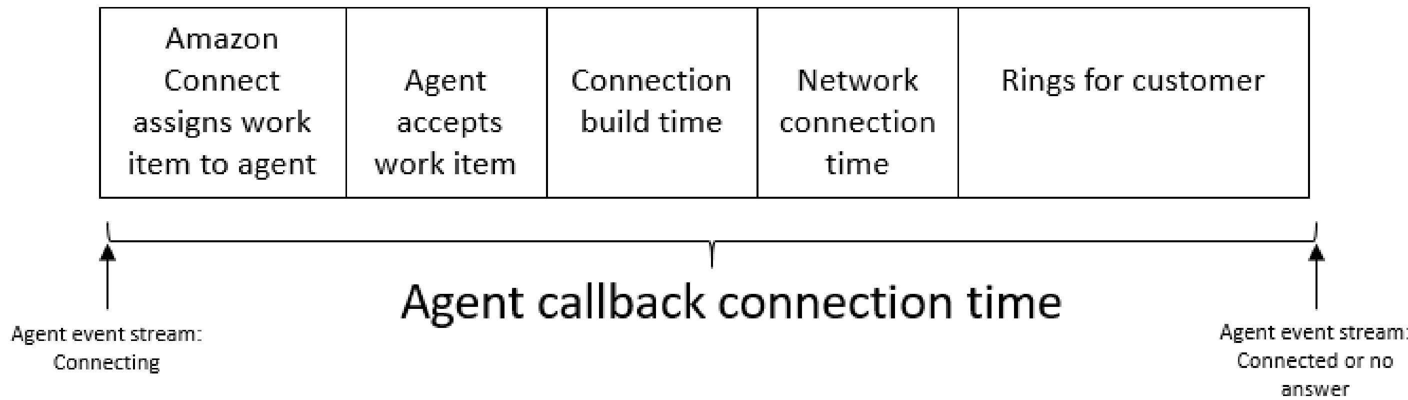
To learn more about agent status and contact states, see Agent status in the Contact Control Panel (CCP) and About contact states in Amazon Connect.

Avg callback connecting time

The average time between when callback contacts are initiated by Amazon Connect reserving the agent for the contact, and the agent is connected.

No equivalent to this metric is available in the GetCurrentMetricData API.

The following image shows the five parts that go into calculating **Avg callback connecting time**: Amazon Connect assign work item to agent, agent accepts work item, connection build time, network connection time, rings for customer. It also shows what is in the agent event stream: Connecting, Connected or no answer.



Avg API Connecting Time

The average time between when a contact is initiated using an Amazon Connect API, and the agent is connected.

Avg hold time

Average time, in seconds, that a contact in the queue was on hold.

This metric doesn't apply to tasks and email so you'll notice a value of 0 on the report for them.

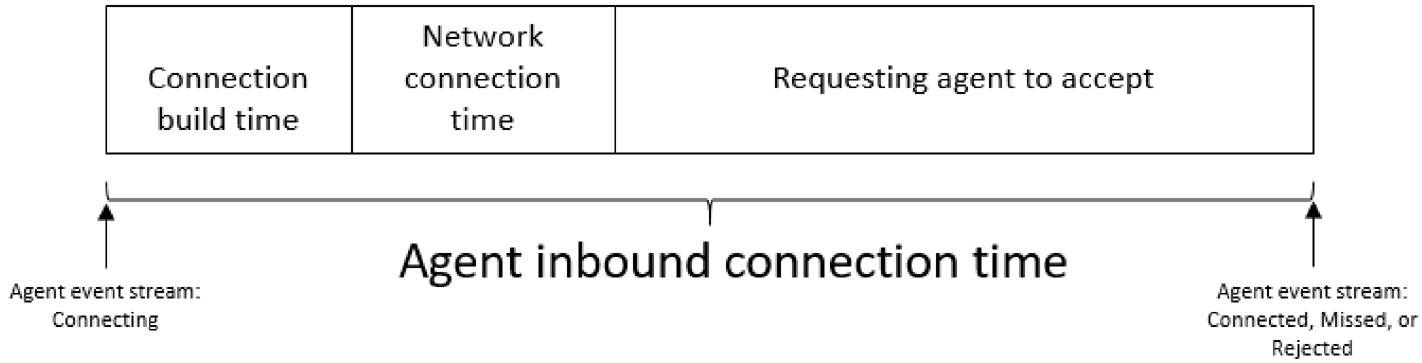
Avg incoming connecting time

The average time between when contacts are initiated Amazon Connect reserving the agent for the contact, and the agent is connected.

In the agent event stream, this time is calculated by averaging the duration between the contact state of STATE_CHANGE event changes from CONNECTING to CONNECTED/MISSED/ERROR.

No equivalent to this metric is available in the GetCurrentMetricData API.

The following image shows the three parts that go into calculating **Avg incoming connecting time**: connection build time, network connection time, and requesting agent to accept. It also shows what is in the agent event stream: Connecting, Connected, Missed, or Rejected.



Avg interaction time

Average time, in seconds, that contacts were connected to and interacting with agents. This does not include hold time, agent pause duration (which applies only to tasks), or time spent waiting in the queue.

Avg interaction and hold time

Average time, in seconds, that contacts in the queue spent interacting with agents and on hold. This is calculated as follows:

Avg hold time + Avg interaction time

Avg queue answer time

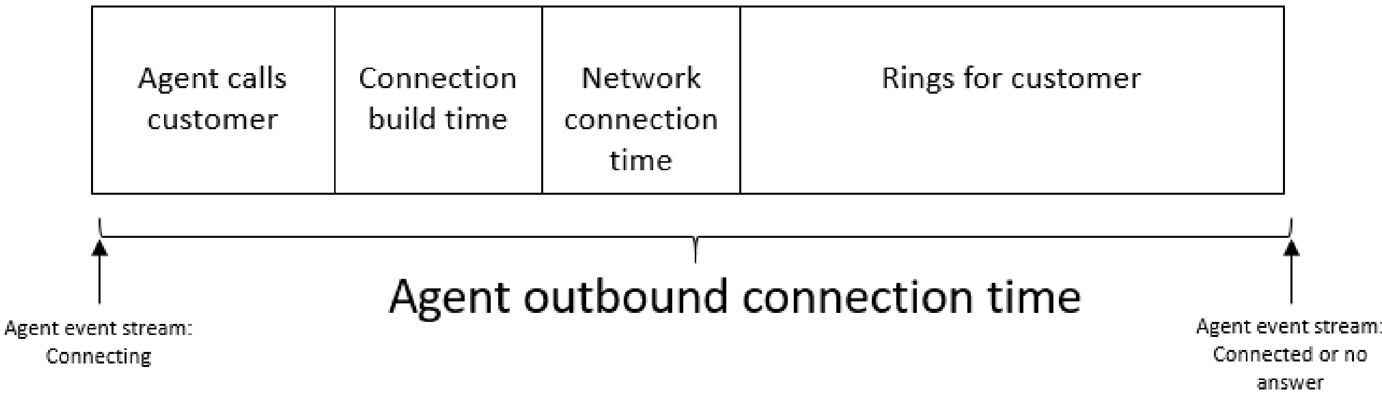
Average time, in seconds, that a contact was in the queue before being answered by an agent. This is calculated using the amount of time that the contact was in the queue, not any time that the contact spent in prior steps of the flow, such as listening or responding to prompts.

Avg outbound connecting time

The average time between when outbound contacts are initiated by Amazon Connect reserving the agent for the contact, and the agent is connected.

No equivalent to this metric is available in the GetCurrentMetricData API.

The following image shows the four parts that go into calculating **Avg outbound connecting time**: agent call customer, connection build time, network connection time, rings for customer. It also shows what is in the agent event stream: Connecting, Connected or No answer.



Callback attempts

The number of contacts where a callback was attempted, but the customer did not pick up.

Callback contacts handled

The count of contacts handled by an agent that were queued callbacks.

Capacity

Displays the maximum capacity that's set in the routing profile currently assigned to the agent. This column can be filtered by channel.

If an agent's routing profile is configured to handle either one voice **or** up to three chats, then their maximum capacity equals three, when not filtered by channel.

Consult

Deprecated May 2019. When used in a report, it returns a dash (-).

The count of contacts in the queue that were handled by an agent, and the agent consulted with another agent or a call center manager during the contact.

Contact State

The state of the contacts the agent is currently handling. The state can be: **Connected**, **On Hold**, **After contact work**, **Paused**, **Incoming**, **Calling**, or **Missed contact**.

For queued callbacks, the contact state can also **Callback incoming** or **Callback dialing**.

If a manager is using the Manager Monitor feature to monitor a particular agent as they interact with a customer, the manager's contact state is Monitoring; the agent's contact state is Connected.

Contacts abandoned in X seconds

The count of contacts disconnected without being connected to an agent for 0 to X seconds.

The preset values for X are: 15, 20, 25, 30, 45, 60, 90, 120, 180, 240, 300, and 600 but you can define a custom duration for this metric such as minutes, hours, or days. The maximum duration for a custom value is 7 days. That's because in Amazon Connect you can't have a contact that goes longer than 7 days.

In the GetMetricDataV2 API, this metric can be retrieved by using `SUM_CONTACTS_ABANDONED_IN_X`.

Contacts answered in X seconds

The count of contacts that were answered by an agent between 0 and X seconds of being placed in the queue, based on the value of EnqueueTimestamp.

The preset values for X are: 15, 20, 25, 30, 45, 60, 90, 120, 180, 240, 300, and 600 but you can define a custom duration for this metric such as minutes, hours, or days. The maximum duration for a custom value is 7 days. That's because in Amazon Connect you can't have a contact that goes longer than 7 days.

In the GetMetricDataV2 API, this metric can be retrieved by using `SUM_CONTACTS_ANSWERED_IN_X`.

Contacts transferred out

The count of contacts transferred out from queue to queue, and transferred out by an agent using the CCP.

Duration

Amount of time that the agent has been in the current Agent Activity State.

Error

A count of agents in Error state. An agent is included in this metric if they miss a call or reject a chat/task (most common). They could also be counted if there is a connection failure.

In the GetCurrentMetricData API, this metric can be retrieved by using `AGENTS_ERROR`.

Handled

The count of contacts in the queue that were answered by an agent.

Handled in

The count of incoming contacts handled by an agent during the specified time range that were initiated using one of the following methods: inbound call, transfer to agent, transfer to queue, or queue-to-queue transfer.

Handled out

The count of contacts handled by an agent during the specified time range that were initiated by an agent placing an outbound call using the CCP. All calls made by agents are counted in, as long as they use the CCP, a custom CCP or other client app that use the Amazon Connect Streams API.

Hold abandons

The count of contacts that disconnected while the customer was on hold. A disconnect could be because the customer hung up while on hold, or that there was a technical issue with the contact while on hold.

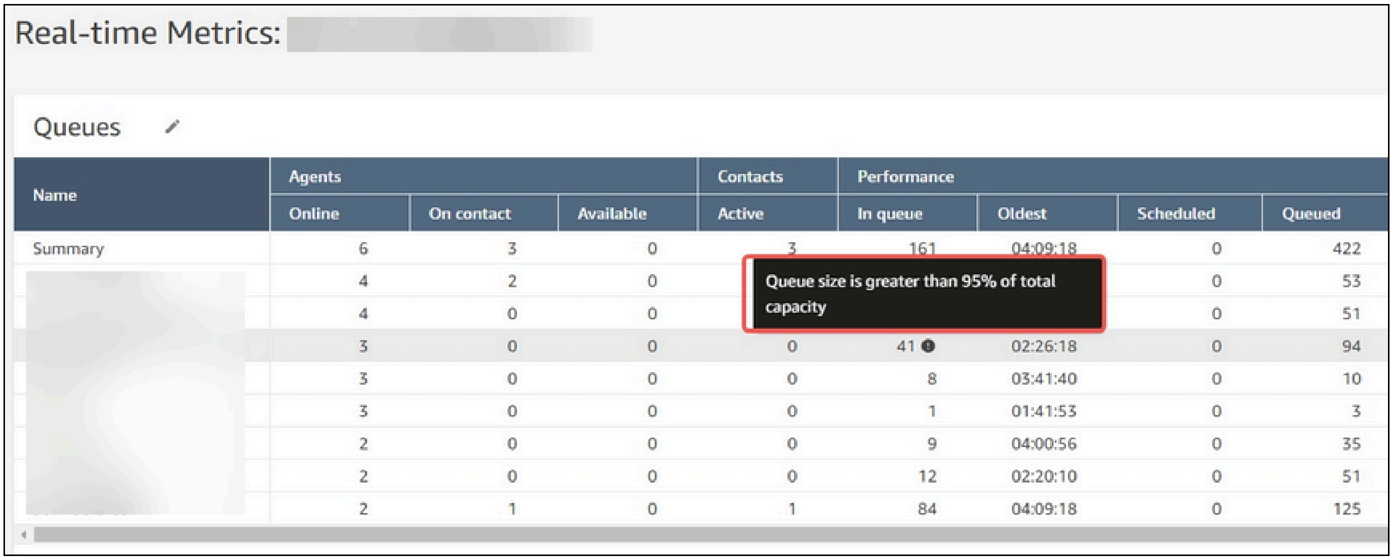
In queue

The count of contacts currently in the queue. The queue is updated when the contact is routed to the agent, before the agent accepts the contact.

To learn how this is different from Scheduled contacts in a callback scenario, see How Initial delay affects Scheduled and In queue metrics in Amazon Connect.

In the GetCurrentMetricData API, this metric can be retrieved by using `CONTACTS_IN_QUEUE`.

When queue size is greater than 95% of capacity, a message is displayed, as shown in the following image. For more information about queue capacity, see Set queue capacity.



Max queued

The longest time that a contact spent waiting in the queue. This includes all contacts added to the queue, even if they were not connected with an agent, such as abandoned contacts.

NPT (Non-Productive Time)

The count of agents who have set their status in the CCP to a custom status. That is, their CCP status is other than **Available** or **Offline**.

> **Tip**
>
> Although agents aren't routed any *new inbound* contacts while their CCP status is set to a custom status, it's possible for them to change their CCP status to a custom status while still handling a contact. For example, let's say an agent is being routed contacts very quickly. To go on break, they set their status to **Break** proactively, while still finishing up the last contact. This allows them to go on break and avoid accidentally missing a contact that's routed to them in the sliver of time between the last contact ending and setting their status to Break.
>
> Because agents can be **On call** or doing **ACW**, for example, while their CCP is set to a custom status, this means it's possible for agents to be counted as **On call** and **NPT** at the same time.

In the GetCurrentMetricData API, this metric can be retrieved by using `AGENTS_NON_PRODUCTIVE`.

Non-talk time percent

The non-talk time in a voice conversation as a percent of the total conversation duration. To calculate non-talk time percent, Amazon Connect totals all the intervals in which participants remained silent (non-talk time), and then divides this total by the total conversation duration.

> **Note**
>
> This metric is available only for contacts analyzed by Contact Lens conversational analytics.

Occupancy

Percentage of time that an agent was active on contacts. This percentage is calculated as follows:

(Agent on contact (wall clock time) / (Agent on contact (wall clock time) + Agent idle time))

Where:

- (Agent on contact + Agent idle time) = total amount of agent time
- So (Agent on contact)/(total amount of agent time) = percentage of time agents were active on contacts.

> **Important**
>
> **Occupancy** doesn't account for concurrency. That is, an agent is considered 100% occupied for a given interval if they are handling at least one contact for that entire duration.

Oldest

Length of time in the queue for the contact that has been in the queue the longest.

In the GetCurrentMetricData API, this metric can be retrieved by using `OLDEST_CONTACT_AGE`.

On contact

The count of agents currently on a contact. An agent is "on a contact" when they are handling at least one contact that is either connected, on hold, in After contact work, paused, or outbound ring.

In the GetCurrentMetricData API, this metric can be retrieved by using AGENTS_ON_CONTACT. This metric used to be named On call. You can still use AGENTS_ON_CALL to retrieve data for this metric.

Online

The count of agents who have set their status in the CCP to something other than **Offline**. For example, they may have set their status to Available, or to a custom value such as Break or Training.

The Online metric doesn't tell you how many agents can be routed contacts. For that metric, see Available.

This metric can be confusing so let's look at an example. Say you see this in a Queues report:

- Online = 30
- On Call = 1
- NPT = 30
- ACW = 0
- Error = 0
- Available = 0

This means 30 agents have set their status in the CCP to a custom status. 1 of those 30 agents is currently on a contact.

In the GetCurrentMetricData API, this metric can be retrieved by using AGENTS_ONLINE.

Queue

The name of the queue associated with the contact the agent is currently handling.

Queued

The count of contacts added to the queue during the specified time range.

Routing Profile

The routing profile for the agent.

Scheduled

The count of customers in the queue for which there is a callback scheduled.

To learn how this is different from In queue contacts in a callback scenario, see How Initial delay affects Scheduled and In queue metrics in Amazon Connect.

In the GetCurrentMetricData API, this metric can be retrieved by using `CONTACTS_SCHEDULED`.

SL *X*

Percentage of contacts removed from the queue between 0 and *X* after being added to it (Service Level). A contact is removed from the queue when one of the following occurs: an agent answers the call, the customer abandons the call, or the customer requests a call back.

For X, you can choose from pre-set times in seconds: 15, 20, 25, 30, 45, 60, 90, 120, 180, 240, 300, and 600.

Custom service levels

You can also create custom service level metrics. You can also choose from additional durations, such as minutes, hours, or days.

You can add up to 10 custom service levels per report.

The maximum duration for a custom service level is 7 days. That's because in Amazon Connect you can't have a contact that goes longer than 7 days.

Staffed

The count of agents who are online in the CCP, and not in NPT (a custom status).

Another way of thinking about this is, there are two scenarios in which **Staffed** is not incremented:

- The agent's status in the CCP is set to **Offline**.
- The agent's status in the CCP is set to a custom status.

For example, let's say an agent sets their status in the CCP to a custom status such as Break and they make an outbound call. Now the agent is **On call**, but **Staffed** is 0.

If the agent sets their status in the CCP to **Available** and makes an outbound call, the agent is **On call** and **Staffed** is 1.

This metric is available on the Queues report.

In the GetCurrentMetricData API, this metric can be retrieved by using AGENTS_STAFFED.

Step contacts queued

The count of contacts that entered a specific routing step in the queue. If a contact goes through multiple routing steps it will be counted each time.

In the GetCurrentMetricData API, this metric can be retrieved by using STEP_CONTACTS_QUEUED.

Step expired %

Percentage of contacts for which the specific routing step expired. This is calculated by dividing number of contacts that expired in a specific step by the total number of contacts that entered that routing step.

In the GetCurrentMetricData API, this metric can be retrieved by using PERCENT_CONTACTS_STEP_EXPIRED.

Step joined %

Percentage of contacts that joined with an agent at the routing step. This is calculated by dividing the number of contacts that joined in a specific step divided by the total number of contacts that entered that routing step.

In the GetCurrentMetricData API, this metric can be retrieved by using PERCENT_CONTACTS_STEP_JOINED.

Transferred in

The count of contacts transferred into the queue during the specified time range.

Transferred in by agent

The count of contacts transferred in by an agent using the CCP.

Transferred in from queue

The count of contacts transferred into the queue from another queue during a **Customer queue flow**.

Transferred out

The count of contacts transferred out of the queue during the specified time range.

Transferred out by agent

The count of contacts transferred out by an agent using the CCP.

Transferred out from queue

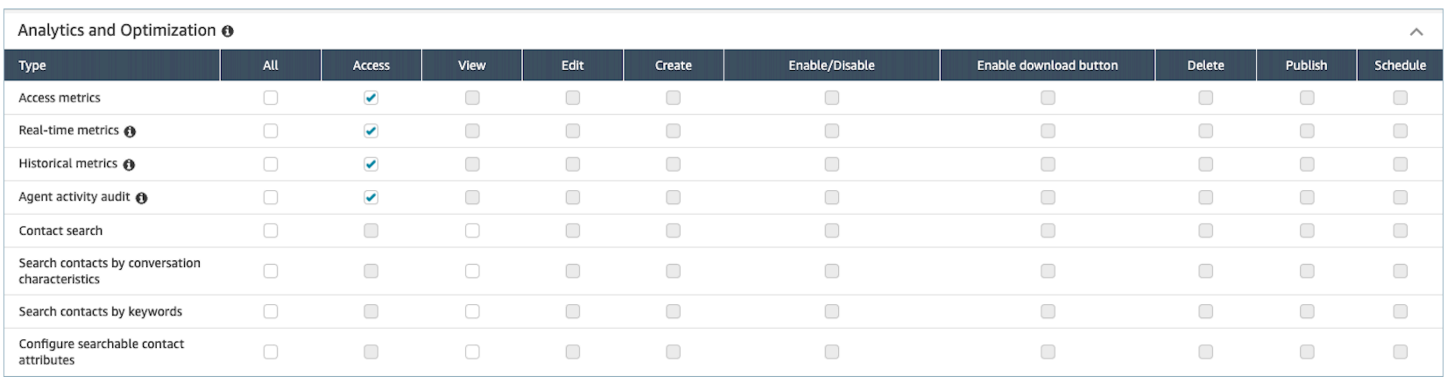
The count of contacts transferred out of the queue to another queue during a **Customer queue flow**.

Permissions to view real-time metrics reports in Amazon Connect

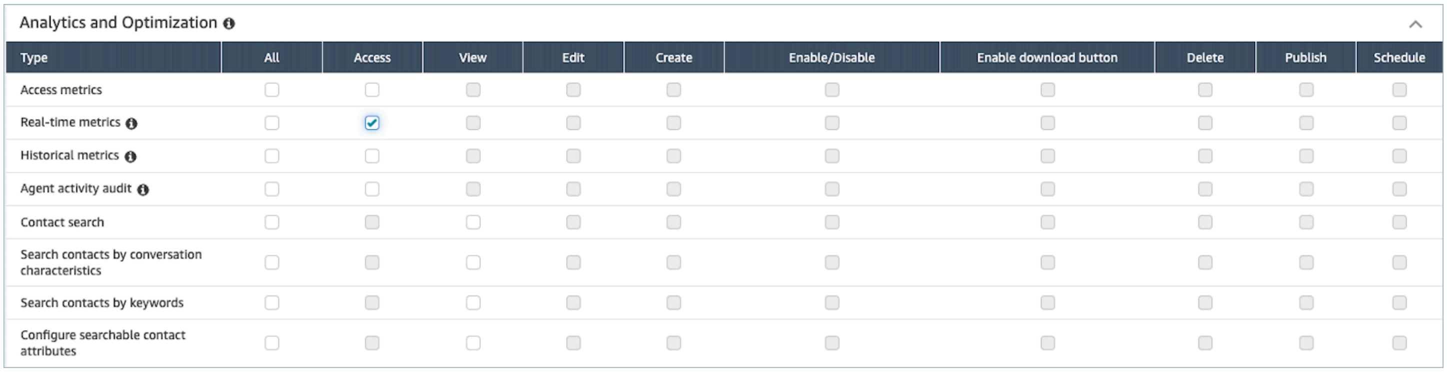
To view real-time metrics reports, you need to be assigned to a security profile that has either the **Access metrics - Access** permission or the **Real-time metrics - Access** permission. Note the following behavior when you assign these permissions:

- When **Access metrics - Access** is selected, the **Real-time metrics**, **Historical metrics**, and **Agent activity audit** permissions are also automatically assigned.
- When **Access metrics - Access** is assigned, you have access to all real-time and historical metrics reports.

The following image shows the **Analytics and Optimization** section of the **Security profile permissions** page. The **Access** option is selected for **Access metrics**, **Real-time metrics**, **Historical metrics**, and **Agent activity audit**.



If only **Real-time metrics** is selected, you have access only to real-time metrics and no other analytics pages or reports. The following image shows the **Analytics and Optimization** section, with only **Real-time metrics - Access** selected.



Analytics and Optimization

Type	All	Access	View	Edit	Create	Enable/Disable	Enable download button	Delete	Publish	Schedule

Real-time metrics tag-based access control in Amazon Connect

You can use resource tags and access control tags to apply granular access to users, queues, and routing profiles for real-time metrics. For example, you can control who has access to view specific users, queues, and routing profiles on the **Real-time metrics** page.

You can configure tag-based access controls by using the Amazon Connect admin website or the TagResource API.

Contents

Important things to know

- Amazon Connect can display up to 100 resources at a time on a real-time metrics table. For example, in an Agents table it can display up to 100 agents at a time. In a Queues table it can display up to 100 queues, and so on.
- Very often fewer than 100 agents will appear on a real-time metrics table at any given time when tagging is enabled. Here's why:
  - Amazon Connect can return a maximum of 100 agents at a time.
  - When tagging is enabled, Amazon Connect selects the first 100 agents who have the appropriate tags, and then displays only those agents in that group of 100 **who are active**

(Online or On Contact). Because not all of the 100 tagged agents may be active, it is very likely fewer than 100 tagged agents will be displayed in the table.

  - For example, you have 200 tagged agents. In the first group of 100 tagged agents only 50 are online. Amazon Connect selects the first 100 tagged agents but displays only 50 because they are currently active. It does not select the first 100 active agents.
  - For instructions that explain how to view the status of hundreds of agents when tagging is enabled, see How to view hundreds of agents, queues, and routing profiles on the real-time metrics report.
- You can filter and group tables only by the primary resource (agent, queue, or routing profile). You cannot filter and group tables by non-primary resources. For example, you cannot filter by queue in an Agent table and you cannot group by queue in a Routing profile table.
- The drill-down button is disabled within tables except for **View queue graphs**. For example, you cannot choose **View agents** in a Queue table.
- Access to the homepage service level dashboard is disabled.
- Access to view **Agent Queues** is disabled.
- The **Agent Adherence** table is not supported.

How to enable tag-based access control for real-time metrics

1. Apply resource tags, for example, to agents, queues, and routing profiles. For a list of which resources support tagging, see Add tags to resources in Amazon Connect.
2. Apply access control tags. In this step, you need to provide tag information in the condition element of an IAM policy. For more information, see Apply tag-based access control in Amazon Connect.

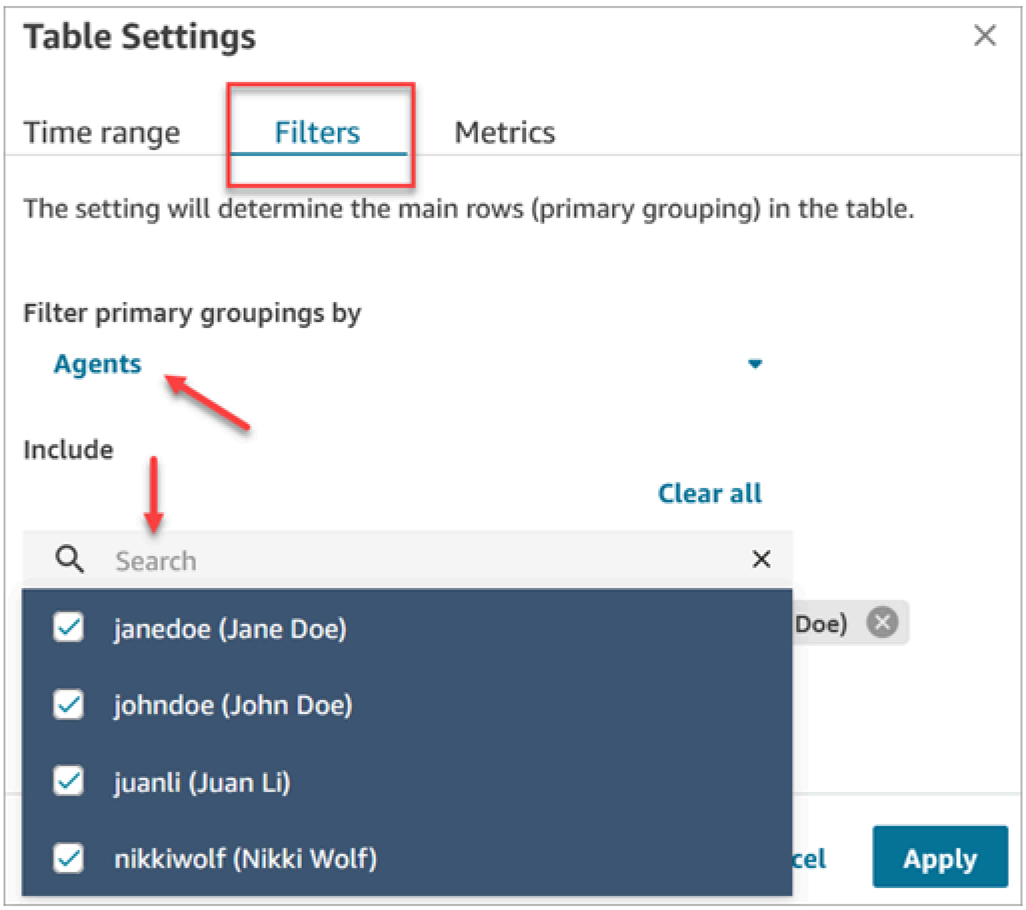
   > **Note**
   >
   > You must configure user resource tags and access control tags before tag-based access control is applied to users for the agent activity audit report.

3. Assign the required security profile permissions to users who are going to view the real-time metrics reports with tagging enabled. They need permissions to access the reports, and permissions to access the resources. For more information, see Required security profile permissions.

How to view hundreds of agents, queues, and routing profiles on the real-time metrics report

Amazon Connect displays up to 100 resources at a time on the real-time metrics report. For agents in particular when tags are applied it's very likely that fewer than 100 agents will be displayed. We recommend the following workaround to view the status of hundreds of agents, queues, and routing profiles when tags are applied.

1. Add one table for each group of 100 resources. For example, you have 500 agents. You would create 5 Agent tables.
2. For each table, manually filter to add up to 100 resources. For example, to add agents to the first table, you would choose to filter by **Agents**, and then choose 100 agents to include in the table, as shown in the following image. In table 2, add the next group of 100 agents, and so on.



3. You will be able to view the data for all 500 resources across the 5 tables. When tags are applied to agents, each table will likely display fewer than 100 agents because not all of them may be active at the same time.

How to transition to tag-based access control

If you open a saved report that contains tables with users, queues, or routing profiles that you don't have access to anymore due to tag-based access control, or if groupings or non-primary filters are applied to tables, you won't see data in those tables.

To view the data, perform one of the following steps:

- Edit your table filters to include the agents, queues, or routing profiles that you have access to.
- Create a new report that includes the resources you have access to.
- Remove the groupings and non-primary filters from the table.

Required security profile permissions

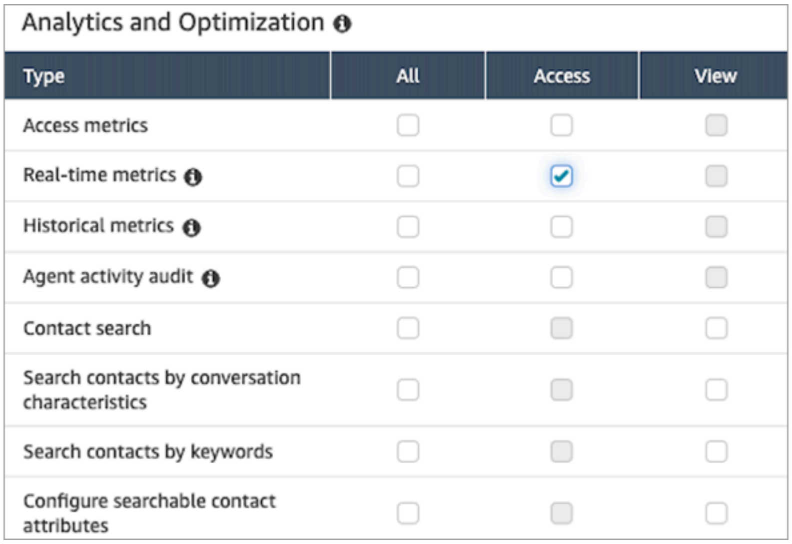
To view real-time metrics reports that have tag-based access controls applied to them, you need to be assigned to a security profile that has permissions to:

- Access metrics.
- Access the resources you want to view, such as routing profiles, queues, and agents.

Permissions to access metrics

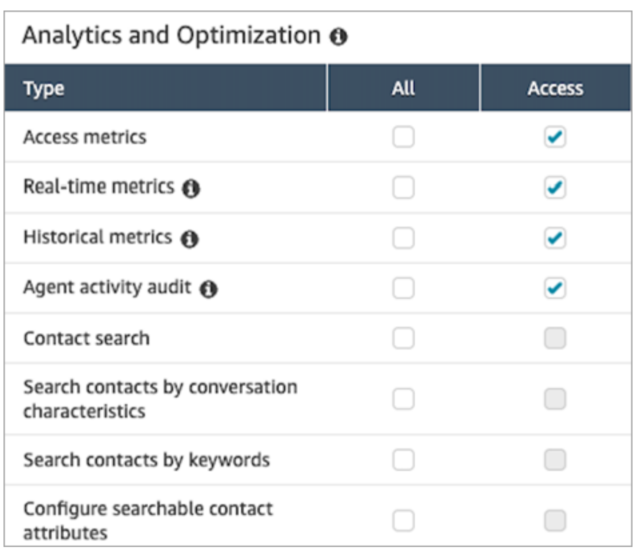
You need one of the following **Analytics and Optimization** security profile permissions:

- **Access metrics - Access**
- **Real-time metrics - Access**, as shown in the following image of the **Analytics and Optimization** section of the security profiles page.



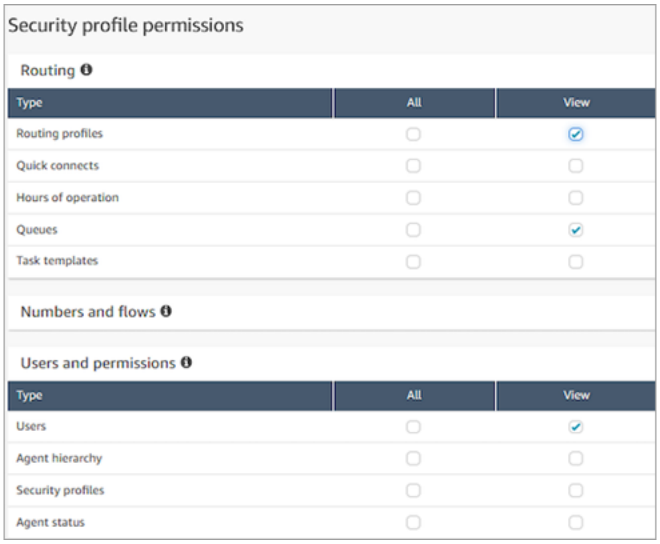
When you enable **Access metrics - Access**, permissions are also automatically granted to **Real-time metrics** , **Historical metrics**, and **Agent activity audit**. The following image shows all of these permissions granted.

> **Note**
>
> When users have all of these permissions, they can see all data for historical metrics for which tag-based access controls are not currently applied.



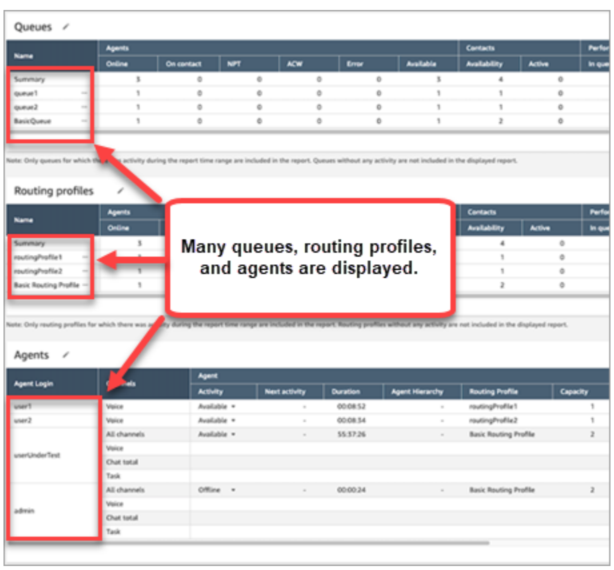
Permissions to access resources

The following image shows an example of security profile permissions that grant users the ability to view routing profiles, queues, and Amazon Connect user accounts. **Routing profiles - View**, **Queues - View**, and **Users - View** are selected.

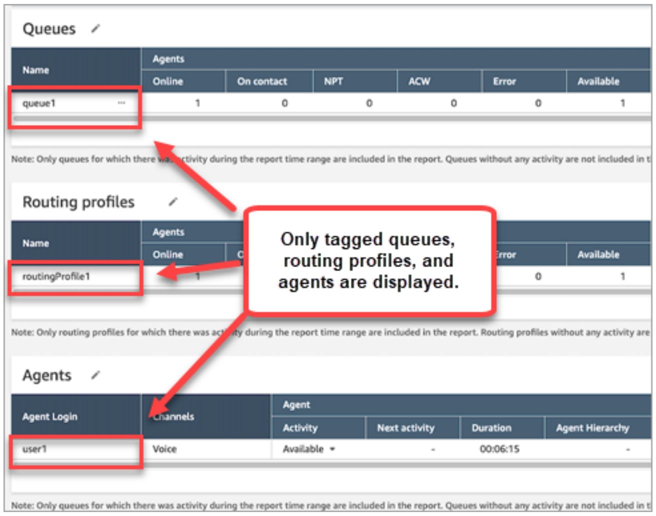


Example report with tag-based access controls applied

Without tag-based access controls, all queues, routing profiles, and agents appear on the **Real-time metrics** page, as shown in the following image.



With tag-based access controls, a limited set of queues, routing profiles, and agents appear on the **Real-time metrics** page, as shown in the following image.



How often real-time metrics refresh in Amazon Connect

Data in real-time metrics reports is refreshed as follows:

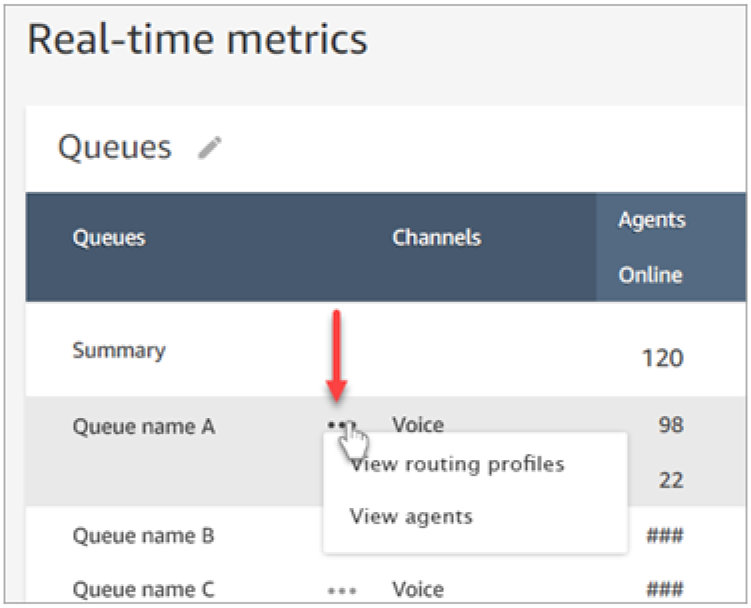
- The **Real-time metrics** page refreshes every 15 seconds, as long as the page is active. For example, if you have multiple tabs open in your browser and navigate to a different tab, the real-time metric page won't be updated until you return to it.
- Metrics such as **Active** and **Availability** refresh as activity occurs, with a small system delay for processing the activity.
- Agent near real-time metrics, such as **Missed** and **Occupancy**, refresh as activity occurs, with a small delay for processing.
- Contact near real-time metrics refresh about a minute after a contact ends.

Use pre-filtered tables for Routing profiles and Queues tables in Amazon Connect

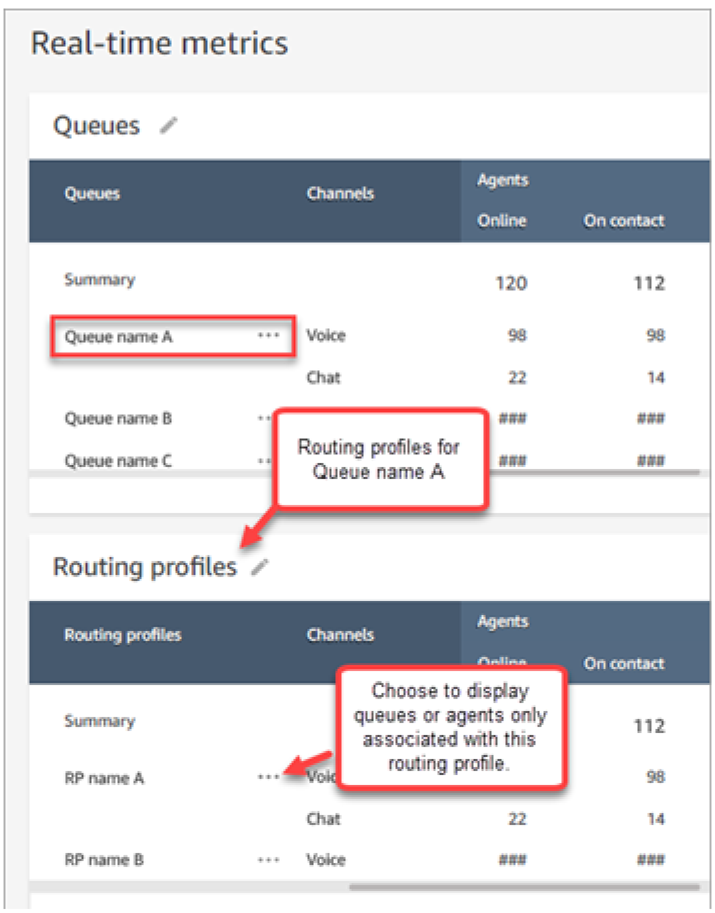
In real-time metrics reports, for **Routing profiles** and **Queues** tables, you can open pre-filtered tables that display the associated queues, routing profiles, or agents. These one-click filters provide a way for you to drill into the performance data.

Example 1: Queues table -> Routing profiles table -> Agents table

For example, at a **Queues** table, choose the dropdown and then choose **View routing profiles**, as shown in the following image.

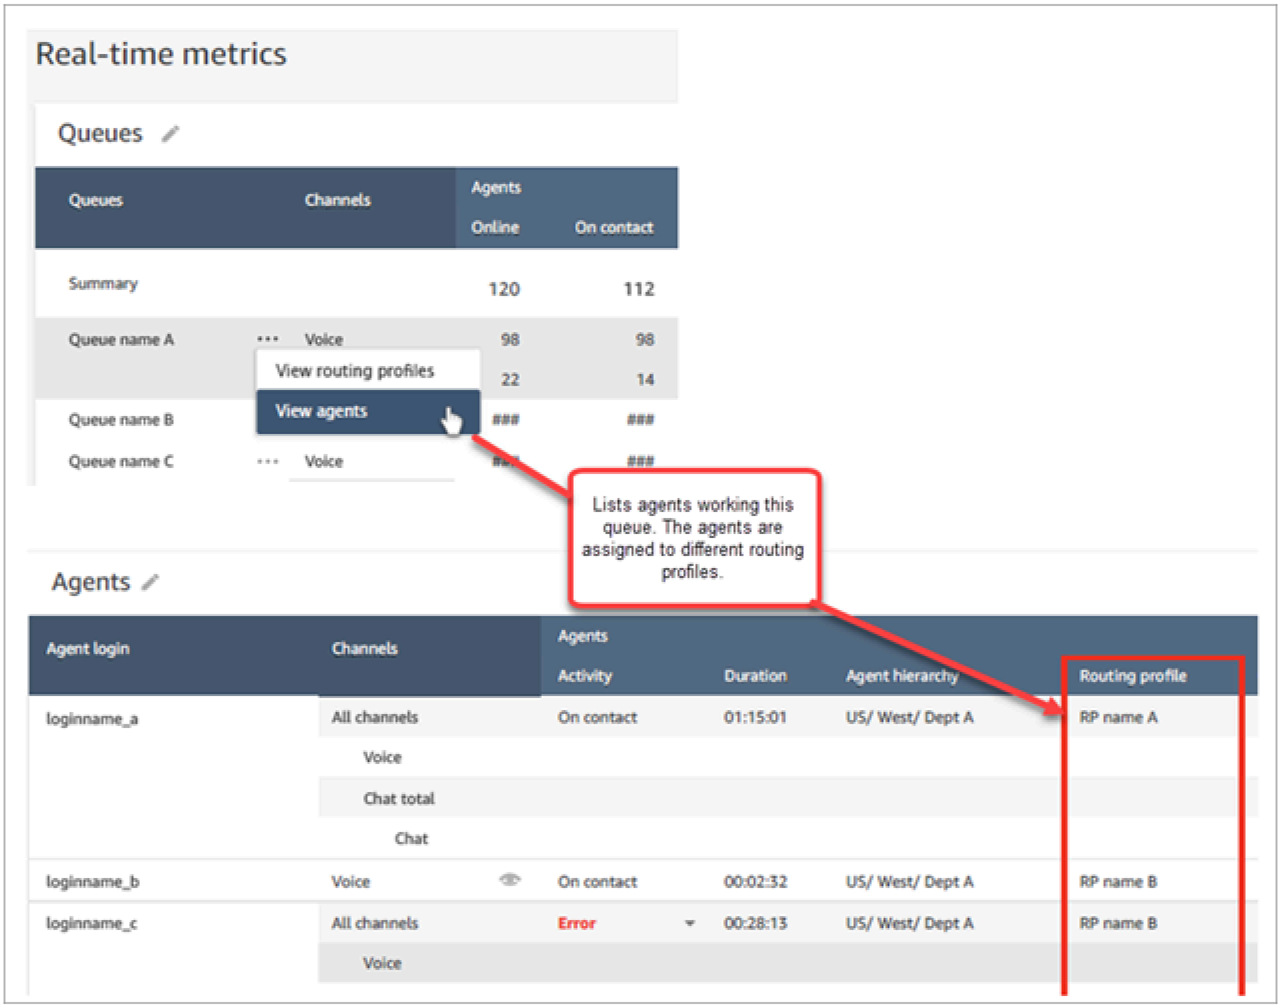


Below the **Queues** table, a **Routing profiles** table appears, as shown in the following image. It is filtered to display only the routing profiles associated with the queue. On the **Routing profiles** table, you can choose quick filters to display queues or agents *only associated with that routing profile*.



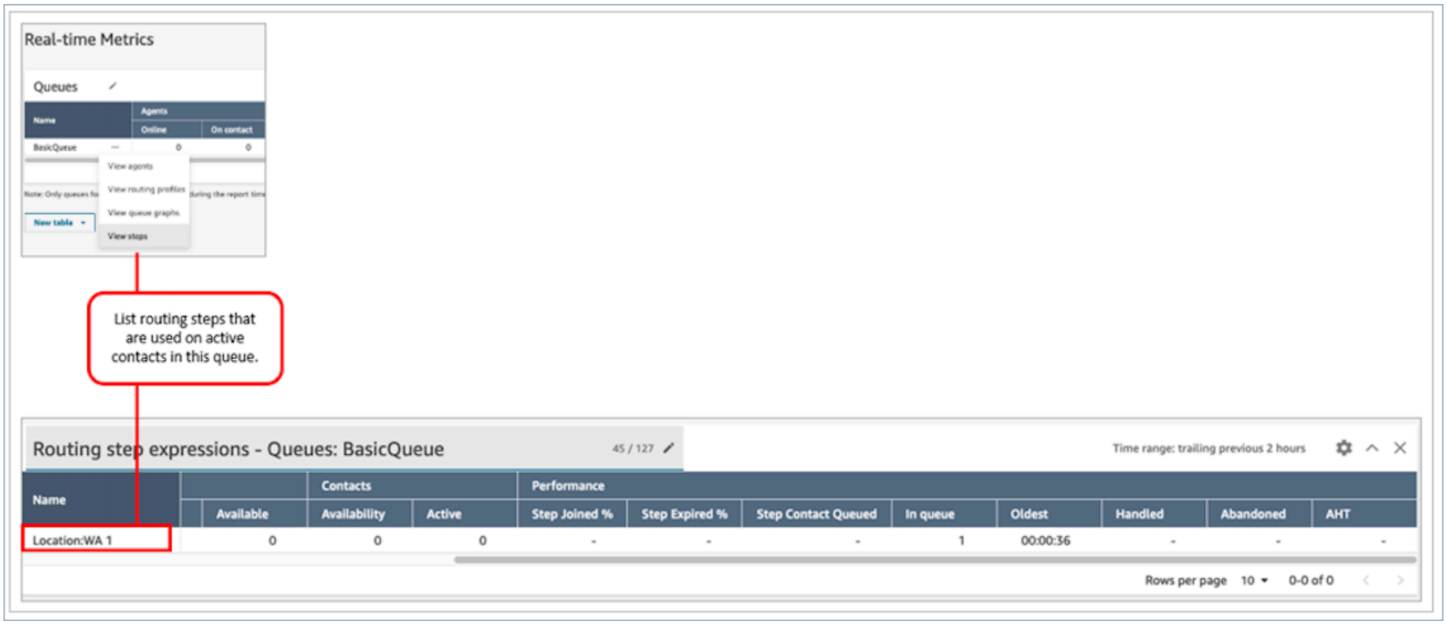
Example 2: Queues table -> Agents table

At the **Queues** table, choose **View agents**. Below the **Queues** table, an **Agents** table appears. It is filtered to display all the agents working that queue, as shown in the following image. The agents may be associated with different routing profiles.



Example 3: Queues table -> Steps table

At the **Queues** table, choose **View Steps**. Below the **Queues** table, a **Steps** table appears. It is filtered to display all the routing steps that are being used on active contacts in that queue, as shown in the following image.

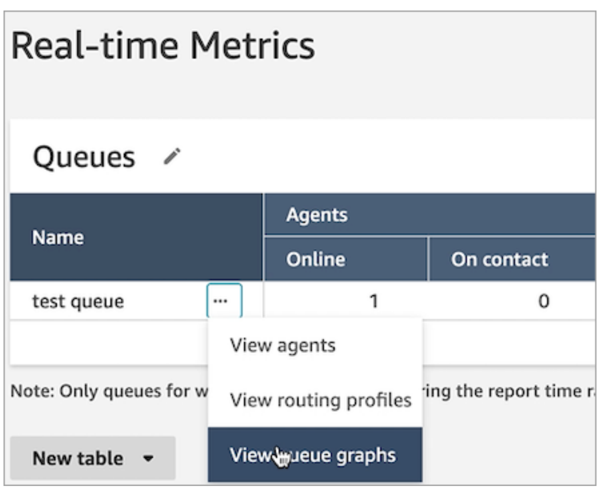


Visualize historical queue data in Amazon Connect

You can visualize historical queue data using time series graphs to help identify patterns, trends, and outliers such as Service Level, Contacts Queued, and Average Handle Time.

To view queue data

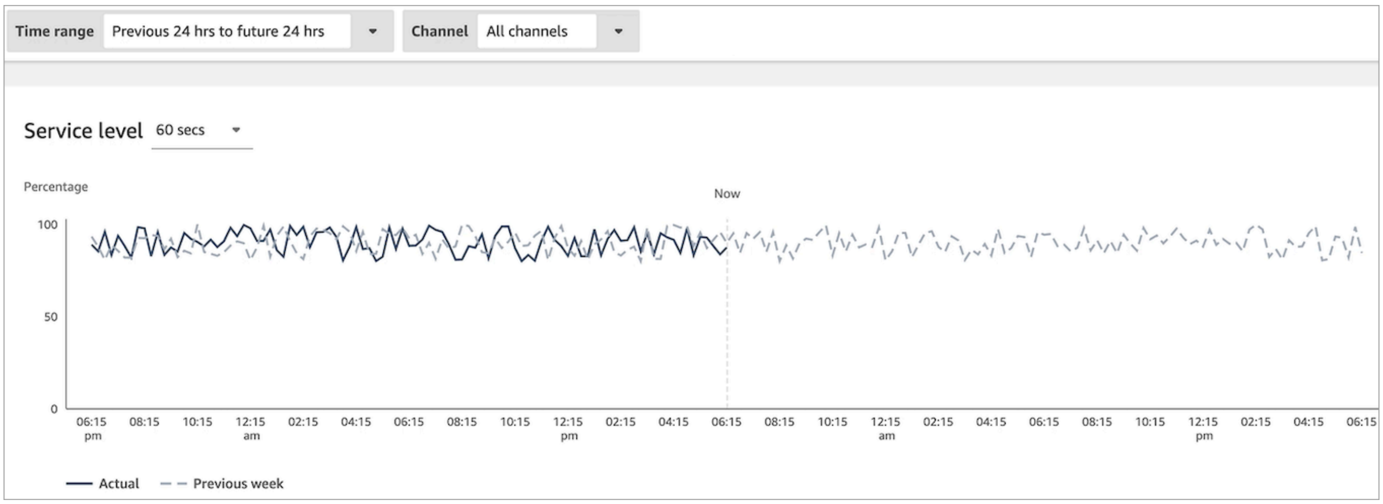
1. On the **Real-time Metrics** page, display the Queues table.
2. Select **View queue graphs** from the dropdown menu. The following image shows the dropdown menu for a queue named **test queue**.



3. After you select **View queue graphs**, you are directed to the queue visualization dashboard.
4. The Queue dashboard automatically refreshes every 15 minutes. You can:

- Configure a time range of up to 24 hours.
- Select the channel of your choice.
- Customize the service level thresholds.

The following image shows an example Queue dashboard. It displays a graph of service level data for the queue. **Time range** is set to **Previous 24 hours to future 24 hours**. **Channel** is set to **All channels**. **Service level** is set to **60 seconds**.

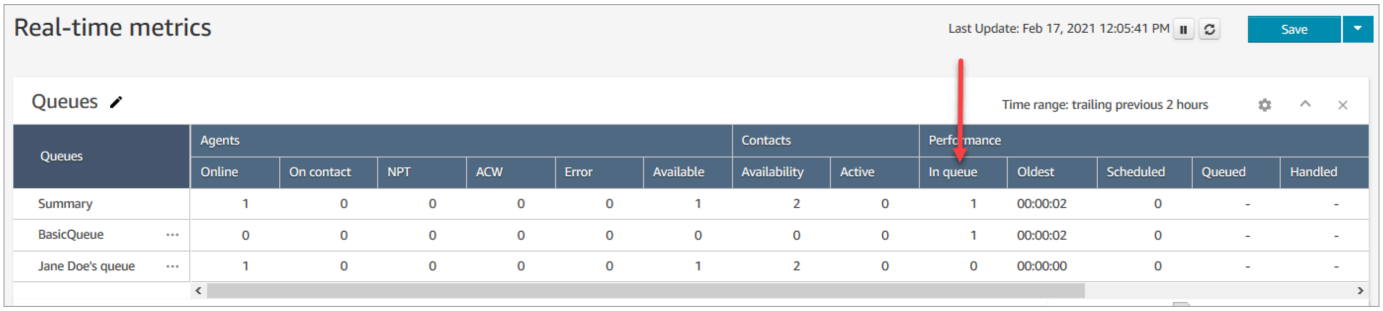


View the number of contacts waiting in an Amazon Connect contact center queue

To see the number of customers waiting in queue

1. Go to **Analytics and optimization**, **Real-time metrics**, **Queues**.
2. On the **Real-time metrics** page, **Queues** table, view the data in the **In queue** column.

   In queue shows the count of all customers who are in waiting a queue for an agent, including the callback customers.



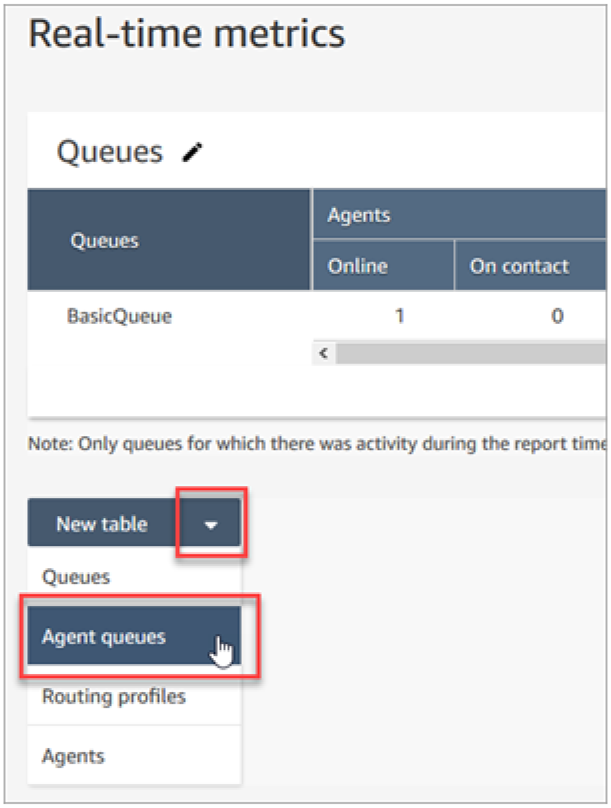
View how many contacts are in a contact center agent's queue

To see how many contacts are in an agent's personal queue, add an **Agent queues** table to your **Real-time metrics**, **Queues** report. Then view these two metrics:

- **In Queue**—how many contacts are in an agent's personal queue.
- **Queued**—the number of contacts added to their personal queue during the specified time range.

Use the following procedure.

1. Go to **Analytics and optimization**, **Real-time metrics**, **Queues.**
2. Choose **New table**, **Agent queues** as shown in the following image.



The **In queue** column displays how many contacts are in the agent's queue.

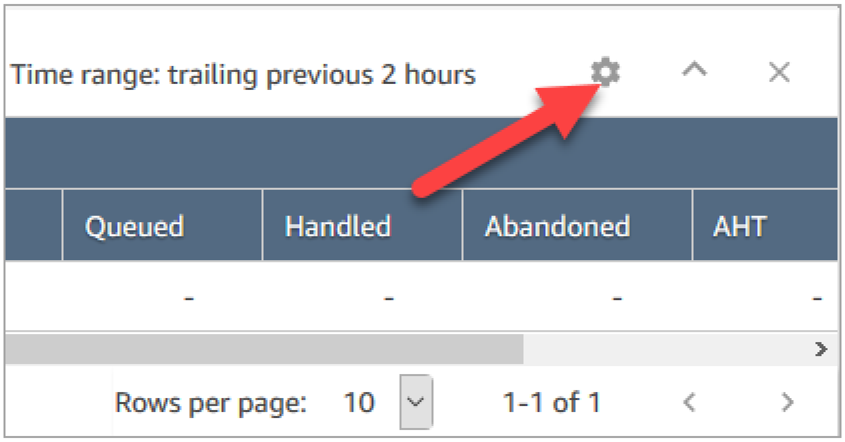
3. Review the metrics in then **In queue** and **Queue** columns.

> **Tip**
>
> An agent is included in the **Agent queues** table only if they are online or there is at least one contact in the their queue.

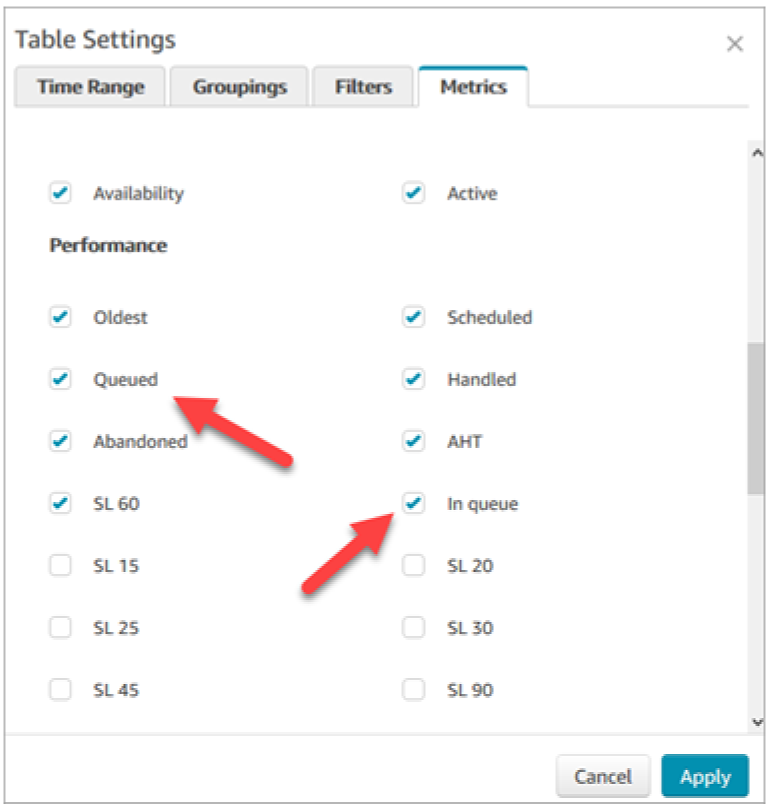
Add In Queue and Queue to the Agent queue table

If **In queue** or **Queue** don't appear in your **Agent queue** table, use the following steps to add them.

1. On the **Agent queues** table, choose **Settings**, as shown in the following image.



2. Choose the **Metrics** tab.
3. Scroll to the **Performance** section and choose **In queue** and **Queued**, and then **Apply**, as shown in the following table.



The changes appear in your table immediately.

4. Choose **Save** to add this report to your list of Saved reports.

View contacts in a contact center queue waiting for a callback

To see only the number of customers who are waiting for a call back, you need to create a queue that only takes callback contacts. To learn how to do this, see Set up routing in Amazon Connect.

Currently there isn't a way to see the phone numbers of the contacts waiting for callbacks.

Create a real-time metrics report for your contact center

You can create a real-time metrics report to view real-time or near-real time metrics data for activity in your contact center. You must have permission to access metric data. The **CallCenterManager** and **QualityAnalyst** security profiles include this permission. For more information, see Security profiles for Amazon Connect and Contact Control Panel (CCP) access.

To create a real-time metrics report

1. Log in to the Amazon Connect admin website at https://*instance name*.my.connect.aws/.
2. Choose **Analytics and optimization**, **Real-time metrics**.
3. Choose one of the following report types. They group and order the data in different ways and include different metrics by default.
   - **Queues**
   - **Agents**
   - **Routing profiles**
4. To add another report to the page, choose **New table** and then choose a report type. You can add multiple reports of the same report type.

   There's no limit to the number of tables you can add, but you might start experiencing performance issues if you add a lot of them.
5. To customize a report, choose the gear icon from its table.
6. On the **Time Range** tab, do the following:
   a. For **Trailing windows for time**, select the time range, in hours, for the data to include in the report.
   b. (Optional) If you select **Midnight to now**, the time range is from midnight to the current time, based on the **Time Zone** that you select. If you select a time zone other than the one you are currently in, the time range starts at midnight for the calendar day in that time zone, not your current time zone.

7. (Optional) On the **Filters** tab, specify filters to scope the data to be included in the report. The available filters depend on the report type. The following are the possible filters:

   - **Queues**—Includes data only for the queues that you select from **Include**.
   - **Routing profiles**—Includes data only for the routing profiles that you select from **Include**.
   - **Agents**—Includes data only for the agents that you select from **Include**.
   - **Agent Hierarchies**—Includes data only for the agent hierarchies that you select from **Include**.
   - **Channel**—Available for Queues and Routing Profile report type. Includes data only for Channels you select.

8. On the **Metrics** tab, choose the metrics and fields to include in the report. The available metrics and fields depend on the report type and filters that you select. For more information, see Real-time metrics definitions in Amazon Connect.
9. When you are finished customizing the report, choose **Apply**.
10. (Optional) To save your report for future reference, choose **Save**, provide a name for the report, and then choose **Save**.

    To view your saved real-time metrics reports, choose **Analytics and optimization**, **Dashboards and reports**, and then choose the **Real-time metrics** tab.

Troubleshoot no metrics or too few rows in a queues report in Amazon Connect

It's possible to run a manually configured queues report and have no metrics returned, or fewer rows than expected.

This is because a queues report only includes data for a maximum of 100 queues, using one row per queue. If a queue doesn't have any activity* during the time range for the report, it's excluded from the report rather than included with null values. This means that if you create a report, and there is no activity for any of the queues included in the report, your report will not include any data.

This applies to the `GetCurrentMetricsData` API as well. This means that if a queue is not considered active, if you query for its metrics using the API you won't get any data.

> **Tip**
>
> *Here's how we define whether a queue is active: there's at least one contact in queue or there's at least one online agent for that queue. Otherwise, it's considered inactive. Real-time metrics reports do not include agents who have been inactive for approximately the past 5 minutes. For example, after the agent changes their CCP status to **Offline**, their username continues to appear in the Real-time metrics report for another approximately 5 minutes. At the 5 minute point, the agent no longer appears in the report.

In the following situations, you could end up with no metrics or fewer rows than expected:

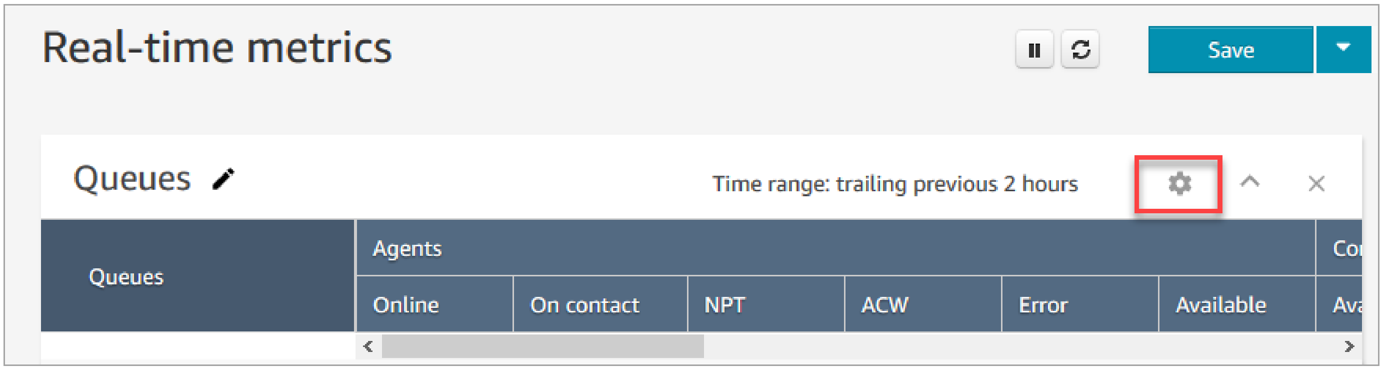
1. You're attempting to run a report with no filters or groupings, and have more than 100 queues in your instance. The report pulls metrics for the first 100 queues, and then displays only those that are active.
2. You're attempting to run a report with filters and groupings, but it still has more than 100 queues matching that criteria. To process this request, Amazon Connect applies all the specified filters and groupings. This pulls the first 100 queues matching that criteria. Then out of those queues, it displays only the active ones.

   For example, let's say you have 300 queues in your instance. Of these, 200 match your criteria; 100 are active and by coincidence all happen to be Queues #100-#200. When you run the report, you'd get just 1 row (Queue #100) since the other 99 queues that were returned (Queues #1-#99) were considered inactive and were not displayed.
3. You're running a report with fewer than 100 queues. While you may expect to see metrics for all filtered queues, only active queues are shown on the real-time metrics report page. Try changing the settings for the report, such as changing the time range.

List queues grouped by routing profile in Amazon Connect

This topic shows you how to display a list of queues grouped by routing profile in your Amazon Connect contact center.

1. Go to **Analytics and optimization**, **Real-time metrics**, **Queues**.
2. Click **Settings**.

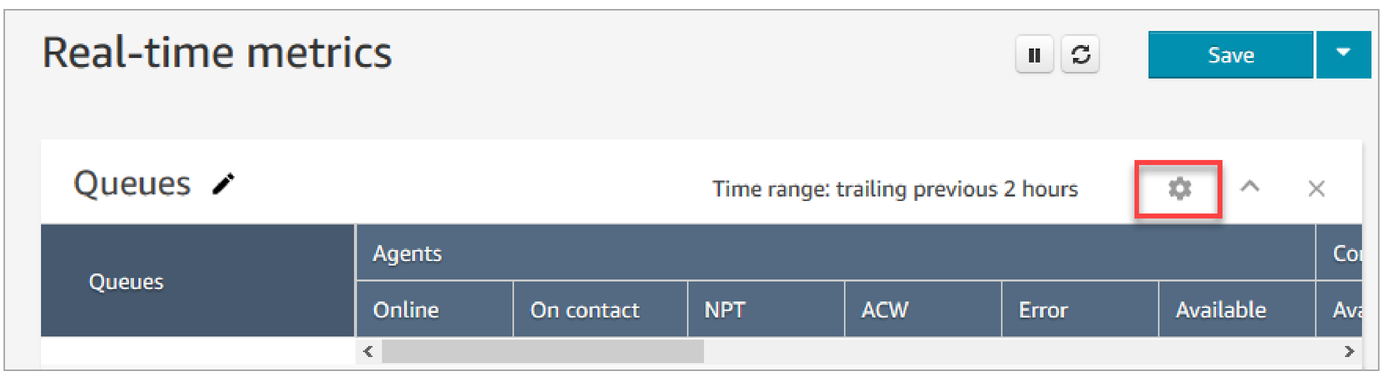


3. On the **Groupings** tab, choose **Queues grouped by routing profiles**.
4. Choose **Apply**.

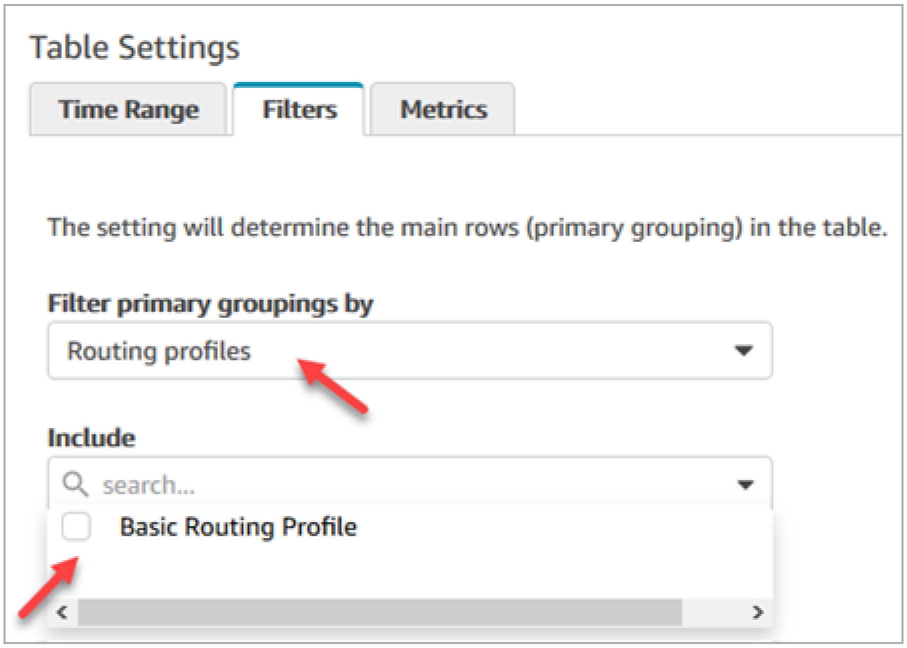
List agents grouped by routing profile in Amazon Connect

This topic shows you how to display a list of agents grouped by routing profile in your Amazon Connect contact center.

1. Go to **Analytics and optimization**, **Real-time metrics**, **Queues**.
2. Choose **New table**, **Agents**.
3. Click **Settings**, as shown in the following image.



4. On the **Filters** tab, choose **Routing profiles** from the **Filter primary groupings by** dropdown list. In **Include**, select the routing profiles you want included in the table, as shown in the following image.

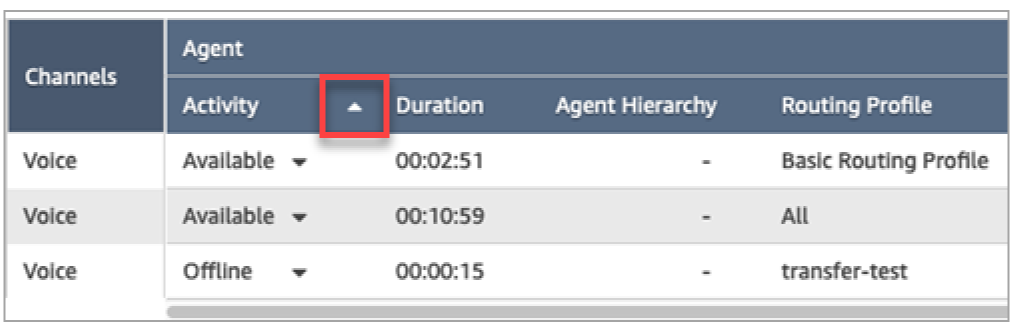


5. Choose **Apply**.

Sort agents by activity in a real-time metrics report in Amazon Connect

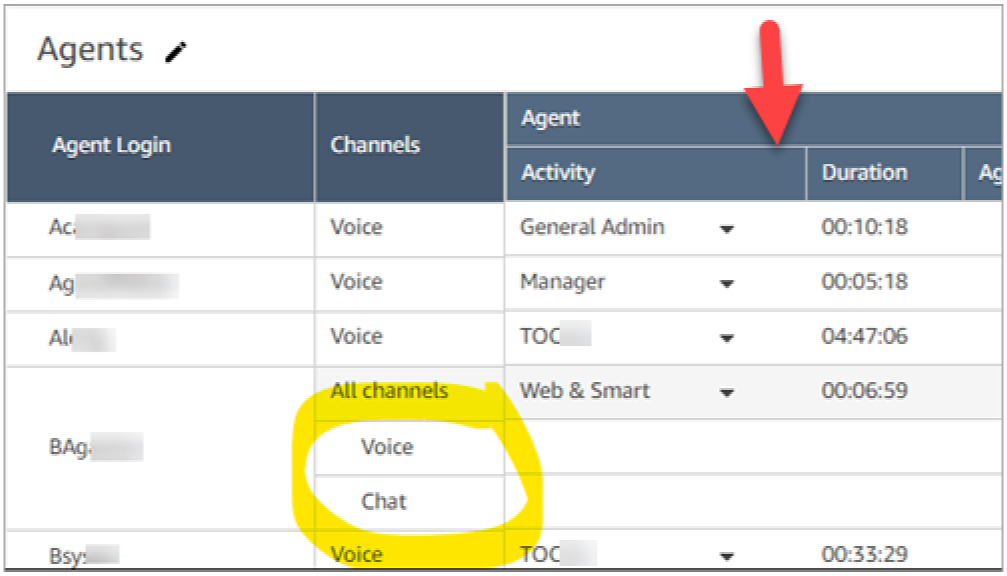
On the real-time metrics **Agents** report, you can sort agents by **Activity** when agents are enabled to use the same channel.

For example, the following image shows that you can sort agents by the **Activity** column because all the agents are enabled to use the same channel: voice.



Channels	Agent			
	Activity	Duration	Agent Hierarchy	Routing Profile
Voice	Available	00:02:51	-	Basic Routing Profile
Voice	Available	00:10:59	-	All
Voice	Offline	00:00:15	-	transfer-test

However, if one or more agents are enabled to handle voice, chat, and tasks—or any two of the channels—you can't sort them by the **Activity** column because of the multiple channels. In this case, there's no option to sort by the **Activity** column, as shown in the following image:



> **Note**
>
> The real-time metrics Agents report doesn't support secondary sorting. For example, you can't sort by **Activity**, and then sort by **Duration**.

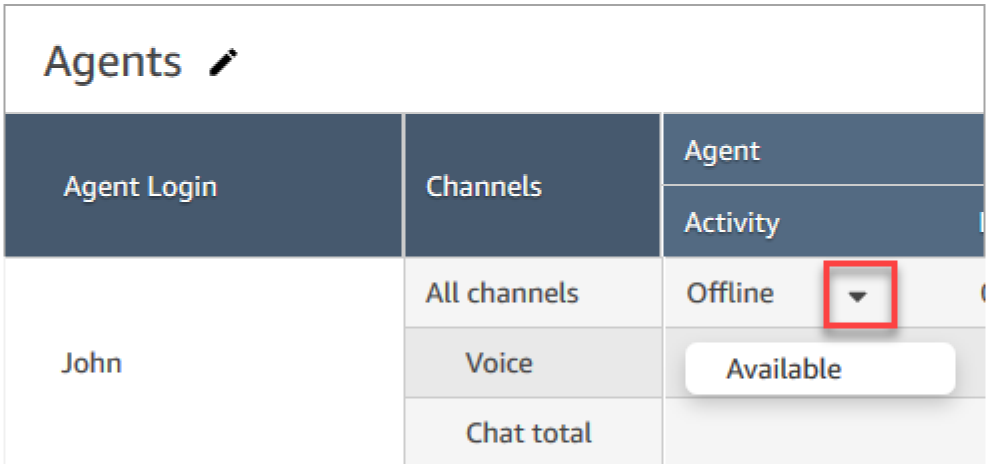
Change the "Agent activity" status in a metrics report in the Contact Control Panel (CCP)

Agents manually set their status in the Contact Control Panel (CCP). However, on the real-time metrics report, managers can manually change the **Agent Activity** status of an agent. This overrides what the agent has set in the CCP.

The value that's displayed in the **Agent Activity** column can be either:

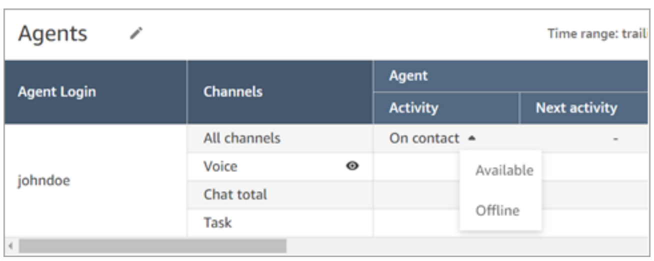
- The agent's availability status, such as **Offline**, **Available**, or **Break**.
- The contact state, such as **Incoming** or **On contact**.

When you choose the **Agent Activity** column, you can select and change an agent's *availability status*, such as **Offline**, **Available**, or **Break**. The following image shows an example where only the **Available** status is in the dropdown list of the **Activity** column.

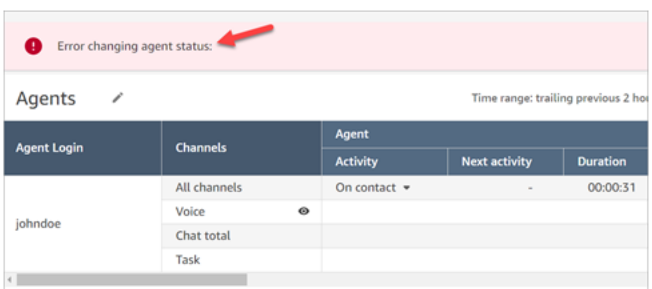


This change appears in the agent event stream.

However, when a *contact state* is displayed in the **Agent Activity** column, such as **Incoming** or **On contact**, you cannot change it to **Available** or **Offline**, for example, even though those options are displayed in the dropdown menu, as shown in the following image. This means you can't set the agent's next status while they are on a contact.



You'll get an error message that says *Error changing agent status*, as shown in the following image.



Note

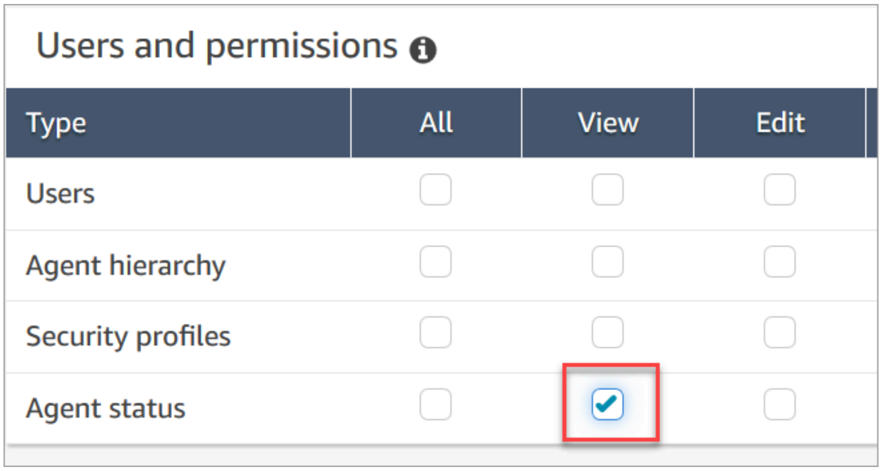
The Real-time metrics report does not display who changed the agent's status.

Required permissions to change an agent's activity status

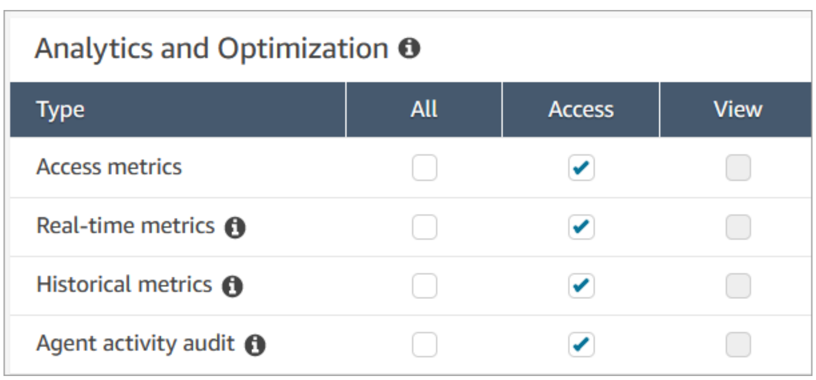
For someone such as a manager to be able to change an agent's activity status, they need to be assigned a security profile that has the following permissions:

- View - Agent Status
- Access metrics

The **Agent status - View** permission is shown in the following image of the **Users and permissions** section of the security profile page.



The **Access metrics - Access** permission is shown in the following image of the **Analytics and Optimization** section of the security profile page.



Download real-time metrics for Amazon Connect

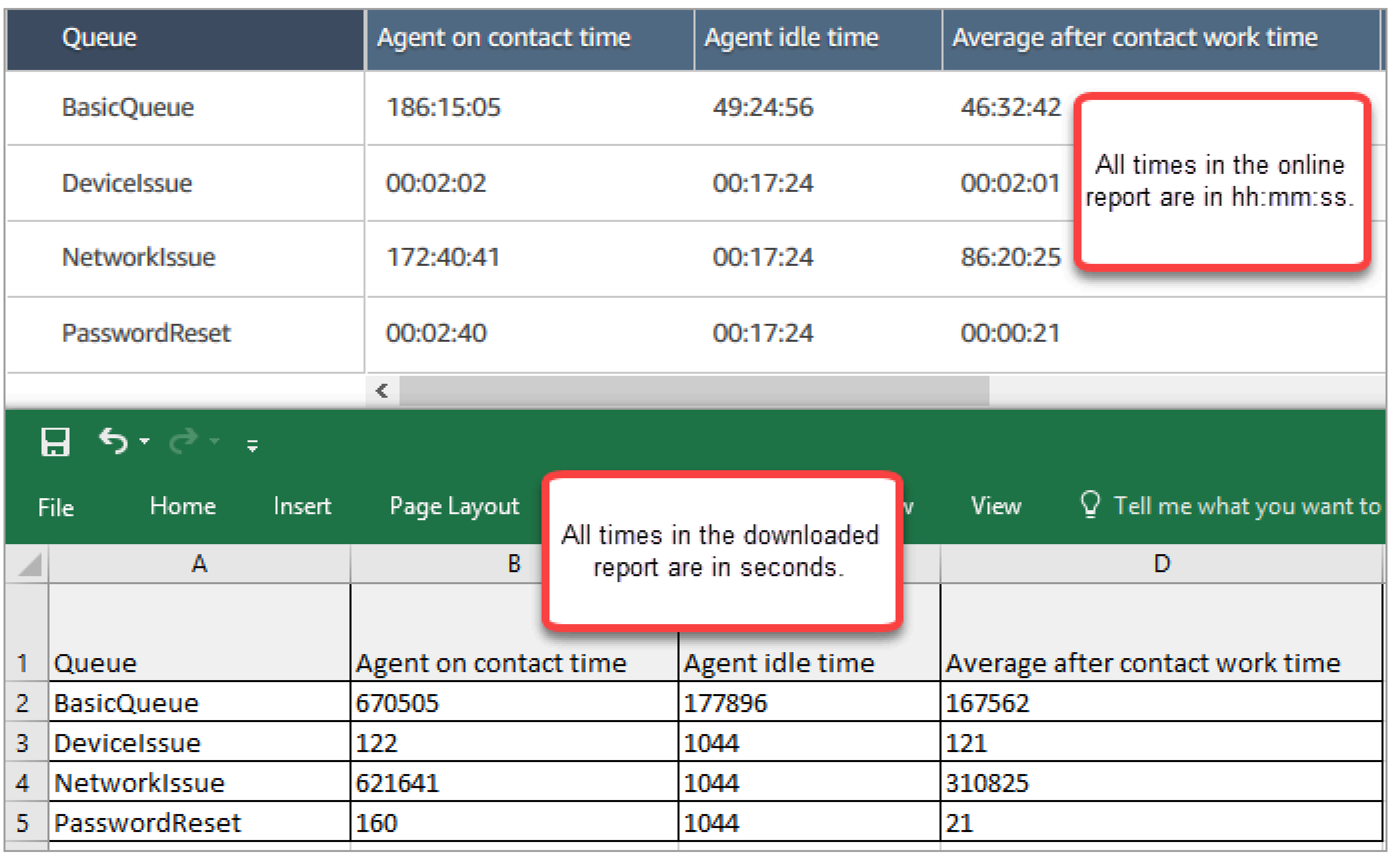
You can download the data included in your report as a comma-separated value (CSV) file so that you can use it with other applications. If there is no data for one of the selected metrics, the field in the downloaded CSV file contains a dash.

All exported times are in seconds.

To download a real-time metrics report as a CSV file

1. Create the report.
2. Choose the down arrow next to **Save** in the top-right corner of the page and choose **Download CSV**.
3. When prompted, confirm whether to open or save the file.

The following image shows real-time metrics in a Queue table. All times in the online report are in hours:minutes:seconds (hh:mm:ss). Below the image of the Queue table, there is an image of the same data in a downloaded CSV file opened with Excel. All times in the downloaded report are in seconds.



You can convert the seconds to minutes using an Excel formula. Alternatively, if you have a short report, you can copy and paste the data from Amazon Connect to Excel and it will preserve the format.

Historical metrics reports in Amazon Connect

Historical metrics reports include data about past, completed activity and performance in your contact center. Amazon Connect includes built-in historical reports that you can start using right away. You can also build your own custom reports.

When creating and analyzing your historical metrics reports, keep in mind that there are two categories of metrics:

Contact record-driven metrics

These metrics are based on formed contact record records. For a given interval, contact records whose disconnect date falls in the interval are selected to calculate metrics. For example, if a contact starts at 05:23 and ends at 06:15, this contact contributes 52 minutes of metrics for the 06:00-06:30 interval.

Example contact record-driven metrics are **Service level**, **Agent interaction time**, and **After contact work time**.

Agent activity-driven metrics

These metrics are based on agent activities, like agent status changes, agent conversation changes. The metrics reflect on the actual time the activity happens. For example, if agent handles a contact from 05:23 to 06:15, the **Agent on contact time** has 7 minutes for the 05:00-05:30 interval, 30 minutes for the 05:30-06:00 interval, and 15 minutes for the 06:00-06:30 interval.

For example, an agent activity-driven metric is **Non-Productive Time**.

You can customize the report settings to get the view of the data that is most meaningful for your organization. You can change the time frame for the report, which metrics are included in the report, and how data is grouped in the report. After you have customized a report, you can save it for future reference. You can generate a report using a recurring schedule that you define.

Contents

Historical metrics definitions in Amazon Connect

This topic lists all historical metrics in alphabetical order. For lists of metrics that apply only to a specific feature area, see these topics:

- Amazon Connect Cases metrics
- Amazon Connect bot metrics and analytics
- Conversational analytics metrics in Amazon Connect
- Outbound campaign metrics in Amazon Connect
- Schedule Adherence metrics in Amazon Connect

The following metrics are available to include in historical metrics reports in Amazon Connect unless otherwise noted.

Developers can use the GetMetricDataV2 and GetMetricData APIs to get a subset of the following historical metrics from the specified Amazon Connect instance.

> **Tip**
>
> We recommend using the GetMetricDataV2 API. It provides more flexibility, features, and the ability to query longer time ranges than `GetMetricData`. Use it to retrieve historical agent and contact metrics for the last 3 months, at varying intervals. You can also use it to build custom dashboards to measure historical queue and agent performance. For example, you can track the number of incoming contacts for the last 7 days, with data split by day, to see how contact volume changed per day of the week.

Abandonment rate

The percent of queued contacts that were disconnected without being connected to an agent. Contacts queued for callback are not counted as abandoned.

In the GetMetricDataV2 API, this metric can be retrieved by using `ABANDONMENT_RATE`.

Type: String

Min value: 0.00%

Max value: 100.00%

Category: contact record-driven metric

Adherence

This metric is available in AWS Regions only where Forecasting, capacity planning, and scheduling is available.

The percentage of time that an agent correctly follows their schedule.

In the GetMetricDataV2 API, this metric can be retrieved by using `AGENT_SCHEDULE_ADHERENCE`.

Type: String

Min value: 0.00%

Max value: 100.00%

Category: Agent activity driven metric

> **Note**
>
> Any time you change the schedule, Schedule Adherence is re-calculated up to 30 days in the past from the current date (not the date of the schedule), if schedules are changed.

For a list of all schedule adherence metrics, see Schedule Adherence metrics in Amazon Connect.

Adherent time

This metric is available in AWS Regions only where Forecasting, capacity planning, and scheduling is available.

The total time an agent adhered to their schedule.

In the GetMetricDataV2 API, this metric can be retrieved by using `AGENT_ADHERENT_TIME`.

Type: String

Category: Agent activity driven metric

For a list of all schedule adherence metrics, see Schedule Adherence metrics in Amazon Connect.

After contact work time

The total time that an agent spent doing ACW for a contact. In some businesses, also known as Call Wrap Up time.

You specify the amount of time an agent has to do ACW in their agent configuration settings. When a conversation with a contact ends, the agent is automatically allocated to do ACW for the contact. They stop doing ACW for a contact when they indicate they are ready for another contact in the CCP.

In the GetMetricData API, this metric can be retrieved by using `AFTER_CONTACT_WORK_TIME`.

In the GetMetricDataV2 API, this metric can be retrieved by using `SUM_AFTER_CONTACT_WORK_TIME`.

Type: String (*hh:mm:ss*)

Category: contact record-driven metric

Agent answer rate

Percentage of contacts routed to an agent that were answered.

In the GetMetricDataV2 API, this metric can be retrieved by using `AGENT_ANSWER_RATE`.

Type: String

Min value: 0.00%

Max value: 100.00%

Category: Agent activity-driven metric

Agent API connecting time

The total time between when a contact is initiated using an Amazon Connect API, and the agent is connected.

In the GetMetricDataV2 API, this metric can be retrieved by using `SUM_CONNECTING_TIME_AGENT` with a MetricFilters parameter set as follows:

- `MetricFilterKey = INITIATION_METHOD`
- `MetricFilterValues = API`

Type: String (*hh:mm:ss*)

Category: Agent activity-driven metric

Agent callback connecting time

The total time between when a callback contact is initiated by Amazon Connect reserving the agent for the contact, and the agent is connected.

In the GetMetricDataV2 API, this metric can be retrieved by using `SUM_CONNECTING_TIME_AGENT` with a MetricFilters parameter set as follows:

- `MetricFilterKey = INITIATION_METHOD`
- `MetricFilterValues = CALLBACK`

Type: String (*hh:mm:ss*)

Category: Agent activity-driven metric

Agent first name

The first name of the agent, as entered in their Amazon Connect user account. This metric is available only when grouping by agent.

Type: String

Length: 1-255

Agent idle time

After the agent sets their status in the CCP to **Available**, this is the amount of time they weren't handling contacts + any time their contacts were in an Error state.

Agent idle time includes the amount of time from when Amazon Connect starts routing the contact to the agent to when the agent picks up or declines the contact. After an agent accepts the contact, the agent is no longer considered idle.

> **Note**
>
> This metric can't be grouped or filtered by queue. For example, when you create a historical metrics report and filter by one or more queues, Agent idle time is not displayed.

In the GetMetricDataV2 API, this metric can be retrieved by using `SUM_IDLE_TIME_AGENT`.

Type: String (*hh:mm:ss*)

Category: Agent activity-driven metric

Agent incoming connecting time

The total time between when a contact is initiated by Amazon Connect reserving the agent for the contact, and the agent is connected.

In the agent event stream, this is the duration between the contact state of `STATE_CHANGE` event changes from `CONNECTING` to `CONNECTED`/`MISSED`/ `ERROR`.

In the GetMetricDataV2 API, this metric can be retrieved by using `SUM_CONNECTING_TIME_AGENT` with a MetricFilters parameter set as follows:

- `MetricFilterKey = INITIATION_METHOD`
- `MetricFilterValues = INBOUND`

Type: String (*hh:mm:ss*)

Category: Agent activity-driven metric

Agent interaction and hold time

Sum of Agent interaction time and Customer hold time.

In the GetMetricDataV2 API, this metric can be retrieved by using `SUM_INTERACTION_AND_HOLD_TIME`.

Type: String (*hh:mm:ss*)

Category: contact record-driven metric

Agent interaction time

Total time that agents spent interacting with customers on inbound and outbound contacts. This does not include Customer Hold Time, After Contact Work Time, or agent pause duration (which applies only to tasks).

In the GetMetricDataV2 API, this metric can be retrieved by using `SUM_INTERACTION_TIME`.

Type: String (*hh:mm:ss*)

Category: contact record-driven metric

Agent last name

The last name of the agent, as entered in their Amazon Connect user account. This metric is available only when grouping by agent.

Type: String

Length: 1-255

Agent name

The name of the agent, displayed as follows: **Agent last name**, **Agent first name**. This metric is available only when grouping by agent.

Agent non-response

The count of contacts routed to an agent but not answered by that agent, including contacts abandoned by the customer.

If a contact is not answered by a given agent, we attempt to route it to another agent to handle; the contact is not dropped. Because a single contact can be missed multiple times (including by the same agent), it can be counted multiple times: once for each time it is routed to an agent but not answered.

This metric appears as **Contacts missed** in scheduled reports and exported CSV files.

In the GetMetricData API, this metric can be retrieved by using `CONTACTS_MISSED`.

In the GetMetricDataV2 API, this metric can be retrieved by using `AGENT_NON_RESPONSE`.

Type: Integer

Category: Agent activity-driven metric

Agent non-response without customer abandons

The count of contacts routed to an agent but not answered by that agent, excluding contacts abandoned by the customer.

If a contact is not answered by a given agent, Amazon Connect attempts to route it to another agent to handle; the contact is not dropped. Because a single contact can be missed multiple times (including by the same agent), it can be counted multiple times: once for each time it is routed to an agent but not answered.

This metric supports only voice contacts. For chat, task, and email contacts, the same functionality is provided by the **Agent non-response** metric.

In the GetMetricDataV2 API, this metric can be retrieved by using `AGENT_NON_RESPONSE_WITHOUT_CUSTOMER_ABANDONS`.

Data for this metric is available starting from October 1, 2023 0:00:00 GMT.

Type: Integer

Category: Agent activity-driven metric

Agent on contact time

Total time that an agent spent on a contact, including Customer Hold Time and After Contact Work Time. This does **not** include time spent on a contact while in a custom status or **Offline** status.

(Custom status = the agent's CCP status is other than **Available** or **Offline**. For example, Training would be a custom status.)

> **Tip**
>
> If you want to include the time spent in a custom status and **Offline** status, see Contact handle time.

In the GetMetricDataV2 API, this metric can be retrieved by using `SUM_CONTACT_TIME_AGENT`.

Type: String (*hh:mm:ss*)

Category: Agent activity-driven metric

Agent outbound connecting time

Total time between when an outbound contact is initiated by Amazon Connect reserving the agent for the contact, and the agent is connected.

In the GetMetricDataV2 API, this metric can be retrieved by using `SUM_CONNECTING_TIME_AGENT` with a MetricFilters parameter set as follows:

- `MetricFilterKey = INITIATION_METHOD`
- `MetricFilterValues = OUTBOUND`

Type: String (*hh:mm:ss*)

Category: Agent activity-driven metric

Agent talk time percent

The talk time by an agent in a voice conversation as a percent of the total conversation duration. To calculate this metric, Amazon Connect totals all the intervals in which an agent was engaged in conversation (talk time agent), and then divides this total by the total conversation duration.

In the GetMetricDataV2 API, this metric can be retrieved by using `PERCENT_TALK_TIME_AGENT`.

- Type: Percent

- Category: Conversational analytics driven metric

For a list of all metrics driven by Contact Lens Conversational analytics, see Conversational analytics metrics in Amazon Connect.

> **Note**
>
> This metric is available only for contacts analyzed by Contact Lens conversational analytics.

API contacts

The count of contacts that were initiated using an Amazon Connect API operation, such as `StartOutboundVoiceContact`. This includes contacts that were not handled by an agent.

In the GetMetricDataV2 API, this metric can be retrieved by using `CONTACTS_CREATED` with a MetricFilters parameter set as follows:

- `MetricFilterKey = INITIATION_METHOD`
- `MetricFilterValues = API`

Type: Integer

Category: contact record-driven metric

API contacts handled

The count of contacts that were initiated using an Amazon Connect API operation, such as `StartOutboundVoiceContact`, and handled by an agent.

In the GetMetricData API, this metric can be retrieved by using `API_CONTACTS_HANDLED`.

In the GetMetricDataV2 API, this metric can be retrieved by using `CONTACTS_HANDLED` with a MetricFilters parameter set as follows:

- `MetricFilterKey` = `INITIATION_METHOD`
- `MetricFilterValues` = `API`

Type: Integer

Category: contact record-driven metric

Average active time

The average time, from start to finish, that an agent was working on a contact (average active time). It includes talk time, hold time, custom status time, and After Contact Work (ACW) time. It applies to both inbound and outbound calls.

(Custom status = the agent's CCP status other than **Available** or **Offline**. For example, Training would be a custom status.)

In the GetMetricDataV2 API, this metric can be retrieved by using `AVG_ACTIVE_TIME`.

Type: String (*hh:mm:ss*)

Category: contact record-driven metric

Average agent pause time

Average time that contact got paused after being connected to agent during inbound and outbound contacts.

This metric applies only to tasks.

In the GetMetricDataV2 API, this metric this metric can be retrieved by using `AVG_AGENT_PAUSE_TIME`.

Type: String (*hh:mm:ss*)

Category: contact record-driven metric

Average after contact work time

Average amount of time that an agent spent doing After Contact Work (ACW) for contacts. This is calculated by averaging AfterContactWorkDuration (from the contact record) for all contacts included in the report, based on the selected filters.

In the GetMetricDataV2 API, this metric this metric can be retrieved by using `AVG_AFTER_CONTACT_WORK_TIME`.

Type: String (*hh:mm:ss*)

Category: contact record-driven metric

Average agent API connecting time

The average time between when a contact is initiated using an Amazon Connect API, and the agent is connected.

In the GetMetricDataV2 API, this metric can be retrieved by using `AVG_AGENT_CONNECTING_TIME` with a MetricFilters parameter set as follows:

- `MetricFilterKey` = `INITIATION_METHOD`
- `MetricFilterValues` = `API`

Type: String (*hh:mm:ss*)

Category: Agent activity-driven metric

Average agent callback connecting time

The average time between when a callback contact is initiated by Amazon Connect reserving the agent for the contact, and the agent is connected.

In the GetMetricDataV2 API, this metric can be retrieved by using `AVG_AGENT_CONNECTING_TIME` with a MetricFilters parameter set as follows:

- `MetricFilterKey` = `INITIATION_METHOD`
- `MetricFilterValues` = `CALLBACK`

Type: String (*hh:mm:ss*)

Category: Agent activity-driven metric

Average agent greeting time

This metric represents the average first response time of agents on chat, indicating how quickly they engage with customers after joining the chat. It is calculated by dividing the total time it takes for an agent to initiate their first response by the number of chat contacts.

In the GetMetricDataV2 API, this metric can be retrieved by using `AVG_GREETING_TIME_AGENT`.

Type: String (*hh:mm:ss*)

Category: Conversational analytics driven metric

For a list of all metrics driven by Contact Lens Conversational analytics, see Conversational analytics metrics in Amazon Connect.

> **Note**
>
> This metric is available only for contacts analyzed by Contact Lens conversational analytics.

Average agent incoming connecting time

The average time between when contact is initiated by Amazon Connect reserving the agent for the contact, and the agent is connected. This is the ring time for configurations where the agent is not set to auto-answer.

No equivalent to this metric is available in the `GetMetricData` API.

In the GetMetricDataV2 API, this metric can be retrieved by using `AVG_AGENT_CONNECTING_TIME` with a MetricFilters parameter set as follows:

- `MetricFilterKey` = `INITIATION_METHOD`
- `MetricFilterValues` = `INBOUND`

Type: String (*hh:mm:ss*)

Category: Agent activity-driven metric

Average agent interaction and customer hold time

Average of the sum of the agent interaction and customer hold time. This is calculated by averaging the sum of the following values from the contact record: AgentInteractionDuration and CustomerHoldDuration.

In the GetMetricData API, this metric can be retrieved by using `INTERACTION_AND_HOLD_TIME`.

In the GetMetricDataV2 API, this metric can be retrieved by using `AVG_INTERACTION_AND_HOLD_TIME`.

Type: String (*hh:mm:ss*)

Category: contact record-driven metric

Average agent interaction time

Average time that agents interacted with customers during inbound and outbound contacts. This does not include Customer Hold Time or After Contact Work Time.

In the GetMetricData API, this metric can be retrieved by using `INTERACTION_TIME`.

In the GetMetricDataV2 API, this metric can be retrieved by using `AVG_INTERACTION_TIME`.

Type: String (*hh:mm:ss*)

Category: contact record-driven metric

Average agent interruptions

This metric quantifies the average frequency of agent interruptions during customer interactions by dividing the total number of agent interruptions by the total number of contacts.

In the GetMetricDataV2 API, this metric can be retrieved by using `AVG_INTERRUPTIONS_AGENT`.

Type: String (*hh:mm:ss*)

Category: Conversational analytics driven metric

For a list of all metrics driven by Contact Lens Conversational analytics, see Conversational analytics metrics in Amazon Connect.

> **Note**
>
> This metric is available only for contacts analyzed by Contact Lens conversational analytics.

Average agent interruption time

Average of total agent interruption time while talking to a contact. Calculating the average duration of agent interruptions during contact conversations involves summing the interruption intervals within each conversation and dividing the total by the number of conversations that experienced at least one interruption.

In the GetMetricDataV2 API, this metric can be retrieved by using AVG_INTERRUPTION_TIME_AGENT.

Type: String (*hh:mm:ss*)

Category: Conversational analytics driven metric

For a list of all metrics driven by Contact Lens Conversational analytics, see Conversational analytics metrics in Amazon Connect.

> **Note**
>
> This metric is available only for contacts analyzed by Contact Lens conversational analytics.

Average agent outbound connecting time

The average time between when an outbound contact is initiated by Amazon Connect reserving the agent for the contact, and the agent is connected.

In the GetMetricDataV2 API, this metric can be retrieved by using AVG_AGENT_CONNECTING_TIME with a MetricFilters parameter set as follows:

- MetricFilterKey = INITIATION_METHOD
- MetricFilterValues = OUTBOUND

Type: String (*hh:mm:ss*)

Category: Agent activity-driven metric

Average agent talk time

Average time that was spent talking in a conversation by an agent. This is calculated by summing up the durations of all intervals during which the agent was speaking and then dividing that sum by the total number of contacts.

In the GetMetricDataV2 API, this metric can be retrieved by using AVG_TALK_TIME_AGENT.

Type: String (*hh:mm:ss*)

Category: Conversational analytics driven metric

For a list of all metrics driven by Contact Lens Conversational analytics, see Conversational analytics metrics in Amazon Connect.

Average bot conversation time

The average duration of completed conversations for which the invoking resource (flow or flow module) started between the specified start and end time. It can be filtered on specific conversation outcomes with `BOT_CONVERSATION_OUTCOME_TYPE` metric level filter.

In the GetMetricDataV2 API, this metric can be retrieved by using `AVG_BOT_CONVERSATION_TIME`.

Data for this metric is available starting from December 2, 2024 00:00:00 GMT.

Type: String (*hh:mm:ss*)

Category: Flow driven metric

Calculation logic: Sum(Conversation Start Time - Conversation End Time of all filtered conversations) / (Count of all filtered conversations)

For a list of all bot metrics, see Amazon Connect bot metrics and analytics.

Average bot conversation turns

The average number of turns for completed conversations for which the invoking resource (flow or flow module) started between the specified start and end time. It can be filtered on specific conversation outcomes with `BOT_CONVERSATION_OUTCOME_TYPE` metric level filter.

A single turn is a request from the client application and a response from the bot.

In the GetMetricDataV2 API, this metric can be retrieved by using `AVG_BOT_CONVERSATION_TURNS`.

Data for this metric is available starting from December 2, 2024 00:00:00 GMT.

Type: Double

Category: Flow driven metric

Calculation logic: Sum(Conversation Turn of all filtered conversations) / (Count of all filtered conversations)

For a list of all bot metrics, see Amazon Connect bot metrics and analytics.

Average case resolution time

The average amount of time spent to resolve a case during the provided time interval.

In the GetMetricDataV2 API, this metric can be retrieved by using `AVG_CASE_RESOLUTION_TIME`.

Type: String (*hh:mm:ss*)

Category: Case driven metric

For a list of all case driven metrics, see Amazon Connect Cases metrics.

Average contact duration

The average duration of a contact is calculated by taking the difference between their initiation time and their disconnect time (from the contact record) and dividing it by the total number of contacts. This metric reflects the average amount of time a contact spends from the moment the contact initiates the interaction to when the contact disconnects.

In the GetMetricDataV2 API, this metric can be retrieved by using `AVG_CONTACT_DURATION`.

Type: String (*hh:mm:ss*)

Category: contact record-driven metric

Average contacts per case

The average number of contacts (calls, chat, tasks, and email) for cases created during the provided time interval.

In the GetMetricDataV2 API, this metric can be retrieved by using `AVG_CASE_RELATED_CONTACTS`.

Type: String

Category: Case driven metric

For a list of all case driven metrics, see Amazon Connect Cases metrics.

Average conversation duration

The average conversation duration of voice contacts with agents is determined by calculating the total time from the start of the conversation until the last word spoken by either the agent or the customer. This value is then divided by the total number of contacts to provide an average representation of the conversation time spent on the call.

In the GetMetricDataV2 API, this metric can be retrieved by using `AVG_CONVERSATION_DURATION`.

Type: String (*hh:mm:ss*)

Category: Conversational analytics driven metric

For a list of all metrics driven by Contact Lens Conversational analytics, see Conversational analytics metrics in Amazon Connect.

> **Note**
>
> This metric is available only for contacts analyzed by Contact Lens conversational analytics.

Average customer hold time

Average time that customers spent on hold while connected to an agent. This is calculated by averaging CustomerHoldDuration (from the contact record).

In the GetMetricData API, this metric can be retrieved by using `HOLD_TIME`.

In the GetMetricDataV2 API, this metric can be retrieved by using `AVG_HOLD_TIME`.

This average only includes contacts that went on hold.

Type: String (*hh:mm:ss*)

Category: contact record-driven metric

This metric doesn't apply to tasks and email so you'll notice a value of 0 on the report for them.

Average customer hold time all contacts

Average hold time for all contacts handled by an agent. The calculation includes contacts that were never put on hold.

In the GetMetricDataV2 API, this metric can be retrieved by using `AVG_HOLD_TIME_ALL_CONTACTS`.

Type: String (*hh:mm:ss*)

Category: contact record-driven metric

Average customer talk time

Average time that was spent talking in a conversation by a customer. This is calculated by summing up the durations of all intervals during which the customer was speaking and then dividing that sum by the total number of contacts.
