

# Time-domain separation of optical properties from structural transitions in resonantly bonded materials

## ELLIPSOMETRY AND RAMAN ANALYSIS OF PHASE TRANSFORMATION

Figure S1a shows the measured dielectric function for three thermally prepared states. The amorphous state achieved after annealing to 75 °C is similar to the one achieved after quenching from the crystalline state. The values for the dielectric function reported here are different to those by Shportko et al<sup>1</sup>; however, we find a much better agreement with the dielectric functions found in references 2 and 3. This variation is likely due to the metastability of both crystalline and amorphous phases of GST. Small variations in composition and preparation can alter the state of the material, and substrates and capping layers can induce strain, resulting in slightly different optical values. However, in all cases the energy dependence of the dielectric function follows the same trend. Figure S1b shows the Raman spectra for the different states, which are in excellent agreement with other publications<sup>4–7</sup>. The spectrum obtained after pumping the crystalline sample with a fluence just above the phase transformation threshold is in excellent agreement with the amorphous state spectrum, whereas regions excited with a higher fluence match the as-deposited phase spectra more closely. This indicates that the local bonding strongly depends on the temperature reached after excitation, even though long range order is lost in both cases.

**Figure S1 | Static Characterization of GST Samples** **a**, Ellipsometry measurements of the dielectric function of GST in its different states prepared thermally. **b**, Raman measurements of the thermally prepared states of GST (solid lines) and the laser transformed regions (dashed lines)

**Figure S2 | Measured Reflectivity and Transmission of GST Films Used to Calculate the Time-Dependent Dielectric Function** **a**, Short timescale dynamics **b**, long time dynamics. Dashed lines show the frequency independence of optical phonons (**a**) and acoustic phonons (**b**) on the pump fluence.

### BELOW-THRESHOLD DATA

The optical data in Figure 2 of the manuscript is derived from the changes in reflectivity and transmissivity of the sample measured using conventional lock-in detection. Figure S2 shows both the data on short (a) and long (b) timescales used to extract the recovery time. On short timescales we observe coherent oscillations that can be attributed to coherent Raman-active phonons (see Figure S3); these predominantly influence the transmission. The dashed line marks the end of one oscillation period and indicates that the coherent phonon frequency remains constant for all pump fluences. On longer timescales we observe a slower oscillation corresponding to the breathing motion of the film, and the frequency is set by the speed of sound of the material. As the period of oscillation for both the optical and acoustic phonons remains constant, we conclude that there is no weakening of the lattice potential in this excitation regime.

### TRANSFER MATRIX METHOD

Reflection and transmission from a layered sample can be converted into the complex dielectric function using a transfer matrix method<sup>8</sup>. A general transfer matrix is written as:

$$T_n = \begin{pmatrix} \cos(2\pi n \delta/\lambda) & -\frac{i}{n} \sin(2\pi n \delta/\lambda) \\ -i n \sin(2\pi n \delta/\lambda) & \cos(2\pi n \delta/\lambda) \end{pmatrix} \quad (1)$$

where  $n$  is the complex refractive index,  $\delta$  is the layer thickness and  $\lambda$  is the wavelength of the light. The transmission,  $T$ , and reflection coefficient,  $R$ , for the multilayer system studied here can then be obtained from the combined system  $T_{SiO_2} T_{GST} T_{Si_3N_4}$  with the light entering the  $Si_3N_4$  layer from air and leaving the GST layer into the  $SiO_2$

substrate. A small amount of light is further reflected from the SiO<sub>2</sub>-air interface. This reflection is treated incoherently, i.e. light originating from multiple reflections inside the SiO<sub>2</sub> layer does not interfere.

The time dependent dielectric function is obtained by calculating  $T_{GST}$  for a range of complex refractive indices  $n' = n + \Delta$ , and the average is taken of the values of  $n'$  that satisfy both  $R(t)$  and  $T(t)$  simultaneously. From the resulting value for  $n'$  the dielectric function can be obtained. The same method is used for calculating the complex dielectric function above the amorphization threshold.

We fit the change in dielectric function with the following phenomenological model in the reversible regime:

$$\Delta\epsilon = -Ae^{-\frac{t}{\tau}} - B\left(1 - e^{-\frac{t}{\tau}}\right), t > 0 \quad (2)$$

where A and B are complex and  $\tau$  is the recovery time of the optical signal (from Figure 1). The signal is then convolved with a Gaussian pulse of 40 fs FWHM to account for the experimental resolution. The results of the fit are shown in Figure S3 for the highest reversible fluence excitation, and an excellent fit is obtained. We attribute the A term to the dynamics of the resonantly bonded state. We can see that the dynamics of this term occur in both the real and imaginary part of the dielectric function. The coherent phonon signal, on the other hand, is only observed on the imaginary part of the dielectric function (i.e. the real part of B is small), and is in good agreement with the static Raman scattering signal.

**Figure S3 | Typical Fitting results for the broadband dielectric function** **a**, shows the fit parameters for the two terms in Equation 2, together with the residual. **b**, The Fourier transform of the residual obtained from the imaginary part from **a**, compared to the static Raman measurement.

## SINGLE-SHOT OPTICAL TECHNIQUE

The linear chirp imparted on the probe beam, generated by passing through a thick glass block, results in a time-dependent instantaneous frequency. The pump and probe beams are timed so that roughly 1/3 of the probe beam has passed through the sample before the pump beam arrives. As a result, each color in the beam experiences a different value of the transient refractive index of the sample. If we assume that the resulting  $\Delta R/R$  and  $\Delta T/T$  due to the time dependent dielectric function is independent of the probe frequency within our laser spectrum, we can extract the time-dependent signal.

The frequency-to-time calibration was achieved by using a motorized delay stage to change the relative arrival time between pump and probe beams. The time zero position was found by fitting an error function to the signal at each

**Figure S4 | Calibration of the spectral signal into the time domain** **a**, The physical pump-probe delay is varied and the rising edge of the signal fit to an error function. The laser spectrum is shown in the background. **b**, The time zero point from (a) is plotted for different physical probe delays and shows the pulse has a linear chirp of 15.4 fs/px. **c**, The recorded dynamics are shown to be independent of wavelength within the measured spectral range. After shifting the time traces by the appropriate time delay, the exact same dynamics are observed. Note that the increased noise at negative delays for  $t = -1.5$  ps and positive delays for 1.5 ps is due to the loss of intensity at the edges of the spectrum.

delay as shown in Figure S4a. Figure S4b shows the extracted chirp of the pulse, which is 15.4 fs/pixel. Figure S4c shows that the ultrafast optical change of GST is independent of the probe wavelength. A limited spectral range was chosen for the dynamics due to the decrease in spectral intensity at the wings of the spectrum, resulting in more noise on the data.

To measure the irreversible dynamics we perform three measurements at each position on the sample. First, we measure a reflection ( $R_1$ ) and transmission ( $T_1$ ) spectrum of the sample when there is no pump beam. We then

**Figure S5 | Measured  $\Delta T/T$  and  $\Delta R/R$  Time Traces Using the Single Shot Technique**

measure the same spectra ( $R_2$  and  $T_2$ ) when a pump beam excites the sample. The third measurement of the transmission and reflection spectra is again performed without the pump beam ( $R_3$ ,  $T_3$ ) to observe any permanent change. This process is repeated at 5 different points on the sample and then averaged. The permanent transmission change plotted in Figure 1d of the paper is obtained by averaging  $(T_3/T_1)-1$  for each power. The dynamics of the reflectivity are obtained using  $\Delta R/R = (R_2/R_1) - 1$  and the equivalent for  $\Delta T/T$ . These dynamics are shown in Figure S5 and are processed in the same way as the below-threshold data to calculate the dielectric function.
