UCLA LANDSLIDES 2019

Thomas 04/04/2019
What does everyone think of the calculation used here to measure the factor of safety?

Jean Bruno 21:48
do we have reports of any other landslides happening in Italy or other countries in Europe?

Thomas 04/04/2019
this links to the previous report of 2015

the groundwater level of 8 mm per decade. They further calculated a decrease in the displacement rate of the earthflow in the range 1.5-3.0 mm per decade, leading to a maximum total displacement of 77 to 86 cm in the 51-year period 2010-2060. A relevant conclusion of the study was that the expected climate change did not play a relevant role in the dynamic behavior of the slow landslide in clay, due to the moderate decrease in the amount of annual precipitation and limited effect of temperature increase on evaporation and groundwater level.

Adopting the same simulation chain and global and regional climate models, Rianna et al. (2014) investigated a slow, deep-seated landslide in clay affecting the NE slope of the Orvieto hill, Umbria, central Italy. A 30-year-long monitoring record of the slide was used to establish a link between rainfall and rate of landslide movement (Tommasi et al., 2006), including a distinct reduction in the rate related to a decreasing trend in the maximum annual 4-month cumulated rainfall. Coupling historical data with high-resolution (up to 8 km) climate projections provided by COSMO-CLM for two IPCC emission scenarios (RCP4.5 and RCP8.5, Meinshausen et al., 2011), the authors obtained a quantitative estimate of the expected slope displacement until the end of 21st century, and concluded that the predicted local climate changes will be responsible for a significant deceleration of the landslide movement.

A few investigators used the physically-based modelling approach to evaluate the effects of climate change on populations of mainly shallow landslides. Chang and Chiang (2011) determined a worst-case scenario for shallow landslide occurrence in a mountain catchment of Taiwan in the 21st century. From 21 GCMs, they selected an optimal GCM (CGCM2.3.2, Yukimoto et al., 2006), and the related monthly precipitation. They downscaled annual 24-h rainfall maxima (considered a good predictor for typhoons), and used it as input for the calculation of the stability conditions of a slope, measured by the factor of safety. They estimated an increase of about 15% in the average annual maximum rainfall from 1960 to 2008 to 2010-2099 and, as a result, a 12% increase in the average total unstable area between the considered periods.

Melchiorre and Frattini (2012) coupled a hydrological-stability model to eleven GCM scenarios and Monte Carlo simulations to evaluate changes in slope stability conditions of shallow landslides in central Norway. The GCM data were used to evaluate soil saturation conditions and pressure heads through the hydrological model, and an infinite slope stability model used to compute the factor of safety. They found diverging slope stability results for the future scenarios, and concluded

year 2100. Comparing this result with thresholds calibrated on historical data in the period 1963-2007 they suggested an increase in the total number of debris flows of approximately 30% by the end of the 21st century.

Jomelli et al. (2009) investigated the impact of future climate change on the geographical and temporal occurrence of debris flows in the Massif des Ecrins, in the French Alps. They used downscaled rainfall and temperature data obtained from three simulations of the ARPEGE GCM (Déqué et al., 1994), under the A2 IPCC scenario (Houghton et al., 2001), for the 30-year future period 2070-2099. The projections showed a decrease in the number of intense rainfall events and an increase in temperature, compared to the calibration period 1970-1999. Given the decrease in the number of intense rainfall events, the authors estimated a 30% reduction in the temporal occurrence of debris flows, and given the increase in temperature, they estimated a shift of the 0 °C isotherm to a higher elevation, which was expected to result in a 20% reduction in the number of slopes affected by shallow slope instabilities, and a shift in the elevation of the areas susceptible to debris flow initiation.

Turkington et al. (2016) predicted trends in debris flows activity, measured by the number of days with debris flows, for the period 2010-2099, in the Barcelonnette valley, France, and the Fella catchment, Italy, under the RCP4.5 and RCP8.5 scenarios. For their experiment, they used a probabilistic approach to determine a dependence between rainfall events and debris flow occurrence (Turkington et al., 2014), and bias-corrected climate projections of two meteorological proxies i.e., daily rainfall from 1950 to 2009, and Convective Available Potential Energy (CAPE) from 1979 and 2011. Using an ensemble of 32 climate scenarios (from 3 RCMs and up to 6 GCMs, Jacob et al., 2014) for the rainfall proxy, and eight climate scenarios (from 4 GCMs, Taylor et al., 2011) for the CAPE proxy, they found an increase of up to 6% per decade in the number of days with debris flows towards the end of 21st century, in both study areas, and acknowledged that their projections depended strongly on the proxy used, and to a lesser extent to the GCM, RCM, and the RCP scenarios.

Lastly, Ciabatta et al. (2016) investigated the impact of climate change on landslide occurrence in Umbria, central Italy, using GCM projections applied in an existing regional landslide early warning system (Ponziani et al., 2012). First, they assessed the performance of the system using a catalogue of 235 shallow landslides in Umbria from 1990 to 2013. Next, they exploited hourly rainfall and temperature records obtained from

The screenshot shows the Mendeley user interface. On the left is a navigation menu with 'Subscription' highlighted. The main content area is titled 'Subscription' and 'Packages'. It displays the 'Mendeley Institutional Edition' package with details: '100 GB personal library space, 100 collaborators, 100 GB group library space, 1000 groups' and an expiration date of 'Expires on 28/01/2022'. Below this is a note: 'Note: When changing packages please note all other PAID packages will be cancelled.' At the bottom, there are two storage usage sections: 'Personal Space' (472 MB / 100 GB) and 'Shared Space' (40.1 MB / 100 GB). On the right, a user profile dropdown menu is open, showing options like 'Settings & Privacy', 'Download Mendeley', 'Help Guides', 'Support Center', and 'Sign Out'. A red callout bubble points to the expiration date and contains two bullet points: '로그인 날짜로부터 1년간 유효' and '구독만기 전에 로그인 하여 만기일 연장'. The 'deley' logo is in the top left, and 'EBSCO VIER' is in the bottom right.

Creating and using custom collections

The screenshot shows the Mendeley interface. On the left is a sidebar with navigation options: Recently Read, Favorites, My Publications, Trash, and a section titled 'COLLECTIONS'. Under 'COLLECTIONS', there are several categories: Astrophysics, Metamorphic Principles, Data Modelling, High Energy Masses, Dark matter, and Thesis Papers. At the bottom of the 'COLLECTIONS' section, there is a 'New collection' button with a dashed border and a mouse cursor pointing to it. On the right, a list of publications is displayed in a table format. Each row contains a colored dot, a star icon, a checkbox, the author names, the year, and the start of the title. The publications listed are:

Using the action panel

The screenshot shows the Mendeley Library interface. On the left is a sidebar with navigation options: '+ Add new', 'All References', 'Recently Added', 'Recently Read', 'Favorites', 'My Publications', 'Trash', 'COLLECTIONS' (Astrophysics, Metamorphic Principles, Thesis Papers), 'PRIVATE GROUPS' (Clinical Trial 2019, UCL Medicine Lab), and 'PUBLIC GROUPS' (UCL Medicine 2003 Class). The main area displays a table of 'All References' with columns for Authors, Year, Title, Source, Added, and File. Two references are selected, and an action panel is open over them, showing options: 'Collection', 'Private Group', and 'Public Group'. A red box highlights the 'Collection' option, and a red arrow points from a text box on the right to it. At the bottom of the table, it says '2 reference selected' and there are buttons for 'Add to', 'Mark as', and 'Delete'.

Reading PDFs

The screenshot displays the Mendeley Desktop application interface. At the top, there is a 'Library' tab and a 'Notebook' search bar. The main window shows a PDF document titled 'Implications of climate change on landslide hazard in Central Italy'. The document content is visible, with several paragraphs of text. A toolbar at the top of the PDF viewer includes navigation and editing tools. On the right side, an 'Annotations' panel is open, showing three annotation boxes with timestamps (21:48) and text: 'Interesting information. Must read later', 'research why did this increase happen', and 'share this with the team for later analysis'. The user's name 'Thomas' is visible in the top right corner.

1. Introduction

Some concepts in the field of HCI are commonly used by prac-
titioners even if a lack of empirical research has prevented their
full understanding and impact. User experience (UX) could be
one of those fashion and fuzzy terms that is increasingly used even
tho
n reached yet regarding its def-
initi
ors question the added value of
UX
its such as usability, ergonomics
or user acceptance (Baccarella & Bastien, 2009), some also agree
that UX is a "truly extended and distinct perspective on the quality
of interactive products" (Hassenzahl, 2008).

Since the 2000s, the concept of UX is widely used but under-
stood in different ways (Law, Roto, Hassenzahl, Vermeeren, &

be explained by the fact that UX

Implications of climate change on landslide hazard in Central Italy

[Shared] Landslides in a changing climate

Evaluation of the Effects of Climate Changes on Landslide Activity ...

Info Annotations Notebook

UCLA LANDSLIDES 2019

- Thomas 04/04/2019
What does everyone think of the calculation used here to measure the factor of safety?
- Jean Bruno 21:48
do we have reports of any other landslides happening in Italy or other countries in Europe?
- Thomas 04/04/2019
this links to the previous report of 2015

the groundwater level of 8 mm per decade. They further calculated a decrease in the displacement rate of the earthflow in the range 1.5–3.0 mm per decade, leading to a maximum total displacement of 77 to 86 cm in the 51-year period 2010–2060. A relevant conclusion of the study was that the expected climate change did not play a relevant role in the dynamic behavior of the slow landslide in clay, due to the moderate decrease in the amount of annual precipitation and limited effect of temperature increase on evaporation and groundwater level.

Adopting the same simulation chain and global and regional climate models, Kianna et al. (2014) investigated a slow, deep-seated landslide in clay affecting the NE slope of the Orvieto hill, Umbria, central Italy. A 30-year-long monitoring record of the slide was used to establish a link between rainfall and rate of landslide movement (Tommasi et al., 2006), including a distinct reduction in the rate related to a decreasing trend in the maximum annual 4-month cumulated rainfall. Coupling historical data with high-resolution (up to 8 km) climate projections provided by COSMO-CLM for two IPCC emission scenarios (RCP4.5 and RCP8.5, Meinshausen et al., 2011), the authors obtained a quantitative estimate of the expected slope displacement until the end of 21st century, and concluded that the predicted local climate changes will be responsible for a significant deceleration of the landslide movement.

A few investigators used the physically-based modelling approach to evaluate the effects of climate change on populations of mainly shallow landslides. Chang and Chiang (2011) determined a worst-case scenario for shallow landslide occurrence in a mountain catchment of Taiwan in the 21st century. From 21 GCMs, they selected an optimal GCM (CGCM2.3.2, Yukimoto et al., 2006), and the related monthly precipitation. They downscaled annual 24-h rainfall maxima (considered a good predictor for typhoons), and used it as input for the calculation of the stability conditions of a slope, measured by the factor of safety. They estimated an increase of about 15% in the average annual maximum rainfall from 1960 to 2008 to 2010–2099 and, as a result, a 12% increase in the average total unstable area between the considered periods.

Melchiorre and Frattini (2012) coupled a hydrological-stability model to eleven GCM scenarios and Monte Carlo simulations to evaluate changes in slope stability conditions of shallow landslides in central Norway. The GCM data were used to evaluate soil saturation conditions and pressure heads through the hydrological model, and an infinite slope stability model used to compute the factor of safety. They found diverging slope stability results for the future scenarios, and concluded

year 2100. Comparing this result with thresholds calibrated on historical data in the period 1963–2007 they suggested an increase in the total number of debris flows of approximately 30% by the end of the 21st century.

Jomelli et al. (2009) investigated the impact of future climate change on the geographical and temporal occurrence of debris flows in the Massif des Ecrins, in the French Alps. They used downscaled rainfall and temperature data obtained from three simulations of the ARPEGE GCM (Déqué et al., 1994), under the A2 IPCC scenario (Houghton et al., 2001), for the 30-year future period 2070–2099. The projections showed a decrease in the number of intense rainfall events and an increase in temperature, compared to the calibration period 1970–1999. Given the decrease in the number of intense rainfall events, the authors estimated a 30% reduction in the temporal occurrence of debris flows, and given the increase in temperature, they estimated a shift of the 0 °C isotherm to a higher elevation, which was expected to result in a 20% reduction in the number of slopes affected by shallow slope instabilities, and a shift in the elevation of the areas susceptible to debris flow initiation.

Turkington et al. (2016) predicted trends in debris flows activity, measured by the number of days with debris flows, for the period 2010–2099, in the Barcelonnette valley, France, and the Fella catchment, Italy, under the RCP4.5 and RCP8.5 scenarios. For their experiment, they used a probabilistic approach to determine a dependence between rainfall events and debris flow occurrence (Turkington et al., 2014), and bias-corrected climate projections of two meteorological proxies i.e., daily rainfall from 1950 to 2009, and Convective Available Potential Energy (CAPE) from 1979 and 2011. Using an ensemble of 32 climate scenarios (from 3 RCMs and up to 6 GCMs, Jacob et al., 2014) for the rainfall proxy, and eight climate scenarios (from 4 GCMs, Taylor et al., 2011) for the CAPE proxy, they found an increase of up to 6% per decade in the number of days with debris flows towards the end of 21st century, in both study areas, and acknowledged that their projections depended strongly on the proxy used, and to a lesser extent to the GCM, RCM, and the RCP scenarios.

Lastly, Ciabatta et al. (2016) investigated the impact of climate change on landslide occurrence in Umbria, central Italy, using GCM projections applied in an existing regional landslide early warning system (Ponziani et al., 2012). First, they assessed the performance of the system using a catalogue of 235 shallow landslides in Umbria from 1990 to 2013. Next, they exploited hourly rainfall and temperature records obtained from
