0.0.1 Welcome to mlxtend's documentation!

Mlxtend (machine learning extensions) is a Python library of useful tools for the day-to-day data science tasks.

0.2 Examples

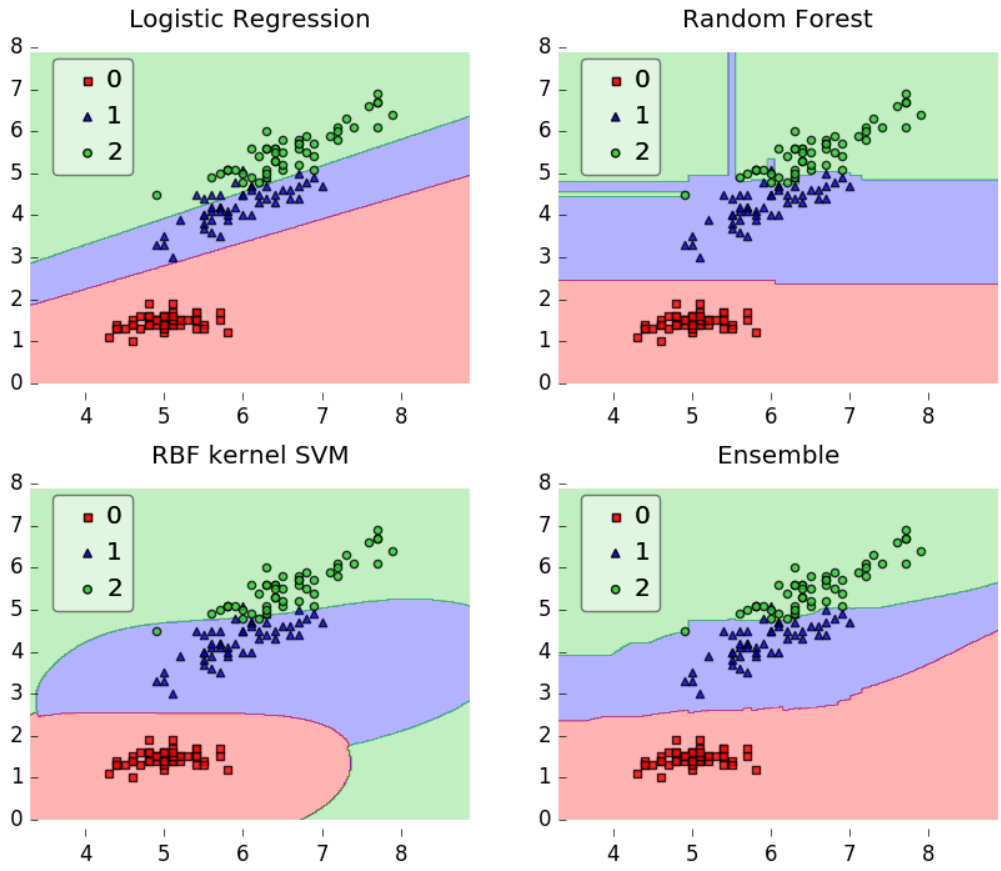
```
import numpy as np
import matplotlib.pyplot as plt
import matplotlib.gridspec as gridspec
import itertools
from sklearn.linear_model import LogisticRegression
from sklearn.svm import SVC
from sklearn.ensemble import RandomForestClassifier
from mlxtend.classifier import EnsembleVoteClassifier
from mlxtend.data import iris_data
from mlxtend.plotting import plot_decision_regions

# Initializing Classifiers
clf1 = LogisticRegression(random_state=0)
clf2 = RandomForestClassifier(random_state=0)
clf3 = SVC(random_state=0, probability=True)
eclf = EnsembleVoteClassifier(clfs=[clf1, clf2, clf3],
                              weights=[2, 1, 1], voting='soft')

# Loading some example data
X, y = iris_data()
X = X[:,[0, 2]]

# Plotting Decision Regions

gs = gridspec.GridSpec(2, 2)
fig = plt.figure(figsize=(10, 8))
```



```
labels = ['Logistic Regression',
          'Random Forest',
          'RBF kernel SVM',
          'Ensemble']

for clf, lab, grd in zip([clf1, clf2, clf3, eclf],
                         labels,
                         itertools.product([0, 1],
                         repeat=2)):
    clf.fit(X, y)
    ax = plt.subplot(gs[grd[0], grd[1]])
    fig = plot_decision_regions(X=X, y=y,
                                clf=clf, legend=2)
    plt.title(lab)

plt.show()
```

If you use mlxtend as part of your workflow in a scientific publication, please consider citing the mlxtend repository with the following DOI:

0.4 Contact

I received a lot of feedback and questions about mlxtend recently, and I thought that it would be worthwhile to set up a public communication channel. Before you write an email with a question about mlxtend, please consider posting it here since it can also be useful to others! Please join the Google Groups Mailing List!

If Google Groups is not for you, please feel free to write me an email or consider filing an issue on GitHub's issue tracker for new feature requests or bug reports. In addition, I setup a Gitter channel for live discussions.

1 classifier.Adaline

An implementation of the ADAptive LInear NEuron, Adaline, for binary classification tasks.

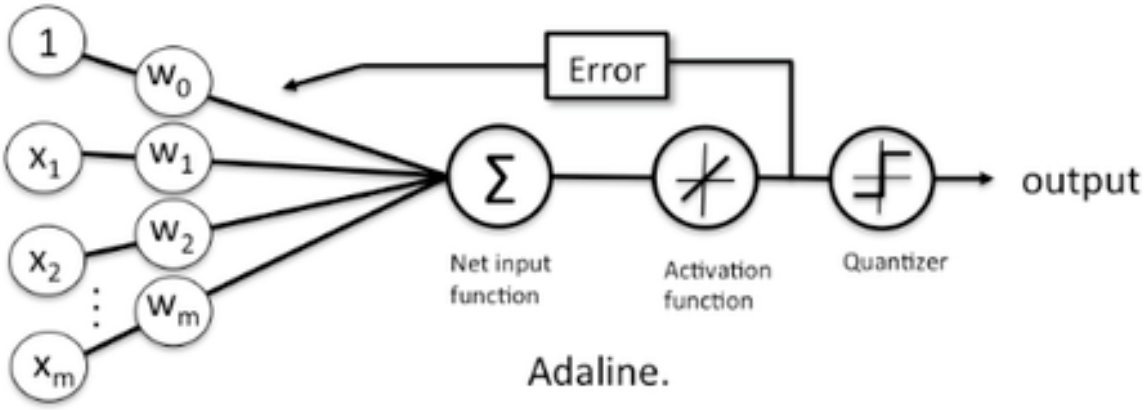
```
from mlxtend.classifier import Adaline
```

1.1 Overview

An illustration of the ADAptive LInear NEuron (Adaline) – a single-layer artificial linear neuron with a threshold unit:

The Adaline classifier is closely related to the Ordinary Least Squares (OLS) Linear Regression algorithm; in OLS regression we find the line (or hyperplane) that minimizes the vertical offsets. Or in other words, we define the best-fitting line as the line that minimizes the sum of squared errors (SSE) or mean squared error (MSE) between our target variable (y) and our predicted output over all samples i in our dataset of size n.

$$SSE = \sum_i (\text{target}^{(i)} - \text{output}^{(i)})^2$$



$$MSE = \frac{1}{n} \times SSE$$

LinearRegression implements a linear regression model for performing ordinary least squares regression, and in Adaline, we add a threshold function $g(\cdot)$ to convert the continuous outcome to a categorical class label:

$$y = g(z) = \begin{cases} 1 & \text{if z} \geq 0 \\ -1 & \text{otherwise.} \end{cases}$$

An Adaline model can be trained by one of the following three approaches:

- Normal Equations
- Gradient Descent
- Stochastic Gradient Descent

1.1.1 Normal Equations (closed-form solution)

The closed-form solution should be preferred for "smaller" datasets where calculating (a "costly") matrix inverse is not a concern. For very large datasets, or datasets where the inverse of $[X^T X]$ may not exist (the matrix is non-invertible or singular, e.g., in case of perfect multicollinearity), the gradient descent or stochastic gradient descent approaches are to be preferred.

The linear function (linear regression model) is defined as:

$$z = w_0 x_0 + w_1 x_1 + ... + w_m x_m = \sum_{j=0}^{m} w_j x_j = \mathbf{w}^T \mathbf{x}$$

where y is the response variable, $\mathbf{x}$ is an m-dimensional sample vector, and $\mathbf{w}$ is the weight vector (vector of coefficients). Note that w_0 represents the y-axis intercept of the model and therefore $x_0 = 1$.

Using the closed-form solution (normal equation), we compute the weights of the model as follows:

$$\mathbf{w} = (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T y$$

1.1.2 Gradient Descent (GD) and Stochastic Gradient Descent (SGD)

In the current implementation, the Adaline model is learned via Gradient Descent or Stochastic Gradient Descent.

See Gradient Descent and Stochastic Gradient Descent and Deriving the Gradient Descent Rule for Linear Regression and Adaline for details.

Random shuffling is implemented as:

- for one or more epochs
  - randomly shuffle samples in the training set
    - for training sample i
      - compute gradients and perform weight updates

1.2 Example 1 - Closed Form Solution

```
from mlxtend.data import iris_data
from mlxtend.plotting import plot_decision_regions
from mlxtend.classifier import Adaline
import matplotlib.pyplot as plt

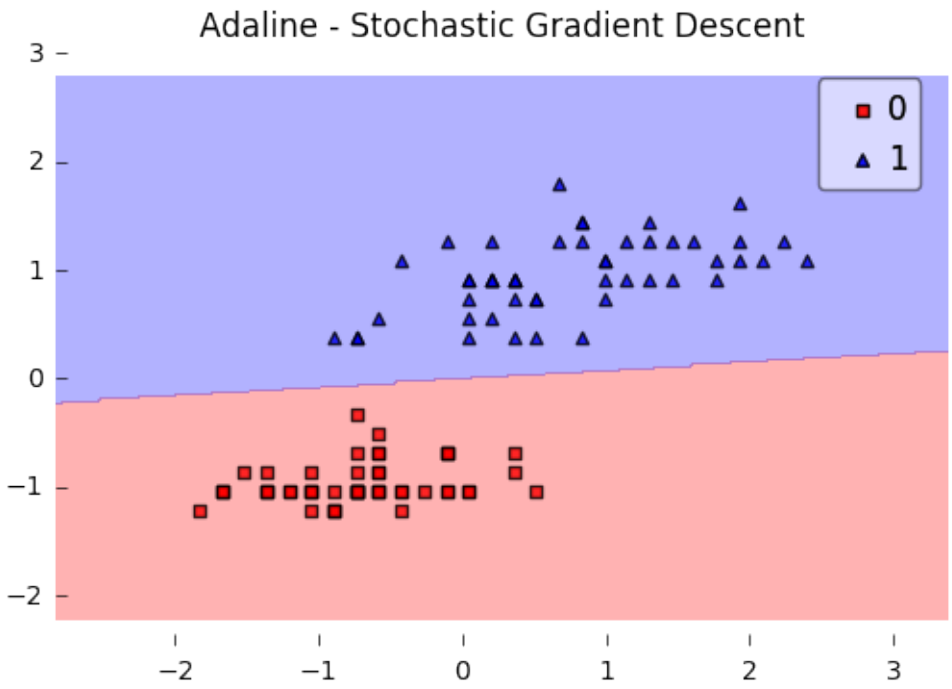
# Loading Data

X, y = iris_data()
X = X[:, [0, 3]] # sepal length and petal width
X = X[0:100] # class 0 and class 1
y = y[0:100] # class 0 and class 1

# standardize
X[:,0] = (X[:,0] - X[:,0].mean()) / X[:,0].std()
X[:,1] = (X[:,1] - X[:,1].mean()) / X[:,1].std()

ada = Adaline(epochs=30,
              eta=0.01,
              minibatches=None,
              random_seed=1)
ada.fit(X, y)
plot_decision_regions(X, y, clf=ada)
plt.title('Adaline - Stochastic Gradient Descent')

plt.show()
```



1.3 Example 2 - Gradient Descent

```
from mlxtend.data import iris_data
from mlxtend.plotting import plot_decision_regions
from mlxtend.classifier import Adaline
import matplotlib.pyplot as plt

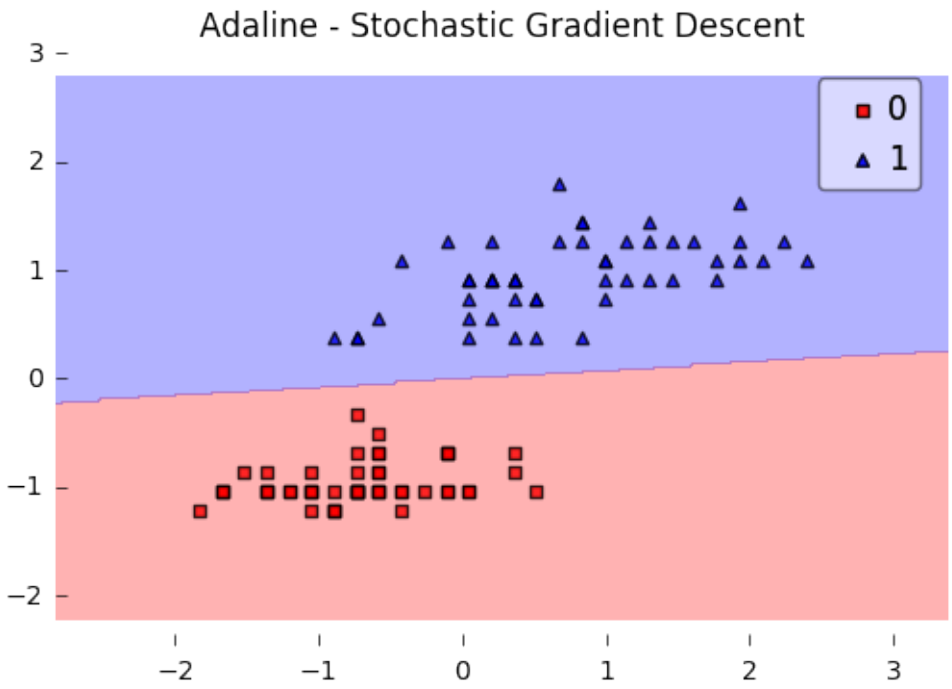
# Loading Data

X, y = iris_data()
X = X[:, [0, 3]] # sepal length and petal width
X = X[0:100] # class 0 and class 1
y = y[0:100] # class 0 and class 1

# standardize
X[:,0] = (X[:,0] - X[:,0].mean()) / X[:,0].std()
X[:,1] = (X[:,1] - X[:,1].mean()) / X[:,1].std()

ada = Adaline(epochs=30,
              eta=0.01,
              minibatches=1, # for Gradient Descent Learning
              random_seed=1,
              print_progress=3)

ada.fit(X, y)
plot_decision_regions(X, y, clf=ada)
plt.title('Adaline - Stochastic Gradient Descent')
```



```
plt.show()
```

```
plt.plot(range(len(ada.cost_)), ada.cost_)
plt.xlabel('Iterations')
plt.ylabel('Cost')
```

```
Iteration: 30/30 | Cost 3.79 | Elapsed: 0:00:00 | ETA: 0:00:00
```

```
<matplotlib.text.Text at 0x10eb32908>
```

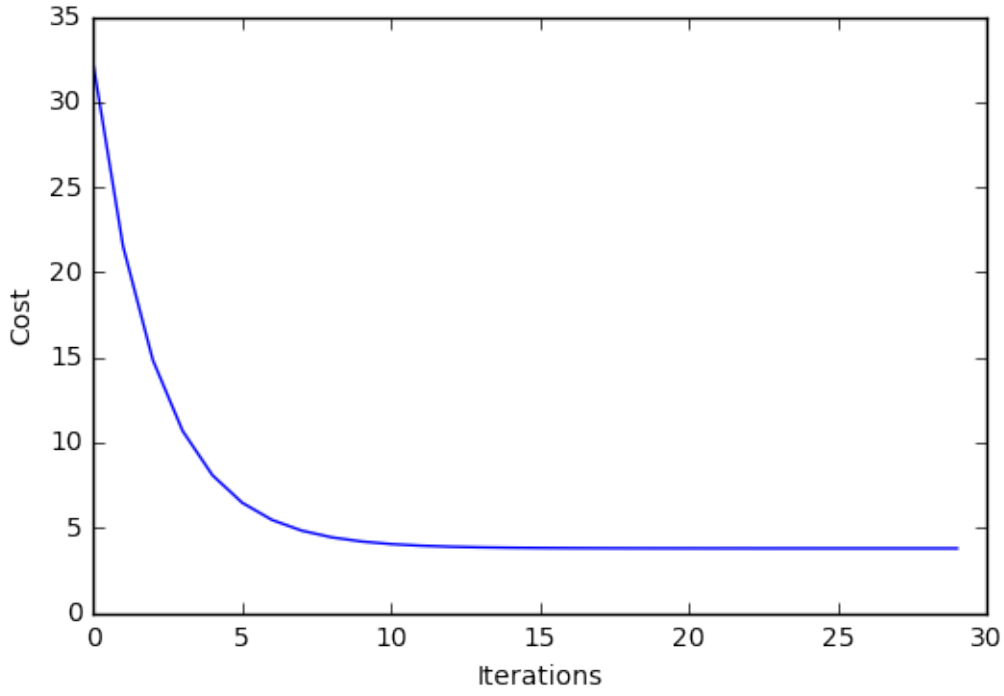
1.4 Example 3 - Stochastic Gradient Descent

```
from mlxtend.data import iris_data
from mlxtend.plotting import plot_decision_regions
from mlxtend.classifier import Adaline
import matplotlib.pyplot as plt

# Loading Data

X, y = iris_data()
X = X[:, [0, 3]] # sepal length and petal width
X = X[0:100] # class 0 and class 1
y = y[0:100] # class 0 and class 1

# standardize
```



```
X[:,0] = (X[:,0] - X[:,0].mean()) / X[:,0].std()
X[:,1] = (X[:,1] - X[:,1].mean()) / X[:,1].std()

ada = Adaline(epochs=15,
              eta=0.02,
              minibatches=len(y), # for SGD learning
              random_seed=1,
              print_progress=3)

ada.fit(X, y)
plot_decision_regions(X, y, clf=ada)
plt.title('Adaline - Stochastic Gradient Descent')
plt.show()

plt.plot(range(len(ada.cost_)), ada.cost_)
plt.xlabel('Iterations')
plt.ylabel('Cost')
plt.show()
```

```
Iteration: 15/15 | Cost 3.81 | Elapsed: 0:00:00 | ETA: 0:00:00
```

1.5 Example 4 - Stochastic Gradient Descent with Minibatches

2 API

Adaline(eta=0.01, epochs=50, minibatches=None, random_seed=None, print_progress=0)

ADAptive LInear NEuron classifier.

Note that this implementation of Adaline expects binary class labels in {0, 1}.

Parameters

- `eta` : float (default: 0.01)

  solver rate (between 0.0 and 1.0)

- `epochs` : int (default: 50)

  Passes over the training dataset. Prior to each epoch, the dataset is shuffled if `minibatches > 1` to prevent cycles in stochastic gradient descent.

- `minibatches` : int (default: None)

  The number of minibatches for gradient-based optimization. If None: Normal Equations (closed-form solution) If 1: Gradient Descent learning If len(y): Stochastic Gradient Descent (SGD) online learning If 1 < minibatches < len(y): SGD Minibatch learning

14

- `random_seed` : int (default: None)
  Set random state for shuffling and initializing the weights.
- `print_progress` : int (default: 0)
  Prints progress in fitting to stderr if not solver='normal equation' 0: No output 1: Epochs elapsed and cost 2: 1 plus time elapsed 3: 2 plus estimated time until completion

Attributes

- `w_` : 2d-array, shape={n_features, 1}
  Model weights after fitting.
- `b_` : 1d-array, shape={1,}
  Bias unit after fitting.
- `cost_` : list
  Sum of squared errors after each epoch.

2.0.1 Methods

fit(X, y, init_params=True)

Learn model from training data.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` : array-like, shape = [n_samples]
  Target values.
- `init_params` : bool (default: True)
  Re-initializes model parameters prior to fitting. Set False to continue training with weights from a previous model fitting.

Returns

- `self` : object

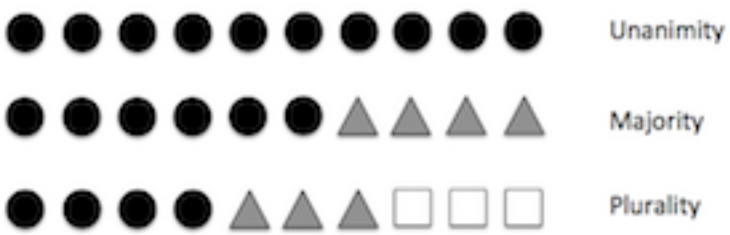
predict(X)

Predict targets from X.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns



- `target_values` : array-like, shape = [n_samples]
  Predicted target values.

score(X, y)

Compute the prediction accuracy

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` : array-like, shape = [n_samples]
  Target values (true class labels).

Returns

- `acc` : float
  The prediction accuracy as a float between 0.0 and 1.0 (perfect score).

3 `classifier.EnsembleVoteClassifier`

Implementation of a majority voting `EnsembleVoteClassifier` for classification.

```
from mlxtend.classifier import EnsembleVoteClassifier
```

4 Overview

The `EnsembleVoteClassifier` is a meta-classifier for combining similar or conceptually different machine learning classifiers for classification via majority or plurality voting. (For simplicity, we will refer to both majority and plurality voting as majority voting.)

The `EnsembleVoteClassifier` implements "hard" and "soft" voting. In hard voting, we predict the final class label as the class label that has been predicted most frequently by the classification models. In soft voting, we predict the class labels by averaging the class-probabilities (only recommended if the classifiers are well-calibrated).

Note

If you are interested in using the EnsembleVoteClassifier, please note that it is now also available through scikit learn (>0.17) as VotingClassifier.

P_f

4.0.1 Majority Voting / Hard Voting

Hard voting is the simplest case of majority voting. Here, we predict the class label $\hat{y}$ via majority (plurality) voting of each classifier C_j:

$$\hat{y} = mode\{C_1(\mathbf{x}), C_2(\mathbf{x}), ..., C_m(\mathbf{x})\}$$

Assuming that we combine three classifiers that classify a training sample as follows:

- classifier 1 -> class 0
- classifier 2 -> class 0
- classifier 3 -> class 1

$$\hat{y} = mode\{0, 0, 1\} = 0$$

Via majority vote, we would we would classify the sample as "class 0."

4.0.2 Weighted Majority Vote

In addition to the simple majority vote (hard voting) as described in the previous section, we can compute a weighted majority vote by associating a weight w_j with classifier C_j:

$$\hat{y} = \arg\max_i \sum_{j=1}^{m} w_j \chi_A\big(C_j(\mathbf{x}) = i\big),$$

where χ_A is the characteristic function $[C_j(\mathbf{x}) = i \ \in A]$, and A is the set of unique class labels.

Continuing with the example from the previous section

- classifier 1 -> class 0
- classifier 2 -> class 0
- classifier 3 -> class 1

assigning the weights {0.2, 0.2, 0.6} would yield a prediction $\hat{y} = 1$:

$$\arg\max_i [0.2 \times i_0 + 0.2 \times i_0 + 0.6 \times i_1] = 1$$

4.0.3 Soft Voting

In soft voting, we predict the class labels based on the predicted probabilities p for classifier – this approach is only recommended if the classifiers are well-calibrated.

$$\hat{y} = \arg\max_i \sum_{j=1}^{m} w_j p_{ij},$$

where w_j is the weight that can be assigned to the jth classifier.

Assuming the example in the previous section was a binary classification task with class labels $i \in \{0, 1\}$, our ensemble could make the following prediction:

- $C_1(\mathbf{x}) \rightarrow [0.9, 0.1]$
- $C_2(\mathbf{x}) \rightarrow [0.8, 0.2]$
- $C_3(\mathbf{x}) \rightarrow [0.4, 0.6]$

Using uniform weights, we compute the average probabilities:

$$p(i_0 \mid \mathbf{x}) = \frac{0.9 + 0.8 + 0.4}{3} = 0.7 p(i_1 \mid \mathbf{x}) = \frac{0.1 + 0.2 + 0.6}{3} = 0.3$$

$$\hat{y} = \arg\max_i \left[p(i_0 \mid \mathbf{x}), p(i_1 \mid \mathbf{x})\right] = 0$$

However, assigning the weights {0.1, 0.1, 0.8} would yield a prediction $\hat{y} = 1$:

$$p(i_0 \mid \mathbf{x}) = 0.1 \times 0.9 + 0.1 \times 0.8 + 0.8 \times 0.4 = 0.49 p(i_1 \mid \mathbf{x}) = 0.1 \times 0.1 + 0.2 \times 0.1 + 0.8 \times 0.6 = 0.51$$

$$\hat{y} = \arg\max_i \left[p(i_0 \mid \mathbf{x}), p(i_1 \mid \mathbf{x})\right] = 1$$

4.1 Example 1 - Classifying Iris Flowers Using Different Classification Models

```
from sklearn import datasets

iris = datasets.load_iris()
X, y = iris.data[:, 1:3], iris.target

from sklearn import model_selection
from sklearn.linear_model import LogisticRegression
from sklearn.naive_bayes import GaussianNB
from sklearn.ensemble import RandomForestClassifier
import numpy as np

clf1 = LogisticRegression(random_state=1)
clf2 = RandomForestClassifier(random_state=1)
clf3 = GaussianNB()

print('5-fold cross validation:\n')

labels = ['Logistic Regression', 'Random Forest', 'Naive Bayes']

for clf, label in zip([clf1, clf2, clf3], labels):

    scores = model_selection.cross_val_score(clf, X, y,
                                             cv=5,
                                             scoring='accuracy')
    print("Accuracy: %0.2f (+/- %0.2f) [%s]"
          % (scores.mean(), scores.std(), label))
```

```
5-fold cross validation:

Accuracy: 0.90 (+/- 0.05) [Logistic Regression]
Accuracy: 0.93 (+/- 0.05) [Random Forest]
Accuracy: 0.91 (+/- 0.04) [Naive Bayes]
```

```
from mlxtend.classifier import EnsembleVoteClassifier

eclf = EnsembleVoteClassifier(clfs=[clf1, clf2, clf3], weights=[1,1,1])

labels = ['Logistic Regression', 'Random Forest', 'Naive Bayes', 'Ensemble']
for clf, label in zip([clf1, clf2, clf3, eclf], labels):

    scores = model_selection.cross_val_score(clf, X, y,
                                             cv=5,
                                             scoring='accuracy')
    print("Accuracy: %0.2f (+/- %0.2f) [%s]"
          % (scores.mean(), scores.std(), label))
```

```
Accuracy: 0.90 (+/- 0.05) [Logistic Regression]
Accuracy: 0.93 (+/- 0.05) [Random Forest]
Accuracy: 0.91 (+/- 0.04) [Naive Bayes]
Accuracy: 0.95 (+/- 0.05) [Ensemble]
```

4.1.0.1 Plotting Decision Regions

```
import matplotlib.pyplot as plt
from mlxtend.plotting import plot_decision_regions
import matplotlib.gridspec as gridspec
import itertools

gs = gridspec.GridSpec(2, 2)

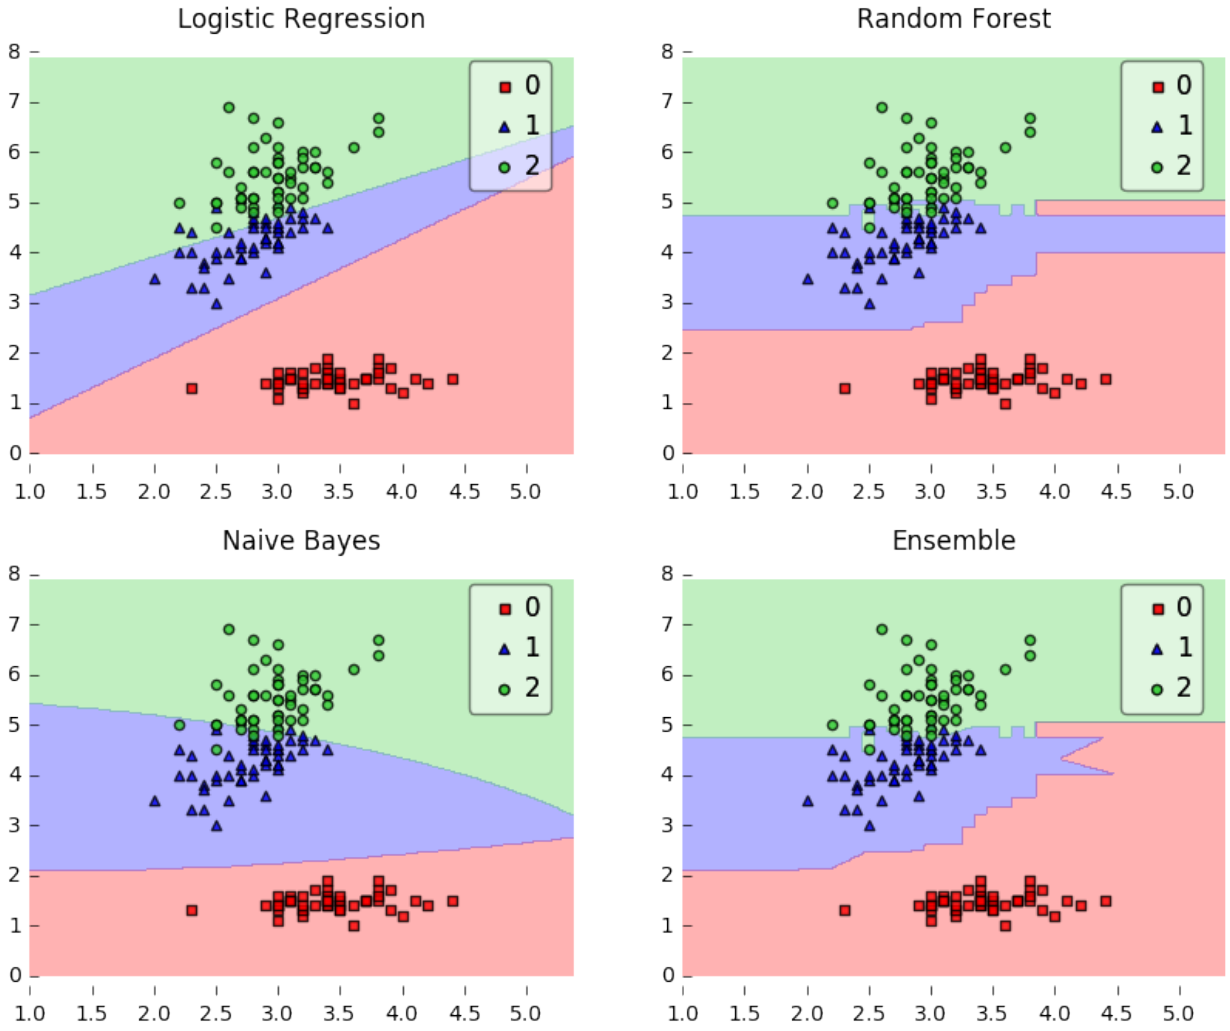
fig = plt.figure(figsize=(10,8))

labels = ['Logistic Regression', 'Random Forest', 'Naive Bayes', 'Ensemble']
for clf, lab, grd in zip([clf1, clf2, clf3, eclf],
                         labels,
                         itertools.product([0, 1], repeat=2)):

    clf.fit(X, y)
    ax = plt.subplot(gs[grd[0], grd[1]])
    fig = plot_decision_regions(X=X, y=y, clf=clf)
    plt.title(lab)
```

```
import matplotlib.pyplot as plt
from mlxtend.plotting import plot_decision_regions
import matplotlib.gridspec as gridspec
import itertools

gs = gridspec.GridSpec(2, 2)
```



Logistic Regression

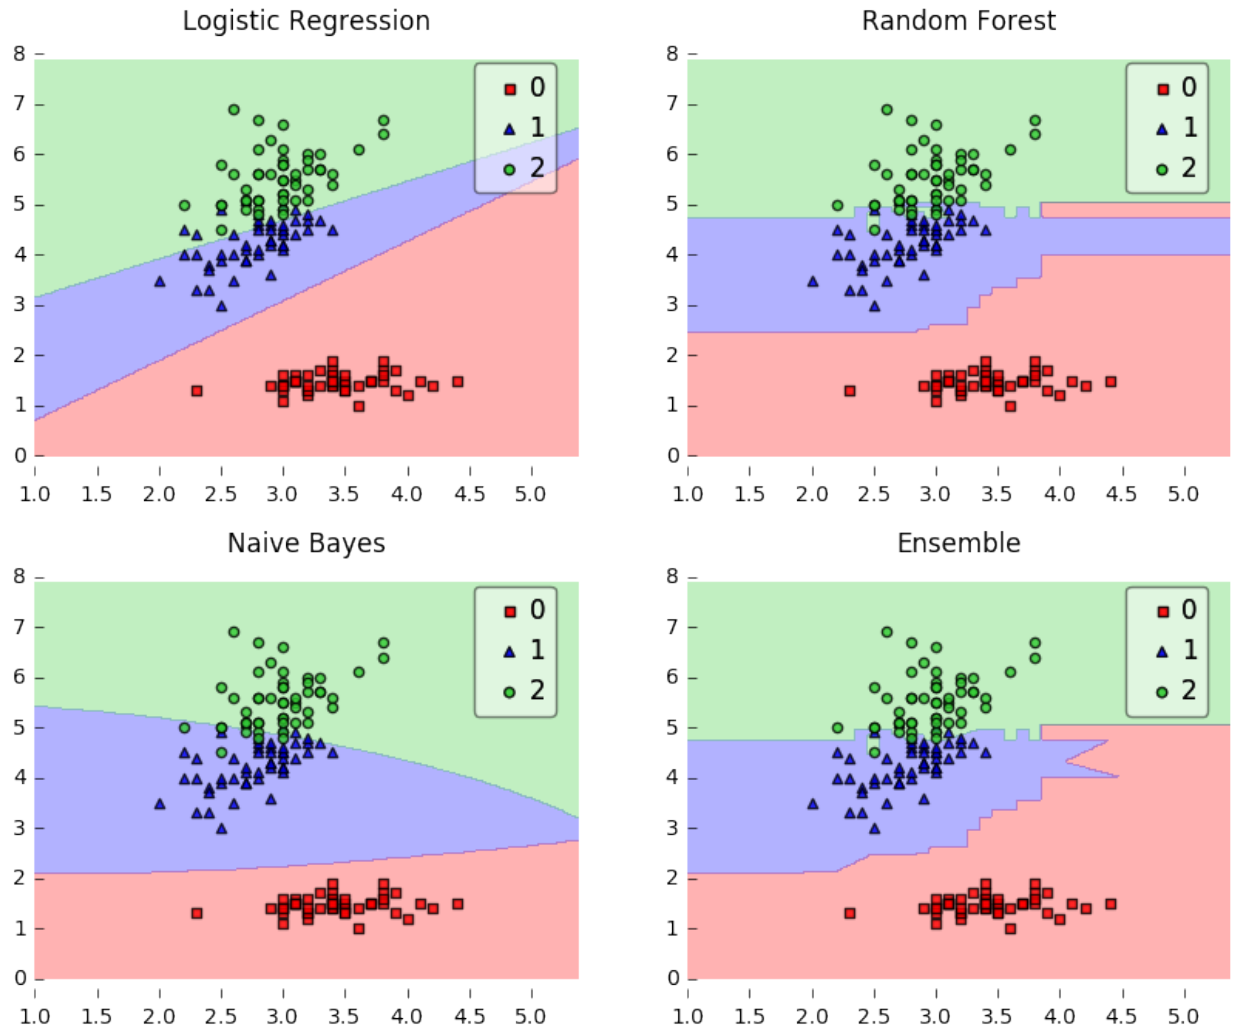
1.0 1.5 2.0 2.5 3.0 3.5 4.0 4.5 5.0



```
fig = plt.figure(figsize=(10,8))

labels = ['Logistic Regression', 'Random Forest', 'Naive Bayes', 'Ensemble']
for clf, lab, grd in zip([clf1, clf2, clf3, eclf],
                         labels,
                         itertools.product([0, 1], repeat=2)):

    clf.fit(X, y)
    ax = plt.subplot(gs[grd[0], grd[1]])
    fig = plot_decision_regions(X=X, y=y, clf=clf)
    plt.title(lab)
```

4.2 Example 2 - Grid Search

```
from sklearn import datasets
```

```
iris = datasets.load_iris()
X, y = iris.data[:, 1:3], iris.target

from sklearn.model_selection import GridSearchCV
from sklearn.linear_model import LogisticRegression
from sklearn.naive_bayes import GaussianNB
from sklearn.ensemble import RandomForestClassifier
from mlxtend.classifier import EnsembleVoteClassifier

clf1 = LogisticRegression(random_state=1)
clf2 = RandomForestClassifier(random_state=1)
clf3 = GaussianNB()
eclf = EnsembleVoteClassifier(clfs=[clf1, clf2, clf3], voting='soft')

params = {'logisticregression__C': [1.0, 100.0],
          'randomforestclassifier__n_estimators': [20, 200],}

grid = GridSearchCV(estimator=eclf, param_grid=params, cv=5)
grid.fit(iris.data, iris.target)

cv_keys = ('mean_test_score', 'std_test_score', 'params')

for r, _ in enumerate(grid.cv_results_['mean_test_score']):
    print("%0.3f +/- %0.2f %r"
          % (grid.cv_results_[cv_keys[0]][r],
             grid.cv_results_[cv_keys[1]][r] / 2.0,
             grid.cv_results_[cv_keys[2]][r]))

0.953 +/- 0.01 {'logisticregression__C': 1.0, 'randomforestclassifier__n_estimators': 20}
0.960 +/- 0.01 {'logisticregression__C': 1.0, 'randomforestclassifier__n_estimators': 200}
0.960 +/- 0.01 {'logisticregression__C': 100.0, 'randomforestclassifier__n_estimators': 20}
0.953 +/- 0.02 {'logisticregression__C': 100.0, 'randomforestclassifier__n_estimators': 200}
```

Note: If the `EnsembleClassifier` is initialized with multiple similar estimator objects, the estimator names are modified with consecutive integer indices, for example:

```
clf1 = LogisticRegression(random_state=1)
clf2 = RandomForestClassifier(random_state=1)
eclf = EnsembleVoteClassifier(clfs=[clf1, clf1, clf2],
                              voting='soft')

params = {'logisticregression-1__C': [1.0, 100.0],
          'logisticregression-2__C': [1.0, 100.0],
          'randomforestclassifier__n_estimators': [20, 200],}

grid = GridSearchCV(estimator=eclf, param_grid=params, cv=5)
grid = grid.fit(iris.data, iris.target)
```

Note

The `EnsembleVoteClass` also enables grid search over the `clfs` argument. However, due to the current implementation of `GridSearchCV` in scikit-learn, it is not possible to search over both, differenct classifiers and classifier parameters at the same time. For instance, while the following parameter dictionary works

```
params = {'randomforestclassifier__n_estimators': [1, 100],
'clfs': [(clf1, clf1, clf1), (clf2, clf3)]}
```

it will use the instance settings of `clf1`, `clf2`, and `clf3` and not overwrite it with the `'n_estimators'` settings from `'randomforestclassifier__n_estimators': [1, 100]`.

4.3 Example 3 - Majority voting with classifiers trained on different feature subsets

Feature selection algorithms implemented in scikit-learn as well as the `SequentialFeatureSelector` implement a `transform` method that passes the reduced feature subset to the next item in a `Pipeline`.

For example, the method

```
def transform(self, X):
    return X[:, self.k_feature_idx_]
```

returns the best feature columns, `k_feature_idx_`, given a dataset X.

Thus, we simply need to construct a `Pipeline` consisting of the feature selector and the classifier in order to select different feature subsets for different algorithms. During `fitting`, the optimal feature subsets are automatically determined via the `GridSearchCV` object, and by calling `predict`, the fitted feature selector in the pipeline only passes these columns along, which resulted in the best performance for the respective classifier.

```
from sklearn import datasets

iris = datasets.load_iris()
X, y = iris.data[:, :], iris.target

from sklearn.model_selection import GridSearchCV
from sklearn.linear_model import LogisticRegression
from sklearn.naive_bayes import GaussianNB
from sklearn.ensemble import RandomForestClassifier
from mlxtend.classifier import EnsembleVoteClassifier
from sklearn.pipeline import Pipeline
from mlxtend.feature_selection import SequentialFeatureSelector

clf1 = LogisticRegression(random_state=1)
clf2 = RandomForestClassifier(random_state=1)
clf3 = GaussianNB()

# Creating a feature-selection-classifier pipeline

sfs1 = SequentialFeatureSelector(clf1,
                                 k_features=4,
                                 forward=True,
                                 floating=False,
                                 scoring='accuracy',
                                 verbose=0,
                                 cv=0)
```

```
clf1_pipe = Pipeline([('sfs', sfs1),
                      ('logreg', clf1)])

eclf = EnsembleVoteClassifier(clfs=[clf1_pipe, clf2, clf3],
                              voting='soft')

params = {'pipeline__sfs__k_features': [1, 2, 3],
          'pipeline__logreg__C': [1.0, 100.0],
          'randomforestclassifier__n_estimators': [20, 200]}

grid = GridSearchCV(estimator=eclf, param_grid=params, cv=5)
grid.fit(iris.data, iris.target)

cv_keys = ('mean_test_score', 'std_test_score', 'params')

for r, _ in enumerate(grid.cv_results_['mean_test_score']):
    print("%0.3f +/- %0.2f %r"
          % (grid.cv_results_[cv_keys[0]][r],
             grid.cv_results_[cv_keys[1]][r] / 2.0,
             grid.cv_results_[cv_keys[2]][r]))
```

```
0.953 +/- 0.01 {'pipeline__sfs__k_features': 1, 'pipeline__logreg__C': 1.0, 'randomforestclassifier__n_
0.947 +/- 0.02 {'pipeline__sfs__k_features': 1, 'pipeline__logreg__C': 1.0, 'randomforestclassifier__n_
0.953 +/- 0.01 {'pipeline__sfs__k_features': 2, 'pipeline__logreg__C': 1.0, 'randomforestclassifier__n_
0.947 +/- 0.02 {'pipeline__sfs__k_features': 2, 'pipeline__logreg__C': 1.0, 'randomforestclassifier__n_
0.953 +/- 0.01 {'pipeline__sfs__k_features': 3, 'pipeline__logreg__C': 1.0, 'randomforestclassifier__n_
0.953 +/- 0.02 {'pipeline__sfs__k_features': 3, 'pipeline__logreg__C': 1.0, 'randomforestclassifier__n_
0.947 +/- 0.02 {'pipeline__sfs__k_features': 1, 'pipeline__logreg__C': 100.0, 'randomforestclassifier__
0.953 +/- 0.02 {'pipeline__sfs__k_features': 1, 'pipeline__logreg__C': 100.0, 'randomforestclassifier__
0.947 +/- 0.02 {'pipeline__sfs__k_features': 2, 'pipeline__logreg__C': 100.0, 'randomforestclassifier__
0.947 +/- 0.02 {'pipeline__sfs__k_features': 2, 'pipeline__logreg__C': 100.0, 'randomforestclassifier__
0.960 +/- 0.01 {'pipeline__sfs__k_features': 3, 'pipeline__logreg__C': 100.0, 'randomforestclassifier__
0.953 +/- 0.02 {'pipeline__sfs__k_features': 3, 'pipeline__logreg__C': 100.0, 'randomforestclassifier__
```

The best parameters determined via GridSearch are:

```
grid.best_params_
```

```
{'pipeline__logreg__C': 100.0,
 'pipeline__sfs__k_features': 3,
 'randomforestclassifier__n_estimators': 20}
```

Now, we assign these parameters to the ensemble voting classifier, fit the models on the complete training set, and perform a prediction on 3 samples from the Iris dataset.

```
eclf = eclf.set_params(**grid.best_params_)
eclf.fit(X, y).predict(X[[1, 51, 149]])
```

```
array([0, 1, 2])
```

4.3.0.1 Manual Approach

Alternatively, we can select different columns "manually" using the `ColumnSelector` object. In this example, we select only the first (sepal length) and third (petal length) column for the logistic regression classifier (`clf1`).

```
from mlxtend.feature_selection import ColumnSelector

col_sel = ColumnSelector(cols=[0, 2])

clf1_pipe = Pipeline([('sel', col_sel),
                      ('logreg', clf1)])

eclf = EnsembleVoteClassifier(clfs=[clf1_pipe, clf2, clf3],
                              voting='soft')
eclf.fit(X, y).predict(X[[1, 51, 149]])
```

```
array([0, 1, 2])
```

Furthermore, we can fit the `SequentialFeatureSelector` separately, outside the grid search hyperparameter optimization pipeline. Here, we determine the best features first, and then we construct a pipeline using these "fixed," best features as seed for the `ColumnSelector`:

```
sfs1 = SequentialFeatureSelector(clf1,
                                 k_features=2,
                                 forward=True,
                                 floating=False,
                                 scoring='accuracy',
                                 verbose=1,
                                 cv=0)

sfs1.fit(X, y)

print('Best features', sfs1.k_feature_idx_)

col_sel = ColumnSelector(cols=sfs1.k_feature_idx_)

clf1_pipe = Pipeline([('sel', col_sel),
                      ('logreg', clf1)])
```

```
Features: 2/2

Best features (0, 2)
```

```
eclf = EnsembleVoteClassifier(clfs=[clf1_pipe, clf2, clf3],
                              voting='soft')
eclf.fit(X, y).predict(X[[1, 51, 149]])
```

```
array([0, 1, 2])
```

4.4 Example 5 - Using Pre-fitted Classifiers

```
from sklearn import datasets

iris = datasets.load_iris()
X, y = iris.data[:, 1:3], iris.target
```

Assume that we previously fitted our classifiers:

```
from sklearn import model_selection
from sklearn.linear_model import LogisticRegression
from sklearn.naive_bayes import GaussianNB
from sklearn.ensemble import RandomForestClassifier
import numpy as np

clf1 = LogisticRegression(random_state=1)
clf2 = RandomForestClassifier(random_state=1)
clf3 = GaussianNB()

for clf in (clf1, clf2, clf3):
    clf.fit(X, y)
```

By setting `refit=False`, the `EnsembleVoteClassifier` will not re-fit these classifers to save computational time:

```
from mlxtend.classifier import EnsembleVoteClassifier
import copy
eclf = EnsembleVoteClassifier(clfs=[clf1, clf2, clf3], weights=[1,1,1], refit=False)

labels = ['Logistic Regression', 'Random Forest', 'Naive Bayes', 'Ensemble']

eclf.fit(X, y)

print('accuracy:', np.mean(y == eclf.predict(X)))
```

```
accuracy: 0.973333333333
```

However, please note that `refit=False` is incompatible to any form of cross-validation that is done in e.g., `model_selection.cross_val_score` or `model_selection.GridSearchCV`, etc., since it would require the classifiers to be refit to the training folds. Thus, only use `refit=False` if you want to make a prediction directly without cross-validation.

4.5 Example 6 - Ensembles of Classifiers that Operate on Different Feature Subsets

If desired, the different classifiers can be fit to different subsets of features in the training dataset. The following example illustrates how this can be done on a technical level using scikit-learn pipelines and the `ColumnSelector`:

```
from sklearn.datasets import load_iris
from mlxtend.classifier import EnsembleVoteClassifier
```

```
from mlxtend.feature_selection import ColumnSelector
from sklearn.pipeline import make_pipeline
from sklearn.linear_model import LogisticRegression

iris = load_iris()
X = iris.data
y = iris.target

pipe1 = make_pipeline(ColumnSelector(cols=(0, 2)),
                      LogisticRegression())
pipe2 = make_pipeline(ColumnSelector(cols=(1, 2, 3)),
                      LogisticRegression())

eclf = EnsembleVoteClassifier(clfs=[pipe1, pipe2])

eclf.fit(X, y)

EnsembleVoteClassifier(clfs=[Pipeline(steps=[('columnselector', ColumnSelector(cols=(0, 2))), ('logisti
          intercept_scaling=1, max_iter=100, multi_class='ovr', n_jobs=1,
          penalty='l2', random_state=None, solver='libl...='l2', random_state=None, solver='liblinear',
          verbose=0, warm_start=False))])],
            refit=True, verbose=0, voting='hard', weights=None)
```

5 API

EnsembleVoteClassifier(clfs, voting='hard', weights=None, verbose=0, refit=True)

Soft Voting/Majority Rule classifier for scikit-learn estimators.

Parameters

- `clfs` : array-like, shape = [n_classifiers]

  A list of classifiers. Invoking the `fit` method on the `VotingClassifier` will fit clones of those original classifiers that will be stored in the class attribute `self.clfs_` if `refit=True` (default).

- `voting` : str, {'hard', 'soft'} (default='hard')

  If 'hard', uses predicted class labels for majority rule voting. Else if 'soft', predicts the class label based on the argmax of the sums of the predicted probalities, which is recommended for an ensemble of well-calibrated classifiers.

- `weights` : array-like, shape = [n_classifiers], optional (default=`None`)

  Sequence of weights (`float` or `int`) to weight the occurances of predicted class labels (`hard` voting) or class probabilities before averaging (`soft` voting). Uses uniform weights if `None`.

- `verbose` : int, optional (default=0)

  Controls the verbosity of the building process.

  - `verbose=0` (default): Prints nothing
  - `verbose=1`: Prints the number & name of the clf being fitted
  - `verbose=2`: Prints info about the parameters of the clf being fitted
  - `verbose>2`: Changes `verbose` param of the underlying clf to self.verbose - 2

- `refit` : bool (default: True)

  Refits classifiers in `clfs` if True; uses references to the `clfs`, otherwise (assumes that the classifiers were already fit). Note: refit=False is incompatible to mist scikit-learn wrappers! For instance, if any form of cross-validation is performed this would require the re-fitting classifiers to training folds, which would raise a NotFitterError if refit=False. (New in mlxtend v0.6.)

Attributes

- `classes_` : array-like, shape = [n_predictions]
- `clf` : array-like, shape = [n_predictions]

  The unmodified input classifiers
- `clf_` : array-like, shape = [n_predictions]

  Fitted clones of the input classifiers

Examples

```
>>> import numpy as np
>>> from sklearn.linear_model import LogisticRegression
>>> from sklearn.naive_bayes import GaussianNB
>>> from sklearn.ensemble import RandomForestClassifier
>>> from mlxtend.sklearn import EnsembleVoteClassifier
>>> clf1 = LogisticRegression(random_seed=1)
>>> clf2 = RandomForestClassifier(random_seed=1)
>>> clf3 = GaussianNB()
>>> X = np.array([[-1, -1], [-2, -1], [-3, -2], [1, 1], [2, 1], [3, 2]])
>>> y = np.array([1, 1, 1, 2, 2, 2])
>>> eclf1 = EnsembleVoteClassifier(clfs=[clf1, clf2, clf3],
... voting='hard', verbose=1)
>>> eclf1 = eclf1.fit(X, y)
>>> print(eclf1.predict(X))
[1 1 1 2 2 2]
>>> eclf2 = EnsembleVoteClassifier(clfs=[clf1, clf2, clf3], voting='soft')
>>> eclf2 = eclf2.fit(X, y)
>>> print(eclf2.predict(X))
[1 1 1 2 2 2]
>>> eclf3 = EnsembleVoteClassifier(clfs=[clf1, clf2, clf3],
...                                voting='soft', weights=[2,1,1])
>>> eclf3 = eclf3.fit(X, y)
>>> print(eclf3.predict(X))
[1 1 1 2 2 2]
>>>
```

5.0.1 Methods

fit(X, y)

Learn weight coefficients from training data for each classifier.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  Training vectors, where n_samples is the number of samples and n_features is the number of features.

- `y` : array-like, shape = [n_samples]
  Target values.

Returns

- `self` : object

*fit_transform(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- `X` : numpy array of shape [n_samples, n_features]
  Training set.
- `y` : numpy array of shape [n_samples]
  Target values.

Returns

- `X_new` : numpy array of shape [n_samples, n_features_new]
  Transformed array.

get_params(deep=True)

Return estimator parameter names for GridSearch support.

predict(X)

Predict class labels for X.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `maj` : array-like, shape = [n_samples]
  Predicted class labels.

predict_proba(X)

Predict class probabilities for X.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `avg` : array-like, shape = [n_samples, n_classes]
  Weighted average probability for each class per sample.

score(X, y, sample_weight=None)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

- `X` : array-like, shape = (n_samples, n_features)
  Test samples.
- `y` : array-like, shape = (n_samples) or (n_samples, n_outputs)
  True labels for X.
- `sample_weight` : array-like, shape = [n_samples], optional
  Sample weights.

Returns

- `score` : float
  Mean accuracy of self.predict(X) wrt. y.

*set_params(**params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

transform(X)

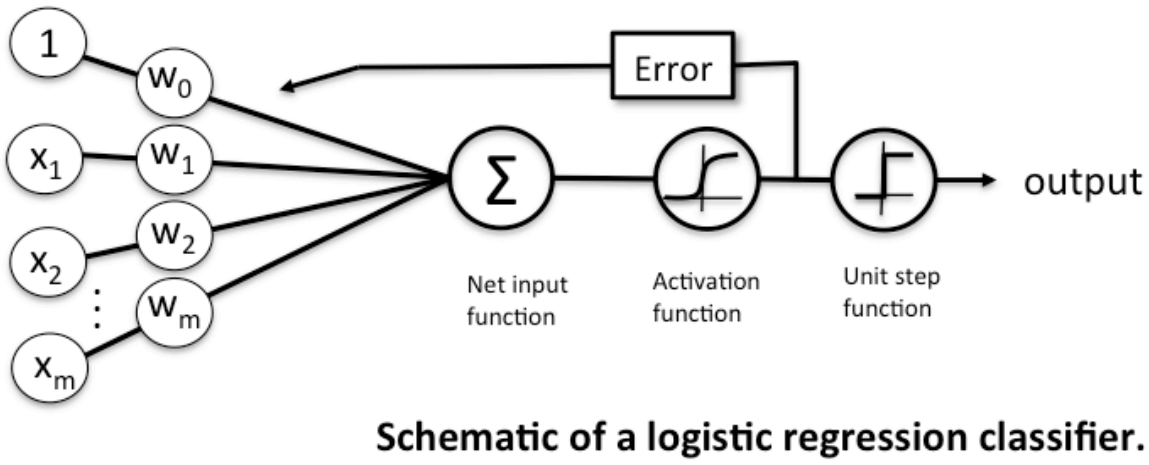
Return class labels or probabilities for X for each estimator.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `If`voting='soft'" : array-like = [n_classifiers, n_samples, n_classes]
  Class probabilties calculated by each classifier.
- `If`voting='hard'" : array-like = [n_classifiers, n_samples]
  Class labels predicted by each classifier.



Schematic of a logistic regression classifier.

6 classifier.LogisticRegression

A logistic regression class for binary classification tasks.

```
from mlxtend.classifier import LogisticRegression
```

6.1 Overview

Related to the `Perceptron` and 'Adaline', a Logistic Regression model is a linear model for binary classification. However, instead of minimizing a linear cost function such as the sum of squared errors (SSE) in Adaline, we minimize a sigmoid function, i.e., the logistic function:

$$\phi(z) = \frac{1}{1 + e^{-z}},$$

where z is defined as the net input

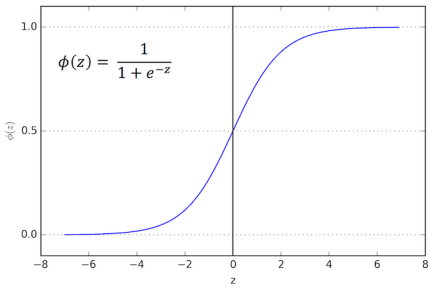
$$z = w_0 x_0 + w_1 x_1 + ... + w_m x_m = \sum_{j=0}^{m} w_j x_j = \mathbf{w}^T \mathbf{x}.$$

The net input is in turn based on the logit function

$$logit(p(y = 1 \mid \mathbf{x})) = z.$$

Here, $p(y = 1 \mid \mathbf{x})$ is the conditional probability that a particular sample belongs to class 1 given its features $\mathbf{x}$. The logit function takes inputs in the range [0, 1] and transform them to values over the entire real number range. In contrast, the logistic function takes input values over the entire real number range and transforms them to values in the range [0, 1]. In other words, the logistic function is the inverse of the logit function, and it lets us predict the conditional probability that a certain sample belongs to class 1 (or class 0).

After model fitting, the conditional probability $p(y = 1 \mid \mathbf{x})$ is converted to a binary class label via a threshold function $g(\cdot)$:



$$y = g(z) = \begin{cases} 1 & \text{if } \phi(z) \geq 0.5 \\ 0 & \text{otherwise.} \end{cases}$$

or equivalently:

$$y = g(z) = \begin{cases} 1 & \text{if z} \geq 0 \\ 0 & \text{otherwise.} \end{cases}$$

6.1.1 Objective Function – Log-Likelihood

In order to parameterize a logistic regression model, we maximize the likelihood $L(\cdot)$ (or minimize the logistic cost function).

We write the likelihood as

$$L(\mathbf{w}) = P(\mathbf{y} \mid \mathbf{x}; \mathbf{w}) = \prod_{i=1}^{n} P\big(y^{(i)} \mid x^{(i)}; \mathbf{w}\big) = \prod_{i=1}^{n} \Big(\phi\big(z^{(i)}\big)\Big)^{y^{(i)}} \Big(1 - \phi\big(z^{(i)}\big)\Big)^{1-y^{(i)}},$$

under the assumption that the training samples are independent of each other.

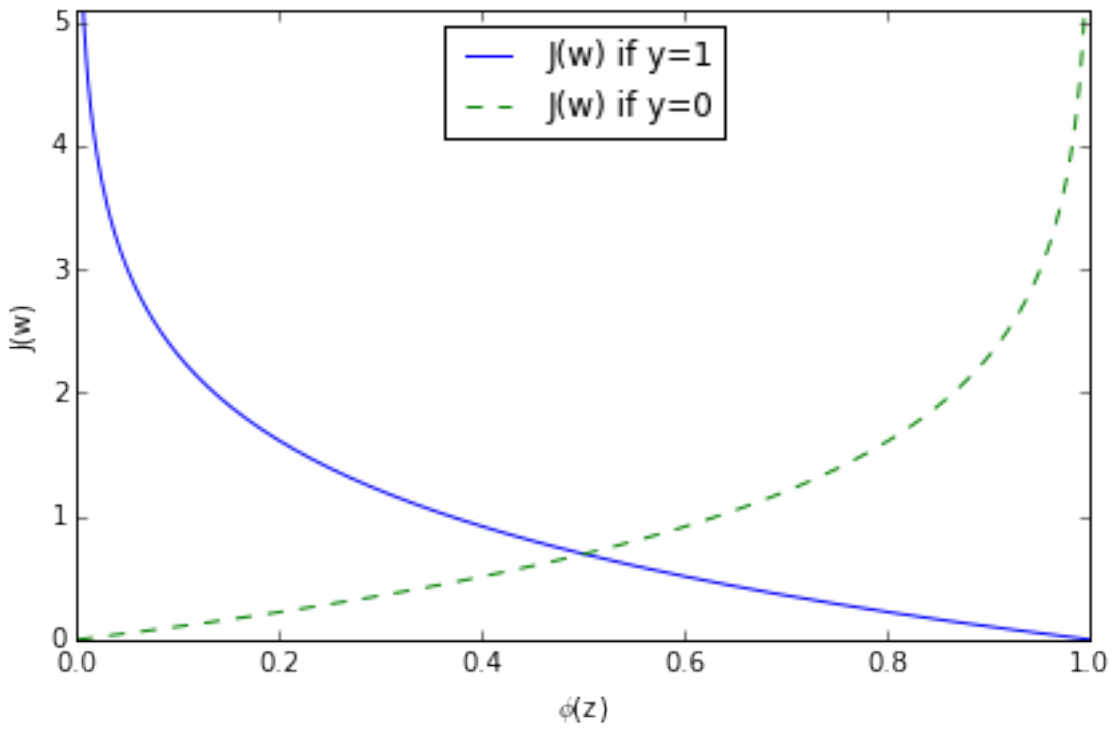
In practice, it is easier to maximize the (natural) log of this equation, which is called the log-likelihood function:

$$l(\mathbf{w}) = \log L(\mathbf{w}) = \sum_{i=1}^{n} y^{(i)} \log\Big(\phi\big(z^{(i)}\big)\Big) + \big(1 - y^{(i)}\big) \log\big(1 - \phi\big(z^{(i)}\big)\big)$$

One advantage of taking the log is to avoid numeric underflow (and challenges with floating point math) for very small likelihoods. Another advantage is that we can obtain the derivative more easily, using the addition trick to rewrite the product of factors as a summation term, which we can then maximize using optimization algorithms such as gradient ascent.

6.1.2 Objective Function – Logistic Cost Function

An alternative to maximizing the log-likelihood, we can define a cost function $J(\cdot)$ to be minimized; we rewrite the log-likelihood as:



$$J(\mathbf{w}) = \sum_{i=1}^{m} -y^{(i)} log\Big(\phi\big(z^{(i)}\big)\Big) - \big(1 - y^{(i)}\big) log\Big(1 - \phi\big(z^{(i)}\big)\Big)$$

$$J\big(\phi(z), y; \mathbf{w}\big) = \begin{cases} -log\big(\phi(z)\big) & \text{if } y = 1 \\ -log\big(1 - \phi(z)\big) & \text{if } y = 0 \end{cases}$$

As we can see in the figure above, we penalize wrong predictions with an increasingly larger cost.

6.1.3 Gradient Descent (GD) and Stochastic Gradient Descent (SGD) Optimization

6.1.3.1 Gradient Ascent and the log-likelihood

To learn the weight coefficient of a logistic regression model via gradient-based optimization, we compute the partial derivative of the log-likelihood function – w.r.t. the jth weight – as follows:

$$\frac{\partial}{\partial w_j} l(\mathbf{w}) = \left(y \frac{1}{\phi(z)} - (1 - y) \frac{1}{1 - \phi(z)} \right) \frac{\partial}{\partial w_j} \phi(z)$$

As an intermediate step, we compute the partial derivative of the sigmoid function, which will come in handy later:

$$\frac{\partial}{\partial z}\phi(z) = \frac{\partial}{\partial z}\frac{1}{1+e^{-z}} \tag{1}$$

$$\tag{2}$$

$$= \frac{1}{(1+e^{-z})^2}e^{-z} \tag{3}$$

$$\tag{4}$$

$$= \frac{1}{1+e^{-z}}\left(1 - \frac{1}{1+e^{-z}}\right) \tag{5}$$

$$\tag{6}$$

$$= \phi(z)\big(1-\phi(z)\big) \tag{7}$$

Now, we re-substitute

$$\frac{\partial}{\partial z}\phi(z) = \phi(z)\big(1-\phi(z)\big)$$

back into in the log-likelihood partial derivative equation and obtain the equation shown below:

$$\left(y\frac{1}{\phi(z)} - (1-y)\frac{1}{1-\phi(z)}\right)\frac{\partial}{\partial w_j}\phi(z) \tag{8}$$

$$\tag{9}$$

$$= \left(y\frac{1}{\phi(z)} - (1-y)\frac{1}{1-\phi(z)}\right)\phi(z)\big(1-\phi(z)\big)\frac{\partial}{\partial w_j}z \tag{10}$$

$$\tag{11}$$

$$= \big(y(1-\phi(z)) - (1-y)\phi(z)\big)x_j \tag{12}$$

$$\tag{13}$$

$$= \big(y-\phi(z)\big)x_j \tag{14}$$

Now, in order to find the weights of the model, we take a step proportional to the positive direction of the gradient to maximize the log-likelihood. Futhermore, we add a coefficient, the learning rate η to the weight update:

$$w_j := w_j + \eta\frac{\partial}{\partial w_j}l(\mathbf{w}) \tag{15}$$

$$\tag{16}$$

$$w_j := w_j + \eta\sum_{i=1}^{n}\big(y^{(i)} - \phi(z^{(i)})\big)x_j^{(i)} \tag{17}$$

Note that the gradient (and weight update) is computed from all samples in the training set in gradient ascent/descent in contrast to stochastic gradient ascent/descent. For more information about the differences between gradient descent and stochastic gradient descent, please see the related article Gradient Descent and Stochastic Gradient Descent.

The previous equation shows the weight update for a single weight j. In gradient-based optimization, all weight coefficients are updated simultaneously; the weight update can be written more compactly as

$$\mathbf{w} := \mathbf{w} + \Delta\mathbf{w},$$

where

$$\Delta \mathbf{w} = \eta \nabla l(\mathbf{w})$$

6.1.3.2 Gradient Descent and the logistic cost function

In the previous section, we derived the gradient of the log-likelihood function, which can be optimized via gradient ascent. Similarly, we can obtain the cost gradient of the logistic cost function $J(\cdot)$ and minimize it via gradient descent in order to learn the logistic regression model.

The update rule for a single weight:

$$\Delta w_j = -\eta \frac{\partial J}{\partial w_j} \tag{18}$$

$$= -\eta \sum_{i=1}^{n} \big(y^{(i)} - \phi\big(z^{(i)}\big) x^{(i)}\big) \tag{19}$$

The simultaneous weight update:

$$\mathbf{w} := \mathbf{w} + \Delta \mathbf{w}$$

where

$$\Delta \mathbf{w} = -\eta \nabla J(\mathbf{w}).$$

6.1.3.3 Shuffling

Random shuffling is implemented as:

- for one or more epochs
  - randomly shuffle samples in the training set
    - for training sample i
      - compute gradients and perform weight updates

6.1.4 Regularization

As a way to tackle overfitting, we can add additional bias to the logistic regression model via a regularization terms. Via the L2 regularization term, we reduce the complexity of the model by penalizing large weight coefficients:

$$L2 : \frac{\lambda}{2} \|\mathbf{w}\|_2 = \frac{\lambda}{2} \sum_{j=1}^{m} w_j^2$$

In order to apply regularization, we just need to add the regularization term to the cost function that we defined for logistic regression to shrink the weights:

$$J(\mathbf{w}) = \sum_{i=1}^{m} \left[-y^{(i)} log\Big(\phi\big(z^{(i)}\big)\Big) - \big(1 - y^{(i)}\big) log\Big(1 - \phi\big(z^{(i)}\big)\Big) \right] + \frac{\lambda}{2} \sum_{j=1}^{m} w_j^2$$

The update rule for a single weight:

$$\Delta w_j = -\eta\left(\frac{\partial J}{\partial w_j} + \lambda w_j\right) \tag{20}$$

$$= -\eta \sum_{i=1}^{n} \left(y^{(i)} - \phi\left(z^{(i)}\right)x^{(i)}\right) - \eta\lambda w_j \tag{21}$$

The simultaneous weight update:

$$\mathbf{w} := \mathbf{w} + \Delta\mathbf{w}$$

where

$$\Delta\mathbf{w} = -\eta\left(\nabla J(\mathbf{w}) + \lambda\mathbf{w}\right).$$

For more information on regularization, please see Regularization of Generalized Linear Models.

6.2 Example 1 - Gradient Descent

```
from mlxtend.data import iris_data
from mlxtend.plotting import plot_decision_regions
from mlxtend.classifier import LogisticRegression
import matplotlib.pyplot as plt

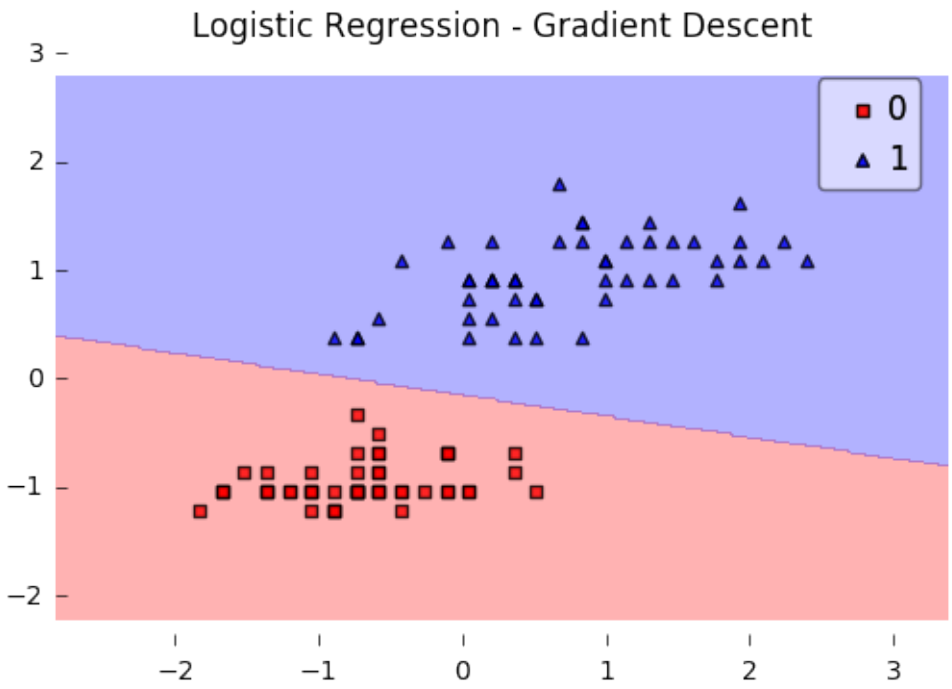
# Loading Data

X, y = iris_data()
X = X[:, [0, 3]] # sepal length and petal width
X = X[0:100] # class 0 and class 1
y = y[0:100] # class 0 and class 1

# standardize
X[:,0] = (X[:,0] - X[:,0].mean()) / X[:,0].std()
X[:,1] = (X[:,1] - X[:,1].mean()) / X[:,1].std()

lr = LogisticRegression(eta=0.1,
                        l2_lambda=0.0,
                        epochs=100,
                        minibatches=1, # for Gradient Descent
                        random_seed=1,
                        print_progress=3)
lr.fit(X, y)

plot_decision_regions(X, y, clf=lr)
plt.title('Logistic Regression - Gradient Descent')
```



```
plt.show()

plt.plot(range(len(lr.cost_)), lr.cost_)
plt.xlabel('Iterations')
plt.ylabel('Cost')
plt.show()

Iteration: 100/100 | Cost 0.32 | Elapsed: 0:00:00 | ETA: 0:00:00
```

6.2.1 Predicting Class Labels

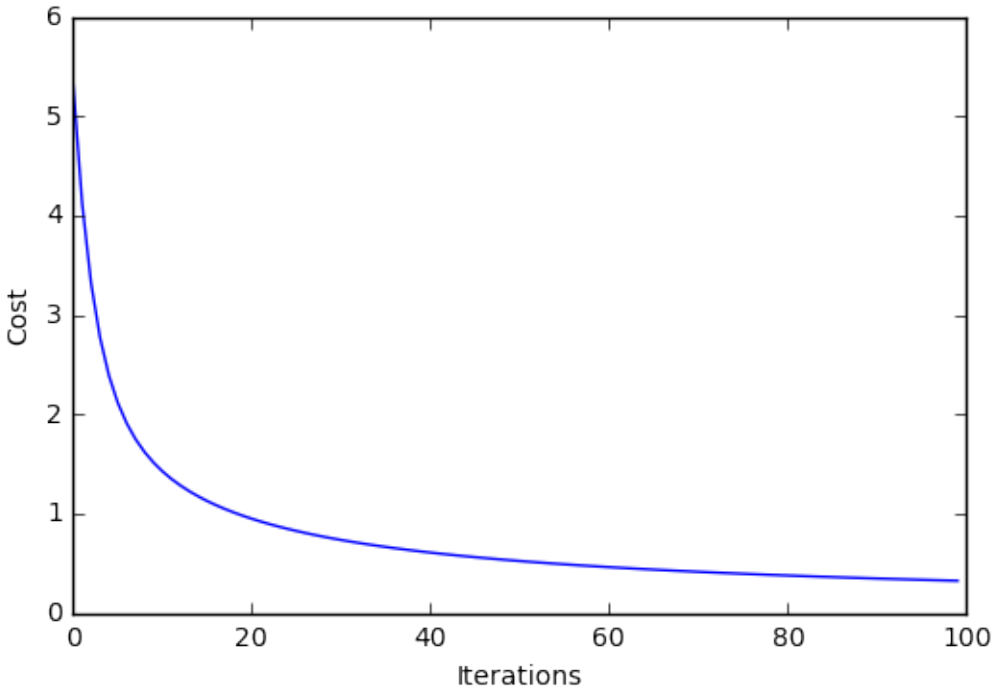
```
y_pred = lr.predict(X)
print('Last 3 Class Labels: %s' % y_pred[-3:])

Last 3 Class Labels: [1 1 1]
```

6.2.2 Predicting Class Probabilities

```
y_pred = lr.predict_proba(X)
print('Last 3 Class Labels: %s' % y_pred[-3:])

Last 3 Class Labels: [ 0.99997968  0.99339873  0.99992707]
```



6.3 Example 2 - Stochastic Gradient Descent

```
from mlxtend.data import iris_data
from mlxtend.plotting import plot_decision_regions
from mlxtend.classifier import LogisticRegression
import matplotlib.pyplot as plt

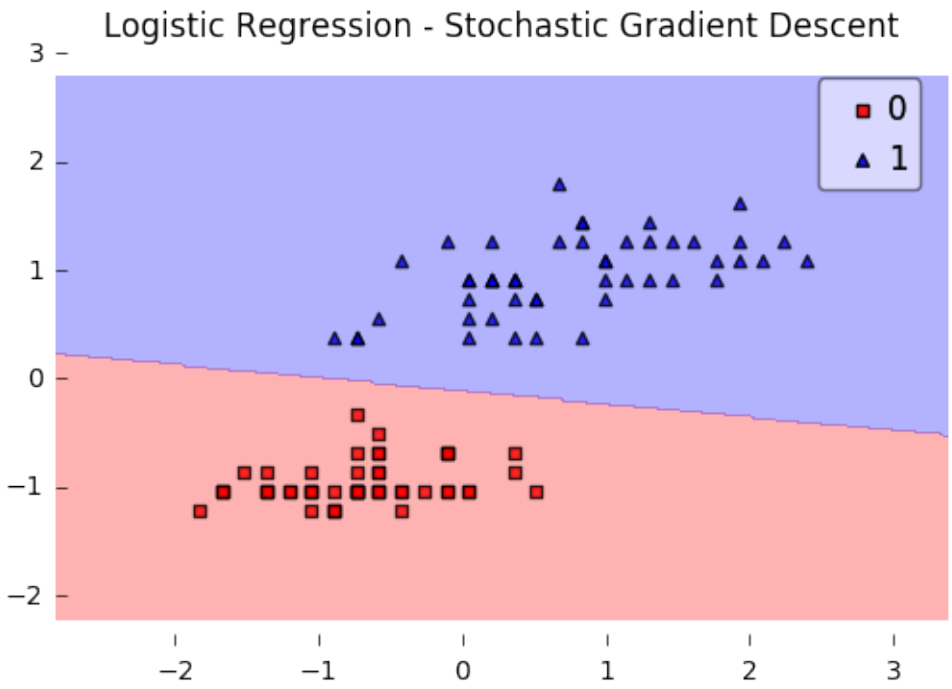
# Loading Data

X, y = iris_data()
X = X[:, [0, 3]] # sepal length and petal width
X = X[0:100] # class 0 and class 1
y = y[0:100] # class 0 and class 1

# standardize
X[:,0] = (X[:,0] - X[:,0].mean()) / X[:,0].std()
X[:,1] = (X[:,1] - X[:,1].mean()) / X[:,1].std()

lr = LogisticRegression(eta=0.5,
                        epochs=30,
                        l2_lambda=0.0,
                        minibatches=len(y), # for SGD learning
                        random_seed=1,
                        print_progress=3)
lr.fit(X, y)

plot_decision_regions(X, y, clf=lr)
plt.title('Logistic Regression - Stochastic Gradient Descent')
```



```
plt.show()

plt.plot(range(len(lr.cost_)), lr.cost_)
plt.xlabel('Iterations')
plt.ylabel('Cost')
plt.show()

Iteration: 30/30 | Cost 0.27 | Elapsed: 0:00:00 | ETA: 0:00:00
```

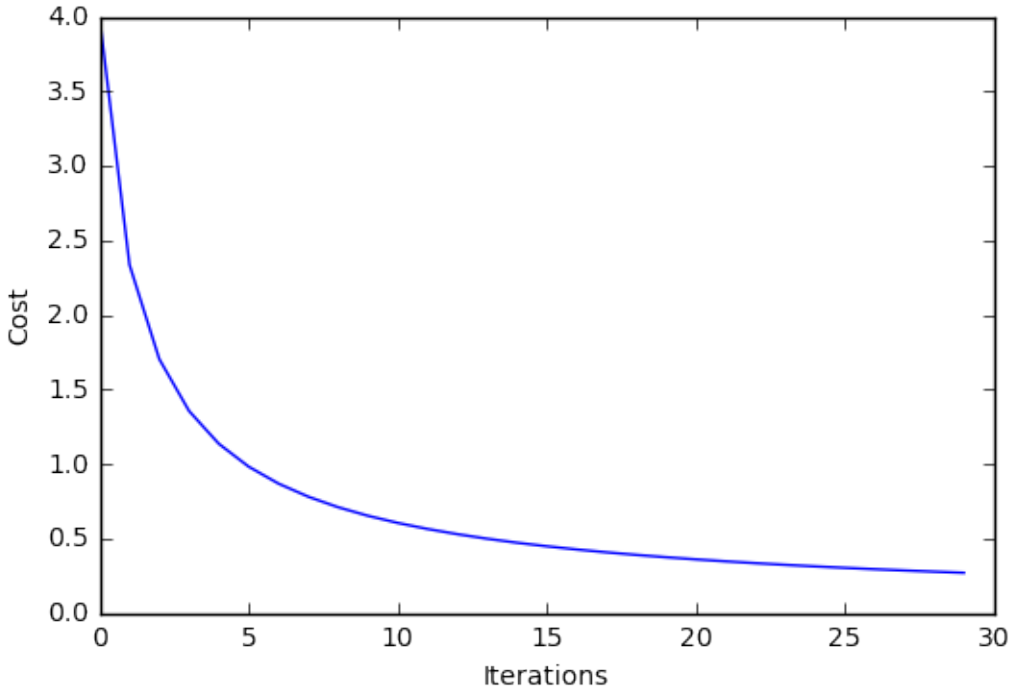
6.4 Example 3 - Stochastic Gradient Descent w. Minibatches

Here, we set `minibatches` to 5, which will result in Minibatch Learning with a batch size of 20 samples (since 100 Iris samples divided by 5 minibatches equals 20).

```
from mlxtend.data import iris_data
from mlxtend.plotting import plot_decision_regions
from mlxtend.classifier import LogisticRegression
import matplotlib.pyplot as plt

# Loading Data

X, y = iris_data()
X = X[:, [0, 3]] # sepal length and petal width
X = X[0:100] # class 0 and class 1
y = y[0:100] # class 0 and class 1
```



```
# standardize
X[:,0] = (X[:,0] - X[:,0].mean()) / X[:,0].std()
X[:,1] = (X[:,1] - X[:,1].mean()) / X[:,1].std()

lr = LogisticRegression(eta=0.5,
                        epochs=30,
                        l2_lambda=0.0,
                        minibatches=5, # 100/5 = 20 -> minibatch-s
                        random_seed=1,
                        print_progress=3)
lr.fit(X, y)

plot_decision_regions(X, y, clf=lr)
plt.title('Logistic Regression - Stochastic Gradient Descent')
plt.show()

plt.plot(range(len(lr.cost_)), lr.cost_)
plt.xlabel('Iterations')
plt.ylabel('Cost')
plt.show()

Iteration: 30/30 | Cost 0.25 | Elapsed: 0:00:00 | ETA: 0:00:00
```

Logistic regression classifier.

Note that this implementation of Logistic Regression expects binary class labels in {0, 1}.

Parameters

- `eta` : float (default: 0.01)

  Learning rate (between 0.0 and 1.0)

- `epochs` : int (default: 50)

  Passes over the training dataset. Prior to each epoch, the dataset is shuffled if `minibatches > 1` to prevent cycles in stochastic gradient descent.

- `l2_lambda` : float

  Regularization parameter for L2 regularization. No regularization if l2_lambda=0.0.

- `minibatches` : int (default: 1)

  The number of minibatches for gradient-based optimization. If 1: Gradient Descent learning If len(y): Stochastic Gradient Descent (SGD) online learning If 1 < minibatches < len(y): SGD Minibatch learning

- `random_seed` : int (default: None)

  Set random state for shuffling and initializing the weights.

- `print_progress` : int (default: 0)

  Prints progress in fitting to stderr. 0: No output 1: Epochs elapsed and cost 2: 1 plus time elapsed 3: 2 plus estimated time until completion

Attributes

- `w_` : 2d-array, shape={n_features, 1}

  Model weights after fitting.

- `b_` : 1d-array, shape={1,}

  Bias unit after fitting.

- `cost_` : list

  List of floats with cross_entropy cost (sgd or gd) for every epoch.

7.0.1 Methods

fit(X, y, init_params=True)

Learn model from training data.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  Training vectors, where n_samples is the number of samples and n_features is the number of features.

- `y` : array-like, shape = [n_samples]

  Target values.

- `init_params` : bool (default: True)

  Re-initializes model parameters prior to fitting. Set False to continue training with weights from a previous model fitting.

Returns

- `self` : object

predict(X)

Predict targets from X.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `target_values` : array-like, shape = [n_samples]

  Predicted target values.

predict_proba(X)

Predict class probabilities of X from the net input.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `Class 1 probability` : float

score(X, y)

Compute the prediction accuracy

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  Training vectors, where n_samples is the number of samples and n_features is the number of features.

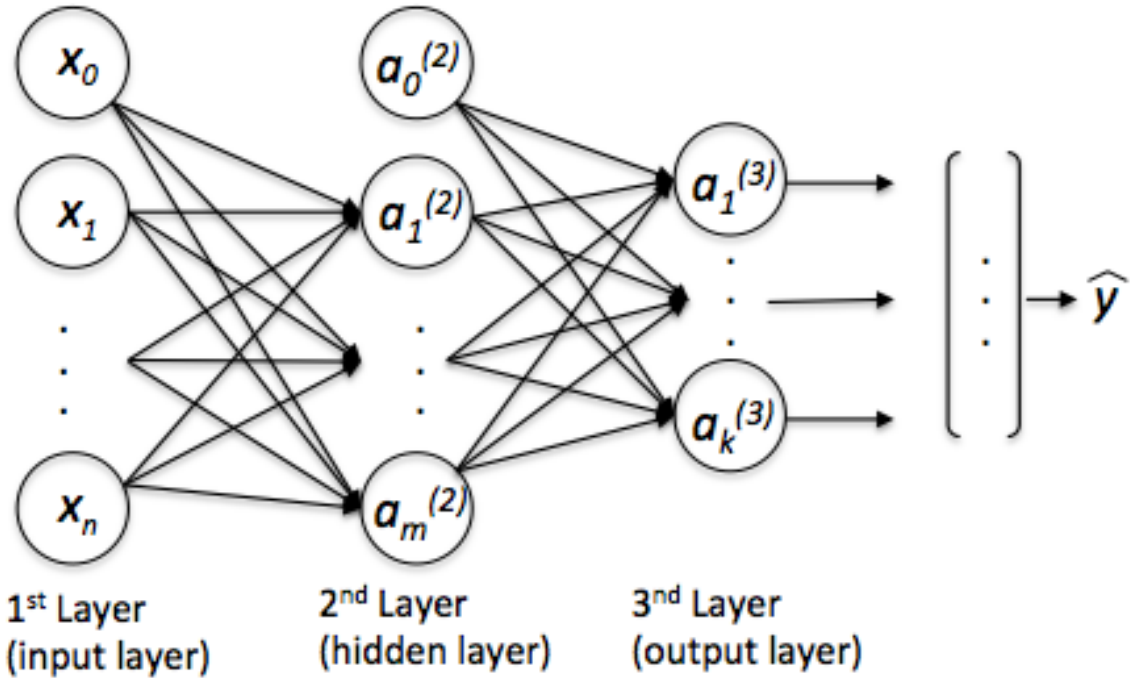
- `y` : array-like, shape = [n_samples]

  Target values (true class labels).

Returns

- `acc` : float

  The prediction accuracy as a float between 0.0 and 1.0 (perfect score).



8 classifier.MultiLayerPerceptron

Implementation of a multilayer perceptron, a feedforward artificial neural network.

from mlxtend.classifier import MultiLayerPerceptron

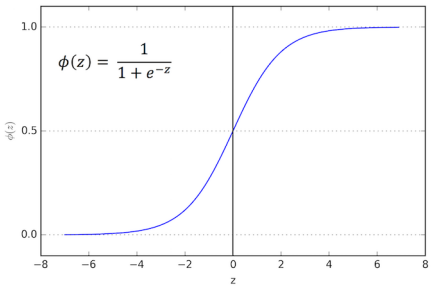
8.1 Overview

Although the code is fully working and can be used for common classification tasks, this implementation is not geared towards efficiency but clarity – the original code was written for demonstration purposes.

8.1.1 Basic Architecture

The neurons x_0 and a_0 represent the bias units ($x_0 = 1$, $a_0 = 1$).

The ith superscript denotes the ith layer, and the jth subscripts stands for the index of the respective unit. For example, $a_1^{(2)}$ refers to the first activation unit **after** the bias unit (i.e., 2nd activation unit) in the 2nd layer (here: the hidden layer)



$$\mathbf{a}^{(2)} = \begin{bmatrix} a_0^{(2)} \\ a_1^{(2)} \\ \vdots \\ a_m^{(2)} \end{bmatrix}. \tag{22}$$

Each layer (l) in a multi-layer perceptron, a directed graph, is fully connected to the next layer $(l+1)$. We write the weight coefficient that connects the kth unit in the lth layer to the jth unit in layer $l+1$ as $w_{j,k}^{(l)}$.

For example, the weight coefficient that connects the units

$a_0^{(2)} \rightarrow a_1^{(3)}$

would be written as $w_{1,0}^{(2)}$.

8.1.2 Activation

In the current implementation, the activations of the hidden layer(s) are computed via the logistic (sigmoid) function $\phi(z) = \frac{1}{1+e^{-z}}$.

(For more details on the logistic function, please see `classifier.LogisticRegression`; a general overview of different activation function can be found here.)

Furthermore, the MLP uses the softmax function in the output layer, For more details on the logistic function, please see `classifier.SoftmaxRegression`.

8.2 Example 1 - Classifying Iris Flowers

Load 2 features from Iris (petal length and petal width) for visualization purposes:

```
from mlxtend.data import iris_data
X, y = iris_data()
X = X[:, [0, 3]]

# standardize training data
X_std = (X - X.mean(axis=0)) / X.std(axis=0)
```

Train neural network for 3 output flower classes ('Setosa', 'Versicolor', 'Virginica'), regular gradient decent (`minibatches=1`), 30 hidden units, and no regularization.

8.2.1 Gradient Descent

Setting the `minibatches` to `1` will result in gradient descent training; please see Gradient Descent vs. Stochastic Gradient Descent for details.

```
from mlxtend.classifier import MultiLayerPerceptron as MLP

nn1 = MLP(hidden_layers=[50],
          l2=0.00,
          l1=0.0,
          epochs=150,
          eta=0.05,
          momentum=0.1,
          decrease_const=0.0,
          minibatches=1,
          random_seed=1,
          print_progress=3)

nn1 = nn1.fit(X_std, y)
```

```
Iteration: 150/150 | Cost 0.06 | Elapsed: 0:00:00 | ETA: 0:00:00
```

```
from mlxtend.plotting import plot_decision_regions
import matplotlib.pyplot as plt

fig = plot_decision_regions(X=X_std, y=y, clf=nn1, legend=2)
plt.title('Multi-layer Perceptron w. 1 hidden layer (logistic sigmoid)')
plt.show()
```

```
import matplotlib.pyplot as plt
plt.plot(range(len(nn1.cost_)), nn1.cost_)
plt.ylabel('Cost')
plt.xlabel('Epochs')
plt.show()
```

```
print('Accuracy: %.2f%%' % (100 * nn1.score(X_std, y)))
```

```
Accuracy: 96.67%
```

8.2.2 Stochastic Gradient Descent

Setting `minibatches` to `n_samples` will result in stochastic gradient descent training; please see Gradient Descent vs. Stochastic Gradient Descent for details.

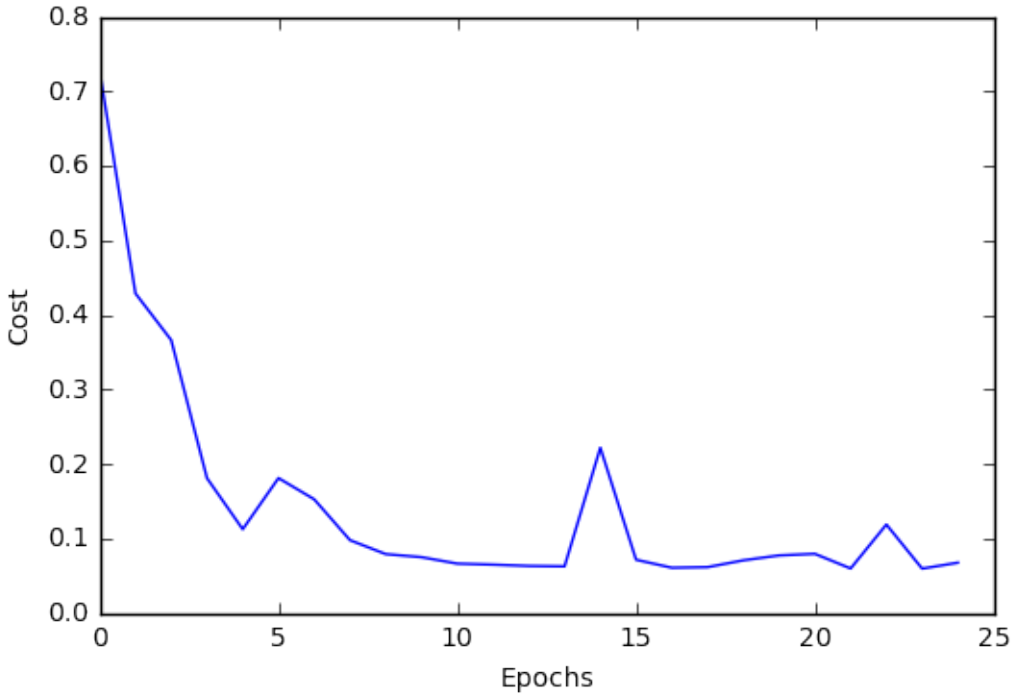
```
nn2 = MLP(hidden_layers=[50],
          l2=0.00,
          l1=0.0,
          epochs=5,
          eta=0.005,
          momentum=0.1,
          decrease_const=0.0,
          minibatches=len(y),
          random_seed=1,
          print_progress=3)

nn2.fit(X_std, y)

plt.plot(range(len(nn2.cost_)), nn2.cost_)
plt.ylabel('Cost')
plt.xlabel('Epochs')
plt.show()
```

```
Iteration: 5/5 | Cost 0.11 | Elapsed: 00:00:00 | ETA: 00:00:00
```

Continue the training for 25 epochs…



```
nn2.epochs = 25
nn2 = nn2.fit(X_std, y)
```

```
Iteration: 25/25 | Cost 0.07 | Elapsed: 0:00:00 | ETA: 0:00:00
```

```
plt.plot(range(len(nn2.cost_)), nn2.cost_)
plt.ylabel('Cost')
plt.xlabel('Epochs')
plt.show()
```

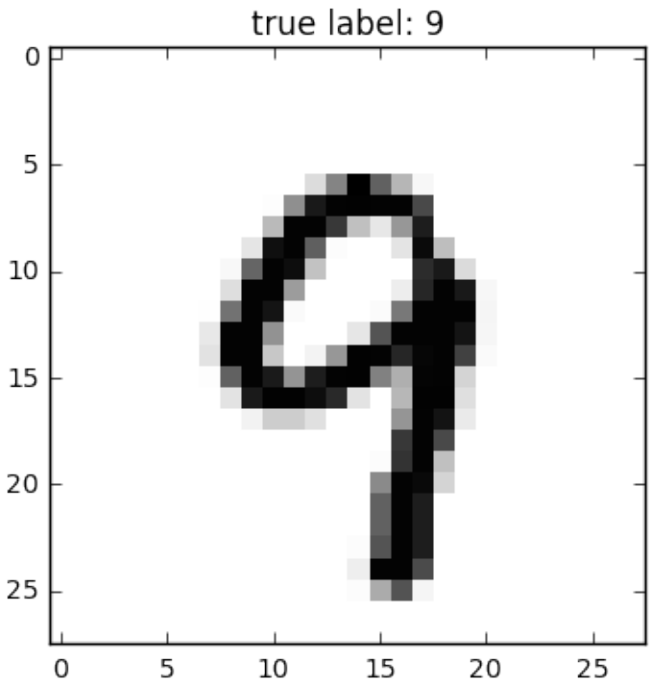
8.3 Example 2 - Classifying Handwritten Digits from a 10% MNIST Subset

Load a **5000-sample subset** of the MNIST dataset (please see `data.loadlocal_mnist` if you want to download and read in the complete MNIST dataset).

```
from mlxtend.data import mnist_data
from mlxtend.preprocessing import shuffle_arrays_unison

X, y = mnist_data()
X, y = shuffle_arrays_unison((X, y), random_seed=1)
X_train, y_train = X[:500], y[:500]
X_test, y_test = X[500:], y[500:]
```

Visualize a sample from the MNIST dataset to check if it was loaded correctly:



```
import matplotlib.pyplot as plt

def plot_digit(X, y, idx):
    img = X[idx].reshape(28,28)
    plt.imshow(img, cmap='Greys',  interpolation='nearest')
    plt.title('true label: %d' % y[idx])
    plt.show()

plot_digit(X, y, 3500)
```

Standardize pixel values:

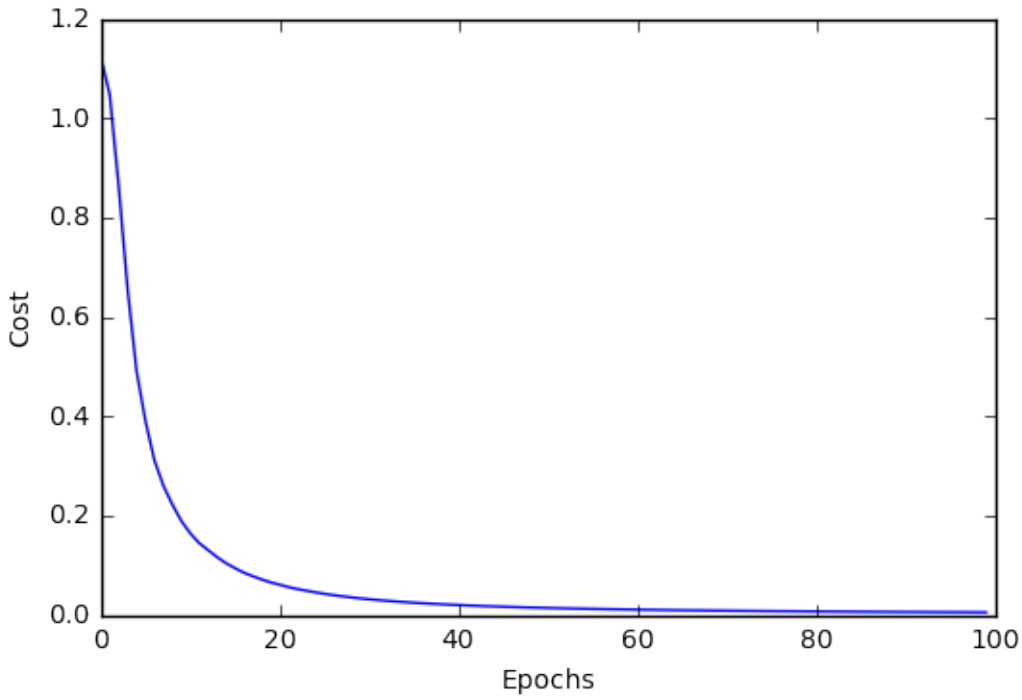
```
import numpy as np
from mlxtend.preprocessing import standardize

X_train_std, params = standardize(X_train,
                                  columns=range(X_train.shape[1]),
                                  return_params=True)

X_test_std = standardize(X_test,
                         columns=range(X_test.shape[1]),
                         params=params)
```

Initialize the neural network to recognize the 10 different digits (0-10) using 300 epochs and mini-batch learning.

```
nn1 = MLP(hidden_layers=[150],
          l2=0.00,
```



```
          l1=0.0,
          epochs=100,
          eta=0.005,
          momentum=0.0,
          decrease_const=0.0,
          minibatches=100,
          random_seed=1,
          print_progress=3)
```

Learn the features while printing the progress to get an idea about how long it may take.

```
import matplotlib.pyplot as plt

nn1.fit(X_train_std, y_train)

plt.plot(range(len(nn1.cost_)), nn1.cost_)
plt.ylabel('Cost')
plt.xlabel('Epochs')
plt.show()
```

```
Iteration: 100/100 | Cost 0.01 | Elapsed: 0:00:17 | ETA: 0:00:00
```

```
print('Train Accuracy: %.2f%%' % (100 * nn1.score(X_train_std, y_train)))
print('Test Accuracy: %.2f%%' % (100 * nn1.score(X_test_std, y_test)))
```

```
Train Accuracy: 100.00%
Test Accuracy: 84.62%
```

Please note that this neural network has been trained on only 10% of the MNIST data for technical demonstration purposes, hence, the lousy predictive performance.

9 API

MultiLayerPerceptron(eta=0.5, epochs=50, hidden_layers=[50], n_classes=None, momentum=0.0, l1=0.0, l2=0.0, dropout=1.0, decrease_const=0.0, minibatches=1, random_seed=None, print_progress=0)

Multi-layer perceptron classifier with logistic sigmoid activations

Parameters

- `eta` : float (default: 0.5)

  Learning rate (between 0.0 and 1.0)

- `epochs` : int (default: 50)

  Passes over the training dataset. Prior to each epoch, the dataset is shuffled if `minibatches > 1` to prevent cycles in stochastic gradient descent.

- `hidden_layers` : list (default: [50])

  Number of units per hidden layer. By default 50 units in the first hidden layer. At the moment only 1 hidden layer is supported

- `n_classes` : int (default: None)

  A positive integer to declare the number of class labels if not all class labels are present in a partial training set. Gets the number of class labels automatically if None.

- `l1` : float (default: 0.0)

  L1 regularization strength

- `l2` : float (default: 0.0)

  L2 regularization strength

- `momentum` : float (default: 0.0)

  Momentum constant. Factor multiplied with the gradient of the previous epoch t-1 to improve learning speed w(t) := w(t) - (grad(t) + momentum * grad(t-1))

- `decrease_const` : float (default: 0.0)

  Decrease constant. Shrinks the learning rate after each epoch via eta / (1 + epoch*decrease_const)

- `minibatches` : int (default: 1)

  Divide the training data into k minibatches for accelerated stochastic gradient descent learning. Gradient Descent Learning if `minibatches` = 1 Stochastic Gradient Descent learning if `minibatches` = len(y) Minibatch learning if `minibatches` > 1

- `random_seed` : int (default: None)

  Set random state for shuffling and initializing the weights.

- `print_progress` : int (default: 0)

  Prints progress in fitting to stderr. 0: No output 1: Epochs elapsed and cost 2: 1 plus time elapsed 3: 2 plus estimated time until completion

Attributes

- `w_` : 2d-array, shape=[n_features, n_classes]
  Weights after fitting.
- `b_` : 1D-array, shape=[n_classes]
  Bias units after fitting.
- `cost_` : list
  List of floats; the mean categorical cross entropy cost after each epoch.

9.0.1 Methods

fit(X, y, init_params=True)

Learn model from training data.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` : array-like, shape = [n_samples]
  Target values.
- `init_params` : bool (default: True)
  Re-initializes model parameters prior to fitting. Set False to continue training with weights from a previous model fitting.

Returns

- `self` : object

predict(X)

Predict targets from X.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `target_values` : array-like, shape = [n_samples]
  Predicted target values.

predict_proba(X)

Predict class probabilities of X from the net input.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `Class probabilties` : array-like, shape= [n_samples, n_classes]

score(X, y)

Compute the prediction accuracy

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` : array-like, shape = [n_samples]
  Target values (true class labels).

Returns

- `acc` : float
  The prediction accuracy as a float between 0.0 and 1.0 (perfect score).

10 classifier.Perceptron

Implementation of a Perceptron learning algorithm for classification.

```
from mlxtend.classifier import Perceptron
```

10.1 Overview

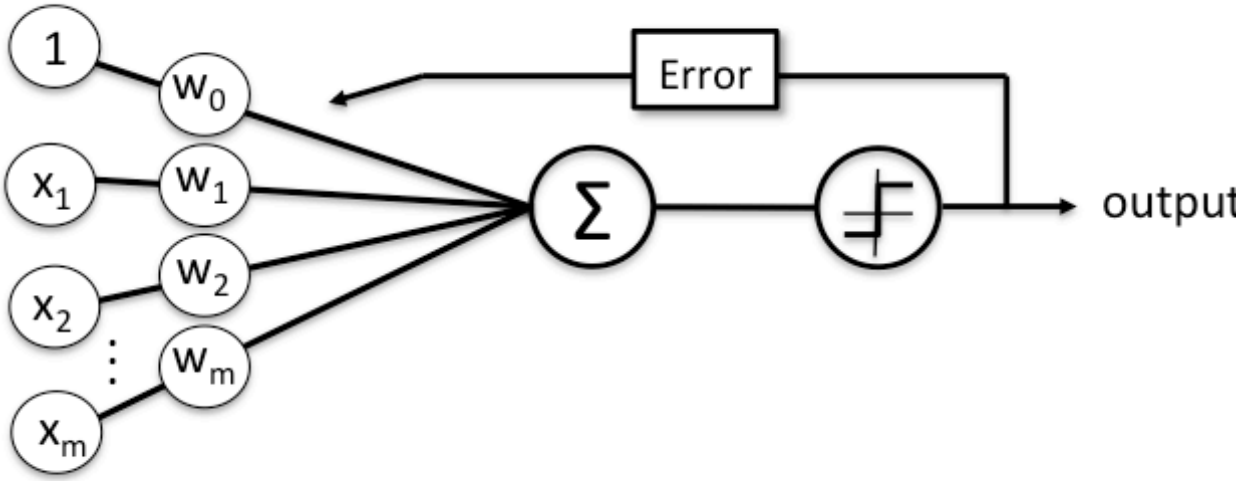
The idea behind this "thresholded" perceptron was to mimic how a single neuron in the brain works: It either "fires" or not. A perceptron receives multiple input signals, and if the sum of the input signals exceed a certain threshold it either returns a signal or remains "silent" otherwise. What made this a "machine learning" algorithm was Frank Rosenblatt's idea of the perceptron learning rule: The perceptron algorithm is about learning the weights for the input signals in order to draw linear decision boundary that allows us to discriminate between the two linearly separable classes +1 and -1.

10.1.0.1 Basic Notation

Before we dive deeper into the algorithm(s) for learning the weights of the perceptron classifier, let us take a brief look at the basic notation. In the following sections, we will label the *positive* and *negative* class in our binary classification setting as "1" and "-1", respectively. Next, we define an activation function $g(\mathbf{z})$ that takes a linear combination of the input values $\mathbf{x}$ and weights $\mathbf{w}$ as input ($\mathbf{z} = w_1x_1 + \cdots + w_mx_m$), and if $g(\mathbf{z})$ is greater than a defined threshold θ we predict 1 and -1 otherwise; in this case, this activation function g is a simple "unit step function," which is sometimes also called "Heaviside step function."

$$g(z) = \begin{cases} 1 & \text{if } z \geq \theta \\ -1 & \text{otherwise.} \end{cases}$$

where



Schematic of a perceptron classifier.

$$z = w_1 x_1 + \cdots + w_m x_m = \sum_{j=1}^{m} x_j w_j = \mathbf{w}^T \mathbf{x}$$

$\mathbf{w}$ is the feature vector, and $\mathbf{x}$ is an m-dimensional sample from the training dataset:

$$\mathbf{w} = \begin{bmatrix} w_1 \\ \vdots \\ w_m \end{bmatrix} \quad \mathbf{x} = \begin{bmatrix} x_1 \\ \vdots \\ x_m \end{bmatrix}$$

In order to simplify the notation, we bring θ to the left side of the equation and define $w_0 = -\theta$ and $x_0 = 1$ so that

$$g(z) = \begin{cases} 1 & \text{if } z \geq 0 \\ -1 & \text{otherwise.} \end{cases}$$

and

$$z = w_0 x_0 + w_1 x_1 + \cdots + w_m x_m = \sum_{j=0}^{m} x_j w_j = \mathbf{w}^T \mathbf{x}.$$

10.1.0.2 Perceptron Rule

Rosenblatt's initial perceptron rule is fairly simple and can be summarized by the following steps:

1. Initialize the weights to 0 or small random numbers.
2. For each training sample $\mathbf{x^{(i)}}$:
    2. Calculate the *output* value.
    3. Update the weights.

The output value is the class label predicted by the unit step function that we defined earlier (output $= g(\mathbf{z})$) and the weight update can be written more formally as $w_j := w_j + \Delta w_j$.

The value for updating the weights at each increment is calculated by the learning rule

$\Delta w_j = \eta \left(\text{target}^{(i)} - \text{output}^{(i)}\right) x_j^{(i)}$

where η is the learning rate (a constant between 0.0 and 1.0), "target" is the true class label, and the "output" is the predicted class label.

aIt is important to note that all weights in the weight vector are being updated simultaneously. Concretely, for a 2-dimensional dataset, we would write the update as:

$\Delta w_0 = \eta(\text{target}^{(i)} - \text{output}^{(i)})$
$\Delta w_1 = \eta(\text{target}^{(i)} - \text{output}^{(i)}) \, x_1^{(i)}$
$\Delta w_2 = \eta(\text{target}^{(i)} - \text{output}^{(i)}) \, x_2^{(i)}$

Before we implement the perceptron rule in Python, let us make a simple thought experiment to illustrate how beautifully simple this learning rule really is. In the two scenarios where the perceptron predicts the class label correctly, the weights remain unchanged:

- $\Delta w_j = \eta(-1^{(i)} - -1^{(i)}) \, x_j^{(i)} = 0$

- $\Delta w_j = \eta(1^{(i)} - 1^{(i)})\ x_j^{(i)} = 0$

However, in case of a wrong prediction, the weights are being "pushed" towards the direction of the positive or negative target class, respectively:

- $\Delta w_j = \eta(1^{(i)} - -1^{(i)})\ x_j^{(i)} = \eta(2)\ x_j^{(i)}$
- $\Delta w_j = \eta(-1^{(i)} - 1^{(i)})\ x_j^{(i)} = \eta(-2)\ x_j^{(i)}$

It is important to note that the convergence of the perceptron is only guaranteed if the two classes are linearly separable. If the two classes can't be separated by a linear decision boundary, we can set a maximum number of passes over the training dataset ("epochs") and/or a threshold for the number of tolerated misclassifications.

```

10.3 API

Perceptron(eta=0.1, epochs=50, random_seed=None, print_progress=0)

Perceptron classifier.

Note that this implementation of the Perceptron expects binary class labels in {0, 1}.

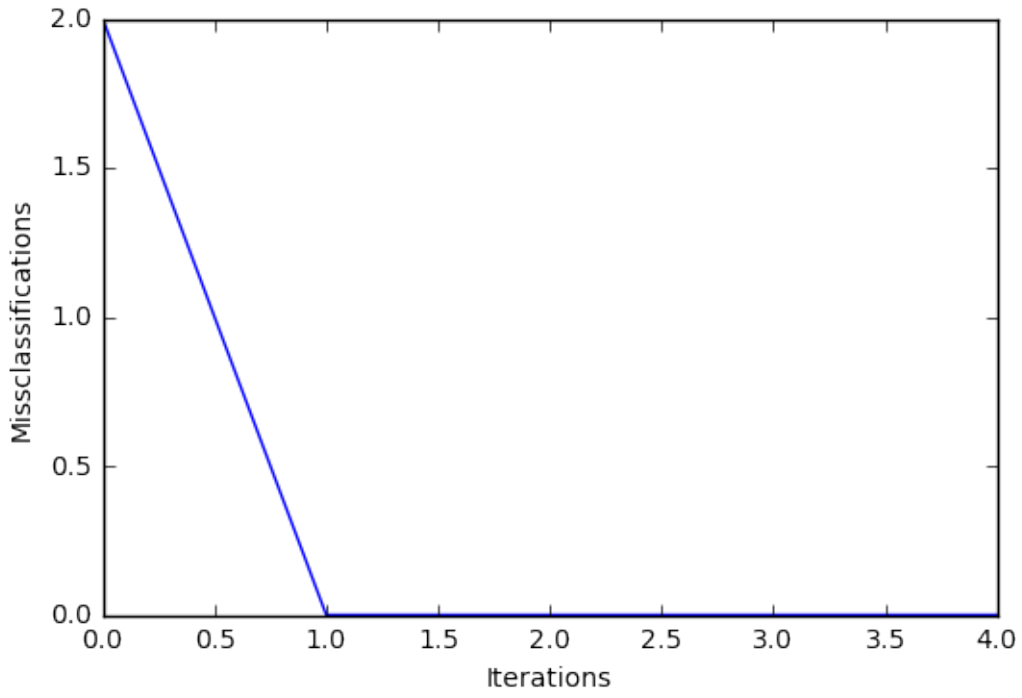
Parameters

- `eta` : float (default: 0.1)

  Learning rate (between 0.0 and 1.0)

- `epochs` : int (default: 50)

  Number of passes over the training dataset. Prior to each epoch, the dataset is shuffled to prevent cycles.



- `random_seed` : int
  Random state for initializing random weights and shuffling.
- `print_progress` : int (default: 0)
  Prints progress in fitting to stderr. 0: No output 1: Epochs elapsed and cost 2: 1 plus time elapsed 3: 2 plus estimated time until completion

Attributes

- `w_` : 2d-array, shape={n_features, 1}
  Model weights after fitting.
- `b_` : 1d-array, shape={1,}
  Bias unit after fitting.
- `cost_` : list
  Number of misclassifications in every epoch.

10.3.1 Methods

fit(X, y, init_params=True)

Learn model from training data.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

- `y` : array-like, shape = [n_samples]
  Target values.
- `init_params` : bool (default: True)
  Re-initializes model parameters prior to fitting. Set False to continue training with weights from a previous model fitting.

Returns

- `self` : object

predict(X)

Predict targets from X.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `target_values` : array-like, shape = [n_samples]
  Predicted target values.

score(X, y)

Compute the prediction accuracy

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` : array-like, shape = [n_samples]
  Target values (true class labels).

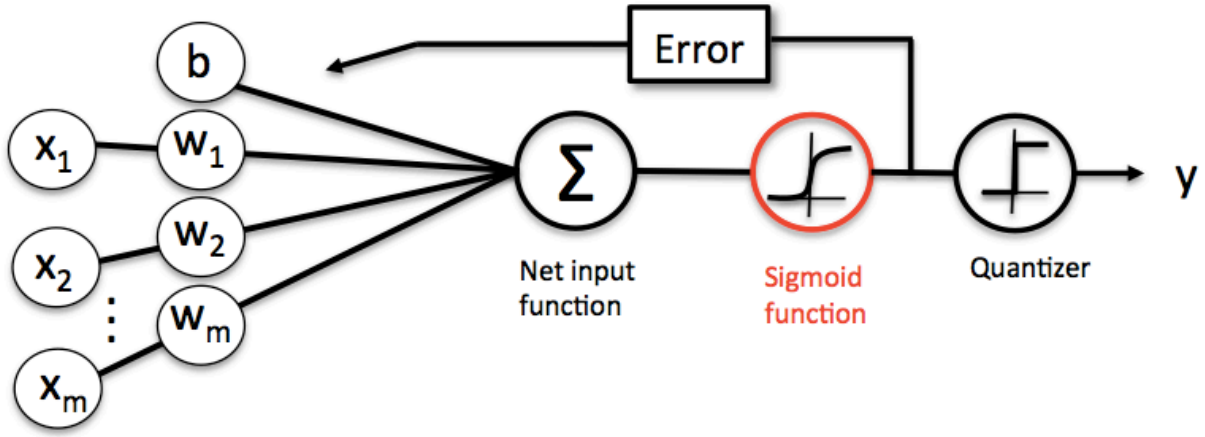
Returns

- `acc` : float
  The prediction accuracy as a float between 0.0 and 1.0 (perfect score).

11 classifier.SoftmaxRegression

A logistic regression class for multi-class classification tasks.

```
from mlxtend.classifier import SoftmaxRegression
```



11.1 Overview

Softmax Regression (synonyms: *Multinomial Logistic*, *Maximum Entropy Classifier*, or just *Multi-class Logistic Regression*) is a generalization of logistic regression that we can use for multi-class classification (under the assumption that the classes are mutually exclusive). In contrast, we use the (standard) *Logistic Regression* model in binary classification tasks.

Below is a schematic of a *Logistic Regression* model, for more details, please see the `LogisticRegression` manual.

In *Softmax Regression* (SMR), we replace the sigmoid logistic function by the so-called *softmax* function $\phi_{softmax}(\cdot)$.

$$P(y = j \mid z^{(i)}) = \phi_{softmax}(z^{(i)}) = \frac{e^{z^{(i)}}}{\sum_{j=0}^{k} e^{z_k^{(i)}}},$$

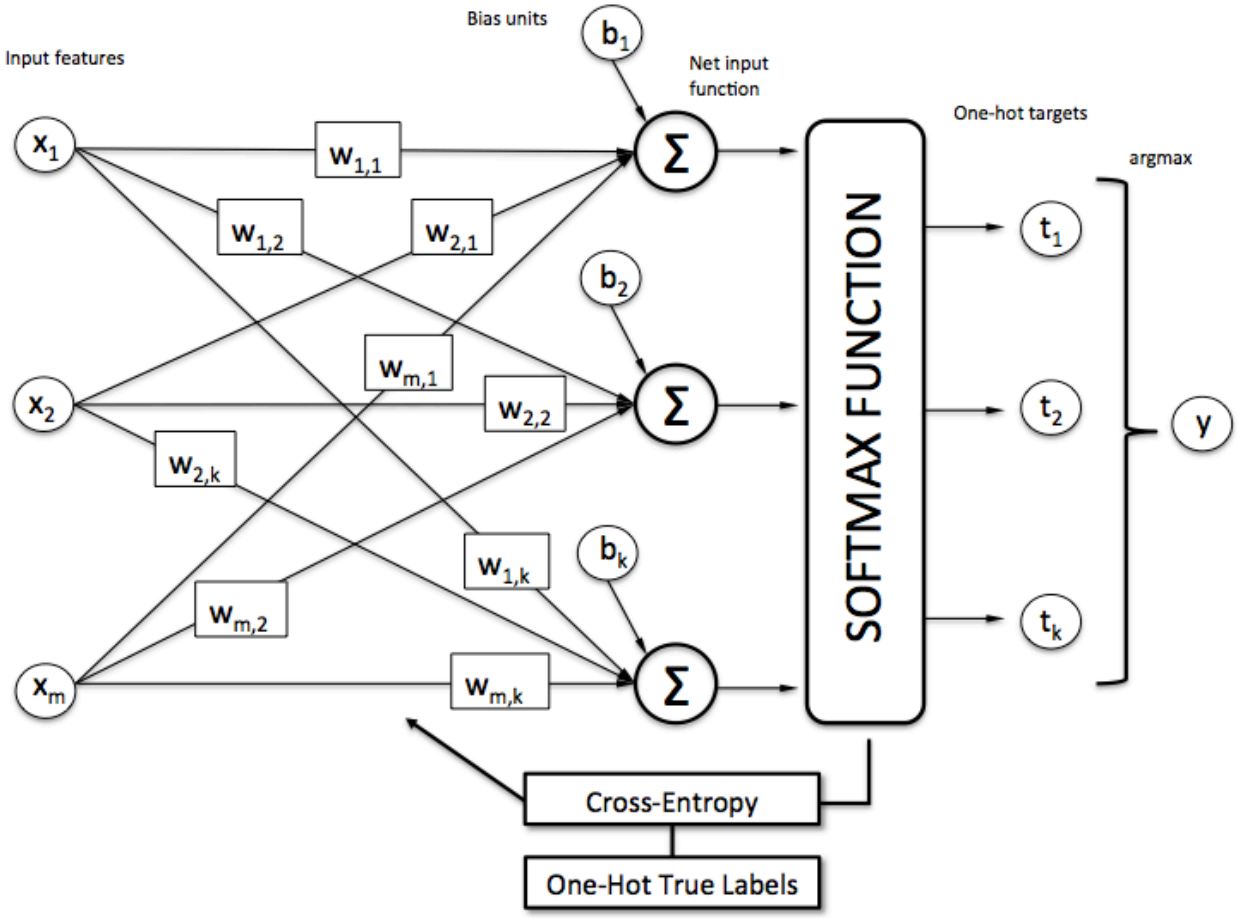
where we define the net input z as

$$z = w_1 x_1 + ... + w_m x_m + b = \sum_{l=1}^{m} w_l x_l + b = \mathbf{w}^T \mathbf{x} + b.$$

($\mathbf{w}$ is the weight vector, $\mathbf{x}$ is the feature vector of 1 training sample, and b is the bias unit.)
Now, this softmax function computes the probability that this training sample $\mathbf{x}^{(i)}$ belongs to class j given the weight and net input $z^{(i)}$. So, we compute the probability $p(y = j \mid \mathbf{x}^{(\mathbf{i})}; \mathbf{w}_j)$ for each class label in $j = 1, \ldots, k.$. Note the normalization term in the denominator which causes these class probabilities to sum up to one.

To illustrate the concept of softmax, let us walk through a concrete example. Let's assume we have a training set consisting of 4 samples from 3 different classes (0, 1, and 2)

- $x_0 \rightarrow$ class 0
- $x_1 \rightarrow$ class 1
- $x_2 \rightarrow$ class 2
- $x_3 \rightarrow$ class 2



Bias units
Input features
Net input function
One-hot targets
argmax
SOFTMAX FUNCTION
Cross-Entropy
One-Hot True Labels

```
import numpy as np

y = np.array([0, 1, 2, 2])
```

First, we want to encode the class labels into a format that we can more easily work with; we apply one-hot encoding:

```
y_enc = (np.arange(np.max(y) + 1) == y[:, None]).astype(float)

print('one-hot encoding:\n', y_enc)
```

```
one-hot encoding:
 [[ 1.  0.  0.]
 [ 0.  1.  0.]
 [ 0.  0.  1.]
 [ 0.  0.  1.]]
```

A sample that belongs to class 0 (the first row) has a 1 in the first cell, a sample that belongs to class 2 has a 1 in the second cell of its row, and so forth.

Next, let us define the feature matrix of our 4 training samples. Here, we assume that our dataset consists of 2 features; thus, we create a 4x2 dimensional matrix of our samples and features. Similarly, we create a 2x3 dimensional weight matrix (one row per feature and one column for each class).

```
X = np.array([[0.1, 0.5],
              [1.1, 2.3],
              [-1.1, -2.3],
              [-1.5, -2.5]])

W = np.array([[0.1, 0.2, 0.3],
              [0.1, 0.2, 0.3]])

bias = np.array([0.01, 0.1, 0.1])

print('Inputs X:\n', X)
print('\nWeights W:\n', W)
print('\nbias:\n', bias)
```

```
Inputs X:
 [[ 0.1  0.5]
 [ 1.1  2.3]
 [-1.1 -2.3]
 [-1.5 -2.5]]

Weights W:
 [[ 0.1  0.2  0.3]
 [ 0.1  0.2  0.3]]

bias:
 [ 0.01  0.1   0.1 ]
```

To compute the net input, we multiply the 4x2 matrix feature matrix `X` with the 2x3 (n_features x n_classes) weight matrix `W`, which yields a 4x3 output matrix (n_samples x n_classes) to which we then add the bias unit:

$$\mathbf{Z} = \mathbf{X}\mathbf{W} + \mathbf{b}.$$

```
X = np.array([[0.1, 0.5],
              [1.1, 2.3],
              [-1.1, -2.3],
              [-1.5, -2.5]])

W = np.array([[0.1, 0.2, 0.3],
              [0.1, 0.2, 0.3]])

bias = np.array([0.01, 0.1, 0.1])

print('Inputs X:\n', X)
print('\nWeights W:\n', W)
print('\nbias:\n', bias)
```

```
Inputs X:
 [[ 0.1  0.5]
 [ 1.1  2.3]
 [-1.1 -2.3]
 [-1.5 -2.5]]

Weights W:
 [[ 0.1  0.2  0.3]
 [ 0.1  0.2  0.3]]

bias:
 [ 0.01  0.1   0.1 ]
```

```
def net_input(X, W, b):
    return (X.dot(W) + b)

net_in = net_input(X, W, bias)
print('net input:\n', net_in)
```

```
net input:
 [[ 0.07  0.22  0.28]
 [ 0.35  0.78  1.12]
 [-0.33 -0.58 -0.92]
 [-0.39 -0.7  -1.1 ]]
```

Now, it's time to compute the softmax activation that we discussed earlier:

$$P(y = j \mid z^{(i)}) = \phi_{softmax}(z^{(i)}) = \frac{e^{z^{(i)}}}{\sum_{j=0}^{k} e^{z_k^{(i)}}}.$$

```
def softmax(z):
    return (np.exp(z.T) / np.sum(np.exp(z), axis=1)).T

smax = softmax(net_in)
print('softmax:\n', smax)
```

```
softmax:
 [[ 0.29450637  0.34216758  0.36332605]
 [ 0.21290077  0.32728332  0.45981591]
 [ 0.42860913  0.33380113  0.23758974]
 [ 0.44941979  0.32962558  0.22095463]]
```

As we can see, the values for each sample (row) nicely sum up to 1 now. E.g., we can say that the first sample
`[ 0.29450637  0.34216758  0.36332605]` has a 29.45% probability to belong to class 0.

Now, in order to turn these probabilities back into class labels, we could simply take the argmax-index position of each row:

[[0.29450637 0.34216758 **0.36332605**] -> 2
[0.21290077 0.32728332 **0.45981591**] -> 2
[**0.42860913** 0.33380113 0.23758974] -> 0
[**0.44941979** 0.32962558 0.22095463]] -> 0

```
def to_classlabel(z):
    return z.argmax(axis=1)

print('predicted class labels: ', to_classlabel(smax))
```

```
predicted class labels:  [2 2 0 0]
```

As we can see, our predictions are terribly wrong, since the correct class labels are `[0, 1, 2, 2]`. Now, in order to train our logistic model (e.g., via an optimization algorithm such as gradient descent), we need to define a cost function $J(\cdot)$ that we want to minimize:

$$J(\mathbf{W};\mathbf{b}) = \frac{1}{n}\sum_{i=1}^{n} H(T_i, O_i),$$

which is the average of all cross-entropies over our n training samples. The cross-entropy function is defined as

$$H(T_i, O_i) = -\sum_{m} T_i \cdot log(O_i).$$

Here the T stands for "target" (i.e., the *true* class labels) and the O stands for output – the computed *probability* via softmax; **not** the predicted class label.

```
def cross_entropy(output, y_target):
    return - np.sum(np.log(output) * (y_target), axis=1)

xent = cross_entropy(smax, y_enc)
print('Cross Entropy:', xent)
```

```
Cross Entropy: [ 1.22245465  1.11692907  1.43720989  1.50979788]
```

```
def cost(output, y_target):
    return np.mean(cross_entropy(output, y_target))

J_cost = cost(smax, y_enc)
print('Cost: ', J_cost)
```

```
Cost:  1.32159787159
```

In order to learn our softmax model – determining the weight coefficients – via gradient descent, we then need to compute the derivative

$$\nabla \mathbf{w}_j \, J(\mathbf{W}; \mathbf{b}).$$

I don't want to walk through the tedious details here, but this cost derivative turns out to be simply:

$$\nabla \mathbf{w}_j \, J(\mathbf{W}; \mathbf{b}) = \frac{1}{n} \sum_{i=0}^{n} \left[\mathbf{x}^{(i)} \, \left(O_i - T_i \right) \right]$$

We can then use the cost derivate to update the weights in opposite direction of the cost gradient with learning rate η:

$$\mathbf{w}_j := \mathbf{w}_j - \eta \nabla \mathbf{w}_j \, J(\mathbf{W}; \mathbf{b})$$

for each class

$$j \in \{0, 1, ..., k\}$$

(note that $\mathbf{w}_j$ is the weight vector for the class $y = j$), and we update the bias units

$$\mathbf{b}_j := \mathbf{b}_j - \eta \left[\frac{1}{n} \sum_{i=0}^{n} \left(O_i - T_i \right) \right].$$

As a penalty against complexity, an approach to reduce the variance of our model and decrease the degree of overfitting by adding additional bias, we can further add a regularization term such as the L2 term with the regularization parameter λ:

L2: $\frac{\lambda}{2} ||\mathbf{w}||_2^2$,

where

$$||\mathbf{w}||_2^2 = \sum_{l=0}^{m} \sum_{j=0}^{k} w_{i,j}$$

so that our cost function becomes

$$J(\mathbf{W}; \mathbf{b}) = \frac{1}{n} \sum_{i=1}^{n} H(T_i, O_i) + \frac{\lambda}{2} ||\mathbf{w}||_2^2$$

and we define the "regularized" weight update as

$$\mathbf{w}_j := \mathbf{w}_j - \eta \left[\nabla \mathbf{w}_j \, J(\mathbf{W}) + \lambda \mathbf{w}_j \right].$$

(Please note that we don't regularize the bias term.)

11.2 Example 1 - Gradient Descent

```
from mlxtend.data import iris_data
from mlxtend.plotting import plot_decision_regions
from mlxtend.classifier import SoftmaxRegression
import matplotlib.pyplot as plt

# Loading Data

X, y = iris_data()
X = X[:, [0, 3]] # sepal length and petal width

# standardize
X[:,0] = (X[:,0] - X[:,0].mean()) / X[:,0].std()
X[:,1] = (X[:,1] - X[:,1].mean()) / X[:,1].std()

lr = SoftmaxRegression(eta=0.01,
                       epochs=500,
                       minibatches=1,
                       random_seed=1,
                       print_progress=3)
lr.fit(X, y)

plot_decision_regions(X, y, clf=lr)
plt.title('Softmax Regression - Gradient Descent')
plt.show()

plt.plot(range(len(lr.cost_)), lr.cost_)
plt.xlabel('Iterations')
plt.ylabel('Cost')
plt.show()
```

```
Iteration: 500/500 | Cost 0.06 | Elapsed: 0:00:00 | ETA: 0:00:00
```

11.2.0.1 Predicting Class Labels

```
y_pred = lr.predict(X)
print('Last 3 Class Labels: %s' % y_pred[-3:])
```

```
Last 3 Class Labels: [2 2 2]
```

11.2.0.2 Predicting Class Probabilities

```
y_pred = lr.predict_proba(X)
print('Last 3 Class Labels:\n %s' % y_pred[-3:])
```

```
Last 3 Class Labels:

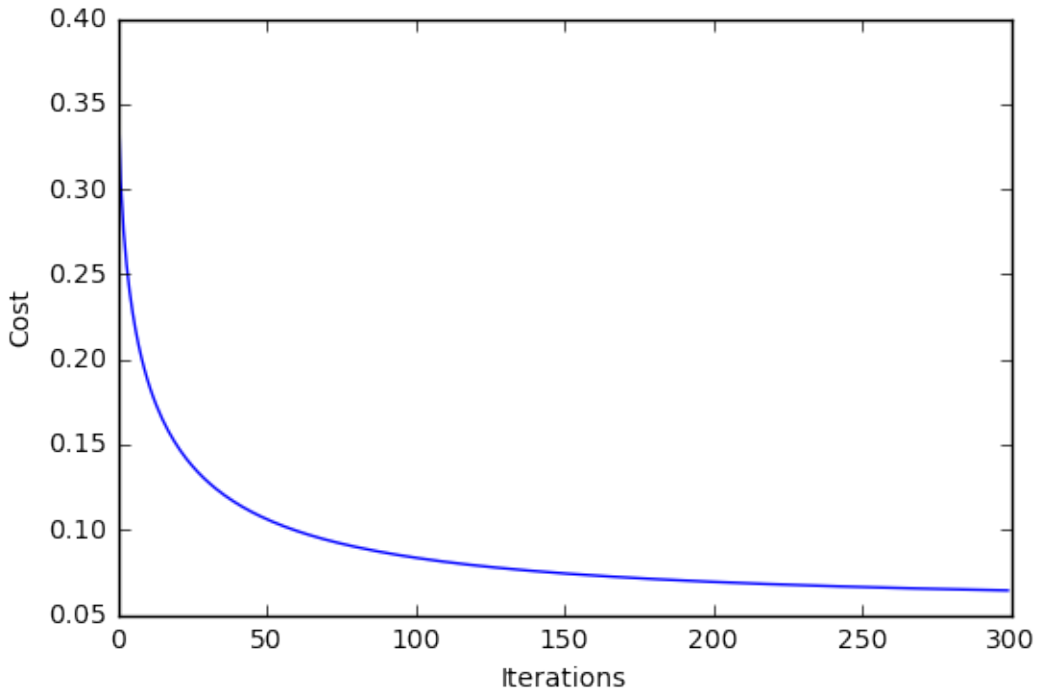
lr.fit(X, y)

plot_decision_regions(X, y, clf=lr)
plt.title('Softmax Regression - Stochastic Gradient Descent')
plt.show()

plt.plot(range(len(lr.cost_)), lr.cost_)
plt.xlabel('Iterations')
plt.ylabel('Cost')
plt.show()
```



12 API

SoftmaxRegression(eta=0.01, epochs=50, l2=0.0, minibatches=1, n_classes=None, random_seed=None, print_progress=0)

Softmax regression classifier.

Parameters

- `eta` : float (default: 0.01)

  Learning rate (between 0.0 and 1.0)

- `epochs` : int (default: 50)

  Passes over the training dataset. Prior to each epoch, the dataset is shuffled if `minibatches > 1` to prevent cycles in stochastic gradient descent.

- `l2` : float

  Regularization parameter for L2 regularization. No regularization if l2=0.0.

- `minibatches` : int (default: 1)

  The number of minibatches for gradient-based optimization. If 1: Gradient Descent learning If len(y): Stochastic Gradient Descent (SGD) online learning If 1 < minibatches < len(y): SGD Minibatch learning

- `n_classes` : int (default: None)

  A positive integer to declare the number of class labels if not all class labels are present in a partial training set. Gets the number of class labels automatically if None.

- `random_seed` : int (default: None)
  Set random state for shuffling and initializing the weights.
- `print_progress` : int (default: 0)
  Prints progress in fitting to stderr. 0: No output 1: Epochs elapsed and cost 2: 1 plus time elapsed 3: 2 plus estimated time until completion

Attributes

- `w_` : 2d-array, shape={n_features, 1}
  Model weights after fitting.
- `b_` : 1d-array, shape={1,}
  Bias unit after fitting.
- `cost_` : list
  List of floats, the average cross_entropy for each epoch.

12.0.1 Methods

fit(X, y, init_params=True)

Learn model from training data.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` : array-like, shape = [n_samples]
  Target values.
- `init_params` : bool (default: True)
  Re-initializes model parameters prior to fitting. Set False to continue training with weights from a previous model fitting.

Returns

- `self` : object

predict(X)

Predict targets from X.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `target_values` : array-like, shape = [n_samples]
  Predicted target values.

predict_proba(X)

Predict class probabilities of X from the net input.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `Class probabilties` : array-like, shape= [n_samples, n_classes]

score(X, y)

Compute the prediction accuracy

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` : array-like, shape = [n_samples]
  Target values (true class labels).

Returns

- `acc` : float
  The prediction accuracy as a float between 0.0 and 1.0 (perfect score).

13 `classifier.StackingClassifier`

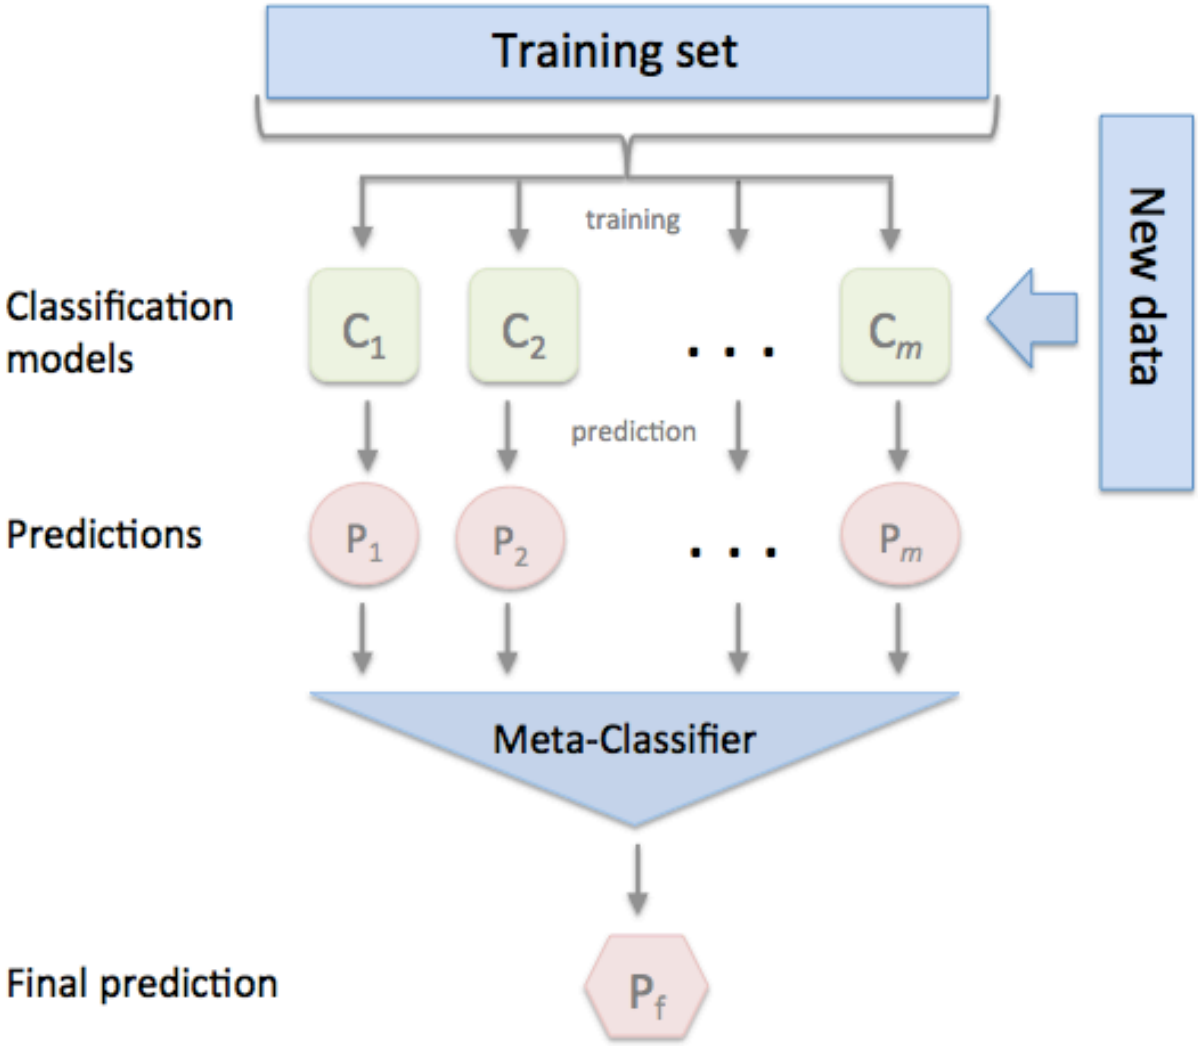
An ensemble-learning meta-classifier for stacking.

from mlxtend.classifier import StackingClassifier

14 Overview

Stacking is an ensemble learning technique to combine multiple classification models via a meta-classifier. The individual classification models are trained based on the complete training set; then, the meta-classifier is fitted based on the outputs – meta-features – of the individual classification models in the ensemble. The meta-classifier can either be trained on the predicted class labels or probabilities from the ensemble.

The algorithm can be summarized as follows (source: [1]):



Training set
training
New data
Classification models
C_1
C_2
C_m
prediction
Predictions
P_1
P_2
P_m
Meta-Classifier
Final prediction
P_f

Algorithm 19.7 Stacking

Input: Training data $\mathcal{D} = \{\mathbf{x}_i, y_i\}_{i=1}^{m}$ ($\mathbf{x}_i \in \mathbb{R}^n$, $y_i \in \mathcal{Y}$)
Output: An ensemble classifier H

Step 1: Learn first-level classifiers
for $t \leftarrow 1$ to T **do**
    Learn a base classifier h_t based on $\mathcal{D}$
end for
Step 2: Construct new data sets from $\mathcal{D}$
for $i \leftarrow 1$ to m **do**
    Construct a new data set that contains $\{\mathbf{x}'_i, y_i\}$, where $\mathbf{x}'_i = \{h_1(\mathbf{x}_i), h_2(\mathbf{x}_i), \ldots, h_T(\mathbf{x}_i)\}$
end for
Step 3: Learn a second-level classifier
Learn a new classifier h' based on the newly constructed data set
return $H(\mathbf{x}) = h'(h_1(\mathbf{x}), h_2(\mathbf{x}), \ldots, h_T(\mathbf{x}))$

for clf, lab, grd in zip([clf1, clf2, clf3, sclf],
                         ['KNN',
                          'Random Forest',
                          'Naive Bayes',
                          'StackingClassifier'],
                          itertools.product([0, 1], repeat=2)):

    clf.fit(X, y)
    ax = plt.subplot(gs[grd[0], grd[1]])
    fig = plot_decision_regions(X=X, y=y, clf=clf)
    plt.title(lab)
```

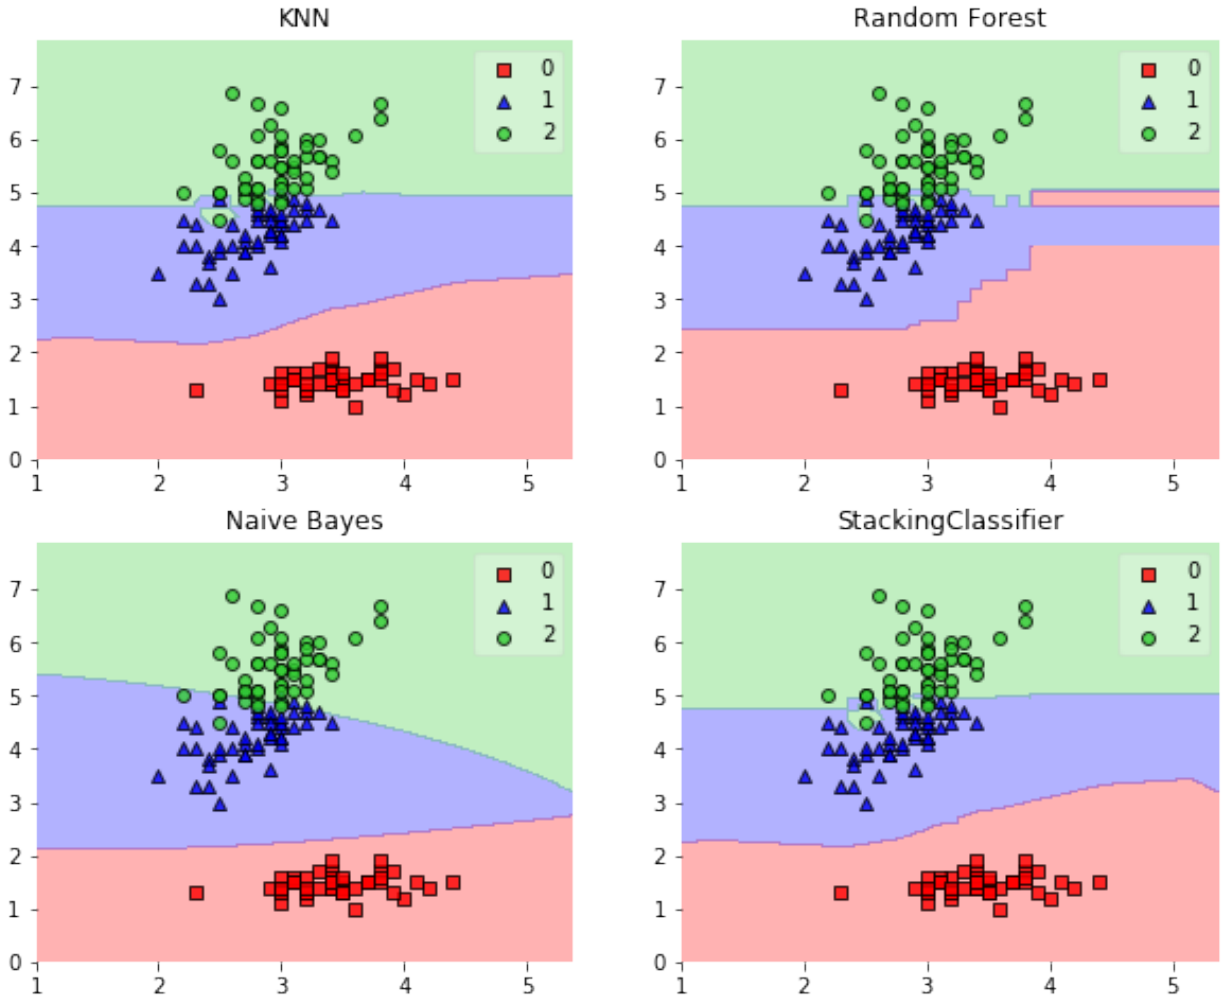
14.2 Example 2 - Using Probabilities as Meta-Features

Alternatively, the class-probabilities of the first-level classifiers can be used to train the meta-classifier (2nd-level classifier) by setting `use_probas=True`. If `average_probas=True`, the probabilities of the level-1 classifiers are averaged, if `average_probas=False`, the probabilities are stacked (recommended). For example, in a 3-class setting with 2 level-1 classifiers, these classifiers may make the following "probability" predictions for 1 training sample:

- classifier 1: [0.2, 0.5, 0.3]
- classifier 2: [0.3, 0.4, 0.4]

If `average_probas=True`, the meta-features would be:

- [0.25, 0.45, 0.35]



KNN
Random Forest
Naive Bayes
StackingClassifier
0
1
2

In contrast, using `average_probas=False` results in k features where, k = [n_classes * n_classifiers], by stacking these level-1 probabilities:

- [0.2, 0.5, 0.3, 0.3, 0.4, 0.4]

```
clf1 = KNeighborsClassifier(n_neighbors=1)
clf2 = RandomForestClassifier(random_state=1)
clf3 = GaussianNB()
lr = LogisticRegression()
sclf = StackingClassifier(classifiers=[clf1, clf2, clf3],
                          use_probas=True,
                          average_probas=False,
                          meta_classifier=lr)

print('3-fold cross validation:\n')

for clf, label in zip([clf1, clf2, clf3, sclf],
                      ['KNN',
                       'Random Forest',
                       'Naive Bayes',
                       'StackingClassifier']):

    scores = model_selection.cross_val_score(clf, X, y,
                                             cv=3, scoring='accuracy')
    print("Accuracy: %0.2f (+/- %0.2f) [%s]"
          % (scores.mean(), scores.std(), label))
```

```
3-fold cross validation:

Accuracy: 0.91 (+/- 0.01) [KNN]
Accuracy: 0.91 (+/- 0.06) [Random Forest]
Accuracy: 0.92 (+/- 0.03) [Naive Bayes]
Accuracy: 0.94 (+/- 0.03) [StackingClassifier]
```

14.3 Example 3 - Stacked Classification and GridSearch

To set up a parameter grid for scikit-learn's `GridSearch`, we simply provide the estimator's names in the parameter grid – in the special case of the meta-regressor, we append the `'meta-'` prefix.

```
from sklearn.linear_model import LogisticRegression
from sklearn.neighbors import KNeighborsClassifier
from sklearn.naive_bayes import GaussianNB
from sklearn.ensemble import RandomForestClassifier
from sklearn.model_selection import GridSearchCV
from mlxtend.classifier import StackingClassifier

# Initializing models

clf1 = KNeighborsClassifier(n_neighbors=1)
clf2 = RandomForestClassifier(random_state=1)
clf3 = GaussianNB()
lr = LogisticRegression()
```

```
sclf = StackingClassifier(classifiers=[clf1, clf2, clf3],
                          meta_classifier=lr)

params = {'kneighborsclassifier__n_neighbors': [1, 5],
          'randomforestclassifier__n_estimators': [10, 50],
          'meta-logisticregression__C': [0.1, 10.0]}

grid = GridSearchCV(estimator=sclf,
                    param_grid=params,
                    cv=5,
                    refit=True)
grid.fit(X, y)

cv_keys = ('mean_test_score', 'std_test_score', 'params')

for r, _ in enumerate(grid.cv_results_['mean_test_score']):
    print("%0.3f +/- %0.2f %r"
          % (grid.cv_results_[cv_keys[0]][r],
             grid.cv_results_[cv_keys[1]][r] / 2.0,
             grid.cv_results_[cv_keys[2]][r]))

print('Best parameters: %s' % grid.best_params_)
print('Accuracy: %.2f' % grid.best_score_)
```

```
0.667 +/- 0.00 {'kneighborsclassifier__n_neighbors': 1, 'meta-logisticregression__C': 0.1, 'randomforest
0.667 +/- 0.00 {'kneighborsclassifier__n_neighbors': 1, 'meta-logisticregression__C': 0.1, 'randomforest
0.927 +/- 0.02 {'kneighborsclassifier__n_neighbors': 1, 'meta-logisticregression__C': 10.0, 'randomfores
0.913 +/- 0.03 {'kneighborsclassifier__n_neighbors': 1, 'meta-logisticregression__C': 10.0, 'randomfores
0.667 +/- 0.00 {'kneighborsclassifier__n_neighbors': 5, 'meta-logisticregression__C': 0.1, 'randomforest
0.667 +/- 0.00 {'kneighborsclassifier__n_neighbors': 5, 'meta-logisticregression__C': 0.1, 'randomforest
0.933 +/- 0.02 {'kneighborsclassifier__n_neighbors': 5, 'meta-logisticregression__C': 10.0, 'randomfores
0.940 +/- 0.02 {'kneighborsclassifier__n_neighbors': 5, 'meta-logisticregression__C': 10.0, 'randomfores
Best parameters: {'kneighborsclassifier__n_neighbors': 5, 'meta-logisticregression__C': 10.0, 'randomfo
Accuracy: 0.94
```

In case we are planning to use a regression algorithm multiple times, all we need to do is to add an additional number suffix in the parameter grid as shown below:

```
from sklearn.model_selection import GridSearchCV

# Initializing models

clf1 = KNeighborsClassifier(n_neighbors=1)
clf2 = RandomForestClassifier(random_state=1)
clf3 = GaussianNB()
lr = LogisticRegression()
sclf = StackingClassifier(classifiers=[clf1, clf1, clf2, clf3],
                          meta_classifier=lr)

params = {'kneighborsclassifier-1__n_neighbors': [1, 5],
          'kneighborsclassifier-2__n_neighbors': [1, 5],
          'randomforestclassifier__n_estimators': [10, 50],
          'meta-logisticregression__C': [0.1, 10.0]}
```

```
grid = GridSearchCV(estimator=sclf,
                    param_grid=params,
                    cv=5,
                    refit=True)
grid.fit(X, y)

cv_keys = ('mean_test_score', 'std_test_score', 'params')

for r, _ in enumerate(grid.cv_results_['mean_test_score']):
    print("%0.3f +/- %0.2f %r"
          % (grid.cv_results_[cv_keys[0]][r],
             grid.cv_results_[cv_keys[1]][r] / 2.0,
             grid.cv_results_[cv_keys[2]][r]))

print('Best parameters: %s' % grid.best_params_)
print('Accuracy: %.2f' % grid.best_score_)
```

```
0.667 +/- 0.00 {'kneighborsclassifier-1__n_neighbors': 1, 'kneighborsclassifier-2__n_neighbors': 1, 'me
0.667 +/- 0.00 {'kneighborsclassifier-1__n_neighbors': 1, 'kneighborsclassifier-2__n_neighbors': 1, 'me
0.907 +/- 0.03 {'kneighborsclassifier-1__n_neighbors': 1, 'kneighborsclassifier-2__n_neighbors': 1, 'me
0.913 +/- 0.03 {'kneighborsclassifier-1__n_neighbors': 1, 'kneighborsclassifier-2__n_neighbors': 1, 'me
0.667 +/- 0.00 {'kneighborsclassifier-1__n_neighbors': 1, 'kneighborsclassifier-2__n_neighbors': 5, 'me
0.667 +/- 0.00 {'kneighborsclassifier-1__n_neighbors': 1, 'kneighborsclassifier-2__n_neighbors': 5, 'me
0.927 +/- 0.02 {'kneighborsclassifier-1__n_neighbors': 1, 'kneighborsclassifier-2__n_neighbors': 5, 'me
0.913 +/- 0.03 {'kneighborsclassifier-1__n_neighbors': 1, 'kneighborsclassifier-2__n_neighbors': 5, 'me
0.667 +/- 0.00 {'kneighborsclassifier-1__n_neighbors': 5, 'kneighborsclassifier-2__n_neighbors': 1, 'me
0.667 +/- 0.00 {'kneighborsclassifier-1__n_neighbors': 5, 'kneighborsclassifier-2__n_neighbors': 1, 'me
0.927 +/- 0.02 {'kneighborsclassifier-1__n_neighbors': 5, 'kneighborsclassifier-2__n_neighbors': 1, 'me
0.913 +/- 0.03 {'kneighborsclassifier-1__n_neighbors': 5, 'kneighborsclassifier-2__n_neighbors': 1, 'me
0.667 +/- 0.00 {'kneighborsclassifier-1__n_neighbors': 5, 'kneighborsclassifier-2__n_neighbors': 5, 'me
0.667 +/- 0.00 {'kneighborsclassifier-1__n_neighbors': 5, 'kneighborsclassifier-2__n_neighbors': 5, 'me
0.933 +/- 0.02 {'kneighborsclassifier-1__n_neighbors': 5, 'kneighborsclassifier-2__n_neighbors': 5, 'me
0.940 +/- 0.02 {'kneighborsclassifier-1__n_neighbors': 5, 'kneighborsclassifier-2__n_neighbors': 5, 'me
Best parameters: {'kneighborsclassifier-1__n_neighbors': 5, 'kneighborsclassifier-2__n_neighbors': 5, '
Accuracy: 0.94
```

Note

The `StackingClassifier` also enables grid search over the `classifiers` argument. However, due to the current implementation of `GridSearchCV` in scikit-learn, it is not possible to search over both, differenct classifiers and classifier parameters at the same time. For instance, while the following parameter dictionary works

```
params = {'randomforestclassifier__n_estimators': [1, 100],
'classifiers': [(clf1, clf1, clf1), (clf2, clf3)]}
```

it will use the instance settings of `clf1`, `clf2`, and `clf3` and not overwrite it with the `'n_estimators'` settings from `'randomforestclassifier__n_estimators': [1, 100]`.

14.4 Example 4 - Stacking of Classifiers that Operate on Different Feature Subsets

The different level-1 classifiers can be fit to different subsets of features in the training dataset. The following example illustrates how this can be done on a technical level using scikit-learn pipelines and the `ColumnSelector`:

```
from sklearn.datasets import load_iris
from mlxtend.classifier import StackingClassifier
from mlxtend.feature_selection import ColumnSelector
from sklearn.pipeline import make_pipeline
from sklearn.linear_model import LogisticRegression

iris = load_iris()
X = iris.data
y = iris.target

pipe1 = make_pipeline(ColumnSelector(cols=(0, 2)),
                      LogisticRegression())
pipe2 = make_pipeline(ColumnSelector(cols=(1, 2, 3)),
                      LogisticRegression())

sclf = StackingClassifier(classifiers=[pipe1, pipe2],
                          meta_classifier=LogisticRegression())

sclf.fit(X, y)

StackingClassifier(average_probas=False,
          classifiers=[Pipeline(steps=[('columnselector', ColumnSelector(cols=(0, 2))), ('logisticregres
          intercept_scaling=1, max_iter=100, multi_class='ovr', n_jobs=1,
          penalty='l2', random_state=None, solve...='l2', random_state=None, solver='liblinear', tol=0.
          verbose=0, warm_start=False))])],
          meta_classifier=LogisticRegression(C=1.0, class_weight=None, dual=False, fit_intercept=True,
          intercept_scaling=1, max_iter=100, multi_class='ovr', n_jobs=1,
          penalty='l2', random_state=None, solver='liblinear', tol=0.0001,
          verbose=0, warm_start=False),
          use_features_in_secondary=False, use_probas=False, verbose=0)
```

15 API

StackingClassifier(classifiers, meta_classifier, use_probas=False, average_probas=False, verbose=0, use_features_in_secondary=False)

A Stacking classifier for scikit-learn estimators for classification.

Parameters

- `classifiers` : array-like, shape = [n_classifiers]

  A list of classifiers. Invoking the `fit` method on the `StackingClassifer` will fit clones of these original classifiers that will be stored in the class attribute `self.clfs_`.

- `meta_classifier` : object

  The meta-classifier to be fitted on the ensemble of classifiers

- `use_probas` : bool (default: False)

  If True, trains meta-classifier based on predicted probabilities instead of class labels.

- `average_probas` : bool (default: False)

  Averages the probabilities as meta features if True.

- `verbose` : int, optional (default=0)

  Controls the verbosity of the building process.

  - `verbose=0` (default): Prints nothing
  - `verbose=1`: Prints the number & name of the regressor being fitted
  - `verbose=2`: Prints info about the parameters of the regressor being fitted
  - `verbose>2`: Changes `verbose` param of the underlying regressor to self.verbose - 2

- `use_features_in_secondary` : bool (default: False)

  If True, the meta-classifier will be trained both on the predictions of the original classifiers and the original dataset. If False, the meta-classifier will be trained only on the predictions of the original classifiers.

Attributes

- `clfs_` : list, shape=[n_classifiers]

  Fitted classifiers (clones of the original classifiers)

- `meta_clf_` : estimator

  Fitted meta-classifier (clone of the original meta-estimator)

15.0.1 Methods

fit(X, y)

Fit ensemble classifers and the meta-classifier.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  Training vectors, where n_samples is the number of samples and n_features is the number of features.

- `y` : array-like, shape = [n_samples] or [n_samples, n_outputs]

  Target values.

Returns

- `self` : object

*fit_transform(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- `X` : numpy array of shape [n_samples, n_features]
  Training set.
- `y` : numpy array of shape [n_samples]
  Target values.

Returns

- `X_new` : numpy array of shape [n_samples, n_features_new]
  Transformed array.

get_params(deep=True)

Return estimator parameter names for GridSearch support.

predict(X)

Predict target values for X.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `labels` : array-like, shape = [n_samples] or [n_samples, n_outputs]
  Predicted class labels.

predict_proba(X)

Predict class probabilities for X.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `proba` : array-like, shape = [n_samples, n_classes] or a list of n_outputs of such arrays if n_outputs > 1.
  Probability for each class per sample.

score(X, y, sample_weight=None)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

- `X` : array-like, shape = (n_samples, n_features)
  Test samples.
- `y` : array-like, shape = (n_samples) or (n_samples, n_outputs)
  True labels for X.
- `sample_weight` : array-like, shape = [n_samples], optional
  Sample weights.

Returns

- `score` : float
  Mean accuracy of self.predict(X) wrt. y.

*set_params(**params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

16 `classifier.StackingCVClassifier`

An ensemble-learning meta-classifier for stacking using cross-validation to prepare the inputs for the level-2 classifier to prevent overfitting.

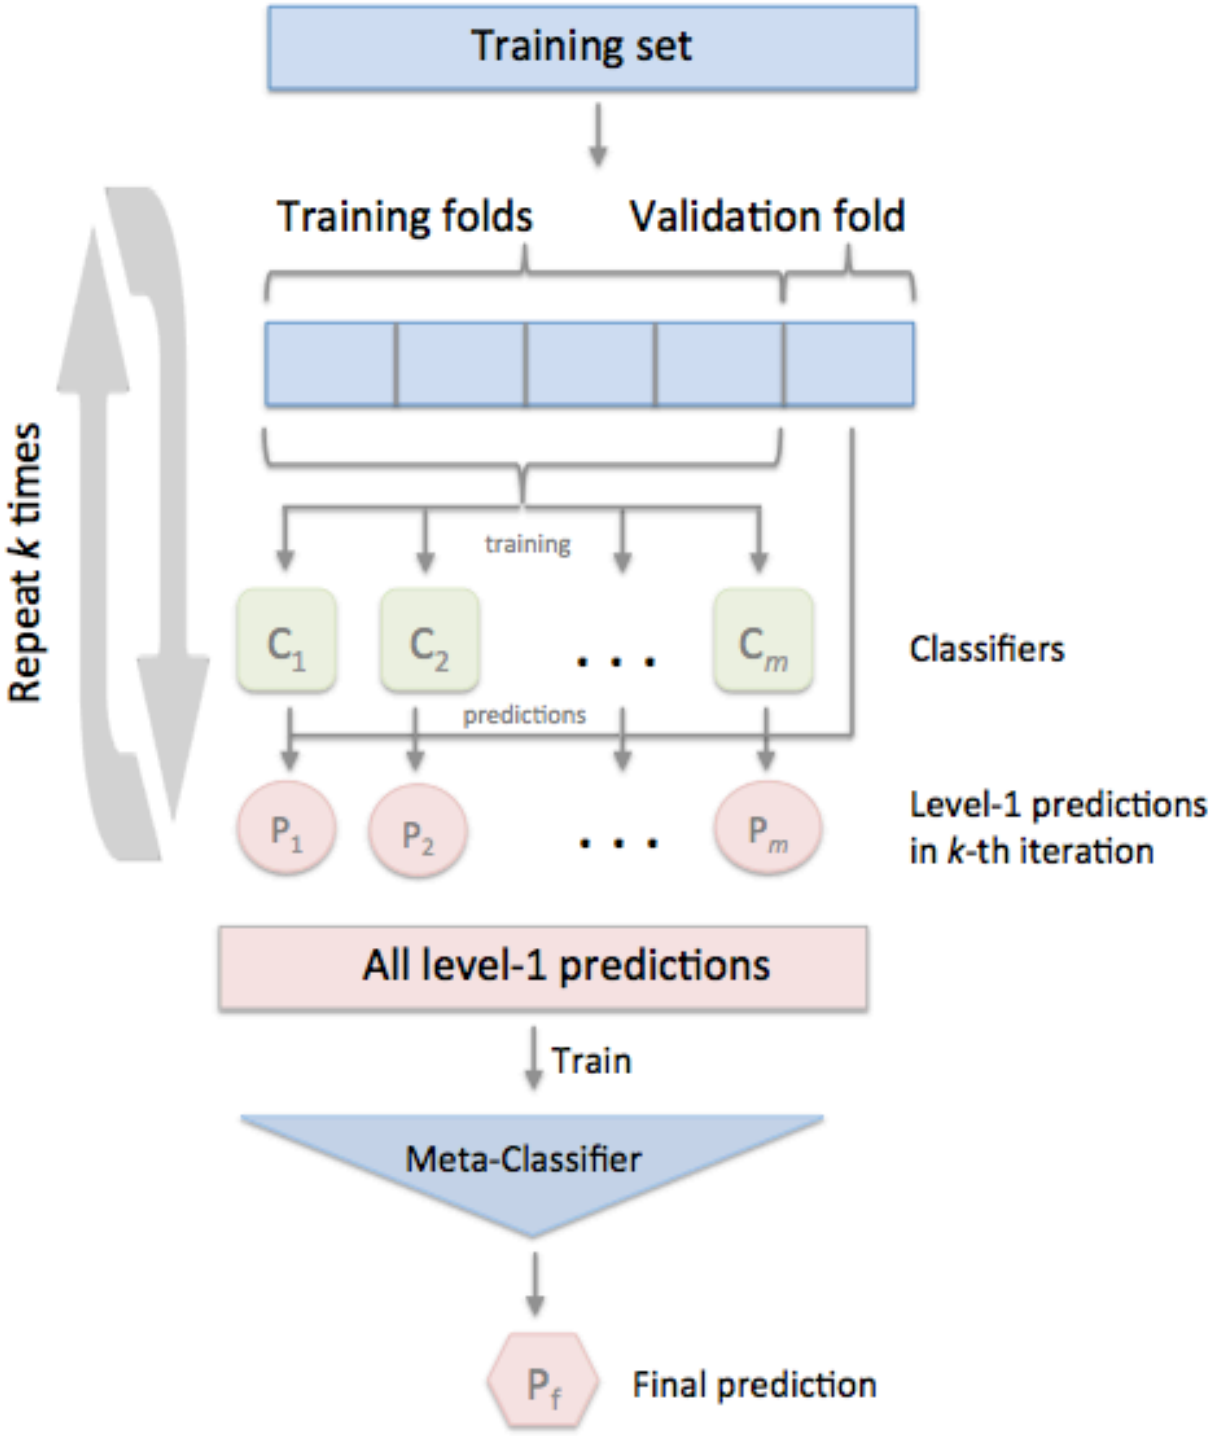
```
from mlxtend.classifier import StackingCVClassifier
```

17 Overview

Stacking is an ensemble learning technique to combine multiple classification models via a meta-classifier. The `StackingCVClassifier` extends the standard stacking algorithm (implemented as `StackingClassifier`) using cross-validation to prepare the input data for the level-2 classifier.

In the standard stacking procedure, the first-level classifiers are fit to the same training set that is used prepare the inputs for the second-level classifier, which may lead to overfitting. The `StackingCVClassifier`, however, uses the concept of cross-validation: the dataset is split into k folds, and in k successive rounds, *k-1* folds are used to fit the first level classifier; in each round, the first-level classifiers are then applied to the remaining 1 subset that was not used for model fitting in each iteration. The resulting predictions are then stacked and provided – as input data – to the second-level classifier. After the training of the `StackingCVClassifier`, the first-level classifiers are fit to the entire dataset as illustrated in the figure below.

More formally, the Stacking Cross-Validation algorithm can be summarized as follows (source: [1]):



Training set
Training folds
Validation fold
Repeat k times
training
C1
C2
. . .
Cm
Classifiers
predictions
P1
P2
. . .
Pm
Level-1 predictions in k-th iteration
All level-1 predictions
Train
Meta-Classifier
Pf
Final prediction

Algorithm 19.8 Stacking with K-fold Cross Validation

Input: Training data $\mathcal{D} = \{\mathbf{x}_i, y_i\}_{i=1}^{m}$ ($\mathbf{x}_i \in \mathbb{R}^n$, $y_i \in \mathcal{Y}$)
Output: An ensemble classifier H

Step 1: Adopt cross validation approach in preparing a training set for second-level classifier
Randomly split $\mathcal{D}$ into K equal-size subsets: $\mathcal{D} = \{\mathcal{D}_1, \mathcal{D}_2, \ldots, \mathcal{D}_K\}$
for $k \leftarrow 1$ to K **do**
    Step 1.1: Learn first-level classifiers
    for $t \leftarrow 1$ to T **do**
        Learn a classifier h_{kt} from $\mathcal{D} \setminus \mathcal{D}_k$
    end for
    Step 1.2: Construct a training set for second-level classifier
    for $\mathbf{x}_i \in \mathcal{D}_k$ **do**
        Get a record $\{\mathbf{x}'_i, y_i\}$, where $\mathbf{x}'_i = \{h_{k1}(\mathbf{x}_i), h_{k2}(\mathbf{x}_i), \ldots, h_{kT}(\mathbf{x}_i)\}$
    end for
end for
Step 2: Learn a second-level classifier
Learn a new classifier h' from the collection of $\{\mathbf{x}'_i, y_i\}$
Step 3: Re-learn first-level classifiers
for $t \leftarrow 1$ to T **do**
    Learn a classifier h_t based on $\mathcal{D}$
end for
return $H(\mathbf{x}) = h'(h_1(\mathbf{x}), h_2(\mathbf{x}), \ldots, h_T(\mathbf{x}))$

17.1 Example 1 - Simple Stacking CV Classification

```
from sklearn import datasets

iris = datasets.load_iris()
X, y = iris.data[:, 1:3], iris.target

from sklearn import model_selection
from sklearn.linear_model import LogisticRegression
from sklearn.neighbors import KNeighborsClassifier
from sklearn.naive_bayes import GaussianNB
from sklearn.ensemble import RandomForestClassifier
from mlxtend.classifier import StackingCVClassifier
import numpy as np

RANDOM_SEED = 42

clf1 = KNeighborsClassifier(n_neighbors=1)
clf2 = RandomForestClassifier(random_state=RANDOM_SEED)
clf3 = GaussianNB()
lr = LogisticRegression()

# The StackingCVClassifier uses scikit-learn's check_cv
# internally, which doesn't support a random seed. Thus
# NumPy's random seed need to be specified explicitely for
# deterministic behavior
np.random.seed(RANDOM_SEED)
sclf = StackingCVClassifier(classifiers=[clf1, clf2, clf3],
                            meta_classifier=lr)

print('3-fold cross validation:\n')

for clf, label in zip([clf1, clf2, clf3, sclf],
                      ['KNN',
                       'Random Forest',
                       'Naive Bayes',
                       'StackingClassifier']):

    scores = model_selection.cross_val_score(clf, X, y,
                                             cv=3, scoring='accuracy')
    print("Accuracy: %0.2f (+/- %0.2f) [%s]"
          % (scores.mean(), scores.std(), label))
```

```
3-fold cross validation:

Accuracy: 0.91 (+/- 0.01) [KNN]
Accuracy: 0.90 (+/- 0.03) [Random Forest]
```

```
Accuracy: 0.92 (+/- 0.03) [Naive Bayes]
Accuracy: 0.93 (+/- 0.02) [StackingClassifier]
```

```
import matplotlib.pyplot as plt
from mlxtend.plotting import plot_decision_regions

                          'Naive Bayes',
                          'StackingCVClassifier'],
                          itertools.product([0, 1], repeat=2)):

    clf.fit(X, y)
    ax = plt.subplot(gs[grd[0], grd[1]])
    fig = plot_decision_regions(X=X, y=y, clf=clf)
    plt.title(lab)
plt.show()
```

17.2 Example 2 - Using Probabilities as Meta-Features

Alternatively, the class-probabilities of the first-level classifiers can be used to train the meta-classifier (2nd-level classifier) by setting `use_probas=True`. For example, in a 3-class setting with 2 level-1 classifiers, these classifiers may make the following "probability" predictions for 1 training sample:

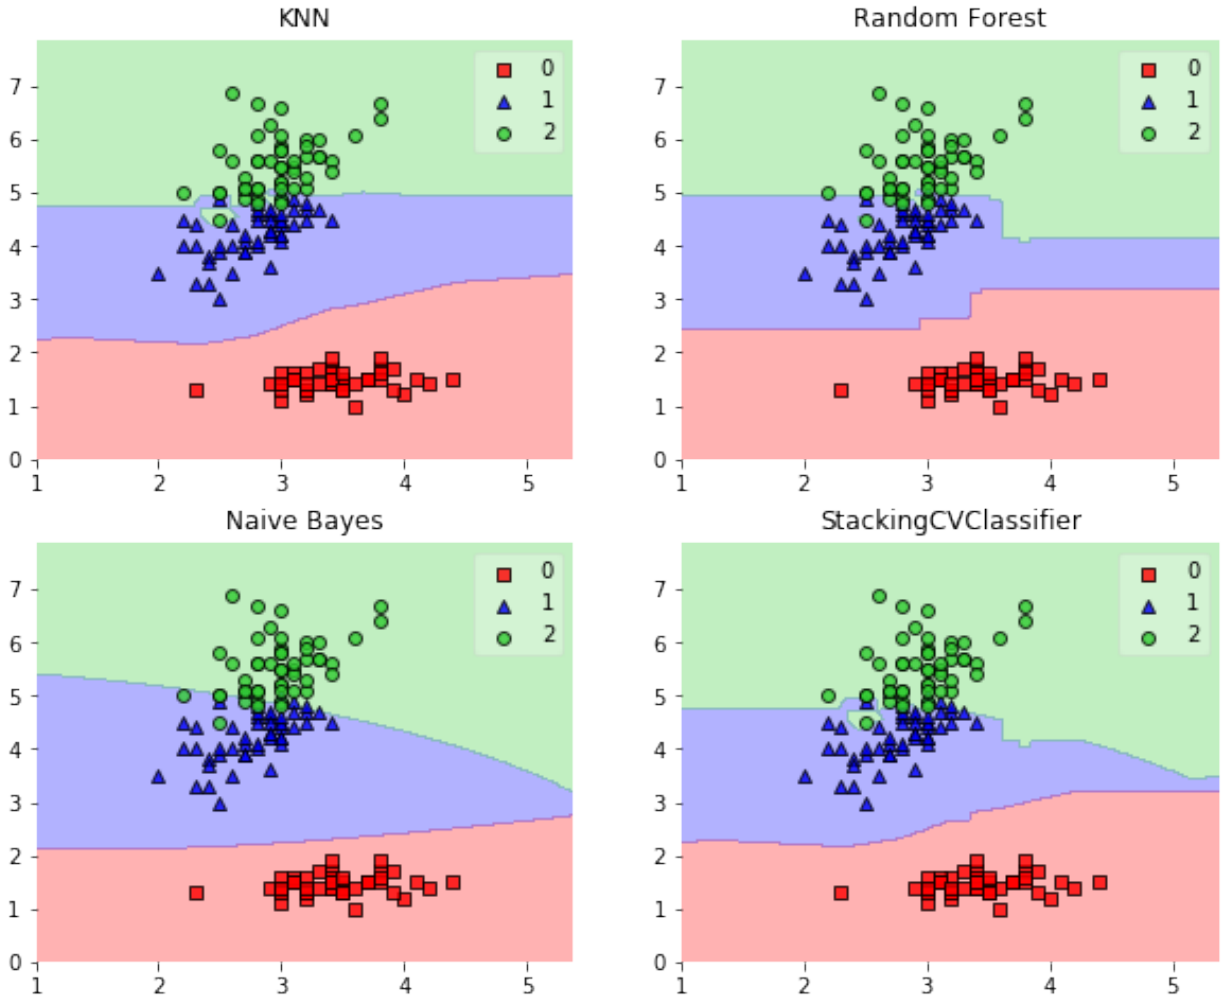
- classifier 1: [0.2, 0.5, 0.3]
- classifier 2: [0.3, 0.4, 0.4]

This results in k features, where k = [n_classes * n_classifiers], by stacking these level-1 probabilities:

- [0.2, 0.5, 0.3, 0.3, 0.4, 0.4]

```
clf1 = KNeighborsClassifier(n_neighbors=1)
clf2 = RandomForestClassifier(random_state=1)
clf3 = GaussianNB()
lr = LogisticRegression()

# The StackingCVClassifier uses scikit-learn's check_cv
# internally, which doesn't support a random seed. Thus
# NumPy's random seed need to be specified explicitely for
# deterministic behavior
np.random.seed(RANDOM_SEED)
sclf = StackingCVClassifier(classifiers=[clf1, clf2, clf3],
                            use_probas=True,
                            meta_classifier=lr)
```



KNN
Random Forest
Naive Bayes
StackingCVClassifier
0
1
2

```
print('3-fold cross validation:\n')

for clf, label in zip([clf1, clf2, clf3, sclf],
                      ['KNN',
                       'Random Forest',
                       'Naive Bayes',
                       'StackingClassifier']):

    scores = model_selection.cross_val_score(clf, X, y,
                                             cv=3, scoring='accuracy')
    print("Accuracy: %0.2f (+/- %0.2f) [%s]"
          % (scores.mean(), scores.std(), label))
```

```
3-fold cross validation:

Accuracy: 0.91 (+/- 0.01) [KNN]
Accuracy: 0.91 (+/- 0.06) [Random Forest]
Accuracy: 0.92 (+/- 0.03) [Naive Bayes]
Accuracy: 0.95 (+/- 0.04) [StackingClassifier]
```

17.3 Example 3 - Stacked CV Classification and GridSearch

To set up a parameter grid for scikit-learn's `GridSearch`, we simply provide the estimator's names in the parameter grid – in the special case of the meta-regressor, we append the `'meta-'` prefix.

```
from sklearn.linear_model import LogisticRegression
from sklearn.neighbors import KNeighborsClassifier
from sklearn.naive_bayes import GaussianNB
from sklearn.ensemble import RandomForestClassifier
from sklearn.model_selection import GridSearchCV
from mlxtend.classifier import StackingCVClassifier

# Initializing models

clf1 = KNeighborsClassifier(n_neighbors=1)
clf2 = RandomForestClassifier(random_state=RANDOM_SEED)
clf3 = GaussianNB()
lr = LogisticRegression()

# The StackingCVClassifier uses scikit-learn's check_cv
# internally, which doesn't support a random seed. Thus
# NumPy's random seed need to be specified explicitely for
# deterministic behavior
np.random.seed(RANDOM_SEED)
sclf = StackingCVClassifier(classifiers=[clf1, clf2, clf3],
                            meta_classifier=lr)

params = {'kneighborsclassifier__n_neighbors': [1, 5],
          'randomforestclassifier__n_estimators': [10, 50],
          'meta-logisticregression__C': [0.1, 10.0]}

grid = GridSearchCV(estimator=sclf,
```

```
                    param_grid=params,
                    cv=5,
                    refit=True)
grid.fit(X, y)

cv_keys = ('mean_test_score', 'std_test_score', 'params')

for r, _ in enumerate(grid.cv_results_['mean_test_score']):
    print("%0.3f +/- %0.2f %r"
          % (grid.cv_results_[cv_keys[0]][r],
             grid.cv_results_[cv_keys[1]][r] / 2.0,
             grid.cv_results_[cv_keys[2]][r]))

print('Best parameters: %s' % grid.best_params_)
print('Accuracy: %.2f' % grid.best_score_)
```

```
0.673 +/- 0.01 {'kneighborsclassifier__n_neighbors': 1, 'meta-logisticregression__C': 0.1, 'randomfores
0.667 +/- 0.00 {'kneighborsclassifier__n_neighbors': 1, 'meta-logisticregression__C': 0.1, 'randomfores
0.920 +/- 0.02 {'kneighborsclassifier__n_neighbors': 1, 'meta-logisticregression__C': 10.0, 'randomfore
0.893 +/- 0.02 {'kneighborsclassifier__n_neighbors': 1, 'meta-logisticregression__C': 10.0, 'randomfore
0.667 +/- 0.00 {'kneighborsclassifier__n_neighbors': 5, 'meta-logisticregression__C': 0.1, 'randomfores
0.667 +/- 0.00 {'kneighborsclassifier__n_neighbors': 5, 'meta-logisticregression__C': 0.1, 'randomfores
0.947 +/- 0.02 {'kneighborsclassifier__n_neighbors': 5, 'meta-logisticregression__C': 10.0, 'randomfore
0.947 +/- 0.02 {'kneighborsclassifier__n_neighbors': 5, 'meta-logisticregression__C': 10.0, 'randomfore
Best parameters: {'kneighborsclassifier__n_neighbors': 5, 'meta-logisticregression__C': 10.0, 'randomfo
Accuracy: 0.95
```

In case we are planning to use a regression algorithm multiple times, all we need to do is to add an additional number suffix in the parameter grid as shown below:

```
from sklearn.model_selection import GridSearchCV

# Initializing models

clf1 = KNeighborsClassifier(n_neighbors=1)
clf2 = RandomForestClassifier(random_state=RANDOM_SEED)
clf3 = GaussianNB()
lr = LogisticRegression()

# The StackingCVClassifier uses scikit-learn's check_cv
# internally, which doesn't support a random seed. Thus
# NumPy's random seed need to be specified explicitely for
# deterministic behavior
np.random.seed(RANDOM_SEED)
sclf = StackingCVClassifier(classifiers=[clf1, clf1, clf2, clf3],
                            meta_classifier=lr)

params = {'kneighborsclassifier-1__n_neighbors': [1, 5],
          'kneighborsclassifier-2__n_neighbors': [1, 5],
          'randomforestclassifier__n_estimators': [10, 50],
          'meta-logisticregression__C': [0.1, 10.0]}

grid = GridSearchCV(estimator=sclf,
```

```
                    param_grid=params,
                    cv=5,
                    refit=True)
grid.fit(X, y)

cv_keys = ('mean_test_score', 'std_test_score', 'params')

for r, _ in enumerate(grid.cv_results_['mean_test_score']):
    print("%0.3f +/- %0.2f %r"
          % (grid.cv_results_[cv_keys[0]][r],
             grid.cv_results_[cv_keys[1]][r] / 2.0,
             grid.cv_results_[cv_keys[2]][r]))

print('Best parameters: %s' % grid.best_params_)
print('Accuracy: %.2f' % grid.best_score_)
```

```
0.673 +/- 0.01 {'kneighborsclassifier-1__n_neighbors': 1, 'kneighborsclassifier-2__n_neighbors': 1, 'me
0.667 +/- 0.00 {'kneighborsclassifier-1__n_neighbors': 1, 'kneighborsclassifier-2__n_neighbors': 1, 'me
0.920 +/- 0.02 {'kneighborsclassifier-1__n_neighbors': 1, 'kneighborsclassifier-2__n_neighbors': 1, 'me
0.893 +/- 0.02 {'kneighborsclassifier-1__n_neighbors': 1, 'kneighborsclassifier-2__n_neighbors': 1, 'me
0.667 +/- 0.00 {'kneighborsclassifier-1__n_neighbors': 1, 'kneighborsclassifier-2__n_neighbors': 5, 'me
0.667 +/- 0.00 {'kneighborsclassifier-1__n_neighbors': 1, 'kneighborsclassifier-2__n_neighbors': 5, 'me
0.947 +/- 0.02 {'kneighborsclassifier-1__n_neighbors': 1, 'kneighborsclassifier-2__n_neighbors': 5, 'me
0.940 +/- 0.02 {'kneighborsclassifier-1__n_neighbors': 1, 'kneighborsclassifier-2__n_neighbors': 5, 'me
0.667 +/- 0.00 {'kneighborsclassifier-1__n_neighbors': 5, 'kneighborsclassifier-2__n_neighbors': 1, 'me
0.667 +/- 0.00 {'kneighborsclassifier-1__n_neighbors': 5, 'kneighborsclassifier-2__n_neighbors': 1, 'me
0.953 +/- 0.02 {'kneighborsclassifier-1__n_neighbors': 5, 'kneighborsclassifier-2__n_neighbors': 1, 'me
0.927 +/- 0.03 {'kneighborsclassifier-1__n_neighbors': 5, 'kneighborsclassifier-2__n_neighbors': 1, 'me
0.667 +/- 0.00 {'kneighborsclassifier-1__n_neighbors': 5, 'kneighborsclassifier-2__n_neighbors': 5, 'me
0.667 +/- 0.00 {'kneighborsclassifier-1__n_neighbors': 5, 'kneighborsclassifier-2__n_neighbors': 5, 'me
0.940 +/- 0.03 {'kneighborsclassifier-1__n_neighbors': 5, 'kneighborsclassifier-2__n_neighbors': 5, 'me
0.940 +/- 0.03 {'kneighborsclassifier-1__n_neighbors': 5, 'kneighborsclassifier-2__n_neighbors': 5, 'me
Best parameters: {'kneighborsclassifier-1__n_neighbors': 5, 'kneighborsclassifier-2__n_neighbors': 1, 'n
Accuracy: 0.95
```

Note

The `StackingCVClassifier` also enables grid search over the `classifiers` argument. However, due to the current implementation of `GridSearchCV` in scikit-learn, it is not possible to search over both, differenct classifiers and classifier parameters at the same time. For instance, while the following parameter dictionary works

```
params = {'randomforestclassifier__n_estimators': [1, 100],
'classifiers': [(clf1, clf1, clf1), (clf2, clf3)]}
```

it will use the instance settings of `clf1`, `clf2`, and `clf3` and not overwrite it with the `'n_estimators'` settings from `'randomforestclassifier__n_estimators': [1, 100]`.

17.4 Example 4 - Stacking of Classifiers that Operate on Different Feature Subsets

The different level-1 classifiers can be fit to different subsets of features in the training dataset. The following example illustrates how this can be done on a technical level using scikit-learn pipelines and the `ColumnSelector`:

```
from sklearn.datasets import load_iris
from mlxtend.classifier import StackingCVClassifier
from mlxtend.feature_selection import ColumnSelector
from sklearn.pipeline import make_pipeline
from sklearn.linear_model import LogisticRegression

iris = load_iris()
X = iris.data
y = iris.target

pipe1 = make_pipeline(ColumnSelector(cols=(0, 2)),
                      LogisticRegression())
pipe2 = make_pipeline(ColumnSelector(cols=(1, 2, 3)),
                      LogisticRegression())

sclf = StackingCVClassifier(classifiers=[pipe1, pipe2],
                            meta_classifier=LogisticRegression())

sclf.fit(X, y)
```

```
StackingCVClassifier(classifiers=[Pipeline(steps=[('columnselector', ColumnSelector(cols=(0, 2))), ('log
          intercept_scaling=1, max_iter=100, multi_class='ovr', n_jobs=1,
          penalty='l2', random_state=None, solve...='l2', random_state=None, solver='liblinear', tol=0.0
          verbose=0, warm_start=False))])],
           cv=2,
           meta_classifier=LogisticRegression(C=1.0, class_weight=None, dual=False, fit_intercept=True,
          intercept_scaling=1, max_iter=100, multi_class='ovr', n_jobs=1,
          penalty='l2', random_state=None, solver='liblinear', tol=0.0001,
          verbose=0, warm_start=False),
           shuffle=True, stratify=True, use_features_in_secondary=False,
           use_probas=False, verbose=0)
```

18 API

StackingCVClassifier(classifiers, meta_classifier, use_probas=False, cv=2, use_features_in_secondary=False, stratify=True, shuffle=True, verbose=0)

A 'Stacking Cross-Validation' classifier for scikit-learn estimators.

New in mlxtend v0.4.3

Notes

The StackingCVClassifier uses scikit-learn's check_cv internally, which doesn't support a random seed. Thus NumPy's random seed need to be specified explicitely for deterministic behavior, for instance, by setting np.random.seed(RANDOM_SEED) prior to fitting the StackingCVClassifier

Parameters

- `classifiers` : array-like, shape = [n_classifiers]

  A list of classifiers. Invoking the `fit` method on the `StackingCVClassifer` will fit clones of these original classifiers that will be stored in the class attribute `self.clfs_`.

- `meta_classifier` : object

  The meta-classifier to be fitted on the ensemble of classifiers

- `use_probas` : bool (default: False)

  If True, trains meta-classifier based on predicted probabilities instead of class labels.

- `cv` : int, cross-validation generator or an iterable, optional (default: 2)

  Determines the cross-validation splitting strategy. Possible inputs for cv are:

  - None, to use the default 2-fold cross validation,
  - integer, to specify the number of folds in a `(Stratified)KFold`,
  - An object to be used as a cross-validation generator.
  - An iterable yielding train, test splits. For integer/None inputs, it will use either a `KFold` or `StratifiedKFold` cross validation depending the value of `stratify` argument.

- `use_features_in_secondary` : bool (default: False)

  If True, the meta-classifier will be trained both on the predictions of the original classifiers and the original dataset. If False, the meta-classifier will be trained only on the predictions of the original classifiers.

- `stratify` : bool (default: True)

  If True, and the `cv` argument is integer it will follow a stratified K-Fold cross validation technique. If the `cv` argument is a specific cross validation technique, this argument is omitted.

- `shuffle` : bool (default: True)

  If True, and the `cv` argument is integer, the training data will be shuffled at fitting stage prior to cross-validation. If the `cv` argument is a specific cross validation technique, this argument is omitted.

- `verbose` : int, optional (default=0)

  Controls the verbosity of the building process.

  - `verbose=0` (default): Prints nothing
  - `verbose=1`: Prints the number & name of the regressor being fitted and which fold is currently being used for fitting
  - `verbose=2`: Prints info about the parameters of the regressor being fitted
  - `verbose>2`: Changes `verbose` param of the underlying regressor to self.verbose - 2

Attributes

- `clfs_` : list, shape=[n_classifiers]

  Fitted classifiers (clones of the original classifiers)

- `meta_clf_` : estimator

  Fitted meta-classifier (clone of the original meta-estimator)

18.0.1 Methods

fit(X, y, groups=None)

Fit ensemble classifers and the meta-classifier.

Parameters

- `X` : numpy array, shape = [n_samples, n_features]

  Training vectors, where n_samples is the number of samples and n_features is the number of features.

- `y` : numpy array, shape = [n_samples]
  Target values.
- `groups` : numpy array/None, shape = [n_samples]
  The group that each sample belongs to. This is used by specific folding strategies such as GroupKFold()

Returns

- `self` : object

*fit_transform(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- `X` : numpy array of shape [n_samples, n_features]
  Training set.
- `y` : numpy array of shape [n_samples]
  Target values.

Returns

- `X_new` : numpy array of shape [n_samples, n_features_new]
  Transformed array.

get_params(deep=True)

Return estimator parameter names for GridSearch support.

predict(X)

Predict target values for X.

Parameters

- `X` : numpy array, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `labels` : array-like, shape = [n_samples]
  Predicted class labels.

predict_proba(X)

Predict class probabilities for X.

Parameters

- `X` : numpy array, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `proba` : array-like, shape = [n_samples, n_classes]
  Probability for each class per sample.

score(X, y, sample_weight=None)

Returns the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters

- `X` : array-like, shape = (n_samples, n_features)
  Test samples.
- `y` : array-like, shape = (n_samples) or (n_samples, n_outputs)
  True labels for X.
- `sample_weight` : array-like, shape = [n_samples], optional
  Sample weights.

Returns

- `score` : float
  Mean accuracy of self.predict(X) wrt. y.

*set_params(**params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

19 cluster.Kmeans

A implementation of k-means clustering.

```
from mlxtend.cluster import Kmeans
```

19.1 Overview

Clustering falls into the category of unsupervised learning, a subfield of machine learning where the ground truth labels are not available to us in real-world applications. In clustering, our goal is to group samples by similarity (in k-means: Euclidean distance).

The k-means algorithms can be summarized as follows:

1. Randomly pick k centroids from the sample points as initial cluster centers.
2. Assign each sample to the nearest centroid $\mu(j)$, $j \in 1, ..., k$.
3. Move the centroids to the center of the samples that were assigned to it.
4. Repeat steps 2 and 3 until the cluster assignments do not change or a user-defined tolerance or a maximum number of iterations is reached.

19.1.1 References

19.2 Example 1 - Three Blobs

19.2.0.1 Load some sample data:

```
import matplotlib.pyplot as plt
from mlxtend.data import three_blobs_data

X, y = three_blobs_data()
plt.scatter(X[:, 0], X[:, 1], c='white')
plt.show()
```

19.2.0.2 Compute the cluster centroids:

```
from mlxtend.cluster import Kmeans

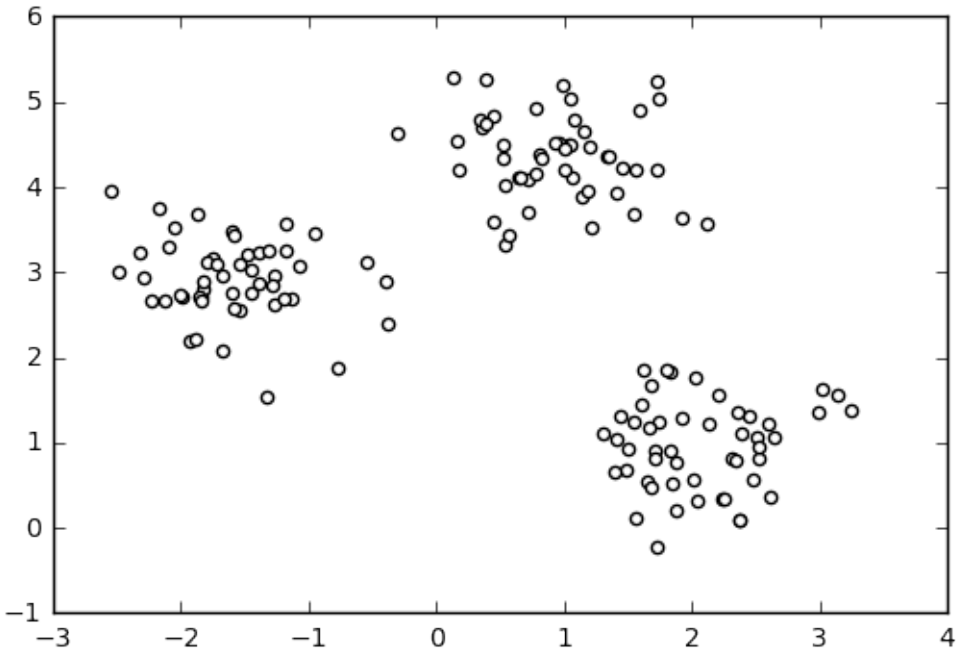
km = Kmeans(k=3,
            max_iter=50,
            random_seed=1,
            print_progress=3)

km.fit(X)

print('Iterations until convergence:', km.iterations_)
print('Final centroids:\n', km.centroids_)
```

```
Iteration: 2/50 | Elapsed: 00:00:00 | ETA: 00:00:00

Iterations until convergence: 2
Final centroids:
 [[-1.5947298   2.92236966]
 [ 2.06521743  0.96137409]
 [ 0.9329651   4.35420713]]
```



19.2.0.3 Visualize the cluster memberships:

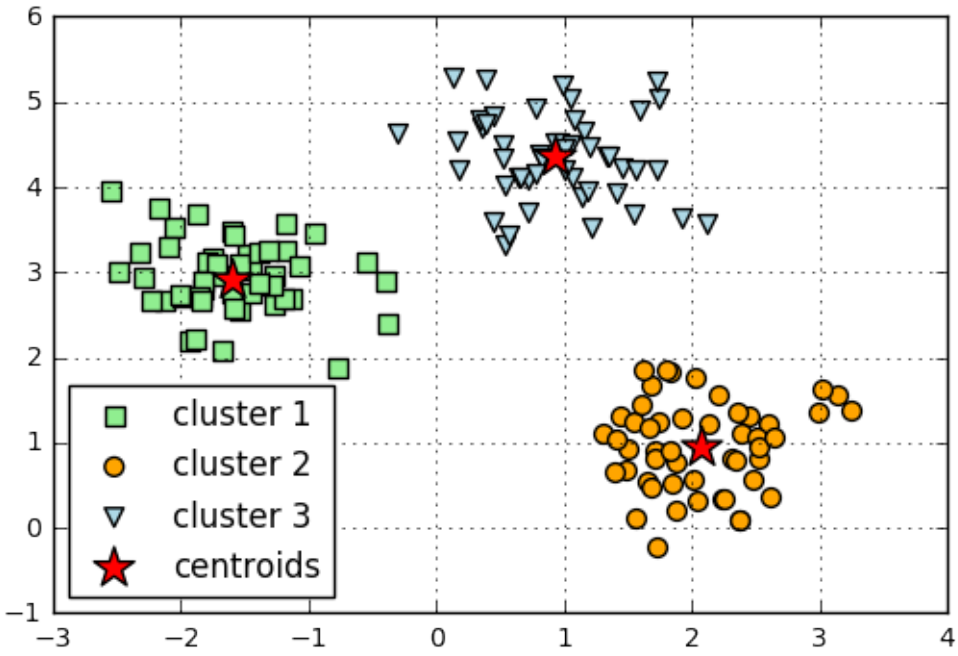
```
y_clust = km.predict(X)

plt.scatter(X[y_clust == 0, 0],
            X[y_clust == 0, 1],
            s=50,
            c='lightgreen',
            marker='s',
            label='cluster 1')

plt.scatter(X[y_clust == 1,0],
            X[y_clust == 1,1],
            s=50,
            c='orange',
            marker='o',
            label='cluster 2')

plt.scatter(X[y_clust == 2,0],
            X[y_clust == 2,1],
            s=50,
            c='lightblue',
            marker='v',
            label='cluster 3')

plt.scatter(km.centroids_[:,0],
            km.centroids_[:,1],
            s=250,
```



```
            marker='*',
            c='red',
            label='centroids')

plt.legend(loc='lower left',
           scatterpoints=1)
plt.grid()
plt.show()
```

19.3 API

Kmeans(k, max_iter=10, convergence_tolerance=1e-05, random_seed=None, print_progress=0)

K-means clustering class.

Added in 0.4.1dev

Parameters

- `k` : int

  Number of clusters

- `max_iter` : int (default: 10)

  Number of iterations during cluster assignment. Cluster re-assignment stops automatically when the algorithm converged.

- `convergence_tolerance` : float (default: 1e-05)

  Compares current centroids with centroids of the previous iteration using the given tolerance (a small positive float)to determine if the algorithm converged early.

- `random_seed` : int (default: None)

  Set random state for the initial centroid assignment.

- `print_progress` : int (default: 0)

  Prints progress in fitting to stderr. 0: No output 1: Iterations elapsed 2: 1 plus time elapsed 3: 2 plus estimated time until completion

Attributes

- `centroids_` : 2d-array, shape={k, n_features}

  Feature values of the k cluster centroids.

- `custers_` : dictionary

  The cluster assignments stored as a Python dictionary; the dictionary keys denote the cluster indeces and the items are Python lists of the sample indices that were assigned to each cluster.

- `iterations_` : int

  Number of iterations until convergence.

19.3.1 Methods

fit(X, init_params=True)

Learn model from training data.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  Training vectors, where n_samples is the number of samples and n_features is the number of features.

- `init_params` : bool (default: True)

  Re-initializes model parameters prior to fitting. Set False to continue training with weights from a previous model fitting.

Returns

- `self` : object

predict(X)

Predict targets from X.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `target_values` : array-like, shape = [n_samples]

  Predicted target values.

20 data.autompg_data

A function that loads the `autompg` dataset into NumPy arrays.

```
from mlxtend.data import autompg_data
```

20.1 Overview

The Auto-MPG dataset for regression analysis. The target (`y`) is defined as the miles per gallon (mpg) for 392 automobiles (6 rows containing "NaN"s have been removed. The 8 feature columns are:

Features

1. cylinders: multi-valued discrete
2. displacement: continuous
3. horsepower: continuous
4. weight: continuous
5. acceleration: continuous
6. model year: multi-valued discrete
7. origin: multi-valued discrete
8. car name: string (unique for each instance)

- Number of samples: 392
- Target variable (continuous): mpg

20.1.1 References

- Source: https://archive.ics.uci.edu/ml/datasets/Auto+MPG
- Quinlan,R. (1993). Combining Instance-Based and Model-Based Learning. In Proceedings on the Tenth International Conference of Machine Learning, 236-243, University of Massachusetts, Amherst. Morgan Kaufmann.

20.2 Example - Dataset overview

```
from mlxtend.data import autompg_data
X, y = autompg_data()

print('Dimensions: %s x %s' % (X.shape[0], X.shape[1]))
print('\nHeader: %s' % ['cylinders', 'displacement',
                        'horsepower', 'weight', 'acceleration',
                        'model year', 'origin', 'car name'])
print('1st row', X[0])
```

```
Dimensions: 392 x 8

Header: ['cylinders', 'displacement', 'horsepower', 'weight', 'acceleration', 'model year', 'origin', '
1st row [  8.00000000e+00   3.07000000e+02   1.30000000e+02   3.50400000e+03
   1.20000000e+01   7.00000000e+01   1.00000000e+00              nan]
```

Note that the feature array contains a `str` column ("car name"), thus it is recommended to pick the features as needed and convert it into a `float` array for further analysis. The example below shows how to get rid of the `car name` column and cast the NumPy array as a `float` array.

```
X[:, :-1].astype(float)
```

```
array([[   8. ,  307. ,  130. , ...,   12. ,   70. ,    1. ],
       [   8. ,  350. ,  165. , ...,   11.5,   70. ,    1. ],
       [   8. ,  318. ,  150. , ...,   11. ,   70. ,    1. ],
       ...,
       [   4. ,  135. ,   84. , ...,   11.6,   82. ,    1. ],
       [   4. ,  120. ,   79. , ...,   18.6,   82. ,    1. ],
       [   4. ,  119. ,   82. , ...,   19.4,   82. ,    1. ]])
```

20.3 API

autompg_data()

Auto MPG dataset.

- `Source` : https://archive.ics.uci.edu/ml/datasets/Auto+MPG
- `Number of samples` : 392
- `Continuous target variable` : mpg

  Dataset Attributes:

  - 1) cylinders: multi-valued discrete
  - 2) displacement: continuous
  - 3) horsepower: continuous
  - 4) weight: continuous
  - 5) acceleration: continuous
  - 6) model year: multi-valued discrete
  - 7) origin: multi-valued discrete
  - 8) car name: string (unique for each instance)

Returns

- `X, y` : [n_samples, n_features], [n_targets]

  X is the feature matrix with 392 auto samples as rows and 8 feature columns (6 rows with NaNs removed). y is a 1-dimensional array of the target MPG values.

21 data.boston_housing_data

A function that loads the `boston_housing_data` dataset into NumPy arrays.

```
from mlxtend.data import boston_housing_data
```

21.1 Overview

The Boston Housing dataset for regression analysis.

Features

1. CRIM: per capita crime rate by town
2. ZN: proportion of residential land zoned for lots over 25,000 sq.ft.
3. INDUS: proportion of non-retail business acres per town
4. CHAS: Charles River dummy variable (= 1 if tract bounds river; 0 otherwise)
5. NOX: nitric oxides concentration (parts per 10 million)
6. RM: average number of rooms per dwelling
7. AGE: proportion of owner-occupied units built prior to 1940
8. DIS: weighted distances to five Boston employment centres
9. RAD: index of accessibility to radial highways
10. TAX: full-value property-tax rate per $10,000
11. PTRATIO: pupil-teacher ratio by town
12. B: 1000(Bk - 0.63)^2 where Bk is the proportion of b. by town
13. LSTAT: % lower status of the population

- Number of samples: 506
- Target variable (continuous): MEDV, Median value of owner-occupied homes in $1000's

21.1.1 References

21.2 Example 1 - Dataset overview

```
from mlxtend.data import boston_housing_data
X, y = boston_housing_data()

print('Dimensions: %s x %s' % (X.shape[0], X.shape[1]))
print('1st row', X[0])
```

```
(506, 14)
Dimensions: 506 x 13
1st row [  6.32000000e-03   1.80000000e+01   2.31000000e+00   0.00000000e+00
   5.38000000e-01   6.57500000e+00   6.52000000e+01   4.09000000e+00
   1.00000000e+00   2.96000000e+02   1.53000000e+01   3.96900000e+02
   4.98000000e+00]
```

21.3 API

boston_housing_data()

Boston Housing dataset.

- `Source` : https://archive.ics.uci.edu/ml/datasets/Housing

- `Number of samples` : 506
- `Continuous target variable` : MEDV

  MEDV = Median value of owner-occupied homes in $1000's

  Dataset Attributes:

  - 1) CRIM per capita crime rate by town
  - 2) ZN proportion of residential land zoned for lots over 25,000 sq.ft.
  - 3) INDUS proportion of non-retail business acres per town
  - 4) CHAS Charles River dummy variable (= 1 if tract bounds river; 0 otherwise)
  - 5) NOX nitric oxides concentration (parts per 10 million)
  - 6) RM average number of rooms per dwelling
  - 7) AGE proportion of owner-occupied units built prior to 1940
  - 8) DIS weighted distances to five Boston employment centres
  - 9) RAD index of accessibility to radial highways
  - 10) TAX full-value property-tax rate per $10,000
  - 11) PTRATIO pupil-teacher ratio by town
  - 12) B 1000(Bk - 0.63)^2 where Bk is the prop. of b. by town
  - 13) LSTAT % lower status of the population

Returns

- `X, y` : [n_samples, n_features], [n_class_labels]

  X is the feature matrix with 506 housing samples as rows and 13 feature columns. y is a 1-dimensional array of the continuous target variable MEDV

22 data.iris_data

A function that loads the `iris` dataset into NumPy arrays.

```
from mlxtend.data import iris_data
```

22.1 Overview

The Iris dataset for classification.

Features

1. Sepal length
2. Sepal width
3. Petal length
4. Petal width

- Number of samples: 150
- Target variable (discrete): {50x Setosa, 50x Versicolor, 50x Virginica}

22.1.1 References

- Source: https://archive.ics.uci.edu/ml/datasets/Iris
- Bache, K. & Lichman, M. (2013). UCI Machine Learning Repository. Irvine, CA: University of California, School of Information and Computer Science.

22.2 Example 1 - Dataset overview

```
from mlxtend.data import iris_data
X, y = iris_data()

print('Dimensions: %s x %s' % (X.shape[0], X.shape[1]))
print('\nHeader: %s' % ['sepal length', 'sepal width',
                        'petal length', 'petal width'])
print('1st row', X[0])
```

```
Dimensions: 150 x 4

Header: ['sepal length', 'sepal width', 'petal length', 'petal width']
1st row [ 5.1  3.5  1.4  0.2]
```

```
import numpy as np
print('Classes: Setosa, Versicolor, Virginica')
print(np.unique(y))
print('Class distribution: %s' % np.bincount(y))
```

```
Classes: Setosa, Versicolor, Virginica
[0 1 2]
Class distribution: [50 50 50]
```

22.3 API

iris_data()

Iris flower dataset.

- `Source` : https://archive.ics.uci.edu/ml/datasets/Iris
- `Number of samples` : 150
- `Class labels` : {0, 1, 2}, distribution: [50, 50, 50]

  0 = setosa, 1 = versicolor, 2 = virginica.

  Dataset Attributes:

  - 1) sepal length [cm]
  - 2) sepal width [cm]
  - 3) petal length [cm]
  - 4) petal width [cm]

Returns

- `X, y` : [n_samples, n_features], [n_class_labels]

  X is the feature matrix with 150 flower samples as rows, and 4 feature columns sepal length, sepal width, petal length, and petal width. y is a 1-dimensional array of the class labels {0, 1, 2}

23 data.loadlocal_mnist

A utility function that loads the MNIST dataset from byte-form into NumPy arrays.

```
from mlxtend.data import loadlocal_mnist
```

23.1 Overview

The MNIST dataset was constructed from two datasets of the US National Institute of Standards and Technology (NIST). The training set consists of handwritten digits from 250 different people, 50 percent high school students, and 50 percent employees from the Census Bureau. Note that the test set contains handwritten digits from different people following the same split.

The MNIST dataset is publicly available at http://yann.lecun.com/exdb/mnist/ and consists of the following four parts: - Training set images: train-images-idx3-ubyte.gz (9.9 MB, 47 MB unzipped, and 60,000 samples) - Training set labels: train-labels-idx1-ubyte.gz (29 KB, 60 KB unzipped, and 60,000 labels) - Test set images: t10k-images-idx3-ubyte.gz (1.6 MB, 7.8 MB, unzipped and 10,000 samples) - Test set labels: t10k-labels-idx1-ubyte.gz (5 KB, 10 KB unzipped, and 10,000 labels)

Features

Each feature vector (row in the feature matrix) consists of 784 pixels (intensities) – unrolled from the original 28x28 pixels images.

- Number of samples: 50000 images
- Target variable (discrete): {50x Setosa, 50x Versicolor, 50x Virginica}

23.1.1 References

- Source: http://yann.lecun.com/exdb/mnist/
- Y. LeCun and C. Cortes. Mnist handwritten digit database. AT&T Labs [Online]. Available: http://yann. lecun. com/exdb/mnist, 2010.

23.2 Example 1 Part 1 - Downloading the MNIST dataset

1) Download the MNIST files from Y. LeCun's website

- http://yann.lecun.com/exdb/mnist/train-images-idx3-ubyte.gz
- http://yann.lecun.com/exdb/mnist/train-labels-idx1-ubyte.gz
- http://yann.lecun.com/exdb/mnist/t10k-images-idx3-ubyte.gz
- http://yann.lecun.com/exdb/mnist/t10k-labels-idx1-ubyte.gz

for example, via

```
curl -O http://yann.lecun.com/exdb/mnist/train-images-idx3-ubyte.gz
```

2) Unzip the downloaded gzip archives

for example, via

```
gunzip t*-ubyte.gz
```

23.3 Example 1 Part 2 - Loading MNIST into NumPy Arrays

```
from mlxtend.data import loadlocal_mnist
```

```
X, y = loadlocal_mnist(
        images_path='/Users/Sebastian/Desktop/train-images-idx3-ubyte',
        labels_path='/Users/Sebastian/Desktop/train-labels-idx1-ubyte')
```

```
print('Dimensions: %s x %s' % (X.shape[0], X.shape[1]))
print('\n1st row', X[0])
```

```
Dimensions: 60000 x 784
```

```
1st row [  0   0   0   0   0   0   0   0   0   0   0   0   0   0   0   0   0   0
   0   0   0   0   0   0   0   0   0   0   0   0   0   0   0   0   0

   0   0   0   0   0   0   0   0   0   0   0   0   0   0   0   0   0   0
   0   0   0   0   0   0   0   0   0   0]
```

```
import numpy as np

print('Digits:  0 1 2 3 4 5 6 7 8 9')
print('labels: %s' % np.unique(y))
print('Class distribution: %s' % np.bincount(y))
```

```
Digits:  0 1 2 3 4 5 6 7 8 9
labels: [0 1 2 3 4 5 6 7 8 9]
Class distribution: [5923 6742 5958 6131 5842 5421 5918 6265 5851 5949]
```

23.3.1 Store as CSV Files

```
np.savetxt(fname='/Users/Sebastian/Desktop/images.csv',
           X=X, delimiter=',', fmt='%d')
np.savetxt(fname='/Users/Sebastian/Desktop/labels.csv',
           X=y, delimiter=',', fmt='%d')
```

23.4 API

loadlocal_mnist(images_path, labels_path)

Read MNIST from ubyte files.

Parameters

- `images_path` : str
  path to the test or train MNIST ubyte file
- `labels_path` : str
  path to the test or train MNIST class labels file

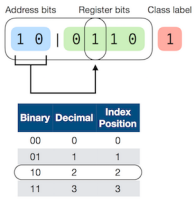
Returns

- `images` : [n_samples, n_pixels] numpy.array
  Pixel values of the images.
- `labels` : [n_samples] numpy array
  Target class labels

24 data.make_multiplexer_dataset

Function that creates a dataset generated by a n-bit Boolean multiplexer for evaluating supervised learning algorithms.

```
from mlxtend.data import make_multiplexer_dataset
```



24.1 Overview

The `make_multiplexer_dataset` function creates a dataset generated by an n-bit Boolean multiplexer. Such dataset represents a dataset generated by a simple rule, based on the behavior of a electric multiplexer, yet presents a relatively challenging classification problem for supervised learning algorithm with interactions between features (epistasis) as it may be encountered in many real-world scenarios [1].

The following illustration depicts a 6-bit multiplexer that consists of 2 address bits and 4 register bits. The address bits converted to decimal representation point to a position in the register bit. For example, if the address bits are "00" (0 in decimal), the address bits point to the register bit at position 0. The value of the register position pointed to determines the class label. For example, if the register bit at position is 0, the class label is 0. Vice versa, if the register bit at position 0 is 1, the class label is 1.

In the example above, the address bits "10" (2 in decimal) point to the 3rd register position (as we start counting from index 0), which has a bit value of 1. Hence, the class label is 1.

Below are a few more examples:

1. Address bits: [0, 1], register bits: [1, 0, 1, 1], class label: 0
2. Address bits: [0, 1], register bits: [1, 1, 1, 0], class label: 1
3. Address bits: [1, 0], register bits: [1, 0, 0, 1], class label: 0
4. Address bits: [1, 1], register bits: [1, 1, 1, 0], class label: 0
5. Address bits: [0, 1], register bits: [0, 1, 1, 0], class label: 1
6. Address bits: [0, 1], register bits: [1, 0, 0, 1], class label: 0
7. Address bits: [0, 1], register bits: [0, 1, 1, 1], class label: 1
8. Address bits: [0, 1], register bits: [0, 0, 0, 0], class label: 0
9. Address bits: [1, 0], register bits: [1, 0, 1, 1], class label: 1
10. Address bits: [0, 1], register bits: [1, 1, 1, 1], class label: 1

Note that in the implementation of the multiplexer function, if the number of address bits is set to 2, this results in a 6 bit multiplexer as two bit can have 2^2=4 different register positions (2 bit + 4 bit = 6 bit). However, if we choose 3 address bits instead, 2^3=8 positions would be covered, resulting in a 11 bit (3 bit + 8 bit = 11 bit) multiplexer, and so forth.

24.2 Example 1 – 6-bit multiplexer

This simple example illustrates how to create dataset from a 6-bit multiplexer

```
import numpy as np
from mlxtend.data import make_multiplexer_dataset
```

```
X, y = make_multiplexer_dataset(address_bits=2,
                                sample_size=10,
                                positive_class_ratio=0.5,
                                shuffle=False,
                                random_seed=123)

print('Features:\n', X)
print('\nClass labels:\n', y)
```

```
Features:
 [[0 1 0 1 0 1]
 [1 0 0 0 1 1]
 [0 1 1 1 0 0]
 [0 1 1 1 0 0]
 [0 0 1 1 0 0]
 [0 1 0 0 0 0]
 [0 1 1 0 1 1]
 [1 0 1 0 0 0]
 [1 0 0 1 0 1]
 [1 0 1 0 0 1]]

Class labels:
 [1 1 1 1 1 0 0 0 0 0]
```

24.3 API

make_multiplexer_dataset(address_bits=2, sample_size=100, positive_class_ratio=0.5, shuffle=False, random_seed=None)

Function to create a binary n-bit multiplexer dataset.

New in mlxtend v0.9

Parameters

- `address_bits` : int (default: 2)

  A positive integer that determines the number of address bits in the multiplexer, which in turn determine the n-bit capacity of the multiplexer and therefore the number of features. The number of features is determined by the number of address bits. For example, 2 address bits will result in a 6 bit multiplexer and consequently 6 features (2 + 2^2 = 6). If `address_bits=3`, then this results in an 11-bit multiplexer as (2 + 2^3 = 11) with 11 features.

- `sample_size` : int (default: 100)

  The total number of samples generated.

- `positive_class_ratio` : float (default: 0.5)

  The fraction (a float between 0 and 1) of samples in the `sample_size`d dataset that have class label 1. If `positive_class_ratio=0.5` (default), then the ratio of class 0 and class 1 samples is perfectly balanced.

- `shuffle` : Bool (default: False)

Whether or not to shuffle the features and labels. If `False` (default), the samples are returned in sorted order starting with `sample_size`/2 samples with class label 0 and followed by `sample_size`/2 samples with class label 1.

- `random_seed` : int (default: None)

  Random seed used for generating the multiplexer samples and shuffling.

Returns

- `X, y` : [n_samples, n_features], [n_class_labels]

  X is the feature matrix with the number of samples equal to `sample_size`. The number of features is determined by the number of address bits. For instance, 2 address bits will result in a 6 bit multiplexer and consequently 6 features (2 + 2^2 = 6). All features are binary (values in {0, 1}). y is a 1-dimensional array of class labels in {0, 1}.

25 data.mnist_data

A function that loads the `MNIST` dataset into NumPy arrays.

from mlxtend.data import mnist_data

25.1 Overview

The MNIST dataset was constructed from two datasets of the US National Institute of Standards and Technology (NIST). The training set consists of handwritten digits from 250 different people, 50 percent high school students, and 50 percent employees from the Census Bureau. Note that the test set contains handwritten digits from different people following the same split.

Features

Each feature vector (row in the feature matrix) consists of 784 pixels (intensities) – unrolled from the original 28x28 pixels images.

- Number of samples: A subset of 5000 images (the first 500 digits of each class)
- Target variable (discrete): {500x 0, ..., 500x 9}

25.1.1 References

    0.    0.    0.    0.]
```

```
import numpy as np
print('Classes: Setosa, Versicolor, Virginica')
print(np.unique(y))
print('Class distribution: %s' % np.bincount(y))
```

```
Classes: Setosa, Versicolor, Virginica
[0 1 2 3 4 5 6 7 8 9]
Class distribution: [500 500 500 500 500 500 500 500 500 500]
```

25.3 Example 2 - Visualize MNIST

```
%matplotlib inline
import matplotlib.pyplot as plt
def plot_digit(X, y, idx):
    img = X[idx].reshape(28,28)
    plt.imshow(img, cmap='Greys',  interpolation='nearest')
    plt.title('true label: %d' % y[idx])
    plt.show()
plot_digit(X, y, 4)
```

25.4 API

mnist_data()

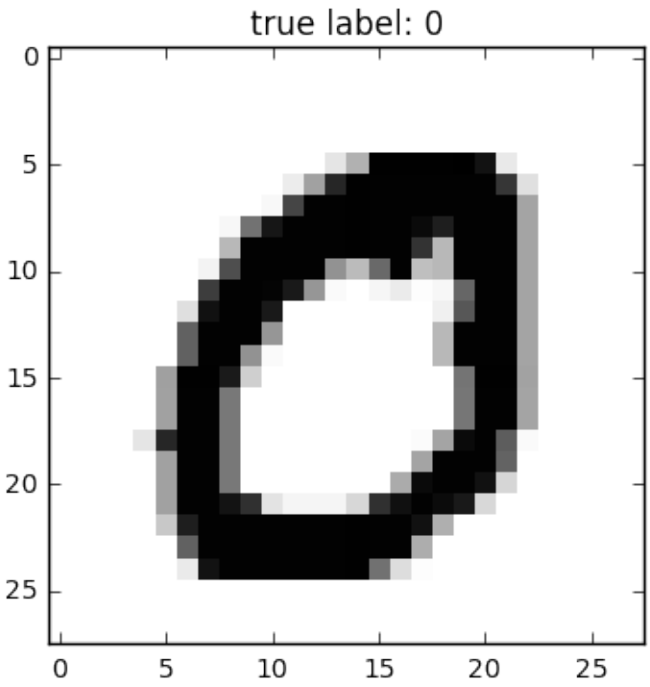
5000 samples from the MNIST handwritten digits dataset.

- `Data Source` : http://yann.lecun.com/exdb/mnist/

Returns

- `X, y` : [n_samples, n_features], [n_class_labels]

  X is the feature matrix with 5000 image samples as rows, each row consists of 28x28 pixels that were unrolled into 784 pixel feature vectors. y contains the 10 unique class labels 0-9.



26 data.three_blobs_data

A function that loads the `three_blobs` dataset into NumPy arrays.

```
from mlxtend.data import three_blobs_data
```

26.1 Overview

A random dataset of 3 2D blobs for clustering.

- Number of samples : 150
- Suggested labels ∈ {0, 1, 2}, distribution: [50, 50, 50]

26.1.1 References

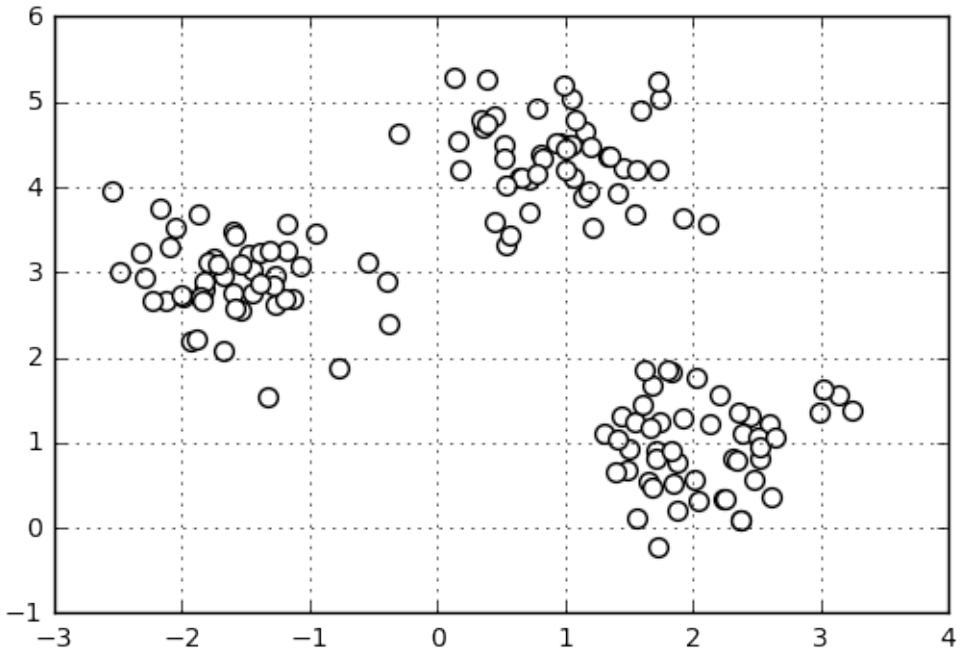
-

26.2 Example 1 - Dataset overview

```
from mlxtend.data import three_blobs_data
X, y = three_blobs_data()

print('Dimensions: %s x %s' % (X.shape[0], X.shape[1]))

print('1st row', X[0])
```



```
Dimensions: 150 x 2
1st row [ 2.60509732  1.22529553]
```

```
import numpy as np

print('Suggested cluster labels')
print(np.unique(y))
print('Label distribution: %s' % np.bincount(y))
```

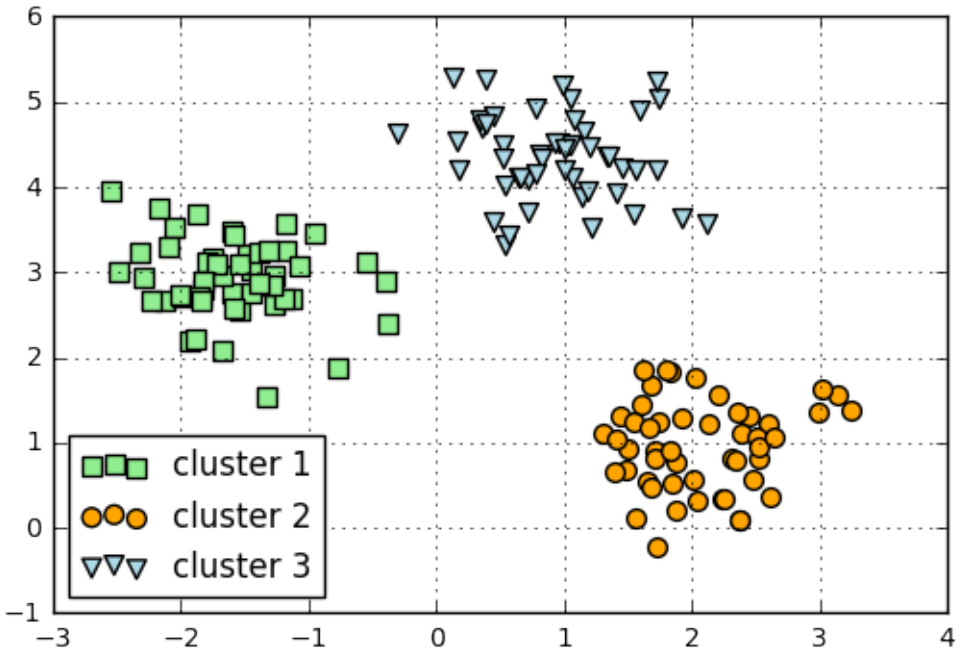
```
Suggested cluster labels
[0 1 2]
Label distribution: [50 50 50]
```

```
import matplotlib.pyplot as plt

plt.scatter(X[:,0], X[:,1],
            c='white',
            marker='o',
            s=50)

plt.grid()
plt.show()
```

```
plt.scatter(X[y == 0, 0],
            X[y == 0, 1],
            s=50,
            c='lightgreen',
```



```
            marker='s',
            label='cluster 1')

plt.scatter(X[y == 1,0],
            X[y == 1,1],
            s=50,
            c='orange',
            marker='o',
            label='cluster 2')

plt.scatter(X[y == 2,0],
            X[y == 2,1],
            s=50,
            c='lightblue',
            marker='v',
            label='cluster 3')

plt.legend(loc='lower left')
plt.grid()
plt.show()
```

26.3 API

three_blobs_data()

A random dataset of 3 2D blobs for clustering.

- `Number of samples` : 150

- `Suggested labels` : {0, 1, 2}, distribution: [50, 50, 50]

Returns

- `X, y` : [n_samples, n_features], [n_cluster_labels]

  X is the feature matrix with 159 samples as rows and 2 feature columns. y is a 1-dimensional array of the 3 suggested cluster labels 0, 1, 2

27 data.wine_data

A function that loads the `Wine` dataset into NumPy arrays.

```
from mlxtend.data import wine_data
```

27.1 Overview

The Wine dataset for classification.

Samples	178
Features	13
Classes	3
Data Set Characteristics:	Multivariate
Attribute Characteristics:	Integer, Real
Associated Tasks:	Classification
Missing Values	None

column	attribute
1)	Class Label
2)	Alcohol
3)	Malic acid
4)	Ash
5)	Alcalinity of ash
6)	Magnesium
7)	Total phenols
8)	Flavanoids
9)	Nonflavanoid phenols
10)	Proanthocyanins
11)	Color intensity
12)	Hue
13)	OD280/OD315 of diluted wines
14)	Proline

class	samples
0	59
1	71
2	48

```

27.3 API

wine_data()

Wine dataset.

- `Source` : https://archive.ics.uci.edu/ml/datasets/Wine
- `Number of samples` : 178
- `Class labels` : {0, 1, 2}, distribution: [59, 71, 48]

  Dataset Attributes:

  - 1) Alcohol
  - 2) Malic acid

  - 3) Ash
  - 4) Alcalinity of ash
  - 5) Magnesium
  - 6) Total phenols
  - 7) Flavanoids
  - 8) Nonflavanoid phenols
  - 9) Proanthocyanins
  - 10) Color intensity
  - 11) Hue
  - 12) OD280/OD315 of diluted wines
  - 13) Proline

Returns

- `X, y` : [n_samples, n_features], [n_class_labels]

  X is the feature matrix with 178 wine samples as rows and 13 feature columns. y is a 1-dimensional array of the 3 class labels 0, 1, 2

28 evaluate.bootstrap

An implementation of the ordinary nonparametric bootstrap to bootstrap a single statistic (for example, the mean. median, R^2 of a regression fit, and so forth).

```
from mlxtend.evaluate import bootstrap
```

28.1 Overview

The bootstrap offers an easy and effective way to estimate the distribution of a statistic via simulation, by drawing (or generating) new samples from an existing sample with replacement. Note that the bootstrap does not require making any assumptions about the sample statistic or dataset being normally distributed.

Using the bootstrap, we can estimate sample statistics and compute the standard error of the mean and confidence intervals as if we have drawn a number of samples from an infinite population. In a nutshell, the bootstrap procedure can be described as follows:

1. Draw a sample with replacement
2. Compute the sample statistic
3. Repeat step 1-2 n times
4. Compute the standard deviation (standard error of the mean of the statistic)
5. Compute the confidence interval

Or, in simple terms, we can interpret the bootstrap a means of drawing a potentially endless number of (new) samples from a population by resampling the original dataset.

Note that the term "bootstrap replicate" is being used quite loosely in current literature; many researchers and practitioners use it to define the number of bootstrap samples we draw from the original dataset. However, in the context of this documentation and the code annotation, we use the original definition of bootstrap repliactes and use it to refer to the statistic computed from a bootstrap sample.

28.1.1 References

- [1] Efron, Bradley, and Robert J. Tibshirani. An introduction to the bootstrap. CRC press, 1994. Management of Data (ACM SIGMOD '97), pages 265-276, 1997.

28.2 Example 1 – Bootstrapping the Mean

This simple example illustrates how you could bootstrap the mean of a sample.

```
import numpy as np
from mlxtend.evaluate import bootstrap

rng = np.random.RandomState(123)
x = rng.normal(loc=5., size=100)
original, std_err, ci_bounds = bootstrap(x, num_rounds=1000, func=np.mean, ci=0.95, seed=123)
print('Mean: %.2f, SE: +/- %.2f, CI95: [%.2f, %.2f]' % (original,
                                                        std_err,
                                                        ci_bounds[0],
                                                        ci_bounds[1]))
```

```
Mean: 5.03, SE: +/- 0.11, CI95: [4.80, 5.26]
```

28.3 Example 2 - Bootstrapping a Regression Fit

This example illustrates how you can bootstrap the R^2 of a regression fit on the training data.

```
from mlxtend.data import autompg_data

from sklearn.linear_model import LinearRegression
from sklearn.metrics import r2_score

X, y = autompg_data()

lr = LinearRegression()

def r2_fit(X, model=lr):
    x, y = X[:, 0].reshape(-1, 1), X[:, 1]
    pred = lr.fit(x, y).predict(x)
    return r2_score(y, pred)

original, std_err, ci_bounds = bootstrap(X, num_rounds=1000,
                                         func=r2_fit,
                                         ci=0.95,
                                         seed=123)
print('Mean: %.2f, SE: +/- %.2f, CI95: [%.2f, %.2f]' % (original,
                                                        std_err,
                                                        ci_bounds[0],
                                                        ci_bounds[1]))
```

```
Mean: 0.90, SE: +/- 0.01, CI95: [0.89, 0.92]
```

28.4 API

bootstrap(x, func, num_rounds=1000, ci=0.95, ddof=1, seed=None)

Implements the ordinary nonparametric bootstrap

Parameters

- `x` : NumPy array, shape=(n_samples, [n_columns])

  An one or multidimensional array of data records

- `func` :

  A function which computes a statistic that is used to compute the bootstrap replicates (the statistic computed from the bootstrap samples). This function must return a scalar value. For example, `np.mean` or `np.median` would be an acceptable argument for `func` if `x` is a 1-dimensional array or vector.

- `num_rounds` : int (default=1000)

  The number of bootstrap samnples to draw where each bootstrap sample has the same number of records as the original dataset.

- `ci` : int (default=0.95)

  An integer in the range (0, 1) that represents the confidence level for computing the confidence interval. For example, `ci=0.95` (default) will compute the 95% confidence interval from the bootstrap replicates.

- `ddof` : int

  The delta degrees of freedom used when computing the standard error.

- `seed` : int or None (default=None)

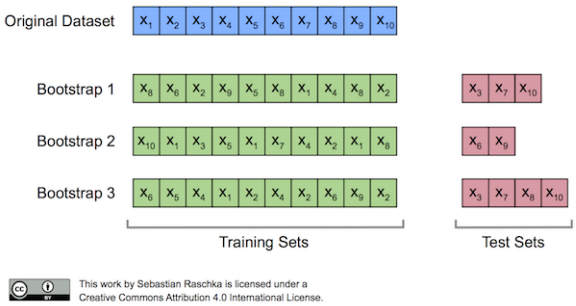
  Random seed for generating bootstrap samples.

Returns

```
original, standard_error, (lower_ci, upper_ci)
Returns the statistic of the original sample (`original`),
the standard error of the estimate, and the
respective confidence interval bounds.
```

Examples

```
>>> from mlxtend.evaluate import bootstrap
>>> rng = np.random.RandomState(123)
>>> x = rng.normal(loc=5., size=100)
>>> original, std_err, ci_bounds = bootstrap(x,
...                                          num_rounds=1000,
...                                          func=np.mean,
...                                          ci=0.95,
...                                          seed=123)
>>> print('Mean: %.2f, SE: +/- %.2f, CI95: [%.2f, %.2f]' % (original,
...                                                         std_err,
...                                                         ci_bounds[0],
...                                                         ci_bounds[1]))
Mean: 5.03, SE: +/- 0.11, CI95: [4.80, 5.26]
>>>
```



29 evaluate.BootstrapOutOfBag

An implementation of the out-of-bag bootstrap to evaluate supervised learning algorithms.

```
from mlxtend.evaluate import BootstrapOutOfBag
```

29.1 Overview

Originally, the bootstrap method aims to determine the statistical properties of an estimator when the underlying distribution was unknown and additional samples are not available. Now, in order to exploit this method for the evaluation of predictive models, such as hypotheses for classification and regression, we may prefer a slightly different approach to bootstrapping using the so-called Out-Of-Bag (OOB) or Leave-One-Out Bootstrap (LOOB) technique. Here, we use out-of-bag samples as test sets for evaluation instead of evaluating the model on the training data. Out-of-bag samples are the unique sets of instances that are not used for model fitting as shown in the figure below [1].

The figure above illustrates how three random bootstrap samples drawn from an exemplary ten-sample dataset $(X_1, X_2, ..., X_{10})$ and their out-of-bag sample for testing may look like. In practice, Bradley Efron and Robert Tibshirani recommend drawing 50 to 200 bootstrap samples as being sufficient for reliable estimates [2].

29.1.1 References

- [1] https://sebastianraschka.com/blog/2016/model-evaluation-selection-part2.html
- [2] Efron, Bradley, and Robert J. Tibshirani. An introduction to the bootstrap. CRC press, 1994. Management of Data (ACM SIGMOD '97), pages 265-276, 1997.

29.2 Example 1 – Evaluating the predictive performance of a model

The `BootstrapOutOfBag` class mimics the behavior of scikit-learn's cross-validation classes, e.g., `KFold`:

```
from mlxtend.evaluate import BootstrapOutOfBag
import numpy as np

oob = BootstrapOutOfBag(n_splits=3)
for train, test in oob.split(np.array([1, 2, 3, 4, 5])):
    print(train, test)
```

```
[4 2 1 3 3] [0]
[2 4 1 2 1] [0 3]
[4 3 3 4 1] [0 2]
```

Consequently, we can use `BootstrapOutOfBag` objects via the `cross_val_score` method:

```
from sklearn.datasets import load_iris
from sklearn.linear_model import LogisticRegression
from sklearn.model_selection import cross_val_score

iris = load_iris()
X = iris.data
y = iris.target
lr = LogisticRegression()

print(cross_val_score(lr, X, y))
```

```
[ 0.96078431  0.92156863  0.95833333]
```

```
print(cross_val_score(lr, X, y, cv=BootstrapOutOfBag(n_splits=3, random_seed=456)))
```

```
[ 0.92727273  0.96226415  0.94444444]
```

In practice, it is recommended to run at least 200 iterations, though:

```
print('Mean accuracy: %.1f%%' % np.mean(100*cross_val_score(
    lr, X, y, cv=BootstrapOutOfBag(n_splits=200, random_seed=456))))
```

```
Mean accuracy: 94.8%
```

Using the bootstrap, we can use the percentile method to compute the confidence bounds of the performance estimate. We pick our lower and upper confidence bounds as follows:

- $ACC_{lower} = \alpha_1 th$ percentile of the ACC_{boot} distribution
- $ACC_{lower} = \alpha_2 th$ percentile of the ACC_{boot} distribution

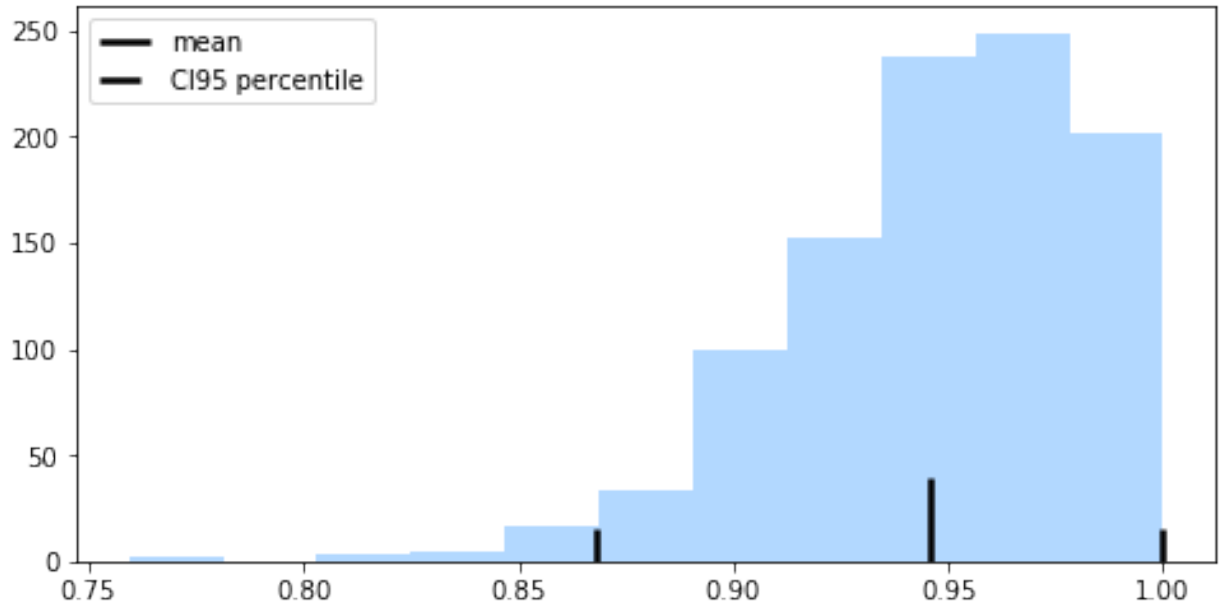
where $\alpha_1 = \alpha$ and $\alpha_2 = 1 - \alpha$, and the degree of confidence to compute the $100 \times (1 - 2 \times \alpha)$ confidence interval. For instance, to compute a 95% confidence interval, we pick $\alpha = 0.025$ to obtain the 2.5th and 97.5th percentiles of the b bootstrap samples distribution as the upper and lower confidence bounds.

```
import matplotlib.pyplot as plt
%matplotlib inline

accuracies = cross_val_score(lr, X, y, cv=BootstrapOutOfBag(n_splits=1000, random_seed=456))
mean = np.mean(accuracies)

lower = np.percentile(accuracies, 2.5)
upper = np.percentile(accuracies, 97.5)

fig, ax = plt.subplots(figsize=(8, 4))
ax.vlines(mean, [0], 40, lw=2.5, linestyle='-', label='mean')
```



```
ax.vlines(lower, [0], 15, lw=2.5, linestyle='-.', label='CI95 percentile')
ax.vlines(upper, [0], 15, lw=2.5, linestyle='-.')

ax.hist(accuracies, bins=11,
        color='#0080ff', edgecolor="none",
        alpha=0.3)
plt.legend(loc='upper left')

plt.show()
```

29.3 API

BootstrapOutOfBag(n_splits=200, random_seed=None)

Parameters

- `n_splits` : int (default=200)
  Number of bootstrap iterations. Must be larger than 1.
- `random_seed` : int (default=None)
  If int, random_seed is the seed used by the random number generator.

Returns

- `train_idx` : ndarray
  The training set indices for that split.

- `test_idx` : ndarray
  The testing set indices for that split.

Examples

```
raise ValueError('test')
```

29.3.1 Methods

get_n_splits(X=None, y=None, groups=None)

Returns the number of splitting iterations in the cross-validator

Parameters

- `X` : object
  Always ignored, exists for compatibility with scikit-learn.
- `y` : object
  Always ignored, exists for compatibility with scikit-learn.
- `groups` : object
  Always ignored, exists for compatibility with scikit-learn.

Returns

- `n_splits` : int
  Returns the number of splitting iterations in the cross-validator.

split(X, y=None, groups=None)

y : array-like or None (default: None) Argument is not used and only included as parameter for compatibility, similar to `KFold` in scikit-learn.

- `groups` : array-like or None (default: None)
  Argument is not used and only included as parameter for compatibility, similar to `KFold` in scikit-learn.

30 evaluate.confusion_matrix

Functions for generating confusion matrices.

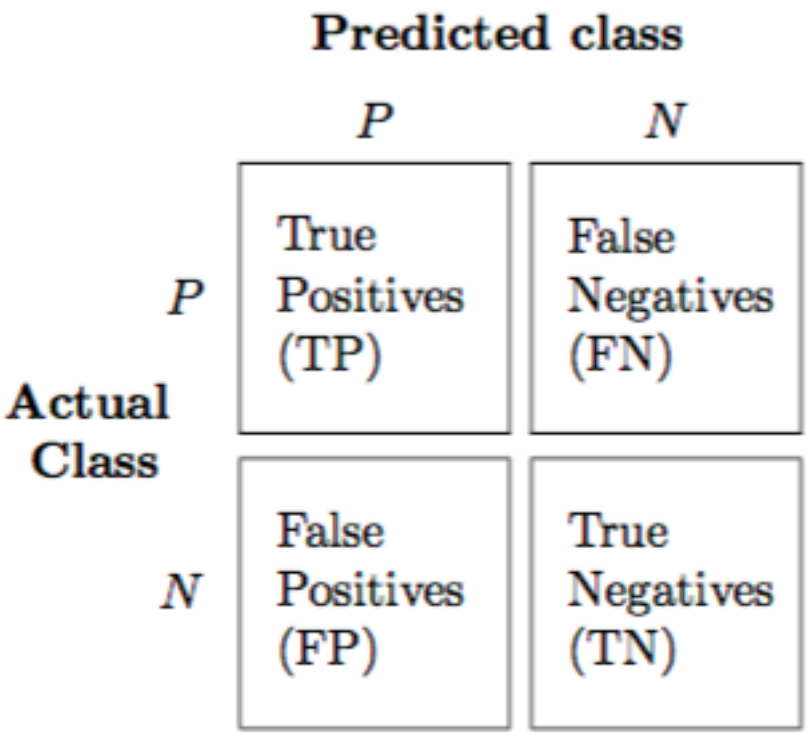
```
from mlxtend.evaluate import confusion_matrix
from mlxtend.evaluate import plot_confusion_matrix
```

30.1 Overview

30.1.1 Confusion Matrix

The *confusion matrix* (or *error matrix*) is one way to summarize the performance of a classifier for binary classification tasks. This square matrix consists of columns and rows that list the number of instances as absolute or relative "actual class" vs. "predicted class" ratios.

Let P be the label of class 1 and N be the label of a second class or the label of all classes that are *not class 1* in a multi-class setting.



30.1.2 References

- –

30.2 Example 1 - Binary classification

```
from mlxtend.evaluate import confusion_matrix

y_target =    [0, 0, 1, 0, 0, 1, 1, 1]
y_predicted = [1, 0, 1, 0, 0, 0, 0, 1]

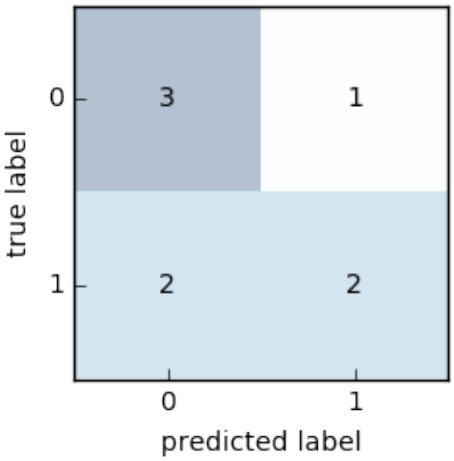
cm = confusion_matrix(y_target=y_target,
                      y_predicted=y_predicted)
cm
```

```
array([[3, 1],
       [2, 2]])
```

To visualize the confusion matrix using matplotlib, see the utility function `mlxtend.plotting.plot_confusion_matrix`:

```
import matplotlib.pyplot as plt
from mlxtend.plotting import plot_confusion_matrix

fig, ax = plot_confusion_matrix(conf_mat=cm)
plt.show()
```



30.3 Example 2 - Multi-class classification

```
from mlxtend.evaluate import confusion_matrix

y_target =    [1, 1, 1, 0, 0, 2, 0, 3]
y_predicted = [1, 0, 1, 0, 0, 2, 1, 3]

cm = confusion_matrix(y_target=y_target,
                      y_predicted=y_predicted,
                      binary=False)
cm
```

```
array([[2, 1, 0, 0],
       [1, 2, 0, 0],
       [0, 0, 1, 0],
       [0, 0, 0, 1]])
```

To visualize the confusion matrix using matplotlib, see the utility function `mlxtend.plotting.plot_confusion_matrix`:

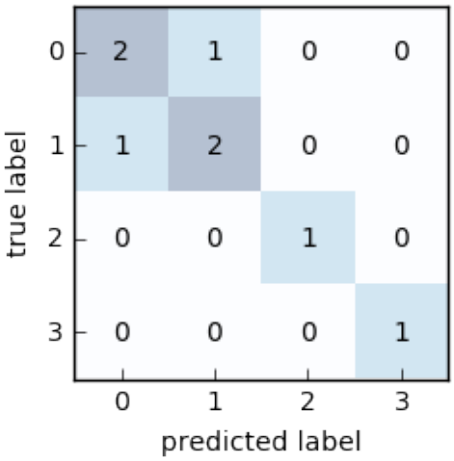
```
import matplotlib.pyplot as plt
from mlxtend.evaluate import confusion_matrix

fig, ax = plot_confusion_matrix(conf_mat=cm)
plt.show()
```

30.4 Example 3 - Multi-class to binary

By setting `binary=True`, all class labels that are not the positive class label are being summarized to class 0. The positive class label becomes class 1.

```
import matplotlib.pyplot as plt
from mlxtend.evaluate import confusion_matrix
```



```
y_target =    [1, 1, 1, 0, 0, 2, 0, 3]
y_predicted = [1, 0, 1, 0, 0, 2, 1, 3]

cm = confusion_matrix(y_target=y_target,
                      y_predicted=y_predicted,
                      binary=True,
                      positive_label=1)
cm
```

```
array([[4, 1],
       [1, 2]])
```

To visualize the confusion matrix using matplotlib, see the utility function `mlxtend.plotting.plot_confusion_matrix`:

```
from mlxtend.plotting import plot_confusion_matrix

fig, ax = plot_confusion_matrix(conf_mat=cm)
plt.show()
```

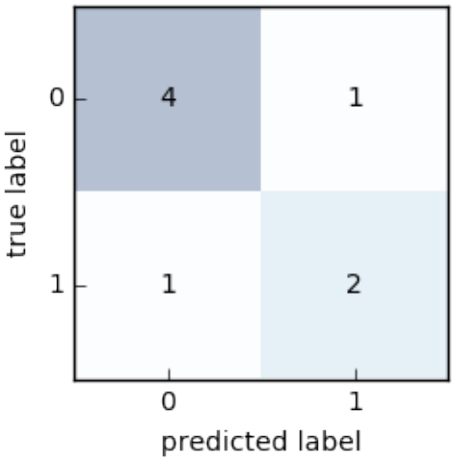
30.5 API

confusion_matrix(y_target, y_predicted, binary=False, positive_label=1)

Compute a confusion matrix/contingency table.

Parameters

- `y_target` : array-like, shape=[n_samples]
  True class labels.
- `y_predicted` : array-like, shape=[n_samples]
  Predicted class labels.



- `binary` : bool (default: False)

  Maps a multi-class problem onto a binary confusion matrix, where the positive class is 1 and all other classes are 0.

- `positive_label` : int (default: 1)

  Class label of the positive class.

Returns

- `mat` : array-like, shape=[n_classes, n_classes]

31 evaluate.lift_score

Scoring function to compute the LIFT metric, the ratio of correctly predicted positive examples and the actual positive examples in the test dataset.

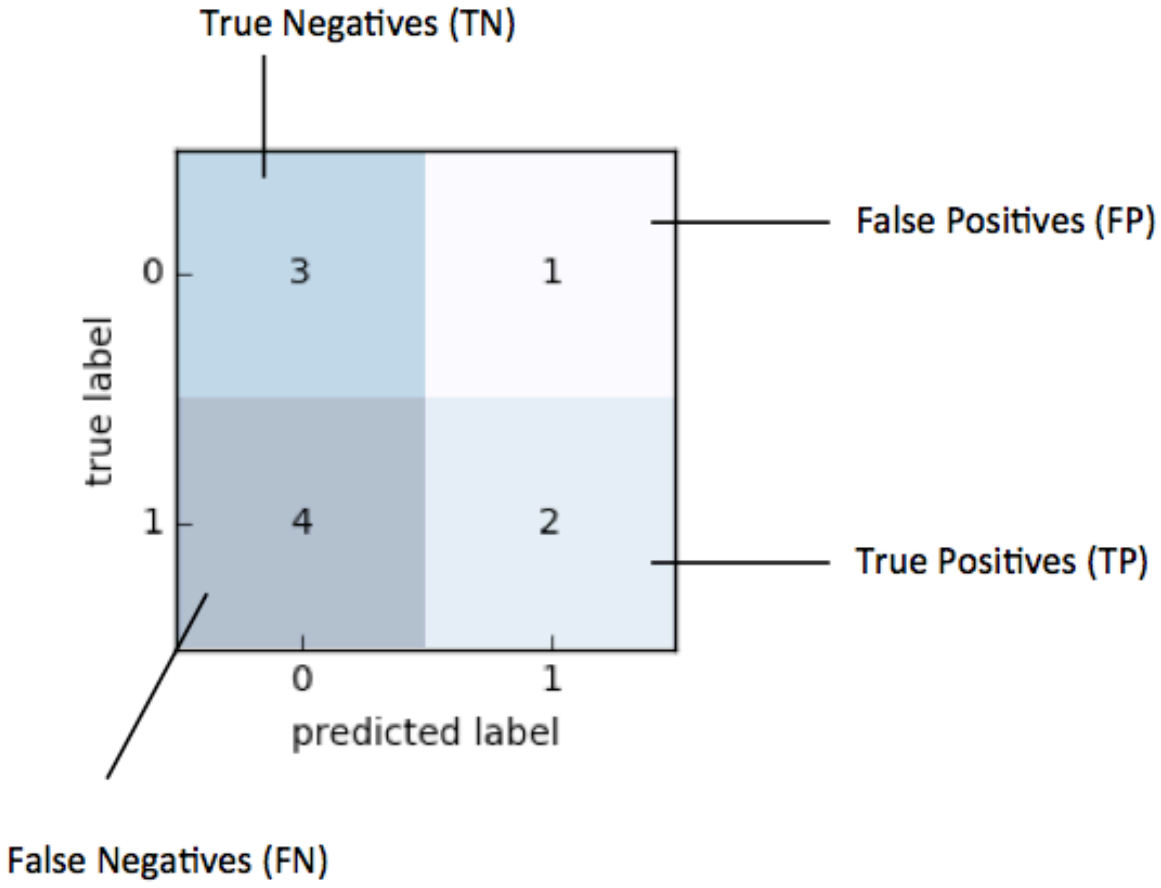
```
from mlxtend.evaluate import lift_score
```

31.1 Overview

In the context of classification, *lift* [1] compares model predictions to randomly generated predictions. Lift is often used in marketing research combined with *gain and lift* charts as a visual aid [2]. For example, assuming a 10% customer response as a baseline, a lift value of 3 would correspond to a 30% customer response when using the predictive model. Note that *lift* has the range $[0, \infty]$.

There are many strategies to compute *lift*, and below, we will illustrate the computation of the lift score using a classic confusion matrix. For instance, let's assume the following prediction and target labels, where "1" is the positive class:

- true labels : $[0, 0, 1, 0, 0, 1, 1, 1, 1, 1]$
- prediction : $[1, 0, 1, 0, 0, 0, 0, 1, 0, 0]$



True Negatives (TN)
False Positives (FP)
True Positives (TP)
False Negatives (FN)
true label
predicted label
0
1
3
1
4
2
0
1

Then, our confusion matrix would look as follows:

Based on the confusion matrix above, with "1" as positive label, we compute *lift* as follows:

$$\text{lift} = \frac{(TP/(TP+FN)}{(TP+FP)/(TP+TN+FP+FN)}$$

Plugging in the actual values from the example above, we arrive at the following lift value:

$$\frac{2/(2+4)}{(2+1)/(2+3+1+4)} = 1.11.$$

An alternative way to computing lift is by using the *support* metric [3]:

$$\text{lift} = \frac{\text{support}(\text{true labels} \cup \text{prediction})/N}{\text{support}(\text{true labels})/N \times \text{support}(\text{prediction})/N},$$

where N is the number of samples in the datset. Plugging the values from our example into the equation above, we arrive at

$$\frac{2/10}{(6/10 \times 3/10)} = 1.11.$$

31.2 Example 1 - Computing Lift

This examples demonstrates the basic use of the `lift_score` function using the example from the *Overview* section.

```
import numpy as np
from mlxtend.evaluate import lift_score

y_target =    np.array([0, 0, 1, 0, 0, 1, 1, 1, 1, 1])
y_predicted = np.array([1, 0, 1, 0, 0, 0, 0, 1, 0, 0])

lift_score(y_target, y_predicted)
```

```
1.1111111111111112
```

31.3 Example 2 - Using `lift_score` in `GridSearch`

The `lift_score` function can also be used with scikit-learn objects, such as `GridSearch`:

```
from sklearn.datasets import load_iris
from sklearn.model_selection import train_test_split
from sklearn.model_selection import GridSearchCV
from sklearn.svm import SVC
from sklearn.metrics import make_scorer

# make custom scorer
lift_scorer = make_scorer(lift_score)

iris = load_iris()
X, y = iris.data, iris.target

X_train, X_test, y_train, y_test = train_test_split(
    X, y, test_size=0.2, stratify=y, random_state=123)

hyperparameters = [{'kernel': ['rbf'], 'gamma': [1e-3, 1e-4],
                    'C': [1, 10, 100, 1000]},
                   {'kernel': ['linear'], 'C': [1, 10, 100, 1000]}]

clf = GridSearchCV(SVC(), hyperparameters, cv=10,
                   scoring=lift_scorer)
clf.fit(X_train, y_train)

print(clf.best_score_)
print(clf.best_params_)

3.0
{'gamma': 0.001, 'kernel': 'rbf', 'C': 1000}
```

31.4 API

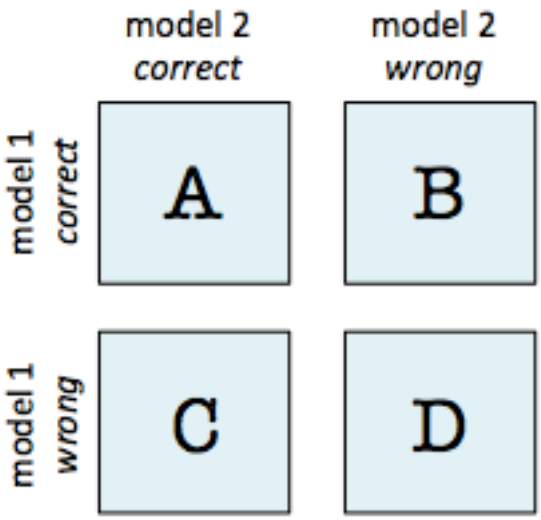
lift_score(y_target, y_predicted, binary=True, positive_label=1)

Lift measures the degree to which the predictions of a classification model are better than randomly-generated predictions.

The in terms of True Positives (TP), True Negatives (TN), False Positives (FP), and False Negatives (FN), the lift score is computed as: [TP/(TP+FN)] / [(TP+FP) / (TP+TN+FP+FN)]

Parameters

- `y_target` : array-like, shape=[n_samples]
  True class labels.
- `y_predicted` : array-like, shape=[n_samples]
  Predicted class labels.
- `binary` : bool (default: True)
  Maps a multi-class problem onto a binary, where the positive class is 1 and all other classes are 0.



- `positive_label` : int (default: 0)
  Class label of the positive class.

Returns

- `score` : float
  Lift score in the range [0, ∞]

32 evaluate.mcnemar_table

Function to compute a 2x2 contingency table for McNemar's Test

```
from mlxtend.evaluate import mcnemar_table
```

32.1 Overview

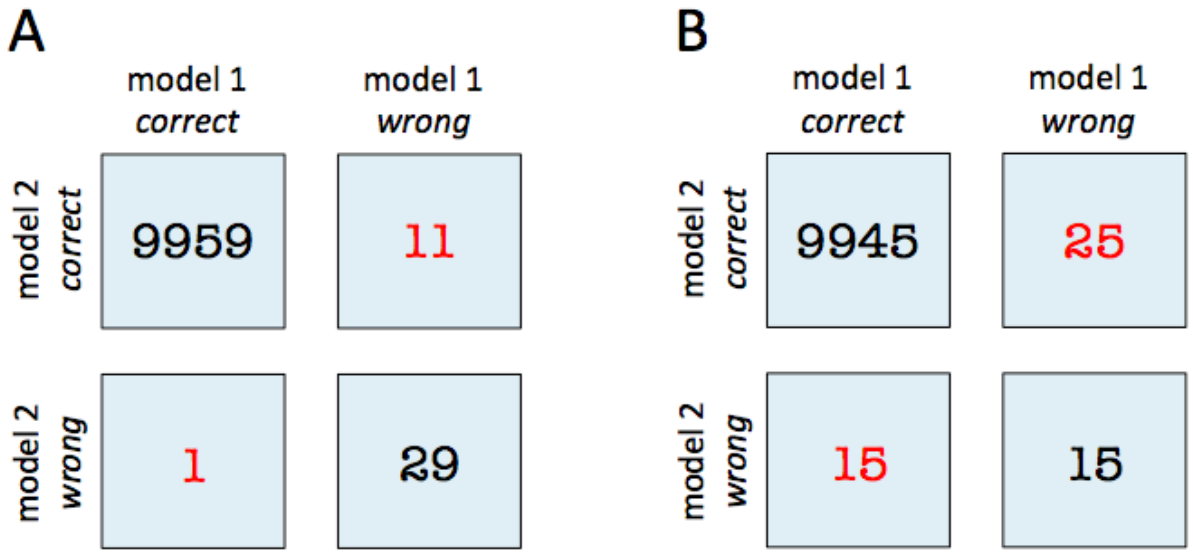
32.1.1 Contigency Table for McNemar's Test

A 2x2 contigency table as being used in a McNemar's Test (`mlxtend.evaluate.mcnemar`) is a useful aid for comparing two different models. In contrast to a typical confusion matrix, this table compares two models to each other rather than showing the false positives, true positives, false negatives, and true negatives of a single model's predictions:

For instance, given that 2 models have a accuracy of with a 99.7% and 99.6% a 2x2 contigency table can provide further insights for model selection.

In both subfigure A and B, the predictive accuracies of the two models are as follows:

- model 1 accuracy: 9,960 / 10,000 = 99.6%



- model 2 accuracy: 9,970 / 10,000 = 99.7%

Now, in subfigure A, we can see that model 2 got 11 predictions right that model 1 got wrong. Vice versa, model 2 got 1 prediction right that model 2 got wrong. Thus, based on this 11:1 ratio, we may conclude that model 2 performs substantially better than model 1. However, in subfigure B, the ratio is 25:15, which is less conclusive about which model is the better one to choose.

32.1.2 References

- Edwards AL: Note on the "correction for continuity" in testing the significance of the difference between correlated proportions. Psychometrika. 1948, 13 (3): 185-187. 10.1007/BF02289261.
- https://en.wikipedia.org/wiki/McNemar%27s_test

32.2 Example 2 - 2x2 Contigency Table

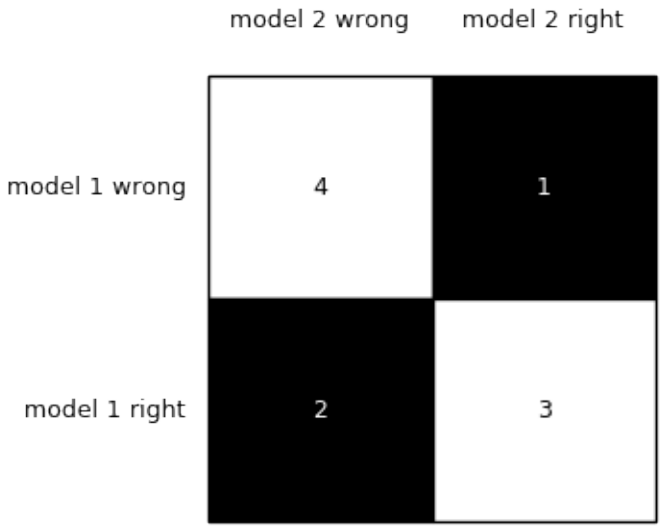
```
import numpy as np
from mlxtend.evaluate import mcnemar_table

y_true = np.array([0, 0, 0, 0, 0, 1, 1, 1, 1, 1])

y_mod1 = np.array([0, 1, 0, 0, 0, 1, 1, 0, 0, 0])
y_mod2 = np.array([0, 0, 1, 1, 0, 1, 1, 0, 0, 0])

tb = mcnemar_table(y_target=y_true,
                   y_model1=y_mod1,
                   y_model2=y_mod2)

tb
```



```
array([[4, 1],
       [2, 3]])
```

To visualize (and better interpret) the contigency table via matplotlib, we can use the `checkerboard_plot` function:

```
from mlxtend.plotting import checkerboard_plot
import matplotlib.pyplot as plt

brd = checkerboard_plot(tb,
                        figsize=(3, 3),
                        fmt='%d',
                        col_labels=['model 2 wrong', 'model 2 right'],
                        row_labels=['model 1 wrong', 'model 1 right'])
plt.show()
```

32.3 API

mcnemar_table(y_target, y_model1, y_model2)

Compute a 2x2 contigency table for McNemar's test.

Parameters

- `y_target` : array-like, shape=[n_samples]
  True class labels as 1D NumPy array.
- `y_model1` : array-like, shape=[n_samples]
  Predicted class labels from model as 1D NumPy array.

- `y_model2` : array-like, shape=[n_samples]
  Predicted class labels from model 2 as 1D NumPy array.

Returns

- `tb` : array-like, shape=[2, 2]
  2x2 contingency table with the following contents: a: tb[0, 0]: # of samples that both models predicted correctly b: tb[0, 1]: # of samples that model 1 got right and model 2 got wrong c: tb[1, 0]: # of samples that model 2 got right and model 1 got wrong d: tb[1, 1]: # of samples that both models predicted incorrectly

33 `evaluate.mcnemar`

McNemar's test for paired nominal data

```
from mlxtend.evaluate import mcnemar
```

33.1 Overview

McNemar's Test [1] (sometimes also called "within-subjects chi-squared test") is a statistical test for paired nominal data. In context of machine learning (or statistical) models, we can use McNemar's Test to compare the predictive accuracy of two models. McNemar's test is based on a 2 times 2 contigency table of the two model's predictions.

33.1.1 McNemar's Test Statistic

In McNemar's Test, we formulate the null hypothesis that the probabilities $p(b)$ and $p(c)$ are the same, or in simplified terms: None of the two models performs better than the other. Thus, the alternative hypothesis is that the performances of the two models are not equal.

The McNemar test statistic ("chi-squared") can be computed as follows:

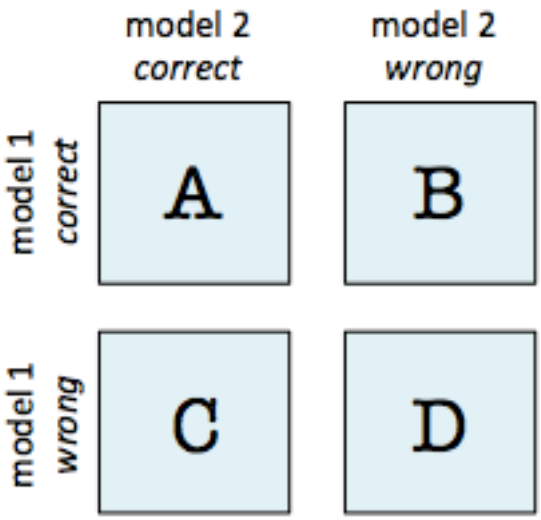
$$\chi^2 = \frac{(b-c)^2}{(b+c)},$$

If the sum of cell c and b is sufficiently large, the χ^2 value follows a chi-squared distribution with one degree of freedom. After setting a significance threshold, e.g,. $\alpha = 0.05$ we can compute the p-value – assuming that the null hypothesis is true, the p-value is the probability of observing this empirical (or a larger) chi-squared value. If the p-value is lower than our chosen significance level, we can reject the null hypothesis that the two model's performances are equal.

33.1.2 Continuity Correction

Approximately 1 year after Quinn McNemar published the McNemar Test [1], Edwards [2] proposed a continuity corrected version, which is the more commonly used variant today:

$$\chi^2 = \frac{(\mid b-c \mid -1)^2}{(b+c)}.$$



33.1.3 Exact p-values

As mentioned earlier, an exact binomial test is recommended for small sample sizes ($b + c < 25$ [3]), since the chi-squared value is may not be well-approximated by the chi-squared distribution. The exact p-value can be computed as follows:

$$p = 2 \sum_{i=b}^{n} \binom{n}{i} 0.5^i (1 - 0.5)^{n-i},$$

where $n = b + c$, and the factor 2 is used to compute the two-sided p-value.

33.1.4 Example

For instance, given that 2 models have a accuracy of with a 99.7% and 99.6% a 2x2 contigency table can provide further insights for model selection.

In both subfigure A and B, the predictive accuracies of the two models are as follows:

- model 1 accuracy: 9,960 / 10,000 = 99.6%
- model 2 accuracy: 9,970 / 10,000 = 99.7%

Now, in subfigure A, we can see that model 2 got 11 predictions right that model 1 got wrong. Vice versa, model 2 got 1 prediction right that model 2 got wrong. Thus, based on this 11:1 ratio, we may conclude that model 2 performs substantially better than model 1. However, in subfigure B, the ratio is 25:15, which is less conclusive about which model is the better one to choose.

In the following coding examples, we will use these 2 scenarios A and B to illustrate McNemar's test.

- [3] https://en.wikipedia.org/wiki/McNemar%27s_test

33.2 Example 1 - Creating 2x2 Contigency tables

The `mcnemar` funtion expects a 2x2 contingency table as a NumPy array that is formatted as follows:

Such a contigency matrix can be created by using the `mcnemar_table` function from `mlxtend.evaluate`. For example:

```
import numpy as np
from mlxtend.evaluate import mcnemar_table

# The correct target (class) labels
y_target = np.array([0, 0, 0, 0, 0, 1, 1, 1, 1, 1])

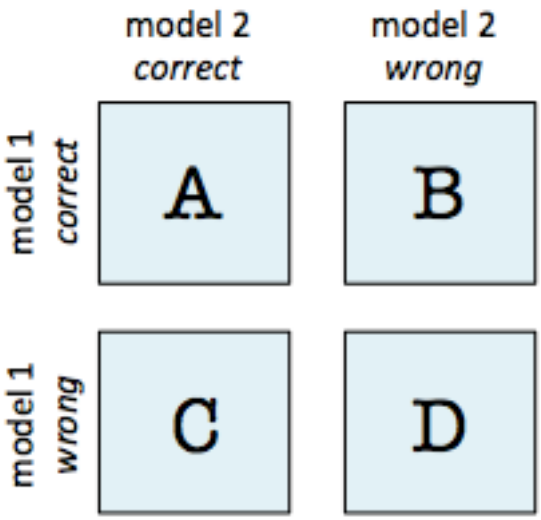
# Class labels predicted by model 1
y_model1 = np.array([0, 1, 0, 0, 0, 1, 1, 0, 0, 0])

# Class labels predicted by model 2
y_model2 = np.array([0, 0, 1, 1, 0, 1, 1, 0, 0, 0])

tb = mcnemar_table(y_target=y_target,
                   y_model1=y_model1,
                   y_model2=y_model2)

print(tb)
```

```
[[4 1]
 [2 3]]
```



33.3 Example 2 - McNemar's Test for Scenario B

No, let us continue with the example mentioned in the overview section and assume that we already computed the 2x2 contigency table:

```
import numpy as np

tb_b = np.array([[9945, 25],
                 [15, 15]])
```

To test the null hypothesis that the predictive performance of two models are equal (using a significance level of $\alpha = 0.05$), we can conduct a corrected McNemar Test for computing the chi-squared and p-value as follows:

```
from mlxtend.evaluate import mcnemar

chi2, p = mcnemar(ary=tb_b, corrected=True)
print('chi-squared:', chi2)
print('p-value:', p)
```

```
chi-squared: 2.025
p-value: 0.154728923485
```

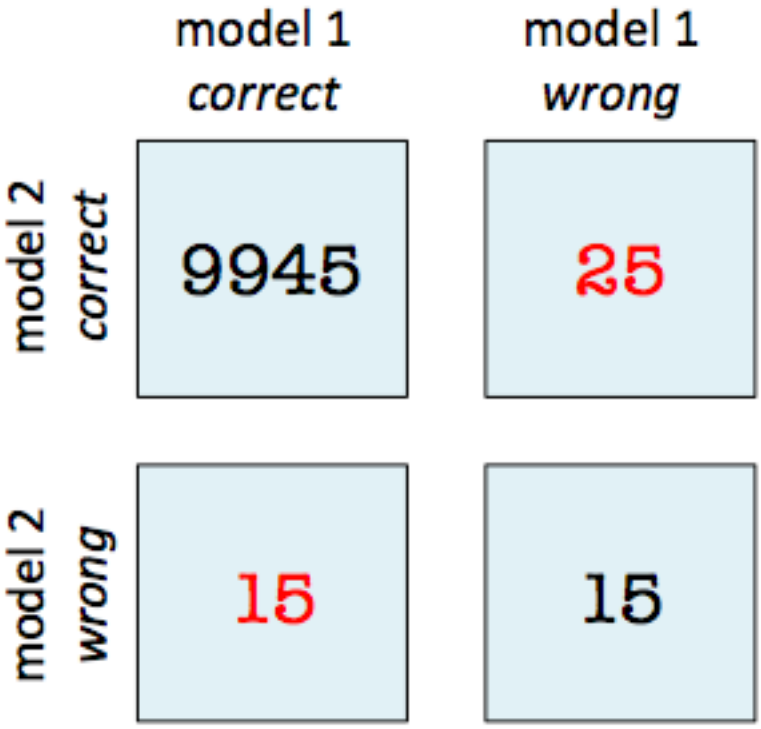
Since the p-value is larger than our assumed significance threshold ($\alpha = 0.05$), we cannot reject our null hypothesis and assume that there is no significant difference between the two predictive models.

33.4 Example 3 - McNemar's Test for Scenario A

In contrast to scenario B (Example 2), the sample size in scenario A is relatively small (b + c = 11 + 1 = 12) and smaller than the recommended 25 [3] to approximate the computed chi-square value by the chi-square distribution well.

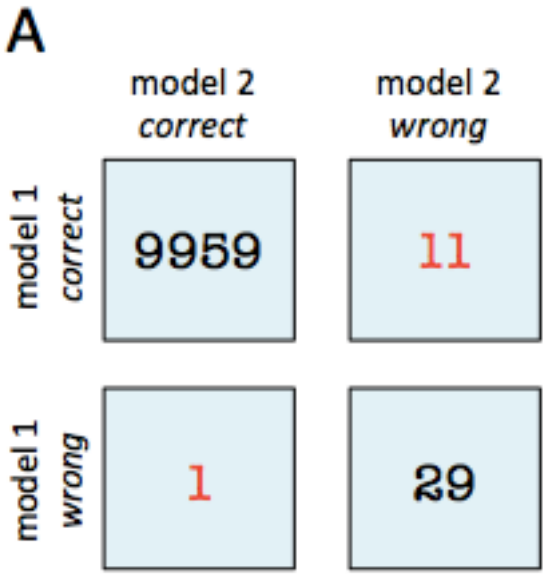
In this case, we need to compute the exact p-value from the binomial distribution:

B



model 1
correct
model 1
wrong
model 2
correct
9945
25
model 2
wrong
15
15

A



model 2
correct
model 2
wrong
model 1
correct
9959
11
model 1
wrong
1
29

```
from mlxtend.evaluate import mcnemar
import numpy as np

tb_a = np.array([[9959, 11],
                 [1, 29]])

chi2, p = mcnemar(ary=tb_a, exact=True)

print('chi-squared:', chi2)
print('p-value:', p)

chi-squared: None
p-value: 0.005859375
```

Assuming that we conducted this test also with a significance level of $\alpha = 0.05$, we can reject the null-hypothesis that both models perform equally well on this dataset, since the p-value ($p \approx 0.006$) is smaller than α.

33.5 API

mcnemar(ary, corrected=True, exact=False)

McNemar test for paired nominal data

Parameters

- `ary` : array-like, shape=[2, 2]

  2 x 2 contigency table (as returned by evaluate.mcnemar_table), where a: ary[0, 0]: # of samples that both models predicted correctly b: ary[0, 1]: # of samples that model 1 got right and model 2 got wrong c: ary[1, 0]: # of samples that model 2 got right and model 1 got wrong d: aryCell [1, 1]: # of samples that both models predicted incorrectly

- `corrected` : array-like, shape=[n_samples] (default: True)

  Uses Edward's continuity correction for chi-squared if `True`

- `exact` : bool, (default: False)

  If `True`, uses an exact binomial test comparing b to a binomial distribution with n = b + c and p = 0.5. It is highly recommended to use `exact=True` for sample sizes < 25 since chi-squared is not well-approximated by the chi-squared distribution!

Returns

- `chi2, p` : float or None, float

  Returns the chi-squared value and the p-value; if `exact=True` (default: `False`), `chi2` is `None`

34 evaluate.permutation_test

An implementation of a permutation test for hypothesis testing – testing the null hypothesis that two different groups come from the same distribution.

```
from mlxtend.evaluate import permutation_test
```

34.1 Overview

Permutation tests (also called exact tests, randomization tests, or re-randomization tests) are nonparametric test procedures to test the null hypothesis that two different groups come from the same distribution. A permutation test can be used for significance or hypothesis testing (including A/B testing) without requiring to make any assumptions about the sampling distribution (e.g., it doesn't require the samples to be normal distributed).

Under the null hypothesis (treatment = control), any permutations are equally likely. (Note that there are (n+m)! permutations, where n is the number of records in the treatment sample, and m is the number of records in the control sample). For a two-sided test, we define the alternative hypothesis that the two samples are different (e.g., treatment != control).

1. Compute the difference (here: mean) of sample x and sample y
2. Combine all measurements into a single dataset
3. Draw a permuted dataset from all possible permutations of the dataset in 2.
4. Divide the permuted dataset into two datasets x' and y' of size n and m, respectively
5. Compute the difference (here: mean) of sample x' and sample y' and record this difference
6. Repeat steps 3-5 until all permutations are evaluated
7. Return the p-value as the number of times the recorded differences were more extreme than the original difference from 1. and divide this number by the total number of permutations

Here, the p-value is defined as the probability, given the null hypothesis (no difference between the samples) is true, that we obtain results that are at least as extreme as the results we observed (i.e., the sample difference from 1.).

More formally, we can express the computation of the p-value as follows ([2]):

$$p(t > t_0) = \frac{1}{(n+m)!} \sum_{j=1}^{(n+m)!} I(t_j > t_0),$$

where t_0 is the observed value of the test statistic (1. in the list above), and t is the t-value, the statistic computed from the resamples (5.) $t(x'_1, x'_2, ..., x'_n, y'_1, y'_2, ..., x'_m) = |\bar{x}' - \bar{y}'|$, and I is the indicator function.

Given a significance level that we specify prior to carrying out the permutation test (e.g., alpha=0.05), we fail to reject the null hypothesis if the p-value is greater than alpha.

Note that if the number of permutation is large, sampling all permutation may not computationally be feasible. Thus, a common approximation is to perfom k rounds of permutations (where k is typically a value between 1000 and 2000).

- [3] Pitman, E. J. G., Significance tests which may be applied to samples from any population, Royal Statistical Society Supplement, 1937, 4: 119-30 and 225-32

34.2 Example 1 – Two-sided permutation test

Perform a two-sided permutation test to test the null hypothesis that two groups, "treatment" and "control" come from the same distribution. We specify alpha=0.01 as our significance level.

```
treatment = [ 28.44,  29.32,  31.22,  29.58,  30.34,  28.76,  29.21,  30.4 ,
              31.12,  31.78,  27.58,  31.57,  30.73,  30.43,  30.31,  30.32,
              29.18,  29.52,  29.22,  30.56]
control = [ 33.51,  30.63,  32.38,  32.52,  29.41,  30.93,  49.78,  28.96,
            35.77,  31.42,  30.76,  30.6 ,  23.64,  30.54,  47.78,  31.98,
            34.52,  32.42,  31.32,  40.72]
```

Since evaluating all possible permutations may take a while, we will use the approximation method (see the introduction for details):

```
from mlxtend.evaluate import permutation_test

p_value = permutation_test(treatment, control,
                           method='approximate',
                           num_rounds=10000,
                           seed=0)
print(p_value)
```

```
0.0066
```

Since p-value < alpha, we can reject the null hypothesis that the two samples come from the same distribution.

34.3 API

permutation_test(x, y, func='x_mean != y_mean', method='exact', num_rounds=1000, seed=None)

Nonparametric permutation test

Parameters

- `x` : list or numpy array with shape (n_datapoints,)

  A list or 1D numpy array of the first sample (e.g., the treatment group).

- `y` : list or numpy array with shape (n_datapoints,)

  A list or 1D numpy array of the second sample (e.g., the control group).

- `func` : custom function or str (default: 'x_mean != y_mean')

  function to compute the statistic for the permutation test.

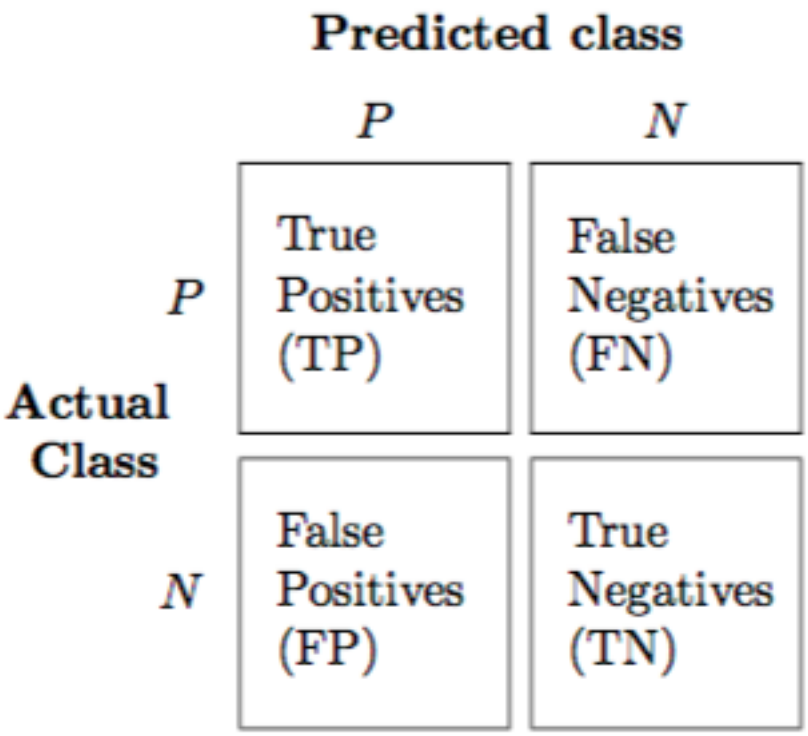
  - If 'x_mean != y_mean', uses `func=lambda x, y: np.abs(np.mean(x) - np.mean(y))` for a two-sided test.
  - If 'x_mean > y_mean', uses `func=lambda x, y: np.mean(x) - np.mean(y))` for a one-sided test.
  - If 'x_mean < y_mean', uses `func=lambda x, y: np.mean(y) - np.mean(x))` for a one-sided test.

- `method` : 'approximate' or 'exact' (default: 'exact')

  If 'exact' (default), all possible permutations are considered. If 'approximate' the number of drawn samples is given by `num_rounds`. Note that 'exact' is typically not feasible unless the dataset size is relatively small.

- `num_rounds` : int (default: 1000)

  The number of permutation samples if `method='approximate'`.



- `seed` : int or None (default: None)

  The random seed for generating permutation samples if `method='approximate'`.

Returns

p-value under the null hypothesis

35 `evaluate.scoring`

A function for computing various different performance metrics.

```
from mlxtend.evaluate import scoring
```

35.1 Overview

35.1.1 Confusion Matrix

The *confusion matrix* (or *error matrix*) is one way to summarize the performance of a classifier for binary classification tasks. This square matrix consists of columns and rows that list the number of instances as absolute or relative "actual class" vs. "predicted class" ratios.

Let P be the label of class 1 and N be the label of a second class or the label of all classes that are *not class 1* in a multi-class setting.

35.1.2 Error and Accuracy

Both the prediction *error* (ERR) and *accuracy* (ACC) provide general information about how many samples are misclassified. The *error* can be understood as the sum of all false predictions divided by the number of total predications, and the the accuracy is calculated as the sum of correct predictions divided by the total number of predictions, respectively.

$$ERR = \frac{FP + FN}{FP + FN + TP + TN} = 1 - ACC$$

$$ACC = \frac{TP + TN}{FP + FN + TP + TN} = 1 - ERR$$

35.1.3 True and False Positive Rates

The *True Positive Rate* (TPR) and *False Positive Rate* (FPR) are performance metrics that are especially useful for imbalanced class problems. In *spam classification*, for example, we are of course primarily interested in the detection and filtering out of *spam*. However, it is also important to decrease the number of messages that were incorrectly classified as *spam* (*False Positives*): A situation where a person misses an important message is considered as "worse" than a situation where a person ends up with a few *spam* messages in his e-mail inbox. In contrast to the *FPR*, the *True Positive Rate* provides useful information about the fraction of *positive* (or *relevant*) samples that were correctly identified out of the total pool of *Positives*.

$$FPR = \frac{FP}{N} = \frac{FP}{FP + TN}$$

$$TPR = \frac{TP}{P} = \frac{TP}{FN + TP}$$

35.1.4 Precision, Recall, and the F1-Score

Precision (PRE) and *Recall* (REC) are metrics that are more commonly used in *Information Technology* and related to the *False* and *True Prositive Rates*. In fact, *Recall* is synonymous to the *True Positive Rate* and also sometimes called *Sensitivity*. The F_1-Score can be understood as a combination of both *Precision* and *Recall*.

$$PRE = \frac{TP}{TP + FP}$$

$$REC = TPR = \frac{TP}{P} = \frac{TP}{FN + TP}$$

$$F_1 = 2 \cdot \frac{PRE \cdot REC}{PRE + REC}$$

35.1.5 Sensitivity and Specificity

Sensitivity (SEN) is synonymous to *Recall* and the *True Positive Rate* whereas *Specificity (SPC)* is synonymous to the *True Negative Rate* – *Sensitivity* measures the recovery rate of the *Positives* and complimentary, the *Specificity* measures the recovery rate of the *Negatives*.

$$SEN = TPR = REC = \frac{TP}{P} = \frac{TP}{FN + TP}$$

$$SPC = TNR = \frac{TN}{N} = \frac{TN}{FP + TN}$$

35.1.6 Matthews Correlation Coefficient

Matthews correlation coefficient (MCC) was first formulated by Brian W. Matthews [3] in 1975 to assess the performance of protein secondary structure predictions. The MCC can be understood as a specific case of a linear correlation coefficient (*Pearson's R*) for a binary classification setting and is considered as especially useful in unbalanced class settings. The previous metrics take values in the range between 0 (worst) and 1 (best), whereas the MCC is bounded between the range 1 (perfect correlation between ground truth and predicted outcome) and -1 (inverse or negative correlation) – a value of 0 denotes a random prediction.

$$MCC = \frac{TP \times TN - FP \times FN}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}}$$

35.1.7 Average Per-Class Accuracy

The "overall" accuracy is defined as the number of correct predictions (*true positives* TP and *true negatives* TN) over all samples n:

$$ACC = \frac{TP + TN}{n}$$

in a binary class setting:

In a multi-class setting, we can generalize the computation of the accuracy as the fraction of all true predictions (the diagonal) over all samples n.

$$ACC = \frac{T}{n}$$

Considering a multi-class problem with 3 classes (C0, C1, C2)

let's assume our model made the following predictions:

We compute the accuracy as:

$$ACC = \frac{3 + 50 + 18}{90} \approx 0.79$$

Now, in order to compute the ***average per-class accuracy***, we compute the binary accuracy for each class label separately; i.e., if class 1 is the positive class, class 0 and 2 are both considered the negative class.

$$APC\ ACC = \frac{83/90 + 71/90 + 78/90}{3} \approx 0.86$$

	C0	C1	C2
C0	3	0	0
C1	7	50	12
C2	0	0	18

35.2 Example 1 - Classification Error

```
from mlxtend.evaluate import scoring

y_targ = [1, 1, 1, 0, 0, 2, 0, 3]
y_pred = [1, 0, 1, 0, 0, 2, 1, 3]
res = scoring(y_target=y_targ, y_predicted=y_pred, metric='error')

print('Error: %s%%' % (res * 100))

Error: 25.0%
```

35.3 API

scoring(y_target, y_predicted, metric='error', positive_label=1, unique_labels='auto')

Compute a scoring metric for supervised learning.

Parameters

- `y_target` : array-like, shape=[n_values]
  True class labels or target values.
- `y_predicted` : array-like, shape=[n_values]
  Predicted class labels or target values.
- `metric` : str (default: 'error')
  Performance metric: 'accuracy': (TP + TN)/(FP + FN + TP + TN) = 1-ERR
  'per-class accuracy': Average per-class accuracy
  'per-class error': Average per-class error
  'error': (TP + TN)/(FP+ FN + TP + TN) = 1-ACC
  'false_positive_rate': FP/N = FP/(FP + TN)
  'true_positive_rate': TP/P = TP/(FN + TP)
  'true_negative_rate': TN/N = TN/(FP + TN)
  'precision': TP/(TP + FP)
  'recall': equal to 'true_positive_rate'
  'sensitivity': equal to 'true_positive_rate' or 'recall'
  'specificity': equal to 'true_negative_rate'
  'f1': 2 * (PRE * REC)/(PRE + REC)
  'matthews_corr_coef': (TP*TN* - *FP*FN) / (sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)})

Where: [TP: True positives, TN = True negatives,
TN: True negatives, FN = False negatives]

- `positive_label` : int (default: 1)
  Label of the positive class for binary classification metrics.
- `unique_labels` : str or array-like (default: 'auto')
  If 'auto', deduces the unique class labels from y_target

Returns

- `score` : float

36 feature_extraction.LinearDiscriminantAnalysis

Implementation of Linear Discriminant Analysis for dimensionality reduction

from mlxtend.feature_extraction import LinearDiscriminantAnalysis

36.1 Overview

Linear Discriminant Analysis (LDA) is most commonly used as dimensionality reduction technique in the pre-processing step for pattern-classification and machine learning applications. The goal is to project a dataset onto a lower-dimensional space with good class-separability in order avoid overfitting ("curse of dimensionality") and also reduce computational costs.

Ronald A. Fisher formulated the *Linear Discriminant* in 1936 (The Use of Multiple Measurements in Taxonomic Problems), and it also has some practical uses as classifier. The original Linear discriminant was described for a 2-class problem, and it was then later generalized as "multi-class Linear Discriminant Analysis" or "Multiple Discriminant Analysis" by C. R. Rao in 1948 (The utilization of multiple measurements in problems of biological classification)

The general LDA approach is very similar to a Principal Component Analysis, but in addition to finding the component axes that maximize the variance of our data (PCA), we are additionally interested in the axes that maximize the separation between multiple classes (LDA).

So, in a nutshell, often the goal of an LDA is to project a feature space (a dataset n-dimensional samples) onto a smaller subspace k (where $k \leq n - 1$) while maintaining the class-discriminatory information.
In general, dimensionality reduction does not only help reducing computational costs for a given classification task, but it can also be helpful to avoid overfitting by minimizing the error in parameter estimation ("curse of dimensionality").

36.1.0.1 Summarizing the LDA approach in 5 steps

Listed below are the 5 general steps for performing a linear discriminant analysis.

1. Compute the d-dimensional mean vectors for the different classes from the dataset.
2. Compute the scatter matrices (in-between-class and within-class scatter matrix).
3. Compute the eigenvectors ($\mathbf{e_1}$, $\mathbf{e_2}$, ..., $\mathbf{e_d}$) and corresponding eigenvalues ($\lambda_\mathbf{1}$, $\lambda_\mathbf{2}$, ..., $\lambda_\mathbf{d}$) for the scatter matrices.
4. Sort the eigenvectors by decreasing eigenvalues and choose k eigenvectors with the largest eigenvalues to form a $k \times d$ dimensional matrix $\mathbf{W}$ (where every column represents an eigenvector).
5. Use this $k \times d$ eigenvector matrix to transform the samples onto the new subspace. This can be summarized by the mathematical equation: $\mathbf{Y} = \mathbf{X} \times \mathbf{W}$ (where $\mathbf{X}$ is a $n \times d$-dimensional matrix representing the n samples, and $\mathbf{y}$ are the transformed $n \times k$-dimensional samples in the new subspace).

36.2 Example 1 - LDA on Iris

```
from mlxtend.data import iris_data
from mlxtend.preprocessing import standardize
from mlxtend.feature_extraction import LinearDiscriminantAnalysis

X, y = iris_data()
X = standardize(X)

lda = LinearDiscriminantAnalysis(n_discriminants=2)
lda.fit(X, y)
X_lda = lda.transform(X)

import matplotlib.pyplot as plt

with plt.style.context('seaborn-whitegrid'):
    plt.figure(figsize=(6, 4))
    for lab, col in zip((0, 1, 2),
                        ('blue', 'red', 'green')):
        plt.scatter(X_lda[y == lab, 0],
                    X_lda[y == lab, 1],
                    label=lab,
                    c=col)
    plt.xlabel('Linear Discriminant 1')
    plt.ylabel('Linear Discriminant 2')
    plt.legend(loc='lower right')
    plt.tight_layout()
    plt.show()
```

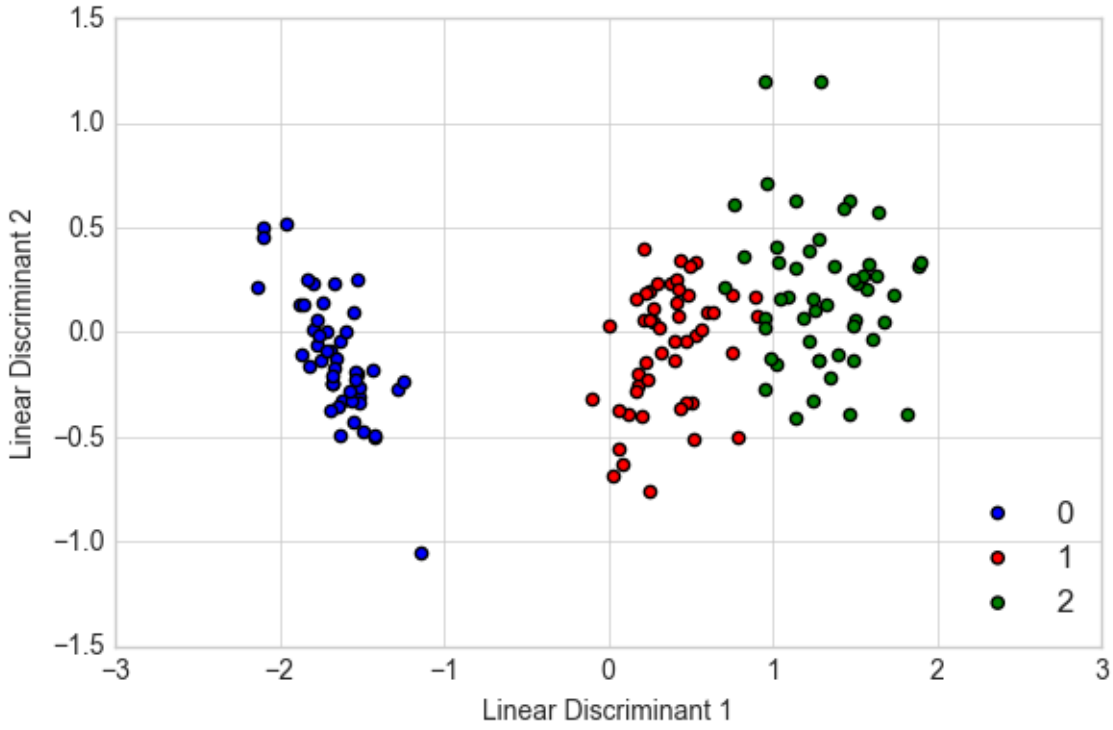
36.3 Example 2 - Plotting the Between-Class Variance Explained Ratio

```
from mlxtend.data import iris_data
from mlxtend.preprocessing import standardize
from mlxtend.feature_extraction import LinearDiscriminantAnalysis

X, y = iris_data()
X = standardize(X)

lda = LinearDiscriminantAnalysis(n_discriminants=None)
lda.fit(X, y)
X_lda = lda.transform(X)

import numpy as np
```



```
tot = sum(lda.e_vals_)
var_exp = [(i / tot)*100 for i in sorted(lda.e_vals_, reverse=True)]
cum_var_exp = np.cumsum(var_exp)

with plt.style.context('seaborn-whitegrid'):
    fig, ax = plt.subplots(figsize=(6, 4))
    plt.bar(range(4), var_exp, alpha=0.5, align='center',
            label='individual explained variance')
    plt.step(range(4), cum_var_exp, where='mid',
             label='cumulative explained variance')
    plt.ylabel('Explained variance ratio')
    plt.xlabel('Principal components')
    plt.xticks(range(4))
    ax.set_xticklabels(np.arange(1, X.shape[1] + 1))
    plt.legend(loc='best')
    plt.tight_layout()
```

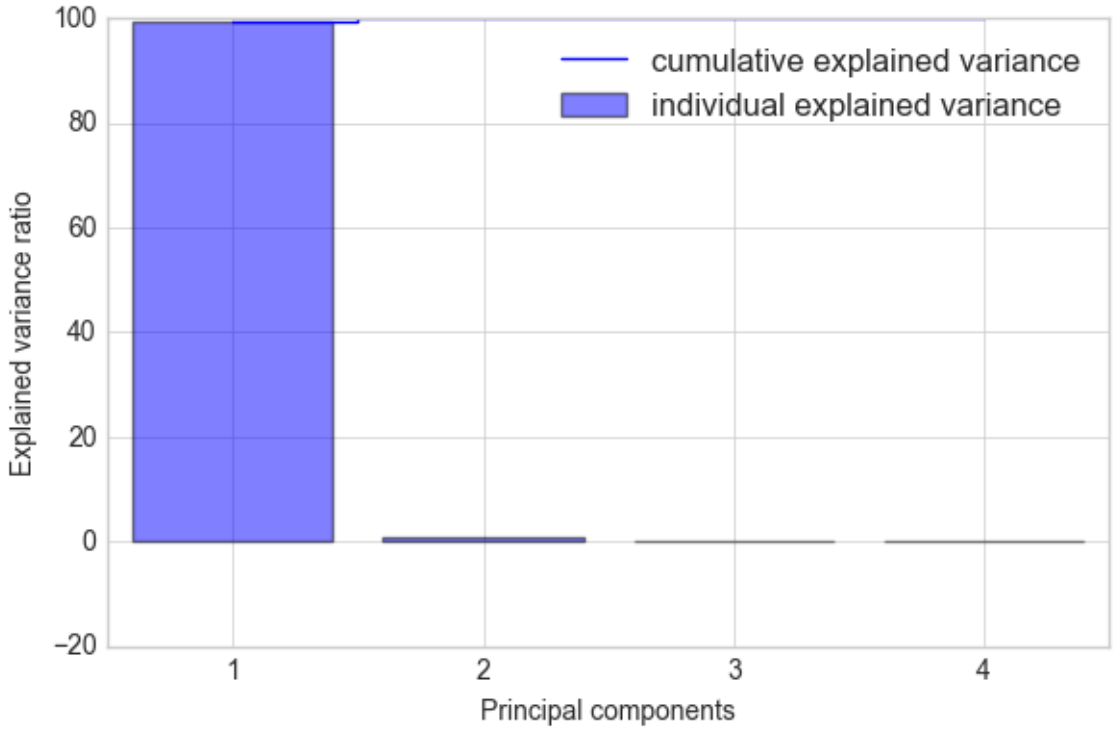
36.4 API

LinearDiscriminantAnalysis(n_discriminants=None)

Linear Discriminant Analysis Class

Parameters

- `n_discriminants` : int (default: None)
  The number of discrimants for transformation. Keeps the original dimensions of the dataset if `None`.



Attributes

- `w_` : array-like, shape=[n_features, n_discriminants]
  Projection matrix
- `e_vals_` : array-like, shape=[n_features]
  Eigenvalues in sorted order.
- `e_vecs_` : array-like, shape=[n_features]
  Eigenvectors in sorted order.

36.4.1 Methods

fit(X, y, n_classes=None)

Fit the LDA model with X.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` : array-like, shape = [n_samples]
  Target values.

- `n_classes` : int (default: None)

  A positive integer to declare the number of class labels if not all class labels are present in a partial training set. Gets the number of class labels automatically if None.

Returns

- `self` : object

transform(X)

Apply the linear transformation on X.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `X_projected` : np.ndarray, shape = [n_samples, n_discriminants]

  Projected training vectors.

37 feature_extraction.PrincipalComponentAnalysis

Implementation of Principal Component Analysis for dimensionality reduction

from mlxtend.feature_extraction import PrincipalComponentAnalysis

37.1 Overview

The sheer size of data in the modern age is not only a challenge for computer hardware but also a main bottleneck for the performance of many machine learning algorithms. The main goal of a PCA analysis is to identify patterns in data; PCA aims to detect the correlation between variables. If a strong correlation between variables exists, the attempt to reduce the dimensionality only makes sense. In a nutshell, this is what PCA is all about: Finding the directions of maximum variance in high-dimensional data and project it onto a smaller dimensional subspace while retaining most of the information.

37.1.1 PCA and Dimensionality Reduction

Often, the desired goal is to reduce the dimensions of a d-dimensional dataset by projecting it onto a (k)-dimensional subspace (where $k < d$) in order to increase the computational efficiency while retaining most of the information. An important question is "what is the size of k that represents the data 'well'?"

Later, we will compute eigenvectors (the principal components) of a dataset and collect them in a projection matrix. Each of those eigenvectors is associated with an eigenvalue which can be interpreted as the "length" or "magnitude" of the corresponding eigenvector. If some eigenvalues have a significantly larger magnitude than others that the reduction of the dataset via PCA onto a smaller dimensional subspace by dropping the "less informative" eigenpairs is reasonable.

37.1.2 A Summary of the PCA Approach

- Standardize the data.
- Obtain the Eigenvectors and Eigenvalues from the covariance matrix or correlation matrix, or perform Singular Vector Decomposition.
- Sort eigenvalues in descending order and choose the k eigenvectors that correspond to the k largest eigenvalues where k is the number of dimensions of the new feature subspace ($k \leq d$).
- Construct the projection matrix $\mathbf{W}$ from the selected k eigenvectors.
- Transform the original dataset $\mathbf{X}$ via $\mathbf{W}$ to obtain a k-dimensional feature subspace $\mathbf{Y}$.

37.2 Example 1 - PCA on Iris

```
from mlxtend.data import iris_data
from mlxtend.preprocessing import standardize
from mlxtend.feature_extraction import PrincipalComponentAnalysis

X, y = iris_data()
X = standardize(X)

pca = PrincipalComponentAnalysis(n_components=2)
pca.fit(X)
X_pca = pca.transform(X)

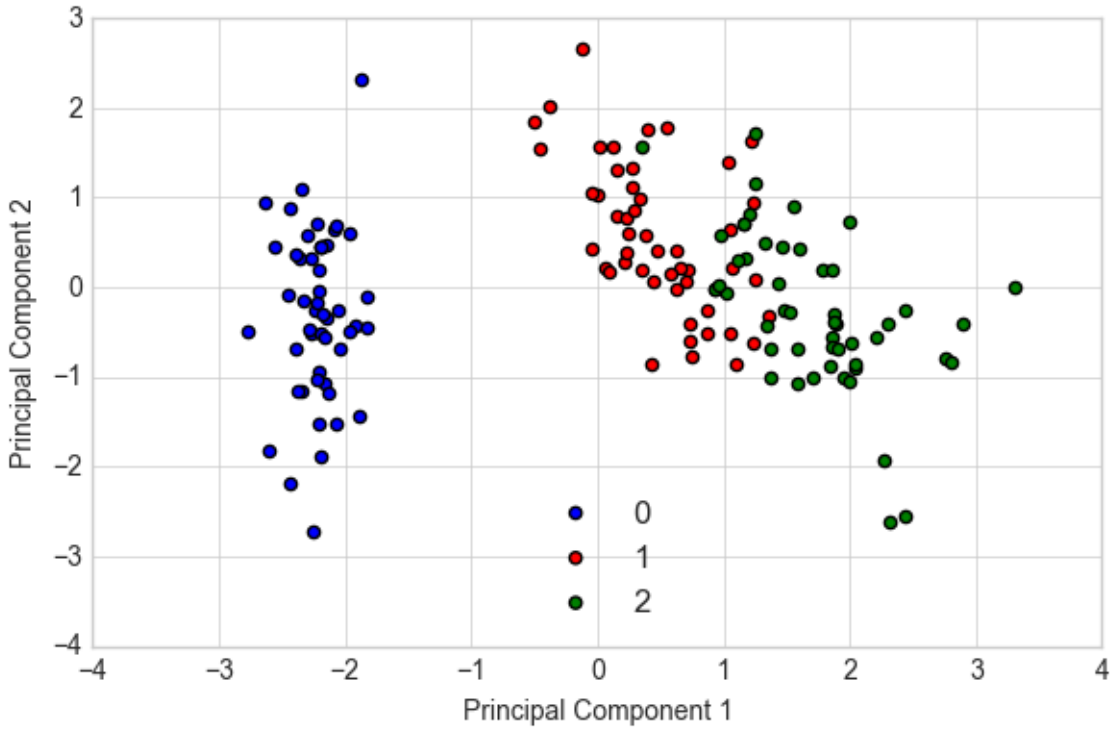
import matplotlib.pyplot as plt

with plt.style.context('seaborn-whitegrid'):
    plt.figure(figsize=(6, 4))
    for lab, col in zip((0, 1, 2),
                        ('blue', 'red', 'green')):
        plt.scatter(X_pca[y==lab, 0],
                    X_pca[y==lab, 1],
                    label=lab,
                    c=col)
    plt.xlabel('Principal Component 1')
    plt.ylabel('Principal Component 2')
    plt.legend(loc='lower center')
    plt.tight_layout()
    plt.show()
```

37.3 Example 2 - Plotting the Variance Explained Ratio

```
from mlxtend.data import iris_data
from mlxtend.preprocessing import standardize

X, y = iris_data()
X = standardize(X)
```

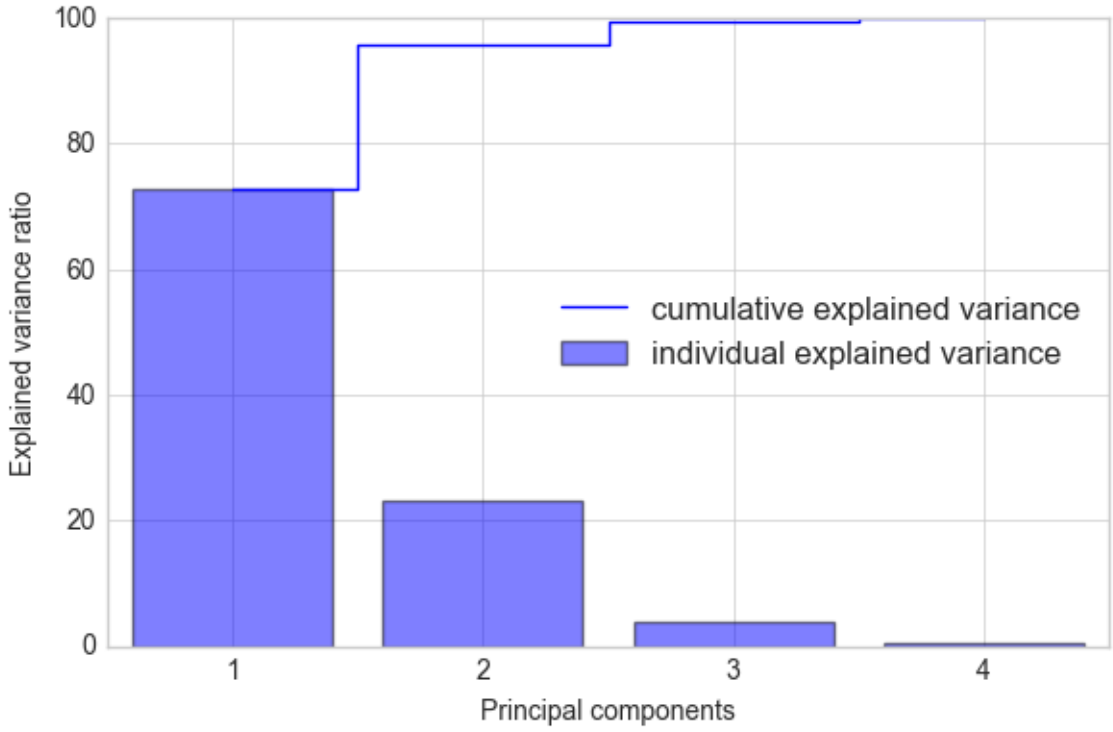


```
pca = PrincipalComponentAnalysis(n_components=None)
pca.fit(X)
X_pca = pca.transform(X)

import numpy as np

tot = sum(pca.e_vals_)
var_exp = [(i / tot)*100 for i in sorted(pca.e_vals_, reverse=True)]
cum_var_exp = np.cumsum(var_exp)

with plt.style.context('seaborn-whitegrid'):
    fig, ax = plt.subplots(figsize=(6, 4))
    plt.bar(range(4), var_exp, alpha=0.5, align='center',
            label='individual explained variance')
    plt.step(range(4), cum_var_exp, where='mid',
             label='cumulative explained variance')
    plt.ylabel('Explained variance ratio')
    plt.xlabel('Principal components')
    plt.xticks(range(4))
    ax.set_xticklabels(np.arange(1, X.shape[1] + 1))
    plt.legend(loc='best')
    plt.tight_layout()
```



37.4 Example 3 - PCA via SVD

While the eigendecomposition of the covariance or correlation matrix may be more intuitiuve, most PCA implementations perform a Singular Vector Decomposition (SVD) to improve the computational efficiency. Another advantage of using SVD is that the results tend to be more numerically stable, since we can decompose the input matrix directly without the additional covariance-matrix step.

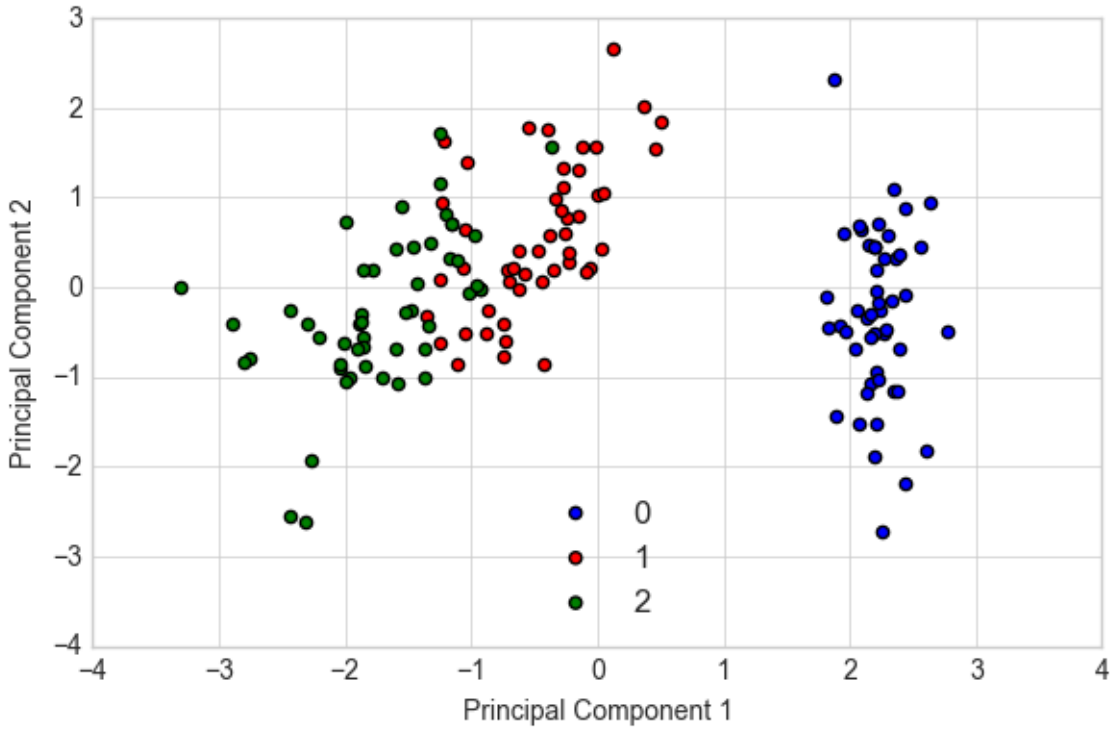
```
from mlxtend.data import iris_data
from mlxtend.preprocessing import standardize
from mlxtend.feature_extraction import PrincipalComponentAnalysis

X, y = iris_data()
X = standardize(X)

pca = PrincipalComponentAnalysis(n_components=2,
                                 solver='svd')
pca.fit(X)
X_pca = pca.transform(X)

import matplotlib.pyplot as plt

with plt.style.context('seaborn-whitegrid'):
    plt.figure(figsize=(6, 4))
    for lab, col in zip((0, 1, 2),
                        ('blue', 'red', 'green')):
        plt.scatter(X_pca[y==lab, 0],
                    X_pca[y==lab, 1],
```



```
                label=lab,
                c=col)
plt.xlabel('Principal Component 1')
plt.ylabel('Principal Component 2')
plt.legend(loc='lower center')
plt.tight_layout()
plt.show()
```

If we compare this PCA projection to the previous plot in example 1, we notice that they are mirror images of each other. Note that this is not due to an error in any of those two implementations, but the reason for this difference is that, depending on the eigensolver, eigenvectors can have either negative or positive signs.

For instance, if v is an eigenvector of a matrix Σ, we have

$$\Sigma v = \lambda v,$$

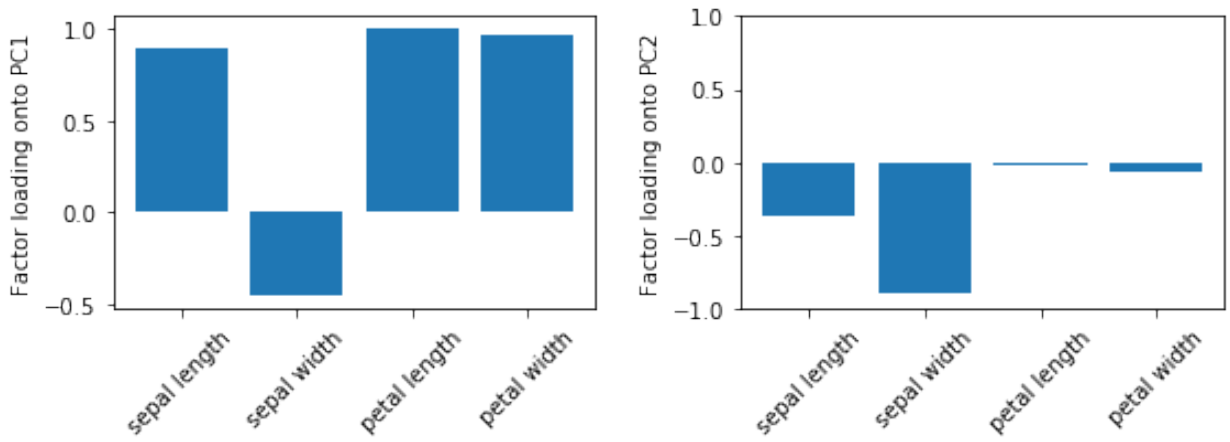
where λ is our eigenvalue

then $-v$ is also an eigenvector that has the same eigenvalue, since

$$\Sigma(-v) = -\Sigma v = -\lambda v = \lambda(-v).$$

37.5 Example 4 - Factor Loadings

After evoking the `fit` method, the factor loadings are available via the `loadings_` attribute. In simple terms, the the loadings are the unstandardized values of the eigenvectors. Or in other words, we can interpret the



loadings as the covariances (or correlation in case we standardized the input features) between the input features and the and the principal components (or eigenvectors), which have been scaled to unit length.

By having the loadings scaled, they become comparable by magnitude and we can assess how much variance in a component is attributed to the input features (as the components are just a weighted linear combination of the input features).

```
from mlxtend.data import iris_data
from mlxtend.preprocessing import standardize
from mlxtend.feature_extraction import PrincipalComponentAnalysis
import matplotlib.pyplot as plt

X, y = iris_data()
X = standardize(X)

pca = PrincipalComponentAnalysis(n_components=2,
                                 solver='eigen')
pca.fit(X);

xlabels = ['sepal length', 'sepal width', 'petal length', 'petal width']

fig, ax = plt.subplots(1, 2, figsize=(8, 3))

ax[0].bar(range(4), pca.loadings_[:, 0], align='center')
ax[1].bar(range(4), pca.loadings_[:, 1], align='center')

ax[0].set_ylabel('Factor loading onto PC1')
ax[1].set_ylabel('Factor loading onto PC2')

ax[0].set_xticks(range(4))
ax[1].set_xticks(range(4))
ax[0].set_xticklabels(xlabels, rotation=45)
ax[1].set_xticklabels(xlabels, rotation=45)
plt.ylim([-1, 1])
plt.tight_layout()
```

For instance, we may say that most of the variance in the first component is attributed to the petal features (although the loading of sepal length on PC1 is also not much less in magnitude). In contrast, the remaining variance captured by PC2 is mostly due to the sepal width. Note that we know from Example 2 that PC1 explains most of the variance, and based on the information from the loading plots, we may say that petal features combined with sepal length may explain most of the spread in the data.

37.6 API

PrincipalComponentAnalysis(n_components=None, solver='eigen')

Principal Component Analysis Class

Parameters

- `n_components` : int (default: None)
  The number of principal components for transformation. Keeps the original dimensions of the dataset if `None`.
- `solver` : str (default: 'eigen')
  Method for performing the matrix decomposition. {'eigen', 'svd'}

Attributes

- `w_` : array-like, shape=[n_features, n_components]
  Projection matrix
- `e_vals_` : array-like, shape=[n_features]
  Eigenvalues in sorted order.
- `e_vecs_` : array-like, shape=[n_features]
  Eigenvectors in sorted order.

37.6.1 Methods

fit(X)

Learn model from training data.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `self` : object

transform(X)

Apply the linear transformation on X.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `X_projected` : np.ndarray, shape = [n_samples, n_components]
  Projected training vectors.

38 feature_extraction.RBFKernelPCA

38.1 RBF Kernel Principal Component Analysis

Implementation of RBF Kernel Principal Component Analysis for non-linear dimensionality reduction

    from mlxtend.feature_extraction import RBFKernelPCA

38.2 Overview

Most machine learning algorithms have been developed and statistically validated for linearly separable data. Popular examples are linear classifiers like Support Vector Machines (SVMs) or the (standard) Principal Component Analysis (PCA) for dimensionality reduction. However, most real world data requires nonlinear methods in order to perform tasks that involve the analysis and discovery of patterns successfully.

The focus of this overview is to briefly introduce the idea of kernel methods and to implement a Gaussian radius basis function (RBF) kernel that is used to perform nonlinear dimensionality reduction via BF kernel principal component analysis (kPCA).

38.2.1 Principal Component Analysis

The main purpose of principal component analysis (PCA) is the analysis of data to identify patterns that represent the data "well." The principal components can be understood as new axes of the dataset that maximize the variance along those axes (the eigenvectors of the covariance matrix). In other words, PCA aims to find the axes with maximum variances along which the data is most spread.

For more details, please see the related article on `mlxtend.feature_extraction.PrincipalComponentAnalysis`.

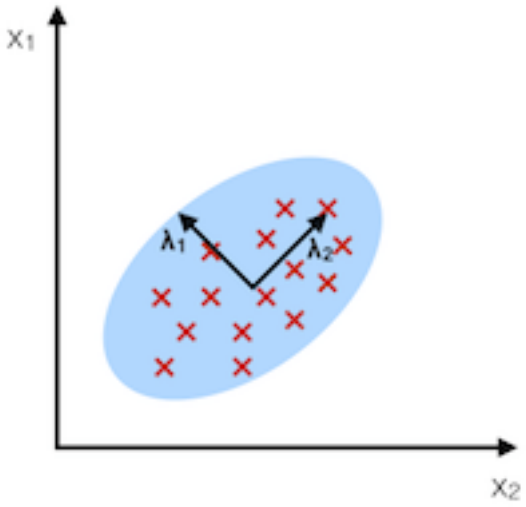
38.2.2 Nonlinear dimensionality reduction

The "classic" PCA approach described above is a linear projection technique that works well if the data is linearly separable. However, in the case of linearly inseparable data, a nonlinear technique is required if the task is to reduce the dimensionality of a dataset.

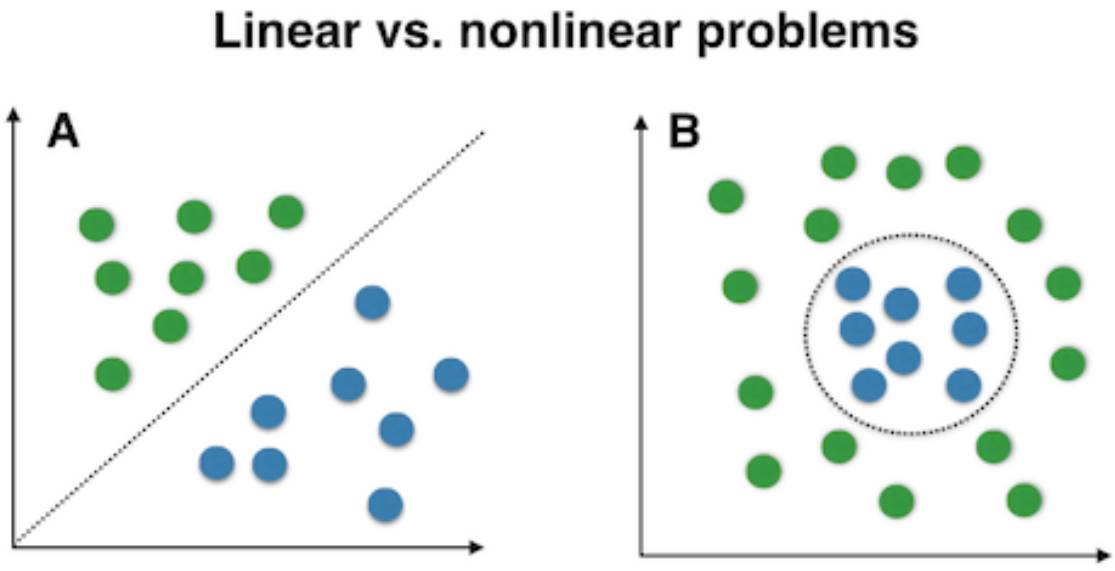
38.2.3 Kernel functions and the kernel trick

The basic idea to deal with linearly inseparable data is to project it onto a higher dimensional space where it becomes linearly separable. Let us call this nonlinear mapping function ϕ so that the mapping of a sample $\mathbf{x}$ can be written as $\mathbf{x} \rightarrow \phi(\mathbf{x})$, which is called "kernel function."

Now, the term "kernel" describes a function that calculates the dot product of the images of the samples $\mathbf{x}$ under ϕ.



x1
λ1
λ2
x2



Linear vs. nonlinear problems
A
B

$$\kappa(\mathbf{x_i}, \mathbf{x_j}) = \phi(\mathbf{x_i})\phi(\mathbf{x_j})^T$$

More details about the derivation of this equation are provided in this excellent review article by Quan Wang: Kernel Principal Component Analysis and its Applications in Face Recognition and Active Shape Models.[1]

In other words, the function ϕ maps the original d-dimensional features into a larger, k-dimensional feature space by creating nononlinear combinations of the original features. For example, if $\mathbf{x}$ consists of 2 features:

$$\mathbf{x} = \begin{bmatrix} x_1 & x_2 \end{bmatrix}^T \qquad \mathbf{x} \in IR^d$$

$$\Downarrow \phi$$

$$\mathbf{x}' = \begin{bmatrix} x_1 & x_2 & x_1x_2 & x_1^2 & x_1x_2^3 & \dots \end{bmatrix}^T \qquad \mathbf{x} \in IR^k (k >> d)$$

Often, the mathematical definition of the RBF kernel is written and implemented as

$$\kappa(\mathbf{x_i}, \mathbf{x_j}) = exp\left(- \gamma \, \|\mathbf{x_i} - \mathbf{x_j}\|_2^2 \right)$$

where $\gamma = \frac{1}{2\sigma^2}$ is a free parameter that is to be optimized.

38.2.4 Gaussian radial basis function (RBF) Kernel PCA

In the linear PCA approach, we are interested in the principal components that maximize the variance in the dataset. This is done by extracting the eigenvectors (principle components) that correspond to the largest eigenvalues based on the covariance matrix:

$$\text{Cov} = \frac{1}{N} \sum_{i=1}^{N} \mathbf{x_i} \mathbf{x_i}^T$$

Bernhard Scholkopf (Kernel Principal Component Analysis [2]) generalized this approach for data that was mapped onto the higher dimensional space via a kernel function:

$$\text{Cov} = \frac{1}{N} \sum_{i=1}^{N} \phi(\mathbf{x_i})\phi(\mathbf{x_i})^T$$

However, in practice the the covariance matrix in the higher dimensional space is not calculated explicitly (kernel trick). Therefore, the implementation of RBF kernel PCA does not yield the principal component axes (in contrast to the standard PCA), but the obtained eigenvectors can be understood as projections of the data onto the principal components.

38.2.5 RBF kernel PCA step-by-step

38.2.5.1 1. Computation of the kernel (similarity) matrix.

In this first step, we need to calculate

$$\kappa(\mathbf{x_i}, \mathbf{x_j}) = exp\Big(- \gamma \ \|\mathbf{x_i} - \mathbf{x_j}\|_2^2 \Big)$$

for every pair of points. E.g., if we have a dataset of 100 samples, this step would result in a symmetric 100x100 kernel matrix.

38.2.5.2 2. Eigendecomposition of the kernel matrix.

Since it is not guaranteed that the kernel matrix is centered, we can apply the following equation to do so:

$$K' = K - \mathbf{1_N}K - K\mathbf{1_N} + \mathbf{1_N}K\mathbf{1_N}$$

where $\mathbf{1_N}$ is (like the kernel matrix) a $N \times N$ matrix with all values equal to $\frac{1}{N}$. [3]

Now, we have to obtain the eigenvectors of the centered kernel matrix that correspond to the largest eigenvalues. Those eigenvectors are the data points already projected onto the respective principal components.

38.2.6 Projecting new data

So far, so good, in the sections above, we have been projecting an dataset onto a new feature subspace. However, in a real application, we are usually interested in mapping new data points onto the same new feature subspace (e.g., if are working with a training and a test dataset in pattern classification tasks).

Remember, when we computed the eigenvectors α of the centered kernel matrix, those values were actually already the projected datapoints onto the principal component axis $\mathbf{g}$.

If we want to project a new data point $\mathbf{x}$ onto this principal component axis, we'd need to compute $\phi(\mathbf{x})^T\mathbf{g}$.

Fortunately, also here, we don't have to compute $\phi(\mathbf{x})^T\mathbf{g}$ explicitely but use the kernel trick to calculate the RBF kernel between the new data point and every data point j in the training dataset:

$$\phi(\mathbf{x})^T\mathbf{g} = \sum_j \alpha_i \ \phi(\mathbf{x}) \ \phi(\mathbf{x_j})^T$$

$$= \sum_j \alpha_i \ \kappa(\mathbf{x}, \mathbf{x_j})$$

and the eigenvectors α and eigenvalues λ of the Kernel matrix $\mathbf{K}$ satisfy the equation $\mathbf{K}\alpha = \lambda\alpha$, we just need to normalize the eigenvector by the corresponding eigenvalue.

38.3 Example 1 - Half-moon shapes

We will start with a simple example of 2 half-moon shapes generated by the `make_moons` function from scikit-learn.

```
import matplotlib.pyplot as plt
from sklearn.datasets import make_moons

X, y = make_moons(n_samples=50, random_state=1)

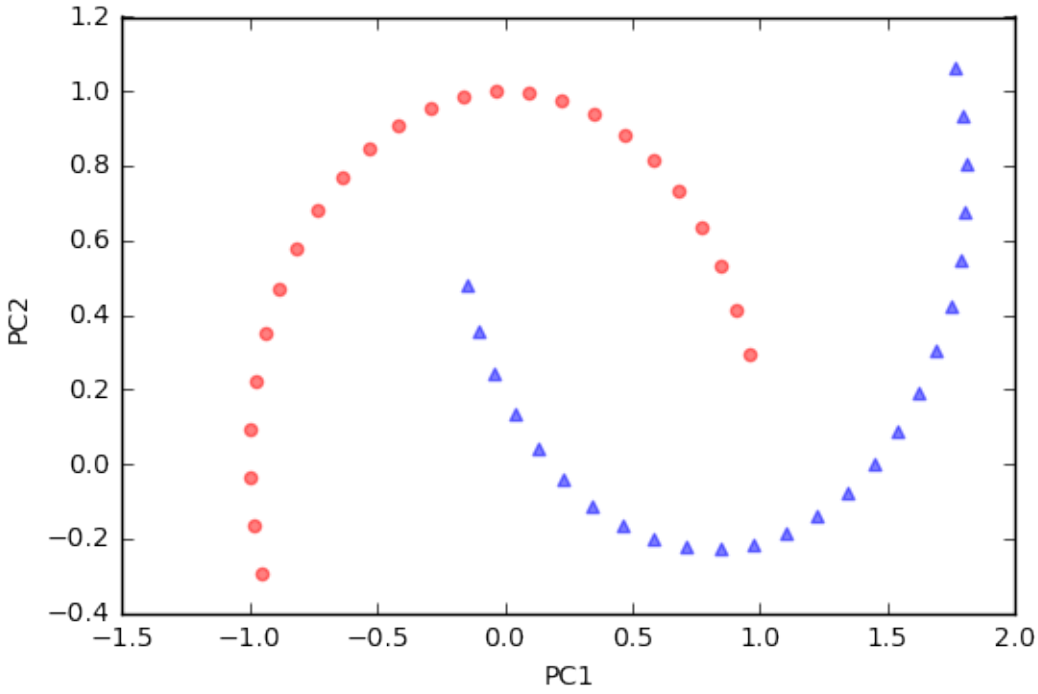
plt.scatter(X[y==0, 0], X[y==0, 1],
            color='red', marker='o', alpha=0.5)
plt.scatter(X[y==1, 0], X[y==1, 1],
            color='blue', marker='^', alpha=0.5)
plt.ylabel('y coordinate')
plt.xlabel('x coordinate')

plt.show()
```

Since the two half-moon shapes are linearly inseparable, we expect that the "classic" PCA will fail to give us a "good" representation of the data in 1D space. Let us use `PCA` class to perform the dimensionality reduction.

```
from mlxtend.feature_extraction import PrincipalComponentAnalysis as PCA

pca = PCA(n_components=2)
X_pca = pca.fit(X).transform(X)
```



```
plt.scatter(X_pca[y==0, 0], X_pca[y==0, 1],
            color='red', marker='o', alpha=0.5)
plt.scatter(X_pca[y==1, 0], X_pca[y==1, 1],
            color='blue', marker='^', alpha=0.5)

plt.xlabel('PC1')
plt.ylabel('PC2')
plt.show()
```

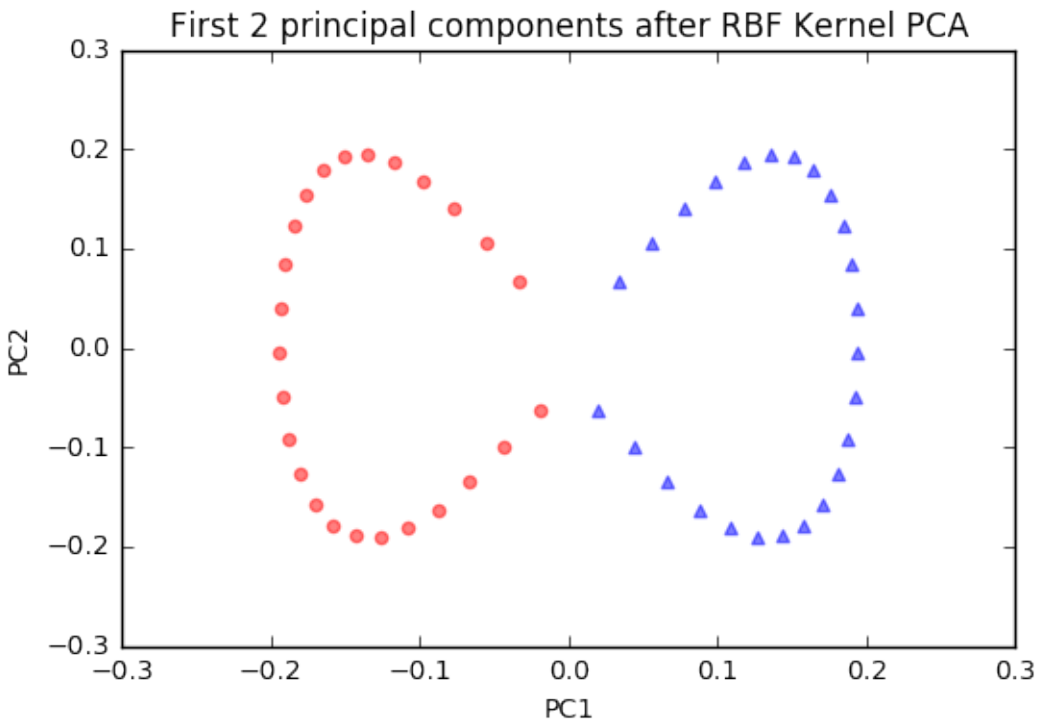
As we can see, the resulting principal components do not yield a subspace where the data is linearly separated well. Note that PCA is a unsupervised method and does not "consider" class labels in order to maximize the variance in contrast to Linear Discriminant Analysis. Here, the colors blue and red are just added for visualization purposes to indicate the degree of separation.

Next, we will perform dimensionality reduction via RBF kernel PCA on our half-moon data. The choice of γ depends on the dataset and can be obtained via hyperparameter tuning techniques like Grid Search. Hyperparameter tuning is a broad topic itself, and here I will just use a γ-value that I found to produce "good" results.

```
from mlxtend.data import iris_data
from mlxtend.preprocessing import standardize
from mlxtend.feature_extraction import RBFKernelPCA as KPCA

kpca = KPCA(gamma=15.0, n_components=2)
kpca.fit(X)
X_kpca = kpca.X_projected_
```

Please note that the components of kernel methods such as RBF kernel PCA already represent the projected data points (in contrast to PCA, where the component axis are the "top k" eigenvectors thar are used to



contruct a projection matrix, which is then used to transform the training samples). Thus, the projected training set is available after fitting via the `.X_projected_` attribute.

```
plt.scatter(X_kpca[y==0, 0], X_kpca[y==0, 1],
            color='red', marker='o', alpha=0.5)
plt.scatter(X_kpca[y==1, 0], X_kpca[y==1, 1],
            color='blue', marker='^', alpha=0.5)

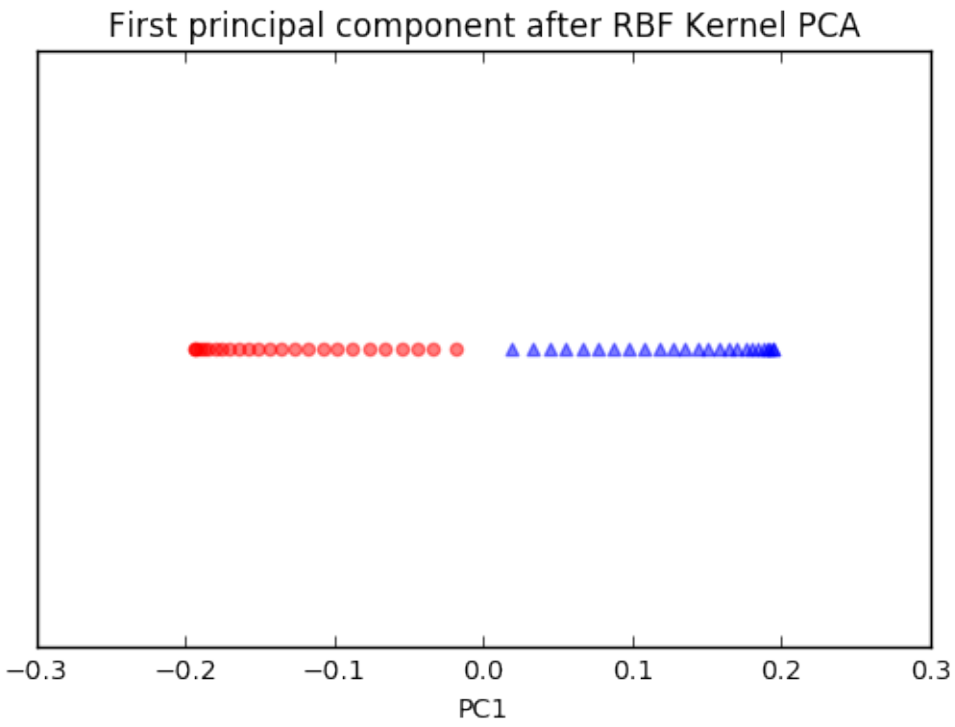
plt.title('First 2 principal components after RBF Kernel PCA')
plt.xlabel('PC1')
plt.ylabel('PC2')
plt.show()
```

The new feature space is linearly separable now. Since we are often interested in dimensionality reduction, let's have a look at the first component only.

```
import numpy as np

plt.scatter(X_kpca[y==0, 0], np.zeros((25, 1)),
            color='red', marker='o', alpha=0.5)
plt.scatter(X_kpca[y==1, 0], np.zeros((25, 1)),
            color='blue', marker='^', alpha=0.5)

plt.title('First principal component after RBF Kernel PCA')
plt.xlabel('PC1')
plt.yticks([])
plt.show()
```



We can clearly see that the projection via RBF kernel PCA yielded a subspace where the classes are separated well. Such a subspace can then be used as input for generalized linear classification models, e.g., logistic regression.

38.3.0.1 Projecting new data

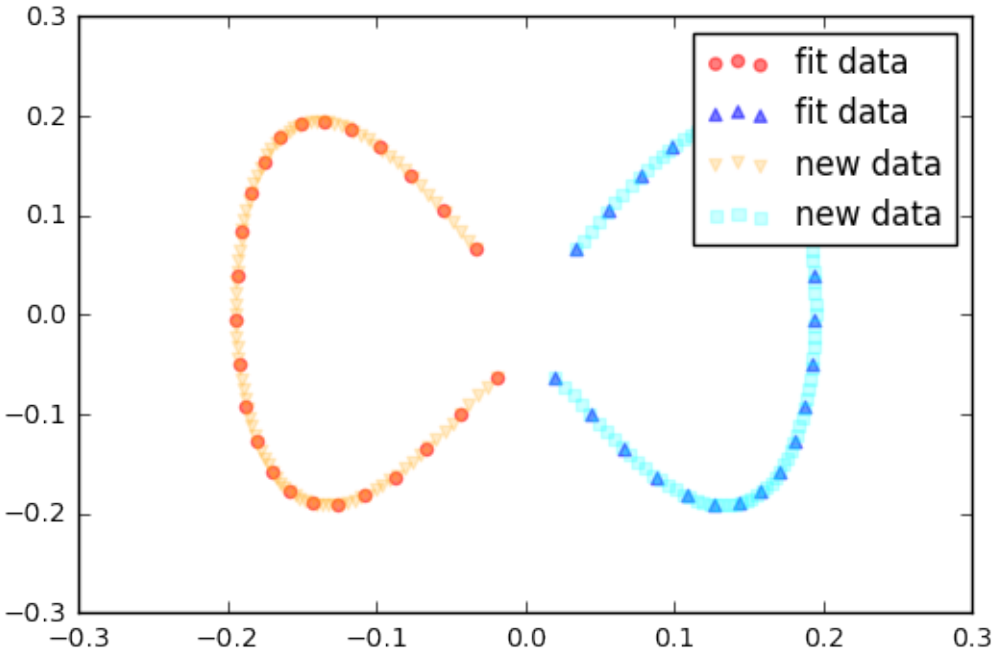
Finally, via the transform method, we can project new data onto the new component axes.

```
import matplotlib.pyplot as plt
from sklearn.datasets import make_moons

X2, y2 = make_moons(n_samples=200, random_state=5)
X2_kpca = kpca.transform(X2)

plt.scatter(X_kpca[y==0, 0], X_kpca[y==0, 1],
            color='red', marker='o', alpha=0.5, label='fit data')
plt.scatter(X_kpca[y==1, 0], X_kpca[y==1, 1],
            color='blue', marker='^', alpha=0.5, label='fit data')

plt.scatter(X2_kpca[y2==0, 0], X2_kpca[y2==0, 1],
            color='orange', marker='v',
            alpha=0.2, label='new data')
plt.scatter(X2_kpca[y2==1, 0], X2_kpca[y2==1, 1],
            color='cyan', marker='s',
            alpha=0.2, label='new data')
```



```
plt.legend()
plt.show()
```

38.4 Example 2 - Concentric circles

Following the concepts explained in example 1, let's have a look at another classic case: 2 concentric circles with random noise produced by scikit-learn's `make_circles`.

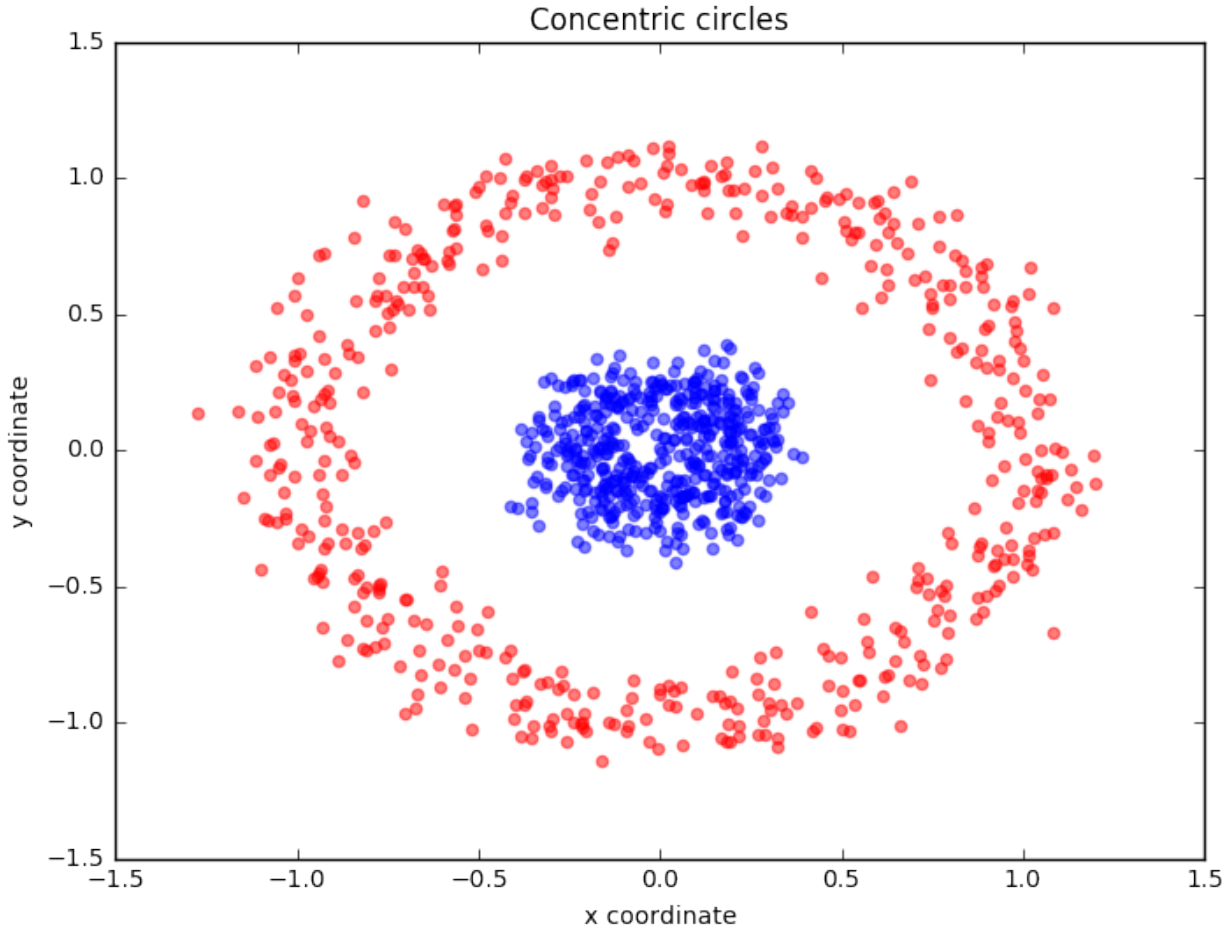
```
from sklearn.datasets import make_circles

X, y = make_circles(n_samples=1000, random_state=123,
                    noise=0.1, factor=0.2)

plt.figure(figsize=(8,6))

plt.scatter(X[y==0, 0], X[y==0, 1], color='red', alpha=0.5)
plt.scatter(X[y==1, 0], X[y==1, 1], color='blue', alpha=0.5)
plt.title('Concentric circles')
plt.ylabel('y coordinate')
plt.xlabel('x coordinate')
plt.show()

from mlxtend.data import iris_data
from mlxtend.preprocessing import standardize
from mlxtend.feature_extraction import RBFKernelPCA as KPCA
```



Concentric circles

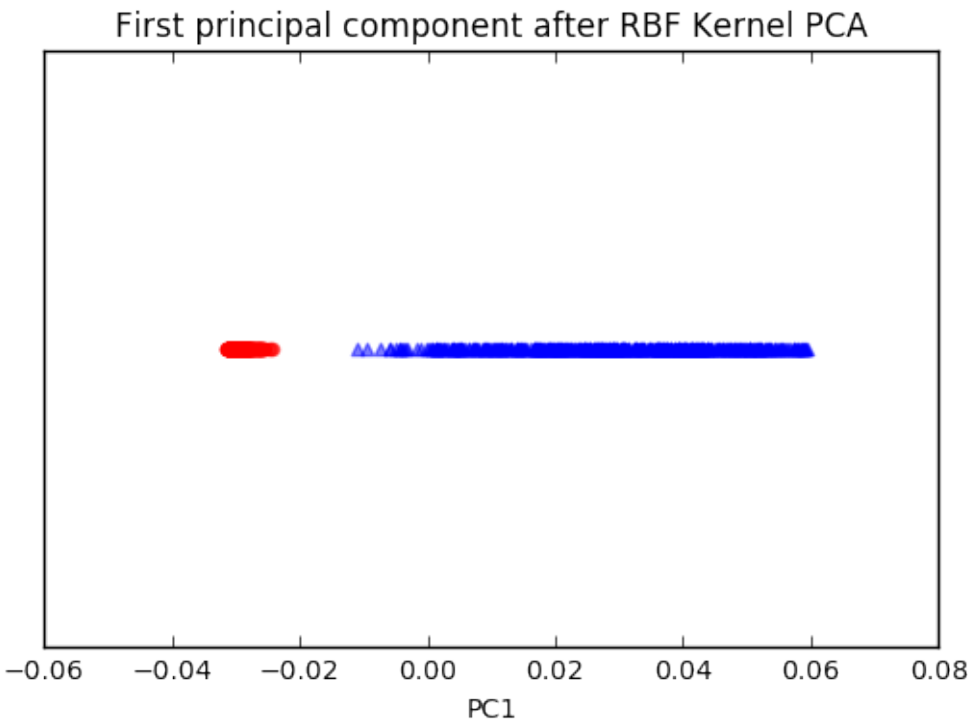
```
kpca = KPCA(gamma=15.0, n_components=2)
kpca.fit(X)
X_kpca = kpca.X_projected_

plt.scatter(X_kpca[y==0, 0], X_kpca[y==0, 1],
            color='red', marker='o', alpha=0.5)
plt.scatter(X_kpca[y==1, 0], X_kpca[y==1, 1],
            color='blue', marker='^', alpha=0.5)

plt.title('First 2 principal components after RBF Kernel PCA')
plt.xlabel('PC1')
plt.ylabel('PC2')
plt.show()

plt.scatter(X_kpca[y==0, 0], np.zeros((500, 1)),
            color='red', marker='o', alpha=0.5)
plt.scatter(X_kpca[y==1, 0], np.zeros((500, 1)),
            color='blue', marker='^', alpha=0.5)

plt.title('First principal component after RBF Kernel PCA')
plt.xlabel('PC1')
plt.yticks([])
plt.show()
```



38.5 API

RBFKernelPCA(gamma=15.0, n_components=None, copy_X=True)

RBF Kernel Principal Component Analysis for dimensionality reduction.

Parameters

- `gamma` : float (default: 15.0)
  Free parameter (coefficient) of the RBF kernel.
- `n_components` : int (default: None)
  The number of principal components for transformation. Keeps the original dimensions of the dataset if `None`.
- `copy_X` : bool (default: True)
  Copies training data, which is required to compute the projection of new data via the transform method. Uses a reference to X if False.

Attributes

- `e_vals_` : array-like, shape=[n_features]
  Eigenvalues in sorted order.
- `e_vecs_` : array-like, shape=[n_features]
  Eigenvectors in sorted order.
- `X_projected_` : array-like, shape=[n_samples, n_components]
  Training samples projected along the component axes.

38.5.1 Methods

fit(X)

Learn model from training data.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `self` : object

transform(X)

Apply the non-linear transformation on X.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `X_projected` : np.ndarray, shape = [n_samples, n_components]
  Projected training vectors.

39 feature_selection.ColumnSelector

Implementation of a column selector class for scikit-learn pipelines.

```
from mlxtend.feature_selection import ColumnSelector
```

39.1 Overview

The `ColumnSelector` can be used for "manual" feature selection, e.g., as part of a grid search via a scikit-learn pipeline.

39.1.1 References

-

39.2 Example 1 - Fitting an Estimator on a Feature Subset

Load a simple benchmark dataset:

```
from sklearn.datasets import load_iris

iris = load_iris()
X = iris.data
y = iris.target
```

The `ColumnSelector` is a simple transformer class that selects specific columns (features) from a datast. For instance, using the `transform` method returns a reduced dataset that only contains two features (here: the first two features via the indices 0 and 1, respectively):

```
from mlxtend.feature_selection import ColumnSelector

col_selector = ColumnSelector(cols=(0, 1))
# col_selector.fit(X) # optional, does not do anything
col_selector.transform(X).shape
```

```
(150, 2)
```

Similarly, we can use the `ColumnSelector` as part of a scikit-learn `Pipeline`:

```
from sklearn.neighbors import KNeighborsClassifier
from sklearn.preprocessing import StandardScaler
from sklearn.pipeline import make_pipeline

pipe = make_pipeline(StandardScaler(),
                     ColumnSelector(cols=(0, 1)),
                     KNeighborsClassifier())

pipe.fit(X, y)
pipe.score(X, y)
```

```
0.83999999999999997
```

39.3 Example 2 - Feature Selection via GridSearch

Example 1 showed a simple useage example of the `ColumnSelector`; however, selecting columns from a dataset is trivial and does not require a specific transformer class since we could have achieved the same results via

```
classifier.fit(X[:, :2], y)
classifier.score(X[:, :2], y)
```

However, the `ColumnSelector` becomes really useful for feature selection as part of a grid search as shown in this example.

Load a simple benchmark dataset:

```
from sklearn.datasets import load_iris

iris = load_iris()
X = iris.data
y = iris.target
```

Create all possible combinations:

```
from itertools import combinations

all_comb = []
for size in range(1, 5):
    all_comb += list(combinations(range(X.shape[1]), r=size))
print(all_comb)
```

```
[(0,), (1,), (2,), (3,), (0, 1), (0, 2), (0, 3), (1, 2), (1, 3), (2, 3), (0, 1, 2), (0, 1, 3), (0, 2, 3
```

Feature and model selection via grid search:

```
from mlxtend.feature_selection import ColumnSelector
from sklearn.neighbors import KNeighborsClassifier
from sklearn.preprocessing import StandardScaler
from sklearn.model_selection import GridSearchCV
from sklearn.pipeline import make_pipeline

pipe = make_pipeline(StandardScaler(),
                     ColumnSelector(),
                     KNeighborsClassifier())

param_grid = {'columnselector__cols': all_comb,
              'kneighborsclassifier__n_neighbors': list(range(1, 11))}

grid = GridSearchCV(pipe, param_grid, cv=5, n_jobs=-1)
grid.fit(X, y)
print('Best parameters:', grid.best_params_)
print('Best performance:', grid.best_score_)
```

```
Best parameters: {'columnselector__cols': (2, 3), 'kneighborsclassifier__n_neighbors': 1}
Best performance: 0.98
```

39.4 API

ColumnSelector(cols=None)

Base class for all estimators in scikit-learn

Notes

All estimators should specify all the parameters that can be set at the class level in their `__init__` as explicit keyword arguments (no `*args` or `**kwargs`).

39.4.1 Methods

fit(X, y=None)

Mock method. Does nothing.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` : array-like, shape = [n_samples] (default: None)

Returns

self

fit_transform(X, y=None)

Return a slice of the input array.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` : array-like, shape = [n_samples] (default: None)

Returns

- `X_slice` : shape = [n_samples, k_features]
  Subset of the feature space where k_features <= n_features

get_params(deep=True)

Get parameters for this estimator.

Parameters

- `deep` : boolean, optional
  If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- `params` : mapping of string to any
  Parameter names mapped to their values.

*set_params(**params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

transform(X, y=None)

Return a slice of the input array.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` : array-like, shape = [n_samples] (default: None)

Returns

- `X_slice` : shape = [n_samples, k_features]
  Subset of the feature space where k_features <= n_features

40 feature_selection.ExhaustiveFeatureSelector

Implementation of an *exhaustive feature selector* for sampling and evaluating all possible feature combinations in a specified range.

```
from mlxtend.feature_selection import ExhaustiveFeatureSelector
```

40.1 Overview

This exhaustive feature selection algorithm is a wrapper approach for brute-force evaluation of feature subsets; the best subset is selected by optimizing a specified performance metric given an arbitrary regressor or classifier. For instance, if the classifier is a logistic regression and the dataset consists of 4 features, the alogorithm will evaluate all 15 feature combinations (if `min_features=1` and `max_features=4`)

- {0}
- {1}
- {2}
- {3}
- {0, 1}
- {0, 2}
- {0, 3}
- {1, 2}
- {1, 3}
- {2, 3}
- {0, 1, 2}
- {0, 1, 3}
- {0, 2, 3}
- {1, 2, 3}
- {0, 1, 2, 3}

and select the one that results in the best performance (e.g., classification accuracy) of the logistic regression classifier.

40.2 Example 1 - A simple Iris Example

Initializing a simple classifier from scikit-learn:

```
from sklearn.neighbors import KNeighborsClassifier
from sklearn.datasets import load_iris
from mlxtend.feature_selection import ExhaustiveFeatureSelector as EFS

iris = load_iris()
X = iris.data
y = iris.target

knn = KNeighborsClassifier(n_neighbors=3)

efs1 = EFS(knn,
           min_features=1,
           max_features=4,
           scoring='accuracy',
           print_progress=True,
           cv=5)

efs1 = efs1.fit(X, y)

print('Best accuracy score: %.2f' % efs1.best_score_)
print('Best subset:', efs1.best_idx_)

Features: 15/15

Best accuracy score: 0.97
Best subset: (0, 2, 3)
```

Via the `subsets_` attribute, we can take a look at the selected feature indices at each step:

```
efs1.subsets_

{0: {'avg_score': 0.65999999999999992,
  'cv_scores': array([ 0.53333333,  0.63333333,  0.73333333,  0.76666667,  0.63333333]),
  'feature_idx': (0,)},
 1: {'avg_score': 0.56666666666666665,

  'feature_idx': (1, 2, 3)},
 14: {'avg_score': 0.96666666666666679,
  'cv_scores': array([ 0.96666667,  0.96666667,  0.93333333,  0.96666667,  1.        ]),
  'feature_idx': (0, 1, 2, 3)}}
```

40.3 Example 2 - Visualizing the feature selection results

For our convenience, we can visualize the output from the feature selection in a pandas DataFrame format using the `get_metric_dict` method of the `ExhaustiveFeatureSelector` object. The columns `std_dev` and `std_err` represent the standard deviation and standard errors of the cross-validation scores, respectively.

Below, we see the DataFrame of the Sequential Forward Selector from Example 2:

```
import pandas as pd

iris = load_iris()
X = iris.data
y = iris.target

knn = KNeighborsClassifier(n_neighbors=3)

efs1 = EFS(knn,
           min_features=1,
           max_features=4,
           scoring='accuracy',
           print_progress=True,
           cv=5)

efs1 = efs1.fit(X, y)

df = pd.DataFrame.from_dict(efs1.get_metric_dict()).T
```

```
df.sort_values('avg_score', inplace=True, ascending=False)
df
```

```
Features: 15/15
```

```

feature_max = len(metric_dict[k_feat[-1]]['feature_idx'])
plt.xticks(k_feat,
           [str(metric_dict[k]['feature_idx']) for k in k_feat],
           rotation=90)
plt.show()
```

40.4 Example 3 - Exhaustive Feature Selection for Regression

Similar to the classification examples above, the `SequentialFeatureSelector` also supports scikit-learn's estimators for regression.

```
from sklearn.linear_model import LinearRegression
from sklearn.datasets import load_boston

boston = load_boston()
X, y = boston.data, boston.target

lr = LinearRegression()

efs = EFS(lr,
          min_features=10,
          max_features=12,
          scoring='neg_mean_squared_error',
          cv=10)

efs.fit(X, y)

print('Best MSE score: %.2f' % efs.best_score_ * (-1))
print('Best subset:', efs.best_idx_)

Features: 377/377

Best subset: (0, 1, 4, 6, 7, 8, 9, 10, 11, 12)
```

40.5 Example 4 - Using the Selected Feature Subset For Making New Predictions

```
# Initialize the dataset

from sklearn.neighbors import KNeighborsClassifier
from sklearn.datasets import load_iris
from sklearn.model_selection import train_test_split

iris = load_iris()
X, y = iris.data, iris.target
X_train, X_test, y_train, y_test = train_test_split(
         X, y, test_size=0.33, random_state=1)

knn = KNeighborsClassifier(n_neighbors=3)

# Select the "best" three features via
# 5-fold cross-validation on the training set.

from mlxtend.feature_selection import ExhaustiveFeatureSelector as EFS

efs1 = EFS(knn,
           min_features=1,
```

```
            max_features=4,
            scoring='accuracy',
            cv=5)
efs1 = efs1.fit(X_train, y_train)

Features: 15/15

print('Selected features:', efs1.best_idx_)

Selected features: (2, 3)

# Generate the new subsets based on the selected features
# Note that the transform call is equivalent to
# X_train[:, efs1.k_feature_idx_]

X_train_efs = efs1.transform(X_train)
X_test_efs = efs1.transform(X_test)

# Fit the estimator using the new feature subset
# and make a prediction on the test data
knn.fit(X_train_efs, y_train)
y_pred = knn.predict(X_test_efs)

# Compute the accuracy of the prediction
acc = float((y_test == y_pred).sum()) / y_pred.shape[0]
print('Test set accuracy: %.2f %%' % (acc*100))

Test set accuracy: 96.00 %
```

40.6 Example 5 - Exhaustive Feature Selection and GridSearch

```
# Initialize the dataset

from sklearn.datasets import load_iris
from sklearn.model_selection import train_test_split

iris = load_iris()
X, y = iris.data, iris.target
X_train, X_test, y_train, y_test = train_test_split(
         X, y, test_size=0.33, random_state=1)
```

Use scikit-learn's `GridSearch` to tune the hyperparameters of the `LogisticRegression` estimator inside the `ExhaustiveFeatureSelector` and use it for prediction in the pipeline. **Note that the `clone_estimator` attribute needs to be set to `False`.**

```
from sklearn.model_selection import GridSearchCV
from sklearn.pipeline import make_pipeline
from sklearn.linear_model import LogisticRegression
from mlxtend.feature_selection import ExhaustiveFeatureSelector as EFS

lr = LogisticRegression(multi_class='multinomial',
```

```
                        solver='lbfgs',
                        random_state=123)

efs1 = EFS(estimator=lr,
           min_features=2,
           max_features=3,
           scoring='accuracy',
           print_progress=False,
           clone_estimator=False,
           cv=5,
           n_jobs=1)

pipe = make_pipeline(efs1, lr)

param_grid = {'exhaustivefeatureselector__estimator__C': [0.1, 1.0, 10.0]}

gs = GridSearchCV(estimator=pipe,
                  param_grid=param_grid,
                  scoring='accuracy',
                  n_jobs=1,
                  cv=2,
                  verbose=1,
                  refit=False)

# run gridearch
gs = gs.fit(X_train, y_train)

Fitting 2 folds for each of 3 candidates, totalling 6 fits

[Parallel(n_jobs=1)]: Done   6 out of   6 | elapsed:    2.7s finished
```

... and the "best" parameters determined by GridSearch are ...

```
print("Best parameters via GridSearch", gs.best_params_)

Best parameters via GridSearch {'exhaustivefeatureselector__estimator__C': 1.0}
```

40.6.0.1 Obtaining the best k feature indices after GridSearch

If we are interested in the best k best feature indices via `SequentialFeatureSelection.best_idx_`, we have to initialize a `GridSearchCV` object with `refit=True`. Now, the grid search object will take the complete training dataset and the best parameters, which it found via cross-validation, to train the estimator pipeline.

```
gs = GridSearchCV(estimator=pipe,
                  param_grid=param_grid,
                  scoring='accuracy',
                  n_jobs=2,
                  cv=2,
                  verbose=1,
                  refit=True)
```

After running the grid search, we can access the individual pipeline objects of the `best_estimator_` via the `steps` attribute.

```
gs = gs.fit(X_train, y_train)
gs.best_estimator_.steps
```

```
Fitting 2 folds for each of 3 candidates, totalling 6 fits
```

```

[Parallel(n_jobs=2)]: Done   6 out of   6 | elapsed:    3.8s finished
```

```
[('exhaustivefeatureselector',
  ExhaustiveFeatureSelector(clone_estimator=False, cv=5,
              estimator=LogisticRegression(C=1.0, class_weight=None, dual=False, fit_intercept=True,
            intercept_scaling=1, max_iter=100, multi_class='multinomial',
            n_jobs=1, penalty='l2', random_state=123, solver='lbfgs',
            tol=0.0001, verbose=0, warm_start=False),
              max_features=3, min_features=2, n_jobs=1,
              pre_dispatch='2*n_jobs', print_progress=False,
              scoring='accuracy')),
 ('logisticregression',
  LogisticRegression(C=1.0, class_weight=None, dual=False, fit_intercept=True,
            intercept_scaling=1, max_iter=100, multi_class='multinomial',
            n_jobs=1, penalty='l2', random_state=123, solver='lbfgs',
            tol=0.0001, verbose=0, warm_start=False))]
```

Via sub-indexing, we can then obtain the best-selected feature subset:

```
print('Best features:', gs.best_estimator_.steps[0][1].best_idx_)
```

```
Best features: (2, 3)
```

During cross-validation, this feature combination had a CV accuracy of:

```
print('Best score:', gs.best_score_)
```

```
Best score: 0.97
```

```
gs.best_params_
```

```
{'exhaustivefeatureselector__estimator__C': 1.0}
```

Alternatively, if we can set the "best grid search parameters" in our pipeline manually if we ran `GridSearchCV` with `refit=False`. It should yield the same results:

```
pipe.set_params(**gs.best_params_).fit(X_train, y_train)
print('Best features:', pipe.steps[0][1].best_idx_)
```

```
Best features: (2, 3)
```

40.7 API

*ExhaustiveFeatureSelector(estimator, min_features=1, max_features=1, print_progress=True, scoring='accuracy', cv=5, n_jobs=1, pre_dispatch='2*n_jobs', clone_estimator=True)*

Exhaustive Feature Selection for Classification and Regression. (new in v0.4.3)

Parameters

- `estimator` : scikit-learn classifier or regressor
- `min_features` : int (default: 1)

  Minumum number of features to select
- `max_features` : int (default: 1)

  Maximum number of features to select
- `print_progress` : bool (default: True)

  Prints progress as the number of epochs to stderr.
- `scoring` : str, (default='accuracy')

  Scoring metric in {accuracy, f1, precision, recall, roc_auc} for classifiers, {'mean_absolute_error', 'mean_squared_error', 'median_absolute_error', 'r2'} for regressors, or a callable object or function with signature `scorer(estimator, X, y)`.
- `cv` : int (default: 5)

  Scikit-learn cross-validation generator or `int`. If estimator is a classifier (or y consists of integer class labels), stratified k-fold is performed, and regular k-fold cross-validation otherwise. No cross-validation if cv is None, False, or 0.
- `n_jobs` : int (default: 1)

  The number of CPUs to use for evaluating different feature subsets in parallel. -1 means 'all CPUs'.
- `pre_dispatch` : int, or string (default: '2*n_jobs')

  Controls the number of jobs that get dispatched during parallel execution if `n_jobs > 1` or `n_jobs=-1`. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be: None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs An int, giving the exact number of total jobs that are spawned A string, giving an expression as a function of n_jobs, as in `2*n_jobs`

- `clone_estimator` : bool (default: True)

  Clones estimator if True; works with the original estimator instance if False. Set to False if the estimator doesn't implement scikit-learn's set_params and get_params methods. In addition, it is required to set cv=0, and n_jobs=1.

Attributes

- `best_idx_` : array-like, shape = [n_predictions]

  Feature Indices of the selected feature subsets.

- `best_score_` : float

  Cross validation average score of the selected subset.

- `subsets_` : dict

  A dictionary of selected feature subsets during the sequential selection, where the dictionary keys are the lengths k of these feature subsets. The dictionary values are dictionaries themselves with the following keys: 'feature_idx' (tuple of indices of the feature subset) 'cv_scores' (list individual cross-validation scores) 'avg_score' (average cross-validation score)

40.7.1 Methods

fit(X, y)

Perform feature selection and learn model from training data.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  Training vectors, where n_samples is the number of samples and n_features is the number of features.

- `y` : array-like, shape = [n_samples]

  Target values.

Returns

- `self` : object

fit_transform(X, y)

Fit to training data and return the best selected features from X.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

Feature subset of X, shape={n_samples, k_features}

get_metric_dict(confidence_interval=0.95)

Return metric dictionary

Parameters

- `confidence_interval` : float (default: 0.95)

  A positive float between 0.0 and 1.0 to compute the confidence interval bounds of the CV score averages.

Returns

Dictionary with items where each dictionary value is a list with the number of iterations (number of feature subsets) as its length. The dictionary keys corresponding to these lists are as follows: 'feature_idx': tuple of the indices of the feature subset 'cv_scores': list with individual CV scores 'avg_score': of CV average scores 'std_dev': standard deviation of the CV score average 'std_err': standard error of the CV score average 'ci_bound': confidence interval bound of the CV score average

get_params(deep=True)

Get parameters for this estimator.

Parameters

- `deep` : boolean, optional

  If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- `params` : mapping of string to any

  Parameter names mapped to their values.

*set_params(**params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

transform(X)

Return the best selected features from X.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

Feature subset of X, shape={n_samples, k_features}

41 feature_selection.SequentialFeatureSelector

Implementation of *sequential feature algorithms* (SFAs) – greedy search algorithms – that have been developed as a suboptimal solution to the computationally often not feasible exhaustive search.

```
from mlxtend.feature_selection import SequentialFeatureSelector
```

41.1 Overview

Sequential feature selection algorithms are a family of greedy search algorithms that are used to reduce an initial d-dimensional feature space to a k-dimensional feature subspace where $k < d$. The motivation behind feature selection algorithms is to automatically select a subset of features that is most relevant to the problem. The goal of feature selection is two-fold: We want to improve the computational efficiency and reduce the generalization error of the model by removing irrelevant features or noise. A wrapper approach such as sequential feature selection is especially useful if embedded feature selection – for example, a regularization penalty like LASSO – is not applicable.

In a nutshell, SFAs remove or add one feature at the time based on the classifier performance until a feature subset of the desired size k is reached. There are 4 different flavors of SFAs available via the `SequentialFeatureSelector`:

1. Sequential Forward Selection (SFS)
2. Sequential Backward Selection (SBS)
3. Sequential Floating Forward Selection (SFFS)
4. Sequential Floating Backward Selection (SFBS)

The ***floating*** variants, SFFS and SFBS, can be considered as extensions to the simpler SFS and SBS algorithms. The floating algorithms have an additional exclusion or inclusion step to remove features once they were included (or excluded), so that a larger number of feature subset combinations can be sampled. It is important to emphasize that this step is conditional and only occurs if the resulting feature subset is assessed as "better" by the criterion function after removal (or addition) of a particular feature. Furthermore, I added an optional check to skip the conditional exclusion steps if the algorithm gets stuck in cycles.

How is this different from *Recursive Feature Elimination* (RFE) – e.g., as implemented in `sklearn.feature_selection.RFE`? RFE is computationally less complex using the feature weight coefficients (e.g., linear models) or feature importance (tree-based algorithms) to eliminate features recursively, whereas SFSs eliminate (or add) features based on a user-defined classifier/regression performance metric.

The SFAs are outlined in pseudo code below:

41.1.1 Sequential Forward Selection (SFS)

Input: $Y = \{y_1, y_2, ..., y_d\}$

- The ***SFS*** algorithm takes the whole d-dimensional feature set as input.

Output: $X_k = \{x_j \mid j = 1, 2, ..., k;\ x_j \in Y\}$, where $k = (0, 1, 2, ..., d)$

- SFS returns a subset of features; the number of selected features k, where $k < d$, has to be specified *a priori*.

Initialization: $X_0 = \emptyset$, $k = 0$

- We initialize the algorithm with an empty set $\emptyset$ ("null set") so that $k = 0$ (where k is the size of the subset).

Step 1 (Inclusion):

$x^+ = \text{ arg max } J(x_k + x), \text{ where } x \in Y - X_k$
$X_k + 1 = X_k + x^+$
$k = k + 1$
Go to Step 1

- in this step, we add an additional feature, x^+, to our feature subset X_k.
- x^+ is the feature that maximizes our criterion function, that is, the feature that is associated with the best classifier performance if it is added to X_k.
- We repeat this procedure until the termination criterion is satisfied.

Termination: $k = p$

- We add features from the feature subset X_k until the feature subset of size k contains the number of desired features p that we specified *a priori*.

41.1.2 Sequential Backward Selection (SBS)

Input: the set of all features, $Y = \{y_1, y_2, ..., y_d\}$

- The SBS algorithm takes the whole feature set as input.

Output: $X_k = \{x_j \mid j = 1, 2, ..., k;\ x_j \in Y\}$, where $k = (0, 1, 2, ..., d)$

- SBS returns a subset of features; the number of selected features k, where $k < d$, has to be specified *a priori*.

Initialization: $X_0 = Y$, $k = d$

- We initialize the algorithm with the given feature set so that the $k = d$.

Step 1 (Exclusion):

$x^- = \text{ arg max } J(x_k - x), \text{ where } x \in X_k$
$X_k - 1 = X_k - x^-$
$k = k - 1$
Go to Step 1

- In this step, we remove a feature, x^- from our feature subset X_k.
- x^- is the feature that maximizes our criterion function upon re,oval, that is, the feature that is associated with the best classifier performance if it is removed from X_k.
- We repeat this procedure until the termination criterion is satisfied.

Termination: $k = p$

- We add features from the feature subset X_k until the feature subset of size k contains the number of desired features p that we specified *a priori*.

41.1.3 Sequential Floating Backward Selection (SFBS)

Input: the set of all features, $Y = \{y_1, y_2, ..., y_d\}$

- The SFBS algorithm takes the whole feature set as input.

Output: $X_k = \{x_j \mid j = 1, 2, ..., k;\ x_j \in Y\}$, where $k = (0, 1, 2, ..., d)$

- SFBS returns a subset of features; the number of selected features k, where $k < d$, has to be specified *a priori*.

Initialization: $X_0 = Y$, $k = d$

- We initialize the algorithm with the given feature set so that the $k = d$.

Step 1 (Exclusion):

$x^- = \ \arg\max\ J(x_k - x),\ \text{where } x \in X_k$
$X_k - 1 = X_k - x^-$
$k = k - 1$
Go to Step 2

- In this step, we remove a feature, x^- from our feature subset X_k.
- x^- is the feature that maximizes our criterion function upon re,oval, that is, the feature that is associated with the best classifier performance if it is removed from X_k.

Step 2 (Conditional Inclusion):
$x^+ = \ \arg\max\ J(x_k + x),\ \text{where } x \in Y - X_k$
if J(x_k + x) > J(x_k + x):
$X_k + 1 = X_k + x^+$
$k = k + 1$
Go to Step 1

- In Step 2, we search for features that improve the classifier performance if they are added back to the feature subset. If such features exist, we add the feature x^+ for which the performance improvement is max.
- Steps 1 and 2 are repeated until the **Termination** criterion is reached.

Termination: $k = p$

- We add features from the feature subset X_k until the feature subset of size k contains the number of desired features p that we specified *a priori*.

41.1.4 Sequential Floating Forward Selection (SFFS)

Input: the set of all features, $Y = \{y_1, y_2, ..., y_d\}$

- The ***SFFS*** algorithm takes the whole feature set as input, if our feature space consists of, e.g. 10, if our feature space consists of 10 dimensions (***d = 10***).

Output: a subset of features, $X_k = \{x_j \mid j = 1, 2, ..., k;\ x_j \in Y\}$, where $k = (0, 1, 2, ..., d)$

- The returned output of the algorithm is a subset of the feature space of a specified size. E.g., a subset of 5 features from a 10-dimensional feature space (***k = 5, d = 10***).

Initialization: $X_0 = Y$, $k = d$

- We initialize the algorithm with an empty set ("null set") so that the ***k = 0*** (where ***k*** is the size of the subset)

Step 1 (Inclusion):
$x^+ =$ arg max $J(x_k + x)$, where $x \in Y - X_k$
$X_k + 1 = X_k + x^+$
$k = k + 1$
Go to Step 2
Step 2 (Conditional Exclusion):
$x^- =$ arg max $J(x_k - x)$, where $x \in X_k$
if $J(x_k - x) > J(x_k - x)$:
$X_k-1 = X_k - x^- $
$k = k - 1$
Go to Step 1

- In step 1, we include the feature from the ***feature space*** that leads to the best performance increase for our ***feature subset*** (assessed by the ***criterion function***). Then, we go over to step 2
- In step 2, we only remove a feature if the resulting subset would gain an increase in performance. We go back to step 1.

- Steps 1 and 2 are repeated until the **Termination** criterion is reached.

Termination: stop when ***k*** equals the number of desired features

41.2 Example 1 - A simple Sequential Forward Selection example

Initializing a simple classifier from scikit-learn:

```
from sklearn.neighbors import KNeighborsClassifier
from sklearn.datasets import load_iris

iris = load_iris()
X = iris.data
y = iris.target
knn = KNeighborsClassifier(n_neighbors=4)
```

We start by selection the "best" 3 features from the Iris dataset via Sequential Forward Selection (SFS). Here, we set `forward=True` and `floating=False`. By choosing `cv=0`, we don't perform any cross-validation, therefore, the performance (here: `'accuracy'`) is computed entirely on the training set.

```
from mlxtend.feature_selection import SequentialFeatureSelector as SFS

sfs1 = SFS(knn,
           k_features=3,
           forward=True,
           floating=False,
           verbose=2,
           scoring='accuracy',
           cv=0)

sfs1 = sfs1.fit(X, y)
```

```
[Parallel(n_jobs=1)]: Done   1 out of   1 | elapsed:    0.0s remaining:    0.0s
[Parallel(n_jobs=1)]: Done   4 out of   4 | elapsed:    0.0s finished

[2017-09-07 06:40:45] Features: 1/3 -- score: 0.96[Parallel(n_jobs=1)]: Done   1 out of   1 | elapsed:
[Parallel(n_jobs=1)]: Done   3 out of   3 | elapsed:    0.0s finished

[2017-09-07 06:40:45] Features: 2/3 -- score: 0.973333333333[Parallel(n_jobs=1)]: Done   1 out of   1 |
[Parallel(n_jobs=1)]: Done   2 out of   2 | elapsed:    0.0s finished

[2017-09-07 06:40:45] Features: 3/3 -- score: 0.973333333333
```

Via the `subsets_` attribute, we can take a look at the selected feature indices at each step:

```
sfs1.subsets_
```

```
{1: {'avg_score': 0.95999999999999996,
  'cv_scores': array([ 0.96]),
  'feature_idx': (3,)},
 2: {'avg_score': 0.97333333333333338,
  'cv_scores': array([ 0.97333333]),
  'feature_idx': (2, 3)},
 3: {'avg_score': 0.97333333333333338,
  'cv_scores': array([ 0.97333333]),
  'feature_idx': (1, 2, 3)}}
```

Furthermore, we can access the indices of the 3 best features directly via the `k_feature_idx_` attribute:

```
sfs1.k_feature_idx_
```

```
(1, 2, 3)
```

Finally, the prediction score for these 3 features can be accesses via `k_score_`:

```
sfs1.k_score_
```

```
0.97333333333333338
```

41.3 Example 2 - Toggling between SFS, SBS, SFFS, and SFBS

Using the `forward` and `floating` parameters, we can toggle between SFS, SBS, SFFS, and SFBS as shown below. Note that we are performing (stratified) 4-fold cross-validation for more robust estimates in contrast to Example 1. Via `n_jobs=-1`, we choose to run the cross-validation on all our available CPU cores.

```
# Sequential Forward Selection
sfs = SFS(knn,
          k_features=3,
          forward=True,
          floating=False,
          scoring='accuracy',
          cv=4,
          n_jobs=-1)
sfs = sfs.fit(X, y)

print('\nSequential Forward Selection (k=3):')
print(sfs.k_feature_idx_)
print('CV Score:')
print(sfs.k_score_)

##################################################

# Sequential Backward Selection
sbs = SFS(knn,
          k_features=3,
          forward=False,
          floating=False,
          scoring='accuracy',
          cv=4,
          n_jobs=-1)
sbs = sbs.fit(X, y)

print('\nSequential Backward Selection (k=3):')
print(sbs.k_feature_idx_)
print('CV Score:')
print(sbs.k_score_)

##################################################

# Sequential Floating Forward Selection
sffs = SFS(knn,
           k_features=3,
           forward=True,
           floating=True,
           scoring='accuracy',
           cv=4,
           n_jobs=-1)
sffs = sffs.fit(X, y)

print('\nSequential Floating Forward Selection (k=3):')
print(sffs.k_feature_idx_)
print('CV Score:')
print(sffs.k_score_)
```

```
###################################################

# Sequential Floating Backward Selection
sfbs = SFS(knn,
           k_features=3,
           forward=False,
           floating=True,
           scoring='accuracy',
           cv=4,
           n_jobs=-1)
sfbs = sfbs.fit(X, y)

print('\nSequential Floating Backward Selection (k=3):')
print(sfbs.k_feature_idx_)
print('CV Score:')
print(sfbs.k_score_)
```

```
Sequential Forward Selection (k=3):
(1, 2, 3)
CV Score:
0.972756410256

Sequential Backward Selection (k=3):
(1, 2, 3)
CV Score:
0.972756410256

Sequential Floating Forward Selection (k=3):
(1, 2, 3)
CV Score:
0.972756410256

Sequential Floating Backward Selection (k=3):
(1, 2, 3)
CV Score:
0.972756410256
```

In this simple scenario, selecting the best 3 features out of the 4 available features in the Iris set, we end up with similar results regardless of which sequential selection algorithms we used.

41.4 Example 3 - Visualizing the results in DataFrames

For our convenience, we can visualize the output from the feature selection in a pandas DataFrame format using the `get_metric_dict` method of the SequentialFeatureSelector object. The columns `std_dev` and `std_err` represent the standard deviation and standard errors of the cross-validation scores, respectively.

Below, we see the DataFrame of the Sequential Forward Selector from Example 2:

```
import pandas as pd
pd.DataFrame.from_dict(sfs.get_metric_dict()).T
```

```
<tr style="text-align: right;">
```

```
  <th></th>
  <th>avg_score</th>
  <th>ci_bound</th>
  <th>cv_scores</th>
  <th>feature_idx</th>
  <th>std_dev</th>
  <th>std_err</th>
</tr>

<tr>
  <th>1</th>
  <td>0.952991</td>
  <td>0.0660624</td>
  <td>[0.974358974359, 0.948717948718, 0.88888888888...</td>
  <td>(3,)</td>
  <td>0.0412122</td>
  <td>0.0237939</td>
</tr>
<tr>
  <th>2</th>
  <td>0.959936</td>
  <td>0.0494801</td>
  <td>[0.974358974359, 0.948717948718, 0.91666666666...</td>
  <td>(2, 3)</td>
  <td>0.0308676</td>
  <td>0.0178214</td>
</tr>
<tr>
  <th>3</th>
  <td>0.972756</td>
  <td>0.0315204</td>
  <td>[0.974358974359, 1.0, 0.944444444444, 0.972222...</td>
  <td>(1, 2, 3)</td>
  <td>0.0196636</td>
  <td>0.0113528</td>
</tr>
```

Now, let's compare it to the Sequential Backward Selector:

```
pd.DataFrame.from_dict(sbs.get_metric_dict()).T
```

```
<tr style="text-align: right;">
  <th></th>
  <th>avg_score</th>
  <th>ci_bound</th>
  <th>cv_scores</th>
  <th>feature_idx</th>
  <th>std_dev</th>
  <th>std_err</th>
</tr>

<tr>
  <th>3</th>
```

```
  <td>0.972756</td>
  <td>0.0315204</td>
  <td>[0.974358974359, 1.0, 0.944444444444, 0.972222...</td>
  <td>(1, 2, 3)</td>
  <td>0.0196636</td>
  <td>0.0113528</td>
</tr>
<tr>
  <th>4</th>
  <td>0.952991</td>
  <td>0.0372857</td>
  <td>[0.974358974359, 0.948717948718, 0.91666666666...</td>
  <td>(0, 1, 2, 3)</td>
  <td>0.0232602</td>
  <td>0.0134293</td>
</tr>
```

We can see that both SFS and SFBS found the same "best" 3 features, however, the intermediate steps where obviously different.

The `ci_bound` column in the DataFrames above represents the confidence interval around the computed cross-validation scores. By default, a confidence interval of 95% is used, but we can use different confidence bounds via the `confidence_interval` parameter. E.g., the confidence bounds for a 90% confidence interval can be obtained as follows:

```
pd.DataFrame.from_dict(sbs.get_metric_dict(confidence_interval=0.90)).T
```

```
<tr style="text-align: right;">
  <th></th>
  <th>avg_score</th>
  <th>ci_bound</th>
  <th>cv_scores</th>
  <th>feature_idx</th>
  <th>std_dev</th>
  <th>std_err</th>
</tr>

<tr>
  <th>3</th>
  <td>0.972756</td>
  <td>0.0242024</td>
  <td>[0.974358974359, 1.0, 0.944444444444, 0.972222...</td>
  <td>(1, 2, 3)</td>
  <td>0.0196636</td>
  <td>0.0113528</td>
</tr>
<tr>
  <th>4</th>
  <td>0.952991</td>
  <td>0.0286292</td>
  <td>[0.974358974359, 0.948717948718, 0.91666666666...</td>
  <td>(0, 1, 2, 3)</td>
  <td>0.0232602</td>
  <td>0.0134293</td>
</tr>
```

41.5 Example 4 - Plotting the results

After importing the little helper function plotting.plot_sequential_feature_selection, we can also visualize the results using matplotlib figures.

```
from mlxtend.plotting import plot_sequential_feature_selection as plot_sfs
import matplotlib.pyplot as plt

sfs = SFS(knn,
          k_features=4,
          forward=True,
          floating=False,
          scoring='accuracy',
          verbose=2,
          cv=5)

sfs = sfs.fit(X, y)

fig1 = plot_sfs(sfs.get_metric_dict(), kind='std_dev')

plt.ylim([0.8, 1])
plt.title('Sequential Forward Selection (w. StdDev)')
plt.grid()
plt.show()
```

```
[Parallel(n_jobs=1)]: Done   1 out of   1 | elapsed:    0.0s remaining:    0.0s
[Parallel(n_jobs=1)]: Done   4 out of   4 | elapsed:    0.0s finished

[2017-09-07 06:40:48] Features: 4/4 -- score: 0.973333333333
```

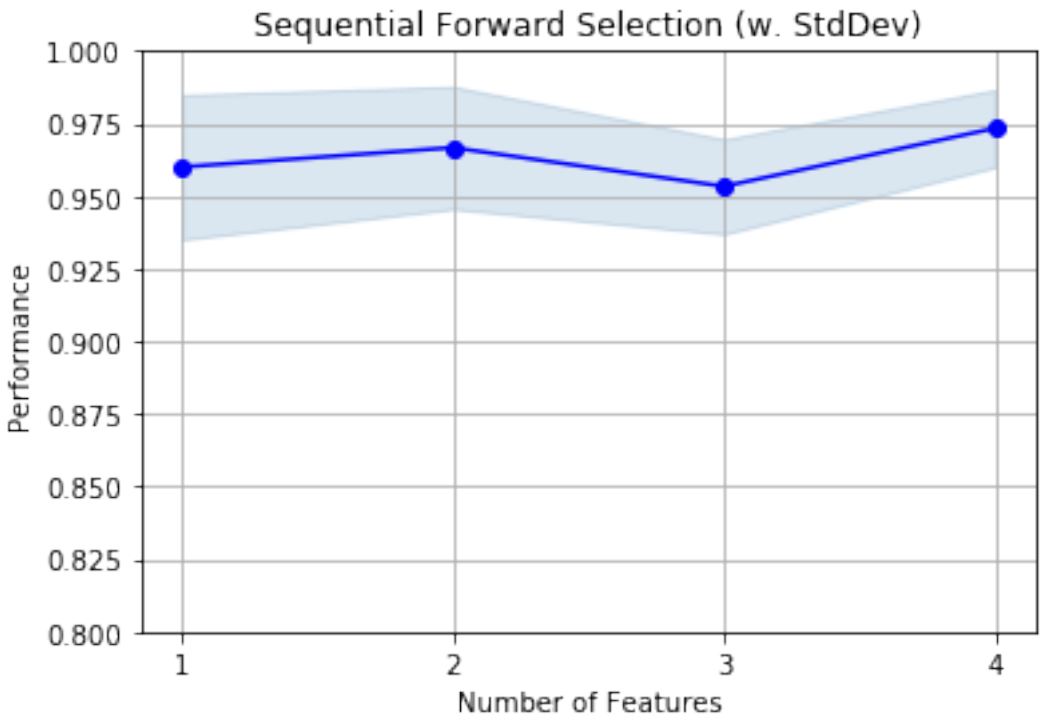
41.6 Example 5 - Sequential Feature Selection for Regression

Similar to the classification examples above, the SequentialFeatureSelector also supports scikit-learn's estimators for regression.

```
from sklearn.linear_model import LinearRegression
from sklearn.datasets import load_boston

boston = load_boston()
X, y = boston.data, boston.target

lr = LinearRegression()
```



```
sfs = SFS(lr,
          k_features=13,
          forward=True,
          floating=False,
          scoring='neg_mean_squared_error',
          cv=10)

sfs = sfs.fit(X, y)
fig = plot_sfs(sfs.get_metric_dict(), kind='std_err')

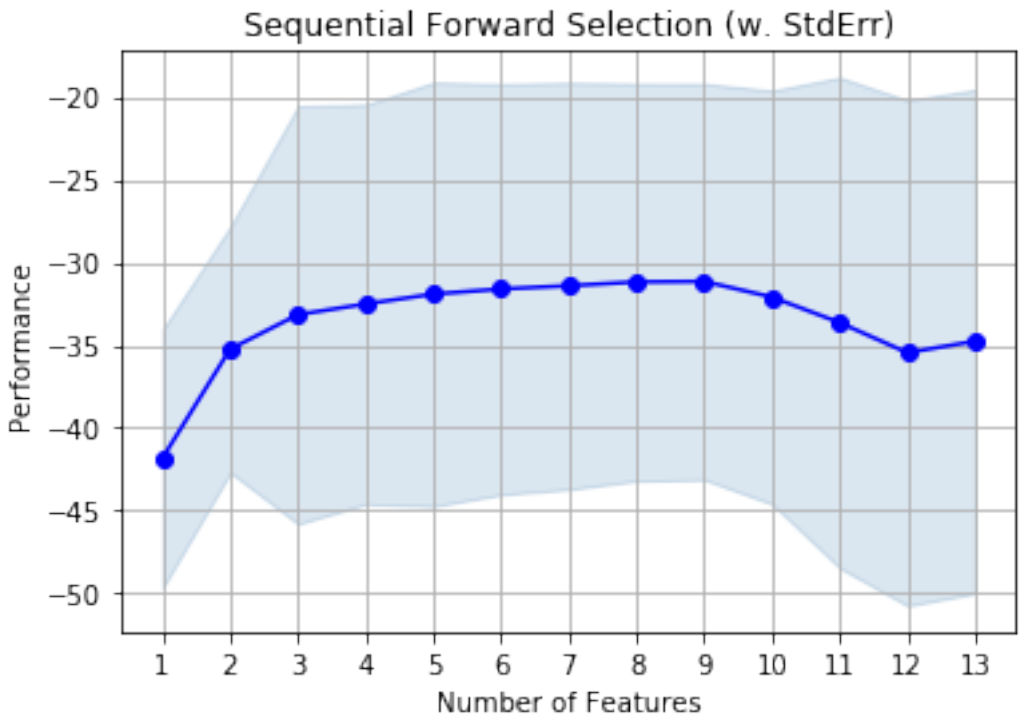
plt.title('Sequential Forward Selection (w. StdErr)')
plt.grid()
plt.show()
```

41.7 Example 6 – Using the Selected Feature Subset For Making New Predictions

```
# Initialize the dataset

from sklearn.neighbors import KNeighborsClassifier
from sklearn.datasets import load_iris
from sklearn.model_selection import train_test_split

iris = load_iris()
X, y = iris.data, iris.target
X_train, X_test, y_train, y_test = train_test_split(
```



```
        X, y, test_size=0.33, random_state=1)

knn = KNeighborsClassifier(n_neighbors=4)

# Select the "best" three features via
# 5-fold cross-validation on the training set.

from mlxtend.feature_selection import SequentialFeatureSelector as SFS

sfs1 = SFS(knn,
           k_features=3,
           forward=True,
           floating=False,
           scoring='accuracy',
           cv=5)
sfs1 = sfs1.fit(X_train, y_train)

print('Selected features:', sfs1.k_feature_idx_)

Selected features: (1, 2, 3)

# Generate the new subsets based on the selected features
# Note that the transform call is equivalent to
# X_train[:, sfs1.k_feature_idx_]

X_train_sfs = sfs1.transform(X_train)
```

```
X_test_sfs = sfs1.transform(X_test)

# Fit the estimator using the new feature subset
# and make a prediction on the test data
knn.fit(X_train_sfs, y_train)
y_pred = knn.predict(X_test_sfs)

# Compute the accuracy of the prediction
acc = float((y_test == y_pred).sum()) / y_pred.shape[0]
print('Test set accuracy: %.2f %%' % (acc * 100))
```

```
Test set accuracy: 96.00 %
```

41.8 Example 7 – Sequential Feature Selection and GridSearch

```
# Initialize the dataset

from sklearn.neighbors import KNeighborsClassifier
from sklearn.datasets import load_iris
from sklearn.model_selection import train_test_split

iris = load_iris()
X, y = iris.data, iris.target
X_train, X_test, y_train, y_test = train_test_split(
         X, y, test_size=0.33, random_state=1)
```

Use scikit-learn's `GridSearch` to tune the hyperparameters inside and outside the `SequentialFeatureSelector`:

```
from sklearn.model_selection import GridSearchCV
from sklearn.pipeline import Pipeline
from mlxtend.feature_selection import SequentialFeatureSelector as SFS
import mlxtend

knn = KNeighborsClassifier(n_neighbors=2)

sfs1 = SFS(estimator=knn,
           k_features=3,
           forward=True,
           floating=False,
           scoring='accuracy',
           cv=5)

pipe = Pipeline([('sfs', sfs1),
                 ('knn', knn)])

param_grid = [
  {'sfs__k_features': [1, 2, 3, 4],
   'sfs__estimator__n_neighbors': [1, 2, 3, 4]}
  ]

gs = GridSearchCV(estimator=pipe,
                  param_grid=param_grid,
```

```
                  scoring='accuracy',
                  n_jobs=1,
                  cv=5,
                  refit=False)

# run gridearch
gs = gs.fit(X_train, y_train)
```

... and the "best" parameters determined by GridSearch are ...

```
print("Best parameters via GridSearch", gs.best_params_)
```

```
Best parameters via GridSearch {'sfs__estimator__n_neighbors': 1, 'sfs__k_features': 3}
```

41.8.0.1 Obtaining the best k feature indices after GridSearch

If we are interested in the best k feature indices via `SequentialFeatureSelection.k_feature_idx_`, we have to initialize a `GridSearchCV` object with `refit=True`. Now, the grid search object will take the complete training dataset and the best parameters, which it found via cross-validation, to train the estimator pipeline.

```
gs = GridSearchCV(estimator=pipe,
                  param_grid=param_grid,
                  scoring='accuracy',
                  n_jobs=1,
                  cv=5,
                  refit=True)
gs = gs.fit(X_train, y_train)
```

After running the grid search, we can access the individual pipeline objects of the `best_estimator_` via the `steps` attribute.

```
gs.best_estimator_.steps
```

```
[('sfs', SequentialFeatureSelector(clone_estimator=True, cv=5,
                estimator=KNeighborsClassifier(algorithm='auto', leaf_size=30, metric='minkowski',
              metric_params=None, n_jobs=1, n_neighbors=1, p=2,
              weights='uniform'),
                floating=False, forward=True, k_features=3, n_jobs=1,
                pre_dispatch='2*n_jobs', scoring='accuracy', verbose=0)),
 ('knn',
  KNeighborsClassifier(algorithm='auto', leaf_size=30, metric='minkowski',
              metric_params=None, n_jobs=1, n_neighbors=2, p=2,
              weights='uniform'))]
```

Via sub-indexing, we can then obtain the best-selected feature subset:

```
print('Best features:', gs.best_estimator_.steps[0][1].k_feature_idx_)
```

```
Best features: (0, 1, 3)
```

During cross-validation, this feature combination had a CV accuracy of:

```
print('Best score:', gs.best_score_)
```

```
Best score: 0.94
```

```
gs.best_params_
```

```
{'sfs__estimator__n_neighbors': 1, 'sfs__k_features': 3}
```

Alternatively, if we can set the "best grid search parameters" in our pipeline manually if we ran `GridSearchCV` with `refit=False`. It should yield the same results:

```
pipe.set_params(**gs.best_params_).fit(X_train, y_train)
print('Best features:', pipe.steps[0][1].k_feature_idx_)
```

```
Best features: (0, 1, 3)
```

41.9 Example 8 – Selecting the "best" feature combination in a k-range

If `k_features` is set to to a tuple `(min_k, max_k)` (new in 0.4.2), the SFS will now select the best feature combination that it discovered by iterating from `k=1` to `max_k` (forward), or `max_k` to `min_k` (backward). The size of the returned feature subset is then within `max_k` to `min_k`, depending on which combination scored best during cross validation.

```
X.shape
```

```
(150, 4)
```

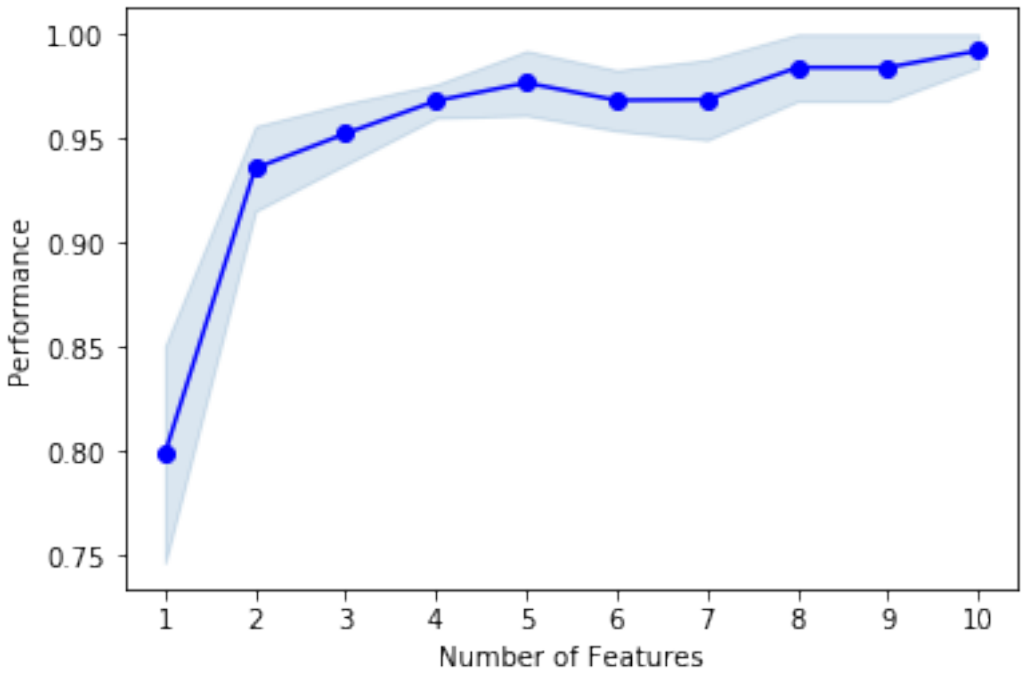
```
from mlxtend.feature_selection import SequentialFeatureSelector as SFS
from sklearn.neighbors import KNeighborsClassifier
from mlxtend.data import wine_data
from sklearn.model_selection import train_test_split
from sklearn.preprocessing import StandardScaler
from sklearn.pipeline import make_pipeline

X, y = wine_data()
X_train, X_test, y_train, y_test= train_test_split(X, y,
                                                   stratify=y,
                                                   test_size=0.3,
                                                   random_state=1)

knn = KNeighborsClassifier(n_neighbors=2)

sfs1 = SFS(estimator=knn,
           k_features=(3, 10),
           forward=True,
           floating=False,
           scoring='accuracy',
           cv=5)

pipe = make_pipeline(StandardScaler(), sfs1)
```



```
pipe.fit(X_train, y_train)

print('best combination (ACC: %.3f): %s\n' % (sfs1.k_score_, sfs1.k_feature_idx_))
print('all subsets:\n', sfs1.subsets_)
plot_sfs(sfs1.get_metric_dict(), kind='std_err');
```

```
best combination (ACC: 0.992): (0, 1, 2, 3, 6, 8, 9, 10, 11, 12)

all subsets:
 {1: {'feature_idx': (6,), 'cv_scores': array([ 0.84615385,  0.6       ,  0.88      ,  0.79166667,  0.8
```

42 API

*SequentialFeatureSelector(estimator, k_features=1, forward=True, floating=False, verbose=0, scoring=None, cv=5, n_jobs=1, pre_dispatch='2*n_jobs', clone_estimator=True)*

Sequential Feature Selection for Classification and Regression.

Parameters

- `estimator` : scikit-learn classifier or regressor
- `k_features` : int or tuple or str (default: 1)

  Number of features to select, where k_features < the full feature set. New in 0.4.2: A tuple containing a min and max value can be provided, and the SFS will consider return any feature combination between min and max that scored highest in cross-validtion. For example, the tuple (1, 4) will return any combination from 1 up to 4 features instead of a fixed number of features k. New in 0.8.0: A string

argument “best” or “parsimonious”. If “best” is provided, the feature selector will return the feature subset with the best cross-validation performance. If “parsimonious” is provided as an argument, the smallest feature subset that is within one standard error of the cross-validation performance will be selected.

- `forward` : bool (default: True)

  Forward selection if True, backward selection otherwise

- `floating` : bool (default: False)

  Adds a conditional exclusion/inclusion if True.

- `verbose` : int (default: 0), level of verbosity to use in logging.

  If 0, no output, if 1 number of features in current set, if 2 detailed logging i ncluding timestamp and cv scores at step.

- `scoring` : str, callable, or None (default: None)

  If None (default), uses ‘accuracy’ for sklearn classifiers and ‘r2’ for sklearn regressors. If str, uses a sklearn scoring metric string identifier, for example {accuracy, f1, precision, recall, roc_auc} for classifiers, {‘mean_absolute_error’, ‘mean_squared_error’/‘neg_mean_squared_error’, ‘median_absolute_error’, ‘r2’} for regressors. If a callable object or function is provided, it has to be conform with sklearn’s signature `scorer(estimator, X, y)`; see http://scikit-learn.org/stable/modules/generated/sklearn.metrics.make_scorer.html for more information.

- `cv` : int (default: 5)

  Scikit-learn cross-validation generator or `int`. If estimator is a classifier (or y consists of integer class labels), stratified k-fold is performed, and regular k-fold cross-validation otherwise. No cross-validation if cv is None, False, or 0.

- `n_jobs` : int (default: 1)

  The number of CPUs to use for evaluating different feature subsets in parallel. -1 means ‘all CPUs’.

- `pre_dispatch` : int, or string (default: ’2*n_jobs’)

  Controls the number of jobs that get dispatched during parallel execution if `n_jobs > 1` or `n_jobs=-1`. Reducing this number can be useful to avoid an explosion of memory consumption when more jobs get dispatched than CPUs can process. This parameter can be: None, in which case all the jobs are immediately created and spawned. Use this for lightweight and fast-running jobs, to avoid delays due to on-demand spawning of the jobs An int, giving the exact number of total jobs that are spawned A string, giving an expression as a function of n_jobs, as in `2*n_jobs`

- `clone_estimator` : bool (default: True)

  Clones estimator if True; works with the original estimator instance if False. Set to False if the estimator doesn’t implement scikit-learn’s set_params and get_params methods. In addition, it is required to set cv=0, and n_jobs=1.

Attributes

- `k_feature_idx_` : array-like, shape = [n_predictions]

  Feature Indices of the selected feature subsets.

- `k_score_` : float

  Cross validation average score of the selected subset.

- `subsets_` : dict

  A dictionary of selected feature subsets during the sequential selection, where the dictionary keys are the lengths k of these feature subsets. The dictionary values are dictionaries themselves with the following keys: 'feature_idx' (tuple of indices of the feature subset) 'cv_scores' (list individual cross-validation scores) 'avg_score' (average cross-validation score)

42.0.1 Methods

fit(X, y)

Perform feature selection and learn model from training data.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  Training vectors, where n_samples is the number of samples and n_features is the number of features.

- `y` : array-like, shape = [n_samples]

  Target values.

Returns

- `self` : object

fit_transform(X, y)

Fit to training data then reduce X to its most important features.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

Reduced feature subset of X, shape={n_samples, k_features}

get_metric_dict(confidence_interval=0.95)

Return metric dictionary

Parameters

- `confidence_interval` : float (default: 0.95)

  A positive float between 0.0 and 1.0 to compute the confidence interval bounds of the CV score averages.

Returns

Dictionary with items where each dictionary value is a list with the number of iterations (number of feature subsets) as its length. The dictionary keys corresponding to these lists are as follows: 'feature_idx': tuple of the indices of the feature subset 'cv_scores': list with individual CV scores 'avg_score': of CV average scores 'std_dev': standard deviation of the CV score average 'std_err': standard error of the CV score average 'ci_bound': confidence interval bound of the CV score average

get_params(deep=True)

Get parameters for this estimator.

Parameters

- `deep` : boolean, optional
  If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- `params` : mapping of string to any
  Parameter names mapped to their values.

*set_params(**params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

transform(X)

Reduce X to its most important features.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

Reduced feature subset of X, shape={n_samples, k_features}

43 file_io.find_filegroups

A function that finds files that belong together (i.e., differ only by file extension) in different directories and collects them in a Python dictionary for further processing tasks.

    from mlxtend.file_io import find_filegroups

43.1 Overview

This function finds files that are related to each other based on their file names. This can be useful for parsing collections files that have been stored in different subdirectories, for examples:

```
input_dir/
    task01.txt
    task02.txt
    ...
log_dir/
    task01.log
    task02.log
    ...
output_dir/
    task01.dat
    task02.dat
    ...
```

43.1.1 References

- –

43.2 Example 1 - Grouping related files in a dictionary

Given the following directory and file structure

```
dir_1/
    file_1.log
    file_2.log
    file_3.log
dir_2/
    file_1.csv
    file_2.csv
    file_3.csv
dir_3/
    file_1.txt
    file_2.txt
    file_3.txt
```

we can use `find_filegroups` to group related files as items of a dictionary as shown below:

```
from mlxtend.file_io import find_filegroups

find_filegroups(paths=['./data_find_filegroups/dir_1',
                       './data_find_filegroups/dir_2',
                       './data_find_filegroups/dir_3'],
                substring='file_')
```

```
{'file_1': ['./data_find_filegroups/dir_1/file_1.log',
  './data_find_filegroups/dir_2/file_1.csv',
  './data_find_filegroups/dir_3/file_1.txt'],
 'file_2': ['./data_find_filegroups/dir_1/file_2.log',
  './data_find_filegroups/dir_2/file_2.csv',
  './data_find_filegroups/dir_3/file_2.txt'],
 'file_3': ['./data_find_filegroups/dir_1/file_3.log',
  './data_find_filegroups/dir_2/file_3.csv',
  './data_find_filegroups/dir_3/file_3.txt']}
```

43.3 API

find_filegroups(paths, substring='', extensions=None, validity_check=True, ignore_invisible=True, rstrip='', ignore_substring=None)

Find and collect files from different directories in a python dictionary.

Parameters

- `paths` : `list`

  Paths of the directories to be searched. Dictionary keys are build from the first directory.

- `substring` : `str` (default: '')

  Substring that all files have to contain to be considered.

- `extensions` : `list` (default: None)

  `None` or `list` of allowed file extensions for each path. If provided, the number of extensions must match the number of `paths`.

- `validity_check` : `bool` (default: None)

  If `True`, checks if all dictionary values have the same number of file paths. Prints a warning and returns an empty dictionary if the validity check failed.

- `ignore_invisible` : `bool` (default: True)

  If `True`, ignores invisible files (i.e., files starting with a period).

- `rstrip` : `str` (default: '')

  If provided, strips characters from right side of the file base names after splitting the extension. Useful to trim different filenames to a common stem. E.g,. "abc_d.txt" and "abc_d_.csv" would share the stem "abc_d" if rstrip is set to "_".

- `ignore_substring` : `str` (default: None)

  Ignores files that contain the specified substring.

Returns

- `groups` : `dict`

  Dictionary of files paths. Keys are the file names found in the first directory listed in `paths` (without file extension).

44 file_io.find_files

A function that finds files in a given directory based on substring matches and returns a list of the file names found.

```
from mlxtend.file_io import find_files
```

44.1 Overview

This function finds files based on substring search. This is especially useful if we want to find specific files in a directory tree and return their absolute paths for further processing in Python.

44.1.1 References

- –

44.2 Example 1 - Grouping related files in a dictionary

Given the following directory and file structure

```
dir_1/
    file_1.log
    file_2.log
    file_3.log
dir_2/
    file_1.csv
    file_2.csv
    file_3.csv
dir_3/
    file_1.txt
    file_2.txt
    file_3.txt
```

we can use `find_files` to return the paths to all files that contain the substring `_2` as follows:

```
from mlxtend.file_io import find_files

find_files(substring='_2', path='./data_find_filegroups/', recursive=True)
```

```
['./data_find_filegroups/dir_1/file_2.log',
 './data_find_filegroups/dir_2/file_2.csv',
 './data_find_filegroups/dir_3/file_2.txt']
```

44.3 API

find_files(substring, path, recursive=False, check_ext=None, ignore_invisible=True, ignore_substring=None)

Find files in a directory based on substring matching.

Parameters

- `substring` : `str`
  Substring of the file to be matched.
- `path` : `str`
  Path where to look.
- `recursive` : `bool`
  If true, searches subdirectories recursively.
- `check_ext` : `str`
  If string (e.g., '.txt'), only returns files that match the specified file extension.
- `ignore_invisible` : `bool`
  If `True`, ignores invisible files (i.e., files starting with a period).
- `ignore_substring` : `str`
  Ignores files that contain the specified substring.

Returns

- `results` : `list`
  List of the matched files.

45 frequent_patterns.apriori

45.1 Frequent Itemsets via Apriori Algorithm

Apriori function to extract frequent itemsets for association rule mining

from mlxtend.frequent_patterns import apriori

45.2 Overview

Apriori is a popular algorithm [1] for extracting frequent itemsets with applications in association rule learning. The apriori algorithm has been designed to operate on databases containing transactions, such as purchases by customers of a store. A itemset is considered as "frequent" if it meets a user-specified support threshold. For instance, if the support threshold is set to 0.5 (50%), a frequent itemset is defined as a set of items that occur togehter in at least 50% of all transactions in the database.

[1] Agrawal, Rakesh, and Ramakrishnan Srikant. "Fast algorithms for mining association rules." Proc. 20th int. conf. very large data bases, VLDB. Vol. 1215. 1994.

45.4 Example 1

The `apriori` function expects data in a one-hot encoded pandas DataFrame. Suppose we have the following transaction data:

```
dataset = [['Milk', 'Onion', 'Nutmeg', 'Kidney Beans', 'Eggs', 'Yogurt'],
           ['Dill', 'Onion', 'Nutmeg', 'Kidney Beans', 'Eggs', 'Yogurt'],
           ['Milk', 'Apple', 'Kidney Beans', 'Eggs'],
           ['Milk', 'Unicorn', 'Corn', 'Kidney Beans', 'Yogurt'],
           ['Corn', 'Onion', 'Onion', 'Kidney Beans', 'Ice cream', 'Eggs']]
```

We can transform it into the right format via the `OnehotTransactions` encoder as follows:

```
import pandas as pd
from mlxtend.preprocessing import OnehotTransactions

oht = OnehotTransactions()
oht_ary = oht.fit(dataset).transform(dataset)
df = pd.DataFrame(oht_ary, columns=oht.columns_)
df
```

```
<tr style="text-align: right;">
  <th></th>
  <th>Apple</th>
  <th>Corn</th>
  <th>Dill</th>
  <th>Eggs</th>
  <th>Ice cream</th>
  <th>Kidney Beans</th>
  <th>Milk</th>
  <th>Nutmeg</th>
  <th>Onion</th>
  <th>Unicorn</th>
  <th>Yogurt</th>
</tr>

<tr>
  <th>0</th>
  <td>0</td>
  <td>0</td>
  <td>0</td>
  <td>1</td>
  <td>0</td>
  <td>1</td>
  <td>1</td>
  <td>1</td>
  <td>1</td>
  <td>0</td>
  <td>1</td>
</tr>
<tr>
  <th>1</th>
  <td>0</td>
  <td>0</td>
  <td>1</td>
  <td>1</td>
  <td>0</td>
  <td>1</td>
  <td>0</td>
  <td>1</td>
  <td>1</td>
  <td>0</td>
  <td>1</td>
</tr>
<tr>
  <th>2</th>
  <td>1</td>
  <td>0</td>
  <td>0</td>
  <td>1</td>
  <td>0</td>
  <td>1</td>
  <td>1</td>
  <td>0</td>
  <td>0</td>
```

```
  <td>0</td>
  <td>0</td>
</tr>
<tr>
  <th>3</th>
  <td>0</td>
  <td>1</td>
  <td>0</td>
  <td>0</td>
  <td>0</td>
  <td>1</td>
  <td>1</td>
  <td>0</td>
  <td>0</td>
  <td>1</td>
  <td>1</td>
</tr>
<tr>
  <th>4</th>
  <td>0</td>
  <td>1</td>
  <td>0</td>
  <td>1</td>
  <td>1</td>
  <td>1</td>
  <td>0</td>
  <td>0</td>
  <td>1</td>
  <td>0</td>
  <td>0</td>
</tr>
```

Now, let us return the items and itemsets with at least 60% support:

```
from mlxtend.frequent_patterns import apriori

apriori(df, min_support=0.6)
```

```
<tr style="text-align: right;">
  <th></th>
  <th>support</th>
  <th>itemsets</th>
</tr>

<tr>
  <th>0</th>
  <td>0.8</td>
  <td>[3]</td>
</tr>
<tr>
  <th>1</th>
  <td>1.0</td>
  <td>[5]</td>
```

```
</tr>
<tr>
  <th>2</th>
  <td>0.6</td>
  <td>[6]</td>
</tr>
<tr>
  <th>3</th>
  <td>0.6</td>
  <td>[8]</td>
</tr>
<tr>
  <th>4</th>
  <td>0.6</td>
  <td>[10]</td>
</tr>
<tr>
  <th>5</th>
  <td>0.8</td>
  <td>[3, 5]</td>
</tr>
<tr>
  <th>6</th>
  <td>0.6</td>
  <td>[3, 8]</td>
</tr>
<tr>
  <th>7</th>
  <td>0.6</td>
  <td>[5, 6]</td>
</tr>
<tr>
  <th>8</th>
  <td>0.6</td>
  <td>[5, 8]</td>
</tr>
<tr>
  <th>9</th>
  <td>0.6</td>
  <td>[5, 10]</td>
</tr>
<tr>
  <th>10</th>
  <td>0.6</td>
  <td>[3, 5, 8]</td>
</tr>
```

By default, `apriori` returns the column indices of the items, which may be useful in downstream operations such as association rule mining. For better readability, we can set `use_colnames=True` to convert these integer values into the respective item names:

```
apriori(df, min_support=0.6, use_colnames=True)
```

```
<tr style="text-align: right;">
```

```
  <th></th>
  <th>support</th>
  <th>itemsets</th>
</tr>

<tr>
  <th>0</th>
  <td>0.8</td>
  <td>[Eggs]</td>
</tr>
<tr>
  <th>1</th>
  <td>1.0</td>
  <td>[Kidney Beans]</td>
</tr>
<tr>
  <th>2</th>
  <td>0.6</td>
  <td>[Milk]</td>
</tr>
<tr>
  <th>3</th>
  <td>0.6</td>
  <td>[Onion]</td>
</tr>
<tr>
  <th>4</th>
  <td>0.6</td>
  <td>[Yogurt]</td>
</tr>
<tr>
  <th>5</th>
  <td>0.8</td>
  <td>[Eggs, Kidney Beans]</td>
</tr>
<tr>
  <th>6</th>
  <td>0.6</td>
  <td>[Eggs, Onion]</td>
</tr>
<tr>
  <th>7</th>
  <td>0.6</td>
  <td>[Kidney Beans, Milk]</td>
</tr>
<tr>
  <th>8</th>
  <td>0.6</td>
  <td>[Kidney Beans, Onion]</td>
</tr>
<tr>
  <th>9</th>
  <td>0.6</td>
  <td>[Kidney Beans, Yogurt]</td>
```

```
</tr>
<tr>
  <th>10</th>
  <td>0.6</td>
  <td>[Eggs, Kidney Beans, Onion]</td>
</tr>
```

45.5 Example 2

The advantage of working with pandas `DataFrames` is that we can use its convenient features to filter the results. For instance, let's assume we are only interested in itemsets of length 2 that have a support of at least 80 percent. First, we create the frequent itemsets via `apriori` and add a new column that stores the length of each itemset:

```
frequent_itemsets = apriori(df, min_support=0.6, use_colnames=True)
frequent_itemsets['length'] = frequent_itemsets['itemsets'].apply(lambda x: len(x))
frequent_itemsets
```

```
<tr style="text-align: right;">
  <th></th>
  <th>support</th>
  <th>itemsets</th>
  <th>length</th>
</tr>

<tr>
  <th>0</th>
  <td>0.8</td>
  <td>[Eggs]</td>
  <td>1</td>
</tr>
<tr>
  <th>1</th>
  <td>1.0</td>
  <td>[Kidney Beans]</td>
  <td>1</td>
</tr>
<tr>
  <th>2</th>
  <td>0.6</td>
  <td>[Milk]</td>
  <td>1</td>
</tr>
<tr>
  <th>3</th>
  <td>0.6</td>
  <td>[Onion]</td>
  <td>1</td>
</tr>
<tr>
  <th>4</th>
  <td>0.6</td>
```

```
  <td>[Yogurt]</td>
  <td>1</td>
</tr>
<tr>
  <th>5</th>
  <td>0.8</td>
  <td>[Eggs, Kidney Beans]</td>
  <td>2</td>
</tr>
<tr>
  <th>6</th>
  <td>0.6</td>
  <td>[Eggs, Onion]</td>
  <td>2</td>
</tr>
<tr>
  <th>7</th>
  <td>0.6</td>
  <td>[Kidney Beans, Milk]</td>
  <td>2</td>
</tr>
<tr>
  <th>8</th>
  <td>0.6</td>
  <td>[Kidney Beans, Onion]</td>
  <td>2</td>
</tr>
<tr>
  <th>9</th>
  <td>0.6</td>
  <td>[Kidney Beans, Yogurt]</td>
  <td>2</td>
</tr>
<tr>
  <th>10</th>
  <td>0.6</td>
  <td>[Eggs, Kidney Beans, Onion]</td>
  <td>3</td>
</tr>
```

Then, we can select the results that satisfy our desired criteria as follows:

```
frequent_itemsets[ (frequent_itemsets['length'] == 2) &
                   (frequent_itemsets['support'] >= 0.8) ]
```

```
<tr style="text-align: right;">
  <th></th>
  <th>support</th>
  <th>itemsets</th>
  <th>length</th>
</tr>

<tr>
```

```
  <th>5</th>
  <td>0.8</td>
  <td>[Eggs, Kidney Beans]</td>
  <td>2</td>
</tr>
```

45.6 API

apriori(df, min_support=0.5, use_colnames=False)

Get frequent itemsets from a one-hot DataFrame **Parameters**

- `df` : pandas DataFrame

  pandas DataFrame in one-hot encoded format. For example Apple Bananas Beer Chicken Milk Rice 0 1 0 1 1 0 1 1 1 0 1 0 0 1 2 1 0 1 0 0 0 3 1 1 0 0 0 0 4 0 0 1 1 1 1 5 0 0 1 0 1 1 6 0 0 1 0 1 0 7 1 1 0 0 0 0

- `min_support` : float (default: 0.5)

  A float between 0 and 1 for minumum support of the itemsets returned. The support is computed as the fraction transactions_where_item(s)_occur / total_transactions.

- `use_colnames` : bool (default: False)

  If true, uses the DataFrames' column names in the returned DataFrame instead of column indices. **Returns**

pandas DataFrame with columns ['support', 'itemsets'] of all itemsets that are >= min_support.

46 frequent_patterns.association_rules

46.1 Association Rules Generation from Frequent Itemsets

Function to generate association rules from frequent itemsets

```
from mlxtend.frequent_patterns import association_rules
```

46.2 Overview

Rule generation is a common task in the mining of frequent patterns. *An association rule is an implication expression of the form $X \rightarrow Y$, where X and Y are disjoint itemsets* [1]. A more concrete example based on consumer behaviour would be $\{Diapers\} \rightarrow \{Beer\}$ suggesting that people who buy diapers are also likely to buy beer. To evaluate the "interest" of such an association rule, different metrics have been developed. The current implementation make use of the `confidence` and `lift` metrics.

46.2.1 Metrics

The currently supported metrics for evaluating association rules and setting selection thresholds are listed below. Given a rule "A -> C", A stands for antecedant and C stands for consequent.

46.2.1.1 'support':

$$\text{support}(A \to C) = \text{support}(A \cup C), \quad \text{range: } [0, 1]$$

- introduced in [3]

The support metric is defined for itemsets, not assocication rules, and computes the proportion of transactions that contain the antecedant A. Typically, support is used to measure the abundance or frequency (often interpreted as significance or importance) of an itemset in a database. We refer to an itemset as a "frequent itemset" if you support is larger than a specified minimum-support threshold. Note that due to the *downward closure* proporty, all subsets of a frequent itemset are also frequent.

46.2.1.2 'confidence':

$$\text{confidence}(A \to C) = \frac{\text{support}(A \to C)}{\text{support}(A)}, \quad \text{range: } [0, 1]$$

- introduced in [3]

The confidence of a rule A->C is the probability of seeing the consequent in a transaction given that it also contains the antecedent. Note that the metric is not symmetric or directed; for instance, the confidence for A->C is different than the confidence for C->A. The confidence is 1 (maximal) for a rule A->C if the consequent and antecedent always occur together.

46.2.1.3 'lift':

$$\text{lift}(A \to C) = \frac{\text{confidence}(A \to C)}{\text{support}(C)}, \quad \text{range: } [0, \infty]$$

- introduced in [4]

The lift metric is commonly used to measure how much more often the antecedent and consequent of a rule A->C occur together than we would expect if they were statistically independent. If A and C are independent, the Lift score will be exactly 1.

46.2.1.4 'leverage':

$$\text{levarage}(A \to C) = \text{support}(A \to C) - \text{support}(A) \times \text{support}(C), \quad \text{range: } [-1, 1]$$

- introduced in [5]

Leverage computes the difference between the observed frequency of A and C appearing together and the frequency that would be expected if A and C were independent. An leverage value of 0 indicates independence.

46.2.1.5 'conviction':

$$\text{conviction}(A \rightarrow C) = \frac{1 - \text{support}(C)}{1 - \text{confidence}(A \rightarrow C)}, \quad \text{range: } [0, \infty]$$

- introduced in [6]

A high conviction value means that the consequent is highly depending on the antecedent. For instance, in the case of a perfect confidence score, the denominator becomes 0 (due to 1 - 1) for which the conviction score is defined as 'inf'. Similar to lift, if items are independent, the conviction is 1.

46.4 Example 1

The `generate_rules` takes dataframes of frequent itemsets as produced by the `apriori` function in *mlxtend.association*. To demonstrate the usage of the `generate_rules` method, we first create a pandas `DataFrame` of frequent itemsets as generated by the `apriori` function:

```
import pandas as pd
from mlxtend.preprocessing import OnehotTransactions
from mlxtend.frequent_patterns import apriori

dataset = [['Milk', 'Onion', 'Nutmeg', 'Kidney Beans', 'Eggs', 'Yogurt'],
           ['Dill', 'Onion', 'Nutmeg', 'Kidney Beans', 'Eggs', 'Yogurt'],
           ['Milk', 'Apple', 'Kidney Beans', 'Eggs'],
           ['Milk', 'Unicorn', 'Corn', 'Kidney Beans', 'Yogurt'],
           ['Corn', 'Onion', 'Onion', 'Kidney Beans', 'Ice cream', 'Eggs']]

oht = OnehotTransactions()
oht_ary = oht.fit(dataset).transform(dataset)
df = pd.DataFrame(oht_ary, columns=oht.columns_)
frequent_itemsets = apriori(df, min_support=0.6, use_colnames=True)

frequent_itemsets
```

```
<tr style="text-align: right;">
  <th></th>
  <th>support</th>
  <th>itemsets</th>
</tr>

<tr>
  <th>0</th>
  <td>0.8</td>
  <td>[Eggs]</td>
</tr>
<tr>
  <th>1</th>
  <td>1.0</td>
  <td>[Kidney Beans]</td>
</tr>
<tr>
  <th>2</th>
  <td>0.6</td>
  <td>[Milk]</td>
</tr>
<tr>
  <th>3</th>
  <td>0.6</td>
  <td>[Onion]</td>
</tr>
<tr>
  <th>4</th>
  <td>0.6</td>
  <td>[Yogurt]</td>
</tr>
<tr>
  <th>5</th>
  <td>0.8</td>
  <td>[Eggs, Kidney Beans]</td>
</tr>
<tr>
  <th>6</th>
  <td>0.6</td>
  <td>[Eggs, Onion]</td>
</tr>
<tr>
  <th>7</th>
  <td>0.6</td>
  <td>[Kidney Beans, Milk]</td>
</tr>
<tr>
  <th>8</th>
  <td>0.6</td>
  <td>[Kidney Beans, Onion]</td>
</tr>
<tr>
  <th>9</th>
  <td>0.6</td>
```

```
  <td>[Kidney Beans, Yogurt]</td>
</tr>
<tr>
  <th>10</th>
  <td>0.6</td>
  <td>[Eggs, Kidney Beans, Onion]</td>
</tr>
```

The `generate_rules()` function allows you to (1) specify your metric of interest and (2) the according threshold. Currently implemented measures are **confidence** and **lift**. Let's say you are interesting in rules derived from the frequent itemsets only if the level of confidence is above the 90 percent threshold (`min_threshold=0.7`):

```
from mlxtend.frequent_patterns import association_rules

association_rules(frequent_itemsets, metric="confidence", min_threshold=0.7)
```

```
<tr style="text-align: right;">
  <th></th>
  <th>antecedants</th>
  <th>consequents</th>
  <th>antecedent support</th>
  <th>consequent support</th>
  <th>support</th>
  <th>confidence</th>
  <th>lift</th>
  <th>leverage</th>
  <th>conviction</th>
</tr>

<tr>
  <th>0</th>
  <td>(Eggs)</td>
  <td>(Kidney Beans)</td>
  <td>0.8</td>
  <td>1.0</td>
  <td>0.8</td>
  <td>1.00</td>
  <td>1.00</td>
  <td>0.00</td>
  <td>inf</td>
</tr>
<tr>
  <th>1</th>
  <td>(Kidney Beans)</td>
  <td>(Eggs)</td>
  <td>1.0</td>
  <td>0.8</td>
  <td>0.8</td>
  <td>0.80</td>
  <td>1.00</td>
  <td>0.00</td>
  <td>1.000000</td>
```

```
</tr>
<tr>
  <th>2</th>
  <td>(Eggs)</td>
  <td>(Onion)</td>
  <td>0.8</td>
  <td>0.6</td>
  <td>0.6</td>
  <td>0.75</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>1.600000</td>
</tr>
<tr>
  <th>3</th>
  <td>(Onion)</td>
  <td>(Eggs)</td>
  <td>0.6</td>
  <td>0.8</td>
  <td>0.6</td>
  <td>1.00</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>inf</td>
</tr>
<tr>
  <th>4</th>
  <td>(Milk)</td>
  <td>(Kidney Beans)</td>
  <td>0.6</td>
  <td>1.0</td>
  <td>0.6</td>
  <td>1.00</td>
  <td>1.00</td>
  <td>0.00</td>
  <td>inf</td>
</tr>
<tr>

<tr>
  <th>7</th>
  <td>(Eggs, Onion)</td>
  <td>(Kidney Beans)</td>
  <td>0.6</td>
  <td>1.0</td>
  <td>0.6</td>
  <td>1.00</td>
  <td>1.00</td>
  <td>0.00</td>
  <td>inf</td>
</tr>
<tr>
  <th>8</th>
  <td>(Eggs, Kidney Beans)</td>
  <td>(Onion)</td>
  <td>0.8</td>
  <td>0.6</td>
  <td>0.6</td>
  <td>0.75</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>1.600000</td>
</tr>
<tr>
  <th>9</th>
  <td>(Kidney Beans, Onion)</td>
  <td>(Eggs)</td>
  <td>0.6</td>
  <td>0.8</td>
  <td>0.6</td>
  <td>1.00</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>inf</td>
</tr>
<tr>
  <th>10</th>
  <td>(Eggs)</td>
  <td>(Kidney Beans, Onion)</td>
  <td>0.8</td>
  <td>0.6</td>
  <td>0.6</td>
  <td>0.75</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>1.600000</td>
```

```
</tr>
<tr>
  <th>11</th>
  <td>(Onion)</td>
  <td>(Eggs, Kidney Beans)</td>
  <td>0.6</td>
  <td>0.8</td>
  <td>0.6</td>
  <td>1.00</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>inf</td>
</tr>
```

46.5 Example 2

If you are interested in rules fulfilling a different interest metric, you can simply adjust the parameters. E.g. if you are interested only in rules that have a lift score of >= 1.2, you would do the following:

```
rules = association_rules(frequent_itemsets, metric="lift", min_threshold=1.2)
rules
```

```
<tr style="text-align: right;">
  <th></th>
  <th>antecedants</th>
  <th>consequents</th>
  <th>antecedent support</th>
  <th>consequent support</th>
  <th>support</th>
  <th>confidence</th>
  <th>lift</th>
  <th>leverage</th>
  <th>conviction</th>
</tr>
```

```
<tr>
  <th>0</th>
  <td>(Eggs)</td>
  <td>(Onion)</td>
  <td>0.8</td>
  <td>0.6</td>
  <td>0.6</td>
  <td>0.75</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>1.600000</td>
</tr>
<tr>
  <th>1</th>
  <td>(Onion)</td>
  <td>(Eggs)</td>
  <td>0.6</td>
```

```
  <td>0.8</td>
  <td>0.6</td>
  <td>1.00</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>inf</td>
</tr>
<tr>
  <th>2</th>
  <td>(Eggs, Kidney Beans)</td>
  <td>(Onion)</td>
  <td>0.8</td>
  <td>0.6</td>
  <td>0.6</td>
  <td>0.75</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>1.600000</td>
</tr>
<tr>
  <th>3</th>
  <td>(Kidney Beans, Onion)</td>
  <td>(Eggs)</td>
  <td>0.6</td>
  <td>0.8</td>
  <td>0.6</td>
  <td>1.00</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>inf</td>
</tr>
<tr>
  <th>4</th>
  <td>(Eggs)</td>
  <td>(Kidney Beans, Onion)</td>
  <td>0.8</td>
  <td>0.6</td>
  <td>0.6</td>
  <td>0.75</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>1.600000</td>
</tr>
<tr>
  <th>5</th>
  <td>(Onion)</td>
  <td>(Eggs, Kidney Beans)</td>
  <td>0.6</td>
  <td>0.8</td>
  <td>0.6</td>
  <td>1.00</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>inf</td>
```

```
</tr>
```

Pandas `DataFrames` make it easy to filter the results further. Let's say we are ony interested in rules that satisfy the following criteria:

1. at least 2 antecedants
2. a confidence > 0.75
3. a lift score > 1.2

We could compute the antecedent length as follows:

```
rules["antecedant_len"] = rules["antecedants"].apply(lambda x: len(x))
rules
```

```
<tr style="text-align: right;">
  <th></th>
  <th>antecedants</th>
  <th>consequents</th>
  <th>antecedent support</th>
  <th>consequent support</th>
  <th>support</th>
  <th>confidence</th>
  <th>lift</th>
  <th>leverage</th>
  <th>conviction</th>
  <th>antecedant_len</th>
</tr>

<tr>
  <th>0</th>
  <td>(Eggs)</td>
  <td>(Onion)</td>
  <td>0.8</td>
  <td>0.6</td>
  <td>0.6</td>
  <td>0.75</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>1.600000</td>
  <td>1</td>
</tr>
<tr>
  <th>1</th>
  <td>(Onion)</td>
  <td>(Eggs)</td>
  <td>0.6</td>
  <td>0.8</td>
  <td>0.6</td>
  <td>1.00</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>inf</td>
```

```
  <td>1</td>
</tr>
<tr>
  <th>2</th>
  <td>(Eggs, Kidney Beans)</td>
  <td>(Onion)</td>
  <td>0.8</td>
  <td>0.6</td>
  <td>0.6</td>
  <td>0.75</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>1.600000</td>
  <td>2</td>
</tr>
<tr>
  <th>3</th>
  <td>(Kidney Beans, Onion)</td>
  <td>(Eggs)</td>
  <td>0.6</td>
  <td>0.8</td>
  <td>0.6</td>
  <td>1.00</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>inf</td>
  <td>2</td>
</tr>
<tr>
  <th>4</th>
  <td>(Eggs)</td>
  <td>(Kidney Beans, Onion)</td>
  <td>0.8</td>
  <td>0.6</td>
  <td>0.6</td>
  <td>0.75</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>1.600000</td>
  <td>1</td>
</tr>
<tr>
  <th>5</th>
  <td>(Onion)</td>
  <td>(Eggs, Kidney Beans)</td>
  <td>0.6</td>
  <td>0.8</td>
  <td>0.6</td>
  <td>1.00</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>inf</td>
  <td>1</td>
</tr>
```

Then, we can use pandas' selection syntax as shown below:

```
rules[ (rules['antecedant_len'] >= 2) &
       (rules['confidence'] > 0.75) &
       (rules['lift'] > 1.2) ]
```

```
<tr style="text-align: right;">
  <th></th>
  <th>antecedants</th>
  <th>consequents</th>
  <th>antecedent support</th>
  <th>consequent support</th>
  <th>support</th>
  <th>confidence</th>
  <th>lift</th>
  <th>leverage</th>
  <th>conviction</th>
  <th>antecedant_len</th>
</tr>
```

```
<tr>
  <th>3</th>
  <td>(Kidney Beans, Onion)</td>
  <td>(Eggs)</td>
  <td>0.6</td>
  <td>0.8</td>
  <td>0.6</td>
  <td>1.0</td>
  <td>1.25</td>
  <td>0.12</td>
  <td>inf</td>
  <td>2</td>
</tr>
```

46.6 API

association_rules(df, metric='confidence', min_threshold=0.8)

Generates a DataFrame of association rules including the metrics 'score', 'confidence', and 'lift'

Parameters

- `df` : pandas DataFrame

  pandas DataFrame of frequent itemsets with columns ['support', 'itemsets']

- `metric` : string (default: 'confidence')

  Metric to evaluate if a rule is of interest. Supported metrics are 'support', 'confidence', 'lift', 'leverage', and 'conviction' These metrics are computed as follows:

  - support(A->C) = support(A+C) [aka 'support'], range: [0, 1]
  - confidence(A->C) = support(A+C) / support(A), range: [0, 1]
  - lift(A->C) = confidence(A->C) / support(C), range: [0, inf]
  - leverage(A->C) = support(A->C) - support(A)*support(C), range: [-1, 1]

  - conviction = [1 - support(C)] / [1 - confidence(A->C)], range: [0, inf]

- `min_threshold` : float (default: 0.8)

  Minimal threshold for the evaluation metric to decide whether a candidate rule is of interest.

Returns

pandas DataFrame with columns "antecedent support", "consequent support", "support", "confidence", "lift", "leverage", "conviction" of all rules for which metric(rule) >= min_threshold.

47 general_concepts.activation-functions

48 general_concepts.gradient-optimization

48.0.1 Gradient Descent (GD) Optimization

Using the Gradient Decent optimization algorithm, the weights are updated incrementally after each epoch (= pass over the training dataset).

Compatible cost functions $J(\cdot)$

- Sum of squared errors (SSE) [mlxtend.regressor.LinearRegression, mlxtend.classfier.Adaline]:

$$J(\mathbf{w}) = \frac{1}{2}\sum_i (\text{target}^{(i)} - \text{output}^{(i)})^2$$

- Logistic Cost (cross-entropy) [mlxtend.classfier.LogisticRegression]: ...

The magnitude and direction of the weight update is computed by taking a step in the opposite direction of the cost gradient

$$\Delta w_j = -\eta \frac{\partial J}{\partial w_j},$$

where η is the learning rate. The weights are then updated after each epoch via the following update rule:

$$\mathbf{w} := \mathbf{w} + \Delta \mathbf{w},$$

where $\Delta \mathbf{w}$ is a vector that contains the weight updates of each weight coefficient w, which are computed as follows:

$$\Delta w_j = -\eta \frac{\partial J}{\partial w_j} = -\eta \sum_i (\text{target}^{(i)} - \text{output}^{(i)})(-x_j^{(i)}) = \eta \sum_i (\text{target}^{(i)} - \text{output}^{(i)}) x_j^{(i)}.$$

Essentially, we can picture Gradient Descent optimization as a hiker (the weight coefficient) who wants to climb down a mountain (cost function) into valley (cost minimum), and each step is determined by the steepness of the slope (gradient) and the leg length of the hiker (learning rate). Considering a cost function with only a single weight coefficient, we can illustrate this concept as follows:

Activation function	Equation	Example	1D Graph
Unit step (Heaviside)	$\phi(z) = \begin{cases} 0, & z < 0, \\ 0.5, & z = 0, \\ 1, & z > 0, \end{cases}$	Perceptron variant	Sign (Signum)	$\phi(z) = \begin{cases} -1, & z < 0, \\ 0, & z = 0, \\ 1, & z > 0, \end{cases}$	Perceptron variant	Linear	$\phi(z) = z$	Adaline, linear regression	Piece-wise linear	$\phi(z) = \begin{cases} 1, & z \geq \frac{1}{2}, \\ z + \frac{1}{2}, & -\frac{1}{2} < z < \frac{1}{2}, \\ 0, & z \leq -\frac{1}{2}, \end{cases}$	Support vector machine	Logistic (sigmoid)	$\phi(z) = \frac{1}{1 + e^{-z}}$	Logistic regression, Multi-layer NN	Hyperbolic tangent	$\phi(z) = \frac{e^{z} - e^{-z}}{e^{z} + e^{-z}}$	Multi-layer Neural Networks	Rectifier, ReLU (Rectified Linear Unit)	$\phi(z) = max(0, z)$	Multi-layer Neural Networks	Rectifier, softplus	$\phi(z) = \ln(1 + e^{z})$	Multi-layer Neural Networks	

48.0.2 Stochastic Gradient Descent (SGD)

In Gradient Descent optimization, we compute the cost gradient based on the complete training set; hence, we sometimes also call it *batch gradient descent*. In case of very large datasets, using Gradient Descent can be quite costly since we are only taking a single step for one pass over the training set – thus, the larger the training set, the slower our algorithm updates the weights and the longer it may take until it converges to the global cost minimum (note that the SSE cost function is convex).

In Stochastic Gradient Descent (sometimes also referred to as *iterative* or *on-line* gradient descent), we **don't** accumulate the weight updates as we've seen above for Gradient Descent:

- for one or more epochs:
  - for each weight j
    - $w_j := w + \Delta w_j$, where: $\Delta w_j = \eta \sum_i (\text{target}^{(i)} - \text{output}^{(i)}) x_j^{(i)}$

Instead, we update the weights after each training sample:

- for one or more epochs, or until approx. cost minimum is reached:
  - for training sample i:
    - for each weight j
      - $w_j := w + \Delta w_j$, where: $\Delta w_j = \eta (\text{target}^{(i)} - \text{output}^{(i)}) x_j^{(i)}$

Here, the term "stochastic" comes from the fact that the gradient based on a single training sample is a "stochastic approximation" of the "true" cost gradient. Due to its stochastic nature, the path towards the global cost minimum is not "direct" as in Gradient Descent, but may go "zig-zag" if we are visuallizing the cost surface in a 2D space. However, it has been shown that Stochastic Gradient Descent almost surely converges to the global cost minimum if the cost function is convex (or pseudo-convex)[1].

48.0.2.1 Stochastic Gradient Descent Shuffling

There are several different flavors of stochastic gradient descent, which can be all seen throughout the literature. Let's take a look at the three most common variants:

48.0.2.2 A)

- randomly shuffle samples in the training set
  - for one or more epochs, or until approx. cost minimum is reached
    - for training sample i
      - compute gradients and perform weight updates

48.0.2.3 B)

- for one or more epochs, or until approx. cost minimum is reached
  - randomly shuffle samples in the training set
    - for training sample i
      - compute gradients and perform weight updates

48.0.2.4 C)

- for iterations t, or until approx. cost minimum is reached:
  - draw random sample from the training set
    - compute gradients and perform weight updates

In scenario A [3], we shuffle the training set only one time in the beginning; whereas in scenario B, we shuffle the training set after each epoch to prevent repeating update cycles. In both scenario A and scenario B, each training sample is only used once per epoch to update the model weights.

In scenario C, we draw the training samples randomly with replacement from the training set [2]. If the number of iterations t is equal to the number of training samples, we learn the model based on a *bootstrap sample* of the training set.

48.0.3 Mini-Batch Gradient Descent (MB-GD)

Mini-Batch Gradient Descent (MB-GD) a compromise between batch GD and SGD. In MB-GD, we update the model based on smaller groups of training samples; instead of computing the gradient from 1 sample (SGD) or all n training samples (GD), we compute the gradient from $1 < k < n$ training samples (a common mini-batch size is $k = 50$).

MB-GD converges in fewer iterations than GD because we update the weights more frequently; however, MB-GD let's us utilize vectorized operation, which typically results in a computational performance gain over SGD.

48.0.4 Learning Rates

- An adaptive learning rate η: Choosing a decrease constant d that shrinks the learning rate over time: $\eta(t+1) := \eta(t)/(1 + t \times d)$
- Momentum learning by adding a factor of the previous gradient to the weight update for faster updates: $\Delta \mathbf{w}_{t+1} := \eta \nabla J(\mathbf{w}_{t+1}) + \alpha \Delta w_t$

49 general_concepts.linear-gradient-derivative

Linear Regression and Adaptive Linear Neurons (Adalines) are closely related to each other. In fact, the Adaline algorithm is a identical to linear regression except for a threshold function $\phi(\cdot)_T$ that converts the continuous output into a categorical class label

$$\phi(z)_T = \begin{cases} 1 & if\ z \geq 0 \\ 0 & if\ z < 0 \end{cases},$$

where z is the net input, which is computed as the sum of the input features $\mathbf{x}$ multiplied by the model weights $\mathbf{w}$:

$$z = w_0 x_0 + w_1 x_1 \dots w_m x_m = \sum_{j=0}^{m} x_j w_j = \mathbf{w}^T \mathbf{x}$$

(Note that x_0 refers to the bias unit so that $x_0 = 1$.)

In the case of linear regression and Adaline, the activation function $\phi(\cdot)_A$ is simply the identity function so that $\phi(z)_A = z$.

Now, in order to learn the optimal model weights $\mathbf{w}$, we need to define a cost function that we can optimize. Here, our cost function $J(\cdot)$ is the sum of squared errors (SSE), which we multiply by $\frac{1}{2}$ to make the derivation easier:

$$J(\mathbf{w}) = \frac{1}{2} \sum_i \left(y^{(i)} - \phi(z)_A^{(i)}\right)^2,$$

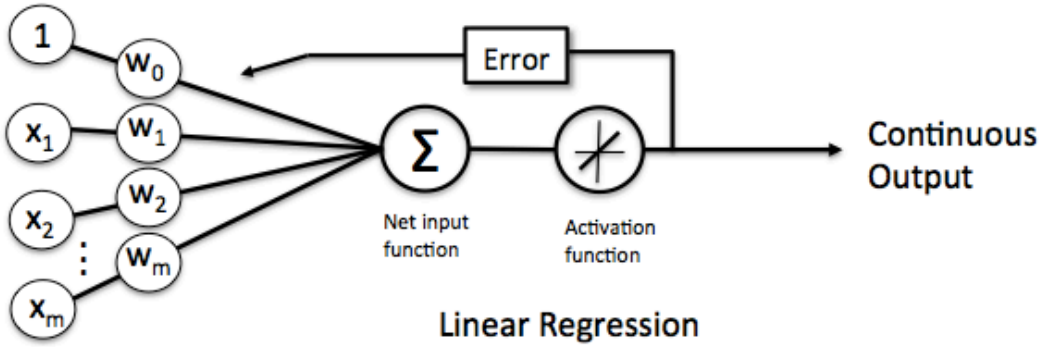
where $y^{(i)}$ is the label or target label of the ith training point $x^{(i)}$.

(Note that the SSE cost function is convex and therefore differentiable.)

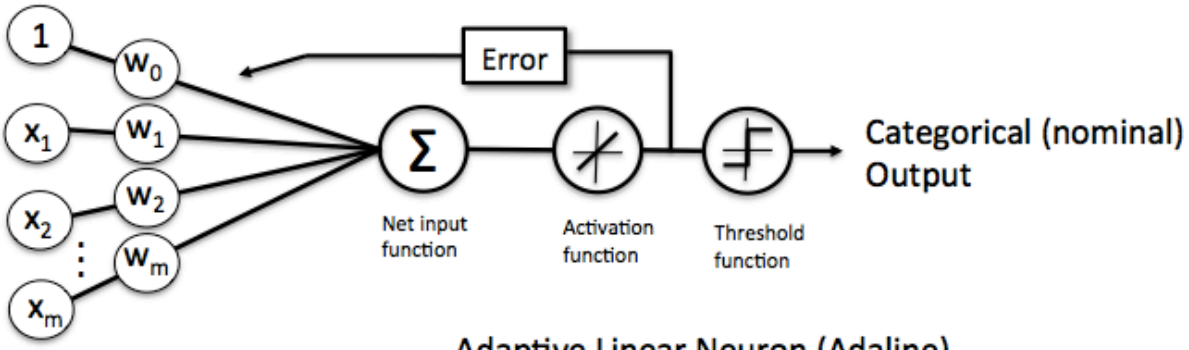
In simple words, we can summarize the gradient descent learning as follows:

1. Initialize the weights to 0 or small random numbers.
2. For k epochs (passes over the training set)
    2. For each training sample $x^{(i)}$
        1. Compute the predicted output value $\hat{y}^{(i)}$
        2. Compare $\hat{y}^{(i)}$ to the actual output $y^{(i)}$ and Compute the "weight update" value
        3. Update the "weight update" value
    3. Update the weight coefficients by the accumulated "weight update" values

Which we can translate into a more mathematical notation:



Linear Regression



Adaptive Linear Neuron (Adaline)

1. Initialize the weights to 0 or small random numbers.
2. For k epochs
    3. For each training sample $x^{(i)}$
        1. $\phi(z^{(i)})_A = \hat{y}^{(i)}$
        2. $\Delta w_{(t+1),\,j} = \eta(y^{(i)} - \hat{y}^{(i)})x_j^{(i)}$ (where η is the learning rate);
        3. $\Delta w_j := \Delta w_j + \Delta w_{(t+1),\,j}$
    4. $\mathbf{w} := \mathbf{w} + \Delta\mathbf{w}$

Performing this global weight update

$$\mathbf{w} := \mathbf{w} + \Delta\mathbf{w},$$

can be understood as "updating the model weights by taking an opposite step towards the cost gradient scaled by the learning rate η"

$$\Delta\mathbf{w} = -\eta\nabla J(\mathbf{w}),$$

where the partial derivative with respect to each w_j can be written as

$$\frac{\partial J}{\partial w_j} = -\sum_i \big(y^{(i)} - \phi(z)_A^{(i)}\big)x_j^{(i)}.$$

To summarize: in order to use gradient descent to learn the model coefficients, we simply update the weights $\mathbf{w}$ by taking a step into the opposite direction of the gradient for each pass over the training set – that's basically it. But how do we get to the equation

$$\frac{\partial J}{\partial w_j} = -\sum_i \big(y^{(i)} - \phi(z)_A^{(i)}\big)x_j^{(i)}?$$

Let's walk through the derivation step by step.

$$\begin{aligned}
&\frac{\partial J}{\partial w_j} \\
&= \frac{\partial}{\partial w_j}\frac{1}{2}\sum_i \big(y^{(i)} - \phi(z)_A^{(i)}\big)^2 \\
&= \frac{1}{2}\frac{\partial}{\partial w_j}\sum_i \big(y^{(i)} - \phi(z)_A^{(i)}\big)^2 \\
&= \frac{1}{2}\sum_i \big(y^{(i)} - \phi(z)_A^{(i)}\big)\frac{\partial}{\partial w_j}\big(y^{(i)} - \phi(z)_A^{(i)}\big) \\
&= \sum_i \big(y^{(i)} - \phi(z)_A^{(i)}\big)\frac{\partial}{\partial w_j}\Big(y^{(i)} - \sum_i \big(w_j^{(i)}x_j^{(i)}\big)\Big) \\
&= \sum_i \big(y^{(i)} - \phi(z)_A^{(i)}\big)(-x_j^{(i)}) \\
&= -\sum_i \big(y^{(i)} - \phi(z)_A^{(i)}\big)x_j^{(i)}
\end{aligned}$$

50 general_concepts.regularization-linear

50.1 Overview

We can understand regularization as an approach of adding an additional bias to a model to reduce the degree of overfitting in models that suffer from high variance. By adding regularization terms to the cost function, we penalize large model coefficients (weights); effectively, we are reducing the complexity of the model.

50.2 L2 regularization

In L2 regularization, we shrink the weights by computing the Euclidean norm of the weight coefficients (the weight vector $\mathbf{w}$); λ is the regularization parameter to be optimized.

$$L2 : \lambda \|\mathbf{w}\|_2 = \lambda \sum_{j=1}^{m} w_j^2$$

For example, we can regularize the sum of squared errors cost function (SSE) as follows:

$$SSE = \sum_{i=1}^{n} \left(\text{target}^{(i)} - \text{output}^{(i)}\right)^2 + L2$$

Intuitively, we can think of regression as an additional penalty term or constraint as shown in the figure below. Without regularization, our objective is to find the global cost minimum. By adding a regularization penalty, our objective becomes to minimize the cost function under the constraint that we have to stay within our "budget" (the gray-shaded ball).

In addition, we can control the regularization strength via the regularization parameter λ. The larger the value of λ, the stronger the regularization of the model. The weight coefficients approach 0 when λ goes towards infinity.

50.3 L1 regularization

In L1 regularization, we shrink the weights using the absolute values of the weight coefficients (the weight vector $\mathbf{w}$); λ is the regularization parameter to be optimized.

$$L1 : \lambda \|\mathbf{w}\|_1 = \lambda \sum_{j=1}^{m} |w_j|$$

For example, we can regularize the sum of squared errors cost function (SSE) as follows:

$$SSE = \sum_{i=1}^{n} \left(\text{target}^{(i)} - \text{output}^{(i)}\right)^2 + L1$$

At its core, L1-regularization is very similar to L2 regularization. However, instead of a quadratic penalty term as in L2, we penalize the model by the absolute weight coefficients. As we can see in the figure below, our "budget" has "sharp edges," which is the geometric interpretation of why the L1 model induces sparsity.

51 math.num_combinations

A function to calculate the number of combinations for creating subsequences of k elements out of a sequence with n elements.

from mlxtend.math import num_combinations

51.1 Overview

Combinations are selections of items from a collection regardless of the order in which they appear (in contrast to permutations). For example, let's consider a combination of 3 elements (k=3) from a collection of 5 elements (n=5):

- collection: {1, 2, 3, 4, 5}
- combination 1a: {1, 3, 5}
- combination 1b: {1, 5, 3}
- combination 1c: {3, 5, 1}
- ...
- combination 2: {1, 3, 4}

In the example above the combinations 1a, 1b, and 1c, are the "same combination" and counted as "1 possible way to combine items 1, 3, and 5" – in combinations, the order does not matter.

The number of ways to combine elements (**without replacement**) from a collection with size n into subsets of size k is computed via the binomial coefficient ("n choose k"):

$$\binom{n}{k} = \frac{n(n-1)\dots(n-k+1)}{k(k-1)\dots 1} = \frac{n!}{k!(n-k)!}$$

To compute the number of combinations **with replacement**, the following, alternative equation is used ("n multichoose k"):

$$\binom{n}{k} = \binom{n+k-1}{k}$$

51.1.1 References

- https://en.wikipedia.org/wiki/Combination

51.2 Example 1 - Compute the number of combinations

```
from mlxtend.math import num_combinations

c = num_combinations(n=20, k=8, with_replacement=False)
print('Number of ways to combine 20 elements'
      ' into 8 subelements: %d' % c)
```

```
Number of ways to combine 20 elements into 8 subelements: 125970
```

```
from mlxtend.math import num_combinations

c = num_combinations(n=20, k=8, with_replacement=True)
print('Number of ways to combine 20 elements'
      ' into 8 subelements (with replacement): %d' % c)
```

```
Number of ways to combine 20 elements into 8 subelements (with replacement): 2220075
```

51.3 Example 2 - A progress tracking use-case

It is often quite useful to track the progress of a computational expensive tasks to estimate its runtime. Here, the `num_combination` function can be used to compute the maximum number of loops of a `combinations` iterable from itertools:

```
import itertools
import sys
import time
from mlxtend.math import num_combinations

items = {1, 2, 3, 4, 5, 6, 7, 8}
max_iter = num_combinations(n=len(items), k=3,
                            with_replacement=False)

for idx, i in enumerate(itertools.combinations(items, r=3)):
    # do some computation with itemset i
    time.sleep(0.1)
    sys.stdout.write('\rProgress: %d/%d' % (idx + 1, max_iter))
    sys.stdout.flush()
```

```
Progress: 56/56
```

51.4 API

num_combinations(n, k, with_replacement=False)

Function to calculate the number of possible combinations.

Parameters

- `n` : `int`

  Total number of items.

- `k` : `int`

  Number of elements of the target itemset.

- `with_replacement` : `bool` (default: False)

  Allows repeated elements if True.

Returns

- `comb` : `int`

  Number of possible combinations.

52 `math.num_permutations`

A function to calculate the number of permutations for creating subsequences of k elements out of a sequence with n elements.

```
from mlxtend.math import num_permutations
```

52.1 Overview

Permutations are selections of items from a collection with regard to the order in which they appear (in contrast to combinations). For example, let's consider a permutation of 3 elements (k=3) from a collection of 5 elements (n=5):

- collection: {1, 2, 3, 4, 5}
- combination 1a: {1, 3, 5}
- combination 1b: {1, 5, 3}
- combination 1c: {3, 5, 1}
- ...
- combination 2: {1, 3, 4}

In the example above the permutations 1a, 1b, and 1c, are the "same combination" but distinct permutations – in combinations, the order does not matter, but in permutation it does matter.

The number of ways to combine elements (**without replacement**) from a collection with size n into subsets of size k is computed via the binomial coefficient ("n choose k"):

$$k! \binom{n}{k} = k! \cdot \frac{n!}{k!(n-k)!} = \frac{n!}{(n-k)!}$$

To compute the number of permutations **with replacement**, we simply need to compute n^k.

52.1.1 References

- https://en.wikipedia.org/wiki/Permutation

52.2 Example 1 - Compute the number of permutations

```
from mlxtend.math import num_permutations

c = num_permutations(n=20, k=8, with_replacement=False)
print('Number of ways to permute 20 elements'
      ' into 8 subelements: %d' % c)
```

```
Number of ways to permute 20 elements into 8 subelements: 5079110400
```

```
from mlxtend.math import num_permutations

c = num_permutations(n=20, k=8, with_replacement=True)
print('Number of ways to combine 20 elements'
      ' into 8 subelements (with replacement): %d' % c)
```

```
Number of ways to combine 20 elements into 8 subelements (with replacement): 25600000000
```

52.3 Example 2 - A progress tracking use-case

It is often quite useful to track the progress of a computational expensive tasks to estimate its runtime. Here, the `num_combination` function can be used to compute the maximum number of loops of a `permutations` iterable from itertools:

```
import itertools
import sys
import time
from mlxtend.math import num_permutations

items = {1, 2, 3, 4, 5, 6, 7, 8}
max_iter = num_permutations(n=len(items), k=3,
                            with_replacement=False)

for idx, i in enumerate(itertools.permutations(items, r=3)):
    # do some computation with itemset i
    time.sleep(0.01)
    sys.stdout.write('\rProgress: %d/%d' % (idx + 1, max_iter))
    sys.stdout.flush()
```

```
Progress: 336/336
```

52.4 API

num_permutations(n, k, with_replacement=False)

Function to calculate the number of possible permutations.

Parameters

- `n` : `int`

  Total number of items.

- `k` : `int`

  Number of elements of the target itemset.

- `with_replacement` : `bool`

  Allows repeated elements if True.

Returns

- `permut` : `int`

  Number of possible permutations.

53 plotting.category_scatter

A function to quickly produce a scatter plot colored by categories from a pandas `DataFrame` or NumPy `ndarray` object.

from mlxtend.general_plotting import category_scatter

53.1 Overview

53.1.1 References

- –

53.2 Example 1 - Category Scatter from Pandas DataFrames

```
import pandas as pd
from io import StringIO

csvfile = """label,x,y
class1,10.0,8.04
class1,10.5,7.30
class2,8.3,5.5
class2,8.1,5.9
class3,3.5,3.5
class3,3.8,5.1"""

df = pd.read_csv(StringIO(csvfile))
df
```

```
<tr style="text-align: right;">
  <th></th>
  <th>label</th>
  <th>x</th>
  <th>y</th>
</tr>
```

```
<tr>
  <th>0</th>
  <td>class1</td>
  <td>10.0</td>
  <td>8.04</td>
</tr>
<tr>
  <th>1</th>
  <td>class1</td>
  <td>10.5</td>
  <td>7.30</td>
</tr>
<tr>
  <th>2</th>
  <td>class2</td>
  <td>8.3</td>
  <td>5.50</td>
</tr>
<tr>
  <th>3</th>
  <td>class2</td>
  <td>8.1</td>
  <td>5.90</td>
</tr>
<tr>
  <th>4</th>
  <td>class3</td>
  <td>3.5</td>
  <td>3.50</td>
</tr>
<tr>
  <th>5</th>
  <td>class3</td>
  <td>3.8</td>
  <td>5.10</td>
</tr>
```

Plotting the data where the categories are determined by the unique values in the label column `label_col`. The `x` and `y` values are simply the column names of the DataFrame that we want to plot.

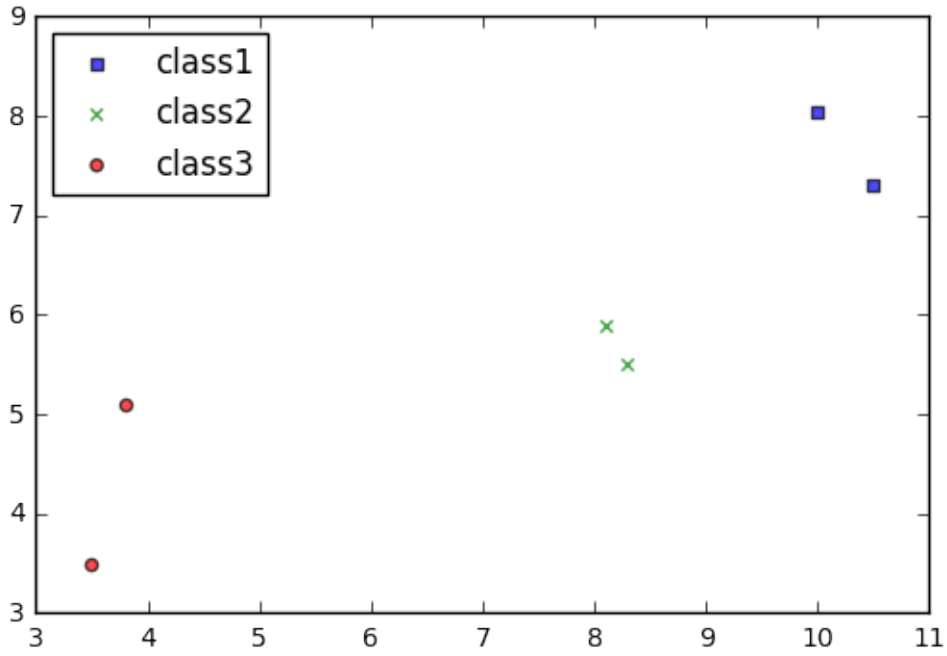
```
import matplotlib.pyplot as plt
from mlxtend.plotting import category_scatter

fig = category_scatter(x='x', y='y', label_col='label',
                       data=df, legend_loc='upper left')
```

53.3 Example 2 - Category Scatter from NumPy Arrays

```
import numpy as np
from io import BytesIO

csvfile = """1,10.0,8.04
```



```
1,10.5,7.30
2,8.3,5.5
2,8.1,5.9
3,3.5,3.5
3,3.8,5.1"""

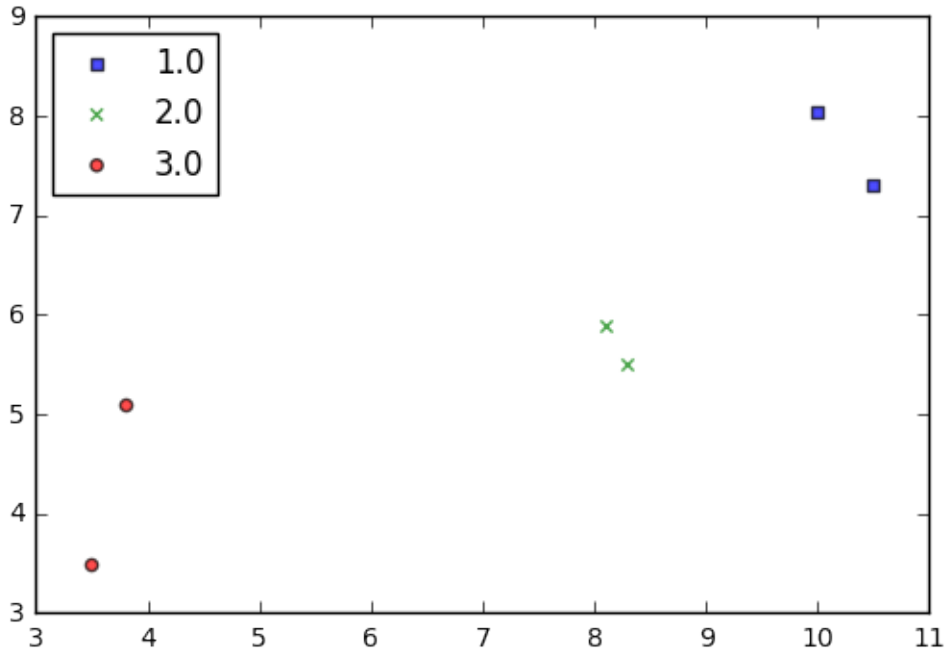
ary = np.genfromtxt(BytesIO(csvfile.encode()), delimiter=',')
ary
```

```
array([[  1.  ,  10.  ,   8.04],
       [  1.  ,  10.5 ,   7.3 ],
       [  2.  ,   8.3 ,   5.5 ],
       [  2.  ,   8.1 ,   5.9 ],
       [  3.  ,   3.5 ,   3.5 ],
       [  3.  ,   3.8 ,   5.1 ]])
```

Now, pretending that the first column represents the labels, and the second and third column represent the `x` and `y` values, respectively.

```
import matplotlib.pyplot as plt
from mlxtend.plotting import category_scatter

fix = category_scatter(x=1, y=2, label_col=0,
                       data=ary, legend_loc='upper left')
```



53.4 API

category_scatter(x, y, label_col, data, markers='sxo^v', colors=('blue', 'green', 'red', 'purple', 'gray', 'cyan'), alpha=0.7, markersize=20.0, legend_loc='best')

Scatter plot to plot categories in different colors/markerstyles.

Parameters

- `x` : str or int
  DataFrame column name of the x-axis values or integer for the numpy ndarray column index.
- `y` : str
  DataFrame column name of the y-axis values or integer for the numpy ndarray column index
- `data` : Pandas DataFrame object or NumPy ndarray.
- `markers` : str
  Markers that are cycled through the label category.
- `colors` : tuple
  Colors that are cycled through the label category.
- `alpha` : float (default: 0.7)
  Parameter to control the transparency.
- `markersize` : float (default' : 20.0)
  Parameter to control the marker size.

- `legend_loc` : str (default: 'best')

  Location of the plot legend {best, upper left, upper right, lower left, lower right} No legend if legend_loc=False

Returns

- `fig` : matplotlig.pyplot figure object

54 plotting.checkerboard_plot

Function to plot a checkerboard plot / heat map via matplotlib

```
from mlxtend.plotting import checkerboard plot
```

54.1 Overview

Function to plot a checkerboard plot / heat map via matplotlib.

54.1.1 References

- –

54.2 Example 1 - Default

```
from mlxtend.plotting import checkerboard_plot
import matplotlib.pyplot as plt
import numpy as np

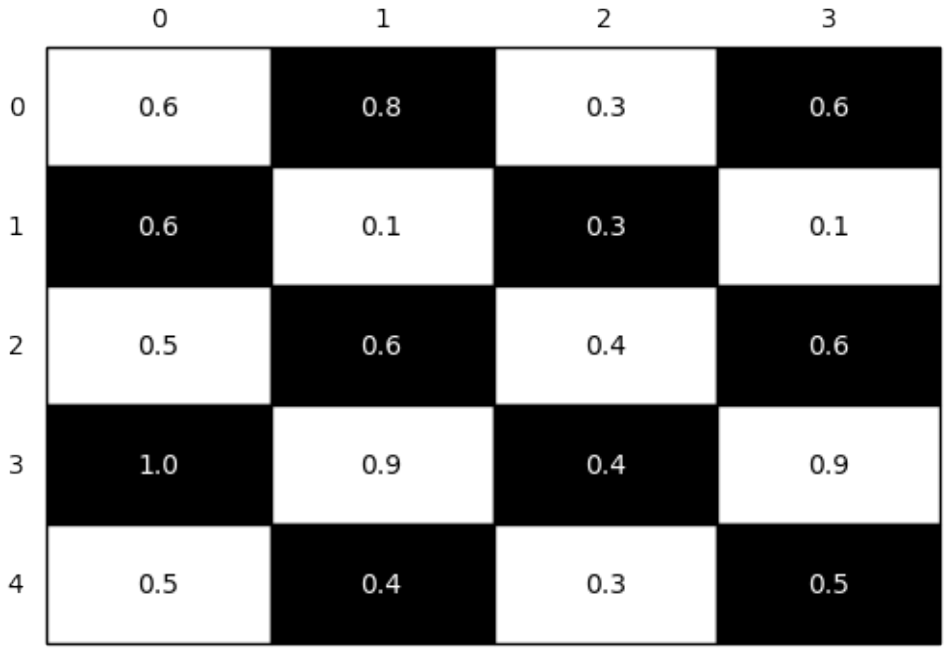
ary = np.random.random((5, 4))

brd = checkerboard_plot(ary)
plt.show()
```

54.3 Example 2 - Changing colors and labels

```
from mlxtend.plotting import checkerboard_plot
import matplotlib.pyplot as plt
import numpy as np

checkerboard_plot(ary,
                  col_labels=['abc', 'def', 'ghi', 'jkl'],
                  row_labels=['sample %d' % i for i in range(1, 6)],
                  cell_colors=['skyblue', 'whitesmoke'],
                  font_colors=['black', 'black'],
                  figsize=(4.5, 5))
plt.show()
```



54.4 API

checkerboard_plot(ary, cell_colors=('white', 'black'), font_colors=('black', 'white'), fmt='%.1f', figsize=None, row_labels=None, col_labels=None, fontsize=None)

Plot a checkerboard table / heatmap via matplotlib.

Parameters

- `ary` : array-like, shape = [n, m]

  A 2D Nnumpy array.

- `cell_colors` : tuple or list (default: ('white', 'black'))

  Tuple or list containing the two colors of the checkerboard pattern.

- `font_colors` : tuple or list (default: ('black', 'white'))

  Font colors corresponding to the cell colors.

- `figsize` : tuple (default: (2.5, 2.5))

  Height and width of the figure

- `fmt` : str (default: '%.1f')

  Python string formatter for cell values. The default '%.1f' results in floats with 1 digit after the decimal point. Use '%d' to show numbers as integers.

- `row_labels` : list (default: None)

  List of the row labels. Uses the array row indices 0 to n by default.

- `col_labels` : list (default: None)
  List of the column labels. Uses the array column indices 0 to m by default.
- `fontsize` : int (default: None)
  Specifies the font size of the checkerboard table. Uses matplotlib's default if None.

Returns

- `fig` : matplotlib Figure object.

55 plotting.ecdf

A function to conveniently plot an empirical cumulative distribution function.

from mlxtend.ecdf import ecdf

55.1 Overview

A function to conveniently plot an empirical cumulative distribution function (ECDF) and adding percentile thresholds for exploratory data analysis.

55.1.1 References

- –

55.2 Example 1 - ECDF

```
from mlxtend.data import iris_data
from mlxtend.plotting import ecdf
import matplotlib.pyplot as plt

X, y = iris_data()

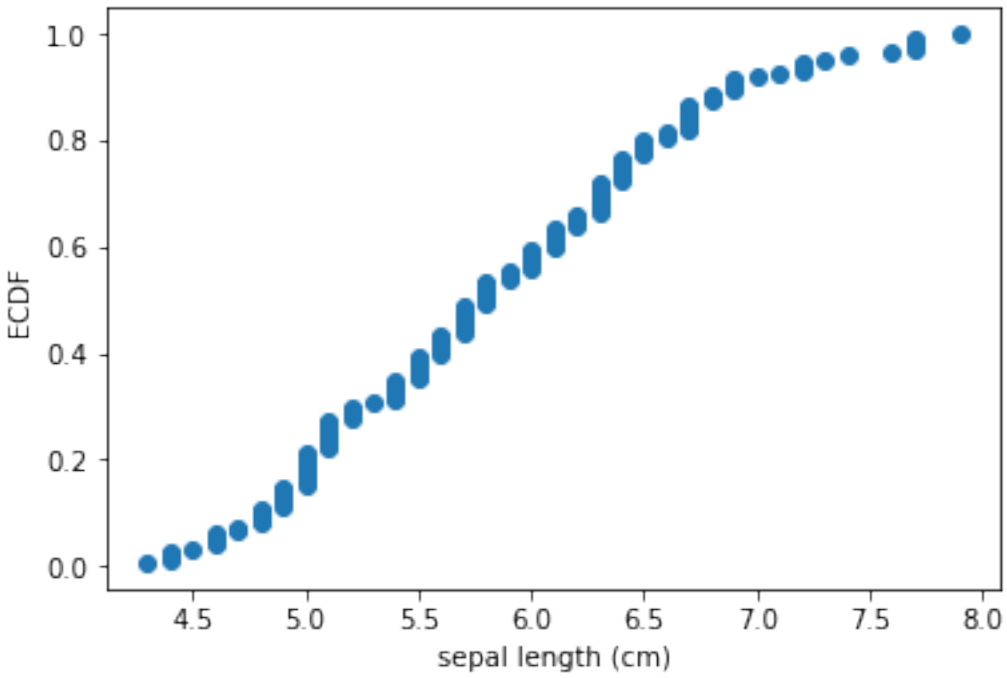
ax, _, _ = ecdf(x=X[:, 0], x_label='sepal length (cm)')
plt.show()
```

55.3 Example 2 - Multiple ECDFs

```
from mlxtend.data import iris_data
from mlxtend.plotting import ecdf
import matplotlib.pyplot as plt

X, y = iris_data()

# first ecdf
x1 = X[:, 0]
ax, _, _ = ecdf(x1, x_label='cm')
```



```
# second ecdf
x2 = X[:, 1]
ax, _, _ = ecdf(x2, ax=ax)

plt.legend(['sepal length', 'sepal width'])
plt.show()
```

55.4 Example 3 - ECDF with Percentile Thresholds

```
from mlxtend.data import iris_data
from mlxtend.plotting import ecdf
import matplotlib.pyplot as plt

X, y = iris_data()

ax, threshold, count = ecdf(x=X[:, 0],
                            x_label='sepal length (cm)',
                            percentile=0.8)

plt.show()

print('Feature threshold at the 80th percentile:', threshold)
print('Number of samples below the threshold:', count)
```

```
Feature threshold at the 80th percentile: 6.5
Number of samples below the threshold: 120
```

55.5 API

ecdf(x, y_label='ECDF', x_label=None, ax=None, percentile=None, ecdf_color=None, ecdf_marker='o', percentile_color='black', percentile_linestyle='–')

Plots an Empirical Cumulative Distribution Function

Parameters

- `x` : array or list, shape=[n_samples,]
  Array-like object containing the feature values
- `y_label` : str (default='ECDF')
  Text label for the y-axis
- `x_label` : str (default=None)
  Text label for the x-axis
- `ax` : matplotlib.axes.Axes (default: None)
  An existing matplotlib Axes. Creates one if ax=None
- `percentile` : float (default=None)
  Float between 0 and 1 for plotting a percentile threshold line
- `ecdf_color` : matplotlib color (default=None)
  Color for the ECDF plot; uses matplotlib defaults if None
- `ecdf_marker` : matplotlib marker (default='o')
  Marker style for the ECDF plot
- `percentile_color` : matplotlib color (default='black')
  Color for the percentile threshold if percentile is not None
- `percentile_linestyle` : matplotlib linestyle (default='–')
  Line style for the percentile threshold if percentile is not None

Returns

- `ax` : matplotlib.axes.Axes object
- `percentile_threshold` : float
  Feature threshold at the percentile or None if `percentile=None`
- `percentile_count` : Number of if percentile is not None
  Number of samples that have a feature less or equal than the feature threshold at a percentile threshold or None if `percentile=None`

56 plotting.enrichment_plot

A function to plot step plots of cumulative counts.

```
from mlxtend.general_plotting import category_scatter
```

56.1 Overview

In enrichment plots, the y-axis can be interpreted as "how many samples are less or equal to the corresponding x-axis label."

56.1.1 References

- –

56.2 Example 1 - Enrichment Plots from Pandas DataFrames

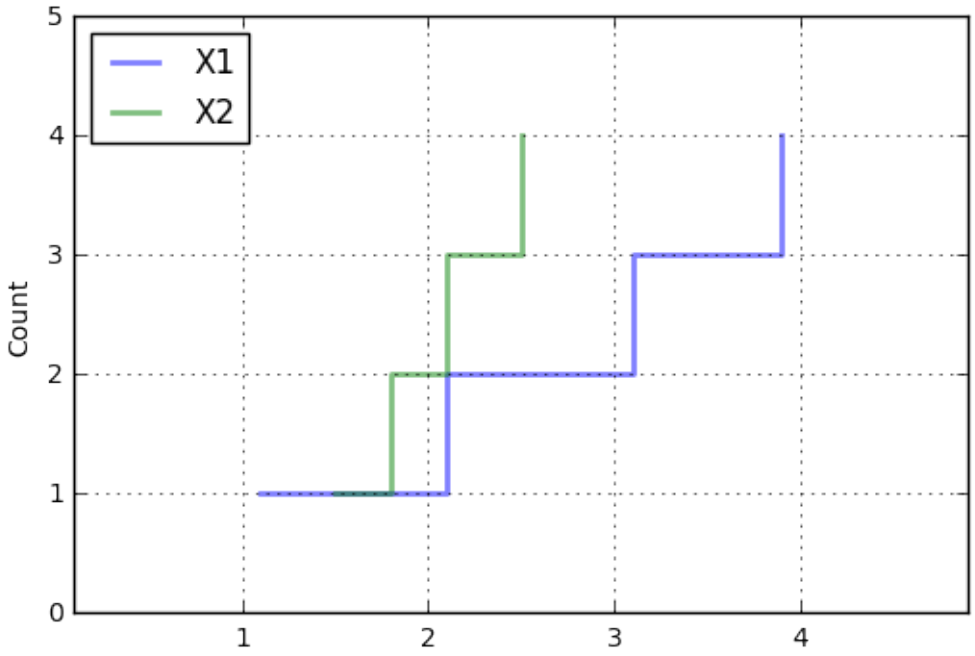
```
import pandas as pd
s1 = [1.1, 1.5]
s2 = [2.1, 1.8]
s3 = [3.1, 2.1]
s4 = [3.9, 2.5]
data = [s1, s2, s3, s4]
df = pd.DataFrame(data, columns=['X1', 'X2'])
df
```

```
<tr style="text-align: right;">
  <th></th>
  <th>X1</th>
  <th>X2</th>
</tr>

<tr>
  <th>0</th>
  <td>1.1</td>
  <td>1.5</td>
</tr>
<tr>
  <th>1</th>
  <td>2.1</td>
  <td>1.8</td>
</tr>
<tr>
  <th>2</th>
  <td>3.1</td>
  <td>2.1</td>
</tr>
<tr>
  <th>3</th>
  <td>3.9</td>
  <td>2.5</td>
</tr>
```

Plotting the data where the categories are determined by the unique values in the label column `label_col`. The `x` and `y` values are simply the column names of the DataFrame that we want to plot.

```
import matplotlib.pyplot as plt
from mlxtend.plotting import enrichment_plot
```



```
ax = enrichment_plot(df, legend_loc='upper left')
```

56.3 API

enrichment_plot(df, colors='bgrkcy', markers='', linestyles='-', alpha=0.5, lw=2, where='post', grid=True, count_label='Count', xlim='auto', ylim='auto', invert_axes=False, legend_loc='best', ax=None)

Plot stacked barplots

Parameters

- `df` : pandas.DataFrame

  A pandas DataFrame where columns represent the different categories. colors: str (default: 'bgrcky') The colors of the bars.

- `markers` : str (default: '')

  Matplotlib markerstyles, e.g, 'sov' for square,circle, and triangle markers.

- `linestyles` : str (default: '-')

  Matplotlib linestyles, e.g., '-,–' to cycle normal and dashed lines. Note that the different linestyles need to be separated by commas.

- `alpha` : float (default: 0.5)

  Transparency level from 0.0 to 1.0.

- `lw` : int or float (default: 2)

  Linewidth parameter.

- `where` : {'post', 'pre', 'mid'} (default: 'post')
  Starting location of the steps.
- `grid` : bool (default: `True`)
  Plots a grid if True.
- `count_label` : str (default: 'Count')
  Label for the "Count"-axis.
- `xlim` : 'auto' or array-like [min, max] (default: 'auto')
  Min and maximum position of the x-axis range.
- `ylim` : 'auto' or array-like [min, max] (default: 'auto')
  Min and maximum position of the y-axis range.
- `invert_axes` : bool (default: False)
  Plots count on the x-axis if True.
- `legend_loc` : str (default: 'best')
  Location of the plot legend {best, upper left, upper right, lower left, lower right} No legend if legend_loc=False
- `ax` : matplotlib axis, optional (default: None)
  Use this axis for plotting or make a new one otherwise

Returns

- `ax` : matplotlib axis

57 plotting.plot_confusion_matrix

Utility function for visualizing confusion matrices via matplotlib

```
from mlxtend.plotting import plot_confusion_matrix
```

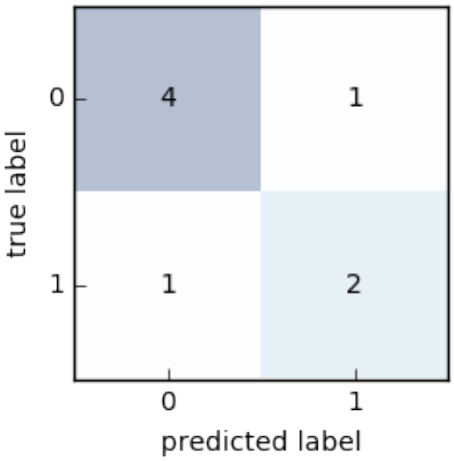
57.1 Overview

57.1.1 Confusion Matrix

For more information on confusion matrices, please see `mlxtend.evaluate.confusion_matrix`.

57.1.2 References

- –



57.2 Example 1 - Binary and Multi-Class

```
from mlxtend.plotting import plot_confusion_matrix
import matplotlib.pyplot as plt
import numpy as np

binary = np.array([[4, 1],
                   [1, 2]])

fig, ax = plot_confusion_matrix(conf_mat=binary)
plt.show()

multiclass = np.array([[2, 1, 0, 0],
                       [1, 2, 0, 0],
                       [0, 0, 1, 0],
                       [0, 0, 0, 1]])

fig, ax = plot_confusion_matrix(conf_mat=multiclass)
plt.show()
```

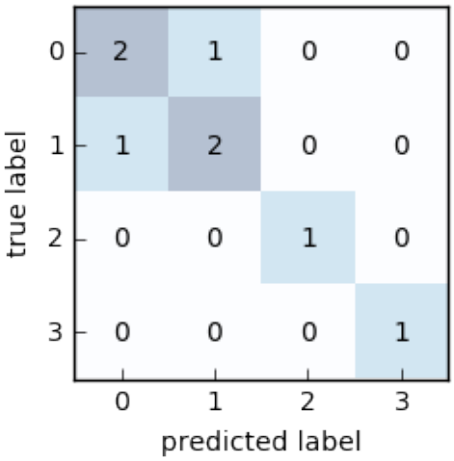
57.3 API

plot_confusion_matrix(conf_mat, hide_spines=False, hide_ticks=False, figsize=(2.5, 2.5), cmap=None, alpha=0.3)

Plot a confusion matrix via matplotlib.

Parameters

- `conf_mat` : array-like, shape = [n_classes, n_classes]
  Confusion matrix from evaluate.confusion matrix.
- `hide_spines` : bool (default: False)
  Hides axis spines if True.



- `hide_ticks` : bool (default: False)
  Hides axis ticks if True
- `figsize` : tuple (default: (2.5, 2.5))
  Height and width of the figure
- `cmap` : matplotlib colormap (default: `None`)
  Uses matplotlib.pyplot.cm.Blues if `None`

Returns

- `fig, ax` : matplotlib.pyplot subplot objects
  Figure and axis elements of the subplot.

58 plotting.plot_decision_regions

A function for plotting decision regions of classifiers in 1 or 2 dimensions.

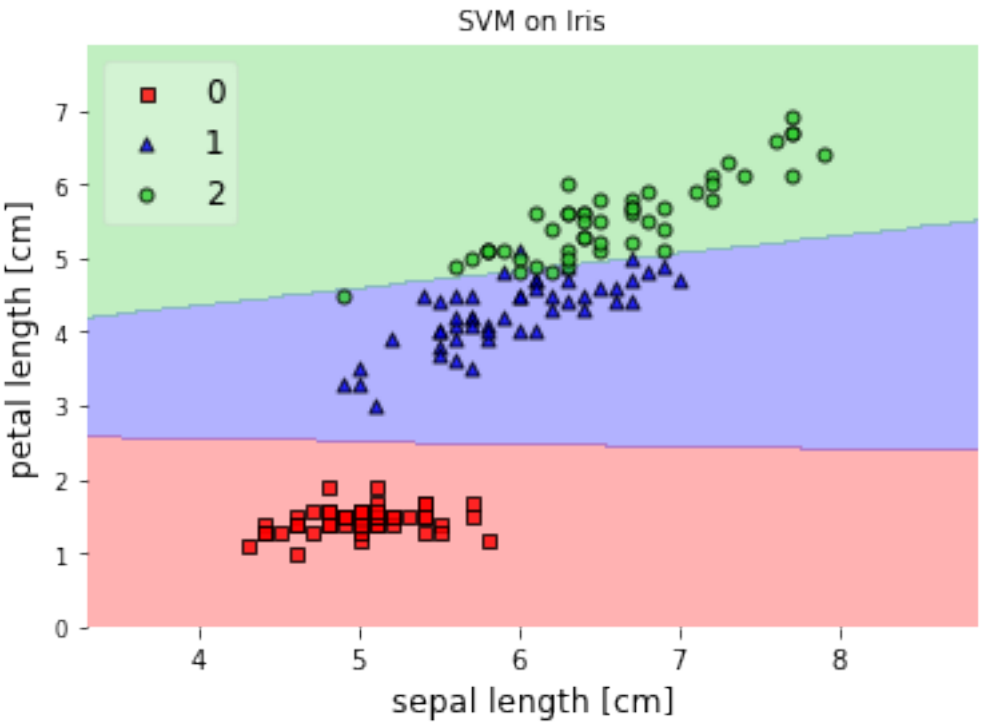
from mlxtend.plotting import plot_decision_regions

58.0.1 References

-

58.1 Example 1 - Decision regions in 2D

```
from mlxtend.plotting import plot_decision_regions
import matplotlib.pyplot as plt
from sklearn import datasets
from sklearn.svm import SVC
```



```
# Loading some example data
iris = datasets.load_iris()
X = iris.data[:, [0, 2]]
y = iris.target

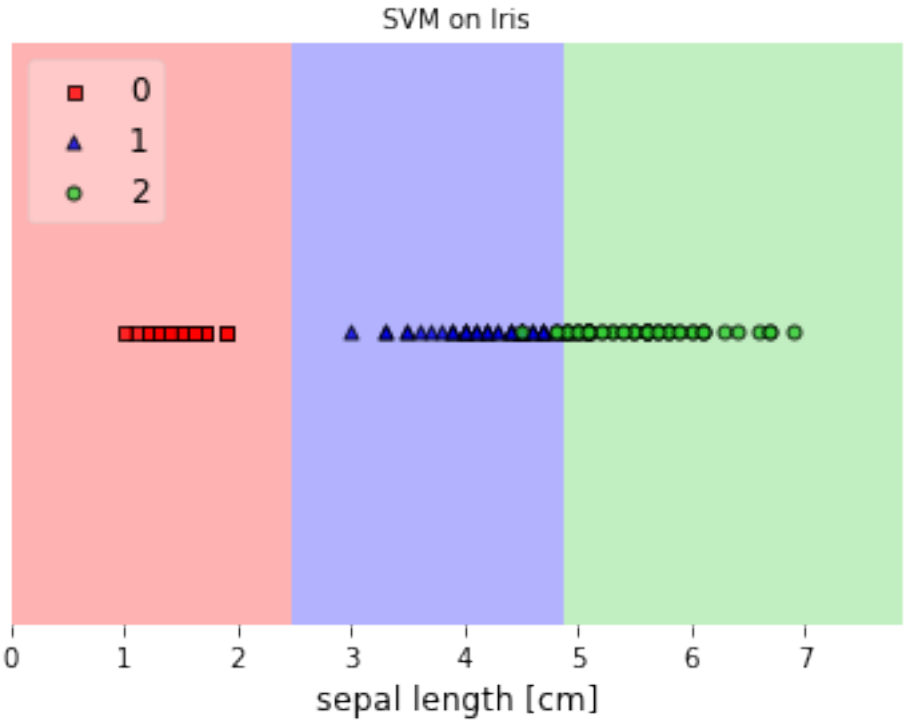
# Training a classifier
svm = SVC(C=0.5, kernel='linear')
svm.fit(X, y)

# Plotting decision regions
plot_decision_regions(X, y, clf=svm,
                      res=0.02, legend=2)

# Adding axes annotations
plt.xlabel('sepal length [cm]')
plt.ylabel('petal length [cm]')
plt.title('SVM on Iris')
plt.show()
```

58.2 Example 2 - Decision regions in 1D

```
from mlxtend.plotting import plot_decision_regions
import matplotlib.pyplot as plt
from sklearn import datasets
from sklearn.svm import SVC
```



```
# Loading some example data
iris = datasets.load_iris()
X = iris.data[:, 2]
X = X[:, None]
y = iris.target

# Training a classifier
svm = SVC(C=0.5, kernel='linear')
svm.fit(X, y)

# Plotting decision regions
plot_decision_regions(X, y, clf=svm,
                      res=0.02, legend=2)

# Adding axes annotations
plt.xlabel('sepal length [cm]')
plt.title('SVM on Iris')

plt.show()
```

58.3 Example 3 - Decision Region Grids

```
from sklearn.linear_model import LogisticRegression
from sklearn.naive_bayes import GaussianNB
from sklearn.ensemble import RandomForestClassifier
```

```
from sklearn.svm import SVC
from sklearn import datasets
import numpy as np

# Initializing Classifiers
clf1 = LogisticRegression(random_state=1)
clf2 = RandomForestClassifier(random_state=1)
clf3 = GaussianNB()
clf4 = SVC()

# Loading some example data
iris = datasets.load_iris()
X = iris.data[:, [0,2]]
y = iris.target

import matplotlib.pyplot as plt
from mlxtend.plotting import plot_decision_regions
import matplotlib.gridspec as gridspec
import itertools
gs = gridspec.GridSpec(2, 2)

fig = plt.figure(figsize=(10,8))

labels = ['Logistic Regression', 'Random Forest', 'Naive Bayes', 'SVM']
for clf, lab, grd in zip([clf1, clf2, clf3, clf4],
                         labels,
                         itertools.product([0, 1], repeat=2)):

    clf.fit(X, y)
    ax = plt.subplot(gs[grd[0], grd[1]])
    fig = plot_decision_regions(X=X, y=y, clf=clf, legend=2)
    plt.title(lab)

plt.show()
```

58.4 Example 4 - Highlighting Test Data Points

```
from mlxtend.plotting import plot_decision_regions
from mlxtend.preprocessing import shuffle_arrays_unison
import matplotlib.pyplot as plt
from sklearn import datasets
from sklearn.svm import SVC

# Loading some example data
iris = datasets.load_iris()
X, y = iris.data[:, [0,2]], iris.target
X, y = shuffle_arrays_unison(arrays=[X, y], random_seed=3)

values = [-4.0, -1.0, 1.0, 4.0]
width = 0.75
for value, ax in zip(values, axarr.flat):
    plot_decision_regions(X, y, clf=svm,
                          filler_feature_values={2: value},
                          filler_feature_ranges={2: width},
                          res=0.02, legend=2, ax=ax)
    ax.set_xlabel('Feature 1')
    ax.set_ylabel('Feature 2')
    ax.set_title('Feature 3 = {}'.format(value))

# Adding axes annotations
fig.suptitle('SVM on make_blobs')
plt.show()
```

59 API

plot_decision_regions(X, y, clf, feature_index=None, filler_feature_values=None, filler_feature_ranges=None, ax=None, X_highlight=None, res=0.02, legend=1, hide_spines=True, markers='s^oxv<>', colors='red,blue,limegreen,gray,cyan')

Plot decision regions of a classifier.

Please note that this functions assumes that class labels are labeled consecutively, e.g,. 0, 1, 2, 3, 4, and 5. If you have class labels with integer labels > 4, you may want to provide additional colors and/or markers as `colors` and `markers` arguments. See http://matplotlib.org/examples/color/named_colors.html for more information.

Parameters

- `X` : array-like, shape = [n_samples, n_features]

  Feature Matrix.

- `y` : array-like, shape = [n_samples]

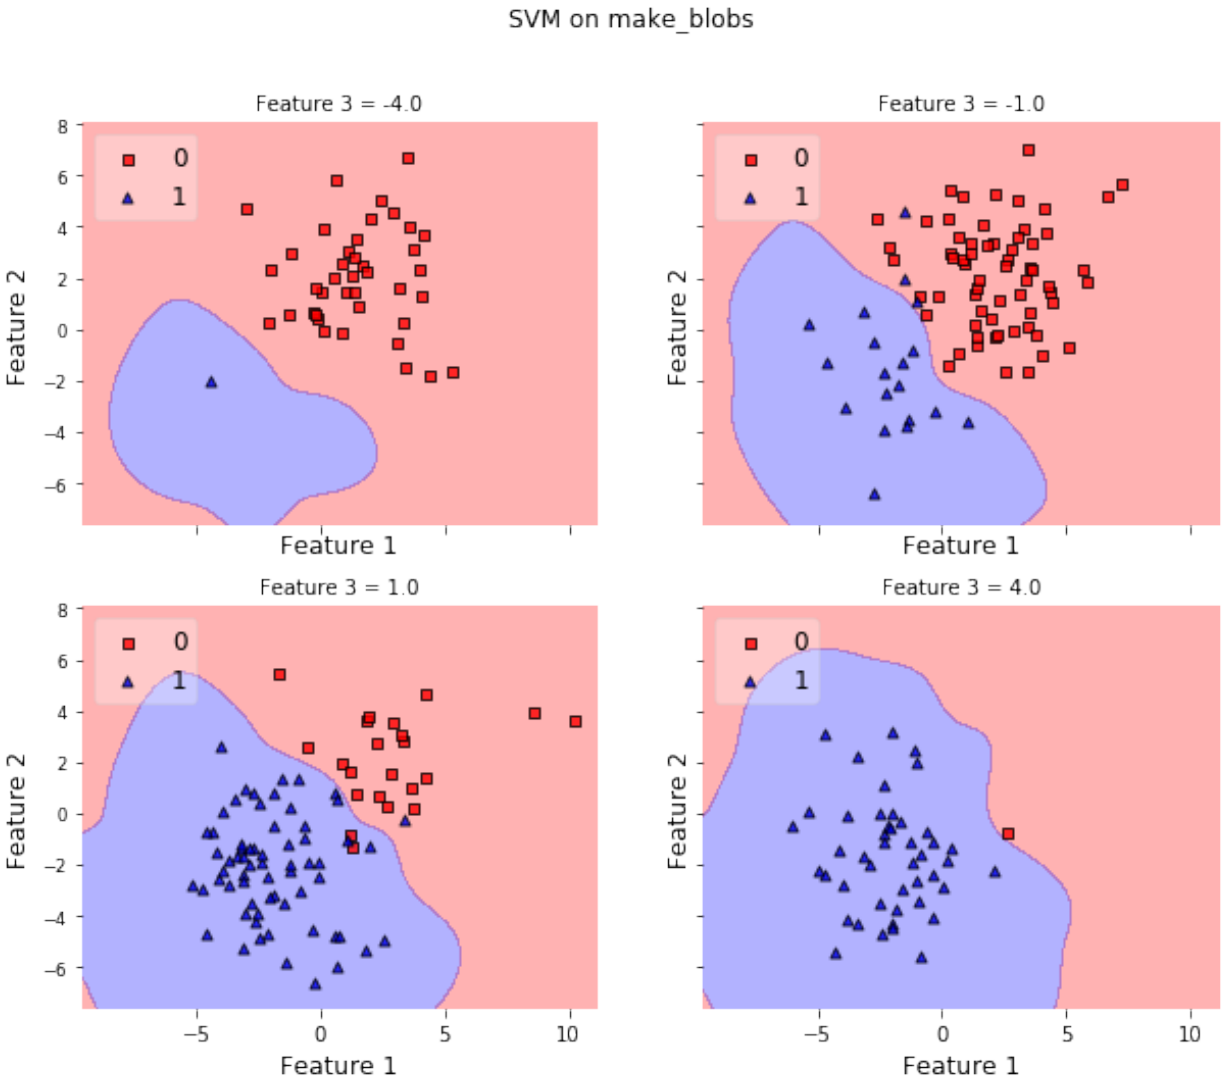
  True class labels.

- `clf` : Classifier object.

  Must have a .predict method.

- `feature_index` : array-like (default: (0,) for 1D, (0, 1) otherwise)

  Feature indices to use for plotting. The first index in `feature_index` will be on the x-axis, the second index will be on the y-axis.



SVM on make_blobs
Feature 3 = -4.0
Feature 3 = -1.0
Feature 3 = 1.0
Feature 3 = 4.0
0
1
Feature 1
Feature 2

- `filler_feature_values` : dict (default: None)

  Only needed for number features > 2. Dictionary of feature index-value pairs for the features not being plotted.

- `filler_feature_ranges` : dict (default: None)

  Only needed for number features > 2. Dictionary of feature index-value pairs for the features not being plotted. Will use the ranges provided to select training samples for plotting.

- `ax` : matplotlib.axes.Axes (default: None)

  An existing matplotlib Axes. Creates one if ax=None.

- `X_highlight` : array-like, shape = [n_samples, n_features] (default: None)

  An array with data points that are used to highlight samples in `X`.

- `res` : float or array-like, shape = (2,) (default: 0.02)

  Grid width. If float, same resolution is used for both the x- and y-axis. If array-like, the first item is used on the x-axis, the second is used on the y-axis. Lower values increase the resolution but slow down the plotting.

- `hide_spines` : bool (default: True)

  Hide axis spines if True.

- `legend` : int (default: 1)

  Integer to specify the legend location. No legend if legend is 0.

- `markers` : str (default 's^oxv<>')

  Scatterplot markers.

- `colors` : str (default 'red,blue,limegreen,gray,cyan')

  Comma separated list of colors.

Returns

- `ax` : matplotlib.axes.Axes object

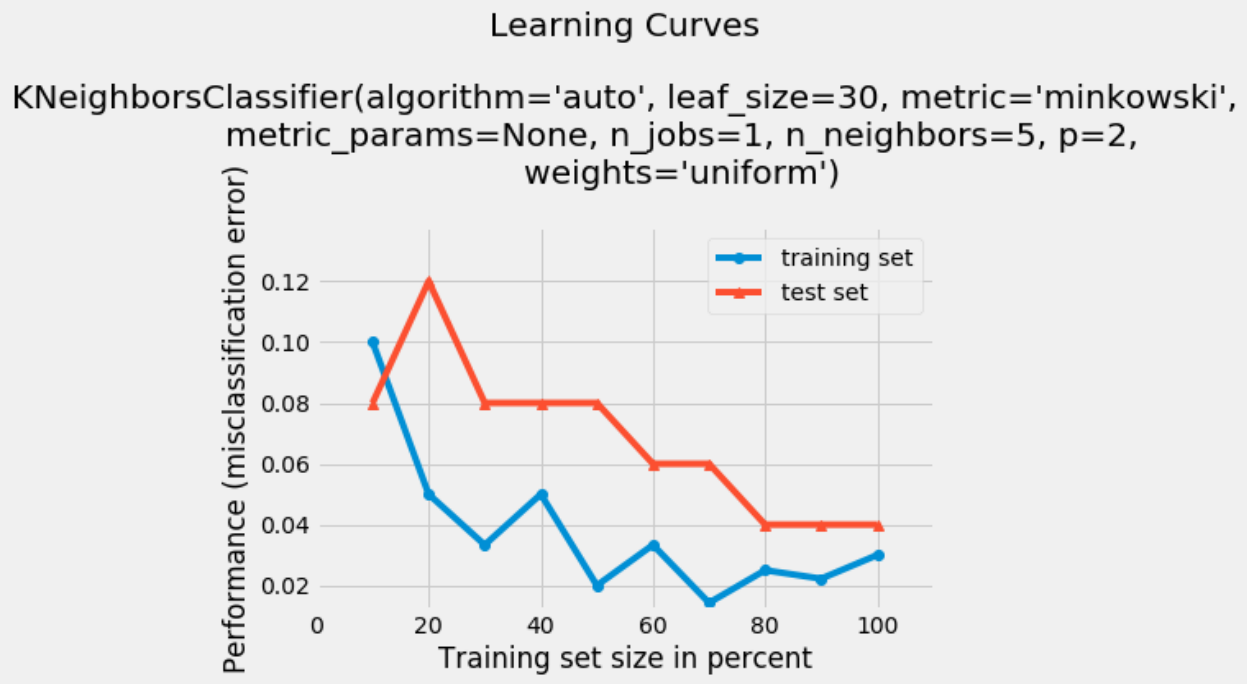
60 plotting.plot_learning_curves

A function to plot learning curves for classifiers. Learning curves are extremely useful to analyze if a model is suffering from over- or under-fitting (high variance or high bias). The function can be imported via

```
from mlxtend.plotting import plot_learning_curves
```

60.0.1 References

-



60.1 Example 1

```
from mlxtend.plotting import plot_learning_curves
import matplotlib.pyplot as plt
from mlxtend.data import iris_data
from mlxtend.preprocessing import shuffle_arrays_unison
from sklearn.neighbors import KNeighborsClassifier
import numpy as np

# Loading some example data
X, y = iris_data()
X, y = shuffle_arrays_unison(arrays=[X, y], random_seed=123)
X_train, X_test = X[:100], X[100:]
y_train, y_test = y[:100], y[100:]

clf = KNeighborsClassifier(n_neighbors=5)

plot_learning_curves(X_train, y_train, X_test, y_test, clf)
plt.show()
```

60.2 API

plot_learning_curves(X_train, y_train, X_test, y_test, clf, train_marker='o', test_marker='^', scoring='misclassification error', suppress_plot=False, print_model=True, style='fivethirtyeight', legend_loc='best')

Plots learning curves of a classifier.

Parameters

- `X_train` : array-like, shape = [n_samples, n_features]
  Feature matrix of the training dataset.
- `y_train` : array-like, shape = [n_samples]
  True class labels of the training dataset.
- `X_test` : array-like, shape = [n_samples, n_features]
  Feature matrix of the test dataset.
- `y_test` : array-like, shape = [n_samples]
  True class labels of the test dataset.
- `clf` : Classifier object. Must have a .predict .fit method.
- `train_marker` : str (default: 'o')
  Marker for the training set line plot.
- `test_marker` : str (default: '^')
  Marker for the test set line plot.
- `scoring` : str (default: 'misclassification error')
  If not 'misclassification error', accepts the following metrics (from scikit-learn): {'accuracy', 'average_precision', 'f1_micro', 'f1_macro', 'f1_weighted', 'f1_samples', 'log_loss', 'precision', 'recall', 'roc_auc', 'adjusted_rand_score', 'mean_absolute_error', 'mean_squared_error', 'median_absolute_error', 'r2'}
- `suppress_plot=False` : bool (default: False)
  Suppress matplotlib plots if True. Recommended for testing purposes.
- `print_model` : bool (default: True)
  Print model parameters in plot title if True.
- `style` : str (default: 'fivethirtyeight')
  Matplotlib style
- `legend_loc` : str (default: 'best')
  Where to place the plot legend: {'best', 'upper left', 'upper right', 'lower left', 'lower right'}

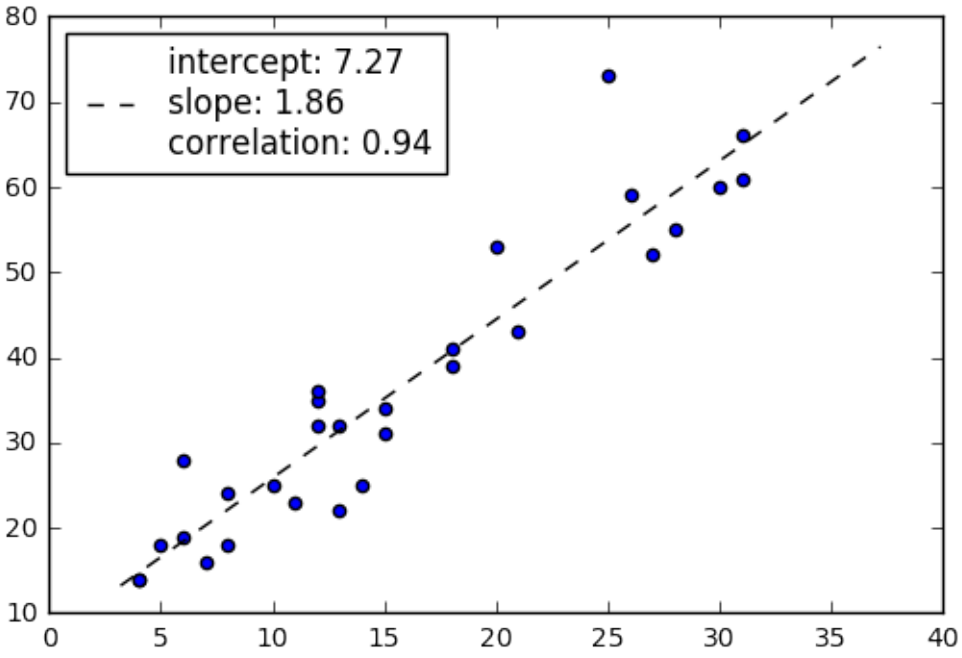
Returns

- `errors` : (training_error, test_error): tuple of lists

61 plotting.plot_linear_regression

A function to plot linear regression fits.

```
from mlxtend.plotting import plot_linear_regression
```



61.1 Overview

The `plot_linear_regression` is a convenience function that uses scikit-learn's `linear_model.LinearRegression` to fit a linear model and SciPy's `stats.pearsonr` to calculate the correlation coefficient.

61.1.1 References

- –

61.2 Example 1 - Ordinary Least Squares Simple Linear Regression

```
import matplotlib.pyplot as plt
from mlxtend.plotting import plot_linear_regression
import numpy as np

X = np.array([4, 8, 13, 26, 31, 10, 8, 30, 18, 12, 20, 5, 28, 18, 6, 31, 12,
   12, 27, 11, 6, 14, 25, 7, 13,4, 15, 21, 15])

y = np.array([14, 24, 22, 59, 66, 25, 18, 60, 39, 32, 53, 18, 55, 41, 28, 61, 35,
   36, 52, 23, 19, 25, 73, 16, 32, 14, 31, 43, 34])

intercept, slope, corr_coeff = plot_linear_regression(X, y)
plt.show()
```

61.3 API

plot_linear_regression(X, y, model=LinearRegression(copy_X=True, fit_intercept=True, n_jobs=1, normalize=False), corr_func='pearsonr', scattercolor='blue', fit_style='k–', legend=True, xlim='auto')

Plot a linear regression line fit.

Parameters

- `X` : numpy array, shape = [n_samples,]

  Samples.

- `y` : numpy array, shape (n_samples,)

  Target values model: object (default: sklearn.linear_model.LinearRegression) Estimator object for regression. Must implement a .fit() and .predict() method. corr_func: str or function (default: 'pearsonr') Uses `pearsonr` from scipy.stats if corr_func='pearsonr'. to compute the regression slope. If not 'pearsonr', the `corr_func`, the `corr_func` parameter expects a function of the form func(,) as inputs, which is expected to return a tuple `(<correlation_coefficient>, <some_unused_value>)`. scattercolor: string (default: blue) Color of scatter plot points. fit_style: string (default: k–) Style for the line fit. legend: bool (default: True) Plots legend with corr_coeff coef., fit coef., and intercept values. xlim: array-like (x_min, x_max) or 'auto' (default: 'auto') X-axis limits for the linear line fit.

Returns

- `regression_fit` : tuple

  intercept, slope, corr_coeff (float, float, float)

62 `plotting.plot_sequential_feature_selection`

A matplotlib utility function for visualizing results from `feature_selection.SequentialFeatureSelector`.

from mlxtend.plotting import plot_sequential_feature_selection

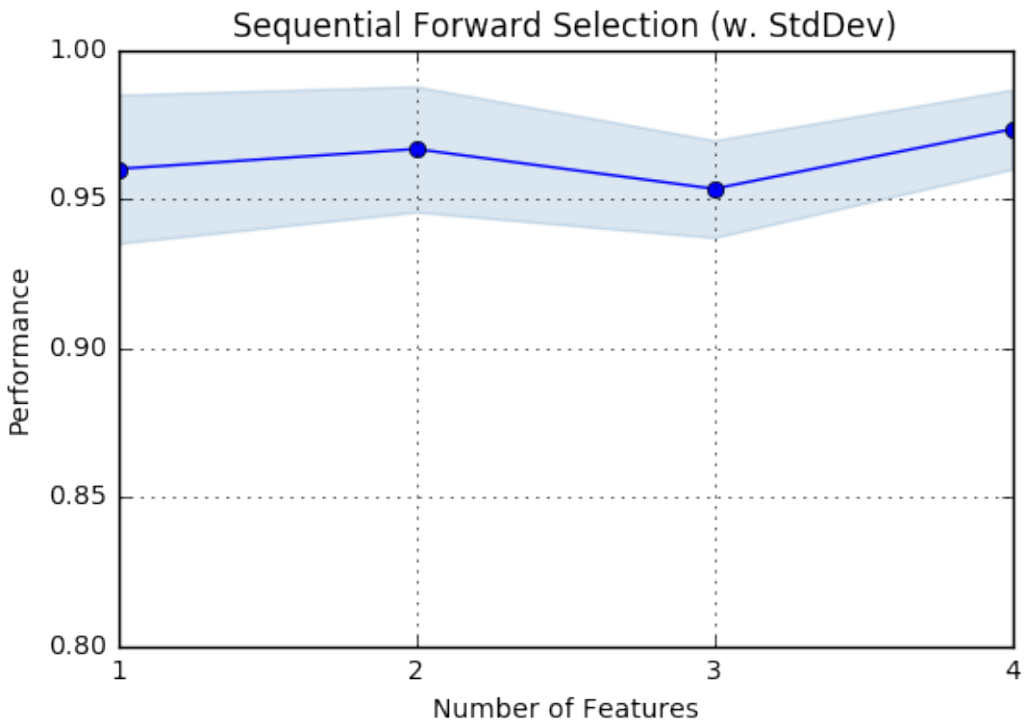
63 Overview

for more information on sequential feature selection, please see `feature_selection.SequentialFeatureSelector`.

63.1 Example 1 - Plotting the results from SequentialFeatureSelector

```
from mlxtend.plotting import plot_sequential_feature_selection as plot_sfs
from mlxtend.feature_selection import SequentialFeatureSelector as SFS
import matplotlib.pyplot as plt
from sklearn.neighbors import KNeighborsClassifier
from sklearn.datasets import load_iris

iris = load_iris()
X = iris.data
y = iris.target
knn = KNeighborsClassifier(n_neighbors=4)
```



```
sfs = SFS(knn,
          k_features=4,
          forward=True,
          floating=False,
          scoring='accuracy',
          cv=5)

sfs = sfs.fit(X, y)

fig1 = plot_sfs(sfs.get_metric_dict(), kind='std_dev')

plt.ylim([0.8, 1])
plt.title('Sequential Forward Selection (w. StdDev)')
plt.grid()
plt.show()

Features: 4/4
```

64 API

plot_sequential_feature_selection(metric_dict, kind='std_dev', color='blue', bcolor='steelblue', marker='o', alpha=0.2, ylabel='Performance', confidence_interval=0.95)

Plot feature selection results.

Parameters

- `metric_dict` : mlxtend.SequentialFeatureSelector.get_metric_dict() object
- `kind` : str (default: "std_dev")
  The kind of error bar or confidence interval in {'std_dev', 'std_err', 'ci', None}.
- `color` : str (default: "blue")
  Color of the lineplot (accepts any matplotlib color name)
- `bcolor` : str (default: "steelblue").
  Color of the error bars / confidence intervals (accepts any matplotlib color name).
- `marker` : str (default: "o")
  Marker of the line plot (accepts any matplotlib marker name).
- `alpha` : float in [0, 1] (default: 0.2)
  Transparency of the error bars / confidence intervals.
- `ylabel` : str (default: "Performance")
  Y-axis label.
- `confidence_interval` : float (default: 0.95)
  Confidence level if `kind='ci'`.

Returns

- `fig` : matplotlib.pyplot.figure() object

65 plotting.stacked_barplot

A function to conveniently plot stacked bar plots in matplotlib using pandas `DataFrame`s.

```
from mlxtend.general_plotting import category_scatter
```

65.1 Overview

A matplotlib convenience function for creating barplots from DataFrames where each sample is associated with several categories.

65.1.1 References

- –

65.2 Example 1 - Stacked Barplot from Pandas DataFrames

```
import pandas as pd

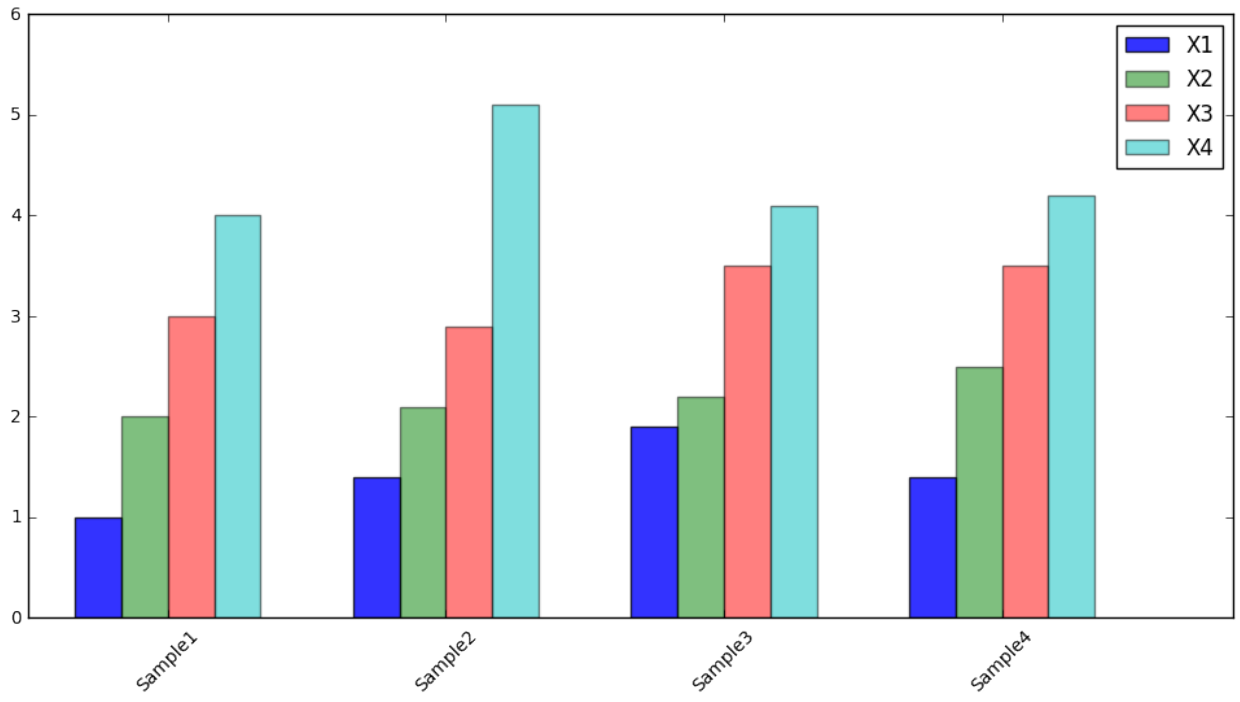
s1 = [1.0, 2.0, 3.0, 4.0]
s2 = [1.4, 2.1, 2.9, 5.1]
s3 = [1.9, 2.2, 3.5, 4.1]
s4 = [1.4, 2.5, 3.5, 4.2]
data = [s1, s2, s3, s4]

df = pd.DataFrame(data, columns=['X1', 'X2', 'X3', 'X4'])
df.columns = ['X1', 'X2', 'X3', 'X4']
df.index = ['Sample1', 'Sample2', 'Sample3', 'Sample4']
df
```

```
<tr style="text-align: right;">
  <th></th>
  <th>X1</th>
  <th>X2</th>
  <th>X3</th>
  <th>X4</th>
</tr>

<tr>
  <th>Sample1</th>
  <td>1.0</td>
  <td>2.0</td>
  <td>3.0</td>
  <td>4.0</td>
</tr>
<tr>
  <th>Sample2</th>
  <td>1.4</td>
  <td>2.1</td>
  <td>2.9</td>
  <td>5.1</td>
</tr>
<tr>
  <th>Sample3</th>
  <td>1.9</td>
  <td>2.2</td>
  <td>3.5</td>
  <td>4.1</td>
</tr>
<tr>
  <th>Sample4</th>
  <td>1.4</td>
  <td>2.5</td>
  <td>3.5</td>
  <td>4.2</td>
</tr>
```

By default, the index of the `DataFrame` is used as column labels, and the `DataFrame` columns are used for the plot legend.



```
import matplotlib.pyplot as plt
from mlxtend.plotting import stacked_barplot

fig = stacked_barplot(df, rotation=45, legend_loc='best')
```

65.3 API

stacked_barplot(df, bar_width='auto', colors='bgrcky', labels='index', rotation=90, legend_loc='best')

Function to plot stacked barplots

Parameters

- `df` : pandas.DataFrame

  A pandas DataFrame where the index denotes the x-axis labels, and the columns contain the different measurements for each row. bar_width: 'auto' or float (default: 'auto') Parameter to set the widths of the bars. if 'auto', the width is automatically determined by the number of columns in the dataset. colors: str (default: 'bgrcky') The colors of the bars. labels: 'index' or iterable (default: 'index') If 'index', the DataFrame index will be used as x-tick labels. rotation: int (default: 90) Parameter to rotate the x-axis labels.

- `legend_loc` : str (default: 'best')

  Location of the plot legend {best, upper left, upper right, lower left, lower right} No legend if legend_loc=False

Returns

- `fig` : matplotlib.pyplot figure object

66 preprocessing.CopyTransformer

A simple transformer that returns a copy of the input array, for example, as part of a scikit-learn pipeline.

> from mlxtend.preprocessing import CopyTransformer

66.1 Example 1

```
from sklearn.pipeline import Pipeline
from sklearn.model_selection import GridSearchCV
from sklearn.ensemble import RandomForestClassifier
from sklearn.feature_extraction.text import CountVectorizer
from mlxtend.preprocessing import CopyTransformer
import re
import numpy as np

X_train = np.array(['abc def ghi', 'this is a test',
                    'this is a test', 'this is a test'])
y_train = np.array([0, 0, 1, 1])

pipe_1 = Pipeline([
    ('vect', CountVectorizer()),
    ('to_dense', CopyTransformer()),
    ('clf', RandomForestClassifier())
])

parameters_1 = dict(
    clf__n_estimators=[50, 100, 200],
    clf__max_features=['sqrt', 'log2', None],)

grid_search_1 = GridSearchCV(pipe_1,
                             parameters_1,
                             n_jobs=1,
                             verbose=1,
                             scoring='accuracy',
                             cv=2)

print("Performing grid search...")
print("pipeline:", [name for name, _ in pipe_1.steps])
print("parameters:")
grid_search_1.fit(X_train, y_train)
print("Best score: %0.3f" % grid_search_1.best_score_)
print("Best parameters set:")
best_parameters_1 = grid_search_1.best_estimator_.get_params()
for param_name in sorted(parameters_1.keys()):
    print("\t%s: %r" % (param_name, best_parameters_1[param_name]))

Performing grid search...
pipeline: ['vect', 'to_dense', 'clf']
parameters:
Fitting 2 folds for each of 9 candidates, totalling 18 fits
```

```
Best score: 0.500
Best parameters set:
    clf__max_features: 'sqrt'
    clf__n_estimators: 50

[Parallel(n_jobs=1)]: Done  18 out of  18 | elapsed:    2.9s finished
```

66.2 API

CopyTransformer()

Transformer that returns a copy of the input array

66.2.1 Methods

fit(X, y=None)

Mock method. Does nothing.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` : array-like, shape = [n_samples] (default: None)

Returns

self

fit_transform(X, y=None)

Return a copy of the input array.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` : array-like, shape = [n_samples] (default: None)

Returns

- `X_copy` : copy of the input X array.

get_params(deep=True)

Get parameters for this estimator.

Parameters

- `deep` : boolean, optional
  If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- `params` : mapping of string to any
  Parameter names mapped to their values.

*set_params(**params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

transform(X, y=None)

Return a copy of the input array.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` : array-like, shape = [n_samples] (default: None)

Returns

- `X_copy` : copy of the input X array.

67 preprocessing.DenseTransformer

A simple transformer that converts a sparse into a dense numpy array, e.g., required for scikit-learn's `Pipeline` when, for example, `CountVectorizers` are used in combination with estimators that are not compatible with sparse matrices.

> from mlxtend.preprocessing import DenseTransformer

67.1 Example 1

```
from sklearn.pipeline import Pipeline
from sklearn.model_selection import GridSearchCV
from sklearn.ensemble import RandomForestClassifier
from sklearn.feature_extraction.text import CountVectorizer
from mlxtend.preprocessing import DenseTransformer
import re
import numpy as np

X_train = np.array(['abc def ghi', 'this is a test',
                    'this is a test', 'this is a test'])
y_train = np.array([0, 0, 1, 1])
```

```
pipe_1 = Pipeline([
    ('vect', CountVectorizer()),
    ('to_dense', DenseTransformer()),
    ('clf', RandomForestClassifier())
])

parameters_1 = dict(
    clf__n_estimators=[50, 100, 200],
    clf__max_features=['sqrt', 'log2', None],)

grid_search_1 = GridSearchCV(pipe_1,
                             parameters_1,
                             n_jobs=1,
                             verbose=1,
                             scoring='accuracy',
                             cv=2)

print("Performing grid search...")
print("pipeline:", [name for name, _ in pipe_1.steps])
print("parameters:")
grid_search_1.fit(X_train, y_train)
print("Best score: %0.3f" % grid_search_1.best_score_)
print("Best parameters set:")
best_parameters_1 = grid_search_1.best_estimator_.get_params()
for param_name in sorted(parameters_1.keys()):
    print("\t%s: %r" % (param_name, best_parameters_1[param_name]))

Performing grid search...
pipeline: ['vect', 'to_dense', 'clf']
parameters:
Fitting 2 folds for each of 9 candidates, totalling 18 fits
Best score: 0.500
Best parameters set:
    clf__max_features: 'sqrt'
    clf__n_estimators: 50

[Parallel(n_jobs=1)]: Done  18 out of  18 | elapsed:    3.9s finished
```

67.2 API

DenseTransformer(return_copy=True)

Convert a sparse array into a dense array.

67.2.1 Methods

fit(X, y=None)

Mock method. Does nothing.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` : array-like, shape = [n_samples] (default: None)

Returns

self

fit_transform(X, y=None)

Return a dense version of the input array.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` : array-like, shape = [n_samples] (default: None)

Returns

- `X_dense` : dense version of the input X array.

get_params(deep=True)

Get parameters for this estimator.

Parameters

- `deep` : boolean, optional
  If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- `params` : mapping of string to any
  Parameter names mapped to their values.

*set_params(**params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

transform(X, y=None)

Return a dense version of the input array.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.
- `y` : array-like, shape = [n_samples] (default: None)

Returns

- `X_dense` : dense version of the input X array.

68 preprocessing.MeanCenterer

A transformer object that performs column-based mean centering on a NumPy array.

from mlxtend.preprocessing import MeanCenterer

68.1 Example 1 - Centering a NumPy Array

Use the `fit` method to fit the column means of a dataset (e.g., the training dataset) to a new `MeanCenterer` object. Then, call the `transform` method on the same dataset to center it at the sample mean.

```
import numpy as np
from mlxtend.preprocessing import MeanCenterer
X_train = np.array(
                    [[1, 2, 3],
                     [4, 5, 6],
                     [7, 8, 9]])
mc = MeanCenterer().fit(X_train)
mc.transform(X_train)

array([[-3., -3., -3.],
       [ 0.,  0.,  0.],
       [ 3.,  3.,  3.]])
```

68.2 API

MeanCenterer()

Column centering of vectors and matrices.

Attributes

- `col_means` : numpy.ndarray [n_columns]
  NumPy array storing the mean values for centering after fitting the MeanCenterer object.

68.2.1 Methods

fit(X)

Gets the column means for mean centering.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Array of data vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

self

fit_transform(X)

Fits and transforms an arry.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  Array of data vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `X_tr` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  A copy of the input array with the columns centered.

transform(X)

Centers a NumPy array.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  Array of data vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `X_tr` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  A copy of the input array with the columns centered.

69 preprocessing.minmax_scaling

A function for min-max scaling of pandas DataFrames or NumPy arrays.

```
from mlxtend.preprocessing import MinMaxScaling
```

An alternative approach to Z-score normalization (or standardization) is the so-called Min-Max scaling (often also simply called "normalization" - a common cause for ambiguities). In this approach, the data is scaled to a fixed range - usually 0 to 1. The cost of having this bounded range - in contrast to standardization - is that we will end up with smaller standard deviations, which can suppress the effect of outliers.

A Min-Max scaling is typically done via the following equation:

$$X_{sc} = \frac{X - X_{min}}{X_{max} - X_{min}}.$$

One family of algorithms that is scale-invariant encompasses tree-based learning algorithms. Let's take the general CART decision tree algorithm. Without going into much depth regarding information gain and impurity measures, we can think of the decision as "is feature x_i >= some_val?" Intuitively, we can see that it really doesn't matter on which scale this feature is (centimeters, Fahrenheit, a standardized scale – it really doesn't matter).

Some examples of algorithms where feature scaling matters are:

- k-nearest neighbors with an Euclidean distance measure if want all features to contribute equally
- k-means (see k-nearest neighbors)

- logistic regression, SVMs, perceptrons, neural networks etc. if you are using gradient descent/ascent-based optimization, otherwise some weights will update much faster than others
- linear discriminant analysis, principal component analysis, kernel principal component analysis since you want to find directions of maximizing the variance (under the constraints that those directions/eigenvectors/principal components are orthogonal); you want to have features on the same scale since you'd emphasize variables on "larger measurement scales" more.

There are many more cases than I can possibly list here … I always recommend you to think about the algorithm and what it's doing, and then it typically becomes obvious whether we want to scale your features or not.

In addition, we'd also want to think about whether we want to "standardize" or "normalize" (here: scaling to [0, 1] range) our data. Some algorithms assume that our data is centered at 0. For example, if we initialize the weights of a small multi-layer perceptron with tanh activation units to 0 or small random values centered around zero, we want to update the model weights "equally." As a rule of thumb I'd say: When in doubt, just standardize the data, it shouldn't hurt.

69.1 Example 1 - Scaling a Pandas DataFrame

```
import pandas as pd

s1 = pd.Series([1, 2, 3, 4, 5, 6], index=(range(6)))
s2 = pd.Series([10, 9, 8, 7, 6, 5], index=(range(6)))
df = pd.DataFrame(s1, columns=['s1'])
df['s2'] = s2
df
```

```
<tr style="text-align: right;">
  <th></th>
  <th>s1</th>
  <th>s2</th>
</tr>

<tr>
  <th>0</th>
  <td>1</td>
  <td>10</td>
</tr>
<tr>
  <th>1</th>
  <td>2</td>
  <td>9</td>
</tr>
<tr>
  <th>2</th>
  <td>3</td>
  <td>8</td>
</tr>
<tr>
  <th>3</th>
  <td>4</td>
  <td>7</td>
</tr>
```

```
<tr>
  <th>4</th>
  <td>5</td>
  <td>6</td>
</tr>
<tr>
  <th>5</th>
  <td>6</td>
  <td>5</td>
</tr>
```

```
from mlxtend.preprocessing import minmax_scaling

minmax_scaling(df, columns=['s1', 's2'])
```

```
<tr style="text-align: right;">
  <th></th>
  <th>s1</th>
  <th>s2</th>
</tr>
```

  <td>1.0</td>
  <td>0.0</td>
</tr>
```

69.2 Example 2 - Scaling a NumPy Array

```
import numpy as np

X = np.array([[1, 10], [2, 9], [3, 8],
              [4, 7], [5, 6], [6, 5]])
X
```

```
array([[ 1, 10],
       [ 2,  9],
       [ 3,  8],
       [ 4,  7],
       [ 5,  6],
       [ 6,  5]])
```

```
from mlxtend.preprocessing import minmax_scaling

minmax_scaling(X, columns=[0, 1])
```

```
array([[ 0. ,  1. ],
       [ 0.2,  0.8],
       [ 0.4,  0.6],
       [ 0.6,  0.4],
       [ 0.8,  0.2],
       [ 1. ,  0. ]])
```

69.3 API

minmax_scaling(array, columns, min_val=0, max_val=1)

Min max scaling of pandas' DataFrames.

Parameters

- `array` : pandas DataFrame or NumPy ndarray, shape = [n_rows, n_columns].
- `columns` : array-like, shape = [n_columns]
  Array-like with column names, e.g., ['col1', 'col2', ...] or column indices [0, 2, 4, ...]
- `min_val` : `int` or `float`, optional (default=`0`)
  minimum value after rescaling.
- `min_val` : `int` or `float`, optional (default=`1`)
  maximum value after rescaling.

Returns

- `df_new` : pandas DataFrame object.
  Copy of the array or DataFrame with rescaled columns.

70 preprocessing.one-hot_encoding

70.1 One-Hot Encoding

A function that performs one-hot encoding for class labels.

from mlxtend.preprocessing import one_hot

70.2 Overview

Typical supervised machine learning algorithms for classifications assume that the class labels are *nominal* (a special case of *categorical* where no order is implied). A typical example of an nominal feature would be "color" since we can't say (in most applications) that "orange > blue > red".

The `one_hot` function provides a simple interface to convert class label integers into a so-called one-hot array, where each unique label is represented as a column in the new array.

For example, let's assume we have 5 data points from 3 different classes: 0, 1, and 2.

```
y = [0, # sample 1, class 0
     1, # sample 2, class 1
     0, # sample 3, class 0
     2, # sample 4, class 2
     2] # sample 5, class 2
```

After one-hot encoding, we then obtain the following array (note that the index position of the "1" in each row denotes the class label of this sample):

```
y = [[1,  0,  0], # sample 1, class 0
     [0,  1,  0], # sample 2, class 1
     [1,  0,  0], # sample 3, class 0
     [0,  0,  1], # sample 4, class 2
     [0,  0,  1]  # sample 5, class 2
     ])
```

70.3 Example 1 - Defaults

```
from mlxtend.preprocessing import one_hot
import numpy as np

y = np.array([0, 1, 2, 1, 2])
one_hot(y)
```

```
array([[ 1.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  1.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  1.]])
```

70.4 Example 2 - Python Lists

```
from mlxtend.preprocessing import one_hot

y = [0, 1, 2, 1, 2]
one_hot(y)
```

```
array([[ 1.,  0.,  0.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  1.],
       [ 0.,  1.,  0.],
       [ 0.,  0.,  1.]])
```

70.5 Example 3 - Integer Arrays

```
from mlxtend.preprocessing import one_hot

y = [0, 1, 2, 1, 2]
one_hot(y, dtype='int')
```

```
array([[1, 0, 0],
       [0, 1, 0],
       [0, 0, 1],
       [0, 1, 0],
       [0, 0, 1]])
```

70.6 Example 4 - Arbitrary Numbers of Class Labels

```
from mlxtend.preprocessing import one_hot

y = [0, 1, 2, 1, 2]
one_hot(y, num_labels=10)
```

```
array([[ 1.,  0.,  0.,  0.,  0.,  0.,  0.,  0.,  0.,  0.],
       [ 0.,  1.,  0.,  0.,  0.,  0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  1.,  0.,  0.,  0.,  0.,  0.,  0.,  0.],
       [ 0.,  1.,  0.,  0.,  0.,  0.,  0.,  0.,  0.,  0.],
       [ 0.,  0.,  1.,  0.,  0.,  0.,  0.,  0.,  0.,  0.]])
```

70.7 API

one_hot(y, num_labels='auto', dtype='float')

One-hot encoding of class labels

Parameters

- y : array-like, shape = [n_classlabels]

  Python list or numpy array consisting of class labels.

- `num_labels` : int or 'auto'

  Number of unique labels in the class label array. Infers the number of unique labels from the input array if set to 'auto'.

- `dtype` : str

  NumPy array type (float, float32, float64) of the output array.

Returns

- `ary` : numpy.ndarray, shape = [n_classlabels]

  One-hot encoded array, where each sample is represented as a row vector in the returned array.

71 preprocessing.OnehotTransactions

71.1 One-Hot Encoding of Transaction Data

One-hot encoder class for transaction data in Python lists

    from mlxtend.preprocessing import OnehotTransactions

71.2 Overview

Encodes database transaction data in form of a Python list of lists into a one-hot encoded NumPy integer array.

71.3 Example 1

Suppose we have the following transaction data:

```
from mlxtend.preprocessing import OnehotTransactions

dataset = [['Apple', 'Beer', 'Rice', 'Chicken'],
           ['Apple', 'Beer', 'Rice'],
           ['Apple', 'Beer'],
           ['Apple', 'Bananas'],
           ['Milk', 'Beer', 'Rice', 'Chicken'],
           ['Milk', 'Beer', 'Rice'],
           ['Milk', 'Beer'],
           ['Apple', 'Bananas']]
```

Using and `OnehotTransaction` object, we can transform this dataset into a one-hot encoded format suitable for typical machine learning APIs. Via the `fit` method, the `OnehotTransaction` encoder learns the unique labels in the dataset, and via the `transform` method, it transforms the input dataset (a Python list of lists) into a one-hot encoded NumPy integer array:

```
oht = OnehotTransactions()
oht_ary = oht.fit(dataset).transform(dataset)
oht_ary
```

```
array([[1, 0, 1, 1, 0, 1],
       [1, 0, 1, 0, 0, 1],
       [1, 0, 1, 0, 0, 0],
       [1, 1, 0, 0, 0, 0],
       [0, 0, 1, 1, 1, 1],
       [0, 0, 1, 0, 1, 1],
       [0, 0, 1, 0, 1, 0],
       [1, 1, 0, 0, 0, 0]])
```

After fitting, the unique column names that correspond to the data array shown above can be accessed via the `columns_` attribute:

```
oht.columns_
```

```
['Apple', 'Bananas', 'Beer', 'Chicken', 'Milk', 'Rice']
```

For our convenience, we can turn the one-hot encoded array into a pandas DataFrame:

```
import pandas as pd

pd.DataFrame(oht_ary, columns=oht.columns_)
```

```
<tr style="text-align: right;">
  <th></th>
  <th>Apple</th>
  <th>Bananas</th>
  <th>Beer</th>
  <th>Chicken</th>
  <th>Milk</th>
  <th>Rice</th>
</tr>

<tr>
  <th>0</th>
  <td>1</td>
  <td>0</td>
  <td>1</td>
  <td>1</td>
  <td>0</td>
  <td>1</td>
</tr>
<tr>
  <th>1</th>
  <td>1</td>
  <td>0</td>
  <td>1</td>
  <td>0</td>
  <td>0</td>
  <td>1</td>
</tr>
<tr>
  <th>2</th>
```

```
  <td>1</td>
  <td>0</td>
  <td>1</td>
  <td>0</td>
  <td>0</td>
  <td>0</td>
</tr>
<tr>
  <th>3</th>
  <td>1</td>
  <td>1</td>
  <td>0</td>
  <td>0</td>
  <td>0</td>
  <td>0</td>
</tr>
<tr>
  <th>4</th>
  <td>0</td>
  <td>0</td>
  <td>1</td>
  <td>1</td>
  <td>1</td>
  <td>1</td>
</tr>
<tr>
  <th>5</th>
  <td>0</td>
  <td>0</td>
  <td>1</td>
  <td>0</td>
  <td>1</td>
  <td>1</td>
</tr>
<tr>
  <th>6</th>
  <td>0</td>
  <td>0</td>
  <td>1</td>
  <td>0</td>
  <td>1</td>
  <td>0</td>
</tr>
<tr>
  <th>7</th>
  <td>1</td>
  <td>1</td>
  <td>0</td>
  <td>0</td>
  <td>0</td>
  <td>0</td>
</tr>
```

If we desire, we can turn the one-hot encoded array back into a transaction list of lists via the

`inverse_transform` function:

```
first4 = oht_ary[:4]
oht.inverse_transform(first4)
```

```
[['Apple', 'Beer', 'Chicken', 'Rice'],
 ['Apple', 'Beer', 'Rice'],
 ['Apple', 'Beer'],
 ['Apple', 'Bananas']]
```

71.4 API

OnehotTransactions()

One-hot encoder class for transaction data in Python lists

Parameters

None

Attributes

columns_: list List of unique names in the `X` input list of lists

71.4.1 Methods

fit(X)

Learn unique column names from transaction DataFrame

Parameters

- `X` : list of lists

  A python list of lists, where the outer list stores the n transactions and the inner list stores the items in each transaction.

  For example, [[‘Apple’, ‘Beer’, ‘Rice’, ‘Chicken’], [‘Apple’, ‘Beer’, ‘Rice’], [‘Apple’, ‘Beer’], [‘Apple’, ‘Bananas’], [‘Milk’, ‘Beer’, ‘Rice’, ‘Chicken’], [‘Milk’, ‘Beer’, ‘Rice’], [‘Milk’, ‘Beer’], [‘Apple’, ‘Bananas’]]

fit_transform(X)

Fit a OnehotTransactions encoder and transform a dataset.

inverse_transform(onehot)

Transforms a one-hot encoded NumPy array back into transactions.

Parameters

- `onehot` : NumPy array [n_transactions, n_unique_items]

  The NumPy one-hot encoded integer array of the input transactions, where the columns represent the unique items found in the input array in alphabetic order

  For example, array([[1, 0, 1, 1, 0, 1], [1, 0, 1, 0, 0, 1], [1, 0, 1, 0, 0, 0], [1, 1, 0, 0, 0, 0], [0, 0, 1, 1, 1, 1], [0, 0, 1, 0, 1, 1], [0, 0, 1, 0, 0, 1, 0], [1, 1, 0, 0, 0, 0]]) The corresponding column labels are available as self.columns_, e.g., [‘Apple’, ‘Bananas’, ‘Beer’, ‘Chicken’, ‘Milk’, ‘Rice’]

Returns

- `X` : list of lists

  A python list of lists, where the outer list stores the n transactions and the inner list stores the items in each transaction.

  For example, [[‘Apple’, ‘Beer’, ‘Rice’, ‘Chicken’], [‘Apple’, ‘Beer’, ‘Rice’], [‘Apple’, ‘Beer’], [‘Apple’, ‘Bananas’], [‘Milk’, ‘Beer’, ‘Rice’, ‘Chicken’], [‘Milk’, ‘Beer’, ‘Rice’], [‘Milk’, ‘Beer’], [‘Apple’, ‘Bananas’]]

transform(X)

Transform transactions into a one-hot encoded NumPy array.

Parameters

- `X` : list of lists

  A python list of lists, where the outer list stores the n transactions and the inner list stores the items in each transaction.

  For example, [[‘Apple’, ‘Beer’, ‘Rice’, ‘Chicken’], [‘Apple’, ‘Beer’, ‘Rice’], [‘Apple’, ‘Beer’], [‘Apple’, ‘Bananas’], [‘Milk’, ‘Beer’, ‘Rice’, ‘Chicken’], [‘Milk’, ‘Beer’, ‘Rice’], [‘Milk’, ‘Beer’], [‘Apple’, ‘Bananas’]]

Returns

- `onehot` : NumPy array [n_transactions, n_unique_items]

  The NumPy one-hot encoded integer array of the input transactions, where the columns represent the unique items found in the input array in alphabetic order

  For example, array([[1, 0, 1, 1, 0, 1], [1, 0, 1, 0, 0, 1], [1, 0, 1, 0, 0, 0], [1, 1, 0, 0, 0, 0], [0, 0, 1, 1, 1, 1], [0, 0, 1, 0, 1, 1], [0, 0, 1, 0, 1, 0], [1, 1, 0, 0, 0, 0]]) The corresponding column labels are available as self.columns_, e.g., [‘Apple’, ‘Bananas’, ‘Beer’, ‘Chicken’, ‘Milk’, ‘Rice’]

72 preprocessing.shuffle_arrays_unison

A function for NumPy arrays in unison.

> from mlxtend.preprocessing import shuffle_arrays_unison

72.1 Example 1 - Scaling a Pandas DataFrame

```
import numpy as np
from mlxtend.preprocessing import shuffle_arrays_unison
X = np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]])
y = np.array([1, 2, 3])
print('X:\n%s' % X)
print('y:\n%s' % y)
```

```
X:
[[1 2 3]
 [4 5 6]
 [7 8 9]]
y:
[1 2 3]
```

```
X2, y2 = shuffle_arrays_unison(arrays=[X, y], random_seed=3)
print('X2:\n%s' % X2)
print('y2:\n%s' % y2)
```

```
X2:
[[4 5 6]
 [1 2 3]
 [7 8 9]]
y2:
[2 1 3]
```

72.2 API

shuffle_arrays_unison(arrays, random_seed=None)

Shuffle NumPy arrays in unison.

Parameters

- `arrays` : array-like, shape = [n_arrays]
  A list of NumPy arrays.
- `random_seed` : int (default: None)
  Sets the random state.

Returns

- `shuffled_arrays` : A list of NumPy arrays after shuffling.

Examples

```
>>> import numpy as np
>>> from mlxtend.preprocessing import shuffle_arrays_unison
>>> X1 = np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]])
>>> y1 = np.array([1, 2, 3])
>>> X2, y2 = shuffle_arrays_unison(arrays=[X1, y1], random_seed=3)
>>> assert(X2.all() == np.array([[4, 5, 6], [1, 2, 3], [7, 8, 9]]).all())
>>> assert(y2.all() == np.array([2, 1, 3]).all())
>>>
```

73 preprocessing.standardize

A function that performs column-based standardization on a NumPy array.

from mlxtend.preprocessing import standardize

73.1 Overview

The result of standardization (or Z-score normalization) is that the features will be rescaled so that they'll have the properties of a standard normal distribution with

$\mu = 0$ and $\sigma = 1$.

where μ is the mean (average) and σ is the standard deviation from the mean; standard scores (also called z scores) of the samples are calculated as

$$z = \frac{x - \mu}{\sigma}.$$

Standardizing the features so that they are centered around 0 with a standard deviation of 1 is not only important if we are comparing measurements that have different units, but it is also a general requirement for the optimal performance of many machine learning algorithms.

One family of algorithms that is scale-invariant encompasses tree-based learning algorithms. Let's take the general CART decision tree algorithm. Without going into much depth regarding information gain and impurity measures, we can think of the decision as "is feature x_i >= some_val?" Intuitively, we can see that it really doesn't matter on which scale this feature is (centimeters, Fahrenheit, a standardized scale – it really doesn't matter).

Some examples of algorithms where feature scaling matters are:

- k-nearest neighbors with an Euclidean distance measure if want all features to contribute equally
- k-means (see k-nearest neighbors)
- logistic regression, SVMs, perceptrons, neural networks etc. if you are using gradient descent/ascent-based optimization, otherwise some weights will update much faster than others
- linear discriminant analysis, principal component analysis, kernel principal component analysis since you want to find directions of maximizing the variance (under the constraints that those directions/eigenvectors/principal components are orthogonal); you want to have features on the same scale since you'd emphasize variables on "larger measurement scales" more.

There are many more cases than I can possibly list here … I always recommend you to think about the algorithm and what it's doing, and then it typically becomes obvious whether we want to scale your features or not.

In addition, we'd also want to think about whether we want to "standardize" or "normalize" (here: scaling to [0, 1] range) our data. Some algorithms assume that our data is centered at 0. For example, if we initialize the weights of a small multi-layer perceptron with tanh activation units to 0 or small random values centered around zero, we want to update the model weights "equally." As a rule of thumb I'd say: When in doubt, just standardize the data, it shouldn't hurt.

73.2 Example 1 - Standardize a Pandas DataFrame

```
import pandas as pd

s1 = pd.Series([1, 2, 3, 4, 5, 6], index=(range(6)))
s2 = pd.Series([10, 9, 8, 7, 6, 5], index=(range(6)))
df = pd.DataFrame(s1, columns=['s1'])
df['s2'] = s2
df
```

```
<tr style="text-align: right;">
  <th></th>
  <th>s1</th>
  <th>s2</th>
</tr>

<tr>
  <th>0</th>
  <td>1</td>
  <td>10</td>
</tr>
<tr>
  <th>1</th>
  <td>2</td>
  <td>9</td>
</tr>
<tr>
  <th>2</th>
  <td>3</td>
  <td>8</td>
</tr>
<tr>
  <th>3</th>
  <td>4</td>
  <td>7</td>
</tr>
<tr>
  <th>4</th>
  <td>5</td>
  <td>6</td>
</tr>
<tr>
  <th>5</th>
  <td>6</td>
  <td>5</td>
</tr>
```

```
from mlxtend.preprocessing import standardize
standardize(df, columns=['s1', 's2'])
```

```
<tr style="text-align: right;">
  <th></th>
  <th>s1</th>
  <th>s2</th>
</tr>

<tr>
  <th>0</th>
  <td>-1.46385</td>
  <td>1.46385</td>
</tr>
<tr>
  <th>1</th>
```

```
  <td>-0.87831</td>
  <td>0.87831</td>
</tr>
<tr>
  <th>2</th>
  <td>-0.29277</td>
  <td>0.29277</td>
</tr>
<tr>
  <th>3</th>
  <td>0.29277</td>
  <td>-0.29277</td>
</tr>
<tr>
  <th>4</th>
  <td>0.87831</td>
  <td>-0.87831</td>
</tr>
<tr>
  <th>5</th>
  <td>1.46385</td>
  <td>-1.46385</td>
</tr>
```

73.3 Example 2 - Standardize a NumPy Array

```
import numpy as np

X = np.array([[1, 10], [2, 9], [3, 8], [4, 7], [5, 6], [6, 5]])
X
```

```
array([[ 1, 10],
       [ 2,  9],
       [ 3,  8],
       [ 4,  7],
       [ 5,  6],
       [ 6,  5]])
```

```
from mlxtend.preprocessing import standardize
standardize(X, columns=[0, 1])
```

```
array([[-1.46385011,  1.46385011],
       [-0.87831007,  0.87831007],
       [-0.29277002,  0.29277002],
       [ 0.29277002, -0.29277002],
       [ 0.87831007, -0.87831007],
       [ 1.46385011, -1.46385011]])
```

73.4 Example 3 - Re-using parameters

In machine learning contexts, it is desired to re-use the parameters that have been obtained from a training set to scale new, future data (including the independent test set). By setting `return_params=True`, the

`standardize` function returns a second object, a parameter dictionary containing the column means and standard deviations that can be re-used by feeding it to the `params` parameter upon function call.

```
import numpy as np
from mlxtend.preprocessing import standardize

X_train = np.array([[1, 10], [4, 7], [3, 8]])
X_test = np.array([[1, 2], [3, 4], [5, 6]])

X_train_std, params = standardize(X_train,
                                  columns=[0, 1],
                                  return_params=True)
X_train_std
```

```
array([[-1.33630621,  1.33630621],
       [ 1.06904497, -1.06904497],
       [ 0.26726124, -0.26726124]])
```

```
params
```

```
{'avgs': array([ 2.66666667,  8.33333333]),
 'stds': array([ 1.24721913,  1.24721913])}
```

```
X_test_std = standardize(X_test,
                         columns=[0, 1],
                         params=params)
X_test_std
```

```
array([[-1.33630621, -5.0779636 ],
       [ 0.26726124, -3.47439614],
       [ 1.87082869, -1.87082869]])
```

73.5 API

standardize(array, columns=None, ddof=0, return_params=False, params=None)

Standardize columns in pandas DataFrames.

Parameters

- `array` : pandas DataFrame or NumPy ndarray, shape = [n_rows, n_columns].
- `columns` : array-like, shape = [n_columns] (default: None)

  Array-like with column names, e.g., [‘col1’, ‘col2’, …] or column indices [0, 2, 4, …] If None, standardizes all columns.
- `ddof` : int (default: 0)

  Delta Degrees of Freedom. The divisor used in calculations is N - ddof, where N represents the number of elements.
- `return_params` : dict (default: False)

  If set to True, a dictionary is returned in addition to the standardized array. The parameter dictionary contains the column means (‘avgs’) and standard deviations (‘stds’) of the individual columns.

- `params` : dict (default: None)

  A dictionary with column means and standard deviations as returned by the `standardize` function if `return_params` was set to True. If a `params` dictionary is provided, the `standardize` function will use these instead of computing them from the current array.

Notes

If all values in a given column are the same, these values are all set to `0.0`. The standard deviation in the `parameters` dictionary is consequently set to `1.0` to avoid dividing by zero.

Returns

- `df_new` : pandas DataFrame object.

  Copy of the array or DataFrame with standardized columns.

74 regressor.LinearRegression

A implementation of Ordinary Least Squares simple and multiple linear regression.

```
from mlxtend.regressor import LinearRegression
```

74.1 Overview

Illustration of a simple linear regression model:

In Ordinary Least Squares (OLS) Linear Regression, our goal is to find the line (or hyperplane) that minimizes the vertical offsets. Or in other words, we define the best-fitting line as the line that minimizes the sum of squared errors (SSE) or mean squared error (MSE) between our target variable (y) and our predicted output over all samples i in our dataset of size n.

$$SSE = \sum_i \left(\text{target}^{(i)} - \text{output}^{(i)}\right)^2$$

$$MSE = \frac{1}{n} \times SSE$$

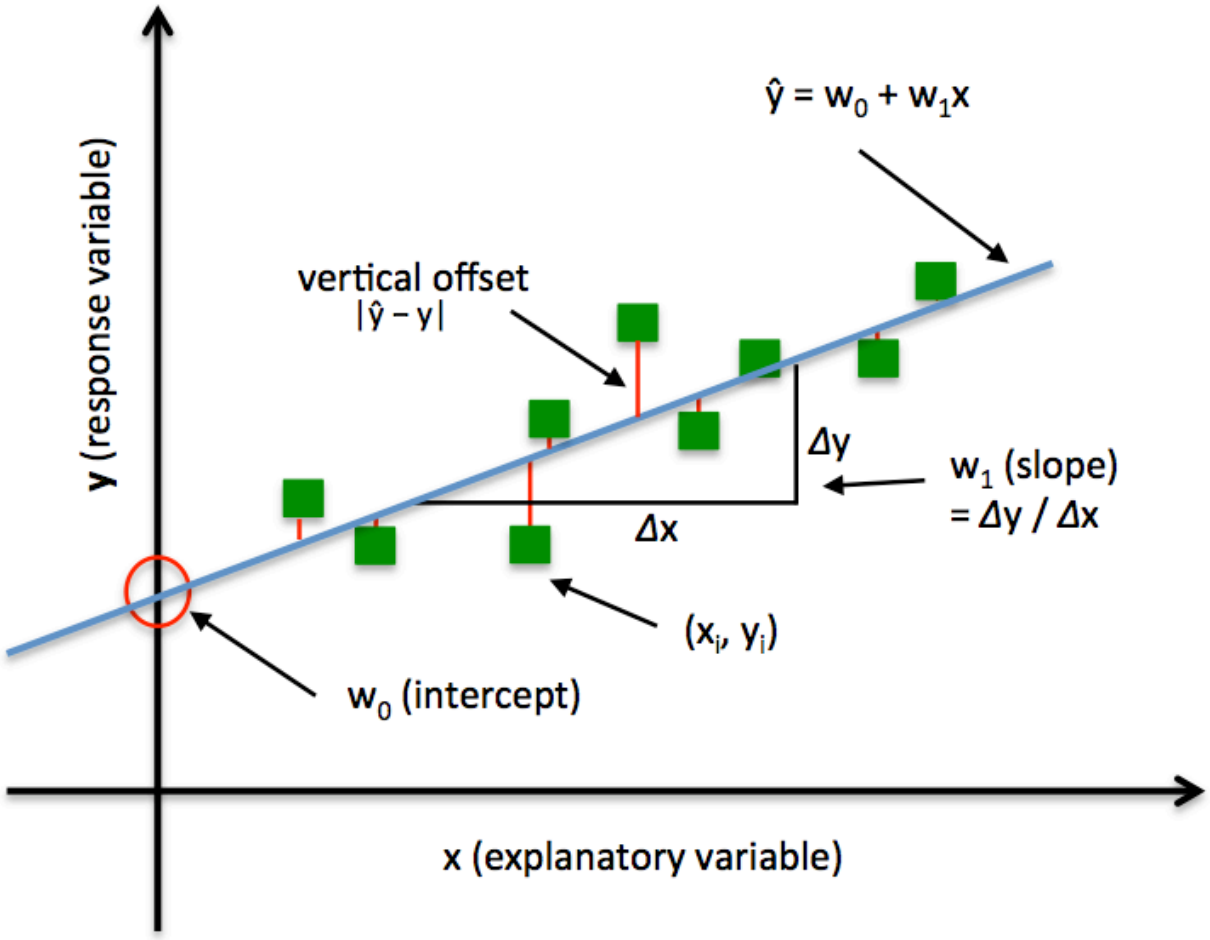
Now, `LinearRegression` implements a linear regression model for performing ordinary least squares regression using one of the following three approaches:

- Normal Equations
- Gradient Descent
- Stochastic Gradient Descent

74.1.1 Normal Equations (closed-form solution)

The closed-form solution should be preferred for "smaller" datasets where calculating (a "costly") matrix inverse is not a concern. For very large datasets, or datasets where the inverse of $[X^T X]$ may not exist (the matrix is non-invertible or singular, e.g., in case of perfect multicollinearity), the gradient descent or stochastic gradient descent approaches are to be preferred.

The linear function (linear regression model) is defined as:



ŷ = w0 + w1x
vertical offset
|ŷ − y|
y (response variable)
Δy
w1 (slope)
= Δy / Δx
Δx
(xi, yi)
w0 (intercept)
x (explanatory variable)

$$y = w_0 x_0 + w_1 x_1 + ... + w_m x_m = \sum_{i=0}^{n} = \mathbf{w}^T \mathbf{x}$$

where y is the response variable, $\mathbf{x}$ is an m-dimensional sample vector, and $\mathbf{w}$ is the weight vector (vector of coefficients). Note that w_0 represents the y-axis intercept of the model and therefore $x_0 = 1$.

Using the closed-form solution (normal equation), we compute the weights of the model as follows:

$$\mathbf{w} = (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T y$$

74.1.2 Gradient Descent (GD) and Stochastic Gradient Descent (SGD)

See Gradient Descent and Stochastic Gradient Descent and Deriving the Gradient Descent Rule for Linear Regression and Adaline for details.

Random shuffling is implemented as:

- for one or more epochs
  - randomly shuffle samples in the training set
    - for training sample i
      - compute gradients and perform weight updates

74.2 Example 1 - Closed Form Solution

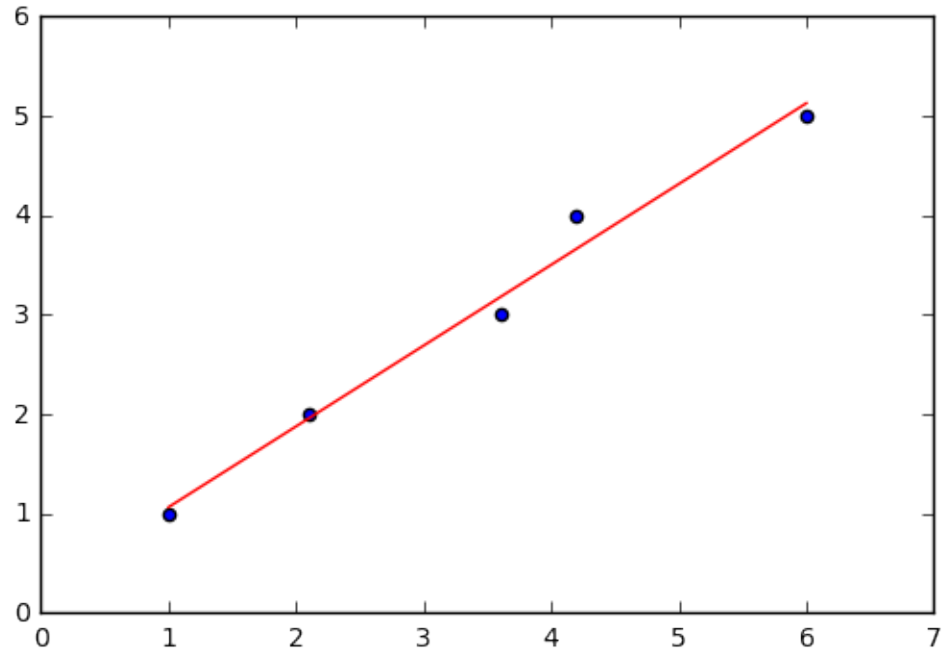
```
import numpy as np
import matplotlib.pyplot as plt
from mlxtend.regressor import LinearRegression

X = np.array([ 1.0, 2.1, 3.6, 4.2, 6])[:, np.newaxis]
y = np.array([ 1.0, 2.0, 3.0, 4.0, 5.0])

ne_lr = LinearRegression(minibatches=None)
ne_lr.fit(X, y)

print('Intercept: %.2f' % ne_lr.b_)
print('Slope: %.2f' % ne_lr.w_[0])

def lin_regplot(X, y, model):
    plt.scatter(X, y, c='blue')
    plt.plot(X, model.predict(X), color='red')
    return
```



```
lin_regplot(X, y, ne_lr)
plt.show()

Intercept: 0.25
Slope: 0.81
```

74.3 Example 2 - Gradient Descent

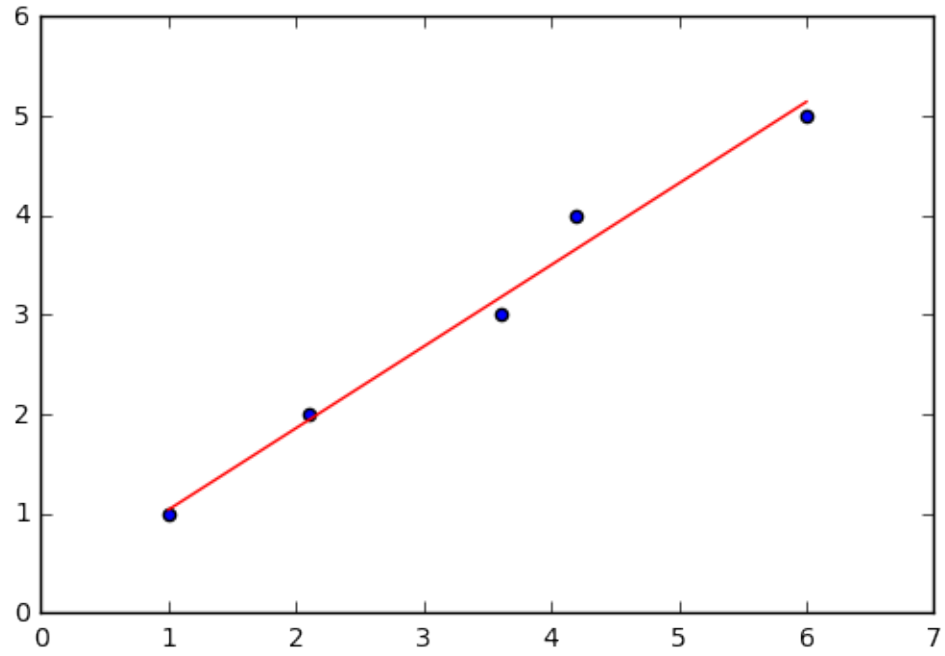
```
import numpy as np
import matplotlib.pyplot as plt
from mlxtend.regressor import LinearRegression

X = np.array([ 1.0, 2.1, 3.6, 4.2, 6])[:, np.newaxis]
y = np.array([ 1.0, 2.0, 3.0, 4.0, 5.0])

gd_lr = LinearRegression(eta=0.005,
                         epochs=100,
                         minibatches=1,
                         random_seed=123,
                         print_progress=3)
gd_lr.fit(X, y)

print('Intercept: %.2f' % gd_lr.w_)
print('Slope: %.2f' % gd_lr.b_)

def lin_regplot(X, y, model):
    plt.scatter(X, y, c='blue')
```



```
    plt.plot(X, model.predict(X), color='red')
    return

lin_regplot(X, y, gd_lr)
plt.show()
```

```
Iteration: 100/100 | Cost 0.08 | Elapsed: 0:00:00 | ETA: 0:00:00

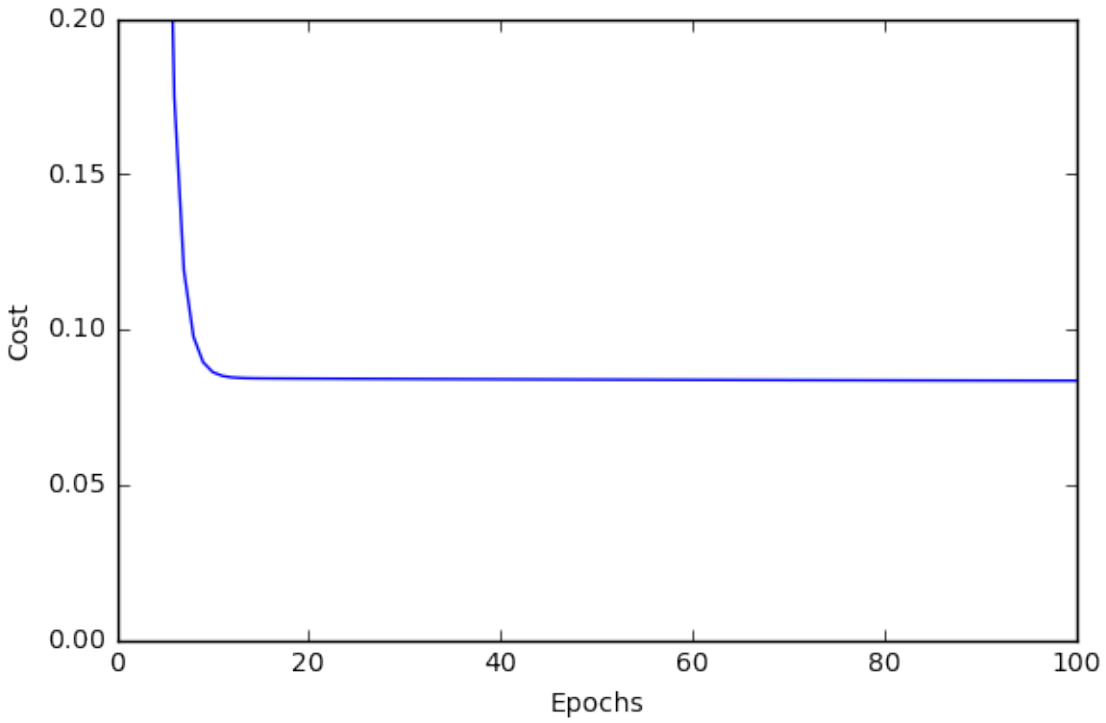
Intercept: 0.82
Slope: 0.22
```

```
# Visualizing the cost to check for convergence and plotting the linear model:

plt.plot(range(1, gd_lr.epochs+1), gd_lr.cost_)
plt.xlabel('Epochs')
plt.ylabel('Cost')
plt.ylim([0, 0.2])
plt.tight_layout()
plt.show()
```

74.4 Example 3 - Stochastic Gradient Descent

```
import numpy as np
import matplotlib.pyplot as plt
from mlxtend.regressor import LinearRegression
```



```
X = np.array([ 1.0, 2.1, 3.6, 4.2, 6])[:, np.newaxis]
y = np.array([ 1.0, 2.0, 3.0, 4.0, 5.0])

sgd_lr = LinearRegression(eta=0.01,
                          epochs=100,
                          random_seed=0,
                          minibatches=len(y))
sgd_lr.fit(X, y)

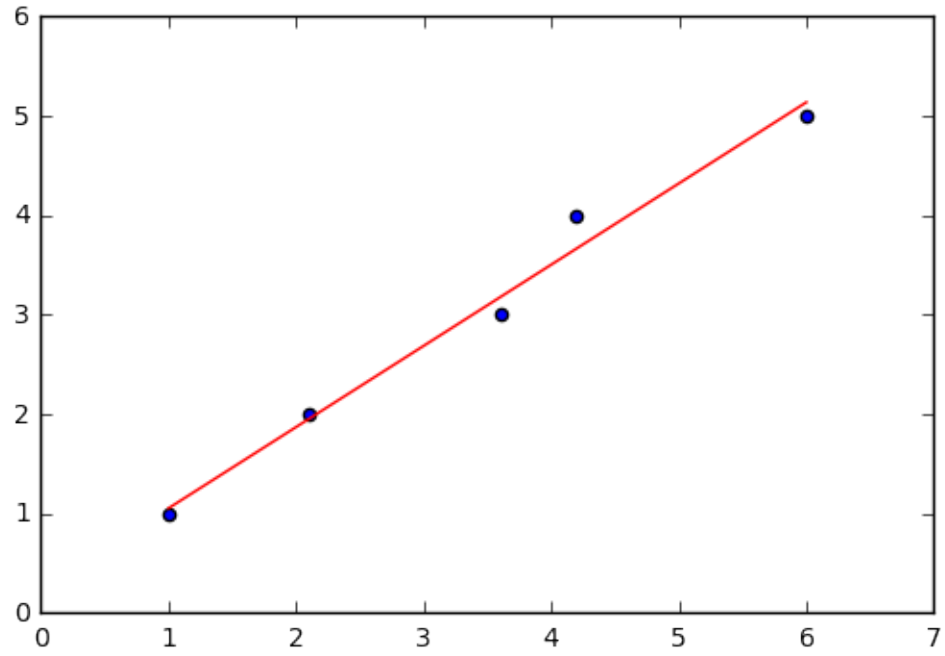
print('Intercept: %.2f' % sgd_lr.b_)
print('Slope: %.2f' % sgd_lr.w_)

def lin_regplot(X, y, model):
    plt.scatter(X, y, c='blue')
    plt.plot(X, model.predict(X), color='red')
    return

lin_regplot(X, y, sgd_lr)
plt.show()

Intercept: 0.24
Slope: 0.82

plt.plot(range(1, sgd_lr.epochs+1), sgd_lr.cost_)
plt.xlabel('Epochs')
plt.ylabel('Cost')
```



```
plt.ylim([0, 0.2])
plt.tight_layout()
plt.show()
```

74.5 Example 3 - Stochastic Gradient Descent with Minibatches

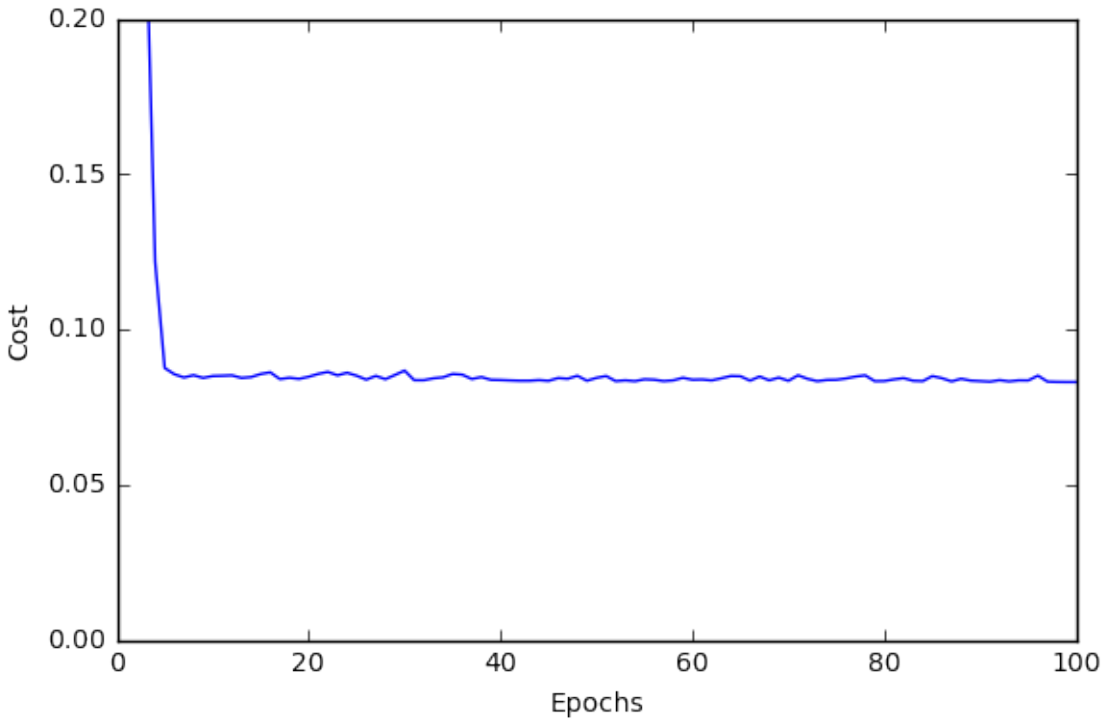
```
import numpy as np
import matplotlib.pyplot as plt
from mlxtend.regressor import LinearRegression

X = np.array([ 1.0, 2.1, 3.6, 4.2, 6])[:, np.newaxis]
y = np.array([ 1.0, 2.0, 3.0, 4.0, 5.0])

sgd_lr = LinearRegression(eta=0.01,
                          epochs=100,
                          random_seed=0,
                          minibatches=3)
sgd_lr.fit(X, y)

print('Intercept: %.2f' % sgd_lr.b_)
print('Slope: %.2f' % sgd_lr.w_)

def lin_regplot(X, y, model):
    plt.scatter(X, y, c='blue')
    plt.plot(X, model.predict(X), color='red')
    return
```



```
lin_regplot(X, y, sgd_lr)
plt.show()
```

```
Intercept: 0.24
Slope: 0.82
```

```
plt.plot(range(1, sgd_lr.epochs+1), sgd_lr.cost_)
plt.xlabel('Epochs')
plt.ylabel('Cost')
plt.ylim([0, 0.2])
plt.tight_layout()
plt.show()
```

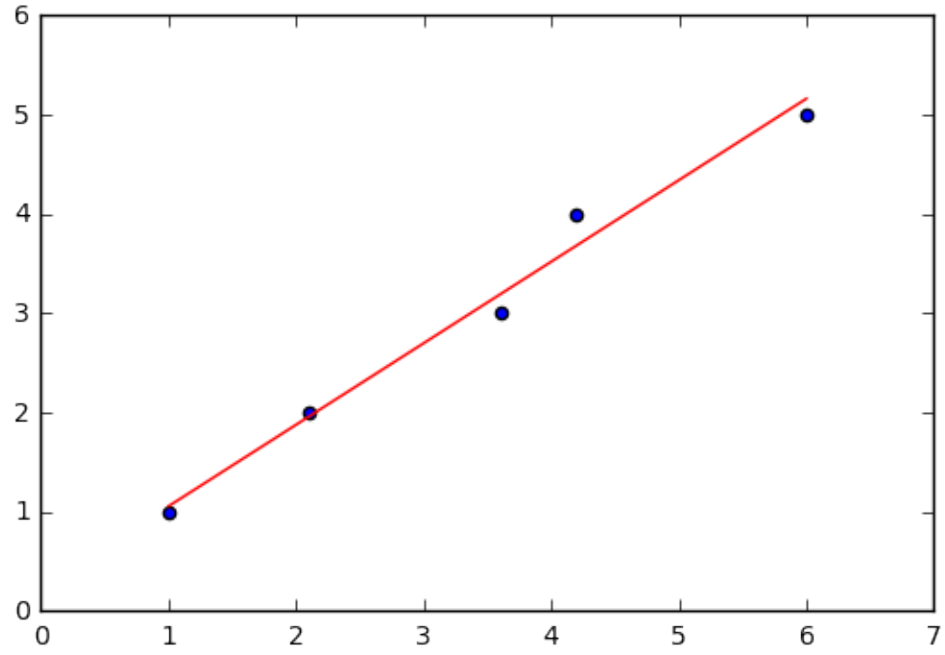
74.6 API

LinearRegression(eta=0.01, epochs=50, minibatches=None, random_seed=None, print_progress=0)

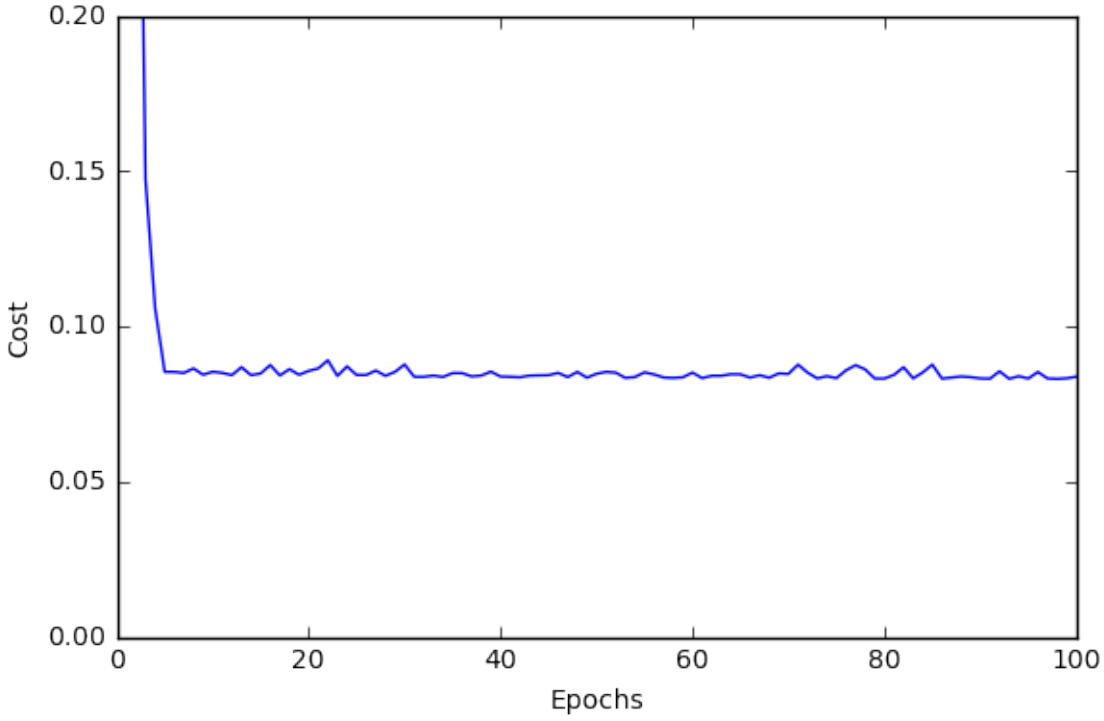
Ordinary least squares linear regression.

Parameters

- `eta` : float (default: 0.01)
  solver rate (between 0.0 and 1.0)



0
1
2
3
4
5
6
0
1
2
3
4
5
6
7



0.20
0.15
0.10
0.05
0.00
Cost
0
20
40
60
80
100
Epochs

- `epochs` : int (default: 50)

  Passes over the training dataset. Prior to each epoch, the dataset is shuffled if `minibatches > 1` to prevent cycles in stochastic gradient descent.

- `minibatches` : int (default: None)

  The number of minibatches for gradient-based optimization. If None: Normal Equations (closed-form solution) If 1: Gradient Descent learning If len(y): Stochastic Gradient Descent learning If 1 < minibatches < len(y): Minibatch learning

- `random_seed` : int (default: None)

  Set random state for shuffling and initializing the weights.

- `print_progress` : int (default: 0)

  Prints progress in fitting to stderr if not solver='normal equation' 0: No output 1: Epochs elapsed and cost 2: 1 plus time elapsed 3: 2 plus estimated time until completion

Attributes

- `w_` : 2d-array, shape={n_features, 1}

  Model weights after fitting.

- `b_` : 1d-array, shape={1,}

  Bias unit after fitting.

- `cost_` : list

  Sum of squared errors after each epoch; ignored if solver='normal equation'

74.6.1 Methods

fit(X, y, init_params=True)

Learn model from training data.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  Training vectors, where n_samples is the number of samples and n_features is the number of features.

- `y` : array-like, shape = [n_samples]

  Target values.

- `init_params` : bool (default: True)

  Re-initializes model parameters prior to fitting. Set False to continue training with weights from a previous model fitting.

Returns

- `self` : object

predict(X)

Predict targets from X.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `target_values` : array-like, shape = [n_samples]
  Predicted target values.

75 regressor.StackingCVRegressor

An ensemble-learning meta-regressor for stacking regression

    from mlxtend.regressor import StackingCVRegressor

75.1 Overview

Stacking is an ensemble learning technique to combine multiple regression models via a meta-regressor. The `StackingCVRegressor` extends the standard stacking algorithm (implemented as `StackingRegressor`) using out-of-fold predictions to prepare the input data for the level-2 classifier.

In the standard stacking procedure, the first-level regressors are fit to the same training set that is used prepare the inputs for the second-level regressor, which may lead to overfitting. The `StackingCVRegressor`, however, uses the concept of out-of-fold predictions: the dataset is split into k folds, and in k successive rounds, k-1 folds are used to fit the first level regressor. In each round, the first-level regressors are then applied to the remaining 1 subset that was not used for model fitting in each iteration. The resulting predictions are then stacked and provided – as input data – to the second-level regressor. After the training of the `StackingCVRegressor`, the first-level regressors are fit to the entire dataset for optimal predicitons.

75.1.1 References

- Breiman, Leo. "Stacked regressions." Machine learning 24.1 (1996): 49-64.
- Analogous implementation: `StackingCVClassifier`

75.2 Example 1: Boston Housing Data Predictions

In this example we evaluate some basic prediction models on the boston housing dataset and see how the R^2 and MSE scores are affected by combining the models with `StackingCVRegressor`. The code output below demonstrates that the stacked model performs the best on this dataset – slightly better than the best single regression model.

```
from mlxtend.regressor import StackingCVRegressor
from sklearn.datasets import load_boston
from sklearn.svm import SVR
from sklearn.linear_model import Lasso
from sklearn.ensemble import RandomForestRegressor
from sklearn.model_selection import cross_val_score
import numpy as np

RANDOM_SEED = 42
```

Final prediction

```
X, y = load_boston(return_X_y=True)

svr = SVR(kernel='linear')
lasso = Lasso()
rf = RandomForestRegressor(n_estimators=5,
                           random_state=RANDOM_SEED)

# The StackingCVRegressor uses scikit-learn's check_cv
# internally, which doesn't support a random seed. Thus
# NumPy's random seed need to be specified explicitely for
# deterministic behavior
np.random.seed(RANDOM_SEED)
stack = StackingCVRegressor(regressors=(svr, lasso, rf),
                            meta_regressor=lasso)

print('5-fold cross validation scores:\n')

for clf, label in zip([svr, lasso, rf, stack], ['SVM', 'Lasso',
                                                'Random Forest',
                                                'StackingClassifier']):
    scores = cross_val_score(clf, X, y, cv=5)
    print("R^2 Score: %0.2f (+/- %0.2f) [%s]" % (
        scores.mean(), scores.std(), label))

5-fold cross validation scores:

R^2 Score: 0.45 (+/- 0.29) [SVM]
R^2 Score: 0.43 (+/- 0.14) [Lasso]
R^2 Score: 0.52 (+/- 0.28) [Random Forest]
R^2 Score: 0.58 (+/- 0.24) [StackingClassifier]

# The StackingCVRegressor uses scikit-learn's check_cv
# internally, which doesn't support a random seed. Thus
# NumPy's random seed need to be specified explicitely for
# deterministic behavior
np.random.seed(RANDOM_SEED)
stack = StackingCVRegressor(regressors=(svr, lasso, rf),
                            meta_regressor=lasso)

print('5-fold cross validation scores:\n')

for clf, label in zip([svr, lasso, rf, stack], ['SVM', 'Lasso',
                                                'Random Forest',
                                                'StackingClassifier']):
    scores = cross_val_score(clf, X, y, cv=5, scoring='neg_mean_squared_error')
    print("Neg. MSE Score: %0.2f (+/- %0.2f) [%s]" % (
        scores.mean(), scores.std(), label))

5-fold cross validation scores:

Neg. MSE Score: -33.69 (+/- 22.36) [SVM]
Neg. MSE Score: -35.53 (+/- 16.99) [Lasso]
```

```
Neg. MSE Score: -27.32 (+/- 16.62) [Random Forest]
Neg. MSE Score: -25.64 (+/- 18.11) [StackingClassifier]
```

75.3 Example 2: GridSearchCV with Stacking

In this second example we demonstrate how `StackingCVRegressor` works in combination with `GridSearchCV`. The stack still allows tuning hyper parameters of the base and meta models!

To set up a parameter grid for scikit-learn's `GridSearch`, we simply provide the estimator's names in the parameter grid – in the special case of the meta-regressor, we append the `'meta-'` prefix.

```
from mlxtend.regressor import StackingCVRegressor
from sklearn.datasets import load_boston
from sklearn.linear_model import Lasso
from sklearn.linear_model import Ridge
from sklearn.ensemble import RandomForestRegressor
from sklearn.model_selection import GridSearchCV

X, y = load_boston(return_X_y=True)

ridge = Ridge()
lasso = Lasso()
rf = RandomForestRegressor(random_state=RANDOM_SEED)

# The StackingCVRegressor uses scikit-learn's check_cv
# internally, which doesn't support a random seed. Thus
# NumPy's random seed need to be specified explicitely for
# deterministic behavior
np.random.seed(RANDOM_SEED)
stack = StackingCVRegressor(regressors=(lasso, ridge),
                            meta_regressor=rf,
                            use_features_in_secondary=True)

params = {'lasso__alpha': [0.1, 1.0, 10.0],
          'ridge__alpha': [0.1, 1.0, 10.0]}

grid = GridSearchCV(
    estimator=stack,
    param_grid={
        'lasso__alpha': [x/5.0 for x in range(1, 10)],
        'ridge__alpha': [x/20.0 for x in range(1, 10)],
        'meta-randomforestregressor__n_estimators': [10, 100]
    },
    cv=5,
    refit=True
)

grid.fit(X, y)

print("Best: %f using %s" % (grid.best_score_, grid.best_params_))
```

```
Best: 0.673590 using {'lasso__alpha': 0.4, 'meta-randomforestregressor__n_estimators': 10, 'ridge__alpha
```

```
cv_keys = ('mean_test_score', 'std_test_score', 'params')

for r, _ in enumerate(grid.cv_results_['mean_test_score']):
    print("%0.3f +/- %0.2f %r"
          % (grid.cv_results_[cv_keys[0]][r],
             grid.cv_results_[cv_keys[1]][r] / 2.0,
             grid.cv_results_[cv_keys[2]][r]))
    if r > 10:
        break
print('...')

print('Best parameters: %s' % grid.best_params_)
print('Accuracy: %.2f' % grid.best_score_)
```

```
0.622 +/- 0.10 {'lasso__alpha': 0.2, 'meta-randomforestregressor__n_estimators': 10, 'ridge__alpha': 0.0
0.649 +/- 0.09 {'lasso__alpha': 0.2, 'meta-randomforestregressor__n_estimators': 10, 'ridge__alpha': 0.1
0.650 +/- 0.09 {'lasso__alpha': 0.2, 'meta-randomforestregressor__n_estimators': 10, 'ridge__alpha': 0.1
0.667 +/- 0.09 {'lasso__alpha': 0.2, 'meta-randomforestregressor__n_estimators': 10, 'ridge__alpha': 0.2
0.629 +/- 0.09 {'lasso__alpha': 0.2, 'meta-randomforestregressor__n_estimators': 10, 'ridge__alpha': 0.2
0.663 +/- 0.08 {'lasso__alpha': 0.2, 'meta-randomforestregressor__n_estimators': 10, 'ridge__alpha': 0.3
0.633 +/- 0.08 {'lasso__alpha': 0.2, 'meta-randomforestregressor__n_estimators': 10, 'ridge__alpha': 0.3
0.637 +/- 0.08 {'lasso__alpha': 0.2, 'meta-randomforestregressor__n_estimators': 10, 'ridge__alpha': 0.4
0.649 +/- 0.09 {'lasso__alpha': 0.2, 'meta-randomforestregressor__n_estimators': 10, 'ridge__alpha': 0.4
0.653 +/- 0.09 {'lasso__alpha': 0.2, 'meta-randomforestregressor__n_estimators': 100, 'ridge__alpha': 0
0.648 +/- 0.09 {'lasso__alpha': 0.2, 'meta-randomforestregressor__n_estimators': 100, 'ridge__alpha': 0
0.645 +/- 0.09 {'lasso__alpha': 0.2, 'meta-randomforestregressor__n_estimators': 100, 'ridge__alpha': 0
...
Best parameters: {'lasso__alpha': 0.4, 'meta-randomforestregressor__n_estimators': 10, 'ridge__alpha': 0
Accuracy: 0.67
```

Note

The `StackingCVRegressor` also enables grid search over the `regressors` argument. However, due to the current implementation of `GridSearchCV` in scikit-learn, it is not possible to search over both, differenct classifiers and classifier parameters at the same time. For instance, while the following parameter dictionary works

```
params = {'randomforestregressor__n_estimators': [1, 100],
'regressors': [(regr1, regr1, regr1), (regr2, regr3)]}
```

it will use the instance settings of `regr1`, `regr2`, and `regr3` and not overwrite it with the `'n_estimators'` settings from `'randomforestregressor__n_estimators': [1, 100]`.

75.4 API

StackingCVRegressor(regressors, meta_regressor, cv=5, shuffle=True, use_features_in_secondary=False)

A 'Stacking Cross-Validation' regressor for scikit-learn estimators.

New in mlxtend v0.7.0

Notes

The StackingCVRegressor uses scikit-learn's check_cv internally, which doesn't support a random seed. Thus NumPy's random seed need to be specified explicitely for deterministic behavior, for instance, by setting np.random.seed(RANDOM_SEED) prior to fitting the StackingCVRegressor

Parameters

- `regressors` : array-like, shape = [n_regressors]

  A list of classifiers. Invoking the `fit` method on the `StackingCVRegressor` will fit clones of these original regressors that will be stored in the class attribute `self.regr_`.

- `meta_regressor` : object

  The meta-classifier to be fitted on the ensemble of classifiers

- `cv` : int, cross-validation generator or iterable, optional (default: 5)

  Determines the cross-validation splitting strategy. Possible inputs for cv are:

  - None, to use the default 5-fold cross validation,
  - integer, to specify the number of folds in a `KFold`,
  - An object to be used as a cross-validation generator.
  - An iterable yielding train, test splits. For integer/None inputs, it will use `KFold` cross-validation

- `use_features_in_secondary` : bool (default: False)

  If True, the meta-classifier will be trained both on the predictions of the original regressors and the original dataset. If False, the meta-regressor will be trained only on the predictions of the original regressors.

- `shuffle` : bool (default: True)

  If True, and the `cv` argument is integer, the training data will be shuffled at fitting stage prior to cross-validation. If the `cv` argument is a specific cross validation technique, this argument is omitted.

75.4.1 Methods

fit(X, y, groups=None)

Fit ensemble regressors and the meta-regressor.

Parameters

- `X` : numpy array, shape = [n_samples, n_features]

  Training vectors, where n_samples is the number of samples and n_features is the number of features.

- `y` : numpy array, shape = [n_samples]

  Target values.

- `groups` : numpy array/None, shape = [n_samples]

  The group that each sample belongs to. This is used by specific folding strategies such as GroupKFold()

Returns

- `self` : object

*fit_transform(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- `X` : numpy array of shape [n_samples, n_features]
  Training set.
- `y` : numpy array of shape [n_samples]
  Target values.

Returns

- `X_new` : numpy array of shape [n_samples, n_features_new]
  Transformed array.

get_params(deep=True)

Get parameters for this estimator.

Parameters

- `deep` : boolean, optional
  If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns

- `params` : mapping of string to any
  Parameter names mapped to their values.

predict(X)

None

score(X, y, sample_weight=None)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the regression sum of squares ((y_true - y_pred) ** 2).sum() and v is the residual sum of squares ((y_true - y_true.mean()) ** 2).sum().

Best possible score is 1.0 and it can be negative (because the

model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

- `X` : array-like, shape = (n_samples, n_features)
  Test samples.
- `y` : array-like, shape = (n_samples) or (n_samples, n_outputs)
  True values for X.
- `sample_weight` : array-like, shape = [n_samples], optional
  Sample weights.

Returns

- `score` : float

  R^2 of self.predict(X) wrt. y.

*set_params(**params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

76 regressor.StackingRegressor

An ensemble-learning meta-regressor for stacking regression

    from mlxtend.regressor import StackingRegressor

76.1 Overview

Stacking regression is an ensemble learning technique to combine multiple regression models via a meta-regressor. The individual regression models are trained based on the complete training set; then, the meta-regressor is fitted based on the outputs – meta-features – of the individual regression models in the ensemble.

76.1.1 References

- Breiman, Leo. "Stacked regressions." Machine learning 24.1 (1996): 49-64.

76.2 Example 1 - Simple Stacked Regression

```
from mlxtend.regressor import StackingRegressor
from mlxtend.data import boston_housing_data
from sklearn.linear_model import LinearRegression
from sklearn.linear_model import Ridge
from sklearn.svm import SVR
import matplotlib.pyplot as plt
import numpy as np

# Generating a sample dataset
np.random.seed(1)
X = np.sort(5 * np.random.rand(40, 1), axis=0)
y = np.sin(X).ravel()
y[::5] += 3 * (0.5 - np.random.rand(8))

76.3 Example 2 - Stacked Regression and GridSearch

To set up a parameter grid for scikit-learn's `GridSearch`, we simply provide the estimator's names in the parameter grid – in the special case of the meta-regressor, we append the `'meta-'` prefix.

```
from sklearn.model_selection import GridSearchCV
from sklearn.linear_model import Lasso

# Initializing models

lr = LinearRegression()
svr_lin = SVR(kernel='linear')
ridge = Ridge(random_state=1)
lasso = Lasso(random_state=1)
svr_rbf = SVR(kernel='rbf')
regressors = [svr_lin, lr, ridge, lasso]
stregr = StackingRegressor(regressors=regressors,
                           meta_regressor=svr_rbf)

params = {'lasso__alpha': [0.1, 1.0, 10.0],
          'ridge__alpha': [0.1, 1.0, 10.0],
          'svr__C': [0.1, 1.0, 10.0],
          'meta-svr__C': [0.1, 1.0, 10.0, 100.0],
          'meta-svr__gamma': [0.1, 1.0, 10.0]}

grid = GridSearchCV(estimator=stregr,
                    param_grid=params,
                    cv=5,
                    refit=True)
grid.fit(X, y)

for params, mean_score, scores in grid.grid_scores_:
        print("%0.3f +/- %0.2f %r"
              % (mean_score, scores.std() / 2.0, params))
```

```

Note

The `StackingRegressor` also enables grid search over the `regressors` argument. However, due to the current implementation of `GridSearchCV` in scikit-learn, it is not possible to search over both, differenct classifiers and classifier parameters at the same time. For instance, while the following parameter dictionary works

```
params = {'randomforestregressor__n_estimators': [1, 100],
'regressors': [(regr1, regr1, regr1), (regr2, regr3)]}
```

it will use the instance settings of `regr1`, `regr2`, and `regr3` and not overwrite it with the `'n_estimators'` settings from `'randomforestregressor__n_estimators': [1, 100]`.

76.4 API

StackingRegressor(regressors, meta_regressor, verbose=0)

A Stacking regressor for scikit-learn estimators for regression.

Parameters

- `regressors` : array-like, shape = [n_regressors]

  A list of regressors. Invoking the `fit` method on the `StackingRegressor` will fit clones of those original regressors that will be stored in the class attribute `self.regr_`.

- `meta_regressor` : object

  The meta-regressor to be fitted on the ensemble of regressors

- `verbose` : int, optional (default=0)

  Controls the verbosity of the building process.

  - `verbose=0` (default): Prints nothing
  - `verbose=1`: Prints the number & name of the regressor being fitted
  - `verbose=2`: Prints info about the parameters of the regressor being fitted
  - `verbose>2`: Changes `verbose` param of the underlying regressor to self.verbose - 2

Attributes

- `regr_` : list, shape=[n_regressors]

  Fitted regressors (clones of the original regressors)

- `meta_regr_` : estimator

  Fitted meta-regressor (clone of the original meta-estimator)

- `coef_` : array-like, shape = [n_features]

  Model coefficients of the fitted meta-estimator

- `intercept_` : float

  Intercept of the fitted meta-estimator

76.4.1 Methods

fit(X, y)

Learn weight coefficients from training data for each regressor.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]

  Training vectors, where n_samples is the number of samples and n_features is the number of features.

- `y` : array-like, shape = [n_samples] or [n_samples, n_targets]

  Target values.

Returns

- `self` : object

*fit_transform(X, y=None, **fit_params)*

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

Parameters

- `X` : numpy array of shape [n_samples, n_features]
  Training set.
- `y` : numpy array of shape [n_samples]
  Target values.

Returns

- `X_new` : numpy array of shape [n_samples, n_features_new]
  Transformed array.

get_params(deep=True)

Return estimator parameter names for GridSearch support.

predict(X)

Predict target values for X.

Parameters

- `X` : {array-like, sparse matrix}, shape = [n_samples, n_features]
  Training vectors, where n_samples is the number of samples and n_features is the number of features.

Returns

- `y_target` : array-like, shape = [n_samples] or [n_samples, n_targets]
  Predicted target values.

score(X, y, sample_weight=None)

Returns the coefficient of determination R^2 of the prediction.

The coefficient R^2 is defined as (1 - u/v), where u is the regression sum of squares ((y_true - y_pred) ** 2).sum() and v is the residual sum of squares ((y_true - y_true.mean()) ** 2).sum().

Best possible score is 1.0 and it can be negative (because the

model can be arbitrarily worse). A constant model that always predicts the expected value of y, disregarding the input features, would get a R^2 score of 0.0.

Parameters

- `X` : array-like, shape = (n_samples, n_features)
  Test samples.
- `y` : array-like, shape = (n_samples) or (n_samples, n_outputs)
  True values for X.
- `sample_weight` : array-like, shape = [n_samples], optional
  Sample weights.

Returns

- `score` : float
  R^2 of self.predict(X) wrt. y.

*set_params(**params)*

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as pipelines). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Returns

self

76.4.2 Properties

*coef_*

None

*intercept_*

None

77 text.generalize_names

A function that converts a name into a general format `<last_name><separator><firstname letter(s)>(all lowercase)`.

> from mlxtend.text import generalize_names

77.1 Overview

A function that converts a name into a general format `<last_name><separator><firstname letter(s)>(all lowercase)`, which is useful if data is collected from different sources and is supposed to be compared or merged based on name identifiers. E.g., if names are stored in a pandas `DataFrame` column, the apply function can be used to generalize names: `df['name'] = df['name'].apply(generalize_names)`

77.1.1 References

- –

77.2 Example 1 - Defaults

```
from mlxtend.text import generalize_names

generalize_names('Pozo, José Ángel')

'pozo j'

generalize_names('José Pozo')
```

```
'pozo j'
```

```
generalize_names('José Ángel Pozo')
```

```
'pozo j'
```

77.3 Example 2 - Optional Parameters

```
from mlxtend.text import generalize_names
```

```
generalize_names("Eto'o, Samuel", firstname_output_letters=2)
```

```
'etoo sa'
```

```
generalize_names("Eto'o, Samuel", firstname_output_letters=0)
```

```
'etoo'
```

```
generalize_names("Eto'o, Samuel", output_sep=', ')
```

```
'etoo, s'
```

77.4 API

generalize_names(name, output_sep='', firstname_output_letters=1)

Generalize a person's first and last name.

Returns a person's name in the format `<last_name><separator><firstname letter(s)> (all lowercase)`

Parameters

- `name` : `str`
  Name of the player
- `output_sep` : `str` (default: '')
  String for separating last name and first name in the output.
- `firstname_output_letters` : `int`
  Number of letters in the abbreviated first name.

Returns

- `gen_name` : `str`
  The generalized name.

78 text.generalize_names_duplcheck

A function that converts a name into a general format `<last_name><separator><firstname letter(s)>` `(all lowercase)` in a `pandas DataFrame` while avoiding duplicate entries.

from mlxtend.text import generalize_names_duplcheck

78.1 Overview

Note that using `mlxtend.text.generalize_names` with few `firstname_output_letters` can result in duplicate entries. E.g., if your dataset contains the names "Adam Johnson" and "Andrew Johnson", the default setting (i.e., 1 first name letter) will produce the generalized name "johnson a" in both cases.

One solution is to increase the number of first name letters in the output by setting the parameter `firstname_output_letters` to a value larger than 1.

An alternative solution is to use the `generalize_names_duplcheck` function if you are working with pandas DataFrames.

By default, `generalize_names_duplcheck` will apply `generalize_names` to a pandas DataFrame column with the minimum number of first name letters and append as many first name letters as necessary until no duplicates are present in the given DataFrame column. An example dataset column that contains the names

78.1.1 References

- –

78.2 Example 1 - Defaults

Reading in a CSV file that has column `Name` for which we want to generalize the names:

- Samuel Eto'o
- Adam Johnson
- Andrew Johnson

```
import pandas as pd
from io import StringIO

simulated_csv = "name,some_value\n"\
                "Samuel Eto'o,1\n"\
                "Adam Johnson,1\n"\
                "Andrew Johnson,1\n"

df = pd.read_csv(StringIO(simulated_csv))
df
```

```
<tr style="text-align: right;">
  <th></th>
  <th>name</th>
  <th>some_value</th>
</tr>
```

```
<tr>
  <th>0</th>
  <td>Samuel Eto'o</td>
  <td>1</td>
</tr>
<tr>
  <th>1</th>
  <td>Adam Johnson</td>
  <td>1</td>
</tr>
<tr>
  <th>2</th>
  <td>Andrew Johnson</td>
  <td>1</td>
</tr>
```

Applying `generalize_names_duplcheck` to generate a new DataFrame with the generalized names without duplicates:

```
from mlxtend.text import generalize_names_duplcheck
df_new = generalize_names_duplcheck(df=df, col_name='name')
df_new
```

```
<tr style="text-align: right;">
  <th></th>
  <th>name</th>
  <th>some_value</th>
</tr>

<tr>
  <th>0</th>
  <td>etoo s</td>
  <td>1</td>
</tr>
<tr>
  <th>1</th>
  <td>johnson ad</td>
  <td>1</td>
</tr>
<tr>
  <th>2</th>
  <td>johnson an</td>
  <td>1</td>
</tr>
```

78.3 API

generalize_names_duplcheck(df, col_name)

Generalizes names and removes duplicates.

Applies mlxtend.text.generalize_names to a DataFrame with 1 first name letter by default and uses more first name letters if duplicates are detected.

Parameters

- `df` : `pandas.DataFrame`
  DataFrame that contains a column where generalize_names should be applied.
- `col_name` : `str`
  Name of the DataFrame column where `generalize_names` function should be applied to.

Returns

- `df_new` : `str`
  New DataFrame object where generalize_names function has been applied without duplicates.

79 `text.tokenizer`

Different functions to tokenize text.

> from mlxtend.text import tokenizer_[type]

79.1 Overview

Different functions to tokenize text for natural language processing tasks, for example such as building a bag-of-words model for text classification.

79.1.1 References

- –

79.2 Example 1 - Extract Emoticons

```
from mlxtend.text import tokenizer_emoticons

tokenizer_emoticons('</a>This :) is :( a test :-)!')

[':)', ':(', ':-)']
```

79.3 Example 2 - Extract Words and Emoticons

```
from mlxtend.text import tokenizer_words_and_emoticons

tokenizer_words_and_emoticons('</a>This :) is :( a test :-)!')

['this', 'is', 'a', 'test', ':)', ':(', ':-)']
```

79.4 API

tokenizer_emoticons(text)

Return emoticons from text

Example: >>> tokenizer_emoticons('This :) is :(a test :-)!') [':)', ':(', ':-)']

tokenizer_words_and_emoticons(text)

Convert text to lowercase words and emoticons.

Example: >>> tokenizer_words_and_emoticons('This :) is :(a test :-)!') ['this', 'is', 'a', 'test', ':)', ':(', ':-)']

80 utils.Counter

A simple progress counter to print the number of iterations and time elapsed in a for-loop execution.

from mlxtend.utils import Counter

80.1 Overview

The `Counter` class implements an object for displaying the number of iterations and time elapsed in a for-loop. Please note that the `Counter` was implemented for efficiency; thus, the `Counter` offers only very basic functionality in order to avoid relatively expensive evaluations (of if-else statements).

80.1.1 References

- –

80.2 Example 1 - Counting the iterations in a for-loop

```
from mlxtend.utils import Counter

import time

cnt = Counter()
for i in range(20):
    # do some computation
    time.sleep(0.1)
    cnt.update()

20 iter | 2 sec
```

Note that the first number displays the current iteration, and the second number shows the time elapsed after initializing the `Counter`.

80.3 API

Counter(stderr=False, start_newline=True)

Class to display the progress of for-loop iterators.

Parameters

- `stderr` : bool (default: True)
  Prints output to sys.stderr if True; uses sys.stdout otherwise.
- `start_newline` : bool (default: True)
  Prepends a new line to the counter, which prevents overwriting counters if multiple counters are printed in succession.

Attributes

- `curr_iter` : int
  The current iteration.
- `start_time` : int
  The system's time in seconds when the Counter was initialized.

80.3.1 Methods

update()

Print current iteration and time elapsed.

81 Installing mlxtend

81.0.1 PyPI

To install mlxtend, just execute

```
pip install mlxtend
```

Alternatively, you download the package manually from the Python Package Index https://pypi.python.org/pypi/mlxtend, unzip it, navigate into the package, and use the command:

```
python setup.py install
```

81.0.1.0.1 Upgrading via `pip`

To upgrade an existing version of mlxtend from PyPI, execute

```
pip install mlxtend --upgrade --no-deps
```

Please note that the dependencies (NumPy and SciPy) will also be upgraded if you omit the `--no-deps` flag; use the `--no-deps` ("no dependencies") flag if you don't want this.

81.0.2 Conda

The mlxtend package is also available through conda forge.

To install mlxtend using conda, use the following command:

```
conda install mlxtend --channel conda-forge
```

or simply

```
conda install mlxtend
```

if you added conda-forge to your channels (`conda config --add channels conda-forge`).

81.0.3 Dev Version

The mlxtend version on PyPI may always one step behind; you can install the latest development version from the GitHub repository by executing

```
pip install git+git://github.com/rasbt/mlxtend.git
```

Or, you can fork the GitHub repository from https://github.com/rasbt/mlxtend and install mlxtend from your local drive via

```
python setup.py install
```

82 Release Notes

The CHANGELOG for the current development version is available at https://github.com/rasbt/mlxtend/blob/master/docs/sources/CHANGELOG.md.

82.0.1 Version 0.9.0 (2017-10-21)

82.0.1.0.1 Downloads

- Source code (zip)
- Source code (tar.gz)

82.0.1.0.2 New Features

- Added `evaluate.permutation_test`, a permutation test for hypothesis testing (or A/B testing) to test if two samples come from the same distribution. Or in other words, a procedure to test the null hypothesis that that two groups are not significantly different (e.g., a treatment and a control group). (#250)
- Added `'leverage'` and `'conviction` as evaluation metrics to the `frequent_patterns.association_rules` function. (#246 & #247)

- Added a `loadings_` attribute to `PrincipalComponentAnalysis` to compute the factor loadings of the features on the principal components. (#251)
- Allow grid search over classifiers/regressors in ensemble and stacking estimators. (#259)
- New `make_multiplexer_dataset` function that creates a dataset generated by a n-bit Boolean multiplexer for evaluating supervised learning algorithms. (#263)
- Added a new `BootstrapOutOfBag` class, an implementation of the out-of-bag bootstrap to evaluate supervised learning algorithms. (#265)
- The parameters for `StackingClassifier`, `StackingCVClassifier`, `StackingRegressor`, `StackingCVRegressor`, and `EnsembleVoteClassifier` can now be tuned using scikit-learn's `GridSearchCV` (#254 via James Bourbeau)

82.0.1.0.3 Changes

- The `'support'` column returned by `frequent_patterns.association_rules` was changed to compute the support of "antecedant union consequent", and new `antecedant support'` and `'consequent support'` column were added to avoid ambiguity. (#245)
- Allow the `OnehotTransactions` to be cloned via scikit-learn's `clone` function, which is required by e.g., scikit-learn's `FeatureUnion` or `GridSearchCV` (via Iaroslav Shcherbatyi). (#249)

82.0.1.0.4 Bug Fixes

- Fix issues with `self._init_time` parameter in `_IterativeModel` subclasses. (#256)
- Fix imprecision bug that occurred in `plot_ecdf` when run on Python 2.7. (264)
- The vectors from SVD in `PrincipalComponentAnalysis` are no being scaled so that the eigenvalues via `solver='eigen'` and `solver='svd'` now store eigenvalues that have the same magnitudes. (#251)

82.0.2 Version 0.8.0 (2017-09-09)

82.0.2.0.1 Downloads

- Source code (zip)
- Source code (tar.gz)

82.0.2.0.2 New Features

- Added a `mlxtend.evaluate.bootstrap` that implements the ordinary nonparametric bootstrap to bootstrap a single statistic (for example, the mean. median, R^2 of a regression fit, and so forth) #232
- `SequentialFeatureSelecor`'s `k_features` now accepts a string argument "best" or "parsimonious" for more "automated" feature selection. For instance, if "best" is provided, the feature selector will return the feature subset with the best cross-validation performance. If "parsimonious" is provided as an argument, the smallest feature subset that is within one standard error of the cross-validation performance will be selected. #238

82.0.2.0.3 Changes

- `SequentialFeatureSelector` now uses `np.nanmean` over normal mean to support scorers that may return `np.nan` #211 (via mrkaiser)
- The `skip_if_stuck` parameter was removed from `SequentialFeatureSelector` in favor of a more efficient implementation comparing the conditional inclusion/exclusion results (in the floating versions) to the performances of previously sampled feature sets that were cached #237
- `ExhaustiveFeatureSelector` was modified to consume substantially less memory #195 (via Adam Erickson)

82.0.2.0.4 Bug Fixes

- Fixed a bug where the `SequentialFeatureSelector` selected a feature subset larger than then specified via the `k_features` tuple max-value #213

82.0.3 Version 0.7.0 (2017-06-22)

82.0.3.0.1 Downloads

- Source code (zip)
- Source code (tar.gz)

82.0.3.0.2 New Features

- New mlxtend.plotting.ecdf function for plotting empirical cumulative distribution functions (#196).
- New `StackingCVRegressor` for stacking regressors with out-of-fold predictions to prevent overfitting (#201via Eike Dehling).

82.0.3.0.3 Changes

- The TensorFlow estimator have been removed from mlxtend, since TensorFlow has now very convenient ways to build on estimators, which render those implementations obsolete.
- `plot_decision_regions` now supports plotting decision regions for more than 2 training features #189, via James Bourbeau).
- Parallel execution in `mlxtend.feature_selection.SequentialFeatureSelector` and `mlxtend.feature_selection.E` is now performed over different feature subsets instead of the different cross-validation folds to better utilize machines with multiple processors if the number of features is large (#193, via [@whalebot-helmsman](https://github.com/whalebot-helmsman)).
- Raise meaningful error messages if pandas `DataFrame`s or Python lists of lists are fed into the `StackingCVClassifer` as a `fit` arguments (198).
- The `n_folds` parameter of the `StackingCVClassifier` was changed to `cv` and can now accept any kind of cross validation technique that is available from scikit-learn. For example, `StackingCVClassifier(..., cv=StratifiedKFold(n_splits=3))` or `StackingCVClassifier(..., cv=GroupKFold(n_splits=3))` (#203, via Konstantinos Paliouras).

82.0.3.0.4 Bug Fixes

- `SequentialFeatureSelector` now correctly accepts a `None` argument for the `scoring` parameter to infer the default scoring metric from scikit-learn classifiers and regressors (#171).
- The `plot_decision_regions` function now supports pre-existing axes objects generated via matplotlib's `plt.subplots`. (#184, see example)
- Made `math.num_combinations` and `math.num_permutations` numerically stable for large numbers of combinations and permutations (#200).

82.0.4 Version 0.6.0 (2017-03-18)

82.0.4.0.1 Downloads

- Source code (zip)
- Source code (tar.gz)

82.0.4.0.2 New Features

- An `association_rules` function is implemented that allows to generate rules based on a list of frequent itemsets (via Joshua Goerner).

82.0.4.0.3 Changes

- Adds a black `edgecolor` to plots via `plotting.plot_decision_regions` to make markers more distinguishable from the background in `matplotlib>=2.0`.
- The `association` submodule was renamed to `frequent_patterns`.

82.0.4.0.4 Bug Fixes

- The `DataFrame` index of `apriori` results are now unique and ordered.
- Fixed typos in autompg and wine datasets (via James Bourbeau).

82.0.5 Version 0.5.1 (2017-02-14)

82.0.5.0.1 Downloads

- Source code (zip)
- Source code (tar.gz)

82.0.5.0.2 New Features

- The `EnsembleVoteClassifier` has a new `refit` attribute that prevents refitting classifiers if `refit=False` to save computational time.
- Added a new `lift_score` function in `evaluate` to compute lift score (via Batuhan Bardak).
- `StackingClassifier` and `StackingRegressor` support multivariate targets if the underlying models do (via kernc).
- `StackingClassifier` has a new `use_features_in_secondary` attribute like `StackingCVClassifier`.

82.0.5.0.3 Changes

- Changed default verbosity level in `SequentialFeatureSelector` to 0
- The `EnsembleVoteClassifier` now raises a `NotFittedError` if the estimator wasn't `fit` before calling `predict`. (via Anton Loss)
- Added new TensorFlow variable initialization syntax to guarantee compatibility with TensorFlow 1.0

82.0.5.0.4 Bug Fixes

- Fixed wrong default value for `k_features` in `SequentialFeatureSelector`
- Cast selected feature subsets in the `SequentialFeautureSelector` as sets to prevent the iterator from getting stuck if the `k_idx` are different permutations of the same combination (via Zac Wellmer).
- Fixed an issue with learning curves that caused the performance metrics to be reversed (via ipashchenko)
- Fixed a bug that could occur in the `SequentialFeatureSelector` if there are similarly-well performing subsets in the floating variants (via Zac Wellmer).

82.0.6 Version 0.5.0 (2016-11-09)

82.0.6.0.1 Downloads

- Source code (zip)
- Source code (tar.gz)

82.0.6.0.2 New Features

- New `ExhaustiveFeatureSelector` estimator in `mlxtend.feature_selection` for evaluating all feature combinations in a specified range
- The `StackingClassifier` has a new parameter `average_probas` that is set to `True` by default to maintain the current behavior. A deprecation warning was added though, and it will default to `False` in future releases (0.6.0); `average_probas=False` will result in stacking of the level-1 predicted probabilities rather than averaging these.
- New `StackingCVClassifier` estimator in 'mlxtend.classifier' for implementing a stacking ensemble that uses cross-validation techniques for training the meta-estimator to avoid overfitting (Reiichiro Nakano)
- New `OnehotTransactions` encoder class added to the `preprocessing` submodule for transforming transaction data into a one-hot encoded array
- The `SequentialFeatureSelector` estimator in `mlxtend.feature_selection` now is safely stoppable mid-process by control+c, and deprecated print_progress in favor of a more tunable verbose parameter (Will McGinnis)
- New `apriori` function in `association` to extract frequent itemsets from transaction data for association rule mining
- New `checkerboard_plot` function in `plotting` to plot checkerboard tables / heat maps
- New `mcnemar_table` and `mcnemar` functions in `evaluate` to compute 2x2 contingency tables and McNemar's test

82.0.6.0.3 Changes

- All plotting functions have been moved to `mlxtend.plotting` for compatibility reasons with continuous integration services and to make the installation of `matplotlib` optional for users of `mlxtend`'s core functionality
- Added a compatibility layer for `scikit-learn 0.18` using the new `model_selection` module while maintaining backwards compatibility to scikit-learn 0.17.

82.0.6.0.4 Bug Fixes

- `mlxtend.plotting.plot_decision_regions` now draws decision regions correctly if more than 4 class labels are present
- Raise `AttributeError` in `plot_decision_regions` when the `X_higlight` argument is a 1D array (chkoar)

82.0.7 Version 0.4.2 (2016-08-24)

82.0.7.0.1 Downloads

- Source code (zip)
- Source code (tar.gz)
- PDF documentation

82.0.7.0.2 New Features

- Added `preprocessing.CopyTransformer`, a mock class that returns copies of imput arrays via `transform` and `fit_transform`

82.0.7.0.3 Changes

- Added AppVeyor to CI to ensure MS Windows compatibility
- Dataset are now saved as compressed .txt or .csv files rather than being imported as Python objects
- `feature_selection.SequentialFeatureSelector` now supports the selection of `k_features` using a tuple to specify a "min-max" `k_features` range
- Added "SVD solver" option to the `PrincipalComponentAnalysis`
- Raise a `AttributeError` with "not fitted" message in `SequentialFeatureSelector` if `transform` or `get_metric_dict` are called prior to `fit`
- Use small, positive bias units in `TfMultiLayerPerceptron`'s hidden layer(s) if the activations are ReLUs in order to avoid dead neurons
- Added an optional `clone_estimator` parameter to the `SequentialFeatureSelector` that defaults to `True`, avoiding the modification of the original estimator objects
- More rigorous type and shape checks in the `evaluate.plot_decision_regions` function
- `DenseTransformer` now doesn't raise and error if the input array is *not* sparse
- API clean-up using scikit-learn's `BaseEstimator` as parent class for `feature_selection.ColumnSelector`

82.0.7.0.4 Bug Fixes

- Fixed a problem when a tuple-range was provided as argument to the `SequentialFeatureSelector`'s `k_features` parameter and the scoring metric was more negative than -1 (e.g., as in scikit-learn's MSE scoring function) (wahutch](https://github.com/wahutch))
- Fixed an `AttributeError` issue when `verbose` > 1 in `StackingClassifier`
- Fixed a bug in `classifier.SoftmaxRegression` where the mean values of the offsets were used to update the bias units rather than their sum
- Fixed rare bug in MLP `_layer_mapping` functions that caused a swap between the random number generation seed when initializing weights and biases

82.0.8 Version 0.4.1 (2016-05-01)

82.0.8.0.1 Downloads

- Source code (zip)
- Source code (tar.gz)
- PDF documentation

82.0.8.0.2 New Features

- New TensorFlow estimator for Linear Regression (`tf_regressor.TfLinearRegression`)
- New k-means clustering estimator (`cluster.Kmeans`)
- New TensorFlow k-means clustering estimator (`tf_cluster.Kmeans`)

82.0.8.0.3 Changes

- Due to refactoring of the estimator classes, the `init_weights` parameter of the `fit` methods was globally renamed to `init_params`
- Overall performance improvements of estimators due to code clean-up and refactoring
- Added several additional checks for correct array types and more meaningful exception messages
- Added optional `dropout` to the `tf_classifier.TfMultiLayerPerceptron` classifier for regularization
- Added an optional `decay` parameter to the `tf_classifier.TfMultiLayerPerceptron` classifier for adaptive learning via an exponential decay of the learning rate eta
- Replaced old `NeuralNetMLP` by more streamlined `MultiLayerPerceptron` (`classifier.MultiLayerPerceptron`); now also with softmax in the output layer and categorical cross-entropy loss.
- Unified `init_params` parameter for fit functions to continue training where the algorithm left off (if supported)

82.0.9 Version 0.4.0 (2016-04-09)

82.0.9.0.1 New Features

- New `TfSoftmaxRegression` classifier using Tensorflow (`tf_classifier.TfSoftmaxRegression`)
- New `SoftmaxRegression` classifier (`classifier.SoftmaxRegression`)
- New `TfMultiLayerPerceptron` classifier using Tensorflow (`tf_classifier.TfMultiLayerPerceptron`)
- New `StackingRegressor` (`regressor.StackingRegressor`)
- New `StackingClassifier` (`classifier.StackingClassifier`)
- New function for one-hot encoding of class labels (`preprocessing.one_hot`)
- Added `GridSearch` support to the `SequentialFeatureSelector` (`feature_selection/.SequentialFeatureSelector`
- `evaluate.plot_decision_regions` improvements:
  - Function now handles class y-class labels correctly if array is of type `float`
  - Correct handling of input arguments `markers` and `colors`
  - Accept an existing `Axes` via the `ax` argument
- New `print_progress` parameter for all generalized models and multi-layer neural networks for printing time elapsed, ETA, and the current cost of the current epoch
- Minibatch learning for `classifier.LogisticRegression`, `classifier.Adaline`, and `regressor.LinearRegression` plus streamlined API
- New Principal Component Analysis class via `mlxtend.feature_extraction.PrincipalComponentAnalysis`
- New RBF Kernel Principal Component Analysis class via `mlxtend.feature_extraction.RBFKernelPCA`
- New Linear Discriminant Analysis class via `mlxtend.feature_extraction.LinearDiscriminantAnalysis`

82.0.9.0.2 Changes

- The `column` parameter in `mlxtend.preprocessing.standardize` now defaults to `None` to standardize all columns more conveniently

82.0.10 Version 0.3.0 (2016-01-31)

82.0.10.0.1 Downloads

- Source code (zip)
- Source code (tar.gz)

82.0.10.0.2 New Features

- Added a progress bar tracker to `classifier.NeuralNetMLP`
- Added a function to score predicted vs. target class labels `evaluate.scoring`
- Added confusion matrix functions to create (`evaluate.confusion_matrix`) and plot (`evaluate.plot_confusion_matr` confusion matrices
- New style parameter and improved axis scaling in `mlxtend.evaluate.plot_learning_curves`
- Added `loadlocal_mnist` to `mlxtend.data` for streaming MNIST from a local byte files into numpy arrays
- New `NeuralNetMLP` parameters: `random_weights`, `shuffle_init`, `shuffle_epoch`
- New `SFS` features such as the generation of pandas `DataFrame` results tables and plotting functions (with confidence intervals, standard deviation, and standard error bars)
- Added support for regression estimators in `SFS`
- Added Boston `housing dataset`
- New `shuffle` parameter for `classifier.NeuralNetMLP`

82.0.10.0.3 Changes

- The `mlxtend.preprocessing.standardize` function now optionally returns the parameters, which are estimated from the array, for re-use. A further improvement makes the `standardize` function smarter in order to avoid zero-division errors
- Cosmetic improvements to the `evaluate.plot_decision_regions` function such as hiding plot axes
- Renaming of `classifier.EnsembleClassfier` to `classifier.EnsembleVoteClassifier`
- Improved random weight initialization in `Perceptron`, `Adaline`, `LinearRegression`, and `LogisticRegression`
- Changed `learning` parameter of `mlxtend.classifier.Adaline` to `solver` and added "normal equation" as closed-form solution solver
- Hide y-axis labels in `mlxtend.evaluate.plot_decision_regions` in 1 dimensional evaluations
- Sequential Feature Selection algorithms were unified into a single `SequentialFeatureSelector` class with parameters to enable floating selection and toggle between forward and backward selection.
- Stratified sampling of MNIST (now 500x random samples from each of the 10 digit categories)
- Renaming `mlxtend.plotting` to `mlxtend.general_plotting` in order to distinguish general plotting function from specialized utility function such as `evaluate.plot_decision_regions`

82.0.11 Version 0.2.9 (2015-07-14)

82.0.11.0.1 Downloads

- Source code (zip)
- Source code (tar.gz)

82.0.11.0.2 New Features

- Sequential Feature Selection algorithms: SFS, SFFS, SBS, and SFBS

82.0.11.0.3 Changes

- Changed `regularization` & `lambda` parameters in `LogisticRegression` to single parameter `l2_lambda`

82.0.12 Version 0.2.8 (2015-06-27)

- API changes:
  - `mlxtend.sklearn.EnsembleClassifier` -> `mlxtend.classifier.EnsembleClassifier`
  - `mlxtend.sklearn.ColumnSelector` -> `mlxtend.feature_selection.ColumnSelector`
  - `mlxtend.sklearn.DenseTransformer` -> `mlxtend.preprocessing.DenseTransformer`
  - `mlxtend.pandas.standardizing` -> `mlxtend.preprocessing.standardizing`
  - `mlxtend.pandas.minmax_scaling` -> `mlxtend.preprocessing.minmax_scaling`
  - `mlxtend.matplotlib` -> `mlxtend.plotting`
- Added momentum learning parameter (alpha coefficient) to `mlxtend.classifier.NeuralNetMLP`.
- Added adaptive learning rate (decrease constant) to `mlxtend.classifier.NeuralNetMLP`.
- `mlxtend.pandas.minmax_scaling` became `mlxtend.preprocessing.minmax_scaling` and also supports NumPy arrays now
- `mlxtend.pandas.standardizing` became `mlxtend.preprocessing.standardizing` and now supports both NumPy arrays and pandas DataFrames; also, now `ddof` parameters to set the degrees of freedom when calculating the standard deviation

82.0.13 Version 0.2.7 (2015-06-20)

- Added multilayer perceptron (feedforward artificial neural network) classifier as `mlxtend.classifier.NeuralNetMLP`.
- Added 5000 labeled trainingsamples from the MNIST handwritten digits dataset to `mlxtend.data`

82.0.14 Version 0.2.6 (2015-05-08)

- Added ordinary least square regression using different solvers (gradient and stochastic gradient descent, and the closed form solution (normal equation)
- Added option for random weight initialization to logistic regression classifier and updated l2 regularization
- Added `wine` dataset to `mlxtend.data`
- Added `invert_axes` parameter `mlxtend.matplotlib.enrichtment_plot` to optionally plot the "Count" on the x-axis
- New `verbose` parameter for `mlxtend.sklearn.EnsembleClassifier` by Alejandro C. Bahnsen
- Added `mlxtend.pandas.standardizing` to standardize columns in a Pandas DataFrame
- Added parameters `linestyles` and `markers` to `mlxtend.matplotlib.enrichment_plot`
- `mlxtend.regression.lin_regplot` automatically adds np.newaxis and works w. python lists
- Added tokenizers: `mlxtend.text.extract_emoticons` and `mlxtend.text.extract_words_and_emoticons`

82.0.15 Version 0.2.5 (2015-04-17)

- Added Sequential Backward Selection (mlxtend.sklearn.SBS)
- Added `X_highlight` parameter to `mlxtend.evaluate.plot_decision_regions` for highlighting test data points.
- Added mlxtend.regression.lin_regplot to plot the fitted line from linear regression.
- Added mlxtend.matplotlib.stacked_barplot to conveniently produce stacked barplots using pandas `DataFrame`s.
- Added mlxtend.matplotlib.enrichment_plot

82.0.16 Version 0.2.4 (2015-03-15)

- Added `scoring` to `mlxtend.evaluate.learning_curves` (by user pfsq)

- Fixed setup.py bug caused by the missing README.html file
- matplotlib.category_scatter for pandas DataFrames and Numpy arrays

82.0.17 Version 0.2.3 (2015-03-11)

- Added Logistic regression
- Gradient descent and stochastic gradient descent perceptron was changed to Adaline (Adaptive Linear Neuron)
- Perceptron and Adaline for {0, 1} classes
- Added `mlxtend.preprocessing.shuffle_arrays_unison` function to shuffle one or more NumPy arrays.
- Added shuffle and random seed parameter to stochastic gradient descent classifier.
- Added `rstrip` parameter to `mlxtend.file_io.find_filegroups` to allow trimming of base names.
- Added `ignore_substring` parameter to `mlxtend.file_io.find_filegroups` and `find_files`.
- Replaced .rstrip in `mlxtend.file_io.find_filegroups` with more robust regex.
- Gridsearch support for `mlxtend.sklearn.EnsembleClassifier`

82.0.18 Version 0.2.2 (2015-03-01)

- Improved robustness of EnsembleClassifier.
- Extended plot_decision_regions() functionality for plotting 1D decision boundaries.
- Function matplotlib.plot_decision_regions was reorganized to evaluate.plot_decision_regions .
- evaluate.plot_learning_curves() function added.
- Added Rosenblatt, gradient descent, and stochastic gradient descent perceptrons.

82.0.19 Version 0.2.1 (2015-01-20)

- Added mlxtend.pandas.minmax_scaling - a function to rescale pandas DataFrame columns.
- Slight update to the EnsembleClassifier interface (additional `voting` parameter)
- Fixed EnsembleClassifier to return correct class labels if class labels are not integers from 0 to n.
- Added new matplotlib function to plot decision regions of classifiers.

82.0.20 Version 0.2.0 (2015-01-13)

- Improved mlxtend.text.generalize_duplcheck to remove duplicates and prevent endless looping issue.
- Added `recursive` search parameter to mlxtend.file_io.find_files.
- Added `check_ext` parameter mlxtend.file_io.find_files to search based on file extensions.
- Default parameter to ignore invisible files for mlxtend.file_io.find.
- Added `transform` and `fit_transform` to the `EnsembleClassifier`.
- Added mlxtend.file_io.find_filegroups function.

82.0.21 Version 0.1.9 (2015-01-10)

- Implemented scikit-learn EnsembleClassifier (majority voting rule) class.

82.0.22 Version 0.1.8 (2015-01-07)

- Improvements to mlxtend.text.generalize_names to handle certain Dutch last name prefixes (van, van der, de, etc.).
- Added mlxtend.text.generalize_name_duplcheck function to apply mlxtend.text.generalize_names function to a pandas DataFrame without creating duplicates.

82.0.23 Version 0.1.7 (2015-01-07)

- Added text utilities with name generalization function.
- Added and file_io utilities.

82.0.24 Version 0.1.6 (2015-01-04)

- Added combinations and permutations estimators.

82.0.25 Version 0.1.5 (2014-12-11)

- Added `DenseTransformer` for pipelines and grid search.

82.0.26 Version 0.1.4 (2014-08-20)

- `mean_centering` function is now a Class that creates `MeanCenterer` objects that can be used to fit data via the `fit` method, and center data at the column means via the `transform` and `fit_transform` method.

82.0.27 Version 0.1.3 (2014-08-19)

- Added `preprocessing` module and `mean_centering` function.

82.0.28 Version 0.1.2 (2014-08-19)

- Added `matplotlib` utilities and `remove_borders` function.

82.0.29 Version 0.1.1 (2014-08-13)

- Simplified code for ColumnSelector.

83 How to Contribute

I would be very happy about any kind of contributions that help to improve and extend the functionality of mlxtend.

83.1 Quick Contributor Checklist

This is a quick checklist about the different steps of a typical contribution to mlxtend (and other open source projects). Consider copying this list to a local text file (or the issue tracker) and checking off items as you go.

1. [ ] Open a new "issue" on GitHub to discuss the new feature / bug fix

2. [ ] Fork the mlxtend repository from GitHub (if not already done earlier)

3. [ ] Create and check out a new topic branch (please don't make modifications in the master branch)
4. [ ] Implement the new feature or apply the bug-fix

5. [ ] Add appropriate unit test functions in `mlxtend/*/tests`
6. [ ] Run `nosetests ./mlxtend -sv` and make sure that all unit tests pass

7. [ ] Check/improve the test coverage by running `nosetests ./mlxtend --with-coverage`
8. [ ] Check for style issues by running `flake8 ./mlxtend` (you may want to run `nosetests` again after you made modifications to the code)
9. [ ] Add a note about the modification/contribution to the `./docs/sources/changelog.md` file

10. [ ] Modify documentation in the appropriate location under `mlxtend/docs/sources/`

11. [ ] Push the topic branch to the server and create a pull request
12. [ ] Check the Travis-CI build passed at https://travis-ci.org/rasbt/mlxtend
13. [ ] Check/improve the unit test coverage at https://coveralls.io/github/rasbt/mlxtend
14. [ ] Check/improve the code health at https://landscape.io/github/rasbt/mlxtend

84 Tips for Contributors

84.1 Getting Started - Creating a New Issue and Forking the Repository

- If you don't have a GitHub account, yet, please create one to contribute to this project.
- Please submit a ticket for your issue to discuss the fix or new feature before too much time and effort is spent for the implementation.

- Fork the `mlxtend` repository from the GitHub web interface.

- Clone the `mlxtend` repository to your local machine by executing `git clone https://github.com/<your_username>/m`

84.2 Syncing an Existing Fork

If you already forked mlxtend earlier, you can bring you "Fork" up to date with the master branch as follows:

84.2.0.1 1. Configuring a remote that points to the upstream repository on GitHub

List the current configured remote repository of your fork by executing

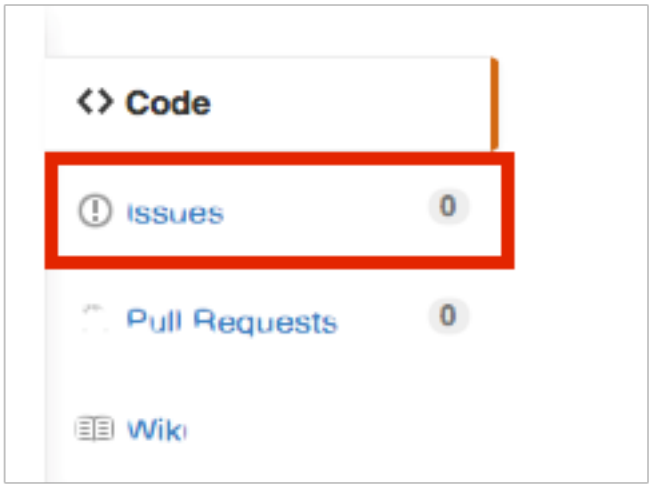
```
$ git remote -v
```

If you see something like

```
origin  https://github.com/<your username>/mlxtend.git (fetch)
origin  https://github.com/<your username>/mlxtend.git (push)
```

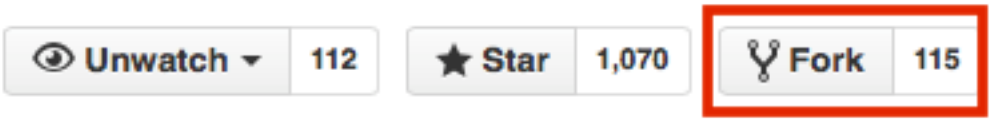
you need to specify a new remote *upstream* repository via

```
$ git remote add upstream https://github.com/rasbt/mlxtend.git
```



Code
Issues 0
Pull Requests 0
Wiki

Unwatch 112
Star 1,071
Fork 115
pen
New issue



Unwatch 112
Star 1,070
Fork 115

Now, verify the new upstream repository you've specified for your fork by executing

```
$ git remote -v
```

You should see following output if everything is configured correctly:

```
origin  https://github.com/<your username>/mlxtend.git (fetch)
origin  https://github.com/<your username>/mlxtend.git (push)
upstream    https://github.com/rasbt/mlxtend.git (fetch)
upstream    https://github.com/rasbt/mlxtend.git (push)
```

84.2.0.2 2. Syncing your Fork

First, fetch the updates of the original project's master branch by executing:

```
$ git fetch upstream
```

You should see the following output

```
remote: Counting objects: xx, done.
remote: Compressing objects: 100% (xx/xx), done.
remote: Total xx (delta xx), reused xx (delta x)
Unpacking objects: 100% (xx/xx), done.
From https://github.com/rasbt/mlxtend
 * [new branch]      master     -> upstream/master
```

This means that the commits to the `rasbt/mlxtend` master branch are now stored in the local branch `upstream/master`.

If you are not already on your local project's master branch, execute

```
$ git checkout master
```

Finally, merge the changes in upstream/master to your local master branch by executing

```
$ git merge upstream/master
```

which will give you an output that looks similar to

```
Updating xxx...xxx
Fast-forward
SOME FILE1                    |    12 +++++++
SOME FILE2                    |    10 +++++++
2 files changed, 22 insertions(+),
```

84.3 *The Main Workflow - Making Changes in a New Topic Branch

Listed below are the 9 typical steps of a contribution.

84.3.0.1 1. Discussing the Feature or Modification

Before you start coding, please discuss the new feature, bugfix, or other modification to the project on the project's issue tracker. Before you open a "new issue," please do a quick search to see if a similar issue has been submitted already.

84.3.0.2 2. Creating a new feature branch

Please avoid working directly on the master branch but create a new feature branch:

```
$ git branch <new_feature>
```

Switch to the new feature branch by executing

```
$ git checkout <new_feature>
```

84.3.0.3 3. Developing the new feature / bug fix

Now it's time to modify existing code or to contribute new code to the project.

84.3.0.4 4. Testing your code

Add the respective unit tests and check if they pass:

```
$ nosetests -sv
```

Use the `--with-coverage` flag to ensure that all code is being covered in the unit tests:

```
$ nosetests --with-coverage
```

84.3.0.5 5. Documenting changes

Please add an entry to the `mlxtend/docs/sources/changelog.md` file. If it is a new feature, it would also be nice if you could update the documentation in appropriate location in `mlxtend/sources`.

84.3.0.6 6. Committing changes

When you are ready to commit the changes, please provide a meaningful `commit` message:

```
$ git add <modifies_files> # or `git add .`
$ git commit -m '<meaningful commit message>'
```

84.3.0.7 7. Optional: squashing commits

If you made multiple smaller commits, it would be nice if you could group them into a larger, summarizing commit. First, list your recent commit via

Note
Due to the improved GitHub UI, this is no longer necessary/encouraged.

```
$ git log
```

which will list the commits from newest to oldest in the following format by default:

```
commit 046e3af8a9127df8eac879454f029937c8a31c41
Author: rasbt <mail@sebastianraschka.com>
Date:   Tue Nov 24 03:46:37 2015 -0500

    fixed setup.py

commit c3c00f6ba0e8f48bbe1c9081b8ae3817e57ecc5c
Author: rasbt <mail@sebastianraschka.com>
Date:   Tue Nov 24 03:04:39 2015 -0500

        documented feature x

commit d87934fe8726c46f0b166d6290a3bf38915d6e75
Author: rasbt <mail@sebastianraschka.com>
Date:   Tue Nov 24 02:44:45 2015 -0500

        added support for feature x
```

Assuming that it would make sense to group these 3 commits into one, we can execute

```
$ git rebase -i HEAD~3
```

which will bring our default git editor with the following contents:

```
pick d87934f added support for feature x
pick c3c00f6 documented feature x
pick 046e3af fixed setup.py
```

Since `c3c00f6` and `046e3af` are related to the original commit of `feature x`, let's keep the `d87934f` and squash the 2 following commits into this initial one by changes the lines to

```
pick d87934f added support for feature x
squash c3c00f6 documented feature x
squash 046e3af fixed setup.py
```

Now, save the changes in your editor. Now, quitting the editor will apply the `rebase` changes, and the editor will open a second time, prompting you to enter a new commit message. In this case, we could enter `support for feature x` to summarize the contributions.

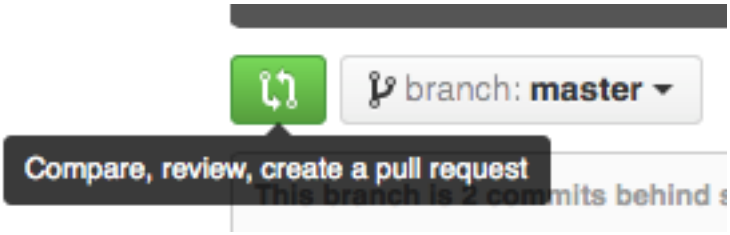
84.3.0.8 8. Uploading changes

Push your changes to a topic branch to the git server by executing:

```
$ git push origin <feature_branch>
```

84.3.0.9 9. Submitting a `pull request`

Go to your GitHub repository online, select the new feature branch, and submit a new pull request:



85 Notes for Developers

85.1 Building the documentation

The documentation is built via MkDocs; to ensure that the documentation is rendered correctly, you can view the documentation locally by executing `mkdocs serve` from the `mlxtend/docs` directory.

For example,

```
~/github/mlxtend/docs$ mkdocs serve
```

85.1.1 1. Building the API documentation

To build the API documentation, navigate to `mlxtend/docs` and execute the `make_api.py` file from this directory via

```
~/github/mlxtend/docs$ python make_api.py
```

This should place the API documentation into the correct directories into the two directories:

- `mlxtend/docs/sources/api_modules`
- `mlxtend/docs/sources/api_subpackes`

85.1.2 2. Editing the User Guide

The documents containing code examples for the "User Guide" are generated from IPython Notebook files. In order to convert a IPython notebook file to markdown after editing, please follow the following steps:

1. Modify or edit the existing notebook.
2. Execute all cells in the current notebook and make sure that no errors occur.
3. Convert the notebook to markdown using the `ipynb2markdown.py` converter

```
~/github/mlxtend/docs$ python ipynb2markdown.py --ipynb_path ./sources/user_guide/subpackage/notebooknar
```

Note

If you are adding a new document, please also include it in the pages section in the `mlxtend/docs/mkdocs.yml` file.

85.1.3 3. Building static HTML files of the documentation

First, please check the documenation via localhost (http://127.0.0.1:8000/):

```
~/github/mlxtend/docs$ mkdocs serve
```

Next, build the static HTML files of the mlxtend documentation via

```
~/github/mlxtend/docs$ mkdocs build --clean
```

To deploy the documentation, execute

```
~/github/mlxtend/docs$ mkdocs gh-deploy --clean
```

85.1.4 4. Generate a PDF of the documentation

To generate a PDF version of the documentation, simply `cd` into the `mlxtend/docs` directory and execute:

```
python md2pdf.py
```

85.2 Uploading a new version to PyPI

85.2.1 1. Creating a new testing environment

Assuming we are using `conda`, create a new python environment via

```
$ conda create -n 'mlxtend-testing' python=3 numpy scipy pandas
```

Next, activate the environment by executing

```
$ source activate mlxtend-testing
```

85.2.2 2. Installing the package from local files

Test the installation by executing

```
$ python setup.py install --record files.txt
```

the `--record files.txt` flag will create a `files.txt` file listing the locations where these files will be installed.

Try to import the package to see if it works, for example, by executing

```
$ python -c 'import mlxtend; print(mlxtend.__file__)'
```

If everything seems to be fine, remove the installation via

```
$ cat files.txt | xargs rm -rf ; rm files.txt
```

Next, test if `pip` is able to install the packages. First, navigate to a different directory, and from there, install the package:

```
$ pip install mlxtend
```

and uninstall it again

```
$ pip uninstall mlxtend
```

85.2.3 3. Deploying the package

Consider deploying the package to the PyPI test server first. The setup instructions can be found here.

```
$ python setup.py sdist bdist_wheel upload -r https://testpypi.python.org/pypi
```

Test if it can be installed from there by executing

```
$ pip install -i https://testpypi.python.org/pypi mlxtend
```

and uninstall it

```
$ pip uninstall mlxtend
```

After this dry-run succeeded, repeat this process using the "real" PyPI:

```
$ python setup.py sdist bdist_wheel upload
```

85.2.4 4. Removing the virtual environment

Finally, to cleanup our local drive, remove the virtual testing environment via

```
$ conda remove --name 'mlxtend-testing' --all
```

85.2.5 5. Updating the conda-forge recipe

Once a new version of mlxtend has been uploaded to PyPI, update the conda-forge build recipe at https://github.com/conda-forge/mlxtend-feedstock by changing the version number in the `recipe/meta.yaml` file appropriately.

86 Contributors

For the current list of contributors to mlxtend, please see the GitHub contributor page at https://github.com/rasbt/mlxtend/graphs/contributors.
