## CYCLONE HAZARD CLIMATOLOGY

JUNE, 2023

India Meteorological Department, New Delhi

## PREFACE

India experiences various types of natural hazards including cyclones, floods, droughts, earthquakes, landslides, heat waves, cold waves, thundersqualls and tornadoes. About 80% of these hazards are hydro-meteorological in nature. Among these, the tropical cyclones (TCs) are most disastrous weather events that pose a potential threat to coastal population, marine and aviation community of the region. The risk management of the TCs depends on several factors including (i) hazard & vulnerability analysis, (ii) preparedness & planning, (iii) early warning, (iv) prevention and mitigation.

This document presents the hazard proneness of various districts along the coastline based on the frequency of landfalling cyclones, probable maximum precipitation, probable maximum winds and probable maximum storm surge, ninety-six districts including 72 districts touching the coast and 24 districts not touching the coast, but lying within 100 km from the coast have been classified based on their proneness. Out of 96 districts, 12 are very highly prone, 41 are highly prone, 30 are moderately prone, and the remaining 13 are less prone. Twelve very highly prone districts include South and North 24 Praganas, Medinipur, and Kolkata of West Bengal, Balasore, Bhadrak, Kendrapara, and Jagatsinghpur districts of Odisha, Nellore, Krishna, and east Godavari districts of Andhra Pradesh and Yanam of Puducherry.

This document also presents the Maximum Probable Frequency of all the categories of heavy rainfall events for different seasons and ever recorded highest rainfall over the coastal stations during the period 1901-2019. During the period 1961-2020, the cyclone return period, maximum probable precipitation, maximum probable storm surge and cyclone landfall count have also been prepared and presented here. The document also presents maximum sustained wind in each district based on IMD's best track data for the period 1981-2020 and maximum storm surge height maps in annual scale for each of the coastal districts in association with cyclones. The normalised vulnerability index has also been prepared based on population and housing density data as per Census information.

District-wise Hazard and vulnerability information in this document will help the disaster managers and planners in better decision making to effectively mitigate disasters associated with TCs.

I place on record the contribution by Climate Research Services, Pune and Cyclone Warning Division for preparation of this document.

## Introduction

India Meteorological Department has prepared climatology of cyclone hazard prone districts of India and determined the probable frequency of heavy rainfall events, annual districtwise extreme wind speed, return period of cyclones and normalised vulnerability index of cyclones.

The cyclone hazard proneness of various districts of India along the coast and interior districts near to coast which are affected by cyclones is based on frequency of total cyclones, total severe cyclones, actual/estimated maximum wind strength, Probable Maximum Storm Surge (PMSS) associated with the cyclones and Probable Maximum Precipitation (PMP) for all districts. Ninety-six districts including 72 districts touching the coast and 24 districts not touching the coast, but lying within 100 km from the coast have been classified based on their proneness.

Based on the data during the period 1901-2019, *Maximum Probable Frequency of all the categories of Heavy rainfall Events (Number of Days), for monsoon (June-September), post monsoon (October-December, Annual and ever recorded highest rainfall over the coastal stations have been presented. The annual extreme wind speed districtwise has been determined and presented based on past 15 years data from 490 stations across the country.* From these 490 stations data, the month-wise annual maximum wind series data has been prepared for computation of 50 years return period extreme values. The Annual extreme wind speed districtwise have been prepared and presented.

For computation of cyclone return period and maximum probable precipitation, maximum probable storm surge and cyclone landfall count the data during the period 1961-2020 has been considered. **Cyclone return periods** (CS, SCS, and combining CS and SCS) are computed in coastal districts for all the month and annual scale. Cyclone return periods are the frequency at which a certain cyclone intensity can be expected within a given distance of a given location within a specified buffer zone around the district (we have considered 50 nm as a buffer zone).The **maximum probable precipitation** of each district corresponding to cyclone days is computed from the daily station rainfall data for the period. **Cyclone Landfall Count** for each district gives the total number of cyclone (of any intensities) made landfall over the district during the period. These maps are made for all the months and on an annual scale.For the computation of **Maximum sustained wind** in each district IMD Best Track Cyclone data for the period 1981-2020 is used. **Maximum Storm surge** heights map in annual scale gives the maximum storm surge heights in meter each of the coastal district experienced so far associated with cyclone. The population density data and housing density data from Census data has been considered for determination of normalised vulnerability index.

# Chapter-1

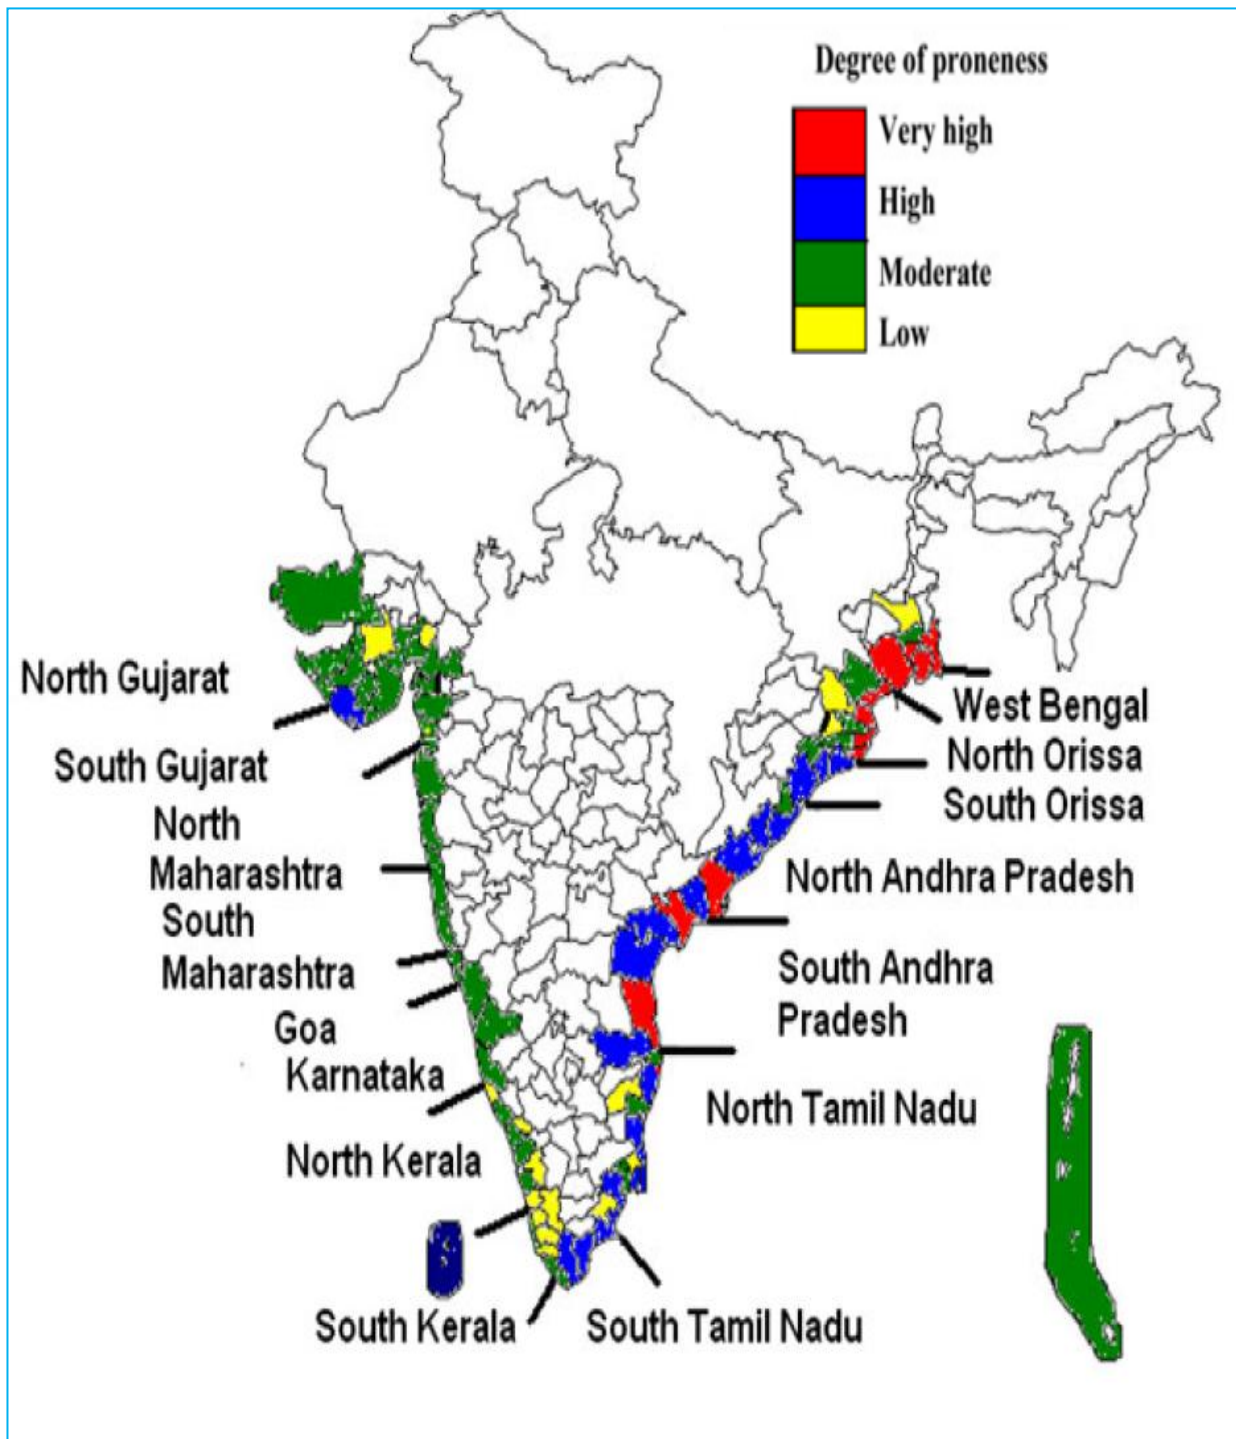

## Cyclone Hazard Prone Districts of India

- India Meteorological Department, has prepared cyclone hazard proneness of districts of India based on frequency of total cyclones, total severe cyclones, actual/estimated maximum wind strength, Probable Maximum Storm Surge (PMSS) associated with the cyclones and Probable Maximum Precipitation (PMP) for all districts as presented in **Fig. 1.1**. The hazard maps prepared by committee constituted by NDMA in 2012 indicating total number of severe cyclones (maximum sustained wind speed (MSW) of 48 knots or more), total number of cyclones (MSW of 34 knots or more), actual/estimated MSW, probable maximum storm surge, daily probable maximum precipitation over coast are presented in **Fig.1.2 (a-e)**. The cyclone parameters for various districts are presented in **Table 1.1-1.5**.
- Hundred districts including 74 districts touching the coast and 26 districts not touching the coast, but lying within 100 km from the coast have been classified based on their proneness. Out of 100 districts, 12 are very highly prone, 25 are highly prone, 48 are moderately prone, and the remaining 15 are less prone. Twelve very highly prone districts include South and North 24 Praganas, Medinipur, and Kolkata of West Bengal, Balasore, Bhadrak, Kendrapara, and Jagatsinghpur districts of Odisha, Nellore, Krishna, and east Godavari districts of Andhra Pradesh and Yanam of Puducherry. The remaining districts of Odisha and Andhra Pradesh, which touch the coast are highly prone districts. The north Tamil Nadu coastal districts are more prone than the south Tamil Nadu districts (south of about 10°N latitude). Most of the coastal districts of Gujarat and northKonkan are also highly prone districts. The remaining districts in the west coast and south Tamil Nadu are either moderately prone or less prone districts
- For details about the data, methodology and results the following publication may kindly be referred:Cyclone hazard prone districts of India, M. Mohapatra, 2015, Journal of Earth System Science, 124, No.3, pp. 515-526) andClassification of Cyclone Hazard Prone Districts of India, M. Mohapatra, G.S. Mandal, B.K. Bandyopadhyay, AjitTyagi, U.C. Mohanty, 2012, Nat Hazards, 63:1601–1620
- This classification is only based on hazard criteria. Vulnerability of the place has not been taken into consideration. Therefore, composite cyclone risk of a district, which is the product of hazard and vulnerability, needs to be assessed separately through detailed study. Such an initiative is being taken by NDMA through the World Bank assisted National Cyclone Risk Mitigation Project (NCRMP).
- The maximum sustained surface wind (MSW) indicated against a district in this report is the 3-min average wind speed normally recorded by IMD. Keeping in mind that it is the 3-second peak-gust wind speed that is usually adopted for design of buildings and structures (Lakshmanan et al. 2009, Structural Engineering Research Centre (SERC), Chennai), the MSW indicated against the

districts (Mohapatra et al. 2012) need to be multiplied by an appropriate factor for design of all buildings and structures in general and for the design of the post-disaster service structures (such as cyclone shelters, hospitals, transmission lines and communication towers, schools, etc.), in particular.

- In this list of cyclone hazard prone districts of the country, some of the districts of northeast India appearing in the list prepared by BMTPC have not appeared. This is because those districts are away from the coast and no parts of these districts were affected by storm surge requiring large scale evacuation of population. Floods due to cyclones over these districts are also very rare. These districts are mostly affected by depressions. Also interior districts of coastal states were not considered though some of these may be affected by storm wind and very high rainfall causing damage and destruction to life and properties.
- The analysis is based on the estimation of daily point PMP by IMD. The criteria adopted for categorization of PMP is arbitrary and subjective. However, IMD and Central Water Commission are developing a new PMP atlas based on longer and latest data. The PMP atlas needs to be prepared considering the actual extreme rainfall over the districts due to TCs only. There is scope for reanalysis of TC hazard proneness based on PMP of districts in association with TCs.
- The wind data in association with TC is based on the period of 1971–2010. It is mainly based on the wind estimated by Dvorak's technique (Dvorak 1984) and post-cyclone survey report along with the coastal observations available from IMD's observational network. There is further scope for improvement in estimation of TC wind hazard with upgradation of observational network with high wind speed recorder (HWSR), DopplerWeather Radar and validation of Dvorak's technique based on instrumented aircraft observation from the core and periphery of the TC.
- The study is based on the residual storm surge height in association with the TC crossing coast. It does not take into consideration the total water envelope due to astronomical tide, in-shore current, river discharge, and heavy rainfall distribution, etc. All these factors can influence the storm surge and hence resultant tidal wave. Therefore, there is further scope to estimate the storm surge hazard based on total water envelope and coastal inundation and hence to modify the hazard proneness of the coastal districts. Studies are in progress by various researchers including those from Indian National Centre for Ocean Information Services (INCOIS), Hyderabad and Centre for Atmospheric Sciences, Indian Institute of Technology (IIT), Delhi to develop the models for total water envelope and coastal inundation due to landfall of TC.
- The factors such as probable maximum wind strength, PMSS, and daily PMP are used to determine the degree of proneness based on the observed datasets. However, if speed and the size of the storm vary, then it is going to have an impact on all the aforementioned factors based on maximum duration of the wind

strength/rainfall/storm surge and maximum area (size) to be impacted by the landfalling TC. Hence, the degree of proneness may vary in such conditions.

## Chapter-2

### Extreme Rainfall

Rainfall events of high intensities are in most cases caused by floods, waterlogging, landslides and many other disasters. Information of maximum probable frequencies (number of days) of extreme rainfall events (heavy, very heavy, or extremely heavy) of each district from the past record of more than 100 years can identify the districts vulnerable to extreme events. In order to view the climate change impact on extreme rainfall events in various decades, the extreme rainfall information is made available for different decades and periods viz. 1951-60, 1961-70, 1971-80, 1981-1990, 1991- 2000, 2001-2010, 2011-2019, 1901-2019 and 1951-2019.

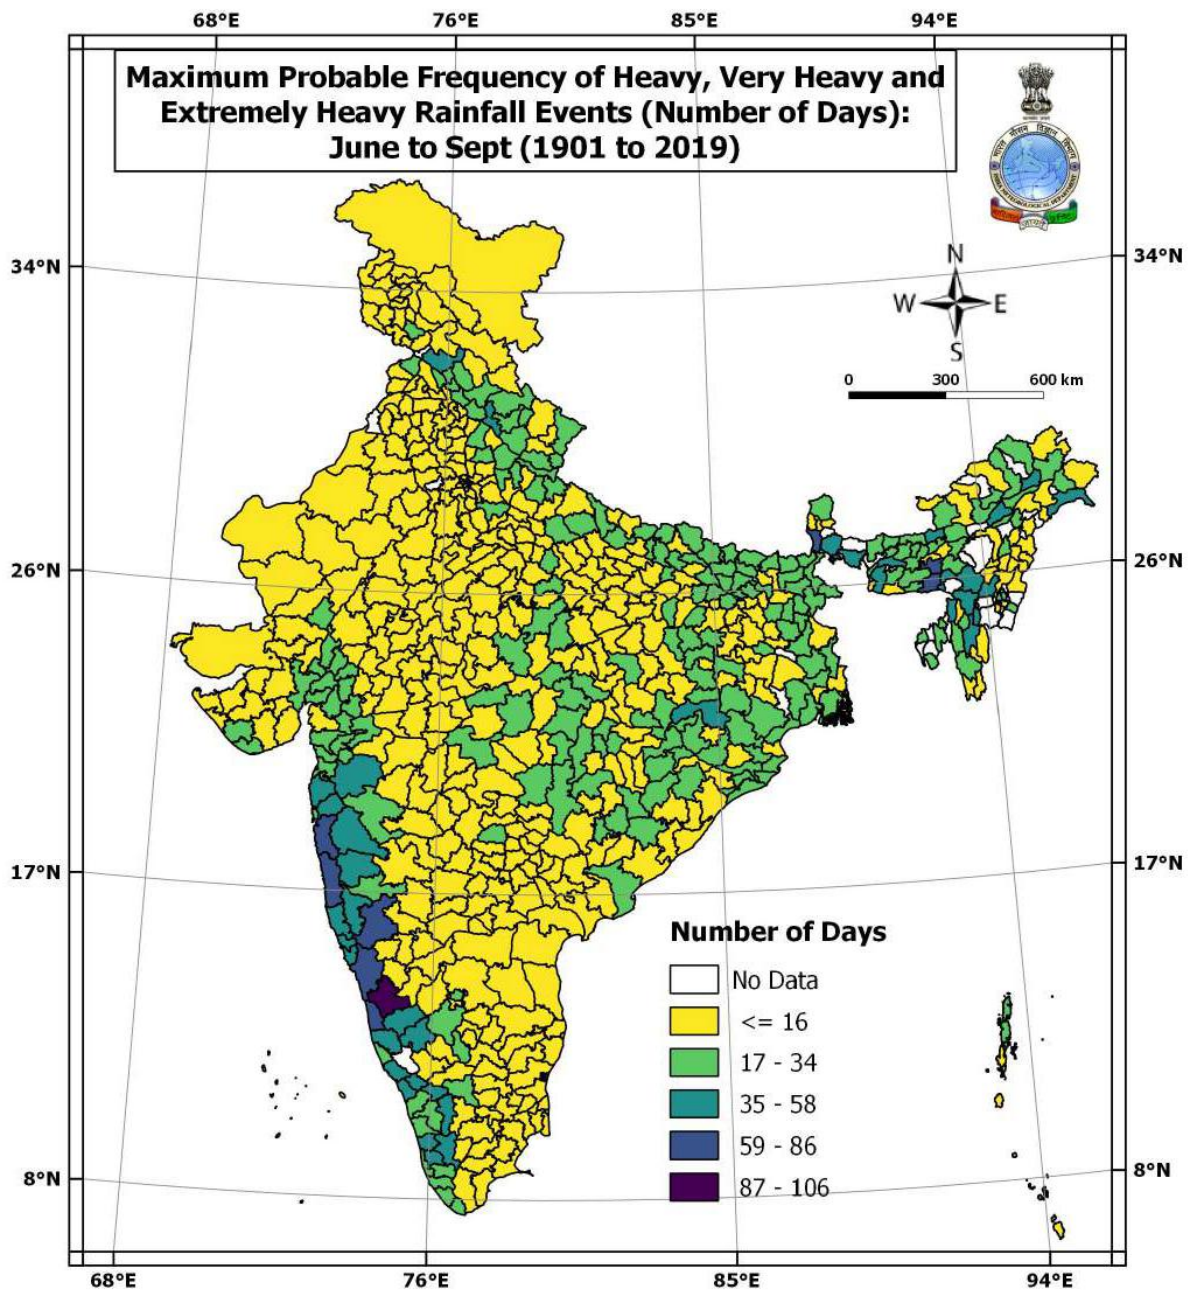

The user has to select the period from the drop-down menu available while clicking on Extreme Rainfall. After selecting the desired period/decade, one can get the vulnerability maps for four seasons, annual and for the monsoon months viz. June, July, August, and September. For any season/month or annual, there are three events viz. maximum probable frequency of Heavy rainfall event, maximum probable frequency of Very Heavy & Extremely Heavy rainfall events, and maximum probable frequency of Heavy, Very Heavy & Extremely Heavy rainfall events. For extracting maximum probable frequency, we have considered the maximum frequency among all the raingauge stations in the district for the selected period. The hazard caused by the extreme rainfall event is generally not limited to a point station where the observation is made but may spread wider areas of the district and cause an impact on increasing flood events, water quality, health, and other societal problems. Thus the climatology of the frequency of extreme rainfall events is helpful to identify the districts vulnerable to frequent extreme rainfall events.

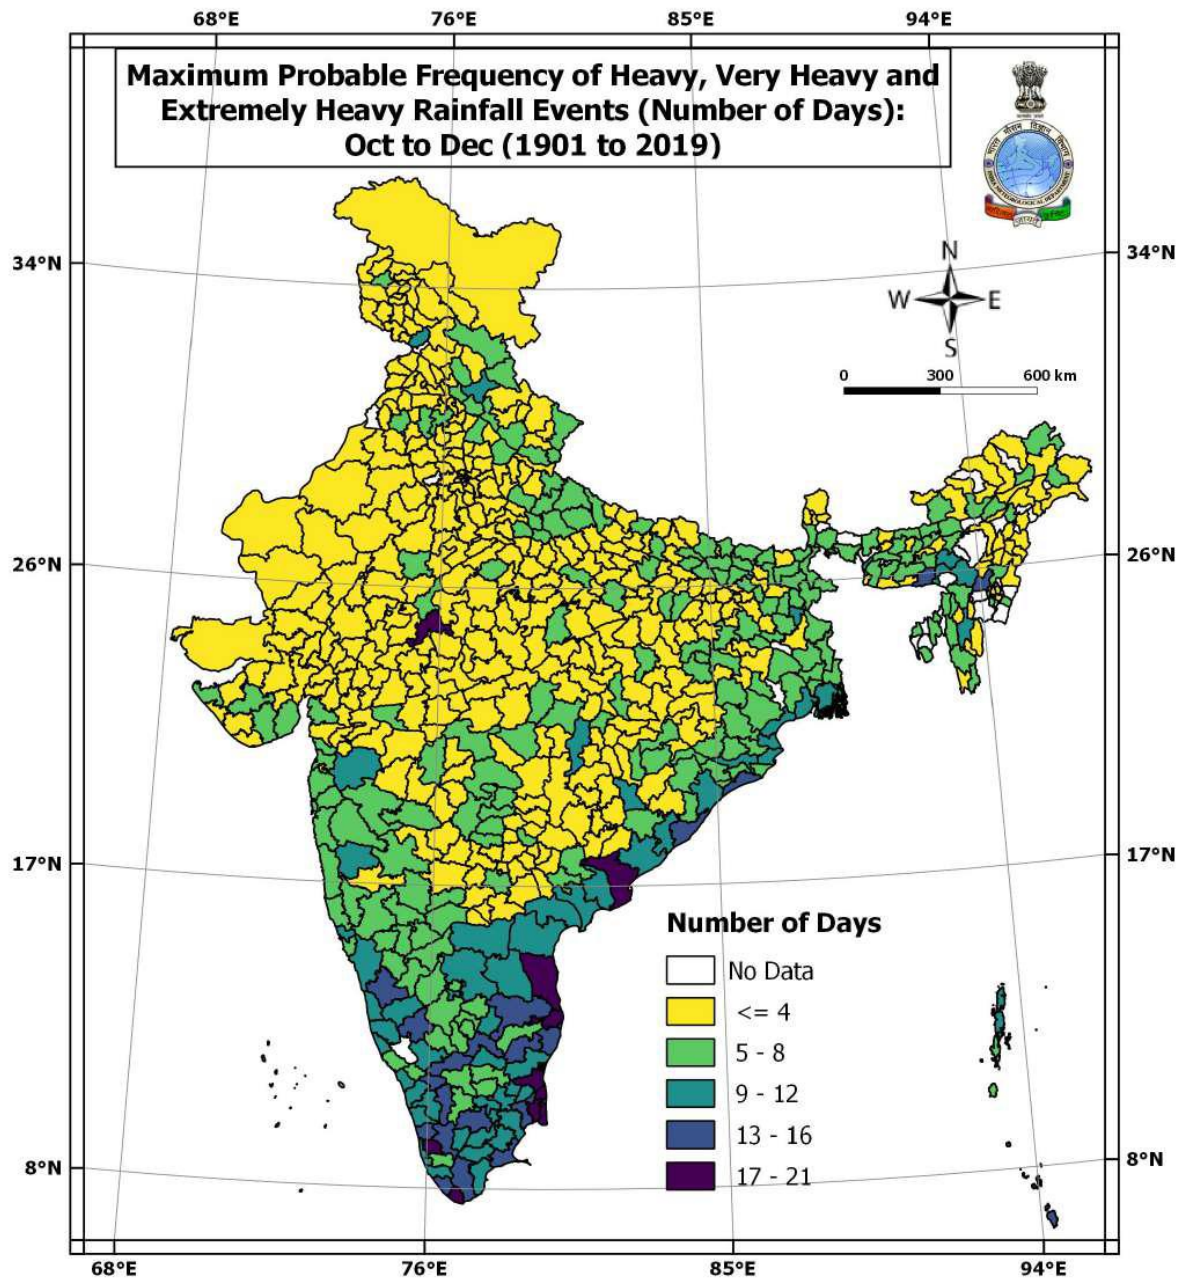

The terminologies used by the India Meteorological Department for different categories of Intensity of Rainfall (in 24 hours):

S. No.	Terminology	Rainfall range in mm	Rainfall range in cm	Percentile
1	Very Light Rainfall	Trace-2.4		
2	Light Rainfall	2.5-15.5	Upto 1	Upto 65
3	Moderate Rainfall	15.6-64.4	02-06	65-95
4	Heavy Rainfall	64.5-115.5	07-11	95-99
5	Very Heavy Rainfall	115.6-204.4	12-20	99-99.9
6	Extremely Heavy RF	≥ 204.5	21 cm or more	>99.9
7	Exceptionally Heavy RF	When the amount is a value near about the highest recorded rainfall at or near the station for the month or season. However, this term will be used only when the actual rainfall amount exceeds 12 cm.		

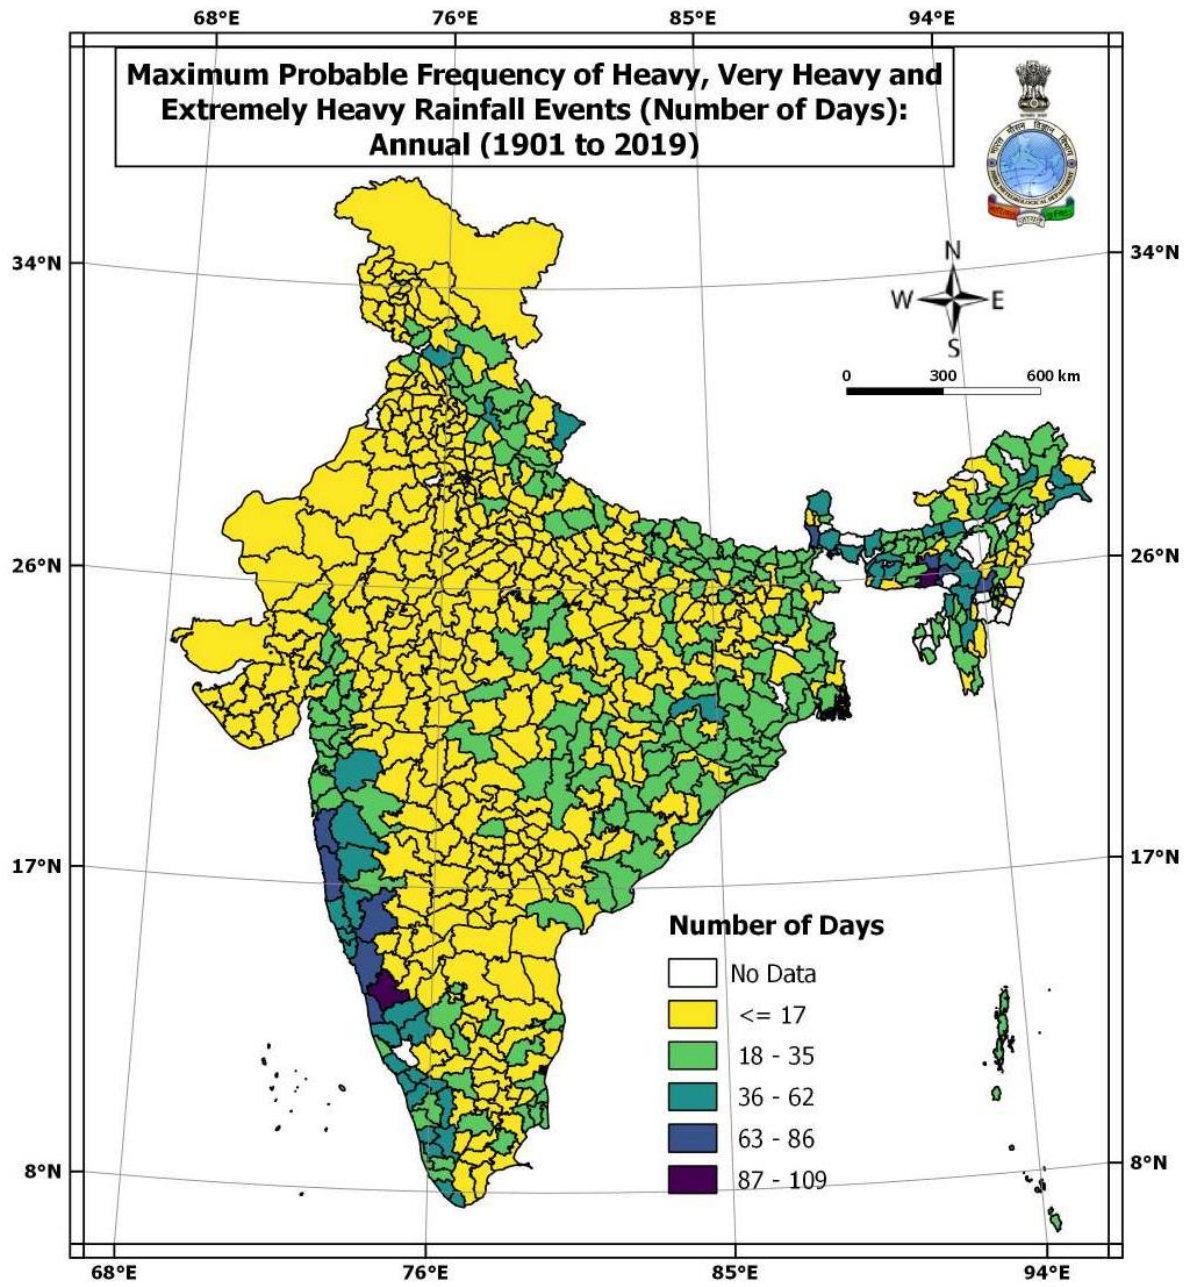

**However, the extreme rainfall analysis is done only for three categories viz., Heavy RF, Very Heavy RF and Extremely Heavy RF. The figures below give the**

maximum probable frequency of all categories of Heavy RF events for the two monsoon seasons and on Annual Scale. The information on the monthly scale for different decades during the period 1951-2019 is available in the website.

The ever recorded highest rainfall in all the stations in the coastal districts based on the available data for the period (1901-2020) is given in Table 1. The coastal districts are selected based on the paper M. Mohapatra , "Cyclone hazard proneness of districts of India", J. Earth Syst. Sci. 124, No. 3, April 2015, pp. 515-526.

Table -1

## Chapter-3

### Wind Hazard

Extreme wind that may be associated with any weather systems like thunderstorms, cyclones etc is one of the major hazards to the society as the extreme wind can damage any structure, including the building of various types, electrical infrastructure, telecom industry, agriculture, and forest as well as transport and other sectors. We have initially used hourly wind data from 39 IMD autographic stations with 15 years or more data to compute extreme wind. This hourly data also report the daily maximum gusty wind speed. Since the number of autographic data stations is very small, we have also considered daily synoptic hour data of 490 stations with 15 years or more data. From these 490 stations data, we have prepared month-wise annual maximum wind series data for computation of 50 years return period extreme values. Since these 490 synoptic stations are not reporting gusty wind speed, 50 years of extreme return values were first extracted to represent extreme gusty wind speed. Then the relation between hourly extreme values and maximum gust wind speed for 39 autographic stations were obtained and average over all the 39 stations to establish the relationship between maximum wind and gusty wind over India. We have then multiplied this factor to 50 years return period extreme values obtained from annual maximum series to obtain 50 years return period extreme values of maximum gusty wind speed of 490 stations. Using QGIS raster statistics, finally, monthly wind hazard maps are prepared for 12 months and for annual. In addition, the Normalized Vulnerability Index is being calculated for each district as per the formula mentioned in equation 1.

The Annual extreme wind speed districtwise is given in the figure below. The monthly figures are available on the website.

## Chapter-4

### Cyclones

India Meteorological Department (IMD) monitors and provides impact-based early warning services for various meteorological disaster events at different temporal and spatial scales to support disaster risk reduction management. As a part of these services, IMD has now prepared a Web version of Climate Hazards and Vulnerability Atlas of India for the thirteen most hazardous meteorological events, viz. Cold wave, Heat Wave, Flood, Lightning, Snowfall, Dust Storm, Hail Storm, Thunderstorm, Fog, Strong winds, Extreme rainfall, Drought and Cyclone that cause loss of life, injury or other health impacts, property damage, loss of livelihoods and services, social and economic disruption or environmental damage. The web Atlas is depicted using Geographic Information System (GIS) tools and is made available in IMD, Pune website (<https://www.imdpune.gov.in/hazardatlas/index.html>). The Atlas provides districts maps on Hazard events and vulnerability for all the calendar months and at annual scale. The Hazard maps are prepared based on the climatological data, census data on population and housing density and using different statistical and mathematical methods.

**Cyclone:** It is one of the major meteorological disasters in coastal areas of India. Cyclones are intense low-pressure areas from the center of which pressure increases outwards. The amount of pressure drop in the center and the rate at which it increases outwards gives the intensity of the cyclones and the strength of winds. The criteria followed by the India Meteorological Department (IMD) to classify the low pressure systems in the Bay of Bengal and in the Arabian Sea as adopted by the World Meteorological Organisation (W.M.O.) are given in the following Table:

**Table: Criteria for classification of cyclonic disturbances over the North Indian Ocean**

Type of disturbance	Associated maximum sustained wind
1. Low Pressure Area	Not exceeding 17 knots (<31 kmph )
2. Depression(D)	17 to 27 knots (31-49 kmph)
3. Deep Depression(DD)	28 to 33 knots (50-61 kmph )
4. Cyclonic Storm(CS)	34 to 47 knots (62-88 kmph )
5. Severe Cyclonic Storm(SCS)	48 to 63 knots (89-117 kmph )
6. Very Severe Cyclonic	64 to 119 knots (118-221 kmph )
7. Super Cyclonic Storm	120 knots and above ( $\geq$ 222 kmph )

We have considered IMD Cyclone data from Cyclone e Atlas for the period 1961-2020 for computation of several parameters. Since in cyclone eAtlas information on cyclone is combined for SCS, VCS and Super Cyclonic Storm and termed as SCS, in all our maps we have produced the information on Cyclonic Storm (CS) and

Severe Cyclonic Storm (that combined SCS, VCS and Super Cyclonic Storm). In order view the climate vulnerability of cyclones in various decades, the information is made available for different decades and periods viz. 1961-70, 1971-80, 1981-1990, 1991-2000, 2001-2010, 2011-2020 and 1961-2020. The user has to select the period from the drop-down menu available while clicking on cyclone. After selecting the desired period/decade, one can get the vulnerability maps.

**Cyclone return periods** (CS, SCS, and combining CS and SCS) are computed in coastal districts for all the month and annual scale. The methodology is based on computing the Hurricane return period by NOAA. Cyclone return periods are the frequency at which a certain cyclone intensity can be expected within a given distance of a given location within a specified buffer zone around the district (we have considered 50 nm as a buffer zone). (Ref: NOAA Technical Memorandum NWS NHC 38). Cyclone return periods maps are given for CS, SCS and ALL categories.

The **maximum probable precipitation** of each district corresponding to cyclone days is computed from the daily station rainfall data for the period. Considering the horizontal scales of the cyclone and their effect in producing rainfall in the broader area, a buffer zone of 2.5° around each district is used. Also, to identify the rainfall related to cyclone activity only, we have considered the rainfall of all the stations for the cyclone days and within 500 km of the cyclone location. These maps are made on a monthly and annual scale.

**Cyclone Landfall Count** for each district gives the total number of cyclone (of any intensities) made landfall over the district during the period. These maps are made for all the months and on an annual scale.

For the computation of **Maximum sustained wind** in each district IMD Best Track Cyclone data for the period 1981-2020 is used, and the same buffer zone of 2.5° is considered. This map is made for an annual scale.

**Maximum Storm surge** heights map in annual scale gives the maximum storm surge heights in meter each of the coastal district experienced so far associated with cyclone.

We have also considered population density data and housing density data from Census data. The **Normalized vulnerability index** is calculated as described by equation 1 for each parameter viz. maximum probable precipitation, cyclone return period, maximum sustained wind, storm surge height, housing, and population density. Finally, weighted average **Normalized Cyclone Vulnerability index** is computed with suitable weights.

Here few maps are given as example for annual all intensities (CS and SCS) Cyclone return period, Maximum Probable precipitation, Cyclone Landfall count and Normalized Cyclone Vulnerability index etc. All other maps of different categories cyclone in various period can be downloaded from the e book of "Climate Hazard

and Vulnerability Atlas of India” (chrome-extension:https://imdpune.gov.in/hazardatlas/hazard.pdf) These maps are made on an annual scale.
