May 2020

The research described in this publication was carried out by the Jet Propulsion Laboratory, California Institute of Technology, under a contract with the National Aeronautics and Space Administration.

Charles E. Kolb Jr. May 21, 1945 - January 5, 2020

The members of the NASA Panel for Data Evaluation dedicate this publication in memory of our long-time associate, Charles E. Kolb Jr., known as Chuck to all of his many friends. Chuck had an amazing career in science through his nearly 50-year association with Aerodyne Research Inc. where he was President and CEO for the past 35 years. Chuck collaborated across a broad range of disciplines working with scientists in government agencies, private industry, and academia on research issues in atmospheric and environmental chemistry, combustion chemistry, chemical lasers, materials chemistry, and the chemical physics of rocket and aircraft exhaust plumes. As a result of his exceptional research accomplishments, Chuck received numerous industry awards and academic recognitions; he was a member of the National Academy of Engineering, and a fellow of the American Physical Society, the American Geophysical Union, the American Association for the Advancement of Science, and the Optical Society of America.

Chuck's broad scientific expertise together with his vision of science as a universal language and a diplomatic tool was key to his joining the NASA Data Panel in 1992. He approached every panel task with a genuine enthusiasm and was able to break down complex topics for both scientists and lay people alike. In addition to updating the panel recommendations for metal reactions, Chuck undertook the extremely challenging task of providing preferred values of evaluated data for the rates of heterogeneous reactions in recognition of the ever-growing importance of such processes in many atmospheric science issues. As a result of his efforts, the 1992 NASA Data Panel report (JPL 92-20) listed such recommendations for the first time. This section has expanded significantly over the years as can be seen by its comprehensiveness in the current report. As have the many members of the scientific community with whom Chuck interacted, all of the Data Panel members have benefitted from Chuck's wisdom, insights and mentoring. His keen intellect, thoughtful leadership, steadfast friendship, and fundamental kindness will be missed by all.

ABSTRACT

This is the nineteenth in a series of evaluated sets of rate constants, photochemical cross sections, heterogeneous parameters, and thermochemical parameters compiled by the NASA Panel for Data Evaluation.

The data are used primarily to model stratospheric and upper tropospheric processes, with particular emphasis on the ozone layer and its possible perturbation by anthropogenic and natural phenomena.

The evaluation is available in electronic form from the following Internet URL:

http://jpldataeval.jpl.nasa.gov/

This evaluation should be cited using the following format:

J. B. Burkholder, S. P. Sander, J. Abbatt, J. R. Barker, C. Cappa, J. D. Crounse, T. S. Dibble, R. E. Huie, C. E. Kolb, M. J. Kurylo, V. L. Orkin, C. J. Percival, D. M. Wilmouth, and P. H. Wine "Chemical Kinetics and Photochemical Data for Use in Atmospheric Studies, Evaluation No. 19," JPL Publication 19-5, Jet Propulsion Laboratory, Pasadena, 2019 http://jpldataeval.jpl.nasa.gov.

TABLE OF CONTENTS

INTRODUCTION

This compilation of kinetic and photochemical data is the 19th evaluation prepared by the NASA Panel for Data Evaluation. The Panel was established in 1977 by the NASA Upper Atmosphere Research Program Office for the purpose of providing a critical tabulation of the latest kinetic and photochemical data for use by modelers in computer simulations of atmospheric chemistry. Table I-1 lists this publication's editions:

Table I-1: Editions of this Publication

	Edition	Reference
1	NASA RP 1010, Chapter 1	Hudson et al.[1]
2	JPL Publication 79-27	DeMore et al.[13]
3	NASA RP 1049, Chapter 1	Hudson and Reed[2]
4	JPL Publication 81-3	DeMore et al.[11]
5	JPL Publication 82-57	DeMore et al.[9]
6	JPL Publication 83-62	DeMore et al.[10]

19	JPL Publication 19-5	Burkholder et al.

In addition to the current edition, several previous editions are available for download from http://jpldataeval.jpl.nasa.gov/. This document is not available in printed form.

Contributions to the evaluation from past panel members are gratefully acknowledged. Past panel members and years of contribution are listed in Table I-2.

Table I-2: Past Panel Members

Panel Member	Years of Contribution
D. M. Golden	1977–2011
M. J. Molina	1977–2006
W. B. DeMore	1977–2000
R. F. Hampson	1977–2000
R. T. Watson	1977–1985
J. J. Margitan	1977–1985
L. J. Stief	1977–1981
D. Garvin	1977
C. J. Howard	1979–1997
F. Kaufman	1979–1981
A. R. Ravishankara	1982–2006
G. K. Moortgat	2000–2011
R. R. Friedl	2000–2011

B. J. Finlayson-Pitts	2002–2006

Current panel members, and their major responsibilities for the current evaluation are listed in Table I-3.

Table I-3: Panel Members and their Major Responsibilities for the Current Evaluation

Panel Member	Responsibility
J. B. Burkholder, co-Chair	Editorial review NO$_x$ reactions Photochemistry References
S. P. Sander, co-Chair	Editorial review IO$_x$ reactions
J. P. D. Abbatt	Heterogeneous processes
J. R. Barker	Three-body reactions Equilibrium constants
C. Cappa	Aerosol optical properties
J. D. Crounse	Isoprene nitrate
T. S. Dibble	Three-body reactions Equilibrium constants
R. E. Huie	Aqueous chemistry Henry's Law coefficients Thermodynamic parameters
C. E. Kolb	Heterogeneous processes Na chemistry
M. J. Kurylo	Halocarbon reactions
V. L. Orkin	Halocarbon reactions
C. J. Percival	Criegee intermediate chemistry
D. M. Wilmouth	Photochemistry
P. H. Wine	SO$_x$ reactions

As shown above, each Panel member concentrates their efforts on a given area or type of data. Nevertheless, the Panel's final recommendations represent a consensus of the entire Panel. Each member reviews the basis for all recommendations and is cognizant of the final decision in every case.

I.1 Basis of the Recommendations

In so far as possible, all recommendations are based on laboratory measurements. In order to provide recommendations that are as up-to-date as possible, preprints and written private communications are accepted, but only when it is expected that they will appear as published journal articles. Recommendations are not adjusted to fit observations of atmospheric concentrations. The Panel considers the question of consistency of data with expectations based on the theory of reaction kinetics, and when a discrepancy appears to exist this fact is pointed out in the accompanying note. The major use of theoretical extrapolation of data is in connection with three-body reactions, in which the required pressure or temperature dependence is sometimes unavailable from laboratory measurements, and can be estimated by use of appropriate theoretical treatment. In some cases where no experimental data are available, the Panel may provide estimates of rate constant parameters based on analogy to similar reactions for which data are available.

I.2 Scope of the Evaluation

In the past (releases 1-12 of this evaluation), it was the practice of the Panel to reevaluate the entire set of reactions with individual Panel members taking responsibility for specific chemical families or processes. In recent years, the upper troposphere and lower stratosphere (UT/LS) have become the primary areas of focus for model calculations and atmospheric measurements related to studies of ozone depletion and climate change. Because the UT/LS is a region of relatively high chemical and dynamical complexity, a different approach was adopted for subsequent releases of the evaluation. Specifically, the entire reaction set of the data evaluation is no longer re-evaluated for each release. Instead, specific subsets are chosen for re-evaluation, with several Panel members working to develop recommendations for a given area. This approach makes it possible to treat each subset in greater depth, to examine the consistency of the recommended parameters within a given chemical family, and to expand the scope of the evaluation to new areas. It is the aim of the Panel to consider the entire set of kinetics, photochemical, and thermodynamic parameters every three review cycles. Each release of the evaluation will contain not only the new evaluations, but also recommendations for every process that has been considered in the past. In this way, the tables for each release constitute a complete set of recommendations.

It is recognized that important new laboratory data may be published that lie outside the specific subset chosen for re-evaluation. In order to ensure that these important data receive prompt consideration, each evaluation may also have a “special topics” category. Feedback from the atmospheric modeling community is solicited in the selection of reactions for this category.

For the current evaluation, the specific evaluation subsets include the following:

- NO_x reactions
- Halocarbon reactions
- Isoprene nitrate chemistry
- Reactions of sulfur compounds
- Na and Hg reactions
- Pressure dependent and chemical activation reactions
- Photochemistry of organic compounds, chlorofluorocarbons, and Criegee intermediates
- Heterogeneous processes on liquid water, water ice, alumina and solid alkali halide salts
- Aqueous halogen activation reactions
- Gas-liquid solubility (Henry’s Law Constants)
- Thermodynamic parameters (entropy and enthalpy of formation)

I.3 Format of the Evaluation

Changes or additions to the data tables are indicated by shading. A new entry is completely shaded, whereas a changed entry is shaded only where it has changed. In some cases, only the note has been changed, in which case the corresponding note number in the table is shaded.

The notes associated with each entry are an essential component of the evaluation. Thus, the reader is strongly encouraged to consult these notes as they contain important information that could not conveniently be included in the Table of recommended parameters. In several cases, the note for a bimolecular reaction contains a three-parameter Arrhenius expression that better represents the accepted experimental data over a much broader temperature range than the two-parameter Arrhenius expression given in the table, whose applicability is limited to a narrower temperature range as indicated in the note. For Henry's Law constants, where three-parameter expressions are given in the table, two-parameter representations over a more limited temperature range are included in the note. In the Table of Thermochemical Properties, values in the original units are often given. Table entries for some reactions provide rate constant recommendations for individual reaction channels. In this case, the recommendation for the total reaction rate constant is given separately in the note.

Every note in Tables 1-3 and in the photochemistry section includes a "time stamp" indicating the latest revision date for changes in the recommendation or in the note as well as the date of the most recent evaluation. In some cases, a reaction may have undergone a complete re-evaluation without changes in the recommendations (i.e., Table entries) or in the note. For such reactions, the date of the evaluation will be updated even though the re-evaluation did not result in any changes.

I.4 Computer Access

This document is available online in the form of individual chapters and as a complete document in Adobe PDF (Portable Data File) format. Files may be downloaded from http://jpldataeval.jpl.nasa.gov/. This document is not available in printed form.

To receive email notification concerning releases of new publications and errata, a mailing list is available. To subscribe, send a blank message to join-jpl-dataeval@list.jpl.nasa.gov with "Subscribe" (without quotes) in the subject line.

For more information, contact Stanley Sander (Stanley.Sander@jpl.nasa.gov) or James Burkholder (James.B.Burkholder@noaa.gov).

I.5 Data Formats

In Table 1 (Rate Constants for Bimolecular Reactions) the reactions are grouped into the classes O_x, HO_x, NO_x, Organic Compounds, FO_x, ClO_x, BrO_x, IO_x, SO_x, and Metal Reactions. The data in Table 2.1 (Rate Constants for Association Reactions) are presented in the same order as in the bimolecular reactions section. The presentation of photochemical cross section data follows the same sequence. Most of the major Heterogeneous Processes Section tables follow the O_x, HO_x, NO_x, Organic Compounds, FO_x, ClO_x, BrO_x, IO_x, SO_x, and Metal Reactions listing sequence for the gaseous uptake species. There are minor deviations that usually occur in the order of halogen atom containing gases or how reactants with more than one halogen species are listed. This is true for Table 5-1, Table 5-2, Table 5-4, Table 5-6 and Table 5-7. The same sequence of gaseous heterogeneous reactants, with minor exceptions, is used in listing gas/surface mass accommodation and other reversible gas uptake coefficients (Table 5-1), gas/surface reactive uptake kinetics (Table 5-2) and Henry's Law Constants for pure water (Table 5-4), aqueous acids (Table 5-6) and sea water or sea water simulations (Table 5-7).

I.6 Units

Rate constants, *k*, are given in units of concentration expressed as molecules per cubic centimeter and time in seconds. That is, for first-, second-, and third-order reactions, units of *k* are s^{-1}, cm^3 $molecule^{-1}$ s^{-1}, and cm^6 $molecule^{-2}$ s^{-1}, respectively. Absorption cross sections are expressed as cm^2 $molecule^{-1}$, base e. For reactions in the aqueous phase, following the convention in that area of study, we use the concentration units mol L^{-1}. Thus, second-order rate constants are in units of L mol^{-1} s^{-1}. Thermodynamic quantities are expressed in units of Joules and moles. Thus, enthalpies are given in units of kJ mol^{-1} and entropies in units of J K^{-1} mol^{-1}. Henry's Law constants are given in units of mol L^{-1} atm^{-1}.

I.7 Noteworthy Changes/Updates in this Evaluation

The citations within the evaluation have been updated to include doi's in nearly all cases.

1.7.1 Bimolecular Reactions (Section 1)

The entire NO_x chemistry section has been evaluated and updated. Several pressure dependent reactions have been moved to the Termolecular section (Table 2.1), as noted.

Reactions of Criegee intermediates (CH_2OO, CH_3CHOO, and $CH_3CH(OO)CH_3$) have been updated and/or added to the evaluation.

The isoprene nitrate formation reaction has been added to the organic chemistry sub-section.

A review and update of FO_x, ClO_x, BrO_x and IOx reactions was conducted for this evaluation with particular emphasis on the reactions of OH and Cl with hydrocarbons and halocarbons. Many of the recommendations are based (at least in part) on relative rate investigations in which the derivation of the target rate constant was based on the rate constant for one or more reference reactions. In cases where significant revisions were made in the recommended rate parameters for reactions that were used as references in relative rate studies, the effect on other reaction recommendations was tracked and appropriate revisions were made.

The sulfur reaction section includes updates to recommendations and/or notes for the following reactions: OH + H_2S, OCS, and SO; HO_2 + SO_2, Cl + H_2S, SH + Cl_2, BrCl, Br_2, and F_2; $HOSO_2$ + O_2; and $CH_3SCH_2O_2$ + NO.

Evaluations of the Na + CO and NaOH + H reactions and other updates have been added to the metal chemistry sub-section.

1.7.2 Termolecular Reactions (Section 2)

Several reactions have been added/updated to Table 2. Reactions with a chemical activation (CA) mechanism have been moved to Table 2.2 and a description of the CA mechanism added to the introduction.

1.7.3 Equilibrium Constants (Section 3)

Several new entries and updates, including Na and Hg reactions, have been added to Table 3.

1.7.4 Photochemical Data (Section 4)

Notes have been revised and updated as indicated in Table 4-1. Recommended uncertainty estimates for the absorption cross sections and photolysis quantum yields are included within the notes. (However, not all molecules include uncertainty estimates.) Absorption cross section uncertainty factors are primarily based on the wavelength regions most critical to atmospheric photolysis. New entries include. N_2O_3, CH_3CH_2OH, $(CH_3)_2CHOH$, CH_2OO, CH_3CHOO, $(CH_3)_2COO$, CH_3CH_2CHOO, HC(O)OOH, CH_2FCH_2OH, CHF_2CH_2OH, CF_3CH_2OH, $(CF_3)_2CHOH$, CCl_2FCCl_2F (CFC-112), CCl_3CClF_2 (CFC-112a), CCl_3CF_3

(CFC-113a), CCl_2FCF_3 (CFC-114a), $CHCl_2CClF_2$ (HCFC-122), $CHClFCCl_2F$ (HCFC-122a), $CHClFCClF_2$ (HCFC-123a), CH_2FCCl_2F (HCFC-132c), $CH_2=CHCl$, $CHCl=CCl_2$, $CCl_2=CCl_2$, $CH_2=CBrCF_2CF_3$, $CH_2=CHCF_2CF_2Br$, $CH_2=CHCFClCF_2Br$, and CH_3SSCH_3.

1.7.5 Heterogeneous Processes (Section 5)

In this section, evaluations of heterogeneous uptake processes focused on the kinetics of several highly reactive gaseous atmospheric species including: OH on ice and liquid water; O_3 on aqueous bromide solutions; N_2O_5 on liquid water, aqueous nitrate and halide solutions and mineral dust; and HO_2 on aqueous salt solutions, mineral dust and organic surfaces. In the case of N_2O_5, uptake coefficients measured in laboratories were compared with those occurring on ambient particles during field measurements. A number of new or revised values for aqueous Henry's Law constants have been added. Finally, a new evaluation area has been added to this section: the review and evaluation of aerosol optical properties for atmospherically relevant ambient aerosol components. Initial activity evaluated the complex refractive index of ammonium sulfate over wavelengths from the far infrared to the near ultraviolet.

1.7.6 Aqueous Chemistry (Section 6)

This new section was established to recognize the possible importance of homogeneous, aqueous-phase processes in atmospheric chemistry. This initial iteration contains a table of aqueous reactions that may be involved in the activation of halides – that is, their conversion to halogen molecules. Rate constants and/or equilibrium constants are provided and there are links to notes on the sources of the data. Several of these notes are quite extensive, reflecting the complexity of the studies underlying the results.

1.7.7 Thermodynamic Parameters (Section 7)

The Table of Thermodynamic Properties has been further expanded to about 900 species. The Table is divided into 90 groups, each linked to the notes for those species. The references for each group are at the end of the notes for that group. In addition, there is a list of groups at the beginning of the Table, with links to the individual groups.

1.7.8 Bibliography – Master (Section 8)

In addition to the bibliographies included at the end of each section, all references cited within the evaluation are summarized in this section. References have been updated to include new references, full titles, and doi's.

I.8 Acknowledgements

Financial support from the NASA Upper Atmosphere Research and Tropospheric Chemistry Programs is gratefully acknowledged.

SECTION 1. BIMOLECULAR REACTIONS

Table of Contents

1.1 Introduction

In Table 1 (Rate Constants for Bimolecular Reactions) the evaluated reactions are grouped into the classes O_x, $O(^1D)$, Singlet O_2, HO_x, NO_x, Organic Compounds, FO_x, ClO_x, BrO_x, IO_x, SO_x, and Metals. Some of the reactions in Table 1 are actually more complex than simple two-body, bimolecular, reactions. To explain the pressure and temperature dependences occasionally measured in reactions of this type, it is necessary to consider the bimolecular class of reactions in terms of two subcategories, direct (concerted) and indirect (nonconcerted) reactions.

A direct, or concerted, bimolecular reaction is one in which the reactants A and B proceed to products C and D without the intermediate formation of an AB adduct that has appreciable bonding, i.e., there is no bound intermediate; only the transition state $[AB]^{\#}$ lies between reactants and products.

$$A + B \rightarrow [AB]^{\#} \rightarrow C + D$$

The reaction of OH with CH_4 forming $H_2O + CH_3$ is an example of a reaction of this class.

The rate constants for these reactions can, in general, be reasonably well represented by the Arrhenius expression

$$k(T) = A\times\exp(-E/RT)$$

over the temperature range of atmospheric interest. Very useful correlations between the expected structure of the transition state $[AB]^{\#}$ and the Arrhenius A-factor of the reaction rate constant can be made, especially in reactions that are constrained to follow a well-defined approach of the two reactants in order to minimize energy requirements in the making and breaking of bonds. The recommended parameters, A and E/R, are given in Table 1 as discussed below and the temperature range associated with their recommended use is given in the corresponding reaction note (e.g. "below 400 K"). Rate constants for reactions of this type are not pressure dependent.

However, even for this class of reactions, deviation in the temperature dependence from the simple Arrhenius expression mentioned above may be apparent over the full range of the experimental data considered in the evaluation, and even over the more limited temperature range used to derive the Arrhenius expression recommendation. Deviation from Arrhenius behavior is typically exhibited as curvature in the Arrhenius plot - a concave upward curvature in $\ln(k(T))$ versus 1/T. There are several possible factors that may contribute to this curvature such as multiple reaction channels, the existence of reactant conformers, tunneling, and others. In cases where curvature was experimentally resolved, the reaction note emphasizes the temperature range over which the Arrhenius parameters given in Table 1 are applicable and also provides a recommended three-parameter expression

$$k(T) = A\times(T/298)^{n}\times\exp(-E/RT)$$

where n is a fit parameter, that better represents the overall temperature dependence.

The indirect or nonconcerted class of bimolecular reactions is characterized by a more complex reaction path involving a potential well between reactants and products, leading to a bound adduct (or reaction complex) formed between the reactants A and B:

$$A + B \leftrightarrow [AB]^{*} \rightarrow C + D$$

The intermediate $[AB]^*$ is different from the transition state $[AB]^{\#}$, in that its lifetime substantially exceeds the characteristic time of intermolecular vibrations and, thus, it is considered a bound molecule. Of course, transition states are involved in all reactions, both forward and backward, but are not explicitly shown in the equation above. An example of a reaction of this class is ClO + NO, which normally produces $Cl + NO_2$. Reactions of the nonconcerted type can have more complex temperature dependences and can exhibit a pressure dependence if the lifetime of $[AB]^*$ is comparable to the rate of its collisional deactivation. This arises because the relative rate at which a complex $[AB]^*$ decomposes to products C + D or back to reactants A + B is a sensitive function of its internal energy. Thus, in reactions of this type, the distinction between the bimolecular and termolecular classification becomes less meaningful, and it is especially necessary to study such reactions under the temperature and pressure conditions in which they are to be used in model calculations, or, alternatively, to develop reliable theoretical bases for extrapolation of the experimental data. In several cases where sufficient data exist, reactions of this type are treated in Section 2 and included in the corresponding table for termolecular reactions.

As mentioned above, the recommended rate constant tabulation for bimolecular reactions (Table 1) is given in Arrhenius form, $k(T) = A\times\exp(-E/RT)$, and contains the following information:

1. Reaction stoichiometry and products (if known)

2. Temperature range of available kinetic data, not necessarily the temperature range for the recommended Arrhenius parameters
3. Arrhenius *A*-factor: ***A***
4. Recommended temperature dependence (“activation temperature”): ***E*/R**
5. Recommended rate constant at 298 K: ***k*(298 K)**
6. Rate constant uncertainty factor at 298 K: ***f*(298 K)** (see below)
7. A parameter used to calculate the rate constant uncertainty at temperatures other than 298 K: ***g*** (see below)
8. Index for a detailed note containing references to the literature, the basis of recommendation and, in several cases, alternative methods to calculate the rate constant.

For a few reactions, the recommendations for *A*, *E*/R and *k*(298 K) are italicized in blue font. These represent estimates by the Panel in cases where there are either no literature data, where the existing data are judged to be of insufficient quality to base a recommendation, or where the recommendation is based on an extrapolation of very limited experimental data.

1.2 The Evaluation Procedure

The process of evaluating chemical kinetic data does not conform to a simple set of mathematical rules. There is no “one size fits all” algorithm that can be applied and each reaction must be examined on a case-by-case basis. Consideration of uncertainties in the kinetic and photochemical parameters used in atmospheric models plays a key role in determining the reliability of and uncertainty in the model results. Quite often the cause(s) of differences in experimental results from various laboratories can’t be determined with confidence and making recommendations for the uncertainties of the rate constant is often more difficult than for making recommendations of the Arrhenius parameters themselves. In many cases, investigators suggest possible qualitative reasons for disagreements among datasets. Thus, data evaluators necessarily must consider a variety of factors in assigning a recommendation, including such aspects as the chemical complexity of the system, sensitivities and shortcomings of the experimental techniques employed, similarities or trends in reactivity, and the level of agreement among studies using different techniques.

A recommendation for *k*(298 K) is typically made by averaging the rate constants from those studies deemed to be of sufficiently high quality / reliability and free from chemical interferences that could have biased the results. In cases where a study provides reliable data over a range of temperatures of atmospheric interest, the value of *k*(298 K) used in the averaging process is typically obtained from a weighted non-linear least-squares fit to the data from that study, *k*(T) versus T, assuming equal relative uncertainties in the rate constants reported at the different temperatures. In deriving a recommended Arrhenius temperature dependence (*E*/R), the selected data sets are examined to ascertain the temperature range over which a standard Arrhenius fit to the data provides an adequate representation. Each data set is then scaled by a constant factor so that the Arrhenius expressions describing the individual data sets give the recommended *k*(298 K) and a weighted non-linear least-squares fit to all of these scaled data is then made. This typical process is helpful in avoiding biases resulting from systematic errors associated with an individual data set or from the fact that the individual data sets may have been obtained over significantly different temperature ranges. In cases where the selected data sets have been obtained over similar ranges of temperature, a fit to the combined scaled data often yields a value for *E*/R not very different from that obtained by averaging the *E*/R values from the individual studies. The recommended Arrhenius pre-exponential factor “A” is then calculated based on the recommended values for *k*(298 K) and *E*/R.

1.3 Uncertainty Estimates

The parameters *f*(298 K) and g given in Table 1 can be used to calculate an estimated rate constant uncertainty at any given temperature, corresponding to approximately one standard deviation, from the following expression:

$$f(\mathrm{T}) = f(298\ \mathrm{K})\exp\left|g\left(\frac{1}{\mathrm{T}} - \frac{1}{298}\right)\right|$$

where the exponent is an absolute value.

Note that, since *f*(298 K) and g have been defined to correspond to approximately one standard deviation, *f*(T) yields a similar uncertainty interval. The more commonly used 95% confidence limits at a given temperature can be obtained by multiplying and dividing the recommended value of the rate constant at that temperature by the factor $f^2(\mathrm{T})$. It should be emphasized that the parameter g has been defined exclusively for use with *f*(298 K) in the above expression and should not be interpreted as the uncertainty in the Arrhenius activation temperature (E/R). Thus, g is dependent on the value selected for f(298 K). For example, reactions for which f(298 K) is rather large may require only a small value of g to represent an adequate total rate constant uncertainty at other temperatures.

The uncertainty factor f(298 K), corresponding to approximately one standard deviation in the case of normally distributed data, was assigned such that all of the data used in deriving the average are encompassed within the band derived by multiplying and dividing k(298 K) by f^2(298 K), i.e., two standard deviations, which is considered a 95% confidence interval for the evaluation. In some cases, a slightly higher value of f(298 K) may be recommended to encompass outlying data that were not used in the averaging but could not be entirely rejected. The uncertainty factor "g" was then selected for use in the f(T) expression described below such that f^2(T) encompasses all of the data used in the evaluation over the temperature range of the recommendation. Neither f(298 K) nor g is derived from a rigorous statistical treatment of the available data, which generally are too limited to permit such analyses and, more importantly, do not follow a normal statistical distribution. Rather, the uncertainty estimation is based on knowledge of the techniques, the difficulties of the experiments, and the potential for systematic errors.

This approach is based on the fact that rate constants are typically known with greater certainty at room temperature where the experimental data are more abundant and often more reliable. The overall uncertainty normally increases at other temperatures where there are fewer data. In addition, data obtained at temperatures far distant from 298 K may be less accurate than at room temperature due to various experimental difficulties or complications.

The uncertainty represented by f(T) is normally symmetric; i.e., the rate constant may be greater than or less than the recommended value, k(T), by the factor f(T). In a few cases in Table 1 asymmetric uncertainties are given in the temperature coefficient. For these cases, the factors by which a rate constant is to be multiplied or divided to obtain, respectively, the upper and lower limits are not equal, except at 298 K where the factor is simply f(298 K).

Finally, there is obviously no way to quantify "unknown" errors. The spread in results among different techniques for a given reaction may provide some basis for an uncertainty estimate, but the possibility of the same, or compensating, systematic errors in all the studies can't be disregarded. Comparisons among rate constants recommended for similar reactions or for reactions within a homologous series of compounds can also help in the assignment of uncertainty factors. For measurements subject to large systematic errors, the true rate constant may be much further from the recommended value than would be expected and allowed for with any reasonable values of f(T) based on the data available for the evaluation. For example, there have been cases in the past where the recommended rate constants have changed by factors well outside of the uncertainties that had been assigned in the absence of quantitative knowledge of systematic errors. However, as experimental techniques improve together with improved understanding of various reactive processes and with significant expansion of the kinetic and thermodynamic database for the recommendations, exceptionally large changes are becoming less likely.

Rate Constants for Bimolecular Reactions

1.4 O$_x$ Reactions

1.4.1 Table 1A: O$_x$ Reactions

Reaction	Temperature Range of Exp. Data(K) [a]	*A*-Factor	*E*/R	*k*(298 K)[b]	*f*(298 K)[c]	*g*	Note
$O + O_2 \xrightarrow{M} O_3$		(See Table 2-1)					
$O + O_3 \rightarrow O_2 + O_2$	220–409	8.0×10^{-12}	2060	8.0×10^{-15}	1.10	200	A1

Shaded areas indicate changes or additions since JPL15-10.

[a] Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

[b] Units are cm^3 $molecule^{-1}$ s^{-1}.

[c] *f*(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(\mathrm{T}) = f(298\ \mathrm{K})\exp\left|g\left(\frac{1}{\mathrm{T}} - \frac{1}{298}\right)\right|$$

Note that the exponent is an absolute value.

1.4.2 Notes: O$_x$ Reactions

A1. **$O + O_3$.** The recommended rate expression is from Wine et al.[5] and is a linear least-squares fit of all data (unweighted) from Davis et al.,[2] McCrumb and Kaufman,[3] West et al.,[4] Arnold and Comes,[1] and Wine et al.[5] (Table: 83-62, Note: 83-62, Evaluation: 10-6) Back to Table

Shaded areas indicate changes or additions since JPL15-10. Italicized blue entries denote estimates.

[a] Recommended product channel branching ratios are temperature independent unless noted otherwise.

[b] Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

[c] The total rate coefficient (i.e., $O(^1D)$ loss) is defined as A × exp(-*E*/RT) in units of cm^3 $molecule^{-1}$ s^{-1}.
The rate coefficient for an individual reaction channel, if provided, is defined as Branching Ratio × A × exp(-*E*/RT) in units of cm^3 $molecule^{-1}$ s^{-1}.

[d] Units of cm^3 $molecule^{-1}$ s^{-1}.

[e] *f*(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(\mathrm{T}) = f(298\ \mathrm{K})\exp\left|g\left(\frac{1}{\mathrm{T}} - \frac{1}{298}\right)\right|$$

Note that the exponent is an absolute value.

1.5.2 Notes: $O(^1D)$ Reactions

A2. **$O(^1D)$ Reactions**. $O(^1D)$ reactions are complex with several possible exothermic reaction pathways, which include (1) collisional (physical) quenching of $O(^1D)$ to ground state oxygen atoms, $O(^3P)$, (2) abstraction or addition-elimination reaction, and (3) reactive quenching to form $O(^3P)$ and products other than the reactant, including stable and radical species. The recommended total rate coefficient parameters given in the table are for the disappearance of $O(^1D)$. The details of deriving a recommended rate coefficient are given in the note for each reaction. In deriving recommended values, direct measurements are used whenever possible. However, rate coefficients measured via relative rate techniques have been considered for checking consistency in measured elementary reaction rate coefficients. The ratios of the rate coefficients for $O(^1D)$ reactions measured using the same method (and often the same apparatus) may be more accurate and precise than the individual recommended rate coefficients. The ratios of rate coefficients can be obtained from the original references. The weight of the evidence indicates that the results from Heidner and Husain,[4] Heidner et al.,[3] and Fletcher and Husain[1,2] contain systematic errors and, therefore, are not considered in the determination of the recommendations.

The basis for the product branching ratio recommendations for deactivation and chemical reaction are described in the individual reaction notes. The collisional quenching channel and yield is listed as the first (possibly only) reaction pathway for each reaction given in the table. Reactive quenching channels, i.e., channels that produce $O(^3P)$ and reaction products, are included for the O_2 and O_3 reactions, but have not been identified in the majority of the other experimental studies. Bromine, chlorine, and hydrogen are more easily displaced than fluorine from halocarbons and, therefore, typically account for major reaction product yields in the form of BrO, ClO, and OH radicals. The uncertainties in the recommended branching ratios are taken from the experimental studies (see notes) where possible. For some channels, a range of values is provided in parenthesis that is consistent with the other reported uncertainties and a total branching ratio of unity.

A3. **$O(^1D) + O_2$**. The recommended 298 K rate coefficient was derived from the studies of Blitz et al.,[4] Amimoto et al.,[11,2] Lee and Slanger,[9,10] Davidson et al.,[5,6] Dunlea and Ravishankara,[7] Streit et al.,[13] Strekowski et al.,[14] and Takahashi et al.[15] The temperature dependence was computed by normalizing the results of Strekowski et al., Dunlea and Ravishankara, and Streit et al. to the 298 K value recommended here. The deactivation of $O(^1D)$ by O_2 leads to the production of $O_2(^1\Sigma)$ with an efficiency of (80 ± 20)% (Noxon,[11] Biedenkapp and Bair,[3] Snelling,[12] and Lee and Slanger[9]). $O_2(^1\Sigma)$ is produced in the $v = 0$, 1, and 2 vibrational levels in the amounts 60%, 40%, and <3%, respectively (Gauthier and Snelling[8] and Lee and Slanger[9]). The fractional deactivation of $O(^1D)$ that leads to the excitation of $O_2(^3\Sigma)$ to $O_2(^1\Delta)$ is expected to be ~20%. An $O_2(^1\Sigma)$ yield of (80 ± 20)% is recommended with the $O_2(^1\Delta)$ yield accounting for the balance of the reaction.

A4. **$O(^1D)$ + O_3.** The room temperature rate coefficient was derived from the results of Davidson et al.,[4,5] Streit et al.,[8] Amimoto et al.,[1,2] Wine and Ravishankara,[10-12] Talukdar and Ravishankara,[9] and Dunlea and Ravishankara.[6] The reaction of $O(^1D)$ with O_3 gives $O_2 + O_2$ or $O_2 + O + O$ as products. Davenport et al.[3] and Amimoto et al.[2] report that, on average, one ground state O atom is produced per $O(^1D)$ reacting with O_3. Dunlea et al.[7] have shown that the yield of $O(^3P)$ in this reaction is close to, but not exactly, unity. Dunlea et al. suggest a small, but significant decrease in the O atom yield with decreasing temperature. An $O(^3P)$ yield of unity at all temperatures is recommended until the results from the Dunlea et al. study are confirmed. (Table: 06-2, Note: 15-10, Evaluated: 10-6) Back to Table

A5. **$O(^1D) + H_2$.** The recommendation is based on the room temperature rate coefficient data from Davidson et al.,[2,3] Force and Wiesenfeld,[4,5] Wine and Ravishankara,[10] Talukdar and Ravishankara,[8] Blitz et al.,[1] and Vranckx et al.[9] Davidson et al. (200–350 K) and Vranckx et al. (227–453 K) report that *k* is independent of temperature. Wine and Ravishankara[10] and Vranckx et al.[9] report the yield of $O(^3P)$ to be <4.9% and (0.7 ± 0.7)%, respectively. Hence, the major products of this reaction are H + OH with a recommended yield of unity. Koppe et al.[6] report a 2.7 times larger rate coefficient at a collisional energy of 0.12 eV. This does not agree with the observations of Davidson et al.[3] and Vranckx et al. who reported that *k* is independent of temperature and Matsumi et al.[7] who report no change in *k* when translationally hot $O(^1D)$ was moderated with Ar.

A6. **$O(^1D) + H_2O$.** The recommended *k*(298 K) is based on the results of Davidson et al.,[3] Amimoto et al.,[1] Wine and Ravishankara,[12,13] Gericke and Comes,[6] Dunlea and Ravishankara,[5] Carl,[2] and Takahashi et al.,[10] but is weighted towards the study of Dunlea and Ravishankara because they used several different methods to quantify the water vapor concentration. The results of Lee and Slanger[8] and Dillon et al.[4] are consistent with the recommended value. The temperature dependence of the rate coefficient was derived from the data of Streit et al.[9] and Dunlea and Ravishankara, after normalizing the results from the two studies to the *k*(298 K) value recommended here. The $O_2 + H_2$ product yield was measured by Zellner et al.[14] to be (1 +0.5/–1)% and Glinski and Birks[7] to be (0.6 +0.7/–0.6)%. The yield of $O(^3P)$ from $O(^1D) + H_2O$ is reported to be less than (4.9 ± 3.2)% by Wine and Ravishankara,[13] (2 ± 1)% by Takahashi et al.,[11] and <0.3% by Carl.[2] The recommended yield of OH in this reaction is 2.0. To calculate the rates of OH production via $O(^1D)$ reactions in the atmosphere, the quantities of interest are the ratios of the rate coefficients for the reaction of $O(^1D)$ with H_2O to those with N_2 and O_2. Ratio data are given in the original references for this reaction.

A7. **O(^{1}D) + N_2**. The rate coefficient recommendation for this reaction is taken from Ravishankara et al.,[4] which included the results from Strekowski et al.,[5] Blitz et al.,[1] and Dunlea and Ravishankara[3] in their analysis. The more recent results from Takahashi et al.[6] and Dillon et al.[2] are in agreement with the recommendation. Strekowski et al. reported the rate coefficient for O(^{1}D) removal by air and their results are in excellent agreement with the value derived using the current recommendation for O(^{1}D) removal by N_2 and O_2. The reaction leads to 100% quenching of O(^{1}D) to O(^{3}P) with no significant reactive channels (see Table 2). (Table: 06-2, Note: 15-10, Evaluated: 10-6) Back to Table

(6) Takahashi, K.; Takeuchi, Y.; Matsumi, Y. Rate constants of the O(^{1}D) reactions with N_2, O_2, N_2O, and H_2O at 295 K. *Chem. Phys. Lett.* **2005**, *410*, 196-200, doi:10.1016/j.cplett.2005.05.062.

A8. **O(^{1}D) + N_2O**. This reaction has two reactive channels, one producing 2NO and the other producing N_2 + O_2. For atmospheric calculations of NO_x production, the rate coefficient for the channel that produces NO is critical, while the overall rate coefficient is important for deriving the loss rate of N_2O. The recommendation for the overall room temperature rate coefficient for the removal of $O(^1D)$ by N_2O was derived from a weighted average of the results from Davidson et al.,[6] Amimoto et al.,[1] Wine and Ravishankara,[13] Blitz et al.,[2] Dunlea and Ravishankara,[8] Carl,[5] Takahashi et al.,[11] Dillon et al.,[7] and Vranckx et al.[12] The temperature dependence of the rate coefficient was derived from the results of Davidson et al. (204–359 K), Dunlea and Ravishankara (220–370 K), and Vranckx et al. (227–715 K); only data at <400 K were considered in the evaluation, after normalization to the k(298 K) value recommended here for the overall rate coefficient. The recommended rate coefficients for the $N_2 + O_2$ and 2NO product channels were evaluated for 298 K, the only temperature at which such data are available. The branching ratio, R, $k(NO + NO)/k(Total)$ is taken from Cantrell et al.[4] who reported R = 0.57 as well as an analysis of all measurements from 1957–1994 that led them to recommend R = 0.61 ± 0.06, where the uncertainty is the 95% confidence interval. Their recommended branching ratio agrees well with earlier measurements of the quantum yield from N_2O photolysis (Calvert and Pitts[3]). Dependencies of the branching ratio on $O(^1D)$ translational energy and temperature are at present not clearly resolved. The recommended rate coefficients for the two channels as a function of temperature were derived assuming that the branching ratio for the two channels is invariant with temperature.

The yield of $O(^3P)$ from $O(^1D) + N_2O$ (physical quenching or chemical reaction) has been determined to be <0.04, 0.04 ± 0.02, 0.056 ± 0.009, and 0.005 ± 0.002 by Wine and Ravishankara,[13] Nishida et al.,[10] Carl,[5] and Vranckx et al.[12] at 298 K, respectively. Vranckx et al. report a slight increase in the $O(^3P)$ yield with increasing temperature (248–600 K) and their reported yield supersedes the anomalously high value reported by Carl[5] from the same laboratory. A recommended $O(^3P)$ yield of <0.01 is based on the Vranckx et al. study. A direct measurement of the NO yield from the $O(^1D) + N_2O$ reaction in synthetic air by Greenblatt and Ravishankara[9] and the re-analysis by Dunlea and Ravishankara[8] agrees very well with the value predicted using the recommended $O(^1D)$ rate coefficients for N_2, O_2, and N_2O and the $O(^1D) + N_2O$ product branching ratio to give NO + NO. Better reactive channel branching ratio measurements at stratospheric temperatures and/or measurements of the NO yield in this reaction as a function of temperature below 298 K would be useful.

A9. $O(^1D) + NH_3$. The recommended rate coefficient and temperature dependence is taken from Davidson et al.[1] Sanders et al.[2] have detected the products $NH(a^1\Delta)$ and OH formed in the reaction. They report that the yield of $NH(a^1\Delta)$ is in the range 3–15% of the amount of the OH detected. A unit reaction yield is recommended. Further studies are needed to quantify the reaction channel branching ratios.

A10. O(^{1}D) + HCN. Strekowski et al.[1] measured the total rate coefficient over the temperature range 211 to 425 K. Their results, the only study available, are recommended. There are several possible exothermic product channel pathways. Strekowski et al. report an O(^{3}P) yield at 298 K to be ~0.3 and observed the O(^{3}P) yield to have a negative temperature dependence. A significant H atom product channel, ~0.35, was determined at 298 K. The recommended reactive yield was taken from this work.
(Table 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

A11. O(^{1}D) + CH_3CN. Strekowski et al.[1] measured the total rate coefficient over the temperature range 193 to 430 K. Their results, the only study available, are recommended. There are several possible exothermic product channel pathways. Strekowski et al. report a minor O(^{3}P) collisional quenching yield over the entire temperature range. A H atom yield of 0.16 ± 0.03 at 298 K was reported. The recommended reactive yield was taken from this work.
(Table 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Strekowski, R. S.; Nicovich, J. M.; Wine, P. H. Kinetic and mechanistic study of the reactions of O($^1D_2$) with HCN and CH_3CN. *ChemPhysChem* **2010**, *11*, 3942-3955, doi:10.1002/cphc.201000550.

A12. O(^{1}D) + CO_2. k(298 K) was derived from the studies of Davidson et al.,[3] Streit et al.,[9] Amimoto et al.,[1] Dunlea and Ravishankara,[5] Shi and Barker,[8] and Blitz et al.[2] Temperature dependence was computed after normalizing the results of Dunlea and Ravishankara and Streit et al. (only the data in the range of 200 to 354 K) to the value of k(298 K) recommended here. The rate coefficient at 195 K reported by Blitz et al. is consistent with the recommendation.

This reaction produces O(^{3}P) and CO_2, and is expected to proceed through the formation of a CO_3 complex (see for example DeMore and Dede[4]). This complex formation leads to isotopic scrambling (see for example Perri et al.[6]). There appears to be a small, but non-negligible, channel for O(^{1}D) quenching. A reactive channel to give CO and O_2 has been reported,[7] but needs better quantification. A quenching yield of unity is recommended.

(9) Streit, G. E.; Howard, C. J.; Schmeltekopf, A. L.; Davidson, J. A.; Schiff, H. I. Temperature dependence of O(^{1}D) rate constants for reactions with O_2, N_2, CO_2, O_3, and H_2O. *J. Chem. Phys.* **1976**, *65*, 4761-4764, doi:10.1063/1.432930.

A13. O(^{1}D) + CH$_4$. The recommended overall rate coefficient for the removal of O(^{1}D) by CH$_4$ at room temperature is a weighted average of the results from Davidson et al.,[4] Blitz et al.,[1] Dillon et al.,[5] and Vranckx et al.[11] The temperature dependence of the rate coefficient was derived from the results of Davidson et al. (198–357 K), Dillon et al. (223–297 K), and Vranckx et al. (227–450 K) The recommended rate coefficients for the product channels (a) CH_3 + OH, (b) CH_3O or CH_2OH + H and (c) CH_2O + H_2 were evaluated for 298 K, the only temperature at which such data are available. Lin and DeMore[6] analyzed the final products of N_2O/CH_4 photolysis mixtures and concluded that (a) accounted for about 90% and (c) accounted for about 9%. Casavecchia et al.[2] used a molecular beam experiment to observe H and CH_3O (or CH_2OH) products. They reported that the yield of H_2 was <25% of the yield of H from channel (b). Satyapal et al.[9] observed the production of H atoms in a pulsed laser experiment and reported an H atom yield of 25 ± 8%. Matsumi et al.[8] reported the H atom yield in low pressure gas mixtures to be (15 ± 3)%. Chen et al.[3] used laser infrared kinetic spectroscopy to study product formation and report yields of (67 ± 5)%, (30 ± 10)%, and 5% for channels a, b, and c, respectively. The yield of O(^{3}P) via the physical quenching of O(^{1}D) by CH$_4$ has been reported by several groups. Wine and Ravishankara,[12] Matsumi et al.,[7] and Takahashi et al.[10] reported O(^{3}P) yields of <4.3%, <5%, and <1%, respectively. Vranckx et al.[11] reported the most sensitive O(^{3}P) yield measurement to date and obtained a yield of 0.002 ± 0.003. We recommend the following branching ratios (a) (75 ± 15)%, (b) (20 ± 10)%, (c) (5 ± 5)%, and no O(^{1}D) collisional quenching . It is assumed that the branching ratio for the three reactive channels is invariant with temperature.

A14. O(^{1}D) + HCl. The recommended room temperature rate coefficient is based on the measurements of Davidson et al.,[3] Wine et al.,[5] and Chichinin.[1] The temperature dependence is based on the measurements of Davidson et al. Product studies by Wine et al. indicate: O(^{3}P) + HCl (9 ± 5)%; H + ClO (24 ± 5)%; and OH + Cl (67 ± 10)%. Takahashi et al.[4] report that the O(^{3}P) yield is (15 ± 4)%. Chichinin[2] report the H + ClO channel to be (18 ± 4)%. The recommended total reactive yield is based on an average of the Wine et al. and Takahashi et al. results with an estimated uncertainty that encompasses the range of the measurements at the 2σ level. The H + ClO channel branching ratio is the average of the Wine et al. and Chichinin results with the balance of the reactive channel leading to the formation of Cl + OH.

(4) Takahashi, K.; Wada, R.; Matsumi, Y.; Kawasaki, M. Product branching ratios for O(^{3}P) atom and ClO radical formation in the reactions of O(^{1}D) with chlorinated compounds. *J. Phys. Chem.* **1996**, *100*, 10145-10149, doi:10.1021/jp952710a.
(5) Wine, P. H.; Wells, J. R.; Ravishankara, A. R. Channel specific rate constants for reactions of O(^1D) with HCl and HBr. *J. Chem. Phys.* **1986**, *84*, 1349-1354, doi:10.1063/1.450526.

A15. O(^{1}D) + HF. The recommended values of *k*(298 K) and the reactive yield are those reported by Sorokin et al.,[1] the only study available. It is assumed that the rate coefficient and product yields are independent of temperature. The reactive products of this reaction are F + OH. The channel to give H + FO is endothermic and, hence, considered to be unimportant.
(Table: 06-2, Note: 06-2, Evaluated: 06-2) Back to Table

(1) Sorokin, V. I.; Gritsan, N. P.; Chichinin, A. I. Collisions of O(^{1}D) with HF, F_2, XeF_2, NF_3, and CF_4: Deactivation and reaction. *J. Chem. Phys.* **1998**, *108*, 8995-9003, doi:10.1063/1.476346.

A16. O(^{1}D) + NF_3. The recommended value for *k*(298 K) is based on the results of Zhao et al.,[4] Dillon et al.,[2] and the value reported by Baasandorj et al.[1] at 296 K. The *k*(298 K) value reported by Sorokin et al.[3] is a factor of two lower and not considered in the recommendation. The recommended Arrhenius parameters are derived from a fit to these data after normalization to *k*(298 K). Sorokin et al., Zhao et al., and Baasandorj et al. report reactive yields of 0.70, >0.95, and 0.87 +0.13/-0.15, respectively. The recommended reactive yield is an average of the values reported by Zhao et al. and Baasandorj et al. The reactive yield is expected to be independent of temperature. Sorokin et al. observed a high FO radical reaction product yield. Dillon et al. observed a high F-atom yield and attribute the FO formation in the Sorokin et al. study to secondary chemistry. No recommendation is given for the reaction products.

(4) Zhao, Z.; Laine, P. L.; Nicovich, J. M.; Wine, P. H. Reactive and non-reactive quenching of O(^{1}D) by the potent greenhouse gases SO_2F_2, NF_3, and SF_5CF_3. *Proc. Nat. Acad. Sci.* **2010**, *107*, 6610-6615, doi:10.1073/pnas.0911228107.

A17. O(^{1}D) + HBr. The recommended rate coefficient at 298 K was taken from Wine et al.[3] There are no reports on the temperature dependence of this rate coefficient. Because it is close to a collisional rate coefficient, the rate coefficient is assumed to be temperature independent. On the basis of O(^{3}P) and H(^{2}S) atom detection, Wine et al. reported physical quenching, HBr + O(^{3}P), in this reaction to be (20 ± 7)%, which is recommended here assuming that no reactive quenching occurs, and the H + BrO reactive product channel to be <4.5%. In a crossed molecular beam study of this reaction, Balucani et al.[1] found the BrO yield to be >(14 ± 6)%. Using transient UV absorption spectroscopy, Cronkhite et al.[2] found the BrO yield to be (20 ± 4)%, which is recommended here. The balance of the reaction leads to the formation of Br + OH products.

A18. $O(^1D) + Cl_2$. The recommended $k(298\ K)$ is based on the studies of Wine et al.[6] and Sorokin et al.[4] There are no reports on the temperature dependence of this rate coefficient. The rate coefficient is assumed to be temperature independent because $k(298\ K)$ is close to a collisional rate coefficient. Wine et al. report a $O(^3P)$ yield of 0.25 ± 0.10. The Cl atom measurements of Chichinin[1] are consistent with a ClO + Cl yield of 0.7. These values are in excellent agreement with the directly measured ClO yield of 74 ± 15% by Takahashi et al.[5] and 77 ± 10% by Feierabend et al.[2] Feierabend et al. also reported no measurable (<10%) change in the ClO radical yield at 202 K. An indirect study by Freudenstein and Biedenkapp[3] is in reasonable agreement with the yield of ClO. Though energetically allowed, the formation of Cl_2O is expected to be negligible under atmospheric pressure and temperature conditions. On the basis of the Wine et al., Takahashi et al. and Feierabend et al. studies the recommended total reactive and Cl + ClO channel yield is 0.75 ± 0.07, independent of temperature.

A19. $O(^1D) + CCl_2O$. The recommended value of $k(298\ K)$ is derived from the values reported by Chichinin[1] and Strekowski et al.[3] The relative rate study of Jayanty et al.[2] is consistent with the recommended value. The temperature dependence is taken from Strekowski et al. There are three possible reactive channels: CO + ClO + Cl; CO_2 + 2 Cl; $CO_2 + Cl_2$. In the stratosphere, all these processes will lead to CO_2 and ClO. Chichinin reports that the above 3 reactions account for (80 ± 15)% of $O(^1D)$ loss with 20% leading to $O(^3P)$. Strekowski et al. report a $O(^3P)$ yield of 0.20 ± 0.04, which is the basis of the recommendation. The rate coefficient for the loss of CCl_2O via reaction with $O(^1D)$ may be greater than 80% of the overall rate coefficient recommended here due to reactive quenching of $O(^1D)$ to $O(^3P)$.

(3) Strekowski, R. S.; Nicovich, J. M.; Wine, P. H. Quenching of $O(^1D_2)$ by Cl_2CO: kinetics and $O(^3P_J)$ yield. *Chem. Phys. Lett.* **2000**, *330*, 354-360, doi:10.1016/S0009-2614(00)01105-2.

A20. $O(^1D)$ + CClFO. The recommended rate coefficient is derived from data of Fletcher and Husain.[1] For consistency, the recommended value was derived using a scaling factor (0.5) that corrects for the difference between rate coefficients from the Husain laboratory and the recommendations for other $O(^1D)$ rate coefficients given in this evaluation. Based on consideration of similar $O(^1D)$ reactions, it is assumed that E/R equals zero and the A-factor has been set equal to $k(298\ K)$. The branching ratios are estimated based on measured values for similar compounds.
(Table: 82-57, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Fletcher, I. S.; Husain, D. The collisional quenching of $O(2^1D_2)$ by $COCl_2$, COFCl and COF_2 using atomic absorption spectroscopy in the vacuum ultraviolet. *J. Photochem.* **1978**, *8*, 355-361, doi:10.1016/0047-2670(78)80158-0.

A21. $O(^1D) + CF_2O$. The recommendation is from the data of Wine and Ravishankara.[4] Their result is preferred over the value of Fletcher and Husain[2] because it appears to follow the pattern of decreased reactivity with increased fluorine substitution observed for other halocarbons. This reaction has only been studied at 298 K. Based on consideration of similar $O(^1D)$ reactions, it is assumed that E/R equals zero and the A-factor has been set equal to $k(298\ K)$. Wine and Ravishankara report (71 ± 7)% quenching of $O(^1D)$ to $O(^3P)$. Using relative

rate methods, Atkinson et al.[1] and Jayanty et al.[3] measured reactive yields of 0.5 ± 0.15 and 0.70, respectively. The recommended reactive yield is an average of these studies.
(Table: 82-57, Note: 15-10, Evaluated: 15-10) Back to Table

A22. O(^{1}D) + CH_3Cl. The *k*(298 K) recommendation is an average of the values reported by Matsumi et al.[3] and Force and Wiesenfeld.[2] There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. There have been several product channels observed for this reaction. Matsumi et al. observed the formation of H and Cl atoms with a 0.27 ratio. Force and Wiesenfeld reported an O(^{3}P) yield of 0.09, which is the basis for the total reactive yield recommendation. Takahashi et al.[4] and Feierabend et al.[1] have reported ClO radical yields that are in excellent agreement, (0.47 ± 0.10) and (0.46 ± 0.06), respectively, which is recommended. The recommended product branching ratios for the H and Cl atom channels accounts for the remaining product yield in the ratio reported by Matsumi et al.

A23. O(^{1}D) + CCl_4. The recommended *k*(298 K) value is based on the data from Davidson et al.[1] and Force and Wiesenfeld.[3] The temperature independence of the rate coefficient is taken from Davidson et al. Force and Wiesenfeld reported this reaction to be (14 ± 6)% collisional quenching. Takahashi et al.[4] and Feierabend et al.[2] report ClO radical yields of (90 ± 19)% and (79 ± 4)%, respectively. The recommended value is taken from the more precise Feierabend et al. study. Additional product channels may also be possible.
(Table: 82-57, Note: 15-10, Evaluated: 15-10) Back to Table

A24. O(^{1}D) + CH_3CCl_3. Nilsson et al.[1] reported a room temperature reactive rate coefficient of (2.93 ± 1.2) × 10^{-10} cm^3 $molecule^{-1}$ s^{-1} (1σ error limit) that was obtained using a relative rate method with CH_4 as the reference compound. The recommended total rate coefficient was calculated assuming a 0.9 reactive yield.
(Table 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Nilsson, E. J. K.; Andersen, V. F.; Nielsen, O. J.; Johnson, M. S. Rate coefficients for the chemical reactions of CH_2F_2, $CHClF_2$, CH_2FCF_3 and CH_3CCl_3 with $O(^1D)$ at 298 K. *Chem. Phys. Lett.* **2012**, *554*, 27-32, doi:10.1016/j.cplett.2012.10.001.

A25. $O(^1D) + CH_3Br$. The recommended rate coefficient at 298 K was taken from Thompson and Ravishankara.[2] There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Thompson and Ravishankara report that the yield of $O(^3P)$ from physical quenching is (0 ± 7)%. On the basis of this single study, a unit reactive yield is recommended. Using transient UV absorption spectroscopy, Cronkhite et al.[1] measured the BrO yield to be (44 ± 5)%. The balance of the reaction is expected to lead to OH radical formation, although no experimental data are currently available.
(Table: 94-26, Note: 15-10, Evaluated: 10-6) Back to Table

A26. $O(^1D) + CH_2Br_2$. The recommendation for *k*(298 K) is based on data from Thompson and Ravishankara,[1] the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. They report that the yield of $O(^3P)$ from physical quenching is (5 ± 7)%. On the basis of this work, a reactive yield of $0.95^{+0.05}_{-0.10}$ is recommended. There are no product studies available, although the major channels are expected to lead to BrO and OH radical formation.
(Table: 94-26, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Thompson, J. E.; Ravishankara, A. R. Kinetics of $O(^1D)$ reactions with bromocarbons. *Int. J. Chem. Kinet.* **1993**, *25*, 479-487, doi:10.1002/kin.550250607.

A27. $O(^1D) + CHBr_3$. The recommendation for *k*(298 K) is based on data from Thompson and Ravishankara,[1] the only study available. The rate coefficient is large compared to analogous compounds. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. They report that the yield of $O(^3P)$ from physical quenching is (32 ± 8)%. A reactive yield of 0.70 ± 0.1 is recommended. There are no product studies available, although the formation of BrO is expected to be a major product channel.
(Table: 94-26, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Thompson, J. E.; Ravishankara, A. R. Kinetics of $O(^1D)$ reactions with bromocarbons. *Int. J. Chem. Kinet.* **1993**, *25*, 479-487, doi:10.1002/kin.550250607.

A28. $O(^1D) + CH_3F$ (HFC-41). The *k*(298 K) recommendation is the average of the measurements of Force and Wiesenfeld[2] and Schmoltner et al.[4] There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. The $O(^3P)$ product yield was reported to be (25 ± 3)% by Force and Wiesenfeld, (11 ± 5)% by Schmoltner et al., and (19 ± 5)% by Takahashi et al.[5] The recommended branching ratio is an average of these studies, with an uncertainty that encompasses the mean value from all studies at the 2σ level. Burks and Lin[1] reported observing vibrationally excited HF as a product. Park and Wiesenfeld[3] observed the formation of OH ($X^2\Pi$, v" = 0, 1) in this reaction.

A29. $O(^1D) + CH_2F_2$ (HFC-32). The *k*(298 K) recommendation is based on the measurement of Schmoltner et al.,[4] the only total rate coefficient study available. Using a relative rate technique, Green and Wayne[2] measured the loss of CH_2F_2 relative to the loss of N_2O. Their value when combined with the current recommendation for the $O(^1D) + N_2O$ reaction yields a rate coefficient for reactive loss of CH_2F_2 that is about three times the result of Schmoltner et al. Nilsson et al.[3] reported a 298 K reactive rate coefficient of $(4.78 \pm 1.02) \times 10^{-11}$ cm^3 molecule^{-1} s^{-1} in a relative rate experiment with the $O(^1D) + CH_4$ reaction as the reference. This corresponds to a reactive yield of 0.94 using the current total rate coefficient recommendation. Schmoltner et al. reported an $O(^3P)$ yield of (70 ± 11)%, which provides the basis of the reaction yield recommendation, assuming that it is due entirely to physical quenching. Burks and Lin[1] reported observing vibrationally excited HF as a product.
(Table: 94-26, Note: 15-10, Evaluated: 10-6) Back to Table

(4) Schmoltner, A. M.; Talukdar, R. K.; Warren, R. F.; Mellouki, A.; Goldfarb, L.; Gierczak, T.; McKeen, S. A.; Ravishankara, A. R. Rate coefficients for reactions of several hydrofluorocarbons with OH and $O(^1D)$ and their atmospheric lifetimes. *J. Phys. Chem.* **1993**, *97*, 8976-8982, doi:10.1021/j100137a023.

A30. $O(^1D) + CHF_3$ (HFC-23). *k*(298 K) was measured by Force and Wiesenfeld[5] and Schmoltner et al.,[6] while Baasandorj et al.[2,3] measured the rate coefficient at 298 K and over the temperature range 217–373 K. The results from these studies are in good agreement and the results from the Baasandorj et al. study are recommended. The $O(^3P)$ product yield was reported to be (77 ± 15)% by Force and Wiesenfeld and (102 ± 3%) by Schmoltner et al. Using a relative rate technique, Baasandorj et al.[2,3] measured the reactive rate coefficient (relative to the $O(^1D) + NF_3$ reaction) at room temperature. They obtained a reactive yield of 0.25 ± 0.05, using the current *k*(298 K) recommendation for the HFC-23 reaction. This result is in good agreement with the Force and Wiesenfeld result. The reaction yield recommendation is based on the more precise Baasandorj et al. studies. There is no apparent explanation for the high quenching yield reported in the Schmoltner et al. study. Although physical quenching is the dominant process, detectable yields of vibrationally excited HF have been reported by Burks and Lin[4] and Aker et al.,[1] which indicate the formation of HF + CF_2O products.

A31. $O(^1D) + CHCl_2F$ (HCFC-21). The recommendation is based on the total rate coefficient measurements of Davidson et al.[1] over the temperature range 188–343 K. Takahashi et al.[3] and Feierabend et al.[2] report the yield of ClO to be (74 ± 15)% and (73 ± 5)%, respectively. These studies are in excellent agreement and provide the recommendation for the ClO product channel branching ratio. It is expected that the OH radical, or other products, may also be formed in this reaction. An OH channel yield based on comparison with other HCFCs is estimated to be ~0.06.

(Table: 90-1, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Davidson, J. A.; Schiff, H. I.; Brown, T. J.; Howard, C. J. Temperature dependence of the rate constants for reactions of O(^{1}*D*) atoms with a number of halocarbons. *J. Chem. Phys.* **1978**, *69*, 4277-4279, doi:10.1063/1.437113.

(2) Feierabend, K. J.; Papanastasiou, D. K.; Burkholder, J. B. ClO radical yields in the reaction of O(^{1}D) with Cl_2, HCl, chloromethanes and chlorofluoromethanes. *J. Phys. Chem. A* **2010**, *114*, 12052-12061, doi:10.1021/jp10776lt.

(3) Takahashi, K.; Wada, R.; Matsumi, Y.; Kawasaki, M. Product branching ratios for O(^{3}P) atom and ClO radical formation in the reactions of O(^{1}D) with chlorinated compounds. *J. Phys. Chem.* **1996**, *100*, 10145-10149, doi:10.1021/jp952710a.

A32. O(^{1}D) + $CHClF_2$ (HCFC-22). The rate coefficient recommendation is based on the measurements of Davidson et al.,[4] Warren et al.[8] and Baasandorj et al.[3] Davidson et al. (173–343 K) and Baasandorj et al. (217–373 K) determined that the rate coefficient has no temperature dependence between 173 and 343 K. Warren et al.[8] report an O(^{3}P) yield of (28 ± 6)%, which they interpret to be due to collisional quenching of O(^{1}D) to O(^{3}P). Using a relative rate technique, Baasandorj et al. measured the reactive rate coefficient (relative to the O(^{1}D) + NF_3 reaction) at room temperature. They obtained a reaction yield of 0.75 ± 0.05, using the current *k*(298 K) recommendation for the NF_3 and HCFC-22 reactions, which is in good agreement with the Warren et al. result. A relative rate measurement by Green and Wayne,[6] with O(^{1}D) + N_2O as the reference reaction, is ~25% higher than the recommended *k*(298 K) value. A relative rate measurement by Atkinson et al.[2] gives a rate coefficient about a factor of two too high. A relative rate measurement by Nilsson et al.,[7] with O(^{1}D) + CH_4 as the reference reaction, reported a reactive rate coefficient of $(8.69 \pm 1.72) \times 10^{-11}$ cm^3 molecule^{-1} s^{-1} corresponding to a reactive yield of 0.85 ± 0.17 using the current total rate coefficient recommendation. The recommended total reactive yield of 0.75 is taken from the more precise Baasandorj et al. study.

This reaction has been shown to have multiple product channels. Addison et al.[1] reported the following product yields: ClO (55 ± 10)%, CF_2 (45 ± 10)%, O(^{3}P) (28 +10/ –15)%, and OH 5%, where the O(^{3}P) was interpreted to come from a branch yielding CF_2 and HCl. Feierabend et al.[5] reported a ClO radical yield of 0.56 ± 0.03, which agrees very well with the Addison et al. measurement and is the basis of the recommendation. An OH product channel yield of 0.05 is recommended and the balance of the reactive yield is assigned to other products. (Table: 92-20, Note: 15-10, Evaluated: 15-10) Back to Table

A33. O(^{1}D) + CHF_2Br. The recommended rate coefficient at room temperature and its temperature dependence are based on the study of Strekowski et al.[2] (211–425 K), which is the only available investigation of this reaction. They report a branching ratio for O(^{3}P) production of (39 ± 6)% independent of temperature and a branching ratio for H atom production of 2^{+1}_{-2}% at 298 K. Cronkhite et al.[1] report a BrO yield of (39 ± 7)% at room temperature. The recommended reactive yield is 0.60 with a significant yield, ~0.2, of unidentified reaction products.

(Table: 06-2, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Cronkhite, J. M.; Wine, P. H. Branching ratios for BrO production from reactions of O(^{1}D) with HBr, CF_3Br, CH_3Br, CF_2ClBr, and CF_2HBr. *Int. J. Chem. Kinet.* **1998**, *30*, 555-563, doi:10.1002/(SICI)1097-4601(1998)30:8<555::AID-KIN4>3.0.CO;2-R.

A34. O(^{1}D) + CCl_3F (CFC-11). The recommended rate coefficient is based on the data from Davidson et al.[2] (173–343 K), Force et al.[4] (298 K), and Baasandorj et al.[1] (217–373 K), which are in good agreement and show the reaction to be independent of temperature between 173 and 373 K. Force and Wiesenfeld[4] reported this reaction to be (12 ± 4)% quenching of O(^{1}D) to O(^{3}P). Using a relative rate technique, Baasandorj et al. measured the reactive rate coefficient (relative to the O(^{1}D) + N_2O reaction) at room temperature and 240 K (no temperature dependence was observed). They obtained a reactive yield of 0.90 ± 0.07, using the current k(298 K) recommendation for the N_2O and their measured total rate coefficient, which is recommended here.

Takahashi et al.[5] and Feierabend et al.[3] report ClO yields of (88 ± 18)% and (79 ± 4)%, respectively, in good agreement with the results from the Force and Wiesenfeld and Baasandorj et al. studies. The more precise Feierabend et al. yield is recommended. On the basis of these recommendations, a ~10% yield of unidentified reaction products is possible.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

A35. O(^{1}D) + CCl_2F_2 (CFC-12). The recommended rate coefficient is based on the data from Davidson et al.[2] (173–343 K), Force et al.[4] (298 K), and Baasandorj et al.[1] (217–373 K), which are in good agreement and show the reaction to have a weak negative temperature dependence between 173 and 373 K.

Force and Wiesenfeld[4] report this reaction to be (14 ± 7)% quenching, which is assumed here to be due to physical quenching and is the basis for the recommendation. Takahashi et al.[5] report a ClO yield of (87 ± 18)% in good agreement with the Force and Wiesenfeld study. Takahashi et al.[5] and Feierabend et al.[3] report ~~a~~ ClO yields of (87 ± 18)% and (76 ± 6)%, respectively. The more precise Feierabend et al. yield is recommended. On the basis of the recommendations, there may be ~10% yield of unidentified reaction products.

A36. O(^{1}D) + CClF$_3$ (CFC-13). The rate coefficient recommendation is based on the room temperature measurement by Ravishankara et al.[2] There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Ravishankara et al. report (31 ± 10)% collisional quenching of O(^{1}D) to O(^{3}P). Takahashi et al.[3] report yields of O(^{3}P) (16 ± 5)% and ClO (85 ± 18)%. Feierabend et al.[1] report a ClO radical yield of (82 ± 6)%, which is in good agreement with the Takahashi et al. work. The more precise Feierabend et al. ClO product channel yield is recommended for the reactive yield with the balance of the reaction yield assigned to physical quenching. The recommended quenching yield is less than the Ravishankara et al. value, but near to their estimated uncertainty limits.

A37. O(^{1}D) + 1,2-*c*-C$_4$Cl$_2$F$_6$ (*E*,*Z*). Papdimitriou et al.[1] measured the total and reactive rate coefficients at 296 K for a 0.475:0.525 (*E*,*Z*) isomeric mixture. It is assumed that the isomers have equivalent reactivity and their results, the only study available, are recommended. The reactive rate coefficient was measured relative to the N$_2$O and CCl$_2$F$_2$ (CFC-12) reactions and the obtained rate coefficients agreed to within 10% using the current recommendations for the reference reactions. Consistent with the measured reactive yield and the observed trend for other CFCs, it is expected that the reaction is ~15% physical quenching. CF$_2$O and *c*-C$_4$F$_6$ products were observed, although not quantified.
(Table 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Papadimitriou, V. C.; McGillen, M. R.; Smith, S. C.; Jubb, A. M.; Portmann, R. W.; Hall, B. D.; Fleming, E. L.; Jackman, C. H.; Burkholder, J. Phys. Chem. A* **2013**, *117*, 11049-11065, doi:10.1021/jp407823k.

A38. O(^{1}D) + CClBrF$_2$ (Halon-1211). The recommended rate coefficient at room temperature, *k*(298 K), is based on the data from Thompson and Ravishankara,[2] the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Thompson and Ravishankara report a O(^{3}P) yield of 0.36 ± 0.04. On the basis of this work a total reactive yield of 0.65 is recommended. Cronkhite et al.[1] report a BrO yield of 0.31 ± 0.06 at room temperature. On the basis of these studies, a ~0.34 yield of yet unidentified reaction products is possible.
(Table: 94-26, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Cronkhite, J. M.; Wine, P. H. Branching ratios for BrO production from reactions of O(^{1}D) with HBr, CF$_3$Br, CH$_3$Br, CF$_2$ClBr, and CF$_2$HBr. *Int. J. Chem. Kinet.* **1998**, *30*, 555-563, doi:10.1002/(SICI)1097-4601(1998)30:8<555::AID-KIN4>3.0.CO;2-R.

(2) Thompson, J. E.; Ravishankara, A. R. Kinetics of O(^{1}D) reactions with bromocarbons. *Int. J. Chem. Kinet.* **1993**, *25*, 479-487, doi:10.1002/kin.550250607.

A39. O(^{1}D) + CBr$_2$F$_2$ (Halon-1202). The *k*(298 K) recommendation is based on data from Thompson and Ravishankara,[1] the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Thompson and Ravishankara report a O(^{3}P) yield of 0.54 ± 0.06. Assuming this to be physical quenching, a reactive yield of 0.45 is recommended.
(Table: 94-26, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Thompson, J. E.; Ravishankara, A. R. Kinetics of O(^{1}D) reactions with bromocarbons. *Int. J. Chem. Kinet.* **1993**, *25*, 479-487, doi:10.1002/kin.550250607.

A40. O(^{1}D) + CBrF$_3$ (Halon-1301). The recommended rate coefficient at room temperature is based on data from Thompson and Ravishankara,[3] the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Thompson and Ravishankara report a O(^{3}P) yield of 0.59 ± 0.08. Lorenzen-Schmidt et al.[2] measured the CBrF$_3$ removal rate relative to N$_2$O and report that the rate coefficient for CBrF$_3$ loss in this reaction is (4.0 ± 0.4) × 10^{-11} cm^3 molecule^{-1} s^{-1}, which is in excellent agreement with the results of Thompson and Ravishankara. Cronkhite et al.[1] report a BrO yield of

0.49 ± 0.07 at room temperature, which is greater than the inferred reactive yield from Thompson and Ravishankara. A reactive yield and BrO yield of 0.45 ± 0.08 is recommended, where the uncertainty limits encompass the results from the Cronkhite et al. and Thompson and Ravishankara studies.
(Table: 94-26, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Cronkhite, J. M.; Wine, P. H. Branching ratios for BrO production from reactions of $O(^1D)$ with HBr, CF_3Br, CH_3Br, CF_2ClBr, and CF_2HBr. *Int. J. Chem. Kinet.* **1998**, *30*, 555-563, doi:10.1002/(SICI)1097-4601(1998)30:8<555::AID-KIN4>3.0.CO;2-R.

(3) Thompson, J. E.; Ravishankara, A. R. Kinetics of $O(^1D)$ reactions with bromocarbons. *Int. J. Chem. Kinet.* **1993**, *25*, 479-487, doi:10.1002/kin.550250607.

A41. $O(^1D)$ + CF_4 (CFC-14). The recommended rate coefficient upper limit is based on the work of Ravishankara et al.,[2] who report a (92 ± 8)% $O(^3P)$ yield. Force and Wiesenfeld[1] measured a quenching rate coefficient about 10 times larger. Shi and Barker[3] report an upper limit that is consistent with the recommendation. The small rate coefficient for this reaction makes it vulnerable to interference from reactant impurities. For this reason only an upper limit for the total rate coefficient is recommended with no reactive yield recommendation.
(Table: 92-20, Note: 10-6, Evaluated: 10-6) Back to Table

A42. $O(^1D)$ + CH_3CH_2F (HFC-161). The *k*(298 K) recommendation is based on the data from Schmoltner et al.,[1] the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. They report that the yield of $O(^3P)$ to be 0.18 ± 0.05. A reactive yield of 0.82 is recommended. Although no product studies are available, the OH radical is expected to be a major reaction product.
(Table: 94-26, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Schmoltner, A. M.; Talukdar, R. K.; Warren, R. F.; Mellouki, A.; Goldfarb, L.; Gierczak, T.; McKeen, S. A.; Ravishankara, A. R. Rate coefficients for reactions of several hydrofluorocarbons with OH and $O(^1D)$ and their atmospheric lifetimes. *J. Phys. Chem.* **1993**, *97*, 8976-8982, doi:10.1021/j100137a023.

A43. $O(^1D)$ + CH_3CHF_2 (HFC-152a). The recommended rate coefficient at room temperature is an average of the data from Warren et al.[2] and Kono and Matsumi,[1] which agree to within 25%. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Warren et al. report an $O(^3P)$ yield of 0.54 ± 0.07. Kono and Matsumi report an $O(^3P)$ yield of 0.34 ± 0.06, an OH yield of 0.15 ± 0.02, and that a large fraction of the reaction, ~0.50, leads to unidentified products. There is a significant discrepancy in the reactive yield between these two studies. The recommended physical quenching yield is an average of the Warren et al. and Kono and Matsumi results, 0.45 ± 0.15, where the uncertainty limit encompasses the results from both studies. The OH yield from the Kono and Matsumi study is recommended with the balance of the reactive yield assigned to unidentified products.
(Table: 10-6, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Kono, M.; Matsumi, Y. Reaction processes of $O(^1D)$ with fluoroethane compounds. *J. Phys. Chem. A* **2001**, *105*, 65-69, doi:10.1021/jp001786q S1089-5639(00)01786-2.

(2) Warren, R.; Gierczak, T.; Ravishankara, A. R. A study of $O(^1D)$ reactions with CFC substitutes. *Chem. Phys. Lett.* **1991**, *183*, 403-409, doi:10.1016/0009-2614(91)90402-U.

A44. $O(^1D)$ + CH_3CCl_2F (HCFC-141b). The *k*(298 K) recommendation is based upon the measurement of Warren et al.,[1] the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Warren et al. report an $O(^3P)$ yield of 0.31 ± 0.05, which assuming physical quenching is the basis for the recommendation. ClO and OH radical reaction product channels are expected to be significant, although no product studies are currently available.
(Table: 92-20, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Warren, R.; Gierczak, T.; Ravishankara, A. R. A study of O(^{1}D) reactions with CFC substitutes. *Chem. Phys. Lett.* **1991**, *183*, 403-409, doi:10.1016/0009-2614(91)90402-U.

A45. O(^{1}D) + CH_3CClF_2 (HCFC-142b). Warren et al.[3] (298 K) and Baasandorj et al.[1] (217–373 K) measured the total rate coefficient for this reaction. The room temperature results from these studies are in reasonable agreement, to within 15%, and the average value from these studies is recommended. Baasandorj et al. reported the reaction to be temperature independent over the 217 to 373 K range.

Warren et al. report an O(^{3}P) yield of 0.26 ± 0.05. Green and Wayne,[2] who measured the loss of CH_3CF_2Cl relative to the loss of N_2O, obtained a reactive yield of 0.75 ± 0.2 when the current recommendation for O(^{1}D) + N_2O is used. Using a relative rate technique, Baasandorj et al. measured the reactive rate coefficient (relative to the O(^{1}D) + HCFC-22 and CFC-115 reactions) at room temperature to be $(1.11 \pm 0.03) \times 10^{-11}$ cm^3 molecule^{-1} s^{-1}. This corresponds to a reactive yield of 0.55 ± 0.05 using the current total rate coefficient recommendations. This is significantly less than reported by Warren et al. The recommended reactive yield is an average of the Warren et al. and Baasandorj et al. results, where the uncertainty limit encompasses the results from both studies.
(Table: 15-10, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Baasandorj, M.; Fleming, E. L.; Jackman, C. H.; Burkholder, J. B. O(^{1}D) kinetic study of key ozone depleting substances and greenhouse gases. *J. Phys. Chem. A* **2013**, *117*, 2434-2445, doi:10.1021/jp312781c.
(2) Green, R. G.; Wayne, R. P. Relative rate constants for the reactions of O(^{1}D) atoms with fluorochlorocarbons and with N_2O. *J. Photochem.* **1976/77**, *6*, 371-374, doi:10.1016/0047-2670(76)85076-9.
(3) Warren, R.; Gierczak, T.; Ravishankara, A. R. A study of O(^{1}D) reactions with CFC substitutes. *Chem. Phys. Lett.* **1991**, *183*, 403-409, doi:10.1016/0009-2614(91)90402-U.

A46. O(^{1}D) + CH_3CF_3 (HFC-143a). Kono and Matsumi[3] (298 K) and Baasandorj et al.[1] (217–373 K) have measured the total rate coefficient for this reaction. The room temperature results from these studies are in poor agreement with a ~50% difference. Baasandorj et al. reported the reaction to have a weak negative temperature dependence, $E/R = -20$ K, over the 217 to 373 K temperature range. The recommended k(298 K) is from the average of these two studies and the recommended temperature dependence is taken from Baasandorj et al.

Kono and Matsumi report an O(^{3}P) yield of 0.18 ± 0.04, an OH yield of 0.38 ± 0.06, and that ~0.40 of the reaction occurs through unidentified product channels. That is ~0.80 of the reaction leads to loss of CH_3CF_3. The relative rate coefficient measurement by Green and Wayne,[2] who measured the loss of CH_3CF_3 relative to N_2O, is in poor agreement with the results from Kono and Matsumi. Using the current recommendation for the O(^{1}D) + N_2O rate coefficient, the Green and Wayne reaction yield would be 1.05 ± 0.20. Using a relative rate technique, Baasandorj et al. measured the reactive rate coefficient (relative to the O(^{1}D) + NF_3, HCFC-22, and CFC-115 reactions) at room temperature to be $(3.91 \pm 0.11) \times 10^{-11}$ cm^3 molecule^{-1} s^{-1}. This corresponds to a reactive yield of 0.65 ± 0.05 using the current total rate coefficient recommendations. This is less than obtained from the Kono and Matsumi O(^{3}P) yield measurement. The recommended total reactive yield is taken from Baasandorj et al. due, in part, to the consistency of results obtained with multiple reference compounds, along with the OH yield from the Kono and Matsumi study.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

(2) Green, R. G.; Wayne, R. P. Relative rate constants for the reactions of O(^{1}D) atoms with fluorochlorocarbons and with N_2O. *J. Photochem.* **1976/77**, *6*, 371-374, doi:10.1016/0047-2670(76)85076-9.
(3) Kono, M.; Matsumi, Y. Reaction processes of O(^{1}D) with fluoroethane compounds. *J. Phys. Chem. A* **2001**, *105*, 65-69, doi:10.1021/jp001786q S1089-5639(00)01786-2.

A47. O(^{1}D) + $CH_2ClCClF_2$ (HCFC-132b). The recommendation is based on the room temperature relative rate measurement of Green and Wayne,[1] the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Green and Wayne measured the loss of CH_2ClCF_2Cl relative to the loss of N_2O. The recommendation for N_2O is used to obtain the recommended value. There are no product studies available for this reaction. On the basis of results obtained for other halocarbons, a reactive yield of 0.9 is estimated.
(Table: 90-1, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Green, R. G.; Wayne, R. P. Relative rate constants for the reactions of O(^{1}D) atoms with fluorochlorocarbons and with N_2O. *J. Photochem.* **1976/77**, *6*, 371-374, doi:10.1016/0047-2670(76)85076-9.

A48. O(^{1}D) + CH_2ClCF_3 (HCFC-133a). The *k*(298 K) recommendation is based on the room temperature measurement of Warren et al.,[2] the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Warren et al. report an O(^{3}P) yield of 0.20 ± 0.05. Assuming that all O(^{3}P) production is via physical quenching, a reactive yield of 0.80 ± 0.05 is recommended. No product studies are currently available. The results from the Green and Wayne[1] study, who measured the loss of CH_2ClCF_3 relative to the loss of N_2O, agree with the recommendation when the current recommendation for N_2O is used.
(Table: 92-20, Note; 15-10, Evaluated: 10-6) Back to Table

(1) Green, R. G.; Wayne, R. P. Relative rate constants for the reactions of O(^{1}D) atoms with fluorochlorocarbons and with N_2O. *J. Photochem.* **1976/77**, *6*, 371-374, doi:10.1016/0047-2670(76)85076-9.
(2) Warren, R.; Gierczak, T.; Ravishankara, A. R. A study of O(^{1}D) reactions with CFC substitutes. *Chem. Phys. Lett.* **1991**, *183*, 403-409, doi:10.1016/0009-2614(91)90402-U.

A49. O(^{1}D) + CH_2FCF_3 (HFC-134a). The recommended total rate coefficient at room temperature is based on data from Warren et al.[3] and Kono and Matsumi,[1] which are in excellent agreement. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Warren et al.[3] reported an O(^{3}P) yield of 0.94 +0.06/–0.01. Kono and Matsumi reported an O(^{3}P) yield of 0.65 ± 0.06, an OH yield of 0.24 ± 0.04, and that a small fraction of the reaction, ~0.11, leads to other products. Nilsson et al.,[2] using a relative rate method with O(^{1}D) + CH_4 as the reference reaction, report a 298 K reactive rate coefficient of $(6.10 \pm 1.43) \times 10^{-11}$ cm^3 $molecule^{-1}$ s^{-1}, which is greater than the recommended total rate coefficient. The product yields reported in the Kono and Matsumi study are recommended.
(Table: 92-20, Note: 10-6, Evaluated: 10-6) Back to Table

(1) Kono, M.; Matsumi, Y. Reaction processes of O(^{1}D) with fluoroethane compounds. *J. Phys. Chem. A* **2001**, *105*, 65-69, doi:10.1021/jp001786q S1089-5639(00)01786-2.
(2) Nilsson, E. J. K.; Andersen, V. F.; Nielsen, O. J.; Johnson, M. S. Rate coefficients for the chemical reactions of CH_2F_2, $CHClF_2$, CH_2FCF_3 and CH_3CCl_3 with O(^{1}D) at 298 K. *Chem. Phys. Lett.* **2012**, *554*, 27-32, doi:10.1016/j.cplett.2012.10.001.
(3) Warren, R.; Gierczak, T.; Ravishankara, A. R. A study of O(^{1}D) reactions with CFC substitutes. *Chem. Phys. Lett.* **1991**, *183*, 403-409, doi:10.1016/0009-2614(91)90402-U.

A50. O(^{1}D) + $CHCl_2CF_3$ (HCFC-123). The *k*(298 K) recommendation is based on the room temperature measurement by Warren et al.,[2] the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. The relative rate measurement of Green and Wayne,[1] who measured the loss of $CHCl_2CF_3$ relative to the loss of N_2O, agrees well with the recommendation when the current recommendation for N_2O is used. Warren et al. reported an O(^{3}P) yield of 0.21 ± 0.08, which assuming it is due to physical quenching is the basis of the reactive yield recommendation.
(Table: 92-20, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Green, R. G.; Wayne, R. P. Relative rate constants for the reactions of O(^{1}D) atoms with fluorochlorocarbons and with N_2O. *J. Photochem.* **1976/77**, *6*, 371-374, doi:10.1016/0047-2670(76)85076-9.
(2) Warren, R.; Gierczak, T.; Ravishankara, A. R. A study of O(^{1}D) reactions with CFC substitutes. *Chem. Phys. Lett.* **1991**, *183*, 403-409, doi:10.1016/0009-2614(91)90402-U.

A51. O(^{1}D) + $CHClFCF_3$ (HCFC-124). The *k*(298 K) recommendation is based on the room temperature measurement of Warren et al.,[1] the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Warren et al. reported an O(^{3}P) yield of 0.31 ± 0.10, which assuming it is due to physical quenching is the basis of the reactive yield recommendation.
(Table: 92-20, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Warren, R.; Gierczak, T.; Ravishankara, A. R. A study of O(^{1}D) reactions with CFC substitutes. *Chem. Phys. Lett.* **1991**, *183*, 403-409, doi:10.1016/0009-2614(91)90402-U.

A52. O(^{1}D) + CHF_2CF_3 (HFC-125). The total rate coefficient has been measured by Warren et al.[4] (298 K), Kono and Matsumi[3] (298 K), and Baasandorj et al.[1] (217–373 K). The *k*(298 K) results from Kono and Matsumi and Baasandorj et al. are in excellent agreement, while the results from Warren et al. are nearly a factor of 10 greater. Baasandorj et al. report a weak negative temperature dependence, $E/R = -25$ K, for the reaction. The results from the Baasandorj et al. study are recommended.

Warren et al. reported an O(^{3}P) yield of 0.85 + 0.15/–22. Kono and Matsumi reported an O(^{3}P) yield of 0.24 ± 0.04, an OH yield of 0.60 ± 0.10, and that a fraction of the reaction, ~0.15, leads to other products. Green and Wayne[2] measured the loss of CHF$_2$CF$_3$ relative to the loss of N$_2$O and report a reactive rate coefficient that is significantly greater than the present k(298 K) recommendation. Using a relative rate technique, Baasandorj et al. measured the reactive rate coefficient (relative to the O(^{1}D) + NF$_3$ and HFC-23 reactions) at room temperature to be $(7.33 \pm 0.9) \times 10^{-12}$ cm^3 molecule^{-1} s^{-1}. This corresponds to a reactive yield of 0.73 ± 0.09 using the current total rate coefficient recommendation. This is in good agreement with that obtained from the Kono and Matsumi O(^{3}P) yield measurement. The recommended total reactive yield of 0.75 ± 0.05 is taken from the Kono and Matsumi and Baasandorj et al. studies with an OH yield of 0.60 ± 0.10 from the Kono and Matsumi study.
(Table: 92-20, Note: 15-10, Evaluated: 15-10) Back to Table

(4) Warren, R.; Gierczak, T.; Ravishankara, A. R. A study of O(^{1}D) reactions with CFC substitutes. *Chem. Phys. Lett.* **1991**, *183*, 403-409, doi:10.1016/0009-2614(91)90402-U.

A53. O(^{1}D) + CCl$_3$CF$_3$ (CFC-113a). The k(298 K) recommendation is taken from the measurement by Baasandorj et al.,[1] the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Baasandorj et al. reported a ClO radical yield of 0.79 ± 0.10 (2σ), which represents a lower-limit for the total reactive yield. A total reactive yield of 0.9 is estimated for this reaction with the balance assigned to physical quenching.
(Table: 92-20, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Baasandorj, M.; Feierabend, K. J.; Burkholder, J. B. Rate coefficients and ClO radical yields in the reaction of O(^{1}D) with CClF$_2$CCl$_2$F, CCl$_3$CF$_3$, CClF$_2$CClF$_2$, and CCl$_2$FCF$_3$. *Int. J. Chem. Kinet.* **2011**, *43*, 393-401, doi:10.1002/kin.20561.

A54. O(^{1}D) + CCl$_2$FCClF$_2$ (CFC-113). The k(298 K) recommendation is taken from the studies of Baasandorj et al.[1] (298 K) and Baasandorj et al.[2] (217–373 K). Baasandorj et al.[2] found no temperature dependence to the reaction over the 217–373 K range. Baasandorj et al.[1] reported a ClO radical yield of 0.80 ± 0.10 (2σ), which may represent a lower-limit for the reactive yield. A reactive yield of 0.9 is estimated for this reaction.
(Table: 92-20, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Baasandorj, M.; Feierabend, K. J.; Burkholder, J. B. Rate coefficients and ClO radical yields in the reaction of O(^{1}D) with CClF$_2$CCl$_2$F, CCl$_3$CF$_3$, CClF$_2$CClF$_2$, and CCl$_2$FCF$_3$. *Int. J. Chem. Kinet.* **2011**, *43*, 393-401, doi:10.1002/kin.20561.
(2) Baasandorj, M.; Fleming, E. L.; Jackman, C. H.; Burkholder, J. B. O(^{1}D) kinetic study of key ozone depleting substances and greenhouse gases. *J. Phys. Chem. A* **2013**, *117*, 2434-2445, doi:10.1021/jp312781c.

A55. O(^{1}D) + CCl$_2$FCF$_3$ (CFC-114a). The k(298 K) recommendation is taken from the measurement by Baasandorj et al.,[1] the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. Baasandorj et al.[1] reported a ClO radical yield of 0.79 ± 0.10 (2σ), which may represent a lower-limit for the reactive yield. A total reactive yield of 0.9 is estimated for this reaction.
(Table: 92-20, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Baasandorj, M.; Feierabend, K. J.; Burkholder, J. B. Rate coefficients and ClO radical yields in the reaction of O(^{1}D) with CClF$_2$CCl$_2$F, CCl$_3$CF$_3$, CClF$_2$CClF$_2$, and CCl$_2$FCF$_3$. *Int. J. Chem. Kinet.* **2011**, *43*, 393-401, doi:10.1002/kin.20561.

A56. O(^{1}D) + CClF$_2$CClF$_2$ (CFC-114). The total rate coefficient has been measured by Ravishankara et al.[3] (298 K), Baasandorj et al.[1] (298 K), and Baasandorj et al.[2] (217–373 K). The k(298 K) results from these studies are

in very good agreement. Baasandorj et al.[2] report a weak negative temperature dependence, $E/R = -25$ K, for the reaction over the 217–373 K range. The recommended rate coefficient is taken from this study. Ravishankara et al. reported the reaction to be (25 ± 9)% quenching of $O(^1D)$ to $O(^3P)$. Baasandorj et al.[1] reported a ClO radical yield of 0.85 ± 0.12 (2σ), which may represent a lower-limit for the reaction yield. The reaction yields from the Ravishankara et al. and Baasandorj et al. studies overlap, within the combined uncertainties, and a total reactive yield of 0.9 is recommended.
(Table: 92-20, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Baasandorj, M.; Feierabend, K. J.; Burkholder, J. B. Rate coefficients and ClO radical yields in the reaction of $O(^1D)$ with $CClF_2CCl_2F$, CCl_3CF_3, $CClF_2CClF_2$, and CCl_2FCF_3. *Int. J. Chem. Kinet.* **2011**, *43*, 393-401, doi:10.1002/kin.20561.
(2) Baasandorj, M.; Fleming, E. L.; Jackman, C. H.; Burkholder, J. B. $O(^1D)$ kinetic study of key ozone depleting substances and greenhouse gases. *J. Phys. Chem. A* **2013**, *117*, 2434-2445, doi:10.1021/jp312781c.
(3) Ravishankara, A. R.; Solomon, S.; Turnipseed, A. A.; Warren, R. F. Atmospheric lifetimes of long-lived halogenated species. *Science* **1993**, *259*, 194-199, doi:10.1126/science.259.5092.194.

A57. $O(^1D) + CClF_2CF_3$ (CFC-115). The rate coefficient has been measured by Ravishankara et al.[2] (298 K) and Baasandorj et al.[1] (217–373 K). The k(298 K) values from these studies are in reasonable agreement and the average value is recommended. Baasandorj et al. measured a weak negative temperature dependence, $E/R = -30$ K, for the reaction, which is recommended.

Ravishankara et al. reported an $O(^3P)$ yield of 0.70 ± 0.07. Using a relative rate technique, Baasandorj et al. measured the reactive rate coefficient (relative to the $O(^1D) + NF_3$, HFC-22, and HFC-125 reactions) at room temperature to be $(5.16 \pm 0.9) \times 10^{-11}$ cm^3 molecule^{-1} s^{-1}. This corresponds to a reactive yield of 0.86 ± 0.06 using the current total rate coefficient recommendations. This is in poor agreement with the Ravishankara et al. value. The recommended reactive yield is taken from Baasandorj et al. due, in part, to the consistency of results obtained with multiple reference compounds. There are no product studies available for this reaction.
(Table: 92-20, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Baasandorj, M.; Fleming, E. L.; Jackman, C. H.; Burkholder, J. B. $O(^1D)$ kinetic study of key ozone depleting substances and greenhouse gases. *J. Phys. Chem. A* **2013**, *117*, 2434-2445, doi:10.1021/jp312781c.

A58. $O(^1D) + CBrF_2CBrF_2$ (Halon-2402). The k(298 K) recommendation is based on data from Thompson and Ravishankara,[2] the only study available. They reported an $O(^3P)$ yield of 0.25 ± 0.07. Lorenzen-Schmidt et al.[1] measured the Halon removal rate relative to the N_2O removal rate and report a reactive rate coefficient of $(8.8 \pm 1.2) \times 10^{-11}$ (a reactive yield of 0.55), which is significantly less than inferred by Thompson and Ravishankara. The Thompson and Ravishankara product yield is recommended with an uncertainty that encompasses the Lorenzen-Schmidt et al. result at the 2σ level. There are no product studies available for this reaction.
(Table: 94-26, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Lorenzen-Schmidt, H.; Weller, R.; Schrems, O. Kinetics and mechanisms of the reactions of $O(^1D)$ atoms with CF_3Br and CF_3BrCF_2Br in the gas phase and in solid argon matrices. *Ber. Bunsenges. Phys. Chem.* **1994**, *98*, 1622-1629, doi:10.1002/bbpc.19940981220.

A59. $O(^1D) + CF_3CF_3$ (PFC-116). The k(298 K) recommendation is based on the work of Ravishankara et al.[2] The small rate coefficient for this reaction makes it vulnerable to interference from reactant impurities. For this reason, k(298 K) may be an upper limit. Ravishankara et al. report a $O(^3P)$ yield of 0.85 ± 0.15. Using a relative rate technique, Baasandorj et al.[1] measured the reactive rate coefficient for this reaction, relative to the $O(^1D) + CHF_3$ reaction, to be $<3 \times 10^{-14}$ cm^3 molecule^{-1} s^{-1}. On the basis of this study, an upper limit of 0.2 for the reactive yield is recommended.
(Table: 94-26, Note: 15-10, Evaluated: 15-10) Back to Table

A60. $O(^1D) + CF_3CHFCF_3$ (HFC-227ea). Baasandorj et al.[1] measured the total rate coefficient over the temperature range 217 to 373 K. Their results, the only study available, are recommended. Using a relative rate technique, Baasandorj et al. measured the reactive rate coefficient for this reaction relative to the $O(^1D) + NF_3$, HFC-23, and HFC-125 reactions to be $(6.99 \pm 0.5) \times 10^{-12}$ cm^3 molecule^{-1} s^{-1}. On the basis of this study, a reactive yield of 0.72 ± 0.07 is recommended.
(Table 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Baasandorj, M.; Fleming, E. L.; Jackman, C. H.; Burkholder, J. B. $O(^1D)$ kinetic study of key ozone depleting substances and greenhouse gases. *J. Phys. Chem. A* **2013**, *117*, 2434-2445, doi:10.1021/jp312781c.

A61. $O(^1D) + CHF_2CH_2CF_3$ (HFC-245fa). There are no experimental studies of the rate coefficient for this reaction. The rate coefficient and product yield are estimated based on trends observed for other HFCs.
(Table 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

A62. $O(^1D) + CHF_2CF_2CF_2CHF_2$ (HFC-338pcc). The k(298 K) recommendation is based on data from Schmoltner et al.,[1] the only study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. They reported an $O(^3P)$ yield of 0.97 ± 0.09. On the basis of this study, a reactive yield of $0.05^{+0.1}_{-0.05}$ is recommended.
(Table: 94-26, Note: 15-10, Evaluated: 10-6) Back to Table

A63. $O(^1D)$ + c-C_4F_8. The k(298 K) recommendation for perfluorocyclobutane is based on the work of Ravishankara et al.,[2] the only study available. The small rate coefficient for this reaction makes it vulnerable to interference from reactant impurities. For this reason, k(298 K) may be an upper limit. Ravishankara et al. reported an $O(^3P)$ yield of 1.00 +0/-0.15. Using a relative rate technique, Baasandorj et al.[1] measured the reactive rate coefficient for this reaction relative to the $O(^1D) + CHF_3$ reaction to be $<3.5 \times 10^{-14}$ cm^3 molecule^{-1} s^{-1}. On the basis of the Baasandorj et al. study, an upper limit of 0.04 for the reaction yield is recommended.
(Table: 92-20, Note: 15-10, Evaluated: 10-6) Back to Table

Rate coefficients for reactions of several hydrofluorocarbons with OH and $O(^1D)$ and their atmospheric lifetimes. *J. Phys. Chem.* **1993**, *97*, 8976-8982, doi:10.1021/j100137a023.

A65. $O(^1D) + C_5F_{12}$ (CFC-41-12). The k(298 K) recommendation is based on data from Ravishankara et al.,[2] the only total rate coefficient study available. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. The small rate coefficient for this reaction makes it vulnerable to interference from reactant impurities. For this reason, k(298 K) may be an upper limit. Ravishankara et al. reported an $O(^3P)$ yield of 0.79 ± 0.12. Using a relative rate technique, Baasandorj et al.[1] measured the reactive rate coefficient for this reaction relative to the $O(^1D) + CHF_3$ reaction to be $<5 \times 10^{-14}$ cm^3 molecule^{-1} s^{-1}. On the basis of the Baasandorj et al. study, an upper limit of 0.12 for the reactive yield is recommended.
(Table: 94-26, Note: 15-10, Evaluated: 10-6) Back to Table

A66. O(^{1}D) + C_6F_{14} (PFC-51-14). The *k*(298 K) recommendation is based on data from Ravishankara et al.,[2] the only total rate coefficient study available. The small rate coefficient for this reaction makes it vulnerable to interference from reactant impurities. For this reason, *k*(298 K) may be an upper limit. Ravishankara et al. reported an O(^{3}P) yield of 0.75 ± 0.09. Using a relative rate technique, Baasandorj et al.[1] measured the reactive rate coefficient for this reaction relative to the O(^{1}D) + CHF_3 reaction to be $<1.6 \times 10^{-13}$ cm^3 molecule^{-1} s^{-1}. On the basis of the Baasandorj et al. study, an upper limit of 0.16 for the reaction yield is recommended.
(Table: 94-26, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Baasandorj, M.; Hall, B. D.; Burkholder, J. B. Rate coefficients for the reaction of O(^{1}D) with the atmospherically long-lived greenhouse gases NF_3, SF_5CF_3, CHF_3, C_2F_6, *c*-C_4F_8, *n*-C_5F_{12}, and *n*-C_6F_{14}. *Atmos. Chem. A67. O(^{1}D) + 1,2-(CF_3)$_2$c-C_4F_6. The *k*(298 K) recommendation is based on data from Ravishankara et al.,[1] the only total rate coefficient study available. They reported an O(^{3}P) yield of 0.84 ± 0.16. The small rate coefficient for this reaction makes it vulnerable to interference from reactant impurities. For this reason only an upper limit for the total rate coefficient and no reactive yield is recommended.
(Table: 94-26, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Ravishankara, A. R.; Solomon, S.; Turnipseed, A. A.; Warren, R. F. Atmospheric lifetimes of long-lived halogenated species. *Science* **1993**, *259*, 194-199, doi:10.1126/science.259.5092.194.

A68. O(^{1}D) + C_4F_{10}. The *k*(298 K) recommendation is taken from the estimated upper limit for reactive loss given by Ravishankara et al.,[1] the only study available. The small rate coefficient for this reaction makes it vulnerable to interference from reactant impurities. For this reason an upper limit for the rate coefficient and no reactive yield is recommended.
(Table: 10-6, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Ravishankara, A. R.; Solomon, S.; Turnipseed, A. A.; Warren, R. F. Atmospheric lifetimes of long-lived halogenated species. *Science* **1993**, *259*, 194-199, doi:10.1126/science.259.5092.194.

A69. O(^{1}D) + SF_6. The *k*(298 K) recommendation is based on the work of Ravishankara et al.,[1] the only study available. They reported an O(^{3}P) yield of 0.32 ± 10. The small rate coefficient for this reaction makes it vulnerable to interference from reactant impurities. For this reason, *k*(298 K) may be an upper limit and a reactive yield upper limit of 0.7 is recommended.
(Table: 92-20, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Ravishankara, A. R.; Solomon, S.; Turnipseed, A. A.; Warren, R. F. Atmospheric lifetimes of long-lived halogenated species. *Science* **1993**, *259*, 194-199, doi:10.1126/science.259.5092.194.

A70. O(^{1}D) + SO_2. The room temperature rate coefficient is taken from the work of Zhao et al.,[1] which is the only study for this reaction. Although no studies are available, the reaction rate coefficient is expected to have negligible temperature dependence. Zhao et al. reported the branching ratio for reactive loss to be 0.76 ± 0.12 (2σ), which is the basis of the recommendation.
(Table: 10-6, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Zhao, Z.; Laine, P. L.; Nicovich, J. M.; Wine, P. H. Reactive and non-reactive quenching of O(^{1}D) by the potent greenhouse gases SO_2F_2, NF_3, and SF_5CF_3. *Proc. Nat. Acad. Sci.* **2010**, *107*, 6610-6615, doi:10.1073/pnas.0911228107.

A71. O(^{1}D) + SO_2F_2. The recommendation is based on the measurements of Dillon et al.[1] and Zhao et al.,[2] which are in good agreement. Although Dillon et al. report a temperature independent rate coefficient over the temperature range 220–300 K, a weak negative temperature dependence is apparent in their data. Zhao et al. (199–351 K) report a negative temperature dependence, *E*/R = –98 K, that reproduces both data sets very well and is recommended. Dillon et al. reported a collisional quenching yield of 0.55 ± 0.04, independent of temperature. The results from Zhao et al. are in agreement with this result, but are less precise. The

recommended reactive yield is taken from Dillon et al. Dillon et al. provide qualitative evidence that F atoms may be formed as a reaction product.
(Table: 10-6, Note: 15-10, Evaluated: 10-6) Back to Table

(1) Dillon, T. J.; Horowitz, A.; Crowley, J. N. The atmospheric chemistry of sulphuryl fluoride, SO_2F_2. *Atmos. Chem. Phys.* **2008**, *8*, 1547-1557, doi:10.5194/acp-8-1547-2008.
(2) Zhao, Z.; Laine, P. L.; Nicovich, J. M.; Wine, P. H. Reactive and non-reactive quenching of $O(^1D)$ by the potent greenhouse gases SO_2F_2, NF_3, and SF_5CF_3. *Proc. Nat. Acad. Sci.* **2010**, *107*, 6610-6615, doi:10.1073/pnas.0911228107.

A72. $O(^1D) + SF_5CF_3$. Zhao et al.[2] and Baasandorj et al.[1] have reported upper limits for the room temperature rate coefficient. There are no reports on the temperature dependence of this rate coefficient and it is assumed to be temperature independent. The determination of the small rate coefficient for this reaction makes it vulnerable to interference from reactant impurities. Baasandorj et al. reported a *k*(298 K) value that is greater than reported by Zhao et al., which is most likely due to the presence of sample impurities. For this reason only an upper limit for the rate coefficient is recommended. Using a relative rate technique, Baasandorj et al. measured the reactive rate coefficient for this reaction relative to the $O(^1D) + CHF_3$ reaction to be $<5.8 \times 10^{-14}$ cm^3 molecule^{-1} s^{-1}. On the basis of this study and the Zhao et al. *k*(298 K) value, an upper limit of 0.3 for the reaction yield is recommended.

1.6 Singlet O_2 Reactions

1.6.1 Table 1A: Singlet O_2 Reactions

Reaction	Temperature Range of Exp. Data (K) [a]	*A*-Factor	*E*/R	*k*(298 K)[b]	*f*(298 K)[c]	*g*	Notes
$O_2(^1\Delta) + O \rightarrow$ products	298			$<2\times10^{-16}$			A73
$O_2(^1\Delta) + O_2 \rightarrow$ products	100–450	3.6×10^{-18}	220	1.7×10^{-18}	1.2	100	A74
$O_2(^1\Delta) + O_3 \rightarrow O + 2O_2$	283–360	5.2×10^{-11}	2840	3.8×10^{-15}	1.2	500	A75
$O_2(^1\Delta) + H_2O \rightarrow$ products	298			4.8×10^{-18}	1.5		A76
$O_2(^1\Delta) + N \rightarrow NO + O$	195–300			$<9\times10^{-17}$			A77
$O_2(^1\Delta) + N_2 \rightarrow$ products	298			$<10^{-20}$			A78
$O_2(^1\Delta) + CO_2 \rightarrow$ products	298			$<2\times10^{-20}$			A79
$O_2(^1\Sigma) + O \rightarrow$ products	300			8×10^{-14}	5.0		A80
$O_2(^1\Sigma) + O_2 \rightarrow$ products	298			3.9×10^{-17}	1.5		A81
$O_2(^1\Sigma) + O_3 \rightarrow$ products	210–370	3.5×10^{-11}	135	2.2×10^{-11}	1.15	50	A82
$O_2(^1\Sigma) + H_2 \rightarrow$ products $O_2(^1\Sigma) + H_2 \rightarrow 2\ OH$	173–393	6.4×10^{-12}	600	8.5×10^{-13} $<4\times10^{-17}$ (See Note)	1.15	100	A83
$O_2(^1\Sigma) + H_2O \rightarrow O_2 + H_2O$	250–370	3.9×10^{-12}	–125	5.9×10^{-12}	1.3	100	A84
$O_2(^1\Sigma) + N \rightarrow$ products	300			$<10^{-13}$			A85
$O_2(^1\Sigma) + N_2 \rightarrow$ products	203–370	1.8×10^{-15}	–45	2.1×10^{-15}	1.1	100	A86
$O_2(^1\Sigma) + N_2O \rightarrow$ products $O_2(^1\Sigma) + N_2O \rightarrow NO + NO_2$	210–370	7.0×10^{-14}	–75	9.0×10^{-14} $<2\times10^{-17}$ (See Note)	1.3	50	A87
$O_2(^1\Sigma) + CO_2 \rightarrow$ products	245–362	4.2×10^{-13}	0	4.2×10^{-13}	1.2	200	A88

Shaded areas indicate changes or additions since JPL15-10.

[a] Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

[b] Units are cm^3 $molecule^{-1}$ s^{-1}.

[c] *f*(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(\mathrm{T}) = f(298\ \mathrm{K})\exp\left|g\left(\frac{1}{\mathrm{T}} - \frac{1}{298}\right)\right|$$

Note that the exponent is an absolute value.

1.6.2 Notes: Singlet O_2 Reactions

A73. **$O_2(^1\Delta)$ + O**. The recommendation is based on the upper limit reported by Clark and Wayne.[2] (Table: 92-20, Note: 92-20, Evaluation: 10-6) Back to Table

(1) Baasandorj, M.; Hall, B. D.; Burkholder, J. B. Rate coefficients for the reaction of $O(^1D)$ with the atmospherically long-lived greenhouse gases NF_3, SF_5CF_3, CHF_3, C_2F_6, *c*-C_4F_8, *n*-C_5F_{12}, and *n*-C_6F_{14}. *Atmos. Chem. Phys.* **2012**, *12*, 11753-11764, doi:10.5194/acp-12-11753-2012.

A74. **$O_2(^1\Delta)$ + O_2**. The recommendation is the average of eight room temperature measurements: Steer et al.,[9] Findlay and Snelling,[5] Borrell et al.,[2] Leiss et al.,[6] Tachibana and Phelps,[10] Billington and Borrell,[1] Raja et al.,[8] and Wildt et al.[11] The temperature dependence is derived from the data of Findlay and Snelling and Billington and Borrell. Several other less direct measurements of the rate coefficient agree with the recommendation, including Clark and Wayne,[3] Findlay et al.,[4] and McLaren et al.[7] Wildt et al.[12] report observations of weak emission in the near IR due to collision-induced radiation. Wildt et al.[13] give rate coefficients for this process. (Table: 92-20, Note: 94-26, Evaluation: 10-6) Back to Table

A75. **$O_2(^1\Delta)$ + O_3**. The recommendation is the average of the room temperature measurements of Clark et al.,[4] Findlay and Snelling,[6] Becker et al.,[3] and Collins et al.[5] Several less direct measurements agree well with the recommendation (McNeal and Cook,[9] Wayne and Pitts,[12] and Arnold and Comes[2]). The temperature dependence is from the studies of Findlay and Snelling and Becker et al., which agree very well, although both covered a relatively small temperature range. An earlier study by Clark et al. covered a much larger range and found a much smaller temperature coefficient. The reason for this discrepancy is not clear. The yield of O + $2O_2$ products appears to be close to unity, based on many studies of the quantum yield of O_3 destruction near the peak of the Hartley band, e.g. measurements of the number of O_3 molecules destroyed per photon absorbed (von Ellenrieder et al.,[11] Ravishankara et al.,[10] Lissi and Heicklen,[8] and references cited therein) and measurements of O_3 loss and O atom temporal profiles in pulsed experiments (Klais et al.[7] and Arnold and

Comes[2]). Anderson et al.[1] report that the rate coefficient for atom exchange between $O_2(^1\Delta)$ and O_3 is $<5 \times 10^{-16}$ at 300 K.

A76. $O_2(^1\Delta) + H_2O$. The recommendation is the average of the measurements reported by Becker et al.[1] and Findlay and Snelling.[3] An earlier study by Clark and Wayne[2] reported a value about three times larger.
(Table: 92-20, Note: 92-20, Evaluation: 10-6) Back to Table

A77. $O_2(^1\Delta) + N$. The recommendation is an upper limit based upon the measurement reported by Westenberg et al.,[4] who used ESR to detect $O_2(X^3\Sigma$ and $a^1\Delta)$, $O(^3P)$ and $N(^4S)$ with a discharge flow reactor. They used an excess of $O_2(^1\Delta)$ and measured the decay of N and the appearance of O at 195 and 300 K. They observed that the reaction of N with $O_2(^1\Delta)$ is somewhat slower than its reaction with $O_2(^3\Sigma)$. The recommended rate constant value for the latter provides the basis for the recommendation. Clark and Wayne[1,2] and Schmidt and Schiff[3] reported observations of an $O_2(^1\Delta)$ reaction with N that is about 30 times faster than the recommended limit. Schmidt and Schiff attribute the observed loss of $O_2(^1\Delta)$ in excess N to a rapid energy exchange with some constituent in discharged nitrogen, other than N.

A80. $O_2(^1\Sigma) + O$. The recommendation is based on the measurement reported by Slanger and Black.[1]
(Table: 92-20, Note: 92-20, Evaluation: 10-6) Back to Table

(1) Slanger, T. G.; Black, G. Interactions of O_2 $(b^1\Sigma_g^+)$ with $O(^3P)$ and O_3. *J. Chem. Phys.* **1979**, *70*, 3434-3438, doi:10.1063/1.437877.

A81. $O_2(^1\Sigma) + O_2$. The recommendation is the average of the room temperature values reported by Martin et al.,[5] Lawton et al.,[3] and Lawton and Phelps,[4] which are in excellent agreement. Measurements by Thomas and Thrush,[6] Chatha et al.,[1] and Knickelbein et al.[2] are in reasonable agreement with the recommendation. Knickelbein et al. report the yield of $O_2(^1\Delta)$ product to be approximately unity.
(Table: 92-20, Note: 92-20, Evaluation: 10-6) Back to Table

A82. $O_2(^1\Sigma) + O_3$. The recommendation is based on the room temperature measurements of Gilpin et al.,[6] Gauthier and Snelling,[5] Slanger and Black,[9] Choo and Leu,[3] Shi and Barker,[8] Turnipseed et al.,[11] and Dunlea et al.[4]

Measurements by Snelling,[10] Amimoto and Wiesenfeld,[1] and Ogren et al.[7] are in agreement with the recommendation. The value from the study of Biedenkapp and Bair[2] is lower than the recommended value. The temperature dependence is taken from the results of Dunlea et al., who measured the rate coefficient between 210 and 370 K. The results of Choo and Leu, which encompassed 295–362 K, are consistent with the recommended value. This reaction has multiple product channels. The yield of $O + 2O_2$ products is reported to be (70 ± 20)% by Slanger and Black and Amimoto and Wiesenfeld. The remaining ~30% of the reaction is expected to lead to quenching to $O_2(^1\Delta$ or $^3\Sigma)$ while leaving ozone intact; the electronic state of O_2 that is produced in all these channels is not known.

A83. $O_2(^1\Sigma) + H_2$. The rate coefficient for this reaction, at or around 298 K, has been measured by Kohse-Höinghaus and Stuhl,[6] Braithwaite et al.,[2] Choo and Leu,[3] Singh and Setser,[8] Wildt et al.,[10] Michelangeli et al.,[7] Borrell and Richards,[1] Hohmann et al.,[5] and Talukdar et al.[9] k(298 K) was derived from the results of all of the above studies except for the results of Singh and Setser and Borrell and Richards, which are clearly outside of the range of values obtained by others.

The temperature dependence of the rate coefficient was computed using the results of Braithwaite et al., Hohmann et al., and Talukdar et al. The results of Kohse-Höinghaus and Stuhl were not included, because they are assumed to be superseded by those of Hohmann et al. from the same group. It is suspected that the Kohse-Höinghaus and Stuhl study was hampered by impurities in their system, as discussed in Talukdar et al.

The rate coefficient for the reaction to produce 2 OH radicals is listed separately as an upper limit at 298 K and is based on the results of Talukdar et al. The same upper limit was shown to be valid even at 209 K. Therefore, this upper limit is recommended for all atmospheric calculations.

This reaction could also produce $O(^3P) + H_2O$. However, there is no evidence for the formation of $O(^3P)$ (Dunlea et al.[4]). Therefore, it is assumed that $O_2(^1\Sigma)$ is removed exclusively via quenching. The electronic state of O_2 that is produced is not known.

A84. $O_2(^1\Sigma)$ + H_2O. The recommendation is the average of room temperature measurements reported by Stuhl and Niki,[8] Avilés et al.,[1] Shi and Barker,[7] and Dunlea et al.[3] Measurements reported by O'Brien and Myers[6] are lower, most likely due to an interference from $O_2(^1\Sigma)$ regeneration. The results of Derwent and Thrush[2] and Thomas and Thrush[9] are in agreement with the recommendation. The value reported by Gauthier and Snelling[5] has a very large uncertainty and hence overlaps with the recommendation. It is not clear why the results of Filseth et al.[4] are lower than all the other reported values; perhaps, they had an error in measuring water vapor concentration. The temperature dependence of the reaction is taken from the only reported value of Dunlea et al. Wildt et al.[10] report that the yield of $O_2(^1\Delta)$ is greater than 90%. There are no thermodynamically allowed reactive channels for this reaction. Therefore, the reaction products are written as O_2 + H_2O.[3]

A85. $O_2(^1\Sigma)$ + N. The recommendation is based on the upper limit reported by Slanger and Black.[1]
(Table: 92-20, Note: 92-20, Evaluation: 10-6) Back to Table

(1) Slanger, T. G.; Black, G. Interactions of O_2 ($b^1\Sigma_g^+$) with $O(^3P)$ and O_3. *J. Chem. Phys.* **1979**, *70*, 3434-3438, doi:10.1063/1.437877.

A86. $O_2(^1\Sigma)$ + N_2. The recommendation for room temperature is the average of measurements reported by Izod and Wayne,[5] Stuhl and Welge,[11] Filseth et al.,[4] Martin et al.,[7] Kohse-Höinghaus and Stuhl,[6] Choo and Leu,[2] Wildt et al.,[12] Shi and Barker,[10] and Dunlea et al.[3] Less direct measurements reported by Noxon,[9] Myers and O'Brien,[8] and Chatha et al.[1] are consistent with the recommendation. The temperature dependence of the rate coefficient is derived from the results of Kohse-Höinghaus and Stuhl between 203 and 349 K and of Dunlea et al. between 210 and 370 K.

There are no exothermic reaction channels. The channel to produce 2 NO molecules is endothermic by 5.6 kcal mol^{-1} at 298 K.

A87. $O_2(^1\Sigma) + N_2O$. The rate coefficient for the removal of $O_2(^1\Sigma)$ by N_2O at 298 K is derived from the studies of Filseth et al.,[3] Borrell et al.,[1] and Dunlea et al.[2] The results of Gauthier and Snelling[4] have a large uncertainty, which overlaps the recommended value within their quoted error bars. The temperature dependence of this rate coefficient is taken from Dunlea et al., the only temperature dependent study.

There are many possible reactive channels for this reaction:

$$O_2(^1\Sigma_g^+) + N_2O \rightarrow NO + NO_2 \qquad \Delta_{rxn}H_{298} = -27.6\ \text{kcal/mol} \qquad (a)$$
$$\rightarrow N_2 + O_3 \qquad \Delta_{rxn}H_{298} = -23.0\ \text{kcal/mol} \qquad (b)$$
$$\xrightarrow{M} N_2O_3 \qquad \Delta_{rxn}H_{298} = -37.3\ \text{kcal/mol} \qquad (c)$$
$$\rightarrow O_2(^3\Sigma_g^-) + N_2O \qquad \Delta_{rxn}H_{298} = -37.5\ \text{kcal/mol} \qquad (d)$$
$$\rightarrow O_2(^1\Delta_g) + N_2O \qquad \Delta_{rxn}H_{298} = -15.0\ \text{kcal/mol} \qquad (e)$$

Dunlea et al. have placed upper limits of $<2 \times 10^{-4}$, $<1 \times 10^{-3}$, and $<3 \times 10^{-3}$ for channel (a + c), channel (b), and overall N_2O loss, respectively, from this reaction at 298 K. Based on these results, we recommend an upper limit for NO_x production of $<2 \times 10^{-17}$ cm^3 $molecule^{-1}$ s^{-1}. The upper limit for NO_x production from this reaction is assumed to be valid for all atmospheric temperatures.

A88. **$O_2(^1\Sigma) + CO_2$.** The recommendation is the average of measurements reported by Filseth et al.,[5] Davidson et al.,[3] Avilés et al.,[1] Muller and Houston,[7] Choo and Leu,[2] Wildt et al.,[10] Hohmann et al.,[6] Dunlea et al.,[4] and Shi and Barker[8] at room temperature. The temperature dependence is from the work of Choo and Leu. Muller and Houston and Singh and Setser[9] give evidence that $O_2(^1\Delta)$ is a product. Wildt et al. report a $O_2(^1\Delta)$ yield of ≥90%.

1.7 HO$_x$ Reactions

1.7.1 Table 1B: HO$_x$ Reactions

Reaction	Temperature Range of Exp. Data (K)[a]	*A*-Factor	*E*/R	*k*(298 K)[b]	*f*(298 K)[c]	*g*	Note
$O + OH \rightarrow O_2 + H$	136–515	1.8×10^{-11}	–180	3.3×10^{-11}	1.15	50	B1
$O + HO_2 \rightarrow OH + O_2$	229–391	3.0×10^{-11}	–200	5.9×10^{-11}	1.05	50	B2
$O + H_2O_2 \rightarrow OH + HO_2$	283–386	1.4×10^{-12}	2000	1.7×10^{-15}	1.2	100	B3
$H + O_2 \xrightarrow{M} HO_2$		(See Table 2-1)					
$H + O_3 \rightarrow OH + O_2$	196–424	1.4×10^{-10}	470	2.9×10^{-11}	1.1	40	B4
$H + HO_2 \rightarrow 2\ OH$	245–300	7.2×10^{-11}	0	7.2×10^{-11}	1.2	100	B5
$\rightarrow O + H_2O$		1.6×10^{-12}	0	1.6×10^{-12}	1.5	100	
$\rightarrow H_2 + O_2$		6.9×10^{-12}	0	6.9×10^{-12}	1.4	100	
$OH + O_3 \rightarrow HO_2 + O_2$	190–357	1.7×10^{-12}	940	7.3×10^{-14}	1.15	50	B6
$OH + H_2 \rightarrow H_2O + H$	200–1050	2.8×10^{-12}	1800	6.7×10^{-15}	1.05	100	B7
$OH + HD \rightarrow$ products	248–418	5.0×10^{-12}	2130	4.0×10^{-15}	1.15	50	B8
$OH + OH \rightarrow H_2O + O$	233–580	1.8×10^{-12}	0	1.8×10^{-12}	1.25	50	B9
$\xrightarrow{M} H_2O_2$		(See Table 2-1)					
$OH + HO_2 \rightarrow H_2O + O_2$	252–420	4.8×10^{-11}	–250	1.1×10^{-10}	1.15	50	B10
$OH + H_2O_2 \rightarrow H_2O + HO_2$		(See Note)					B11
$HO_2 + O_3 \rightarrow OH + 2O_2$	197–413	1.0×10^{-14}	490	1.9×10^{-15}	1.15	80	B12
$HO_2 + HO_2 \rightarrow H_2O_2 + O_2$	222–1120	3.0×10^{-13}	–460	1.4×10^{-12}	1.15	100	B13
$\xrightarrow{M} H_2O_2 + O_2$		2.1×10^{-33} [M]	–920	4.6×10^{-32} [M]	1.2	200	
$HO_2 + HO_2 \bullet H_2O \rightarrow$ products	298–350	5.4×10^{-11}	410	1.4×10^{-11}	2	100	B14

Shaded areas indicate changes or additions since JPL15-10.

[a] Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

[b] Units are cm^3 molecule^{-1} s^{-1}.

[c] *f*(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(\mathrm{T}) = f(298\ \mathrm{K})\exp\left|g\left(\frac{1}{\mathrm{T}} - \frac{1}{298}\right)\right|$$

Note that the exponent is an absolute value.

1.7.2 Notes: HO_x Reactions

B1. **O + OH**. The recommended rate coefficient was obtained from the studies of Westenberg et al.[8] (228–340 K), Lewis and Watson[4] (221–499 K), Howard and Smith[2] (250–515 K), Smith and Stewart[7] (158–294 K), and Robertson and Smith[5] (136–377 K). The recommendation is consistent with earlier work near room temperature as reviewed by Lewis and Watson,[4] and with the measurements of Brune et al.[1] (300 K), and Robertson and Smith[6] (295 K). The ratio $k(O + HO_2)/k(O + OH)$ measured by Keyser[3] agrees with the recommended values.

B2. **$O + HO_2$**. The recommended values are based on the results of studies over a range of temperatures by Keyser[5] (229–372 K) and Nicovich and Wine[9] (266–391 K) and the room temperature studies of Sridharan et al.,[12] Ravishankara et al.,[10] and Brune et al.[1] Earlier studies by Hack et al.[4] and Burrows et al.[2,3] are not considered because the $OH + H_2O_2$ reaction was important in these studies and the value used for its rate constant in their analyses has been shown to be in error. A study by Lii et al.[8] is also not considered because of the insensitivity of the observed decays to $O + HO_2$. Data from Ravishankara et al.[10] at 298 K show no dependence on pressure between 10 and 500 Torr N_2. The ratio $k(O + HO_2)/k(O + OH)$ measured by Keyser[6] agrees with the rate constants recommended here. Sridharan et al.[11] showed that the reaction products correspond to abstraction of an oxygen atom from HO_2 by the O reactant. Keyser et al.[7] reported <1% $O_2(^1\Delta)$ yield.

B3. **O + H_2O_2**. There are two direct studies of the O + H_2O_2 reaction: Davis et al.[2] (283–368 K) and Wine et al.[4] (298–386 K). The recommended value is a fit to the combined data. An indirect measurement of the E/R value by Roscoe[3] is consistent with the recommendation. The A factor for both data sets is quite low compared to similar atom-molecule reactions. A somewhat higher activation barrier reported by Albers et al.[1] over the temperature range 370–800 K is suggestive of a non-linear temperature dependence.
(Table: 06-2, Note: 06-2, Evaluated: 10-6) Back to Table

B4. **H + O_3**. The recommendation is an average of the results of Lee et al.[8] (219–360 K) and Keyser[7] (196–424 K), which are in agreement over the 220–360 K range. Results by Seeley et al.[9] and Finlayson-Pitts and Kleindienst[3] agree well with the present recommendation. An earlier study by Clyne and Monkhouse[1] is in very good agreement on the temperature dependence in the range 300–560 K, but lies about 60% below the recommended values. Although we have no reason not to believe the Clyne and Monkhouse values, we prefer the two studies that are in agreement, especially since they were carried out over the temperature range of interest. Reports of a channel forming HO_2 + O (Finlayson-Pitts and Kleindienst[3]: ~25%, and Force and Wiesenfeld[5]: ~40%) have been contradicted by other studies (Howard and Finlayson-Pitts[6]: <3%; Washida et al.[11]: <6%; Finlayson-Pitts et al.[4]: <2%; and Dodonov et al.[2]: <0.3%). Secondary chemistry is believed to be responsible for the observed O-atoms in this system. Washida et al.[10] measured an upper limit (<0.1%) for the production of singlet molecular oxygen for the reaction.

B5. **$H + HO_2$**. There are five studies of this reaction: Hack et al.[2] (293 K), Hack et al.[1] (293 K), Thrush and Wilkinson[8] (298 K), Sridharan et al.[7] (296 K), and Keyser[4] (245–300 K). Related early work and combustion studies are referenced in Sridharan et al. All five studies used discharge flow systems. It is difficult to obtain a direct measurement of the rate constant for this reaction because both reactants are radicals and the products OH and O are reactive toward the HO_2 reactant. The recommendation is based on the kinetics and product data of Sridharan et al. and Keyser, because those measurements were the most direct and required the fewest corrections. Keyser found the rate coefficient and product yields to be independent of temperature for $245 < T < 300$ K. The total rate constant measurements of, $(5.0 \pm 1.3) \times 10^{-11}$ cm^3 molecule^{-1} s^{-1} by Thrush and Wilkinson[8] and $(4.65 \pm 1) \times 10^{-11}$ by Hack et al.[1] are significantly less than the recommended total rate constant, 8.05×10^{-11} cm^3 molecule^{-1} s^{-1}. Hislop and Wayne,[3] Keyser et al.,[5] and Michelangeli et al.[6] reported on the yield of $O_2(b^1\Sigma)$ formed in the $H_2 + O_2$ channel as $(2.8 \pm 1.3) \times 10^{-4}$, $<8 \times 10^{-3}$, and $<2.1 \times 10^{-2}$, respectively as a fraction of the overall reaction.

B6. **$OH + O_3$**. The recommended values are based on the results of studies over a range of temperatures by Anderson and Kaufman[1] (220–450 K), Ravishankara et al.[5] (238–357 K), Smith et al.[6] (240–295 K) and Nizkorodov et al.[4] (190–315 K) and the room temperature measurements of Kurylo,[3] Zahniser and Howard,[7] and Kulcke et al.[2] The recommended E/R and k(298 K) values are based on averages of the individual E/R and k(298 K) values obtained in the above mentioned studies. The value reported by Kulcke et al.[2] has been corrected for a minor contribution from $k(HO_2 + O_3)$.

B7. OH + H_2. The OH + H_2 reaction has been the subject of numerous studies. The recommendation is fixed to the average of eleven studies at 298 K: Greiner,[2] Stuhl and Niki,[7] Westenberg and deHaas,[10] Smith and Zellner,[6] Atkinson et al.,[1] Overend et al.,[4] Tully and Ravishankara,[9] Zellner and Steinert,[11] Ravishankara et al.,[5] Talukdar et al.,[8] and Orkin et al.[3] The temperature dependent studies of Orkin et al. (200–480 K), Talukdar et al. (230–420 K), and Ravishankara et al. (250–1050 K) find that the reaction does not follow a simple Arrhenius expression over a large range of temperature. The recommended temperature dependence is based on the average of E/R values determined in the above-mentioned studies for temperatures below 300 K. Accordingly, the recommended Arrhenius expression is only valid between 200–300 K. Even over this range the simple Arrhenius expression likely overestimates, near 250 K, and underestimates, near 200 K, the data by approximately 10%.

B8. OH + HD. The recommendation is based on direct measurements made by Talukdar et al.[2] using pulsed photolysis-laser induced fluorescence over the temperature range 248–418 K. The recommendation is in excellent agreement with the ratio $k(OH + H_2)/k(OH + HD) = 1.65 \pm 0.05$ at 298 K reported by Ehhalt et al.[1] when combined with the recommended $k(OH + H_2)$.

B9. OH + OH. The recommendation for the OH + OH reaction is the average of eight measurements performed near 298 K at low bath gas pressures: Westenberg and deHaas,[9] McKenzie et al.,[6] Clyne and Down,[3] Trainor and von Rosenberg,[7] Farquharson and Smith,[4] Wagner and Zellner,[8] Bedjanian et al.,[2] and Bahng and MacDonald.[1] The rate coefficients reported in these studies fall in the range $(1.4–2.7) \times 10^{-12}$ cm^3 $molecule^{-1}$

s^{-1}. Wagner and Zellner (250–580 K) reported a slight positive temperature dependence of the rate coefficient in contrast with that reported by Bedjanian et al. (233–360 K), who report a small negative temperature dependence. The earlier work of Wagner and Zellner may have been complicated by an increased contribution of the OH + H reaction due to an underestimate of its reaction rate. Theoretical calculations by Harding and Wagner[5] suggest that tunneling substantially influences the reaction rate coefficient. In taking account of the tunneling contribution, the rate coefficient is found to have a minimum value near room temperature. In view of the predicted behavior and given that the experimental data are consistent with each other, within the stated uncertainties, the recommendation is a temperature independent value for the rate coefficient over the temperature range 200–300 K.

B10. OH + HO_2. A study by Keyser[8] appears to resolve a discrepancy among low-pressure discharge flow experiments that all gave rate coefficients near 7×10^{-11} cm^3 $molecule^{-1}$ s^{-1}: Keyser,[7] Thrush and Wilkinson,[16] Sridharan et al.,[13,14] Temps and Wagner,[15] Rozenshtein et al.,[11] and atmospheric pressure studies that gave rate coefficients near 11×10^{-11} cm^3 $molecule^{-1}$ s^{-1}: Lii et al.,[10] Hochanadel et al.,[6] DeMore,[3] Cox et al.,[2] Burrows et al.,[1] and Kurylo et al.[9] Laboratory measurements using a discharge flow experiment and a chemical model analysis of the results by Keyser[8] demonstrate that the previous discharge flow measurements were probably subject to interference from small amounts of O and H. In the presence of excess HO_2, these atoms generate OH and result in a rate coefficient measurement that falls below the true value. The temperature dependence is from Keyser,[8] who covered the range 254 to 382 K. A flow tube study by Schwab et al.[12] reported $k = (8.0 +3/–4) \times 10^{-11}$ cm^3 $molecule^{-1}$ s^{-1}. These workers measured the concentrations of HO_2, OH, O, and H and used a computer model of the relevant reactions to test for interference. A flow tube study by Dransfeld and Wagner[4] employing an isotope labeled ^{18}OH reactant obtained $k = (11 \pm 2) \times 10^{-11}$ cm^3 $molecule^{-1}$ s^{-1} in good agreement with the recommendation. They attributed about half of the reactive events to isotope scrambling because control experiments with ^{16}OH gave $k = 6 \times 10^{-11}$ cm^3 $molecule^{-1}$ s^{-1}. It should be noted that their control experiments were subject to the errors described by Keyser[8] due to the presence of small amounts of H and O, whereas their ^{18}OH measurements were not. Kurylo et al.[9] found no evidence of significant scrambling in isotope studies of the OH and HO_2 reaction. An additional careful study of the reaction temperature dependence would be useful. Hippler and Troe[5] have analyzed data for this reaction at temperatures up to 1250 K. In summary, this has historically been a difficult reaction to study. Earlier problems appear to have been resolved, as discussed above, and results now tend to converge on a central value, but the recommended value is still subject to a large uncertainty.

B11. OH + H_2O_2. The rate coefficient for this reaction shows non-Arrhenius behavior between 96 and 1250 K with a minimum value near room temperature. Data from a number of studies are in relatively good agreement between 300 and 500 K after normalization to account for the H_2O_2 UV absorption cross section recommendation in this evaluation. Hippler and Troe[1] analyzed data for this reaction at temperatures up to 1250 K. The studies of Keyser[2] (245–423 K), Sridharan et al.[7] (250–459 K), Wine et al.[11] (273–410 K), Kurylo et al.[3] (250–370 K), Lamb et al.[4] (241–413 K), and Vaghjiani et al.[9] (273–410 K) show that the reaction displays a small positive temperature dependence (E/R = ~160 K) over the 300–500 K range. Measurements at room temperature by Marinelli and Johnston,[5] Riffault et al.,[6] Turnipseed et al.,[8] and Vakhtin et al.[10] agree with the other studies. A value of 1.8×10^{-12} cm^3 $molecule^{-1}$ s^{-1} is obtained by averaging the room temperature data. Lamb et al. and Vaghjiani report that k increases slightly with decreasing temperature for temperatures below 300 K while other studies show a slight positive temperature dependence. Vakhtin et al. used a pulsed Laval nozzle technique to study the reaction at very low temperatures (96–165 K) and report a significant increase in k with decreasing temperature. They suggest that the reaction mechanism includes the formation of a hydrogen-bonded complex. The recommendation is a temperature independent value of 1.8×10^{-12} cm^3 $molecule^{-1}$ s^{-1} with $f(298 \text{ K}) = 1.15$ and $g = 45$ over the temperature range of 200–300 K.

B12. $HO_2 + O_3$. The recommended values are based on results of studies over a range of temperatures by DeMore[1] at 231 to 334 K, Zahniser and Howard[9] at 245 to 365 K, Manzanares et al.[4] at 298 K, Sinha et al.[7] at 243 to 413 K, Wang et al.[8] at 233 to 400 K, and Herndon et al.[3] at 200 to 298 K. The data of Simonaitis and Heicklen[6] and DeMore and Tschuikow-Roux[2] were not considered. The temperature dependence studies show varying degrees of curvature in the Arrhenius plots, with the E/R decreasing at lower temperature. This is especially evident in the low temperature data of Herndon et al. where a number of measures were taken to control potential kinetic complications. The recommended E/R and $k(298\ K)$ values are based on averages of the individual E/R and $k(298\ K)$ values. Furthermore, only data at temperatures less than 298 K were used for the E/R determination. Accordingly, the recommendation is not valid for T>298 K. Additional temperature dependence data are needed for this reaction over a larger range to more fully characterize the non-linear behavior of the rate constant. The mechanism of the reaction has been studied using ^{18}O labeled HO_2 by Sinha et al., who reported that the reaction occurs (75 ± 10)% via H atom transfer at 297 K and by Nelson and Zahniser,[5] who reported branching ratios for H transfer vs O transfer over the range 226–355 K. They report that the H atom transfer decreases from (94 ± 5)% at (226 ± 11) K to (88 ± 5)% at (355 ± 8) K.

B13. $HO_2 + HO_2$. The overall rate coefficient for this reaction is the sum of a pressure-independent bimolecular component and a pressure-dependent termolecular component. Two separate expressions are given for these rate coefficients. Both components contribute to the overall loss of HO_2 under atmospheric conditions and have negative temperature dependencies. This reaction also has a dependence on H_2O that needs to be included in atmospheric model calculations. Christensen et al.[2,3] found that kinetic studies that used CH_3OH as an HO_2 radical precursor were possibly complicated by the formation of a weakly bound reactive HO_2-CH_3OH adduct, particularly important at low temperatures. The magnitude of the CH_3OH effect on the measured rate coefficients is dependent on the CH_3OH concentration and temperature in the particular study.

The recommended bimolecular and termolecular expressions for the $HO_2 + HO_2$ reaction were obtained from a global fit of the rate coefficient data that had negligible complications due to the presence of CH_3OH. The analysis included data obtained at low pressure (<30 Torr) from Thrush and Tyndall[27,28] (7–20 Torr, 298–358 K), Simonaitis and Heicklen[21] (5–770 Torr, 296 K), Sander[19] (1 Torr, 298 K), Takacs and Howard[24,25] (1–7 Torr, 252–391 K), Kurylo et al.[13] (25–600 Torr, 298 K), and Tang et al.[26] (30 Torr, 253–323 K) and data obtained at higher pressure (>30 Torr) from Sander et al.[20] (100–700 Torr, 298 K), Simonaitis and Heicklen,[21] Kurylo et al.,[13] Christensen[3] (100 Torr, 222–295 K), Kircher and Sander[12] (100–700 Torr, 230–420 K) (only data above 298 K were used in the analysis), and Maricq and Szente[16] (200 Torr, 210–365 K). The rate coefficient data obtained using transient UV absorption detection of HO_2[12,13,16,20,21] were scaled to the currently recommended HO_2 absorption cross sections. Rate coefficient studies of Kurylo et al., Sander et al.,[20] and Kircher and Sander found little difference in the measured rate coefficient when N_2 or O_2 was used as the bath gas. The recommended termolecular expression applies to M = air. The experimental data is reproduced to within ±20% using the recommended parameters. The rate coefficient data reported by Maricq and Szente are systematically 20% higher than the current recommendation. Systematic discrepancies also exist in the low-temperature rate coefficient data where the results from Christensen et al. are ~25% lower than the current recommendation at 222 K. Hamilton and Lii[9] and Sander et al.[20] have reported the dependence of the rate coefficient on isotopic (H/D) substitution. Lightfoot et al.[14] reported rate coefficients at atmospheric pressure over the temperature range 298–777 K that are in agreement with the recommended value at 298 K. This study indicates an upward curvature in the rate coefficient at temperatures above 500 K. A high temperature (750–1120 K) study by Hippler et al.[10] confirms the strong curvature. The current recommendation does not account for the non-Arrhenius behavior and is valid only for temperatures below 500 K.

Stone and Rowley[22] reported rate coefficient data at 760 Torr over the temperature range 236–309 K that were later shown by Christensen et al.[2] to be systematically overestimated due to the use of very high concentrations of CH_3OH. The Stone and Rowley[22] data were not included in the present evaluation. The rate coefficient data and temperature dependence reported by Cox and Burrows[4] is in general agreement with this recommendation. Data from Rozenshtein et al.[18] are consistent with the low-pressure recommendation but they report no change in the rate coefficient with pressure up to 1 atm. Results reported by Thrush and Wilkinson[29] and Dobis and Benson[6] are inconsistent with the recommendation.

The $HO_2 + HO_2$ reaction exhibits a dependence on H_2O concentration due to the formation of a weakly bound reactive $HO_2 \cdot H_2O$ complex. English et al.[7] report a bond energy of 6.9 kcal mol^{-1} for the complex (also see Table 3). There are numerous studies of the rate coefficient H_2O dependence (Hamilton,[8] Hochanadel et al.,[11] Hamilton and Lii,[9] Cox and Burrows,[4] DeMore,[5] Lii et al.,[15] Sander et al.,[20] Andersson et al.,[1] Stone and Rowley,[22] English et al.,[7] and Tang et al.[26]) that are in good agreement. The effective rate coefficient in the presence of H_2O can be obtained by multiplying the recommended rate coefficient by the factor given by Lii et al.[15] and Kircher and Sander:[12] $[1 + 1.4 \times 10^{-21} [H_2O] \exp(2200/T)]$.

The major reaction products at 300 K have been identified as $H_2O_2 + O_2$ by Su et al.,[23] Niki et al.,[17] Sander et al.,[20] and Simonaitis and Heicklen.[21]

B14. $HO_2 + HO_2\text{-}H_2O$. The enhancement of the $HO_2 + HO_2$ reaction in the presence of H_2O vapor has been ascribed to the formation of a $HO_2\text{-}H_2O$ complex and the higher reactivity of the complex over that of HO_2. The recommendation is based upon the studies of Kanno et al.[1,2] who analyzed the enhancement of HO_2 decays in the presence of H_2O. Enhancement factors were obtained at 298, 325, and 350 K and a total pressure of 50 Torr N_2. A pressure dependence of the rate coefficient has not been measured and a pressure independent value is recommended.

1.8 NO$_x$ Reactions

1.8.1 Table 1C: NO$_x$ Reactions

Reaction	Temperature Range of Exp. Data (K) [a]	*A*-Factor	*E*/R	*k*(298 K)[b]	*f*(298 K)[c]	*g*	Note
$O + NO \xrightarrow{M} NO_2$		(See Table 2-1)					
$O + NO_2 \rightarrow NO + O_2$		(See Table 2-1)					
$O + NO_2 \xrightarrow{M} NO_3$		(See Table 2-1)					
$O + NO_3 \rightarrow O_2 + NO_2$	298–329	1.3×10^{-11}	0	1.3×10^{-11}	1.5	150	C 1
$O + N_2O_5 \rightarrow$ products	223–300			$<3.0\times10^{-16}$			C 2
$O + HNO_3 \rightarrow OH + NO_3$	298			$<3.0\times10^{-17}$			C 3
$O + HO_2NO_2 \rightarrow$ products	228–297	7.8×10^{-11}	3400	8.6×10^{-16}	3.0	750	C 4
$H + NO_2 \rightarrow OH + NO$	195–2000	1.35×10^{-10}	0	1.35×10^{-10}	1.2	150	C 5
$OH + NO \xrightarrow{M} HONO$		(See Table 2-1)					
$OH + NO_2 \xrightarrow{M} HNO_3$		(See Table 2-1)					
$OH + NO_3 \rightarrow$ products	298			2.0×10^{-11}	1.5		C 6
$OH + HONO \rightarrow H_2O + NO_2$	278–1400	3.0×10^{-12}	–250	6.9×10^{-12}	1.3	100	C 7
$OH + HNO_3 \rightarrow H_2O + NO_3$		(See Table 2-1)					
$OH + HO_2NO_2 \rightarrow$ products	218–335	4.5×10^{-13}	–610	3.5×10^{-12}	1.3	50	C 8
$OH + NH_3 \rightarrow H_2O + NH_2$	228–2360	1.7×10^{-12}	710	1.6×10^{-13}	1.15	100	C 9
$HO_2 + NO \rightarrow NO_2 + OH$	183–1270	3.44×10^{-12}	–260	8.2×10^{-12}	1.10	0	C10
$NO_2^* + H_2O \rightarrow OH + HONO$		(See Note)					C11
$HO_2 + NO_2 \xrightarrow{M} HO_2NO_2$		(See Table 2-1)					
$HO_2 + NO_2 \rightarrow HONO + O_2$	296			$<5\times10^{-16}$			C12
$HO_2 + NO_3 \rightarrow$ products	263–338			3.5×10^{-12}	1.5		C13
$HO_2 + NH_2 \rightarrow$ products	298			4.8×10^{-11}	2.0		C14
$N + O_2 \rightarrow NO + O$	280–1220	3.3×10^{-12}	3150	8.5×10^{-17}	1.25	400	C15
$N + O_3 \rightarrow NO + O_2$	298			$<2.0\times10^{-16}$			C16

Reaction	Temperature Range of Exp. Data (K) [a]	*A*-Factor	*E*/R	*k*(298 K)[b]	*f*(298 K)[c]	*g*	Note
$N + NO \rightarrow N_2 + O$	196–3660	2.1×10^{-11}	–100	3.0×10^{-11}	1.3	100	C17
$N + NO_2 \rightarrow N_2O + O$	223–700	5.8×10^{-12}	–220	1.2×10^{-11}	1.5	100	C18
$NO + O_3 \rightarrow NO_2 + O_2$	195–443	3.0×10^{-12}	1500	1.9×10^{-14}	1.07	130	C19
$NO + NO_3 \rightarrow 2NO_2$	209–703	1.7×10^{-11}	–125	2.6×10^{-11}	1.15	50	C20
$NO_2 + O_3 \rightarrow NO_3 + O_2$	231–362	1.2×10^{-13}	2450	3.2×10^{-17}	1.15	150	C21
$NO_2 + NO_3 \rightarrow NO + NO_2 + O_2$	236–538	(See Note)					C22
$NO_2 + NO_3 \xrightarrow{M} N_2O_5$		(See Table 2-1)					
$NO_3 + NO_3 \rightarrow 2NO_2 + O_2$	298–1100	8.5×10^{-13}	2450	2.3×10^{-16}	1.5	500	C23
$NH_2 + O_2 \rightarrow$ products	295–2300			$<6.0\times10^{-21}$			C24
$NH_2 + O_3 \rightarrow$ products	248–380	4.3×10^{-12}	930	1.9×10^{-13}	2.0	200	C25
$NH_2 + NO \rightarrow$ products	200–2500	4.0×10^{-12}	–450	1.8×10^{-11}	1.3	150	C26
$NH_2 + NO_2 \rightarrow N_2O + H_2O$ $\rightarrow H_2NO + NO$	295–910	6.0×10^{-12}	–385	2.2×10^{-11}	1.3	300	C27
$NH + NO \rightarrow N_2O + H$ $\rightarrow N_2 + OH$	269–3350	4.9×10^{-11}	0	4.9×10^{-11}	1.25	200	C28
$NH + NO_2 \rightarrow N_2O + OH$ $\rightarrow NO + HNO$	269–377	3.5×10^{-13}	–1140	1.6×10^{-11}	2.0	100	C29
$O_3 + HNO_2 \rightarrow O_2 + HNO_3$	226–300			$<5.0\times10^{-19}$			C30
$N_2O_5 + H_2O \rightarrow 2HNO_3$	290–298			$<2.0\times10^{-21}$			C31
$N_2(A,v) + O_2 \rightarrow$ products	80–560			2.5×10^{-12}, v=0	1.5		C32
$N_2(A,v) + O_3 \rightarrow$ products	298			4.1×10^{-11}, v=0	2.0		C33

Shaded areas indicate changes or additions since JPL15-10.

[a] Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

[b] Units are cm^3 molecule^{-1} s^{-1}.

[c] *f*(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(\mathrm{T}) = f(298\ \mathrm{K})\exp\left|g\left(\frac{1}{\mathrm{T}} - \frac{1}{298}\right)\right|$$

Note that the exponent is an absolute value.

1.8.2 Notes: NO_x Reactions

C1. **O + NO_3.** The recommended 298 K rate coefficient is an average of the results from Graham and Johnston[2] at 298 and 329 K and Canosa-Mas et al.[1] at 298 K. Over the limited temperature range of the Graham and Johnston study there was no measurable temperature dependence, which is the basis for the current recommendation.
(Table: 19-5, Note: 19-5, Evaluated: 19-5) Back to Table

(1) Canosa-Mas , C. E.; Carpenter, P. J.; Wayne, R. P. The reaction of NO_3 with atomic oxygen. *J. Chem. Soc. Faraday Trans 2* **1989**, *85*, 697-707, doi:10.1039/f29898500697.
(2) Graham, R. A.; Johnston, H. S. The photochemistry of NO_3 and the kinetics of the N_2O_5-O_3 system. *J. Phys. Chem.* **1978**, *82*, 254-268, doi:10.1021/j100492a002.

C2. **O + N_2O_5.** The recommendation is based on the study by Kaiser and Japar.[1]
(Table: 82-57, Note: 82-57, Evaluated: 19-5) Back to Table

(1) Kaiser, E. W.; Japar, S. M. The kinetics of the gas phase reaction of O(^{3}P) with N_2O_5. *Chem. Phys. Lett.* **1978**, *54*, 265-268, doi:10.1016/0009-2614(78)80097-9.

C3. **O + HNO_3.** The upper limit reported by Chapman and Wayne[1] is accepted.
(Table: 82-57, Note: 82-57, Evaluated: 19-5) Back to Table

(1) Chapman, C. J.; Wayne, R. P. The reaction of atomic oxygen and hydrogen with nitric acid. *Int. J. Chem. Kinet.* **1974**, *6*, 617-630, doi:10.1002/kin.550060502.

C4. **O + HO_2NO_2.** The recommended value is based on the study of Chang et al.[1] The large uncertainty in E/R and k at 298 K are due to the fact that the recommendation is based on a single study.
(Table: 82-57, Note: 82-57, Evaluated: 19-5) Back to Table

(1) Chang, J. S.; Trevor, P. L.; Barker, J. R. O(^3P) + $HOONO_2$ → Products: Temperature-dependent rate constant. *Int. J. Chem. Kinet.* **1981**, *13*, 1151-1161, doi:10.1002/kin.550131106.

C5. **H + NO_2.** The recommended value of k(298 K) is derived from the studies of Wagner et al.,[6] Bemand and Clyne,[2] Clyne and Monkhouse,[3] Michael et al.,[5] and Ko and Fontijn.[4] The temperature dependence recommendation is from the studies of Wagner et al. (243–461 K), Ko and Fontijn (296–755 K), and Michael et al. (195–400 K) for temperatures $<$500 K. The data from Wategaonkar and Setser[7] and Agrawalla et al.[1] were not considered.

C6. **OH + NO_3.** The recommendation is derived from an unweighted average of the results of Boodaghians et al.,[2] Mellouki et al.,[3] Becker et al.,[1] and Mellouki et al.[4] There are no temperature dependence data available and no recommendation is given. The reaction products are expected to be HO_2 + NO_2.
(Table: 19-5, Note: 19-5, Evaluated: 19-5) Back to Table

C7. **OH + HONO.** The recommendation is derived from the temperature dependence measurements of Burkholder et al.[1] (298–373 K). The results from Jenkin and Cox,[3] (278–342 K), which supersede the earlier room temperature study of Cox et al.,[2] obtained using a molecular modulation technique are in reasonable agreement with the Burkholder et al. results, but show a positive temperature dependence, $E/R = 450$ K. The direct measurements of Burkholder et al., who used on line diode array UV absorption measurements to quantify the HONO and NO_2 concentration in their slow flow pulsed laser photolysis-laser induced fluorescence experiments, are preferred. The recommended uncertainty factors encompass the results from both studies and reflect increased uncertainty at temperatures below the range of the available experimental data.
(Table: 19-5, Note: 19-5, Evaluated: 19-5) Back to Table

C8. **OH + HO_2NO_2.** The available studies for this reaction show significant scatter and relatively poor agreement. The recommendation is based on the study of Jiménez et al.[3] (218–335 K, 10–100 Torr (He)), who provide a thorough study over a range of temperature and pressure and accounting of secondary contributions to the observed OH radical loss. Jiménez et al. used a pulsed laser photolysis-laser induced fluorescence technique with the HO_2NO_2 concentration measured on line using diode array UV absorption. H_2O_2, HNO_3, and NO_2 impurities in their HO_2NO_2 sample were measured on line using mass spectrometry and UV/IR absorption measurements. Corrections for the impurity contributions to the observed pseudo first-order rate coefficient were in the range 5-25%. The impurities contributed <10% to the overall uncertainty in the measured rate coefficient. The room temperature data of Trevor et al.,[6] Barnes et al.,[1] Smith et al.,[5] and Barnes et al.[2] are 15–50% greater than the recommended value, but with the possible exception of Smith et al. agree to within the combined range of estimated absolute uncertainties. Trevor et al. (246–324 K) reported a temperature invariant value of 4.0×10^{-12} cm^3 molecule^{-1} s^{-1}. Smith et al. (240–300 K) observed a negative temperature dependence with an E/R value of $-(650 \pm 30)$ K in good agreement with the Jiménez et al. study. Jiménez et al. report a weak non-Arrhenius behavior that is described by the expression $k(T) = 8.8 \times 10^{-19}\ T^2 \exp(1130/T)$ cm^3 molecule^{-1} s^{-1}. The early Barnes et al.[1] study was carried out at room temperature and 1 Torr total pressure, while their later study was performed in the pressure range 1–300 Torr N_2 and temperature range 268–295 K. Within this limited temperature range no rate coefficient temperature dependence was observed. In addition, k(298 K) derived in Barnes et al.[1] was revised upward in the later study from 4.1×10^{-12} to 5.0×10^{-12} cm^3 molecule^{-1} s^{-1} due to a change in the reference reaction rate coefficient. No rate coefficient pressure dependence was observed in the Barnes et al. and Jiménez et al. studies. The less precise value for k(298 K) reported by Littlejohn and Johnston[4] is in fair agreement with the recommended value. The recommended uncertainty factors are sufficient to encompass all of the available experimental data.

Jiménez et al. reported that the $HO_2 + HNO_3$ and $NO_3 + H_2O_2$ reaction product channels have yields of <10% and <5%, respectively, at 298 K. They deduce that the major reaction pathway leads to the formation of H_2O, O_2, and NO_2.

(4) Littlejohn, D.; Johnston, H. S. Rate constant for the reaction of hydroxyl radicals and peroxynitric acid. *EOS* **1980**, *61*, 966.
(5) Smith, C. A.; Molina, L. T.; Lamb, J. J.; Molina, M. J. Kinetics of the reaction of OH with pernitric and nitric acids. *Int. J. Chem. Kinet.* **1984**, *16*, 41-55, doi:10.1002/kin.550160107
(6) Trevor, P. L.; Black, G.; Barker, J. R. Reaction rate constant for $OH + HOONO_2 \rightarrow$ products over the temperature range 246 to 324 K. *J. Phys. Chem.* **1982**, *86*, 1661-1669, doi:10.1021/j100206a035.

C9. **$OH + NH_3$.** The recommended value at 298 K is the average of the values reported by Stuhl,[10] Smith and Zellner,[8] Perry et al.,[6] Silver and Kolb,[7] Stephens,[9] and Diau et al.[2] The values reported by Pagsberg et al.[5] and Cox et al.[1] were not considered because these studies involved the analysis of a complex mechanism and the results are well outside the error limits implied by the above six direct studies. The results of Kurylo[4] and Hack et al.[3] were not considered because of their large discrepancies with the other direct studies (factors of 3.9 and 1.6 at room temperature, respectively). The kinetic data displays non-Arrhenius behavior at temperatures >300 K. The recommended temperature dependence is based on the data below 300 K from the studies of Smith and Zellner[8] (228–472 K) and Diau et al.[2] (273–453 K) with the *A*-factor taken to yield the recommended room temperature value. The non-Arrhenius behavior is reasonably well reproduced between 228 and 500 by:

$$k(T) = 2.55 \times 10^{-13} (T/298)^2 \exp(150/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$$

and falls within the range of the recommended uncertainty factors.

(10) Stuhl, F. Absolute rate constant for the reaction $OH + NH_3 \rightarrow NH_2 + H_2O$. *J. Chem. Phys.* **1973**, *59*, 635-637, doi:10.1063/1.1680069.

C10. **HO_2 +NO.** The recommendation for the HO_2 + NO reaction is based on the average of eight measurements of the rate coefficient at room temperature and below: Howard and Evenson[7] (296 K), Howard[6] (232–363 K), Hack et al.[5] (293 K), Jemi-Alade and Thrush[9] (297 K), Seeley et al.[12] (206–293 K), Bohn and Zetsch[2] (298 K), and Bardwell et al[1] (193–298 K). All of these studies are in quite good agreement. The results of Imamura and Washida[8] (298 K) and Leu[10] (269–426 K) were not considered due to the relatively large reported uncertainty limits. The result from Burrows et al.[3] (298 K) has been disregarded because of an error in the reference rate coefficient, $k(OH + H_2O_2)$. The study of Rozenshtein et al.[11] (298 K) has been disregarded due to an inadequate treatment of possible secondary reactions. The Glaschick-Schimpf et al.[4] (298 K) result was not considered because of complications associated with the HO_2 detection method. The relative rate data of Thrush and Wilkinson[13] (298 K) was superseded by Jemi-Alade and Thrush[9] from the same laboratory and not included in the recommendation analysis. The recommended Arrhenius parameters are obtained from a fit to all the accepted data after normalization to the recommended *k*(298 K) value.

C11. NO_2* + H_2O. The reaction of NO_2 with H_2O to produce OH and HONO is endothermic by about 40 kcal mole^{-1} (ground state reactants and products). However, absorption of light by NO_2 at wavelengths less than 718 nm can exceed the thermodynamic threshold if all the NO_2 internal energy is available for reaction. Crowley and Carl[2] photolyzed NO_2/H_2O mixtures in the 430–450 nm spectral region and observed an OH action spectrum that mimicked the absorption features of NO_2. Because the dependence of the OH signal on photolysis laser energy was second order, they suggested that two-photon absorption of NO_2 produced $O(^1D)$ in their experiment which reacted with water vapor to produce OH. The energetic threshold for $O(^1D)$ production is 488 nm. When they performed the same experiment with 532 nm photolysis, no OH production was observed giving an upper limit for the OH branching fraction (reactive vs. unreactive quenching) of 7×10^{-5}. Li et al.[3] carried out laser pump/probe experiments at photolysis wavelengths between 560 and 640 nm in NO_2/H_2O mixtures. In contrast to Crowley and Carl, they found significant OH production in this wavelength range. Their experiments showed a unity slope dependence of OH production on laser energy, suggesting a one-photon process. Overtone pumping was used to check for the presence of HONO and HNO_3, which might be the source of the observed OH radicals. The rate constant for the NO_2* + H_2O reaction was determined to be 1.7×10^{-13} cm^3 molecule^{-1} s^{-1} for NO_2 excitation at 565, 590 and 612.5 nm with an overall uncertainty of ±50%. This is large enough to have a significant impact on HO_x production in the troposphere. Carr et al.[1] performed a laser pump/probe experiment at 567.5 and 563.5 nm in NO_2/H_2O mixtures. These experiments failed to detect OH formation, resulting in an upper limit of 6×10^{-5} for the reactive branching fraction.

Although this reaction is potentially important, in view of the disagreement in the published results, the Panel makes no recommendation on this reaction until additional credible studies are carried out.

C12. HO_2 + NO_2. Tyndall et al.[2] obtained an upper-limit to the rate coefficient for the HONO + O_2 product channel of 5×10^{-16} cm^3 $molecule^{-1}$ s^{-1} based on photolysis experiments at 296 K and 760 Torr of N_2 in an environmental chamber with FTIR analysis. The results from this study are the basis of the recommendation. Dransfield et al.[1]reported no detectable HONO formation in a discharge-flow experiment with FTIR detection at 296 K and 120 Torr of N_2 that is consistent with the Tyndall et al. results.

C13. HO_2 + NO_3. The recommendation for *k*(298 K) is based on a weighted average of the data of Hall et al.,[2] Mellouki et al.,[3] Becker et al.,[1] and Mellouki et al.[4] There are insufficient data on which to base the temperature dependence of the rate coefficient. The measured branching ratios for the OH + NO_2 + O_2 channel range from 0.57 to 1.0. The most direct measurement is derived from the study of Mellouki et al.,[4] which obtained a value of 1.0 +0.0/–0.3 at 298 K.
(Table: 94-26, Note: 94-26, Evaluated: 19-5) Back to Table

C14. HO_2 + NH_2. The 298 K relative rate studies of Cheskis and Sarkisov[1] and Pagsberg et al.[2] differ by nearly a factor of three. The recommended *k*(298 K) value is the average of the values reported in these studies. There are no temperature dependence studies available and no recommendation is given. The identity of the products is not known; however, it is suggested that the most probable reaction channels give either NH_3 + O_2 or HNO + H_2O as products.
(Table: 19-5, Note: 19-5, Evaluated: 19-5) Back to Table

C15. N + O_2. The recommended expression is derived from the data of Kistiakowsky and Volpi[5] (394–516 K), Wilson[7] (300–910 K), Becker et al.[2] (280–333 K), Westenberg et al.[6] (298 K), Clark and Wayne[3] (298 K), Winkler et al.[8] (298 K), Barnett et al.[1] (298 K), and Fernandez et al.[4] (404–1221 K). The rate coefficient data displays a non-Arrhenius behavior between 300 and 1200 K and the recommended Arrhenius expression was obtained from the experimental data at temperatures less than 500 K. *k*(298 K) is derived from the Arrhenius expression and is in agreement with the determinations at room temperature.

C16. **N + O_3.** The recommendation is based on the results of Barnett et al.[1] The value of $(1.0 \pm 0.2) \times 10^{-16}$ cm^3 molecule^{-1} s^{-1} reported by Barnett et al. is considered an upper-limit rather than a determination. The low values reported by Barnett et al., Stief et al.,[5] and Garvin and Broida[3] cast doubt on the much greater rate coefficients reported by Phillips and Schiff[4] and Chen and Taylor.[2]

C17. **N + NO.** The recommended temperature dependence is based on the discharge flow-resonance fluorescence studies of Wennberg and Anderson[15] (213–339 K) and the discharge flow-resonance fluorescence and flash photolysis-resonance fluorescence study of Lee et al.[10] (196–370 K). There is agreement between these studies and the more recent work of Nakayama et al.[12] (295 K). There is relatively poor agreement between these studies and the results of Clyne and McDermid[4] (298–670 K), Kistiakowsky and Volpi[9] (298 K, lower-limit), Herron[6] (298 K), Phillips and Schiff[13] (298 K), Lin et al.[11] (298 K), Sugawara et al.[14] (298 K), Cheah and Clyne[3] (298 K), Husain and Slater[7] (300 K), Clyne and Ono[5] (298 K), Brunning and Clyne[2] (289 K), Jeoung et al.[8] (298 K), and Bergeat et al.[1] (48–211 K).

C18. N + NO₂. The recommendation for *k*(298 K) is from the discharge flow-resonance fluorescence study of Wennberg and Anderson[6] (223–366 K). This study had significantly better sensitivity for N(^{4}S) than the 293 K discharge flow-resonance fluorescence study of Clyne and Ono,[2] which obtained a value about four times smaller. The room temperature study of Nakayama et al.[5] reports *k*(298 K) a factor of 1.6 lower than Wennberg and Anderson. The recommended uncertainty factor encompass the Nakayama et al. result. The results of Husain and Slater[3] (298 K) and Clyne and McDermid[1] (298 K) are not considered. The temperature dependence is obtained from the study of Wennberg and Anderson. Wennberg and Anderson report atomic oxygen to be the principal reaction product, in agreement with Clyne and McDermid. A recent study by Iwata et al.[4] suggested an upper limit of 3.3×10^{-13} cm^3 molecule^{-1} s^{-1} for the corresponding reaction involving N(^{2}D) and N(^{2}P) atoms (sum of all reaction channels).

C19. NO + O₃. The recommended values are based on the results of studies over a range of temperatures by Birks et al.[2] (203.5–361 K), Lippmann et al.[5] (283–443 K), Ray and Watson[8] (212–422 K), Michael et al.[6] (195–369 K), Borders and Birks[3] (203.8–353.2 K), and Moonen et al.[7] (298–328 K) and the room temperature studies of Stedman and Niki[10] and Bemand et al.[1] The six temperature-dependent studies were given equal weighting in the recommendation by averaging over the *E*/R's from each individual data set. Following the Moonen et al. recommendation, their 200 K data point was excluded. All of the temperature dependence studies show some non-Arrhenius behavior, although increasing scatter between the data sets is evident at the lower temperatures. The non-Arrhenius behavior, between 204 and 440 K, is described well by the expression:

$$k(T) = 3.32 \times 10^{-13} \times (T/298)^{2.25} \times \exp(-850/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$$

This non-Arrhenius parameterization falls within the recommended range of uncertainty for temperatures less than 300 K.

Clough and Thrush,[4] Birks et al., Schurath et al.,[9] and Michael et al. have reported individual Arrhenius parameters for the two primary reaction channels producing ground and excited molecular oxygen.

C20. $NO + NO_3$. The recommendation is based on the temperature dependent studies of Hammer et al.[2] (209–410 K), Sander and Kircher[3] (224–328 K), and Tyndall et al.[4] (223–353 K) and the room temperature study of Brown et al.,[1] which are in good agreement. The recommended temperature dependence is taken from an unweighted linear least-squares fit of the data from the three temperature dependence studies after scaling to the recommended *k*(298 K) value. The A-factor was adjusted to agree with the recommended *k*(298 K) value.

C21. $NO_2 + O_3$. The recommended expression is derived from a least squares fit to the data of Davis et al.[2] (260–343 K), Graham and Johnston[3] (231–298 K), Huie and Herron[4] (259–362 K), and Cox and Coker[1] (298 K). The data of Verhees and Adema[6] (277–340 K) and Stedman and Niki[5] (298 K) were not considered because of systematic discrepancies with the other studies.

C22. **NO_2 + NO_3.** The existence of the reaction channel forming NO + NO_2 + O_2 has not been firmly established. However, studies of N_2O_5 thermal decomposition that monitor NO_2 (Daniels and Johnston;[3] Johnston and Tao;[5] Cantrell et al.[1], and Wangberg et al.[6]) and NO (Hjorth et al.,[4] Cantrell et al.[2], and Wangberg et al.[6]) require reaction(s) that decompose NO_3 into NO + O_2. The rate coefficient from the first three studies is obtained from the product kK_{eq}, where K_{eq} is the equilibrium constant for $NO_2 + NO_3 \rightarrow N_2O_5$, while for the latter two studies the rate coefficient is obtained from the ratio $k/k(NO + NO_3)$, where $k(NO + NO_3)$ is the rate constant for the reaction $NO + NO_3 \rightarrow 2NO_2$. Using K_{eq} and $k(NO + NO_3)$ from this evaluation, $4.35 \times 10^{-14} \exp(-1335/T)$ cm^3 $molecule^{-1}$ s^{-1} represents the available experimental data reasonably well. An overall uncertainty factor of 2 is recommended.

(6) Wangberg, I.; Ljungstrom, E.; Olsson, B. E. R.; Davidsson, J. Temperature-dependence of the reaction $NO_3 + NO_2 \rightarrow NO + NO_2 + O_2$ in the range from 296 K to 332 K. *J. Phys. Chem.* **1992**, *96*, 7640-7645, doi:10.1021/j100198a029.

C23. **NO_3 + NO_3.** The recommendation for k(298 K) is from the studies of Graham and Johnston[2] (298–329 K) and Biggs et al.[1] (298 K). The temperature dependence is from Graham and Johnston.
(Table: 94-26, Note: 19-5, Evaluated: 19-5) Back to Table

C24. **NH_2 + O_2.** This reaction has several product channels which are energetically possible, including NO + H_2O and HNO + OH. With the exception of the studies of Hack et al.[2] and Jayanty et al.[3] and several studies at high temperature, there is no evidence for a reaction. The following upper-limits have been measured at 298 K (cm^3 $molecule^{-1}$ s^{-1}): 3×10^{-18} (Lesclaux and Demissy[4]), 8×10^{-15} (Pagsberg et al.[8]), 1.5×10^{-17} (Cheskis and Sarkisov[1]), 3×10^{-18} (Lozovsky et al.[5]), 1×10^{-17} (Patrick and Golden[9]) and 7.7×10^{-18} (Michael et al.[7]), 6×10^{-21} (Tyndall et al.[10]), and 3×10^{-20} (Lozovsky et al.[6]). The recommendation is based on the study of Tyndall et al., which was sensitive to reaction paths leading to the products NO, NO_2, and N_2O. The reaction forming NH_2O_2 cannot be ruled out, but it is apparently not important in the atmosphere.

C25. **$NH_2 + O_3$.** There is poor agreement among the studies of Cheskis et al.,[2] $k(298) = 1.5 \times 10^{-13}$ cm^3 molecule^{-1} s^{-1}, Patrick and Golden[5] (272–348 K), $k(298\text{ K}) = 3.25 \times 10^{-13}$ cm^3 molecule^{-1} s^{-1}, Hack et al.[3] (250–358 K), $k(298) = 1.84 \times 10^{-13}$ cm^3 molecule^{-1} s^{-1}, Bulatov et al.,[1] $k(298) = 1.2 \times 10^{-13}$ cm^3 molecule^{-1} s^{-1}, and Kurasawa and Lesclaux[4] (298–380 K), $k(298) = 0.62 \times 10^{-13}$ cm^3 molecule^{-1} s^{-1}. The very low value of Kurasawa and Lesclaux may be due to regeneration of NH_2 from secondary reactions (see Patrick and Golden), and it is disregarded here. The discharge flow value of Hack et al. is nearly a factor of two less than the recent Patrick and Golden flash photolysis value. The large discrepancy between Bulatov et al. and Patrick and Golden eludes explanation. The recommendation is the k(298 K) average of these four studies, and E/R is an average of the values reported by Patrick and Golden (1151 K) and Hack et al. (710 K).

C26. **$NH_2 + NO$.** The recommended value for k(298 K) is the average of the values reported by Lesclaux et al.[11] (300–500 K), Hancock et al.[9] (298 K), Sarkisov et al.[13] (298 K), Stief et al.[17] (216–480 K), Andresen et al.[1] (295 K), Whyte and Phillips[19] (298 K), Dreier and Wolfrum[5] (295 K), Atakan et al.[2] (294–1024 K), Wolf et al.[20] (293–612 K), Diau et al.[3] (297–673 K), Imamura and Washida[10] (298 K), and Yamasaki et al.[21] (298 K). The results of Gordon et al.,[7] Gehring et al.,[6] Hack et al.,[8] and Silver and Kolb[14] were not considered because they lie at least 2 standard deviations from the average of the previous group. The results tend to separate into two groups. The flash photolysis results average 1.8×10^{-11} cm^3 molecule^{-1} s^{-1} (except for the pulse radiolysis study of Gordon et al.), while those obtained using the discharge flow technique average 0.9×10^{-11} cm^3 molecule^{-1} s^{-1}. The apparent discrepancy cannot be due simply to a pressure effect as the pressure ranges of the flash photolysis and discharge flow studies overlapped and none of the studies observed a pressure dependence for k. Whyte and Phillips have suggested that the difference may be due to decomposition of the adduct NH_2NO, which occurs on the timescale of the flow experiments, but not the flash experiments. There have been many studies of the temperature dependence but most have investigated the regime of interest to combustion and only two have gone below room temperature (Hack et al. (209–505 K) and Stief et al. (216–480 K). Each study reported k to decrease with increasing temperature. The recommended temperature dependence is taken from a fit to the Stief et al. data at room temperature and below. The reaction proceeds along a complex potential energy surface, which results in product branching ratios that are strongly dependent on temperature. *Ab initio* calculations by Walch[18] show the existence of four saddle points in the potential surface leading to $N_2 + H_2O$ without a reaction barrier. Elimination to form $OH + HN_2$ can occur at any point along the surface. While results from early studies on the branching ratio for OH formation differ significantly,

the most recent studies (Hall et al., Dolson,[4] Silver and Kolb,[15] Atakan et al., Stephens et al.,[16] and Park and Lin[12]) agree on a value around 0.1 at 300 K, with $N_2 + H_2O$ making up the balance.

(20) Wolf, M.; Yang, D. L.; Durant, J. L. Kinetic studies of NH_x radical reactions. *J. Photochem. Photobiol. A: Chem.* **1994**, *80*, 85-93, doi:i10.1016/1010-6030(93)01037-3.

(21) Yamasaki, K.; Watanabe, A.; Tanaka, A.; Sato, M.; Tokue, I. Kinetics of the reaction $NH_2(X^2B_1, \nu_2 = 0$ and 1) + NO. *J. Phys. Chem. A* **2002**, *106*, 6563-6569, doi:10.1021/jp013306g.

C27. **$NH_2 + NO_2$.** Hack et al.[2] (298 K), Kurasawa and Lesclaux[4] (298–505 K), Whyte and Phillips[10] (298 K), Xiang et al.[11] (298 K), Bulatov et al.[1] (295–620 K), Meunier et al.[6] (298 K), Park and Lin[7] (300–910 K), and Klippenstein et al.[3] (295–625 K) have reported rate coefficient data near room temperature. The results of Hack et al. and Meunier et al. are significantly less than the other studies and were not included in the recommendation. The results of Bulatov et al. are systematically less than the other studies at elevated temperatures and are not included in the recommendation. The recommended k(298 K) value is an average of the other studies listed above. The recommended temperature dependence is taken from the studies of Meunier et al., Park et al., and Klippenstein et al. for temperatures <500 K. Presently there are no kinetic measurements available for temperatures <295 K.

There have been several studies of the product branching yields. Hack et al. reported that the predominant reaction channel produces $N_2O + H_2O$ with a yield at 298 K of >95%. Using pulse radiolysis combined with infrared detection of N_2O and NO, Meunier et al. report (59 ± 3)% and (40 ± 5)% yields at 298 K for the $N_2O + H_2O$ and $H_2NO + NO$ product channels, respectively. Using pulsed laser photolysis combined with time-resolved infrared diode laser detection of N_2O and NO products, Lindholm and Hershberger[5] report (24 ± 4)% and (76 ± 10)% yields at 298 K for the $N_2O + H_2O$ and $H_2NO + NO$ product channels, respectively. This study supersedes that of Quandt and Hershberger.[8] Park and Lin[7] measured the $N_2O + H_2O$ product channel yield, using pulsed laser photolysis with mass spectroscopy detection, over the temperature range 300–900 K and report a (19 ± 2)% yield independent of temperature. Song et al.[9] reported a $N_2O + H_2O$ product channel yield of 0.17 ± 0.04 over the temperature range 1330–1527 K. A $N_2O + H_2O$ product channel yield of 20% is recommended with the $H_2NO + NO$ channel as the balance of the reaction.

C28. NH + NO. The recommendation is derived from the room temperature results of Hansen et al.,[3] Cox et al.,[1] Harrison et al.,[4] and Okada et al.[5] The temperature dependence is from Harrison et al. (270–373 K). Several studies have reported product yield data for this reaction. Durant[2] used a discharge-flow technique with mass spectrometric detection of products and reported a $N_2O + H$ branching yield of 0.8 ± 0.4 at 298 K. Okada et al. reported $N_2O + H$ and $OH + N_2$ branching yields at 295 K of 0.65 and 0.30, respectively (Okada et al. supersedes the Yamasaki et al.[7] study from the same group). Quandt and Hershberger[6] measured the $N_2O + H$ product branching yield at 298 K to be 0.77 ± 0.08.

C29. NH + NO_2. The recommendation is derived from the low-pressure (1 Torr) pulsed laser photolysis-laser induced fluorescence temperature-dependence study of Harrison et al.[1] (269–377 K). The assigned uncertainty factors are relatively large to reflect the limited available data. Quandt and Hershberger[2] measured N_2O + OH and NO + HNO product branching ratios at 298 K to be 0.41 ± 0.15 and 0.59 ± 0.15, respectively, using pulsed laser photolysis of HN_3 to produce NH and time-resolved infrared diode laser spectroscopy to monitor N_2O and NO formation.

C31. N_2O_5 + H_2O. The recommended value at 298 K is based on the studies of Tuazon et al.,[4] Atkinson et al.,[1] and Hjorth et al.[2] Sverdrup et al.[3] obtained an upper limit that is a factor of four smaller than that obtained in the other studies, but the higher upper limit is recommended because of the difficulty of distinguishing between homogeneous and heterogeneous processes in the experiment. See the heterogeneous chemistry section of this evaluation for additional rate data for this reaction.

C32. $N_2(A,v)$ + O_2. Rate coefficients for the overall reaction for the v = 0, 1 and 2 vibrational levels of $N_2(A)$ have been made by Dreyer et al.,[3] Zipf,[11] Piper et al.,[7] Iannuzzi and Kaufman,[6] Thomas and Kaufman,[10] Thomas et al.,[9]and De Sousa et al.[2] The results of these studies are in relatively good agreement. The recommended values are (2.5 ± 0.4), (4.0 ± 0.6), and (4.5 ± 0.6) (10^{-12} cm^3 $molecule^{-1}$ s^{-1}), from the work of De Sousa et al. The only temperature dependence data are from De Sousa et al., who obtained $k(T,v) = k(v,298\ K)(T/300)^{0.55}$ for v = 0,1,2. The observation of high N_2O production initially reported by Zipf[11] has not been reproduced by other groups, and the branching ratio for this channel is probably less than 0.02 (Iannuzzi et al.,[5] Black et al.,[1] De Sousa et al.,[2] and Fraser and Piper[4]). Thomas and Kaufman[8] report the 2NO product channel branching ratio to be <0.1%. The branching ratios for the other channels are poorly established, although there is strong evidence for the formation of both $O(^3P)$ and $O_2(B^3\Sigma_u^-)$.

C33. $N_2(A,v) + O_3$. The only study is that of Bohmer and Hack,[1] who obtained 298 K rate coefficients of 4.1 ± 1.0, 4.1 ± 1.2, 8.0 ± 2.3, and 10 ± 3.0 (10^{-11} cm^3 molecule^{-1} s^{-1}) for the loss of the v = 0–3 vibrational levels of $N_2(A)$, respectively. This study determined that the 2NO + $O(^3P)$ product channel accounts for about 20% of the reaction products.

1.9 Reactions of Organic Compounds

1.9.1 Table 1D: Reactions of Organic Compounds

Reaction	Temperature Range of Exp. Data (K) [a]	*A*-Factor	*E*/R	*k*(298 K)[b]	*f*(298 K)[c]	*g*	Note
O + CH_3 → products	259–341	1.1×10^{-10}	0	1.1×10^{-10}	1.3	250	D 1
O + HCN → products	469–900	1.0×10^{-11}	4000	1.5×10^{-17}	10	0	D 2
O + C_2H_2 → products	(See Note)	3.0×10^{-11}	1600	1.4×10^{-13}	1.3	250	D 3
O + H_2CO → products	250–748	3.4×10^{-11}	1600	1.6×10^{-13}	1.25	250	D 4
O + CH_3CHO → CH_3CO + OH	298–475	1.8×10^{-11}	1100	4.5×10^{-13}	1.25	200	D 5
O_2 + HOCO → HO_2 + CO_2	298			2×10^{-12} (See Note)	2		D 6
O_3 + C_2H_2 → products	243–323	*1.0×10^{-14}*	*4100*	1.0×10^{-20}	3	500	D 7
O_3 + C_2H_4 → products	178–373	1.2×10^{-14}	2630	1.7×10^{-18}	1.25	100	D 8
O_3 + C_3H_6 → products	183–362	6.5×10^{-15}	1900	1.1×10^{-17}	1.15	200	D 9
O_3 + $CH_2{=}C(CH_3)CHO$ → products	240–324	1.5×10^{-15}	2110	1.3×10^{-18}	1.1	200	D10
O_3 + $CH_3C(O)CH{=}CH_2$ → products	240–324	8.5×10^{-16}	1520	5.2×10^{-18}	1.15	100	D11
O_3 + $CH_2{=}C(CH_3)CH{=}CH_2$ → products	242–353	1.1×10^{-14}	2000	1.3×10^{-17}	1.1	200	D12
OH + CO → Products		(See Table 2-1)					D13
OH + CH_4 → CH_3 + H_2O	178–2025	2.45×10^{-12}	1775	6.3×10^{-15}	1.1	100	D14
OH + $^{13}CH_4$ → $^{13}CH_3$ + H_2O	273–353	See Note					D15
OH + CH_3D → products	249–420	3.5×10^{-12}	1950	5.0×10^{-15}	1.15	200	D16
OH + H_2CO → H_2O + HCO	228–2500	5.5×10^{-12}	–125	8.5×10^{-12}	1.15	50	D17
OH + CH_3OH → products	210–1350	2.9×10^{-12}	345	9.1×10^{-13}	1.10	60	D18
OH + CH_3OOH → products	203–423	3.8×10^{-12}	–200	7.4×10^{-12}	1.4	150	D19
OH + HC(O)OH → products	296–445	4.0×10^{-13}	0	4.0×10^{-13}	1.2	100	D20
OH + HC(O)C(O)H → products	210–390	1.15×10^{-11}	*0*	1.15×10^{-11}	1.5	200	D21
OH + $HOCH_2CHO$ → products	233–362	1.1×10^{-11}	*0*	1.1×10^{-11}	1.2	200	D22
OH + HCN → products	296–563	1.2×10^{-13}	400	3.1×10^{-14}	3	150	D23
OH + C_2H_2 $\xrightarrow{M}$ products		(See Table 2-1)					

Reaction	Temperature Range of Exp. Data (K) [a]	*A*-Factor	*E*/R	*k*(298 K)[b]	*f*(298 K)[c]	*g*	Note
$OH + C_2H_4 \xrightarrow{M}$ products		(See Table 2-1)					
$OH + C_2H_6 \rightarrow H_2O + C_2H_5$	226–2000	7.66×10^{-12}	1020	2.5×10^{-13}	1.05	20	D24
$OH + CH_3CHO \rightarrow$ products	202–900	4.63×10^{-12}	–350	1.5×10^{-11}	1.05	20	D25
$OH + CH_3OC(O)H \rightarrow$ products	233–372	8.43×10^{-12}	460	1.8×10^{-13}	1.15	50	D26
$OH + CH_3CH_2OH \rightarrow$ products	216–498	3.35×10^{-12}	0	3.35×10^{-12}	1.05	20	D27
$OH + CH_3C(O)OH \rightarrow$ products	229–802	3.15×10^{-14}	–920	6.9×10^{-13}	1.15	100	D28
$OH + C_3H_8 \rightarrow$ products	190–908	9.19×10^{-12}	630	1.11×10^{-12}	1.03	20	D29
$OH + C_2H_5CHO \rightarrow C_2H_5CO + H_2O$	240–372	4.9×10^{-12}	–405	1.9×10^{-11}	1.05	80	D30
$OH + 1\text{–}C_3H_7OH \rightarrow$ products	263–372	4.4×10^{-12}	–70	5.6×10^{-12}	1.05	80	D31
$OH + 2\text{–}C_3H_7OH \rightarrow$ products	220–745	2.10×10^{-12}	–270	5.2×10^{-12}	1.03	20	D32
$OH + C_2H_5C(O)OH \rightarrow$ products	240–445	1.2×10^{-12}	0	1.2×10^{-12}	1.1	200	D33
$OH + CH_3C(O)CH_3$ $\rightarrow H_2O + CH_3C(O)CH_2$ $\rightarrow CH_3 + CH_3C(O)OH$	242–1650	(See Note)		< 2% of k			D34
$OH + CH_3OCH_2OCH_3 \rightarrow$ products	252–372	2.12×10^{-12}	-250	4.9×10^{-12}	1.1	50	D35
$OH + n\text{-}C_4H_{10} \rightarrow$ products	185–509	1.02×10^{-11}	430	2.4×10^{-12}	1.03	20	D36
$OH + iso\text{-}C_4H_{10} \rightarrow$ products	213–864	4.86×10^{-12}	250	2.1×10^{-12}	1.05	20	D37
$OH + n\text{-}C_5H_{12} \rightarrow$ products	224–900	1.49×10^{-11}	400	3.9×10^{-12}	1.05	50	D38
$OH + iso\text{-}C_5H_{12} \rightarrow$ products	213–407	6.55×10^{-12}	170	3.7×10^{-12}	1.07	20	D39
$OH + cyclo\text{-}C_5H_{10} \rightarrow$ products	209–491	1.68×10^{-11}	370	4.85×10^{-12}	1.05	50	D40
$OH + CH_2{=}C(CH_3)CHO \rightarrow$ products	234–423	9.6×10^{-12}	–360	3.2×10^{-11}	1.15	100	D41
$OH + CH_3C(O)CH{=}CH_2 \rightarrow$ products	232–424	2.7×10^{-12}	–580	1.9×10^{-11}	1.07	100	D42
$OH + CH_2{=}C(CH_3)CH{=}CH_2 \rightarrow$ products	240–422	3.0×10^{-11}	–360	9.9×10^{-11}	1.1	50	D43

Shaded areas indicate changes or additions since JPL15-10. Italicized *blue* entries denote estimates.

[a] Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

[b] Units are cm^3 $molecule^{-1}$ s^{-1}.

[c] *f*(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(\mathrm{T}) = f(298\ \mathrm{K})\exp\left|g\left(\frac{1}{\mathrm{T}} - \frac{1}{298}\right)\right|$$

Note that the exponent is an absolute value.

1.9.2 Notes: Reactions of Organic Compounds

D1. **O + CH_3.** The recommended k(298 K) is the weighted average of the measurements by Washida and Bayes,[3] Washida,[2] and Plumb and Ryan.[1] The E/R value is based on the results of Washida and Bayes,[3] who found k to be independent of temperature between 259 and 341 K.
(Table: 83-62, Note: 83-62, Evaluated: 83-62) Back to Table

D2. **O + HCN.** Because it is a very slow reaction, there are no studies of this reaction below 450 K. Davies and Thrush[1] studied this reaction between 469 and 574 K while Perry and Melius[3] studied it between 540 and 900 K. Results of Perry and Melius are in agreement with those of Davies and Thrush. Our recommendation is based on these two studies. The higher-temperature (T>1000 K) combustion-related studies of Roth et al.,[4] Szekely et al.,[5] and Louge and Hanson[2] have not been considered. This reaction has two reaction pathways: O + HCN → H + NCO, ΔH = –2 kcal/mol (k_a); and O + HCN → CO + NH (k_b), ΔH = –36 kcal/mol. The branching ratio k_a/k_b for these two channels has been measured to be ~2 at T = 860 K. The branching ratio at lower temperatures, which is likely to vary significantly with temperature, is unknown.

(5) Szekely, A.; Hanson, R. K.; Bowman, C. In *Twentieth Symposium (International) on Combustion*; The Combustion Institute, 1984; pp 647-654.

D3. **O + C_2H_2.** The value at 298 K is an average of ten measurements (Arrington et al.,[2] Sullivan and Warneck,[8] Brown and Thrush,[3] Hoyermann et al.,[4,5] Westenberg and deHaas,[10] James and Glass,[6] Stuhl and Niki,[7] Westenberg and deHaas,[11] and Aleksandrov et al.[1]). There is reasonably good agreement among these studies. Arrington et al.[2] did not observe a temperature dependence, an observation that was later shown to be erroneous by Westenberg and deHaas.[10] Westenberg and deHaas,[10] Hoyermann et al.,[5] and Aleksandrov et al.[1] are the only authors who have measured the temperature dependence below 500 K. Westenberg and deHaas observed a curved Arrhenius plot at temperatures higher than 450 K. In the range 194–450 K, Arrhenius behavior provides an adequate description and the E/R obtained by a fit of the data from these three groups in this temperature range is recommended. The A-factor was calculated to reproduce k(298 K). This reaction can have two sets of products, i.e., C_2HO + H or CH_2 + CO. Under molecular beam conditions C_2HO has been shown to be the major product. The study by Aleksandrov et al. using a discharge flow-resonance fluorescence method (under undefined pressure conditions) indicates that the C_2HO + H channel contributes no more than 7% to the net reaction at 298 K, while a similar study by Vinckier et al.[9] suggests that both CH_2 and C_2HO are formed.

D4. O + H_2CO. The recommended values for *A*, *E*/R and *k*(298 K) are the averages of those determined by Klemm[3] (250 to 498 K) using flash photolysis-resonance fluorescence, by Klemm et al.[4] (298 to 748 K) using discharge flow-resonance fluorescence, and Chang and Barker[1] (296 to 436 K) using discharge flow-mass spectrometry techniques. All three studies are in good agreement. The *k*(298 K) value is also consistent with the results of Niki et al.,[6] Herron and Penzhorn,[2] and Mack and Thrush.[5] Although the mechanism for O + H_2CO has been considered to be the abstraction reaction yielding OH + HCO, Chang and Barker suggest that an additional channel yielding H + HCO_2 may be occurring to the extent of 30% of the total reaction. This conclusion is based on an observation of CO_2 as a product of the reaction under conditions where reactions such as O + HCO → H + CO_2 and O + HCO → OH + CO apparently do not occur. This interesting suggestion needs independent confirmation.

D5. O + CH_3CHO. The recommended *k*(298 K) is the average of three measurements by Cadle and Powers,[2] Mack and Thrush,[3] and Singleton et al.,[4] which are in good agreement. Cadle and Powers and Singleton et al. studied this reaction as a function of temperature between 298 and 475 K and obtained very similar Arrhenius parameters. The recommended E/R value was obtained by considering both sets of data. This reaction is known to proceed via H-atom abstraction (Mack and Thrush,[3] Avery and Cvetanovic,[1] and Singleton et al.[4]).

D6. O_2 + HOCO. HOCO is produced by the association of OH with CO (See Table 2). The rate coefficient for the reaction of O_2 with HOCO has been measured by Petty et al.[2] and Nolte et al.[1] and the recommendation is based on these measurements. There are no reports on the temperature dependence of this reaction; however, the value at 298 K would be appropriate for all atmospheric conditions. The products of this reaction are HO_2,

as shown by Nolte et al., and CO_2, as seen in numerous previous studies where it has been known to be the product of the reaction of OH with CO in air.

D7. **O_3 + C_2H_2.** The database for this reaction is not well established. Room temperature measurements (Cadle and Schadt,[2] DeMore,[3] DeMore,[4] Stedman and Niki,[7] Pate et al.,[6] and Atkinson and Aschmann[1]) disagree by as much as an order of magnitude. It is probable that secondary reactions involving destruction of ozone by radical products resulted in erroneously high values for the rate constants in several of the previous measurements. The present recommendation for k(298 K) is based on the room temperature value of Atkinson and Aschmann,[1] which is the lowest value obtained and therefore perhaps the most accurate. The temperature dependence is estimated, based on an assumed A-factor of 10^{-14} cm^3 $molecule^{-1}$ s^{-1} similar to that for the O_3 + C_2H_4 reaction and corresponding to the expected five-membered ring structure for the transition state (DeMore[3,4]). Further studies, particularly of the temperature dependence, are needed. Major products in the gas phase reaction are CO, CO_2, and HCOOH, and chemically-activated formic anhydride has been proposed as an intermediate of the reaction (DeMore,[4] and DeMore and Lin[5]). The anhydride intermediates in several alkyne ozonations have been isolated in low temperature solvent experiments (DeMore and Lin[5]).

D9. **O_3 + C_3H_6.** The rate constant of this reaction is well established over the temperature range 185 to 360 K. The present recommendation is based largely on the data of Herron and Huie,[5] in the temperature range 235–362 K. (Note that a typographical error in Table 2 of that paper improperly lists the lowest temperature as 250 K, rather than the correct value, 235 K.) The recommended Arrhenius expression agrees within 25% with the low temperature (185–195 K) data of DeMore,[4] and is consistent with, but slightly higher (about 10%) than the data of Treacy et al.[10] and slightly lower (about 40%) than the data of Adeniji et al.[1] in the temperature range 260–294 K. Room temperature measurements of Cox and Penkett,[3] Stedman et al.,[9] Japar et al.,[6,7] and Atkinson et al.[2] and Neeb and Moorgat[8] are in good agreement (10% or better) with the recommendation.

D10. **O_3 + CH_2=C(CH_3)CHO.** The recommended *E*/R is based on the single temperature dependence study by Treacy et al.[7] The recommended 298 K rate constant is obtained from an unweighted fit to $\ln k = \ln A - E/RT$ of the ambient temperature results of Atkinson et al.,[2] Grosjean and Grosjean,[4] Kamens et al.,[5] Neeb et al.,[6] and Treacy et al.[7] in conjunction with the recommended *E*/R. While OH was scavenged only in the studies of Grosjean and Grosjean and Neeb et al., the studies where OH was not scavenged report results that agree well with the studies where OH was scavenged. By monitoring the production of cyclohexanone + cyclohexanol under conditions where OH was >95% scavenged by cyclohexane, Aschmann et al.[1] report an upper limit OH yield of 20^{+10}_{-13} percent. Ozone + alkene reactions proceed via initial formation of a primary ozonide that decomposes to a carbonyl compound plus a Criegee biradical with two different carbonyl/Criegee pairs produced (depending on which O−O bond cleaves); the Criegee biradical/carbonyl pairs produced in this case are $CH_3C(O)CHO$ (methyl glyoxal) + •CH_2OO• and H_2CO + CH_3C•(OO•)CHO. Grosjean et al.[3] report carbonyl product yields to be 58% $CH_3C(O)CHO$ and 12% H_2CO.

D11. O_3 + $CH_3C(O)CH=CH_2$. The recommended *E*/R is based on the single temperature dependence study by Treacy et al.[8] The recommended 298 K rate constant is obtained from an unweighted fit to $\ln k = \ln A - E/RT$ of the ambient temperature results of Atkinson et al.,[2] Grosjean et al.,[3] Grosjean and Grosjean,[4] Kamens et al.,[5] Neeb et al.,[6] and Treacy et al.[8] in conjunction with the recommended *E*/R. While OH was scavenged only in the more recent studies of Grosjean et al., Grosjean and Grosjean, and Neeb et al., the studies where OH was not scavenged report results that agree well with the studies where OH was scavenged. The yield of OH is reported to be 0.16 ± 0.08 and 0.16 ± 0.05 by Aschmann et al.[1] and Paulson et al.,[7] respectively. Ozone + alkene reactions proceed via initial formation of a primary ozonide that decomposes to a carbonyl compound plus a Criegee biradical with two different carbonyl/Criegee pairs produced (depending on which O−O bond cleaves); the Criegee biradical/carbonyl pairs produced in this case are $CH_3C(O)CHO$ (methyl glyoxal) + $\bullet CH_2OO\bullet$ and H_2CO + $CH_3C(O)C\bullet HOO\bullet$. Grosjean et al.[3] report carbonyl product yields to be 87% $CH_3C(O)CHO$ and 5% H_2CO; these investigators also report a 5% yield of $CH_3C(O)C(O)OH$ (pyruvic acid). D12. O_3 + $CH_2=C(CH_3)CH=CH_2$. The recommended *E*/R is based on an unweighted fit to the temperature-dependent rate constants reported by Khamaganov and Hites[13] to $\ln k = \ln A - E/RT$, while the recommended *A*-factor is based on the ambient temperature rate constants reported by Greene and Atkinson,[6] Grosjean et al.,[7] Grosjean and Grosjean,[8] Neeb and Moortgat,[16] Klawatsch-Carrasco et al.,[14] and Karl et al.[12] In all of the above studies, measures were taken to prevent secondary consumption of reactants by OH radicals, which are known to be generated in ozone + alkene reactions. Results from early studies by Adeniji et al.,[1] Atkinson et al.,[3] and Treacy et al.,[19] while in reasonable agreement with other studies, are not used to arrive at the recommendation because OH radicals were not scavenged in those studies. The Arrhenius parameters reported by Avzianova and Ariya[4] are not accepted because of inconsistencies in their paper that the authors were unable to resolve (private communication from Ariya). Donahue et al.[5] have directly detected OH as a product of the O_3 +

isoprene reaction, and OH yields have been reported in a number of studies where OH production was monitored indirectly by following the loss of an OH scavenger or the production of a product of an OH + scavenger reaction.[2,9,10,15-18] At room temperature and atmospheric pressure of air, reported OH yields from seemingly careful studies range from 0.19 to 0.53 with an average value of 0.32. The chemical pathways leading to OH production are too complex to discuss in this note; the interested reader is referred to a review article by Johnson and Marston.[11] As discussed by Johnson and Marston, the reaction proceeds via initial formation of a primary ozonide that decomposes to a carbonyl compound plus a Criegee biradical with several different carbonyl/Criegee pairs produced; the Criegee biradicals can react unimolecularly from a chemically activated state or be collisionally deactivated and live long enough to undergo bimolecular reactions under atmospheric conditions.

D13. OH + CO. See note for the OH + CO reaction in Section 2.
Back to Table

D14. OH + CH_4. This reaction has been extensively studied by Vaghjiani and Ravishankara,[8] Saunders et al.,[6] Finlayson-Pitts et al.,[3] Dunlop and Tully,[2] Mellouki et al.,[5] and Gierczak et al.,[4] who measured the absolute rate coefficients for this reaction using discharge flow and pulsed photolysis techniques. Sharkey and Smith[7] have reported a high value (7.7×10^{-15} cm^3 molecule^{-1} s^{-1}) for k(298 K), and this value has not been considered here. The current recommendation for k(298 K) was derived from the results of Vaghjiani and Ravishankara, Dunlop and Tully, Saunders et al., Mellouki et al., Finlayson-Pitts et al., and Gierczak et al. The temperature dependence of this rate coefficient has been measured by Vaghjiani and Ravishankara (223–420 K), Dunlop and Tully (above 298 K), Finlayson-Pitts et al. (278–378 K), and Mellouki et al. (233–343 K). Gierczak et al. have extended the measurements of k to 195 K, and it appears that the rate coefficient does not strictly follow an Arrhenius expression. The recommended E/R was obtained from these results using data below 300 K.

A more accurate representation of the rate constant as a function of temperature is obtained by using the three-parameter expression: $k(T) = 2.80 \times 10^{-14} T^{0.667} \exp(-1575/T)$ cm^3 molecule^{-1} s^{-1}. This three-parameter fit may be preferred for lower stratosphere and upper troposphere calculations. A report on this rate coefficient by Bonard et al.[1] agrees very well with the value recommended here.

D15. OH + $^{13}CH_4$. This reaction has been studied relative to the OH + $^{12}CH_4$ reaction, since the ratio of the rate constants (the kinetic isotope effect, KIE) is the quantity needed for quantifying methane sources. Rust and Stevens,[3] Davidson et al.,[2] Cantrell et al.,[1] and Saueressig et al.[4] have reported KIE = k_{12}/k_{13} at room temperature to be 1.0036 ± 0.0013, 1.010 ± 0.007, 1.0055 ± 0.0009, and 1.0039 ± 0.0004, respectively (all uncertainties are stated as 95% confidence intervals). Cantrell et al.'s data supersede the results of Davidson et al. The recommended value of KIE = 1.0039 +0.0015/-0.0010 is the result of the latest most comprehensive study by Saueressig et al. However, the more conservative uncertainty is recommended because of the nature of these measurements and unresolved difference with the earlier result of Cantrell et al. Cantrell et al. find KIE = k_{12}/k_{13} to be independent of temperature between 273 and 353 K.
Note that the ratio of collision frequencies for these reactions (due to small difference in colliding masses) is 1.0155. Thus, the observed KIE cannot be explained by the slight change in the relative velocity of the colliding reactant molecules.

D16. OH + CH_3D. The rate coefficient for this reaction has been measured between 249 and 422 K using a pulsed laser photolysis-laser induced fluorescence system by Gierczak et al.[3] The recommended values of *k*(298 K) and *E*/R are from this study. The recommendation agrees within about 10% at 298 K with the rate constant measured by DeMore[1] in a relative rate study over the temperature range 298–360 K. The difference, while small in an absolute sense, is nevertheless significant for the isotopic fractionation of atmospheric CH_3D and CH_4 by OH. An earlier result of Gordon and Mulac[4] at 416 K is in good agreement with the extrapolated data of both of these determinations. However, that measurement has not been explicitly included in this recommendation because the experiments were carried out at higher temperatures and therefore are less applicable to the atmosphere. The rate coefficients for the reactions of OH with other deuterated methanes have also been measured (Dunlop and Tully,[2] Gierczak et al.,[5] Gordon and Mulac[4]).

D17. OH + H_2CO. The value for *k*(298 K) is the average of those determined by Niki et al.,[6] Atkinson and Pitts,[1] Stief et al.,[9] Yetter et al.,[11] Temps and Wagner,[10] and Sivakumaran et al.[7] The value reported by Morris and Niki[3] is expected to be superseded by the later report of Niki et al.,[6] although it agrees within the stated uncertainty. There are two relative values that are not in agreement with the recommendations. The value of Niki et al.[4] relative to the OH + C_2H_4 reaction is higher, while the value of Smith[8] relative to the OH + OH reaction is lower. The rate coefficients reported by Zabarnick et al.[12] at and above 298 K are consistently higher than those recommended here, but overlap within the combined uncertainty. The temperature dependence was calculated from the data of Stief et al. obtained below 298 K and from the data of Sivakumaran et al. below 330 K after normalizing the results of both studies to *k*(298 K) recommended here. There is a clear indication that the Arrhenius plot of this rate coefficient is curved with a positive activation energy at temperatures above ~330 K. It is therefore important that the recommended rate coefficients be used only in the 200–300 K temperature range. The abstraction reaction shown in the table is the major channel (Temps and Wagner,[10] Niki et al.[5]); other channels may contribute to a small extent (Horowitz et al.[2]). There is no indication that this rate coefficient is pressure dependent at atmospheric pressures and temperatures.

D18. OH + CH_3OH. The recommended value for k(298 K) is the average of direct studies by Overend and Paraskevopoulos,[10] Ravishankara and Davis,[12] Hägele et al.,[4] Meier et al.,[9] McCaulley et al.,[8] Wallington and Kurylo,[14] Hess and Tully,[5] Jimenez et al.,[6] and Dillon et al.[3] When these measurements were not at exactly 298 K, their values were recalculated for 298 K by using the E/R recommended here. Indirect measurements by Campbell et al.,[2] Barnes et al.,[1] Tuazon et al.,[13] Picquet et al.,[11] and Klopffer et al.[7] are in good agreement with the recommended value. The temperature dependence of k has been measured by Hägele et al., Meier et al., Greenhill and O'Grady, Wallington and Kurylo, Hess and Tully, Jimenez et al., and Crowley et al. The recommended value of E/R was calculated using the results obtained at temperature below 330 K by Wallington and Kurylo, Meier et al., Hess and Tully, Jimenez et al., and Crowley et al. The results of Greenhill and O'Grady are in reasonable agreement with the recommendation at and above 298 K, but are clearly lower than the recommendation below 298 K. Hess and Tully report a curved Arrhenius plot over the temperature range 298–1000 K, while Meier et al. did not observe such a curvature. This reaction has two pathways: abstraction of the H-atom from the methyl group to give $CH_2OH + H_2O$ or from the OH group to give $CH_3O + H_2O$. The results of Hagele et al., Meier et al., and Hess and Tully suggest that H abstraction from the methyl group is the dominant channel below room temperature. At 298 K, for example, the branching ratio for the formation of CH_2OH is about 0.85 and increases as the temperature decreases. In the Earth's atmosphere, the eventual products of OH + CH_3OH reaction are the same for both reaction channels: CH_2O and HO_2.

D19. OH + CH_3OOH. The recommended value for *k*(298 K) is the average of the rate coefficients measured by Niki et al.[1] and Vaghjiani and Ravishankara,[2] which differ by nearly a factor of two. Niki et al. measured the rate coefficient relative to that for OH with C_2H_4 (= 8.0×10^{-12} cm^3 $molecule^{-1}$ s^{-1}) by monitoring CH_3OOH disappearance using an FTIR system. Vaghjiani and Ravishankara monitored the disappearance of OH, OD, and ^{18}OH in excess CH_3OOH in a pulsed photolysis-LIF system. They measured k between 203 and 423 K and report a negative activation energy with $E/R = -190$ K; the recommended E/R is based on their results. The reaction of OH with CH_3OOH occurs via abstraction of H from the oxygen end to produce the CH_3OO radical and from the CH_3 group to produce the CH_2OOH radical, as originally proposed by Niki et al. and confirmed by Vaghjiani and Ravishankara. CH_2OOH is unstable and falls apart to CH_2O and OH within a few microseconds. The possible reaction of CH_2OOH with O_2 is unimportant under atmospheric conditions (Vaghjiani and Ravishankara). The recommended branching ratios are,

$$OH + CH_3OOH \rightarrow CH_3O_2 + H_2O \qquad (a) \qquad 70\%$$

$$OH + CH_3OOH \rightarrow CH_2OOH + H_2O \qquad (b) \qquad 30\%,$$

(from Vaghjiani and Ravishankara) and are nearly independent of temperature.

D20. OH + HC(O)OH. The recommended value of *k*(298 K) is the average of those measured by Zetzsch and Stuhl,[5] Wine et al.,[4] Jolly et al.,[2] Dagaut et al.,[1] and Singleton et al.[3] The temperature dependence of *k* has been studied by Wine et al. and by Singleton et al., who observed *k* to be essentially independent of temperature.

Wine et al. found the rate coefficient for the OH + HC(O)OH reaction to be the same as that for OH + DC(O)OH reaction. Jolly et al. found the formic acid dimer to be unreactive toward OH, i.e., abstraction of the H atom attached to C was not the major pathway for the reaction. A comprehensive study of Singleton et al. showed that reactivity of HC(O)OH is essentially the same as that of DC(O)OH, but DC(O)OD reacts much slower than HC(O)OH and DC(O)OH. These observations show that the reaction proceeds via abstraction of the acidic H atom. Wine et al. and Jolly et al. also found that H atoms are produced in the reaction, which is consistent with the formation of HC(O)O, which would rapidly fall apart to CO_2 and H. End product studies are also consistent with the formation of CO_2 and H_2O in this reaction (Singleton et al.[3]). The products of this reaction would be mostly HC(O)O and H_2O. The fate of HC(O)O in the atmosphere will be to give HO_2 either directly via reaction with O_2 or via thermal decomposition to H atom, which adds to O_2.

Wine et al. have suggested that, in the atmosphere, the formic acid could be hydrogen bonded to a water molecule and its reactivity with OH could be lowered because the hydrogen bonded water would obstruct the abstraction of the H atom. This suggestion needs to be checked.

D21. **OH + HC(O)C(O)H.** The only available data are from the 298 K relative rate study of Plum et al.[1] and the results are recommended here. Because the rate coefficient is so large, it is unlikely to have a substantial temperature dependence and an *E*/R of zero is recommended. This reaction is expected to proceed via H-abstraction to yield H_2O, CO and HCO.
(Table: 06-2, Note: 06-2, Evaluated: 06-2) Back to Table

(1) Plum, C. N.; Sanhueza, E.; Atkinson, R.; Carter, W. P. L.; Pitts, J. N., Jr. OH radical rate constant and photolysis rates of α-dicarbonyls. *Environ. Sci. Technol.* **1983**, *17*, 479-484, doi:10.1021/es00114a008.

D22. **OH + $HOCH_2CHO$.** The available data are from relative rate studies at 298 K (Bacher et al.,[1] Niki et al.,[3] and Mellouki et al.[2]). The recommendation is based on all these studies, which are in good agreement. Because the rate coefficient is very large, it is unlikely to have a substantial temperature dependence. Therefore, we recommend an *E*/R of zero. There are three possible sites for H-abstraction: the alcohol group, the CH_2 group and the carbonyl group. Of these, the likely pathways for abstraction are from the latter two sites:

$$\mathrm{OH + HOCH_2CHO \rightarrow H_2O + HOC(H)CHO} \qquad (a)$$
$$\mathrm{OH + HOCH_2CHO \rightarrow H_2O + HOCH_2CO} \qquad (b)$$

Niki et al. have shown that the branching ratio for channel (b) is 0.8 and for channel (a) is 0.2. It is unlikely that the branching ratio changes significantly with temperature.

D23. **OH + HCN.** This reaction is pressure dependent. The recommended value is the high pressure limit measured by Fritz et al.[2] using a laser photolysis-resonance fluorescence apparatus. Phillips[4] studied this reaction using a discharge flow apparatus at low pressures and found the rate coefficient to have reached the high pressure limit at ~10 Torr at 298 K. Fritz et al.'s results contradict this finding. They agree with Phillip's measured value, within a factor of two, at 7 Torr, but they find *k* to increase further with pressure. Bunkan et al.[1] report the $^{12}C/^{13}C$ and $^{14}N/^{15}N$ kinetic isotope effects at T = 298 K and P = 1.00 atm to be 0.9733 ± 0.0012 and 0.9840 ± 0.0016, respectively (uncertainties are 1σ). The reaction mechanism has been investigated theoretically by Galano[3] and Bunkan et al. They find that OH adds (over a barrier of ~16 kJ mol^{-1}) to the carbon atom in HCN. It is predicted theoretically that, under atmospheric conditions, HC(OH)N reacts with O_2 to generate nitroso formaldehyde (HC(O)NO) and recycle OH.[1,3] The rate constant for the HC(OH)N + O_2 reaction at T = 298 K and P = 1.00 atm is evaluated theoretically to be 9×10^{-16} cm^3 $molecule^{-1}$ s^{-1}.[1]

D24. **OH + C_2H_6.** There are numerous studies of this reaction at 298 K (Greiner,[11] Horne and Norrish,[14] Greiner,[12] Overend et al.,[21] Howard and Evenson,[15] Leu,[18] Lee and Tang,[17] Tully et al.,[29] Jeong et al.,[16] Smith et al.,[25] Baulch et al.,[2] Schmidt et al.,[23] Edney et al.,[9] Tully et al.,[28] Nielsen et al.,[20] Stachnik et al.,[26] Wallington et al.,[30] Bourmada et al.[3] Zabarnick et al.,[31] Abbatt et al.,[1] Schiffman et al.,[22] Dobe et al.,[7] Sharkey and Smith,[24] Finlayson-Pitts,[10] Talukdar et al.,[27] Crowley et al.,[6] Cavalli et al.,[4] Donahue et al.,[8] Clarke et al.,[5] Heathfield et al.,[13] and Li et al.[19]). The recommended value for k(298 K) is an average of the majority of the results reported at room temperature (Overend et al.,[21] Howard and Evenson,[15] Leu,[18] Lee and Tang,[17] Tully et al.,[29] Smith et al.,[25] Baulch et al.,[2] Schmidt et al.,[23] Tully et al.,[28] Stachnik et al.,[26] Wallington et al.,[30] Bourmada et al.,[3] Zabarnick et al.,[31] Abbatt et al.,[1] Schiffman et al.,[22] Dóbé et al.,[7] Finlayson-Pitts,[10] Talukdar et al.,[27] Crowley et al.,[6] Cavalli et al.,[4] Donohue et al.,[8] Clarke et al.,[5] Heathfield et al.,[13] and Li et al.[19]). The room temperature studies not used were either of lower precision (as evidenced by data scatter) or yielded somewhat higher rate constants.

The temperature dependence of the rate coefficient below 298 K has been measured by Jeong et al.,[16] Stachnik et al.,[26] Smith et al.,[25] Wallington et al.,[30] Talukdar et al.,[27] Crowley et al.,[6] and Clarke et al.[5] The last six of these studies are in good agreement (the data from Jeong et al.[16] exhibiting noticeable upward curvature below 298 K). Thus the recommended value for E/R is derived from a combined fit to the data below 300 K from the aforementioned six studies after each data set was normalized to the recommended value for k(298 K). D25. OH + CH_3CHO. The recommended values for *k*(298 K) and *E*/R come from a combined fit to the data of Sivakumaran and Crowley[13] and Zhu et al.[21] at T ≤300 K. There are 14 other studies of this reaction that provide the room temperature rate constant (Morris et al.,[9] Niki et al.,[10] Atkinson and Pitts,[1] Kerr and Sheppard,[7] Semmes et al.,[12] Michael et al.,[8] Dobe et al.,[6] Balestra-Garcia et al.,[2] Scollard et al.,[11] Tyndall et al.,[17] Taylor et al.,[14] D'Anna et al.,[5] Wang et al.,[20] and Taylor et al.[15]). The average value of *k*(298 K) from all of these studies is identical to that derived from the above fit. The study by Michael et al.[8] also provided data down to 244 K. While these data are far more scattered than those from Sivakumaran and Crowley[13] and Zhu et al.,[21] they are encompassed by the 95% confidence limits of the recommendation.

Measurements of H_2O formation yields were conducted by Wang et al.,[20] Butkovskaya et al.,[3] and Vandenberk and Peeters.[18] These investigators reported values of ~100%, (97.7 ± 4.7)%, and (89 ± 6)%, respectively at about room temperature. Butkovskaya et al.[3] report identical yields at both 298 K and 248 K. Tyndall et al.[16] concluded that more than 90% of the reaction proceeds via H-atom abstraction based on no measurable detection of acidic acid formation. Cameron et al.[4] detected CH_3 and CH_3CO radicals and H-atoms. The major reaction pathway was determined to be $CH_3CHO + OH \rightarrow CH_3CO + H_2O$ with a measured yield of (93 ± 18)%. Butkovskaya et al.[3] detected CH_2CHO radicals to obtain a branching ratio for H-atom abstraction from the CH_3 group of $5.1^{+2.4}_{-1.7}\%$. Vöhringer-Martinez et al.[19] studied the effect of water vapor on the reaction rate constant at temperatures between 300 K and 60 K. They found little-to no effect at 300 K and enhancements approaching a factor of 2 at temperatures below 100 K.

D26. OH + $CH_3OC(O)H$. Both recommended values for *k*(298 K) and *E*/R come from a fit to the data of Le Calve et al.,[3] who studied the reaction by using an absolute technique between 233 K and 372 K. Results of room temperature studies reported by Good et al.[1] and Szilagyi et al.[4] are in very good agreement with the recommended value. The recommended uncertainty at 95% confidence interval also encompasses the room temperature result reported by Wallington et al.,[5] which is 25% larger than the recommended value.

Jimenez et al.[2] studied this reaction at very low temperatures between 22 and 64 K to find the substantially larger rate constant of OH disappearance, which increases with decreasing temperature from 1.2×10^{-11} cm^3 $molecule^{-1}$ s^{-1} at 64 K to 1.2×10^{-10} cm^3 $molecule^{-1}$ s^{-1} at 22 K. The large rate constant of the OH removal can be associated with either adduct formation at low temperatures or H-abstraction chemical reaction.

D27. OH + C_2H_5OH. There are numerous studies of the reaction rate constant at room temperature (Campbell et al.,[1] Overend and Paraskevopoulos,[13] Ravishankara and Davis,[16] Kerr and Stocker,[7] Greenhill and O'Grady,[4] Wallington and Kurylo,[18] Hess and Tully,[5] Nelson et al.,[10] Picquet et al.,[14] Oh and Andino,[11] Sorensen et al.,[17] Jimenez et al.,[6] Wu et al.,[19] Dillon et al.,[3] Kovacs et al.,[8] Rajakumar et al.,[15] Carr et al.,[2] and Orkin et al.[12]). The recommended *k*(298 K) is an average of the rate constants measured by Campbell et al.,[1] Kerr and Stocker,[7] Wallington and Kurylo,[18] Hess and Tully,[5] Nelson et al.,[10] Sorensen et al.,[17] Jimenez et al.,[6] Wu et al.,[19] Dillon et al.,[3] Kovacs et al.,[8] Rajakumar et al.,[15] and Orkin et al.[12] The room temperature studies not used were either of lower precision (as evidenced by data scatter) or yielded systematically higher or lower rate constants. Comprehensive studies of this reaction at sub-ambient temperatures were done by Jimenez et al.,[6] Dillon et al.,[3] and Orkin et al.[12] The last two studies resulted in indistinguishable rate constants at low temperatures and coincide with the recommended value of *k*(298 K). The analysis of the data at low temperatures suggests a temperature independent reaction rate constant between 210 K and 298 K and provide the basis for the recommended *E*/R.

This reaction has three possible product channels: (a) $CH_3CH_2O + H_2O$, (b) $CH_3CHOH + H_2O$, and (c) $CH_2CH_2OH+H_2O$. At room temperature, channel (b) is the major pathway accounting for (75% ± 15%) of the reaction (Meier et al.[9]) which is consistent with the thermochemistry of these three possible pathways. The branching ration for channel (b) is expected to increase with decreasing temperature.

D28. OH + $CH_3C(O)OH$. The recommended values of *k*(298 K) and *E*/R are derived from a combined fit to the data of Singleton et al.,[8] Butkovskaya et al.,[1] Crunaire et al.,[2] Vimal and Stevens,[9] Khamaganov et al.,[7] Huang et al.,[6] and Huang et al.[5] at T $\leq$300 K. Data from these studies are in reasonable agreement below 300 K. However, above 300 K there is not a consistent picture of the temperature dependence of the rate constant with *E*/R values ranging from ~ –500 K to ~–1000 K. In an earlier study by Dagaut et al.[3] at room temperature and above, an *E*/R value of +170 K was obtained. For this reason data from this study were not included in the combined fit, although *k*(298 K) from this study is in good agreement with recommended value. All studies required corrections for the presence of acetic acid dimer especially at temperatures below 298 K and they assumed no reactivity between OH and the dimer. This latter assumption is based on results from Singleton et al.[8] However, in the same study Singleton et al.[8] found that the rate constant for the reaction of OH with the dimer of propionic acid is equal to or greater than that of the rate constant of OH with propionic acid monomer. This result suggests that uncertainties regarding the reactivity of acetic acid dimer may remain. Such uncertainties would propagate into uncertainties in the reactivity of the monomer, especially at lower temperatures.

Three studies give similar results for the reaction mechanism. Butkovskaya et al.[1] reported a yield of (64 ± 17)% over the temperature range of 300–249 K for H-atom abstraction from the carboxyl group, ($OH + CH_3C(O)OH \rightarrow CH_3 + CO_2 + H_2O$). At room temperature, De Smedt et al.[4] and Crunaire et al.[2] reported similar

yields of (64 ± 14)% and (78 ± 13)%, respectively. Observations by Singleton et al.[8] regarding the decrease in reactivity upon D substitution on the carboxylic site and no change in reactivity upon substitution on the methyl group, are reasonably consistent with these mechanistic studies.

D29. **OH + C_3H_8.** There are numerous studies of this reaction at room temperature. However, we have based our evaluation on only the more comprehensive studies in which the temperature dependence of the rate constant was determined over the range that included room temperature. Results of eight absolute studies by Droege and Tully[5] (293–854 K), Talukdar et al.[9] (233–376 K), Mellouki et al.[7] (233–363 K), Donahue et al.[4] (300–390 K), Clarke et al.[2] (190–360 K), Kozlov et al.[6] (210–480 K), Bryukov et al.[1] (296–908 K), Morin et al.,[8] (230–908 K) and one relative rate study by DeMore and Bayes[3] (227–428 K) have been analyzed to derive the current recommendation. The results of the latter study were re-calculated by using the current recommendation for the rate constant of a reference reaction, OH + C_2H_6. The recommended value of k(298 K) is an average of the nine values derived from the fit to these individual data sets. All of these values agree within ≈2% with the recommended $k(298\ K) = 1.11 \times 10^{-12}$ cm^3 molecule^{-1} s^{-1}. Although a fit to the data from earlier study by Tully et al.[10] (297–690 K) yields the same k(298 K) as other studies considered here, these data were not used in making recommendation because they exhibit larger scattering and they are probably superseded by the later study of Droege and Tully. Due to the noticeable curvature in the Arrhenius plot over the studied temperature range, the recommended Arrhenius expression is only valid between 190 and 300 K. The recommended E/R was derived from a composite fit to the data from Talukdar et al, Mellouki et al., Clarke et al., Kozlov et al., and Morin et al. between 210 and 300 K after each data set was scaled to the recommended k(298 K).

The Arrhenius plot of the temperature dependence exhibits a noticeable curvature near room temperature and above. Therefore, we recommend the three-parameter expression derived from a fit to the data of Kozlov et al. over the temperature range from 210 to 480 K after data were scaled to match the recommended value of k(298 K).

$$k(T) = 1.99 \times 10^{-12}\ (T/298)^{1.81} \exp(-174/T)$$

This reaction has two possible channels, i.e., abstraction of the primary and the secondary H-atom. From the analysis of reactivity of various deuterated propanes, Droege and Tully estimated that OH reacts with $-CH_2-$ groups approximately 2.5 times faster than with $-CH_3$ at room temperature; this difference decreases down to a factor of 1.1 at 500 K and a factor of 0.8 at 850 K. Based on their observations between 295 and 854 K the rate constants for these two reaction channels above room temperature can be presented as

$$k_{\text{primary}}(T) = 1.97 \times 10^{-11} \times (T/298)^{1.23} \exp(-675/T)$$
$$k_{\text{secondary}}(T) = 8.54 \times 10^{-13} \times (T/298)^{1.54} \exp(-19/T)$$

D30. OH + C_2H_5CHO. The recommended value at 298 K is an average of the results from Niki et al.,[4] Audley et al.,[1] Kerr and Sheppard,[3] Semmes et al.,[6] Papagni,[5] Thévenet,[7] and D'Anna.[2] The temperature dependence has been measured by Thévenet. The *E*/R is taken from Thévenet and the *A*-factor is adjusted to reproduce *k*(298 K). Vandenberk and Peeters[8] measured unity yields of H_2O from the reaction and conclude that the reaction proceeds exclusively by H-abstraction of the aldehydic H-atom.

D31. OH + 1-C_3H_7OH. There have been a number of room temperature measurements that are in excellent agreement. The recommended value is an average of the results from absolute kinetics studies by Overend and Paraskevopoulos,[6] Wallington and Kurylo,[7] Nelson et al.,[4] and Yujing and Mellouki.[9] Relative rate studies of Nelson et al., Oh and Andino,[5] Wu et al.,[8] and Cheema et al.[3] are in excellent agreement with the recommended value. The indirect study of Campbell[2] is consistent with, but 30% lower than the recommended value. The reaction is observed to be nearly temperature independent; Yujing and Mellouki find a slight positive temperature dependence while Cheema et al. find a small negative temperature dependence. The recommended E/R value is based on the direct study of Yujing and Mellouki. End product studies carried out by Azad and Andino[1] support predictions based on the structure-activity relationship that identify the primary reaction channels as hydrogen abstraction by the OH radical from the α(~75%) and β(~20%) carbons.

D32. OH + 2-C_3H_7OH. The recommendation is based on results of the most comprehensive absolute measurements of temperature dependences extended to below room temperature, which are reported by Yujing and Mellouki,[11] Rajakumar et al.,[8] and Orkin et al.[6] The recommended value for k(298 K) is an average of values derived from the data reported in these papers. The recommended uncertainty encompasses the earlier room temperature data of Klopffer et al.,[3] Overend and Paraskevopoulos,[7] Dunlop and Tully,[2] and the newer relative rate results of Wu et al.[10] (reference compound is C_3H_8). It barely overlaps with the reported uncertainties of the earlier results reported by Wallington and Kurylo[9] (absolute measurements) and Nelson et al.[5] (both relative rate and absolute measurements). The result of a relative rate study by Lloyd et al.[4] is, within its wide error limits, consistent with the recommendation.

The recommended value for E/R (to be used only below 298 K) is derived from a combined fit to the data below 298 K of Rajakumar et al.[8] averaged at each temperature and Orkin et al.[6] The Arrhenius plot of the temperature dependence exhibits a noticeable curvature near room temperature and above. Results reported by Dunlop and Tully, Rajakumar et al., and Orkin et al. reveal a "bowl" shaped temperature dependence with a minimum near 400 K. Therefore, we recommend the three-parameter expression derived from a fit to the data of Orkin et al. over the temperature range from 220 K to 370 K after data were scaled to match the recommended value of k(298 K).

$$k(\mathrm{T}) = 3.55 \times 10^{-13} (\mathrm{T}/298)^{2.06} \exp(+800/\mathrm{T})$$

This expression combined with f(T) = 1.03 encompasses the data of Yujing and Mellouki, Rajakumar et al., and Orkin et al. and also the above room temperature data of Dunlop and Tully up to 587 K at 95% confidence intervals.

Caravan et al.[1] reported the OH removal rate constant at very low temperatures as large as to ~4 × 10^{-11} cm^3 $molecule^{-1}$ s^{-1} at 138 K and ~(6–7) × 10^{-11} cm^3 $molecule^{-1}$ s^{-1} at 90 K. Although reaction products were not experimentally observed, authors suggest that the increased OH removal rate constant describes an H-abstraction reaction rather than a non-reactive low-temperature adduct formation. These results are consistent with the trend observed for below room temperature data: although a very long extrapolation beyond the measurement range is always suspicious, the recommended three-parameter expression would yield ~2.4 × 10^{-11} cm^3 $molecule^{-1}$ s^{-1} at 138 K.

By using isotopic substitution, Dunlop and Tully determined that the primary reaction channel below 400 K involves H atom abstraction by OH from the α-site. This result is in agreement with estimates based on the structure-activity relationship (Yujing and Mellouki[11]).

D33. OH + $C_2H_5C(O)OH$. Studies of this reaction have been confined to 298 K and above because of the tendency of propionic acid to dimerize at lower temperatures and higher concentrations. Kinetic isotope effects measured by Singleton et al.[2] are consistent with a two channel mechanism proposed previously for OH reaction with acetic acid. In the propionic acid case, the channel involving direct abstraction of an alkyl hydrogen is predominant, thus accounting for the observed temperature independence of the rate constant. The recommended temperature independent rate constant, is based on an average of the results of Singleton et al. and Dagaut et al.[1] taken at a variety of temperatures between 298 K and 446 K. An study room temperature measurement by Zetsch and Stuhl[3] is ~30% higher, but consistent with the recommendation. Further studies below 298 K would be desirable in order to investigate possible non-Arrhenius behavior.

D34. OH + $CH_3C(O)CH_3$. The rate coefficient for this reaction has been measured at temperatures close to 298 K by Cox et al.,[2] Zetzsch,[14] Chiorboli et al.,[1] Kerr and Stocker,[5] Wallington and Kurylo,[11] Le Calve et al.,[6] Wollenhaupt et al.,[12] Gierczak et al.,[3] and Yamada et al.[13] Cox reported only an upper limit of $<5 \times 10^{-13}$ cm^3 molecule^{-1} s^{-1}, which is consistent with this recommendation. The primary aim of Chiorboli et al. was to examine the atmospheric degradation of styrene, which produces acetone. They employed a relative rate measurement and reported a value of k(298 K) that is almost three times faster than the recommended value. Because of possible complications in their system, we have not included their results in arriving at the recommended value. Wallington and Kurylo, Le Calve et al., Wollenhaupt et al., Gierczak et al., and Yamada et al. have reported k as a function of temperature; all these studies directly measured the rate constant using the pulsed photolysis method where the temporal profile of OH was measured using resonance fluorescence or laser induced fluorescence. The extensive data of Wollenhaupt et al. and Gierczak et al. seem to show that this rate coefficient does not follow an Arrhenius expression. The results of Le Calve et al. and Wallington et al. are in general agreement with the results of Wollenhaupt et al. and Gierczak et al. The non-Arrhenius behavior was not evident in the results of Wallington et al. and Le Calve et al. because they measured the rate constant at a few temperatures and did not explore temperature below 240 K, where the curvature becomes increasingly evident. Yamada et al. measured k only above room temperature and their values are consistently lower than those of all the others noted above. As they noted in their paper, Yamada et al. did not measure the acetone concentration in the reactor and, thus, could have overestimated its concentration leading to consistently lower values of k. We have not included data of Yamada et al.[13] in deriving the fit because of this possible systematic error and because they did not report k under atmospheric temperatures. The following recommendation reproduces all reported data, except that of Chiorboli et al. within the recommended uncertainty of 25% at all temperatures:

$$k(T) = 1.33 \text{ x } 10^{-13} + 3.82 \times 10^{-11}\exp(-2000/T) \ \text{cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$$

This reaction can proceed via the abstraction of an H atom or via the formation of a complex that decomposes to give many different products, which include CH_3 + $CH_3C(O)OH$, CH_3OH + $CH_3C(O)$, CH_4 + CH_3CO_2, and H_2O + $CH_3C(O)CH_2$. The branching ratios for the formation of different sets of products could vary with temperature. Wollenhaupt et al.[12] have deduced that CH_3 radicals are produced with a yield of ~50% at 298 K and ~30% at 233 K. A similar branching ratio has also been reported by Vasvári et al.[10] The results of Gierczak et al. on the OH + $CD_3C(O)CD_3$ reaction, whose rate coefficient nearly obeys an Arrhenius expression between 240 and 400 K and is nearly an order of magnitude smaller than the non-deuterated analog at 250 K, suggest that H abstraction may be the dominant channel. Vandenberk et al.,[9] Tyndall et al.,[8] and Talukdar et al.,[7] clearly show that $CH_3C(O)OH$ is a minor, if not negligible, product of this reaction and that the reaction proceeds to abstract an H atom. The results of Yamada et al. are consistent with this finding. Theoretical calculations of Henon et al.[4] and Vandenberk et al.[9] also suggest that formation of acetic acid is negligible**.** We recommend that the products of this reaction be taken as H_2O and $CH_3C(O)CH_2$.

D35. OH + $CH_3OCH_2OCH_3$. The rate constant of this reaction has been measured at temperatures close to 298 K by Wallington et al.[3] (relative rate data with C_2H_4 and cyclohexane as reference compounds), Porter et al.[1] (average value derived from relative rate study with diethyl ether, di-n-butyl ether, di-n-propyl ether, and C_2H_5OH as reference compounds is reported), and Thüner et al.[2] (relative rate data with cyclohexane as the reference compound). Porter et al.[1] reported the temperature dependence of the rate constant derived from results of absolute rate study between 252 and 372 K, which exhibits a noticeable curvature in the Arrhenius plot. The result of absolute rate measurements at 346 K reported by Wallington et al.[3] agrees with this dependence. The recommended value for *k*(298 K) is an average of all reported results. The recommended value for *E*/R is based on the temperature dependence reported by Porter et al.[1] below 298 K.

D36. OH + *n*-C_4H_{10}. There are numerous studies of this reaction at room temperature. However, we have based our evaluation only on the more comprehensive studies in which the temperature dependence of the rate constant was determined over a temperature range that included room temperature. Thus the recommended value for *k*(298 K) is an average of the five values derived from the fit to the data from the absolute studies of Droege and Tully[5] (294–509 K), Donahue et al.[3] (300–390 K), Talukdar et al.[8] (231–378 K), Donahue and Clarke[4] (185–295 K), and relative rate study of DeMore and Bayes[2] (235–361 K) recalculated using the current recommendations for the reference reaction OH + C_3H_8. The results of first three absolute studies are indicative of the curvature in the Arrhenius plot. Therefore, the recommended value for *E*/R was obtained from a combined fit to the data sets extended below room temperature by Talukdar et al., Donahue and Clarke, and DeMore and Bayes after scaling each one to the recommended *k*(298 K). Only data below 330 K have been used for this combined fit. The recommended uncertainty of *k*(298 K) encompasses the latest from the earlier obtained room temperature results of Schmidt et al.,[7] Barnes et al.,[1] and Schiffman et al.,[6]. All of these eight determinations at room temperature agree to within 4% with the recommended value.

From the analysis of reactivity of various deuterated n-butanes Droege and Tully estimated that OH reacts with -CH_2- groups approximately 6 times faster than with -CH_3 at room temperature; this difference decreases at 509 K down to a factor of ~3.

D37. OH + *iso*-C_4H_{10}. There a number of room temperature measurements of this reaction, which are in good agreement, whereas only two studies of temperature dependence extend to below room temperatures. The recommended value for *k*(298 K) is an average of four absolute measurements by Tully et al.,[9] Schiffman et al.,[6] Talukdar et al.,[8] Donahue et al.,[4] and three relative rate measurements by Darnall et al.,[3] Atkinson et al,[1] and Wilson et al.[10] Results of relative rate studies have been recalculated using the current recommendation for the rate constant of the reference reaction, OH + n-C_4H_{10}, which was used in all measurements. Room temperature results reported by Bohland et al.,[2] Schmidt et al.,[7] and Edney et al.[5] have not been used because of their reported large uncertainties, which, however, overlap the recommended value. Four studies of the temperature dependence of this reaction, Tully et al. (293–864 K), Talukdar et al. (213–372 K), Donahue et al. (300–390 K), and Wilson et al. (229–347 K), reveal the curvature of the Arrhenius plot of the rate constant. Therefore, the recommended value for *E*/R was derived from a combined fit to the data below 300 K from Talukdar et al. and Wilson et al. after scaling each data set to the recommended *k*(298 K).

From the analysis of reactivity of various deuterated iso-butanes Tully et al. estimated that at room temperature ≈70% of the reaction proceeds via H-abstraction from the central carbon atom yielding *tert*-butyl radical (*tert*-C_4H_9) with only ≈30% abstraction occurring from -CH_3 groups. This branching ratio decreases down to ≈50% at 500 K and ≈25% at 1000 K.

D38. OH + n-C_5H_{12}. The recommended value for k(298 K) is an average of the values derived from the fit to the data from the temperature dependent absolute studies of Donahue et al.,[6] Talukdar et al.,[9] and Morin et al.[7] and relative rate studies of DeMore and Bayes[5] (with C_3H_8 and n-C_4H_{10} as reference compounds). The values derived from the individual studies agree with the recommended value of k(298 K) within ≈6%. Results of earlier studies at room temperature by Atkinson et al.,[2] (which probably supersedes the earlier study from the same group by Darnall et al.,[4] Nolting et al.,[8] and Abbatt et al.[1] (which is probably superseded by results of Donahue et al.) agree with the recommended value within the combined uncertainties, except the result of a relative study by Cox et al.,[3] which is 25% larger. All studies of the temperature dependence of this reaction by Donahue et al. (300 – 390 K), Talukdar et al. (231–378 K), DeMore and Bayes (233–364 K), and Morin et al. (248–900 K) revealed the curvature of the Arrhenius plot of the rate constant. Therefore, the recommended value for E/R was derived from a combined fit to the data sets of Talukdar et al. and DeMore and Bayes below 300 K after scaling each one to the recommended k(298 K). The data of Morin et al. was not used because they have been obtained mainly at higher temperatures and have larger uncertainty.

(9) Talukdar, R. K.; Mellouki, A.; Gierczak, T.; Barone, S.; Chiang, S.-Y.; Ravishankara, A. R. Kinetics of the reactions of OH with alkanes. *Int. J. Chem. Kinet.* **1994**, *26*, 973-990, doi:10.1002/kin.550261003.

D39. OH + *iso*-C_5H_{12}. Only relative rate data are available for this reaction. The recommended values for *k*(298 K) and *E*/R are based on results of Wilson et al.[4] between 213 and 407 K. They used OH + *n*-C_4H_{10} and OH + *iso*-C_4H_{10} as the reference reactions and the rate constant of the latter reaction has been derived in the same study by using the first one as the reference. Therefore, all the results have been recalculated using the current recommendation for the rate constant of the reference reaction, OH + *n*-C_4H_{10}, below 330 K. Two photochemical sources were used to make OH for each set of reference rate measurements, direct H_2O photolysis and N_2O photolysis followed by the $O(^1D) + H_2$ reaction. There is an excellent agreement between room temperature rate constants derived from the four data sets and they agree with the recommended value of *k*(298 K) within less than 3%. The data exhibit the curvature in the Arrhenius plot and, therefore, the recommended value for *E*/R was derived from the combined fit to the two data sets that are extended below 300 K. There are four earlier relative rate studies of this reaction at room temperature. The value reported by Atkinson et al.[1] coincides with the recommendation and probably supersedes the earlier data from the same group obtained by using the same reference compound, *n*-C_4H_{10}, by Lloyd et al. [Lloyd et al., 1976 New Reference] and Darnall et al.,[3] which are smaller by 35% and 10%, respectively. The room temperature value determined by Cox et al.[2] (a reference compound was C_2H_4) is ≈10% smaller than the recommended value whereas its reported uncertainty is ±10%.

(3) Darnall, K. R.; Atkinson, R.; Pitts, J. N., Jr. Rate constants for the reaction of the OH radical with selected alkanes at 300 K. *J. Phys. Chem.* **1978**, *82*, 1581-1584, doi:10.1021/j100503a001.

(4) Wilson, E. W.; Hamilton, W. A.; Kennington, H. R.; Evans, B.; Scott, N. W.; DeMore, W. B. Measurement and estimation of rate constants for the reactions of hydroxyl radical with several alkanes and cycloalkanes. *J. Phys. Chem. A* **2006**, *110*, 3593-3604, doi:10.1021/jp055841c.

D40. OH + *cyclo*-C_5H_{10}. The data available for this reaction near room temperature are in good agreement. The recommended value for *k*(298 K) is an average of *k*(298 K) values derived from relative rate studies by Atkinson et al.,[1] (by using OH + *cyclo*-C_6H_{12}, as reference reaction), Kramp and Paulson[7] (measured by using four reference compounds, *n*-noane, propene, *trans*-2 butene, and butadiene), DeMore and Bayes[2] (*n*-C_4H_{10}, and *n*-C_6H_{14} were used as reference compounds), Wilson et al.[9] (*n*-C_4H_{10}, and *cyclo*-C_6H_{12} were used as reference compounds), and Singh et al.[8] (*n*-C_6H_{14} and *cyclo*-C_6H_{12} were used as reference compounds) and absolute studies by Jolly et al.[6] (pulsed photolysis followed by the UV absorption measurements), Droege and Tully,[4] (pulsed photolysis–LIF), and Gennaco et al.,[5] (a turbulent flow reactor–LIF). Note, that the rate constants for reference reactions of OH with *n*-C_6H_{14}, and *cyclo*-C_6H_{12} used in recalculating the relative data of DeMore and Bayes and Wilson et al. have been derived from the results of relative rate measurements of these reactions reported in the same papers by using the currently recommended rate constants of their "primarily" reference reactions, OH + C_3H_8 and OH + *n*-C_4H_{10}. Thus, obtained values were also used for recalculating the results of Atkinson et al. and Singh et al. The recommended value for *E*/R was derived from the combined fit to thus recalculated results of relative studies by DeMore and Bayes (273–423 K), Singh et al. (240–340 K), and Wilson et al. (209–407 K) and absolute study of Gennaco et al. (250–351 K) after each data set was scaled to the recommended *k*(298 K). Results of Droege and Tully (295–491 K) are extended to higher temperatures and exhibit a slightly stronger temperature dependence; they were not used in the fit. Data reported by Donahue et al.,[3] (a turbulent flow reactor–LIF) are highly scattered and therefore were not used in this evaluation; they exceed the recommended rate constant by 10–30% between 300 and 390 K.

D41. OH + CH_2=C(CH_3)CHO (methacrolein). The recommended E/R is that obtained from an unweighted fit to ln k = ln A – E/RT of the rate constants reported by Gierczak et al.[7] (234-373 K), which is the only study that reports rate constants at T <295 K. The recommended value for k(298 K) is the average of ambient temperature rate constants obtained in the flash photolysis studies of Kleindienst et al.,[9] Gierczak et al.,[7] and Chuong and Stevens,[2] the turbulent flow reactor study of Chuong and Stevens,[3] and the relative rate study of Atkinson et al.,[1] with all rate constants adjusted to 298 K using the recommended E/R. In a second relative rate study, Edney et al.[6] obtain a value for k(298 K) that is significantly faster than the rate constants reported in all other studies. Temperature-dependent rate constants reported by Kleindienst et al. and Chuong and Stevens in their flash photolysis studies are encompassed by the recommended error limits for all temperatures below 400 K. Product studies by Tuazon and Atkinson[11] and Orlando and Tyndall[10] demonstrate that, in air at T ~298 K and P ~1 atm, abstraction of the aldehydic hydrogen accounts for 45-50% of overall reactivity and addition to the double bond accounts for the rest; more than 80% of addition is to the terminal carbon. Chuong and Stevens[3] observe OH recycling in the presence of O_2 and NO at T = 300 K and conclude that (i) methacrolein-based peroxy radicals (OH−methacrolein−OO) react with NO with k ~2×10^{-11} cm^3 $molecule^{-1}$ s^{-1} and (ii) the peroxy radical + NO reactions produce NO_2 with a yield of ~90% and organic nitrates with a yield of ~10%. A turbulent flow reactor study by Hsin and Elrod[8] obtains OH−methacrolein−OO + NO rate constants that are a factor of two slower than those reported by Chuong and Stevens. In a combined experimental/theoretical study, Crounse et al.[4] provide evidence that OH−methacrolein−OO undergoes a 1,4 H shift of the aldehydic hydrogen to OO at a rate of ~0.5 s^{-1} to form a radical that rapidly decomposes to recycle OH. In a theoretical study, da Silva concludes that chemically activated OH−methacrolein and OH−methacrolein−OO strongly impact product distributions and OH recycling.[5]

D42. OH + $CH_3C(O)CH=CH_2$ (Methyl Vinyl Ketone, MVK). The recommendation is based on the temperature-dependent flash photolysis studies of Kleindienst et al.[7] and Gierczak et al.,[4] the room temperature turbulent flow reactor study of Chuong and Stevens,[3] and the room temperature relative rate studies of Atkinson et al.[1] and Holloway et al.[5] Chuong and Stevens[2] observe pressure-dependent rate constants in 1–5 Torr Helium over the temperature range 300–422 K. All data used to arrive at the recommendation were obtained under (presumably) high pressure limit conditions, i.e., P >16 Torr. All data points reported in each temperature dependent study were scaled by a factor equal to the ratio $k(298)_{\mathrm{Arr}}/k(298)_{\mathrm{ave}}$ where $k(298)_{\mathrm{Arr}}$ is the 298 K rate constant obtained from the best fit Arrhenius expression describing the individual T-dependent data set and $k(298)_{\mathrm{ave}}$ is the average of all reported high-P limit room temperature rate constants. The best fit Arrhenius expression for the scaled data is recommended. A product study by Tuazon and Atkinson[8] demonstrates that reactivity is dominated by addition to the double bond with 72 ± 28 % of the addition being to the terminal carbon. Chuong and Stevens[3] observe OH recycling in the presence of O_2 and NO at T = 300 K and conclude that (i) MVK-based peroxy radicals (OH-MVK-OO) react with NO with $k \sim 2 \times 10^{-11}$ $\mathrm{cm^3\ molecule^{-1}\ s^{-1}}$ and (ii) the peroxy radical + NO reactions produce NO_2 with a yield of ~90% and organic nitrates with a yield of ~10%. A turbulent flow reactor study by Hsin and Elrod[6] obtains OH-MVK-OO + NO rate constants that are more than a factor of two slower than those reported by Chuong and Stevens.

D43. OH + $CH_2=C(CH_3)CH=CH_2$. The recommended *E*/R is the average of values obtained from the temperature-dependent data sets of Kleindienst et al.,[12] Campuzano-Jost et al.,[2,3] Gill and Hites,[7] Park et al.,[16] and Hites and Turner;[9] each data set was analyzed using an unweighted fit to $\ln k = \ln A - E/RT$. The recommended *k*(298 K) is the average of the values obtained from the best fit Arrhenius expressions for the five temperature-dependent studies plus the ambient temperature results reported by Winer et al.[20] (based on data reported by Grimsrud et al.[8]), Cox et al.,[5] Ohta,[15] Atkinson and Aschmann,[1] Edney et al.,[6] Stevens et al.,[19] McGivern et al.,[13] Zhang et al.,[21] McQuaid et al.,[14] Iida et al.,[10] Karl et al.,[11] Singh and Li.[17] Ambient temperature results obtained at temperatures other than 298 K were adjusted using the recommended E/R. Only results obtained under (investigator-reported) high pressure limit conditions are considered; this excludes the data of Chuong and Stevens[4] at T >300 K and the data of Singh and Li at T = 340 K. Data from the Laval nozzle study of Spangenberg et al.[18] are not considered because the investigated T, P conditions are not relevant for application to atmospheric chemistry. Singh and Li report the Arrhenius expression $k = 2.33 \times 10^{-11}$ exp(444/T) cm^{3}molecule^{-1}s^{-1} 240−340 K; their reported temperature dependence is not used to evaluate E/R because (high pressure limit) rate constants are reported only at 298 K. Although the detailed pressure-dependence remains a subject of disagreement,[4,10,11,13,19] it is clear that the reaction is in its high-pressure limit under all relevant atmospheric conditions.

D44. OH + CH_3CN. This rate coefficient has been measured as a function of temperature by Harris et al.[2] between 298 and 424 K, Kurylo and Knable[4] between 250 and 363 K, Rhasa[6] between 295 and 520 K, and Hynes and Wine[3] between 256 and 388 K. In addition, the 298 K value has been measured by Poulet et al.[5] The 298 K results of Harris et al. are in disagreement with all other measurements and therefore have not been included. The recommended 298 K value is a weighted average of all other studies. The temperature dependence was computed using the results of Kurylo and Knable, the lower temperature values (i.e., 295–391 K) of Rhasa, and the data of Hynes and Wine. Three points are worth noting: (a) Rhasa observed a curved Arrhenius plot even in the temperature range of 295 to 520 K, and therefore extrapolation of the recommended expression could lead to large errors; (b) Hynes and Wine observed a pressure dependent increase of *k*(298 K) that levels off at about 1 atmosphere, and this observation is contradictory to the results of other investigations; (c) Hynes and Wine have carried out extensive pressure, temperature, O_2 concentration, and isotope variations in this reaction. Hynes and Wine postulate that the reaction proceeds via addition as well as abstraction pathways. They observe OH regeneration in the presence of O_2. The recommended *k*(298 K) and *E*/R are applicable for only lower tropospheric conditions. Because of the unresolved questions of pressure dependence, the recommended value may not be applicable under upper tropospheric and stratospheric conditions. At T= 296 K and P = 700 Torr air, Tyndall et al. observe that HC(O)CN, an expected end product when reaction is initiated by H-abstraction, is formed with a yield of 0.4 ± 0.2.[7] The OH regeneration in the presence of O_2 reported by Hynes and Wine has been explained theoretically by Galano as resulting from initial formation of a $CH_3C(OH)N$ adduct that rearranges and dissociates to OH + $CH_3C(O)NO$.[1] In agreement with the observations of Hynes and Wine and Tyndall et al., Galano's theoretical analysis predicts similar branching ratios for H-abstraction and addition. (Table: 92-20, Note: 15-10, Evaluated: 92-20) Back to Table

D45. OH + CH_3ONO_2. The rate coefficient for this reaction at 298 K has been measured by Kerr and Stocker,[4] Nielsen et al.,[5] Gaffney et al.,[2] Talukdar et al.,[2] Kakesu et al.,[3] and Shallcross et al.[6] The results of Kerr and Stocker and of Nielsen et al. are a factor of ten higher than those reported by the other groups. There are no obvious reasons for the reported differences but the lower values are preferred for a number of reasons. Firstly, Talukdar et al. have carried out a large number of checks which ruled out possible effects in their system due to the regeneration of OH via secondary reactions, to bath gas pressure, and to formation of an adduct that could undergo further reaction in the presence of oxygen. Secondly, the lower values are more consistent with reactivity predictions of Atkinson and Aschmann,[1] who assumed that the series of nitrate reactions proceed by H-atom abstraction pathways. Kinetic measurements of Talukdar et al. performed with isotopically substituted

hydroxyl radical (OH, ^{18}OH, and OD) and methyl nitrate (CH_3ONO_2 and CD_3ONO_2) are consistent with this reaction proceeding via an H-atom abstraction pathway. Accordingly, the recommended value of k(298 K) is based on an average of the values given by Gaffney et al, Talukdar et al., Kakesu et al., and Shallcross et al. Further verification of the reaction mechanism by identification of the products of the reaction is needed. The temperature dependence of the rate coefficient has been measured by Nielsen et al., Talukdar et al., and Shallcross et al. While Nielsen et al. report a negative activation energy, Talukdar et al. and Shallcross et al. report positive values. For the reasons given above, the temperature dependence recommended here is based on an average of Talukdar et al. and Shallcross et al.

D46. OH + $CH_3C(O)O_2NO_2$ (Peroxy Acetyl Nitrate, PAN). This reaction has been studied by four groups Winer et al.,[4] Wallington et al.,[3] Tsalkani et al.,[2] and Talukdar et al.[1] Winer et al. obtained only an upper limit for the rate coefficient. Tsalkani et al. noted that their system was very ill-behaved and obtained a value of k(298 K) that is a factor of ~2 lower than that obtained by Wallington et al. The pulsed photolysis study of Wallington et al. yielded consistent results, but PAN was not directly measured and photodissociation of H_2O in the vacuum UV, where PAN absorbs strongly, was used as the OH source. The recent study of Talukdar et al.[1] yielded much lower rate coefficients. These investigators measured the PAN concentration directly in their system, minimized secondary reactions due to the photodissociation of PAN, and carried out extensive tests for decomposition of PAN, impurities, and secondary reactions. The recommended upper limit is a factor of two higher than the highest value measured by Talukdar et al. at 298 K and at 272 K. The quoted upper limit is expected to be valid at all atmospheric temperatures. The products of the reaction are not known. Further measurements of the rate coefficients and information on the reaction pathways are needed.

(3) Wallington, T. J.; Atkinson, R.; Winer, A. M. Rate constants for the gas phase reaction of OH radicals with peroxyacetyl nitrate (PAN) at 273 and 297 K. *Geophys. Res. Lett.* **1984**, *1*, 861-864, doi:10.1029/GL011i009p00861.
(4) Winer, A. M.; Lloyd, A. C.; Darnall, K. R.; Atkinson, R.; Pitts, J. N., Jr. Rate constnts for the reaction of OH radicals with *n*-propyl acetate, *sec*-butyl acetate, tertrahydrofuran and peroxyacetyl nitrate. *Chem. Phys. Lett.* **1977**, *51*, 221-226, doi:10.1016/0009-2614(77)80388-6.

D47. OH + $C_2H_5ONO_2$. The rate constant for this reaction at 298 K has been measured by Kerr and Stocker,[2] Nielsen et al.,[3] Talukdar et al.,[5] Kakesu et al.,[1] and Shallcross et al.[4] As in the case of the reaction of OH with CH_3ONO_2, the results of Kerr and Stocker and of Nielsen et al. are larger (by a factor of 3) than those of the more recent studies. The reasons for the differences are not clear. Because of the exhaustive tests carried out

(see the note for the OH + CH_3ONO_2 reaction), the values of Talukdar et al., Kakesu et al., and Shallcross et al. are recommended. Nielsen et al., Talukdar et al., and Shallcross et al. have measured the rate constant as a function of temperature. As with the OH + CH_3ONO_2 reaction, Nielsen et al. report a negative activation energy while Talukdar et al. and Shallcross et al. have observed a small positive activation energy. Talukdar et al. note that the rate coefficient for this reaction does not strictly follow Arrhenius behavior, consistent with the abstraction of both the primary and the secondary H atoms. Above 298 K, E/R values measured by Shallcross et al. and Talukdar et al. are in excellent agreement. Only Talukdar et al. have kinetics data below 298 K and the recommended E/R value was obtained by fitting the rate coefficients measured by Talukdar et al. at or below 298 K. The large uncertainty encompasses the results of Kerr and Stocker and Nielsen et al.

D48. OH + 1-$C_3H_7ONO_2$. The reaction has been studied by Kerr and Stocker[2] and Atkinson and Aschmann[1] at room temperature and by Nielsen et al.[3] between 298 and 368 K. The results of the three studies are in good agreement at room temperature. Nielsen et al. find that the reaction is temperature independent within the measurement uncertainty over the range studied. However as discussed above, the Nielson et al. results for the analogous reactions of OH with CH_3ONO_2 and $C_2H_5ONO_2$, yield negative activation energies that disagree with the positive activation energies obtained by others. Judging from the E/R's for the analogous reactions, one might expect the E/R for this reaction to be on the order of 300 K. Accordingly, we place a large uncertainty on the recommended temperature dependence. A thorough investigation of the temperature dependence of this reaction is needed.

D49. OH + 2-$C_3H_7ONO_2$. The reaction has been studied by Atkinson and Aschmann,[1] Atkinson et al.,[2] and Becker and Wirtz[3] at room temperature and by Talukdar et al.[4] over the range 233 and 395 K. The results of Atkinson and Aschmann supersede those of Atkinson et al. There is fair agreement between the results of the three studies at room temperature, with roughly a factor of two spread in the values. The recommendation is based on an average of the room temperature values and the E/R measured by Talukdar et al.

D50. $HO_2 + CH_2O$. There is sufficient evidence to suggest that HO_2 adds to CH_2O (Su et al.,[2,3] Veyret et al.,[5] Zabel et al.,[6] Barnes et al.,[1] and Veyret et al.[4]). The recommended *k*(298 K) is the average of values obtained by Su et al.,[2] Veyret et al.,[5] and Veyret et al.[4] The temperature dependence observed by Veyret et al.[4] is recommended. The value reported by Barnes et al. at 273 K is consistent with this recommendation. The adduct $HO_2•CH_2O$ seems to isomerize to $HOCH_2OO$ reasonably rapidly and reversibly. There significant discrepancies between measured values of the equilibrium constants for this reaction.

D51. $HO_2 + CH_3O_2$. This recommendation is taken from the evaluated review of Tyndall et al.[4] The kinetics of this reaction have been studied by using UV absorption following pulsed photolytic production of the radicals. These authors first analyzed the available data for the products of the reaction and concluded that the major products are CH_3OOH and O_2. They used this product yield information with their evaluated UV absorption cross sections for HO_2 and CH_3O_2 to reanalyze the UV absorption profiles measured in kinetics experiments by Dagaut et al.[1] and by Lightfoot et al.,[3] the two groups that carried out the most extensive studies. They found that rate coefficients reported by these two groups need to be increased by ~20%. The recommended value is based on the average of the corrected data from these two groups. The temperature dependence was evaluated by Tyndall et al. by assuming that the absorption cross sections of CH_3O_2 and HO_2 are independent of temperature at the wavelengths used for the kinetics studies. The products of this reaction are shown as $CH_3OOH + O_2$ in the table. However, Elrod et al.[2] have determined that the reaction also yields $CH_2O + H_2O + O_2$ with yields that range from 0.1 at 298 K to 0.3 at 220 K. In anticipation of further work, the recommended product yield for the CH_2O channel is zero. The uncertainties of both *k*(298 K) and *E*/R are those presented in Tyndall et al.

D52. $HO_2 + C_2H_5O_2$. The recommended value is the weighted average of those measured by Cattell et al.,[1] Dagaut et al.,[2] Fenter et al.,[3] and Maricq and Szente.[4] In all experiments the rate coefficient was obtained by modeling the reaction system. Also, the calculated rate coefficients depended on the UV absorption cross sections of both $C_2H_5O_2$ and HO_2. The absorption cross section of $C_2H_5O_2$ is not well-defined. The value reported by Dagaut et al. would be ~30% higher if the cross sections used by Maricq and Szente were used. The recommended E/R is derived from the measurements of Dagaut et al., Fenter et al., and Maricq and Szente. Wallington and Japar[5] have shown that $C_2H_5O_2H$ and O_2 are the only products of this reaction.

D53. $HO_2 + CH_3C(O)O_2$. This recommendation is taken from the evaluated review of Tyndall et al.[5] This reaction has two sets of products:

$$CH_3C(O)O_2 + HO_2 \rightarrow CH_3C(O)O_2H + O_2 \quad (a)$$

$$CH_3C(O)O_2 + HO_2 \rightarrow CH_3C(O)OH + O_3 \quad (b)$$

The majority of the reaction proceeds via channel (a), but there is clear evidence for channel (b). Tyndall et al. reevaluated the available data on end products of this reaction, particularly those of Crawford et al.,[1] Moortgat et al.,[3] and Horie and Moortgat,[2] and concluded that channel (a) contributes ~80% while channel (b) contributes ~20% at 298 K. They also concluded that $k_a/k_b = 37 \times \exp(-660/T)$ with a large uncertainty in this value. They derived the overall rate coefficient for this reaction, which has been measured only by following the radical concentrations via UV absorption. They based their recommendation mostly on the results of Moortgat et al.[3] and Tomas et al.[4] The uncertainties of both k(298 K) and E/R are those presented in Tyndall et al.

D54. $HO_2 + CH_3C(O)CH_2O_2$. This recommendation is taken from the evaluated review of Tyndall et al.[2] This reaction has been studied by only Bridier et al.[1] and Tyndall et al. based their recommendation on this one study. The uncertainties of both k(298 K) and E/R are those presented in Tyndall et al.

D55. $NO_3 + CH_2=C(CH_3)CHO$ (methacrolein). The recommendation is the average of the results of relative rate studies by Chew et al.[2] and Canosa-Mas et al.[1] The Chew et al. study supersedes an earlier study by the same group.[3] Chew et al. report two rate constants obtained using propene and 1-butene as reference compounds while Canosa-Mas et al. report a single rate constant obtained using propene as the reference. Two flow tube studies[1,4] report faster rate constants, presumably due to the presence of reactive impurities in methacrolein samples. Reaction can proceed via addition to the double bond or via abstraction of the aldehydic hydrogen atom. In 760 Torr O_2, Canosa-Mas et al. observe production of both methyl glyoxal ($CH_3C(O)CHO$), likely formed via reactions involving a primary addition product, and MPAN ($CH_2=C(CH_3)C(O)OONO_2$), likely formed via reactions involving the H-abstraction product. Product yields have not been reported.

D56. $NO_3 + CH_3C(O)CH=CH_2$ (Methyl Vinyl Ketone, MVK). In a low pressure flow tube study where NO_3 was produced by thermal decomposition of N_2O_5 and detected by long path diode laser absorption at 662 nm, Rudich et al.[3] measured a rate constant of $(1.0 \pm 0.2) \times 10^{-16}$ cm^{3}molecule^{-1} s^{-1}; acknowledging that "our experiment is not suited to accurately measuring such low rate coefficients," Rudich et al. chose to report their result as an upper limit, i.e., $k < 1.2 \times 10^{-16}$ cm^{3}molecule^{-1} s^{-1}. In units of 10^{-16} cm^{3}molecule^{-1} s^{-1}, Canosa-Mas et al.[1] report $k = 3.2 \pm 0.6$ based on a low pressure flow tube study where NO_3 was produced via the F + HNO_3 reaction and detected by laser induced fluorescence; these authors also obtained a rate constant of 5.3 ± 1.9 (corrected using updated information for the $NO_3 + C_2H_4$ reference reaction) from a relative rate study in 760 Torr N_2. Kwok et al. report $k < 6 \times 10^{-16}$ cm^{3}molecule^{-1} s^{-1} based on a relative rate study in 740 Torr air using $NO_3 + C_3H_6$ as the reference reaction.[2] The recommendation, $k < 4 \times 10^{-16}$ cm^{3}molecule^{-1} s^{-1}, is consistent with the results reported in both absolute rate constant determinations. The initial step in the reaction of NO_3 with MVK is addition of NO_3 to the double bond. In 760 Torr O_2 bath gas, Canosa-Mas et al. observe methyl glyoxal ($CH_3C(O)CHO$) as a reaction product; they propose a pathway where NO_3 adds to the terminal carbon followed by formation of a peroxy radical that reacts with a second NO_3 to form (via multiple steps) $CH_3C(O)CHO$ + HCHO + $2NO_2$ + O_2.

D57. **NO_3 + CH_2=C(CH_3)CH=CH_2.** The recommended E/R is obtained from an unweighted fit of the single temperature-dependent data set of Dlugokencky and Howard[6] to ln k = ln A – E/RT (E/R = 446 K, 251–381 K). The recommended 298 K rate constant is an unweighted average of ambient temperature results reported by Atkinson et al.,[1,2] Dlugokencky and Howard[6] (rate constant obtained from the best fit Arrhenius expression), Barnes et al.,[3] Wille et al.,[10] Ellermann et al.,[7] Berndt and Boge,[5] Suh et al.,[9] and Stabel et al.[8] Ambient temperature results obtained at temperatures other than 298 K were adjusted using the recommended E/R. The 298 K rate constant reported by Benter and Schindler[4] is not considered because (a) it is faster than all others in the literature and (b) it is superseded by a later study from the same group.[10]

D58. **NO_3 + CO.** The upper limit is based on the results of Hjorth et al.,[2] who monitored isotopically labeled CO loss in the presence of NO_3 by FTIR. Burrows et al.[1] obtained an upper limit of 4×10^{-16} cm^3 $molecule^{-1}$ s^{-1}, which is consistent with the Hjorth et al. study. Products are expected to be NO_2 + CO_2, if the reaction occurs.

D59. **NO_3 + CH_2O.** There are three measurements of this rate coefficient at 298 K: Atkinson et al.,[1] Cantrell et al.,[2] and Hjorth et al.[3] The value reported by Atkinson et al.,[1] $k = (3.23 \pm 0.26) \times 10^{-16}$ cm^3 $molecule^{-1}$ s^{-1}, is corrected to 5.8×10^{-16} cm^3 $molecule^{-1}$ s^{-1} to account for the different value of the equilibrium constant for the $NO_3 + NO_2 \leftrightarrow N_2O_5$ reaction that was measured subsequent to this study by the same group using the same apparatus. This correction is in accordance with their suggestion (Tuazon et al.[4]). The values reported by Cantrell et al. and Hjorth et al., $k = 6.3 \times 10^{-16}$ cm^3 $molecule^{-1}$ s^{-1} and $(5.4 \pm 1.1) \times 10^{-16}$ cm^3 $molecule^{-1}$ s^{-1}, respectively, are in good agreement with the corrected value of Atkinson et al. The recommended value is the average of these three studies. Cantrell et al. have good evidence to suggest that HNO_3 and CHO are the products of this reaction. The temperature dependence of this rate coefficient is unknown, but comparison with the analogous NO_3 + CH_3CHO reaction suggests a large E/R.

D60. **$NO_3 + CH_3CHO$.** There are four measurements of this rate constant: Morris and Niki,[4] Atkinson et al.,[1] Cantrell et al.,[2] and Dlugokencky and Howard.[3] The value reported by Atkinson et al., $k = (1.34 \pm 0.28) \times 10^{-15}$ cm^3 molecule^{-1} s^{-1}, is corrected to 2.4×10^{-15} cm^3 molecule^{-1} s^{-1} as discussed for the $NO_3 + H_2CO$ reaction above and as suggested by Tuazon et al.[5] The recommended value is the average of the values obtained by Atkinson et al., Cantrell et al., and Dlugokencky and Howard. The results of Morris and Niki agree with the recommended value when their original data are re-analyzed using a more recent value for the equilibrium constant for the reaction $NO_2 + NO_3 \leftrightarrow N_2O_5$ as shown by Dlugokencky and Howard. Dlugokencky and Howard have studied the temperature dependence of this reaction. Their measured value of *E*/R is recommended. The *A*-factor has been calculated to agree with the *k*(298 K) recommended here. Morris and Niki, and Cantrell et al. observed the formation of HNO_3 and PAN in their studies, which strongly suggests that HNO_3 and CH_3CO are the products of this reaction.

D61. **$CH_3 + O_2$.** This bimolecular reaction is not expected to be important, based on the results of Baldwin and Golden,[1] who found $k < 5 \times 10^{-17}$ cm^3 molecule^{-1} s^{-1} for temperatures up to 1200 K. Klais et al.[3] failed to detect OH (via $CH_3 + O_2 \rightarrow CH_2O + OH$) at 368 K and placed an upper limit of 3×10^{-16} cm^3 molecule^{-1} s^{-1} for this rate coefficient. Bhaskaran et al.[2] measured $k = 1 \times 10^{-11} \exp(-12{,}900/T)$ cm^3 molecule^{-1} s^{-1} for $1800 < T < 2200$ K. The latter two studies thus support the results of Baldwin and Golden. Studies by Selzer and Bayes[5] and Plumb and Ryan[4] confirm the low value for this rate coefficient. Previous studies of Washida and Bayes[6] are superseded by those of Selzer and Bayes. Plumb and Ryan have placed an upper limit of 3×10^{-16} cm^3 molecule^{-1} s^{-1} based on their inability to find HCHO in their experiments. A study by Zellner and Ewig[7] suggests that this reaction is important at combustion temperature but is unimportant for the atmosphere.

D62. $CH_3 + O_3$. The recommended *A*-factor and *E*/R are those obtained from the results of Ogryzlo et al.[4] The results of Simonaitis and Heicklen,[6] based on an analysis of a complex system, are not used. Washida et al.[7] used $O + C_2H_4$ as the source of CH_3. Studies on the $O + C_2H_4$ reaction (Schmoltner et al.,[5] Kleinermanns and Luntz,[3] Hunziker et al.,[1] and Inoue and Akimoto[2]) have shown this reaction to be a poor source of CH_3. Therefore, the results of Washida et al. are also not used.

D63. $HCO + O_2$. The value of *k*(298 K) is the average of the determinations by Washida et al.,[12] Shibuya et al.,[8] Veyret and Lesclaux,[11] Langford and Moore,[3] Nesbitt et al.,[5] Temps et al.,[9] and Ninomiya et al.[6] There are three measurements of k where HCO was monitored via the intracavity dye laser absorption technique (Reilly et al.,[7] Nadtochenko et al.,[4] and Gill et al.[1]). Even though these studies agree with the recent measurements of Nesbitt et al., the only recent measurement to obtain a low value, they have not been included in deriving the recommended value of *k*(298 K). However, the uncertainty has been increased to overlap with those measurements. The main reason for not including them in the average is the possible depletion of O_2 in those static systems (as suggested by Veyret and Lesclaux). Also, these experiments were designed more for the study of photochemistry than kinetics. The temperature dependence of this rate coefficient has been measured by Veyret and Lesclaux, Timonen et al.,[10] and Nesbitt et al. While Timonen et al. obtain a slightly positive activation energy, Veyret and Lesclaux, and Nesbitt et al. measure slightly negative activation energy. It is very likely that the Arrhenius expression is curved. We recommend an *E*/R value of zero, with an uncertainty of 100 K. Veyret and Lesclaux preferred a T^n form ($k = 5.5 \times 10^{-11}\ T^{-(0.4\pm0.3)}$ cm^3 molecule^{-1} s^{-1}). Hsu et al.[2] suggest that this reaction proceeds via addition at low temperature and abstraction at higher temperatures.

D64. $CH_2OH + O_2$. The rate coefficient was first measured directly by Radford[7] by detecting the HO_2 product in a laser magnetic resonance spectrometer. The wall loss of CH_2OH could have introduced a large error in this measurement. Radford also showed that the previous measurement of Avramenko and Kolesnikova[1] was in error. Wang et al.[8] measured a value of 1.4×10^{-12} cm^3 $molecule^{-1}$ s^{-1} by detecting the HO_2 product. Recently, Dobe et al.,[2] Grotheer et al.,[3] Payne et al.,[6] Grotheer et al.,[4] and Nesbitt et al.[5] have measured k(298 K) to be close to 1.0×10^{-11} cm^3 $molecule^{-1}$ s^{-1} under conditions where wall losses are small. This reaction appears to exhibit a very complex temperature dependence. Based on the recent data of Grotheer et al.[4] and Nesbitt et al.,[5] *k* appears to increase from 200 K to approximately 250 K in an Arrhenius fashion, levels off at approximately 300 K, decreases from 300 to 500 K, and finally increases as temperature is increased. This complex temperature dependence is believed to be due to the formation of a $CH_2(OH){\bullet}O_2$ adduct which can isomerize to $CH_2O{\bullet}HO_2$ or decompose to reactants. The $CH_2O{\bullet}HO_2$ isomer can also decompose to CH_2O and HO_2 or reform the original adduct. At temperatures less than 250 K, the data of Nesbitt et al. suggests an *E*/R value of ~1700 K. For atmospheric purposes, the value *E*/R = 0 is appropriate.

D65. $CH_3O + O_2$. The recommended value for *k*(298 K) is the average of those reported by Lorenz et al.[5] and Wantuck et al.[8] The recommended *E*/R was obtained using the results of Gutman et al.[4] (413 to 608 K), Lorenz et al.[5] (298 to 450 K), and Wantuck et al.[8] (298 to 498 K). These investigators have measured k directly under pseudo–first order conditions by following CH_3O via laser induced fluorescence. Wantuck et al. measured *k* up to 973 K and found the Arrhenius plot to be curved; only their lower temperature data are used in the fit to obtain *E*/R. The A factor has been adjusted to reproduce the recommended *k*(298 K). The previous high temperature measurements (Barker et al.[1] and Batt and Robinson[2]) are in reasonable agreement with the derived expression. This value is consistent with the 298 K results of Cox et al.,[3] obtained from an end product analysis study, and with the upper limit measured by Sanders et al.[7] The *A*-factor appears low for a hydrogen atom transfer reaction. The reaction may be more complicated than a simple abstraction. At 298 K, the products of this reaction are HO_2 and CH_2O, as shown by Niki et al.[6]

D66. **CH_3O + NO.** The reaction of CH_3O with NO proceeds mainly via addition to form CH_3ONO (Batt et al.,[1] Wiebe and Heicklen,[4] Frost and Smith,[2] and Ohmori et al.[3]). However, a fraction of the energized CH_3ONO adducts decomposes to CH_2O + HNO, and appear to be a bimolecular channel. This reaction has been investigated by direct detection of CH_3O via laser-induced fluorescence (Zellner,[5] Frost and Smith,[2] Ohmori et al.[3]). End-product studies (Batt et al.,[1] Wiebe and Heicklen[4]) are generally consistent with this conclusion. Since the fraction of the CH_3ONO adduct that falls apart to CH_2O + HNO decreases with increasing pressure and decreasing temperature, it is not possible to derive a "bimolecular" rate coefficient. A value of $k < 8 \times 10^{-12}$ cm^3 $molecule^{-1}$ s^{-1} can be deduced from the work of Frost and Smith[2] and Ohmori et al.[3] for lower atmospheric conditions.

D67. **$CH_3O + NO_2$.** The reaction of CH_3O with NO_2 proceeds mainly via the formation of CH_3ONO_2. However, a fraction of the energized adducts fall apart to yield $CH_2O + HNO_2$. The bimolecular rate coefficient reported here is for the fraction of the reaction that yields CH_2O and HNO_2. It is not meant to represent a bimolecular metathesis reaction. The recommended value was derived from the study of McCaulley et al.[1] and is discussed in the section on association reactions.

D68. **$CH_3O_2 + O_3$.** This recommendation is taken from the evaluated review of Tyndall et al.[1] Their recommendation is based mostly on the recent study by Tyndall et al.[2] The temperature dependence is based on the assumption that the only possible reaction which can occur is the O atom transfer from the CH_3O_2 radical and that the activation energy of ~2 kcal mol^{-1} for this O-atom transfer is similar to that in the $HO_2 + O_3$ reaction. The uncertainties of both k(298 K) and E/R are those presented in Tyndall et al.

(2) Tyndall, G. S.; Wallington, T. J.; Ball, J. C. FTIR product study of the reactions CH_3O_2 + CH_3O_2 and CH_3O_2 + O_3. *J. Phys. Chem. A* **1998**, *102*, 2547-2554, doi:10.1021/jp972784h.

D69. CH_3O_2 + CH_3O_2. This recommendation is taken from the evaluated review of Tyndall et al.[1] There are two confirmed sets of products for this reaction.

$$CH_3O_2 + CH_3O_2 \rightarrow CH_3O + CH_3O + O_2 \qquad (a)$$

$$CH_3O_2 + CH_3O_2 \rightarrow CH_3OH + HCHO + O_2 \qquad (b)$$

The relative product yield, k_a/k_b, was evaluated by Tyndall et al. to be (26.2 ± 6.6) × exp ((–1130 ± 240)/T). They concluded that there was no evidence for the formation of the CH_3OOCH_3. The kinetics of this reaction have been studied by using UV absorption following pulsed photolytic production of the radicals. Tyndall et al. used the values of k/σ measured by a large number of groups along with the σ values from their evaluation to calculate k. (σ is the absorption cross section of the radical at the wavelength at which it was monitored.) They only used the kinetics data obtained at wavelengths larger than 240 nm, since the absorption by HO_2 radicals that are unavoidably produced in these measurements can significantly contribute to the measured UV profiles at shorter wavelengths. They noted that the values of k/σ measured by various groups were much more accurate than the values of σ measured by the same groups. The value of k obtained by this method was then corrected using the above branching ratio for the production of CH_3O that leads to the unavoidable occurrence of the CH_3O_2 + HO_2 side reaction; this side reaction consumes another CH_3O_2 radical. The uncertainties of both k(298 K) and E/R are those presented in Tyndall et al.
(Table: 02-25, Note: 02-25, Evaluated: 02-25) Back to Table

(1) Tyndall, G. S.; Cox, R. A.; Granier, C.; Lesclaux, R.; Moortgat, G. K.; Pilling, M. J.; Ravishankara, A. R.; Wallington, T. J. Atmospheric chemistry of small organic peroxy radicals. *J. Geophys. Res.* **2001**, *106*, 12157-12182, doi:10.1029/2000JD900746.

D70. CH_3O_2 + NO. This recommendation is taken from the evaluated review of Tyndall et al.[1] They evaluated the available information to deduce that the main set of products under atmospheric conditions is CH_3O + NO_2. They noted, however, that a very small yield, <0.5%, of CH_3ONO_2 is also possible. The rate coefficient for the reaction at 298 K and its temperature dependence is based on numerous direct studies of this reaction that have been reported. The uncertainties of both k(298 K) and E/R are those presented in Tyndall et al.
(Table: 02-25, Note: 02-25, Evaluated: 02-25) Back to Table

(1) Tyndall, G. S.; Cox, R. A.; Granier, C.; Lesclaux, R.; Moortgat, G. K.; Pilling, M. J.; Ravishankara, A. R.; Wallington, T. J. Atmospheric chemistry of small organic peroxy radicals. *J. Geophys. Res.* **2001**, *106*, 12157-12182, doi:10.1029/2000JD900746.

D71. CH_3O_2 + $CH_3C(O)O_2$. This recommendation is taken from the evaluated review of Tyndall et al.[2] This reaction has two sets of products:

$$CH_3C(O)O_2 + CH_3O_2 \rightarrow CH_3 + CO_2 + CH_3O + O_2 \qquad (a)$$

$$CH_3C(O)O_2 + CH_3O_2 \rightarrow CH_3C(O)OH + HCHO + O_2 \qquad (b)$$

Tyndall et al. reanalyzed the previously available data on the branching ratios for this reaction and concluded that the branching ratio for channel (a) was k_a/k = 0.9 ± 0.1 and k_b/k = 0.1 ± 0.1 at 298 K. They also concluded that branching ratios could not be derived for other temperatures from the existing data and therefore did not make a recommendation for the temperature dependence. The recommendation from Tyndall et al. is based on the work of Roehl et al.[1] and Villenave et al.[3] Their recommended temperature dependence for the overall rate coefficient is based on analogy with other RO_2 reactions. The uncertainties of both k(298 K) and E/R are those presented in Tyndall et al.
(Table: 02-25, Note: 02-25, Evaluated: 02-25) Back to Table

D72. $CH_3O_2 + CH_3C(O)CH_2O_2$. This recommendation is taken from the evaluated review of Tyndall et al.[3] This reaction has three possible sets of products:

$$CH_3C(O)CH_2O_2 + CH_3O_2 \rightarrow CH_3C(O) + HCHO + CH_3O + O_2 \qquad (a)$$

$$CH_3C(O)CH_2O_2 + CH_3O_2 \rightarrow CH_3C(O)CH_2OH + HCHO + O_2 \qquad (b)$$

$$CH_3C(O)CH_2O_2 + CH_3O_2 \rightarrow CH_3C(O)CHO + CH_3OH + O_2 \qquad (c)$$

The branching ratios for these channels, $k_a/k = 0.3 \pm 0.1$, $k_b/k = 0.2 \pm 0.1$, and $k_c/k = 0.5 \pm 0.1$, are based on the work of Bridier et al.[1] and Jenkin et al.[2] The overall rate coefficient for this reaction has been studied only at 298 K by Bridier et al. and the recommendation is based on this value. The recommended values of E/R and g are based on analogy with other RO_2 reactions. The uncertainties of both $k(298\text{ K})$ and E/R are those presented in Tyndall et al.

D73. $C_2H_5 + O_2$. This is a complex reaction that involves the formation of a $C_2H_5O_2$ adduct, which can either be stabilized by collisions or fall apart to HO_2 and C_2H_4 (Wagner et al.,[3] Bozzelli and Dean,[1] and Kaiser et al.[2]). The fraction of the energized adducts that fall apart to give HO_2 and C_2H_4 will decrease with increasing pressure and decreasing temperature, i.e., as the $C_2H_5O_2$ formation increases. The C_2H_4-formation channel cannot be separated from the addition reaction. We recommend a conservative upper limit as a guide to the extent of this reaction. This upper limit is applicable only for lower atmospheric pressure and temperature conditions.

D74. $C_2H_5O + O_2$. The recommendation is based on the pulsed laser photolysis studies of Gutman et al.[1] and Hartmann et al.[2] In both these studies, removal of C_2H_5O in an excess of O_2 was directly monitored via laser induced fluorescence. Gutman et al. measured k at only two temperatures, while Hartmann et al. measured k at 5 temperatures between 295 and 411 K. The E/R is from Hartmann et al. The 298 K value deduced from an indirect study by Zabarnick and Heicklen[3] is in reasonable agreement with the recommended value.

D75. $C_2H_5O_2 + C_2H_5O_2$. $k(298\text{ K})$ has been studied by Adachi et al.,[1] Anastasi et al.,[3] Munk et al.,[8] Cattell et al.,[5] Anastasi et al.,[2] Wallington et al.,[10] Bauer et al.,[4] and Fenter et al.[6] All the above determinations used only UV absorption to monitor $C_2H_5O_2$ and hence measured k/σ, where σ is the absorption cross section of $C_2H_5O_2$ at the monitoring wavelength. These investigators also measured the σ that was used in evaluating the rate coefficient. There are large discrepancies in the measured values of σ. For this evaluation, we have used the

cross sections recommended here and recalculated the values of *k* from each investigation. The recommended k is based on the results of Cattell et al., Wallington et al., Bauer et al., and Fenter et al. In all these experiments the observed rate coefficient is higher than the true rate coefficient because of secondary reactions involving HO_2. HO_2 is formed by the reaction of CH_3CH_2O with O_2 and it reacts with $C_2H_5O_2$ to enhance the observed rate coefficient (see Wallington et al.[11] or Lightfoot et al.[7] for further discussion). Based on product branching ratios discussed below, which determine the magnitude of the necessary correction, the recommended rate coefficient is 0.6 times the average observed rate coefficient. The recommended value of *E*/R was obtained from the results of Anastasi et al., Wallington et al., Cattell et al., Bauer et al., and Fenter et al. The observed products (Niki et al.[9]), suggest that at 298 K the channel to yield 2 $C_2H_5O + O_2$ accounts for about 60% of the reaction; the channel to yield $CH_3CHO + C_2H_5OH + O_2$ accounts for about 40% of the reaction; and the channel to yield $C_2H_5O_2C_2H_5 + O_2$ accounts for less than 5% of the reaction. These branching ratios were used to obtain the true rate coefficient from the observed rate coefficient.

D76. $C_2H_5O_2 + NO$. The recommended *k*(298 K) is obtained from the results of Plumb et al.,[6] Sehested et al.,[7] Daële et al.,[3] Eberhard and Howard,[4] and Maricq and Szente.[5] The value reported by Adachi and Basco,[1] which is a factor of three lower than the recommended value, was not used. The rate coefficient for the CH_3O_2 + NO reaction measured by Basco and co-workers (Adachi et al.[2]) using the same apparatus is also much lower than the value recommended here. The recommended temperature dependence is derived from Eberhardt and Howard[4] and Maricq and Szente,[5] which are in good agreement.

D77. $CH_3C(O)O_2 + CH_3C(O)O_2$. This reaction has been studied by Addison et al.,[1] Basco and Parmar,[2] Moortgat et al.,[4] Maricq and Szente,[3] and Roehl et al.,[5] using UV absorption techniques. The recommended value is obtained from the data of Moortgat et al., Maricq and Szente, and Roehl et al. As pointed out by Moortgat et al., the six times lower value of k obtained by Addison et al. is likely due to the use of incorrect UV absorption cross sections for the peroxy radical. The *k* obtained by Basco and Parmar is ~2 times lower than the recommended value. This discrepancy is possibly due to neglecting the UV absorption of CH_3O_2 and other stable products in their data analysis (Moortgat et al., Maricq and Szente). The recommended temperature dependence was calculated from the data of Moortgat et al. and Maricq and Szente. Addison et al. reported the formation of O_3, which was attributed to the reaction channel that produces $CH_3C(O)OCH_3C(O) + O_3$. Moortgat et al. place an upper limit of 2% for this channel. The main products of this reaction appear to be $CH_3C(O)O + O_2$. The $CH_3C(O)O$ radicals rapidly decompose to give CH_3 and CO_2.

D78. $CH_3C(O)O_2 + NO$. This recommendation is from Tyndall et al.[1] These authors have argued that the only set of products of importance in the atmosphere is the production of $CH_3 + CO_2 + NO_2$. This is because the alkoxy radical produced upon O abstraction from the peroxy radical by NO will be unstable towards decomposition to give CH_3 and CO_2. The rate coefficient for the reaction was deduced primarily from direct studies, but was found to be consistent with the relative rate studies. In the relative rate studies, this rate coefficient was measured relative to the rate coefficient for the reaction of $CH_3C(O)O_2$ with NO_2.
(Table: 02-25, Note: 10-6, Evaluated: 10-6) Back to Table

D79. $CH_3C(O)CH_2O_2 + NO$. This recommendation is from Tyndall et al.[4] They deduced, based on the results of Sehested et al.,[3] Jenkin et al.,[1] and Orlando et al.,[2] that the products of this reaction are $CH_3C(O)CH_2O + NO_2$. The $CH_3C(O)CH_2O$ radical decomposes rapidly to give $CH_3C(O) + CH_2O$. The only kinetics study of this reaction by Sehested et al. forms the basis for the rate coefficient at 298 K. This value is uncertain because of the corrections that had to be made in the study of Sehested et al. to account for the production of NO_2, the monitored species, via the reaction of peroxy radicals (such as $CH_3C(O)O_2$ and CH_3O_2) with NO. The temperature dependence of the reaction is derived based on analogy with other peroxy radical reactions.

D80. **$HOC_5H_8O_2$ + NO.** This reaction has been the subject of a number of studies due to its potential importance, particularly in the branching to and fate of $RONO_2$, in controlling NO_x lifetime (and thus O_3 production) in the lower terrestrial atmosphere in regions with high isoprene emissions. Six isomers of $HOC_5H_8O_2$ have been shown to form from reactions of OH and O_2 with isoprene. These isomers interconvert on timescales shorter than their lifetime in the atmosphere (see Note for isoprene + OH reaction). The recommendations provided here are bulk averages for the RO_2 distribution at short RO_2 lifetimes, i.e., the RO_2 distribution formed near the kinetic limit of HOC_5H_8 + O_2, as the majority of the experimental data are for conditions near this limit and are not isomer resolved.

Total rate coefficient: The recommendation for the overall rate coefficient is taken as the average of the Stevens et al.,[15] Chuong and Stevens,[2] Zhang et al.,[19] Miller et al.,[8] Park et al.,[9] and Ghosh et al.[6] studies. With the exception of the result from Reitz et al,[13] there is good agreement among the experimental determinations. The Reitz et al.[13] result is not in agreement with that of Zhang et al.[19] from the same group, using a different method, and it is stated in Zhang et al.[19] "…ongoing OH cycling studies in the North group have obtained a rate constant of less than the value reported by Reitz et al. …" Therefore, the result of Reitz et al.[13] is not included in the recommendation. From a lack of pressure dependence in k_{total} over experimental conditions (1.3–200 hPa), it is clear that the total reaction rate coefficient is in the high-pressure limit for reactions occurring in the atmosphere. As only room temperature results for this reaction have been reported, the temperature dependence E/R of –350 K is estimated from measurements of $CH_3CH_2CH_2O_2$[3,4] and $CH_3CH(O_2)CH_3$[5] peroxy radicals reacting with NO, and the observed invariance of the total RO_2 + NO rate coefficient for a number of RO_2.[8] The *A*-factor is calculated from the recommended 298 K rate coefficient and the estimated E/R. A high uncertainty has been assigned to the temperature dependence due to the estimation methods.

Reaction branching to $RONO_2$ ($k_2/(k_{\text{total}})$): In contrast to the good agreement between determinations for the total rate coefficient for $HOC_5H_8O_2$ with NO, reports of the branching fraction to stabilized $RONO_2$ are quite varied, ranging from 0.044 to 0.14 for conditions near room temperature and 1 atmosphere. The recommendation for the branching fraction at 297 K in 993 hPa of air is based on the average of the results from Tuazon, et al.[17] (corrected for $O(^3P)$ chemistry, see Paulson et al.[12]), Sprengnether, et al.,[14] and Teng et al.[16]:

$$k_2/k_{\text{total}}\ (297\text{ K, 993 hPa}) = 0.13 \pm 0.04$$

The branching fraction from Xiong et al.,[18] falls within the uncertainty of the recommendation, but is not used in the recommendation due to its dependence on the assumed (calculated) isoprene RO_2 isomer distribution. In addition, results from Chen et al.[1] and Lockwood, et al.[7] are not used to arrive at a recommendation as these results are superseded by the study of Xiong et al.[18] from the same group. It is stated in Xiong et al.[18]: "Previous IN studies conducted in our group using GC methods consistently resulted in lower IN yields (Chen et al.[1]; Lockwood et al.[7]). We partially attribute the discrepancy of our previous and current work to the possible loss of the 1,2-IN isomer in the GC column and metal sample injection system." Data reported by Paulot et al.[11] are consistent with the recommendation, but not used as this result was not based on authentic $RONO_2$ standards. Additional data at reduced pressures from Sprengnether et al.,[14] Chuong and Stevens,[2] and Patchen et al.[10] are not used at this time as there are not sufficient data to recommend the pressure dependence of the branching fraction for this reaction. However, based on studies of similar reactions it is expected that the pressure and temperature variation of the branching fraction for this reaction is significant for atmospheric conditions, and further study is required for evaluation of these parameters.

D81. $CH_2OO + H_2O \rightarrow$ products. The recommendation is based on the results of Sheps et al.[11] and Berndt et al.[4] The recommendation is the average of the two rate coefficients with equal weighting given to the two methods. Berndt et al.[4] generated CH_2OO from the ozonolysis of ethene in an atmospheric pressure flow tube and detected the CH_2OO via the titration of CH_2OO with SO_2 to produce sulfuric acid, which is detected via PTRMS. Sheps et al. coupled CH_2OO production by UV laser flash photolysis of CH_2I_2/O_2 with either time-resolved MPIMS mass spectroscopic or UV spectroscopic monitoring of CH_2OO over the pressure range 30-100 Torr. They observe a well-defined quadratic dependence of the pseudo first-order CH_2OO decay rate coefficient on $[H_2O]$, and obtained the recommended bimolecular rate coefficient by adding a linear term to the fit of decay coefficient as a function of $[H_2O]$. Chao et al.[5] also observed a well-defined quadratic dependence of the pseudo first-order CH_2OO decay rate coefficient on $[H_2O]$, and obtained an upper limit bimolecular rate coefficient of $<1.5 \times 10^{-15}$ from estimation of the maximum possible contribution to the observed kinetics from a process whose pseudo first-order rate coefficient varied linearly as a function of $[H_2O]$. A similar experiment is reported by Lewis et al.,[6] but with more scatter in the data. A less sensitive upper limit is also reported by Welz et al.,[14] who observed no significant increase in the CH_2OO decay rate upon addition of up to 3×10^{16}

H_2O per cm^3 to their reaction mixtures; Welz et al. produced CH_2OO in the same manner as Chao et al. and Lewis et al., but employed photoionization mass spectrometry as the CH_2OO detection technique and lower total pressures than the other studies. Theoretical work by Ryzhkov and Ariya[10] suggests that the CH_2OO + H_2O rate coefficient may be significantly slower than any of the experimental rate coefficients/upper limits. Experimental rate coefficients slower than the current recommendation are reported by Ouyang et al.[8] and Stone et al.[12] As discussed by Lewis et al., misinterpretation of complex chemical mechanisms are likely to have been a problem in the Ouyang et al. and Stone et al. studies; also, Chao et al. suggest that interferences to detected signals from reaction products could have been a problem in these studies. Suto et al.,[13] Newland et al.,[7] Becker et al.,[3] report significantly faster rate coefficients than those obtained in other studies based on competitive kinetics results with CH_2OO + SO_2 used as the reference reaction. Both Suto et al. and Becker et al. employed the highly exothermic C_2H_4 + O_3 reaction to generate CH_2OO, suggesting that reactions of non-thermalized CH_2OO could impact the competitive kinetics results. Also, the O_3 + C_2H_4 reaction is known to produce OH. Based on theoretical studies by Aplincourt and Ruiz-López,[2] Ryzhkov and Ariya,[9] and Anglada et al.,[1] it is well-established that CH_2OO interacts with H_2O to form a hydrogen bonded complex that isomerizes rapidly to hydroxymethyl hydroperoxide (HMHP, $HOCH_2OOH$). HMHP is stable ~190 kJ mol^{-1} relative to CH_2OO + H_2O.

D82. $CH_2OO + (H_2O)_2$. The recommendation for *k*(298 K) is the average of the value reported by Chao et al.,[3] Sheps et al.,[8] and the value obtained from an Arrhenius expression describing the temperature dependent rate coefficients reported by Smith et al.[9] The Smith et al. study reports the only available temperature dependent data, so the recommended E/R is obtained from the Arrhenius fit to their data. As a result of the limited studies extrapolation of the experimental results to other temperatures is not recommended. All three studies produce CH_2OO by UV laser flash photolysis of CH_2I_2/O_2. Chao et al. and Smith et al. (same research group) utilize time-resolved UV spectroscopic monitoring of CH_2OO for kinetics, whereas Sheps et al., use a combination time-resolved MPIMS mass spectroscopic or UV spectroscopic monitoring of CH_2OO. All three studies well-defined quadratic dependence of the pseudo-first order CH_2OO decay rate coefficient on [H_2O], and the source of information they used to obtain an equilibrium coefficient for $2\ H_2O \leftrightarrow (H_2O)_2$ is also the basis for the recommendation in Table 3 of this document.[7] A similar (to Chao et al., Smith et al. and Sheps et al.) experiment is reported by Lewis et al.,[5] but with more scatter in the data; these authors obtain a rate coefficient somewhat slower than the recommendation. Berndt et al.[2] report a somewhat faster rate coefficient than those obtained in the other studies based on competitive kinetics results with $CH_2OO + SO_2$ used as the reference reaction; these investigators employed the highly exothermic $C_2H_4 + O_3$ reaction to generate CH_2OO, suggesting that reactions of non-thermalized CH_2OO could impact the competitive kinetics results. Lewis et al. speculate that enhanced formation of $(H_2O)_2$ in the mass spectrometer sampling region could have been a problem in the Berndt et al. study. Unlike earlier studies that employed $O_3 + C_2H_4$ as the CH_2OO source,[1,10] Berndt et al. added propane to their reaction mixtures to scavenge OH radicals; this could explain why they observed a quadratic dependence of CH_2OO reactivity on [H_2O] that was not observed in the earlier studies. The recommended uncertainty (*f*) is chosen so f^2 approximately brackets the results of the four experimental studies. The indirect study of Nguyen et al., report an approximate rate coefficient of ~1×10^{-12} cm^3 molecule^{-1} s^{-1}, which is in broad agreement with the direct studies. The theoretical work of Ryzhkov and Ariya,[6] shows that CH_2OO interacts with $(H_2O)_2$ to form hydrogen bonded ring complexes which isomerize rapidly to hydrogen bonded complexes of H_2O with hydroxymethyl hydroperoxide (HMHP, $HOCH_2OOH$) that are stable by ~190 kJ mol^{-1} relative to $CH_2OO + (H_2O)_2$; as discussed theoretically by Crehuet et al.,[4] these complexes can undergo unimolecular conversion to $HCOOH + 2\ H_2O$ or $H_2O_2 + H_2CO + H_2O$. Sheps et al., have quantified the branching ratio for the reaction using MPIMPS and found that $\Phi_3(CH_2O) = (40 \pm 10)\%$, $\Phi_3(HCOOH) < 10\%$ HMHP is then $(55 \pm 15)\%$. Theoretical analysis by Smith et al. confirms that the unusually large negative activation energy they observe experimentally is consistent with the mechanism described above.

D83. CH_3CHOO (*syn* and *anti* conformers) + H_2O, $(H_2O)_2$. Experimental measurements of *k*(298 K) have been reported by Taatjes et al.[6] and Sheps et al.[5] In both studies CH_3CHOO was produced by UV laser flash photolysis of CH_3CHI_2/O_2. Taatjes et al. monitored CH_3CHOO using time-resolved photoionization mass spectrometry; the *anti* and *syn* conformers could be differentiated in the detection scheme because they have different ionization potentials. Sheps et al. used time-resolved broadband (300–450 nm) cavity-enhanced spectrometry to monitor both conformers simultaneously; they determined spectra of the individual conformers based on their very different reactivities toward H_2O and SO_2. Both studies employed relatively low total pressures of 4 Torr O_2[6] and 5–20 Torr He.[5] The rate constant reported by Sheps et al. for reaction of the more reactive *anti* conformer with H_2O is over a factor of two faster than the one reported by Taatjes et al. In both studies, only upper limits could be obtained for the *syn*–CH_3CHOO + H_2O rate constant, with the Sheps et al. upper limit being a factor of twenty smaller than the Taatjes et al. upper limit. The Sheps et al. rate constants are recommended because their approach appears to provide better sensitivity and selectivity for detection of the individual conformers. The recommended uncertainty in the *anti*–CH_3CHOO + H_2O rate constant is somewhat larger than reported by Sheps et al. pending independent verification of their result.

The CH_3CHOO + water reactions have been studied theoretically by Anglada et al.,[1,2] Ryzhkov and Ariya,[4] and Kuwata et al.[3] The more reactive *anti* conformer is found to lie 14–15 kJ mol^{-1} higher in energy than the *syn* conformer.[2,3] There is general agreement that reaction proceeds via initial formation of a hydrogen-bonded complex that isomerizes to the hydroxyl hydroperoxide $CH_3CH(OH)OOH$. The *syn* conformer is unreactive because the transition state for the isomerization reaction lies 22 kJ mol^{-1} higher in energy than CH_3CHOO + H_2O reactants; for the *anti* conformer, isomerization takes place rapidly over a "submerged" barrier that lies 7 kJ mol^{-1} lower in energy than reactants.[2] Rate constants for conversion of CH_3CHOO + H_2O to the hydroperoxide at T = 298 K and P = 1 atm are predicted in all four theoretical studies. There is general agreement that the *anti* conformer is more reactive than the *syn* conformer by factors of $(4-7) \times 10^4$. The most recent theoretical work[2] predicts a rate constant for *anti*-CH_3CHOO + H_2O that is a factor of 7 faster than the experimental value, whereas all three earlier theoretical studies predict *anti*-CH_3CHOO + H_2O rate constants that are substantially slower than the experimental value (factors of 10,[1] 35,[4] and 80[3]).

To explain available experimental observations, there is no need to postulate the occurrence of a reaction of CH_3CHOO with $(H_2O)_2$. It should be pointed out, however, that the Taatjes et al. study was limited to P_{H2O} $\leq$1.4 Torr and the Sheps et al. study was limited to P_{H2O} $\leq$4.3 Torr. The data of Sheps et al. do show slight indication of upward curvature with increasing $[H_2O]$ in the plot of the pseudo-first order *anti*-CH_3CHOO decay rate vs. $[H_2O]$. In their theoretical study, Ryzhkov and Ariya calculated rate constants for reactions of *syn*- and *anti*-CH_3CHOO with both H_2O and $(H_2O)_2$; they predict that at 298 K $(H_2O)_2$ is 1.0×10^5 times more reactive than H_2O with the *syn* conformer and 4.2×10^3 times more reactive with the *anti* conformer. For CH_2OO, where experimental evidence verifies the dominance of the $(H_2O)_2$ reaction, the reactivity ratio obtained theoretically by Ryzhkov and Ariya is 1.8×10^5. Experiments at higher total pressures and higher H_2O partial pressures appear necessary for quantitatively assessing the importance of $(H_2O)_2$ reaction as a loss process for CH_3CHOO in the atmosphere.

D84. CH_2OO + NO. There have been two studies of the reaction of CH_2OO + NO, Welz et al.[2] directly observed CH_2OO via photoionization mass spectrometry and Stone et al.[1] follow CH_2OO via the laser induced fluorescence of the product HCHO. Welz et al.[2] report an upper limit of $<6\times 10^{-14}$ cm^3 $molecule^{-1}$ s^{-1} whereas Stone eta l., report an upper limit of $<2 \times 10^{-13}$ cm^3 $molecule^{-1}$ s^{-1}. Stone et al.[1] note that there are considerable uncertainties in their reported upper limit as their retrieved rate coefficients have increased uncertainty as a result of biexponential behavior and used relatively low concentrations of NO in their experiments. Thus the lower upper of limit Welz et al.[2] is recommended.

D85. CH_2OO + NO_2. The recommendation is the average of the rate coefficients reported by Welz et al.[5] (7(+3/-2) × 10^{-12} cm^3 $molecule^{-1}$ s^{-1})and Stone et al.[4] ($1.5 \pm 0.5 \times 10^{-12}$ cm^3 $molecule^{-1}$ s^{-1}) with equal weighting given to the two studies (independent of the number of rate coefficients reported in each study). There has been one published relative rate for the reaction of CH_2OO + NO_2. Ouyang et al.[3] report a relative rate of $k_{CH2OO+NO2}/k_{CH2OO+H2O}$ of $(2.8 \pm 1.1) \times 10^5$, however the relative rate coefficient may have been influenced by the much faster reaction of the water dimer with the Criegee intermediate so is not considered in the current evaluation.

Ouyang et al.[3] suggest that NO_3 is the major product from the reaction, however [2] and Caravan et al.[1] suggest that little or no NO_3 is formed via the reaction. Caravan et al.[1] observe the CH_2OO-NO_2 adduct, however, as of yet, there have been no quantitative evaluations of the branching ratio for the reaction.

D86. $CH_2OO + HNO_3 \rightarrow$ products. There has been one study of the reaction of $CH_2OO + HNO_3$ [1] using direct detection of CH_2OO via UV absorption spectroscopy. Foreman et al.[1] do not measure reaction products however suggest that the reaction product is nitrooxymethyl hydroperoxide (NMHP) using CCSD/cc-pVDZ quantum chemical calculations.

D87. $CH_2OO \rightarrow$ products. Berndt et al.[1] generated CH_2OO from the ozonolysis of ethene in an atmospheric pressure flow tube and detected the CH_2OO via the titration of CH_2OO with SO_2 to produce sulfuric acid, which is detected via PTRMS found (0.19 ± 0.07) s^{-1}. The most complete study of the unimolecular decay of CH_2OO has been carried out by Stone et al.[2] who used a combination of time resolved cavity enhanced broadband UV absorption spectroscopy, for direct monitoring of CH_2OO, and laser induced fluorescence, for monitoring of OH decomposition products to study the decomposition between 450 and 650 K and pressures in the range of 2–350 Torr. They found that $k_0 = 3.2 \times 10^{-4}\ (T/298)^{-5.81} \exp(-12770/T)$ $cm^3\ s^{-1}$, $k_\infty = 1.4 \times 10^{13}\ (T/298)^{0.06} \exp(-10010/T)\ s^{-1}$ and $F_c = 0.447$. This corresponds to a unimolecular decay of $k_1 = 1.1 \times 10^{-3}\ s^{-1}$in Helium at 760 Torr and 298 K and they report a decay of $k_1 = 8.6 \times 10^{-3}\ s^{-1}$in N_2 at 760 Torr and 298 K. Berndt et al.[1] report a somewhat faster rate coefficient than those obtained by Stone et al. Berndt et al.[1] employed the highly exothermic $C_2H_4 + O_3$ to generate CH_2OO suggesting that the reactions of non-thermalized CH_2OO could impact the kinetic results. Stone et al. could not observe a radical loss that could be unequivocally assigned to the unimolecular decay of CH_2OO at atmospheric temperatures, so we are unable to make a recommendation at this point.

D88. $CH_2OO + CH_2OO$. There have been 4 experimental determinations of the CH_2OO self-reaction by Buras et al.,[1] Su et al.,[3] Ting et al.,[4] and Chhantyal-Pun et al.[2] The recommendation is the average of the rate coefficients reported by Buras et al.,[1] Ting et al.,[4] and Chhantyal-Pun et al.[2] with equal weighting given to the three studies (independent of the number of rate coefficients reported in each study). The studies report rate coefficients of (6.0 ± 2.1) × 10^{-11} cm^3 $molecule^{-1}$ s^{-1}, (8.0 ± 4) × 10^{-11} cm^3 $molecule^{-1}$ $s^{-1}$and (7.35 ± 0.63) × 10^{-11} cm^3 $molecule^{-1}$ s^{-1} respectively. Su et al.[3] report a rate coefficient that is a factor of 5 higher than the other studies. In the follow on study from the same group by Ting et al.[4] it was pointed out that the initial study ignored secondary chemistry and had large errors associated with absorption cross section and thus is not considered in the evaluation.

D89. $CH_2OO + HC(O)OH \rightarrow$ products. There have been two studies of the reaction of CH_2OO + HCOOH both reported in Welz et al.[2] using direct detection of CH_2OO either via photoionization mass spectrometry or UV absorption spectroscopy. Both methods report an identical rate coefficient. Neeb et al.[1] report a relative rate of $k_{CH2OO+HCOOH}/k_{CH2OO+H2O} = 14000$; however the reference rate coefficient is not well defined, as it is likely the reported relative rate has been influenced the much faster water dimer reaction, so is not considered in the current evaluation. Neeb et al.[1] suggest that the reaction forms HMPF ($HC(O)OCH_2OOH$) and Welz et al. [2] observe product peaks that are assumed to be dissociative ions from HMPF.

Ed.* **2014**, *53*, 4547-4550, doi:10.1002/anie.201400964.

D90. $CH_2OO + CH_3CHO$. There have been four studies in total of this reaction. Two direct studies of the reaction of $CH_2OO + CH_3CHO$ [6] use CH_2OO production by UV laser flash photolysis of CH_2I_2/O_2. Taatjes et al.[6] detect the CH_2OO via photoionization mass spectrometry and Elsamra et al.[2] use laser absorption technique at 375 nm. Two indirect studies [1] generated CH_2OO from the ozonolysis of ethene in an atmospheric pressure flow tube and detected the CH_2OO via the titration of CH_2OO with SO_2 to produce sulphuric acid, which is detected via PTRMs and Stone et al.[5] follow CH_2OO via the laser induced fluorescence of the product HCHO. Earlier work by Horie et al.[3] in an atmospheric pressure FTIR relative rate study report a relative rate of CH_2OO with Hexafluoroacetone compared to CH_3CHO. Only an approximate relative rate is reported and their relative rate assumes 100% conversion to the propene ozonide, which as the authors note they found evidence for the formation of CO_2 and HCHO as well as the ozonide, as a result the relative rate study is not considered in this evaluation.

At room temperature the four studies agree within the stated experimental uncertainties. Taatjes et al., report a value of $(9.5 \pm 0.7) \times 10^{-13}$ cm^3 molecule^{-1} s^{-1}at 4 Torr; Berndt et al., report a value of $(1.7 \pm 0.5) \times 10^{-12}$ cm^3 molecule^{-1} s^{-1} at atmospheric pressure, Elsamra et al.[2] report a value of $(1.1 \pm 0.1) \times 10^{-12}$ cm^3 molecule^{-1} s^{-1} at 4. Torr and Stone et al., report a value of $(1.48 \pm 0.04) \times 10^{-12}$ cm^3 molecule^{-1} s^{-1} at 25 Torr. Stone et al.[5] suggest that the difference between high pressure and low pressure studies could be as a result of a pressure dependent rate of reaction. Elsamra et al.[2] carried out experiments as a function of pressure from 4 to 50 Torr and suggest that there could be a very weak pressure dependence. However, within the quoted experimental error, the rate coefficients reported by Elsamra et al.[2] are in agreement. A weak pressure dependence is also suggested by theoretical calculations of Jalan et al.[4] However, given the associated uncertainty between the studies and the lack of a single study that covers a large range of pressures the recommendation is the average of the four rate coefficients with equal weighting given to the four methods. Elsamra et al.[2] study reports the only available temperature dependent data, so the recommended E/R is obtained from the Arrhenius fit to their data.

Horie et al.[3] observe propene ozonide as a reaction product. Whereas Taatjes et al.[6] do not observe any peaks (parent or dissociative) that can be associated with the ozonide in their photoionization mass spectra, however Taatjes et al.[6] observe acetic acid. It is possible that the barriers for isomerization or decomposition for the secondary ozonide are near or below the energy of the reactants and at the low pressures used by Taatjes et al.[6] that collisional stabilization of the secondary ozonide does not occur, explaining the difference with the experimental results of Horie et al.[3] Elsamra et al.[2] also attempted to quantify the reaction products using photoionization mass spectrometry but were not able to observe any products. As of yet, no quantitative assessment of the product branching ratios have been reported.

D91. $CH_2OO + CH_3C(O)OH \rightarrow$ products. There have been two studies of the reaction of $CH_2OO + CH_3COOH$ at 298 K both reported in Welz et al.[1] using direct detection of CH_2OO either via photoionization mass spectrometry ($1.3 \pm 0.1 \times 10^{-10}$ cm^3 molecule^{-1} s^{-1}) or UV absorption spectroscopy ($1.2 \pm 0.1 \times 10^{-10}$ cm^3 molecule^{-1} s^{-1}). The recommendation is the average of the two rate coefficients reported by Welz et al.[1] with equal weighting given to the two methods. Welz et al.[1] suggest that reaction proceeds via the formation of the CH_2OO-CH_3COOH adduct, however the product ions that were detected are most probably produced via the dissociative ionization of the adduct and no attempt was made to assess the branching ratio so no recommendation on product formation can be made.

Ed.* **2014**, *53*, 4547-4550, doi:10.1002/anie.201400964.

D92. $CH_2OO + CH_2{=}CH_2 \rightarrow$ products. There has been one study of the reaction of CH_2OO + ethene [1] using CH_2OO production by UV laser flash photolysis of CH_2I_2/O_2 and direct detection of CH_2OO via UV absorption spectroscopy at 350 nm. Buras et al.[1] measured the rate coefficient as a function of pressure from 10 to 50 Torr and within experimental error was found to be independent of pressure. The rate coefficient was measured at three temperatures and was found to have a positive temperature dependence. The temperature dependence was predicted using B3LYP/MG3s theoretical calculations and suggest that the reaction proceeds via the formation of a pre-reactive complex before a 1,3 cycloaddition to the double bond. The theoretical calculations suggest that Arrhenius plots should be significantly curved, however, it is not possible assess experimentally given the limited amount of temperatures that the rate coefficient was determined experimentally. The theoretical calculations are approximately an order of magnitude faster than the experimentally determined rate coefficients and agreement is only qualitative, suggesting that the Arrhenius plots should be curved. Buras et al.[1] suggest that the disagreement is as a result of inadequate estimation of flux through shallow/submerged saddle points.
(Table: 19-05, Note: 19-05, Evaluated: 19-05) Back to Table

(1) Buras, Z. J.; Elsamra, R. M. I.; Jalan, A.; Middaugh, J. E.; Green, W. H. Direct kinetic measurements of reactions between the simplest Criegee intermediate CH_2OO and alkenes. *J. Phys. Chem. A* **2014**, *118*, 1997-2006, doi:10.1021/jp4118985.

D93. $CH_2OO + CH_3C(O)CH_3$. There have been two direct studies of the reaction of $CH_2OO + CH_3C(O)CH_3$. [2,4]. The direct studies both produce CH_2OO via by UV laser flash photolysis of CH_2I_2/O_2 [2,4]. Taatjes et al.,[4] detect the CH_2OO via photoionization mass spectrometry and Elsamra et al.[2] use laser absorption technique at 375 nm. There has been a further indirect study by Berndt et al.,[1] which generated CH_2OO from the ozonolysis of ethene in an atmospheric pressure flow tube. Berndt et al., detected the CH_2OO via the titration of CH_2OO with SO_2 to produce sulphuric acid, and the subsequent sulphuric acid was detected via PTRMs. All three studies are in good agreement and the recommendation is the average of the three rate coefficients with equal weighting given to the three methods. Elsamra et al.[2] carried out experiments as a function of pressure and within experimental error, the rate coefficient is independent of pressure. Elsamra et al.[2] study reports the only available temperature dependent data, so the recommended *E*/R is obtained from the Arrhenius fit to their data. Elsamra et al. and Taatjes et al.[2,4] observe the secondary ozonide 3,3-dimethyl-1,2,4-trioxolane and methoxy methyl acetate as the main products of the reaction, however no quantification of the branching is reported. Elsamra et al.[2] show that the relative yield of the SOZ has a weak pressure dependence, which is consistent with the theoretical calculations of Jalan et al.[3]

D94. $CH_2OO + CH_2{=}CHCH_3$. There has been one study of the reaction $CH_2OO + CH_2{=}CHCH_3$ (propene)[1] using CH_2OO production by UV laser flash photolysis of CH_2I_2/O_2 and direct detection of CH_2OO via UV absorption spectroscopy at 350 nm. Buras et al.[1] measured the rate coefficient as a function of pressure from 10 to 50 Torr and within experimental error found it to be independent of pressure. The rate coefficient was measured at three temperatures and was found to have a positive temperature dependence. The temperature dependence was predicted using B3LYP/MG3s theoretical calculations that suggest the reaction proceeds via the formation of a pre-reactive complex before a 1,3 cycloaddition to the double bond. The theoretical calculations suggest that Arrhenius plots should be significantly curved; however, it is not possible assess this experimentally given the limited range of temperatures investigated. The theoretical calculations are approximately an order of magnitude faster than the experimentally determined rate coefficients and agreement is only qualitative, suggesting that the Arrhenius plots should be curved. Buras et al.[1] suggest that the disagreement is as a result of inadequate estimation of flux through shallow/submerged saddle points.

D96. $CH_2OO + (CH_3)_2C{=}CH_2$ (*iso*-butene). There has been one study of the reaction of CH_2OO + *iso*-butene [1] using CH_2OO production by UV laser flash photolysis of CH_2I_2/O_2 and direct detection of CH_2OO via UV absorption spectroscopy at 350 nm. Buras et al.[1] measured the rate coefficient as a function of pressure from 10 to 50 Torr and within experimental error was found to be independent of pressure. The rate coefficient was measured at three temperatures and was found to have a positive temperature dependence. The temperature dependence was predicted using B3LYP/MG3s theoretical calculations and suggest that the reaction proceeds via the formation of a pre-reactive complex before a 1,3 cycloaddition to the double bond. The theoretical calculations suggest that Arrhenius plots should be significantly curved, however, it is not possible assess experimentally given the limited amount of temperatures that the rate coefficient was determined experimentally. The theoretical calculations are approximately an order of magnitude faster than the experimentally determined rate coefficients and agreement is only qualitative, suggesting that the Arrhenius plots should be curved. Buras et al.[1] suggest that the disagreement is as a result of inadequate estimation of flux through shallow/submerged saddle points.

D97. $CH_2OO + CH_3CH{=}CHCH_3$. There has been one study of the reaction of $CH_2OO + CH_3CH{=}CHCH_3$ (2-butene)[1] using CH_2OO production by UV laser flash photolysis of CH_2I_2/O_2 and direct detection of CH_2OO via UV absorption spectroscopy at 350 nm.[1] Buras et al.[1] measured the rate coefficient as a function of pressure from 10 to 50 Torr and within experimental error was found to be independent of pressure. The 2-butene was used as supplied and no quantification of the fraction of *trans* versus *cis* isomers was stated. However, as pointed out by the authors the *trans* isomer is expected to be relatively more reactive than the *cis* isomer and the *trans* isomer is thermodynamically more stable. Thus, the measure rate coefficient should be more representative of the reactivity of the *trans* isomer. The rate coefficient was measured at three temperatures and was found to have a positive temperature dependence. The temperature dependence was predicted using B3LYP/MG3s theoretical calculations and suggest that the reaction proceeds via the formation of a pre-reactive complex before a 1,3 cycloaddition to the double bond. The theoretical calculations suggest that Arrhenius plots should be significantly curved; however, it is not possible assess this experimentally given the limited range of temperatures investigated. The theoretical calculations are approximately an order of magnitude faster than the experimentally determined rate coefficients and agreement is only qualitative. Buras et al.[1] suggest that the disagreement is as a result of inadequate estimation of flux through shallow/submerged saddle points.

D98. $CH_2OO + CF_3C(O)OH$. There has been one study of the reaction of CH_2OO + TFA (trifluoroacetic acid) [1] using CH_2OO production by UV laser flash photolysis of CH_2I_2/O_2 and detection of CH_2OO using cavity ring-down spectroscopy at 355 nm between 10 and 100 Torr. The recommended *E*/R is obtained from the Arrhenius fit to their data. Theoretical work at the DF-HF//DF-LCCSD(T)-F12a/aug-cc-pVTZ//B3LYP/6-31 + G(d) level suggest that the reaction proceeds via a pre-reactive complex and suggest that the temperature dependence is

best described by a non-Arrhenius expression $k = AT^2 exp\left(\frac{\Delta H}{RT}\right) + k_r$ where k_r is the high temperature limit from the fit to the experimental data where $A = (3.8 \pm 2.6) \times 10^{-18}$ cm^3 s^{-1} K^{-2}, ΔH = (13.1 ± 1.5) kJ mol^{-1} and $k_r = 2.5 \times 10^{-10}$ cm^3 s^{-1}. As a result of the apparent curvature of the temperature dependence, it is not recommended to extrapolate the Arrhenius expression beyond the experimental temperatures studied.

D99. $CH_2OO + CF_3C(O)CF_3$ (HFA) → products. There have been two studies of the reaction of CH_2OO + HFA Taatjes et al.[2] and Liu et al.[1] The Taatjes et al. study was carried out at 4 Torr who reported a value of 3.53 ± 0.29 × 10^{-11} cm^3 molecule^{-1} s^{-1} and the Liu et al. study was carried out at 50 Torr who reported a value of 3.33 ± 0.27 × 10^{-11} cm^3 molecule^{-1} s^{-1}. The two determinations of the rate coefficients are in good agreement and would suggest that the rate coefficient is pressure independent. The recommendation is the average of the two rate coefficients reported with equal weighting given to the two methods. Taatjes et al.[2] observe the secondary ozonide 3,3-di(trifluoromethyl)-1,2,3-trioxolane and (trifluoromethoxy)methyl trifluoroacetate as the main products of the reaction, however no quantification of the branching is reported.

D101. $CH_2OO + H_2S$ → products. There has been one study of the reaction of $CH_2OO + H_2S$ [1] using direct detection of CH_2OO via UV absorption spectroscopy at 340 nm. Smith et al.[1] measure that rate coefficient as a function of pressure from 100 to 500 Torr and within experimental error was found to be independent of pressure. The rate coefficient was measured at three temperatures and was found to have a weak temperature dependence. The weak temperature dependence agrees with the theoretical QCISD(T)/CBS calculations. No reaction products are measured, however, QCISD(T)/CBS calculations suggest that the reaction proceeds via the formation of a complex.
(Table: 19-05, Note: 19-05, Evaluated: 19-05) Back to Table

D102. $CH_2OO + SO_2$. The recommendation is the average of rate constants reported in the experimental studies of Chhantyal-Pun et al.,[1] Liu et al.,[5] Sheps,[6] Stone et al.,[7] and Welz et al.,[9] with equal weighting given to each of the five studies (independent of the number of rate constants reported in each study). In all five studies CH_2OO was produced by laser flash photolysis of CH_2I_2/O_2, while kinetic information was obtained by (i) monitoring reactant CH_2OO using photoionization mass spectrometry,[7,9] cavity ring down spectroscopy,[1] or broadband cavity-enhanced spectrometry,[6] (ii) product H_2CO using laser induced fluorescence (LIF),[7] or (iii) OH, deduced

to be a tracer for CH_2OO kinetics, using LIF.[5] The available data suggest that the rate constant is independent of pressure over the range 1.5–450 Torr $N_2 + O_2$, and the average rate constants reported in the five studies all fall within the range (3.4−4.1) × 10^{-11} cm^3 $molecule^{-1}$ s^{-1}. A theoretical kinetic analysis predicts a rate constant in qualitative agreement with the experimental value.[4] An early mechanistic study by Hatakeyama et al.[2] suggested that, under the laboratory conditions employed, an initially formed CH_2OO-SO_2 adduct either decomposes to HCOOH + SO_2 or reacts with a second SO_2, leading to production of $H_2CO + SO_3$. A theoretical study by Jiang et al.[3] suggests that reaction proceeds via formation of a cyclic adduct that is bound by 117 kJ mol^{-1} and dissociates over barriers that are lower in energy than reactants to produce $H_2CO + SO_3$ and HCOOH + SO_2; the barrier to formation of the more stable products (HCOOH + SO_2) is predicted to be larger than the barrier to formation of the less stable products ($H_2CO + SO_3$). Vereecken et al.[8] have theoretically considered the role of singlet biradicals in the reaction mechanism and concluded that it is substantial; their master equation analysis suggests that, under atmospheric conditions, reaction is in the low pressure regime and the energized cyclic adduct fragments to 68% $H_2CO + SO_3$, 15% HC(=O)−OS(=O)OH (formyl sulfinic ester), and 17% SO + >C(O•)O• (singlet bisoxy diradical).

D103. *anti*-$CH_3CHOO + SO_2$. Experimental measurements of *k*(298 K) have been reported by Taatjes et al.[2] and Sheps et al.[2] In both studies CH_3CHOO was produced by UV laser flash photolysis of CH_3CHI_2/O_2. Taatjes et al. monitored CH_3CHOO using time-resolved photoionization mass spectrometry; the *anti* and *syn* conformers could be differentiated in the detection scheme because they have different ionization potentials. Sheps et al. used time-resolved broadband (300–450 nm) cavity-enhanced spectrometry to monitor both conformers simultaneously; they determined spectra of the individual conformers based on their very different reactivities toward H_2O and SO_2. The rate constant reported by Sheps et al. is more than a factor of three faster than the one reported by Taatjes et al. The Sheps et al. rate constant is recommended because their approach appears to provide better sensitivity and selectivity for detection of the *anti* conformer in the presence of the less reactive *syn* conformer. The recommended uncertainty is somewhat larger than reported by Sheps et al. pending independent verification of their result. Theoretical analysis by Kuwata et al.[1] suggests that the *anti* conformer is 14 kJ mol^{-1} higher in energy than the *syn* conformer. Theoretical analysis by Vereecken et al.[3] suggests that (unlike CH_2OO-SO_2) nearly all energized $CH_3CHCOO-SO_2$ adduct is stabilized under atmospheric conditions.

Shaded areas indicate changes or additions since JPL15-10. Italicized blue entries denote estimates.

[a] Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

[b] Units are cm^3 $molecule^{-1}$ s^{-1}.

[c] *f*(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(\mathrm{T}) = f(298\ \mathrm{K})\exp\left|g\left(\frac{1}{\mathrm{T}} - \frac{1}{298}\right)\right|$$

Note that the exponent is an absolute value.

1.10.2 Notes: FO_x Reactions

E1. **O + FO.** The recommended value for *k*(298 K) is based on results of the room temperature study of Bedzhanyan et al.[1] The temperature dependence of the rate constant is expected to be small, as it is for the analogous ClO reaction.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) Back to Table

(1) Bedzhanyan, Y. R.; Markin, E. M.; Politenkova, G. G.; Gershenzon, Y. M. Experimental study of elementary reactions of FO radicals. III. Reactions with oxygen and nitrogen atoms. *Kinetics and Catalysis* **1993**, *33*, 797-801.

E2. **O + FO_2.** The recommended Arrhenius parameters are estimated, as there are no experimental data. The rate constant for such a radical-atom process is expected to approach the gas collision frequency, and is not expected to exhibit a strong temperature dependence.
(Table: 82-57, Note: 82-57, Evaluated: 82-57) Back to Table

E3. **OH + CH_3F (HFC-41).** The recommended value for *k*(298 K) is an average of the values from Schmoltner et al.,[8] Nip et al.,[7] Hsu and DeMore,[4] and DeMore[2] (with the relative rate constants from the last two studies listed above recalculated based on the current recommendations for the rate constants for the OH + CH_3CHF_2 and OH + CH_3Cl reference reactions, respectively.) The recalculation procedure for relative rate measurements referenced to the OH + CH_3CHF_2 reaction is discussed in the note for that reaction. The recommended value for *E*/R is an average of the values obtained in the studies of Schmoltner et al.,[8] Hsu and DeMore,[4] and DeMore.[2] The results of Howard and Evenson,[3] Jeong and Kaufman,[5] Bera and Hanrahan,[1] and Wallington and Hurley[9] appear to be systematically lower than those of the other studies over the temperature region of interest and were not used to derive the recommended parameters. The results from the 298 K study by Kowalczyk et al.,[6] although in good agreement with the recommended value for *k*(298 K), also were not used since the results reported in this study for several halocarbons vary widely (ranging from 10% agreement with recommendations to as much as 3 orders of magnitude disagreement with recommendations).

E4. **OH + CH_2F_2 (HFC-32).** The recommended value of *k*(298 K) is an average from the studies of Nip et al.,[7] Jeong and Kaufman,[5] Talukdar et al.,[9] Hsu and DeMore[4] (recalculated using the three-parameter expression given in the current recommendation for the rate constant for the OH + CH_3CHF_2 reference reaction), and Szilagyi et al.[8] The recommended value for *E*/R is derived from a fit to the data from Jeong and Kaufman,[5] Talukdar et al.,[9] and Hsu and DeMore[4] below 400 K after scaling each data set to the recommended value for *k*(298 K). The results of Howard and Evenson,[3] Clyne and Holt,[2] Bera and Hanrahan,[1] and Kowalczyk et al.[6] are somewhat more scattered and were not used in deriving the recommended parameters.

E5. OH + CHF_3 (HFC-23). The recommended value for *k*(298 K) is an average of the values reported in the absolute rate study of Schmoltner et al.[9] and in the relative rate studies of Hsu and DeMore[5] (recalculated based on the current recommendation for the rate constant for the OH + CHF_2CF_3 reference reaction) and of Chen et al.[2] (two relative rate determinations recalculated based on the current recommendations for the rate constants for the OH + CHF_2CF_3 and OH + CHF_2Cl reference reactions). The recommended value for *E*/R is derived from a fit to the data from these same three studies after scaling each data set to the recommended value of *k*(298 K). The results of Jeong and Kaufman[6] and Medhurst et al.,[7] being predominantly above room temperature, were not used in deriving the recommended parameters. The results from Clyne and Holt[3] and Bera and Hanrahan[1] were also not used due to their inconsistency with the other studies. The room temperature values of Howard and Evenson[4] and Nip et al.[8] are encompassed within the 2σ confidence limits.

E6. OH + CH_3CH_2F (HFC-161). The recommended value for *k*(298 K) is an average of the values from Nip et al.,[3] Schmoltner et al.,[4] and Kozlov et al.[2] The value of E/R is derived from a fit to the data from the latter two studies at room temperature and below after scaling each data set to the value recommended for *k*(298 K). The relative rate study by Hsu and DeMore[1] reports a temperature dependence that is markedly stronger than those of Schmoltner et al.[4] and Kozlov et al.,[2] which are in excellent agreement. This difference is due to significantly lower rate constant values being in the Hsu and DeMore study in the region near room temperature. The Hsu and DeMore temperature dependence for HFC-161 is also significantly stronger than measured and recommended for HFC-152 and HFC-152a, where similar dependences would be expected. Curvature in the Arrhenius plot is evident from the study by Kozlov et al.,[2] which was conducted over an extended temperature range above and below room temperature. Singleton et al.[5] determined that 85 ± 3% of the abstraction by OH is from the fluorine-substituted methyl group at room temperature. Hence, curvature in the Arrhenius plot may be due to the increasing importance of hydrogen abstraction from the unsubstituted methyl group with increasing temperature, although similar curvature was observed in the case of OH + CH_2FCH_2F with two identical fluoromethyl groups. Due to such curvature, the recommended Arrhenius parameters should not be used for calculating rate constants above room temperature. Rather, one should use the three-parameter expression that is derived from a fit to the data of Kozlov et al. over the temperature range from 210 K to 480 K after the data were scaled to match the recommended value of *k*(298 K):

$$k(\mathrm{T}) = 3.1 \times 10^{-13}\ (\mathrm{T}/298)^{2.45}\ \exp(-103/\mathrm{T})$$

E7. OH + CH_3CHF_2 (HFC-152a). The recommended value for *k*(298 K) is an average of the values from the absolute rate studies of Howard and Evenson,[5] Handwerk and Zellner,[4] Nip et al.,[10] Gierczak et al.[3] (two different determinations), and Kozlov et al.,[7] and from the relative rate studies of Hsu and DeMore[6] (two determinations that have been recalculated based on the current recommendations for the rate constants of the OH + CH_4 and OH + CH_3CCl_3 reference reactions), Wilson et al.[12] (two determinations that have been recalculated based on the current recommendations for the rate constants of the OH + C_2H_6 and OH + c-C_3H_6 reference reactions), and Taketani et al.[11] (two determinations that have been recalculated based on the current recommendations for the rate constants of the OH + C_2H_2 and OH + C_2H_4 reference reactions). There are systematic differences in the temperature dependencies determined in the absolute studies (particularly below room temperature) and relative studies (conducted at room temperature and above). Curvature in the Arrhenius plot (as suggested by the data of Gierczak et al.[3]) has been more clearly demonstrated in the study of Kozlov et al.[7] and seems to explain the earlier cited differences between the relative and absolute rate data. This curvature may be due to the presence of two hydrogen-abstraction reaction channels, although similar curvature was observed in case of OH + CH_2FCH_2F with two identical fluoromethyl groups. Hence, care must be taken in deriving a recommended rate expression suitable for atmospheric modeling (in the temperature region below room temperature).

In spite of the noticeable Arrhenius curvature over the temperature range from 210 K to 480 K, the data below 300 K can be well represented by a two-parameter Arrhenius expression. Thus, the recommended value for *E*/R is derived from a combined fit to the data (T ≤300 K) of Gierczak et al.[3] and Kozlov et al.[7] after scaling each data set to the recommended value for *k*(298 K). The studies by Clyne and Holt,[2] Brown et al.,[1] and

Nielsen[9] all yield systematically higher rate constants and were not used in deriving the recommended parameters. The study by Liu et al.[8] is superseded by that of Kozlov et al.[7] In light of the observed Arrhenius curvature, the Arrhenius parameters recommended for temperatures below 300 K are not suitable for use in recalculating rate constants from relative rate studies conducted at temperatures above 300 K in which the OH + CH_3CHF_2 reaction was the reference. For such purposes, we recommend use of the three-parameter expression derived from a fit to the data of Kozlov et al.[7] over the temperature range from 210 K to 480 K after the data were scaled to match the recommended value of k(298 K):

$$k(T) = 7.57 \times 10^{-14}\ (T/298)^{3.02}\ \exp(-247/T)$$

The site-specific rate coefficients were estimated by Kozlov et al.[7] (assuming that the observed curvature in the Arrhenius plot is entirely due to different reaction channels) to be 33% reaction at the CH_3 group and 67% H atom abstraction from the CHF_2 group.

E8. OH + CH_2FCH_2F (HFC-152). The recommended value for *k*(298 K) is an average of the values from the absolute rate studies of Martin and Paraskevopoulos[2] and Kozlov et al.[1] and from the relative rate studies of Wilson et al.[3] (three determinations recalculated using the current recommendations for the reference reactions of OH with HFC-152a, cyclopropane, and ethane). The value for *E*/R is from a fit to the data of Kozlov et al.[1] at room temperature and below. The data above room temperature from Kozlov et al.[1] are in excellent agreement with the three relative rate data sets of Wilson et al.[3] Together, they show a pronounced curvature in the Arrhenius plot, which may indicate the existence of different conformers for HFC-152, each with differing temperature populations and reactivities. The data over the temperature range from 210 K to 480 K can be represented by the three-parameter expression from Kozlov et al. after the latter was scaled to match the recommended *k*(298 K):

$$k(T) = 4.23 \times 10^{-14} (T/298)^{3.85} \exp(+247/T)$$

(Table: 10-6, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Kozlov, S. N.; Orkin, V. L.; Kurylo, M. J. An investigation of the reactivity of OH with fluoroethanes: CH_3CH_2F (HFC-161), CH_2FCH_2F (HFC-152), and CH_3CHF_2 (HFC-152a). *J. Phys. Chem. A* **2003**, *107*, 2239-2246, doi:10.1021/jp022087b.

E11. OH + CH_2FCF_3 (HFC-134a). The recommended value for *k*(298 K) is an average of the values derived from the absolute rate studies of Gierczak et al.[5] (two determinations using discharge flow and pulsed photolysis), Leu and Lee,[7] Liu et al.,[8] and Orkin and Khamaganov,[10] from the relative rate study of DeMore[4] (three determinations that have been recalculated based on the current recommendations for the rate constants of the reference reactions OH + CH_4, OH + CH_3CCl_3, and OH + CHF_2CF_3), and from the room temperature investigations of Bednarek et al.[1] and Martin and Paraskevopoulos.[9] The value for *E*/R is derived from a

combined fit (T ≤400 K) to the data from the first five investigations listed above after each data set was scaled to the recommended value of k(298 K), together with the single determination at T = 270 K by Zhang et al.[11] The data from Liu et al.[8] above 350 K were excluded from the combined fit since they significantly exceed the results from the other studies at these temperatures, and subsequent experiments from the same laboratory have demonstrated that a systematic underestimation of the reaction cell temperature above 350 K may have been responsible. The data at 243 K and 223 K from the pulsed photolysis – LIF study by Gierczak et al.[5] were also excluded from the combined fit since this data set (obtained at T <298 K) exhibits a substantially weaker Arrhenius temperature dependence (E/R = 1310 K) when compared with that from other studies conducted mainly above T = 270 K. This could be indicative of curvature in the Arrhenius plot at lower temperatures. Nevertheless, the "g" uncertainty factor was selected to encompass these low temperature data. The data of Brown et al.,[2] Clyne and Holt[3] and Jeong et al.[6] are considerably higher than those from all other studies and were not used in deriving the recommended parameters.

E12. OH + CHF_2CHF_2 (HFC-134). The recommended Arrhenius parameters are based on results of the three relative rate measurements by DeMore,[2] which have been recalculated based on the current rate constant recommendations for the OH + CH_3CCl_3, OH + CH_2FCF_3, and OH + CHF_2CF_3 reference reactions. The room temperature value of Clyne and Holt[1] agrees within the 2σ confidence limits.

E13. OH + CHF_2CF_3 (HFC-125). The recommended values for both k(298 K) and E/R were derived from a fit (as described in the Introduction, Section 1.2) to the data reported by Talukdar et al.[5] The recommended uncertainty was set to encompass the results of the relative rate studies by DeMore,[3] and Young et al.[6] The temperature dependent data of Brown et al.[1] and Clyne and Holt[2] were not used in deriving the recommended

parameters since they exhibit considerable scatter and the derived rate constants are systematically higher than those from the other studies, which may be indicative of impurity effects. The room temperature result reported by Martin and Paraskevopoulos[4] was not used for similar reasons, although it barely overlaps with the recommended uncertainty interval.

E14. OH + CH_3CHFCH_3 (HFC-281ea). The recommended value for *k*(298 K) is an average of values derived from fits to each of five relative rate data sets of DeMore and Wilson[1] (using infrared detection with C_2H_6, C_3H_8, and C_2H_5Cl as reference compounds and gas chromatography with C_2H_6 and C_3H_8 as reference compounds). All of the data were recalculated based on the current recommendations for the rate constants of the reference compounds reacting with OH. The recommended value for *E*/R is derived from the combined fit to all data from this study after each data set was scaled to the recommended value of *k*(298 K).
(Table: 02-25, Note: 15-10, Evaluated: 15-10) Back to Table

Rate coefficients for the reactions of OH with $CF_3CH_2CH_3$ (HFC-263fb), CF_3CHFCH_2F (HFC-245eb), and $CHF_2CHFCHF_2$ (HFC-245ea) between 238 and 375 K. *J. Phys. Chem. A* **2006**, *110*, 6724 - 6731, doi:10.1021/jp056248y.

E16. OH + $CH_2FCF_2CHF_2$ (HFC-245ca). There is an approximate 50% difference between the absolute rate constant results of Zhang et al.[2] and those derived from the relative rate data of Hsu and DeMore[1] (recalculated using the current recommendation for the rate constant of the OH + CH_4 reference reaction) over the common temperature region of the measurements. Both data sets, however, exhibit nearly identical temperature dependencies. The recommended value for *k*(298 K) is an average of the values from both studies. The recommended value for *E*/R is derived from a combined fit to the data from both studies after each data set was scaled to the recommended value of k(298 K).

(1) Hsu, K. J.; DeMore, W. B. Rate constants and temperature dependences for the reactions of hydroxyl radical with several halogenated methanes, ethanes, and propanes by relative rate measurements. *J. Phys. Chem.* **1995**, *99*, 1235-1244, doi:10.1021/j100004a025.

(2) Zhang, Z.; Padmaja, S.; Saini, R. D.; Huie, R. E.; Kurylo, M. J. Reactions of hydroxyl radicals with several hydrofluorocarbons: The temperature dependencies of the rate constants for $CHF_2CF_2CH_2F$ (HFC-245ca), $CF_3CHFCHF_2$ (HFC-236ea), CF_3CHFCF_3 (HFC-227ea), and $CF_3CH_2CH_2CF_3$ (HFC-356ffa). *J. Phys. Chem.* **1994**, *98*, 4312-4315, doi:10.1021/j100067a017.

E17. OH + $CH_3CF_2CF_3$ (HFC-245cb). The recommended Arrhenius parameters are based on the data of Orkin et al.[1] The Arrhenius parameters for this reaction are expected to be similar to those for OH + CH_3CF_3 (HFC-143a). Hence, the 95% confidence limits have been selected to encompass the recommendation for the latter reaction.
(Table: 15-10, Note: 15-10), Evaluated: 15-10) Back to Table

E18. OH + $CHF_2CHFCHF_2$ (HFC-245ea). Nelson et al.[1] measured the room temperature rate constant for this reaction. Rajakumar et al.[2] studied the temperature dependence in experiments conducted above and below room temperature. However, this study was complicated by the presence of a reactive impurity, as demonstrated by some additional low temperature results obtained with a purified sample. The recommended value for *E*/R was derived from a fit to the original data from Rajakumar et al.[2] corrected for the effect of reactive impurities at T ≥298 K and the data obtained with the purified sample below 298 K. The recommended value for *k*(298 K) is an average of the value obtained from this fit and the value reported by Nelson et al.,[1] which are in excellent agreement.

E21. OH + $CH_2FCF_2CF_3$ (HFC-236cb). The recommended rate expression is estimated as being the same as that for the reaction of OH with CH_2FCF_3 (HFC-134a), since these reactions are expected to have similar Arrhenius parameters. This estimate is preferred over the results reported by Garland et al.,[1] the only published

experimental study. The A-factor reported in that study is much lower than expected, and the reported *E*/R = 1107 K is lower than that reported for any similar halocarbon reaction.
(Table: 15-10, Note: 10-6, Evaluated: 15-10) Back to Table

(1) Garland, N. L.; Medhurst, L. J.; Nelson, H. H. Potential chlorofluorocarbon replacements: OH reaction rate constants between 250 and 315 K and infrared absorption spectra. *J. Geophys. Res.* **1993**, *98*, 23107-23111, doi:10.1029/93JD02550.

E22. OH + CHF_2CHFCF_3 (HFC-236ea). The recommended value for *k*(298 K) is an average of the values from the relative rate study of Hsu and DeMore[2] (recalculated based on the current recommendation for the rate constant of the OH + CH_4 reference reaction) and from the absolute study of Nelson et al.[3] The temperature dependence is from Hsu and DeMore.[2] The higher and somewhat more scattered values of Garland et al.[1] and Zhang et al.[4] were not used in deriving the recommended expression.
(Table: 02-25, Note: 02-25, Evaluated: 02-25) Back to Table

(1) Garland, N. L.; Medhurst, L. J.; Nelson, H. H. Potential chlorofluorocarbon replacements: OH reaction rate constants between 250 and 315 K and infrared absorption spectra. *J. Geophys. Res.* **1993**, *98*, 23107-23111, doi:10.1029/93JD02550.

(3) Nelson, D. D.; Zahniser, M. S.; Kolb, C. E.; Magid, H. OH reaction kinetics and atmospheric lifetime estimates for several hydrofluorocarbons. *J. Phys. Chem.* **1995**, *99*, 16301-16306, doi:10.1021/j100044a016.
(4) Zhang, Z.; Padmaja, S.; Saini, R. D.; Huie, R. E.; Kurylo, M. J. Reactions of hydroxyl radicals with several hydrofluorocarbons: The temperature dependencies of the rate constants for $CHF_2CF_2CH_2F$ (HFC-245ca), $CF_3CHFCHF_2$ (HFC-236ea), CF_3CHFCF_3 (HFC-227ea), and $CF_3CH_2CH_2CF_3$ (HFC-356ffa). *J. Phys. Chem.* **1994**, *98*, 4312-4315, doi:10.1021/j100067a017.

E23. OH + $CF_3CH_2CF_3$ (HFC-236fa). The recommended rate expression is derived from a combined fit to the data from the relative rate study of Hsu and DeMore[5] (recalculated based on the current recommendation for the rate constant of the reference reaction OH + CHF_2CF_3) and from the absolute rate study of Gierczak et al.[4] The higher results of Nelson et al.[6] and of Garland and Nelson,[3] which superseded the earlier results of Garland et al.[2] were not used. A relative rate determination at room temperature by Barry et al.[1] yields a rate constant in excellent agreement with the recommended value. However, the extremely small measured rate constant ratio (due to the use of OH + $CH_3CF_2CH_2CF_3$ as the reference) is associated with fairly large uncertainty. Hence, this determination was not directly used in the evaluation.

E24. OH + CF_3CHFCF_3 (HFC-227ea). The recommended value for *k*(298 K) is the average of values derived from the absolute rate studies of Nelson et al.,[2] Zellner et al.,[5] Zhang et al.,[6] and Tokuhashi et al.,[3] and from the relative rate studies of Hsu and DeMore[1] (two determinations that have been recalculated based on the current recommendations for the rate constants of the reference reactions OH + CH_4 and OH + CHF_2CF_3) and

Wallington et al.[4] (two determinations that have been recalculated based on the current recommendations for the rate constants of the reference reactions OH + C_2H_4 and OH + C_2H_2). The recommended value for E/R is derived from a fit to the data below 400 K reported by Nelson et al.,[2] Zellner et al.,[5] Tokuhashi et al.,[3] and Hsu and DeMore[1] after scaling each data set to the recommended value for k(298 K).

Phys. Chem.* **1994**, *98*, 4312-4315, doi:10.1021/j100067a017.

E25. OH + $CH_3CF_2CH_2CF_3$ (HFC-365mfc). The recommended value of k(298 K) is an average of the values obtained from fits to the data from the absolute rate study of Mellouki et al.[2] and of the relative rate study of Barry et al.[1] (recalculated using the current recommendation for the rate constant of the reference reaction OH + CH_3CCl_3). The value for E/R is an average of the values for this parameter from the same two studies.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

E26. OH + $CF_3CH_2CH_2CF_3$ (HFC-356mff). The recommended value of k(298 K) is an average of the values from Nelson et al.[1] and Zhang et al.[2] The temperature dependence is from a fit to the data of Zhang et al., excluding the lowest temperature points (at 260 K), which are somewhat higher than an extrapolation from other data in that study.
(Table: 02-25, Note: 02-25, Evaluated: 02-25) Back to Table

E27. OH + $CH_2FCH_2CF_2CF_3$ (HFC-356mcf). The recommended values for both k(298 K) and E/R are based on the data of Nelson et al.[1]
(Table: 02-25, Note: 02-25, Evaluated: 02-25) Back to Table

(1) Nelson, D. D.; Zahniser, M. S.; Kolb, C. E.; Magid, H. OH reaction kinetics and atmospheric lifetime estimates for several hydrofluorocarbons. *J. Phys. Chem.* **1995**, *99*, 16301-16306, doi:10.1021/j100044a016.

E28. OH + $CHF_2CF_2CF_2CF_2H$ (HFC-338pcc). The recommended value for *k*(298 K) is an average of values derived from fits to the data of Schmoltner et al.[1] and Zhang et al.[2] The recommended value for *E*/R is derived from the combined fit to the data from both studies after each data set was scaled to the recommended value of *k*(298 K).
(Table: 02-25, Note: 15-10, Evaluated: 15-10) Back to Table

E29. OH + $CHF_2CF_2CF_2CF_3$ (HFC-329p). The recommended value for *k*(298 K) is an average of two relative rate measurements of Young et al.[1] using C_2H_2 and C_2H_4 as reference compounds. Although the average values derived from these measurements are in good agreement (5%), the reported uncertainty due to data scattering is ~13%. In the same study, the reactivity of this compound was found to be indistinguishable from that of CHF_2CF_3. The value for *E*/R was estimated to be similar to that for the reactions of OH with CHF_2CF_3 and $CHF_2(CF_2)_4CF_3$ and the uncertainty was chosen to encompass the recommended values for these two reactions, which are ~12% larger.
(Table: 19-5, Note: 19-5, Evaluated: 19-5) Back to Table

(1) Young, C. J.; Hurley, M. D.; Wallington, T. J.; Mabury, S. A. Atmospheric chemistry of CF_3CF_2H and $CF_3CF_2CF_2CF_2H$: Kinetics and products of gas-phase reactions with Cl atoms and OH radicals, infrared spectra, and formation of perfluorocarboxylic acids. *Chem. Phys. Lett.* **2009**, *473*, 251-256, doi:10.1016/j.cplett.2009.04.001.

E30. OH + $CHF_2(CF_2)_4CF_3$ (HFC-52-13p). The recommended values for both *k*(298 K) and *E*/R are averages of values derived from relative rate data of Chen et al.[1] that have been recalculated based on the current recommendations for the rate constants of the reference reactions and absolute data obtained in the same study (below 400 K) in the same study, which are ~20% smaller.
(Table: 19-5, Note: 19-5, Evaluated: 19-5) Back to Table

(1) Chen, L.; Tokuhashi, K.; Kutsuna, S.; Sekiya, A. Rate constants for the gas-phase reaction of $CF_3CF_2CF_2CF_2CF_2CHF_2$ with OH radicals at 250-430 K. *Int. J. Chem. Kinet.* **2004**, *33*, 26–33, doi:10.1002/kin.10170.

E31. OH + $CHF_2(CF_2)_6CF_3$ (HFC-72-17p). The recommended value for *k*(298 K) is an average of two values derived from relative rate data reported by Chen et al.[1] that have been recalculated based on the current recommendations for the rate constants of the reference reactions with CHF_2CF_3 and CH_2FCF_3. The value for *E*/R was derived from a combined fit to recalculated data after each data set was normalized to the recommended value of *k*(298 K). The rate constants obtained exceed those for the similar reactions of OH with CHF_2CF_3 and $CHF_2(CF_2)_4CF_3$ by ~35%. Thus, the recommended uncertainties were chosen to encompass the values recommended for these latter reactions.
(Table: 19-5, Note: 19-5, Evaluated: 19-5) Back to Table

E33. OH + $CF_3CHFCHFCF_2CF_3$ (HFC-43-10mee). The recommended value for *k*(298 K) is an average of values derived from absolute studies by Schmoltner et al.[1] and Zhang et al.[2] The recommended value for *E*/R is derived

from a combined fit to the data from Schmoltner et al. and Zhang et al. after scaling each data set to the recommended value for *k*(298 K).
(Table: 02-25, Note: 02-25, Evaluated: 02-25) Back to Table

(1) Schmoltner, A. M.; Talukdar, R. K.; Warren, R. F.; Mellouki, A.; Goldfarb, L.; Gierczak, T.; McKeen, S. A.; Ravishankara, A. R. Rate coefficients for reactions of several hydrofluorocarbons with OH and O(^{1}D) and their atmospheric lifetimes. *J. Phys. Chem.* **1993**, *97*, 8976-8982, doi:10.1021/j100137a023.
(2) Zhang, Z.; Saini, R. D.; Kurylo, M. J.; Huie, R. E. Rate constants for the reactions of the hydroxyl radical with $CHF_2CF_2CF_2CHF_2$ and $CF_3CHFCHFCF_2CF_3$. *Chem. Phys. Lett.* **1992**, *200*, 230-234, doi:10.1016/0009-2614(92)80003-T.

E34. OH + $CF_3CF_2CH_2CH_2CF_2CF_3$ (HFC-55-10mcff). The recommended value for *k*(298 K) is that reported by Nelson et al.[1] As expected, the rate constant is similar to that for OH + $CF_3CH_2CH_2CF_3$. Hence, the recommendation for *E*/R is estimated as being approximately the same as that for this reaction.
(Table: 02-25, Note: 02-25, Evaluated: 02-25) Back to Table

(1) Nelson, D. D.; Zahniser, M. S.; Kolb, C. E.; Magid, H. OH reaction kinetics and atmospheric lifetime estimates for several hydrofluorocarbons. *J. Phys. Chem.* **1995**, *99*, 16301-16306, doi:10.1021/j100044a016.

E35. OH + CH_2=CHF. The recommended values for *k*(298 K) and *E*/R are from the absolute study by Baasandorj et al.[1] Data from the relative rate study by Chen et al.[2] are in reasonable agreement with the recommendation but are significantly more scattered. Baasandorj et al. found the rate constant to be pressure independent between 20 and 600 Torr, indicating that the high-pressure limit was achieved at these pressures for the reaction of this fluorinated alkene. Since this is the simplest of the halogenated alkenes, it implies that the recommendations for all of the halogenated alkene reactions included in Table 1 represent the high-pressure limits for the rate constants. The results of Perry et al.[3] are ~10% larger at room temperature, with the agreement improving above room temperature. These data are encompassed within the recommended uncertainty.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

E36. OH + CH_2=CF_2. The recommended value for *k*(298 K) is an average of values derived from the absolute study by Baasandorj et al.[1] and the relative rate study by Chen et al.[2] The value recommended for *E*/R is derived from a combined fit to the data from Baasandorj et al. and Chen et al.[2] after scaling each data set to the recommended value for *k*(298 K). Baasandorj et al. found the rate constant to be pressure independent between 20 and 600 Torr, indicating that the high-pressure limit was achieved for the reaction of this fluorinated alkene. Howard[3] studied this reaction at lower pressures and found a smaller rate constant that increased with pressure between 0.7 Torr and 7 Torr. This dependence is consistent with the recommended high-pressure limit from Baasandorj et al.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

E37. OH + CHF=CF_2. The recommended value for *k*(298 K) is an average of the values derived from the results of relative rate study by Chen et al.,[2] (average of two measurements with n-pentane and cyclohexane as reference compounds) and the absolute rate constant measurements by Baasandorj and Burkholder[1] and

Tokuhashi et al.[3] The k(298 K) values derived from these individual studies differ from the recommended value by 2%, 7%, and 5%, respectively. The value for E/R was derived from a combined fit to the data from the same three studies after each data set was normalized to the recommended value of k(298 K).

E38. OH + CF_2=CF_2. The recommended value for k(298 K) is an average of the values determined in the studies of Acerboni et al.[1] (two relative rate determinations referenced to the rate constants for the reactions of OH with propene and cyclohexane) and the absolute rate studies of Orkin et al.[2] and Orkin et al.[3] The value for E/R is derived from a fit to the data of Orkin et al.[3] As discussed for the OH + CH_2=CHF reaction, the recommended rate constant represents the high-pressure limit for this reaction.
(Table: 02-25, Note: 10-6, Evaluated: 10-6) Back to Table

E39. OH + CH_2=$CHCH_2F$. The recommended values for both k(298 K) and E/R are derived from a fit to the data from the absolute study by Albaladejo et al.[1] Based on results obtained for other fluorinated alkenes the recommended rate constant represents the high-pressure limit for this reaction.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

(1) Albaladejo, J.; Ballesteros, B.; Jimenez, E.; Diaz de Mera, Y.; Martinez, E. Gas-phase OH radical-initiated oxidation of the 3-halopropenes studied by PLP-LIF in the temperature range 228-388 K. *Atmos. Environ.* **2003**, *37*, 2919-2926, doi:10.1016/S1352-2310(03)00297-8.

E40. OH + CH_2=$CHCF_3$. The recommended value for k(298 K) is an average of the values from the absolute rate constant measurements by Orkin et al.[2] and González et al.[1] The room temperature results from the two relative rate studies by Sulbaek Andersen et al.[3] (recalculated using the current recommendations for the reference reactions OH + C_2H_4 and OH + C_2H_2) are somewhat lower but are encompassed within the combined reported uncertainties. The recommended value for E/R is derived from a combined fit to the data from Orkin et al.[3] and González et al.[1] after scaling each data set to the recommended value for k(298 K). González et al. found the rate constant to be pressure independent between 50 and 650, Torr indicating that the recommended rate constant represents the high-pressure limit for this reaction.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

A: Chem.* **2005**, *176*, 124-128, doi:10.1016/j.jphotochem.2005.06.015.

E41. OH + CH_2=$CFCF_3$. The results of absolute reaction rate studies by Orkin et al.,[2] Papadimitriou et al.,[4] and Orkin et al.[3] agree to better than 3% over the entire common temperature range of measurements between 220 K to 370 K. The recommended Arrhenius parameters are derived from a combined fit at T ≤300 K to the data of Papadimitriou et al.[4] and Orkin et al.,[3] which supersedes Orkin et al.[2] and has higher reported accuracy. The two relative rate determinations at 298 K by Nielsen et al.[1] (recalculated using the current rate constant recommendations for the reference reactions OH + C_2H_4 and OH + C_2H_2) lie outside the 95% uncertainty band assigned to k(298 K). Papadimitriou et al.[4] found the rate constant to be pressure independent between 25 and 600 Torr and Orkin et al.[3] found the rate constant to be pressure independent between 30 and 300 Torr, indicating that the high-pressure limit is achieved for this reaction. The data at above room temperature exhibit slight curvature in the Arrhenius plot.
(Table: 10-6, Note: 15-10, Evaluated: 10-6) Back to Table

(2) Orkin, V. L.; Huie, R. E.; Kurylo, M. J. Rate constants for the reactions of OH with HFC-245cb ($CH_3CF_2CF_3$) and some fluoroalkenes (CH_2CHCF_3, CH_2CFCF_3, CF_2CFCF_3, and CF_2CF_2). *J. Phys. Chem. A* **1997**, *101*, 9118-9124, doi:10.1021/jp971994r.
(3) Orkin, V. L.; Martynova, L. E.; Ilichev, A. N. High-accuracy measurements of OH reaction rate constants and IR absorption spectra: CH_2=CF-CF_3 and *trans*-CHF=CH-CF_3. *J. Phys. Chem. A* **2010**, *114*, 5967-5979, doi:10.1021/jp9092817.
(4) Papadimitriou, V. C.; Talukdar, R. K.; Portmann, R. W.; Ravishankara, A. R.; Burkholder, J. B. CF_3CF=CH_2 and (Z)-CF_3CF=CHF: temperature dependent OH rate coefficients and global warming potentials. *Phys. Chem. Chem. Phys.* **2008**, *10*, 808-820, doi:10.1039/b714382f.

E42. OH + (E)-CHF=$CHCF_3$. The data obtained by Orkin et al.[1] exhibit a very weak temperature dependence and curvature in the Arrhenius plot between 370 K and 220 K. The recommended values for both *k*(298 K) and *E*/R are derived from a fit to the data of Orkin et al. at T ≤300 K. Orkin et al. found the rate constant to be pressure independent between 30 and 200 Torr, indicating that the high-pressure limit is achieved for this reaction. Results of relative rate measurements reported by Zhang et al.[3] are in good agreement with the absolute data of Orkin et al. when C_5H_{10} was used as a reference compound. However, their results obtained with C_4H_{10} as a reference compound are in good agreement with Orkin et al. above 280 K whereas the data below 270 K are noticeably lower. The two relative rate determinations at 298 K by Sondergaard et al.[2] (recalculated using the current recommendations for the rate constants of the reference reactions OH + C_2H_4 and OH + C_2H_2) lie about 20% higher than the recommended value. The data over the temperature range from 220 K to 370 K can be better represented by the three-parameter expression from Orkin et al.:

$$k(\mathrm{T}) = 1.12 \times 10^{-13}\ (\mathrm{T}/298)^{2.03}\ \exp(+552/\mathrm{T})$$

E43. OH + (*Z*)-CHF=$CHCF_3$. The recommended value for *k*(298 K) is an average of the values derived from two sets of relative rate measurements between 253 K and 328 K reported by Zhang et al.[2] (using n-butane and n-pentane as reference compounds). The value for *E*/R was derived from a combined fit to the two data sets after each one was normalized to the recommended value of *k*(298 K). Results of relative rate study of Nilsson et al.[1] at 296 K, recalculated using the current recommendations for the rate constants of the reference reactions OH + C_2H_4 and OH + C_2H_2, are 20–30% lower. The recommended uncertainty was chosen to encompass these results. The data reported by Zhang et al.[2] were preferred for deriving recommendations because their results for another isomer, (*E*)-CHF=$CHCF_3$, reported in the same paper are in good agreement with the available results of absolute measurements.

Atmospheric chemistry of *cis*-$CF_3CH=CHF$: Kinetics of reactions with OH radicals and O_3 and products of OH radical initiated oxidation. *Chem. Phys. Lett.* **2009**, *473*, 233–237, doi:10.1016/j.cplett.2009.03.076.
(2) Zhang, N.; Chen, L.; Mizukado, J.; Quan, H.; Suda, H. Rate constants for the gas-phase reactions of (*Z*)-$CF_3CH=CHF$ and (*E*)-$CF_3CH=CHF$ with OH radicals at 253–328 K. *Chem. Phys. Lett.* **2015**, *621*, 78–84, doi:10.1016/j.cplett.2014.12.044.

E44. OH + (E)-CHF=CFCF$_3$. The recommended value for *k*(298 K) is an average of the two relative rate determinations by Hurley et al.,[1] recalculated using the current recommendations for the rate constants of the reference reactions OH + C_2H_4 and OH + C_2H_2. The value for *E*/R is estimated from that for similar fluorinated propenes. Based on the results obtained for other fluorinated alkenes, the recommended rate constant represents the high-pressure limit for this reaction.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

(1) Hurley, M. D.; Ball, J. C.; Wallington, T. J. Atmospheric chemistry of the Z and E isomers of $CF_3CF=CHF$; Kinetics, mechanisms, and products of gas-phase reactions with Cl atoms, OH radicals, and O_3. *J. Phys. Chem. A* **2007**, *111*, 9789-9795, doi:10.1021/jp0753530.

E45. OH + (Z)-CHF=CFCF$_3$. The recommended value for *k*(298 K) is from Papadimitriou et al.[2] who found the rate constant to be pressure independent between 25 and 600 Torr, indicating that the high-pressure limit is achieved for this reaction. The two room temperature values from the relative rate studies by Hurley et al.[1] are in very good agreement with this recommendation. Papadimitriou et al.[2] found weak curvature in the Arrhenius plot from 206 K to 380 K. Thus, the recommended value for *E*/R is derived from a fit to their data at T ≤300 K. The data over the temperature range from 206 K to 380 K can be represented by the three-parameter expression obtained from the fit to the data reported by Papadimitriou et al.

$$k(\mathrm{T}) = 1.55 \times 10^{-13}\ (\mathrm{T}/298)^{1.92}\ \exp(+633/\mathrm{T})$$

(Table: 10-6, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Hurley, M. D.; Ball, J. C.; Wallington, T. J. Atmospheric chemistry of the Z and E isomers of $CF_3CF=CHF$; Kinetics, mechanisms, and products of gas-phase reactions with Cl atoms, OH radicals, and O_3. *J. Phys. Chem. A* **2007**, *111*, 9789-9795, doi:10.1021/jp0753530.
(2) Papadimitriou, V. C.; Talukdar, R. K.; Portmann, R. W.; Ravishankara, A. R.; Burkholder, J. B. $CF_3CF=CH_2$ and (Z)-$CF_3CF=CHF$: temperature dependent OH rate coefficients and global warming potentials. *Phys. Chem. Chem. Phys.* **2008**, *10*, 808-820, doi:10.1039/b714382f.

E46. OH + CF$_2$=CFCF$_3$. The recommended value for *k*(298 K) is an average of the values reported in the absolute rate constant investigations by McIlroy and Tully,[3] Orkin et al.,[4] Orkin et al.,[5] and Tokuhashi et al.[6] (two studies) and in the relative rate study by Mashino et al.[2] (using two different reference gases). All of these individual *k*(298 K) values are in excellent agreement and lie within 3% of the recommended value. Results of the room temperature relative rate study by Acerboni et al.[1] are internally inconsistent and exceed the recommended value by ~12% and ~60% when C_2H_4 and C_3H_6, respectively, were used as reference compounds. Although the first value overlaps the recommended *k*(298 K) within the reported uncertainty, the reason for the large difference when C_3H_6 was used as the reference compound is not clear, especially since the result for OH + C_2F_4 reported by the same group using the same reference reaction is in good agreement with other available data. The recommended value for *E*/R is derived from a fit of the data of Orkin et al.[5] at T ≤300 K. Based on results obtained for other fluorinated alkenes, the recommended rate constant represents the high-pressure limit for this reaction. The complete data set of Orkin et al.[5] between 230–480 K exhibits pronounced curvature in the Arrhenius plot and can be best fit by the three-parameter expression:

$$k(\mathrm{T}) = 9.75 \times 10^{-14}\ (\mathrm{T}/298)^{1.94}\ \exp(+922/\mathrm{T})$$

This expression encompasses all data from the studies used in deriving the recommendation within an *f*(T) factor of 1.05 between 230 K to 480 K.

(5) Orkin, V. L.; Poskrebyshev, G. A.; Kurylo, M. J. Rate constants for the reactions between OH and perfluorinated alkenes. *J. Phys. Chem. A* **2011**, *115*, 6568-6574, doi:10.1021/jp201663j.

(6) Tokuhashi, K.; Takahashi, A.; Kaise, M.; Kondo, S.; Sekiya, A.; Fujimoto, E. Rate constants for the reactions of OH radicals with CF_3OCF=CF_2 and CF_3CF=CF_2. *Chem. Phys. Lett.* **2000**, *325*, 189-195, doi:10.1016/S0009-2614(00)00626-6.

E47. OH + CF_2=CF-O-CF_3. The recommended values for k(298 K) and E/R were derived from a fit to the data of Tokuhashi et al.[3] This recommendation is reasonably consistent with that for the similar reaction of OH with CF_2=$CFCF_3$, which was studied by several groups including Tokuhashi et al. Results of the relative rate study of Mashino et al.[2] at 296 K, recalculated using the current recommendations for the rate constants of the reference reactions OH + C_2H_4 and C_2H_2, are 32% lower. Results of the absolute study between 253 K and 348 K reported by Li et al.[1] exhibit an opposite temperature dependence of the rate constant with E/R = +870 K. Such behavior is inconsistent with recommended parameters of the similar reaction, OH + CF_2=$CFCF_3$, and other fast reactions of fluorinated alkenes, all of which exhibit a weak negative temperature dependence at room temperature and below, i.e., E/R <0.

(3) Tokuhashi, K.; Takahashi, A.; Kaise, M.; Kondo, S.; Sekiya, A.; Fujimoto, E. Rate constants for the reactions of OH radicals with CF_3OCF=CF_2 and CF_3CF=CF_2. *Chem. Phys. Lett.* **2000**, *325*, 189-195, doi:10.1016/S0009-2614(00)00626-6.

E48. OH + CF_2=CFCF=CF_2. Only two relative rate studies of this reaction near room temperature have been conducted. There is approximately a 25-30% difference between the results from these studies using different reference compounds and approximately the same difference between the results when the same reference compound, C_2H_4, was used. Thus, the recommended value for k(298 K) is an average of all values determined in the relative rate studies of Acerboni et al.[1] (using ethene, propene, and cyclohexane as reference compounds) and of Wallington and Hurley[2] (using ethene and acetylene as reference compounds). The current recommendations for the rate constants of the reactions of OH with reference compounds were used to recalculate the results of each of the relative rate measurements. The recommended value for E/R is estimated as being approximately the same as that for OH + CF_2=CF_2.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

E49. OH + CH_2=$CHCF_2CF_3$. The recommended value for k(298 K) is an average of the two relative rate study results by Sulbaek Andersen et al.,[1] which were recalculated using the current rate constant recommendations for the reference reactions OH + C_2H_4 and OH + C_2H_2. The recommended value for E/R is estimated as being the same as that for OH + CH_2=$CHCF_3$. Sulbaek Andersen et al. determined the rate constants at T = 296 K for OH reactions with CH_2=CHC_xF_{2x+1} (for x=1,2,4,6,8), and the recommendation given here covers all of these compounds. Based on results obtained for other fluorinated alkenes, the recommended rate constant represents the high-pressure limit for this reaction.

and 8): Kinetics of gas-phase reactions with Cl atoms, OH radicals, and O_3. *J. Photochem. Photobiol. A: Chem.* **2005**, *176*, 124-128, doi:10.1016/j.jphotochem.2005.06.015.

E50. OH + (E)-$CF_3CH=CHCF_3$. The recommended values for *k*(298 K) and *E*/R were derived from a fit to the data between 211 K and 373 K reported by Baasandorj et al.[1] The result of relative rate study at 296 K reported by Østerstrøm et al.[2] is 18% larger than the recommended value when C_3H_8 was used as a reference compound, but 50% larger when C_2H_6 was used as the reference compound.
(Table: 19-5, Note: 19-5, Evaluated: 19-5) Back to Table

(1) Baasandorj, M.; Marshall, P.; Waterland, R. L.; Ravishankara, A. R.; Burkholder, J. B. Rate coefficient measurements and theoretical analysis of the OH + (*E*)-$CF_3CH=CHCF_3$ reaction. *J. Phys. Chem. A* **2018**, *122*, 4635–4646, doi:10.1021/acs.jpca.8b02771.
(2) Østerstrøm, F. F.; Andersen, S. T.; Sølling, T. I.; Nielsen, O. J.; Andersen, M. P. S. Atmospheric chemistry of *Z*- and *E*-$CF_3CH=CHCF_3$. *Phys. Chem. Chem. Phys.* **2017**, *19*, 735–750, doi:10.1039/c6cp07234h.

E51. OH + (*Z*)-$CF_3CH=CHCF_3$. The recommended values for both *k*(298 K) and *E*/R are derived from a fit to the data below 300 K of Baasandorj et al.[1] The complete data set of Baasandorj et al. between 212–374 K exhibits pronounced curvature in the Arrhenius plot and can be best fit by the three-parameter expression:

$$k(\mathrm{T}) = 3.68 \times 10^{-14}\ (\mathrm{T}/298)^{2.33}\ \exp(+774/\mathrm{T})$$

The results of the 296 K relative rate study by Østerstrøm et al.[2] are 10% and 16% smaller and overlap the recommended value within reported uncertainties when C_2H_6 and C_3H_8 were used as reference compounds respectively.
(Table: 15-10, Note: 19-5, Evaluated: 19-5) Back to Table

(1) Baasandorj, M.; Ravishankara, A. R.; Burkholder, J. B. Atmospheric chemistry of (*Z*)-$CF_3CH=CHCF_3$: OH radical reaction rate coefficient and global warming potential. *J. Phys. Chem. A* **2011**, *115*, 10539-10549, doi:10.1021/jp206195g.
(2) Østerstrøm, F. F.; Andersen, S. T.; Sølling, T. I.; Nielsen, O. J.; Andersen, M. P. S. Atmospheric chemistry of *Z*- and *E*-$CF_3CH=CHCF_3$. *Phys. Chem. Chem. Phys.* **2017**, *19*, 735–750, doi:10.1039/c6cp07234h.

E52. OH + (*E*)-$CF_3CF=CFCF_3$. The data reported by Orkin et al.[2] for this individual isomer exhibit curvature in the Arrhenius plot. The recommended values for both *k*(298 K) and *E*/R are derived from a fit to the data of Orkin et al.[2] at T <300 K, the only temperature range where these recommended Arrhenius parameters should be used. The data over the broader temperature range from 230 K to 370 K can be represented by the three-parameter expression obtained from the fit to the data reported by Orkin et al.:[2]

$$k(\mathrm{T}) = 7.5 \times 10^{-14}\ (\mathrm{T}/298)^{1.68}\ \exp(+612/\mathrm{T})$$

Cometto et al.[1] and Young et al.[3] studied the reaction of OH with the industrial mixture of the two isomers, *(E)*-octafluoro-2-butene and *(Z)*-octafluoro-2-butene, at room temperature using a relative rate technique. They reported rate constants that are 35% and 25% lower than the recommended value, respectively, without including uncertainties in the reference rate constants. Orkin et al.[2] separated and analyzed the individual isomer abundance to find that the industrial mixture contains ~71% of the more reactive *(E)*-octafluoro-2-butene and ~ 29% of the less reactive *(Z)*-octafluoro-2-butene. Therefore, the result reported by Young et al. is in quantitative agreement with that calculated for such a mixture using the individual isomer rate constants of Orkin et al.[2] The result reported by Cometto et al. appears too low for such a mixture based on the values recommended here.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

(2) Orkin, V. L.; Poskrebyshev, G. A.; Kurylo, M. J. Rate constants for the reactions between OH and perfluorinated alkenes. *J. Phys. Chem. A* **2011**, *115*, 6568-6574, doi:10.1021/jp201663j.
(3) Young, C. J.; Hurley, M. D.; Wallington, T. J.; Mabury, S. A. Atmospheric chemistry of perfluorobutenes ($CF_3CF=CFCF_3$ and $CF_3CF_2CF=CF_2$): Kinetics and mechanisms of reactions with OH radicals and chlorine atoms, IR spectra, global warming potentials, and oxidation to perfluorocarboxylic acids. *Atmos. Environ.* **2009**, *43*, 3717-3724, doi:10.1016/j.atmosenv.2009.04.025.

E53. OH + (*Z*)-$CF_3CF{=}CFCF_3$. The data reported by Orkin et al.[2] for this individual isomer exhibit a weak temperature dependence and curvature in the Arrhenius plot. The recommended values for both $k(298\ K)$ and E/R are derived from a fit to the data of Orkin et al.[2] at $T < 300$ K, the only temperature range where these recommended Arrhenius parameters should be used. The data over the broader temperature range from 230 K to 370 K can be represented by the three-parameter expression obtained from the fit to the data reported by Orkin et al.:

$$k(T) = 3.0 \times 10^{-14}\ (T/298)^{2.61}\ \exp(+760/T)$$

Cometto et al.[1] and Young et al.[3] studied the reaction of OH with the industrial mixture of the two isomers, *(E)*-octafluoro-2-butene and *(Z)*-octafluoro-2-butene, at room temperature using a relative rate technique. Orkin et al.[2] separated and analyzed the individual isomer abundance to find that the industrial mixture contains ~29% of the less reactive *(Z)*-octafluoro-2-butene and ~71% of the more reactive *(E)*-octafluoro-2-butene. The rate constant reported by Young et al. agrees with that calculated for such a mixture using the individual isomer rate constants measured by Orkin et al. within the total combined uncertainty. The result reported by Cometto et al. appears too low for such a mixture based on the values recommended here.

Environ.* **2009**, *43*, 3717-3724, doi:10.1016/j.atmosenv.2009.04.025.

E54. OH + $CF_2{=}CFCF_2CF_3$. The recommended value for $k(298\ K)$ is an average of two relative rate study results at 296 K reported by Young et al.,[1] recalculated using the current recommendations for the rate constants of the reference reactions OH + C_2H_4 and OH + C_2H_2. These recalculated values differ from each other by 13%. The value for E/R is estimated to be the same as that for OH + $CF_2{=}CFCF_3$ and the uncertainty was chosen to encompass the recommended rate constants for this similar reaction.

E58. **OH + *cyclo*-CH=CHCF$_2$CF$_2$CF$_2$-.** The recommended values for *k*(298 K) and *E*/R were derived from a combined fit to the data from Guo et al.,[1] a relative rate study with C_3H_8 and CH_3CHFCH_3 as reference compounds. The reported *k*(298 K) values from this study agree within 3%.

(Table: 19-5, Note: 19-5, Evaluated: 19-5) Back to Table

(1) Guo, Q.; Zhang, N.; Uchimaru, T.; Chen, L.; Quana, H.; Mizukado, J. Atmospheric chemistry of cyc-CF$_2$CF$_2$CF$_2$CH=CH-: Kinetics, products, and mechanism of gas-phase reaction with OH radicals, and atmospheric implications. *Atmos. Environ.* **2018**, *179*, 69–75, doi:10.1016/j.atmosenv.2018.02.005.

E59. **OH + *cyclo*-CF=CFCF$_2$CF$_2$CF$_2$-.** The recommended value for *k*(298 K) is an average of results derived from a relative rate study by Zhang et al.[2] recalculated using the current recommendations for the rate constants of the reference reactions OH + CH_2F_2 and OH + CH_3F. The reported *k*(298 K) values from this study agree within 2%. In another relative rate study at 296 K, Wallington and Hurley[1] reported a rate constant, which is inexplicably larger by a factor of 2.4. The recommended value for *E*/R was derived from a combined fit to the recalculated data of Zhang et al.

(Table: 19-5, Note: 19-5, Evaluated: 19-5) Back to Table

(2) Zhang, N.; Uchimaru, T.; Guo, Q.; Qing, F.; Chen, L.; Mizukado, J. Atmospheric chemistry of perfluorocyclopentene (cyc-CF$_2$CF$_2$CF$_2$CF=CF-): Kinetics, products, and mechanism of gas-phase reaction with OH radicals, and atmospheric implications. *Atmos. Environ.* **2017**, *160*, 46–54, doi:10.1016/j.atmosenv.2017.04.012.

E60. **OH + (*E*)-CHF=CHCF(CF$_3$)$_2$.** The reaction was studied by Papadimitriou and Burkholder[1] using an absolute technique between 214 and 380 K and a relative rate technique at 296 K with two reference compounds, CH_3CH_2F and CH_2=CFCF$_3$. The data exhibit a noticeable curvature in the Arrhenius plot. The recommended value for *k*(298 K) is an average of results derived from all three measurements, which agree with the recommended value within 3%. The recommended value of *E*/R was derived from a fit to the data between 214 and 296 K, a range over which the rate constant is essentially temperature independent. The data over the broader temperature range from 214 to 380 K can be represented by the three-parameter expression derived from the data after scaling to the recommended *k*(298 K):

$$k(\mathrm{T}) = 5.44 \times 10^{-14}\ (\mathrm{T}/298)^{2.17} \exp(+528/\mathrm{T})$$

(Table: 19-5, Note: 19-5, Evaluated: 19-5) Back to Table

(1) Papadimitriou, V. C.; Burkholder, J. B. OH radical reaction rate coefficients, infrared spectrum, and global warming potential of (CF$_3$)$_2$CFCH=CHF (HFO-1438ezy(*E*)). *J. Phys. Chem. A* **2016**, *120*, 6618–6628, doi:10.1021/acs.jpca.6b06096.

E61. **OH + (CF$_3$)$_2$C=CFCF$_2$CF$_3$.** The rate constant reported by Orkin et al.[2] decreases with decreasing temperature and exhibits pronounced curvature in the Arrhenius plot between 250 K and 370 K. The recommended values for both *k*(298 K) and *E*/R are derived from a fit to the data of Orkin et al. between ~300 K and 250 K, the temperature region where the rate constant reached a minimum and became essentially temperature independent. The data over the complete temperature range from 370 K to 250 K can be represented by the three-parameter expression reported by Orkin et al.

$$k(T) = 2.17 \times 10^{-15} (T/298)^{3.90} \exp(+1044/T)$$

The uncertainty parameters were chosen to encompass the possible increase of the rate constant at lower temperatures (below 250 K) following this three-parameter expression. Jubb et al.[1] measured the rate constant ratio for $CH_3OC_7F_{13}$ to both $(CF_3)_2C{=}CFCF_2CF_3$ and (Z)-$CF_3CH{=}CHCF_3$ at 298 K, thereby enabling calculation of a room temperature rate constant for $(CF_3)_2C{=}CFCF_2CF_3$ from the current k(298 K) recommendation for (Z)-$CF_3CH{=}CHCF_3$. The resulting value is in excellent agreement with that recommended here.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Jubb, A. M.; Gierczak, T.; Baasandorj, M.; Waterland, R. L.; Burkholder, J. B. Methyl-perfluoroheptene-ethers ($CH_3OC_7F_{13}$): Measured OH radical reaction rate coefficients for several isomers and enantiomers and their atmospheric lifetimes and global warming potentials. *Environ. E62. **OH + CF_3OH.** There are no measurements of the rate coefficient of this reaction. The recommendation is based on the recommended limit for the reverse reaction rate coefficient and an estimated equilibrium constant. The thermochemistry of CF_3O and CF_3OH are taken from *ab initio* calculations (Montgomery et al.[2] and Schneider and Wallington[3]) and laboratory measurements (Huey et al.[1]) to estimate $\Delta G°_{298}(OH + CF_3OH \rightarrow CF_3O + H_2O)$ to be about (2 ± 4) kcal mol^{-1}. In considering the large uncertainty in the free energy change, the estimated rate coefficient limit is based on the assumption that the reaction is approximately thermoneutral.
(Table: 97-4, Note: 97-4, Evaluated: 97-4) Back to Table

E63. **OH + CH_2FCH_2OH.** The recommended values for k(298 K) and E/R are averages of the parameters derived from fits to the data of Rajakumar et al.[2] and Orkin et al.[1] for T <300 K with the former data corrected for an apparent error in the UV absorption cross section of CH_2FCH_2OH (which was used to determine the reactant concentration). When this correction is made, the data from these two studies are indistinguishable. The room temperature rate constant determined in the relative rate study of Sellevåg et al.[3] is about 50% greater than that recommended. The data over the temperature range 230 K to 370 K from both Rajakumar et al.[2] and Orkin et al.[1] exhibit curvature in the Arrhenius plot (more evident in the higher precision data from the latter study) and can be represented by the three-parameter expression reported by Orkin et al.:

$$k(T) = 3.47 \times 10^{-14} (T/298)^{4.5} \exp(+977/T)$$

(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

Environ.* **2004**, *38*, 6725-6735, doi:10.1016/j.atmosenv.2004.09.023.

E64. **OH + CHF_2CH_2OH.** The recommended value of k(298 K) is an average of the values reported in the absolute rate studies of Kovacs et al.[1] and Orkin et al.[2] The value of E/R is derived from a fit at T ≤300 K to the data of Orkin et al.,[2] which are the only temperature dependent data available. The room temperature rate constant determined in the relative rate study of Sellevåg et al.[3] is about 80% greater than that recommended. The data over the temperature range from 220 K to 370 K exhibit a curvature in the Arrhenius plot and can be represented by the three-parameter expression that is derived from a fit to the data of Orkin et al.[2] over the temperature range from 220 K to 370 K after the data were scaled to match the recommended value of k(298 K):

$$k(T) = 3.73 \times 10^{-14} (T/298)^{4.25} \exp(+578/T)$$

(Table: 10-6, Note: 15-10, Evaluated: 10-6) Back to Table

Environ.* **2004**, *38*, 6725-6735, doi:10.1016/j.atmosenv.2004.09.023.

E65. OH + CF_3CH_2OH. The recommended value for *k*(298 K) is an average of the values reported in the absolute rate studies of Wallington et al.,[6] Tokuhashi et al.[5] (two determinations), Kovacs et al.,[2] and Orkin et al.,[3] and the relative rate study of Hurley et al.[1] (using OH + C_2H_2 as the reference reaction). The value of *k*(298 K) reported by Sellevåg et al.[4] is significantly larger than those from all of the other studies and was not used in deriving the recommended value. The recommended value for *E*/R is an average of the values derived from fits to the data below 300 K of Tokuhashi et al.[5] and Orkin et al.[3] The data over the temperature range from 220 K to 370 K exhibit a curvature in the Arrhenius plot and can be represented by the three-parameter expression derived from a fit to the data of Orkin et al.[3] after the data were scaled to match the recommended *k*(298 K):

$$k(T) = 2.57 \times 10^{-14} (T/298)^{4.0} \exp(+405/T)$$

(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

E66. OH + $CF_3CH_2CH_2OH$. The recommended value of *k*(298 K) is an average of all available results: absolute rate constant studies reported by Kelly et al.,[4] Jimenez et al.,[3] Antiñolo et al.[1] and relative rate studies reported by Kelly et al. (average of three measurements) and Hurley et al.[2] (average of two measurements). The temperature dependence was studied by Antiñolo et al. The scatter in their temperature dependent data is too large to allow a reliable determination of *E*/R. Hence, the recommended value of *E*/R was estimated to be the same as that for the similar reaction of OH with CH_2FCH_2OH. The recommended uncertainty factor, *f*(298 K), assigned to represent the scatter of the room temperature data, adequately represents the uncertainty over the entire temperature range of atmospheric interest.
(Table: 19-5, Note: 19-5, Evaluated: 19-5) Back to Table

A* **2005**, *109*, 347–355, doi:10.1021/jp0467402.

E67. OH + $CF_3CF_2CH_2OH$. The recommended value for *k*(298 K) is an average of the values derived from the data of Tokuhashi et al.[4] (discharge flow and pulsed photolysis absolute rate studies) and from the relative rate studies of Chen et al.[2] (recalculated based on the current recommendation for the rate constant for the OH + CH_2Cl_2 reference reaction) and Hurley et al.[3] (recalculated based on the current recommendation for the rate constant for the OH + C_2H_2 reaction). The recommended value for *E*/R is derived from the combined fit to the temperature dependent data of Tokuhashi et al.[4] (T <400 K) and Chen et al.[2] after scaling each data set to the recommended value of *k*(298 K). The data reported by Antiñolo et al.[1] are scattered, as in the case of their OH + $CF_3CH_2CH_2OH$ reaction data, and exceed the recommendation by 20%. Hence, these data were not used in deriving the recommendation.
(Table: 10-6, Note: 19-5, Evaluated: 15-10) Back to Table

(1) Antiñolo, M.; González, S.; Ballesteros, B.; Albaladejo, J.; Jiménez, E. Laboratory studies of $CHF_2CF_2CH_2OH$ and $CF_3CF_2CH_2OH$: UV and IR absorption cross sections and OH rate coefficients between 263 and 358 K. *J. Phys. Chem. A* **2012**, *116*, 6041–6050, doi:10.1021/jp2111633.

E68. OH + $(CF_3)_2CHOH$. The results of the absolute measurements reported by Tokuhashi et al.[2] (three determinations) and Orkin et al.[1] are in excellent agreement over the common temperature range of the measurements. The recommended *k*(298 K) is the same value obtained in both studies. The data from Orkin et al.[1] exhibit a noticeable curvature in the Arrhenius plot between 220 K and 370 K, which is most pronounced at lower temperatures. Because of this curvature, the recommended value for *E*/R is derived from a fit to the data from both studies only between 298 K and 250 K. The data over the temperature range from 220 K to 370 K can be represented by the three-parameter expression that is derived from a fit to the data of Orkin et al.:[1]

$$k(\mathrm{T}) = 5.7 \times 10^{-16}\ (\mathrm{T}/298)^{6.65}\ \exp(+1125/\mathrm{T})$$

The *g*-factor is set to encompass the low temperature extrapolation of both the recommended two-parameter Arrhenius expression and the three-parameter expression from Orkin et al.[1]

E69. OH + $CF_3CHFCF_2CH_2OH$. The recommended value of *k*(298 K) is an average of the values derived from the two relative rate studies of Chen et al.[1] (recalculated using the recommended rate constants for the reference reactions) and the two absolute rate studies of Chen et al.[1] The recommended value for *E*/R is derived from a fit to all of the data (for T <~300 K) from both the relative rate and absolute rate determinations after scaling each data set to the recommended *k*(298 K).

(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Chen, L.; Tokuhashi, K.; Kutsuna, S.; Sekiya, A.; Yonei, Y.; Yamamoto, A. Kinetic study of the gas-phase reaction of $CF_3CHFCF_2CH_2OH$ with OH radicals at 230–430 K. *Chem. Phys. Lett.* **2003**, *382*, 277-282, doi:10.1016/j.cplett.2003.09.162.

E70. OH + $CF_3CF_2CF_2CF_2CH_2OH$. The recommended value for *k*(298 K) is from the relative rate study of Hurley et al.[1] (recalculated using the current recommendation for the rate constant of the OH + C_2H_2 reference reaction). The recommended value for *E*/R is estimated as being the same as that for the reaction of OH with $CF_3CF_2CH_2OH$.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

(1) Hurley, M. D.; Wallington, T. J.; Sulbaek Andersen, M. P.; Ellis, D. A.; Martin, J. W.; Mabury, S. A. Atmospheric chemistry of fluorinated alcohols: Reaction with Cl atoms and OH radicals and atmospheric lifetimes. *J. Phys. Chem. A* **2004**, *108*, 1973, doi:10.1021/jp0373088.

E71. OH + CH_3OCHF_2 (HFE-152a). The recommended Arrhenius parameters are derived from a fit to the data of Orkin et al.[1]
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Orkin, V. L.; Khamaganov, V. G.; Guschin, A. G. Photochemical properties of hydrofluoroethers CH_3OCHF_2, CH_3OCF_3, and $CHF_2OCH_2CF_3$: Reactivity toward OH, IR absorption cross sections, atmospheric lifetimes, and global warming potentials. *J. Phys. Chem. A* **2014**, *118*, 10770-10777, doi:10.1021/jp506377w.

E72. OH + CH_3OCF_3 (HFE-143a). The recommended value for *k*(298 K) is an average of the values derived in the studies of Orkin et al.,[3] Hsu and DeMore[2] (two relative rate determinations that have been recalculated based on the current recommendations for the rate constants of the OH + CH_3CHF_2 and OH + CH_2F_2 reference reactions), and Chen et al.[1] (two relative rate determinations that have been recalculated based on the current recommendations for the rate constants of the OH + CH_4 and OH + CH_3CCl_3 reference reactions). The recalculation procedure for relative rate measurements referenced to the OH + CH_3CHF_2 reaction is discussed in the note for that reaction. The room temperature result of Zhang et al.[4] was not used in the derivation since it is significantly higher than the values of the other studies and was likely influenced by the presence of reactive impurities. The recommended value for *E*/R is derived from a fit to the data from Orkin et al.,[3] Hsu and DeMore,[2] and Chen et al.[1] (for T <400 K) after scaling each data set to the recommended *k*(298 K).

E73. OH + CHF_2OCHF_2 (HFE-134). The recommended value of *k*(298 K) is an average of the values derived in the relative rate studies of Hsu and DeMore[2] (recalculated using the current recommendation for the rate constant of the OH + CH_3CCl_3 reference reaction) and of Wilson et al.[4] (recalculated using the current recommendation for the rate constant of the OH + CHF_2CF_3 reference reaction) and the absolute rate study of Orkin et al.[3] The recommended value for *E*/R is derived from a combined fit to the data from these three studies after scaling each data set to the recommended value of *k*(298 K). The more scattered data of Garland et al.[1] were not used in derivation of the recommended value.

E74. OH + CHF_2OCF_3 (HFE-125). The recommended Arrhenius parameters are based on results of the relative rate study of Hsu and DeMore[1] (recalculated using the current recommendation for the rate constant of the OH + CHF_3 reference reaction). Additional measurements by Hsu and DeMore[1] relative to OH + CHF_2CF_3 and OH + CH_4 are encompassed well within the 2σ uncertainty limits, but were not used for assigning the recommended rate expression due to the large differences in reactivity between the two reference species and the target molecule. The room temperature result of Zhang et al.[2] lies significantly higher than the recommended value, possibly due to the presence of reactive impurities in the sample.
(Table: 02-25, Note: 02-25, Evaluated: 02-25) Back to Table

(1) Hsu, K. J.; DeMore, W. B. Temperature-dependent rate constants and substituent effects for the reactions of hydroxyl radicals with three partially fluorinated ethers. *J. Phys. Chem.* **1995**, *99*, 11141-11930, doi:10.1021/j100028a014.

E75. OH + $CH_3OCHFCF_3$. The recommended value for *k*(298 K) is an average of values derived from two relative rate determinations by Chen et al.[1] (recalculated using the current recommendations for the rate constants of the reference reactions OH + C_2H_6 and OH + CH_3CHF_2). The recommended *E*/R is derived from a fit to these data after scaling each individual data set to the recommended *k*(298 K).

(1) Chen, L.; Kutsuna, S.; Tokuhashi, K.; Sekiya, A. Kinetics and mechanisms of $CF_3CHFOCH_3$, $CF_3CHFOC(O)H$, and $FC(O)OCH_3$ reactions with OH radicals. *J. Phys. Chem. A* **2006**, *110*, 12845-12851, doi:10.1021/jp064917h.

E76. OH + $CH_2FOCH(CF_3)_2$ (Sevoflurane). The recommended value for *k*(298 K) is an average of the values from the two studies (one relative rate and one absolute) by Sulbaek Andersen et al.[3] The room temperature rate constants determined by Brown et al.[1] are approximately a factor of two higher than recommended here and may be indicative of impurity effects. The room temperature rate constant determined by Langbein et al.[2] is approximately 30% lower than recommended and is encompassed within the 95% confidence limits. The recommended value for *E*/R is derived from an Arrhenius fit to the data from the absolute rate constant measurements of Sulbaek Andersen et al.[3]
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

A* **2012**, *116*, 5806-5820, doi:10.1021/jp2077598.

E77. OH + $CH_3OCF_2CHF_2$. The recommended value for *k*(298 K) is an average of the values from the two absolute determinations by Tokuhashi et al.[2] using pulsed photolysis and discharge flow techniques. The recommended value for *E*/R is derived from a fit to the pulsed photolysis data below 400 K. A room temperature measurement by Heathfield et al.[1] is nearly an order of magnitude higher than recommended, which may be due to reactive impurities.

E79. OH + $CHF_2OCH_2CF_3$ (HFE-245fa2). The recommended value of *k*(298 K) is an average of the values reported in the absolute studies of Zhang et al.[3] and Orkin et al.[1] and in the relative rate study of Oyaro et al.[2] (recalculated using the current recommendations for the rate constants of the OH + CH_3CCl_3 and OH + CHF_2CH_2F reference reactions). The recommended value of E/R is derived from a fit to the data of Orkin et al.[1]

E80. OH + $CHF_2OCHFCF_3$ (Desflurane). The recommended value for *k*(298 K) is an average of the values obtained in the absolute rate studies of Langbein et al.[1] and Sulbaek Andersen et al.[3] The values of the room temperature rate constant determined in the two relative rate studies of Oyaro et al.[2] (relative to the reactions of OH with CH_3CCl_3 and CHF_2CH_2F) are approximately 50% greater than the recommended value. The recommendation for *E*/R is derived from a fit to the data of Sulbaek Andersen et al., which is the only study of the temperature dependence of this reaction.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

A* **2012**, *116*, 5806-5820, doi:10.1021/jp2077598.

E81. OH + $CHF_2OCF_2CHF_2$. The recommended value for *k*(298 K) is an average of the relative rate determinations of Chen et al.[1] (two studies that were recalculated using the current recommendations for the reference reactions of OH with $CH_3OCF_2CF_3$ and $CH_3OCF_2CF_2CF_3$) and Wilson et al.[2] (two studies that were recalculated using the current recommendations for the reference reactions of OH with HFC-134a and HFC-143a). The

recommended value for E/R is from a combined fit to the data of Chen et al.[1] and Wilson et al.[2] after each data set was scaled to the recommended value of k(298 K).

E83. OH + $CH_3OCF_2CF_2CF_3$. The recommended value for k(298 K) is an average of the values reported by Tokuhashi et al.[2] (two absolute measurement studies) and Ninomiya et al.[1] (two relative rate determinations, which have been recalculated based on the current recommendations for the rate constants of the OH + CH_4 and OH + CH_3Cl reference reactions). The recommended value for E/R is determined from a fit to the data (below 400 K) of Tokuhashi et al. The expression, as expected, is similar to those for the OH + CH_3OCF_3 and OH + $CH_3OCF_2CF_3$ reactions.
(Table: 02-25, Note: 02-25, Evaluated: 02-25) Back to Table

Kinet.* **1999**, *31*, 846-853, doi:10.1002/(SICI)1097-4601(1999)31:12<846::AID-KIN2>3.0.CO;2-4.

E84. OH + $CH_3OCH(CF_3)_2$ (HFE-356mm1). The recommendations are based on the relative rate data of Chen et al.[1] obtained between 253 K and 328 K (recalculated using the recommended values for the rate constants of the reference reactions) and the rate constants measured by Orkin et al.[2] between 230 K and 370 K by using an absolute technique. The recommended value for k(298 K) is an average of values from these three studies, which are in excellent agreement.

The data of Orkin et al. over the entire range of measurements exhibit a noticeable curvature in the Arrhenius plot. The recommended E/R is an average of the values derived from the two data sets of Chen et al. and the value derived from a fit to the data of Orkin et al. below 298 K. The data over the broader temperature range from 230 to 370 K can be represented by the three-parameter expression obtained from a fit to the Orkin et al. data after scaling to the recommended k(298 K):

$$k(\mathrm{T}) = 7.46 \times 10^{-14}\ (\mathrm{T}/298)^{2.99} \exp(+342/\mathrm{T})$$

Phys. Chem. A* **2017**, *121*, 5675–5680, doi:10.1021/acs.jpca.7b04256.

E85. OH + $CH_3OCF(CF_3)_2$. The recommendation for *k*(298 K) is an average of the values from the absolute measurements of Tokuhashi et al.[2] (three determinations) and Andersen et al.[1] The recommended value for *E*/R is derived from a fit to the temperature-dependent data of Tokuhashi et al.[2] below 400 K. The uncertainties, which were originally set to encompass the recommendations for the similar OH + CH_3OCF_3 and OH + $CH_3OCF_2CF_3$ reactions have been reduced slightly to account for the additional data point at 298 K.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

E86. OH + $CH_3OC_4F_9$. The recommended values for both *k*(298 K) and *E*/R were derived from the relative rate data reported by Chen et al.[3] who studied both isomers, *n*-$CH_3OC_4F_9$ and *iso*-$CH_3OC_4F_9$, using two reference reactions. The results obtained with different reference compounds agree to within 5% and no difference in the reactivity of the isomers was observed. The recommended *k*(298 K) and *E*/R are the average of values derived from all four measurements. Results of relative rate measurements reported by Wallington et al.[5] at 295 K (recalculated using the current recommendation for the rate constant of the OH + CH_3Cl reference reaction) are in good agreement with the recommendation. Measurements in the same study using OH + CH_4 as the reference reaction exhibit considerably more scatter. These latter authors also reported no difference in the reactivity of isomers. A relative rate study by Cavalli et al.[2] at 298 K yielded a rate constant about 60% lower than recommended and the results of a relative rate study by Oyaro and Nielsen[4] are 35% higher. The temperature dependent data reported by Bravo et al.,[1] are more than 60% higher and yield steeper temperature dependence.

The recommended value for *k*(298 K) is an average of the values from the two absolute determinations by Tokuhashi et al.[1] using pulsed photolysis and discharge flow techniques. The recommended value for *E*/R is derived from a fit to the pulsed photolysis data below 400 K.
(Table: 02-25, Note: 15-10, Evaluated: 02-25) Back to Table

(1) Tokuhashi, K.; Takahashi, A.; Kaise, M.; Kondo, S.; Sekiya, A.; Yamashita, S.; Ito, H. Rate constants for the reactions of OH radicals with $CH_3OCF_2CHF_2$, $CHF_2OCH_2CF_2CHF_2$, $CHF_2OCH_2CF_2CF_3$, and $CF_3CH_2OCF_2CHF_2$ over the temperature range 250-430 K. *J. Phys. Chem. A* **2000**, *104*, 1165-1170, doi:10.1021/jp991421+.

E89. OH + $CHF_2OCH(CF_3)_2$. The recommended value for *k*(298 K) is an average of the values from the two relative rate determinations by Wilson et al.,[1] recalculated using the current rate constant recommendations for the OH + HFC-134a and OH + HFC-143a reference reactions. The recommended value for *E*/R is derived from a combined fit to the data after scaling each data set to the recommended value for *k*(298 K).
(Table: 10-6, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Wilson, E. W., Jr.; Hamilton, W. A.; Mount, H. R.; DeMore, W. B. Rate constants for the reactions of hydroxyl radical with several fluoroethers by the relative rate method. *J. Phys. Chem. A* **2007**, *111*, 1610-1617, doi:10.1021/jp068355d.

E90. OH + $CH_3CH_2OCF_2CHF_2$. The recommended parameters are from a combined fit to the data obtained by Tokuhashi et al.[2] (three absolute determinations) below 400 K. A room temperature rate constant determined by Heathfield et al.[1] is about a factor of two greater than that recommended.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

(2) Tokuhashi, K.; Takahashi, A.; Kaise, M.; Kondo, S. Rate constants for the reactions of OH radicals with CH_3OCF_2CHFCl, CHF_2OCF_2CHFCl, $CHF_2OCHClCF_3$, and $CH_3CH_2OCF_2CHF_2$. *J. Geophys. Res.* **1999**, *104*, 18681-18688, doi:10.1029/1999JD900278.

E91. OH + $CF_3CH_2OCH_2CF_3$. The recommended value for *k*(298 K) is an average of the rate constants measured in the absolute study of Orkin et al.[1] and in the relative rate studies of Oyaro et al.[2] and Wilson et al.[3] (two determinations). The relative rate data were recalculated using the current rate constant recommendations for the OH reactions with the reference compounds ($CHCl_3$ for Oyaro et al.[2] and HFC-152a and HFC-161 for Wilson et al.[3]). The recommended value for *E*/R is an average of the values for this parameter derived from fits to the Orkin at al.[1] and Wilson et al.[3] data.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

E92. OH + $CF_3CH_2OCF_2CHF_2$ (HFE-347pcf2). The recommended value for *k*(298 K) is an average of the rate constants measured in the absolute study of Tokuhashi et al.[3] (three studies) and in the relative rate experiments of Chen et al.[1] (two studies relative to OH + CH_3CCl_3 and OH + CHF_2Cl) and of Wilson et al.[4] (two studies relative to OH + HFC-152a and OH + HFC-32). All results of the relative rate studies were recalculated using the current recommendations for the reference reactions. The recommended value of *E*/R is from a combined fit to the data from all three groups after scaling each data set to the recommended *k*(298 K). The room

temperature rate constant reported by Heathfield et al.[2] is about an order or magnitude greater than that from any of the other investigation and was not used to derive the recommendations given here.

E93. OH + $CF_3CHFCF_2OCH_2CF_2F_3$. The recommended value for both k(298 K) and E/R were derived from a combined fit to the data from the relative rate determinations by Chen et al.,[1] recalculated using the current recommendation for the rate constant of the OH reference reactions with $CH_3OC_2F_5$ and $CH_3OC_3F_7$.
(Table: 19-5, Note: 19-5, Evaluated: 19-5) Back to Table

(1) Chen, L.; Kutsuna, S.; Tokuhashi, K.; Sekiya, A. Kinetics study of the gas-phase reactions of $CHF_2CF_2OCHF_2$ and $CF_3CHFCF_2OCH_2CF_2CF_3$ with OH radicals at 253-328 K. *Chem. Phys. Lett.* **2005**, *403*, 180-184, doi:10.1016/j.cplett.2005.01.002.

E94. OH + $CHF_2OCF_2OCHF_2$. The recommended value for k(298 K) is from the relative rate study by Cavalli et al.,[1] recalculated using the current recommendation for the rate constant of the reference reaction OH + CH_4. The value for k(298 K) is identical to that for OH + CHF_2OCHF_2, which might be expected to have a slightly higher rate constant. The value for E/R is estimated as being similar to that for the reaction of OH with CHF_2OCHF_2.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

(1) Cavalli, F.; Glasius, M.; Hjorth, J.; Rindone, B.; Jensen, N. R. Atmospheric lifetimes, infrared spectra and degradation products of a series of hydrofluoroethers. *Atmos. Environ.* **1998**, *32*, 3767-3773, doi:10.1016/S1352-2310(98)00106-X.

E95. OH + $CHF_2OCF_2CF_2OCHF_2$. The recommended value for k(298 K) is from the relative rate study by Cavalli et al.,[1] recalculated using the current recommendation for the rate constant of the reference reaction OH + CH_4. However, the value for k(298 K) is a factor of two greater than that measured in the same study for OH + $CHF_2OCF_2OCHF_2$, which might be expected to have a similar rate constant. Hence, the recommended value for f(298 K) was chosen to encompass the rate constant recommended for the reaction of OH with $CHF_2OCF_2OCHF_2$. As with OH + $CHF_2OCF_2OCHF_2$, the value for E/R is estimated as being similar to that for the reaction of OH + CHF_2OCHF_2.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

(1) Cavalli, F.; Glasius, M.; Hjorth, J.; Rindone, B.; Jensen, N. R. Atmospheric lifetimes, infrared spectra and degradation products of a series of hydrofluoroethers. *Atmos. Environ.* **1998**, *32*, 3767-3773, doi:10.1016/S1352-2310(98)00106-X.

E96. OH + $CHF_2OCF_2CF_2OCF_2OCHF_2$. The recommended value for k(298 K) is from the relative rate study by Cavalli et al.,[1] recalculated using the current recommendation for the rate constant of the reference reaction OH + CH_4. The value for k(298 K) is almost the same as that measured for OH + $CHF_2OCF_2CF_2OCHF_2$ in the same study. For both compounds, the measured values for k(298 K) are inexplicably a factor of two greater than that measured in the same study for OH + $CHF_2OCF_2OCHF_2$, which might be expected to have the same or even slightly higher rate constant. Hence, the recommended value for f(298 K) was selected accordingly. As with OH + $CHF_2OCF_2OCHF_2$ and OH + $CHF_2OCF_2CF_2OCHF_2$, the value for E/R is estimated as being similar to that for the reaction of OH + CHF_2OCHF_2.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

(1) Cavalli, F.; Glasius, M.; Hjorth, J.; Rindone, B.; Jensen, N. R. Atmospheric lifetimes, infrared spectra and degradation products of a series of hydrofluoroethers. *Atmos. Environ.* **1998**, *32*, 3767-3773, doi:10.1016/S1352-2310(98)00106-X.

E97. **F + O_3.** The recommended parameters are based on results of the room temperature study of Bedzhanyan et al.[1] and the temperature-dependent study of Wagner et al.[2] The recommendation appears to be quite reasonable in view of the well-known reactivity of atomic chlorine with O_3.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) Back to Table

(1) Bedzhanyan, Y. R.; Markin, E. M.; Gershenzon, Y. M. Experimental study of elementary reactions of FO radicals. I. Sources and measurement of absolute concentrations. The reaction F + O_3 → FO + O_2. *Kinetics and Catalysis* **1993**, *33*, 594-601.

E98. **F + H_2.** The value of k(298 K) seems to be well established with the results reported by Zhitneva and Pshezhetskii,[10] Heidner et al.,[5,6] Wurzberg and Houston,[9] Dodonov et al.,[4] Clyne et al.,[3] Bozzelli,[1] Igoshin et al.,[7] Clyne and Hodgson,[2] and Stevens et al.[8] being in excellent agreement (range of k being 2.3–3.0 × 10^{-11} cm^3 $molecule^{-1}$ s^{-1}). The recommended value at 298 K is taken to be the average of the values reported in these references. Values of E/R range from 433–595 K (Heidner et al.; Wurzberg and Houston; Igoshin et al.; and Stevens et al.). The recommended value of E/R is derived from a fit to the data in these studies.

E99. **F + H_2O.** The recommended temperature-independent value for this rate constant is based on results reported in the study by Stevens et al.[2] over the temperature range 240–373 K using a discharge flow system with chemical conversion of fluorine atoms to deuterium atoms and detection of the latter by resonance fluorescence. This value is in excellent agreement with the room temperature results of Frost et al.[1] and Walther and Wagner.[3] In a limited temperature-dependent study, Walther and Wagner reported an E/R value of 400 K. Although these data have not been included in the derivation of the recommended value for E/R, with the exception of the one low temperature data point, they are encompassed within the indicated uncertainty limits.

E100. F + HNO_3. The recommendation is based on results of the temperature-dependent study of Wine et al.[4] and the room temperature results of Mellouki et al.,[2] Rahman et al.,[3] and Becker et al.[1] The rate constant values at room temperature are in good agreement. The study of Wine et al.[4] was conducted over the temperature range 260–373 K. Below 320 K the data were fit by the Arrhenius expression recommended here, whereas at higher temperatures a temperature-independent value was found, suggesting the occurrence of different mechanisms in the two temperature regimes.

E102. FO + O_3. The recommended upper limit for *k*(298 K) is based on the results of Li et al.[2] in a study using a discharge flow-mass spectrometric technique. FO was produced in the reaction of F atoms with excess O_3. No appreciable decay of FO, and only a small increase in FO_2, was detected, allowing an upper limit to the rate constant of 10^{-14} cm^3 $molecule^{-1}$ s^{-1} to be derived. A two orders of magnitude higher upper limit was derived by Sehested et al.[3] A lower value of the upper limit was derived by Colussi and Grela[1] from a re-analysis of data on the quantum yields for ozone destruction in F_2/O_3 mixtures reported by Staricco et al.[4] The results of the recent, more direct, study of Li et al.[2] are preferred over the earlier results of Staricco et al. There are two possible pathways which are exothermic, resulting in the production of F + $2O_2$ or FO_2 + O_2.

E105. FO_2 + O_3. The recommended upper limit for *k*(298 K) is based on results of Sehested et al.[2] A higher upper limit has been reported by Li et al.[1]
(Table: 94-26, Note: 97-4, Evaluated: 97-4) Back to Table

(1) Li, Z.; Friedl, R. R.; Sander, S. P. Kinetics of FO_2 with NO, NO_2, O_3, CH_4 and C_2H_6. *J. Phys. Chem.* **1995**, *99*, 13445-13451, doi:10.1021/j100036a019.
(2) Sehested, J.; Sehested, K.; Nielsen, O. J.; Wallington, T. J. Atmospheric chemistry of FO_2 radicals: Reaction with CH_4, O_3, NO, NO_2, and CO at 295 K. *J. Phys. Chem.* **1994**, *98*, 6731-6739, doi:10.1021/j100078a014.

E106. FO_2 + NO. The recommended parameters are based on results of Li et al.,[1] the only temperature-dependent study. The recommended value for *k*(298 K) is nearly a factor of 2 less than that reported by Sehested et al.[2]
(Table: 97-4, Note: 97-4, Evaluated: 97-4) Back to Table

(1) Li, Z.; Friedl, R. R.; Sander, S. P. Kinetics of FO_2 with NO, NO_2, O_3, CH_4 and C_2H_6. *J. Phys. Chem.* **1995**, *99*, 13445-13451, doi:10.1021/j100036a019.
(2) Sehested, J.; Sehested, K.; Nielsen, O. J.; Wallington, T. J. Atmospheric chemistry of FO_2 radicals: Reaction with CH_4, O_3, NO, NO_2, and CO at 295 K. *J. Phys. Chem.* **1994**, *98*, 6731-6739, doi:10.1021/j100078a014.

E107. FO_2 + NO_2. The recommended parameters are based on the results of Li et al.,[1] the only temperature-dependent study. The recommended value for *k*(298 K) is a factor of 2.5 less than the results of Sehested et al.[2] This discrepancy might be attributable to a small NO impurity in the NO_2 sample used in the Sehested et al. study.
(Table: 97-4, Note: 97-4, Evaluated: 97-4) Back to Table

E110. CF_3O + O_2. The recommendation is based upon the results of Turnipseed et al.[1] who reported *k*(373 K) $\leq 4 \times 10^{-17}$ cm^3 $molecule^{-1}$ s^{-1}. Assuming an *E*/R of 5000 K, which is equal to the reaction endothermicity, yields the recommended *A* and *k*(298 K) limits. By comparison to other reactions involving abstraction by O_2, the *A*-factor is likely to be much smaller.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) Back to Table

(1) Turnipseed, A. A.; Barone, S. B.; Ravishankara, A. R. Kinetics of the reactions of CF_3O_x radicals with NO, O_3, and O_2. *J. Phys. Chem.* **1994**, *98*, 4594-4601, doi:10.1021/j100068a019.

E111. CF_3O + O_3. The recommended value for *k*(298 K) is based on the average of room temperature measurements reported by Turnipseed et al.,[6] Wallington and Ball,[7] and Bourbon et al.[1] Turnipseed et al. and Bourbon et al. made direct measurements using LIF detection of CF_3O with pulsed photolysis and flow tube reactors, respectively. Wallington and Ball used a competitive reaction scheme with IR absorption detection and CF_3O + CH_4 as the reference reaction. The recommended *A* factor is estimated by comparison to other CF_3O reactions, and the *E*/R is calculated to agree with the recommended *k*(298 K). Upper limits reported by Maricq and Szente,[3] Nielsen and Sehested,[5] and Wallington et al.[8] are consistent with the *k*(298 K) recommendation. Measurements reported by Fockenberg et al.[2] and Meller and Moortgat[4] give rate coefficients about an order of magnitude less than the recommended value. Although the reason for this discrepancy is not known, both studies may have possibly been affected by significant secondary chemistry. The reaction products have not been observed.

E112. $CF_3O + H_2O$. The recommendation is based upon the measurement of k(381 K) $\le 2\times10^{-16}$ cm^3 $molecule^{-1}$ s^{-1} reported by Turnipseed et al.[1] As for the reaction $CF_3O + O_3$, the A factor is estimated, and the E/R is calculated to fit k(381 K). The limits $k = (0.2–40) \times 10^{-17}$ cm^3 $molecule^{-1}$ s^{-1} at 296 ± 2 K given by Wallington et al.[2] are consistent with the recommendation.

E113. $CF_3O + NO$. The recommended value for k(298 K) is based upon the room temperature rate coefficients reported by Sehested and Nielsen,[7] Turnipseed et al.,[8] and Jensen et al.,[6] which are in very good agreement. An earlier low value given by Bevilacqua et al.[1] is superseded by Jensen et al. The temperature-dependence is derived from measurements by Turnipseed (233–360 K) and Jensen et al. (231–393 K). The room temperature results from Bourbon et al.[3] and Bhatnagar and Carr[2] and the results from the temperature dependence study by Dibble et al.[5] are in good agreement with the recommendation. The reaction products have been reported by Chen et al.,[4] Bevilacqua et al.,[1] Bhatnagar and Carr,[2] and Dibble et al.[5]

E114. $CF_3O + NO_2$. There are no published measurements of the rate coefficient for this reaction. The reaction products have been reported by Chen et al.,[1] who used photolysis of CF_3NO to prepare CF_3O_2 and subsequently CF_3O in 700 Torr of air at 297 ± 2 K. They considered two product channels: (a) CF_3ONO_2 obtained via three-body recombination and (b) $CF_2O + FNO_2$ obtained via fluorine transfer. Products from both channels were observed and found to be thermally stable in their reactor. They report $k_a/(k_a + k_b) \ge 90\%$ and $k_b/(k_a + k_b) \le 10\%$, thus the formation of CF_3ONO_2 is the dominant channel at 700 Torr and 297 K.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) Back to Table

(1) Chen, J.; Young, V.; Zhu, T.; Niki, H. Long path Fourier transform infrared spectroscopic study of the reactions of CF_3OO and CF_3O radicals with NO_2. *J. Phys. Chem.* **1993**, *97*, 11696-11698, doi:10.1021/j100147a024.

E115. $CF_3O + CO$. The kinetics of this reaction were studied by Turnipseed et al.,[1] who used pulsed laser photolysis with pulsed laser-induced fluorescence detection and a flow tube reactor with chemical ionization detection to obtain data at temperatures from 233 to 332 K and at pressures from 0.8 to about 300 Torr in He and at about 300 Torr in SF_6. The reaction was found to be predominantly a three-body recombination, presumably producing CF_3OCO, as described in Table 2-1. The bimolecular reaction has at least two product channels: (a) $CF_2O + CFO$ and (b) $CF_3 + CO_2$. The recommended upper limit for the bimolecular rate coefficient is derived from the low-pressure results of Turnipseed et al., where the reaction was in the fall-off region. Their low-pressure data indicate that $k_b < 4 \times 10^{-16}$ cm^3 $molecule^{-1}$ s^{-1} at 298 K. The fate of the CF_3OCO adduct is

uncertain, and it may lead to the regeneration of CF_3 or CF_3O radicals in the atmosphere. Wallington and Ball[2] report a yield of 96 ± 8% CO_2 at one atmosphere and 296 ± 2 K.
(Table: 94-26, Note: 97-4, Evaluated: 97-4) Back to Table

(1) Turnipseed, A. A.; Barone, S. B.; Jensen, N. R.; Hanson, D. R.; Howard, C. J.; Ravishankara, A. R. Kinetics of the reactions of CF_3O radicals with CO and H_2O. *J. Phys. Chem.* **1995**, *99*, 6000-6009, doi:10.1021/j100016a041.
(2) Wallington, T. J.; Ball, J. C. Atmospheric chemistry of CF_3O radicals: Reactions with CH_4, CD_4, CH_3F, CF_3H, ^{13}CO, C_2H_5F, C_2D_6, C_2H_6, CH_3OH, *i*-C_4H_8, and C_2H_2. *J. Phys. Chem.* **1995**, *99*, 3201-3205, doi:10.1021/j100010a034.

E116. $CF_3O + CH_4$. The recommended value of *k*(298 K) is an average of the values reported in the absolute studies of Saathoff and Zellner,[8] Barone et al.,[1] Jensen et al.,[6] Bourbon et al.,[4] and Bednarek et al.,[2] which are all in excellent agreement. Kelly et al.[7] used a relative method with FTIR detection to determine the ratio $k(CF_3O + CH_4)/k(CF_3O + C_2H_6) = R = 0.01 \pm 0.001$ at 298 ± 2 K. This ratio is considerably smaller than that calculated from the rate constants recommended in this evaluation, which is R = 0.017. However, a relative rate measurement reported by Wallington and Ball[9] yields R = 0.0152 ± 0.0023 at 296 K, which is in good agreement with that calculated from the recommended rate coefficients. A relative rate measurement reported by Chen et al.[5] using FTIR methods also gives a low result for the rate coefficient for this reaction, thus, in better agreement with the value of R from Kelly et al.[7] The recommended temperature dependence is from the data of Barone et al. (247–360 K), Jensen et al. (231–385 K), and Bednarek et al. (235–401 K), which agree very well. Measurements at higher temperatures by Bourbon et al. (296–573 K) yield a higher value *E*/R (1606 K). The CF_3OH product was observed by Jensen et al. and Bevilacqua et al.[3]

(9) Wallington, T. J.; Ball, J. C. Atmospheric chemistry of CF_3O radicals: Reactions with CH_4, CD_4, CH_3F, CF_3H, ^{13}CO, C_2H_5F, C_2D_6, C_2H_6, CH_3OH, *i*-C_4H_8, and C_2H_2. *J. Phys. Chem.* **1995**, *99*, 3201-3205, doi:10.1021/j100010a034.

E117. $CF_3O + C_2H_6$. The recommended value for *k*(298 K) is based on results reported by Saathoff and Zellner,[5] Barone et al.,[1] and Bourbon et al.,[2] which are in excellent agreement. Chen et al.[3] measured the rate coefficient relative to that for the CF_3O + NO reaction in 700 Torr of air at 297 K. Their ratio is in good agreement with the values recommended in this evaluation. Kelly et al.[4] used a relative method with FTIR detection to determine the ratio $k(CF_3O + CH_4)/k(CF_3O + C_2H_6) = R = 0.01 \pm 0.001$ at 298 ± 2 K. This does not agree with the ratio calculated using the rate constants recommended in this evaluation, which is R = 0.017. However, a relative rate measurement reported by Wallington and Ball[6] yields R = 0.0152 ± 0.0023 at 296 K in good agreement with that calculated using the recommended rate coefficients. The recommended temperature dependence is from the work of Barone et al., who studied the reaction over the temperature range from 233 to 360 K. Measurements by Bourbon et al. (295–573 K) give a higher *E*/R (642 K). The products are inferred by analogy to other reactions of CF_3O with organic compounds.

E118. $CF_3O_2 + O_3$. The recommended upper limit for *k*(298 K) is from the measurements reported by Ravishankara et al.,[4] who used chemical ionization detection of CF_3O_2 with a flow tube reactor. No measurable reaction was observed in their study. The less direct studies of Nielsen and Sehested,[3] Maricq and Szente,[1] and Turnipseed et al.[5] report somewhat larger upper limits to the rate coefficient. An observable reaction was reported in an indirect measurement by Meller and Moortgat.[2] However, their result for the $CF_3O + O_3$ reaction is not consistent with the value recommended in this evaluation, suggesting that their study may have interference from unknown reactions. The products are assumed to be $CF_3O + 2O_2$.

(5) Turnipseed, A. A.; Barone, S. B.; Ravishankara, A. R. Kinetics of the reactions of CF_3O_x radicals with NO, O_3, and O_2. *J. Phys. Chem.* **1994**, *98*, 4594-4601, doi:10.1021/j100068a019.

E119. CF_3O_2 + CO. The recommended upper limit for *k*(298 K) is from Turnipseed et al.,[2] who used chemical ionization mass spectrometric detection of CF_3OO with a flow tube reactor at 296 K. This result is at odds with an earlier study by Czarnowski and Schumacher,[1] who deduced a "fast reaction" when they observed the thermal decomposition of CF_3OOOCF_3 to accelerate in the presence of CO at 315–343 K. It is possible that the reaction of CF_3O with CO could account for their observations.

(2) Turnipseed, A. A.; Barone, S. B.; Jensen, N. R.; Hanson, D. R.; Howard, C. J.; Ravishankara, A. R. Kinetics of the reactions of CF_3O radicals with CO and H_2O. *J. Phys. Chem.* **1995**, *99*, 6000-6009, doi:10.1021/j100016a041.

E120. CF_3O_2 + NO. The recommended value for *k*(298 K) is an average of the room temperature rate coefficients reported by Plumb and Ryan,[6] Dognon et al.,[4] Peeters et al.,[5] Bevilacqua et al.,[1] Sehested and Nielsen,[7] Turnipseed et al.,[8] Bourbon et al.,[3] and Bhatnagar and Carr,[2] all of which are in excellent agreement. The temperature dependence is derived from the results of Dognon et al. Several studies have confirmed the identity of the products.

Shaded areas indicate changes or additions since JPL15-10. Italicized blue entries denote estimates.

[a] Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

[b] Units are cm^3 $molecule^{-1}$ s^{-1}.

[c] *f*(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(\mathrm{T}) = f(298\ \mathrm{K})\exp\left|g\left(\frac{1}{\mathrm{T}} - \frac{1}{298}\right)\right|$$

Note that the exponent is an absolute value.

1.11.2 Notes: ClO_x Reactions

F1. **O + ClO.** There have been six studies of this rate constant over an extended temperature range using a variety of techniques: Leu[5]; Margitan;[6] Schwab et al.;[10] Ongstad and Birks;[9] Nicovich et al.;[7] and Goldfarb et al.[3] The recommended value is based on a least squares fit to the data reported in these studies and in the earlier studies of Zahniser and Kaufman[11] and Ongstad and Birks.[8] Values reported in the early studies of Bemand et al.[1] and Clyne and Nip[2] are significantly higher and were not used in deriving the recommended value. Leu and Yung[4] were unable to detect $O_2(^1\Delta)$ or $O_2(^1\Sigma)$ and set upper limits to the branching ratios for their production of 4.4×10^{-4} and 2.5×10^{-2}, respectively.

F2. **O + OClO.** The recommended value is based on results of the DF-RF study of Gleason et al.[4] Over the temperature range from 400 K down to 240 K, their data are well fitted by the recommended Arrhenius expression, but at lower temperatures down to 200 K their data show an abrupt change to a negative temperature dependence. At 200 K, the value measured is a factor of 3 higher than that calculated from the Arrhenius expression. It appears that the earlier experiments of Bemand et al.[1] were complicated by secondary chemistry. The low temperature data of Gleason et al. qualitatively support the results of Colussi[2] and Colussi et al.[3] over an extended pressure range that demonstrate the importance of the termolecular reaction O + OClO + M → ClO_3 + M (see entry for this reaction in Table 2-1). Mauldin et al.[5] also observed product formation at low temperatures and higher pressures that is consistent with adduct formation. It should be noted that the termolecular rate constants derived by Gleason et al. on the basis of their low temperature data are not consistent with the termolecular rate constant expression recommended in this evaluation (factor of 3 difference).

F3. **O + Cl_2O.** The recommended value is based on the results of Stevens and Anderson[4] and Miziolek and Molina,[3] which are in good agreement. The significantly lower values of Wecker et al.[5] are not included, nor are earlier results by Basco and Dogra[1] and Freeman and Phillips[2] due to data analysis difficulties in both studies.

F4. **O + HCl.** The recommended value is based on the results of Brown and Smith,[2] Wong and Belles,[7] Ravishankara et al.,[5] Hack et al.,[3] Singleton and Cvetanovic,[6] and Mahmud et al.[4] near 300 K, but not on the results reported by Balakhnin et al.,[1] which are substantially higher. A large uncertainty is attached to the temperature dependence below room temperature due to the limited number and range (no data below 290 K) of measurements.

(7) Wong, E. L.; Belles, F. R.; NASA TN D-6495 NASA Washington, D. C., 1971.

F5. **O + HOCl.** The recommended value is based on results of Schindler et al.[1] In this study the rate constant was found to be practically independent of temperature in the range 213–298 K. Product analysis indicated that Cl atom abstraction is the primary reaction channel, a conclusion that is supported by ab initio studies carried out by Xu and Lin,[3] Wang et al.,[2] and Schindler et al.
(Table: 97-4, Note: 10-6, Evaluated: 10-6) Back to Table

F6. **O + $ClONO_2$.** The recommended values are based on the results reported by Goldfarb et al.,[2] Molina et al.,[4] and Kurylo.[3] The room temperature results of Tyndall et al.[6] and Adler-Golden and Wiesenfeld[1] are in excellent

agreement with the recommended value. The value reported by Ravishankara et al.[5] at 245 K is a factor of 2 greater than the results from the other studies, and this may possibly be attributed to (a) secondary kinetic complications, (b) the presence of NO_2 as a reactive impurity in the $ClONO_2$, or (c) formation of reactive photolytic products. Goldfarb et al. measured an essentially unit yield (±30%) of NO_2 from the reaction between the temperatures 248 K and 298 K.

F8. O_3 + Cl_2O_2. The recommended upper limit is taken from the study of DeMore and Tschuikow-Roux[1] measured at 195 K.
(Table: 90-1, Note: 90-1, Evaluated: 10-6) Back to Table

(1) DeMore, W. B.; Tschuikow-Roux, E. Ultraviolet spectrum and chemical reactivity of the ClO dimer. *J. Phys. Chem.* **1990**, *94*, 5856-5860, doi:10.1021/j100378a046.

F9. OH + Cl_2. The recommended room temperature value is the average of the results reported by Bryukov et al.,[2] Gilles et al.,[3] Boodaghians et al.,[1] Loewenstein and Anderson,[5] Ravishankara et al.,[6] and Leu and Lin.[4] The temperature dependence is based on an error-weighted average of the Gilles et al. and Boodaghians et al. E/R values. Loewenstein and Anderson determined that the exclusive products are Cl + HOCl.

F10. OH + ClO. The reaction has two known product channels under atmospheric conditions: OH + ClO → Cl + HO_2 and OH + ClO → HCl + O_2. Most studies measured the rate coefficients for the overall reaction (OH + ClO → products), which is presumably the sum of the two channels. The assessment of the overall reaction (OH + ClO → products) is based on a fit to the data of Hills and Howard[3] (219–373 K), Lipson et al.[7] (208–298 K), Kegley-Owen et al.[4] (234–356 K), Poulet et al.[8] (298 K), Wang and Keyser[11] (218–298 K), and Bedjanian et al.[1] (230–360 K). Data reported in the studies of Burrows et al.,[2] Ravishankara et al.,[9] and Leu and Lin[5] were not used in deriving the recommended value because the concentration of ClO was determined by an indirect method. The recommendation for the Cl + HO_2 channel is obtained from the equilibrium constant for this channel, combined with the recommended value for the reverse reaction. The minor reaction channel forming HCl poses significant experimental difficulties due to complications associated with the measurement of the HCl reaction product. Early studies inferred the HCl branching ratio without measuring HCl. These included the 298 K measurements of the yield of the Cl + HO_2 channel by Leu and Lin[5] (>0.65), Burrows et al.[2] (0.85 ± 0.2), and Hills and Howard[3] (0.86 ± 0.14). Poulet et al.[8] measured the Cl + HO_2 product yield to be 0.98 ± 0.12 using mass spectrometry, but their HCl sensitivity was marginal. These studies were not considered in the evaluation. Later studies by Lipson et al.[7] using mass spectrometry and by Wang and Keyser[12] using diode laser spectroscopy improved the precision of the HCl product channel measurements. Lipson et al.[6] measured rate constants for the HCl channel over the temperature range 207–298 K and reported a branching ratio of (7 ± 3%), while Wang and Keyser[12] measured the HCl yield between 218–298 K, obtaining (9.0 ± 4.8) %, independent of temperature. The Wang and Keyser rate constant was computed from the HCl yield and their overall rate constant.[11] Measurements by Tyndall et al.[10] and Bedjanian et al.[1] were also considered. (Although the values for the HCl channel obtained by Lipson et al. from combining the values obtained in Lipson et al.[6,7] and Bedjanian et al.[1] are in agreement, their values for the overall reaction differ by 40–70%.) The recommendation for the HCl channel is unchanged from JPL 06-2, and the error limits have been reduced.

(12) Wang, J. J.; Keyser, L. F. HCl yield from the OH + ClO reaction at temperatures between 218 and 298 K. *J. Phys. Chem. A* **2001**, *105*, 6479-6489, doi:10.1021/jp0106449.

F11. OH + OClO. The recommended value is that reported by Gierczak et al.[1] over the range 242–392 K. An earlier study by Poulet et al.[2] between 298 K and 473 K is in fair agreement with the recommendation. Differences between the studies may lie in the methods used to determine the OClO concentration. Gierczak et al. used in situ optical measurements of OClO, whereas Poulet et al. relied on measured flows of dilute

mixtures. Product HOCl was detected in the Poulet et al. study by modulated molecular beam mass spectrometry. The branching ratio for the channel to produce HOCl + O_2 was determined to be close to unity, but experimental uncertainty would allow it to be as low as 0.80.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

(2) Poulet, G.; Zagogianni, H.; Le Bras, G. Kinetics and mechanism of the OH + ClO_2 reaction. *Int. J. Chem. Kinet.* **1986**, *18*, 847-859, doi:10.1002/kin.550180805.

F12. OH + Cl_2O. The reaction has been studied as a function of temperature by Stevens and Anderson[4] and Hansen et al.[2] The results of these two studies are in excellent agreement at temperatures below 300 K. Hansen et al. suggest that data taken above 300 K by Stevens and Anderson were complicated by wall decomposition of Cl_2O. The recommended value of E/R is the average of the individual E/R values from the two studies for data below 300 K. The recommended value for k(298 K) is an average of the results from Stevens and Anderson, Hansen et al., Ennis and Birks,[1] and Leu and Lin.[3]
(Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

(2) Hansen, J. C.; Friedl, R. R.; Sander, S. P. Kinetics of the OH + ClOOCl and OH + Cl_2O reactions: Experiment and theory. *J. Phys. Chem. A* **2008**, *112*, 9229-9237, doi:10.1021/jp8007706.
(3) Leu, M.-T.; Lin, C. L. Rate constants for the reactions of OH with ClO, Cl_2, and Cl_2O at 298K. *Geophys. Res. Lett.* **1979**, *6*, 425-428, doi:10.1029/GL006i006p00425.
(4) Stevens, P. S.; Anderson, J. G. Kinetic and mechanistic study of X + ClOCl → products (X = Br, CI, F, O, OH, N) over the temperature range 240-373 K. *J. Phys. Chem.* **1992**, *96*, 1708-1718, doi:10.1021/j100183a040.

F13. OH + Cl_2O_2. The recommended value is based on results from the study of Hansen et al.[1] using a discharge flow technique coupled with direct detection of OH and Cl_2O_2 via resonance fluorescence and mass spectrometric techniques, respectively. Ab initio calculations by Hansen et al. support the finding of a negative temperature dependence.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

(1) Hansen, J. C.; Friedl, R. R.; Sander, S. P. Kinetics of the OH + ClOOCl and OH + Cl_2O reactions: Experiment and theory. *J. Phys. Chem. A* **2008**, *112*, 9229-9237, doi:10.1021/jp8007706.

F14. OH + HCl. The recommended value is based on a least squares fit to the data over the temperature range 204–300 K reported in the studies of Molina et al.,[8] Keyser,[7] Ravishankara et al.,[10] Battin-Leclerc et al.,[1] and Bryukov et al.[2] In these studies particular attention was paid to the determination of the absolute concentration of HCl by UV and IR spectrophotometry. Earlier studies by Takacs and Glass,[15] Zahniser et al.,[16] Smith and Zellner,[13] Ravishankara et al.,[9] Hack et al.,[4] Husain et al.,[5] Cannon et al.,[3] Husain et al.,[6] and Smith and Williams[12] had reported somewhat lower room temperature values. The data of Sharkey and Smith[11] over the temperature range 138–216 K, Battin-Leclerc et al.[1] below 240 K, and Bryukov et al. over the temperature range 298–1015 K, depart from normal Arrhenius behavior. Quantum chemical and transition state calculations performed by Battin-Leclerc et al.,[1] Bryukov et al.,[2] and Steckler et al.[14] generally support the existence of a weakly bound complex; however, a large tunneling effect is required to explain the low temperature data. Additional work at low temperature is needed to confirm the strong non-Arrhenius behavior.

F15. OH + HOCl. In the only reported study of this system, Ennis and Birks[1] reported the value of this rate constant at room temperature to lie in the range $(1.7–9.5) \times 10^{-13}$ cm^3 molecule^{-1} s^{-1}. A temperature-dependent expression has been estimated by choosing a pre-exponential factor by analogy with the OH + H_2O_2 reaction and selecting the midpoint of the experimental range for the room temperature rate constant. Theoretical calculations by Wang et al.,[2] however, suggest that tunneling may play an important role at lower temperatures and give rise to a significant curvature in the Arrhenius curve. The large uncertainty factor is needed to encompass the entire range.

F16. OH + $ClNO_2$. The recommended value is based on results of the direct studies of Ganske et al.[1,2] using the discharge flow-resonance fluorescence technique. Mass spectrometric studies showed HOCl to be the major chlorine-containing product, with no evidence for a channel to produce $HONO_2$ + Cl.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) Back to Table

(2) Ganske, J. A.; Ezell, M. J.; Berko, H. N.; Finlayson-Pitts, B. J. The reaction of OH with $ClNO_2$ at 298 K: kinetics and mechanisms. *Chem. Phys. Lett.* **1991**, *179*, 204-210, doi:10.1016/0009-2614(91)90317-3.

F17. OH + $ClONO_2$. The results reported by Zahniser et al.[2] and Ravishankara et al.[1] are in good agreement at ~245 K (within 25%), considering the difficulties associated with handling $ClONO_2$. The recommended value is that of Zahniser et al. Neither study reported data on the reaction products.
(Table: 82-57, Note: 82-57, Evaluated: 10-6) Back to Table

(1) Ravishankara, A. R.; Davis, D. D.; Smith, G.; Tesi, G.; Spencer, J. A study of the chemical degradation of $ClONO_2$ in the stratosphere. *Geophys. Res. Lett.* **1977**, *4*, 7-9, doi:10.1029/GL004i001p00007.

F18. OH + CH_3Cl. The recommended value for *k*(298 K) is an average of the values from the relative rate study of Hsu and DeMore[6] (recalculated based on the current recommendation for the rate constant of the OH + CH_3CHF_2 reference reaction, as described in the note for that reaction) and the absolute rate studies of Herndon et al.[4] and Orkin et al.[8] The recommended value for *E*/R was obtained from a fit to the data of Herndon et al.[4] below room temperature. Data from the earlier studies of Howard and Evenson,[5] Perry et al.,[10] Davis et al.,[3] Paraskevopoulos et al.,[9] Jeong and Kaufman[7], and Taylor et al.[11] (with the exception of their 298 K data point) are reasonably well encompassed within the 2σ uncertainty limits. The room temperature value from Taylor et al.[11] is inconsistent with the higher temperature results in the same study and with the other investigations and lies outside of the 2σ band, as do the higher room temperature values of Cox et al.[2] and Brown et al.[1]

F19. OH + CH_2Cl_2. The recommended values for *k*(298 K) and *E*/R are derived from a combined fit to the data from the absolute rate studies of Villenave et al.[9] and Herndon et al.[3] and the relative rate study of Hsu and DeMore[5] (two determinations, which have been recalculated based on the current recommendations for the rate constants of the OH + CH_3CHF_2 and OH + CH_3CH_2F reference reactions). The renormalization procedure is discussed in the note for the OH + CH_3CHF_2 reaction. The lowest temperature data (219–220 K) of Herndon et al. were not used in the fit since they appear to be systematically higher than expected from the data at 227 K and above, a difference that could possibly be due to the presence of residual reactive stabilizer in the sample of CH_2Cl_2. The results of Cox et al.[1] and Davis et al.[2] support the recommendation. The results from Taylor et al.,[8] Jeong and Kaufman,[6] Perry et al.,[7] and Howard and Evenson[4] lie considerably higher than the recommendation and were not used in deriving the recommended parameters.

F20. OH + $CHCl_3$. The recommended value for *k*(298 K) is an average of the values from the relative rate study of Hsu and DeMore[3] (which has been recalculated based on the current recommendation for the rate constant of the OH + CH_3CHF_2 reference reaction, as described in the note for that reaction) and the absolute rate studies of Taylor et al.[6] (which superseded Taylor et al.[5]), Jeong and Kaufman,[4] Davis et al.,[1] and Howard and Evenson.[2] The recommended value of *E*/R is an average of values for this parameter derived in all of the above studies with the exception of Howard and Evenson, which was conducted only at room temperature.

F21. OH + CCl_4. The recommended value for *k*(298 K) was obtained by setting the Arrhenius pre-exponential factor (*A*) to 1×10^{-11} cm^3 molecule^{-1} s^{-1} and equating the activation energy (E) to the reaction endothermicity reported in this evaluation and in IUPAC. The JPL 10-6 evaluation had been based on upper limits of the rate constant reported by Cox et al.,[2] by Howard and Evenson,[3] and by Clyne and Holt.[1] None of these experimental studies indicated any evidence for reaction between these species.

F24. OH + CHF_2Cl (HCFC-22). Studies of this reaction show very good agreement among both absolute and relative rate constant measurements. The recommended value for *k*(298 K) is an average of the values from the relative rate data of Hsu and DeMore[7] (which has been recalculated based on the current recommendation for the rate constant of the OH + CH_4 reference reaction), and the absolute rate studies of Orkin and Khamaganov[9], Fang et al.,[4] Atkinson et al.,[1] Watson et al.,[11] Chang and Kaufman,[2] Paraskevopoulos et al.,[10] and Jeong and Kaufman.[8] The recommended value for *E*/R is derived from a combined fit to these same data sets after scaling each one to the recommended value for *k*(298 K). The more scattered results of Handwerk and Zellner[5] are in general agreement. The results from the studies of Howard and Evenson[6] and Clyne and Holt[3] are significantly different from those of the other studies and were not used in the derivation.

F27. OH + CCl_2FCClF_2 (CFC-113), $CClF_2CClF_2$ (CFC-114), CF_3CClF_2 (CFC-115). The recommended kinetic parameters for these reactions are estimated as being the same as presently recommended for OH + CCl_4.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

F28. OH + CH_3CH_2Cl. The recommended value for *k*(298 K) is an average of the values reported by Howard and Evenson,[2] Paraskevopoulos et al.,[5] Kasner et al.,[3] and Herndon et al.[1] The recommended value for *E*/R is an average of the values for this parameter determined by Kasner et al. and Herndon et al. Data from the study by Markert and Nielsen[4] were not used to derive the recommended parameters, as they are somewhat more scattered.
(Table: 02-25, Note: 02-25, Evaluated: 02-25) Back to Table

F30. OH + CH_3CCl_3. The recommended value for *k*(298 K) is an average of the values from the absolute rate studies of Talukdar et al.[8] and Finlayson-Pitts et al.,[2] and a relative rate study of DeMore[1] (recalculated based on the current recommendation for the rate constant of the OH + CH_4 reference reaction). The temperature dependence is a fit to the data between 243 K and 379 K of Talukdar et al.[8] These studies indicate both a lower *k*(298 K) and *E*/R than were reported in earlier studies by Nelson et al.,[7] Jeong and Kaufman,[3] and Kurylo et al.[5] More recent measurements by Jiang et al.[4] and Lancar et al.[6] yield rate constants that are slightly higher at 298 K than this recommendation.

F31. OH + CH_3CFCl_2 (HCFC-141b). Studies of this reaction have shown that the presence of reactive impurities can have an appreciable effect on the accurate determination of its small rate constant. The recommended value of *k*(298 K) is the average of the values derived from the absolute studies of Talukdar et al.[7] (by DF-LMR and LP-LIF, for which only data obtained with the purer sample of HCFC-141b were considered) and Lancar et al.[4] and from the relative rate study of Huder and DeMore[2] (two determinations that were recalculated based on the current recommendations for the rate constants for the reference reactions OH + CH_4 and OH + CH_3CCl_3). The recommended value for *E*/R is derived from a combined Arrhenius fit below 400 K to the data of Talukdar et al.[7] (without their lowest temperature data) and Lancar et al.[4] after scaling each data set to the recommended *k*(298 K). Huder and DeMore[2] reported only Arrhenius expressions derived from their relative rate measurements (i.e., no actual rate constants were tabulated). Their reported values for *E*/R are nearly identical to the value recommended here. The results of absolute measurements of Zhang et al.[8] (which supersede those reported in Liu et al.[5]) were complicated by secondary chemistry that may not have been completely accounted for; nevertheless, they are encompassed within the recommended 2σ uncertainty limits. Earlier measurements by Brown et al.[1] yielded significantly higher rate constants at every temperature, most likely due to the presence

of very reactive impurities (such as $CH_2=CCl_2$) in their HCFC-141b sample. Talukdar et al.[7] reported similar problems in their preliminary measurements. The room temperature result of Mörs et al.[6] is 15% smaller than recommended but is encompassed within the recommended 2σ uncertainty limits. The room temperature rate constant reported by Kowalczyk et al.[3] is inexplicably a factor of 8 smaller than recommended. The results reported by these authors for several other halocarbons vary widely (ranging from 10% agreement with recommendations to as much as 3 orders of magnitude disagreement).

(12) Zhang, Z.; Huie, R. E.; Kurylo, M. J. Rate constants for the reactions of OH with CH_3CFCl_2 (HCFC-141b), CH_3CF_2Cl (HCFC-l42b), and CH_2FCF_3 (HFC-134a). *J. Phys. Chem.* **1992**, *96*, 1533-1535, doi:10.1021/j100183a008.

F33. OH + CH_2ClCF_2Cl (HCFC-132b). The recommended parameters are derived from the data of Watson et al.,[2] which were corrected by these authors for the presence of alkene impurities. The data of Jeong et al.,[1] indicating faster rate constants, may have been affected by such impurities; hence they were not included in deriving the recommendation.

(Table: 02-25, Note: 02-25, Evaluated: 02-25) Back to Table

(1) Jeong, K. M.; Hsu, K. J.; Jeffries, J. B.; Kaufman, F. Kinetics of the reactions of OH with C_2H_6, CH_3CCl_3, $CH_2ClCHCl_2$, $CH_2ClCClF_2$, and CH_2FCF_3. *J. Phys. Chem.* **1984**, *88*, 1222-1226, doi:10.1021/j150650a041.

(2) Watson, R. T.; Ravishankara, A. R.; Machado, G.; Wagner, S.; Davis, D. D. A kinetics study of the temperature dependence of the reactions of OH($^2\Pi$) with CF_3CHCl_2, CF_3CHClF, and CF_2ClCH_2Cl. *Int. J. Chem. Kinet.* **1979**, *11*, 187-197, doi:10.1002/kin.550110210

F34. OH + CH_2FCFCl_2 (HCFC-132c). The recommended Arrhenius parameters are derived from the data of Orkin et al.[1]

(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Orkin, V. L.; Khamaganov, V. G.; Kasimovskaya, E. E.; Guschin, A. G. Photochemical properties of some Cl-containing halogenated alkanes. *J. Phys. Chem. A* **2013**, *117*, 5483-5490, doi:10.1021/jp400408y.

F35. OH + CH_2ClCF_3 (HCFC-133a). The recommended parameters are derived from the data of McGillen et al.,[6] which is the only study to fully cover the lower temperatures of atmospheric interest. The value of the rate constant at room temperature from Howard and Evenson[5] is in good agreement with the recommended value for k(298 K), while systematic differences exist with the k(298 K) values derived from the absolute measurements of Handwerk and Zellner[4] (~50%) and Fang et al.[3] (~60%) and from the relative rate study of DeMore[2] (~15%) using OH + CH_3CCl_3 as the reference reaction. Despite these systematic differences, the recommended temperature dependences derived from the last three studies listed above are in reasonable agreement with the recommended E/R The data of Clyne and Holt[1] are quite scattered, and the values above room temperature are considerably higher than those from other studies. Hence, these data were not used in deriving the recommended parameters.

F38. OH + $CHCl_2CF_3$ (HCFC-123). The recommended value of *k*(298 K) is the average of the values from the absolute studies of Gierczak et al.[3] (two determinations), Liu et al.,[6] and Yamada et al.,[9] and from the relative rate study by Hsu and DeMore[5] (recalculated based on the current recommendation for the rate constant for the OH + CH_3CHF_2 reference reaction, as discussed in the note for that reaction). The recommendation for the temperature dependence is derived from a fit to the data of these investigations after scaling each data set to the recommended value for *k*(298 K). The temperature dependence data of Nielsen,[7] Watson et al.,[8] Clyne and Holt,[2] and Brown et al.[1] and the room temperature data of Howard and Evenson[4] were not used in deriving the recommended parameters.

F39. OH + $CHFClCF_2Cl$ (HCFC-123a). The recommended parameters are derived from the data of Orkin and Khamaganov.[1]
(Table: 02-25, Note: 02-25, Evaluated: 02-25) Back to Table

(1) Orkin, V. L.; Khamaganov, V. G. Determination of rate constants for reactions of some hydrohaloalkanes with OH radicals and their atmospheric lifetimes. *J. Atmos. Chem.* **1993**, *16*, 157-167, doi:10.1007/BF00702785.

F40. OH + $CHFClCF_3$ (HCFC-124). The recommended value for k(298 K) is an average of the values from the studies of Watson et al.,[4] Gierczak et al.,[1] (2 studies), Yamada et al.,[5] and Hsu and DeMore[3] (two relative rate determinations, which have been recalculated based on the current recommendations for the rate constants of the OH + CH_4 and OH + CHF_2CHF_2 reference reactions). The room temperature rate constant of Howard and Evenson[2] is considerably higher than these other values and was not included in the average. The recommended temperature dependence is an average of the dependencies derived from these same studies (but using only data below 400 K from Gierczak et al.[1] and Yamada et al.[5]).

(3) Yujing, M.; Mellouki, A. Rate constants for the reactions of OH with chlorinated propanes. *Phys. Chem. Chem. Phys* **2001**, *3*, 2614-2617, doi:10.1039/b102971c.

F43. OH + $CH_3CF_2CFCl_2$ (HCFC-243cc). The recommended Arrhenius parameters are derived from the data of Nelson et al.[1] The uncertainties have been assigned to reflect the assumption that the rate constant for this reaction should be less than that for OH + CH_3CF_2Cl.
(Table: 02-25, Note: 02-25, Evaluated:02-25) Back to Table

(1) Nelson, D. D., Jr.; Zahniser, M. S.; Kolb, C. E. Chemical kinetics of the reactions of the OH radical with several hydrochlorofluoropropanes. *J. Phys. Chem.* **1992**, *96*, 249-253, doi:10.1021/j100180a048.

F44. OH + $CHCl_2CF_2CF_3$ (HCFC-225ca). The recommended value for *k*(298 K) is an average of the values from Nelson et al.[2] and Zhang et al.[3] The recommendation for *E*/R is derived from the data of Nelson et al.[2] The temperature-dependence data of Brown et al.[1] were not considered because the relatively large rate constants at and below room temperature and the Arrhenius curvature are suggestive of sample impurities. The temperature dependence results of Zhang et al.[3] are in reasonable agreement with those of Nelson et al.[2] over the temperature range of measurement overlap. However, the complete Zhang et al.[3] data set yields a value for *E*/R much larger than currently recommended for the OH + $CHCl_2CF_3$ (HCFC-123) reaction, for which the activation energy should be similar.
(Table: 02-25, Note: 02-25, Evaluated: 02-25) Back to Table

(3) Zhang, Z.; Liu, R.; Huie, R. E.; Kurylo, M. J. Rate constants for the gas phase reactions of the OH radical with $CF_3CF_2CHCl_2$ (HCFC-225ca) and CF_2ClCF_2CHClF (HCFC-225cb). *Geophys. Res. Lett.* **1991**, *18*, 5-7, doi:10.1029/90GL02647.

F45. OH + CF_2ClCF_2CHFCl (HCFC-225cb). The recommended parameters are derived from a combined fit to the temperature-dependence data of Nelson et al.[1] and Zhang et al.,[2] which are in excellent agreement.
(Table: 15-10, Note: 02-25, Evaluated: 02-25) Back to Table

(1) Nelson, D. D., Jr.; Zahniser, M. S.; Kolb, C. E. Chemical kinetics of the reactions of the OH radical with several hydrochlorofluoropropanes. *J. Phys. Chem.* **1992**, *96*, 249-253, doi:10.1021/j100180a048.
(2) Zhang, Z.; Liu, R.; Huie, R. E.; Kurylo, M. J. Rate constants for the gas phase reactions of the OH radical with $CF_3CF_2CHCl_2$ (HCFC-225ca) and CF_2ClCF_2CHClF (HCFC-225cb). *Geophys. Res. Lett.* **1991**, *18*, 5-7, doi:10.1029/90GL02647.

F46. OH + $CF_3CH_2CFCl_2$ (HCFC-234fb). The recommended value for *k*(298 K) is from the relative rate study of Barry et al.[1] The value for *E*/R is estimated as being slightly less than that for OH + $CF_3CH_2CF_3$.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

(1) Barry, J.; Locke, G.; Scollard, D.; Sidebottom, H.; Treacy, J.; Clerbaux, C.; Colin, R.; Franklin, J. 1,1,1,3,3,-pentafluorobutane (HFC-365mfc): Atmospheric degradation and contribution to radiative forcing. *Int. J. Chem. Kinet.* **1997**, *29*, 607-617, doi:10.1002/(SICI)1097-4601(1997)29:8<607::AID-KIN6>3.0.CO;2-Y.

F47. OH + CH_2=CHCl. The recommended value for *k*(298 K) is an average of the values reported by Howard,[1] Perry et al.,[3] Liu et al.,[2] and Yamada et al.[4] The recommended value for *E*/R is an average of the values for this parameter derived from fits to the data of Perry et al., Liu et al., and Yamada et al. at temperatures below about 400 K. In the 400–500 K region, the rate constant levels off before increasing at higher temperatures, suggesting the stronger importance of an abstraction mechanism at the higher temperatures. As discussed in note for the OH + CH_2=CHF reaction, the recommended rate constant represents the high-pressure limit for this reaction.

F48. OH + (E)-CHCl=CHCl. The recommended value for *k*(298 K) is an average of the values reported in the absolute rate studies of Abbatt and Anderson,[1] Zhang et al.,[5] Yamada et al.,[4] and Canosa-Mas et al.[2] The recommended value for *E*/R is derived from a combined fit to the data below 400 K from the first three studies listed above after scaling to the recommended value for *k*(298 K). The data from the room temperature relative rate study of Tuazon et al.[3] are significantly lower than those in the absolute studies and were not used in deriving the recommended value for k(298 K).

F49. OH + (Z)-CHCl=CHCl. The recommended value for *k*(298 K) is an average of the values reported in the absolute rate studies of Abbatt and Anderson,[1] and Zhang et al.[3] The recommended value for *E*/R is derived from a combined fit to the data of these two studies after scaling to the recommended value for *k*(298 K). The data from the room temperature relative rate study of Tuazon et al.[2] were not used in deriving the recommended value for *k*(298 K). While in agreement with the recommended value, this same study yielded significantly different results than recommended for the trans isomer.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Abbatt, J. P. D.; Anderson, J. G. High-pressure discharge flow kinetics and frontier orbital mechanistic analysis for OH + CH_2CCl_2, *cis*-CHClCHCl, *trans*-CHClCHCl, $CFClCF_2$, and CF_2CCl_2 → Products. *J. Phys. Chem.* **1991**, *95*, 2382-2390, doi:10.1021/j100159a049.

(2) Tuazon, E. C.; Atkinson, R.; Aschmann, S. M.; Goodman, M. A.; Winer, A. M. Atmospheric reactions of chloroethenes with the OH radical. *Int. J. Chem. Kinet.* **1988**, *20*, 241-265, doi:10.1002/kin.550200305

(3) Zhang, Z.; Liu, R. F.; Huie, R. E.; Kurylo, M. J. A gas-phase reactivity study of OH radicals with 1,l-dichloroethene and *cis*- and *trans*-l,2-dichloroethene over the temperature range 240-400 K. *J. Phys. Chem.* **1991**, *95*, 194-196, doi:10.1021/j100154a039.

F50. OH + CH_2=CCl_2. The recommended value for *k*(298 K) is an average of the values reported by Abbatt and Anderson,[1] Yamada et al.[6], and Zhang et al.[7] The room temperature results of Edney et al.,[3] Tuazon et al.,[5] and Canosa-Mas et al.[2] lie somewhat outside of the range of the other studies and were not used in deriving the recommendation. The recommended value for *E*/R is derived from a combined fit to the data of Abbatt and Anderson,[1] Yamada et al.[6], and Zhang et al.[7] after scaling each data set to the value recommended for *k*(298 K). The data of Kirchner et al.[4] were not used in deriving the recommended parameters since they were obtained at very low pressure, and the much stronger temperature dependence obtained may be indicative of a pressure

dependence above room temperature. As discussed in the note for the OH + CH_2=CHF reaction, the recommended rate constant represents the high pressure limit for this reaction.

F51. OH + CHCl=CCl_2. The recommended value for *k*(298 K) is the mean of the values reported by Howard,[3] Chang and Kaufman,[1] Kirchner et al.,[5] Klopffer et al.,[6] Edney et al.,[2] and Tichenor et al.[7] The recommended value of *E*/R is an average of values for this parameter derived by Chang and Kaufman,[1] Kirchner et al.,[5] and Tichenor et al.[7] The value for *k*(298 K) derived from a relative rate study by Winer et al.[8] is a factor of ~2 greater than the other values and is not considered in deriving the recommended value. An absolute study by Jiang et al.[4] yielding a significantly higher value for *k*(298 K), as well as a considerably stronger temperature dependence (*E*/R = –970 K), is assumed to be superseded by Tichenor et al.[7] As discussed in the note for the OH + CH_2=CHF reaction, the recommended rate constant represents the high pressure limit for this reaction.

F52. OH + CCl_2=CCl_2. The recommended value for *k*(298 K) is the mean of the values reported by Howard,[2] Chang and Kaufman,[1] and Kirchner et al.[3] The room temperature value reported by Winer et al.[5] is more than a factor of 10 greater and was not used in deriving the recommendation. The recommended value for *E*/R is an average

of values for this parameter derived by Chang and Kaufman[1] and Kirchner et al.[3] A study by Tichenor et al.[4] yields a value for *k*(298 K) slightly lower than these other studies, but a temperature dependence less than half of that recommended. While the results of Tichenor et al.[4] were not used in deriving the recommendations, they are encompassed within the 2σ confidence limits. As discussed in the note for the OH + CH_2=CHF reaction, the recommended rate constant represents the high-pressure limit for this reaction.

F53. OH + CF_2=CFCl. The recommended Arrhenius parameters are derived from the data of Abbatt and Anderson.[1] The value for *k*(298 K) reported by Howard[2] is in very good agreement with that recommended here.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

F54. OH + (E)-CHCl=CHF_3. The recommended value for *k*(298K) is an average of the values determined by Orkin et al.[2] and Gierczak et al.[1] The value reported in the room temperature relative rate study by Sulbaek-Andersen et al.,[3] while only about 15% larger than the recommended value, has much greater uncertainty due to uncertainties in the reference reaction rate constants. The data reported by Orkin et al.[2] and Gierczak et al.[1] exhibit somewhat different temperature dependences. Orkin et al.[2] report significant curvature in the Arrhenius plot over the temperature range 220–370 K that is best fit by a modified three-parameter Arrhenius expression

$$k(\mathrm{T}) = 1.03 \times 10^{-13}\ (\mathrm{T}/298)^{2.29} \exp(+384/\mathrm{T}).$$

This curvature is not seen in the data reported by Gierczak et al.[1] The recommended value for *E*/R is an average of the *E*/R values derived from the individual fits to the Orkin et al.[2] and Gierczak et al.[1] data for T <300 K.

Atmospheric chemistry of *trans*-CF_3CH=CHCl: Kinetics of the gas-phase reactions with Cl atoms, OH radicals, and O_3. *J. Photochem. and Photobiol. A: Chem.* **2008**, *199*, 92-97, doi:10.1016/j.jphotochem.2008.05.013.

F55. OH + (Z)-CHCl=$CHCF_3$. The recommended Arrhenius parameters are derived from a fit to the data of Gierczak et al.[1] for T <298 K. Above 298 K, the Arrhenius plot exhibits pronounced curvature such that the entire data set from 213–373 K is best fit by a modified three-parameter Arrhenius expression:

$$k(\mathrm{T}) = 1.15 \times 10^{-13}\ (\mathrm{T}/298)^{1.38} \exp(+628/\mathrm{T}).$$

Below 298 K this expression and the simple Arrhenius parameterization yield nearly identical values for the rate constant.

(1) Gierczak, T.; Baasandorj, M.; Burkholder, J. B. OH + (*E*)- and (*Z*)-1-chloro-3,3,3-trifluoropropene-1 ($CF_3CH{=}CHCl$) reaction rate coefficients: Stereoisomer-dependent reactivity. *J. Phys. Chem. A* **2014**, *118*, 11015-11025, doi:10.1021/jp509127h.

F56. OH + CH_3OCF_2CHFCl. The recommendation is based on the data reported by Tokuhashi et al.[2], which exhibit a weak curvature in the Arrhenius plot between 250 and 430 K. The recommended values for both *k*(298 K) and *E*/R were derived from a fit to the data from Tokuhashi et al. between 250 and 298 K. The only other study of this reaction by Heathfield et al.[1] resulted in *k*(298 K), which is a factor of 4.5 larger. Such a high rate constant is inconsistent with those measured for other haloethers. The data over the broader temperature range from 250 to 430 K can be represented by the three-parameter expression obtained from a fit to the data reported by Tokuhashi et al.:

$$k(T) = 3.39\times10^{-13}\ (T/298)^{1.87}\ \exp(-657/T)$$

F57. OH + $CHF_2OCHClCF_3$ (Isoflurane). The recommended value for *k*(298 K) is an average of the results from Tokuhashi et al.,[5] Langbein et al.,[3] and Sulbaek-Andersen et al.[4] The recommended value for *E*/R is derived from a fit to the two temperature dependent data sets of Tokuhashi et al.[5] The room temperature data determined in the discharge-flow experiments by Brown et al.[2] and Beach et al.[1] lie about 30% higher than recommended here. However, the data from Beach et al.[1] above room temperature agree well with those of Tokuhashi et al.[5]

F61. HO_2 + Cl. The recommendations for the two reaction channels are based upon the results of Hickson and Keyser,[5] who measured both channels using the discharge flow-resonance fluorescence technique coupled with infrared diode laser spectroscopy, detecting HO, HO_2, Cl, and HCl; by Lee and Howard,[6] who measured the total rate constant and the OH + ClO channel using a discharge flow system with laser magnetic resonance detection of HO_2, OH, and ClO; and by Riffault et al.,[9] who measured the total rate constant and the OH + ClO channel using the discharge flow mass spectrometric technique. The studies of Lee and Howard and Riffault et al. suggest that the total rate constant is temperature independent with a value of $(4.2 \pm 0.7) \times 10^{-11}$ and $(4.4 \pm 0.6) \times 10^{-11}$ cm^3 $molecule^{-1}$ s^{-1} over the temperature range 250–420 K and 230–360 K, respectively. The Hickson and Keyser study concludes that the HCl channel may be represented as $(1.4 \pm 0.3) \times 10^{-11} \exp[(269 \pm 58)/T]$ for temperatures from 256 to 296 K, while the OH channel is given by $(12.7 \pm 4.1) \times 10^{-11} \exp[-(801 \pm 94)/T]$ for temperatures of 226–336 K, the sum of which yields 4.3×10^{-11} cm^3 $molecule^{-1}$ s^{-1} at 298 K with a small temperature dependence. These values for the total rate constant are in agreement with the results of indirect studies relative to Cl + H_2O_2 (Leu and DeMore,[7] Poulet et al.,[8] and Burrows et al.[1]) or to Cl + H_2 (Cox[3]). The contribution of the reaction channel producing OH + ClO (22% at room temperature) is much higher than the upper limit reported by Burrows et al. (1% of total reaction). Cattell and Cox,[2] using a molecular modulation-UV absorption technique over the pressure range 50–760 Torr, report results in good agreement with those of Lee and Howard both for the overall rate constant and for the relative contribution of the two reaction channels. A study by Dobis and Benson[4] reports a total rate constant in good agreement with this recommendation but a much lower contribution (5 ± 3%) of the channel producing OH + ClO. The equilibrium constant for the channel producing ClO + OH can be calculated with excellent accuracy. The recommended value for this channel comes from the combination of this equilibrium constant and the rate constant for the reverse reaction.

F62. HO_2 + ClO. The recommended value for k(298 K) is based on studies by Hickson et al.,[4] Nickolaisen et al.,[8] Knight et al.,[5] and Stimpfle et al.,[10] which studied the reaction as a function of temperature. Earlier room temperature measurements by Reimann and Kaufman,[9] Leck et al.,[6] Burrows and Cox,[1] and Cattell and Cox[2] are slightly lower than the current recommendation. The studies of Cattell and Cox and Nickolaisen et al. were performed over extended pressure ranges and did not observe a pressure dependence. The most recent studies find the T-dependence to be characterized by linear Arrhenius behavior over the entire temperature range and do not support the finding of Stimpfle et al. of non-Arrhenius behavior. The recommended value for E/R is based on an average of individual E/R values for each of the first four studies listed above over their entire temperature ranges. The two most probable pairs of reaction products are (1) HOCl + O_2 and (2) HCl + O_3. Finkbeiner et al.,[3] using matrix isolation/ FTIR spectroscopy, studied product formation between 210 and 300 K at 700 Torr. HOCl was observed to be the dominant product (>95% at all temperatures). Upper limits ranging from 0.3% to 2% have been determined for the channel (2) room temperature branching ratio by Leu,[7] Leck et al., Knight et al., and Finkbeiner et al. Slightly larger branching ratio (<5%) upper limit values for k_2/k were determined at temperatures below 250 K by Finkbeiner et al. and Leck et al. However, no direct evidence of product channels other than channel (1) was found. Theoretical calculations are in generally good agreement on the structures and relative energetics of the intermediates in this reaction system (see the summary in Hickson et al.[4]). In particular, Xu et al.[11] reported quantum chemistry and master equation calculations that are in reasonable agreement with the experiments. For atmospheric conditions, their calculations identified only two significant channels: the pressure-independent abstraction reaction to form HOCl + O_2 and pressure-dependent formation of HOOOCl, which has thermal decomposition lifetimes ranging from hours to days under stratospheric conditions. At 250 K and 400 Torr of N_2, they calculate that the abstraction reaction constitutes ~60–70% of the total rate constant for ClO + HO_2, supporting the notion that a significant pressure-dependence exists. Further experimental studies on the formation, lifetime, and atmospheric fate of HOOOCl are warranted. (Table: 09-31, Note: 10-6, Evaluated: 10-6) Back to Table

F63. $H_2O + ClONO_2$. The recommendation is based on the upper limits to the homogeneous bimolecular rate constant reported by Atkinson et al.[1] and Hatakeyama and Leu.[2,3] Atkinson et al. observed by FTIR analysis the decay of $ClONO_2$ in the presence of H_2O in large-volume (2500 and 5800 liters) Teflon or Teflon-coated chambers. Their observed decay rate gives an upper limit to the homogeneous gas phase rate constant, and they conclude that the decay observed is due to heterogeneous processes. Hatakeyama and Leu, using a static photolysis system with FTIR analysis, derived a similar upper limit. Rowland et al.[4] concluded that the decay they observed resulted from rapid heterogeneous processes. The homogeneous reaction is too slow to have any significant effect on atmospheric chemistry.

F64. NO + OClO. The Arrhenius parameters are estimated based on 298 K data reported by Bemand et al.[1] Temperature data by Li et al.[2] are in good agreement with Bemand et al. at 298 K and display a negative temperature dependence over the range 220–367 K. However, the Li et al. data appear to be complicated by the secondary reaction of Cl with OClO.

F66. NO_3 + HCl. The recommended upper limit is that reported by Mellouki et al.[3] in a study using DF-EPR techniques. This upper limit shows that this reaction is of negligible importance in stratospheric chemistry. Somewhat lower upper limits have been reported by Cantrell et al.[2] and Canosa-Mas et al.[1]; the latter study also reports Arrhenius parameters at higher temperatures (333–473 K).

(1) Leu, M.-T.; Hatkeyama, S.; Hsu, K. J. Rate constants for reactions between atmospheric reservoir species. 1. HCl. *J. Phys. Chem.* **1989**, *93*, 5778-5784, doi:10.1021/j100352a026.

F68. **Cl + O_3.** The results reported for k(298 K) by Watson et al.,[13] Zahniser et al.,[14] Kurylo and Braun,[8] Clyne and Nip,[4] Nicovich et al.,[10] Seeley et al.,[11] and Beach et al.[1] are in good agreement, and have been used to determine the recommended value at this temperature. The values reported by Leu and DeMore[9] (due to the large reported uncertainties) and Clyne and Watson[5] (the value is inexplicably high) are not considered. The seven studies used for the k(298 K) recommendation report rate constants that agree to within 30-40% over the temperature range 205–300 K and all report similar values for the Arrhenius activation energy with the exception of Nicovich et al. and Seeley et al. who obtained significantly weaker temperature dependences. Nevertheless, there is no reason to prefer any one set of data over any other; therefore, the recommended E/R is the mean of the seven values for this parameter between 205 and 300 K. DeMore[7] directly determined the ratio $k(Cl + O_3)/k(Cl + CH_4)$ at 197–217 K to be within 15% of that calculated from the absolute rate constant values recommended here.

Vanderzanden and Birks[12] have interpreted their observation of oxygen atoms in this system as evidence for some production (0.1–0.5%) of O_2 ($^1\Sigma$) in this reaction. The possible production of singlet molecular oxygen in this reaction has also been discussed by DeMore,[6] in connection with the Cl_2 photosensitized decomposition of ozone. However Choo and Leu[3] were unable to detect $O_2(^1\Sigma)$ or $O_2(^1\Delta)$ in the Cl + O_3 system and set upper limits to the branching ratios for their production of 5×10^{-4} and 2.5×10^{-2}, respectively. They suggested two possible mechanisms for the observed production of oxygen atoms, involving reactions of vibrationally excited ClO radicals with O_3 or with Cl atoms, respectively. Burkholder et al.,[2] in a study of infrared line intensities of the ClO radical, present evidence in support of the second mechanism. In their experiments with excess Cl atoms, the vibrationally excited ClO radicals produced in the Cl + O_3 reaction can react with Cl atoms to give Cl_2 and oxygen atoms, which can then remove additional ClO radicals. These authors point out the possibility for systematic error from assuming a 1:1 stoichiometry for $[Cl]:[O_3]_o$ when using the Cl + O_3 reaction as a quantitative source of ClO radicals for kinetic and spectroscopic studies.

F69. **$Cl + H_2$.** The recommended value for *k*(298 K) is an average of the values measured by Westenberg and deHaas,[12] Lee et al.,[8] Miller and Gordon,[9] and Kita and Stedman.[6] The value of *k*(298 K) derived in the flash photolysis - resonance fluorescence study of Davis et al.[4] agrees with these studies but was likely overestimated by ~10% (the authors assumed that the fluorescence signal, I_f was proportional to $[Cl]^{0.9}$, whereas a linear relationship between I_f and [Cl] probably held under their experimental conditions). Room temperature determinations by Kumaran et al.[7] (from a study that was actually focused primarily on high temperature measurements) and Eberhard et al.[5] (focused on obtaining yields of HCl product in different vibrational levels) are both in reasonable agreement with the recommendation, as are the results from the relative rate studies by Su et al.[11] and by Rodebush and Klingelhoefer.[10] The value for *E*/R is derived from a fit to the data at temperatures below 300 K reported by Westenberg and deHaas,[12] Lee et al.,[8] and Miller and Gordon.[9] The value is in good agreement with that determined by Adusei and Fontijn,[1] although these data lie systematically lower than the results from other studies. Extrapolation above room temperature using the recommended Arrhenius parameters is in reasonable agreement with the data of Benson et al.[3] and Kita and Stedman.[6] For a discussion of the large body of rate data at high temperatures, see the review by Baulch et al.[2] Miller and Gordon[9] and Kita and Stedman[6] also measured the rate of the reverse reaction and found the ratio to be in good agreement with equilibrium constant data.

F70. **Cl + H_2O_2.** The absolute rate coefficients determined at ~298 K by Watson et al.,[6] Leu and DeMore,[3] Michael et al.,[4] Poulet et al.,[5] and Keyser[2] range in value from (3.6–6.2) × 10^{-13}. The studies of Michael et al., Keyser, and Poulet et al. are presently considered to be the most reliable. The recommended Arrhenius parameters are those reported by Keyser. The *A*-factor reported by Michael et al. is considerably lower than that expected from theoretical considerations and may possibly be attributed to decomposition of H_2O_2 at temperatures above 300 K. The data of Michael et al. at and below 300 K are in good agreement with the Arrhenius expression reported by Keyser. Heneghan and Benson,[1] using mass spectrometry, confirmed that this reaction proceeds only by the abstraction mechanism giving HCl and HO_2 as products.

F71. **Cl + NO_3.** The recommended value at room temperature is based on the discharge flow-EPR study of Mellouki et al.[5] and the discharge flow-mass spectrometric study of Becker et al.[1] The results of these direct absolute rate studies are preferred over results of the earlier relative rate studies of Cox et al.,[3] Burrows et al.,[2] and Cox et al.,[4] in all of which NO_3 was monitored in the photolysis of Cl_2-$ClONO_2$-N_2 mixtures. Complications in the chemistry of the earlier systems probably contributed to the spread in reported values. This radical-radical reaction is expected to have negligible temperature dependence, which is consistent with the results from the study of Cox et al.[4] in which the complications must have been temperature independent.

F72. **Cl + N_2O.** This rate coefficient has been determined in a study of the halogen-catalyzed decomposition of nitrous oxide at about 1000 K by Kaufman et al.[1] The largest value reported was 10^{-17} cm^3 $molecule^{-1}$ s^{-1}, with an activation energy of 34 kcal/mol. Extrapolation of these results to low temperature shows that this reaction cannot be of any significance in atmospheric chemistry. Kinetic isotope effects observed by Lesar et al.[2] are consistent with a reaction transition state where the chlorine atom is bonded to the oxygen atom of nitrous oxide with a planar trans arrangement of atoms.

F73. Cl + HNO_3. The recommended upper limit at room temperature is that reported in the study of Wine et al.,[5] in which long-path laser absorption spectroscopy was used to look for the appearance of NO_3 following the pulsed laser photolysis of Cl_2-HNO_3 mixtures, with no evidence for NO_3 production observed. In the same study, a less sensitive upper limit was derived from monitoring Cl atom decay by resonance fluorescence. A less sensitive upper limit was also found in the discharge flow-EPR study of Zagogianni et al.[6] Higher values obtained in earlier studies (Leu and DeMore,[3] Kurylo et al.,[2] and Clark et al.[1]), as well as the higher temperature results of Poulet et al.[4] are not used.

F74. Cl + HO_2NO_2. The only study of this reaction is by Simonaitis and Leu[1] using the low pressure discharge flow technique coupled with resonance fluorescence detection of Cl and mass spectrometric detection of HO_2NO_2 ion fragments. Consistent results were obtained monitoring either Cl or HO_2NO_2 decays and retrieved rate constants were less than 1×10^{-13} cm^3 molecule^{-1} s^{-1} for all conditions. Impurities in the HO_2NO_2 sample (especially H_2O_2) complicated the measurements. A limited temperature study over the 296–399 K range suggests that E/R is in the range of 500–1500 K. Given the experimental difficulties, only an upper limit is recommended for the reaction rate.

(1) Simonaitis, R.; Leu, M. T. Rate constant for the reaction Cl + HO_2NO_2 → Products. *Int. J. Chem. Kinet.* **1985**, *17*, 293-301, doi:10.1002/kin.550170306.

F75. Cl + CH_4. The recommended value for *k*(298 K) = 1.0×10^{-13} cm^3 molecule^{-1} s^{-1} is obtained as an average of the values derived from the absolute rate constant studies of Manning and Kurylo,[15] Whytock et al.,[28] Michael and Lee,[17] Lin et al.,[14] Zahniser et al.,[29] Keyser,[8] Ravishankara and Wine,[22] Heneghan et al.[7] (which is assumed to supersede the results obtained by Baghal-Vayjooee et al.[1]), Dobis and Benson,[6] Sawerysyn et al.,[23] Lazarou et al.,[11] Beichert et al.,[2] Seeley et al.,[25] Pilgrim et al.,[18] Mellouki et al.,[16] Wang and Keyser,[26] and Bryukov et al.,[3] all of which fall in the range (0.9–1.13) × 10^{-13} cm^3 molecule^{-1} s^{-1}. Other absolute studies by Davis et al.,[5] Clyne and Walker,[4] Poulet et al.,[19] Leu and DeMore,[13] Watson et al.,[27] and Schlyer et al.[24] yield rate constant values slightly higher than those of the aforementioned studies. In some cases, this may be due to uncertainties in correcting the data for Cl atom loss via reaction with trace levels of ethane and propane in the methane samples used. Thus, these results were not used in deriving the recommended value for *k*(298 K). The values derived for *k*(298 K) from the competitive chlorination studies of Pritchard et al.,[20] Pritchard et al.,[21] Knox,[9] Knox and Nelson,[10] Lee and Rowland,[12] and Lin et al.[14] are in the range (0.8–1.6) × 10^{-13} cm^3 molecule^{-1} s^{-1} when the original data are referenced to the presently recommended rate constant values for the reference reactions of Cl with H_2 and C_2H_6; these studies were not used in deriving the recommended value for *k*(298 K). In particular, the reference reaction Cl + C_2H_6 has a rate constant more than three orders of magnitude greater than that of Cl + CH_4, thus making it far from ideal for a competitive chlorination study.

Nine of the aforementioned absolute studies used in the derivation of *k*(298 K) were performed at temperatures below 300 K (Manning and Kurylo,[15] Whytock et al.,[28] Lin et al.,[14] Zahniser et al.,[29] Keyser,[8] Ravishankara and Wine,[22] Heneghan et al.,[7] Seeley et al.,[25] and Wang and Keyser[26]). The agreement among all studies below 300 K is reasonably good, with values of E/R ranging from 1170 K to 1320 K. The recommended *E*/R = 1270 K is derived from a combined fit to all data below 300 K from these nine studies after scaling each of the individual data sets to the recommended *k*(298 K). Systematic differences in activation energies are apparent when calculated using data obtained below 300 K versus data from above 300 K. Three studies have been performed over the temperature region between 200 and 500 K (Whytock et al.,[28] Zahniser et al.,[29] and Keyser[8]), and in each case non-linear Arrhenius behavior was observed.

The curvature in the Arrhenius plot over the temperature range from 180 K to 410 K can be fit by the three-parameter expression:

$$k(180\text{–}410\ \mathrm{K}) = 2.36 \times 10^{-12}\ (\mathrm{T}/298)^{1.37} \exp(-939/\mathrm{T}).$$

Below 307 K, this expression yields values for k(T) within 2% of those calculated using the Arrhenius parameters recommended above. The three-parameter expression is recommended for use in calculating the rate constants from the results of relative rate studies conducted both above and below room temperature in which the Cl + CH_4 reaction is used as the reference.

Ravishankara and Wine[22] observed that at temperatures below 240 K the apparent bimolecular rate constant was dependent on the chemical composition of the reaction mixture. They suggested that the effect was due to a non-equilibration of the $^2P_{1/2}$ and $^2P_{3/2}$ states of atomic chlorine when the mixture did not contain an efficient spin equilibrator, and thus the results obtained at lower pressure using the discharge flow and competitive chlorination techniques may be in error at the lower temperatures (<240 K). However, subsequent studies did not reproduce this observation. Therefore, only data obtained by Ravishankara and Wine[22] above 240 K were used here in the global fit.

F76. **Cl + CH_3D.** The recommended value for *k*(298 K) is an average of the relative rate determinations by Feilberg et al.,[2] Sauer et al.,[3] Saueressig et al.[4] (two measurements), and Tyler et al.,[5] all of which are in excellent agreement. The recommended value of *E*/R is derived from a combined fit to the data reported in the last three papers listed above after scaling each individual data set to the recommended *k*(298 K). The uncertainty in the data reported by Boone et al.[1] (both in the measured rate constant ratio and in the temperature of the experiment) significantly exceeds those of other studies. Hence, these data were not used in the evaluation. However, this result is encompassed within the recommended 2σ uncertainty. The result originally reported by Wallington and Hurley[6] was corrected in a personal communication from the authors as later reported by Saueressig et al.[4] The corrected value is in excellent agreement with the recommendation at the temperature of the experiment. Note that a three-parameter expression recommended for the reaction Cl + CH_4 was used to derive the rate constants from the rate constant ratios reported in the original papers. The excellent agreement among all of the results reported for the reaction between Cl and CH_3D used in deriving this recommendation could be well encompassed within uncertainty limits calculated with *f*(298 K) = 1.03 and g = 50. However, all of the above mentioned studies are relative rate measurements that utilize the same reference reaction, Cl + CH_4. Thus, all of these determinations can be affected by the same systematic uncertainty in the reference rate constant. The recommended uncertainty parameters, *f*(298 K) and g account for this added uncertainty.

F77. **Cl + H_2CO.** The results from five of the six published studies (Michael et al.,[4] Anderson and Kurylo,[1] Niki et al.,[5] Fasano and Nogar,[2] and Poulet et al.[6]) are in good agreement at ~298 K, but are ~50% greater than the value reported by Foon et al.[3] The recommended value at 298 K is obtained by combining the absolute values reported by Michael et al., Anderson and Kurylo, and Fasano and Nogar, with the values obtained by combining the ratio of $k(Cl + H_2CO)/k(Cl + C_2H_6)$ reported by Niki et al. (1.3 ± 0.1) and by Poulet et al. (1.16 ± 0.12) with the recommended value of 5.7×10^{-11} cm^3 $molecule^{-1}$ s^{-1} for $k(Cl + C_2H_6)$ at 298 K. The recommended value of E/R is obtained from a least-squares fit to all the data reported in Michael et al. and in Anderson and Kurylo. The A-factor was adjusted to agree with the recommended value at 298 K.

F78. **Cl + HC(O)OH.** The room temperature kinetics of this reaction have been studied by Wallington et al.[3] and Li et al.[1] Wallington et al. used a relative rate technique at atmospheric pressure, while Li et al. employed flash photolysis at a pressure of 10 Torr. The results of the two studies are in excellent agreement and have been averaged together to derive the recommended value for k(298 K). Reaction products have been investigated by Tyndall et al.[2] at room temperature and 700 Torr pressure. They measured the CO_2 yield to be 96 ± 5% and suggested that the HOCO complex reacted with either O_2 or Cl_2 in their experiment to give the observed product.

F79. **Cl + CH_3O_2.** The recommended value for k(298 K) is based on results of Maricq et al.,[3] Jungkamp et al.,[2] and Daële and Poulet.[1] All three studies agree that this overall reaction is very fast. However, there is a discrepancy in the reported values of the branching ratios for the two pathways producing $ClO + CH_3O$ (a) and $HCl + CH_2O_2$ (b). The branching ratio for the reaction channels producing $HCl + CH_2O_2$ (b) was reported to be 50% by both Maricq et al. and Jungkamp et al. but was reported to be 90% by Daële and Poulet. Because of this large discrepancy no branching ratios are recommended.

F80. Cl + CH_3OH. This recommendation for k(298 K) is based on results of the absolute rate studies of Michael et al.,[4] Payne et al.,[7] Dobe et al.,[1] Pagsberg et al.,[6] and Tyndall et al.,[10] and results obtained in the competitive chlorination studies of Wallington et al.,[11] Lightfoot et al.,[2] Nelson et al.,[5] and Tyndall et al. The temperature independence of the rate constant was reported by Michael et al. in a direct study. This is consistent with the indirect results of Lightfoot et al., who deduced the rate coefficient for this reaction relative to that for methane as a function of temperature. This reaction can have two sets of products: CH_2OH + HCl, channel (a) and CH_3O + HCl, channel (b). Product analysis and isotopic substitution have established that the reaction proceeds via channel (a) rather than via channel (b); see Radford,[8] Radford et al.,[9] Meier et al.,[3] and Payne et al.[7] This reaction has been used in the laboratory as a source of CH_2OH and as a source of HO_2 by the reaction of CH_2OH with O_2.

F81. Cl + CH_3OOH. The recommended value for k(298 K) is taken from the only study of this reaction by Wallington et al.,[1] who measured the rate relative to Cl + C_2H_6 at 295 K and atmospheric pressure.

(Table: 02-25, Note: 02-25, Evaluated: 02-25) Back to Table

F82. Cl + CH_3ONO_2. This reaction has been studied at 298 K by Nielsen et al.[1] using a relative rate technique. The reference compound was ethane. The recommended value is adjusted from that given by Nielsen et al. using the currently recommended value for k(Cl + C_2H_6). The temperature dependence is estimated by assuming an A-factor equal to approximately 20 times that of OH + CH_3ONO_2. This is consistent with observed Cl/OH A-factor ratios for primary H-abstraction from alkanes.

(Table: 02-25, Note: 02-25, Evaluated: 02-25) Back to Table

(1) Nielsen, O. J.; Sidebottom, H. W.; Donlon, M.; Treacy, J. An absolute- and relative-rate study of the gas-phase reaction of OH radicals and Cl atoms with *n*-alkyl nitrates. *Chem. Phys. Lett.* **1991**, *178*, 163-170, doi:10.1016/0009-2614(91)87051-C.

F83. **Cl + C_2H_6.** The recommended value for k(298 K) is an average of the absolute rate coefficients reported in the studies of Manning and Kurylo,[17] Lewis et al.,[15] Dobis and Benson,[6] Beichert et al.,[3] Pilgrim et al.,[19] Tyndall et al.,[24] Hitsuda et al.,[9] Bryukov et al.,[4] and Hickson and Keyser,[8] all of which fall in the range (5.3–6.1) × 10^{-11} cm^3 $molecule^{-1}$ s^{-1}. The value derived by Ray et al.,[21] in a study where the primary focus was not the determination of the rate constant for the target reaction, lies in the same range. A somewhat higher value reported by Davis et al.[5] was probably overestimated by ~10% (the authors assumed that the fluorescence signal, I_f was proportional to $[Cl]^{0.9}$, whereas a linear relationship between I_f and [Cl] probably held under their experimental conditions). The rate constant reported by Schlyer et al.[22] lies significantly lower than those from all other absolute studies, while the values from Mellouki et al.[18] and Kaiser et al.[11] lie slightly higher. Room temperature rate constants derived from the relative rate experiments of Pritchard et al.,[20] Knox and Nelson,[13] Atkinson and Aschmann,[1] Atkinson and Ashmann,[2] Tschuikow-Roux et al.,[23] Wallington et al.,[25] Beichert et al.,[3] Hooshiyar and Niki,[10] and Lin et al.[16] exhibit considerably more scatter even when recalculated based on the same (current) recommendations for the rate constants of the reference reactions. Nevertheless, most are encompassed within the 2σ uncertainty limits recommended for the value of k(298 K). The relative rate results of Kelly et al.[12] and Lee and Rowland[14] are significantly lower than other room temperature measurements. The recommended value for E/R is taken from a combined fit to the data of Manning and Kurylo,[17] Dobis and Benson,[6] and Hickson and Keyser[8] after scaling all three data sets to the recommended value of k(298 K). The data from Lewis et al.[15] and Lin et al.[16] below 300 K are encompassed by the 2σ uncertainty bands. The temperature dependent studies by Pilgrim et al.[19] and Bryukov et al. did not extend below room temperature. An extrapolation of the recommended Arrhenius parameters and the 2σ uncertainty bands above room temperature encompasses the data of Pilgrim et al. but not those of Bryukov et al., which are characterized by a much stronger temperature dependence. The data obtained at very low temperatures (167–48 K) in Laval nozzle experiments by Hickson et al.[7] strongly support the current recommendations.

F84. Cl + $C_2H_5O_2$. The recommended values of *k*(298 K) for the two reaction channels are based on results of Maricq et al.[1]
(Table: 94-26, Note: 94-26, Evaluated: 94-26) Back to Table

(1) Maricq, M. M.; Szente, J. J.; Kaiser, E. W.; Shi, J. Reaction of chlorine atoms with methylperoxy and ethylperoxy radicals. *J. Phys. Chem.* **1994**, *98*, 2083-2089, doi:10.1021/j100059a017.

F85. Cl + CH_3CH_2OH. The rate coefficient for this reaction has been studied at 298 K by four groups using a relative rate technique: Nelson et al.,[2] Wallington et al.,[4] Edelbüttel -Einhaus et al.,[1] and Taatjes et al.[3] Nelson et al. measured this rate constant relative to Cl + cyclohexane, while the others used Cl + C_2H_6 as the reference reaction. Taatjes et al. also measured this rate coefficient by measuring the temporal profile of the HCl product. The agreement between these five measurements is quite good, and the recommendation for *k*(298 K) is based on the average value. Taatjes et al. studied the temperature dependence of this rate coefficient above 298 K and found it to be essentially independent of temperature. We recommend the same temperature independence at atmospheric temperatures.

This reaction can have three sets of products: CH_2CH_2OH + HCl, channel (a); CH_3CHOH, channel (b); and CH_3CH_2O channel (c). Taatjes et al. have deduced that channel (c) is negligible and that channel (a) is about 8% at 298 K. Therefore, the majority of reaction is expected to occur via channel (b). It is very unlikely that these branching ratios will change significantly at lower atmospheric temperatures.

F86. Cl + $CH_3C(O)OH$. The recommended value for *k*(298 K) is based on the room temperature study by Koch and Moortgat[1] using a relative rate technique. Deuterium substitution of the methyl hydrogens decreased the observed rate by a factor of 3.75. In addition, CO and CO_2 reaction products were observed in a stoichiometric ratio of 1:1. These observations were interpreted in terms of methyl hydrogen abstraction from acetic acid to form the $CH_2C(O)OH$ radical followed by reaction with O_2 to form a peroxy radical. Thermal decomposition of the peroxy radical produces HCHO, CO_2, and atomic H. In the laboratory system, the HCHO reacts with atomic chlorine to yield CO.

F87. Cl + CH_3CN. The recommended Arrhenius parameters are based on the study by Tyndall et al.,[4] using both relative and absolute methods over a wide range of experimental conditions. These results are preferred over those of earlier studies by Kurylo and Knable,[1] Poulet et al.,[3] and Olbregts et al.[2] Product studies reported by Tyndall et al.[4] show that reaction proceeds predominantly, if not exclusively, by hydrogen atom abstraction.

F88. Cl + $C_2H_5ONO_2$. Wallington et al.[2] and Nielsen et al. [1] have measured the rate of this reaction at room temperature relative to atomic chlorine reactions with ethyl chloride and ethane, respectively. The two studies are in excellent agreement, and the recommended value is based on an average of the two. The values given in Wallington et al. and Nielsen et al. were adjusted based on the currently accepted values of the reference rate constants. The temperature dependence is estimated by assuming an *A*-factor equal to approximately 20 times that of OH + CH_3ONO_2. This is consistent with observed Cl/OH *A*-factor ratios for primary H-abstraction from alkanes.

F89. Cl + $CH_3CO_3NO_2$ (PAN). The recommended upper limit for *k*(298 K) is based on results of the relative rate study of Wallington et al.[2] In this study, no reaction of PAN was observed in the presence of Cl atoms. These results are preferred over the results of the direct study of Tsalkani et al.[1] using a discharge flow system with EPR detection of Cl atom decay (in which the authors reported a rate constant of $(3.7 \pm 1.7) \times 10^{-13}$ cm^3 $molecule^{-1}$ s^{-1}). In both studies, the major impurity in the PAN samples would be the alkane solvent. The presence of 0.1% tridecane in the PAN sample used by Tsalkani et al. could account for the observed Cl atom decay; however, solvent impurities in the PAN sample would be of no consequence in the relative rate study of Wallington et al.

(2) Wallington, T. J.; Andino, J. M.; Ball, J. C.; Japar, S. M. Fourier transform infrared studies of the reaction of C1 atoms with PAN, PPN, CH_3OOH, HCOOH, CH_3COCH_3 and $CH_3COC_2H_5$ at 295 ± 2 K. *J. Atmos. Chem.* **1990**, *10*, 301-313, doi:10.1007/BF00053865.

F90. Cl + C_3H_8. The recommended values for k(298 K) and E/R for two individual reaction channels are presented in the Table. The recommended k(298 K) values are the means of the results from the competitive chlorination studies by Knox and Nelson,[8] Kelly et al.,[7] Tschuikow-Roux et al.,[14] Tyndall et al.,[15] and Sarzynski and Sztuba.[13] The recommended E/R values are based on the data of Sarzynski and Sztuba obtained between 300 K and 400 K.

The recommended value for k(298 K) for the overall reaction given below is the mean of results of the competitive chlorination studies of Pritchard et al.,[12] Knox and Nelson,[8] Kelly et al.,[7] Tschuikow-Roux et al.,[14] Atkinson and Aschmann,[1] Wallington et al.,[16] Beichert et al.,[2] Hooshiyar and Niki,[6] Tyndall et al.[15] (two determinations), and Sarzynski and Sztuba,[13] and the absolute rate studies of Lewis et al.,[9] Beichert et al.,[2] Pilgrim et al.,[11] Mellouki,[10] Hitsuda et al.[5] , and Choi et al.[3] The recommended value of E/R = 0 for the overall reaction is based on the data obtained between 300 and 400 K by Sarzynski and Sztuba. The data obtained at very low temperatures (167–48 K) in Laval nozzle experiments by Hickson et al.[4], the data of Pilgrim et al.,[11] extended to higher temperatures (292–700 K) , and the measurements by Choi et al.[3] at 298 K and 195 K exhibit no variation with temperature and, thus, support this recommendation.

$$A = 1.45 \times 10^{-10}\ \text{cm}^3\ \text{molecule}^{-1}\ \text{s}^{-1}$$
$$E/\text{R} = 0$$
$$k(298\ \text{K}) = 1.4 \times 10^{-10}\ \text{cm}^3\ \text{molecule}^{-1}\ \text{s}^{-1}$$
$$f(298\ \text{K}) = 1.05$$
$$g = 0$$

The sum of the recommended rate constant expressions for the two channels gives the same values as the rate constant expression recommended for the total reaction.

F91. Cl + $CH_3C(O)CH_3$. The recommended value for *k*(298 K) is an average of the values derived in the relative rate studies by Carr et al.,[2] Christensen et al.,[3] Martinez et al.,[4] Orlando et al.,[7] Romanias et al.,[8] and Wallington et al.[10] and in the absolute rate studies by Romanias et al.,[8] Takahashi et al.,[9] and Zhao et al.,[11] all of which agree to within 15–20%. Room temperature rate constants reported by Notario et al.[5] and Albaladejo et al.[1] are about 40–50% greater than the recommended value, whereas the value reported by Olsson et al.[6] is approximately 25% lower than recommended. Because of the level of disagreement with eight other studies, the results of the last three investigations listed above were not included in deriving the recommended value for *k*(298 K). The recommended value for *E*/R is derived from an Arrhenius fit to the data of Orlando et al.[7] and Zhao et al.[11] and the absolute rate data of Romanias et al.[8] after scaling each data set to the recommended value for *k*(298 K). The relative rate data from Romanias et al. were not included due to uncertainties in the rate constants for the reference reactions. Nevertheless, the rate constant values derived from these relative rate experiments are in good agreement with the recommended rate expression. Although the data of Orlando et al.[7] lie systematically about 13% lower than those of Zhao et al.,[11] the *E*/R values reported in both studies are nearly identical. End product studies clearly show that the products of this reaction are $CH_3C(O)CH_2$ and HCl. (Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

F92. Cl + CH_2=C(CH_3)CHO (Methacrolein). The recommendation is based on the relative rate studies of Kaiser et al.[4] and Orlando et al.[5] with the error limits adjusted to encompass the results of Canosa-Mas et al.[1,2] and Wang et al.[7] Kaiser et al. report that the 297 K rate coefficient is pressure dependent at P <100 Torr N_2, a result that is confirmed theoretically by Sun et al.,[6] who also calculate a 297 K high pressure limit rate constant in excellent agreement with the recommendation. The available information suggests that the rate constant measured by Canosa-Mas et al. in a low-pressure discharge flow study[1] is too fast. Experimental yields of HCl are reported by Canosa-Mas et al.[1] (18 ± 2%) and Kaiser et al. (27 ± 3%). Additional product studies by Kaiser et al. lead these authors to conclude that ~90% of the HCl production is via abstraction of the aldehydic hydrogen with the other 10% being attributable to abstraction of a methyl hydrogen. Sun et al. obtain a theoretical HCl yield of 12% with essentially all HCl production resulting from abstraction of the aldehydic hydrogen. Molar yields of carbon-containing products in NO_x-free air at P ~1 atm and T ~297 K have been reported by Kaiser et al. (44 ± 5% $ClCH_2C(O)CH_3$; 27 ± 3% CO_2; 14 ± 2% HCHO) and Orlando et al. (52 ± 4% CO; 42 ± 5% $ClCH_2C(O)CH_3$; 23 ± 2% CO; 18 ± 2% HCHO; ~5% ClCHO); the significant yield of $ClCH_2C(O)CH_3$ suggests that addition of Cl to the terminal carbon of the double bond is an important reaction pathway. A turbulent flow reactor study by Hsin and Elrod[3] obtains a Cl-methacrolein-OO + NO rate constant of $(1.17 \pm 0.11) \times 10^{-11}$ cm^3 $molecule^{-1}$ s^{-1}.

F93. Cl + $CH_3C(O)CH$=CH_2 (MVK). The recommendation is based on the relative rate studies of Canosa-Mas et al.,[2] Finlayson-Pitts et al.,[3] Orlando et al.,[5] and Wang et al.,[6] all of which were carried out at room temperature using ~1 atm N_2 [2,3,6] or air[5] bath gas. In a low-pressure flow tube study, Canosa-Mas et al.[1] obtain rate constants that are about a factor of two slower than the recommended value. Product yields reported by Orlando et al. in NO_x-free air at P = 1 atm and T = 298 K are 75% $ClCH_2CHO$, 58 ± 5% CO_2, 47 ± 7% HCHO, 8% CH_3OH, 7 ± 1% ClCHO, and 6% $CH_3C(O)OOH$; the large observed yield of $ClCH_2CHO$ leads to the conclusion that the dominant reaction pathway is addition to the terminal carbon atom of the double bond. A turbulent flow reactor study by Hsin and Elrod[4] obtained a Cl-MVK-OO + NO rate constant of $(1.14 \pm 0.14) \times 10^{-11}$ cm^3 $molecule^{-1}$ s^{-1}.

(6) Wang, W.; Ezell, M. J.; Ezell, A. A.; Soskin, G.; Finlayson-Pitts, B. J. Rate constants for the reactions of chlorine atoms with a series of unsaturated aldehydes and ketones at 298 K: structure and reactivity. *Phys. Chem. Chem. Phys.* **2002**, *4*, 1824-1831, doi:10.1039/b111557j.

F94. Cl + CH_2=$C(CH_3)CH$=CH_2 (Isoprene). The recommended 298 K rate constant is an average of room temperature results reported by Ragains and Finlayson-Pitts,[10] Fantechi et al.,[4] Notario et al.,[4,7] Bedjanian et al.,[2] Stutz et al.,[11] Finlayson-Pitts et al.,[5] Canosa-Mas et al.,[3] Suh and Zhang,[12] Albaladejo,[1] Orlando et al.,[8] and Xing et al.[13] The recommended E/R is based on the single temperature dependence study by Bedjanian et al.,[2] which covered the range 233–320 K. Although the atmospheric pressure relative rate studies of Ragains and Finlayson-Pitts, Fantechi et al., Finlayson-Pitts et al., and Canosa-Mas et al. suggest a 298 K rate constant that is nearly 20% faster than the recommended value, Bedjanian et al. report little or no pressure dependence over the range 0.25–3.0 Torr He, and Xing et al. report no pressure dependence at pressures above 1 Torr Ar. A recommended temperature-dependent yield for HCl is given by the expression $1.1\exp(-595/T)$; the temperature dependence is that reported by Bedjanian et al. while the pre-exponential factor is adjusted to give a 298 K yield of 0.15, the average of values reported by Bedjanian et al., Ragains and Finlayson-Pitts, Fantechi et al., Suh and Zhang, and Xing et al. The reported 298 K HCl yields are in excellent agreement even though they were obtained under very different conditions of pressure and bath gas, i.e., 1 Torr He,[2] 10 Torr He,[12] 700 Torr N_2,[13] 740 Torr Air,[4] and 760 Torr N_2.[10] Molar yields of carbon-containing products in NO_x-free air at P ~1 atm and T ~297 K have been reported by Nordmeyer et al.[6] (9 ± 5% $CH_3C(O)CH$=CH_2; unquantified but significant yields of $ClCH_2C(O)C(CH_3)$=CH_2 and its isomers), Fantechi et al. (4.4 ± 3.3% ClCHO; 1.1 ± 0.8% HCOOH; 25.7 ± 7.4% CO), and Orlando et al. (9.5 ± 1.0% HCHO; 5.1 ± 0.7% ClCHO; unquantified amount of $ClCH_2C(O)C(CH_3)$=CH_2). A turbulent flow reactor study by Patchen et al.[9] obtains a Cl-isoprene-OO + NO rate constant of $(1.15 \pm 0.11) \times 10^{-11}$ cm^3 $molecule^{-1}$ s^{-1} (there are six isomers of Cl-isoprene-OO that could be generated, but the distribution in the Patchen et al. study is presumably the same as would be formed in the atmosphere).

F95. Cl + $C_2H_5CO_3NO_2$. Wallington et al.[1] have measured this rate constant relative to Cl + CH_3Cl. The recommended value of *k*(298 K) is adjusted from that given by Wallington et al. using the currently recommended value for the reference reaction rate constant.
(Table: 02-25, Note: 02-25, Evaluated: 02-25) Back to Table

(1) Wallington, T. J.; Andino, J. M.; Ball, J. C.; Japar, S. M. Fourier transform infrared studies of the reaction of C1 atoms with PAN, PPN, CH_3OOH, HCOOH, CH_3COCH_3 and $CH_3COC_2H_5$ at 295 ± 2 K. *J. Atmos. Chem.* **1990**, *10*, 301-313, doi:10.1007/BF00053865.

F96. Cl + 1-$C_3H_7ONO_2$. The recommended value of *k*(298 K) is based on studies by Wallington et al.[2] and Nielsen et al.,[1] who measured the rate constant at room temperature relative to atomic chlorine reactions with ethyl chloride and ethane, respectively. The two studies are in excellent agreement, and the recommended value is based on an average of the two.
(Table: 10-6, Note: 10-6), Evaluated: 10-6) Back to Table

F97. Cl + 2-$C_3H_7ONO_2$. The recommended value of *k*(298 K) is taken from Wallington et al.,[1] who studied the reaction at 295 K relative to Cl + C_2H_5Cl.
(Table: 10-6, Note: 10-6) Back to Table

(1) Wallington, T. J.; Hinman, M. M.; Andino, J. M.; Siegl, W. O.; Japar, S. M. A relative rate study of the reaction of Cl atoms with a series of alkyl nitrates and nitro alkanes in air at 295 ± 2K. *Int. J. Chem. Kinet.* **1990**, *22*, 665-671, doi:10.1002/kin.550220702.

F98. Cl + OClO. The recommended value for *k*(298 K) is the mean of the values reported by Toohey[2] and by Bemand et al.[1], which are in good agreement. The slight negative temperature dependence reported by Toohey[2] is accepted but with error limits that encompass the temperature independence reported in the Bemand et al. study.
(Table: 90-1, Note: 90-1, Evaluated: 10-6) Back to Table

(2) Toohey, D. W. Kinetic and Mechanistic Studies of Reactions of Bromine and Chlorine Species Important in the Earth's Stratosphere. Ph. D. Thesis, Harvard University, 1988.

F99. Cl + ClOO. The recommended Arrhenius parameters are based on the studies by Mauldin et al.[5] and Baer et al.,[2] in which ClOO was formed by the pulsed photolysis of Cl_2/O_2 mixtures and its overall loss rate was

monitored by UV absorption. In both studies k was found to be independent of temperature. These results are preferred over the results of the earlier, indirect studies of Johnston et al.,[4] Cox et al.,[3] and Ashford et al.[1] The earlier studies did show that the predominant reaction pathway is that yielding $Cl_2 + O_2$ as products. From the branching ratio data of Cox et al., Ashford et al., and Nicholas and Norrish,[6] it can be estimated that this reaction channel constitutes 95% of the overall reaction with ClO + ClO the products of the minor (5%) reaction channel.

F100. $Cl + Cl_2O$. The recommended parameters are determined from results of the temperature-dependent study of Stevens and Anderson[4] and the results of two independent absolute rate coefficient studies reported by Ray et al.,[3] which used the discharge flow-resonance fluorescence and discharge flow-mass spectrometric techniques. The recommended value for k(298 K) is in agreement with the results of Burrows and Cox,[2] who determined the ratio $k(Cl + Cl_2O)/k(Cl + H_2) = 6900$ in modulated photolysis experiments. The earlier value reported by Basco and Dogra[1] has been rejected.

F101. $Cl + Cl_2O_2$. The recommended Arrhenius parameters are from Ingham et al.[2] in a study between 217 K and 298 K using a DF-MS/RF technique. The room temperature value reported by Cox and Hayman[1] in a study using a static photolysis technique with photodiode array UV spectroscopy is in excellent agreement with the recommended value.

F102. Cl + HOCl. The recommended parameters are based on results over the temperature range 243–365 K reported by Cook et al.[1] and the room temperature result of Kukui et al.[3] The earlier work of Vogt and Schindler[4] is thought to have been plagued by complexities with the F-atom titration procedure used for HOCl calibration. Ennis and Birks[2] and Kukui et al. reported that the major reaction channel gives the products $Cl_2 + OH$ with measured yields of 91 ± 6% and 96 ± 5%, respectively. Theoretical calculations by Wang et al.[5] lend support to the predominance of the $Cl_2 + OH$ channel at all temperatures below 300 K.

F103. Cl + ClNO. The recommended value for *k*(298 K) is the mean of the values reported by Abbatt et al.,[1] Chasovnikov et al.,[2] Nesbitt et al.,[8] and Kita and Stedman.[6] The room temperature result of Chesnokov [3] is in fair agreement with the recommended value. The laser photolysis-LMR study of Chasovnikov et al.[2] provides rate data for each Cl atom spin state, and they attribute the low value reported by Nelson and Johnston[7] in a laser flash photolysis-resonance fluorescence study to reaction of the Cl $^2P_{1/2}$ state. Adsorption and decomposition of ClNO on the walls of their static system may account for the very low value of Grimley and Houston.[5] The results of Clyne and Cruse[4] in a discharge flow-resonance fluorescence study are significantly lower than all of the later studies. The recommended Arrhenius parameters are from the study of Abbatt et al.[1]

F104. Cl + $ClONO_2$. The recommended Arrhenius parameters are based on the results of Yokelson et al.[3] and those of Margitan[2], which are in excellent agreement. The slightly higher values of Kurylo et al.[1] lie just outside the stated uncertainties. Yokelson et al. report that at 298 K, more than 95% of this reaction proceeds by the reaction channel giving $Cl_2 + NO_3$ as products.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

(2) Margitan, J. J. Chlorine nitrate photochemistry. Photolysis products and kinetics of the reaction Cl + $ClONO_2 \rightarrow Cl_2 + NO_3$. *J. Phys. Chem.* **1983**, *87*, 674-679, doi:10.1021/j100227a029.

(3) Yokelson, R. J.; Burkholder, J. B.; Goldfarb, L.; Fox, R. W.; Gilles, M. K.; Ravishankara, A. R. Temperature dependent rate coefficient for the Cl + $ClONO_2$ reaction. *J. Phys. Chem.* **1995**, *99*, 13976-13983, doi:10.1021/j100038a032.

F105. Cl + CH_3Cl. The recommended value for *k*(298 K) is the mean of results of the absolute rate studies of Manning and Kurylo,[6] Beichert et al.,[1] and Bryukov et al.[2] and the relative rate studies of Wallington et al.,[11] Beichert et al.,[1] Orlando[7] (two independent determinations), and Sarzyński et al.[9] The recommended *E*/R is derived from a fit to the data below 300 K from Manning and Kurylo[6] and from the two relative rate studies of Orlando[7] after scaling each data set to the recommended value for *k*(298 K). While the 298 K results reported by Clyne and Walker[3] are in good agreement, the value of the activation energy derived by these researchers is significantly higher than that recommended, similar to the situation encountered for the Cl + CH_4 reaction. Hence, it is assumed that the discharge flow-mass spectrometric studies of these authors were subject to a systematic error. The *E*/R obtained between 300 K and 400 K by Bryukov et al.,[2] from a study primarily focused at higher temperatures, is in good agreement with that recommended here. The early relative rate studies by Pritchard et al.,[8] Goldfinger et al.,[4] Knox,[5] and Tschuikow-Roux et al.,[10] were not used to derive the recommended parameters since they were performed at temperatures above 298 K and, with the exception of Pritchard et al., yield somewhat higher values for E/R.

F106. Cl + CH_2Cl_2. The recommended value for *k*(298 K) is an average of the values measured in the relative rate studies of Niki et al.,[7] Beichert et al.,[1] Catoire et al.,[3] and Orlando[8] (two independent determinations), and in the absolute rate study of Bryukov et al.[2] For this evaluation, all of the relative rate measurements were recalculated based on the current recommendations for the rate constant of the reference reactions. The recommended value for *E*/R is derived from the data of Orlando and agrees with a fit to the data of Bryukov et al. (obtained at room temperature and above) up to 400 K. Above 400 K, these latter data increase more rapidly with temperature. The relative rate studies of Goldfinger et al.,[5] Knox,[6] and Tschuikow-Roux et al.[9] were performed at temperatures above 298 K and yield significantly higher values for E/R, with the exception of one of the Knox et al. determinations (relative to CH_4), which gives a value of *E*/R in good agreement with that

recommended. The results of Clyne and Walker[4] are higher than those from any other study and were not used in deriving the recommended parameters.

F107. Cl + $CHCl_3$. The recommended value for k(298 K) is an average of the values measured in the relative rate studies of Beichert et al.,[1] Brahan et al.[2] (two independent determinations), Catoire et al.,[4] and Orlando[9] (two independent determinations). The recommended temperature dependence is derived from a fit to the two determinations by Orlando and agrees with a fit to the absolute rate data of Bryukov et al.[3] (obtained at room temperature and above) up to 400 K. Above 400 K, these latter data increase more rapidly with temperature. The room temperature value determined in the relative rate study by Yu and Wijnen[11] is a factor of 50 greater than recommended and was not considered in the recommendation. The results of the absolute investigation of Clyne and Walker[5] are also higher and more scattered than those from most other studies and were not used, nor was the room temperature value derived from the study by Jeoung et al.,[7] which is more than a factor of two lower than recommended. The relative rate study by Goldfinger et al.[6] performed near 500 K obtained values higher than those in more recent investigations. The relative rate study of Knox[8] yields a similar temperature dependence to that recommended but with rate constant values systematically lower than other studies. The absolute study by Talhaoui et al.[10] yielded a 298 K rate constant somewhat lower than recommended and a temperature dependence somewhat higher. For this evaluation, all of the relative rate measurements were recalculated based on the current recommendations for the rate constant of the reference reactions.

F108. Cl + CH_3F (HFC-41). The recommended value for k(298 K) is an average of the values from the absolute rate studies of Manning and Kurylo[2] and Hitsuda et al.[1] and the relative rate studies of Tschuikow-Roux et al.,[3] Tuazon et al.,[4] and Wallington et al.[5] The recommended value for E/R is based on the study of Tschuikow-Roux et al. conducted at room temperature and above. However, in formulating this recommendation for E/R, the reported temperature dependence of Tschuikow-Roux et al. was reduced slightly (by approximately 100 K) to account for what appears to be a small systematic difference between the activation energies obtained in their similar investigations of the Cl + CH_3Cl and Cl + CH_3Br reactions above room temperature and the recommendations that are based on data at 300 K and below. The temperature dependence reported by Manning and Kurylo is significantly lower, seemingly due to a shift in their data below 250 K. This lower value of E/R is not consistent with the recommended values of E/R for Cl + CH_3Cl and Cl + CH_3Br when compared with those for OH + CH_3F, OH + CH_3Cl, and OH + CH_3Br. Hence, it appears that the Manning and Kurylo data may have been influenced by some systematic error at the lower temperatures.

F109. Cl + CH_2F_2 (HFC-32). The recommended value for k(298 K) is an average of the values from the relative rate study of Nielsen et al.[1] and from an Arrhenius fit to the relative rate data of Nilsson et al.[2] obtained in two independent studies, all recalculated using the rate constant for the reference reaction (Cl + CH_4) recommended in this evaluation. The recommended value for E/R is obtained from a fit to the data of Nilsson et al.[2] below 410 K. The rate constants determined in the relative rate study of Tschuikow-Roux et al.[3] lie systematically higher than those of Nielsen et al.[1] and Nilsson et al.[2] but yield a temperature dependence similar to that recommended here.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

F110. Cl + CHF_3 (HFC-23). The recommended upper limit for *k*(298 K) is based on results from the absolute rate study by Jourdain et al.[2] Results from the relative rate study by Coomber and Whittle[1] yield an upper limit that is a factor of 50 smaller.
(Table: 06-2, Note: 15-10, Evaluated: 06-2) Back to Table

(1) Coomber, J. W.; Whittle, E. Photochlorination of methane and fluoroform Dissociation energy D(CF_3-H) and entropy of CF_3 radical. *Trans. Faraday Soc.* **1966**, *62*, 2183-2190, doi:10.1039/tf9666202183.

F111. Cl + CH_2FCl (HCFC-31). The recommended value for *k*(298 K) is an average of the room temperature results from the absolute rate study by Jourdain et al.[1] and the relative rate studies by Tuazon et al.[3] and Wallington et al.[4] The temperature dependence is estimated from a comparison among the Cl and OH reactions with CH_2F_2, CH_2Cl_2, and CH_2FCl. The recommended value of *E*/R (essentially the same as that for the OH + CH_2FCl reaction) is slightly lower than that determined by Tschuikow-Roux et al.,[2] recalculated based on the current recommendation for the rate constant of the reference reaction (Cl + CH_4). However, as discussed for other Cl + halomethane reactions, there appears to be a small systematic overestimation in the temperature dependences determined by these authors.

F112. Cl + $CHFCl_2$ (HCFC-21). The recommended value for *k*(298 K) is the average of the results from the relative rate study of Tuazon et al.[4] and the absolute rate study of Talhaoui et al.[3] These results are preferred over the earlier room temperature results of Glavas and Heicklen.[1] The room temperature value of Jourdain et al.[2] is approximately 50% higher than the recommendation. The recommended value for *E*/R is derived from the data of Talhaoui et al.

F114. Cl + CH_3CCl_3. The recommended value for k(298 K) is an average of the results from the absolute rate study by Talhaoui et al.[4] and the relative rate studies of Platz et al.[3] and Nilsson et al.,[2] both recalculated using the rate constant for the reference reaction (Cl + CH_4) recommended in this evaluation. The recommended value for E/R is derived from a combined fit to the data of Talhaoui et al.[4] and Nilsson et al.[2] for T <400 K after scaling each data set to the recommended value for k(298 K). The results obtained by Cillien et al.[1] in a relative rate study conducted over a very narrow temperature range above room temperature are encompassed by the recommended 2σ uncertainty. The results of the relative rate study of Tschuikow-Roux et al.,[5] although exhibiting a similar temperature dependence, lie systematically higher than the results of all other investigations.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

F115. Cl + CH_3CH_2F (HFC-161). The recommended values for both k(298 K) and E/R for each of the two reaction channels are averages of the individual values derived in the relative rate studies of Cadman et al.,[1] Martens et al.,[3] and Tschuikow-Roux et al.,[4] with each recalculated based on the current recommendation for the rate constant of the reference reaction. The value for k(298 K) of the total reaction obtained from a sum of the two channels is in excellent agreement with the value obtained in the absolute rate study by Hitsuda et al.[2] The parameters for the total reaction are:

$$A = 2.28 \times 10^{-11}\ \text{cm}^3\ \text{molecule}^{-1}\ \text{s}^{-1}$$
$$E/\text{R} = 370\ \text{K}$$
$$k(298\ \text{K}) = 6.6 \times 10^{-12}\ \text{cm}^3\ \text{molecule}^{-1}\ \text{s}^{-1}$$
$$f(298\ \text{K}) = 1.1$$
$$g = 100$$

(4) Tschuikow-Roux, E.; Yano, T.; Niedzielski, J. Reactions of ground state chlorine atoms with fluorinated methanes and ethanes. *J. Chem. Phys.* **1985**, *82*, 65-74, doi:10.1063/1.448737.

F116. Cl + CH_3CHF_2 (HFC-152a). The recommended values for k(298 K) for each of the two reaction channels are based on an average of the individual values from the relative rate studies of Cadman et al.,[1] Martens et al.,[2] and Yano and Tschuikow-Roux[6] (with each recalculated based on the current recommendation for the rate constant of the appropriate reference reaction). The sum of these average values of k(298 K) for the two channels is 2.4×10^{-13} cm^3 molecule^{-1} s^{-1}. However, a more reliable value for k(298 K) = 2.5×10^{-13} cm^3 molecule^{-1} s^{-1} for the overall reaction can be obtained from an average of the results from the relative rate studies of Wallington and Hurley,[5] Tuazon et al.,[4] and Taketani et al.[3] and from the absolute study of Taketani et al.[3] Therefore, for consistency with the total rate constant recommendation, k(298 K) for each channel was scaled by a factor 1.04 (i.e., 2.5/2.4) to obtain the recommended values given in Table 1. The recommended value for E/R for each channel is an average of those determined by Cadman et al.,[1] Martens et al.,[2] and Yano and Tschuikow-Roux.[6] There are no available experimental data on the temperature dependence of the rate constant of the total reaction. A simulated fit to the sum of the rate constants recommended for individual channels yields E/R = 970 K, which is recommended here. Thus, the recommended parameters for the total reaction are:

$$A = 6.5 \times 10^{-12}\ \text{cm}^3\ \text{molecule}^{-1}\ \text{s}^{-1}$$
$$E/\text{R} = 970\ \text{K}$$
$$k(298\ \text{K}) = 2.5 \times 10^{-13}\ \text{cm}^3\ \text{molecule}^{-1}\ \text{s}^{-1}$$
$$f(298\ \text{K}) = 1.1$$
$$g = 100$$

F117. Cl + CH_2FCH_2F (HFC-152). The recommended value for k(298 K) is an average of the values derived in the relative rate studies of Yano and Tschuikow-Roux[2] and Wallington et al.[1] (two determinations), after recalculating each one based on the current recommendation for the rate constant of the appropriate reference reaction. The recommended temperature dependence was determined from a fit to the data of Yano and Tschuikow-Roux, which were obtained at room temperature and above. The temperature dependence may exhibit curvature below room temperature, similar to that for OH + CH_2FCH_2F. Such curvature is most probably encompassed by the assigned uncertainty parameters.

F118. Cl + CH_3CFCl_2 (HCFC-141b). The recommended value for *k*(298 K) is an average of the values derived in the absolute rate studies of Talhaoui et al.[2] and Warren and Ravishankara[5] and in the relative rate studies of Wallington and Hurley[4] and Tuazon et al.[3] The room temperature results of Talhaoui et al. are assumed to supersede those of Sawerysyn et al.[1] The recommended *E*/R is derived from the data of Talhaoui et al. The data of Warren and Ravishankara[5] above room temperature exhibit considerable scatter, apparently due to Cl atom regeneration from decomposition of the radical product (CH_2-$CFCl_2$). Hence, this study was not used in deriving the recommended temperature dependence.

F127. Cl + CHF_2CF_3 (HFC-125). The recommended value for *k*(298 K) is an average of the results from the relative rate studies of Tuazon et al.,[4] Sehested et al.,[3] Edney and Driscoll,[2] and Young et al.,[5] all conducted only at room temperature and recalculated using the current recommendations for the rate constants of the reference reactions. The temperature dependence is estimated from a comparison among the Cl and OH reactions with CH_2FCF_3, CHF_2CHF_2, and CHF_2CF_3. The relative rate study by Coomber and Whittle[1] conducted between 303 K and 399 K corresponds to a value for *k*(298 K) a factor of 2.5 greater than that recommended. However, the value for *E*/R derived by these authors is only slightly lower than that estimated.

F128. ClO + O_3. There are two possible channels for this reaction: ClO + O_3 → ClOO + O_2 (k_1); and ClO + O_3 → OClO + O_2 (k_2). The recommended upper limit for k_1 at 298 K is based on results of Stevens and Anderson.[2] These authors also report that $k_1 = (4 \pm 2) \times 10^{-16}$ cm^3 molecule^{-1} s^{-1} at 413 K. These data can be combined to derive the recommended Arrhenius parameters, $A = 2 \times 10^{-12}$ cm^3 molecule^{-1} s^{-1} and $E/\mathrm{R} > 3600$ K. The upper limit for k_2 is based on results reported by DeMore et al.[1] and Wongdontri-Stuper et al.[3] The Arrhenius parameters for k_2 were estimated.

F130. ClO + NO. The absolute rate coefficients determined in the four discharge flow-mass spectrometric studies (Clyne and Watson,[2] Leu and DeMore,[4] Ray and Watson[5] and Clyne and MacRobert[1]) and the discharge flow laser magnetic resonance study of Lee et al.[3] are in excellent agreement at room temperature, and are averaged to yield the recommended value for k(298 K). The value reported by Zahniser and Kaufman[7] from a competitive study is not used in the derivation of the recommended value, as it is about 33% higher. The magnitudes of the temperature dependences reported by Leu and DeMore[4] and Lee et al. are in excellent agreement. Although the E/R value reported by Zahniser and Kaufman[7] is in fair agreement with the other values, it is not considered as it is dependent upon the E/R value assumed for the Cl + O_3 reaction. The Arrhenius expression is derived from a least-squares fit to the data reported by Clyne and Watson, Leu and DeMore, Ray and Watson, Clyne and MacRobert, and Lee et al. Theoretical rate calculations by Sayin and McKee[6] give a reaction activation energy (~0.35 kcal/mol) over the temperature range 200–400 K that is supportive of the experimental values.

F131. ClO + NO_3. The recommended parameters are based on results reported by Cox et al.,[3] Cox et al.,[4] Biggs et al.,[2] and Kukui et al.[6] Biggs et al. report the rate constant to be independent of temperature, consistent with the results of Cox et al.[4] The study of Kukui et al. supersedes the earlier study of Becker et al.[1] from the same laboratory, which had indicated the major products to be OClO + NO_2. There is now agreement among all studies that the major reaction channel forms ClOO + NO_2 (see Biggs et al.,[2] Cox et al.,[4] and Kukui et al.[6]). From a study of the OClO/NO_3 system, Friedl et al.[5] conclude that at 220 K the formation of ClOO + NO_2 is favored.

F135. ClO + H_2CO. The Arrhenius parameters are estimated based on the upper limit for *k*(298 K) determined by Poulet et al.[1] using the discharge flow-EPR technique.
(Table: 81-3, Note: 81-3, Evaluated: 81-3) Back to Table

(1) Poulet, G.; Le Bras, G.; Combourieu, J. E.P.R. study of the reactivity of ClO with H_2CO at 298 K. *Geophys. Res. Lett.* **1980**, *7*, 413-414, doi:10.1029/GL007i005p00413.

F136. ClO + CH_3O_2. The recommended value for *k*(298 K) is an average of values derived from the temperature dependent data of Helleis et al.[3] (225–355 K), Kukui et al.[6] (233–300 K), and Leather et al.[7] (223–298 K). Two other measurements at only room temperature by Simon et al.[8] and Kenner et al.[5] are 30% larger and 20% smaller, respectively, but overlap the recommended value within the reported uncertainties.

Helleis et al.[3] and Kukui et al.[6] observed very weak temperature dependences of the rate constant with the reported E/R values of +114 K and –80 K, respectively. The data from these studies differ by less than 40% over the entire temperature range. In contrast, the study by Leather et al.[7] yielded a much stronger temperature dependence with a reported *E*/R value of 626 K. Helleis et al.[3] and Kukui et al.[6] used a low pressure discharge flow technique, whereas Leather et al.[7] employed a turbulent flow reactor with substantially higher pressure. Thus, the data from this latter study should be free from possible interferences due to wall reactions. The combination of lower radical concentrations and higher total pressure in the Leather et al.[7] study provides the basis for the temperature dependence recommended here. Thus, the recommended value for *E*/R is derived from a fit to the data of Leather et al.[7] Nevertheless, in the absence of a definitive explanation for the difference between the results from the high and low pressure studies (which is as large as a factor of 2 to 3 at T = 200 K) values of the uncertainty parameters, *f* and *g*, were assigned to encompass the data from all three temperature dependence studies at the 95% confidence level. Note that assymetric values for "*g*" are assigned in the Table. To determine the upper band for *f*(T) one should use *g* = 300, whereas *g* = 20 should be used to determine the lower band of *f*(T).

There is general agreement that the only important reaction channels are those resulting in the production of $ClOO + CH_3O$ (a) and $CH_3OCl + O_2$ (b). However, there is disagreement on their relative importance. At room temperature, Helleis et al.,[3] Simon et al.,[8] Kukui et al.,[6] and Helleis et al.[4] report that reaction channel (a) is the major channel. However it is reported to be the minor channel by Biggs et al.[1] and Daële and Poulet.[2] Helleis et al.[4] (which supersedes the earlier data from Helleis et al.[3]) found that channel (b) increases from 14% at room temperature to 24% at 220 K whereas Kukui et al.[6] found this value to increase from 19% at room temperature to 43% at 230 K, i.e., indicating that both channels can be significant at the low temperatures of the polar stratosphere. All studies of the branching ratios were performed using a low-pressure discharge flow technique. Leather et al.[7] provided no branching ratio information from their higher pressure studies. Given the possibility of the influence of wall processes in the low-pressure studies, no recommendation on the branching ratio is made. Nevertheless, channel (a) appears to play a significant role.

F137. ClO + ClO. There are three bimolecular channels for this reaction:

$$ClO + ClO \rightarrow Cl_2 + O_2\ (k_1)$$

$$ClO + ClO \rightarrow ClOO + Cl\ (k_2)$$

$$ClO + ClO \rightarrow OClO + Cl\ (k_3)$$

The recommended values for the individual reaction channels are from the study of Nickolaisen et al.[8] This study, using a flash photolysis/long path ultraviolet absorption technique, is the most comprehensive study of this system, covering a wide range of temperature and pressure. These results are preferred over the results of earlier studies of the total bimolecular rate coefficient at low pressures by Clyne and Coxon,[1] Clyne and White,[3] and Clyne et al.,[2] and those of other studies reported by Hayman et al.,[5] Cox and Derwent,[4] Simon et al.,[9] Horowitz et al.,[6] and Horowitz et al.[7] The room temperature branching ratios are k_1:k_2:k_3 = 0.29:0.50:0.21. The reaction exhibits both bimolecular and termolecular reaction channels (see entry in Table 2-1). The

termolecular reaction dominates at pressures higher than about 10 Torr. The equilibrium constant for formation of the ClO dimer, ClOOCl, is given in Table 3.

F138. HCl + $ClONO_2$. Five studies of the kinetics of this system have been published, in which the following upper limits to the homogeneous bimolecular rate constant were reported: 10^{-19} cm^3 molecule^{-1} s^{-1} by a static wall-less long-path UV absorption technique and a steady-state flow FTIR technique (Molina et al.[6]); 5 × 10^{-18} cm^3 molecule^{-1} s^{-1} using a flow reactor with FTIR analysis (Friedl et al.[3]); 8.4 × 10^{-21} cm^3 molecule^{-1} s^{-1} using a static photolysis system with FTIR analysis (Hatakeyama and Leu[4] and Leu et al.[5]); and 1.5 × 10^{-19} cm^3 molecule^{-1} s^{-1} by FTIR analysis of the decay of $ClONO_2$ in the presence of HCl in large-volume (2500 and 5800 liters) Teflon or Teflon-coated chambers (Atkinson et al.[1]). Earlier, Birks et al.[2] had reported a higher upper limit. All studies found this reaction to be catalyzed by surfaces. The differences in the reported upper limits can be accounted for in terms of the very different reactor characteristics and detection sensitivities of the various studies. The recommended upper limit for k(298 K) is based on the studies of Hatakeyama and Leu[4] and Leu et al.[5], which apparently are the most sensitive. The homogeneous reaction is too slow to have any significant effect on atmospheric chemistry.

F139. $CH_2ClO + O_2$. The CH_2ClO radical is reported to be resistant to unimolecular dissociation into Cl + CH_2O products, according to chain reaction/product analysis studies by Sanhueza and Heicklen[5] and Niki et al.,[4] and kinetics studies by Catoire et al.[2] The recommended value for *k*(298 K) is based on the work of Kaiser and Wallington,[3] in which the competition between reaction with O_2 and HCl elimination in a complex photochemical reaction system using FTIR detection of stable products was studied. The recommendation is a factor of 5 higher than estimated using the empirical relationship given by Atkinson and Carter.[1] The fate of CH_2ClO in the atmosphere is reaction with O_2.

F140. $CH_2ClO_2 + HO_2$. The recommended Arrhenius parameters are derived from the measurements of Catoire et al.,[1] in which pulsed photolysis with UV absorption detection was used at 1 atm pressure and 251–588 K.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) Back to Table

(1) Catoire, V.; Lesclaux, R.; Lightfoot, P. D.; Rayez, M.-T. Kinetic study of the reactions of CH_2ClO_2 with itself and with HO_2, and theoretical study of the reactions of CH_2ClO, between 251 and 600 K. *J. Phys. Chem.* **1994**, *98*, 2889-2898, doi:10.1021/j100062a027.

F141. CH_2ClO_2 + NO. The recommended value for *k*(298 K) is from Sehested et al.,[1] who used pulsed radiolysis and UV absorption detection of NO_2 to measure the rate coefficient. The temperature dependence is estimated by analogy to similar RO_2 + NO reactions.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) Back to Table

(1) Sehested, J.; Nielsen, O. J.; Wallington, T. J. Absolute rate constants for the reaction of NO with a series of peroxy radicals in the gas phase at 295 K. *Chem. Phys. Lett.* **1993**, *213*, 457-464, doi:10.1016/0009-2614(93)89142-5.

F142. CCl_3O_2 + NO. The recommended value for *k*(298 K) is an average of the values from Ryan and Plumb[3] and Dognon et al.,[1] which are in good agreement. The temperature dependence is derived from the data of Dognon et al., which covered the temperature range 228–413 K. The CCl_3O primary product of the reaction of CCl_3O_2 with NO decomposes rapidly to eliminate Cl, according to Lesclaux et al.[2]

F143. CCl_2FO_2 + NO. The recommended Arrhenius parameters are based on the measurements made by Dognon et al.[1] using pulsed photolysis with mass spectrometry detection at 1–10 Torr and 228–413 K. These results supersede the earlier study of Lesclaux and Caralp.[2] The CCl_2FO radical primary product of the CCl_2FO_2 + NO reaction is reported by Lesclaux et al.[3] and Wu and Carr[4] to rapidly decompose to eliminate Cl and to give the products indicated.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) Back to Table

F144. $CClF_2O_2$ + NO. The recommended value for *k*(298 K) is an average of the determinations reported by Dognon et al.,[1] who used pulsed photolysis with mass spectrometry detection at 1–10 Torr and 228–413 K, and Sehested et al.,[2] who used pulsed radiolysis with UV absorption detection of the NO_2 product at 1 atm and 298 K. The recommended value for *E*/R is derived from the data of Dognon et al.[1] Wu and Carr[3] observed the $CClF_2O$ radical primary product to rapidly dissociate to CF_2O and Cl.

Shaded areas indicate changes or additions since JPL15-10. Italicized blue text denote estimates.

[a] Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

[b] Units are cm^3 $molecule^{-1}$ s^{-1}.

[c] *f*(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(\mathrm{T}) = f(298\ \mathrm{K})\exp\left|g\left(\frac{1}{\mathrm{T}}-\frac{1}{298}\right)\right|$$

Note that the exponent is an absolute value.

1.12.2 Notes: BrO_x Reactions

G1. **O + BrO.** The preferred value is based on the value reported by Thorn et al.[2] using a dual laser flash photolysis-long path absorption-resonance fluorescence technique. Clyne et al.[1] reported a value approximately 40% lower.
(Table: 97-4, Note: 97-4, Evaluated: 10-6) Back to Table

(1) Clyne, M. A. A.; Monkhouse, P. B.; Townsend, L. W. Reactions of O ^3P_J atoms with halogens: The rate constants for the elementary reactions O + BrCl, O + Br_2, and O + Cl_2. *Int. J. Chem. Kinet.* **1976**, *8*, 425-449, doi:10.1002/kin.550080309.

G2. **O + HBr.** Results of the flash photolysis-resonance fluorescence study of Nava et al.[2] for 221–455 K and the laser flash photolysis-resonance fluorescence study of Nicovich and Wine[3] for 250–402 K provide the only data at stratospheric temperatures. Results reported include those of Singleton and Cvetanovic[4] for 298–554 K by a phase-shift technique, and discharge flow results of Brown and Smith[1] for 267–430 K and Takacs and Glass[5] at 298 K. The recommended parameters are based on the results of Nava et al., Nicovich and Wine, and Singleton and Cvetanovic over the same temperature range, since these results are less subject to complications due to secondary chemistry than are the results using discharge flow techniques. The uncertainty at 298 K has been set to encompass these latter results.

G3. **O + HOBr.** The recommended value for *k*(298 K) is the mean of results of Monks et al.[2] and Kukui et al.[1] The temperature dependence is from Nesbitt et al.[3] The *A*-factor from that study has been adjusted to fit the recommended room temperature value. Kukui et al. determined that the Br atom abstraction channel is the only pathway at room temperature.

(3) Nesbitt, F. L.; Monks, P. S.; Payne, W. A.; Stief, L. J.; Toumi, R. The reaction O(^{3}P) + HOBr: Temperature dependence of the rate constant and importance of the reaction as an HOBr stratospheric loss process. *Geophys. Res. Lett.* **1995**, *22*, 827-830, doi:10.1029/95GL00375.

G4. **O + $BrONO_2$.** The recommendation is based on the study of Soller et al.[2] using a laser flash photolysis–resonance fluorescence technique over the temperature range 227–339 K. The recommended uncertainty parameters are larger than those reported by Soller et al. pending independent confirmation of their results. Burkholder[1] has coupled laser flash photolysis with detection of NO_3 by long path absorption spectroscopy to show that the NO_3 yield is >0.85 at 298 K.

G5. **OH + Br_2.** The recommended value for *k*(298 K) is the average of the values reported by Poulet et al.,[5] Loewenstein and Anderson,[4] Gilles et al.,[3] and Bedjanian et al.[1] The temperature dependence is an average of the *E*/R values of Gilles et al. and Bedjanian et al. The room temperature results of Boodaghians et al.[2] are 40% lower than the recommended value for *k*(298 K) and were not considered due to their large experimental uncertainty. Loewenstein and Anderson determined that the exclusive products are Br + HOBr.
(Table: 06-2, Note: 06-2, Evaluated: 06-2) Back to Table

(5) Poulet, G.; Laverdet, G.; Le Bras, G. Kinetics and products of the reaction of hydroxyl radical with molecular bromine. *Chem. Phys. Lett.* **1983**, *94*, 129-132, doi:10.1016/0009-2614(83)87225-X.

G6. **OH + BrO.** The recommended value of *k*(298 K) is an average of the results of Gilles et al.[2] and Bedjanian et al.[1] The only temperature-dependent study is from Bedjanian et al. The recommendation for *E*/R is based on their results. The likely products of this reaction are Br + HO_2. Bedjanian et al. attempted to measure the branching ratio for HBr formation, but there were significant problems from secondary chemistry. An upper limit of 3% was reported for the HBr yield.
(Table: 06-2, Note: 06-2, Evaluated: 06-2) Back to Table

(1) Bedjanian, Y.; Riffault, V.; Le Bras, G.; Poulet, G. Kinetics and mechanism of the OH and OD reactions with BrO. *J. Phys. Chem. A* **2001**, *105*, 6154-6166, doi:10.1021/jp010369q.

G7. **OH + HBr.** The recommended value for *k*(298 K) is the average of the values reported by Ravishankara et al.[7] using FP-RF, Jourdain et al.[6] using DF-EPR, Cannon et al.[3] using FP-LIF, Ravishankara et al.[8] using LFP-RF and LFP-LIF, and Bedjanian et al.[2] using DF-MS. Values reported by Takacs and Glass[11] and Husain et al.[4] as well as the preliminary value of Smith and Zellner[10] are a factor of 2 lower and were not included in the derivation of the recommended value. The recommendation for the temperature dependence is derived from the data of Bedjanian et al.[2] This study obtained a small negative temperature dependence that is in qualitative agreement with the Laval nozzle studies of Sims et al.,[9] Atkinson et al.,[1] and Jaramillo et al.[5] over the 200–300 K temperature range. The data of Ravishankara et al.[7] show no dependence on temperature over the range 249–416 K.

G8. OH + CH_3Br. There are four studies of this reaction using different techniques that report 298 K rate constant values agreeing to within 10% and data that agree to better than 30% over a broad range of temperatures. The recommended value for *k*(298 K) was obtained from an average of the data from these four studies: the relative rate study of Hsu and DeMore[4] (recalculated based on the recommendation for the rate constant for the OH + CH_3CHF_2 reference reaction given in the present evaluation and as discussed in the note for that reaction) and the absolute determinations by Chichinin et al.,[1] Mellouki et al.,[5] and Zhang et al.[7] The results of these extensive studies are preferred over the higher values reported in the earlier studies of Davis et al.[2] and Howard and Evenson.[3] Although the room temperature value reported by Howard and Evenson[3] is ~20% larger, it overlaps the recommended value within the reported experimental uncertainty. The data from Davis et al.[2] yield a *k*(298 K) value that is more than 30% larger than recommended, with the difference between their measured rate constants and those recommended increasing at lower temperatures. This is suggestive of the presence of reactive impurities in the sample of methyl bromide. Also considered, but not used in deriving the recommended Arrhenius parameters are data from the relative rate and absolute studies of Nilsson et al.[6] These data lie higher than the results from almost all of the previous measurements, and exceed the recommended value of *k*(298 K) by ~38% and 60%, respectively. The relative rate results barely overlap the recommended *k*(298 K) value within the combined 95% confidence limits when the uncertainties in the reference rate constants are included. While the high rate constants obtained in the absolute measurements of Nilsson et al. cannot be explained, significantly higher rate constant values were also previously obtained using the same apparatus for the OH reactions with HFC-152a and HCFC-123. The recommended value for *E*/R was derived from a fit to the data of Mellouki et al.[5] below 300 K. The somewhat more scattered low temperature data of Chichinin et al.[1] and Zhang et al.[7] are encompassed within the recommended uncertainties.

G9. OH + CH_2Br_2. The recommended value for *k*(298 K) is an average of the values from the absolute studies of Mellouki et al.[2] and Zhang et al.[4] and from the relative rate measurements of DeMore[1] (recalculated based on the recommendation for the rate constant for the OH + CH_2Cl_2 reference reaction given in this evaluation) and

Orlando et al.[3] (recalculated based on the recommendation for the rate constant for the OH + $CH_3C(O)CH_3$ reference reaction given in this evaluation). The recommended value of *E*/R is derived from an Arrhenius fit to the data of Mellouki et al.[2] The uncertainty parameters reflect the latest understanding of the reactivities of this and similar compounds.

G10. OH + $CHBr_3$. The recommended Arrhenius parameters are derived from the data from the absolute rate study of Orkin et al.[2] The results from the relative rate study of DeMore[1] (recalculated based on the recommendation for the rate constant for the OH + CH_2Cl_2 reference reaction given in this evaluation) lie systematically lower and exhibit a stronger temperature dependence. The results of the Orkin et al.[2] investigation have been used in the rate constant recommendations for the OH reactions with $CHBr_3$, $CHClBr_2$, and $CHCl_2Br$. The observed systematic changes in the rate constants and temperature dependences found in this study are consistent with expectations based on increasing Cl atom substitution.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

G11. OH + CH_2ClBr. The recommended value for *k*(298 K) is an average of the values from two relative rate studies by DeMore[2] (recalculated based on the recommended rate constant for the OH + CH_2Cl_2 reference reaction) and Bilde et al.[1] (recalculated using the recommended rate constant for the OH + CH_2Br_2 reference reaction) and two absolute determinations by Orkin et al.,[3] all of which are in good agreement. The recommended *E*/R is obtained from a fit to the data of DeMore and Orkin et al. after scaling each data set to the recommended *k*(298 K).
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

(2) DeMore, W. B. Experimental and estimated rate constants for the reactions of hydroxyl radicals with several halocarbons. *J. Phys. Chem.* **1996**, *100*, 5813-5820, doi:10.1021/jp953216+.
(3) Orkin, V. L.; Khamaganov, V. G.; Guschin, A. G.; Huie, R. E.; Kurylo, M. J. Atmospheric fate of chlorobromomethane: Rate constant for the reaction with OH, UV spectrum, and water solubility. *J. Phys. Chem. A* **1997**, *101*, 174-178, doi:10.1021/jp962428j.

G12. OH + $CHClBr_2$. The recommended Arrhenius parameters are derived from the data from the absolute rate study of Orkin et al.[1] As discussed in the note for the reaction of OH with $CHBr_3$, the observed systematic changes in the rate constants for the OH reactions with $CHBr_3$, $CHClBr_2$, and $CHCl_2Br$ and the temperature dependences found in this study are consistent with expectations based on increasing Cl atom substitution and provide the basis for the assignment of the uncertainty parameters.
(Table: 15-10, Note: 15-10, Evaluated 15-10) Back to Table

(1) Orkin, V. L.; Khamaganov, V. G.; Kozlov, S. N.; Kurylo, M. J. Measurements of rate constants for the OH reactions with bromoform ($CHBr_3$), $CHBr_2Cl$, $CHBrCl_2$, and epichlorohydrin (C_3H_5ClO). *J. Phys. Chem. A* **2013**, *117*, 3809-3818, doi:10.1021/jp3128753.

G13. OH + $CHCl_2Br$. The recommended Arrhenius parameters are derived from the data from the absolute rate study of Orkin et al.[2] As discussed in the note for the reaction of OH with $CHBr_3$, the observed systematic changes in the rate constants for the OH reactions with $CHBr_3$, $CHClBr_2$, and $CHCl_2Br$ and the temperature dependences found in this study are consistent with expectations based on increasing Cl atom substitution and provide the basis for the assignment of the uncertainty parameters. The room temperature rate constants determined in the relative rate study by Bilde et al.[1] (recalculated using the recommended rate constants for the OH + CH_2Br_2 and CH_2ClBr reference reactions) lie approximately 20% and 50% lower respectively than recommended.
(Table: 15-10, Note: 15-10, Evaluated 15-10) Back to Table

(1) Bilde, M.; Wallington, T. J.; Ferronato, C.; Orlando, J. J.; Tyndall, G. S.; Estupiñan, E.; Haberkorn, S. Atmospheric chemistry of CH_2BrCl, $CHBrCl_2$, $CHBr_2Cl$, $CF_3CHBrCl$, and CBr_2Cl_2. *J. Phys. Chem. A* **1998**, *102*, 1976-1986, doi:10.1021/jp9733375.
(2) Orkin, V. L.; Khamaganov, V. G.; Kozlov, S. N.; Kurylo, M. J. Measurements of rate constants for the OH reactions with bromoform ($CHBr_3$), $CHBr_2Cl$, $CHBrCl_2$, and epichlorohydrin (C_3H_5ClO). *J. Phys. Chem. A* **2013**, *117*, 3809-3818, doi:10.1021/jp3128753.

G14. OH + CHF_2Br (Halon-1201). There are very consistent results from four studies of this reaction: Talukdar et al.[4] (using two different measurement techniques, DF-LMR and PLP-LIF), Orkin and Khamaganov[3] (using DF-EPR), and Hsu and DeMore[2] (relative rate measurements recalculated using the recommended rate constant for the OH + CH_4 reference reaction). Talukdar et al.[4] noted a slight curvature in the Arrhenius plot at the higher temperatures, which is also supported by the data from Orkin and Khamaganov.[3] Below 400 K, all four data sets exhibit nearly identical temperature dependences with *E*/R values ranging from 1271 to 1338 K^{-1}. The recommended value for *k*(298 K) is an average of the rate constants derived from each of the four studies. The recommended value for *E*/R is derived from a combined fit to the data from these four studies below 400 K after each data set was scaled to the recommended *k*(298 K). These data are preferred over the consistently higher results reported by Brown et al.[1]

(3) Orkin, V. L.; Khamaganov, V. G. Rate constants for reactions of OH radicals with some Br-containing haloalkanes. *J. Atmos. Chem.* **1993**, *16*, 169-178, doi:10.1007/BF00702786.
(4) Talukdar, R.; Mellouki, A.; Gierczak, T.; Burkholder, J. B.; McKeen, S. A.; Ravishankara, A. R. Atmospheric lifetime of CHF_2Br, a proposed substitute for halons. *Science* **1991**, *252*, 693-695, doi:10.1126/science.252.5006.693.

G15. OH + CF_2Br_2 (Halon-1202). The *A* factor was estimated and a lower limit for *E*/R was derived using the upper limit for the 298 K rate constant reported by Burkholder et al.[1] in a study using pulsed photolysis-LIF and DF-LMR techniques.
(Table: 02-25, Note: 02-25, Evaluated: 15-10) Back to Table

G16. OH + CF_3Br (Halon-1301). The *A*-factor was estimated and a lower limit for *E*/R was derived using the upper limit for the 460 K rate constant reported by Orkin and Khamaganov.[3] These parameters were then used to calculate an upper limit for *k*(298 K). The upper limit for *k*(298 K) determined by Burkholder et al.[1] using pulsed photolysis-LIF and DF-LMR techniques at room temperature is understandably higher. A less sensitive upper limit was also reported by Le Bras and Combourieu.[2]

G17. OH + CF_2ClBr (Halon-1211). A lower limit for *E*/R was derived using an estimated *A* factor of 1 × 10^{-12} and the upper limit for the 373 K rate constant reported by Burkholder et al.[1] in a study using pulsed photolysis-LIF and DF-LMR techniques. These parameters were then used to calculate an upper limit for *k*(298 K). A less sensitive upper limit was reported by Clyne and Holt.[2]
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Burkholder, J. B.; Wilson, R. R.; Gierczak, T.; Talukdar, R.; McKeen, S. A.; Orlando, J. J.; Vaghjiani, G. L.; Ravishankara, A. R. Atmospheric fate of CF_3Br, CF_2Br_2, CF_2ClBr, and CF_2BrCF_2Br. *J. Geophys. Res.* **1991**, *96*, 5025-5043, doi:10.1029/90JD02735.

Reaction kinetics involving ground $X^2\Pi$ and excited $A^2\Sigma^+$ hydroxyl radicals Part 1.-Quenching kinetics of OH $A^2\Sigma^+$ and rate constants for reactions of OH $X^2\Pi$ with CH_3CCl_3 and CO. *J. Chem. Soc. Faraday Trans. 2* **1979**, *75*, 569-581, doi:10.1039/f29797500569.

G18. OH + CH_3CH_2Br. The recommended values for *k*(298 K) and *E*/R are derived from a fit to the data (T ≤300 K) of Herndon et al.[2] These data suggest a curvature of the Arrhenius plot similar to that found for the OH reaction with CH_3CH_2F. The data of Qiu et al.[3] (which include earlier data reported by the same research group in Xing et al.[4]) were not used because they were obtained mainly above room temperature and exhibit a very steep temperature dependence resulting in a value for *E*/R that is larger than the *E*/R value obtained from data at T >298 K for the OH reaction with CH_3CH_2F. The *k*(300 K) value reported by Donaghy et al.[1] seems too low for this reaction when compared with the recommendation for the presumably slower (and better studied) OH reaction with CH_3CH_2F.

G25. OH + $CH_2BrCH_2CH_3$. The recommended value for *k*(298 K) is an average of *k*(298 K) values derived from Arrhenius fits to the data from Donaghy et al.[1] (using cyclopropane as the reference reactant), Teton et al.,[6] Nelson et al.,[5] Herndon et al.,[3] Gilles et al.,[2] and Kozlov et al.[4] Significant curvature in the Arrhenius plot has been observed over the 480 K to 210 K temperature range, due to the three different hydrogen-abstraction reaction channels. These channels have been quantified in the study of Gilles et al. In spite of the noticeable Arrhenius curvature, the data below 300 K can be reasonably well represented by a two-parameter Arrhenius expression. The recommended value of E/R is an average of the *E*/R values obtained from fits to the data (for T ≤300 K) from Gilles et al.[2] and Kozlov et al.[4] The data over the complete temperature range (210–480 K) can be represented by the three-parameter equation from Kozlov et al.[4]

$$k(\mathrm{T}) = 3.0 \times 10^{-13}\ (\mathrm{T}/298)^{2.8} \exp(+369/\mathrm{T})$$

G26. OH + $CH_3CHBrCH_3$. The recommendation for *k*(298 K) is an average of the values derived from the absolute rate studies of Herndon et al.,[3] Kozlov et al.,[4] and Bryukov et al.[1] and from the relative rate study of Donaghy et al.[2] (using cyclopropane as the reference reactant). Significant curvature in the Arrhenius plot has been observed over the 480 K to 210 K temperature range, presumably due to the existence of two different hydrogen-abstraction channels. In spite of the noticeable Arrhenius curvature, the data below 300 K can be reasonably well represented by a two-parameter Arrhenius fit. The recommended value for *E*/R is an average of the parameters derived from Arrhenius fits to the data (T ≤300 K) of Herndon et al.[3] and Kozlov et al.,[4] which are in excellent agreement. The absolute temperature-dependent data of Teton et al.[5] lie systematically higher than those from the three more recent studies. The data over the complete temperature range (210–480 K) can be represented by the three-parameter equation from Kozlov et al.[4]

$$k(\mathrm{T}) = 1.66 \times 10^{-13}\ (\mathrm{T}/298)^{2.95}\ \exp(+461/\mathrm{T})$$

(5) Teton, S.; El-Boudali, A.; Mellouki, A. Rate constants for the reactions of OH radicals with 1- and 2-bromopropane. *J. Chim. Phys.* **1996**, *93*, 274-282, doi:10.1051/jcp/1996930274.

G27. OH + $CHBr{=}CF_2$. The recommended Arrhenius parameters are derived from the data of Orkin et al.[1] (Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Orkin, V. L.; Louis, F.; Huie, R. E.; Kurylo, M. J. Photochemistry of bromine-containing fluorinated alkenes: Reactivity toward OH and UV spectra. *J. Phys. Chem. A* **2002**, *106*, 10195-10199, doi:10.1021/jp014436s.

G28. OH + $CFBr{=}CF_2$. The recommended Arrhenius parameters are derived from the data of Orkin et al.[1] (Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

(1) Orkin, V. L.; Louis, F.; Huie, R. E.; Kurylo, M. J. Photochemistry of bromine-containing fluorinated alkenes: Reactivity toward OH and UV spectra. *J. Phys. Chem. A* **2002**, *106*, 10195-10199, doi:10.1021/jp014436s.

G29. OH + $CH_2{=}CBrCF_3$. The recommended Arrhenius parameters are derived from a fit to the data (T <300 K) of Patten et al.[2] Earlier, less extensive data from the same laboratory (Orkin et al.[1]) are in excellent agreement. The room temperature data from the relative rate study of Sulbaek-Andersen et al.[3] are also in very good agreement after recalculation using the latest recommended values for the reference reactions. While a standard Arrhenius parameterization provides a very good representation of the rate constants below room temperature, a pronounced curvature can be seen in the data over the full temperature range. Thus, the data over the complete temperature range (220–370 K) can be represented by the three-parameter equation:

$$k(\mathrm{T}) = 4.85 \times 10^{-13}\ (\mathrm{T}/298)^{0.92}\ \exp(+613/\mathrm{T})$$

G33. HO_2 + Br. The recommended value for *k*(298 K) was obtained from an average of the results of Laverdet et al.,[2] Toohey et al.,[5] and Bedjanian et al.[1] The results of Posey et al.[3] were not considered because of problems with the experimental method. The results of Poulet et al.[4] were also not considered because of complications associated with secondary reactions. The recommendation for the temperature dependence is based on the results of Bedjanian et al.[1]
(Table: 06-2, Note: 06-2, Evaluated: 06-2) Back to Table

G34. HO_2 + BrO. The recommendation for *E*/R is based on results of the temperature-dependent studies of Elrod et al.,[5] Li et al.,[7] and Bedjanian et al.[1] It is assumed that the Bedjanian et al. results supersede those of Larichev

et al.[6] since the same experimental technique was used, and the same research group was involved in both studies. The recommended value of *k*(298 K) is the mean of the values reported in these studies, as well as those of Cronkhite et al.[4] and Bloss et al.[2] The room temperature value of Bridier et al.,[3] which was not obtained under pseudo–first-order decay conditions, was not included in derivation of the recommendation. Bedjanian et al. have determined an upper limit of 0.4% for production of HBr and O_3 at 298 K. From a study of the reverse reaction above room temperature, Mellouki et al.[8] determined by extrapolation that the yield of HBr + O_3 is an insignificant fraction (<0.01%) of the total reaction down to 200 K.

(8) Mellouki, A.; Talukdar, R. K.; Howard, C. J. Kinetics of the reactions of HBr with O_3 and HO_2: The yield of HBr from HO_2 + BrO. *J. Geophys. Res.* **1994**, *99*, 22949-22954, doi:10.1029/94JD02144.

G35. **NO_3 + HBr.** The recommendation accepts the upper limit reported by Mellouki et al.[2] in a study using DF-EPR techniques. This upper limit shows that this reaction is of negligible importance in stratospheric chemistry. Canosa-Mas et al.[1] reported a value that is consistent, within experimental error, with the upper limit of Mellouki et al.
(Table: 90-1, Note: 92-20, Evaluated: 10-6) Back to Table

(1) Canosa-Mas, C. E.; Smith, S. J.; Toby, S.; Wayne, R. P. Laboratory studies of the reactions of the nitrate radical with chloroform, methanol, hydrogen chloride and hydrogen bromide. *J. Chem. Soc. Faraday Trans. 2* **1989**, *85*, 709-725, doi:10.1039/f29898500709.

G36. **Cl + CH_3Br.** The recommended value for *k*(298 K) is an average of the results from the absolute rate studies of Gierczak et al.,[1] Kambanis et al.,[3] and Piety et al.,[5] and from the relative rate study of Orlando et al.[4] The recommended value for *E*/R is derived from a combined fit to the data from these same four studies restricted to temperatures of 400 K and below after scaling of each data set to the recommended value of *k*(298 K). Results of the relative rate study of Tschuikow-Roux et al.[6] were not used in the derivation of the recommended values since they appear to be systematically higher than the results of the other investigations. The products of this reaction are expected to primarily be CH_2Br and HCl. The possible production of CH_3Cl + Br is very small in the atmosphere.[2] While a standard Arrhenius parameterization provides a very good representation of the rate constants below 400 K, a pronounced curvature can be seen in the data of Piety et al.[5] particularly above 400 K. The data over the complete temperature range (210–700 K) can be represented by the three-parameter equation

$$k(\mathrm{T}) = 4.60 \times 10^{-12}\ (\mathrm{T}/298)^{1.2} \exp(-700/\mathrm{T})$$

(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

G37. Cl + CH_2Br_2. The recommended value for *k*(298 K) is an average of the results from the absolute rate studies of Gierczak et al.[1] and Kambanis et al.[2] and from the relative rate experiments of Orlando et al.[3] (an average of three studies). The recommended value for *E*/R is based on a combined fit to the data (T <300 K) from these same studies after scaling each one to the recommended value for *k*(298 K). Results of the relative rate study of Tschuikow-Roux et al.[4] were not used in derivation of the recommended parameters since they are significantly greater at 298 K and correspond to a temperature dependence substantially stronger than derived from the data of other investigations.
(Table: 06-2, Note: 06-2, Evaluated: 06-2) Back to Table

G38. Cl + $CHBr_3$. The recommended parameters are based on the only reported study of this reaction by Kambanis et al.,[1] which employed a very low pressure reactor and monitored reactants and products using mass spectrometry.
(Table: 06-2, Note: 06-2, Evaluated: 06-2) Back to Table

(1) Kambanis, K. G.; Lazarou, Y. G.; Papagiannakopoulos, P. J. Absolute rate constants for the reactions of Cl atoms with CH_3Br, CH_2Br_2, and $CHBr_3$. *J. Phys. Chem.* **1997**, *101*, 8496-8502, doi:10.1021/jp9719671.

G39. Cl + CH_2ClBr. The recommended value for *k*(298 K) is an average of two relative rate determinations by Bilde et al.[1] (recalculated based on the recommended rate constants for the reference reactions). The temperature dependence is estimated from a comparison with the reactions of Cl with CH_2Cl_2 and CH_2Br_2. The relative rate investigation by Tschuikow-Roux et al.[2] gives a value for k(298 K) only slightly larger than recommended, but a temperature dependence that is significantly stronger and inconsistent with that recommended for the Cl + CH_2Cl_2 and Cl + CH_2Br_2 reactions.
(Table: 06-2, Note: 06-2, Evaluated: 06-2) Back to Table

G40. Br + O_3. The results reported for *k*(298 K) by Clyne and Watson,[1] Leu and DeMore,[2] Michael et al.,[3] Michael and Payne,[4] Toohey et al.,[7] Nicovich et al.,[5] and Ninomiya et al.[6] are in excellent agreement. The recommended

value at 298 K is derived as the mean of these seven values. There is less agreement among reported temperature dependences, with E/R values ranging from ~900 K^{-1} (Leu and DeMore and Toohey et al.) to ~600 K^{-1} (Michael et al. and Michael and Payne). The recommended value of E/R is an average of the E/R values from the five temperature-dependent studies (not including Clyne and Watson and Ninomiya et al., which were room temperature only).

G41. Br + H_2O_2. The recommended upper limit for k(298 K) is based on results reported by Toohey et al.[5] using a discharge flow-resonance fluorescence-laser magnetic resonance technique. Their upper limit determined over the temperature range 298–378 K is consistent with less sensitive upper limits determined by Leu[2] and Posey et al.[4] using a discharge flow-mass spectrometric technique. The much higher value reported by Heneghan and Benson[1] may result from the presence of excited Br atoms in their very low pressure reactor. The pre-exponential factor was estimated to be the same as that for the Cl + H_2O_2 rate constant, and the E/R value was fit to the upper limit at 298 K. Mellouki et al.[3] have measured the rate of the reverse reaction.

G43. Br + H_2CO. There have been two direct studies of this rate constant as a function of temperature: Nava et al.,[2] using a flash photolysis–resonance fluorescence technique, and Poulet et al.,[3] using a discharge flow-mass spectrometric technique. These results are in reasonably good agreement. The recommended Arrhenius parameters were derived from a least-squares fit to the data reported in these two studies. The higher room temperature value of Le Bras et al.,[1] using a discharge flow–EPR technique, has been shown to be in error due

to secondary chemistry (Poulet et al.). The relative rate study of Ramacher et al.[4] is in good agreement with the recommendation.

G44. Br + CH_2=C(CH_3)CHO. A single relative rate study by Sauer et al.,[2] which employed air as the bath gas at P = 1 atm and T = 301 K, has been reported. The process studied by Sauer et al. is not an elementary reaction. The overall rate constant for loss of methacrolein (CH_2=C(CH_3)CHO) via a multi-reaction sequence was measured relative to the overall rate constant for loss of trans-2-butene via a similar multi-reaction sequence. The multi-reaction sequence involves addition of Br to the alkenes to form bromo-alkyl radicals that react with O_2 in competition with decomposition back to Br + alkene reactants. The rate constant for the reference reaction (Br + trans-2-butene) was measured relative to Br + propene, and the relative rate constants were put on an absolute scale by measuring the Br + propene rate constant relative to that of the well-studied H-abstraction reaction Br + CH_3CHO.[1] A complicated dependence of the overall rate constant on temperature, pressure, and [O_2] is likely, so the recommended rate constant and associated uncertainty are only appropriate for temperatures close to 301 K, pressures close to 1 atm, and O_2 mixing ratios close to those present in air. Sauer et al. report that, at P = 1 atm N_2 + O_2 and T = 301 K, the observed rate constant increases by nearly a factor of 4 as the O_2 partial pressure increases from 0.027 to 1.00 atm. In 900 mbar of synthetic air at 296 K, the following molar product yields are reported by Sauer et al.: HBr, ~0; $CH_3C(O)CH_2Br$, 0.60 ± 0.09; CO, 0.68 ± 0.08, CO_2, 0.10 ± 0.03; H_2CO, 0.08 ± 0.03. Small yields of CH_3OH and CH_3OOH are also reported. Sauer et al. conclude that the dominant reaction pathway is addition of Br to the terminal carbon atom of the double bond.

G45. Br + $CH_3C(O)CH$=CH_2. A single relative rate study by Sauer et al.,[2] which employed air as the bath gas at P = 1 atm and T = 301 K, has been reported. The process studied by Sauer et al. is not an elementary reaction. The overall rate constant for loss of MVK ($CH_3C(O)CH$=CH_2) via a multi-reaction sequence was measured relative to the overall rate constant for loss of trans-2-butene via a similar multi-reaction sequence. The multi-reaction sequence involves addition of Br to the alkenes to form bromo-alkyl radicals that react with O_2 in competition with decomposition back to Br + alkene reactants. The rate constant for the reference reaction (Br + trans-2-butene) was measured relative to Br + propene, and the relative rate constants were put on an absolute scale by measuring the Br + propene rate constant relative to that of the well-studied H-abstraction reaction Br + CH_3CHO.[1] A complicated dependence of the overall rate constant on temperature, pressure, and [O_2] is likely, so the recommended rate constant and associated uncertainty are only appropriate for temperatures close to 301 K, pressures close to 1 atm, and O_2 mixing ratios close to those present in air. Sauer et al. report that, at P = 1 atm N_2 + O_2 and T = 301 K, the observed rate constant increases by about a factor of 2.5 as the O_2 partial pressure increases from 0.027 to 0.395 atm. In 900 mbar of synthetic air at 296 K, the following molar product yields are reported by Sauer et al.: HBr, ~0; CH_2BrCHO, 1.13 ± 0.21; CO_2, 0.61 ± 0.09; H_2CO, 0.39 ± 0.05. Small yields of CH_3OH, CH_3OOH, $CH_3C(O)OH$, and $CH_3C(O)OOH$ are also reported. Sauer et al. conclude that the dominant reaction pathway is addition of Br to the terminal carbon atom of the double bond.

G46. Br + CH_2=$C(CH_3)CH$=CH_2 $\overset{M}{\leftrightarrow}$ adduct $\overset{O_2}{\leftrightarrow}$ products. One relative rate study by Bierbach et al.,[1] which employed air as the bath gas at P = 1 bar and T = 298 K, has been reported. The process studied by Bierbach et al. is not an elementary reaction. The overall rate constant for loss of isoprene via the above multi-reaction sequence was measured relative to the overall rate constant for loss of 1,3-butadiene via a similar multi-reaction sequence; a sequence of relative rate studies were carried out using progressively less reactive reference compounds (2,3-dimethyl-2-butene, trans-2-butene, propene, and acetaldehyde (CH_3CHO), with all relative rate constants being put on an absolute scale using the well-known rate constant for the elementary H-abstraction reaction of Br with CH_3CHO. A Br + CH_2=$C(CH_3)CH$=CH_2 rate constant of 7.4×10^{-11} cm^3 $molecule^{-1}$ s^{-1}, about a factor of three smaller than the gas kinetic collision rate constant, is reported by Bierbach et al. The uncertainty in the rate constant reported by Bierbach et al. is substantial because (i) five rate constant ratios had to be measured to extract the desired rate constant and (ii) all reactions studied except Br + CH_3CHO occurred via complex reaction sequences. Laine et al.[2] have reported a laser flash photolysis–resonance fluorescence study where monitoring of Br kinetics as a function of temperature, pressure, [CH_2=$C(CH_3)CH$=CH_2], and [O_2] has allowed elementary rate constants for H abstraction, Br addition, adduct decomposition, and adduct reaction with O_2 to be deduced; these authors also estimated the temperature dependence of the adduct−O_2 unimolecular decomposition rate constant. The results of Laine et al. suggest that in the atmosphere CH_2=$C(CH_3)CH$=CH_2 is lost irreversibly on essentially every collision with Br at temperatures below 275 K. At higher temperatures, Laine et al. suggest that Br + CH_2=$C(CH_3)CH$=CH_2 may be regenerated via unimolecular reactions rapidly enough to compete with bimolecular reactions of the peroxy radical(s) both in the atmosphere and in environmental chambers. Until additional information becomes available, a recommendation that would prove useful for atmospheric modeling, particularly in warmer environments, cannot be made.

(2) Laine, P. L.; Sohn, Y. S.; Nicovich, J. M.; McKee, M. L.; Wine, P. H. Kinetics of elementary steps in the reactions of atomic bromine with isoprene and 1,3-butadiene under atmospheric conditions. *J. Phys. Chem. A* **2012**, *116*, 6341-6357, doi:10.1021/jp212127v.

G47. Br + CH_2=$C(CH_3)CH$=CH_2 → CH_2=$C(\cdot CH_2)CH$=CH_2 + HBr. The recommendation is based on the results of Laine et al.[1] at temperatures (526–673 K) where adduct decomposition is so rapid that the adduct represents a negligible reservoir for Br. The estimated uncertainty is large because data are only available from a single study and because the long extrapolation to the atmospherically relevant temperature regime (200–300 K) is based on the assumption of Arrhenius behavior. The recommended uncertainty spans all values consistent with the 2σ error limits for *A* and *E*/R reported by Laine et al.
(Table: 15-10, Note: 15-10, Evaluated: 15-10). Back to Table

G48. Br−CH_2=$C(CH_3)CH$=CH_2 + O_2 → products. The recommendation is based on the results of Laine et al.,[1] who extracted kinetic information from observation of the effect of added O_2 on the kinetics of Br equilibration with Br−CH_2=$C(CH_3)CH$=CH_2 following laser flash photolysis of CF_2Br_2/ CH_2=$C(CH_3)CH$=$CH_2/N_2/O_2$ mixtures. The obtained rate constant at T = 297 K was found to be independent of pressure over the range 50 to 700 Torr (mostly N_2). There are several possible isomers of Br−CH_2=$C(CH_3)CH$=CH_2; calculations (G4 method) reported by Laine et al. show that the energetically most stable isomer is $CH_2BrC^{\bullet}(CH_3)CH$=$CH_2$, but there is no experimental information concerning the distribution of isomers formed via Br addition to CH_2=$C(CH_3)CH$=CH_2. The rather large recommended uncertainty results from the somewhat indirect nature of the rate constant determination and the lack of a confirming study.
(Table: 15-10, Note: 15-10, Evaluated: 15-10) Back to Table

G49. Br + OClO. The recommended value for *k*(298 K) is the mean of the values reported by Clyne and Watson[1] and Toohey.[2] In the study of Clyne and Watson, correction for the effect of the rapid reverse reaction was required. The temperature dependence reported by Toohey[2] is accepted but with increased error limits.

G51. Br + Cl_2O_2. The recommended Arrhenius parameters are those determined in a study by Ingham et al.[1] between 223 and 298 K using a DF-MS/RF technique. Ingham et al. found that BrCl was the only major Br-containing product from the reaction.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

(1) Ingham, T.; Sander, S. P.; Friedl, R. R. Kinetics and product studies of the reaction of Br, Cl, and NO with ClOOCl using discharge-flow mass spectrometry. *Faraday Discuss.* **2005**, *130*, 89-110, doi:10.1039/b500179j.

G52. BrO + O_3. The *A* factor was estimated to be similar to that estimated for the ClO + O_3 reaction and a lower limit for *E*/R was calculated using an upper limit for *k*(298 K) of 2×10^{-17} cm^3 $molecule^{-1}$ s^{-1} based on the studies of Rattigan et al.[2] and Rowley et al.[3] The recommended upper limit for *k*(298 K) is a factor of 2.5 less than the upper limit of 5×10^{-17} derived by Mauldin et al.[1] Both Rattigan et al.[2] and Rowley et al.[3] report a value of $\sim 2 \times 10^{-18}$ cm^3 $molecule^{-1}$ s^{-1} at room temperature for the channel to produce OBrO + O_2.

G53. BrO + NO. The results of three low pressure mass spectrometric studies (Clyne and Watson,[2] Ray and Watson,[4] and Leu[3]) and a high pressure UV absorption study (Watson et al.[5]), which all used pseudo–first-order conditions, are in excellent agreement at 298 K and are thought to be much more reliable than an earlier low pressure UV absorption study (Clyne and Cruse[1]). The results of the two temperature-dependent studies (Leu and Watson et al.) are in good agreement and both show a small negative temperature dependence. The preferred Arrhenius expression was derived from a least-squares fit to all the data reported in the four studies mentioned above. By combining the data reported by Watson et al. with those from the three mass spectrometric studies, it can be shown that this reaction does not exhibit any observable pressure dependence between 1 and 700 Torr total pressure. The temperature dependences of *k* for the analogous ClO and HO_2 reactions are also negative and are similar in magnitude.

G54. BrO + NO_3. The recommended value for *k*(298 K) is the geometric mean of the lower and upper limits reported by Mellouki et al.[1] in a study using DF-EPR techniques. These reported limits are encompassed within the indicated uncertainty limits.
(Table: 90-1, Note: 92-20, Evaluated: 10-6) Back to Table

(1) Mellouki, A.; Poulet, G.; Le Bras, G.; Singer, R.; Burrows, J. P.; Moortgat, G. K. Discharge flow kinetic study of the reactions of NO_3 with Br, BrO, HBr, and HCl. *J. Phys. Chem.* **1989**, *93*, 8017-8021, doi:10.1021/j100361a012.

G55. BrO + ClO. Friedl and Sander,[4] using DF/MS techniques, measured the overall rate constant over the temperature range 220–400 K and also over this temperature range determined branching ratios for the reaction channels producing BrCl and OClO. The same authors in a separate study using flash photolysis–ultraviolet absorption techniques (Sander and Friedl[7]) determined the overall rate constant over the temperature range 220–400 K and pressure range 50–750 Torr and also determined the branching ratio for OClO production at 220 K and 298 K. The results by these two independent techniques are in excellent agreement, with the overall rate constant showing a negative temperature dependence. Turnipseed et al.[9] using DF/MS techniques also found a negative temperature dependence, reporting measurements of the overall rate constant and direct measurements of the branching ratios for the BrCl and OClO channels. Several other studies have reported only room temperature values: Toohey and Anderson,[8] using DF/RF/LMR techniques, reported room temperature values of the overall rate constant and the branching ratio for OClO production. They also found evidence for the direct production of BrCl in a vibrationally excited Π state. Poulet et al.,[6] using DF/MS techniques, reported room temperature values of the overall rate constant and branching ratios for OClO and BrCl production. Overall room temperature rate constant values reported also include a result from the DF/MS study of Clyne and Watson[2] and a very low value derived in the flash photolysis study of Basco and Dogra.[1] The recommended Arrhenius expressions for the individual reaction channels are taken from the studies of Friedl and Sander[4] and Turnipseed et al.[9] These studies contain the most comprehensive sets of rate constant and branching ratio data. The overall rate constants reported in these two studies are in good agreement (20%) at room temperature and in excellent agreement at stratospheric temperatures. Both studies report that OClO production by channel (1) accounts for 60% of the overall reaction at 200 K and that the BrCl yield by channel (3) is about 8%, relatively independent of temperature. The recommended expressions are consistent with the body of data from all older studies except those of Hills et al.[5] and Basco and Dogra.[1] Recent results from Ferracci and Rowley[3] using laser flash photolysis-absorption spectroscopy to measure the overall rate constant and branching ratio of the OClO channel are substantially higher than the recommended values and include a positive temperature dependence for the branching ratio of the OClO channel, in disagreement with past studies. Secondary chemistry is likely the cause of the discrepancies.

(9) Turnipseed, A. A.; Birks, J. W.; Calvert, J. G. Kinetics and temperature dependence of the BrO + ClO reaction. *J. Phys. Chem.* **1991**, *95*, 4356-4364, doi:10.1021/j100164a035.

G56. BrO + BrO. Measurements of the overall rate constant can be divided into categories—those in which BrO was monitored by UV absorption and those in which BrO was monitored by mass spectrometry. Gilles et al.[4] re-analyzed the results of the UV absorption studies and scaled the reported values of the rate constant to the UV absorption cross sections reported in their paper. When scaled in this manner, the room temperature rate constant values reported in the UV absorption studies (Sander and Watson,[11] Mauldin et al.,[9] Bridier et al.,[1] Rowley et al.,[10] Laszlo et al.,[8] and Gilles et al.) come into very good agreement among themselves and also with results of the mass spectrometric studies of Clyne and Watson[2] and Lancar et al.[7] This provides the basis for the recommended value for *k*(298 K). The temperature dependence is based on results of Sander and Watson, Turnipseed et al.[12] and Gilles et al. The results of Harwood et al.[5] are in good agreement with the recommendation.

There are two possible bimolecular channels for this reaction: BrO + BrO → 2Br + O_2 (k_1) and BrO + BrO → Br_2 + O_2 (k_2). The partitioning of the total rate constant into these two components, k_1 and k_2, has been determined at room temperature by Sander and Watson,[11] Turnipseed et al.,[12] and Lancar et al.,[7] by Jaffe and Mainquist[6] from 258 to 333 K, by Cox et al.[3] from 278 to 348 K, and by Mauldin et al.[9] from 220 to 298 K. All are in agreement that $k_1/k = 0.85 \pm 0.03$ at 298 K. From the values of $k_1/k = 0.85$ at 298 K (all studies) and 0.68 at 220 K (Mauldin et al. and Cox et al. extrapolated), one can derive the temperature-dependent expression $k_1/k = 1.60 \exp(-190/T)$. From the recommended Arrhenius expression for the overall rate constant $k = k_1 + k_2$ and the expression for the branching ratio k_1/k, one can derive the following Arrhenius expressions for the individual reaction channels:

$$k_1 = 2.4 \times 10^{-12} \exp(40/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$$

$$k_2 = 2.8 \times 10^{-14} \exp(860/T) \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$$

G57. **OBrO + O_3.** The upper limit for k(298 K) was determined by Li et al.[1] using DF/MS. (Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

(1) Li, Z. J.; Jeong, G. R.; Person, E. Kinetics of reactions of OBrO with NO, O_3, OClO, and ClO at 240-350 K. *Int. J. Chem. Kinet.* **2002**, *34*, 430-437, doi:10.1002/kin.10069.

G58. **OBrO + NO.** The recommended Arrhenius parameters are those determined by Li et al.[1] using DF/MS to monitor the decay of OBrO in excess NO. A possible complication in these experiments may be related to secondary reactions of Br with OBrO and is reflected in the large uncertainty assigned to this recommendation. (Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

(1) Li, Z. J.; Jeong, G. R.; Person, E. Kinetics of reactions of OBrO with NO, O_3, OClO, and ClO at 240-350 K. *Int. J. Chem. Kinet.* **2002**, *34*, 430-437, doi:10.1002/kin.10069.

G59. **CH_2BrO_2 + NO.** The recommended value for k(298 K) is based on the 298 K measurement of Sehested et al.,[4] who used pulsed radiolysis with UV absorption detection of the NO_2 product formation rate. The temperature dependence is estimated based on analogy to similar RO_2 + NO reactions. The CH_2BrO product has been shown to undergo rapid unimolecular decomposition to yield CH_2O + Br by Chen et al.[1] and Orlando et al.[3] The domination of this channel over the reaction of CH_2BrO with O_2 is consistent with the fate of other alkoxy radicals (Chen et al. and Orlando et al.), but contradicts the earlier result of Nielson et al.[2] (Table: 94-26, Note: 97-4, Evaluated: 97-4) Back to Table

1.13 IO_x Reactions

1.13.1 Table 1H: IO_x Reactions

Reaction	Temperature Range of Exp. Data (K) [a]	*A*-Factor	*E*/R	*k*(298 K)[b]	*f*(298 K)[c]	*g*	Notes
$O + I_2 \rightarrow IO + I$	298	1.3×10^{-10}	0	1.3×10^{-10}	1.2	250	H 1
$O + IO \rightarrow O_2 + I$	298	1.4×10^{-10}	0	1.4×10^{-10}	1.2	0	H 2
$OH + I_2 \rightarrow HOI + I$	294–298			1.8×10^{-10}	2.0		H 3
$OH + HI \rightarrow H_2O + I$	298			3.0×10^{-11}	2.0		H 4
$OH + CH_3I \rightarrow H_2O + CH_2I$	271–423	2.9×10^{-12}	1100	7.2×10^{-14}	1.5	300	H 5
$OH + CF_3I \rightarrow HOI + CF_3$	271–450	2.5×10^{-11}	2070	2.4×10^{-14}	1.3	200	H 6
$HO_2 + I \rightarrow HI + O_2$	283–353	1.5×10^{-11}	1090	3.8×10^{-13}	2.0	500	H 7
$HO_2 + IO \rightarrow$ products	273–373	1.3×10^{-11}	–570	8.8×10^{-11}	1.15	100	H 8
$NO_3 + HI \rightarrow HNO_3 + I$		(See Note)					H 9
$Cl + CH_3I \rightarrow CH_2I + HCl$	273–363	$2.9x10^{-11}$	1000	$1.0x10^{-12}$	1.5	250	H10
$I + O_3 \rightarrow IO + O_2$	231–337	2.0×10^{-11}	830	1.2×10^{-12}	1.2	100	H11
$I + NO \xrightarrow{M} INO$		(See Table 2-1)					
$I + NO_2 \xrightarrow{M} INO_2$		(See Table 2-1)					
$I + BrO \rightarrow IO + Br$	298			1.2×10^{-11}	2.0		H12
$IO + CH_3O_2 \rightarrow$ products		(See Note)					H13
$IO + NO \rightarrow I + NO_2$	240–370	8.6×10^{-12}	–230	1.9×10^{-11}	1.1	50	H14
$IO + NO_2 \xrightarrow{M} IONO_2$		(See Table 2-1)					
$IO + ClO \rightarrow I + OClO$	200–362	2.7×10^{-12}	–280	6.9×10^{-12}	1.3	150	H15
$\rightarrow I + Cl + O_2$	200–362	1.2×10^{-12}	–280	3.1×10^{-12}	1.3	150	
$\rightarrow ICl + O_2$	200–362	0.92×10^{-12}	–280	2.3×10^{-12}	1.3	150	
$IO + BrO \rightarrow Br + OIO$	204–388	4.4×10^{-12}	–760	5.6×10^{-11}	1.25	300	H16
$\rightarrow Br + I + O_2$	204–388	5.5×10^{-13}	–760	7.0×10^{-12}	1.5	300	
$\rightarrow I + OBrO$	204–388	4.4×10^{-13}	–760	5.6×10^{-12}	1.5	300	
$\rightarrow IBr + O_2$	204–388	1.1×10^{-13}	–760	1.4×10^{-12}	2.0	300	
$IO + IO \rightarrow$ products	250–373	1.5×10^{-11}	–500	8.0×10^{-11}	1.5	500	H17

Reaction	Temperature Range of Exp. Data (K) [a]	*A*-Factor	*E*/R	*k*(298 K)[b]	*f*(298 K)[c]	*g*	Notes
$INO + INO \rightarrow I_2 + 2NO$	320–450	8.4×10^{-11}	2620	1.3×10^{-14}	2.5	600	H18
$INO_2 + INO_2 \rightarrow I_2 + 2NO_2$	320–450	2.9×10^{-11}	2600	4.7×10^{-15}	3.0	1000	H19

Shaded areas indicate changes or additions since JPL15-10.

[a] Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

[b] Units are cm^3 molecule^{-1} s^{-1}.

[c] *f*(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(\mathrm{T}) = f(298\ \mathrm{K})\exp\left|g\left(\frac{1}{\mathrm{T}} - \frac{1}{298}\right)\right|$$

Note that the exponent is an absolute value.

1.13.2 Notes: IO_x Reactions

H1. **$O + I_2$.** Based on the room temperature data of Ray and Watson,[3] Laszlo et al.,[2] Turnipseed et al.,[5] Hölscher et al.,[1] and Tucceri et al.[4] The recommended value of k(298 K) is derived from an unweighted average of the five studies. The molecular beam study of Parrish and Herschbach[6] suggests a zero activation energy, consistent with the near gas kinetic value of k(298 K).

H2. **O + IO.** Based on the room temperature data of Canosa-Mas et al.,[1] Laszlo et al.,[2] and Payne et al.,[3] obtained from an unweighted average of the three studies. There are no temperature-dependence data. The reaction is near gas-kinetic at 298 K so the temperature dependence is likely to be small, or zero.

H8. **HO_2 + IO.** The recommended value for k(298 K) is the average of values obtained from the Arrhenius expressions reported by Cronkhite et al. (274–373 K)[2] and Knight and Crowley (273–353 K).[5] The recommended room temperature uncertainty limits encompass the results of Maguin et al.[6] and Canosa-Mas et al.[1] and overlap with the uncertainty interval reported by Jenkin et al.[4] The recommended E/R is obtained from a weighted fit ($1/k^2$ weighting factors) of the combined data of Cronkhite et al. and Knight and Crowley (one average rate constant per temperature studied) to the Arrhenius equation after scaling each individual set of rate constants by a constant factor so that the Arrhenius expressions describing the individual data sets each give the recommended k(298 K). In low pressure (~1 Torr He) flow tube studies, both Knight and Crowley and Maguin et al. observe HOI as a reaction product, but a quantitative HOI yield has not been reported. Computational results by Drougas and Kosmas[3] confirm the existence of energetically favorable pathways to HOI + $O_2(^1\Delta)$ products via both HOOIO and HOOOI intermediates. Drougas and Kosmas also predict that HOOIO can isomerize to the very stable $HOIO_2$ species (bound by ~220 kJ mol^{-1} relative to IO + HO_2). The predicted transition states for HOOIO isomerization and dissociation are approximately equal in energy to each other and to the HO_2 + IO reactants.

H10. Cl + CH_3I. This reaction, thought to be a simple H abstraction reaction, has been shown by Ayhens et al.[1] to be quite complex. At low temperatures, Cl atom reversibly adds to CH_3I to form CH_3ICl. Thus, there are at least two channels for this reaction,

$$Cl + CH_3I \rightarrow CH_2I + HCl \qquad (a)$$

$$Cl + CH_3I \leftrightarrow CH_3ICl \qquad (b)$$

The rate coefficient for channel (a) has been measured by Ayhens et al. above 364 K, Kambanis et al.[5] between 273 and 363 K, Bilde and Wallington[2] at 298 K, and Cotter et al.[3] at 298 K. The recommendation is based on these studies.

Under atmospheric conditions reaction (b) to form the adduct is about two orders of magnitude faster than reaction (a). However, the fate of the CH_3ICl adduct in the atmosphere is unclear. Its lifetime, based on the studies of Ayhens et al., can be as long as a few seconds at 200 K and a few hundred Torr pressure. Therefore, it is possible that it could react with O_2 or be photolyzed. At 298 K, in one atmosphere of O_2, it appears that the overall fate of the CH_3ClI is to decompose back to the reactants, based on the work of Bilde and Wallington.[2] Therefore, if O_2 were to react with CH_3ICl, this rate coefficient has to be less than about 10^{-17} cm^3 $molecule^{-1}$ s^{-1}, using the rate coefficient for its decomposition measured by Ayhens et al. If the rate coefficient for $CH_3ICl + O_2$ were to remain approximately the same, i.e., 10^{-17} cm^3 $molecule^{-1}$ s^{-1}, at lower temperatures, the possible loss of CH_3ICl via reaction with O_2 cannot be ignored. Further, the possible atmospheric photolysis of CH_3ICl may be important if it has a J-value greater than 0.1 s^{-1}.

There is a third possible product channel for this reaction to yield CH_3Cl + I (Goliff and Rowland[4]). Based on the results of Bilde and Wallington and Goliff and Rowland, we recommend that the rate coefficient for the $Cl + CH_3I \rightarrow CH_3Cl + I$ reaction to be less than $0.2k_a$ at 298 K. Since such a reaction is likely to have a significant barrier in the gas phase, even though it is exothermic by ~14 kcal mol^{-1} at 298 K, the branching ratio for the production of CH_3Cl and I in the atmosphere will be likely less than that at 298 K.

H11. I + O_3. The recommended value of *k*(298 K) is based on an unweighted average of the room temperature values of Jenkin et al.,[3] Sander,[4] Tucceri et al.,[5] Buben et al.,[1] Turnipseed et al.,[6] and Hölscher et al.[2] The recommended *E*/R is obtained from the temperature-dependence studies of Buben et al., Turnipseed et al., and Hölscher et al.

H13. IO + CH_3O_2. There have been three room temperature studies (Bale et al.,[1] Dillon et al.,[2] and Dillon et al.,[3]) and one temperature dependence study (Enami et al.[4]). This reaction is exceptionally difficult to study due to the almost unavoidable interference from secondary reactions. The results fall into two groups: Bale et al.[1] and Enami et al.[4] obtain relatively large rate constants at room temperature ($(6.0 \pm 1.3) \times 10^{-11}$ and $(7.0 \pm 3.0) \times 10^{-11}$ cm^3 molecule^{-1} s^{-1}, respectively, while the two studies by Dillon et al. obtained much smaller rate constants ($(2 \pm 1) \times 10^{-12}$and $(3.4 \pm 1.4) \times 10^{-12}$ cm^3 molecule^{-1} s^{-1}, respectively. Although Dillon et al.[3] make a compelling case for the rate constant being smaller than 1×10^{-11} cm^3 molecule^{-1} s^{-1}, because of the difficulties caused by known and unknown secondary reactions, and the large disparity between the results of the two sets of studies, a recommendation is not be provided.

H14. IO + NO. The recommendation is based on the 298 K data of Ray and Watson,[7] Dillon et al.,[3] and Atkinson et al.,[1] and the temperature-dependence data of Hölscher et al.,[4] Knight et al.,[6] Turnipseed et al.,[8] and Daykin and Wine.[2] The results of Inoue et al.[5] at 298 K is excluded because they lie several standard deviations above the other studies.

H15. IO + ClO. Based on results of Turnipseed et al.[2] and Bedjanian et al.[1] Both studies carried out branching ratio measurements. Bedjanian et al. obtained channel-specific branching ratios at 298 K of (0.545 ± 0.026), (0.25 ± 0.018), and (0.195 ± 0.016) for the I + OClO, I + Cl + O_2, and ICl + O_2 channels, respectively. Turnipseed et al. measured the yield of the non-I atom producing channels to be 0.14 ± 0.04 at 298 K, which is consistent with the results of Bedjanian et al. To obtain the recommendations, the 298 K branching ratios from Bedjanian et al. are applied to the rate expression for the overall reaction, which is obtained by averaging the 298 K values from the two studies and adopting the *E*/R from Turnipseed et al. This rate expression is given by $k(\mathrm{T}) = 4.82 \times 10^{-12} \exp(-280/\mathrm{T})$.

H16. IO + BrO. There are four studies of this reaction from Gilles et al.,[2] Laszlo et al.,[3] Bedjanian et al.,[1] and Rowley et al.[4] Gilles et al. measured the temperature dependence of the rate constant for the non-I atom product channels from 204–388 K. Laszlo et al. measured the 298 K rate constant for the overall reaction with no branching ratio information. Bedjanian et al. measured the 298 K rate constant for the overall reaction and found that the Br + OIO branching ratio is larger than 0.65. Upper limits for branching ratios were obtained for the other channels. Rowley et al. measured the temperature dependence of the overall reaction over the range 210–333 K, also finding that the Br + OIO branching ratio is larger than 0.65. To obtain the recommendations for the four channels, *E*/R was adopted from the Rowley et al. study, and *k*(298 K) for the overall reaction from the average of the Rowley et al., Bedjanian et al. and Laszlo et al. studies. The *k*(298 K) results of Gilles et al. was not considered because their technique was insensitive to the channels producing I atoms. The branching ratio ranges and upper-limits from Bedjanian et al. and Rowley et al. were used to derive channel-specific rate constant expressions assuming that the same *E*/R applies to each channel. This may be a poor assumption based on the much lower *E*/R (–260 K) obtained by Gilles et al. for the non-I atom channels than the *E*/R obtained by Rowley et al. (–760 K) for the overall reaction. However, until more precise channel-specific data can be obtained, this assumption has been adopted.

H17. IO + IO. Sander[3] reported a negative temperature dependence over the temperature range 250–373 K for the overall rat constant and for the absorption cross section at 427.2 nm. Harwood et al.[1] reported that the overall rate constant and the absorption cross section to be independent of temperature from 253 to 320 K. The recommended room temperature value is the average of the values reported by Sander, Harwood et al., and Laszlo et al.[2] The recommended temperature dependence is the average of the values reported by Sander and by Harwood et al., with an uncertainty sufficient to encompass the two reported values. The *A*-factor has been fitted to the recommended room temperature rate constant and the recommended temperature dependence. The overall rate constant for the decay of IO in the absence of ozone has been found to be independent of pressure by Sander, Laszlo et al., and Harwood et al. A comparison of the overall rate observed in excess ozone to that in the absence of ozone was interpreted by Sander and by Harwood et al. to imply that formation of the dimer I_2O_2 is the dominant reaction channel in the IO self-reaction.

1.14 SO_x Reactions

1.14.1 Table 1I: SO_x Reactions

Reaction	Temperature Range of Exp. Data (K) [a]	*A*-Factor	*E*/R	*k*(298 K)[b]	*f*(298 K)[c]	*g*	Note
$O + SH \rightarrow SO + H$	295			1.6×10^{-10}	5.0		I 1
$O + CS \rightarrow CO + S$	150–305	2.7×10^{-10}	760	2.1×10^{-11}	1.1	250	I 2
$O + H_2S \rightarrow OH + SH$	205–502	9.2×10^{-12}	1800	2.2×10^{-14}	1.7	550	I 3
$O + OCS \rightarrow CO + SO$	239–808	2.1×10^{-11}	2200	1.3×10^{-14}	1.15	150	I 4
$O + CS_2 \rightarrow CS + SO$	218–543	3.2×10^{-11}	650	3.6×10^{-12}	1.2	150	I 5
$O + SO_2 \xrightarrow{M} SO_3$		(See Table 2-1)					
$O + CH_3SCH_3 \rightarrow CH_3SO + CH_3$	252–557	1.3×10^{-11}	–410	5.0×10^{-11}	1.1	100	I 6
$O + CH_3SSCH_3 \rightarrow CH_3SO + CH_3S$	270–571	3.9×10^{-11}	–290	1.03×10^{-10}	1.1	100	I 7
$O + CH_3S(O)CH_3 \rightarrow$ products	266–383	2.0×10^{-12}	–440	8.8×10^{-12}	1.2	200	I 8
$O_3 + H_2S \rightarrow$ products	~298			$<2.0\times10^{-20}$			I 9
$O_3 + CH_3SCH_3 \rightarrow$ products	301			$<1.5\times10^{-19}$			I10
$O_3 + SO_2 \rightarrow SO_3 + O_2$	300	3.0×10^{-12}	>7000	$<2.0\times10^{-22}$			I11
$O_3 + SO_2F_2 \rightarrow$ products	294-296			$<1.0\times10^{-23}$			I12
$OH + H_2S \rightarrow SH + H_2O$	228–885	3.3×10^{-12}	–100	4.6×10^{-12}	1.1	50	I13
$OH + OCS \rightarrow$ products	255–517	7.2×10^{-14}	1070	2.0×10^{-15}	2.0	200	I14
$OH + CS_2 \rightarrow SH + OCS$	251–520			$<2.0\times10^{-15}$			I15
$OH + CS_2 \rightarrow CS_2OH \xrightarrow{O_2}$ products		(See Note)		1.2×10^{-12} at P_{air} = 1 atm	1.25		I16
$CS_2OH + O_2 \rightarrow$ products	249–348	2.8×10^{-14}	0	2.8×10^{-14}	1.2	100	I17
$OH + CH_3SH \rightarrow CH_3S + H_2O$	244–430	9.9×10^{-12}	–360	3.3×10^{-11}	1.07	75	I18
$OH + CH_3SCH_3 \rightarrow H_2O + CH_2SCH_3$	248–573	1.2×10^{-11}	280	4.7×10^{-12}	1.1	100	I19
$OH + CH_3SCH_3 \overset{M}{\leftrightarrow} (CH_3)_2SOH \xrightarrow{O_2}$ products		(See Note)		2.0×10^{-12} at P_{air} = 1 atm	1.2		I20
$(CH_3)_2SOH + O_2 \rightarrow$ products	222–297	8.5×10^{-13}	0	8.5×10^{-13}	1.25	0	I21
$OH + CH_3SCH_2Cl \rightarrow$ products	298			2.5×10^{-12}	2.0		I22

Reaction	Temperature Range of Exp. Data (K) ^{a}	*A*-Factor	*E*/R	*k*(298 K)^b	*f*(298 K)^c	*g*	Note
$OH + CH_3SSCH_3 \rightarrow$ products	249–368	6.0×10^{-11}	–400	2.3×10^{-10}	1.2	200	I23
$OH + CH_3S(O)CH_3 \rightarrow$ products	298–401	6.1×10^{-12}	–800	8.9×10^{-11}	1.2	500	I24
$OH + CH_3S(O)OH \rightarrow$ products	298			9.0×10^{-11}	1.4		I25
$OH + CH_3SO_3H \rightarrow CH_3SO_3 + H_2O$		(See Note)					I26
$OH + CH_3SC_2H_5$ H-abstraction rxns.	242–299	8.0×10^{-12}	0	8.0×10^{-12}	1.1	50	I27
$OH + CH_3SC_2H_5 \overset{M}{\leftrightarrow} CH_3S(OH)C_2H_5 \overset{O_2}{\rightarrow}$ products	242–346	(See Note)		2.3×10^{-12} at P_{air} = 1 atm	1.3		I28
$CH_3S(OH)C_2H_5 + O_2 \rightarrow$ products	242–296	1.0×10^{-12}	0	1.0×10^{-12}	1.5	0	I29
$OH + S \rightarrow H + SO$	298			6.6×10^{-11}	3.0		I30
$OH + SO \rightarrow H + SO_2$	295–703	2.6×10^{-11}	–330	7.9×10^{-11}	1.15	150	I31
$OH + SO_2 \overset{M}{\rightarrow} HOSO_2$		(See Table 2-1)					
$OH + SO_2F_2 \rightarrow$ products	294–333			$<1.0\times10^{-16}$			I32
$HO_2 + H_2S \rightarrow$ products	298			$<3.0\times10^{-15}$			I33
$HO_2 + CH_3SH \rightarrow$ products	298			$<4.0\times10^{-15}$			I33
$HO_2 + CH_3SCH_3 \rightarrow$ products	298			$<5.0\times10^{-15}$			I33
$HO_2 + SO_2 \rightarrow$ products	295–300			$<1.0\times10^{-18}$			I34
$NO_2 + SO_2 \rightarrow$ products	298			$<2.0\times10^{-26}$			I35
$NO_3 + H_2S \rightarrow$ products	298			$<8.0\times10^{-16}$			I36
$NO_3 + OCS \rightarrow$ products	297			$<1.0\times10^{-16}$			I37
$NO_3 + CS_2 \rightarrow$ products	297–298			$<4.0\times10^{-16}$			I38
$NO_3 + CH_3SH \rightarrow$ products	254–367	$4.4x10^{-13}$	–210	8.9×10^{-13}	1.25	200	I39
$NO_3 + CH_3SCH_3 \rightarrow CH_3SCH_2 + HNO_3$	256–376	1.9×10^{-13}	–530	1.1×10^{-12}	1.1	150	I40
$NO_3 + CH_3SSCH_3 \rightarrow$ products	280–382	$5.0x10^{-13}$	–60	6.1×10^{-13}	1.25	150	I41
$NO_3 + CH_3S(O)CH_3 \rightarrow$ products	295–298			2.9×10^{-13}	1.6		I42
$NO_3 + CH_3SC_2H_5 \rightarrow$ products	298			2.5×10^{-12}	1.5		I43
$NO_3 + SO_2 \rightarrow$ products	298–303			$<7.0\times10^{-21}$			I44

Reaction	Temperature Range of Exp. Data (K) ^{a}	*A*-Factor	*E*/R	*k*(298 K)^b	*f*(298 K)^c	*g*	Note
$N_2O_5 + CH_3SCH_3 \rightarrow$ products	296			$<1.0\times10^{-17}$			I45
$CH_3O_2 + SO_2 \rightarrow$ products	298–423			$<5.0\times10^{-17}$			I46
$F + CH_3SCH_3 \rightarrow$ products	298			2.4×10^{-10}	2.0		I47
$Cl + H_2S \rightarrow HCl + SH$	202–914	3.4×10^{-11}	–225	7.3×10^{-11}	1.1	50	I48
$Cl + SO_2F_2 \rightarrow$ products	296–333			$<1.5\times10^{-18}$			I49
$Cl + OCS \rightarrow$ products	298			$<1.0\times10^{-16}$			I50
$Cl + CS_2 \rightarrow$ products		(See Table 2-1)					
$CS_2Cl + O_2 \rightarrow$ products	230–298			$<2.5\times10^{-16}$			I51
$Cl + CH_3SH \rightarrow CH_3S + HCl$	193–430	1.2×10^{-10}	–150	2.0×10^{-10}	1.1	100	I52
$Cl + CH_3SCH_3 \rightarrow CH_3SCH_2 + HCl$	240–421	9.4×10^{-11}	–190	1.8×10^{-10}	+1.2/ –2.5	0	I53
$Cl + CH_3SCH_3 \rightarrow$ products (P = 1 atm)	240–356	3.5×10^{-10}	0	3.5×10^{-10}	1.2	0	
$(CH_3)_2SCl + O_2 \rightarrow$ products	298			$<4.0\times10^{-18}$			I54
$(CH_3)_2SCl + NO \rightarrow$ products	298			1.2×10^{-11}	1.25		I54
$(CH_3)_2SCl + NO_2 \rightarrow$ products	298			2.7×10^{-11}	1.25		I54
$Cl + CH_3S(O)CH_3 \rightarrow CH_3S(O)CH_2 + HCl$	270–571	1.4×10^{-11}	0	1.4×10^{-11}	1.2	150	I55
$Cl + CH_3S(O)CH_3 \xrightarrow{M} CH_3(Cl)S(O)CH_3$		(See Note)					I55
$CH_3(Cl)S(O)CH_3 + O_2 \rightarrow$ products	296			$<3.0\times10^{-18}$			I56
$CH_3(Cl)S(O)CH_3 + NO \rightarrow$ products	296			1.2×10^{-11}	1.5		I56
$CH_3(Cl)S(O)CH_3 + NO_2 \rightarrow$ products	296			2.1×10^{-11}	1.5		I56
$Cl + CH_3SC_2H_5 \rightarrow$ products (P = 1 atm)	298			3.8×10^{-10}	1.2		I57
$Cl_2 + CH_3SCH_3 \rightarrow$ products	294–298			$<5.0\times10^{-14}$			I58
$ClO + OCS \rightarrow$ products	298			$<2.0\times10^{-16}$			I59

Reaction	Temperature Range of Exp. Data (K) [a]	*A*-Factor	*E*/R	*k*(298 K)[b]	*f*(298 K)[c]	*g*	Note
$ClO + CH_3SCH_3 \rightarrow$ products	259–335	2.1×10^{-15}	–340	6.6×10^{-15}	1.5	300	I60
$ClO + CH_3S(O)CH_3 \rightarrow$ products	298			$<2.0\times10^{-14}$			I61

Shaded areas indicate changes or additions since JPL15-10.

[a] Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

[b] Units are cm^3 $molecule^{-1}$ s^{-1}.

[c] *f*(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(\mathrm{T}) = f(298\ \mathrm{K})\exp\left|g\left(\frac{1}{\mathrm{T}} - \frac{1}{298}\right)\right|$$

Note that the exponent is an absolute value.

1.14.2 Notes: SO_x Reactions

I1. **O + SH.** This recommendation accepts the results of Cupitt and Glass.[1] The large uncertainty reflects the absence of any confirming investigation.
(Table: 82-57, Note: 82-57, Evaluated: 82-57) Back to Table

(1) Cupitt, L. T.; Glass, G. P. Reactions of SH with atomic oxygen and hydrogen. *Int. J. Chem. Kinet.* **1975**, *Symp. 1*, 39-50.

I2. **O + CS.** The room temperature recommendation is an average of the rate constants determined by Slagle et al.,[4] Bida et al.,[1] Lilenfeld and Richardson,[3] and Hancock and Smith.[2] The temperature dependence is that of Lilenfeld and Richardson, with the *A*-factor adjusted to yield the recommended value of *k*(298 K).

I3. **O + H_2S.** This recommendation is derived from an un-weighted least-squares fit of the data of Singleton et al.[4] and Whytock et al.[8] The results of Slagle et al.[6] show very good agreement for *E*/R in the temperature region of overlap (300–500 K) but lie systematically higher at every temperature. The uncertainty factor at 298 K has been chosen to encompass the room temperature rate constant values of Slagle et al.[6] and Hollinden et al.[3] Other than the 263 K data point of Whytock et al. and the 281 K point of Slagle et al., the main body of rate constant data below 298 K comes from the study of Hollinden et al., which indicates a dramatic change in *E*/R in this temperature region. Thus, the parameter *g* was set to account for these observations. Such a non-linearity in the Arrhenius plot might indicate a change in the reaction mechanism from abstraction (as written) to addition. An addition channel (resulting in H atom displacement) has been proposed by Slagle et al.,[6] Singleton et al.,[4] and Singleton et al.[5] In the latter two studies, an upper limit of 20% was placed on the displacement channel. Direct observations of product HSO were made in the reactive scattering experiments of Clemo et al.[1] and Davidson et al.[2] A threshold energy of 3.3 kcal/mole was observed (similar to the activation energy measured in earlier studies), suggesting the importance of this direct displacement channel. Addition products from this reaction have been seen in a matrix by Smardzewski and Lin.[7] Further kinetic studies in the 200–300 K temperature range, as well as quantitative direct mechanistic information, could clarify these issues.

I4. **O + OCS.** The value of k(298 K) is the average of the determinations by Westenberg and de Haas,[10] Klemm and Stief,[5] Wei and Timmons,[9] Manning et al.,[6] and Breckenridge and Miller.[1] The recommended value of E/R is the average value taken from the first three listed studies. Hsu et al.[4] report that this reaction proceeds exclusively by a stripping mechanism. The vibrational and rotational state distributions in the SO and CO products have been reported by Chen et al.[2] and Nickolaisen et al.,[7] respectively. The kinetic isotope effect $k(^{34}S)/k(^{32}S)$ was reported by Hattori et al.[3] to be 0.9783 ± 0.0062 at 298 K. A theoretical calculation of potential energy surfaces and T-dependent rate coefficients (200–2500 K) has been reported by Saheb et al.[8]

I5. **O + CS_2.** The value of k(298 K) is an average of the rate constants determined by Wei and Timmons,[9] Westenberg and de Haas,[10] Slagle et al.,[8] Callear and Smith,[3] Callear and Hedges,[2] Homann et al.,[6] Borissenko et al.,[1] and Graham and Gutman.[5] The E/R value is an average of the determinations by Wei and Timmons and Graham and Gutman. The g value has been set to encompass the temperature-dependent data of Westenberg and deHaas. The principal reaction products are thought to be CS + SO. However, Hsu et al.[7] report that 1.4% of the reaction at 298 K proceeds through a channel yielding CO + S_2 and calculate a rate constant for the overall process in agreement with that recommended. Graham and Gutman[5] have found that 9.6% of the reaction proceeds to yield OCS + S at room temperature. Using time-resolved diode laser spectroscopy, Cooper and Hershberger[4] determined the branching ratios for the CO- and OCS-producing channels to be (3.0 ± 1.0)% and (8.5 ± 1.0)%, respectively.

I6. **O + CH_3SCH_3.** This recommendation is based on a fit of the data from Nip et al.,[4] Lee et al.,[3] and Lee et al.[2] Product studies by Cvetanovic et al.[1] indicate that the reaction proceeds almost entirely by addition followed by rapid fragmentation to the products as written. Pavanaja et al.[5] examined the pressure and reactant ratio dependencies of $OH(A^2\Sigma^+)$ and $SO_2(^3B, {}^1B)$ emissions in this reaction system. Their observations are consistent with initial product formation as written, followed by secondary generation of both OH and SO_2.

I7. **O + CH_3SSCH_3.** This recommendation averages the 298 K rate constants of Nip et al.[4] and Borissenko et al.,[1] which are in good agreement with each other, but are about a factor of 2 slower than the value reported by Lee et al.[3] The recommendation for E/R has been obtained from an un-weighted Arrhenius fit that employs all available data, but scales the data of Lee et al. downward by a factor of 2.04 to bring their data into agreement with the other data at room temperature. Product studies by Cvetanovic et al.[2] indicate that the reaction proceeds mainly by addition followed by rapid fragmentation to the products as written. Pavanaja et al.[5] examined the pressure and reactant ratio dependencies of $OH(A^2\Sigma^+)$ and $SO_2(^3B, {}^1B)$ emissions in this reaction system. Their observations are consistent with initial product formation as written, followed by secondary generation of both OH and SO_2.

(5) Pavanaja, U. B.; Upadhyaya, H. P.; Sapre, A. V.; Rao, K. V. S. R.; Mittal, J. P. Chemiluminescent reaction of oxygen atoms with dimethyl disulfide and dimethyl sulfide. *J. Chem. Soc. Faraday. Trans.* **1994**, *90*, 825-829, doi:10.1039/ft9949000825.

I8. **O + $CH_3S(O)CH_3$.** The recommended 298 K rate constant is the average of values reported from a laser flash photolysis – resonance fluorescence study by Pope et al.,[2] and from a discharge flow − mass spectrometry study by Riffault et al.[3] A rate constant reported by Barnes et al.[1] (with no details about how the rate constant was obtained) is somewhat faster than the recommendation, but in agreement to within the recommended uncertainty factor. The recommended value for *E*/R is from Pope et al. The recommended value for the

parameter *g* is larger than the value reported by Pope et al. to reflect the fact that only a single temperature dependence study has been reported. In their study at one Torr total pressure, Riffault et al. found that the products $SO_2 + 2\ CH_3$ are produced with near unit yield.

I9. **$O_3 + H_2S$.** This upper limit was determined by Becker et al.[1] based on measurements of the rates of SO_2 production and O_3 consumption. The heterogeneous reaction between H_2S and O_3 occurs more rapidly than the gas phase reaction in most laboratory systems. A detailed potential energy surface for $H_2S + {}^1O_3$ has been reported by Mousavipour et al.[2]

I10. **$O_3 + CH_3SCH_3$.** The recommendation is based on the study of Du et al.[1] which gives a more sensitive upper limit than an earlier study by Martinez and Herron.[2] Du et al. used cyclohexane to scavenge OH radicals and high levels of O_2 to scavenge oxygen atoms and convert more reactive carbon-centered radicals to less reactive peroxy radicals. Their reported rate constant is $(1.04 \pm 0.21) \times 10^{-19}$ cm^3 $molecule^{-1}$ s^{-1}. Because of the potential for interference from wall reaction or reactions involving radicals generated via secondary chemistry, the recommendation is an upper limit equal to the rate constant reported by Du et al. plus twice its reported uncertainty.

I13. **$OH + H_2S$.** The recommended values for *k*(298 K) and *E*/R are derived from a composite un-weighted least-squares fit to the Arrhenius equation ($\ln k$ vs. T^{-1}) using the individual scaled data points at $T \leq 300$ K only of Perry et al.,[11] Cox and Sheppard,[3] Wine et al.,[17] Leu and Smith,[7] Michael et al.,[10] Lin,[8] Lin et al.,[9] Wang and Lee,[14] Barnes et al.,[1] Lafage et al.,[6] and Wang et al.[13] The studies of Leu and Smith,[7] Lin et al.,[9] Michael et al.,[9] and Lafage et al.[6] show a non-Arrhenius temperature dependence of *k* with a minimum occurring near room temperature. Each data set is scaled by the ratio *k*(298 K)/<*k*(298 K)> where *k*(298 K) is the value obtained from the best fit Arrhenius expression or, for the studies that observed non-Arrhenius behavior, the best fit three-parameter expression of the form $k = A\ T^n \exp(-E/RT)$ and <*k*(298 K)> is the average of the *k*(298 K) values obtained as described above. The scaled data show a clear non-Arrhenius temperature dependence such that the following three-parameter expression is required over the full temperature range where data are available (228–518 K):

$$k(T) = 7.95 \times 10^{-20}\ T^{+2.68} \exp(+783/T)\ \text{cm}^3\ \text{molecule}^{-1}\ \text{s}^{-1}$$

Lafage et al. and Michael et al. discuss the results in terms of a two-channel reaction scheme involving direct H atom abstraction and complex (adduct) formation. Lafage et al. analyzed their results above room temperature to yield an apparent *E*/R = 400 K for the abstraction channel, in good agreement with the *E*/R value determined above room temperature by Westenberg and de Haas.[15,16] The results of these latter workers lie systematically higher (by about 70%), presumably due to secondary reactions. The room temperature value measured by Stuhl[12] lies just outside the 2σ error limit set for *k*(298 K). Theoretical work by Ellingson and Truhlar[5] and by Du and Zhang[4] supports the non-Arrhenius temperature dependence reported by some investigators (see above); Ellingson and Truhlar attribute the unusual temperature dependence to the existence of a pre- reactive complex (bound by 18 kJ mol^{-1}) with a submerged classical barrier on the reaction path. At low temperatures, the long-range attraction dominates and the rate constant decreases with increasing temperature. However, as the temperature is increased, the variational transition state vibrations transverse to the reaction path become tighter, the effective barrier becomes higher, and the temperature trend reverses. Du and Zhang find theoretically that there is no rate enhancement under atmospheric conditions due to catalysis by H_2O or $(H_2O)_2$. Butkovskaya and Setser[2] have observed infrared emission from vibrationally excited levels of the reaction product H_2O.

I14. OH + OCS. The recommendation is based on the 298 K study of Wahner and Ravishankara[11] and the temperature dependent (255−483 K) study of Cheng and Lee.[2] Because the data of Cheng and Lee suggest slight curvature in the Arrhenius plot, only their data at T≤ 423 K were used to arrive at the recommended Arrhenius parameters. The room temperature rate constants from the above-mentioned studies are a factor of 3 higher than the earlier determination by Leu and Smith.[7] As discussed in the later studies, this difference may be due to an overcorrection of the Leu and Smith data to account for OH reaction with H_2S impurities and also to possible regeneration of OH. The work by Wahner and Ravishankara[11] supersedes the study of Ravishankara et al.[8] The Wahner and Ravishankara study minimized complications due to secondary and/or excited state reactions that presumably were interfering with the experiments of Atkinson et al.[1] and Kurylo.[5] A relative rate study by Schmidt et al.[10] suggests a somewhat faster *k*(298K) than recommended, but agrees with the recommended value within the (undesirably large) combined uncertainty limits. The upper limit for *k*(298 K) reported by Cox and Sheppard[3] is too insensitive to permit comparison with more recent studies. The room temperature measurements of Wahner and Ravishankara demonstrate the lack of an effect of total pressure (or O_2 partial pressure) on the rate constant and are supported by the more limited pressure- and O_2-dependent studies of Cheng and Lee. A theoretical calculation of potential energy surfaces and T-dependent rate coefficients (200−2500 K) has been reported by Saheb et al.[9] Theoretical work by Schmidt et al. suggests that the 298 K rate constant is pressure-dependent, increasing by about a factor of two ($3.5-7.2 \times 10^{-16}$ cm^3 $molecule^{-1}$ s^{-1}) when air pressure increases from 10 Torr to 700 Torr. The theoretical results not only predict a pressure dependence that has not yet been observed experimentally, but also predict rate constants that are substantially smaller than those reported experimentally. Furthermore, the theoretical results provide mechanistic information that suggests potential problems with experimental studies where OH kinetics are directly monitored (see below).

Product observations by Leu and Smith indicate that SH is a primary product of this reaction and tentatively confirm the suggestion of Kurylo and Laufer[6] that the predominant reaction pathway is to produce SH + CO_2 through a complex (adduct) mechanism similar to that observed for the OH + CS_2 reaction. However, the absence of an O_2/pressure effect for OH + OCS is in marked contrast with the strong dependence seen in studies of OH + CS_2 (see note for the latter reaction). The theoretical analysis of Schmidt et al. (discussed briefly above) suggests that the pressure-independent channel involves transfer of the sulfur atom to OH to generate SOH + CO while the pressure-dependent channel involves formation of an energized OC(OH)S* adduct that can redissociate to OH + OCS reactants in competition with stabilization. Schmidt et al. suggest that dissociation of OC(OH)S* to CO_2 + SH can be important at elevated temperatures, but not under atmospheric conditions. Schmidt et al. further suggest that under atmospheric conditions both stabilized and unstabilized adducts can react with O_2 to recycle OH. The possibility that the experiments of Cheng and Li and Wahner and Ravishankara were "blind" to the addition channel because OH, the monitored species in both studies, was rapidly regenerated is an important question that will require additional experimentation to address.

Low pressure (1–2.5 Torr) experiments by Greenblatt and Howard[4] have shown that the rate coefficient for oxygen atom exchange in the reaction of ^{18}OH with OCS is less than 10^{-17} cm^3 $molecule^{-1}$ s^{-1} at 296 and 373 K, suggesting that H atom migration in the energized complex is rather slow.

I15. **$OH + CS_2 \rightarrow SH + OCS$.** There is a consensus of experimental evidence that this reaction proceeds very slowly as a direct bimolecular process. Wine et al.[8] set an upper limit on k(298 K) of 1.5×10^{-15} cm^3 molecule^{-1} s^{-1}. A consistent upper limit is also reported by Iyer and Rowland[4] for the rate of direct production of OCS, suggesting that OCS and SH are primary products of the bimolecular process. This mechanistic interpretation is further supported by the studies of Leu and Smith[6] and Biermann et al.,[2] which set somewhat higher upper limits on k(298 K). The more rapid reaction rates measured by Atkinson et al.,[1] Kurylo,[5] and Cox and Sheppard[3] may be attributable to severe complications arising from excited state and secondary chemistry in their photolytic systems. The Cox and Sheppard study in particular may have been affected by the reaction of electronically excited CS_2 (produced via the 350 nm photolysis) with O_2 (in the 1-atm synthetic air mixture) as well as by the accelerating effect of O_2 on the $OH + CS_2$ reaction itself, which has been observed by other workers as summarized below. The possible importance of electronically excited CS_2 reactions in the tropospheric oxidation of CS_2 to OCS has been discussed by Wine et al.[7]

I16. **$OH + CS_2 \rightarrow CS_2OH \xrightarrow{O_2}$ products.** An accelerating effect of O_2 on the $OH + CS_2$ reaction rate has been observed by Jones et al.,[3] Barnes et al.,[1] and Hynes et al.,[2] along with a near unity product yield for SO_2 and OCS. In the latter two studies the effective bimolecular rate constant was found to be a function of total pressure ($O_2 + N_2$), and exhibited an appreciably negative temperature dependence. These observations are consistent with the formation of a long-lived adduct as postulated by Kurylo[4] and Kurylo and Laufer[5] followed by its reaction with O_2:

$$\mathrm{OH + CS_2 + M \underset{k_b}{\overset{k_a}{\rightleftarrows}} CS_2OH + M}$$

$$\mathrm{CS_2OH + O_2 \xrightarrow{k_c} Products}$$

The effective second order rate constant for CS_2 or OH removal in the above reaction scheme can be expressed as

$$1/k_{eff} = (k_b/k_ak_c)(1/P_{O2}) + (1/k_a)(1/P_M)$$

where P_{O2} is the partial pressure of O_2 and P_M equals $P_{O2} + P_{N2}$. The validity of this expression requires that k_a and k_b are invariant with the P_{O_2}/P_{N_2} ratio. A $1/k$ vs $1/P_{O2}$ plot of the data of Jones et al.[3] taken at atmospheric pressure exhibits marked curvature, suggesting a more complex mechanistic involvement of O_2, whereas the data of Barnes et al.[1] and Hynes et al.[2] are more satisfactorily represented by this analytical expression. Nevertheless, while the qualitative features of the data from all three laboratories agree, there are some quantitative inconsistencies. First, under similar conditions of O_2 and N_2 pressures, the Barnes et al. rate constants lie approximately 60% higher than those of Jones et al. and up to a factor of 2 higher than those derived by Hynes et al. Secondly, two fits each of both the Barnes et al. and Hynes et al. data can be made: one at fixed P_M and varying P_{O2}, and the other at fixed P_{O2} and varying P_M (i.e., varying added N_2). Within each data set, rate constants calculated from both fits agree reasonably well for mole fractions of O_2 near 0.2 (equivalent to air) but disagree by more than a factor of 2 for measurements in a pure O_2 system. Finally, the temperature dependence (from 264–293 K) of the k_{eff} values from Barnes et al. varies systematically from an E/R of -1300 K for experiments in pure O_2 (at 700 Torr total pressure) to -2900 K for experiments in a 50 Torr O_2 plus 650 Torr N_2 mixture. An Arrhenius fit of the Hynes et al. data (from 251–348 K) recorded in synthetic air at 690 Torr yields an $E/R = -3300$ K, although the data show marked curvature over the temperature range of study. These observations suggest that k_a and k_b may not be independent of the identity of M. For this reason, we limit our recommendation to air mixtures (i.e., $P_{O2}/P_{N2} = 0.25$) at atmospheric pressure. Since most CS_2 is oxidized within the atmospheric boundary layer, such restriction does not limit the applicability of this recommendation in atmospheric modeling.

The present recommendation accepts the measurements of Hynes et al.,[2] which appear to be the most sensitive of the three investigations. Thus, $k(298\ K)$ is derived from the Arrhenius fit of the data near room temperature.

$$k(298\ K) = 1.2 \times 10^{-12}\ cm^3\ molecule^{-1}\ s^{-1}$$

To compute values of k below 298 K, we have accepted the analysis of Hynes et al.:

$$k(T) = (1.25 \times 10^{-16} \exp(4550/T))/(T + 1.81 \times 10^{-3} \exp(3400/T))\ cm^3\ molecule^{-1}\ s^{-1}.$$

This recommendation is only valid for one atmosphere pressure of air. It is interesting to note that measurements by Hynes et al.[2] at approximately 250 K and 700 Torr total pressure result in k_{eff} values that are independent of the amount of O_2 for partial pressures between 145 and 680 Torr. This suggests that the adduct is quite stable with respect to dissociation into the reactants ($OH + CS_2$) at this low temperature and that the effective rate constant for reactant removal approaches the elementary rate constant for adduct formation. I17. **$CS_2OH + O_2$.** Three groups have obtained kinetic information about this reaction by observing either the perturbation of OH/CS_2OH equilibration kinetics upon addition of O_2, or by modeling the dependence of the observed rate constant for OH loss on $[O_2]$. Hynes et al.,[2] Murrells et al.,[7] and Diau and Lee[1] agree quite well on the value of k, with an average value of 2.8×10^{-14} cm^3 molecule^{-1} s^{-1} independent of temperature and pressure being recommended. Diau and Lee also report rate constants for the reactions of the adduct (CS_2OH) with NO and NO_2 to be 7.3×10^{-13} and 4.2×10^{-11} cm^3 molecule^{-1} s^{-1}, respectively.

From a mechanistic viewpoint, the primary products of this reaction determine the products of CS_2 oxidation in air. Lovejoy et al.[4] have shown that the yields of HO_2 and SO_2 are equal and near unity. Further insight is provided by the mechanistic study of Stickel et al.,[8] who observe OCS and CO product yields of (0.83 ± 0.08) and (0.16 ± 0.03), respectively. The results from this study are interpreted to imply that OCS and CO are formed either as primary products of the $CS_2OH + O_2$ reaction or as products of a secondary reaction between a primary product and O_2. These same authors report an SO_2 yield of (1.15 ± 0.10), with the results suggesting that only about 75% of the SO_2 is formed as a prompt product, with the remainder generated via a slow reaction of SO (generated as a prompt product of the $CS_2OH + O_2$ reaction) with O_2. Insight into the specific reaction pathways can be gleaned from the study of Lovejoy et al.[3] in which the rate constant for the reaction of $CS_2OD + O_2$ was found to be the same as that for $CS_2OH + O_2$, indicating that simple H atom abstraction is not the likely process. Rather, HO_2 production most likely involves complex formation followed by HO_2 elimination. Lovejoy et al.[5] found that the ^{18}O atom in the ^{18}OH reactant is transferred predominantly (90 ± 20)% to the SO_2 product. These findings are consistent with an S–O-bonded CS_2–OH adduct and preservation of the S–O bond in the steps leading to SO_2 formation.

Theoretical studies by Zhang and Qin[9] and by McKee and Wine[6] have provided further insight into the reaction mechanism. The initial step is, indeed, formation of SCS−OH followed by addition of O_2 to the carbon atom. A key subsequent step appears to be an O atom transfer to the sulfur bearing the hydroxyl group which leads directly to HOSO + OCS. The reaction $HOSO + O_2 \rightarrow HO_2 + SO_2$ is expected to occur rapidly under atmospheric conditions. One remaining problem is identification of the pathway for generation of CO, which is observed as a minor product.

I18. **OH + CH_3SH.** This recommendation is based on a composite fit to the data of Atkinson et al.,[1] Wine et al.,[10] Wine et al.,[11] and Hynes and Wine,[5] which are in excellent agreement. The results from the relative rate study of Barnes et al.[2] are in agreement with this recommendation and indicate that the higher value of Cox and Sheppard[4] is due to complications resulting from the presence of O_2 and NO in their reaction system. MacLeod et al.[7,8] and Lee and Tang[6] obtained rate constants at 298 K approximately 50% lower than recommended here. These authors also obtained lower values for the ethanethiol reaction in comparison with results from studies upon which the methanethiol recommendation is made. Wine et al.[11] present evidence that this reaction proceeds via adduct formation to produce a species that is thermally stable over the temperature range and time scales of the kinetic measurements. Tyndall and Ravishankara[9] have determined the yield of CH_3S (via laser–induced fluorescence) to be unity, indicating that any adduct must be short lived (less than 100 µs). Longer lifetimes would have led to anomalies in the OH decay kinetics used for the rate constant determinations. Butkovskaya and Setser,[3] based on observations of IR emissions from the products of the reactions of OH and OD with CH_3SH and CH_3SD, conclude that H-abstraction from the methyl group occurs with a yield of 24 ± 8% for the OH reactions and 11 ± 4% for the OD reactions. Hynes and Wine[5] observed that the rate constant is independent of O_2 partial pressure.

I19. OH + CH_3SCH_3 → H_2O + CH_2SCH_3. The OH + CH_3SCH_3 reaction is complex, proceeding by both H-abstraction and reversible addition pathways. In the presence of atmospheric levels of O_2, adduct reaction with O_2 makes the addition pathway partially irreversible. Only kinetic data obtained in the absence of O_2 and at low enough CH_3SCH_3 concentrations for the adduct to be a negligible reservoir for OH are considered in evaluation of the H-abstraction rate constant. Thus, this recommendation is based on the results of Hynes et al.,[8] Wine et al.,[22] Hsu et al.,[7] Abbatt et al.,[1] Barone et al.,[6] Turnipseed et al.,[15] Williams et al.,[19-21] and Wang et al.[18] The earlier larger rate constant values of Atkinson et al.[3] and Kurylo[10] are presumably due to reactive impurities, while those of MacLeod et al.[11] were most likely overestimated because of heterogeneous reactions. Unlike other temperature dependence studies, the rate constants reported by Albu et al.[2] (at T = 250−299 K) suggest a significant negative activation energy, leading to suspicion of an interference from adduct reaction with impurity O_2. Absolute determinations lower than those recommended were obtained by Martin et al.,[12] Wallington et al.,[17] and Nielsen et al.[13] The reasons for these differences are not readily apparent. Confirmation that H-abstraction is the dominant pathway under the experimental conditions specified above comes from the studies of Stickel et al.[14] and Turnipseed et al.[15] Stickel et al. used tunable diode laser spectroscopy to measure an HDO product yield of 0.84 ± 0.15 for the OD + CH_3SCH_3 reaction in 10−30 Torr N_2, while Turnipseed et al. used laser induced fluorescence observations of CH_3S production from OH + CH_3SCH_3 to show that the branching ratio for the CH_3S elimination channel is <0.04 and the direct H-abstraction yield is 0.84 ± 0.26. Further support for the dominance of the H-abstraction pathway comes from the work of Zhao et al.,[23] who obtained an upper limit yield of 0.07 for the methyl elimination channel in the OD + CH_3SCH_3 reaction. Barnes et al.,[4,5] Turnipseed et al., and Urbanski et al.[16] report that the abstraction product CH_3SCH_2 is converted predominantly to CH_3S under atmospheric conditions. Barnes et al.[4] measure a 0.7% yield of OCS under low NO_x conditions, which they attribute to further oxidation of CH_3S. A theoretical study by Jorgensen and Kjaergaard suggests that complexation of CH_3SCH_3 with a single water molecule can speed up the reaction by lowering the energy of the transition state relative to the energy of the reactants.[9]

I20. OH + CH_3SCH_3 → $(CH_3)_2SOH$ → products. The OH + CH_3SCH_3 reaction is complex, proceeding by both direct H-abstraction and reversible addition pathways. A recommendation for the direct reaction is given separately in Table 1 (see above). The product of the reversible addition pathway reacts with O_2 creating an irreversible path as well. Mechanistically, this pathway is described by combining the rate constants k_f for the addition step, k_r for the reverse dissociation step, and k_{O2} for the adduct reaction with O_2. The equilibrium constant for the reversible addition process is $K_c = k_f/k_r$. Recommendations for K_c, k_f, and k_{O2} are found in Tables 3, 2, and 1, respectively. Subtracting the temperature-dependent H-abstraction rate constant from the overall irreversible rate constant (which depends on T, P, and P_{O2}) yields the rate constant for irreversible addition (k_{ia}), which can be expressed as:

$$k_{ia} = K_c\, k_{O2}\,[O_2] \,/\, (1 + (K_c\, k_{O2}\,[O_2] \,/\, k_f)).$$

Much of the kinetic data available for evaluating this reaction were obtained for OH + CD_3SCD_3. Although the methyl hydrogens are not directly involved in the reaction, the rate constants for OH addition reactions with CH_3SCH_3 and CD_3SCD_3 differ somewhat[6] as they are in the low-pressure limit where the value depends on the density of states, which are different for the two isotopomers. The recommended expression (units are cm^3 $molecule^{-1}$ s^{-1}),

$$k_{ia}(T,[O_2],[M]) = 8.2 \times 10^{-39}\,[O_2] \exp(+5376/T) \,/\, (1 + 1.05 \times 10^{-5}\,([O_2]\,/\,[M]) \exp(+3644/T)),$$

is based on the recommendations for K_c, k_f, and k_{O2} given elsewhere in this evaluation. It reproduces the data of Hynes et al.,[2] Williams et al.,[4-6] and Albu et al.[1] quite well for both isotopomers and for all mole fractions of O_2 in N_2/O_2 mixtures; however, it should be used with caution at temperatures below 240 K (where no data are available) or above 310 K (where k_{ia} is very small). The 298 K relative rate study of Wang et al.[3] suggests rate constants in air and pure O_2 at atmospheric pressure that are about a factor of two faster than those predicted by the above expression. Since the kinetic data of Hynes et al. and Williams et al. were obtained by monitoring OH loss, the overall rate constant for removal of CH_3SCH_3 would be underestimated if the adduct + O_2 reaction generated OH + dimethylsulfone ($CH_3(O)S(O)CH_3$) with a significant yield; the available data cannot rule out a small but significant branching ratio for this channel.

I21. $(CH_3)_2SOH + O_2$. All available kinetic data for this reaction were obtained by measuring k_{obs} for the OH + CH_3SCH_3 reaction as a function of O_2 partial pressure (k_{obs} ≡ the sum of the rate constants for H-abstraction and irreversible addition). Much of the available data were obtained for OH + CD_3SCD_3. Since the methyl hydrogens are not directly involved in the reaction, the rate constant is expected to be virtually the same for CH_3SCH_3 as for CD_3SCD_3; hence, data for both reactants are used in the evaluation. The recommendation is based on the data of Hynes et al.,[3] Barone et al.,[1] and Williams et al.[8,9] The Hynes et al. study supersedes an earlier report of a considerably faster rate constant.[4] Over the range of experimental conditions where data are available (222–267 K and 30–200 Torr), the rate constant appears to be independent of temperature and pressure. By monitoring the regeneration of OH in the presence of NO, Hynes et al.[2] and Turnipseed et al.[7] have determined the yield for the HO_2 + $CH_3S(O)CH_3$ (DMSO) channel to be ~0.5. A theoretical study by

Ramirez-Anguita et al.[5] suggests possible pathways for generating CH_3SOH + CH_3OO/CH_2OOH. A second theoretical study by the same authors supports the experimental finding that the rate constant has little temperature or pressure dependence.[6]

I22. OH + CH_3SCH_2Cl. The recommendation is based on the low-pressure discharge flow resonance fluorescence study of Shallcross et al.[1] The uncertainty reflects the fact that only one study performed under a limited range of experimental conditions has been reported. Shallcross et al. suggest that the likely reaction pathway is H-abstraction under the low-pressure conditions of their experiments. However, further experimental and/or theoretical research is needed before an addition-elimination pathway involving C−S bond cleavage can be ruled out. If H-abstraction dominates at low pressure, then under atmospheric conditions the rate constant could be significantly faster than reported by Shallcross et al. due to the occurrence of an irreversible addition channel at higher pressure and in the presence of O_2.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

I23. OH + CH_3SSCH_3. This recommendation is based on the temperature–dependent studies of Wine et al.[7] and Abbatt et al.[1] and the room temperature relative rate study of Cox and Sheppard.[5] Domine and Ravishankara[6] have observed both CH_3S (via laser–induced fluorescence) and CH_3SOH (via photo-ionization mass spectrometry) as products of this reaction. At 298 K, the yield of CH_3S alone was quantified at approximately 30%. An FTIR product study of the photooxidation of dimethyl disulfide by Barnes et al.[2] presents evidence that oxidation of the CH_3SOH product is the principal source of the methane sulfonic acid observed. Butkovskaya and Setser[3] have observed that HDO and D_2O are produced from OD + CH_3SSCH_3 in the same proportion and with the same vibrational state distributions as the products observed by the same investigators in a similar study of the OD + CH_3SD reaction,[4] leading these authors to suggest that the major product channel for OD + CH_3SSCH_3 is CH_3SD + CH_3SO.

I24. **OH + $CH_3S(O)CH_3$.** The recommended 298 K rate constant is the average of the direct studies of Hynes and Wine,[4] Urbanski et al.,[8] and Kukui et al.,[6] which employed three different experimental approaches and are in excellent agreement. Competitive kinetics studies by Barnes et al.[2] and Falbe-Hanson et al.[3] report rate constants in 1 atm. of air about a factor of 1.5 slower than those obtained in the direct studies. The recommended value for *E*/R is based on the only study of the temperature dependence,[4] where a significant negative activation energy was observed. The large uncertainty in E/R reflects the availability of very limited data (none below room temperature). The experimental studies of Urbanski et al., Kukui et al., and Arsene et al.,[1] as well as the theoretical study of Wang and Zhang,[9] provide strong evidence that the dominant reaction channel is production of CH_3 + $CH_3S(O)OH$ (MSIA, methanesulfinic acid). Arsene et al. attribute the failure to observe MSIA production in the chamber study of Sorensen et al.[7] to loss via secondary gas phase and condensed phase oxidation before sampling. A theoretical study by Jorgensen and Kjaergaard suggests that the H-abstraction may be more important under atmospheric conditions than previously thought because (i) complexation of $CH_3S(O)CH_3$ with a single water molecule can speed up the H-abstraction reaction by lowering the energy of the transition state relative to the energy of the reactants and (ii) under atmospheric conditions a significant fraction of $CH_3S(O)CH_3$ is complexed with H_2O.[5] However, as mentioned above, experimental information suggests that methyl elimination, not H-abstraction, is the dominant reaction pathway.

I25. OH + $CH_3S(O)OH$. The recommendation is based on a turbulent flow reactor − chemical ionization mass spectrometry study by Kukui et al.,[2] which was carried out with OH in excess over $CH_3S(O)OH$ at total pressures of 200−400 Torr N_2. The large uncertainty factor results from the facts that (1) only a single room temperature study is reported in the literature and (2) $CH_3S(O)OH$ is a difficult species to study in the gas phase because of its low vapor pressure. Kukui et al. found that SO_2 was produced as a reaction product with near unit yield, suggesting that the dominant reaction channel (at least in the absence of O_2) is production of CH_3 + SO_2 + H_2O. Theoretical studies by Gonzalez-Garcia et al.[1] and Tian et al.[3] provide strong evidence that the $CH_3S(O)OH$−OH adduct is too short-lived to react with O_2 under atmospheric conditions.

I26. OH + CH_3SO_3H. No gas-phase experimental data are available for this reaction, but a detailed theoretical study has been reported by Jorgensen et al.[1] Equilibrium and transition state structures were optimized using B3LYP density functional theory with the aug-cc-pV(T+d)Z basis set. Energies of stable species and transition states were refined using CCSD(T)-F12A theory with the VDZ-F12 basis set. Two different mechanisms were identified for producing CH_3SO_3 + H_2O, hydrogen atom transfer and proton coupled electron transfer. The 298 K rate constant was calculated using conventional transition state theory and found to be 8.3×10^{-15} cm^3 $molecule^{-1}$ s^{-1}. Given that a 5 kJ mol^{-1} error in a transition state energy can cause a factor of ten error in a calculated rate constant, the uncertainty in the theoretical rate constant is estimated to be around one order of magnitude. The role of water complexation with both reactants was examined theoretically and found to have no effect on the predicted rate constant under tropospheric conditions.

I27. OH + $CH_3SC_2H_5$ → H-abstraction products. The recommendation is based on the 299 K study of Hynes et al.[2] and the temperature dependent (242−296 K) study of Williams et al.[4] Oksdath-Mansilla et al.[3] obtained a 298 K rate constant from a relative rate study that is 40% faster than the recommended value. A theoretical study by Cao et al.[1] suggests that abstraction of the secondary hydrogen is dominant (92% at 200 K and 85% at 300 K), with abstraction of the methyl hydrogen accounting for 7% of overall reactivity at 200 K and 12% at 300 K.

I28. OH + $CH_3SC_2H_5 \overset{M}{\leftrightarrow} CH_3S(OH)C_2H_5 \xrightarrow{O_2}$ products. The OH + $CH_3SC_2H_5$ reaction is complex, proceeding by both direct H-abstraction and reversible addition pathways. A recommendation for the H-abstraction reaction is given separately in Table 1 (see above). The product of the reversible addition pathway reacts with O_2 creating an irreversible addition path as well. Mechanistically, this pathway is described by combining the rate constants k_f for the addition step, k_r for the reverse dissociation step, and k_{O2} for the adduct reaction with O_2. The equilibrium constant for the reversible addition process is $K_c = k_f/k_r$. Subtracting the H-abstraction rate constant (which depends only on T) from the overall observed rate constant (which depends on T, P, and P_{O2}) yields the rate constant for irreversible addition (k_{ia}), which can be expressed as

$$k_{ia} = K_c\, k_{O2}\, [O_2] / (1 + (K_c\, k_{O2}\, [O_2] / k_f)).$$

The expression given below (units are cm^3 $molecule^{-1}$ s^{-1}) is obtained by substituting values for K_c, k_f, and k_{O2} that are derived from the results of Williams et al.[5] into the expression given above. Because data are available only over a limited range of experimental conditions, the expression below should be used only for *air bath gas at P = 680 ± 80 Torr and T >240 K.*

$$k_{ia}(T, 680 \pm 80 \text{ Torr air}) = 1.17 \times 10^{-38} \exp(+5290/T) \;/\; (7.25 \times 10^{-22}\, T + 3.59 \times 10^{-26} \exp(+4170/T)).$$

The expression reproduces the laser flash photolysis data of Williams et al.,[5] and the relative rate data of Oksdath-Mansilla et al.[1,2] quite well. The relative rate study of Wang et al.[4] suggests values for $k_{abstraction} + k_{ir}$ in 760 Torr air at T = (297−346 K) that are faster than suggested by the above expression and are inconsistent with the results of the other available studies. Oksdath-Mansilla et al. report the following product yields in NO_x-free air at P = 760 Torr and T = 298 K (where irreversible addition is a minor but significant reaction pathway): SO_2, 51 ± 2%; CH_3CHO, 57 ± 3%; HCHO, 46 ± 4%.[3]

Phys.* **2007**, *9*, 4370-4382, doi:10.1039/b703957n.

I29. **$CH_3S(OH)C_2H_5 + O_2$.** The recommendation is based on the results of Williams et al.,[1] who extracted rate constants from measurements of k_{obs} for the OH + $CH_3SC_2H_5$ reaction as a function of O_2 partial pressure (k_{obs} ≡ the sum of the rate constants for H-abstraction and irreversible addition). The derived rate constants were found to be independent of temperature (242−296 K) and pressure (200−600 Torr $N_2 + O_2$).

I31. **OH + SO.** The recommendation is based on the results of Blitz et al.[1] , who report the only temperature dependent data. Earlier studies by Fair and Thrush[2] and Jourdain et al.[3] report room temperature rate constants that are less precise but in good agreement with the results of Blitz et al. Only Blitz et al. data at T ≤503 K are used to obtain the recommended value for E/R since data at higher temperatures show a significant non-Arrhenius temperature dependence. The recommended value for g is conservative because only one temperature dependence study has been reported. High level electronic structure calculations by Rodriguez-Linares et al.[4] suggest that the evolution from reactants to H + SO_2 products involves multiple transition states. I32. OH + SO_2F_2. The recommended upper limit is based on the relative rate experiments of Papadimitriou et al.[2] Less sensitive upper limits are reported by Dillon et al.[1] and Sulbaek-Andersen et al.[3]
(Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

I33. HO_2 + H_2S, HO_2 + CH_3SH, HO_2 + CH_3SCH_3. These upper limits are taken from the discharge flow laser magnetic resonance study of Mellouki and Ravishankara.[3] The H_2S value disagrees with the rate constant reported by Bulatov et al.[2] by approximately three orders of magnitude. The reason for this difference is not readily apparent. However, the recommended upper limit is consistent with the values for CH_3SH and CH_3SCH_3, which respectively agree with upper limits from the work of Barnes et al.[1] and Niki (reported as a private communication in the Mellouki and Ravishankara paper).

I34. HO_2 + SO_2. This upper limit is based on the atmospheric pressure study of Graham et al.[2] A low pressure laser magnetic resonance study by Burrows et al.[1] places a somewhat higher upper limit on k(298 K) of 4 × 10^{-17} cm^3 $molecule^{-1}$ s^{-1} (determined relative to OH + H_2O_2); their limit is based on the assumption that the products are OH and SO_3, an assumption that theoretical work by Wang and Hou[4] suggests is incorrect. Wang and Hou find that reaction proceeds via an energized HO_2SO_2 complex that is stabilized in competition with dissociation to O_2 + HOSO. At 300 K and 760 Torr N_2, calculated rate coefficients in units of 10^{-17} $cm^3 molecule^{-1} s^{-1}$ are 1.1 for complex stabilization and 2.4 for production of O_2 + HOSO. However, at atmospheric temperatures, pressures, and O_2 partial pressures, both reactions are rapidly reversible, so there is no net reaction. The weight of evidence from the other cited studies suggests an error in the earliest determination by Payne et al.[3]

I35. **NO_2 + SO_2.** This recommendation is based on the study of Penzhorn and Canosa[2] using second derivative UV spectroscopy. While these authors actually report a measured value for k(298 K), their observations of strong heterogeneous and water vapor catalyzed effects prompt us to accept their measurement as an upper limit. This value is approximately two orders of magnitude lower than that for a dark reaction observed by Jaffe and Klein,[1] much of which may have been due to heterogeneous processes. Penzhorn and Canosa suggest that the products of this reaction are NO + SO_3.

I36. **NO_3 + H_2S.** This recommendation accepts the upper limit set by Dlugokencky and Howard[2] based on experiments in which NO_3 loss was followed in the presence of large concentrations of H_2S. Less sensitive upper limits for the rate constant have been reported by Wallington et al.[3] and Cantrell et al.[1]

I38. **NO_3 + CS_2.** This upper limit is based on the study of Burrows et al.[1] A somewhat higher upper limit was derived in the relative rate study of MacLeod et al.[2]

I39. **NO_3 + CH_3SH.** The recommended values are derived from a composite fit to the data of Wallington et al.,[5] Rahman et al.,[4] and Dlugokencky and Howard.[1] The room temperature rate constant derived in the relative rate experiments of MacLeod et al.[3] is in good agreement with the recommended value. The suite of investigations shows the rate constant to be pressure independent over the range 1–700 Torr. Dlugokencky and Howard place an upper limit of 5% on the production of NO_2 via this reaction at low pressure. Based on the product distribution observed in their investigation, Jensen et al.[2] propose a reaction mechanism initiated by abstraction of the hydrogen atom from the SH group, possibly after formation of an initial adduct as suggested by Wallington et al. and Dlugokencky and Howard.

Chem.* **1986**, *90*, 5393-5396, doi:10.1021/j100412a099.

I40. NO_3 + CH_3SCH_3. The recommended value for *k*(298 K) is obtained by averaging the rate constants reported by Tyndall et al.,[11] Dlugokencky and Howard,[4] and Daykin and Wine.[3] The recommended value of *E*/R is that reported by Dlugokencky and Howard. Tyndall et al. and Nakano et al.[9] report data over rather narrow temperature ranges that are consistent with the Dlugokencky and Howard result. The relative rate study of Atkinson et al.[1] yields a rate constant at room temperature that is about a factor two lower than the recommended value. Wallington et al.[12,13] also report rate constants that are somewhat lower than the recommended values; their results are suspect because their reaction mixtures contained F_2 in ten-fold excess over CH_3SCH_3, and it is now well-established that F_2 and CH_3SCH_3 react with each other rapidly.[7,8,10] The results of Nakano et al. are suspect because of the likely presence of background NO_3 associated with the use of N_2O_5 + hν as the NO_3 source. The experimental data from all investigations demonstrate the pressure independence of the rate constant over the range 1–740 Torr. Jensen et al.[5] propose a mechanism that involves hydrogen abstraction as the first step to explain their observed product distribution. In a later study, Jensen et al.[6] measured a kinetic isotope effect for the rate constant for CH_3SCH_3 vs. that for CD_3SCD_3 of $k_H/k_D = (3.8 \pm 0.6)$, in agreement with the kinetic isotope effect reported by Daykin and Wine; this provides further confirmation of the H-abstraction mechanism. Butkovskaya and Le Bras[2] utilized chemical titration of the primary radical produced from NO_3 + CH_3SCH_3 in a discharge flow mass spectrometry system to show that the reaction produces predominantly CH_3SCH_2 + HNO_3. An upper limit of 2% was placed on the reaction channel yielding CH_3 + CH_3SONO_2.

(13) Wallington, T. J.; Atkinson, R.; Winer, A. M.; Pitts Jr., J. N. Absolute rate constants for the gas-phase reactions of the NO_3 radical with CH_3SCH_3, NO_2, CO, and a series of alkanes at 298 ± 2 K. *J. Phys. Chem.* **1986**, *90*, 4640-4644, doi:10.1021/j100410a034.

I41. **$NO_3 + CH_3SSCH_3$.** The recommendation is based on the temperature dependent studies of Wallington et al.[5] and Dlugokencky and Howard.[2] All data points in each temperature dependent study were scaled by a factor equal to the ratio $k(298\ K)_{Arr}/k(298\ K)_{ave}$ where $k(298\ K)_{Arr}$ is the 298 K rate constant obtained from Arrhenius expression describing the individual T-dependent data set and $k(298\ K)_{ave}$ is the average of the two $k(298\ K)_{Arr}$ values. The best fit of the scaled data to $\ln k = \ln A - E/RT$ is recommended. The investigation by Atkinson et al.[1] indicates that the relative rate technique cannot be considered as yielding reliable rate data for this reaction due to chemical complexities. Thus, the much lower room temperature results from the study of MacLeod et al.[4] can be considered to be erroneous. Based on their observations of intermediate and end products, Jensen et al.[3] proposed a reaction mechanism in which the initial addition of NO_3 to one of the sulfur atoms results in formation of $CH_3S + CH_3SO + NO_2$.

N., Jr. Kinetics and mechanisms of the gas phase reactions of the NO_3 radical with a series of reduced sulfur compounds. *J. Geophys. Res.* **1986**, *91*, 5338-5346, doi:10.1029/JD091iD05p05338.
(5) Wallington, T. J.; Atkinson, R.; Winer, A. M.; Pitts, J. N., Jr. Absolute rate constants for the gas-phase reactions of the NO_3 radical with CH_3SH, CH_3SCH_3, CH_3SSCH_3, H_2S, SO_2, and CH_3OCH_3 over the temperature range 280-350 K. *J. Phys. Chem.* **1986**, *90*, 5393-5396, doi:10.1021/j100412a099.

I42. **$NO_3 + CH_3S(O)CH_3$.** The recommended value for $k(298\ K)$ is the geometric mean of the rate constants reported by Barnes et al.[1] and Falbe-Hansen et al.[2] from similar competitive kinetics studies; the reported rate constants and associated 2σ uncertainties in units of 10^{-13} cm^3 $molecule^{-1}$ s^{-1} are 1.7 ± 0.6 (Barnes et al.) and 5.0 ± 3.8 (Falbe-Hansen et al.). In both studies, the only observed sulfur-containing end-product was dimethylsulfone ($CH_3(O)S(O)CH_3$). Barnes et al. suggest that reaction proceeds via formation of an adduct that rapidly decomposes to $NO_2 + CH_3(O)S(O)CH_3$.

I43. **$NO_3 + CH_3SC_2H_5$.** The recommendation is the geometric mean of rate constants for NO_3 reactions with CH_3SCH_3 (k_1) and $C_2H_5SC_2H_5$ (k_2) reported by Daykin and Wine,[1] while the recommended uncertainty is large enough to include both k_1 and k_2 within its limits. Observation of the trend in rate constants for reactions of NO_3 radicals with CH_3SCH_3, CD_3SCD_3, and $C_2H_5SC_2H_5$ suggests that H-transfer is the dominant pathway for these reactions.[1] Products of the $NO_3 + CH_3SC_2H_5$ reaction measured in an environmental chamber by Jensen et al.[2] using a combination of FTIR and ion chromatographic detection also supports H-transfer as the dominant pathway and suggests that yields of the H-transfer products $CH_2SCH_2CH_3$ and CH_3SCHCH_3 are approximately equal.

I45. $N_2O_5 + CH_3SCH_3$. This recommendation is based on the value estimated by Tyndall and Ravishankara[2] from the study by Atkinson et al.[1]
(Table: 92-20, Note: 92-20, Evaluated: 92-20) Back to Table

I46. $CH_3O_2 + SO_2$. This recommendation accepts the results from the study of Sander and Watson.[4] These authors conducted experiments using much lower CH_3O_2 concentrations than employed in the earlier investigations of Sanhueza et al.[5] and Kan et al.,[3] both of which resulted in *k*(298 K) values approximately 100 times greater. A later report by Kan et al.[2] postulates that these differences are due to the reactive removal of the $CH_3O_2SO_2$ adduct at high CH_3O_2 concentrations prior to its reversible decomposition into CH_3O_2 and SO_2. They suggest that such behavior of $CH_3O_2SO_2$ or its equilibrated adduct with O_2 ($CH_3O_2SO_2O_2$) would be expected in the studies yielding high k values, while decomposition of $CH_3O_2SO_2$ into reactants would dominate in the Sander and Watson experiments. It does not appear likely that such secondary reactions involving CH_3O_2, NO, or other radical species would be rapid enough, if they occur under normal atmospheric conditions to compete with the adduct decomposition. This interpretation, however, does not explain the high rate constant derived by Cocks et al.[1] under conditions of low [CH_3O_2].

I47. $F + CH_3SCH_3$. This recommendation is based on the discharge flow mass spectrometric study by Butkovskaya et al.[1] The uncertainty placed on this recommendation has been increased over that estimated by the authors to reflect the lack of confirming investigations. Titration of the primary organic radical products indicated that

the reaction proceeds via two channels to produce HF + CH_3SCH_2 and CH_3 + CH_3SF with a branching ratio of approximately 0.8/0.2 respectively.

I48. Cl + H_2S. This recommendation is based on the work of Nicovich et al.[10] and Gao et al.,[5] who conducted careful studies with attention to sources of possible systematic error; only the Gao et al. data at T ≤500 K are considered in arriving at the recommendation. The recommended rate constant at 298 K is in good agreement with that determined by Nesbitt and Leone,[9] who refined the data of Braithwaite and Leone,[1] but is significantly greater than the values reported by Clyne and Ono,[4] Clyne et al.,[3] Nava et al.,[8] and Chen et al.[2] The small, but clearly observed, negative activation energy determined by Nicovich et al. and Gao et al. contrasts with the lack of a temperature dependence observed by Nava et al. The Nicovich et al. study yields consistent results for both H_2S and CH_3SH as well as for D_2S and CD_3SD. In addition, Hossenlopp et al.[6] report a room temperature rate constant for Cl + D_2S that is in excellent agreement with the value reported by Nicovich et al. Lu et al.[7] also measured a temperature–independent rate constant but report a value at 298 K that is about 40% greater than those of Nicovich et al. and Gao et al. The presence of 4000 Torr of CF_3Cl bath gas in the Lu et al. study may suggest a slight pressure dependence of the rate constant, although Nicovich et al. observed no pressure dependence for pressures ranging up to 600 Torr N_2 and Gao et al. observed no pressure dependence over the range 30–100 Torr Ar. A theoretical study by Wilson and Hirst[11] suggests the dominance of an addition-elimination pathway with a small but significant fraction of reactive events occurring via a direct hydrogen abstraction mechanism.

I49. Cl + SO_2F_2 → products. The recommended upper limit is a factor of 3 higher than that reported in the relative rate experiments of Sulbaek-Andersen et al.[2] to account for a large uncertainty in the rate constant for the reference reaction they employed (Cl + CF_3CH_3). A less sensitive upper limit is reported by Papadimitriou et al.[1].

Technol.* **2009**, *43*, 1067-1070, doi:10.1021/es802439f.

I50. **Cl + OCS.** This upper limit is based on the minimum detectable decrease in atomic chlorine measured by Eibling and Kaufman.[2] Based on the observation of product SCl, these authors set a lower limit on *k*(298 K) of 10^{-18} cm^3 $molecule^{-1}$ s^{-1} for the SCl + CO reaction channel. Considerably higher upper limits on *k*(298 K) were determined in the studies of Clyne et al.[1] and Nava et al.[3]

I51. **CS_2Cl + O_2.** This recommendation is based on the study of Nicovich et al.[2] who employed a laser flash photolysis resonance fluorescence technique to observe the effect of added O_2 on the kinetics of the Cl + CS_2 ↔ CS_2Cl equilibration reactions. Martin et al.[1] report competitive kinetics results which they interpret as suggesting a fast CS_2Cl + O_2 reaction, but Wallington et al.[3] have suggested that secondary production of OH in the photochemical system employed by Martin et al. is responsible for the observed dependence of the CS_2 loss rate on [O_2].

I52. **Cl + CH_3SH.** This recommendation is based on the results of Nicovich et al.,[4] who used laser flash photolysis with resonance fluorescence detection to study the reactions of Cl with H_2S, D_2S, CH_3SH, and CD_3SD. The room temperature determination by Nesbitt and Leone[2] is in good agreement with the recommended value. The *k*(298 K) value from the study of Mellouki et al.[1] is nearly a factor of 2 lower. However, the low sensitivity of EPR detection of Cl atoms did not permit these latter authors to conduct a precise determination of k under pseudo first–order conditions, and a more complex analysis of experiments conducted under second–order conditions was required. Nesbitt and Leone[3] report that 2 ± 1% of the reaction occurs via abstraction of an H atom from the CH_3 group. A theoretical study by Wang et al. supports abstraction of H from the SH group as the dominant reaction pathway at atmospheric temperatures, but predicts that abstraction of H from the CH_3 group becomes important at higher temperatures.[5] A theoretical study by Wilson and Hirst[6] predicts a Cl−S adduct bond strength (298 K) of 57 kJ mol^{-1}, but is unable to deduce the relative importance of addition-elimination vs. direct hydrogen abstraction pathways.

I53. **Cl + CH_3SCH_3.** Stickel et al.[9] have used laser flash photolysis resonance fluorescence to measure the rate constant between 240 and 421 K, over the pressure range 3–700 Torr. The rate constant is near the gas-kinetic collision limit but increases with increasing pressure from a low-pressure limit of 1.8×10^{-10} to a value of 3.3×10^{-10} cm^3 molecule^{-1} s^{-1} at 700 Torr. The yield of HCl at 297 K, measured by diode laser spectroscopy, decreased from near unity at low pressure to a value of approximately 0.5 at 203 Torr, suggesting that stabilization of a $(CH_3)_2SCl$ adduct becomes competitive with hydrogen atom abstraction with increasing pressure. These investigators also observed a negative temperature dependence for the reaction at low pressure. Butkovskaya et al.[2] conducted a discharge flow mass spectrometry study at 298 K, in which they determined that the reaction proceeds to form HCl + CH_3SCH_2 almost exclusively at 1 Torr total pressure. The sum of all other possible channels was estimated at less than 3%. Zhao et al.[13] used laser photolysis coupled with CH_3 detection by time–resolved tunable diode laser absorption spectroscopy to determine an upper limit yield of 0.02 for CH_3 elimination at 298 K and pressures in the range 10–30 Torr. Langer et al.[6] coupled cw photolysis with gas chromatographic detection of products to show that the yield of CH_3Cl is $(1.34 \pm 0.07) \times 10^{-3}$. Theoretical studies by Wilson and Hirst,[12] Resende and De Almeida,[8] and Thompson et al.[10] support the experimentally observed dominance of the H-abstraction pathway at low pressure. Diaz-de-Mera et al.[3] have employed a discharge flow − mass spectrometry technique to measure rate constants at pressures of 0.5−1.0 Torr He over the temperature range 259−364 K. The 298 K rate constant reported by Diaz-de-Mera et al. is nearly a factor of 3 slower than the low-temperature limit value reported by Stickel et al. Furthermore, Diaz-de-Mera et al. report a small positive activation energy whereas Stickel et al. report a small negative activation energy. The present recommendation for the H-abstraction pathway is based on an extrapolated low-pressure limit rate constant obtained from the data of Stickel et al., with the uncertainty adjusted to encompass the result of Diaz-de-Mera et al. The data of Stickel et al. suggest that a high-pressure limit is reached at P ~150 Torr. Urbanski and Wine[11] have observed the UV-visible absorption spectrum of $(CH_3)_2SCl$ in 155 Torr O_2 and used absorbance rise−time data to derive a rate constant that agrees well with those measured by Stickel et al. at pressures of 150−750 Torr N_2. Enami et al.[4] have observed the kinetics of adduct formation using cavity ring down spectroscopy, and derived rate constants over the temperature and pressure ranges 278−318 K and 20−300 Torr N_2 that also agree well with those reported by Stickel et al. Room temperature competitive kinetics measurements by Nielsen et al.[7] at 740 Torr, Kinnison et al.[5] at 760 Torr, and Arsene et al.[1] at 750 Torr agree quite well with the results of Stickel et al., Urbanski and Wine, and Enami et al. Kinnison et al. and Arsene et al. report that the rate constant at atmospheric pressure is ~20% faster in synthetic air than in N_2 bath gas, suggesting that the $(CH_3)_2SCl$ adduct reacts with O_2; however, the results of Urbanski and Wine, and Enami et al. argue against the occurrence of such a reaction. Stickel et al. report that the high-pressure rate constant in N_2 is independent of temperature whereas Arsene et al. report large negative activation energies in both N_2 and synthetic air bath gases. The large negative activation energies reported by Arsene et al. seem unlikely to result from a two-channel elementary reaction (H-abstraction and addition); hence, the recommended E/R is that reported by Stickel et al.

I54. $(CH_3)_2SCl + O_2$, NO, NO_2. The recommended values for k(298 K) are based on the study of Urbanski and Wine[2] which combined laser flash photolytic production of $(CH_3)_2SCl$ with kinetic observations by time-resolved absorption spectroscopy. The recommended uncertainties for the NO and NO_2 reactions are larger than those reported by Urbanski and Wine pending independent confirmation of their results. As in the Urbanski and Wine study, Enami et al.[1] report no observable reaction between $(CH_3)_2SCl$ and O_2.
(Table: 06-2, Note: 06-2, Evaluated: 06-2) Back to Table

(1) Enami, S.; Nakano, Y.; Hashimoto, S.; Kawasaki, M.; Aloisio, S.; Francisco, J. S. Reactions of Cl atoms with dimethyl sulfide: A theoretical calculation and an experimental study with cavity ring-down spectroscopy. *J. Phys. Chem. A* **2004**, *108*, 7785-7789, doi:10.1021/jp049772y.

I55. $Cl + CH_3S(O)CH_3 \rightarrow CH_3S(O)CH_2 + HCl$. The recommended value of k(298 K) for H-abstraction is based on the analysis of Nicovich et al.,[4] who fit the combined room temperature data of Nicovich et al., Martinez et al.,[3] and Riffault et al.,[5] which spanned an effective N_2 pressure range of 0.3−505 Torr, to the sum of a pressure-dependent component and a pressure-independent component and attributed the pressure-independent component to H-abstraction. The temperature dependence studies of Martinez et al. (273−335 K) and Nicovich et al. (438−571 K) suggest the possibility of curvature in the Arrhenius plot. The recommended E/R (= 0) is appropriate for the 200−300 K temperature regime but not for higher temperatures. Vandresen and Resende[7] report a theoretical rate constant of 1.2×10^{-10} cm^3 molecule^{-1} s^{-1}, i.e., a factor of seven faster than the value suggested by experimental results. A theoretical study by Mao et al. suggests that DMSO complexation with water affects the rate constant for the H-abstraction reaction.[2] It has been predicted theoretically by Asatryan and Bozzelli[1] and confirmed experimentally by Taatjes et al.[6] that the peroxy radical formed via reaction of product $\bullet CH_2S(O)CH_3$ with O_2 rapidly dissociates to produce the Criegee intermediate, CH_2OO.

I56. $CH_3(Cl)S(O)CH_3 + O_2$, NO, NO_2. The recommendations are based on the study of Kleissas et al.[1] which combined laser flash photolytic production of $CH_3(Cl)S(O)CH_3$ with kinetic observations by time-resolved absorption spectroscopy. The recommended uncertainties for the NO and NO_2 reactions are larger than those reported by Kleissas et al. pending independent confirmation of their results.

I57. $Cl + CH_3SC_2H_5$. The recommendation for k(298 K) is the average of rate constants reported in two relative rate studies that employed a total of five different reference compounds;[1,2] all data were obtained at T = 298 K and P = 760 Torr air. Since both pressure independent H-abstraction pathways and a pressure dependent addition pathway are likely to be important, the recommended rate coefficient is only valid for P ~1 atm $N_2 + O_2$. The following product yields are reported in 760 Torr of NO_x-free air: 43% for HCl, 55% for SO_2, 58% for CH_3CHO, and 58% for H_2CO.[3]

I58. $Cl_2 + CH_3SCH_3$. Dyke et al.[3] have employed a flow tube technique with reactant and product detection by photoelectron spectroscopy to obtain a rate constant of $(3.4 \pm 0.7) \times 10^{-14}$ cm^3 $molecule^{-1}$ s^{-1} at 294 K and 1.6−3.0 Torr helium bath gas (the reported uncertainty is 1σ, precision); this rate constant is consistent with an upper limit value of 8×10^{-14} cm^3 $molecule^{-1}$ s^{-1} at 298 K in 1 Torr helium reported by Butkovskaya et al.[1] Dyke et al.[2] have obtained the photoelectron spectrum of a reaction intermediate that they assign as $(CH_3)_2S{-}Cl_2$ (each Cl bound to S). A theoretical analysis suggests that the observed intermediate is stable by 26.3 kcal mol^{-1} relative to reactants and dissociates over a 29.0 kcal mol^{-1} barrier to the end products $HCl + CH_3SCH_2Cl$, both of which were observed by photoelectron spectroscopy.[2] Because it is not clear how Dyke et al. differentiated gas phase reaction of Cl_2 with CH_3SCH_3 from reaction on the flow tube walls in their investigation,[3] the recommendation treats their result plus two standard deviations as an upper limit for the gas phase rate constant.

I59. ClO + OCS; ClO + SO_2. These recommendations are based on the discharge flow mass spectrometric data of Eibling and Kaufman.[1] The upper limit on k(298 K) for ClO + OCS was set from the minimum detectable decrease in ClO. No products were observed. The upper limit on k(298 K) for ClO + SO_2 is based on the authors' estimate of their SO_3 detection limit. The upper limit for this same reaction based on the minimum detectable decrease in ClO was not used due to the potential problem of ClO reformation from the $Cl + O_3$ source reaction.

I60. ClO + CH_3SCH_3. The 298 K recommendation is the average of the values reported in discharge flow mass spectrometry studies by Barnes et al.[1] and Diaz-de-Mera et al.[2] Barnes et al. prefer their more recent rate constant to one a factor of 4 higher that they determined using an earlier version of their apparatus. The recommendation for E/R is based on the temperature dependence observed by Diaz-de-Mera et al. over the range 259–335 K. The uncertainty factors reflect the fact that the two reported values for k(298 K) differ by more than a factor of two and that the activation energy is defined by data from a single study over a moderately narrow temperature range.

I61. ClO + $CH_3S(O)CH_3$. The recommendation is based on the results of a low-pressure discharge flow mass spectrometry study by Riffault et al.[1] These investigators were also able to establish an even lower upper limit of 2×10^{-15} cm^3 $molecule^{-1}$ s^{-1} for the channel that produces Cl atoms
(Table: 06-2, Note: 06-2, Evaluated: 06-2) Back to Table

I62. ClO + SO. The value of k(298 K) is an average of the determinations by Clyne and MacRobert[2] and Brunning and Stief.[1] The temperature independence is taken from the latter study with the A–factor recalculated to fit the k(298 K) recommendation.

I63. Br + H_2S, Br + CH_3SH. These recommendations are based on the study by Nicovich et al.[1] who measured both the forward and reverse reactions by time–resolved resonance fluorescence detection of Br atoms. The uncertainties placed on these recommendations have been increased over those estimated by the authors to reflect the absence of any confirming investigations.

Temperature dependent kinetics studies of the reactions $Br(^2P_{3/2}) + H_2S \leftrightarrow SH + HBr$ and $Br(^2P_{3/2}) + CH_3SH \leftrightarrow CH_3S + HBr$. Heats of formation of SH and CH_3S radicals. *J. Phys. Chem.* **1992**, *96*, 2518-2528, doi:10.1021/j100185a025.

I64. Br + CH_3SCH_3. It is well-established based on studies by Wine et al.,[6] Ingham et al.,[2] and Nakano et al.[5] that, under atmospheric conditions, attack of Br on CH_3SCH_3 occurs predominantly by addition to the sulfur atom. Above 375 K, adduct decomposition is so rapid that the addition channel is effectively negligible. Jefferson et al.[3] report high temperature experiments where the individual hydrogen transfer reactions $Br + CH_3SCH_3 \rightarrow CH_3SCH_2 + HBr$ (forward reaction) and $CH_3SCH_2 + HBr \rightarrow Br + CH_3SCH_3$ (reverse reaction) were isolated in a laser flash photolysis resonance fluorescence system, and their kinetics were separately studied over the temperature range 386−604 K. These investigators determined Arrhenius expressions for the forward and reverse reactions to be $9.0 \times 10^{-11} \exp(-2386/T)$ and $8.6 \times 10^{-13} \exp(+836/T)$ cm^3 $molecule^{-1}$ s^{-1}, respectively. Analysis of the equilibrium data also permitted determination of the heat of formation of CH_3SCH_2 (see Appendix 1). Extrapolation of the Jefferson et al. Arrhenius expression to 298 K gives a rate constant for the non-adduct-forming part of the Br + CH_3SCH_3 reaction (presumably direct hydrogen abstraction) of 3.0×10^{-14} cm^3 $molecule^{-1}$ s^{-1}. This estimated rate constant agrees quite well with the value of $(4.9 \pm 2.0) \times 10^{-14}$ cm^3

molecule^{-1} s^{-1} obtained in a competitive kinetics study at atmospheric pressure in air by Ballesteros et al.,[1] and is consistent with an upper limit of 1 × 10^{-13} cm^3 molecule^{-1} s^{-1} reported in a similar study by Maurer et al.[4] Direct comparison of the Jefferson et al. and Ballesteros et al. kinetic data is warranted only if essentially all adduct formation is reversible in the Ballesteros et al. experiment, which is possible based on the apparent absence of an adduct + O_2 pathway,[4,5] but is not yet well-established. The recommendation for the pressure-independent bimolecular reaction is based on extrapolation of the Arrhenius expression of Jefferson et al. to the atmospheric temperature regime. The large uncertainty reflects the need for a rather long extrapolation.

I65. **$Br + CH_3S(O)CH_3$.** The recommendation is based on the results of a low-pressure discharge flow mass spectrometry study by Riffault et al.[2] These authors obtained an upper limit for the total rate constant of 1.5 × 10^{-14} cm^3 molecule^{-1} s^{-1}, and also report channel−specific rate constants in units of 10^{-15} cm^3 molecule^{-1} s^{-1} of 11 ± 3 for the H−abstraction channel and 1.2 ± 0.3 for the methyl elimination channel. A competitive kinetics study in 740 Torr air by Ballesteros et al.[1] reports a less sensitive upper limit rate constant of 6 × 10^{-14} cm^{3}molecule^{-1}s^{-1}.
(Table: 06-2, Note: 06-2, Evaluated: 06-2) Back to Table

(1) Ballesteros, B., N. R. Jensen, and J. Hjorth FT-IR study of the kinetics and products of the reactions of dimethylsulphide, dimethylsulphoxide and dimethylsulphone with Br and BrO. *J. Atmos. Chem.* **2002**, *43*, 135-150, doi:10.1023/A:1019922224137.

I66. **$BrO + CH_3SH$.** The recommendation is based on the low-pressure discharge flow mass spectrometry study of Aranda et al.[1] A significant negative activation energy of -6.9 ± 2.0 kJ/mol was observed at P = 1.0 Torr He over the temperature range 259−333 K. At T = 298 K, reported rate coefficients in units of 10^{-14} cm^3 molecule^{-1} s^{-1} increase with increasing helium pressure from 2.7 ± 0.5 at P = 0.5 Torr to 4.9 ± 0.4 at P = 3.0 Torr. HOBr was observed as a reaction product suggesting that an important reaction pathway is addition of BrO to CH_3SH followed by dissociation to HOBr + CH_3S in competition with dissociation to reactants. Until kinetic data are reported at higher pressures, no recommendation of appropriate rate constants for atmospheric modeling is made.
(Table: 10-6, Note: 10-6, Evaluated: 10-6) Back to Table

(1) Aranda, A.; Diaz de Mera, Y.; Rodríguez, D.; Salgado, S.; Martinez, E. Kinetic and products of the BrO + CH_3SH reaction: Temperature and pressure dependence. *Chem. Phys. Lett.* **2002**, *357*, 471-476, doi:10.1016/S0009-2614(02)00561-4.

I67. **$BrO + CH_3SCH_3$.** This recommendation is an average of results obtained in the discharge flow studies of Barnes et al.[2] and Bedjanian et al.,[3] and the flash photolysis studies of Ingham et al.[4] and Nakano et al.[5] The flash photolysis studies were carried out at pressures of 60–200 Torr and give rate constants that are almost a factor of two greater than those obtained in the discharge flow studies at P ~1 Torr. The error limits in the present evaluation are adjusted to include all available data. A new study to investigate the pressure dependence of the rate constant is needed. Both Bedjanian et al. and Ingham et al. have shown that DMSO ($CH_3S(O)CH_3$)

is produced with near unit yield. Ballesteros et al.[1] report that the rate constants for BrO + CH_3SCH_3 and BrO + CD_3SCD_3 are identical, a result that is consistent with reaction proceeding via formation of a short-lived adduct that rapidly decomposes to Br + DMSO.

(5) Nakano, Y., M. Goto, S. Hashimoto, M. Kawasaki, and T. J. Wallington Cavity ring-down spectroscopic study of the reactions of Br atoms and BrO radicals with dimethyl sulfide. *J. Phys. Chem. A* **2001**, *105*, 11045-11050, doi:10.1021/jp012326f.

I68. BrO + CH_3SSCH_3. The recommendation is based on a competitive kinetics study in 740 Torr air by Ballesteros et al.[1] The large uncertainty factor results from the fact that the reported rate constant is measured relative to an assumed value of 3.2×10^{-13} cm^3 $molecule^{-1}$ s^{-1} for the BrO + CH_3SCH_3 rate constant, which has an uncertain pressure dependence (see above), and from the fact that there is only a single study upon which to base a recommendation.
(Table: 06-2, Note: 06-2, Evaluated: 06-2) Back to Table

(1) Ballesteros, B., N. R. Jensen, and J. Hjorth FT-IR study of the kinetics and products of the reactions of dimethylsulphide, dimethylsulphoxide and dimethylsulphone with Br and BrO. *J. Atmos. Chem.* **2002**, *43*, 135-150, doi:10.1023/A:1019922224137.

I69. BrO + $CH_3S(O)CH_3$. The recommendation is based on a competitive kinetics study in 740 Torr air by Ballesteros et al.[1] A low-pressure discharge flow mass spectrometry study by Riffault et al.,[2] gives an upper limit that is consistent with the recommendation. The large uncertainty factor results primarily from the fact that the reported rate constant is obtained from a series of competitive kinetics experiments that are referenced to an assumed value of 3.2×10^{-13} cm^3 $molecule^{-1}$ s^{-1} for the BrO + CH_3SCH_3 rate constant, which has an uncertain pressure dependence (see above).
(Table: 06-2, Note: 06-2, Evaluated: 06-2) Back to Table

I70. BrO + SO. This recommendation is based on the measurements of Brunning and Stief[1] performed under both excess BrO and excess SO conditions. The rate constant is supported by the lower limit assigned by Clyne and MacRobert[2] from measurements of SO_2 production.
(Table: 87-41, Note: 87-41, Evaluated: 87-41) Back to Table

(1) Brunning, J.; Stief, L. J. Rate constant for the reaction SO + BrO → SO_2 + Br. *J. Chem. Phys.* **1986**, *85*, 2591-2594, doi:10.1063/1.451066.
(2) Clyne, M. A. A.; MacRobert, A. J. Kinetic studies of free radical reactions by mass spectrometry. II. The reactions of SO + ClO, SO + OClO and SO + BrO. *Int. J. Chem. Kinet.* **1981**, *13*, 187-197, doi:10.1002/kin.550130208.

I71. IO + CH_3SH. The value of *k*(298 K) comes from the study by Maguin et al.[1] using discharge flow mass spectrometry. The investigators establish a branching ratio near unity for the production of HOI. The uncertainty factor reflects the absence of confirming investigations.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) Back to Table

(1) Maguin, F.; Mellouki, A.; Laverdet, G.; Poulet, G.; Le Bras, G. Kinetics of the reactions of the IO radical with dimethyl sulfide, methanethiol, ethylene, and propylene. *Int. J. Chem. Kinet.* **1991**, *23*, 237-245, doi:10.1002/kin.550230306.

I72. IO + CH_3SCH_3. The recommendation is based on the temperature-dependent studies of Gravestock et al.[5] and Dillon et al.[4] and the 298 K studies of Maguin et al.,[7] Barnes et al.,[1] and Knight et al.[6] All data points in each temperature dependent study were scaled by a factor equal to the ratio $k(298\text{ K})_{\text{Arr}}/k(298\text{ K})_{\text{ave}}$ where $k(298\text{ K})_{\text{Arr}}$ is the 298 K rate constant obtained from the best fit Arrhenius expression describing the individual T-dependent data set and $k(298\text{ K})_{\text{ave}}$ is the average of all reported 298 K rate constants (using $k(298\text{ K})_{\text{Arr}}$ from the T-dependent studies). The best fit of the scaled data to $\ln k = \ln A - E/\text{RT}$ is recommended. The studies of Maguin et al. and Barnes et al. supersede earlier, less direct measurements by the same groups,[2,8] which reported much greater rate constants. Nakano et al.[9] employed a laser flash photolysis cavity ring down spectroscopy technique to investigate the temperature and pressure dependence of the rate constant. These investigators report that the 298 K rate constant increases from 1 to 25 × 10^{-14} cm^3 molecule^{-1} s^{-1} as pressure increases from 5 to 100 Torr N_2, then levels off at higher pressure. Nakano et al. also investigated the temperature dependence of the rate constant at P = 100 Torr and observed a very strong negative temperature dependence, i.e., $E/\text{R} = -2230 \pm 460$ K. The pressure dependence reported by Nakano et al. is in conflict with the results of Daykin and Wine,[3] Gravestock et al., and Dillon et al. (no observed P – dependence at 297 ± 1 K) while the temperature dependence reported by Nakano et al. is in conflict with the results of Gravestock et al. and Dillon et al.

I73. S + O_2. The recommended value for k(298 K) is the average of values reported by Fair and Thrush,[5] Fair et al.,[6] Donovan and Little,[4] Davis et al.,[3] Clyne and Townsend,[1] Clyne and Whitefield,[2] Miyoshi et al.,[8] and Lu et al.[7] The recommended value for E/R is the average of E/R values obtained from the data sets of Davis et al. (25 Torr CO_2, 252−423 K, $E/\text{R} = +1$ K), Davis et al. (20−200 Torr He, 298−422 K, $E/\text{R} = -204$ K), Clyne and Whitefield (~1 Torr Ar, 296−393 K, $E/\text{R} = -129$ K), and Lu et al. (50 Torr Ar, 298−505 K, $E/\text{R} = -66$ K). Lu et al. report non-Arrhenius behavior at T >505 K. A theoretical analysis by Lu et al. suggests that reaction occurs almost exclusively via a SOO(^{1}A′) intermediate at T <500 K, whereas other channels involving SOO(^{1}A″) as an intermediate and formation of SOO(^{3}A″) followed by isomerization to SO_2 before dissociation, become important at higher temperatures and account for the observed rapid increase of the rate constant with increasing temperature above 500 K. High temperature kinetic data reported by Saito et al.[9] (1900−2200 K), Tsuchiya et al. (980−1610 K),[10] and Woiki and Roth (1200−3500 K)[11] are reasonably consistent with the rate constants predicted theoretically by Lu et al.

I74. **$S + O_3$.** This recommendation accepts the only available experimental data of Clyne and Townsend.[1] In this study the authors measure a value of the rate constant for $S + O_2$ in reasonable agreement with that recommended above.
(Table: 82-57, Note: 82-57, Evaluated: 82-57) Back to Table

(1) Clyne, M. A. A.; Townsend, L. W. Rate constant measurements for rapid reactions of ground state sulphur $3p^4(^3P_J)$ atoms. *Int. J. Chem. Kinet.* **1975**, *Symp. 1*, 73-84.

I75. **$SO + O_2$.** The recommended E/R is the average of values reported by Black et al. ($E/R = 2370$ K, 250–420 K)[1] and Schurath and Goede ($E/R = 2180$ K, 262–363 K),[5] while the recommended $k(298\text{ K})$ is the average of values computed from the Arrhenius expressions reported in the same two studies. The room temperature rate constant obtained from the Black et al. study[1] supersedes an earlier value[1] as recommended by the authors. The recommended values for $k(T)$ lie significantly higher than an extrapolation of the higher temperature data of Homann et al.,[4] but are consistent with the more recent high temperature study of Garland.[3] A room temperature upper limit on k set by Breckenridge and Miller[2] is consistent with the recommendation.

I79. SO_3 + 2 H_2O. Several research groups have attempted to quantify the rate of sulfuric acid formation via this reaction in the gas phase. Reiner and Arnold[6] placed an upper limit of 2.4×10^{-15} cm^3 $molecule^{-1}$ s^{-1} on the rate constant, slightly lower than that determined by Wang et al.[8] The inability to cite the results as other than an upper limit is due to the difficulty in excluding all heterogeneous effects from the experiments. The higher rate constant reported earlier by Castleman et al.[1] may have resulted from an underestimation of the effects of such heterogeneous reactions. Subsequently, Reiner and Arnold[7] sought to improve their rate constant determination by more detailed quantification of heterogeneous contributions. They derived a value of 1.2×10^{-15} cm^3 $molecule^{-1}$ s^{-1}, independent of pressure (from 31–260 mbar of synthetic air). Evidence was also obtained that H_2SO_4 was, indeed, the product of the reaction.

Kolb et al.[3] attempted to measure the gas phase rate constant using a turbulent flow reactor designed to minimize wall effects. Their results, when analyzed as representing a bimolecular reaction, support a rate constant in the range $(1–7) \times 10^{-15}$ cm^3 $molecule^{-1}$ s^{-1}. However, a more detailed analysis of the data indicated that the gas phase reaction was second order in water vapor. The reaction rate was also observed to increase as the temperature was lowered from 333 K to 243 K. These observations, together with calculations by Morokuma and Mugurama,[5] led the latter authors to suggest that SO_3 consumption likely involved its reaction with the water dimer or the reaction $SO_3{-}H_2O$ + H_2O, leading to the formation of sulfuric acid.

A laminar flow reactor study by Lovejoy et al.[4] over the temperature range 250 to 360 K also revealed SO_3 loss to be second order in water concentration and independent of pressure (from 20 to 80 Torr of N_2 at 300 K). These latter authors measured a strong negative temperature dependence for the rate constant and a significant kinetic isotope effect ($k_{H2O} \approx 2k_{D2O}$), leading them to describe the reaction as proceeding via the rapid association between SO_3 and H_2O followed by a slower reaction between the adduct and water to form sulfuric acid. Lovejoy at al.'s measurement of a −54 kJ mol^{-1} "activation" energy was viewed as energetically inconsistent with a SO_3 + water dimer reaction mechanism since it would require a large negative activation energy for the $SO_3 + (H_2O)_2$ step. Jayne et al.[2] have carried out a turbulent flow reactor study over the temperature range 283 to 370 K and the pressure range 100 to 760 Torr N_2. Their results provide further support for a mechanism involving formation of an $SO_3{-}H_2O$ adduct that reacts with a second H_2O to form H_2SO_4, and the rate constants they report agree quite well with those reported by Lovejoy et al. The recommended expression for first order loss of SO_3,

$$k^{I} = 8.5 \times 10^{-41} \exp(+6540/T)\,[H_2O]^2\ s^{-1} \quad ([H_2O] \text{ in molecules cm}^{-3})$$

is the best fit of the combined data of Lovejoy et al. and Jayne et al. to an Arrhenius form.

I81. **$SH + O_2$.** This upper limit for k(298 K) is based on the study by Stachnik and Molina[6] utilizing experiments sensitive to the production of OH. Somewhat higher upper limits of 1.0×10^{-17} and 1.5×10^{-17} cm^3 molecule^{-1} s^{-1} were assigned by Friedl et al.[3] and Wang et al.[8] respectively from the sensitivities for OH detection and SH decay respectively. An even higher upper limit by Black,[2] based on the lack of SH decay, may have been complicated by SH regeneration. Much less sensitive upper limits have been calculated by Tiee et al.,[7] ^{18} cm^3 molecule^{-1} s^{-1}) for the rate constant for the sum of the two $SH + O_2$ reaction channels (producing OH + SO and H + SO_2). The HSO_2 potential energy surface has been studied theoretically by Ballester and Varandas,[1] Garrido et al.,[4] Resende and Ornellas,[5] and Zhou, et al.[9] Resende and Ornellas and Zhou et al. predict that at atmospheric temperatures (i) OH + SO are the dominant bimolecular products and (ii) the rate constant is orders of magnitude slower than the upper limit reported by Stachnik and Molina.

I82. **SH + O_3.** The value for k(298 K) is an average of the determinations by Friedl et al.[1] (laser induced fluorescence detection of SH), Schonle et al.[4] (mass spectrometric detection of reactant SH and product HSO) as revised by Schindler and Benter,[3] and Wang and Howard[5] (laser magnetic resonance detection of SH). The temperature dependence is from Wang and Howard with the *A*–factor calculated to agree with the recommended value for k(298 K). The recommendation for g reflects the fact that the temperature dependence comes from measurements above room temperature and, thus, extrapolation to lower temperatures may be subject to additional uncertainties. Wang and Howard report observing a minor reaction channel that produces H + SO + O_2. A theoretical study by Resende and Ornellas[2] concludes that if reaction occurs on the ground state potential energy surface, the rate constant should be several orders of magnitude slower than the experimental value.

I83. **SH + H_2O_2.** This recommended upper limit for k(298 K) is based on the study of Friedl et al.[1] Their value is calculated from the lack of SH decay (measured by laser induced fluorescence) and the lack of OH production (measured by resonance fluorescence). The three possible product channels are H_2S + HO_2, HSOH + OH, and HSO + H_2O.

(Table: 85-37, Note: 85-37, Evaluated: 85-37) Back to Table

(1) Friedl, R. R.; Brune, W. H.; Anderson, J. G. Kinetics of SH with NO_2, O_3, O_2, and H_2O_2. *J. Phys. Chem.* **1985**, *89*, 5505-5510, doi:10.1021/j100271a038.

I84. **SH + NO_2.** The recommendation is based on the temperature-dependent measurements of Wang et al.[10] and Herndon and Ravishankara.[5] All data points in each study were scaled by a factor equal to the ratio $k(298\ \mathrm{K})_{\mathrm{Arr}}/k(298\ \mathrm{K})_{\mathrm{ave}}$ where $k(298\ \mathrm{K})_{\mathrm{Arr}}$ is the 298 K rate constant obtained from the best fit Arrhenius expression describing the individual T-dependent data set and $k(298\ \mathrm{K})_{\mathrm{ave}}$ is the average of the $k(298\ \mathrm{K})_{\mathrm{Arr}}$ values from the two studies. The best fit of the scaled data to $\ln k = \ln A - E/\mathrm{R}T$ is recommended. Wang et al. suggest that the lower values of k(298 K) reported by Black,[1] Friedl et al.,[4] and Bulatov et al.[2] are due to SH regeneration from the H_2S source compound. Herndon and Ravishankara suggest that simultaneous detection of SH and SO may have corrupted earlier studies where laser induced fluorescence was employed as the detection technique.[1,4] In the study by Stachnik and Molina,[9] attempts were made at minimizing SH regeneration, and the reported value of k(298 K) was significantly greater than that from the earlier studies, but still 30% less than that measured by Wang et al., who used two independent SH source reactions. A slightly larger rate constant measured by Schonle et al.,[8] as revised by Schindler and Benter,[7] is not recommended due to the somewhat more limited database for their determination. The reaction as written represents the most exothermic channel. In fact, HSO has been detected as a product by Leu and Smith,[6] Bulatov et al.,[2] Schonle et al.,[8] and Wang et al. The absence of a primary deuterium isotope effect, as observed by both Wang et al. and Herndon and Ravishankara, coupled

with the large magnitude of the rate constant suggests that the (four–center intermediate) channels producing SO + HNO and OH + SNO are of minor importance. No evidence for a three–body combination reaction was found by either Black or Friedl et al. Based on a pressure independence of the rate constant between 30 and 300 Torr, Black set an upper limit of 7.0×10^{-31} cm^6 $molecule^{-2}$ s^{-1} for the termolecular rate constant. Similarly, Stachnik and Molina[9] observed no change in decay rate between 100 and 730 Torr with O_2 (although these O_2 experiments were designed primarily to limit SH regeneration). The recommendation given here is supported by the discharge flow laser induced fluorescence study of the SD + NO_2 reaction by Fenter and Anderson.[3] These investigators report a 298 K rate constant of 6.8×10^{-11} cm^3 $molecule^{-1}$ s^{-1}, which compares favorably with the values of 7.3×10^{-11} and 6.6×10^{-11} cm^3 $molecule^{-1}$ s^{-1} determined by Wang et al. and Herndon and Ravishankara, respectively, in studies of the same reaction. Fenter and Anderson also obtained an *E*/R value of –210 K, very similar to the –279 K value derived by Herndon and Ravishankara for the SD reaction and the values –240 K and –270 K derived by Wang et al. and Herndon and Ravishankara, respectively, for the SH reaction.

I85. SH + N_2O. The recommendation is the upper limit rate constant reported by Herndon et al.[1] As discussed by Herndon et al., the much greater (four orders of magnitude) rate constant reported by Ravichandran et al.[2] appears to result from mis−interpretation of the source of electronically excited HSO, chemiluminescence from which was employed by Ravichandran et al. to follow the reaction kinetics.
(Table: 06-02, Note: 06-02, Evaluated: 06-2) Back to Table

I86. SH + Cl_2. The recommended 298 K rate constant is the average of the one reported by Nesbitt and Leone,[2] who studied the kinetics of the Cl + H_2S → SH + HCl, SH + Cl_2 → ClSH + Cl chain reaction using a laser flash photolysis − IR emission technique, and the one reported by Fenter and Anderson,[1] who employed a discharge flow − laser induced fluorescence technique to study the SD + Cl_2 reaction over the temperature range 273−373 K; the Fenter and Anderson results are corrected for the secondary kinetic isotope effect using the theoretical results of Wang et al.,[3] who report $k_H / k_D = 1.11 \exp(-71/T)$. The recommended value for *E*/R is taken from the work of Fenter and Anderson corrected as described above for the secondary kinetic isotope effect. The recommended value for the parameter *g* reflects the absence of confirming studies.

I87. SH + BrCl; SH + Br_2; SH + F_2. The recommendations for these reactions are derived from the experimental data of Fenter and Anderson[1] for the SD reactions corrected for the secondary kinetic isotope effect using the theoretical results of Wang et al.[2,3] Wang et al. report k_H / k_D = 0.81 exp(−50/T) for BrCl and 1.08 exp(−49/T) for Br_2;[2] their results for SH(SD) + F_2 suggest that k_H / k_D = 1.036, 1.048, and 1.056 at 298K, 338 K, and 373 K, respectively,[3] the three temperatures where experimental SD rate constants are reported by Fenter and Anderson. The recommended uncertainties have been increased over those estimated by Fenter and Anderson to reflect the absence of any confirming investigations as well as uncertainty in the theoretical secondary kinetic isotope effects. For the SD + BrCl reaction, the channel producing ClSD + Br is reported by Fenter and Anderson to be described by the rate expression $k = 2.3 \times 10^{-11}$ exp(+100/T) cm^3 $molecule^{-1}$ s^{-1}, thereby accounting for 43% of overall reactivity at 298 K and 51% at 373 K. On the other hand, Wang et al.[2] predict theoretically that reaction proceeds almost exclusively to produce BrSD (BrSH) + Cl products at atmospheric temperatures, with the ClSD (ClSH) + Br channel becoming important only at higher temperatures.

I88. HSO + O_2. This recommendation is based on the study by Lovejoy et al.,[2] who employed laser magnetic resonance monitoring of HSO in a discharge flow system. The upper limit thus derived for k(298 K) is nearly two orders of magnitude smaller than measured by Bulatov et al.[1]
(Table: 92-20, Note: 92-20, Evaluated: 92-20) Back to Table

(1) Bulatov, V. P.; Sarkisov, O. M.; Kozliner, M. Z.; Ergorov, V. G. Mechanism of hydrogen sulfide photooxidation in atmosphere. *Khim. Fiz.* **1986**, *5*, 1031-1036.

I89. HSO + O_3. This recommended value for k(298 K) is based on the determinations by Friedl et al.[1] and Wang and Howard.[3] In the first study, performed at higher O_3 concentrations, greater quantities of HSO were produced in the flow tube and SH approached a steady state due to its generation via HSO + O_3. The rate constant for this reaction was thus determined relative to SH + O_3 from measurements of the steady state SH concentration as a function of the initial SH concentration. In the second study, the rate constant and its branching ratio were measured at two temperatures. At room temperature, the overall rate constant is in excellent agreement with that of Friedl et al. More recently, Lee et al.[2] determined a room temperature rate constant of 4.7×10^{-14} cm^3 $molecule^{-1}$ s^{-1} for the sum of all reaction channels not producing HS. This value is approximately 30% greater than that measured by Wang and Howard for the same channels. Lee et al. derive an Arrhenius activation energy of 1120 K for these channels from data between 273and 423 K, in agreement with the more limited temperature-dependent data of Wang and Howard.

The lack of an isotope effect when SD was employed in the Friedl et al. study suggests that the products of the HSO + O_3 reaction are SH + $2O_2$ (analogous to those for HO_2 + O_3). However, Wang and Howard found that only 70% of the reaction leads to HS formation. In addition, their observations of HO_2 production in the presence of O_2 suggests the existence of a reaction channel producing HSO_2 + O_2 followed by $HSO_2 + O_2 \rightarrow HO_2 + SO_2$. At the present time, no recommendation is given for the product channels. Further mechanistic work is suggested, since it is important to understand whether this reaction in the atmosphere leads to HS regeneration or to oxidation of the sulfur.

(3) Wang, N. S.; Howard, C. J. Kinetics of the reactions of HS and HSO with O_3. *J. Phys. Chem.* **1990**, *94*, 8787-8794, doi:10.1021/j100388a009.

I90. HSO + NO; HSO + NO_2. The recommendations for these reactions are based on the study by Lovejoy et al.[3] in which laser magnetic resonance was used to monitor HSO in a discharge flow system. Their upper limit for the NO reaction is a factor of 25 smaller than the rate constant measured by Bulatov et al.[2] using intracavity laser absorption at pressures between 10 and 100 Torr. Since it is unlikely that this reaction rate undergoes a factor of 25 increase between 1 Torr (the pressure of the Lovejoy et al. work) and 10 Torr, the higher rate constant may be due to secondary chemistry associated with the HSO production methods employed.

The recommendation for the NO_2 reaction is a factor of 2 higher than the rate constant reported by Bulatov et al.[1] Lovejoy et al. have attributed this difference to HSO regeneration under the experimental conditions used by Bulatov et al.[1] The product assignment for this reaction is discussed in the note for the $HSO_2 + O_2$ reaction. (2) Bulatov, V. P.; Kozliner, M. Z.; Sarkisov, O. M. Reactions of SH and HSO radicals with nitrogen oxide. *Khim. Fiz.* **1985**, *4*, 1353-1357.

(3) Lovejoy, E. R.; Wang, N. S.; Howard, C. J. Kinetic studies of the reactions of HSO with NO_2, NO, and O_2. *J. Phys. Chem.* **1987**, *91*, 5749-5755, doi:10.1021/j100306a046.

I91. $HSO_2 + O_2$. This recommendation is based on the rate of HO_2 formation measured by Lovejoy et al.[1] upon addition of O_2 to the HSO + NO_2 reaction system. While HSO_2 was not observed directly, a consideration of the mechanistic possibilities for HSO + NO_2, coupled with measurements of the HO_2 production rate at various O_2 pressures, led these authors to suggest that HSO_2 is both a major product of the HSO + NO_2 reaction and a precursor for HO_2 via reaction with O_2.
(Table: 87-41, Note: 87-41, Evaluated: 87-41) Back to Table

(1) Lovejoy, E. R.; Wang, N. S.; Howard, C. J. Kinetic studies of the reactions of HSO with NO_2, NO, and O_2. *J. Phys. Chem.* **1987**, *91*, 5749-5755, doi:10.1021/j100306a046.

I92. $HOSO_2 + O_2$. This recommendation is based on the studies of Gleason et al.[3] and Gleason and Howard[2] in which the $HOSO_2$ reactant was monitored using a chemical ionization mass spectrometric technique. Gleason and Howard conducted their measurements over the 297–423 K temperature range in the only temperature dependence investigation, and these authors report the same 297 K rate coefficient as the one reported by Gleason et al. The recommended uncertainty parameter g is increased from the E/R error limits quoted by Gleason and Howard to account for potential uncertainties in extrapolating their data to sub–ambient temperatures. The recommended value of k(298 K) derives further support from the studies of Margitan[6] and Martin et al.,[7] both of whom used modeling fits of OH radical decays in the OH + SO_2 + M reaction system in the presence of O_2 and NO. In this latter analysis, the $HOSO_2$ reacts with O_2, yielding HO_2, which subsequently regenerates OH through its reaction with NO. Theoretical electronic structure and kinetics calculations by Huynh and coworkers[5] provides additional support for the recommendation. The infrared spectrum of $HOSO_2$ has been recorded in low temperature matrix isolation experiments by Hashimoto et al.[4] and Nagase et al.[8] Mass spectrometric detection of $HOSO_2$ in the gas phase has also been reported by Egsgaard et al.[1]

I93. **CS + O_2.** The recommendation given for *k*(298 K) is based on the work of Black et al.[1] using laser induced fluorescence to monitor CS. This value agrees with the somewhat less precise determination by Richardson [2] using OCS formation rates. The latter author presents evidence that this reaction channel dominates over the one producing SO + CO by more than a factor of 10. Measurements by Richardson at 293 K and 495 K yield an *E*/R of 1860 K. However, use of this activation energy with the recommended value of *k*(298 K) results in an unusually low Arrhenius *A*-factor of 1.5×10^{-16} cm^3 $molecule^{-1}$ s^{-1}. In view of this, no recommendation is given for the temperature dependence.

I96. **CH_3S + O_3.** The recommendation for *k*(298 K) is the average of room temperature rate constants reported by Tyndall and Ravishankara,[5] Domine et al.,[2] Turnipseed et al.,[4] and Martinez et al.[3] The recommendation for *E*/R is the average of values obtained from least squares fits of the temperature-dependent data of Turnipseed et al. and Martinez et al. using only rate constants at temperatures below 345 K. A failure to observe significant reaction in the study by Black and Jusinski[1] is interpreted as due to rapid regeneration of CH_3S in their system. Tyndall and Ravishankara[5] corrected their measured 298 K rate constant downward by ~20% to account for CH_3S regeneration via the CH_3SO + O_3 reaction, but the magnitude of the correction is now highly uncertain in light of the results of Domine et al. and Turnipseed et al. Domine et al. measured the yield of CH_3SO to be 15%.

I97. CH_3S + NO. The upper limit for the bimolecular reaction between CH_3S and NO is based on estimates by Balla et al.,[1] who conducted a temperature dependence study of the termolecular reaction.
(Table: 92-20, Note: 92-20, Evaluated: 92-20) Back to Table

(1) Balla, R. J.; Nelson, H. H.; McDonald, J. R. Kientics of the reaction of CH_3S with NO, NO_2 and O_2. *Chem. Phys.* **1986**, *109*, 101-107, doi:10.1016/0301-0104(86)80188-4.

I98. CH_3S + NO_2. The recommendation for *k*(298 K) is the average of room temperature rate constants reported by Tyndall and Ravishankara,[6] Domine et al.,[3] Turnipseed et al.,[5] Martinez et al.,[4] and Chang et al.[2] The recommendation for *E*/R is the average of values reported by Turnipseed et al., Martinez et al., and Chang et al. An earlier study by Balla et al.[1] appears to have been affected by secondary reactions resulting from high radical concentrations. Tyndall and Ravishankara determined the NO yield to be (80 ± 20)%. Together with the unity yield of CH_3SO obtained by Domine et al., this implies that the primary reaction channel is as written.

I99. CH_3S + CO. The recommendation is based on the study of Koch et al.,[1] who generated CH_3S by laser flash photolysis of CH_3SSCH_3 and monitored the loss of CH_3S by laser induced fluorescence. The rate of loss of CH_3S was found to be independent of [CO] up to levels of approximately 10^{17} molecules cm^{-3}. No enhancement of the CH_3S loss rate was observed when O_2 was added to the reaction mixture, confirming that CH_3SOO is also unreactive toward CO. Electronic structure calculations are consistent with experimental observations, suggesting that there is a significant barrier (~12 kJ mol^{-1}) to formation of a very weakly bound (~9 kJ mol^{-1}) CH_3S-CO adduct.

I100. CH_3S + Br_2. The recommendation is based on the study of Nicovich et al.,[1] who coupled laser flash photolysis of $Br_2/CH_3SH/H_2/N_2$ mixtures with resonance fluorescence detection of Br atoms to monitor the kinetics of Br approach to steady state ($Br + CH_3SH \rightarrow CH_3S + HBr$; $CH_3S + Br_2 \rightarrow CH_3SBr + Br$). The recommended uncertainty is larger than estimated by Nicovich et al. to reflect the slightly indirect nature of the rate constant determination and the lack of a confirming study.

I101. CH_2SH + O_2. This recommended value for *k*(298 K) is the average of the rate constants obtained by Rahman et al.[2] in a fast flow mass spectrometry system and Anastasi et al.[1] using a pulse radiolysis − kinetic absorption apparatus. The value of Anastasi et al. is nearly twice that of Rahman et al. It is difficult at present to indicate a preference for the results of one study over the other, and the value of *f*(298 K) has been chosen to reflect this uncertainty. Since this is a fast bimolecular reaction, one would expect the products to be HO_2 + CH_2S, by analogy with the reaction between CH_2OH and O_2.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) Back to Table

I103. CH_2SH + NO. The recommended value of *k*(298 K) comes from the study by Anastasi et al.[1] using a pulse radiolysis kinetic absorption apparatus. The uncertainty factor reflects the absence of any confirming investigations.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) Back to Table

(1) Anastasi, C.; Broomfield, M.; Nielsen, O. J.; Pagsberg, P. Kinetics and mechanisms of the reactions of CH_2SH radicals with O_2, NO, and NO_2. *J. Phys. Chem.* **1992**, *96*, 696-701, doi:10.1021/j100181a034.

I104. $CH_2SH + NO_2$. The recommended value for *k*(298 K) is an average of the rate constants obtained by Rahman et al.[2] in a fast flow mass spectrometry system and by Anastasi et al.,[1] using a pulse radiolysis kinetic absorption apparatus. The value of Rahman et al. is nearly twice that of Anastasi et al. It is difficult to indicate a preference for the results of one study over the other, and the value of *f*(298 K) has been chosen to reflect this uncertainty.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) Back to Table

(1) Anastasi, C.; Broomfield, M.; Nielsen, O. J.; Pagsberg, P. Kinetics and mechanisms of the reactions of CH_2SH radicals with O_2, NO, and NO_2. *J. Phys. Chem.* **1992**, *96*, 696-701, doi:10.1021/j100181a034.

I105. $CH_3SO + O_3$. The recommended value for *k*(298 K) is an average of values reported by Domine et al.[2] and Borissenko et al.[1] It is supported by the study of Tyndall and Ravishankara,[3] in which the rate constant was derived from a complex analysis of the $CH_3S + O_3$ reaction system. Borissenko et al. measured the rate constant relative to the rate constant for the $CH_3SO + NO_2$ reaction; they report that the $CH_3SO + NO_2$ rate constant is greater by a factor of 47. Domine et al. place the direct yield of CH_2SO at approximately 10% and that of CH_3S at 13% at low pressure. Borissenko et al. report that the SO_2 yield is near unity in 100−600 Torr N_2.
(Table: 06-2, Note: 06-2, Evaluated: 06-2) Back to Table

(1) Borissenko, D.; Kukui, A.; Laverdet, G.; Le Bras, G. Experimental study of SO_2 formation in the reactions of CH_3SO radical with NO_2 and O_3 in relation with the atmospheric oxidation mechanism of dimethyl sulfide. *J. Phys. Chem. A* **2003**, *107*, 1155-1161, doi:10.1021/jp021701g.

I106. $CH_3SO + NO_2$. This recommendation is based on the direct measurements of Domine et al.[2] The results are supported by somewhat less direct measurements of Tyndall and Ravishankara,[6] Mellouki et al.,[5] and Kukui et al.[3] The results of Kukui et al. suggest a small negative activation energy, but their data set is not extensive enough to warrant a recommendation for E/R without independent confirmation. Borissenko et al.[1] report that the SO_2 yield drops from ~0.4 in 100 Torr N_2 to ~0.25 in 660 Torr N_2. A detailed theoretical singlet potential energy surface has been reported by Lesar.[4]
(Table: 06-2, Note: 15-10, Evaluated: 06-2) Back to Table

(5) Mellouki, A.; Jourdain, J. L.; Le Bras, G. Discharge flow study of the $CH_3S + NO_2$ reaction mechanism using $Cl + CH_3SH$ as the CH_3S source. *Chem. Phys. Lett.* **1988**, *148*, 231-236, doi:10.1016/0009-2614(88)80305-1.

(6) Tyndall, G. S.; Ravishankara, A. R. Kinetics and mechanism of the reactions of CH_3S with O_2 and NO_2 at 298 K. *J. Phys. Chem.* **1989**, *93*, 2426-2435, doi:10.1021/j100343a041.

I107. $CH_3SOO + O_3$, $CH_3SOO + NO$, $CH_3SOO + NO_2$. These recommendations are based on the experiments of Turnipseed et al.[1] in which CH_3S was monitored by laser induced fluorescence in equilibrium with CH_3SOO. The upper limit for the O_3 reaction was determined from experiments at 227 K. The results for the NO and NO_2 reactions were independent of temperature over the ranges 227–256 K and 227–246 K, respectively. The uncertainties placed on these recommendations have been increased over those estimated by the authors to reflect the absence of any confirming investigations.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) Back to Table

(1) Turnipseed, A. A.; Barone, S. B.; Ravishankara, A. R. Reactions of CH_3S and CH_3SOO with O_3, NO_2, and NO. *J. Phys. Chem.* **1993**, *97*, 5926-5934, doi:10.1021/j100124a025.

I108. $CH_3SO_2 + NO_2$. This recommendation is based on the study by Ray et al.[1] using a discharge flow reactor equipped with laser induced fluorescence and mass spectrometric detection. The CH_3SO_2 was produced by the sequential oxidation of CH_3S and CH_3SO by NO_2 and is to be differentiated from the weakly bound adduct, CH_3SOO, formed by the reaction of CH_3S with O_2 at low temperature (Turnipseed et al.[2]). The uncertainty limit on the rate constant has been increased over that given by the authors to reflect the absence of any confirming investigation. However, some additional support for this recommendation does come from the study of the $CH_3S + NO_2$ reaction by Tyndall and Ravishankara.[3] These authors observed fluorescence from a product species tentatively identified as CH_3SO_2, produced by the reaction of CH_3SO with NO_2. Computer simulation of the rise and fall of the fluorescence signal yielded an approximate rate constant value for the reaction $CH_3SO_2 + NO_2$ of 7.0×10^{-12} cm^3 $molecule^{-1}$ s^{-1}. However, an unambiguous differentiation between the production and disappearance rate constants was not possible.
(Table: 97-4, Note: 97-4, Evaluated: 97-4) Back to Table

(1) Ray, A.; Vassalli, I.; Laverdet, G.; Le Bras, G. Kinetics of the thermal decomposition of the CH_3SO_2 radical and its reaction with NO_2 at 1 Torr and 298 K. *J. Phys. Chem.* **1996**, *100*, 8895-8900, doi:10.1021/jp9600120.

(2) Turnipseed, A. A.; Barone, S. B.; Ravishankara, A. R. Reactions of CH_3S and CH_3SOO with O_3, NO_2, and NO. *J. Phys. Chem.* **1993**, *97*, 5926-5934, doi:10.1021/j100124a025.

I109. $CH_3SCH_2 + NO_3$. The recommended value for *k*(298 K) is based on the experiments of Butkovskaya and Le Bras.[1] The uncertainty factor reflects the absence of any confirming investigation.
(Table: 94-26, Note: 94-26, Evaluated: 94-26) Back to Table

(1) Butkovskaya, N. I.; Le Bras, G. Mechanism of the NO_3 + DMS reaction by discharge flow mass spectrometry. *J. Phys. Chem.* **1994**, *98*, 2582-2591, doi:10.1021/j100061a014.

I110. $CH_3SCH_2O_2 + NO$. The recommended 298 K rate constant is based on the experiments of Urbanski et al.,[2] which are less impacted by secondary chemistry complications than the experiments of Wallington et al.[3] or Turnipseed et al.;[1] the error limits are chosen to encompass the rate constants reported in all three studies. The *E*/R value is taken from Urbanski et al., who report the only available temperature dependence data. The recommended value for the parameter g is larger than reported by Urbanski et al. pending independent confirmation of their result. Urbanski et al. observed that the reaction produces formaldehyde (H_2CO) with unit yield, suggesting that the CH_3SCH_2O product rapidly decomposes to $CH_3S + H_2CO$.
(Table: 06-2, Note: 19-5, Evaluated: 06-2) Back to Table

Atmospheric chemistry of dimethyl sulfide: UV spectra and self-reaction kinetics of CH_3SCH_2 and $CH_3SCH_2O_2$ radicals and kinetics of the reactions $CH_3SCH_2 + O_2 \rightarrow CH_3SCH_2O_2$ and $CH_3SCH_2O_2 + NO \rightarrow CH_3SCH_2O + NO_2$. *J. Phys. Chem.* **1993**, *97*, 8442-8449, doi:10.1021/j100134a013.

I111. $CH_3SCH_2O_2 + CH_3SCH_2O_2$. The recommended 298 K rate constant is the average of values reported by Wallington et al.[2] using a pulse radiolysis UV absorption technique and Urbanski et al.[1] using a laser flash photolysis tunable diode laser absorption technique. Urbanski et al. observed that the reaction produces formaldehyde with unit yield, suggesting that the dominant reaction pathway is 2 $CH_3SCH_2O_2 \rightarrow$ 2 $CH_3SCH_2O + O_2$ (CH_3SCH_2O rapidly decomposes to $CH_3S + H_2CO$).
(Table 06-02, Note 06-02, Evaluated: 06-2) Back to Table

(2) Wallington, T. J.; Ellermann, T.; Nielsen, O. J. Atmospheric chemistry of dimethyl sulfide: UV spectra and self-reaction kinetics of CH_3SCH_2 and $CH_3SCH_2O_2$ radicals and kinetics of the reactions $CH_3SCH_2 + O_2 \rightarrow CH_3SCH_2O_2$ and $CH_3SCH_2O_2 + NO \rightarrow CH_3SCH_2O + NO_2$. *J. Phys. Chem.* **1993**, *97*, 8442-8449, doi:10.1021/j100134a013.

I112. $CH_3SS + O_3$. The recommended is value for k(298 K) is based on the discharge flow photoionization mass spectrometry study by Domine et al.[1] The uncertainty factor reflects the absence of any confirming investigations. The rate constant ratio for the reactions of CH_3SS with O_3 and NO_2 is consistent with the rate constant ratio for the corresponding CH_3S reactions.
(Table: 92-20, Note: 92-20, Evaluated: 92-20) Back to Table

(1) Domine, F.; Ravishankara, A. R.; Howard, C. J. Kinetics and mechanisms of the reactions of CH_3S, CH_3SO, and CH_3SS with O_3 at 300 K and low pressures. *J. Phys. Chem.* **1992**, *96*, 2171-2178, doi:10.1021/j100184a027.

I113. $CH_3SS + NO_2$; $CH_3SSO + NO_2$. The recommended values for k(298 K) are based on the discharge flow photoionization mass spectrometry study by Domine et al.[1] The rate constant ratio for these two reactions agrees with that observed for reactions of other RS/RSO radicals with NO_2. The assigned uncertainties reflect this agreement but acknowledge the absence of any confirming investigation. In the Domine et al. study, CH_3SSO was produced by reacting away all CH_3SS with high NO_2 concentrations. Thus, as expected, O atom transfer may be the primary channel in the CH_3SS reaction.
(Table: 92-20, Note: 92-20, Evaluated: 92-20) Back to Table

Shaded areas indicate changes or additions since JPL15-10. Italicized entries in blue denote estimates.

[a] Temperature range of available experimental data. This is not necessarily the range of temperature over which the recommended Arrhenius parameters are applicable. See the corresponding note for each reaction for such information.

[b] Units are cm^3 $molecule^{-1}$ s^{-1}.

[c] f(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(\mathrm{T}) = f(298\ \mathrm{K})\exp\left|g\left(\frac{1}{\mathrm{T}} - \frac{1}{298}\right)\right|,$$ note that the exponent is an absolute value.

1.15.2 Notes: Metal Reactions

J1. **Na + O_3**. The recommendation is based on the measurements of Ager et al.,[1] Worsnop et al.[6] as corrected in Worsnop et al.,[7] and Plane et al.[3] The data of Worsnop et al. supersede earlier work from that laboratory (Silver and Kolb[5]). Measurements made by Husain et al.[2] at 500 K are somewhat lower, probably because they did not recognize that secondary chemistry, $NaO + O_3 \rightarrow Na + 2O_2$, interferes with the rate coefficient measurement. The temperature dependence is from results of Worsnop et al.[7] (214–294 K) and Plane et al.[3] (208–377 K). Ager et al.[1] estimated that the $NaO_2 + O$ product channel is ≤5%. Evidence that the NaO product is in the $^2\Sigma^+$ excited electronic state was reported by Shi et al.[4] and Wright et al.[8]

J2. **Na + N_2O.** The recommendation incorporates the data of Husain and Marshall,[4] Ager et al.,[1] Plane and Rajasekhar,[5] and Worsnop et al.[7] Silver and Kolb[6] measured a rate coefficient at 295 K that is lower and is superseded by Worsnop et al. Helmer and Plane[3] report a measurement at 300 K in excellent agreement with the recommendation. Subsequently, Gómez Martin et al.[2] measured the rate constant for the $Na + N_2O$ reaction at 295, 300, and 320 K; these near room temperature results are also in "excellant agreement" with the recommended 298 K value. Earlier, less direct studies were discussed by Ager et al.[1] The NaO product does not react significantly with N_2O at room temperature [k (for $Na + N_2 + O_2$ products) $\leq 10^{-16}$ cm^3 molecule^{-1} s^{-1} and k (for $NaO_2 + N_2$ products) $\leq 2 \times 10^{-15}$ cm^3 molecule^{-1} s^{-1} (Ager et al.)]. Wright et al. [8] used UV photoelectron spectroscopy to determine the product NaO is formed predominantly in the excited $^2\Sigma^+$ state.

J3. **Na + Cl_2.** Two measurements of the rate coefficient for this reaction are in excellent agreement: Silver[1] and Talcott et al.[2] The recommended value is the average of these room temperature results.
(Table 87-41, Note: 87-41, Evaluated: 87-41) Back to Table

(1) Silver, J. A. Room temperature rate constant for the reaction of Na with Cl_2. *J. Chem. Phys.* **1986**, *84*, 4718-4720, doi:10.1063/1.450003.

J4. **NaO + O**. The recommendation is based on measurements by Plane and Husain[3] and Griffin et al.[1] The Na + O_3 reaction produces NaO predominately in the low laying A $^2\Sigma^+$ state which can radiatively and collisionally decay slowly to the X $^2\Pi$ ground state. The Plane and Husain[3] experiment was configured so the predominant reactant was NaO X $^2\Pi$ while the Griffin et al.[1] experiment was designed to maximize NaO A $^2\Sigma^+$ concentrations. While the two states may not have identical reaction rate constants, their energy difference is small compared to reaction exothermicity and both states show reaction rate constants near the collisional limit. Since this reaction in the atmosphere will probably proceed through a mixture of the two lowest NaO electronic states and data are available at only one temperature for each state, the recommended rate constant is an average of the two measurements. Plane and Husain[3] reported that ~0.01 of the Na product is in the 3^2P excited state, while Griffin et al.[1] report a Na 3^2P product branching ratio of 0.14 ± 0.04. This difference is consistent with the orbital correlation predictions of products for reaction of each NaO state as presented by Herschbach et al.[2]
(Table: 06-2, Note: 06-2, Evaluated: 06-2) Back to Table

(3) Plane, J. M. C.; Husain, D. Determination of the absolute rate constant for the reaction O + NaO → Na + O_2 by time-resolved atomic chemiluminescence at λ = 589 nm [Na(3 ^2P_J) → Na(3 $^2S_{1/2}$) + hv]. *J. Chem. Soc. Faraday Trans. 2* **1986**, *82*, 2047-2052, doi:10.1039/f29868202047.

J5. **NaO + O_3.** This reaction was studied by Silver and Kolb,[3] Ager et al.,[1] and Plane et al.,[2] who agree on the rate coefficient and branching ratio. This agreement may be fortuitous because Silver and Kolb used an indirect method and an analysis based on their rate coefficient for the Na + O_3 reaction, which is about 1/2 of the recommended value. Ager et al. employed a somewhat more direct measurement, but the study is complicated by a chain reaction mechanism in the Na/O_3 system. Plane et al. reported rate coefficient measurements for the NaO_2 + O_2 product channel over the temperature range 207–377 K using pulsed photolysis LIF methods. The recommendation for that channel is based on all three studies, and the recommendation for the Na + $2O_2$ channel is based upon the results of Silver and Kolb and Ager et al. The latter reaction channel may also have a significant temperature dependence.

(2) Plane, J. M. C.; Nien, C.-F.; Allen, M. R.; Helmer, M. A kinetic investigation of the reactions Na + O_3 and NaO + O_3 over the temperature range 207-377 K. *J. Phys. Chem.* **1993**, *97*, 4459-4467, doi:10.1021/j100119a033.

(3) Silver, J. A.; Kolb, C. E. Determination of the absolute rate constants for the room temperature reactions of atomic sodium with ozone and nitrous oxide. *J. Phys. Chem.* **1986**, *90*, 3263-3266, doi:10.1021/j100405a042.

J6. **NaO + H_2.** Our prior recommendation was based on two 297 K and one 294 K measurements by Ager and Howard[1] who reported the NaOH + H product channel rate constant. They also reported evidence of a Na + H_2O product channel and that a small fraction of the Na from this channel is in the 3^2P excited state. Using direct mass spectral measurements of both NaO depletion and NaOH production in their flow reactor Gómez

Martin et al.[2] demonstrated that the Na + H_2O product channel is minor with a branching ratio estimate of (1.02 ± 0.14)%. They reported NaO + H_2 → NaOH + H rate constant measurements for 266 and 310 K that are ~5 times lower than Ager and Howard's three earlier measurements at 297, 297, and 294 K. Ager and Howard reported an averaged room temperature rate constant of $(2.6 \pm 1.0) \times 10^{-11}$ cm^3 $molecule^{-1}$ s^{-1} compared to $(4.9 \pm 1.2) \times 10^{-12}$ cm^3 $molecule^{-1}$ s^{-1} at 310 K and $(6.0 \pm 3.0) \times 10^{-12}$ cm^3 $molecule^{-1}$ s^{-1} at 266 K reported by Gómez Martin et al. Gómez Martin et al. discuss possible reasons for the large discrepancy but do not identify definative problems with either group's experiments. Because of the large unexplained discrepancy between the Ager and Howard and Gómez Martin et al. studies, no recommendation is given for this reaction.
(Table 19-5, Note: 19-5, Evaluated: 19-5) Back to Table

(1) Ager, J. W., III; Howard, C. J. Gas phase kinetics of the reactions of NaO with H_2, D_2, H_2O, and D_2O. *J. Chem. Phys.* **1987**, *87*, 921-925, doi:10.1063/1.453726.
(2) Gómez Martin, J. C.; Garraway, S. A.; Plane, J. M. C. Reaction kinetics of meteoric sodium reservoirs in the upper atmosphere. *J. Phys. Chem. A* **2016**, *120*, 1330-1346, doi:10.1021/acs.jpca.5b00622.

J7. **NaO + H_2O.** The prior recommendation was based on a room temperature (298 ± 1 K) measurement of ($2.2 \pm 0.4 \times 10^{-10}$ cm^3 $molecule^{-1}$ s^{-1}) by Ager and Howard[1] and a temperature dependent measurement by Cox and Plane[2] with the more extensive temperature dependent data favored. Cox and Plane's near room temperature (T= 310 K) rate constants are (9.8 ± 2.4) and $(9.3 \pm 1.0) \times 10^{-11}$ cm^3 $molecule^{-1}$ s^{-1}. While Gómez Martin et al.[3] reported a 310 K rate constant value of $(2.4 \pm 0.6) \times 10^{-10}$ cm^3 $molecule^{-1}$ s^{-1}; in excellent agreement with Ager and Howard[1] and poor agreement with Cox and Plane.[2] Gómez Martin et al. discuss potential reasons for the discrepency with the earlier measurement and conclude their latter result is more likely to be correct. After reviewing the results of all three studies, they recommend a near room temperature value of k(300–310 K) = $(2.3 \pm 0.5) \times 10^{-10}$ cm^3 $molecule^{-1}$ s^{-1} and an Arrhenius temperature dependence determined by a 2 kJ activation energy: $k(260\text{–}716\ \text{K}) = 5.06 \times 10^{-10} \exp(-240/T)$ cm^3 $molecule^{-1}$ s^{-1}; which we adopt.
(Table: 19-5, Note: 19-5, Evaluated: 19-5) Back to Table

(1) Ager, J. W., III; Howard, C. J. Gas phase kinetics of the reactions of NaO with H_2, D_2, H_2O, and D_2O. *J. Chem. Phys.* **1987**, *87*, 921-925, doi:10.1063/1.453726.

J8. **NaO + NO.** The recommendation is based on an indirect measurement reported by Ager et al.[1]
(Table 87-41, Note: 87-41, Evaluated: 87-41) Back to Table

(1) Ager, J. W., III; Talcott, C. L.; Howard, C. J. Gas phase kinetics of the reactions of Na and NaO with O_3 and N_2O. *J. Chem. Phys.* **1986**, *85*, 5584-5592, doi:10.1063/1.451573.

J9. **NaO + CO.** Two flow reactor measurements have published room temperature rate constant measurements Kolb et al.[2] reported $k(294\ \text{K}) = (2.1 \pm 0.5) \times 10^{-10}$ cm^3 $molecule^{-1}$ s^{-1} and 26 years later Gómez Martin et al.[1] reported $k(300\ \text{K}) = (1.2 \pm 0.4) \times 10^{-10}$ cm^3 $molecule^{-1}$ s^{-1}. These results overlap within their estimated errors. An averaged rate constant of $k(294\text{–}300\ \text{K}) = (1.6 \pm 0.5) \times 10^{-10}$ cm^3 $molecule^{-1}$ s^{-1} is recommended.

SECTION 2. TERMOLECULAR REACTIONS

Table of Contents

Tables

2.1 Introduction

Recombination rate constants for simple association reactions (Table 2-1) of the type $A + B \leftrightarrow [AB]^{*} \xrightarrow{M} AB$ (where the asterisk denotes rovibrational excitation) are pressure dependent. The low-pressure-limiting rate constants are given in the form:

$$k_0(T) = k_0^{298}\left(\frac{298}{T}\right)^{n} \text{ cm}^{6} \text{ molecule}^{-2} \text{ s}^{-1}, \tag{2.1}$$

(where k_o^{300} has been adjusted for air as the third body). The limiting high-pressure rate constant is given in a similar form:

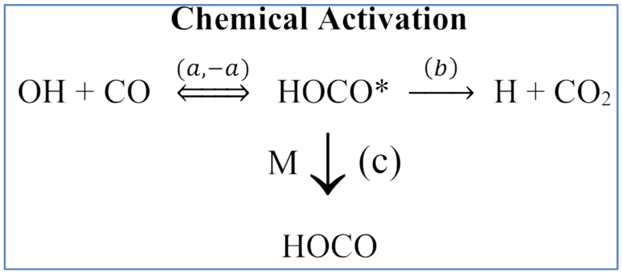
$$k_{\infty}(T) = k_{\infty}^{298}\left(\frac{298}{T}\right)^{m} \text{ cm}^{3} \text{ molecule}^{-1} \text{ s}^{-1}. \tag{2.2}$$

To obtain the effective second-order rate constant for a given condition of temperature and pressure (altitude), the following formula is used:

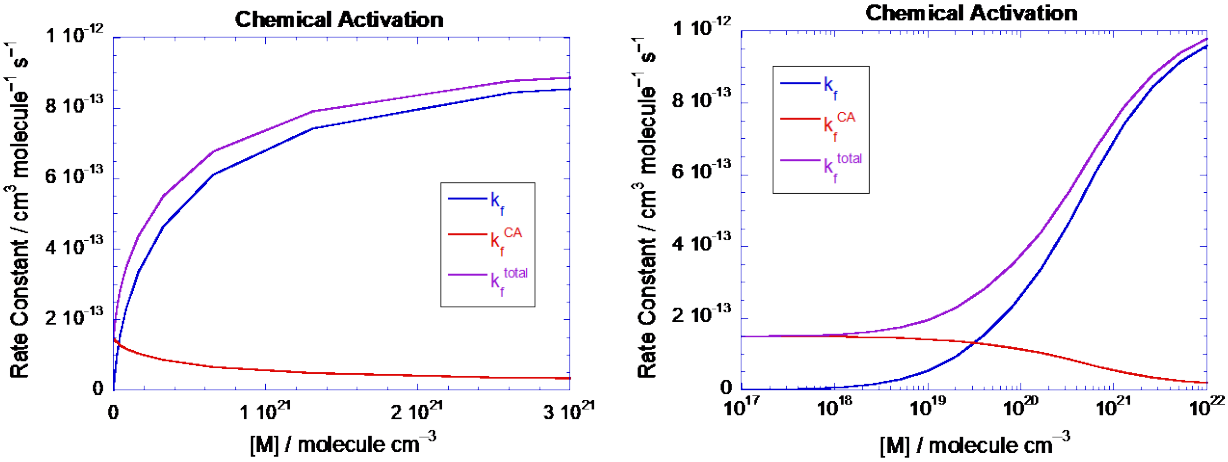
$$k_f(T,[M]) = \left\{\frac{k_{\infty}(T)k_0(T)[M]}{k_{\infty}(T)+k_0(T)[M]}\right\} 0.6^{\left\{1+\left[log_{10}\left(\frac{k_0(T)[M]}{k_{\infty}(T)}\right)\right]^{2}\right\}^{-1}} \tag{2.3}$$

where $[M]$ is the total gas concentration. The fixed value 0.6 that appears in this formula fits the data for all listed reactions adequately, although in principle this quantity is temperature-dependent and may be different for each reaction. However, there are rarely sufficient data to accommodate additional parameters. The four parameters, $k_o(298)$, n, $k_{\infty}(298)$, and m are given in Table 2.1 for simple association reactions.

Some association reactions produce not only the recombination product, but additional products that appear to originate from a simple bimolecular reaction. For example, the reaction between OH and CO produces not only HOCO, the recombination product, but also H and CO_2, which resemble the products of a simple metathesis reaction. This is an example of a **chemical activation reaction**, which takes place on a potential energy surface that includes HOCO*, the rovibrationally excited free radical intermediate. The reactions involving this intermediate can be described with the following reaction scheme:



The net loss of reactants is thus the sum of two pressure-dependent processes, an association to yield HOCO and the chemical activation process yielding H and CO_2. In the limit of zero pressure (i.e., [M] = 0), the only products are H + CO_2. The yield of H + CO_2 is diminished and the yield of HOCO is increased as the pressure rises. In the limit of very high pressure, the only product is HOCO. The pressure-dependent rate constants are shown here in two common formats:



Figures: Two common formats showing the same chemical reaction rate constants as functions of pressure for a chemical activation system.

The chemical activation reaction scheme illustrated above is the basis for a model[1,2,5] that describes the contributions from the two coupled processes:

1) Eq. 2.3 ($k_f(T,[M])$) for the association reaction (e.g. for producing HOCO). This is the same expression that is used for simple association reactions.

2) Eq. 2.4 $k_f^{CA}(T,[M])$ for the formation of the “chemical activation products” (e.g. for producing H + CO_2):

$$k_f^{CA}(T,[M]) = k_{int}(T)\left[1 - \frac{k_f(T,[M])}{k_\infty(T)}\right] \tag{2.4}$$

where $k_{int}(T)$ is the second order rate constant at $[M] = 0$ (i.e., the zero-pressure intercept) given by the Arrhenius expression in Eq. 2.5.

$$k_{int}(T) = A\,exp(-B/T) \tag{2.5}$$

The total rate constant for loss of reactants is given by Eq. 2.6:

$$k_f^{total}(T,[M]) = k_f(T,[M]) + k_f^{CA}(T,[M]) \tag{2.6}$$

The six parameters, $k_o(298)$, n, $k_\infty(298)$, m, A, and B, are listed in Table 2.2 for chemical activation systems.

The discussion that follows outlines the general methods we have used in establishing this table, and the notes to the table discuss specific data sources. Recent advances in theory have allowed direct calculation of rate constants for some reactions using RRKM/Master Equation methods.

2.2 Low-Pressure-Limiting Rate Constant, $k^x_o(T)$

Troe[4] has described a simple method for obtaining low-pressure-limiting rate constants. In essence this method depends on the definition:

$$k_o^x(T) \equiv \beta_x k_{o,sc}^x \tag{2.7}$$

Here sc signifies "strong" collisions, x denotes the bath gas, and β_x is an efficiency parameter ($0 < \beta_x < 1$), which provides a measure of energy transfer. The strong collision rate constant can be calculated with some accuracy from knowledge of molecular parameters available from experiment and more from theory.

The coefficient β_x is related to the average energy transferred in a collision with gas x, $\langle \Delta E \rangle_x$, via:

$$\frac{\beta_x}{\left(1-\sqrt{\beta_x}\right)} = \frac{\langle \Delta E \rangle_x}{F_E kT} \tag{2.8}$$

Notice that $\langle \Delta E \rangle$ is quite sensitive to β. F_E is the correction factor of the energy dependence of the density of states (a quantity of the order of 1.1 for most species of stratospheric interest).

For some of the reactions of possible stratospheric interest reviewed here, there exist data in the low-pressure limit (or very close thereto), and we have chosen to evaluate and unify this data by calculating $k_o^x(T)$ for the appropriate bath gas x and computing the value of β_x corresponding to the experimental value.[4] A compilation[3] gives details for many of the reactions considered here.

From the β_x values (most of which are for N_2, i.e., β_{N2}), we compute $\langle \Delta E \rangle_X$ according to the above equation. Values of $\langle \Delta E \rangle_{N2}$ of approximately 0.3–1 kcal $mole^{-1}$ are generally expected. If multiple data exist, we average the values of $\langle \Delta E \rangle_{N2}$ and recommend a rate constant corresponding to the β_{N2} computed in the equation above.

Master equation calculations allow direct calculation of low-pressure rate constants and of β_x.

Where no data exist, we have sometimes estimated the low-pressure rate constant by taking $\beta_{N2} = 0.3$ at T = 298 K, a value based on those cases where data exist.

2.3 Temperature Dependence of Low–Pressure Limiting Rate Constants: $(298/T)^n$

The value of n recommended here comes from measurements or, in some cases, a calculation of $\langle \Delta E \rangle_{N2}$ from the data at 298 K, and a computation of β_{N2}(200 K) assuming that $\langle \Delta E \rangle_{N2}$ is independent of temperature in this range. This β_{N2}(200 K) value is combined with the computed value of k_o^{sc}(200 K) to give the expected value of the actual rate constant at 200 K. This latter, in combination with the value at 298 K, yields the value of $\boldsymbol{n}$.

This procedure can be directly compared with measured values of k_o(200 K) when those exist. Unfortunately, very few values at 200 K are available. There are often temperature-dependent studies, but some ambiguity exists when one attempts to extrapolate these down to 200 K. If data are to be extrapolated beyond the measured temperature range, a choice must be made as to the functional form of the temperature dependence.

There are two general ways of expressing the temperature dependence of rate constants. Either the Arrhenius expression:

$$k_o(T) = A \exp(-E/RT) \tag{2.9}$$

or the form:

$$k_o(T) = A' \, T^{-n} \tag{2.10}$$

is employed. Neither of these extrapolation techniques is soundly based, and since they often yield values that differ substantially, we have used the power law expression above as the basis of our recommendations.

2.4 High-Pressure-Limit Rate Constants, $k_\infty(T)$

High-pressure rate constants can often be obtained experimentally, but those for the relatively small species of stratospheric importance usually reach the high-pressure limit at inaccessibly high pressures. This leaves two sources of these numbers, the first being estimates based upon theory, and the second being extrapolation of fall-off data up to higher pressures.

Stratospheric conditions generally render reactions of interest much closer to the low-pressure limit and thus are fairly insensitive to the high-pressure value. This means that while the extrapolation is long, and the value of $k_\infty(T)$ is often not very accurate, a "reasonable guess" of $k_\infty(T)$ will then suffice. In a few cases, we have declined to guess since the low-pressure limit is effective over the entire range of stratospheric conditions.

2.5 Temperature Dependence of High-Pressure-Limiting Rate Constants: $(298/T)^m$

Commonly, there are very few data upon which to base a recommendation for values of $\boldsymbol{m}$. Values in Tables 2.1 and 2.2 are often estimated, based on models for the transition state of bond-association reactions and whatever data are available. In general, the temperature dependence of these rate constants is expected to be small.

2.6 Uncertainty Estimates

For three-body reactions (Tables 2.1 and 2.2) uncertainties are assigned using a procedure that is analogous to that employed for bimolecular reactions in Table 1-1. Values of $f(298\ \mathrm{K})$ are given for these rate constants at room temperature and assumed to be valid at all pressures. The additional uncertainty arising from the temperature extrapolation is expressed with a g-factor as in Table 1-1. Given that uncertainties for an expression with four parameters are expressed with only two parameters, a certain amount of arbitrariness is involved in their choice.

Shaded areas indicate changes or additions since JPL15-10**.**
The values quoted are suitable for air as the third body, M.

[a] Units are cm^6 $molecule^{-2}$ s^{-1}.

[b] Units are cm^3 $molecule^{-1}$ s^{-1}.

f(298 K) is the uncertainty factor at 298 K. To calculate the uncertainty at other temperatures, use the expression:

$$f(T) = f(298)\exp\left|g\left(\frac{1}{T} - \frac{1}{298}\right)\right|$$

Note that the exponent is an absolute value

2.7 Notes for Table 2-1: Termolecular Reactions

JPL Publication numbers for the most recent revision of the table entry, note and evaluation date are given at the end of each note.

A1. **O + O_2.** Low pressure limit and T dependence are an average of Klais et al.,[10] Huie et al.,[7] and Lin and Leu.[11] These studies in N_2 and Ar are in the temperature range $200 < T/K < 268$. The result is in agreement with the study of Hippler et al.[6] and the extrapolated recommendation fits their lower pressure N_2 data down to 100 K. High pressure studies by Croce de Cobos and Troe[2] are in agreement with this recommendation. Rawlins et al.[14] estimate values in Ar between 80 and 150 K from nascent vibrational distributions that are a factor of two higher than the recommendation extrapolated to 80 K. The temperature dependence of the rate constant determined from the experimental data are in excellent agreement with the value of $n = 2.36$ determined from the calculations of Patrick and Golden.[13] However there is some reason to believe that a radical-complex plays a role in this process.[6,8,12,19] Kaye[9] has calculated isotope effects for this reaction, using methods similar to those discussed in the Introduction of this document (see Troe[17] and Patrick and Golden[13]). Isotope effects have been reported by Anderson et al.[1] and Gross and Billing.[4] Measurements of isotopic fractionation by Mauersberger and colleagues[18] and Thiemens and co–workers[15] reveal distinctly non–statistical effects. Various attempts at theoretical explanations exist,[5] but the detailed knowledge of the potential energy surface required is unavailable. A summary of theoretical and experimental studies by Schinke et al.[16] goes into great detail on this subject as does a study by Gao and Marcus.[3]

A2. **O(^{1}D) + N_2.** Recommended parameters (including *f* and *g*) are from Estupiñán et al.[1] whose detection capabilities were more advanced than those employed in earlier studies. Kajimoto and Cvetanovic[3] report a value at 296 K of 6.5×10^{-37} cm^6 s^{-1}. Maric and Burrows[4] extract $(8.8 \pm 3.3) \times 10^{-37}$ cm^6 s^{-1} from a study of the photolysis of synthetic air. Gaedtke et al.[2] report an approximate value of 10^{12} in molar units, which translates to 2.8×10^{-36} in molecular units. The rate constant is extremely low in this special system due to electronic curve crossing.

B1. **H + O_2.** Studies by Kurylo,[8] Wong and Davis,[13] Hsu et al.,[7] Hsu et al.,[6] Cobos et al.,[4] Pirraglia et al.,[10] Carleton et al.,[3] Troe,[12] Bates et al.,[1] Michael et al.,[9] and Fernandes et al.[5] have been considered. All are in good agreement. A theoretical study by Sellevåg et al.[11] contributes to knowledge of the reaction. The experimental/theoretical study by Fernandes et al.[5] provides an estimate of the high pressure limit, which is adopted in this recommendation. Because only a few measurements have been reported at low temperatures in the atmospheric range, data from a wider range of conditions were considered. Thus, the recommendation for the low-pressure limit is based on a least-squares analysis (using the adopted high-pressure limit) of all of the data from the studies listed above with $T \leq 500$ K and N_2 concentration $< 10^{20}$ molecules cm^3. The estimated error limits were chosen so that all of the data used for the recommendation fall within the 2σ error bounds. Two studies[1,9] have pointed out the large effect of water vapor as the collider gas. Baulch et al.[2] have evaluated this reaction over the temperature range $298 < T/K < 1500$.
