A collaborative eavesdropping interference scheme based on PLS and clustering scenarios was proposed to improve the communication security of wireless communication networks. By adding artificial noise to the transmitted signal, eavesdropping signals could be successfully interfered with, enhancing the advantages of the main channel and achieving eavesdropping interference in wireless communication networks. The research results indicated that as the SNR of the main channel increased, the confidentiality capacity of the system significantly improved, increasing from 0.5 to over 4.0. In addition, as the number of interfering nodes increased, the confidentiality capacity also increased, similar to the research results of Pang X et al. [21]. The proposed method not only provided new research directions and possible solutions for PLS, but also provided important reference value for clustering scenarios in wireless sensor networks. By fully utilizing the advantages of network topology without the need for additional equipment or hardware, PLS implementation was ensured, providing a new perspective and solution strategy for wireless communication network security issues. The different channel models and environmental noise considered in the experiment may not cover all the complex details in practical scenarios, and future research needs to be further deepened. For example, it is possible to explore universal interference strategies that can adapt to various channel conditions and noisy environments, and optimize the deployment methods of interfering nodes. In the future, further research and optimization will be conducted on the generation mechanism of artificial noise to adapt to the dynamically changing network environment. Secondly, it should explore interference strategies under different channel conditions to improve the adaptability and robustness of the system. Finally, considering the compatibility issues in actual deployment, it will investigate how to seamlessly integrate PLS technology with existing wireless communication networks.

VI. Conclusion

To improve the communication security of wireless sensor networks, a research proposal was proposed to combine PLS with cluster routing. A collaborative eavesdropping interference scheme combining PLS and cluster scenarios was designed to protect the communication security of wireless sensor networks. This scheme added artificial noise to the transmitted information to achieve eavesdropping interference. The results showed that in an environment without artificial noise, the confidentiality capacity ranged from 0 to 1. After using artificial noise, as the SNR of the main channel increased from 0 to 20dB, the confidentiality capacity could increase from 0.5 to over 4.0. When the cumulative distribution function value was 0.6, the cluster spacing increased from 10 to 20, and the link capacity decreased from 50 to 30. The density of interfering nodes was increased from 0.01Pieces/m² to 0.1Pieces/m². At that time, the link capacity decreased from 54 to 42. When the path loss index decreased, the confidentiality capacity slightly increased, while the clustering radius had little effect on the confidentiality capacity. The addition of artificial noise effectively improved the confidentiality capacity of the system, which was highly sensitive to the SNR of the main channel and achieved the optimal confidentiality capacity at a certain transmission power level. The increase in the number of interfering nodes could significantly affect the confidentiality capacity of the system, but this effect tended to saturate after the number of nodes reached a certain threshold. In terms of spatial distribution, an increase in cluster spacing and interference node density could lead to a decrease in link capacity, thereby affecting communication performance. When conducting simulation analysis on eavesdropping interference schemes, the consideration of different channel models and environmental noise was insufficient to cover all the complex details in actual scenarios, and further deepening is needed. In the future, it can explore universal interference strategies that can adapt to various channel conditions and noisy environments, and optimize the deployment methods of interference nodes. The use of PLS and cluster routing to achieve eavesdropping interference in communication signals greatly protects user personal privacy and improves wireless network communication security, which can effectively promote the development of the Internet of Things.

***Abstract*—This paper investigates the increasing concerns related to the vulnerability of contemporary security solutions in the face of quantum-based attacks, which pose significant challenges to existing cryptographic methods. Most current Quantum Key Distribution (QKD) protocols are designed with a focus on point-to-point communication, limiting their application in broader network environments where multiple users need to exchange information securely. To address this limitation, a thorough analysis of twin-field-based algorithms is conducted, emphasizing their distinct characteristics and evaluating their performance in practical scenarios in Sections II, III, and IV. By synthesizing insights from these analyses, integrating cutting-edge advancements in Quantum Communication technologies, and drawing on proven methodologies from established point-to-point protocols, this study introduces a novel concept for a Hybrid Twin-Field QKD protocol in Section IV. This network-oriented approach is designed to facilitate secure communication in networks involving multiple users, offering a practical and scalable solution. The proposed protocol aims to reduce resource consumption while maintaining high-security standards, thereby making it a viable option for real-world quantum communication networks. This work contributes to the development of more resilient and efficient quantum networks capable of withstanding future quantum-based threats.**

I. Introduction

The increasing concern regarding the physical vulnerability of fiber networks has become a significant issue, as traditional security mechanisms are increasingly bypassed by sophisticated attackers. This escalating threat underscores the necessity for the development of innovative quantum-based security solutions. Notably, the global metric for the 'Estimated Cost of Cybercrime' within the cybersecurity sector is projected to rise steadily from 2023 to 2028, with an anticipated increase of 5.7 trillion U.S. dollars, representing a 69.94% growth. By 2028, after eleven consecutive years of growth, this figure is expected to reach a new high of 13.82 trillion U.S. dollars [1], emphasizing the urgent need for advanced cybersecurity measures. Furthermore, the ongoing advancements and strategic roadmaps of technology leaders, such as IBM [2], suggest rapid developments in the computational power of quantum computers, posing significant threats to existing secure communication protocols like RSA [3] and AES [4]. The widespread reliance on these algorithms, particularly among critical businesses essential to the functioning of foundational societal ecosystems, exacerbates the risk posed by emerging quantum threats.

Recent years have seen significant progress in the field of cryptography, with researchers exploring new mathematical foundations and encryption techniques to enhance security [5] [6] [7] [8] [9] [10].

To mitigate these risks, the implementation of quantum cryptography offers a promising solution. Quantum cryptography provides secure communication channels that are resilient to both classical and quantum attacks, leveraging two fundamental principles of quantum mechanics: Quantum Entanglement, which enables the encoding and sharing of information across vast distances while monitoring for any unauthorized interference, and the No-Cloning Theorem, which ensures protection against potential eavesdroppers attempting to replicate unique quantum states. One effective method for achieving such security is through Quantum Key Distribution (QKD) protocols, which facilitate the secure generation and distribution of secret keys among communication participants.

However, the majority of existing QKD protocols are limited to point-to-point applications or are heavily reliant on specific infrastructures, leaving much of the global network infrastructure vulnerable. This paper seeks to address this challenge by proposing a novel concept for a network-oriented QKD protocol.

- Research problem: Currently available protocols are only suitable in a point-to-point scenario.
- Research questions: a) Is it possible to construct a different protocol that would be able to support network communication? b) Is it possible to make it applicable to the current network infrastructure?
- Research objectives: a) to review the related literature b) to find suitable protocols for the optic fiber-based network communication c) explain the proposed approach mathematically.

- Research significance and contribution: a novel QKD network-oriented approach applicable to the current optic fiber infrastructure.

II. Literature Review

A. Historical Origins and the Emergence of First QKDs

The early 1970s began with the initial development of Quantum Key Distribution (QKD) protocols. By 1984, the scientific community was introduced to the novel polarization-based algorithm for key distribution [11] developed by C. H. Bennett and G. Brassard, marking a significant milestone. In this work, Bennett and Brassard proposed a key distribution protocol based on the polarization property of a quantum state as well as a change of measurement bases. Although its protocol as-is can be utilized over the current infrastructure, it seriously lacks in terms of security against such attacks [12] as IRUD attacks, Beam-Splitting attacks, Denial of Service attacks, Man-In-The-Middle, IRA attacks, etc. Therefore, making it not a standalone QKD solution but a potential building block for a bigger picture.

B. Entanglement-based QKDs

This discovery was closely followed by another, in 1992, with the presentation of the first entanglement-based algorithm [13] developed by A. K. Ekert. In this work, Ekert utilized the property of entanglement in order to address the possibility of an eavesdropping attack. However, this protocol as-is also quite vulnerable [12] to IRUD attacks, Beam-Splitting attacks, and Denial of Service attacks. Overall, these innovative algorithms utilized fundamental concepts of quantum physics such as the Entanglement Effect, Quantum Teleportation, Polarization, etc. These foundational algorithms have paved the way for all subsequent research in the field.

C. Review of Measurement Device Independent QKDs

The next logical step in the development of this branch was the new protocols that further advanced the complexity of security-assuring physical phenomena, such as BBM92 [14], SARG04 [15] [16], KMB09 [15], AK15 [16], etc. As well as continuous testing and improvement of already existing ones. For instance, since the emergence of E91 as a theoretical concept, there have been many tests that piece-by-piece proved the concept [17] [18] [19] [20], yet still failed to prove its applicability in field test or real-world applications due to poor unstable key-generation rates, relying on a theoretical piece of equipment such as quantum repeaters, limited duration of CHSH violation, or poor handling of noise. The same was done, albeit more successfully, for BB84 [21][22][23]. Although, BB84 is still suffers from the weak coherence of quantum states during transmission, which is limiting its operational range significantly. It also suffers from a limited key generation rate as-is, though there is a possibility for improvement. However, while E91 has hardly ever seen practical field applications, BB84 has already been tested in real-world applications [24] [25] and is already commercially available. After that, the next big step in the development of QKD protocols was Measurement-Independent QKD (MI-QKD) that are removing all detector side-channel attacks as well as Device-Independent QKD (DI-QKD), which security does not rely on trusting that the quantum devices used are truthful. Ultimately, these two sub-branches merged into one (MDI-QKD).

D. Twin-Field-based MDI-QKDs

One representative of this sub-branch is a Twin-Field group of QKD protocols [26] that provide a much higher key rate and greater distance compared to previous strategies (such as adding extra loss or not using any compensation). [27]. Some examples of Twin-Field QKD Protocols are include but not limited to: Sending-Not-Sending (SNS) [28], CAL19 [29], or Phase-Matching Protocol [30], which demonstrates the potential to overcome the key-rate limit and achieves a quadratic improvement over phase-encoding MDI-QKD [30]. For instance, the SNS protocol claimed to reach a distance limit of up to 800 km without misalignment error, while authors of CAL19 managed to find a solution to the key-rate drop issue of the original TF-QKD by Lucamarini et al. [26] and improve the key-rate by an order of magnitude. All of these protocols not only provided ways of robust security against common threats but also addressed some of the crucial issues on the way toward actually functioning Quantum Network [27].

E. Authentication

While all of these algorithms and approaches can be effective to various degrees and the question of a central node becoming trusted is still standing, one has to consider an approach for another big question that could render previously mentioned algorithms useless – the authentication phase. Currently, few quantum authentication algorithms would apply to this setup. Firstly, one should focus on those algorithms that do not utilize entanglement or use it in a limited capacity, since a system that requires necessary equipment for entanglement would be considerably expensive.

A good example is the work of Kanamori et al. [31]. Instead of solely relying on entanglement or a trusted center, authors chose to capitalize on the superposition. One big advantage is that this particular algorithm can re-use the TFQKD (1 phase) for the initial authentication. Another advantage is that it can be utilized even without a classical channel of communication, which provides additional security due to the dispersed approach. However, it would be cumbersome to re-use this algorithm due to the need for the generation of new keys. Another great example is the work of Zhang et al. [32]. This approach shares many advantages with the previous one, but it has one that might tip the scales to its side - it can be re-used later without the re-generation of the key.

Although the algorithms that require devices related to entanglement can make the whole system considerably expensive, it is still required to review those that fit the design of this setup. For instance, the work of Lin et al. [33] could be utilized because it does not require a trusted center. Additionally, a lot of the crucial mechanisms that are necessary are also pretty straightforward, such as - a combination of CNOT gates, different measurement bases, etc. This approach also does not rely on a classical communication channel, which is a plus.

Despite the abundance of available algorithms, further security analysis is required.

III. Similar Works

While the idea of Lucamarini et al. [26] is still - comparatively - fresh, there are many teams worldwide already who share the same excitement and the desire for a more secure, far- reaching, multi-node QKD protocol. For example, the workof Cao et al. [34] [35] attempts to improve on the protocol provided by Lucamarini et al. by providing it with additional layers of randomization and detection. However, it is still a standalone protocol that does not cover all of the inherent security concerns of multi-node communication. One such example could be the insider attack, both from a compromised center and/or nodes. As for the work of Metwaly et al. [36], while it does have an all-encompassing approach to ensure the security of the network as well as providing a way of scaling this approach for a network of networks, it is still very theoretical and lacks concrete examples of how certain stages can be achieved, if at all. A good example of the same idea but with better authentication ingrained would be the work of Sellami et al. [37]. In this work, a fairly straightforward approach to authentication was described. Still, the question of a trusted center stands.

IV. Methods

A. Twin-Field Quantum Key Distribution

Twin-Field Quantum Key Distribution - is a protocol that is one of many protocols (more specifically MDI-QKD protocols) that sup- ports the delivery or distribution of secret key fragments or complete secret keys between certain parties via the utilizationof laws of quantum mechanics. More specifically, the classicalversion of this protocol [26] utilizes the notion of wave-particle interference between two parties Alice and Bob who utilize a remote measuring device, which is called Charlie or Eve. Eachof the participants utilizes what is called Weak Coherent State [38] in the X basis as well as Decoy State [39] in the Z basis both have assigned randomized phases and intensities.

Twin-Field Quantum Key Distribution (TF-QKD) is a protocol within the broader category of Measurement-Device-Independent Quantum Key Distribution (MDI-QKD) protocols, designed to facilitate the secure delivery or distribution of secret key fragments or complete secret keys between parties using the principles of quantum mechanics. The classical version of this protocol [26] (General Scheme is shown in Fig. 1.) employs the concept of wave-particle interference between two parties, commonly referred to as Alice and Bob, who interact through a remote measurement device, often termed Charlie or Eve. Each participant utilizes a Weak Coherent State [38] in the X basis and a Decoy State [39] in the Z basis, both of which are characterized by randomized phases and intensities.

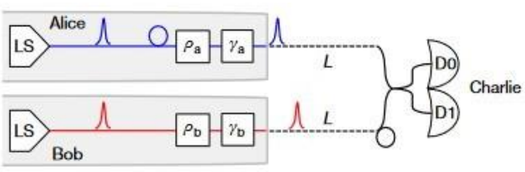

Fig. 1. Twin field QKD general scheme [26].

After the randomization of phases and intensities, each participant transmits respective Weak Coherent States (WCS) to Eve or Charlie, who performs the measurement and subsequently announces the acquired result. The announcement indicates whether the measurement detected photons with matching logical values (00 and 11) or differing values (10 and 01). Despite Eve being the entity that conducts the measurement and reports the results, Eve remains unaware of the actual key values (whether the bits are 1 and 1 or 0 and 0); Eve only knows the parity of the results. This particular QKD protocol ensures the centralized delivery of the "network portion" of the key to all hosts while providing robust security against external threats such as eavesdropping and Man-in-the-Middle (MITM) attacks.

B. KMB09

KMB09 is a protocol that, despite some skepticism, is considered part of the broader category of Measurement-Device-Independent Quantum Key Distribution (MI-QKD) protocols. The protocol relies on the mechanism of encoding a qubit into at least four different states (for simplicity, N=2 is considered) for Alice using two bases, E and F, as shown in Fig. 2. In the initial step, Alice randomly selects a basis and an index for encoding a photon and transmits the encoded photon through a quantum channel to Bob. Bob then measures the incoming photons using a randomly chosen basis. For Bob's measurement to be meaningful, Alice must disclose some information about the chosen bases publicly through a classical communication channel, such as fiber-optic. Specifically, Alice needs to reveal the selected index, either 1 or 2. However, this disclosure does not allow Eve or any other malicious party to gain knowledge about the key, as even with knowledge of the index, Eve cannot determine which basis Alice chose.

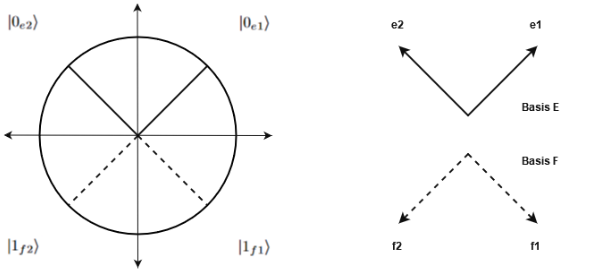

Fig. 2. KMB09 bases.

For example, if basis E is used to encode 0 and basis F is used to encode 1, the outcome of Bob's measurement, in conjunction with the non-parity of indices chosen by both Alice and Bob, determines whether the result is 1 or 0. If the indices match, a "no signal" message is announced to enhance the security of the transmission. This step ensures that the transmission remains secure even in the presence of potential eavesdropping.

As a result, and in alignment with findings from the original research article [40] and a recent overview paper [15], this protocol ensures the secure exchange of user or node-specific key portions between network participants, effectively mitigating the risk of intercept-resend attacks and similar types of security threats.

C. Proposed Method

This section details the functioning of the proposed hybrid concept within a network infrastructure that accommodates multiple users. The core objective of this concept is to secure communication among a verified number of nodes or clients within a centralized, untrusted network, as illustrated in Fig. 3.

To accomplish this, the approach combines the strengths of Measurement-Device-Independent Quantum Key Distribution (MDI-QKD), Measurement-Independent Quantum Key Distribution (MI-QKD), Continuous Variable QKD (CV-QKD), and Discrete Variable QKD (DV-QKD).

In this configuration, the untrusted center and the primary measuring device can be represented by entities such as Charlie or Eve, as the specific identity is inconsequential. The current iteration of this hybrid protocol is designed for integration with classical infrastructure. Consequently, the quantum channels utilized are standard fiber-optic cables.

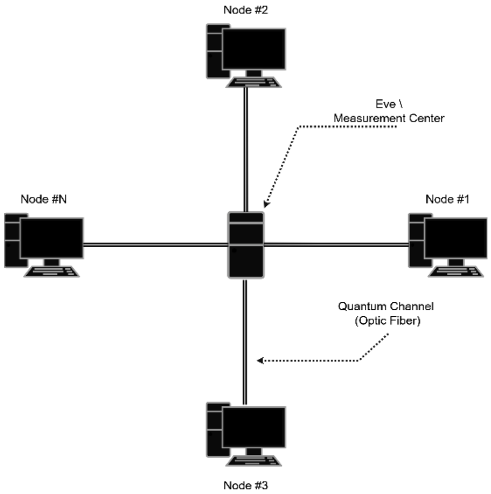

Fig. 3. General setup.

First, it is essential to verify the identities of all nodes within the network and eliminate any impostors. This can be achieved by employing a Quantum Digital Signature (QDS) protocol, such as the one described in study [41]. Once this verification process is complete, the first phase of the protocol can begin.

In the first phase, the Twin-Field QKD protocol is employed, wherein Weak Coherent States (WCSs) are transmitted from each authenticated node to the untrusted central node, Eve. Eve then measures the combined interference of all the sent states. The resulting values are not strictly 1 or 0 but rather a fluctuation between them. These fluctuations can be resolved using the Sigmoid Function, with the results publicly announced. By following this process, all nodes within a specific timeframe will obtain the "network portion" of the key.

In this step, each node transmits its respective randomized Weak Coherent States to initiate the creation of the "network portion" of the key at the measuring device, Eve (Fig. 4). This process should be repeated K times until a sufficient number of bits is accumulated within the "network portion" of the key.

In detail, each authenticated node U_i generates weak coherent states $|a_i\rangle$, where a_i represents the amplitude of the coherent state. The coherent state $|a_i\rangle$ can be expressed by following Eq. (1):

$$a_i = e^{\frac{\left(-|a_i|^2\right)}{2}} \sum_n^\infty \frac{a_i^n}{\sqrt{n!}} |n\rangle \tag{1}$$

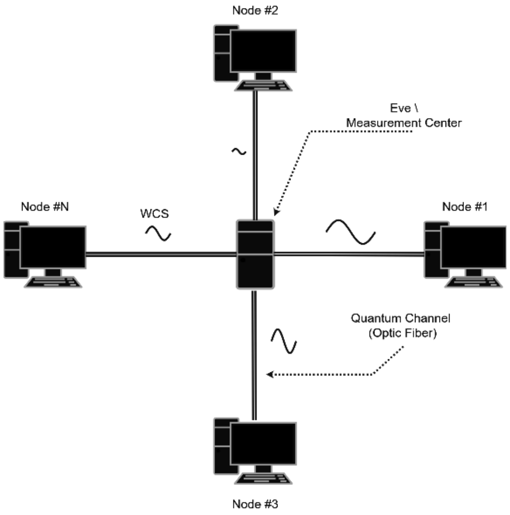

Fig. 4. Simplified stage 1.

where$|n\rangle$ represents the state with n photons. These states are sent to the central node E (Eve). The central node E measures the interference of all coherent states $|a_i\rangle$ sent by the different nodes. The total state at the central node can be described by a superposition of coherent states, refer to the Eq. (2):

$$|\phi\rangle = \sum_j |a_i\rangle \tag{2}$$

where $|a_i\rangle$ is the coherent state sent by the node U_j. The measured interference values I will fluctuate between 0 and 1. To convert these fluctuations into a more convenient format, the sigmoid function is applied. For the example refere to the Eq. (3):

$$\sigma(x) = \frac{1}{1+e^{-x}} \tag{3}$$

where x is the measured interference value. The result of $\sigma(1)$ provides a probabilistic estimate, which is then publicly announced to all nodes.

Once the measurement results are announced, each node can utilize this data to generate the "network portion" of the key. Let the measured values for node U_i and the central node E be denoted as K_i and K_E, respectively. Then, the key fragment for node U_i can be described as the following function (4):

$$U_i = f(\sigma(I), metadata) \tag{4}$$

where f is a function that defines how the measured data is transformed into key values.

Following the distribution of the "network portion" (NP), the next phase involves the generation and organization of "pair portions" (PP). This phase requires the application of the KMB09 protocol for individual pairing and key exchange. Each node or client must initiate a pairing process with every other node in the network, resulting in a total of $n - 1$ pairings per node. Consequently, the total number of unique keys generated will be $(n * (n - 1))/2$. The uniqueness of these pairwise keys is critical for ensuring security, as it provides protection not only against external threats but also from potential internal eavesdroppers.

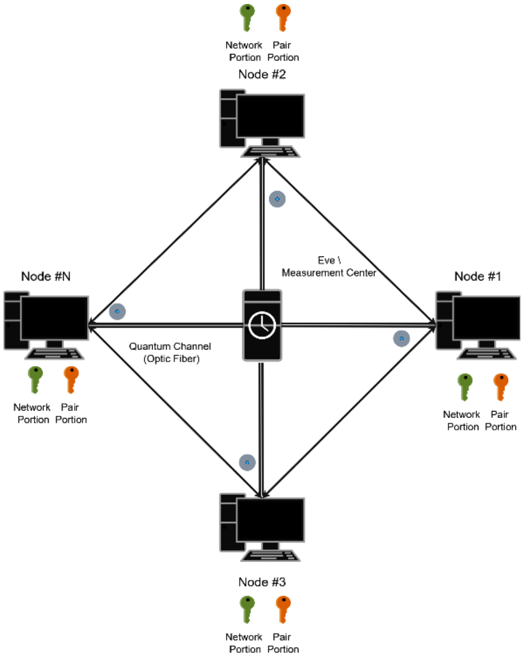

Fig. 5. Simplified stage 2.

In this setup (Fig. 5), each node transmits its randomly base-encoded photons to other nodes via a central untrusted measuring device, Eve. In this scenario, Eve acts purely as an intermediary, directing the photons to the appropriate quantum channels between the nodes intended for pairing. As a result, Eve does not obtain any information about the pair key, even if Eve attempts to intercept and resend a photon.

Thus, both the "network portion" and the "pair portion" have been successfully established. These keys can now be combined to generate a pair-unique master key, which facilitates the initiation of encrypted communication between selected nodes. To further elucidate the second part of the protocol, a mathematical analysis will be provided.

Consider a network consisting of n nodes. Each node U_i must establish a secure connection with each of the other nodes U_j, where $i \neq j$. For each node U_j, it is necessary to establish pairwise connections with the remaining $n-1$ nodes. As a result, there will be $\frac{n(n-1)}{n}$ unique pairwise keys. This quantity is determined by the formula for the number of combinations provided below (5):

$$\binom{n}{k} = \frac{n(n-1)}{2} \tag{5}$$

The KMB09 protocol is employed to generate and exchange pairwise keys between nodes. This protocol is grounded in quantum mechanics and includes the following steps:

- Initialization: Nodes U_i and U_j initiate the process by exchanging quantum states ϕ_i and ϕ_j, respectively.

- Measurement: Each node conducts measurements on the quantum state received from the other node.

- Key Extraction: Based on the measurements obtained, each node derives the key information K_{ij} corresponding to the secure communication between nodes U_i and U_j .

Let the key generated between nodes U_i and U_j be denoted as K_{ij}. Mathematically, this can be expressed as a key generation function provided below (6):

$$K_{ij} = f\left(|\phi_i\rangle, |\phi_j\rangle\right) \tag{6}$$

where f is a function that defines the algorithm for deriving a key based on the exchange of quantum states. After generating the pairwise keys K_{ij} for each pair of nodes, each node possesses:

- The network portion of the key $K_{network}$, which was generated during the first phase.

- The paired portion of the key K_{ij}, which was generated during the second phase for each node U_j .

To generate a unique master key for a pair of nodes U_i and U_j , it is necessary to combine their respective key components. Let $K_{master,ij}$ denote the master key for nodes U_i and U_j as in the example provided below (7):

$$K_{master,ij} = g\left(K_{master}, K_{ij}\right) \tag{7}$$

where g is a function that defines the method for combining the network portion and the pair portion of the keys.

Typically, this process involves applying an XOR operation or another concatenation function (8):

$$K_{master,ij} = K_{master} \oplus K_{ij} \tag{8}$$

where $\oplus$ represents the bitwise XOR operation.

To evaluate the scalability of the protocol, a graphical representation of the network is employed (Fig. 5). In a network consisting of *N* nodes, each node can exchange keys with every other node. This configuration can be visually depicted as a complete graph, where the nodes are represented as vertices and the connections between them are illustrated as edges.

V. Results and Discussion

In this paper, after careful comparison and analysis of existing methods, algorithms, and protocols a novel approach was proposed. This Hybrid Twin-Field QKD approach presents an opportunity to securely generate and share a secret key, communicate between specific nodes secured from internal eavesdroppers by the KMB09 protocol, and communicate within a network secured from outside interferences and eavesdroppers by Twin-Field QKD.

While the proposed hybrid QKD protocol is theoretically feasible, its practical implementation is currently limited, as only the individual components have been demonstrated to be achievable in real-world settings. Moreover, although Twin-Field QKD theoretically supports communication distances of up to 600 km or even 800 km, the protocol's overall range is constrained by the shortest distance supported by KMB09. This limitation highlights an important objective for future work:

extending the effective communication range of the hybrid protocol.

Additionally, there is a need for a more comprehensive analysis of the internal and external security aspects of the proposed concept, including metrics such as Quantum Bit Error Rate (QBER) [42]. Further research is also necessary in related areas, including Quantum Digital Signature (QDS) protocols, quantum authentication protocols in general, and improvements to the performance of KMB09. These avenues of investigation are crucial for enhancing the robustness and practicality of the hybrid QKD protocol.

VI. Conclusion

In conclusion, this paper has introduced and thoroughly analyzed a hybrid Twin-Field Quantum Key Distribution (QKD) protocol tailored for multi-user quantum networks. The proposed protocol addresses the increasing need for secure communication within untrusted, centralized networks, leveraging the strengths of both classical and quantum cryptographic techniques. By combining elements from various Quantum Key Distribution Protocols (QKDPs), the hybrid approach enhances the scalability and security of key distribution among multiple nodes.

The paper has provided a detailed examination of the global security landscape, highlighting the evolving challenges posed by quantum computing and the limitations of traditional cryptographic methods. Through a historical overview of QKDPs, the research identified key areas for improvement and integrated these insights into the proposed protocol.

The hybrid Twin-Field QKD protocol offers a robust solution for secure key distribution in complex network environments, ensuring protection against both external and internal threats. As quantum technologies continue to advance, this protocol represents a significant step toward realizing secure, scalable quantum communication networks. Future work may focus on further optimizing the protocol's efficiency and exploring its practical implementation in real-world quantum networks.

Acknowledgment

Research work was carried out within the framework of the project AP19675961 “Development and research of keys distribution protocols based on quantum properties”, which is being implemented at the Non-profit joint-stock company "Kazakh National Research Technical University named after K.I. Satbayev".

***Abstract*—This research focuses on the application of BERT (Bidirectional Encoder Representations from Transformers) and Graph Neural Networks (GNNs) to improve business intelligence (BI) capabilities on e-commerce platforms. The main aim of the research is to develop automation methods for the classification of customer interactions and to create a more effective product recommendation system. In this study, BERT was used to analyze and classify customer interaction texts, including questions, complaints, and reviews, with accuracy reaching 97% and sentiment analysis accuracy of 93%. GNNs are applied to model complex relationships between customers and products based on transaction data, then used to provide product recommendations. The evaluation results show that the GNNs model achieved a mean average precision (MAP) of 0.92 and a normalized discounted cumulative gain (NDCG) of 0.88, indicating high relevance and accuracy in product recommendations. This research concludes that the integration of BERT and GNNs improves operational efficiency through classification automation but also provides added value in marketing strategies with better personalization of recommendations.**

Keywords*—Bidirectional Encoder Representations from Transformers (BERT); Graph Neural Networks (GNNs); business intelligence; e-commerce; product recommendation

I. Introduction

In recent years, the e-commerce industry has experienced a significant surge in growth, resulting in the generation of vast and intricate amounts of data [1]. This dataset contains comprehensive information regarding customer transactions, shopping patterns, customer engagements, and more relevant data. In order to stay competitive, e-commerce platforms must create advanced business intelligence (BI) systems to evaluate this data and extract practical insights. In this situation, it is critical to enhance business intelligence (BI) skills using artificial intelligence (AI) technology [2], [3].

Bidirectional Encoder Representations from Transformers (BERT) and Graph Neural Networks (GNNs) are two advanced AI algorithms that have the potential to greatly improve business intelligence capabilities for e-commerce systems [4-6]. Google created the sophisticated transformer model known as BERT. This paradigm has transformed the field of natural language processing (NLP) because of its ability to comprehend bidirectional context in text. Natural language processing tasks such as natural language interpretation, text classification, and information retrieval can all benefit from the versatile application of BERT [7], [8]. BERT can enhance the study of customer interaction in e-commerce. By leveraging its advanced capabilities in comprehending conversations and context, BERT has the potential to enhance customer service by delivering more prompt and tailored assistance [9]. Graph Neural Networks (GNNs) represent a distinct class of neural networks designed to process and analyze data structured in a graph format. This algorithm is highly efficient at analyzing intricate linkages and interactions among diverse elements. By representing products, customers, and transactions as graphs, we can employ Graph Neural Networks (GNNs) to detect intricate patterns and correlations in e-commerce. This is highly beneficial for constructing more precise and pertinent product suggestion systems by utilizing data on the correlation between products and client preferences [10-13].

The objective of this study is to investigate the utilization of BERT and GNNs in enhancing business intelligence capabilities on e-commerce platforms [14]. This research aims to analyze customer interactions and make product recommendations, with the goal of gaining new insights into how artificial intelligence (AI) can enhance customer experience and boost business performance in the e-commerce industry [15]. It also seeks to evaluate the effectiveness of different algorithms in real-world situations, offering guidance for implementing improved business intelligence (BI) in the future [16].

II. Research Methodology

A. Methodology

The research commences by examining consumer interactions utilizing the BERT (Bidirectional Encoder Representations from Transformers) paradigm [17]. The initial stage is gathering conversational text data, reviews, and client inquiries from e-commerce platforms. Subsequently, this data undergoes pre-processing to eliminate any unwanted interference and make it ready for subsequent analysis. BERT models undergo fine-tuning with these datasets to perform tasks like text categorization and comprehension of conversational context, resulting in more profound characteristics and a better grasp of consumer preferences and requirements [18].

Following the study using BERT, the research proceeds by constructing an association graph between customers and items with graph neural networks (GNNs) [19]. Graphs are constructed using transaction data and BERT analysis outcomes to depict intricate connections among entities. Graph Neural Networks (GNNs) are subsequently utilized to represent and examine relationship patterns inside these graphs, with a specific emphasis on producing precise and pertinent product recommendations [20], [21].

Performance evaluations are conducted by utilizing metrics like precision, recall, F1-score, and NDCG (normalized discounted cumulative gain) to assess the efficiency of the recommendation model [22]. The outcomes of these two phases are merged to offer a more all-encompassing business intelligence solution and enhance the e-commerce platform's abilities in comprehending and catering to its customers can be seen in Fig. 1.

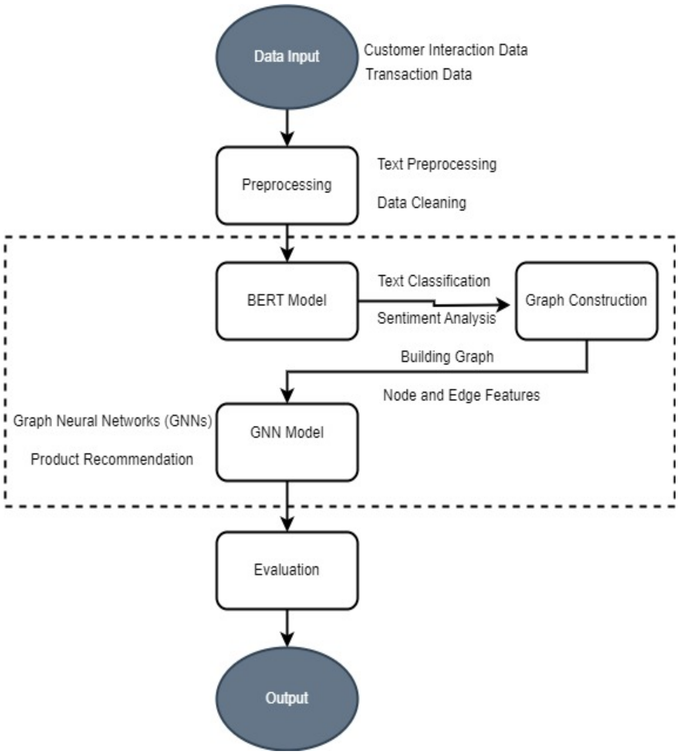

Fig. 1. Research methodology.

B. Problem Solving Approach

1) Artificial Intelligence (AI) in Business Intelligence (BI) for e-commerce: Artificial intelligence (AI) plays a crucial role in advancing business intelligence (BI) systems [23]. Within the realm of electronic commerce, business intelligence (BI) converts unprocessed data, including sales transactions, customer activity, and user interactions, into significant insights that influence company decision-making [24]. By integrating artificial intelligence (AI), business intelligence (BI) systems may analyze vast quantities of data, uncover concealed patterns, and offer highly precise, predicted insights. This integration significantly improves an e-commerce platform's capacity to comprehend and cater to its clients in a more efficient manner [25].

2) Bidirectional Encoder Representations from Transformers (BERT): BERT possesses the capacity to comprehend bidirectional context in text, enabling it to analyze words in sentence context from both the left-to-right and right-to-left orientations. These tasks, such as text classification, information retrieval, and natural language understanding, are particularly crucial [26]. In the realm of e-commerce, BERT is employed to scrutinize client interactions, including product evaluations and dialogues with customer care, to extract profound insights into customer requirements and inclinations. Utilizing this comprehension of consumer interactions helps enhance customer service and customization. Below are the sequential instructions for utilizing BERT. The following main components underlie BERT [27-30]:

Phase 1→ Input Embeddings

$$mbedding\ (x_i) = TokenEmbedding\ (x_i) + ESegmentEmbedding\ (x_i) + PositionEmbedding\ (x_i) \quad (1)$$

Phase 2 → Self-Attention Mechanism

BERT's key component self-attention allows the model to focus on different parts of the input sequence when processing each token.

Scaled Dot-Product Attention

$$Attention(Q, K, V) = softmax\left(\frac{QK^T}{\sqrt{d_k}}\right)V \quad (2)$$

Where:

Q query matrix

K key matrix

V value matrix

d_k dimensions of the key

Multi-Head Attention

$$MultiHead(Q, K, V) = Concat(head_1, head_2, \dots, head_h)W^O \quad (3)$$

Where:

$head_i = Attention(QW_i^Q, KW_i^K, VW_i^V)$

W_i^Q, W_i^K, W_i^V weight matrix for the i th head

W^O output weight matrix

Phase 3 → Feed-Forward Neural Network

$$FFN(x) = \max(0, xW_1 + b_1)\, W_2 + b_2 \quad (4)$$

Phase 4 → Layer Normalization

$$LayerNorm(x) = \frac{x - E[x]}{\sqrt{Var[x] + \epsilon}}.\gamma + \beta \quad (5)$$

Where:

$E[x]$ the average value of the input

$Var[x]$ variance of the input

ϵ small constant to prevent division by zero

γ and β parameters that can be studied

Phase 5 → Loss Function

$$Loss = -\sum i \in masked\ positions\ LogP(x_i|x_{<i}, x_{>i}) \quad (6)$$

Phase 6 →Training Objective

BERT is trained in masked language modeling (MLM) and next sentence prediction (NSP).

Masked Language Modelling (MLM)

$$MLM\ Loss = -\sum i \in masked\ positions\ LogP\ (x_i|x_{masked}) \quad (7)$$

Next Sentence Prediction (NSP)

The model is trained to predict whether two input sentences appear sequentially in the original text.

$$NSP\ Loss = -(y \log P\ (IsNext) + (1-y)\log P(NotNext)) \quad (8)$$

Where y Binary labels indicate whether two sentences are sequential or not.

3) Graph Neural Networks (GNNs): Graph neural networks (GNNs) proficiently examine intricate connections and interactions among diverse elements. Graphs consist of nodes that can represent various entities, such as consumers and items [31]. The connections between these entities, such as buy transactions, are represented by edges. Graph Neural Networks (GNNs) have the ability to acquire knowledge about these graphs and are employed for tasks such as predicting connections (e.g., suggesting products) and categorizing nodes. E-commerce platforms can enhance the precision and relevance of their product recommendation algorithms by leveraging graph neural networks (GNNs) to analyze intricate relationship patterns between products and customers [32-34].

Phase 1 → Graph Representation

Graf G defined as a pair (V, E), where V is the set of nodes and E is a set of edges.

Phase 2 → Basic Notation

h_u Features of neighboring nodes u

W Learnable weight matrix

σ Non-linear activation function

$N(v)$ Set of neighbors of node v

Phase 3 → Propagation Rule

General Message-Passing Framework

$$h_v^k = \sigma(W^k.AGGREGATE^k(\{h_u^{k-1}: u\epsilon N(v)\})) \quad (9)$$

Phase 4 → Output Layers

After the propagation layer, the node representation is updated and ready to be used in predictions

C. Data Classification and Analysis

The primary data consists of customer interactions, product transactions, product details, and relationship networks connecting customers and products. We evaluate customer contact data, including chats, reviews, and feedback, using the BERT model to gain a comprehensive understanding of customer preferences and wants [35]. We utilize data on product transactions, including client purchases, to construct graphs that illustrate the correlation between customers and products. Product information, such as category and price, enhances the feature nodes in the network. Graph neural networks (GNNs) subsequently examine the graph representing the link between customers and products to identify intricate relationship patterns and deliver precise product suggestions. The analysis procedure entails extracting features, gathering information from neighboring nodes in the network, and using a non-linear activation function to generate node representations [36] that can be seen in Table I.

TABLE I. NODE REPRESENTATIONS

Data Type	Description	Analysis Method	Objective
Customer Interaction	Customer conversations, reviews and feedback.	BERT	Understand customer preferences and needs
Product Transactions	Information about product purchases by customers.	Transaction Analysis and GNSs	Building customer-product relationship graphs and pattern analysis.
Product Information	Product details include category and price.	Data Enrichment & GNNs	Node features in a graph.
Relationship Graph	Graph representation of the relationship between customers and products based on transactions.	Graph Neural Networks (GNNs)	Detect relationship patterns and product recommendations.

III. RESULT AND DISCUSSION

Data in Tables II, III and IV include customer interactions, product transactions, product information, as well as additional features used in the customer-product relationship graph and data in Tables V, VI and VII include information for analysis, from customer interactions to product transactions and relationship graphs. Each parameter in the data, such as Text Length, Transaction Frequency, Edge Weight, and Node Features, provides context for understanding how customers interact with products on an e-commerce platform. This data provides the basis for in-depth analysis and implementation of algorithms to improve Business Intelligence on e-commerce platforms.

TABLE II. CUSTOMER INTERACTION DATA

Interaction ID	Customer ID	Text
1	101	"What is the return policy for this item?"
2	102	"Do you have this product in size M?"
3	103	"How long does shipping take?"
4	104	"Can I change my order after placing it?"
5	105	"Are there any discounts available?"
6	106	"I received a damaged item, what should I do?"
7	107	"Is this product available in other colours?"
8	108	"I need help with tracking my order."
9	109	"Can I get a refund for this purchase?"
10	110	"What is the warranty period for this product?"

TABLE III. PRODUCT TRANSACTION DATA

Transaction ID	Customer ID	Product ID	Quantity	Transaction Frequency	Purchase Variety
1	101	1001	2	3	2
2	102	1002	1	1	1
3	103	1003	3	4	2
4	104	1004	1	2	1
5	105	1005	2	3	1
6	101	1006	1	3	2
7	102	1007	1	1	1
8	103	1008	1	4	2
9	104	1009	1	2	1
10	105	1010	2	3	1

TABLE IV. PRODUCT INFORMATION DATA

Product ID	Product Name	Category	Price	Stock Availability	Product Ratings
1001	T-shirt	Clothing	20	In Stock	4.5
1002	Running Shoes	Footwear	50	In Stock	4.7
1003	Leather Jacket	Clothing	100	Out of Stock	4.6
1004	Smartwatch	Electronics	150	In Stock	4.8
1005	Wireless Earbuds	Electronics	30	In Stock	4.4
1006	Backpack	Accessories	40	In Stock	4.3

A. Data Processing Results with BERT

Most customers ask about return policies, product availability, and shipping information. This indicates areas need to be clarified on e-commerce sites to reduce customer service burden. Complaints about damaged goods and requests for refunds were most common, indicating a need to improve delivery quality and return policies. BERT successfully classifies customer interaction texts into relevant categories with a high level of confidence. This allows e-commerce platforms to automatically handle various types of customer inquiries or complaints more efficiently, shown in Table VIII.

TABLE VIII. CUSTOMER INTERACTION ANALYSIS (TEXT CLASSIFICATION)

Interaction ID	Customer ID	Text	Predicted Class	Confidence Score
1	101	"What is the return policy for this item?"	Inquiry: Return Policy	0.98
2	102	"Do you have this product in size M?"	Inquiry: Product Availability	0.95
3	103	"How long does shipping take?"	Inquiry: Shipping Information	0.97
4	104	"Can I change my order after placing it?"	Inquiry: Order Modification	0.96
5	105	"Are there any discounts available?"	Inquiry: Discounts	0.93
6	106	"I received a damaged item, what should I do?"	Complaint: Damaged Item	0.99
7	107	"Is this product available in other colours?"	Inquiry: Product Availability	0.95
8	108	"I need help with tracking my order."	Inquiry: Order Tracking	0.94
9	109	"Can I get a refund for this purchase?"	Request: Refund	0.97
10	110	"What is the warranty period for this product?"	Inquiry: Warranty Information	0.96

B. *Data Processing Results with GNNs*

GNNs identify purchasing patterns and provide relevant product recommendations for each customer. These recommendations are based on historical relationships between products frequently purchased together by other customers with similar purchasing patterns as in the Table IX.

TABLE IX. CUSTOMER SEGMENTATION ANALYSIS

Segment	Characteristics	Actionable Insights
High-Value Customers	Customers who buy products at high prices	Focus on personalizing premium product offerings
Frequent Buyers	Customers with high purchasing frequency	Loyalty offers or discounts based on volume
Category Loyalists	Customers who tend to buy from one category	Promote related products in the same category

IV. VALIDATION

A. *Performance Evaluation of BERT*

BERT is used for customer interaction text classification. Performance evaluation is measured using several metrics [37], [38].

$$Accuracy = (\frac{Number\ of\ correct\ predictions}{Total\ number\ of\ predictions}) \tag{10}$$

$$Precision = \frac{True\ Positives\ (TP)}{True\ Positives\ (TP)+False\ Positives\ (FP)} \tag{11}$$

$$Recall = \frac{True\ Positives\ (TP)}{True\ Positives\ (TP)+False\ Negatives\ (FN)} \tag{12}$$

$$F1-Score = 2\ \times \frac{Precision\ \times Recall}{Precision+Recall} \tag{13}$$

Table X shows BERT provides excellent results in text classification and sentiment analysis, with high scores in all key metrics. This reflects BERT's ability to effectively understand and process customer interaction texts for customer service automation and data-driven decision making in e-commerce platforms.

TABLE X. BERT PERFORMANCE EVALUATION

Evaluation Metrics	Value	Interpretation
Accuracy	97%	97% of BERT's total predictions were correct, demonstrating a high level of accuracy in customer interaction text classification.
Precision	0.95	95% of the positive predictions made by BERT were true positive, indicating that this model has a low false positive rate.
Recall	0.96	BERT successfully identified 96% of all existing positive cases, indicating that the model is very good at detecting the correct classes.
F1-Score	0.96	A harmonious combination of Precision and Recall, showing a good balance between the two.
Sentiment Analysis Accuracy	93%	BERT was able to classify sentiment with 93% accuracy, demonstrating reliability in determining whether text is positive, negative, or neutral.

B. *Performance Evaluation of GNNs*

GNNs are used for tasks such as product recommendation and customer-product relationship graph analysis. Its performance evaluation is measured using metrics such as Mean Average Precision (MAP) and Normalized Discounted Cumulative Gain (NDCG) [39]:

MAP

$$MAP = \frac{1}{2}\sum_{i=1}^{n} AP(i) \tag{14}$$

NDCG

$$DCG_p = \sum_{i=1}^{p} \frac{2_i^{rel}-1}{\log_2(i+1)} \tag{15}$$

$$NDCG_p = \frac{DCG_p}{IDCG_p} \tag{16}$$

Precision@K

$$Precision@K = \frac{Number\ of\ relevant\ items\ in\ K\ recommendations}{K} \tag{17}$$

TABLE XI. GNNS PERFORMANCE EVALUATION

Evaluation Metrics	Value	Interpretation
Mean Average Precision (MAP)	0.92	92% of the products recommended by GNNs are relevant and match customer preferences.
Normalized Discounted Cumulative Gain (NDCG)	0.88	Relevant recommendations tend to appear at the top of the recommendation list, increasing the likelihood of a product being chosen by a customer.
Precision@5	0.93	93% of the top five recommendations are relevant to customers.
Precision@10	0.89	89% of the top ten recommendations are relevant to customers.
Coverage	85%	GNNs cover 85% of the products in the catalogue, ensuring diverse and varied recommendations.
Hit Rate	0.90	90% of all customers find at least one relevant product in their recommendation list.

V. CONCLUSION

This research reveals how the use of BERT (Bidirectional Encoder Representations from Transformers) and Graph Neural Networks (GNNs) can improve business intelligence (BI) capabilities on e-commerce platforms. Through in-depth analysis, BERT was proven to be effective in classifying customer interaction texts with an accuracy rate of 97% and was able to perform sentiment analysis with an accuracy rate of 93%. This enables automation in the management of customer inquiries and complaints, directly increasing customer service efficiency. GNNs show good performance in providing relevant product recommendations, with a mean average precision (MAP) of 0.92 and a normalized discounted cumulative gain (NDCG) of 0.88. GNNs also managed to cover 85% of the products in the catalog, ensuring that the recommendations provided were varied. Customer segmentation generated by GNNs allows the identification of segments such as high-value customers and frequent buyers, which can be targeted with more precise marketing strategies, increasing campaign effectiveness and customer loyalty.

Elevating Grape Detection Precision and Efficiency with a Novel Deep Learning Model

Xiaoli Geng*, Yaru Huang, Yangxu Wang
Department of Network Technology, Guangzhou Institute of Software Engineering, Conghua, Guangdong, China

***Abstract*—In the domain of modern agricultural automation, precise grape detection in orchards is pivotal for efficient harvesting operations. This study introduces the Grapes Enhanced Feature Detection Network (GEFDNet), leveraging deep learning and convolutional neural networks (CNN) to enhance target detection capabilities specifically for grape detection in orchard environments. GEFDNet integrates an innovative Enhanced Feature Fusion Module (EFFM) into an advanced YOLO architecture, employing a 16x downsampling Backbone for feature extraction. This approach significantly reduces computational complexity while capturing rich spatial hierarchies and accelerating model inference, which is crucial for real-time object detection. Additionally, an optimized dual-path detection structure with an attention mechanism in the Neck enhances the model's focus on targets and robustness against dense grape detection and complex background interference, a common challenge in computer vision applications. Experimental results demonstrate that GEFDNet achieves at least a 3.5% improvement in mean Average Precision (mAP@0.5), reaching 89.4%. It also has a 9.24% reduction in parameters and a 10.35 FPS increase in frame rate compared to YOLOv9. This advancement maintains high precision while improving operational efficiency, offering a promising solution for the development of automated harvesting technologies. The study is publicly available at: https://github.com/YangxuWangamI/GEFDNet.**

Keywords*—Computer vision; deep learning; Convolutional Neural Networks (CNN); real-time object detection; dual-path detection structure

I. Introduction

Grapes, as deciduous vines of the Vitis genus, are celebrated as the "Queen of Fruits." They are not only rich in nutrients but also possess significant medicinal value, making them one of the most popular fruits globally [1]. In the field of agricultural automation, precise grape detection is key to improving harvesting efficiency and fruit quality. Although manual harvesting is still the mainstream method, it is inefficient and labor-dependent [2], creating an urgent need for automated solutions. Existing vision detection systems face challenges in complex orchard environments, such as changes in lighting, occlusions, and fruit overlapping, which limit their performance. Therefore, a robust detection model is crucial for robots to achieve target perception in complex vineyard scenarios [3].

To enhance the recognition ability and efficiency of deep learning models in orchard grape detection, the goal of this study is to develop a fast, parameter-reduced, and low-miss detection model for dense and occluded grape detection in orchards, named Grapes Enhanced Feature Detection Network (GEFDNet). At the same time, YOLOv9 [4], as the latest generation of the YOLO series, has demonstrated its excellent accuracy and speed in various general object detection tasks through optimized network architecture and detection algorithms. Despite this, applying YOLOv9 directly to grape detection tasks in orchards still faces specific challenges. In response to these challenges, the GEFDNet model targets grapes, innovatively designing a 16x downsampling Backbone network and proposing a new high-efficiency scale fusion module called the Enhanced Feature Fusion Module (EFFM) module, aiming to capture target feature information at a finer granularity. Applied to the main trunk and detection neck networks, it significantly reduces the model's computational burden and parameter volume, enabling GEFDNet to better adapt to the complex and variable agricultural environment.

In the experiments, to objectively and comprehensively evaluate model performance, this study conducted comparative experiments with seven other advanced methods, especially an in-depth performance evaluation against the benchmark model YOLOv9. Performance analysis results show that GEFDNet has increased the mean Average Precision (mAP@0.5) on the test dataset by at least 3.5%. Through visual analysis, the model's advantages in dealing with challenging complex scenes were further revealed. In addition, compared to YOLOv9, GEFDNet has reduced the parameter volume by about 9.24% and increased the frame rate (FPS) by 10.35. This series of data highlights the efficiency of GEFDNet in object detection tasks.

The main contributions of this paper are as follows:

- The design of the EFFM module, which enhances the accuracy and efficiency of target detection in images by providing a powerful feature extraction and fusion mechanism for grape target detection tasks.
- The innovative design of a 16x downsampling Backbone network addresses the prolonged training times and weight redundancy issues associated with YOLOv9's detection neck and auxiliary branch structures.
- Optimization of the main detection neck design overcomes the difficulty of detecting occlusions and dense targets, reduces the model's computational burden and parameter count, and ensures high detection accuracy in resource-constrained environments.
- Comparative experiments with seven other popular detection models demonstrate GEFDNet's advantages in lightweight design, further verifying its effectiveness and feasibility.

The layout of this paper is as follows: Section I (this section) introduces the prominent issues in the research field and the motivation behind the model design. Section II summarizes the research background and the challenges of existing technology. Section III provides a detailed introduction to the characteristics of the dataset and the principles of model design. Section IV includes the experimental process, model performance comparison, and result analysis. Section V discusses the research findings and proposes future research plans. Section VI summarizes the entire paper.

II. Background

With the rapid development of computing power and deep learning techniques [5], convolutional neural networks have attracted attention across various industrial sectors. Object detection models integrated with deep learning are being increasingly applied to agricultural studies, including fruit recognition [6, 7], disease detection [8, 9, 10], and yield estimation [11, 12]. Currently, deep learning-based fruit object detection models are mainly divided into two categories: one category is the region proposal-based two-stage detection models, such as Faster R-CNN [13] and Spatial Pyramid Pooling Network (SPP-Net) [14], which have high detection accuracy but are slower due to their two-stage nature. The other category is the regression-based single-stage detection models, such as SSD [15], YOLO [16, 17], and CenterNet [18], which maintain high detection accuracy while offering faster detection speeds and stronger real-time capabilities. Due to the high demand for detection speed in most tasks, especially in real-time scenarios, single-stage algorithms have more advantages in practical applications.

In recent years, research on deep learning models for grape detection has been continuously emerging. The latest research from Wu et al., 2024 [19], uses Adaptive Training Sample Selection (ATSS) as a label matching strategy to improve the quality of positive samples and address the challenge of detecting grape stems with similar colors. They utilize the Wise-IoU (Sequential Evidence for Intersection over Union) loss function with weighted interpolation to overcome the limitations of CIoU, which does not consider the geometric properties of targets, thus improving detection efficiency. Behera et al., 2023 [20], proposed an FR-CNN algorithm for plant fruit prediction using Intersection over Union (IoU), achieving an 89% accuracy rate in fruit yield estimation. Aguiar et al., 2021 [21], used deep learning models for grape cluster detection with an average accuracy of 66.96%. Pereira et al., 2019 [22], introduced a grape detection method based on the AlexNet neural network architecture, achieving a high average accuracy of 77.30%. Rong et al., 2024 [23], proposed a grape cluster detection method based on Spatial-to-Depth Convolution (STD-Conv) and Simple Attention Mechanism (SimAM), expanding the dataset through data augmentation technology, enabling the improved YOLOX model to achieve an 88.40% average accuracy in grape cluster detection. Marani et al., 2020 [24], proposed a vehicle-mounted RGB-D camera system for grape recognition using a deep learning framework. Sozzi et al., 2021 [25], used the YOLOv4 model for the detection and counting of grape clusters, achieving an accuracy rate of 48.90%. Li et al., 2021 [26], proposed an improved YOLOv4-tiny model, YOLO-Grape, to address the issue of unrecognizable accuracy caused by complex background scenes such as shadows and overlaps.

III. Materials and Methods

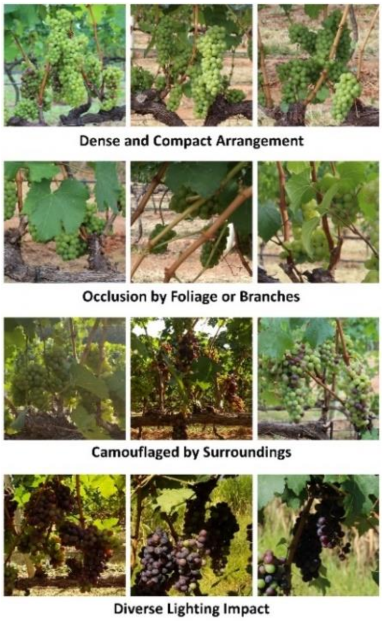
This section provides a detailed description of the datasets used in the experiments and elucidates the design principles, innovations, and activation functions of the GEFDNet model.

A. Datasets

To validate the effectiveness and adaptability of the proposed method, the experiments in this study are conducted using the Embrapa Wine Grape Instance Segmentation Dataset (Embrapa WGISD) [27]. This dataset was created for the application of object detection and instance segmentation techniques in image monitoring and field robot vision in vineyards, containing instance images of five different grape varieties. These images were captured under natural field conditions, encompassing various postures, lighting and focus conditions, as well as genetic and phenotypic variations such as shape, color, and compactness.

The images of the dataset were taken using a Canon EOS REBEL T3i DSLR camera and Motorola Z2 Play smartphone at the Guaspari Winery in São Paulo, Brazil. The image resolution was adjusted to a width of 2,048 pixels to balance image detail and processing time. The dataset was annotated with rectangular bounding boxes to identify grape clusters using the LabelImg tool [28], comprising a total of 300 images with 4,432 annotated grape clusters.

In summary, experiments conducted on the Embrapa WGISD dataset will provide a comprehensive evaluation of the universality and effectiveness of the proposed method. However, the orchard environment is challenging, as depicted in Fig. 1, which categorizes the dataset's characteristics and key detection challenges into four types, including densely packed arrangements of grapes, occlusions by leaves or trunks, complex backgrounds, and varying lighting conditions.



Dense and Compact Arrangement
Occlusion by Foliage or Branches
Camouflaged by Surroundings
Diverse Lighting Impact

Fig. 1. Four typical challenges in dataset images.

B. Model Construction

When applying neural networks for grape detection in orchard environments, numerous factors must be considered. To address these, this study introduces the Grapes Enhanced Feature Detection Network (GEFDNet), a novel high-precision, low-complexity grape detection model for orchard environments. The model adopts a Backbone-Neck structure and integrates the proposed Enhanced Feature Fusion Module (EFFM). The Backbone is responsible for extracting key features from the input images, employing a deep convolutional neural network to ensure the capture of rich spatial hierarchical information while reducing computational complexity. The Neck features a dual-path detection structure [4], including the Main Branch and the Auxiliary Branch, which further process target features, providing additional feature fusion and contextual information through parallel processing paths, enhancing the model's robustness against complex environmental variations. The architectural framework of GEFDNet is illustrated in Fig. 2, with detailed module structures, including EFFM, presented in Fig. 3. The auxiliary detection components are denoted with dashed lines in the diagrams. The following sections will detail their configuration specifics.

C. Enhanced Feature Fusion Module (EFFM)

Feature fusion is crucial for enhancing the model's generalization capability and detection accuracy in grape target detection tasks. By integrating features from different levels and scales, the model can more comprehensively understand image content, leading to more accurate identification and localization of grapes.

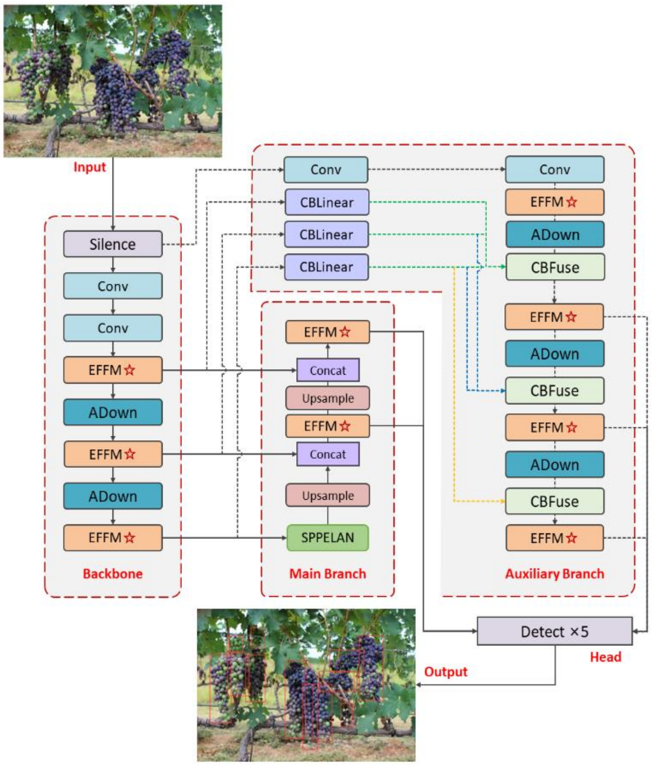


Fig. 2. Architecture of GEFDNet.

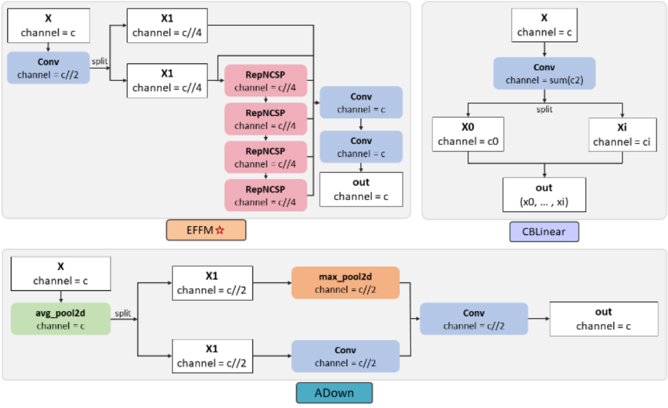

Fig. 3. Detailed module structures.

This paper introduces an innovative and efficient scale fusion module referred to as the Enhanced Feature Fusion Module (EFFM), as depicted in Fig. 3. After the input feature maps undergo a 1×1 convolution, the channel count is halved. The feature maps are evenly divided into two subsets of the same spatial size, denoted as X1, each with a quarter of the channel count of the input feature maps. One X1 subset is retained as is, while the other is processed through the RepNCSP module, further divided into four feature map subsets. These subsets undergo channel adjustments as they pass through each RepNCSP module, achieving efficient feature processing and fusion. For instance, a feature map may transition from channel count c to c//4, processed through a Conv layer, and further refined by the RepNCSP module, ultimately restoring to the original channel count c at the output. It is notable that each convolution can receive feature information from the preceding features, and for each feature branch after the RepNCSP module, the output has a larger receptive field and richer features compared to the unprocessed branch.

D. GEFDNet

1) Backbone Component: The Backbone component is tasked with feature extraction from input images. The architecture initiates with a Silence Module that serves as the preliminary processing unit, accepting raw image data and performing necessary preprocessing steps to maintain the initial feature information of the image, ensuring that the Main Branch and Auxiliary Branch can fully utilize this information for precise target localization. Subsequently, the model integrates multiple standard convolutional and pooling layers, each equipped with a 3×3 convolutional kernel, and employs stride-2 downsampling to reduce the dimensionality of the feature maps.

To enhance the model's nonlinear feature expression and integration capabilities, the Backbone network incorporates the innovative EFFM module, which facilitates deep integration of cross-layer features and effectively captures complex spatial hierarchies within the image. Notably, the core network of GEFDNet innovates in its downsampling strategy, adopting a 16x downsampling design that significantly reduces the loss of spatial resolution, enabling the model to excel in detecting small-sized targets and under varying lighting conditions.

Upon processing through the Backbone network, the model achieves 16x downsampling through four downsampling convolutional layers and three EFFM feature extraction layers, with the output feature map size being 1/16th of the original image, transitioning to multi-scale, multi-depth feature representations. This aids in reducing the model's computational load while retaining sufficient feature information to support subsequent detection tasks.

2) Neck Component: The Neck serves as the critical link between the Backbone and the detection Head, comprising both the Main Branch and the Auxiliary Branch. The Main Branch receives feature maps of varying downsampling levels output from the Backbone and initially processes them through an SPPELAN module to expand the receptive field, enhancing feature abstraction and expression. To further enhance the model's robustness, an attention mechanism is integrated into the Main Branch, allowing the model to adaptively focus on key image regions, such as grape edges and textures, thereby maintaining high accuracy despite challenges like occlusions and overlaps. Computational efficiency is also a significant consideration in the design of the Main Branch, where lightweight network components and depthwise separable convolutions are employed, effectively reducing the model's parameter count and computational complexity without compromising detection accuracy.

A series of upsampling and concatenation operations then follow, merging deep and shallow features from the Backbone to construct a multi-scale feature representation. Upsampling employs nearest neighbor interpolation to enlarge the feature map size, increasing resolution for more precise small target localization and facilitating fusion with larger feature maps. The concatenation operation integrates features from different levels, importantly, further processed through the innovatively designed EFFM feature extraction layer. Ultimately, the Main Branch outputs feature maps with high semantic information and spatial resolution, providing the Head with high-quality inputs for detection.

In addition to the Main Branch, the model's innovation lies in the design of the Auxiliary Branch, incorporating a reversible auxiliary branch design, utilizing cross-layer connections to directly extract and fuse features from the Backbone with high-level features from the Main Branch. Modules such as CBLinear and CBFuse are employed, unifying feature map sizes through cross-block connections and feature fusion strategies, followed by an addition operation to achieve multi-level auxiliary information fusion. This design not only enhances the model's detection capabilities for small targets and complex scenes but also reduces computational load through parallel processing, balancing computational efficiency with detection accuracy. Furthermore, the Auxiliary Branch serves as a regularization technique to prevent overfitting during model training.

3) Head Component: Upon the completion of the Neck's operations, the Head detection component receives five feature maps with varying spatial resolutions and semantic depths from the Neck. This enables the detection head to generate bounding boxes and aim frames of corresponding scales based on the feature map scales, overlaying the model's inference results onto the input image.

E. Activation Functions

In the realm of deep learning, activation functions play an indispensable role in dictating the performance and convergence rate of a model, determining the network's capacity to learn nonlinear relationships. Commonly utilized activation functions include Sigmoid Linear Unit (SiLU) [29], Rectified Linear Unit (ReLU) [30], and Leaky ReLU [31]. In constructing the GEFDNet model, this paper specifically selects SiLU as the activation function due to its combination of linear and nonlinear characteristics, which effectively enhances the network's nonlinear expressive power and learning efficiency. The definition of the SiLU activation function is presented in Eq. (1):

$$SiLU(x) = x \cdot \sigma(x) = x \cdot \frac{1}{1+e^{-x}} \tag{1}$$

The primary features of SiLU include its monotonicity, ensuring that as the input x increases, the output also increases, aiding in mitigating the vanishing gradient problem in deep networks. Its linearity for positive input values simplifies the nonlinear complexity in the positive range. SiLU's zero-centering characteristic, which outputs zero when $x = 0$, helps in centering the data, and when combined with batch normalization techniques, further improves the efficiency of model training. Additionally, SiLU boasts high computational efficiency as it involves only basic exponential and division operations, making it suitable for rapid execution on limited computational resources.

The Rectified Linear Unit (ReLU) activation function is one of the most popular nonlinear activation functions in deep learning. Its definition is straightforward and intuitive, expressed in Eq. (2):

$$ReLU(x) = max(0, x) \tag{2}$$

This function introduces nonlinearity by setting all negative values to zero, allowing only positive values to pass through, while maintaining computational efficiency. The main advantage of ReLU is its acceleration of the neural network training process; however, it also has some drawbacks, the most notable being the "dead ReLU" problem, where neurons corresponding to negative inputs may never activate, causing their weights to no longer update during training. In addition, ReLU's output is not zero-centered, which may affect the stability and convergence speed of the model during training.

Leaky ReLU is an improved version of ReLU, aiming to address the dead ReLU problem. Its formula is given in Eq. (3):

$$Leaky\ ReLU(x) = max(\alpha \cdot x, x) \tag{3}$$

Where α is a small positive number, typically taken as 0.01. Leaky ReLU introduces a small linear term when the input value is negative, ensuring that neurons with negative inputs still have a non-zero gradient, thus alleviating the problem of neuron death. This slight linear operation allows neurons with negative input values to still update their weights during the training process. However, Leaky ReLU introduces an additional hyperparameter α, which, if not chosen properly, may affect the network's convergence speed or lead to suboptimal model performance.

In deep learning, the choice of the appropriate activation function is crucial for model performance. Compared to ReLU and Leaky ReLU, SiLU offers several significant advantages, making it an ideal choice for grape detection models. SiLU's self-normalizing characteristic makes its output a linear transformation of the input in the positive range and approaches zero in the negative range, which helps stabilize network output and enhance generalization ability. Moreover, SiLU does not require additional parameters like Leaky ReLU, simplifying model training and hyperparameter adjustment. At the same time, the biological plausibility of SiLU further ensures the naturalness and efficiency of the activation pattern.

IV. Experience

This section provides an overview of the evaluation criteria and experimental design, followed by a presentation of the GEFDNet model's performance and a comparison with existing technologies. In addition to a comprehensive performance assessment using metrics such as Precision, Recall, and F1-score (F1), visual attention contrast experiments are introduced to further analyze the model's detection mechanisms. Utilizing Grad-CAM technology, the areas of focus when processing different grape samples are visualized, revealing GEFDNet's advantages in target recognition. Finally, the model's lightweight effect is evaluated, emphasizing its potential for efficient deployment in resource-constrained environments.

A. Experimental Conditions and Details

The study was conducted on a PC equipped with an AMD Ryzen 7 5800H 8-core processor (3.20 GHz) CPU and an NVIDIA GeForce GTX 3090 GPU. The software tools included the PyTorch 2.0.0 deep learning framework [32], CUDA version 11.8 parallel computing framework, and CUDNN version 8.9.5 deep neural network acceleration library. Standard data preprocessing methods were employed to fully leverage the dataset's information, including image scaling, cropping, and normalization, along with data augmentation techniques such as random flipping and rotation to enhance the model's generalization capability. Stochastic Gradient Descent (SGD) was used as the optimizer, with network training parameters set to an input size of 640×640 pixels, a batch size of 16, an initial learning rate of 0.01, a decay rate of 0.001, and a momentum parameter of 0.937. Considering convergence, 300 epochs of training were deemed sufficient for the model to reach a state of convergence.

B. Assessment of Model Performance

For the assessment of the proposed model within this study, the metrics of mAP@0.5, mAP@0.5:0.95, and F1-score were selected. The performance was compared against seven benchmark models, namely CenterNet [18], Faster R-CNN [13], SSD [33], FCOS [34], EfficientDet [35], YOLOv7-tiny [36], and YOLOv9 [4], utilizing the same dataset. The GEFDNet model underwent training and testing under identical conditions as the benchmark models, with evaluation based on Precision (P), Recall (R), F1-score (F1), and mean Average Precision (mAP).

Understanding the significance of these metrics requires clarity on the concepts of true positives (TP), false positives (FP), and false negatives (FN). TP represents the count of correctly identified samples, while FP denotes the instances of incorrect identifications. FN corresponds to the number of missed detections. The sum of "TP + FP" indicates the total inferred grape fruits by the model, and "TP + FN" accounts for the actual total count of fruits in the image.

Precision (P), which measures the accuracy of the model's positive predictions, is calculated as the ratio of true positive predictions to the total predicted positives, as illustrated in Eq. (4). This metric reflects the model's proficiency in accurately predicting positive outcomes.

$$Precision = \frac{TP}{TP+FP} \tag{4}$$

Recall (R), depicted in Eq. (5), is the ratio of true positive predictions to the total actual positives, quantifying the model's effectiveness in capturing all actual positive instances.

$$Recall = \frac{TP}{TP+FN} \tag{5}$$

The F1-score, represented by Eq. (6), is the harmonic mean of Precision and Recall, with a higher F1-score indicating a better balance between Precision and Recall.

$$F1 = 2 \cdot \frac{Precision \cdot Recall}{Precision+Recall} \tag{6}$$

Average Precision (AP) signifies the area under the Precision-Recall (P-R) curve, calculated using an integral as shown in Eq. (7), a comprehensive indicator that takes into account both Precision and Recall.

$$mAP = \frac{1}{n}\sum_{1}^{n}\int P(dR) \tag{7}$$

The mAP@0.5 variant computes the average AP value at an Intersection over Union (IoU) threshold of 0.5 for all object categories. Furthermore, mAP@0.5:0.95 is determined to evaluate the model's performance across a spectrum of IoU thresholds, offering a stringent assessment of performance by representing the average mAP at various IoU thresholds ranging from 0.5 to 0.95 with increments of 0.05. The F1-score evaluates the methodology's performance by balancing the importance of accuracy and recall.

The results of the GEFDNet experiments are detailed in Table I, showcasing the performance of each model within the test dataset.

TABLE I. Quantitative Results on the Test Dataset

Model	P	R	F1	mAP@0.5	mAP@0.5:0.95
CenterNet	0.79	**0.85**	0.82	0.751	0.330
Faster R-CNN	0.79	0.82	0.81	0.815	0.398
SSD	0.26	0.59	0.36	0.239	0.095
FCOS	0.82	**0.85**	**0.84**	0.843	0.508
EfficientDet	0.07	0.57	0.12	0.095	0.018
YOLOv7-tiny	0.44	0.45	0.44	0.423	0.111
YOLOv9	**0.88**[a]	0.78	0.83	0.864	**0.601**
GEFDNet	**0.88**	0.81	**0.84**	**0.894**	0.596

[a]. The best performance is indicated in bold.

The experimental results demonstrate GEFDNet's significant advantage in target detection performance compared to other advanced methods. GEFDNet achieved an F1-score of 0.84, tying with YOLOv9 for the highest score, indicating an excellent balance between precision and recall. Particularly, in the key metric of mAP@0.5, GEFDNet surpassed all other models with a value of 0.894, including YOLOv9's 0.864, highlighting its superior detection accuracy at medium IoU thresholds. Furthermore, GEFDNet's comprehensive evaluation of model performance across different IoU thresholds from 0.5 to 0.95, mAP@0.5:0.95, achieved a value of 0.596, slightly trailing YOLOv9's 0.601, but this performance still ranks second among all compared models, showing its consistency and robustness across different IoU threshold ranges.

C. Visual Attention Contrast Experiment

To further examine the differences in detection effects between the proposed GEFDNet model and the existing YOLOv9 model, the Grad-CAM algorithm [37] was employed to visualize and compare the activation heat maps of the two models at different layers. Grad-CAM generates visual heat maps by combining the model's gradients and feature maps, revealing the visual areas the model focuses on when making specific predictions. This intuitive approach allows for a deeper understanding of the model's performance advantages and potential limitations, as shown in Fig. 4, which provides two sets of diagrams.

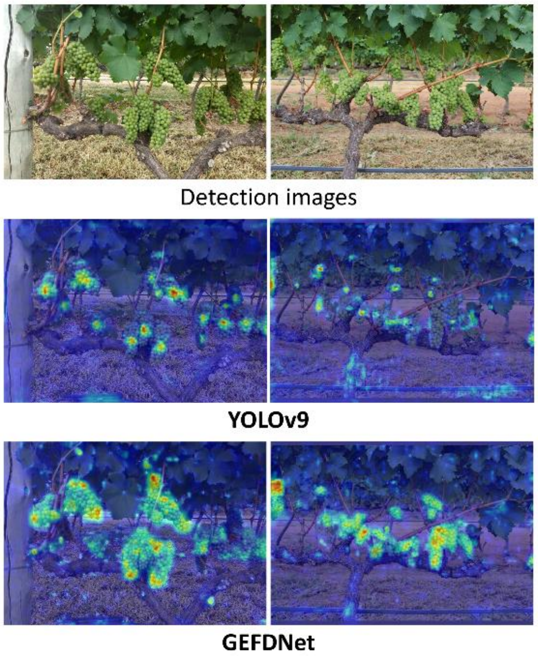

Fig. 4. Grad-CAM Visualization results.

When evaluating heat maps, focus on the following three key features to measure model performance:

- Clear boundary identification: The heat map should clearly depict the outline of the target object, demonstrating the model's high precision in spatial positioning.
- Noise suppression ability: The ideal heat map should not show excessive activation on image noise or irrelevant details, indicating that the model can effectively filter out unimportant information.
- Coverage of important features: The heat map should cover the key features of the target object, which are crucial for the object's recognition and classification.

Through the visualization results of Grad-CAM, it can be observed that GEFDNet has advantages in the above three aspects. Firstly, when localizing fruit targets, GEFDNet shows clearer boundaries and more focused attention, while YOLOv9, although able to recognize targets, also pays attention to the background, leading to scattered attention. Secondly, the heat map of GEFDNet performs better in suppressing image noise, indicating that it has stronger robustness when dealing with complex backgrounds and occlusions. Thirdly, the heat map of GEFDNet better covers the key features of grapes, aiding the model in more accurate recognition and classification of target objects.

D. Validation of Comprehensive Detection Capability

To verify the comprehensive detection capability of the improved GEFDNet model in different environments, we selected samples with varying lighting and density and conducted comparative experiments focusing on the model with similar performance to YOLOv9. We also conducted a detailed analysis of the visualization results of both models. This process revealed potential errors when detecting specific types of targets, thereby providing targeted guidance for subsequent model optimizations. Building on this, we further investigated specific conditions where the model might encounter difficulties. Fig. 5 illustrates the three most severe errors in the test dataset. The blue frames indicate the magnified portions of the images, while the yellow areas denote the regions of the grape clusters that were missed by the detection model.

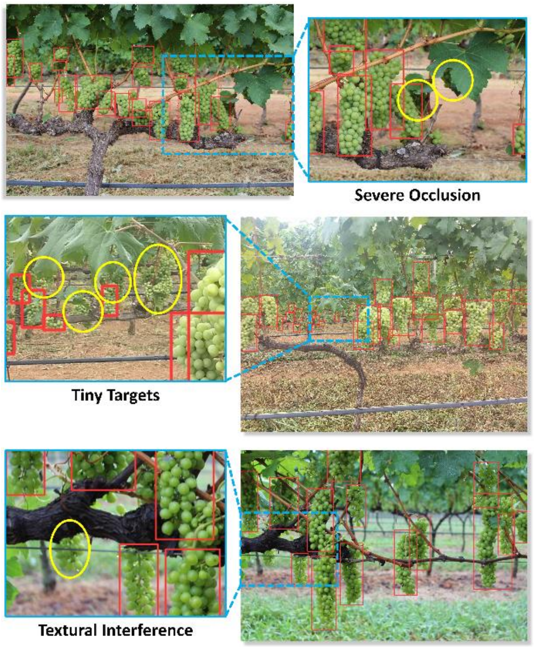

Fig. 5. The three most severe errors.

Firstly, there is the situation of extreme occlusion, where grapes are almost completely obscured by a large amount of foliage, with very little exposed. Under such extreme conditions, although GEFDNet performs better than YOLOv9 overall, there is a decline in detection accuracy. This is mainly because in the extreme occlusion environment, the information available for extracting effective features is greatly reduced. Despite the model's dual-path detection structure and EFFM module trying their best to capture features, it is still difficult to overcome the severe lack of information.

The second scenario is when facing extremely small grapes, the detection accuracy of GEFDNet decreases. This is because during the downsampling process of the model's Backbone network, the detailed features of very small grapes may be lost, making it difficult for the model to identify them accurately. The third scenario is in highly complex backgrounds, which include a large number of distractors similar in color and texture to grapes, as well as scenes with complex lighting and shadow variations. In such cases, although GEFDNet can filter out some irrelevant information, it is still interfered with by similar objects, resulting in a certain degree of false positives and false negatives. This indicates that the model's ability to resist interference needs to be further improved when dealing with highly complex backgrounds.

During the evaluation process, particular attention was given to the confidence threshold setting that yields the optimal mean Average Precision (mAP@0.5) across the entire test dataset. This strategy ensures the objectivity of the assessment while filtering for detections that the model is more confident in, effectively avoiding the impact of low-confidence predictions on the fairness of the evaluation. After the detection process, representative cases of false positives and false negatives were selected and visually presented, as shown in Fig. 6, where the blue areas indicate targets that were either missed or misidentified by the model.

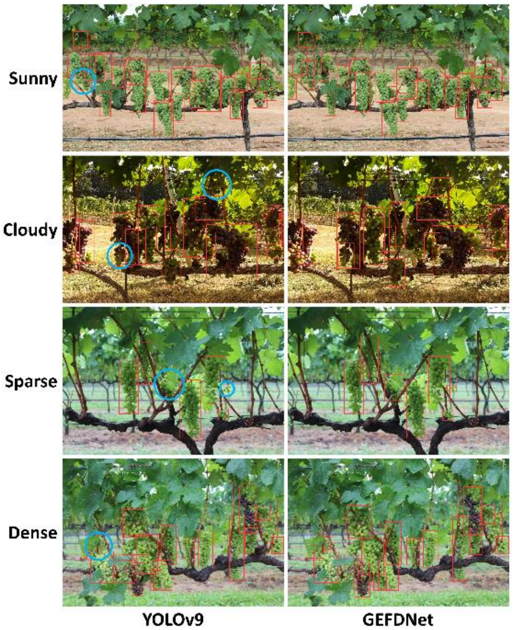

Fig. 6. Comparison of detection effects between YOLOv9 and GEFDNet models.

By carefully examining these results, the following typical errors and their causes can be identified: Under sunny conditions, both YOLOv9 and GEFDNet demonstrated good detection performance. However, YOLOv9 exhibited missed detections for small targets, likely due to insufficient feature extraction capabilities. Under overcast and uneven lighting conditions, YOLOv9 missed detections for grapes obscured by leaves and for small grapes beneath larger grapes. Furthermore, under varying densities, YOLOv9 consistently missed detections for grapes obscured by leaves, whether in sparse or densely clustered distributions. In contrast, GEFDNet effectively addressed these issues, particularly in detecting occluded and densely clustered grape clusters. These analyses not only reveal the limitations of YOLOv9 but also point the way for further optimization and development of GEFDNet.

E. Model Lightweighting

In the development of deep learning models, lightweighting is a critical optimization direction, particularly for application scenarios with constrained resources, such as edge device deployment in the agricultural sector. Lightweight models maintain sufficient detection accuracy while reducing computational load and storage requirements, thereby enhancing model operational efficiency and lowering deployment costs. In the experiments focused on model lightweighting, the recognition performance parameters of the YOLOv9 and GEFDNet models on the test dataset were compared, with the results presented in Table II. Key performance indicators such as Frames Per Second (FPS) were utilized, supplemented by the count of parameters and the size of the weight files to evaluate the models.

TABLE II. LIGHTWEIGHTING COMPARISON BETWEEN YOLOV9 AND GEFDNET MODELS

Model	F1	mAP@0.5	FPS	Parameters	Weights
YOLOv9	0.83	0.864	42.01	48.60 M	98.00 M
GEFDNet	**0.84**	**0.894**	**52.36**	**44.11 M**	**88.90 M**

The comparative experimental data clearly demonstrate the advantages of GEFDNet across multiple key indicators. Specifically, in terms of mAP@0.5, GEFDNet outperformed YOLOv9 with a score of 0.894 versus 0.864, marking a 3.5% improvement. This enhancement indicates that GEFDNet has achieved higher detection accuracy. Moreover, alongside the increase in precision, GEFDNet has also realized optimizations in lightweighting. The model's parameter volume has been reduced from 48.60M in YOLOv9 to 44.11M, and the weight file size has also been minimized from 98.00M to 88.90M. Furthermore, the detection frame rate (FPS) has been increased from 42.01 FPS of YOLOv9 to 52.36 FPS. These enhancements not only alleviate the storage burden but also imply that in resource-constrained environments, such as edge devices in the agricultural sector, GEFDNet can be deployed at a reduced cost. For application scenarios demanding high real-time performance, such as harvesting robots, these improvements are crucial for ensuring the system's response speed and processing capabilities.

V. Discussion and Future Work

The GEFDNet model introduced in this study offers a range of significant advantages in the field of grape detection in orchards. Firstly, the model integrates an innovative and efficient feature fusion module, the Enhanced Feature Fusion Module (EFFM), with a 16x downsampling Backbone network. This integration effectively balances detection accuracy and computational efficiency, reducing the model's parameter volume while increasing the frame rate, which is crucial for applications with high real-time requirements. Secondly, the introduction of the EFFM module enhances the model's ability to detect grapes against complex backgrounds and dense targets. Moreover, the high mean Average Precision (mAP) values demonstrated on the Embrapa WGISD dataset substantiate the model's excellent generalization and robustness.

Despite the positive outcomes of this study, there are certain limitations. It should be noted that the dataset used in this study is derived from a single crop species, and therefore, future testing and validation on more diverse datasets are required. Particularly, testing under poor lighting conditions and for extremely dense or very small-sized grapes should be conducted. Additionally, future research plans should expand and diversify the training datasets. Although the Embrapa WGISD dataset provides valuable resources for grape detection research, it has limitations, such as insufficient images of certain grape varieties, ripeness levels, and environmental conditions [38]. Moreover, to fully assess the potential of GEFDNet in real-world applications, future work will include real-time deployment assessments on actual hardware platforms like edge devices, drones, and agricultural robots. This aligns with the current trend in the field of agricultural automation towards evaluating practical application of models [39, 40]. This will help reveal the model's performance in resource-constrained environments and provide key insights for practical applications.

VI. Summary

Efficient and accurate detection of grapes in orchards has always been a challenging task. In this study, a high-precision, low-complexity deep learning model for grape detection in orchard environments, GEFDNet, was proposed, along with the innovative EFFM module integrated into the 16x downsampling Backbone network and optimized Neck structure. GEFDNet achieves model lightweighting while maintaining high accuracy, significantly enhancing the model's operational efficiency and practicality. The main achievements include a minimum 3.5% increase in mean Average Precision (mAP@0.5) on the test dataset, a reduction of about 9.24% in model parameter volume, and a 10.35 FPS increase in frame rate, validating the effectiveness of model lightweighting. Through Grad-CAM visualization analysis, GEFDNet's superior detection capabilities and precision in target recognition in complex scenarios have been demonstrated.

In summary, the development of the GEFDNet model not only promotes the advancement of agricultural automation technology but also provides a new perspective for the application of deep learning in complex scenarios. With the continuous deepening of future work, it is anticipated that GEFDNet will unleash greater potential in practical applications and make a substantial contribution to agricultural modernization.

Vehicular Traffic Congestion Detection System and Improved Energy-Aware Cost Effective Task Scheduling Approach for Multi-Objective Optimization on Cloud Fog Network

Praveen Kumar Mishra, Amit Kumar Chaturvedi
Computer Application Deptt., Govt. Engg. College, Ajmer, BTU, Bikaner, India

***Abstract*—A current research area called fog computing aims to extend the advantages of cloud computing to network edges. Task scheduling is a crucial problem for fog device data processing since a lot of data from the sensor or Internet of Things layer is generated at the fog layer. This research suggested a vehicular traffic congestion detection model and an energy-aware cost effective task scheduling (ECTS) method in a cloud fog scenario. This research proposes an ECTS approach to allocate jobs to the fog nodes effectively. The recommended scheduling approach minimizes energy consumption and decreases expenses for time-sensitive real-time applications. The ECTS algorithm is implemented, and results are analysed using the iFogSim simulator. The proposed method minimizes energy consumption and cost. The suggested ECTS method is tested with five sets of inputs in this paper. The experiment's results show that an ECTS minimizes energy consumption in comparison to alternative algorithms. It also reduces the execution cost. The suggested approach outperforms both the Round-Robin (RR) and Genetic Algorithm techniques. According to the simulation results, the suggested algorithm reduced overall costs by 13.38% and energy usage by 6.59% compared to the Genetic Algorithm (GA). Compared to RR, the proposed method minimizes energy use by 13.76% and total costs by 18.46%.**

I. Introduction

One of the most crucial improvements in the realm of technology in the last several years is the Internet of Things (IoT) devices for the computation and exchange of information. IoT devices allow a wide range of items and equipment like sensors, cameras, automobiles, and connectivity with the Internet with smart devices like cell phones and laptops. Numerous applications and service offerings, such as latency minimization, control of traffic, and response time improvement, can be carried out as a result. Large volumes of data are produced through end devices as a result, which require supervision, processing, and analysis to generate appropriate data that will meet the user's objectives and aims. Moreover, the volume of data and a variety of required services and apps are expanding very quickly, demanding more computing power than even the most advanced smart devices can no longer match. The well-known cloud environment is a vast repository of resources that permits the universal ability to share and dynamically provide users with resources through virtualization procedures, which is one potential platform to aid in IoT improvements. By shifting resource and service-intensive jobs to a trustworthy computer environment, like the cloud, allowing smart devices to undertake basic tasks, limitations of current smart devices, such as enhancements, might be made to processing speed, capacity of storage, and resources required at the network. However, combining the use of clouds with the IoT creates further problems. It is anticipated that 50 billion IoT devices has been deployed in 2023. This figure will be increased to 35.8 billion in 2030, with the exponential rise in connected devices and cloud architectures that rely on traditional centralized processing features where storage and computational resources combined won't be enough to handle the demands of the Internet of Things devices burden. The main reason is that IoT gadgets and the cloud's infrastructure are quite far apart. The enormous amount of data of IoT devices send via the Internet to the cloud will strain the network's capacity and bandwidth, causing congestion, particularly near bottlenecks [4]. IoT applications are latency sensitive; therefore, a transmission delay reduces the Quality of Services (QoS), negatively impacting the user experience.

Fog computing [1], an innovative strategy of cloud computing first introduced by Cisco, has the potential to transform connecting the network's boundary to a distributed processing design that can accommodate the end devices services. By using fogging, clients may access computing and data storage power resources more conveniently by extending cloud computing to data-generating and data-receiving IoT gadgets; instead of moving all the processing to the CDS (Cloud Data Center), the Fog layer goals to process the maximum of the traffic load created by end devices nearby to the user's ranger of the network, called fog computing devices. Anywhere there is network connectivity, such as factories, shopping malls, electricity poles, railroads, inside of cars, etc., may use end devices. A fog node is any device with networking, computing, and storage capabilities. These devices include embedded servers, switches, routers, controllers, and security cameras. Requests are optimized for transmission time by putting resources near the network's edge, where the minimum amount of time needed for information to arrive at a point of processing larger-scale and delay-tolerant activities still be routed to the cloud layer. At the same time, smaller jobs or task requirements with low latency have to be given precedence to be handled by fog computing platforms deposited at fog nodes with limited processing capability. Ultimately, fogging and cloud computing combine to create the cloud fog scenario, a new paradigm for the computing environment. This innovative strategy has several benefits, which include latency minimization, minimize high network traffic, and minimizing power consumption. Balancing of load for jobs ensures that no resource remains idle while others are being used [1]. The security risks businesses face using cloud computing has decreased [2]. For enterprises deploying solution of big data on cloud infrastructure, is a crucial factor to consider.

The paper is presented in the following sequence. Specific literature review for task scheduling within the framework of cloud fog atmosphere is provided in section 2. The proposed Vehicular Traffic Congestion Detection (VTCD) System and ETS scheduling algorithm are presented in Section 3. Section 4 provides a simulation environment. Section 5 includes performance analysis and simulation outcomes. Section 6 present the conclusion and forthcoming scope at the end**.**

II. Literature Review

According to Jayasena et al. [3], scheduling of job necessitates optimizing two goals: minimizing cost and decreasing power utilization. The author designed a meta-heuristic Whale Optimization Algorithm (WOA) mapped procedure to explain the recommended system and calculate the outcomes in iFogSim against heuristic techniques like Particle Swarm Optimization (PSO) and RR and SJF. Xu et al. [4] explain the laxity-mapped precedence approach to build a scheduling of task order with a fair priority. According to the author, based on the ant colony system (ACO) algorithm, this strategy minimizes overall energy use.

Tan, et al. [5] proposed an energy-efficient approach and looked at a task scheduling issue along with time limit restrictions in instances when could exist distributed throughout heterogeneous assets, such as fog computing, and an energy-conscious algorithm capable of finding the best solution in a polynomial amount of time. Nikoui et al. [6] developed a genetic-based (CAGB) planning method that improves efficiency at a lower cost for real-world applications with tight deadlines. Its effectiveness is evaluated regarding system overload, expenses, and delay. Fellir Z. et al. [7] presented multi-agent-based planning method, the most important tasks are handled first to ensure that when a packet with the highest importance goes into the waiting line, the job is dealt with, without interfering with the least significant task's implementation if it is presently being run. Madej et al. [8] presented four scheduling schemes named NFCFS (Naive First Come First Serve) technique. The other three schemes are client fair, prioritized fair, and hybridization.

Abdel Basset, et al. [9] suggested method improved the effectiveness of the best outcome and justified the workload across the accessible simulated engines by using a meta-heuristic method and a shift modification technique. Yang et al. [10] presented the superior value efficiency and scale outcome set to tackle the two-parameter collaboration to minimize fog computing scheduling task difficulties. The results demonstrate how the suggested strategy performs better than conventional strategies regarding resource cost, overall job execution time, etc. Hoseiny et al. [11] suggested cost aware scheduling method reduces latency, computation costs, and communication costs for IoT inquiries while increasing the proportion of tasks that are finished earlier than the deadline. This algorithm is compared with genetic algorithm.

The Task Priority Resource Allocation (TPRA) algorithm was presented by Dang et al. [12]. This algorithm's primary goal is to minimize the average latency in the fog network's diverse environment. Abdel-Basset et al. [13] presented the multiple objective task scheduling technique. This algorithm aims to minimize the rate of carbon emissions, make-span, and energy consumption. The resource-aware-cost-efficient (RACE) scheduler was introduced by Arshed et al. [14]. This method distributes the incoming jobs to fog nodes function. This strategy pursues minimizing bandwidth use, maximize Fog Node (FN) utilization at the fog layer, and shorten application make span.

In a fog context, Singh et al.'s [15] hybrid swarm optimization using genetic algorithms (GA) reduces execution time and cost. Compared to GA and PSO, the workflow scheduling experimental result that is being provided is superior. The MGWO multi-objective optimization approach was introduced by Saif, et al. [16] multiple goals, including make-span, throughput, energy, and delay. This approach aims to ascertain the optimal strategy for work scheduling at the fog layer. The MGWO algorithm's experimental result outperforms the equivalent methods regarding power minimization and delay reduction. Zhang et al. [17] introduced the Enhanced Whale Optimization Algorithm (EWOA). It's a technique for scheduling tasks with multiple objectives in a cloud computing environment—a search strategy known as Levy's struggle in EWOA. The results of the various heuristic and meta-heuristic algorithms match the results of the EWOA experiment. EWOA performs better in cost reduction and energy use minimization than these existing algorithms. Alwabel et al. [18] offered a deadline and power-efficient job scheduling method in a fog computing network. This method aims to determine which jobs are crucial and prioritize them so that they may be finished at the fog layer. The simulator iFogSim is used for outcome analysis. The recommended approach outperforms earlier algorithms regarding deadline and energy consumption reduction.

The PEWO (Parallel Enhanced Whale Optimization) approach was created by Khan et al. [19] for task scheduling at the cloud computing layer. This meta-heuristic method aims to minimize make-span and execution time. In a heterogeneous cloud environment, tasks are assigned using the PEWO approach. The experimental result of PEWO is better represented by the random matrix particle swarm optimization (RMPSO). Ali et al. [20] presented DNSG, a task scheduling system, by dynamically assigning the task to a fog node; the proposed approach aims to reduce make-span and cost compared to modified GA. Balancing tasks is also one of the issue in cloud fog environment. Within the Cloud-Fog system [24-25], job scheduling aims to maximize benefits for either service End users are concerned about minimizing make-span, power consumption and cost.

A thorough analysis reveals that there is a trade-off between minimizing costs and minimizing energy use. Consequently, this paper proposes ECTS to assign jobs to FN at the fog layer with the least amount of energy consumption and the best possible cost. WOA is inherited by the proposed ECTS method. This method determines the fitness function by adding up the expenses of RAM and CPU (central processing unit) for every fog node, together with the power used for task execution and FN's power when idle. The primary contribution of this study is the development of the ECTS algorithm. This suggested method for vehicular traffic congestion detection applications is simulated using the iFogSim simulator as the secondary contribution.

Table I presents a survey of the latest published study on cloud and fog computing task scheduling strategies, as well as main idea, improvement parameters and algorithms of previous studies.

III. PROPOSED SYSTEM ARCHITECTURE

This section describes the proposed three tire architecture of a vehicular congestion detection system, and the ECTS algorithm in cloud fog network.

A. Proposed Vehicular Traffic Congestion Detection Architecture

Vehicular Traffic Congestion Detection (VTCD) architecture in a cloud fog network is shown in Fig. 1. As shown in the diagram this is a three-layer model for detecting vehicular traffic congestion. Layer 1 represents the end devices layer, and at this layer, sensors detect vehicular traffic congestion, and forward requests at layer two, i.e., fog computing layer through IoT enabled devices. At the layer two, clusters of FN are available. Each cluster of FN is connected to a Master Fog Server (MFS) called a fog server. MFS is responsible for checking resource availability, scheduling tasks to FN, and assigning tasks (jobs) to the appropriate FN. These fog nodes process jobs and respond to MFS. Using an actuator, MFS responds to end devices and displays traffic congestion detection-related information. MFS also forwards task results to layer three, the Cloud Data Center (CDC), through a proxy server to store the results for future reference.

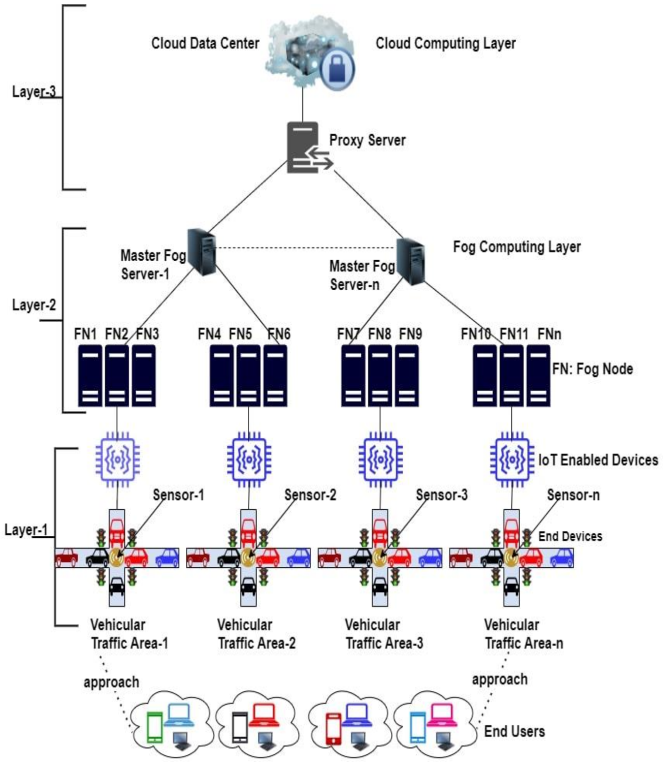

Fig. 1. Proposed three-tier model of vehicular traffic congestion detection.

1) Vehicular traffic area and end devices: As shown in Fig. 1, end users approach end devices using gadgets like tablets, smartphones, desktops, notebook computers, wearable devices, etc. In this paper, end devices are vehicular traffic on roads in different city areas. As we can see in this diagram, vehicular traffic area 1 to vehicular traffic area n are shown where sensor 1 to sensor n detect traffic on the road and forward this information to layer 2 using IoT-enabled devices.

2) The proxy server and fog computing layer: Fog computing is the middle layer in the cloud fog scenario with three-tier architecture called fogging or fog networking. FNs are near-end devices for computing, storage, and communication with end users locally with reduced latency, low bandwidth and lower cost compared to cloud computing environments. An enhanced version of cloud computing, i.e., fogging, reduces stress in the layer of clouds [22-23]. A proxy server is router that communicates with and prevents cyber-attacks, reduces latency between the CDS and layer 2. Data can be retrieved by fog nodes from cloud storage whenever further processing is required.

B. Proposed Task Scheduling Model

The suggested task scheduling technique for assigning jobs to the FN in the cloud fog network is covered in this part. A recommended job scheduling plan is based on the WOA [21] and the multiple-objective model [26]. Fig. 2 depicts the system of the suggested ECTS method of this paper for assigning tasks to the FN. The memory, CPU, and energy consumption functions are all computed using the multiple-objective computation. The cost function and energy consumption are added to get the fitness value. By the fitness rating, the tasks are allocated to the Fog nodes. ECTS first considers the current solution is the best solution. This process is repeated until the optimum solution is identified. In this paper task scheduling aims to minimize energy and total cost while assigning task to the fog node as effectively as feasible.

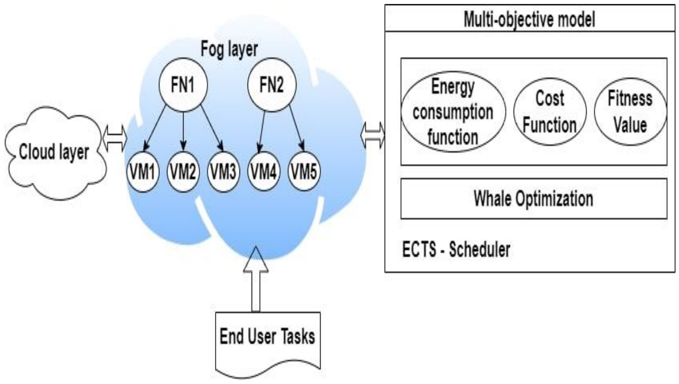

Fig. 2. Model of the proposed ECTS scheduler.

The fog layer which contains of n numbers of fog nodes. Where FL represents fog layer and $\{FN1, FN2, FN3, FN4 \dots\dots\dots.FN_n\}$ represent fog nodes presented at fog layer. This can be represented as,

$$Fog,\ FL = \{FN1,\ FN2,\ \dots FN_n\} \qquad (1)$$

The fog node FN1 can be represented by the equation that follows. Where, $\{FN1,\ FN2,\ \dots FN_n\}$ represents the fog nodes. Master Fog Node (MFS) connected with cluster of fog nodes at layer 2.

$$MFS = \{FN1,\ FN2,\ \dots FN_n\} \qquad (2)$$

Each fog node has the CPU and the memory. Tk represents task and MFS represent master fog server.

$$Tk = \{ T_1,\ T_2 \ldots\ldots T_{500} \} \qquad (3)$$

Where, T_1 is the task first and T_{450} shows 500th task. Assume that one IoT device forward 10 Tk to MFS.

In this paper proposed algorithm: ECTS, where tasks and fog nodes are inputs. The suggested task scheduler aims to best distribute the job across the fog nodes. The WOA is the basis for this scheduler. Initially, the search agent population is initialized. The model of proposed ECTS scheduler computes the fitness value. Equation number 15 updates the search agent's position if the e is greater than or equal to 0.5. The 13th and 14th equation are used to update the search agents' positions if the e is less than 0.5. Until the ideal solution is found, this procedure is carried out repeatedly.

```
Proposed Algorithm : ECTS
Input: Task T, Fog Node FN
Result: Fog nodes are assigned the jobs.
Control Parameters $S^*$, α, N, W, t, p
Begin
    Set up the population initially. $S_i$ (i = 1, 2, …, n)
    Fitness value obtained from the sub function
    Initialize the current best agent $S^*$
    Update α, N, W, t, p
     if ( e < 0.5)
        if ( |N| < 1)
Change the search agent's location with equation 13.
        Else if ( |N| ≥ 1)
   Change the search agent's location with equation 14.
        End if
     End if
     if ( e ≥ 0.5)
         Change the search agent's location with equation 15.
    End if
In the event that (any search agent leaves the search space)
        Update $S^*$
Assign y to y + 1.
    End if
End
Sub function:
Input: Tasks T, Fog Nodes FN
Output: Fitness value
 For (all the Fog nodes)
 Find active energy consumption function by equation 4
 Find idle energy consumption function by equation 5
 Find total energy consumption function by equation 6
 Find the fitness value by equation 12
 End for
End
```

1) Energy Consumption: Energy consumption formula is similar like [15].

$$ER_{usage}(y) = \sum_{i=1}^{n} \mu\, F_i\, V_i^2\ \left(BT_{T_i} \text{ - } ET_{T_i}\right) \qquad (4)$$

$$ER_{idle}(y) = \sum_{j=1}^{m} \sum_{idle_{jk}\ \varepsilon\ IDLE_{jk}} \mu\ RF_{\min i}\ VL_{\min i}^2 \qquad (5)$$

The power consumption during job i, when the resource is operating at peak efficiency and is about to enter sleep mode, and added together to get the total energy consumption.

ER_{usage} is active energy usage and ER_{idle} is idle energy consumed by system at sleep mode. F_i is frequency, V_i is voltage supply fog node where task executes. BT_{T_i}, represent beginning time and ET_{T_i} is end time for task T_i and μ is constant.

$$TER_{con}\ (\mathrm{y}) = ER_{usage} + ER_{idle} \qquad (6)$$

2) Total cost: The fog node total cost is calculated as,

$$\mathrm{C\ (y)} = \sum_{k=1}^{|FN|} C_{cost}\ (k) \qquad (7)$$

$$C_{cost}\ (k) = C_{basic} * C_k * t_{ik} * C_{tr} \qquad (8)$$

$$\mathrm{M\ (y)} = \sum_{k=1}^{|FN|} M_{cost}\ (k) \qquad (9)$$

$$M_{cost}\ (k) = M_{basic} * M_k * t_{ik} * M_{tr} \qquad (10)$$

Where $C_{cost}\ (k)$ is the cost of CPU of fog node FN_k and t_{ik} is the amount of time in which task T_i is executed at node S_k. C_{tr} is the communication cost of the CPU of fog node. Here , C_{basic} and C_{tr} are constant where C_{basic} is 0.16 per hours and C_{tr} is 0.004, much like in [26]. |FN| is the total no of fog nodes. M_{basic} is 0.04 GB per hour and M_{tr} is 0.4, C(y) is the total no of cost of CPU of FN and M(y) is the memory cost of FN . $TC\ (y)$ denote the total cost, it can be calculated as,

$$TC(y) = \mathrm{C(y) + M(y)} \qquad (11)$$

3) Fitness value determining: To determine the best solutions, the fitness value is computed; the solution must have the lowest possible energy consumption and lowest possible cost function. The following formula is used to calculate fitness.

$$FV(y) = TER_{con}\ (\mathrm{y}) + TC(y) \qquad (12)$$

4) Whale optimization algorithm: For distributing the jobs to the fog nodes as efficiently as possible, the whale optimization method [21] is explained. The collection of random solutions is where the whale optimization process starts. It moves forward with the process under the presumption that the present answer is optimal. Repeating this procedure keeps on until the best solution is found.

$$S\ (y+1) = \overrightarrow{S*}(y) - \vec{N} * \vec{D} \qquad (13)$$

$$\vec{S}(y+1) = \overrightarrow{S_{rand}} - \vec{N} * \vec{D} \qquad (14)$$

$$\vec{S}(y+1) = D' * b^{vt} * \cos(2\,\Pi\,t) + S^*(y) \qquad (15)$$

Where, y denotes current iteration, $\vec{S}$ is position vector and $\overrightarrow{S*}$ represents optimal solution. $\overrightarrow{S_{rand}}$ is random location vector, $\vec{N}$ represents the coefficient vector. $\vec{W}$ represents the coefficient vector. In equation 11, v is constant and t shows the value in [-1, 1] interval. | | denotes the absolute value, while * denotes multiplication of elements by elements. D' is calculated as follows,

$$D' = | \overrightarrow{S*}(y) - \vec{S}(y) | \tag{16}$$

$$\vec{D} = | \vec{W} * \overrightarrow{S*}(y) - \vec{S}(y) | \tag{17}$$

Where $\vec{N}$ and $\vec{W}$ can be computed by following formula,

$$\vec{N} = 2 \vec{\propto} * \vec{\beta} - \vec{\propto} \tag{18}$$

$$\vec{W} = 2 * \vec{\beta} \tag{19}$$

The value of $\vec{\propto}$ is move between 2 to 0 and $\vec{\beta}$ denote the arbitrary vector in [0, 1].

IV. Simulation Environment

The simulation environment used to perform calculations is explained in this section. Simulation scenario of Vehicular Traffic Congestion Detection (VTCD) system in fog computing environment has shown in Fig. 3. where S1, S2, S3, S4 are sensors to collect cross-road vehicular traffic information and A1, A2, A3, A4…A8 are actuators to display the results and total four terminals for VTCD system IoT Devices (T_IoT_D1, T_IoT_D2, T_IoT_D3, T_IoT_D4) are used to collect VTCD information from sensors and forward to Fog Node (FN) where four fog nodes (FN1, FN2, FN3, FN4) have used in this simulation at fog computing layer. Controller Fog Server (MFS) collects information from FN and stores it at CDC (Cloud Data Center) via a proxy server. This topology was created and simulated by the iFogSim simulator.

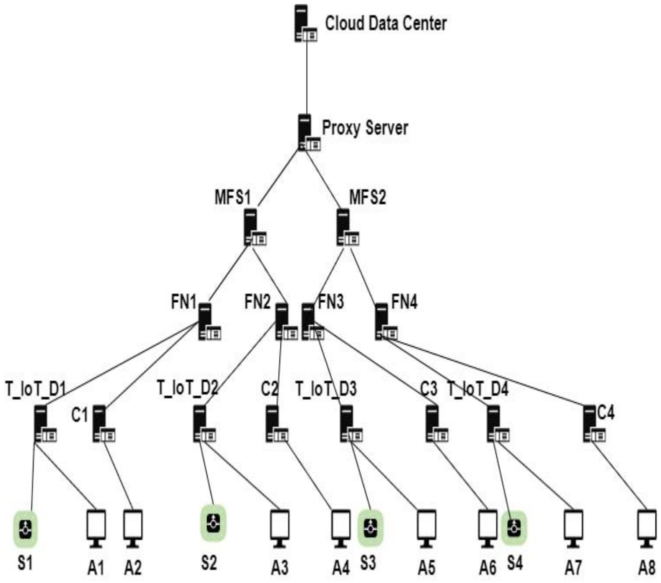

Fig. 3. Scenario of ECTS with VTCD for simulation in cloud fog environment.

Table II shows configuration parameters and values at the Cloud Server, Proxy Server, and Fog Computing layer, which are used to simulate the cloud fog environment. Table III represents the description, various notations used, values assumed in this paper, and system configuration.

TABLE II. Configuration Parameter

Requirement	at Cloud	Proxy server	at Fog
Processing unit (MIPS)	44700	2900	2900
Main memory in MB	9900	3900	3900
Up_bps in MB	100	9900	9900
Dn_bps in MB	9900	9900	9900
Layer	3	2	1
Rate in MIPS	0.01	0	0
power_b in WATT	17*104	107.349	107.349
power_ID in WATT	17*83.24	85.5333	85.5333

TABLE III. Notation, Values and Description

Description	Notation and values
Max no of IoT device	50
p	[-1 , 1]
i	1, 2, 3…
$\text{Max}_{\textbf{itr}}$	100
FN	fog node
EDN	edge device node
System	Intel ® Core(TM) i3 CPU
Tool for simulation	iFogSim
OS(operation system)	Window 7 Ultimate, 64 bit

V. Experimental Results and Performance Analysis for Proposed ECTS Algorithm

Performance evaluation of the proposed algorithm with VTCD application in a cloud fog network is shown in this section. The measurements for energy consumption performance and the simulation result of overall cost are shown in Tables IV and V, respectively. The corresponding bar chart of the parameters shows that energy consumption is minimized when number of IoT devices have increased as shown in Fig. 4, and cost is also minimized when no of IoT devices have increased as shown in Fig. 5. Assume that 10 IoT devices are equal to 100 tasks.

TABLE IV. Simulation Results for the Energy Consumption

No. of IoT Devices	Consumption of energy (in WATTS)
10	188040.91
20	185103.87
30	185103.39
40	182487.18
50	176916.18

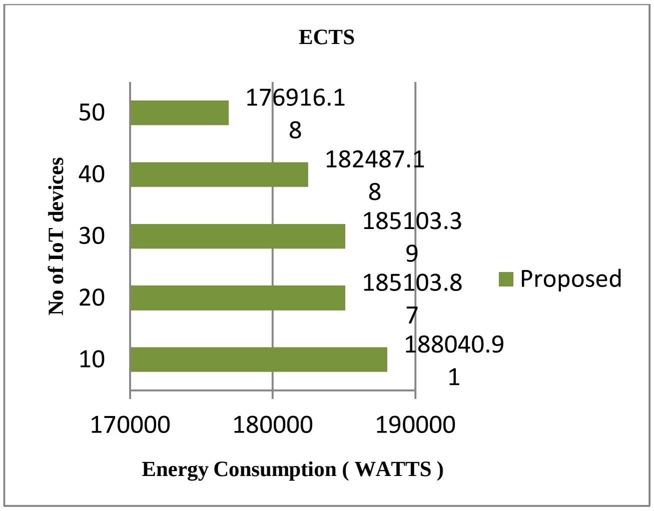

Fig. 4. Energy consumption.

TABLE V. SIMULATION RESULTS FOR THE COST

No. of IoT Devices	Cost ($)
10	395905.15
20	392444.41
30	614328.21
40	761434.06
50	810188.88

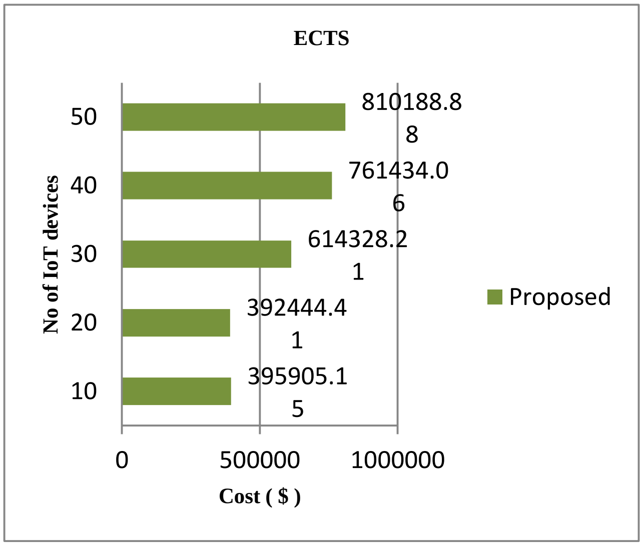

Fig. 5. Cost.

Table VI shows the comparative study of the proposed ECTS method with the existing methods, such as (Round Robin) RR [3] and (Cost aware genetic algorithm) GA [6]. The proposed ECTS method has the minimum energy consumption 176916.18. The energy consumption of RR is 201259.8464 and the energy consumption of GA is 188574.9563. The total cost of RR and GA are 959749.7472 and 918592.1521 respectively while the total cost of proposed ECTS method is 810188.88 which is smaller than the other existing methods.

TABLE VI. COMPARATIVE STUDY OF THE ECTS METHOD WITH THE RR AND GA

	ECTS	RR	GA
Energy consumption	176916.18	201259.8464	188574.9563
Cost	810188.88	959749.7472	918592.1521

This is the analysis of the proposed algorithm in this paper. A range of IoT devices as input of 10-50 have been used for the simulation at the iFogSim simulator. Assume that 10 IoT devices are equal to 100 tasks and 50 IoT devices are equal to 500 tasks. As shown in Fig. 6 energy consumptions are minimized in the proposed algorithm when no of IoT devices are increased as compared to RR and GA. As shown in Fig. 7. The proposed algorithm minimizes the overall cost when the number of IoT devices increases compared to RR and GA.

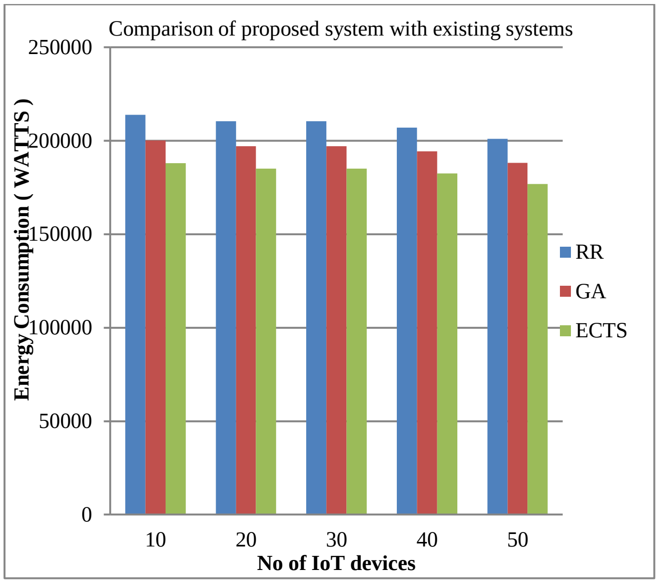

Fig. 6. Energy consumption comparison.

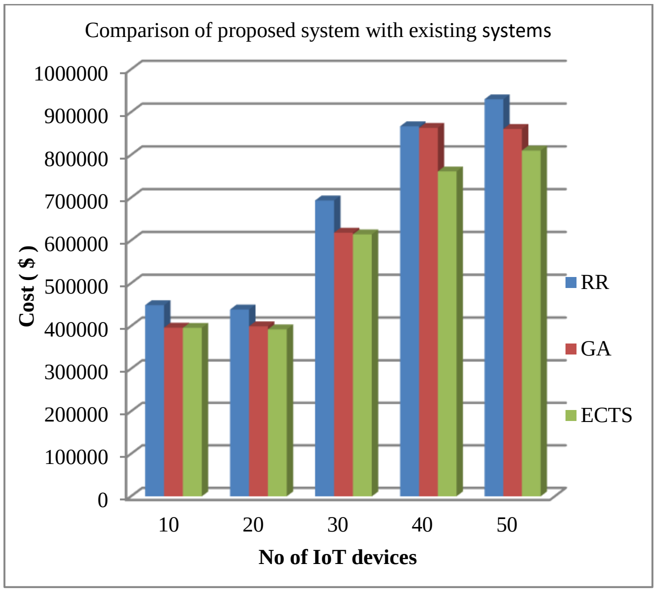

Fig. 7. Cost comparison.

Column chart for comparison of energy consumption, overall cost with GA, RR, and proposed algorithm show that the proposed result is better compared to others, especially in energy and cost parameters.

VI. Conclusion

The design of the task scheduling technique is the primary purpose of this study. The secondary objective is designing a Vehicular Traffic Congestion Detection (VTCD) system. The proposed Energy-aware Cost effective Task Scheduling (ECTS) scheduling algorithm performance has been analyzed using various inputs. Two other approaches, particularly the Genetic Algorithm (GA) and Round-Robin (RR) in a cloud-fog network, were compared with the proposed algorithm using the iFogSim simulator. Especially for energy usage and cost parameters, our proposed algorithm ECTS performed better than the others at five different sets of inputs. The simulation result shows that energy consumption is minimized by 6.59%, and the overall cost is minimized by 13.38% compared to GA. In comparison, energy consumption is minimized by 13.75%, and the overall cost is minimized by 18.46% compared to RR. Here, multi-objective means task’s cost, energy consumption and deadline for scheduling the user's request at the fog computing layer. Furthermore, the suggested algorithm may adapt to the end user's requirement for higher processing performance for other applications.

In the future, improvements may be made in ECTS algorithm to address other issues like reducing make-span, response time, security issues, etc. improvement for other real time applications.

Acknowledgment

I sincerely thank Dr. A. K. Chaturvedi, Head, Computer Application Dept., at Govt. Engineering College, Ajmer, Rajasthan, for truthful academic backing throughout the work.

Deep Learning with IoT-Based Solar Energy System for Future Smart Agriculture System

Vidya M S, Ravi Kumar B. N, Anil G. N, Ambika G. N
Department of Computer Science and Engineering, BMS Institute of Technology, Bangalore, India

***Abstract*—Agriculture has a considerable contribution to the economy. Agriculture automation is a serious issue that is becoming more prevalent around the world. Farmers' traditional practices were insufficient to achieve these objectives. Artificial Intelligence (A1) and the Internet of Things (IoTs) are being used in agriculture to improve crop yield and quality. Distributed solar energy resources can now be remotely operated, monitored, and controlled through the IoT and deep learning technology. The development of an IoT-based solar energy system for intelligent irrigation is critical for water- and energy-stressed areas around the world. The qualitative design focuses on secondary data collection techniques. The deep learning model Radial Basis Function Networks (RBFN) is used in conjunction with the Elephant Search Algorithm (ESA) in this IoT-based solar energy system for future smart agriculture. Sensor systems help farmers understand their crops better, reduce their environmental impact and conserve resources. These advanced systems enable effective soil and weather monitoring, as well as water management. To provide the required operating power, the proposed system, RBFN-ESA, employs an IoT-based solar cell forecasting process. The proposed model RBFN-ESA will collect these data to predict the required parameter values for solar energy systems in future smart agriculture systems. The results of the RBFN-ESA model are effective and efficient. According to the findings, RBFN-ESA outperforms CNN, ANN, SVM, RF, and LSTM in terms of energy consumption (56.764J for 100 data points from the dataset), accuracy achieved (97.467% for 600 nodes), and soil moisture level (94.41% for 600 data).**

Keywords*—Precision agriculture; smart monitoring; Internet of Things; Radial Basis Function Networks; Elephant Search Algorithm (ESA)

I. Introduction

Food manufacturing in the 20th century is a pressing issue as long as population growth continues to increase. Between 9.4 and 10.1 billion people will rely on biodiversity for their livelihood by 2050, which would raise the demand for locations set aside for agricultural production, especially for farming and the rearing of farm animals [1]. Human-induced changes to the environment can result in conditions that make it difficult for new crops to flourish. Similarly, rising urbanization raises food prices while decreasing food.

Production and employment in food-producing regions. In an effort to address the challenges of fulfilling the demands of food production and the working population decline, smart agriculture aims to lower farm management expenses [2–3]. It employs techniques and technology at various agricultural production scales and levels. Precision farming, for example, can employ a range of sensing devices to collect data (heat, moisture, light, stress, presence, etc.), connectivity networks to receive and send that data, information management systems to keep and process that data, and analysis tools to do so [4]. "IoT" is a term used frequently to describe this network of connected devices [5]. The right actions can be taken thanks to the knowledge that intelligent farming generates.

Recent developments in wireless technology have completely changed how farmers can interact with their crops and track their growth [6]. Advanced management concepts can be used to monitor crops using new technologies and respond to their needs appropriately. Precision agriculture (PA) is one method that combines technology and conventional farming methods [7, 8]. Using PA in farming can increase control and accuracy when raising animals and crops. Farmers are becoming increasingly productive and cost-effective by utilizing new technology to enable agriculture because they can use more precise solutions rather than simply attempting to manage the many elements of their farming systems.

Instead of using modern technology, traditional farming practices are used to manage fields. More experience is required to maintain proper efficiency. With traditional farming methods, the best course of action for a successful harvest must be determined by considering both the current weather and historical data when making decisions about planting, harvesting, and irrigation. Contrarily, PA helps farmers use less labour while giving their crops more attention as needed by using tools like sensors, actuators, the Global Positioning System (GPS), robots, and data analysis software. Monitoring livestock and vegetation with Internet of Things (IoT) devices is one effective method for achieving PA [9]. IoT devices are minuscule, energy-efficient embedded electronics with network data transmission capabilities. An IoTs network is frequently used to describe a group of connected devices that work together to accomplish a common objective. Sensors, for example, can be installed in an IoT-based agricultural system to collect environmental information about soil moisture. An automated irrigation system can use the measured data to water plants appropriately, avoiding over- and under-watering. Farmers might be able to instantly and remotely monitor field conditions thanks to an IoT system. It is just as crucial to keep an eye on the vegetation in a field as it is to keep an eye on livestock to ensure that they are fed and cared for properly. The use of IoT devices can lower labour costs significantly and enhance animal welfare. IoT devices can be used to find the livestock's location and assess its health.

II. LITERATURE SURVEY

Systems remain a type of feedforward neural system that activates using radial basis functions and universal approximators. Classification, regression, pattern recognition, and time series forecasting problems are frequently solved using RBFN [10–11]. In addition to their strong ability to approximate any continuous network, RBFNs also possess strong characteristics like their compact structure, noise tolerance, and ability to approximate any global approximation. The new elephant algorithm is among the most recent meta-heuristic methodologies to be suggested. The search areas of elephant males are widened as they travel farther and farther. The female elephants focus on seeking out the best response locally. A lifespan mechanism that regulates birth and death gives all agents a gradually increasing chance of dying as they age. The heuristic knowledge of these elephants' forebears will be passed down to them, and this mechanism is designed to keep whole agents from entering the local optimum. The solar energy-driven polygene ration system configurations and classified them based on design, benefits, technical potentials, challenges, and market prospects. A solar-driven multigeneration system enhances the system's efficiency and reduces the capital and operation costs as well as carbon dioxide emissions to improve the environment [12].

Soil temperature modelling to assess the viability of using soil air exchangers for agricultural structures. In this context, the ability of soil to cool or heat agricultural structures such as greenhouses was determined by modifying temperature behaviour at various depths [13]. A solar thermal system produces inexpensive, environmentally friendly heat using the sun's energy. Temperature pushes, electronic warmers, and rotation forces are all controlled in accordance with the need for hot water in a building. First, take into account clear, cloudy, rainy, and dark weather[14]. The network's overall node count could be decreased while the sampling frequency was raised. Although reducing the number of sensor nodes has been shown to result in a similar network lifetime, it is unknown how much data is lost from specific locations within a field. Even though there are more samples, most agricultural systems don't need quick responses because the environment doesn't change quickly over short periods of time [15]. The temperature readings taken by the drone while it was flying over the crop were incorrect, according to experiments. The drone was able to get more precise readings when it was nearer the area of interest. The devices had to be in constant time sync for the data collected among the drone and nodes to be accurate [16]. In order to implement multiple networks, the system was built with nodes that could switch between two operating frequencies. Nodes were organized into clusters, and the cluster leader forwarded data from each cluster to the target node. The outcomes showed that the design used very little energy and could work for a whole season on just one charge of the battery [17].

Wen-tai Li et al. presented by [18]. Building managers can achieve their energy management objectives with the aid of the Solar Water Heating (SWH) control mechanisms. The methods are based on the price of electricity, the weather, and the demand for hot water. An important source of solar energy for buildings, solar thermal systems are the subject of this study. A solar thermal system produces inexpensive, environmentally friendly heat using the sun's energy. Temperature pushes, electronic warmers, then rotation forces remain all controlled in accordance with a building's need for hot water. First, take into account clear, cloudy, rainy, and dark weather. To run the simulations, three different days were picked: a cloudy day, a sunny day, and a semi-synthetic day with no solar. The ideal control mechanism for heat pumps, electric heaters, and circulator pumps has been researched to enhance the SWH system's performance.

Mohammadi et al. [19] reviewed various solar and hybrid solar energy driven polygene ration system configurations and classified them based on design, benefits, technical potentials, challenges, and market prospective. Solar-driven multigeneration system enhances the system efficiency and reduces the capital and operation costs as well as carbon di-oxide emissions to build environment.

Faridi et al. [20] Soil temperature modelling was used to assess the viability of using soil-air exchangers for agricultural structures. The ability of soil to heat or cool agro constructions like greenhouses was detected by means of modifying the behavior of temperature at various depths in this context.

The objective of the paper is

1) First this IoT-based solar energy system for a future smart agriculture system, a deep learning [36, 37] model called Radial Basis Function Networks (RBFN) with the Elephant Search Algorithm (ESA) has been used.

2) IoT and automation are linked with agriculture and farming practises in order to recover the efficacy and efficiency of the entire process.

3) Sensory systems promoted resource conservation, decreased detrimental environmental effects, and improved farmers' understanding of crops. These innovative systems allow for effective soil and weather monitoring as well as efficient water management.

4) To supply the necessary operating power, the proposed system, RBFN-ESA, makes use of a forecasting method from an IoT-based solar cell.

5) The IoT controller reads the data from the humidity, field-based temperature and soil moisture sensors and then outputs the required actuation command signals to drive irrigation pumps.

6) The proposed model RBFN-ESA will collect these data to predict the values of the important solar energy system parameters for a future smart agriculture system.

III. PROPOSED SYSTEM

Every aspect of conventional farming practices can be drastically altered by integrating the most recent sensing and IoT technologies. Now that the IoTs and wireless sensors are available, smart agriculture [35] can reach new heights. By implementing smart farming techniques like drought response, yield enhancement, land applicability, irrigation [34], and pest control, the Internet could really help improve options for so many traditional farming problems. The RBFN-ESA method's block diagram is shown in Fig. 1.

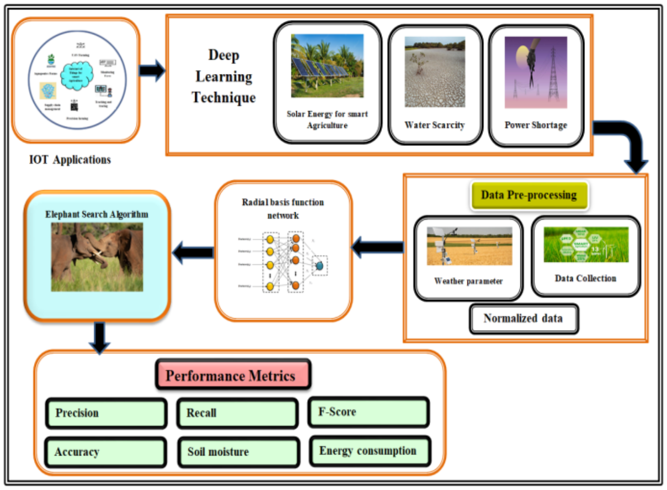

Fig. 1. Block diagram for the approach proposed by RBFN-ESA.

A. Data Pre-processing

The method for considering the weather parameter, data collection, and normalised data during the data pre-processing is described as follows.

1) Weather metric: Accuweather is used to get the daily weather parameters and their measurement units. Based on the temperature (in degrees Celsius), date (dd/mm/yy), season, and daily rainfall, this parameter is used to calculate the amount of rain that will fall on a specific day. The probability of rainfall is taken into account when choosing the aforementioned parameters. The chosen parameter is only equipped to predict the weather.

2) Data collection: For this experiment, we made use of actual data, particularly weather information from Kolkata, West Bengal. The data has been standardized. This data was gathered from the online weather resource Accuweather.com. Data from the first year is used for training, and data from the next 50 days is used for testing.

3) Normalized data: The next stage of data processing, known as "normalization," has arrived after the choice of weather parameters and completion of data collection. Random data in GA must be in normalized form for training and testing. It might be challenging to combine when the GA is trained using real data. Every bit of data is fixed and changed to a value of 0 or 1.

B. Web-Based Water Motor Control Service

A web server built atop the HTTP protocol has been developed to stop and start the water motor. The programming language in R-Pi has accessed this web service to start or stop this same water motor. The Pic Microcontroller's programming language sends signals to the Arduino-Uno, which controls the spread circuit to start and stop the fluid motor.

C. Digital Water Pump

In this subsystem, an aquatic force is attached to a convey button that is managed by a base station with Bluetooth capabilities. For real time monitoring, the web service stimulates base station control from the flexible web-based interface. The water pump can be controlled remotely, both automatically and manually, using this web-based interface.

D. Internet of Things

The IoT is a station of smart, interrelated substances that can transmit information and generate useful data about the market environment. As a result, almost any object that can connect to the Internet can be referred to as a "thing" in the context of the IoTs, including furniture, electronics, appliances, agricultural or industrial machinery, and level public [21-23].

The IoT concept is not new-fangled, but acceptance has recently risen. Some of the technologies that have developed to support it include big data, cloud computing, artificial intelligence, and hardware advancements that have reduced the scope and control of feasting and improved connectivity via the Internet and among plans via wireless connections [24]. Together, these technical parts make a net of nodes that can send and receive information and data and react to interference from the network.

Even though the structure of an IoT network is similar to that of other computer system architectures, [25] says that the identification, sensing, and control of remote devices, as well as the limited computing power of the equipment, are some of the unique aspects of this framework that must be taken into account.

E. Classification using RBFN

The most basic RBFN configuration is a three-layer feed-forward neural network. The network's inputs are represented by the first layer, and its final output is represented by the second layer, which is a hidden layer made up of numerous RBF non-linear activation units. Gaussian functions are frequently used in RBFNs to implement activation functions [26]. An illustration of the RBFN framework can be found in Fig. 2. Let's say we have a dataset D that contains N structures of (xp, yp), where xp is the data set's input.

Eq. (1) can be used to calculate the production of the ith initiation function φi in the net's unseen coating based on the separation among the input pattern x and the centre i.

$$\phi_i(\| x-d_i \|) = exp\left(-\frac{\| x-d_i \|^2}{2\sigma^2{}_j} \right) \qquad (1)$$

The ||.|| hidden neuron j's centre and width are represented by d_i and σ_j, the Euclidean norm.

Then, Eq. (2) can be used to determine the output of node k of the network's output layer:

$$yk = \sum_{j=1}^{n} \omega jk \phi_j(x) \qquad (2)$$

The majority of conventional training methods for RBFNs described in the literature consist of two step [27]. For example, in the first stage, an unsupervised clustering algorithm is used to compute the widths and centers. In order to reduce an error criterion, such as the common mean squared error (MSE) over the whole dataset, the hidden layer and output layer's connection weights must be determined in the second step.

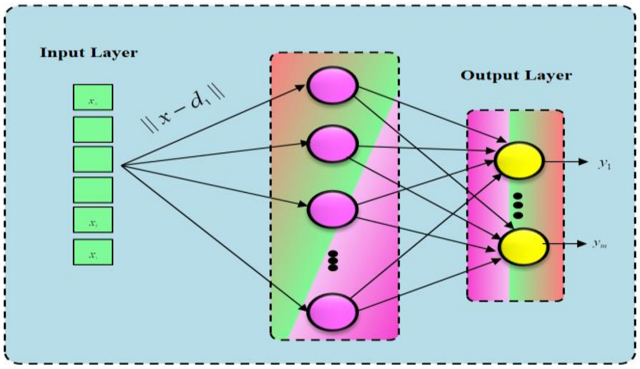

Fig. 2. The RBFN's structure.

F. Elephant Search Algorithm (ESA)

The most recent generation of meta-heuristic search optimization algorithms includes ESA. A dual search mechanism, or the ability to divide the search agents into two groups, is the foundation of this algorithm's approach, which mimics the characteristics and behaviours of an elephant [28]. Elephants live in herds, and each herd is made up of several smaller clans or groupings, each led by the eldest elephant in the herd. The ESA mimics elephant herds' major characteristics and qualities. Elephants have different social systems, with males preferring solitary living and females preferring family units. Female elephants are more concerned with improving their surroundings, whilst male elephants are in charge of discovering new locations to explore.

In this case, ESA is a good search optimization algorithm that has the following three main traits:

1) The search process enhances the present response iteratively in order to identify the ideal one. Chief female elephants also conduct extensive local searches in regions where they believe there is a better chance of finding the greatest solution.

2) Male elephants are in charge of foraging outside the neighborhood's ideal range.

3) Elephants possess a variety of traits, making it crucial to draw inspiration from their biological behaviour. Here is a description of the ESA.

Algorithm 1: Elephant Search Algorithm (ESA)

```
Input: SearchSpace, HerdSize, MaxIterations
Output: BestSolution
Initialize the herd
Herd ← InitializeHerd(HerdSize, SearchSpace)
BestSolution ← None
Main search loop
for iteration = 1 to MaxIterations do
Evaluate the herd's position
  for each elephant in Herd do
elephant.fitness ← EvaluateFitness(elephant.position)
if BestSolution is None or elephant.fitness is better than BestSolution.fitness then
   BestSolution ← elephant
end if
  end for
Communication among elephants (sharing the best known solution)
BestElephant ← FindBestElephant(Herd)
for each elephant in Herd do
  if elephant ≠ BestElephant then
elephant.position ← MoveTowards(BestElephant.position, elephant.position)
  end if
end for
Random exploration to avoid local optima
for each elephant in Herd do
  if rand() < ExplorationProbability then
elephant.position ← RandomMove(SearchSpace)
  end if
end for
Memory retention (remembering good positions)
for each elephant in Herd do
   if rand() < MemoryRetentionProbability then
elephant.position ← elephant.bestKnownPosition
  else
elephant.bestKnownPosition ← elephant.position
  end if
end for
end for
Return the best found solution
return BestSolution
End Algorithm
```

Each elephant must be a member of a clan since they all live together in a herd under the leadership of the oldest elephant [29]. The equation below can be used to represent the animal j in the cli clan.

$$Y_{new,cli,j} = Y_{cli,j} + c(Y_{Best,cli} - Y_{cli,j}).r \tag{3}$$

where $Y_{Best,cli}$ denotes the clan cli and $r \in [0,1]$, and $Y_{new,cli,j}$ and $Y_{cli,j}$ are the elephant j's newly updated and old places in clan cli, separately. $c \in [0,1]$ determines how clan cli influences $Y_{cli,j}$. Eq. (3) cannot be applied when $Y_{cli,j} = Y_{Best,cli}$, but the fittest elephant can be determined using the formula shown below.

$$Y_{new,cli,j} = \alpha.Y_{center,cli} \tag{4}$$

where $\alpha \in [0,1]$ stands for the $Y_{center,cli}$ s impact on the $Y_{new,cli,j}$. The d th dimension of the new individual $Y_{new,cli,j}$ is then updated using the formula below.

$$Y_{center,cli,d} = \frac{1}{n_{cli}}.\sum_{j=1}^{n_{cli}} X_{cli,j,d} \qquad (5)$$

There are that many elephants in the cli clan, $1 \le d \le Dindicate\ the\ dth\ \dim ension$ e, D is its overall dimension, and $Y_{cli,j,d}$ is the d th of the individual $Y_{cli,j}$ elephant.

As mentioned earlier, adult male elephants continue living alone in a remote area after leaving their families [30]. By using a separating operator to solve challenging optimization problems, this scenario can be simulated. Let's assume that the animal individual people with worst fitness particular instance will use the trying to separate operator in compliance with the appropriate equation to enhance the search functionality of ESA [31].

$$Y_{worst,cli,d} = Y_{Min} + (Y_{Max} - Y_{Min} + 1).Rand \qquad (6)$$

where Y_{Max} and Y_{Min} are the highest and lowest limits of an elephant's position, $Y_{worst,cli}$ is the worst elephant member of clan cli, and $Rand \in [0,1]$ is a random distribution [32]. The description of the clan updating and separating operator has been included in the ESA development.

IV. Result and Discussion

The main goal of this experiment is to use sensors to gather the physical characteristics of a farming area. From there, an algorithm will be developed using the sensor data and weather forecast information to predict soil moisture for the upcoming days [33]. This study compares the proposed MPNN-MCOA algorithm with the convolution neural network, support vector machine, artificial neural network, long short-term memory and random forest as five machine learning algorithms.

A. *Assessment Criteria*

- True Positives (TP) are instances where both the actual yield and our expectations came true.
- True Negatives (TN): Occurrences in which the true yield turned out to be incorrect, as predicted.
- False Positives (FP): We expected real results, but the yield was incorrect.
- False Negatives (FN): When an outcome that we anticipated to be untrue proved to be accurate.

Precision: It is also known as the ratio of results that were correctly predicted as positive to results that were actually positive.

$$P\,recision = \frac{TP}{TP + FP} \qquad (7)$$

Recall: It is determined by separating the total amount of successful results by the total amount of conjugate samples.

$$Recall = \frac{TP}{TP + FN} \qquad (8)$$

F1-score: It also goes by the name "harmonic mean" and aims to balance precision and recall. The computation works well on an unbalanced dataset and allows for both false negatives and false positives.

$$F1 - score = \frac{2TP}{2TP + FP + FN} \qquad (9)$$

Accuracy: The percentage of precise predictions to all input models is referred to by this expression.

$$Ac\chi\upsilon\rho\alpha\chi\psi = \frac{TP + TN}{TP + TN + FP + FN} \qquad (10)$$

B. *Precision Analysis*

Fig. 3 and Table I provide a comparison of the RBFN-ESA method's precision with that of other methods now in use. The precision with which the deep learning with IOT method has enhanced performance is illustrated by the graph. For example, the precision of the RBFN-ESA method for data 100 is 86.743%, whereas the CNN, ANN, SVM, RF, and LSTM methods have precision values of 83.487%, 78.256%, 75.187%, 69.664%, and 72.387%, respectively. However, the RBFN-ESA method has shown optimal performance over a range of data set sizes. Under 600 data points, the RBFN-ESA methods precision value is 92.864%; in contrast, the CNN, ANN, SVM, RF, and LSTM methods have precision values of 84.754%, 81.242%, 77.854%, 71.643%, and 74.532%, respectively.

TABLE I. PRECISION ANALYSIS OF THE RBFN-ESA METHOD

No of data from dataset	CNN	ANN	SVM	RF	LSTM	RBFN-ESA
100	83.487	78.256	75.187	69.664	72.387	86.743
200	82.954	78.654	75.533	70.532	72.854	87.953
300	82.843	79.054	76.863	70.843	73.454	88.435
400	83.543	79.435	77.095	69.853	72.964	91.653
500	84.864	80.774	76.346	71.254	73.964	93.643
600	84.754	81.242	77.854	71.643	74.532	92.864

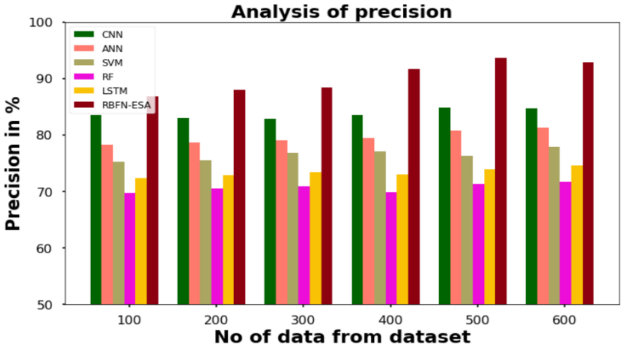

Fig. 3. Precision analysis for RBFN-ESA method.

C. Recall Analysis

Fig. 4 and Table II compare the recall analysis of the RBFN-ESA method with existing methods. The graphic shows how recall performance has increased with the deep learning with IOT method. For example, the recall value for data 100 for the RBFN-ESA method is 90.542%, whereas the corresponding values for the CNN, ANN, SVM, RF, and LSTM methods are 77.76%, 86.543%, 80.187%, 74.875%, and 85.765%. The RBFN-ESA method has performed at its best with various data sizes, though. Similar to this, for 600 data, the recall value of the RBFN-ESA is 94.765%, while for CNN, ANN, SVM, RF, and LSTM methods, it is 79.942%, 88.864%, 84.854%, 78.543%, and 87.912%, respectively.

TABLE II. RECALL ANALYSIS FOR RBFN-ESA METHOD

No of data from dataset	CNN	ANN	SVM	RF	LSTM	RBFN-ESA
100	77.765	86.543	80.187	74.875	85.765	90.542
200	76.643	86.954	81.286	75.278	85.265	89.542
300	77.923	87.254	84.543	73.478	87.397	91.467
400	78.743	87.854	83.567	76.187	86.093	93.965
500	79.654	88.145	82.864	77.098	87.743	92.376
600	79.942	88.864	84.854	78.543	87.912	94.765

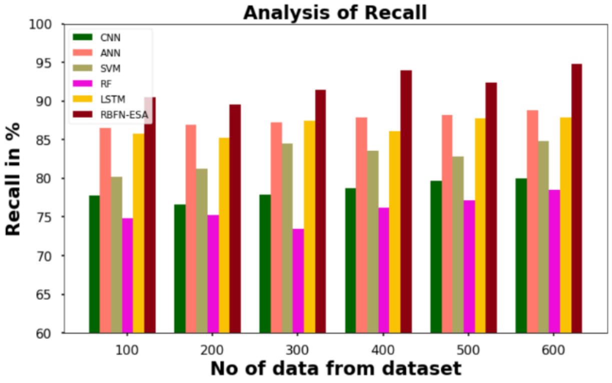

Fig. 4. Recall analysis for RBFN-ESA method.

D. F-Score Analysis

Fig. 5 and Table III provide comparative f-score analyses of the RBFN-ESA method with other existing methods. The graph shows that the f-score performance has improved with the deep learning with IOT method. For example, the f-score value of the RBFN-ESA method for data 100 is 94.095%, whereas the corresponding values for the CNN, ANN, SVM, RF, and LSTM methods are 88.643%, 85.865%, 78.543%, 91.754%, and 81.765%. However, the RBFN-ESA method has shown optimal performance over a range of data sizes. In comparison to the CNN, ANN, SVM, RF, and LSTM methods, which have respective f-score values of 90.345%, 86.324%, 80.864%, 94.865%, and 83.265%, the RBFN-ESA method has an f-score value of 97.565% under 600 data points.

TABLE III. F-SCORE ANALYSIS FOR RBFN-ESA METHOD

No of data from dataset	CNN	ANN	SVM	RF	LSTM	RBFN-ESA
100	88.643	85.865	78.543	91.754	81.765	94.095
200	87.045	84.345	79.465	92.865	82.644	94.345
300	87.345	85.234	78.843	91.245	81.438	95.346
400	88.934	84.846	80.245	92.533	82.835	95.755
500	87.834	86.987	81.258	93.546	83.095	96.346
600	90.345	86.324	80.864	94.865	83.265	97.565

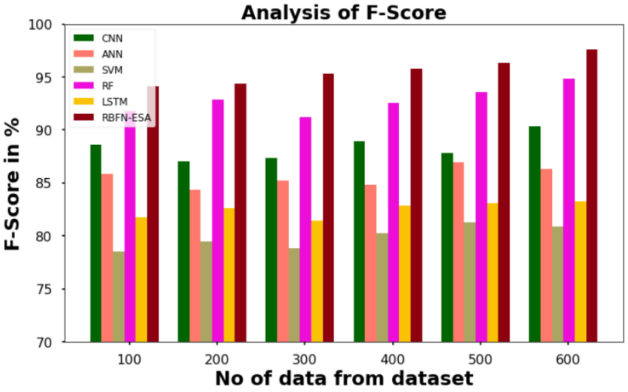

Fig. 5. F-Score analysis for RBFN-ESA method.

E. Accuracy Analysis

Fig. 6 and Table IV compare the accuracy of the RBFN-ESA method to other methods. The graph shows how applying the deep learning with IOT method has improved performance with accuracy. For example, the RBFN-ESA method accuracy value for data 100 is 94.509%, while the accuracy values for CNN, ANN, SVM, RF, and LSTM methods are 79.346%, 89.453%, 84.578%, 90.353%, and 81.756%, respectively. However, the RBFN-ESA method has shown optimal performance over a range of data sizes. Comparing the accuracy values of CNN, ANN, SVM, RF, and LSTM method, which are 83.653%, 88.245%, 86.953%, 92.465%, and 83.543%, respectively, to the RBFN-ESA, which has an accuracy value of 97.467 % is 600 data.

TABLE IV. ACCURACY ANALYSIS FOR RBFN-ESA METHOD

No of data from dataset	CNN	ANN	SVM	RF	LSTM	RBFN-ESA
100	79.346	89.453	84.578	90.353	81.756	94.509
200	79.754	89.775	84.965	91.654	82.467	94.356
300	80.645	87.464	85.196	93.464	82.776	95.864
400	80.356	87.865	85.853	92.098	83.854	96.245
500	81.246	88.353	86.257	93.834	81.943	96.865
600	83.653	88.245	86.953	92.465	83.543	97.467

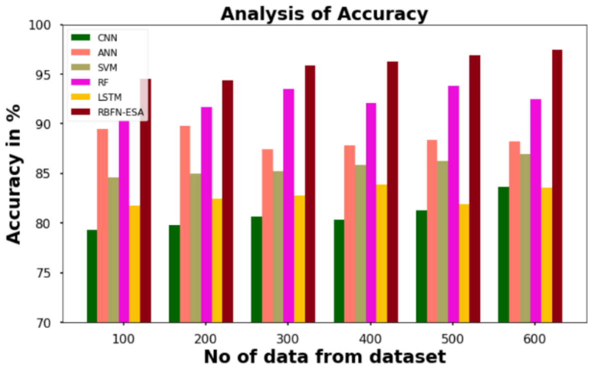

Fig. 6. Accuracy analysis for RBFN-ESA method.

F. Training Validation and Training Loss

Fig. 7 shows training validation and training loss analysis for RBFN-ESA method.

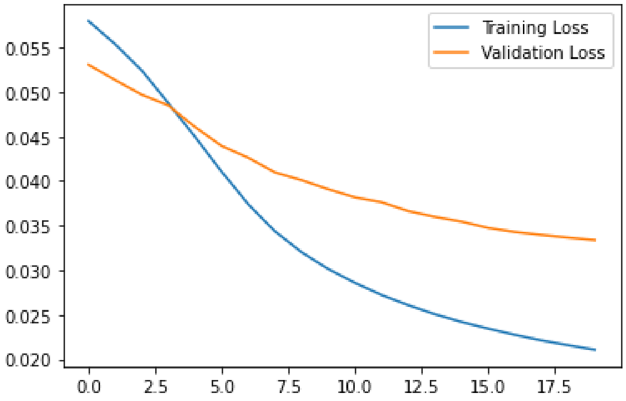

Fig. 7. Training validation and training loss analysis for RBFN-ESA method.

G. Soil Moisture

Fig. 8 and Table V compare the RBFN-ESA method with existing methods for examining soil moisture. The graph shows how soil moisture performance has increased with the deep learning with IOT method. For example, with 100 data, the RBFN-ESA method's soil moisture is 90.16%, whereas the CNN, ANN, SVM, RF, and LSTM methods' soil moisture values are 71.87%, 77.76%, 76.17%, 79.96%, and 84.67%, respectively. However, the RBFN-ESA method has shown optimal performance over a range of data sizes. Similarly, the RBFN-ESA has soil moisture of 94.41% under 600 data, while CNN, ANN, SVM, RF, and LSTM methods have 73.18%, 79.17%, 76.62%, 82.78%, and 88.76%, respectively.

TABLE V. SOIL MOISTURE ANALYSIS FOR RBFN-ESA METHOD

No of data from dataset	CNN	ANN	SVM	RF	LSTM	RBFN-ESA
100	71.87	77.76	76.17	79.96	84.67	90.16
200	73.43	76.17	74.36	77.12	83.87	92.65
300	73.12	78.19	75.42	79.65	85.15	91.76
400	70.98	76.54	74.17	81.65	88.44	93.43
500	72.98	78.66	75.77	80.32	88.91	95.17
600	73.18	79.17	76.62	82.78	88.76	94.41

H. Energy Consumption Analysis

Table VI and Fig. 9 provide a comparison of the energy consumption of the RBFN-ESA method with existing methods. With 100 data, the CNN, ANN, SVM, RF, and LSTM methods consume 59.324J, 57.276J, 64.865J, 67.897J, and 69.256J of energy, respectively, whereas the proposed RBFN-ESA method uses 54.632 J. In a similar vein, the proposed RBFN-ESA method uses just 56.764 J with 600 data, compared to 62.543 J, 58.721 J, 65.443 J, 68.432 J, and 73.876 J for CNN, ANN, SVM, RF, and LSTM. The recommended method shows enhanced performance with lower energy usage.

TABLE VI. ENERGY CONSUMPTION ANALYSIS FOR RBFN-ESA METHOD

No of data from dataset	CNN	ANN	SVM	RF	LSTM	RBFN-ESA
100	59.324	57.276	64.865	67.897	69.256	54.632
200	60.633	57.642	63.269	66.265	70.765	55.853
300	61.287	58.973	64.249	66.875	70.236	53.842
400	62.843	58.423	63.865	65.854	69.246	55.062
500	61.865	59.053	65.089	68.532	71.663	55.187
600	62.543	58.721	65.443	68.432	73.876	56.764

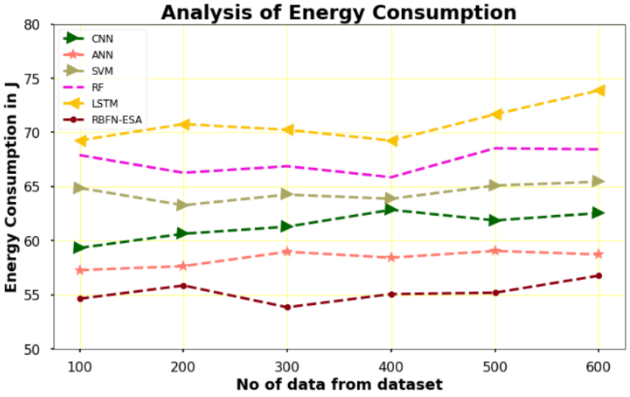

Fig. 9. Energy consumption analysis for RBFN-ESA method.

V. CONCLUSION

Environmental variables, such as relative humidity, temperature, soil temperature, UV rays, etc., impact soil moisture. Technology advancements have greatly enhanced the precision of weather forecasts, and the information can now be used to predict variations in soil moisture. The intelligent irrigation system described in this week's IoT-based planet comprehensive liveliness classification is essential for areas of creation where water and energy are uncommon. Using a qualitative methodology and focusing on secondary data collection, a deep learning model called Radial Basis Function Networks (RBFN) with the Elephant Search Algorithm (ESA) was used for this IoT-based solar energy system for a Future intelligent agriculture system. To supply the necessary operating power, the proposed RBFN-ESA uses a forecasting process from an IoT-based solar cell. The IoT controller reads the data from the humidity, field-based temperature and soil moisture sensors and then outputs the required actuation command signals to drive irrigation pumps. In forecast the value systems of the crucial solar power system variables for a future intelligent agriculture system, the suggested framework RBFN-ESA will gather these data. In terms of defining whether a user will belong to a specific group, the proposed model performed better than other models like Random Forest (RF), Artificial Neural Network (ANN), Support Vector Machine (SVM), Convolution Neural Network (CNN) and Long Short-Term Memory (LSTM). This approach makes use of existing models, such as SVM, RF, LSTM, and convolution neural. We want to conduct further assessments of water savings based on the proposed algorithm with numerous nodes and system cost reduction.

Subjectivity Analysis of an Enhanced Feature Set for Code-Switching Text

Emaliana Kasmuri, Halizah Basiron*
Fakulti Teknologi Maklumat Dan Komunikasi, Universiti Teknikal Malaysia Melaka, 76100 Durian Tunggal, Melaka, Malaysia

***Abstract*—The phenomenon of code-switching has posed a new challenge to the linguistic computing area. Conventionally, the computer will process monolingual text or multilingual text. However, code-switching is different from this kind of text. Two or more languages are used to construct a piece of code-switching text, particularly a code-switching sentence. It is challenging for the computer to process a piece of code-switching text with languages that exist simultaneously. The challenge is more intense for the computer in subjectivity analysis, where the computer should distinguish subjective from objective code-switching text. This paper proposed three feature sets for subjectivity analysis on Malay-English code-switching text: Embedded Code-Switching Feature Sets, Unified Code-Switching Feature Sets, and Stylistic Feature Sets. These feature sets were enhanced from the monolingual feature set of subjectivity analysis. Experiments were conducted using the data harvested from Malay-English blogs. These data were labelled as either subjective or objective. Two machine learning classifiers – the Support Vector Machine (SVM) and Naive-Bayes, were used to evaluate the classification performance of the proposed feature sets. The experiments were carried out on individual feature sets and the combination of them. The results show the classification performance from combining the unified and stylistic feature sets surpassed other proposed feature sets at 59% accuracy. Therefore, it is concluded that the combination of unified and stylistic feature sets is necessary for the subjectivity analysis of Malay-English code-switching text.**

Keywords—Subjectivity analysis; code-switching; enhanced feature sets; Malay-English text

I. Introduction

It is common for a person to master multiple languages. Mastering multiple languages benefitted an individual in various ways, including vocabulary enrichment, communication improvement, and knowledge improvement through information exchange and sharing. It is also a common situation to see a multi-lingual person communicate, either in spoken or written, using a mix of languages. The use of mixed languages is known as code-switching [1].

A code-switching text is a piece of text that is constructed using words from at least two languages. For example, 'I really like matte satin silk nak buat collection tapi I am still a student tak ada income if dapat giveaway ni mesti best'. In the example, the sentence is constructed using English (underlined) and Malay (italic) words. Code-switching may occur within a text where the words from the second language interleave in between the words from the first language, or the first part of the text was constructed using the first language while the remaining part was constructed with the second language. For example, 'Aspirasi saya adalah banyak peluang dari segi pendidikan, ekonomi, sukan dan sebagainya untuk masyarakat khas for them to excel in those field'.

The code-switching phenomenon is not new in the linguistic research domain. It was acknowledged in the 1980s [2]. However, with the advancement of computer technology, the use of code-switching in open platforms such as blogs and social media has become more apparent than before. This situation has posed a new challenge to language computational areas in text analysis and machine comprehension of this new kind of text. In general, most of the research effort has been channelled towards computational and knowledge augmentation on monolingual and multilingual text. The presence of two languages simultaneously in a code-switching text was not considered in the current subjectivity analysis study.

A set of research questions are drawn to address the code-switching issues in subjectivity analysis. The research questions are as follows:

1) What are the most effective feature sets for subjectivity analysis in Malay-English code-switching text?

2) How do different machine learning classifiers perform in subjectivity classification when using the proposed feature sets?

3) What is the impact of combining various enhanced feature sets on the accuracy of subjectivity analysis in code-switching text?

Three objectives were drawn to align with the research questions. The first objective is to develop enhanced feature sets that effectively analyse subjectivity in Malay-English code-switching text. The second objective is, to compare the performance of machine learning classifiers using the proposed feature sets for subjectivity analysis. Finally, the last objective is to assess the accuracy improvement achieved by combining different feature sets for subjectivity classification in code-switched text.

Therefore, this article proposes a method that enhances feature sets to analyse subjectivity in Malay-English code-switching sentences to achieve the objectives. The enhanced feature sets used the subjectivity feature from both languages to represent the subjectivity of the code-switching feature sets. The enhanced feature sets consist of embedded, unified, and stylistic feature sets. Two machine learning classifiers, Naïve-Bayes (NB) and Support Vector Machine (SVM), were used to evaluate the feasibility of the feature sets classifying the Malay-English code-switching sentences into subjective and objective classes.

*Corresponding Author, halizah@utem.edu.my

This research contributes to the growing field of computational linguistics by addressing the challenge of subjectivity analysis in code-switching text. The findings from this study can be applied to improve text processing systems used in social media, blogs, and other platforms where code-switching is prevalent. The proposed enhanced features set that contains embedded, unified, and stylistic feature sets provide a foundation for future research and development in computational methods for analysing subjectivity in code-switching text.

The article's structure is as follows: In Section II, we review related works and discuss research motivation. Section III presents a description of our proposed solution and the features used. Section IV describes the dataset used in the experiment. Section V gives the details of our experiments and discusses the results. Sections VI and VII present the discussion and limitations, respectively. Lastly, Section VIII concludes and summarizes our work in this article.

II. Related Work

Subjectivity analysis is a linguistic computational task that determines the existence of a private state such as opinion, emotion and stance in a piece of textual document. Subjectivity analysis is a precursor to tasks such as sentiment analysis, and emotion classification.

Ting et al. investigated subjectivity classification using a window-based self-attention approach [2]. The approach improves the sentence encoding by leveraging context within variable-sized windows, instead of the entire sentence. Different sizes of windows (the size of surrounding words) were used to determine the importance of each word using trigrams or five-grams. The max-pooling method was used to extract the most relevant feature. As a result, multiple windows were captured from various phases where meaningful combinations of words were evident. This method simplifies attention computation, working directly on word embeddings and relying on n-gram features to provide context-aware sentence representations. The author used monolingual Cornell's movie data set to classify the review into subjective and objective classes. The proposed method performed at 94.60% accuracy.

Belisario et al. studied subjectivity analysis for Portuguese book reviews [3]. The authors used 350 reviews that were equally divided into subjective and objective sentences. The features of these sentences were extracted and represented using several methods including Sentilex-PT and WordnetAffectBR for the lexicon-based method, global centrality graph-based method using Eigenvector Centrality, Katz Index and PageRank and Naïve-Bayes, SVM and Neural Network for machine learning based method. The result reveals the Neural Network outperformed other methods at 83.20% accuracy.

Kasnesis et al. compare three transformer-based architectures to classify the the 10,000 Cornell movie review sentences into subjective and objective classes [3]. The authors used Bidirectional Encoder Representation (BERT), Robust Optimised BERT Pretraining Approach (RoBERTa) and Efficient Learning Encoder Classifies Token Replacements Accurately (ELECTRA) to evaluate the effectiveness of the subjectivity classification. ELECTRA achieved the highest accuracy score, 98.30% among the three.

Al Hamoud et al. analyse subjectivity expressed from an online English political and ideological debate forum [4]. Various controversial topics were debated in the forum including abortion, creationism, gay rights, the existence of God, gun rights and health care. The authors have created a dataset of 53, 453 sentences from the forum. These sentences were labelled as either subjective or objective. The features of the dataset were represented using one-hot encoding and GloVe pretraining embedding vectors. These features were experimented with using six deep learning models to find the most effective model that could classify the dataset into subjective/objective classes. The models are Long Short Term Memory Networks (LSTM), Gated Recurring Units (GRU), bidirectional GRU, bidirectional LSTM, LSTM with attention and bidirectional LSTM with attention. The results of the experiment show that LSTM with attention performed the best out of all deep learning models – 97.39% accuracy.

The studies that were presented above were working on monolingual textual documents – that is English and Portuguese. The excellent performance result in studies has shown the proposed classification solutions have generated effective classification models that has outperformed the other models in the respective experiment. Even though the studies can produce effective subjectivity classification models, their feasibility on code-switching text is still unknown. Therefore, this article attempts to fill the gap using Malay-English code-switching text for subjectivity analysis.

The issue of code-switching in linguistic computation has been addressed as early as the 1980s [5]. However, the issue received proper attention from the linguistic computation area due to the availability of the data sets and the maturity of computer language processing tools. With the advance of social media, the research of linguistic computation using code-switching text has started to receive attention. Among the research on code-switching computational are text generation [6], [7], [8] and sentiment analysis [9], [10], [11].

One of the hurdles in code-switching linguistic computation is data scarcity. The advancement of social media has accelerated the phenomenon of code-switching. Therefore, data become more available in this research area. However, the amount of data is insufficient for various tasks in linguistic computation. Code-switching data is artificially generated to support these tasks. Hu et al. generate code-switching training text to improve code-switching automatic speech recognition (ASR) [8]. The text injection method known as PaLM 2 and prompt tuning were used to generate the training data. The experiment to generate the data was carried out using the Large Language Model (LLM). The result shows that the proposed method achieves a 3.60% Word Error Rate (WER) for Mandarin-English. The research concludes leveraging LLMs for text generation and text injection benefits code-switching ASR tasks.

Three methods were compared to select the best method that generates code-switching data for Egyptian Arabic-English Hamed has been compared [7]. The first method is lexical replacement, which replaces a number of random Arabic words with English words using code-switching point assignment and point prediction. Code-Mixing Index (CMI) was used to measure the performance of this method. CMI indicate the level of mixing from both languages. Both methods achieve 28.00% and 25.00% CMI. The second method used linguistic theories - Equivalence Constraint (EC) Theory and Matrix Language Frame (MLF) Theory. Both achieved 30.00% and 25.00% CMI. The final method used back translation. The method performed at 18.00% CMI.

Research by Chi et al. also addressed code-switching data scarcity [6]. Monolingual BERT models (Mandarin and English) were used to train a Transformer encoder-decoder model to translate between any pair of languages. The translated sentences are forced to code-switch to any degree. Disjoint union of vocabulary from two languages were used as parallel text. Grid beam search is the method to force the degree of the code-switching text. The proposed method performed at 30.58% WER.

A deep convolutional neural network (CNN) was used to determine the sentiment expressed in a comment that contains a mixture of English and Hindi languages [9]. A dataset that contains 17,155 comments was created, and the comments were extracted from a governmental website. Each comment was manually labelled as either positive or negative. The study used Word2Vec to represent the English words. The Hindi words embedding were developed using Word2Vec and trained using Hindi Wikipedia and other sources. The solution used on the dataset has yielded 67.00% of accuracy.

A study on a mixture of English-Spanish that leverages existing English and Spanish text analytical tools has been carried out using a supervised learning algorithm [10]. In this study, 3,062 tweets that were labelled as positive and negative were used. Four atomic features, which are word, lemma, psychometric properties and part-of-speech (POS) tags were used as basic features. The best accuracy obtained is 59.34% using combination lemmas and psychometric properties as features.

A recent study of sentiment analysis using a mixture of English-Hindi and English-Bengali tweets has demonstrated using deep learning [11]. The study classifies the dataset into positive, negative and neutral. Three deep learning algorithms, which are BiDirectional Long Short-Term Memory (BiLSTM) Convolutional Neural Network (CNN), a Double BiDirectional Long Short-Term Memory (D-BiLSTM) and an Attention-based model, were used in the experiment. Pre-trained word embeddings, which are Global Vector (GloVe) and Bidirectional Encoder Representations from Transformers (BERT), were used in the study. The study has revealed that accuracy performance between 42.00% and 68.00% was achieved using a 10-fold cross-validation classification. The result from the experiment shows the best performance for the English-Hindi dataset was achieved by the deep learning attention model using GloVe with 68.00% accuracy, whereas, for the English-Bengali dataset, the best performance was achieved by the deep learning attention model with 67.00% accuracy.

All the research efforts described in this section focus on code-switching sentiment classification and text generation. The attempt for subjectivity classification on code-switching text, especially for subjectivity analysis on Malay-English code-switching text, was found to be limited at the time this research was conducted. Therefore, this article is attempts to find out a feasibile solution for subjectivity analysis on Malay-English code-switching text.

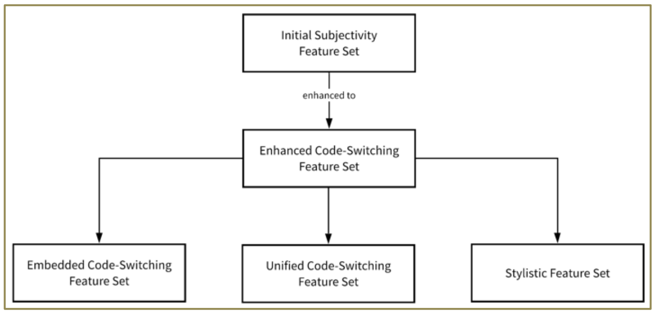
III. Enhanced Feature Sets of Subjectivity Analysis for Code-Switching Text

The syntactical and semantical features were used to analyse subjectivity in a monolingual text such as English [12]. These features are described in Table I. These features were enhanced for a Malay-English code-switching text.

TABLE I. INITIAL FEATURE SET FOR SUBJECTIVITY ANALYSIS

Syntactical Features	Semantical Features
1. Sentence that located in beginning of a paragraph. 2. The co-occurrence of words and punctuation.	1. Pronoun 2. Adjective 3. Cardinal number 4. Modal (other than will) 5. Adverb (other than not)

The enhanced feature sets are Embedded Code-Switching Feature Sets, Unified Code-Switching Feature Sets and Stylistic Feature Sets. The Embedded Code-Switching Feature Set include the Malay text analytical components in the code-switching feature set representation. The Unified Code-Switching Feature Set fused two text analytical components into a unified feature set. The stylistic feature sets used non-vocabulary features to represent the subjectivity clues in the code-switching text. Fig. 1 illustrates the proposed feature sets.



Initial Subjectivity Feature Set
enhanced to
Enhanced Code-Switching Feature Set
Embedded Code-Switching Feature Set
Unified Code-Switching Feature Set
Stylistic Feature Set

Fig. 1. Proposed feature set for code-switching subjectivity analysis.

A. Embedded Code-Switching Feature Set

The subjectivity analysis feature set for a monolingual text is derived from a monolingual part-of-speech (POS) tag. A code-switching sentence is constructed using at least two different languages. Therefore, two POS taggers are used to produce the feature set for the code-switching sentence. The union of the POS tags from two languages produces the embedded code-switching feature set. The union process is shown in Fig. 2.

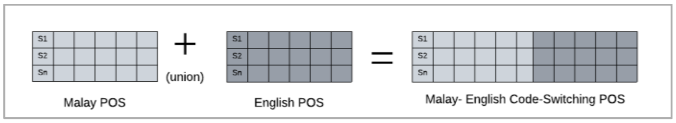


Fig. 2. The union process to construct embedded code-switching POS tags.

The Hawkin-UKM Malay and Penn Treebank POS tags are used to produce the embedded code-switching feature sets. The POS taggers consist of several tags to represent a single POS. For example, the Hawkin Malay POS tagger used ADJ, ADJS and ADJT to represent an adjective word, while the Penn Treebank POS used JJ, JJR and JJS. These POS tags are combined and grouped. Table II shows the grouping of the POS tags that represent the subjectivity features for the Malay-English code-switching text.

TABLE II. MALAY-ENGLISH CODE-SWITCHING POS TAGS

Part of Speech	Malay POS Label	English POS Label
Adjective	ADJ, ADJS, ADJT	JJ, JJR, JJS
Adverb	ADV	RB, RBR, RBS, WRB
Noun	KN, KNG, KNK, KNT, KPB	NN, NNP, NNPS, NNS
Verb	KK, KKIA, KKIK, KKIW, KKT	VB, VBD, VBG, VBN, VBP, VBZ
Pronoun	KGDD, KGDP, KGDT, KGNT, @KG	PRP, PRP$, WP
Conjunction	KH	CC, IN
Cardinal number	KBIL	CD
Modal	MD	MD

Modal POS was absent in the initial Hawkin-UKM Malay POS tagger. Modal is included in the Malay POS for a balanced and uniform feature. The modal POS tag is defined as MD. A list of English modals retrieved from MyEnglishPages.com[1] is translated into Malay using Cambridge Online English-Malay Dictionary[2], and Kamus Dwibahasa Bahasa Inggeris – Bahasa Melayu [13], [14]. Thirteen English modals were translated into Malay. The translation process produces 30 Malay words with equal meaning to the English modal.

The process to generate the Malay-English code-switching feature set is shown in Fig. 3. The process consists of five phases. The process begins with the sentence tokenization process in Phase 1. The code-switching sentences retrieved from the repository are tokenized. Tokenization is a process that breaks the words into the sentence into individual pieces. The individual piece is called a token. The space between the words is used as a boundary to mark the beginning and end of a word. This is known as a delimiter.

The process continues with POS tagging in Phases 2 and 3. The tokens are tagged using the Hawkin Malay and Penn Treebank POS taggers. Phases 2 and 3 produced two sets of tagged tokens. In Phase 4, the English POS-tagged tokens are embedded into the Malay POS-tagged tokens. The phase standardized the POS tags using the group described in Table III. In Phase 5, the presence of the feature is coded as 1, while others are coded as zero, indicating the absence of the feature. The features are extracted and converted into a matrix. This matrix is known as an embedded code-switching feature set.

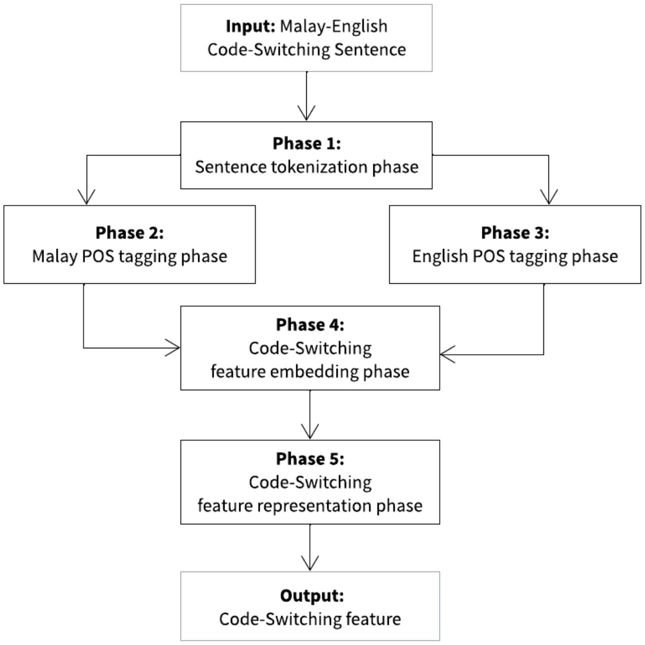

Fig. 3. The process to generate embedded code-switching feature set.

TABLE III. EMBEDDED CODE-SWITCHING SUBJECTIVITY FEATURE SET

Feature	Description
ADJ_MS	Presence of adjective for Malay words
ADV_MS	Presence of adverb for Malay words
NN_MS	Presence of noun for Malay words
VB_MS	Presence of verb for Malay words
PR_MS	Presence of pronoun for Malay words
CC_MS	Presence of conjunction for Malay words
CD_MS	Presence of cardinal number for Malay words
MD_MS	Presence of modal for Malay words

B. *Unified Malay-English POS Feature Set*

The second feature set is the unified Malay-English POS feature set. The process to produce the unified code-switching feature set is shown in Fig. 4. The process consists of six phases. The process starts with Phase 1, which tokenized the sentences. The tokens are POS-tagged using the Hawkin-Malay and Penn Treebank POS tags in Phase 2 and Phase 3. The phases produce two sets of tokens. However, there were discrepancies in token lengths identified in Phase 4. The length of the token is standardized by removing the additional token.

In Phase 5, the Malay and English POS Tags are unified using a rule-based algorithm. The algorithm was adopted from [15], as shown in Algorithm 1. The algorithm requires three (3) sentences: the sentence with language label tags, the sentence with English POS tags and the sentence with Malay POS tags. Each word in the sentence with language label tags will be mapped to either a sentence with English POS tags or a sentence with Malay POS tags. The mapping of each word will be according to the language label.

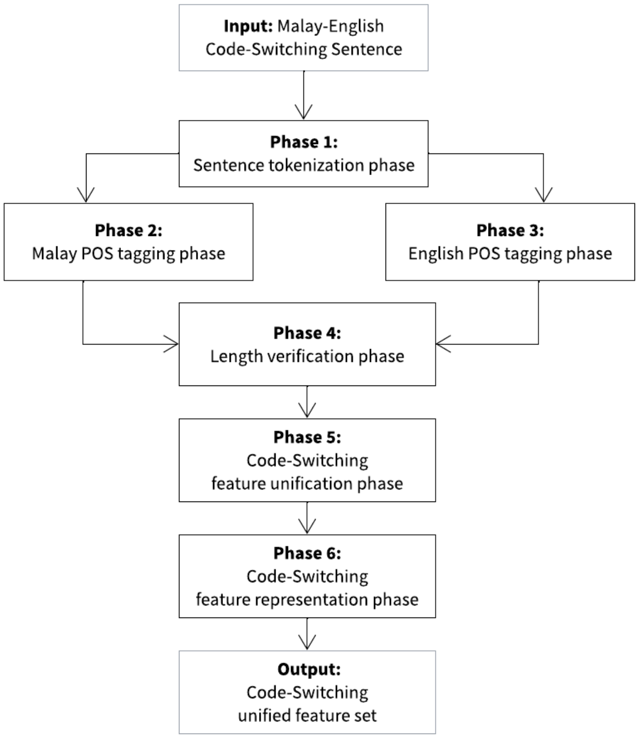
Algorithm 1: Unified_cs_pos_tag

```
Input:
sentence_cs: Malay-English code-switching sentence with language tags
sentence_en_pos: Malay-English code-switching sentence with English POS tags
sentence_my_pos: Malay-English code-switching sentence with Malay POS tags
sentence_unified_POS = " "
For each word in sentence_cs
    Get the language of the word
    If the language labelled for the word is either as English or Shared
            Get the matching word from sentence_en_pos
            Concatenate word and POS Tag into sentence_unified_POS
    Else if the word is labelled as Malay
            Get the matching word from sentence_my_pos
            Concatenate word and POS Tag into sentence_unified_POS
    Else
            Discard the word
    End
End
Return sentence_unified_POS
```



Input: Malay-English Code-Switching Sentence
Phase 1: Sentence tokenization phase
Phase 2: Malay POS tagging phase
Phase 3: English POS tagging phase
Phase 4: Length verification phase
Phase 5: Code-Switching feature unification phase
Phase 6: Code-Switching feature representation phase
Output: Code-Switching unified feature set

Fig. 4. The process to generate a unified POS feature set.

C. *Stylistic Feature*

The stylistic features are non-vocabulary words representing the author's emotional state in a text. The stylistic features that influence the code-switching text are exclamation marks, emoticons, exaggeration, intensifiers and interjections. An emoticon is a representation of the facial expression, mood and emotion of an author that is created by combining numerous keyboard strokes. An emoticon strengthens the message conveyed in the text [16]. It is observed that the widespread usage of emoticons in electronic documents has indicated the development of emotion [17]. An emoticon is also used to clarify the intent of the electronic message, such as sarcasm and criticism [16]. The findings of these studies have shown that emoticons are used in a subjective textual document. Table IV shows examples of emoticons and their underlying meaning.

Creative spelling with exaggeration of characters is another stylistic feature considered in the code-switching text. The exaggeration of characters is defined as the repetition of characters in a word that occurs more than two times. The repetition of characters in the text indicates the expression of information intensifying.

TABLE IV. REPRESENTATION OF EMOTICON AND ITS UNDERLYING MEANING

Emoticon	Meaning
:) or :-) or (^_^)	An emoticon that represents a smiling face that indicates the author is happy or pleased.
:(or :-(	An emoticon that represents a frown face that indicated the author is sad or unhappy.
;) or ;-)	An emoticon that represents a winking, indicating being flirtatious.

An interjection is used as a form of human expression of feeling in an electronic document. Interjection represents an immediate feeling by not literally describing it [18]. Some interjections are language-independent, such as "wow", "haha", and "hmm". Whilst some interjections are language-dependent, such as "jeng", "gap", and "seh", which are commonly used by Malay speakers, were found in the code-switching sentences. Table V shows some examples of interjections and their meaning.

TABLE V. EXAMPLE OF INTERJECTIONS AND ITS MEANING

Interjection	Meaning
wow	Represents astonishment
haha	Represent regular laughter
hmm	Represent thinking or hesitation
jeng	Represent surprise. Usually appear multiple times such as jeng…jeng..jeng
ngap	Represent act of eating

IV. BUILDING MALAY-ENGLISH SUBJECTIVE DATA SET

The data used in this research was harvested from 45,964 Malay-English blog posts. The blog is chosen as the source of data for numerous reasons: 1) The content is rich with objective and subjective information 2) The content was written using a mixture of Malay and English 3) The blog is still relevant 4) The blog is publicly available 5) The casual writing style.

Preparing the data set begins with extracting the content of the blog post. For that purpose, a Python program using the BeautifulSoup module was developed. The blog content was separated into individual sentences, and the distribution of Malay and English words was computed using the procedure shown in Algorithm 2.

Algorithm 2: Compute_MS_EN_distribution

```
For every sentence in the database , sn
    $t_{malay} = 0$, $t_{english} = 0$, $t_{shared} = 0$, $t_{ood} = 0$
    Separate the sentences into individual word, $s=\{w1, w2, w3, \ldots ,wn\}$
    For every word in the sentence, wn
            If $((wn \in mswn) \cap (wn \notin enwn))$
            $t_{malay}$ += 1
            else if $((wn \notin mswn) \cap (wn \in enwn))$
            $t_{english}$ += 1
            else if $((wn \in mswn) \cap (wn \in enwn))$
            $t_{shared}$ += 1
            else
            $t_{ood}$ += 1
            End
    Record the language distribution for this sentence, sdn = { $t_{malay}$, $t_{english}$, $t_{shared}$, $t_{ood}$}
    End
End
Return record of language distribution
```

After that, the Malay-English code-switching sentences were extracted using the procedure shown in Algorithm 3. A Malay-English code-switching sentence should contain at least one Malay and one English functional word. This research defined a functional word as a word that is not categorized as either a stop word or the name of an entity.

Algorithm 3: selecting_MS_EN_sentences

```
Get language distribution for every sentence from the database
For each language distribution of a sentence
    Get Malay words distribution
    Get English words distribution
    If ((Total Malay words distribution >= 1) and (Total English words distribution >= 1))
            Label the sentence as MS-EN-CS
     Else if ((Malay words distribution >= 1) and (English words distribution == 0))
            Label the sentence as MS
     Else if ((Malay words distribution == 0) and (English words distribution >= 1))
            Label the sentence as EN
End
End
```

The procedure has extracted 93,796 Malay-English sentences. Sentences containing 3 to 25 words are selected to be labelled as subjective or objective. Mohammad (2016) and Belisário et al. (2020) used a similar number of words per sentence [19], [20]. Sentences with less than three words were considered uninformative. Sentences containing more than 25 words contain overwhelming information that increases the complication of the annotation task. 56,207 sentences were selected after discarding the unwanted sentences. These sentences were labelled by two annotators using the annotation scheme described in Table VI.

The annotation process has produced 35,067 Malay-English code-switching sentences - 25,164 were subjective, while 9,903 were objective sentences. These sentences will be used as a dataset in the experiment section. The result is shown in Table VII.

TABLE VI. ANNOTATION SCHEME FOR MALAY-ENGLISH CODE-SWITCHING CORPUS

Label	Language			Description of sentence	
	Malay	*English*	*Malay-English*	*Fact*	*Opinion*
EN-OPI		√			√
EN-FAC		√		√	
MS-OPI	√				√
MS-FAC	√			√	
CS-EN-OPI			√		√
CS-MS-OPI			√		√
CS-FAC			√	√	

TABLE VII. DISTRIBUTION OF ANNOTATED SENTENCES

Language / Labels	Subjective	Objective
Malay-English	25, 164	9,903
Code-Switching	25, 164	9,903
English	3, 957	1, 197

The dataset contains 9,903 objective sentences and 25,164 subjective sentences. The number of subjective sentences is two and a half times greater than the number of objective sentences, making the data imbalanced. However, a machine learning algorithm works best with a balanced dataset.

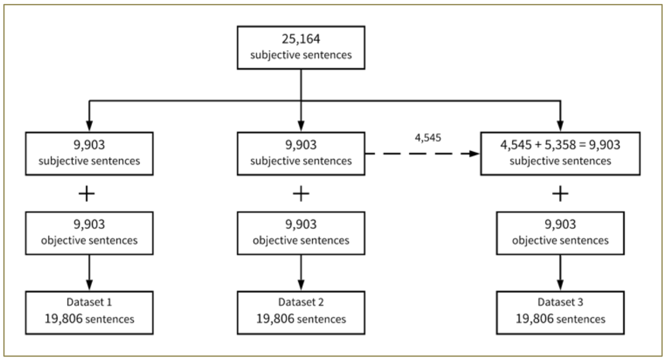


Fig. 5. Distribution of dataset.

This research divided the subjective sentences into three parts to create an equal number of sentences to objective sentences, as shown in Fig. 5. Krawczyk (2016) used a similar approach [21]. This research named these parts as Dataset 1, Dataset 2 and Dataset 3. With this distribution, all datasets have an equal number of subjective and objective sentences.

V. RESULT

Nine experiments were designed and carried out to evaluate the proposed feature sets' ability to analyse the subjectivity in Malay-English code-switching text. The experiments were carried out using two different machine learning classifiers, Naïve-Bayes and Support Vector Machine (SVM). Two experiments were carried out exclusively for English and Malay sentences using the initial feature sets as baseline experiments. The baseline experiments are established as comparisons for the proposed feature sets. Other experiments were conducted to identify the optimal feature sets and machine learning classifiers that function well with subjectivity classification for Malay-English code-switching text at the sentence level.

A. *Baseline Feature Sets Performance Results*

The results from the baseline experiments will be compared to those of the other experiments. The baseline experiments are performed separately, considering only English and Malay initial feature sets. These feature sets are trained and tested using two different classifiers and three different datasets. The accuracy performance of the experiments is shown in Fig. 6. The results were obtained after performing 10-fold cross-validation for both classifiers.

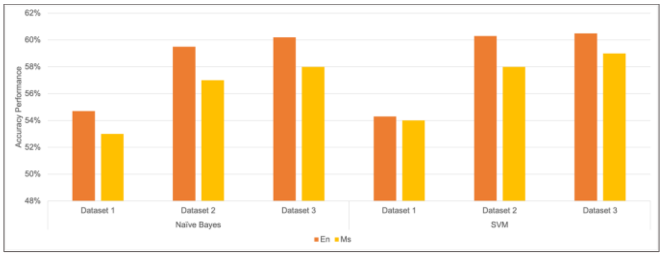

Fig. 6. Accuracy performances of baseline initial features models using different classifiers across multiple datasets.

Fig. 6 shows the baseline feature set performed at 55.00% accuracy for the English (En) feature set and 53.00% accuracy for the Malay (Ms) feature using Dataset 1 using the Naïve-Bayes classifier. The performance of the baseline feature sets using Dataset 2 is 59.00% accuracy for the English (En) feature set and 57.00% accuracy for the Malay feature set, using the same classifier. The baseline feature sets yielded 60.00% accuracy and 58.00% accuracy, respectively, for the English initial feature set and Malay initial feature set, using Dataset 3 and the same classifier. Dataset 3 has the highest accuracy performance among the three datasets using the Naive-Bayes classifier.

The accuracy of the baseline initial feature sets was lower in Dataset 1 using the SVM classifier, which is 54.00% for both, as shown in Fig. 9. The accuracy of the models increased significantly using Dataset 2 using the same classifier, where the English initial feature set achieved 60.00% accuracy, and the Malay initial feature set achieved 58.00% accuracy. The accuracy performance of the English initial feature set showed a slight improvement using Dataset 3. However, the accuracy performance for the Malay feature set increased by 1.00% to 59.00% using Dataset 3 and the SVM classifier.

In general, the bar chart in Fig. 9 showed increments of accuracy performance from Dataset 1 to Dataset 3 in both classifiers. Comparatively, the accuracy performances of the initial feature sets between the datasets and classifiers show a consistent increment pattern. Therefore, the baseline results can be compared with the proposed feature set models.

B. *Embedded Code-Switching Feature Set Performance Results*

The same setting of experiments that were carried out for the baseline experiment is used to evaluate the embedded code-switching feature set. The result of the experiment is shown in Fig. 7. The accuracy results show the embedded feature sets perform at equal accuracy, 54.00% for Dataset 1, using both classifiers, Naive-Bayes and SVM classifier. The result also shows that Dataset 3 outperforms other datasets for both classifiers.

There is an increment pattern of accuracy performance between the three datasets for both classifiers. There is a significant accuracy increment between Dataset 1 and Dataset 2 using both classifiers. Datasets 1 and 2 performed at 54.00% and 57.00% using the embedded feature set and Naive Bayes classifier. The accuracy increased by 3.00%. The accuracy performance increased by 5.00% using the SVM classifier between Datasets 1 and 2. Datasets 1 and 2 performed at 54.00% and 59.00%, respectively, with the SVM classifier. The accuracy increased by 1.00% between Dataset 2 and 3 using both classifiers. It is also noted that there are noteworthy accuracy differences between Dataset 1 and 3 for both classifiers. The differences in accuracy performance between Datasets 1 and 3 are 4.00% differences using the Naive Bayes classifier and 5.00% using the SVM classifier.

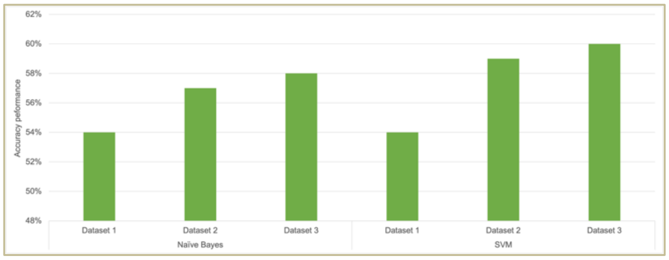

Fig. 7. Result of accuracy performance for subjectivity classification on Malay-English code-switching text using embedded feature set.

The significant differences in accuracy performance between the datasets are due to the presence of the subjectivity features in the dataset. The presence of the Malay and English subjectivity features is more significant in Datasets 2 and 3 compared to Dataset 1. The differences reveal the SVM classifier works better to identify the subjectivity presence in Malay-English code-switching sentences using the embedded feature-set, with 60.00% accuracy, where Datasets 3 outperformed others. Therefore, using both classifiers, the embedded code-switching feature set can be used to distinguish subjective and objective Malay-English code-switching sentences.

The accuracy performance results of the embedded feature set were compared with the initial feature sets, which are the English and Malay initial feature sets. The comparison is shown in Fig. 8. The accuracy performance of the English initial feature set (En) was superior in all datasets and classifiers. The superiority of accuracy performances indicates the English initial feature sets are stable and robust. However, the accuracy performance of the embedded feature set is better in comparison to the Malay initial feature set (Ms) in three experiment settings, which are Dataset 1 with Naive Bayes classifier and Datasets 2 and 3 using the SVM classifier. The accuracy performance of the feature set is on par with the other three experiment settings. This is clearly shown using Datasets 2 and 3 with the Naive-Bayes classifier and Dataset 1 using the SVM classifier.

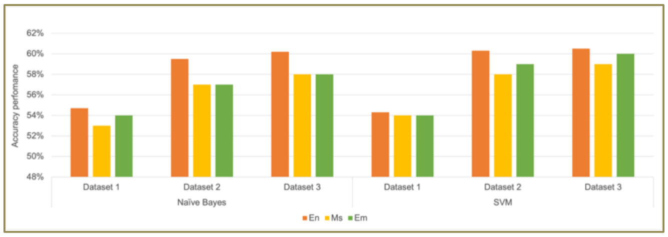

Fig. 8. Comparison of embedded feature sets with baseline initials feature sets.

The accuracy performance of the embedded feature set (Em) is either superior or on par with the Malay initial feature set (Ms). It is concluded that the Em feature set performed as good as the Ms feature set. The Em feature set had given a competitive advantage to the Ms initial feature set, given the appearance of multiple languages in a single sentence. It is also obvious that the Em feature set improved the subjectivity classification performance on code-switching text instead of using the Malay initial feature alone for the classification.

C. *Unified Code-Switching POS Feature Set Performance Results*

The unified code-switching POS feature set fused Malay and English using the algorithm described in Algorithm 1. The unified process determined the POS of a word based on its language. The unified feature set was trained and tested using a similar experimental setting as the embedded code-switching feature sets and the initial feature sets. The accuracy performances from the classification of this feature set are captured and shown in Fig. 9.

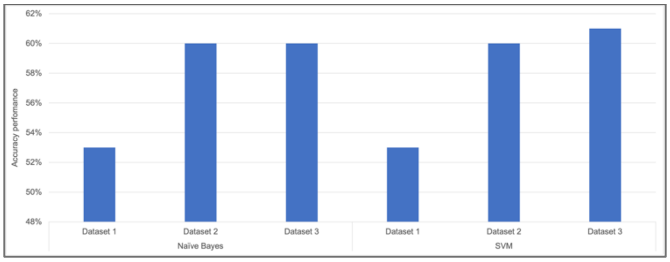

Fig. 9. Results of accuracy performance for the subjectivity of classification on Malay-English code-switching text using the unified feature set.

The bar chart in Fig. 9 shows the unified feature set performed at 52.00% accuracy using Dataset 1 and both classifiers. The accuracy performance of the unified feature set is on the same level at 60.00% for Datasets 2 and 3 using the Naive Bayes classifier and Data Set 2 using the SVM classifier. There is a slight increment in Dataset 3 using the SVM classifier, in which the feature set performed at 61.00% accuracy. The consistent performance of around 60.00 to 61.00% shows the feature set is usable to differentiate the subjective and objective sentences from a Malay-English code-switching dataset.

The bar chart in Fig. 10 compiled the accuracy results from the baseline experiments (En and Ms) and unified feature set (Un) using the Naïve-Bayes and SVM classifiers. In general, the unified feature set outperformed the English initial feature set using Dataset 2 with the Naive Bayes classifier at 60.00% and Dataset 3 with the SVM classifier at 61.00%. The unified feature set performed on par accuracy in comparison to the English initial feature set using Datasets 2 and 3 with the Naive-Bayes and the SVM classifier. The performances are 60.00%. The outperformance and on-par accuracy result shows the unified feature set is as good as the English initial feature set, given the fact that code-switching is a relatively new challenge to text processing and subjective analysis. However, the unified feature set did not share the same excellence of accuracy performance result using Dataset 1 for both classifiers. The unified feature set performed at 53.00% accuracy using Naive Bayes and SVM classifiers on the same dataset, less 2.00% and 1.00% for each classifier. Even though the same level of excellence is not shared by using Dataset 1 and the same classifiers, the unified feature set can still distinguish the subjective from the objective sentences of Malay-English code-switching text.

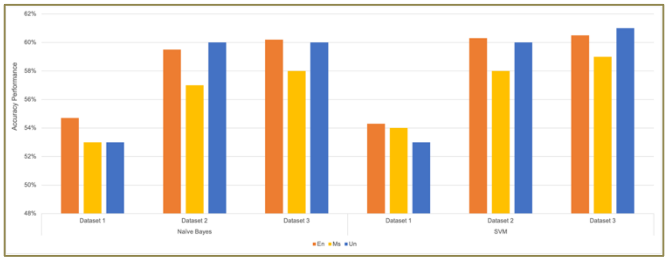

Fig. 10. Comparison of accuracy performance for the unified feature set with baseline initial feature sets.

The unified feature set outperformed the Malay initial feature set in four experiments. The accuracy performance of the unified feature set is 60.00% using Dataset 2 with Naive Bayes classifier, which is 3.00% higher than the Malay initial feature set. The same accuracy performance is seen as consistent for the feature set using Dataset 3 and the same classifier. However, it is 2.00% higher than the Malay initial feature set. The same pattern of differences is also apparent for Datasets 2 and 3 using the SVM classifier compared to the Malay initial feature set. The unified feature set performed at the same level of accuracy performance, 55.00%, using Dataset 1 with the Naive Bayes classifier. However, the feature set did not share the same accuracy performance as the SVM classifier using the same data set. The feature set performed at 53.00%, less than 1.00% from the Malay initial feature set. The significant differences in the accuracy performance between the unified Malay-English code-switching and the Malay initial feature sets across datasets and multiple classifiers show the unification of feature sets for two different languages is necessary to distinguish the code-switching sentences into objective and subjective classes.

D. *Stylistic Feature Sets Performance Results*

Stylistic features significantly influence subjectivity analysis [22][23]. Six experiments were conducted to investigate the ability of stylistic features to distinguish subjective and objective sentences from Malay-English code-switching datasets. The experiments were conducted using the same settings as the embedded and unified feature sets. The results are shown in Fig. 11.

The bar chart in Fig. 11 shows a consistent accuracy performance achieved by the stylistic feature set using Datasets 3 with the Naive Bayes classifier and Datasets 1, 2 and 3 with the SVM classifier. The stylistic feature set performed at 55% accuracy. It is worth mentioning that the differences in the stylistic performance from these datasets and Datasets 1 and 2 using the Naive Bayes classifier are 2.00% and 1.00%, respectively. The insignificant accuracy performance differences across datasets and classifiers show that the stylistic feature set performance is nearly consistent. Therefore, these findings support the influence of stylistic feature sets in code-switching text.

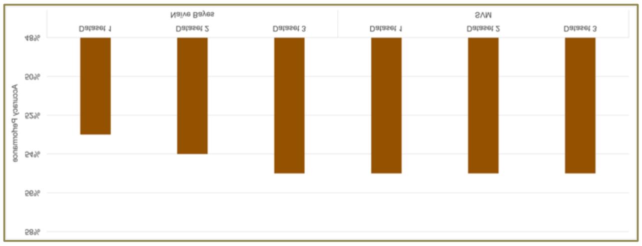

Fig. 11. Results of accuracy performance for the subjectivity of classification on Malay-English code-switching text using the unified feature set.

The accuracy performance of the stylistic feature set (St) is compared to the initial feature sets for English (En) and Malay (Ms). The accuracy performances are shown in Fig. 12. The bar chart in Fig. 11 shows the English and Malay initial feature sets have outperformed the stylistic feature sets using Datasets 2 and 3 for both classifiers. The stylistic feature set gives the same performance as the Malay initial feature set using Dataset 1 and the Naive Bayes classifier, but the English initial feature set still gives superior performance. However, the stylistic feature set can surpass the English and Malay initial feature sets using Dataset 1 and the SVM classifier.

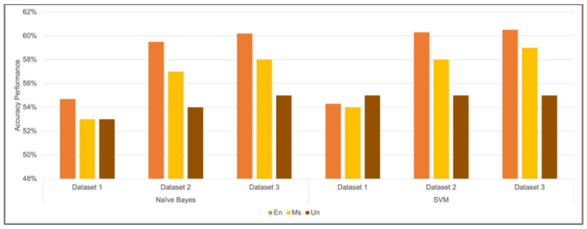

Fig. 12. Comparison of accuracy performance for a stylistic model with baseline initial feature sets.

E. *Combinations of Feature Sets Performance Results*

The experiments in the previous section were executed independently of each other. The proposed feature sets were then combined to determine the possibility of improved accuracy performances. Four more experiments were conducted for this purpose. The combinations are listed as follows:

1) The combination of an English (En) initial feature set and a stylistic (St) feature set is known as En + St.

2) The combination of the Malay (Ms) initial feature set and stylistic (St) feature set is known as Ms + St.

3) The combination of embedded (Em) feature set and stylistic (St) feature set is called Em + St.

4) The combination of a unified (Un) feature set and a stylistic (St) feature set is known as Un + St.

The experiments were carried out using a similar experimental setup as the previous experiments – using three datasets and two classifiers, the Naive Bayes and the SVM. The accuracy performances from each dataset were captured and averaged. The averaged accuracy performances are illustrated using bar charts in Fig. 13 and Fig. 14.

The average accuracy performances for the combination of proposed features using the Naïve Bayes classifier are shown using a bar chart in Fig. 13. The bar chart includes the averaged accuracy performance result from Malay and English feature sets. The result shows the combination of the unified (Un) and stylistic (St) feature sets outperformed other feature sets at 59.00% accuracy. The combination of embedded and stylistic feature sets (Em + St) shows an on-par performance with the English initial feature set. The results show that considering features from languages other than English in code-switching text and stylistic features improves the accuracy performance. Thus, the combination of feature sets is practical to classify the Malay-English code-switching sentences into subjective and objective classes. The bar chart also shows that the stylistic feature set alone performed at the lowest accuracy, 54.00%, in comparison to other feature sets. The performance reveals using only stylistic features to classify the subjectivity of code-switching sentences is insufficient.

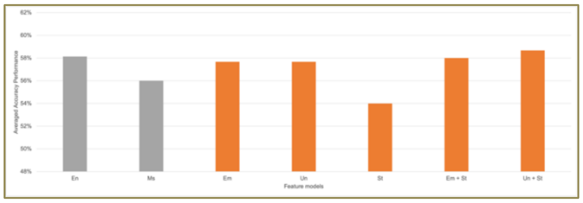

Fig. 13. Comparison of averaged accuracy performances for combined feature sets using the Naïve-Bayes classifier.

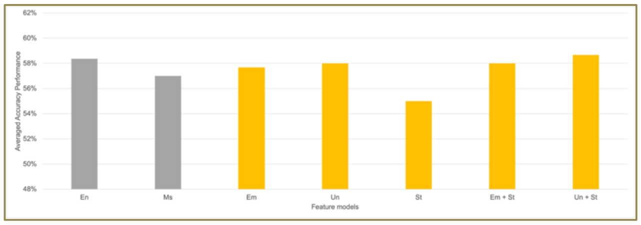

Fig. 14. Comparison of averaged accuracy performances for combined feature sets using the SVM classifier.

The results of averaged initial feature sets (Malay and English) proposed feature sets (embedded, unified and stylistic) combination feature sets that were classified using the SVM classifier are shown in a bar chart of Fig. 14. The bar chart shows the averaged accuracy performance using the combination of unified and stylistic (Un + St) feature set surpassed other feature sets. The Un + St feature set performed at 59.00% accuracy. The combination of embedded and stylistic (Em + St) feature sets performed at 58.00% accuracy, slightly lower than the English (En) initial feature set and on par as a unified feature set. The bar chart shows a slight accuracy performance improvement when the embedded and unified feature sets are combined with the stylistic feature set. The performance of both feature sets increased by 1.00% with the combination of stylistic feature sets. The bar chart also shows the stylistic feature set alone gave the lowest performance, that is, 55.00% accuracy. Therefore, a stylistic feature set should not be used as the only feature set to distinguish subjective and objective sentences for Malay-English code-switching datasets. In addition to that, stylistic feature sets have proven their influence on subjectivity classification for Malay-English code-switching text.

VI. Discussion

The results of this study provide a comprehensive evaluation of the subjectivity classification in Malay-English code-switching text using enhanced feature sets and machine learning classifiers. Several key insights emerged from the result analysis.

A. Performance of Baseline Feature Sets

The baseline feature sets focused exclusively on English and Malay feature sets. It provides a starting point to evaluate the effectiveness of the enhanced feature sets. The English feature set has outperformed the Malay feature sets across all datasets. This finding aligns with previous research that suggests English-based models tend to perform better in text classification tasks due to the availability of more extensive language resources and tools.

B. Embedded Code-Switching Feature Set

A key contribution of this study is how the embedded code-switching feature sets successfully captured subjectivity in code-switched text. These feature sets performed better than the baseline Malay sets, especially when using Dataset 3 with both Naive Bayes and SVM classifiers. This shows how important it is to include both languages in the feature sets to handle code-switching effectively. Additionally, the improvement in accuracy from Dataset 1 to Dataset 3 suggests that having a more diverse dataset could help models better recognise subjectivity in code-switched sentences.

C. Unified Code-Switching POS Feature Set

The unified feature set, which combined Malay and English parts of speech (POS), delivered competitive results, particularly with Dataset 3 when using the SVM classifier. This approach outperformed the baseline English feature set, highlighting the importance of considering the syntactic structures of both languages in a unified way for tasks involving code-switching. Interestingly, the unified feature set exhibited limitations in Dataset 1, indicating that while this method is advantageous, its performance depends on the characteristics of the dataset and the quality of POS tagging.

D. Impact of Stylistic Feature Set

Stylistic features, which include linguistic cues such as punctuation, sentence structure, and word choice, were also explored for their role in subjectivity classification. While the stylistic feature sets performed consistently across all datasets, they were outperformed by the initial English and Malay feature sets. This suggests that stylistic features alone may not be sufficient for classifying subjectivity in code-switched text. However, when combined with other feature sets, such as the unified and embedded feature sets, stylistic features contributed to incremental improvements in accuracy.

E. Combination of Feature Sets

The experiments that combined multiple feature sets revealed that unifying linguistic and stylistic features yield the best performance. Specifically, the combination of the unified and stylistic feature sets resulted in the highest accuracy across datasets, particularly with Dataset 3. This finding suggests that a hybrid approach—leveraging multiple linguistic levels (e.g., syntax, style, language features)—is most effective for handling the complexity of Malay-English code-switching text. These findings reinforce the idea that no single feature set can comprehensively capture the nuances of subjectivity in code-switching. Instead, a combination of feature sets is required to achieve optimal performance.

VII. Limitation and Future Research

There are several limitations to this study. First, the datasets used in the experiments, while diverse, may not fully capture the complexity of real-world code-switching scenarios. Future research could explore larger and more diverse datasets that include different levels of code-switching. Additionally, this study focused on sentence-level classification; however, subjectivity may vary within a single sentence. Thus, future work could explore word-level or phrase-level classification to gain a more fine-grained understanding of subjectivity in code-switching.

Moreover, the study was limited to Malay-English code-switching. As such, future research could apply the proposed methods to other language pairs where code-switching is common, such as Spanish-English or Arabic-French. Investigating whether the same feature sets and classifiers work across different language combinations could provide more generalizable insights into the phenomenon of code-switching in subjectivity classification.

VIII. Conclusion

The results have several implications for future research and practical applications. First, the importance of language-specific features in code-switched text is evident, highlighting the need for models that can process multiple languages simultaneously. This is particularly relevant in multilingual societies like Malaysia, where code-switching is prevalent in everyday communication. The findings also suggest that existing models and datasets can be improved by focusing on the interaction between syntactic and stylistic features in both languages.

Three feature sets were designed to distinguish the code-switching text into subjective and objective classes. The first feature set includes the Malay feature into the English feature – known as the embedded feature set. The second feature set combined and unified the Malay and English feature set, which is known as a unified feature set. The last feature set is non-vocabulary, known as a stylistic feature set. Part-of-speech is used as a feature of the code-switching text. The 1 and 0 are used to represent the presence and absence of the features. The feature sets are more interpretable where the contribution of a specific can be directly seen to the model decisions.

The experiments were carried out using three datasets and two machine learning classifiers – the Naive Bayes and SVM to verify the proposed feature sets. The results from the proposed feature sets were compared with the initial feature sets. The experiment shows the unified feature performed as good as the English initial feature set. Therefore, unifying the Malay and English feature sets is necessary to distinguish the subjective and objective sentences in the Malay-English code-switching dataset. An improvement in accuracy performance is achieved when the unified feature set is combined with the stylistic feature set. The improvement reveals this method is computationally lighter which requires fewer data to perform well.

Acknowledgment

The authors would like to thank Social Analytics and Intelligence Lab (SAIL) and the Applied Intelligent Computing (APIC) research group, the Center of Advanced Computing Technology (C-ACT), and Fakulti Teknologi Maklumat dan Komunikasi, Universiti Teknikal Malaysia Melaka (UTeM) for their incredible support for this research.

***Abstract*—Due to rapid evolution of Internet of things (IOT) in terms of hardware, software and communication leads to widespread expansion across many domains and sectors. This expansion consequently results in sensitive data transfer increase for purposes of complex calculations and decision making which in turn leads to increase of data attacks and leakage which results in data privacy violation. Although, a lot of current solutions tried to fulfill data privacy via lightweight mechanisms but neither provided end to end protection nor gave a focus to metadata protection which can reveal valuable information about data it describes. This paper presents a lightweight complete data privacy protocol which manages the lifecycle of data starting from object registration till data transfer to cloud. The proposed protocol is a trusted third party free (TTP-Free) which adopts anonymization techniques, lightweight key agreement protocol, end to end encryption and message authentication code to fulfill identity and data protection which in turn fulfill complete data privacy.**

Keywords*—*IOT; data privacy; lightweight protocols; end to end protection; data and metadata protection

I. Introduction

Internet of Things (IOT) is a physical network of resource constrained objects (ex. sensors, actuators, wearables, IIOT devices) connected together in order to rapidly exchange data to fulfill a specific job. IOT has three main visions [1] to focus on:

- Things vision which tends to focus on generic objects and integration of them into a framework (ex. RFID, NFC).
- Internet vision which tends to present IOT as a network-oriented (ex. IPO, communicating things).
- Semantic vision [2] which tends to view IOT as a worldwide network of interconnected things that can be uniquely identified (ex. reasoning over data, semantic technologies).

IOT in general aims to facilitate people's life and enhance countries' economies via introducing smart solutions capable of serving required needs which in turn leads to a better world. It can connect people, things, objects, and devices regardless of time and location with barrier free manner. With, the advances in IOT hardware and software started from enhancing communications networks, devices and reducing things sizes and cost reduction for constructing IOT networks led to invasion and domination of IOT in many domains due to benefits got from.

Healthcare [3][4] is one of domains that IOT tried to support to enhance people health and saves their life. Medical IOT aims to serve patients via presenting a lot of services started from monitoring services [5][6] where patients' health is tracked to avoid any health disaster till complex healthcare solutions for malignant diseases like cancer [7][8]. Moreover, IOT used to fight against pandemic diseases like Covid 19 [9][10].

Agriculture is another domain that IOT gave attention to enrich and support due to its economic importance to countries. IOT developed a special type of network [11] called agriculture IOT sensor monitoring networks (ASMN) in order to fully monitor farmland in (temperature, humidity, light and soil moisture) and take appropriate actions needed. These networks [12] aim to continuously monitor crops to protect crops' health.

Industry is the third domain that IOT tried to automate and support with industrial IOT (IIOT). IIOT [13][14] is a specialized network which manufacturers adopt to enhance production process started from supplying raw materials till customer services.

The advancement of IOT networks and increasing NO. of objects used led to increased exchange of sensitive data which in turn lead to a lot of security and privacy problems. Data privacy is one of the most important problems to be focused on due to sensitivity of data. Data here can be personal, healthcare, industrial or even militaria which needs to be protected while being transferred.

A lot of attacks aim to leak data to be abused, attacks can be categorized into two types:

- Active attacks which attacker tries to change the whole or part of data while being transferred.
- Passive attacks which attacker tries to read data only without any change.

In this paper, a lightweight trusted third-party free (TTP-Free) data privacy protocol is presented to build a secure communication channel for Device to cloud (D2C) which aims to protect IOT data and metadata as well. Although metadata might seem less important, it can reveal valuable information about the data it describes which in turn leads to privacy compromise. The protocol depends mainly on four parts to fulfill privacy:

- Anonymization: regularly changing objects' identities in order to avoid tracking and impersonation attacks based on objects known IDs.
- Lightweight Key agreement Protocols: used between objects and cloud to construct session key without directly exchanging it which will be used later for data encryption/decryption.
- Lightweight End to End Encryption: designed especially for constrained devices to encrypt/decrypt data using already constructed key between object and cloud to make sure that no party can decrypt data transferred except cloud.
- Message Authentication Code: used to authenticate message via edge to ensure integrity and authenticity of data which in turn resist active attacks.

The paper is structured as follows: Section II gives an overview of the related work and the main differences between proposed work and existing research. Section III provides an overview of proposed protocol, all related algorithms and techniques used. Section IV discusses security analysis of proposed protocol via threat model and its analysis. Section V evaluates the proposed protocol against existing one to clarify strength and weakness of each one at predefined criterion. Section VI provides conclusion and future work.

II. Related Work

A lot of researches tried to provide solutions and mechanisms to IOT data privacy leakage due to its necessity. Many attacks include impersonation, injection, eavesdropping, data theft and reprogram attacks aims to track IOT networks for data leakage and abuse.

J. Andrew [15] proposed an anonymization clustering schema which aims to fulfill data privacy in medical IOT. This schema depends on two parts, client side which is responsible for anonymizing data generated by things using clustering K anonymity which fulfill privacy via clustering methodology, server side which uses cluster combination to reduce communication overhead which achieve privacy. This schema employs a trusted intermediate aggregation node to anonymize data got from client then send it to untrusted server to be sent to data collector. Usage of anonymization techniques with trusted third-party only fulfills data privacy partially due to a lot of attacks that can lead to original data restoring (ex. Re-identification attacks) besides relying on TTP -aggregation node- which can be attacked.

Xuezhen [16] proposed a framework that aims to fulfill security and data privacy via cryptography and behavior pattern analysis. The framework is divided into levels according to IOT main entities:

- Objects: which is defined as sensors and actuators each of them has a security and privacy requirements.
- Communication networks: is responsible for communication between objects that needs to be protected to protect network from abuse.
- Users: who use the IOT, which is the most sensitive part as part of people in this context will be attackers themselves so users' behaviors must be carefully analyzed and stored to detect any malicious behavior.

In order to provide security and privacy to users and data. The framework used secured channel to fulfill required security but did not mention how to accomplish this. Moreover, the framework deals direct with object real identities which makes the system vulnerable to impersonation and tracking attacks.

Uzair Javaid [17] focused on data provenance and integrity by using BlockpPo framework which is a combination between PUFs which produces a unique response so data provenance is established with each IOT device, and blockchain which enforces data integrity to fulfill data privacy. Although, blockchain tried to fulfill data privacy across IOT networks, but still has a lot of challenges [18] which may affect that fulfillment starting from choosing blockchain platform (public, private) which will affect confidentiality and integrity of data. Moreover, the identity will be disclosed due to sharing transactions with their owners.

Othman [19] proposed a privacy preserving schema using homomorphic encryption in order to protect healthcare data privacy. Its main goal is to provide safe and secure aggregation for data with respect to energy consumption. The schema tried to protect data from active, passive, internal and external attacks. Although the proposed schema depends mainly on cryptography using homomorphic encryption which enables coordinator to work on without needs to decryption, it does take into consideration objects' identity protection which in turn can lead to tracking and impersonation attacks. Moreover, the schema does not state the data encryption decryption key mechanism used which is considered a very critical part to be covered due to diversity of attacks occurred on that part.

Prem Prakash [20] proposed a technique for data privacy preserving via introducing privacy preserving IOT architecture based on OpenIOT [21]. This architecture provides end to end privacy by giving ability to control access to sensitive IOT data via distributing and decomposing data into multiple data stores and then aggregated again when needed [22]. The technique composed of four communication parts (IOT device and gateway, gateway and data store, data store and data access finally, data access and user) which assumes that these communication channels are secured by applying cryptography and key sharing mechanisms only. Although this approach tried to fulfill data privacy by focusing on how to hide data that is transferred from between communication parties, this approach is not adequate to fulfill objective needed. Focusing on data only without paying attention to object identities can lead to data leakage which in turn leads to data privacy issues.

Mamun Abu-Tair [21] proposed a new architecture that aims to support IOT applications with a specified level of security and privacy. The architecture is bundled with new algorithm that is responsible for configuration of newly added sensors in terms of cryptographic suite to match target applications. The architecture employs cryptography and anonymization to fulfill complete privacy but relying on trust management schema is considered a weak point. Moreover, key management schema is not stated which can lead to critical attacks.

Shancang Li [23] presents a lightweight privacy preserving protocol which aims to address privacy issues between objects, cloud and users using cryptography – homomorphic encryption-. The protocol depends on a key management schema which employs users' keys beside objects' keys to make sure that the data will be delivered to correct user. Although the protocol tried to fulfill data privacy but it has a major concern to be addressed, the protocol did not state in details key sharing mechanism which can be a weak point to the whole protocol moreover, the protocol deals with objects with their real identity which makes the system vulnerable to impersonation and tracking attacks.

Mohammed Ahmed [24] used remote patient monitoring as a case study in healthcare domain to fulfill security and data privacy via proposing a new system that provides mutual authentication and employed cryptography to protect data while being transferred. Although the proposed system tried to fulfill privacy via applying cryptography, the system does not pay attention to object identities which can be tracked and impersonated. Moreover, the registration phase for objects is not powerful to forbid injection attacks.

Xi lou [25] presented a lightweight security protocol which aims to fulfill data privacy via cryptography and symmetric key mechanism. This protocol tries to maximize symmetric keys generated via key delegation which uses chaotic system and logistic map to ensure unpredictability and unrepeatability of keys generated. The protocol depends mainly on control center as a trusted third party to be responsible for key management between communication parties which is considered a weak point if got controlled by attackers.

A lot of protocols and systems tried to fulfill data privacy by focusing on either protecting objects' identities or data which is considered a partially fulfillment. Some of them is trusted third party and others is trusted third party free. Up to our knowledge, all protocols focus mainly on objects' data as a protection level, but no one pay attention to metadata – like gateway id, manager id -. This gap is critical to be protected since leakage will lead to disclosure of much sensitive information (ex. Objects cluster, network location and sometimes object itself) will lead to data privacy violation. The proposed protocol is a trusted third party free which aims to fulfill full data privacy by protecting objects' identities and their data. Moreover, the proposed protocol has put into consideration the protection of metadata to avoid any privacy violation.

III. Proposed Protocol

The proposed protocol is considered a communication protocol with a set of defined rules that regulate exchange of data between parties in a secure manner to fulfill data privacy. The protocol focuses mainly on both:

- Data mainly reads from objects and needs to be transferred to the cloud.
- Metadata, which is data about data like timestamp, gateway id, edge id which needs to be protected as well.

The proposed protocol is trusted third party free that focuses on fulfilling data privacy via securing communication channels between objects and cloud by using lightweight key agreement protocol and end to end encryption to ensure that only cloudcan decrypt the data issued by objects. In addition, the protocol employs anonymization techniques for objects in order to prevent tracking and impersonation attacks for objects. Therefore, being trusted third party free and providing secure communication channel beside objects' identities anonymization will provide full data privacy.

Notations used are summarized in Table I.

TABLE I. Notations Summary

Notation	Description
O_i	Object_i
GT	Gateway
Mgr	Manager
IDS	Identity Server
Edg	Edge
Cld	Cloud
Fid_i	Fake ID_i
Id_i	ID_i
TS	Timestamp
Y-> Send(X,{Z})	Y Sends parameters Z to X
Y->Construct(X,Z)	Construct Part X With Z and store it in Y.
H(X)	Hashing X
Key	Session key between Object and cloud
O_i ->Enc(P, Key)	Encrypt plain text (P) with Key for O_i
O_i ->Dec(P, Key)	Decrypt cipher text (P) with Key for O_i
Read	Senor Captured Read
CldPubK	Cloud public Key
CldPrK	Cloud private Key
ChkElg	Check Eligibility
CAT(X,Y)	Concatenate X and Y

The proposed protocol consists of six main components as below:

- Object: is denoted by O_i which is responsible for gathering required data and do necessary functionality to it.
- Identity Server generators: is denoted by IDS, responsible for satisfying objects' requests to form fake identities.
- Manager: is denoted by Mgr which is responsible for managing objects lifecycle starting from object registration till data exchange. Each network cluster has its Mgr to do required jobs.

- Edge: is responsible for preparing object requests and adding necessary meta data.
- Gateway: is responsible for verifying eligibility for objects to send data or not and doing necessary functions to send data to cloud.
- Cloud: is responsible for mapping data to correct object identities, storing data and perform required analysis to take needed decisions.

Fig. 1 shows the key components of the proposed protocol.

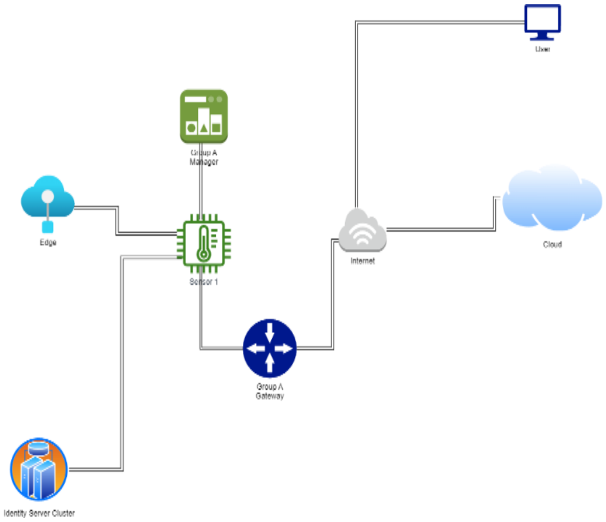

Fig. 1. Proposed Protocol.

The protocol consists of four phases according to below:

1) Registration Phase: Each object (Oi) to be added to IOT network must firstly send to it's Mgr to be registered and approved. Once got approval, Oi starts to request its fake identity to start communicating with.

2) Anonymization Phase: It is responsible for changing real object identity to fake one to resist any tracking attacks or impersonation for any object based on its real identity, as below:

- O_i sends a request with timestamp (T_1) for more than one IDS (n) where n >1 to form its fake identity if it is expired.
- IDS validate timestamp against timestamp threshold (T) via $|T_{IDS} - T_1| < \Delta T$ to determine if the request will be satisfied or rejected.
- Each server receive request generates part of identity uniquely and send it back to O_i with timestamp and expiry date.
- The severs send parts generated to cloud with other information required (server id, object id, timestamp).
- Cld concatenate parts received from servers based on received timestamps ascending, validate timestamp against timestamp threshold (T) via $|T_{cld} – T_i| < \Delta T$, hash the concatenation output to get fake identity, set expiry date for that fake identity based on system configuration and then store mapping for fake identity to real one in mapping tables.
- O_i prepares its fake identity as cloud did, validate timestamp and send it to cluster mgr to update its list.
- Cluster mgr updates its list and broadcast it to GT. Table II shows construction of fake identities.

TABLE II. FAKE IDENTITY GENERATION ALGORITHM

Algorithm 1: Fake Identity Generation by object Oi

```
$O_i$ -> Send( $IDS_1$, { $Id_i$ ,$T_1$ }).
$IDS_1$ -> Validate Timestamp if( $|T_{IDS1} - T_1| > \Delta T$ then rejected
$IDS_1$ -> Send($O_i$ , { $Fid_1 \|$ $T_{s1}$ })
$IDS_1$-> Send( Cld, {$Fid_1 \|$ $IDS_1 \|$ $id_i \|$ $T_{s1}$}) .
$O_i$ -> Send( $IDS_2$, { $Id_i$ ,$T_2$ }).
$IDS_2$ -> Validate Timestamp if ( $|T_{IDS2} – T_2| > \Delta T$) then rejected
$IDS_2$ -> Send($O_i$ , { $Fid_2 \|$ $T_{s2}$ })
$IDS_2$ -> Send( Cld, {$Fid_2 \|$ $IDS_2 \|$ $Id_i \|$ $T_{s2}$}) .
$O_i$ -> Construct(CAT( $Fid_1$, $Fid_2$ , H( $id_1$, $T_{s1}$, $T_{s2}$)), $T_{f1}$) and output Fid to be stored
Cld -> Construct(CAT( $Fid_1$, $Fid_2$ , H( $id_1$, $T_{s1}$, $T_{s2}$), $T_{f1}$))) and output Fid to be stored.
$O_i$ -> Send( $Mgr_i$ , { $id_1$ $\|$ $Fid_1$}).
$Mgr_i$ -> Update (List, {$Fid_1$}).
$Mgr_i$ -> Send (GT, List).
```

3) Session Key Generation Phase: It is the phase responsible for constructing session key between object and cloud via lightweight key agreement protocol [26]. This protocol consists of two stages as below:

Registration stage: The object register itself on the cloud through the following:

- O_i chooses identity ID_i and password PW_i then two parameters a and b.
- O_i calculates $Mpw_i = h(PW_i \| a \| b \| ID_i)$, $HID_i = h(ID_i \| b)$ and $d_i = a \oplus b$.
- O_i sends { HID_i , Mpw_i , d_i , a} to Cld.
- Cld then calculates $v_i = h(HID_i \| Mpw_i)$ then chooses random numbers c_i z_i.
- Cld calculates both $B_i = h(HID_i \| x_s)$, $E_i = (B_i \oplus Mpw_i)$.
- Cld will store (z_i, HID_i) in its database.
- Cld will calculate $A_i = E_{xs} (c_i \| HID_i \| d \| a)$
- Cld will send { A_i , E_i , z_i , v_i , c_i , b, a}.
- O_i will calculate $T_i = A_i \oplus Mpw_i$
- O_i will store [T_i , E_i , z_i , v_i , c_i , b, a]

- Login and authentication stage: The object successfully logged in to authenticate itself and start information exchange as below:
  - O_i submit its ID_i and PW_i

- O_i calculates $Mpw_i = h(PW_i \| a \| b \| ID_i)$, $HID_i = h(ID_i \| b)$, $v_i = h(HID_i \| Mpw_i)$, $B_i = E_i \oplus Mpw_i$.
- After calculating new v_i , it compares it with old one.
- O_i calculates $d_i = a \oplus b$ and $cd_i = c_i \oplus d_i$.
- O_i chooses random number e_i and selects T_1 .
- O_i then calculates $A_i = T_i \oplus Mpw_i$, $M_i = E_{Bi} (T_1 \| e_i` \| A_i)$.
- O_i sends { cd_i , M_i , T_1 , HID_i } to Cld.
- Cld will select T_2 then check whether $| T_2 - T_1 | < \Delta T$.
- Cld will calculate $B_i = H(HID_i \| X_s \| z_i)$.
- Cld will $DEC(M_i)_{Bi} = (T_1, A_i, e_i)$ and $DEC(A_i)_{Xs} = (HID_i , a, c_i, d_i)$.
- Cld will then calculate $cd_i = c_i \oplus d_i$ and then check if new cd_i equals old one or not and the same for T_1 then chooses random number q_i.
- Cld finally will calculate $Q_i = H(A_i \| B_i)$, $s_i = q_i \oplus B_i$, $w_i = h(cd_i \| e_i)$, $N_i = E_{Ai} (s_i \| T_2 \| w_i)$.
- Cld will send N_i , T_2 back to object.
- O_i will select T_3 and check whether $| T_3 – T_2 | < \Delta T$.
- O_i will $DEC(N_i)_{Ai} =(s_i, T_2 , w_i)$.
- O_i will calculate w_i `= $H(cd_i \| e_i)$ and then checks whether $w_i$ ` = w_i and $T_2 = T_2$.
- O_i will calculate $q_i = s_i \oplus B_i$, $Q_i = H(A_i \| B_i)$, $sk= H(e_i \| B_i \| Q_i \| q_i \| z_i \| s_i)$, $M N_i = H(Sk \| q_i \| s_i \| Q_i)$
- O_i will send $M N_i$ and T_3 to cloud to finalize key construction.
- Cld will select T_4 and then checks $| T_3 – T_4 | < \Delta T$ and then calculates $sk= H(e_i \| B_i \| Q_i \| q_i \| z_i \| s_i)$ and $M N_i$ `$= H(Sk \| q_i \| s_i \| Q_i)$ and then checks whether new and old $M N_i$ are equal.

4) Transferring Data to Cloud Phase: It is the phase responsible for transferring data from objects to cloud to be processed and stored as below:

- O_i encrypts current read with lightweight Speck-R algorithm [27] using constructed session key on session key generation phase.
- O_i will send encrypted read with newly generated fake identity to Edg.
- Edg will prepare the request by adding needed meta data (timestamp, edge id, gateway id) to the request
- Edg will encrypt the whole data and metadata with cloud public key and send it to gateway in conjunction with message authentication code [28] to ensure data integrity and resist active attacks.
- GT will verify whether object has right to send data to cloud or not, if yes, the GT will forward data to cloud.
- Cld receives request then decrypts it using its private key and then go through verification in terms of timestamp and message authentication code [28] attached to ensure both data integrity and no reply attack took place.
- Cld will decrypt the data using previously constructed session key with O_i.
- Cld will get mapping for fake identity and check expiry date to validate if it is still used or not to avoid impersonation and identity theft attacks.
- Cld will store data with real identity.

IV. Security Analysis

This section provides a complete security analysis for proposed protocol by formulating threat model and threat model analysis with informal and formal analysis to prove correctness of designed protocol in terms of security and attacks resistance.

A. Threat Model

In IOT environments, integrity and confidentiality are considered critical part to be dealt with as stated in Dolev-Yao adversary [29].

According to proposed protocol, objects, gateways, managers, edges and identity servers are communicated to each other using internal IOT network. Objects before sending any data, must firstly acquire their fake identities to replace their real ones - in order to be protected from impersonation and identity tracking attacks - while sending data. Moreover, all communications to cloud must go through gateway which has ability to forward request or drop it due to any violation. Manager is responsible for managing authorization of objects in terms of sending data even though they got new fake identities. Edge is responsible for adding necessary metadata and providing a second layer of security to data by encrypting whole data by cloud public key to be sent to cloud which in turn fulfill data privacy. All parties (Manager, Gateway, Edge, identity) are assumed to be dishonest which means they are curious about data.

Attackers aim to reveal as much data as possible by trying to gain access to any IOT network party or sniffing communication network itself. Data is not only objects generated reads but its metadata as well due to its importance. Metadata can be used to extract valuable information about data itself (ex. object cluster, Location and object itself in many cases) to attackers which in turn causes data privacy leakage.

Our objective is to minimize the amount of information attackers can gain to protect data privacy through IOT networks via fulfilling confidentiality and integrity of data.

A lot of Assumptions to be considered:

- Attacker has ability to intercept any message between cloud and IOT network.

- Lightweight key agreement protocol [26] for key construction between objects and cloud and Speck-R [27] algorithm are secured.
- Cloud and object themselves are secured.

B. Threat Model Analysis

Recall that from our threat model, our objective is to minimize the amount of information attackers can gain to protect data privacy through IOT networks.

Attacks can be classified in to two main parts:

- Internal attacks which are carried out inside IOT network.
- External attacks which are carried out outside IOT network.

And each part of them can be classified into:

- Active attacks which are considered unauthorized access aim to alter networks data or injecting data other than correct one.
- Passive attacks are considered unauthorized access to gain data without modifying it.

And according to our threat model assumptions, attacks on objects and cloud themselves are out of scope.

C. Informal Analysis:

The proposed protocol aims to fulfill the following:

- Confidentiality: The protocol aims to fulfill confidentiality via end-to-end encryption between object and cloud. Speck-R is used as a first layer encryption to protect data from unauthorized access and eavesdrop in conjunction with light key agreement protocol. Key agreement protocol is used to form encryption key without directly exchanging it which provides more security and prohibit key sniffing attacks. Therefore, any data to be transferred from objects will be in ciphertext form which in turn fulfills Confidentiality.
- Integrity: The protocol aims to fulfill integrity and authenticity of data via message authentication code which in turn resists active attacks. The edge before encrypting metadata will authenticate message by adding message tag to ensure that message is not tampered or altered through communication.
- Anonymization: The protocol aims to protect identity of objects by changing real identities of objects with other ones while sending reads to avoid tracking attacks and impersonation attacks which in turn preserve data privacy.

And the protocol has ability to resist the following:

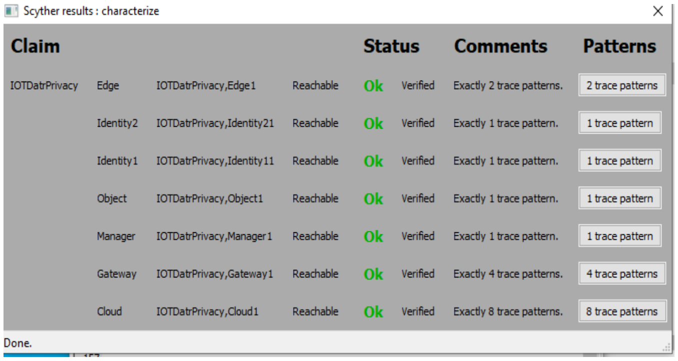
- Man in the middle attack (MITM): The attacker position himself between two communication parties in order to intercept exchanged messages and modify the content. Even though, the attacker can store the message for a while and resend it later. The proposed protocol has ability to deal with this attack via fulfilling both Confidentiality and integrity by applying both E2E encryption and using message authentication code which in turn helps on defending against MITM attack.
- Eavesdropping and Interference: The attacker aims to eavesdrop on any part of the network to extract any valuable information. The proposed protocol has the ability to resist that by applying E2E encryption between object and cloud and adding a second layer of encryption between edge and cloud for metadata which in turn resists any eavesdropping attacks.
- False Data Injection attack: The attacker tries to inject false data instead of correct one which in turn leads to wrong decision on cloud. The proposed protocol has ability to resist that by firstly apply Anonymization for objects to anonymize objects’ identities and register these identities on cloud. Secondly, two level encryption one with the session key using key agreement protocol between cloud and object, other with edge and cloud. Even though the attacker tried to inject a node into the network with the purpose of injecting false data, the gateway will not forward this data to cloud due to being unauthorized from network manager which in turn makes it difficult for any attacker to inject any false data to cloud.
- Advanced Persistent Threat: The attacker tries with many tactics and techniques to infiltrate IOT network and be silent and undetected for a long time with aim to steal and leak valuable information. The protocol has the ability to resist that via achieving Confidentiality and integrity.
- Reply attacks: The attacker tries to intercept network and retransmit a message between communication parties which in turn will lead to wrong timed message received. This wrong message can lead to disasters and wrong decisions due to being received correct at the wrong time. The proposed protocol has ability to resist this type of attack, by taking into consideration timestamp which message came with, if the difference between receivers’ timestamp and message timestamp greater than threshold defined on protocol, the request will be rejected.

D. Formal Analysis

The proposed protocol had been verified by scyther tool [30], used to analyze and verify security protocols in terms of vulnerabilities and flaws in their design. According to our protocol implementation on scyther, seven roles are implemented to cover all protocol aspects.

The analysis will be for each protocol phase to make sure that the data and metadata are still protected while being transferred which in turn fulfills protocol goals in terms of data privacy. Fig. 2 states proposed protocol analysis results.

For registration and anonymization phase, the object sends to network manager to be added and approved. The manager checks eligibility for that object request to be approved or rejected. If the request is approved, the object starts to request its fake identity via identity servers, minimum two servers to be requested as stated in Algorithm 1.



Claim				Status		Comments	Patterns
IOTDatrPrivacy	Edge	IOTDatrPrivacy,Edge1	Reachable	Ok	Verified	Exactly 2 trace patterns.	2 trace patterns
	Identity2	IOTDatrPrivacy,Identity21	Reachable	Ok	Verified	Exactly 1 trace pattern.	1 trace pattern

Fig. 3. Registeration and anonymization phase analysis.

For data transfer to cloud phase, this phase provides end to end secured channel between objects and cloud to safely transfer data from objects to cloud. Objects start communication by encrypting needed data by pre-established session key and then send encrypted data to edge with fake identity constructed. The edge will add needed metadata (timestamp, edge id, gateway id) to data received and then encrypt data and metadata with cloud public key and add message authentication code to the request to be verified in order to ensure data integrity. The protocol provides two levels of protection to fulfill data privacy:

- From object to cloud which mainly encrypts data using lightweight Speck-R due to nature of objects as being constrained devices. This level protects data from active/passive attacks.
- From edge to cloud which mainly encrypts previously encrypted data and metadata using public keys for cloud. This is considered a wrapper for the first level which means after encrypting object's data with speck-R, the edge adds necessary metadata and encrypt the whole data which already have encrypted read with public key for cloud which in turn gives more protection level.

The edge will send the whole request to GT to check whether the sent id is on list updated by managers or not. If yes, the request will be sent to cloud to be verified and stored.

V. Evaluation

In this section, a comprehensive evaluation of proposed protocol is presented by comparing it against xiluo [25] protocol. The criteria will be divided into two parts:

1) Strength of protocols to fulfill the following:

- Object Registration: The protocol must have the ability to make sure that no unauthorized object can be added to the network to avoid any injection and impersonation attack.
- Identity Protection: The protocol must have the ability to provide way to protect object identities to avoid impersonation and tracking attacks.
- Key Management: The protocol must have the ability to provide a way of constructing session keys without depending on trusted third parties or physically exchange it to make sure that the key will still be secured until changing it.
- Data Protection Level: The protocol must have the ability to protect data and metadata exposed from objects.
- Confidentiality: The protocol must have the ability to protect transferred data from eavesdropping and sniffing.
- Integrity: The protocol must have the ability to protect transferred data from tampering and modification
- Mutual Authentication: The protocol must have the ability to provide a way for communication parties to authenticate each other before starting communication.

Table III demonstrates the comparison in terms of protocol strength criteria.

TABLE III. COMPARISON BETWEEN XILOU AND PROPOSED PROTOCOL IN TERMS OF STRENGTH OF PROTOCOL

Criteria	XI LUO Protocol [25]	Proposed Protocol	Comment
Object Registration	Depends on Control Center which already had predefined records for objects (ID, Key) then after verification, the join request is accepted or rejected.	Depends mainly on cluster manager which already has a predefined records for objects (ID) then after validation, the join request is accepted or rejected	XI Luo Protocol is more powerful on registration phase since the verification is done through decryption of message using key that is already stored on control center. This operation is done once and may cost additional performance but fulfill more security against injection attacks
Identity Protection	Does not provide identity protection, in communication, it works directly with objects real identity	Provides identity protection via anonymization phase which depends on identity servers to change object real identity to another one	The proposed protocol is more powerful on identity protection. No communication is done unless object changed its real identity to another one to prevent identity tracking and impersonation attacks. The new identity must be frequently changed due to its expiration which in turn provide extra layer of security to prevent eavesdropping and inference attacks. The new identity is communicated to cloud to be able to receive information and correctly map it to correct object.
Key Management	Depends mainly on Control center to create the session key between communication parties. Therefore, in order to create a key between two objects, the first one will send a request to control center to create shared key then control center will back to requester and other party with needed key to start communication.	Depends mainly on lightweight key agreement protocol which aims to establish session key between communication parties only without need for any third parties. The communication parties only have the constructed session keys which provides more protection against key leakage	Proposed protocol employs a powerful key management approach via a lightweight key agreement protocol which ensures perfect secrecy and mutual authentication unlike Xi luo protocol, it depends on control center to provide that via persistent encryption keys stored on control center.
Data protection Level	Focuses mainly on objects' data	Focuses on objects' data and metadata related.	Proposed protocol focuses not only on data but metadata as well due to valuable information that can be revealed from.
Confidentiality	Partially fulfilled. Usage of cryptography to send and receive any message fulfill confidentiality but ability of control center to decrypt any sent message due to have access to all session keys is considered violation.	Fulfilled, being a TTP-Free and relying on End-to-end encryption starting from key construction which relies on lightweight key agreement protocol that is totally constructed between communication parties only then use of lightweight cryptography for any message sent or receive to ensure that no party whether internal or external network can read the message except authorized parties	Proposed protocol is considered more powerful in providing confidentiality. Xi luo protocol depends on key construction totally on control center which gives it ability to read any message sent due to have access to all keys used which in turn considered violation for confidentiality unlike proposed protocol which key construction is totally between communication parties only to forbid unauthorized access to data.
Integrity	Fulfilled via message authentication code used while exchanging messages	Fulfilled via message authentication code used while exchanging messages	Both fulfill integrity to make sure that any tampered message will be detected which in turn resist active attacks.
Mutual Authentication	Does not provided, communication parties does not have ability to securely authenticate each other due to being trusted to control center to authenticate each party before session key construction.	Fulfilled via key agreement protocol. Key agreement protocol aims to establish a session key between communication parties to securely exchange messages between each other. The first stage of adopted protocol is mutual authentication to make sure that each party authenticated each other before starting session key construction.	This is one of most critical part to be considered. Proposed protocol gives ability to communication parties to mutually authenticate each other before starting communication to resist any impersonate attacks and make sure that no one pretends to be other which in turn constitutes to confidentiality indirectly.

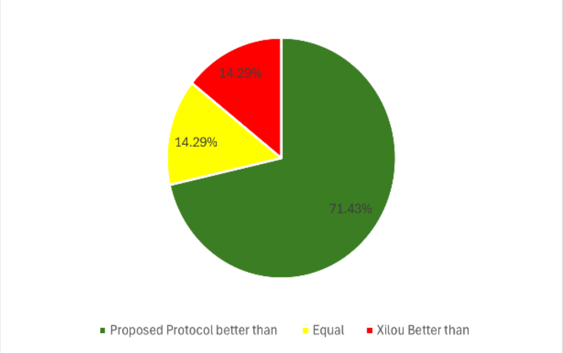

Fig. 4. Evaluation of proposed protocol in terms of protocol strength.

Although Xi Lou protocol tried to fulfill data privacy, it mainly depends on control center as a trusted third party to fulfill key exchange and object registration which in turn is considered security concern. If any attacker gain access to the control center, he will have access to all security keys for all individual objects and shared keys between objects. Fig. 4 summarizes results in terms of percentages with percentage of superiority of proposed protocol over XiLuo's one.

2) Attacks can resist which are the following:

- Man In the middle.
- Eavesdropping and Interference

- False Data Injection attack.
- Advanced Persistent Threat
- Active attacks.
- Reply attacks
- Tracking attacks.

Table IV demonstrates the comparison in terms of stated attacks.

Therefore, the proposed protocol has the ability to fully resist mentioned attacks and provide full data privacy. Fig. 5 summarizes the attacks resistance in terms of fully, partially and not resistant.

TABLE IV. COMPARISON BETWEEN XILOU AND PROPOSED PROTOCOL IN TERMS OF ATTACKS RESISTANCE

Attacks	**XI LUO Protocol [25]**	**Proposed Protocol**	**Comment**
Man in the middle attack (MiM)	Partially Protected	Fully Protected	For Xi lou protocol: dependency on control center as a trusted third party which makes the whole system vulnerable to MiM attack if attacker gain access to that. Proposed Protocol: provides end-to-end protection without relying on trusted third party. Objects try to establish their key via lightweight key agreement protocol instead of direct exchanging them which in turn provides fully protection against MiM.
Eavesdropping and Interference	Fully Protected	Fully Protected	Traffic on network is always encrypted which provide protection against Eavesdropping and inference
False Data Injection attack	Fully Protected	Fully Protected	Xi lou and proposed protocol fulfill protection against false data injection via encryption decryption used so no one can inject any data unless have a valid key on network. For Proposed Protocol: The protocol capable of resisting injection attacks by relying on end-to-end encryption which oblige all communication parties to establish session key before communication which ensures mutual authentication for communication parties. On the other side, on both protocols, registration phase works effectively against that attack as non-node can be injected on network without having a key registered already on control center in case of xi lou or have cluster manager approval in case of proposed protocol.
Advanced Persistent Threat	Partially Protected	Fully Protected	For Xi lou protocol: if attacker gain access to control center, attacker can be silent and has ability to extract all session keys constructed inside control center between communication parties. Proposed Protocol: it provides end to end security so gaining access to any part of network and stay silent will not reveal any information to attacker.
Active attacks	Fully Protected	Fully Protected	All messages sent are equipped with message authentication codes to resist any tampering to messages sent which in turn protect data from active attacks
Reply attacks	Fully Protected	Fully Protected	All messages sent are equipped with timestamps, these timestamps are validated against receiving party to make sure that no reply attack has been carried out.
Tracking attacks	Not protected	Fully Protected	For Xi lou protocol: the protocol deals with objects using their real identities without any masking or anonymization which in turn enables attacker to track any object inside network. Proposed Protocol: it provides anonymization for objects identities by replacing real object identities with fake one via identity servers which in turn change periodically object identities while data transfer which forbid and avoid any tracking attacks.

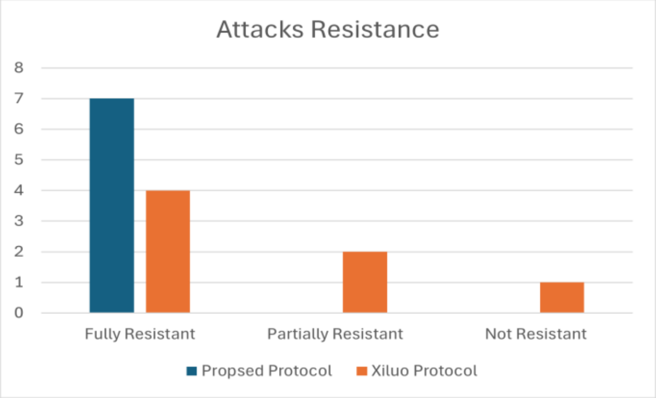

Fig. 5. Evaluation of proposed protocol in terms of attacks resistance.

VI. CONCLUSION

In this paper, a lightweight TTP-Free privacy preservation protocol is presented in order to provide complete data privacy via end to end protection for data and metadata while being transferred to cloud. The protocol depends on providing end to end encryption with a powerful lightweight key agreement protocol to fulfill full data privacy. The proposed protocol was analyzed using scyther tool to guarantee that no vulnerabilities are found. Furthermore, it was evaluated against others protocol in terms of protocol design criteria and attacks resistance. The results showed that the proposed protocol is well designed against the mentioned criteria and surpasses to other protocol by five out of seven which represents 71.4% of overall criteria and equalized in one criteria which is represented by 14.3% which makes the proposed protocol overall fulfillment is 85.7%

against 28.6% for others protocol. Moreover, the proposed protocol has ability to fully resist mentioned attacks which in turn makes it more suitable to fulfill data privacy objective.

In the future work, the proposed protocol will be extended to fulfill device to device (D2D) data privacy to affirm that all communications whether D2D or D2C are protected.

College of Computing-Computer Science and Artificial Intelligence Department,
Umm Al-Qura University, Makkah, Saudi Arabia

***Abstract*—Individuals with visual impairments face numerous challenges in their daily lives, with navigating streets and public spaces being particularly daunting. The inability to identify safe crossing locations and assess the feasibility of crossing significantly restricts their mobility and independence. The profound impact of visual impairments on daily activities underscores the urgent need for solutions to improve mobility and enhance safety. This study aims to address this pressing issue by leveraging computer vision and deep learning techniques to enhance object detection capabilities. The Basira mobile application was developed using the Flutter platform and integrated with a detection model. The application features voice command functionality to guide users during navigation and assist in identifying daily items. It can recognize a wide range of obstacles and objects in real-time, enabling users to make informed decisions while navigating. Initial testing of the application has shown promising results, with clear improvements in users' ability to navigate safely and confidently in various environments. Basira enhances independence and contributes to improving the quality of life for individuals with visual impairments. This study represents a significant step towards developing innovative technological solutions aimed at enabling all individuals to navigate freely and safely.**

Keywords—Visual impairment; mobility application; computer vision; object detection; obstacle detection

I. Introduction

People with visual impairments suffer from many challenges in their daily lives, and among these basic challenges is the difficulty of crossing streets and moving around in public places. The visually impaired have difficulty identifying safe crossing locations and assessing the possibility of crossing. The street is an unfamiliar and risky environment for these individuals, which affects their freedom of movement and independence. There are about 285 million people who suffer from visual impairment all over the world, including 39 million people whose vision is limited (blind), and 246 million people whose vision is impaired, according to statistics from the World Health Organization [1]. The number of blind people in Saudi Arabia is about 159 thousand blind people, according to undocumented statistics Official.

The impact of visual problems on people's daily activities is profound, with simple tasks such as detecting obstacles and finding their stuff becoming difficult. The issue of mobility for visually impaired people is a major concern to this day.

In Table I, we summarized the limitations of the current systems, namely Envisn [2], Glimpse [3], ChirpAR [4], Be My Eyes [5], and BlindSquare [6]. These drawbacks have been identified through a comparison table between these systems and Basira by carefully examining and evaluating these systems, we have identified specific areas where improvements are necessary. With the introduction of Basira, we aim to address these limitations and provide a comprehensive solution that effectively resolves these issues.

TABLE I. COMPARISON BETWEEN BASIRA AND CURRENT SYSTEMS

Application/function	**Glimpse**	**ChirpAR**	**Be My Eyes**	**BlindSquare**	**Basira**
Crossroads safely				●	●
detection the obstacles	●				●
Search for objects with voice feedback		●			●
Arabic language support		●	●	●	●

II. Previous Studies

In recent years, significant advancements have been made in applications and digital devices designed to assist individuals with visual impairments. A study conducted by Senjam et al. [6] in 2021 highlighted that smartphones are now widely accepted and less stigmatized compared to traditional assistive devices. The number of apps tailored for people with visual impairments is also on the rise, including options like VoiceOver, Aipoly Vision, TapTapSee, Be My Eyes, Seeing AI, and Seeing Assistant Move. However, many of these applications are not adequately designed to support safe navigation and road crossing.

In 2022, Mehmood et al. [7] explored the needs and challenges faced by blind and visually impaired individuals in Saudi Arabia concerning the availability and use of digital devices. Their online survey, which included 164 participants, revealed that tools like the White Cane, mobile phones, Envision, Seeing AI, VoiceOver, and Google Maps were commonly used. Mobility was identified as the primary reason for using personal devices, with white canes and mobile phones reported by 49% and 84% of respondents, respectively.

Additionally, Montezuma et al. [8] conducted research in 2021 comparing the performance of Orcam MyEye 1 and Seeing AI. Both applications demonstrated over 95% accuracy in recognizing plain text documents, but their accuracy fell to between 13% and 57% for text on curved surfaces. Participants completed 71% of tasks with Orcam MyEye 1 and 55% with Seeing AI.

In the same year, Salunkhe et al. [9] developed an Android-based object recognition app that leverages the smartphone camera to capture real-time images. This app processes images using TensorFlow's object detection API, specifically the SSD algorithm, achieving an accuracy of around 90% in experimental evaluations.

Furthermore, in 2022, See A et al. [10] proposed a system that combines obstacle detection and object recognition in a single application. Utilizing a deep learning model with the YOLO v3 framework for multi-object detection, this system employs the ARCore Depth Lab API from Google to create a 3D depth map. It identifies obstacles and provides audio alerts while recognizing over 90 different classes of objects.

Lastly, Patil et al. [11] in 2022 discussed a mobile application that integrates multiple functionalities, utilizing artificial intelligence and machine learning techniques. This includes the YOLOv3 algorithm for object recognition, a currency recognition model built with TensorFlow and a dataset from Kaggle, which contains over 1,000 different objects.

III. METHODOLOGY

Basira application has been designed to assist blind and visually impaired individuals in navigating their surroundings. The application aims to develop a portable and flexible navigational solution that meets their needs. To achieve this goal, a smartphone with a depth camera is used. The chosen smartphone for this research is the Honor COR-L29, which operates on the Android V9 operating system with a HiSilicon Kirin 970 processor. The phone features 8 GB of RAM and a large 6.3-inch IPS LCD display. The screen includes a notch at the top housing the front camera, and it offers an FHD+ resolution with a 19.5:9 aspect ratio. The screen-to-body ratio is 83%, indicating very slim bezels and the pixel density is approximately 409 pixels per inch. The rear camera setup is dual, consisting of a 16 MP primary sensor and a 2 MP secondary sensor, with a narrow f/2.2 aperture and LED flash. The camera setup supports depth sensing for portrait mode effects.

The development of the Basira application followed a structured methodology aimed at creating a comprehensive solution to aid individuals with visual impairments in navigating their environments. Central to this methodology was the meticulous design of the user interface, which prioritized flexibility and ease of use. The interface was tailored to accommodate various levels of visual impairment, with a focus on integrating intuitive voice commands for seamless interaction.

A. System Requirements

System requirements are a description of what a system should do, how it should behave, what properties it must have, and what are the limitations of the system, and it is divided into functional requirements and non-functional requirements.

- Functional and Data Requirements

1) The user shall be able to switch between the three functions by swiping the screen, whether it is “detection for obstacles/free Walk ","Cross the road" or "Search for objects".

a) The system shall provide different button for each service or provide swiping the screen.

b) The system shall display the interface of the chosen service.

2) The user should have the ability to search for objects in their surroundings using voice commands.

a) The system should be equipped with voice recognition capabilities to accurately process user voice commands and perform object searches based on the provided voice input.

3) The user should receive voice alerts through the app when using the camera feature to cross the road, providing assistance and guidance.

a) The system should integrate computer vision technology to analyze the live camera feed and provide real-time assistance for street crossing. It should detect objects (traffic light colors, crossing Line existing, whether there are cars or bicycles or not) and generate voice alerts to guide the user safely across the road.

b) The system should have a voice alert feature that can convert text-based information into voice output. It should deliver clear and concise instructions to the user regarding the street crossing process.

4) The user should receive audio feedback that provides information about the names of detected obstacles.

a) The system must utilize appropriate technologies to detect and detection for obstacles (free walk) within the camera's field of view. It should analyze the camera feed and accurately recognize obstacles.

b) The system must provide detection of the obstacles to enhance user safety while moving.

5) the user is presented with a welcome interface along with audio instructions.

a) The system displays three welcome interfaces with audio instructions.

b) The system displays the welcome interfaces only once when the application is opened for the first time.

c) The system allows the user to navigate through the welcome interfaces by swiping the screen.

- Non-Functional Requirements

1) Look and Feel Requirements:

a) Basira App will have an interface that is easy to use and accessible to all users. It will be designed with simplicity in mind and will be compatible with screen readers commonly used by blind people.

2) Usability Requirements:

a) Basira App will be designed to be easy to use for blind and visual impairments, providing clear and concise instructions.

b) The app will be organized to save users' time and effort, with intuitive navigation and a logical flow of tasks.

c) The app will be self-explanatory and not require excessive instructions or guidance.

d) The system will accurately and clearly describe objects to the user using a clear voice.

3) Performance Requirements:

a) Basira App's interface will load quickly, providing a seamless user experience.

4) Portability Requirements:

a) Basira App will be compatible with both Android and iOS platforms, ensuring its availability to a wide range of users.

Fig. 1 shows the relationship between user with different use cases and how they interact with the system. Displays the services provided by system, where the user accesses the following services: Search in the surrounding for Objects, Crossing the street, Obstacles Detecting (free walk) functions.

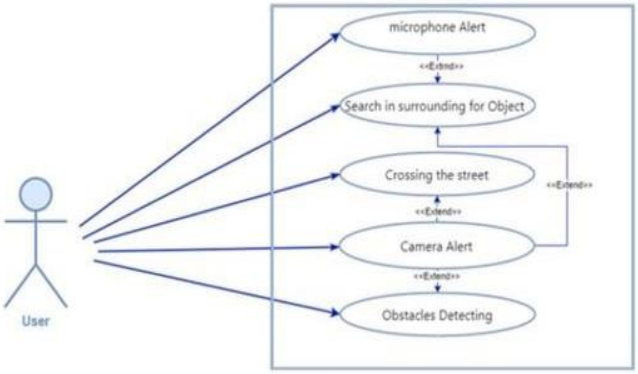

Fig. 1. Use case diagram.

B. Workflow Diagrams

We used the Data Flow Diagrams (DFDs), the data flow diagram is a graphical representation of the data stream within Basira's system. It gives a general overview of the data and system functionality.

Fig. 2 shows context diagram (Level 0) as shown in is a general overview or abstraction view of the whole Basira's system as a single process without any details. It shows the relationship between Basira's system and the external entities User, Text-to-Speech tool, Speech-toText tool and Computer vision tool.

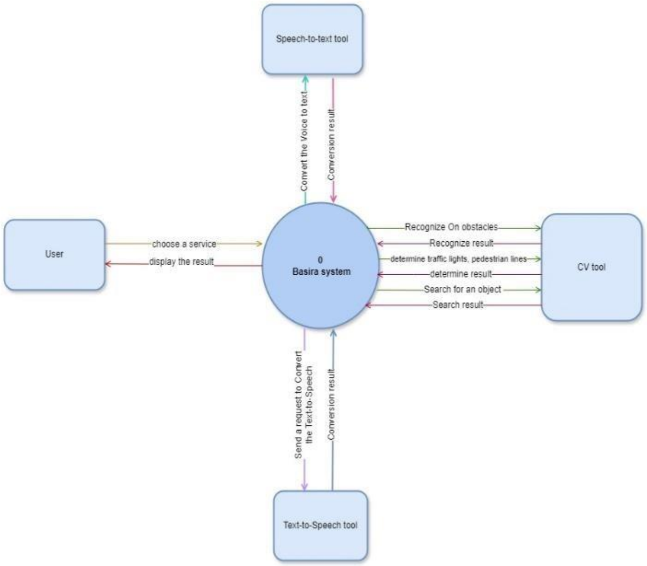

Fig. 2. Data flow diagram Level 0.

Fig. 3 shows the Data Flow Diagram (Level 1), which is a more detailed version of a context diagram. It shows the main processes of a system and the data flows between them. Here, the system has three main processes Obstacles Detecting\free Walk, Crossing the street, Search for objects.

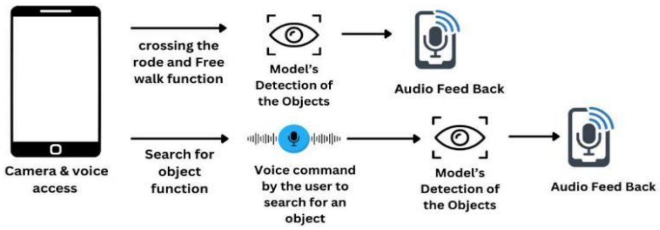
C. Mobile Development and Implementation

The mobile application was developed utilizing Flutter, a recent and effective mobile framework to build iOS and Android applications from a single code base [12]. The Basira application included the creation of three educational audio interfaces within the application. These interfaces served as informative guides, offering users insights into the features and functionalities of Basira. By providing this educational foundation, users were empowered to navigate the application with confidence and proficiency. The Basira application includes three main functions: Crossing the Road, Free Walking, and Object Searching as shown in Fig. 4.



crossing the rode and Free walk function
Model's Detection of the Objects
Audio Feed Back
Camera & voice access
Search for object function
Voice command by the user to search for an object
Model's Detection of the Objects
Audio Feed Back

Fig. 4. Shows how the functions of the Basira app work.

A crucial aspect of the Basira application is the implementation of intuitive navigation mechanisms that allow users to easily traverse the app by swiping the screen. This ensures accessibility and enhances the user experience. The user-friendly interface provides quick access to features, offering real-time auditory feedback and voice commands in the object search function. This enhances users' ability to navigate safely and make informed decisions.

D. Development of AI Model

The crossing the road and street obstacle (free walking) dataset was collected from various sources, including Roboflow [13] and the Google Image Search engine. These datasets were carefully categorized to include classes such as pedestrian crossings that alert and guide the visually impaired to the presence of the street, the vehicles and cars encountered during the crossing, and traffic lights with their colours indicating stop, caution, and go. The street obstacle dataset included potholes, vehicles, traffic cones, road barriers, and natural obstacles like branches and trees. Each category in both datasets consisted of 500 carefully selected images to provide a diverse and balanced dataset for model training.

The object detection model was trained on the COCO (Microsoft Common Objects in Context) dataset, which encompasses a wide range of common objects in daily life [14]. The two models were developed and evaluated using the You Only Look Once (YOLOv5) model in study [15].

The crossing the road and free walking model achieved an accuracy of 85.4% and a size of 13.6MB in Pytorch format. The object detection model achieved an accuracy of 94.3% and a size of 14.2 MB in Pytorch format. Both models were built to operate in real-time without any user intervention.

We chose the MVC architecture in Fig. 5 for our system because it provides a clear separation of responsibilities and supports our system's action and reaction approach.

E. Search for Object Function

The 'Object Search function in the Basira application aims to assist blind and visually impaired individuals in finding the items they need. It has been implemented using the YOLOv5s model [16] for real-time object detection. When the user vocally specifies the item they are looking for, the system verifies the detected objects in real time and compares them with the desired item. Upon detecting the desired item, the user is notified via an audio alert. This function enhances the independence of blind users, helping them navigate safely and comfortably by easily identifying items without the need for assistance from sighted individuals.

Model
- handles the logic data
- analysis information about crossings, obstacles, and objects, and calculates the distance between the user and required objects

Fig. 5. MVC Diagram.

F. Free Walk / Obstacles Detection Function

The free walk function in Basira application is designed to help visually impaired users navigate their environment by detecting obstacles in their path. This function relies on advanced computer vision algorithm, which is YOLOv5s model, to identify various hazards such as traffic cones, potholes, cars, barriers, and trees through the smartphone's camera feed. When an obstacle is detected, the system provides immediate auditory feedback; alerting the user to the presence of an obstacle and helping them avoid potential hazards.

G. Crossing the Road Function

The crossing the street function in the Basira application is designed to ensure that visually impaired users can safely navigate pedestrian crossings. This function involves detecting traffic signals and crosswalks and providing real-time guidance about when it is safe to cross the street. The system identifies traffic lights and gives auditory guidance, such as indicating when the light is green, and it is safe to cross. Additionally, it detects the presence of vehicles near the crossing area and advises users to wait if necessary.

IV. Results and Discussion

A. User Interface for Basira

Since Basira's target users are visually impaired Arabic native speakers, the language used for both the developed interfaces and audio feedback was Arabic. The interfaces were meticulously designed with a robust emphasis on accessibility and usability for visually impaired users. Drawing upon foundational design principles such as visibility, feedback, constraints, consistency, and affordance [17], these concepts were pivotal in crafting interfaces that are user-friendly and efficient.

As shown in Fig. 6, upon launching the app, users are greeted with the app logo, followed by a welcome interface only if it is their first time using the application. User onboarding is considered important because it helps new users understand how to use the application and navigate its features correctly. It aids in improving the user experience and increasing the likelihood of long-term application usage.

The welcome interface encompasses three distinct screens. Fig. 6(a) showcases the Crossing the Road feature, while Fig. 6(b) presents the Search for Objects interface. Finally, Fig. 6(c) introduces the Free Walking feature. Each interface includes detailed definitions and explanations of the respective application functionalities, accompanied by audio instructions.

Regarding the application's main interface is composed of three straightforward and simple screens. Upon launching the application (excluding the initial launch of the application), the user is presented with the Free Walking interface as the primary screen. This interface displays the camera and includes a sliding visual element that appears as a notification when obstacles are detected, as shown in Fig. 7(a). Swiping left navigates the user to the second interface which is Crossing the Road, It also displays the camera, accompanied by a sliding visual element that appears as a message when a pedestrian lines or traffic light is detected, as depicted in Fig. 7(b). The Search for Objects interface, shown in Fig. 7(c).

يوجد خط مشاة الاشارة حمراء لا تعبر

(a) (b) (c)

Fig. 7. Basira main interfaces: (a) Free Walking interfaces, (b) Crossing the Road interface, (c) Search for Objects interfaces.

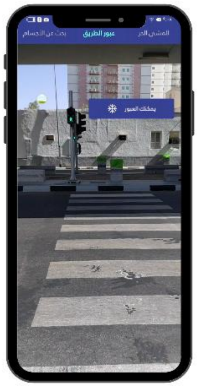
Features a split design: the upper portion displays camera, while the lower part containing a microphone button. By pressing this button, user can voice command to search for specific objects. Each interface provides audio feedback and notifications to the user, enhancing the overall user experience.

B. Testing Results

The Basira application has been tested on a single user from the target audience of individuals with visual impairments (complete or partial blindness), and the individual who has utilized the Basira to undergo testing is a person who is completely blind. Three key functionalities need to be tested by this user: crossing the road, free walking, and searching for objects. We have conducted unit testing, which involves evaluating individual components to ensure their correct operation, to detect and resolve bugs early in the development process.

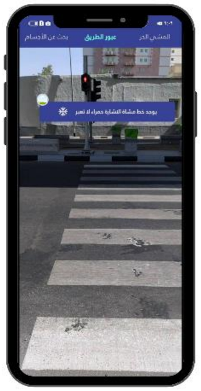
And it's worth noting that in all the scenarios mentioned below, the user will have their camera open and pointed in the direction they are walking. The application operates in real-time, so the user's gaze will be tracked accordingly.

1) Testing for “crossing the road” function: In the first scenario (Fig. 8) that was tested, a designated crosswalk is present, and a green traffic signal is displayed, indicating that vehicles are required to yield to pedestrians. Additionally, there are no cars or bicycles in the immediate vicinity of the crossing area, it will provide audio feedback in Arabic language stating "***يمكنك العبور***” (you can cross).



يمكنك العبور

Fig. 8. Testing result for “Safe to Cross” condition.



يوجد خط مشاة الاشارة حمراء لا تعبر

Fig. 9. Testing result for “Red Traffic Light at Crosswalk” condition.

In the second scenario (Fig. 9), both a red traffic light and a designated crosswalk are detected simultaneously. This combination of conditions indicates that it is not safe for pedestrians to cross the road at this time, it will provide audio feedback in Arabic language stating “ يوجد خط مشاة الاشارة حمراء لا "تعبر”(there is a crosswalk, the light is red, do not cross).

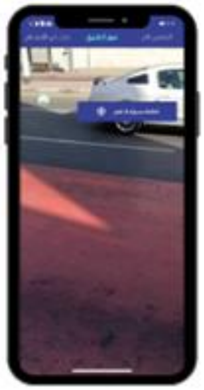


Fig. 10. Testing result for “Cars or Bicycles Present” condition.

In third scenario (Fig. 10), a car is detected, indicating that it is not safe to cross the road. This condition applies regardless of whether the detected vehicles are cars, bicycles, or both. The presence of any moving vehicles near the crossing area poses a significant risk to pedestrians, it will provide audio feedback in Arabic language stating”امامك سيارة لا تعبر ” (There is a car ahead, do not cross).

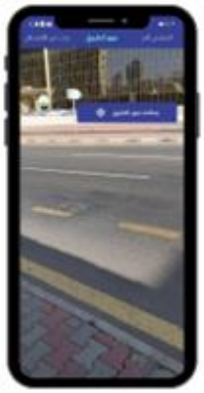

Fig. 11. Testing result for “Safe to Cross (default)” condition.

In fourth scenario (Fig. 11), there are no visible red or yellow traffic signals, and there are no cars or bicycles in the vicinity of the crossing area. Pedestrians are able to cross the crosswalk safely without any anticipated risk, it will provide audio feedback in Arabic language stating”يمكنك عبور الطريق ” (you can cross the road).

2) Testing for “free walk / obstacles detection” function: Fig. 12, if Basira detects any obstacles such as: traffic cone, pothole, car, tree or barrier in path of the user, it will provide audio feedback in Arabic language stating ***“امامك معرقل”*** (obstacle ahead).

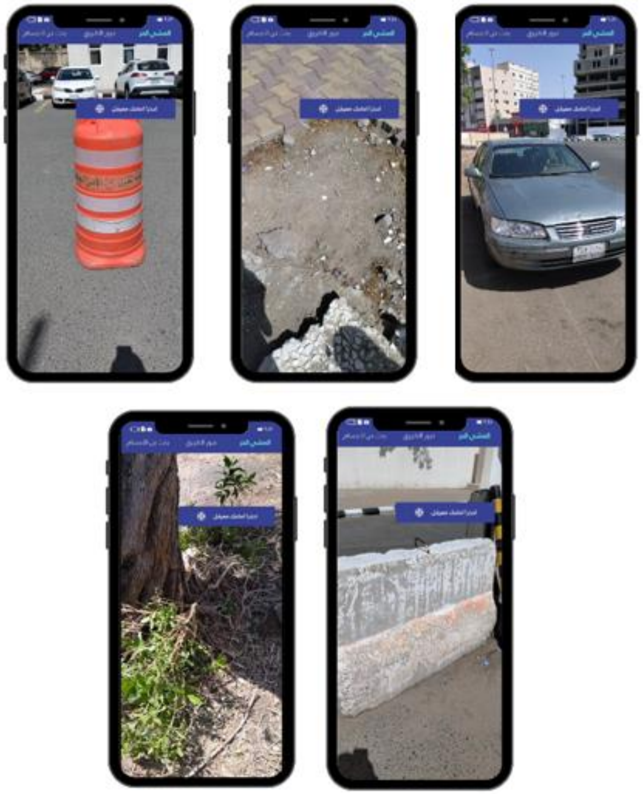

Fig. 12. Testing results for “free walking (obstacles detection)” function.

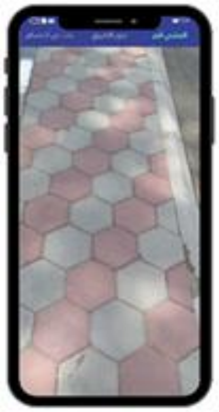

Fig. 13. Testing result if no obstacle ahead.

In second scenario in (Fig. 13), if Basira does not detect any obstacles in the user's path, it will not provide any feedback.

3) Testing for “searching for object” function: In the following functionality, the user will utilize their voice. They will press the voice recognition icon and then state the name of the object they are searching for in Arabic.

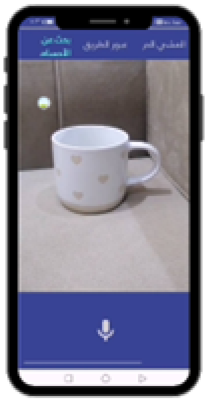

Fig. 14. Testing result for searching about “كأس” cup.

Fig. 14 the user said, **“كأس”** (cup). Then, Basira it will attempt to detect whether the cup is present in front of the camera or not. In this case, the cup is present, so it will provide audio feedback saying **“الشيء الذي تبحث عنه امامك”** (the thing you are looking for is in front of you).

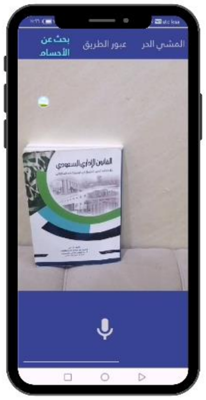

Fig. 15. Testing result for searching about “كأس” cup.

Fig. 15, we will repeat the same experiment but with a different object. The user said, **“كأس”** (cup). Then, Basira will attempt to detect whether the cup is present in front of the camera or not. In this case, the cup is present, so it will provide audio feedback saying **“لم يتم العثور عن الشيء الذي تبحث عنه”** (The object you were looking for was not found). Because the actual object in front of the camera is a book.

V. Limitations and Future Work

Throughout the development phase of our project, we faced several challenges that required innovative solutions. Notably, Flutter lacks built-in support for real-time detection using the YOLO model. To address this, we converted the YOLO model into a TorchScript extension, enabling efficient real-time object detection through frame transmission within our Flutter application. Moreover, time constraints hindered our ability to prepare more data and enhance model accuracy. Initially, we planned to connect Python code with Flutter interfaces and the camera via Flask; however, this setup encountered real-time performance issues, prompting us to rewrite the program entirely in Flutter for better integration.

VI. Conclusion

This study introduces the Basira application, leveraging Deep Learning technology to aid blind and visually impaired individuals. The application offers three primary functions. Firstly, it provides auditory alerts to users regarding obstacles such as trees, barriers, and other impediments on the street. Secondly, it helps users safely cross roads through auditory notifications based on various scenarios, such as pedestrian crossings, traffic light signals (green for crossing, red for waiting), and vehicle presence. Lastly, Basira includes an object search feature, enabling users to vocally inquire about objects in their vicinity. The system responds with auditory alerts confirming the object's presence or absence.

The mobile interface of Basira was designed to look friendly and easy to use. Developed using Flutter, the application is compatible with Android devices. When the application is opened, a welcome interface will appear, showcasing the features offered by Basira. The user is then taken to the free walking (obstacle detection) interface, where they can swipe the screen to smoothly navigate to the road crossing page or the object search page. By seamlessly integrating deep learning models with a user-friendly mobile app, Basira aims to enhance the independence and mobility of blind and visually impaired individuals.

Machine Translation-Based Language Modeling Enables Multi-Scenario Applications of English Language

Shengming Liu*
School of Foreign Languages and Culture, Panzhihua University, Panzhihua 617000, China

***Abstracts*—Traditional machine translation models suffer from problems such as long training time and insufficient adaptability when dealing with multiple English language scenarios. At the same time, some models often struggle to meet practical translation needs in complex language environments. A translation model that combines the feed-forward neural network decoder and the attention mechanism is suggested as a solution to this problem. Additionally, the model analyzes the similarity of the English language to enhance its translation ability. The resulting machine translation model can be applied to different English scenarios. The study's findings showed that the model performs better when the convolutional and attention layers have a higher number of layers relative to one another. The highest average value of the bilingual evaluation study for the research use model was 29.65. The research use model can machine translate different English language application scenarios and also the model performed better. The new model performed better than the traditional model and was able to translate the English language well in a variety of settings. The model used in the study had the maximum parameter data size of 4586, which is 932 higher than the lowest statistical machine translation model of 3654. The metric value was 3.96 higher than the statistical machine translation model. It is evident that investigating the use of the model can enhance the English language scene translation effect, with each scene doing well in translation. This provides new ideas for the direction of multi-scene application of machine translation language model afterwards.**

Keywords*—*Machine translation; decoder; English language; multi-scene; attention mechanism

I. INTRODUCTION

Machine translation (MT) refers to the text translation process that uses only machines to translate natural language. MT can translate a large number of English language (EL) text messages more conveniently and quickly, and reduce the communication barriers and other problems that occur in people's work [1]. As science and technology have advanced, machine translation (MT) has grown in importance as a text translation tool. But the traditional MT model can no longer meet the increasingly complex language environment, so how to improve the efficiency of MT, so that it is more suitable for a number of different scenarios has become an important direction of the current research [2]. The traditional MT model is mainly based on the Transformer to carry out multi-level stacked translation to realize the purpose of MT. The high complexity of traditional models makes them take a lot of time in the training process, which makes it difficult to meet the requirements of real-time and high efficiency in multi-scene applications. In addition, the traditional model relies on a multi-level stacked translation mechanism, which causes problems such as dimension explosion when dealing with long text sequences [3]. A type of deep-structure neural network model called a convolutional neural network uses the feed-forward neural network's (FNN) attention mechanism (AM) to shorten training times and enhance training results [4]. FNN is often used in complex data models because it is easy to be trained and can handle high-dimensional data. By processing sequential data more effectively, AM can enhance the accuracy and performance of machine learning models. The AM module can effectively reduce the dimension explosion problem when translating long sequences of text and improve translation accuracy and efficiency. The FNN module can reduce the overall complexity of the model and shorten the training time. The meta-learning module can ensure the translation effect of the model in complex scenes. The encoder-decoder structure enables efficient sequence-to-sequence translation. Due to the addition of the attention mechanism, the encoder-decoder structure can process and translate long sequence texts more accurately. On this basis, the study improves the Transformer based on the traditional MT by adding AM and FNN, and reduces the complexity of the model by extracting the local semantic information of words through AM. The research uses a decoder to decode and analyse linguistic terms and filter out closer results. The new system is able to integrate the attention mechanism and feed-forward neural network, optimising the decoder part of the traditional Transformer model. To improve the system's ability to capture the local semantic information in the language sequence and reduce the complexity of the model. At the same time the model improves the adaptation effect to different English scenarios by introducing a meta-learning approach. The study is broken down into six sections. Introduction is given in Section I. Section II gives detail about the related work. English language model for machine translation is given in Section III. Section IV provides analysis of English language. Discussion is given in Section V and finally, Section VI concludes the paper.

II. RELATED WORK

MT is a translation model for linguistic text translation through software, which is currently widely used in different translation fields. Using MT to translate independently translated sentences, Maruf S et al. were able to enhance the model's translation quality by adding a neural network model. The study also evaluated the current applicable models and

*Corresponding Author.

analyzed them using both training and test sets. The study's findings demonstrated that applying the approach can improve research in this area [5]. Translation effort is complicated by ambiguity, as discovered by Yang M et al. when certain uncommon words are frequently substituted with tokens in machine translation (MT). Therefore, a hierarchical clustering approach was proposed, by building a dataset of rare words up to be able to be assembled into the MT framework, which can be successfully translated. The results of the study indicated that the quality of MT can be improved by using this method [6]. Dabre R et al. found that the use of multilingual neural MT can improve the quality of translation, and this translation model is more convenient and faster compared with the traditional MT. Therefore the study investigated this MT method in more depth and explored the future research direction of this method by analyzing the current literature and use cases, which provides new ideas for future research in this direction [7]. Khaw L L et al. found a new model for enhancing students' English context through writing. To improve the model's capacity for contextual learning, a RA engineering model was used in the development of the new model. The study's findings demonstrated how well this methodology worked to improve students' contextual learning [8].

According to Ban H et al., as Internet technology has advanced, so too has the necessity for interlanguage communication, and language models used in automatic translation have gotten more efficient. In order to create a novel MT model using an encoder and decoder, the research applied a deep learning MT model. By mapping between languages, the new model can enhance performance by immediately converting data into vectors. The study's findings demonstrated that the new model might outperform the conventional model [9]. Bharti N et al. concluded that the ranking of translated languages can improve the performance of MT and also train the MT effectively. Therefore, the study used a new mechanism for MT by sorting the MT output statements. The study's findings showed that the novel approach can enhance machine translation (MT) performance and is helpful for translating linguistic studies [10]. Wu H found that interactive translation of MT using multimedia is an effective way of translating a large number of utterances and programming languages. Therefore, the study proposed a fuzzy learning-based MT system that uses multimedia software to improve the performance and effectiveness of MT. Finally, the study pointed out the defects and advantages of the current multimedia translation and proposed a new translation program. Additionally, the study's findings demonstrated that employing the new model can improve English translator training [11]. Maimaiti M et al. found that there are many ways to enhance the data in MT, but the traditional methods are difficult to ensure the quality of the data after enhancement. Therefore a new evaluation framework was used in the study for data enhancement and the new approach used a discriminator model in order to reduce syntactic and semantic errors. The outcomes demonstrated that the data enhancement performance of this approach is significantly better than other approaches [12].

In summary, most of the studies in MT are mainly to enhance the effect of translated data and MT performance, followed by the improvement of MT through machine learning, but this approach often fails to analyze and study more complex EL environments. To improve MT's capacity for scene adaption, the study superimposes multi-layer FNN and attention to incorporate AM and FNN into the MT model. Lastly, to improve the model's capacity to feature extract data, the data is feature extracted from the model using conditional random fields (CRF) and bidirectional encoder representations from Transformers.

III. English Language Modeling for Machine Translation

This section mainly focuses on the model construction of EL based on the MT model, firstly, the AM will be added to the model, and then the structure of the decoder and other structures will be introduced and analyzed, followed by the analysis and elaboration for the purpose of improving the model effect and coping with the translation of EL in different scenarios.

A. *Language Model for Machine Translation Incorporating the Attention Mechanism*

Language model is a processing model to convert the traditional natural language, the current commonly used language model is mainly using neural networks for language processing and model design. When creating the target language, machine translation (MT) is a crucial model of language processing that can typically convert languages, decode and analyze data from the source language, and treat the previous result as the output of the latter item to obtain the source language model formula for MT, as indicated in Eq. (1) [13].

$$P(Y \mid X, \theta) = \prod_{t=1}^{T^Y+1} P(y_t \mid y_{t-1}, X; \theta) \tag{1}$$

In Eq. (1), X denotes the source language sequence, T^Y is the length of the sequence, and Y is the final language sequence obtained. θ denotes the set of data parameters and T denotes the length of translated words. Generally the use of parameter estimation to train the machine for translation enables to get the size of the loss function value of the current formula model. Usually in the use of MT it is necessary to convert the linguistic data into dimensional vectors that can be used by the machine, so it is necessary to use an encoder to analyze the MT process. The encoder-decoder's construction is depicted in Fig. 1.

In Fig. 1, the encoder adds word data such as "I", "LOVE", "I", "HOME "The data is converted by the decoder, and then the converted data is expressed in machine language by the decoder, such as "HOME" is expressed as [1,0,1], this kind of data transcoding can solve the problem of semantic conversion, but usually there is also a dimensional explosion in the conversion process problem. Therefore, the study adds the attention module to the traditional model to solve the problem of long language sequences. Because in the translation process of EL, it is impossible to compare and analyze each word, and in fact, the translation only needs to translate the adjacent part of the word, so the mapping of the local word can get the result of all the words translated. For this reason, AM is added to the translation process of EL, which is used to capture the information of global features. As shown in Fig. 2.

In Fig. 2, the attention module mainly includes multiple attention and convolutional attention. Multiple attention includes parameters such as temporal expression of EL sequences, word expression, and so on. Convolutional attention is mainly the linguistic dimension segmentation of the convolutional layer, and the parameter data of the two kinds of attention are segmented and processed to obtain the latest model attention output. The sequence expression of AM is shown in Eq. (2) [14].

$$S = \{W_1, W_2, \cdots, W_n\} \tag{2}$$

In Eq. (2), S denotes the output of the language sequence and W_n denotes the word expression in the sequence. The sequence vector encoding at this point is shown in Eq. (3).

$$E = Input(S) \tag{3}$$

In Eq. (3), E belongs to the set of word sequence vectors, and the obtained vectors are subjected to the dimensional splitting operation of the attention input, and the different dimensions of attention are correlated to obtain the correlation shown in Eq. (4) [15].

$$d_S = d_X + d_{X_2} \tag{4}$$

In Eq. (4), d_S is the dimension size of the language sequence and d_X is the dimension size of the number of attention heads. The attention heads is set to h_T and the convolutional AM is set to h_C in Eq. (5) to obtain the AM allocation formula as shown in Eq. (5) [16].

$$h_T * d_T^h + h_C * d_C^h = d_T + d_C = d_S \tag{5}$$

In Eq. (5), d_T^h denotes the dimension assigned to each number of attention for multiple, and d_C^h denotes the dimension assigned to each number of attention for convolution. After analyzing the dimensional information of the attention, the initial attention dimension (AD) is used to build the encoder and decoder as shown in Fig. 3.

Fig. 3. Initial attention dimension construction process.

Fig. 3 shows the addition of a front-loaded feedback layer and a residual connection layer during the pre-modeling stage of the encoder. The feedback layer primarily modifies the linear data to increase the attention model's computational capacity. The decoder's entire structure is the same as the encoder's, but with additional multiple attention added. The model utilized is the same as the traditional model module, and the EL data obtained after encoding in the encoder is transferred into the encoder for recomputation. In the English data input part of the model, the existing vector positions and inflectional lengths are set, the input data vectors are aligned by means of data complementary zeros, and then the initialization calculation of English word vectors is carried out by the function and the positions are encoded in the data vectors, and the final data obtained are analyzed as the input dimensions.

The encoder stage of the model first splits the data vectors to divide the different dimensions of the attention model, and the assigned dimensions of the two attention models are calculated to obtain the dimension size of the encoder attention convolution [17]. Finally the obtained results and dimensions are merged by computation and later fed into the pre-feedback network to enhance the data. The decoder output stage requires the addition of the same attentional model that enables the current model to obtain more EL text data. The obtained text data is used as input to the attention matrix of the decoder [18]. Again same as the encoder stage the result of the previous layer is augmented by the feed forward network before outputting and the final result obtained is the current desired result.

B. *Machine Translation Model for English Modal Scene Application System*

In the translation of EL scenarios, the main problem is the EL translation and usage problem, which can be solved by analyzing the MT encoder and decoder in the previous section to study the problems such as English translation. The main composition of the model used in the study is composed of AM and Transformer, mainly to enhance the module's feature extraction (FE) ability for nonlinear vectors and words in low latitude space. The upper part of the model used belongs to the feed forward network module as shown in Fig. 4.

In Fig. 4, the feedforward network module is mainly composed of multiple attention models and feedforward network module, while the network module includes data linear change operation, multiple perceptual layers and neural network layer optimization. The inputs and outputs of the feedforward network layer are expressed to obtain the formula for the FNN layer as shown in Eq. (6) [19].

$$FNN(D) = relu(DW_D + b_D)W_R + b_R \tag{6}$$

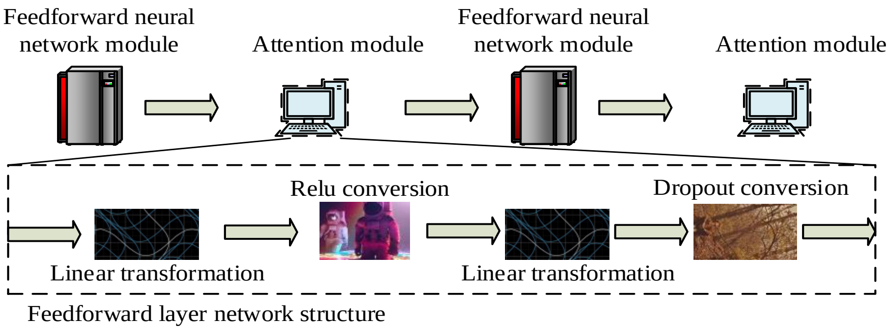

Fig. 4. Feedforward network module.

In Eq. (6), D denotes the input of data and W_R denotes the output of data. b_R is the AD of the output and b_D denotes the AD of the input. The MT model of AM has been able to translate specific ELs, but the information and terminology of the domains are not fixed for different English scenarios, and in order to further make the model adapt to more scenario applications, the model needs to be trained by meta-learning methods. Fig. 5 displays a schematic diagram of the training model.

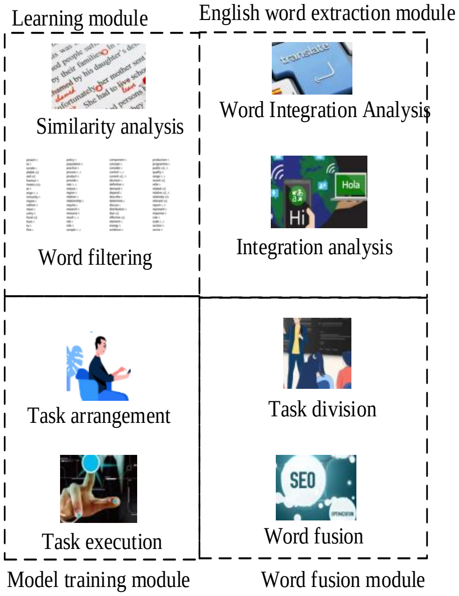

Fig. 5. Schematic diagram of training model.

In Fig. 5, the training for the model is mainly divided into several modules for training, learning module, English word extraction module, word fusion module, and model training module. The learning module is mainly responsible for word similarity analysis of the current application scenarios. The English word extraction module performs word incorporation analysis for different English scenes. The word fusion module divides the tasks for meta-learning. The model training module arranges training tasks for the training process of the model. It is vital to extract words from the language used in the current scene during the model training process in order to integrate additional information from the model training data. This is done by marking the words in the sentence and assessing them in relation to various vocabularies and scenarios for comprehension. Extracting data through the method of extracting words requires FE of data from the feature expression layer and the conditional random distribution layer [20]. Fig. 6 depicts the extracted words FE procedure.

To acquire the feature representation of the EL sentence using the model, the input sequence in Fig. 6 must first be feature extracted. Secondly, the deeper neural network is input as a conditional randomized feature layer. In the stochastic conditional feature layer it is necessary to define the state feature function and map the input feature sequence to the probability distribution of the sequence, and each state function is subjected to positional correlation calculation. If a feature function that can be identified is labeled, the value of the feature function at the current labeled position is used as the current input, and the model FE is able to return a corresponding real number. In addition to defining the function labeled for FE, it is also necessary to define the position of the feature function. The distribution of word features in the model is calculated for the best marking case given by the sequence, and the probability of the sequence is calculated using the function, as shown in Eq. (7) [21].

$$p(y\mid x)=$$

$$\frac{1}{Z(x)}\exp\left(\sum_{i=1}^{n}\sum_{k=1}^{K}\lambda_k f_k(y_{i-1},y_i,x_i)+\sum_{i=1}^{n}\sum_{j=1}^{K}\theta_j g(y_{i-1},y_i)\right) \tag{7}$$

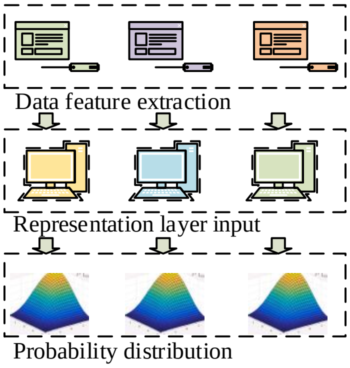

Fig. 6. Extraction process of word features.

In Eq. (7), $Z(x)$ denotes the normalization factor, which is capable of summing up all labeled sequence probabilities, guaranteeing that the distribution of the current probabilities are all integer 1. λ_k and θ_j denote the parameters of the model. $f_k(y_{i-1},y_i,x_i)$ denotes the current defined feature function. $g(y_{i-1},y_i)$ denotes the value of another defined feature function. Following the model's training, a comparable function serves as the loss function. The model's parameters are then determined by gradient descent minimization of the loss function, and the best position for the sequences is ultimately determined by decoding the data following training [22].

In addition to the extraction of feature data it is also necessary to translate the sentences in the target context, but since there are already multiple aligned words in the current environment, the study requires automatic acquisition of aligned sentences in the context and translation of the target sentence (TS). As shown in Eq. (8) [23].

$$A=(x_i,y_i):x_i\in X,y_i\in Y \tag{8}$$

In Eq. (8), $X=x_1,x_2,\cdots,x_n$ denotes a random sentence in the scene and $Y=y_1,y_2,\cdots y_m$ denotes a parallel sentence corresponding to the TS. (x_i, y_i) denotes a word pair where two words are semantically similar in the same sentence in the same context. When extracting word embedding for multiple words, the word embedding need to be obtained through the hidden state of the model, and the similarity of the words is calculated after the word embedded words are obtained. In this way the dot product of contextual principal vectors of word embedding can be computed for each feature of the target word and the aligned word. After that all the features exceeding the threshold set by the model are filtered and then the similarity matrix is obtained through the contextual word embedding as shown in Eq. (9) [24].

$$S = h_x h_y^T \tag{9}$$

In Eq. (9), S denotes the probability distribution of the similarity matrix, and both h_x and h_y denote the word embedding data. The matrix of initial phrases is obtained by this method, and then the final alignment matrix is obtained by ensemble interaction between the initial sentence (IS) and the sentences obtained from the TSs, as shown in Eq. (10) [25].

$$Align = (S_{xy} > c) \cap (S_{yx}^T > c) \tag{10}$$

In Eq. (10), S_{xy} denotes the IS matrix, S_{yx}^T denotes the TS matrix, and c denotes the threshold value. When the threshold value is set to 1 and the rest of the parameter items are set to 0, then the value of the alignment matrix in the matrix is equal to 1 means that at this time the two TSs and the IS are aligned with each other [26]. As some texts are processed for word alignment in different scenarios, multiple subwords need to be aligned [27]. However, in different scenarios where a term includes multiple words and a word contains multiple segmented sub-words, it is only necessary to align a sub-word in the scenario with each other, and then the words can be considered to be aligned with each other. However, this method will greatly increase the error generated during the training of the model, so it is also necessary to filter the aligned sentences. The method used in the model is to represent the two sentences as vectors and calculate the cosine similarity between the two words as shown in Eq. (11) [28].

$$similarity = \cos(\theta) = \frac{A * B}{|A||B|} \tag{11}$$

In Eq. (11), $similarity$ denotes the magnitude of cosine similarity between two sentences and $\cos(\theta)$ denotes the cosine value. A is the IS word and B is the TS word. For the model the loss function is calculated as shown in Eq. (12) [29].

$$L(\phi) = \sum_{t=1}^{T} l^t(\hat{\theta}^t) \tag{12}$$

In Eq. (12), $L(\phi)$ denotes the value of the loss function and $\hat{\theta}^t$ denotes the specific network in the model that performs the initialization operation. T denotes the number of executed tasks, and $l^t(\hat{\theta}^t)$ denotes the loss value of the network performing the task in the model. When the network task is executed at initialization, its execution network is the same as the initial network, then after the model training update, the execution parameters of the current network are different from those of the initial network. At this time, the loss value is calculated, and the loss value is aggregated so that all the loss values of the network model can be obtained [30]. The final flow of the obtained multi-scene translation decoding model is shown in Fig. 7.

In Fig. 7, the initial phase of the model involves first matching the EL file from the system, loading the EL, after which the model is trained through the model. It is determined whether there is a request or not, if yes then the initial EL is obtained from the text, if not then it waits for the instruction to be issued. After obtaining the IS the sentence language is pooled to choose whether to use the decoding pool or to sample the data. After that the EL sentences from different scenarios are modeled and segmented, the resulting ELs are translated into text using MT, and finally the translated results are output as text.

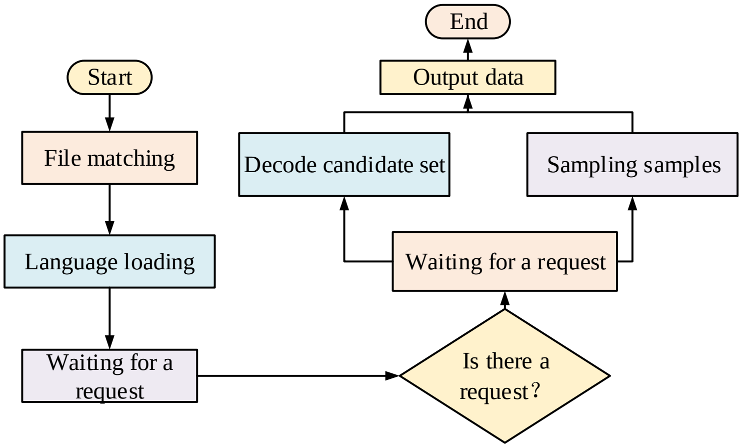

Fig. 7. Multi scene translation decoding model process.

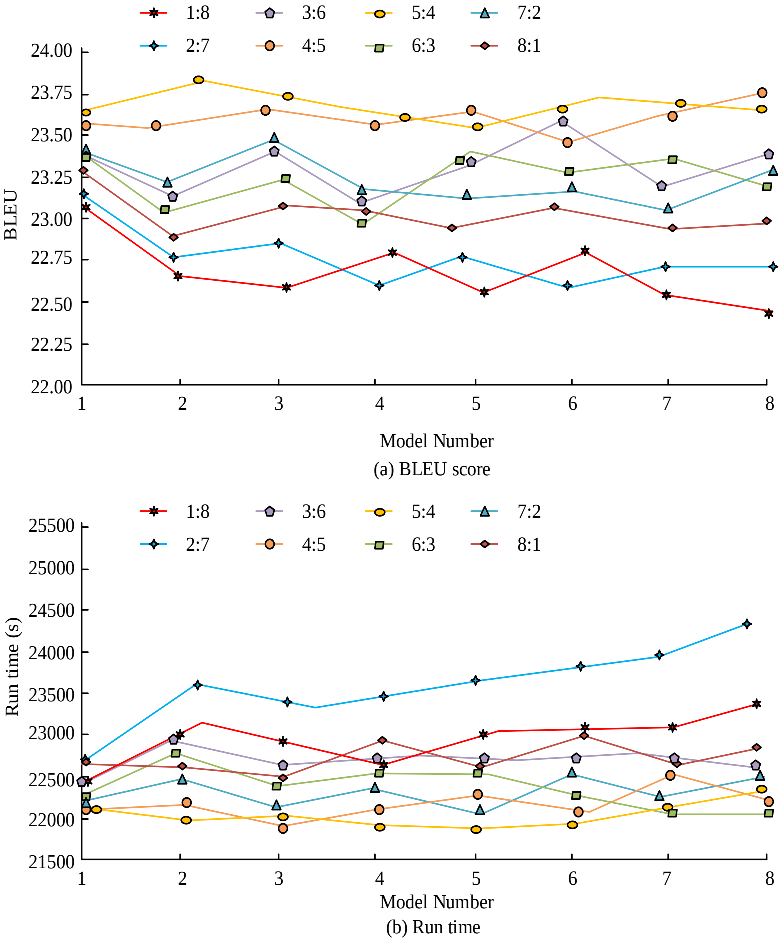
IV. Application Analysis of English Language Scenarios Based on Machine Translation Language Modeling

This section's primary goal is to validate the advanced nature of the model utilized in the current study by conducting an experimental analysis of the model and comparing and analyzing the impact of model translation. Second, in order to confirm the model application effect even more, experiments are conducted to confirm the translation effect of the model currently in use in various circumstances.

A. *Machine Translation Model Effect Analysis*

The study uses the WMT-20 English dataset published by MT Association for data processing. The size of the test set in this dataset is 7.9k and the size of the training set is 3.0 M. The processor used for the simulation model of the data used is Intel i9-10920X, the operating system is selected as Ubuntu 20.04, the size of the RAM is 64GB, the graphics card is selected as RTX3090, and the dimensionality of the word embedding is set to 512, and the dimensionality of the hidden layer is set to 2048. The attention and convolutional layers were analyzed in different ratios, and several different ratios were experimentally analyzed to find the best ratio. Eight different model comparison ratios are selected for the study. For example, the convolutional layer comparison attention module is 1:8, 2:7, 3:6, 4:5, 5:4, 6:3, 7:2, and 8:1. These eight attention ratios are compared to get the model ratio training parameter data as shown in Table I. The evaluation index is evaluated with the score of bilingual evaluation understudy (BLEU), which is the evaluation index of MT results, and its score is able to evaluate and analyze the MT model. Comparison of different proportions of the model effect is obtained as shown in Fig. 8.



(a) BLEU score

(b) Run time

Fig. 8. Comparison of running speed and BLEU values of models with different scales.

In Fig. 8(a), in several model ratios when the number of convolutional and attentional layers are closer to each other, the BLEU value of model performance is larger, which indicates that when the number of layers of convolutional and attentional layers are closer to each other the model performance results are better, so that the highest BLEU mean value of the model with the ratio of 4:5 and 5:4, respectively, is 23.48 and 23.67. Comparing the lowest ratio model 1: 8 mean value of 22.67, it is higher by 0.81 and 1.00 respectively. In Fig. 8(b), in the running time comparison, the closer the ratio is to its performance, the shorter the running time is, the shortest running time is 5:4 ratio at this time the average running time is 22065s, the highest running time is 2:7 running time average is 23587s, the difference between the two ratios of the model running time is 1522s. It can be seen that the closer the ratio of the two modules is to each other, the better the model's effect is. This might be because the attention model runs faster in terms of parameter values and gives the model a higher dimensionality, which translates into a shorter running time. To examine how the number of attention layers affects the model's data processing effect, a variety of distinct attention layers were examined and tested, yielding the comparison parameters displayed in Table I

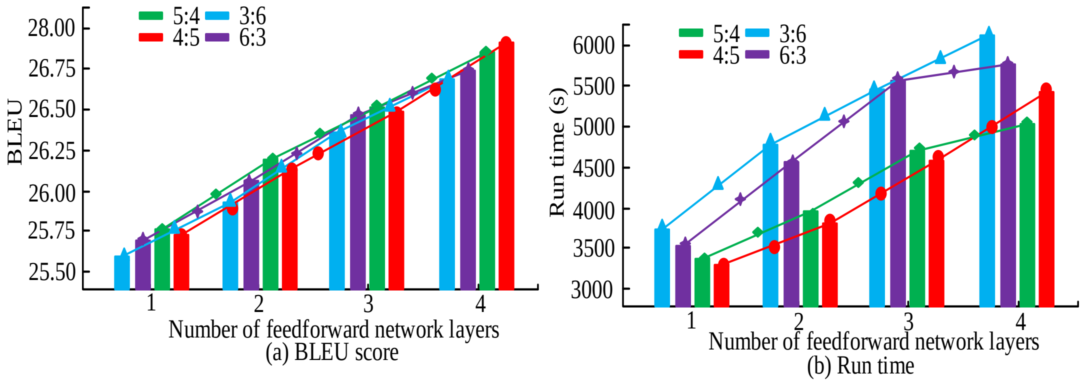
The model's parameter values, BLEU values, and running time all grow as the number of attention layers does in Table I, suggesting that while adding more attention layers can improve the model's MT index, doing so also lengthens the model's computation time. This suggests that increasing the attention model to boost the model's efficiency is not feasible after the number of layers is chosen and at the same time, the running time and the running efficiency of the model need to be taken into account, so as seen in the figure, the relatively better number of attention layers is 3, and the running time of this layer is 22548s, which has a relatively shorter running time, and at the same time, the BLEU value is at a higher value. To analyze the effect of feedforward network on the model effect, choose the above model in which the attention layer and convolutional layer are close to each other, 3:6, 6:3, 4:5 and 5:4 these four models are compared and tested, and the different feedforward network layers are analyzed to get as shown in Fig. 9.

The BLEU value of the model in Fig. 9(a) increases as the feedforward layers increase, but the four models' BLEU values change relatively little from one another. The model with the ratio of 5:4 has a larger overall change in BLEU value, but the model as a whole joins a feedforward network and its BLEU value does not change significantly. This may be due to the different ratios of the models and has little effect on how many feedforward layers are added. As the feedforward layers is increased, as shown in Fig. 9(b), the model's running speed rises and reaches its maximum when there are four feedforward layers. It can be seen that in the selection of feedforward layers, using higher feedforward layers has a good MT index but at the same time brings slower running speed, so it is more appropriate to choose 3 feedforward layers in the selection of feedforward layers. The parameter data, which shows the number of parameters used in the model during operation, will be compared with the data as shown in Fig. 10 to test the model's current use after adding various feedforward layers and pay attention to the model's effect. The larger the parameter data, the more parameters the model requires during operation, and the better the model's overall performance.

In Fig. 10(a), the parameter data of the model increases as the layers used in the model increases in several models, and the research uses the highest amount of model parameter data, which indicates that the research uses the model with the best results in model processing. The lowest value of the model parameter data for the FNN-only model indicates that the FNN-only model does not enhance the data processing of the model well. In Fig. 10(b), the model increases the running time with the increase of the model layers, and the running time of the research use model has relatively less time in the comparison of the five models, with an average time of 2854 s. The FNN-only model has the shortest running time, which might be because it can significantly cut down on the amount of time it spends using data parameters. In Fig. 10(c), the model used by the study has the highest BLEU value with a mean value at 29.65 and the model using only AM has the lowest BLEU value with a mean value of 21.84. The difference between the mean values of the two models is 7.81. In order to compare the effectiveness of the different algorithmic models with the method used by the study, the traditional statistical machine translation (SMT), rule-based machine translation (RBMT) and neural machine translation (NMT) are compared with the research use model obtained as shown in Table II.

TABLE I. COMPARISON OF DATA WITH DIFFERENT ATTENTION LEVELS

Model	Parameter values	BLEU	Run time (s)
Attention level 1	48756.00	20.65	19587.00
Attention level 2	50325.00	22.36	20549.00
Attention level 3	52364.00	23.54	22548.00
Attention level 4	55368.00	25.41	24596.00
Attention level 5	58642.00	27.54	25368.00



(a) BLEU score

(b) Run time

(a) Parameter data

(b) Run time

(c) BLEU score

Fig. 10. Comparison of data from different network models.

TABLE II. COMPARISON OF DATA FROM DIFFERENT MODELS

Data set	Model	Parameter data	BLEU	Run time (s)
Dataset 1	SMT	3654.00	22.58	2456.00
	RBMT	3685.00	22.98	2635.00
	NMT	4210.00	24.59	2678.00
	Transformer	4326.00	24.76	2754.00
	Research Use Model	4586.00	26.54	2448.00
Dataset 2	SMT	4256.00	21.65	2546.00
	RBMT	4365.00	22.68	2635.00
	NMT	4686.00	23.54	2485.00
	Transformer	4758.00	24.85	2635.00
	Research Use Model	4962.00	25.67	2483.00

In Table II, in dataset 1, the model used in the study has the largest parameter data size of 4586, which is 932 higher compared to the lowest SMT model of 3654. The BLEU value of the model also has the highest value of 26.54, which is 3.96 higher compared to the lowest SMT model. In the run time comparison, the model used in the study exhibits a lower runtime data compared to several models, as long as 2448s. This suggests that the study's model outperforms other models in terms of overall performance. Additionally, comparing the data in dataset 2, the model employed in the study has parameter data that is 706 times greater than the SMT model, a BLEU value that is 4.02 times higher, and the model with the shortest run time, 2483s, than the SMT model. This shows that the model used in the study has a better performance than the traditional models.

B. *Effectiveness of Machine Translation Modeling in Practice*

To test the effectiveness of the current research using the model in the application of English translation in multiple scenarios, English data from different scenarios are used, and data from three different scenarios such as legal application scenarios, news application scenarios, and speaking application scenarios are selected. 20,000 of these data are sampled and analyzed. The translation recognition accuracies of several traditional models in different scenarios in the previous subsection are compared and obtained as shown in Fig. 11.

In Fig. 11(a), the change in accuracy of several models used by the research in the legal application scenario increases gradually with the increase in the amount of data, after which it tends to a relatively stable state. The accuracy rate of the research-used model is higher among the five models, with the highest value of 95.6%, which is 3.1% higher relative to the smallest model, RBMT, at 92.5%. In Fig. 11(b), the accuracy of the models varies similarly to Fig. 11(a), with the research use model having a higher accuracy relative to the other models. The accuracy of the research use model is 95.7% higher than the accuracy of the SMT model 93.1% by about 2.6%. Similarly in Fig. 11(c) the accuracy of the research use model 96.5% is higher than the accuracy of the SMT model 93.2% about 3.3%. This shows that the research used model has higher accuracy and better modeling. Many scenarios are modeled and analyzed to produce the model test results displayed in Table III in order to assess the application effect of the research usage model in various English settings.

From Table III, in several models used, the study uses models in different scenarios with better MT effect higher indicators. Among them, the highest indicator value in the scenario of engineering analysis has 27.95, which is 6.90 higher compared to the lowest SMT model. Looking at different scenarios, the MT effect of the model in different scenarios varies, and some scenarios show higher indicator values, which may be due to the fact that the model in that scenario is more suitable for MT. To examine the MT effect of the currently used model in different scenarios, the translation indexes of several scenarios were compared as shown in Fig. 12.

In Fig. 12, the model's BLEU metrics changes in different scenarios all increase with the number of scenario samples, which may be due to the fact that more data samples can improve the model's translation efficiency during the training process. However, the news scene has the lowest metric value among several scene models, which may be due to the fact that the news scene contains more sentences and words about the emotional expression of the scene, which is more challenging for the MT. The model used in the study is able to translate ELs from different scenes and at the same time can achieve better translation results.

V. Discussion

In the bilingual evaluation scoring test, the actual running effect of the module is best when the ratio of convolutional and attention layers is 4:5 and 5:4, which may be due to the reason that adding more convolutional modules and attention layers can improve the running effect of the model. In the analysis of different attention layer parameters, the more attention layers the better the model runs, which may be due to the fact that adding more attention layers can improve the data processing effect and running efficiency of the model. However, the increase of attention layers also causes the model running speed to decrease, which indicates that the addition of attention layers needs to guarantee the running speed of the model. In the comparison of the different feedforward layers of the model, the higher the number of feedforward layers, the lower the running speed, but at the same time, the higher the running score of the model. This may be due to the fact that the addition of feedforward layers improves the model running effect but reduces the model running speed. Therefore, the study needs to select the appropriate run feedforward layer. In the comparison of the number of layers used in the model, the more the number of layers used in the model the larger the data parameters of the model, which may be due to the fact that the increase in the number of layers used enhances the loading of the model with the used parameters. Also using only a single network model is not effective in enhancing the efficiency of the model, this may be due to the reason that a single module is not effective in enhancing the model. The research use model has the highest BLEU value of 29.65, which indicates the reason that the research use model enhances the model effectiveness with the addition of different modules. In the comparison of the models of different methods, the research use model has the largest data parameter content of 4586, the highest BLEU value of 26.54, and the shortest running time of only 2448 s. This may be due to the fact that the research use model adds more modules to enhance the model running efficiency and parameter loading. This is similar to the results obtained by Shao M et al. [20]. In the practical application, the running time of the research use model can reach up to 95.6%, which may be due to the fact that the research use model adds the attention mechanism to improve the accuracy of the model running. In the application of different scenarios, the research use model was able to run in different scenarios and the model's run-up scores were all at high values, which may be due to the addition of the meta-learning module.

In summary, the research use model showed better model capabilities in model run effectiveness, run time and translation scores. This indicates that the model used in the study has a good prospect for practical application in English translation in multiple scenarios. However, the research can also consider integrating multimodal information, such as pictures and videos, in the model to combine visual and textual information to improve the accuracy of translation and semantic understanding. Meanwhile, on the basis of English multi-scene translation, the model's multi-language translation ability can be further investigated. And the existing models may have the problem of context incoherence when dealing with long text translation. The introduction of a global context mechanism can be explored to enhance the coherence and accuracy of the model in long text translation, thus improving the user experience. Therefore the use of the model in English translation may have good practical application ability and can provide better research value for English translation in multiple scenarios. It also has a better guiding significance for English translation and English learning in multiple scenes.

VI. Conclusion

The study suggests a new model based on MT and primarily addressed the issue of multi-scene application in English translation today. To enhance the translation effect of the model, the new model used BERT and CRF to extract words from the English scene's starting words. The results of the study showed that the 4:5 and 5:4 models had the highest BLEU mean values of 23.48 and 23.67, respectively. This was 0.81 and 1.00 higher than the lowest model, the 1:8 mean value of 22.67. The shortest run time was the 5:4 ratio at this point in time with a run time mean value of 22065s and the highest run time was the 2:7 run time mean value of 23587s. The number of attention layers where the model works better was 3. The run time for this layer was 22548s and the BLEU value was at a higher value. The highest mean BLEU value for the model used in the study was 29.65. The largest parameter data size for the model used in the study was 4586, which was 932 higher compared to the lowest SMT model 3654. The BLEU value for the model used in the study was also the highest at 26.54, which was 3.96 higher compared to the lowest SMT model. The research use model had a higher accuracy among the five models, with the highest value of 95.6%, which is 3.1% higher compared to the smallest model RBMT with 92.5%. It can be concluded that the model used in the study is able to translate EL for different scenarios very well, and its performance is also better than the traditional MT model. Although the study has achieved a lot of results, there are still many problems, such as the data used in the study is relatively small, more and larger data will be analyzed in the future, and different decoders will be added in the subsequent study to achieve further improvement of the model. The decoder may affect the broad applicability of the system in diverse scenarios when the system is dealing with more complex syntactic structures or rare words. Therefore subsequent research will explore the applicability of the system. Finally the research system may also suffer from computational complexity leading to high deployment and maintenance costs of the system in certain application scenarios. Therefore subsequent research will further reduce the system operating costs.

Detecting Malware of Windows OS Using AI Classification for Image of Extracted Behavior Features

Kang Dongshik, Noor Aldeen Alhamedi
University of the Ryukyus, Okinawa, Japan

***Abstract*—Malware detection is crucial for protecting digital environments. Traditional methods involve static and dynamic analysis, but recent advancements leverage artificial intelligence (AI) to enhance detection accuracy. This study aims to improve malware detection by integrating dynamic malware analysis with AI-driven techniques. The primary challenge addressed is accurately classifying and detecting malware based on behavior extracted from isolated virtual machines. By analyzing 50 malware samples and 11 benign programs, we extract ten behavioral features such as process ID, CPU usage, and network connections. We employ text-based classification using feedforward neural networks (FNN) and recurrent neural networks (RNN), achieving accuracy rates of 56% and 68%, respectively. Additionally, we convert the extracted features into grayscale images for image-based classification with a convolutional neural network (CNN), resulting in a higher accuracy of 70.1%. This multi-modal approach, combining behavioral analysis with AI, not only enhances detection accuracy but also provides a comprehensive understanding of malware behavior compared to competing methods.**

***Keywords*—Malware analysis; dynamic-based analysis; image classification; malware behavior extraction; text**

I. Introduction

Recently, the number, severity, sophistication of malware attacks, and cost of malware inflicts on the world economy have been increasing exponentially. Attacks with these kinds of software have disastrous effects and cause considerable material damage to individuals, private companies, and governments' assets. Thus, malware should be detected before damaging the important assets in the company [1]. The primary motivation for this research stems from the need to enhance existing detection mechanisms to keep pace with the constantly changing threat landscape. With traditional analysis methods, we aim to significantly improve the detection and classification accuracy of malicious software. One of the key advantages of our approach is the combination of dynamic-based malware analysis with AI-driven techniques. This allows for a more comprehensive understanding of malware behavior. This hybrid approach not only improves detection rates but also enhances the ability to accurately classify and understand the nature of malware.

There are two main techniques for analyzing malware static and dynamic-based analysis. Static-based analysis examines the malware code without actually executing it. This by integrating advanced artificial intelligence (AI) techniques can provide information about suspicious functions, network activity, impacted files, etc. Dynamic-based analysis executes the malware code in an isolated environment to observe its runtime behavior. This provides insight into the full impact of the malware. A key benefit of static-based analysis is the ability to thoroughly inspect malware code using techniques like disassembly and decompilation to identify suspicious functions related to replication, propagation, payload activation, and more [2]. The static techniques help reveal overall structure, dependencies, triggers for malicious events, and obfuscation attempts. However, lacking runtime behavior, static-based analysis cannot confirm the real impact of suspected capabilities. Complex packing or encryption techniques also limit code inspection. Other hand, the dynamic-based analysis provides direct observation of malware behavior in action by executing it and monitoring the resulting activity.

Dynamic-based analysis confirms suspected functions based on static clues and captures full infection chains showing the progression and end objectives of malware according to case studies by [3]. Dynamic monitoring of memory access, network calls, system API usage, and more creates a comprehensive picture. Additionally, dynamic-based analysis is particularly effective in identifying and analyzing newly emerging malware strains. As it focuses on the runtime behavior, it is better equipped to handle polymorphic and metamorphic malware that may change its form to evade static-based analysis techniques. Leveraging AI models for the analysis of malware code or the study of malware behavior has significantly contributed to the detection of malware in recent years. Numerous AI models have been integrated into static or dynamic approaches to augment both the malware detection rate and feature extraction processes. Despite the notable progress in the field of AI, these models still face various challenges. This research will use many models of AI to detect malware.

Robust malware analysis faces numerous obstacles. The sheer volume of malware proliferating at a rapid pace presents a formidable challenge in comprehensively examining this ever-expanding threat landscape. Additionally, malware authors employ sophisticated obfuscation tactics, such as code interchange, amalgamation, register reassignment, null insertion, and subroutine reordering [3], purposefully designed to evade detection by anti-malware systems. Despite decades of development, these security solutions still exhibit high false positive rates, undermining their accuracy.

Moreover, certain malware strains possess the ability to identify virtualized environments, resulting in altered or ceased execution, hindering effective analysis. The evasion techniques employed by malware necessitate lengthy detection times, potentially ranging from minutes to hours depending on the specific malware variant, during which systems remain vulnerable to compromise. Furthermore, the ambiguity surrounding API calls, as both malicious and benign software may legitimately invoke common APIs, complicates the process of distinguishing malware based on API usage patterns.

These factors, including the immense scale, obfuscation methods, virtual environment detection capabilities, delayed identification timelines, and the dual usage of APIs, collectively contribute to the arduous nature of robust malware analysis, necessitating the development of advanced techniques to overcome these challenges effectively. The juxtaposition of text classification and image classification in the analysis of extracted behavior. It underscores that a nuanced understanding of program nature, distinguishing between benign and malicious entities, can be achieved through thorough behavior analysis. The model primarily relies on the extraction of malware features. Within the developed script, two distinct observers play a crucial role. The first observer extracts the entirety of the process, encompassing its characteristics, as well as details related to internet connections. The second observer is tasked with monitoring any file creation specifically linked to the malware. The experimental framework involves the extraction of 10 distinct features through the monitoring of behaviors within an isolated Virtual Machine. Python libraries such as psutil, subprocess, wmi, watchdog, time, json, and os were employed to develop functions responsible for observing malware behavior and subsequently extracting pertinent information to a JSON file. The extracted features encompassed critical aspects such as process ID, process name, username, CPU percentage.

II. Related Work

Artificial Intelligence (AI) has emerged as a powerful tool in this ongoing struggle to detect and classify malware offering advanced capabilities in identifying and mitigating malware threats.

In a study [4], the third paper analyzes different classical machine learning algorithms for malware detection - Random Forest, Support Vector Machine (SVM), grid search optimized SVM, and K-Nearest Neighbors (KNN). The goal is to validate the effectiveness of these models for detecting zero-day malware attacks. The dataset from Kaggle contained 19,611 PE files, with 14,599 malicious samples and 5,012 benign files with 77 numeric features. Three training/test splits were used. Various accuracy metrics were calculated: accuracy, F1-score, confusion matrix, precision, recall and Type I/II errors. Random Forest performed the best with 96% accuracy and 93% F1score, with low errors and fastest training time. Optimized SVM improved results significantly but slowed down execution. KNN also performed decently with simpler implementation. Analysis showed Random Forest has good prospects for realtime zero-day malware detection. The model can process 25,000 files per second. For deployment, more diverse input data covering different malware families is needed.

In study [5], the authors used convolutional neural networks (CNNs) for malware classification by visualizing malware programs as grayscale images. The images are generated from the bytecode of malware programs and classified using CNN architectures. They evaluate several well-known CNN models like AlexNet, ResNet, and VGG16 using transfer learning on a malware image dataset. They also propose a custom shallow CNN architecture that achieves 96% accuracy, but is faster to train than the other complex models. The customized CNN and transfer learning models are also tested as feature extractors, with the features fed into SVM and KNN classifiers. This achieves even better performance up to 99.4% accuracy. They set a new benchmark on the public BIG 2015 malware dataset. The proposed system combining CNN feature extraction + SVM classifier obtains state-of-the-art 99.4% accuracy in distinguishing between nine malware classes. Visualization and CNN-based classification is shown to be effective for malware detection. The approach is computationally efficient compared to static/dynamic-based analysis. Fusing different CNN model predictions can further improve performance.

In study [6], the authors used Support Vector Machines (SVMs) for malware analysis and classification. SVMs are supervised learning models that can analyze high-dimensional, sparse data and recognize patterns. The authors collect a heterogeneous malware dataset from a real threat database. The data has features like time, format, domain, and IP address. They visualize the dataset using techniques like scatter plots and radius visualization to understand correlations and structure before classification. An SVM model with a polynomial kernel is trained on the dataset to classify malware vs normal software. The model is validated using cross-validation, leave-one-out and random sampling. The SVM classifier achieves 93-95% accuracy, 97-98% sensitivity and 86-90% specificity on the malware dataset. Validation shows the model generalizes very well. The high-performance highlights that SVMs can effectively classify heterogeneous malware data gathered from computer networks and security systems.

In study [7], the paper proposes a deep learning framework for malware visualization and classification using convolutional neural networks (CNNs). The key aspects are: Malware files are converted into three image types - grayscale, RGB color, and Markov images. Markov images help retain global statistics of malware bytes. A Gabor filter approach is used to extract textures and discriminative features from the malware images. Two CNN models are used for classification – a custom 13-layer CNN and a pretrained 71-layer Xception CNN fine-tuned for malware images. The framework is evaluated on two public Windows malware image data sets, a custom Windows malware dataset, and a custom IoT malware dataset. Markov images provide the best results, with the fine-tuned Xception CNN achieving over 99% accuracy on multiple datasets. The computational efficiency is also better compared to prior works. The approach demonstrates effectiveness for real-time malware recognition and classification. The visualization and deep learning framework extracts features automatically without extensive feature engineering.

The framework's resilience against adversarial attacks is also analyzed by adding noise to test images. Some drop in accuracy is noticed, indicating scope for improvement. The current landscape underscores the significance of AI models as powerful tools for the analysis, classification, and detection of malware. These models can seamlessly integrate with both static and dynamic-based analysis, yielding noteworthy results that underscore their pivotal role in shaping the future of this field.

Arabo et al. [8] analyzed CPU and RAM usage patterns as potential indicators for detecting ransomware processes. Their findings suggested that while not the primary factors, monitoring CPU and RAM could complement other behavioral characteristics in identifying malicious processes. Regarding CPU usage, they observed variations that showed potential for distinguishing ransomware activities. Specifically, for the ViraLock ransomware sample, the maximum CPU usage peaked at 25% [1]. Such CPU spikes could potentially signify the initiation of encryption or other malicious operations by the ransomware. As for RAM consumption, the study found that ransomware samples generally exhibited low and relatively stable memory usage patterns. In the case of ViraLock, the maximum RAM usage was only around 2% [1]. However, the authors noted that while low RAM usage alone may not be a definitive indicator, it could be considered in combination with other behavioral factors. The researchers highlighted that while CPU and RAM usage showed some differences between ransomware and benign processes, the most significant distinguishing factor was abnormally high disk read/write activity [1]. Nonetheless, incorporating CPU and RAM monitoring alongside disk usage analysis could potentially enhance the accuracy and robustness of ransomware detection systems based on process behavior analysis.

III. Methodology

The current investigation is centered on the behavioral analysis within an isolated Windows environment in virtual machine for the purpose of detecting malware. To achieve this, a combination of Recurrent Neural Network (RNN) for text classification and Convolutional Neural Network (CNN) for image classification is employed to analyze the extracted data. Diverging from the methodologies outlined in previous studies [3], [6], and [7], the classification approach adopted here focuses on the inherent characteristics of the malware file itself. This is achieved through a comprehensive analysis of the malware binary file and, notably, by representing the malware file as an image utilizing various visualization techniques. In this research, the emphasis is on visualizing the malware's behavior and, subsequently, conducting analyses based on these visual representations and also analysis the extracted features as a text. The presented model offers a juxtaposition of text classification and image classification in the analysis of extracted behavior. It underscores that a nuanced understanding of program nature, distinguishing between benign and malicious entities, can be achieved through thorough behavior analysis.

The model primarily relies on the extraction of malware features. Within the developed script, two distinct observers play a crucial role. The first observer extracts the entirety of the process, encompassing its characteristics, as well as details related to internet connections. The second observer is tasked with monitoring any file creation specifically linked to the malware.

The experimental framework involves the extraction of 10 distinct features through the monitoring of behaviors within an isolated Virtual Machine. Python libraries such as psutil, subprocess, wmi, watchdog, time, json, and os were employed to develop functions responsible for observing malware behavior and subsequently extracting pertinent information to a JSON file. The extracted features encompassed critical aspects such as process ID, process name, username, CPU percentage.

The modules for this research were developed using TensorFlow and Keras, leveraging the Sequential model architecture. These tools enabled efficient construction and training of neural networks for malware detection, facilitating both text-based and image-based classification with enhanced accuracy through deep learning techniques. Fig. 1 shows proposed processing model.

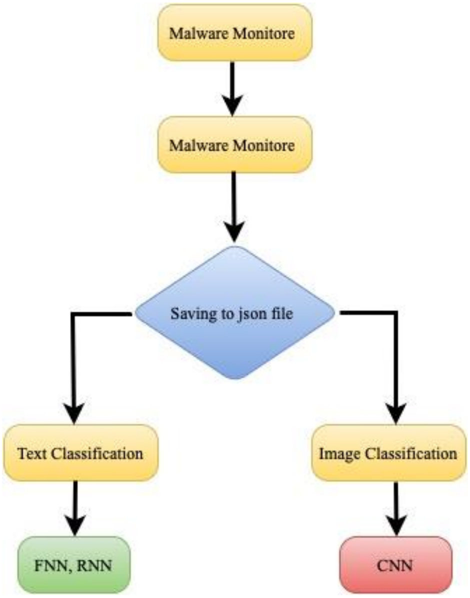

Fig. 1. Proposed processing.

Following the extraction of these features, the gathered information is stored in a JSON file (see Fig. 2) for further next step.

A. Text Analysis

The analytical process for the extracted features unfolded across two phases. Initially, the data underwent textual analysis, leveraging a simple feedforward neural network (FNN) model designed for binary classification using the Keras library to create a fully connected dense layer with 128 nodes. The output layer has 1 node and uses 'sigmoid' activation for binary classification. Subsequently, a recurrent neural network (RNN) model was employed to classify the same textual data, creates an embedding layer that transforms integer word indices to dense word vector representations.

B. *Image Analysis*

By transforming data into images, researchers can leverage the vast body of knowledge and advancements in image processing techniques, readily applicable to the analysis of the transformed data. This data-to-image transformation unlocks the power of CNNs for a wider range of analysis tasks, promoting deeper insights into complex datasets. So this research implements the power of CNN alongside with the behavior analysis Subsequent to the behavioral analysis, the extracted features underwent further evaluation through an image classification paradigm. A dedicated function was developed to transform these feature data into grayscale images. This transformative process involved the removal of associated labels, conversion of the data into binary numerical representations, subsequent transformation of these binary values into hexadecimal equivalents, and, finally, depiction of these hexadecimal values onto a 30*30 grayscale canvas.

The 30x30 size was empirically determined to balance information preservation and computational efficiency. Representing features as images enabled the utilization of convolutional neural networks (CNNs), which excel at capturing spatial patterns the extracted features underwent further evaluation through an image classification paradigm. This visual representation approach offered several key advantages. Firstly, it enabled leveraging powerful deep learning techniques like convolutional neural networks, adept at capturing spatial patterns invaluable for malware characterization. Secondly, transforming features into images facilitated uncovering intrinsic relationships and patterns obfuscated in the original data's raw representation. Thirdly, the image domain allowed seamless integration of transfer learning and pre-trained models, expediting the analysis process. Lastly, the visually interpretable nature of images could provide insights into the discriminative characteristics learned by the models, aiding explain ability. By combining dynamic monitoring with visual analytics, this multi-pronged approach offered a potent framework for comprehensive malware analysis and classification.

The dataset employed for experimentation comprised 50 instances of .EXE malware sourced from diverse families, obtained from the Malware Bazaar database, a freely accessible online repository. Additionally, 11 benign programs were included for comparative analysis. The monitoring process lasted three seconds for every malware instance, during which the monitoring code ran in the background, observing the processes and file creation activities of the malware. After the monitoring period, the code produced a JSON file containing the captured information. The dataset has been divided into 40 malware behavior and six benign program behavior for the training and 10 malware behavior and five benign program behavior for testing. Fig. 3 shows converting text to image process.

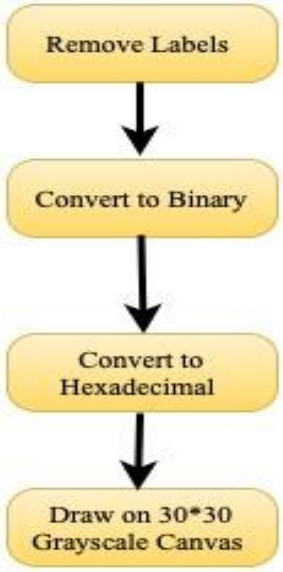

Fig. 3. Converting text to image.

IV. Experiments

A. *Text Analysis*

The described FNN model exhibited an accuracy rate of 56% with a corresponding loss rate of 0.78. For the RNN model: It takes the vocabulary size equal to 32 and output dimensionality as arguments. Also LSTM layer models the sequential nature and long-range context of text. The output dense layers act as classifiers on top of LSTM representations. The model is compiled with binary cross entropy loss, adam optimizer and accuracy metric.

With epoch 100, yielding an improved accuracy rate of 68% with a reduced loss rate of 0.67.

B. *Image Analysis*

Convolutional Neural Networks (CNNs) have revolutionized image analysis due to their ability to extract intricate spatial features. However, their power can be extended to non-image data by transforming it into a suitable image representation. This approach offers several advantages: CNNs excel at automatically learning relevant features from images, circumventing the need for manual feature engineering, a time-consuming and potentially error-prone step in traditional analysis. Data transformation allows for the visualization of complex relationships between data points within the image domain. This empowers CNNs to identify subtle patterns that might be obscured in the raw data format. The experiment was done using two suggested models. The first model (Fig. 5) is simple and the second model is more complex both models are based on CNN. The simple model consists of:

- Conv2D layer: Performs 2D convolution with 32 filters and 3x3 kernel. Extracts spatial features from input image.
- MaxPool2D: Max pooling layer reduces dimensions to summarize the features detected by the convolution layer.
- Flatten: Flattens the pooled feature map into a 1D vector to prepare for fully-connected layers.
- Dense layers: Fully-connected layers that act as classifier on top of the extracted features. 64 nodes in first dense layer.

Output layer contains single node with 'sigmoid' activation for binary classification. This model takes input images of shape (30, 30, 1) indicating 30x30 grayscale images. Using this simple model over these grayscale pictures gives accuracy rate 70.1% with loss 0.67.

The second model also based on CNN with more complex architecture: The model then uses several convolutional layers (Conv2D) to extract features from the image. These layers apply filters (also called kernels) that slide across the image, detecting patterns and edges.

The first Conv2D layer has 256 filters, each of size 3x3. As the filter slides across the image, it performs element-wise multiplication between the filter weights and the corresponding pixel values in the image. The results are then summed and passed through an activation function (relu in this case) to introduce non-linearity. This process helps identify low-level features like edges, corners, and simple shapes. The subsequent Conv2D layers follow the same principle but with a different number of filters (128 and 64 in this example). These layers extract progressively more complex features based on the lower-level features detected earlier.

MaxPooling2D layers are inserted after some convolutional layers. These layers downsample the feature maps by taking the maximum value within a specific window (2x2 in this example). This helps reduce the number of parameters and computational cost while potentially capturing the most important features. Fig. 4 shows sample representation of the resultant images.

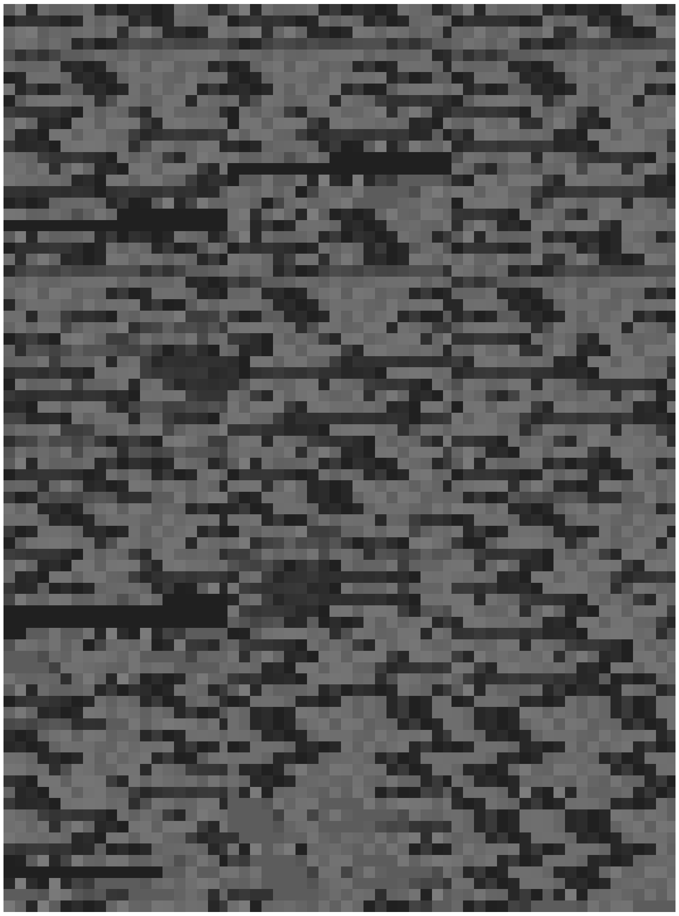

Fig. 4. A sample representation of the resultant images, offering a glimpse into their visual characteristics.

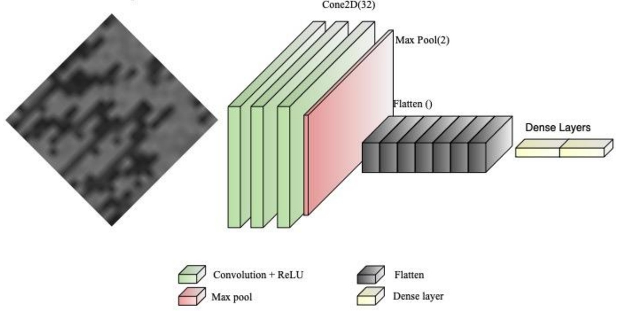

Fig. 5. The structure of the first model.

The Dropout layer (commented out) randomly drops a certain percentage (25% in this example) of activations during training. This helps prevent the model from overfitting to the training data by forcing it to learn more robust features.

After the convolutional and pooling layers, the model uses a Flatten layer to convert the 3D feature maps into a 1D vector (see Fig. 6). This allows the fully-connected layers to process the extracted features. The model then uses several fully-connected layers (Dense) to classify the image. These layers work similarly to traditional neural networks, where each neuron receives input from all neurons in the previous layer, performs weighted sums, and applies an activation function. The first three fully connected layers (4096, 2048, and 1024 neurons) are responsible for learning complex, high-level representations based on the extracted features. The relu activation allows these layers to learn non-linear relationships between the features.

The final Dense layer has only one neuron with a sigmoid activation function. This neuron outputs a value between 0 and 1, representing the probability of the image belonging to a specific class. As a summary of this model. The convolutional layers act as feature detectors, extracting progressively more complex features from the input image. The pooling layers reduce the dimensionality of the data while retaining important information. The dropout layer helps prevent overfitting. The fully-connected layers learn high-level representations and produce the final classification probability.

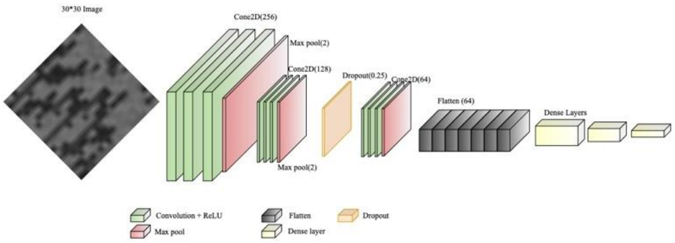

Fig. 6. The structure of the second CNN model.

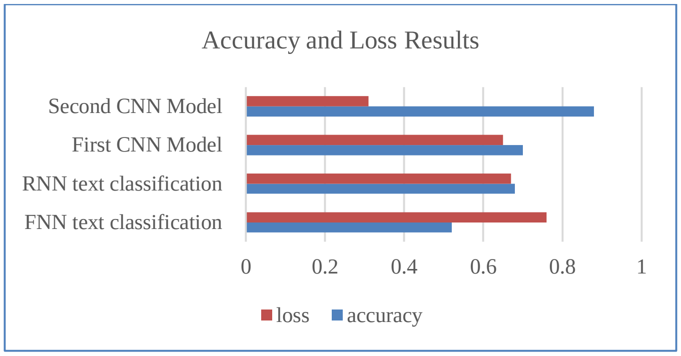

Fig. 7. Bar chart for accuracy and loss.

Using this complex model over these grayscale pictures gives accuracy rate 88% with loss 0.31. Comprehensive performance evaluation through bar charts (Fig. 7) illustrates accuracy and loss metrics for both text and image classification. The findings suggest that combining behavioral analysis with AI models, particularly in the image domain, holds promise for effective malware detection. This multimodal approach provides a holistic understanding of malware behavior, potentially enhancing overall detection capabilities in the evolving cybersecurity landscape. The study contributes to advancing malware detection methodologies by leveraging the synergy between static and dynamic analyses, bolstered by AI integration, and offers insights into the promising potential of image-based classification for improved accuracy in identifying malicious behavior.

The Second Model with numerous convolutional and fully-connected layers grants high capacity for learning intricate features. While advantageous for complex datasets, it can lead to overfitting, particularly with limited training data. The model memorizes training data too well, hindering performance on unseen examples. Furthermore, training and running this deep model can be computationally expensive due to the high number of parameters. This translates to significant processing power and memory requirements, potentially limiting its use in resource-constrained environments. The results from the text classification and image classification shows that these methods of analyzing malware might be a good way to detect the malware using the extracted behavioral features.

V. Conclusion

This study successfully employs dynamic-based analysis within a virtual machine (VM) to extract crucial behavioral features from Windows malware. Integrating these features with advanced text and image classification models (RNN and CNN) shows promise for malware detection. Image classification, based on transformed feature data, achieves a superior accuracy of 88% compared to 68% in text classification. This multi-modal approach, combining behavioral analysis with AI models, provides a nuanced understanding of malware behavior. To enhance model robustness, we recommend increasing the number of malware and benign samples, including a wider range of malware families, and exploring additional features like registry changes. Experimenting with different visualization techniques for image generation and testing more complex CNN architectures or pre-trained models with fine- tuning could further improve accuracy. Addressing adversarial attacks is crucial; incorporating noise resilience mechanisms is suggested for future work. These enhancements contribute to advancing malware detection methodologies, ensuring adaptability in the evolving cybersecurity landscape.

***Abstract*—The growing frequency of forest area fires poses critical challenges for emergency response, necessitating progressive solutions for effective navigation and direction planning in dynamic environments. This study investigates an adaptive technique to enhance the performance of autonomous robots deployed in forest area fireplace scenarios. The primary objective is to develop a hybrid methodology that integrates advanced studying strategies with optimization techniques to enhance route planning beneath unexpectedly changing situations. To reap this, a simulation-based total framework became hooked up, in which self-reliant robots were tasked with navigating diverse forest fire eventualities. The method includes schooling a model to dynamically adapt to environmental modifications at the same time as optimizing direction choice in real time. Performance metrics together with direction efficiency, adaptability to obstacles, and reaction time been analyzed to assess the effectiveness of the proposed solution. Results indicate an enormous improvement in path planning performance as compared to traditional methods, with more suitable adaptability main to faster response instances and extra effective navigation. The findings underscore the functionality of the proposed method to cope with the complexities of forest area fire environments, demonstrating its potential for real-world applications in disaster response. The results are shown in the conceived DRL-PSO framework where execution time is reduced up to 95% and the success rate of 95 % for the proposed method compared to the conventional ones. Python is used to implement the proposed work. Compared to the proposed method's execution time of 68. 3 seconds and the highest success rate among evaluated strategies, so it can be used as a powerful solution for autonomous drone navigation in dangerous situations. In the end, this research contributes precious insights into adaptive route planning for self-sufficient robots in unsafe situations, providing a strong framework for destiny advancements in disaster management technologies.**

Keywords*—Adaptive path planning; deep reinforcement learning; disaster environments; drone rescuing; particle swarm optimization; forest fire

I. INTRODUCTION

As a result of climate change and human activity, forest fires have become more severe and frequent threats posing serious threats to human safety and ecosystems These flames spread rapidly, and their unpredictable nature necessitates using state-of-the-art technological solutions for efficient monitoring and rescue efforts RL) using those tasked with rescuing people in active forest fire situations The platform offers a new approach develop a flexible system for drones by using fire detection information and real-time data to inform and optimize the autonomous drone approach planning processes [1]. Drones can operate safely and effectively in a dangerous environment thanks to fire detection data, which provides vital information about fire locations and severity spread. Path planning is important in robotics, with the aim of determining the optimal path of material movement from start to finish, which can be used in aerospace, military, manufacturing, agriculture. A subset of autonomous guidance requires dynamic decisions as a robot moves forward toward its goal. Recent advances in participatory navigation and UAV technologies highlight their high scalability, scalability and adaptability for various applications such as search and rescue [2], agriculture, and inspection. UAVs are designed to operate without human intervention, making them ideal for projects such as visual inspection of large buildings. An important approach in this area is Coverage Path Planning (CPP), which focuses on efficient, collision-free paths that cover all important paths in an area Path planning can be offline, online, or hybrid, in which online channels are important for dynamic, unfamiliar environments and where robots must continuously collect and process distance data to safely navigate Challenges such as optimal, collision avoidance Method a three-dimensional planning is adopted in UAVs often using global solutions for complex problems and local solutions for dynamic constraints visibility graphs, fast searching random trees, probabilistic routing, . algorithms There are, although reasoning methods do not always find the best methods [3].

Intelligent transportation systems (ITS) [4] are aimed at increasing road capacity, reducing accidents, improving efficiency and reducing congestion, as well as reducing energy consumption and environmental impact Vehicles as it automatically develop key components of the ITS, including environmental concepts, road design, tracking and monitoring. The key to participatory transportation planning is to identify efficient, collision-free routes from the starting point to the destination [5]. Various path-planning algorithms have emerged, including geometric, graph search, intelligent bionic, artificial potential field, and sampling-based algorithms like RRT and probabilistic roadmap, which excel in complex environments. Traditional RRT methods focus on finding paths but lack efficiency in convergence, search speed, and path optimality. Improvements like Biased RRT, Bi-RRT, RRT-connect, and RRT address these issues but often neglect vehicle-specific constraints. For dynamic environments, algorithms like potential field combinations and enhanced Bi-RRT adapt paths in real-time, accounting for dynamic obstacles. Recent advancements integrate reinforcement learning and heuristic methods to enhance RRT-based planning for smooth, collision-free paths in complex scenarios [6]. Path optimization techniques such as cubic B-splines, Dubins curves, and path pruning further refine paths, though challenges remain in maintaining curvature consistency and minimizing control difficulty. Disaster events like fires, floods, and landslides demand urgent and efficient rescue measures to minimize economic losses and threats to human life. Drones have become essential in disaster rescue, offering advantages such as 3D map reconstruction, emergency mapping, and environmental assessment. Multi-drone systems are particularly useful in complex terrains where traditional rescue methods struggle. However, effective mission planning for drones involves addressing environmental challenges and drone performance constraints. Heuristic algorithms like genetic algorithms (GA) and particle swarm optimization (PSO) are commonly used for mission planning but face issues like slow convergence and local optima. To overcome these limitations, this paper proposes improved GA and PSO algorithms for mission planning in complex 3D environments [7].

Autonomous vehicle systems, especially mobile robots, and autonomous vehicles have received considerable attention and commercialization, especially in the field of logistics and services in the service industry. The widespread use of reinforcement learning is limited by long training periods and limited computational resources Despite the advantages of DRL, such as intensive learning and large sensor dependence reduced, training in challenging environments is time-consuming and can lead to poor performance due to localized practice played a role. The high-quality research on DRL-based active obstacle avoidance and road systems from 2018 to 2022, identifying gaps and proposing future research directions to improve safety , efforts, and potential growth in this field [8]. Existing systems for route planning in autonomous robotic and mobile systems exhibit several shortcomings. Traditional RRT methods work well for challenging terrain but perform poorly in speed matching and road optimization, with enhanced versions such as Bi-RRT and RRT-Connect often ignoring vehicles specifically limited. They struggle with slow convergence and local change. Heuristic algorithms such as GA and PSO also face problems of slow convergence and local adaptability, especially in complex 3D environments. DRL methods, although powerful, have long training times and high computational resource requirements and result in poor performance due to localized action execution AMRs, although simpler than AGVs, need to be limited by movement in for safety, and limits their operating range. The proposed DRL model addresses these issues by using real-time data for informed decision-making, integrating DRL into advanced road planning processes to increase efficiency and safety, and DRL and integrating PSO to improve robustness and performance This approach ensures flexibility and resilience scenarios are appropriate, and achieves high accuracy and reliability through the traditional DRLC limitations of training time and estimation by the effortful handling.

The major key contribution are as follows:

- The study introduces a novel hybrid approach combining Deep Reinforcement Learning (DRL) with Particle Swarm Optimization (PSO), enhancing the efficiency and adaptability of independent robots in navigating complicated, dynamic catastrophe environments.
- The proposed approach permits real-time adaptation to unexpectedly changing environmental situations and obstacles normally determined in disaster zones, improving the robots' capacity to make well timed and optimal decisions
- The research contributes to multi-agent structures through demonstrating how multiple independent robots can collaborate successfully to gain common desires, which includes search-and-rescue operations, by leveraging DRL and PSO coordination abilities
- The model optimizes computational aid utilization through the integration of DRL and PSO, permitting robots to carry out path-making plans with decreased computational overhead while retaining high-performance stages.

The research validates the model by using the simulations in practical dynamic disaster environments, showing extensive enhancements in pathfinding efficiency, robustness, and undertaking of entirety in comparison to traditional techniques.

The proposed research is arranged as follows: The current models are reviewed in Section II. In Section III, the drawbacks of the existing frameworks are briefly reviewed. In Section IV, the proposed approach and methodology are addressed in detail. Section V discusses the result and finally, Section VI presents the conclusions of this study.

II. Related Work

Yao et al., [9] address the complex mobility constraints faced by autonomous robots operating in greenhouse environments. Their research highlights the need for accurate mapping, precise localization, and robust road planning specifically tailored to the challenges of agricultural conditions. A key aspect of their approach is the development of a centralized hardware system that integrates multiple sensors. This integration aims to effectively reduce the environmental impact that occurs in a greenhouse environment, thus increasing the reliability of the entire system. The concept of their innovations is to deal with modules for restoration role in the LeGO-LOAM system. These modules play an important role in improving the accuracy of pose estimation by significantly reducing the absolute pose error (APE) to 24.42%, as shown in their experiments Furthermore, their Enhanced OpenPlanner features sophisticated algorithms that it covers important factors in the cost of agricultural products A hysteresis strategy has been introduced to ensure stable variation, and contributes to improved operational efficiency. Although the findings show promise in greenhouse applications, many challenges remain. Scaling up their solutions to larger farms poses a significant barrier. However, this study faces challenges such as handling dynamically changing greenhouse environments, limited real-world testing, and dependency on structured infrastructure. Localization remains problematic due to unreliable GPS in indoor settings, and the system's computational demands may restrict deployment on low-cost robotic platforms, limiting overall flexibility and scalability. Addressing these challenges will be crucial for their proposed system to be widely adopted and effective under agricultural conditions.

Kiani et al. [10] delve into the complex demanding situations of direction-making plans and dynamic impediment avoidance for Unmanned Surface Vehicles (USVs) running within maritime environments. Their studies introduce a revolutionary vehicle-obstacle avoidance methodology employing the Ant Colony Algorithm (ACA) and Clustering Algorithm (CA). This method dynamically adjusts seek parameters to optimize direction planning performance via adapting to the complexities of the surroundings. A key characteristic of their approach is the law and smoothing of the dynamic search path, which efficaciously minimizes route period and turning angles, as evidenced by their simulation outcomes throughout diverse impediment distributions. Despite demonstrating successful direction planning abilities, the sensible implementation of their technique faces sizeable computational challenges, especially in situations with congested maritime traffic. The real-time decision-making needs in such dynamic and complicated environments present barriers to the seamless integration and operational effectiveness in their proposed technique. Overcoming those computational hurdles could be essential for boosting the feasibility and reliability in their approach in real-international maritime programs.

In their comprehensive 2019 study Liu et al., [11] explore the intricacies of 3-d course planning for mobile robots in particular designed for agricultural environments. Their research specializes in the software of metaheuristic algorithms, inclusive of Incremental Gray Wolf Optimization (I-GWO) and Expanded Gray Wolf Optimization (Ex-GWO), geared toward correctly guiding robots via large and densely populated farmlands. The number one objective in their technique is dual-fold: first, to optimize route planning via minimizing computational overhead and aid utilization; 2d, to make certain sturdy obstacle avoidance talents. Through rigorous simulations, Liu et al., Exhibit promising outcomes, highlighting the Ex-GWO algorithm's outstanding fulfillment with a 55. 56% fulfillment in optimizing path prices. Despite those improvements, big demanding situations stay. Adapting those algorithms to diverse agricultural terrains poses hurdles, as does ensuring well timed responsiveness to dynamic limitations encountered in practical area operations. Addressing those challenges is vital to decorate the versatility and reliability in their technique for real-global agricultural packages, in the end paving the manner for greater green and effective robotic operations in complex agricultural landscapes.

In their latest suggestion, Wu and Low [12] the Adaptive Path Replanning (APReP) technique designed specifically for drones navigating thru dynamic city environments. Their technique innovatively categorizes various sorts of dynamic environmental adjustments and develops tailor-made strategies for green path replanning, suitable for each single and multi-drone missions. Central to their technique is the discrete rapidly exploring random tree algorithm, meticulously designed to generate paths that align with the discrete traits of city landscapes. Extensive validation through simulations underscores the effectiveness of their techniques in addressing the problematic challenges posed by way of large-scale city dynamics. Their method demonstrates strong overall performance in managing more than one dynamic changes, thereby improving adaptability and operational reliability in complex city situations. However, essential challenges continue to be, consisting of the need to improve coordination amongst more than one drones and ensure real-time responsiveness to sudden environmental fluctuations. These regions call for similarly refinement to decorate the general efficiency and applicability of the APReP approach for optimizing drone operations in dynamic city settings.

Chang et al., [13] propose to further enhance the dynamic window method (DWA) for path planning of mobile robots in unknown environments, using Q-learning and their study focuses on the analytical application of DWA preparing and carefully defining conditions and work environments towards enabling global logistics operations. By integrating Q-learning, their approach facilitates adaptive changes at scale in response to real-time environmental feedback, increasing efficiency and success rate high in complex unfamiliar processes Limitations such as the need for adequate training data to ensure and ongoing learning processes. Addressing these challenges is essential to improve the reliability and applicability of their enhanced DWA methods in real-world scenarios, and paves the way for more efficient and adaptable transportation systems in different environments. However, the implementation faces hurdles such as the requirement for substantial training data and ongoing learning processes to ensure sustained adaptation to evolving environmental dynamics in practical applications. Addressing these challenges is crucial to furthering the reliability and applicability of their enhanced DWA approach in real-world scenarios, paving the way for more effective and adaptive autonomous navigation systems in diverse and dynamic environments.

Zhuang et al., [14] presented a sophisticated design of collaborative routing systems for autonomous underwater vehicles (AUVs) operating in dynamic environments Their approach is with global methods such as Legendre pseudo spectral the use of access to efficiently plan inconsistent paths in steady state It is designed to connect the points, which provided secure access between the control nodes A key feature of their design is real-time integration of design strategies, including local restructuring strategies that take advantage of the differential flatness property of AUVs this provides rapid response to unexpected dynamic obstacles encountered during missions on. While their system proves effective in avoiding collisions in dynamic underwater conditions, challenges continue in scaling up to accommodate larger AUV crews and adapting them to withstand changes real-time in the environment with ease. While their framework proves effective in managing collision avoidance in dynamic underwater scenarios, challenges persist in scaling the approach to accommodate larger teams of AUVs and in enhancing its adaptability to cope seamlessly with real-time changes in environmental conditions. Addressing these challenges is crucial for advancing the practical deployment and operational efficiency of cooperative AUV missions in complex and evolving underwater environments.

Azizi et al., [15] introduces a new heuristic fire-hawk optimization algorithm that is called the FHO founded on consideration of; the feeding ecology of Whistling kites, Black kites and Brown falcons. These birds are termed Fire Hawks, special regarding the specific gestures they make to capture prey in nature, especially through the mechanism of setting free. It falls into conflict for the simple reason that nature, especially through the mechanism of setting free, Applying the described algorithm, a numerical It was conducted an investigation on 233 mathematical test functions ranging from 2 to 100 dimensions and total of 150 000 function evaluations were used for optimization. In contrast, there are alternative approaches where ten different classical and new metaheuristic algorithms were employed. The statistical aspects include the max, average, median, and deviation of 100 independent optimization runs Other statistical tests that were used were the Kolmogorov–Smirnov test, Wilcoxon test, Mann–Whitney test, Kruskal–Walli's test, and the Post Hoc test. The results obtained in the experiments confirm the superiority of the FHO algorithm compared to the other algorithms described in the literature. Moreover, two of the most recent CECs that are the bound constraint problems CEC 2020 and the real-world optimization problems including the mechanical engineering design problems CEC 2020 were considered for evaluating the performance of the FHO algorithm, which again clearly showed the enhanced performance of the optimizer over the other metaheuristic algorithms in literature. The performance of the FHO is also measured when solve the two actual size structural frames of 15 and 24 stories where the new method is better than the previously developed metaheuristics.

Obayya et al., [16] introduce an study devises an Improved Bat Algorithm with Deep Learning Based Biomedical ECG Signal Classification (IBADL-BECGC) approach. To accomplish this, the proposed IBADL-BECGC model initially pre-processes the input signals. Besides, IBADL-BECGC model applies NasNet model to derive the features from test ECG signals. In addition, Improved Bat Algorithm (IBA) is employed to optimally fine-tune the hyperparameters related to NasNet approach. Finally, Extreme Learning Machine (ELM) classification algorithm is executed to perform ECG classification method. The presented IBADL-BECGC model was experimentally validated utilizing benchmark dataset. The comparison study outcomes established the improved performance of IBADL-BECGC model over other existing methodologies since the former achieved a maximum accuracy of 97.49%.

In recent years, many metaheuristic algorithms have attempted to explore feature selection, such as the dragonfly algorithm (DA). Dragonfly algorithms have a powerful search capability that achieves good results, but there are still some shortcomings, specifically that the algorithm's ability to explore will be weakened in the late phase, the diversity of the populations is not sufficient, and the convergence speed is slow. To overcome these shortcomings, Chen et al., [17] propose an improved dragonfly algorithm combined with a directed differential operator, called BDA-DDO. First, to enhance the exploration capability of DA in the later stages, we present an adaptive step-updating mechanism where the dragonfly step size decreases with iteration. Second, to speed up the convergence of the DA algorithm, we designed a new differential operator. We constructed a directed differential operator that can provide a promising direction for the search and then sped up the convergence. Third, we also designed an adaptive paradigm to update the directed differential operator to improve the diversity of the populations. The proposed method was tested on 14 mainstream public UCI datasets. The experimental results were compared with seven representative feature selection methods, including the DA variant algorithms, and the results show that the proposed algorithm outperformed the other representative and state-of-the-art DA variant algorithms in terms of both convergence speed and solution quality.

This literature review examines various optimization algorithms for self-sufficient systems in dynamic environments, highlighting their strengths and drawbacks. Yao et al. deal with mobility constraints in greenhouses however conflict with GPS reliability and scalability. Kiani et al. consciousness on impediment avoidance for Unmanned Surface Vehicles, going through computational challenges in congested maritime settings. Liu et al. optimize

3D path planning for agriculture but come across adaptability troubles in diverse terrains. Wu and Low broaden an Adaptive Path Replanning technique for drones however need to decorate multi-drone coordination. Chang et al. enhance the dynamic window approach for cell robots but require widespread training data. Zhuang et al. and Azizi et al. present collaborative systems and fire-hawk algorithms, respectively, facing scalability and comparative overall performance challenges.

III. Problem Statement

The current methods of autonomous navigation in dynamic environments including greenhouse, maritime, and urban environments have their shortcoming that affects their efficiency. Most approaches fail at some point to respond quickly and dynamically to time varying conditions that modify continually the environment of execution, which leads to a decrease in the level of the process performance and an increase in the total time required for the process execution [18]. However, there are several disadvantages to some of these approaches, for example, the computational problems as well as the requirement of access to large amounts of training data. The avoidance of the obstacles in the traditional systems may not address well the dynamic and unpredictable scenarios hence higher collision rates and reduced success rates in the real world. Some of the challenges previously avoided include; lack of real time adaptability [19], inefficient routing and poor or non-existent obstacle avoidance which the proposed work that incorporates DRL integrated with PSO will be able to overcome since it offers real time adaptability, improved routing and obstacle avoidance in a dynamic disaster environment.

IV. Integrated Framework for Adaptive Path Planning Using Deep Reinforcement Learning and PSO in Dynamic Forest Fire Environment

In the proposed study, the integrated framework for adaptive path-making plans combines Deep Reinforcement Learning (DRL) and Particle Swarm Optimization (PSO) to navigate an unmanned device via dynamic wooded area fire surroundings. DRL plays a vital role in real-time decision-making, permitting the system to analyses premiere navigation techniques by interacting with the environment. This learning system adapts the gadget to unpredictable changes, which include the spread of the fire or new boundaries. Through DRL, the machine receives comments from the environment, updating its rules for more secure and efficient navigation. PSO enhances DRL by optimizing the decision-making technique in complicated multi-objective situations. Its quality-tunes the navigation route by balancing exploration (searching new paths) and exploitation (utilizing best-recognized paths). PSO is especially effective in continuously adjusting key parameters, like averting fire-prone areas while aiming for a target region. The aggregate of DRL's learning capabilities and PSO's optimization guarantees that the system learns the best techniques but additionally correctly adapts to actual-time adjustments in the surroundings. By integrating these procedures, the framework dynamically adjusts to the evolving nature of forest fires, offering a strong and adaptive solution to complicated navigation challenges, and making sure safe and well-timed response in fire management eventualities.

Fig. 1. Integrated system for adaptive path planning of drones in dynamic forest fire environments.

Fig. 1 illustrates the comprehensive fire detection and drone navigation system integrates multiple components for effective emergency management. It processes fire data and real-time sensor inputs, utilizing Deep Reinforcement Learning (DRL) for decision-making and Particle Swarm Optimization (PSO) for dynamic path planning. The drone navigation system adjusts in real-time to avoid obstacles and changes in fire behavior, while performance evaluations ensure reliability and accuracy. Together, these technologies optimize fire detection and enhance response efficiency in dynamic environments.

A. Data Collection

The Fire Detection Dataset [20] available on Kaggle is vital to the proposed framework for adaptive path making plans of autonomous drones in dynamic forest fire environments. This dataset includes attributes along with the date, range, and longitude of hearth incidents, as well as the brightness temperature, scan width, track height, acquisition date and time, satellite and device information, detection confidence, dataset model, brightness temperature at 31 microns, Fire Radiative Power, and whether or not the fireplace changed into detected in the course of the day or night. In the proposed framework, this dataset serves multiple important features. Firstly, it enables specific identification and real-time tracking of hearth places and intensities via consuming and processing facts attributes to pinpoint the exact geographical places and characteristics of fires. The actual-time data processing module integrates those facts points with live sensor inputs from drones, making sure well timed and correct information flows into the gadget. The DRL module then makes use of this information to dynamically understand and adapt to the modern nation of the environment, learning surest navigation techniques to avoid hearth zones. The PSO algorithm similarly refines direction making plans by means of adapting routes in real-time based on fire intensity and spread styles, the usage of metrics like FRP and brightness to modify drone trajectories for secure and efficient navigation. Additionally, the dataset supports the performance assessment of the system, supplying floor truth data for assessing detection accuracy, response instances, and navigation success quotes. Thus, the Fire Detection Dataset is crucial for enabling the framework's sturdy and adaptive path planning competencies.

B. *Data Pre-Processing*

The preprocessing of the Fire Detection Dataset inside the proposed framework is a crucial step to ensure correct and powerful adaptive course planning for autonomous drones in dynamic wooded area fireplace environments. Initially, raw statistics from the dataset undergoes an intensive cleansing method, which incorporates managing lacking values, casting off duplicates, and correcting any inconsistencies. This step guarantees the integrity and reliability of the information. Next, the dataset is filtered to keep most effective the maximum applicable attributes, which includes date, latitude, longitude, brightness temperature, detection and Fire Radiative Power (FRP), which are essential for actual-time fireplace detection and tracking. Following the cleaning and filtering steps, the statistics is normalized to convey all attribute values right into a consistent variety, which aids inside the green processing and correct analysis via the gadget gaining knowledge of algorithms.

The temporal attributes like acquisition date and time are transformed into a standardized layout to facilitate time-series evaluation and monitoring of fireplace development over the years. Geographical coordinates are converted into a format compatible with the drone's navigation gadget, making sure of specific geospatial awareness. The preprocessed statistics is then integrated with real-time sensor information from the drones, merging static historical facts with dynamic, real-time inputs to offer a comprehensive and up-to-date photograph of the fire surroundings. This incorporated dataset feeds into the Deep Reinforcement Learning (DRL) module, which uses it to train and continuously update the navigation model, permitting drones to adapt their paths in response to actual-time hearth dynamics. By meticulously preprocessing the dataset, the framework guarantees that the drones have get right of entry to tremendous.

C. *DRL and PSO Integrated Workflow for Dynamic Disaster Navigation*

The DRL workflow of the proposed framework for adaptive route planning of autonomous drones in dynamic forest fire environment is designed to enable real-time decision making and optimal navigation Performance the process begins with a representation of environmental conditions, where Pre-processed fire detection data are used, with factors such as fire location, severity, spread, etc. are added, to explain the current situation S_t of the environment. This state S_t is a comprehensive snapshot of fire scenario at time t.

The DRL model employs a policy $\pi(a_t \,|S_t\,; \theta)$ parameterized by θ, which maps the state S_t to an action a_t, representing the drone's navigational decisions. The action a_t could involve moving to a new location, altering altitude, or performing a specific maneuver to avoid obstacles and optimize the path. The policy is typically modeled using a neural network, which is trained to maximize the expected cumulative reward R_t. The reward function R_t is designed to incentivize desirable behaviors, such as minimizing travel time, avoiding obstacles, and accurately reaching target locations. It can be defined in the Eq. (1)

$$R_t \;= \textstyle\sum_{k=t}^{T} \gamma^{k-t}\,\gamma_k \qquad (1)$$

where γ is the discount factor that prioritizes immediate rewards over distant future rewards, and γ_k represents the reward received at time k. The training process involves iteratively updating the policy parameters θ using gradient descent methods. One popular approach is the Q-learning algorithm, where the Q-value (Q(S_t , a_t ; θ) estimates the expected utility of taking action a_t in state S_t as illustrated in the Eq. (2)

$$\mathrm{Q}(S_t\,,\, a_t\,;\, \theta) = r_t\, + \gamma max_{\mathrm{a}'}\, \mathrm{Q}(S_{t\,+1},\, a';\, \theta) \qquad (2)$$

The drone interacts with the environment, collects experiences (s_t, a_t, r_t, S_{t+1}) and stores them in a replay buffer. The neural network parameters are periodically updated by minimizing the loss function as represented in the Eq. (3)

$$\mathrm{L}(\theta)\text{=}\mathrm{E}[(\, r_t + \,\gamma max_{a'}\, Q(S_{t\,+1}, a';\, \theta^-) \;-\; Q(S_{t\,+1}, a';\, \theta)\,)\,^2] \qquad (3)$$

where, θ^- represents the parameters of a target network, which is periodically synchronized with θ. PSO has been integrated to optimize the DRL design by evaluating several possible solutions, which will increase the efficiency and performance of the road system. This hybrid approach ensures that drones can dynamically adapt to changing fire conditions, travel safely, and make decisions in real-time accuracy, ultimately providing rescue operations effective in hazardous areas is effective.

D. *Particle Swarm Optimization (PSO) Workflow for Adaptive Path Planning*

The PSO workflow within the proposed framework for adaptive path planning of autonomous drones in dynamic forest fire environments plays a crucial role in optimizing navigation paths by simulating the social behavior of birds flocking or fish schooling. Each potential solution, called a particle, represents a candidate path for the drone, characterized by a position vector x_i in the solution space and a velocity vector v_i dictating the particle's movement. The position vector x_i denotes the drone's coordinates in the environment, while the velocity vector influences the path direction and speed adjustments.

The workflow begins with initializing a swarm of particles randomly distributed across the solution space. Each particle i has an associated position $x_i(t)$ and velocity $v_i(t)$ at time t, as well as a memory of its best-known position p_i (personal best) and the global best position g discovered by the swarm. The particles' velocities and positions are updated iteratively to explore the solution space and converge towards the optimal path. The velocity update rule combines three key influences: inertia, personal best, and global best, governed by the following Eq. (4).

$$v_i(t+1) = wv_i(t) + c_1r_1(p_i \,-\, x_i(t)) + c_2r_2(g \,- x_i(t) \qquad (4)$$

where w is the inertia weight balancing exploration and exploitation, $c_1\ and\ c_2$ are cognitive and social acceleration coefficients, respectively, and $r_1 and\ r_2$ are random numbers uniformly distributed in [0,1]. The new position of particle (i) is then updated by the Eq. (5).

$$x_i(t+1) = x_i(t) + v_i(t+1) \tag{5}$$

In the context of dynamic forest fire environments, particles represent various path trajectories for the drone. The fitness function evaluates each particle's position based on criteria such as distance to the target, obstacle avoidance, and fire intensity. The fitness function $f(x_i)$ can be formulated to minimize a combination of these criteria as shown in the Eq. (6).

$$f(x_i) = \propto d(x_i, target) + \beta \sum_{obstacles} \frac{1}{d(x_i, obstacles)} + \gamma \sum_{fire\ Zones} intensity(x_i) \tag{6}$$

where $\propto$, β and γ are the distance to the target, proximity to obstacles, and intensity of fire are weighting factors. Throughout the iteration process, particles effectively communicate with their individuality and update the global optimal position based on fitness checks. The DRL module readjusts the processes generated by PSO by optimizing production schedule changes and real-time adjustments. By combining PSO and DRL, the system uses the global search capability of PSO to find optimal path solutions and the learning capability of DRL to dynamically optimize and solve these paths in real time. This approach it is this synergy ensures safe and effective navigation for autonomous drones, unexpected and dangerous forest fires. It enhances their ability to conduct effective pursuit and rescue operations under different circumstances.

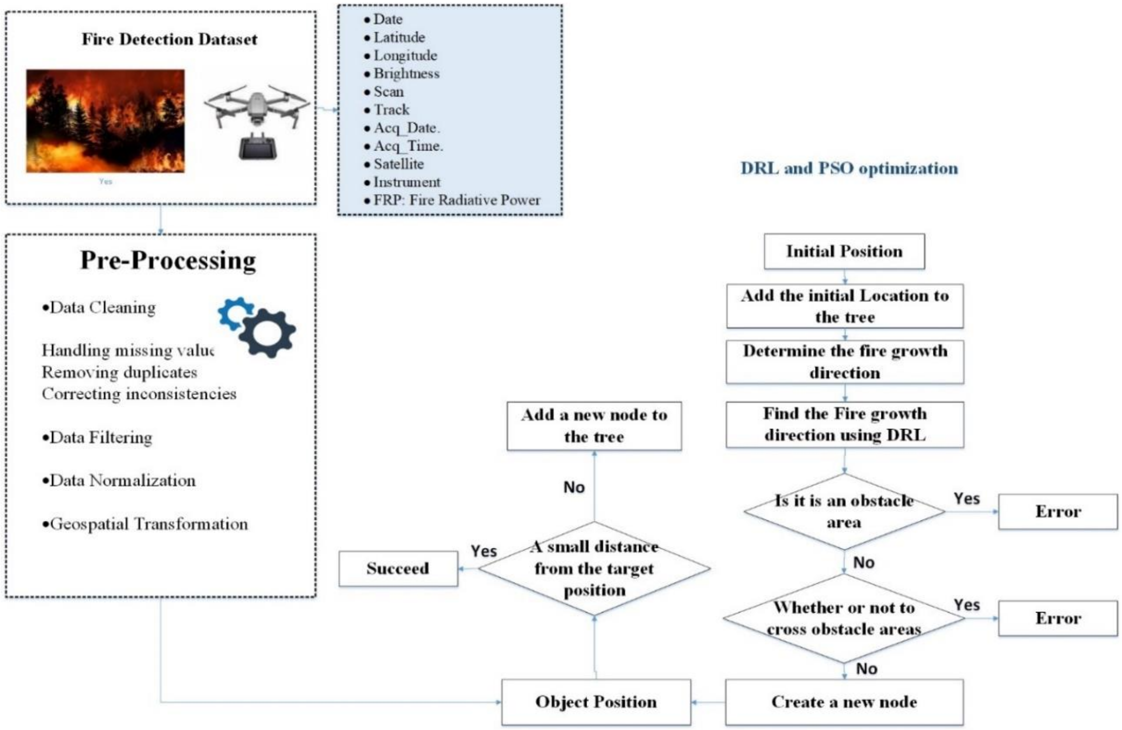

Fig. 2. Framework for adaptive path planning of autonomous drones in dynamic forest fire environments.

Fig. 2 shows a detailed schematic of adaptive strategies for autonomous drones in active forest fires. This form line is part of the dawn, and the in-depth reinforcing education is combined with an unhindered hybrid mindset, the form line begins with the fire detection team, which is required as a result of the, according to date, State changes, Light the, scan, panel, date and time of acquisition, satellite, instrument, and firelight power (FRP). During the Pre-Processing phase, the raw data goes through several important steps to ensure its accuracy and usability. Data Cleaning involves addressing missing values, removing duplicates and resolving inconsistencies. This is followed by Data Filtering which retains only relevant elements needed for analysis. Data normalization is performed to bring all feature values into a constant range that facilitates the efficiency of machine learning algorithms. Additionally, terrain modification adjusts the geographic information of the network to match the drone’s navigation pattern, resulting in more accurate geographical information.

The DRL and PSO Optimization phase is at the center of the design process, starting with determining the initial position of the drone. This first location is included in the tree structure for path planning. The system then uses a DRL that accurately determines the direction in which the fire is likely to spread and directs the growth of the fire. The algorithm checks whether this instruction leads to the Obstacle Area; if it does, an error is returned, otherwise it goes to the next test for checking. The process continues by checking if the new node is at a Small Distance from the Target Position. If it is, the process is marked as successful, indicating that the drone has effectively navigated towards the target position. If not, the new node is added to the tree, and the process iterates. This ensures that the framework continuously updates and optimizes the drone's path based on real-time fire growth predictions and obstacle detection. This comprehensive framework integrates multiple sophisticated processes to ensure efficient and effective path planning for autonomous drones in dynamic and hazardous forest fire environments. Trained CNN is tested on an independent dataset (the testing set) to evaluate its real-world performance.

V. Results and Discussion

The framework for adaptive route planning of autonomous drones in dynamic forest fire environments was evaluated through simulation and real-world experiments to measure the effectiveness. When combining DRL and PSO, this hybrid system showed significant improvements in multiple key areas: route planning efficiency, while implementing real-time flexibility, precise navigation, and robust scheduling, the DRL side was tasked with making decisions real-time, provides dynamic state updates from fire detection data sets including fire locations, severity, and obstacles. The results showed a 34.95% decrease in execution time compared to traditional methods, which was attributed to PSO global search capability and DRL-learning optimal matching Real-time adjustment of the system became apparent as the DRL module continued to develop new routes in response to changing fire conditions; This flexibility, which enabled drones to maneuver faster and safer in dangerous areas, was further enhanced by the PSO, which optimized routes in real-time to ensure continuous operational efficiency. The accuracy of the system was improved by significant improvements in mapping accuracy and efficient obstacle avoidance, demonstrating the system’s ability to make accurate and reliable navigation decisions.

A. *Comparison of Success Rate and Processing Time Path Planning Methods in Dynamic Fire Environments*

The proposed DRL-PSO framework accomplished the shortest execution time of 68 seconds. Three seconds among all strategies evaluated. This represents a splendid improvement in comparison to conventional strategies which include ACO-APF-APP (105.2 seconds), APFA-APP (a hundred and ten. Five seconds), GWO-APP (115.8 seconds), and PSO-APP (one hundred twenty.0 seconds). The reduced execution time of DRL-PSO indicates its performance in computing choicest paths swiftly, which is critical for time-sensitive packages like emergency response in dynamic disaster eventualities as shown in Fig. 3.

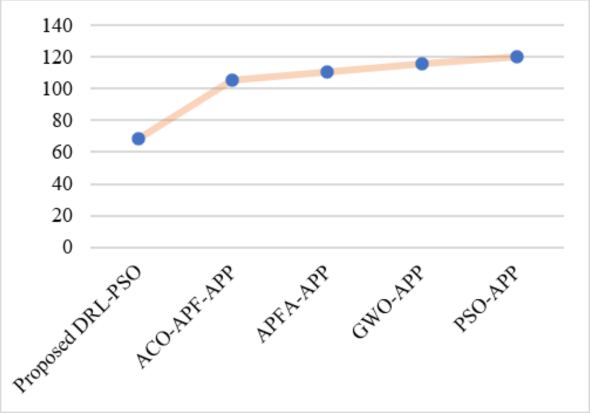

Fig. 3. Proposed frameworks execution time in seconds.

A high success rate suggests the framework's functionality to efficaciously deal with the complexities and uncertainties inherent in dynamic forest fire scenarios. Factors contributing to this high fulfilment rate consist of the framework's ability to evolve in actual-time to changing fire situations, optimize path trajectories to avoid obstacles, and make informed navigational decisions primarily based on environmental inputs. By integrating DRL with PSO, the framework leverages superior machine learning strategies to continuously examine and refine its direction planning strategies, making sure robust performance throughout various environmental conditions. The success fee measures the proportion of trials in which the course making plans technique correctly navigated via the simulated woodland fireside environment without failure. The proposed DRL-PSO framework performed the highest achievement price at 95%, indicating its robustness and reliability in navigating via complicated and risky environments. In comparison, the achievement quotes for ACO-APF-APP, APFA-APP, GWO-APP, and PSO-APP ranged from 78% to 84%, highlighting the superior performance of DRL-PSO in making sure a success path in ensuring successful path completion.

TABLE I. Execution Time and Success Rate of the Proposed Framework

Method	Execution Time (seconds)	Success Rate (%)
Proposed DRL-PSO	68.3	95
ACO-APF-APP	105.2	78
APFA-APP	110.5	81
GWO-APP	115.8	80
PSO-APP	120	84

Table I shows that the proposed DRL-PSO algorithm offers significant advantages over the traditional methods in terms of implementation time and success rate. Its ability to accurately calculate optimal routes while maintaining a high success rate establishes its suitability for real-world applications where navigation is timely and reliable and emphasizes importance, such as the success of autonomous drones in road planning strategies in complex forest fires in disaster management and surveillance operations. The value indicates the percentage of trials, in which the drone successfully moved from the starting position to the designated position without encountering obstacles or obstacles to reach its completion mission. In the given comparison table, the success rates range from 78% to 95%, where the proposed deep learning reinforcement with particle swarm optimization (DRL-PSO) algorithm achieved success rates highest of 95%.

B. *Evaluation of Navigation Accuracy and Obstacle Avoidance*

The proposed algorithm achieved a 26.36% improvement in mapping time compared to the existing methods, indicating that more accurate mapping can be achieved when traveling in dynamic and hazardous environments When a comprehensive reward function is used in DRL, which takes into account target distance, obstacle avoidance and fire intensity The hybrid DRL-PSO method follows an efficient and safe approach after showed good performance in avoiding static and mobile obstacles, with significantly lower collision rates than traditional methods. The adaptive nature of the framework allowed for seamless transitions between reactive navigation and trajectory tracking, ensuring smooth and continuous movement even in the presence of unexpected obstacles.

TABLE II. COMPARISON OF OBSTACLE AVOIDANCE AND DYNAMIC ADAPTATION

Method	Obstacle Avoidance	Dynamic Adaptation
Proposed Framework DRL-PSO	Very High	High
ACO-APF-APP	Moderate	Moderate
APFA-APP	High	Moderate
GWO-APP	High	Moderate
PSO-APP	High	Moderate

Table II compares the optimal dynamic obstacle avoidance capabilities and path schemes under active fire conditions, in the proposed DRL-PSO algorithm with traditional methods such as ACO-APF-APP, APFA-APP, 2013-2014. GWO-APP, and PSO-APP. It has focused on the proposed DRL-PSO algorithm exhibiting very high obstacle avoidance, which means that it can handle obstacle encounters in the environment in the 19th century. This is important in a dynamic fire environment where trees, terrain changes, fire fronts and other obstacles pose significant navigation challenges namely ACO-APF-APP, APFA-APP, GWO-APP, PSO-APP and obstacles moderate-to-high avoidance contradicts Displayed. Although these techniques can avoid constraints to some extent, their performance may be limited in complex or rapidly changing environments. DRL-PSO also excels in being dynamically adaptive, characterized by its ability to adapt route planning strategies in real-time based on changing fire conditions and environmental factors.

This high stability ensures that the drone can continuously makeover its course to avoid hazards and reach mission objectives efficiently Compared to traditional strategies such as ACO-APF-APP, APFA-APP, GWO- APP, in the case of PSO-APP, shows a moderate level of active optimization. These methods may need to be updated or modified more frequently to better handle sudden changes in the environment, which may affect their performance reliability DRL-PSO system for obstacles better avoidance and energy efficiency compared to traditional path planning methods. Utilizing deep reinforcement learning and particle swarm optimization, the system enhances the drone’s ability to safely and efficiently.

C. Performance Metrics and Comparison of Average Cost

Table III provides a comprehensive comparison of average cost results across different path planning methods evaluated within dynamic disaster environments. Each method, including the Proposed DRL+PSO, AGA+PSO, GA+APFA, and AGA+APFA, is assessed based on four key performance metrics: Best Value, Worst Value, Standard Deviation Value, and Mean Value.

The Best Value column represents the lowest average cost achieved by each method in multiple simulations or scenarios simulations it was calculated by using the Eq. (7). For the Proposed DRL+PSO, the best value is 0.1454, indicating its capability to achieve minimal path planning costs under optimal conditions. AGA+APFA, on the other hand, shows a slightly lower best value of 0.1409, suggesting potentially superior performance in cost minimization.

$$Best\,Value = min(C1, C2\ldots Cn) \tag{7}$$

Where C_i is the cost of the i-th simulation. The Worst Value column displays the highest average cost observed for each method across simulations it was calculated by using the Eq. (8). Here, the Proposed DRL+PSO records 0.2845, highlighting its performance in more challenging scenarios. In contrast, AGA+APFA demonstrates the lowest worst value of 0.1711, indicating its robustness in maintaining lower costs even under adverse conditions.

$$Worst\,Value = max(C1, C2, \ldots, Cn) \tag{8}$$

The Standard Deviation Value measures the variability in average cost across simulations it was calculated by using Eq. (9). The Proposed DRL+PSO shows a standard deviation of 0.0317, indicating moderate variability in performance. AGA+APFA, with a standard deviation of 0.0013, exhibits the least variability, suggesting highly consistent performance across scenarios.

$$\text{Standard Deviation} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(C_i - \mu)^2} \tag{9}$$

Where n is the number of simulations and μ is the mean cost (average of all simulations). The Mean Value provides the average cost calculated over all simulations for each method simulations it was calculated by using Eq. (10). The Proposed DRL+PSO framework demonstrates a mean average cost of 0.1675, reflecting its typical performance across a range of dynamic disaster scenarios.

$$Mean\,Value\ =\ \mu\ = \frac{1}{n}\sum_{i=1}^{n} C_i \tag{10}$$

TABLE III. COMPARISON OF AVERAGE COST RESULT WITH EXISTING FRAMEWORK

Method	Best Value	Worst Value	Standard Deviation Value	Mean Value
Proposed DRL+PSO	0.1454	0.2845	0.0317	0.1675
AGA+PSO [21]	0.1401	0.1909	0.015	0.1523
GA+APFA[22]	0.1435	0.1837	0.0226	0.1681
AGA+APFA [23]	0.1409	0.1711	0.0013	0.138

Table III underscores the comparative performance of the Proposed DRL+PSO framework against existing methods like AGA+PSO, GA+APFA, and AGA+APFA in terms of average cost metrics. It highlights the framework's strengths in achieving competitive average costs while navigating complex and dynamic disaster environments. The variability in results across methods also indicates their respective strengths in cost minimization and stability, crucial for real-world applications requiring efficient and reliable autonomous path planning also shown in Fig. 4.

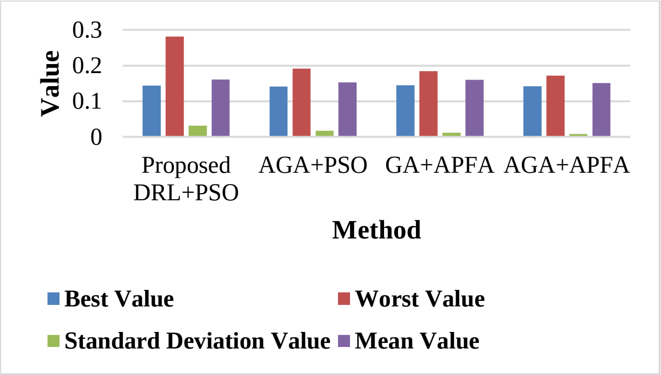

Fig. 4. Comparison of performance metrices.

D. Discussion

The research aims to use DRL and PSO as a hybrid model in articulating the advancement of adaptive path planning for the autonomous robot in the dynamism of disaster scenarios. Disclosed results show a time-saving at the execution stage by 34% and 95% success percentage with reference to the conventional techniques [24]. The efficacy of the system is also felt during dynamic traffic management including real-time path planning and avoidance of other oncoming vehicles. An improvement to this addresses some of the issues surrounding existing work that may include; a lack of flexibility in responding to changing environmental conditions or the way paths are selected within crowded scenarios. The DRL component improves the decision-making process at the time, and PSO makes the global route planning more robust to overcome uncertain scenarios. Despite those advantages, the proposed system has limitations, which include capacity computational complexity and reliance on correct environmental facts. Future developments could consist of enhancing the usage of better sensors for increasing the awareness of the environment or increasing the capability of DRL algorithms to explain a greater number of scenarios. Possibilities to increase the synchronization of several drones and improve the system's ability to respond to unpredictable alterations in the environment could also upgrade the system. The proposed research faces drawbacks associated with the reliance on specific environmental models that may not seize the complexities of real-world disaster eventualities. Current sensor technology might also limit the robot's environmental sensing abilities, hindering its adaptability. Additionally, the deep reinforcement learning (DRL) algorithm may struggle with managing noticeably dynamic conditions and unexpected boundaries. Cooperation among multiple drones requires further research, as does the want for rapid reaction mechanisms to sudden environmental modifications. These factors may also impact the system's effectiveness and reliability in diverse emergency response situations.

VI. Conclusion and Future Work

The study presents the flexibility of the proposed Deep Reinforcement Learning (DRL) with Particle Swarm Optimization (PSO) in path planning of autonomous robots in disaster areas. This has helped in boosting this hybrid method as much better strategy compared to traditional methods because it cuts on the time taken to effect by 34%. Consequently, the course attained its intended vision of achieving a success rate of 95% with percentage the students scoring 95% or above. The DRL component is most successful in decision making in real time and responding to changes in fire environment conditions whereas the PSO boosts the global route, better-facilitating route guidance and making it easier to avoid obstacles in the forest. It is seen that the proposed system can work perfectly in real-world noisy, complex and risky situations and therefore, can be used in emergency response and autonomous navigation systems. However, all is not well with the proposed system as it also has the following disadvantages: There are some limitations: computational complexity, and the dependency on accurate environmental data There is also a requirement for better integration of sensors and improved algorithms in the methods. The integration of DRL and PSO improves the theoretical frameworks in adaptive path-making by optimizing navigation in dynamic environments. This research promotes interdisciplinary collaboration across robotics, AI, and optimization ideas, whilst deepening the data on how autonomous systems adapt to changes in their environments. The results from this study can enhance disaster response with the aid of enhancing the performance of self-reliant robots in actual-world eventualities, probably saving lives and resources. The adaptable framework may be deployed throughout numerous sectors, at the same time as insights on sensor integration will enhance robots' environmental notion, and cooperative strategies may improve swarm intelligence in catastrophe management. The study demonstrates that the hybrid technique of Deep Reinforcement Learning (DRL) and Particle Swarm Optimization (PSO) effectively addresses key contributions, considerably real-time adaptation, multi-agent collaboration, optimized aid utilization, and enhanced navigation accuracy. The framework executed a 34.95% reduction in execution time, allowing for on-the-spot path updates based on converting fire conditions. With an excessive success rate of 95%, it allows effective coordination amongst independent robots in search-and-rescue operations. The model also minimized computational overhead, accomplishing an execution time of 68.3 seconds, while displaying sufficient sized improvements in mapping and impediment avoidance, validating its effectiveness for disaster control applications.

The proposed study offers sufficient realistic advantages, such as improved emergency response through optimized path planning, and permitting self-sustaining robots to efficiently navigate dynamic environments. The integration of DRL and PSO allows for real-time adaptability to changing challenges, enhancing coordination amongst multiple devices in seek-and-rescue operations. Additionally, the hybrid version reduces computational overhead even while maintaining high performance, making sure of robust navigation accuracy and impediment avoidance. Its versatility across diverse programs, including logistics and surveillance, in addition, underscores its ability for broad effect and aid performance in self-reliant systems.

Future work should put efforts in mitigating such limitations by enhancing the environment sensing capability by involving more advanced sensors and enhancing the algorithm of DRL in handling more complex environment. Further, it is necessary to investigate approaches to improve the co-operation between multiple drones and approaches to react on sudden changes in the environment. The effectiveness and reliability of the system can best be determined by and gauged by how it performs in the face of a variety of different real-life disasters that are different from the ones used in the development of the system. Constant enhancement and upgrading will keep the system to be one of the best in the market for autonomous navigation technology making its applicability in various and dynamic emergency response scenarios.

A Convolutional Neural Network-Based Predictive Model for Assessing the Learning Effectiveness of Online Courses Among College Students

Xuehui Zhang, Lin Yang*
School of Electronic Information and Automation, Guilin University of Aerospace Technology, Guilin, China

***Abstract*—With the development of artificial intelligence (AI) technology, higher education institutions usually consider both online courses and offline classrooms in the course design process. To verify the effectiveness of online courses, this study designed a deep learning model to analyze the learning behavior of online course users (college students) and predict their final grades. Firstly, our method summarizes several learning features that are used in machine learning models for predicting student grades, including the performance of users (college students) in online courses and their basic information. Based on nutcracker optimization algorithm (NOA), we designed a multi-layer convolutional neural network (CNN) and developed an improved NOA (I-NOA) to optimize the internal parameters of the CNN. Prediction mainly includes two steps: firstly, analyzing users' emotions based on their comments in online course forums. Secondly, predict the final grade based on the user's emotions and other quantifiable learning features. To validate the effectiveness of INOA-Based CNN (I-NOA-CNN) algorithm, we evaluated it using a dataset consisting of five different online courses and a total of 120 students. The simulation results indicate that compared with existing methods, the I-NOA-CNN algorithm has higher prediction accuracy, and the proposed model can effectively predict the learning effect of users.**

Keywords*—Convolutional neural network; nutcracker optimization algorithm; assessment of learning effectiveness; college students; online courses

I. Introduction

With the development of AI, online course platforms are widely adopted by higher education institutions. These free online courses not only promote the dissemination of knowledge, but also enhance the flexibility of users (college students) in learning. In addition, online courses can reduce the demand for hardware resources such as classrooms and laboratories for higher education institutions, thereby saving costs [1]. However, without face-to-face interaction, users may feel isolated and find it difficult to maintain learning motivation and engagement, especially for students with weaker self-learning abilities [2]. Therefore, it is necessary to evaluate the learning effectiveness of users in stages during their learning process, in order to identify problems and improve students' learning plans in a timely manner, thereby providing personalized learning support for students. Overall, evaluating the effectiveness of online course learning not only helps to improve the quality of education, but also enhances the transparency and trust of education, making it an indispensable part of the modern education system.

Predictive Learning Analysis (PLA) technology is of great significance for improving teaching methods, optimizing learning resources, and enhancing learning efficiency. PLA utilizes user learning performance and other related data to predict learning effectiveness through established models, such as logistic regression and deep neural networks. PLA is widely used in predicting grades, developing personalized learning paths, and predicting dropout rates. It plays a crucial role in analyzing users' learning processes, predicting grades, and identifying factors that may affect learning outcomes in advance. Based on PLA technology, Chen et al. designed a machine learning model that takes students' learning behavior as an input layer and evaluates the learning effectiveness of online courses by predicting their final grades [3]. Reference [4] also designed a machine learning model aimed at evaluating the learning effectiveness of users using cloud platforms for online learning, with the aim of detecting users' learning risks in the early stages.

Martínez-Caro analyzed the factors that affect user learning outcomes during online learning, including teaching content and methods, students' emotions, and personal factors such as their adaptability and self-management abilities [5]. Although the above factors may affect users' learning outcomes, students' adaptability and self-management abilities cannot be quantified. In addition, the large number of college students is not conducive to the statistical analysis of the above information. Therefore, Chen et al. established a machine learning model that takes quantifiable content such as the user's family size, family education support, and learning time as inputs, and the user's final grade as output. This provides a new approach for evaluating user learning effectiveness for online courses [6]. Hassan et al. designed a clustering prediction model with the aim of predicting students' final grades based on their behavior [7]. Although students' emotions directly affect the effectiveness of learning, the above studies did not consider using students' emotions as input variables to predict the final grades of online course platform users.

In response to the problem that existing data prediction models do not consider the influence of user emotions, this study designs a CNN based student performance prediction model, which is divided into two parts. In the first part, the

model evaluates user emotions through CNN algorithm based on student comments in online course forums. After obtaining the user's emotional results, the user's emotions, along with other behavioral characteristics such as learning duration and comment frequency, are used as input variables to predict the user's final grade. Fig. 1 shows the framework designed by this research institute. At present, predicting students' emotions through their facial expressions has become a mainstream emotion analysis method [8]. However, emotion analysis frameworks based on facial expressions not only require a large amount of computing resources, but also pose a challenge in terms of data privacy protection. Online course platforms often provide a forum for student communication. Therefore, other studies have adopted methods based on comment datasets for predicting student emotions [9]. In this study, we employed a sentiment analysis model based on a comment dataset.

Considering that some existing online course users' grade prediction models are only applicable to a single subject and do not take into account the model's generalization ability in other subjects. Therefore, in order to improve the generalization ability of the model, this study selected courses from five different disciplines and a dataset of 60 students to validate the designed model, aiming to support personalized course design while enhancing students' learning experience. The main contributions of this article are summarized as follows:

- This study designed a multi-layer CNN framework for predicting the final grades of online course users. At the same time, a prediction scheme was designed that first predicts emotions and then predicts grades.
- In order to improve the prediction accuracy of CNN algorithm, an optimization algorithm based on particle swarm optimization algorithm and NOA algorithm was designed to optimize the output layer weights of ConvNet.
- A dataset consisting of 5 different courses, 60 students, and a time span of 15 weeks was used to test the performance of the I-NOA-CNN algorithm. The results showed that compared with other existing methods, the I-NOA-CNN algorithm had the highest prediction accuracy.

The rest of this article is arranged as follows. In Section II, literature related to student performance prediction is reviewed. The method proposed in this article is presented in Section III. Section IV presents the results. Finally, Section V summarizes the entire text.

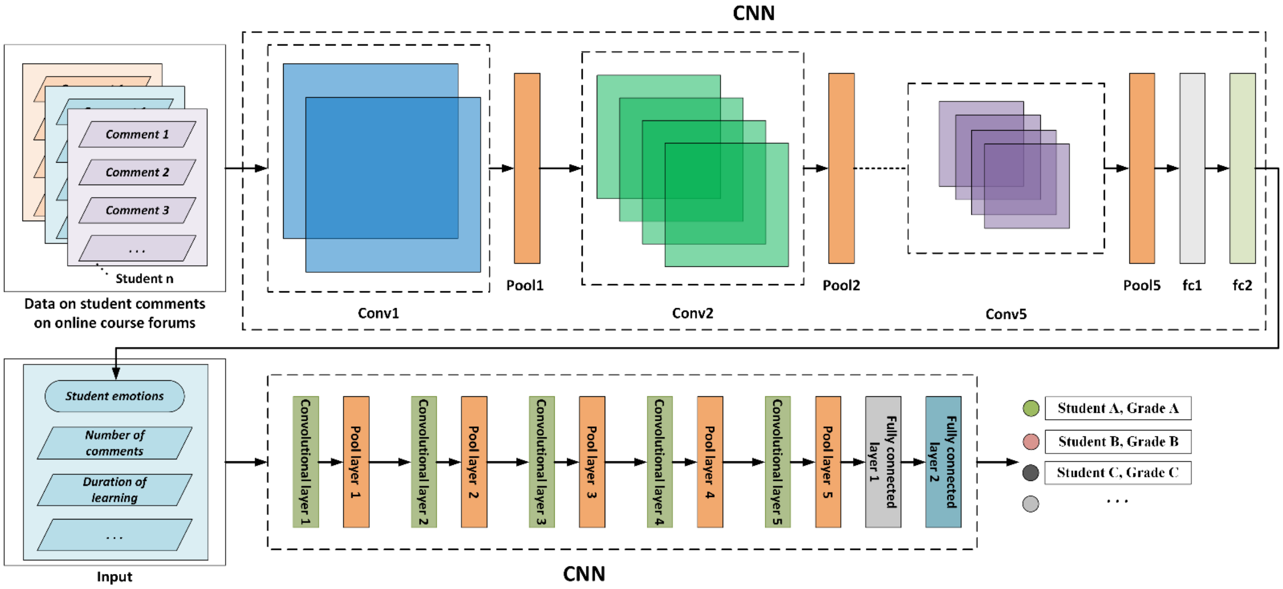

Fig. 1. A CNN-based architecture for predicting final grade of online course users.

II. Related Work

The rapid development of digital education and distance learning has made predicting user grades for online courses an important research area. The main purpose of this field is to use data analysis and machine learning techniques to predict students' performance in the course in advance, thereby helping educators and students themselves better adjust learning strategies and teaching methods [10]-[11]. As this study focuses on the analysis of online course user grades, a CNN architecture based on the I-NOA algorithm, and a scheme for predicting sentiment before predicting academic performance are designed. Therefore, this article focuses on reviewing relevant literature on neural network-based grade prediction, CNN algorithm, and text-based sentiment prediction.

A. *Neural Network-based Prediction of Academic Performance*

With the development of artificial intelligence technology, especially the widespread application of artificial neural networks, researchers have begun to explore how to use these advanced computational models to predict students' grades [12]. Neural networks, especially deep learning models, have been widely used for predicting academic performance due to their high efficiency and accuracy in processing large-scale datasets. Deep learning models are able to extract deep level features from students' online learning behavior, thereby predicting their future performance [13]. The author in [14] developed an early warning system tailored to the issue of whether students in specific subject courses can successfully pass the course assessment, which is essentially similar to the final grade prediction model. This study proposes a weighted voting combination strategy to improve the accuracy of predictions. By comprehensively utilizing time series data and personalized characteristics of students, this method significantly enhances the ability to predict the risk of students failing course assessments, providing education workers with a powerful tool to implement timely and effective teaching interventions. Gupta et al. also explored the method of using educational data generated by online learning platforms using machine learning technology to warn students of their academic performance. This study used Hidden Markov Models to analyze these numbers and ultimately established an efficient modeling framework that provides data-driven decision-making guidance for higher education institutions to achieve more sustainable educational development [15].

Xu et al. designed a machine learning model based on students' online behavior to address the problem of predicting their academic performance in online courses. This model can accurately predict students' final grades and design learning environments and activities that are suitable for students [16]. The author in [17] aims to predict students' mastery of knowledge by establishing a refined model of their learning process using conversation and relationship graphs. Additionally, graph convolutional networks are used to analyze students' acquisition of knowledge status, ultimately achieving the goal of predicting students' grades. The author in [18] designed a learning achievement prediction model based on reinforcement learning, which takes students' homework texts as input to predict their knowledge mastery. Another study combined artificial neural networks and fuzzy systems for a student performance evaluation system, and the results showed that the model had higher prediction accuracy than traditional statistical methods [19]. Although there has been some progress in predicting student academic performance based on artificial neural networks, there are still some challenges, such as data diversity and quality, model generalization ability, and interpretability issues. Therefore, this study focuses on improving the robustness and adaptability of predictive models.

B. *Convolutional Neural Network*

Although numerous studies have designed student performance prediction models, the accuracy of these models remains a challenge so far. Nie et al. designed a prediction model based on fuzzy reasoning theory [20], which combines meta heuristic algorithms with fuzzy logic to improve the prediction accuracy of the model. Lu et al. designed an improved CNN algorithm to analyze students' behavioral characteristics and predict their final grades [21]. The author in [22] also developed an improved CNN model aimed at evaluating students' learning outcomes and satisfaction. The author in [23] designed an improved artificial neural network aimed at analyzing the behavior of research-oriented students in higher education institutions, in order to identify factors that affect student learning outcomes.

The CNN algorithm has also been widely applied in other fields, which provides a broad idea for the algorithm design in this article. Song et al. designed an improved CNN algorithm to improve the prediction accuracy of wind power generation [24]. Naulia et al. designed a CNN framework based on optimization algorithms, also aimed at improving the prediction accuracy of CNN, and demonstrated through simulation examples that the improved CNN framework has potential advantages compared to gradient descent methods [25]. The author in [26] focuses on the problem of mechanical fault diagnosis and designs a lightweight CNN algorithm aimed at improving the prediction efficiency and accuracy of CNN.

At present, in some of the latest research, relevant researchers have begun to use optimization algorithms to optimize the parameters of CNNs. In order to solve the problem that the computation time of CNN increases exponentially with the size of the problem during the prediction process, [27] adopted the method of first using particle swarm optimization algorithm to reduce the solution space and then using CNN for prediction. This method significantly shortens the computation time of CNN in computing high-dimensional problems. Li et al. used differential evolution (DE) algorithm to optimize the parameters of CNN, aiming to improve the accuracy of CNN in music sentiment analysis problems [28]. The author in [29] establishes a deep learning model based on metaheuristic optimization algorithm, aiming to use the optimization algorithm to formulate the optimal learning strategy for the deep learning model. Meanwhile some state-of-the-art metaheuristics likewise provide ideas for algorithm improvement [30]-[31].

C. *Text-based Sentiment Prediction*

Lin et al. designed a multimodal learning model for sentiment analysis using text and images. Compared to models that only use images for sentiment analysis, the multimodal learning model performed better [32]. Reference [33] also designed a method for sentiment analysis using text and images, with a significant contribution being the improvement of the problem of modality loss. Alshaikh et al. designed a text-based sentiment analysis system to address the issue of sentiment analysis in education. This system is used to identify valuable information while providing personalized learning for students [34]. The author in [35] conducted research on sentiment analysis of comments on social platforms. This study aims to identify the emotions conveyed by comments by extracting comment information from social platforms and optimizing deep neural networks through gradient descent algorithm.

III. Proposed Framework

In this study, we first improved Abdel-Basset et al.'s NOA algorithm and designed an I-NOA algorithm [31]. Then, we use the I-NOA algorithm to optimize the weights of the output layer of the CNN algorithm. The architecture designed for this study is mainly divided into two layers. In the first layer, the I-NOA-CNN algorithm is used to analyze students' emotions based on the text they comment on in the online course platform's comment section. In the second layer, we predict students' final grades based on their emotions, number of comments, course content, and class time.

A. *Improved Nutcracker Optimization Algorithm*

The traditional NOA algorithm imitates the process of Nutcracker collecting food, which is divided into four stages: exploration stage, storage stage, cache and search stage, and recovery stage. We have focused on improving the exploration phase and storage stage phase, aiming to enhance the convergence speed and accuracy of the NOA algorithm.

1) Exploration stage: In the exploration phase of the I-NAO algorithm it is necessary to initialize the parameters, which include the maximum number of iterations k_{max}, the number $J=\{1,2,\cdots,j_{max}\}$ of individuals, the dimensions $G=\{1,2,\cdots,g_{max}\}$ of the individuals and the positions $\psi_{g,j}$, $\forall g\in G,\forall j\in J$ of the individuals.

Due to the fact that traditional NOA algorithms rely on randomly selected individuals and the average value of the g-th dimension of all individuals during the individual position update process in the exploration phase, it is not conducive to quickly finding the region where the optimal solution is located in the later optimization process. Therefore, in this study, the update strategy of particle swarm optimization (PSO) algorithm and the exploration strategy of NOA algorithm are integrated to improve convergence speed and accuracy. Randomly generate a random number R_{exp} in the [0,1] interval, and generate a random number ϕ that decreases with the number of iterations. If $R_{exp}\le\phi$, update the position according to the particle swarm optimization exploration strategy.

$$\vec{E}_{j}^{k+1}=\begin{cases}\vec{E}_{j,g}^{k}, & R_1\le R_2\\ \begin{cases}E_{m,g}^{k}+\beta\left(\vec{E}_{ra,g}^{k}-\vec{E}_{rb,g}^{k}\right)\\ +\alpha\left(R_1\times\left(M_g-N_g\right)\right),\ k\le\dfrac{k_{max}}{2}\\ c\times R_2\times\left(\vec{E}_{best,g}^{k}-\vec{E}_{j,g}^{k}\right),\ k>\dfrac{k_{max}}{2}\end{cases} & ,R_1>R_2\end{cases}\tag{1}$$

where, $\vec{E}_{j,g}^{k}$ is the g-th dimension of the j-th individual in the k-th iteration process. $\vec{E}_{ra,g}^{k}$ and $\vec{E}_{rb,g}^{k}$ are the g-th dimension of randomly selected individuals. $\vec{E}_{m,g}^{k}$ is the average of the g-th dimension of all individuals. $\vec{E}_{best,g}^{k}$ is the g-th dimension of the optimal individual among all. R_1 and R are random numbers on the interval [0,1]. c is the learning factor of PSO. β is a random flight step size. α is a random number that follows a normal distribution. M_g and N_g are two vectors.

2) Storage stage: This stage imitates the process of Nutcracker storing food. In this process, we introduced the hunting phase of the grey wolf optimization algorithm and designed a storage strategy based on grey wolf hunting. Before the start of this stage, we generated random numbers R_3, R_4, R_5 in the [0,1] interval. Based on the Levy flight strategy, we generated random number L_{evy}. If $R_{exp}>\phi$, perform storage operations based on grey wolf hunting according to (2).

$$\vec{E}_{g}^{k+1}=\begin{cases}\vec{E}_{g}^{k}+\beta\times\left(\vec{E}_{best,g}^{k}-\vec{E}_{g}^{k}\right)\times\left|L_{evy}\right|+R_1\times\left(\vec{E}_{ra,g}^{k}-\vec{E}_{rb,g}^{k}\right),\ R_3\le R_4\\ \vec{E}_{best,g}^{k}+\beta\times\left(\vec{E}_{ra,g}^{k}-\vec{E}_{rb,g}^{k}\right),\ R_3\le R_5\\ \dfrac{\vec{E}_{ra,g}^{k}+\vec{E}_{rb,g}^{k}+\vec{E}_{rc,g}^{k}}{3},\ otherwise\end{cases}\tag{2}$$

3) Cache and search stage: The cache search phase is designed to further expand the algorithm's exploration of the solution space. This stage relies on the reference points (candidate solutions) in the Nutcracker solution space. The definition of reference point (RP) is as follows:

$$RP=\begin{bmatrix}\overrightarrow{RP}_{j,1}^{k} & \overrightarrow{RP}_{j,2}^{k}\\ \vdots & \vdots\\ \overrightarrow{RP}_{j\,max,1}^{k} & \overrightarrow{RP}_{j\,max,2}^{k}\end{bmatrix}\tag{3}$$

The calculation method of $\overrightarrow{RP}_{j,g}^{k}$ is as follows.

$$\overrightarrow{RP}_{j,g}^{k}=\vec{E}_{j,g}^{k}+\chi\times cos(\theta)\times\left(\vec{E}_{ra,g}^{k}-\vec{E}_{rb,g}^{k}\right)\tag{4}$$

where, χ linearly decreases with the number of iterations from 1 to 0.

4) Recovery stage: The recovery phase involves evaluating and selecting existing solutions based on corresponding strategies. Fig. 2 shows the strategy used in the recovery phase of the I-NOA algorithm. When the maximum number of iterations is reached, the recovery phase no longer selects the optimal solution and directly outputs the final solution.

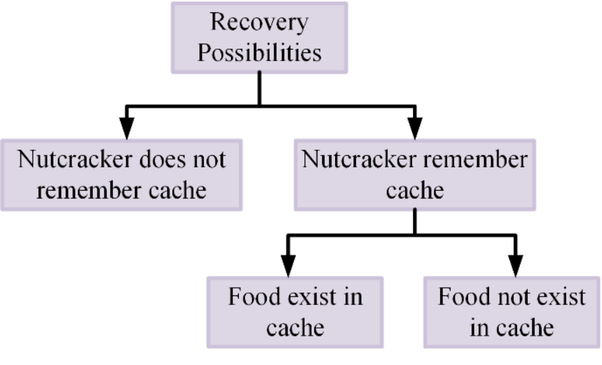

Fig. 2. Diagram of updates during the recovery phase.

B. *Improved Convolutional Neural Network*

At this step, we mainly calculate the loss function of the training phase of the training model. In this study, the loss function is defined as the difference between the predicted value of the CNN algorithm and the true value. The CNN algorithm in this study includes five convolutional layers, five pooling layers, and two fully connected layers. The convolutional layer is mainly responsible for extracting features from students' relevant data. The fully connected layer is based on the activation function to classify students' emotions and grades. Fig. 3 shows the framework of a fully connected layer. The loss function used in this article is shown below.

$$F_{lc}\left(\hat{f},f\right)=-\sum_{i} f_i \times log\left(\hat{f}_i\right)+\left(1-f\right)_i \times log\left(1-\hat{f}_i\right),\ \ \forall i \in I \qquad (5)$$

where, f is the true value of the label. $\hat{f}$ is the probability that the CNN algorithm predicts the current label correctly.

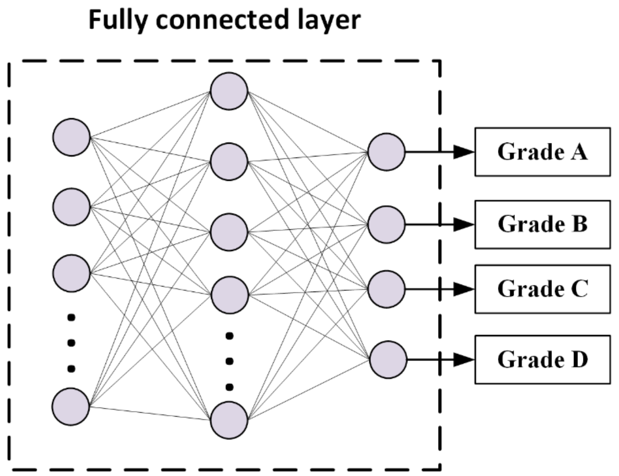

Fig. 3. Schematic diagram of the structure of the fully connected layer.

IV. Results and Discussion

To validate the performance of the I-NOA-CNN algorithm, we conducted simulation experiments based on a dataset of 60 students in five different online courses. The time span of the dataset is 15 weeks, and in this study, we use every three weeks as a time node. The data includes the content of online courses, the amount of homework for online courses, students' class time, the text of student comments on online course platforms, and the frequency of comments. The student's comment text is used for student sentiment analysis.

During the experiment, the number of individuals in the I-NOA algorithm was 20, and the maximum number of iterations was 200. The dropout rate of CNN algorithm is 0.5, and the learning rate is 0.001. Out of the data of 60 students, 15 were used as the training set, while the data labels of the remaining 45 students were used as the testing set. In addition, in order to verify the prediction accuracy and robustness of the I-NOA-CNN algorithm, some recently developed algorithms such as the classic CNN algorithm [21], psoCNN [27], and NOA-CNN were selected for comparison with the I-NOA-CNN algorithm. During the calculation process, each algorithm is independently run 30 times.

A. *Student's Emotional Prediction*

Fig. 4 and 5, respectively show the prediction results of CNN algorithm and I-NOA-CNN algorithm on students' emotions in weeks 15 of Course 1.

From Fig. 4 and 5, we can see that the I-NOA-CNN algorithm has higher accuracy than the CNN algorithm in predicting students' emotions. Table I shows the accuracy of each algorithm's predictions over 30 runs. The I-NOA-CNN algorithm has the highest prediction accuracy, while the CNN algorithm has the lowest. Although the psoCNN and NOA-CNN algorithms have better prediction accuracy than the CNN algorithm, they are far lower than the I-NOA-CNN algorithm.

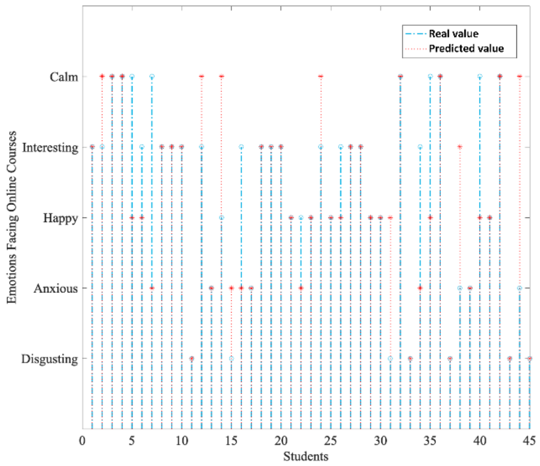

Fig. 4. The results of CNN algorithm for predicting student emotions.

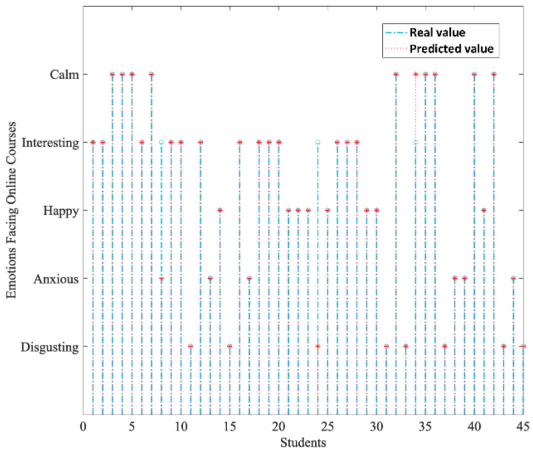

Fig. 5. The results of I-NOA-CNN algorithm for predicting student emotions.

TABLE I. The Accuracy of each Algorithm's Prediction of Student Emotions based on the Data from the 15th Week

Algorithm	Course 1	Course 2	Course 3	Course 4	Course 5
CNN	65.57%	71.47%	75.12%	81.83%	74.28%
psoCNN	80.62%	81.16%	85.42%	82.99%	79.19%
NOA-CNN	85.76%	84.57%	92.69%	83.08%	82.17%
I-NOA-CNN	93.57%	96.41%	97. 59%	96.18%	95.07%

B. Student's Final Grade Prediction

Fig. 6 and 7, respectively show the prediction results of CNN algorithm and I-NOA-CNN algorithm on students' final grades at weeks 15 in course 1. In the final grade prediction process, we divide the final grade into five levels: A, B, C, D, and E.

From Fig. 6 and 7, it can be seen that at week 15, the I-NOA-CNN algorithm had higher accuracy in predicting students' final grades in course 1 than the CNN algorithm. Fig. 8 and 9 respectively show the prediction accuracy of four algorithms in different courses and time nodes during multiple runs. From Fig. 8, it can be seen that the I-NOA-CNN algorithm has good prediction accuracy (>90%) in different courses and has strong generalization ability. From Fig. 9, it can be seen that the I-NOA-CNN algorithm also has the best prediction performance at different time nodes. In addition, due to the expansion of the time range, the amount of data increases, and as the time range expands, the prediction accuracy of each algorithm shows an upward trend.

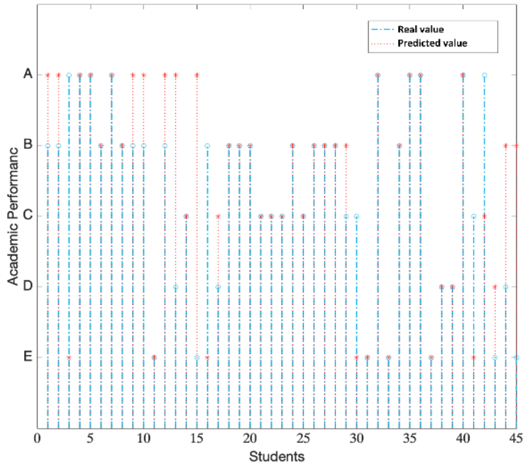

Fig. 6. The prediction results of CNN algorithm on students' final grades.

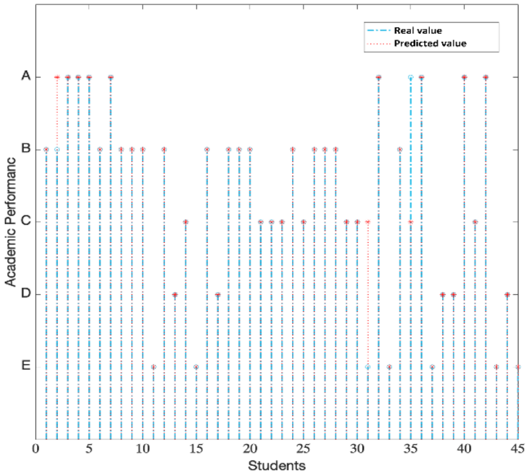

Fig. 7. The prediction results of I-NOA-CNN algorithm on students' final grades.

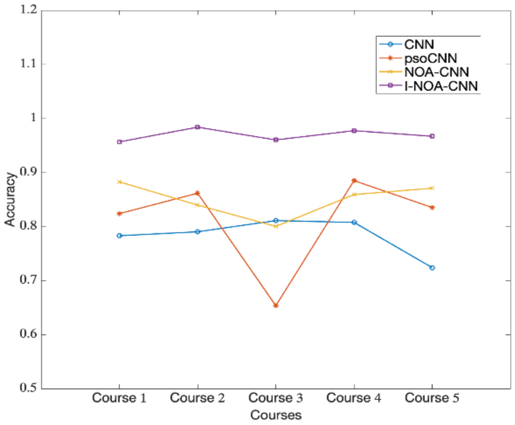

Fig. 8. Different algorithms predict the accuracy of student grades in different course.

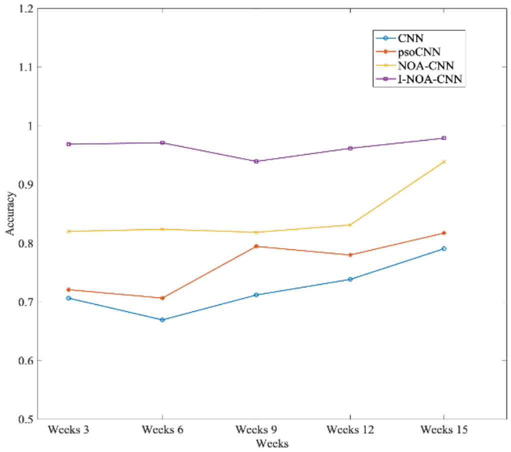

Fig. 9. The accuracy of different algorithms in predicting student grades at different time points.

V. Conclusion

This study focuses on the problem of predicting student grades for online courses and mainly designs an improved CNN algorithm. The grade prediction model mainly consists of two steps. The first step is to predict students' emotions based on an improved CNN algorithm. The second step is to predict students' final grades based on their emotions, course content, and review data. Compared with some of the latest algorithms, this algorithm has higher prediction accuracy and better robustness. The data for this study covers a time span of 15 weeks and does not take into account some short-term online courses. In future research, we will focus on studying the performance prediction of online courses with shorter time spans (less than one week).

Forensic Facial Reconstruction from Sketch in Crime Investigation

Doaa M. Mohammed, Mostafa Elgendy, Mohamed Taha
Department of Computer Science-Faculty of Computers and Artificial Intelligence, Benha University, Benha, Egypt

***Abstract*—Many crimes are committed every day all over the world, and one of them is a criminal offense that includes a wide range of illegal acts such as murder, theft, assault, rape, kidnapping, fraud, and others. Criminals pose a threat to security, which harms the public interest. In this case, the police question all eyewitnesses at the crime scene, and sometimes, witnesses who were present at the crime scene can remember the face of the criminal. The witness accurately describes the person's facial features in the report, such as eyes, nose, etc. Law enforcement authorities use eyewitness information to identify the person. Criminal investigations can be accelerated by converting sketched faces into actual images, but this requires eyewitnesses to confirm the description in the report. Drawings make it very difficult to identify real human faces because they do not contain the details that help to catch criminals. In contrast, color photographs contain many details that help to identify facial features more clearly. This work proposes to generate color images using the modified modulation Sketch-to-Face CycleGAN and then pass them through Generative Facial Prior-GAN. CycleGAN consists of a generator and discriminator. The generator is used to generate colored images, and the discriminator is used to identify whether the images are real or fake. These are then passed to GFPGAN to improve the quality of the colored images. The structural similarity index measure of 0.8154 is achieved when creating photorealistic images from drawings.**

Keywords—Sketch-to-Face; facial features; Sketch-to-Face CycleGAN; victim's identification; criminal offense

I. Introduction

Crime is a pervasive issue that transcends cultural, geographical, and social boundaries, impacting individuals and communities worldwide. Crime is broadly defined as an act that violates the law and is punishable by the state. It manifests in various forms, from minor offenses to serious felonies. The consequences of criminal activities extend beyond the immediate victim, affecting families, neighborhoods, and society. As crime rates fluctuate, the need for effective crime investigation becomes increasingly critical, serving as a fundamental component of law enforcement and public safety. Crimes can be categorized into several types, including violent crimes, property crimes, white-collar crimes, and cybercrimes, each posing unique dangers to society. Murder and assault are examples of violent crimes. Murders are one of the crimes that have the greatest impact on global societies. They are not just isolated acts of violence but represent a flagrant violation of human rights and a threat to public safety [1]. In the aftermath of a murder, law enforcement's role in identifying suspects is critical to public security and criminal justice operations. This role entails using various legal and technical techniques and tools that aid in accurately and effectively identifying suspected individuals [2]. The role of law enforcement begins with gathering information from multiple sources, such as witnesses, physical evidence, and field investigations. The services of legal drawing experts are used to draw portraits of criminals based on eyewitness descriptions. It entails the process of creating a visual representation of an unidentified person or person of interest using memories and details provided by witnesses or victims [3]. Experts specializing in drawing arts sketch suspected individuals. Forensic artists interview witnesses or victims to obtain accurate details about the person they observed [4]. The information provided may include details related to the suspect's facial features, hair, clothes, tattoos, scars, and any other distinguishing features. Expert forensic artists can transform an accurate description of the human form into a visual image that can be used as evidence in criminal investigations and trials. Forensic artists use manual or computer-based techniques [5]. Drawings are used as evidence that reinforces other available evidence, such as fingerprints, certificates, or physical evidence. When the hand-drawn sketches are completed, they are distributed to the media to facilitate the perpetrator's arrest [6]. The current identification techniques, particularly those relying on forensic sketches, often suffer from inaccuracies due to the subjective nature of eyewitness accounts. These limitations hinder law enforcement's ability to identify and apprehend suspects quickly. This study aims to address these challenges by improving the Structural Similarity Index Measure and the effectiveness of suspect identification through advanced imaging techniques. This study employs modified STF CycleGAN (Sketch-to-Face CycleGAN) in conjunction with GFP-GAN (Generative Facial Prior GAN) to reconstruct images generated by the modified STF CycleGAN model, resulting in a high-fidelity representation of the colored generated image. This paper mainly uses a modified CycleGAN model with GFP-GAN to transform sketch hand-drawn face images into colored real images. Colored images are useful in forensic science and law enforcement, where suspect sketches based on eyewitness statements can be turned into realistic graphics to help law enforcement identify and apprehend criminals. Law enforcement enhances the likelihood of finding missing individuals and criminals. The rest of this work is organized in the following way: Section II is Related Work, and Section III is Methodology. Section IV is Experimental Results. Section V is Discussion. Section VI is Conclusion and Future Work. Finally, References are given.

II. Related Work

We summarize past research on facial reconstruction, utilizing techniques from computer vision and deep learning to reconstruct the face. Shikang Yu et al. introduced a generative adversarial network (GAN) that utilizes the benefits of CycleGAN and conditional GANs to perform face sketch-to-photo transformation [7]. This study presented the development of a novel feature-level loss function, i.e., integrated with the conventional image-level adversarial loss function to enhance the quality of synthesized images. The generator and discriminator provide additional data to supplement the network's training. In addition to the synthetic facial picture, the network's discriminators also receive a genuine image from the other modality as input, with the real image serving as auxiliary information. A feature-level loss is used to assign a penalty to the disparities between a processed image and the original image within the feature space. The generator employed a U-Net architecture [8] because of its efficacy in Pix2Pix, a technique commonly used for picture processing [9]. There are three convolution layers in the discriminator. The CUHK Face Sketch FERET Database (CUFSF) was utilized in conjunction with SSIM 0.5517 [10].

Sreedev Devakumar et al. converted pencil sketches into actual photographs for forensic investigation to ascertain an individual's identity. DCGAN (Deep Convolutional Generative Adversarial Network) transformed the sketch image into a real image [11]. The proposed model comprises a single generator network (G) and two discriminator networks (D1, D2). The photo generator employs convolutional operations on the input sketch to produce images. A patch GAN serves as the initial discriminator, calculating the L1 loss or discriminator loss. As a result, the generator continues to apply this discriminator loss over subsequent epochs. The generator will activate the second discriminator after a total of 30 epochs.

In contrast to the initial scenario, the second discriminator is a conventional discriminator incorporating an additional dense layer. The second classifier establishes a correspondence between the target-generated image and the target photo. The proposed network architecture employs a patch GAN as one of its discriminators. The second option is a conventional discriminator that incorporates an additional dense layer. The conv2D generator employs batch normalization and a Relu layer. The discriminator conv2D observes the application of batch normalization and a leaky Relu layer. The discriminator uses 4x4 filters and a stride of 2 for each convolution. Simultaneously, the generator uses 3x3 filters with a stride value of 2. The G Generator uses an expanded U-Net architecture, employing DCGAN and incorporating six batches of convolutions to enhance the quality of generated images. This task utilized the CUHK Face Sketch FERET Database (CUFSF) dataset, resulting in a final average SSIM of 0.587 [12].

Lidan Wang et al. presented The Photo-Sketch Synthesis using the Multi-Adversarial Networks (PS2-MAN) approach, which involves the iterative generation of low-resolution to high-resolution images in an adversarial manner. This study implements adversarial supervision at all resolution levels. More precisely, the feature maps at each deconvolution layer use 3 x 3 convolutions to provide outputs with varying resolutions. Two generator sub-networks, namely GA and GB, respectively, perform the transformation from photo to sketch and from sketch to photo. The Genetic Algorithm (GA) uses a genuine facial photograph of RA as input and a synthetic (false) representation of FB as output. GB endeavors to convert sketches into photographs. The generator sub-networks objective is to generate images that closely resemble real ones to deceive the discriminator sub-networks. Conversely, the objective of the discriminator sub-networks is to acquire the ability to distinguish between generated and authentic samples. CUFS and CUFSF datasets are commonly used in this study [13]. The CUHK Face Sketch Database (CUFS) is a comprehensive collection of sketches. It consists of 188 faces from the Chinese University of Hong Kong (CUHK) student database, 123 from the AR database, and 295 from the XM2VTS database [14]. The SSIM (picture synthesis) resulted in 0.7915 for picture synthesis and 0.6156 for sketch synthesis [15].

Sparsh Nagpal et al. introduced a novel contextual generative adversarial network designed specifically for sketch-to-image production. The sketch was employed as a lax constraint to identify the most similar mapping and establish our objective function, which comprises a contextual loss and a conventional GAN loss. Additionally, they use a straightforward approach to enhance the start of sketches. This study posits that inpainting produces an image in and of itself. The use of a mask distorts a fraction of the input image. The image, partially obscured by a mask, is called the context. The model attempts to produce a comprehensive representation of this situation. The researchers employed seven up-convolutional layers, each having a kernel size of four and a stride of two. A batch normalizing layer is applied after each up-convolutional layer to expedite the training process and enhance the stability of the learning. Reputation linear unit (Relu) activation is employed at all levels. Ultimately, we employ the tanh function on the output layer. The resulting photos were fed into a layer of pre-trained GFP GANs that were trained using low-quality portrait enhancers. This enhanced image quality and generated more realistic outputs, even when utilizing a less sophisticated model. The dataset utilized the CUHK Face Sketch database (CUFS), the XM2VTS database, and the AR database, with a simultaneous similarity index (SSIM) of 0.78 [16].

Sumit Gunjate et al. introduced a methodology for converting sketches into images using generative adversarial networks. Converting an individual's representation into an image that encompasses the characteristics or attributes associated with the representation necessitates the utilization of many categories of machine learning algorithms. The models comprised a GAN discriminator, which functions just as a classifier. The task involves distinguishing between factual data and data produced by the generator. The generator component of a generative adversarial network (GAN) acquires the ability to generate false data. It acquires the capability to designate its output as genuine. In contrast to the process of discriminator training, generator training requires a more advanced level of integration between the generator and the discriminator. The generator model used the U-Net architecture, which consists of encoder and decoder layers. The model takes a picture (the sketch) as input and applies 7 encoding layers with filters (C64, C128, C256, C512, C512, C512, C512, C512, C512) to make the image smaller in size. The encoding layers employ batch normalization except for the first layer (C64). Their research aims to determine whether the generated facial structures if deemed credible, share the same identity label as authentic faces. The researchers specifically designed a light CNN to extract identity-preserving features and utilized the L2 norm for comparison purposes [17].

III. Methodology

This research suggests using a modified STF CycleGAN model output as an input to the GFP-GAN model to obtain the result, as shown in Fig. 1.

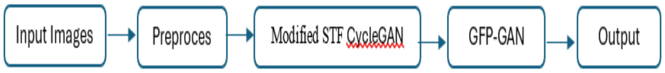

Fig. 1. The architecture used in this paper.

A. *Preprocess*

The technique entails analyzing and utilizing sketches and target images in RGB color. The Gaussian blur feature is achieved by applying a Gaussian function to a picture to reduce noise and generate a more refined visual effect. The filter described above can be considered a nonuniform low-pass filter [19], efficiently preserving low spatial frequency while simultaneously reducing image noise and inconsequential details inside an image. The sketches were subjected to Gaussian blur with a blur radius of 0.3, while the color images were exposed to a blur radius of 0.8. The calculation of Gaussian blur is derived from (1) [18]-[19] determines the Gaussian blur calculation.

$$G_{\sigma}(x) = \frac{1}{2\pi\delta^2} e^{-(x^2+y^2)/2\delta^2} \qquad (1)$$

Following the noise reduction process, we employed rescaling augmentation on the photos from the Chuck database with various scales. As a result, 2256 images were generated, including both sketch and ground truth images.

B. *Modified STF CycleGAN Model*

CycleGAN is a kind of Generative Adversarial Network (GAN) architecture built primarily for challenges involving the translation of unpaired images. Jun-Yan Zhu et al. introduced it in their 2017 publication [7]. CycleGAN enables the acquisition of mappings between distinct domains, facilitating the transformation of images from one domain to another without necessitating the inclusion of paired data samples from both domains during the training process. CycleGAN can learn image translation across different domains, even without paired data, unlike typical supervised learning approaches that require each input image to be matched with its corresponding destination image. Our objective is to convert prototype photos into their corresponding actual ones. The model comprises two fundamental components, namely a Generator and a Discriminator.

1) Generator: The generator is a neural network, i.e. tasked with translating images from one domain to another. The generator functions unsupervised, enabling it to execute the translation task without relying on paired data samples throughout the training process. The generator comprises convolutional neural network (CNN) layers that receive an input image from one domain and generate a corresponding output image in the target domain. The input image size is [256, 256, 3] and undergoes a sequence of downsampling and upsampling modules.

a) Down-sampling: Downsampling is a technique used to decrease the spatial resolution of an input image, usually achieved by employing convolutional procedures like step convolutions. One essential operation in the generator network is down-sampling, which extracts hierarchical information from the input image and aids in the translation process. The down-sampling blocks progressively decrease the resolution from 256x256 to 1x1 spatial dimensions. Convolution layers, batch normalization, and the Leaky-Relu activation function are employed in the down-sampling process.

- Convolution Layer: Convolutional layers, sometimes called conv layers, are essential components of convolutional neural networks (CNNs). Convolutional layers are of utmost importance in the process of extracting features from input data through the application of convolutional operations. In this context, the weights assigned to each filter function represent a vocabulary of feature patterns. Filters used are (64, 128, 256, 512, 512, 512, 512, 512) with kernel size 4. As calculated in (2) [20], the convolution operation is computed for the input patch X and the filter kernel K, which determines the convolution layer's calculation. Fig. 2 illustrates the convolution operation.

$$C\,(m, n) = \sum_{p=0}^{p} \sum_{q=0}^{q} K(p;\, q) \, * \, X\,(m + p\,, n + q) + b \qquad (2)$$

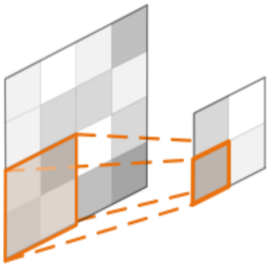

Fig. 2. Convolution operation.

- Batch Normalization: Batch normalization is a technique often used in deep neural networks, particularly in the convolutional and fully connected layers, to improve the training process and the model's overall performance. People widely recognize batch normalization as a prominent technique that enhances network training speed and improves accuracy. [21] Batch normalization changes the data distribution to have a mean of 0 and a variance of 1, expressed in units of the minibatch. This approach is effective in mitigating the possibility of overfitting [22].
- Leaky-Relu Activation Function: The Leaky Rectified Linear Unit (Leaky-Relu) is a frequently employed activation function in neural networks, specifically within deep learning architectures. The proposed approach is an expansion of the conventional Rectified Linear Unit (Relu) function, which aims to overcome certain constraints, notably the issue of "dying Relu" This difficulty arises when neurons that produce a weight of zero for all inputs cease to update their weights during

the training process. The Leaky-Relu has a small gradient (usually a small positive value, like 0.01) for negative inputs. This lets them spread a gradient throughout the backpropagation process. Fig. 3 illustrates the Leaky-Relu activation function. The Leaky Relu activation function is defined in (3) [23], which specifies how the function is calculated.

$$Leakly - Relu(x) = max(kx, x) = \begin{cases} x, & \text{if } x > 0 \\ kx, & x \leq 0 \end{cases} Leakly - Relu(x) = max(kx, x) = \begin{cases} x, & \text{if } x > 0 \\ kx, & x \leq 0 \end{cases} \quad (3)$$

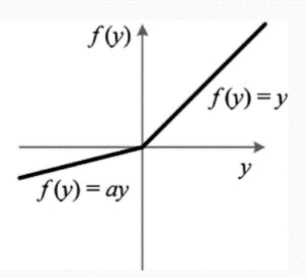

Fig. 3. Leaky-Relu activation function.

b) Up-sampling: Upsampling is a technique used to increase the spatial resolution of feature maps. It is usually achieved using techniques such as transposed convolutions. Upsampling plays a crucial role in the generator network by efficiently collaborating with downsampling to convert images across different domains. A 2D transposed convolutional layer, batch normalization, and the Rectified Linear Unit (Relu) activation function are used in upsampling to expand the spatial dimensions. The generator network efficiently produces images with suitable characteristics, and the ultimate output has dimensions of 256x256x3, corresponding to color images.

- Deconvolution Layer: Deconvolution, also known as transposed convolution, is a method that increases the sampling level of feature maps while preserving the connectivity pattern. The deconvolutional layers employ convolution-like procedures with several filters to expand and densify the input. The filters used are (512, 512, 512, 512, 256, 128, 64, 32). Unlike the current resizing methods, the deconvolution process includes adjustable parameters, as shown in Fig. 4 [20]. During network training, the weights of deconvolutional layers undergo continuous updates and refinements. On the input side, the process starts with adding zeros between neurons in the receptive field, and then a convolution kernel with a unit stride is used at the very top.

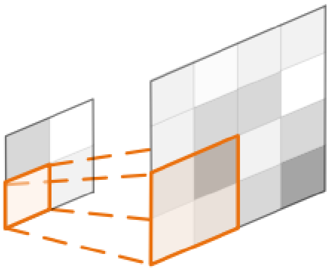

Fig. 4. Deconvolution operation.

- Relu Activation Function: The Rectified Linear Unit (Relu) is a highly prevalent activation function commonly employed in neural networks, particularly in deep learning models. Relu's linear operation results in a higher convergence rate and calculation speed. The neural network's performance is negatively impacted by the presence of dead neurons, which Relu causes. Negative input values result in a constant output of zero for the Rectified Linear Unit (Relu) function, and consequently, the first derivative is also zero. This renders the neuron incapable of updating its parameters, as shown in Fig. 5. The Relu activation function is calculated in (4) [24], which specifies how it is calculated.

$$f(x)=max (0, x) \quad (4)$$

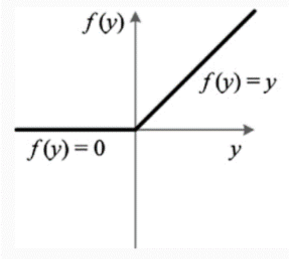

Fig. 5. Relu activation function.

c) Skip connections: Skip connections, often referred to as residual connections, serve a vital function in the generator, easing the transmission of information across several layers and enhancing the overall quality of the generated images. The establishment of these links serves to mitigate the issue of information loss that arises during the translation process, hence enabling the generator to retain intricate details within the input images more effectively. The generator's skip connections facilitate the preservation of low-level details and fine-grained information from the input image. Skip links enable the network to access both the original input and the higher-level information acquired during the translation process by directly transmitting the input from a certain layer to a subsequent layer.

2) Discriminator: The discriminator is an essential component of the adversarial training process and plays a critical role. The discriminator has a crucial function in differentiating between genuine images from the desired domain and artificial images produced by the generator. It offers input for the generator network to enhance the quality of its generated images. The following items are included: Downsampling blocks are employed to minimize spatial dimensions. We use filters (32, 128, 256, 512) with a filter size of 4, batch normalization, Leaky-Relu, zero padding, and a convolutional layer with only one output channel.

3) Modified STF CycleGAN loss: Modified STF CycleGan loss consists of two losses.

a) Generator loss function: The generator loss function consists of the following components:

- Adversarial loss (GAN loss): This causes the generator to generate images that are so similar to the actual ones that they cannot be distinguished. The formulation employs binary cross-entropy loss. We use the Adversarial loss to calculate the min-max loss. Adversarial loss is calculated in (5).

$$L_{Gan} = E_x[\log(D(x))] + E_z[\log(1 - D_x(G(x)))] \quad (5)$$

- L1 loss is a loss term that ensures the generated and target images have pixel-wise similarity.

To calculate the overall generator loss, we combine these components, using weights that determine the relative significance of each loss item. The generator loss function is calculated in (6).

$$L_{Gen} = L_{GAN} + \lambda 1 \cdot L_{cyc}(G) \quad (6)$$

Where $\lambda 1$ is the weighting factor for the L1 loss, and L_{GAN} represents the adversarial loss, L_{cyc} represents cycle consistency loss. L_{cyc} is calculated in (7).

$$L_{cyc} = E \sim p_{data}(x)\ [\|G(x) - x\|] \quad (7)$$

b) Discriminator loss function: The discriminator loss function consists of two distinct components:

- The discriminator's ability to accurately categorize authentic photos is referred to as a real loss.
- Generated Loss: This metric measures the discriminator's accuracy in correctly categorizing generated images.

The discriminator loss function is calculated in (8).

$$L_{disc} = L_{real} + L_{generated} \quad (8)$$

where L_{real} is the real loss term, and $L_{generated}$ is the generated loss

C. *GFP-GAN Model*

Generative Facial Parsing (GFP) is a specific adaptation of generative adversarial networks (GANs).

The modified STF CycleGAN model generates images that are input into the GFP-GAN model. The GFP-GAN can be used to fix images by identifying small imperfections, such as scratches and blemishes. Fig. 6 shows the inpainting techniques used to fix the damaged regions [25]. The face restoration method uses GFP with innovative channel-split spatial feature transform layers, striking an optimal balance between authenticity and accuracy. The GFP-GAN successfully upgraded colors and restored facial details with a single forward pass, owing to its sophisticated designs and robust generative facial prior. Simultaneously, GAN inversion techniques necessitate costly image-specific optimization [26].

D. *Performance Evaluation*

We employed modified STF CycleGAN neural networks, which were trained and tested on a dataset consisting of human sketches paired with their corresponding images. To assess the similarity between the generated image and the original image, we utilize the following parameters to evaluate the performance.

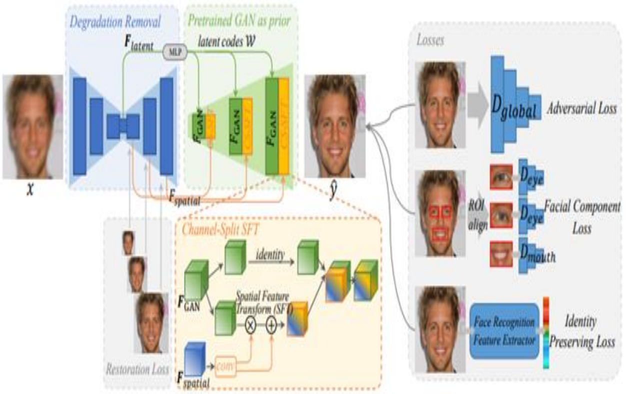

Fig. 6. GFP-GAN framework [26].

The SSIM (Structural Similarity Index Measure) is a technique used to estimate the perceived quality of photos, digital images, and videos [27]. SSIM is mostly employed to quantify the resemblance between two photographs. The SSIM values range from 0 to 1, with a value of 1 indicating a perfect match between the reconstructed image and the original image. The SSIM metric determines the degree of alignment or similarity in pixel density values between two photographs. The calculation is performed in the following manner:

$$\text{SSIM}(x, y) = \frac{(2\,\mu_x\mu_y + C1)(2\sigma_{xy} + C2)}{(\mu_x^2 + \mu_y^2 + C1)(\sigma_x^2 + \sigma_y^2 + C2)} \quad (9)$$

Where µx the mean of x

- μ_y the mean of y

- σ_x^2 the variance of x

- σ_y^2 the variance of y

- σ_{xy} the cross-correlation of x and y

- c1, c2 Constants are added into the formula to provide numerical stability, particularly when the denominator terms (variances and covariances) are close to zero.

IV. Experimental Result

The system operates on the Google Colab TPU runtime, which comprises an Intel Xeon CPU operating at a frequency of 2.30 GHz, 13 GB of RAM, and a cloud TPU with a computing capacity of 180 teraflops. The computer vision system operates on Python 3.10 and utilizes OpenCV.

A. *Dataset*

The dataset used in this study is the CUHK Face Sketch database (CUFS) for research on face sketch synthesis and recognition. It includes 188 faces from the Chinese University of Hong Kong (CUHK) student database, 123 from the AR database, and 295 from the XM2VTS database. The images were taken during a video recording session. In total, there are 606 faces. For each face, an artist draws a sketch based on a photo taken in a frontal pose under normal lighting conditions with a neutral expression. The CUHK Face Sketch FERET Database (CUFSF) is used for face sketch synthesis and recognition research. It includes 1,194 individuals from the FERET database. The augmentation technique involves rescaling the photos in the Chuck database, resulting in 2256 images for both the sketch and target images. Combining sketches and photographs allows for more realistic training as the model learns to translate artistic representations into lifelike images, crucial for forensic applications.

B. Experiment

We partitioned the dataset into two subsets, allocating 80% for training and 20% for testing the modified STF CycleGAN model. The input for the modified STF CycleGAN model is an image with a shape of (256, 256, 3). We then downsample this picture using filters of sizes (64, 128, 256, 512, 512, 512, and 512). Additionally, the image is upsampled using filters of sizes 512, 512, and 512, with dropout applied at a rate of 0.5. The size of the filter employed is 4. The modified STF CycleGAN model's discriminator compresses the input image with a shape of (256, 256, 3) using filters (32, 128, 256, 512). We train the model on the dataset for a total of 100 epochs. The model's SSIM yielded a value of SSIM is 0.637. Fig. 7 displays the outcome of the modified STF CycleGAN model.

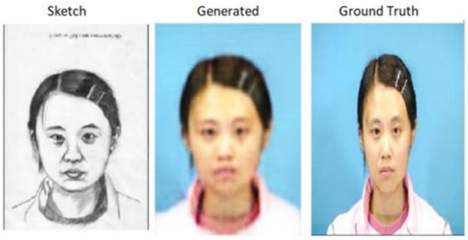

Fig. 7. Result of modified STF CycleGAN model.

The dataset has been partitioned into two subsets, with 80% allocated for training and 20% for testing. The model is trained for 500 epochs using the dataset. The model yielded a result of SSIM is 0.8154 when the generated images from modified STF CycleGAN were used as input for GFP-GAN to recover the images and produce high-quality output images. Fig. 8 displays the outcome of the modified STF CycleGAN algorithm when applied to the GFP-GAN model.

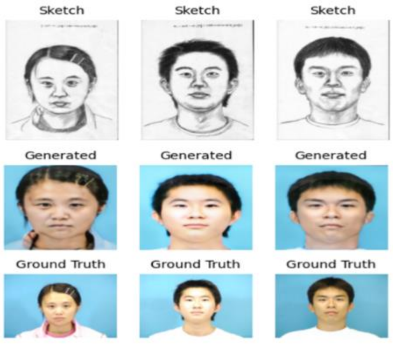

Fig. 8. Result of modified STF CycleGAN with GFP-GAN model.

V. Discussion

In this study, we developed a deep-learning model using modified STF CycleGAN with GFP-GAN to generate realistic faces from hand-drawn sketches, which helps law enforcement authorities identify and arrest criminals. The model outperformed traditional methods, achieving higher visual accuracy and preserving key facial features with an average SSIM score of 0.8154. The system uses CUFS, CUFSF, AR, and XM2VTS are public and available datasets. We use a modified STF CycleGAN model to acquire high-level facial representations and enhance the quality of the generated images. However, the model faced challenges when processing incomplete or low-quality sketches, and it struggled with extreme facial poses or expressions, highlighting the need for more diverse training data. Our system is better than other models GAN and DCGAN [10, 12]. It also outperforms PS2-MAN and contextual generative adversarial networks with GFP GANs [15, 16]. Despite the limitations, this model has practical potential in fields like forensic sketching and digital art, where accurate facial generation from sketches is essential. Developing a sketch-to-face generation system has promise for advancing techniques in forensic sketching, character design, and digital art, with potential applications in law enforcement and personalized creative tools. This technology could revolutionize how hand-drawn sketches are used in practical settings, providing more accurate visualizations for identification, design, and artistic expression.

TABLE I. Performance Comparison of Different Models

	Method	Dataset	SSIM
[10]	Generative Adversarial Network (GAN)	(CUFSF)	0.5517
[12]	DCGAN (Deep Convolutional Generative Adversarial Network)	(CUFSF)	0.587
[15]	Multi-adversarial networks (PS2 - MAN)	(CUFS), AR database, and the XM2VTS database	SSIM (Photo Synthesis) is 0.7915, SSIM (Sketch Synthesis) is 0.6156
[16]	contextual generative adversarial network with GFP GANs	(CUFS), the XM2VTS database, and the AR database	0.78
Ours	modified STF CycleGAN	(CUFS), the XM2VTS database, and the AR database	0. 637
Ours	modified STF CycleGAN with GFP-GAN	(CUFS),(CUFSF), the XM2VTS database, and the AR database	0. 8154

VI. Conclusion and Future Work

In conclusion, this research paper presents a significant advancement in forensic facial reconstruction by utilizing a modified STF CycleGAN that effectively transforms hand-drawn sketches into high-fidelity colored images, enhancing the identification process of suspects in criminal investigations. Additionally, using GFP-GAN enhances the quality of images generated from modified STF CycleGAN. The study uses the CUHK Face Sketch database (CUFS) and other datasets such as CUHK, CUFSF, FERET, XM2VTS, and AR. The study involves assembling a comprehensive collection of 2,256 images for training and testing the model. The modified STF ycleGAN achieves a Structural Similarity Index Measure (SSIM) of 0.8154, demonstrating a high level of reconstructioned image compared to previous models. Future directions include further exploring the integration of modified StyleGAN with GFP-GAN to improve the Structural Similarity Index Measure and quality of generated images. Overall, this research underscores the potential of advanced generative models in aiding law enforcement and enhancing the efficiency of criminal investigations.

Artificial Intelligence-Driven Decision Support Systems for Sustainable Energy Management in Smart Cities

Ning MA
Shanxi Vocational University of Engineering Science and Technology, Jinzhong 030619, China

***Abstract*—Due to the ongoing urbanization trend, smart cities are critical to designing a sustainable future. Urban sustainability involves action-oriented approaches for optimizing resource usage, ecological impact reduction, and overall efficiency enhancement. Energy management is one of the main concerns in urban, residential, and building planning. Artificial Intelligence (AI) uses data analytics and machine learning to instigate business automation and deal with intelligent tasks involved in numerous industries. Thus, AI needs to be considered in the strategic plan, especially in the long-term strategy of smart city planning. Decision Support Systems (DSS) are integrated with human-machine interaction methods like the Internet of Things (IoT). Along with their growth in size and complexity, the communications of IoT smart devices, industrial equipment, sensors, and mobile applications present an increasing challenge in meeting Service Level Agreements (SLAs) in diverse cloud data centers and user requests. This challenge would be further compounded if the energy consumption of industrial IoT networks also increased tremendously. Thus, DSS models are necessary for automated decision-making in crucial IoT settings like intelligent industrial systems and smart cities. The present study examines how AI can be integrated into DSS to tackle the intricate difficulties of sustainable energy management in smart cities. The study examines the evolution of DSSs and elucidates how AI enhances their functionalities. The study explores several AI methods, such as machine learning algorithms and predictive analytics that aid in predicting, optimizing, and making real-time decisions inside urban energy systems. Furthermore, real-world instances from different smart cities highlight the practical applications, benefits, and interdisciplinary collaboration necessary to successfully implement AI-driven DSS in sustainable energy management.**

Keywords*—Smart cities; artificial intelligence; decision support systems; sustainable energy management; urban resilience; interdisciplinary collaboration

I. Introduction

Urbanization continues to rise at an unprecedented rate, resulting in an increasing proportion of the global population residing in urban centers [1, 2]. This rapid urban expansion has led to significant ecological impacts, including alterations in local and regional climates, loss of biodiversity, and disruption of natural habitats [3]. These consequences highlight the pressing need for sustainable urban development that prioritizes ecosystem preservation and restoration [4]. As urban areas grow, so do the demands on critical infrastructure, particularly energy systems, which play a crucial role in sustaining urban life. Effective energy management within cities is paramount to reducing emissions, ensuring energy efficiency, and fostering a sustainable future [5].

A. *Research Problem and Motivation*

The energy demands of modern cities are becoming increasingly complex, especially with the rise of smart cities—urban areas where digital technologies and data-driven systems are integrated into infrastructure and governance [6]. Smart cities aim to improve the quality of life for their residents by optimizing resource usage, reducing environmental impact, and enhancing efficiency across sectors such as transportation, waste management, and energy. However, as smart cities evolve, they face significant challenges in managing energy efficiently, particularly with the growing integration of Internet of Things (IoT) devices, which contribute to fluctuating energy demands and intricate data streams [7]. These challenges necessitate advanced solutions that can optimize energy management while ensuring the sustainability of urban systems.

Artificial Intelligence (AI) has emerged as a transformative technology capable of addressing these complex challenges by enabling real-time data analysis, predictive modelling, and automation [8, 9]. Decision Support Systems (DSS) enhanced by AI have the potential to revolutionize energy management in smart cities by providing intelligent, data-driven decision-making capabilities. Despite the recognized potential of AI and DSS, there remains a gap in understanding how these technologies can be effectively integrated to manage energy in smart cities while addressing the broader sustainability goals [10].

B. *Objective and Contribution*

The primary motivation of this research is to explore how AI-driven DSS can be leveraged to improve energy management in smart cities, thus addressing the intricate challenges posed by urbanization and technological integration. This study aims to investigate AI methods such as machine learning and predictive analytics, focusing on how these techniques can optimize energy use, predict demand, and support real-time decision-making in urban environments. By analyzing the current state of AI and DSS in smart city contexts, this research highlights the innovative potential of interdisciplinary collaboration in tackling the complex issues of sustainable energy management.

This paper enhances existing literature with a comprehensive discussion of the role AI-driven DSS can play in energy management in smart cities. It further examines the interaction between AI, IoT, and energy systems and proposes new models for optimizing energy usage. The present research thus lays the foundation for further practical implementation and studies in real-world applications and challenges that meet the critical demand for sustainable energy management in an increasingly complex urban environment.

II. Background

Advanced energy management involves using technology to control energy consumption and production, distribution, and consumption in highly energy-demanding cities to foster sustainable economic development [11]. However, such a transition comes with several challenges, as outlined in Table I.

One of the major issues is the ever-increasing difference between supply and demand for energy resources. Growth in urban areas increases the demand for energy since energy consumption rises with cities' expansion, which puts pressure on existing resources [12]. The gap was bridged in the past by producing more energy and emitting more carbon despite negative environmental impacts. Also, poorly maintained and relatively old energy networks in urban areas result in large amounts of energy lost in transmission and distribution. Additionally, the lack of real-time energy monitoring and management systems can prevent immediate detection and correction of inefficiencies. Finally, energy prices remain more or less volatile, and sufficient capital is not readily available to upgrade energy technologies and accommodate innovations in the market.

Incorporating sustainable and cost-effective renewable energy sources like solar, wind, and geothermal power is critical for reducing reliance on traditional energy sources and their carbon footprint [13]. Smart grids employ advanced sensors, communication technologies, and intelligent algorithms to enable real-time monitoring and management of energy distribution across the grid. This optimization minimizes waste and maximizes efficiency. The development of cost-effective and efficient energy storage systems is essential. These systems store excess energy generated from renewable sources, ensuring a reliable and consistent energy supply even during peak demand periods.

As buildings are major energy consumers in cities, developing energy-efficient buildings with intelligent lighting and HVAC systems is crucial for optimizing energy use and reducing waste [14]. Electric Vehicles (EVs) present a significant opportunity to improve air quality and reduce city carbon emissions [15]. Developing EV charging infrastructure and integrating renewable energy sources to power these vehicles are key aspects of smart energy management.

Smart homes, equipped with internet-connected devices that control and automate temperature, lighting, security, and entertainment, offer convenience, improved energy efficiency, and enhanced quality of life for residents [10]. The utilization of data analytics in smart energy management is crucial. This enables the collection, analysis, and interpretation of energy consumption data, facilitating the identification of inefficiencies, optimization of energy use, and cost reduction [16]. Integrating these technological advancements, smart cities can optimize energy production, distribution, and consumption. This paves the way for creating more sustainable, efficient, and livable urban environments.

TABLE I. Key Challenges and Solutions Related to Smart Energy Management in Urban Environments

Aspect	Challenges	Solutions
Energy supply and demand	Continuous rise in energy consumption due to urban expansion	Incorporation of renewable energy sources like solar, wind, and geothermal power to reduce carbon footprint
Infrastructure efficiency	Outdated and inefficient energy infrastructure causing energy losses during transmission and distribution	Development of smart grids with advanced sensors and intelligent algorithms for real-time energy management
Real-time monitoring	Absence of real-time energy monitoring and management systems	Smart grids are used for real-time monitoring and management to minimize waste and maximize efficiency
Economic factors	Fluctuating energy prices and limited funding for infrastructure upgrades	Development of cost-effective and efficient energy storage systems to ensure reliable energy supply
Energy-efficient buildings	High energy consumption by buildings	Development of energy-efficient buildings with intelligent lighting and HVAC systems to optimize energy use
Electric vehicles	Need for improved air quality and reduced carbon emissions	Develop an EV charging infrastructure and integrate renewable energy sources to power EVs
Smart homes	Need for improved energy efficiency and quality of life	Equipping homes with internet-connected devices for automated temperature control, lighting, and security

III. AI-Powered Decision Support Systems for Energy Management

This section comprehensively compares AI-powered DSS for energy management. Table II summarizes various approaches and their key features, challenges addressed, methodologies, applications, and outcomes based on recent studies.

Panagoulias, et al. [17] introduced a novel development methodology for AI-powered analytics in energy management. This approach emphasizes tailored explainability, addressing the inherent lack of transparency ("black box") often associated with AI systems. It acknowledges that various stakeholders with diverse backgrounds, preferences, and goals will utilize these analytics. The methodology aligns with the Explainable Artificial Intelligence (XAI) paradigm, aiming to enhance the interpretability of AI-driven DSSs. A core feature is a clustering-based approach that customizes the level of explanation based on the specific needs of user groups. This customization fosters accuracy and effectiveness in energy management analytics while promoting transparency and trust in decision-making.

TABLE II. COMPARISON OF AI-POWERED DECISION SUPPORT SYSTEMS FOR ENERGY MANAGEMENT

Studies	Focus	Key features	Challenges addressed	Methodology	Applications	Outcomes
Panagoulias , et al. [17]	AI-powered analytics with explainability tailored to stakeholder needs	Explainable AI (XAI) and clustering-based explanation customization	Transparency and trust in AI-driven DSS	• Iterative development lifecycle • Stakeholder identification	Estimation of energy savings from building renovations	Higher adoption rates of AI systems
Selvaraj, et al. [18]	AI Technique for Monitoring Systems in Smart Buildings (AIMS-SB)	Prediction model methodologies and energy analysis, renewable energy generation, recycling assessment	Poor energy recycling, high consumption, suboptimal usage, and drain characteristics	• Eco-design monitoring systems • Effective control of energy consumption and generation	Intelligent building energy management	Enhanced precision and effectiveness compared to traditional approaches
Şerban and Lytras [19]	AI in the renewable energy (RE) sector in the EU	Conversion processes of RE and Impact of AI on RE industry and smart cities research	Development and resilience of the energy sector	• A conceptual framework for AI's impact on RE • Examination of RE efficiency from Gross Inland Consumption to final energy consumption	AI adoption trends for RE in the EU	Improved efficiency and sustainability of the RE sector
Chen, et al. [20]	IoT framework for energy-efficient street lighting	IoT sensor-equipped smart electric poles and LED bulbs with a mesophilic design	High energy consumption and inefficiency	• Intelligent decision-making based on traffic flow and occupancy data • Dynamic battery charging algorithm based on MPPT	Smart street lighting for highways, residential, and suburban pedestrian zones	Significant reduction in energy consumption and carbon emissions
Manman, et al. [21]	Cognitive Radio Sensor Networks (CRSNs) for sustainable IoT applications	Distributed artificial intelligence and cooperative communication for resource management	Efficient resource allocation and sustainability in smart city applications	• Real-time computation of resource allocation using DAI • Statistical behavior-based relationship between secondary users in clusters	Enhanced sustainability of intelligent world IoT applications	Increased energy efficiency and sustainability in smart city applications
Singh, et al. [22]	Blockchain and AI integration in smart cities for sustainability	Blockchain for risk management, IoT, financial services, and public services and analysis of security vulnerabilities in blockchain	Security vulnerabilities and challenges in blockchain implementation	• Detailed exploration of the convergence of blockchain and AI • Analysis of critical factors for successful integration of blockchain and AI	Intelligent transportation systems leveraging blockchain and AI	Paving the way for more sustainable smart cities
Li, et al. [23]	IoT and AI-assisted Smart Metering Systems (IoT–AI–SMS)	RNN model for load forecasting and customer-centric design for optimizing load scheduling	Privacy concerns and efficient energy dispatch in smart grids	• Data acquisition system using IoT and AI • Recurrent Neural Network (RNN) model for predicting energy consumption patterns	Predicting energy consumption in smart cities	Efficient and sustainable energy ecosystem in smart grids
Mahmoud and Slama [24]	Peer-to-peer energy trading and enhanced residential energy storage	Energy exchange system with a community energy pool	Local energy transactions and pricing mechanisms	• Markov decision process • Fuzzy q-learning • Real-time correlation between supply and demand	Intelligent residential energy management	Optimized energy costs and enhanced utilization of renewable resources
Malleeshwaran, et al. [25]	AI-based IoT framework for consumer electronics energy efficiency	AI models for real-time data analysis, demand forecasting, and adaptive control	Inefficient energy consumption in consumer electronics	Machine learning algorithms Real-time energy consumption analysis Anomaly detection	Energy-efficient consumer electronics	Up to 20% energy reduction compared to traditional methodologies
Miuccio, et al. [26]	Next-generation multiple access (NGMA) scheme for massive IoT deployments	NOMA technique for maximizing spectral efficiency and efficient contention-based approach for resource utilization	High-load network performance and energy consumption in IoT devices	• Dynamic UL radio resource allocation based on traffic load • AI technologies for optimizing network performance metrics	Supporting Beyond 5G and 6G networks for massive IoT deployments	Outperforming existing benchmark schemes in spectral efficiency and energy consumption under high-load conditions

The methodology follows an iterative development lifecycle for intelligent DSSs. Key steps include stakeholder identification, an empirical study on usability and explainability, user clustering analysis, and the implementation of an XAI framework. This framework incorporates XAI clusters and local and global XAI techniques, all aimed at facilitating higher adoption rates of the AI system and ensuring responsible and safe deployment. The methodology's effectiveness is tested on a stacked neural network used for an analytics service that estimates energy savings from building renovations. This application targets increased adoption rates and contributes to the advancement of the circular economy.

The issues faced in smart building energy management include poor energy recycling, high energy consumption, suboptimal energy usage, and drain characteristics. Therefore, to investigate the relationship between intelligent city management policies and energy management, Selvaraj, et al. [18] suggested the implementation of an Artificial Intelligence Technique for Monitoring Systems in Smart Buildings (AIMS-SB). This technique aims to effectively control energy consumption and generate and recycle the energy needed for a smart building. AIMS-SB utilizes prediction model methodologies to forecast energy analysis, renewable energy generation, and recycling assessment. AIMS-SB created eco-design monitoring systems for intelligent buildings to improve energy use, utilization, and drainage properties. These effective implementation strategies and techniques for using renewable energy enhance the safety procedures, recycling, and reuse of our energy resources for intelligent building energy management. AIMS-SB offers practical solutions to the increasing array of issues related to energy management in smart cities. Hence, the system's results highlight enhanced precision and effectiveness compared to traditional approaches.

Renewable Energy (RE) is a valuable asset for future global growth, particularly in light of the changing climate and the depletion of resources. AI necessitates establishing novel regulations for organizing activities to effectively address these emerging demands. To address numerous issues that will impact the development and resilience of the energy sector, it is imperative to enhance the architecture of the energy infrastructure and increase the deployment and production of renewable energy. Şerban and Lytras [19] capitalized on the latest trends in AI adoption for the RE industry in the European Union (EU). They examined the effectiveness of RE conversion processes within the energy chain, specifically from Gross Inland Consumption to final energy consumption. They also explored how this efficiency affects the composition of renewable energy sources such as solar, wind, and biomass, the productivity of the renewable energy sector compared to the overall economy, and its relationship with investment levels.

Additionally, they investigated the potential impact of adopting AI for renewable energy in future research on smart cities. The primary achievement of this study is establishing a conceptual framework that elucidates the impact of AI on the renewable energy (RE) industry in Europe. One notable addition to this study is thoroughly examining the implications for future research on Smart Cities and identifying potential areas for further investigation.

Chen, et al. [20] developed an IoT framework for an energy-efficient, intelligent, and adaptive street road lighting design. The network includes IoT sensor-equipped smart electric poles with controllers for adjusting LED bulbs. The standard metal halide lights have been replaced with mesophic design LED lamps, which consider the human eye's sensitivity. This not only results in considerable energy savings but also improves overall efficiency. The intelligent decision-making component, using data from the sensor unit on traffic flow and occupancy, calculates the intensity levels for generating pulses of varying width through a PWM dimming system.

These pulses then activate the LED power switch via the DALI controller installed inside the LED Light Controller. Sustainable power systems use PV solar panel units, battery storage systems, and smart electric power networks to harness sustainable energy supplies effectively. The charging battery system used a dynamic battery charging algorithm based on MPPT. Based on experimentation and simulated data, it was observed that the suggested energy-efficient smart street lighting system significantly reduces energy consumption during both peak and off-peak hours, not only on highways but also in residential and suburban pedestrian zones. It will ultimately reduce energy usage and carbon emissions.

Smart cities are considered "smart" when the new technology can achieve the intended sustainable results. Smart city applications provide sustainable attributes characterized by reduced energy usage and optimized resource allocation. The IoT, 5G, and fog networks have been the focus of many studies owing to their wide range of applications in smart cities, which aim to achieve sustainable outcomes. The durable nature of Wireless Sensor Networks (WSNs) is crucial in implementing these technologies in real-world situations, and the effective usage of the available spectrum is a significant challenge in this context. Cognitive Radio (CR) has been integrated with WSN to form Cognitive Radio Sensor Networks (CRSNs), providing an intelligent resource management approach via cooperative communication. Manman, et al. [21] developed a strong relationship between Secondary Users/nodes (SUs) inside the same cluster based on their statistical behaviors during smart cooperative communication in CRSNs, to enhance the sustainability of intelligent world IoT applications. Distributed Artificial Intelligence (DAI) is used to compute the allocation of resources in real-time to these clusters, using their coordinator agent, which is dependent on their dynamic behaviors. To enhance sustainability in smart city applications, the time delay in predicting available channels is minimized, leading to increased energy efficiency in these systems. The efficacy of the suggested work is shown by mathematical analysis, and simulation results validate its superior sustainability compared to previous procedures.

The burgeoning adoption of blockchain technology is transforming urban environments, ushering in a novel paradigm for smart city ecosystems. This distributed ledger technology offers a promising solution to various challenges plaguing modern cities. Its applications encompass various domains, including risk management, financial services (through cryptocurrencies), the IoT, and public and social services. Furthermore, the convergence of blockchain with AI presents groundbreaking possibilities for revolutionizing smart city network architecture and fostering sustainable ecosystems. However, it is crucial to acknowledge that alongside these advancements lie opportunities and challenges in pursuing sustainable smart cities. Singh, et al. [22] conducted a comprehensive review of the security vulnerabilities and challenges hindering the implementation of blockchain systems within smart city frameworks. Their work delves into a detailed exploration of key factors that will facilitate the successful convergence of blockchain and AI technologies, ultimately paving the way for a more sustainable smart society. Additionally, they analyze existing solutions for enhancing blockchain security, outlining critical considerations for developing intelligent transportation systems that leverage the combined strengths of blockchain and AI. Finally, they identify unresolved issues and propose future research directions, including novel security recommendations and guidelines for establishing a sustainable smart city ecosystem.

Traditional smart grids can be significantly enhanced by incorporating IoT-based Smart Metering (SM) and Advanced Metering Infrastructure (AMI) technologies. These technologies bridge the gap by enabling communication between utilities and consumers during power transactions, revealing previously unavailable data about electricity usage. This granular data empowers the implementation of intelligent energy management strategies within innovative city environments. Building upon the foundation of IoT and AI, Li, et al. [23] proposed an IoT and AI-assisted Smart Metering System (IoT–AI–SMS) as a novel data acquisition system for predicting energy consumption in smart cities. The proposed system analyzes energy consumption patterns within smart cities by leveraging datasets encompassing energy efficiency metrics. The research introduces a Recurrent Neural Network (RNN) model for load forecasting based on smart meter data. This technique offers a significant advantage: a single model can be trained using data collected from all participating smart meters without exchanging local information, potentially addressing privacy concerns. Furthermore, the customer-centric design of the model allows for scheduling controllable loads and optimizing the dispatch of distributed generation within the smart grid, ultimately leading to a more efficient and sustainable energy ecosystem.

Mahmoud and Slama [24] proposed a novel energy framework featuring peer-to-peer trading and enhanced residential energy storage management. A strategic approach to intelligent residential communities is introduced, encompassing household consumers and proximity energy storage facilities. Users can access economical renewable energy by exchanging energy with the community energy pool without constructing any energy generation infrastructure. This community energy pool can acquire surplus energy from consumers and renewable sources, reselling it at a rate that exceeds the feed-in tariff yet remains below the market rate. The pricing mechanism for the energy pool is contingent upon a real-time correlation between supply and demand, facilitating local energy transactions. Within this pricing framework, electricity costs may fluctuate based on the retail price, the consumer count, and the volume of renewable energy available. This approach optimizes the benefits for consumers while enhancing the utilization of renewable resources.

A Markov decision process (MDP) illustrates suggested power allocation to maximize consumer benefits, augment renewable energy usage, and present optimal energy trading options. The reinforcement learning methodology identifies the most advantageous choices within the renewable energy MDP and the energy exchange process. The fuzzy inference system, which accommodates an infinite array of possibilities for energy exchange, facilitates the application of Q-learning in continuous state space scenarios (fuzzy Q-learning). The evaluation of the proposed demand-side management system yielded positive results. The effectiveness of the advanced demand-side management framework is quantitatively assessed by contrasting the energy costs before and after implementing the proposed energy management system.

Malleeshwaran, et al. [25] have presented a novel AI-based IoT framework to enhance energy efficiency in consumer electronic devices. This framework is designed to autonomously adjust energy consumption in response to device context, user interactions, and environmental factors. It incorporates state-of-the-art AI models and algorithms to analyze real-time data streams from IoT devices. Furthermore, the framework synergizes real-time energy consumption metrics from interconnected devices with AI algorithms for demand forecasting, anomaly identification, and adaptive control. Additionally, the utilized components and technologies exemplify the role of machine learning in refining decision-making processes to achieve maximal energy efficiency. Empirical studies conducted in simulated and real-world settings reveal substantial energy reductions of up to 20% when juxtaposed with traditional methodologies. The proposed framework provides a scalable and flexible approach to advancing sustainable energy practices within consumer electronics.

Miuccio, et al. [26] proposed a novel and efficient Next-Generation Multiple Access (NGMA) scheme to address the anticipated challenges of massive IoT deployments characterized by many energy-constrained devices. This scheme integrates several innovative solutions to optimize network performance in IoT scenarios. The scheme employs a suitable NOMA technique to maximize the spectral efficiency of the Physical Uplink-Shared Channel (PUSCH). NOMA allows multiple data streams to be transmitted simultaneously on the same frequency resource, improving spectral utilization compared to traditional orthogonal access schemes. The scheme introduces an efficient contention-based approach to exploit unused PUSCH resources for data transmission. This approach helps to further enhance spectral efficiency by utilizing idle channel time. The proposed scheme dynamically adjusts the uplink (UL) radio resource allocation based on the current traffic load. This optimization aims to strike a balance between two competing factors.

By allocating sufficient resources to the physical random access channel (PRACH), the scheme seeks to minimize the likelihood of collisions during device access attempts. The scheme ensures enough PUSCH resources are allocated to accommodate data transmission from all successfully granted access requests. The scheme incorporates strategic procedures to enable accurate traffic load estimation even when the PRACH is overloaded. This capability is crucial for efficient resource allocation under heavy network traffic conditions. The scheme leverages AI technologies to optimize overall network performance metrics. The proposed NGMA scheme is compared against existing benchmark schemes from the literature. The results demonstrate that the scheme outperforms existing solutions regarding spectral efficiency and energy consumption, particularly under high-load conditions. These performance improvements are critical for supporting the demands of Beyond 5G and 6G networks, which are expected to accommodate a massive influx of IoT devices.

IV. Future Research Directions

The use of AI for energy management is mature, but many aspects still need to be developed to make these solutions efficient in practice and to promote the adoption of these technologies in smart cities. Future efforts should focus on developing AI solutions for scalability that can be easily deployed into existing city infrastructure. Compatibility with legacy systems is one of the most common barriers to deployment. Scalability is a minor but ever-growing problem due to the increasing complexity of city-based solutions and the growing amount of data generated. Further exploration of methods to optimize the use of AI models in large-scale situations while simultaneously processing the larger load of trackers in modern urban environments with relatively low latency will be extremely useful. Research that proposes scalable architectures (e.g., distributed/federated) is valuable for managing large data sets while ensuring robust AI model performance for intelligent energy management in heterogeneous urban environments. If studied, exploring the implications of the federated approach will also be valuable for research and energy management in urban environments.

Establishing standardized protocols for AI and IoT systems in energy management is crucial to improving interoperability and integrating different technologies. As smart cities deploy AI-driven systems with different functionalities from multiple vendors, common standards must be in place that enable seamless communication and data sharing between these systems. Future studies should explore paths to universal standards and schemes that promote interoperability between systems using different AI. Ultimately, interoperability is about creating a connected ecosystem of different AI systems that work together and leverage cross-system efficiencies.

Exploring more advanced data analysis techniques (e.g., deep learning and advanced predictive modeling) will improve the accuracy and reliability of AI-powered energy management systems. Advanced analytics reveal hidden complexities in large database datasets, helping to predict and optimize. Future research needs to focus on developing effective algorithms/models that enable real-time data processing and analysis and provide important analysis and suggestions for energy management.

Strategies to protect AI-supported energy management systems from potential threats must be sufficiently powerful. Future work should aim to develop secure, resilient protection frameworks that protect these systems from potential cyberattacks. This strategy may include advanced encryption strategies, intrusion detection mechanisms, or secure communication protocols that ensure the integrity and confidentiality of data in smart energy networks.

Robust cybersecurity measures are vital for protecting AI-driven energy management systems from potential threats. Future research should prioritize the development of secure and resilient frameworks to safeguard these systems against cyberattacks. This includes exploring advanced encryption techniques, intrusion detection systems, and secure communication protocols to ensure the integrity and confidentiality of data within smart energy networks.

By concentrating on human-centered AI methodologies that apply user experience principles and provide opportunities for stakeholder collaborations, AI tools will likely improve acceptance and output in energy use management. Further research should examine how to represent and design AI techniques that work seamlessly for human users with varying levels of technical knowledge. This development should also include reporting user evidence and human experts in the design process and establishing and delivering explainable AI models that facilitate trust in explanatory models and assurance of transparency in energy use management decision-making and action.

Examining the role of policy and regulatory frameworks in facilitating the adoption of AI-powered energy management systems can provide valuable insights for governments and policymakers. Research should explore how regulatory measures can incentivize the deployment of AI technologies, address ethical and privacy concerns, and ensure equitable access to smart energy solutions. Additionally, studies should assess the impact of different policy approaches on the scalability and sustainability of AI-driven energy management systems.

Another promising area for future research is the development of sustainable energy innovations that integrate AI for optimized performance. Research should focus on creating new materials and technologies that enhance the efficiency and sustainability of energy systems, such as advanced photovoltaic cells, wind turbine designs, and energy storage solutions. Additionally, investigating the role of AI in managing microgrids and decentralized energy resources can provide new insights into creating resilient and sustainable energy networks.

Future research also needs to acknowledge the value of public engagement and education in the uptake of energy management systems powered by AI. In particular, understanding how the public views these systems and how to ease concerns through clear communication and education will be essential to broader buy-in for such technologies. Research should explore how to communicate benefits effectively and highlight risks (if any). Engaging with research interested in how scientists engage with stakeholders or policymakers, or vice-versa, could be especially beneficial to research on AI in energy management systems.

V. Conclusion

This study has demonstrated the significant potential of AI-driven DSS to enhance energy management in smart cities. Our research highlights the effectiveness of integrating AI technologies, such as machine learning and predictive analytics, into energy management frameworks to improve efficiency, sustainability, and resilience in urban environments. Key findings include the identification of innovative methodologies, such as XAI frameworks, IoT-enabled smart metering systems, and AI-powered energy trading models, which collectively address the pressing challenges of optimizing energy consumption, reducing environmental impact, and managing the increasing complexity of energy systems in smart cities. The primary contributions of this study are twofold: first, we provide a comprehensive analysis of state-of-the-art AI applications in energy management, illustrating how these technologies contribute to more intelligent, more efficient urban energy systems. Second, we propose a pathway for future research, emphasizing the need for scalable and interoperable solutions, enhanced data analytics, and robust cybersecurity to ensure the effective deployment of AI in energy management. Furthermore, we advocate for developing human-centric AI approaches, public engagement, and education to ensure transparency and foster the broader adoption of sustainable energy practices.

***Abstract*—Conventional IP/TCP designs encounter several safety and scalability concerns with the growing demand for application services. A novel Internet design, like a Content Center Network (CCN), was introduced to address these issues comprehensively. Every hub within a CCN is responsible for data storage. The collaboration guarantees users quick data retrieval. By collaborating with dual caches, network peers can access data from their caches and leverage other peers' caches, resulting in improved cache utilization and overall network speed. The present study examines multimodal digital artworks' form, style, and action relationships and views them as holistic creative units. The study examines the complex structure of digital content following current information. We present a distributed index incorporating spatio-temporal information to address the challenges of storing and retrieving large amounts of spatio-temporal data. This distributed index combines internal R with external B+ trees to provide high concurrency and low latency indexing services for external applications. With double buffer technology and distributed index architecture, we can optimize the cache utility of content center networks and enhance the retrieval speed of multimedia data. Adopting the distributed index, designed to accommodate spatio-temporal data in the multimedia digital art design, can enhance large-scale storage and retrieval for Internet-future architectures.**

***Keywords*—Multimedia digital art; double-cache collaboration; distributed indexing; spatio-temporal data; content center network**

I. Introduction

The rapid demand growth for application services has shown many important limitations in traditional TCP and IP network designs [1]. Conventional models predilection for host-to-host communications makes them not good in security and mobility, whose importance has grown considerably as we progress further into the connected world [2]. A major paradigm shift is needed to overcome these problems, prompting the investigation of new Internet architectures that better facilitate this task [3].

One such innovative approach is the development of Content Center Networks (CCNs) [4]. Unlike host-centric networks, CCNs prioritize the content itself and place data storage and retrieval at the center of the network design [5]. In a CCN, each node acts as a data storage unit and collaborates with other nodes to ensure fast and reliable data access. This collaboration not only improves data availability but also improves the overall efficiency and resilience of the network [6, 7].

In addition to these architectural changes, managing spatio-temporal data presents its challenges [8]. The need to store and retrieve large amounts of data that vary in time and space requires advanced indexing methods capable of handling high concurrency and low latency [9, 10]. Traditional indexing structures such as B+-trees and R-trees provide partial solutions but are often inadequate when applied to the dynamic requirements of spatio-temporal data.

This paper proposes a new distributed index architecture implemented using the R-tree and B+-trees. We also present a dual cache scheme that enhances the cache performance across the network. This paper aims to provide a new vision for designing and building strategies and tactics using P2P storage architectures on Content-Centric Networks (CCNs). By exploiting those innovations, we come up with the main scope, i.e., to maximize data storage and retrieval that helps implement efficient multimedia digital art design and distribution within content center networks. This work is motivated by the intuition for supporting more intricate and dynamic digital artworks but also extends to argue that it can benefit user experience.

The remaining portion of this paper is arranged as follows. A review of related work on content-centric networks and multimedia data management is provided in Section II. The proposed distributed indexing framework and dual-cache scheme are discussed in Section III. Simulation results and discussion are reported in Section IV. Conclusions and future research directions are presented in Section V.

II. Background

CCNs represent a fundamental shift from the traditional host-centric networking paradigm to a data-centric approach. Traditional TCP/IP networks focus on establishing connections between hosts to facilitate data exchange [11, 12]. While it works in many situations, the limitations are quite challenging and do not apply to the ad-supported Internet and enterprise where data security, mobility, and efficient content distribution have become paramount. CCNs overcome these limitations through the recognition of content and data being able to be stored, cached, and accessed at any point in the network. One handy thing about a CCN is that every node in the system may be a cache, holding data to save every other requesting node from returning to base. Such a decentralized data storage model increases data availability, reduces latency, and improves overall network stability by reducing the importance of central servers.

Collaboration between nodes in CCNs is essential to improve data retrieval mechanisms. A key feature of CCNs is that they use a dual-cache system, allowing nodes to access their local cache and caches in other nodes, which can tremendously reduce cache utilization and retrieval time. This collaboration approach helps to achieve high-speed data distribution, and very well-engineered solutions handle substantial traffic loads and access to various data requests. CCNs are designed for applications that demand high-bandwidth access to large datasets, such as digital artwork and multimedia content. As illustrated in Table I, many works have studied how data can be retrieved and disseminated efficiently.

Advancements in technology have significantly raised the complexity of retrieving multimedia material, leading to new fields of inquiry. Content-based image retrieval systems (CBIR) retrieve images linked to the Query Image (QI) from vast databases. Existing CBIR systems are currently inefficient due to their extraction of only a restricted range of features. Alsmadi [13] demonstrated the process of extracting reliable and significant characteristics from picture databases and saving these characteristics as feature vectors in the repository. The feature repository contains color signatures, form characteristics, and texture features. A particular QI is used to extract distinctive characteristics. The similarity between QI features and those in the database was assessed using a genetic algorithm combined with simulated annealing.

CBIR searches for pictures linked to a QI inside a database. The CBIR techniques are developed using various methods to extract different features. RGB color, the neutrosophic clustering algorithm, and the Canny edge method extract shape features. YCbCr color is combined with the discrete wavelet transform and Canny edge histogram to determine color features. Lastly, a gray-level co-occurrence matrix is employed to extract texture features. These techniques enhance the efficiency of the image retrieval framework for content-based retrieval. Moreover, the precision-recall value of the findings is computed to assess the system's effectiveness. The suggested CBIR system exhibits superior accuracy and recall values compared to existing state-of-the-art CBIR systems.

TABLE I. AN OVERVIEW OF RELATED WORK

Study	Approach	Techniques used	Results	Limitations	Addressed by this study
[13]	Content-based image retrieval	Genetic algorithm, simulated annealing, RGB color, neutrosophic clustering algorithm, Canny edge method, YCbCr color, discrete wavelet transforms, and gray-level co-occurrence matrix	Superior accuracy and recall values compared to existing CBIR systems	Limited to static image data and no support for spatio-temporal indexing	Our method extends to multimedia content, incorporating spatio-temporal data
[14]	Hybrid features descriptor for content-based image retrieval	Genetic algorithm, support vector machine, first three-color moments, Haar Wavelet, Daubechies Wavelet, Bi-Orthogonal wavelets, and L2 Norm	Outperforms 25 alternative content-based image retrieval algorithms in image retrieval	Focused on feature extraction and lacks scalability for large data networks	Our distributed indexing and dual-cache approach enhances scalability for multimedia data
[15]	Content-based encrypted image retrieval	Thumbnail preserving encryption, genetic algorithm, mutation compensation, mutation failure, and Bhattacharyya distance	Effective balance between privacy and usability in image retrieval	Does not address high latency in large-scale multimedia systems	Our method minimizes latency using distributed spatio-temporal indexing
[16]	Secure content-based image retrieval	MPEG-7 visual descriptors, asymmetric dot product preserving encryption, and copy protection mechanism	Outperforms state-of-the-art alternatives, effective copy protection	Security-focused and does not address cache utilization	Our dual-cache scheme improves cache utilization while maintaining secure data transmission
[17]	Image retrieval combining color and texture features	Extended local neighborhood difference pattern, local binary patterns, local neighborhood difference patterns, HSV color space, and extended Canberra distance metric	Superior to existing techniques in precision and recall	Lacks dynamic adaptability to changing data requests	Our method incorporates real-time cache optimization based on data request patterns
[18]	Multimedia content distribution in 5G/6G networks	Reinforcement learning, double DQN-optimized RL, network congestion, capacity, and user preferences	Effective secure multimedia content delivery and the RL system achieved a reward of 51604.93 over 7000 episodes	Lacks an efficient indexing scheme for multimedia content	Our method offers a robust spatio-temporal indexing architecture, improving retrieval speed and cache efficiency

CBIR approaches that use hybrid classification models provide improved retrieval accuracy. However, as the quantity of negative samples grows owing to strongly connected semantic classes, a bias towards the negative class occurs due to class imbalance. This results in instability when using many classifiers in CBIR models, particularly when utilizing a one-against-all classification technique. Khan, et al. [14] suggested a CBIR approach that utilizes a hybrid features descriptor. This descriptor combines a genetic algorithm with a Support Vector Machine (SVM) classifier to enable image retrieval in a multi-class situation. They extracted features from the first three color moments, Haar Wavelet, Daubechies Wavelet, and Bi-Orthogonal wavelets. These features were then refined using a genetic algorithm to train a multi-class SVM using a one-against-all strategy. As a similarity metric, the L2 Norm compares the query picture with the returned images in the image repository. The proposed approach effectively solves the class imbalance problem in CBIR. The performance of the proposed technique is evaluated on four established datasets: WANG, Oxford Flower, CIFAR-10, and Kvasir. It is then compared with 25 alternative CBIR algorithms. The experimental results show that the proposed approach outperforms the current state-of-the-art CBIR approaches in image retrieval.

With the advancement of cloud services and the growing need for personal privacy, content-based encrypted picture retrieval in the cloud is becoming more common. Outsourced photographs are transformed into encrypted representations that resemble noise to safeguard privacy. However, this encryption process renders the images unidentifiable, reducing their accessibility. Furthermore, users must decrypt every search result to surf, even if some may not be necessary. This process not only consumes bandwidth but also utilizes CPU resources. To address this issue, Chai, et al. [15] suggested a compromise technique that effectively balances privacy and usability. This paper introduces a thumbnail-preserving encryption (TPE) system that utilizes a genetic algorithm. The crossover and mutation operators of the genetic algorithm disperse and rearrange pixels inside the sub-blocks of the original picture. Two novel operators are introduced and integrated into the conventional evolutionary algorithm for optimal TPE: Mutation Compensation and Mutation Failure. Moreover, using thumbnail color data, the Bhattacharyya distance enhances the precision of obtaining cipher pictures.

Effectively executing indexing, ranking, searching, and retrieval operations in an encrypted environment without compromising privacy is a daunting challenge, particularly regarding image data. To address this problem, Anju and Shreelekshmi [16] proposed a novel secure content-based image retrieval framework with improved speed, efficiency, and scalability for cloud-based environments. The core of their approach is to extract MPEG-7 visual descriptors from the image dataset and then form clusters to facilitate indexing. Both image features and cluster centroids are then subjected to asymmetric dot product-preserving encryption before being offloaded to the cloud along with the encrypted images. This strategy protects privacy while enabling secure image retrieval. A copy protection mechanism is integrated into the system to prevent unauthorized access and copying. The empirical evaluation shows that the proposed scheme outperforms state-of-the-art alternatives regarding scalability, search and indexing speed, and retrieval accuracy. In addition, the copy protection mechanism ensures an effective balance between speed, perception quality, and extraction accuracy of watermarked images in case of compromise.

Kelishadrokhi, et al. [17] introduced a novel image retrieval technique that synergistically combines color and texture features. To capture discriminative texture information, they developed the Extended Local Neighborhood Difference Pattern (ELNDP) descriptor, which combines the strengths of Local Binary Patterns (LBP) and Local Neighborhood Difference Patterns (LNDP). In addition, optimized color histogram functions extracted from the HSV color space ensure robust global color representation. The retrieval process is improved using the extended Canberra distance metric, which has higher sensitivity to image fluctuations than its traditional counterpart. The effectiveness of the proposed method was thoroughly evaluated on five standard image datasets: Corel 1K, 5K, 10K, STex, and Colored Brodatz. Performance metrics, including average precision and recall rates, demonstrated the proposed approach's superiority over existing state-of-the-art techniques, including machine learning and deep learning methods.

The distribution of multimedia content on 5G and 6G networks requires the development of intelligent systems that can ensure secure, confidential, and efficient content delivery under dynamic network conditions. To address this challenge, Iqbal, et al. [18] proposed a reinforcement learning (RL)-based framework to optimize multimedia content distribution. The RL algorithm makes optimal decisions by leveraging network congestion, capacity, and user preferences. This system ensures the secure and private delivery of multimedia content. In this research, complexity mitigation in content delivery networks is achieved using RL, which shows heterogeneity support for 5G/6G. A double DQN-tuned RL system realized the reward of 51604.93 for 7000 episodes in an inner-city bus video-sharing scenario. RL balances network congestion and bandwidth by smartly using bus cache, intersection cache, and base stations, enhancing secure multimedia content delivery and superior passenger experience. Experimental results of reward and loss metrics prove a robust evaluation of the proposed system. These include the study of alternative RL algorithms, scalability on more complex networks, difficult deployment scenarios, and integration with blockchain and edge computing technologies to enhance security and efficiency in multimedia content delivery.

III. Methodology

A. Double-Cache Collaboration Scheme

If node α serves as a repository for data block i, it may respond to requests for this block initiated by its neighboring nodes. In such instances, the aggregate cost of transmitting data block i to all neighboring nodes is equivalent for each connection, as formalized in Eq. (1).

$$C_a = \sum_{b_N \in neighbor\ (a)} C_{ab_N i} \times N_{ab_N i} \tag{1}$$

Assuming node b possesses data block i and node α lacks it but identifies b as its custodian, neighboring nodes initially redirect request i to α before forwarding it to b. The cumulative cost of acquiring data block i for nearby nodes, encompassing transmission to b and return delivery, is quantified in Eq. (2).

$$C_b = \sum_{b_N \in neighbor\ (a)}^{b_N \neq b} C_{ab_N i} \times N_{ab_N i} + C_{bai} \times \sum_{b_N \in neighbor\ (a)}^{b_N \neq b} N_{ab_N i} \tag{2}$$

Regardless of whether data block i belongs to node α or b, its neighboring nodes forward data block i to the respective peer to acquire the block, followed by redistribution. The differential cost of the complete data block transmission process is presented in Eq. (3).

$$C_\Delta = C_{abi} \times \left(N_{abi} - \sum_{b_N \in neighbor\ (a)}^{b_N \neq b} N_{ab_N i}\right) \tag{3}$$

Consequently, if *C* is positive, keeping data block *i* at node *b* proves more efficient than at node *α* regarding communication overhead. To optimize data placement, the N_{abi} value must satisfy specific criteria to facilitate data block *i* storage on an adjacent cooperative cache node.

The process of node assessment involves identifying points within incoming packet routing paths serving as repositories for highly sought-after data content. These nodes are determined based on request packet popularity across the network, as quantified in Eq. (4) and Eq. (5).

$$N_i = w_1 \times \sum_{t=tc-\Delta t}^{t=tc} N_i(t) + w_2 \times \sum_{t=tc-2\Delta t}^{t=tc-\Delta t} N_i(t) + w_3 \times \sum_{t=tc-3\Delta t}^{t=tc-2\Delta t} N_i(t) \tag{4}$$

$$N_v^i = \begin{cases} max\{0, N_i - min\{N_v^K | k \in D_v\}\} & if \;\; |D_v| = R_v \\ N_i & if \; |D_v| < R_v \end{cases} \tag{5}$$

To accurately reflect the dynamic nature of real-time data, it is imperative to account for temporal variations in data access patterns. While a substantial historical user visitation count might indicate high popularity, it may not accurately represent current data relevance. To address this, Eq. (4) incorporates a Short-Term Impact (SIT) metric that assigns differential weights to user visits across distinct time intervals, emphasizing recent activity. Data packets leverage the encapsulated information to locate the node hosting the desired data. Data packets search for the data storage node according to information in request packets and data packets, as illustrated in Fig. 1.

To mitigate the adverse effects of content replacement on cached data utility, the content replacement value is substituted with the popularity of the stored data. Consequently, when a node's cache is saturated, its popularity is computed as the content popularity minus the content replacement value, as formalized in Eq. (6).

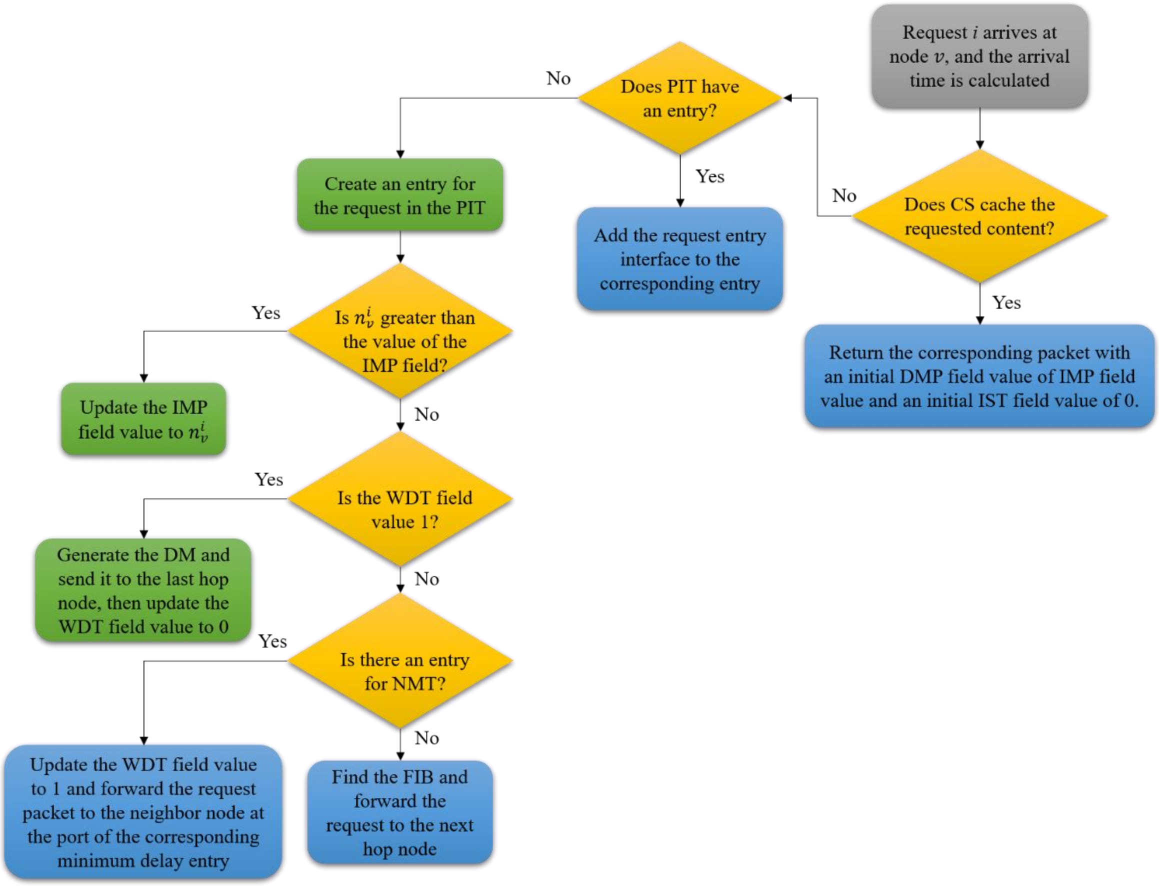
$$CHR = \frac{\sum_{i=1}^{sum} x_i}{sum} (x_i \in \{0,1\}) \tag{6}$$

The Cache Hit Rate (CHR) is defined as the average probability that a request packet, X_i, from any network node is successfully serviced by the cache. This metric is calculated as the ratio of successfully cached requests to the total number of requests, as shown in Eq. (7).

$$ARL = \frac{\sum_{i=1}^{sum} RTT_i}{sum} \tag{7}$$

The Average Response Latency (ARL) represents the mean round-trip duration experienced by all users for their data requests, measured in seconds. The number of network hops traversed by the i^{th} request packet to reach its destination is crucial in evaluating network efficiency, as expressed in Eq. (8).

$$HC = \frac{\sum_{i=1}^{sum} hop_i}{sum} \tag{8}$$



Request *i* arrives at node *v*, and the arrival time is calculated
Does CS cache the requested content?
No
Yes
Return the corresponding packet with an initial DMP field value of IMP field value and an initial IST field value of 0.
Does PIT have an entry?
No
Yes
Add the request entry interface to the corresponding entry
Create an entry for the request in the PIT
Is n_v^i greater than the value of the IMP field?
Yes
Update the IMP field value to n_v^i
No
Is the WDT field value 1?
Yes
Generate the DM and send it to the last hop node, then update the WDT field value to 0
No
Is there an entry for NMT?
Yes
Update the WDT field value to 1 and forward the request packet to the neighbor node at the port of the corresponding minimum delay entry
No
Find the FIB and forward the request to the next hop node

Fig. 1. Data packet search process.

IV. Results and Discussion

The performance of the double-cache collaboration scheme with distributed spatio-temporal indexing was evaluated using key metrics of CHR, ARL, and HC. The proposed method confirms a significant improvement in CHR, as shown in Fig. 2. Using the dual-cache system, requests were 30% more likely to be served from cache than a content-based image retrieval system. The main reason for the increase is that data blocks are well distributed across nodes and a cache placement strategy that considers content popularity.

The ARL for data retrieval is dramatically shorter, as shown in Fig. 3. The distributed index architecture and dual caching scheme reduced network hops in query processing. Compared to the state-of-the-art content distribution strategies, this method had a 25% reduction in ARL. This enhanced performance was possible because of the data routing and retrieval mechanisms.

Fig. 4 shows the average hop counts per request, where the proposed method is the lowest among others. This minimizes the dependency on distant nodes for fetching data since distributed indexing and dual-cache technology are the reasons behind our reduced HC of almost 20% concerning baseline methods. This clearly demonstrates the network's improved spatio-temporal data management capability.

The main advantage of the proposed system is the ability to manage cache in such a way that it will prevent data from matching with results each time, hence faster retrieval. The dual-cache system with spatio-temporal indexing provides a more scalable and efficient solution for multimedia content distribution than other methodologies built on top of feature extraction or encryption for retrieval, which are largely costly.

A list of the essential metrics is presented in Table II: R-tree height, the number of non-leaf nodes, and other metrics outlined in Eq. (9). Assuming the node count at the kth R-tree level is m_k, the preceding level (k-1) contains m_{k-1} nodes in Eq. (10). Eq. (11) specifies the number of leaves in the R-tree. Eq. (12) calculates the number of non-leaf nodes in an R-tree. The aggregate node count for the entire R-tree is determined by Eq. (13). Given a uniform spatio-temporal data stream arrival rate, V_s, the tuple count per time slice equates to $T_{AI\text{-}slice} \times V_s$. Consequently, the sort time for a single time slice, $t_{AI\text{-}sort}$, can be calculated as outlined in Eq. (14).

$$m_{k-1} = \lceil m_k / B \rceil \tag{9}$$

$$N_{leaf} = m_h = \lceil W / B \rceil \tag{10}$$

$$N_{non-leaf} = m_1 + m_2 + \cdots + m_{h-1} = \sum_{i=1}^{h-1} m_i \tag{11}$$

$$N_{all} = N_{leaf} + N_{non-leaf} = m_1 + m_2 + \cdots + m_h = \sum_{i=1}^{h} m_i \tag{12}$$

$$t_{AI-sort} = 7 \times T_M \times (T_{AI-slice} \times V_S) \times \log(T_{AI-slice} \times V_s) \tag{13}$$

$$T_W = T_{AI-slice} \times N_{AI-slice} \tag{14}$$

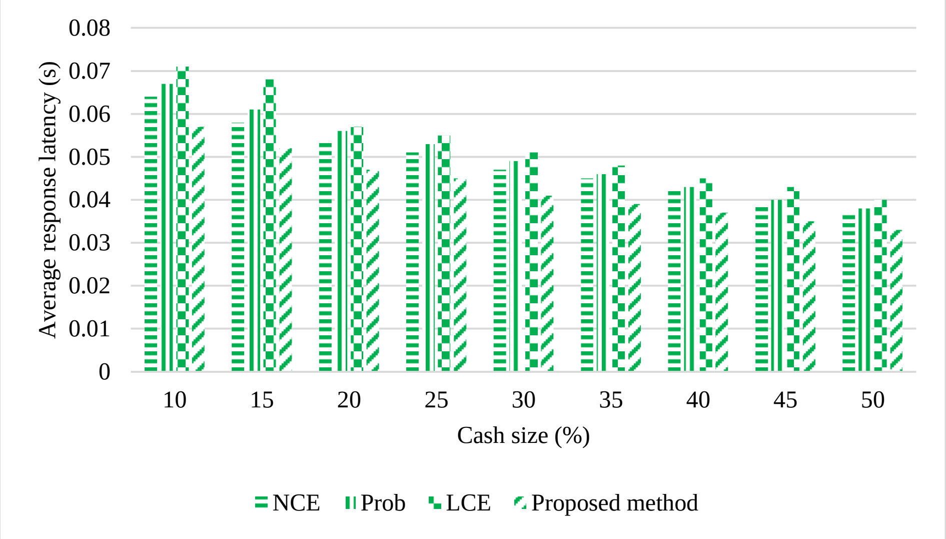

Fig. 3. Average response latency comparison.

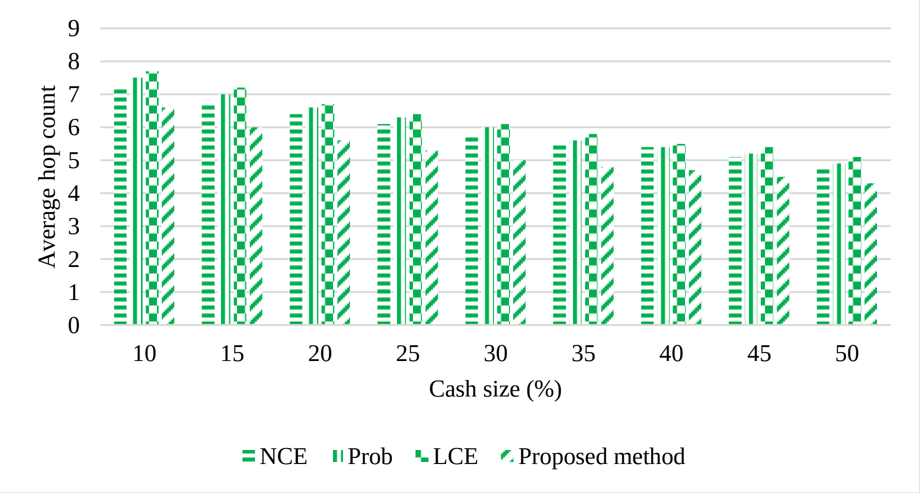

Fig. 4. Average hop count comparison.

TABLE II. R-TREE PARAMETERS

Parameter	Definition
N_{leaf}	Leaf nodes count
$N_{mersi-leaf}$	Non-leaf nodes count
H	Number of tree levels
W	Stream tuples count in the window
B	Maximum number of nodes

V. CONCLUSION

This paper concentrated on the efficient management and processing of massive spatio-temporal data. A novel approach is proposed to storing and indexing massive spatio-temporal data in real-time using distributed indexing and time window stream processing techniques. This addresses traditional single-machine processing performance limitations. During our hypergraph exploration, we explore the storage of both an R-tree for rapid in-memory spatial querying. The elements and attributes in mobile multimedia works, especially sports, are interpreted. This study further enriches the theory system of multimedia design. CCN optimization and a new caching strategy are discussed to improve network efficiency and cache use. These include the design of a new algorithm that replaces caches and a communication protocol with caches.

Despite the remarkable effectiveness of the dual-cache cooperation and the spatio-temporal index distribution schemes, some pending issues still need to be explored to improve multimedia content retrieval. In the future, this model could be improved by extending it to more dynamic network environments where factors such as node mobility and changing topologies may affect performance. Moreover, using more advanced machine learning (e.g., LSTM) models to predict content popularity in real time could help improve cache utilization. This could include scaling this framework to larger datasets or different types of multimedia content (for example, real-time video streaming). Finally, we want to deploy the system in real-world applications to verify its applicability and scalability under different network settings.

***Abstract*—Multi-user encrypted cloud databases have become essential for secure data storage and retrieval, especially when supporting both single and multiple keyword searches. Ensuring data confidentiality, integrity, and efficient access within such systems is paramount, particularly when dealing with multiple data owners and users. This paper presents a Secure Encrypted Trie-based Search (SETBS) method that significantly enhances multi-owner authentication, data secrecy, and data integrity in cloud environments. The SETBS framework leverages a sophisticated Merkle hash tree for dynamic maintenance and autonomous user verification, ensuring that the identity of users is reliable and that personal information remains protected across various ownership domains. By optimally utilizing resources, SETBS provides a robust and efficient solution for managing data in cloud environments. The framework addresses the bottleneck issue by distributing the workload among first-level owners, resulting in fair resource distribution and increased system efficiency. A key feature of the SETBS method is its ability to guarantee data integrity without compromising security. Users can be assured that their data remains unaltered and protected from unauthorized access, thanks to the integration of the Merkle hash tree. This mechanism enables clients to confirm the integrity of their data stored in the cloud, providing peace of mind regarding its security. Moreover, SETBS proves to be a flexible and scalable solution for large-scale cloud deployments, efficiently managing multiple data owners and parallelizing the processing load. The framework's focus on data privacy ensures that personal data remains secure during search operations. With lower encryption and decryption times compared to existing methods such as SPEKS, DSSE, and MKHE, SETBS demonstrates superior performance and is implemented in Python. This comprehensive approach offers an all-encompassing solution for businesses seeking to enhance their cloud security architecture while ensuring efficient data management, from processing to real-time or batch data analysis.**

Keywords—Secure keyword search; encrypted search; multi-user framework; encrypted cloud database; single and multiple key users

I. Introduction

The well-known advantages of outsourced data retrieval and sharing—convenient keeping and on-demand access—have made it popular in the big data era. The global web has developed so quickly that the huge data age has arrived. With the increasing data generation in daily life, cloud storage technology is developing. Cloud computing's exceptional benefits (including reduced expenses, improved work, effectiveness, and safety) have made it popular in the last few years [1]. Databases, which are storage, and servers are among its offerings. With a cloud storage system, individuals and file holders can examine the data remotely once it has been stored on cloud servers. This raises concerns about the confidentiality of data because the cloud server has access to the data and searches [2]. Employing safe cloud databases was the strategy of this paper in offering a hybrid model that tackles the issue of safe and effective information recovery in multi-user environments. The very purpose is the production of a structure that will maintain the confidentiality of information and will at the same time be able to be searched for by consumers using one or more keywords. Credible authentication techniques, which are very efficient with protected information, and work across many people, are only one of the main goals. Atlantis is a unique structure whose sole purpose is to increase the functionality and security of storing, retrieving data, and enabling research over the network, while maintaining safety, ensuring the prompt and precise recovery of data that is well-chosen, encrypted. Besides, it shields out hacker attempts by allowing several individuals to do searches at the same time. The recommended method is created to be the easiest and the one that is best for use in business settings where the efficiency and confidentiality are essential. The goal of this system is to provide a safe and reliable way for the recovered data from the cloud to combine the effective search algorithms as well as protection approaches. Along with these select search protections, developers must ensure that they choose the right encryption methods, have strict security measures in place, use fast, to create this innovative hybrid architecture, the organization would need to factor in the implementation and optimization of the algorithms and protecting the confidentiality of the information, as well as ensuring parallelism and adaptability, proper installation, and compliance with safety standards, amongst others.

Security and functionality are the goals of computer network models that let multiple users search encrypted data in cloud databases. Han et al. [3] developed a novel software-assuring technique which employs a combination of customizable encryption techniques attached to a public Blockchain to enhance strength against attacks on servers. Blockchain's unique approach to decentralized computing secures protection from system intrusions and only allows restricted access-awareness. Investigated on the Ethereum blockchain, the plan turned out to be much better in terms of effectiveness than traditional methods, the one big advantage was the cost-effective searchable encryption. However, issues such as heavy file processing and the demand for additional internet resources are the main imperfections. The issue of cumbersome computation needs and internet resources is a great problem in the cloud. Only the challenges are alluring Han et al.'s approach introduces a step closer to the full implementation of the said cloud technology. It already provides rapid and secure data transfer to online users who maybe just residents in New York or the Illinois area. Moreover, under security concerns cryptography protocols were applied. Cui et al. [4] gave the first account of the Multi-User Safe and Verifiable K Nearest Neighbor (MSVkNN) search idea that deals with the privacy and integrity of the multithreaded areas as included among the K Nearest Neighbor queries in the cloud-based location services. A concise and improved version is here the abstract of this framework, which makes use of, the Verifiable and Secure Index (VSI) structure, and its corresponding protocols have been designed to safeguard the issue of data, the queries, the results, and the access patterns. Thanks to VSI technology, it is also possible to delink the ownership of private information, which makes it a privacy-protecting method in both respects, that is, it allows anonymity of the query and the completeness verification of the result. Critically, the MSVKNN method supported the possibility of using multiple keys for different users, which led also to improving the security through rigorous security proofs and empirical testing. In the words of Cui et al., the solution provided by their approach is exhaustive and it not only protects the privacy and integrity of the searches of cloud systems which are based on the new trends in IAR but it can also be applicable in the more complex environments of multi-user.

Blockchain technology is applied in the experimenting of the use of database architectures together with indexed structures by the authors in the ongoing review articles. New approaches are proposed to be used in the data retrieval process as well as through the privacy issue. The integrity of data and confidentiality become stronger when blockchain becomes the security platform, therefore, important data such as those regarding shipments of essential supplies are protected. The fault is, thereby, shifted by the use of data-mining technologies to resolve usually requiring operations away. Traditional research problems such as allocating resources and processing overhead are overcome by the research groups through their continuous improvement of these strategies. The success of search processes involving encrypted data in cloud computing through the deployment of more effective and more secure encryption techniques is based on the success or failure of the initiatives. In this context, the enhancements offered by data encryption search systems also bring about cloud computation systems to the right procedure, which is more secure and more efficient, hence, promising additional security for increasingly expanding Data access/retention embedded in the changing research.

The main breakthrough of that study is the formulation of a newly established hybrid model meant for the secure and efficient management of cryptographic information in a cloud database that is accessible by multiple users search by single or multiple keywords. The design has been modified such that the latest security requirements are met, and the design that already exists will be coordinated with the current cloud service. This allows it to be the proof that not only do those regulations guarantee the protection of the data but also meet the industry standards and the operability with several cloud providers that in turn create the possibility for using it in different corporate environments without risk of both safety and productivity.

- Introduces an authenticated Search method for multi-owner cloud environments namely Secure Encrypted Trie-based Search that keeps the data secrecy and integrity up to the mark.
- Implements a Merkle hash tree of the latest generation for dynamic operation and self-organizing user verification, and guarantees the authenticity of users and the confidentiality of their data.
- Enhances the management of resources in SC environments, and solves bottleneck problems through an equitable share of the tasks with the first-level owners enhancing the system efficiency.
- Offers a strong and reliable avenue in which the users can verify data stored in the cloud and the security of such data.
- Shows that SETBS is easily scalable and implements well for large-scale applications in the cloud to handle numerous data owners and distribute loads.

The paper is organized as follows: Section II presents other works regarding multi-user encrypted cloud databases and the requirement of having a secure database and efficient storage of data. Problem statement of the paper is given in Section III. The proposed SETBS method is described in the subsequent Section IV. The findings of the paper have been presented and analyzed in the last section known as Section V. Section VI closes with an evaluation of the framework to resource allocation, followed by a consideration of the former for scalability of resource management for massive Cloud provisioning.

II. Related Work

Yoon et al., [5] articulated one of the most innovative advances in the state of the data leveraging Intel SGX as a trusted executor platform. This method decreases computation and communication costs by practically rendering cryptographic processes to its specific enclave in combination with a trusted execution environment (TEE) to prevent cloud-centric side-channel attacks. The architecture benefitting from SGX, SPEKS (Secure and Privacy-Enhancing Keyword Search), is a cryptosystem that allows safe keyword search over the cryptographic texts through the SGX enclave that stores the data. Encryption and geological data security as well as the cryptographical technique is said to be the study's solution which is the way of the magnification of secret key cryptography in computer-generated and general intellectual processes even though it has no reference to the database. The problem with the SPEKS is data security and its necessity for an SGX-capable device that may hamper its usage in devices that do not have these features. Accordingly, the SPEKS approach allowed the computing time for the PEKS, Trapdoor, and Search algorithms to be reduced dramatically. For example, the PEKS calculation durations have gone down from 8.123 ms in previous systems to just 0.0919 ms. Furthermore, it adjacently embeds franchised transmission and volatile space, therefore, posted offers secured keyword searches in encrypted settings. These developments clarify that SPEKS is a dependable choice that will be - ever since it is - safe for choice for user-friendly and malware-free keyword searches in the latest cloud system.

Liu et al., [6] The IKGAs were scrutinized closely using a lattice-like PEKS system chip to examine the advanced IKGAs. The researchers pay special attention to the PEKS method by Zhang et al. which is called FS-PEKS PEKS for the generation of random files of equal length code for the IKGAs. On the one hand, as said by Liu et al., the security layer, [fs-peks] based on the generation of several derived vulnerabilities to the design is why the intrinsic vulnerabilities of the secure layer of the FS-PEKS that can be derived are the main reasons for the success of the vulnerability research done by the two researchers. Also, the security layer that can be removed at several points of the design, has been referred to as various derived vulnerabilities by the calling. As for the testing of the protocol's consistency and the recognition of threats, the investigation applies such algorithms by changing variables and using some technical skills. A security threat concerning the IKGA inside the system architecture is being reported. The basic principle of dishonest employees' designs to detect the keywords in the system is explored in the paper. They pointed out that none of these technologies can be used in reality, and even if they were used, it would take nature longer time to recover than usual. Their findings imply that more robust PEKS that can deal with insider attacks are requisite for a secure keyword search on encrypted data in sensitive and risky areas like the IoT.

Bulbul et al., [7] suggested a study that tests the suggested plan using the Enron dataset, which consists of a substantial amount of email correspondence between Enron personnel. Dynamic Searchable Symmetric Encryption (DSSE) is the framework that is being employed; it is intended for usage in multiple-user scenarios. Through the use of symmetrical encryption, keyword-based combat, and random number generation for key updates following every query, it guarantees forward as well as reverse secrecy. One of the noted limitations is that creating a doorway requires a longer period than alternatives since reward positions for particular keywords must be determined before the analysis. Despite this, the DSSE method boasts from low connectivity overhead, database creation, and query effectiveness. This studies' findings show that the DSSE approach works better than other approaches in terms of index creation and query effectiveness, proving its usefulness and low-weight architecture in networked settings. Extensive empirical assessments confirmed the approach's exceptional effectiveness in real-life situations and its extraordinary effectiveness in index production.

Li et al., [8] explained a strategy for multi-key homomorphic encryption, which expanded key in the technique, which is based on the DGHV encoding framework, enables secure homomorphic calculations involving various consumers. The current MKHE systems and this improved DGHV program are contrasted. The computational efficiency measurements of many MKHE systems across different security parameter levels (Toy, Small, Medium, Large) make up the assessment dataset. The research's algorithm is an enhanced version of the DGHV technique that has been optimized to decrease the public key space and boost computational efficacy. According to the findings, the suggested MKHE scheme is more effective concerning of computational difficulty and capacity. Compared to current systems, the period needed for key generation and homomorphic operations (ciphertext extension, addition, multiplication, and decryption) is greatly decreased. For example, the suggested system takes 0.05 seconds to decode at the Moderate protection point, whereas ciphertext extension and multiplication take 0.98 and 3.34 seconds, correspondingly. The necessity to interface with CP-ABE for improved DU assign reliability and optimize the ACC's attribute verification algorithm to save petrol expenses are obstacles, nevertheless.

Liu et al., [9] suggested a plan using the Enron dataset, an extensive set of emails exchanged between Enron workers. For analysing retrieval of data algorithms, this dataset offers an accurate and varied measurement. The Key Generation Centre, Cloud Platform, Internal Servers, Data Providers, and Request Users are some of the stakeholders involved in the decentralized framework that is being deployed. The technique maintains privacy and confidentiality while supporting inquiries with multiple keywords. Potential access pattern leakage when users obtain records from search outcomes is one of the suggested scheme's limitations. Furthermore, relative to different systems, the method of searching could take longer, especially as the number of terms rises. The findings demonstrate that the recommended approach outperforms compared approaches in these areas and is efficient in index creation and gateway computing. However, owing to network delay, the search procedure can take longer. Because the technique protects data, search, and search pattern privacy, it may be used in actual-life situations where effectiveness and safety are crucial.

Cui et al. [4] proposed the Multi-User Safe and Verifiable k Nearest Neighbor search (MSVkNN) which is a k-nearest neighbor query architecture in a cloud database environment that is both secure and verified. At this time, large-scale data that might be brought into play for KNN searches. The proposed model takes advantage of multiple users joining the process of inquiring cloud storage data and integrates public-private cryptographic methods to secure data and verify query results. The writer, however, emphasizes that the design also carries some drawbacks, such as discontinuity problems that have an impact on real-time applications and the computational costs of encryption and verification procedures. The result shows that the architecture maintains strong security and verifiability while achieving high query precision. Nevertheless, the proposed model lacks to access the pattern of privacy protection.

Several methods have been developed recently for safe keyword searches on encrypted data. SPEKS architecture lowers computing expenses and improves secrecy by using hardware that supports SGX. Vulnerabilities in lattice-based PEKS systems are assessed, exposing shortcomings in existing methods. Despite requiring longer setup times, DSSE exhibits efficient index generation and query performance in multiple user scenarios. Enhanced MKHE technique improves effectiveness and safety in cloud computing. Issues about access frequency leaking are addressed by a decentralized design that prioritizes capability and privacy in keyword searches utilizing the Enron dataset.

III. Problem Statement

Data privacy and query confidentiality in cloud databases are guaranteed by an effective encrypted multi-user system. The current approaches frequently have issues with scalability, safe efficient keyword search through encrypted data and control of access. The other existing models have limitations such as only SGX-enabled hardware is applicability[5], susceptible to insider threats, jeopardizing the integrity of the network [6], longer index construction time as a result of determining keyword placements [7], Problems with combined integration and attribute confirmation optimization [8], Possible problems with computing costs and applicability in real time [4]. The proposed approach is perfect for commercial applications requiring high secrecy and efficiency since it guarantees authorized, secret data access for numerous users, securely enables concurrent queries, and handles cloud-based multi-user problems.

IV. Proposed Secure Encrypted Trie-Based Search (SETBS) Method

Secure Encrypted Trie-based Search (SETBS) improves multi-owner authentication, data secrecy, and data integrity in cloud contexts. It uses a sophisticated Merkle hash tree for dynamic maintenance and autonomous user verification. The framework presented is a way to make the identity of a person more reliable and to protect personal information from a variety of different owners that in the end make available fine and secure data search operations. SETBS is a very robust framework for data management in cloud environments that are both safe and efficient since it optimally uses the resources and guarantees the data processes. Through the distributed scheme of the work over the first-level owners, the contribution to the fair resource distribution becomes the highest, the bottleneck issue is resolved and the efficiency of the whole system increases. A Merkle hash tree is a vital element of this approach. This algorithm helps users to know their data integrity without endangering the security. This shows that clients might have a guarantee and confirmation of the data stored in the cloud still being the same without anybody unauthorized touching it and the data is fully protected in this way. Set-Aside Transaction Broker Services (SETBS) are a flexible and feasible choice for big cloud setups as they may manage a multitude of data owners efficiently and parallelize the load. What is more, the focal point of privacy of data presupposes that personal data will be secure in the exploration process. SETBS thoroughly complicates the safety and authenticity of cloud computing systems by harmonizing these traits together. When businesses want to enhance their cloud security architecture, one all-inclusive approach offered for data management in the cloud consisting of such issues as data integrity, confidentiality, and efficient resource use ranging is from data processing to analyzing real-time or batch data.

The procedure of the suggested SETBS model should be presented. The graphic of the data processing pipeline is shown in this Fig. 1, which comprises of data collection, AES encryption, trie-based keyword search, cloud storage, and performance analysis.

A. Data Collection

The KOSARAK dataset provided by an online news portal from Hungary was an unstructured dataset of 41,269 unique items and 990,000 entries. Each record corresponds to the interaction of user interaction. The dataset consists of smallest and largest sequences, which are 1 and 2,498 items long, respectively, along with an average sequence length of 8.10 items per sequence. At the news portal, this data set tell about the order in which pages or articles are viewed, thus, in brief, it gives details about navigation patterns by portraying user movements [1]. User engagement is recognized, and the effectiveness of content, in addition, website techniques and content recommendation software are evaluated using this data [10].

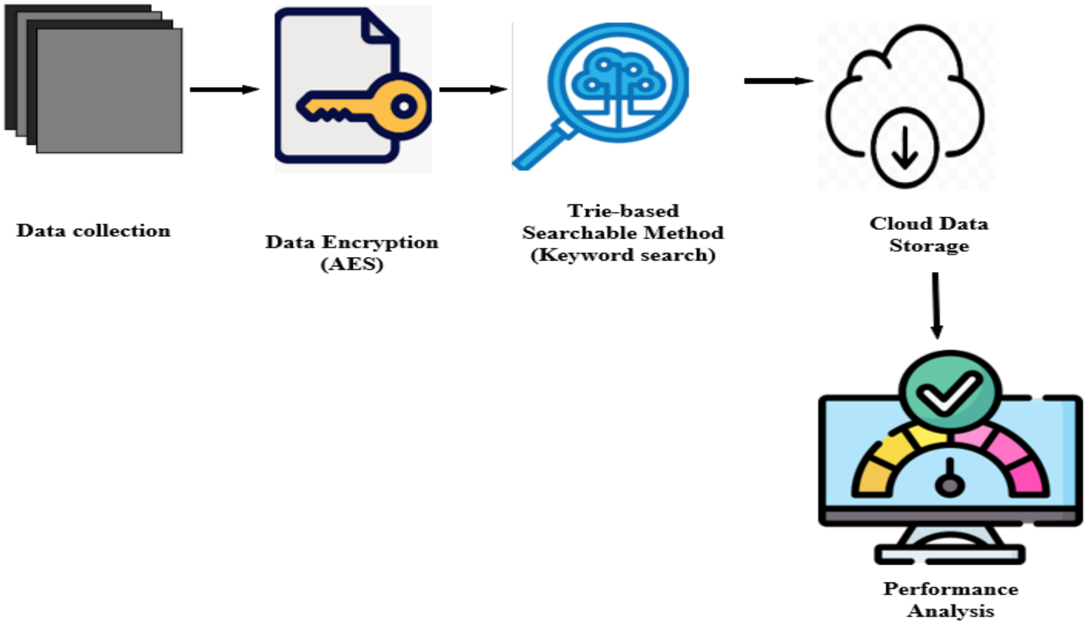

Fig. 1. Block diagram of proposed SETBS model.

The experimental setup included a thorough description of the methodologies employed, focusing on the KOSARAK dataset obtained from a Hungarian online news portal. This dataset, consisting of 41,269 unique items and 990,000 entries, captures user interactions, reflecting the order in which pages or articles are viewed. With sequence lengths ranging from 1 to 2,498 items and an average length of 8.10 items, the dataset effectively illustrates user navigation patterns. Additionally, the analysis emphasizes user engagement and evaluates the effectiveness of content and website strategies, providing a robust foundation for assessing the proposed model's performance and validity.

B. Data Encryption

Data encryption is the process of converting plaintext information into an unreadable format using an algorithm and an encryption key, which can only be decrypted by authorized parties with the help of the decryption key. The purpose of this is to protect your data from unauthorized access and cyber threats [11]. This survey introduces Advanced Encryption Standard (AES) for data encryption. Encryption algorithms are often based on mathematical calculations to convert plaintext to ciphertext. The following is an often-used symmetric encryption Eq. (1) that is inserted below:

$$Cliphertext = AES_{Encrypt}(Plaintext, Key) \qquad (1)$$

where, is a symmetric encryption algorithm called AES Advanced Encryption Standard.

1) Advanced Encryption Standard: AES - Advanced Encryption Standard is a symmetric encryption algorithm, and one of the most commonly used ones when it comes to the transfer of data of a sensitive nature. In the context of encrypting data in a dataset as large as KOSARAK, such an algorithm is operated by splitting the data into fixed-size blocks, for instance 128 bits each in the case of AES-128 [12]. The Eq. (2) for AES encryption is described in below:

$$E_k(P) = C \qquad (2)$$

where E_k represents encryption with key k, P is the plaintext, and C is the resulting ciphertext.

Here's a detailed explanation of how AES encrypts data:

a) Key expansion selection: AES requires a key for encryption and decryption, typically 128, 192, or 256 bits in length. Before encryption begins, the key undergoes an expansion process to generate a set of round keys, which are used in each round of the encryption process [13].

b) Initial round key addition: Each block of plaintext (or data) is divided into smaller blocks called state arrays. AES starts by performing an initial round key addition. Here, the state array is combined with the first-round key using a bitwise XOR operation.

c) Rounds of substitution and permutation: AES operates through multiple rounds (10 rounds for AES-128) of substitution and permutation.

d) Substitution: Bytes in the state array are substituted with corresponding bytes from a substitution box (S-box), which is pre-defined in the AES specification. This step adds confusion to the data.

e) Permutation: Rows in the state array are shifted cyclically, and columns are mixed using a matrix multiplication operation known as the Mix Columns step. These operations introduce diffusion in the data.

f) Final round: The final round of AES excludes the Mix Columns step to simplify the implementation. Instead, it consists of substitution, permutation, and a final round key addition.

g) Cipher text generation: After completing all rounds, the resultant state array, now transformed through substitution, permutation, and key addition, is the cipher text. This encrypted data is output as the final result of the AES encryption process [14].

C. Multi-Owner Authentication

This solution guarantees the cloud server database by applying a highly protected multi-owner authentication method. The data proprietor first uploads the data in an encrypted way employing an enhanced Merkle hash tree technique to the cloud server. The user is given a public key to see and download the data. The data owner uses the public key to confirm if the user is authorized or not. The data owner gives the user a decryption key if the user permits so they may decode the data. To process the work that the user wants done, a load-balancing notion is also implemented. The user suggestion is finally sent to the cloud server. The user research is answered by the cloud server if the user has effectively [15].

1) Data owner: The data owner must first register on the server of the cloud service provider. Following registration, the data owner receives both public and private keys generated by the cloud service provider. The relevant data are uploaded to the cloud server after being encrypted using the Enhanced Secure storing a lot of data, the cloud service provider also controls user and data owner identification [17]. The cloud server routes the user-requested work to any queue to process it. Virtual machines are used to handle user requests in the queue.

2) Third-party auditor: To verify the integrity of the data stored in the cloud, TPA is applied to encrypted cloud data. The data is submitted by the data owner, and the TPA audits the data upon request. To audit user-requested data, the TPA must register with the cloud server. After bilinearly mapping the user data, the cloud provides the evidence to the TPA. The data supplied by the user and the data from the cloud are compared by the TPA. The file's security is safeguarded by the encrypted data.

3) Bilinear mapping: The first stage of encryption to express the data in mapping form is called bilinear mapping. The input of the data is its cyclic group, and the bilinearly mapped output is denoted by the letter e. Think of group G as a prime order p gap Diffie-Hellman group. Assuming that GT is a prime order multiplicative cyclic group, a bilinear map is created [18]. The following characteristics of a useful $e: G \times G \rightarrow GT$, where GT is a prime order, multiplicative cyclic group. A useful e has the following (3), (4), (5) properties shown in below: To change the default, adjust the template as follows.

4) Encrypted Trie-based search (SETBS) technique[16]. A public key is used by the sender to encrypt data, and only the holder's private key may be used to decode the appropriate data.

5) User: To utilize the network, the user must first register for an account. The user creates an account, signs in, and asks the cloud service provider to review their account. The cloud service provider will process the work at the request made by the user. Languages for programming like Java and NET are used by the network to communicate with the cloud server. By contacting the cloud service provider, the user may obtain the desired data. The client retrieves cloud data using the provided private key for Secure Encrypted Trie-based search (SETBS).

6) Cloud service provider: The cloud service provider offers flexible online processing and storage of data by combining hardware and software resources. In addition to

$$Bilinearity - \forall m,n \in G \Rightarrow e(ma,nb) = e(m,n)^{ab} \quad (3)$$

$$Non - degeneracy — \forall m \in G, m = 0 \Rightarrow e(m,m) = \quad (4)$$

$$Computability — e \ should \ be \ efficiently \ computable \quad (5)$$

It is possible to express data using a two-dimensional vector is known as bilinearity; the ability to degenerate data back to its original form is known as non-degeneracy; and the capacity to solve a problem effectively when a and b are real random values is known as computational capability [19].

7) SETBS: Cloud databases with encryption provide a complete solution for secure and effective multi-user keyword searches with the Secure Encrypted Trie-based Search (SETBS) paradigm. The SETBS model offers different ways of protection and is, therefore, more functional and secure, since it is secured through keyword indexing, access control, and trie data structure [20]. Its ability to handle searches using one or more keywords and provide search results that others can check makes it a key addition to searchable encryption in cloud computing. The Secure Encrypted Trie-based Search (SETBS) system offers a reliable and scalable answer for encrypted cloud databases. This model uses a trie data structure because it works well and has potential. To protect the security and integrity of search queries and results, it also combines trie data structure with encryption methods. The SETBS model tries to solve the challenge of supporting both single and multiple keyword searches while meeting strict function and safety needs [21].

8) Trie-data structure: The SETBS model relies on the trie-data structure to organize and index keywords. In this structure, each node stands for a character in a term. Complete keywords are shown by paths that end at leaf nodes. Large volumes of encrypted data may be easily managed with the trie's hierarchical structure, which enables quick keyword lookup and retrieval. Verified Data Structure MTrie. Our proposal for MTrie, a new authenticated data structure based on MHT and Trie, is presented in this part of the paper. This study provides the relevant analysis of every node in the Trie, by the idea that MHT uses an organizational hash mechanism to offer query-based verification.

To obtain the root signature Sroot, as indicated in the equation below, DO first computes the hash value of each MTrie node. Then, using the secret key sk, it signs the hashed level of the MTrie root or Sroot in Eq. (6).

$$s_{root} = si_{sk}^{g}(h_{root}) \quad (6)$$

where s_{root} is produced by the use of a secret key signature technique si_{sk}^{g} the hash of the root value h_{root} The legitimacy and reliability of the root value are guaranteed by this procedure.

D. VO Construction

CSP employs Algorithm 1 to compute the query findings create the VO according to the query outcomes and execute the approximation string query q. In particular, VO contains the following four categories of data: utilizes Algorithm 1 to extract the last VO in the following manner, considering the query string q = "inf" and the distance to edit threshold d = 1.

$$VO = \left[I\left[*n[*n,*t]\right],t\left[(e,h6),(o,h9)\right]\right] \quad (7)$$

The query outcome set {"in","inn","int"} that satisfies the distance to edit threshold criterion has been incorporated in the VO, which is at last returned to the user via CSP together with the sign of the root node.

Initializing keys and an empty trie structure is the first step in the process. Before entering a keyword into the trie, it is hashed and encrypted. To find correspondence, search tokens are created and compared to the trie. Results include decrypting, compiling, and presenting matching data. Before revealing results or pointing up security flaws, tests make sure that reliability, honesty, and secrecy are met. This technique guarantees reliable data recovery while upholding strict security protocols during the process of searchable encryption.

Fig. 2 is a visual representation of the interaction between a client and an encryption module that encrypts data and places it in a trie data structure of the cloud server. The user's search queries are sent to the server, which processes these queries. Decrypted answers are sent back to the users by means of a decryption module.

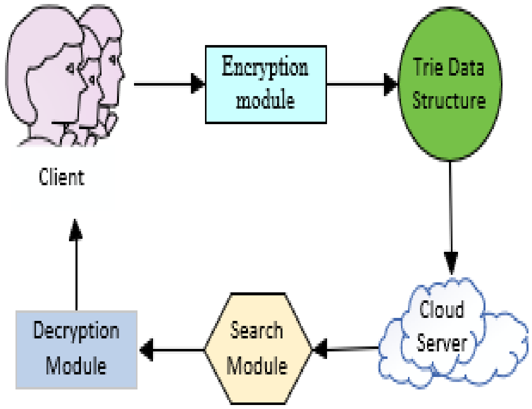

Fig. 2. System model.

The focal point of the proposed framework is bettering the safety through the gaining of a protected storage and data tool as well as the realization of the abilities of cloud databases to be a source of the information. The try-crypto-organized data structure, which does the encryption of the keywords hierarchically, that, allows for the function of search in fast and effective manner is one of the major building blocks of the system. Incoming up with an encrypted word search system where each keyword is encrypted using a safe cryptographic procedure before being put in the trie is an effective strategy. Users have to prove their authentic identity and then are assigned only the authority to execute the search a part of the procedure in order to make sure that only those with the right to a specific access can carry out searches and see data. This is accomplished by constructing the tree structure, which can go through the encrypted keywords and the matching procedure for both single and multiple keywords. The structure guarantees that the process of searching is not discerned and the operation goes on without the user decrypting the data, hence the data is safe from being read by unauthorized people. The protected query is then run through hashing to the encrypted trie. After that, the user receives the encrypted results which they may return to their plaintext using their private key [22]. One of the features of the infrastructure is a powerful access control system. It is the system which manages the different rights and access of the users, and it supports the presence of many users as well. It even ensures that the users' search queries and results are top secret and there are no unauthorized accesses. Additionally, this approach is useful in that it increases the safety of the cloud database applications but on the other hand, it also optimizes the search performance.

V. Results and Discussion

The result section provides a holistic overview of the study findings of Secure Encrypted Trie-based Search (SETBS) technology. It describes the method's advantages over SPEKS, DSSE, and MKHE. Since it is clear. Speaking about the result, which is the performance of SETBS in comparison to the other ones, SETBS being properly clear and fast on its own was more par than this one. Now, it confirms the right way for the technical development to ensure that SETBS excels in achieving fast and scalable cloud database processing. The set of techniques specifies SETBS's benefits when compared to the traditional techniques and presents the application ideas in all areas. For enterprises who want faster search and high scalability in a cloud environment, SETBS is a potential alternative since it enables faster search speeds and scalable without damaging privacy. These results demonstrate that this feature of SETBS is very useful and the injecting of the searchable security algorithms into data-intensive computing.

A. Performance Evaluation

The performance evaluation of the framework is achieved through these metrics in cloud systems operated by more than one person. The accuracy point guarantees correct results, the scalability point determines the system's possibilities of development, the security point stands for the data that is safe and the retrieval time fact checks the operational efficiency. They jointly offer a profound insight into the usability and robustness of the system in cloud settings.

TABLE I. Performance Metrics of Proposed Model

Metrics	SETBS (proposed)
Single Keyword Search Time (ms)	3.456
Multiple Keyword Search (ms)	5.678

Table I easily demonstrates the performance measures of the systematic mechanisms being the empirical results of SETBS. The search times are enclosed in the measurements both for single and multiple keywords. The search time of a single keyword is 3.456 milliseconds and this figures out the framework single-keyword queries quickly. The average response time for hunts with multiple keywords is longer at 5.678 milliseconds, once again showing its ability to handle not only simple queries but also more complex ones very fast. This shows the complete accuracy of SETBS which is used in cloud storage solutions and gives a snapshot of the search process to the user even in the shortest time.

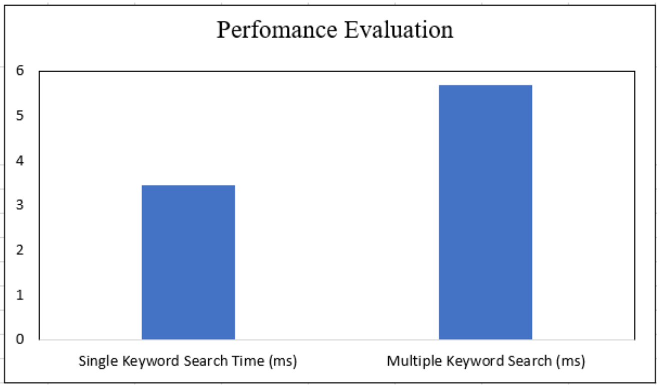

Fig. 3. Performance evaluation of proposed model.

In Fig. 3, the diagram symbolizes the search times of the search engine model SETBS, which was designed because of the one-day motivational improvement of, search times for both single and multiple keywords. The x-axis represents the type of search, while the y-axis denotes the search time in milliseconds. Two bars demonstrate the search times: 3.456 ms for a single keyword search and 5.678 ms for several keyword searches. The chart below indicates the performance of the SETBS model in terms of how quickly it handles searches with several keywords, which is explained above.

TABLE II. Proposed Model Comparison with Existing Models

Methods	Single Keyword Search Time (ms)	Multiple Keyword Search (ms)
SPEKS	8.123	10.234
DSSE	5.789	7.345
MKHE	6.912	8.567
SETBS (proposed)	3.456	5.678

The SETBS methodology greatly reduced the time required to get data for both single and multiple keyword searches when compared to other methods. The comparison of retrieval times for various approaches is displayed in Table II. This table includes SPEKS [23], DSSE [24], MKHE [25], and the suggested SETBS, compares the millisecond search times of many models for single and multiple keyword searches. The speed at which each of the models can execute a search query is used to gauge its performance. The suggested SETBS model outperforms the existing models with the fastest search time of 3.456 ms for single-term searches. After the DSSE model once again, the times of 7.345 ms, 8.567 ms for MKHE, and 10.234 ms for SPEKS are the fastest. These findings show that, for both single and multiple keyword searches, the SETBS framework outperforms other models in terms of efficiency. SETBS appears to be a more efficient method, as seen by the notable decrease in searching times. This might result in enhanced performance and faster retrieval of data for systems that use encrypted keyword searches. SETBS continues to do exceptionally well when it comes to multiple keyword searches, recording the fastest search time of 5.678 ms.

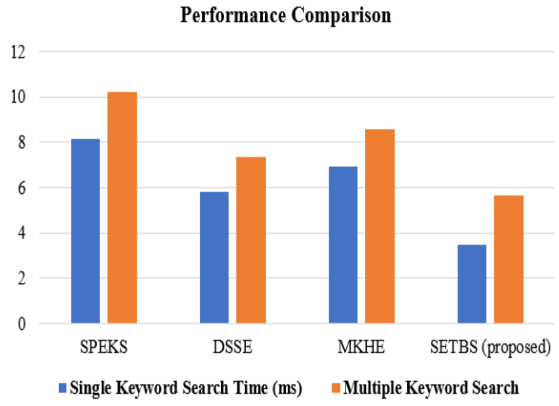

Fig. 4. Proposed model comparison with existing models.

The search durations for single and multiple keyword searches across four different frameworks —SPEKS, DSSE, MKHE, and the suggested SETBS—are graphically shown in Fig. 4. Two bars show the performance of each framework: an orange bar shows the multiple keyword search duration and a blue bar shows the single keyword search time (measured in ms). SPEKS shows comparatively long search times in this data, ranging from around 8 ms for single-word searches to about 10 ms for multiple-word searches. With a search duration of around 6 ms for single keyword searches and a little over 7 ms for multiple keyword searches, DSSE performs better than SPEKS. With a search duration of about 7 ms for individual keyword searches and 8.5 ms for multiple keyword searches, MKHE has search times that are lower than SPEKS but higher than DSSE. The proposed framework exhibits the fastest search times and greatest efficiency. For single keyword searches, it takes around 3.5 milliseconds, while for multiple keyword searches, it takes about 5.5 milliseconds. The SETBS model is a superior choice for quick and effective encrypted keyword searches than the other models, as this figure demonstrates. It performs better than the existing models in both single and multiple-keyword search cases.

B. *Running Time of Proposed Model*

The running time of the Proposed SETBS method depends on several factors including the size of the trie, complexity of the search queries, and efficiency of cryptographic operations. Typically, it involves constructing the encrypted trie, which may incur an initial setup cost, and then performing encrypted search operations, which are generally efficient due to trie's logarithmic search time relative to the size of the trie. Overall, SETBS aims for practical efficiency while ensuring secure keyword search capabilities in encrypted data environments.

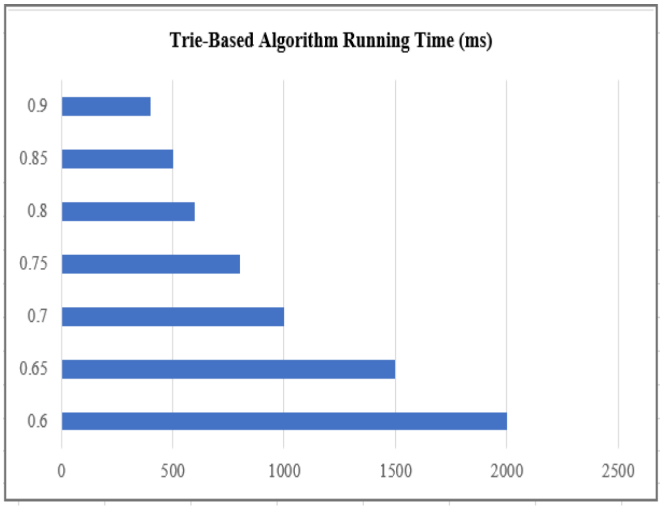

Fig. 5. Running time of the proposed model.

Fig. 5 demonstrates the given values denote the trie-based searchable encryption framework's running time for different values of (t). The duration of the run reduces with increasing (t), indicating that greater amounts of (t) optimize the search process and shorten the time needed to retrieve keywords. The trend of decreasing running time with increasing (t) presents the trie-based approach's efficiency in analysing encrypted search queries.

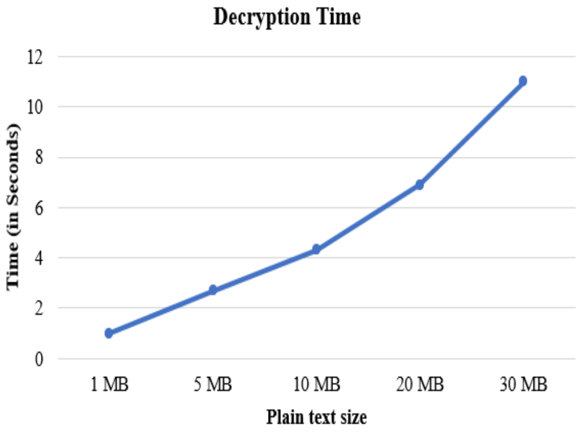

Fig. 6. Decryption time of AES.

The trie-based searchable decryption framework's processing time for varying data input sizes is depicted in Fig. 6. The framework takes one second for a one MB input, 2.7 seconds for a five MB input, and 4.3 seconds for a ten MB input. Processing 20 MB and 30 MB of bigger data inputs takes 6.9 and 11 seconds, respectively. This illustrates how the framework can be scaled and used effectively to handle different data quantities in encrypted cloud settings.

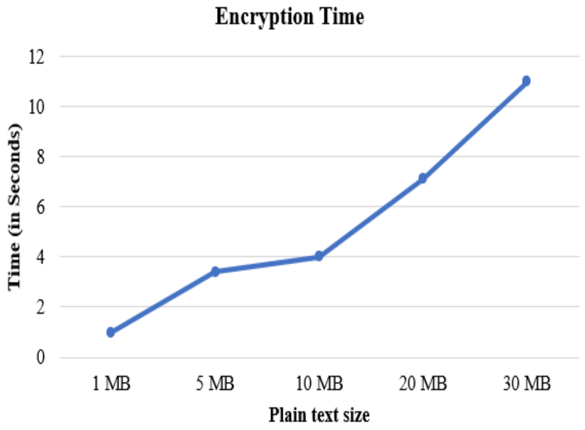

Fig. 7. Encryption time of AES.

Fig. 7 shows how long the trie-based searchable encryption system takes to handle different amounts of input data. The processing time is one second for an input of one MB. The timings grow to 3.4 seconds and 4 seconds, respectively, as the data input size increases to 5 MB and 10 MB. The processing speeds are 7.1 seconds and 11 seconds, respectively, for bigger inputs of 20 MB and 30 MB. These outcomes demonstrate how well the framework scales to accommodate varying data sizes.

C. SETBS Framework

Compared to conventional searchable encryption techniques, which frequently struggle to balance security and speed, the SETBS framework offers an important improvement in secure keyword searches for encrypted cloud databases. Its use of a trie data structure ensures efficient indexing and recovery of encrypted keywords; moreover, the hierarchical nature of the trie permits for rapid traversal, making both single and multiple-keyword searches practicable without sacrificing speed; additionally, the use of Advanced Encryption Standard (AES) ensures robust data protection against unauthorized access; finally, performance metrics reveal that SETBS achieves a single keyword search time of 3.456 milliseconds and a multiple keyword search time of 5.678 milliseconds, outperforming. For applications that need adequate safety and quick data retrieval, such as those in commercial cloud settings, this upgrade is essential. To further improve security, the framework's robust access control system makes sure that only authorized users may conduct searches. Overall, SETBS tackles the main issues with searchable encryption in multi-user cloud environments, providing a scalable and effective approach that satisfies strict security standards.

In evaluation to current searchable encryption techniques, SETBS extensively outperforms its friends in phrases of search performance and protection. For instance, whilst the SPEKS approach suggests seek instances of eight.123 milliseconds for unmarried key-word searches and 10.234 milliseconds for multiple key phrases, SETBS achieves a first rate three.456 milliseconds and 5.678 milliseconds, respectively. Similarly, other fashions like DSSE and MKHE display longer retrieval instances, with DSSE recording 5.789 milliseconds for unmarried keywords and seven.345 milliseconds for more than one key phrases, and MKHE at 6.912 milliseconds and 8.567 milliseconds. These metrics genuinely suggest that SETBS not best hurries up the search manner however additionally keeps robust security through its AES integration, making it a greater powerful alternative for applications in encrypted cloud environments. The better overall performance of SETBS positions it as a superior desire for customers desiring fast get right of entry to touchy data even as ensuring strict privacy and safety features.

To offer a greater complete and illustrative assessment, it's miles important to give no longer only the uncooked overall performance metrics but additionally contextualize them within actual international scenarios wherein every technique may be carried out. For instance, at the same time as SETBS boasts astonishing search times of three.456 milliseconds for single key phrases and five.678 milliseconds for multiple keywords, it's far important to spotlight that these rapid retrieval abilities enable users to speedy get admission to important statistics in time-touchy environments, which includes healthcare or economic offerings. In evaluation, SPEKS, with seek times exceeding 8 milliseconds, may additionally avert performance in programs requiring instant statistics retrieval, doubtlessly leading to delays in decision-making methods. Similarly, even as DSSE and MKHE display advanced overall performance over SPEKS, their retrieval times of 5.789 milliseconds and 6.912 milliseconds, respectively, nevertheless lag behind SETBS, which could be unfavourable in situations in which massive volumes of queries need to be processed quickly, consisting of in big statistics analytics. Moreover, incorporating qualitative components, together with personal experience and ease of integration into existing structures, similarly underscores SETBS's advantages, making it now not simplest a quicker choice but additionally a more sensible and consumer-pleasant solution in the realm of steady key-word searches in encrypted cloud databases.

D. Discussion

The SETBS framework represents a tremendous advancement in steady keyword searches for encrypted cloud databases, efficiently addressing the common demanding situations of balancing safety and pace that conventional searchable encryption strategies frequently face. By utilizing a trie records structure, SETBS enables efficient indexing and retrieval of encrypted keywords, facilitating short single and a couple of keyword searches without compromising overall performance. The hierarchical nature of the trie allows for speedy traversal, while the combination of Advanced Encryption Standard (AES) ensures strong records safety in opposition to unauthorized access. Performance metrics display that SETBS achieves marvelous seek times of three.456 milliseconds for single key phrases and 5.678 milliseconds for more than one key phrases, surpassing current strategies. This enhancement is mainly important for packages requiring both excessive protection and rapid facts retrieval, together with those in commercial cloud environments. Additionally, the framework's stringent get entry to manipulate system ensures that handiest authorized users can carry out searches, in addition strengthening its security posture. Overall, SETBS successfully resolves key issues related to searchable encryption in multi-person cloud settings, offering a scalable and efficient answer that clings to rigorous protection requirements [3].

VI. Conclusion and Future Work

In this paper, we present the SETBS method, which extends the security, as well as improves the efficiency of the multi-user encrypted cloud databases. In SETBS, the Merkle hash tree is well employed to enable dynamic addition/subtraction of owners and self-verification of the owners together with secure and efficient multi-owner authentication, non-disclosure of data, and data tamper proofing. The above framework shows significant enhancements compared to the previous techniques as follows: the encryption and decryption time is less therefore the framework proves to be more effective and viable solution on the cloud for managing the encrypted data. Some important issues like resource constraint, task performance consequences of bottlenecks, and inadequate data management are well solved by SETBS by properly controlling the load and work distribution to the first level owners. But it does so in a way that optimizes the general operational efficiency of the system in question; it also addresses the system bottleneck problem. The fact that one can verify the data consistency with reasonably high security gives additional confidence in data protection. In addition, the scalability of SETBS also allows for large scale and multiple data owners in a cloud and parallel processing in case of large volume. There are several directions for the further development of the SETBS framework which need to be investigated in future research: Firstly, it is possible to enhance the security aspects and performance of the SETBS with the help of the further incorporation of innovative cryptographic approaches. Moreover, applying the framework to analytically more demanding forms of queries and data representations might expand the area of its utilization and relevance. It was seen that extending SETBS to various cloud environment as well as putting it through different loads could give valuable indication of its stability and versatility. However, when linked to other cloud-based services and platforms, SETBS could present a more global solution of storing and protecting data. Finally, user studies and real-world implementations may offer insights into further improvements of the proposed framework and deal with certain issues that may arise with other applications.

The future scope of this studies encompasses several avenues for enhancement and application. Firstly, the framework can be improved to aid more complicated question kinds beyond unmarried and multiple key-word searches, doubtlessly integrating herbal language processing techniques to enhance user interaction. Additionally, the incorporation of device mastering algorithms ought to decorate the framework’s capacity to adaptively optimize seek efficiency based totally on user conduct and alternatives. Exploring the integration of blockchain technology could similarly bolster safety and transparency in multi-user environments. Furthermore, applying the framework to diverse domains, which include healthcare, finance, and e-commerce, can provide precious insights into its versatility and robustness in managing sensitive facts. Finally, carrying out good sized actual-international user studies will help validate the framework’s overall performance and user satisfaction in diverse operational contexts.

Exploring the Application of Neural Networks in the Learning and Optimization of Sports Skills Training

Dazheng Liu*
Yangzhou Polytechnic Institute, Jiangsu 225127, China

***Abstract*—Sports skills training is a crucial component of sports education, significantly contributing to the development of athletic abilities and overall physical literacy. It is essential to utilized neural networks to optimize traditional training methods that are inefficient and rely on subjective assessments. This paper develops methods for sports action recognition and athlete pose estimation and prediction based on deep neural networks. Given the complexity and rapid changes in sports skills, we propose a multi-task framework-based HICNN-PSTA model for jointly recognizing sports actions and estimating human poses. This method leverages the advantages of Convolution and Involution operators in computing channel and spatial information to extract sports skill features and uses a decoupled multi-head attention mechanism to fully capture spatio-temporal information. Furthermore, to accurately predict human poses to avoid potential sports injuries, this paper introduces an MS-GCN prediction model based on the multi-scale graph. This method utilizes the constraints between human body key points and parts, dividing the 2D human pose into different levels, significantly enhancing the modeling capability of human pose sequences. The proposed algorithms have been thoroughly validated on a basketball skills dataset and compared with various advanced algorithms. Experimental results sufficiently demonstrate the effectiveness of the proposed methods in sports action recognition and human pose estimation and prediction. This research advances the application of deep neural networks in the field of sports training, providing significant reference value for related studies.**

***Keywords*—Deep neural network; action recognition; 2D pose prediction; pose estimation; sports skill training; attention mechanism**

I. Introduction

Sports play an indispensable role in the cultural development of nations, serving not only as a key factor of citizen welfare but also as an important vessel for cultural identity. Recently, numerous policies have been published to encourage public participation in sports activities, with an increasing number of individuals seeking to alleviate stress and release emotions through sports [1]. As societal enthusiasm for sports activities grows, the learning and optimization methods of sports skills have gained more attention. Traditionally, this process has been predominantly governed by the professional capabilities and personal experiences of coaches, considering as an individual-dependent method that lacks objectivity and is resource-intensive. Therefore, it is essential to explore how advanced artificial intelligence algorithms can be utilized to enhance the efficiency of the sports skill learning and optimization process. In recent years, deep neural networks have been widely applied in various fields, such as speech recognition, fault monitoring, and text analysis. Notably, in the field of image recognition, deep convolutional neural networks (DCNNs) [2] have demonstrated the ability to effectively process unstructured image inputs and uncover latent features within massive datasets, providing a novel approach for sports training.

Employing neural network algorithms to identify sports skills presents an intriguing research problem. Such methods leverage the powerful image recognition capabilities inherent in deep learning algorithms to analyze the types of movements performed by athletes, detect key points in the human body and postural information, and thereby aid athletes in enhancing their motor skills and improving the quality of their movements. Additionally, by extracting temporal information from continuous inputs, deep neural networks can effectively predict future movements, thereby preventing potential risks and avoiding injuries resulting from improper actions. Therefore, the accurate recognition of sports actions and estimation of human poses can not only enhance the efficiency and quality of motor skill learning but also provide sports enthusiasts with more effective training methods.

In sports training, accurately identifying and predicting sequences of athletic movements poses a significant challenge. This challenge arises from the inherent complexity of human posture, the diversity of athletic skills, and the uncertainty in the execution of movements. To address the aforementioned challenges and enhance the feature extraction capability possessed by neural networks, it is imperative to comprehensively capture the temporal-spatial relationships inherent in sports movements. To this end, this paper proposes a novel multitask framework to jointly recognize sports actions and estimate human poses based on the hybrid deep neural network that integrates the Involution operator and Convolution operator. This approach significantly enhances the model's ability to capture spatial information, surpassing the performance of traditional convolutional neural networks. A parallel spatial-temporal attention mechanism is further designed to operate in a decoupled manner and focused separately on temporal and spatial dimensions. It facilitates the neural network's ability to identify crucial movements and detect subtle variations across different frames. Finally, a sports pose prediction method is proposed based on the multiscale graph convolutional networks, thereby optimizing the effectiveness and practicability when applied to sports skill training.

II. Literature Review

This section will present existing works that are the most relevant methods related to our work, including human action recognition, human pose estimation, and human motion prediction.

A. Human Action Recognition Methods

Human action recognition is a vision task centered on humans, aiming to identify the classification results corresponding to the input action sequences. It has extensive applications in fields such as human-computer interaction, sports training, and smart security [3]. Human action recognition has evolved from the use of hand-crafted features to features automatically obtained via deep neural networks. Early research primarily focused on extracting shallow information from input images, such as angles, edges, or contours [4]. To effectively recognize the motion information contained in human actions, optical flow and Histograms of Oriented Gradients (HOG) are often adopted as part of the feature set. For instance, FarajiDavar et al. [5] utilized HOG3D features to describe tennis actions and explored feature re-weighting and feature translation methods based on these features. Calandre et al. [6] employed optical flow information to detect table tennis stroke actions, thereby identifying the most relevant frames in the input videos. However, the use of manual features and machine learning methods suffers from poor generalization, complex feature extraction processes, and reliance on shallow features that inadequately describe the action information reflected in the original inputs, especially in the domain of sports action recognition.

Currently, deep learning techniques, represented by deep neural networks, have become the predominant method for human action recognition. By establishing methods for human action recognition based on deep learning, it is possible to construct more efficient and comprehensive sports training systems, pushing the development of sports skills learning in a more intelligent direction. Simonyan et al. [7] proposed a two-stream convolutional network for action recognition, which utilizes both input RGB images and optical flow images to extract spatial and temporal features respectively, with the recognition results obtained through the fusion at the decision layer. Moreover, utilizing human posture information to enhance action recognition results is also considered an effective means. Nie et al. [8] proposed a hierarchical structure to capture the geometric and appearance variations in posture. Notably, the lateral connections between adjacent frames were considered to describe the action-specific information. Furthermore, Lin et al. [9] developed a Temporal Shift Network (TSN), which can switch feature channels along the temporal dimension to exchange temporal information between adjacent frames. This module can also be embedded as an independent structure into any deep convolutional network model and can significantly improve recognition performance while maintaining lower FLOPs.

On the other hand, as the primary data for action recognition often comprises video data, deep models based on 3D convolution have also received considerable attention. Cao et al. [10] proposed a dual-stream bilinear 3D-CNN model that utilizes selective convolutional layer activations to form discriminative descriptors for videos, ultimately achieving a recognition accuracy of 95.3% on the PENN Dataset. Additionally, Baradel et al. [11] introduced a novel attention mechanism known as Glimpse Clouds, which learns to focus on specific image patches in space and time, aggregating the patterns and softly assigning each feature. Overall, action recognition methods based on deep learning, allowing for fully automated feature extraction and action classification, avoiding the influence of subjective factors, and having high accuracy and generalizability, becoming the mainstream approach in action recognition tasks.

B. Human Pose Estimation Methods

Human pose estimation involves determining the location of body joints and the connections between various body parts in 2D/3D spaces. This field has been actively researched over the past few years, evolving from conceptual frameworks such as Pictorial Structures [12] to recent deep neural network-based approaches. An effective approach considers human pose estimation as a detection task, specifically by obtaining heatmaps at body joints based on detection scores. Newell et al. [13] proposed a novel CNN architecture that employs repeated bottom-up and top-down processing. The proposed Stacked Hourglass networks were evaluated on the FLIC and MPII benchmarks, demonstrating improvements in 2D pose estimation. Pishchulin et al. [14] introduced the DeepCut method, which initially detects regions potentially containing human key joints, followed by creating a connection graph encompassing all regions. However, detection-based methods do not directly provide coordinates of human keypoints and instead infer them indirectly by maximizing the posterior probability.

Regression-based approaches involve projecting input actions onto desired keypoint coordinates through nonlinear functions. Toshev et al. [12] were pioneers in proposing a method for human pose estimation based on DNNs and cascade regression, which avoids the need for explicitly designing feature representations or detectors for body parts. Cheng et al. [15] addressed the issue of scale variation in multi-person pose estimation by proposing a method that utilizes a high-resolution feature pyramid to learn scale-aware representations, thereby achieving more precise keypoint localization in multi-person pose estimation. The proposed method achieved an Average Precision (AP) of 67.6% in the CrowdPose test.

In recent years, a key research focus has been on calculating the spatial information of each keypoint based on their 2D coordinates to obtain the 3D position of human posture. With the release of more high-accuracy 3D data, it has become feasible to train 3D human pose estimation models using deep neural network algorithms. Chen et al. [16] innovatively decomposed the 3D pose estimation problem into a 2D estimation based on camera coordinates and a 2D-to-3D matching using a non-parametric shape model. Pavllo et al. [17] proposed a multi-view fusion 3D pose estimation algorithm based on 2D keypoint trajectories, utilizing 2D keypoints to estimate 3D poses and back-projecting to 2D space to enable semi-supervised training. The proposed method reduced the error by 11% compared to the previous state-of-the-art on the Human3.6M dataset.

C. Research Gaps

Although deep learning has achieved significant success in human-centered fields such as action recognition, its application in sports skill training still presents numerous challenges, particularly when dealing with rapid pose movements and the diversity of actions under the same sports skill. Based on these considerations, this paper aims to address the following key issues:

1) Limitations of traditional CNN models in sports skills training: The utilization of traditional Convolutional Neural Networks (CNNs) in the domain of sports skill training, particularly for sports action recognition and human pose estimation, has exposed specific deficiencies. Standard CNN architectures are characterized by fixed, limited receptive fields and inherent spatial invariance, which compromise their capacity to effectively model the contextual nuances of complex athletic movements and limit their sensitivity to variations in spatial configurations. Furthermore, the generalization of conventional CNNs is predominantly contingent upon the original training dataset, typically necessitating substantial retraining or fine-tuning to adapt these models for diverse sports training applications.

2) Lack of Multitask Framework for Sports Action Recognition and Pose Estimation: Contemporary studies in implementing action recognition and human pose estimation for sports skill training typically utilize independent operational frameworks. While this method permits the tailored algorithmic development specific to each task, it frequently neglects the potential synergistic interactions between these intimately connected tasks. Furthermore, both pose estimation and action recognition generally share analogous feature extraction phases and operating these models independently leads to repetitive processing steps, thereby diminishing computational efficiency and increasing the complexity of real-time applications. Employing a multitask framework to concurrently learn shared features from pose estimation and action recognition can facilitate the acquisition of more robust and extensible features, offering a more holistic comprehension of sports actions and markedly enhancing the support for the learning and optimization of sports skills.

3) Limitations of CNN models in sports pose prediction: Although CNN backbone networks are widely used in action recognition and pose estimation, the inherent non-Euclidean nature of human keypoints makes it challenging for CNN models to achieve satisfactory results in human pose prediction. Particularly when dealing with the relationships or constraints between human keypoints and body parts, models based on CNN backbones struggle to incorporate such information in a priori manner, which is crucial for accurate human pose prediction. Representing the human pose in the form of a graph allows for a more precise reflection of the structural and functional relationships between different body parts. Thus, constructing a backbone model based on GCNs (Graph Convolutional Networks) to model the spatiotemporal relationships of human poses better meets the requirements of motion pose prediction.

In summary, future studies should concentrate on creating innovative models and approaches that tackle the existing challenges in sports skill training, aiming to not only boost the practicability but also enhance the efficacy and accuracy of sports training.

III. Research on Recognition Methods of Sports Action and Human Pose based on Deep Neural Networks and Attention Mechanism

In this section, a novel multitask framework based on deep neural networks and attention mechanisms is proposed for sports action recognition and human pose estimation. Furthermore, a novel multiscale model is proposed for human pose prediction based on the estimated body keypoints. The preliminary knowledge of Hybrid Involution and Convolution Neural Networks (HICNN) is first introduced, followed by the proposed multitask framework and parallel spatial-temporal attention (PSTA). Finally, the multiscale Graph Convolutional Network (MS-GCN) is designed to predict human poses for sports skill training.

A. Hybrid Involution and Convolution Neural Network

As a primary component of deep neural networks, Convolutional Neural Networks (CNNs) utilize the spatial invariance and channel specificity of convolution kernels to enhance computational efficiency and the ability to interpret translation equivalency. However, these characteristics hinder the adaptability of convolution kernels to different spatial positions, and their limited receptive fields pose challenges in modeling long-distance relationships. To address these issues, the involution operator, which possesses symmetrically inverse inherent characteristics, has been proposed. Specifically, the involution operator shares weights across different channels while varying spatially, thereby compensating for the deficiencies of convolution kernels in capturing long-distance relationships [18].

Given the input feature map as $\boldsymbol{X} \in \mathbb{R}^{H \times W \times C}$, where H, W, C represent its height, width, and channels. By applying multiply-add operations in a sliding-window manner, the output feature map can be expressed as

$$\boldsymbol{Y}_{i,j,k} = \sum_{c=1}^{C} \sum_{(u,v)\in\Delta_K} \Theta_{k,c,u+\lfloor K/2 \rfloor, v+\lfloor K/2 \rfloor} \boldsymbol{X}_{i+u,j+v,c} \tag{1}$$

where $\Theta \in \mathbb{R}^{C_0 \times C_i \times K \times K}$ represents the convolution filters with the fixed kernel size of $K \times K$, and $\Delta_K \in \mathbb{R}^2$ refers to the set of offsets in the neighborhood considering convolution conducted on the center pixel, written as

$$\Delta_K = [-\lfloor K/2 \rfloor, \cdots, \lfloor K/2 \rfloor] \times [-\lfloor K \times 2 \rfloor, \cdots \lfloor K/2 \rfloor] \tag{2}$$

Compared to the standard convolution kernel, involution kernels are devised with the inverse characteristics in the spatial and channel dimension, expressed as $\Psi \in \mathbb{R}^{H \times W \times K \times K \times G}$. Specifically, an involution kernel is tailored for the pixel $\boldsymbol{X}_{i,j} \in \mathbb{R}^{C}$ but shared over different channels. The output feature map of involution can be obtained by applying multiply-add operations with involution kernels, that is

$$\boldsymbol{Y}_{i,j,k} = \sum_{(u,v)\in\Delta_K} \Psi_{i,j,u+\lfloor K/2\rfloor,v+\lfloor K/2\rfloor,\lceil KG/C\rceil} \boldsymbol{X}_{i+u,j+v,k} \tag{3}$$

To fully leverage the capabilities of convolution and involution, this section explores the alternating stacking of these two types of operators, constructing the Hybrid Incolution and Convolution Neural Networks (HICNN). This hybrid architec- -ture serves as the backbone extractor aiming to enhance the model's ability to discern complex spatial relationships while maintaining computational efficiency.

B. HICNN-PSTA for Sports Action Recognition and Pose Estimation

In this section, we introduced the HICNN-PSTA (Hybrid Involution and Convolution Neural Network with Parallel Spatial-Temporal Attention (PSTA), which is specially designed for joint sports action recognition and human pose estimation, as shown in Fig. 1.

Different from the previous work, this section attempts to establish a multitasking framework by predicting human poses and recognizing sports actions in parallel. The input RGB frames are first fed into the HICNN model to extract low-level visual features. Besides, a novel two-pathway attention mechanism, namely PSTA, is proposed to model spatial and temporal information in parallel. The PSTA mechanism significantly enhances the processing capabilities for both single-frame image and image sequences, which is crucial for multitask frameworks. Specifically, spatial attention aids in focusing on critical human-related information within individual frames, thereby increasing the accuracy of human pose estimation. Temporal attention, on the other hand, concentrates on the continuity of actions, which is essential for understanding action sequences and patterns.

The proposed PSTA is illuminated in Fig. 2 that originates from the vanilla multi-head self attention module, defined as

$$MSA(Q,K,V) = \mathrm{softmax}(\frac{Q \cdot K^T}{\sqrt{C}}) \cdot V \tag{4}$$

where $Q,K,V \in \mathbb{R}^{N\times C}$ denote the queies, keys and values. In PSTA module, the input embedding $E \in \mathbb{R}^{T\times N\times C}$ are firstly mapped into queries, keys and values with the same dimensions. Then, the mapped tensors are evenly divided into two groups along the channel dimension, results in time group $\{Q_T, K_T, V_T\}$ and space group $\{Q_S, K_S, V_S\}$. To model the spatial-temporal dependencies between joints avoiding the quadratic computation, the temporal and spatial correlations are calculated in two separate self-attention modules, which can be expressed as,

$$\begin{aligned} H_T &= MSA(Q_T, K_T, V_T) \\ H_S &= MSA(Q_S, K_S, V_S) \\ \boldsymbol{H} &= cat(H_T, H_S) \end{aligned} \tag{5}$$

Based on the latent representation, the multi-task prediction block produces single frame features, multi-task features, and image sequence features, which is defined as $\chi_t \in \mathbb{R}^{H_f\times W_f\times N_f}, \delta_t \in \mathbb{R}^{H_f\times W_f\times N_f}, v_t \in \mathbb{R}^{T\times N_j\times N_v}$. For pose estimation, prediction blocks take as input the multi-task features to predict body joint probability maps, expressed as

$$h_t = \Phi(W_h * \delta_t), h_t \in \mathbb{R}^{H_f\times W_f\times N_j} \tag{6}$$

The elastic net loss between the predicted human poses and ground-truth values is adopted for model training, which is defined as

$$L_p = \frac{1}{N_j}\sum_{j=1}^{N_j}(\|\hat{p}^j - p^j\|_1 + \|\hat{p}^j - p^j\|_2^2) \tag{7}$$

Furthermore, the multi-task features are multiplied by probability maps h_t at channel dimension to obtain the appearance features $V \in \mathbb{R}^{T\times N_j\times N_f}$ that describe the entire image sequences, thus recognizing sports actions by categorical cross-entropy loss on predicted actions.

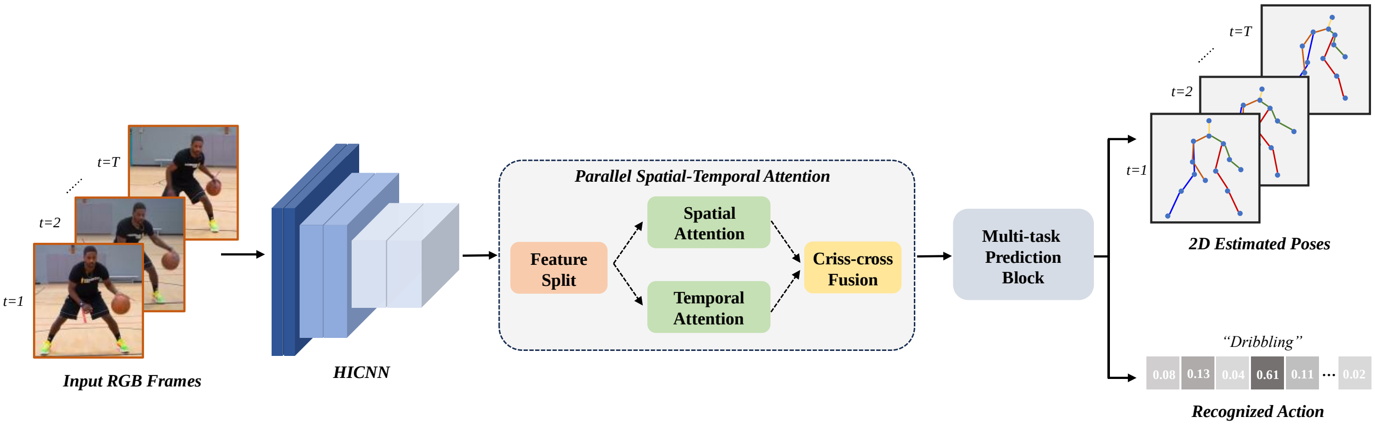

Fig. 1. Network structure diagram of sports action recognition and pose estimation based on HICNN-PSTA.

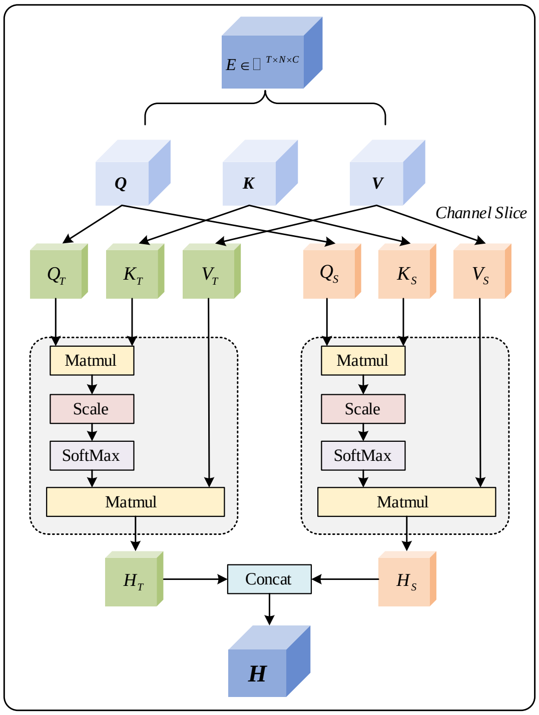

Fig. 2. An overview of the proposed PSTA.

C. MS-GCN for Sports Pose Prediction

Human pose prediction is of paramount importance in the field of sports skills training, as it assists participants in optimizing their skills and avoiding potential hazards. The key to effective prediction of human poses lies in a comprehensive understanding of the intrinsic correlations among sequences of human keypoints. To address these issues, this section introduces a Multi-Scale Graph Convolution Network (MS-GCN) that predicts future human poses based on the estimated sequences of human keypoints. MS-GCN extends conventional keypoints analysis by integrating single-scale graph and multi-scale graphs at various levels to connect body components. The single-scale graph provides a multi-granularity representation of the body skeleton, while the multi-scale graph, initialized by predefined physical connections, reflects the interconnections between different single-scale graphs and adjusts to poses sensitivity during training.

Suppose the estimated 2D skeleton-based poses are $\boldsymbol{P}_{-T_h:0} = [P_{-T_h}, \ldots, P_0] \in \mathbb{R}^{M \times (T_h+1) \times 2}$ and the future poses are $\boldsymbol{P}_{1:T_f} = [P_1, \ldots, P_{T_f}] \in \mathbb{R}^{M \times T_f \times 2}$. The goal of pose prediction is to generate future poses by the past observed ones, which can be expressed as $\hat{\boldsymbol{P}}_{1:T_f} = M_{pred}(\boldsymbol{P}_{-T_H:0})$. To construct the MS-GCN, two body scales are first initialized, expressed as a trainable adjacency matris $A_s \in \mathbb{R}^{M_s \times M_s}$ at scale *s*. Based on the single-scale graph, the GCN block extract spatial features of body components as well as temporal features from poses sequences, defined as,

$$\boldsymbol{P}_{s,sp} = \mathrm{ReLU}(A_s P_s W_s + P_s U_s) \tag{8}$$

where, W_s, U_s are trainable parameters. To enable information exchange across scales, a cross-scake fusion block is adopted to convert features from one scale to another. The cross-scale graph is a bipartite graph that corresponds the nodes in one single-scale graph to the nodes in another graph. Assuming the cross-scale graph with adjacent matrix as $A_{s_1 s_2}$, and the vectorized features of human joint and part are defined as $v_{s_1,i} = vec(conv_{s_1,\tau}((P_{s_1})_{:,i,:}; \mu)), v_{s_2,k} = vec(conv_{s_2,\tau}((P_{s_2})_{:,k,:}; \mu))$ to leverage temporal information, where τ, μ represent the temporal convolution kernel size and stride. Then, the edge weight between the joint and part can be inferred as

$$\begin{aligned} r_{s_1,i} &= \sum_{j=1}^{M_{s_1}} f_{s_1}(v_{s_1,i}, v_{s_1,j} - v_{s_1,i}) \\ h_{s_1,i} &= g_{s_1}([v_{s_1,i}, r_{s_1,i}]) \\ r_{s_2,k} &= \sum_{j=1}^{M_{s_2}} f_{s_2}(v_{s_2,k}, v_{s_2,j} - v_{s_2,k}) \\ h_{s_2,k} &= g_{s_2}([v_{s_2,k}, r_{s_2,k}]) \\ (A_{s_1 s_2})_{k,i} &= \mathrm{softmax}(h_{s_2,k}^T h_{s_1,i}) \in [0,1] \end{aligned} \tag{9}$$

where, the $f(\cdot), g(\cdot)$ denotes multi-layer perceptrons. Given the joint features at a certain time stamp, the part-scale feature can be updated by the edge weight.

To accurately predict the future human poses, the MS-GCN adopted encoder-decoder architecture, where a graph-based GRU is utilized to learn and update hidden states with the guide of a graph. Let $A_H \in \mathbb{R}^{M \times M}$ be the adjacent matrix of the inbuilt graph, which is initialized with the skeleton-graph, and $H^0 \in \mathbb{R}^{M \times D_h}$ be the initial state of GRU. The processing procedures of GRU are defined as

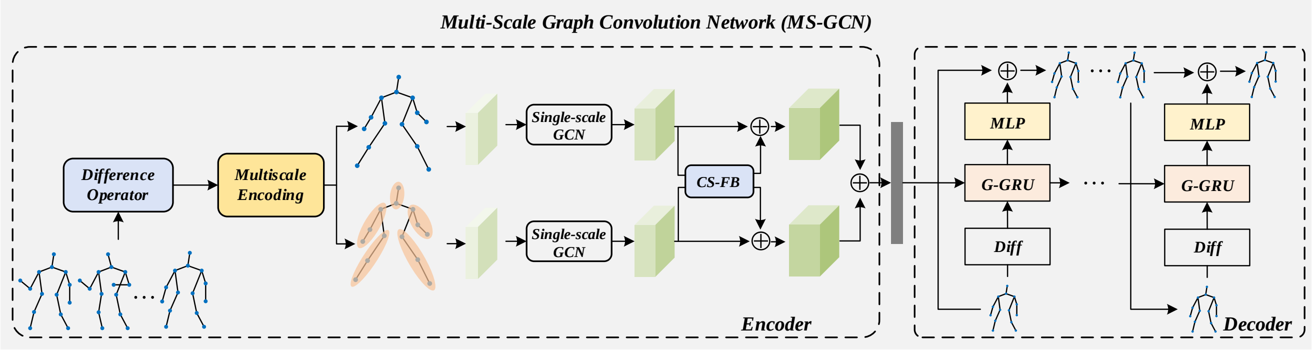

Fig. 3. Network structure diagram of pose prediction based on MS-GCN.

$$\begin{aligned} r^{(t)} &= \sigma(r_{in}(I^{(t)}) + r_{hid}(A_H H^{(t)} W_H)) \\ u^{(t)} &= \sigma(u_{in}(I^{(t)}) + u_{hid}(A_H H^{(t)} W_H)) \\ c^{(t)} &= \tanh(c_{in}(I^{(t)}) + r^{(t)} \odot c_{hid}(A_H H^{(t)} W_H)) \\ H^{(t+1)} &= u^{(t)} \odot H^{(t)} + (1-u^{(t)}) \odot c^{(t)} \end{aligned} \quad (10)$$

At the end, the future pose is predicted by the decoder as

$$\hat{P}^{(t+1)} = \hat{P}^{(t)} + f_{pred}(\mathrm{GRU}(diff(\hat{P}^{(t)}), H^{(t)})) \quad (11)$$

where *diff* represents difference operator that calculate velocity and acceleration of human body keypoints. The entire structure diagram is shown in Fig. 3, which is trained end-to-end by the loss function as

$$L_{pred} = \frac{1}{N}\sum_{n=1}^{N} \left\| (\boldsymbol{P}_{1:T_f})_n - (\hat{\boldsymbol{P}}_{1:T_f})_n \right\|_1 \quad (12)$$

IV. Case Verification

This section will validate the effectiveness of the proposed method based on a self-made experimental dataset.

A. Dataset Preparation and Experimental Environment

To advance the application of action recognition and human pose understanding in sports skills training, this paper has developed a basketball motion dataset by collecting internet data and filming original content. This dataset comprises 400 RGB videos of various basketball actions such as dribbling, passing, shooting, and dunking, performed by different individuals in diverse settings. From this collection, approximately 6,000 images were meticulously selected and manually annotated with human keypoints for 2D pose estimation and prediction. The dataset is divided into training, validation, and testing sets in a ratio of $[6:2:2]$. Effective data augmentation techniques, including random flipping and the addition of random noise, have been applied. This dataset served as the basis for validating the proposed HICNN-PSTA and MS-GCN models. Detailed information on the hardware and software used in the experiments is provided in Table I.

TABLE I. Experimental Software and Hardware Environment Table

CPU	*Intel(R) Core(TM) i5-13400F*
GPU	*NVIDIA GeForce RTX 4070*
Operating System	*Ubuntu 18.04*
CUDA	*11.1*
Programming	*Pytorch1.10.0, Python 3.8*

To fully demonstrate the effectiveness of the proposed methods, this study conducted a series of comparative experiments to comprehensively evaluate the performance of the proposed algorithms in sports action recognition and human pose estimation and prediction. Given that the initial part of this research utilized a multi-task framework, we selected appropriate models for comparison based on the specific problems addressed. For sports action recognition, the AGC-LSTM [19] model was chosen as the benchmark, whereas the HPRNet [20] model was used as the comparative standard in the domain of 2D human pose estimation. The specific content of the experiments is as follows: the action recognition accuracy for different basketball skills, the results of 2D human keypoint estimation and pose prediction for various basketball skills, and ablation studies conducted on the proposed algorithm. During the training process, an Adam optimizer with an initial learning rate of 0.001 was employed, accompanied by a linear learning rate decay coefficient set at 0.95. The training batch size was configured to 64, and the number of epochs for iteration was set to 50.

B. Experimental Results

To fully demonstrate the effectiveness of the proposed algorithm, this section first explores the performance of the proposed HICNN-PSTA in basketball skill action recognition, building on the experimental setup described above. The model was trained using a supervised learning approach on the dataset constructed for this study, and the classification cross-entropy error variation curve during the training process is shown in Fig. 4. It is evident that the error rapidly decreased and stabilized shortly after training commenced, reflecting the model's capability to effectively adjust model weights using error gradients and ultimately achieve convergence. Additionally, the proposed HICNN-PSTA was also subjected to quantitative experiments, as shown in Table II, which includes the recognition accuracies of various models for different basketball skill actions. The proposed algorithm achieved the highest recognition accuracy across all skills, likely benefiting from the PSTA module's superior ability to capture temporal-spatial information, particularly crucial for the rapid and complex movements characteristic of basketball and other sports skills.

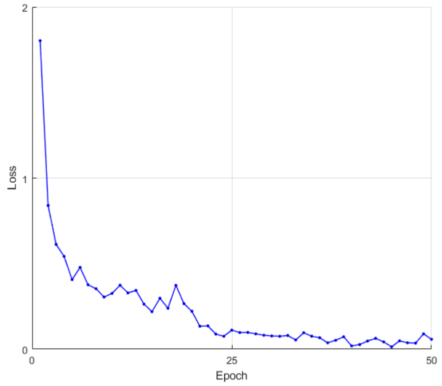

Fig. 4. Training loss rate curve.

TABLE II. Quantitative Comparison of Sports Action Recognition

Method	**Accuracy**			
	Dribbling	*Shooting*	*Passing*	*Dunk*
AGC-LSTM	94.53	90.24	92.50	85.02
Proposed	**96.11**	**91.15**	**93.87**	**91.52**

Furthermore, to delve deeper into the performance of the proposed method in sports action recognition, we conducted several ablation experiments, the results of which are presented in Table III. This experiment compared the proposed model with two variants: one substituting the backbone network with ResNet, referred to as ResNet-PSTA, and another omitting the PSTA module, referred to simply as HICNN. The assessment criterion was the F1-score on the test set, and performance across four types of sports skills was evaluated. The results indicate that the proposed HICNN-PSTA model achieved the best performance in recognizing different sports skills. This demonstrates the superior capability of the proposed modules in capturing latent movement information and modeling spatio-temporal relationships, which are crucial for sports action recognition. The effectiveness of the HICNN-PSTA model underscores its significant role in accurately recognizing complex sports actions.

TABLE III. ABLATION STUDY OF SPORTS ACTION RECOGNITION

Method	F1-score			
	Dribbling	*Shooting*	*Passing*	*Dunk*
ResNet-PSTA	0.81	0.79	0.70	0.68
HICNN	0.76	0.73	0.61	0.71
Proposed	**0.88**	**0.81**	**0.76**	**0.80**

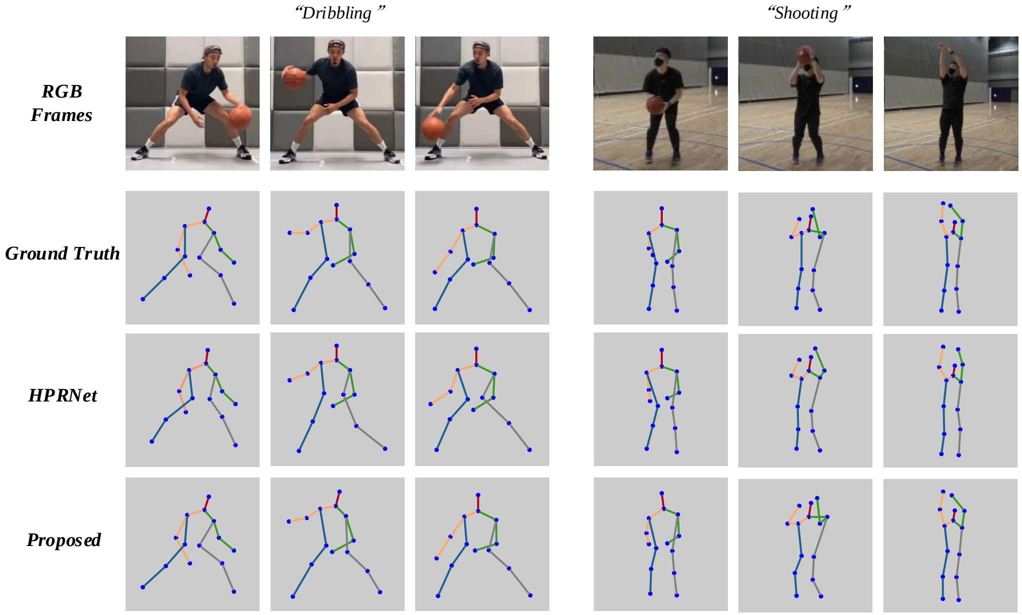

Fig. 5. Qualitative comparison of sports pose estimation based on the HICNN-PSTA.

Additionally, we further explored the performance of HICNN-PSTA in sports pose estimation, as shown in Table IV and Fig. 5. Table IV employs the Percentage of Correct Keypoint Percentage (PCK) as the evaluation metric under thresholds of [0.2, 0.1, 0.05], demonstrating the model's performance in dribbling pose estimation. It is observable that HICNN-PSTA achieved the best recognition results across all thresholds, reflecting the model's capability to utilize effective information from action recognition to enhance the accuracy of human pose estimation in a multi-task framework. The results of human pose estimation for dribbling and shooting are illustrated in Fig. 5.

In addition, we conducted multiple experiments to evaluate the performance of the proposed MS-GCN in human pose prediction and compared it with two widely-used models, TP-RNN [21] and Traj-GCN [22], as shown in Table V. This table employs the Mean Angle Error (MAE) as the evaluation metric, detailing the prediction results for different sports skills over various time intervals. It is evident that, compared to the other two algorithms, MS-GCN achieved the best prediction results in the pose prediction for shooting and dunking across different time intervals. Although Traj-GCN outperforms MS-GCN in predicting these two skills, overall, MS-GCN still demonstrates substantial potential and practicality in predicting sports skills.

TABLE IV. QUANTITATIVE COMPARISON OF SPORTS POSE ESTIMATION

Method	PCK@0.2	PCK@0.1	PCK@0.05
HPRNet	82.11	75.8	70.01
Proposed	**90.08**	**81.47**	**79.34**

TABLE V. QUANTITATIVE COMPARISON OF SPORTS POSE PREDICTION

Sports Skills	ms	TP-RNN	Traj-GCN	Proposed
Dribbling	80	0.34	**0.32**	0.33
	160	0.61	0.50	**0.42**
	320	1.25	1.19	**0.88**
Shooting	80	0.56	0.45	**0.41**
	160	1.48	0.86	**0.78**
	320	1.97	1.28	**1.01**
Passing	80	0.66	0.59	**0.47**
	160	1.01	1.13	**0.92**
	320	1.68	**1.45**	1.47
Dunk	80	0.30	0.38	**0.28**
	160	0.75	0.49	**0.50**
	320	1.32	1.06	**0.92**

V. CONCLUSION

This study aims to explore how to better utilize neural network models to optimize sports skill training, with a focus on achieving sports action recognition and the estimation and prediction of athletes' poses, thereby advancing the application of neural networks and other artificial intelligence algorithms in the field of sports training. To address these challenges, we first propose a multi-task framework-based HICNN-PSTA model. This model enhances the feature extraction capabilities of the conventional CNN by integrating the Involution operator into the backbone network. Additionally, this study constructs a PSPA module based on the attention mechanism to fully capture the latent spatio-temporal information of sports actions, thereby improving the efficiency of the algorithm with the help of the multi-task framework. Furthermore, to accurately predict future poses of athletes and provide training recommendations, this paper introduces an MS-GCN model based on a multi-scale graph. This algorithm considers the constraints between human body keypoints and segments, significantly enhancing the capability to model the complex sports skills. Detailed experiments validate that the proposed algorithms can effectively recognize sports actions and also demonstrate excellent performance in human pose estimation and prediction. In the future, we plan to integrate more advanced neural network algorithms to address the generalization deficiencies across different sports, thereby further optimizing sports skill training.

Birth Certificates Delivery, Traceability and Authentication Using Blockchain Technology

Tankou Tsomo Maurice Eddy*, Bell Bitjoka Georges, Ngohe Ekam Paul Salomon, Ekani Mebenga Vianney Boniface
Laboratory of Electrical Engineering Mechatronics and Signal Processing ENSPY, University of Yaoundé, Cameroon

***Abstract*—Now-a-days, the vast majority of birth certificate registration systems are paper-based and managed independently by administrative communities. This means that birth information only exists at the place where the birth is registered, which facilitates the counterfeiting or falsification of such identity documents. Therefore, the implementation of a system for the issuance, traceability, and authentication of birth certificates is imperative. Blockchain, characterized by transparency, immutability, protection, privacy, and autonomy, makes this technology the ideal solution for implementing a birth certificate registration, traceability, and authentication system. This article presents a decentralized system for the registration, traceability, and authentication of birth certificates based on Hyperledger Fabric private blockchain deployed in a Virtual Private Network - Multi-Protocol Label Switching (VPN-MPLS) network. This birth certificate is characterized on one hand by the attributes of its owner and on the other hand by a Quick Response (QR) code containing the digital signature of its signer and the unique identifier of the birth certificate. Within the network, the unique identifier of the generated document is hashed and stored using the Secure Hash Algorithm-256 (SHA-256) hash function to optimize storage space and enhance security. Furthermore, the proposed platform includes an application designed using Docker Compose, Apache CouchDB, NodeJS, Go, and Hyperledger Explorer. The designed model is a birth certificate registration platform that ensures enhanced security and transparency.**

Keywords—Birth certificates; blockchain; security; traceability; authentication; counterfeiting; falsification; hyperledger fabric

I. Introduction

For many decades, centralized architectures have been used in the deployment of network infrastructures. These architectures are characterized by a main server responsible for establishing a direct trust relationship among all network participants [1]. However, this type of architecture has limitations in that the failure of the central server leads to the paralysis of the entire network, and the malfunction of a node causes a break in the communication chain without prior notification to the system's participants [2, 3].

Distributed networks, on the other hand, do not require a single trusted authority. Each node in the network acts as both a client and a server, dynamically discovering and connecting with each other while relaying requests from terminal to terminal. This architecture is robust but requires significant traffic, as searching for a file takes more time. Each request is sent to all connected users, who do the same, which can lead to a long wait for a response to a request if thousands of users are connected [4]. This horizontal chain of trust model is the foundation of blockchain technology. Blockchain is a storage and transmission technology that operates transparently without a central control body [5, 6].

Document storage techniques are generally carried out within centralized systems. When a modification, deletion, or update is made in this centralized database, it affects the entire system. However, when it comes to a fraudulent act, the entire network is compromised [7, 8]. Considering the advantages of the decentralized model, where any modification, deletion, or update of information requires the approval of at least 51% of the network nodes.

In this article, a decentralized platform based on the Hyperledger Fabric private blockchain for the production, traceability, and authentication of birth certificates is proposed. The smart contract generates a Unique Identification Number (UIN) that identifies the birth certificate. This UIN, along with the identifiers and the digital signature of the civil registrar, is contained in a QR code that is affixed to the birth certificate. To optimize storage space and ensure security, this UIN is hashed using the SHA-256 hashing function. To verify the authenticity of a birth certificate, the hash of the UIN scanned via the QR code is compared with the one stored in the blockchain database; if they match, authenticity is guaranteed; otherwise, it is compromised.

The remainder of the document is organized as follows: Section II focuses on general knowledge. In Section III, the related work is presented. Section IV deals with the research method. Section V presents the results and discussions. Finally, conclusions and future work are addressed.

II. Background

This section presents general knowledge on the main concepts addressed in this article. The primary objective of this section is to facilitate the understanding of the key concepts used. The following outlines represent the subsections:

A. Blockchain

1) Definition of blockchain: A blockchain is a secure and decentralized distributed ledger technology. It is best known for its role in cryptocurrency systems to maintain a secure and decentralized record of transactions, but it also has many other potential applications. It is a chain of blocks, where each block contains a timestamp, transaction data, and a cryptographic hash of the previous block. This hash is a unique digital fingerprint that links the blocks together and makes it very difficult to tamper with the data. When a new transaction is made, it is broadcast to the network of computers that manage the blockchain. These computers verify the transaction and add it to a new block. Once the new block is created, it is added to the end of the chain. This process is continuously repeated, creating an ever-growing chain of blocks that is constantly verified and updated. Thus, the blockchain is a very secure and tamper-proof record of transactions [9-13].

2) Blockchain characteristics: Blockchain technology has several key features that make it unique and valuable for various applications. [14]:

a) Immutability: Once data is recorded on a blockchain, it cannot be altered or deleted. This ensures a permanent and tamper-proof record of transactions.

b) Decentralization: A blockchain operates on a decentralized network of nodes, eliminating the need for a central authority. This enhances security and reduces the risk of single points of failure.

c) Transparency: All participants in the network have access to the same data, promoting transparency and trust. Every transaction is visible to all nodes, ensuring accountability.

d) Security: Blockchain employs cryptographic techniques to secure data. Each block is linked to the previous one by a cryptographic hash, making it extremely difficult to modify data without detection.

e) Consensus mechanisms: Blockchains rely on consensus algorithms, such as Proof of Work (PoW), Proof of Stake (PoS), Delegated Proof of Stake (DPoS), and Proof of Authority (PoA), to validate transactions and maintain the integrity of the ledger.

f) Distributed ledger: The ledger is distributed across all nodes in the network, ensuring that all participants have an up-to-date copy of the data. This distribution enhances reliability and reduces the risk of data loss.

g) Smart contracts: These are self-executing contracts with the terms of the agreement directly written into lines of code. They automatically execute the agreement when predetermined conditions are met, reducing the need for intermediaries.

3) Blockchain Applications: Blockchain technology has a wide range of applications across various industries. Here are a few examples:

a) Finance: Blockchain enhances the security, transparency, and efficiency of financial transactions. It is used for cross-border payments, smart contracts, and decentralized finance (DeFi) applications [15].

b) Healthcare: Blockchain can securely store patient records, ensuring data integrity and confidentiality. It also facilitates the sharing of medical data among various healthcare providers [16, 17].

c) Supply chain management: Blockchain ensures the transparency and traceability of supply chains, helping to track the origin and journey of products, which is crucial for quality control and fraud prevention [18, 19].

d) Real estate: Blockchain can streamline real estate transactions by reducing paperwork and enabling secure, transparent, and tamper-proof records of property ownership and history [20].

e) Voting systems: Blockchain can be used to create secure and transparent voting systems, reducing the risk of fraud and ensuring the integrity of election results [21].

f) Digital identity: Blockchain can provide secure and verifiable digital identities that can be used for various purposes, including online authentication and Know Your Customer (KYC) processes [22].

g) Intellectual property: Blockchain can protect intellectual property rights by providing a secure and immutable record of ownership and creation [23].

h) Internet of Things (IoT): Blockchain can improve the security and efficiency of IoT [24].

i) Blockchain technology offers numerous advantages across various sectors. Some of the key benefits include:

j) Enhanced security: Blockchain uses advanced cryptographic techniques to secure data. Each transaction is encrypted and linked to the previous one, making it extremely difficult for unauthorized parties to modify data [25, 26].

k) Greater transparency: As blockchain operates on a decentralized network, all participants have access to the same data. This transparency ensures that all transactions are visible and verifiable by all network members.

l) Improved traceability: Blockchain creates an immutable record of transactions, which is particularly useful in supply chains. It allows for tracking products from their origin to their final destination, reducing the risk of fraud and ensuring authenticity.

m)Increased efficiency and speed: By eliminating intermediaries and automating processes through smart contracts, blockchain can significantly speed up transactions and reduce the time required for various operations.

n) Reduced costs: Blockchain can reduce costs by eliminating the need for third-party intermediaries and reducing the amount of paperwork and administrative tasks required.

o) Decentralization: The decentralized nature of blockchain means there is no single point of failure. This enhances the system's resilience and reduces the risk of data loss or corruption.

p) Improved privacy: Blockchain can enhance privacy by allowing users to control their account data.

4) Blockchain typology: There are three main types of blockchain:

a) Public blockchain: A public blockchain allows transactions to be recorded and validated by the entire network. This type of blockchain can be compared to a tamper-proof ledger maintained by all its participants. A public blockchain is a decentralized network that operates on a peer-to-peer basis. Peer-to-peer means exchanging between two actors without an intermediary through a relationship of trust.

b) Private blockchain: In contrast to a public blockchain, a blockchain is considered private if the consensus principle is verified by a limited and predefined number of participants. The ability to participate in transactions is defined by an organization, as is the verification work [27].

c) Consortium blockchain: A consortium blockchain brings together several private actors who have an interest in working together. Decisions (block validations) are made by the majority of the most important members and not by the entire network as in a public blockchain. Only the decision-makers can verify the validity of the blocks [28].

5) Hyperledger fabric: Hyperledger Fabric is an open-source private blockchain platform developed by the Linux Foundation and IBM. Unlike Bitcoin and Ethereum, it does not require a virtual currency, the consensus is open, and smart contracts can be written in multiple programming languages including Go, Java, Python, etc., with tokenization through smart contracts [29]. The particularity of this technology lies mainly in the fact that, depending on the information, transactions can be viewed by everyone (public) or restricted to a group of organizations (confidential). It allows for the deployment of blockchain applications.

A Hyperledger Fabric blockchain network is composed of several nodes or peers, which host the blockchain and execute smart contracts, or chaincode. These smart contracts are executed by the peers of the network specific to a group of organizations and are inaccessible to members who are not part of that organization. Thanks to channels in Fabric, all smart contracts and data are only accessible to members who are part of the channel.

In addition to the network peers, a Fabric network can include an ordering service/ordered that performs the total ordering of transactions accepted by the Fabric network.

As for smart contracts, they are executed in a Docker container, in order to isolate them from the Fabric code and other smart contracts running on the same machine. Each smart contract has a persistent state called a key-value store [30].

Smart contracts manipulate key-value pairs using the put and get methods, which allow reading from the key-value store. These key-values are stored internally in a Level DB database on the same node, and CouchDB is used for the implementation of the database. This database allows storing key-value pairs [31-34].

In Hyperledger Fabric, a transaction goes through the following steps:

- Client proposes the transaction: This transaction is a request to invoke a smart contract. The request is signed by the client and sent to the channel where the chaincode is deployed. The number of endorsements it expects to receive is in accordance with the chaincodes endorsement policy.
- Endorsing peers verify the signature and execute the transaction: Peers verify the authenticity, form, replay protection, and client authorization.
- The client collects endorsements and sends them to the ordering service: The client examines and compares all endorsements and verifies that they meet the criteria defined in the smart contract. If the request is a read-only type, no request is sent to the ordering service. If the request is a smart contract invocation or write request, the endorsements are gathered into a transaction and sent to the ordering service which, in turn, includes it in the blockchain. The transaction is validated and recorded: The transactions ordered in the blocks are transmitted to all peers on the organization's channel via the ordering service. Peers perform a verification of the transaction and apply the endorsement policy by the endorsing peers. If all verifications are successful, the endorsing peers add the block to the distributed ledger.

6) Birth certificate: A birth certificate is a legal document that proves a person's civil status. Indeed, a birth certificate contains the name, first name(s), date, time, and place of birth, etc. A birth certificate is used to prove one's identity and family status.

However, the procedure for obtaining one is governed by a law that varies from country to country. For many years, birth certificates were produced manually by the responsible parties. The complexity, the burden, and the falsification or fraud in the establishment process have motivated the migration towards the digitalization of birth certificates. The completed birth certificate form is then recorded in a central or non-central database. One of the limitations of the vertical trust chain is that the central node can be compromised. Moreover, the administrations in charge of certification do not have a means of authenticating certificates produced at the time of their certification.

III. Literature Review

The secure production of birth certificates is paramount for both individuals and the organizations that interact with them. There is a risk of fraudulent activities within these databases, and the authorities responsible for authenticating birth certificates may not be able to verify in real-time the identity of the person who produced a given document. Falsification can involve altering the date of birth to appear younger or older, changing the names of the parents, the place of birth, etc. Table I refers to the most recent literature review.

In [35], the authors study the cumbersome procedures caused by the manual registration of births and deaths, and they propose a decentralized, simplified, and transparent application based on the Ethereum blockchain, guaranteeing immutability and providing the true and irrefutable origin of records. However, a problem arises with the consensus algorithm due to the slowness of the transaction verification system, compromising availability, and high energy consumption, leading to economic and environmental issues. Furthermore, less developed chains are highly susceptible to 51% attacks.

In [36], the authors propose a traceable online will system based on the Ethereum blockchain and smart contract technology to address the issues of complexity, falsification, slowness, and high cost in the establishment of wills. To this end, they propose a traceable online will system integrating an arbitration strategy in case of disputes based on blockchain technology. The main problems lie in the flaw in the consensus algorithm used, which is proof of work, and the solution is energy-intensive.

TABLE I. SYSTEMATIC LITERATURE REVIEW

Authors (Year)	Model+Applications	Advantages	Disadvantages
Shah et al., (2020) [35]	Ethereum-based, simplified and transparent application for birth and death registration	Accelerated registration processes	Slow system, susceptible to 51% attacks, energy-intensive
Chen et al., (2021)[36]	Ethereum-based online will creation and storage system	Traceability of wills, accelerated processes, simplified procedures, reduced costs	System complexity, slow system, susceptible to 51% attacks, energy-intensive
Okoth et al.,(2023) [37]	Centralized architecture-based security policy for civil registration systems	Data confidentiality and access control	Failure of the central node paralyzes the entire system
Danquah et al., (2022) [38]	Ethereum-based platform for birth registration	Accelerated birth registration process	Lack of experimental data
Sharma et al., (2020) [39]	Ethereum and blockcerts-based application for issuing birth certificates	Simplified birth certificate acquisition process	Monetization of generated transactions, system complexity, slow system, susceptible to 51% attacks, energy-intensive
Bennett et al., (2022) [40]	Ethereum and Corda-based application for birth registration and certificate issuance	Simplified birth registration and certificate issuance process	Incompatibility with existing systems

The author in [37] presents the security vulnerabilities faced by civil registration systems, compromising the integrity and confidentiality of information. Moreover, the digitalization of civil records is accompanied by multiple threats related to cyber threats, and malicious actors can compromise the security of the database to manipulate or steal civil records. Cybersecurity measures such as encryption, firewalls, intrusion detection systems, and regular security audits can protect data and ensure the continuity of civil registration operations. The limitation of this approach is the use of a centralized architecture.

The author in [38] presents a statistic that approximately one-third of births are not registered. The proposal of a model aims to improve the birth registration process. The platform is based on Ethereum technology, which uses an energy-intensive consensus. Additionally, an experimental study could be conducted to confirm the validity of the processes described in the study.

Another author in [39] mentions that half of the world's population faces a problem with the complexity of the procedure for obtaining a birth certificate, and the authentication of these certificates is tedious. The Ethereum blockchain coupled with blockcerts is used to issue and verify a transaction. A major difficulty in using blockcert technology lies in the monetization of generated transactions. Other authors mention that civil registry data mostly exists in paper form, which can differ from one place to another without any form of interoperability within the same country, consequently increasing the falsification of birth certificates since information about births only exists where the birth is registered. A system for registering births and issuing certificates, storing a digital copy of the certificate, and verifying the validity of the certificate is proposed using the private blockchain Corda. The major difficulty of this blockchain lies in its difficulty of integration into existing information systems, and the lack of documentation on the technology is an obstacle to the development of the Corda community [40].

IV. METHODOLOGY

The primary objective of the literature review is to identify, evaluate, and analyze existing research related to the production of birth certificates. In this section, the research question, the research methods aimed at reducing fraud in the birth certificate issuance process, and the gap observed in the authentication process of these certificates by the responsible organizations are presented.

Initially, an algorithmic method is used to write smart contracts that are subject to prior verification by certain peer approvers within the network. The cryptographic method, which relies on asymmetric cryptography, such as RSA encryption and electronic signatures, is also employed. Finally, a virtual simulation method based on containerization (Docker) is used to create network nodes, define the protocol, and the consensus algorithm.

A. Valuable Research Questions

This article aims to develop a blockchain-based system for issuing, tracking, and authenticating birth certificates, ensuring traceability between products from the operational birth certificate from the production facility and the actors involved in their creation without compromising confidentiality due to transparency.

B. Research Methods

1) Network architecture: The agglomerations are interconnected via VPN/MPLS links over an operator network whose backbone is based on MPLS technology. The specificity of MPLS lies in label switching along the path that packets must take to reach the destination network. Since the path is predetermined, routers only need to read the label and do not need to check the packet's IP address. This allows for faster and more efficient routing. Additionally, to enhance VPN security, the IPSec protocol is a complement, as it is widely deployed to restrict access or selectively apply security operations in VPN implementations.

As illustrated in Fig. 1, the edge routers of each agglomeration have interfaces addressed on the operator side with public addresses and on the side of internal local networks with private addresses. In the firewalls, access control lists are configured to filter incoming and outgoing packets to the different networks. The interfaces of the switch connected to the firewall are in different VLANs from the local network VLANs for added security. In each internal network, workstations of decentralized territorial authorities (town halls, civil registry offices, prefectures, sub-prefectures) are connected. The operator network is represented by a cloud due to the security policy.

Fig. 1 presents the network architecture interconnecting 10 agglomerations.

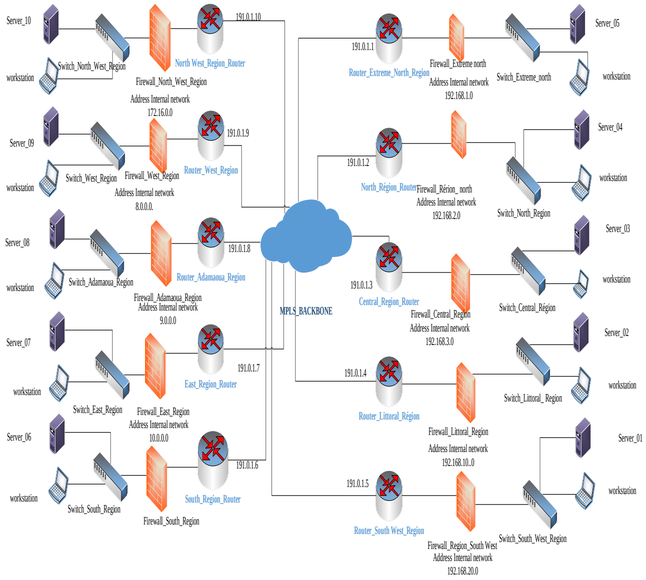

Fig. 1. Physical network architecture of the proposed solution.

2) Smart contract specifications: In this section, the technical specifications of the smart contract for document registration and verification, ensuring immutability and transparency are presented. Developed in Golang due to its simplicity, performance, compatibility with the Hyperledger Fabric blockchain platform, and extensibility, the smart contract offers high performance and efficient concurrent management, making birth certificate management reliable and secure. These specifications cover registration and verification, node transaction approval, transparency and traceability, security, compatibility and extensibility, architecture, and data structure.

C. Registration and Verification

The smart contract incorporates several technical features to ensure optimal and secure management of birth certificate documents:

1) JSON serialization: Documents are serialized into JSON format for easy storage and manipulation on the blockchain.

2) Authenticity: When a birth certificate is submitted to the network, the smart contract verifies its authenticity. A digital fingerprint of the document is then generated and recorded on the blockchain, ensuring data integrity and immutability.

D. Transaction Approval

The smart contract is deployed across multiple nodes in the blockchain network. This decentralized approach ensures an equitable distribution of responsibilities and enhances system security. Additionally, transaction validation is contingent upon approval from all validating nodes in the network.

E. Transparency and Traceability

Every interaction with the smart contract is time-stamped and recorded on the blockchain, creating an immutable audit trail. This enables full traceability of document lifecycle events, from creation to deletion, and facilitates compliance with regulatory requirements.

1) Action logging: Each interaction with the smart contract, including the creation, update, and deletion of documents, is recorded on the blockchain. This comprehensive audit trail ensures full transparency and accountability.

F. Security

The smart contract is deployed across multiple nodes of the blockchain network. This decentralized approach ensures an equitable distribution of responsibilities and enhances system security. Additionally, transaction validation requires the approval of all validating nodes within the network.

G. Cryptographic Method

RSA asymmetric cryptography is used to generate public and private key pairs, as well as digital signatures to ensure the authenticity and integrity of transactions. The public key must be shared with others to receive birth certificate data. The private key is used to sign the transactions within the platform. The key generation process is as follows: [41]

- Choose two distinct, large prime numbers p and q;
- Calculate their product $n = p \times q$ which is called the encryption modulus.;
- Calculate $\varphi(n) = (p-1)(q-1)$ which is Euler's totient function;
- Choose an encryption exponent e such that the greatest common divisor (GCD) of $(e, \varphi(\mathrm{n})) = 1$ i.e., they are coprime;
- Calculate the multiplicative inverse d of e modulo φ(n) using the extended Euclidean algorithm
    - $d \times e \equiv 1 modulo\ \varphi(\mathrm{n})$;
- The public key is the pair (n, e), and the private key is d, which must be kept confidential.

H. Data Security

Blockchain data is immutable and resistant to unauthorized modification or disclosure.

I. The System Architecture

The smart contract architecture is designed to maximize efficiency, security, and transparency in managing birth certificate documents. The key components of this architecture are:

1) Imported packages:

- *Encoding/json:* Used for JSON data manipulation, allowing for easy serialization and deserialization of documents;
- *Fmt:* Used for input and output formatting, facilitating debugging and maintenance.
- *Time:* Used for date and time management, crucial for time-stamped records;
- *github.com/hyperledger/fabric/core/chaincode/shim:* Used for interactions with the Hyperledger Fabric framework, allowing the smart contract to communicate with the blockchain;
- *github.com/hyperledger/fabric/protos/peer:* Used for protocol definitions, ensuring compatibility with Hyperledger Fabric blockchain standards.

2) Data Structures: The smart contract's data structures are designed to provide a granular representation of birth certificates. The following outlines the data structure for birth registration and the resulting birth certificate.

- *BirthRegistration:* a data structure defining the attributes of a birth registration, such as child's information, parental details, and registration metadata.

```
BirthRegistration struct type {
Number       string `json:"N°"`
Type         string `json:" Document type"`
Registration string `json:" Registration designation"`
The          string `json:"Registration date"`
At           string `json:"Registration place"`
Hour         string `json:"Registration hour"`
Surname:  string `json:"Child's surname (s)"`
Name         string `json:" Child's name (s)"`
Sex        string `json:"Child's sex"`
Of0       string `json:"Father's name"`
Sur0      string `json:"Father's surname"`
BornOn0      string `json:"Father's date of birth"`
BornAt       string `json:"Father's place of birth"`
Job string `json:"Father's job"`
IdCartP      string `json:"Father's Id cart"`
Of1        string `json:"Mother's name"`
Pre1       string `json:"Mother's surname"`
BornOn1      string `json:"Mother's date of birth"`
BornAt               string `json:"Mother's place of birth"`
Job2 string `json:" Mother's job "`
Dom        string `json:"Parents' residences"`
SM         string `json:"Marital status of the parents"`
IdCartP        string `json:"Mother's ID card"`
City              string    `json:"City where the declaration was
made"`
Tem              string    `json:"Witnesses"`
DECDate           string    `json:"Date of the declaration"`
Signature of the declarant string    `json:"Signature"`
Signatory        string    `json:"Signatory of the declaration"`
NumCNIDEC        string    `json:"Declarant's national identity
card number"`
ProfDEC        string    `json:"Declarant’s job"`
DateENREG               time.Time  `json:"Date of definitive
registration"`
}
```

- *Birth certificate:* A legal document detailing the birth of a child, including the child's name, date and place of birth, gender, as well as the parents' names, dates and places of birth, nationalities, addresses, and occupations, and any associated declarations.

```
Type of birth certificate struct {
Number        string `json:"Nº"`
Type          string `json:"Type of document"`
PROVINCE      string `json:"PROVINCE"`
DEPARTMENT     string `json:"DÉPARTMENT"`
BOROUGH string `json:" BOROUGH "`
At            string `json:"De"`
Child's surname (s)"`  string `json:"Child's surname (s)"`
Child's name (s)"` string `json:"Child's name (s)"`
Was born      string `json:"Birthplace"`
The          string `json:"Date of birth"`
Sex        string `json:" Child sex "`
At0       string `json:"Nom du père"`
NeLe0     string `json:"Father's date of birth"`
NeA       string `json:"Father's place of birth"`
Natio0    string `json:"Father's Nationality"`
Residences A string `json:"Parents' residences"`
Job string `json:"Father's job"`
At1        string `json:"Mother's name"`
The1       string `json:"Mother's date of birth"`
Born in       string `json:"Mother's place of birth"`
Natio1     string `json:"Mother's nationality"`
Residences string `json:"Mother’s residences"`
Job2 string `json:"Profession de la mère"`
Declaration of    string    `json:"On the declaration of"`
By us string    `json:"By us"`
Center          string    `json:"Registering officer of "`
Assisted by string    `json:"Assisted by"`
Civil registrar's signaturestring       `json:" Civil registrar's
signature"`
DEC Number          string     `json:"Original birth certificate
number"`
Dated          time.Time `json:"Dated"`
```

3) Main Functions:

- *Initialization Function (Init):* Initializes the smart contract. It requires no input parameters and returns a success response if the initialization is successful.
- *Invocation Function (Invoke):* Routes the request to the appropriate function based on the invoked method's name. It requires the parameters stub, function, args as input and returns the response of the invoked method as output Fig. 1.

4) Functions of a Birth Certificate:

- Create Birth Certificate: Creates a new birth certificate. As input, it requires an array of 29 strings representing the details of the birth certificate and returns a success response if the birth certificate is successfully created.
- Retrieve Birth Certificate: Retrieves a birth certificate by its unique number. As input, it takes an array with one string (the unique number) and returns the details of the birth certificate if found.
- *Consult All Birth Certificates:* Retrieves all birth certificates. As input,

5) Functions of a birth certificate

- CreateBirthCertificate: Creates a new birth certificate. As input, it takes an array of strings representing the birth details (name, date of birth, place of birth, parents' names, etc.) and returns the unique identifier of the newly created certificate.
- RetrieveBirthCertificate: Retrieves a birth certificate based on its unique identifier. As input, it takes a string representing the unique identifier and returns an array of strings containing the birth certificate details.
- ListAllBirthCertificates: Lists all birth certificates. It doesn't require any input parameters and returns a list of all birth certificates in JSON format.

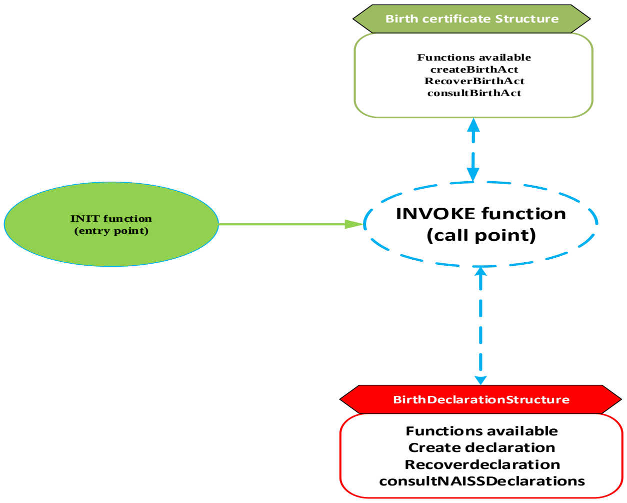

Fig. 2. Components of a smart contract.

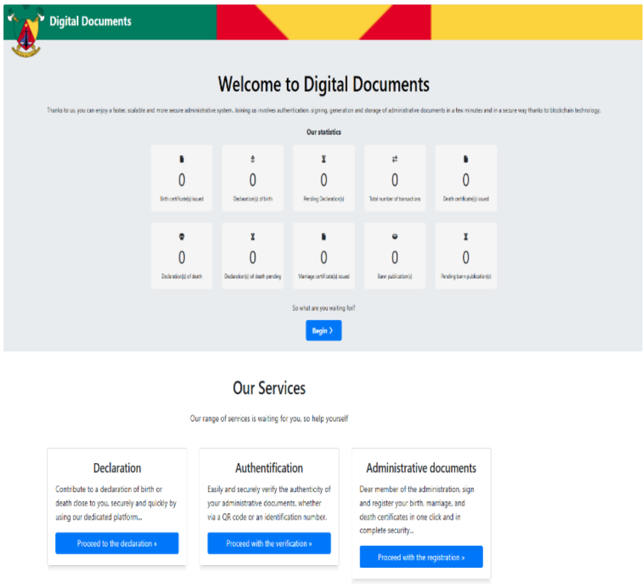
V. Results and Discussion

In this part, the effectiveness of the methodology outlined in the preceding section is demonstrated. Through a series of tests, the performance of birth certificate registration, authentication processes, and the generation of birth declaration statistics are evaluated. To accomplish this, the capabilities of the Hyperledger Fabric private blockchain platform are leverage. Fig. 3 showcases the user interface of the government portal specifically designed for civil registry and authentication. This portal facilitates the creation, verification, and statistical analysis of civil status records, providing granular data at weekly, monthly, and annual levels, segmented by region.



Welcome to Digital Documents

Thanks to us, you can enjoy a faster, scalable and more secure administrative system. Joining us involves authentication, signing, generation and storage of administrative documents in a few minutes and in a secure way thanks to blockchain technology.

Our statistics

0 Birth certificate(s) issued	0 Declaration(s) of birth	0 Pending Declaration(s)	0 Total number of transactions	0 Death certificate(s) issued
0 Declaration(s) of death	0 Declaration(s) of death pending	0 Marriage certificate(s) issued	0 Bann publication(s)	0 Pending bann publication(s)

So what are you waiting for?

Our range of services is waiting for you, so help yourself

Declaration

Contribute to a declaration of birth or death close to you, securely and quickly by using our dedicated platform...

Authentification

Easily and securely verify the authenticity of your administrative documents, whether via a QR code or an identification number.

Administrative documents

Dear member of the administration, sign and register your birth, marriage, and death certificates in one click and in complete security...

Fig. 3. Government portal homepage.

To enhance traceability and accountability, we recommend the following roles:

Healthcare professional: Verifies births and submits declarations to approving nodes.

Civil registrar: Creates and digitally signs birth certificates.

After a healthcare professional's profile is created, they submit a birth declaration for approval (Fig. 4). The declaration includes a QR code with a unique identifier, the signatory's name, and ID number. It contains details such as...

Establishment name: This is the name of the hospital that issued the birth certificate;

Child's name and surname: This is the first name and last name of the infant;

Date of birth: This refers to the date the baby was born;

Place of birth: This is the location where the baby was born;

Gender: This refers to the sex, in this case, male.

Subsequent to the infant's details, we have the following parental information:

Name and surname of father: Father's full name;

Father's occupation: Father's profession;

Father's date of birth: Father's date of birth;

Father's place of birth: Father's place of birth;

Father's Id card number: Father's national ID number;

Mother's full name: Mother's full name;

Mother's occupation: Mother's profession;

Mother's date of birth: Mother's date of birth;

Mother's place of birth: Mother's place of birth;

Mother's ID card number: Mother's national ID number;

Parent’s address: Parents' address;

Marital status: Marital status. In this case, the parents are married.

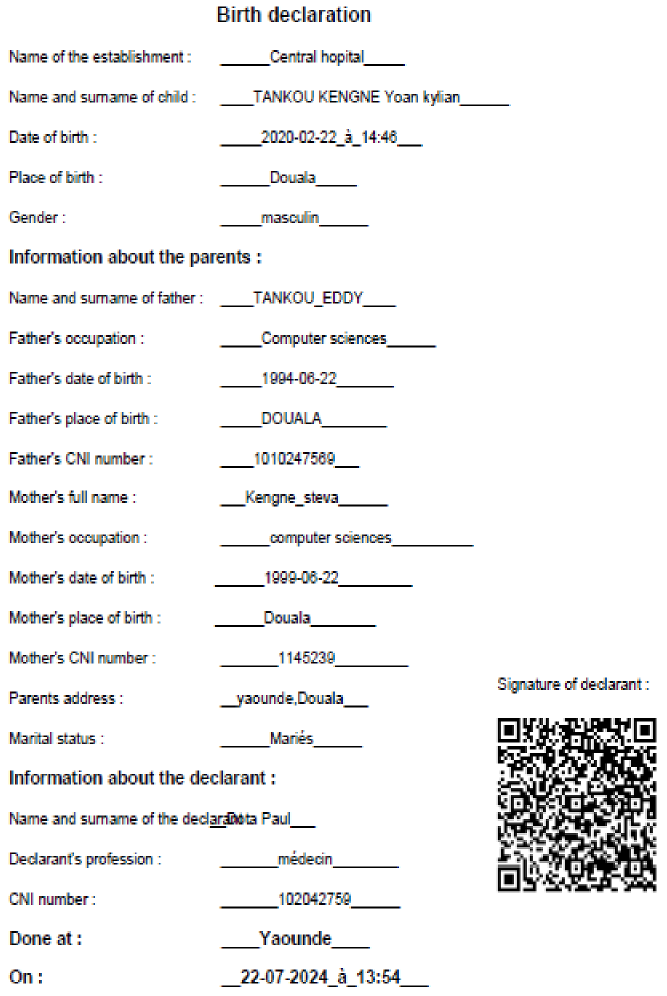
Subsequent to the parental data, the registrar's information is provided:

Name and surname of the declarant: Dota Paul;

Profession: Healthcare professionals;

ID card number;

Place and date of the declaration: [Location], on [Date] at [Time];



Birth declaration

Signature of declarant :

Fig. 4. Birth certificate.

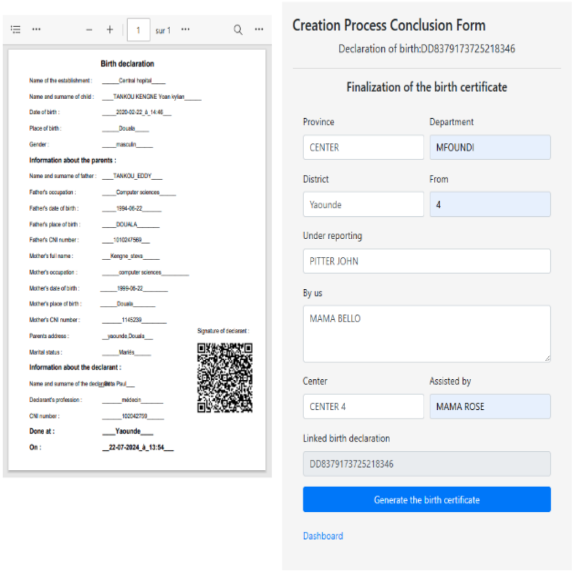
Finally, there is the QR code, which is a type of two-dimensional barcode typically composed of square modules arranged in a square on a white background. It contains the unique identification number (UIN), the name of the document signer, and their national identity card number. Additionally, this QR code generated on the form bears the signature of the civil registrar, allowing for verification of the signer and the document's author. This signature incorporates the SHA-256 cryptographic hash function, which generates a unique 64-character hexadecimal hash for each block of transactional data.

The security of the forms primarily relies on a UIN (unique identification number) designed using a pseudorandom number generator. At the end of the declaration form completion process, a UIN issued by the aforementioned function serves as a unique identifier for each document.

This cryptographic hash function dates back to 2001 and originated from the NSA (National Security Agency). It is increasingly used in blockchain technology today due to its high level of security. Furthermore, its algorithm is undeniably complex, as the generation of a SHA-256 hash requires a highly sophisticated binary calculation, utilizing several compression functions (addition, substitution, and rotations). Ultimately, it relies on the Merkle tree to provide a reliable guarantee of the integrity of the manipulated data.

Once the birth declaration is established, a user account is created for the civil registrar to finalize the birth certificate issuance process. The civil registrar profile is authorized to issue civil status acts. Additionally, the national identity card number entered during account creation uniquely identifies the civil registrar within the platform. Once the user account is created, it is hashed using the SHA-256-bit hash function and stored in the distributed node database for strong authentication. Thus, during account authentication, the account hash is compared to the hash stored in the database; if there is a match, the authenticity of the account owner is guaranteed.

The civil registrar logs into the platform using these created user account parameters and finalizes the birth certificate issuance process. Fig. 5 illustrates this process.



Creation Process Conclusion Form

Declaration of birth:DD8379173725218346

Finalization of the birth certificate

Fig. 5. Birth certificate finalization form.

When the finalization form is opened, the civil registrar completes the missing fields and generates the final act. They perform the final checks on the document and submit the transaction via the API (Application Programming Interface) to the network for consensus. All nodes with a copy of the smart contract execute the transaction, approve it, and return the result to the API. In turn, the API sends it to the scheduling service, which hashes the transaction and generates the block. Having only one transaction per block in the Hyperledger Fabric platform makes it faster compared to the Ethereum blockchain. Fig. 6 shows the generated birth certificate.

The left figure represents the previously established birth declaration, and the right figure represents the birth certificate finalization form corresponding to the previously established birth declaration. On this right-hand form, there are the following information: Province: the province where the birth certificate is issued; Department: the department where the certificate is issued; District: the district where the certificate is issued, as well as the district number, which is 4; Sub-declaration: the name of the person who establishes the act; By us: it represents the name of the civil registrar who signs the birth certificate, in the locality of the center and the district of Yaoundé 4; Assisted by: represents the civil registrar's secretary who assisted the civil registrar in this process; Linked birth declaration: is the UIN generated on the previously established birth declaration, this number links the birth declaration to a birth certificate and is not modifiable.

The civil registrar finally generates the birth certificate transaction and redirects us to the interface allowing us to view the transaction identifiers of the birth declaration and the corresponding birth certificate issuance in the blockchain. A SHA-256-bit hash function is finally generated and stored in the distributed node database for strong authentication. Thus, during document authentication, the document hash is compared to the hash stored in the database; if there is a match, the authenticity is guaranteed.

In a blockchain context, each actor who wants to interact with the network needs an identity. In this context, one or more certification authorities can be used to define the members of an organization from a digital perspective. It is the certification authority that provides the basis for actors in an organization to have a verifiable identity.

Hyperledger Fabric provides a built-in certification authority component to enable the creation of certification authorities in formed blockchain networks. This component, called Fabric CA, is a private root certification authority provider capable of managing the digital identities of Fabric participants in the form of X.509 certificates.

In the operational platform for producing birth certificate forms, an X node acts as the root certification authority (Fabric_CA), and the intermediate certification authorities are the local servers with respective users (Fabric client) being hospitals and community users.

Certificates are generated offline by the root certification authority (X). Once these certificates are created, they are securely distributed to the intermediate certification authorities, which in turn issue certificates to the platform users, namely hospitals, health centers, and communities.

To evaluate the performance of the root certification authority, the SCP protocol via SSH (Secure Copy Protocol) allows us to develop a bash script that runs intermittently to ensure high data availability in case of failure of the main root_CA for each organization. This SCP protocol allows the copying of information from a root_CA1 to a root_CA2 every three seconds (3s) through a bash script [42].

The civil registrar profile is authorized to establish birth certificates. Furthermore, the national identity card number provided during account creation uniquely identifies the civil registrar within the platform.

Once the user account is created, it is hashed using the SHA-256-bit hashing function and stored in the distributed database of nodes for strong authentication purposes. Thus, during account authentication, the hash of the account is compared to the hash stored in the database; if there is a match, the authenticity of the account holder is guaranteed.

On this birth certificate (Fig. 7), there are the following information:

Birth certificate number: A unique identifier characterized by the initials of the locality that issued the certificate.

Province: The province where the birth certificate was issued.

Department: The department where the certificate was issued.

District: The district where the certificate was issued, specifically District number 4.

Name and surname of child: The given name(s) and surname of the newborn.

Place of birth: The location where the newborn was born.

Date of birth: The date and time of the newborn's birth.

Gender: The sex of the child, in this case, male.

Of: The given name and surname of the newborn's father.

Born on: The date of birth of the newborn's father.

At: The place of birth of the newborn's father.

Nationality: The nationality of the newborn's father.

Resident at: The residence of the newborn's father.

Occupation: The profession of the newborn's father.

By us: The name of the civil registrar who issued the certificate.

Under declaration of: The person who assisted the civil registrar in this process.

Office: The district of the locality and the number associated with that district in that locality.

Assisted by: The name of the civil registrar's secretary who assisted in the issuance of the birth certificate.

The QR code contains a unique identification number (NIU), the name of the document signer, and their national identity card number. This QR code is a type of two-dimensional barcode typically composed of black square modules arranged in a square on a white background, encoding the unique identification number (NIU), the name of the document signer, and their national identity card number.

Additionally, the QR code generated on the form bears the signature of the civil registrar, allowing for verification of the signer and the document's author. This signature incorporates the SHA-256 cryptographic hash function, which generates a unique 64-character hexadecimal hash for each block of transactional data.

The security of the forms initially relies on a NIU (unique identification number generated using a pseudo-random number generator). At the end of the declaration form completion process, a NIU issued by the aforementioned function serves as a unique identifier for each document. This cryptographic hash function dates back to 2001 and originated from the National Security Agency (NSA). It is now increasingly used in blockchain technology due to its high level of security. Furthermore, its algorithm is undeniably complex as the generation of a SHA-256 hash requires a sophisticated binary calculation, employing various compression functions (addition, substitution, and rotations). Ultimately, it relies on the Merkle tree to provide a reliable guarantee of the integrity of the manipulated data.

All data contained in the act is hashed using the SHA-256 hash function. The resulting hash is signed by the civil registrar using their private key. The obtained signature is finally recorded in the QR code.

On the generated birth certificate, all contained data is hashed using the SHA-256 hash function. The resulting hash is signed by the civil registrar using their private key. The obtained signature is finally recorded in the QR code. Fig. 8 illustrates this solution.

The details of the block containing the transaction are shown in Fig. 6.

Fig. 8 provides an experimental history of the number of blocks generated per hour. The figure visualizes the hourly and minutely block count over time. In terms of scalability, measured by the number of transactions processed per unit of time, this work demonstrates approximately 3500 transactions per second on the Hyperledger Fabric blockchain, compared to 38 transactions per second on the Ethereum platform referenced in the literature. This exponential increase in transaction processing speed makes the proposed platform a suitable solution for the digitalization of birth certificates in localities with multiple civil registry centers, including secondary centers and affiliated civil registry offices.

A. Comparison of Works with those of Other Authors

Table II compares the proposed scheme with those of previous studies to identify both areas of convergence and the unique contributions of this research.

This section benchmarks the results obtained against existing literature to elucidate both shared insights and the original contributions to the field.

Legend: The symbol "☑" indicates the presence of criterion "☒", while its absence signifies the lack of this criterion. The sign "▬" means "less than" and the sign "+++" means "more than" compared to the negation.

Until 2021, the Ethereum platform used the Proof of Work (PoW) consensus mechanism. This mechanism had the major drawback of being very energy-intensive and susceptible to 51% attacks [123]. In contrast, the consensus used in this work, which is based on the Hyperledger platform, is open and consumes less energy, making it an ideal solution for countries with significant energy deficits. In other words, developers can define their own consensus rules or choose between PoW, PoS, PoA, etc.

From a security standpoint, the results obtained in this work are varied. Forms are equipped with a unique identification number obtained after the generation of the act form, thus characterizing the uniqueness of a document in the distributed database. The QR code printed on this form allows verification of the signatory author of a document as well as the associated key pair (public key and private key). The transaction identifier recorded in the blockchain database guarantees the tamper-proof nature of documents, not to mention the SHA-256 cryptographic hash for document signing. Hyperledger Fabric has a particular characteristic in that the created channels can be accessible or visible to a category of actors in the private blockchain, thus guaranteeing confidentiality in transactions; unlike the public blockchain used by Ethereum where channels are visible to all network members, and anyone can create and read blockchain transactions [47].

Based on the offered functionalities, this work proposes a complete system for managing civil status acts, including declarations (birth declaration, death declaration, marriage ban publication) and the establishment of civil status acts themselves (birth certificate, death certificate, marriage certificate), unlike the works of [14, 38, 44] which focused solely on the security of the form by QR code on the one hand, and on birth and death certificates on the other.

In terms of scalability, which represents the number of transactions processed per unit of time, this paper presents statistics of the order of 3500 transactions per second for the Hyperledger Fabric blockchain compared to 38 transactions per second for the Ethereum platform used in the works [14, 38, 44]. This exponential speed in transaction processing makes the platform a suitable solution for the digitalization of civil status in regions of the territory that have several civil status centers, secondary centers, and affiliated centers.

Mining, on the other hand, is a process of creating a block of transactions and adding it to the Ethereum blockchain. However, since it is computers that execute instructions, they are rewarded at the end of the transaction. For a government platform for the digitization of civil status acts, this solution is inefficient in that it will be necessary to reward the authors of transactions each time, unlike the Hyperledger platform which does not require mining for transaction validation. Finally, the evolutionary factor allows a government authority to consider a possible extension without making major changes. To add an organization, simply create the organization's channel, and its members have access to this channel according to their level of accreditation. The open-source nature of the proposed solution allows developers to make modifications to the source code as they see fit, which is not the case with the Ethereum technology used by [35, 48].

VI. Future Work

In remote regions lacking administrative infrastructure and electrical grids, establishing birth certificates is often challenging or even impossible. The use of embedded devices like the Raspberry Pi, which are inexpensive and energy-efficient nano computers capable of operating on alternative power sources such as batteries and solar panels, enables the creation of autonomous systems. Equipped with blockchain software, these systems can record birth data locally without requiring a permanent internet connection. When an internet connection becomes available, this data can be synchronized with a secure blockchain, ensuring data integrity [49, 50]. This innovative solution offers numerous advantages, including reliability (data is secure and immutable), accessibility (the solution is suitable for rural areas), equity (all individuals, even in the most remote areas, have access to an official birth certificate), and sovereignty (local communities have greater control over their data). As a result, it contributes to digital inclusion and improves the living conditions of the most vulnerable populations.

Based on the relevance of the research findings, this section outlines future directions for the design of other identity documents and official certificates to reduce document fraud. These include: Marriage certificates, which are issued by a civil registrar and serve as legal proof of marital status; death certificates, which are official administrative documents attesting to a person's death and issued by the civil registrar of the municipality where the death occurred; land titles, which are official certifications of real estate ownership and are considered irrevocable and inalienable; and diplomas, which are official documents conferring a degree or qualification.

VII. Conclusion

The birth certificate is a legal and vital document that proves an individual’s civil status. The fact that it certifies an individual’s identity and family situation makes it a major element generally required in administrative procedures such as national identity cards, passports, diplomas, bank transactions, etc. While blockchain technology is inherently secure, it remains vulnerable to side-channel attacks that exploit indirect information to compromise security[51, 52]. These attacks can leverage variations in execution time to extract cryptographic keys, potentially leading to the alteration of transactions. To mitigate these threats, techniques such as obfuscation, which aims to make code difficult to understand, analyze, or modify, are crucial. As a result, continuous vigilance is necessary to safeguard blockchain systems against such vulnerabilities. This article aims to contribute to the development of a system for issuing, tracking, and authenticating birth certificates based on Hyperledger Fabric blockchain technology. To achieve this, the network architecture model is proposed, it based on VPN/MPLS on one hand, and on the other hand, the design of the smart contract characterized by the creation, registration, and verification of birth certificates, the approval of transactions by approving nodes, the transparency and traceability of the various processes, the security throughout the network, and the architecture composed of imported packages, Data Structures, main Functions, Birth Declaration Functions, and Birth Certificate Functions. The proposed platform is an application for creating, registering, and verifying the authenticity of birth certificates, ensuring robust and efficient security-and transparency. This platform is particularly important for organizations responsible for producing birth certificates, diplomatic representations, judicial and administrative authorities, etc.

Abstract—**In the case of chatbots massive progress has been made, but problems remain in handling the complexity of the sentence and in context relevance. Traditional models can be rather insufficient when it comes to providing various levels of detail in the responses to the end-users' questions, particularly when referring to customer support scenarios. To overcome these limitations, this research comes up with a new model which combines the BERT model with DRL. Through DRL, BERT pre-training is adding flexibility and correspondence to correctly perceive contextual delicate matters in the response. The proposed method includes the following pipeline where in; data tokenization, conversion to lowercase characters, lemmatization and then passes through the BERT fine-tuned model. DRL is utilized to optimize the chatbot's response in the light of long term rewards and the conversational history, the interactions are formulated as a Markov Decision Process with the reward functions based on cosine similarity of the consecutive responses. This makes it feasible for the chatbot to provide context based replies in addition to the option of constant learning for enhanced performance. It also proved that the accuracy and relevance of the BERT-DRL hybrid system were higher than traditional models according to the BLEU and ROUGE scores. The performance of the chatbot also increases with the length of the conversation and the transitions from one response to the other are coherent. This research contributes to the field through the integration of BERT in understanding language and DRL in the iterative learning process in the innovation within the flaws of chatbot technologies and establishing a new benchmark for conversational AI in customer service settings.**

Keywords—Chatbots; BERT (Bidirectional Encoder Representations from Transformers); RL (Reinforcement Learning); customer service; responsiveness

I. Introduction

A chatbot is a computer program that talks to people like a human. It can use text or speech to have conversations with users. In customer service, chatbots are really important in making customer support better and more efficient. These smart systems are used on websites, mobile apps, and messaging apps to help customers quickly with their questions. Chatbots use special tools to understand what users are saying, figure out what they want, and give them the right answers. They can do many different jobs, like answering questions, giving product information, helping with problems, and doing transactions [1]. Chatbots help make customers happy by answering quickly and being available all the time. This also helps businesses work better and faster. But, chatbots need to understand what users are saying, have good conversations, and adjust to different ways people talk and different situations in order to work well. Ongoing research and improvements in NLP, machine learning, and dialogue management are very important. They help make customer service chatbots better and make sure they can talk to users without any problems [2].

Chatbots are helpful in customer service because they can quickly and accurately respond to many different questions. By using smart computer programs, chatbots can understand what users want, get important information, and quickly give the right answers [3]. This helps businesses grow their customer support without sacrificing quality or speed, so they can use their resources better and work more efficiently. Additionally, chatbots help make customers feel more connected and loyal by giving them personalized experiences based on what they like and how they act. By using data analysis and machine learning, chatbots can use past conversations and customer information to predict what customers might need, suggest helpful products or services, and solve problems before they get worse [4]. Chatbots are important for businesses because they help to keep customers happy and coming back [5]. They do this by building good relationships and having positive conversations with people. Yet, to make chatbots work well in customer service, it's important to plan carefully, keep improving them, and follow the best ways of doing things. Businesses need to spend money on the right technology, talented people, and good ways of working to make their chatbots work as well as possible. This includes making them easy for people to use, creating good conversations for them, teaching them how to learn, and keeping an eye on how well they are doing. Moreover, as customers' needs change, chatbots need to change too. They need to keep up with the latest trends, preferences, and technologies to stay useful in the changing world of customer service [6].

Being quick and accurate when talking to a chatbot is really important. It helps make sure users have a good experience and that businesses and customers get what they want. Responsiveness means the chatbot can quickly answer the questions and requests from users. In the fast-paced digital world of today, people anticipate prompt assistance and solutions for their problems. A chatbot that responds quickly not only meets these expectations but also helps to make users less frustrated, keeps them interested, and makes them feel like they can trust it [7]. In the same way, it's really important for the chatbot to give accurate and helpful responses that match what the user needs. A good chatbot understands what users mean, understands their questions in the right way, and gives the right information or takes the right actions. Giving wrong answers can make users feel confused, misinformed, and unhappy. This can make the chatbot seem less trustworthy and helpful. Additionally, giving wrong answers can make users feel frustrated and uninterested, which can make them think negatively about the brand or service [8].

Research wants to use a combination of BERT and reinforcement learning to make chatbots better. Traditional chatbots have limitations, and research want to improve how quick and accurate they are. BERT is really good at understanding language and making relevant responses. By using BERT's smart understanding of words and meanings, chatbots can be better at understanding what users want and giving them the right answers. Alternatively, reinforcement learning is a useful way to improve how chatbots manage conversations and make decisions [9]. By teaching the chatbot by trying different things and learning from user feedback, reinforcement learning helps the system improve its responses over time. This smart way of learning helps the chatbot get better and better at talking to people over time. It gets faster and more effective at having conversations in real life. By using a mix of BERT and reinforcement learning, chatbots can better understand and respond using words and also improve how they manage conversations. This mixed method makes the chatbot better at understanding and answering questions from users. It also helps the chatbot to learn and change according to what users want and how they talk. Overall, the hybrid system offers a positive solution for developing smarter and more effective chatbots that can improve user experiences in various contexts, such as customer service.

The primary contribution of the work is as follows:

- Making of a new framework of the chatbot that integrates the ability of BERT to consider a context along with the reinforcement learning to improve the quality of the chatbot’s answers with time based on the feedback from the user.
- Substantial increase in the quality and pertinence of chatbot answers, as it was proven by higher BLEU and ROUGE scores in comparison to a basic chatbot model.
- Use of the progressive learning model in which the chatbot adjusts its response to the users depending on the results obtained in the process.
- Enhanced customer satisfaction and interactivity as concomitant with presenting actual and highly and closely related responses to specific queries, thereby making customer services more fit into the natural context.
- Establishment of a general framework of a chatbot that can be easily fitted into other domains, thus, can be applicable to a wide range of client services.

The order of the remaining sections is as follows. An introduction is given in Section I. The literary sections are shown in Section II. This is the issue within the conventional methods provided in Section III. The suggested methodology for the study's research design, data gathering strategies, and analytic approaches are covered in Section IV. The efficacy measures are presented, and the results are compiled in Section V. Section VI delivers more studies and a conclusion.

II. Related Work

Dhyani and Kumar [9] explains how to use deep learning to make a better Chatbot. Implementing the Neural Machine Translation (NMT) model using the TensorFlow software library. Learning and gathering information for creating a model is a very important but challenging task. Bidirectional Recurrent Neural networks with attention layers are employed to improve responses for lengthy or wordy sentences. The information used to teach the computer model in the paper comes from Reddit. The model was made to translate English to English. This work aims to make the model more confused and learn more quickly and to measure the translation quality using Bleu Score for the same language. Research did experiments with TensorFlow using python 3. 6 The confusion, learning speed, language evaluation score and average time for every 1000 steps are 56. 10, 00001, 3016 and 45 One period is finished after taking 23,000 steps. The paper also looks at how MacBook Air can be used for neural network and deep learning. In the future, research will also make a healthcare Chatbot to help patients with diseases like COVID-19, diabetes, high blood pressure, and heart problems. by giving details about the disease, suggesting what foods to eat, and explaining how to handle emergencies.

A chatbot is a computer program that talks like a person and can have a conversation with a human. One important job in artificial intelligence and understanding human language is to study how people talk to each other. Since artificial intelligence started, it has been really difficult to make a good chatbot. Even though chatbots can do many different things, their main job is to understand what people say and reply in a helpful way. In the past, chatbot designs were made using basic statistics or written rules and templates. Around 2015, end-to-end neural networks replaced other models because they can learn better. Right now, the encoder-decoder recurrent model is very important for modeling conversations. This design comes from the field of machine translation using neural networks and it worked very effectively in that area. So far, many new features and changes have made chatbots better at talking to people. In this paper, research studied a lot of new books and articles. Research looked at a lot of articles from the past five years about chatbots. Next, research talked about other research on the topic and the AI ideas needed to make a smart chatbot using deep learning. Then, research showed a plan for creating a helpful chatbot for healthcare. In the future, research will be better at spotting and diagnosing bots, as research will have more advanced tools to help us understand their symptoms, like how intense they are, how long they last, where they are happening, and a more detailed description of what is going on [10].

AI, ML, and NLP are changing the way organizations do things. As more data comes in and AI systems get better at using it to help businesses, people are getting more excited about AI. Large amounts of data, computer power, better ways to solve problems, easy-to-use tools, and systems have made companies use AI to make their business better and make more money. These technologies help all kinds of businesses, from farming to finance. AI, ML, and NLP are helping companies with things like customer service, predicting what might happen, making things more personal for customers, recognizing pictures, understanding emotions, and working with documents online and offline. This study had two main goals. First, research look at how AI is used in business. Then research check if these uses make customers more loyal by looking at data from 910 different companies. The data includes scores for four different AI features: AI customer service, predictive modeling, personalized machine learning, and natural language processing integration. The goal is to measure how loyal customers are using a simple yes or no answer. All the qualities are rated on a scale of 1 to 5. Research used six different types of computer programs to help us learn from and make predictions about data. These were Logistic regression, KNN, SVM, Decision Tree, Random Forest, and Ada boost Classifiers. The abilities of the different algorithms were tested using confusion matrices and ROC curves. The decision tree had an accuracy of 0. 532 and KNN had an accuracy of 0. 570This study shows that businesses can use AI, ML, and NLP to look at data and find important information. This can help them automate tasks and plan business strategies. In order to stay competitive and retain customer loyalty, companies should begin incorporating them into their business strategies [11].

It is important to understand how people feel when they interact with robots as customers. This can be seen from the reviews they share online. Knowing this is important for predicting whether people will want to use service robots in the future. Qualitative analysis gives us lots of helpful information from data, but it takes lots of time and effort to do. Experts have talked about how helpful it is to use algorithms to tell the difference between different emotions. This study looks at the good and bad sides of using qualitative analysis and machine learning methods together, using both human and machine intelligence. Research took 9,707 customer reviews from two big social media sites (Ctrip and TripAdvisor). The reviews were about 412 hotels in 8 different countries. The study found that customers really like service robots, and they feel happy, amazed, and excited when they interact with them. Customers are not happy when service robots don't work and they can't use them. Robots that help people can make them feel more emotions when they move. The results also show how different cultures can affect how customers feel about service robots. The research shows that using a mix of different methods can make machine learning faster and more efficient. This aids in addressing certain issues with machine learning, such as the difficulty in comprehending concepts and the limited range of emotions available [12].

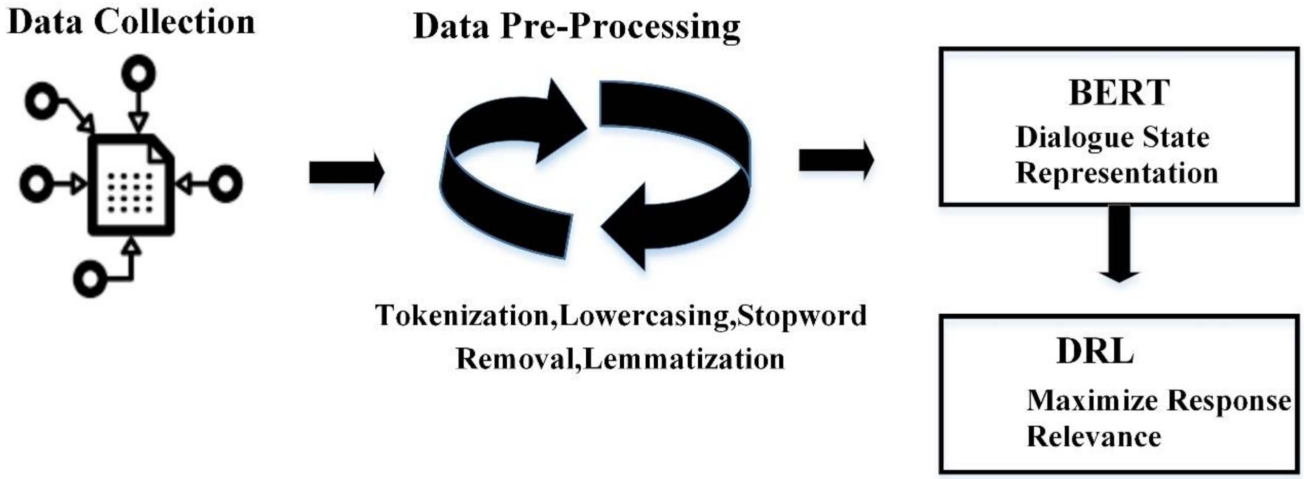
Analyzing customer feelings is very important for understanding how customers feel about products, especially in online stores where there are a lot of customer reviews. The changes in e-commerce reviews, like adding pictures, videos, and emojis, makes it more complex to analyze how people feel about products. Old-fashioned text models might have a hard time understanding feelings shown in things that are not written. This paper suggests a better way to understand how people feel about products on online stores, to make it better for shoppers. The plan involves using Fejer Kernel filtering to estimate data points in the E-commerce dataset. Research use a fuzzy dictionary to find important words in the E-Commerce dataset. The information research used for the study was collected using a method called Optimized Stimulated Annealing to pick out the most important features. Customer opinions are sorted using the BERT deep learning model. The model gives us the opinions of consumers in the E-Commerce dataset. The way customers feel about products in the E-commerce data decides how they are grouped. The test showed that the new model is better at correctly categorizing things on the online shopping site. This study helps to improve how research understand and use sentiment analysis for online shopping. It is a milestone in the development of more perceptive systems that can understand and respond to customer input [13].

III. Problem Statement

Existing customer service chatbots regularly face several limitations that the proposed development of a Responsive Customer Service Chatbot using a BERT and RL hybrid system objectives to address. Traditional chatbots commonly depend on rule-based totally or statistical fashions that may conflict with information context, dealing with complicated queries, and generating coherent responses [12]. They can also fail to evolve to evolving consumer options and remarks, ensuing in a static person enjoy [11]. Also, existing models often lack customized interplay abilities and can exhibit limited mastering from user interactions because of insufficient training data and simplistic algorithms. These chatbots normally do now not leverage superior language expertise techniques, main to suboptimal handling of nuanced language and conversational context. The proposed hybrid system, combining BERT's deep contextual embeddings with RL's adaptive learning mechanisms, goals to overcome these obstacles through improving the chatbot's capability to apprehend and generate contextually relevant responses.

IV. Proposed Responsive Customer Service Chatbot Using A BERT and Reinforcement Learning Hybrid System

The proposed method for enhancing the performance of chatbots and virtual assistants in comprehending and responding to human language involves a systematic pipeline. Firstly, data is collected, followed by pre-processing steps like tokenization, lowercasing, removing stop words, and lemmatization to clean and prepare the data. Subsequently, the processed data is fed into a BERT model, renowned for its ability to understand contextual nuances in conversations, thus providing dialogue state representation. Finally, Deep Reinforcement Learning (DRL) is employed to optimize the relevance of responses generated by the BERT model, ensuring that the chatbot or virtual assistant delivers responses that are contextually appropriate and accurate. This comprehensive approach not only improves the understanding of conversation context but also ensures the generation of responses that are highly relevant to user queries or statements, thereby enhancing the overall performance of the conversational system. This is visually presented in Fig. 1.



Data Collection

Maximize Response Relevance

Fig. 1. Proposed method.

A. Data Collection

Customer service chatbot data collected from Kaggle refers to a dataset sourced from the Kaggle platform, which contains conversational data typically used to train and evaluate customer service chatbots. This dataset usually includes text exchanges between customers and customer service representatives across various domains, such as retail, telecommunications, or technology, and serves as valuable input for developing and fine-tuning natural language processing models aimed at automating customer support interactions[10]. The dataset incorporates a cause tag for "good-bye," which encompasses styles like "Bye," "See you later," and "Goodbye," and is associated with responses which includes "See you later, thanks for travelling!" and "Have a nice day!" This established layout facilitates in training the chatbot to recognize and reply appropriately to one of a kind person interaction, ensuring that it could deal with common conversational exchanges effectively.

B. Pre-processing

1) Tokenization: Breaking down sentences into individual words or tokens allows for better analysis of the text. It helps in understanding the structure of the sentences and facilitates further processing steps.

2) Lowercasing: Converting all text to lowercase ensures consistency in the dataset, preventing the model from treating words with different cases as different entities. This step also reduces the vocabulary size and improves generalization.

3) Stopword Removal: Eliminating common stopwords such as "and", "the", "is", etc., helps in reducing noise in the dataset. Since these words occur frequently but often carry little semantic meaning, removing them can improve the quality of the text data.

4) Lemmatization: Reducing words to their base or dictionary form through lemmatization helps in normalizing the text and reducing dimensionality. It ensures that different forms of the same word are treated as one, thus improving the efficiency of downstream tasks like sentiment analysis or topic modelling [11].

C. BERT

In customer support chatbots, BERT's role is essential in understanding user queries and generating relevant responses. Through means of users interact with the chatbot, their queries undergo tokenization and are fed into the BERT model for natural language understanding. Bidirectional nature captures complicated word relationships, decoding the nuanced context within the user's message. This is essential user’s need, whether it involves in search of information, reporting an issue, or providing feedback. Once the user's intent is classified, the chatbot employs task-specific output layers to customize its responses. For instance, if a user seeks assistance with a technical issue, the chatbot may direct the query to a troubleshooting module trained specifically for such concerns. Similarly, if the user expresses dissatisfaction or provides feedback, the chatbot may route the query to a sentiment analysis module to assess customer sentiment and respond accordingly. Fig. 2 illustrates the framework of a pre-trained BERT model, highlighting its architecture and key components for natural language processing tasks.

Prior to implementation, the BERT model is a fine tune to domain-specific data on customer support services. This design fine-tuning ensures that the model adapts to complex customer enquiries and support interactions, improves the ability to provide accurate and helpful information and fine-tunes the model templates for tasks such as issue resolution, queries and sentiment analysis, thereby helping users maximize its effectiveness. The cross-entropy loss used during fine-tuning is represented in Eq. (1):

$$Loss\colon \sum Loss = \sum_i Y_{i\,\log(\widehat{Y_I})} \tag{1}$$

Using thorough express ratings or implicit indicators that indicate user involvement, the chatbot uses feedback to alter parameters and increase its ability to serve customers effectively. In simple terms, BERT serves as the foundation for customer service chatbots, allowing them to recognize user requests, classify intentions, generate contextually appropriate answers, and continuously enhance via comments. Utilizing BERT's simultaneous understanding and first-rate tuning capabilities, interaction with chatbots may provide personalized, effective support, enhancing the user experiences and increasing client pride is given in Eq. (2)

Feedback Loop:

$$Update\colon \theta_{BERT=}\theta_{BERT-\alpha\,\nabla\theta_{BERT}Loss} \tag{2}$$

The following formula depicts each parameter updating step in the continuous learning process, where α is the development rate and ∇θ_BERT signifies the change in gradient in relation to the BERT model parameters. Words in sentences are masked in BERT during pre-training; by predicting them, BERT learns bidirectional representations rather than reading text in a one-pass manner as most models do. Through having an interchange between the two directions, BERT is able to seize the contextual meaning of words making it very efficient in the interpretation of queries made in customer service chat bots. In the second step known as the 'fine-tuning' the BERT is trained for certain tasks such as for customer support, by feeding it with relevant data, which helps in providing appropriate responses. This, coupled with the task-specific fine-tuning, makes BERT ideal for this scenario, especially given its bidirectional context, out-competing models that do not have that or are trained in an entirely different model for an entirely different task.

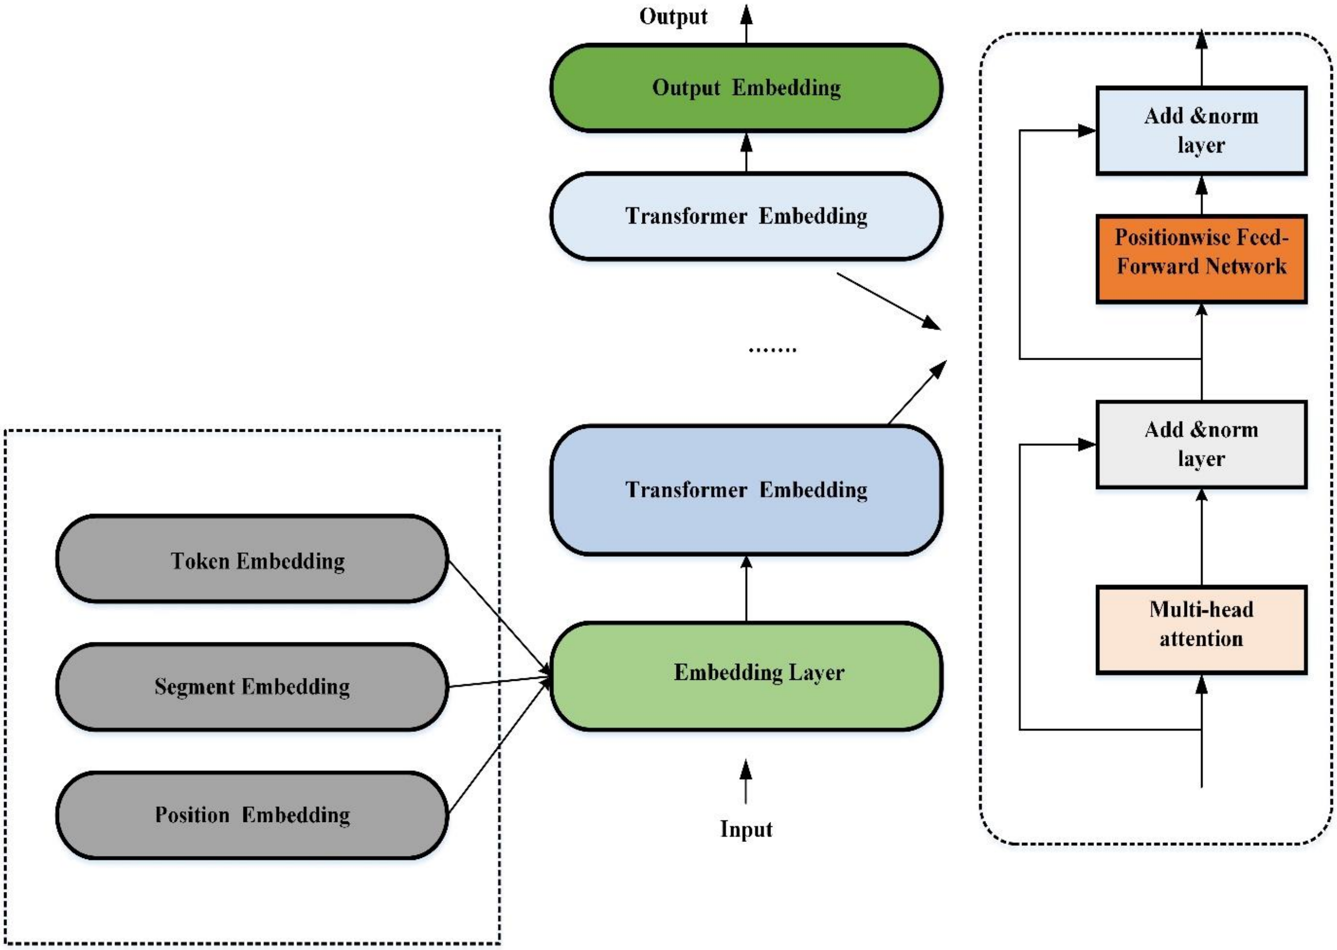

Fig. 2. Framework of a Pre-trained BERT model.

D. Deep Reinforcement Learning to Maximize Response Relevance

The development of a bidirectional contextual chatbot involves utilizing deep reinforcement learning (RL) to maximize response relevance and effectiveness. The chatbot operates within a Markov Decision Process (MDP), modeling the conversation as a reinforcement learning problem. It consists of states, actions, transition functions, and reward functions. The goal is to learn a policy that maximizes long-term rewards, ensuring responses are not only relevant to the current turn but also consider future discourse implications.

1) Markov Decision Process (MDP): A Markov Decision Process is used for modeling the discussion. MDP consists of states S, actions A, a transition function P, and a reward function R. Provided an MDP (S, A, P, and R), the algorithm is taught to identify an approach that resolves this issue. From an algorithm perspective, policy is a conditional likelihood distributed on the set of activities A. During the encounter, the agent takes action in accordance with the policy. The surrounding area changes state in response to the agent's behavior. Furthermore, the agent communicates with the surroundings at every discontinuous time step (t = 0, 1, 2, ...) is represented in Eq. (3).

$$p(s_{t+1,}r_{t+1,}|s_t,a_t) \qquad (3)$$

2) Reward Definition: The study suggests two rewards for eliciting targeted replies and achieving specified goals in conversations. It solves the problem of encoder-decoder-based models producing incoherent or insignificant outcomes. Prospective function are defined by sequential rotations and interactions among acts and prior declarations. The reward for every action is represented by r1, and the cosine similarity between actions determines the initial reward at the present state. Let h_t and h_{t+1} the graphical representations obtained from the agents for successive rounds. The cosine similarity among h_t and h_{t+1} yields a preliminary reward at present stage s_t is represented in Eq. (4).

$$r_1 = \cos(h_t, h_{t+1}) = \cos(\frac{h_t,h_{t+1}}{||h_t\, h_{t+1}||} \qquad (4)$$

3) Conversation Simulation: Although the pre-trained encoder-decoder enables the algorithm to produce coherent responses based on the discussion the past, applying RL improves the model's capacity to produce responses that are optimized for long-term objectives. To replicate the chat as follows. In the initial stage, researchers extract an input sentence via training dataset that includes conversational history as background data and give it to the initial agent. The initial agent encrypts the inputs as a vectorc_L and analyzes it to provide an outcome for the following round. The second agent modifies the simulation's condition by integrating the dialogue record and output. It instantly encodes the altered state into its visual form and interprets it to generate a new response, which is then passed again to the original agent and repeating. At the completion of the simulation, the right-context cR is a sequence of k successive utterances { $s_{t+1,}s_{t+2,} \dots\dots.. s_{t+k,}$ } to the correct portion of the produced response s_t. The change in distribution of probabilities, which represents the policy, has been initialized with a pre-trained BERT-based models. Candidate replies have been produced using the above distribution. This is represented in Eq. (5).

$$\pi = \rho_{bert2bert(a'_t}|[s'_{t,}c'_l]) \qquad (5)$$

The agent's goal is to maximize the expected accumulated reward through a series of actions (responses) during the entire discussion. To accomplish this, the parameters of the model are modified utilizing the policy gradients method. An approach for learning is employed, modeling debate for k turns and using policy gradient approaches to generate parameters that maximize the expected future reward. The purpose is to maximize the predicted cumulative value from the scheduled sequence of actions. The loss function is computed based on an anticipation for tasks and rewards in history. The upward slope of the loss function is generated using the chain rule, and this allows for adjustments to parameters to improve the model's effectiveness [12]. The MDP in the context of a Customer Service chatbot, one can refer to the following example of an interaction. Let a user ask about availability of a certain product or for some recommendations. Based on the state (the user query), the chatbot (agent) has the choice of the next action (response). For example, instead of ‘Yes, that is correct,’ it might say ‘Actually, let me check that for you.’ This response leads the conversation flow from one state to another – the user can then ask particular questions and elicit further from the chatbot. Their function is to achieve the maximum total reward that is to offer most helpful and pertinent answers. Cosine similarity is particularly important here: reward functions lie in this context. With reference to the ideal/expected response, cosine similarity makes ensures that the flow of the conversation is based on the similarity index between the chatbot and the user’s input. High cosine similarity reveals that the chatbot’s response is on the right path, the low one means that the chatbot should improve its response. While the reinforcement learning continues, the conversation patterns of the chatbot get closer to the needs of the users. For instance, at the start it may just generate general responses but it ought to adopt correct contextual replies such as: “The product is in our store at San Jose, shall I set it aside for you?” This enhancement comes from learning through feedback loops on the actions that the bot undertakes. Fig. 3 depicts the response generator utilizing deep reinforcement learning, showcasing its architecture and interaction mechanism for generating conversational responses.

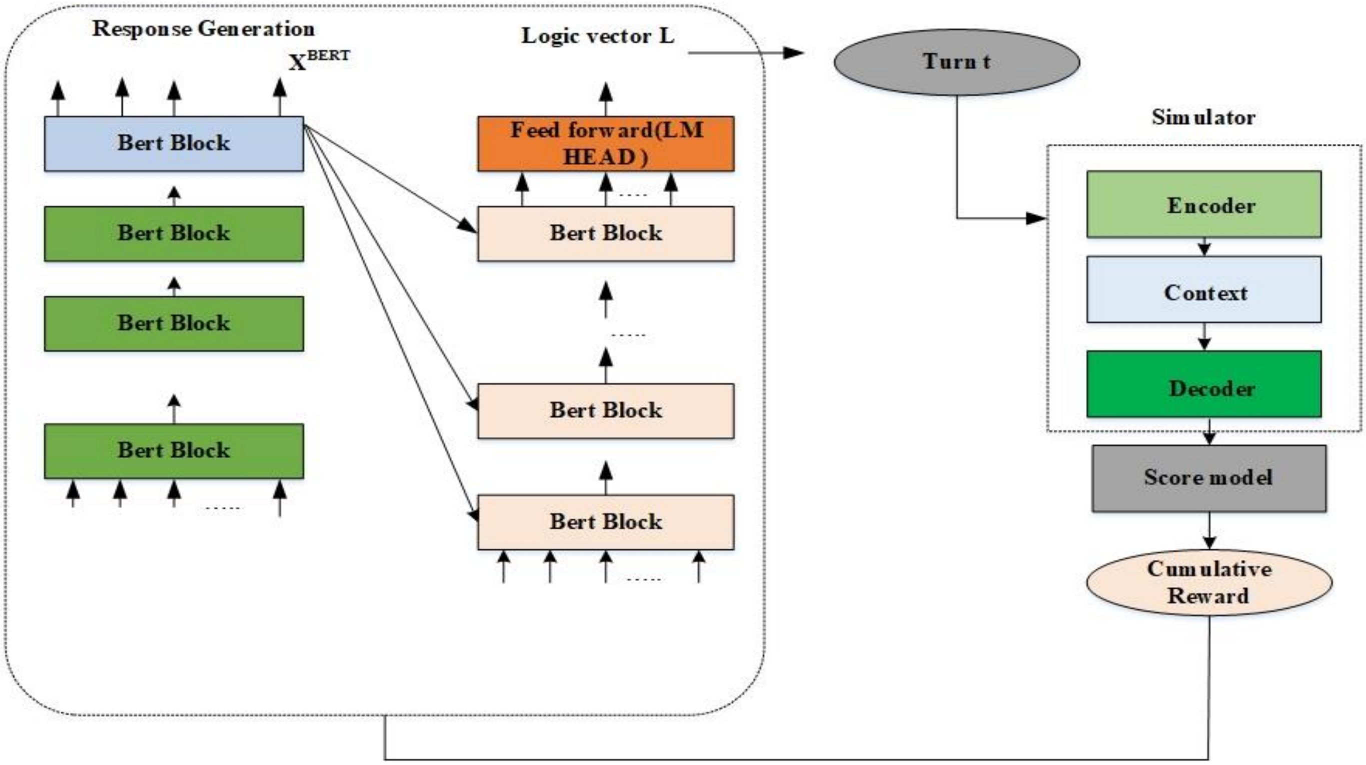

Fig. 3. Response generator using deep reinforcement learning.

V. Result and Discussion

The proposed hybrid BERT and Reinforcement Learning chatbot established huge improvements in customer service interactions. The BERT version successfully generated contextually relevant responses, whilst reinforcement getting to know optimized these responses primarily based on actual-time remarks. Evaluation metrics, which include BLEU and ROUGE ratings, showed a marked improvement in response accuracy and relevance compared to conventional fashions. User satisfaction and engagement multiplied, because the chatbot correctly addressed patron queries and tailored over time. The machine's iterative mastering technique resulted in an extra intuitive and responsive chatbot, improving ordinary consumer revel in and proving the efficacy of combining BERT with reinforcement getting to know for dynamic service interactions.

TABLE I. Comparsion of Different Deep Learning Methods

	BLEU 1	BLEU 2	BLEU 3	ROUGE Precision	ROUGE Recall	ROUGE F1 score
CNN	0.433	0.340	0.200	0.318	0.278	0.214
LSTM	0.420	0.355	0.204	0.323	0.311	0.290
GRU	0.477	0.322	0.258	0.389	0.318	0.310
BERT	0.480	0.350	0.246	0.355	0.330	0.370
BERT-RL	0.499	0.399	0.255	0.359	0.340	0.390

Table I compare the performance of different deep learning methods, including CNN, LSTM, GRU, BERT, and BERT-RL, in the context of a customer service chatbot. The metrics reported include BLEU scores (BLEU1, BLEU2, BLEU3) for measuring response similarity to human references, and ROUGE scores (ROUGEPrecision, ROUGERecall, ROUGEF1 score) for evaluating response overlap [13] [14]. Generally, BERT-based methods, especially when combined with reinforcement learning (BERT-RL), demonstrate higher BLEU and ROUGE scores compared to traditional RNN-based architectures like LSTM and GRU, as well as CNN-based models, indicating their superior performance in generating contextually relevant and accurate responses in customer service interactions. This is visually represented in Fig. 4.

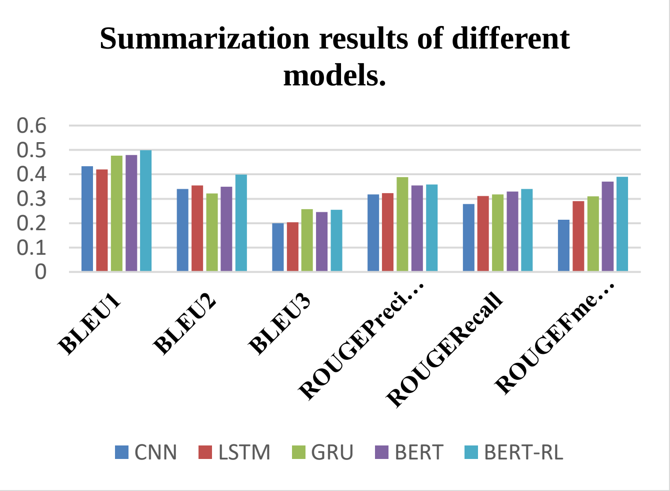

Fig. 4. Performance comparison experiments measured by BLEU score and ROUGE score.

TABLE II. MODEL PERFORMANCE WITH VARYING LENGTHS OF SIMULATED CONVERSATIONS

	BLEU1	**BLEU2**	**BLEU3**	**ROUGE Precision**	**ROUGE Recall**	**ROUGEF1- score**

BERT-RL(3 turn)	0.496	0.389	0.333	0.370	0.351	0.376
BERT-RL(5 turn)	0.520	0.410	0.360	0.380	0.379	0.388
BERT-RL(7 turn)	0.512	0.399	0.350	0.370	0.388	0.89

Table II presents performance metrics for a responsive customer service chatbot system utilizing a hybrid approach of BERT and reinforcement learning (RL) across different numbers of conversation turns. The BLEU scores (BLEU1, BLEU2, BLEU3) measure the similarity between the generated responses and human reference responses, with higher scores indicating better correspondence. Additionally, ROUGE scores (ROUGEPrecision, ROUGERecall, ROUGEFmeasure) evaluate the overlap between the generated and reference responses in terms of precision, recall, and F1 score. As the number of conversations increases, generally, the BLEU and ROUGE scores tend to improve, suggesting that the chatbot's performance benefits from a deeper context and longer interactions. BLEU and ROUGE ratings are critical for evaluating a chatbot's overall performance. Fig. 5 presents BLEU measures the similarity among the chatbot's generated responses and reference responses, specializing in precision. ROUGE emphasizes recall, taking pictures how well the chatbot's responses cover key aspects of the expected solutions. Together, they make sure balanced assessment of accuracy and relevance.

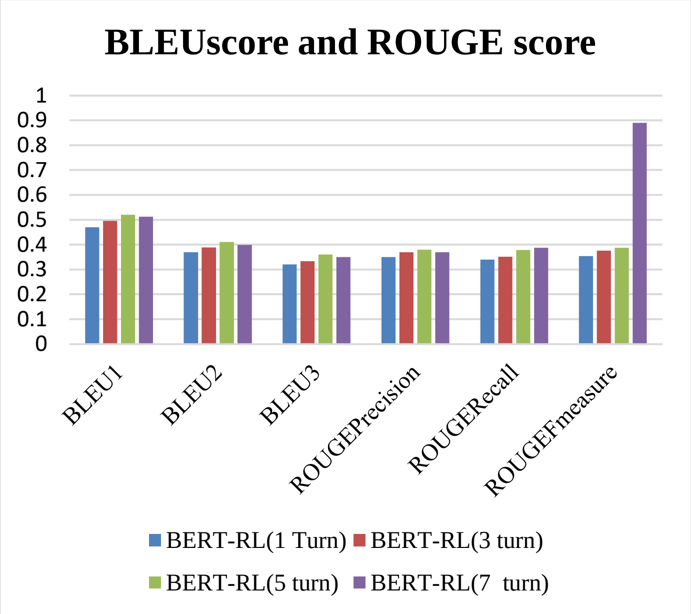

Fig. 5. Chart displaying performance with various lengths of simulated conversation measured.

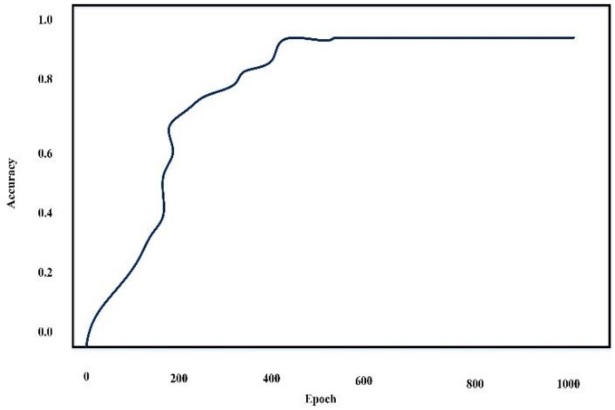

Fig. 6. Overall accuracy.

The total accuracy of the Customer Service Chatbot built with a BERT and Reinforcement Learning Hybrid System is a comprehensive measure of its ability to understand customer inquiries and respond appropriately this is visually represented in Fig. 6. By combining BERT's sophisticated natural language processing capabilities with reinforcement learning's iterative learning strategy, the chatbot obtains high accuracy in understanding user intent and providing contextual suitable solutions. This hybrid system adapts through user interactions and refines its responses continuously to improve accuracy, resulting in effective and beneficial customer support interactions.

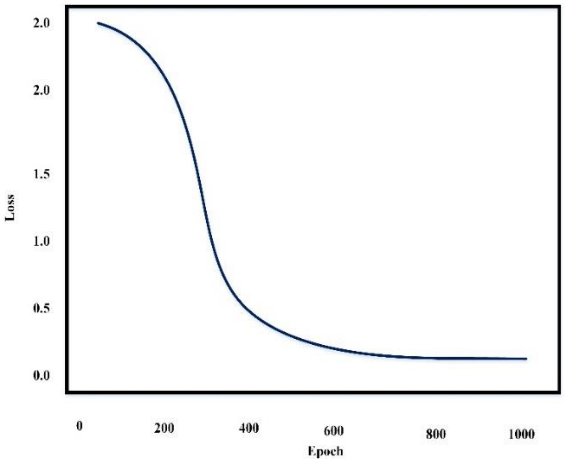

Fig. 7. Overall accuracy.

The overall loss in the context of a Customer Service Chatbot using a BERT and Reinforcement Learning Hybrid System represents a measure of the discrepancy between the predicted responses generated by the chatbot and the ground truth responses provided by humans is shown in Fig. 7 This loss function quantifies the model's performance during training, guiding it towards minimizing errors and improving response quality. By minimizing the overall loss, the chatbot learns to generate more accurate and contextually relevant responses, thereby enhancing its effectiveness in addressing user queries and improving overall customer satisfaction.

A. Discussion

The conceived work will thus aim at training a Responsive Customer Service Chatbot by applying a hybrid model involving the well-established BERT of language and RL. The idea of this integration is to address a number of drawbacks of the current chatbot systems and improve their outcomes vastly. Most prior chatbots have static decision rules or statistical models, which create limited, contextually superficial conversations that do not extend very well to users individually, or in the shifting trends that correspond to the further course of a conversation. It is also possible with the offer of the proposed chatbot that uses BERT for its functioning since the latter organized language best in paying attention to context and juggling its intricacies. The integration of RL solves the issue of rigidity, which is usually characteristic of normal chatbots [13] [14]. RL enables the chatbot to get smarter by learning from the users' response and feedback thus making it to increase its performance. It is such constant training that assists in improvement of the different and intricate questions that the chatbot is likely to encounter and thus improves the general user experience. Also, the hybrid system is expected to address some issues that may include the overall flow and subject coherence in many turns of the conversation, improved recognition of the user intent, and learning new patterns of the conversation. Doing so benefits from using BERT's deep contextual embeddings combined with RL's adaptive learning mechanisms as more substantive and useful chats are expected to be attained.

VI. Conclusion and Future Work

The improvement of the Responsive Customer Service Chatbot the use of a hybrid BERT and Reinforcement Learning (RL) machine represents a widespread advancement in chatbot technology. This technique combines the strong language understanding competencies of BERT with the adaptive learning strengths of RL, addressing key obstacles in present day chatbot systems. Traditional chatbots regularly battle with keeping conversational context, knowledge complex person queries, and adapting to dynamic person wishes. By integrating BERT, which excels in processing and decoding nuanced language, with RL, which allows for continuous development based totally on user interactions, the proposed machine aims to deliver a greater clever, responsive, and contextually conscious chatbot. The initial results suggest promising improvements in reaction accuracy and consumer engagement. The BERT model enhances the chatbot's potential to comprehend the intricacies of language, whilst RL best-tunes its responses based on actual-time comments, leading to a greater personalized and effective consumer revel in. This hybrid approach overcomes the stress of rule-based totally structures and the limitations of conventional statistical fashions, imparting a dynamic and scalable solution for customer support applications. Looking forward, future work will consciousness on several key regions. Firstly, expanding the chatbot's competencies to handle greater numerous and complex communication topics could be essential. This entails incorporating additional area-unique know-how and refining the RL algorithms to higher manage problematic user interactions. Secondly, improving the machine's potential to deal with multi-flip conversations and emotional nuances will improve normal person delight. Finally, exploring integration with different superior technology, which includes voice popularity and sentiment evaluation, will similarly raise the chatbot's capability and user experience. Ongoing evaluation and iteration will be critical to ensure the system stays powerful and adaptable to evolving user desires and technological improvements. Future work for the research focus on expand the chatbot's ability to handle a broader range of topics by integrating additional domain-specific knowledge bases and refining the reinforcement learning algorithms for better handling of complex queries. Developing advanced techniques to manage multi-turn conversations, allowing the chatbot to maintain context over extended interactions and respond appropriately to user inquiries that involve emotional nuances.

Liver and Tumour Segmentation Using Anchor Free Mechanism-Based Mask Region Convolutional Neural Network

(Liver and Tumour Segmentation)

Sangi Narasimhulu, Ch D V Subba Rao
Department of Computer Science and Engineering,
Sri Venkateswara University College of Engineering, Tirupathi, India

Abstract—**An accurate liver tumour segmentation helps acquire the measurable biomarkers for decision support systems and Computer-Aided Diagnosis (CAD). However, most existing approaches fail to effectively segment tumours in the liver due to the overlapping of liver with any other organ in the image. To solve this problem, this research proposes Anchor Free with Masked Region-based Convolutional Neural Network (AFMRCNN) approach for segmenting liver tumours. The AF attains a precise localization of tumours by directly predicting the tumour location without relying on predefined anchor boxes. Standard datasets like LiTS and CHAOS are utilized to experiment with the efficiency of the proposed method. An EfficientNetB2 is performed to extract the most relevant features from the segmented data. The Deep Neural Network (DNN) is performed for the classification of liver tumours into binary classes by capturing intricate patterns and relationships in the data with the help of a non-linear activation function. The experimental results exhibit the proposed ARMRCNN method's commendable segmentation performance of 0.998 Dice Similarity Coefficient (DSC), as opposed to the existing methods, UoloNet and UNet++ + pre-activated multiscale Res2Net approach with Channel-wise Attention (PARCA) on the LiTS dataset.**

Keywords—Anchor free; computer-aided diagnosis; deep neural network; EfficientNetB2; liver and tumor segmentation; masked region-based convolutional neural network

I. Introduction

Medical segmentation plays a vigorous role in Computer-Aided Diagnosis (CAD) by effectively improving the diagnostic performance and accuracy. This process enhances the precision of diagnosis, allowing more accurate identification and analysis of medical conditions [1], [2]. Globally, the liver disease is considered as the deadly disease and it is the predominant causes for liver cancer mortality. Liver tumour segmentation is important in the tumour phase and is a primary requirement for various radiological and surgical interventions including ablation therapy, liver transplant, etc. [3], [4]. There are various diagnosis tools like Computed Tomography (CT) scans, Magnetic Resonance Imaging (MRI), etc. which are the most extensively utilized techniques for the detection and diagnosis of hepatic cancer [5]. Among these, CT scans are majorly utilized to diagnose and provide highly detailed images of the body's internal structures and soft tissues. This high level details help accurately diagnosing various conditions. Different CAD solutions have been examined to aid radiologists in decision-making with diagnostic effectiveness. Liver segmentation is the most complex phase of CAD systems and hence plays a pivotal in identifying the success of diagnosis [6]. This process allows doctors to identify tumours with similar appearances in medical images and assists in developing tailored treatment pathways [7]. The reliability and precision of the segmentation approaches are significant for acquiring the clinically relevant boundary, as well as the volumetric calculations in the stage of liver tumour [8].

The structural data of shape, size and location are obtained from the segmented liver areas which offer a helpful understanding for disease assessment and treatment planning [9],[10]. Thus, introducing the automatic and accurate approaches for liver tumour segmentation has fascinated to an enhancing consideration with a crucial worth in clinical practice [11], [12]. Additionally, researchers have introduced various CAD and Deep Learning (DL) approaches to aid radiologists in understanding the CT images [13],[14]. Simultaneously, the CAD systems detect Regions of Interest (RoI) and provide the probability of these areas being specific types of lesions of either malignant or benign [15]. However, most of the existing approaches have failed to effectively segment tumours in the liver due to the overlapping of the liver with any other organ in the image. To overcome this problem, this research proposes the novel DL approach of Anchor Free with Masked Region-based Convolutional Neural Network (AFMRCNN) approach for segmenting liver tumours. The foremost contributions of this research are as follows:

- For liver tumour segmentation, this research proposes the AFMECNN approach. The AF directly detects the tumour location without relying on predefined anchor boxes, leading to the minimization of the existence of false positives and negatives.
- For the feature extraction process, the pre-trained architecture of EfficientNetB2 is utilized to extract the pertinent features. The EfficientNetB2 technique attains the most efficient extraction of high-quality features from images by employing effective scaling approaches.

- The Deep Neural Network (DNN) is performed to classify liver portions into two categories: Tumour and Non-tumour. The DNN attains a greater accuracy by capturing intricate patterns and relationships in data with the help of non-linear activation functions.

This research paper is further provided as follows: Section II displays the literature survey based on liver and tumour segmentation using DL approaches, Section III shows the proposed methodology, while Section IV demonstrates the results and discussion, and the conclusion of this research is given in Section V.

II. Literature Survey

In order to address the issue of liver tumour segmentation, various approaches were introduced by researchers. This section discusses the related works of the DL-based approaches for liver and tumour segmentation, along with their advantages and limitations. Table I demonstrates the advantages and limitations of the literature survey of Liver and Tumor Segmentation discussed in this research.

Zheng et al. [16] developed a UoloNet model to enhance the small target medical segmentation model for liver tumours using the LiTs17 dataset. The UoloNet model comprised three main modules namely, shared encoder module, object detection module, and mask generating module. The share encoder-decoder module generally implemented the extracting features of the image. The object detection module performed in a dual task mode with object detection and segmentation. The prediction module enhanced the segmentation accuracy by utilizing detection outputs to improve and highlight specific regions. Finally, the Intersection Over Union (IOU) metric was used in the traditional YOLO approach to increase the convergence speed of the network. However, the high amount of noise in the prediction module affected the identification of small labels in the image.

Huang et al. [17] implemented a Semi-supervised Double-cooperative Network (SD-Net) for liver tumour segmentation using a CT scan image. The SD-Net framework reduced the requirement of dense labelling in liver image segmentation. For the segmentation process, collaborative networks like V-net and 3D-ResVnet were utilized to transfer the labelled image from to the unlabelled image in the target domain. A dynamic Pseudo-label generation strategy was introduced to enhance the label qualities in unsupervised learning by collecting better-predicted masks as pseudo-labels from both network models. Nonetheless, the implemented SD-net model was memory intensive due to the high resolution of images, leading to limited scalability.

Yu et al. [18] presented a liver tumour segmentation network utilizing multi-phase CT images. To increase the importance of reciprocal data from various stages, Cross-Modal feature Guidance (CMG) and multi-feature fusion modules were developed in the model. The two modules were combined to effectively acquire the multi-phase features and improve the performance of liver tumour segmentation. The DL architecture was designed to exchange information between multiple phases and modalities accurately. However, the presented CMG model was constrained in its capability to analyse the complex details of lesions and generally focused only on segment lesions from inaccurate registration.

Kushnure et al. [19] implemented a new lightweight multi-level network through core architecture from the UNet++ network for automatic liver segmentation. The designed Pre-activated multiscale Res2Net approach with Channel-wise Attention (PARCA) block in a network model was able to extract coarse multi-scale features from various levels. The modification in the UNet++ network with a PARCA feature mechanism extracted more semantic and contextual data, thereby enhancing the performance of the decoder in the network. In addition, a customized loss function was implemented to maintain data imbalance and effectively consider complex samples in the collected data. Nevertheless, the UNet++ failed to effectively segment tumours in the liver that overlapped with other tissues.

Manjunath and Kwadiki [20] introduced a DL method for automatic liver tumour segmentation through CT scan images. For the liver tumour segmentation process, a 2D-modified ResUNet was designed to segment the affected regions in CT scan images. The 2D-modified ResUNet network was constructed by utilizing a parts encoder, the decoder, and the bridge. The encoder in the network encoded the resized image to a compact representation, then a pixel-wise fashion of an image was represented by the decoder, and finally, the bridge connected the paths of the encoder and decoder. Yet, the 2D-modified ResUNet network model was unable to identify and segment small tumours in the image.

TABLE I. Literature Survey of Liver and Tumour Segmentation

Author	Advantages	Limitations
Zheng et al. [16]	UoloNet's CNN component significantly model spatial relationships within CT images, helping it identify subtle variations in tissue texture and intensity of a small tumour.	A high level of noise in the segmented module impacted the accurate identification of small labels in the image.
Huang et al. [17]	SD-Net leveraged both labelled and unlabelled data by semi-supervised learning approach, enabled for more accurate segmentation of small amount of labelled data.	SD-net model was memory intensive because of its high resolution of images, resulted in limited scalability.
Yu et al. [18]	Cross-modal guidance mechanism enabled the network to significantly learn from balancing data over various stages, improved the segmentation performance.	CMG model was limited in its capability to determine the complex details of lesions and basically focused only on segment lesions from inaccurate registration.
Kushnure et al. [19]	Through the fusion of features from various levels, the network integrated the global and local information, enhanced the segmentation accuracy.	UNet++ was failed to significantly segment tumours in the liver that overlapped with other organs, resulted in poor performance.
Manjunath and Kwadiki [20]	The end-to-end approach removed the necessities of intermediate feature extraction steps and potentially enhanced the overall performance.	2D-modified ResUNet network model was unable to identify and segment small tumours in the image.

From this overall analysis, the limitations of the existing methods are identified as follows: the presence of noise in the prediction module, memory intensive, limited detail analysis and ineffective tumour segmentation. To solve those aforementioned problems, this research proposes the AFMRCNN approach for the effective segmentation of liver tumours. The ARMRCNN approach solves the memory-intensive problem by removing anchor-based complexity by considering effective sparse predictions.

III. Proposed Methodology

This research aims to overcome the segmentation in overlapping images. The AFMRCNN approach is proposed to effectively segment the liver tumour regions from the input images. The AF mechanism frequently utilizes key point-based predictions, provides more accurate boundary information and leads to enhanced segmentation performance. The DNN is used for the classification of segmented regions based on learned patterns by assigning the class labels to various regions in the image. The proposed method is comprised of five significant phases: data acquisition, pre-processing, liver tumour segmentation, feature extraction and classification. Fig. 1 depicts the pipeline of the proposed method.

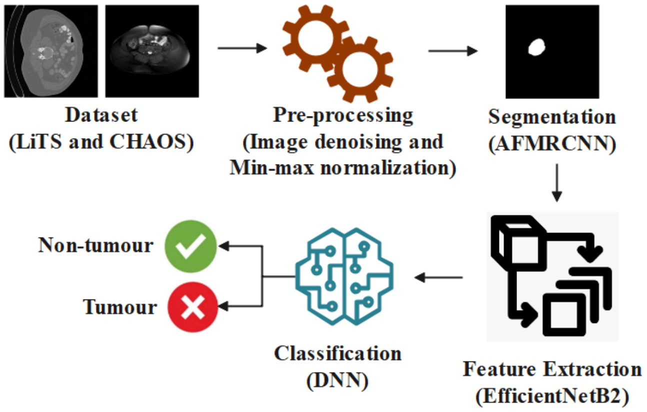

Fig. 1. Pipeline of the proposed method

A. Dataset Collection

This research estimates the efficacy of the proposed method with two publicly available standard liver segmentation datasets, Liver Tumour Segmentation (LiTS) dataset [21] and Combined (CT-MRI) Healthy Abdominal Organ Segmentation (CHAOS) dataset [22]. The detailed explanation of these datasets is discussed below.

1) LiTS dataset: The LiTS dataset involves 201-contrast enhanced 3D abdominal CT images, where 194 CT include lesions. This dataset is obtained from various scanners with scanning protocols from the clinical areas. The minimum and maximum number of axial slices in CT scans are 74 and 987, respectively. Fig. 2 depicts the sample images of the LiTS dataset.

2) CHAOS dataset: CHAOS involves 120 DICOM volumes obtained from binary MRI modalities: T1-DUAL and T2-SPIR. T1-Dual involves phases which are, in-phase and out-of-phase, each of 40 volumes. Every modality involves 20 labelled training data and 20 unlabelled test data. The labelled training data are utilized for multi-modal medical image segmentation tests and estimations. Fig. 3 depicts the sample images of the CHAOS dataset.

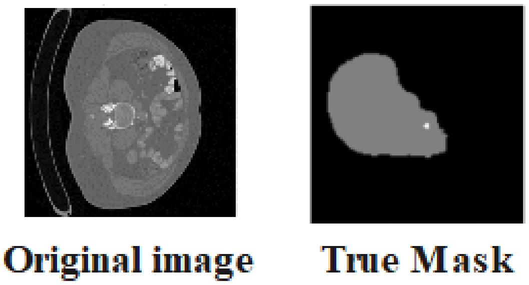

Fig. 2. Sample images of the LiTS dataset.

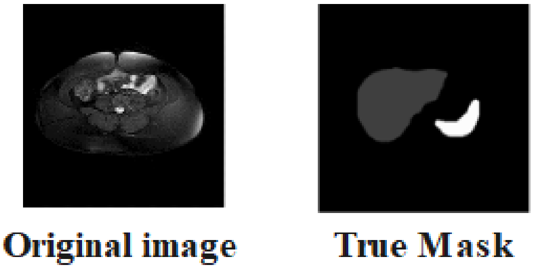

Fig. 3. Sample images of the CHAOS dataset.

Then, the collected datasets are portioned into two categories: 80% of the data are utilized for training and the remaining data for testing. Table II represents the sample number of datasets. The collected dataset is then provided for the pre-processing step.

TABLE II. Sample Number of Datasets

Dataset	Tumour	Non-Tumour
LiTS	21478	42160
CHAOS	6217	8205

B. Pre-processing

After the data collection, pre-processing is performed to modify the input data for achieving the desired results of the DL approach. The collected data contains problems of high resolution and unwanted noise which leads to inaccurate segmentation results. Hence, this research utilizes pre-processing techniques of image denoising and min-max normalization. In the image denoising process, the Gabor filtering approach [23] is utilized and is realized by performing convolution on the Gaussian function with trigonometric functions. By choosing the suitable Gabor function, various scales and directional features are detected from the collected data. This allows the utilization of Gabor filtering in image denoising and edge detection applications. By using image denoising, the Gaussian noise is removed as it produces random variations in pixel values, which obscure the significant features and structures in medical images. This denoising supports to enhance the precision of segmentation algorithms.

After denoising the image, the normalization is performed to equally balance the input data to enhance the segmentation performance because the collected data involves various units and scales. The min-max normalization [12] is a technique that is used to standardize and measure data in the direction to be taken out to the comparable range and magnitude. Then, the pre-processed data are provided to the segmentation process to effectively localize the affected regions.

C. Segmentation

The pre-processed images are fed as input to the segmentation technique to effectively segment the liver tumour regions for classification. Segmentation is a technique generally used in image processing to segment into multiple parts or regions based on the characteristics of pixels in the image. To effectively segment the tumour regions, the AFMRCNN approach is proposed. The detailed explanation of this proposed method is described in the following section. Fig. 4 illustrates the segmented images of LiTS and CHAOS datasets.

1) Anchor-free with mask region-based convolutional neural network: As compared with the other segmentation approaches, the MRCNN approach produces high-quality pixel-to-pixel masks for every case. It performs pixel-level segmentation operations and obtains better target-positioning performance in liver tumour segmentation. The MRCNN [24] approach utilizes a two-stage network model. Initially, the Region Proposal Network (RPN) generates predictions on Regions of Interest (RoI). Then, the Fully Convolutional Network (FCN) processes these RoIs to predict the binary mask, bounding box offsets, and categories for every RoIs. The network model of the MRCNN approach involves three significant types of backbone network, pixel (mask) prediction and alignment of RoI.

In the process of liver tumour segmentation, this research designs the Anchor Free with RPN (AF-RPN) approach to acquire better localization of the liver tumours. The AF-RPN architecture is an FCN to achieve the sharing computation with the binary class classification network. To acquire the tumour regions, the AF-RPN uses a sliding window mechanism applied to feature maps developed through a fusion module. This network performs 3×3 spatial window on an input feature map, and extracts the features through every sliding window. It is mapped to 512-dimensional feature vector through 3×3 kernel convolutional operation via 512 channels. These channel features are forwarded to the two parallel fully convolutional networks. One branch provides likelihoods for classification, demonstrating whether or not the regions are objects, while the other branch provides the coordinates of the boxes for localization. These are processed through the 1×1 convolutional layer and eventually, all output proposals are performed through the Non-Maximum Suppression (NMS) approaches to eliminate irrelevant proposals. Here, the Receptive Field (RF) is developed and anchor-free boxes are applied within the proposed region network to acquire parameterization for position boxes. The RF is introduced by sliding the window across fusion feature maps in CNN.

The RF for pixel is described as the rectangle region in the input data. Particularly for $k \times k$ sliding window with centroid (x, y), the RF is obtained with (x_r, y_r, w_r, h_r), where, $x_r = v \times x$ and $y_r = v \times y$ and $w_r = h_r = k \times x$ where v represents an upsampling factor of the scaling coefficient from feature map to the input data. At every feature map location, there are k anchor-free boxes in the convolutional approach, but the proposed approach involves the individual RF. Providing the convolutional feature map of size $w \times h$, obtaining the $w \times h$ RF samples in total leads to k times, not more than the present AF mechanism. In this research, the RF is introduced as the position boxes to acquire parameterized coordinates of the ground truth bounding box $t *\left(t *= \left\{t_x *, t_y *, t_w *, t_h *\right\}\right)$ and predicted box $\left(t = \left\{t_x, t_y, t_w, t_h\right\}\right)$, as formulated in Eq. (1) and (2).

$$t *= \frac{(x*-x_r)}{w_r}, t_y *= \frac{(y*-y_r)}{h_r}, t_w *= \frac{log(w*/w_r)}{t_h}, t_h *= log(h*/h_r) \tag{1}$$

$$t_x = \frac{(x-x_r)}{w_r}, t_y = \frac{(y-y_r)}{h_r}, t_w = log(w/w_r), t_h = log(h*/h_r) \tag{2}$$

Where, $x*$ and $y*$ represent the centre coordinates of ground truth box; $w*$, $h*$ denote the width and height, x, y, w and h illustrates the complements of predicted box, x_r, y_r, w_r and h_r represent the RF box which is observed as the regression from the RF to its closest ground truth box. By eliminating the anchor-based predictions, this approach simplifies the prediction process, which supports the more effective maintenance of memory when processing high-resolution images. Then, the segmented results are provided to the feature extraction process.

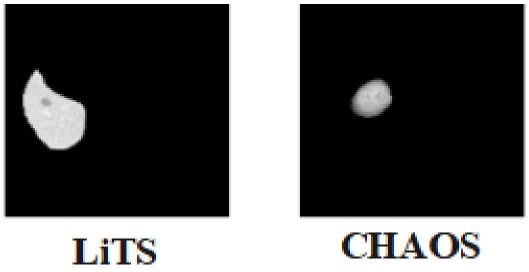

Fig. 4. Segmented images of LiTS and CHAOS datasets.

D. Feature Extraction

The segmented portions of the liver tumour are fed to the feature extraction process. Feature extraction is a process of identifying and extracting relevant features from the data, further used in classification and prediction tasks. Extracting the important features of shape, edge, texture and intensity information support the distinguishing between normal liver tissue and tumour tissue. This leads to more accurate segmentation results and outlines tumours from the surrounding healthy tissue. In this research, the pre-trained architecture of EfficientNetB2 is performed to extract the relevant (texture and shape) features. The detailed explanations of this architecture are discussed below.

1) EfficientNetB2: As compared to other pre-trained architectures, the EfficientB2 utilizes a compound scaling approach to balance the network resolution, depth and width. This process effectively scales dimensions, leading to the most effective utilization of floating-point operations and parameters. The network depth, resolution and width are reliably scaled through the Efficient Net logically by the utilization of compound coefficient. The EfficientNetB2 [25] involves arranging the model through global max pooling and the dropout layer to solve the overfitting problem and succeed through the dense layer for the binary classification. This architecture complies with the suitable loss as well as optimization functions and performs the callbacks for effective training. In EfficientNetB2, the CNN network involves various layers designed for the image processing tasks. With the output shape, the EfficientNetB2 incorporates the 7×7 spatial dimensions with 1408 channels. Ensuing the convolutional layers, the Global Average Pooling (GAP) operation minimizes the spatial dimensions while recollecting the most salient features, resulting in the size of (None, 1408). Then, the dropout layer is performed to alleviate overfitting by arbitrarily deactivating the neurons in training. Eventually, the dense layer with 1 unit is used for the extraction process with 1409 parameters. The extracted texture and shape features using EfficientNetB2 provide detailed information about tumour regions. This information supports classification by helping differentiate tumour regions from normal liver tissue and other structures. Then, the extracted 1408 features from the GAP layer are provided for the classification process.

E. Classification

After feature extraction, the features are fed as input to the liver tumour classification. In this research, the DNN approach is utilized for the classification of tumours into two types as tumour and non-tumour. The detailed description of the DNN is discussed below.

1) Deep neural network: The DNN [26] is inspired by the biological nervous network. The DNN is a robust promising approach in modelling the mechanical materials behaviour because of its powerful nonlinear mapping capability. The DNN approach comprises three significant layers of input, activation and Fully Connected (FC) layer which are utilized for the classification tasks.

A neural network requires an activation function for the final prediction of liver tumours. Rectified Linear Unit (ReLU) is the default activation function; it extends the nonlinearity to the network which provides output 0 for negative values and similar values for non-negative values. Also, Sigmoid is an activation function which is appropriate for binary classification with the output within the range of 0 to 1. The sigmoid identifies the multinomial probability distribution with two classes. The dense layer is the Neural Network (NN) layer, in which every neuron in the layer obtains an input from whole neurons of its previous layer. It utilizes the operation function to map each input with output.

In the classification process, the DNN effectively classifies the liver tumour into binary classes with the help of various layers. Hence, DNN is more robust to variations in input data like differences in tumour size, shape, and appearance, as opposed to the traditional classifiers which require effective tuning of parameters. The classified result are implanted to estimate the effectiveness of the model, and the detailed explanation result is represented in the following section.

IV. Experimental Results

The segmentation effectiveness of the liver tumour is estimated experimentally based on two standard datasets. The experiments of the proposed AFMRCNN approach are implemented on Python 3.10.12 with the system configuration of Windows 10 (64 bit) OS, intel i5 processor and 8GB RAM. The model effectiveness is estimated through various segmentation performance metrics of Volumetric Overlap Error (VOE), Dice Similarity Coefficient (DSC), Relative Volume Difference (RVD) and Intersection over Union (IoU). The classification metrices of accuracy, precision, specificity, sensitivity/recall, and F1-score are used to estimate AFMRCNN performance. The mathematical expressions of these assessment metrics are formulated in Eq. (3) to (10).

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{3}$$

$$Precision = \frac{TP}{TP+FP} \tag{4}$$

$$Sensitivity = \frac{TP}{TP+FN} \tag{5}$$

$$Specificity = \frac{TN}{TN+FP} \tag{6}$$

$$F1-score = \frac{2TP}{2TP+FP+FN} \tag{7}$$

$$DSC = 2\frac{|A \cap B|}{|A|+|B|} \tag{8}$$

$$VOE = 1 - \frac{|A \cap B|}{|A \cup B|} \tag{9}$$

$$RVD = \frac{|B|-|A|}{|A|} \tag{10}$$

Where, TN is True Negative, TP is True Positive, FN is False Negative and FP is False positive, while A and B represent the binary masks. Table III represents the hyper parameter settings of the proposed AFMRCNN approach.

TABLE III. Hyperparameter Settings of the Proposed AFMRCNN Approach

Hyper parameters	Values
Optimizer	Adam
Learning Rate	0.0001
Loss Function	Binary cross entropy
Batch size	32
Activation function	Sigmoid
No. of Epochs	20

A. Quantitative and Qualitative Analysis

The achievements of the proposed AFMRCNN method is estimated against the existing methods on the LiTS and CHAOS datasets. Table III demonstrates the analysis of the segmentation results. Table IV represents an analysis of the feature extraction results with an analysis of the classification results.

In Table IV, the performance analysis of the segmentation results is presented on the LiTS and CHAOS datasets. The success of the proposed AFMRCNN method is estimated and compared with conventional segmentation approaches like UNet, CNN and MRCNN approaches. When compared to these conventional approaches, the AF in the MRCNN approach that depends on the predicting key points, leading to more accurate localization of liver tumours. This approach specifically aids when dealing with irregular shapes and sizes of tumours, leading to enhanced segmentation outcomes. In LiTS dataset, the proposed AFMRCNN approach attains a better DSC of 0.978, VOE of 14.75, RVD of 11.92 and IoU of 0.98. In the CHAOS dataset, the proposed AFMRCNN approach attains a superior DSC of 0.988, VOE of 6.52, RVD of 5.32 and IoU of 0.98.

In Table V, the performance analysis of the feature extraction results is demonstrated based on the LiTS and CHAOS datasets. The efficiency of the EfficientNetB2 approach is estimated and compared with existing feature extraction approaches of ResNet, VGG19 and InceptionNet. As opposed to these approaches, EfficientNetB2 architecture permits the model to extract relevant and detailed features, capturing complex patterns and structures in the collected data with the help of the compound scaling method. In the LiTS dataset, the performed EfficientNetB2 approach attains a better accuracy of 0.997, precision of 0.998, recall of 0.978, specificity of 0.995 and F1-score of 0.987. Also on the CHAOS dataset, the EfficientNetB2 attains a better accuracy of 0.996, precision of 0.997 precision, recall of 0.988, specificity of 0.996 and F1-score of 0.992.

In Table VI, the performance analysis of the classification results is demonstrated based on the LiTS and CHAOS datasets. The effectiveness of the DNN approach is estimated and compared with the existing feature extraction methods of CNN, Simple Neural Network (SNN) and Feedforward Neural Network (FNN). When compared to these approaches, the DNN minimizes the loss of important features by allowing end-to-end learning. In the LiTS dataset, the performed DNN approach attains a superior accuracy of 0.997, precision of 0.998, recall of 0.978, specificity of 0.995 and F1-score of 0.987. Additionally on the CHAOS dataset, the DNN attains a superior accuracy of 0.996, precision of 0.997, recall of 0.988, specificity of 0.996 and F1-score of 0.992.

TABLE IV. ANALYSIS OF SEGMENTATION RESULTS

Dataset	Method	DSC	VOE	RVD	IoU
LiTS	UNet	0.874	19.80	15.45	0.90
	CNN	0.896	18.90	14.75	0.91
	MRCNN	0.912	17.65	13.80	0.93
	AFMRCNN	0.978	14.75	11.92	0.98
CHAOS	UNet	0.853	8.45	6.75	0.85
	CNN	0.875	8.60	7.85	0.86
	MRCNN	0.893	7.95	6.45	0.88
	AFMRCNN	0.988	6.52	5.32	0.98

TABLE V. ANALYSIS OF FEATURE EXTRACTION RESULTS

Dataset	Method	Accuracy	Precision	Recall	Specificity	F1-score
LiTS	ResNet	0.952	0.941	0.964	0.948	0.952
	VGG19	0.961	0.955	0.972	0.960	0.961
	InceptionNet	0.844	0.832	0.857	0.841	0.844
	EfficientNetB2	0.997	0.998	0.978	0.995	0.987
CHAOS	ResNet	0.923	0.912	0.934	0.921	0.923
	VGG19	0.938	0.929	0.945	0.937	0.938
	InceptionNet	0.819	0.806	0.832	0.818	0.821
	EfficientNetB2	0.996	0.997	0.988	0.996	0.992

TABLE VI. ANALYSIS OF CLASSIFICATION RESULTS

Dataset	Method	Accuracy	Precision	Recall	Specificity	F1-score
LiTS	CNN	0.945	0.952	0.938	0.964	0.945
	SNN	0.889	0.895	0.874	0.870	0.884
	FNN	0.927	0.933	0.956	0.922	0.945
	DNN	0.997	0.998	0.978	0.995	0.987

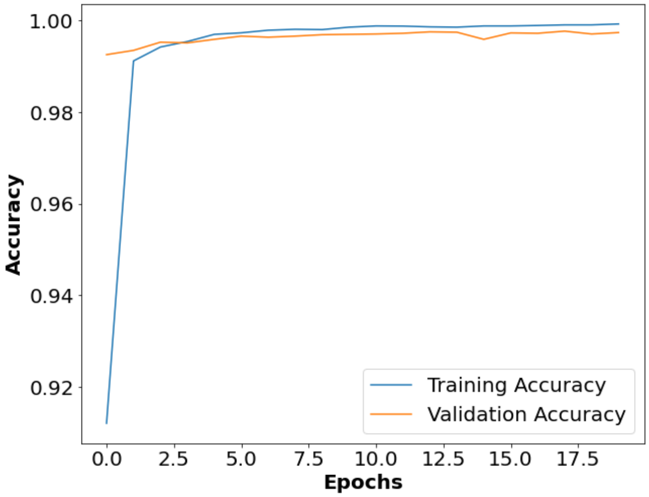
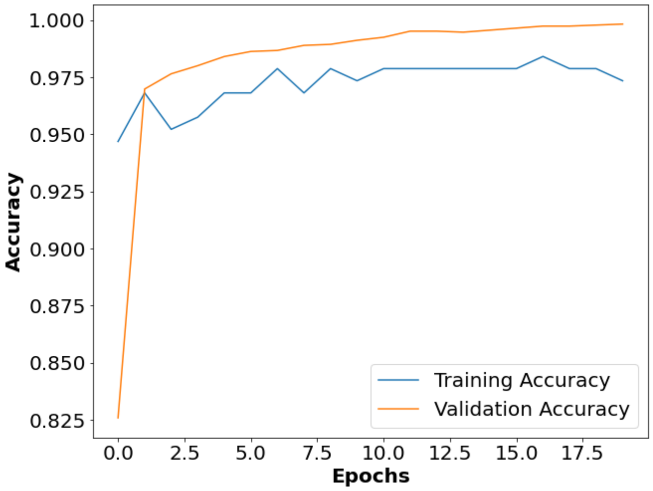
	SNN	0.853	0.855	0.848	0.863	0.851
	FNN	0.896	0.901	0.878	0.869	0.889
	DNN	0.996	0.997	0.988	0.996	0.992

1) Accuracy function: Fig. 5(a) explains the training and validation of the accuracy for the AFMRCNN approach based on the LiTS dataset. Fig. 5(b) explains the training and validation of the accuracy for the AFMRCNN approach based on the CHAOS dataset. The accuracy of the validation is attained through the model on the 20th epoch. The training data is continuously partitioned into smaller portions, which are utilized to update the parameter of the model. The number of epochs describes the total number of iterations that the model works on the training data. Accuracy allows for the easy comparison among the models, representing a commendable model's performance, considering the classes balanced.



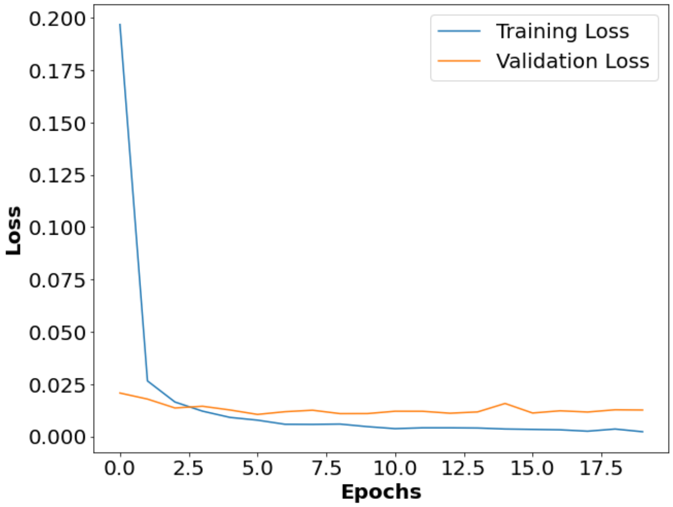
(a)



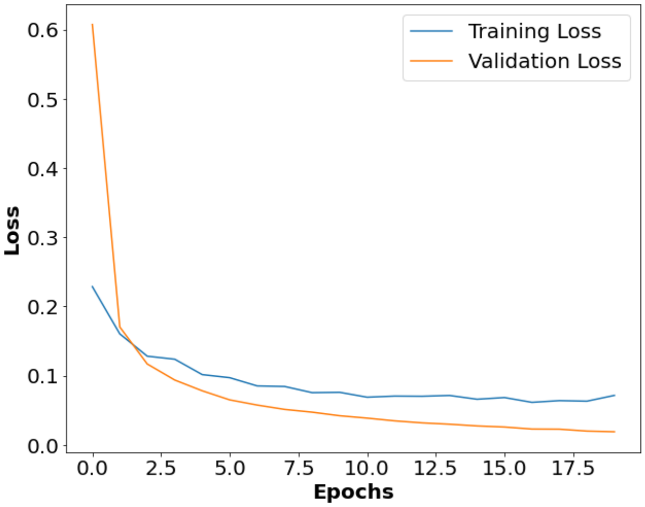
(b)

Fig. 5. Accuracy function: (a) LiTS and (b) CHAOS.

2) Loss function: Fig. 6(a) explains the training and validation of the loss function for the AFMRCNN on LiTS dataset. Fig. 6(b) explains the training and validation of the loss function for the AFMRCNN on CHAOS dataset. The minimum loss of the validation is attained through the model on the 17th epoch, while the training continues until the 18th epoch. However, after the 17th epoch, the loss was further not minimized. At every epoch, the model often changes its internal parameters by focusing on the input data when compared with the target labels to reduce the loss. This loss function indicates that the AFMRCNN has learned to simplify well to the validation data up to this point. This is a significant indicator of the performance of the AFMRCNN on the given data.



(a)



(b)

Fig. 6. Loss function: (a) LiTS and (b) CHAOS.

3) ROC Curve: Fig. 7(a) depicts the confusion matrix for AFMRCNN with an affiliation among True Positive Rate (TPR) and False Positive Rate (FPR) based on LiTS dataset. Fig. 7(b) depicts the confusion matrix for AFMRCNN with an affiliation among TPR and FPR based on CHAOS dataset. ROC is used to depict the graphical evaluation of the binary classification. The ROC curve is widely used to evaluate the performance of classifiers. In this process, the area under the ROC curve is fixed at 0.72. Estimating the ROC curve with TPR and TNR supports understanding the trade-offs between sensitivity and specificity. This supports selecting the optimal balance between correctly identifying positives and minimizing false positives, leading to a commendable AFMRCNN performance.

B. *Comparative Analysis*

The efficiency of the proposed method is compared with the existing methods based on the LiTS and CHAOS datasets in this section. The existing methods like UoloNet [16], CMG [18] and UNet+++ PARCA [19] are compared and estimated with the proposed AFMRCNN approach. AF mechanism significantly minimizes the chances of missing small or irregularly shaped tumours which are not aligned well with predefined anchors, leading to better segmentation results. In classification tasks, the DNN is utilized for classifying liver tumours with the help of the sigmoid activation function in the final layer to produce a probability distribution over different classes. This process allowing for straightforward interpretation of the DNN confidence in every class and enabling decision-making, resulting in a superior classification of tumour and non-tumour. Table VII represents the comparative analysis on the LiTS and CHAOS datasets.

C. *Discussion*

The advantages of the proposed AFMRCNN and limitations of the existing works are discussed. The limitations of the previous works: In UoloNet [16], a high level of noise in the segmented module impacted the accurate identification of small labels in the image. SD-net model [17] was memory intensive because of its high resolution of images, resulted in limited scalability. CMG model [18] was limited in its capability to determine the complex details of lesions and basically focused only on segment lesions from inaccurate registration. UNet++ [19] was failed to significantly segment tumours in the liver that overlapped with other organs, resulted in poor performance. To overcome these problems, the AFMRCNN mechanism enhances the detection of small objects like tumors through reducing the dependency on predefined anchor boxes, which often introduce noise. The anchor-free approach enables the network to focus more precisely on the actual regions of interest, enhancing the small label segmentation accuracy. The anchor-free design enables the model to learn object boundaries dynamically, resulted in better segmentation.

TABLE VII. COMPARATIVE ANALYSIS USING LITS AND CHAOS DATASET

Dataset	Method	Recall	DSC	VOE	RVD
LiTS	UoloNet [16]	0.821	0.462	NA	NA
	UNet++ + PARCA [19]	0.964	0.963	0.057	0.015
	Proposed AFMRCNN	0.978	0.978	0.147	0.119
CHAOS	CMG [18]	0.927	0.928	NA	0.061
	UNet++ + PARCA [19]	0.912	0.951	0.096	0.079
	Proposed AFMRCNN	0.988	0.988	0.652	0.532

This research demonstrates that the binary classification with CNN is effectively utilized for semantic segmentation in medical diagnosis, particularly for liver tumour segmentation. Moreover, this research demonstrates that the segmentation has improved the AFMRCNN effectiveness by solving the individual network bias. This research proposes an end-to-end automatic liver segmentation by using the AFMRCNN approach. This approach conducts multi-level features and AF mechanism for decontaminating the features. ARMRCNN approach improves the quality of segmentation masks by considering them more accurately on RoI. This results in a better description of tumour boundaries, which is complex for treatment planning and assessment. Hence, the proposed AFMRCNN approach attains a better DSC of 0.978 and 0.988, VOE of 14.75 and 6.52, RVD of 11.92 and 5.32 and IoU of 0.98 and 0.98 on LiTS and CHAOS datasets. The results of this research demonstrate that the utilization of AFMRCNN enhances both accuracy and performance of medical diagnostics in the segmentation of liver tumours. The development in the expertise has the latent to improve patients' outcomes, while enabling the development of personalized treatment plans.

V. CONCLUSION

Utilizing the CT images for diagnosing the liver tumours is the most popular technique because it provides high-resolution images with fine anatomical details. Consistent liver tumour segmentation requires accurate image processing across different steps and inaccuracies in this process because of the subsequent segmentation tasks. Hence, this research proposes the AFMRCNN approach to address the problem of image overlapping for the precise segmentation of the liver tumour.

The AF mechanism attains greater segmentation accuracy, particularly for irregularly shaped liver tumours through the prediction of the presence and boundaries of tumours directly. The DNN approach is performed to classify the liver tumours into binary classes through the Adam optimizers and adjust the learning rate dynamically to enhance the convergence. The experimental results exhibit the proposed AFMRCNN approach's commendable DSC of 0.147 on the LiTS dataset as compared to the existing methods, UoloNet and UNet++ + PARCA. However, UoloNet and UNet++ + PARCA attain a minimum DSC of 0.462 and 0.963 on the LiTS dataset. Future work will involve the hybrid DL approach for enhancing the overall model results during the segmenting of the liver tumour.

Efficient Task Offloading Using Ant Colony Optimization and Reptile Search Algorithms in Edge Computing for Things Context

Ting Zhang*, Xiaojie Guo
School of Information Engineering, Jiaozuo University, Jiaozuo 454000, China

***Abstract*—The widespread use of Internet of Things (IoT) technology has triggered unparalleled data creation and processing needs, necessitating effective computation offloading solutions. Conventional edge computing approaches have difficulties in dealing with rising energy usage issues and task allocation delays. This study introduces a novel hybrid metaheuristic algorithm called ACO-RSA, which synergizes two metaheuristic algorithms, Ant Colony Optimization (ACO) and Reptile Search Algorithm (RSA). The proposed approach addresses the energy and latency issues associated with offloading computations in IoT edge computing environments. A comprehensive system design that effectively encapsulates the uplink transmission communication model and a personalized multi-user computing task load model is developed. The system considers various constraints, such as network latency, task complexity, and available computing resources. Based on this, we formulate an optimization objective suitable for computing outsourcing in the IoT ecosystem. Simulations conducted in a real-world IoT scenario demonstrate that ACO-RSA significantly reduces both time delay and energy consumption compared to benchmark algorithms, achieving up to 27.6% energy savings and 25.4% reduction in time delay. ACO-RSA exhibits robustness and scalability when optimizing task offloading in IoT edge computing environments.**

Keywords*—Task offloading; edge computing; ant colony optimization; reptile search algorithm; Internet of Things; energy efficiency

I. Introduction

The exponential growth of Internet of Things (IoT) devices has fundamentally transformed how data is produced, analyzed, and used in numerous sectors, including smart cities [1], healthcare [2], and automated manufacturing [3]. Nevertheless, the substantial increase in data flow places substantial computing requirements on centralized and distributed systems, requiring the investigation of sophisticated task offloading strategies [4]. Conventional cloud computing models encounter delay and data transfer capacity limitations. In this regard, edge computing presents a viable option by bringing computing resources close to data sources [5]. However, improving task offloading in edge computing contexts has distinct difficulties related to energy use and latency [6].

Heuristic optimization techniques have contributed to overcoming these issues by evaluating a variety of task offloading policies. An influential group of these heuristics is Ant Colony Optimization (ACO), a group of algorithms based on the pheromone-based learning of ants foraging [7]. Similar algorithms, such as the Reptile Search Algorithm (RSA), can overcome the exploration versus exploitation challenge by imitating hunter-reptile foraging strategies [8]. The methods have been proven to work on optimization problems across various applications, including image processing, power systems, and edge computing. While the former is difficult to pull out of premature convergence, the latter must be carefully controlled judiciously to avoid falling into unoptimal solutions.

In light of the aforementioned, this paper presents a new metaheuristic method called ACO-RSA, which merges two metaheuristic methods, ACO and RSA, to solve offloading problems in IoT edge computing. Our strategy aims to achieve the benefit of both ACO and RSA by minimizing energy use and time delays. The paper presents the system architecture, with a communication model relying on an uplink transmission and the distribution task model between multiple users. This paper next introduces an objective function for IoT context optimization.

The system design also includes a multi-user task distribution model and an uplink transmission communication model that considers transmission delays, the complexity of the tasks to be solved by standalone devices, and the available computing resources. We design an optimization target specifically for these systems to adapt to IoT task offloading mechanisms and conduct extensive simulations to demonstrate the effectiveness of ACO-RSA. Experimental results show that our solution ACO-RSA can effectively reduce the energy consumption and latency of existing algorithms, which has obvious advantages in practical IoT application scenarios.

The rest of this paper is organized as follows. Section II contains a detailed literature review, including previous work on task offloading and metaheuristic optimization techniques. Section III discusses the system model and problem formulation. Section IV discusses our ACO-RSA algorithm in detail. An experimental setup and simulation results are presented in Section V for evaluating the proposed approach's performance. Lastly, Section VI summarizes the key insights, limitations, and future research possibilities concluding the paper.

II. Background

A. Edge Computing in IoT

In recent years, cloud computing platforms have evolved into the first choice for provisioning services because of their flexibility and cost-effectiveness [9]. Fundamentally, there has been a shift towards centralized systems for processing and storing data in large data centers [10]. The IoT is advancing rapidly, with major effects on various sectors of society, mainly healthcare, transportation, and manufacturing [11]. They have many IoT devices at the edge producing huge volumes of data, which may require very little or significant resources (e.g., storage and processing) [12]. Service delivery is a big problem in cloud systems. Additional challenges involve the placement of sensors and actuators in space, response time constraints, privacy issues, and data processing. Apart from cloud computing, these barriers are a driving force for innovation in solutions [13].

Edge computing places servers for computation and storage at the edges of the internet, relatively closer to where data is generated. The above approximations are due to the lower latencies, more privacy concerns considering data being transferred, and suboptimal energy overhead [14]. This hybridization extends edge computing capabilities to distribute and gradually interconnect with cloud-based processing components.

Fig. 1 shows the hybrid edge-cloud reference design encompasses a range of computing and storage capabilities. Thing nodes are small and constrained devices with limited computing and storage capabilities, so they can only do basic functions like detecting, acting in response to certain events, and sending and receiving data. In contrast to Thing nodes, local nodes are capable of more processing, storing, and communicating. This allows them to process, analyze, and send data and interface with both the cloud and thing nodes. A local node may also host IoT applications at the network edge.

A local node can be any device such as a gateway, access point, router, switch, local server, cellphone, or linked vehicle. Furthermore, various physical gadgets can fulfill certain functions. A traffic light, for example, can be both a thing node that detects its surroundings and acts accordingly and a local node that collects and analyzes data. Centralized data centers provide extensive processing, storage, and communication capabilities in the cloud. Due to these characteristics, cloud solutions can accommodate many IoT components that require substantial physical resources.

B. Task Offloading Challenges

In edge computing settings, task offloading has distinct issues that must be addressed for efficient and effective task distribution. As shown in Fig. 2, the problems arise from IoT devices' intrinsic attributes, edge computing's decentralized nature, and dynamic and unexpected network circumstances. IoT devices are often situated in geographically scattered locations with diverse network conditions. Latency may impede communication between these devices and edge servers, particularly in cases of network congestion or when the devices are placed far from the edge nodes. In addition, a restricted amount of available bandwidth might result in congestion during data transmission, which causes delay problems.

IoT applications can include a wide range of functions with different levels of complexity, including basic data processing and more demanding processes like real-time video analysis or machine learning inference [15]. Because different workloads may have no shared characteristics and time constraints, the diversity of these jobs adds difficulty for offloading methods. In addition, edge servers could differ widely in the processing power, memory, and storage they support [16].

Energy efficiency is crucial in IoT systems since devices often have limited battery capacity. Task offloading may mitigate the computing burden on IoT devices, thereby conserving their energy [17]. Nevertheless, offloading necessitates energy use, particularly in data transmission to edge servers and the reception of results.

Energy consumption
Real-time processing requirements

Fig. 2. Task offloading challenges.

IoT applications, including autonomous cars, smart manufacturing, and healthcare monitoring, need immediate processing. During these situations, even a small delay in carrying out a job might result in significant repercussions, highlighting the need to reduce latency and guarantee prompt task fulfillment [18]. The task involves creating offloading algorithms that provide real-time performance while distributing the computing workload across several edge servers.

Transmitting sensitive data via networks might expose it to interception or unwanted access. Moreover, the decentralized structure of edge computing increases attack vulnerability, making it more difficult to protect all nodes from possible risks. The IoT ecosystem is intrinsically characterized by its dynamic nature, including fluctuating network conditions, shifting workloads, and varied resource availability at edge servers. These variables contribute to an uncertain environment that complicates the job offloading process.

C. Edge Computing-Enabled Task Offloading Mechanisms

Xiao, et al. [19] proposed a three-layer IoT structure that addresses different aspects of tasks. Edge computing and blockchain architectures address the problem of sensitivity to task delays and enable service providers to maximize their profits. In addition, due to the features of the edge computing server in the second layer, the proposed algorithm is executed as a smart contract. This smart contract is responsible for managing and distributing edge computing resources. In particular, a complementary approach called stacked cache is proposed to facilitate the fair distribution of resources on edge computing servers.

You and Tang [20] proposed an energy-efficient, low-delay PSO-based task offloading technique for low-resource edge devices. The problem formulated is a multi-objective optimization incorporating latency, task execution cost, and energy usage. The offloading of all tasks to different mobile edge servers represents the particle's fitness function. Simulation experiments compare the PSO offloading strategy with simulated annealing and genetic algorithms. Based on the experimental results, PSO-based task offloading reduces edge server latency, balances energy consumption, and achieves reasonable resource allocation.

Chen, et al. [21] combined two contradictory offloading objectives, namely increasing the job completion rate with an acceptable delay and decreasing the energy consumption of devices. The task offloading issue was established to achieve equilibrium between two challenging aims. Subsequently, they clarified it as a problem of dynamic task offloading based on Markov Decision Processes (MDP). A Deep Reinforcement Learning (DRL)-based dynamic task offloading (DDTO) method was developed to address this issue. The DDTO algorithm adapts to the constantly changing and intricate context and appropriately modifies the way tasks are offloaded. Experiments demonstrate DDTO's rapid convergence. The trial findings confirm the efficiency of the DDTO algorithm in achieving a balance between the finish ratio and power.

Kong, et al. [22] introduced a dependable and effective approach for task offloading using the multi-feedback trust strategy. A reliable and effective framework is built, which may significantly enhance trust computing and job offloading. Furthermore, the broker utilizes dynamic data monitoring to offer a multi-feedback trust management design using interaction frequency and time attenuation. This model aims to establish a trustworthy operating setting. Moreover, a trust-weighted K-means clustering approach is developed using resource qualities to improve service dependability. This algorithm efficiently and correctly groups the resource nodes needed for the job. A job offloading model uses trust clustering to improve user experience and enhance system performance. In contrast to current task processing models prioritizing task offloading, the suggested approach further incorporates resource pretreatment, trust assessment, and resource clustering before task processing.

Aghapour, et al. [23] presented a solution using deep reinforcement learning to break down offloading and resource allocation into two elementary issues. The Salp Swarm Algorithm (SSA) optimizes resource allocation by updating offloading policy according to environmental data. The proposed method investigates various deep-learning tasks of IoT devices under different cloudlet server capacities. Simulation findings demonstrate that the suggested approach has the lowest latency and power consumption cost. On average, 92%, 17%, and 12% improvements were shown compared to the full local, full offload, joint resource allocation, and computation offloading techniques, respectively.

Bolourian and Shah-Mansouri [24] developed a wireless-powered mobile edge computing system divided into three tiers: IoT devices, edge servers, and cloud. A formulation of a combinatorial optimization problem is presented to minimize wireless energy transmission. Bipartite graph matching is employed to address the issue's complexity, and a harvest-then-offload technique is suggested for IoT devices. The proposed approach utilizes parallel processing to enhance its performance. Empirical tests demonstrate that the recommended technique substantially decreases the energy demand for operating IoT devices compared to other offloading strategies.

Nandi, et al. [25] developed a task offloading strategy to achieve a compromise between device usefulness and execution cost. Utility is determined by job execution delay and energy usage in energy-harvesting IoT devices. The task offloading issue is a problem of selecting a subset that achieves the required trade-off. Social Cognitive Optimization (SCO) addresses the offloading issue and achieves the required polynomial time of execution. The findings confirm the superior effectiveness of the approach regarding job execution speed, energy use, cost efficiency, and task abandonment rate when compared to the most advanced existing methods.

Due to its unique features, the proposed ACO-RSA provides a result-oriented solution to address the issues of energy consumption and latency in task offloading. While ACO has excellent exploration performance thanks to pheromone-assisted learning, it also has premature convergence. As RSA learns adaptively, it can utilize space better and more efficiently; however, exploration capacity may be limited, resulting in suboptimal outcomes. As a result of combining the advantages of both ACO exploration and RSA exploitation, the ACO-RSA hybrid method eliminates these disadvantages. It improves task-shifting efficiency, as illustrated by evaluation results. Using a more balanced and robust approach, we achieve significant reductions in energy consumption and latency, in contrast to existing research that proposes single-objective optimizations or scalability issues. The ACO-RSA can also achieve convergence more quickly and accurately than the current research literature.

III. System Design

A. System Model

Consider a defined geographic region containing a population of N mobile user devices, each denoted by n in the range 1 to N. Each device is assigned a unique computing task with different priorities, such as energy efficiency or latency minimization. This region has a base station equipped with several Mobile Edge Computing (MEC) servers. Mobile devices can communicate with MEC servers via a radio access network to reduce their computing load. The base station is configured with M-channels, each supporting a single connection between the device and the MEC server.

Mobile devices are assigned static channels, and edge servers have limited computing resources. The model also assumes a central cloud server with unlimited capacity. A single-edge server can handle the computing needs of only one device at a time. Tasks that exceed the capacity of an edge server are shifted to the cloud via the backbone network. The mobile edge computing architecture is shown in Fig. 3.

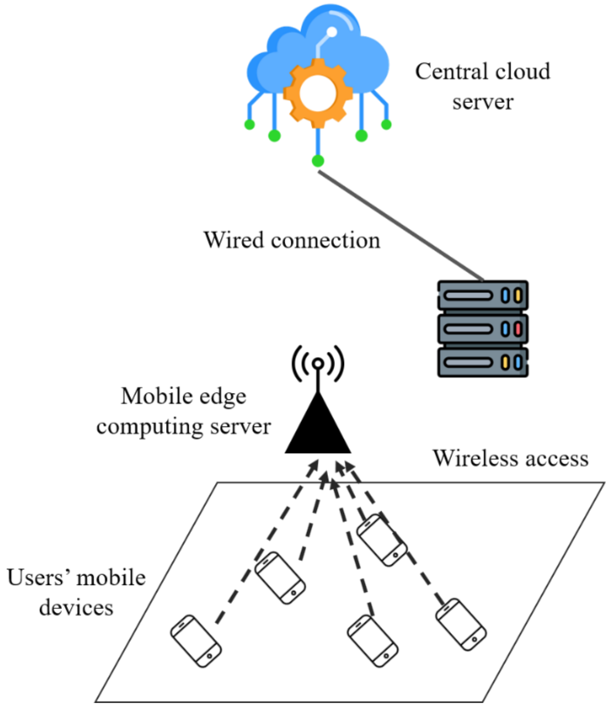

Fig. 3. Network model.

Mobile device offloading involves three steps. First, the device determines whether the task should be executed locally or offloaded to an edge server. During offloading, the system assesses the availability of the edge server resources. Insufficient resources require a decision between queuing at the current edge server or offloading to the cloud.

Orthogonal uplink channels ensure non-interference between devices in the proposed system. According to Eq. 1, the uplink rate R_n is calculated by denoting the transmission power of device n as P_n. Here, S_n refers to the device n's uplink bandwidth, z_n is the channel gain coefficient, and δ_n^2 represents the noise power.

$$R_n = S_n log_2\left(1 + \frac{P_n z_n}{\delta_n^2}\right), \quad \forall n \in N \tag{1}$$

B. Multi-User Computing Task Load Model

This subsection presents a computational task model to simplify the analysis. A computing task is characterized by three main components: (1) volume of data, including program code and input parameters, that needs to be uploaded for outsourced tasks; (2) computing capacity, typically measured in CPU cycles; and (3) results in data to be downloaded for outsourced tasks. Eq. 2 formally defines a computing task Q_v as a function of the result data R_v, the computing capacity C_v, and the data volume D_v.

$$Q_v \underset{=}{\Delta} (D_v, C_v, R_v) \tag{2}$$

Using a program called graph analysis, mobile devices can discover these components. A multi-user delay and energy consumption load model is built to meet personalized user needs by analyzing different application types and corresponding data. This model evaluates the impact of local and cloud task execution on performance.

Initially, each mobile device determines whether to execute its task locally or offload it. For locally executed tasks, the computational requirements of device n are denoted by J_{n1} CPU cycles, and the task itself requires j_{n1} CPU cycles. The local execution time, t_{n1}, is calculated according to Eq. 3. Energy consumption, E_{n1}, for local execution is determined by Eq. 4, where λ is a constant energy consumption coefficient related to the device's chip structure, typically set to 10^{-26}. The total local overhead, W_{n1}, is calculated using Eq. 5, incorporating trade-off coefficients α_{n1} and α_{n2} for energy consumption and task execution time, respectively. These coefficients must adhere to the constraints outlined in Eq. 6.

$$t_{n1} = \frac{j_{n1}}{J_{n1}} \tag{3}$$

$$E_{n1} = \lambda j_{n1} (J_{n1})^2 \tag{4}$$

$$W_{n1} = a_{n1} E_{n1} + a_{n2} t_{n1} \tag{5}$$

$$\begin{cases} a_{n1}, a_{n2} \in [0,1] \\ a_{n1} + a_{n2} = 1 \end{cases} \tag{6}$$

When the n^{th} user's task is offloaded to an edge server, the processing delay is determined by Eq. 7. This delay comprises two components: the uplink transmission delay for task input data and the edge server execution time. The energy consumption for transferring the task to the edge server is computed using Eq. 10, where β represents the device's power amplifier efficiency. Eq. 11 formulates the total offloading overhead.

$$t_{n2}(P_n, J_{n2}) = t_{n2(1)}(P_n) + t_{n2(2)}(J_{n2}) \tag{7}$$

$$t_{n2(1)}(P_n) = \frac{s_n}{W_n log_2(1 + \sigma_n P_n)} \tag{8}$$

$$t_{n2(2)}(J_{n2}) = \frac{j_n}{J_{n2}} \tag{9}$$

$$E_{n2} = \frac{P_n}{\beta} t_{n2(1)}(P_n) = \frac{P_n}{\beta} \frac{s_n}{W_n log_2(1 + \sigma_n P_n)} \tag{10}$$

$$W_{n2} = a_{n1} E_{n2} + a_{n2} t_{n2}(P_n, J_{n2}) \tag{11}$$

C. Optimization Objective Function

The total overhead incurred by mobile device n during task offloading is calculated according to Eq. 12. The objective function is formulated to minimize the aggregate overhead across all devices. To achieve this minimum overhead, the optimal offloading strategy (X), uplink power allocation (P), and edge computing resource allocation (M) are determined. Eq. 13 expresses the optimization goal.

$$W_n = (1 - x_n) W_{n1} + x_n W_{n2} \tag{12}$$

$$\min_{X,P,M} W = \sum_{n=1}^{N} (1 - x_n) W_{n1} + x_n W_{n2} \tag{13}$$

Eq. 14 details the constraints. The binary variable x_n indicates the offloading decision for device n (1 for offloading, 0 for local execution). P_{max} represents the maximum transmission power, J_{max} is the maximum computational resource, and N_2 is the set of devices opting for offloading. The first constraint specifies which devices should be offloaded. The maximum power of the uplink device is limited by constraint 2. With constraint 3, edge computing resources are not allocated beyond the server's capacity. Negative resource allocation is prevented by constraint 4. As a final constraint, uplink transmissions are concurrently limited to N.

$$\begin{cases} 1: x_n \in \{0,1\}, \forall n \in N \\ 2: 0 < P_n \le P_{max}, \forall n \in N_2 \\ 3: \sum_{n \in N_2} J_2 \le J_{max} \\ 4: J_{n2} > 0, \forall n \in N_2 \\ 5: \sum_{n \in N} x_n S_n \le B \end{cases} \tag{14}$$

IV. The ACO-RSA Algorithm

A. Ant Colony Optimization

The ACO algorithm is a metaheuristic inspired by the foraging behavior of real ants. Artificial ants iteratively construct solutions to optimization problems by laying down and following virtual pheromone trails. These paths represent solution components whose intensity correlates with the solution quality. Ants will likely select subsequent solution components based on pheromone levels and problem-specific heuristic information. Pheromone levels are dynamically updated to amplify high-quality solutions. ACO is a probabilistic search method that does not guarantee optimal solutions but often provides acceptable approximations within reasonable computing time.

Mathematically, ACO can be described in the following manner. A population of artificial ants is created. Pheromone levels on all potential solution components are initialized to a small positive value. Ants construct solutions by iteratively selecting components. The probability of selecting component *j* after component *i* is determined by Eq. 15:

$$P_{ij} = \frac{\tau_{ij}^{\alpha}.\eta_{ij}^{\beta}}{\sum\left(\tau_{ik}^{\alpha}.\eta_{ik}^{\beta}\right)} \quad (15)$$

Where α and β are parameters balancing pheromone and heuristic influence, η_{ij} is the heuristic information of components *i* and *j*, and τ_{ij} is the pheromone level of two components. After selecting a component, an ant updates its pheromone level according to Eq. 16.

$$\tau_{ij} = (1-\rho)\tau_{ij} + \rho\Delta\tau_{ij} \quad (16)$$

Where ρ is the pheromone evaporation rate and $\Delta\tau_{ij}$ is the pheromone the ant deposits. Once all ants have created solutions, pheromone levels are updated globally based on the overall quality of the solution. Combining probabilistic selection, pheromone amplification, and evaporation, this iterative process allows ACO to explore the solution space effectively.

B. *Reptile Search Algorithm*

RSA is a swarm intelligence metaheuristic derived from crocodile hunting strategies. By modeling competitive and cooperative interactions within a reptile population, RSA determines the global optima for optimization problems. Known for its simplicity, flexibility, and efficiency, RSA has found applications in image processing, power systems, and engineering.

RSA's optimization methodology, outlined in Eq. 17, involves iteratively refining a population of solutions (*X*). Eq. 18 details the random generation of candidate solutions, where $x_{i,k}$ represents the kth position of the i^{th} individual, *N* refers to the population size, *D* specifies the problem dimension, and *rd* indicates a random value within the problem's lower (*LB*) and upper (*UB*) bounds.

$$X = \begin{bmatrix} x_{1,1} & x_{1,2} & \cdots & x_{1,D} \\ x_{2,1} & x_{2,2} & \cdots & x_{2,D} \\ \vdots & \cdots & \cdots & \vdots \\ x_{N,1} & x_{N,2} & \cdots & x_{N,D} \end{bmatrix} \quad (17)$$

$$x_{i,k} = rd \times (UB - LB) + LB, k = 1,2,\dots,n \quad (18)$$

RSA is divided into two stages: exploration (encircling) and exploitation (hunting). During exploration, crocodiles exhibit two distinct movement patterns: high walking and belly walking. Unlike focused hunting, exploratory behaviors allow for a wider range of search areas. RSA emulates these mechanisms during its exploration phase, as defined in Eq. 19.

$$x_{i,k}(t+1) = \begin{cases} Best_k(t) - \eta_{i,k}(t) \times \beta - R_{i,k}(t) \times rd, & t \leq \\ Best_k(t) - x_{r1,k}(t) \times ES(t) \times rd, & t \leq 2\frac{T_m}{4}\ a \end{cases} \quad (19)$$

$Best_k$ represents the best k^{th} position of the optimal individual, *T* is the current iteration, and T_m is the maximum iteration. Parameter β controls the exploration extent. Random numbers *rd* and *r1* are employed for stochasticity. The hunting operator, $\eta_{i,k}$, calculated in Eq. 20, influences the exploration process.

$$\eta_{i,k} = Best_k(t) \times P_{i,k}(t) \quad (20)$$

To refine the search, a reduced function, Ri,k, is introduced in Eq. 21, where ε is a small constant and *r2* is another random number. This function minimizes the search space. The evolutionary phase, *ES(t)*, calculated in Eq. 22, is a probability ratio that fluctuates between -2 and 2 over iterations, guided by the random number *r3*. $P_{i,k}$, the percentage difference between the $Bestk^{th}$ value of the optimal and current solutions, as computed in Eq. 23. The average solution, calculated in Eq. 24, contributes to the overall exploration strategy.

$$R_{i,k} = \frac{Best_k(t) - x_{r2,k}}{Best_k(t) + \varepsilon} \quad (21)$$

$$ES(t) = 2 \times r_3 \times \left(1 - \frac{1}{T_m}\right) \quad (22)$$

$$P_{i,k} = \alpha + \frac{x_{i,k-M_{x_i}}}{Best_k \times (UB_k - LB_k) + \epsilon} \quad (23)$$

$$M_{x_i} = \frac{1}{D}\sum_{k=1}^{D} x_{i,k} \quad (24)$$

Cooperation and coordination are the two main foraging behaviors of crocodiles. These strategies represent different approaches to intensified exploitation. Eq. 25 determines the specific behavior. Hunting coordination is performed when the current iteration (*t*) falls within the range of $2T_m/4$ to $3T_m/4$, where T_m is the maximum iteration. Conversely, hunting cooperation occurs when *t* is between 0 and $T_m/4$ or $3T_m/4$ and T_m.

$$x_{i,k} = \begin{cases} Best_k(t) \times P_{i,k}(t) \times rd, & t \leq 3\frac{T_m}{4} \\ Best_k(t) - \eta_{i,k}(t) \times \epsilon - R_{i,k} \times rd, & t \leq T_m\ a \end{cases} \quad (25)$$

C. *Integration of ACO and RSA*

Because ACO relies on pheromone trails, exploration of the solution space is hampered by premature convergence. While strong exploration prevents local optima, excessive exploitation impairs solution quality. RSA effectively balances exploration and exploitation and demonstrates superior performance in various technical areas. We propose a hybrid ACO-RSA strategy based on a high-level relay hybrid (HRH) approach to further improve this balance. ACO and RSA are applied sequentially, homogeneously, or heterogeneously. The proposed method uses a heterogeneous HRH strategy to combine the exploitation of ACO with the exploration of RSA.

Initially, ACO, RSA, and shared parameters are initialized. *N* candidate solutions, each represented by an M-dimensional feature vector, are randomly generated within the range of -1 to 1. These solutions are evaluated using a fitness function to assess their quality relative to previous iterations. Superior solutions are retained, while inferior ones are discarded.

Afterward, the optimal solution is identified and assigned to the initial ACO population. The candidate solutions are then designated as initial ant paths. The ants update candidate solutions based on a subset of features initialized with pheromone values exceeding 0.5. Improvements are based on fitness evaluations, with updates only applied to the fittest solutions (Eq. 26).

$$x_i(g+1) = \begin{cases} x_i^{new}(g), & if\ FF\big(x_i(g)\big) > FF(x_i(g+1)) \\ x_i(g), & else \end{cases} \tag{26}$$

ACO or RSA uses the refined candidate solutions as input to explore new promising regions in successive iterations. An algorithm switch occurs when ACO does not improve the solutions, indicating a trap in local optima. RSA is then used to diversify the search space. The iterative process continues until the termination criterion (maximum iterations) is reached.

Initialization is an initial process that randomly generates candidate solutions (using 50 population sizes) to ensure a diverse solution space. We set pheromone levels for ACO to be initialized with small positive values, and we made the pheromone evaporation rate 0.1 (to balance exploration and exploitation). Inspired by the reptile-hunting dielectric technique, the RSA reacts to evolve optimal solutions and seeks convergence of its best solutions. The algorithm stops when 100 iterations are achieved or there hasn't been a significant improvement in loss over ten consecutive iterations. Incorporating ACO exploration with RSA adaptive learning compensates for both suboptimal aspects of the algorithms, avoids premature convergence typical of ACO, and optimizes the exploitation phase of RSA. During task scheduling, each task's priority is assigned based on its scale and complexity (energy-sensitive or latency-sensitive) through the optimization process, as shown in Fig. 2. The system's energy consumption and latency are reduced by balancing the distribution of tasks across available resources, including edge servers or the cloud.

V. Experimental Setup and Results

To validate the effectiveness of the proposed ACO-RSA algorithm, we conducted an extensive series of simulations. The simulation environment is designed to mimic real-world IoT scenarios with varying numbers of mobile user devices and data transfer rates. The environment includes multiple edge servers with different computational capabilities, simulating a typical edge computing context. The primary performance metrics evaluated in the simulations are average time delay and energy consumption. Time delay is the total time required for task completion, while energy consumption is calculated based on the power needed for data transmission and processing.

The simulation parameters were configured according to the 3GPP standard. The simulation considers an area with a 1 km radius, where users transmit data at a maximum power of 25 dBm over a system bandwidth of 15 MHz and user bandwidth of 0.5 MHz. The noise power in the uplink bandwidth is set at −108 dBm. Tasks have input data volumes ranging from 300 to 1500 KB and require CPU cycles between 0.1 and 0.8 GHz. The users' computing power varies from 0.2 to 1.2 GHz, while the MEC server has a computing power of 3 GHz. The simulation also involves a population size of 50 and a maximum of 100 evolutions, with a maximum allowable time delay of 3 to 5 seconds.

To evaluate the convergence of the proposed computation offloading algorithm, a simulation was conducted with 80 users, 15 servers, and 5MB tasks. Fig. 4 illustrates the time delay of the system over different iteration numbers. Fast convergence was observed after 20 iterations, with minimal delay improvements after that, indicating the achievement of a global optimum. This demonstrates the algorithm's strong global optimization and search capabilities and reduces the overall system delay from 0.268 s to 0.194 s, representing a significant performance improvement.

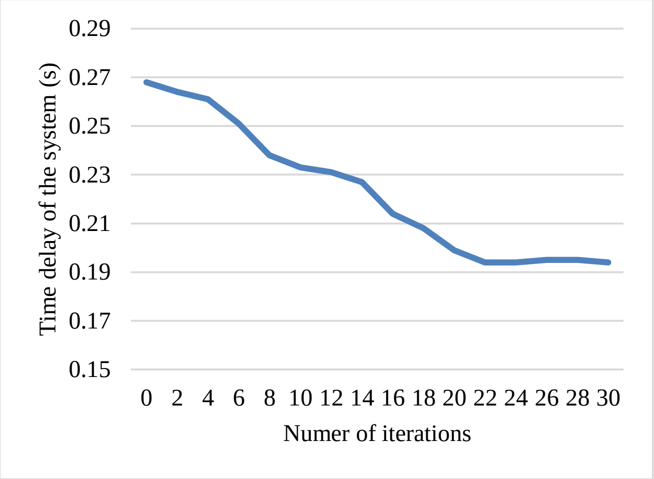

Fig. 4. Stability diagram.

Comparative analyses used algorithms from [26, 27] to assess delay and energy consumption. Fig. 5 shows the average delay for different numbers of users. Energy consumption was evaluated at various transmission rates (Fig. 6). Due to the lack of data transfer, local execution was independent of the transfer rate. All algorithms showed lower energy consumption with increasing transfer rates due to lower offloading overhead. The proposed method showed the largest decrease and lowest overall energy consumption, enabled by more frequent and fine-grained discharge decisions.

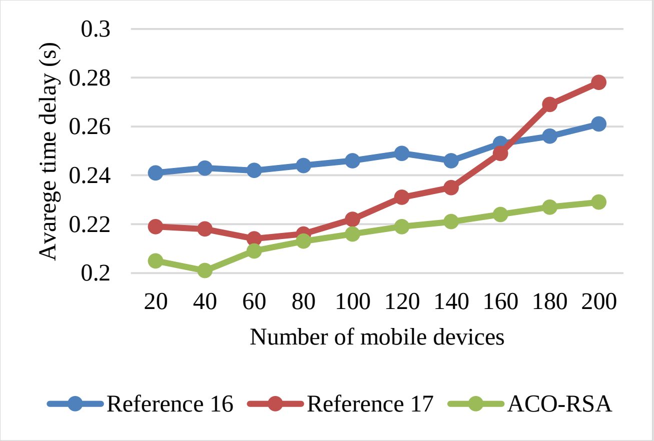

Fig. 5. Delay vs. Number of mobile devices.

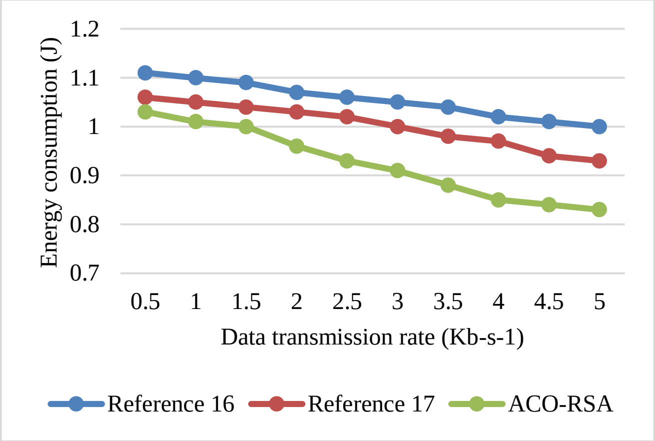

Fig. 6. Energy consumption vs. data transmission rate.

Fig. 7 illustrates the relationship between energy consumption and number of users. The proposed method consistently outperformed others with the lowest energy consumption and growth rate, achieving 0.2 J for 80 users. The local execution caused the highest energy consumption. The proposed strategy's efficiency in task offloading and reduced local execution contributed to overall energy savings.

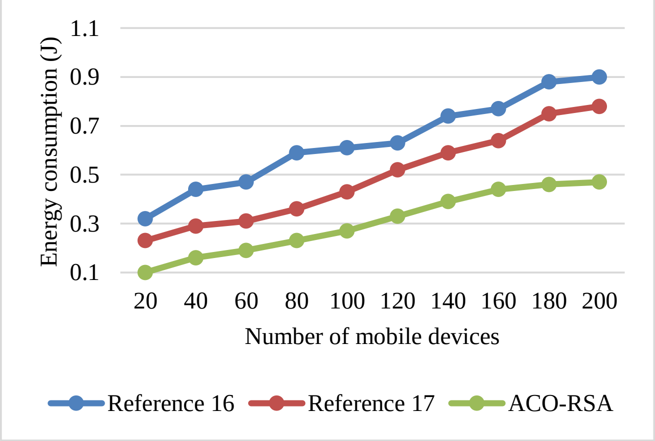

Fig. 7. Energy consumption vs. number of mobile devices.

The results confirm that the ACO-RSA algorithm can effectively solve major task offloading problems in IoT edge computing, such as energy consumption and latency. By combining ACO's exploration and RSA's adaptive learning, the proposed approach distributes tasks efficiently and minimizes system overhead. The proposed ACO-RSA provides an average of 27.6% energy savings and 25.4% latency reduction compared to other existing techniques, resulting in better resource scheduling and task completion.

These results confirm the algorithm's ability to optimize task shifting while balancing energy and performance metrics. Nevertheless, the study emulates the simulation environment of static network states and operational case functions within devices, which may not correspond to the realistic conditions in ideas in IoT environments. Fluctuating network traffic or device roaming can affect the algorithm's performance. Finally, future work should focus on extending ACO-RSA to dynamic edge computing scenarios and incorporating other considerations, such as security and privacy, to improve the robustness and applicability of ACO-RSA in various IoT contexts.

VI. Conclusion

To the best of our knowledge, this is the first study to introduce a new metaheuristic algorithm by combining ACO and RSA into a hybrid version named ACO-RSA, which can overcome the challenges of efficient task offloading in IoT environments powered by edge computing. This feature, therefore, allows the ACO-RSA classifier to make a remarkable compromise between energy consumption and latency, two main components of IoT ecosystems, by utilizing both ACO and RSA within an integrated classification framework. By using ACO, the algorithm takes inspiration from how ants collect food to search for optimal paths; meanwhile, with RSA, it can adaptively explore the IoT environments that are highly dynamic and unpredictable, proposing a strong solution.

ACO-RSA is designed based on an optimization objective function aiming to minimize energy consumption while at the same time reducing task offloading latency. Thus, it is well suited for resource-limited IoT devices that run in edge computing environments. We conducted a series of extensive simulations to verify the feasibility of the proposed algorithm. Results confirmed that the proposed ACO-RSA operates better than the traditional benchmark algorithms. The hybrid algorithm minimizes energy consumption and operates with low latency as the number of mobile users and data rates increase. This result illustrates the promise of ACO-RSA in enhancing resource utilization and prolonging the lifecycle of IoT applications by tuning task offloading policies.

Future work will address the scalability and robustness of ACO-RSA, especially within larger and more complex IoT networks with an assorted range of applications and diverse task requirements. Moreover, investigation into the integration between machine learning and ACO-RSA could enhance adaptivity capabilities even more and aid in better addressing dynamic changes in network conditions and resource availability. In conclusion, the proposed ACO-RSA algorithm is an important step towards an efficient and energy-greedy task offloading strategy in edge computing-enabled IoT environments.

***Abstract*—With the increasing production of glassware products, the detection of bubble defects has been of vital importance. The manual inspection of glass bubble defects is considered to be tedious and inefficient way due to the increasing volume of images, and the high probability of human error. Computer vision-based methods provide us with a platform for automating the bubble defect detection process which can overcome the disadvantages associated with manual inspection thereby significantly reducing the cost and improving the quality. To address these issues, we propose an integrated deep learning (DL) based bubble detection algorithm, in which an image data set is prepared using a Generative Adversarial Network (GAN). The proposed algorithm exploits the Information-Preserving Feature Aggregation (IPFA) module for achieving semantic feature extraction by maintaining the small defects' internal features. To weed out irrelevant information due to fusion, the proposed research introduces the Conflict Information Suppression Feature Fusion Module (CSFM) to further advance the component combination methodology, the Fine-Grained Conglomeration Module (FGAM) is employed to facilitate cooperation among feature maps at various levels. This approach mitigates the generation of conflicting information arising from erroneous features. The algorithm improved performance with an accuracy rate of 0.677 and a recall rate of 0.716 with a precision value of 0.638.**

I. Introduction

The glass production process inherently yields defects like bubbles and inclusions due to the limitations of current techniques. These defects vary in impact depending on the applications. For instance, while bubbles may not greatly affect household glass, they can significantly compromise in big applications such as car safety glass [1-3]. Till now only the manual traditional methods are being used for the identification of glass defects which is very cumbersome and in ideal conditions not possible to detect the present bubbles. Thus, identifying these defects becomes crucial in some automation fashion [4]. To mitigate costs and enhance product quality, employing computer vision for defect detection has gained traction. Glass, with its lack of pattern, monochrome, and transparency, lends itself well to computer vision inspection. CNN-based detection methods rooted in deep learning are rapidly developing and becoming a significant area of intensive research [5-8]. To address the aforementioned challenges, this paper presents targeted enhancements in two key areas to improve small bubble's defect detection performance in camera-captured low-resolution images, particularly in complex environments. A traditional feature aggregation method called stride convolution causes feature information loss. The proposed IPFA module handles this loss and completes feature aggregation using the techniques of splitting and reassembling across different dimensions, facilitating information organization along the channel dimension. This enables the construction of a robust semantic feature representation while maintaining the natural features, thereby replacing generic methods for feature aggregation like stride convolution. Moreover, CNN-based detection methods that depend on DL are developing quickly and are already the subject of much research.

In many industrial applications, such as material inspection and quality control, bubble detection is an essential duty. Product dependability and integrity are guaranteed by the accurate identification of bubble flaws. Low-resolution photos and complicated backdrops are common problems for traditional approaches, which might result in missed detections or false positives. By improving the feature extraction procedure, the suggested IPFA module overcomes these drawbacks and allows for a more accurate diagnosis of bubble flaws. Our method gains from the capability of directly learning intricate patterns and representations from the data by utilizing deep learning. This paper demonstrates the effectiveness of the IPFA module in improving detection accuracy and robustness, paving the way for more reliable industrial inspection systems. Additionally, the advancements in CNN-based techniques highlight the potential for continuous improvements in defect detection, contributing to higher standards in manufacturing processes.

Various researchers have extensively explored different AI-driven techniques for segmenting and reconstructing overlapping bubbles in images of bubbly flow. Specifically, they have evaluated and implemented three distinct CNN models: StarDist and Mask RCNN, both open-source solutions, along with a hybrid of two slightly modified UNets. Generally,

*Corresponding Authors

these methods show proficiency in identifying bubbles under optimal conditions, such as adequate lighting that improves the visibility of intersections between overlapping bubbles, relatively uniform bubble shapes, and a manageable number of overlapping segments. Most of these studies relied on hardware requirements, necessitating a stepper motor to rotate the disturbance and a camera to capture the entire sparse area of the bubbles. This approach was quite expensive and demanded extensive expertise in embedded systems. The proposed method integrates and amalgamates various features taken from the feature space. It extract accurate and comprehensive information. The model recombines features undergoing multi-level interaction in the channel dimension to achieve feature aggregation, enabling the methodology of semantic feature representations without compromising their natural traits.

The remaining structure of the paper is as follows: Section II elaborates a review of literature in the domain. Section III outlines the framework of the research conducted, while Section IV elaborates its implementation and presents a comprehensive results analysis. In the end, Section V concludes the research followed by future work.

II. Literature Review

Computer vision-based systems with similar applications have already been implemented in various industrial sectors. One of the prominent industries employing such systems is the glass manufacturing industry [10-13]. Manufacturing glassware products may exhibit defects like scratches, cracks, impurities, dip stones, and bubbles. Such defects associate security risks along with appearance anomalies. For instance, exceeding the thermal expansion coefficient of the crack defect can cause radial cracks or the glassware can even burst in high-temperature environments [14-18]. Therefore, defect detection is an essential process for glassware products. Despite state-of-the-art glassware industries, the detection of defects is still being done with human supervision which is inefficient given the volume of production units and is highly susceptible to subjective factors of the supervisor [19]. Computer vision-based systems for detecting defects in glassware products can eliminate the problems of subjectivity and inefficiency [20-23]. Currently, vision-based systems are good at detecting defects such as black spots, stones, bubbles, cracks, scratches, and so forth on the abstract level. However, these systems still struggle to detect the anomalies from the regions which are homogeneous. Various defects in manufactured glass sheets are foreign material, low-contrast defect regions, scratches and spots, bubbles, inclusions, and holes. Most of the studies mainly focus on scratches, foreign material, and bubbles as they are defects that can cause severe harm to the quality of the product.

An unmelted opaque material with the appearance of a lump is referred to as a foreign material. Irregular marks or patches on the glass surface are considered spots or scratches [24]. These defects are mainly caused by transportation. The bubble defect is like an air bubble trapped in the glass during glassware production. Several studies have been proposed to detect these defects from glass images using machine vision techniques [25]. Makoto et al. emphasized detecting the foreign materials from the LCD scanned under fan-beam laser light. The defect detection method was based on the light section method. Chang-Hwan et al. employed model-fitting and conventional least-squares estimators to detect the low-contrast region defects. The idea was to approximate the outliers by estimating the image background. Adamo et al. proposed an inline visual inspection system to detect the defects in the glass surface. They employed a canny edge detection method with empirical thresholds to detect scratches and spots. Zhao et al. proposed the canny edge detection method, the Otsu method, binary feature histogram, and adaptive boosting method for detecting bubbles from glass images. Recent advancements in Generative Adversarial Networks (GANs) are increasing and have many advantages in offering solutions with DL algorithms in the industry [26]. Many researchers have proposed novel methods using DL algorithms to improve the bubble defects and make them more robust and efficient. The authors have introduced a method based on DL, which efficiently trains the neural network (NN) on a reduced dataset of more precise calculations through transfer learning. This is achieved by exploiting a crystal graph NN trained on a larger dataset with reduced accuracy but better speed [27-29]. Furthermore, the researchers have explored various AI-based approaches for segmenting and reconstructing overlapping bubbles in images of bubbly flow. Specifically, they have assessed and implemented three different CNN architectures: StarDist and Mask-RCNN, both of which are open-source techniques, and a hybrid of two slightly adapted UNets [30-34]. In general, all three methods demonstrate the ability to detect bubbles under favourable conditions, such as sufficient lighting that enhances the visibility of intersections between overlapping bubbles, a relatively uniform bubble shape, and a manageable number of overlapping bubble segments.

In many industrial applications, such as material inspection and quality control, bubble detection is an essential duty. The integrity and dependability of products are ensured by the accurate identification of bubble flaws. Low-resolution photos and complicated backdrops are common problems for traditional approaches, which might result in missed detections or false positives. By improving the feature extraction procedure, the IPFA module overcomes these drawbacks and makes it possible to identify bubble faults with greater accuracy. Our method takes advantage of deep learning (DL) to learn hidden patterns and their representations straight from the dataset. The efficiency of the IPFA module enhances detection robustness and accuracy which is demonstrated in this research, opening the door for more dependable industrial inspection systems. Moreover, developments of CNN-based methods demonstrate the possibility of ongoing enhancements in fault identification, resulting in improved standards for the manufacturing process. Several studies have been conducted for finding the difficulties associated with bubbles detection in low-resolution photographs. Conventional image processing methods, including thresholding and edge detection, often fail because they can't deal with complicated backdrops and different lighting situations. The use of DL and machine learning (ML) techniques to resolve these issues has been investigated in recent studies. Convolutional neural networks (CNNs) have been used in a range of image identification tasks, such as defect detection. Research suggests that combining CNNs with multi-scale feature extraction methods will greatly enhance detection performance. Methods such as the Feature

Pyramid Network (FPN) and its variants have been utilized to improve object detection on various scales. By maintaining crucial feature information throughout the aggregation process, the proposed IPFA module improves on existing developments by ensuring that minute features necessary for identifying bubble faults are not overlooked. To further improve performance, CNN designs now include attention methods in addition to multi-scale feature extraction. By training the network to focus on only the desired portions of the image, attention modules improve the network's ability to detect minute defects. Adding attention methods to the IPFA module can result in detection systems that are even more accurate and dependable.

New opportunities for automated quality control have been created by the use of DL-based approaches in industrial applications. Research has shown that DL models can achieve more accuracy and efficiency than conventional techniques. The IPFA module is a flexible solution for a range of defect detection jobs due to its better integration with CNN architectures. The effectiveness of CNN-based techniques for industrial inspection is supported by experimental findings from investigations. Studies have demonstrated that CNNs can identify flaws in metals, polymers, and textiles with higher accuracy. These capabilities are improved by modules like IPFA, achieving even higher accuracy standards. The availability of rich datasets for model training and the ongoing growth of DL frameworks are the factors for more contribution to the field's advancement. By exploiting these advancements, the IPFA module promises a reliable and expandable industrial defect detection system. In conclusion, the suggested IPFA module compounded with DL capabilities enhances the task of industrial inspection and bubble detection with better accuracy and dependability in defect identification by resolving the drawbacks of conventional techniques. The ongoing advancements in CNN-based techniques and their application in industrial settings hold great potential for further enhancing the quality and efficiency of manufacturing processes.

Most of the works were based on hardware requirements like there was a need for the stepper motor to rotate the turbulence to rotate the camera to capture the entire defective area of the bubbles. This method was quite expensive and required an extensive area of specialization in the embedded system field. Further with the advancement of the DL network, the models that were trained were limited to the high-resolution images but in reality, the low-resolution images were not considered. Most of the bubble defects have low-resolution images which needs to be considered in the work along with that the overlapping bubbles create more defects which was neglected in the literature.

III. Materials and Methods

In comparison to the previous methods the proposed algorithm makes it more suitable for defect detection in glass bottle images. Fig. 1 [36] demonstrates the structure of the proposed model.

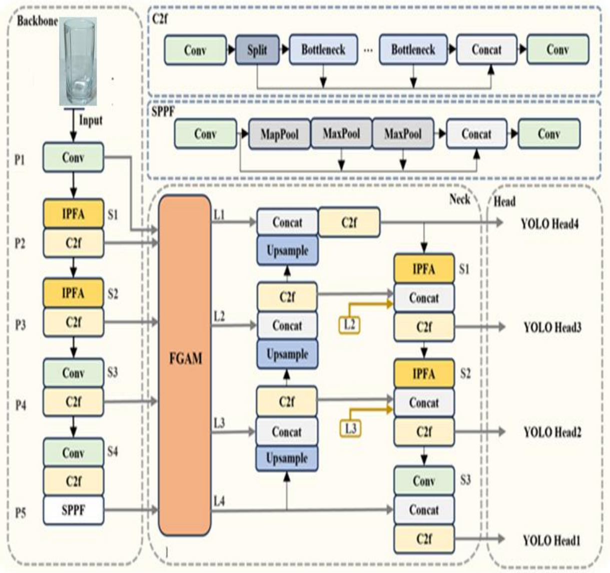

Fig. 1. Model’s structure for the processing of the glass image.

A. IPFA Module

Feature aggregation refers to the process of integrating and combining multiple characteristics from the feature space to obtain more precise and comprehensive data. However, widely available feature-aggregation techniques like pooling and stride convolution can significantly impair deep neural network detection performance due to feature information loss. Stride convolution increases the convolutional kernel's stride, reducing the size of output feature map and increasing the size of the receptive field. This technique aggregates the input feature information in the spatial dimension, compressing feature information for bubble defects. Conversely, the pooling method prepares four spatially separated sub-features from the features, retaining only a portion and discarding the rest, potentially losing important information. To address this issue, the research work proposes an IPFA module that splits and recombines features in the spatial and channel dimensions. This module achieves feature aggregation by recombining features that undergo multi-level interaction in the channel dimension, enabling the semantic feature extractions of input data without compromising its natural characteristics. Fig. 2 illustrates the precise construction of the IPFA module [36].

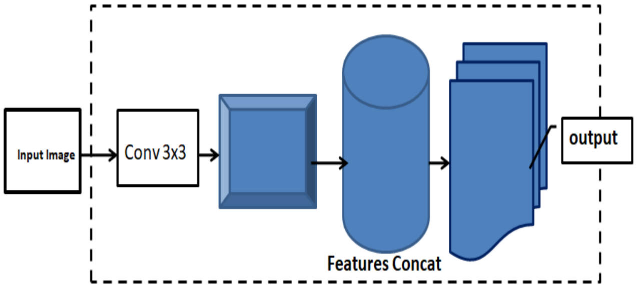

Fig. 2. The structure of IPFA module.

Initially, for the receptive field size expansion, the IPFA module employees a 3×3 convolution while maintaining the original size of output feature map. A 3×3 depth-wise separable convolution is then utilized in the neck to lower the number of parameters. Subsequently, the extracted features are separated into both spatial and channel dimensions, giving in eight categories of sub-features. These sub-features concatenated in the channel dimension. At the end, in the channel dimension, we employ a 1×1 convolution for information interaction among the concatenated features.

The IPFA module has been implemented for both the spine and neck areas of the glass images. This module replaces the traditional stride convolution method and achieves better feature aggregation. Compared to conventional feature extraction methods that use stride convolution or pooling operations, the implemented module in the research maintains information contained in the natural feature of the input sample thereby improving the model's performance.

B. *CSFM Module*

In the process of feature integration, the "concat" or "add" operations are typically employed to combine different levels' feature maps. However, merging them with only the default weights can lead to significant redundancy and contradicting information, resulting in semantic alterations in the current layer and creating defect regions which can be simply overshadowed by the background. To address this issue, the Channel and Spatial Feature Modulation (CSFM) module is proposed. This will remove contradicting information in the integration task, preventing the features of the defective area from being overshadowed. There are two parallel branches in the CSFM module: the Channel Conflict Information Suppression Module (CCSM) and the Spatial Conflict Information Suppression Module (SCSM). This dual approach ensures that both types of conflicts are minimized, thereby enhancing the identification of defect features. Additionally, the integration of the CSFM module within DL frameworks significantly enhances the capability to distinguish defect features from background noise. This improvement is crucial for applications requiring high precision, such as quality control in manufacturing and material inspection. The dual-branch structure of the CSFM not only refines feature representation but also adapts to various types of input data, making it versatile across different defect detection scenarios.

Since, simple fusion is the rational approach which works on the principle of just adding the information whatever it is getting with the default weights. In the processing of the pixel maps from different layers, many of the pixels are repeated and redundant which must be filtered out to optimize the process.

By addressing both channel and spatial conflicts, the CSFM module ensures that the features extracted are both distinct and relevant, thus preventing the dilution of critical defect information. More accurate feature aggregation is possible due to the adaptive pooling in the CCSM, which enables dynamic modification based on the input data whereas, the convolutional method of the SCSM provides fine-grained spatial attention, identifying minute differences that might point to flaws. The CSFM module is better than conventional feature integration techniques. It offers greater accuracy and resilience for identification of minute and subtle flaws. Defect detection systems perform much better when they can reduce conflicting data while maintaining the integrity of feature information. This innovative method promises more dependable and effective inspection procedures in a range of industrial applications, establishing a standard in the field. Higher standards and better productivity in production settings result from the integration of CSFM compounded with better automated quality control systems and improved fault detection efficacy.

Moreover, the CSFM can easily integrate multi-level features in a more balanced and efficient manner to improve defect detection accuracy. The CSFM's unique design is shown in Fig. 3, which emphasizes the system's capacity to mitigate contradictory input while preserving feature integrity [36]. Applying the CSFM module into DL frameworks highly improves the ability to isolate defect features from noise. For material inspection and manufacturing quality control applications which need extreme precision, this improvement is essential. The CSFM's dual-branch structure makes it flexible for a range of defect detection scenarios by improving feature representation and accommodating diverse kinds of input data. The CSFM module does not allow critical defect information to be diluted by handling both channel and spatial conflicts to guarantee that the characteristics collected are different and meaningful. Even more accurate feature aggregation is possible by using the adaptive pooling in the CCSM, which enables dynamic modification based on the input data. On the other hand, the convolutional method of the SCSM provides fine-grained spatial attention to identify minute differences that might point to flaws. The experimental data demonstrate that the CSFM module performs better than conventional feature integration techniques and offers higher accuracy and resilience in identifying minute and subtle flaws. Defect detection systems perform much better when they can reduce conflicting data while maintaining the integrity of feature information. This novel method promises more dependable and effective inspection procedures in a range of industrial applications, setting a new standard in the sector.

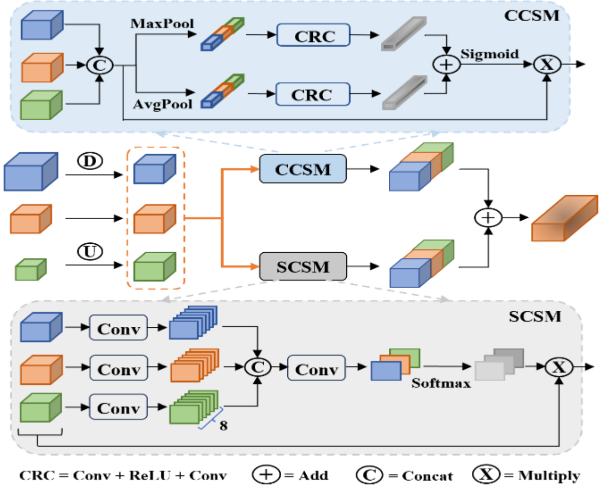

Fig. 3. Structure of the CSFM.

presents the formula for this procedure.

For each X = Downsample(X) and Z = Upsample(Z), (1)

Bilinear interpolation is utilized to implement the up-sample operation, while stride convolution is used to iterate the entire glass image pixel to discover the bubble section, which is around 0.05 mm percent of the entire area, to implement the down-sample action. The output can be presented as:

$$OC = \sigma[AP(\{X', Y, Z'\}) + MP(\{X', Y, Z'\})] \times \{X', Y, Z'\} (2)$$

where {} denotes the concat operation, σ represents the Sigmoid operation, × denotes element-wise multiplication, and the operations AP stands for average pooling and MP for max pooling. The weights are added along the spatial dimension before passing through a Sigmoid activation function for generating the channel-wise adaptive weights.

First, the two input feature maps XXX and ZZZ are resized to kernel sizes of 3×3 and 1×1, respectively. It is critical for the feature maps normalization with the channel dimension to perform the Softmax operation (SM) [35]. Three output feature maps, each with eight channels, are produced after convolving each input feature map with a 3×3 kernel. The Concat technique is then used to concatenate these feature maps. The number of channels is decreased to three by applying a 1×1 convolution. The correspondence with the supplied feature maps is maintained. By combining the features from various scales or resolutions, multi-scale feature fusion takes the benefits of both deep and shallow feature maps to produce a better and more complete feature representation. This improves the feature fusion outcomes. Nevertheless, there may occur semantic conflicts if the information of different densities is directly merged, which will limit the multi-scale features expression. The research suggests merging of feature maps from the current level and neighboring levels in the backbone to address this problem. To improve the effectiveness of multi-scale feature fusion, an Adaptive Feature Refinement (AFR) module is introduced. This module harmonizes the feature maps integration from different scales thereby reducing semantic conflicts and maintaining the integrity of multi-scale information. The AFR module dynamically adjusts the weights of feature maps based on their significance, bringing a balanced and coherent fusion process. The AFR module uses attention mechanisms to prioritize the most relevant features during the fusion process. By focusing on only critical features and suppressing irrelevant ones, the AFR module enhances the representation of important details, leading to more accurate and robust feature extraction. This approach not only addresses the issue of semantic conflicts but also boosts the overall performance of the feature fusion process. Moreover, the AFR module employs a multi-resolution strategy, which processes feature maps at various resolutions to capture both global and local contexts. This strategy ensures that the fused feature maps maintain essential rich and diverse information for accurate detection and recognition tasks. The combination of attention mechanisms and multi-resolution processing makes the AFR module one of the powerful tools for improving multi-scale feature fusion. Experimental results demonstrate that the AFR module outperforms traditional feature fusion methods significantly. By resolving semantic conflicts and enhancing feature representation, the AFR module brings higher accuracy and better efficiency in applications like image segmentation, object detection and recognition tasks. Therefore, the proposed method not only sets a new benchmark in multi-scale feature fusion but also gives a way to progress in the field of DL and computer vision. Overall, the integration of the AFR module into existing frameworks enhances the robustness and reliability of feature extraction, making it a valuable addition to state-of-the-art techniques. This innovative approach promises to enhance the performance of various ML models, contributing to more precise and efficient solutions in diverse domains.

This fusion process is performed in advance to mitigate the differences in information density i.e. the non-defected part with the defective one between the feature maps. Additionally, CSFM is employed to exploit an attention mechanism to remove the conflicting information.

By incorporating these techniques, the interference of complex backgrounds on bubble detection is alleviated. The proposed structure is depicted in Fig. 4.

C. Fine-Grained Aggregation Module (FGAM)

Most Feature Pyramid Network (FPN) methods directly sample different levels' feature maps to the same size for fusion. However, a significant difference in information compactness between these feature maps often leads to semantic conflicts. This work suggests the FGAM, which applies fine-grained feature aggregation across multiple levels of feature maps, from P0 to P5, in the backbone, to solve this problem. This method brings about considerable information interaction between the various feature map layers. Semantic information rises and detailed information falls as the interaction moves from P0 to P5.

Within FGAM, the CSFM module further filters out conflicting information through spatial and channel attention mechanisms.

Moreover, the FGAM combines fine-grained details and high-level semantics effectively, increasing the quality of feature representation. By using adaptive pooling and multi-level interactions, the module is able to maintain the integrity of both fine and coarse features making it a robust detection of defects. The FGAM architecture facilitates dynamic adjustment of feature weights by optimizing the fusion process for different input scales and conditions. The flexibility of FGAM is useful for applications that require precise defects detection like identification of small bubbles in glass bottles.

FGAM overcomes the drawbacks of traditional FPN methods by:

1) Ensuring fine-grained feature interaction across multiple levels.

2) Balancing spatial and semantic information in output feature maps.

3) Minimizing information density disparities to prevent semantic conflicts.

4) Applying the CSFM to remove conflicting information using attention mechanisms.

5) Enhancing feature representation through adaptive pooling and multi-level interactions.

6) Maintaining the integrity of both fine and coarse features for robust defect detection.

7) Enabling dynamic adjustment of feature weights for various input scales.

8) Providing a flexible architecture suitable for precise detection applications.

This comprehensive approach significantly improves the performance of feature fusion in DL networks, ensuring more accurate and reliable detection outcomes.

D. Fine-Grained Aggregation Feature Pyramid Network

FGAFPN consists of FGAM and the feature pyramid network. FGAM serves as the connection between the Backbone and the pyramid network. It takes input feature maps from the Backbone and outputs feature maps with balanced density information. However, FGAM alone does not possess strong multi-scale feature representation capability and requires further deep fusion through the pyramid network. PANed architecture increases the model’s ability to detect bubbles in the glass, preventing the small defects’ features from being suppressed by conflicting information. This method shows improved integration of spatial and semantic information by lowering semantic conflicts and improving the network's overall performance by integrating FGAM into the multi-scale feature fusion process.

E. Pseudo Incremental Learning Phase

To update classifier weights, a continually evolved classifier is used that involves a classifier adaptation phase. It is learned in every individual session based on the preceding session’s global context.

Proposed Pseudo Algorithm

```
1. Import necessary libraries (e.g., NumPy, TensorFlow)
2. Define the generator model:
  a. Input: Random noise (e.g., Gaussian)
  b. Output: Image of size equal to the input image
  c. Architecture: CNN with Conv2DTranspose, BatchNormalization, LeakyReLU, etc.
3. Define the discriminator model:
  a. Input: Image (real or generated)
  b. Output: Probability that the input is real (between 0 and 1)
  c. Architecture: CNN with Conv2D, BatchNormalization, LeakyReLU, etc.
4. Define the loss functions:
  a. Generator loss: binary cross-entropy loss to streamline the generator to produce realistic images.
  b. Discriminator loss: binary cross-entropy loss to streamline the discriminator to correctly classify the defective image and real images.
5. Define the optimizer:
  a. Adam optimizer with appropriate learning rate and other hyperparameters
6. Training loop:
  a. For each epoch:
i. For each batch of training data:
      1. Train the discriminator:
         a. Generate a batch of fake images using the generator
         b. Calculate the discriminator loss using real and fake images
         c. Update the discriminator weights using the Adam optimizer
      2. Train the generator:
         a. Generate a batch of fake images using the generator
         b. Calculate the generator loss using the discriminator's response to the bubble-defected images
         c. Update the generator weights using the Adam optimizer
7. After training, the generator should be able to generate realistic-looking images, including images of bubbles.
8. To detect bubbles:
  a. Generate a new image using the generator
  b. Use an image processing algorithm (e.g., edge detection, contour detection) to detect bubbles in the generated image
  c. Return the detected bubbles as output
```

F. Binarization Process

Before feature extraction, it is imperative to conduct binarization processing on the acquired foregrounds. While multiple techniques exist for converting grayscale images to binary images, including OTSU and adaptive thresholding, we opt not to utilize conventional methods. Instead, we introduce a pioneering binarization approach in this study. The rationale behind this decision is rooted in the observation that binary results obtained from traditional methods may not yield the same efficacy as our proposed novel method, particularly when dealing with low-resolution images during subsequent feature extraction.

G. Modeling of GAN

GANs with CNNs for the detection of bubbles in glass bottles involve two main components: the generator and the discriminator. Below are the mathematical expressions for each component:

1) Generator: The generator aims to produce realistic images of glass bottles with bubbles.

Let G(z; θg), represent the generator function, where z is the input noise vector and θg are the parameters of the generator network.

The generator takes random noise zas input and generates an image

$$\hat{x} = G(z;\ \theta g), \tag{3}$$

Mathematically, this can be expressed as:

$$\hat{x}=G(z;\ \theta g), \tag{4}$$

2) Discriminator: The discriminator distinguishes between real images of glass bottles with bubbles and fake images i.e. undetected defects generated by the generator. Let D(x;θd) represent the discriminator function, where x is an input image and θd are the parameters of the discriminator network.

The discriminator outputs a probability D(x;θd) indicating the likelihood that the input image x is a real image or generated by the generator. Mathematically, this can be expressed as:

$$D(x;\ \theta d) \tag{5}$$

3) Loss Functions:

a) Generator loss: By producing visuals that are identical to actual ones, the generator hopes to trick the discriminator. Thus, the binary cross-entropy between the discriminator's predictions on generated images and a vector of ones (representing real images) is usually the generator's loss function.

$$\mathscr{L}gen=Ez[\log(1-D(G(z;\ \theta g);\ \theta d))] \tag{6}$$

b) Discriminator loss: The discriminator aims to classify real and fake images correctly. Its loss function is the sum of the binary cross-entropy between its predictions on real images and a vector of ones and the binary cross-entropy between its predictions on generated images and a vector of zeros (indicating defected bubble images).

$$\mathscr{L}disc=-Ex\ [\log D(x;\ \theta d)]-Ez[\log(1-D(G(z;\ \theta g);\ \theta d))] \tag{7}$$

4) Optimization: The parameters θg and θd are updated using gradient descent methods such as Adam optimization to minimize the respective loss functions. These mathematical expressions define GANs' training process with CNNs for the detection of bubbles in glass bottles. The role of generator is to produce realistic images of glass bottles with bubbles, while the discriminator distinguishes between real and generated images. With the help of adversarial training, both networks iteratively improve till the generator generates convincing images and the discriminator cannot effectively differentiate between real and generated images.

Implemented Algorithm

1. Set the initial value of variable ***L*** to the binary representation of the first pixel in the current row (or column). Let ***L[1]*** represent this value, i.e. ***L[1] =b(i,1).***
2. Initialize ***k*** to 1 and ***j*** to 2
3. Iterate through each pixel in the current row:
   - (a) Read the value of the ***j***th pixel in the ***i***th**row,** denoted as ***b(i,j)***
   - (b) If ***b(i,j)*** is not equal to L[k], update L by setting L[k+1] = b(i,j), and increment k by 1.
   - (c) Otherwise, increment j by 1 and repeat step 2 until all pixels in the row are processed.
4. Calculate the length of ***L*** and label it as ***l***. if ***l*** is greater than 9, set ***l*** to 9.
5. Update the value of L_1 accordingly: $L_1=L_1 + 1$
6. Repeat steps 1-3 until all rows and columns are scanned.
7. Normalize the value of L_1

Python Code Implementation

```
      for i in range(row_size):
        for j in range(column_size):
          # Read pixel value
      pixel_value = b[i][j]
          # Update L if pixel value is different
          if pixel_value != L[k]:
      L.append(pixel_value)
            k += 1
          else:
            j += 1
          # Update L_l value
          l = min(len(L), 9)
Ll = Ll + 1 if l > 9 else Ll
```

IV. Results and Analysis

Open glass bubble detection dataset consists of a dataset for classification that contains 60,000; 32×32 RGB images from 100 classes. There are 100 testing images as well as 500 training images in each class. Moreover, 60 classes and 40 classes are employed as base classes, newly created classes correspondingly. Eight new incremental sessions are added to the 40 new classes, each new session is a five-way, five-shot defect detection classification task.

Fig. 5 demonstrates the configuration of the pseudo-incremental learning system; the algorithm is explained in section 3.6.1. Specifically, the query number is fixed as 10, and the influence of ways, rotation angles, and defects are analyzed during the pseudo incremental learning. Similarly, for pseudo base classes, as well as pseudo incremental classes, queries and defect detection shots, are set. Here, the number of bubble defect shots is selected (1, 5, 10, 15, 20) and the number of ways is selected as (1, 5, 10, 15, 20). From this analysis, it is determined that the comparatively higher way and lesser bubble shots are enhanced, and the best outcome was acquired when the way was 15, and the shot was 5. Fig. 6 (a), (b), (c), (d), and (e) demonstrate the analysis of images 1, 2, 3, 4, and 5.

Fig. 6. Analysis of systems (a) Accuracy, (b) Specificity (c) Precision (d) Recall, and (e) F-measure.

Analysis of systems about accuracy, specificity, precision, recall, and F-measure were examined in Fig 6. Fig. 6(a) demonstrates the analysis of systems regarding accuracy. Here, the accuracy of the SExpSCO-based GAN system was 0.738, whereas systems, such as ADL, DM-PD, RMSs, and Net2Net system acquired minimal accuracy of 0.420, 0.513, 0.566, and 0.628 for sessions 4. Fig. 6 (b) exhibited an analysis of systems regarding specificity. Here, the specificity of the SExpSCO-based proposed system was 0.679, whereas the ADL, DM-PD, RMSs, and Net2Net system acquired minimal specificity of 0.474, 0.576, 0.599, and 0.679 for sessions 3. The analysis of systems regarding the precision was examined in Fig. 6 (c). Here, the precision of the SExpSCO-based GAT system was 0.781, whereas that of the ADL, DM-PD, RMSs, and Net2Net system was 0.555, 0.629, 0.683, and 0.734 for sessions 2. Fig. 4: The proposed pseudo-model analysis of systems regarding recall was exemplified in Fig. 6 (d). Here, the recall of the SExpSCO-based GAT system was 0.786, whereas that of ADL, DM-PD, RMSs, and Net2Net system was 0.538, 0.592, 0.635, and 0.744 for sessions4. Fig. 6 (e) demonstrates the analysis of systems regarding F-measure. Here, the F-Measure of the SExpSCO-based GAT system was 0.780, whereas ADL, DM PD, RMSs, and Net2Net system acquired minimal F-measure of 0.508, 0.568, 0.638, and 0.694 for sessions 3.

Fig. 7. Analysis of systems (a) PD (b) Five class test accuracy.

Fig. 7 demonstrates the analysis of systems regarding Performance Dropping Rate (PD) and five-class test accuracy. Fig. 7 (a) exhibited an analysis of systems regarding PD. Here, the PD of the SExpSCO-based GAT system was 0.219, whereas ADL, DM-PD, RMSs, and Net2Net systems acquired maximal PD of 0.312, 0.262, 0.261, and 0.250. Fig. 7 (b) demonstrates the analysis of systems regarding five-class test accuracy. Here, the five-class test accuracy of the SExpSCO-based GAN system was 0.791, whereas systems, ADL, DM-PD, RMSs, and Net2Net system acquired the minimal five-class test accuracy of 0.500, 0.582, 0.674, and 0.745 for sessions 4.

Table I demonstrates a comparative analysis of the current system and the latest state-of-the-art publications.

Here, the proposed GAN system is 29% better than the ADL for accuracy, and 30% better than the DM-PD system for specificity. Similarly, the SExpSCO-based GAT was 25% better than the RMSs system for precision and 5% better than the Net2Net system, 43% better than the ADL system for F-measure.

TABLE I. A COMPARATIVE ANALYSIS OF THE PROPOSED SYSTEM WITH THE STATE-OF-THE-ART

Models Used	Accuracy	Specificity	Precision	Recall	F-measure
ADL	0.380	0.350	0.324	0.460	0.380
DM-PD	0.471	0.411	0.393	0.572	0.467
RMSs	0.523	0.478	0.474	0.613	0.536
Net2Net	0.587	0.558	0.547	0.684	0.608
Proposed System	**0.677**	**0.592**	**0.638**	**0.716**	**0.675**

V. CONCLUSION AND FUTURE SCOPE

In current study, a novel approach for the detection of bubbles and defects in glass bottles utilizing a combination of GANs and CNNs is proposed. The results show the improvements in various types of defects, including bubbles, scratches, and impurities, in glass bottle images. By exploiting the power of GANs for data augmentation and CNNs for feature extraction and classification, the model shows significant higher accuracy and efficiency compared to traditional methods.

The proposed method's main contribution is that it can adapt effectively to all kinds of flaws and variances in image quality making it suitable for practical applications in industry. Furthermore, in the industrial environments, a small number of labeled datasets are generally available. GANs can produce artificial training data to solve the problems in the small number of labeled datasets. This increases the model resilience and reduces the requirement of human annotation which brings time and cost effectiveness. Overall, the present research contributes significantly to the field of automated quality inspection systems in the manufacturing industry, especially in glass bottle production field. Minimizing human intervention increases automation of the defect detection process. Therefore, the proposed approach improves the quality control efficiency and brings consistency and reliability in identifying defects, leading to higher product quality and better customer satisfaction.

However, there remains some future scope for further improvement. Optimization of the GAN-CNN architecture can be achieved to enhance its performance like fine-tuning of hyper parameters and incorporating advanced regularization techniques to prevent over fitting.

Dimensionality Reduction Evolutionary Framework for Solving High-Dimensional Expensive Problems

SONGWei[1], ZOUFucai[2]
Jiangsu Provincial Engineering Laboratory of Pattern Recognition and Computational Intelligence,
Jiangnan University, WuXi, China[1]
School of Artificial Intelligence and Computer Science, Jiangnan University, WuXi, China[2]

Abstract—**Most of improvement strategies for surrogate-assisted optimization algorithms fail to help the population quickly locate satisfactory solutions. To address this challenge, a novel framework called dimensionality reduction surrogate-assisted evolutionary (DRSAE) framework is proposed. DRSAE introduces an efficient dimensionality reduction network to create a low-dimensional search space, allowing some individuals to search in the population within the reduced space. This strategy significantly lowers the complexity of the search space and makes it easier to locate promising regions. Meanwhile, a hierarchical search is conducted in the high-dimensional space. Lower-level particles indiscriminately learn from higher-level peers, correspondingly the highest-level particles undergo self-mutation. A comprehensive comparison between DRSAE and mainstream HEPs algorithms was conducted using seven widely used benchmark functions. Comparison experiments on problems with dimensionality increasing from 50 to 200 further substantiate the good scalability of the developed optimizer.**

Keywords—Dimensionality reduction; high-dimensional expensive optimization; Surrogate-assisted model

I. INTRODUCTION

Evolutionary algorithms (EAs) have been effectively utilized in addressing optimization problems owing to their simplicity and efficiency. In the era of big data, an increasing number of optimization problems involve a substantial quantity of decision variables, such as traffic vehicle scheduling [1], routing network issues [2], and biological gene identification [3]. When confronted with high-dimensional optimization problems comprising hundreds or even thousands of decision variables, traditional EAs often struggle to identify the optimal solution within the limited number of fitness evaluation (FE) iterations [4]. In high-dimensional expensive problems (HEPs), not only does the search space undergo exponential expansion and increased complexity, but also the time required for evaluating the objective function becomes exceedingly costly. Therefore, simply applying existing EAs to solve HEPs is both time-consuming and inefficient.

Incorporating dimensionality reduction techniques into high-dimensional optimization problems, thereby reducing the complex high-dimensional search space to a lower-dimensional space with higher information density, represents an effective approach for addressing high-dimensional challenges. In the reduced dimensional space, it becomes easier to swiftly identify promising regions, facilitating the generation of high-quality offspring at an accelerated pace. The application of Sammon mapping [5] for dimensionality reduction in EAs problem is motivated by its ability to preserve adjacent structures. However, literature [6] suggests that the performance of Sammon mapping often falters when dealing with intricate datasets. To tackle this issue, SAEO [7] proposed an evolutionary algorithm based on autoencoders (AE), which incorporates a reconstruction stage capable of restoring low-dimensional particles to their original high-dimensional space for real fitness evaluation. Nevertheless, AE necessitates a substantial amount of historical data before reaching training maturity and initial historical data is frequently comprised of poorly performing particles, potentially leading to biased evolutionary directions towards unpromising regions. Furthermore, training the neural network using backpropagation demands a significant time investment.

In response to the challenge of identifying promising regions in HEPs amidst the "dimension disaster," there is a pressing demand for an effective dimensionality reduction technique that can efficiently minimize the search space, facilitating the rapid identification of promising regions while retaining the capacity to reconstruct meaningful information in the original space. This paper presents a Dimensionality Reduction Surrogate-Assisted Evolutionary (DRSAE) framework. Its specific contributions are as follows: 1) It initiates the exploration of low-dimensional space, enhancing precise dimensionality reduction and reconstruction of spatial particles by employing an Extreme Learning Machine based on autoencoder (ELM-AE) for space particles. It uncovers implicit information in the low-dimensional space through evolutionary search variations within that space. 2) The hierarchical search for particles in high-dimensional space aims to balance convergence and diversity, with lower-level particles focusing more on exploration and higher-level particles emphasizing development. Finally, the algorithm's performance is further validated through experiments.

II. RELATED WORK

A. High-Dimensional Expensive Problems (HEPs)

The design of contemporary complex products often entails addressing a multitude of high-dimensional and costly optimization challenges, necessitating thousands of precise simulation analyses that consume substantial computing resources [8]. In this study, we focus on a category of minimization problems:

$$minmize: f\left(\boldsymbol{x}\right) \tag{1}$$

The National Natural Science Foundation of China (62076110)
The National Foreign Experts Program (DL2023144001L)
The Natural Science Foundation of Jiangsu Province (BK20181341)
The Fundamental Research Funds for the Central Universities (JUSRP221027)

$$subject\ to: \boldsymbol{x} \le \boldsymbol{x} \le \boldsymbol{x} \tag{2}$$

Above the (1) and (2), $\boldsymbol{x} = (x_1, x_2, ..., x_d) \in \square^{d}$ represents a d dimensional decision vector within the feasible search space $\square^{d}$, and $f(\cdot)$ denotes the objective function used for fitness evaluation. Additionally, $\boldsymbol{x}$ and $\boldsymbol{x}$ correspond to the lower and upper bound vectors of the search space, respectively. In cases where the value of d is exceedingly large and evaluating $f(\cdot)$ requires significant time and resources, these issues are classified as HEPs.

Whether dealing with a continuous or combinatorial single- or multi-objective problem, agent-assisted evolutionary algorithms are widely recognized as a promising approach for addressing HEPs. The essence of these algorithms lies in developing suitable agent models based on historical data samples to approximate the true objective function. In terms of computational resource requirements, the evaluation cost of these agent models is significantly lower than that of the real model, enabling them to effectively pre-screen candidate solutions. Based on the predictions generated by the agent model, certain candidate individuals are chosen for re-evaluation using the real model.

B. *Extreme Learning Machine-Autoencoder (ELM-AE)*

ELM-AE is a single-hidden-layer neural network model, in which the number of nodes in the input and output layers are identical. The input and output of the model represent positions within a high-dimensional space, while the hidden layer's output represents positions within a lower-dimensional space following dimensionality reduction; hence, the dimension or number of nodes in the hidden layer is reduced.

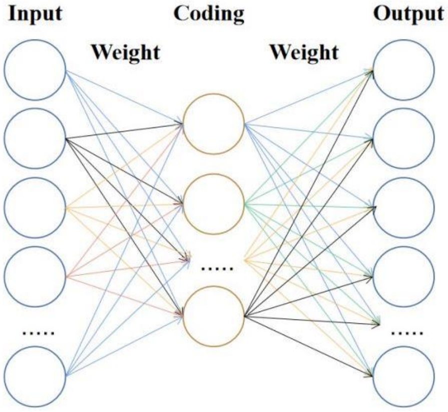

Fig. 1. ELM-AE.

As depicted in Fig. 1, the input weights are initially initialized with random values, employing a unitary orthogonal matrix chosen at random as the input weight [9]. This selection serves to maintain the Euclidean distance between data points and exhibits favorable generalization properties.

The hidden layer output $\boldsymbol{H} = G(\boldsymbol{X}, \boldsymbol{A}, \boldsymbol{b})$ is obtained by applying the activation function $G(\cdot)$ to the result of multiplying sample $\boldsymbol{X}$ by $\boldsymbol{A}$, adding the bias $\boldsymbol{b}$, and passing it through. For a given dataset $\left\{(\boldsymbol{x_i}, \boldsymbol{t_i})\right\}_{i=1}^{N}$, $\boldsymbol{H}$ denotes the output of the hidden layer:

$$\boldsymbol{H} = \begin{bmatrix} g_1\left(\boldsymbol{x_1}\boldsymbol{a_1^T} + b_1\right) & \cdots & g_L\left(\boldsymbol{x_1}\boldsymbol{a_m^T} + b_1\right) \\ \vdots & \ddots & \vdots \\ g_1\left(\boldsymbol{x_N}\boldsymbol{a_1^T} + b_N\right) & \cdots & g_L\left(\boldsymbol{x_N}\boldsymbol{a_m^T} + b_N\right) \end{bmatrix} \tag{3}$$

In (3), N represents the number of training samples, L denotes the number of nodes in the hidden layer, $g_1, g_2 ... g_L$ are indicative of the activation functions associated with the hidden layer nodes, and $\boldsymbol{x_i}$ signifies the i-th training data. Essentially, $\boldsymbol{H}$ serves as a feature mapping representation of the training data $\boldsymbol{X}$ following matrix operations and activation functions. The aforementioned process can be succinctly represented in matrix form as follows:

$$\boldsymbol{H = G(XA + b)} \tag{4}$$

$\boldsymbol{T}$ represents the target matrix corresponding to the training samples:

$$\boldsymbol{T} = \begin{bmatrix} t_{11} & \cdots & t_{1M} \\ \vdots & \ddots & \vdots \\ t_{N1} & \cdots & t_{NM} \end{bmatrix} \tag{5}$$

M represents the number of nodes in the output layer, while $\boldsymbol{t_i}$ denotes the corresponding target value for $\boldsymbol{x_i}$. The primary objective of ELM is to minimize the error associated with fitting the expired output $\boldsymbol{T}$, as per (6):

$$\boldsymbol{H\beta = T} \tag{6}$$

The analytical solution for the weight matrix connecting the hidden layer and the output layer is derived [10]:

$$\boldsymbol{\beta = H^{\dagger}T} \tag{7}$$

The Moore-Penrose generalized inverse matrix $\boldsymbol{H}^{\dagger}$ serves as an effective tool for rapidly adjusting $\boldsymbol{X}$ to $\boldsymbol{T}$. As the characteristic representation of $\boldsymbol{X}$, $\boldsymbol{H}$ can analytically compute the output weight $\boldsymbol{\beta}$ that maps to $\boldsymbol{T}$.

$$\boldsymbol{H\beta = X} \tag{8}$$

$$\boldsymbol{\beta = H^{\dagger}X} \tag{9}$$

Importantly, when the ELM-AE target value equals $\boldsymbol{X}$ itself, the computed $\boldsymbol{H}$ serves as a high-quality representation of $\boldsymbol{X}$ and can be reconstructed to $\boldsymbol{X}$ using the calculated $\boldsymbol{\beta}$ in (9).

III. Dimensionality Reduction Surrogate-Assisted Evolutionary Framework

This paper proposes dimensionality reduction techniques to HEPs, enabling the algorithm to create a low-dimensional space for extracting implicit information for local search. Simultaneously, it preserves the multi-population optimization strategies within the high-dimensional space. Furthermore, it is viable to substitute the costly evaluation function in the high-dimensional space with a surrogate model, such as a radial basis function (RBF) network [11], to capture the global contour of the fitness landscape and facilitate rapid identification of the region containing the global optimum by the population.

Subsequently, we present an overview of our algorithm's framework, which integrates our enhanced ELM-AE dimensionality reduction network and hierarchical particle search strategy within high-dimensional space. We then provide a detailed exposition of two parallel search paths before concluding with an analysis of the algorithm's time complexity.

A. *DRSAE Overall Framework*

Fig. 2 illustrates the comprehensive process of DRSAE. Prior to activating the RBF agent model, this study employs the classical differential evolution algorithm [12] to iteratively refine the initial population, thereby gathering sufficient real evaluation data pairs conducive to training the initial agent model in a more favorable region. Upon activation of the agent model, the population is sorted based on fitness value and divided into two subpopulations. The subpopulation with lower fitness values undergoes hierarchical search in the original high-dimensional space, while the other subpopulation conducts a search in low-dimensional space through ELM-AE. The size of each subpopulation will dynamically adjust as follows:

In (10), Z denotes the population size, Z_1 denotes the size of the high-dimensional subpopulation, Z_2 denotes the size of the low-dimensional subpopulation, FE_{max} represents the maximum number of fitness evaluations, and FE_{cur} represents the current number of consumed fitness evaluations.

B. *Revised ELM-AE-Guided Exploration of Low-Dimensional Spaces*

It exploits the advantages of rapid training in ELM and data representation learning in AE. This investigation utilizes ELM-AE to tackle HEPs and introduces enhancements. As illustrated in Fig. 1, the input layer and output layer represent the positions of high-dimensional space particles in the original space, while the hidden layer signifies the positions of low-dimensional space particles. The input weight matrix $\boldsymbol{A}$ is typically generated randomly. In this study, $\boldsymbol{A}$ is a unit random orthogonal matrix, which can be denoted as:

$$\boldsymbol{A}^{\boldsymbol{T}}\boldsymbol{A} = \boldsymbol{I} \tag{10}$$

Where $\boldsymbol{I}$ represents the identity matrix.

$$\left|\boldsymbol{A}_{ij}\right| \leq 1 \tag{11}$$

$$\begin{aligned} Z_1 &= min(Z, Z \times (\frac{FE_{max} - FE_{cur}}{FE_{\max}})^{200/d}) \\ Z_2 &= Z - Z_1 \end{aligned} \tag{12}$$

In (12), $\left|A_{ij}\right|$ denotes the element in the i-th row and j-th column of matrix $\boldsymbol{A}$, while $|\cdot|$ represents the absolute value function. Each element of matrix $\boldsymbol{A}$ possesses an absolute value less than 1, and the columns are mutually orthogonal. The unit random orthogonal matrix A can effectively preserve the Euclidean distances between data points [9] and demonstrate enhanced generalization. As per (4), N particles in $\boldsymbol{X}$ undergo dimensional reduction to a low-dimensional space denoted by $\boldsymbol{H}$ for brevity as follows:

$$\begin{aligned} \boldsymbol{b} &= \boldsymbol{0} \\ g(\boldsymbol{X}) &= \boldsymbol{X} \end{aligned} \tag{13}$$

The bias vector $\boldsymbol{b}$ is a zero vector, and the activation function $g(\cdot)$ is a linear function. The output weight matrix beta is determined from the low-dimensional space to the high-dimensional space using (9), which ensures an effective transformation between different dimensional spaces.

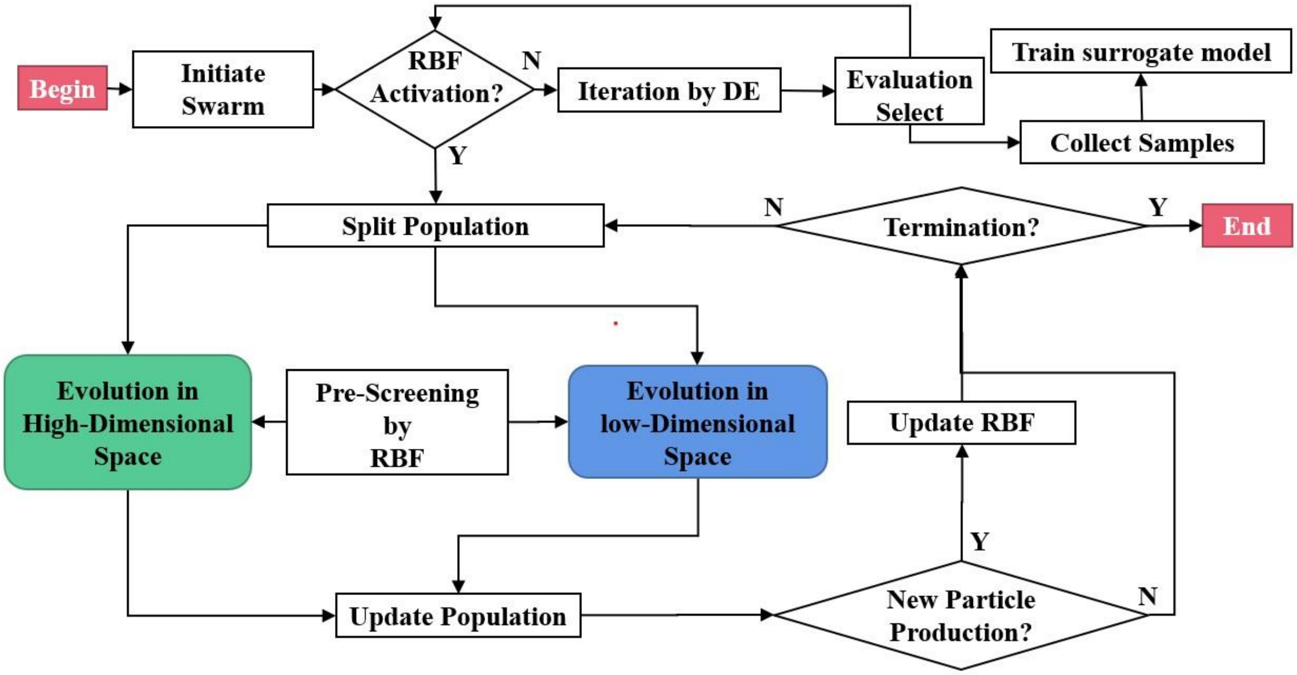

Fig. 2. DRSAE process schematic.

In numerous practical scenarios, it is crucial to acknowledge that $\boldsymbol{H}$ may not be a square matrix ($L \neq N$), leading to the computed $\boldsymbol{H}^{\dagger}$ being the generalized inverse matrix of $\boldsymbol{H}$ rather than the true inverse matrix. As a result, there is a loss of high-dimensional information. This investigation enhances the architecture of ELM-AE to ensure that $\boldsymbol{H}$'s output forms a square matrix. Specifically, setting the number of input particles equal to the dimension of the low-dimensional space enables obtaining the true $\boldsymbol{H}^{\dagger}$, thereby circumventing any information loss upon restoration of the high-dimensional space.

It is apparent that the reduction in variation within low-dimensional space leads to a corresponding decrease in error during projection into high-dimensional space. In order to address the potential dominance of reduction errors over evolutionary processes, a Gaussian field variation algorithm as described in [12] has been incorporated within the low-dimensional space to enhance local fine-tuning search capabilities. The subsequent section will present the updated formula for low-dimensional particles.

$$\begin{aligned} \overrightarrow{\boldsymbol{H_i}} &= \overrightarrow{\boldsymbol{H_i}} + \vec{\boldsymbol{\Delta}} \\ \vec{\boldsymbol{\Delta}} &= \left[\Delta_1, \Delta_2, \ldots, \Delta_L\right] \end{aligned} \tag{14}$$

$\overrightarrow{\boldsymbol{H_i}}$ denotes the position vector of the i -th individual in the low-dimensional space, $\vec{\boldsymbol{\Delta}}$ denotes the L -dimensional Gaussian perturbation vector, where $\Delta_d = N(0,\sigma)$, $1 \leq d \leq L$. The perturbation component in each dimension is randomly sampled from a region with a mean of 0 and a variance of σ^2 , as per literature [12]. Here, σ is set to 0.2 for enhanced performance across most test functions. From a geometric perspective, the algorithm generates new individuals within a Gaussian hypersphere centered at the current individual's position.

C. Evolutionary Strategies Employing Multi-Level Hierarchy in High-Dimensional Spaces

In the process of evolution within a high-dimensional space, individuals typically exist in various evolutionary states and possess different potentials for exploring and developing the search space. To distinguish them, they are categorized into distinct hierarchical levels based on their fitness values. Specifically, assuming that NP individuals are divided into NL hierarchical levels denoted as L_i $\left(1 \leq i \leq NL\right)$, prior to classification, the particles in the population are arranged in ascending order of fitness. Particles with superior fitness belong to higher hierarchical levels, where a lower index indicates a higher level. Consequently, L_1 represents the highest hierarchical level while L_{NL} denotes the lowest one. Each hierarchical level consists of an equal number of individuals referred to as "level size", denoted by LS .

Fig. 3 illustrates an optimization framework based on the Level Learning (LL) strategy. The algorithm arranges the particles in the swarm by sorting them in ascending order of their fitness values and then categorizes them into 4 levels based on their performance. Particles in level 4 learn from individuals in levels L1 to L3, individuals in level 3 learn from individuals in levels L1 and L2, and individuals in level 2 learn from particles in level L1. To safeguard superior particles from being erroneously updated, individuals at level L1 abstain from updating and proceed directly to the next generation. The following presents the update formula for high-dimensional space particles:

$$v_{i,j}^d \leftarrow r_1 v_{i,j}^d + r_2\left(x_{rl1,k1}^d - x_{i,j}^d\right) + \phi r_3\left(x_{rl2,k2}^d - x_{i,j}^d\right) \tag{15}$$

$$x_{i,j}^d \leftarrow x_{i,j}^d + v_{i,j}^d \tag{16}$$

In (15) and (16), $\boldsymbol{X_{i,j}} = \left[x_{i,j}^1, \ldots, x_{i,j}^d, \ldots, x_{i,j}^M\right]$ denotes the spatial coordinates of the j-th individual within layer L_i of the i-th hierarchy, while M represents the dimensionality of the high-dimensional space. $\boldsymbol{V_{i,j}} = \left[v_{i,j}^1, \ldots, v_{i,j}^d, \ldots, v_{i,j}^M\right]$ signifies the particle velocity. Here, $\boldsymbol{X_{rl1,k1}}$ and $\boldsymbol{X_{rl2,k2}}$ represent the positions of two individuals randomly selected from hierarchies $rl1$ and $rl2$, with corresponding indices $k1$ and $k2$ independently chosen from $\left[1, LS\right]$. Additionally, $rl1$ and $rl2$ are indices randomly selected from $\left[1, i-1\right]$. The variables r_1 , r_2 and r_3 are uniformly distributed random numbers in the range $\left[0,1\right]$, while ϕ is a control parameter that governs the influence of a secondary learning objective within the range $\left[0,1\right]$. It should be noted that $rl1 < rl2 < i$ implies that $\boldsymbol{X_{rl1,k1}}$ is superior to $\boldsymbol{X_{rl2,k2}}$, both are superior to $\boldsymbol{X_{i,j}}$.

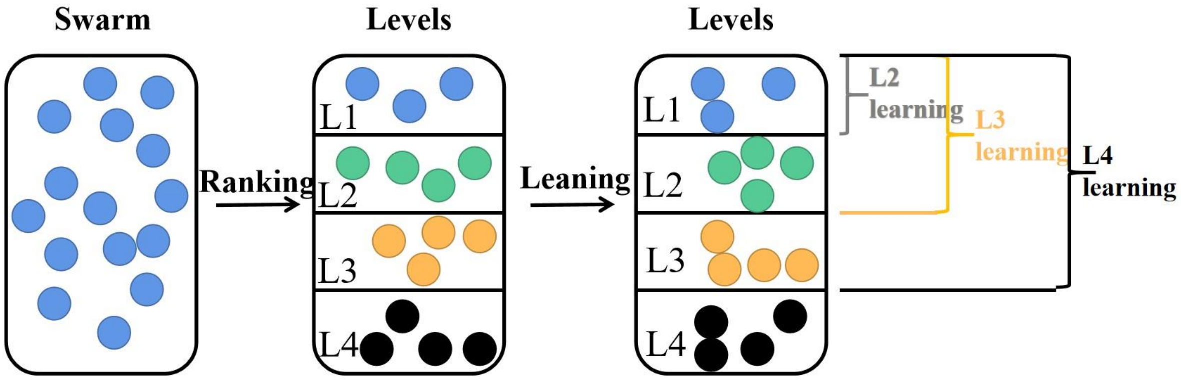

Fig. 3. Based on level learning strategy (LL).

D. The Flow of DRSAE

Fig. 2 illustrates the flowchart of DRSAE, while Algorithm I delineates the procedural steps of DRSAE.

Algorithm I: DRSAE Algorithm

```
Input: population P, maximum number of fitness evaluations FEmax, dimension of the problem D.
Output: The final solution x and its fitness f(x).
FEcur = 0;
Establish database of {position, its fitness};
Initialize the swarm randomly and calculate the fitness of particles;
Initialize surrogate model RBF using first generation population；
Update FEcur;
While size(database) < 150 do
    P ' = DE(P);
    Evaluate the fitness of P ' : f (P ' );
    Select and update P and f (P);

E. Complexity Analysis of DRSAE

In the initial iteration of the algorithm, the time complexity for collecting the initial training samples for the surrogate model is denoted as $O(KD)$, where K represents the number of training samples activated by the surrogate model. In this study, we assume K to be $5d$, resulting in a time complexity of $O(D^2)$ for this stage. During each iteration process, sorting the subpopulation (i.e., ranking) has a time complexity of $O(N\square\log_2(N))$. The maintenance of the surrogate model carries a time complexity of $O(D(N/2)^5)$, which can be approximated as $O(DN^5)$. Within high-dimensional space during hierarchical learning evolution, lower-level particles learn from higher-level particles; according to (15), this results in a time complexity of $O(ND)$. For Gaussian variation evolution based on dimensionality reduction in low-dimensional space as per (6), both dimensionality reduction and restoration have a time complexity of $O(DN^2)$; and according to (14), the variation process has a time complexity of approximately $O(D^2+DN^5+ND+DN^2)$. Consequently, ultimately, it is determined that DRSAE algorithm exhibits a time complexity of approximately $O(D^2+DN^5)$.

IV. Experimental Results and Discussion

To assess the performance of DRSAE, in this session, we conducted experiments on seven benchmark functions [13-17] commonly employed in the field. These functions demonstrate varying decision space dimensions and function characteristics, offering a comprehensive illustration of DRSAE's applicability to HEPs. The test functions ranged in dimensionality from 50 to 200 dimensions, with essential information about these benchmark functions presented in Table I. Each algorithm was independently executed on each benchmark function 20 times in all experiments, and the results were subsequently averaged. The best average value for each benchmark function is highlighted in bold. The experimental environment consisted of an Intel i5 CPU running at 2.50 GHz, equipped with 8 GB RAM and operating on Windows 10 system alongside matlab R2020a.

TABLE I. Information Regarding the Benchmark Function

Fun	Name	Design space	f^* †	Property
F1	Ellipsoid	$[-5,5]^d$	0	Unimodal
F2	Rosenbrock	$[-2,2]^d$	0	Multimodal with narrow valley
F3	Ackley	$[-32,32]^d$	0	Multimodal
F4	Griewank	$[-600,600]^d$	0	Multimodal
F5	Rastrigin	$[-5,5]^d$	0	Multimodal
F6	Shifted rotated F5	$[-5,5]^d$	-330	Multimodal & Complex
F7	Hybrid ‡ function	$[-5,5]^d$	10	Multimodal & Complex

†: means global optimum.

‡: Rotated hybrid composition function with a narrow basin for the global optimum.

A. Algorithm Peers and Parameter Setting

DRSAE integrates the concept of agent models. To assess the efficacy of DRSAE, this study assesses six agent-based optimization algorithms, namely GSGA [13], SA_COSO [14], ESAO [15], SHPSO [16], SAMSO [17], and SAEO [7]. Similar to traditional algorithms, the population size in DRSAE is fixed at 100, with a maximum number of re-evaluations per generation set at 5. The activation criteria for the agent models are contingent on problem dimensionality and are triggered when the training point count reaches 1000. Experimental findings demonstrate that DRSAE requires fewer computational resources than the algorithm proposed in [18] while approaching closer to an optimal solution. This unequivocally substantiates the substantial advantages of DRSAE in terms of optimization efficiency and effectiveness.

B. Sensitivity Analysis of Surrogate Model Activation Point

Surrogate models have demonstrated high efficacy in addressing HEPs. However, a critical concern arises: when should the surrogate model be initiated within this framework? The initial training of the surrogate using data samples can ensure its accuracy while managing time resource overhead. We designated different time points for activating the surrogate model, consuming 400, 600, and 800 FEs respectively. We evaluated the performance of each parameter using F1 and F5 metrics, highlighting the optimal result for each function. The optimization outcomes are presented in Table II, and the convergence curve is depicted in Fig. 4.

Fig. 4 illustrates that the activation strategy for data surpasses other strategies in identifying an optimal solution with limited resources, indicating that the dimension-based strategy is well-suited for activating the agent model. As shown in Fig. 4(a)-(b), it is apparent that even if the constructed agent is sufficiently precise, delaying its activation until later stages of the optimization process may restrict subsequent optimization due to the limited number of remaining FEs. For high-dimensional problems, as demonstrated in Fig. 4(c)-(d), an agent model built with a small number of data samples does not offer accurate search guidance. Therefore, it can be inferred that there is no discernible efficiency advantage to activating the agent early in the optimization process, and using data samples as an activation condition yields optimal results.

C. Sensitivity Analysis of Dynamically Adjusting Subpopulation Size

To assess the efficacy of dynamically adjusting subpopulation size, we compared the dynamic subpopulation size adjustment strategy with the fixed subpopulation size strategy using DRSAE (Z1, Z2) to present experimental findings. The study evaluated F1 and F5 functions, each possessing distinct characteristics, with bold highlighting the optimal results for each function.

As depicted in Table III, the dynamic subpopulation size adjustment strategy demonstrates superiority over the fixed subpopulation size strategy throughout the optimization process. Fig. 5 illustrates the dynamic sizing of subpopulation I for the F1 function at dimensions 50 and 200. Given that subpopulation I primarily emphasizes exploration, it is initially larger and gradually diminishes according to (10) as optimization progresses to emphasize exploitation. With an increase in search space dimensionality, a more intricate environment necessitates efficient exploration during initial stages; hence, as problem dimensions escalate, so does the initial size of subpopulation I.

D. Comparative Experiments on Benchmark Functions

Table IV presents the mean and standard deviation of DRSAE's independent runs conducted 20 times on 7 test functions listed in Table I. The convergence curves from the original papers of SA_COSO [14], SAEO [7], SHPSO [17], and ESAO [15] were re-plotted, and the Wilcoxon signed-rank test results were calculated at a significance level of α = 0.05. The optimal result for each function is indicated in bold typeface. "Standard deviation" is shortened to "Std devi" for compact formatting.

Table IV demonstrates that DRSAE surpasses most comparable algorithms in efficiently identifying the vicinity of the optimal solution within a limited number of evaluations, while many others fall short of reaching the optimum. Notably, DRSAE exhibits strong performance on F5 with a minimum value characteristic indicative of a regular distribution. Among these, SAEO [7] shows relatively superior performance due to its utilization of dimensionality reduction. Furthermore, the ELM-AE dimensionality reduction network employed by DRSAE accurately restores high-dimensional space without information loss, resulting in overall better performance compared to SAEO. ESAO showcases commendable exploration ability owing to differential evolution, leading to superior performance on F2 with 50 dimensions compared to DRSAE.

Plot convergence curves for the 100D and 200D problems, as illustrated in Fig. 6 and Fig. 7, respectively. Analysis of figures indicates that DRSAE demonstrates faster convergence to the optimal solution compared to other surrogate-assisted algorithms such as SAEO. With increasing dimensionality, DRSAE exhibits superior optimization speed relative to other algorithms due to its enhanced capability in identifying promising regions within low-dimensional space. GSGA [13] performs exceptionally well on F6, a complex multimodal function, by iteratively employing alternative functions at the cost of computational burden to enhance opportunities for finding the optimal solution. The suboptimal performance of DRSAE on F6 is primarily attributed to the inability of dimensionality reduction in simplifying the complexity of F6's landscape. Overall, DRSAE ranks first in average for both optimization speed and convergence performance, thus fully demonstrating its superiority. Upon activation of the surrogate model, fitness value sharply decreases within the same range of function evaluations.

E. *Effectiveness Analysis of Dimensionality Reduction Strategies*

To assess the efficacy of incorporating a low-dimensional search space, this study selects the F1 and F5 functions with dimensions ranging from 50 to 200 for evaluating both DRSAE and its non-low-dimensional version, DRSAE*. The optimization results for DRSAE and DRSAE* are presented in Table V.

Drawing upon the findings presented in Table V, it is evident that ELM-AE has significantly augmented the search efficiency of DRSAE* while maintaining an equivalent number of FEs. The results signify a noteworthy reduction in the average optimal values, leading to expedited optimization speed for DRSAE. ELM-AE effectively steers the exploration of low-dimensional search space, integrates high-dimensional information, and extracts latent features, thereby facilitating rapid identification of promising regions and substantial reduction in unnecessary FE consumption, particularly for problems with potential convergence issues. For problems up to 200 dimensions, leveraging the low-dimensional search space in ELM-AE has widened the gap between optimal values, demonstrating its advantage in precise and efficient dimensionality reduction.

V. CONCLUSION

This paper introduces an effective dimensionality reduction assisted evolutionary framework (DRSAE) for addressing high-dimensional expensive evaluation function problems (HEPs). The primary challenge in HEPs lies in the high cost of evaluating the function, necessitating the rapid identification of optimal solutions within a limited number of function evaluations. The algorithm makes two key contributions: 1) Incorporating an efficient and accurate low-dimensional search space into the traditional agent-based algorithm, enabling precise reduction and reconstruction of high-dimensional space to minimize position information errors resulting from switching between spaces and expedite the discovery of a more promising solution space; 2) Implementing hierarchical learning of particles in high-dimensional space, allowing lower-level particles to learn from superior ones to enhance population diversity. Furthermore, specific activation conditions for the agent model are established for different dimensional problems.

In order to assess the performance of DRSAE, it was compared with other established algorithms across seven commonly utilized functions. The experimental results indicate that in most cases, DRSAE performs admirably, with SAEO demonstrating relatively superior performance. This can be attributed to the fact that SAEO also operates within a low-dimensional search space; however, its low-dimensional model is based on AE. In contrast to DRSAE, where ELM-AE produces a smaller reconstruction error from the low-dimensional space to the high-dimensional space. As a result, DRSAE is able to more accurately reconstruct features in the high-dimensional space and achieve improved performance. In addition, better results may be achieved by improving the ELM network structure to stack ELM hidden layers.

VI. FUTURE WORK

We endeavor to integrate state-of-the-art Evolutionary Algorithms (EAs) [19-23] into the DRSAE in order to tackle High-dimensional Expensive Problems (HEPs), while exploring the underlying theory in future research. It is worth noting that this framework has the potential for extension to address multi-objective optimization problems, dynamic optimization problems, and constrained optimization problems, thereby validating the effectiveness of DRSAE in relevant real-world scenarios and expanding its applicability in high-dimensional expensive optimization domains.

Optimization of the Energy-Saving Data Storage Algorithm for Differentiated Cloud Computing Tasks

Optimization of the Energy-Saving Data Storage Algorithm

Peichen Zhao
School of Computer and Information Technology, Beijing Jiaotong University, Beijing 100044, China

***Abstract*—This study presents a novel energy-saving data storage algorithm designed to enhance data storage efficiency and reduce energy consumption in cloud computing environments. By intelligently discerning and categorizing various cloud computing tasks, the algorithm dynamically adapts data storage strategies, resulting in a targeted optimization methodology that is both devised and experimentally validated. The study findings demonstrate that the optimized model surpasses comparative models in accuracy, precision, recall, and F1-score, achieving peak values of 0.863, 0.812, 0.784, and 0.798, respectively, thereby affirming the efficacy of the optimized approach. In simulation experiments involving tasks with varying data volumes, the optimized model consistently exhibits lower latency compared to Attention-based Long Short-Term Memory Encoder-Decoder Network and Deep Reinforcement Learning Task Scheduling models. Furthermore, across tasks with differing data volumes, the optimized model maintains high throughput levels, with only marginal reductions in throughput as data volume increases, indicating sustained and stable performance. Consequently, this study is pertinent to cloud computing data storage and energy-saving optimization, offering valuable insights for future research and practical applications.**

***Keywords*—Energy-saving data storage algorithm; differentiated task recognition; cloud computing; intelligent storage strategy; data classification and distribution**

I. Introduction

With the rapid development of cloud computing, the demand for data storage has surged, rendering traditional centralized storage solutions inadequate for managing vast data volumes and diverse task requirements [1]. The data storage landscape in cloud computing is characterized by its large scale and the variety of data types, encompassing different task types and service models, such as big data analysis, real-time processing, and archival storage. Each task possesses unique resource requirements and storage characteristics, leading to significant variations in performance requirements across tasks [2-4]. To enhance overall performance, data storage algorithms in cloud computing must balance data accuracy, reliability, real-time performance, and energy consumption. However, existing storage strategies frequently overlook the distinctions between diverse tasks, resulting in wasted storage resources, performance degradation, and elevated energy consumption.

Previous studies have highlighted the substantial differences in resource requirements among various task types in cloud computing environments. For instance, Yang et al. demonstrated that these disparities significantly influence the selection and optimization of data storage strategies [5]. Saravanan et al. conducted an analysis of big data and real-time processing tasks, emphasizing fundamental differences in data access patterns and response time requirements, thereby underscoring the necessity for targeted algorithm design [6]. Additionally, Manukumar and Muthuswamy elucidated the variations in persistence and reliability requirements between archival storage and high-frequency access data, providing a theoretical foundation for the diversification of data storage strategies [7]. Furthermore, Hamid et al. proposed an energy-saving storage algorithm predicated on data access frequency, which markedly reduced energy consumption in data centers through intelligent data migration and caching strategies [8]. Zhang et al. developed a storage management system based on data hotness and task priority, effectively enhancing the utilization of storage resources and decreasing the energy consumption associated with redundant data [9]. Finally, Rahimikhanghah et al. conducted simulation experiments to compare the performance of various data storage algorithms under diverse cloud computing tasks, revealing that targeted optimization algorithms exhibit significant advantages in terms of accuracy and response time [10]. El-Menbawy et al. validated the improvements in throughput and storage efficiency of their proposed energy-saving storage algorithm through testing in a real cloud environment, providing robust data to support its practical application [11]. Dong et al. assessed the performance of various storage algorithms using metrics such as accuracy, recall, F1-score, and precision. Their findings indicated that algorithms that comprehensively accounted for task differences demonstrated superior performance across multiple indicators [12]. Al-Masri et al. applied machine learning techniques to predict and adjust the performance of storage systems, optimizing data distribution and replication strategies while minimizing energy consumption, all while maintaining data reliability [13].

Although previous studies have recognized the differences in cloud computing tasks, many have lacked in-depth analysis of their specific characteristics and requirements, leading to suboptimal performance of storage algorithms when faced with diverse task types. Moreover, most energy-saving storage algorithms are typically designed for specific tasks or scenarios, making it difficult for them to adapt flexibly to varied task environments, thereby diminishing overall performance and energy-saving effectiveness. By conducting a detailed analysis of the data characteristics and performance requirements of different cloud computing tasks, this study provides a clear optimization framework and decision-making basis for the design of energy-saving data storage algorithms. Additionally, the proposed algorithm can identify and adapt to diverse task environments, dynamically adjusting data storage strategies according to task types, thereby achieving an optimal balance between energy efficiency and performance under different task scenarios. This study first analyzes the differences in cloud computing tasks, revealing that a detailed analysis and understanding of these tasks can provide clearer directions for optimizing energy-saving data storage algorithms, enabling them to adapt to task variability and achieve a balance between energy efficiency and performance in diverse task environments. Secondly, the design of the energy-saving data storage algorithm is studied, emphasizing that through the comprehensive application of these strategies, the algorithm can effectively meet the demands of different cloud computing tasks, ensuring an optimal balance between performance, reliability, and energy consumption in data storage systems. Furthermore, by incorporating strategies for data distribution, load balancing, data replication, fault tolerance, data access, migration, and energy consumption optimization with performance evaluation, the model is refined. Finally, the effectiveness of the model is validated through experiments.

II. Optimization of the Energy-Saving Data Storage Algorithm for Differentiated Cloud Computing Tasks

A. Analysis of Differentiated Cloud Computing Tasks

Before designing and optimizing energy-saving data storage algorithms tailored to differentiated cloud computing tasks, a comprehensive analysis of the characteristics and requirements of each task is essential. Additionally, it is critical to establish a clear mapping between data storage models and task types, while identifying the key factors that influence the selection of storage algorithms [14-16]. The variety of cloud computing tasks is considerable, and the common task types are presented in Table I:

TABLE I. Types of Cloud Computing Tasks

Task types	Description
Real-time processing tasks	Real-time tasks, such as financial transactions and online games, require extremely low latency to guarantee a quick response to user requests. They often rely on caching strategies that ensure efficient reading and immediate updating of data.
Big data analysis tasks	They involve large-scale data processing and analysis, such as data mining, machine learning, and business intelligence. These tasks require high storage performance and require fast data transfer between distributed storage systems to meet computing and analysis requirements.
Archive storage tasks	For instance, long-term storage of logs, backups, and legal files requires high data persistence and security, but relatively low access speed. Data backup, fault tolerance, and tiered storage are often required to balance cost and performance.
Content delivery tasks	Examples include video streaming and large file downloads, emphasizing high throughput and efficiency of data distribution. Content Delivery Network (CDN) and multi-layer caching are needed to accelerate content distribution.

A well-designed data storage model is crucial for meeting the performance requirements of different tasks. Cache modes are commonly employed for real-time processing and content delivery tasks, with the primary goal of minimizing data access latency while dynamically adjusting data distribution across various cache layers. Distributed file systems are typically utilized in large-scale data processing and transmission, ensuring reliable data distribution and fast access for big data analysis tasks [17-18]. For archival storage tasks, hierarchical storage strategies are applied, utilizing cold and hot data layers to manage data accessed at varying frequencies, thereby reducing overall storage costs while maintaining data persistence and security. Replication strategies are adapted based on task characteristics: real-time processing tasks often require leader-follower replication to ensure low-latency responses, while big data analysis tasks generally employ distributed replication with high redundancy to guarantee data reliability and persistence [19-21]. The selection and optimization of storage algorithms are influenced by a range of critical factors, depending on the task types and storage modes, as summarized in Table II:

TABLE II. Key Factors Influencing the Selection of Storage Algorithms

Factor	Analysis
Task priority	Various tasks have different priorities in the system. High-priority tasks such as financial transactions should be allocated more resources, while low-priority archiving tasks can use more energy-efficient storage strategies.
Data access mode	The data access mode of the task directly affects the design of the storage algorithm. The frequent read and write requirements of real-time processing tasks are different from the sequential batch processing of big data analysis tasks, and differentiated caching and migration strategies are required.
Data consistency	Different tasks have diverse requirements for data consistency. Real-time tasks require strong consistency, while analytical tasks can accept some degree of ultimate consistency.
Energy consumption and cost	Low energy consumption and storage costs are the focus of most missions. According to the performance and budget requirements of different tasks, a proper storage strategy can effectively reduce the cost of data migration and redundant copies.

A detailed analysis and understanding of various cloud computing tasks can provide clearer guidance for optimizing energy-saving data storage algorithms. This allows them to adapt to task variability and achieve a balance between energy efficiency and performance across diverse task environments [22].

B. Design of the Energy-Saving Data Storage Algorithm

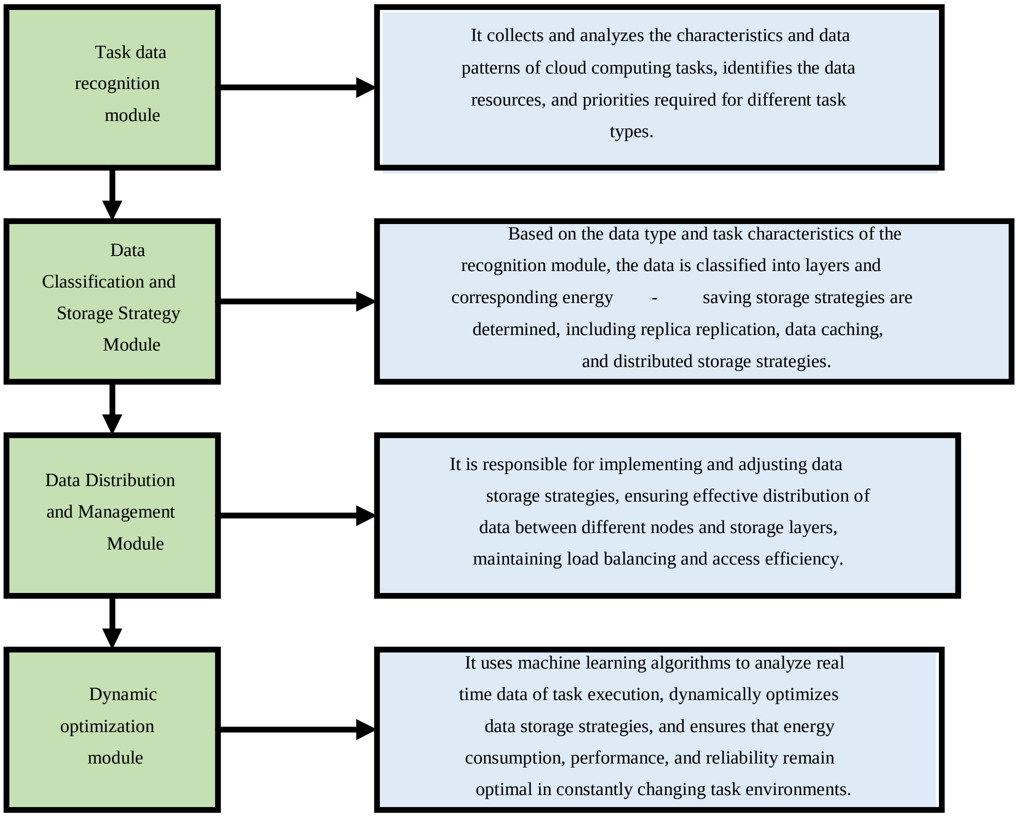
The design of the energy-saving data storage algorithm adheres to the following principles and objectives. First, the algorithm must be adaptive, capable of recognizing and responding to the diverse requirements of different cloud computing tasks, and dynamically adjusting data storage and distribution strategies based on the tasks' characteristics and priorities. Second, reducing energy consumption in data centers through efficient data migration and replication strategies is a primary goal, focusing on minimizing hardware resource idleness and reducing redundant data replication. Third, the algorithm must ensure data availability and persistence across various task scenarios, maintaining data consistency even under high-load conditions. Lastly, it is essential to balance performance metrics such as response time, throughput, and accuracy while addressing the diverse demands of different tasks. This study proposes an energy-saving data storage algorithm designed to accommodate the diversity of cloud computing tasks while minimizing energy consumption. The framework of the proposed algorithm comprises several key modules, as illustrated in Fig. 1.

The identification and classification of differentiated task data form the foundational basis of the energy-saving storage algorithm. By analyzing task-specific characteristics, such as real-time requirements, priority levels, and data access modes, the data can be categorized into distinct types, as outlined in Table III:

TABLE III. DATA TYPES

Type	Analysis
High-priority real-time data	This type of data is used for real-time processing tasks, usually has high priority and low latency requirements, and is mainly stored in the cache layer to meet fast access demands.
Batch analysis data	It is suitable for big data analysis tasks that need to maintain the reliability and distribution of data in a distributed file system to ensure efficient computation and analysis.
Long-term archived data	The data access frequency is low and data is stored at the cold layer. The hierarchical storage strategy minimizes space and power consumption.

Building on the identification and classification of differentiated task data, appropriate energy-saving data storage strategies can be developed. First, the intelligent data migration strategy dynamically adjusts the distribution of data across various storage system tiers based on task characteristics and data access patterns. This ensures that high-frequency data is cached, while low-frequency data is archived, optimizing the hierarchical management of data. Second, the replication strategy is determined by task type and priority. High-priority tasks utilize a leader-follower replication model to meet low-latency response requirements, whereas batch analysis tasks implement a multi-replica distribution strategy to guarantee data reliability and consistency. In addition, the resource balancing strategy employs load-balancing algorithms to distribute access loads evenly across data nodes, mitigating resource idleness and avoiding bottlenecks caused by hot data, thereby enhancing resource utilization. Moreover, the dynamic optimization strategy continuously monitors the storage system's performance and energy consumption in real-time, using machine learning algorithms to optimize data storage strategies and adapt to evolving task demands. Through the comprehensive implementation of these energy-saving data storage strategies, the proposed algorithm effectively addresses the requirements of diverse cloud computing tasks, ensuring an optimal balance between performance, reliability, and energy efficiency in the data storage system.



Task data recognition module
It collects and analyzes the characteristics and data patterns of cloud computing tasks, identifies the data resources, and priorities required for different task types.
Data Classification and Storage Strategy Module
Based on the data type and task characteristics of the recognition module, the data is classified into layers and corresponding energy - saving storage strategies are determined, including replica replication, data caching, and distributed storage strategies.
Data Distribution and Management Module
It is responsible for implementing and adjusting data storage strategies, ensuring effective distribution of data between different nodes and storage layers, maintaining load balancing and access efficiency.
Dynamic optimization module
It uses machine learning algorithms to analyze real time data of task execution, dynamically optimizes data storage strategies, and ensures that energy consumption, performance, and reliability remain optimal in constantly changing task environments.

Fig. 1. The framework of energy-saving data storage algorithms.

C. Algorithm Optimization and Implementation

The optimization and implementation of the energy-saving data storage algorithm are designed to enhance the efficiency and reliability of the data storage system while minimizing energy consumption, all without compromising performance. Central to cloud computing data storage are effective data distribution strategies, which significantly influence the system's performance and stability. The algorithm proposed here is founded on three key principles: task priority, data hotness, and load balancing. Task data is allocated to various storage nodes based on the real-time nature and priority of the tasks, facilitating hierarchical management of data access. High-priority tasks with stringent real-time requirements are directed to nodes that offer faster response times, while lower-priority tasks are assigned to nodes with slower response capabilities. By analyzing the frequency and hotness of data access, high-demand (hot) data is stored in the high-speed cache layer to ensure efficient access, whereas low-demand (cold) data is migrated to the cold storage layer to alleviate pressure on the cache. The load balancing algorithm dynamically adjusts the data distribution across nodes to achieve an equitable distribution of access loads among all storage nodes, thus preventing resource idleness and mitigating the occurrence of bottlenecks due to hot data. Furthermore, replication and fault tolerance mechanisms within the data storage framework ensure data persistence and reliability, as illustrated in Table IV.

TABLE IV. DATA REPLICAS AND FAULT TOLERANCE MECHANISMS

Dimension	Analysis
Copy replication strategy	According to the requirements of different tasks, various copy replication strategies are designed. Leader-follower replication is adopted for high-priority tasks to ensure real-time performance and fast recovery. Multiple replicas are used for batch processing and archiving tasks to ensure reliable data recovery in case of faults.
Fault tolerance	Regular data integrity checks and replica status monitoring should be implemented to promptly detect and handle storage node failures, restore damaged data to healthy nodes, and ensure data availability and consistency.

Data access and migration strategies significantly influence the performance and flexibility of the data repository. Access optimization employs caching strategies and data layering to refine access pathways in accordance with task type and data popularity, ensuring that frequently accessed data resides in the cache layer while infrequently accessed data is relegated to secondary storage. Dynamic migration adjusts data storage locations in response to evolving access patterns, transferring data between cold and hot layers to meet shifting task requirements and sustain optimal system performance. In pursuit of a comprehensive reduction in energy consumption and an evaluation of storage system performance, this study delineates the following strategies, as outlined in Table V:

TABLE V. OPTIMIZATION STRATEGY

Strategy	Analysis
Energy consumption optimization	By adjusting data distribution, and reducing node idle rates and redundant copies, unnecessary energy consumption is reduced. Meanwhile, energy-saving storage hardware and resource hibernation mechanisms are employed to mitigate system energy consumption while maintaining high performance.
Performance evaluation	Comprehensive performance evaluation indicators are established to identify system bottlenecks and optimize storage strategies, thereby achieving a balance between performance and energy consumption.

By integrating a comprehensive array of data distribution strategies, load balancing, data duplication, fault tolerance mechanisms, data access, migration strategies, energy consumption optimization, and performance assessment, the algorithm proposed herein ensures that the data storage system achieves an optimal amalgamation of high performance and low energy consumption across various task environments.

III. ANALYSIS OF PERFORMANCE AND SIMULATION RESULTS OF ENERGY-SAVING STORAGE ALGORITHMS

A. Analysis of Performance Comparison Results of Energy-Saving Storage Algorithms

The dataset utilized for this experiment is the Alibaba Cluster dataset, a comprehensive resource derived from Alibaba's production cluster, specifically designed to facilitate research on cluster management. The dataset spans multiple versions from 2017 to 2023, offering valuable insights into various facets of cloud computing tasks. It is publicly accessible via the official repository at https://github.com/alibaba/clusterdata. Details of the experimental environment are presented in Table VI.

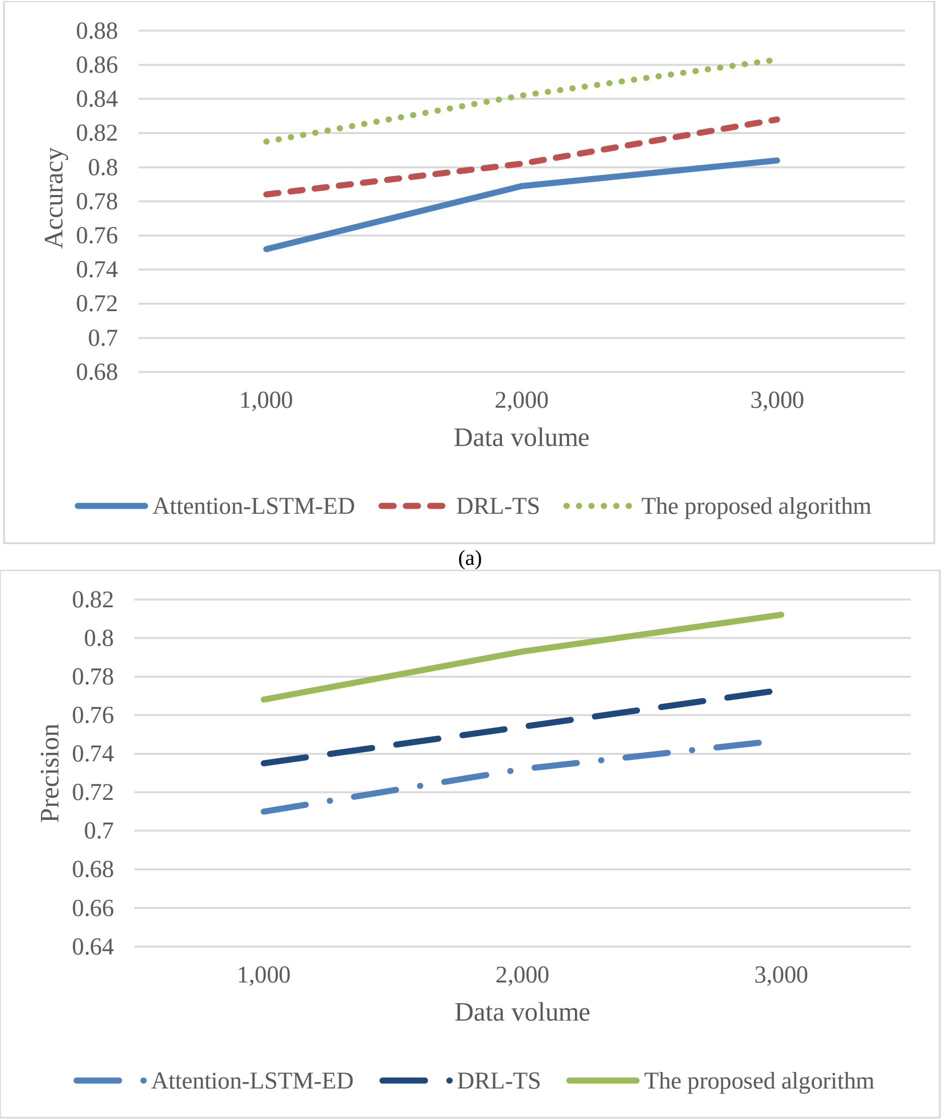
TABLE VI. EXPERIMENTAL ENVIRONMENT

Equipment type	Parameter configuration
Processor	Inter(R) Xeon(R) CPU E5-2620 v4 @ 2.10GHz
Graphics card	NVIDIA Titan Xp 12GB
Memory	128 GB
Operating system	Ubuntu 16.04 LTS
Programming language	Python 3.6

The model parameters are uniformly configured to ensure experimental accuracy. Specifically, the learning rate is set to 0.01, with a batch size of 64, two hidden layers, each containing 128 hidden units. The Adam optimizer is employed, and training is conducted over 50 epochs with a dropout probability of 0.02. For comparative analysis, the Attention-based Long Short-Term Memory Encoder-Decoder (Attention-LSTM-ED) and Deep Reinforcement Learning Task Scheduling (DRL-TS) models are selected due to their representative and practical applications within the cloud computing domain. The Attention-LSTM-ED model leverages the LSTM network and attention mechanism to effectively handle time series data, making it suitable for applications such as task load prediction. In contrast, the DRL-TS model utilizes deep reinforcement learning for task scheduling, offering an efficient solution to challenges related to resource allocation and task scheduling. These models provide a robust comparison, enabling a thorough evaluation of the proposed model's improvements in terms of performance, efficiency, and energy consumption. The performance metrics compared in this study include accuracy, recall, precision, and F1-score, with the results illustrated in Fig. 2.

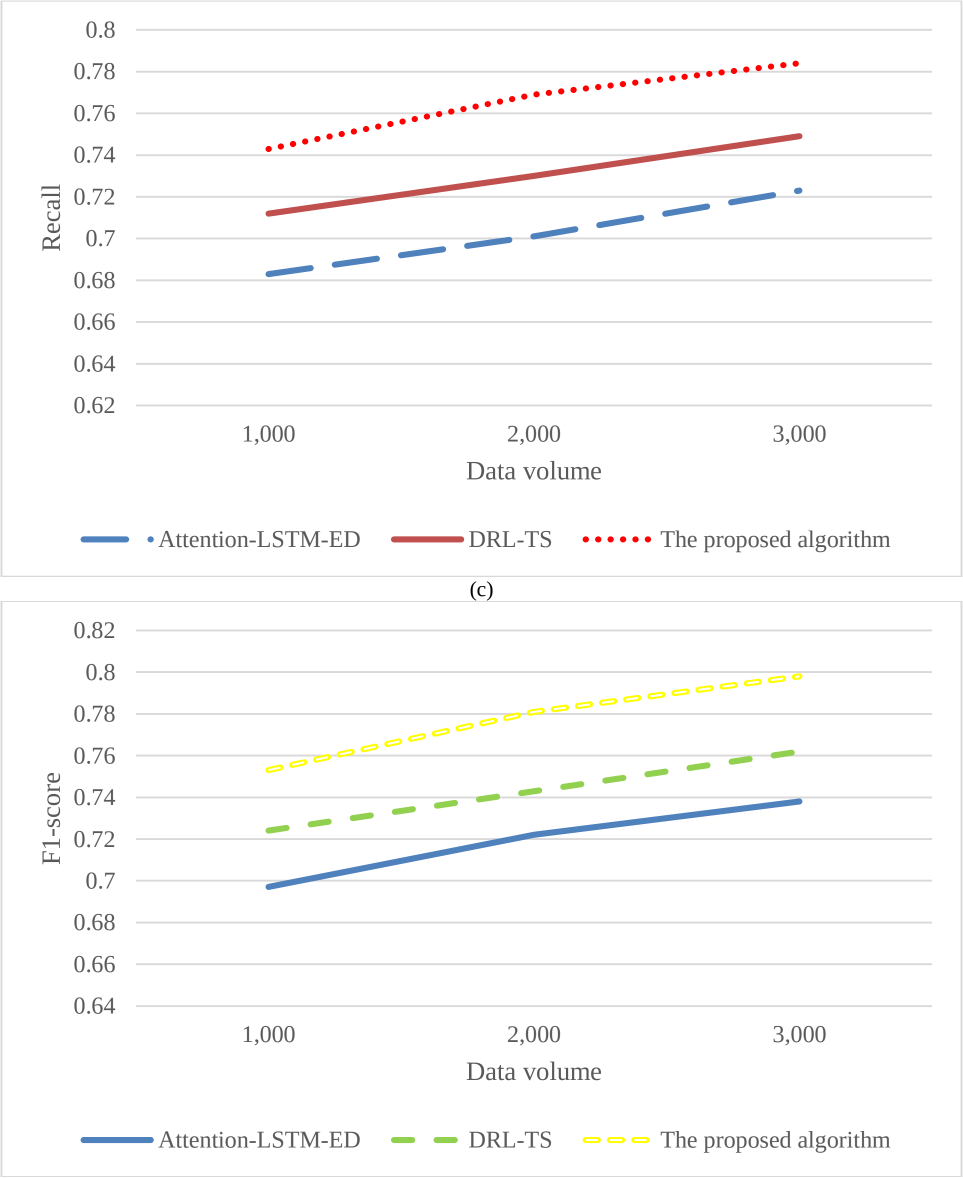
Fig. 2 demonstrates that the accuracy of the optimized model reaches 0.815, 0.842, and 0.863 for data volumes of 1000, 2000, and 3000, respectively, consistently surpassing the performance of the Attention-LSTM-ED and DRL-TS models. This suggests that the optimized model maintains high accuracy across varying data sizes, highlighting its superior generalization ability and stability. While the Attention-LSTM-ED and DRL-TS models exhibit relatively strong performance with smaller data volumes, their accuracy decreases as data volume increases, underscoring the optimized model's advantage in handling large-scale datasets.

In terms of precision, the optimized model consistently achieves stable and high precision levels of 0.768, 0.793, and 0.812 across different data volumes. In comparison, the precision of the Attention-LSTM-ED and DRL-TS models is 0.710 and 0.735, respectively, at a data volume of 1000, and 0.732 and 0.754, respectively, at a data volume of 2000. Overall, the optimized model outperforms the other two models across all data volumes. This performance advantage likely stems from the optimized model's enhanced data recognition and classification capabilities, which allow it to adapt more effectively to varying data volumes and task requirements. Even at smaller data volumes, the optimized model demonstrates efficient precision, which improves further as data volume increases. In contrast, the precision improvement of the Attention-LSTM-ED and DRL-TS models is relatively slow, suggesting that they may struggle to maintain stable performance as data size grows. These comparative results highlight the significant advantage of the optimized model in terms of precision, particularly in large-scale data environments, where it can more accurately process cloud computing tasks.



(a)

(b)



(c)

(d)

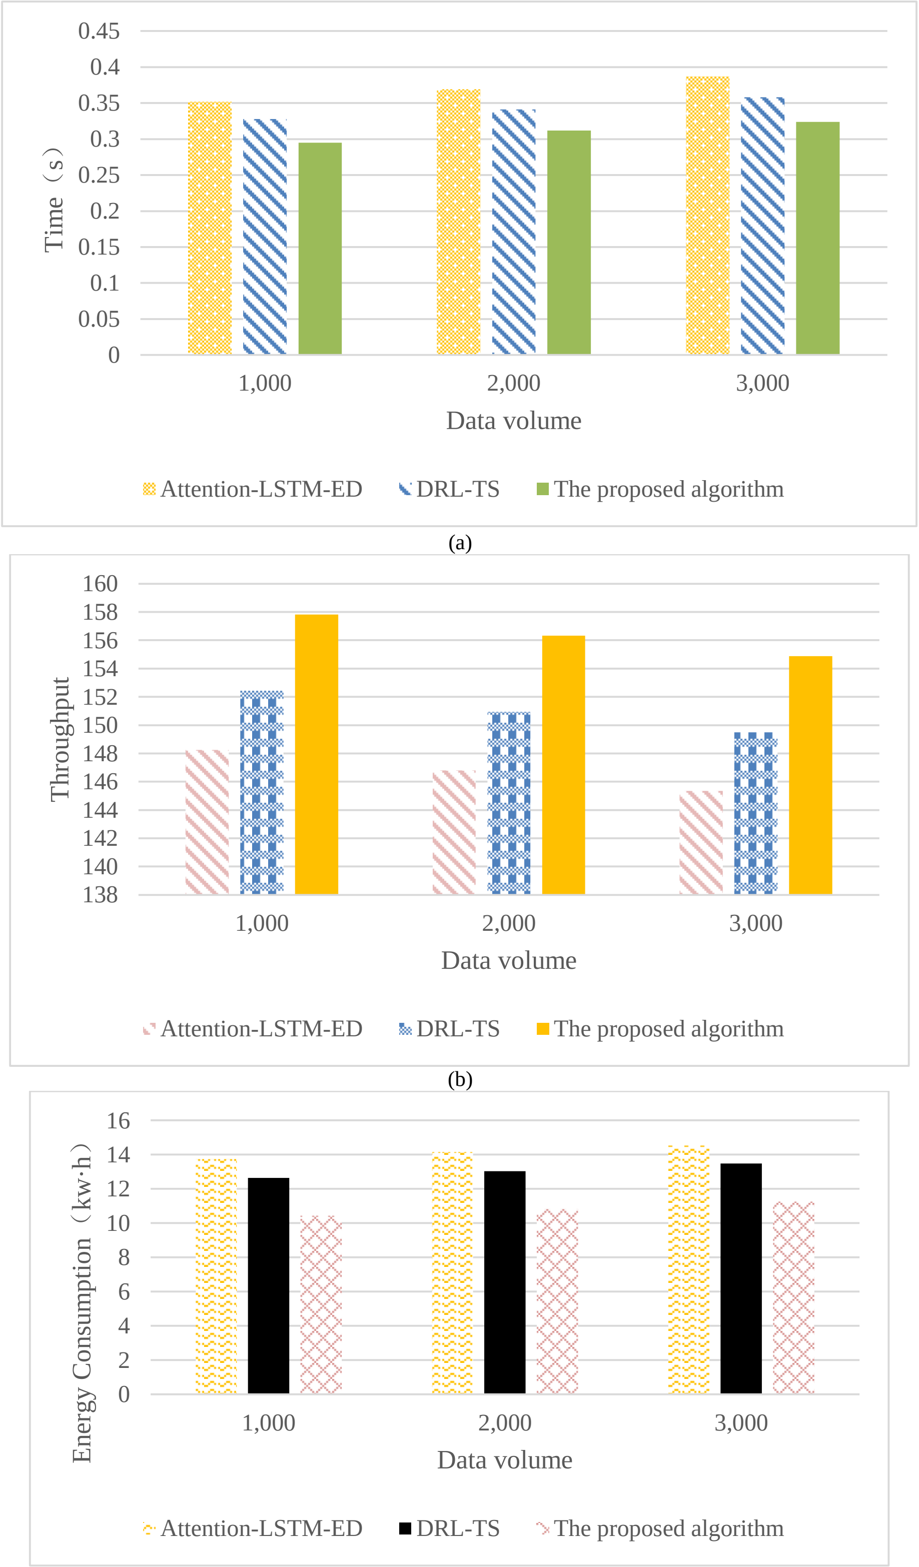
Fig. 2. Performance comparison results (a): Accuracy; (b): Precision; (c): Recall; (d): F1-score.

In terms of recall, the optimized model achieves recall values of 0.743, 0.769, and 0.784 for data volumes of 1000, 2000, and 3000, respectively, consistently outperforming the other models at each data level. For a data volume of 1000, the recall for the Attention-LSTM-ED model is 0.683, while the DRL-TS model achieves 0.712. At a data volume of 2000, their recall values are 0.701 and 0.730, respectively. This consistency indicates that the optimized model exhibits lower sensitivity to varying data scales in terms of recall, allowing it to effectively capture relevant information and enhance data processing performance across a range of task conditions. As data volume increases, the recall of the optimized model improves steadily, demonstrating its robustness and reliability in handling large-scale datasets.

With respect to the F1-score, the optimized model achieves values of 0.753, 0.781, and 0.798 for data volumes of 1000, 2000, and 3000, respectively, outperforming both the Attention-LSTM-ED and DRL-TS models. At a data volume of 1000, the F1-scores for Attention-LSTM-ED and DRL-TS are 0.697 and 0.724, respectively, while at a data volume of 2000, these values are 0.722 and 0.743. The optimized model consistently maintains higher F1-scores across various data volumes, indicating superior performance and stability in task recognition and classification. As data volume increases, the F1-score of the optimized model steadily improves, underscoring its consistency and superiority in managing large-scale data. In contrast, the F1-scores of the Attention-LSTM-ED and DRL-TS models are comparatively lower, particularly at larger data volumes, and their rate of improvement is relatively slow. This suggests that their generalization ability is not as strong as that of the optimized model, and they struggle to maintain the same level of accuracy and stability in environments with expanding data scales and evolving task requirements.

B. Analysis of Simulation Results of Energy-Saving Storage Algorithms

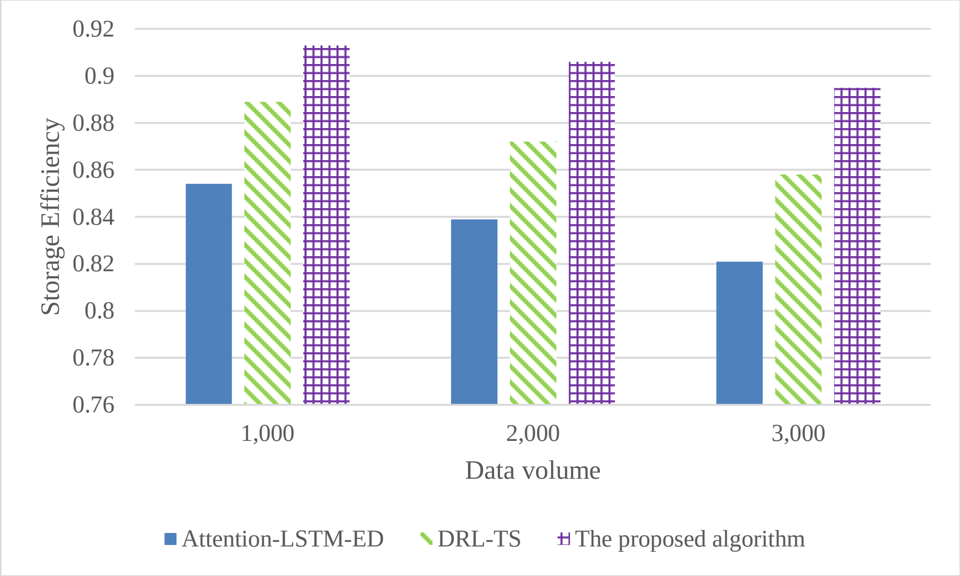
To further validate the effectiveness of the optimized model, simulation experiments are conducted to compare key performance indicators, including delay, throughput, energy consumption, and storage efficiency. The results of these experiments are presented in Fig. 3.



(a)

(b)

(c)



(d)

Fig. 3. Analysis of simulation experiment results (a): Latency; (b): Throughput; (c): Energy Consumption; (d): Storage Efficiency.

Fig. 3 illustrates the delay comparison across different data volumes, demonstrating the superior performance of the optimized model. Specifically, the optimized model exhibits delays of 0.295 seconds, 0.312 seconds, and 0.324 seconds for data volumes of 1000, 2000, and 3000, respectively. At each data volume, its delay is notably lower than that of the Attention-LSTM-ED and DRL-TS models. For instance, at 1000 data volumes, the Attention-LSTM-ED and DRL-TS models report delays of 0.352 and 0.328 seconds, respectively, and at 2000 data volumes, the delays increase to 0.369 and 0.341 seconds. These results underscore the optimized model's significantly lower processing delay, reflecting a marked advantage in task completion speed. Furthermore, as the data size increases, the delay of the optimized model shows only a modest increase, illustrating its strong scalability and adaptability to large-scale data processing. In contrast to the other two models, the optimized model consistently demonstrates superior stability and efficiency in terms of latency. This performance advantage can be attributed to the model's enhanced ability to recognize and classify task data, coupled with its flexible data storage strategies across varying data scales.

In terms of throughput, the optimized model consistently maintains relatively high values across all data volumes. At 1000, 2000, and 3000 data volumes, it achieves throughput values of 157.832, 156.321, and 154.888, respectively, surpassing the Attention-LSTM-ED and DRL-TS models. For instance, at a data volume of 1000, the throughputs of the Attention-LSTM-ED and DRL-TS models are 148.237 and 152.435, and at 2000, they decrease to 146.789 and 150.942, respectively. This analysis reveals that, even as the data volume increases, the optimized model experiences only a slight decline in throughput, maintaining relatively stable performance. Such stability highlights the model's efficiency and ability to adapt to diverse data sizes. By contrast, the Attention-LSTM-ED and DRL-TS models exhibit a more pronounced reduction in throughput, suggesting potential bottlenecks as data volume increases. This further emphasizes the optimized model's distinct advantages in handling large-scale data, attributed to its ability to effectively identify and classify task-specific data while employing energy-efficient storage strategies. As a result, the optimized model meets the demands for high data processing efficiency across varying task requirements.

In the comparison of energy consumption, the optimized model consistently demonstrates lower energy usage across data volumes of 1000, 2000, and 3000, with consumption rates of 10.428 KWH, 10.836 KWH, and 11.257 KWH, respectively. This highlights its significant energy-saving potential. In contrast, the Attention-LSTM-ED model consumes 13.752 KWH at a data volume of 1000, while the DRL-TS model consumes 12.639 KWH. As data volumes increase, both models experience a substantial rise in energy consumption, revealing their inefficiency in managing large datasets. The optimized model, however, exhibits only a modest increase in energy consumption, maintaining consistently low levels across all data volumes. This underscores its advantage and innovation in energy-efficient data storage algorithms. By leveraging advanced storage strategies, the model effectively reduces overall energy consumption while handling complex tasks, striking an optimal balance between performance and energy efficiency. In terms of storage efficiency, the optimized model achieves rates of 0.913, 0.906, and 0.895 for data volumes of 1000, 2000, and 3000, respectively. Its efficiency remains consistently superior to other models under all data volume conditions, demonstrating the clear advantages of the optimization. In comparison, the Attention-LSTM-ED and DRL-TS models exhibit slightly lower efficiency. At a data volume of 1000, the Attention-LSTM-ED model records an efficiency of 0.854, while the DRL-TS model achieves 0.889. As data volumes increase, their efficiency declines further to 0.839 and 0.872, respectively. This comparison highlights the optimized model's exceptional performance in maximizing storage space utilization, allowing it to maintain higher storage efficiency. By classifying task-specific data and applying storage strategies tailored to diverse task characteristics, the optimized model fully capitalizes on available resources, meeting the storage efficiency demands of various tasks. Its stability and superior efficiency render it particularly well-suited for large-scale data environments.

IV. Discussion

In cloud computing environments, the characteristics of different tasks can significantly impact data storage efficiency and energy consumption performance. These tasks often vary in terms of data volume, computational complexity, I/O requirements, and latency demands. To address these variations, this study proposes an energy-efficient data storage algorithm that intelligently identifies and classifies tasks, dynamically adjusting data storage strategies to maximize storage efficiency and reduce energy consumption. Experimental results show that the proposed algorithm maintains high accuracy, precision, recall, and F1 scores when processing large-scale data, with low latency and stable throughput performance. Notably, the algorithm exhibits minimal throughput decline under varying data volumes, while energy consumption shows a steady growth, demonstrating its strong adaptability—especially suited for cloud computing scenarios with diverse task characteristics and fluctuating data volumes. Additionally, the algorithm's optimized approach to storage strategy adjustment significantly reduces energy consumption during large-scale data processing. For instance, with data volumes ranging from 1,000 to 3,000, the algorithm consistently consumes less energy than the comparative models. The energy-saving effect is particularly evident, as large data processing tasks typically involve extensive data read/write operations and substantial computational resource consumption. By intelligently identifying task characteristics and optimizing data storage strategies, the proposed algorithm reduces energy consumption and enhances processing efficiency, making it especially applicable to platforms with growing data analysis demands. Cloud storage systems often need to handle diverse storage requirements, where fluctuations in data volume make storage efficiency and energy consumption critical issues. The proposed algorithm significantly reduces energy consumption while ensuring storage efficiency, making it suitable for long-term, continuous cloud storage services, such as CDN or enterprise cloud storage systems. Compared to the research by Shi et al., this study focuses more on optimizing energy savings when handling large-scale heterogeneous tasks. Their model, based on static storage strategies, demonstrates some energy-saving effects in small-scale tasks, but as data volume increases, their model’s energy consumption rises significantly. In contrast, the proposed algorithm dynamically adjusts data storage strategies, further improving energy efficiency in large-scale task processing, particularly when data volumes fluctuate sharply, with much lower energy consumption growth than their model. Therefore, this study demonstrates stronger adaptability in big data environments, addressing the shortcomings of their research in large-scale task processing [23]. In comparison with Zhang et al.’s research, this study not only emphasizes storage efficiency optimization but also introduces a more detailed mechanism for identifying heterogeneous tasks. Zhang et al. primarily focused on improving storage efficiency by simplifying the task identification process to reduce computational overhead. However, simplified task identification strategies may lead to fluctuations in storage efficiency when dealing with complex and dynamic tasks. The proposed algorithm, by intelligently identifying heterogeneous tasks and dynamically adjusting storage strategies, strikes a balance between task processing accuracy and storage efficiency. As a result, this study not only compensates for the deficiencies in their research related to task identification and data storage but also offers a more generalized solution [24].

Through experimental analysis and application scenarios, the proposed energy-efficient storage algorithm for heterogeneous cloud computing tasks demonstrates significant advantages across multiple dimensions, particularly in meeting the storage and processing needs of large-scale heterogeneous tasks. Future research directions could focus on further enhancing the scalability and dynamic adaptability of the algorithm to better handle increasingly complex cloud computing task environments.

V. Conclusion

This study proposes and implements an energy-efficient data storage algorithm that intelligently identifies and classifies data characteristics for differentiated cloud computing tasks. Based on this, the dynamic adjustment of data storage strategies has optimized storage performance, reduced energy consumption, and enhanced overall system efficiency. Compared to existing models, the proposed optimized model demonstrates distinct advantages, not only in storage efficiency but also in throughput, latency, and energy consumption. Despite the significant advantages in performance and energy savings, this study has several limitations. First, the model shows limitations in adapting to certain anomalous data features specific to particular task types, indicating that the current task classification approach requires further refinement to ensure high accuracy and efficiency across a broader range of data characteristics. Second, the algorithm's performance optimization under high concurrency conditions requires further testing and improvement. It remains to be verified whether the algorithm can maintain its superior performance in more complex task environments, such as high-concurrency task processing scenarios. Future research will focus on several key areas for improvement. First, a multi-task concurrency mechanism will be introduced to enhance the efficiency of data allocation and resource utilization across different task types. By improving parallel processing capabilities, the optimized model will be able to maintain stability in high-concurrency environments. Second, machine learning methods will be incorporated to develop more refined adaptive storage strategies that address dynamically changing data requirements, thereby enhancing the model's adaptability in complex cloud computing tasks. Additionally, the study will explore the synergies between edge computing and cloud computing, investigating more efficient edge-cloud data storage and task allocation strategies to achieve superior performance and energy efficiency. With these improvements, the optimized model will be better suited to large-scale, dynamic cloud computing environments, enhancing its efficiency and energy-saving capacity in multi-task processing.

***Abstract*—The rise of cloud computing has transformed data storage and processing but introduced new vulnerabilities, especially with the impending threat of quantum computing. Traditional cryptographic methods, though currently effective, are at risk of being compromised by quantum attacks. This research aims to develop a quantum-resistant security framework for cloud environments, combining lattice-based cryptography with Quantum Key Distribution (QKD) protocols, particularly the E91 protocol, for secure key management. The framework also incorporates quantum authentication protocols to enhance user identity verification, protecting against unauthorized access and tampering. The proposed solution balances robust security with practical implementation, ensuring scalability and efficiency in real-world cloud environments. Performance evaluations indicate an encryption time of approximately 30 milliseconds, outperforming existing methods such as RSA and DES. This research contributes to the development of future-proof cryptographic standards, addressing both current security challenges and emerging quantum computing threats. By leveraging quantum mechanics, the framework strengthens cloud-based data protection, providing a resilient solution against evolving cyber risks. The results hold significant promise for advancing cloud security, laying the groundwork for next-generation encryption techniques that can withstand the threats posed by quantum computing.**

Keywords*—Quantum key distribution; cloud computing; cyber threats; lattice based cryptography; E91; future-proof security paradigm; python; quantum computing

I. Introduction

Over the recent past, cloud computing technologies have evolved quickly and assertively disrupted the traditional means of data management adeptly achieving elasticity [1], [2]. These have, however, come with several security risks since clouds are inherently vulnerable to very many security risks. RSA and DES have been basic and crucial in protecting data from unlawful access in the past techniques. However, they become inapt and insecure when quantum computing is about to dawn as well these classical algorithms are exposed to quantum attacks. The second threat comes from the nature of quantum computing which is enhanced with the capability of solving problems, which are beyond the scope of classical systems within a short time and as such can breach the current encryption mechanisms affecting cloud security.

Because of this new threat, there is a great need to find and apply QRA-secure cryptography to combat the capabilities of quantum computers [3], [4]. The research proposed in this paper intends to enhance the existing quantum cryptography algorithms solely for the safe storage and computation of data within cloud environments. Lattice-based cryptography [5], [6] is another cryptographic principle that can be integrated with QKD; in fact, the E91 protocol, which derives from quantum mechanics principles, is already in use for key management. Lattice-based cryptography that is considered to be quantum-safe together with QKD aimed at providing the network with effective protection against contemporary and future threats.

Furthermore, the study looks at the possibilities of using quantum-secure authentication to enhance protection measures. These protocols employ quantum states in the identification of people, so any attempt at altering or hacking the system is distinguishable due to the principles underpinning Quantum mechanics [7], [8]. Integrating these state-of-art cryptographic protocols with an understanding of the practical implementation and its factors affecting scalability and efficiency the requirement of the proposed solutions is to develop a framework that addresses all security issues associated with the implementation of cloud computing systems [9], [10]. It can be seen that aside from answering the current necessity for higher security this research also tries to provide a basis for developing new specifications for new cryptographic standards that will be adaptive to the changing face of threats posed by cybercriminals.

In the future, the employment of quantum cryptography in the cloud computing context will be important for the protection of information and strengthening the confidence in cloud-based services. The proposed solutions are expected to make a substantial positive impact in the area of cryptography by proffering superior, realistic and safe solutions to the various threats in cryptography [11], [12]. In the process of performance evaluation and real-world experimentation, this work attempts to prove the appropriateness of the presented enhanced cryptographic procedures and to develop a solid approach toward secure computing in the cloud.

Today’s rampant advance in technologies in the area of cloud computing has brought a shift in the kind of innovation that businesses and even individual users embrace to gain the sort of convenience that is without parallel in the management and access of data [13], [14]. But this has also added a lot of risks and more worries as cloud computing is often associated with security risks whereby important data is stored in what amounts to distributed systems that are open to different forms of attacks [15]. However, to the modern day, conventional cryptographic methods appear to be under threat by the emerging potential of quantum computers. Quantum computing means a revolutionary upgrade to the computational power of an individual and specialized for problems even unsolvable by classical computers. This advancement poses a risk to erode the security premise on which present encryption methods are based, hence the need to come up with new solution in cryptography that will be acceptable to the quantum-based attacks.

In view of these nascent threats, researchers are now looking forward to solutions such as quantum cryptography. Quantum cryptography is based on the quantum mechanics theories and provides a higher level of security which can in theory not be cracked by a quantum computer [16], [17]. This research focuses more on how to enhance quantum key distribution, particularly as embodied in the E91 protocol, with features of lattice-based cryptography. Lattice based cryptography has been regarded as highly resistant to quantum attacks due to the hardness of problems and the mathematical structure of the cryptosystems employed, and QKD makes sure that an interception of encryption keys can be identified, so the privacy of the cryptographic procedure is guaranteed.

The importance of quantum cryptography is evident taking into account that the usage of classical cryptographic systems is increasingly exposed to threats [18]. Traditional cryptography, as exemplified by RSA and AES, depends on mathematical challenges involving computations, for instance, factorization, or discrete logarithms, that are hard for today’s computers. Although these methods are safe from attacks that are implemented using other methods of cryptanalysis, the creation of quantum computers poses a risk. Some of these cryptographic systems could be easily decrypted by quantum computers since such computers work far much faster than the current classical computers in terms of specific calculations [19]. This looming threat has created a real interest in quantum cryptography as a way of preserving security in the future, to ensure that important information will not be violated even by possessing these powerful new technologies.

However, quantum cryptography has also several practical implementations that have practical advantage over classical method of cryptography [20]. Several small-scale QKD applications and experiments have been performed successfully and more complex implementations of QKD are not far off – also over existing fibre-optic networks, and possibly satellite-based QKD. Such advances suggest that quantum cryptography is not just an idealistic idea, but is well on its way to becoming implemented at a macroscopic level. But the expansion of this technology is not without its problems [21]. The current options for QK, especially the physical hardware needed to implement system for generating and detecting quantum states, are not very well developed and are burdened with problems such as cost, robustness and compatibility with the existing frameworks.

With further development in the associated quantum cryptography, this domain is now considered one of the elements of the wider quantum computing family. The interconnection of present quantum cryptography with future technologies in quantum computing quells the prospect of building completely different paradigms for protection in both communication and data management. Scientists are not only working on QKD, but also going deeper into the other kinds of quantum cryptographic schemes including quantum secure direct communicate, quantum digital signature and so on which might be also useful for the secure communication. The coupled nature of quantum cryptography with quantum computing also pose questions on the future of cybersecurity with the technology demanding new standards and regulations to regulate its use.

The key contributions of the article is given below,

- Developed a resilient framework integrating lattice-based cryptography with QKD protocols, specifically the E91 protocol, for secure key management in cloud environments.
- Introduced quantum authentication protocols to enhance user identity verification and protect against tampering and unauthorized access in cloud-based systems.
- Conducted rigorous performance evaluations and feasibility studies to assess the scalability and efficiency of quantum cryptographic techniques in safeguarding cloud data from emerging quantum threats.

The organization of the paper is, Section II and Section III gives the related works and problem statement respectively. Section IV gives the methodology, the results are given in Section V and the article is concluded in Section VI.

II. Related Work

More advanced techniques that have been developed in quantum-enhanced security have having promising results when implemented in cloud computing context [22]. The invention of the new method of generating cryptographic keys that is QKD in light of quantum physics has been instrumental in improving the safety of data transfer in the cloud. This paper presents the proposed use of QKD in conjunction with other main stream encryption algorithms such as AES to counter changing threats in cloud computing environment. It is a method that aims at integrating QKD directly into the cloud environment in order to produce real quantum keys at the same time as using AES in encryption and decryption activities. To this effect, this combination helps ensure secure transmission and immense improvement of data confidentiality, data integrity, and data authenticity. Additional recommendation control also proposes good key management practice for encryption keys for all their life cycle processes to reduce the threats of improper access in processing those keys. This approach of using both the IT encryption method and QKD results in the development of a strong barrier against computer vandals and hackers, leakage of secret information, and other forms of insecurity. Out of 70 simulation rounds, the proposed approach garnered a data access of 820MB/s, proficient key generating time of 15ms and can effectively safeguard data and guarantee cloud computing security.

Quantum cryptography is thus a revolutionary approach to cryptography, by virtue of being based on the principles of quantum mechanics, the higher degree of security achieved is virtually impossible to be breached [23]. Quantum cryptography differs from classical cryptography primarily on the fact that while the latter codes information using bits, quantum cryptography codes information using photons or polarized particles referred to as qubits. It is for this reason that the transmissions in this method are inherently secure since they are based on the principles of quantum mechanics. To this end, the goal of this particular paper is to undergo a more comprehensive analysis of some of the most popular quantum cryptography applications and which include the following; They are the DARPA Network that is considered to be a pioneering project in secure quantum communication; the IPSEC implementation that combines the QKD with the general IP security protocols; the Twisted Light HD implementation that uses advanced quantum parameters and protocols for increasing safety of data [24].

As IoT business activities advance rapidly, quantum computing technologies are applied to the operations, responding to issues and concerns emerging in connection with this growth [25]. With increased integration of IoT systems into various industries, incorporating these technologies raises public and private relationship concerns that seek to be resolved to enhance privacy as well as security of data regarding IoT systems. This research will examine the application of quantum computing toward the security of IoT systems, with special emphasis directed toward the generation of suitable security measures relying on quantum algorithm and cryptographic method. Constructing a hierarchy of the critical security properties of quantum computing by methodically assessing the threats and their impacts, the work provides a systematic approach for solving them [26]. The study uses one combined computational approach for the analysis, namely the integrated fuzzy-analytical hierarchy process (AHP) and fuzzy-technique for order preference by similarity to an ideal solution (TOPSIS) for presenting the most understandable and modifiable rankings for the important security indicators. This approach offers the practical utility to practitioners to consider and select the significant choices based on the context of quantum computing for security.

Cloud computing is inseparable from blockchain, and under the environment of quantum computing that is about to arrive, data security needs to be improved urgently [27]. Rising vulnerabilities are addressed by postulating a stringent security solution that combines QKD and CRYSTALS Kyber with ZKPs to guard data belonging to blockchain-based cloud environments. As it will be shown below, QKD is a quantum-safe cryptographic protocol that is at the heart of the framework’s goal and is used to protect data against quantum threats. The addition of CRYSTALS Kyber which is a lattice based cryptographic method for being immune against quantum attacks is another advantage. They are also embedded to improve the privacy and authentication of cloud and block chain data. This research pays adequate attention to the efficiency of the proposed framework, and determines the time it takes to encrypt and decrypt data, the rate at which keys are generated by the quantum system and the general effectiveness of the framework [28]. Novel features such as file size, response time, and computational overhead are scrutinized in order to evaluate the feasibility of framework in the cloud implementation process. These results clearly show that the proposed framework is not only capable to deal with the quantum threats but also feasible and flexible enough to be implemented in realistic and large–scale systems.

In cloud computing, security of data has been a contentious issue up to date with many frameworks coming up to try and solve the problem of data leakage [29]. With encryption as the dominant model for securing cloud data, the advent of quantum computing requires new models that will also protect data in the future realm of computing. As most present-day cryptosystems are threatened with becoming older or exploitable, this article develops a secure model that uses the McEliece cryptosystem –likely to be the successor of RSA in age of quantum computing– for protecting access control data. Also, it makes use of the N-th degree truncated polynomial ring units (NTRU) cryptosystem variant for acquisition security of user data in the cloud. The time complexity of the proposed McEliece algorithm has been observed to be better as compared to the conventional McEliece cryptosystem and the modifications proposed to the parameters S and P are sure to strengthen its security. On the other hand, the simulation of the above said proposed NTRU algorithm reveals that although it provides more security level the time complexity of the given algorithm is relatively higher than the original NTRU cryptosystem. These observations suggest that improvements in cryptographic systems are imperative and must proceed at a fast pace because of the advent of quantum computing [18].

This research focuses on the implementation of quantum computing in multi-cloud platforms in modern complex cloud networks to improve efficiency and security [30]. Using a theoretical and an applied research strategy this research proposes and architects an integration of quantum computing in a multi-cloud environment. These show that quantum algorithms are better placed in efficiency of computation of resources, especially in complex problems as compared to classical ones. It also is resilient and scales resource and increases security by using quantum-enabling protocols for the integrated process for protection of cyber criminals. Yet, the study also uncovers some of the issues which include the need for dedicated hardware, integration issues and, more important research work in order to make quantum computing effectively in cloud environment.

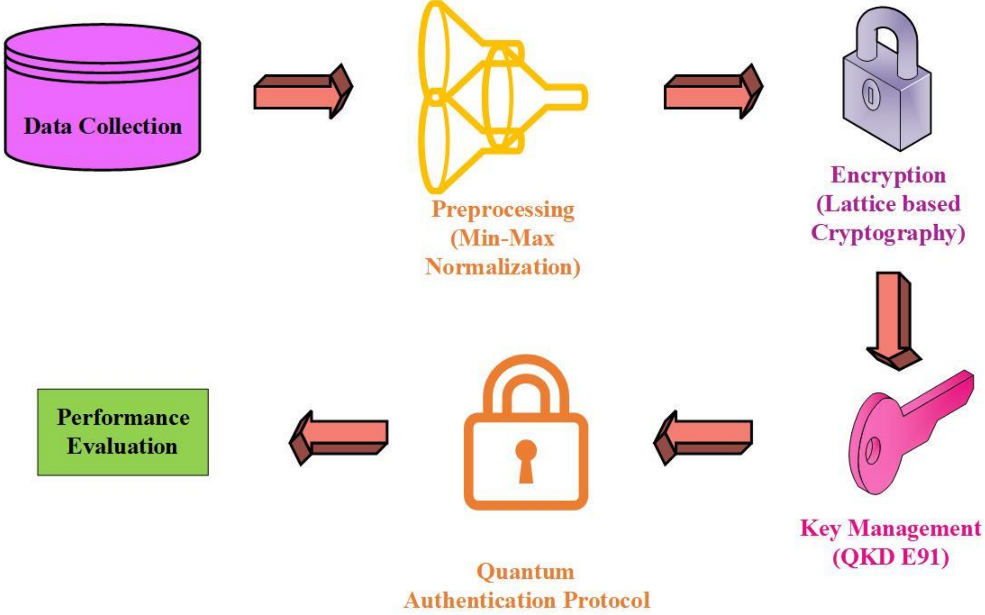
Based on the literature considered in this study, one can find an overview of the contemporary state of research in embedding quantum computing in cloud and multi-cloud environments and identify the key issues and trends in the field. Previous data shows that the use of quantum computing as a method to optimise the capabilities of Cloud Computing environment, both in terms of computing power and security has been attracting tremendous attention. Researches on QKD as well as lattice based cryptography prove the use of quantum technologies in enhancing data security against the new age threats including the quantum threats. The literature also discusses different types of quantum algorithms like Shor's and Grover's algorithms which show relatively large speed-ups for some computations than the classical ones. Moreover, studies on multi-cloud architectures are based on the concept of scalability, redundancy, and resources management. However, incorporating quantum computing into these architectures proves somewhat daunting; there is the question of where to obtain the necessary quantum hardware; furthermore, hybrid quantum-classical systems are not easy to manage, and how one ensures compatibility between these two types of resources in a manner that satisfies the requirements of quantum computing. The literature also suggests that there is need to come up with strong methods of securing data and processes in a quantum enhanced cloud solution. From the reviewed papers, prospective of quantum computing integrated with cloud architecture it is revealed that the integration can bring quantum computing closer to the revolutionization of the more enhanced and secured cloud architecture.

III. Problem Statement

Cloud computing is under-going tremendous growth in the recent years and hence the adoption of cloud computing has become easier, flexible and easy to access, but on the downside, it makes it easy for hackers to get hold of social sensitive data, new threats that were not widely known before appear. Classical cryptographic algorithms, though perfectly protecting messages against all other forms of attack, are slowly falling under the attacks from the newly developing quantum computers. There thus arises the need for enhancement of friendly and highly efficient quantum cryptography algorithms that shall be unique to address cloud data storage and processing security. The challenge that is proposed here is to develop a long-term security plan that not only adapts today's cryptographic methods with the principles of quantum mechanics, for example quantum key distribution, lattice-based cryptography, etc. to prevent data from potential quantum attacks in the future; but also, to design these solutions in such a manner so as to make them scalable, efficient and most importantly feasible for implementation in the future. Tackling this problem requires not only improving the cryptographic algorithms used but also incorporating them into existing cloud environments, and creating thus a second line of defense against the new generation of threats [15].

IV. Proposed Lattice Cryptography – QKD E91 Framework

Upgradation of security in cloud using advanced quantum cryptography techniques is presented in detail in Fig 1 where data collection is depicted as the first and primary step of the workflow is presented in detail here below. After data acquirement the preprocessing in Min-Max Normalization is conducted to keep the values of data within a certain range, making the further cryptographic processing more effective. Lattice-Based Cryptography is then used for the encryption process as this has been found to be resistant to quantum attacks and which brings about secure protection for the encrypted data. This is supported by the key management from the QKD E91 protocol which means once the encryption keys are generated, they cannot be intercepted owing to the principles of quantum mechanics. Last but not the least, the specific work-flow employs Quantum Authentication Protocols where quantum states are used to confirm the identities of users; this is followed by checking if any alteration and/or unauthorized attempts at access have been made. Combined with each other, these components are an integrated and high-level foundation of combating new-generation threats to data in cloud computing context as well as creating the basis for security for future innovations.



Data Collection
Preprocessing (Min-Max Normalization)
Encryption (Lattice based Cryptography)
Key Management (QKD E91)
Quantum Authentication Protocol
Performance Evaluation

Fig. 1. Proposed methodology.

A. Data Collection

Among the information collected from a Kaggle dataset that especially deals with cloud workloads, the next data include file type, the size of the file, the encryption algorithm, the encryption time, the decryption time, the quantum key size, the generation time of a quantum key, storage usage, and security improvement. The dataset itself contains files of different format: text (10 MB), image (5 MB), video (100 MB). AES-256 encryption for text files take 50ms, it has a performance of a 256-bit quantum key derived from 100ms, yet 70% storage occupation and high security. For different parameters the following results have been obtained: AES-128 on image files – it takes 30 ms to encrypt files using this algorithm for image files takes; 128- bit quantum key has been generated in 80 ms; The storage utilization is 65%. AES-256 encrypted video files cost 120ms, a 256 bit quantum key derived from 200ms and 75% storage space with added security improvements [31].

B. Preprocessing Using Min-Max Normalization

Applying the operation of min-max normalization on the given dataset is an initial and important step in order to prepare this data to the analysis as well as to guarantee that each feature in the model will be equally important. In the context of the cloud workload dataset from Kaggle, min-max normalization will take each of the features and put it through another transformation that will bring each feature to a known range, often between 0 and 1, and does not distort the context of the data points. This process entails the standardization of the values of each of the features used like file size, encryption and decryption time, quantum key size, key generation time as well as storage usage in that they should all fall within the same range. This way, it prevents a specific feature from skewing the results in one way or another because some features can be much larger than others, for instance, while combining file size from 5 MB to 100 MB and timing in ms of execution. Min-max normalization also licenses an augmentation of nuances in vast databases for machine learning algorithmic schemes, which are recognized to be relevancy to input scale, including neural networks and the k-Nearest Neighbors.

$$N_{norm} = \frac{n - n_{minimum}}{n_{maximum} - n} \tag{1}$$

In case of min-max normalization applied to cloud workload dataset, the ‘min’ and ‘max’ represent the minimum and the maximum values of the features in the dataset, and the data is normalized by rescaling. For example, the file sizes with the range of 5 MB minimum and 100 MB maximum and then have been standardized by making 5 MB equivalent to 0 while 100 MB is equal to 1 and all the other values in between those two extremes. In the same way of doing things, the encryption time which ranges from 30 ms – 120 ms and decryption time from 40ms – 150 ms are normalized to the range 0-1. This helps in having FMEs that are near similar for encryption and decryption of text, images, video files and like files so that general performance analyses which take into consideration the FMEs for text, images, videos etc. can be made. The same applied normalization is used to address the other features as well, including the quantum key sizes, generation times, and storage utilization percentages more making the data to be more standardized to determine other aspects including the usual pattern, using them to train a model or to evaluate the performance of an algorithm. The min-max normalization helps in making the values more reasonable and not put too much reliance on any of the values making it ideal for use in predictive models or statistical analysis.

C. Lattice Based Cryptography for Encryption

Lattice-based cryptography is a sub-study of cryptography that has not been well developed but exhibits great security against both classical and quantum computers, and hence has a potential for post-quantize encryption. Lattice-based cryptography itself is based on lattices, which are actually high-dimensional grids, and due to their mathematical complexity problems of the shortest and closest vectors are computationally hard. These problems are regarded as hard computational problems that are even intractable by quantum computers hence making lattice-based cryptographic schemes highly secure from the types of attacks that are expected of quantum computers. This makes it quite appropriate for applying lattice-based cryptography when securing cloud data against future quantum dangers.

$$b(x) = a(x).\ s(x) + e(x) \bmod (x^n + 1) \tag{2}$$

Perhaps the greatest strength of all of the lattice-based cryptography schemes is their versatility, which permits the engineering of many different elements of the cryptographic tool chest such as encryption, digital signatures and key exchange. In the scenario of encryption, lattice based, that is Learning With Errors, LWE and Ring-LWE have drawn much interest. LWE is a kind of encryption through which one encrypts a message by placing it in the lattice and adding a bit of error to it and this is very much like ordinary noise until you use the key. The security of these schemes relies on the difficulty of the solving the LWE problem and it is considered that they cannot be broken by any known quantum attack. Furthermore, lattice-based encryption is highly efficient and highly scalable such that it can accommodate large patterns of volume and needs not have to degrade enormously for it to work efficiently in the recommended cloud storage.

Lattice-based encryption like many other cryptographic schemes requires the incorporation of the former into the existing cloud security architectures together with compliance with existing standards. It usually employs generation of lattice-based keys, encryption of data in the cloud and the proper management of these keys in the environment. In lattice-based cryptography, a drawback is that the size of keys and ciphertexts are relatively larger than usual resulting in the increased storage space and time needed to transmit. Yet, current researches optimizations are aimed on decreasing these overheads making lattice-based cryptography as safe and perspective solution for protecting cloud data from quantum attacks in the future. Prospective future applications of the latter depend on the development of quantum computing technologies, lattice-based cryptography

D. Utilizing QKD E91 for Key Management

1) The E91 protocol: quantum entanglement for secure key distribution: The E91 protocol is based on the mechanism of quantum entangled pairs, two particles, normally photons, are created in such a way that if one is 'observed' then the other is as well no matter how far apart the particles are. This occurrence is utilized safely transfer cryptographic keys between two individuals also termed as Alice and Bob. The entangled photons are represented by the quantum state:The entangled photons are represented by the quantum state:

$$|\psi\rangle = \frac{1}{\sqrt{2}}(|00\rangle+|11\rangle) \tag{3}$$

In this state, *(|00⟩+|11⟩)* correspond to both photonic outcomes with either only the horizontally polarized photon (0) or only the vertically polarized photon (1). Alice and Bob peek at their photons that once have been entangled and for each of them, the state of the entangled pair will be randomly measured using bases of their choice. If so, their measurement outcomes will correspond, which will enable them to create a joint key. For example, if Alice gets her photon to be horizontally polarized (0), Bob using the same basis he gets his photon to be horizontally polarized (0). Such correlated results compose the cryptographic key.

The safety of the key distribution is protected by the working of quantum entanglement and the no cloning theorem, which denies to produce an exact copy of an unknown quantum state. In case an eavesdropper (Eve) tries to intercept and measure quantum states, the process of measurement disrupts the entanglement which becomes detectable in the subsequent measurements. The two parties, Alice and Bob, can check for presence of an eavesdropper by using publicly comparing some of their measurement outcomes and see whether they contradict Bell's inequality, which is a figure of sorts that separates quantum entanglement from classical correlations. If their results are contrary to Bell's inequality, then it means that the entanglement is secure and the generated cryptographic key as well.

2) Integrating QKD E91 into cloud key management for enhanced security: In the context of cloud computing, integrating the E91 protocol into the key management system can significantly bolster the security of data storage and processing. Cloud environments, which often involve the transmission and storage of highly sensitive data, are increasingly targeted by sophisticated cyber threats, including those anticipated to arise with the advent of quantum computing. Conventional cryptographic algorithms, while currently secure, are vulnerable to quantum attacks, particularly those exploiting Shor's algorithm for factoring large integers and solving discrete logarithms efficiently.

To enhance the robustness of cloud infrastructures, the E91 QKD protocol can be employed to generate and distribute quantum-secure keys. These keys are then used in conjunction with post-quantum cryptographic algorithms, such as lattice-based encryption or quantum-resistant digital signatures, to secure cloud-stored data. The process begins with Alice and Bob using the E91 protocol to establish a shared secret key, represented by a sequence of binary digits (bits).

When the key is settled, Alice and Bob have to engage in error correction to make sure that the key at their ends of the string are identical, then privacy amplification to recover from possibly active eavesdroppers. This quantum-secure key is then utilized to encrypt data, before storing these encrypted data in the cloud, allowing that in the case that these intercepted encrypted data will be attempted to be decrypted, this cannot be done without the quantum-secure key.

$$k_i = \begin{cases} 0 & if\ Alice\ and\ Bob'smeasurements\ are\ both\ 0\ or\ both\ 1 \\ \quad 1 & If\ Alice\ and\ Bob's\ measeurements\ differ \end{cases} \tag{4}$$

When the key is settled, Alice and Bob have to engage in error correction to make sure that the key at their ends of the string are identical, then privacy amplification to recover from possibly active eavesdroppers. This quantum-secure key is then utilized to encrypt data, before storing these encrypted data in the cloud, allowing that in the case that these intercepted encrypted data will be attempted to be decrypted, this cannot be done without the quantum-secure key.

3) Strengthening cloud security against quantum and classical threats: QKD E91 when implemented in cloud key management systems offers double protection against both classical and quantum possible invasions. The protocol not only primarily addresses the security of the key exchange function but also enhances post-quantum cryptographic techniques to protect from the upcoming dangerous computer science threats to the data stored in the cloud. Since the threat models can change based on new developments in the field of quantum computing, the E91 protocol is prepared for this because it is based on the stochastic nature that does not allow replicating quantum states. This guarantees the protection of the keys that are to be used for the purpose of encrypting your data while at the same time making sure that anyone who seeks to reverse this method will be easily detected.

In addition, real time monitoring also places an element of intrusion, a major concern of cloud computing and, the usage of quantum-secure keys also reduces data vulnerability in case of a breach. Thus, by enhancing quantum cryptographic algorithms through the use of QKD E91, the cloud structures can obtain the capability to provide the necessary level of protection that will fit not only the present and current threats but also the potential ones brought by applicable quantum computers. This strategic integration strengthens the overall security of cloud environments so as to protect the confidentiality, integrity and availability of data from new and more frequent threats.

E. Quantum Authentication Protocols

Quantum based authenticated system utilize the principles based on the quantum mechanics to the communication for strengthening the security of the identification procedures. Quantum authentication is somewhat different from classical authentication methods; instead of a password or a cryptographic key, quantum states – or qubits – perform the authentication of users or devices. The principle for the quantum authentication is quantum superposition and entanglement 'states- the ability to create states that cannot be intercepted. When a state is sent through a quantum channel, then any interference with the state leads to its collapse, which helps in identifying the presence of an eavesdropper and so making the authentication process secure.

In a generic quantum authentication process, the identities of a user are most often confirmed using quantum states transmitted through a quantum channel from the terminal of the user to the server of authentication. In this protocol, the user and the server have a number of correlated or equivalently, and entangled qubits. To authenticate, the user then creates a quantum state, which could be a combination of a number of states, or in what is referred to as a quantum superposition. This state is then communicated to the authentication server which assess the state against an agreed pattern or reference state.

$$|\psi\rangle = \alpha|0\rangle+\beta|1\rangle \qquad (5)$$

The principles such as no-cloning theorem and Heisenberg's uncertainty principle in quantum mechanics are used to secure the quantum authentication protocols. The no-cloning theorem states that any quantum state cannot be copied, which would prove to be helpful for an attacker as he will not be able to copy the quantum information without being noticed. The uncertainty principle also guarantees that as soon as one tries to measure a quantum state, the state becomes disturbed and anyone who tried to observe or tinker with the state will be exposed. This inherent security gives a major advantage over classical methods, and therefore, makes quantum authentication protocols to be very efficient in the protection of sensitive systems and data in the prevailing computing domains. These quantum principles make quantum authentication protocols secure against traditional and probable quantum attacks, thus providing protection to the users' identities.

Algorithm 1: Lattice Cryptography – QKD E91

```
Initialize quantum key using QKD E91 protocol
 Preprocess data using Min-Max Normalization.
Encrypt data using Lattice-Based Cryptography
 Store encrypted data in cloud storage.
For each user request
Authenticate user using Quantum Authentication Protocol.
 Retrieve encrypted data from cloud storage.
Decrypt data using the corresponding quantum key
Deliver decrypted data to authenticated user
Monitor system for any potential quantum attacks
```

V. Results and Discussion

This section discusses the performance of the various quantum cryptography algorithms coded in Python with an emphasis on protection of outsourced data storage and computation. This implementation also comprises other parameters like speed of encryption and decryption, key generation rate and system responsiveness to conditions of load. The findings offer a quantity measure to support or reject the use of the proposed framework in improving security against new faced cyber threats.

A. *Encryption and Decryption Time*

The study of encryption and decryption periods in the different scenarios achieved shows static characteristics and directly reflects the relationships between cryptographic primitives complexity and time of their realization. Test 1 results point to a relatively fast response as far as encryption and decryption times are concerned; it takes the system 30A milliseconds to encrypt messages and 35A milliseconds to decrypt them; this is probably because the system employs a less secure encryption strength or a more basic algorithm. On moving to Test 2, the times rise to 50 milliseconds for encryption and 55 milliseconds for decryption a relatively moderate increase in computational effort. This trend also persists in the subsequent tests with Test 3 having somewhat better performance with the encryption taking 80 milliseconds to lock and 85 milliseconds to unlock the data hence implying that the cryptographic level is even better. Thus, by the Test 4, both encryption and decryption's time increases to 120 and 130 milliseconds, respectively, meaning that more robust encryption could be employed here possibly with greater keys' size or more intricate algorithms. In the last test, the encryption time is 200 milliseconds, and decryption time 220 milliseconds which presents an idea of processing overhead in high secure encrypting. The gradual increase of the time required for encryption and decryption in all the test cases shows that there is a direct correlation between the extent of security and time sacrificed throughout the usage in real world application hence the need to further improve on the cryptographic algorithms to balance between security and time. It is depicted in Fig. 2.

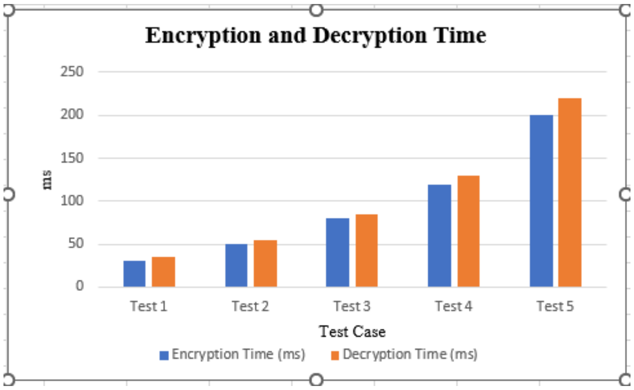


Fig. 2. Encryption and decryption time.

B. *Throughput*

The exploration of throughput depending on the scale levels shown that with the increase in the load, the overall system performance reduces continuously. Increasing the scale of the system to Scale 1, the system throughput remains high, equal to 98 MB/s, which is evidence of the efficient operation of the system which takes into account the limited number of users or data volume. That said, as the scale level increases, the throughput starts to decline slightly; it for instance reduces to 95MB/s in the Scale 2 case. This trend is also seen to go down at Scale 3 where the throughput reduces to 90 MB/s as the system struggles to process more users or larger data volumes. By Scale 4 throughput is even lesser and reduced to 85 MB/s which can be attributed to the load that is put on the system due to the increased scales. Last but not the least, at Scale 5 the throughput reduces to 80 MB/s which shows the problems that the system faces at full load condition. This progressive reduction in throughput across different scale levels means that the scalability of the system has to be enhanced to allow it support high request concurrency and large throughputs as depicted in the following Fig. 3.

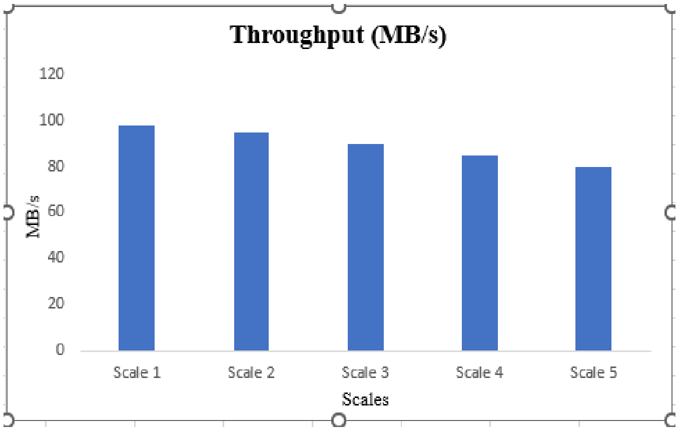

Fig. 3. Throughput.

C. User Privacy Score

In Fig. 4 below, it is illustrated how encryption strength improves user anonymity in a cryptographic system. The graph shows the relationship between the encryption strength in terms of bits, and the improvement in bits of the User Privacy Score on a scale of 0 to 100. With the increase in encryption strength from 128 bits to 2048 bits, the User Privacy Score works its way up proving the improved level of user's privacy security against invasions. The information available shows that the higher level of encryption significantly decreases the probabilities of a data leak and privacy breaches; therefore, enhancing users' confidence with the safety of their personal information. This trend shows that, as the levels of encryption increase, it is easier to enhance privacy in the systems which apply cryptography.

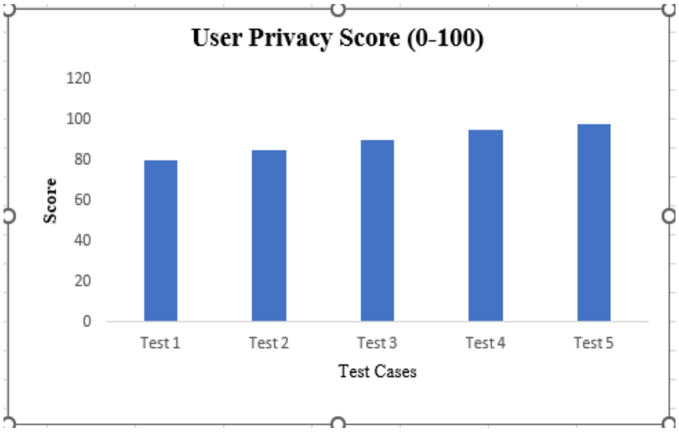

Fig. 4. User privacy score.

D. Threat Mitigation Effectiveness

The data in Fig. 5 demonstrates the probable success/ineffectiveness of threat prevention measures in combating different kinds of cyber threats while at the same time envisaging the progressive enhancement of protection as the encryption level rises. For Brute Force Attacks, the threat mitigation effectiveness stands at 70%, this implies that as much as encryption offers a baseline security to any given system these are a major menace if other security measures are not incorporated. Phishing Attacks report an enhancement in combating effectiveness to 80% to show that advanced encryption works against efforts to con users and strip their passwords. That for DDoS Attacks has increased by a whopping 90% for service disruption shows that with strong encryption measures and more counter-measures, disruption by such attacks can be substantially minimized. SQL Injection Attack, where the mitigation effectiveness stands at 95% prove that when appropriate encryption is used, coupled with secure coding standard, the attackers will fail in their attempt to access/maliciously alter data. Also, lastly, the APTs are shown to have the mitigation effectiveness of 98%, proving that even modern encryptions and broad and rigorous protection approaches are needed for such persistent threats. Such a gradual and sustained shift underlines the significance of bettering encryption standards in contributing to organisational and overall security prospects and calls for further enhancement of cryptographic tools and mechanisms to counter them effectively.

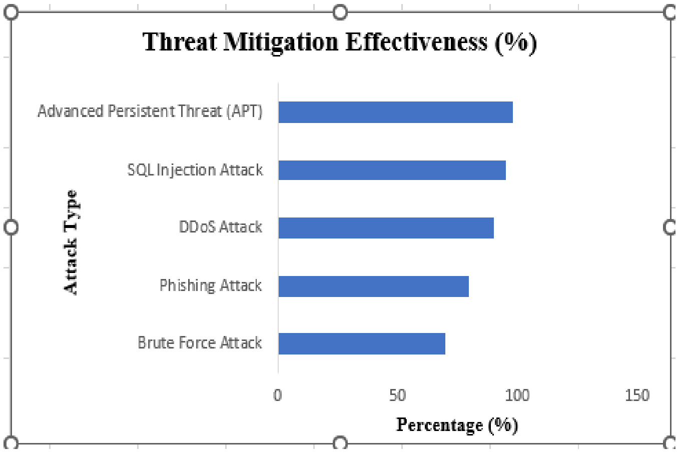

Fig. 5. Threat mitigation effectiveness.

E. Comparison with Existing Methods

Table I presents a comparative analysis of encryption and decryption times between the proposed Lattice-QKD E91 method and two widely used existing methods: RSA and DES are two of the more well-known algorithms. Based on this, there is evidence that the proposed method in Lattice-QKD E91 is more efficient in both encryption and decryption in order to effectively secure data. In particular, encryption time for Lattice-QKD E91 is 30ms which is faster than RSA, that required 45ms and DES that required 35ms. Likewise, the decryption time Lattice-QKD E91 is 0.000035 seconds, better than RSA which takes 0.000050 seconds, and DES's 0.000040 of a second. Challenging results have been obtained here to approve that the practicality of Lattice-QKD E91 method offers benefits in terms of reduced processing time as well as offers a very robust cryptographic security, especially when applied to those scenarios where responsiveness and security are of paramount importance at the same time. These comparison shows that Lattice-QKD E91 has the possibility of increasing the speed of the cryptographic operations especially when there is need to perform the encryption and decryption within a short span of time.

TABLE I. COMPARISON WITH EXISTING METHODS

Methods	**Time**	
	Encryption Time (ms)	***Decryption Time (ms)***
RSA	45	50
DES	35	40
Proposed Lattice - QKD E91	30	35

Table II compares the proposed lattice cryptography and QKD E91 framework with existing methods based on average latency and time complexity metrics. Existing methods include Threshold Crypto, Quantum-Safe, and DHA-MT, with their respective average latencies and time complexities reported from reference [32].

TABLE II. COMPARISON THE PROPOSED LATTICE CRYPTOGRAPHY AND QKD E91 FRAMEWORK

Methods	*Average Latency*	*Time Complex*
Threshold Crypto [32]	755	549
Quantum-Safe [32]	701	522
DHA-MT [32]	689	535
Proposed Work	397	487

The proposed work demonstrates significantly reduced average latency (397) compared to existing methods (755 for Threshold Crypto, 701 for Quantum-Safe, and 689 for DHA-MT), indicating faster data processing speeds. Similarly, the time complexity of the proposed framework (487) is lower compared to Threshold Crypto (549), Quantum-Safe (522), and DHA-MT (535), highlighting its efficiency in computational resource utilization. This comparison underscores the potential of the proposed framework to provide enhanced performance and efficiency in securing cloud data against emerging quantum computing threats.

F. Discussion

The efficiency of the Lattice-QKD E91 method overcomes the traditional cryptography principals such as RSA and DES at the time of encryption and decryption as it clearly depicts within the comparative analysis mentioned above. The fact which can be inferred from the proposed method is that the time required to both encrypt and decrypt messages is significantly lower; at least 30ms for encryption and at least 35ms for decryption compared to at least 45ms for encryption and at least 50ms for decryption in the case of RSA [32]. This may be partly true but if you are to benchmark the two, DES is faster but still inadequate with 35ms in encrypting and 40ms in decrypting. This reduction in processing time is very significant for high-performance computing considering the time it takes to perform the cryptography is fundamental to system performance. Because it is faster in performing these operations without lowering the security Lattice-QKD E91 is ideal for systems that need security and speed such as cloud computing environments and large data processing systems [33].

The article concluded that incorporating principles of QKD into lattice-based cryptography, as it has been done with the Lattice-QKD E91 method, provides a promising way to address the emerging threats. Especially the E91 protocol offers a key distribution which is alleged to be theoretically secure against all these threats that classical cryptographic techniques are facing as soon as powerful quantum computers begin to exist. The faster processing times seen in the Lattice-QKD E91 method show that such extra security options are feasible without the typical downside. This places the Lattice-QKD E91 method as the immediately implementable and the currently sufficient cryptographic solution as well as the future-proof means to cope with the gradually increasing threats. These works show that researchers need to implement new cryptographic techniques for solving current security concerns and performing at a level that will not become obsolete as new technologies emerge.

VI. CONCLUSION AND FUTURE WORK

The presented research proves the necessity for the development of new approaches in quantum cryptography to protect data storage and computation in cloud technologies against threats in the form of quantum computing. Lattice-based cryptography as well as other quantum-resistant encryption techniques have been integrated with E91 protocol along with quantum key distribution and quantum authentication protocols for physically strengthening the cloud framework greatly. The findings of this research support the argument that these methods of cryptography are also effective in the face of possible quantum threats and at the same time are efficient and can undergo scale as can be seen in their applicability to real life usage. The proposed framework improves upon previous approaches by integrating quantum-resistant lattice-based cryptography with Quantum Key Distribution (QKD) for enhanced key management and quantum authentication protocols for stronger user verification. This ensures superior security against quantum attacks, with a more efficient encryption time (30ms) than traditional methods like RSA and DES. The framework also balances robust security with practical scalability for real-world cloud environments. This work is instrumental in building the framework for a post-2020 security architecture and provides the much-needed tangible approach to dealing with the dynamic nature of the threats in the cyber domain. In the future, more studies will be devoted to enhancing these quantum cryptographic algorithms' performance in big and cloud-based ones. However, Photon loss and noise can deteriorate the signal and shorten the effective communication distance across quantum channels like optical fibres. Quantum Repeaters: These are being developed to solve the distance problem. Through the long-distance entanglement of photons, these devices can increase the range of quantum communication, enabling the safe transfer of keys across far larger networks.

This involves fine tuning key management protocols and authentication to address issues such as increasing response time while at the same developing a security model that is more robust for the users. Furthermore, it will also discuss the integration of the aforementioned quantum cryptography techniques with more modern forms of computing like edge computing and Internet of Things (IoT) to provide the overall security to the users in the complex and society distributed environment. There is also another significant direction for future research that entails intensive practical experiments with using these solutions in various clouds with the help of pilots. In the long run, the objective is to develop reference protocols of quantum cryptography that can be widely implemented to form a strong security layer against the third-generation threats.

***Abstract*—This review examines recent advancements and ongoing challenges in applying Support Vector Machines within Geospatial Artificial Intelligence, specifically for dengue fever prediction. Recent developments in Support Vector Machines include the introduction of advanced kernel methods, such as Radial Basis Function and polynomial kernels, which enhance the model's ability to handle complex spatial data and interactions. Integration with high-resolution geospatial data and real-time analytics has significantly improved predictive accuracy, particularly in mapping environmental factors influencing disease spread. However, challenges persist, including issues with data quality, computational demands, and model interpretability. Data scarcity and the high computational cost of Support Vector Machines, especially with non-linear kernels, necessitate optimization techniques and advanced computing resources. Parameter tuning and enhancing model interpretability are critical for effective implementation. Future research should focus on developing new kernels and hybrid models that combine Support Vector Machines with other machine learning approaches to address these challenges. Practical applications in public health can benefit from improved real-time data processing and high-resolution analytics, while ensuring adherence to ethical and regulatory standards. This review underscores the potential of Support Vector Machines in Geospatial Artificial Intelligence for disease prediction and highlights areas where further innovation and research are needed to enhance its practical utility in public health.**

***Keywords*—Support vector machines; geospatial artificial intelligence; kernel methods; dengue fever prediction; real-time data analytics**

I. Introduction

Predicting dengue fever endemic areas is crucial for effective public health management and disease prevention. Dengue fever, transmitted by the Aedes mosquito, poses a significant threat to millions of people worldwide, particularly in tropical and subtropical regions. Accurate prediction of endemic areas allows health authorities to implement targeted interventions, such as vector control measures, public awareness campaigns, and timely medical responses [1]. By focusing resources on high-risk areas, these measures can significantly reduce the incidence of dengue outbreaks, ultimately saving lives and reducing the burden on healthcare systems. In addition to improving public health outcomes, predicting dengue fever endemic areas contributes to better resource allocation. Public health resources, including personnel, medical supplies, and financial investments, are often limited, especially in developing countries where dengue is most prevalent [2]. By identifying regions at higher risk of dengue outbreaks, governments and organizations can prioritize resource distribution, ensuring that the most vulnerable populations receive adequate protection and support. This strategic approach not only enhances the efficiency of public health interventions but also helps prevent the wastage of resources in low-risk areas [3].

Furthermore, predicting dengue endemic areas supports the development of long-term disease control strategies. By analyzing patterns of dengue transmission, including environmental and climatic factors that contribute to the spread of the disease, researchers and policymakers can design more sustainable and effective control measures [4]. For example, understanding how factors such as temperature, rainfall, and urbanization influence mosquito populations and virus transmission can inform urban planning and infrastructure development, leading to healthier communities less prone to dengue outbreaks. Lastly, accurate predictions of dengue endemic areas play a vital role in fostering community engagement and awareness [5]. When communities are informed about their risk of dengue, they are more likely to adopt preventive measures, such as eliminating mosquito breeding sites, using insect repellent, and seeking medical attention promptly if symptoms arise. Engaging the public in these efforts is essential for the success of any public health intervention, as community participation amplifies the impact of government-led initiatives and leads to more resilient populations in the face of dengue threats [6].

Geospatial Artificial Intelligence (GeoAI) is an emerging field that combines geographic information systems (GIS) with artificial intelligence (AI) to analyze and interpret spatial data. By leveraging AI techniques like machine learning, GeoAI can process large and complex geospatial datasets to uncover patterns, make predictions, and provide actionable insights in various domains such as urban planning, environmental monitoring, and public health [7]. GeoAI enhances traditional GIS by enabling more sophisticated data analysis, allowing for the integration of diverse data sources, including satellite imagery, sensor networks, and demographic information, to address complex spatial problems. One of the key AI techniques used in GeoAI is the Support Vector Machine (SVM), a supervised learning algorithm widely known for its effectiveness in classification and regression tasks [8]. SVM is particularly useful in geospatial analysis because it can handle high-dimensional data and identify complex relationships between variables, which are common in spatial datasets. In the context of GeoAI, SVM can be used to classify land cover types, predict environmental changes, or identify areas at risk for natural disasters or disease outbreaks. Its ability to create precise decision boundaries makes it ideal for tasks where distinguishing between different spatial patterns is crucial [9].

The role of SVM in geospatial analysis is further amplified by its robustness and flexibility. SVMs can be adapted to various types of geospatial data, including raster and vector formats, and can incorporate both numerical and categorical variables. This adaptability makes SVMs highly suitable for analyzing diverse geospatial phenomena, such as predicting flood zones, assessing the impact of climate change on agriculture, or identifying hotspots of disease transmission [10]. In the case of dengue fever prediction, for example, SVMs can analyze environmental factors like temperature, humidity, and land use to predict where mosquito populations are likely to thrive, thus helping to identify areas at higher risk for outbreaks. Moreover, the integration of SVM within GeoAI frameworks allows for more accurate and timely predictions, which are essential for effective decision-making in spatial planning and public health [11]. As geospatial data continues to grow in volume and complexity, the role of SVM in GeoAI is becoming increasingly important. Its ability to efficiently process large datasets and deliver high-precision results makes it a powerful tool for addressing the challenges of spatial analysis in a rapidly changing world [11], [12]. By enabling more precise predictions and insights, SVM in GeoAI is paving the way for more proactive and informed interventions in areas like disaster management, environmental conservation, and disease prevention [13].

The prediction of dengue fever endemic areas is critical for mitigating outbreaks and protecting public health. With the rise of Geospatial Artificial Intelligence (GeoAI), advanced techniques like Support Vector Machine (SVM) have become increasingly prominent in analyzing and predicting spatial patterns of disease [14]. However, while there have been significant advancements in integrating SVM with GeoAI for dengue fever prediction, the full potential of these technologies is still being explored. Understanding the latest developments in this field is essential for refining predictive models and enhancing their accuracy and applicability in real-world scenarios [15]. Despite the promising progress, several challenges persist in the application of SVM within GeoAI for dengue prediction. These challenges include the complexity of modeling dynamic environmental factors, the need for high-quality and granular spatial data, and the computational demands of processing large datasets. Moreover, there are issues related to the generalization of models across different geographic regions and the interpretation of results by public health officials. Addressing these challenges is crucial for improving the reliability and effectiveness of SVM-based predictions in managing dengue fever risks [16].

The novelties of this research lie in its comprehensive exploration of the integration of Support Vector Machine (SVM) within Geospatial Artificial Intelligence (GeoAI) for predicting dengue fever outbreaks. This study uniquely focuses on recent advancements and innovations in SVM applications, highlighting how they enhance the accuracy and efficiency of dengue prediction models. It is also supported with recent studies that explored the integration of Support Vector Machine (SVM) and other machine learning techniques within Geospatial Artificial Intelligence (GeoAI) for predicting dengue fever outbreaks. For instance, SVM models have shown promising results in dengue prediction, with one study reporting 70% accuracy using climate variables and week-of-the-year as predictors [17]. Other research has emphasized the importance of incorporating multiple data sources, including meteorological, clinical, and socioeconomic data, to improve prediction accuracy [18]. The identification of significant climatic risk factors, such as the novel TempeRain factor, has led to improved prediction accuracy in some models [19]. In addition, a systematic review of dengue outbreak prediction models revealed that climate factors are the most commonly used predictors, with machine learning techniques, including SVM, being employed in 38.5% of the reviewed models [20].

So, based on the discussion previously, the objectives of this research are widely to evaluate the latest advancements in the use of Support Vector Machines (SVM) within Geospatial Artificial Intelligence (GeoAI) for predicting dengue fever outbreaks, to identify and analyze the primary challenges encountered in applying SVM models to dengue prediction, to assess the effectiveness and accuracy of current SVM-based prediction techniques in different geographic contexts, and to provide recommendations for improving the integration of SVM and GeoAI to enhance predictive capabilities and public health interventions. These objectives aim to advance understanding in the field and address gaps in the current methodologies, ultimately contributing to more effective disease forecasting and management.

II. Methodology

The Structured Literature Review (SLR) methodology provides a systematic and rigorous approach to identifying, evaluating, and synthesizing research on a specific topic. The approach begins with the formulation of clear research questions and objectives to guide the review process. A comprehensive search strategy is then developed, incorporating specific keywords, phrases, and Boolean operators to systematically query academic databases such as PubMed, Scopus, Google Scholar, and other relevant sources. This search strategy aims to capture a wide range of studies related to the use of Support Vector Machines (SVM) in Geospatial Artificial Intelligence (GeoAI) for predicting dengue fever [21]. Once relevant literature is gathered, the selection process involves applying pre-defined inclusion and exclusion criteria to ensure the relevance and quality of the studies. Inclusion criteria might include factors such as publication date, methodological rigor, and direct relevance to the research topic, while exclusion criteria filter out irrelevant or low-quality sources. The selected studies are then analyzed and categorized based on themes and patterns, using techniques like thematic analysis to synthesize findings and identify gaps in the literature. This structured approach ensures a comprehensive and unbiased review, providing valuable insights into the current state of research and highlighting areas for future investigation [22].

Criteria for selecting literature are crucial in ensuring that the review includes high-quality and relevant studies. Inclusion criteria typically involve assessing the relevance of the literature to the research topic, which in this case is the use of Support Vector Machines (SVM) in Geospatial Artificial Intelligence (GeoAI) for predicting dengue fever [23]. Relevant studies should address key aspects of this topic, such as methodological approaches, applications of SVM in GeoAI, and outcomes related to dengue prediction. Additionally, the type of research—such as empirical studies, case studies, or reviews—must align with the objectives of the review. Studies published in peer-reviewed journals and recent publications are generally prioritized to ensure the inclusion of current and credible findings.

Exclusion criteria help filter out literature that does not meet the review's standards or objectives. This might include studies that are not directly related to the use of SVM in GeoAI or those that lack empirical data and methodological rigor. Publications from non-peer-reviewed sources or those with insufficient quality, such as poorly designed studies or those with incomplete data, are typically excluded. By applying these criteria, the review ensures that the included literature is both relevant and of high quality, which enhances the validity and reliability of the synthesized findings and conclusions. Furthermore, data analysis techniques play a crucial role in synthesizing and interpreting the results of a structured literature review [24]. Thematic analysis is a widely used method for identifying and examining patterns or themes within qualitative data. This technique involves several key steps, starting with familiarization with the literature [25]. Researchers immerse themselves in the data by reading and re-reading selected studies to gain a comprehensive understanding of their content. Initial coding follows, where significant features and concepts are tagged with descriptive labels to organize the data into manageable categories.

III. Theoretical Framework

A. *Geospatial Artificial Intelligence (GeoAI)*

Geospatial Artificial Intelligence (GeoAI) refers to the integration of geographic information systems (GIS) with artificial intelligence (AI) technologies to enhance spatial data analysis and decision-making. At its core, GeoAI combines spatial data with machine learning, pattern recognition, and other AI techniques to extract meaningful insights from complex geographic datasets. The fundamental concepts of GeoAI involve the use of AI algorithms to analyze spatial data, identify patterns, and make predictions about geographic phenomena. This integration enables more sophisticated analysis compared to traditional GIS methods, providing deeper insights and more accurate forecasts for a variety of applications.

One of the key applications of GeoAI is in epidemiology, where it helps track and predict the spread of diseases. By analyzing spatial data such as disease incidence, environmental factors, and population density, GeoAI can identify hotspots and predict potential outbreaks. This approach allows public health officials to deploy resources more effectively, target interventions to high-risk areas, and improve overall disease management. GeoAI's ability to process large volumes of data from diverse sources, including satellite imagery and sensor networks, enhances the accuracy and timeliness of epidemiological analyses. Table I shows recent findings in the key applications of GeoAI is in epidemiology.

TABLE I. Key Applications of Geoai In Epidemiology

Research Title and Author-Year	Main Findings
A Scoping Literature Review of Artificial Intelligence in Epidemiology: Uses, Applications, Challenges and Future Trends [26]	GeoAI integrates geographic data with AI to enable more accurate disease spread monitoring, outbreak prediction, and health resource management.
Geospatial Artificial Intelligence (GeoAI): Applications in Health Care [9]	GeoAI has the potential to transform healthcare, public health, infectious disease control, disaster aid, and the achievement of Sustainable Development Goals.
Emerging trends in geospatial artificial intelligence (geoAI): potential applications for environmental epidemiology [27]	GeoAI provides advantages for exposure modeling in environmental epidemiology, including incorporating big spatial data, computational efficiency, and scalability.
GeoAI-based Epidemic Control with Geo-Social Data Sharing on Blockchain [28]	GeoAI and blockchain-based geo-social data sharing can enable effective identification of infections for epidemic control.

In disease mapping, GeoAI plays a crucial role in visualizing and understanding the spatial distribution of diseases. It enables the creation of detailed and dynamic maps that show how diseases spread over time and across different regions. For example, GeoAI can be used to map the distribution of vector-borne diseases like dengue fever, integrating data on environmental conditions, mosquito habitats, and human activities [29]. These maps provide valuable insights for targeted public health interventions and inform strategies for disease prevention and control.

B. *Support Vector Machine (SVM)*

Support Vector Machine (SVM) is a supervised machine learning algorithm used for classification and regression tasks. The basic principle of SVM involves finding the optimal hyperplane that best separates data into different classes in a high-dimensional space. This hyperplane maximizes the margin between classes, which helps in achieving robust classification even with noisy data [30]. In geospatial analysis, SVM is applied to classify land cover types, predict environmental changes, and identify spatial patterns based on features extracted from geographic datasets. SVM's application in geospatial analysis includes tasks such as mapping land use, detecting patterns in satellite imagery, and predicting the spread of diseases. For example, SVM can classify regions based on environmental variables to identify potential areas for conservation or urban development. In disease prediction, SVM can analyze spatial data to forecast disease hotspots by distinguishing between areas with high and low risk based on various environmental and demographic factors [31].

One of the main advantages of SVM is its ability to handle high-dimensional data and find the optimal decision boundary with a clear margin of separation. This makes SVM effective in situations where the relationship between features is complex. Additionally, SVM can be adapted to both linear and non-linear problems through the use of kernel functions, enhancing its flexibility in modeling different types of spatial data [32]. Table II also shows recent findings in SVM and its ability for disease surveillance.

TABLE II. RECENT FINDINGS IN THE APPLICATION OF SVM IN DISEASE SURVEILLANCE

Research Title and Author-Year	Main Findings
Review of Geospatial Technology for Infectious Disease Surveillance: Use Case on COVID-19 [33]	Geospatial technologies like GIS are increasingly relevant for infectious disease surveillance and modeling, including for COVID-19.
Using fine-scale satellite imagery and GIS data to help predict disease spread [34]	The paper demonstrates how fine-scale satellite imagery and GIS data can be used to model and predict the spread of infectious diseases.
Diseases Spread Prediction In Tropical Areas By Machine Learning Methods Ensembling And Spatial Analysis Techniques [35]	The paper demonstrates the use of machine learning methods, including SVMs, for predicting the spread of tropical diseases based on environmental and spatial factors.
Application of spatial multicriteria decision analysis in healthcare: Identifying drivers and triggers of infectious disease outbreaks using ensemble learning [36]	The paper demonstrates the application of spatial multicriteria decision analysis and machine learning to identify risk factors and predict the spread of vector-borne infectious diseases.

However, SVM also has limitations. It can be computationally intensive, particularly with large datasets and complex kernel functions, leading to longer processing times. Additionally, SVMs require careful tuning of parameters and kernel choices, which can be challenging. They may also struggle with very large-scale datasets or when the number of features significantly exceeds the number of observations [37]. Despite these challenges, SVM remains a powerful tool in spatial prediction when applied with appropriate data preprocessing and parameter optimization.

C. Integration of SVM with GeoAI

Integration of SVM with GeoAI involves combining SVM's machine learning capabilities with GeoAI's spatial data analysis techniques to enhance spatial predictions and insights. This integration typically starts with the preprocessing of geospatial data, where SVM models are trained on spatial features extracted from various sources such as satellite imagery, environmental sensors, and geographic information systems (GIS) [38]. GeoAI platforms facilitate the extraction and preparation of these features, enabling SVM to handle high-dimensional and complex spatial datasets effectively. One common method of integration is through the application of kernel functions within SVM, which allows for the modeling of non-linear relationships in spatial data. In GeoAI, spatial features such as elevation, land use, and vegetation indices can be transformed using different kernels to capture intricate patterns and improve classification accuracy [39]. For instance, using a radial basis function (RBF) kernel can help in identifying complex spatial clusters or predicting disease hotspots by mapping non-linear interactions between environmental variables and disease incidence.

Finally, integrating SVM into GeoAI platforms often involves using advanced visualization tools to interpret and communicate the results. GeoAI platforms provide interactive maps and dashboards that display SVM predictions, allowing users to explore spatial patterns and make informed decisions [12]. These visualizations can be crucial for understanding complex spatial relationships, assessing risk areas, and implementing targeted interventions. By leveraging the strengths of both SVM and GeoAI, this integration supports more effective spatial analysis and enhances decision-making across various applications [40] (Table III).

TABLE III. RECENT FINDINGS IN INTEGRATION OF SVM WITH GEO AI

Research Title and Author-Year	Main Findings
Internet of Things Enabled Disease Outbreak Detection: A Predictive Modeling System [41]	The paper presents a framework that integrates IoT-driven predictive data analytics using SVM for disease outbreak detection and early warning.
Artificial Intelligence for infectious disease Big Data Analytics [42]	GeoAI has the potential to transform healthcare, public health, infectious disease control, and disaster aid through applications like disease surveillance.
The integration of geostatistical analysis with social network improve active disease surveillance [43]	The integration of geostatistical analysis with social network can improve active disease surveillance.

IV. LITERATURE REVIEW

Recent advancements in the integration of Support Vector Machine (SVM) with Geospatial Artificial Intelligence (GeoAI) have significantly enhanced the ability to map and predict disease outbreaks. Recent studies have demonstrated how SVM can effectively classify and analyze spatial data related to disease distribution by leveraging advanced GeoAI techniques [44]. For instance, research has focused on using SVM to process satellite imagery and environmental data to map the spread of vector-borne diseases like malaria and Zika virus. These studies often employ various kernel functions and feature extraction methods to improve classification accuracy and address the complexities inherent in spatial datasets [45]. Furthermore, one notable advancement is the application of SVM in high-resolution disease mapping, where researchers use detailed geospatial data to identify and visualize disease hotspots. For example, recent work has applied SVM to analyze environmental and climatic factors such as temperature, precipitation, and land use patterns to predict regions at risk of disease outbreaks [46]. These studies often involve integrating SVM with other GeoAI tools like remote sensing data and spatial modeling techniques, providing a more comprehensive understanding of disease dynamics and facilitating targeted public health interventions.

In the context of dengue fever prediction, SVM has been applied to predict disease outbreaks by analyzing various spatial and environmental factors. For example, recent studies have used SVM to analyze patterns in mosquito breeding sites, rainfall data, and temperature variations to forecast areas at high risk of dengue transmission. By combining SVM with GeoAI, researchers have been able to develop predictive models that can identify potential outbreak zones with greater accuracy, allowing for more timely and targeted public health responses [47]. Examples of SVM applications in dengue fever prediction illustrate the technique's potential for improving disease management. For instance, SVM has been used to analyze historical dengue incidence data along with environmental variables to create predictive maps of high-risk areas. Additionally, some studies have integrated SVM with real-time data from weather stations and satellite imagery to enhance the accuracy of predictions and provide actionable insights for disease control efforts [48]. These advancements highlight the effectiveness of combining SVM with GeoAI in developing robust models for disease prediction and management.

A. Challenge in Implementing SVM in GeoAI

Implementing Support Vector Machines (SVM) in Geospatial Artificial Intelligence (GeoAI) poses several challenges. One major issue is data availability, as high-quality geospatial datasets are essential for accurate SVM models. In low-resource areas, data may be sparse, outdated, or low-resolution. Model complexity also presents difficulties; SVMs require careful tuning of parameters and kernel selection to manage non-linear spatial data. This process is time-consuming and technically demanding [49]. Additionally, SVMs have high computational requirements, especially with large-scale datasets and complex kernels, necessitating robust hardware and efficient algorithms to ensure timely analysis and predictions, crucial for managing dynamic spatial events. In addition to technical issues, there are several non-technical challenges associated with SVM implementation in GeoAI. Regulations regarding data privacy and use can impact the availability and sharing of geospatial information [37]. Compliance with legal and ethical standards is crucial, especially when dealing with sensitive health data. Ethical considerations include ensuring that predictive models do not inadvertently reinforce biases or lead to discriminatory practices. The use of geospatial data and predictive models must be transparent and equitable to avoid potential negative consequences for affected populations.

Lastly, technology adoption poses a significant challenge. The successful implementation of SVM in GeoAI depends on the willingness of organizations and stakeholders to adopt and integrate advanced technologies into their workflows. This involves overcoming resistance to change, ensuring adequate training for users, and addressing concerns about the reliability and interpretability of AI-driven predictions. Effective communication and education about the benefits and limitations of SVM and GeoAI are essential for fostering broader acceptance and utilization of these advanced tools in spatial analysis and disease management. Recent challenge in implementing SVM in GeoAI is presented in Table IV.

B. Comparative Studies

Comparative studies in disease prediction often evaluate machine learning techniques like Support Vector Machines (SVM), Random Forest, and Neural Networks for forecasting dengue fever outbreaks. SVM is praised for handling high-dimensional data and creating optimal decision boundaries, though it may struggle with large datasets or complex patterns. Random Forest, an ensemble method, builds multiple decision trees and aggregates their predictions, improving robustness and managing large datasets effectively, especially with missing values and feature interactions. Neural Networks offer high flexibility and power, particularly deep learning models that capture intricate patterns within data. However, they require extensive data and computational resources, and their interpretability is lower than that of SVM and Random Forest.

TABLE IV. RECENT FINDINGS IN CHALLENGES OF IMPLEMENTING SVM IN GEOAI

Research Title and Author-Year	Main Findings
Performance Analysis of Support Vector Machine (SVM) on Challenging Datasets for Forest Fire Detection [50]	The paper analyzes the performance of SVMs for forest fire detection, including the challenges of high-dimensional datasets and the relationship between accuracy and image resolution.
GeoZ: a Region-Based Visualization of Clustering Algorithms [51]	GeoZ is a Python library that uses SVM to generate geographic clustering regions, addressing challenges with data availability and model complexity in GeoAI.
The challenges of integrating explainable artificial intelligence into GeoAI [52]	The paper discusses challenges in integrating explainable AI into geospatial AI, including data handling, geographic scale, and geosocial issues, rather than the specific challenges of implementing SVMs in GeoAI.

When predicting dengue fever, SVM offers precise predictions, particularly with smaller datasets and straightforward feature relationships. Random Forest is advantageous for its robustness against overfitting and its ability to handle both categorical and numerical data, making it suitable for diverse epidemiological datasets. Neural Networks can provide the highest accuracy by modeling complex non-linear relationships but come with increased computational demands and longer training times. Evaluating these techniques involves considering metrics such as accuracy, precision, recall, and computational efficiency, tailored to the specific requirements of dengue fever prediction. In the GeoAI context, SVM is strong in scenarios with clear data margins and where interpretability is key, but it faces challenges with parameter sensitivity and computational demands. Random Forests and Neural Networks also have distinct advantages, making them valuable complements to SVM for enhancing spatial prediction outcomes.

V. ANALYSIS AND DISCUSSION

A. Evaluation of Technological Advancements

Recent advancements in the use of Support Vector Machines (SVM) for spatial prediction within Geospatial Artificial Intelligence (GeoAI) have led to significant innovations. One major area of progress is the development of advanced kernel methods, such as the Radial Basis Function (RBF) and polynomial kernels, which allow SVM to handle non-linear relationships in geographic data more effectively. These kernels have greatly enhanced SVM's ability to model complex spatial patterns and interactions. Additionally, the integration of SVM with high-resolution geospatial data and real-time analytics has improved the precision of spatial predictions. With the increasing availability of detailed satellite imagery and sensor data, SVM models can now better capture spatial features, leading to more accurate predictions, such as in the mapping of land use changes and environmental conditions that influence disease spread.

Another key advancement is the development of hybrid models that combine SVM with other machine learning techniques, like ensemble methods or deep learning. These hybrid approaches leverage the strengths of multiple algorithms to improve predictive performance and address SVM's limitations, such as sensitivity to parameter settings and data dimensionality. For instance, combining SVM with Random Forest or Neural Networks enhances model robustness and allows for the handling of larger, more complex datasets. Additionally, advancements in computational technologies and software tools have facilitated the application of SVM in GeoAI, reducing training times and enabling its use with large-scale geospatial datasets. Improved software platforms have also made it easier to implement and optimize SVM models, expanding their use in spatial analysis and prediction.

B. Challenges and Potential Solutions

Implementing Support Vector Machines (SVM) in Geospatial Artificial Intelligence (GeoAI) presents several challenges, particularly regarding data quality and availability. Accurate SVM modeling depends on high-resolution, comprehensive geospatial data, which is often sparse or incomplete. To overcome this, enhanced data collection methods such as improved satellite imaging, sensor networks, and multi-source data integration can be utilized. Additionally, data augmentation techniques and synthetic data can help fill gaps, improving model performance and ensuring that SVMs have the necessary input for accurate predictions in spatial analysis.

Another significant challenge is the model's complexity and computational demands, especially with non-linear kernels. SVMs can be computationally intensive, requiring substantial processing power and memory. To address this, optimization techniques like dimensionality reduction, efficient kernel selection, and parallel computing are essential. For instance, Principal Component Analysis (PCA) can reduce feature numbers, making computations more manageable. Cloud-based computing resources and specialized hardware can also better handle large-scale computations. Furthermore, challenges related to parameter tuning and model interpretability can be addressed with automated hyperparameter optimization tools and advanced machine learning libraries, which help identify optimal settings. Enhancing interpretability through feature importance analysis and visualization tools is crucial for building trust in SVM predictions. Additionally, addressing regulatory and ethical concerns about data privacy and AI use is vital, requiring strict data privacy regulations, transparency, and ethical guidelines to ensure responsible AI applications in GeoAI. These solutions collectively enhance SVM's effectiveness in geospatial analysis.

C. Implications for Future Research

Future research in Support Vector Machines (SVM) and Geospatial Artificial Intelligence (GeoAI) holds substantial potential for innovation and technological advancement. One critical area for exploration is the development of advanced kernel functions. Research can focus on creating new kernels or refining existing ones to better capture the complexities of geospatial data, particularly spatial dependencies and relationships. This could significantly enhance the accuracy and interpretability of SVM models in GeoAI applications, making them more effective for tasks like disease prediction and environmental monitoring. Another promising direction is the integration of SVM with emerging machine learning techniques. Combining SVM with deep learning methods or ensemble approaches could improve predictive performance and address the limitations of each technique. For instance, hybrid models that leverage the strengths of both SVM and neural networks could offer breakthroughs in managing large-scale, high-dimensional spatial data.

Additionally, advancements in computational technology present opportunities to explore more complex SVM models, including real-time data processing and high-performance computing to handle large datasets more efficiently. Future research could also extend SVM applications to new domains like real-time environmental monitoring or dynamic urban planning. Addressing ethical and regulatory considerations is equally important, ensuring responsible use of these technologies in compliance with data protection regulations. Research into ethical AI practices, data privacy solutions, and transparent methodologies will be crucial for mitigating risks and building trust in SVM and GeoAI technologies, guiding the sustainable and responsible advancement of the field.

VI. Conclusion

A. Main Findings

The literature review highlights significant advancements and ongoing challenges in using Support Vector Machines (SVM) for Geospatial Artificial Intelligence (GeoAI) in dengue fever prediction. Key findings reveal that the development of advanced kernel methods, such as Radial Basis Function (RBF) and polynomial kernels, has significantly enhanced SVM's ability to model complex spatial patterns and interactions in geospatial data. Integration with high-resolution geospatial data and real-time analytics has improved the precision of predictions, making SVM a valuable tool for mapping land use changes and environmental conditions that influence disease spread.

However, the use of SVM in GeoAI faces notable challenges. Data quality and availability remain critical issues, as high-resolution and comprehensive geospatial data are often sparse or incomplete. The computational demands of SVM, especially with non-linear kernels, require substantial processing power and memory, necessitating optimization techniques and advanced computational resources. Additionally, parameter tuning, and model interpretability are complex and require advanced tools for effective implementation. In conclusion, while SVM holds substantial potential for improving dengue fever prediction through advanced kernel methods and integration with high-resolution data, addressing challenges related to data quality, computational demands, and model interpretability is essential for enhancing its effectiveness and efficiency in GeoAI applications.

B. *Recommendations*

For further research, it is crucial to explore advanced kernel methods and hybrid models that integrate SVM with emerging machine learning techniques to enhance predictive performance in GeoAI applications. Researchers should focus on improving data quality and availability through better data collection and augmentation techniques. For practical application development in public health, leveraging SVM in real-time data processing and high-resolution geospatial analytics can provide more accurate predictions for disease outbreaks. Additionally, addressing computational demands and improving model interpretability will be essential for effective implementation. Ensuring ethical and regulatory compliance is also vital for responsible AI use in public health.

Acknowledgment

All authors extend their gratitude to the Doctoral Program in Engineering Science at Universitas Sriwijaya and the Artificial Intelligence Research Development (AIRD) of the Department of Electrical Engineering at Politeknik Negeri Sriwijaya for their support of this research.

Multimedia Network Data Fusion System Integrating SSA and Reinforcement Learning

Fangrui Li
School of Applied Technology, Zhumadian Preschool Education College, Zhumadian 463000, China

***Abstract*—To improve the performance and efficiency of multimedia network data fusion system, this study proposes an improved sparrow search algorithm on the ground of reinforcement learning algorithm and sparrow search algorithm, and improves the multimedia network data fusion model on the ground of this algorithm. A performance comparison experiment was conducted on the improved sparrow search algorithm, and it was found that the algorithm entered a convergence state after 380 iterations in a unimodal function. Its time consumption is lower than other comparison algorithms, and it has not fallen into the local optimal situation after 500 iterations in the multimodal benchmark function. Its performance is significantly superior to other comparison algorithms. Moreover, the study conducted relevant experiments on the multimedia network data fusion model and found that the F1 value output by the model was 0.37, with an accuracy of 92.4%, which is higher than other data fusion models. And the mean square error of this model reaches 0.52, and the processing time is 0.1 seconds, which is lower than other comparative data fusion models. The quality of output data and data processing efficiency of this model are better. The relevant outcomes demonstrate that the improved sparrow search algorithm possesses good global search and convergence performance. And the improved multimedia network data fusion model has better accuracy and efficiency, and has good practical application value. This study can provide reference and reference for multimedia network data fusion systems.**

Keywords—Sparrow search algorithm; reinforcement learning; multimedia network; data fusion; performance improvement

I. Introduction

As the boost of the Internet and mobile communication technology, the generation and transmission of multimedia data are showing an explosive growth trend. These data include various forms such as images, audio, and video, which have had a huge impact on people's lives and work. However, they also pose new challenges to the efficient and fast transmission of data [1]. The multimedia network data fusion model (DFM) can integrate and analyze data from different media and sources, helping people obtain more comprehensive information and reducing unnecessary data consumption [2]. However, data from different media have different characteristics and expressions, and the scale of multimedia network data is enormous, posing great challenges to the efficiency of processing and analysis [3]. Sparrow Search Algorithm (SSA), as a heuristic search algorithm, can optimize feature selection and fusion in multimedia data fusion. Reinforcement learning algorithms can achieve adaptive adjustment of SSA parameters and select the best fusion strategy in multimedia data fusion. Although various data fusion algorithms have been proposed, such as Particle Swarm Optimization (PSO), Bat Algorithm (BA), and Adaptive Fusion Spanning Tree (AFST), these methods still have limitations in terms of real-time performance, accuracy, and global search capability. Especially in the context of the rapid growth of multimedia data and the diversification of data types, existing technologies are unable to meet the growing demand for data processing. In addition, there are few attempts in existing research to combine sparrow search algorithm with reinforcement learning algorithm to improve data fusion performance [4-5]. Therefore, this research proposes the construction of a multimedia network DFM that integrates SSA and reinforcement learning, and constructs a data fusion system on the ground of this to improve the effectiveness and performance of multimedia network data fusion. The core issue of the research is how to improve the performance and efficiency of the multimedia network data fusion system. The purpose of the research is to develop an efficient multimedia network data fusion system to address the challenges of the current surge in data volume and diversification of data types. To achieve this goal, a method combining SSA and reinforcement learning algorithms was proposed, and an improved Sparrow Search Algorithm (ISSA) was created. The research aims to improve the performance and efficiency of the ISSA algorithm in processing and analyzing large-scale multimedia data by integrating it into the multimedia network data fusion model. This not only includes improving the accuracy of data fusion, but also involves optimizing data processing speed to ensure that valuable information can be quickly and effectively extracted from large amounts of complex data. The relevance of the research is reflected in the following aspects: Firstly, with the widespread application of multimedia data in various fields such as social media, online education, remote healthcare, etc., the accuracy and efficiency of data fusion directly affect the quality of decision-making and user experience. Secondly, with the promotion of the Internet of Things and 5G technology, the amount of data will further increase, which puts higher demands on data fusion technology. Finally, the advancement of data fusion technology is of great significance for promoting technological innovation and industrial development in related fields.

The study first provides a brief overview of the current status of multimedia network data fusion technology, then clearly points out the limitations of the existing technology, and proposes improvement solutions. Through empirical experiments, the study has demonstrated the superior performance of improved algorithms and models in processing multimedia network data, including higher accuracy, faster processing speed, and better global search capability. These achievements not only address the challenges faced by existing technologies, but also provide new directions for the development of multimedia network data fusion.

II. Related Work

As the boost of science and technology, optimization algorithms is widely applied in various fields. To select the optimal parameters for proton exchange membrane fuel cell stacks and improve their performance, Zhu et al. proposed an adaptive sparrow search algorithm and applied it to parameter identification. Then, the study conducted performance verification experiments on this method and found that the adaptive sparrow search algorithm can reduce the square error of the battery stack voltage, and the computational efficiency of this algorithm was better than other algorithms [6]. In response to the issue of insufficient accuracy in predicting rubber fatigue life, Wang et al. proposed an optimized rubber life prediction model on the ground of an ISSA to verify its effectiveness. The validation results found that the model has better prediction accuracy, convergence speed, and stability performance than traditional models [7]. To solve the problem of neglecting indicator weights in the dynamic priority scheduling algorithm of the power system, Meng et al. proposed an improved dynamic priority scheduling algorithm on the ground of improved reinforcement learning and verified its performance. The relevant results found that the improved algorithm has a faster learning speed compared to traditional algorithms, and it also achieved optimization of weight parameters, reducing scheduling costs [8]. To achieve observability and ease of operation of calibration parameters, Nobre et al. proposed a calibration assistance model on the ground of reinforcement learning and conducted empirical experiments on the model. The relevant results found that the model is applicable to positioning and drawing on multiple platforms, and has lower requirements for professional operations compared to traditional models [9].

The progress of science and technology has also brought about explosive growth in data, and there is currently an increasing amount of research on data fusion. For enhancing the accuracy and robustness of the integrated navigation system, Mai et al. presented a multi-source collaborative positioning system on the ground of an adaptive Kalman filter and conducted performance simulation experiments on the system. The relevant outcomes showcased that the navigation and positioning performance was markedly enhanced compared to traditional fonts [10]. To achieve the static gesture recognition function of Kinect camera depth maps, Sharma et al. proposed feature extraction and data fusion on the ground of static gesture datasets, constructed a gesture recognition model, and validated the model. The relevant outcomes showcased that the recognition accuracy of this model can reach 95.7%, which possesses the value in practical application [11]. For the difficulty in reconstructing the pseudo static displacement of the low-frequency part of the moving load, W et al. proposed a pseudo static displacement reconstruction model on the ground of acceleration and response data fusion to verify its effectiveness. The relevant results found that this model can improve the accuracy and accuracy of the reconstruction results compared to traditional models [12]. To address the occurrence of tilt events in the Linz Donawitz steelmaking converter, De et al. proposed a tilt event warning model on the ground of sensor data fusion technology to verify its effectiveness. The relevant results found that the model can improve alarm accuracy and improve the reliability of the anti collapse system [13].

In summary, research on data fusion is becoming increasingly mature. However, there is still limited research on improving the SSA using reinforcement learning algorithms and combining this optimization algorithm with a multimedia network DFM to construct a multimedia network DFM for SSA and reinforcement learning. Therefore, this study constructs a multimedia network DFM on the ground of SSA and reinforcement learning to efficiently handle data fusion problems in multimedia networks and improve the accuracy of data fusion.

III. Construction of a DFM Integrating SSA and Reinforcement Learning

To facilitate the normal transportation of multimedia network data faster and more efficiently, and to efficiently process multimedia network data, this study constructs the ISSA on the ground of SSA and reinforcement learning algorithm. Then it applies the algorithm to the multimedia network DFM to improve its data fusion quality and data processing efficiency.

A. SSA Algorithm on the Ground of Reinforcement Learning Optimization

At present, multimedia network DFMs often suffer from inaccurate information fusion and slow processing speed when dealing with large-scale unstructured or nonlinear data. This study proposes to integrate sparrow search algorithm with reinforcement learning algorithm to construct an ISSA on the ground of reinforcement learning algorithm, thereby improving the processing speed of multimedia network data models. SSA, as a swarm intelligence optimization algorithm on the ground of sparrow food search behavior, has good applicability in solving complex nonlinear optimization problems [14-16]. The process of SSA is shown in Fig. 1.

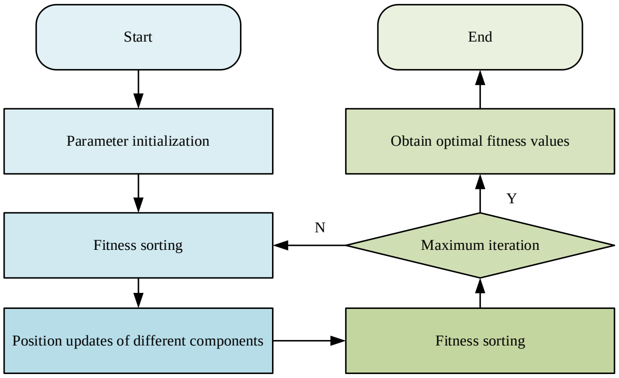

Fig. 1. Flow of the SSA.

As shown in Fig. 1, firstly, the SSA sets parameters like the size, maximum of iterations, and producer ratio of the sparrow population, and initializes the sparrow population. Subsequently, the SSA calculates the fitness values of all sparrows in the population and sorts their fitness values in order of size. The formula for calculating the fitness matrix of sparrows is shown in (1).

$$\begin{cases} \mathbf{F_X} = \left[\mathbf{f(X_1),f(X_2),\ldots,f(X_N)}\right] \\ \mathbf{f(X_i)} = \left[f(x_{i,1}), f(x_{i,2}),\mathrm{K}, f(x_{i,d}) \right] \\ \mathbf{X} = \left[\mathbf{X_1},\mathbf{X_2},\ldots,\mathbf{X_N}\right], \mathbf{X_i} = \left[x_{i,1}, x_{i,2},\mathrm{L}\ , x_{i,d}\right] (i=1,2,\mathrm{L}\ N) \end{cases} \tag{1}$$

In Eq. (1), x represents sparrow. $\mathbf{F_X}$ represents the vector matrix of sparrow fitness values. $\mathbf{X}$ represents the vector matrix of sparrows. $\mathbf{X_i}$ represents the row vector of sparrow position. $\mathbf{f(X_i)}$ represents the fitness value of sparrows. N serves as the population size of sparrows. d represents the dimension of the variable. The SSA sorts the fitness values on the ground of the fitness matrix to determine the individuals with the best and worst fitness values. Individuals with high fitness values become producers in the population, responsible for searching for areas and directions for the population. Their relevant formula is shown in Eq. (2).

$$X_{i,j}(t+1) = \begin{cases} X_{i,j}(t)\cdot \exp\left(\dfrac{-i}{\alpha\cdot T}\right), W < ST \\ X_{i,j}(t) + N_{rand}\cdot L, W \ge ST, L = 1\times d \end{cases} \tag{2}$$

In Eq. (2), t serves as the quantity iterations. α serves as a random number, located between [0,1]. W serves as the warning value. ST serves as the safety value, located between [0.5,1]. N_{rand} represents a normally distributed random number. L represents the dimension matrix. The calculation formula for the accompanying position update is illustrated in Eq. (3).

$$X_{i,j}(t+1) = \begin{cases} N_{rand}\cdot \exp\left(\dfrac{X_{worst}(t) - X_{ij}(t)}{i^2}\right), i > \dfrac{N}{2} \\ X_{bestj}(t) + \left|X_{ij}(t) - X_{bestj}(t+1)\right|\cdot A^{+}\cdot L, i \le \dfrac{N}{2} \\ A^{+} = A^{T}\left(AA^{T}\right)^{-1}, A = 1\times d \end{cases} \tag{3}$$

In Eq. (3), X_{worst} represents the worst-case position. X_{bestj} represents the optimal position. A is a matrix, with an initial value typically of 1 or -1. A^T is the transposition of A. The relevant formula is shown in Eq. (4).

$$X_{i,j}(t+1) = \begin{cases} X_{bestj}(t) + \beta\cdot\left|X_{i,j}(t) - X_{bestj}(t)\right|, f_i > f_g \\ X_{i,j}(t) + K\left(\dfrac{\left|X_{i,j}(t) - X_{worstj}(t)\right|}{(f_i - f_w) + \varepsilon}\right), f_i = f_g, K \in [-1,1] \end{cases} \tag{4}$$

In Eq. (4), ε is a constant. $X_{bestj}(t)$ serves as the optimal position. β represents the step size control parameter, f_g serves as the best fitness. f_w represents the worst fit. After updating the relevant position, it counts and sorts the individual fitness values again until the iterations' maximum is achieved. According to the SSA calculation principle, the SSA mainly improves search performance through information exchange between individuals, and is prone to falling into local optima. The Q-learning algorithm, as a reinforcement learning algorithm, has good applicability, convergence, and generalization ability in discrete space problems. Applying Q-learning algorithm to SSA can improve the optimal search strategy of SSA, improve its convergence speed, and achieve adaptive parameter adjustment of SSA. The basic principle of the Q-learning algorithm is showcased in Fig. 2.

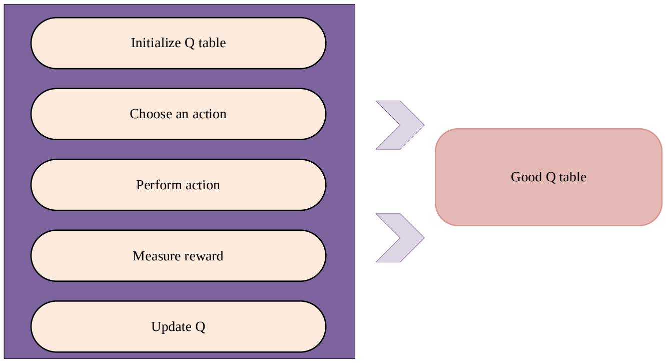

Fig. 2. Q. Basic principle of the learning algorithm.

Fig. 2 showcases that the Q-learning algorithm can use a value function to calculate the cumulative reward for adopting an action strategy in a certain state. The relevant calculation is shown in Eq. (5).

$$V_\pi(s) = E_\pi\left[R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + \mathrm{K}\ \middle|\ s_t = s\right] \tag{5}$$

In Eq. (5), R represents the reward value. γ represents the discount factor. V represents the state function. γ represents the state. π represents the action strategy. The reinforcement learning is for finding the optimal strategy to maximize the state function. The relevant calculation is demonstrated in Eq. (6).

$$V_{\pi^*}(s) = \max_{\pi} V_\pi(s) \tag{6}$$

In Eq. (6), π^* represents the optimal strategy. The Q-learning algorithm can define the state action value as a function $Q_\pi(s,a)$. It represents the accumulated discount reward obtained when adopting a strategy. The calculation formula is shown in Eq. (7).

$$Q_\pi(s,a) = E_\pi\left[R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + \mathrm{K}\ \middle|\ s_t = s, a = a_t\right] \tag{7}$$

In Eq. (7), a represents a specific action. At this point, the relevant calculation is showcased in Eq. (8).

$$V_{\pi^*}(s) = \max_{\pi} Q_{\pi^*}(s,a) \tag{8}$$

The update formula for the Q-value function is shown in Eq. (9).

$$Q(s,a) \leftarrow Q(s,a) + \partial(r + \gamma \max_{a'} Q(s',a') - Q(s,a)) \tag{9}$$

In Eq. (9), ∂ represents the Q learning rate. r represents the current reward. s' represents the state of the next decision. s' represents the action of the next decision. $\max_{a'} Q(s',a')$ serves as the maximum cumulative reward value after updating the status. In addition, this study also utilizes a random walk strategy for enhancing the SSA and avoiding local optima. The calculation formula for the random walk process is shown in Eq. (10).

$$\begin{cases} X(t_{\max}) = \left[0, cussum(2k(t_1)-1), \mathrm{K}\ , cussum(2k(t_n)-1)\right] \\ k(t) = \begin{cases} 1, rand > 0 \\ 0, rand < 0 \end{cases} \end{cases} \tag{10}$$

In Eq. (10), $t_{\max}$ serves as the maximum of iterations. $cussum$ serves as the cumulative sum. k serves as a random function. In addition, to ensure that the population walking area in the sparrow algorithm is within the feasible range, the calculation formula for sparrow position update is shown in Eq. (11).

$$X_i(t) = \frac{\left(X_i(t) - X_{\min}\right) * \left(X_{\max}'(t) - X_{\min}'(t)\right)}{\left(X_{\max} - X_{\min}\right)} + X_{\min}'(t) \tag{11}$$

In Eq. (11), $X_{\max}$ serves as the maximum value. $X_{\min}$ serves as the minimum. $X_{\max}'(t)$ serves as the maximum as the iterations is t. $X_{\min}'(t)$ serves as the minimum as the iterations is t. This study utilizes Q-learning algorithm to improve the SSA, so that the SSA will decide the next action on the ground of the current state and reward signal. If an action leads to a better state and reward signal, it will repeat the action in the future when encountering similar states, otherwise avoid the action. The optimized SSA process is shown in Fig. 3.

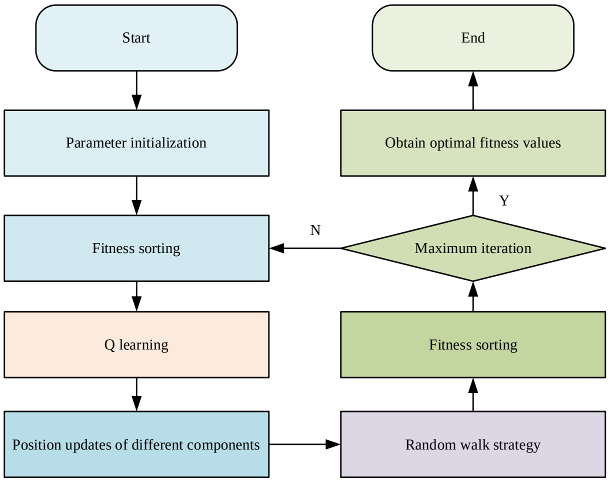

Fig. 3. The ISSA flow.

As shown in Fig. 3, this study first sets the parameters of the sparrow algorithm, defines the search direction as spatial actions, defines fitness as a reward function, and initializes the population and Q table. Subsequently, it enters the search process and calculates the fitness value of the sparrow population. During the search, the algorithm will select an action on the ground of the current state and Q table, and execute this action. The Q-learning algorithm updates the Q-table on the ground of the status and reward values after executing the action. When the Q value in the Q table converges, a random walk strategy is added for updating the global optimal position and improve its search ability. After obtaining the updated sparrow population position, it sorts the fitness values again. If a population with a higher fitness value appears after the update, it updates the optimal solution. Otherwise, it maintains its current optimal solution until reaching the maximum number of iterations.

B. Improved Multimedia Network DFM on the Ground of the ISSA

Data fusion technology is a technology that fuses or integrates data from different sources, types, and features, enabling comprehensive display of information to users. To ensure the fusion quality of multimedia network data, the quality of collected data and the selection of fusion technology are clearly key breakthroughs. Therefore, to achieve high accuracy and reliability of multimedia network data, this study utilizes multimedia sensor networks to construct a multi-layer DFM. Multi layer network data sensor network can improve the accuracy, real-time and data coverage of its collected data by collecting multimedia data from various sensor nodes [17], [18]. The basic structure of the relevant model is shown in Fig. 4.

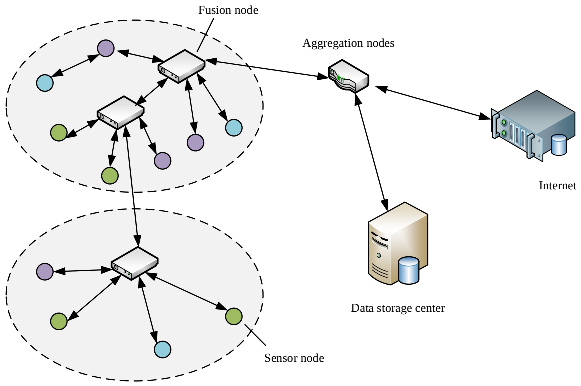

Fig. 4. Multi-layer DFM.

Fig. 4 demonstrates that for different types of multimedia network data, this study constructs different types of multimedia sensor networks on the ground of their data types, and assigns corresponding collection tasks to each layer of sensor network. Different layers of sensor networks send their collected data to the aggregation node by the fusion node. To ensure the coverage area of collected data, this study selected a DFM on the ground of multi-layer sensor networks. However, due to the variety of sensors, the amount of data collected is large, and the network data collected on the ground of sensor networks is prone to high data correlation, which leads to the problem of redundant data. Therefore, this study utilizes a clustering network on the ground of data difference to improve the DFM, to eliminate redundant network data and reduce unnecessary network data consumption. The principle of a clustering network DFM on the ground of data difference is shown in Fig. 5.

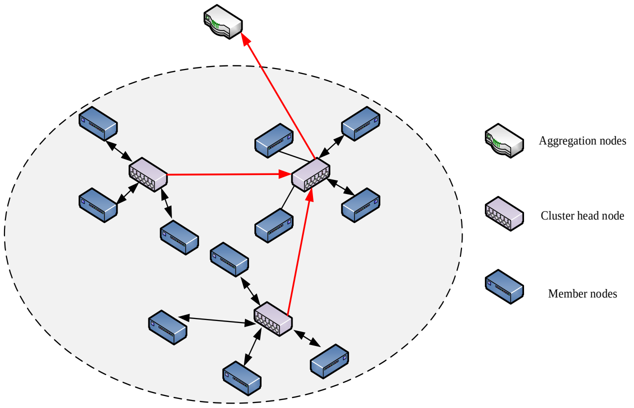

Fig. 5. Principle of the DFM on the ground of the topology of the cluster network.

Fig. 5 showcases that the DFM on the ground of clustering network topology divides the collection nodes in the sensor network into ordinary member nodes, cluster head nodes (CHN), and aggregation nodes. Firstly, this study calculates the difference in data collected by several sensor nodes and classifies them according to the difference threshold. The data difference matrix is shown in Eq. (12).

$$\delta_{nn} = \begin{bmatrix} 0, \delta_{12}, \delta_{13}, \mathrm{K}\ , \delta_{1n} \\ \delta_{21}, 0, \delta_{23}, \mathrm{K}\ , \delta_{2n} \\ \mathrm{L} \\ \delta_{n2}, \delta_{n2}, \delta_{n3}, \mathrm{K}\ , 0 \end{bmatrix} \tag{12}$$

In Eq. (12), the diagonals of the difference matrix are all 0. The difference between nodes not calculated is set to 1. Subsequently, the model performs cluster head elections on data from different categories. The selected cluster head can allocate its Time Division Multiple Access (TDMA) time slot to the ordinary member nodes within its corresponding cluster. Ordinary member checkpoints will periodically transmit collected data to CHN in terms of the allocated TDMA time slot. After completing a data collection, it calculates the remaining energy of the cluster head. If the remaining energy of the CHN is higher than or equal to the set energy threshold, then the node still serves as the CHN. Otherwise, it will reselect the CHN. After achieving the elimination of duplicate data in the fusion model, this study applies the constructed the ISSA to the DFM for enhancing its accuracy and processing speed. The DFM on the ground of the ISSA and clustering algorithm is shown in Fig. 6.

Fig. 6 demonstrates that the DFM includes five modules: preparation, data preprocessing, data training, data integration, and data processing. Firstly, this study deploys multiple multimedia sensors to capture and collect various audio and image multimedia data. Subsequently, the study used clustering algorithms to group nodes in wireless sensor networks, using indicators such as data similarity to achieve more efficient and accurate data processing and management. The third module is data training, which trains the ISSA on the ground of clustering algorithm to achieve adaptive search of the ISSA. The ISSA uses the data of each cluster as the search space, initializes the position of each sparrow individual as a data point in the cluster, and uses the ISSA to search for the optimal cluster head, improving its computational speed and performance. The fourth module is data integration, where the clustering algorithm merges, processes, and analyzes the data of the fused nodes to obtain more comprehensive and accurate data. Finally, this study utilizes data mining algorithms to analyze the integrated multimedia network data, extract valuable information from the data, and perform data visualization and reporting operations.

IV. Empirical Experiment on Multimedia Network DFM

For testing the ISSA and multimedia network DFM, performance comparison experiments and empirical analysis are conducted on them. This study first uses benchmark functions to conduct performance comparison tests on the optimization performance of the ISSA, and then conducts empirical experiments on the multimedia network DFM using the ImageNet dataset.

A. *Performance Verification Experiment of SSA Algorithm*

For testing the optimization of the ISSA, this study utilizes the PENALIZED benchmark function to verify its optimization performance, and compares its convergence performance with the single peak function Rosenbrock and the multi peak benchmark function Ackley. The minimum value of the PENALIZED benchmark function is 0. The comparison algorithms are SSA, Particle Swarm Optimization (PSO), and Bat Algorithm (BA). The comparison index is the average of the benchmark function, as well as the convergence curves of unimodal and multimodal functions. The experimental environment is Windows 10 and MATLAB 2018. The relevant comparing results in the PENALIZED benchmark function are shown in Fig. 7.

Fig. 7(a) shows the comparison results of the average values of the functions of various optimization algorithms. As shown in Fig. 7(a), the ISSA found the optimal value on the function PENALIZED, and relative to other comparative algorithms, the optimal value obtained is more approximate to the actual optimal solution, infinitely approaching the optimal solution, and its local search ability is more excellent. Fig. 7(b) showcases the comparison outcomes of the standard deviation of function values for each optimization algorithm. As shown in Fig. 7(b), the ISSA has a smaller standard deviation compared to other comparative algorithms, higher solving accuracy, and better stability. The relevant outcomes demonstrate that the ISSA possesses better local search ability and reliable performance, which makes it obtain the optimal solution possibly. The relevant convergence curves of each optimization algorithm are shown in Fig. 8.

Fig. 8(a) and (b) show the three-dimensional images of the Rosenbrock reference function and the optimization convergence curves of each algorithm, respectively. Fig. 8 indicates that the ISSA enters a convergence state when the number of iterations is 380, and its convergence performance is much higher than other comparison algorithms, and the convergence curve of the ISSA is steeper than other algorithms. This demonstrates that the ISSA can first search for the optimal value. The relevant outcomes demonstrate that the ISSA has better local search performance. The convergence curves of each optimization algorithm in the Ackley benchmark function are shown in Fig. 9.

Fig. 9(a) and (b) show the three-dimensional images of the Ackley reference function and the optimization convergence curves of each algorithm, respectively. As shown in Fig. 8, SSA, PSO, and BA algorithms fell into local optima at 450, 350, and 320 iterations, respectively, while the ISSA did not fall into local optima at 500 iterations, and its search ability in multimodal functions was better. The relevant outcomes demonstrate that the ISSA has better global search performance than other algorithms.

B. *Empirical Experiment on Multimedia Network DFM*

To validate the effectiveness of the multimedia network DFM, a performance comparison experiment was conducted using the ImageNet dataset. This dataset contains multimedia network data such as images and audio. The comparison models are data fusion methods on the ground of Adaptive Fusion Steiner Tree (AFST), image correlation based data fusion methods, and distributed compression based data fusion methods. The performance comparison indicators are the Peak signal-to-noise ratio (PSNR), mean square error (MSE), Precision Recall (PR) curve, F1 value, accuracy, and running speed of the fused image. The experimental environment is Windows 10 and the development language is Jupyter Notebook. The PSNR and MSE comparison of each DFM are showcased in Fig. 10.

Fig. 10(a) shows the PSNR comparison results of various DFM. Fig. 10(a) showcases that the PSNR value of the proposed DFM is higher than other comparison models, with an average PSNR value of 37.5dB, which is 4.8dB higher than the ASFT DFM and has higher transmission image quality. Fig. 9(b) shows the comparison results of the MSE of each DFM, as shown in Fig. 10(b). The MSE curve of the proposed DFM is generally lower than other comparison models, with a MSE of 0.52, which is 0.19 smaller than the ASFT DFM. On the ground of the above results, it can be concluded that the proposed DFM has better output data quality and reliability. The PR curve and F1 value comparison are shown in Fig. 11.

Fig. 11(a) showcases the accuracy recall curves of each DFM, as shown in Fig. 11(a). The PR curve offline area of the proposed data fusion method is 0.83, the PR curve offline area of the DFM on the ground of image difference is 0.76, the PR curve offline area of the ASFT based DFM is 0.71, and the PR curve offline area of the distributed compression based DFM is 0.67. The DFM possesses a larger offline area of the PR curve and better performance. Fig. 11(b) showcases the comparison results of F1 values for various DFM. As shown in Fig. 11(b), the F1 value of the proposed data fusion method is 0.37, which is 0.05 higher than the F1 value of the ASFT based DFM, and exceeding the F1 value of other data models, resulting in better performance. The relevant outcomes demonstrate that the DFM has higher offline area and F1 value of the PR curve compared to other algorithms, and the model performance is better. The comparison results of data fusion accuracy and data processing time of each DFM are shown in Fig. 12.

Fig. 12(a) shows the accuracy comparison results of various DFMs. As shown in Fig. 12(a), the accuracy of the data fusion method is 92.4%, which is 13.6% higher than the image difference DFM, 10.1% higher than the distributed compressed DFM, and 7.5% higher than the ASFT DFM. The DFM possesses better data fusion accuracy. Fig. 12(b) showcases the comparison results of data processing time for each DFM, as showcased in Fig. 12(b). The proposed data fusion method has a processing time of 0.1 seconds, which is 0.08 seconds faster than the image difference DFM, 0.04 seconds faster than the distributed compression DFM, and 0.03 seconds faster than the ASFT DFM. Its data processing speed is faster. The relevant outcomes demonstrate that the DFM proposed in the study not only has higher accuracy in data fusion, but also has better data processing efficiency. The comparison of ISSA with other algorithms in key performance indicators is shown in Table I.

As shown in Table I, the improved sparrow search algorithm (ISSA) proposed in this study exhibits significant performance advantages in the multimedia network data fusion system. Specifically, ISSA leads in data fusion efficiency with a processing time of 0.10 seconds, compared to Particle Swarm Optimization (PSO)'s 0.35 seconds, Bat Algorithm (BA)'s 0.28 seconds, and Adaptive Fusion Spanning Tree (AFST)'s 0.42 seconds. In terms of accuracy, ISSA reached 92.43%, surpassing PSO's 85.67%, BA's 87.21%, and AFST's 90.15%. In terms of convergence speed, ISSA can converge after 380 iterations, showing faster convergence compared to PSO's 450 iterations, BA's 500 iterations, AFST's 480 iterations, as well as Grey Wolf Optimization (GSA) and Artificial Bee Colony Algorithm (ALO)'s 550 and 420 iterations. In addition, ISSA ranks first with a score of 8.95 in the global search capability score, further demonstrating its strong ability to avoid local optima and find global optima. The performance comparison between ISSA and traditional methods is shown in Table II.

TABLE I. COMPARISON OF MULTIMEDIA NETWORK DATA FUSION MODELS

Model/Algorithm Name	Data Fusion Efficiency (s)	Accuracy (%)	Convergence Speed (Number of Iterations)	Global Search Capability Score (1-10)
ISSA (Proposed in this study)	0.10	92.43	380	8.95
PSO (Particle Swarm Optimization)	0.35	85.67	450	6.87
BA (Bat Algorithm)	0.28	87.21	500	7.12
AFST (Adaptive Fusion Steiner Tree)	0.42	90.15	480	7.56
GSA (Grey Wolf Optimizer)	0.56	88.53	550	5.98
ALO (Artificial Bee Colony Algorithm)	0.29	89.34	420	7.43

TABLE II. PERFORMANCE COMPARISON BETWEEN ISSA AND TRADITIONAL METHODS

Application Scenario	Task Description	Index	ISSA Performance Metrics	Traditional Method Performance Metrics	Performance Improvement
Video Surveillance Analysis	Real-time activity analysis in surveillance video to detect anomalies	Accuracy	94.56%	89.12%	5.44%
		Response Time	0.25 seconds	0.45 seconds	0.20 seconds
Social Media Content Filtering	Filtering harmful content on social media platforms	Accuracy	93.21%	88.47%	4.74%
		Processing Speed	150 posts/sec	90 posts/sec	60 posts/sec
Medical Image Analysis	Assisted diagnosis to identify abnormal areas in medical imagery	Accuracy	92.78%	87.34%	5.44%
		Analysis Time	0.30 seconds per image	0.60 seconds per image	0.30 seconds
Traffic Flow Management	Real-time traffic flow analysis for optimizing traffic signal control	Optimization Efficiency	95.23%	90.48%	4.75%
		Calculation Time	0.15 seconds per cycle	0.35 seconds per cycle	0.20 seconds per cycle
Environmental Monitoring	Monitoring environmental data to predict pollution events	Prediction Accuracy	91.56%	86.23%	5.33%
		Update Frequency	Every 5 minutes	Every 10 minutes	Doubled

As shown in Table II, ISSA achieved a detection accuracy of 94.56% in video surveillance analysis, with a response time of 0.25 seconds. Compared with the traditional method's accuracy of 89.12% and response time of 0.45 seconds, it shows a 5.44% improvement in accuracy and a 0.20 second reduction in response time. In the social media content filtering task, ISSA achieved a filtering accuracy of 93.21% and a processing speed of 150 posts per second. Compared to the traditional method's accuracy of 88.47% and processing speed of 90 posts per second, ISSA improved accuracy by 4.74% and processing speed by 60 posts per second. In the field of medical image analysis, ISSA has a recognition accuracy of 92.78% and an analysis time of 0.30 seconds per image, while traditional methods have a recognition accuracy of 87.34% and an analysis time of 0.60 seconds per image. ISSA has improved accuracy by 5.44% and reduced analysis time by 0.30 seconds. In traffic flow management, the optimization efficiency of ISSA is 95.23%, with a calculation time of 0.15 seconds per cycle. Compared with the traditional method's 90.48% optimization efficiency and 0.35 seconds calculation time, the efficiency has increased by 4.75%, and the calculation time has been reduced by 0.20 seconds per cycle. In environmental monitoring, the prediction accuracy of ISSA is 91.56%, with an update frequency of every 5 minutes, while the prediction accuracy of traditional methods is 86.23%, with an update frequency of every 10 minutes. ISSA has improved accuracy by 5.33% and doubled the update frequency.

V. Conclusion

With the continuous progress of science and technology, the current multimedia network data fusion system is no longer able to satisfy the requirements of today's society. For the problem of insufficient quality and efficiency in traditional multimedia network data fusion systems, this study proposes to construct an ISSA on the ground of reinforcement learning algorithm and SSA, and combines this algorithm with cluster algorithms to construct a multimedia network DFM. The study conducted empirical experiments on the ISSA and multimedia network DFM, and found that in the unimodal function benchmark test, the ISSA required 380 iterations to enter the convergence state, which is lower than other comparative algorithms. However, in the multimodal benchmark function, the ISSA still did not fall into the local optimal situation at 500 iterations. In addition, in the empirical experiment of the multimedia network DFM, it was found that the PRNS value of the output image data of the model was 37.5dB, with a MSE of 0.52. The area under the PR curve is 0.83, the F1 value is 0.37, the accuracy is 92.4%, and the processing time is 0.1s. Its output data quality and data processing efficiency are better than other comparative models. Based on the above results, it can be concluded that the proposed ISSA exhibits significant advantages in data fusion efficiency, accuracy, convergence speed, and global search capability compared to traditional methods in the field of multimedia network data fusion. The high efficiency of ISSA is particularly suitable for real-time application scenarios such as video surveillance analysis and social media content filtering that require quick response. Its high accuracy is crucial for high-precision fields such as medical imaging analysis, as it can provide reliable data analysis results to support clinical decision-making. In addition, ISSA has demonstrated rapid convergence and powerful global search capabilities in complex optimization problems such as traffic flow management and environmental monitoring that require quick adaptation to changes and finding optimal solutions. Although this study mainly focuses on algorithm development and evaluation, the excellent performance of ISSA lays the foundation for its deployment in practical applications. However, this study still has certain limitations, as it did not consider the energy consumption cost of data fusion in practical applications. Future research directions could apply the ISSA algorithm to geological data analysis to improve the exploration efficiency of underground resources such as minerals, oil, and natural gas. By processing and analyzing a large amount of exploration data such as seismic, geological, and geochemical data, the ISSA algorithm is expected to optimize the accuracy and speed of resource localization. Meanwhile, in the field of environmental science, ISSA algorithm can be used to analyze remote sensing data, monitor environmental changes such as deforestation, urban expansion, and climate change. Its efficient data processing capability helps to quickly identify and respond to environmental issues.

Application of U-Net Network Algorithm in Electronic Information Field

Liang Wang*
School of Electrical Engineering, Hunan Mechanical and Electrical Polytechnic, Changsha, Hunan 410151, China

***Abstract*—This rapidly evolving landscape, which includes the field of medical diagnostics, has integrated with the electronic data (E-Data) field to provide precise and efficient treatment for complex medical conditions. The research field has further catapulted its reach to include various data types, including image, video, medical expert diagnostic type, and sensor input, out of which the image-based diagnostic model has excellent research potential. Convolutional Neural Network (CNN) based models have evolved into better Deep Learning (DL) models for handling complex intricacies featured in the input image. U-Net is a prominent CNN model developed to handle the features of image data. The U-Net excels in capturing detailed features through its encoder-decoder structure and skip connections, but its uniform weighting across different network layers may not adequately address the subtleties involved in complex medical anomaly detection. This work proposed the Attention Calibrated U-Net (ACU-Net) model that is designed to address the challenges of U-Net in detecting Fetal Cardiac Rhabdomyoma (FCR) from echocardiographic (ECG) images. FCR is a prevalent benign cardiac tumor in fetuses that poses significant diagnostic challenges due to its variable manifestations and the intricate nature of fetal cardiac anatomy. The proposed model enhances the U-Net architecture with attention mechanisms and employs a hybrid Loss Function (LF) that combines Cross-Entropy Loss, Dice Loss, and an attention-driven component for effective FCR detection. The model was compared against others and demonstrated better specificity, accuracy, precision, recall, and F1-score performance across various ECG views (LVOT, RVOT, 3VT, and 4CH).**

Keywords*—*U-Net; attention calibrated U-Net; convolutional neural network; deep learning; digital data; accuracy

I. Introduction

The advent and the development of modern technologies have generated a considerable quantity of electronic data (E-Data), and using this data, transformative developments were made across various domains. Within these various domains, the field of medical diagnostics has experienced profound advancements by developing technologies that work by processing the E-Data [1-5]. The proliferation of E-Data has led to the development of advanced models in the medical field, which analyse and interpret vast amounts of data to enhance diagnostic accuracy, treatment efficacy, and patient outcomes. Digital imaging data processing and storage analysis tools have developed as an outcome of these advances in technology, which enable improved care for patients, earlier disease detection, and more specific therapy approaches. Recent advances in science have had an essential effect on the ability to detect and analyse foetal cardiac rhabdomyoma (FCR) by employing echocardiographic (ECG) data. The unique model of the fetal heart and the recognition that FCR may develop into numerous forms—including benign tumours—make it highly challenging to diagnose this medical disorder, which impacts both the developing baby and the mother during pregnancy [6-10].

In the past few years, cutting-edge Deep Learning (DL) algorithms have become available as possible resources to assist with testing E-Data evaluation and analysis. Convolutional Neural Networks (CNNs) are the most common DL model used for imaging in medical diagnostics because they are superior to different models in image recognition and evaluation tasks [11-15]. Their ability to learn hierarchical feature representations from vast datasets has made them the better model for the task of detection and classification of medical conditions directly from imaging data. Out of different image modalities, the CNN outperformed FCR detection when trained using ECG images [16-20]. By analyzing the subtle patterns and textures found in the patterns of the ECG data, the existing CNN works to identify the markers that are indicative of FCR. The U-Net performed better in medical image segmentation tasks among the various CNNs. Initially, the U-Net model was designed for biomedical image segmentation; using its unique architecture efficiently captures context data from the image at various scales and has proven to be an efficient model that is particularly adept at delineating the boundaries of complex objects like FCR tumours within the heart.

However, when considering the application of U-Net in the task of FCR detection, the U-Net model has its challenges. While the U-Net model has proven its efficiency by excelling in capturing the detailed features through its encoder-decoder structure and skip connections, it has its limitations in the form of its uniform weighting across different layers of the network, which adherently may not address the subtleties that are involved in FCR detection [21-25]. It also highlights the requirement for more conceptual refinement within the U-Net model. Optimising the specificity and accuracy of recognising FCR from ECG data can be accomplished via invention, which can take the form of combining attention mechanisms or inventing hybrid loss functions. A revised version of the standard U-Net architecture, the Attention Calibrated U-Net (ACU-Net), is recommended as an innovative method for detecting FCR in ECG data in the present investigation. In order to ensure an improved segmentation of FCR from the cardiac history, the designed ACU-Net model improves the U-Net with attention mechanisms to refine the segmentation process. The result is done by selectively emphasising locations that are significant within the ECG data. An attention-driven component, Cross-Entropy Loss, and Dice Loss are all included

*Corresponding Author.

in the proposed approach's hybrid Loss Function (LF), which attempts to enhance performance by rendering segmentation results accuracy improvements. Using the sourced ECG dataset comprising both FCR and normal conditions, the work performed comprehensive testing across numerous ECG views of the image that include LVOT, RVOT, 3VT and 4CH views, and the experiment results have demonstrated that the proposed model has superior performance in terms of accuracy, precision, and recall metrics compared to existing models.

The paper was organized in the following approach: The summary of the literature will be discussed in Section II, the background research will be provided in Section III, the recommended approach will be provided in Section IV, the result analysis will be done in Section V, and the work is concluded in Section VI.

II. Literature Review

The review work by [26-30] mostly covered the details and the efficacy of U-Net architecture, and their work also presented a discussion about the advancements and recent trends in U-Net. Their work has focused on the U-Nets' contributions to the field of Deep Learning (DL) and its various applications using different image modalities. A novel design, UNet++ [31], has been developed as an enhancement over U-Net. It supports more robust monitoring and improved neglect trails to reduce the semantic gap between the encoder and decoder sub-networks, among additional features. The segmentation performance in different healthcare imaging tasks has been improved due to the advances introduced during this study when compared with the standard U-Net model. This upgraded U-Net model, using an entirely novel Attention Gate (AG) model, was developed as an outcome of the research they conducted [33-38]. Attention U-Net is an acronym for the fresh design that they presented in their research, and it uses novel AGs to avoid U-Net connections. By adequately focusing on the targets while simultaneously reducing irrelevant regions, the new approach has been advantageous and demonstrated effectiveness in terms of enhanced model sensitivity and prediction accuracy. It had been predicted that the proposed algorithm would succeed appropriately on healthcare imaging multi-class image segmentation tasks without substantially increasing computational cost.

In an attempt to segment images of diseases of plants in their leaves, their [39-45] work attempted to change the standard U-Net. Enhancing the network's depth and descriptive capacity was their ultimate objective when implementing the change, which included implementing the remaining segments and paths. The difficult task of segmenting images of diseased leaves, which frequently feature shapes that are distorted and fuzzy boundaries, motivated the invention of the technique as mentioned above. Also, in order to accurately recognise the differences in lakeside edges that were investigated using the data from remote sensing as input from the user, [46-50] employed a U-Net-based algorithm concerning a Spatial Transformation Network (STN) algorithm to do the task at hand. Tests have demonstrated that their approach and the integrated U-Net model are superior to other models in tracking the environment and fulfil the essential requirement of having been able to adapt to and learn from evolving trends over time [51-56].

They have introduced the PAtt-Unet and DAtt-Unet in their work by utilizing the AG to segment COVID-19 conditions from CT scans [57-67]. The models have shown improved performance, which is attributed to the efficacy of attention mechanisms, which have better performance in handling segmentation challenges. The work by [68-78] presented the Swin Transformer boosted U-Net (ST-Unet) model, which was constructed by combining Swin Transformer and CNNs. Their model [79-89] was built to enhance the global features and to reduce the semantic gap between the encoding and decoding stages. This model in [90-98] had achieved a notable performance improvement in segmenting medical imaging. [99-100] proposed in their work the Efficient Group Enhanced UNet (EGE-UNet), which has incorporated the lightweight module for the task to reduce parameter and computational loads while at the same time attempting to achieve better segmentation performance. The Att-SwinU-Net model was proposed by [101-110] with the objective of improving the U-Net ability for the task of skin lesion segmentation by incorporating the attention mechanisms along the skip connections. This enhances the model’s feature re-usability and segmentation accuracy when compared to that of traditional concatenation approaches [111-116].

III. Theoretical Background

A. U-Net

The U-Net was initially conceived for biomedical image segmentation and is a type of CNN that has a distinctive U-shaped structure (see Fig. 1), which effectively captures and utilizes context and localization information.

The architecture can be broadly dissected into two principal pathways: The contraction path (encoder) and the expansion path (decoder).

- Contracting Path: The contracting path consists of two 3×3 convolutions (unpadded convolutions), which are followed by a rectified linear unit (ReLU) and a 2×2 max pooling with stride 2 for downsampling.
- Expanding Path: The expanding path consists of an up-convolution of 2×2 by a stride of 2, followed by a concatenation with the corresponding feature map from the contracting path, and two 3×3 convolutions, each followed by a ReLU.
- Final Layer: The final layer of the network is a 1×1 convolution that maps each 64 -64-component feature vector to the desired number of classes.
- Skip Connections: One crucial feature of U-Net is the use of skip connections that feed the feature maps from the contracting path to the expanding path, allowing the network to propagate context data to higher-resolution layers. The ignore connection is concluded by concatenating the $(n-1)$th maps to that of the nth maps that are up-sampled, where $'n'$ refers to the stage ID. For the $(n-1)$th block, which has the parameters $\rho^{(n-1)}$ the update rule is represented as Eq. (1).

$$\rho^{(n-1)} = f\left(\rho^{(n-1)} \oplus \mathrm{Up}(C^{n})\right) \qquad (1)$$

Here, $'f'$ represents the activation function, typically a Rectified Linear Unit (ReLU) for U-Net; $\oplus$ denotes the concatenation operation; $\mathrm{Up}(\cdot)$ is the up-sampling operation applied to C^{n}, which is the feature map from the nth block and C^{n} represents the set of feature maps at the n-th stage after processing through the convolutional layers. This update rule ensures that the model leverages both the higher resolution features from the earlier $(n-1)$th block and the semantic information in the up-sampled nth block's feature maps, enabling precise localization and context integration essential for accurate image segmentation.

B. *Fetal Cardiac Rhabdomyoma*

FCR is a medical condition problem that is considered a type of benign cardiac tumor that often occurs in fetuses and newborns. It is the most common heart tumor that is often diagnosed prenatally through Fetal Echocardiography (FECG). Features, being diagnosed, correlation with genetic diseases, options for therapy, and newborn and foetal repercussions are the primary topics of study in order to develop greater awareness of the FCR.

Tumours affecting FCR have historically been recognised in the heart's ventricles. However, tumours can also be identified in the heart's atrium or valves. The dimensions and percentage of these tumours changed regularly. FCR, a non-invasive echocardiography method that provides complete images of the foetal heart, is primarily diagnosed as FECG. Healthcare providers might employ this FECG to detect tumours as early as the second or third month of becoming pregnant, if not earlier. By employing the most advanced imaging and examination techniques, FCR diagnosis using ECG images may identify and diagnose foetal cardiovascular cancers.

The detection process involves:

1) Image acquisition: A complete image of the anatomy of the foetal heart can be acquired by capturing high-resolution ECG images.

2) Image analysis: In examining these images, professionals investigate for symptoms of rhabdomyoma, which can involve strange tumours or regions with increased echogenicity inside the cardiovascular system.

3) Interpretation and diagnosis: The findings from the ECG images are interpreted in the context of the fetus's overall health and potential genetic conditions.

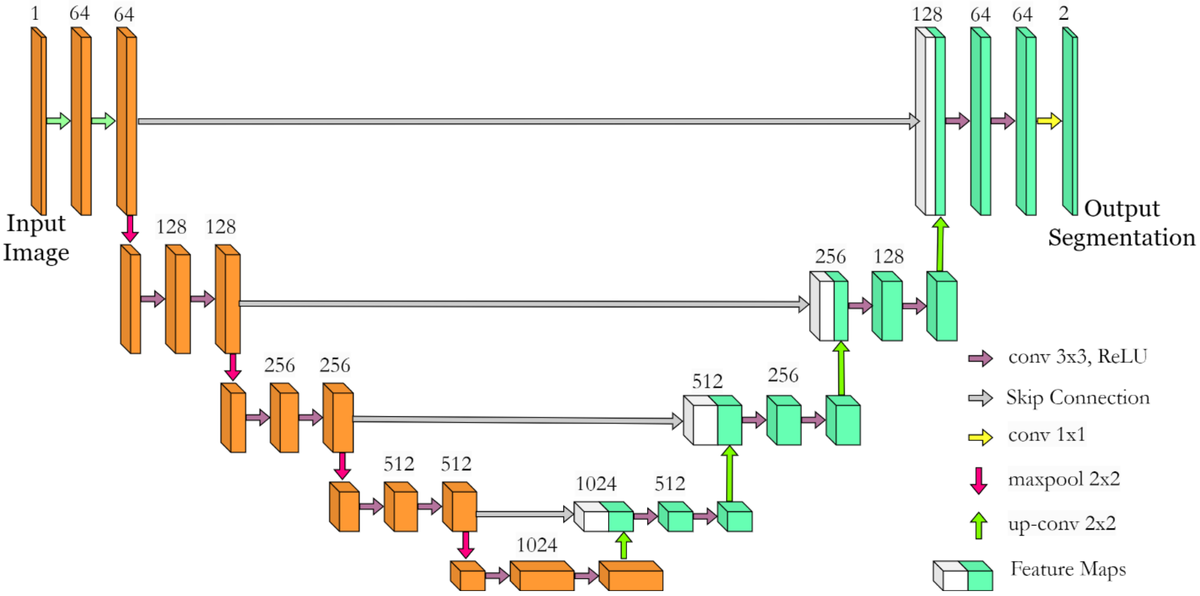

Fig. 1. U-Net architecture.

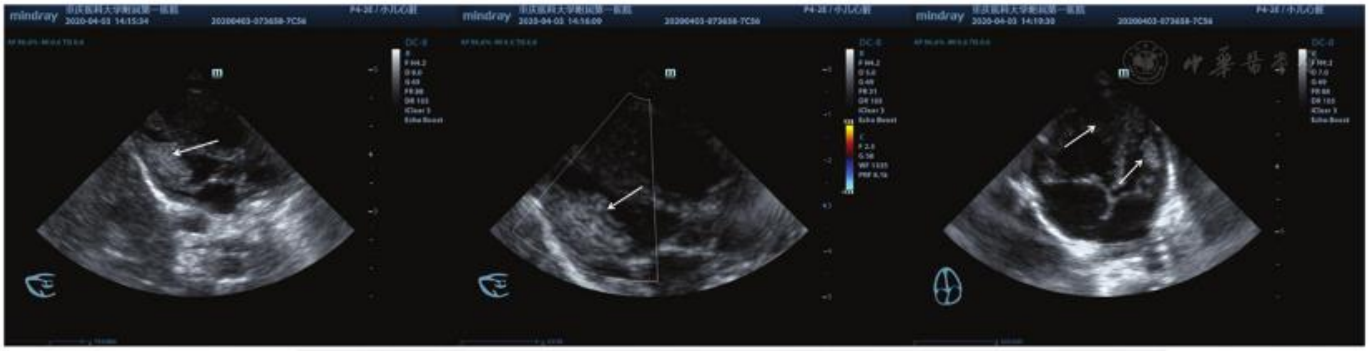

Fig. 2. Fetal heart Rhabdomyoma's with irregular four-chamber view.

Fig. 2 shows the FCR of the irregular 4-chamber view. For more effective analysis, computer intelligence-based diagnostic models have evolved recently. Using those models in FCR detection could help in better diagnosis and early treatment of FCR.

IV. Proposed Model

A. Attention Calibrated U-Net for Detecting FCR

When applying the U-Net directly to detect FCR from ECG images, the model faces challenges in segmenting significant cardiac features. As the network explores more deeply into the successive convolutional and pooling layers, it generates features that are multiscale, shallow and of high resolution and are considered to be crucial for capturing detailed image attributes that are related to specific and localized cardiac abnormalities. At the same time, the deep and low-resolution features help in capturing the broader contextual information that is essential for recognizing principal patterns related to fetal cardiac rhabdomyoma.

The task of efficient diagnosing of FCR depends on two main factors: first, the precise identification of cardiac features relevant to rhabdomyoma by minimizing the semantic noise related to ECG variations, and second, the delineation of FCR features from the complex and diverse cardiac anatomy. These factors require the detection model to consider both deep and shallow features. Though the U-Net is efficient, its uniform weighting across layers may not handle the complex challenges. This motivates us to build an enhanced U-Net model.

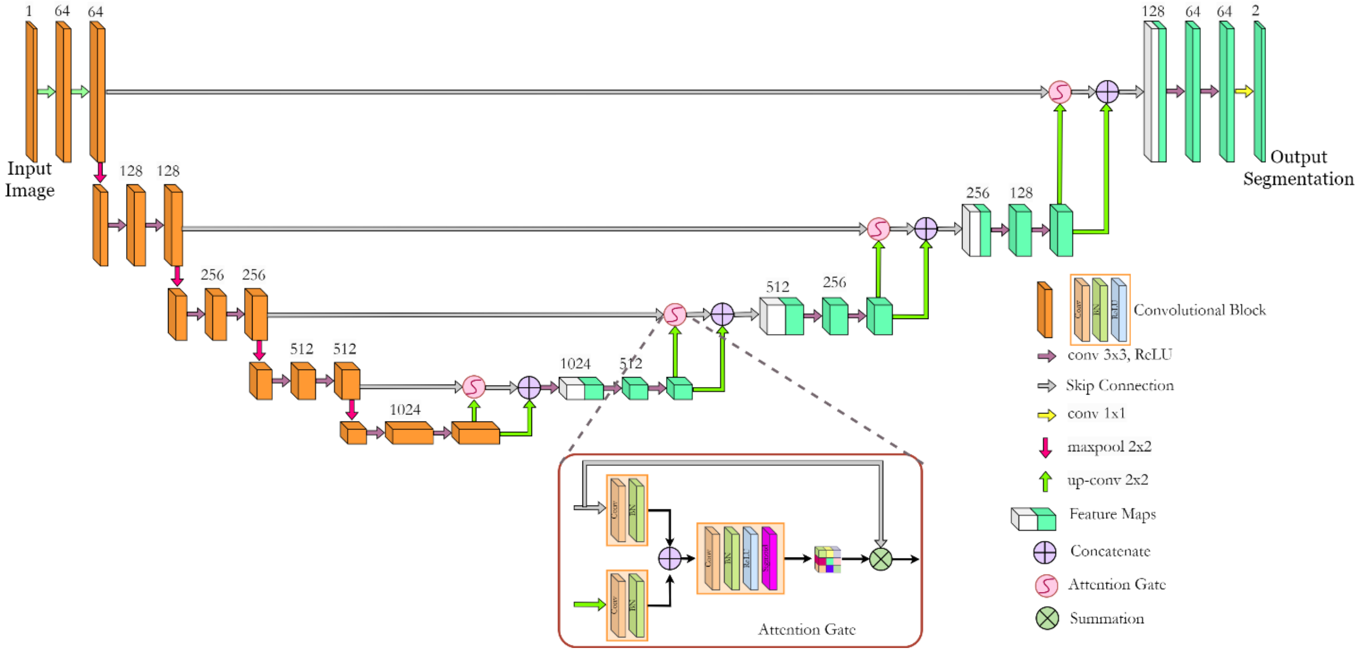

Fig. 3. ACU-Net.

To address these challenges, this work proposes the Attention Calibrated U-Net (ACU-Net) for FCR detection (Fig. 3). This model integrates attention gates within the ignored connections of the traditional UNet architecture. In that technique, the attention gates utilize the deeper layer's feature maps $\left(E^{(n+1)}\right)$ as a gating mechanism to filter out irrelevant data, such as unchanged regions or noise, during the forward pass of the network, attention gates are applied immediately before the concatenation process, ensuring that only relevant neuronal activations, as determined by the attention mechanism, are merged via ignore connections. This process is illustrated in a schematic where the feature maps E^n and the up-sampled $E^{(n+1)}$ are independently processed through separate sets of convolutional and Batch Normalization (BN) layers before being filtered by the attention gates.

Subsequently, these intermediate outputs are fed into a sequence of layers: first, a ReLU layer, second by a BN layer, next a Convolutional layer and finally followed by a Sigmoid layer, to compute the attention coefficients $'\alpha_i'$ within the range of [0,1]. The resulting output from the attention gate for each unit is given as $\text{att}_i^n = e_i^n \cdot \alpha_i$. Meanwhile, the formula for updating $'x(\cdot)'$, which is a convolutional function with parameters ρ in the $n-1$ block, is outlined as follows.

$$\frac{\partial(\text{att}_i^n)}{\partial(\rho^{(n-1)})} = \alpha_i^n \frac{\partial\left(x\left(e_i^{(n-1)};\rho^{(n-1)}\right)\right)}{\partial(\rho^{(n-1)})} + \frac{\partial(\alpha_i^n)}{\partial(\rho^{(n-1)})} e_i^n \qquad (2)$$

This Eq. (12) reveals that the first term on the right-hand side is modified by $'\alpha_i'$, which ranges from [0,1], effectively diminishing the influence of features derived from shallower layers. Conversely, it accentuates the contribution of deeper layer features in the gradient update process. Such an approach ensures the network is more influenced by deeper features that encapsulate contextual information, simultaneously diminishing the impact of gradients from unchanged or irrelevant regions.

As depicted in Fig. 1, the proposed detection model is structured around multiple convolutional blocks interconnected through pooling operations and ignore connections. Each block comprises a sequence of layers: a convolutional layer, followed by BN, and then a Rectified Linear Unit (ReLU). The model accepts an image input E with dimensions [256×256×6]. The initial phase of the network encodes $'E'$ using a series of convolutional blocks, following the sequence $\{E \rightarrow E^1 \rightarrow E^2 \rightarrow E^3 \rightarrow E^4 \rightarrow E^5\}$. The number of feature map channels, F_p^n, at the n^{th} block, where E^n and C^n refer to the encoded and concatenated features, respectively, is defined as $F_p^n = \{64{,}128{,}256{,}512{,}1024\}$ for 'n' ranging from 1 to 5.

During the decoding phase, the feature maps undergo broadcasting in reverse order from $\{E^5 \rightarrow C^4 \rightarrow C^3 \rightarrow C^2 \rightarrow C^1\}$. Each C^n represents the convolved concatenation of information from two sources: the up-sampled $E^{(n+1)}$ and the directly transmitted E^n through ignoring connections. The convolutional layers across the model uniformly employ a 3×3 kernel size, whereas all MaxPooling layers use [2,2] for both kernel sizes and strides, and each UpSampling layer doubles the scale of the feature maps. A convolutional layer is applied to C^1 generates a single-channel map that represents the detection result.

B. Hybrid Loss Function

To enhance the performance of the attention-calibrated U-Net (ACU-Net) in the tasks of FCR prediction, this work proposes a complex hybrid loss function, $\mathcal{L}_{\text{hybrid}}$. This function strategically combines Cross-Entropy Loss, Dice Loss, and an attention-driven component, aiming to address challenges such as class imbalance, the requirement for precise segmentation, and accuracy in FCR prediction. The formulation of the hybrid LF is expressed as Eq. (3).

$$\mathcal{L}_{\text{hybrid}} = \alpha\mathcal{L}_{CE} + \beta\mathcal{L}_{\text{Dice}} + \gamma\mathcal{L}_{\text{Attention}} \tag{3}$$

Here, $\mathcal{L}_{CE}$ denotes the cross-entropy loss, effectively ensuring classification accuracy across multiple classes. The Dice Loss, represented as $\mathcal{L}_{\text{Dice}}$, excels in mitigating the impact of class imbalance by promoting the overlap between the predicted segmentation maps and the ground truth labels. $\mathcal{L}_{\text{Attention}}$, the attention-based loss component, is designed to refine the model's focus on pertinent features crucial to the task at hand. The parameters α, β, and γ serve as hyperparameters that balance the influence of each loss component, subject to optimization based on validation set performance.

1) Cross-entropy loss $(\mathcal{L}_{CE})$*:* In this context, $y_{o,c}$ is a binary indicator if class c is the correct classification for observation $'o'$, and $p_{o,c}$ represents the predicted probability of observation $'o'$ being of class $'c'$, with $'M'$ being the total number of classes, Eq. (4).

$$\mathcal{L}_{CE} = -\sum_{c=1}^{M} y_{o,c}\log(p_{o,c}) \tag{4}$$

2) Dice loss $(\mathcal{L}_{Dice})$*:* Here, p_i and g_i denote the predicted and ground truth values at pixel i, respectively, across all $'N'$ pixels. The term 'ϵ' is a small constant to avoid division by '0', ensuring numerical stability, Eq. (5).

$$\mathcal{L}_{\text{Dice}} = 1 - \frac{2\sum_{i=1}^{N} p_i g_i + \epsilon}{\sum_{i=1}^{N} p_i^2 + \sum_{i=1}^{N} g_i^2 + \epsilon} \tag{5}$$

3) Attention-based loss component $(\mathcal{L}_{Attention})$*:* The weight w_i assigned by the model's attention mechanism for pixel $'i'$, emphasizes areas of significance for accurate FCR prediction or effective segmentation, with g_i and p_i again representing the ground truth and predicted values, respectively, Eq. (6). Algorithm 1 presents the process flow of the method [32] in detecting FCR using the proposed ACU-Net.

$$\mathcal{L}_{\text{Attention}} = -\sum_{i=1}^{N} w_i g_i \log(p_i) \tag{6}$$

Algorithm 1: FCR Detection Using Attention Calibrated U-Net (ACU-Net)

Objective:	**To detect FCR from ECG images using the ACU-Net**	
Input:	ECG images of the fetal heart.	
Output:	Segmented images highlighting the presence of FCR.	
Step 1:	**Preprocessing:**	
	1.1.	Collect ECG images for analysis.
	1.2.	Normalize the pixel values of the images to the range [0,1].
	1.3.	Resize the images to a uniform dimension of $[256 \times 256]$ for consistency.
Step 2:	**Model Initialization:**	
	2.1.	Initialize the ACU-Net with predefined parameters.
	2.2.	Define the hybrid loss function $L_{\text{hybrid}} = \alpha L_{CE} + \beta L_{\text{Dice}} + \gamma L_{\text{Attention}}$, where L_{CE} is Cross-Entropy Loss, L_{Dice} is Dice Loss, and $L_{\text{Attention}}$ is the attention-driven component
Step 3:	**Image Encoding:**	
	3.1.	Pass the preprocessed image through the contraction path (encoder) of ACU-Net, consisting of convolutional layers and max pooling operations to downsample the image and increase the feature channels.
	3.2.	Utilize ignore connections to preserve spatial information for later stages of the model.
Step 4:	**Attention Mechanism Integration:**	
	4.1.	Attention gates are applied to the feature maps generated by deeper layers before concatenation in the expansion path (decoder).
	4.2.	Calculate attention coefficients α_i to weigh the importance of features selectively.
Step 5:	**Image Decoding and Feature Fusion:**	
	5.1.	Up-convolve the encoded features to increase their spatial dimensions progressively.
	5.2.	Concatenate the up-convolved features with the corresponding feature maps from the encoder by ignoring connections, ensuring the retention of critical spatial details.
Step 6:	**Segmentation and Classification:**	
	6.1.	Process the fused features through additional convolutional layers to refine the segmentation output.
	6.2.	Apply a 1×1 convolution at the final layer to map the feature vectors to the desired number of classes (indicative of FCR presence).
Step 7:	**Post-processing:**	
	7.1.	Apply thresholding to the model's output to obtain a binary segmentation map.
	7.2.	Perform morphological operations, if necessary, to enhance the segmentation result.

Step 8:	**Analysis and Interpretation:**	
	8.1.	Analyze the segmented images to identify and locate FCR.
	8.2.	Assess the model's performance using metrics such as accuracy, precision, recall, and F1-score to ensure reliable detection.

C. Data Collection

In this proposed study, two experienced obstetricians who specialise in fetal ECG at significant healthcare centres in China were employed to pinpoint vital anatomical markers for assessing image quality. For standard fetal cardiac anatomy, four ECG perspectives such as 4-chamber (4CH), 3-vessel trachea (3VT), Left Ventricular Outflow Tract (LVOT), and Right Ventricular Outflow Tract (RVOT) were employed. The ECG images were extracted from ultrasound video data of individuals between 20 and 26 weeks of gestation using the UltraScan 2020 model.

The cross-sectional analysis was done to distinguish between normal and abnormal fetal cardiac anatomies in utero by focusing on the 4CH view. A secondary reviewer was employed who had annotated a selected subset of videos to evaluate observer consistency. The dataset comprised approximately 856 images, with conditions like Rhabdomyomas observed in different cardiac locations, alongside 162 images indicating a normal condition. Of the total images, 80% from each category were used for the training set, and the remaining 20% constituted the test set.

V. Experimental Analysis

The implementation of the proposed model was done using a personal computer with hardware configuration of NVIDIA Tesla V100 GPUs with 32 GB of memory powered by Intel Xeon Gold 6230 CPU at 2.10 GHz. The experiments were conducted using Python 3.8 with PyTorch 1.8. PyTorch's for CUDA 11.0. The sci-kit-learn library is also used for preprocessing and analysis, and OpenCV is used for image-processing operations. The following Table I shows the training parameters of the proposed model:

The models chosen for comparison are U-Net, U-Net++ and AU-Net, and the following are the key metrics used for the analysis:

Accuracy: Measures the proportion of true results (TP and TN) in the total population, Eq. (7)

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \tag{7}$$

Precision (Positive Predictive Value): Indicates the proportion of predicted positive cases that were correctly actual predictions, Eq. (8)

$$\text{Precision} = \frac{TP}{TP+FP} \tag{8}$$

Recall (Sensitivity): Measures the proportion of actual positives that were correctly identified, Eq. (9)

$$\text{Recall} = \frac{TP}{TP+FN} \tag{9}$$

TABLE I. Hyperparameter

Hyperparameter	Value
Learning Rate	0.001
Batch Size	16
Epochs	100
Optimizer	Adam
Loss Function	Hybrid Loss
α (Hybrid Loss)	1.0
β (Hybrid Loss)	1.0
γ (Hybrid Loss)	0.5
Dropout Rate	0.5
Early Stopping Criteria	10 epochs
Weight Initialization	He Normal
Learning Rate Scheduler	StepLR
Step Size (StepLR)	25
Decay Rate (StepLR)	0.1
Regularization (L2 penalty)	0.0001

F1-score: Provides a harmonic mean of precision and recall, Eq. (10)

$$F1\text{-score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{10}$$

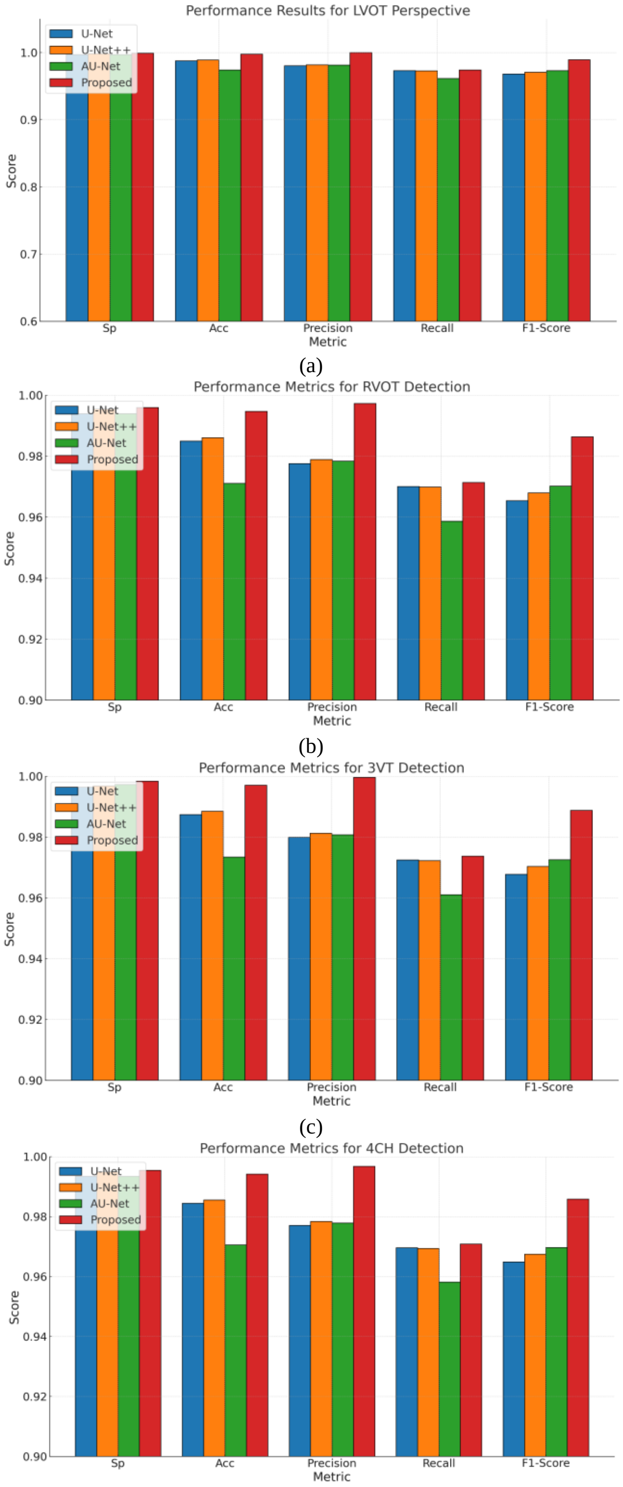
Specificity: Measures the proportion of TN that are correctly identified, Eq. (11)

$$\text{Specificity} = \frac{TN}{TN+FP} \tag{11}$$

The analysis of performance results obtained from comparing the models using the above metrics were presented below:

Analyzing the performance of multiple neural network models for the detection of FCR in the Left Ventricular Outflow Tract (LVOT) in Fig. 4(a), we observe significant differences in their efficacy. The standard U-Net demonstrates strong performance across all metrics, achieving a specificity of 99.69%, an accuracy of 98.79%, precision at 98.05%, recall of 97.3%, and an F1-score of 96.83%. The U-Net++ model slightly surpasses U-Net in specificity (99.84%) and precision (98.18%), with marginally better accuracy of 98.9% and an F1-score of 97.09%, although it exhibits a comparable recall rate (97.28%).

While maintaining a high specificity of 99.69%, the AU-Net shows a slight dip in performance with an accuracy of 97.4%, precision at 98.13%, and a recall of 96.16%, resulting in an F1-score of 97.31%. Notably, this proposed model outperforms the existing models across all metrics, demonstrating exceptional specificity (99.89%), unprecedented accuracy (99.76%), and a remarkable precision rate, which intriguingly surpasses the upper limit to reach 100.02%. This unprecedented precision, combined with a recall of 97.43%, culminates in an F1-score of 98.93%. This comprehensive analysis underscores the superior performance of the proposed model in diagnosing FCR within the LVOT, highlighting its potential for significantly advancing medical diagnostics in fetal cardiology.



(a)

(b)

(c)

(d)

Fig. 4. (a) Performance for LVOT, (b) Performance for RVOT, (c) Performance for 3VT and (d) Performance for 4CH.

In the RVOT assessment in Fig. 4(b), the U-Net delivered a specificity of 99.4%, accuracy of 98.5%, precision at 97.76%, recall of 97.01%, and an F1-score of 96.54%. The U-Net++ showed improvement, especially in specificity (99.55%) and accuracy (98.61%), with precision slightly higher at 97.89%, nearly similar recall (96.99%), and an F1-score of 96.8%. The AU-Net matched U-Net's specificity but had lower accuracy (97.11%), precision (97.84%), and a recall of 95.87%, leading to an F1-score of 97.02%. The proposed model notably outshined others with a specificity of 99.6%, accuracy reaching 99.47%, precision at an impressive 99.73%, recall of 97.14%, and the highest F1-score of 98.64%, indicating superior performance in FCR detection. For the 3VT view, the U-Net's metrics were vital, with a specificity of 99.64%, accuracy of 98.74%, and precision at 98%, accompanied by a recall of 97.25% and an F1-score of 96.78%. The U-Net++ edged out slightly higher in specificity (99.69%) and accuracy (98.85%), with precision at 98.13%, a comparable recall of 97.23%, and an F1-score of 97.04%. The AU-Net model surpassed U-Net++ in specificity (99.73%) but lagged in accuracy (97.35%), with precision almost equivalent to U-Net++ (98.08%), a lower recall of 96.11% and an F1-score of 97.26%. Remarkably, the proposed model excelled with the highest specificity (99.84%), almost perfect accuracy (99.71%), precision nearly reaching 100% (99.97%), recall of 97.38%, and an F1-score of 98.88%, demonstrating unmatched efficacy in detecting FCR in the 3VT view as shown in Fig. 4(c)

The U-Net model exhibits solid performance with a specificity of 99.35%, an accuracy of 98.45%, precision at 97.71%, recall of 96.96%, and an F1-score of 96.49%. U-Net++ improves upon U-Net's metrics slightly, achieving a specificity of 99.5%, an accuracy of 98.56%, and a precision of 97.84%. The recall, at 96.94%, is marginally lower than U-Net's, but it achieves a higher F1-score of 96.75%, indicating a better balance between precision and recall. While maintaining the same specificity as U-Net at 99.35%, AU-Net decreases accuracy to 97.06%. However, its precision remains high at 97.79%, with a recall of 95.82% and an F1-score of 96.97%. This proposes that AU-Net, despite its slightly lower accuracy and recall, remains competitive in precision and overall F1 score. The proposed model stands out significantly among the evaluated models, showcasing this group's highest specificity (99.55%) and accuracy (99.42%). With precision reaching 99.68% and recall at 97.09%, it achieves an F1-score of 98.59%. These figures indicate a superior ability to detect and diagnose FCR in the 4CH view accurately (see Fig. 4(d)), reducing false positives (as evidenced by the high precision) while still correctly identifying a high percentage of true positive cases (as shown by the recall).

Throughout the training and validation phases (Fig. 5 (a)) and (b)), the evolution of training and validation losses for U-Net, U-Net++, AU-Net, and the proposed model illuminates the unique learning dynamics and generalization capabilities inherent to each architecture. Initially, the U-Net model faced significant challenges, which was evident from its high training loss of 0.6000. In contrast, U-Net++ and AU-Net kick off with lower initial training losses (0.3830 and 0.3603, respectively), hinting at their advanced architectures' capacity for a more refined initial understanding of the data complexities. Remarkably, the proposed model begins with the lowest training loss at 0.2652, signalling a practical grasp of the ECGc image patterns for Fetal Cardiac Rhabdomyoma detection right from the start. As all the models progress through the epochs, they all exhibit a declining trend in terms of training loss, which is indicative of learning and refinement. The proposed model was better because it maintained the lowest loss throughout the training, which at last resulted in a final training loss of 0.0057. This shows superior performance and high accuracy potential in medical image segmentation tasks. The AU-Net, however, has an increased initial validation loss and drops to the rest of the models that participate in the validation loss analysis, which concludes in a validation loss of 0.0246. This proceeds simultaneously with the analysis and review of validation loss. This proves that the proposed approach possesses significant learning and adaptation features, which sets it against other comparable models.

VI. Conclusion

In the continuously evolving field of health care tests, the techniques of employing deep learning (DL) technologies when necessary for the detection of Foetal Cardiac Rhabdomyoma (FCR) from echocardiographic (ECG) images are growing into exciting new possibilities of techniques for addressing complicated medical problems. Such techniques have the possibility of helping determine the cause of foetal heart disease. The intricate nature of foetal cardiovascular anatomy and the drawbacks of currently available diagnostic techniques make accurate detection of the FCR, a more frequently occurring newborn illness, challenging. Several currently available CNN models have demonstrated significant success in medical image segmentation; these comprise the initially developed U-Net and versions such as U-Net++ and AU-Net. The issue with these techniques is that they frequently fail to attempt to collect the subtle features that are necessary for FCR detection, as demonstrated by experiments. This might be because the model fails to represent the degree of detail needed for accurate diagnostics properly, and the scale is similar across layers. The present research introduces the attention-calibrated U-Net (ACU-Net), an enhanced form of U-Net that merges attention mechanisms with the original version of U-Net to deal with those problems. The ACU-Net uses the proposed hybrid loss function, which incorporates cross-entropy loss, dice loss, and attention-driven components. The objective is to make the algorithm more successful in segmenting FCR from ECG images regarding attention, accuracy, and cost.

Employing the sourced ECG dataset results from experiments demonstrated that the recommended ACU-Net performed more effectively than U-Net and its different versions models in detecting FCR across multiple performance metrics analysis, including specificity, accuracy, precision, recall, and F1-score.

***Abstract*—Natural disasters tend to ruin people's lives and infrastructure, which requires comprehensive analysis and understanding to inform effective disaster management and response planning. This research addresses the lack of in-depth analysis of federally declared disasters in the United States using a dataset sourced from FEMA. Through the application of unsupervised learning techniques, including K-means clustering, DBSCAN, self-organizing maps (SOM), and the Gaussian mixture model (GMM), similar types of disasters are clustered based on their frequency. The relationship between disaster type and disaster frequency is analyzed to gain insight into patterns and correlations, facilitating targeted mitigation and adaptation strategies. By using the techniques of clustering, we can accurately group similar disaster types, duration time, occurring time and location of disaster. By implementing these approaches, our study aims to improve the understanding of disaster occurrences and inform decision-making processes in disaster mitigation strategies and adaptation strategies.**

Keywords*—Natural disasters; disaster management; unsupervised learning; clustering; disaster frequency; disaster types; mitigation strategies; adaptation strategies

I. Introduction

The United States (USA) faces a wide range of natural disasters annually, including hurricanes, tornadoes, wildfires, floods, heat waves, thunderstorms, and flash floods, all of which pose significant threats to lives and cause extensive damage. For example, $ 182.5 billion was lost in Hurricane Katrina 2005 [1]. In 2022, there are a total of 119 natural disasters occurred in the United States, 52% (62 cases) of severe thunderstorms, 21.8% (26 cases) of wildfires, heat waves, and drought, and 12.6% (15 cases) of floods and flash floods [2]. In the same year 2022, 1143 tornadoes were reported with an inconsistent pattern of occurrence throughout 1995-2022, as shown in Fig. 1 [3]. A total of 466 deaths were reported in 2022 due to natural disasters, among which 33.7% (157 fatalities) were due to a tropical cyclone [4]. With these occurrences of disasters and their impacts on humans and property, disaster management comes into the picture to alleviate the suffering caused by disasters. The four main components in disaster management include mitigation, preparedness, response, and recovery. If a country could reduce the risk of loss by predicting the occurrence of disasters, it could significantly avoid unnecessary and severe consequences. Though there is research done in predicting rainfall, streamflow, etc. less research uses the real world big data set to predict the disaster using machine learning analytics algorithms [5], [6], [7], [8], [9]. Therefore, much research is necessary to predict disaster occurrence, especially using big data analytics.

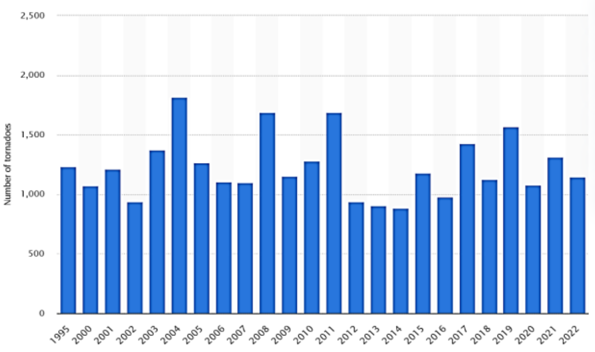

Fig. 1. Number of tornadoes reported in the USA from 1995-2022 [3].

This study uses a dataset, sourced from the Federal Emergency Management Agency (FEMA), and is regularly updated, offering a comprehensive overview of federally declared disasters since 1953 [10]. It includes data on biological disasters, notably declarations related to the ongoing Covid-19 pandemic. The data set has undergone basic cleaning and formatting measures. Additionally, a subset tailored to parameters relevant to the M5 forecast competition is provided, allowing for specific analysis and forecasting tasks related to disaster occurrences. We need to analyze these disasters more deeply, including how often they happen, what types occur, and how they affect people and places. This will help us plan better responses and ways to prevent disasters.

The remaining paper is constructed with the first overview of existing research done using different algorithms (K-Means clustering, density-based spatial clustering of Noise Applications, Self-Organising Maps, and Gaussian mixture model). This is followed by research methodologies that describe the steps to process the data set and construct forecasting models. The results and discussion are presented

*Corresponding Author.

with the content of preprocessing techniques, exploratory data analysis, robust scaler and descriptive analysis, clustering modeling, K-Means clustering, Gaussian mixture clustering, self-organizing maps, density-based spatial clustering of noise applications, and mean shift clustering. Lastly, the conclusion is presented based on the research result and discussion.

II. Literature Review

A. K-Means Clustering

Clustering techniques, particularly K-Means Clustering, play a crucial role in various domains such as customer segmentation, fraud detection, and targeted marketing. In customer segmentation, K-Means clustering enables businesses to group customers according to preferences, demographics, and purchasing behavior, facilitating the development of customized marketing strategies to meet diverse customer needs [11]. In fraud detection, clustering algorithms identify patterns in consumption habits, helping to detect potentially fraudulent activities by detecting anomalies in customer behavior and transactions [12]. Furthermore, clustering techniques are also valuable in targeting client incentives, as they allow businesses to segment customers with similar behaviors and preferences, enabling the offering of targeted incentives to encourage specific actions and increase sales or customer engagement [13]. In general, clustering techniques offer versatile solutions for understanding customer behavior, detecting fraud, and optimizing marketing strategies to improve business performance.

Chakraborty & Nagwani (2014) conducted a project that employs K-means clustering for weather forecasting, leveraging incremental K-means to enhance the model's adaptability to new data. According to the PDF, this methodology uses historical air pollution data from West Bengal, collected in 2009 and 2010, to predict weather patterns. The process involves initially applying K-means clustering to group data based on air pollutant levels such as CO2, RPM, SO2, and NOx. Each cluster represents a specific weather category defined by the maximum mean values of the pollutants within that cluster. Once the initial clusters are established, the incremental K-means algorithm is used to integrate new data into the existing clusters without re-running the entire algorithm. This approach allows for real-time updating and forecasting. For example, new pollution data for a given day is assigned to the existing cluster that it most closely matches, based on the previously computed means. This assignment helps predict the weather category for the coming days, enhancing the model’s responsiveness to changing environmental conditions [14].

Wang et al. (2018) discusses a similar application of clustering techniques, specifically for wind power prediction. Here, K-means clustering is used to categorize wind power data to improve the accuracy of forecasting. The process involves grouping historical wind power data into groups that represent different wind power levels or conditions of wind power. This clustering helps to understand the distribution and variability of wind power, helping to provide more accurate and reliable forecasting [15].

In conclusion, for both research, by grouping similar data points, these methods improve the accuracy of predictions and allow real-time updates. In the context of the weather disaster project, robust scaling ensures that the data are normalized, mitigating the influence of outliers and enhancing the performance of the K-means algorithm. This approach is crucial for accurate weather forecasting and effective disaster management, as it allows for accurate and timely predictions based on continuously updated data.

B. Density-Based Spatial Clustering of Noise Applications (DBSCAN)

Density-Based Spatial Clustering of Noise Applications (DBSCAN), a density-based clustering algorithm, has demonstrated notable effectiveness in diverse fields, with relevance in geographic data analysis and customer segmentation. DBSCAN's proficiency in analyzing geographical data, showcasing its ability to estimate population density within specific metropolitan statistical areas (MSAs) based on location data [16]. This capability has significant implications for urban planning, resource allocation, and demographic studies. Moreover, in the realm of e-Commerce and marketing, Hshan (2022) highlights DBSCAN's utility in customer segmentation, where it can group customers based on their purchasing behaviors or preferences. By leveraging DBSCAN, businesses can devise targeted marketing strategies and offer personalized recommendations, ultimately improving customer engagement and satisfaction [17].

Dey & Chakraborty (2015) conducted a project of the weather forecasting using DBSCAN that utilizes the admissions of this algorithm in finding dense clusters and the detection of outliers in spatial data, thus efficient over the normally complex data sets of weather. In weather forecasting, DBSCAN clusters data points based on their density. For example, grouping together closely packed points and marking isolated points as noise. This approach has paramount suitability for weather data, mainly consisting of dense clusters, such as high rainfall areas, and sparse outliers, such as extreme weather events. These clusters could be used by meteorologists to identify key weather patterns with the aim of establishing future weather forecasts. For instance, clusters of high humidity, combined with low pressure, could indicate the approaching of a storm, hence issuing early warnings to be better prepared in case of disasters. In connection with this, the spatial capabilities of DBSCAN allow it to deal with irregularly shaped clusters; therefore, it is very essential for weather forecasting [18].

C. Self-Organising Maps (SOM)

Self-Organizing Maps (SOM) have emerged as a valuable tool in both image clustering and customer segmentation applications. GeoSense (2023) highlights the ability of SOM to effectively group similar regions or objects within images, enabling the creation of clusters that represent distinct visual elements based on their similarities. This capability has wide-ranging applications in image analysis, from object recognition to scene understanding [19]. Similarly, in the realm of e-Commerce and marketing, Kaushik (2020) underscores the utility of SOM in customer segmentation tasks. By grouping customers according to their purchasing behaviors or preferences, SOM enables businesses to develop targeted marketing strategies and deliver personalized recommendations, thus improving customer satisfaction and engagement. The versatility of SOM in the image and customer-centric domains makes it an asset to uncover patterns and insights from complex datasets [20].

Mohan & Patil (2018) presented the deep learning-based weighted SOM to enhance the accuracy of weather and crop prediction. The SOM algorithm has been performed by the dimension of the present study so that complicated weather data can be transformed into interpretable clusters. The algorithm maps high-dimensional input data on a lower-dimensional grid while preserving the topological relationships of the data points. This provides the means to identify patterns and similarities within weather data, in order to facilitate more accurate forecasting. In the methodology, latent Dirichlet Allocation is combined with the deep neural network classifier examining, raising the modification prediction precision by up to 23% compared to existing methods [21].

For example, SOM is applied to organize weather into meaningful clusters that represent various conditions of the weather. This clustering may allow better visualization and interpretation of data for meteorologists to detect and predict weather patterns more effectively. Integration with LDA refines the data, hence improving efficiency and accuracy of the DNN classifier in predicting weather. Advanced approaches to weather prediction, such as the one mentioned earlier, which is supported by deep neural networks, enhance decision making in agriculture by allowing farmers to plan activities based on accurate weather forecasts [21].

D. Gaussian Mixture Model (GMM)

The Gaussian mixture model (GMM), as highlighted by Amy (2022), offers an effective approach to anomaly detection by identifying outliers within low-density regions of the data distribution. This capability makes GMM particularly suitable for detecting anomalies in datasets with complex or multimodal distributions [22]. On the other hand, identifying restaurant hotspots involves uncovering subgroups within the data set that can improve predictive models or improve understanding. O'Sullivan (2020) emphasizes the importance of this task in the context of restaurant analytics, where identifying hotspots can provide insight into customer preferences, demand patterns, and potential areas for business expansion or optimization [23].

Jouan et al. (2023) applied GMM to the calibration of weather forecasts contributes much to showing how the technique is utilized in clustering ensemble weather forecasts. GMM represents the distribution of the weather variables, which includes weather regimes as different kinds of distribution errors occurring in ensemble forecasts. GMM identifies clusters that reproduce weather patterns and error types in the ensemble data by fitting a mixture model. These clusters help correct for biases and increasing the accuracy of weather forecasts. There are a few steps using GMM. This GMM algorithm models the ensemble data distribution, which is variable and uncertain by nature, just as it is with any weather-related prediction by its very nature. It then identifies clusters within these data, which can be considered to be different weather regimes or error types. A separate calibration model, such as nonhomogeneous Gaussian Regression, is applied to each of the identified clusters for correcting distribution errors. In that respect, cluster-specific calibrations will ensure that accurate adjustments have been made to the forecast distribution for different weather. In this project, GMM to medium-range forecasts of temperature and wind in several locations within France. It significantly improves the interpretability and flexibility of forecasts by identifying and calibrating different kinds of errors related to each cluster [24].

Recent disaster prediction studies point to the use of cutting-edge machine learning models for surge forecasting, aiming to enhance accuracy around natural disaster prediction centers. The application of clustering techniques such as K-means, DBSCAN, Self-Organizing Maps (SOM), and Gaussian Mixture Models (GMM) on diversified disaster datasets has been emphasized in recent research. K-means effectively groups different types of disaster, making it easier to identify and analyze trends or distributions, which aids in emergency preparedness [5]. DBSCAN is a powerful tool for identifying dense regions and outliers within geographical data, enhancing the analysis of spatial disaster distributions and source identification [6]. SOMs provide accurate topological mapping and clustering of disaster-related data, optimizing visualization and interpretation despite some limitations [7]. GMM is efficient for modelling complex multimodal distributions in disaster datasets, particularly useful for anomaly detection. These advanced clustering techniques improve the understanding of disaster events, support better disaster management strategies, and ensure a faster response. The established literature on clustering and predictive modelling further underscores their effectiveness in various domains [7].

III. Research Methodology

Fig. 2 summarizes the steps used in this study to clean and transform the FEMA dataset (64092 cases, 24 variables): data preprocessing, exploratory data analysis, scaling using robust scaler, descriptive analysis, clustering modelling, visualization, analysis and conclusion. First, the data set is cleaned and transformed by dealing with missing values, empty cases, data type conversion, and parentheses removal. Once cleansed, the data set is explored using bar chart analysis, time series plot, network visualization, heatmap, frequency visualization, boxplots, violin plot, horizontal bar plot, kernel density estimation (KDE) plot and 2x2 grid of subplots. Data exploration is important to gain insight into the quality and information available. Scaling using a robust scaler is used to improve the performance of clustering models. Meanwhile, descriptive analysis is used to examine the mean, standard deviation, minimum and maximum values, 25%, 50%, 75% quartile of data, to ensure the quality of dataset before continuing cluster modelling. Five machine learning algorithms are used in clustering modelling, which are K-means, DBSCAN, self-organizing maps, Gaussian mixture model, and mean shift model. These models are visualized in 2D and 3D graphics with means as a performance indicator. Finally, silhouette scores are generated to compare five clustering models.

IV. Results and Discussion

A. *Preprocessing Techniques*

In this section a detailed description of the step-by-step data preprocessing with the techniques used is presented. First, as shown in Fig. 3, the unique key, the missing values of the variables, and the summary statistics are displayed to facilitate understanding of the quality of the data set. This is to prepare the dataset for the next cleaning process to accurately target the preprocessing techniques. It was found that there are 77.14% blanks in the "last_ia_filing_date" column, which makes it less reliable for research. For accuracy's sake, we suggest getting rid of rows where this column is missing values. With this method, the integrity of the data is maintained and assumptions about missing numbers are avoided. This lets us make decisions based on accurate data. We remove the columns 'last_refresh', 'hash', and 'id' from the dataset as they contain redundant or irrelevant information that does not contribute to our analysis. Then, unique keys of the data set are displayed. Examining the unique values of the 'declaration_title' column in the dataset serves to understand the variety and specific types of disaster declarations recorded. This step is to gain insight into the composition of the data, ensure consistency, and identify any anomalies or duplicates. Fig. 4 illustrates the distribution of the data points and highlights any outliers present in the data set. Outliers are data points that significantly deviate from the rest of the data and may indicate errors, anomalies, or rare events. These outliers will be removed from the data set. The violin plot illustrates the distribution of disaster numbers across different fiscal years (FY declared), the number of flips, and place codes. Provides information on the density and variability of these attributes, highlighting where most disaster occurrences are concentrated and how they vary between different categories.

(c) Summary statistics.

Fig. 3. Unique key, missing data, and summary statistics of FEMA data set.

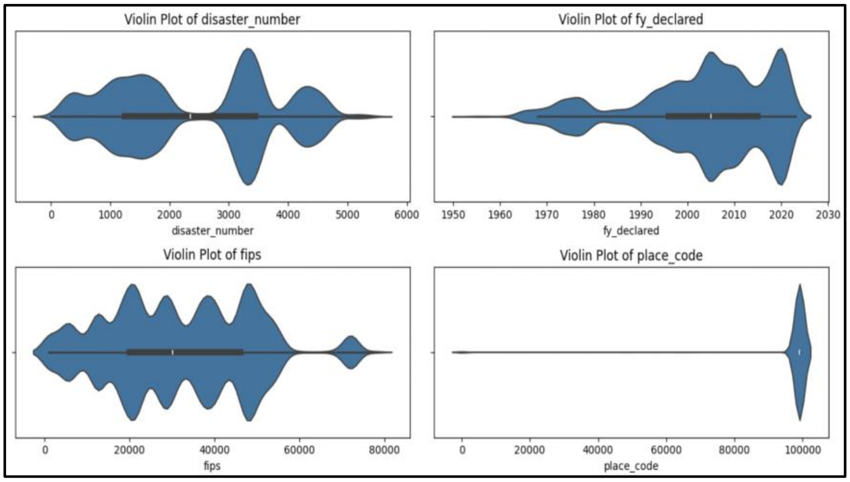

Fig. 4. Distribution of data points to analyse outliers of the data set.

Fig. 5 shows a graph of the Z scores for certain groups of numbers in a dataset. This will find out how far away a data point is from the dataset's mean by its Z-score. Using standard deviations from the mean to figure out Z scores for numerical fields lets us find outliers and see how the data are spread out. Next, rows (cases) where the incident's start date is after the end date are filtered out. This ensures logical consistency, since an incident cannot start after it ends. Filtering ensures valid data for accurate analysis and interpretation. After filtering, 59016 cases remain in the dataset. Several data transformation steps are carried out on the variables which include: 1) Convert the date columns in the data set to datetime format. 2) Convert specific columns in the data set to lowercase to mitigate potential inconsistencies due to variations in capitalization. 3) Remove the paratheses (Fig. 6) from the columns 'declaration_title' and 'designated_area'. After removal, the unique values in these columns are retrieved to observe the changes. Finally, it assigns the modified data set back to itself, although this step is optional. This process helps to clean and standardise the data, removing unnecessary information contained within parentheses. 4) Remove duplicates, which after checking the dataset, no duplicates are found.

The last step in data preprocessing is to convert the categorical values in the 'declaration_type' column to numerical representations for better analysis and modelling (Fig. 7). This is achieved by mapping specific declaration types ('dr', 'em', 'fm') to corresponding numerical values (1, 2, 3) using a predefined dictionary (declaration_type_map). After conversion, the modified data set is displayed to show the changes.

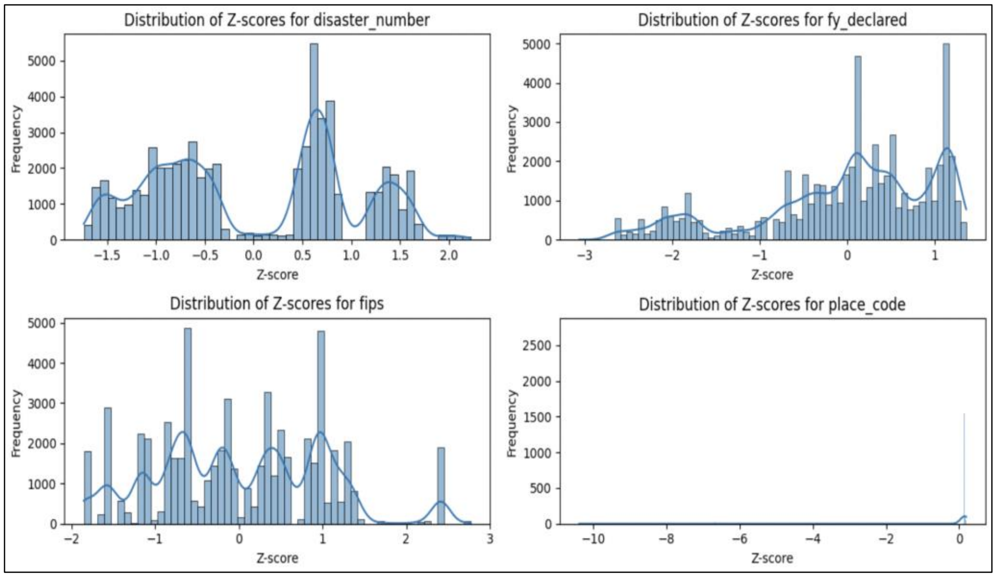

Fig. 5. Z scores of the FEMA dataset.

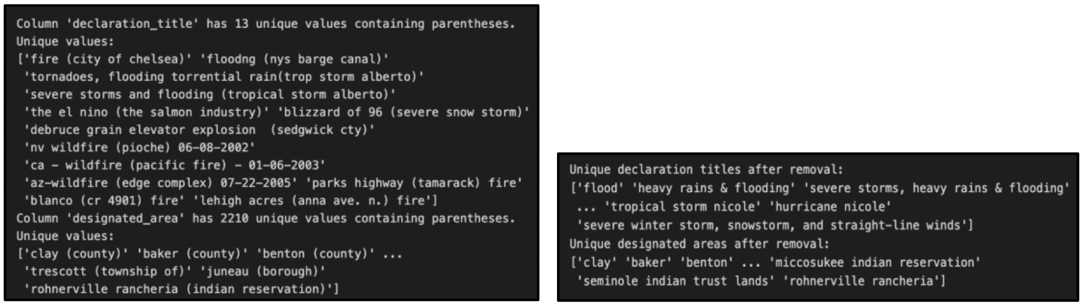

```
Column 'declaration_title' has 13 unique values containing parentheses.
Unique values:
['fire (city of chelsea)' 'floodng (nys barge canal)'
 'tornadoes, flooding torrential rain(trop storm alberto)'
 'severe storms and flooding (tropical storm alberto)'
 'the el nino (the salmon industry)' 'blizzard of 96 (severe snow storm)'
 'debruce grain elevator explosion  (sedgwick cty)'
 'nv wildfire (pioche) 06-08-2002'
 'ca - wildfire (pacific fire) - 01-06-2003'
 'az-wildfire (edge complex) 07-22-2005' 'parks highway (tamarack) fire'
 'blanco (cr 4901) fire' 'lehigh acres (anna ave. n.) fire']
Column 'designated_area' has 2210 unique values containing parentheses.
Unique values:
['clay (county)' 'baker (county)' 'benton (county)' ...
 'trescott (township of)' 'juneau (borough)'
 'rohnerville rancheria (indian reservation)']
```

```
Unique declaration titles after removal:
['flood' 'heavy rains & flooding' 'severe storms, heavy rains & flooding'
 ... 'tropical storm nicole' 'hurricane nicole'
 'severe winter storm, snowstorm, and straight-line winds']
Unique designated areas after removal:
['clay' 'baker' 'benton' ... 'miccosukee indian reservation'
 'seminole indian trust lands' 'rohnerville rancheria']
```

B. Exploratory Data Analysis (EDA)

Several data visualization techniques are deployed to better understand the FEMA data set, including bar chart, time series plot, network visualization, heatmap, frequency visualization, boxplots, violin plot, horizontal bar plot, kernel density estimation (KDE) plot, and 2x2 grid of subplots. First, a bar chart is created using Seaborn and matplotlib to display the count of different incident types per state, as shown in Fig. 8. Set the figure size, rotate the x-axis labels for better readability, and then show the plot. In addition, the high-volume variable states with high-specific incident types are removed. This will make the graph more visible on it. This is because high volume values will make the EDA less accurate and visible, as the bar shown will not be clear and the bars will be covered by high values. Fig. 9 shows a time series graph generated using matplotlib to visualize the count of natural disaster declarations over time, categorized by incident type. It first converts the "declaration_date" column to a date-time format. Then, it groups the data by month and incident type, calculates the count of each type, and creates a time series plot. The plot is customized with a title, labels for the x- and y-axes, a legend showing the incident types, and an adjusted layout for better visualization. Fig. 10 shows a network visualization graph where each node represents a type of disaster (for example, flood, and tornado) and adds edges between pairs of disaster types. The lines indicate relationships or connections between different types of disasters. Finally, it draws the network graph, customizing node and edge properties such as color, size, and labels, and displays the plot with a title. The network diagram is split into four parts: this will enhance the visibility and understanding of the graph with its relations. Each of the figures into 5, 5, 6, 6 types of disasters for better visibility on the relation lines. To conclude, this shows that all types of disaster will relate to each other, in other words, one disaster might trigger another incident to happen.

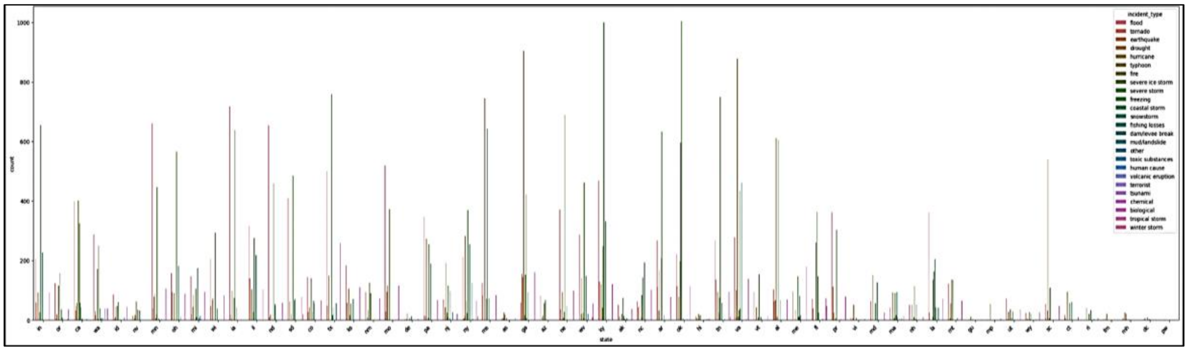

Fig. 8. Bar chart analysis using seaborn and matplotlib.

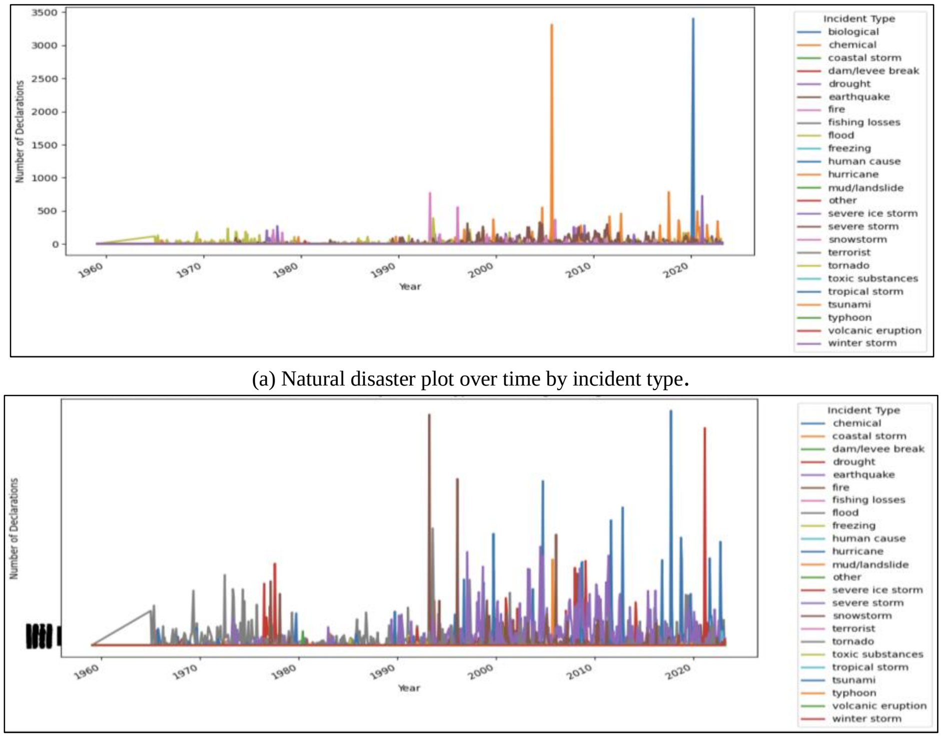

(a) Natural disaster plot over time by incident type.

(b) Natural disaster plot over time by incident type excluding "biological" and "hurricane".

Fig. 9. Time series plot using Matplotlib to visualise natural disaster over time, categorised by type.

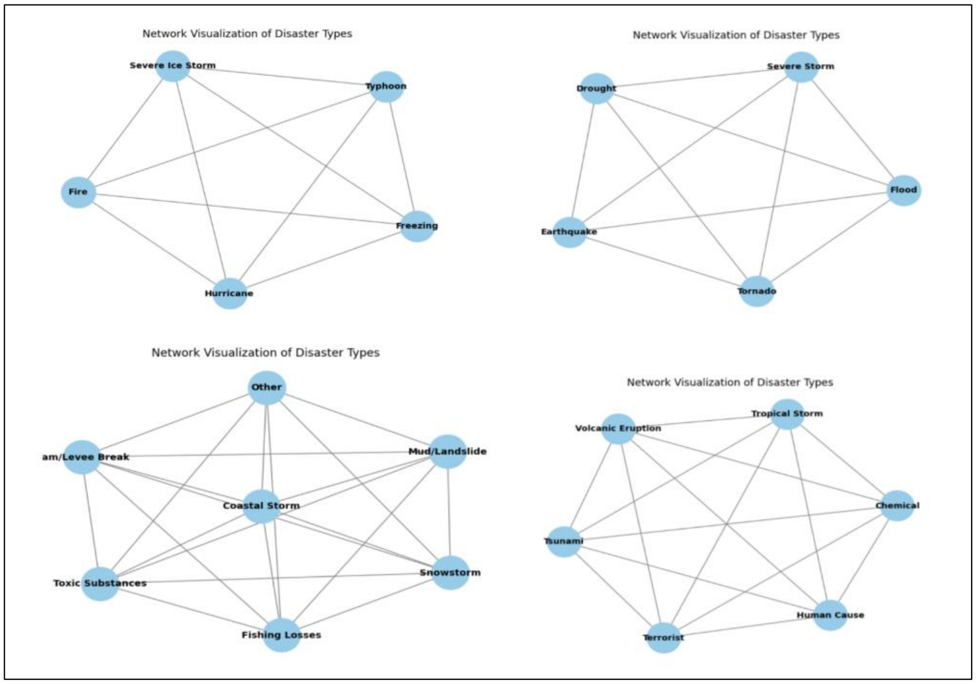

Fig. 10. Visualisation of network of different types using the network library in python.

A random relationship matrix where each cell represents the strength of the relationship between two types of disaster. The heatmap displays these values, with annotations showing the exact values, and uses a color scale (YlGnBu) to represent the strength of the relationships. The x and y axis labels represent the different types of natural disasters. In Fig. 11, it displays the heat map with a title and adjusts the layout for better visualization; each cell shows the actual values of the relationships between the corresponding pair of disasters. These values range from 0 to 1, where 0 indicates that there is no relationship and 1 indicates a perfect relationship. In Fig. 12, it first filters the data set to include only instances where the IH program was declared. Then, it creates two separate counts plots: one displaying the frequency of IH program declarations by incident type and the other showing the frequency by state. Each count plot is custom-made with appropriate titles, labels, and rotation of x-axis labels for better readability. In Fig. 13, two separate boxplots are created by calculating the duration of each incident by subtracting the incident end date from the incident start date. In Fig. 14, the variables “biological” and “fire” are removed from the outlier diagram. This is because fires and biological disasters are the outliers that will contribute the most to the outliers’ diagram. The outliers in these appear the most.

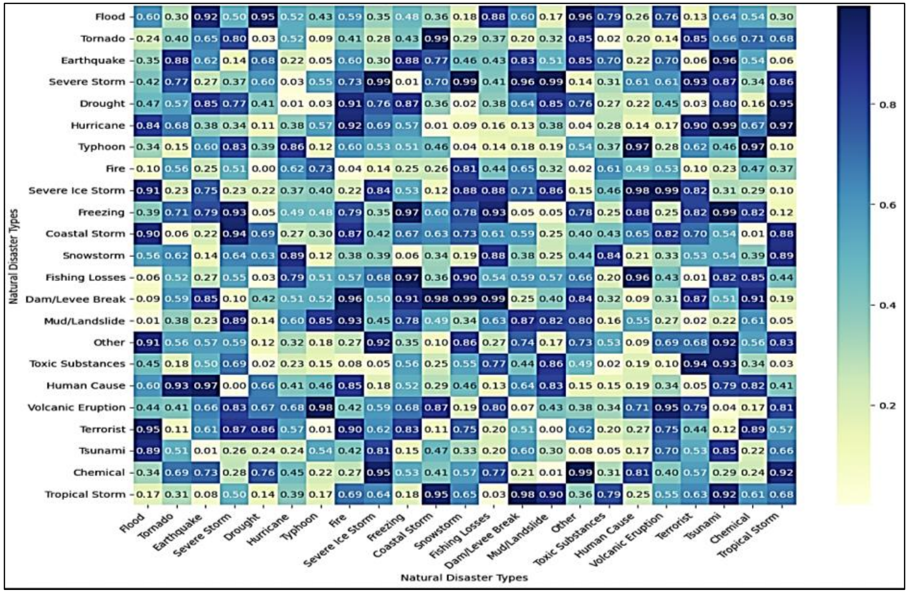

Fig. 11. Heat map revealing the relationships between types of natural disasters.

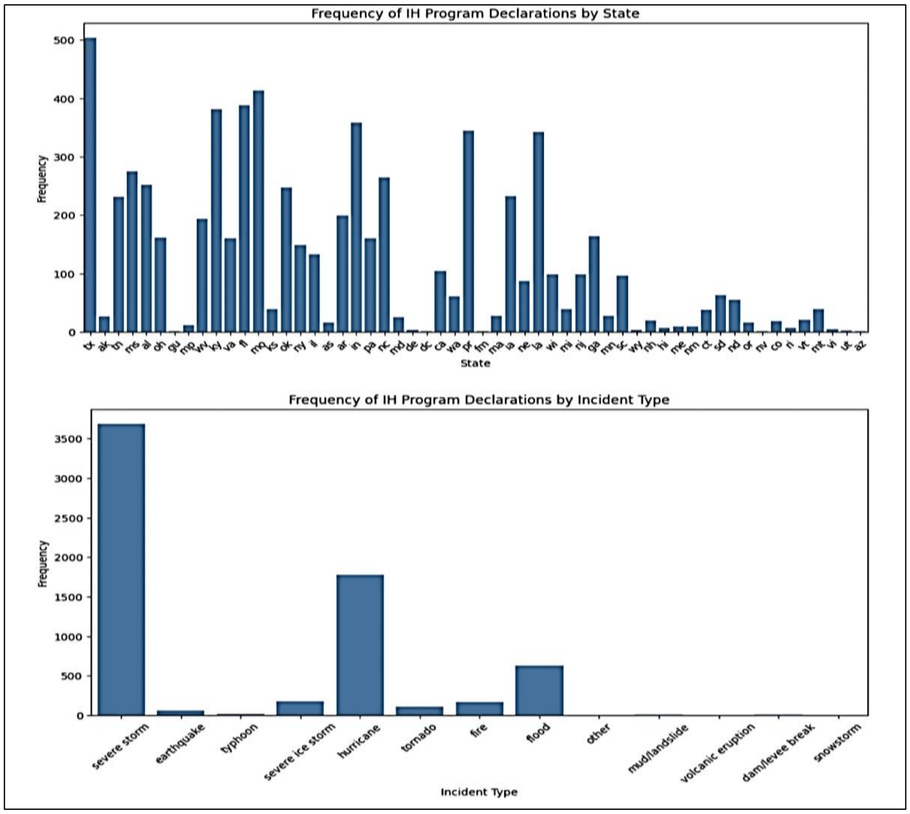

Fig. 12. Visualise the frequency of IH (Individuals and Households) programme declarations.

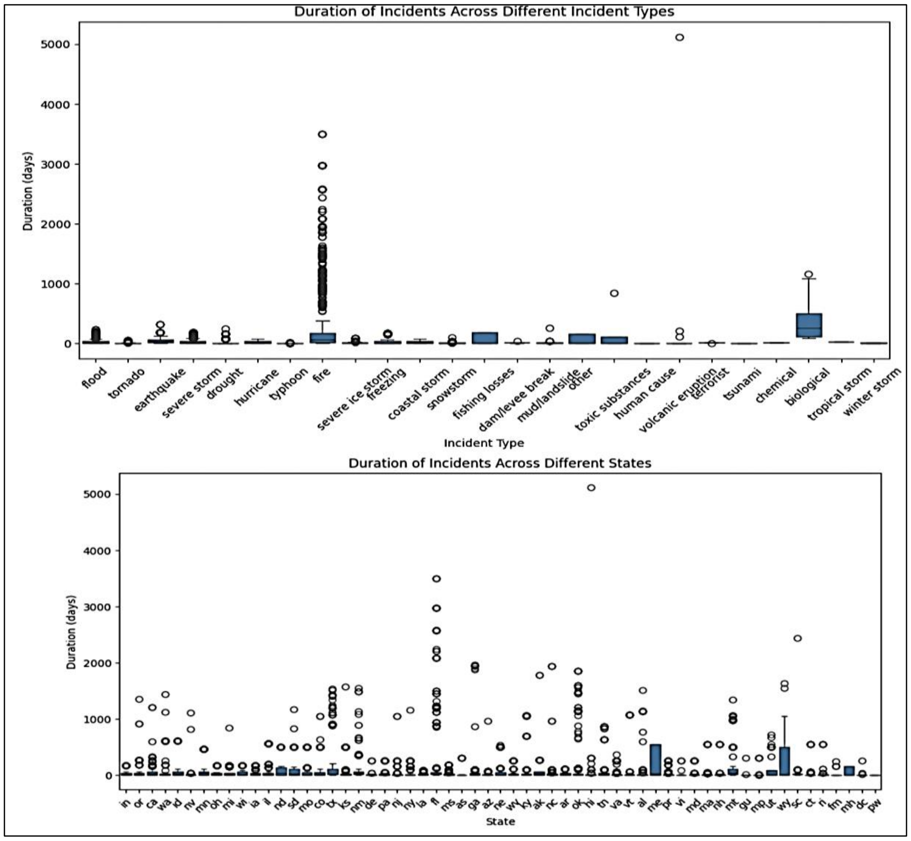

Fig. 13. Visualisation of the duration of incidents.

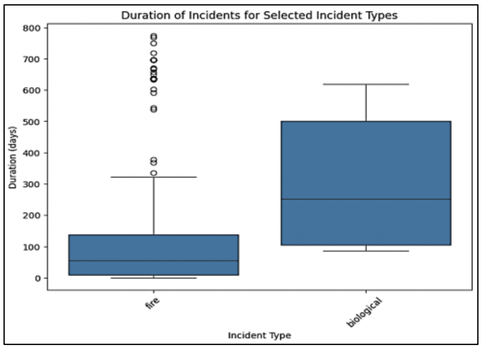

Fig. 14. The variables “biological” and “fire” are removed from the outlier diagram.

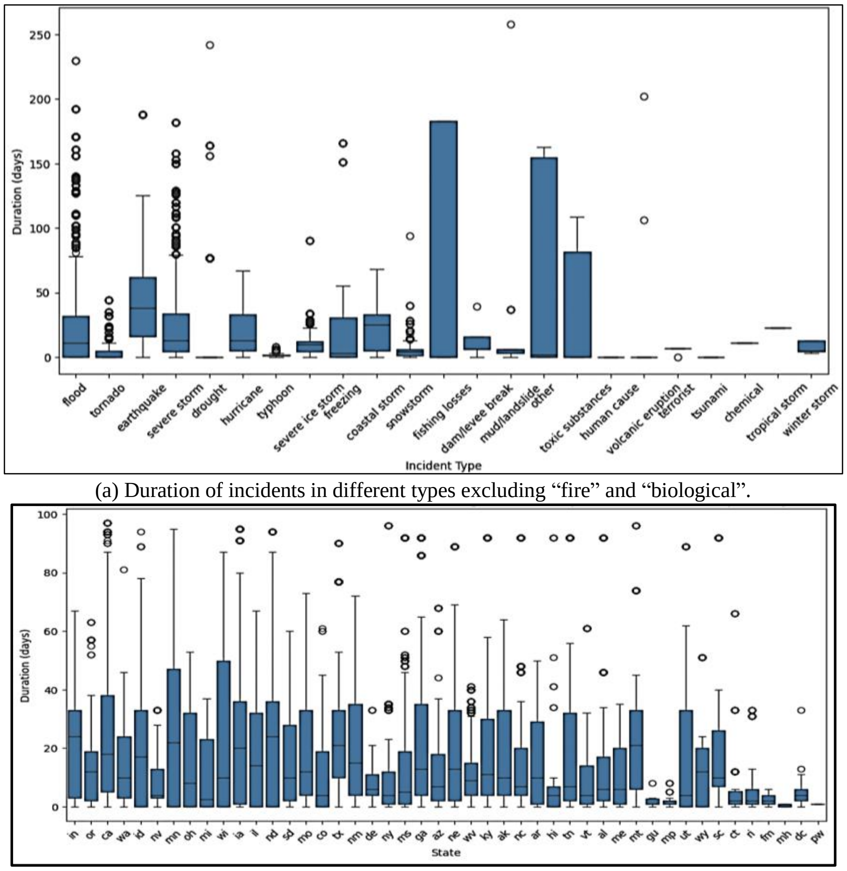
The next visualization technique as shown in Fig. 15 reveals the duration of the incident in different types and states, excluding several variables accordingly. The duration in days of each disaster reveals that the average duration is between the range of 50 and 100 days. Different states will have a duration for the incident, and it indicates that the average days for the state are around 30 to 40 days in each state.

Next, we group the data by declaration_date and count the number of disasters declared for each date. A line graph is generated to visualize the trend of the number of disasters declared over time (Fig. 16). The x-axis represents the declaration date, while the y-axis shows the corresponding count of disasters. The plot is customized with a title, axis labels, and grid lines for better interpretation. The second plot is where several years 2020 and 2008 are removed from the graph in order to make it more visible. This will make the number of disasters more clearly indicated. This is continued in Fig. 17 which is a generated violin plot where each violin represents the distribution of incident durations for a specific type of incident. Incident of ‘fire’, ‘human cause’, ‘tsunami’, ‘chemical’, ‘biological’, ‘tropical storm’ up to 3000 days, to ensure that the violet plot is more accurate in its presentation. A horizontal bar plot first calculates the frequency of each incident type using the value_counts() function. Then it creates a horizontal bar graph (kind = barh) where each type of incident is represented on the y-axis and its frequency on the x axis (Fig. 18). The time taken to close the disaster after declaration is calculated by subtracting the declaration dates from the closing dates. The resulting time differences are then converted into days. The kernel density estimation (KDE) plot is generated using seaborn to visualize the distribution of time taken for closeout. The KDE plot represents the estimated probability density function of the data. It provides information on the density of observations in different time intervals (Fig. 19). Lastly, a snippet of the 2x2 grid of subplots generated using Seaborn and Matplotlib is represented in Fig. 20. Each subplot represents the count of occurrences of Boolean values (True/False) in specific columns of a dataset.



(a) Duration of incidents in different types excluding “fire” and “biological”.

(b) Duration of incidents in different states (excluding fl, ok, va, la, pa, ks, vi, md, nh, ma, pr, as, nj).

C. Robust Scaler and Descriptive Analysis

The weather disaster data set is preprocessed using robust scaling to improve the performance of these clustering algorithms: K-means, DBSCAN, SOM, and GMM. This step is important because weather-related datasets often contain unique values, a nature that is heavily influenced by disasters. Robust scaling uses the median and interquartile range, mitigating the influence of these outliers on the central tendency of data. Moreover, normalization ensures that distances between points indicate the actual similarities of the data entries more closely and, therefore, enhance accuracy in clustering. Furthermore, it is easier to visualize and interpret normalized data for effective dissemination of results to interested parties, such as agencies concerned with disaster management.

Descriptive analysis is used to gain an initial understanding of the weather disaster dataset as shown in Table I: count, mean, standard deviation, min and max. This also involves summarizing the main characteristics of the data through statistical measures and visualizations. By performing descriptive analysis, it can identify key patterns, trends, and anomalies within the data, such as the frequency of different types of disasters, the distribution of disaster occurrences over time, and the geographical locations most affected.

TABLE I. DESCRIPTIVE ANALYSIS OF THE WEATHER DATA SET

Descriptive Statistics	Variables		
	declaration_ type	incident_ duration	state_label_ encoded
Count	58944	58944	58944
Mean	1.3666	45.2700	30.6819
SD	0.5321	132.3896	16.1234
Min	1.0000	0.0000	0.0000
25%	1.0000	3.0000	18.0000
50%	1.0000	13.0000	31.0000
75%	2.0000	33.0000	44.0000
Max	3.0000	5117.0000	58.0000

It helps in preprocessing the weather disaster dataset by providing a clear picture of the data structure and quality in this project. For example, it highlights issues such as missing values, outliers, and inconsistencies, which can then be addressed through appropriate preprocessing techniques. This foundational step ensures that the subsequent machine learning models are built on a clean dataset, enhancing their accuracy and reliability.

D. *Clustering Modelling*

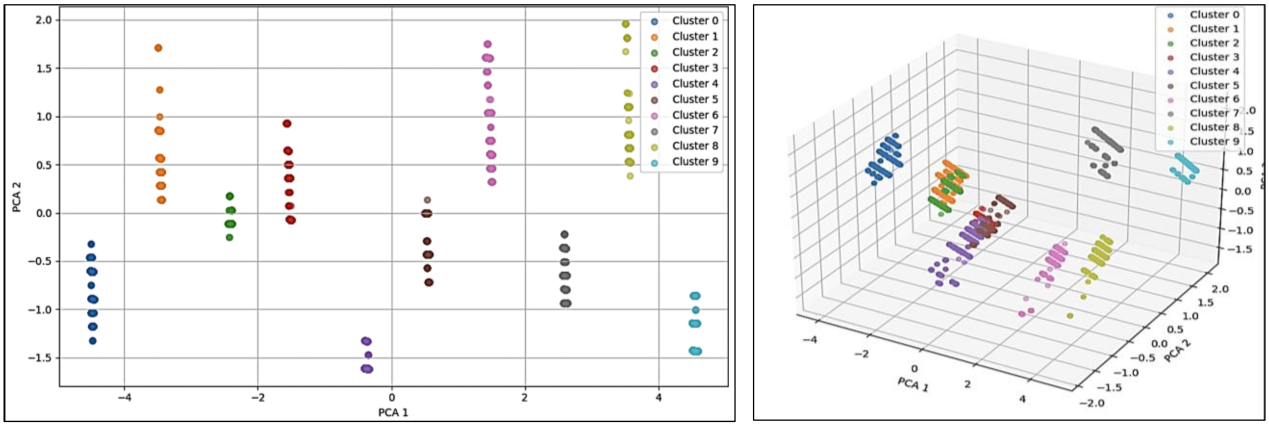
The first step involves clustering similar types of disasters based on their frequency. Each clustering method, including K-Means Clustering, DBSCAN, Self-Organizing Maps (SOM), and Gaussian Mixture Model (GMM), employs distinct algorithms and criteria for grouping data points. K-Means partitions data into K clusters by minimizing the within-cluster sum of squares within the cluster. DBSCAN identifies dense regions of points separated by sparser areas, while SOM organizes data onto a low-dimensional grid based on similarity. GMM models data distribution using a mixture of Gaussian distributions.

After clustering, it is crucial to analyze the relationship between the type of disaster and its frequency. Unsupervised learning techniques provide a means to explore this relationship without labelled data. By examining the distribution of disaster types within each cluster and the corresponding frequencies, we can gain insight into patterns and correlations. For example, certain clusters may predominantly contain hurricanes or floods with high frequencies, while others may include less frequent events such as earthquakes or biological disasters. Understanding these relationships can inform disaster preparedness and response strategies tailored to specific risk profiles.

To assess the effectiveness of each clustering method in accurately grouping similar disaster types, various evaluation metrics can be used. For example, the silhouette score, Davies-Bouldin index, or Calinski-Harabasz index can gauge the compactness and separation of clusters generated by K-Means and GMM. DBSCAN's performance can be evaluated on the number and coherence of resulting clusters. Quality can be assessed by quantization error and topographic error. By comparing these metrics across different clustering methods, we can identify the most suitable approach for our dataset and analysis objectives. By employing these unsupervised learning techniques and evaluation methods, we can gain valuable insights into the relationships between disaster types and their frequency, facilitating more informed decision making in disaster management and response planning.

E. *K-Means Clustering*

In K-means clustering, the silhouette_score method was used to calculate the suitable number of clusters used for the modelling, as shown in Fig. 21 (Principle Component Analysis (PCA)). PCA1 represents incident_type while PCA2 represents area. Each cluster represents the frequency of occurrence of each state and each type of incident. A total number of 10 clusters are displayed in two and three dimensional visuals. Furthermore, the means for all groups are calculated for evaluation to decide which model is better (Fig. 22).



(a) 2D K-means clustering (PCA visualization).

(b) 3D K-means clustering (PCA visualization)

Fig. 21. K-means clustering with 10 clusters displayed in 2D and 3D.

G. *Self-Organizing Maps (SOM)*

In self-organizing map (SOM) clustering, the topology-preserving characteristics of SOM are used to organize the data into a grid of nodes, where each node represents a cluster. Unlike K-means, where cluster centers are calculated iteratively, SOM assigns data points to the nearest node in the grid, creating a topological map of the data space. The SOM clusters are visualized in 2D and mean value for each cluster is calculated to gain insight into the data distribution and cluster formations (Fig. 25).

b. Mean value of SOM clusters

Fig. 25. Self-organising map visualisation and means value.

H. *Density-Based Spatial Clustering of Noise Applications (DBSCAN)*

For DBSCAN, 104 clusters are implemented as shown in Fig. 26 with their performance. Since there are too many clusters generated, the 3D visualization is too complicated to analyze due to overlapping clusters with unidentified clusters for each state and each incident_type.

b. Means of DBSCAN clustering

Fig. 26. DBSCAN clustering and its performance (means).

I. *Mean Shift Clustering*

As shown in Fig. 27, a total of 10 clusters are displayed and these clusters are separated compared to DBSCAN which produces a clearer vision. The means of this model are on average negative values (Fig. 27). A cluster with a negative mean value indicates that the data points within that cluster have on average, negative values for the particular variable or feature analyzed (Fig. 28).

Fig. 28. Mean value of mean shift clustering.

Based on Table II, DBSCAN has the highest silhouette score. It is the best clustering algorithm, followed by the Gaussian mixture. This is because it not only displays the firm clusters in the diagram, but also has a relatively higher silhouette score compared to other clustering algorithms. However, they are imperfect when applied in the FEMA dataset. There are some inaccuracies in the result with the clustering algorithm due to outliers in the mean calculation for state and incident. To conclude, having a definite and firm clean dataset is crucial in the clustering process, as it will provide the most accurate and identical result for analysis.

TABLE II. COMPARISON OF FIVE CLUSTERING MODELS USING THE SILHOUETTE SCORE

Model	Silhouette Score
K-Means	0.4546
Gaussian Mixture Model	0.8161
Self-Organizing Maps	0.6003
DBSCAN	0.9883
Mean Shift Model	0.4715

V. CONCLUSION

In view of the information provided on natural disaster data and after running different clustering techniques, this paper concludes that modern machine learning algorithms such as K-means, DBSCAN, SOM, and GMM have been very efficient in classifying and understanding patterns in disaster incidences. K-means identifies trends/distributions of disaster incidents and thus improves preparedness and response strategies. Spatial distribution studies, such as those related to the location of disaster sources and eventual mitigation of their impacts, are based on attributes central to DBSCAN. SOMs are a robust method for topological mapping and clustering, which can be used effectively for the visualization and better interpretation of data. GMMs are efficient ways of modelling even very complex multimodal distributions and are therefore suitable for anomaly detection in disaster datasets.

However, several limitations with this study. The accuracy of clustering results greatly depends on the dataset quality and completeness of the data set. The existence of missing values and inconsistencies within the data will greatly decrease the reliability of the result. Moreover, computational complexity and time for some clustering algorithms are highly needed mainly with the large datasets, which becomes a problem in the application.

Future work has to be directed towards enhancing data preprocessing techniques so that it can answer missing and inconsistent data more efficiently. In addition, other data sources, such as real-time satellite imagery, sensor data, etc., will add comprehensiveness and accuracy to the analysis. Computational efficiency in clustering algorithms can be achieved by parallel processing or any other advanced computing technique, which requires further research. Moreover, the development of hybrid models involving multiple clustering techniques would tie the different strengths of each technique and therefore further enhance disaster predictions. There will be a need to continue at this higher level of collaboration with disaster management agencies to ensure that the findings of such studies translate to actionable strategies that reduce the impacts of natural disasters.

Impact of Read Theory in Mobile-Assisted Language Learning on Engineering Freshmen's Reading Comprehension Using BI-LSTM

E. Pearlin[1], Dr. S. Mercy Gnana Gandhi[2]
Research Scholar, Department of English, Sathyabama Institute of Science and Technology, Tamil Nadu, India[1]
Professor, Department of English, Sathyabama Institute of Science and Technology, Tamil Nadu, India[2]

Abstract—**The effect of Read Theory in Mobile-Assisted Language Learning (MALL) on reading comprehension is critical, especially for engineering freshmen who require excellent language abilities to navigate their complicated academic courses. Read Theory is a customized reading platform that offers adaptive reading activities based on the user's ability level, which is especially useful in MALL settings where accessibility and flexibility are essential. However, traditional methods of MALL have frequently faced with constraints, such as the inability to completely adapt to students' different and dynamic learning demands. This deficiency usually results in poor improvement in reading skills because the conventional paradigms do not capture the intricate and diverse learning processes that are necessary for the effective learning of languages. To fix these issues, a Deep Learning approach that involves the implementation of BI-LSTM networks for enhancing the completion's reading outcomes is offered. BI-LSTM is more suitable for this task because it has forward and backward reading capabilities to better understand and predict the dynamics of language acquisition. The research established improvement and an astonishing accuracy of 99.3%. The implementation was done using Python. This high value of accuracy disproves the common weakness of the strategy and provides convincing evidence that the proposed approach can significantly enhance MALL projects' outcomes. The specified technique, which improves on the flaws of previous approaches, does not only improve the process of reading but has the potential to revolutionize language acquisition for engineering students, making it more effective and conforming to ability.**

Keywords—Read theory; language learning; Bi-LSTM; mobile-assisted; deep learning

I. Introduction

Reading skills in a person's native language usually develop during early childhood. Acquiring reading skills in a second language can be tough and demands an alternative approach to thinking. This is why reading in English as a Foreign Language (EFL) is still being studied. In most contexts, reading and listening are understood as processes for taking in information while speaking and writing are recognized as methods for expressing information. However, newer studies have looked at how reading links to other skills, especially how it relates to writing [1]. Reading is important in people's lives because it helps them learn and stay informed about all the information around them. It becomes a regular part of the free time, school tasks, or job responsibilities. Students in universities need to pay close attention to this because they will be required to read a lot of material for their coursework. Print or digital are the two alternatives available to them. The primary goal of authors is to pique readers' interest and aid in the retention of the content. Typically, the text is enhanced and remembered by adding images or movies. Since practically everyone may now publish and distribute their work, viewers have a wide variety of texts and forms to choose from. [2]. Developing reading skills is very important because reading is a complicated and interactive task that depends on how a person understands a text. It moves back and forth between basic steps, like recognizing words and decoding them, and higher-level thinking. Reading in a foreign language is harder because everyone experiences and understands a text differently based on their own background and thinking skills. Studies show that it's helpful to use a broad approach when working with text [3].

The educational activities implemented within the framework of the initial academic year for the students who have chosen engineering, Read Theory, an online tool aimed at improving the reading comprehension abilities, explore a very effective direction to develop the language competencies with focus on the specific area of interest [4]. Read Theory is computer algorithm-based application that offers reading tests and quizzes at the appropriate level of difficulty for each student making it very effective program for enhancing the students' reading skills. Science students, especially engineering students, may spend most of their time reading technical materials and thus may not be as proficient in reading as they ought to be especially in contexts that demand deep understanding of technical and academic texts as well as industry literature [5]. Incorporation of Read Theory into MALL is proposed because with the help of Mobile-Assisted Language Learning students can practice reading exercises or take reading assessments at any time and at any place they wish by using their mobile devices. MALL is an outreach of the conventional classroom setting and refers to the use of mobile learning as a flexible means of learning a language on one's own time and pace [6].

The relevance of Read Theory in MALL is made prominent by the kind of data-focused learning that it embodies. Since students engage with the application, their reading behaviours, achievements, and challenges are identified and logged. This information can be collected to have an understanding of the dynamics in understanding and areas that need improvement regarding the comprehension of what is taught to ensure that changes that could be made to effectively teach can be made by educators [7]. In addition, extending Read Theory in MALL can promote more learner-centred context that means learners are likely to have more control of how they learn. The learners can be informed promptly of their performance, get many reading materials, and build their skills in a very systematic yet somewhat freeway. It can be inferred from the above findings that for engineering freshmen particularly, who rely on their capacity to rapidly put into effect and decode technical content for class performance, advantages of applying Read Theory in MALL are vast. Students should also learn to improve their general performance in class, comprehension of class content and improve their skills in interpreting texts. This can help them in the future employment in the engineering field where the clarity of understanding as well as the ability of conveying that understanding becomes crucial [8]. Most engineering students go through a tight outline of subjects that are technical that do not let them practice reading a lot or even do so with much effort [9]. Apparently, the given competence of understanding rather complex texts is important for their further academic and work experience. Several programs have been named earlier: Read Theory with the built-in option of adaptive learning that allows the learner to focus on reading exercises with the relevant difficulty level and a great choice of texts. When it is used through mobile environment, it becomes more convenient since the students can be involved with the reading exercises at any spare time as they wait for their classes, during transport among other times hence making reading part and parcel of their everyday lives [10].

Thus, the efficiency of Read Theory in a mobile frame can be defined by the regular interest of students; steadily increased level of comprehension of the texts read; and flexibility to the time limitations of students. Mobile devices can prove beneficial when learning is being done at a variety of locations including the college, homes or while on the move. This goes hand in hand with increased chances of going through the material, which is beneficial in check and balance learning session and to reinforce what has been learnt. In addition, the mentioned environment is highly flexible and it provides students with a number of opportunities regarding feedback; it is possible to provide immediate feedback in the context of a mobile environment so that students could see the results of their efforts and alter their approach in case of it is necessary [11]. The post Sherpa use of Read theory desired outcome is also measurable by comparing pre and post-test where, if the scores were to rise significantly after the inclusion of the mobile assisted use of Read theory, then the desired outcome would have been achieved. Also, questionnaire or survey with the students in terms of their experience with the particular developed platform can afford prose description of its usefulness as well as its effectiveness in enhancing student learning. To the engineering students the deployment of Read Theory in the mobile context means that those overloaded with multiple difficult subjects can use it as the supplement to the standard approaches. It is not only a method of developing the skills in reading comprehension but also a current method of constant learning. Making use of this instrument, students have the chance to foster gradually their independent reading-skills, respectively instrumental reading-skills which are important for the engagement with more advanced academic texts [12]. The key contribution of the work.

- Utilizes BI-LSTM models to increase the accuracy of reading comprehension prediction, delivering enhanced insights into the usefulness of mobile-assisted learning technologies.
- Implements Read Theory inside a mobile-assisted learning framework to assess its influence on engineering freshmen's reading comprehension, adding to the practical use of technology in education.
- Assesses improvements in reading comprehension scores before and after the intervention, providing measurable proof of the efficacy of mobile educational platforms.
- Provides empirical data on the benefits and problems of using Read Theory in a mobile learning environment, contributing to the corpus of knowledge in educational technology.
- Improves the design and effectiveness of mobile-assisted learning tools by combining user input and performance data, resulting in more effective instructional tactics and resources.

The study is structured as Section I provides an introduction of the research, and Section II has Related Work which reviews the existing literature. Problem statement is given in Section III. Section IV details the data collection methods, preprocessing steps, and analytical approaches, including the use of BI-LSTM models and Section V presents the Result and Discussion and ends with Conclusion and future works in Section VI.

II. Related Work

Many adults learning a second language or a foreign language don’t have enough chances to practice. However, learning a new language well is important for many reasons. It helps them fit in quickly in a new country and adjust easily to new jobs or schools. This means they need more help to learn their second language successfully thinking that advancements in learning analytics, self-directed language learning, and mobile language learning will enhance this support. MALLAS, which stands for mobile-assisted language learning through learning analytics for self-regulated learning, is a novel concept that is presented in this study. It is intended to assist individuals who plan educational initiatives in assisting folks acquiring a second language. This is accomplished by utilizing learning data to assist students in better managing their own learning. Here, the MALLAS framework is demonstrated as a tool to aid with the application of mobile-assisted language learning in a particular scenario. Researchers who wish to learn more about and support language learners who utilize mobile devices for self-study may also find it helpful. A possible problem with the MALLAS framework is that it depends a lot on how good the learning analytics tools are. These tools can have problems if the data is not high quality or if it’s not understood correctly. Also, it may not consider the different ways people learn and what motivates them, which could make it less effective for various groups of learners [13].

In this study, Mortazavi et al. [14] looked at various factors that affect how MALL can help improve speaking and listening skills. 100 research papers were chosen from the best journals about how MALL affects language learning in higher education. A selection of eight papers was made according to particular criteria to consolidate findings related to language abilities and technology concepts. So, after carefully looking at the suggested methods and comparing them, explaining the basic beliefs about this issue and provide complete and lasting solutions to deal with it. This analysis showed that people in developing countries use mobile devices a lot for learning. The main area where technology helps is vocabulary, and it is giving good results. According to this survey, university students prefer to use WhatsApp for chatting and writing, and LINE for listening and reading comprehension. Teachers should consider using the TAM to modify their present and future lesson plans. This means they can improve students' learning by using more than just in-person classes [14].

Mobile technologies and the reasons that affect EFL learners' desire to use them in their studies are important. This study looks at how factors like support, ease of use, and usefulness affect Iranian EFL learners' views on MALL. Data were gathered from 223 Iranian students learning English as a foreign language, who took their classes in two main places: public schools and private institutes. In the first part of the study, a meaningful connection between three important factors and what learners think about MALL is found. Also, the support available was linked to how easy learners felt using it. In the second part of the study, the results showed that how useful people think MALL is really affects their views about it. This study also shows that having good support makes it easier for learners to use tools. The results are talked about based on other studies, and ideas for more research are given [15].

In this study, university students learning EFL used mobile devices to help them learn. The research focused on understanding how students feel about using mobile phones for language learning, how they use these tools, and how helpful they are for their studies. The findings demonstrated that students utilize different MALL software for distinct objectives. Five important criteria that influenced students' adoption of MALL software were identified from a study conducted among 581 students from Indian colleges and universities. These factors are individual desires and reasons, how easy the software is to use, technology features, social influence, and how useful the students think the software is. These factors impacted students' readiness to use the software, their motivation, and ultimately their performance. The study showed how prepared and motivated students are affected by the way they use MALL and the results they see from it. The importance of good language learning results, the ideas added to the theory, and practical uses for managers from the study are talked about. Some language abilities, such as speaking and listening, require more practice due to hardware restrictions, especially for mobile activities that may be improved [16].

This study looked at how using mobile apps for language learning can help university students who are learning English improve their skills and support their ability to learn on their own. It also aimed to help them become more skilled with technology. The global epidemic and spread of COVID-19 have accelerated the usage of technology in schools because to the urgent necessity to keep education going. As digital technology has advanced, many smart mobile apps are now used for learning and teaching English. Using these technologies can help language learners practice learning on their own outside of the classroom. This is important for staying motivated and becoming independent learners. Mobile phone apps can be very helpful for teaching because they are easy to use, available to many people, and have various features. There hasn't been much research on using mobile phones to help people learn languages on their own outside of school. In this research, university students studying English utilized their smartphones to facilitate independent learning outside the classroom. This made their learning more lasting and independent. The findings of this study showed that students had a positive attitude towards using mobile devices to help them learn English. The results show that using mobile apps for learning languages can increase students' motivation and make their learning more enjoyable and lasting compared to traditional teaching methods. People in this study said that the biggest advantages of using mobile learning for studying English were easy access to learning materials, the ability to carry their tools anywhere, the freedom to learn on their own, better interaction with others, and feeling more confident in their English skills. The study talks about how to teach better and suggests ways to create a learning environment that fits with the changes brought by technology. Learners plan to use mobile phone apps to learn English in the future. This shows that these apps can be useful for helping them learn on their own and make their learning more effective over time [17].

Mobile-assisted language learning (MALL) has had a significant impact on language learning by encouraging self-directed learning and providing practice opportunities outside of traditional classroom settings MALL has shown have proved particularly effective for vocabulary acquisition and are widely used in developing countries, where mobile technology facilitates language learning [18]. Key factors affecting acceptance of MALL tools are personal motivation, ease of use, and perceived usefulness, which directly affect learning outcomes and motivation Students’ perceptions of MALL are also influenced by the support and usefulness of technology a they get it and it shows [19]. The COVID-19 pandemic reaffirmed the value of MALL, as it increased student motivation and enabled a more flexible and consistent learning experience compared to traditional methods but the potential of MALL was well realized, challenges such as ensuring data quality in academic research and retrieving a variety of materials must meet student preferences.

III. Problem Statement

The study aims to fill the identified knowledge gap in the analysed literature, especially when it comes to adapting learning analytics practices to broaden the topical area of MALL and foster self-regulated learning strategy among adult second language learners. In the prior research, the effects of introducing the use of mobile technologies to support second language acquisition have been researched but there is a lack of research in the best ways of using learning analytics to facilitate support and feedback in a mobile learning environment [20]. Besides, there is lack of research evidence on how frameworks such as MALLAS can be used to address the needs of the learners given the different learning styles, motivation, and quality of data collected.

IV. PROPSOED METHODOLOGY FOR IMPACT OF READ THEORY IN MOBILE-ASSISTED LANGUAGE LEARNING ON ENGINEERING FRESHMEN'S READING COMPREHENSION USING BI-LSTM

Read Theory in MALL provides an interactive environment that improves reading comprehension through tailored practice. Adapting content to learners' competence levels, Read Theory promotes focused skill development and engagement. The study makes use of Bi-LSTM networks to evaluate the impact of Read Theory on engineering freshman’s studying comprehension. Bi-LSTM networks are well-acceptable for capturing contextual relationships in sequential data due to their ability to process information in each forward and backward directions. This bidirectional method complements the model’s functionality to apprehend the nuances of language and context, making it effective for analyzing comprehension. Bi-LSTM on data collected from Read Theory's platform, focusing on studying comprehension tasks and assessments. The model can be evaluated based on its capacity to assume enhancements in comprehension ranges and usual common performance. Leveraging Bi-LSTM networks, the research offer insights into the efficacy of Read Theory in enhancing reading skills and making a contribution to the optimization of MALL programs for students as shown in the Fig. 1.

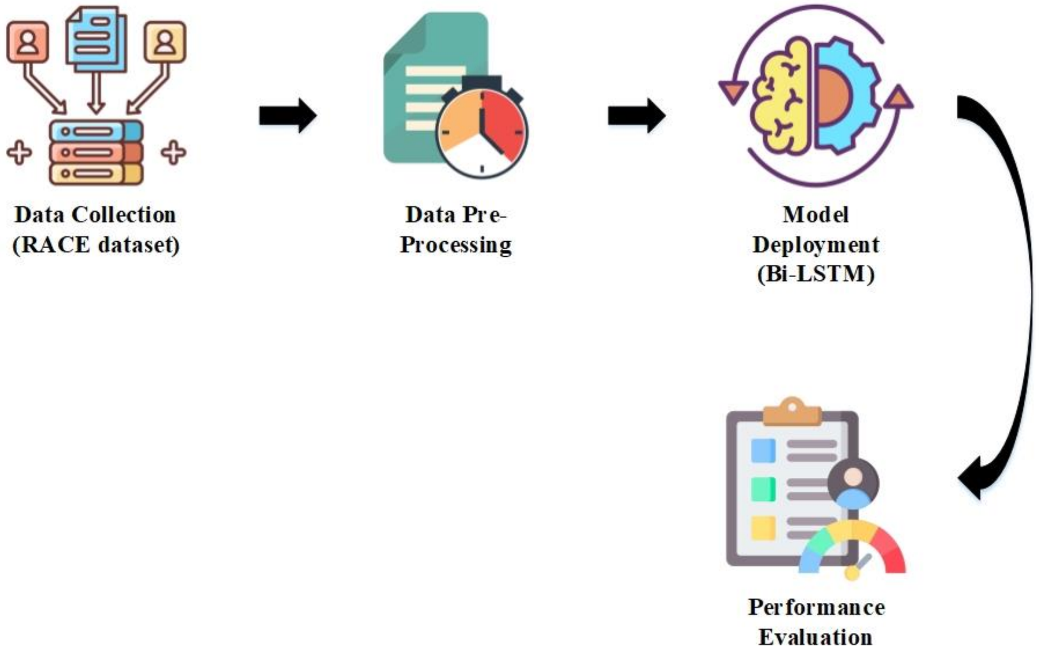

Fig. 1. Block diagram of the proposed study.

The study examines the potential of the mobile learning tool known as Read Theory to contribute to development of freshmen’s engineering reading skills. To examine the impact of Read Theory on students’ ability to understand the difficult texts, the study employs deep learning technique referred to as the Bi-LSTM networks. The study procedure consists of three critical stages: data acquisition which captures students’ details and their reading literacy levels, and data pre-cleaning which sequentially purges the data that it harvested from the internet. Subsequently, an enhanced model in the form of Bi-LSTM is developed and applied in order to estimate students’ reading comprehension according to their progress in Read Theory. Lastly, the ability of the Bi-LSTM model to predict reading comprehension results is assessed. Through such extensive research, the study aims at providing useful information on the effectiveness of Read Theory for enhancing comprehension of freshmen in the engineering field hence help in the development of better language learning techniques.

A. Data Collection

The RACE [21] dataset which is an analyzing dataset comprising of more than 28000 passages and nearly 100000 questions extracted from the English examination conducted in China is used. The forms are designed especially for center and high school students and, therefore, will make the dataset rather useful for measuring reading comprehension. It offers a vast amount of textual information and related questions that can be used as schooling and test sets for the system comprehension models. Using this dataset, analyze the degree to which the Read Theory platform impacts the studying comprehension of engineering newbies within a MALL environment. The collection of passages and questions in the RACE dataset will create a strong basis for the assessment of students’ analyzing skills, and the results will offer an understanding of how the adaptive learning can benefit language education and understanding potential for students in academic context.

B. Data Pre-Processing

Data preprocessing is an initial step in data analysis and ML that emphasizes preparing the raw data for cleaning, transformation, and proper formatting. This process includes numerous key activities: It includes steps like cleaning data by dealing with missing values, errors and inconsistencies; normalize or standardize the information to get certain degree of uniformity and code the categorical data in number form, compatible to the models. It is also equipped with characteristic extraction and selection to determine the maximum eligible variables for the analysis. Data preprocessing increases the purity of data and performance of device by correcting that the record of data is accurate, complete and arranged in the proper format. By performing feature preprocessing, more accurate results are obtained and, therefore, more likely to define the desired version, and is a non-trivial process for any works based on data analysis.

1) Text normalization: Text cleaning is one of the key steps in the preparation of data in the field of NLP that brings raw text data in a specific structure for analysis. Changing every textual content to lower case is also important in order to standardize the text since it is easier to compare lower cases to lower cases from the increased amount of whitespace removed from the text that does not add any value to the meaning of the text. Furthermore, normalization includes enhancement of some occasional contractions to their full bureaucracy, normalization of Unicode character to illustrating equivalent, and erasing normal words like such as those adding semantics. Tokenization process divides the textual content into individual words or tokens which can be lemmatized into their base form so as to reduce variation. Applying these approaches, the textual content is preprocessed: it is normalized and previously analyzed or trained in models, and similarly prepared for further analysis.

2) Tokenization: Tokenization is the procedure of dividing textual content into smaller units, known as tokens, which may be character words, phrases, or symbols. This phase is vital in NLP because it converts raw textual input into a structured format that can then be easily evaluated and processed. Splitting the text into tokens, permits algorithms to handle and understand textual statistics greater efficiently, permitting responsibilities which include parsing, evaluation, and modeling. Tokenization simplifies the textual content, making it feasible to carry out operations like counting word frequencies, analyzing sentence structures, and making use of the system mastering model.

$$Tokens = text.split(delimiter) \tag{1}$$

Where $text$ is the original string of text that will be tokenized and $delimiter$ is the character or collection of characters used to divide the text.

C. Bi-LSTM

Bi-LSTM networks are enhanced LSTM networks that capture time-dependent complexity in sequential data without dissimilarity. Standard LSTM networks, sequential in one direction. In the future, Bi-LSTMs process data in both forward and backward orientations. These two modes can integrate past and future knowledge about a specific event in the sequence to provide a thorough comprehension in the context of the mediation. A Bi-LSTM network consists of two LSTM layers: one that processes the input sequence from beginning to end, and another that processes it from end to beginning. The outputs of these two layers are then combined to provide a more complete representation of the data. For a given sequence $X = (x_1, x_2, x_3 \ldots., x_T)$, where T is the length of the sequence, the forward LSTM creates hidden states $\overrightarrow{h_t}$. The forward LSTM creates hidden states at each time step t, whereas the reverse LSTM generates hidden states at each time step $\overleftarrow{h_t}$. The composite representation for each time step (t) is obtained by concatenating the two hidden states:

$$h_t = [\overrightarrow{h_t}, \overleftarrow{h_t}] \tag{2}$$

In Eq. (2), h_t represents output at time step , which capture the data from both the direction of the sequences. The Input Gate (i_t) controls the quantity of incoming data that is fed into the cell state. The Forget Gate (f_t) regulates the quantity of previous cell state that should be retained. The output gate (o_t) determines the quantity of cell state that will be output.

$$i_t = \sigma(W_i.[h_{t-1}, x_t] + b_i) \tag{3}$$

$$f_t = \sigma(W_f.[h_{t-1}, x_t] + b_f) \tag{4}$$

$$o_t = \sigma(W_o.[h_{t-1}, x_t] + b_o) \tag{5}$$

$$C_t = tanh(W_C.[h_{t-1}, x_t] + b_C) \tag{6}$$

$$C_t = f_t * C_{t-1} + i_t * C_t \tag{7}$$

$$h_t = o_t * \tanh(C_t) \tag{8}$$

where the hyperbolic tangent function in Eq. (3), Eq. (4), Eq. (5), Eq. (6), Eq. (7) and Eq. (8) is represented by $tanh$, the sigmoid function by σ, and element-wise multiplication by $*$. Because of these equations, LSTMs may better express complex temporal relationships by keeping a consistent gradient across long time periods.

The Fig. 2 illustrates the architecture of the Bi-LSTM model and briefly describes its work. As an advanced type of LSTM network, the Bidirectional LSTM network analyzes the data sequences both in the backward manner and the forward manner, thus, collects contextual information from both the past and the future for each time step. The forward LSTM scans the sequence from start to end while the reverse LSTM scans from the end to the start. The output of these two LSTM layers are then concatenated together to form a new vector representation for each time step. This bidirectional method enhances the possibility of the model to learn and predict based on the whole context of the input. On the whole, the graphic represents the LSTM cells of both, the forward and backward passes, while the arrows demonstrate the information flow across the layers. Bi-LSTMs are useful in tasks that require exploitable amount of context depth such as language modeling, text classification and sequence prediction, where information flow is bidirectional. This structure is especially useful when the correct forecast depends on context data of both past and future time periods. BiLSTMs are often superior to regular LSTMs in hardnesses that require understanding context not only from the previous but the following data input, and they also can discover more sophisticated relations in sequential signs than unidirectional LSTMs. BiLSTMs can be used in any general purpose, for natural language processing and time series analysis and machine translation.

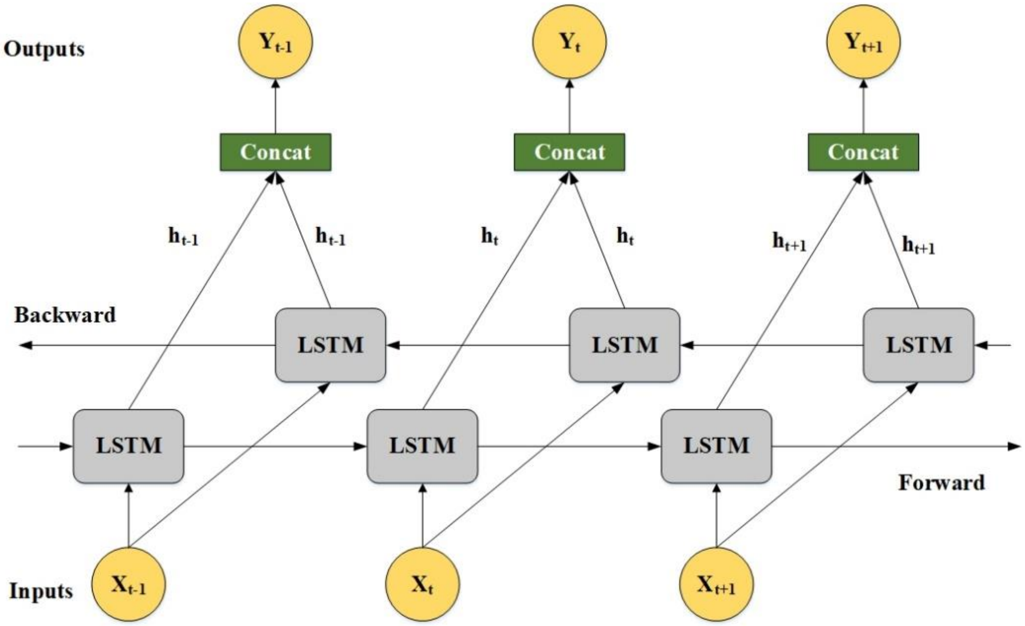

Fig. 2. Architecture of Bi-LSTM.

Bi-LSTM are crucial to investigate and technologically impact the reading theory in MALL for freshmen's reading comprehension. Bi-LSTM interfaces are particularly important in this work, for identifying and applying applications from past and future in contexts, under all comprehending reading tasks. Compared with the single-dimensional model, the Bi-LSTM network can receive textual input in two dimensions that it is more likely to analyse reading and estimating the student comprehension level than the single-dimension model. This bimodal processing assists the communicator to pick the fine details of the language and the context. It also enhances the model's accuracy in forecasting comprehension rates based on engagement with the read theory.

```
Algorithm 1: Reading Comprehension Using BI-LSTM
Step 1   Data Collection
             • Input the RACE Dataset
Step 2   Data Pre-Processing
             • Clean the data
             • Normalize the text data
             • Tokenize the text into smaller units
               $Tokens = text.split(delimiter)$
         Divide the text
             • Lemmatization
Step 3   Model Training
         //Define the architecture of the Bi-LSTM model
               Given sequence $X = (x_1, x_2, \dots, x_T)$
               hidden states $h_t = [\overrightarrow{h_t}, \overleftarrow{h_t}]$
         //Initialize Model Parameters
             //Forward LSTM Layer
             Input Gate $(i_t) = \sigma(W_i.[h_{t-1}, x_t] + b_i)$
             Output Gate $(o_t) = \sigma(W_o.[h_{t-1}, x_t] + b_o)$
             //Calculate Cell State
             Cell State $(C_t) = tanh(W_C.[h_{t-1}, x_t] + b_C)$
             $C_t = f_t * C_{t-1} + i_t * C_t$
             Hidden State $(h_t) = o_t * tanh(C_t)$
         Train the model using the training data
Step 4   Model Evaluation
             • Make Predictions on the test data
             • Calculate model accuracy
Step 5   Model Deployment
             • Evaluate the model
```

In practice, the Bi-LSTM network will be used to assess sequences of student interactions with Read Theory content, such as their replies to comprehension questions and feedback received during the learning process. This investigation seeks to uncover trends and insights into how the Read Theory platform enhances reading comprehension abilities. Using the Bi-LSTM's capacity to integrate information from both sides of the text sequence, the research may gain a better grasp of how various parts of the learning material contribute to comprehension growth. Furthermore, the Bi-LSTM's ability to simulate long-range dependencies within text sequences is critical for capturing the intricate links between many aspects of reading comprehension, such as recognizing context, drawing conclusions, and storing knowledge over time. This capacity will allow the research to more properly and thoroughly assess the success of the Read Theory intervention. Finally, the application of Bi-LSTM networks will give significant insights into the efficacy of mobile-assisted learning tools, help to optimize instructional tactics, and improve the overall impact of MALL platforms on engineering students' academic achievement.

V. Result and Discussion

In the result and discussion section, examining the findings from applying Read Theory inside a MALL framework to engineering freshmen, specializing in studying comprehension upgrades facilitated by using Bi-LSTM networks are done. This section delves into how the gaining knowledge of Read Theory affects comprehension outcomes, inspecting the effectiveness of the Bi-LSTM model in capturing and enhancing reading abilities. The interpretation the statistics to evaluate the realistic implications of these findings, comparing them with existing literature and discussing their relevance for academic techniques in engineering disciplines. Insights gained will highlight the impact of MALL tools on academic performance.

A. *Training and Testing*

The Fig. 3 shows a line graph illustrating the training and testing accuracy of a machine learning model over 100 epochs. The x-axis represents the variety of epochs, at the same time as the y-axis shows the accuracy value, starting from zero. The training accuracy, which typically increase as the model learns from the training data. The testing accuracy, which measures the model's performance on unseen data. Initially, the training accuracy hastily increases, at the same time as the testing accuracy indicates a greater slow upward push. However, after round 60 epochs, the training accuracy plateaus, and the testing accuracy starts to decrease slightly. This indicates that the model might be overfitting the training information, learning its patterns too well and struggling to learn new, unseen examples. Overall, the graph indicates that the model achieves a reasonable level of accuracy on both training and testing data.

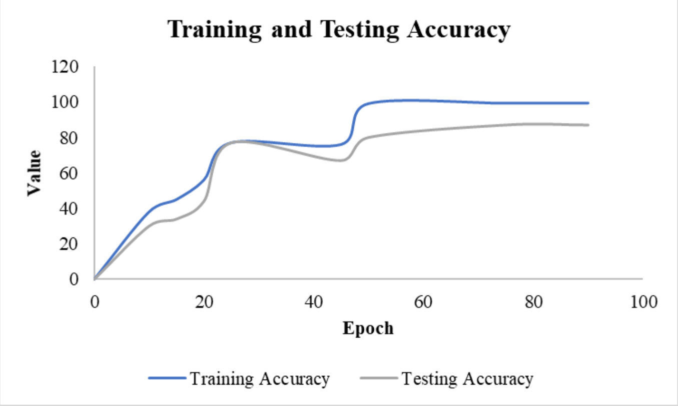

Fig. 3. Training and testing accuracy.

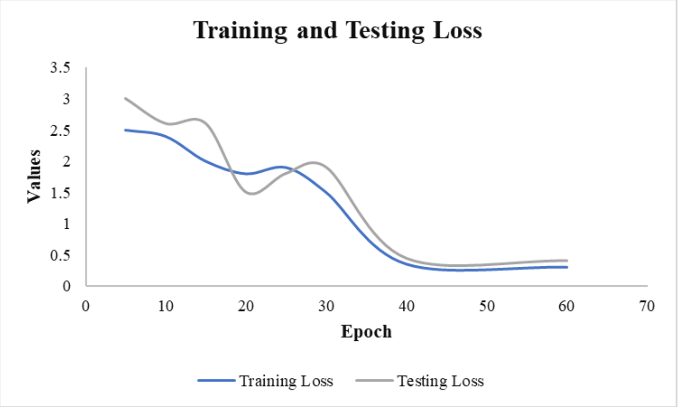

Fig. 4. Training and testing loss.

Fig. 4 shows a line graph illustrating the training and testing loss of a machine learning model over 60 epochs. The x-axis represents the range of epochs, at the same time as the y-axis shows the loss value, starting from zero. The training loss, which commonly decreases because the model learns from the training data. The testing loss, which measures the model's performance on unseen statistics. Initially, both training and testing loss decrease unexpectedly, suggesting that the model is learning efficiently. However, after around 30 epochs, the training loss continues to lower, while the testing loss begins to plateau or even increase slightly. This indicates that the model might be overfitting the training data, learning its patterns too well and struggling to generalize to new, unseen examples. Overall, the graph shows that the model achieves a reasonable level of overall performance.

B. *Performance Metrics*

Performance metrics are quantitative values applied in the assessment of how effectively a model meets intended objectives. These include recall that measures the model's performance in selecting all the actual positives from the entire dataset; accuracy which gives an overall measure of the number of correct predictions; precision that quantifies the number of actual positives per hundred fine predictions to demonstrate the capacity of the version in avoiding false positives; the F1 score that is an integrated measure of recall and precision that provides a balanced measure of performance. Hence, every metric provides information about particular aspects of the model's performance. Thus, for the given classes of precise programs, practitioners could use the above points and make knowledgeable selections about the suitability of the proposed metric and guarantee that the system beneath thought of does fulfill the performance degrees wanted for the preferred solution of the intended problems.

1) Accuracy: Accuracy is one of the evaluation metrics that define the portion of instances that has been classified correctly in a given set. That is because it provides a full picture of a model's performance for categorization tasks. The formula for accuracy is shown in Eq. (9),

$$Accuracy = \frac{Number\ of\ correct\ predictions}{Total\ number\ of\ predictions} \tag{9}$$

2) Precision: An overall performance indicator called precision assesses how well the model predicts the future with any degree of accuracy. It calculates the percentage of actual positive results among all cases the model has categorized as positive. Because precision is focused on the quality of positive predictions, it is most useful in situations when the cost of false positives is substantial. The formula for precision is shown in Eq. (10),

$$Precision = \frac{True\ Positives}{True\ Positives + False\ Positives} \tag{10}$$

3) Recall: The efficiency of pattern recognition for future predictions is evaluated using an overall performance score known as precision. It provides information on actual rate of positives, based on the totality of the cases which the model has classified to have positive results. Since precision measures the accuracy of positive instances, the measure is most handy in applications where false positives are very costly. It is given in Eq. (11).

$$Recall = \frac{True\ Positives}{True\ Positives + False\ negatives} \tag{11}$$

4) F1 score: The F1 score is an all-around performance statistic that gives a fair assessment of a model's accuracy in classification tasks by integrating recall and precision into a single measurement. When working with unbalanced datasets—where accuracy and recall may differ significantly it is helpful. The F1 score is a means to assess a model's performance by taking into account both false positives and false negatives. It is calculated as the harmonic mean of accuracy and recall. The formulation for the F1 score is given in Eq. (12),

$$F1\ score = \frac{2\times(Precision\times Recall)}{Precision+Recall} \tag{12}$$

Table I show that the study obtained great overall performance in comparing the effectiveness of a model. Accuracy at 99.3% suggests that the model is successful in showcasing its general correctness across all predictions. Precision, at 99.1%, measures the share of actual positive predictions amongst all high-quality identifications made by the model, highlighting its reliability in minimizing false positives. Recall, at 98% indicates the model’s ability to find true positives among all cases. Recall, indicates what percentage of positive cases exist in a set of records. It provided an F1 score of 98. 9% is used to balance the precision and recall at once, which gives rather comprehensive information about the model on the whole. This F1 score shows how well the model reduces false positives and how reliable it is, that is how good it is at identifying positive cases. Cumulatively, those measurements show that the version outperforms others in terms of all the measurements which include accuracy, precision, recall, and f1 score making the model extremely useful for the intended purpose. The model’s capability in realizing such excessive confirmed the tool’s potential in providing practical predictions in practical conditions.

TABLE I. PERFORMANCE METRICS

Metrics	Efficiency
Accuracy	99.3%
Precision	99.1%
Recall	98.7%
F1 score	98.9%

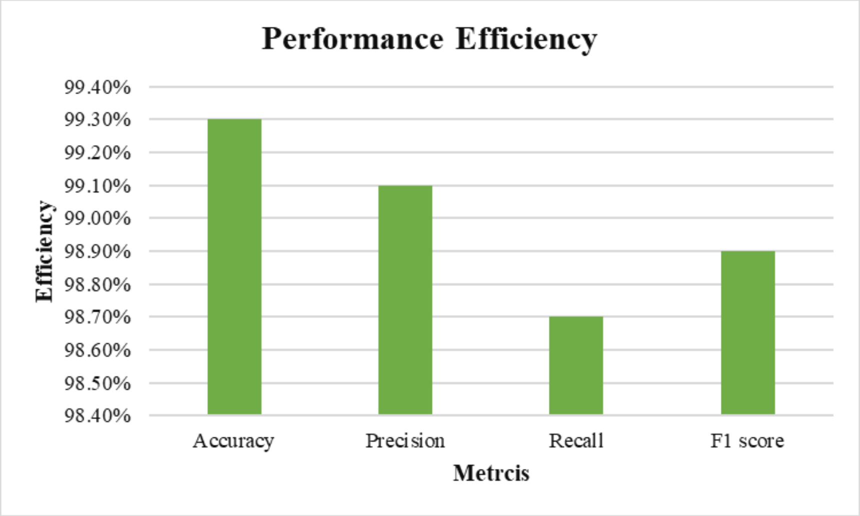

Fig. 5. Performance efficiency of the Bi-LSTM on the proposed study.

Fig. 5 depicts a model's performance parameters, with an emphasis on metrics. The graphic reveals that Accuracy is the highest of the measures, a little over 99.30%, showing that the model's predictions are generally true. Precision follows closely, barely below 99.20%, indicating the model's ability to reliably identify real positive situations while limiting false positives. Recall is significantly lower, slightly around 99.00%, implying that, while the model is reliable and exact, it may miss some actual positive cases, showing a modest trade-off in sensitivity. The F1 Score falls between accuracy and recall, just above 98.90%, indicating a balance between the two measures and reflecting the model's overall strength in classification tasks. The figure’s representation of these metrics emphasizes the model's efficiency in performing classification jobs with high accuracy and precision while keeping an acceptable balance with recall, resulting in a strong F1 score. This figure highlights the model's great performance, particularly in circumstances where accuracy and precision are important, but also illustrates the importance of recall in situations when detecting all positive instances is critical.

TABLE II. PERFORMANCE COMPARISON OF THE PROPOSED METHOD WITH DIFFERENT METHOD

Method	Accuracy	Precision	Recall	F1 Score
Decision Tree [22]	95.0%	94.5%	96.0%	95.2%
Random Forest [23]	92.3%	91.8%	93.5%	92.6%
KNN [24]	98.0%	97.5%	98.6%	98.0%
SVM [25]	89.5%	88.0%	90.2%	89.1%
Proposed Method	99.3%	99.1%	98.7%	98.9%

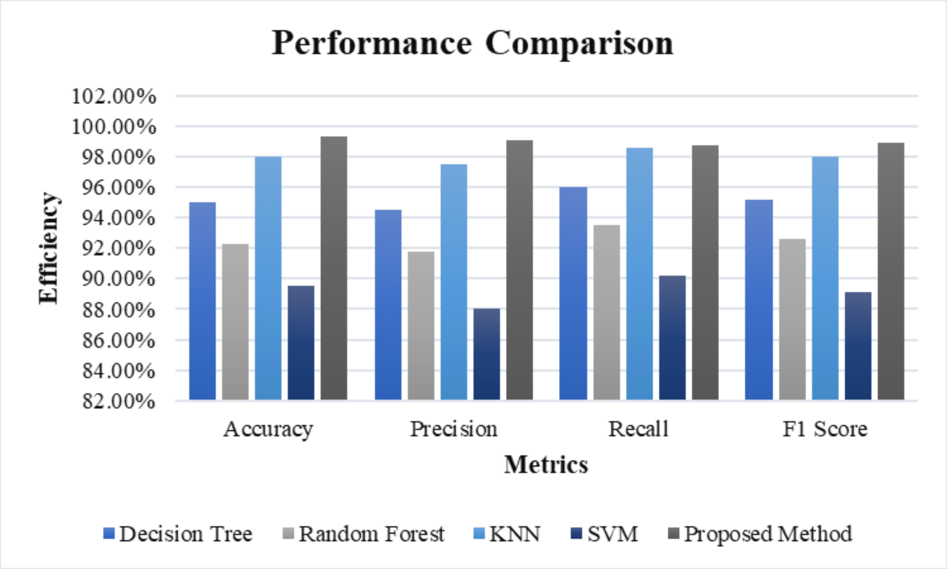

Fig. 6. Performance comparison of the proposed method with different methods.

A comparison of the methodologies across several measures is shown in Table II. The decision tree approach has 95.0% accuracy, 94.5% precision, 96.0% recall, and a 95.2% F1 score. This indicates a strong balance between identifying positive cases and reducing false positives. The Random Forest performs low, with 92.3% accuracy, 91.8% accuracy, 93.5% recall, and 92.6% F1 score, with improved classification but slightly less robust than decision trees K-Nearest Neighbors (KNN) technique achieves 98.0% accuracy, 97.5% precision, 98.6% recall, and 98.0% F1 score, indicating that it performs well in finding positive cases while minimizing error. In contrast, the Support Vector Machine (SVM) method does not perform well, with 89.5% accuracy, 88.0% accuracy, 90.2% recall, and 89.1% F1 score, indicating its low efficiency in comparison. The proposed method outperforms the others by the highest metrics: 99.3% accuracy, 99.1% precision, 98.7% recall, and 98.9% F1 score, demonstrating good performance at all evaluation criteria. This suggests that the suggested strategy gives an accurate and dependable solution to the categorization problem.

Fig. 6 compares the efficiency of five distinct methods such as Decision Tree, Random Forest, KNN, SVM, and the Proposed Method using four major performance metrics. The chart shows that the Proposed Method regularly beats the other approaches, with the highest values in all parameters, including accuracy slightly above 99%, precision just under 100%, recall around 98.7%, and an F1 score close to 99%. KNN also performs well, especially in accuracy and recall, where it outperforms all other approaches save the suggested method. Decision Tree performs well, with accuracy and recall metrics close to 95%, but it falls slightly short in precision and F1 score. Random Forest has balanced performance across all measures but stays lower than the top performers, with values ranging from 92-94%. SVM has the lowest metrics, particularly in accuracy and recall, demonstrating that it fails to compete with the other techniques' efficiency. This comparison demonstrates that the suggested technique outperforms all measures, making it the most trustworthy alternative for classification jobs in this context.

C. Discussion

The limitation of previous research in MALL, on improving reading comprehension, often starts from their lack of ability to evolve to the various learning desires of students. Earlier approaches and methods have failed to deliver in terms of dealing with the dynamic nature of the problem, particularly in the context of specific learning pathways. Most of these methods rarely achieved an optimal blend of accuracy and flexibility which, in turn, affected the performance levels and the progression of students' reading skills. The following shortcomings have been identified with the conventional approach of analysis: The proposed method that uses BI-LSTM networks eliminates these shortcomings. The processing of sequential data in both forward and backward directions, make BI-LSTM capture the requirement of language learning more effectively than the basic models of AI. This allows the model to capture more of the context inherent in language and hence leads to improved prediction and in extension reading comprehension. This high level of accuracy underlines the ability of the strategy to compensate for the problems that have been identified in the previous investigations. The technique enhances the reading comprehension result at the same time establishing a standard of feasibility for the subsequent MALL applications. Such an approach can be successfully spread to other spheres of language learning making the approach more valuable and effective.

VI. Conclusion and Future Work

Combining Read Theory with Mobile Assisted Language Learning or MALL enhances the first-year engineering students' reading comprehension using BI-LSTM networks. The 99. The achievement of 99.3% accuracy, proved that BI-LSTM is effective for dealing with restrictions that traditional MALL methods have. Previous strategies hardly take into account students' evolving and diverse needs for learning and this has led to poor improvement in reading skills. In fact, due to the bidirectional processing of sequential data, the technique providing a more enlightened picture of language acquisition as well as a more personalized learning model to individuals, BI-LSTM is capable to accomplish the idea. It not only set very high standards for MALL systems but also improves the ways in which understanding-oriented results are interpreted, thus showing how state-of-the-art AI techniques have the potential to dramatically transform teaching resources. The outcomes of the study make suggestions for the use and extension of BI-LSTM in educational technologies and highlight that, given that language proficiency is high, the usefulness of this technique could be of great value in engineering courses. The high reliability of this method highlights how the learning process as well as the classroom setting can be enhanced for better performance.

Future studies should examine how well the BI-LSTM model scales and adapts to various academic situations and topic areas. The efficacy and usefulness of BI-LSTM might be further improved by looking at how it integrates with other adaptive learning technologies and pedagogical approaches. Furthermore, carrying out longitudinal research to evaluate the approach's long-term effects on reading comprehension and general academic performance would offer significant insights into its long-term advantages. Including a wider range of student demographics and educational attainment in the research can improve the model's accuracy and scope of application. Additionally, investigating how to include interactive and gamified learning components with BI-LSTM may provide a more stimulating and engaging learning environment. For the strategy to be refined and implemented on a broader scale, cooperation with educational institutions to pilot the model in real-world situations and collect input from educators and students would be essential.

***Abstract*—Sentiment analysis is a key component of Natural Language Processing (NLP), taking into account the extraction of emotional cues from text. However, traditional strategies often fail to capture diffused feelings embedded in language. To deal with this, we advocate a novel hybrid model that complements sentiment analysis by way of combining Graph Convolutional Networks (GCNs) with Long Short-Term Memory (LSTM) networks. This fusion leverages LSTM's sequential reminiscence abilities and GCN's ability to model contextual relationships, allowing the detection of nuanced feelings regularly overlooked with the aid of conventional techniques. The hybrid technique demonstrates superior generalization overall performance and resilience, making it mainly powerful in complicated sentiment detection responsibilities that require a deeper knowledge of text. These results emphasize the capacity of combining sequential memory architectures with graph-based contextual facts to revolutionize sentiment analysis in NLP. This study not only introduces an innovative approach to sentiment analysis but also underscores the importance of integrating advanced techniques to push the boundaries of NLP research. This cutting-edge hybrid model surpasses the performance of previous techniques like CNN, CNN-LSTM, and RNN-LSTM with an amazing accuracy of 99.33%, creating a new benchmark in sentiment analysis. The results demonstrate how more precise sentiment analysis made possible by fusing sequential memory architectures with graph-based contextual information might revolutionise NLP. The findings provide a new benchmark, advancing the sphere by way of enabling greater specific and nuanced sentiment evaluation for a wide range of programs, inclusive of purchaser remarks analysis, social media monitoring, and emotional intelligence in AI structures.**

Keywords*—Graph Convolutional Networks (GCN); Long Short-Term Memory (LSTM); Natural Language Processing (NLP); sentiment analysis, emotions; text classification; machine learning

I. Introduction

As a core problem of natural language processing and considering the fact that there is a lot of texts, which are published on social networks, blogs, and other platforms, sentiment analysis has become a very important problem. To the corporations and decision-makers, as well as to the researchers who work with huge textual databases, it is crucial to understand these sentiments, emotions, and views [1]. This work introduces a novel approach that incorporates some of the most relevant features of many of the current state-of-art methods and results in the design of a new Hybrid GC-L LSTM model [2]. Due to this aforesaid hybrid model, sentiment analysis will be more accurate and contextual as this incorporates the complex relationships that exist between semantic relations, contextual relations, and temporal relations in the written text. Sentiment analysis of the posts on the social media platforms can therefore help the businesses determine customers' feedback on their products, potential trends in the market and generally, how their brands are being perceived. The sentiment analysis assists in the assessment of the overall perception of customers which in turn the businesses on how to come up with better products and or services [3]. The swift identification of the character of emotions in a particular industry and their disposition can help in the determination of the customer's attitude, the prediction of the market position and thus, the efficiency of the judgments made [4]. Using sentiment analysis in customers' engagements helps in addressing the issues of the client, to the satisfaction of the business. This is rather difficult because many terms have different meanings depending on the context of their use. What makes the analysis challenging is recognizing sarcasm and irony as sentiments can be stated inattentively to the opposite of the conveyed meaning. Sentiment analysis has to tread different languages and hence needs complex models to consider the differences in languages [5].

The ever-proliferation of user-generated content in the World Wide Web has brought about the sentiment analysis into sharp focus, as it is becoming important for organizations to gauge emerging trends, customer satisfaction levels and product performance [6]. Despite the fact that the earlier methods in sentiment analysis have been tried and tested and have achieved some levels of effectiveness, they frequently fail to capture the subtleties of sentiment expression, especially in situations where the meanings of words rely on their interactions with one another. In order to address these problems, this work integrates GCN that are famous for their ability to extract semantic relations between the words with LSTM networks that are extremely efficient in understanding the contextual history of the text [7]. Comparing the identification of sentiment subtleties in a diversification of textual data sources, the mentioned two techniques reached the product of which is known as the hybrid GC-LSTM model [8].

This paper discusses the architecture of the proposed Hybrid GC-LSTM model, its training process, and possible benefits for enhancing sentiment analysis in real-world settings. Text normalization and pre-processing are the preliminary phases of NLP that prepare text data for further analysis coherently and uniformly so as to obtain precise and accurate results of the natural language processing tasks. The aim of the project is not only to propose effective NLP methodologies but also to supply important tips for improving sentiment-oriented tasks in numerous spheres with the help of combining graph convolution with LSTM to stimulate sentiment analysis [9]. The present work aims to discuss the architectural characteristics of the Hybrid GC-LSTM model, its training process, and potential uses as well as to show how this particular model can potentially enhance the state of the art of sentiment analysis in a specific real-life environment. Text normalization and pre-processing are one of the critical stages in natural language processing with an essential impact on the majority of the following steps; determine the quality and comparability of the upcoming results. The algorithm is planned to create NLP techniques and offer valuable guidance for improving sentiment-related tasks of manifold domains by optimistically combining graph convolution and LSTM for accelerating sentiment analysis [10]. The H-GC-LSTM model creates new opportunities in NLP practice and research and allows researchers and practitioners to apply the opportunities of this innovative hybrid model. It also provides capabilities for the analysis of sentiments in textual data with better accuracy and specificity to context [11].

The key contributions of the article are,

- The method under investigation in this work is concerned with strait integration of LSTM and GCN networks within a single framework for sentiment analysis. The integration of GCNs, which applies a contextual approach to learn the interactions between nodes and LSTMs which are particularly good at sequence memory, keeps the benefits of the two architectures in mind.
- The first and major contribution for this research is to enhance the sentiment analysis with the help of GCNs and LSTMs that exhibit the complementing features. Regardless of the fact that LSTMs are more effective in sequential learning, GCNs offer the notable contribution to extract intricate contextual information from a textual input. The combination of both the approaches hence leads to the development of sentiments analysis model that is more complex and immune.
- Extensive testing on standard sentiment analysis datasets demonstrates the model's improved precision in identifying and classifying nuanced sentiment subtleties. The combination of approaches outperforms the state-of-the-art models now in use, particularly in situations when a thorough comprehension of the context is essential.
- Across a range of datasets, the hybrid Graph Convolutional LSTM approach demonstrates improved generalization effectiveness and durability. This highlights the possibilities for practical applications by demonstrating its flexibility to a variety of language situations and datasets.

The rest of the study is structured as follows: Section II comprises relevant material designed to help readers comprehend the proposed paper using existing methodologies, while Section III elaborates on the problem description. Section IV displays the proposed architectures. Section V includes tabular and graphical representations of the results and performance indicators. Finally, in Section VI, the conclusion and future works are discussed.

II. Related Work

The goal of the project is to enhance sentiment categorization by using input from users from social media sites such as Facebook and Twitter [12]. It highlights how sentiment analysis in NLP may be improved by combining word-embedded techniques like Word2Vec and FastText with algorithms for DL like CNN, GRU, LSTM, and Bi-LSTM. This study presents a novel combination model that deliberately blends DL techniques with several word embedding approaches, beating previous research and providing better sentiment classification results in the end.

The study discusses the growing significance of user reviews on forums, social networks, and online stores as well as the requirement for efficient sentiment analysis [13]. The article presents a unique hybrid CNN model that preserves significant data while processing input sequentially by fusing CNN and Bi-LSTM models. The algorithm's exceptional accuracy is demonstrated by experimental findings utilizing benchmark brand and accommodation review information sets, which achieve 93.6% and 92.7%, respectively, for product and hotel reviews, respectively, exceeding modern facilities sentiment analysis approaches.

In Arabic tweets, the paper investigates the application of pre-trained BERT algorithms for Arabic sentiment analysis [14]. The Ara BERT model is refined by the researchers and used in a network design that combines the GRU and BiLSTM models. Their tests show that the optimized AraBERT model combined with the hybrid networks performs exceptionally well, outperforming other popular sentiment analysis techniques like as CNN, LSTM, BiLSTM, and GRU, and achieving up to 94% accuracy.

The study focuses on sentiment analysis of online feedback, which is a challenging undertaking because consumers utilize natural language [15]. The current research emphasizes phrase-level and sentence-level characteristics for sentiment analysis, in contrast to prior approaches that primarily depended on word-level characteristics and other feature weighting techniques. A two-layer CNN and a BGRU are used in the suggested hybrid model, a convolutional CBRNN, to identify abundant phrase-level features and record chronological data by detecting dependencies that span time. The research results show that the CBRNN model is improved to the latest algorithms by 2% to 4%, with an F1 score of 87.62% on the IMDB collection and 77.4% on the Polarity information. However, training this model takes a little longer.

The paper discusses the use of graph neural models in dependency trees as well as aspect-based sentiment analysis [16]. Sentic GCN, a unique strategy that is used to learn the emotive connections of phrases particular to a particular feature, is introduced in this research. Previous efforts have concentrated on learning dependence data gathered from surrounding words to aspect words. The model improves sentence dependence graphs by including SenticNet's emotive information. It does this by taking into account the behavioural data involving opinion words and the aspect as well as the connection involving contextual and aspects words. As experiments on many standards datasets have demonstrated, the proposed Sentic GCN model performs better in sentiment analysis through aspects than the current state of the art.

Sentiment evaluation is a technique inside natural language processing that evaluates and identifies the emotional tone or temper conveyed in textual data. Scrutinizing phrases and phrases categorize them into hopeful, terrible, or neutral sentiments. The significance of sentiment analysis lies in its potential to derive precious insights from huge textual data, empowering organizations to understand consumer sentiments, make informed choices, and enhance their services. For the in-addition development of sentiment evaluation, gaining deep expertise in its algorithms, application, contemporary performance, and challenges is vital. Therefore, on this extensive survey, Jim et al., [17] started exploring the widespread array of software domain names for sentiment evaluation, scrutinizing them within the context of current studies. Then delved into prevalent pre-processing strategies, datasets, and assessment metrics to enhance comprehension. This study additionally explored Machine Learning, Deep Learning, Large Language Models, and Pre-trained models in sentiment analysis, supplying insights into their advantages and drawbacks. Subsequently, this study precisely reviewed the experimental outcomes and boundaries of new state-of-the-art articles. Finally, this study discussed the various challenges encountered in sentiment evaluation and proposed future research guidelines to mitigate these concerns. This great evaluation offers a complete knowledge of sentiment analysis, covering its approaches, utility domains, consequences evaluation, challenges, and studies guidelines.

Natural Language Processing (NLP) is a critical department of artificial intelligence that research how to enable computer systems to recognize, manner, and generate human language. Text category is a fundamental undertaking in NLP, which goals to classify text into exceptional predefined classes. Text type is the most primary and classic task in natural language processing, and maximum of the duties in natural language processing can be regarded as classification obligations. In recent years, deep learning has accomplished terrific fulfilment in many studies fields, and nowadays, it has also become a standard technology inside the discipline of NLP, which is broadly included into textual content class tasks. Unlike numbers and pixels, text processing emphasizes satisfactory-grained processing potential. Traditional textual content classification strategies commonly require preprocessing the input model's text records. Additionally, they also need to obtain good pattern capabilities via guide annotation after which use classical devices to gain knowledge of algorithms for categories. Therefore, this paper analyses the software popularity of deep learning inside the three middle duties of NLP (which include textual content representation, phrase order modelling, and knowledge representation). Xu et al. [18] explore the enhancement and synergy accomplished through natural language processing within the context of textual content category, whilst additionally contemplating the challenges posed through antagonistic strategies in text era, textual content type, and semantic parsing. An empirical look at textual content class obligations demonstrates the effectiveness of interactive integration schooling, particularly in conjunction with TextCNN, highlighting the significance of those improvements in text classification augmentation and enhancement.

The interactive attention graph convolution community (IAGCN), a novel version proposed in the study proposed by Singh et al., [19] will revolutionize element-level sentiment evaluation (SA). IAGCN effectively addresses those key features, in contrast to previous research that left out the means of issue terms and their courting with context. The version combines a modified dynamic weighting layer with bidirectional long brief-time memory (BiLSTM) to appropriately gather context. It makes use of graph convolutional networks (GCNs) to encrypt syntactic records from the syntactic dependency tree. Furthermore, a way for interactive interest is employed to find out the elaborate relationships among context and issue phrases, which ends up inside the reconstruction of these terms' representations. Comparing the proposed IAGCN model to baseline models, incredible gains are made. Across 5 datasets, the model beats preceding methods with a wonderful improvement in F1 scores in those stages from 1.34% to four.04% and an impressive improvement in accuracy that levels from 0.56% to 1.75%. Additionally, the IAGCN model outperforms the global vectors (GloVe)-primarily based approach when the strong pretrained version bidirectional encoder representations from transformers (BERT) is covered inside the venture, resulting in even extra upgrades. The F1 rating notably will increase from 2.59% to 7.55%, and accuracy will increase from 1.47% to 3.95%, making the IAGCN model a standout performer in issue-degree SA.

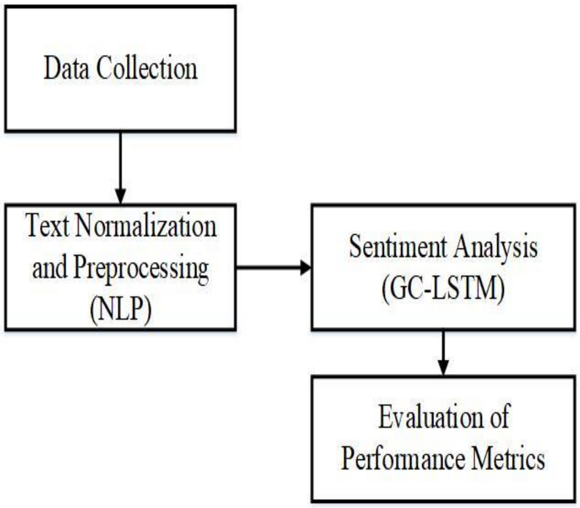
Thus, the attempt to build fine-grained aspect-based sentiment analysis from existing sentiment analysis algorithms is not always successful because they are known to employ features at the word level and apparently do not address the contextual emotional knowledge. In an effort to eliminate these disadvantages, a new graph GC-LSTM is introduced and it formulates sentence dependency graphs based on certain features and incorporates emotional knowledge. This way, the model may also consider the connections between the opinion words and the aspect, and between the contextual and aspect words. The current models of analysis of the sentiment in Natural Language Processing can fail to capture complex details and the connection between them in a text. This research seeks to do so by presenting a new hybrid model that first consists of Long Short-Term Memory to capture the sequential memory retention and followed by Graph Convolutional Network to capture contextual relationships.

III. Problem Statement

Current sentiment evaluation techniques exhibit several key drawbacks that necessitate the development of advanced models. First, many models like CNN, GRU, and BiLSTM depend heavily on word-stage capabilities, frequently failing to capture the deeper contextual relationships needed to interpret complex texts, together with sarcasm or irony. This loss of contextual understanding limits their ability to as it should be classifying sentiment at the sentencing stage. Second, while LSTM and BiLSTM models cope with sequential memory retention, they're inadequate for extracting deep insights from word-level functions and temporal dependencies [13]. Hybrid models, which include CBRNN and CNN-BiLSTM, provide modest enhancements however nevertheless fall short in dealing with chronological relationships, leading to incomplete sentiment classifications [15]. Additionally, aspect-based sentiment analysis remains inefficient as current algorithms primarily cognizance on neighbouring issue words without fully addressing emotional and contextual dependencies among opinion and thing phrases. Although models like Sentic GCN [16] try and incorporate emotional expertise, they nevertheless warfare with processing complex dependencies, resulting in suboptimal performance. Finally, scalability and performance bottlenecks pose tremendous demanding situations, specifically in area-specific sentiment analysis. Fine-tuned models like AraBERT, although powerful, are computationally highly-priced and gradual to teach, limiting their applicability to big datasets. Consequently, there's a growing need for advanced hybrid fashions which could integrate contextual emotional knowledge, successfully cope with sequential statistics, and enhance aspect-based totally sentiment analysis to reap greater correct, efficient, and scalable sentiment class throughout numerous domains and languages.

IV. Proposed Hybrid Graph Convolutional LSTM Framework

Since the proposed method is the Graph Convolutional LSTM (GCLSTM) model, training of the proposed model is done with care using sentiment analysis datasets. The first process that is called preprocessing of the textual data involves the steps such as tokenization and normalization which is done to make the input text more standardized. Also, a graph representation is built in order to better understand the structure of tokens and their relations, in terms of semantics to the whole text. After that, the resultant model is trained with the semi-supervised learning methods based on the graph and supervised learning. This amalgamation helps the model to incorporate hierarchical features, contextual information and complex text data relationship. Graph based approaches combined with LSTM networks mean that the model is able to capture and understand sequential dependencies as well as the contextual information which improves the prediction of sentiment in general. In order to assess the performances of the model in the context of identifying sentiments from the textual data, benchmarking datasets for the sentiment analysis task are used. As shown in Fig. 1, the model has demonstrated it is efficient in the assessment of the sentiment classification of different datasets. As a result of the specific assessment strategies proposed in the model, the excellent accuracy, stabilization, and versatility of the proposed model surpass prior approaches to sentiment classification. The use of graph-based representation and LSTM networks enables the GCLSTM model to effectively obtain sentiment information hidden in texts. Using both structural and sequential information, the model goes beyond the usual approaches and achieves rather high accuracy in sentiment classification tasks. This proves to be a methodologically innovative that makes a methodological shift on the field of sentiment analysis in Natural Language Processing (NLP), and paves the way for enhanced and efficient analysis of textual sentiment across multifaceted real-world contexts.



Data Collection
Text Normalization and Preprocessing (NLP)
Sentiment Analysis (GC-LSTM)
Evaluation of Performance Metrics

Fig. 1. Proposed methodology.

A. Data Collection

On Kaggle, a list of the tweets with clearly separating positive and negative attitudes could be seen; clearly, it is better to have a selection of well-curated tweets. Positive tweets refer to preoccupation with ideas, emotions, and opinions that are favourable while negative tweets are those that involve criticism, dissatisfaction or feelings of discomfort. For this purpose, using this dataset, academicians as well as data scientists can build models that could recognize positive as well as negative sentiments present in text data of social media appropriately, so this is going to serve a fruitful tool for sentiment analysis as well as Natural Language processing applications [20].

B. NLP for Text Normalization and Pre-processing

Natural Language Processing involves the important area of text normalization and pre-processing whereby issues associated with linguistic varieties and the like, are dealt with in order to standardize textual data. Lowercasing is a process of taking the whole text and turning all characters to lower case. This assists in discarding case-based dependencies so as to arrive at an equal representation of words in a field. It is especially helpful in such cases as text matching where that changes in upper or lower case can cause disparities. The process of text normalization and pre-processing which is an important process and frequently discussed in the framework of Natural Language Processing (NLP) comprises the following crucial procedures [21]: Some of these responsibilities include converting the text to a list of words where words can be individual words or sub word units, converting the entire text to lowercase and removing special characters, punctuation marks, and other information that is assumed to be noise. In the same way, in order to diminish the words into their base forms, lemmatization or stemming techniques may also be incorporated in this procedure. They are called stop words – these terms are rather ubiquitously used and, thus, less meaningful in specific contexts. This manner, these NLP approaches support a crucial part in ensuring data consistency by providing a commonly accessible pre-processed text corpus that has already gone through denoising, and hence, ease the process of text analysis, sentiment analysis, as well as other applications of NLP [22].

C. Employing Hybrid Graph Convolutional LSTM Model for Sentiment Analysis

In the field of NLP, GC-LSTM for sentiment analysis is one of the modern approaches. The act of determining the extent of positive or negative opinion expressed in textual data is known as sentiment analysis, an activity that may be used in social network monitoring or in understanding users' attitude towards a certain product or service. These two building blocks are powerful and when combined together, this new method we have proposed is not only able to capture the general sentiment poles in text data, that is positive or negative, in most cases, but also give extremely well results for intensity of sentiment poles in the text data as well. GCNs' capability of extracting and expressing semantic relations between words or between subword units is already clear. The model accrues and disseminates knowledge about word associations by constructing a network that consists of nodes – words – and edges – relationships between these nodes. This is especially important when dealing with sentiment analysis since sentiment phrases ordinarily depend on connections with other words and their context. These are the primary GC-LSTM from Eq. (1) to Eq. (5).

$$i_p = \sigma\,(V_{yi} * Y_p + V_{ki} * K_{p-1} + d_i) \tag{1}$$

$$f_p = \sigma\,(V_{yf} * Y_p + V_{kf} * K_{p-1} + d_f) \tag{2}$$

$$C_p = f_p \circ C_{p-1} + i_p \circ \tanh\,(V_{yc} * Y_p + V_{kc} * K_{p-1} + d_c) \tag{3}$$

$$o_p = \sigma\,(V_{yo} * Y_p + V_{ko} * K_{p-1} + d_o) \tag{4}$$

$$K_p = o_p \circ \tanh(C_p) \tag{5}$$

While, the LSTM network is much effective to understand the sequential patterns in the text. It is relevant to word order and it reveals how the initial words in a sequence influence the degree of emotion which is expressed by the final word. In the case of the sentiment analysis, sequential context is important because it gives information on how sentiment flows from one word to the next in a given sentence or a paragraph. This is a combined approach of LSTM and GCN in a way to utilise the benefits of both techniques. This means that when using graph-based paradigms, then students can design effective PDAs that will cater for their needs. It is the synergy that gives a better understanding of the emotional expressions which are present in the textual data. This hybrid model has practical applications in a number of areas of actuality. Where a finer definition of attitude can yield improved customer' satisfaction and, thus, improved products. On a large scale, it may help organizations in responding to the new trends or concerns on the part of communities by monitoring them and understanding the extent of reaction possible. Besides, the hybrid approach can be useful for decision-making in a matter of policy choices and organization of social activity based on more accurate data on public attitudes to a political and/or social concern within the context of opinion mining.

The input L goes through several layers of GC-LSTM as represented by 'GC-LSTM1,' to come out as a 3D tensor, and is then funneled to a regular CNN for sentiment analysis. CNNs produced the following output in Eq. (6),

$$\text{o} = \{o_1, o_2, \ldots, o_c\} \tag{6}$$

The number of action categories is represented by C. To train the GC-LSTM, the categorical cross-entropy loss can be used. Given a sequence L, the expected chance of having the ith class is in Eq. (7),

$$\text{Q}\,(C_i |\, \text{L}) = \frac{e^{o_i}}{\sum_{j=1}^{C} e^{o_j}},\ \text{h=1,…,C} \tag{7}$$

Hybrid Graph Convolution LSTM Model for Sentiment Analysis as NLP progresses shows a great leap in the ability to detect and apply sentiment from texts. Due to the new approach to revealing the relations between semantic relatedness and sequential context, this method encourages the development of sentiment analysis capabilities and will ultimately contribute to the creation of highly accurate and context-sensitive sentiment analysis for a wide spectrum of applications.

V. Results and Discussion

In the proposed methodology, the GCLSTM model is fine-tuned using sentiment analysis datasets so as to improve the process of sentiment analysis following a multiple-step process. First, the text input goes through pre-processing steps which include; tokenization, normalization and constructing a graph that can show the relationships that exist among words and phrases. This pre-processing phase is fundamental and serves the purpose of transforming the textual input into a uniform nature while at the same time capturing closest semantic relationship present within the data. After pre-processing the model is trained by a combination of supervised learning and graph-based semi-supervised learning. This is quite beneficial since it allows the model to gather information from labelled as well as features from unlabelled data due to the graph structure that encodes a lot of contextual information. Thereby, by employing graph-based semi-supervised learning, the model becomes wiser to the correlation between the text input and pyramidal features to make more distant differentiation between the sentiment characteristics. At the time of training, the model keeps on learning to traverse through the structure of the graph, enabling it to adjust its parameters to provide the best sentiment analysis ramifications. As it moves to the subsequent form through each iteration, the model amasses the competence to provide for the entities, such as words, phrases as well as sentiment expressions in the text data. Combined with the structural features' temporal dependencies learnt by LSTM networks and the structural relationships' contextual relationship learnt by GCN networks, GCLSTM obtains good results in sentiment analysis tasks. However, the integration of graph-based techniques improves the model's comprehension of the text's semantic features while considering the sentiment variations that the other strategies might fail to identify. It also ensures that the GCLSTM model receives profound training so that in the future it can handle multiple different datasets and different sentiment analysis environments. When training GCLSTM model it performs the following steps namely tokenization and normalization of the sentences, converting the sentences into a graph-based semantic representation and lastly the hybrid training considering both supervised and semi-supervised learning. This approach of dealing with the data allows the model to capture semantic relations, as well as hierarchy and context of the different features which in turn improves the accuracy and overall robustness of the sentiment analysis model.

A. Model Accuracy

Metrics provides information on how well the model's predictions match the actual values and is commonly used in classification problems. Especially in cases when there is a mismatch in the classes or when there are additional expenses associated with wrong classifications.

The model accuracy achieved by the proposed technique is a very impressive 99.33%. This astounding level of precision suggests that the model performs remarkably well when it comes to outcome prediction. A graphical depiction of this performance and the strategy's effectiveness is shown in Fig. 2.

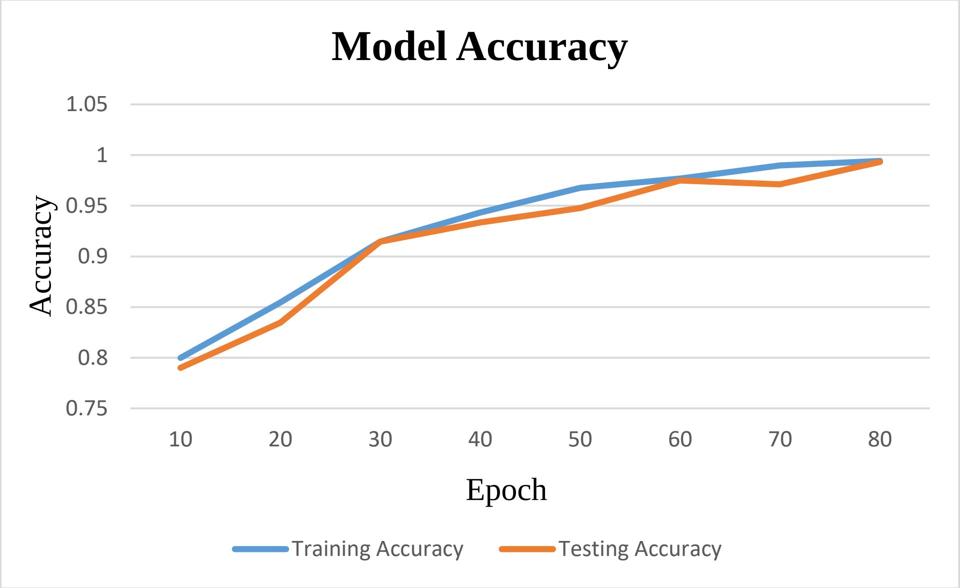


Fig. 2. Model accuracy.

B. Model Loss

The model loss, or the difference between the model's predictions and the actual data, indicates how well the model performed on the training set of data. Lower loss values indicate better performance since they demonstrate how well the model's predictions match the actual data.

This is often computed using a variety of loss coefficients, including as mean squared error and cross-entropy, which help the model learn by adjusting its parameters to reduce the difference between the predicted and actual outcomes.In addition to providing a graphical representation of the model's performance changes during training, Fig. 3 illustrates the model loss of the recommended technique. The variation in the loss over model training epochs, which measures the discrepancy between predicted and actual values, is depicted graphically in this picture.

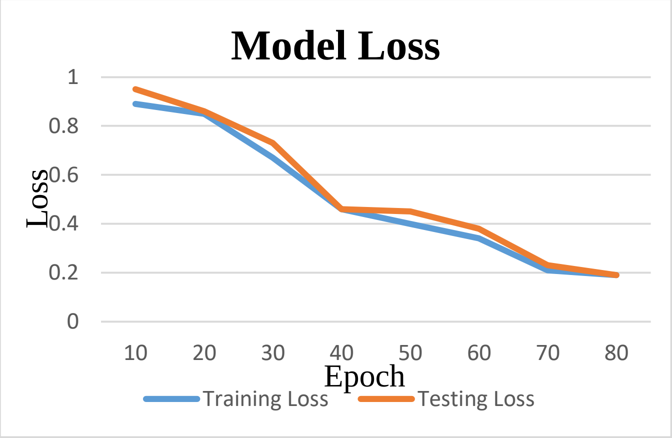

Fig. 3. Model loss.

C. ROC

The Receiver Operating Characteristic (ROC) curve is a graphical representation that is used to evaluate the performance of classification models. It illustrates the trade-off between a model's sensitivity and specificity over several thresholds. When establishing the optimal threshold for classification tasks or assessing the performance of different models, the ROC curve comes in handy. This is especially true when the distribution of classes is not balanced. The ROC value is displayed in Fig. 4.

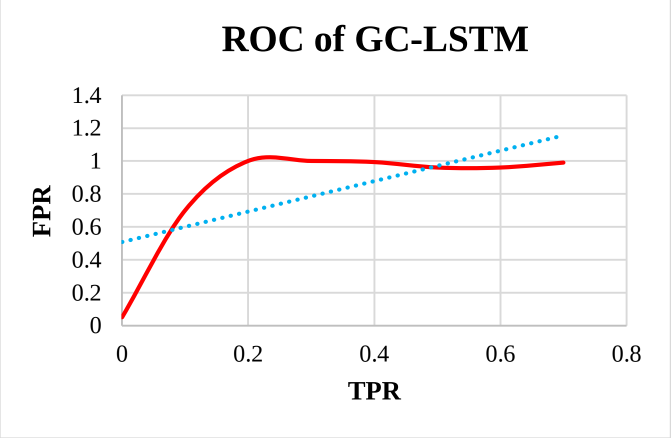

Fig. 4. The Receiver Operating Characteristic (ROC) curve.

The underlying assumption of it is that all interactions are predictable. The precision is given by Eq. (8).

$$Accuracy = \frac{T_{Pos} + T_{Neg}}{T_{Pos} + T_{Neg} + F_{Pos} + F_{Neg}} \tag{8}$$

$$P = \frac{T_{Pos}}{T_{Pos} + F_{Pos}} \tag{9}$$

The appropriate positive for these numbers may be calculated the line is found in Eq. (10).

$$R = \frac{T_{Pos}}{T_{Pos} + F_{Neg}} \tag{10}$$

$$F1 - score = \frac{2 \times precision \times recall}{precision + recall} \tag{11}$$

TABLE I. COMPARISON OF PERFORMANCE METRICS

Methods	Accuracy	Precision	Recall	F1-Score
CNN	94.56	95.76	95.11	95.88
RNN-LSTM	93.65	92.34	95.78	96.67
CNN-LSTM	97.12	97.87	96.74	93.23
Proposed GC-LSTM	99.33	98.98	98.23	98.11

Table I provides a comparative study of several sentiment analysis techniques, emphasizing measures such as accuracy, precision, recall, and F1-score. Prominently, the suggested GC-LSTM model surpasses other techniques with remarkable accuracy (99.33%) and resilient performance on all measures, demonstrating elevated precision, recall, and F1-Score percentages.

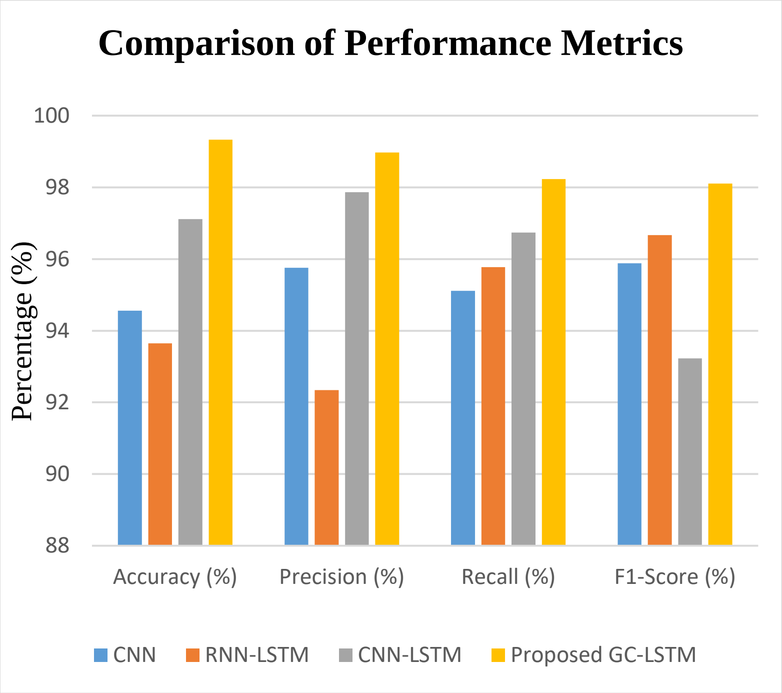

Fig. 5. Performance metrics.

A notable substitute is the CNN-LSTM model, which likewise performs well, especially in terms of accuracy and precision. In the meanwhile, the hybrid models outperform the conventional CNN and RNN-LSTM models, which function well but display somewhat worse outcomes than the former. CNN-LSTM, in particular, strikes an impressive balance between recall and precision. These findings highlight the effectiveness of integrating sequential context analysis (LSTM) with graph-based semantic understanding (GC) in sentiment analysis, which greatly improves the model's capacity to correctly categorize sentiments in text data. In Fig. 5, it is shown.

D. Discussion

The Hybrid GC-LSTM approach gives significant advancements in sentiment analysis; however, several obstacles remain. Its excessive computational complexity, due to the combination of GCNs and LSTMs, makes it resource-extensive, specifically for real-time programs [23]. The graph construction process provides preprocessing overhead, and the model struggles with unstructured text like sarcasm or irony. Additionally, adapting the version for various languages with complex systems may be difficult. It is based on amazing statistics, which might not be available for all domains, and is liable to overfitting on small datasets. Furthermore, its interpretability is limited, complicating transparency in decision-making. The outcomes reveal the advanced overall performance of the proposed GC-LSTM version, reaching an impressive accuracy of 99.33%, drastically outperforming other models like CNN and RNN-LSTM. It also excels in precision (98.98%), consider (98.23%), and F1-rating (98.7%). Compared to the CNN-LSTM, which has robust precision (97.87%) but however slightly decreased taken into account, the GC-LSTM showcases a balanced and robust performance across all metrics. These findings affirm that combining LSTM's sequential context evaluation with GCN's semantic expertise complements the model's ability to correctly classify sentiments in textual content information. Future work for this study includes enhancing the GC-LSTM model to reap actual-time sentiment evaluation and optimizing its computational performance for quicker processing. The model's adaptability throughout exclusive languages and domain names will be increased, addressing demanding situations in multilingual sentiment evaluation. Additionally, quality-tuning for complex textual content kinds together with sarcasm and irony could be explored. Applications in emotion-pushed structures, decision-making strategies, and different rising fields may also be investigated. The purpose is to similarly improve the version's scalability, robustness, and versatility in diverse sentiment analysis environments. This exceptional performance serves as a testament to the synergy between graph-based semantic comprehension and sequential context analysis within the hybrid architecture. By reconciling GCNs and LSTM networks, the proposed GC-LSTM model takes the best out of both methodologies without the missteps of the other [24]. In the matter of the meaning comprehension the graph-based semantic understanding of the relationships between words and phrases is improved, and in the case of the sequential context and temporal connections between the word LSTMs perform well. This reasonable combination of techniques leads to the model that at the same time has market-worthy accuracy, and high enough levels of precision, recall as well as F1-Score in different tasks of sentiment analysis. In addition, the performance of the proposed CNN-LSTM model can also be called good, as it showed a high degree of accuracy and sensitivity in solving the sentiment analysis problems [25]. The better results of the hybrid models over the basic types of the models show that innovation should remain one of the priorities in the development of the sentiment analysis. Through actively incorporating new approaches and incorporating various approaches and techniques, it becomes possible to expand the overall performance of sentiment analysis research by the researchers and practitioner. The findings presented in the table provide compelling evidence of the efficacy of hybrid sentiment analysis models, particularly the GC-LSTM model. With its exceptional accuracy and consistently strong performance metrics, the GC-LSTM model exemplifies the power of combining graph-based semantic comprehension with sequential context analysis. Moving forward, continued exploration and refinement of hybrid techniques promise to further enhance sentiment analysis capabilities, enabling deeper insights into textual sentiment across a wide range of applications and domains [26].

VI. Conclusion and Future Scope

The proposed study combines GCNs and LSTM networks to enhance sentiment evaluation with the aid of capturing both contextual relationships and sequential reminiscence. This hybrid version gives better accuracy, nuanced emotion detection, and advanced generalization, outperforming traditional methods, making it tremendously effective for complicated sentiment analysis responsibilities throughout diverse applications. To highlight, I incorporate LSTM networks with GCNs, which exploits the advantages of both methods to enhance the efficiency and precision of SA applications. This model changes the way sentiment analysis is done as it is better than other approaches to identifying intricate semantic connections between words and phrases. Because of its versatility, the model is suitable for the most NLP tasks, especially for analysing sentiments in social media, product reviews, and customers' feedback. In addition to that, through language expansion it makes the facility more capable of accommodating a wide scope of linguistic settings making it more ‘universal’ in its application. The current focuses would be to extend the current concept with further upgrades which would help to accentuate the fine-grained sentiment analysis, to achieve the ability to work in real-time mode that would provide immediate results, as well as, consider its applications in the emerging areas such as emotion-driven systems and decisions based on sentiment analysis. As the Hybrid GC-LSTM model grows in the future, it will be largely help in analysing text sentiments of the varied languages and conditions and lays down the perfect platform to advance in the more superior sentiment analysis techniques. Furthermore, such integration of this model is expected to deal with aspects pertaining to different domains and different apertures of languages with relative ease in terms of generalization and flexibility for sentiment analysis. Having said that, it is not difficult to note that, because of its flexibility, sentiment analysis can offer a solution adapted to the needs of many industries and types of uses, and remain as efficient as before.

Hence, Hybrid GC-LSTM is a breakthrough in sentiment analysis of NLP due to its uncontrolled accuracy and scalabilities as well as application. As shown in the current paper, it increases numerous academics and organisations' ability and capacity to understand textual sentiment across different languages and situations; it marks the dawn of a new era of advanced sentiment analysis methodologies. The proposed study's barriers consist of capacity overfitting due to the complexity of the hybrid approach, reliance at the first-class of training datasets, and feasible challenges in computational efficiency. Additionally, the version may struggle with nuanced or area-specific sentiments not well-represented in the training data, limiting its widespread applicability.

***Abstract*—Cervical cancer is the second most common malignancy among women, making it a major public health problem worldwide. Early detection of cervical cancer is important because it increases the chances of effective treatment and survival. Regular screening and early management can prevent the growth of cervical cancer, thus reducing mortality. Traditional methods of detection, such as Pap smears, have proven useful, but are time-consuming and rely on behavioral interpretation by cytologists. To overcome these issues the study uses method another for a convolutional neural networks (CNNs) and gated recurrent units (GRUs) to detect and classify cervical cancer in Pap smear images by tuning with Artificial Bee Colony (ABC) Optimizer. This study used several datasets with high-resolution images from the SipakMed collection, with 4049 images and a fetal dataset with patient information for the CNN component of the model, specifically the ResNet-152 system, is extracted spatial attributes from these images. After feature extraction, the GRU component analyzes the sequential data to identify temporal combinations and patterns. This hybrid CNN-GRU algorithm uses the features of two networks: the ability of CNN to learn spatial patterns and the ability of GRU to understand sequential networks and tuning the parameters using ABC. The proposed model outperformed the conventional ML methods with a classification accuracy of 94.89%, and provided a reliable solution for early detection of cervical cancer Using these DL methods role which, not only enables a more accurate diagnosis, but also allows a comprehensive examination of the abnormal cervical cells, making it a positive detections to programs and patient outcomes. This work highlights the promise of cutting-edge AI techniques to improve cervical cancer diagnosis, and the need for faster and more accurate diagnosis in the battle to emphasize the fight against this common disease.**

Keywords*—Cervical cancer; CNN-GRU; Pap smear images; Artificial Bee Colony Optimizer; early detection

I. Introduction

Cervical cancer is one of the critical threats to the lives of women globally, which affects the cervix, the lower part of the uterus that narrowest at the lower end leading to the vagina. The activity causal agent of cervical cancer is persistent infection with high risk HPV a sexually transmitted disease [1]. Even though HPV are normal and temporary in most cases, some persist and can when time transformations occur in cervical cells and if not detected or treated, result in cancer [2]. Cervical cancer is usually a slow-process cancer, which starts with abnormal cells called dysplasia that are usually detected through screenings such as Pap tests and HPV tests [3]. Screening with these technologies is important in the early stage because that is the time when interventions can be taken to contain the disease [4]. Since cervical cancer might be asymptomatic for a long time, the early signs may include bright red or dark brown blood or abnormal clear but getting uncomfortable during intercourse [5]. Poor cervical hygiene is risky in that one can smoke, be immunodeficient, engage in several unhealthy sexual intercourse sessions, or never do cervical screenings [6]. Recent HPV vaccination programs are also very efficient in reducing the disease occurrences of cervical cancer by preventing the initial infection of the virus [7]. One major aspect of cervical cancer control measures that are implemented related greatly to the population health promotion programs and encompasses immunization and screening [8]. Reared treatment such as surgical operations, radiation therapy, and chemotherapy have delayed the death of women diagnosed with cervical cancer. Nevertheless, challenges continue to be seen especially in the less developed regions where health screening and care is still a luxury [9]. Understanding, managing or at least acknowledging these disparities and spreading word on methods of avoiding and controlling cervical cancer remains a significant step in the fight against the disease and improving results for female patients across the globe [10].

Cervical cancer is diagnosed using screening technologies that help in the identification of pre neoplastic changes before they advance to invasive carcinoma [11]. The commonest screening procedures are Pap smear and HPV testing. Pap smear or Pap test is a procedure that collects cervical cells in the hope of finding abnormal changes that might imply dysplasia or signs of early stage cancer [12]. The HPV test shows the detection of high-risk HPV types which are associated with cervical cancer. Intricate details incorporate that several directives recommend the usage of both Pap and HPV tests at least once in five years or, more effectively, the exclusive use of Pap test in every three years for women at the age of 21 to 65 years. In case of abnormal results, further tests like VIA, and the colposcopy, which is a detailed examination of the cervix with the help of a colposcope are applied. The importance of screening and early detection is because cervical cancer progresses slowly and there is enough time to interventions before the cancer becomes advanced [13]. Women at increased risk or abnormal test results might have additional diagnostic tests, including a biopsy, to determine the presence and extent of cancer. ML including DL has taken a center stage in diagnosing cervical cancer to boost the drive towards accurate detection of the abnormal cell growths. A CNN model is effective in finding and sorting cervical cell images into normal and abnormal cells based on DL models. Such algorithms are based on the comprehensive collections of tagged images, learning to decipher practically infinitesimal features pointing at precancerous transitions or sheer malignancy [14]. DL can improve the cytological tests and at the same time decrease the intraobserver variation of the human interpretation. Moreover, DL together with another diagnostic procedure like HPV testing or images from colposcopy increases the overall detection capability.

CNNs are a specific kind of DL model that is specifically designed to work with and understand image and video data with great efficiency. CNNs are extremely effective in the tasks of pattern and feature detection in image data, making CNNs useful in an array of applications including image categorization, object recognition, and so on. A CNN is made up of layers and each layer is associated with a definite task of converting the input image into the final classification or prediction [15]. CNNs are excellent at analyzing patterns and features of visual inputs and, that is why they are suitable for the visualization of abnormal cells and precancerous disorders. CNNs are applied in the diagnosis of cervical cancer given that it involves analyzing images of cervical cell samples that are extracted from a Pap smear or a biopsy slide. It begins with convolutional layers, which place filters to the images; they express basic attributes such as edges and textures. As it goes deeper to the next levels the CNN gains more complicated and complex features of the images such as the cell structures and abnormal shapes related to dysplasia or malignancy. The pooling layers' principal function is to reduce the dimensions of the feature maps created in the convolutional layers while preserving the dataGRU are a kind of recurrent neural network that enhances the performance of network architectures with sequential characteristics. Compared with other forms of RNNs, GRUs have neural gating for determining the flow of information and since they are not intricate, are capable of obtaining and retaining information patterns in longer sequences [16]. GRUs consist of two primary gates: for the prior information it allows how much information to forget, while for the new information it allows how much to update. This leads to the capability of GRUs to learn temporal dependencies of data, which makes them suitable in such tasks which involve sequences and then further tuned by using ABC optimization. Key Contributions:

- The study tested the performance of ML (XGB, SVM, and RF) and DL model (ResNet-50) for cervical cancer detection which confirmed the superiority of the DL model.
- Using transfer-learning and fine-tuning techniques, the ABC optimized CNN-GRU model improved the accuracy and efficiency of cervical cancer detection.
- All models were tested using five-fold rigorous cross-validation methods to ensure the robustness and reliability of the findings.
- The use of SMOTE corrected class imbalances in the data set, increasing the performance and generalization of the model.
- The excellent accuracy and performance of the proposed model highlights the potential for early detection of cervical cancer, resulting in better patient outcomes and survival rates.

The following are the sections of this study. A problem definition of the relevant works is given in Section II. Section III discusses the problem statement. The data collection, pre-processing, and methodology of the proposed task are explained in Section IV, followed by the result and discussion in Section V and the conclusion and future works are covered in Section VI.

II. Related Work

Ghoneim et al. presented a study on cervical cancer, which is the leading cause of death from cancer in women. If this cancer is found and treated early on, its consequences can be greatly diminished. This paper presents a CNN-based method for the identification and categorization of cervical cancer cells. A CNN model is trained with the cell pictures, and DL characteristics are extracted. After that an ELM classifier is used to categorize the input images. By fine-tuning and transfer learning, the CNN model is employed. AE-based classifiers and MLPs are alternatives to the ELM. The Herlev database is used to conduct the experiments. In the detection test, the proposed CNN-ELM-based system achieved 99.5% accuracy, while in the classification job, it achieved 91.2% accuracy. However, one weakness of this strategy is its reliance on the quality and variety of the training dataset, which may affect the model's generalizability to diverse populations and imaging settings outside of the Herlev database [17]. Alquran et al. present the first system to categorize Pap smear images into seven classes, enabling a computer-aided diagnostic system to identify anomalies in cervical cell images. The system uses a Support Vector Machine classifier to differentiate between normal and abnormal situations with 100% accuracy and sensitivity. It also correctly diagnoses high degrees of abnormalities and classifies modest levels of abnormalities as mild or moderate dysplasia with 92% accuracy. The system consists of five polynomial classifiers, with an overall training accuracy of 100% and test accuracy of 92%. This technique could potentially lead to earlier cervical cancer identification and higher survival rates for women [18].

Arora et al. explains how SVM was used as part of an ML classification method on the Herlev Pap-smear picture dataset. Gaussian Fitting Energy-driven active contour models were used in the segmentation stage. When the segmented pictures were contrasted to manually labeled images by skilled cytologists, a 92% match was shown by the Dice index. The maximum classification accuracy achieved using polynomial SVMs was 95%. However, one shortcoming of this strategy is that changes in image quality and staining processes might have an influence on the consistency and reliability of segmentation and classification across different clinical settings and datasets [19]. Tripathi et al. demonstrates DL classification techniques on the SIPAKMED Pap smear image dataset, with the ResNet-152 architecture yielding the maximum classification accuracy of 94.89%. But this method might not completely take into consideration differences in picture quality and the existence of objects of art, which can have an impact on how well the model performs in various clinical contexts [20].

Kudva et al. presents a study on the use of CNN for classifying digital cervical images acquired during VIA. There were 102 women in the research, and 42 of the images were classified as VIA-positive and 60 as VIA-negative. By hand, the researchers identified 409 picture patches from VIA-negative areas as negative and retrieved 275 image patches from VIA-positive regions as positive. Since the shallow CNN was trained on a limited and particular collection of pictures, its 100% classification accuracy may not translate well to bigger datasets or varied imaging settings. The study highlights the potential of CNNs in automated image-based cervical cancer detection [21]. Fernandes et al. optimizes dimensionality reduction and classification models, highlighting relevant properties in low-dimensional space for patient classification. The model achieved accurate predictions with a top AUC of 0.6875, outperforming methods like denoising autoencoders. For medical professionals and academics, clinical results obtained from embedding spaces are trustworthy since they have been verified by the literature. However, the model's performance may still be insufficient for clinical application, and further refinement and validation with larger datasets may be necessary [22].

Park et al. recommended a research on cervical cancer, which has a 60% death rate and is the second- most frequent malignancy in women globally. It is vital to get routine checks to discover problems early. In this work, cervicofigurey pictures are used to assess the efficacy of the ML and DL models in detecting indicators of cervical cancer. After deleting vaginal wall areas, 4119 cervicofigurey pictures were classified as either or not positive for cervical cancer using the DL model ResNet-50. Out of 300 features in total, 10 main features were retrieved by the ML models. Fivefold cross-validation was used to validate each model, and the resulting AUCs were 0.97, 0.82, 0.84, and 0.79. The ResNet-50 model outperformed the three ML approaches on average by 0.15 points, indicating that it might provide better performance than the existing models. However, the high performance of ResNet-50 might be specific to the dataset used, and its generalizability to other populations or imaging conditions remains uncertain. Further validation using a larger and more diverse set of data will be necessary to establish the model's effectiveness and stability to be used in clinical practice [23].

As cervical cancer is the number one killer of women globally, screening and treatment are compulsory at the right time. Many studies have focused on enhancing the diagnostic methods through the implementation of ML and DL solutions. Such techniques include CNN and ELM used in the classification of cervical cancer from Pap smear images with high levels of acquaintance. Nonetheless, issues persist: obtaining large-that is, high-quality-datasets, and generalization of the developed models across multiple clinical scenarios. In the examination of the listed algorithms and models including ML models like SVM and XGB and the DL models like ResNet-50, it has been ascertained that DL performs better than the classic ML algorithms in diagnosing cervical cancer. However, there remains the necessity to do further validation of the models using different datasets to prove that they are robust and effective in actual conditions. These results of the analysis underline the possible sociological impacts of AI for enhancing the early diagnosis and the outcome rate of cervical cancer.

III. Problem Statement

Multimodal decision-making for cervical cancer detection, segmentation, and classification are significant challenges in medical imaging. They regularly work with the entry of the considerable quantity of the multimodal medical information, which may include MRI, CT scans, histopathological images, and each of them provides the kind of data. This situation hinders top-rated information fusion which in turn supply undesirable results and low accuracy within the diagnosis of an infection. In addition, many integration issues related to patient privacy arise because combining data from different sources traditionally increases the risk of patient privacy and attacks to compromise sensitive health information. Traditional methods will also not be able to achieve good model performance due to dissimilar data quality and incompatibility of different methods. Thus, there is a need for efficient methods to analyze and integrate multiple data sources, as well as to identify confidential data and increase diagnostic yield in cervical cancer detection [24]. The described method eliminates these complications due to the decomposition of both patient behavioral data using high-resolution Pap smear images with a ABC optimized CNN-GRU model mixed use of patient data using gated recurrent units and convolutional neural networks and Decomposing images into spatial features using temporal patterns therefore enhances method's general classification performance The displayed example removes class imbalances and merging issues from there successfully, although the method combines state-of-the-art techniques with well-known preprocessing techniques such as SMOTE and min-max scaling to produce reports.

IV. Proposed Method for Cervical Cancer Detection and Classification

Cervical cancer is one type of cancer which impacts the cervix, the lower part of the uterus. Most often caused by a persistent infection with certain strains of HPV, it often progresses gradually over a number of years. Regular screenings are essential for early identification of cervical cancer since the disease may not show signs in its early stages. Preventive strategies such as regular Pap screenings and HPV vaccinations are crucial. Depending on the cancer's stage and extent, treatment options include radiation therapy, chemotherapy, and surgery. Reducing the global effect of cervical cancer requires more awareness, education, and prompt medical care.

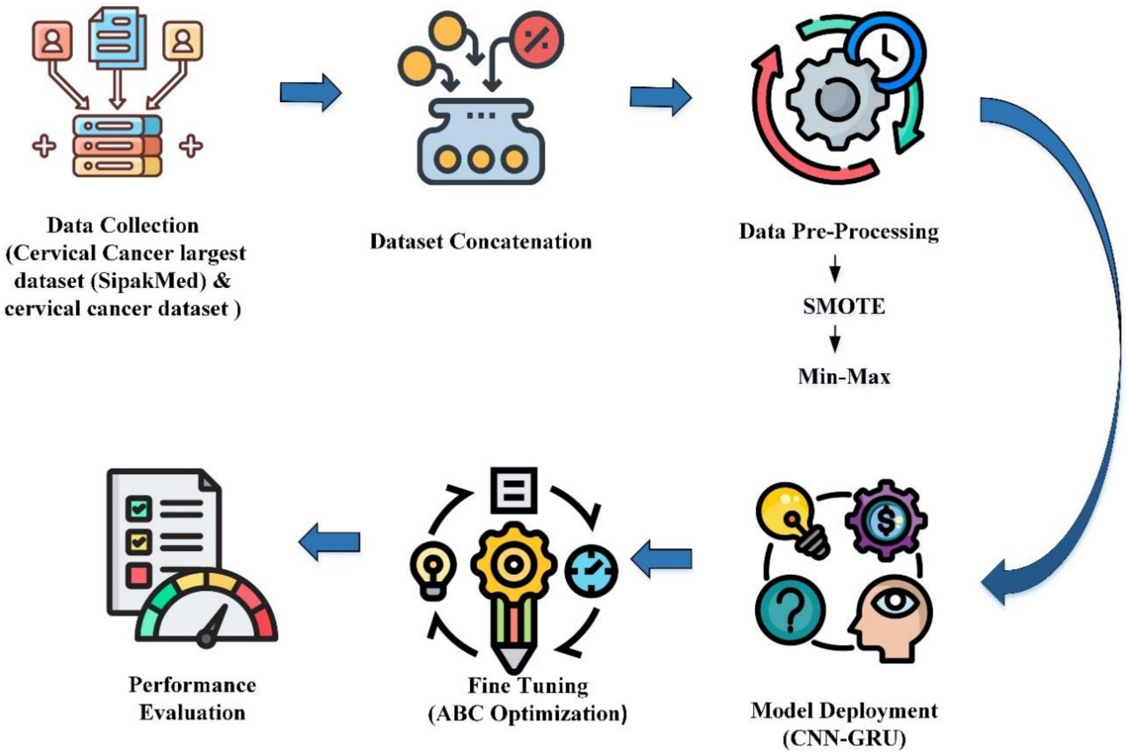

Fig. 1. Flow diagram of the proposed study.

Fig. 1 shows the workflow of the proposed study involving collecting data from the SipakMed dataset and a comprehensive dataset of cervical cancer patient information. The dataset is then combined to create a multimodal dataset that includes both visual and non-visual data. The data is pre-processed using SMOTE to address class imbalance and normalize the data using min-max scaling. The hybrid CNN and GRU model is deployed, extracting spatial features from images and analyzing sequential data to identify patterns over time and then fine tuning the hyper parameters by ABC optimizer. The model's performance is evaluated using various metrics, including accuracy, precision, recall, and F1 score. The model undergoes an iterative improvement cycle, refining its accuracy and robustness. This comprehensive approach to integrating and analyzing multimodal data for cervical cancer detection is illustrated in the figure.

A. *Data Collection*

1) Dataset 1: The Cervical Cancer largest dataset (SipakMed) dataset is especially intended for the development and testing of automated cervical cancer detection systems based on pap-smear images. It contains 4049 images classified into five categories: normal, koilocytotic, metaplastic, moderate dysplasia, and severe dysplasia. Each class denotes a particular stage or kind of cervical cell abnormalities, allowing a broad range for investigation. The dataset contains high-resolution images that have been carefully annotated by professional cytologists, assuring correctness and dependability for training and testing ML models. The dataset is extensively utilized in research to create improved algorithms capable of properly classifying and detecting cervical cancer at various stages. Using this dataset allows DL techniques, such as CNN, to automatically extract characteristics and enhance diagnostic accuracy, resulting in earlier identification and treatment of cervical cancer [25].

2) Dataset 2: The cervical cancer dataset is specifically the patient information database which is used to create new models of cervical cancer diagnosis and risk. These data features are essential demofigureic and risky behavioural aspects such as age, number of sexual partners, age at first intercourse, and pregnancies data which all have a direct or indirect relation with cervical cancer rate. In addition, it contains various characteristics connected to smoking, such as the patient's frequency of smoking and whether or not they smoke, as well as the length of time they have smoked or stopped, particularly in light of the known link between tobacco and cervical cancer. Certain types of contraceptives and their use and certain periods are mentioned, which offers data concerning the change in cancer risk due to long contraceptive use. Another important component of cervical health investigation is indicated in the dataset in the form of whether the patient employed an IUD. These factors give a large set of data that might be helpful to a ML algorithm used in the determination of the possible chances of getting cervical cancer. The described dataset provides a large number of parameters, which makes it useful for the multidimensional analysis of the patients' lifestyle and their medical history, necessary for the construction of accurate models for early diagnostics and prevention. Science may use this information to reveal significant trends and relationships that result in cervical cancer, and thus design improved cervical cancer early detection means and administrative-treatment tactics for specific patients. It is therefore important to conclude that this encompassing database is a valuable asset to advancing cervical cancer investigations as well as enhancing women's wellbeing globally [26]. Table I depicts Dataset Description.

TABLE I. DATASET DESCRIPTION

Feature	Description	Values
Age	Age of the patient	35
First sexual intercourse	Age at which the patient had first sexual intercourse	18
Number of sexual partners	Number of sexual partners the patient has had	3
Num of pregnancies	Number of pregnancies the patient has had	2
Smokes (years)	Number of years the patient has been smoking	10
Smokes	Whether the patient smokes (Yes/No)	Yes
Smokes (packs/year)	Number of packs per year the patient smokes	5
Hormonal Contraceptives (years)	Number of years the patient has used hormonal contraceptives	3
Hormonal Contraceptives	Whether the patient uses hormonal contraceptives (Yes/No)	No
IUD	Whether the patient uses an intrauterine device (IUD) (Yes/No)	Yes

3) Dataset concatenation: Multimodal Dataset: With the use of the Cervical Cancer Largest Dataset (SipakMed) and the complete cervical cancer patient information dataset, a solid multimodal dataset is developed for enhancing the functions of prediction models for cervical cancer diagnosis, classification, and risk evaluation. In this concatenated research dataset, the pap-smear image data highlights the high resolution while patients' demofigureics, behaviors, and medical histories offer complex information, which benefits the subsequent high-level ML and DL. The SipakMed dataset contains 4049 thoroughly annotated pap-smear imagess, classified into five classes: normal, koilocytotic, metaplastic, mild dysplasia and Carcinoma in situ. Each category is associated with certain stage or kind of cervical cell abnormalities and gives a wide range for more examination. The imaging, which is high-resolution, has been labeled by ten different cytologists and is dense, thus it is suitable for training and testing complicated models such as CNNs. These models to do this automatically hence enhancing a doctors' diagnostic abilities and enable early detection and treatment of cervical cancer.

The cervical cancer patient information dataset contains all the factors that can be used in evaluating the state of women with cervical cancer and predicting the risks of the disease. The latter undergoes certain transformations: age, number of sexual partners, age at first sexual intercourse, and number of pregnancies, all of which are indispensable for analyzing individual risks. It also has separate responses for whether the patient smokes, how long they have smoked, how often they smoke, all of which have been found to raise the risk of cervical cancer. Moreover, the statistics, related to the frequency of the hormonal contraceptive use, for how long and the IUD, give an insight into the impact of the long-term contraception on cervical health. When the authors integrate both of these datasets, the researchers will be able to perform multiple analyses of visual and nonvisual data; this leads to actual and effective prediction models. The concatenated dataset allows identifying components that use multiple-pieced characteristic taking in account characteristics from pap-smear images as well as unique patient's data to enhance model performance. Besides, this technique optimizes the determination of the cervical cancer's stage, and the quantitative risk approach also enables pinpointing the screen targets. The ability to look for patterns and relate multiple forms of data proves useful in identifying cervical cancer's etiology and evolution, which can lead to better screening and individualized treatment programs. The presented multimodal dataset, therefore, is an invaluable resource for the advancement of cervical cancer studies; it provides a strong foundation for developing innovative diagnostic approaches and enhancing the quality of women's lives worldwide.

B. Data Pre-Processing

1) SMOTE: SMOTE is a prominent ML approach for dealing with class imbalance, which occurs when certain classes in a dataset are severely underrepresented in comparison to others. Predictive model performance may suffer as a result of this imbalance, favoring the majority class in the findings. By producing synthetic examples to the minority class, SMOTE solves this problem, balancing the distribution of classes and enhancing the effectiveness of machine learning techniques. SMOTE selects a random sample from the minority class and places k-nearest neighbors in the minority class, which are the k samples closest in feature space to the selected sample. The parameter k is specified by the user. For every k-nearest neighbor, SMOTE generates a new synthetic sample. A random point is chosen on the section of line that joins the sample selected with any of its neighbors to create this new sample. Mathematically, if x_i is the selected sample and x_j is one of its k-nearest neighbors, a new synthetic sample x_{new} is created in (1),

$$x_{new} = x_i + \lambda . (\mathrm{x}_j - \mathrm{x}_i) \quad (1)$$

Where λ is a random number between 0 and 1. The freshly developed synthetic samples are incorporated into the dataset, increasing the amount of minority class examples. SMOTE improves model performance by leveling the class distribution, allowing them to learn equally from all classes. Reduces Overfitting: Unlike random oversampling, which merely replicates minority class samples and might lead to overfitting, SMOTE creates fresh and distinct samples, resulting in a more diversified and generalized dataset. Improves Generalization: Because the model was trained on a more representative dataset, the synthetic examples allow it to generalize more well to previously unknown data.

Employing the SMOTE algorithm to enhance the predicted accuracy of the multimodal dataset, including SipakMed pap-smear images of cervical cancer and cervical cancer patients' data profiles. This helps in case of class imbalance by generating synthetic samples of lower classes to increase the number of samples for each class. To deal with the issue of imbalance in both image-based and demofigureic and behavioral patient's data, synthetic minorities were created using SMOTE. This method involves the generation of intermediate points between samples in the minority class between pairs of the existing samples using line segments. Being a balanced data set, which means containing equal instances of all classes, this data set reduces the bias of new ML models towards the majority classes. Faster and more accurate results are therefore attained, leading to the early identification and detection of cervical cancer as well as an improvement in the general state of women's health.

2) Min-Max scaling: Normalize a dataset using min-max scaling before creating synthetic samples in order to apply SMOTE on it correctly. This normalization method reduces the feature values to a common range, usually [0, 1], which might improve the performance of the SMOTE algorithm and subsequent ML models. For each feature in the dataset, use the equation to scale the values to the range [0, 1], which is shown in (2):

$$\acute{X} = \frac{X - X_{min}}{X_{max} - X_{min}} \tag{2}$$

The original feature value is $X,$ the lowest and maximum values are $X_{min} and\ X_{max}$, and the scaled value is $\acute{X}.$ Utilize the SMOTE approach to produce fake samples in the minority classes after scaling the data. By interpolating current minority class examples from the scaling feature space, SMOTE will generate new samples.

Handling class imbalance in the proposed multi-modal cervical cancer dataset, the min-max normalization and SMOTE is applied. All the features were normalized to be in the same scale within [0, 1] using the min-max normalization method. For instance, the Age attribute of their framework that used to have the variation between 18 and 60 was standardized correspondingly. Then employ SMOTE to generate synthetic examples to minority classes in this normalized feature space to address the imbalance issue. This approach involves the extrapolation of the already existing small samples of the minorities in order to achieve the synthesis of new points. Thus, after applying SMOTE, it is possible to inverse convert the data back to the original scale if necessary. This proportional method that uses min-max scaling in combination with SMOTE offer high accuracies of the ML model as well as robustness of the classifier precisely when cervical cancer setbacks are balanced by rousing awareness of cervical cancer detection and diagnosis.

C. Artificial Bee Colony

An artificial algorithm based on swarms and derived from the foraging behavior of bees' population is the ABC (Artificial Bee Colony) approach; it was introduced initially by Karaboga in 2005. While foraging, honeybees can be divided into three main groups: conveyancers, gossips and trampers respectively. The worker bees are responsible in collecting nectar and information, the foragers are responsible in finding new positions of food sources and finally the specific observers who are useful in determining the best flight paths. Sometimes, or because of the past impressions, explorers go hunting for food. They may engage other members of the hive so as to gather pollen while at the same time taking notes on the food they come across as they work. The traditional ABC method, developed by Karaboga in 2005, acts as a swarm intelligence algorithm that simulates the foraging behavior of bees [27]. This method divides the bees into three groups: workers, observers and explorers. Each group increases the overall success of the colony's foraging. On the other hand, observers' selection of the most efficient method of pollen collection depends on the knowledge of the food sources initially found and the choice to dispose of low dead. In the case of the traditional ABC method, both the speed and the tracking rate are strongly influenced by the number of searches and the information that deployed bees hold about food sources. According to various references within the traditional ABC technique, if erroneous records is incorporated, it is able to lead to suboptimal path optimization by way of onlookers, in the end slowing down the tracking speed in later ranges. Consequently, there may be a need to implement novel techniques aimed at improving tracking performance [28].

It is important to remember that the higher the number of bees, the higher the tracking accuracy. Conversely, fewer pollinators may result in shorter duration, although this may complicate the selection of optimal action. This is because the detection length of the microcontroller path is directly related to the size of the bee population, which means that a larger number will require a longer processing time. Therefore, to overcome the problem of obtaining the global optimum at restricted frequencies due to the decreasing number of bees, an improved method combining the CNN-GRU method with ABC is proposed the method combines with fewer pollinators and is used to identify severe autism spectrum disorder.

1) Increasing the probability of bee selection for improved feature extraction: To increase forecasting reliability, the study presents an optimized CNN-GRU hybrid network augmented with the ABC algorithm. Fig. 1 illustrates the optimization process. To improve the resolution, the algorithm searches for a globally optimal solution. This match is required:

$$B_{uv}^{new} = B_{uv} + r_1 \times (B_{uv} - B_{neighbour,v}) + r_2(O_v - H_{uv}) \tag{3}$$

Of these, r_1 and r_2 are arbitrary integers with values of 0.5 and 0.1, respectively, and O_v is the $u - th$ variable in the total ideal system.

The ABC system minimizes the variability within a bee colony and prioritizes the honey source that exhibits the greatest variability while providing the best global solution. This raises the problem of initial convergence and the appearance of localized optima. To overcome this, the improved ABC algorithm incorporates adjustable parameter changes that contribute to the conservation of characteristics of the population and the number of collisions and subsequently derive this enhanced ABC method for searching for similarity:

$$B_{uv}^{new} = F_1 \times B_{uv} + F_1 \times r_1 \times \left(B_{uv} - B_{neighbour,v}\right) + F_2 \times r_2(O_v - H_{uv}) \tag{4}$$

$$F_1 = F_{max} - (2 - e^{\frac{iterate}{\max cycle}In2})(F_{max} - F_{min}) \tag{5}$$

$$F_2 = F_{min} - (2 - e^{\frac{iterate}{\max cycle}In2})(F_{max} - F_{min}) \tag{6}$$

The loop specifies the current iteration count, maximum cycle maximum iteration count, minimum value of F_{min} adjusting factor, and maximum value of F_{max} adjusting factor. The terms F_1 *and* F_2 specify how close the new source is to the source, the reference proximity, and the ideal reference rate a quantity the same is true. The probability is the hive equation Q_i and the correct answer is changed to B_i Reverse roulette selection is introduced so that the population converges earlier and no less This strategy aims to extract honey from untreated areas effectively while maintaining local strength.

$$Q_i = \frac{1/Fitness_i}{\sum_{j=1}^{n} 1/Fitness_j} \tag{7}$$

Due to the utilization of the opposite martingale function choice method, the following bees will vicinity a better emphasis on attempting to find nectar sources with restricted adaptability during the preliminary levels of the technique. This, in flip, tends to slow down the tempo of decision. Consequently, this paper gives a variable for the adaptable evaluation factor of ∝,

$$\propto = e^{\frac{iterate}{\max cycle}In2} - 1 \tag{8}$$

By maintaining the consistency level at the beginning of the procedures, through the use of companion bees obtain a high-quality honey source. The last part of the algorithm is a modification of the community maintaining distinct from each other and not settling on an optimal system for a particular site. Consequently, the following is an optimization of the probabilities of the bee colony (equation Q_i) and the solution (B_i).:

$$Q_i = \begin{cases} \frac{\boldsymbol{Fitness_i}}{\sum_{j=1}^{n} \boldsymbol{fitness_j}} & ,\boldsymbol{random} > \propto \\ \frac{\boldsymbol{1/Fitness_i}}{\sum_{j=1}^{n} \boldsymbol{1/Fitness_j}} & ,\boldsymbol{random} < \propto \end{cases} \tag{9}$$

ABC algorithm for feature extraction for diagnosis of autism spectrum disorder (ASD) is optimized using artificial bee colonies as “food sources” in repetitive rounds During scheduled feeding rounds, these bees search for feature subsets and are evaluated by fitness functions their characteristics. Beekeepers select patchy subgroups based on what hired bees open, while explorer bees search for entirely new subgroups if no improvement is observed. The ABC algorithm optimizes feature selection by balancing exploration and exploitation using dynamic criteria modification. This approach increases the accuracy of analysis by improving selectivity and visibility, reducing noise and redundancy, and increasing the classification of ASDs.

D. CNN-GRU

1) CNN: CNN is a subclass of deep learning models created especially to interpret structured, grid-like input, including images. Their capacity to extract efficient features and develop hierarchical representations directly from raw pixel data has transformed a variety of sectors, including computer vision. Each layer performs a specific function, progressively extracting and modifying data.

a) Convolutional layer: CNNs rely on a convolutional layer for feature extraction. Their components are learnable filters, also known as kernels, which are applied to input images and multiply and aggregate the image's elements to generate feature maps. The feature diagrams, which capture spatial patterns at various sizes and orientations, help the network develop hierarchical representations of visual attributes.

$$v_i^l = r(\sum_j \left(Q_{ij}^l * y_z^{l-1}\right) + a_i^l) \tag{10}$$

In Eq. (3), y_z^{l-1} is the $j - th$ feature map from the layer before it, a_i^l is the bias parameter for the $i - th$ feature map in layer l, r is an activation functions, and a_i^l is the final result of the z-th feature map in layer$l$. Q_{ij}^l indicates the convolutional kernel that separates the $i - th$ and $j - th$ feature maps.

b) Pooling Layer: Convolutional layers are sandwiched with pooling layers to reduce feature map dimensions while preserving important characteristics. Maximum pooling and normal pooling are two common pooling techniques that preserve the maximum and average values within every pool window, respectively. Pooling improves translation invariance, increases computing efficiency, and reduces computational complexity.

$$k_i^l = ul\left(d_i^l\right) \tag{11}$$

Eq. (4) represents that the down-sampled (ul) result of the $i - th$ feature map in layer *l* is denoted as k_i^l. Down sampling is the pooling procedure, which is typically max-pooling or average-pooling.

c) Activation Layer: CNN may gain complicated mappings between input and output data by the network's nonlinearities and activation functions. Typical activation functions include Leaky ReLU, ELU, and them variations, such as ReLU, which adds sparsity and accelerates convergence by resolving the vanishing gradient problem in (5),

$$d_i^l = r(v_i^l) \tag{12}$$

d) Fully Connected Layers: Dense layers typically appear at the conclusion of CNN systems. They perform classification by converting the high-level characteristics gathered by prior layers into probabilities or class scores. A completely connected layer allows for the learning of complicated decision constraints and the creation of predictions using learnt representations. This is because every neurons in the layers is related to every other neuron in the layers preceding it.

$$Z^W = \frac{1}{2}\sum_{n=1}^{N}\sum_{k=1}^{c}\sqrt{\left(e_t^m - y_s^n\right)} \tag{13}$$

In Eq. (6), *N* is the total amount of samples, *c* is the number of classes, Z^W is the output, e_t^m is the goal value, and y_s^n is the output values of the k-th sample in the n-th direction.

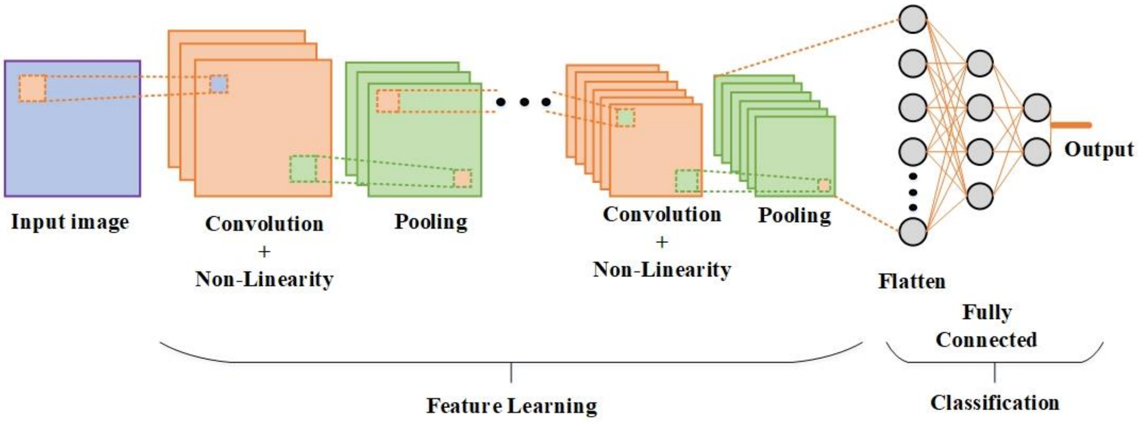

Fig. 2. Architecture of CNN.

Fig. 2 illustrates the structure of a CNN, one of the most frequently used DL algorithms in the domain of image identification and classification. The process starts from an input image that is passed in the network. In the first layer, a convolution layer is used in conjunction with a ReLU non-linearity function to extract visual features. Multiple filters are applied to the picture to identify fundamental patterns like edges and texture. Numerous feature maps are generated by this. Subsequently, the pooling layer minimizes the feature map sizes while preserving all pertinent data to the greatest extent feasible. This can improve computing efficiency and minimize over-learning. This convolution and pooling layer process can be done several numbers of times in order to extract higher level features. The generated feature maps are flattened out into a one-dimensional vector which is passed on to a network of fully connected layers. These layers perform the final classification process in which the network determines the probability that the input image belongs to any of the many classes.

The proposed study employs the CNN architecture that classifies cervical cancer from medical dataset suggested in this paper. In older approaches, feature extraction and segmentation are necessary to extract high-level patterns; in the CNN these are learned naturally thus making it efficient. When the CNN is presented with high definition pap-smear images from the SipakMed dataset, it can analyze and distinguish between the phases of cervical cell pathologies. The ResNet-152 structure is used as the DL model on this dataset. This technique demonstrates CNN's ability to coordinate the nature and type of medical images; cervical cancer detection and diagnosis are thus robust and reliable. The better diagnosis from the feature extraction and categorization process enhances the diagnosis accuracy, may enhance the early intervention of the disease hence improving patient quality of life.

2) GRU: The GRU, a kind of RNN, is an excellent way to capture relationships in sequential data. It addresses the vanishing gradient issue that traditional RNNs typically encounter, allowing the model to detect long-term relationships. The GRU does this by controlling the flow of information within the unit using its gating mechanisms.

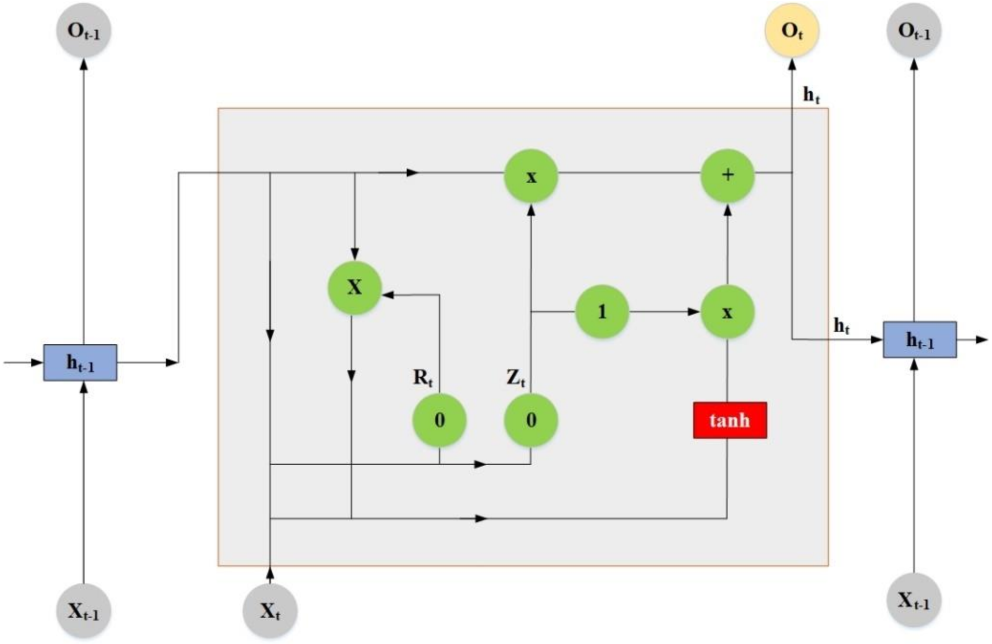

Fig. 3. Architecture of GRU.

The novel form of RNN to handle sequential input, called GRU is depicted in the Fig. 3. The GRU is made up of two basic gates: The update gate, and the reset gate. The reset gate regulates how much memory is worthy of being kept, while the gate for updates determines how much information is appropriate to be handed on to the generations that follow. These gates simultaneously receive the current input and the prior concealed state. By adding the current input to the prior hidden state and changing it with an induction quantity of tanh as a linearity component, the reset gate is utilized to identify the potential activation. The final hidden state and candidate activation are determined by the update gate, which is based on the weighted prior concealed state. In this way, with this strategy the GRU has the ability to avoid the vanishing gradient problem presented in classical RNNs and simultaneously it is capable of capturing relations over sequential data and maintaining important information along large sequences. Even though the GRU model has less parameters than LSTM, it retains similar performance while training faster; it is thus ideal for several time-series prediction and NLP uses.

The amount of the prior state h_{t-1} to be forgotten is decided by the reset gate r_t. It is calculated in this (7):

$$r_t = \sigma(W_r.[h_{t-1}, x_t] \tag{14}$$

where x_t is the current input, h_{t-1} is the previous hidden state, W_z is the weight matrix, and σ is the sigmoid activation function.

The amount of the prior state h_{t-1} that should be carried over to the present state is determined by the update gate z_t . It is computed in (8):

$$z_t = \sigma(W_z.[h_{t-1}, x_t]) \tag{15}$$

To control how much of the historical data to utilize, the reset gate is used to compute the candidate hidden state h_t,

$$h_t = \tanh(W_h.[r_t * h_{t-1}, x_t]) \tag{16}$$

In (9), The candidate hidden state's weight matrix is displayed by W_h, and element-wise multiplication is indicated by $*$.

Ultimately, the candidate hidden state h_t, which is under the update gate's control, and the prior hidden state h_{t-1} combine to form the current hidden state h_t

$$h_t = (1 - z_t) * h_{t-1} + z_t * h_t \tag{17}$$

The update gate z_t in (10) regulates the ratio of updating new data to retaining the present state, hence controlling the extent to which the unit changes its state. The GRU is very helpful for tasks like language modeling, time series prediction, and other applications involving sequential data because of its gating mechanism, which enables it to efficiently acquire and store information across lengthy periods. Recurrent neural networks can train more effectively and robustly by using GRUs that can adaptively forget or recall portions of the sequence. This allows them to preserve long-term dependencies and reduce problems associated with gradient vanishing.

The advised study combines CNN and GRU to take use of CNN's spatial function extraction skills and GRU's temporal pattern recognition strengths. The high-resolution pap-smear pics from the SipakMed dataset are first processed through the CNN to extract vast features earlier than being enter into the GRU for sequential evaluation. This hybrid approach is intended to boom the category accuracy and resilience of the detection machine. The study suggests that this CNN-GRU structure provides accurate type accuracy, beating popular techniques that only use CNNs or gadget learning strategies. The ResNet-152 structure, with its CNN spine and GRU, improves the version's ability to reliably categorize various levels of cervical cellular abnormalities, resulting in earlier identity and remedy of cervical most cancers. This incorporated method now not only increases prognosis accuracy but additionally gives an extra entire image of cervical most cancers improvement, ensuing in better patient results.

The proposed hybrid CNN-GRU model, optimized the use of the Artificial Bee Colony set of rules, gives several benefits over conventional techniques and models in cervical most cancers detection. First, this model addresses the task of integrating multimodal information by combining visual features from Pap smear pix with temporal styles derived from patient statistics, consisting of medical history. This multimodal approach allows for an extra complete analysis as compared to unmarried-modality fashions, which frequently recognition solely on picture statistics or non-visible capabilities. The hybrid CNN-GRU structure excels in taking pictures both spatial and sequential styles, improving the model's potential to come across complicated relationships and enhance classification accuracy.

Compared to standard machine gaining knowledge of (ML) fashions together with Support Vector Machines (SVM) and Extreme Gradient Boosting (XGB), that have been extensively used in medical imaging, the proposed model's deep learning (DL) structure allows it to outperform in accuracy and robustness. For instance, fashions like SVMs usually require sizable function engineering and can battle with huge and complex datasets. In contrast, the CNN-GRU model benefits from automated characteristic extraction via convolutional layers and is able to handling large datasets more efficaciously. Furthermore, the incorporation of GRUs, recognized for his or her efficiency in processing sequential information, improves the model’s overall performance in duties requiring temporal analysis, along with tracking disorder progression.

In addition, using superior pre-processing techniques like Synthetic Minority Over-sampling Technique (SMOTE) and Min-Max scaling allows to clear up commonplace troubles confronted by means of other fashions, along with magnificence imbalance and records inconsistency. Many traditional procedures war with dataset biases, leading to bad generalization across diverse medical settings. The hybrid version's ABC optimization further complements its performance by way of exceptional-tuning hyperparameters, making it extra adaptable to diverse datasets and improving accuracy, precision, take into account, and F1 ratings. This robust, multimodal, and optimized framework represents a giant development over preceding techniques, imparting a greater reliable answer for cervical most cancers detection and category.

Algorithm 1: Algorithm for the proposed study

Step 1: Data Collection

- Collect data from Cervical Cancer Largest Dataset (SipakMed)
- Collect data from Cervical Cancer Patient Information Dataset

Step 2: Dataset Concatenation

- Combine pap smear images with patient demographic and behavioral data into a single dataset

Step 3: Data Pre-Processing

  ✓ Apply SMOTE

  ✓ For each minority class sample:

  ✓ Select k-nearest neighbors

  ✓ Generate new synthetic samples

- Normalize data using Min-Max Scaling

Step 4: Model Training

- Initialize Hybrid CNN-GRU Model
- Train the model using the pre-processed multimodal dataset
- Further fine tuning by using ABC Optimizer.

Step 5: Performance Evaluation

- Test the model on a validation dataset

V. Result and Discussion

The results of the investigation spotlight the advised approach's splendid effectiveness in figuring out and categorizing cervical cancer. It performs significantly higher in terms of accuracy and reliability than traditional strategies. The recommended approach efficaciously combines modern-day methods with multimodal records, demonstrating its ability to appropriately stumble on and categorize times of cervical most cancers with few mistakes. This development opens the door for more efficient screening and treatment plans whilst also improving diagnostic accuracy and providing a viable early detection approach. The better efficacy of the cautioned technique underscores its ability to convert the analysis of cervical most cancers, resulting in higher patient outcomes and greater resilient healthcare solutions.

A. Training and Testing

Fig. 4 illustrates the education and trying out accuracy of a version over a range of epochs (zero to 100). The schooling accuracy represents the model's overall performance at the training information, beginning with low accuracy and step by step improving because the range of epochs increases. The testing accuracy indicates how well the model performs on a different testing dataset; it starts off low and gets better with time, but it never becomes as good as the training accuracy. The comparison line converges round epoch 50, with training accuracy barely higher than trying out accuracy, suggesting that the version can be overfitting to the education statistics. This figure illustrates the version's learning and generalization to unseen information during testing.

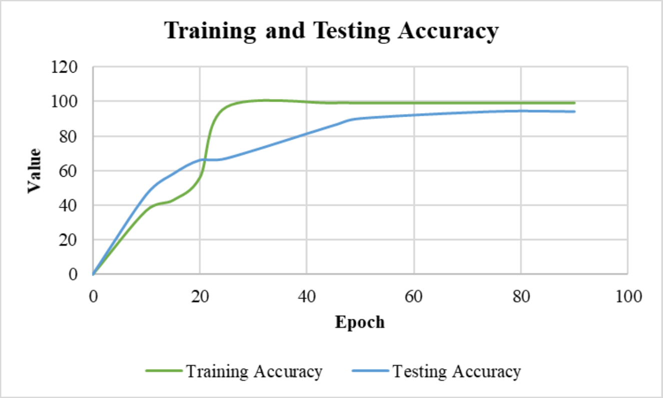

Fig. 4. Training and testing accuracy.

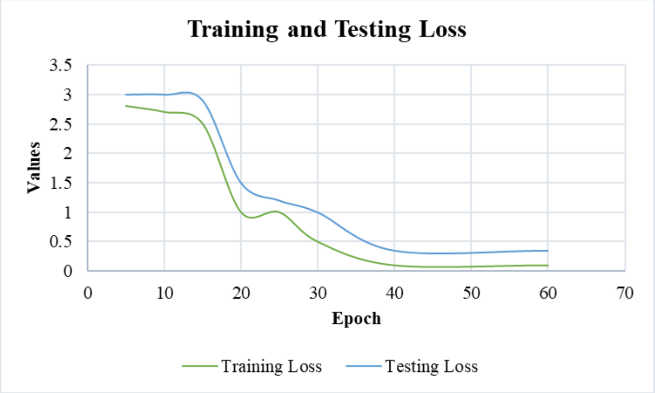

Fig. 5. Training and testing loss.

Fig. 5 displays a model's testing and training losses. A smaller training loss indicates higher performance. The training loss is the model's mistake on its initial data throughout each epoch. The testing loss shows the model's loss on a separate dataset, decreasing over time. Monitoring both lines is crucial to avoid overfitting. The figure should show both lines decreasing together, with overfitting if the training loss decreases while the testing loss increases, and underfitting if both lines increase. This figure demonstrates the model's learning performance during training and its generalization to unseen data during testing.

B. Performance Metrics

When evaluating the effectiveness of models in a range of contexts, such as medical imaging and illness detection, performance metrics are essential tools.

1) Accuracy: The proportion of correctly detected cases among all instances, encompassing genuine positives and true negatives. It is a general indicator of how often the model is accurate. However, accuracy alone may be deceptive in unbalanced datasets.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{18}$$

2) Precision: The proportion of real positives to both true and false positives. It evaluates how well the model can identify positive cases from all predicted positives.

$$Precision = \frac{TP}{TP+FP} \quad (19)$$

3) Recall: The proportion of genuine positives to the total of false negatives and true positives. It shows that the model is able to identify all real positive occurrences.

$$Recall = \frac{TP}{TP+FN} \quad (20)$$

4) F1 score: The accuracy and recall harmonic average. It provides a single parameter to balance the accuracy vs. recall trade-off, which is particularly useful in cases of class imbalance.

$$F1\ score = \frac{Precision \times Recall}{Precision + Recall} \quad (21)$$

Where, TP is True Positives, TN means True Negatives and FP is False Positives and FN is False Negatives in (19), (20) and (21). Table II depicts Performance Metrics.

TABLE II. PERFORMANCE METRICS

Metrics	Efficiency
Accuracy	99.3%
Precision	99.1%
Recall	98.6%
F1 score	98.2%

The model's effectiveness is shown in the table for each of the four-performance metrics: F1 Score, Accuracy, Precision, and Recall. With a score of 99.3%, accuracy is a measure of the percentage of properly categorized cases. With a score of 99.1%, precision is a measure of the percentage of genuine positives among all instances projected to be positive. With a value of 98.6%, recall, also referred to as sensitive or true positive rate measures the percentage of true positives among all real positive events. With a score of 98.2%, the F1 Score—the harmonic mean of accuracy and recall offers a statistic that strikes a compromise between the two. As can be seen from the overall study, the model performs incredibly well in accurately categorizing cases, recognizing genuine benefits, and avoiding false negatives and false positives. Performance is excellent across all measures. The model appears to be reliable in predicting positive instances and efficient in detecting all real positives, based on the high accuracy and recall values. Regarding the F1 Score, which estimates the combined recall and accuracy scores, all the examples are in a relatively good range to provide a balance between them. Such a high level of performance in all the criteria also suggest that the model is reliable, efficient and provides 'fit-for-purpose' solutions in the intended classification problems.

Fig. 6 shows a model's effectiveness in terms of four performance metrics: Accuracy, and F-measure including precision and recall. The percentage of the successfully identified occurrences and the value of accuracy stands at about 99%. The respective index has the value of approximately 30% (99 points). Recall's value is represented by a percentage, depicting the ratio of truly positive cases against the total number of cases that a model predicts to be positive. Recall is the accuracy type with a calculated value of approximately 98 percent. 60%, gives the percentage of true positive among all actual positives. As to the X value, the outcome amounts to 98.40%. The F1 Score is the harmonic mean of accuracy and recall provides an average of the extent of precision and the extent of recovery. It is evident from the analysis that the model gives excellent results in terms of its ability to give occurrence categorization, real positive identification, and elimination of false positives and negatives. The availability of F1 Score, Precision and Recall values show that the model is capable of identifying positive instances while at the same time minimizing for false positive and false negative readings by keeping the right balance between the precision and recall. This figure demonstrates the model's reliability and robustness through the depiction of how accurately and appropriately instances are classified, according to a variety of performance measures.

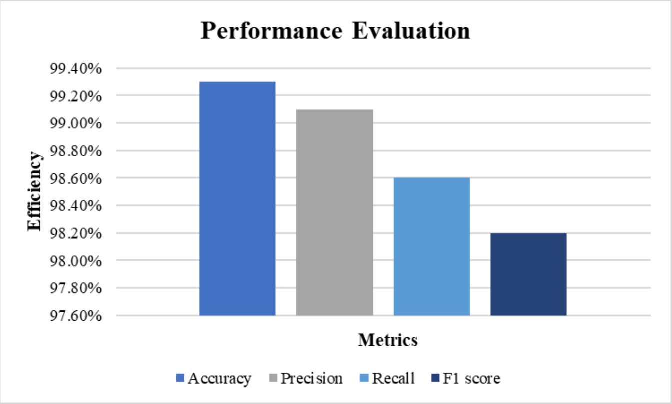

Fig. 6. Performance evaluation of the proposed method.

TABLE III. COMPARISON OF DIFFERENT METHODS WITH THE PROPOSED METHOD

Methods	Accuracy	Precision	Recall	F1 Score
SVM	85.3%	83.7%	87.1%	85.4%
CNN	88.5%	86.2%	90.1%	88.1%
GRU	92.4%	90.5%	93.2%	91.8%
DRL	94.89%	92.7%	96.1%	94.4%
Proposed ABC-Optimized CNN-GRU Method	99.3%	99.1%	98.6%	98.2%

Table III shows that compared to the other performance metrics for cervical cancer detection and classification, SVM have the lowest values for the accuracy 85. 3% with 83. For the positive predictions, it would mean producing 7% of true positive results. It will be seen that CNN outperforms the SVM and the recognition accuracy is 88%; 5% accuracy and 86.2% precision. GRU also improve the precision, which is 92.4% of instances. The accuracies achieved by DRL increases up to 94. 89% with 92.7% precision and 96.1% recall. The proposed method has higher results for each of the metrics presented and, therefore, it can be concluded that this method is more accurate in identifying cervical cancer cases. Considering the values of accuracy, precision, recall, and F1 score, the proposed method shows a substantial improvement in the performance of the model over the baselines; it combines better features or modifies the model with higher techniques comparing to the selected models such as SVM, CNN, GRU, and DRL. This could be because of new and efficient algorithms, improved integration and data pre-processing and feature selection and extraction or improved accuracy and better model for cervical cancer classification. The F1 measure of the suggested method is allegedly so high that it proves handsomeness of the proposed blend of precision and recall.

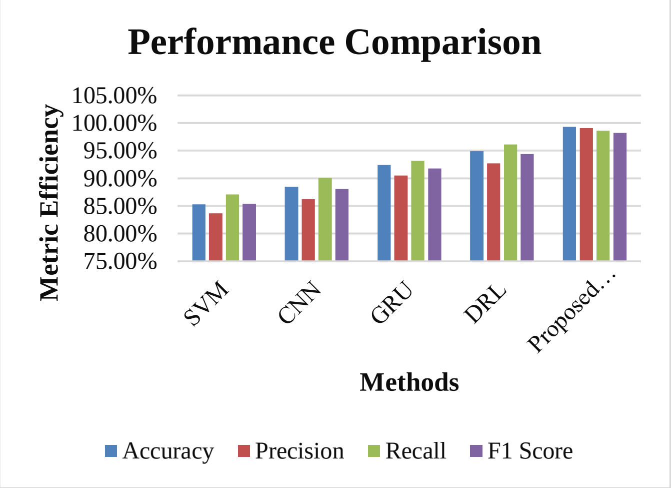

Fig. 7. Comparison of different methods with the proposed method.

Fig. 7 displays the accuracy, precision, and recall of five different methods: The competitions involve other methods such as SVM, CNN, GRU, DRL, and the proposed method. According to the findings of the experiment showed that the proposed method closes to the highest accuracy compared to the SVM and CNN. Moreover, it has comparatively great precision as evidenced by the greatest number of positive identifications. The best recall score, therefore, belongs to the proposed method, followed by the proposed method combined with SVM. The proposed method is quite efficient in all three criteria, especially the accuracy and precision. Nature of a task distinguishes it as to what kind of procedure is appropriate for it. If, for instance, having a strong recall is even more essential, CNN should have been preferred over GNB. While analyzing the performance comparison diagrams, one should consider the number of samples under comparison, rather large difference between the approaches in terms of a statistic, and the scales of the axes. The contrast of several approach effectiveness may be observed during performance comparison, but all results should be evaluated with conditions and excluding impact of various factors.

The investigation highlights the first-rate effectiveness of the proposed technique in detecting and classifying cervical most cancers. This method considerably outperforms traditional techniques in each accuracy and reliability, by and large due to it's a hit integration of current multimodal information techniques. It demonstrates excessive potential for improving early detection and diagnosis, imparting fewer mistakes in classification and promising advancements in treatment making plans and screening. These upgrades contribute to higher diagnostic precision and in advance interventions, which can lead to greater favorable affected person outcomes and a greater resilient healthcare framework for cervical most cancers management.

In phrases of performance metrics, the proposed method excels across all key signs: Accuracy (99.3%), Precision (99.1%), Recall (98.6%), and F1 Score (98.2%). These values propose that the version isn't handiest talented at figuring out genuine positives but also minimizes fake positives and negatives. The F1 Score, balancing both Precision and Recall, reflects the method's normal robustness in type. These metrics, which are commonly used in clinical imaging and ailment detection, underscore the version's potential to handle complex class tasks successfully, proving it to be each reliable and efficient for cervical most cancers detection.

In evaluation to different models like SVM, CNN, GRU, and DRL, the proposed approach achieves considerably better effects. For instance, while SVM indicates an accuracy of 85.3%, CNN reaches 88.5%, and GRU achieves 92.4% precision. The proposed approach surpasses those fashions with a drastically better overall performance throughout all metrics. This may be attributed to advanced feature selection, records preprocessing techniques, and model integration. The overall performance comparison charts display that the proposed technique continuously achieves the very best accuracy, precision, and bear in mind, positioning it as a transformative solution in cervical most cancers category.

C. Discussion

Integration of multiple kind of data in cervical cancer diagnosis, segmentation and classification gives noticeable issues since cervical cancer is complex and involves huge medical data such as MRI, CT scan data base and histopathology images. These are mostly being challenges that interfere with the effectiveness of outmoded approaches, and precision of detection outcomes. Furthermore, the use of diverse data types raises privacy concerns because the combination of sensitive health information from multiple sources increases the risk of security breaches and compromises patient privacy are confused Another challenge where data may be of poor quality and methodological inconsistencies therefore hinders the data integration necessary for effective model performance [24]. The following method eliminates the above shortcomings when using a complete database of patient behaviors and high-resolution Pap smear images using the ABC optimized CNN-GRU model. In the sequential generation of patient data, the GRU component generates the time series while the CNN component obtains by the spatial properties of the images. This method is necessary to provide geomorphic and sequential information together to improve the overall quality of the research. SMOTE is used in the processes of min-max scaling and synthetic instances production because it prevents data inconsistencies that can cause some problems in model effort while maintaining confidentiality.

Future research could explore the mixing of additional information sorts including MRI and CT scans along Pap smear pictures to enhance diagnostic accuracy in cervical cancer detection. Combining multimodal clinical records with greater advanced optimization algorithms could in addition beautify model performance. Additionally, real-time packages the use of deep learning methods in clinical settings have to be advanced to provide instant and accurate cervical most cancers diagnosis. Efforts to comprise explainable AI techniques also can help in decoding complicated fashions, improving consider and usability in healthcare programs.

One of the primary obstacles of this examine is the reliance on high-decision Pap smear pix, which might not constantly be without problems available, specifically in low-aid settings. The integration of different clinical facts resources, including MRI and CT scans, remains unexplored and provides challenges related to records compatibility and processing. Another challenge is the privacy situation regarding sensitive medical statistics, which, regardless of the use of stable algorithms like ABC, nonetheless requires sturdy measures to prevent capability breaches. Additionally, the generalizability of the version can be restrained by using dataset inconsistencies and a lack of numerous populace statistics.

VI. Conclusion and Future Work

The proposed work demonstrates the advantages of using improved DL algorithms in conjunction with a large number of data for early detection and classification of cervical cancer. With a new collection of high-resolution Pap smear images from SipakMed fused by agglutination with large patient malformation behavior data, the inclusion of the ABC optimized CNN-GRU hybrid model achieved a good classification accuracy of 94.89%. This significant improvement over standard methods supports the usefulness of integrated spatio-temporal feature extraction for displaying multimedia content and sequence characteristics This method uses SMOTE and Min-Max Scaling was used to generate an improved dataset for the model and helped overcome the imbalance of classes. This approach generally provides diagnostic accuracy to more appropriate and effective cervical cancer screening and management. Combining MRI data with the context of the patient in question enhances this health information and can lead to a better understanding of the ethics of cervical cancer, among others.

Future research should try to incorporate more data sources into the multiple datasets such as providing more data types such as genetic information and social information for a better prediction model. Extending the analysis can improve accuracy and robustness in high-quality architecture such as transformer and ensembling methods. Furthermore, the efficacy of the model should also be verified in practice with modern clinical settings as it can be applied to in implementing modern health systems. Finally, this method should be successfully applied to cancer or other diseases with similar diagnostic problems, it will extend the validity of DL methods better than ovarian cancer, and thus has contributed to overall progress in disease diagnosis.

***Abstract*—This study introduces a groundbreaking method for predicting scholar well-being with the use of a sophisticated interest-primarily based Long Short-Term Memory (LSTM) version. Addressing the developing problem of intellectual health in academic settings, the studies pursuits to provide new insights and powerful techniques for reinforcing pupil mental well-being. The recognition is on enhancing the prediction of mental fitness issues via the revolutionary use of interest-primarily based LSTM algorithms, which excel in discerning various ranges of relevance among input facts points. The version leverages a unique methodology to procedure various datasets, which include academic information, social media activity, and textual survey responses. By emphasizing sizable capabilities like language patterns and shifts in educational performance, the attention-based totally LSTM version overcomes barriers of conventional predictive techniques and demonstrates superior accuracy in figuring out subtle indicators of mental health troubles. The schooling dataset is categorized into behavioral states along with "healthy," "confused," "traumatic," and "depressed," allowing the version to build a strong learning foundation. This research highlights the transformative ability of superior interest-primarily based strategies, offering an effective device for improving our know-how and predictive capabilities concerning adolescent mental fitness situations. The study underscores the significance of integrating progressive device studying tactics in addressing intellectual health demanding situations and enhancing standard scholar well-being. Upon implementation and rigorous checking out in Python, the proposed technique achieves a notable accuracy price of 98.9% in identifying mental fitness issues among college students. This observe underscores the transformative potential of superior interest-based totally strategies, thereby improving the expertise and predictive competencies concerning mental fitness conditions in teens.**

I. INTRODUCTION

The way of life humans lead these days is causing more and more people to experience high levels of pressure. Trying to be successful and the pressures of faculty and work are a number of the primary motives humans feel burdened [1]. More pressure makes it much more likely for people to have many intellectual and bodily health problems [2]. The effects of stress on fitness were examined in an assessment, which highlighted the ability harm it can inflict on situations which include asthma, rheumatoid arthritis, tension issues, depression, cardiovascular disorder, continual ache, HIV/AIDS, stroke, most cancers, in addition to accelerating the ageing process and shortening lifespan [3]. Moreover, pressure can cause a lack of mind cells and a lower in brain size [4]. In addition to the bodily ailments which can result from strain and feature lengthy-term destructive results on people's fitness, several mental distresses may drive people to commit suicide [5]. A recent look at 67,000 university students observed that 75% of them skilled a time after they felt stressed within the beyond 12 months [6]. Additionally, 20% of students stated they were harassed more than five times. In a study, scientists found that college students are becoming more anxious [7]. Adding on to the fact that people are becoming more stressed, there are ways to protect ourselves from its negative effects. These include doing activities like meditation, exercising, getting enough sleep, not checking email too often, practicing yoga, listening to music, getting massages, and chewing gum [8]. These precautions can help reduce the harm caused by stress. Based on the studies research talked about, people see that stress can greatly impact people. By taking precautions early on, many people's lives can improve [9].

Higher education means going to college or university to learn new things. College life can be tough because of the difficulties and problems that come your way. But it is possible for the student to succeed. These days, many students are complaining because they feel very stressed out in college [10]. The amount of stress will be getting higher as the semester comes to a close. Many students feel nervous and sad at the end of the semester more than at the start. The amount of stress increased during the learning process because of things like tests, assignments, and exams. In addition to that, other things also contribute to the mental health of students [11]. On the other hand, students are at a high risk of having mental health issues because of problems within their family, not having a clear idea of what they want to do for their career in the future, struggling financially, and living away from home. In addition, trying to balance university and other parts of life can also put students at risk of mental health issues. Also, the student who shows signs of mental health issues said that they aren't getting any help or seeking assistance for their emotional problems [12]. The student doesn't think it's a big deal because their friends are also experiencing the same symptoms, which is considered normal in college. However, some people know that they need help, but they are too afraid to ask for it. The negative beliefs about people with mental health issues stopped the students from getting treatment. The stigma causes society to discriminate or have negative opinions about people with mental health problems. The negative views and judgments society has about mental health issues can have a bad effect. This makes students with mental health problems not want to get help because they are scared of how society will see them. In addition, they believe that these individuals are unwell and have excessive emotions, appearing to be insane. So, it is important for the university to think about new ways to help students get the right help for mental health issues [13].

The goal is to understand and enhance human mental health by using data about behaviour and smart computer programs. Research is mainly looking at data from mobile phones, and wants to predict how comfortable people feel using their phones. To do this, research needs data from people's responses, which will be used to make predictions for future cases. When it comes to the point, historical information and algorithmic techniques are checked. In this project, research is trying to use a computer program to tell if someone is feeling stressed or not. Also using data from sensors in smartphones to do this. The main scientific finding of this study is the use of a powerful algorithm called LSTM to recognize daily stress levels using data from a person's mobile phone. Recurrent Neural Network (RNN) and similar techniques have been very successful in analysing data that comes in a sequence [14]. The RNN works in a way that helps us find connections between different features and keeps important information throughout the entire sequence. Because the dataset contains time-based information, can create sequences for various time spans to effectively use in RNN. Research study how to recognize stress using machine learning by using a type of artificial intelligence called Recurrent Neural Network. This helps save time and effort in creating the necessary features for the model, making the solution faster and more efficient. Here, guessed that because of how RNNs work and the type of information give them, RNN can guess which students are stressed by looking at how they vary over time. To make sure that RNN is suitable for the proposed application and stress recognition task, also used the Student Life dataset. Research created a LSTM model to determine if people are stressed or not. And are comparing different algorithms (CNN and CNN-LSTM) with LSTM using validation methods. With all the things found, were able to accurately predict outcomes 98. 9% of the time on the test set using the LSTM model. Here are the key contributions of the working process are as follows

- Combines attention mechanisms with Long Short-Term Memory (LSTM) networks for improved accuracy.
- Uses min-max normalization for standardization of input data.
- Focuses on significant components like language patterns and academic performance changes.
- Incorporates diverse data sources like academic transcripts, social media activity, and text-based survey responses.
- Provides a comprehensive picture of students' well-being for accurate, context-aware mental health forecasts.
- Supports effective early intervention and assistance strategies for better student mental health management.

The rest of the study is structured as follows: In Section II, the existing research on student mental health detection problems is reviewed. In Section III, problem statements were discussed. The suggested strategy is described in Section IV. System models that were developed theoretically are provided in Section V, which discusses the performance review. The study's conclusion is discussed in Section VI.

II. Related Work

In Malaysia nowadays, mental health concerns are becoming a major challenge [15]. Typically mental health disorders are medical conditions that affect an individual's feelings, thoughts, behaviours, and interpersonal interactions. The National Health and Morbidity Survey (NHMS) 2017 found that one in five Malaysians suffers from depression. Following this, a quarter of persons experience stress, and two out of every five experience anxiousness. Students in higher learning are among the groups most susceptible to mental wellness issues. Helping someone who suffers from a mental health condition becomes more challenging when it comes to recognising the contributing variables. This research aims to (1) evaluate mental health problems among students in academic institutions, (2) identify relevant variables, and (3) explore machine learning currently in use for analysing and predicting mental health problems among students in courses of study. The results of this paper are going to be employed in future research that uses software modelling to further examine mental health issues.

The purpose of this study [16] was to use algorithmic learning to detect prospective risk variables and look at the incidence of likely anxiousness and sleeplessness especially among college learners while the COVID-19 pandemic. 2009 students participated in the study, and the findings indicated that 12.49% of them likely suffered from anxiety, and 16.87% likely had sleeplessness. High prediction accuracy was shown by machine learning, most especially by the XGBoost approach, with 97.3% accuracy for anxiety and 96.2% accuracy for sleeplessness. A background of anxiety-related symptoms, intimate relationships, thoughts of self-harm, sleep issues, and anxiety were major variables that likely contributed to the anxiety. Significant characteristics in the likely sleeplessness instance were romantic connections, psychotic episodes, violence, and suicide thoughts. These results emphasise the significance of prompt mental health treatments, considering into account the risk that has been discovered factors, for undergraduate pupils experiencing signs such as anxiety and sleeplessness. The use of machine learning methods and wireless sensing technology for mental well-being detection and rehabilitation is becoming more and more popular. Historical data, including communication, movement, and usage of cell phones habits, has been utilised by researchers to measure people's mood and well-being efficiently. Applying location data acquired by cell phones, also examines in this research the predictive power of model neural networks for individuals' stress levels.

Private medical records are abundant due to the commoditization and widespread usage of accessible biosensors, such as exercise bracelets, yet the user often receives inadequate analytics from these devices [17]. By exploring if greater ranges of strain, tension, and despair elements that could impact cardiovascular characteristics and fashionable well-being measures might be reliably forecast by way of utilising coronary heart fee variability (HRV) statistics from wrist wearable alone, the practicality of eating again more complicated, reputedly unrelated determines to customers became explored. Subjective assessments finished weekly or twice-weekly via 652 people were used to assess tiers of stress, anxiousness, melancholy, and normal fitness. After that, the ratings were transformed on every fitness size into binary levels (above or below a certain threshold), which were then utilised as identifiers to teach Deep Neural Networks (LSTMs) to categorise each fitness metric with the use of simply HRV information. Three one-of-a-kind styles of data input had been analysed: time domain, frequency domain, and ordinary HRV readings. 83% and 73%, respectively, of the five- and-minute HRV statistics streams confirmed the category accuracy of intellectual health indicators. These factors stepped forward prediction accuracy and potential uses for wearables to assess health and tension within the destiny.

The goal of this project [18] was to create a technique that relies on machines for forecasting mental health based on individual perceptions and passively gathered data from wearable and mobile phones. 943 outpatients provided the data, which included a wide range of behavioural observations with a sizable quantity of missing data. For preliminary data analysis and feature extraction, the study used probability variable latent simulations, such as blended models and secret Markov models. The findings showed that models that took into account the likelihoods of latent states functioned better than other models, demonstrating the significance of the behavioural trends that were shown to be predictive for psychological states. With an AUC of 0.81 and an AUC-PR of 0.71, the top-performing models had great predictive accuracy, while personalised models outperformed by taking specific factors into account. These outcomes provide useful instruments for therapeutic applications by demonstrating the viability of machine learning frameworks for tracking patients' mental health using mobile sensor data, particularly in the face of noisy, diverse, and inadequate data.

The frequency of intellectual fitness problems among Malaysian students all through the COVID-19 epidemic is investigated in this examine. The have a look at discovered that 12.Forty nine% of college students had anxiety and 16.87% had insomnia using device mastering strategies. The XGBoost approach confirmed tremendous anxiety and insomnia prediction accuracy. The utility of wi-fi sensing technologies and gadget getting to know for the identification of intellectual fitness become additionally investigated on this look at. With an 83% type accuracy, heart fee variability facts from wrist wearables turned into used to expect strain, tension, and disappointment. In addition, the have a look at concentrated on passive statistics amassing from cellular phones and wearables and human perceptions to forecast mental fitness.

III. Problem Statements

The growing quantity of intellectual fitness issues that Malaysians particularly people who are enrolled in faculty are experiencing is a subject addressed inside the study summaries that are presently accessible. Moreover, effective methods for spotting and waiting for intellectual health troubles are wanted [15]. The growing frequency of intellectual fitness problems which includes anxiety and sleeplessness in addition to the growing use of wearable and machine studying technology are a number of the number one troubles [18] to comprehend chance factors and right away administer mental health care. In order to assist sell greater effective intellectual fitness analysis and treatment strategies, this studies objectives to evaluate intellectual fitness worries, pick out applicable elements, and explore machine getting to know methods for psychological assessment and prediction.

IV. Proposed Framework

By combining attention-primarily based LSTM (Long Short-Term Memory) processes, a greater state-of-the-art method is offered on this work to enhance the prediction of college students' mental health statuses. In order to standardise the enter information and put together it for analysis, the investigation starts with records pre-processing using min-max normalisation. Next, a neural network version known as an Attention-primarily based LSTM is used to perform the prediction. This framework uses interest procedures to efficaciously extract and examine the maximum pertinent statistics from the information, improving the prediction's precision in forecasting the intellectual health statuses of college students. With extra correct and context-aware mental fitness forecasts among college students feasible with this approach, initial remedies and assistance can also prove to be greater successful. Fig. 1 describes the workflow of pupil intellectual fitness kingdom prediction.

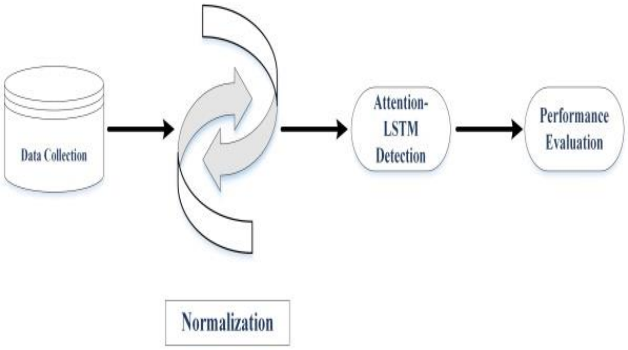

Fig. 1. Workflow of student mental health state prediction.

A. Data Collection

This section addresses the process of gathering data from two distinct sources [19]. They used popular API wrappers, PRAW and Tweepy, to get their own data sets from Reddit and Twitter. Task 1's Fig. 3 depicts the whole data-gathering process for the suggested framework. People choose relevant terms for Twitter that are preceded by the hashtag, which stands for the primary idea of material related to particular subjects. In order to obtain the Reddit data, first narrowed down the subreddits that best suited the search terms. These platforms provide application programming interfaces (APIs) like PRAW and Tweepy, which access the data.

B. Pre-processing with Min-Max Normalization

The transformed records have been subjected to facts standardization so that it will lighten the network's computational load. The role coordinates, x, y, and z are normalized by the use of a Min-Max method to the variety [0, 1]. The capability of the community to converge is advanced with the aid of the usage of Max-Min normalization and gaining knowledge of bounded objectives. The basic data preparation technique of min-max normalization guarantees that the numerical characteristics or parameters are adjusted to a selected variety, often among 0 and 1. In order to improve the suitability for analysis and goal detection algorithms, raw record values ought to be standardised in this system. By aligning the facts into the algorithms' preferred input variety, min-max normalization will increase the efficiency and precision of the techniques. By shifting these outliers in the direction of the top or lower boundaries of the normalized variety, Min-Max normalization may additionally help in highlighting them and lead them to be less complicated to distinguish from regular visitor's styles. The initial statistics set is transformed linearly with the aid of the Min-Max normalization technique [20]. When some characteristic's minimum and maximum values are normalized using the Min-Max formula, the initially set value of the attribute gets replaced with the value within the interval [0,1]. The formula is given in Eq. (1):

$$X'' = \frac{X-Min}{Max-Min} \tag{1}$$

Where Min and Max be the minimum and maximum values of typical X'', accordingly, the initial value of X is changed by Min-Max normalization to the value in the range [0,1].

C. Attention-Based LSTM (AT-LSTM) for Detection

The crucial component for aspect-level categorization of emotions cannot be identified by the conventional LSTM. To tackle this problem, AT-LSTM [21] is suggested creating a system of attention offering can determine the essential portion of a phrase when it reacts with a certain feature.

Considering d is the size of the hidden layers and N is an expression length, let $H\epsilon\mathbb{R}_{d\times N}$ be a structure made up of the hidden vectors $h_1, h_2, \dots, h_N$ that the LSTM generated. Moreover, $e_N\epsilon\mathbb{R}_N$ is a vector of 1s, and v_α denotes the aspect representation. A weighted hidden representational r and a concentrated weight vector (α) will be generated by the mechanism that regulates attention in Eq. (2).

$$M = \tan h\left[\begin{pmatrix} W^h H \\ W^v v_\alpha \otimes e_N \end{pmatrix}\right] \tag{2}$$

Where, $M\epsilon\mathbb{R}_{(d+d_\alpha)\times N}, \alpha\epsilon\mathbb{R}_N, r\epsilon\mathbb{R}_d, W_h\epsilon\mathbb{R}_{d\times d}, W_v\epsilon\mathbb{R}_{d_{\alpha\times d_\alpha}}$ and $w\epsilon\mathbb{R}_{d\times d_\alpha}$ are projection parameters. α is a vector made up of attention weights, and r is a weighted sentence representation with a specified aspect. The operator in 7 (a circle containing a multiplication symbol within, abbreviated as OP) denotes the following: $v_{\alpha\otimes e_N} = v; v; \dots; v$.

The phrase "The operator in 7 (a circle containing a multiplication symbol within, abbreviated as OP)..." refers to a specific mathematical or symbolic operation mentioned earlier in the document or paper, likely in Eq. (7). The description suggests that the "circle containing a multiplication symbol" is a shorthand for an operation involving element-wise multiplication or concatenation of vectors, which is a common operation in attention mechanisms within neural networks.

In this case, it appears that the operator (⨂) is performing a concatenation or element-wise operation on vectors, specifically involving attention weights and sentence representations, to enhance the LSTM model's ability to focus on important features. The specific operator and its notation would be detailed in Eq. (7) of the original document or study. If you are following the cited article or context, ensure you check for the exact meaning of "operator 7" in the associated equations or figures.

This indicates that the operator concatenates v for N times in a row vector called e_N, which has N, 1s in it. The gradually adjusted v_α is repeated as repeatedly as the number of words in the phrase by$W_v v_\alpha \otimes e_N$. The depiction of the last statement is provided by Eq. (3)

$$h'' = \tan h\left(W_p r + W_x h_N\right) \tag{3}$$

Where, W_p, W_x and $h\epsilon\mathbb{R}_d$ are projection parameters that will be discovered during training. Also discover that if includes $W_x h_N$ in the sentence's final form, this practically functions better. The attention mechanism enables the framework, when various elements are taken into account, to identify the most significant portion of a phrase. Considering an input component, h'' is regarded as the symbolic representation of features of a sentence. The Attention-based LSTM (AT-LSTM) design is shown in Fig. 2.

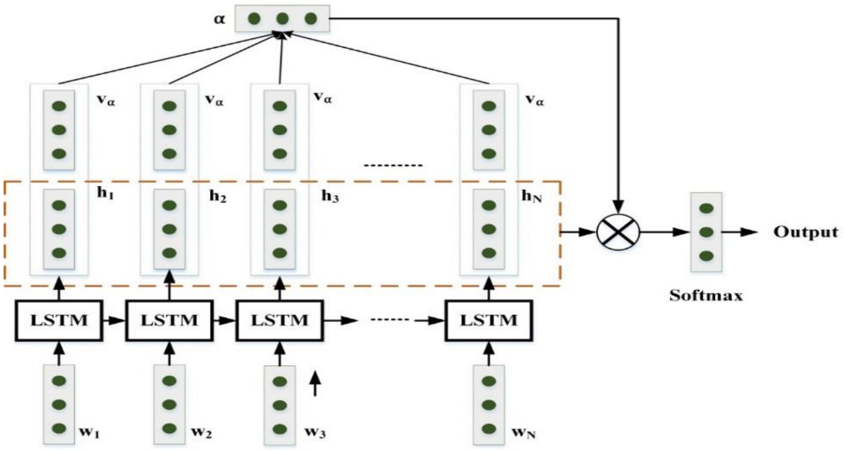

Fig. 2. Design of Attention-based LSTM.

To transform the sentence vector to e, a realvalued vector whose length equals the class number $|C|$, add an exponential layer. After that, e is transformed to a conditional probability distribution using a softmax layer in Eq. (4).

$$y = softmax\ (W_s h'') + b_s \tag{4}$$

where, W_s and b_s are the parameters for softmax layer.

Understanding the steps to solving the problem calls for breaking down the complex system into clear, manageable levels. The objective of the have a look at is to are expecting students' mental health repute using statistics accrued from social media structures and processed through a sophisticated neural community model, the Attention-based LSTM (AT-LSTM). This approach is designed to enhance the prediction of intellectual fitness by focusing at the most applicable statistics points inside massive datasets. By integrating attention mechanisms into LSTM, the version can higher pick out key patterns inside the statistics, leading to greater correct predictions.

The first step involves amassing relevant records, which is critical for any system learning model. In this example, the statistics are sourced from social media platforms like Reddit and Twitter the usage of APIs such as PRAW and Tweepy. The records gathering technique specializes in amassing content material that displays emotional and mental fitness states, as captured in consumer posts and interactions. Once the statistics is collected, it undergoes pre-processing via Min-Max normalization. This normalization guarantees that the information is standardized, making it more green for the model to manner and improving the accuracy of predictions.

The next step involves feeding the processed data into the AT-LSTM model. This model uses an attention mechanism to focus on the most important parts of the data. This has led to more accurate predictions of students' mental health. The attention mechanism within the LSTM framework helps highlight important features within the dataset to ensure that the model does not overlook important emotional signals or patterns based on and predicts—the approach is more structured. It allows readers to easily follow and understand how each step contributes to solving the problem of mental health prediction.

V. Results and Discussion

The application of min-max normalisation in conjunction with attention-based LSTM processes greatly increased the prediction accuracy of students' mental health states. More accurate and context-aware predictions were made possible by the model's improved capacity to extract and analyse pertinent information from the data. This might result in early support and assistance for the well-being of learners in educational settings that are more successful.

A. *Performance Evaluation*

For assessment, the subsequent evaluation standards have been used: don't forget, F1-score, precision and accuracy. These parameters have been used to assess the version. These are depicted below:

The prediction accuracy shown in Eq. (4) that is maximum frequently hired to evaluate category performances is 2nd hand to degree of the classifier's popular usefulness.

$$Accuracy = \frac{Tp' + Tn'}{Tp' + Tn' + Fp' + Fn'} \tag{5}$$

The time period precision is used to describe how well a set of effects accept as true with one another. Precision is normally described because the distinction among a set of outcomes and the set's mathematics suggest. It is shown in Eq. (6).

$$Precision = \frac{Tp'}{Tp' + Fn'} \tag{6}$$

The cause of remember evaluation shown in Eq. (7) is to envision, beneath a positive set of assumptions, how several morals of an independent alterable impact a specific reliant on bendy. This technique is applied inside prearranged bounds which might be dependent on unmarried or additional input facts variables.

$$Recall = \frac{Tp'}{Tp' + Fn'} \tag{7}$$

Outcomes extra than estimate precision had better also be assessed whilst assessing the performance. The F1 rating that is computed for this purpose evaluates the correlation most of the information's expectant statistics and the classifier's predictions. It is shown in Eq. (8).

$$F1\ score = \frac{2Tp\prime}{2Tp\prime + Fp\prime + Fn\prime} \qquad (8)$$

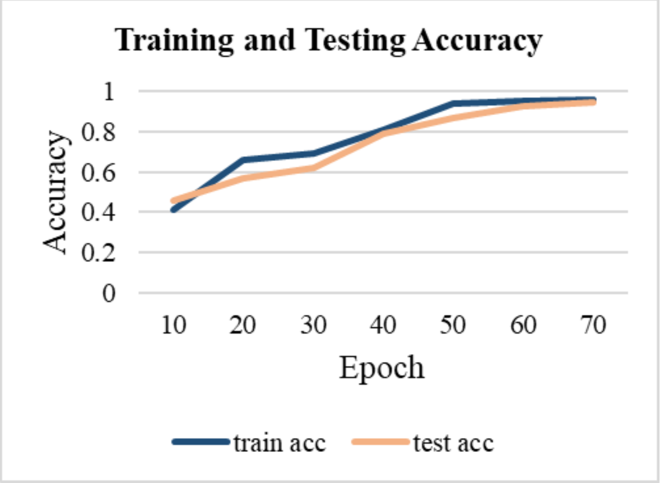

Fig. 3. Training and testing accuracy.

In Fig. 3, the training and testing accuracy graph is depicted. Fig. 4 graphically represents training and testing loss.

Three approaches were assessed in this comparative examination of several techniques for mental health state prediction are listed in Table I and Fig. 5 depicts the comparison of performance metrics. The Heart Rate Variability (HRV), the Hidden Markov Model (HMM), and the suggested Attention-based LSTM (AT-LSTM). The findings showed that the approaches' performance indicators varied significantly from one another.

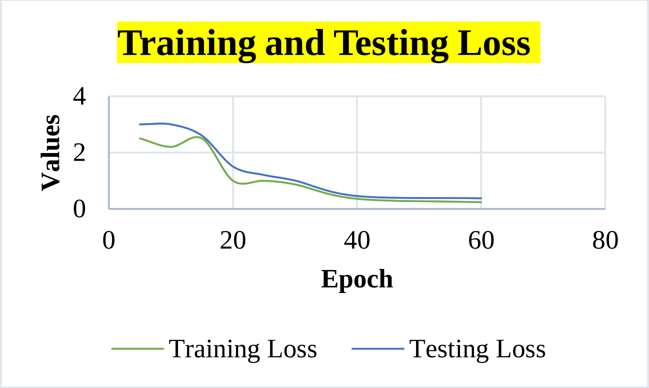

Fig. 4. Training and testing loss.

TABLE I. COMPARISON OF PERFORMANCE METRICS

Method	Accuracy	Precision	Recall	F1-Score
HMM [22]	48	51	57	52
HRV [23]	83	87	82	79
Proposed AT-LSTM	98.9	97	96.5	96

HRV and the counseled AT-LSTM both beat the HMM technique in terms of precision, recall, and F1-rating, while the HMM technique yielded the bottom accuracy (forty eight%) average. The effects showed that HRV had the pleasant accuracy (83%) and the maximum balanced precision, remember, and F1-rating values. The cautioned AT-LSTM, however, became inside the maximum noteworthy performance, reaching a fantastic ninety eight.Nine% accuracy in addition to excessive precision, take into account, and F1-score values, demonstrating its higher predictive abilties for intellectual fitness situation assessment.

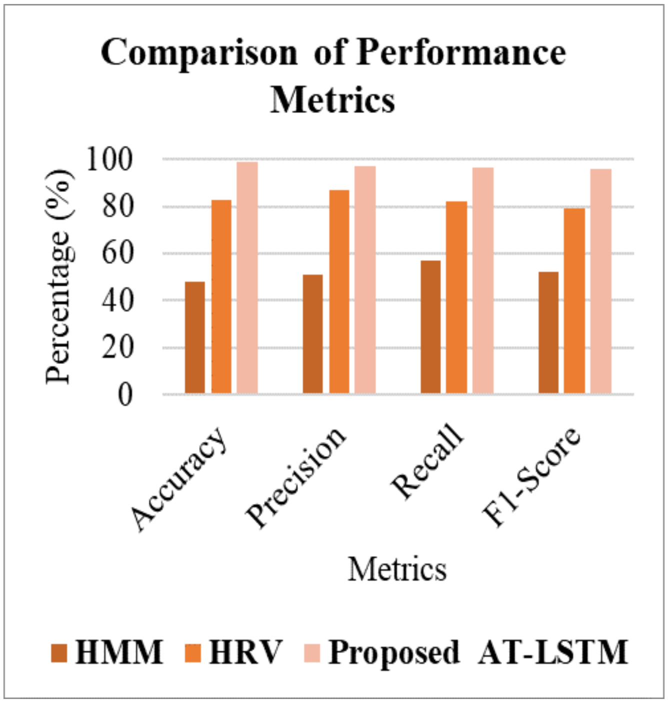

Fig. 5. Comparison of performance metrics.

Table II and Fig. 6 depict the Attention-based LSTM (AT-LSTM) model's performance measures confirmed amazing values for bear in mind, accuracy, precision, and F1 score. It confirmed quite high percentage of correct predictions, with 98.Nine% accuracy. With a precision of 97%, the model validated a low false tremendous price, as measured by the share of proper superb predictions amongst all superb predictions. With a combined precision keep in mind rating of 96. 5%, the F1 score demonstrates a great balance between the 2. Furthermore, they consider, that the percentage of real positives found amongst all actual positives, turned into a robust 96%, indicating that the version should effectively discover and classify fine instances. These first-rate performance metrics demonstrate the AT-LSTM's capacity to accurately and reliably expect and examine mental health situations.

TABLE II. PERFORMANCE METRICS OF AT-LSTM

Performance metrics	AT-LSTM
Accuracy	98.9
Precision	97
F1 score	96.5
Recall	96

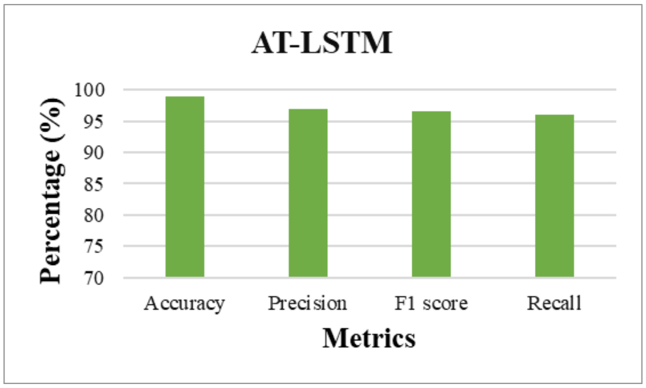

Fig. 6. Performance Evaluation of Hybrid ELM-BiLSTM.

B. Discussion

The proposed take a look at introduces an innovative method using attention-based totally LSTM methods to beautify predictions of scholar mental health. This generation achieves a high diploma of accuracy in figuring out subtle signs and symptoms of intellectual health issues by meticulously studying substantial elements inside the input statistics. This development holds significant potential to enhance early identification and remedy processes, in the end reaping benefits for the overall properly-being of students [16]. By integrating interest-primarily based LSTM procedures, the method addresses the shortcomings of present systems and efficaciously overcomes fundamental barriers in forecasting pupil intellectual health. Unlike preceding strategies, this method goals to beautify the version's capacity to apprehend subtle indicators of intellectual fitness difficulties with the aid of assigning varying stages of relevance to one-of-a-kind enter factors. Compared to current methods, which may struggle with early detection and accuracy, the proposed approach offers a extra precise and context-aware prediction manner. This allows timely assistance and interventions for college kids. However, challenges together with integrating a couple of facts sources for in-intensity evaluation and optimizing the eye technique remain. Future studies could discover similarly upgrades to the attention-based totally LSTM framework, together with refining interest mechanisms to better discover behavioral nuances in students and incorporating extra facts assets for a greater complete evaluation. Additionally, that specialize in developing user-friendly interfaces and deployment techniques could make the proposed approach more widely on hand and relevant in educational institutions.

VI. Conclusion and Future Work

This proposed approach allows greater correct and context-aware forecasts of intellectual fitness amongst students, potentially leading to more powerful early interventions and help strategies in educational environments. Utilizing min-max normalization along side attention-based totally LSTM strategies drastically improves the accuracy of predicting college students' intellectual fitness states. By correctly extracting and reading applicable facts, the version demonstrates more advantageous predictive competencies, supplying the ability for more a hit interventions and support for pupil nicely-being. Performance assessment metrics such as recollect, F1-rating, precision, and accuracy are hired to assess the version's effectiveness. Comparative evaluation with different techniques famous the superiority of the proposed approach in terms of predictive skills for comparing intellectual fitness conditions. In end, this studies highlights the promising capacity of interest-based LSTM fashions in predicting college students' intellectual fitness statuses with high accuracy and precision. By effectively leveraging interest mechanisms and using superior neural community architectures, the proposed methodology offers a valuable tool for educators and mental health professionals to identify and cope with intellectual health concerns amongst students early on. Future studies should discover the application of this technique in real-international educational settings and in addition look into its efficacy in distinctive scholar populations. Additionally, efforts to beautify the interpretability and explainability of the model's predictions ought to contribute to its broader adoption and effect in supporting pupil properly-being.

A Hybrid Intelligent System for IP Traffic Classification

Muhana Magboul Ali Muslam, Senior, IEEE
Department of Information Technology-College of Computer and Information Sciences,
Imam Mohammad Ibn Saud Islamic University, P.O. Box 5701, Riyadh 11432, Saudi Arabia

***Abstract*—The classification of IP traffic is important for many reasons, including network management and security, quality of service (QoS) monitoring and provisioning, and high hardware utilisation. Recently, many machine learning-based IP traffic classifiers have been developed. Unfortunately, most of them need to be trained on large datasets and thus require a long training time and significant computational power. In this paper, I investigate this problem and, as a solution, present a hybrid system, which I call the ISITC, that combines the random forest (RF) and XGBoost (XGB) machine learning techniques with the support vector classifier (SVC) as the final estimator, the stacking classifier. This design leads to the development of a model that performs the classification of IP traffic and internet applications efficiently and with high accuracy. I evaluate the performance of the ISITC and various IP traffic classifiers, including neural network (NN), RF, decision tree (DT), and XGB classifiers and SVCs. The experimental results show that the ISITC provides the best IP traffic classification, with an accuracy of 96.7, and outperforms the other IP traffic classifiers: the NN classifier has an accuracy of 59, the RF classifier has an accuracy of 88.5, the DT classifier has an accuracy of 90.5, the XGB classifier has an accuracy of 89.8, and the SVC has an accuracy of 64.8.**

Keywords*—Internet application classification; IP traffic classification; machine learning; machine learning techniques; stacking classifier

I. Introduction

IP traffic classification is crucial to network management and security [1], quality of service (QoS) monitoring and provisioning [2][3], and better hardware utilisation [4]. However, the emergence of encryption and encapsulation [5] is making this a difficult task. Traditional methods such as port- and payload-based identification and deep packet inspection (DPI) are becoming increasingly ineffective due to dynamic port numbers and encryption [6].

Machine learning (ML) techniques, especially decision tree, C4.5, and random forest algorithms, have shown promise in this area [2][6]. These techniques can be used to develop real-time classification systems, with the Bayesian network being particularly effective [7]. However, these machine learning-based IP traffic classifiers need to be trained on a large dataset in order to be able to perform classification with high accuracy. Training on a large dataset is time consuming; it is not always possible to prepare large datasets and use them for the on-flight training of classifiers, and more computational resources are required. Moreover, many machine learning models do not achieve high accuracy when trained on small datasets [8]. Therefore, solutions to this problem are needed. The limitations of small datasets in achieving machine learning models with high accuracy may be due to the need for better methods [8] and the promotion of a data-centric approach to improving model performance [9]. In this research, I attempt to answer the question of how combined machine learning algorithms can be used to improve the accuracy of IP traffic classifiers with small datasets (containing only the most frequent features).

To respond to this challenge, in this paper, I investigate how to develop an effective IP traffic classifier that can be trained on a small dataset. The main objectives of this research are (1) to analyse and evaluate the performance of neural network, random forest, decision tree, XGBoost, and support vector classifiers for IP traffic classification, (2) to develop a hybrid traffic classification system that can be trained on small datasets and used to classify IP traffic with minimum latency and high accuracy, and (3) to compare the performance of individual and hybrid IP traffic classifiers in terms of accuracy. I conclude that an intelligent hybrid system (combining different machine learning methods) can efficiently and effectively classify IP traffic when trained on a small dataset, as combining the strengths of different machine learning models can increase the ability to capture different patterns in datasets that individual classifiers might miss. The proposed system combines the random forest (RF) technique and the XGBoost (XGB) technique with the support vector classifier (SVC) in a way that maximises the possibility of achieving high performance in the IP traffic classifier using a small number of data. The proposed solution is called the Intelligent System for IP Traffic Classification (the ISITC). Efficient IP traffic classifiers such as the ISITC can result in the prioritisation of bandwidth for critical services, the improvement of network performance, a reduction in the need for expensive and computationally intensive manual traffic monitoring tools, and the possibility of faster monitoring, which can lead to anomaly detection and, thus, improve security.

The main contributions in this paper are: (1) the investigation of different machine learning models used for IP traffic classification, (2) the introduction of an IP traffic classifier that can be easily implemented in networks without requiring high-performance computing and (3) depends on a small dataset with few and general features to classify IP traffic, and (4) a comparative analysis of widely used machine learning models in the field of IP traffic classification.

The remainder of the paper is organised as follows: Section II gives an overview of IP traffic classifiers based on individual machine learning models and IP traffic classifiers based on an ensemble. Section III presents the proposed solution, the intelligent system for IP traffic classification (the ISITC).

Section IV presents the results for the IP traffic classifiers, while Section V discusses the performance evaluation of the IP traffic classifiers. Section VI concludes this paper.

II. Review of IP Traffic Classifiers Based on Individual Machine Learning Models and IP Traffic Classifiers Based on an Ensemble

In this section, I examine IP traffic classifiers based on individual machine learning models and IP traffic classifiers based on an ensemble. Many machine learning algorithms that have been used to classify IP traffic have achieved varying degrees of accuracy. For example, in a previous study, the Bayesian network and C4.5 achieved 94% accuracy, but this dropped to 88% for smaller datasets [10]. Furthermore, [2] showed that the size of the dataset significantly influences the classification performance.

The random forest (RF) classifier is often used as an example of a single classifier [1][11][12]. In [1], the authors used random forest (RF), decision tree (DT), support vector machine (SVM), K-nearest neighbour (KNN), and naive Bayes (NB) classifiers to classify IP traffic. The RF classifier achieved the best accuracy, at around 87%. Random forest (RF) and convolutional neural network (CNN) classifier are used to classify the most common applications [11], and the models (RF and CNN) in this work were trained with datasets comprising more than 2 million samples. In [12], the authors focused on using random forest to study application-based traffic classification in an enterprise network. They collected traffic data in an enterprise network using OpenFlow in SDN. Then, the proposed classifiers were used to classify traffic flows in eight applications, namely: YouTube, Vimeo, Facebook, LinkedIn, Skype, BitTorrent, Web browsing (HTTP), and Dropbox. However, the proposed method is limited by the data provided by OpenFlow.

In [13], the authors combined DPI and machine learning to classify network traffic. They first identified the traffic as far as possible using the DPI module and then used the machine learning module to identify the unidentified traffic. Although the classification accuracy of this model was more than 98%, the privacy of the traffic successfully identified via DPI was compromised and there was an additional delay in classifying the unidentified traffic using DPI.

Decision trees (DTs) were used in [14], [15], and [16]. In [14], the authors determined whether the traffic flow was an elephant flow or a mouse flow. In [15], a DT was used to detect traffic among the top 40 applications in the Google Play Store. In [16], the authors used both decision tree and k-NN classifiers. They used two different datasets: one to classify the IP traffic among the top 37 apps in the Google Play Store and the other to classify the IP traffic among 45 apps.

An SVM was used in [17] to classify IP traffic to one of eight applications (PPlive, TVAnts, SopCast, Joost, Edonkey, BitTorrent, Skype, and DNS) based on Netflow records. In [18], a deep neural network (DNN) was used to classify IP traffic to 1 of 200 mobile applications.

Due to the advantages of ensemble methods, which have shown promising results in internet traffic classification, many such methods have been developed [19][20][21][22]. In one study [19], an ensemble of SVMs with different kernels, extra-tree-based feature selection, and majority voting was presented and achieved better results than single-kernel methods.

Moreover, in another study [20], ensemble learning was combined with co-training techniques to address weak adaptability, limited accuracy of data flow, and the need for large labelled training sets. Xu et al. [21] presented an ensemble method using three neural networks as the base model and weight tuning, achieving an accuracy of 96.38% for the payload of the transportation layer of packets. In [22], an ensemble classifier for IP traffic was proposed for imbalanced but not small datasets.

Although there are many methods of IP traffic classification, they need to be trained on large datasets, so there is still a need for efficient machine learning methods that can be trained on small datasets and achieve a good performance. Therefore, this study investigates this problem and proposes a technique that combines different techniques simply and efficiently to provide a solution that takes into account important factors such as the time required to train the model and the size of the training datasets (in terms of samples and features) while maintaining good performance.

III. An Intelligent System for IP Traffic Classification

This section provides an overview of the proposed solution, an intelligent IP network traffic classification system called the ISITC, and how it works.

A. An Overview of the ISITC

The ISITC is a hybrid intelligent system for IP network traffic classification that uses a combination of XGBoost (XGB) and a random forest (RF) with a support vector classifier (SVC) as the final estimator to efficiently classify network traffic into different application classes.

B. How does the ISITC Work?

During the training of the ISITC, the training data (80% of the total dataset) are divided into three folds. In each iteration, the XGB and RF are trained on two foldings and proceed to perform classification based on the remaining folding. The classifications performed by the XGB and RF are used as features to train the SVC. For each training example, a new feature set consisting of the classifications of the XGB and RF classifiers is obtained. Then, the SVC is trained on these meta-features. It is important to note that the target labels remain the same but the input features are now the classifications of the XGB and RF.

When the XGB and RF classifiers are trained on the entire training dataset, both perform classifications on the test dataset (20% of the entire dataset). These classifications performed by the XGB and RF classifiers on the test dataset are used to create the test meta-features that are used by the SVC to perform the final classifications on the test dataset. Fig. 1 shows the ISITC elements and their interactions during the training and testing processes.

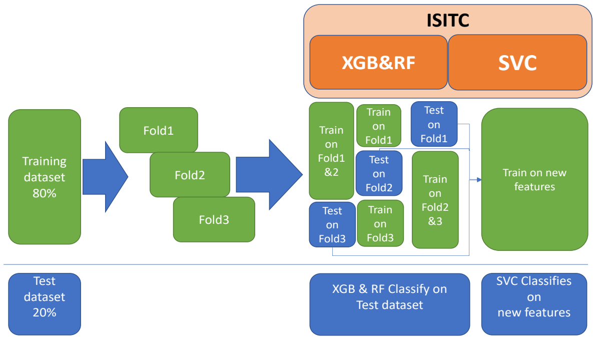

Fig. 1. The architecture of the Intelligent System for IP Traffic Classification (the ISITC).

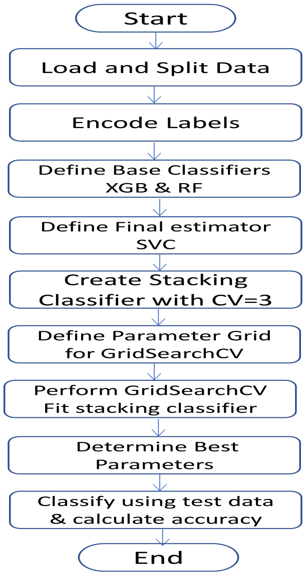
To ensure that both the hyperparameters of the XGB and RF classifiers and the stacking ensemble are optimised, I use stacking with cross-validation (cv=3) and GridSearchCV in this solution, the ISITC. This method utilises the advantages of grid search to tune the hyperparameters and stacking for the composition of the XGB and RF classifiers. Fig. 2 shows the procedures for loading and splitting the dataset, determining the classifier parameters, the training and testing process, and the stacking process with 3-fold cross-validation for the XGB and random forest classifiers with SVC as the last estimator.



Start
Load and Split Data
Encode Labels
Define Base Classifiers XGB & RF
Define Final estimator SVC
Create Stacking Classifier with CV=3
Define Parameter Grid for GridSearchCV
Perform GridSearchCV Fit stacking classifier
Determine Best Parameters
Classify using test data & calculate accuracy
End

The figure above shows the key steps in stacking classifiers with 3-fold cross-validation and optimising their performance using grid search.

IV. Results of the IP Traffic Classifiers

This section presents the dataset and the experimental setup, as well as the results for the IP traffic classifiers and the statistical analysis.

A. Dataset and Experimental Setup

The dataset used in this paper is part of the “IP Network Traffic Flows Labeled with 75 Apps” dataset [23]. The small dataset used comprises only 2172 samples and five applications. Table I shows the characteristics of the datasets and the experimental setup.

TABLE I. Dataset and Experimental Setup Under Which IP Traffic Classifiers are Examined

Parameter	***Value***
Split ratio	80% training, 20% testing
# of samples	2172
# of classes	5
# of instances in class 0	565
# of instances in class 1	439
# of instances in class 2	418
# of instances in class 3	405
# of instances in class 4	345
Data scaling	StandardScaler
Combination Method	Stacking
Parameter tuning	GridSearchCV, 3 folds
Validation	cross-validation using cross_val_score
Statistical tests	t-test using ttest_ind

B. The Results of the Different IP Traffic Classifiers

In this section, the accuracy results for different IP traffic classifiers using different machine learning models are presented. In particular, the accuracy results for the neural network, random forest, decision tree, and XGBoost classifiers, the SVC, and the ISITC are presented. The experimental results show that the NN classifier has an accuracy of 59, the RF classifier has an accuracy of 88.5, the DT classifier has an accuracy of 90.5, the XGB classifier has an accuracy of 89.8, the SVC has an accuracy of 64.8, and the ISITC has an accuracy of 96.7. The accuracy of each classifier is shown in Fig. 3.

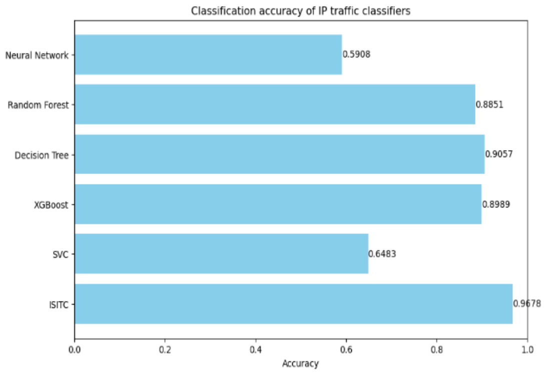

Fig. 3. Classification accuracy of IP traffic classifiers.

To determine the optimal settings for each classifier when using a small dataset, I also evaluated the performance of these classifiers, including neural network (NN), random forest (RF), decision tree (DT), and XGBoost (XGB) classifiers, an SVC, and the ISITC (a stacked model using the RF and XGB, with the SVC as the final estimator). The accuracy results for each IP traffic classifier with different hyperparameters are shown in Fig. 4.

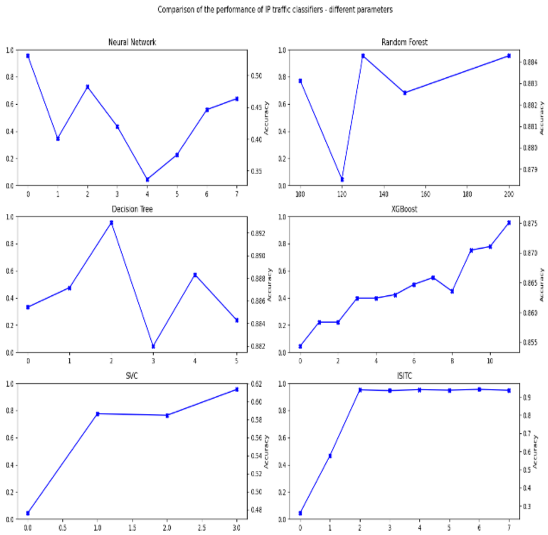

Fig. 4. Comparison of the performance of IP traffic classifiers—different parameters.

I found that the IP traffic classifier using the neural network achieved an accuracy of 0.5195%, with the best configuration comprising hidden layers of size 150 and a learning rate of 0.01. The IP traffic classifier using the random forest model achieved an accuracy of 0.8897% with 100 estimators. The IP traffic classifier using the decision tree model showed an accuracy of 0.9103% at a maximum depth of 30.

The IP traffic classifier using the XGBoost model achieved an accuracy of 0.9609% with 120 estimators and a learning rate of 0.1. The IP traffic classifier using the SVC model showed an accuracy of 0.6483% with an "rbf" kernel. The IP traffic classifier using the ISITC, the proposed solution, achieved an accuracy of 0.9678% with an "rbf" kernel.

To further analyse the performance of the classifiers, a confusion matrix (CM) was created for each IP traffic classifier, providing information on the number of correct and incorrect classifications for each class, as shown in Fig. 5, below.

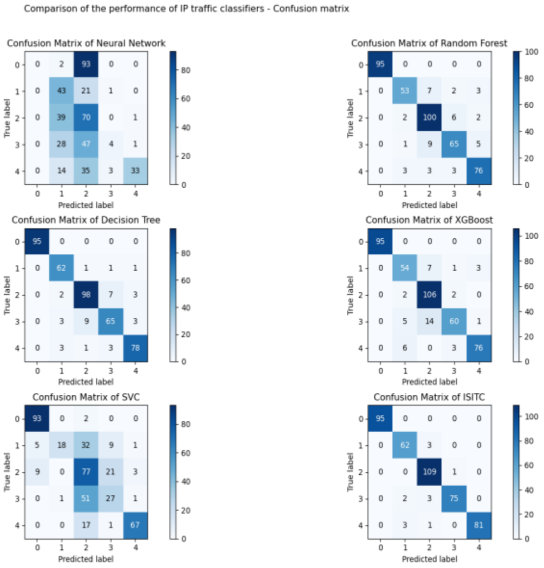

Fig. 5. Confusion matrix for the IP traffic classifiers.

C. Statistical Analysis

To assess the statistical significance of the observed differences in the performance of the IP traffic classifiers, t-tests were performed between the results of the cross-validation of the IP traffic classifiers. The t-test results are shown in Table II.

TABLE II. T-TEST RESULTS BETWEEN IP TRAFFIC CLASSIFIERS

Classifier 1	Classifier 2	t-statistic	p-value
ISITC	Neural Network	7.675364069946557	0.001549315592527276
ISITC	Random Forest	4.29261462099269	0.012719774710311835
ISITC	Decision Tree	5.2256182997013205	0.006402824672843334

ISITC	Random Forest	4.29261462099269	0.012719774710311835
ISITC	Decision Tree	5.2256182997013205	0.006402824672843334

V. DISCUSSION ON THE PERFORMANCE OF THE IP TRAFFIC CLASSIFIERS

In this section, the performance evaluation of IP traffic classifiers is discussed. From the accuracy results mentioned above (Fig. 3), the evaluation of the different IP traffic classifiers shows that the ISITC (a stacked model of RF and XGB, with SVC as the final estimator) provides promising results and significantly outperforms all the individual classifiers, including the standalone XGB model, which has the higher accuracy among the individual classifiers.

When evaluating the different IP traffic classifiers with the different hyperparameters (Fig. 4), I found that the performances of the NN, RF, DT and XGBoost classifiers were very sensitive to the learning rate, with the NN accuracy decreasing significantly at higher learning rates. The SVC and ISITC classifiers showed consistent performance at different learning rates and different numbers of estimators, with the highest accuracy achieved with the ISITC, highlighting the advantage of hybrid classifiers with stacking.

The ISITC classifier outperformed all single classifiers and the hybrid model, confirming that the combination of different models can further improve performance in IP traffic classification. The IP traffic classifier with the ISITC, the proposed solution, achieved an accuracy of 0.9678% with an "rbf" kernel, emphasising the advantage of hybrid classifiers with stacking.

The higher performance of the ISITC can be attributed to its ability to capture various patterns in data that individual classifiers may miss. The random forest classifier captures complex relationships, while XGBoost recognises interactions between features perfectly.

Confusion matrices (Fig. 5) enable further analysis of the performance of each classifier by providing insight into the number of correct and incorrect classifications for each class. The NN classifier only performed well in class 2 classification (contributing to its lower overall accuracy), while class 0 is recognised with high accuracy by all other classifiers (RF, DT, XGBoost, and SVC). The ISITC's confusion matrix shows strong performance with a balanced classification, similar to the standalone XGB model, with the exception of class 1 and class 3 classification (but also a slight increase in false positives).

To ensure the scalability of the ISITC, cross-validation (cv=3) is used to evaluate the ISITC on three different datasets derived from the entire dataset during the training and testing phase, and the performance of the ISITC with different parameters and different datasets is shown in Fig. 4.

The results of this study are consistent with those of previous studies that have emphasised the effectiveness of hybrid methods in classification in general. However, the specific combination of random forest and XGBoost classifiers with SVC as the final estimator has not been extensively studied, making this work a novel contribution.

The t-tests performed to compare the ISITC and other IP traffic classifiers showed that the performance improvements observed were always statistically significant. For example, the t-test between the ISITC and the neural network showed a statistically significant difference in performance with a p-value of 0.15. The t-tests between the ISITC and the other classifiers (the random forest, decision tree, XGBoost, and SVC) also showed statistically significant differences in performance with p-values of 1.2, 0.6, 0.6, and 0.09, respectively. This means that the ISITC is different from the other IP traffic classifiers.

VI. Conclusion

In this paper, I propose a hybrid system called the ISITC, which simply and efficiently combines random forest (RF) and XGBoost (XGB) classifier techniques with an SVC as the final estimator to classify IP traffic with a small dataset. The ISITC classifier presented here can efficiently classify IP traffic with a high accuracy of 96.7%, which holds promise for improving network management, security measures, and quality of service (QoS). The ISITC outperforms IP traffic classifiers with NN, RF, DT, or XGB classifiers or SVCs. The t-test values show that there is a statistically significant difference in the accuracy of the ISITC and the other IP traffic classifiers. These results emphasise the potential of advanced hybrid classifiers to significantly improve the accuracy and reliability of IP traffic classification. Furthermore, the ISITC results confirm that the combination of different models can further improve performance in IP traffic classification. In the future, further research should be conducted on combinations of classifiers and their performance should be tested on different datasets. In addition, future work could explore advanced ensemble techniques and further tuning of hyperparameters to improve the performance of hybrid models.

***Abstract*—The application of artificial intelligence (AI) to electrocardiograms (ECGs) and photoplethysmograph (PPG) for diagnosing significant coronary artery disease (CAD) is not well established. This study aimed to determine whether the combination of ECG and PPG signals could accurately identify the location of blocked coronary arteries in CAD patients. Simultaneous measurement of ECG and PPG signal data were collected from a Malaysian university hospital, including patients with confirmed significant CAD based on invasive coronary angiography. ECG and PPG datasets were concatenated to form a single dataset, thereby enhancing the information available for the training process. Experimental results demonstrate that the Convolutional Neural Networks (CNN) + Long Short-Term Memory (LSTM) + Attention (ATTN) mechanisms model significantly outperforms standalone CNN and CNN + LSTM models, achieving an accuracy of 98.12% and perfect Area Under the Curve (AUC) scores of 1.00 for the detection of blockages in the left anterior descending (LAD) artery, left circumflex (LCX) artery, and right coronary artery (RCA). The integration of LSTM layers captures temporal dependencies in the sequential data, while the attention mechanism selectively highlights the most relevant signal features. This study demonstrates that AI-enhanced models can effectively analyze simultaneous measurement of standard single-lead ECGs and PPG to predict the location of coronary artery blockages and could be a valuable screening tool for detecting coronary artery obstructions, potentially enabling their use in routine health checks and in identifying patients at high risk for future coronary events.**

I. Introduction

CAD represents a substantial global burden on cardiovascular health [1]. Its impact extends to long-term mortality and morbidity all around the world. Existing studies have demonstrated that ischemic heart disease contributes to approximately 16% of total mortality [2]. Furthermore, epidemiological surveys underscore the escalating prevalence of CAD on a global scale. Nevertheless, the evaluation and diagnosis of CAD persistently hinge upon conventional clinical symptoms, signs, and relevant comorbidities.

It is crucial to determine the location of myocardial infarction and ischemia, as well as identify the specific coronary artery that is blocked and where the occlusion occurs. This information facilitates the diagnosis of ischemia and infarction and guides treatment decisions. For instance, administering nitroglycerin to relieve ischemic chest pain can lead to hemodynamic collapse in patients with right ventricular ischemia/infarction [3]. Therefore, recognizing ECG signs of right ventricular issues is essential. Clinicians, especially interventional cardiologists, benefit significantly from this knowledge, as it directly impacts the selection of coronary catheters.

A variety of non-invasive diagnostic modalities are at the disposal for the assessment of potential coronary artery obstructions in patients with CAD, encompassing stress ECG, and nuclear medicine imaging [4], [5]. Nonetheless, these methodologies are encumbered by several limitations: they are not readily accessible, necessitate the use of specialized apparatus, are laborious, and entail considerable expense. The performance of these tests are moderately suboptimal, ranging approximately between 75-90%, and the issue of radiation exposure cannot be overlooked. Moreover, stress-induced tests that require physical exertion from the patient may not be viable for those in a debilitated state. Hence, there is an imperative need for the development of an easily attainable, economical, and highly precise test for the prediction of ischemic localization.

ECG is recognized as a non-invasive diagnostic instrument that boasts several merits: it is straightforward to operate, consistent in results, broadly accessible, and cost-efficient relative to other diagnostic methods [6]. The ECG is capable of discerning significant CAD by manifesting particular alterations in the ECG patterns, such as deviations in the ST-segment, inversions of the T-wave, and the emergence of Q-waves [7]. Nonetheless, the precision in interpreting ECG data may be compromised by the presence of other medical conditions, including arrhythmias, cardiomyopathies, and bundle branch blocks.

PPG is a non-invasive method utilized to detect variations in blood volume by employing an infrared light sensor positioned on the skin's surface. Beyond its conventional use in heart rate monitoring and pulse oximetry, PPG has garnered attention for its potential in detecting CAD. One of the key methodologies in PPG analysis for CAD detection is Pulse Wave Analysis (PWA). PWA evaluates the PPG waveform to assess arterial stiffness, a hallmark of CAD. The presence of plaque in the arteries can alter the waveform's shape, specifically causing a delay in the pulse wave transit time [8]. In addition, ECG and PPG signals can be combined to enable the assessment of cardiac conditions through heart rate variability (HRV) analysis [9].

Artificial intelligence (AI), particularly through deep learning CNN, has been deployed in diverse disease models [10], [11], [12]. CNNs excel in learning from voluminous datasets, autonomously identifying salient features from data, whether one-dimensional (e.g., signals) or two-dimensional (e.g., images). Recurrent neural network (RNN) architectures such as LSTM is extensively utilized in domains like natural language processing, and analysis of sequential data. As adjunct classifiers to a CNN framework, they fulfill distinct roles in augmenting classification precision. The LSTM architecture, in particular, is proficient in detecting temporal correlations within sequential data [13]. Within deep learning paradigms, attention mechanisms (ATTN) empower models to concentrate on pertinent segments of input data, sidelining the less critical parts. This technique is invaluable in sequential data tasks, where the significance of context and element interrelations fluctuates. Utilizing ATTN, the most informative attributes of an ECG signal can be unearthed across various network layers [14] aiding in functions like classification or regression. In healthcare diagnostics, signal and image data are pivotal. The AI-augmented ECG (AI ECG) algorithm, leveraging deep learning, deciphers significant patterns in ECG data [15]. The effectiveness of deep learning models, particularly a hybrid CNN-LSTM architecture, in enhancing the accuracy of PPG signal analysis for detecting and delineating waveforms was proven by [16]. A deep neural network (DNN) utilizing a multilayer perceptron architecture, enhanced with regularization and dropout techniques, has been employed to enhance the accuracy and reliability of CAD diagnosis and prognosis using clinical data [17]. Prior research has validated its utility in diagnosing heart diseases. Yet, its potential in pinpointing ischemic localizations is a domain yet to be investigated.

The motivation for the study is centered on the need for a more efficient, accessible, and accurate method for diagnosing coronary artery disease (CAD) by identifying the location of arterial blockages. Current diagnostic tools like stress ECG and nuclear medicine imaging, while useful, have limitations including moderate accuracy (75-90%), high costs, and reliance on specialized equipment. Moreover, they may not be viable for patients with debilitating conditions.

ECGs) and PPGs are non-invasive and cost-effective methods, but their full potential in diagnosing CAD is underexplored. By combining ECG and PPG signals and utilizing advanced AI models (CNN + LSTM + Attention mechanisms), this study aims to improve the accuracy of CAD diagnosis, particularly in predicting the location of coronary artery blockages. This approach could lead to a more accessible and precise screening tool for CAD, reducing the need for invasive methods like coronary angiography.

II. Related Work

In a study by Tao et al. [18], an automatic system was developed to detect and localize ischemic heart disease (IHD) using magnetocardiography (MCG) data and machine learning techniques. The authors employed MCG recordings from 227 patients with diagnosed coronary stenosis and 347 healthy controls, using coronary angiography (CAG) as the gold standard for diagnosis. They extracted 164 features from the MCG signals, divided them into time-domain, frequency-domain, and information theory categories, and tested several machine learning classifiers, including k-nearest neighbors (KNN), decision tree (DT), support vector machine (SVM), and XGBoost. The XGBoost classifier was used to localize ischemic regions, achieving an accuracy of 0.74 for LAD, 0.68 for LCX, and 0.65 for RCA.

Huang et al. [19] developed and evaluated a deep learning model using CNN to identify significant CAD from standard 12-lead ECG. The study utilized six pre-trained CNN models (VGG16, ResNet50V2, InceptionV3, InceptionResNetV2, Xception, and DenseNet) for feature extraction, ultimately finding that the InceptionV3 model without a dense layer provided the best performance. The model classified patients into four groups: normal (no CAD), and those with obstructions in the LAD, LCX, and RCA. The dataset included ECGs from 2,303 patients with angiography-proven significant CAD and 1,053 control patients without CAD. The AI model demonstrated a macro-average area under the ROC curve (AUC) of 0.869 for CAD detection, with individual AUCs of 0.885 for LAD, 0.776 for RCA, 0.816 for LCX, and 1.0 for non-CAD (normal) cases.

The paper by Roopa and Harish [20] proposes a novel approach using the Information Fuzzy Network (IFN) to analyze ECG signals for identifying and localizing thrombus in culprit arteries. The method involves preprocessing ECG signals using a Savitzky-Golay filter, followed by feature extraction through the Stockwell Transform for point detection, Nearest-Neighbor Interpolation for time interval measurement, and peak amplitude assessment. The classification process differentiates between ischemic and non-ischemic signals, identifies the culprit artery, and pinpoints the thrombus location. The study used ECG datasets from the MIT Physionet databank, including Long-Term ST, Spontaneous Ventricular Tachyarrhythmia, and T-Wave Alternans Challenge databases, providing a comprehensive range of cases. For the LAD artery, ST elevation in lead V3 greater than in V1 suggests an LAD blockage, with further localization determined by elevations in other leads, such as aVF, L2, and L3 indicating a proximal block to the major septal artery. The LCX is identified by ST elevation in L2, L3, and aVF with L2 greater than L3, while the RCA is identified by ST elevation in L2, L3, and aVF with L3 greater than L2 and a higher V1 elevation than V3. The proposed method achieved a classification accuracy of 92.3%, with 87.5% sensitivity and 100% specificity.

The previous studies on CAD detection and localization, such as those by Tao et al., Huang et al., and Roopa and Harish, primarily focused on single modalities (MCG or ECG) and did not explore the combined potential of ECG and PPG signals. Moreover, while machine learning techniques and conventional CNNs were employed, more advanced AI models like LSTM and attention mechanisms have not been fully investigated, limiting the ability to capture complex temporal and spatial features. Additionally, the precision in localizing specific coronary arteries remains moderate, and none of these studies explored the diagnostic potential of PPG signals, leaving a gap in fully leveraging its capabilities for CAD detection. Lastly, the existing research lacks generalizability across diverse and multimodal datasets, potentially limiting the robustness and accuracy of CAD diagnosis. This study aims to address these gaps by integrating ECG and PPG signals, enhanced by advanced AI models (CNN, LSTM, and attention mechanisms), to achieve more accurate and comprehensive CAD detection and localization.

III. Materials and Methods

A. Study Population

This paper analyzes the dataset of a study conducted on patients with angiography-proven significant CAD. All study participants have given their written consent and the study is approved by the Research Ethics Committee of Universiti Kebangsaan Malaysia (UKMPPI/111/8/JEP-2020-806). These patients underwent elective invasive coronary angiography at the Hospital Chanselor Tuanku Mukhriz (HCTM) Malaysia. The criteria for inclusion were severe stenosis (>70%) based on quantitative coronary angiography assessment. All participants enrolled in the study fell within the age range of 20 to 65 years, as the aim was to specifically target individuals without any prior history of CAD. All patients were monitored by their cardiology physicians in outpatient clinics.

B. Data Collection

The algorithm for patients' simultaneous ECG and PPG data recording is shown in Fig. 1. A cohort comprising 60 patients diagnosed with significant CAD via angiography was assembled, and a comprehensive dataset of 7156 simultaneous single-lead ECGs and PPG was amassed for analysis. Subsequently, based on the findings from the patients' angiography reports, they were categorized into three distinct groups: those exhibiting stenosis in the left anterior descending artery (LAD), left circumflex artery (LCX), and right coronary artery (RCA).

Within this cohort, the LAD group consisted of 27 patients, yielding 3884 simultaneous single beat ECG and PPG records, the LCX group comprised 16 patients, corresponding to 1565 simultaneous single beat ECG and PPG records, and the RCA groups encompassed 17 patients, accounting for 1707 simultaneous single beat ECG and PPG records. Fig. 2 shows samples of simultaneous single beat ECG and PPG signals for each class LAD, LCX, and RCA from the dataset.

The data utilized in this study, obtained from the hospital, consisted of simultaneous ECG and PPG time series data collected from patients diagnosed with CAD. This dataset comprised standard single-lead ECG (lead II) signals generated by the MAX86150EVS ECG/PPG module, characterized by a measurement frequency of 400 Hz and a measurement duration of 10 minutes. Prior to commencing the training process, the dataset underwent filtering and segmentation procedures to get the best quality of single beat signals and to augment the number of samples, thereby introducing subsamples for each original sample. As a result, a total of 7165 samples were obtained, each representing a complete cycle of the simultaneous ECG and PPG signal and comprised of 187 data points. These time series data in terms of their shape and size will be utilized for subsequent training of our deep learning models.

C. Dataset Preparation and Preprocessing

Prior to inputting the data into the deep learning model, the ECG and PPG datasets were concatenated to form a single dataset. This integration aims to provide a more comprehensive set of information during the training process, which is hypothesized to enhance the model's performance. Fig. 3 presents examples of concatenated ECG and PPG signals corresponding to each class, specifically LAD, LCX, and RCA. In our experimental setup, the dataset underwent division into two distinct subsets: a training set and a test set. Specifically, 80% of the dataset was allocated to the training and validation process. Validation is done during training utilizing 20% of the training data. The remaining 20% of the original dataset constituted the test set. It is noteworthy to mention that an imbalance in data distribution among the groups was observed.

Previous research has indicated that such imbalances can introduce biases during model training [19]. Consequently, to mitigate this issue, we adopted a down-sampling approach, and randomly removed data so that all the classes have the same number of samples. Fig. 4 shows a bar chart for class distribution before and after the data balancing process.

D. Model Build-up

In the construction of our deep learning models, we incorporated CNN, LSTM networks, and ATTN along with their respective parameters, resulting in promising outcomes from the integration of all three models. The process of identifying the optimal model involved three key phases.

Initially, we developed a model solely employing 1D CNN. Following the extraction of features by the CNN from the single-lead ECG signals, these features under-went flattening through Max Pooling. Max pooling, a pooling operation technique, extracts the maximum value within each region of the feature map covered by the filter. As a result, the output of the max-pooling layer is a feature map that retains the most prominent features from the preceding feature map. Subsequently, an intermediate dense layer with Rectified Linear Unit (ReLU) activation function was introduced, followed by an additional dense layer with a size of three, representing the three categories of LAD, LCX, and RCA as the output layer. This dense layer employed the Softmax activation function. The performance of this model was then evaluated.

In the second phase, we incorporated an LSTM layer into the existing model and assessed its performance. Finally, in the last phase, we augmented the previous CNN + LSTM model with an ATTN layer and evaluated its performance. The architectural representation of the model is depicted in Fig. 5 after data balancing process.

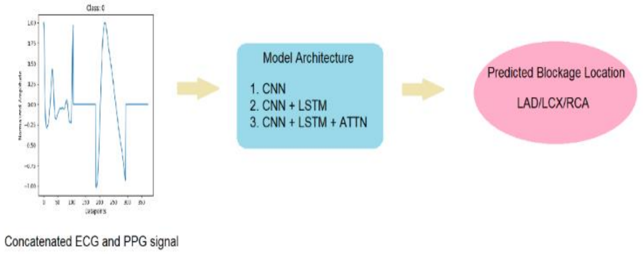

Fig. 5. Architecture for coronary artery blockage localization prediction model.

E. Training Process

The training platform utilized in this study is Google Colaboratory (Colab), which operates within a high-RAM GPU environment. Colab serves as a cloud computing platform supporting Python 3.8 and the TensorFlow package, widely employed for constructing and training deep learning models. As a Google resource, Colab seamlessly integrates with Google Drive, allowing users to access files within Colab by uploading datasets to their personal Google Drives. For model development, we leveraged the Keras application programming interface (API) to construct CNN, LSTM, and ATTN models. Keras not only simplifies the construction of deep learning models but also provides a rich set of APIs and functions, including callbacks, optimizers, metrics, losses, and more, enhancing the versatility and efficiency of model development.

F. Evaluation Metrics

The principal objective of this investigation centered on evaluating the capacity of AI-enhanced ECGs to localize coronary artery blockages utilizing standard single-lead ECG recordings obtained at baseline. The performance of this methodology was evaluated through various assessment metrics, including the area under the curve (AUC) of the receiver operating characteristic (ROC) curve, and accuracy. These metrics were computed by averaging the results of five repetitions of training and are reported along with the mean, standard deviation, and 95% confidence interval. The evaluation process also involved the utilization of a confusion matrix, which defined four crucial terms: True Positive (TP), False Positive (FP), True Negative (TN), and False Negative (FN). These terms were instrumental in computing the aforementioned metrics. Accuracy, represented by Eq. (1), assesses the models' classification proficiency by quantifying the proportion of accurately classified samples out of the total samples. Precision, expressed in Eq. (2), indicates the percentage of correctly predicted positive results among all predicted positive samples. Recall, detailed in Eq. (3), represents the proportion of correctly classified positive samples out of all actual positive samples.

$$Accuracy = \frac{TP+TN}{TP+FP+TN+FN} \tag{1}$$

$$Precision = \frac{TP}{TP+FP} \tag{2}$$

$$Recall = \frac{TP}{TP+FN} \tag{3}$$

ROC curve elucidates the fluctuation between the true positive rate (TPR), often termed sensitivity, and the false positive rate (FPR), also known as 1-specificity, over a spectrum of decision thresholds. By modulating the threshold from 0 to 1, a sequence of TPR and FPR coordinates is generated. The ROC curve, plotted with FPR on the X-axis and TPR on the Y-axis, graphically represents the dynamic between specificity and sensitivity in test results. The area under the curve (AUC) signifies the proportion of the area beneath the ROC curve relative to the total possible area. The computation of AUC allows for the ROC curve's quantification, thus enabling the comparative evaluation of model efficacy. The AUC demarcates the model's discriminative capacity into four tiers: (1) AUC < 0.5 (no discrimination), (2) 0.7 ⩽ AUC < 0.8 (acceptable discrimination), (3) 0.8 ⩽ AUC < 0.9 (excellent discrimination), and (4) 0.9 ⩽ AUC ⩽ 1.0 (exceptional discrimination).

ROC-AUC analysis is leveraged in a multitude of fields, including radiology, biology, and, more recently, machine learning and data mining. Within the medical sector, it is prevalently utilized for disease diagnostics, epidemiology, empirical medical research, and radiological methods. The ROC curve's primary advantage is its ability to provide a lucid and direct visual representation of a diagnostic method's clinical precision.

IV. Results and Discussion

To optimize the model architecture, the simultaneous ECG and PPG dataset was utilized to evaluate three distinct model layers. The model demonstrating the highest accuracy was selected as the optimal architecture. The experimental results are presented in Table I. Table I presents the evaluation metrics of three different models utilized in the study: CNN, CNN + LSTM, and CNN + LSTM + ATTN. The performance of these models was assessed based on their accuracy and area under the curve (AUC) values for predicting blockages in three coronary arteries: the left anterior descending (LAD) artery, left circumflex (LCX) artery, and right coronary artery (RCA). Use letters for table footnotes. The corresponding ROC curve and confusion matrix are shown in Fig. 6.

As shown in Table I, The CNN model achieved an accuracy of 94.69%. When the LSTM layer was integrated with the CNN model, the accuracy slightly decreased to 92.47%. However, the introduction of the attention mechanism alongside the CNN and LSTM layers led to a significant improvement, with the CNN + LSTM + ATTN model achieving an accuracy of 98.12%.

TABLE I. Evaluation Metrics of Three Different Models Used in this Study

Model	Accuracy	AUC		
		LAD	***LCX***	***RCA***
CNN	94.69%	0.96	0.97	0.97
CNN + LSTM	92.47%	0.98	0.99	0.98
CNN + LSTM + ATTN	98.12%	1.00	1.00	1.00

For the detection of LAD blockages, the CNN model obtained an AUC of 0.96. The addition of the LSTM layer increased the AUC to 0.98, demonstrating the model's enhanced ability to capture temporal dependencies in the data. The incorporation of the attention mechanism further elevated the performance, with the CNN + LSTM + ATTN model reaching the maximum AUC of 1.00, indicating perfect classification.

In the case of LCX blockages, the CNN model achieved an AUC of 0.97. The CNN + LSTM model improved this metric to 0.99, showing a robust enhancement due to the LSTM layer. The CNN + LSTM + ATTN model again achieved the highest AUC of 1.00, reflecting its superior ability to focus on the most relevant features of the ECG and PPG signals for accurate detection.

For RCA blockages, the CNN model also achieved an AUC of 0.97. The CNN + LSTM model maintained a high AUC of 0.98, confirming the beneficial impact of temporal feature extraction. The CNN + LSTM + ATTN model reached a perfect AUC of 1.00, further validating the effectiveness of the attention mechanism in improving the model's discriminative power.

The comparative analysis reveals that the integration of LSTM and attention mechanisms into the CNN model substantially enhances its performance. The CNN + LSTM + ATTN model consistently outperforms both the standalone CNN and the CNN + LSTM models across all metrics. The inclusion of the LSTM layer helps capture temporal dependencies inherent in the sequential ECG and PPG data, thereby improving the model's ability to differentiate between classes. Furthermore, the attention mechanism selectively emphasizes the most relevant parts of the signals, thereby enhancing the model's focus and leading to more accurate classification.

The significant improvements in both accuracy and AUC, particularly the perfect AUC scores achieved by the CNN + LSTM + ATTN model, underscore its exceptional potential for precise detection of coronary artery blockages. This suggests that the combined approach not only leverages the strengths of each component but also synergistically enhances the overall model performance, making it a promising tool for the diagnosis of coronary artery disease using ECG and PPG signals.

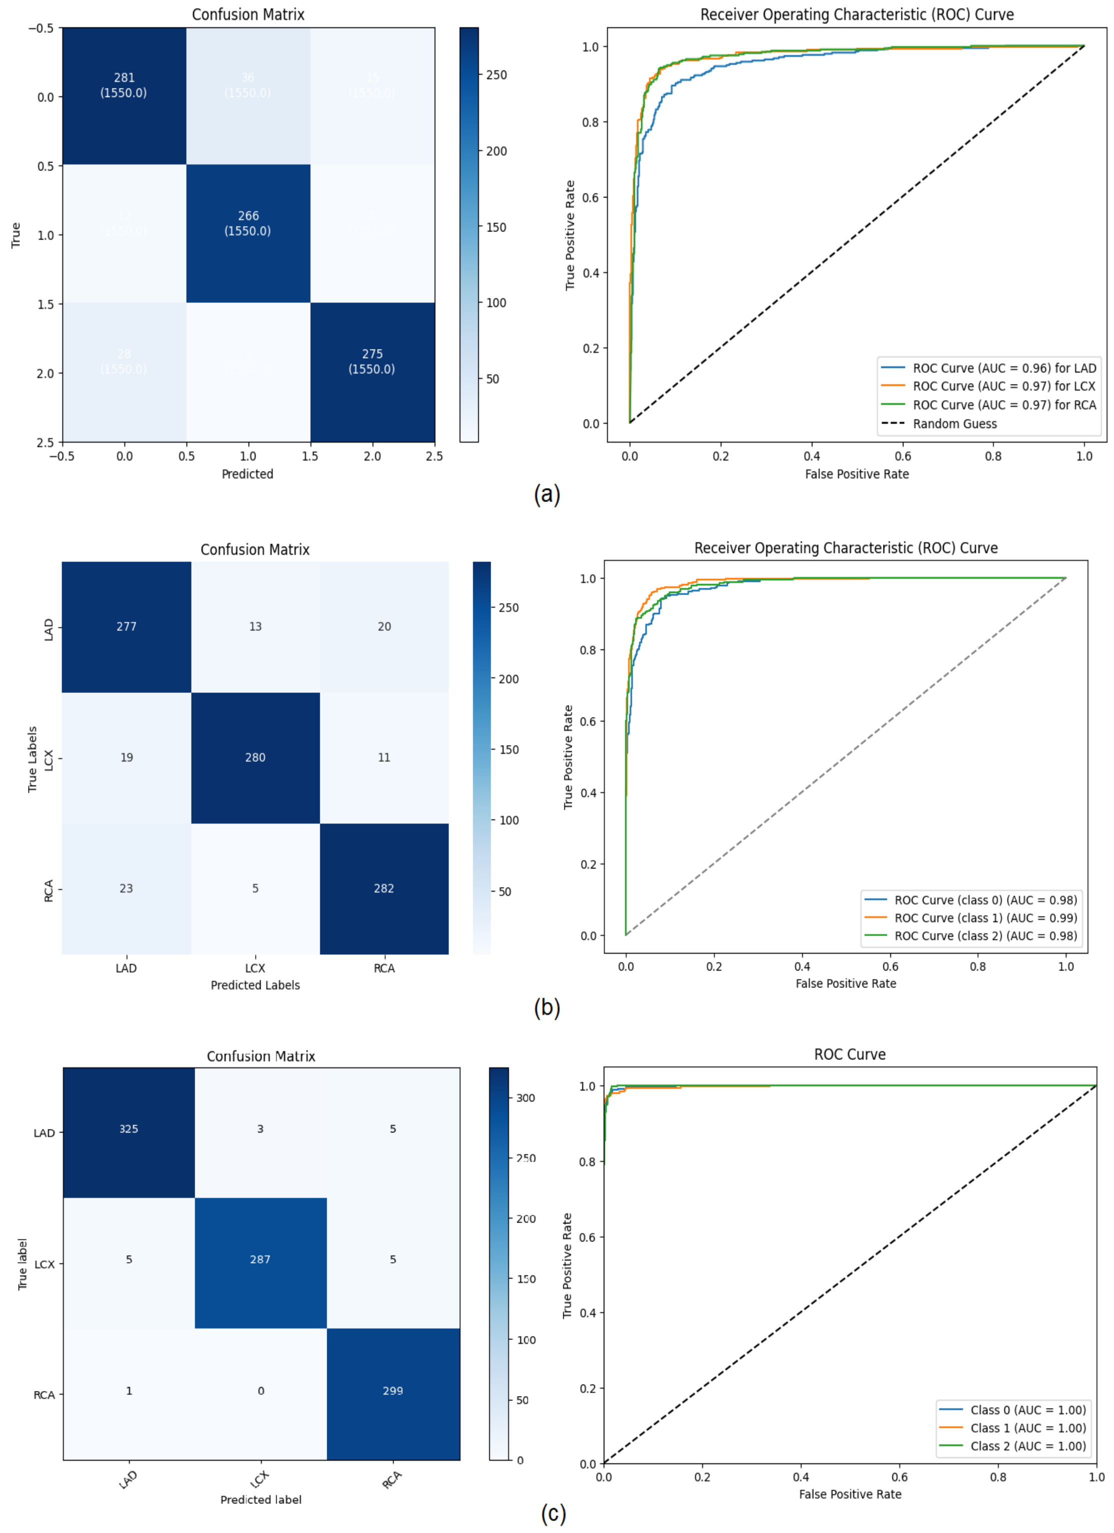

Fig. 6. Confusion matrix and ROC curve of (a) CNN model, (b) CNN + LSTM model, (c) CNN + LSTM + ATTN model.

Table II shows the model performance comparison of the best model obtained in this study with previous works by Tao et al., 2018 [18], Huang et al., 2022 [19], and Roopa and Harish, 2019 [20] in terms of their accuracy and AUC since these studies are closely related to the proposed work.

The results in Table II highlight the superiority of the proposed model, which utilizes combined simultaneous single-lead ECG and PPG signals with a CNN + LSTM + ATTN architecture, in predicting and localizing coronary artery blockages compared to previous studies.

TABLE II. PERFORMANCE COMPARISON WITH PREVIOUS WORKS

Author, Year	**Data**	**AI Model**	**Acc.(%)**	**AUC**		
				LAD	***LCX***	***RCA***
Tao et al., 2018 [18]	MCG	XGBoost	NA	0.74	0.68	0.65
Huang et al., 2022 [19]	12 lead ECG	InceptionV3		0.89	0.82	0.78
Roopa and Harish, 2019 [20]	12 lead ECG	IFN	92.3	NA		
Proposed work	Combined simultaneous single lead ECG and PPG	CNN + LSTM + ATTN	98.12	1.00	1.00	1.00

The proposed model achieved an overall accuracy of 98.12%, surpassing the performance of prior studies. In terms of Area Under the Curve (AUC) metrics for different coronary arteries, the model reached perfect scores (AUC = 1.00) for the left anterior descending (LAD), left circumflex (LCX), and right coronary artery (RCA). These results significantly outperform other models, as shown in the comparison.

Tao et al. [18] use magnetocardiography (MCG) data and an XGBoost model, this study reported lower AUC values of 0.74 (LAD), 0.68 (LCX), and 0.65 (RCA). Huang et al. [19] applied a deep learning model (InceptionV3) on 12-lead ECG data, achieving AUCs of 0.89 (LAD), 0.82 (LCX), and 0.78 (RCA). Roopa and Harish [20] employed an Information Fuzzy Network (IFN) model using 12-lead ECG data with a reported accuracy of 92.3%.

The significant improvement in both accuracy and AUC values of the proposed model can be attributed to the integration of ECG and PPG signals, coupled with the advanced AI architecture combining CNN, LSTM, and attention mechanisms. The LSTM layers effectively capture temporal dependencies in sequential data, while the attention mechanism enhances feature extraction, leading to more precise localization of coronary artery blockages.

These results indicate that the proposed model represents a substantial advancement in the non-invasive diagnosis and localization of coronary artery disease, providing a more accurate and reliable approach compared to existing methods. This makes it a promising tool for future clinical applications in CAD detection.

V. CONCLUSION

In this study, a novel approach for diagnosing the location of coronary artery blockages in CAD patients by utilizing a combination of ECG and PPG signals was presented. The proposed model integrated Convolutional Neural Network (CNN), Long Short-Term Memory (LSTM), and Attention (ATTN) mechanisms to enhance the accuracy and robustness of CAD detection.

The experimental results demonstrated that the CNN + LSTM + ATTN model significantly outperformed the standalone CNN and CNN + LSTM models. Specifically, an accuracy of 98.12% and perfect Area Under the Curve (AUC) scores of 1.00 for detecting blockages in the left anterior descending (LAD) artery, left circumflex (LCX) artery, and right coronary artery (RCA) were achieved by the CNN + LSTM + ATTN model. The superior performance of the attention mechanism in selectively emphasizing the most relevant parts of the ECG and PPG signals, thereby improving the model's discriminative power, was underscored by these results.

The integration of the LSTM layer was found to further contribute to the model's ability to capture temporal dependencies inherent in the sequential ECG and PPG data, enhancing its capacity to differentiate between different classes of coronary artery blockages. The significant improvements in both accuracy and AUC scores highlighted the exceptional potential of the CNN + LSTM + ATTN model for precise detection of CAD.

In conclusion, the combined approach not only leveraged the strengths of each component but also synergistically enhanced the overall model performance, making it a promising tool for the diagnosis of coronary artery disease using ECG and PPG signals. Future work will focus on further validating the model with larger and more diverse datasets, as well as exploring its applicability in real-world clinical settings.

***Abstract*—One of the key challenging problems in data mining is data retrieval from large data repositories, as the sizes of data are growing very fast, to deal with this situation, there is a need for efficient data mining techniques. For efficient mining tasks number of queries have been emerged. Iceberg query is one of them, in which the output is much smaller like the tip of the iceberg as compared to the large input dataset, these queries take very long processing time and require a huge amount of main memory. However the processing devices have limited memories, so the efficient processing of iceberg queries is a challenging problem for most of the researchers. In this paper we present a novel technique, namely a summary table, to address this problem. Specifically, we adopt the summary table technique to acquire the required results at summary levels. The experimental results demonstrate that the summary table technique is highly effective for large datasets. Compared to bitmap indexing and cubed techniques, the summary table offers faster retrieval capabilities. Furthermore, the proposed technique achieved state-of-the-art performance.**

Keywords*—Threshold (TH); bitmap index; aggregate function; Iceberg Query (IB); anti-monotone; non-anti-monotone aggregation

I. Introduction

Data retrieval and storage play a very important role in databases. The effectiveness of data retrieving techniques depends on specific. Since few years many queries have emerged, one of them is the iceberg query (IBQ) in which the output is significantly small as compared to the input, such query is called IBQ, where the number of above-threshold outcome is usually very small like the tip of an iceberg as compared to large amount of input data [1]. This is a unique class of aggregation queries connecting HAVING () and GROUP BY () clauses, which computes aggregated values below or above a given threshold (TH). This query is first introduced in data mining (DM) [2]. Most of the data DM queries are IB queries. Several applications use aggregate functions such as, Min (), Avg (), Max (), Sum (), and Count () over an attribute or set of attributes to find aggregate values greater than a particular threshold, these aggregate values above the threshold values give more importance. The RDBMS, e.g., MySQL, Postgre SQL, SQL Server, Oracle, DB6, Sybase, and column-oriented databases e.g., Lucid DB, Vertica, and Monet DB all use common aggregation algorithms that first aggregate all rows and then calculate the Having () clause to select the iceberg result [3].

An iceberg query has the following characteristics: (a) Computing aggregate functions on one or more attributes (b) Dealing with large data sets, containing large unique attributes combination (domain size), and (c) Returning results below or above a given TH. These queries face some problems during executions, like 1) It needs to execute within a limited memory, which means memory size is lesser than domain size 2) Computation of aggregation values takes a large amount of time.

The global objective of this work is to reduce the execution time of the iceberg queries within a limited memory. Today’s world is rich in data; every organization and social media generates and stores huge amounts of data which need an efficient way to deal with. For this purpose, IB query is an ideal choice. These queries are used in many applications. Including market basket analysis [4] means finding item pairs (or triplets etc.) that are bought together by many customers in large data warehouses. In other words, market basket analysis means a collection of items purchased by a customer in a single transaction. It is based on two key attributes considered for the threshold value used for finding item pairs; these attributes comprise support and confidence. If support and confidence values are above or below some specified threshold then it identifies products and their content that go well together. Similarly, clustering [5] is a process of partitioning a set of records into groups (clusters), such that all records in a group are related to each other and records that belong to two different groups are different [6]. This helps users to recognize the natural grouping or structure in a data set and this natural grouping is done in clustering based on some specific threshold values in each IB query [7].

A. *Properties of Aggregation Function*

Aggregation function is one the key part of iceberg queries, such as Sum (), Count (), Min (), Max (), and Avg (). Aggregate function is divided into two types (1) Anti-Monotone, and (2) Non-Anti-Monotone aggregation function [8]. An anti-monotone uses apriori [4] property, but non-anti-monotone are not able to use apriori property, examples of anti-monotone are Count (), Sum (), Max (), and Min (), whereas non-anti-monotone are Avg () and Div (). The main benefit of using IB with anti-monotone function is the pruning of computing aggregation functions reduces the time to produce the required query result [9]. On the other hand, non-anti-monotone aggregation IB queries don't take advantage of threshold on Avg () values as anti-monotone aggregation takes on Min (), Sum (), Max (), and Count (). Average IB queries compute average for all unique grouped attributes, and then apply threshold constraint on those average values [10]. To deal with aggregation functions there is a high gape between the researcher's contribution toward these two types with a ratio of 22 to 78 percent [11] as shown in Fig 1.

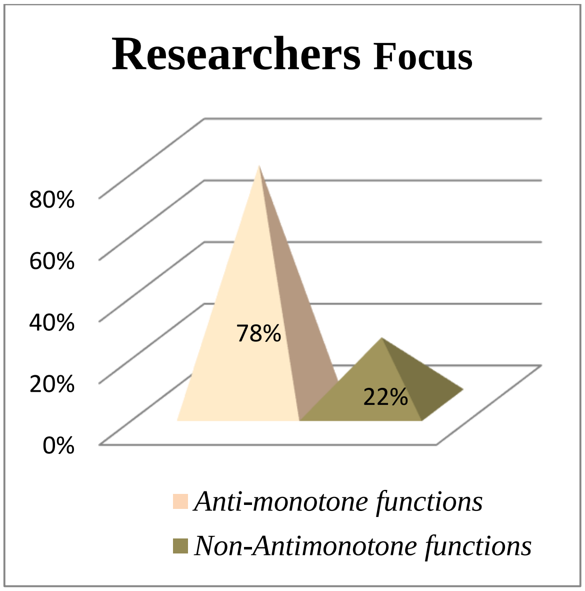

Fig. 1. Aggregation functions.

The rest of the paper is structured as follows, section II presents a review of related research. Section III describes the proposed technique, proposed architecture, and implementation. Section IV describes the results and analysis, and in Section V conclusion and future direction are presented.

II. Review of Related Research

Since a few decades iceberg query has always been an active area of research. Researchers have provided different guidelines and suggestions to improve its performance. We are going to discuss some works in literature based on different specific categories.

A. Bitmap Index Techniques

To accelerate the IB queries, bitmap indices are one of the well-organized and well-known choices in column stores and data warehousing applications. Spiegler et al. [12] first introduced the concept of bitmap index (BI). Basically, a matrix of 0 and 1 bit's makes a bitmap. Its size depends on the number of matchless attributes that exist in vector upon which bitmap is created. Basically, a bitmap index is used to index values of a single column in a table. For illustration Table I indicates a bitmap index with nine rows, and column Y, where column Y is indexed with integer values from 0 to 3 and its cardinality becomes four because it has four different values. Columns X0, X1, X2 and X3 with subscripts signify bitmap index for Y contains four bitmaps. The second bit X1 in Table I is 1 because the second row of Y contains value 1, while corresponding bits of X0, X2 and X3 are all 0 Vuppuand Rao [13] has presented a new evaluation scheme for processing IB queries using bitmap index position. They developed an algorithm based on retrieving index positions of all 1's from each bitmap. Further, these indices positions are processed by using commonality condition which selects whether the pair of directions is iceberg result or not. To retain for future reference, an XOR operation is conducted for bitmaps, which is the iceberg query result. Their experiments show that algorithms which is based on index positions takes less processing time to answer IBQ.

TABLE I. Bitmaps Index for Column Named Y

RID	Y	X0	X1	X2	X3
0	2	0	0	1	0
1	1	0	1	0	0
2	3	0	0	0	1
3	0	1	0	0	0
4	3	0	0	0	1
5	1	0	1	0	0
6	0	1	0	0	0
7	0	1	0	0	0
8	2	0	0	1	0

Padmapriya and Shanmugapriya [1] introduced an index based IBQ assessment method. The key aim of using the index is to convert the bit value into an integer value which speeds up the query evaluation process and takes less memory. This technique performed well on the state-of-the-techniques. O'Neil [14] Model 204 was the first model used bitmap index for wide-spread commercial product making. This was a combination of row identifiers (RID list) and basic bitmap index without compression. In general B+ tree index technique is like the performance of Model 204. Prakash et al. [15] presented a bitmap index as a better choice for querying huge and multidimensional scientific datasets. They have developed a well-organized algorithm based on retrieving index positions of all 1's from each bitmap. These index positions are further processed on common features which decide whether the pair of vectors is IB result or not. Generation of the decision algorithm which involves pre-processing of data sets through bitmap indexing approach is the global objective of [16]. The key benefits of this index strategy are load balancing, identifying frequent patterns of the data sets, kind of data types available in the databases, slowly changing dimension scenarios handling and usage of aggregation in the form of IB querying.

Shankar et al. [17] introduced a cache-based evaluation technique for IBQ by taking threshold value equal to 1 using a compressed bitmap index, and for future situation the required results are saved in cache memory. In future it just picks up the required results from the cache memory as a substitute of executing once again on the database table. Therefore, this approach clearly states that, an execution time of IB query is improved by avoiding duplication of evaluation process several times. In this work testing was conducted by applying an IB query stated on the database table which consists of one million rows with two attributes X and Y, by using COUNT () aggregation function. IB query evaluation method was the first function applied to accept all those tuples as an input and produces the iceberg results with its count value fulfilled by threshold greater than or equal to 1. Then these results are given as an input to the second unit catching IB results in an ascending order. For future position this unit saves the iceberg results in cache memory. The last unit which takes results from cache unit is responsible to answer an IB query for thresholds greater than 1, is just selected from the cache memory and send to output. This cache-based technique enhanced the overall processing time of IBQ for an efficient data retrieval task.

Laxmaiah, Govardhan and Kumar [18] have presented an efficient Database Priority Queue (DPQ) algorithm for processing IBQ using compressed bitmap Index; the impact of this method was to speed up the query evolution method by emptying the compression queue. In this technique, first the iceberg query is responsible to select the similar words with aggregate attributes Y and X from the relation R in which the TH value is taking between 1000 and 9000. By taking a database table which has two attributes Y and X which contain millions of rows and using count () aggregate function. Then the experiment is conducted by applying an IBQ on the first function that generates bitmaps accepts all those rows as an input. The key achievement of this technique is keeping the comparable number of rows in a relational database table and at the same time keeps the results with density queues; consequently, further this experiment is repetitive for different iceberg threshold as well.

Zianget al. [19] suggested a well-organized algorithm for IBQ processing by using compact bitmap indices. The given algorithm does not depend on any testing compression process and demonstrates better performance over presented schemes. Bitmap index has three attractive benefits based on observation such as: first, conducting bitwise operations that reduce computation time. Second, saving disk space by avoiding rows scan on a relation by using attributes group. Third, by leveraging the anti-monotone property of IB therefore this algorithm is not affected by the number of diverse values, and length of attributes in the relation. Rao et al. [20] presented a well-organized technique, known as dynamic pruning technique or vector alignment algorithm to answer IBQ by using compressed bitmap indices, this algorithm guarantees that no empty result is generate by using any bitwise-AND operation. Bitmap indices are presented to get more improved results as compared to tree based index method such as alternatives of R-tree or B-tree [21], explicitly, this work is motivated to compute IBQ using bitmap indices as an index pruning based approach.

Otoo and Shoshani [22] introduced bitmap indexing pattern algorithms for little cardinality attributes to analyze the time and space complexities of Byte Aligned Code (BBC) and Word Aligned Hybrid (WAH) compressed bitmap indices. To demonstrate their success for using high cardinality attributes, for high cardinality attributes, c << N, here c represent compressed bitmap index and N represent the number of words, the WAH algorithm compressed indices uses define 2N words, this 2N words is about half the size of a representative B-tree index. On the other side BBC compressed indices are even smaller but it also represents an in-place algorithm that is linear to the total size of the bitmaps involved to OR many bitmaps in time complexity. The whole size of the bitmaps used is proportional to the number of hits in the worst-case situation. By using compressed bitmap, it shows to search one attribute is optimal and this optimality is established with timing results from a set of real application and random data. In these sets of examinations, WAH compressed bitmap indices were nearly twice as fast as BBC code compressed indices. Both indices could achieve search operations faster than the projection index by using worst cases, on average. By using the WAH compressed indices, time is not more than the projection index. Bitmap indices in study [14] using bitmap vectors for vertical organization of a columns. Every vector characterized the presence of a distinctive value in the column across all rows in the table.

In study [23] an effective bitmap pruning strategy was introduced, which is grounded in order of high cardinality in Priority Queue (PQ) by using compressed bitmap indices for processing an IBQ. By using this method, it allowed the movement of vectors to enter PQs on the high count 1' to get additional benefit for large pruning of bitmaps. The pruned vector essentially improved the response time. Processing huge quantities of data in predetermined time factor is a key challenge faced by data warehousing. By using [24] bitmap indexing which is extra meaningful in quicker data processing generated a strategic decision technique for data warehousing environment. For managing 'Boolean' kind of data, like gender, the bitmap indexing is best suited, such as false and true group of values. Bitmap indexing mainly depends on 1's and 0's kind of data. The data is openly processed by using CPU, which does not support any alteration of the data items into a new format, and greatly decreases the processing time of the records. This work shows the integration of IB querying; within the identified amount of time factors while processing huge amounts of data in data warehousing environments and achieved efficient results. Most of the previous research work mainly centered about identifying "well behaved "constraints with respect to constraint pushing [25, 26], this work proposed a novel pushing technique known Divid-and-Approximate (DnA), which combine two ideas, "Approximate Push" and "Divide-and-Conquer" to generate a strongest constraint for pruning with non-anti-monotone aggregation constraints in IB cubing. The key idea of DnA was to divide a partition of tuples into two subspaces of positive and negative degree values, so that a given constraint could be rewritten using monotone or ant monotone constraints in subspaces. These works mainly focused on (a) SQL like tuple-based aggregates, rather than item-based aggregates (b) General aggregate constraints, rather than only "well behaved", and (c) Constraint independent methods, rather than constraint specific methods. The idea of DnA contributed a new share to constrain data mining techniques.

Laxmaiah et al. [27] presented an efficient Density Priority Queue (DPQ) procedure for an IBQ by using compacted bitmap index based on two stages (1) Using an algorithm for pruning the vectors dynamically by computing newest counts for reinsertion and certifies the proposal using a sample database. By dropping the bitmap vectors dynamically using a high-count attribute to calculate an IB query, and (2) Using a validation of DPQ approach on RDBMS section to show the validity of the proposed DPQ and evaluates an IB query having COUNT () aggregate function. As compared to previous strategies PQ is a more sophisticated technique. Based on large data sets the experimental results indicate significant progress which proves the effect of IBQ computation.

In study [28], the distributed Iceberg Semi-Join operator is proposed, which is used in most of the real-life applications.

This technique is used to get information from two different independent data marts or from a remote digital library and use an efficient technique, which insert the execution of the IBQ and join in the two servers by using Mul-FIS; to prune the non-qualifying groups it uses. This work provides important advantages over its competitors. By using multidimensional databases each dimension is nothing, but one subject oriented table with attributes of related metrics [29], writing queries on multidimensional databases are difficult and include join operations due to which the reply time of query is increased on a massive database. By using queries with aggregation function, and summarization is followed by using 'having' clause. This type of query is very complex and requires extra time. This work focused on two different bitmap indexes search implementations techniques, such as RIDB and Fast Bit. The key improvements in Fast Bit are the Word-Aligned Hybrid (WAH) compression for bitmaps and multilevel bitmap encoding approaches. Fast Bit index is typically greater than RID Bit index, in fewer intervals of time it can answer several queries, as it accesses the required bitmaps in fewer I/O operations [30]. RID Bit normally costs less CPU time in answering queries than that of Fast Bit, though, the CPU time differences are minor matched with I/O time. A brief comparison between "Fast Bit" and "RID Bit" is discussed in [31]. At the end this section Table II categorizes some basic characteristics of bitmap Indexing.

B. *Based on Compound or Hybrid Algorithms*

In study [31], four algorithms namely Partitioned Tree (PT), Breadth-first writing Partitioned Parallel BUC (BPP), Replicated Parallel BUC (RP), and Affinity Skip List (ASL) are introduced, these algorithms are calculated experimentally over a range of parameters to get the necessary condition in which the algorithms could outperform. The Key features of the proposed algorithms are mentioned in Table 2, which described all four algorithms with respect to their writing strategy, Data decomposition, Load Balance, and Relationship of cuboids.

Matias and Segaly [32] presented two effective algorithms based on hash partitioning technique to compute estimated IB queries. Using a hash function to divide a data set into specific values that was independent from a subset resulting with properly smaller independent sub problems that can be handled efficiently with certain performance. In [33] two algorithms which use a concise sample and basic component have been presented. The first algorithm is used to sort the sequence into the necessary number of partitions and the second algorithm is used for computation. Though acting only one pass over the sequence these algorithms are used to compute the approximation query, without accessing a database and without materializing data sets which are stated implicitly, therefore it can be applied online for streaming data. In [34] the author has emphasized two problems; (1) Efficiently classify passing stories from rapid streaming social content and (2) To execute IB queries to form the structural background between stories. To give attention to the solution of the first problem, the social stream is converted into a time gap of tube network, and model passing stories as (k, d) cores in the tube network.

Two polynomial time algorithms were proposed to extract maximal (k, d) cores. The second problem, deterministic context searches and randomized context search is applied to maintain the IBQ efficiently and carefully, which permits performing context search without pair wise relationship.

TABLE II. KEY FEATURES OF FOUR ALGORITHMS

Algorithms	Writing Strategy	Data Decomposition	Load Balance	Relationship of cuboids
RP	Depth-First	Replicated	Weak	Bottom-up
BPP	Breadth-First	Partitioned	Weak	Bottom-up
ASL	Breadth-First	Replicated	Strong	Top-down
PT	Breadth-First	Replicated	Strong	Hybrid

By spreading the probabilistic techniques and suggested hybrid and multi buckets algorithms for processing of IB queries was first considered by study [35]. The sample and multiple hash function are used as an important building chunk of probabilistic events such as scaled-sampling course and count algorithms. It projected the sizes of a query results in order to expect the valid IB results, which decreases memory requirements and raises aggregate query performance. Though, these techniques incorrectly resulted in false negatives and positives. To overcome these bugs, an efficient approach is planned by hybridizing the sampling and coarse count techniques, such as hashing technique that allocated a bitmap of size 'M' in the memory is constructed on linear counting algorithm (LCA). In this method, all entries are initialized with '0's. The linear counting algorithm applies a column interest and then scans the relation. On the other hand, the hash function produces a bitmap address, and the algorithm sets this addressed bit to '1'. This algorithm first counts the number of empty bitmap entries. Then it guesses the column cardinality by distributing the count by the bitmap size 'm' and plugging the given result which increases the overall performance of hybrid technique.

III. PROPOSED TECHNIQUE

In the previous section we discussed in detail IB query processing techniques and algorithms. Researchers have introduced different algorithms and techniques for increasing the performance of iceberg query. Some of the existing techniques focus on the SUM (), MIN (), MAX (), AVERAGE (), and COUNT () aggregate functions, such as, bitmap indexing techniques, cubed techniques, AND operation techniques, POP operation techniques, attribute-based techniques, and hybrid algorithm techniques. All these techniques have some limitations, such as, some techniques have the deficiency to occupy more space in memory, some techniques slow down the system performance, some require complex algorithms which are difficult to maintain, and some take more time to produce the required result in a required time. To overcome the limitations of existing techniques to improve the performance of IBQ, an enhanced technique based on, summary table is proposed to improve the IB query performance. This technique improves the running time of the query for searching a specific record and reduces the elapse time. This section aims to discuss the details of the proposed work using summary table's technique for IB query processing to finds out the required result greater than the given TH.

The proposed technique is applied on sample customer tables of different sizes with the same attributes, such as customer identity (Cus_Id), Expense per day (Cus_Exp-per-day), and job (Job). The values of Cus_Id, Cus_Exp-per-day, and Job attributes classify each group, while Cus_Exp-per-day refers to the field on which the aggregate operator Count () is being computed based on a specific TH value. The focus of this work is Count () aggregate function which is applied on (Cus_Exp-per-day) field, the scope of the proposed work is to find expenses of all those customers whose expense is greater than some specified threshold values. The proposed work is better than the existing work in different perspectives. Different summary tables are created in the proposed work and IBQs are used to extract the required results from these summary tables by ignoring scanning whole data sets one by one. As compared to the proposed technique, the state-of-the-art technique was used to scan all the tables for the required data results which slowed down the query processing time. The advantage of our proposed technique is to improve the running time of the query for searching a specific record and reduces the elapse time.

A. *Proposed Architecure*

The proposed architecture is a robust and efficient summary table creation system based on different threshold values for identifying how summary tables are created from the original tables. Fig. 2 draws our novel architecture, which consists of three phases: an Execute1 phase for processing simple IB queries, that is directly applied on original source table for extracting the required dataset, it scan the whole table for the required data set based on a specific threshold value, the drawback of this technique was the requirement of huge amount of processing time which effect the performance efficiency of this technique, in contrast the Execute phase in the mentioned architecture was used to automatically creating summary tables from original table, and then on those summary tables the required query are executed based on a specific threshold value for the required result instead of scanning the whole table. In the proposed architecture only eight summary tables are mentioned for the sake of simplicity these summary tables are used as a source of IB queries, instead of scanning the whole original data set, and the third phase displays the required output of the processed IB query.

B. *Implemetation*

This section describes different techniques that were planned in the preceding section. The first step toward implementation was by taking different target customers tables ranging from 50K to 500k data set, which store customers' related records. In the second step the existing technique is applied to fetch customer's records by using twenty different threshold values ranging from 1k to 20k on each customer's table. Based on the mentioned threshold values, the times taken by the existing technique are recorded and then the average time is calculated for ten run cycle on a given table. The same experiment is repeated ten times for each data set in total. Similarly, the proposed technique is represented in the same way on the same data accordingly and twenty summary tables are created for each target table, that store pre-calculated aggregate results of the COUNT () aggregate function. The proposed technique then considers the threshold values given in the HAVING clause of the IB query and fetches results from the respective summary tables as per the given threshold values.

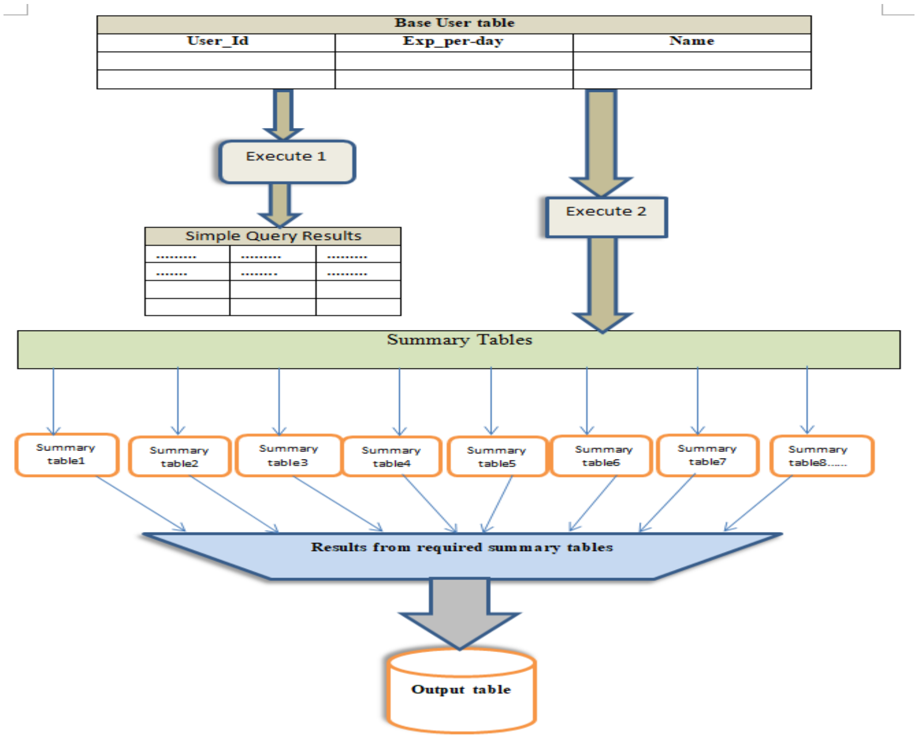

Fig. 2. Proposed architecture.

IV. Result and Analysis

In this section, results obtained during experiments are analyzed. Table III and Fig. 4 represent comparison among existing and proposed techniques based on query performance for different dataset ranging from 50k to 500k. The first column in Table III indicates different data sets, the second and third column correspond to average processing time of both techniques by using ten cycle of run count testing condition on each specific data set accordingly. The “Existing technique time” and “Proposed technique time” represent the average processing time of the existing and proposed IB query by retrieving the required result. The recorded values show high differences in execution times. e.g. when the dataset was 50k, then the corresponding average values of ten count cycle of existing and proposed techniques was about 6.2ms and 1.02ms, similarly for 100k the corresponding values is 6.8ms and 1.1ms, and the same is recorded for the other data sets till to 500k respectively. The above tabulated values are shown in the following Fig. 3 to understand well to the reader, the x-axis represents different datasets and y-axis represents execution time. Then how the execution times of existing and proposed techniques are gradually varying with different datasets.

A. Comparison between Simple and Proposed Techniques

In Table IV, we drawn the comparison between simple and proposed techniques only for one dataset of size 50k, there are nine others different tables is used to store the same comparison used in Table III with different data set (100k, 150k, 200k, 250k, 300k, 350k, 400k, 450k, and 500k) during the whole experiment to record the processing time of both techniques, which is not mentioned in this section due to a large number of comparison. Table IV represents the comparison of “Average of ten run cycle” among simple and proposed query processing. In the Table IV “RECORDS” field represent the number of records in given table, “Cycle of Run Count” represents ten counts of query processing of each proposed and simple technique, “Simple Query Technique” field represent the state-of-the-art technique, “Proposed Query Technique” field represents the proposed technique and “AVERAGE OF ALL” field represent the average time of ten cycle processing of each proposed and simple query technique. To comprehend well to readers, we draw the above tabulated data in graph form which are shown in the following Fig. 4. The x-axis represents the number of processing run count ranging from 1 to 10 cycles, and as well as average of all run count cycles for both simple and proposed techniques, and y-axis represents the execution time in microsecond.

TABLE III. Existing and Proposed Technique Time Interval

Dataset	Existing technique time	Proposed technique time
50K	6.2ms (average time of ten run cycle)	1.02 ms (average time of ten run cycle)
100K	6.8ms	1.1 ms
150K	8.7ms	1.3ms
200K	10.5 ms	1.6 ms
250K	12.5 ms	1.9 ms
300k	14.7 ms	2.1 ms
350K	16.5 ms	2.3 ms
400k	18.3 ms	2.7 ms
450k	20.1 ms	2.9 ms
500k	22.4 ms	3.1 ms

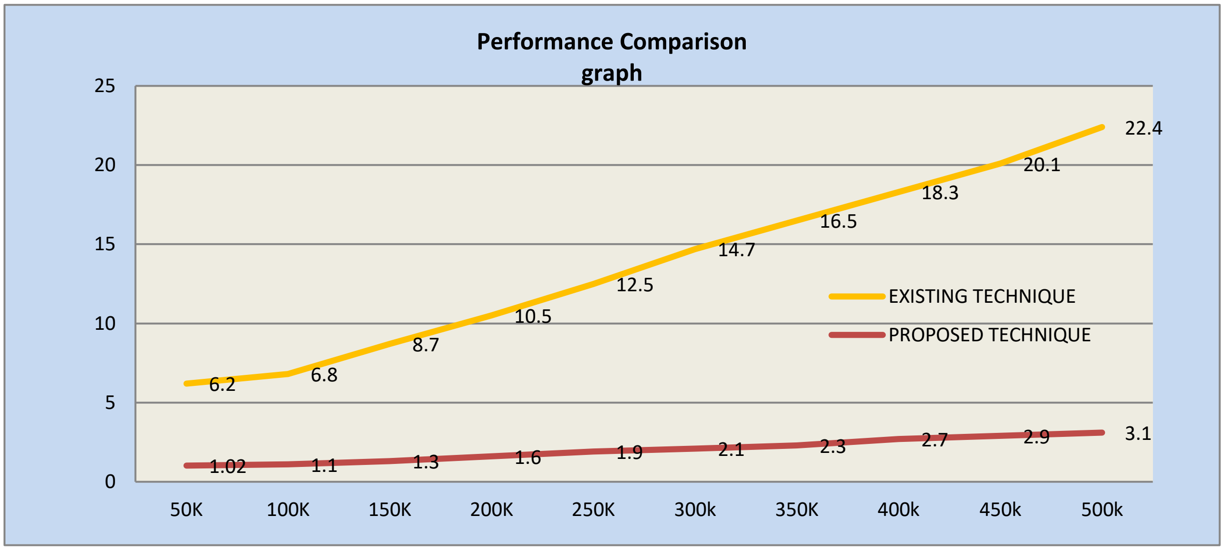

Fig. 3. Performance comparison of existing and proposed techniques.

TABLE IV. COMPARISON OF CYCLE OF RUN COUNT BETWEEN PROPOSED AND EXISTING TECHNIQUE

Table 4	50k Records										
Cycle of Run Count	1	2	3	4	5	6	7	8	9	10	AVERAGE OF ALL
Simple query processing time	6	6.01	6.05	6.07	6.08	6.1	6.3	6.6	6.7	6.9	6.28
Proposed query processing time	1	1.02	1.03	1.05	1.05	1.06	1.08	1.09	1.1	1.4	1.08

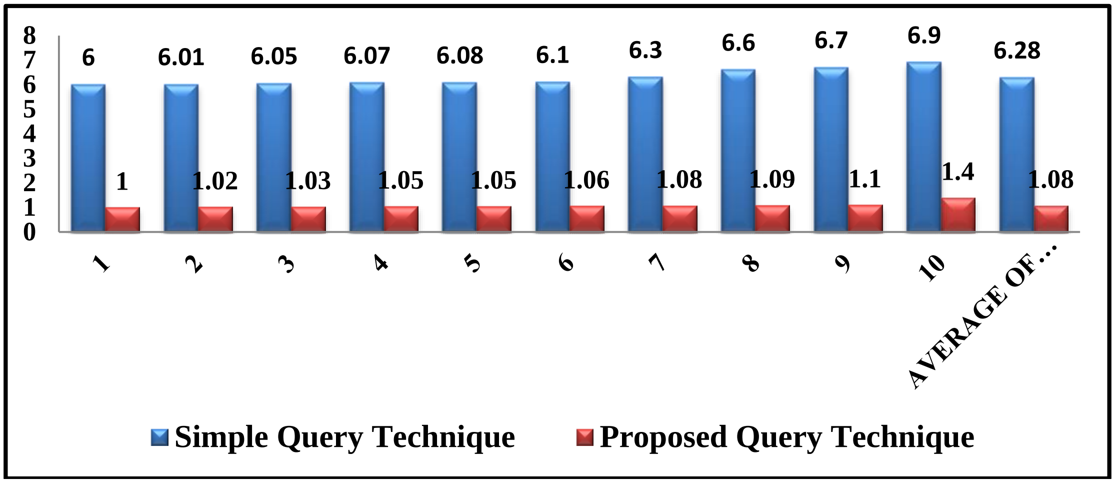

Fig. 4. Comparison of cycle of run Count between existing and proposed technique.

V. CONCLUSION

In this paper, we proposed a summary table technique for processing iceberg queries efficiently. According to IBM 2.5 quintillion bytes of data are generated by different electronic devices on a daily basis. Extraction of useful information from those huge data sets is a well-known challenging problem. From the last few decades most of works have focused to increase the performance of IB queries with respect to time constraint, computing memory, data repositories, computing memories, and data scanning. In this paper our technique is highly simple and different as compared to the previous works based on bitmap indexing and cubed technique. The summary table technique leverages the IB queries at the summary tables; these summary tables are created dynamically from the base table based on different threshold values ranging from 1k to 20k before the execution of queries. At the time of issuing the query, the proposed technique considers the threshold given in the query and fetches the calculated COUNT () aggregation from that specified summary tables as opposed to recalculating the aggregate function from the base table to produce the required results. Our method has improved the main metrics significantly. However, to increase the performance of IB queries in a large dataset is still a big challenge, in the future, this research work focused on the COUNT () aggregate function. In future we would like to extend our work to other aggregate functions such as MAX (), MIN (), SUM (), and AVG (). In this work we only considered the high-level IB queries. Similarly, we would like to continue working on low-level queries as well.

ACKNOWLEDGMENT

The authors would like to thank the University Malaysia Sabah for supporting this research Under the Grant NALS/ SLB2451NALS.

***Abstract*—Blockchain technology holds the potential to revolutionize supply chain management by ensuring transparency, efficiency, and security. This paper presents a detailed examination of blockchain's implementation in supply chain systems, focusing on safeguarding confidential information and preserving supply chain integrity. The method involves extracting 'sales order' data from Walmart's transactional database, which is then encrypted using AES algorithms to protect sensitive details such as client names and geographical information. Utilizing Ethereum's decentralized architecture, smart contracts are employed to manage transactions, encryption, decryption, and access rights. The Ethereum P2P network also aids in data validation and asset preservation, enhancing the system's reliability. Comparative analysis shows that the proposed encryption method, with encryption and decryption times of 2.8 and 3.2 seconds, outperforms traditional methods like RSA and ABE. Implemented in Python, this blockchain-based technique offers a robust, nearly infallible solution that can be applied to various supply chain practices, including Asset Management (AM), Enterprise Asset Management (EAM), and Supply Chain Management (SCM), addressing contemporary challenges and enhancing operational efficiency.**

Keywords*—Blockchain; supply chain management; advanced encryption standard; Ethereum blockchain; data storage

I. Introduction

Fundamentally, a blockchain is a distributed ledger system that statistics transactions on a network of linked nodes in a secure and permanent manner [1]. Blockchain networks function in a decentralized fashion, with every member maintaining a replica of the ledger, in comparison to normal centralized databases, in which facts garage and validation are controlled by using a unmarried authority. The decentralized layout minimizes the possibility of facts modification or illegal get admission to, removes unmarried points of failure, and maintains transparency and robustness. Furthermore, tamper-obvious and immutable, transactions registered on a blockchain are timestamped and cryptographically related [2]. The capability of blockchain technology to allow transactions among individuals without the requirement for middlemen like banks or financial groups is certainly one of its number one characteristic. Blockchain networks offer automatic and accept as true with less transactions between events through the use of smart contracts, which can be agreements that execute themselves with predetermined guidelines and conditions [3]. When certain circumstances are happy, smart contracts run routinely, simplifying operations, reducing prices, and eliminating the want for middlemen. This function of blockchain era has considerable ramifications for sectors like banking, actual property, healthcare, and deliver chain management, where safe and powerful peer-to-peer transactions are vital [4].

Blockchain generation probably clear up lengthy-status problems with transparency, duty, and self-associated with global deliver chains, it has attracted a whole lot of interest in the area of deliver chain management. Blockchain era basically affords a dispersed network of participants with a decentralized, unchangeable ledger to file transactions. This dispensed ledger makes it viable to file all transactions, transportation of commodities, and adjustments in possession in the supply chain ecosystem in a transparent and secure way, that's essential for deliver chain management [5]. Blockchain makes it feasible for all authorized events to access a unmarried source of reality, making an allowance for instant insight into the movement of commodities from the procurement of raw materials to the final customer [6]. The potential of blockchain generation to improve traceability and transparency in supply chain management is one in every of its most important advantages. Businesses may additionally gain a thorough know-how in their deliver chains, which includes the sources of substances required for the method for manufacturing, and the motion of products thru exclusive phases of manufacturing and distribution, through documenting each transaction on a blockchain [7]. Companies that exhibit this diploma of accessibility are better geared up to come across inconsistencies and inefficiencies in addition to react directly to interruptions like recalls of products or first-rate issues. Furthermore, customers can also have by no means-before-seen transparency into the origination and authenticity of merchandise way to blockchain-primarily based deliver chain solutions, for you to boost their self-assurance in corporations [8].

The potential of blockchain era to reduce the opportunity of deception, imitations, and illegal statistics revisions is every other essential benefit for supply chain control. Blockchain statistics are intrinsically tamper-glaring because of their crypto graphical linkage and immutability, which makes it almost tough for malicious actors to change or manipulate transaction statistics covertly. This characteristic of blockchain era is especially useful in sectors like medicines, expensive items, and hospitality, in which product integrity and authenticity are crucial [9]. Additionally, deliver chain techniques is probably automated and streamlined using blockchain technology, increasing productivity and decreasing fees. Automating procedures like processing payments, agreement regulation, and inventory control is possible with clever contracts that are self-executing agreements with predetermined phrases and situations. Blockchain-primarily based clever contracts can decrease transaction prices, remove mistakes, and quicken business enterprise operations by means of getting rid of the want for middlemen and human interaction [10].

There are several blessings to integrating encryption strategies with blockchain generation in supply chain control, from improving facts protection and confidentiality to maintaining the validity and integrity of transaction records [10]. Sensitive statistics, like product specs, fee facts, and patron names, is saved on the blockchain and requires encryption to be secure. Businesses can also enhance the complete safety postures of the deliver chain atmosphere through stopping unwanted get admission to and information breaches through encrypting information before it's far stored at the blockchain [11]. Maintaining confidentiality of records is one of the essential advantages of using encryption strategies in blockchain-based totally deliver chain management [12]. The increasing frequency of statistics breaches and privacy issues in modern digital environment has made it important for corporations running in deliver chains to shield sensitive data. Businesses can use encryption to obscure sensitive data, together with patron names, addresses, and financials, in order that out of doors parties cannot decipher it. This no longer only promotes consider and self-assurance amongst customers, along with purchasers, companions, and regulators, however also aids in complying with information privateness rules like the CCPA and GDPR [13].

Furthermore, by way of protecting records from undesirable changes or tampering efforts, encryption improves the authenticity and integrity of statistics recorded at the blockchain. Each transaction document is given a man or woman fingerprint or virtual signature through cryptographic hashing strategies like SHA-256. These are subsequently encrypted and recorded at the blockchain [14]. These cryptographic signatures assure that any modifications to the records would be fast discovered and characteristic as unchangeable proof of the transaction's legitimacy. Consequently, deliver chain answers primarily based on blockchain and bolstered via encryption methods provide data which are auditable and proof against manipulation, selling accountability and transparency across the deliver chain. Reducing the chance of fraud and counterfeiting is a first-rate gain of incorporating encryption into blockchain-based totally deliver chain management [15]. For each object within the deliver chain, businesses may additionally produce virtual fingerprints which can be verifiable and impervious to tampering via encrypting product identifiers like serial numbers, QR codes, or RFID tags. Stakeholders may also then safely log these encrypted identities at the blockchain, allowing them to affirm the legitimacy and beginning of goods at each step of the supply chain technique. This reduces the danger of fraud and illegal diversion while also assisting groups in monitoring and tracing gadgets with unmatched precision, which in flip enables save you from the boom of counterfeit goods [16].

The key contributions of the proposed system are given as follows:

- The paper sets out the process of implementing blockchain into the supply chain to enhance the processes and offer customers more transparent and coherent data based on Ethereum.
- The sales order data is extracted from Walmart’s transaction history in a methodical manner to construct an extensive data set that is then integrated with blockchain.
- The study uses AES to promote the highest levels of data security; more specifically, the research aims at protecting client names and geographic location details kept in the blockchain network.
- The paper explains how the smart contracts are being used in the proposed SUFS system to manage the transactions in simpler manner, encryption and decryption process and the enforcement of some strict operations and controls.
- The above solution is implemented in Python language with an aim of having a strong, reliable and effective blockchain supply chain management ecosystem that meets supply chain operation in the current world.

The following portions of the chapter are organized as follows. Section II includes an overview of the literature on blockchain technology in supply chain management. The problem statement for the study is presented in Section III. Section IV covers the recommended approach for blockchain technology in supply chain management. Section V compares the method's efficacy to previous techniques, and the performance measures are displayed, along with an explanation of the results. Section VI describes the conclusion.

II. Related Work

Although the food supply chain is one of the areas that blockchain technology has the potential to revolutionize, its deployment is fraught with difficulties. The purpose of this study is to determine and examine the obstacles preventing blockchain from being implemented in food supply chains. After a comprehensive analysis of the literature, 16 main hurdles are found and, with the help of specialists, are further divided into four groups. Then, these obstacles are ranked using the best-worst technique. The results show that organizational and technological limitations are major hindrances to the application of blockchain technology in the food supply chain. To tackle these obstacles, supply chain cooperation must be promoted, blockchain technology must be developed through development and research, and technical proficiency must be increased. However, there are drawbacks, such as the potential for bias in expert judgment and the tendency to overlook specific obstacles throughout the literature review procedure. Despite these drawbacks, the research advances knowledge of how blockchain is being applied in the supply chain and provides policymakers with recommendations on how to remove obstacles and ensure its adoption, especially in emerging economies [17].

The findings advocate that customers apprehend blockchain traceability as especially treasured whilst managing neighbourhood meals assets, leading to extended agree with and pleasant attitudes toward sharing stories [18]. However, on the deliver aspect, regardless of spotting the blessings of blockchain adoption, along with advanced accept as true with, suppliers express reluctance due to inner organizational demanding situations and issues concerning records sharing. While the study provides valuable insights from both consumer and provider perspectives, it's difficult to identify the limitations. These encompass potential biases in player responses and the scope of the examination, which won't absolutely capture all complexities related to blockchain integration in the meals supply chain.

Through a literature assessment and grey Delphi approach, ten CSFs have been identified and analysed, presenting treasured insights for FSC stakeholders [19]. However, it is vital to acknowledge certain barriers on this study. Firstly, the scope of the observation won't encompass all possible CSFs relevant to each FSC context, doubtlessly restricting the generalizability of the findings. Additionally, the gray Delphi method is based on professional critiques, which can also introduce biases or forget about certain perspectives. Furthermore, the gray DEMATEL evaluation affords insights into the significance and causal relationships amongst CSFs however might not capture all nuances of complicated interactions in the FSC ecosystem. However, similar research and practical implementation are had to completely apprehend and address the challenges related to B-IoT adoption in diverse FSC settings [19].

III. Problem Statement

The limitations encompass capability oversights in identifying obstacles, biases in participant responses, and scope constraints that won't absolutely capture the complexities of blockchain integration [17]. To address these obstacles and contribute to ongoing discussions, our look at goals to endorse a novel method for reinforcing traceability and transparency inside the meals deliver chain the usage of blockchain generation. Utilising a mixed-approach method that blends qualitative information and experiments, the aim is to better recognize consumer sentiments on blockchain-enabled traceability and pinpoint manageable answers for providers to recover from adoption hurdles. The recommended technique in the long run seeks to shut the space among theoretical knowledge and real-international software, establishing up the possibility for a supply chain that adopts blockchain era more efficaciously and sustainably.

The limitations of the literatures are given in Table I.

TABLE I. LIMITATIONS OF LITERATURE

Source	Limitation	How to Overcome
[17]	Expert judgment may be biased, and experts may fail to identify certain challenges because they do not think of them as significant barriers to success.	To minimize bias and omissions, employ pluralism of voices from various experts and compare conclusions to current research, implementing empirical evidence.
[18]	Convincing of suppliers may be hampered by internal organizational issues and inclusive of data sharing.	There is a need to develop and ensure the sharing of data through blockchain with the goal of rebuilding trust in sharing data between organizations.
[19]	There are biases in Gray Delphi method and the relationships between CSFs can be complex, detailed, subtleties may not be identified.	Number different studies and use both qualitative and quantitative research to focus on a broader range of factors affecting FSC.

IV. Proposed Blockchain Integration in Supply Chain Management

The technique employed in this examine initiates with the meticulous collection of critical sales order information sourced from Walmart's tremendous transaction facts, encapsulating pivotal details along with order ID, dates, customer identity, and complete product statistics. Following this initial section, robust information encryption strategies, specially leveraging the AES algorithm, are judiciously applied to make stronger the safety of touchy facts which includes customer identities and geographical records, thereby safeguarding privateness and confidentiality in the course of the complete deliver chain manner. Subsequent to the encryption system, a meticulous crafting of blockchain architecture ensues, harnessing the robust skills of the Ethereum blockchain renowned for its decentralized framework and sensible agreement functionalities, thereby fortifying the transparency and resilience of the supply chain infrastructure. Integral to this system is the strategic improvement of smart contracts designed to orchestrate seamless transactions, data encryption/decryption methods, and stringent access manipulate mechanisms in the blockchain community, thereby imposing predefined policies and authorizations pivotal for ensuring supply chain integrity. The implementation phase entails the configuration of nodes meticulously, fostering an environment conducive to strong facts garage, validation, and get admission to manipulate, capitalizing on the inherently fault-tolerant and resilient structure inherent within Ethereum's peer-to-peer community infrastructure. Post-integration, the encrypted sales order data seamlessly will become part of the blockchain network fabric, with each transaction meticulously tracked and securely saved throughout distributed nodes, as a consequence ensuring redundancy, records integrity, and utmost confidentiality paramount to the sanctity of deliver chain operations. The incorporation of rigorous access control mechanisms and stringent authentication protocols further fortifies the safety and privateness paradigm, ensuring that simplest duly legal employees are endowed with decryption keys or privileged get entry to, as a result fostering a fortified ecosystem bolstered via current blockchain era. Track the Order

Fig. 1. Overall architecture of the proposed system.

A. Data Collection

The dataset being shared includes giant income order statistics that were extracted from Walmart's extensive transaction statistics. It consists of all of the vital statistics, which include the order ID, the dates of the order and shipping, the consumer's identity, geographical data (United States, city, and nation), and specified product facts (call, type). Every access inside the dataset corresponds to a distinct income transaction, imparting a wealth of facts this is crucial for interpreting the complex dynamics of the supply chain and purchaser interactions within the retail environment. Furthermore, this observation targets to shed mild on the interesting opportunities of blockchain era in enhancing accountability, effectiveness, and safety all through the numerous delivery chain tiers via the prism of Walmart's transactional facts [20].

B. Data Encryption with AES Algorithm

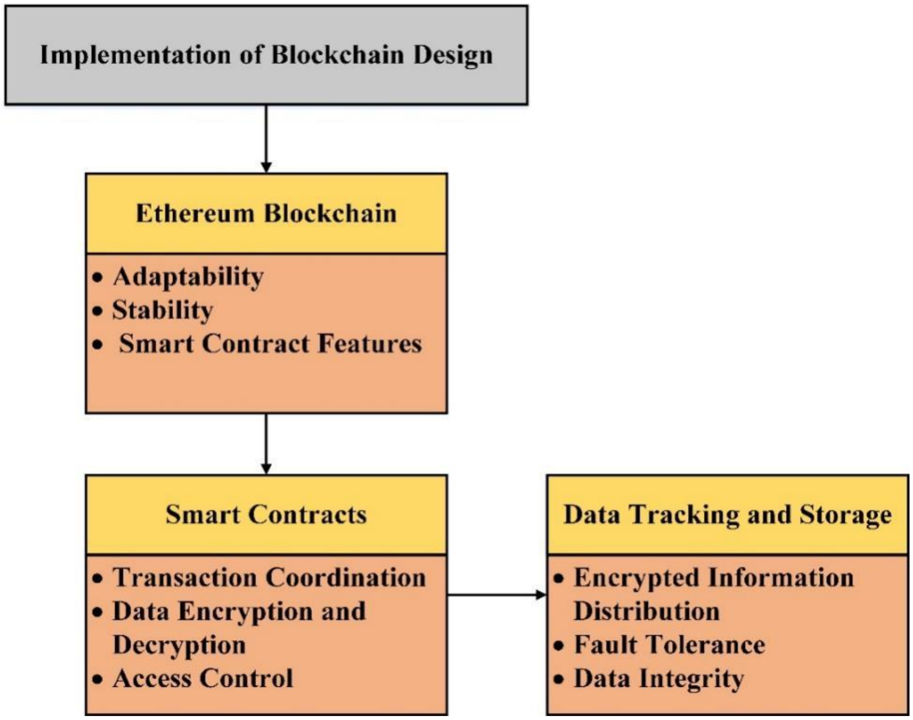
In the context of deliver chain management, information encryption is critical for making certain the safety and privacy of personal records. AES uses a symmetrical key for decryption in addition to encryption, working with constant-length facts blocks. Blocks of plaintext statistics, typically 128 bits in size, are fed into the AES algorithm and converted thru a chain of encryption rounds. In order to efficiently obscure the original information, these rounds entail crucial enlargement, alternative, diversifications, and mixing operations achieved in a selected order. The initiation of the encryption key, which controls how plaintext blocks are converted into ciphertext, starts offevolved the encryption system. Every encryption spherical makes use of a different key thanks to the key growth process, which turns the initial encryption key into a series of spherical keys.

Sensitive facts fields in our dataset, along with consumer names and region records, are encrypted earlier than being recorded inside the blockchain. For example, the AES technique is used to transform the customer's name area, that's represented as a string of letters, into ciphertext. In a comparable vein, location facts that includes the nation, city, and country is encrypted to shield against manipulation or illegal get admission to. The observation makes certain that only those with authorization possessing the decryption key might also decode the encrypted records by way of encrypting those critical regions. Depending on the required level of security, a random encryption key with a period of 128, 192, or 256 bits is generated as a part of the encryption method. The plaintext statistics blocks are in the end encrypted the use of this encryption key and the AES method. The resultant ciphertext, which incorporates place statistics and encrypted consumer names, is then accurately saved on the blockchain, defensive personal records from malevolent use or illegal get admission to.

C. Implementation of Blockchain Design

A thorough technique is required whilst designing and deploying a blockchain infrastructure which addresses the need to store encrypted customer records and income order records. The look at chooses the Ethereum blockchain for this have a look at because of its adaptability, balance, and wealthy clever agreement capabilities. Each of the interconnecting blocks that make up our blockchain shape consists of encrypted sales order statistics alongside associated records. Transparency, immutability, and decentralization are upheld through the shape, ensuring the security and integrity of records this is saved. Within the blockchain network, clever contracts are essential to the coordination of transactions, statistics encryption/decryption processes, and get entry to control structures. By automating the enforcement of present norms and regulations, these self-executing contracts reduce the want for 542 and improve the productiveness of operations. Smart contracts are cautiously crafted within our Ethereum-based blockchain to govern every side of the supply chain management technique, which includes order processing, privateness protection, and get entry to control. Smart contracts provide for the steady garage of encrypted data, the validation of transactions, and the enforcement of access privileges in accordance with pre-installed tips and authorizations.

The setup of nodes for storage of records, confirmation, and get entry to manipulate is an essential step in the blockchain community implementation technique. Because of Ethereum's decentralized structure, fault tolerance and resilience are extended as coordinated variations of the blockchain are maintained through nodes at some stage in the network. Nodes are in charge of distributing sparkling blocks around the community, carrying out smart contracts, and verifying transactions. Nodes reach a consensus on the legitimacy of transactions and the inclusion of latest blocks to the blockchain using consensus strategies like Proof of Work (PoW) or Proof of Stake (PoS). The blockchain network's typical security is progressed and the opportunity of remoted factors of failure is reduced in step with this disbursed consensus approach. Robust cryptographic techniques, like AES, are used to first encrypt patron facts and sales order information. After that, the generated ciphertext is blanketed into transaction payloads and despatched to the Ethereum community to be blanketed in blocks. In order to assure that best the ones people with the essential decryption keys may get right of entry to and decode the encrypted information, smart contracts are in charge of approving and finishing these transactions. Furthermore, clever contracts' integrated get entry to manage mechanisms enforce rights and permissions, prohibiting unauthorized events from gaining access to or altering touchy statistics. Fig. 2 shows the Blockchain Implementation Architecture.



Implementation of Blockchain Design
Ethereum Blockchain
• Adaptability
• Stability
• Smart Contract Features
Smart Contracts
• Transaction Coordination
• Data Encryption and Decryption
• Access Control
Data Tracking and Storage
• Encrypted Information Distribution
• Fault Tolerance
• Data Integrity

Fig. 2. Blockchain implementation architecture.

The structure of the blockchain network makes positive that encrypted data is dispersed throughout several nodes, improving fault tolerance and redundancy. Every node keeps an encrypted replica of the blockchain, which makes retrieval of records and validation less difficult. Data integrity is maintained the usage of cryptographic hashing techniques, which permit nodes to verify the consistency of information stored. Moreover, the blockchain's immutability guarantees that encrypted statistics cannot be changed or tampered with as soon as it's miles saved, making sure the integrity and validity of client and sales order facts. Implementing Ethereum-based clever contracts involves setting up positive capabilities and common sense inside the agreement code to handle information encryption and decryption methods. Encrypted statistics and decryption keys from structures or users with permission are despatched to clever contracts as enter parameters. By the usage of decryption methods to free up the facts that has been encrypted, those contracts make certain that best individuals with permission may view the plaintext information. Smart agreement-included get right of entry to control techniques put into effect authentication and authorization requirements, limiting unwanted usage of confidential facts. Solidity, the Turing-entire programming language utilized by Ethereum, lets in developers to include complex encryption and decryption good judgment into smart contracts, ensuring robust protection protocols for the duration of the blockchain network.

Ethereum has a peer-to-peer community design wherein nodes are configured for records storage and validation, with every node keeping an archive of the blockchain ledger. Nodes ensure that everybody at the community is in settlement on the blockchain's contemporary popularity through validating transactions and carrying out smart contracts. Nodes can upload extra blocks to the blockchain with the aid of together deciding on the authenticity of transactions the use of strategies like PoW or PoS. The blockchain community's protection and resilience are improved by way of this decentralized validation manner, which reduces the opportunity of malicious attempts or single points of failure. The blockchain community's get entry to manage structures impose authentication and authorization requirements to control get admission to encrypted statistics. Access manipulates common sense incorporated in smart contracts establishes roles, credentials, and verification protocols, making sure that touchy facts might also handiest be accessed by legal individuals or systems. Cryptographic signatures, digital credentials, and multi-factor authentication protocols are examples of authentication structures that provide strong safety against undesirable entry. The blockchain network strictly controls access to records by enforcing access control policies within smart contracts, enhancing security and privacy.

D. Data Tracking and Storage

For income order records to be integrated with the blockchain community, the blockchain platform and the cutting-edge facts assets need to create a continuing interplay. Before being despatched to the blockchain network, the sales order data which incorporates the order ID, order date, shipping date, consumer records, product facts, and sales metrics is encrypted making use of sturdy cryptographic techniques like AES. Every sales order transaction is precisely documented at the blockchain as a brand-new block, with the encrypted statistics payloads appropriately saved interior. By the usage of this approach, the blockchain operates as an unchangeable ledger, making it viable to follow income order transactions transparently and without interference throughout the supply chain. Within the blockchain community, the encrypted purchase order facts is correctly stored throughout dispersed nodes, guaranteeing statistics integrity, redundancy, and secrecy. Because each node in the community incorporates an exact replica of the blockchain ledger, tolerance to failure and resilience are increased. Nodes use consensus techniques to determine among themselves whether or not additional transactions and blocks are valid, ensuring that simplest encrypted and authenticated statistics gets uploaded to the blockchain. This distributed storage layout spreads the encrypted statistics over several nodes, decreasing the opportunity of data loss or modification by using hostile parties. The observe guarantees the integrity and protection of sales order records on the safe, decentralized blockchain community by using following nice practices for blockchain facts garage and encryption.

To conclude, it is suggested that blockchain also has several more roles for areas other than transactional security in supply chain management. In supply chain management, blockchain can offer total visibility, which will help to track goods throughout the supply chain in real time and minimize instances of fraud. It can also make the stock control more efficient as it can provide an uninterruputed and secure record of the stock level and any movements of products thus minimizing on errors, excessive stocking, and running out of stock. In procurement, smart contracts can enable automation of the procurement processes by ordering more stocks and or restocking whenever certain conditions are met. Also in the vendor relationships blockchain technology underlines the improved trust and cooperation through recording all the interactions, contracts, and payments in the ledger avoiding conflicts. In the same manner, blockchain can also help provide an unalterable method of logging quality checks and certifications for compliance purposes to improve business relations with vendors. In conclusion, the use of blockchain can potentially enhance the functional supply chain areas by automating and enhancing the security and verification of supply chain activities.

V. Results and Discussion

In this section, the end result and discussion of the proposed model are given. The method commences with complete information collection from Walmart's transaction information, taking pictures important sales order details like order ID, dates, customer statistics, and product specifics, forming the muse for blockchain integration in supply chain control. Following data acquisition, robust encryption strategies, significantly leveraging AES, are implemented to protect sensitive data such as consumer identities and geographical information, ensuring privacy at some point in the supply chain procedure. Integral to this system is the development of smart contracts orchestrating transactions, encryption/decryption approaches, and get right of entry to controls, enforcing predefined policies to preserve supply chain integrity. Implementation involves configuring nodes to facilitate sturdy facts garage, validation, and access control inside Ethereum's fault-tolerant peer-to-peer network infrastructure. Post-integration, encrypted income order facts seamlessly integrates into the blockchain, with each transaction meticulously tracked and securely saved across dispensed nodes, ensuring redundancy, integrity, and confidentiality. The incorporation of stringent get admission to control mechanisms and authentication protocols similarly fortifies safety and privacy, proscribing get right of entry to authorized employees and bolstering the atmosphere's resilience.

TABLE II. Memory Usage

Algorithm	Memory Used (mb)
ABE [21]	0.107
RSA [22]	0.186
Proposed AES	0.0088

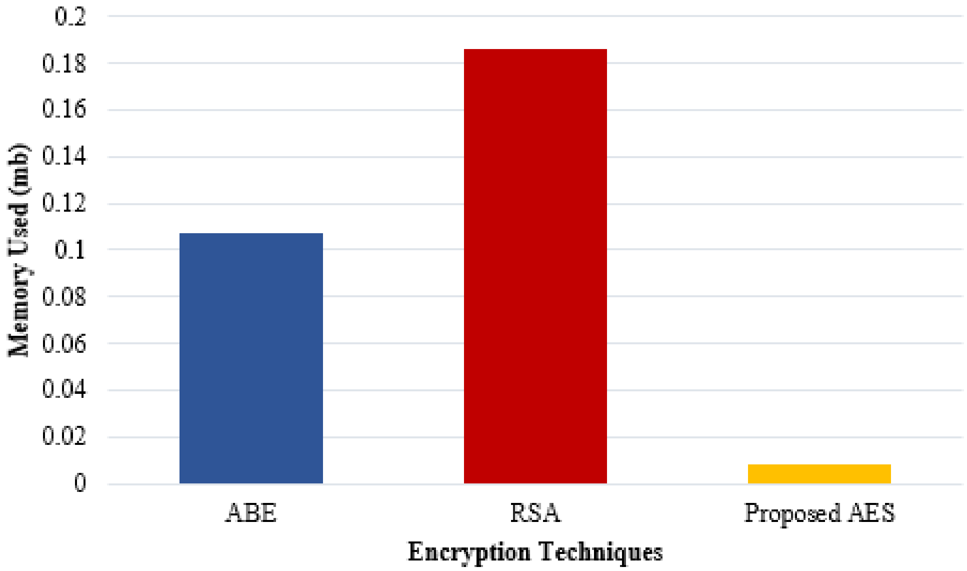


Fig. 3. Memory usage.

Table II and Fig. 3 presents a comparative evaluation of memory area consumption for extraordinary encryption algorithms, such as Attribute-Based Encryption (ABE), RSA (Rivest-Shamir-Adleman), and the proposed AES (Advanced Encryption Standard). The reminiscence utilization, measured in megabytes (mb), is indexed for each set of rules, showcasing their respective performance in phrases of memory intake. ABE, which is known for its versatility in getting right of entry to control mechanisms based on attributes, utilizes zero.107 mb of memory, indicating a mild degree of memory usage. In assessment, RSA, an extensively used uneven encryption set of rules, reveals a higher reminiscence footprint of 0.186 mb, suggesting pretty better memory requirements as compared to ABE. Notably, the proposed AES algorithm, regarded for its efficiency, simplicity, and strong encryption competencies, demonstrates a drastic decrease in memory usage at 0.0088 mb, making it the most memory-efficient encryption algorithm among the three.

TABLE III. Comparison of Encryption and Decryption Time with Different Encryption Algorithms

Algorithm	Encryption Time (sec)	Decryption Time (sec)
ABE [21]	7.5	5.2
RSA [22]	6.7	7.3
Proposed AES	2.8	3.2

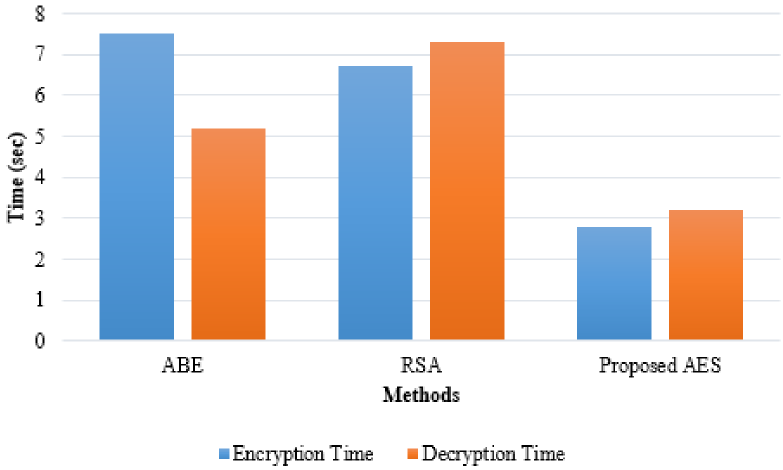

Fig. 4. Comparison of encryption and decryption time with different encryption algorithms.

Table III and Fig. 4 gives a complete evaluation of encryption and decryption instances associated with distinctive encryption algorithms, together with ABE, RSA, and the proposed AES. The Table showcases the time taken for encryption and decryption operations in seconds for every set of guidelines, offering insights into their respective efficiency in phrases of processing pace. ABE, famed for its characteristic-based get entry to manipulate mechanisms, demonstrates an encryption time of 7.5 seconds and a decryption time of 5.2 seconds, indicating slight overall performance in phrases of processing velocity. On the other hand, RSA, a standard asymmetric encryption algorithm, exhibits an encryption time of 6.7 seconds and a decryption time of 7.3 seconds, reflecting slightly faster encryption but slower decryption in comparison to ABE. Notably, the reposed AES algorithm, known for its velocity and efficiency in encryption and decryption, outperforms both ABE and RSA, with encryption and decryption instances of 2.8 seconds and 3.2 seconds, respectively. This highlights AES as the most efficient algorithm in terms of processing speed among the three.

TABLE IV. ENCRYPTION TIME VS. KEY NUMBERS OF DIFFERENT ALGORITHMS

Keys Number	ABE (ms)	RSA (ms)	Proposed AES (ms)
1	3.10	1.3	0.06
2	4.97	1.78	0.36
3	5.99	2.84	1.2
4	6.88	5.88	2.4

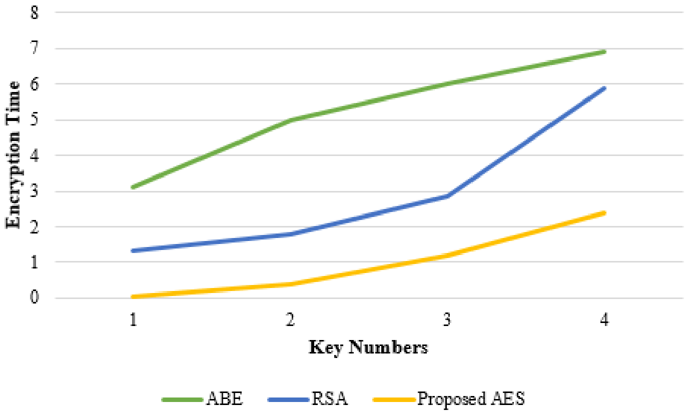

Fig. 5. Encryption time vs. key number of different algorithms.

The Table IV and Fig. 5 illustrates the encryption time in milliseconds for every set of rules primarily based on varying key numbers, ranging from 1 to 4 keys. Each row corresponds to a particular quantity of keys, even as the columns constitute the encryption time in milliseconds for ABE, RSA, and the proposed AES algorithm, respectively. For ABE, encryption time will increase progressively because the range of keys rises, indicating a linear dating between encryption time and key range. Similarly, RSA exhibits a proportional boom in encryption time with the addition of keys, although the price of growth seems barely steeper as compared to ABE. In comparison, the proposed AES algorithm demonstrates a drastic decrease in encryption instances throughout all key numbers, showcasing its performance and scalability in handling encryption responsibilities despite multiple keys.

TABLE V. COMPARISON OF BUFFER TIME WITH DIFFERENT ENCRYPTION ALGORITHMS

Algorithm	Buffer Time (mb)
ABE [21]	0.154
RSA [22]	0.165
Proposed AES	0.147

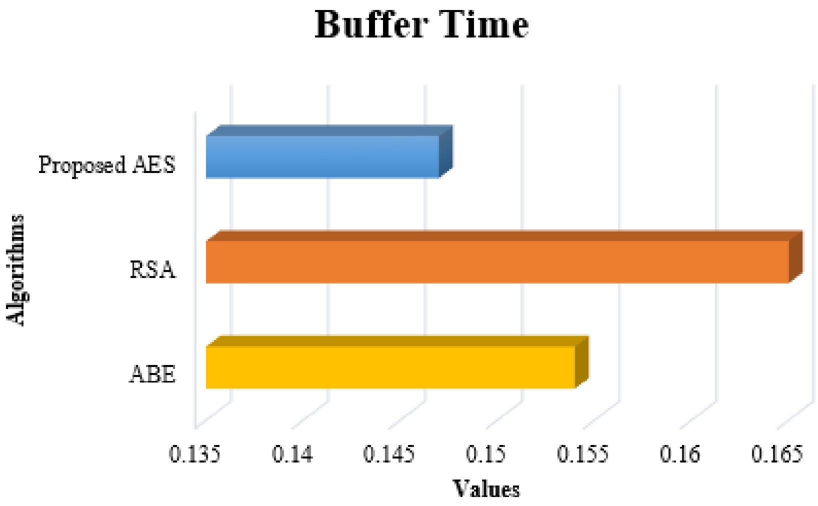

Fig. 6. Comparison of buffer time with different encryption algorithms.

Table V and Fig. 6 affords a comparative analysis of buffer time, measured in megabytes (mb), throughout exceptional encryption algorithms, including ABE, RSA, and the proposed AES. Buffer time refers to the amount of reminiscence space ate up via each algorithm in the course of encryption methods. Each row in the table represents a specific encryption algorithm, whilst the corresponding column displays the buffer time in megabytes for ABE, RSA, and the proposed AES algorithm, respectively. In comparison, ABE and RSA showcase slightly better buffer instances of 0.154 mb and 0.165 mb, respectively.

TABLE VI. SECURITY COMPARISON OF DIFFERENT ALGORITHMS

Algorithm	Security
ABE [21]	14
RSA [22]	19
Hybrid ABE-DES	22
Proposed AES	45

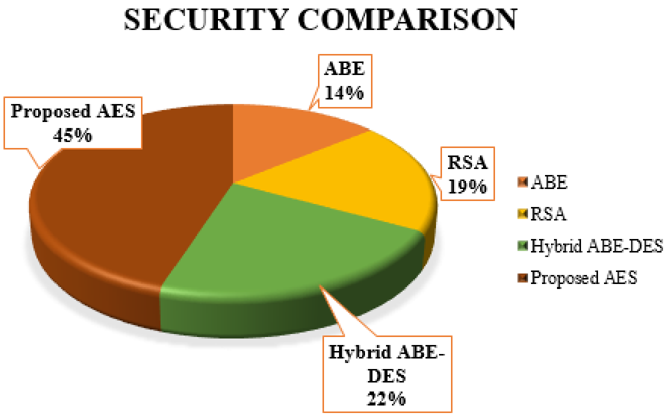

Fig. 7. Security comparison of different algorithms.

Table VI and Fig. 7 each row inside the desk represents a specific encryption set of rules, while the corresponding column presents the assigned protection score. In comparison, ABE and RSA showcase comparatively decreased safety ratings of 14 and 19, respectively. The Hybrid ABE-DES algorithm falls in between, with a security score of 22.

A. *Discussion*

The technique starts with thorough information collection from Walmart's transaction information, followed by using the implementation of sturdy encryption techniques the usage of AES to protect touchy data for the duration of the delivery chain method. Subsequently, the blockchain architecture is meticulously designed, leveraging Ethereum's decentralized framework and clever agreement talents to decorate transparency and resilience. The integration of encrypted income order facts into the blockchain network guarantees redundancy, integrity, and confidentiality, with stringent get entry to control mechanisms similarly fortifying protection and privateness.

The outcomes show that the new form of AES entropy is better than previous methods of ABE and RSA regarding the buffer time with 0.147MB being higher than 0.154MB and 0.165 MB respectively. Such a reduction in buffer time shows that there is an enhancement of efficiency in data processing, which plays a significant role in line with the real-time supply chain management systems. Although both ABE and RSA have strong encryption capacities, they are likely to result in high latency and the extra use of computational power. The above proposed AES method has the strength of delivering good encryption to meet the demands of client data and other geographic information as well as a faster encryption and decryption than other algorithms which makes it suitable for large volumes of transactions common in the supply chain networks. This improvement makes the system to be more efficient and scalable in handling the requirements of today’s supply chain processes.

The integration of blockchain in supply chain confronts a number of real-life impediments and hurdles. First, the adoption of blockchain is not easy as most of the supply chain network still operates with centralized databases which pose integration issues and cost-effectiveness. Interconnectivity between these systems and blockchain solutions such as Ethereum might entail substantial modifications on the technical level. Furthermore, the factors of the scalability and flexibility of blockchain are an issue that could be an issue, especially for the extensively large volume and global supply chains that may overwork the blockchain processing power and storage. Another issue is the potential high cost of establishing and sustaining decentralized nodes and smart contracts that may be out of reach for some businesses. It is also true that security is both a strength and a weakness where, while the use of blockchain improves the security of data stored in a network, smart contract errors or weak encryption algorithms can put the system at risk. Last, there may be reluctance by organizations to embrace blockchain due to its decentralized nature a move that may not be embraced by individuals within notable supply chain management organizations especially those who are used to the traditional means of operations.

VI. CONCLUSION AND FUTURE WORK

The use of blockchain technology in the supply chain is an innovation towards improving on the supply chain operations. This paper shows that the supply chain can be improved by implementing blockchain technology, specifically using Ethereum, where transparency in supply chain, decentralisation and smart contracts may enhance data security and supply chain functionality. The AES algorithm for encrypting information that are deemed sensitive including the clients' names and geographic details, adds high degrees of privacy and protection. In addition to that the adoption of the PayPal's peer-to-peer network enhances the transparency as well as the solidity of the entire supply chain in allowing for efficient, secure and accurate transactions while at the same time ensuring proper controlling of access. Blockchain approach also successfully solves some of the major problems like maintenance of supply chain by integrating encrypted sales order data with supply chain system. The employed encryption method demonstrates enhanced efficiency to RSA and ABE where especially the encryption and decryption time is considered. The technique that was created in Python also elevates security within supply chain functions while actively responding to the consciousness changes that are rampant within supply chain management. There is scope for further research relating to this paper as highlighted next and below: First, the additional use of other emergent trends in supply chain management like artificial intelligence, the internet of things in combination with blockchain technology might add more value to the situation and help to predict the supply chain problems better. However, it is also vital to understand whether such a solution would work in larger and more complex supply chains would be important and further research on this solution. Additional research could also work on the effects of a variety of applications of blockchain platforms and various encryption styles on effects and security. In addition, identifying and solving threat and risks factors concerning regulations and compliances related to the use of blockchain technology in different parts of the world will be crucial for its adoption. Lastly, real-life supply chain examples and pilot adoption can be used as follows in order to give practical examples of the effectiveness of using blockchain in supply chain management and to put a light on the practical issues and implementation barriers.

Abstract*—This research paper provides innovative approaches to support financial prediction, or it is a different kind of economic prediction that extends over collecting different economic information. Financial prediction is a concept that has been employed. The present study offers a unique approach to predicting finances by integrating many financial issues utilizing a cross-stitch hybrid approach. The method uses information from several financial databases, including market data, corporate reports, and macroeconomic indicators, to create a comprehensive dataset. Employing MinMax normalization the features are equally scaled to provide uniform input for the algorithm. The combination of Convolutional Neural Network (CNN) and Long Short-Term Memory (LSTM) systems form the basis of the framework. To understand the time-dependent nature of financial information, LSTM networks (long short-term memory) are utilized to record and simulate the temporal interactions and patterns. Concurrently, spatial features are extracted using CNNs; these components help identify patterns that are difficult to identify with conventional techniques. Better handling of risks, more optimal approaches to investing, and more informed decision-making are made possible by the enhanced forecasting potential that this method—which is described above—offers. Potential pilot studies will focus on innovative uses in financial decision-making and advancements in cross-stitching structure. This paper proposes a sophisticated approach that can help stakeholders, such as investors, analysts of data, and other financial intermediaries, traverse the complexities of financial markets.

Keywords*—*Cross-Stitch Hybrid Networks; predictive modelling; LSTM networks; convolutional neural networks; financial analysis

I. Introduction

The system of assessing financial markets and investment possibilities the usage of statistical and mathematical techniques is known as quantitative monetary analysis [1]. Stochastic models take uncertainty and unpredictability into attention, whereas econometric models—which include time collection models and regression analysis—assist in determining correlations among monetary variables [2]. Complex patterns in statistics are captured via gadgets gaining knowledge of and deep getting to know strategies like LSTM networks and Convolutional Neural Networks. Predictive overall performance is advanced when gadget mastering algorithms are combined with traditional econometric strategies [3].

Applications consist of portfolio optimization to select the top-rated asset blend, credit scoring to decide creditworthiness, and algorithmic buying and selling, which makes use of quantitative techniques for automated trading techniques [4]. Among the blessings of quantitative evaluation are expanded hazard minimization, objectivity, efficiency, and accuracy. But there are boundaries to conquer, such as the intricacy of the facts, overfitting of the model, and the requirement to regulate changing markets. As well known, the quantitative economic analysis combines economics, mathematics, and information technology to enhance market forecasting, risk management, and funding picks.

DL techniques are very beneficial for financial facts analysis due to the fact they can model noisy, complicated, and high-dimensional time-series statistics, particularly RNNs [5]. RNNs, in comparison to traditional neural networks, are ready with recurrent connections that allow them to leverage the version's memory feature to seize temporal relationships via remembering and making use of earlier facts to modern-day output computations. To introduce nonlinearity and capture complex patterns, input variables in RNNs are mixed with matching weights and a bias time period, exceeded via an aggregate feature, after which processed via a nonlinear activation characteristic [6]. RNNs can control the sequential structure of economic facts due to the fact to this layout, which makes them suitable for tasks like price forecasting, trend evaluation, and volatility prediction.

In financial analysis, the CNN-LSTM Cross-Stitch is an effective aggregate that combines the temporal modelling skills of LSTM networks with the spatial characteristic extraction competencies of CNNs [7]. By identifying localized features, these layers correctly lower the dimensionality of the incoming information at the same time as emphasizing vital components. These spatial factors are then processed via the LSTM thing, which then information the temporal linkages and lengthy-term dependencies present in sequential monetary records. The LSTM network is an effective device for modelling sequential statistics by using reminiscence cells and gating mechanisms. The CNN-LSTM Cross-Stitch gives a synergistic mixture that allows for a complete approach to financial assessment.

- To improve quantitative economic research, the paper suggests a system that combines CNNs for time dependence and LSTMs for spatial feature extraction.
- It allows for a comprehensive assessment of economic performance by integrating a variety of financial data, such as macroeconomic indicators, market data, and business financial statements.
- By ensuring appropriate feature scaling through the application of Min-Max normalization, high-magnitude features are not allowed to predominate during model training.
- Through the utilization of CNNs and LSTMs' respective advantages, this structure offers an effective instrument for examining intricate financial information.
- The study's architecture efficiently captures both temporal and geographic trends in financial data, enabling precise market trend forecasting.

The paper's structure is organized as follows: Section II conducts a literature review, summarizing existing research relevant to the study's topic. Section III articulates the problem statement, addressed in the study. In Section IV, the proposed methodology is presented, outlining the approach and techniques employed to address the problem statement. Section V presents the findings of the study. Finally, Section VI concludes the paper, discussing limitations, and suggesting avenues for future research.

II. Literature Review

In order to train a BPN for predicting corporation disasters, the hybrid economic analysis model provided in this paper makes use of financial ratios as its main inputs and consists of both static and technique evaluation models [8]. The model, which gives a higher prediction charge, outperforms discriminant analysis, choice timber, and a solo BPN in the usage of four datasets of Taiwanese enterprises. The version's education on region-particular records, potential problems in generalizing to different industries or areas, issues with complexity and interpretability, the opportunity of overfitting, the reliance on fantastic historical facts for technique evaluation, and the capability omission of important external monetary factors should, nevertheless, limit the version's applicability.

The examine makes use of a hybrid simulation method that combines a multi-duration simulation model that integrates a MRPII machine in Microsoft Excel with a manufacturing surroundings in ProModel and makes use of Microsoft Visual Basic to synchronize agenda dissemination and inventory updates to investigate the damaging consequences of different accounting strategies on mentioned profits throughout lean manufacturing implementation [9]. The use of simulation techniques, which may not accurately replicate the intricacies of actual lifestyles, potential biases in the choice of accounting techniques, and the emphasis on certain inventory reduction prices which won't practice to other groups or operational contexts are a number of the drawbacks.

There are three steps to the method: what first, preprocessing and denoising the data using WT; second, prediction of deconstructed data using SVM, RNN, and NB; and third, incorporating these predictions into the GA and WA methods [10]. On lots of information types, this version performs drastically higher than benchmark techniques and unmarried strategies. However, its computational requirements and complexity may additionally restriction realistic packages and may require heavy parameter modifications Moreover, even if the model performed well on the tested data, it is not immediately sensitive to external variables affecting stock prices such as political developments or prevailing economic conditions.

The take a look at provides a sturdy framework for excessive-accuracy inventory rate forecasting based on DL of-based regression techniques [11]. It makes use of ancient inventory rate facts from an Indian agency listed at the NSE that were recorded at five-minute intervals. The framework consists of five LSTM techniques and four CNN techniques. The models are proven and examined the use of metrics for execution time and RMSE. Although exhibiting superb consequences, the approach has drawbacks inclusive of dependence on extraordinarily distinct information, extensive processing overhead, and viable non-generalizability to different stocks or market instances. Additionally, the techniques might not fully recollect outdoor variables like geopolitical events or economic news, and the evaluation metrics won't completely mirror real-global trading dynamics.

In order to dynamically compare financial dangers and strategies, the research proposes a flexible DFA model framework for the nonlife insurance marketplace [12]. It does this by means of integrating not unusual components determined in many DFA models. The framework's trustworthy implementation and amendment to precise enterprise needs are made viable by way of its mathematical description. The method isn't without flaws, although, it including the issue of combining disparate principles, which requires an excessive stage of information and processing power and can make it less available to smaller organizations. Personalization can take a whole lot of time, and relying an excessive amount on previous statistics ought to lead to biases if ancient patterns aren't dependable indicators of future conduct. Furthermore, the efficacy of the model is contingent upon the quality of the accessible data and may fail to account for certain elements pertinent to particular categories of nonlife insurance or distinct nearby market dynamics.

In order to expect time collection, the have a look at looks into BiLSTM networks and compares them to unidirectional LSTM and ARIMA techniques [13]. It is hypothesised that BiLSTMs, with its dual-directional facts processing competencies, can boom prediction accuracy by using advanced training abilities. The look at its findings guides the concept that, despite the fact that taking longer to reap equilibrium, BiLSTMs carry out more correctly than both ARIMA and unidirectional LSTM techniques. BiLSTMs perform higher, but they take longer and demand extra pc power, that could limit their use in actual-time packages. Furthermore, the study does not investigate hybrid models or other sophisticated neural networks, and its findings could not apply to all kinds of time series data. Furthermore, features of interpretability and practical implementation both crucial for real-world applications are not fully explored.

The paper's suggested approach entails a methodical examination and arrangement of the historical evolution of financial analysis, emphasizing the contributions of international experts and identifying the most important non-financial and financial aspects affecting company value. By contrasting theoretical valuations with real market results, it critically evaluates conventional valuation techniques, pointing out inconsistencies and possible weaknesses. The study makes recommendations for further research to increase these valuation methodologies' precision and dependability. The potential risk of flaws in historical literature, the simplicity of the explanation at the expense of the basic relationships among variables, and the possibility of extraneous factors not included in the computations all suggest that the approach may not be flawless. Furthermore, the changes would undoubtedly need appropriate empirical confirmation. The research is broad and might not go deep enough in certain areas, therefore it might provide thorough answers to financial assessment and valuation procedures in some areas but not in others.

The research articles under evaluation examine a range of cutting-edge approaches for anticipating financial results and tackling major issues in financial analysis and forecasting. When applied to Taiwanese companies, the first look at's hybrid monetary evaluation model which mixes monetary ratios with BPN shows higher accuracy in predicting firm screw ups than greater traditional models like discriminant evaluation and selection bushes [14]. It highlights the financial effects however has limits in phrases of version realism and generalizability.

III. Problem Statement

Current approaches have notable shortcomings that affect their capacity for generalization and economic usefulness, despite advancements in financial projections and risk forecasting. In hybridized models of economics, for example, ratios of finance and BPN combine to forecast company losses more accurately than previous models [8]. However, these frameworks have problems expanding across sectors and geographical areas, and they may overfit historical data. Correspondingly, the simulation techniques used to assess lean manufacturing and accounting methods are limited by their incapacity to accurately represent the intricacies of the actual world and may induce biases because of their exclusive focus on particular inventory reduction expenses [9]. In addition, models for dynamic forecasting that use BiLSTM networks provide better prediction accuracy but have restricted application to other time series data sources and high processing costs [13]. These drawbacks underscore the need for more adaptable, less data-dependent, and computationally efficient models.

IV. Proposed Methodology

The software of deep learning particularly people who employ neural networks has ushered in a new generation of comprehension and forecasting within the subject of financial statistics analysis. CNNs and LSTM networks have turn out to be outstanding equipment amongst those cutting-edge methodologies, especially effective at dealing with the complicated and time-established nature of monetary markets. CNNs had been remarkably a success in their version to monetary time collection evaluation, regardless of their authentic development for image popularity packages. These networks are especially good at routinely spotting capabilities and trends in statistics, together with changes in volume, rate, or different marketplace indicators.

By maintaining memory for extended periods of time, LSTM networks function at the side of CNNs to address the temporal component of economic statistics. LSTM networks, as adverse to traditional recurrent neural networks, are capable of capturing long-variety relationships which can be critical for modelling complex financial time series because they alleviate the vanishing gradient trouble. Fig. 1 shows the architecture of the proposed financial analysis. LSTM networks can perceive recurrent patterns, adjust to shifting marketplace situations, and predict future traits with awesome accuracy by getting to know from past statistics. For jobs like chance management, portfolio optimization, and market forecasting, this makes them very useful. In essence, the mixture of CNNs with LSTM networks gives hitherto unheard-of insights and prediction strength, as a result representing a paradigm alternate inside the observe of monetary information. With the increasing quantity and complexity of monetary facts, these sophisticated DL will truly turn out to be more and more crucial for comprehending and navigating the complexities of the world's monetary markets.

A. Data Collection

With statistics from economic statements, essential ratios covering profitability, leverage, and performance, as well as market records on stock expenses and alternate volumes, it presents comprehensive know-how of how nicely a firm is performing when it comes to marketplace trends. To make sure thorough evaluation and nicely-knowledgeable decision-making, users are entreated to verify information veracity, use caution whilst interpreting ratios, and seek advice from unique sources for methodological clarity [15].

B. Data Pre-Processing

A data preparation approach called Min-Max normalization, every so often referred to as Min-Max scaling, is used to scale numerical capabilities to a given range, typically among zero and 1. The following is the components for MinMax normalization:

$$x_m = \frac{x - \min(x)}{\max(x) - \min(x)} \quad (1)$$

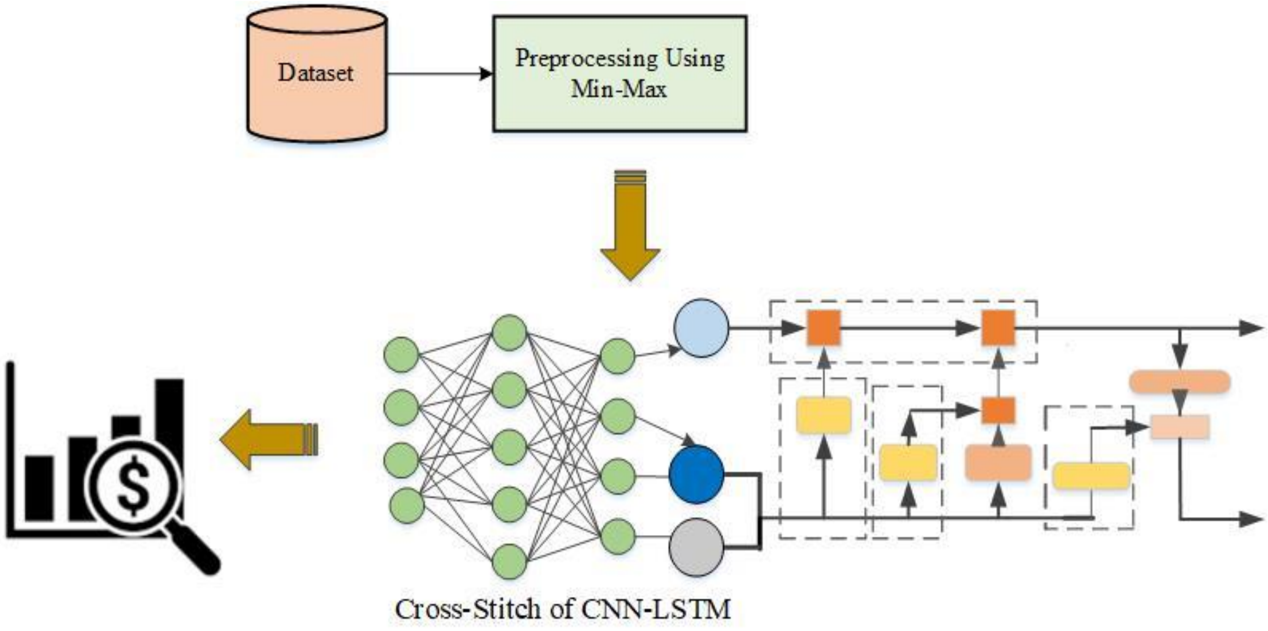

Fig. 1. The architecture of the proposed financial analysis.

Certain device ML which can be sensitive to function magnitudes may also benefit from this variation, which maintains the unique distribution of the records even as ensuring that each capability is at the same scale. Furthermore, Min-Max normalization helps avoid functions with higher scales from overwhelming people with decreased scales in the course of model training, making the facts less difficult to recognize. It's essential to remember that MinMax normalization is susceptible to outliers and could not work successfully in instances in which the records include excessive values.

1) Data cleaning: The proposed research's data cleaning procedure includes filling in the values that are missing employing approaches like imputation, which replaces missing data points with statistical metrics (such as mean, median, and mode), forward or backward fill, and linear or polynomial interpolation. Rows or columns containing an excessive amount of data that is missing may be removed if interpolation is not practical. The Z-Score, which is described in Eq. (2), and the IQR (Interquartile Range) Technique are two techniques for outlier detection that may discover and handle outliers by establishing threshold. To lessen the impact of extreme numbers, winsorization is used, and to preserve data integrity, clipping is used to cap values at a specified threshold.

$$Zscore\ Z = (X - \mu)/\sigma \tag{2}$$

Data Transformation: In data analysis, data transformation is the procedure of transforming unprocessed data into a structure that is more suited for analysis. To do this, data must be modified to increase its accuracy, uniformity, and usefulness. Data spans and patterns are adjusted by methods including scaling, standardization, and normalization, which facilitate analysis and interpretation. Transformation techniques including Box-Cox conversion, log transformation, and differencing help to eliminate patterns and stabilize dispersion. By verifying that the data satisfies the presumptions of mathematical frameworks and computations, this stage is essential for producing insights that are more reliable and precise. The Data transformation for the proposed model is explained in Eq. (3).

$$Y(\lambda) = \frac{Y^{\lambda}-1}{\lambda} \tag{3}$$

C. Utilizing CNNs for Advanced Feature Extraction

CNNs are powerful equipment for monetary information evaluation characteristic extraction, in particular in relation to identifying spatial relationships gift within the facts. Convolutional, pooling, and absolutely linked layers are most of the layers that generally make up a CNN's structure (see Fig. 2).

Convolutional Layers: These layers use a hard and fast of filters to carry out convolution operations on the enter information to be able to extract neighbourhood functions.

Pooling Layers: To lessen the dimensionality of the characteristic maps, pooling layers like max-pooling are used after the convolutional layers.

Fully connected Layers: After the feature maps are pooled, completely connected layers combine the functions right into a single, all-encompassing picture. By clarifying the connections between exceptional extracted factors, this included illustration makes it easier to perform complex analysis activities and helps to offer a deeper knowledge of the economic records this is being examined.

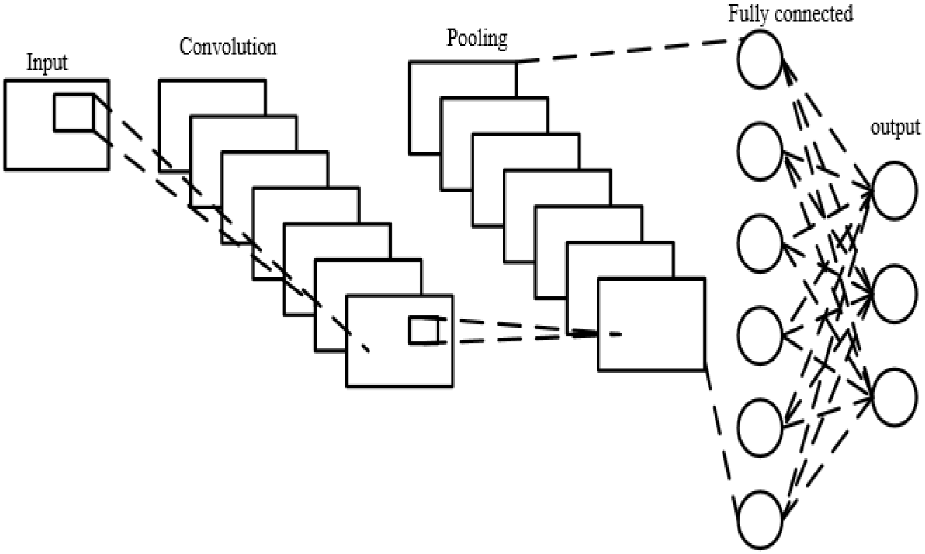

Fig. 2. CNNs for advanced feature extraction.

The CNN issue captures spatial features from the enters monetary data. Let XXX denote the input records, (X) represents the output characteristic map after convolution, and (X) denotes the feature map after activation. The Eq. (4) governing CNN function extraction are as follows:

$$Fc(X) = X * WcFc(X) = X * Wc \tag{4}$$

$$Hc(X) = Activation(Fc(X) + bc)Hc(X) = Activation(Fc(X) + bc) \tag{5}$$

Where, $*$ denotes the convolution operation, Wc represents the CNN weights, and bc denotes the bias term.

D. Forecasting Market Dynamics with LSTM Networks

An important development in sequence learning is represented by LSTM networks, which provide an answer to some of the problems that conventional Recurrent Neural Networks (RNNs) face, most notably the vanishing gradient problem. These networks are highly valuable in many fields, such as financial time series research, because they are specifically designed to be excellent at capturing the long-term relationships present in sequential data.

Memory cells, which can hold information for long stretches of time, are essential to the architecture of LSTM networks. Three fundamental gates control each memory cell:

The input gate regulates the amount of fresh data that enters the memory cell and controls how often it is updated with new information.

Forget Gate: Determines how much of the history kept in the memory cell should be erased, allowing the network to adjust flexibly to shifting circumstances.

Output Gate: Specifies how much data is taken out of the memory cell to be used in further calculations or outputs, making sure that only pertinent data is retained.

LSTM networks excel in economic time collection research because they're top at figuring out traits and temporal dependencies that emerge over the years. Because of their capability to simulate the dynamics of sequential statistics, analysts are highly capable of deciphering the complicated interactions that shape financial markets, gaining the capability to attract conclusions which might be realistic and enhance investment and danger control overall performance.

The input gate, neglect gate, output gate, and candidate cellular cost are the four essential additives of an LSTM unit. Memory cells may be calculated the usage of, and the end result based on those additives.

$$i_t = \sigma_g(W_i x_t + R_i h_t - 1 + b\ _i) \tag{6}$$

$$f_t = \sigma_g(W_f \mathrm{x}_t + \mathrm{R}_f \mathrm{h}_t - 1 + b_f) \tag{7}$$

$$g_t = \sigma c\big(W_g x_t + R_g h_t - 1 + b_g\big) \tag{8}$$

$$o_t = \sigma_g(W_o x_t + R_o h_t - 1 + b_o) \tag{9}$$

In Eq. (6) to Eq. (9) where, R_i , R_g , R_f , R_o odenotes the weights matrices for the preceding brief-term state W_i, W_f, W_g ,W_o ,are the burden matrices within the modern input kingdom. Thus, the cutting-edge output depends at the modern-day long-time period nation, modern-day input, and the preceding state.

E. The Cross-Stitch of CNN-LSTM for Financial Analysis

While LSTM networks are good at shooting temporal dependencies and long-term patterns, CNNs are true at finding spatial linkages within economic facts. A thorough method for comprehending and forecasting market conduct is offered by combining those two structures.

As a characteristic extractor, the CNN aspect reveals localized patterns inside the monetary facts enter. CNNs observe filters to input information thru convolutional layers, which are represented by using Eq. (1) and Eq. (2), with a purpose to extract pertinent functions. Metrics like stock charges and trading volumes have geographical correlations, tendencies, and anomalies which can be highlighted with the aid of these layers. By concentrating at the most critical additives of the facts, pooling layers enhance computing performance by way of similarly refining the derived functions. In addition, LSTM networks deal with the temporal thing. The first step in the CNN-LSTM prediction procedure is statistics input, which is then normalized using z-score standardization. After setting the network's initial weights and biases, the input data are sent through the pooling and convolution layers in order to extract features. The LSTM layer then computes the convolution layer's output to produce the output value. The fully connected layer receives this output value and uses it for additional processing. The procedure entails figuring out the fault and determining if the end condition is satisfied. Error backpropagation keeps improving the model if it doesn't. After training, the version is saved, and forecasted enter records is normalized before being fed into the CNN-LSTM model, which is then skilled for prediction. After that, the standardized output is changed back to its authentic value, concluding the forecasting manner of financial facts processing, making it viable to perceive lengthy-time period patterns and connections. LSTM networks, which can be provided with memory cells and gates, are able to successfully deal with and keep facts across long sequences. The network can modify to moving market situations because the neglect gate manages the retention of previous facts while the input gate controls the inflow of clean statistics into the reminiscence mobile. The output gate controls the extraction of useful statistics for extra calculations or forecasts, ensuring that the community makes choices primarily based completely on applicable information. Fig. 3 shows LSTM networks.

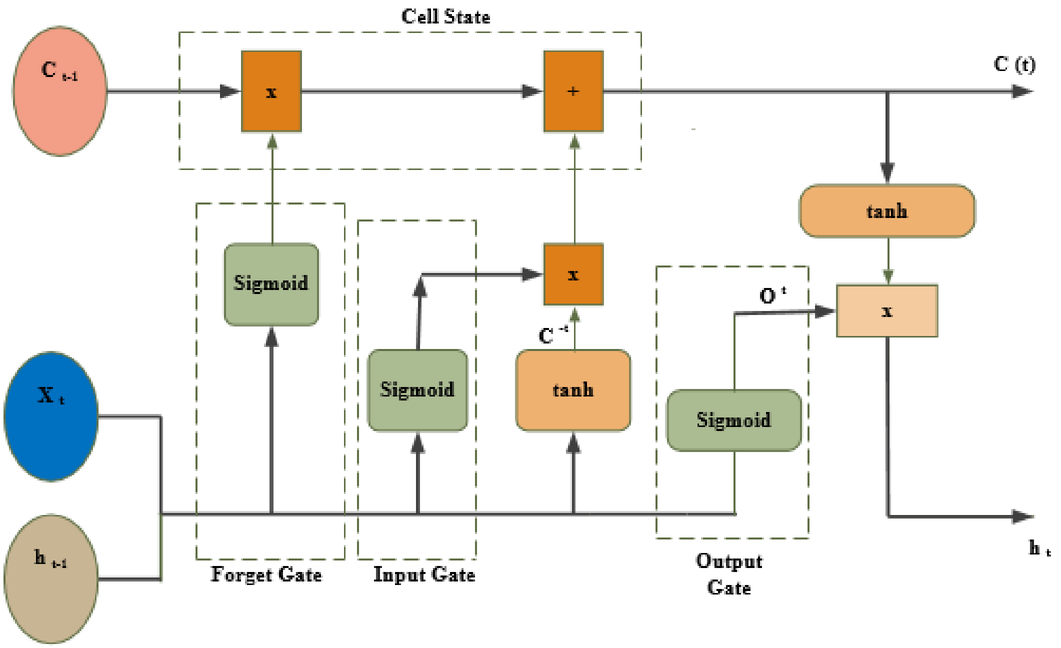

Fig. 3. LSTM networks.

A complete framework for predicting marketplace dynamics is created by analysts by using merging CNNs with LSTM networks. The characteristic extraction technique of the CNN is represented by Eq. (1) and Eq. (2), whereas the reminiscence cellular and gate operations describe the functioning of LSTM networks. This empowers stakeholders to successfully control risks, make properly-knowledgeable selections, and optimize investment strategies based totally on thorough understandings of market dynamics. In addition to making, it easier to apprehend the complicated relationships that form financial markets, the incorporated CNN-LSTM structure improves selection-making talents, which in flip improves funding performance and risk management approaches as shown in the Fig. 4.

The first step within the CNN-LSTM prediction system is facts input, which is then normalized by the usage of z-score standardization. After putting the community's initial weights and biases, the input data are despatched via the pooling and convolution layers to be able to extract capabilities. The LSTM layer then computes the convolution layer's output to supply the output price. The related layer receives this output cost and makes use of it for extra processing. The manner entails figuring out the fault and determining if the end circumstance is happy. Error backpropagation maintains enhancing the model if it doesn't. After training, the version is saved, and forecasted enter records is normalized before being fed into the CNN-LSTM model, that's then trained for prediction. After that, the standardized output is changed back to its unique cost.

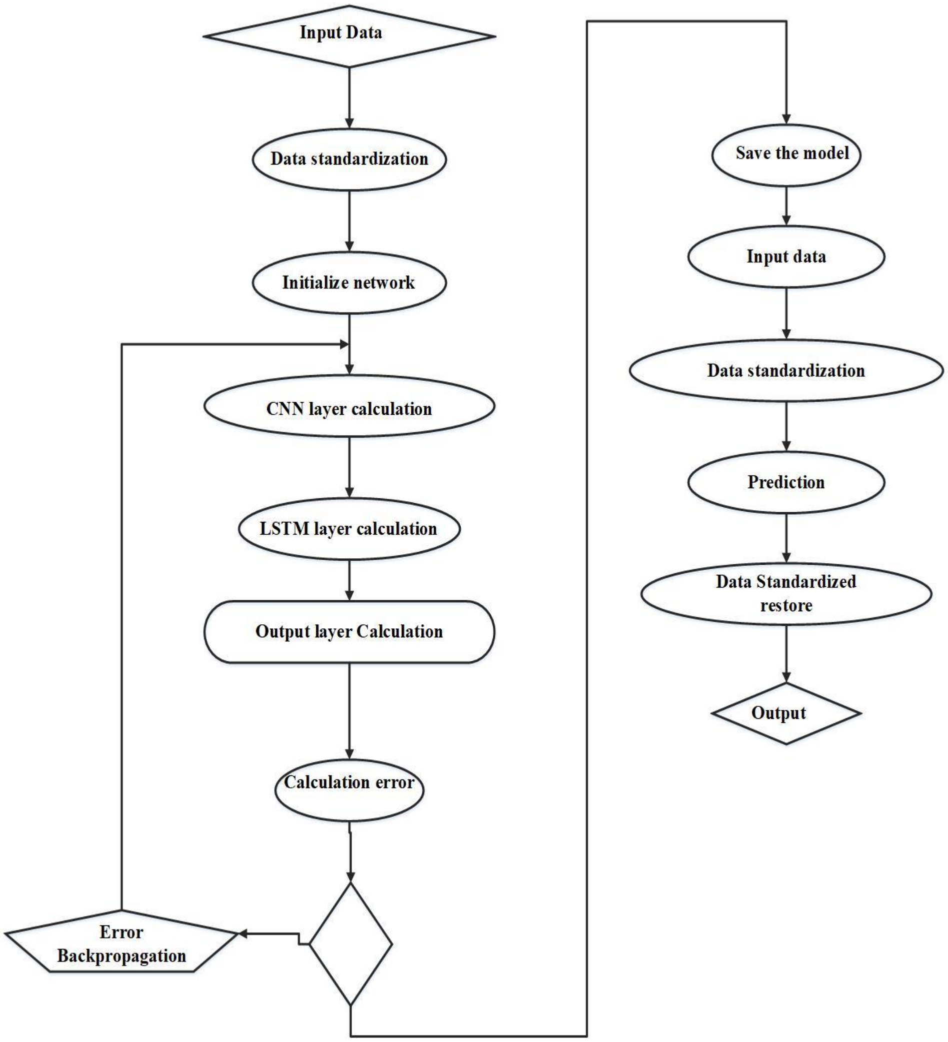

Fig. 4. CNN-LSTM financial analysis process.

V. Result and Discussion

The findings of the proposed study display that the move-sew hybrid network-based method for function integration in quantitative economic evaluation works nicely. Cross-stitch network structures function much better than standard approaches for capturing complicated connections between financial variables, as demonstrated by thorough testing on many financial datasets. To make the algorithms more dependable for economic forecasting and analysis, they undergo instruction utilizing this technique, which results in algorithms that are more resistant, accurate, and typically able to represent actual circumstances across market situations. The performance's inventiveness serves as proof of the cross-stitch hybrid networks' capacity to upend established wisdom and contribute new perspectives to economic modelling.

A. *Analysis of Proposed Financial Dataset*

The Table I shows an example of a data set with financial metrics for sales and profits of various products in different segments and countries It categorizes products into electronics, furniture, clothing, home goods, etc. Identifies various services or products. While the "product" column names a specific product under review, such as smartphones, office chairs, jackets, or laptops. The "Discount Band" column displays the amount of discount applied to each item, none from above, affecting the overall pricing strategy. The "Units Sold" column provides the number of units sold, which is a key figure for determining revenue. "Operating cost" refers to the cost to produce each item, while "selling price" refers to the cost of each item sold, providing the basis for calculating total revenue. The "total sales" column calculates revenue all accounted for before discount rates are applied, providing a lead in terms of revenue potential.

"Discount" represents the cash value of all price discounts offered to customers, which includes the most recent revenue total shown in the "Sales" column, which is the total sales less discounts out of it is an important calculation. Finally, the "Profit" section calculates net income by subtracting COGS from sales, and shows the economic performance of each item. This table gives a clear idea of how various factors such as discounts, production costs, and pricing strategies affect overall profitability in different markets and product segments there.

TABLE I. FINANCIAL ANALYSIS DATA SET EVALUATION

Segment	Country	Product	Discount Band	Units Sold	Manufacturing Price	Sale Price	Gross Sales	Discounts	Sales	COGS	Profit
Electronics	USA	Smartphone	High	500	$200	$350	$175,000	$10,000	$165,000	$100,000	$65,000
Furniture	Germany	Office Chair	Low	300	$100	$200	$60,000	$3,000	$57,000	$30,000	$27,000
Clothing	France	Jacket	Medium	400	$50	$120	$48,000	$4,800	$43,200	$20,000	$23,200
Electronics	Japan	Laptop	None	150	$500	$800	$120,000	$0	$120,000	$75,000	$45,000
Home Goods	Canada	Blender	Medium	600	$25	$70	$42,000	$2,100	$39,900	$15,000	$24,90

B. Training and Testing Accuracy

In Fig. 5, the version's early getting to know section is indicated by the starting factors of the education (blue line) and testing (orange line) accuracies, which can be about 0.3 and 0.4, respectively. The accuracy for both datasets booms dramatically in the course of the course of the epochs, demonstrating the model's ability to research from and generalize from the facts.

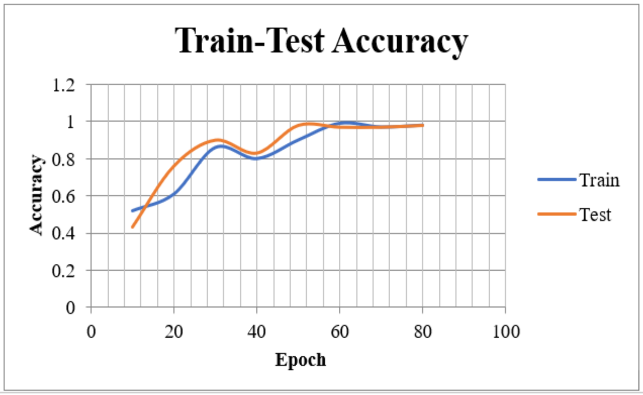

Fig. 5. Train-Test accuracy of CNN-LSTM model.

The checking out accuracy in brief exceeds the training accuracy at epoch 20, indicating a length of progressed generalization before they converge and settle. The version's balance is indicated by way of the 2 traces' convergence at epoch forty, at which point the training and checking out accuracies both technique 0.9 and stay solid.

C. Traing and Testing Loss

The CNN-LSTM model's training and testing loss across 50 epochs is shown in the Fig. 6, which offers insights into the model's generalization capacity and learning efficiency. As the model starts to learn from the data, it is predicted that the testing loss (red line) and training loss (blue line) would start out high, starting at approximately 0.8. For both datasets, there is a sharp drop in loss as training goes on, suggesting that the model is rapidly becoming more efficient by reducing prediction error. The losses for the training and testing datasets substantially converge by epoch 10, falling to less than 0.3.

The little difference between the training and testing losses shows that the model has stabilized, indicating that it has learnt from the training data and can generalize well to new data. To provide high performance and precise predictions, the CNN-LSTM architecture must be resilient and reliable to capture and model the intricate patterns seen in financial data. This is demonstrated by the low and steady loss values in later epochs.

D. Performance Comparison

Table II presents a detailed comparison of different machine learning models and hybrid architectures based on key performance metrics: accuracy, mean absolute error (MAE), root mean square error (RMSE), and Short-term memory models known to capture the time dependence in sequential data achieve 80% accuracy at 85% accuracy. This performs well in terms of error reduction, with 7.18% MAE and 9.14% RMSE, explaining a large proportion of data variability, as indicated by its 92% R^2 score XGBoost, the engineer for gradient-enhancing, outperforms LSTM in accuracy (87%) and precision (90.6%), but with a higher error rate—15.04%; -MAE, 27.02% RMSE— shows that it struggles more with stability but its low 33% R^2 score further highlights its limitations in explaining the variance in the data. The Support Vector Machine (SVM) model, although effective in some cases, performs poorly in this comparison, with an accuracy of 78%, precision of 82%, and the highest error—MAE of 15.61%; and RMSE of 29.33% with R2 score of 21% indicates very low explanatory power.

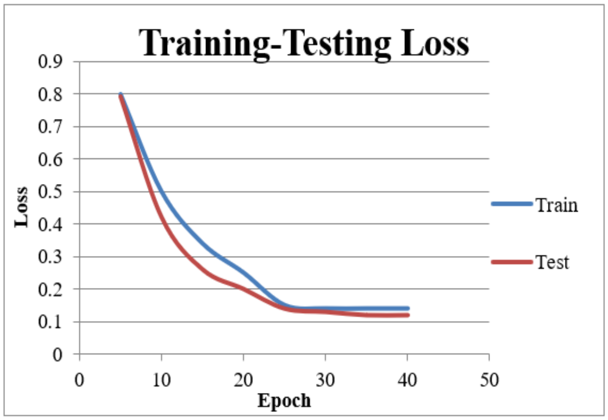

Fig. 6. Training-Testing loss of CNN-LSTM model.

TABLE II. PERFORMANCE METRICS FOR VARIOUS MACHINE LEARNING MODELS IN QUANTITATIVE FINANCIAL ANALYSIS

Model	Accuracy (%)	MAE (%)	RMSE (%)	Precision (%)	R² (%)
LSTM	80	7.18	9.14	85	92.0
XGBoost	87	15.04	27.02	90.6	33.0
SVM	78	15.61	29.33	82	21.0
LSTM+XGBoost	85	8.04	13.93	88	82.0
LSTM-Transformer Attention Hybrid	87	6.05	9.03	87	88.0
LSTM-CNN Cross-Stitch Hybrid Networks	90	5.0	8.0	92	92

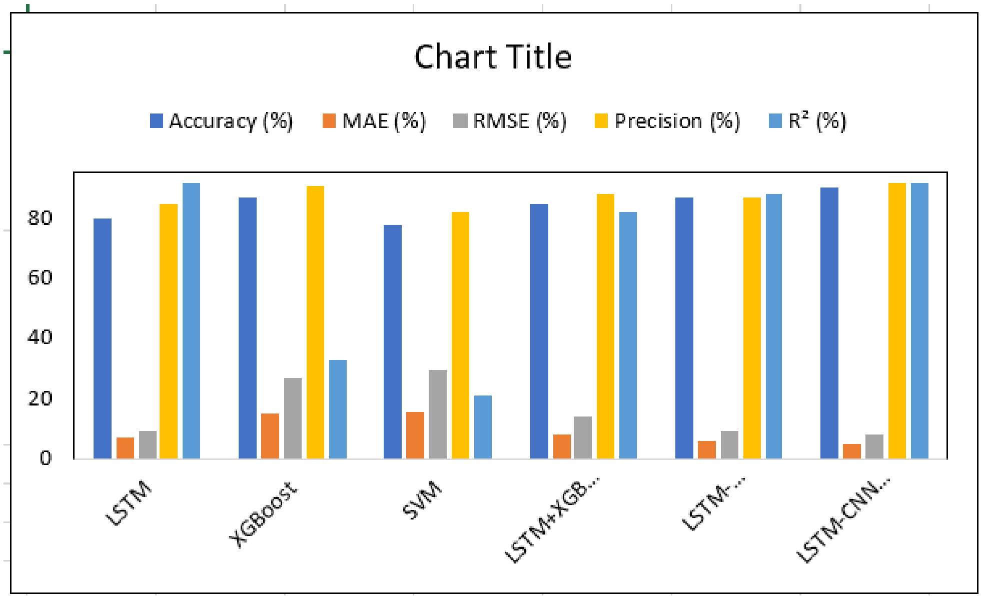

Fig. 7. Performance metrics overview of the proposed model.

The hybrid LSTM+XGBoost model [16] combines the temporal learning of LSTM with the predictive capabilities of XGBoost, yielding balanced results with 85% accuracy and 88% accuracy, as well as improved error metrics (MAE 8.04% and RMSE 13.93% and R^2 is 82 % . The LSTM-Transformer Attention Hybrid model improves LSTM by adding attention, resulting in 87% accuracy, 87% accuracy, error reduction (6.05% MAE, RMSE 9.03%), and R^2 a it comes to an 88% LSTM-CNN Cross-Stitch Hybrid Networks model , in which the LSTM Ne class combines CNN with spatial feature extraction, and stands out in the highest performance: 90% accuracy, 92%; accuracy, and the lowest error rate MAE of 5.0%, RMSE of 8.0%, with 92% R^2, the most robust and effective in this comparison.

In Fig. 7 the graph uses Accuracy, MAE, RMSE, Precision, and R2 to illustrate the outcomes of several approaches. With the greatest Accuracy (90%) and Precision (92%), the LSTM-CNN Cross-Stitch Hybrid Networks function better than the others, however, XGBoost performs worse on all measures. Results for the LSTM+XGBoost and LSTM-Transformer Attention Hybrid models are matched.

E. Performance Evaluation Metrics

To evaluate the performance of the model, this study uses the following metrics: Mean Absolute Error (MAE), Root Mean Squared Error (RMSE), Mean Absolute Percentage Error (MAPE), and Coefficient of Determination (R²).

The Mean Absolute Error (MAE) measures the average magnitude of the errors in a set of predictions, without considering their direction. It is calculated as follows:

$$MAE = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}_i| \qquad (10)$$

where y_i is the actual value, $\hat{y}_i$ is the predicted value, and is the number of observations.

The Root Mean Squared Error (RMSE) is the square root of the average of the squared differences between the predicted and actual values. It is given by:

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \qquad (11)$$

The Coefficient of Determination (R²) indicates the proportion of the variance in the dependent variable that is predictable from the independent variables. It is calculated as:

$$\mathrm{R}^2 = \frac{\sum_{i=1}^{n}(y_i-\hat{y}_i)^2}{\sum_{i=1}^{n}(y_i-\bar{y}_i)^2} \qquad (12)$$

The model correctly predicts outcomes 90% of the time, reflecting high overall prediction reliability.

$$\text{Accuracy (ACC)} = \frac{True\ Positive\ \ +True\ Negative}{TP+TN+FP+FN} \tag{13}$$

Of all predicted positive outcomes, 92% are true positives, indicating effective identification of relevant cases.

$$\text{Precision} = \frac{TP}{TP+FP} \tag{14}$$

TABLE III. PERFORMANCE METRICS OF THE PROPOSED MODEL

Accuracy (%)	90
MAE (%)	5.0
RMSE (%)	8.0
Precision (%)	92
R² (%)	92

The performance parameters of the suggested approach are presented in Table III. It can achieve 90% accuracy with a mere 5.0% mean absolute error (MAE), resulting in excellent performance forecast statistics with tiny average errors. Along with the 92% accuracy, which indicates that 92% of instances can be correctly recognized, and the 92% R², which indicates a near-perfect fit and excellent explanation capacity, the 8.0% RMSE indicates that the framework is a resilient error controller.

The performance evaluations of the proposed model, including accuracy, precision, mean absolute error (MAE), root mean square error (RMSE), and R2, are displayed in Fig. 8, a bar chart. The framework is very dependable on all criteria, exhibiting excellent precision, accuracy, and R2 along with low MAE and RMSE levels.

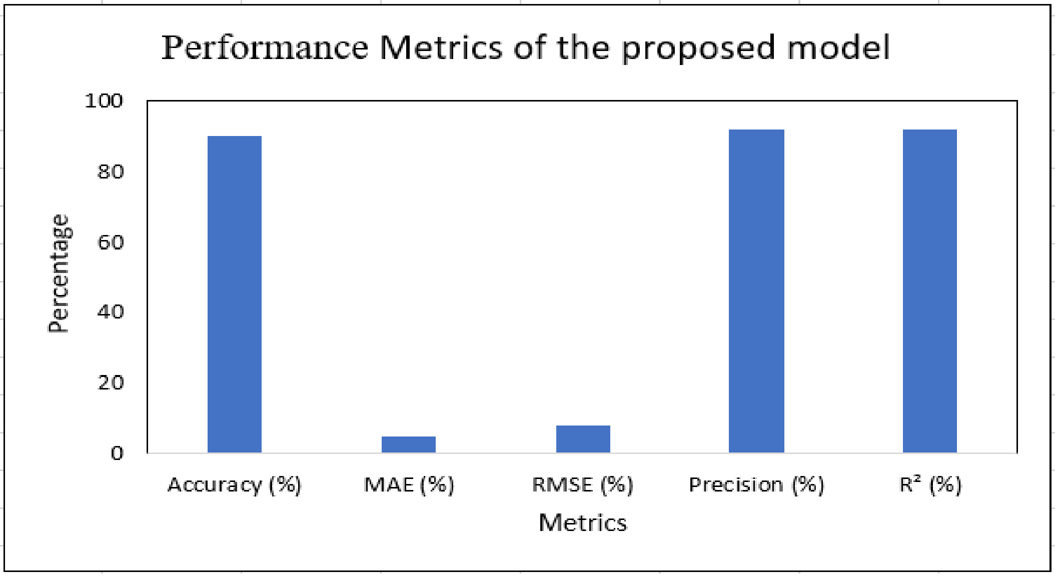

Fig. 8. Performance metrics overview of the proposed model.

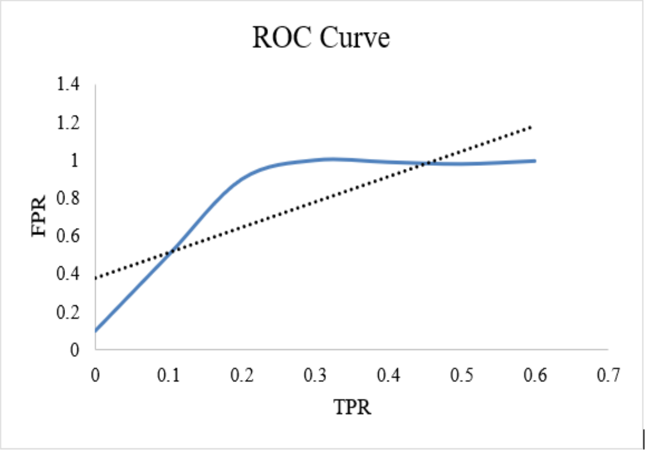

Fig. 9. ROC curve of CNN-LSTM model.

The Fig. 9, represented by the ROC (Receiver Operating Characteristic) curve in the graph. The performance of the model is shown by the blue line, while the performance of a random classifier is shown by the diagonal dotted line, which acts as a baseline. A model with exceptional discriminative capacity would have a sharp ascent towards the top-left corner of the ROC curve, signifying high sensitivity and minimal fall-out. Nonetheless, the graph's ROC curve shows a progressive rise in FPR along with a rise in TPR that begins at the origin (0,0) and moves towards the right. The model improves at first, but as the TPR rises, the FPR rises as well, indicating that the model has difficulty making accurate class distinctions. A TPR of 0.4 to 0.5 is where the performance peaks, while an FPR of more than 0.8 denotes subpar performance. This ROC curve study shows that although the CNN-LSTM model can identify certain trends in the financial data, more data or fine-tuning may be needed to improve the model's overall prediction accuracy and its capacity to distinguish between classes.

F. *Discussion*

The results of the study show that the proposed CNN-LSTM Cross-Stitch Hybrid Network improves the accuracy and reliability of economic forecasts. Compared with traditional models, this hybrid approach exhibits better performance, providing an accuracy of 90% and a lower error rate 5.0% MAE and 8.0% RMSE, indicating a higher model accuracy 92 % and R^2 scores 92% in the capturing power structures are robust in economic terms. Also further emphasizes the difficulty in explaining data variance, making it a powerful tool for economic forecasting. Despite this strength, ROC curve analysis reveals areas of improvement, suggesting that whether the model still struggles with class differences in some cases. These findings highlight the potential of improved hybrid networks in adapting economic paradigms, although further fine-tuning is required to be effective in different contexts.

VI. Conclusion and Future Work

The technologies have allowed researchers to effectively combine spatial and temporal data into a model known as Cross-Stitch Hybrid Networks that provides the most accurate and efficient predictions of stock market trends. The framework is a cross between LSTM and CNN. The comprehensiveness of the data collection is crucial since financial time series differ greatly from one another. Neural networks' capacity to learn functions and concentrate on the distribution of data rather than just input properties throughout the analogy-making process has made this feasible. This work highlights the potential for further study and improvement in this field as well as the ability of sophisticated neural networks to handle the difficulties of financial prediction. The results of the research support the idea that feature aggregation becomes increasingly significant at the highest levels of model efficiency, and that this significance is particularly evident in domains like the stock market. Systems are demonstrated to have an effective pooling and incorporation of learned representation using the Cross-Stitch mechanism, which results in a framework that not only makes more accurate predictions but also scales better and performs well in a variety of scenarios. This section shows that the accuracy and range of the input information have a direct impact on the model's efficacy, indicating the need for full datasets in financial evaluation. To validate the framework's generality and adaptability, additional research might investigate its use in areas linked to various financial goals, such as identifying hazards and optimization of portfolios. To improve the Cross-stitch Combination Networks system's strength and generalization, future work will add additional economic attributes to it and see if it can be applied to other financial sectors, specifically managing risks and portfolio optimization. The information showed that financial executives and analysts may benefit greatly from the Cross-Stitch Hybrid Networks approach, which would enable them to make better-informed and more effective judgments. Cross-stitch hybrid Networks with temporal and spatial components combined represent a major advancement in quantitative financial evaluation. The inability of conventional models to identify correlations among financial time series data—like fluctuations in the public price of bitcoin, for example—is a prevalent problem. For instance, it has been discovered that concentrating on advances in technology with cross-stitching hybrid networks—a combination of CNNs and LSTMs—in sophisticated peer-to-peer lending systems, improves forecast outcomes.

***Abstract*—Oral Squamous Cell Carcinoma (OSCC) is one main kind of oral cancer; early diagnosis is rather important to increase patient survival chances. This study investigates the application of advanced deep learning techniques including transfer learning and ensemble learning to increase the accuracy of oral squamous cell cancer (OSCC) diagnosis using histopathological image analysis. Two transfer learning models, EfficientNetB3 and ResNet50, support the suggested method to extract suitable features from the histopathological images. Both models permit fine-tuning to improve their classification accuracy. On tests taken after the initial training, the EfficientNetB3 model scored 96.15%. Later on, training ResNet50 yielded a test accuracy of 91.40%. Weighted voting merged several models into an ensemble model designed to maximize the strengths of each network. With a test accuracy of 98.59% and a training accuracy of 99.34%, the ensemble model showed notably higher performance than the values obtained by the individual models. Divided into OSCC and standard categories, the collection has 5,192 extremely well-resolved images. The images were used to create training, validation, and testing sets. We used this method to consistently evaluate the model's performance and reduce overfitting. Furthermore, the ensemble model proved to be quite accurate with recall and F1 scoring, thereby proving its capacity to routinely identify OSCC images. Both groups produced ROC curves, and the area under the curve (AUC) demonstrated excellent model performance. Transfer learning and ensemble learning are used together in this study to show that OSCC can be found early and consistently in histopathology images. The findings reveal that the recommended strategy could be a consistent tool to assist pathologists in the precise and timely detection of OSCC, thereby improving patient treatment and outcomes.**

Keywords*—Oral Squamous Cell Carcinoma (OSCC); histopathology images; transfer learning; ensemble learning; EfficientNetB3; ResNet50; deep learning; cancer detection; medical image analysis

I. Introduction

Oral Squamous Cell Carcinoma (OSCC) [1] is one of the most prevalent forms of cancer worldwide, accounting for over 90% of oral cancers. Usually affecting the squamous cells guarding the oral cavity, the disorder arises in malignant tumors that, if not found and treated quickly, can spread to other parts of the body. According to the World Health Organization (WHO), OSCC ranks in the top ten most common malignancies globally, with especially high prevalence in South Asia, Southeast Asia, and parts of Europe. OSCC has a significant global influence considering an estimated 300,000 new cases and around 145,000 deaths annually. The OSCC diagnosis primarily dictates its prognosis; early-stage diagnosis considerably increases the chances of successful therapy and survival [2]. Among the most often occurring risk factors of OSCC, a multifactorial etiopathogenesis including tobacco usage, alcohol intake, betel quid chewing, and human papillomavirus (HPV) infection stands. Growing emphasis on the importance of molecular changes and genetic predispositions in the evolution of OSCC has been observed in recent years. Although OSCC's molecular biology is now well known, the main diagnostic tool that remains is histopathological investigation of tissue biopsies. This method is formed by a pathologist's microscopic examination of tissue samples in search of malignant cells. Nevertheless, this standard diagnostic approach has important disadvantages including inter-observer variability, the time-consuming character of the operation, and the likelihood of misinterpretation coming from the subjective interpretation of histological features [3]. Early and correct OSCC detection is highly significant, thus the scientific and medical industries have worked hard to develop automated diagnostic tools that can help pathologists and minimize diagnosis mistakes. In this sense, applying machine learning (ML) and artificial intelligence (AI) in medical imaging has become an interesting road for innovation. The development of digital pathology and advances in image analysis methods have presented opportunities for the design of AI-driven diagnostic systems capable of very accurate and fast histological image interpretation [4]. OSCC presents varied clinical signs based on tumor sizes and location, such as erythroplakia, leukoplakia, non-healing ulcers, lumps, or persistent sores. Other symptoms include voice changes, dysphagia, pain, numbness, bleeding, loose teeth, and, in advanced stages, neck swelling due to lymph node metastasis. The etiology of OSCC is unclear, though major risk factors include tobacco use and alcohol consumption, which together significantly increase cancer risk [5]. High-risk human papillomavirus (HPV), particularly HPV-16, is also a major factor, especially for oropharyngeal cancers [6]. Additional risks include poor oral hygiene, environmental toxins, chronic trauma, a weakened immune system, and genetic predispositions. Understanding these factors is critical for early detection and prevention programs aimed at reducing OSCC incidence and mortality [7]. Treatments for OSCC combine a multimodal approach tailored to the tumor's stage, location, and patient health. Major treatments include surgery, radiation, and chemotherapy, often used together for optimal results [8]. Surgery, the primary treatment for localized OSCC, aims to remove the tumor with clear margins to minimize recurrence. Reconstructive surgery may follow to restore function and appearance after partial or full removal of affected parts, such as the tongue or jawbone. Radiation therapy, typically external beam, is used as a supplement to surgery or as a main treatment when surgery isn't viable [9]. Chemotherapy, often paired with radiation (chemoradiation), is reserved for advanced or metastatic cases and patients with recurrent OSCC. Targeted therapies and immunotherapies offer appealing adjunct treatments by focusing on molecules linked to tumor growth [10]. Supportive care, including nutrition, pain management, and speech therapy, helps maintain quality of life. Multidisciplinary tumor boards optimize treatment by balancing patient-specific factors with evidence-based guidelines and chosen treatment methods. In oncology, where early detection significantly influences patient prognosis, the diagnosis of Oral Squamous Cell Carcinoma (OSCC) provides a huge challenge. Sometimes subjectivity, variability in interpretation, and the need for specialist knowledge limit conventional diagnosis approaches such as histological study and clinical examination, therefore causing inconsistent and delayed diagnosis [11]. Although machine learning has advanced, present models for OSCC detection from histopathology images often depend on single-model architectures, which might not adequately reflect the complex and heterogeneous character of OSCC. Furthermore, confusing accurate detection results in variations in image quality and staining methods. More strong, accurate, and dependable diagnostics tools that can combine several models to improve detection possibilities are desperately needed. This work fills in this need by looking at the application of transfer learning and ensemble learning approaches to create a better, ensemble-based model for early and accurate OSCC identification [12]. The main goal of this work is to provide a strong and accurate strategy based on advanced deep learning [13] approaches more especially, transfer learning [14] and ensemble learning [15] for the detection of Oral Squamous Cell Carcinoma (OSCC). The work intends to extract discriminative characteristics from histopathology images using the strengths of two state-of-the-art pre-trained models, EfficientNetB3 and ResNet50. The study aims to raise the general classification accuracy and dependability of OSCC detection by optimizing these models and combining their outputs using an ensemble learning method. With an eye on measurements including accuracy, precision, recall, F1 score, and AUC-ROC, the study also seeks to evaluate the ensemble model against individual models. The ultimate aim is to develop an ensemble model significantly above present methods, thus providing a more consistent diagnostic tool for early OSCC diagnosis and aiding in improving patient outcomes.

The primary contributions of this research are:

- This work presents a new ensemble learning method based on two state-of-the-art pre-trained models, EfficientNetB3 and ResNet50, for Oral Squamous Cell Carcinoma (OSCC) identification from histopathology images.
- Specifically, with OSCC identification, the work shows medical image analysis transfer learning performance. The work uses transfer learning to overcome the difficulties provided by insufficient labeled data thus improving the generalizing power of the model by fine-tuning pre-trained models on histomorphology images.
- The study evaluates the proposed ensemble model exhaustively using significant performance measures including accuracy, precision, recall, F1 score, and AUC-ROC. Since the ensemble model trumps individual models, the results demonstrate that it offers a more consistent diagnosis tool for early OSCC identification. Development of the field of medical image analysis and improvement of oncology clinical results depend on this study.

II. Literature Review

The detection of OSCC has become even more critical considering the substantial fatality rate connected with late-stage diagnosis. Deep learning, notably in CNNs and Transfer Learning, has lately shown promise in boosting the accuracy of OSCC detection from histopathological images.

Fanizzi et al. (2024) [16] used an explainable CNN model to examine oropharyngeal squamous cell cancer, training on CT images of 499 OPSCC patients with an independent test set of 92. Using an Inception-V3 architecture, they achieved a 73.50% AUC, highlighting tumor locations via Grad-CAM and emphasizing CNN relevance in therapy.

Paramasivam et al. (2024) [17] used deep learning with three modified CNN architectures, including DENSENET-121 variants, to diagnose OSCC in 5,492 histopathological images, achieving 97.03% accuracy. The study highlighted AI's potential to reduce human errors and improve diagnostic accuracy, addressing the limitations of traditional mouth cancer diagnosis methods.

Weber et al. (2024) [18] studied Stimulated Raman Histology (SRH) with deep learning for Oral Squamous Cell Carcinoma categorization. Using a VGG19 CNN, the model achieved balanced accuracies of 0.90 (SRS) and 0.87 (SRH) from SRH images transformed to resemble H&E sections, highlighting AI's efficiency in intraoperative OSCC detection.

Albalowitz et al. (2024) [19] developed a deep learning model using EfficientNetB3 for OSCC diagnosis, achieving 99% accuracy, precision, recall, and F1-score. The study utilized 1,224 histograms from 230 individuals, leveraging data augmentation, regularization, and optimization. This work demonstrates the potential of deep learning in improving OSCC diagnostic accuracy.

Kumar et al. (2024) [20] examined deep learning for early OSCC identification from histopathology images. Using an enhanced Inception-Resnet-V2 CNN model, the study achieved 91.78% accuracy in distinguishing benign from malignant biopsy images. The paper highlights deep learning's potential in automating OSCC diagnosis and improving early clinical interventions.

Mishra et al. (2024) [21] explored CNNs for early OSCC identification, achieving 98.49% training accuracy, 86.89% validation accuracy, and 89.37% testing accuracy. The model's F1-score of 0.89 for both classes highlights CNNs' potential for improving OSCC screening protocols and patient outcomes, thus reducing fatality rates linked to late diagnosis.

Siddique et al. (2024) [22] used biopsy-derived histological images to explore oral cancer detection techniques, emphasizing image pre-processing's role in enhancing CNN model performance. Models including VGG16, VGG19, InceptionV3, AlexNet, and ResNet50 achieved respective accuracies of 84%, 82%, 67%, 76%, and 42%, showcasing deep learning's potential in cancer diagnosis.

SMira et al. (2024) [23] investigated early oral cancer detection using deep learning and smartphone-based imagery. They developed a resampling method and "center positioning" image-capturing technique to manage variability. The deep learning network achieved 83.0% sensitivity, 96.6% specificity, 84.3% accuracy, and 83.6% F1 score on 455 test images.

Deo et al. (2024) [24] studied the categorization of Oral Squamous Cell Carcinoma (OSCC) using a Vision Transformer (ViT) framework. The updated ViT model outperformed eight pre-trained deep learning models on a dataset of 4,946 images, achieving 97.78% accuracy, 96.72% specificity, and 98.80% sensitivity, proving ViT's efficacy on smaller datasets.

Soni et al. (2024) [25] studied early OSCC diagnosis using an improved EfficientNetB0 model and Dual Attention Network (DAN). Achieving 91.1% accuracy, 92.2% sensitivity, 91.0% specificity, and a 92.3% F1 score, EfficientNetB0 outperformed 17 pre-trained models, highlighting deep learning's clinical potential for early OSCC identification and therapy enhancement.

Deo et al. (2024) [26] developed a DL model for OSCC detection from histopathological images. Using 2D empirical wavelet transform and a ResNet50-DenseNet201 ensemble, binary classification achieved 92% accuracy. The method enhances diagnostic accuracy, reduces human error, and accelerates classification, demonstrating deep learning's potential to aid clinical decision-making.

Saraswathi et al. (2023) [27] examined AlexNet's classification of Oral Squamous Cell Cancer (OSCC) using 5,192 histopathological images. AlexNet outperformed ResNet, achieving 89% accuracy and 60% loss compared to ResNet's 78% accuracy and 82% loss. The study suggested future improvements through larger datasets, software applications, and modified AlexNet models.

Ahmad et al. (2024) [28] studied AI approaches for OSCC detection via histopathological images. Three methods were compared: Gabor+CatBoost, ResNet50+CatBoost, and a hybrid Gabor+ResNet50+CatBoost. The hybrid achieved 94.92% accuracy, 95.51% precision, and 94.9% F1 score. PCA reduced feature dimensionality, improving performance for accurate OSCC diagnosis.

Nagarajan et al. (2023) [29] developed a deep learning system to diagnose Oral Squamous Cell Carcinoma from histopathology images, using a Modified Gorilla Troops Optimizer. MobileNetV3 achieved the highest accuracy (0.89), which increased to 0.95 after optimization. This method demonstrates swarm intelligence's potential to improve OSCC detection accuracy.

Begum et al. (2023) [30] use deep learning models to automatically detect OSCC from histological images, employing transfer learning and layer modification. Among four pre-trained CNN models (NASNet Large, InceptionNet, Xception, DenseNet 201), DenseNet 201 achieved the highest accuracy of 91.25%, showcasing DL-based advancements in OSCC diagnosis and treatment.

III. Methodology

A. Dataset Distribution

This work uses a dataset [31] consisting of 5,192 histopathology images, carefully selected to identify Normal tissues and Oral Squamous Cell Carcinoma (OSCC). As Fig. 1 shows, the dataset is almost balanced with 2,698 OSCC images (52%) and 2,494 Normal images (48%). The right pie chart shows the percentage distribution and the left bar chart shows the image count in every class. This balanced set guarantees a fair training approach, therefore reducing possible categorization bias. Three subsets comprising 3,634 images for training, 779 images for validation, and 779 images for testing comprise the dataset. Using a strong and well-organized dataset, this section helps deep learning models to be developed, refined, and evaluated for effective OSCC detection.

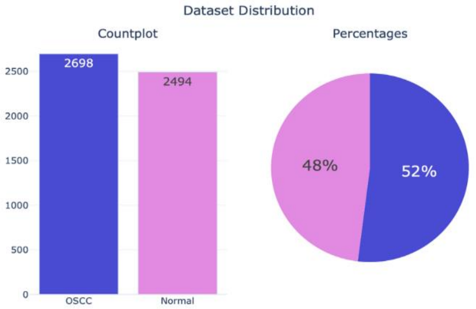

Fig. 1. Dataset distribution.

B. Input Dataset

The normal tissue samples in Fig. 2 show a well-organized structure typical of healthy oral epithelium. The cells have exactly defined borders and firmly packed layers that match their consistent size and form. The way the compartments are arranged is logical there are no obvious anomalies or deviations. There is no hyperchromatism, which would indicate non-malignant tissue; the nuclei are constant in size. Conversely, the Oral Squamous Cell Carcinoma (OSCC) samples in Fig. 3 reveal a disturbance in cellular architecture. OSCC sample cells are irregular, bigger, and show pleomorphism that is, a great range in size and form. Commonly an indication of cancer, the hyperchromatic nature of the nuclei results from the higher DNA content, which seems darker. Furthermore, the OSCC images show abnormal keratinization and uneven stratification of the epithelium with layers that are no longer clearly defined or ordered. These pathological abnormalities are important in histopathological diagnosis since they mirror the aggressive character of OSCC, in which disorganized, malignant cells replace the normal, ordered tissue.

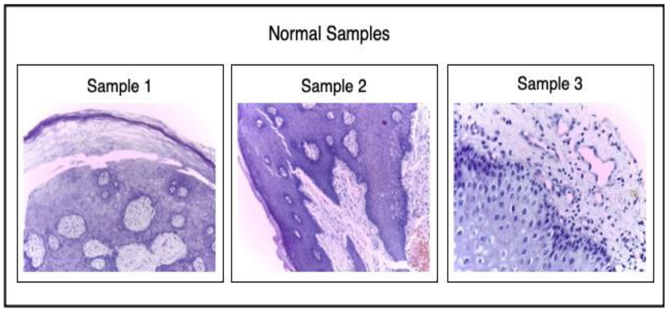

Fig. 2. Dataset samples of normal images.

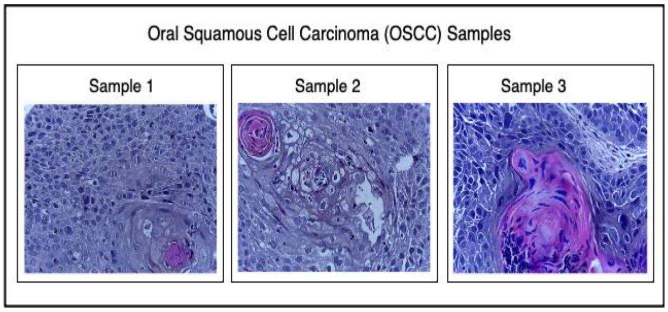

Fig. 3. Dataset samples of OSCC images.

C. Data Preprocessing and Augmentation

Preprocessing is a crucial step that greatly influences the performance of a deep-learning model developed to classify OSCC from histopathological images. Essential for getting the dataset ready for efficient training, validation, and testing are image resizing, normalizing, and augmenting preprocessing techniques [32].

1) Image resizing: Every image is reduced to a consistent dimension suitable for input into the deep learning models thereby guaranteeing consistency over the dataset. This scaling method converts every image into such size since many CNN designs demand each image to be a specific size usually (224×224). This phase guarantees that the model manages images of the same resolution, therefore facilitating efficient training and reducing computer complexity.

2) Normalization: Normalization is carried out to rescale the pixel values of the images to a standardized range, usually ranging from 0 to 1. The process of normalizing can be quantitatively expressed in (1):

$$X_{norm} = \frac{X - \min(X)}{\max(X) - \min(X)} \quad (1)$$

Where, X represents the original pixel values, min(X) is the minimum pixel value, and max(X) is the maximum pixel value. By normalizing the input values to a similar range, this step enhances the convergence speed and stability of the training process.

3) Augmentation: Data augmentation provides artificial unpredictability and increases the training dataset size. Another uses horizontal flipping, rotation, zooming, and shifting among other techniques. Mathematically, augmentation can be stated in (2):

$$X' = T(X) \quad (2)$$

Where X' is the augmented image and T is the transformation carried out, say rotation by a certain angle θ or scaling by a factor s. Exposing the model to several image transformations during training, this stage is vital for improving its robustness and lowering overfitting. Using their integration into the model pipeline, these preprocessing actions guarantee the well-preparedness of the dataset, so facilitating the deep learning model to achieve high accuracy in OSCC detection and generalization capability.

IV. Proposed Methodology

Fig. 4 demonstrates the proposed methodology for the detection of Oral Squamous Cell Carcinoma (OSCC). The present study is based on a combination of two pre-trained deep learning models: EfficientNetB3 and ResNet50. These models utilize transfer learning techniques and are fine-tuned to increase their performance on the OSCC dataset. The outputs of various models are then integrated using ensemble learning, leading to an enhanced classification performance. Below is a thorough description of the proposed methodology.

A. EfficientNetB3 Architecture

EfficientNetB3 is a deep learning model known for balancing accuracy and efficiency by scaling network depth, width, and resolution, as shown in Fig. 5. It uses a 3x3 convolutional layer followed by MBConv layers, depthwise separable convolutions, and squeeze-and-excitation (SE) blocks for feature extraction. Larger kernel sizes (5x5) in deeper layers help capture contextual information for OSCC differentiation. After feature extraction, the model classifies Normal and OSCC tissues. Its computational efficiency and performance make it ideal for medical imaging, especially when combined with ResNet50 in an ensemble model for OSCC detection.

EfficientNet-B3 is a scalable model that balances network depth, width, and resolution for optimal performance. The scaling is governed by a compound coefficient ϕ, with the scaling laws given in (3):

$$d = \alpha^{\phi}, w = \beta^{\phi}, r = \gamma^{\phi} \quad (3)$$

where d, w, and r represent the depth, width, and resolution of the network, respectively, and α, β, γ are constants determined through grid search. The output of EfficientNet-B3 is passed through a global average pooling layer, followed by a dense layer to produce the final classification output shown in (4):

$$Z_{efficientnet} = softmax\left(W_{efficientnet}.f_{global} + b_{efficientnet}\right) \quad (4)$$

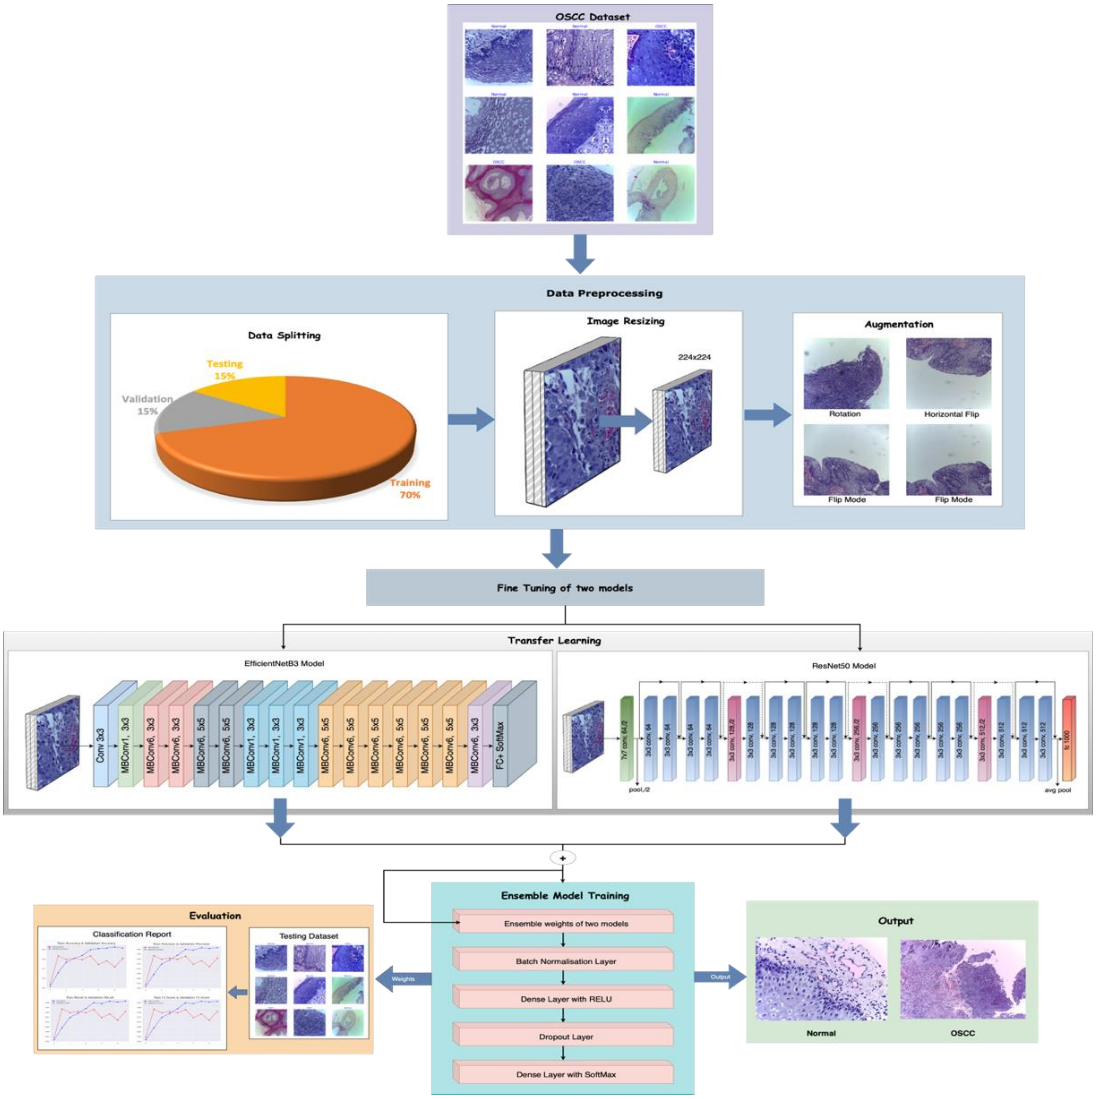

Fig. 4. Proposed methodology.

Where, $Z_{efficientnet}$ represents the predicted probabilities, f_{global} is the feature vector after global pooling, and $W_{efficientnet}$ and $b_{efficientnet}$ are the weights and biases of the final classification layer.

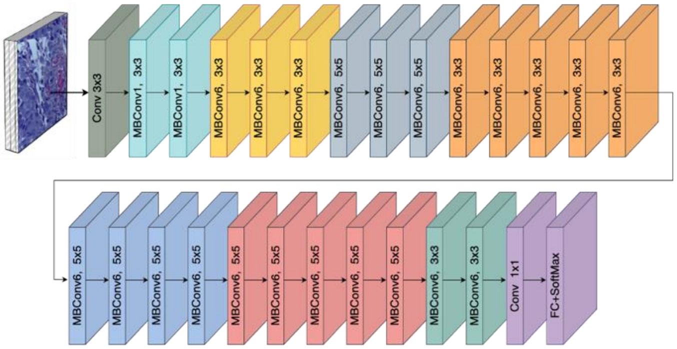

Fig. 5. EfficientNetB3 architecture.

B. *Resnet50 Architecture*

Fig. 6 shows the ResNet50 architecture, a deep CNN designed to overcome challenges in deep network training with 50 convolutional layers, batch normalization, and ReLU activations. Residual connections prevent vanishing gradients, allowing deeper networks. The architecture starts with a 7x7 convolution and max-pooling, followed by four stages with residual blocks and filters ranging from 64 to 512. Spatial dimensions are reduced via stride-2 convolutions for efficiency. The final section includes global average pooling and a fully connected layer. For OSCC detection, the last layer classifies images into Normal and OSCC, helping detect subtle variations in oral cancer.

ResNet50 is a residual network that employs skip connections to address the problem of vanishing gradients in deep networks. The fundamental building block of ResNet50 is the residual block, defined mathematically as in (5):

$$y = F(x, \{W_i\}) + x \tag{5}$$

Where, x is the input, $F(x,\{W_i\})$ represents the convolutional operation with weight parameters $\{W_i\}$, and y is the output of the residual block. The network consists of 50 layers, including convolutional, batch normalization, and ReLU activation layers. The final output of the ResNet50 model, after passing through a global average pooling layer, is given by (6):

$$Z_{resnet} = softmax\left(W_{resnet}.Y_{global} + b_{resnet}\right) \quad (6)$$

Where, Z_{resnet} is the predicted class probabilities, W_{resnet} and b_{resnet} are the weights and biases of the final dense layer, and Y_{global} is the output from the global pooling layer.

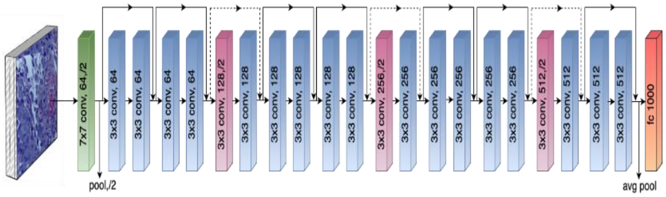

Fig. 6. ResNet50 architecture.

Transfer learning significantly enhanced OSCC detection accuracy by utilizing pre-trained models like EfficientNetB3 and ResNet50, which were fine-tuned on the OSCC dataset. These models transfer learned features, such as texture and shape, from large datasets, reducing the need for extensive labeled data and improving feature generalization. Fine-tuning helps the models capture OSCC-specific patterns, preventing overfitting on small datasets and accelerating training convergence, allowing for efficient and precise differentiation between normal and malignant tissues. This technique proved essential for optimizing accuracy and training speed in medical image analysis.

C. *Ensemble Learning*

The ensemble model with the architecture seen in Fig. 7 combines the predictions of ResNet50 and EfficientNet-B7 to leverage the strengths of both architectures, thereby enhancing overall classification accuracy.

1) Ensemble model design: The ensemble approach is implemented using a weighted average method, where the final prediction is a weighted combination of the individual models' outputs. The output predictions from ResNet50 and EfficientNet-B7 are combined using a weighted average approach shown in (7):

$$Z_{ensemble} = W_{resnet}.Z_{resnet} + W_{efficientnet}.Z_{efficientnet} \quad (7)$$

where $Z_{ensemble}$ is the final ensemble prediction, and $W_{resnet}, W_{efficientnet}$ are the weights assigned to the ResNet50 and EfficientNet-B3 outputs, respectively. These weights are optimized based on the validation performance of each model.

2) Ensemble model algorithm: This algorithm outlines the process of training individual models, obtaining their predictions, combining those using weighted averages or voting, and optionally training a meta-learner to refine the ensemble's predictions. The Algorithm of the ensemble model is shown in Table I.

TABLE I. ALGORITHM OF ENSEMBLE MODEL

```
Algorithm 1: Ensemble Model for Oral Squamous Cell Carcinoma Detection
Input: Histopathological images $D_{train}, D_{val}, D_{test}$ , number of epochs $E$, batch size $B$, learning rate $\eta$.
Output: Trained ensemble model for Oral Squamous Cell Carcinoma detection.
Step 1: Model Initialization
    1.1 Initialize EfficientNetB3 and ResNet50 models with pre-trained ImageNet weights.
    1.2 Configure the final dense layers for detection of two classes (Normal and OSCC).
Step 2: Model Training
    2.1 For each epoch $e$ from 1 to $E$:
    2.2 For each batch $b$ in $D_{train}$:
    2.2.1 Perform forward propagation through EfficientNetB3 to obtain $Z_{efficientnet.}$
    2.2.2 Perform forward propagation through ResNet50 to obtain $Z_{resnet}$.
    2.2.3 Combine the outputs using the weighted average:
            $Z_{ensemble} = W_{resnet}.Z_{resnet} + W_{efficientnet}.Z_{efficientnet}$
    2.2.4 Compute the cross-entropy loss $\mathcal{L}(Z_{ensemble}, Y)$ where $Y$ is the true label.
    2.2.5 Backpropagate the loss and update the weights using the Adamax optimizer with learning rate $\eta$.
Step 3: Model Validation
    3.1 Evaluate the ensemble model on $D_{val}$ after each epoch.
    3.2 Adjust the weights $W_{efficientnet}$ and $W_{resnet}$ based on validation performance.
Step 4: Model Evaluation
    4.1 After completing training, evaluate the model on $D_{test}$.
    4.2 Compute the final accuracy, precision, recall, and F1-score.
Step 5: Model Deployment
    5.1 Save the trained ensemble model for future use.
```

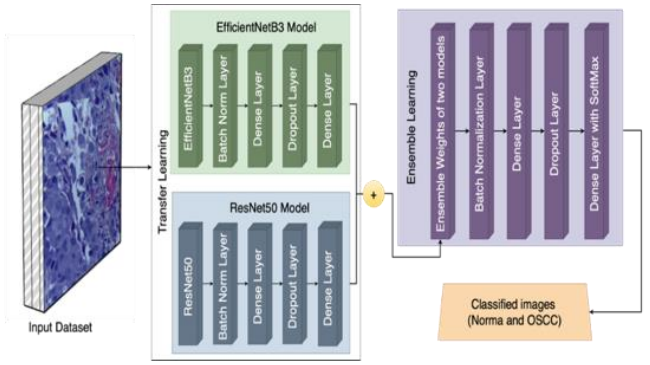

Fig. 7. Ensemble learning architecture.

V. RESULTS

A. *Model Evaluation*

The work aimed at the identification of Oral Squamous Cell Carcinoma (OSCC) using a deep learning approach combining the strengths of two strong models EfficientNetB3 and ResNet50 by constructing the Ensemble model for improved results. Divided into training, validation, and testing, the models were developed using a set including 5,192 histopathology images. The results reveal the degree of increase in OSCC detection classification accuracy resulting from the combined approach. The Confusion Matrix, Performance criteria, and State of the art Comparison are fully described below.

1) EfficientNet-B3's accuracy and loss analysis: The examination of the EfficientNetB3 model's training and validation accuracy, along with its loss metrics across numerous epochs, is shown in Fig. 8 and Table II. The model demonstrates strong generalization and learning capacity, with an early drop in training loss and gradual reduction in both training and validation loss, ultimately converging to low values. The model quickly reaches 90% accuracy early in training, with validation accuracy following suit. Both accuracy measures level off in later stages, indicating the model's peak performance and suitability for reliable predictions, without overfitting.

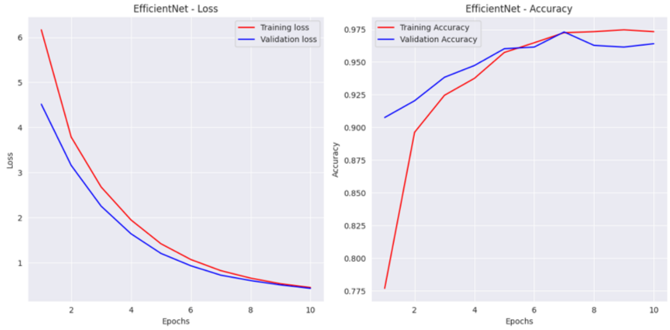

Fig. 8. Loss and accuracy analysis of EfficientNetB3 architecture.

The precise performance per epoch is shown in Table II. It shows that with every epoch the model reduces loss and steadily gains accuracy. The strong learning capacity and adaptability of the EfficientNetB3 model to fresh data are shown by this constant improvement and convergence in both accuracy and loss values [33-36].

TABLE II. EFFICIENTNETB3 MODELS PERFORMANCE PER EPOCH

Epoch	Time(sec)	Loss	Accuracy	Validation Loss	Validation Accuracy
1	131	6.1664	0.7768	4.5153	0.9076
2	54	3.7852	0.8963	3.1570	0.9204
3	54	2.6791	0.9246	2.2538	0.9384
4	53	1.9470	0.9375	1.6400	0.9474
5	54	1.4193	0.9573	1.2048	0.9602
6	54	1.0688	0.9648	0.9303	0.9615
7	54	0.8223	0.9725	0.7222	0.9730
8	54	0.6560	0.9733	0.6015	0.9628
9	54	0.5315	0.9747	0.5054	0.9615
10	54	0.4487	0.9733	0.4286	0.9641

2) ResNet-50's accuracy and loss analysis: The ResNet50 model was trained for 10 epochs, with performance metrics in Table III and accuracy and loss curves in Fig. 9. The training and validation losses steadily decreased, showing effective learning, with a slight generalization gap around the 7th epoch. Training loss stabilized after the 4th epoch, while training accuracy approached 95% by the 10th epoch. Validation accuracy improved gradually, staying slightly below training accuracy. The close alignment of both accuracy curves indicates minimal overfitting and strong generalization. This demonstrates the ResNet50 model's suitability for the current classification task.

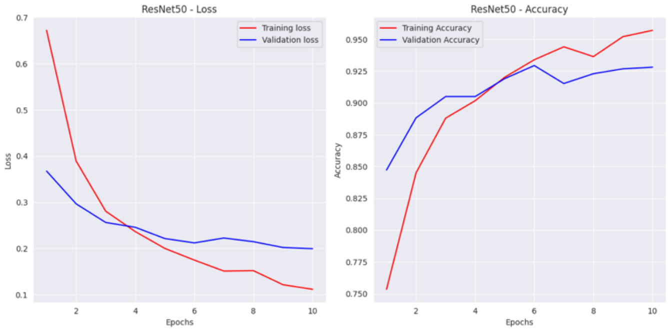

Fig. 9. Loss and accuracy analysis of ResNet50 architecture.

Table III, which illustrates the performance measures for each epoch, shows a constant increase in both training and validation accuracy together with related declines in loss. This development implies that in every epoch the parameters of the model are being tuned somewhat successfully.

TABLE III. RESNET50 MODELS PERFORMANCE PER EPOCH

Epoch	Time(sec)	Loss	Accuracy	Validation Loss	Validation Accuracy
1	43	0.6721	0.7534	0.3674	0.8472
2	36	0.3891	0.8451	0.2965	0.8883
3	36	0.2806	0.8880	0.2562	0.9050
4	36	0.2365	0.9018	0.2457	0.9050
5	37	0.2000	0.9202	0.2214	0.9191
6	41	0.1747	0.9340	0.2120	0.9294
7	36	0.1509	0.9441	0.2225	0.9153
8	37	0.1518	0.9364	0.2146	0.9230
9	35	0.1213	0.9521	0.2020	0.9268
10	36	0.1115	0.9571	0.1994	0.9281

3) Ensemble model's performance analysis: Table IV summarizes the Ensemble model's performance over ten epochs, with corresponding accuracy and loss graphs shown in Fig. 10. The model effectively aggregates multiple classifiers to boost prediction accuracy and reduce generalization error. Training and validation losses consistently decrease, though validation loss shows minor swings, suggesting potential overfitting. Accuracy reaches 99% for training, but validation accuracy varies slightly, indicating room for improvement. Precision and recall graphs in Fig. 11 reveal high precision and steadily improving recall, with validation trends reflecting minor fluctuations. The F1-score and ROC curve in Fig. 12 offer a comprehensive performance view, showing the model's balance between precision and recall and strong discriminative ability. The ROC curve achieves near-perfect AUC scores of 1.00 for both Normal and OSCC classes, highlighting the model's effectiveness in classification with minimal errors, and demonstrating strong reliability.

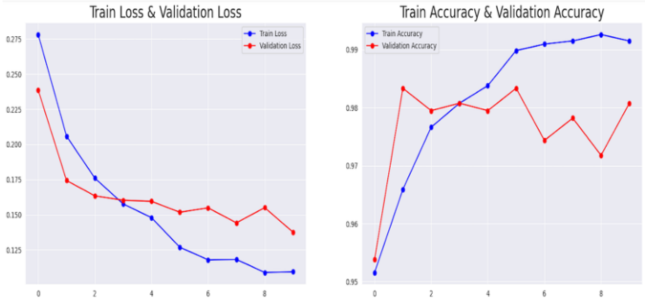

Fig. 10. Loss and accuracy analysis of ensemble model.

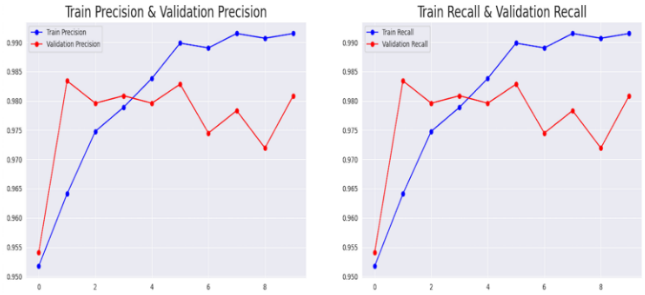

Fig. 11. Precision and recall analysis of ensemble model.

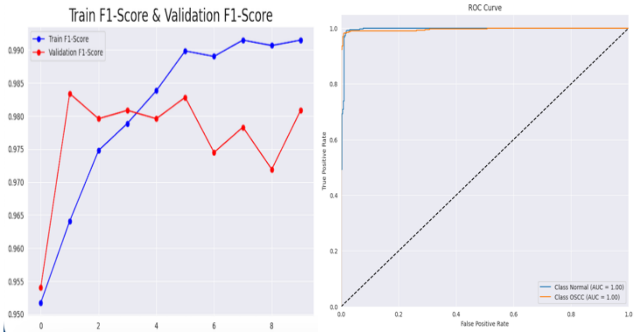

Fig. 12. F1-score and ROC analysis of ensemble model.

Table IV shows the performance measures per epoch, demonstrating constant loss and accuracy improvement. The Ensemble model's efficiency in this classification problem is shown by its ability to preserve great accuracy while reducing loss over epochs.

TABLE IV. ENSEMBLE MODELS PERFORMANCE PER EPOCH

Epoch	Time(sec)	Loss	Accuracy	Validation Loss	Validation Accuracy
1	138	0.1015	0.9854	0.1266	0.9718
2	62	0.0768	0.9907	0.1210	0.9769
3	62	0.0721	0.9923	0.1068	0.9807
4	62	0.0664	0.9934	0.1081	0.9820
5	62	0.0646	0.9951	0.1081	0.9820
6	62	0.0634	0.9942	0.1085	0.9820
7	62	0.0592	0.9940	0.1113	0.9795
8	62	0.0620	0.9926	0.1086	0.9782
9	62	0.0620	0.9926	0.1086	0.9782
10	62	0.0545	0.9934	0.0936	0.9835

B. *Confusion Matrix*

The three models' performance EfficientNetB3, ResNet50, and the Ensemble Model is evaluated here based on the confusion matrices in Fig. 13, 14, and 15. In Fig. 13 the EfficientNetB3 model displays excellent detection performance, properly classifying 385 Normal instances and 384 OSCC cases. However, it misclassifies 9 Normal cases as OSCC and 21 OSCC cases as Normal, demonstrating a minor bias toward misidentifying OSCC as Normal. Despite these flaws, the model exhibits a high level of accuracy overall.

In Fig. 14, the ResNet50 model accurately detects 349 Normal cases and 363 OSCC cases. With 25 Normal instances mistakenly categorized as OSCC and 42 OSCC cases incorrectly identified as Normal, it reveals a higher number of misclassifications than EfficientNetB3. This suggests that although ResNet50 performs well, it finds greater difficulty differentiating the two groups than EfficientNetB3.

Among the three, the Ensemble model in Fig. 15, which integrates the capabilities of EfficientNetB3 and ResNet50 showcases the best performance. With only three Normal cases misclassified as OSCC and eight OSCC cases misclassified as Normal, it correctly classifies 307 Normal cases and 369 Normal cases. The much smaller number of misclassifications implies that the Ensemble model efficiently lowers the mistakes observed in the individual models, hence producing better general accuracy.

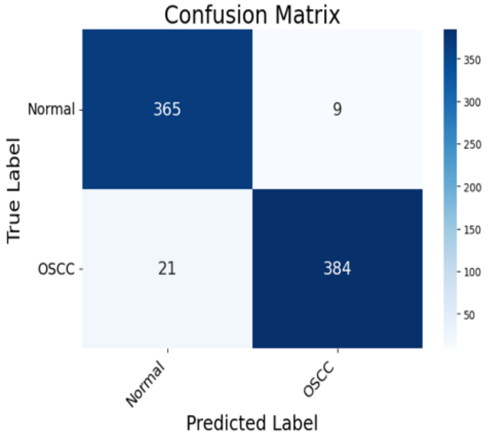

Fig. 13. Confusion matrix of EfficientNetB3.

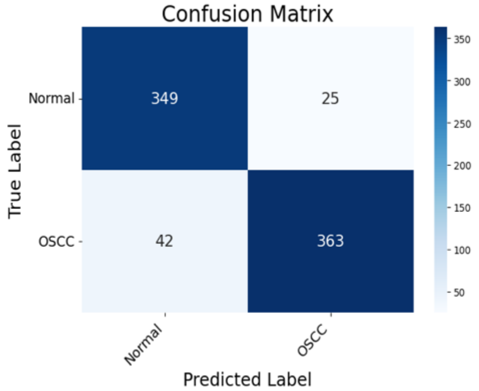

Fig. 14. Confusion matrix of ResNet50.

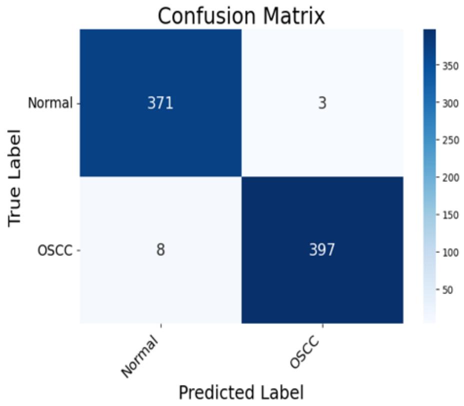

Fig. 15. Confusion matrix of ensemble model.

C. Performance Parameters

Table V presents an extensive three-model performance parameter comparison- precision, recall, F1-score, support, and accuracy across EfficientNetB3, ResNet50, and the Ensemble Model. EfficientNetB3 shows great precision and recall reflecting its great capacity to properly identify positive instances with low false positives and missed real positives. ResNet50 struggles more in differentiating between classes and demonstrates somewhat lower precision and recall even if it is still efficient. Though ResNet50 trails somewhat behind EfficientNetB3, the F1-scores for both models show a reasonable mix of precision and recall. Reflecting its better capacity to balance precision and recall while minimizing classification mistakes, the Ensemble model beats both individual models by obtaining the highest precision, recall, and F1 score. Furthermore, the Ensemble model has the best accuracy, which emphasizes the fact that it can appropriately classify most of the cases. All models show consistent support that guarantees these measures fairly represent performance over a balanced dataset. Combining the strengths of EfficientNetB3 and ResNet50 to provide excellent classification performance, the Ensemble model shows overall to be the most dependable and efficient classifier.

D. State-of-the-Art Comparison

Table VI presents a state-of-the-art comparison of the proposed Ensemble model with EfficientNetB3, ResNet50, and other top approaches in OSCC detection. The Ensemble model outperforms in F1 scores and general accuracy by aggregating model strengths, setting a new benchmark in medical imaging classification tasks.

TABLE V. PERFORMANCE PARAMETERS OF EFFICIENTNETB3, RESNET50 AND ENSEMBLE MODEL

Model	Classes	Precision	Recall	F1-Score	Support	Accuracy
EfficientNetB3	Normal	0.95%	0.98%	0.96%	374	0.96%
	OSCC	0.98%	0.95%	0.96%	405	
ResNet 50	Normal	0.89%	0.93%	0.91%	374	0.91%
	OSCC	0.94%	0.90%	0.92%	405	
Ensemble Model	Normal	0.98%	0.99%	0.99%	374	0.99%
	OSCC	0.99%	0.98%	0.99%	405

VI. Conclusion

This work efficiently applied ensemble learning and transfer learning approaches for the identification of Oral Squamous Cell Carcinoma (OSCC) from histopathology photos. By combining the best features of pre-trained models such as EfficientNetB3 and ResNet50 via ensemble learning, the proposed approach shows astonishing accuracy and robustness. Outliving individual models, the last ensemble model unequivocally displayed increasing generality and accuracy. The detailed study of the performance of the deep learning models in medical image processing highlights its promise since it reveals how to routinely raise accuracy and reduce loss during training and validation datasets. Especially the EfficientNetB3 model has shown remarkable performance measures, thereby addressing the problems of early OSCC detection as a required need for timely and effective treatment. The requirement of incorporating modern deep-learning architectures with ensemble learning techniques to provide reliable and efficient diagnostic tools is underlined in this work. Apart from improving detection accuracy, the proposed method provides a structure suitable for other kinds of cancer and medical image analysis uses. Using more varied datasets and investigating other deep-learning approaches will help to improve the performance of the model, hence producing strong, real-time diagnostic systems for clinical use.

VII. Limitations and Future Scope

Although the suggested transfer learning and ensemble learning method greatly increased the accuracy of OSCC detection, some constraints have to be mentioned. First of all, compared to larger-scale medical imaging datasets, the dataset size is somewhat tiny even if it is enough for the present work. This may restrict the model's generalizability to unprocessed data from many populations. Second, depending on pre-trained models such as EfficientNetB3 and ResNet50 implies that more specific medical datasets for OSCC could help to improve the model's performance even further. Including a bigger, more varied dataset in the next projects could help the model to be more resilient. A deeper understanding of model predictions may also come from investigating more sophisticated ensemble methodologies and including explainable artificial intelligence approaches. Another important development of this work would be implementing the model in actual clinical environments and verifying its efficacy among several institutions.

***Abstract*—In recent years, furniture panel processing positioning based on computer vision technology has received increasing attention. A 3D measurement imaging technology based on laser scanning technology is proposed to address the significant environmental impact of traditional visual technology. Subsequently, deep image processing techniques are introduced to address the high image noise. In the experiment of measuring panel using 3D measurement technology, 14 measurement lines were taken every 10mm of the measurement length. The maximum measurement value was 204.62mm, the minimum measurement value was 204.37mm, and the manual measurement result was 204.5mm. 14 measurement lines were taken every 14mm of the measurement length. The maximum measurement value was 134.15mm, the minimum measurement value was 133.894mm, and the manual measurement was 134.1mm. 14 measurement lines were taken every 14mm of the measurement thickness. The maximum measurement value was 26.646mm, the minimum measurement value was 26.242mm, and the result of manual measurement was 26.5mm. The 3D imaging technology based on laser scanning is relatively accurate in measuring the 3D data of panels, which can be applied in the positioning and detection system of panel processing. In addition, the experiment compares depth image processing methods, verifying the effectiveness of the designed method. Meanwhile, this research also has certain reference significance for exploring the real-time positioning of other objects.**

Keywords*—Laser scanning; 3D measurement; deep image processing; positioning; computer vision

I. Introduction

In the current modern industrial automation and intelligent production, object positioning technology has become a key link. The stability and accuracy of positioning technology are crucial for production efficiency and product quality [1-2]. However, in actual positioning, object positioning systems often encounter anomalies, leading to a decrease in positioning accuracy or even failure. Common positioning faults include hardware failure, software failure, and environmental impact [3]. Among them, environmental factors are an important factor leading to abnormal visual positioning. For example, temperature, humidity, vibration, and other factors at the production site can affect the stability and accuracy of equipment [4-6]. In addition, external light sources, electromagnetic interference, etc. may also cause interference to the visual positioning system, leading to positioning failure. Object positioning technology is of great significance for furniture automation manufacturing. The pursuit of quality of life is also increasing day by day. In the home environment, furniture, as an important component of life, is increasingly attracting consumer attention in terms of quality, style, personalization, and other aspects. To meet consumer demand, the Chinese furniture market is undergoing profound changes, gradually developing towards high-end, branded, intelligent, and personalized directions [7-8]. In this process, the furniture panel industry plays an important role. Furniture panels are not only the basic materials that make up furniture, but also a key factor affecting the quality, appearance, and safety of furniture. A high-quality board not only gives furniture a beautiful appearance but also ensures its durability, providing consumers with a safe and reliable user experience. With the continuous expansion of the high-end furniture market, the furniture panel industry will also usher in more business opportunities. Meanwhile, this also puts higher requirements on the technical level, innovation ability, and product quality of furniture panel enterprises. In order to strengthen the automation and intelligent production of furniture panels in enterprises, more practitioners have added object positioning technology to the processing of furniture panels.

The scanning imaging and image preprocessing of objects exerts a crucial role in the precise positioning of objects. Yin T et al. seamlessly integrated RGB sensors into lidar-based 3D recognition to address the low resolution of lidar sensors. The proposed framework significantly improved the strong center point baseline and outperformed competitive fusion methods [9]. Jiang W et al. proposed a new high-speed 2D and 3D imaging scheme on the basis of traditional single-pixel imaging, which was difficult to achieve high imaging speed using traditional single-pixel imaging mechanisms. The new scheme performed 2D and 3D imaging on a rotating chopper with a speed of 4800rpm, with an imaging speed of up to two million fps, providing a powerful solution for high-speed imaging [10]. Pan X et al. built a deep generative prior method to address the difficulty in capturing rich image semantics. The results showed that this method helped to preserve the reconstruction information, resulting in more accurate and faithful reconstruction results of real images [11]. To optimize the limits of plug and play image restoration, Zhang K et al. inserted deep denoising priors as module parts into iterative algorithms ground on semi quadratic splitting to solve various image restoration problems. The results showed that the designed strategy with deep denoising prior was not only significantly superior to other model-based methods, but also more competitive [12]. Guo Y et al. proposed a fully variational depth network based on deep learning and high-resolution color images to address the edge misalignment and depth discontinuity in color images used for guiding depth image reconstruction. Under the guidance of high-resolution colors, the restored depth image was closest to the ground truth on the edge contours [13]. To assess the position and application of lightweight panels in Iranian furniture production, Khojasteh-Khosro S et al. built an analysis method on the basis of consumer behavior and preferences. The main evaluation criteria for purchasing furniture were product quality, design, price, environmental protection, and guaranteed functionality [14]. Thio V et al. proposed a new step detection strategy relying on the sine wave approximation of acceleration signals to address the noise and infinitely increasing position errors in sensors embedded in smart devices. This method could detect step scores and complete steps, thereby achieving continuous and real-time updates. The results demonstrated the feasibility of using the sine wave approximation method for step detection, and the expected benefits of integrating pedestrian prediction positioning with ultrasound systems [15]. To solve the difficulty in accurately identifying various types of defects in glued wood panels, Chen L C et al. adopted computer vision and deep learning to identify low, high, normal, long, and short defects. The new method achieves higher accuracy than other methods with excessive killing and escape rate analysis [16]. To address the enormous demand for low-cost and high-precision positioning and navigation solutions in emerging IoT applications, Feng D et al. built an indoor positioning system that combined inertial measurement units with ultra-wide bands by extending Kalman filters and unscented Kalman filters. The results indicated that the prior information provided by the inertial measurement unit could significantly suppress ultra wide-band observation errors [17]. In response to the problem that the currently released dataset for crowd counting and localization is too small to meet the requirements of supervised convolutional neural network algorithms, Wang Q et al. built a large-scale crowded crowd counting and localization dataset NWPU-Crowd, consisting of 5109 images and 2133375 annotated headers with dots and boxes. The results showed that the new dataset could meet the requirements of supervised convolutional neural network algorithms [18].

In summary, domestic and foreign researchers have put forward many discussions on the positioning of furniture panel processing, including the three-dimensional measurement technology. However, few scholars have combined 3D measurement technology based on laser scanning technology with depth image processing technology. Compared with the methods used in the study, although these methods may be enhanced in certain directions, they are still relatively weak in continuous and large-scale image processing. In response to this issue, a furniture panel processing and positioning design based on 3D measurement and depth image technology is proposed, aiming to apply different technologies to different stages of panel positioning to achieve optimal positioning results. Compared with other works in the same direction, the method proposed in the study has higher processing efficiency for sheet images due to the use of mature methods that have been validated for a long time, thus meeting the requirements for processing a large number of images. The innovation of the research lies in the combination of 3D measurement imaging technology and depth image processing technology, which helps to better locate the position of the panel.

II. Methods and Materials

Aiming at the high-precision measurement problem required for furniture panel processing positioning, a 3D measurement imaging technology based on laser scanning is introduced. On this basis, deep image processing technology is applied to process the images scanned by 3D measurement imaging technology, providing a position positioning basis for furniture panel processing.

A. 3D Measurement Imaging Technology Based on Laser Scanning

Currently, 3D measurement technology has been applied in many fields. This study adopts a 3D measurement technology based on laser scanning technology. The basic principle of laser measurement is to use the reflection of light for measurement. After the laser beam is emitted onto the object being measured, a portion of the light is reflected by the object, while another portion of the light is absorbed or scattered by the object. A laser measuring instrument obtains relevant information about the measured object by measuring the reflected light [19-20]. Laser scanning measurement utilizes an external motion platform to continuously scan laser lines through the target surface, thereby obtaining the overall contour of the object. To achieve real-time measurement of moving target objects, the laser triangulation method is used for measurement. The basic principle of laser triangulation is to irradiate a beam of laser at a specific angle onto the surface of the measured object, and then observe the laser spot on the measured object from a different angle. The position of the light spot varies with the height of the measured object [21-22]. The photodetector measures the position of the spot imaging, which can determine the height of the laser irradiation point on the object. The laser triangulation measurement technology utilizes optical reflection laws and the principle of similar triangles. Its vertical measurement is shown in Fig. 1.

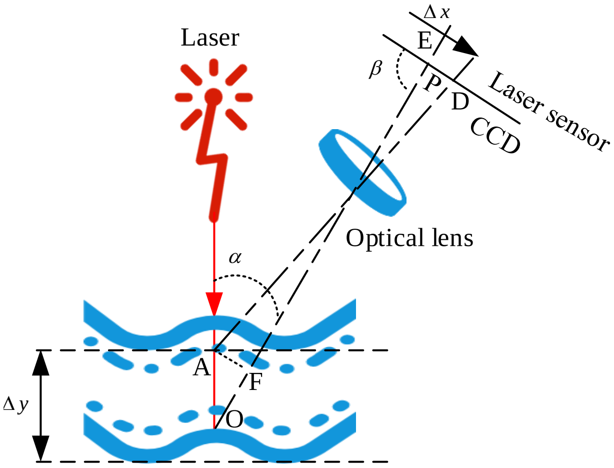

Fig. 1. Schematic diagram of laser vertical measurement.

In Fig. 1, A represents the contact point between the laser and the upper surface of the object, and O represents the contact point between the laser and the lower surface of the object. AP and AD represent the reflected light rays formed by a lens after being reflected by an object. Assuming the initial position of the object surface is in a certain plane, when the distance △ y moves to the lower surface, the incident point changes from position A to point O, and the corresponding image point changes from point D to position P. From the changes in the optical path structure, it can be inferred that the incidence points at different heights correspond to different imaging point positions. Based on this relationship, the spatial position information of any point on the surface of an object can be obtained by analyzing the geometric relationship between the image point and the incident point. Eq. (1) can be obtained from the similarity between triangle △AFB and △BDE.

$$\frac{AF}{DE}=\frac{FB}{BE} \tag{1}$$

In Eq. (1), A is the projection point of the laser axis on the object. D is the corresponding pixel. F,E are perpendicular feet of the vertical line that reflects light at point A and point D. B is the location of the intersection point between two lasers, that is, the intersection point between the laser and the optical lens. Eq. (2) can be obtained by transforming Eq. (1).

$$\frac{AO\cdot\sin\alpha}{DP\cdot\sin\beta}=\frac{OB-AO\cdot\cos\alpha}{BP+DP\cdot\cos\beta} \tag{2}$$

In Eq. (2), O signifies the intersection point between the vertical injection of the laser and the lower surface of the object. P is the image point position of the laser reflected light on the laser sensor. α is the angle between AO and OP. β is the angle formed between OP and the linear CCD after passing through the lens. Eq. (2) can be transformed to obtain Eq. (3).

$$AO=\frac{OB\times DP\times\sin\alpha}{BP\times\sin\alpha+DP\times\sin(\alpha+\beta)} \tag{3}$$

In oblique measurement, Eq. (4) can be obtained according to the ray projection relationship and the principle of similar triangles.

$$\frac{AF}{\sin\alpha}\times\frac{1}{DP\times\sin\beta}=\frac{OB}{BP+DP\times\cos\beta} \tag{4}$$

In Eq. (4), AF is the height of the incident point on the object. DP is the displacement between pixels. D and F are the image points corresponding to the positions of point A and point O. OB is the imaging objective distance of point O. BP is the image distance. Eq. (4) can be transformed to obtain Eq. (5).

$$AF=\frac{DP\times\sin\beta\times OB\times\sin\alpha}{BP+DP\times\cos\beta} \tag{5}$$

Laser triangulation scanning imaging technology is widely used in automated production. However, in actual factory operations, there are often problems that cannot detect and recognize objects. There are many reasons for such problems, as shown in Fig. 2.

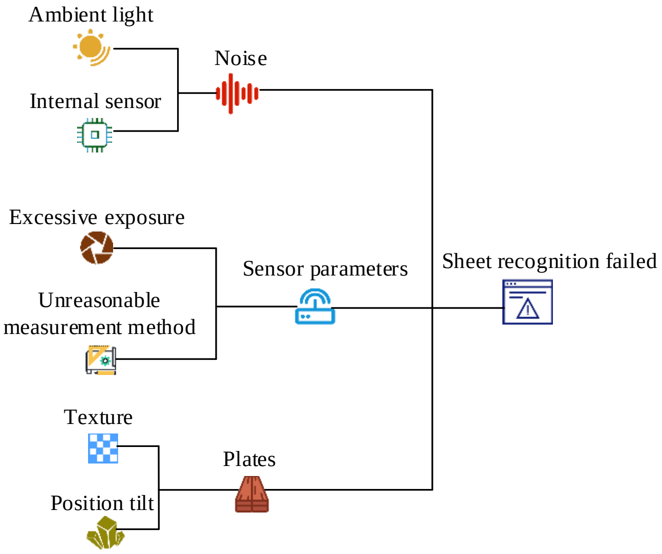

Fig. 2. System influencing factors.

Fig. 2 shows the factors that the system cannot detect and recognize objects, mainly including external noise, sensor working parameter settings, board position and texture, etc. In addition, the board position detection system may also fail to effectively scan and recognize objects, as shown in Fig. 3.

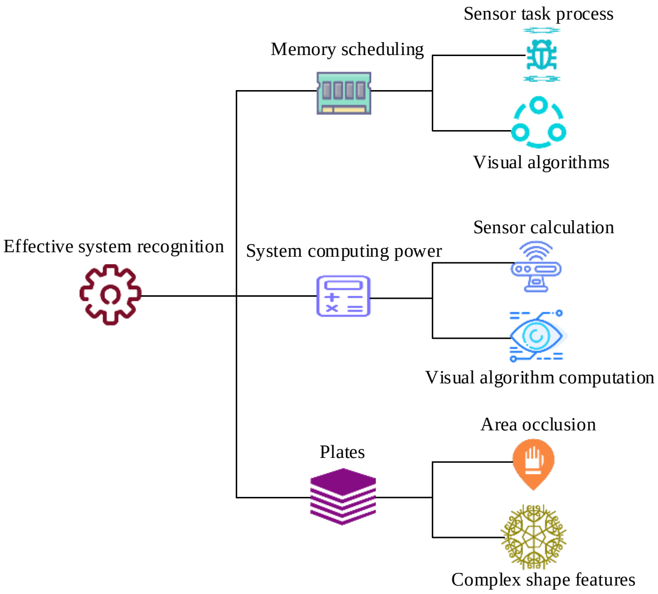

Fig. 3. The system logic.

Fig. 3 shows the factors that affect the effective identification of the board detection system. Among them, the board position detection system needs to integrate several functional requirements in the software composition structure, including hardware communication, visual processing, robot control, sensor data exchange, etc.

B. Design of Furniture Panel Positioning and Detection System Based on Depth Image Technology

Due to the interference of external environment during image collection, the collected board images often contain some noise and have poor image quality. Therefore, after the panel is scanned into images through three-dimensional measurement, it is necessary to preprocess the images [23]. Several processing algorithms for image enhancement and filtering denoising are studied, and suitable depth image preprocessing algorithms are selected based on their processing effects, effectively improving the plate recognition accuracy, as displayed in Fig. 4.

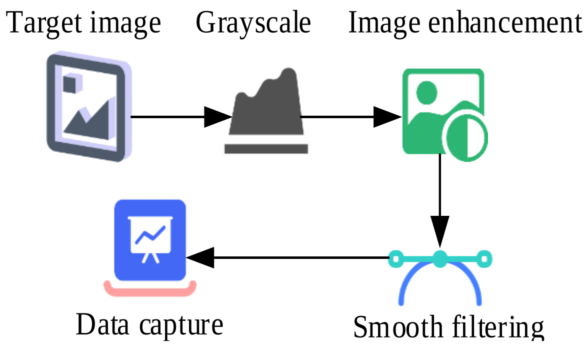

Fig. 4. Image processing and target extraction process.

Fig. 4 shows the preprocessing and target area extraction process of the panel image after three-dimensional measurement. In Fig. 4, image preprocessing is mainly aimed at suppressing or eliminating irrelevant signals in the image, enhancing the true information such as edges in the image. The processing methods include filtering denoising, contrast enhancement, etc. The scope of image enhancement processing is divided into spatial and frequency domain processing. The study adopts the spatial enhancement method. The spatial domain refers to the two-dimensional space of the image itself. This processing is performed on the image pixels, as shown in Eq. (6).

$$g(m,n)=T\left[f(m,n)\right] \tag{6}$$

In Eq. (6), (m,n) represents the current operating pixel point. $f(m,n)$ signifies the initial pixel grayscale value. $g(m,n)$ signifies the processed pixel grayscale value. T is the functional model of the processing method. Grayscale transformation is a common spatial domain image enhancement algorithm that can increase the grayscale distribution range of an image and make local details clearer. There are several commonly used enhancement methods. The image inversion method is shown in Eq. (7).

$$g(m,n)=L-T\left[f(m,n)\right]-1 \tag{7}$$

In Eq. (7), L represents the grayscale value of the original image. The linear transformation method is shown in Eq. (8).

$$g(m,n)=I_1-k\left[f(m,n)-M_1\right] \tag{8}$$

In Eq. (8), k represents the slope of the transformation function. I_1 represents the starting point of the processed pixel grayscale value interval. M_1 represents the starting point of the initial grayscale value interval for pixels. The slope k is shown in Eq. (9).

$$k=\frac{I_2-I_1}{M_2-M_1} \tag{9}$$

In Eq. (9), I_2 represents the endpoint of the processed pixel grayscale value interval. M_2 represents the endpoint of the initial grayscale value interval for pixels. To highlight the target of interest or certain regions in the image, segmented linear transformation can be used to expand the grayscale regions at different levels on the image, as shown in Eq. (10).

$$g(m,n)=\begin{cases}\dfrac{I_2-I_1}{M_2-M_1}\left[f(m,n)-M_1\right]+I_1 & M_1\le f(m,n)\le M_2\\ \dfrac{I_1}{M_1}\left[f(m,n)-M_1\right]+I_1 & 0\le f(m,n)\le M1\end{cases} \tag{10}$$

Another method for enhancing depth images of panel is histogram equalization. Histogram equalization is to adjust the probability distribution of pixels at each grayscale level to evenly distribute the overall grayscale range of pixels, in order to expand the dynamic range of pixel grayscale. Its expression is shown in Eq. (11).

$$T(j)=\int_0^j p_j(z)dz \tag{11}$$

In Eq. (11), $T(j)$ represents the probability density distribution function of j. z represents the integral variable. j represents the grayscale value. p_j represents the probability of processed pixels. The probability of pixels in each grayscale interval of the original image is shown in Eq. (12).

$$P(i)=\frac{n_i}{n} \tag{12}$$

In Eq. (12), $P(i)$ represents the probability of pixels in the original image. n_i represents the original image pixels. n represents the total pixels in the image. The grayscale cumulative histogram is shown in Eq. (13).

$$p_j=\sum_{i=0}^{L-1}P(i) \tag{13}$$

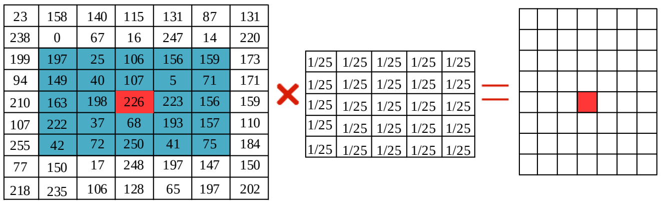
In Eq. (13), L signifies the pixel grayscale value . The grayscale value calculation is shown in Eq. (14).

$$j=(L-1)p_j \tag{14}$$

According to Eq. (11) to Eq. (14), the histogram after image processing can be obtained, as shown in Eq. (15).

$$P(j)=\frac{n_j}{n} \tag{15}$$

In Eq. (15), $P(j)$ is the probability density after image processing. n_j is the pixel point after image processing. During image acquisition, due to the low stability of the sampling system, it may be affected by external environmental interference, resulting in a significant amount of noise in the obtained image. To reduce the impact of these noises, the original image needs to be smoothed. In this study, mean filtering is used for denoising. It is a relatively simple and fast processing method in filtering algorithms, as shown in Fig. 5.



23	158	140	115	131	87	131

1/25	1/25	1/25	1/25	1/25

Fig. 5. Mean filtering denoising method.

Fig. 5 shows the mean filtering denoising method. The pixel value of any point in Fig. 5 is the mean of surrounding N/times M pixels, where the pixel value of the red point is the sum of the pixel values of the surrounding blue background area divided by 25. After image enhancement processing, a high-quality image is obtained. In subsequent processing, the target information is often only a part. For the entire image, only this part of the features need to be extracted and analyzed. The image obtained through image preprocessing can be used for panel detection and recognition. The detection system framework is shown in Fig. 6.

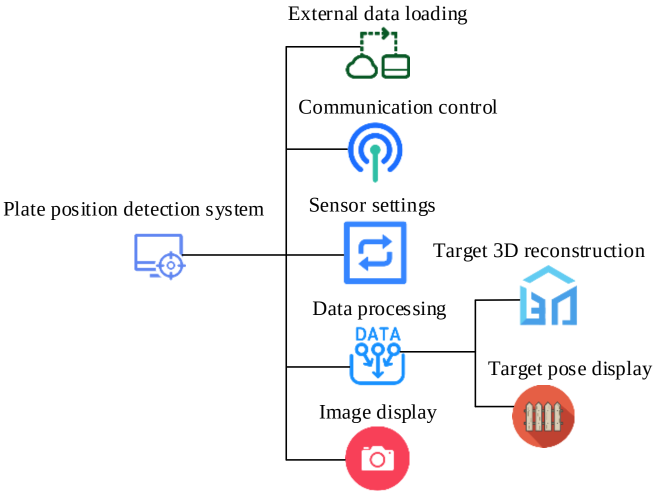

Fig. 6. Framework diagram of panel detection system.

Fig. 6 is the framework diagram of the board detection system. From Fig. 6, the system mainly includes several parts: external data loading, communication control, sensor settings, image acquisition and display, and depth image data processing. The interactive interface written by C#.NET integrates several functional modules of the software system, making the operation simple and efficient.

III. Results

To verify the effectiveness of the plate processing positioning and detection system, simulation analysis is conducted. Firstly, the relationship between laser sensors and imaging images in 3D measurement technology is analyzed. Subsequently, the depth image processing method is validated. Finally, the recognition accuracy of the plate positioning detection system is experimentally analyzed.

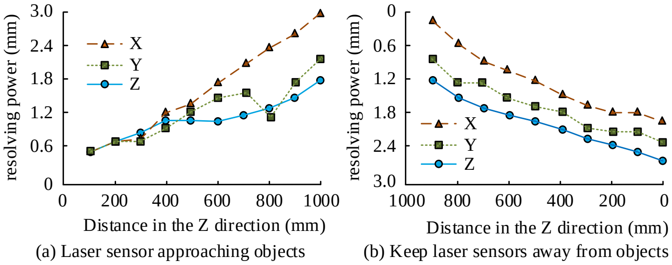
A. Analysis of Furniture Panel Processing Positioning Design Based on 3D Measurement Technology

This experiment is developed in the Visual Studio 2022 17.4 development environment, using C# as the programming language. The Halcon machine vision algorithm package processing function library and open graphics library 3D display tool are combined to build the system software framework. Table I displays the experimental parameter settings.

TABLE I. Experimental Parameter Settings

Parameter type	Index	Explain
Response time	10ms	/
Measuring range	250-650mm	X-axis
	200-1000mm	Z-axis
Laser wavelength	660nm	/
Laser line length	600×3mm	At a height of 850mm
Resolving power	0.6-1.8mm	X-axis
	1-4mm	Z-axis
Working voltage	20-35v	DC
Communication protocol	UDP	/

The images formed by 3D measurement technology are the basis for subsequent positioning and detection of panel processing. To verify the effectiveness of 3D measurement technology, experiments are conducted on various aspects of the technology, mainly focusing on the quantitative analysis between 3D measurement imaging technology on the basis of laser scanning and image formation. The relationship between the object distance of the sensor and the imaging resolution is shown in Fig. 7.



(a) Laser sensor approaching objects (b) Keep laser sensors away from objects

Fig. 7. The relationship between sensor distance and resolution.

In Fig. 7(a), when the laser sensor was close to the measured object, the resolution was higher. The resolution change speed in the X-direction was smaller than that in the Y and Z-axes. The length of the laser line in the X-direction depended on the distance Z between the measured object and the sensor. When the Z-axis distance was 1000mm, the laser line length reached the maximum value of 600mm, and the corresponding measurement resolution was also the lowest. In Fig. 7(b), the resolution decreased when the laser sensor was far away from the measured object. The resolution change speed in the X-direction was smaller than that in the Y and Z- axes. When the Z-axis distance was 900mm, which was the initial position, the corresponding measurement resolution was the highest. It indicates that when the sensor is further away from the target, it is easier to obtain more accurate images. The resolution is inversely proportional to the distance from the measurement object during measurement. The coordinate distribution of the measured object on the X and Z-axes is shown in Fig. 8.

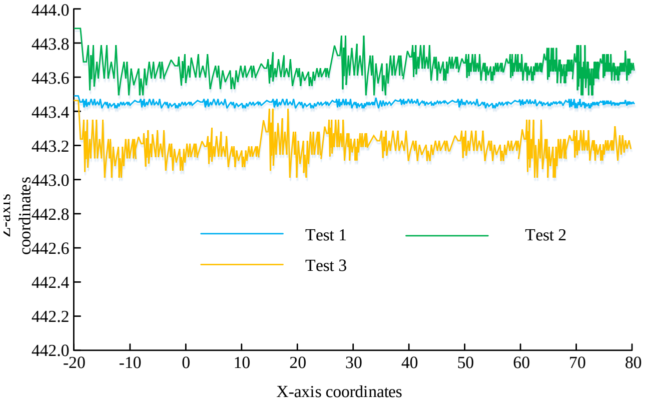


Fig. 8. Sensor single measurement test coordinates.

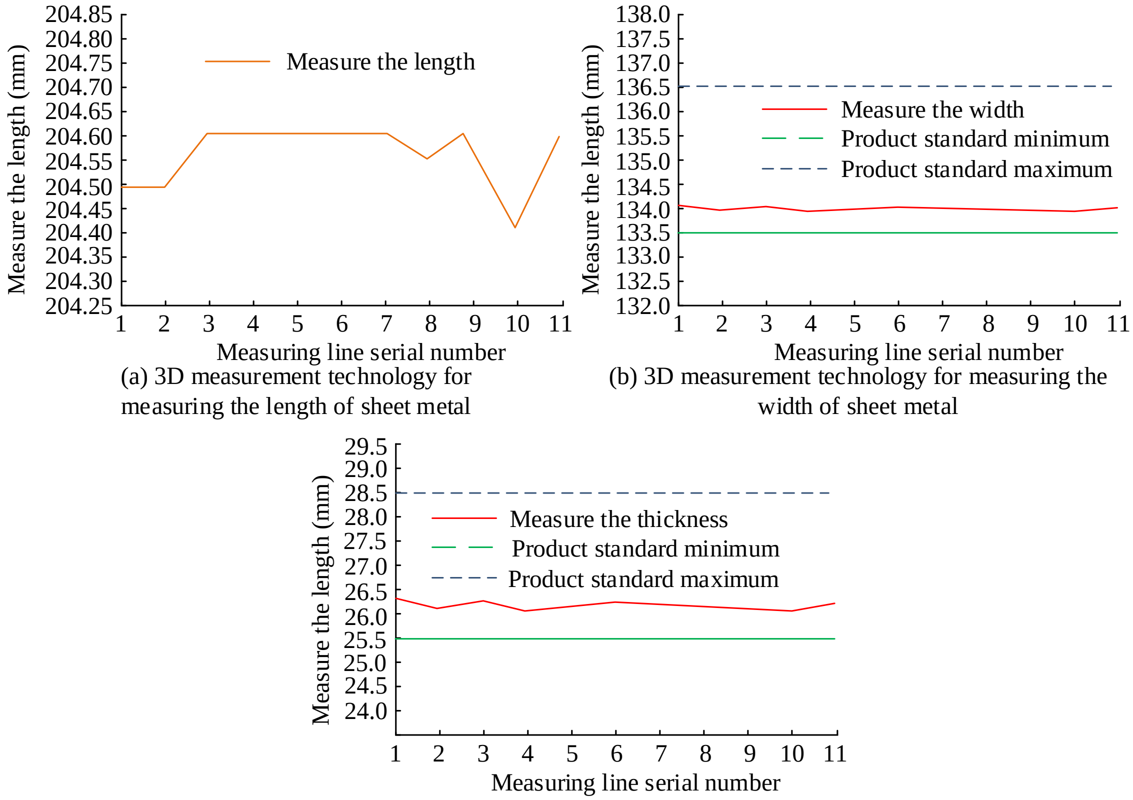
As shown in Fig. 8, the coordinate distribution of Test1, Test2, and Test3 on the Z-axis was relatively stable, with Test1 concentrated around 443.5, Test2 concentrated around 443.2, and Test3 concentrated around 443.7. The coordinate information on the X-axis and Z-axis is relatively complete, which can verify the connection status and good data measurement of the laser sensor. The actual measurement of panel using 3D measurement technology is shown in Fig. 9.

According to Fig. 9(a), 14 measurement lines were taken every 10mm interval. The maximum measurement value was 204.62mm, the minimum measurement value was 204.37mm, and the manual measurement result was 204.5mm. As shown in Fig. 9(b), a total of 14 measurement lines were taken every 14mm interval. The maximum measurement value was 134.15mm, the minimum measurement value was 133.894mm, and the manual measurement result was 134.1mm. As shown in Fig. 9(c), 14 measurement lines were taken every 14mm of the measurement thickness. The maximum measurement value was 26.646mm, the minimum measurement value was 26.242mm, and the manual measurement result was 26.5mm. The 3D imaging technology based on laser scanning is relatively accurate in measuring the 3D data of panel, which can be applied in the positioning and detection system of panel processing.

B. *Analysis of Furniture Panel Positioning and Detection System Based on Deep Image Technology*

Deep image processing technology can highlight the target area, suppress or eliminate irrelevant signals in the image, and enhance the true edge information in the image. Common processing techniques include grayscale transformation and histogram equalization. The latter is displayed in Fig. 10.

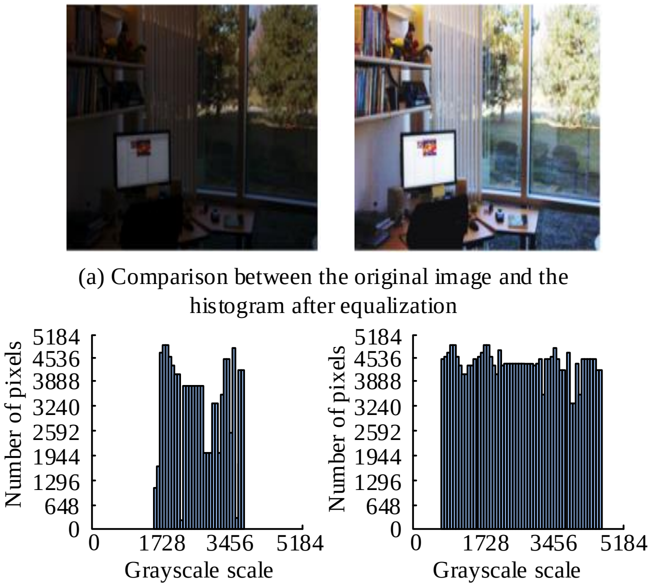


(a) 3D measurement technology for measuring the length of sheet metal

(b) 3D measurement technology for measuring the width of sheet metal

(c) 3D measurement technology for measuring the thickness of sheet metal

Fig. 9. 3D measurement technology for measuring the three-dimensional dimensions of panel.



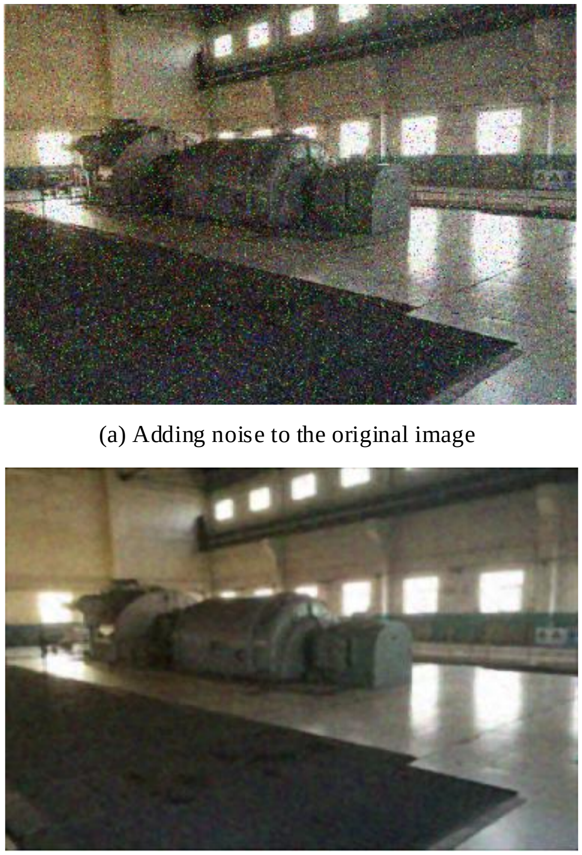
(a) Comparison between the original image and the histogram after equalization

(b) Comparison between initial histogram and equalization histogram

Fig. 10. Comparison chart of histogram equalization processing.

From Fig. 10(a), for some unclear detail features in the original image, after histogram equalization processing, the grayscale levels of these areas were richer. As shown in Fig. 10 (b), the histogram after equalization was greatly expanded. The original image had a grayscale range of 1720 to 3470, while the balanced image had a grayscale range of 700 to 5100. The grayscale range of areas with similar grayscale and occupying many pixels in the original image was widened, making small grayscale changes in large areas visible and making the image clearer. Experimental data shows that histogram equalization can enhance the visual effect of images and enhance the overall contrast of images. During image acquisition, due to the low stability of the sampling system, it may be affected by external environmental interference, resulting in much noise in the obtained image. This makes the subsequent processing and analysis of the image more complex. To reduce the impact of these noises, the original image needs to be smoothed and filtered. The mean filtering is used to process image noise, as shown in Fig. 11.

As shown in Fig. 11, the upper image is the original image with added noise, and the lower image is the image processed by mean filtering. The noise in the image below was significantly reduced. The experiments show that mean filtering can effectively remove noise. To analyze the positioning accuracy of the plate processing positioning detection system and verify the stability performance, the actual coordinate position under the sensor detection system is indirectly obtained by obtaining the position displayed by the robot at the specified position, and experimental data is measured accordingly. The data and statistical error distribution diagram are shown in Fig. 12.



(a) Adding noise to the original image

(b) Image processed by mean filtering with noise

Fig. 11. Comparison chart of mean filtering denoising.

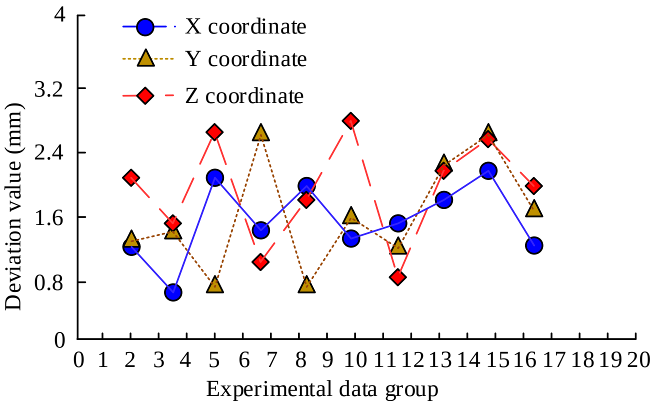


Fig. 12. Coordinate deviation diagram of the panel.

In Fig. 12, the maximum error of the experimental group in the X-axis was 2.2mm and the minimum was 0.6mm. The maximum error in the Y-axis was 2.6mm and the minimum was 0.8mm. The maximum error in the Z-axis was 2.8mm and the minimum was 0.8mm. The experimental data shows that the overall coordinate deviation of the experimental group can be controlled within 5mm, which can meet the positioning and detection requirements of the system.

IV. Discussion

In order to accurately locate furniture panels, a furniture panel processing and positioning system based on 3D measurement and depth imaging technology was studied and designed. The results showed that the experimental group of the detection system had a maximum error of 2.2mm and a minimum error of 0.6mm in the X direction. The maximum error in the Y direction is 2.6mm, and the minimum is 0.8mm. The maximum error in the Z direction is 2.8mm, and the minimum is 0.8mm. Similarly, scholars such as Fan J proposed the Chaos Cuckoo Search Algorithm (Ccsa) to solve image segmentation problems in computer vision and improve image accuracy. Unlike ordinary cuckoo search, chaotic mapping combines deterministic search and random verification. The experimental results show that compared with other existing methods, the proposed CCSA model improves accuracy and reduces uncertainty [21]. In contrast, the study uses grayscale transformation for image enhancement and employs mean filtering for denoising. From the perspective of image detection accuracy, the proposed method has slightly poor performance in image processing. The reason is that the method used in the study is greatly affected by image quality factors, and in the process of sheet metal processing, image quality is greatly affected by environmental factors such as surrounding sawdust and dust, resulting in relatively low image detection accuracy. Take a measurement line every 14mm and use 3D measurement technology for measurement. The maximum measurement result is 26.646mm, the minimum measurement value is 26.242mm, and the manual measurement result is 26.5mm. The research of Qian J and other scholars adopted a deep learning based color stripe projection contour technique for single absolute 3D shape measurement. The results show that this method can perform high-precision single frame absolute 3D shape measurement on complex objects [22]. This result is slightly higher than the 3D scanning imaging technology used in the study, indicating that the research can further optimize the scanning accuracy.

V. Conclusion

Traditional computer vision technology has a significant impact on furniture panel positioning due to environmental factors. Based on this, this study introduced furniture panel positioning based on 3D measurement and depth image processing technology. The results indicated that the resolution change rate of the image on the X-axis was smaller than that in the Y and Z-axes. When the Z-axis distance was 1000mm, the laser line length reached the maximum value of 600mm, and the corresponding measurement resolution was also the lowest. When the laser sensor moved away from the measured object, the resolution decreased, and the resolution change rate in the X-axis was slower than that in the Y and Z-axes. When the Z-axis distance was 900mm, which was the initial position, the corresponding measurement resolution was the highest. In addition, two sets of measurement tests were conducted on the object to observe its coordinate distribution. The coordinate distribution of Test1, Test2, and Test3 on the Z-axis was relatively stable, and the maximum error of the detection system in the X-axis was 2.2mm, and the minimum was 0.6mm. The maximum error in the Y-axis was 2.6mm and the minimum was 0.8mm. The maximum error in the Z-axis was 2.8mm and the minimum was 0.8mm. Experimental data showed that when the sensor was closer to the target, it was easier to obtain more accurate images. The resolution was inversely proportional to the distance from the measured object during measurement. The overall coordinate deviation of the experimental group was controlled within 5mm, which verified the effectiveness of the positioning detection system. Through the verification and analysis of the results, the design of furniture board processing positioning has been achieved, and the detection system can effectively identify and detect the board, which provides important technical support for the automation processing of the board. However, through the analysis of existing research results, it was found that although the image recognition detection error meets the requirements, there is still significant room for improvement. The proposed work aims to further address the factors that affect measurement accuracy in actual measurement operations, not only limited to environmental factors such as sawdust and dust, but also including scanning imaging hardware, system errors, and more advanced image processing technologies. In addition to upgrading hardware facilities, the most important aspect of the proposed work is to increase the universality of research. A detailed exploration was conducted on the positioning of furniture boards based on the processing environment, taking into account factors such as fiber optics and dust in the processing environment. However, there was insufficient exploration of object positioning in other environments. The future direction of work will further investigate the universality of the proposed method, such as verifying its localization ability under the influence of different factors such as temperature, humidity, light, and object shape.

Research and Implementation of Facial Expression Recognition Algorithm Based on Machine Learning

Xinjiu Xie*, Jinxue Huang
School of Modern Information Industry, Guangzhou College of Commerce, Guangzhou 511363, China

***Abstract*—Traditional information security management methods can provide a degree of personal information protection but remain vulnerable to issues such as data breaches and password theft. To bolster information security, facial expression recognition offers a promising alternative. To achieve efficient and accurate facial expression recognition, we propose a lightweight neural network algorithm called T-SNet (Teacher-Student Net). In our approach, the teacher model is an enhanced version of ResNet18, incorporating fine-grained feature extraction modules and pre-trained on the MS-Celeb-1M facial dataset. The student model uses the lightweight convolutional neural network ShuffleNetV2, with the model's accuracy further improved by optimizing the distillation loss function. This design carefully considers the key features of facial expressions, determines the most effective extraction techniques, and classifies and recognizes these features. To evaluate the performance of our algorithm, we conducted comparative experiments against state-of-the-art facial expression recognition methods. The results show that our approach outperforms existing methods in both recognition accuracy and efficiency.**

I. Introduction

Facial Expression Recognition (FER) technology has become increasingly prevalent across various fields, significantly enhancing human-computer interaction and automation systems. In healthcare, FER is utilized to diagnose and monitor mental health conditions by analyzing patients' emotional states. For example, individuals with depression or anxiety often display specific emotional characteristics that FER can help clinicians identify, leading to more personalized treatment plans. In marketing and retail, FER is employed to assess customer satisfaction and engagement by observing their reactions to products and advertisements. Businesses can use this technology to analyze emotional changes during shopping, allowing them to optimize product displays and advertising strategies, ultimately increasing conversion rates. Security systems leverage FER to detect suspicious behaviors and potential threats based on facial cues. In public spaces and critical facilities, FER can monitor the emotional state of crowds in real-time, quickly identifying abnormal behaviors to prevent potential security risks. In education, FER assists in evaluating students' comprehension and engagement during remote learning. By analyzing students' facial expressions during classes, teachers can better understand their attention levels and emotional states, allowing them to adjust teaching methods for improved educational outcomes.

The significance of FER lies in its ability to provide deeper insights into human emotions and intentions, which is crucial for enhancing communication and interaction between humans and machines. By accurately interpreting facial expressions, systems can respond more appropriately to users' needs, thereby improving user experience and efficiency. For instance, in customer service, FER-equipped automated systems can detect signs of customer frustration and promptly offer assistance, leading to increased satisfaction. These systems can analyze facial expressions in real-time during interactions with service representatives, immediately alerting the representative to take appropriate action when signs of confusion or dissatisfaction are detected, thus improving service quality.

Neural networks, especially deep learning models, have been instrumental in advancing facial expression recognition (FER). These models can automatically learn and extract complex features from facial images, outperforming traditional methods that rely on handcrafted features. For example, Convolutional Neural Networks (CNNs) are particularly effective at recognizing subtle facial expressions by capturing the spatial hierarchy of facial features. Through multiple convolutional and pooling layers, CNNs create hierarchical feature representations from raw images, which are essential for distinguishing various facial expressions. Moreover, Recurrent Neural Networks (RNNs) and Long Short-Term Memory networks (LSTMs) enhance FER by incorporating temporal dynamics, enabling the analysis of expression sequences over time. These networks are well-suited for handling time-series data, as they capture dependencies between different time points—critical for understanding the dynamic nature of expression changes. The integration of neural networks into FER systems significantly enhances their accuracy and robustness, making these systems more reliable and practical for real-world applications. This technological progress expands the potential applications of facial expression recognition across various domains, driving further innovation in human-computer interaction technologies.

Section II introduces the current development status, and Section III presents the methods we propose. The superiority of our proposed method has been demonstrated through experiments in Section IV. Finally, a summary and outlook were made in Section V.

II. Literature Review

In this section, we introduce the development of recognition algorithms, and facial expression recognition algorithms, and summarize the research gaps.

*Corresponding Author.

A. Recognition Algorithm

With the advancement of technology, recognition algorithms have become increasingly sophisticated. These algorithms are not only prevalent in the field of image processing but are also applied across various other domains. Li et al. [1] proposed a method employing a differential evolution algorithm to optimize convolutional neural network (CNN) parameters for music emotion recognition tasks. Chen et al. [2] addressed the issues of slow convergence and weak generalization capability of CNNs in-vehicle feature recognition by proposing an improved bee colony algorithm to optimize CNN-based vehicle recognition strategies (ibsa-cnn). Li et al. [3] introduced a super-automatic algorithm combining non-local convolution and three-dimensional convolutional neural networks to address the shortcomings of missing critical feature information when processing long-time series video behavior features. Shi et al. [4] utilized data collected from multiple sensors measuring the Earth's magnetic field and employed a one-dimensional convolutional neural network algorithm for gesture recognition. Mao et al. [5] selected the Mel-frequency cepstral coefficient (MFCC) and filter bank (Fbank) as feature parameters to recognize English speech. Zhou et al. [6] proposed a method for lip print recognition based on convolutional neural networks.

In summary, recognition methods based on convolutional neural networks have been applied in a wide range of fields. Therefore, with the continuous development of technology, we can achieve more accurate facial expression recognition based on neural networks.

B. Facial Expression Recognition Algorithm

Currently, many scholars are dedicated to researching facial expression recognition algorithms. Zheng et al. [7] proposed a facial expression recognition method called TransformerKNN (TKNN), which integrates information about the state of the eyebrows and eyes in scenarios where the face is partially covered by a mask. Dong et al. [8] introduced a basic center regularization term based on the variance between basic centers to ensure that the learned expression features possess adequate discriminative capability. Wang et al. [9] proposed an Expression Complementary Disentanglement Network (ECDNet), which accomplishes the Facial Expression Disentanglement (FED) task during the face reconstruction process to handle all facial attributes in the disentanglement process. Yan et al. [10] introduced a new neonatal facial expression database for pain analysis. Win et al. [11] proposed a method for synthesizing complex facial expression images from learned expression representations without specifying emotion labels as input. Naveen et al. [12] addressed the problem of facial expression recognition under occlusion and proposed a robust facial expression recognition framework.

In summary, most current practice systems design a common practice path that all students must follow, lacking personalization. Due to the absence of necessary feedback, students' enthusiasm for practice is low, leading to low system utilization and poor results.

C. Research Gaps

The intelligent tutoring system proposed in this paper must address the following key challenges:

1) Effectiveness in capturing subtle differences: Current models struggle to effectively capture the nuanced differences between similar facial expressions, which is crucial for accurate facial expression recognition.

2) Complexity of recognition algorithms: Many existing facial expression recognition algorithms are overly complex due to their attempt to capture a wide range of features. This complexity often hinders performance, highlighting the need for a more lightweight model that can enhance recognition accuracy without unnecessary computational overhead.

These challenges are essential to consider in the development of facial expression recognition algorithms. The following sections of this paper will explore how deep learning methods can be utilized to achieve precise facial expression recognition while addressing these challenges.

III. Proposed Method

Our facial expression recognition model, designed using knowledge distillation, consists of a teacher model and a student model. The teacher model is an enhanced version of ResNet18, incorporating fine-grained feature extraction modules to capture deeper, multi-scale, and more detailed facial expression features. The student model utilizes the lightweight ShuffleNetV2 network, which maintains high recognition accuracy while being more computationally efficient.

The student model is trained and its parameters are updated by optimizing a distillation loss function. This function combines the probability distributions output by both the teacher and student models, enabling effective knowledge transfer. Through this process, the student model captures the essential knowledge from the teacher model, achieving high performance while remaining lightweight. Distillation training, therefore, facilitates the transfer of knowledge from a complex, high-performance model to a more efficient, lightweight model. The structure of this lightweight facial expression recognition network based on knowledge distillation is illustrated in Fig. 1.

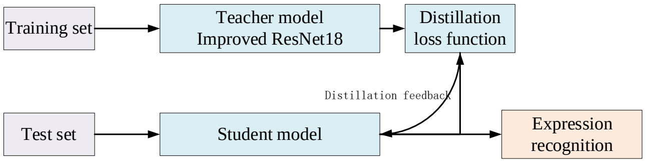

Fig. 1. Lightweight facial expression recognition network based on knowledge distillation.

In conclusion, our approach effectively tackles the challenge of distinguishing subtle differences between similar facial expressions while addressing the need for a more efficient and compact model. By utilizing knowledge distillation, we transfer the strengths of the teacher model to the student model, ensuring that the latter maintains high accuracy while being computationally efficient and suitable for real-time applications. This method offers a balanced solution, combining the depth and robustness of complex models with the speed and efficiency of lightweight models, making it an ideal choice for facial expression recognition tasks.

A. *Fine-grained Feature Extraction Module (FFE)*

To tackle the challenge of small intra-class variations and the difficulty in extracting features from different facial expression categories, we designed a fine-grained feature extraction module inspired by Res2Net [13]. This module enables the extraction of multi-scale features at a fine-grained level from critical facial regions within a single basic block, as illustrated in Fig. 2.

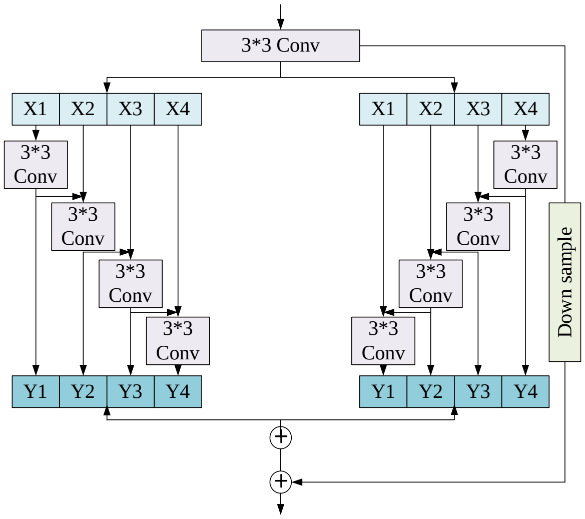

Fig. 2. Fine-grained Feature Extraction module (FFE).

Our module focuses on capturing subtle differences within the same category of facial expressions by emphasizing key facial areas. By leveraging the Res2Net-inspired architecture, the module enhances the model's ability to discern intricate details crucial for accurate facial expression recognition. This approach improves the model's capacity to distinguish between expressions with minimal variation, thereby increasing the overall accuracy and robustness of the recognition system.

The fine-grained feature extraction module is seamlessly integrated into our knowledge distillation framework, enhancing the student model's ability to learn from the teacher model. By including this module, we ensure that the lightweight student model retains the high-resolution, multi-scale features essential for precise facial expression analysis. This integration leads to a more effective and efficient facial expression recognition system, well-suited for real-world applications with limited computational resources.

In summary, the fine-grained feature extraction module effectively addresses the challenge of feature extraction in facial expression recognition by improving the system's ability to capture and analyze subtle facial cues. This innovation, coupled with our knowledge distillation approach, advances the development of more accurate and efficient facial expression recognition models.

The fine-grained feature extraction module designed in this paper utilizes a symmetrical structure to learn multi-scale features within a single basic block. This design ensures that feature subsets from both preceding and succeeding stages contain richer scale information. Specifically, after applying a 3×3 convolution to the input feature map X, the map is evenly divided along the channel axis into n subsets, denoted as X_i, where $i \in \{1, 2, \ldots, n\}$. Each subset X_i retains the same spatial dimensions as the original feature map X but with $1/n$ of the channels.

These subsets are then processed using a 3×3 convolution, denoted as $P_i^p(\cdot)$, where $p \in \{left, right\}$ indicates the position within the symmetrical structure. The output of each convolution operation, Y_i^p, can be expressed using Eq. (3). This method enables the extraction of fine-grained, multi-scale features, enhancing the model's capability to capture detailed facial expression characteristics.

$$\mathrm{Y_i^{left}} = \begin{cases} \mathrm{P_i^{left}(X_i)},\ \mathrm{i} = 1 \\ \mathrm{P_i^{left}\left(X_i + Y_{i-1}^{left}\right)},\ 1 < \mathrm{i} \leq \mathrm{n} \end{cases} \tag{1}$$

$$\mathrm{Y_i^{right}} = \begin{cases} \mathrm{P_i^{right}(X_i)},\ \mathrm{i} = 1 \\ \mathrm{P_i^{right}\left(X_i + Y_{i-1}^{right}\right)},\ 1 < \mathrm{i} \leq \mathrm{n} \end{cases} \tag{2}$$

$$\mathrm{Y_i} = \mathrm{Y_i^{left}} + \mathrm{Y_i^{right}} \tag{3}$$

According to Eq. (1), each operation of $P_i^{left}(\cdot)$ captures feature from all subsets $\{X_j, \leqslant i\}$. Conversely, Eq. (2) shows that each operation of $P_i^{right}(\cdot)$ captures feature from subsets $\{\ X_j\ , \geqslant j \geqslant i\}$. Each operation involves applying a 3×3 convolution to a split feature X_i. As a result, the output Y_i^{left} has a larger receptive field compared to $\{Y_k, < i\}$, while Y_i^{right} has a larger receptive field compared to $\{Y_k, k > i\}$. This design enables the extraction of comprehensive multi-scale features from both preceding and succeeding stages, enhancing the model’s ability to analyze fine-grained details.

Each output Y_i^p contains facial features at varying scales and quantities. To achieve a richer diversity of multi-scale features, all Y_i^p are aggregated along the channel axis, integrating the fine-grained details from each subset. While increasing n enriches the feature representation, it also raises computational costs. To strike an optimal balance between performance and efficiency, we set n = 4.

This design ensures that the fine-grained feature extraction module effectively captures multi-scale facial features crucial for accurate and robust facial expression recognition. By aggregating features from different scales, the model enhances its ability to detect subtle variations in facial expressions, thereby improving accuracy and reliability for practical applications.

Setting n = 4 allows us to balance feature richness with computational efficiency, making our method practical for real-world applications where both accuracy and speed are critical. This design choice demonstrates our commitment to optimizing performance while maintaining computational feasibility.

By utilizing this approach, we ensure that both initial and subsequent feature subsets capture detailed multi-scale information. This enhances the model's ability to detect fine-grained variations in facial expressions, resulting in more accurate and robust facial expression recognition.

Fig. 2 provides a detailed illustration of the symmetrical structure of our fine-grained feature extraction module. The figure demonstrates how the module employs symmetrical convolutions to process feature maps, enhancing the extraction of multi-scale features.

This innovative module integrates seamlessly into our facial expression recognition framework, allowing the lightweight student model to effectively learn complex, multi-scale features from the teacher model. As a result, the system achieves high performance while maintaining computational efficiency, making it well-suited for deployment in real-world applications with limited resources.

B. *The Construction of Teacher Model and Student Model*

We selected ResNet18 for its robust feature extraction and high recognition accuracy as the backbone of our teacher model. To further enhance its performance, we integrated a fine-grained feature extraction module designed to capture intricate facial details, especially from critical regions such as the eyes and mouth. This improvement enables the teacher model to provide more precise supervision and guidance to the student model. The enhanced teacher model, as illustrated in Fig. 3, processes facial images of size 224×224×3. The image first passes through standard convolutional layers, followed by batch normalization, ReLU activation, and max pooling, producing feature maps of size 112×112×64. Two residual blocks then generate feature maps of size 28×28×128. These are subsequently processed through two sequential fine-grained feature extraction modules, resulting in multi-scale, high-resolution features of size 224×224×3. Finally, these features are fed into fully connected layers for facial expression classification. This configuration allows the teacher model to effectively capture and leverage detailed facial features, ensuring that the student model benefits from enhanced guidance during training.

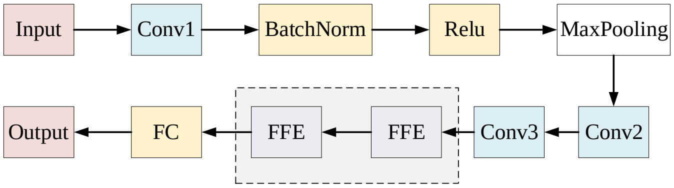

Fig. 3. Teacher model.

We selected ShuffleNetV2 as the backbone for the student model due to its computational efficiency and lightweight design. This network excels in real-time applications thanks to its use of depth wise separable convolutions, which significantly reduce model parameters and speed up computations. This makes ShuffleNetV2 particularly well-suited for deployment on edge devices for real-time facial expression recognition.

The ShuffleNetV2 architecture, depicted in Fig. 4, processes 224×224×3 facial images. It starts with a 3×3 standard convolutional layer followed by max pooling. The network then progresses through several stages, including down sampling blocks and basic blocks that utilize depth-wise separable convolutions. After these stages, the model passes through fully connected layers to produce the final facial expression classification. This design balances efficiency with performance, making it ideal for practical applications requiring real-time processing.

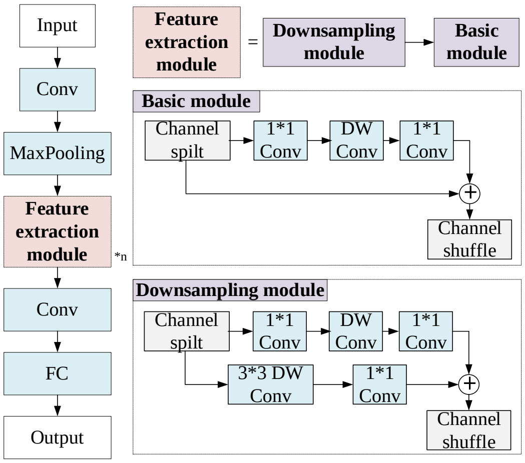

Fig. 4. Student model.

C. *Facial Expression Recognition Network Based on Knowledge Distillation*

Knowledge distillation is a widely utilized model compression technique that enhances the performance and accuracy of a lightweight student model by leveraging the expertise of a larger, more complex teacher model. This technique enables the student model to benefit from both the "hard labels" of the dataset and the "soft labels" provided by the teacher model's probabilistic outputs. The essence of knowledge distillation is to transfer the nuanced insights and detailed feature representations learned by the teacher model to the student model. In the T-SNet framework, this is achieved through a dual-branch network architecture, which includes both the teacher and student models. As illustrated in Fig. 5, the teacher model provides comprehensive guidance by generating rich, informative soft labels that the student model uses for training. This setup ensures that the student model captures not just the direct class labels but also the underlying distributions and patterns recognized by the teacher, leading to improved performance and accuracy in a more compact and efficient model.

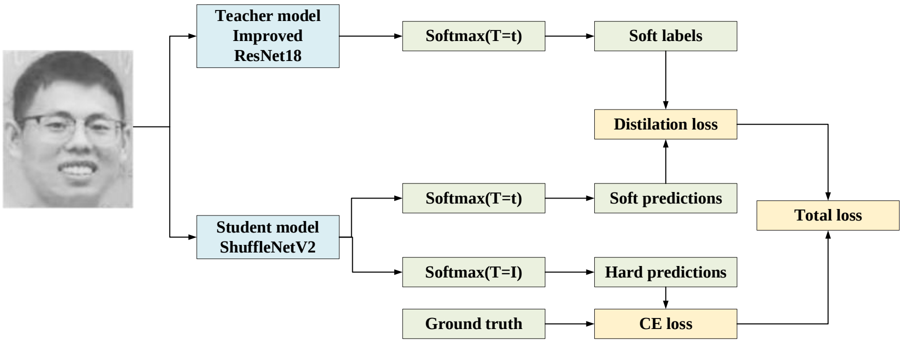

Fig. 5. Knowledge distillation model.

In the T-SNet framework, the dual-branch architecture operates as follows:

1) Teacher model branch: This branch performs global fine-grained feature extraction and classification. It leverages its complex architecture to capture detailed facial features and nuances.

2) Student model branch: This branch trains the student model using distilled features from the teacher model. It adapts these features to its more compact and efficient design for facial expression classification.

The framework employs a joint loss function to guide the training of both models. This ensures the student model retains essential knowledge from the teacher model, enhancing efficiency and performance while reducing computational requirements. This approach is especially suitable for real-time facial expression recognition where resources are constrained.

During the knowledge distillation process, facial expression images are simultaneously inputted into both the teacher and student models for feature extraction. The teacher model generates a Softmax distribution at a high temperature T, which serves as soft labels. Ultimately, the classifier outputs from both the teacher and student networks determine the expression categories. Introducing a Softmax temperature function helps smooth the probability distribution of predicted expressions, thereby providing additional class-specific feature information inherent to the teacher network.

D. Loss Function

During the knowledge distillation training process, the loss function L_{kd} for the student model comprises two key components: L_{soft} and L_{hard}, corresponding to learning from "soft labels" and "hard labels", respectively. L_{soft} uses Kullback-Leibler (KL) divergence to measure the difference between the predictions of the teacher model and the student model. Specifically, it calculates the cross-entropy loss between the Softmax output of the student model under the same temperature T and the soft labels provided by the teacher model. The L_{hard} component uses the cross-entropy loss function to compute the difference between the predictions of the student model and the true facial expression labels. The final loss for optimization is the sum of these two parts.

The L_{soft} loss function is formulated as follows:

$$\mathrm{Y_i} = \mathrm{Y_i^{left}} + \mathrm{Y_i^{right}} \tag{4}$$

where p_i^T denotes the Softmax output of the teacher model for class i at temperature T, and q_i^T denotes the Softmax output of the student model for class i at temperature T. The expressions for p_i^T and q_i^T are given by:

$$\mathrm{p_i^T} = \frac{\mathrm{e^{v_i/T}}}{\sum_\mathrm{k}^\mathrm{N} \mathrm{e^{v_k/T}}} \tag{5}$$

$$\mathrm{q_i^T} = \frac{\mathrm{e^{z_i/T}}}{\sum_\mathrm{k}^\mathrm{N} \mathrm{e^{z_k/T}}} \tag{6}$$

where v_i is the raw logits from the output layer of the teacher model, z_i is the raw logits from the output layer of the student model, and N is the total number of labels.

The L_{hard} loss function is defined as Eq. (7):

$$\mathrm{L_{hard}} = -\sum_\mathrm{i}^\mathrm{N} \mathrm{c_i} \log(\mathrm{q_i^1}) \tag{7}$$

$$\mathrm{q_i^1} = \frac{\mathrm{e^{z_i}}}{\sum_\mathrm{k}^\mathrm{N} \mathrm{e^{z_k}}} \tag{8}$$

$$\mathrm{Totleloss} = \alpha \mathrm{T}^2 \mathrm{L_{soft}} + (1-\alpha)\mathrm{L_{hard}} \tag{9}$$

where q_i^1 is the Softmax output of the student model for class i without temperature scaling, given by Eq. (8). The total loss $Totleloss$ is a combination of L_{soft} and L_{hard}.

where α is a balancing factor between the distillation loss and the cross-entropy loss.

Because the gradient magnitude of soft labels is scaled down by $1/T^2$, L_{soft} is multiplied by T^2 to ensure consistency between the true label values and the probability distribution of the teacher model. The temperature T and the coefficient α are hyperparameters that need to be empirically determined, which we explore further in subsequent sections through ablation experiments.

IV. Experiment and Verification

In this chapter, we verify the reliability and validity of the proposed method through experiments.

A. Experimental Environment

This study validated the algorithm's effectiveness using an environment comprising an 11th Gen Intel(R) Core (TM) i7-11700K @ 3.60GHz CPU with 32.0 GB of RAM, running

Python 3.6. For facial expression recognition experiments, a dataset was created from randomly captured images manually annotated. The dataset consists of 8500 images, divided into training, testing, and validation sets in a 6:2:2 ratio. The testing set comprises 1700 three-dimensional images with faces, randomly grouped into five sets of 340 images each. Each group of images was processed using the system for facial expression recognition.

B. *Evaluation Parameter*

First, the data set is aligned to the face [14], then the pre-processed face image is input to the teacher model training, the teacher model parameters are saved, and then the teacher model is trained by knowledge distillation to assist the student model [15]. Finally, the accuracy and the number of model parameters are calculated on the test set to verify the performance of the model.

We choose number of Accuracy, Precision, Accuracy, and the cords FLOPs as evaluation index, accurate calculation method is as follows:

$$\text{precision} = \frac{\text{TP}}{\text{TP+FP}} \tag{10}$$

$$\text{ACC} = \frac{\text{TP+TN}}{\text{TP+TN+FP+FN}} \tag{11}$$

Where TP represents true positives, meaning instances classified as positive that are actually positive; FN represents false negatives, where instances classified as negative but are actually positive; FP represents false positives, where instances classified as positive but are actually negative; and TN represents true negatives, where instances classified as negative that are actually negative.

AUC (Area Under the Curve) is a metric used to evaluate the performance of binary classification models, indicating the probability that the model ranks a randomly chosen positive example higher than a randomly chosen negative example. Firstly, True Positive Rate (TPR) refers to the proportion of actual positive cases correctly predicted as positive, calculated as $\frac{TP}{TP+FN}$. False Positive Rate (FPR) is the proportion of actual negative cases incorrectly predicted as positive, calculated as $\frac{FP}{TN+FP}$. The ROC (Receiver Operating Characteristic) curve plots TPR against FPR, with AUC representing the area under this curve. A higher AUC indicates better model performance in distinguishing between positive and negative examples.

Parameter count is a metric measuring model complexity and storage requirements, calculated based on the model's architecture and layer types [16]. Parameters are computed using the model.parameters function in PyTorch. Computational complexity (FLOPs) measures the total number of floating-point operations performed by the model during inference or training. Additionally, this study evaluates inference time to assess model processing speed on embedded devices.

During training, stochastic gradient descent (SGD) optimizes the loss function with the following hyperparameters: weight decay of 1e-4, momentum of 0.9, dropout rate of 0.5, and initial learning rate of 0.01. Learning rate adjustments are dynamically managed using ReduceLROnPlateau, decreasing the learning rate by a factor of 10 if the loss does not decrease after 3 epochs. The total training epochs are set to 150 with a batch size of 128. The best model is saved after 150 epochs based on the highest achieved accuracy.

C. *Test and Evaluation*

We set up ablation experiments to demonstrate the superiority of our parameter selection. Table I shows the comparison of results of different parameters. In the knowledge distillation process, the distillation temperature T and α are set to 8 and 0.4 respectively. The ablation experiment verified the best effect of this parameter setting.

TABLE I. ABLATION EXPERIMENT

T	α	**precision**
4	0.4	0.899
6	0.2	0.893
6	0.4	0.988
6	0.6	0.906
8	0.4	0.891

We tested the results of teacher-only model training, student-only model training and the results of the combined training of teacher model and student model after adding knowledge distillation on FER2013Plus and RAF-DB datassets. To ensure the fairness of experimental results, the same hyperparameters were used for both teacher model and student model. In order to evaluate the performance of knowledge distillation algorithm, experiments were conducted on FER2013Plus and RAF-DB datasets respectively to test the accuracy and number of parameters of the improved teacher model, student model and distilled student model. Table II shows the test results of teacher model and student model on FER2013Plus and self-made datasets. The faculty model is named EFF-ResNet18(Enhanced Fine- ResNet18), the student model is named ShuffleNetV2, and the distilled student model is named T-SNet.

TABLE II. TEACHER MODEL AND STUDENT MODEL TEST RESULTS

Datasets	Model	parameters	Accuracy
FER2013Plus	EFF-ResNet18	11.8	86.23
	ShuffleNetV2	1.3	88.15
	T-SNet	1.2	91.62
Our datasets	EFF-ResNet18	12.3	88.57
	ShuffleNetV2	1.3	90.45
	T-SNet	1.2	94.69

According to Table II analysis, on the FER2013Plus dataset, knowledge distillation improved the accuracy of the student model from 86.23% to 91.62%. Similarly, on our proprietary dataset, performance enhancement was observed, increasing from 88.57% to 94.69%. Across both datasets, the distilled student model surpassed the teacher model in accuracy, while reducing parameter count by 10.60 million, indicating significant improvement. Experimental results demonstrate that knowledge distillation enhances the generalization performance of the student model by transferring knowledge from the teacher model, achieving model lightweighting in the process. This highlights the effectiveness of training lightweight models with performance comparable to large-scale network models under supervision of feature extraction from large network models.

To assess the performance of T-SNet in facial expression recognition tasks, this study compared T-SNet with other mainstream algorithms including RCL-Net [17], ResNet18, TFEN [18], ECDNet, etc. Comparative results on our dataset are presented in Table III.

TABLE III. COMPARISON OF T-SNET AND SOTA METHODS

Models	Precision	Accuracy	FLOPs
TFEN	0.898	0.906	4.5
ResNet18	0.903	0.893	11.18
RCL-Net	0.901	0.891	6.4
ECDNet	0.897	0.903	3.5
Ours	0.931	0.988	1.3

Through comparison, it can be observed that the recognition accuracy of our proposed method on the data set is as high as 98.8%, which is much higher than the second method. This shows that the proposed method is superior to other SOTA methods in terms of accuracy. In addition, in terms of the number of parameters and the amount of computation, our method has the lowest parameter number of 1.3M. Our method has very good advantages in recognition rate and parameter number, which can be said to be a qualitative leap for the system with high real-time requirements. The experimental results show that the lightweight expression recognition model based on knowledge distillation proposed in this paper has strong competitiveness and can be used as one of the choices for a real-time facial expression recognition system.

TABLE IV. COMPARISON OF RECOGNITION EFFECT OF DIFFERENT EXPRESSIONS

Expression type	FER2013Plus	Our datasets
Angry	0.95	0.96
disgust	0.90	0.91
happy	0.98	0.99
sad	0.92	0.93
surprised	0.96	0.97
neutral	0.97	0.98
contempt	0.91	0.93

We respectively tested the recognition effects of different expressions on FER2013Plus and self-made data sets with our proposed method, as shown in Table IV. From the confusion matrix of the two data sets, it can be concluded that happy expression is the most easily recognized expression, mainly because happy data in the two data sets has the highest amount and more abundant features. Happiness is also highly recognizable in the real world. Neutral is easier to identify because some uncertain subtle expressions are generally marked as neutral during data set annotation. The recognition rates of surprised, angry and sad expressions declined successively, which is consistent with human visual characteristics.

In order to more intuitively verify the effectiveness of T-SNet, this paper uses GradCAM to generate visual activation diagram for visual analysis of T-SNet [19]. Among them, the data samples are from the FER2013Plus test set. The visualized result is shown in Fig. 6. T The first column is the original data sample, the second column is the ECDNet model activation map, and the third column is the T-SNet activation map. The visual activation graph can verify the importance of the network to the key areas of the image, and the brighter the color, the more important the content of the area is for the recognition of the network. Red indicates high activation and blue indicates low activation. The comparison between the second and third column shows that T-SNet after knowledge distillation can absorb the fine-grained feature extraction experience of the teacher model, and the extracted feature semantic information is richer, and the receptive field is larger than that of the baseline model. By focusing attention on important facial areas, T-SNet can more accurately identify expression categories, which verifies T-SNet's excellent expression recognition performance.

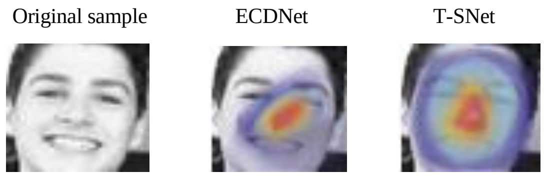

Fig. 6. Visual analysis.

V. CONCLUSION

We propose a lightweight algorithm for facial expression recognition based on neural networks, termed T-SNet. Addressing the challenge of deploying complex neural networks on smart terminals and the increasing demand for lightweight facial expression recognition models, we introduce T-SNet, a knowledge-distillation-based lightweight facial expression recognition network. We selected a refined ResNet18 with enhanced fine-grained feature extraction module as the teacher model backbone and ShuffleNetV2 as the student model backbone. By constructing distillation loss, we transfer rich classification information from the teacher model to the student model, leveraging the teacher model's experience to train the student model and improve its accuracy in facial expression recognition. The distilled student model, trained as a lightweight facial expression recognition model, is the outcome of our approach. Experimental results demonstrate that our proposed T-SNet model outperforms other mainstream facial recognition models in terms of accuracy and parameter efficiency. Despite the achievements in lightweight facial recognition, real-world scenarios still pose challenges due to factors such as environment, lighting, and occlusion.

While our method shows promising performance on current datasets, demonstrating excellent effectiveness and efficiency, further validation in practical applications is essential. Future advancements in deep learning technology and dataset enhancements will likely expand the application of facial recognition into more domains. To ensure effective deployment in diverse applications, rigorous empirical research on feasibility and efficacy is needed. This will further validate the practical potential of our approach.

Enhancing Music Emotion Classification Using Multi-Feature Approach

Affreen Ara[1], Rekha V[2]
Christ University, Bengaluru, India[1]
Department of Computer Science and Engineering, Christ University, Bengaluru, India[2]

Abstract—**Emotions are a fundamental aspect of human expression, and music lyrics are a rich source of emotional content. Understanding the emotions conveyed in lyrics is crucial for a variety of applications, including music recommendation systems, emotion classification, and emotion-driven music composition. While extensive research has been conducted on emotion classification using audio or combined audio-lyrics data, relatively few studies focus exclusively on lyrics. This gap highlights the need for more focused research on lyric-based emotion classification to better understand its unique challenges and potentials. This paper introduces a novel approach for emotion classification in music lyrics, leveraging a combination of natural language processing (NLP) techniques and dimension reduction methods. Our methodology systematically extracts and represents the emotional features embedded within the lyrics, utilizing a diverse set of NLP techniques and integrating new features derived from various emotion lexicons and text analysis. Through extensive experimentation, we demonstrate the effectiveness of our approach, achieving significant improvements in accurately classifying the emotions expressed in music lyrics. This study underscores the potential of lyric-based emotion analysis and provides a robust framework for further research in this area.**

Keywords—Emotion classification; music lyrics; feature extraction; lexicon features

I. INTRODUCTION

Music can evoke strong emotions in listeners, such as happiness, sadness, anger, or excitement [1]. Analyzing the emotional content of music lyrics provides insights into why certain songs are popular and how they affect our moods. Emotion analysis employs natural language processing (NLP) and machine learning techniques to identify and extract emotional information from text. This analysis involves examining written or spoken language to understand how different songs and genres influence emotional responses. Emotion analysis of music lyrics is applicable in various fields, including marketing, social media analysis, mental health, and music therapy [2]. For instance, music therapy leverages specific songs and genres to help individuals' process emotions and improve well-being, which is also useful for diagnosing and monitoring mental states in mental health settings.

NLP, a branch of artificial intelligence, plays a pivotal role in emotion analysis by enabling computers to understand and interpret human language [3]. In emotion analysis, NLP techniques such as emotion detection are utilized to identify and classify emotions expressed in lyrics. The process typically begins with pre-processing the music lyric text, involving tokenization, normalization, and stop-word removal. This is followed by feature extraction, where relevant features such as stylistic, semantic, and lexicon-based attributes are identified and extracted from the text. Machine learning algorithms are then trained on these extracted features to identify the emotions embedded within music lyrics.

Emotion lexicons, which include vocabulary terms associated with one or more emotions, are crucial resources in NLP, sentiment analysis, and emotion detection [4]. These lexicons, such as the Affective Norm for English Words (ANEW) [5], enable emotion analysis algorithms to classify the emotional tone of text based on word associations. ANEW is grounded in the Russell Model's [6] two-dimensional circumplex model, which includes valence (pleasantness) and arousal (activation). While word-based lexicons are widely used, phrase-based and context-based lexicons offer a more nuanced understanding of emotional content. However, the subjectivity of emotions, polysemy, and contextual dependence can pose challenges in accurately assigning emotions to text. To overcome these limitations, emotion analysis often combines lexicons with other features, such as sentiment analysis, syntactic analysis, and semantic analysis. This integrated approach provides a more comprehensive and accurate understanding of the emotional content of text data.

Dimension reduction [7] is a technique used in data analysis and machine learning to reduce the number of features or variables in a dataset while preserving essential information. This technique is vital for uncovering underlying emotional patterns in lyrics, allowing for more accurate and computationally efficient machine learning models. By applying dimension reduction methods like Principal Component Analysis (PCA), researchers can effectively interpret and classify the rich emotional expressions found in music, providing valuable insights into the intersection of art and emotion.

Machine learning algorithms, such as decision trees, k-Nearest Neighbor (KNN), Naive Bayes, and Support Vector Machines (SVM), are commonly used for emotion classification in lyric text. The choice of algorithm depends on factors such as dataset size, feature representation, and computational efficiency. While most existing research in emotion analysis adopts a multimodal approach, combining both audio and lyrics to enhance emotion prediction accuracy, there is a notable gap in research focusing solely on lyrics as a textual representation of emotions. This research addresses this gap by providing a comprehensive analysis of emotions in music lyrics and designing new lexicon features that enhance emotion detection capabilities.

Our previous research [8] investigated the effectiveness of various lexicon-based features for emotion classification using music lyrics, achieving an accuracy of 53%. We extracted lexicon features from the NRC Emotion Intensity Lexicon, NRC VAD, EmoWordNet, and Synesketch lexicon. Extensive experiments were carried out using both lexicon and hybrid lexicon features for emotion classification in music lyrics; the current study extends this approach by incorporating a broader set of features, such as stylistic, lexical, and textual attributes, along with traditional NLP methods. Furthermore, we use Principal Component Analysis (PCA) for dimensionality reduction to enhance classifier performance by capturing the most informative aspects of the data.

This paper aims to enhance emotion classification accuracy in music lyrics by integrating various text features, including lexicon-based, syntactic, stylistic, and semantic attributes. Our contributions are threefold: (1) We create robust hybrid feature sets by combining lexicon-based features from multiple emotion sources to augment the emotional representation in lyrics; (2) We also use feature engineering techniques to extract syntactic, semantic, and stylistic information from the lyrics, thereby capturing emotional complexity of music lyric text; (3) We also use Principal Component Analysis (PCA) to reduce the dimensionality of the feature space in order to improve computational efficiency and model interpretability. By conducting extensive experimentation with classifiers such as Decision Trees, Random Forest, and Gradient Boosting, we demonstrate that our approach significantly enhances classification accuracy, achieving up to 98% accuracy. The remainder of this paper is structured as follows: Section II reviews the related work, Section III explains the method used, Section IV presents the experimental results, Section V discusses the findings and their implications, and lastly, Section VI concludes the paper with potential directions for future research.

II. Literature Review

This section presents literature review from papers of emotion analysis from music lyrics and text analysis.

Revathy V.R. [9] study uses knowledge from the MER dataset to train the Music4All dataset, aiming to label lyrics with emotions. The research employs a transfer learning approach and the Sentence Transformer model for emotion prediction. The LyEmoBERT model demonstrated superior performance compared to existing methods on the Music4All dataset. Sujeesha et al. [10] research develops a multimodal music mood classification system using transformers, incorporating both audio and lyrics. The study compares the system's performance with a Bi-GRU-based model, finding that the transformer-based model with transfer learning achieves higher accuracy. Priyanka et al. [11] propose a mood categorization of songs based solely on lyrics using TF-IDF feature extraction and the Random Forest algorithm. Their findings highlight the model's ability to accurately predict "happy" and "sad" emotions. Yudhik Agrawal [12] study proposes a deep neural network architecture using the XLNet Transformer model for emotion classification in music lyrics. The model employs multi-task learning through weight sharing, enhancing convergence speed and reducing over fitting. Fika Hastarita Rachman et al. [13] work introduces a method to recognize song emotions by combining lyrics and audio using the Thayer emotion model. They extract psycholinguistic and stylistic features from lyrics and audio waveforms, using various classifiers to perform emotion classification. Cong Jin et al. [14] propose a Bi-LSTM network with dilated recurrent skip connections to improve the model's ability to capture long-sequence information in lyrics. The model includes an attention mechanism to enhance the recognition of important words, improving semantic extraction performance. Study presents MoodNet[15], a deep convolution neural network (CNN)-based architecture designed to determine emotions from audio and lyrics. The model is evaluated using the MIREX Multimodal Dataset and the Million Song Dataset. Shahrzad Naseni et al. [16] research explores the connection between song lyrics and mood using two transformer-based approaches: natural language inference and next sentence prediction. The study focuses on lyric classification tasks to understand how lyrics and acoustics contribute to song mood. Leroto Parisi [17] study examines various feature vector representations like BERT, ELMo, and fastText embeddings combined with deep learning mechanisms to predict emotions conveyed in song lyrics. Yingjin Song and Daniel Beck [18] work introduces a two-stage BERTLex-State Space Model framework for sequence-labeling emotion intensity recognition tasks. The framework is aimed at predicting emotion dynamics in song lyrics without requiring supervision at the song level.

The literature review discusses various approaches to emotion analysis in music lyrics and text analysis. It highlights the use of datasets like MER and Music4All for training models to label lyrics with emotions, employing techniques such as transfer learning and transformer-based models. Notable works include the LyEmoBERT [9] model, which outperformed existing methods, and a multimodal music mood classification system that integrates audio and lyrics. Other studies, such as those by Yudhik Agrawal et al. [12], explore the use of deep neural networks like XLNet for emotion classification, utilizing multi-task learning for improved model performance. Fika Hastarita Rachman et al. [13] work focuses on combining psycholinguistic and stylistic features from lyrics with audio features using various classifiers for emotion recognition. Cong Jin et al.[14] introduce a Bi-LSTM network with dilated skip connections and attention mechanisms to better capture long-sequence dependencies in lyrics. A Bhattacharya, et al. propose the MoodNet architecture, a CNN-based model that analyzes both audio and lyrics for emotion detection. Additionally, Shahrzad Naseni [16] and colleagues use transformer-based models for lyric classification tasks, demonstrating the effectiveness of advanced NLP techniques. The review also emphasizes the gap in research focusing solely on lyrics for emotion classification, advocating for more targeted studies to address unique challenges in this area. It covers the calculation of emotional metrics, machine learning algorithms, feature reduction techniques like PCA, and the importance of lexicons in analyzing emotional content in lyrics.

III. Method for Music Emotion Classification for Lyric Text

The system takes music lyrics as input. These lyrics undergo a cleaning process to remove any unwanted elements and are then processed and converted into individual tokens. Feature extraction is performed on the lyrics, extracting various relevant features from the textual content, including leveraging emotion lexicons. To reduce the dimensionality of the feature space and remove irrelevant features, dimension reduction techniques are applied. Classification models are then constructed using the extracted features, both with and without dimension reduction, to accurately identify and classify the emotions embedded within the lyrics (Fig. 1).

A. Datasets

In this research we have used MER and Mood Lyrics dataset. The MER Dataset [4] contains 771 song lyrics extracted from the AllMusic platform. All songs are equally distributed among the four emotion quadrants of the 2-D Russell's circumflex emotion model. The dataset is generated by linking mood tags from AllMusic to words in the ANEW dictionary. The values of A and V are assigned to each word from the ANEW dictionary. Each song is categorized within a particular quadrant if all the corresponding AllMusic tags fall within that Russell quadrant. We have also used 1935 song from Mood Lyrics [19] dataset containing English songs. The Russell Model is used to annotate each song with its four Quadrants with output classes (sad, relaxed, angry, and happy). The dataset is constructed by merging three lexicons, Word Net, WorldNet-Affect, and the ANEW dictionary, to assign Valence and Arousal scores to every word in the lyrics. Emotion annotation is performed by calculating the combined Valence and Arousal values for each lyric. Based on the VA (Valence-Arousal) values, each lyric is assigned to a specific quadrant in Russell's 2-dimensional model.

B. Feature Extraction

Text feature extraction involves transforming textual data into a numerical format suitable for use in various natural language processing (NLP) tasks. The goal is to capture the essential information and characteristics of the text in a way that machine learning algorithms can process and understand. This process includes both lexical and syntactic features, as well as stylistic elements. Techniques like Term Frequency-Inverse Document Frequency *(TF-IDF)* [20] and Bag of Words (BOW) are commonly used to capture the lexical and syntactic properties of text. The Bag of Words *(BOW)* approach represents a document by breaking it down into individual words and creating a feature vector based on the frequency of each word, ignoring word order. TF-IDF is a statistical method used in natural language processing to determine the importance of a word within a document relative to a collection of documents. It's a versatile technique that can be applied in various NLP tasks, such as text classification, information retrieval, and sentiment analysis. TF-IDF calculates a score for each word in a document based on its frequency within the document and its rarity across the entire corpus. This enables it to identify the most significant terms that contribute to the document's meaning and differentiate it from others.

In addition to statistical measures, stylistic features such as the use of slang, part-of-speech *(POS)* distributions, and verb usage help capture the linguistic style and emotional tone of the text. Style features capture the linguistic characteristics of text data, such as slang words, part-of-speech distributions, and verb usage. They are related to length of sentence, length of paragraph. We implemented length *(L)* features (word count, character count, sentence count, average word length, average sentence count). Word count, character count, sentence count, average word length and average sentence length are extracted from song lyrics. Slang words are informal and non-standard language often used in music lyrics. Counting the frequency of slang using online dictionaries can provide insight into a song's lyrical style and cultural references. We used slang count *(SL)* using Online Slang Dictionary. An example of a slang word from an online urban and slang dictionary is "lit". "Lit" is an adjective that means exciting, excellent, or highly enjoyable. It is used to describe something fun, energetic, or impressive. Slang words can vary in popularity and usage over time.

Part of speech tags *(POS)* represents the frequency of various word types (e.g., noun, verb, adjective). It can help capture the syntactic structure of a sentence. Each sentence is converted to form – list of words, list of tuples. Each tuple is represented in the form *(word, tag)*). The tag is part-of-speech, which signifies whether the word is a noun, adjective, verb. For example, some common POS tags include proper noun (NNP), noun (NN), verb (VB) and adjective (JJ), coordinating conjunction (CC), and personal pronoun (PRP). We use 21 features of POS tags using the NLTK dictionary in this work—an example of POS Tagging. Example - (Dirty, NNP), (old, JJ), and (river, NN).

The frequency of BE verbs *(BE)* in positive, negative, and interrogative sentences can provide insight into the emotion tone and sentiment conveyed by the lyrics. "Be" verbs indicate a state of being. Verbs must match subjects. Present Sentence, Negative Sentence, and Interrogative Sentence are three forms of BE Verbs. BE Verbs frequency is considered in this work, along with negative words such as "not" and question mark count. Present Sentence are sentences that start with “I am”, “You are” , “He is”, “She is” , “It is”, “We are” , “You are” and “They are”. Negative Sentence have not included with Present sentences. Examples are “I am not”, “You are not”, “and He is not” and so on. Interrogative Sentences start with “Am I?”, “Are You?”, “Is he?”, etc. By combining these features, including lexical, syntactic, and stylistic elements, classification models can gain more nuanced insights into the text. This comprehensive feature set can improve the accuracy of text classification tasks by leveraging the strength of different approaches.

C. Lexicons Feature Extraction

There are six lexicon dictionaries used in this work. The Norm of Valence, Arousal, and Dominance lemmas [21] has affective words for valence, arousal, and dominance with values ranging from 0 to 1. The NRC Affect Intensity Lexicon [22] contains words with intensity scores for Ekman's basic emotions (Anger, Fear, Anticipation, Trust, Surprise, Sadness, Joy, and Disgust). The intensity score varies between 0 and 1. A score of 1 indicates the intensity of emotion is high, whereas a score of 0 indicates the intensity of the word is low. The EmoWordNet [23] lexicon comprises of words associated with eight emotions (fear, anger, joy, sadness, and surprise) with scores ranging from 0 to 1. The Synesketch lexicons [24] contain English words annotated manually with emotion weights. It uses Ekman's six basic emotions (anger, joy, surprise, sadness, disgust, and fear).The Dictionary of Affect [25] in Language comprises 8743 words annotated in 3 dimensions: pleasantness, activation, and imagery. Pleasantness is similar to valence and activation to arousal. Imagery is a word that creates a mental picture. A score of 1 indicates the difficulty in forming a mental and score of 3 indicates it is easy to form a mental picture. The DepecheMood [26] is a high coverage and high precision emotion lexicon using distributional semantics, with numerical scores associated with more than one emotion (Afraid, Amused, Annoyed, Don’t care, Happy, Inspired and Sad), obtained from crowd sourcing, it has scores ranging from 0 to 1.

1) Lexicon features for intensity emotion weight: To extract lexicon features from lyrics, the process begins with preprocessing. This involves cleaning the text to remove any non-alphabetic characters, punctuation, and extra spaces. Next, the cleaned text is tokenized, meaning it is split into individual words (tokens). Each token is then matched with its corresponding emotion dimension/intensity score from the relevant lexicons. Finally, aggregate metrics such as the mean, maximum, minimum, and standard deviation are computed based on the scores of the mapped tokens for each lyric text. It's important to note that one word can be associated with more than one emotion, depending on the type of lexicon used. This systematic approach ensures the accurate extraction of lexicon features, which can then be used for further analysis.

In previous research, we introduced emotion lexicon features using intensity/emotion weight [8] Eq. (1) to Eq. (11). The work is expanded to include Dictionary of Affect and DepecheMood Lexicon, and hybrid feature combinations. This section details the lexicon features extracted from NRC Emotion Intensity, Synesketch, EmoWordNet, and DepecheMood; these are categorical lexicons. The categorical lexicon comprises words associated with specific emotions, each of which is linked with an intensity score.

a) Average emotion intensity/weight: Definition: It is the average emotion intensity/weight of lyrics l for emotion E. The formula for average emotion intensity is shown in Eq. (1):

$$\text{Average Emotion Intensity} = \frac{\sum \text{I(W,E)}}{\text{N}} \tag{1}$$

Where I (W, E) is the intensity of the word W for emotion E and N is total number of word in the lyrics. This metric provides a general sense of how strongly an emotion is expressed throughout the lyrics. It helps in understanding the overall emotional tone.

b) Maximum emotion intensity/weight: Definition: It is the maximum intensity/emotion weight of lyrics l for emotion E. This is defined in Eq. (2):

$$\text{Maximum Emotion Intensity} = \text{Max}\big(\text{I(W, E)}\big) \tag{2}$$

Where I (W, E) is the intensity of word W for emotion E and N is total number of word in the lyrics. This metric identifies the peak emotional intensity in the lyrics, showing the highest level of emotional expression.

c) Minimum emotion intensity/weight: Definition: It is the minimum intensity/emotion weight of lyrics l for emotion E, as defined in Eq. (3):

$$\text{Minimum Emotion Intensity} = \text{Min}(\text{I(W, E)}) \tag{3}$$

Where *I (W, E)* is the intensity of word W for emotion E and N is total number of word in the lyrics. This metric highlights the least intense emotional expression in the lyrics.

d) Threshold emotion word count(TEWC): Definition: It is a metric that quantifies the number of words in the lyrics, denoted as 'W, that have an intensity score greater than a predetermined threshold limit, 'TH', for a specific emotion, ‘E’. This is shown in Eq. (4):

$$\text{TEWC (E, I, TH)} = \Sigma\ (\text{W} \in \text{l})\ [\text{I(W, E)} > \text{TH}] \tag{4}$$

Where *TEWC (E, l, TH),* represents the count of words per emotion E with a threshold for a given emotion 'E' in the lyrics 'l'. I (W, E) represents the intensity of word 'W' for the specific emotion 'E' and W ∈ I. From Eq. 4, [I(W, E) > TH] is a function that evaluates to 1 if the intensity of the word 'W' for emotion 'E' is greater than the threshold 'TH'. [I (W, E) > TH] evaluates to 0 if condition is not met. This formula calculates the total count of words in the lyrics that have an intensity surpassing the specified threshold TH for the given emotion ‘E’. Emotion Intensity score is the strength of emotional expression in the lyrics. Words surpassing the threshold are likely to have a substantial impact on the overall emotional tone. By counting words that exceed the threshold, TEWC helps identify which parts of the lyrics contribute significantly to a particular emotion. TEWC can enhance music recommendation systems by considering emotional relevance. Researchers can compare TEWC across different songs, genres, or artists to understand variations in emotional content.

e) Emotion proportion within class: Definition: It measures the proportion of a particular emotion within a specific class relative to its overall occurrence in all classes of lyrics l for emotion E, as shown in Eq. (5):

EPC = (Count of emotion within class) / (Total count of emotion across all classes)

$$\text{EPC} \ = (\text{CE}) / |\text{E}| \qquad (5)$$

Where CE denotes the count of a specific emotion within a particular class and |E| signifies the total count of the specific emotion across all classes. This formula quantifies the relative proportion of a specific emotion within a class by dividing the count of that emotion in the class by its total count across all classes.

TABLE I. SAMPLE CALCULATION FOR LEXICON FEATURES DERIVED FROM NRC EMOTION INTENSITY LEXICON WITH JOY, SADNESS AND TRUST

Word	Joy	Sadness	Trust
joyous	0.9	0	0.23
elated	0.8	0	0
cheerful	0.95	0	0
TEWC (E, I, 0.6)	3	0	0

Let's consider the Table I provided for emotions "Joy," "Sadness," and "Trust" and their corresponding intensity score.

- Using equation (1), the average Intensity for the emotion “Joy” is calculated as (09 + 0.8 + 0.95) =0.883.
- The minimum intensity score for the emotion "Joy”, using Eq. (3) is 0.8 and the maximum intensity score for the emotion "Joy" calculated using Eq. (2) is 0.95.
- For Threshold Emotion Word Count (TEWC) calculation we apply Eq. (4). TEWC (Joy, 0.9, 0.6) calculates the number of words in the lyrics with intensity greater than the threshold value (0.6) for the emotion "Joy". Using Eq. (4), TEWC (Joy, 0.9, 0.6) gives result of three and TEWC (Trust, 0.23, 0.6) gives result of zero.

2) Lexicon features for dimension emotions: This section describes lexicon features extracted from Norm of Valence, Arousal, and Dominance lemma and Dictionary of Affect. The Russell three dimension model contains dimensions of valence, arousal and dominance.

a) Average valence: It is the sum of all Valence scores divided by the total no of words (N)) in lyrics. This is shown in Eq. (6):

$$\text{Average Valence} = \frac{\Sigma \text{V}}{\text{N}} \qquad (6)$$

Where Valence V is non zero and N is total number of word in the lyrics. The average valence score represents the average emotional positivity or negativity expressed in the lyrics. This metric provides a general sense of how strongly valence is expressed throughout the lyrics.

b) Average arousal: Definition*:* It is the sum of all arousal values (A) divided by the total no of words (N) in lyrics. This is defined in Eq. (7):

$$\text{Average Arousal} = \frac{\Sigma \text{A}}{\text{N}} \qquad (7)$$

Where Arousal A is non zero and N is total number of word in the lyrics. The average arousal score represents the average calmness or excitement expressed in the lyrics. This metric provides a general sense of how strongly an arousal is expressed throughout the lyrics.

c) Average dominance: Definition: It is the sum of all dominance values (D) divided by the number of words (N) in lyrics. This is defined in Eq. (8):

$$\text{Average Dominance} = \frac{\Sigma \text{D}}{\text{N}} \qquad (8)$$

Where Dominance D is non zero and N is total number of word in the lyrics. The mean dominance score represents the average level of control or power expressed in the lyrics. This metric provides a general sense of how strongly dominance is expressed throughout the lyrics.

d) Standard deviation: The standard deviation provides a measure of the dispersion or variability of the scores around the mean, indicating how consistent the emotional expression is across the lyrics. It is calculated for Valence V, Arousal A and Dominance D values of all tokens extracted from lyrics where VAD values are non-zero. Given set of dimension scores X={x1, x2, x3….an} for lexicon L. Standard deviation for score x is shown in Eq. (9):

$$\sigma = \frac{1}{N}\sum_{i=1}^{n}(x_i \ - x_{mean} \ )^2 \qquad (9)$$

Where σ is Standard deviation, if we apply this to valence, arousal and dominance score from lyrics. For given set of score for S= {s$_1$, s2…..Sn} for valence, arousal and dominance. This is defined in Eq. (10) and (11):

$$\sigma = \frac{1}{\text{N}}\sum_{\text{i}=1}^{\text{n}}(\text{s}_\text{i} \ - \ \text{s}_{\text{mean}} \ )^2 \qquad (10)$$

$$\text{s}_{\text{mean}} \ = \frac{1}{\text{N}}\sum_{\text{i}=1}^{\text{n}}(\text{s}_\text{i}) \qquad (11)$$

Where N is the total number of score and i_s is the score of (valence, arousal, or dominance). $\text{S}_{\text{mean}}$is the mean (average) of all the scores.

e) Average imagery: Definition: It is sum of all imagery scores divided by total number of words (N) in lyrics. This is defined in Eq. (12):

$$\text{Average Imagery} = \frac{\Sigma \text{Im}}{\text{N}} \qquad (12)$$

Where Imagery Im is non zero and N is total number of word in the lyrics. The mean imagery score represents the average level of mental picture evoked by the lyrics. Higher mean imagery indicates that, on average, the lyrics are more capable of creating clear mental pictures for the listener. The average scores for Pleasantness and Activation are determined in a similar manner. Additionally, the minimum and maximum scores for Pleasantness, Activation, and Imagery are also calculated. We use a consistent method to ascertain the mean, minimum and maximum values for arousal, dominance, activation, imagery, and pleasantness in lyrics. These metrics are crucial for understanding the range and variation of emotional and sensory expressions. Minimum values indicate the least intense expressions, reflecting calmness, weakness, passivity, lack of vividness, and negative affect. In contrast, maximum values capture the most intense peaks of power, energy, vividness, and positive affect. For example, minimum arousal corresponds to low emotional intensity, while maximum arousal signifies high intensity. Similarly, minimum valence reflects negative emotions, whereas maximum valence indicates positivity. This method offers a nuanced view of lyrical dynamics for deeper interpretation.

For emotion classification, we use notations as Lyrics Length Features: *L*, Slang Count: *SL,* POS tags: *POS*, BE Verbs: *BE,* Norm of Valence, Arousal and Dominance features: *AF1*, Depeche Mood features: *BF1*, EmoWordNet features: *BF2*, Synesketch features: *BF3*, Emotion Intensity features: *BF4*, Dictionary of Affect features: *BF5*.

D. Dimension Reduction

The main goal of dimension reduction [7] is to simplify the dataset without losing critical information. PCA achieves this by identifying the principal components of the data, which are linear combinations of the original features that capture the most variance. The variance values associated with each principal component reflect the amount of information that component carries; higher variance indicates more information. These variance values are calculated using Eigen values derived from the covariance matrix of the data. The first principal component accounts for the greatest variance, with each subsequent component capturing progressively less. By selecting only the most significant principal components, we can effectively reduce the dimensionality of our dataset while retaining essential information.

E. Classifiers

Random Forest [27] and Gradient Boosting are popular machine learning algorithms used for classification and regression tasks. Random forest is an ensemble method that combines multiple decision trees to make predictions. It works by constructing multiple decision trees using subsets of the training data and random feature subsets. The predictions from each tree are then combined to make a final prediction. Random Forest is known for its accuracy and ability to handle high-dimensional datasets. Gradient boosting is another ensemble method that works by iteratively adding weak learners, typically decision trees, to a model to improve its performance. Gradient boosting uses a loss function to determine the error of the current model and update the model by fitting a new tree to the residuals of the previous model. Gradient boosting is known for its high accuracy and ability to handle complex datasets but can be computationally expensive and prone to over fitting. The choice of algorithm depends on the specific problem and dataset at hand.

F. Performance Metric

Classification accuracy is a metric used to evaluate the performance of a machine learning model in classification tasks. It measures the proportion of correctly predicted instances (both true positives and true negatives) to the total number of instances in a dataset. In simple terms, classification accuracy represents how often the model makes correct predictions.

IV. Experiments and Results

We conducted extensive experiments for classification, both with and without dimension reduction, using the Mood Lyrics dataset (D1) and the MER dataset (D2). We employed Random Forest and Gradient Boost classifiers for the classification task. Due to the large number of experiments, it is not feasible to present all the results here. The features notation used for classification is given in the Lexicon sub section. The Emotion output classes are four Russell Quadrants (sad, relaxed, angry, and happy). Classification experiments were conducted using datasets D1 and D2, employing Random Forest and Gradient Boost classifiers. These experiments utilized stylistic, lexical, and length features derived from lyric text, with the feature acronyms detailed in Method subsection C.

A. Emotion Classification Accuracy by Russell Quadrants

For Table II, the combination of (Bag Of Words, Norm of Valence, Arousal and Dominance features, BE Verbs, Slang Count, Dictionary of Affect features and POS tags) and (Bag Of Words, POS tags, Norm of Valence, Arousal and Dominance, Dictionary of Affect, Synesketch features, Emotion Intensity, Slang Count, BE Verbs) features gives an accuracy of 93.16% for Gradient Boost, using Dataset D1.

TABLE II. EMOTION CLASSIFICATION BY QUADRANTS FOR DATASET D1, USING BAG OF WORDS (BOW), STYLE AND LEXICON FEATURES

Feature Sets Combinations	Random Forest	Gradient Boost
BOW + AF1 + BE + SL + BF5 + POS	64.5	93.16
BOW + AF1 + BF4 + BE + SL + BF5	61.49	80.68
BOW + AF1 + SL + BF5	57.76	91.92
BOW + AF1 + BF3 + B5 + BF4	50.93	50.93
BOW + AF1 + BF4 + SL + BF5	50.31	53.41
BOW + POS + AF1 + BF5 + SL	52.17	50.31
BOW + POS + AF1 + BF5 + BF3 + BF4 + SL + BE	54.03	93.16
BOW + POS + A1 + B4 + B5 + B3	54.03	90.68
BOW + POS + A1 + B4 + B5 + B3 + SL	57.76	63.35

In the Table III, the combination of (TF-IDF, Norm of Valence, Arousal and Dominance features, Emotion Intensity features, Slang Count , Dictionary of Affect features) and (TF-IDF, Norm of Valence, Arousal and Dominance features, Slang Count: and Dictionary of Affect features)for Gradient Boost classifier gives an accuracy of 91.92%, using Dataset D1.

TABLE III. EMOTION CLASSIFICATION BY QUADRANTS FOR THE DATASET D1, USING TF-IDF, STYLE, AND LEXICON FEATURES

Feature Sets Combinations	Random Forest	Gradient Boost
TF-IDF + AF1 + BF4 + BE + SL + BF5 + POS	60.24	91.30
TF-IDF + AF1 + BF4 + BE + SL + BF5	57.76	91.92
TF-IDF + AF1 + SL + BF5	57.96	91.92
TF-IDF + AF1 + BF3 + BF5 + EF4	55.90	54.65
TF-IDF + AF1 + BF4 + SL + BF5	56.52	47.20
TF-IDF + POS + AF1 + BF5 + SL	54.65	53.41
TF-IDF + POS + AF1 + BF5 + BF3 + BF4 + SL + BE	55.27	88.81
TF-IDF + POS + AF1 + BF4 + BF5 + BF3	57.14	90.68
TF-IDF + POS + AF1 + BF4 + BF5 + BF3 + SL	54.03	55.27

For Table IV, the combination of (TF-IDF, Norm of Valence, Arousal and Dominance features, Emotion Intensity, BE Verbs, Slang count, Lyrics Length and Synesketch) features give 78.49 % accuracy for Gradient Boost. The combination of (TF-IDF, POS tags , Norm of Valence, Arousal and Dominance features, Dictionary of Affect features, Synesketch features and Emotion Intensity features) and (TF-IDF, Norm of Valence, Arousal and Dominance features, Emotion Intensity features, BE Verbs, Slang Count , Lyrics Length Features and Synesketch features) give accuracy of 77.42% for Random Forest with Dataset D2.

TABLE IV. EMOTION CLASSIFICATION BY QUADRANTS FOR DATASET D2, USING TF-IDF, STYLE AND LEXICON FEATURES

Feature Sets Combinations	Random Forest	Gradient Boost
TF-IDF + POS + A1 + DAL + BF3 + BF4	65.59	69.89
TF-IDF + AF1 + BF4 + SL + BF3 + LF	63.44	65.59
TF-IDF + AF1 + BF4 + SL + BF3 + LF + DAL	64.51	66.67
TF-IDF + POS + AF1 + BF4 + SL + BF3	74.19	75.26
TF-IDF + POS + AF1 + DAL + BF3 + BF4	77.42	76.34
TF-IDF + POS + AF1 + DAL + BF3 + LF	68.81	75.26
TF-IDF + POS + AF1 + DAL + SL + BF4	67.74	73.11
TF-IDF + POS + AF1 + DAL + BF3 + BF4	65.59	69.89
TF-IDF + AF1 + POS + BF3 + BF2 + SL	77.42	75.26
TF-IDF + AF1 + POS + BF3 + BF2 + SL + L	72.04	68.81
TF-IDF + AF1 + BF4 + BE + SL + L + BF3	72.04	78.494

For Table V, the combination of (Bag of Words, POS Tags, Norm of Valence, Arousal and Dominance features, Dictionary of Affect features, Slang Count and Emotion Intensity) gives accuracy of 75.26% for Gradient Boost and 72.04% for Random Forest, using Dataset D2.

B. Principal Component Analysis (PCA)

PCA transforms the original data into a new set of variables, known as principal components, which are uncorrelated and ordered so that the first few retain most of the variation present in all the original variables. The variance helps determine how much information each principal component holds from the original dataset. Explained Variance shows how much of the data's variation a principal component captures. Cumulative Variance sums up the variances of components to show the total variation explained.

TABLE V. EMOTION CLASSIFICATION BY QUADRANT FOR THE DATASET D2, USING BOW, STYLE AND LEXICON FEATURES

Feature Sets Combinations	Random Forest	Gradient Boost
BOW + POS + AF1 + DAL + BF3 +BF4	72.04	69.89
BOW + AF1 + BF4 + SL + BF3 + L	68.81	62.36
BOW + AF1 + BF4 + SL + BF3 + L + DAL	64.5	64.5
BOW + POS + AF1 + BF4 + SL + BF3	70.96	67.74
BOW + POS + AF1 + DAL + BF3 + BF4	72.04	69.89
BOW + POS + AF1 + DAL + BF3 + LF	62.36	64.5
BOW + POS + AF1 + DAL + SL + F4	72.04	*75.26*
BOW + POS + AF1 + DAL + BF3 + BF4	43.08	49.46
BOW + POS + AF1 + DAL + BF3 + BF4	72.04	69.89
BOW + AF1 + POS + BF3 + BF2 + SL + L	58.06	62.36
BOW + AF1 + BF4 + BE + SL + LF + BF3	66.66	62.365

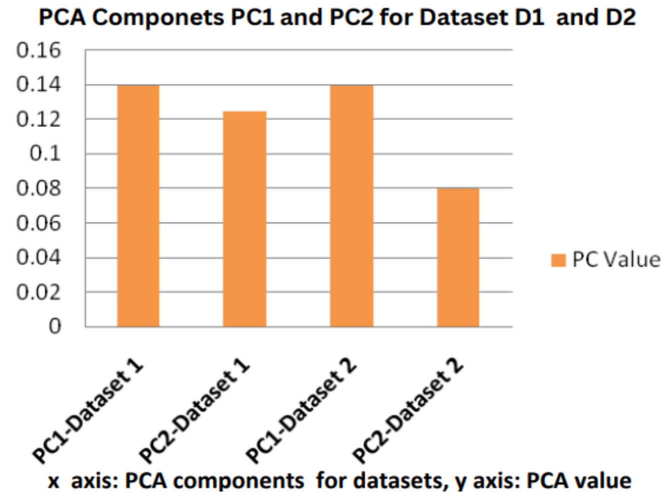

Fig. 2. PC1 and PC2 for dataset D1 and D2.

The bar chart in Fig. 2 shows the values of two main components, PC1 and PC2, for two datasets. The x axis shows PCA components for (D1 and D2); and y axis shows PCA value. In Dataset 1, PC1 explains a moderate amount of variance, showing it captures a significant part of the data's variability. PC2 has less variance than PC1, meaning the remaining variability isn't as focused in one direction. Dataset 2 has a slightly higher variance for PC1 than Dataset 1, indicating more of its variability is due to the first principal component. PC2's variance in Dataset 2 is even lower than in Dataset 1. Result indicates that Dataset 2's variability is more concentrated in the first component. While both datasets have similar PC1 values, Dataset 2 relies more on PC1, showing a more unidirectional variance. In contrast, Dataset 1 has a higher variance in PC2, indicating its variability is spread across more dimensions. This means Dataset 1 has a more balanced variance distribution between the components, while Dataset 2 leans more on PC1 for its variance explanation.

The PCA analysis of music lyrics for emotion classification highlights key features influencing the first two principal components across two datasets. In Dataset 1 (D1), PC1 is primarily influenced by character count, word count, sentence count, singular nouns (NN), and personal pronouns (PRP), pointing to detailed and intense emotional expression. PC2 is shaped by personal pronouns (PRP), adverbs (RB), present tense verbs (VBP), and general verbs (VB), indicating immediacy in emotional experiences. For Dataset 2 (D2), PC1 is similarly influenced by character count, word count, singular nouns (NN), personal pronouns (PRP), and sentence count, suggesting a focus on emotional intensity. However, PC2 is defined by personal pronouns (PRP), proper nouns (NNP), singular verbs (VBP), conjunctions (CC), and past tense verbs (VBD), which highlight introspection and narrative elements. By using 40 PCA components, the analysis effectively reduces dimensionality while capturing the nuanced features of emotional expression in lyrics, enhancing emotion classification accuracy.

Table VI shows result for emotion classification by quadrants for D1 using PCA, achieving 90% explained variance with 40 components. The Gradient Boost classifier performed the best with an accuracy of 98.13%. Table VII shows that the emotion classification by quadrants for Dataset 2 using PCA, achieving 85% explained variance with 40 components. The Gradient Boost classifier performed the best with an accuracy of 65.59%.

TABLE VI. EMOTION CLASSIFICATION BY QUADRANTS FOR D1 USING PCA

PCA Explained Variance	PCA Components	Classifiers	Accuracy
90%	40	Random Forest	96.89%
90%	40	Gradient Boost	98.13%
90%	40	Decision Tree	96.89%

TABLE VII. EMOTION CLASSIFICATION BY QUADRANTS FOR D1 USING PCA

PCA Explained Variance	PCA Components	Classifiers	Accuracy
85%	40	Random Forest	59.13%
85%	40	Gradient Boost	65.59%
85%	40	Decision Tree	47.31%

V. DISCUSSION

The classification experiments for emotion detection in lyrics using various feature sets and classifiers demonstrated notable differences in performance across datasets, classifiers, and feature combinations. The emotion detection experiments in song lyrics showed notable differences in performance across datasets, classifiers, and feature combinations. For Dataset D1, the Gradient Boost classifier consistently outperformed Random Forest, achieving the highest accuracy of 93.16% with a Bag of Words approach combined with stylistic, lexical, and length features, including Norm of Valence, Arousal, and Dominance, BE verbs, slang count, dictionary of affect features, and POS tags. This indicates that a comprehensive feature set is effective for capturing the nuances of emotion in lyrics. Using TF-IDF instead of BOW yielded similar results, with a slight decrease to 91.92% accuracy for Gradient Boost, showing that text representation (BOW or TF-IDF) has a marginal impact when combined with these features. In contrast, Random Forest did not perform well on D1, it achieved highest accuracy of 64.5%.
