For Dataset D2, the results were less consistent. Gradient Boost achieved the best accuracy of 78.49% using TF-IDF, AF1, BE verbs, slang count, lyrics length, and Synesketch features, highlighting the importance of emotional content and syntactic complexity. Random Forest also performed relatively well on D2, with an accuracy of 77.42% using a different feature set. The result suggests shows that, it might be more effective for this dataset due to differences in data distribution or emotional expression. Principal Component Analysis (PCA) for dimensionality reduction further clarified the effectiveness of feature sets. For D1, using 40 PCA components, Gradient Boost achieved an accuracy of 98.13%, showing that PCA effectiveness in capturing the most informative aspects of the data. However, for D2, the highest accuracy with PCA was 65.59%, indicating that PCA might not capture the emotional nuances as effectively as in D1. Overall Dataset D1 generally achieved higher classification accuracy than D2. The difference in performance is likely due to differences in dataset characteristics. The results emphasize the need for comprehensive feature sets and suitable algorithms to capture emotional complexity in lyrics. PCA is effective for reducing dimensionality and enhancing classifier performance, especially for Dataset D1, though its impact varies with different datasets and feature representations.

The use of PCA highlights its value in reducing dimensionality and enhancing classifier performance when sufficient variance is retained, as seen with Dataset D1. However, the mixed results for Dataset D2 indicate that while PCA can improve efficiency, it may also overlook some nuances if the components do not adequately represent the data's emotional characteristics. In music emotion recognition from lyrics, our method has shown superior effectiveness compared to both transformer-based and traditional approaches. For Dataset D1, the Gradient Boost classifier achieved an accuracy of 93.16%, which improved to 98.13% with PCA.

This study builds upon our previous work [8] by incorporating a more diverse set of features and applying Principal Component Analysis (PCA) for dimensionality reduction. While the prior study primarily used lexicon-based features, the current work integrates a wide range of NLP, textual, stylistic, and lexical features. This expanded feature set includes POS tags, DAL, slang count, BE verbs, length-based attributes, and affective dictionaries. The use of the expanded feature set allows for a more comprehensive analysis of emotional nuances in song lyrics. The application of PCA for dimensionality reduction is another novel aspect, resulting in improved accuracy and model interpretability. The results of this approach are significant, with an accuracy of 98.13% achieved on Dataset D1 using PCA, compared to 93.16% without PCA. This performance surpasses previous methods in the field. For instance, Transformer-based models like XLNet [12] achieved 83% accuracy on the Mood Lyrics dataset, while traditional Bag of Words and TF-IDF approaches reported accuracies [29] between 65.49% and 67.98%. Malheiro et al. attained an F1 score of 73.6% for MER Lyrics [4] using the SVM classifier. This study achieved a remarkable accuracy of 98.13% on Dataset D1, surpassing previous research that employed multi-modal deep learning approaches by Pyrovolakis et al. (2022) [28] and Transformer-model [12]. Jiddy Abdullah [29] achieved classification accuracies of 76% and 83% using Support Vector Machine (SVM) and K-Nearest Neighbors (KNN) classifiers, respectively, on the Mood Lyrics dataset. Malheiro et al. (2016) [4] utilized emotionally relevant features; this study's uses broader integration of stylistic, lexical, and content features which led to superior performance. Accuracy gains are crucial for fine-grained emotion detection applications, but they come with increased computational cost and complexity. While this may limit scalability, the benefits often outweigh the added resources, making the improvement worthwhile in many practical scenarios.

Despite these improvements, the study has limitations. These include potential issues with generalizability across different datasets and a lack of exploration into the impact of various hyper parameters for the Gradient Boost classifier and other dimension reduction methods. Additionally, the focus on accuracy may have overlooked other important metrics. This study shows that using various features with methods like PCA to reduce complexity effectively captures the emotions in song lyrics, improving upon the accuracy and representation issues of past approaches.

VI. Conclusion

In conclusion, this research significantly advances the field of emotion analysis in music lyrics by filling a critical gap with a focused study on the textual representation of emotions. The development of an NLP-based framework and the introduction of hybrid lexicon features have proven to be instrumental in enhancing emotion detection capabilities. The NLP-based framework and novel lexicon features significantly enhance emotion detection. Advanced classification techniques like Gradient Boost and Decision Trees, along with innovative feature extraction and dimension reduction, have achieved high accuracy in emotion classification. The superior performance of Gradient Boost classifiers highlights the importance of choosing appropriate algorithms for handling high-dimensional data. This research provides valuable insights into understanding emotional expressions in music. However, it also faces limitations, such as reliance on specific features and the resource-intensive nature of initial computations for large datasets. Additionally, model generalizability across diverse datasets remains a challenge. Future research directions could include exploring other emotion datasets, feature engineering and integrating deep learning approaches.

Art Image Color Sequence Data Processing Method Based on Artificial Intelligence Technology

Xujing Zhao, Xiwen Chen, Jianfei Shen*
School of Visual Arts, Hunan Mass Media Vocational and Technical College, Changsha 410000, China

***Abstract*—With the traditional quality enhancement methods cannot control the best field density range resulting in too large threshold value of colour difference in art works. Therefore, a research on art works quality enhancement based on image processing technology is proposed. The CIE L* a* b* color space model is established to divide the color magnitude and then transform the color space by RGB space conversion model. On this basis, the quality of art works is enhanced according to the process of the quality enhancement of art works. As considering that the actual density is not within the control range, the image processing technology is used to separate targets to solve this problem. In the experiment, Adobe Illustrator CS6 software was used to make the experimental color target and six test samples were selected to test whether the distribution results of the two methods in different degree of color difference perception met the quality enhancement requirements. The experimental results show that the quality enhancement effect of the proposed method is better and more in line with the design requirements.**

Keywords—Artworks; quality enhancement; image processing technology; color space model; target separation; experimental color target

I. Introduction

Graphic artworks mainly come from original works and reproductions. The materials of the original works are various. The most common ones are canvas, paper, wood board, stele, and murals [1]. The mid-term steles and murals are immovable, so the digitalization method is special. Scan with a camera or contactless. Photography or non-contact scanning are inseparable from the intervention of optical lenses, so certain physical deformation is inevitable [2]. Of course, modern optical lenses have developed to a high level of technology, so generally, only professional lens components can be used to avoid obvious deformation problems. Modern printing has completely adopted the digital technology process to handle each production link, and the rough division is input and output. The first is the digital input link. The reason for the different colors of the same set of prints is that different digital materials are used. Although the same technology and materials are used in printing, the image files used are not produced by a unified image digital standard [3]. So it is difficult to adjust to the same color effect in post-processing. For art professionals, the expressiveness of the color of the work is sometimes even more important than the accuracy of the graphics [4]. The sharpest criticism, I have heard in the digitization of art works is the overall tone of many digitized images and the original work. They are all reversed. For example, the overall tone of the original work is warmer, and the result obtained after scanning is cooler. Moreover, such pictures are obtained by professionals after repeatedly adjusting the color curve of the scanner [5]. The problem of color deviation between the digitized art image and the original is a problem that exists widely in the book digitization project but has not been significantly improved [6].

Today, with the rapid development of computer graphics and image processing technology, image processing technology is used for image beautification processing and applied to the field of art to improve the imaging quality and visual sense of the image [7]. The beautification processing of art images mainly includes image noise reduction, image information fusion, image enhancement and image white balance deviation compensation, etc. In the process of landscape image acquisition, due to the influence of the light intensity and the physical characteristics of the acquisition device itself, the original images usually collected need to be processed in post-processing [8]. Image beautification technology is the key to post-art image processing. Image understanding is a science that automatically extracts information through computer programs [9]. It is the process of recognizing image content and interpreting and expressing it in natural language. Specifically, image description can be understood as a special translation process from image to text, in which multi-party knowledge in the fields of CV, NLP and machine learning is used [10]. For humans, the process of "seeing pictures and talking" from images to texts is a very basic ability, but for machines, it is to build associations between completely different modeling systems. The process of automatic image understanding firstly obtains the cognition of the image content through the model, and secondly, the binary cognition needs to be converted into the form of natural language for output [11].

The traditional method of enhancing the quality of works of art is achieved by calculating the dot gain value of works of art. Although the color reproducibility can be enhanced, the optimal solid density cannot be determined, resulting in ghosting and deformation of works of art [12]. Ghosting and deformation are caused by failing to control the difference in density within a certain range. In order to solve this problem, this paper proposes a method for enhancing the quality of artworks based on image processing technology [13]. In the study of domestic and foreign cases, it is found that the use of color defect detection, noise processing, color division and other methods can effectively enhance the quality of various art works. In order to overcome the instability of the subjective visual inspection method used in the detection, some foreign scholars, based on the image processing technology, combined with the concept of machine vision, carried out real-time detection with the help of detectors, and realized the online control of the quality of art works [14]. On this basis, adjust the acquired information, and use multiple color line scan cameras to capture the surface information of the artwork, compare it with the standard artwork, and analyze and detect defects point by point. However, this method still lacks certain practicality. In this design, this method is used as a reference to complete the design. In terms of expression, the model has further requirements for readability [15]. The generated text description should not only reflect the information of the image, but also take into account the fluency of the language [16]. After years of development, current image understanding technologies can usually be classified into three methods: template-based methods, retrieval-based methods, and end-to-end automatic understanding methods based on deep learning [17].

The quality enhancement method of artworks based on image processing technology is a collection of various techniques that can improve the visual effect of artworks. First establish the CIE *L* a* b** color space model, divide the color magnitude, and then apply a simple algorithm to give a three-dimensional color histogram [18]. After feature extraction, detect color defects, classify images, and enhance the quality of artwork. In the research process, it is found that the application of defect identification algorithm will affect the effect of enhancing the quality of artworks [19]. For this reason, dynamic thresholds are used to set pixel points to achieve inspection-free and shorten the inspection time [20]. In order to ensure the feasibility of the established method, the method of numerical comparison is used in the experiment to verify whether the quality enhancement method of art works based on image processing technology meets the needs of use.

Section I of the study elaborated on the background description of various technologies that can enhance the visual effects of artworks. Section II analyzed the construction of machine learning in the context of artificial intelligence by various scholars. Compared to re-creating works of a specific style through extensive training, correctly establishing the artistic understanding ability of machines is more in line with the long-term needs of artificial intelligence cognitive intelligence. Section III describes the artistic image processing scheme. Section IV conducted simulation experiments, analyzed experimental parameter settings, established an RGB space conversion model, and then used raw data to model color targets according to experimental requirements. Section V summarizes the entire text. The enhancement effects of the two methods were compared numerically. The experimental results indicate that the method meets the design requirements.

II. Related Work

The research on the processing method of artistic image color sequence data based on artificial intelligence technology is highly relevant for improving the digital efficiency of artistic creation, accurately controlling color transition and expression, and promoting the deep integration of the art field and technological innovation. This study aims to analyze and optimize the color sequence of artistic images through intelligent algorithms, providing powerful color processing tools for artists and designers, and promoting the personalized and diversified development of artistic creation. Assisting the artistic process with artificial intelligence technology is an emerging topic in recent years, but it has a vitality that cannot be ignored. The study in [21] organizes the computational aesthetics task of combining art and artificial intelligence from the perspective of human cognition. The particularity of art makes researchers pay special attention to what kind of performance machines can have in this field, how to make machines have the same understanding and aesthetic power as humans, and whether existing technologies can endow machines with intelligence in this area. In the understanding of artificial intelligence art, there are two schools of thought. One school believes that artificial intelligence replaces only repetitive labor and techniques, and cannot replace human free will to create. The other faction recognizes the autonomous creativity of artificial intelligence and believes that artificial intelligence has the potential to replace human designers to achieve independent creation. Repetitive work is just replaced with a higher priority; and the process of being replaced takes longer for links that require more creativity. The researchers conducted a variety of research explorations against these two viewpoints.

The advantages of deep learning in tasks such as feature selection and image matching provide new options for image restoration. Currently, it has great auxiliary significance for tasks such as restoration of historical relics and video special effects rendering. Bertalmio et al. used the idea of partial differentiation [22] to complete and repair the image, and use the information outside the entire area to repair the contour inward. Pathak et al. Combining the codec architecture and generative adversarial network technology [23], the image information is complemented by the judgment of the prediction map, and the image can also be filled in the case of large-area information defects, and the completed image can be semantically. It matches the original image. Iizuka et al. added the judgment of local information on the basis of the former, and the output repair map takes into account global and local information, which is semantically consistent with the overall semantics, and also strengthens the performance of details locally [24]. Image restoration guided by artificial intelligence technology is especially suitable for the restoration of stained and damaged paintings.

When expanding the research boundaries of artificial intelligence (AI) systems' emotional response capabilities, it innovatively shifts the focus to AI's ability to understand and respond to emotional tones in artistic image color sequence data [25]. The research aims to explore in depth how the emotional tendencies contained in color sequences in artistic images affect the judgment and decision-making process of AI systems, particularly through an AI based method for processing color sequence data in artistic images. In order to construct this research scenario, some scholars carefully selected a series of art promotional images of vacation rentals as experimental materials [26]. These images not only showcase different vacation environments, but also convey diverse emotional atmospheres through changes in color sequences. Using advanced image analysis techniques, extract color sequence data from images and design algorithms to identify and analyze the emotional tones (such as positive, negative, or neutral) contained in these color sequences. There are still many controversies about the intelligence and originality of works obtained by intelligent machines through style imitation.

Compared with re-creating works of a specific style through a lot of training, the correct establishment of the machine's artistic understanding ability is more in line with the long-term needs of artificial intelligence cognitive intelligence. Although Gatys et al.'s art transfer model and subsequent Prisma applications have achieved significant results in art style imitation, there is still controversy over the intelligence and originality of intelligent machines obtaining works through style imitation. This reflects the limitations of artificial intelligence in the field of artistic creation - that is, current technology is more focused on imitation rather than creation. Considering that errors are prone to occur in color difference space conversion, the RGB space conversion model is used to improve the conversion accuracy. On this basis, according to the process of improving the quality of artistic works, enhance the quality of artistic works. Finally, the enhancement effects of the two methods were compared numerically.

III. Art Picture Processing Scheme

A. Color Scale Division

In order to avoid the difference in color evaluation, the color difference evaluation standard is divided into the demand level, as shown in Table I.

TABLE I. COLOR DIFFERENCE EVALUATION STANDARD

Color Difference Value	Color Difference Evaluation	Visual Perception Cognition
0-1.5	Slight chromatic aberration	Very little difference
1.5-2.5	Small color difference	Slight difference
2.5-3.5	Small color difference	The difference is obvious
3.5-4.5	Large color difference	The difference is very obvious
4.5 以上	Large color difference	Strong difference

Select a device-dependent color space according to Table I. In information collection, images in RGB color mode should be used to enhance the connectivity of components. The value in the RGB color space is 0~256, which is divided into 257 levels. When the value of R, G, B is 0, the color space will appear black. If the value of R, G, B is 255, R, G, B will appear cyan in turn. If the values of R, G, and B is 255, 0, and 255 in sequence, the color space presents magenta. In terms of grayscale information, the values of R, G, and B are the same, the color components will increase, and the image will gradually change from black to white. The color range of the RGB color space is small, and color defects will appear when the magnitude is divided. For this reason, the CIE *L** *a** *b** color space model is established, and the expression is:

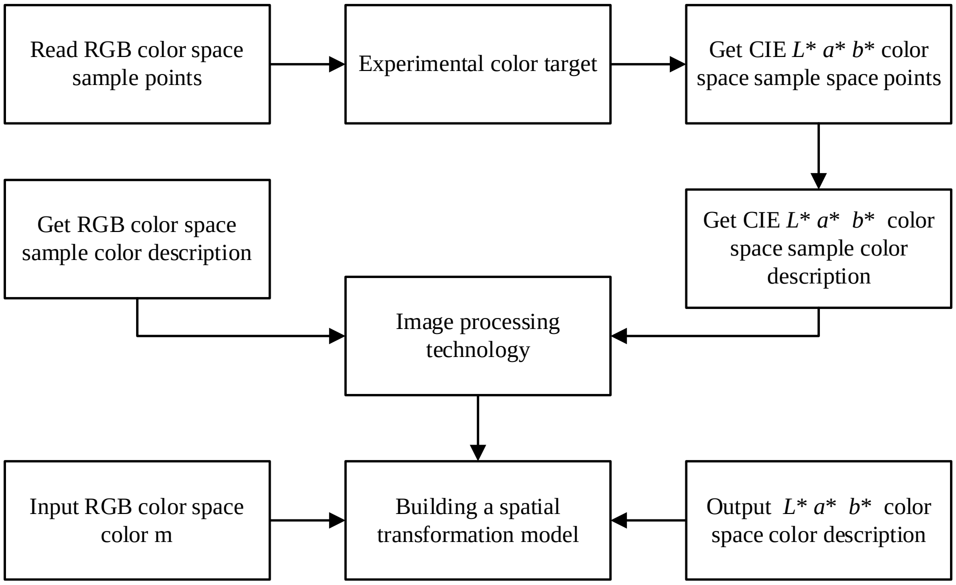
$$\begin{cases} L^* = 106\left(Y/Y_n\right)^{1/3} \\ a^* = 500\left[f\left(X/X_n\right) - f\left(Y/Y_n\right)\right] \\ b^* = 200\left[f\left(X/X_n\right) - f\left(Z/Z_n\right)\right] \end{cases} \quad (1)$$

Where *L** represents the brightness of the artwork, *a** represents the red-green axis, *b** represents the yellow-blue axis. It can be seen from Formula (1) that in the RGB color space, *L** represents the brightness of the luminance axis, and when the color space is 0, it appears black. When the color space is 50, it is white. When the color space is between 0 and 50, it is gray. X, Y, Z represent the tristimulus values under the color of the light source. Color defects can be detected by applying Formula (1), and color levels can be accurately divided.

B. Color Space Conversion

After dividing the color level, in order to realize the nonlinear conversion of the color space, it is necessary to use image processing technology to measure the source color patch data of the RGB space model. The specific conversion steps are as follows:

1) Use image processing technology to build two spatial transformation models, and select standard sample colors. The RGB space conversion model is shown in Fig. 1.



Read RGB color space sample points
Experimental color target
Get CIE L* a* b* color space sample space points
Get RGB color space sample color description
Get CIE L* a* b* color space sample color description
Image processing technology
Input RGB color space color m
Building a spatial transformation model
Output L* a* b* color space color description

Fig. 1. RGB space conversion model.

Applying the RGB space conversion model, the L*, a*, b* expressions are:

$$a^* = \sum a_1 R^i G^j B^k \tag{2}$$

$$b^* = \sum a_2 R^i G^j B^k \tag{3}$$

Where *i*, *j*, *k* represents the order of R, G, B, respectively. And a_0, a_1, a_2 represent the color description data of R, G, B, and its value is not determined according to the color that needs to be adjusted.

Apply Formula (2) to Formula (4) to complete the conversion of color space. Without the choice of sample point requirements when solving for polynomial coefficients, it is impossible to ensure the accuracy of color conversion for all regions. In order to reduce the occurrence of such phenomena, a polynomial method is used to select an original point and add it to the RGB space conversion model to enhance the accuracy of the model transformation. The specific formula is:

$$W_{RCB} = a_0 + a_1 R + a_2 G + a_3 B \tag{4}$$

Where W_{RGB} represents the balanced color after model transformation; a3 represents the color description data of *R*, *G*, *B*, the same as a0~a2.

2) According to the determined model, calculate the optimal parameters.

3) After completing the conversion of the chromaticity information of the original color space, the data of each cube vertex is measured by using a three-dimensional look-up table, and a cube is formed to ensure that the overall color space has high precision. Then divide the RGB space into N^3 cubes, and measure the *L**, *a**, *b** values of the vertices of each cube. Calculate the surrounding vertices according to the RGB space conversion table, and use the vertices on the three-dimensional geometric solid to calculate the converted color data.

4) Color space conversion using neural network. The schematic diagram of the neural network structure is shown in Fig. 2. The conversion of color space is completed by transmitting information through the input layer, hidden layer, and output layer.

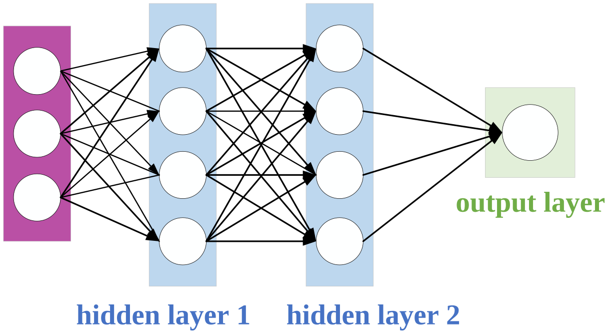


Fig. 2. Schematic diagram of neural network structure.

C. Methods of Enhancing the Quality of Works of Art

First divide the color scale of the artwork, and then convert the color space. In order to enhance the quality of art works, use color defect detection to determine the color difference threshold.

The specific operation steps are as follows:

Step 1: Determine the color defect threshold, and measure the *L**, *a**, *b** values according to user requirements.

Step 2: Set the values of luminance information ΔL, Δa and Δb according to the threshold requirement of the total color difference ΔE_{ab}. If one item does not meet the requirements, it means that the quality enhancement effect of the artwork is unqualified. If the threshold point of the total color difference ΔE_{ab} exceeds 60% of the original image, it is an overall color cast or a local color cast.

Step 3: Step3: Judging whether it is in line with the quality enhancement effect of art works, the judgment is based on:

1) When $\Delta L > 5.05$, it means that the artwork to be inspected is brighter than the standard artwork, and the quality enhancement effect is ideal.

2) When $\Delta L < -5.05$, it means that the artwork to be inspected is darker than the standard artwork, and the quality enhancement effect is not good.

3) When $\Delta a > 4.65$, it means that the artwork to be inspected is redder than the standard artwork, and the quality enhancement effect is better.

4) When $\Delta a < -4.65$, it means that the artwork to be inspected is greener than the standard artwork, and the quality enhancement effect is better.

5) When $\Delta b > 3.21$, it means that the artwork to be inspected is more yellow than the standard artwork, and the quality enhancement effect is good.

6) When $\Delta b < -3.21$, it means that the artwork to be inspected is bluer than the standard artwork, and the quality enhancement effect is poor.

Step 4: After screening, select qualified samples, and use image processing technology to enhance the visual effect of art works to meet quality standards.

Taking into account the problem of image difference, image processing technology is used to separate the target from the back. Let the artwork after the difference shadow be $f(i,j)$, the binarization threshold is Th, and after binarization, the artwork is $g(i,j)$, and the calculation formula is:

$$f(i,j) = \begin{cases} 0, & f(i,j) < \text{Th} \\ 255, & f(i,j)..\text{Th} \end{cases} \tag{5}$$

Set the Th threshold to 56, and apply Formula (6) to eliminate the shadow. Combining the above steps, the design of a method for enhancing the quality of art works based on image processing technology is completed.

D. Image Beautification Processing Implementation

This paper analyzes the application of computer graphics and image processing technology in art, and on the basis of image noise reduction preprocessing, the beautification of night scene images is carried out. This paper proposes a night scene image beautification processing technology based on illumination multiple chromatic aberration compensation, adopts the illumination adaptive equalization technology to optimize the white balance of the night scene image, and searches for the threshold value according to the edge contour information of the image. The neighborhood of the feature point *i* in the image noise distribution is defined by N_{i} as:

$$N_i = \left\{ i' \in S \middle| \left[dist\left(i, i'\right) \right]^2 ,, \; r, i \neq i' \right\} \tag{6}$$

In the white balance processing of night scene images, the illumination adaptive equalization technology is used to optimize the white balance of night scene images. Use $dist\left(i, i'\right)$ to describe the distance of pixels in the neighborhood of the night scene image to be beautified, *r* is a constant, and get the multiple color difference kernels of the night scene image to be beautified.

$$R_i = \frac{1}{\gamma_{ije}} \sum_j d\left(\Box i - j \Box_2\right) l\left(g_i - g_{j1}\right) \tag{7}$$

The morphological segmentation method is used to deconvolute the image completely blindly. In the sparse prior regularization distribution space, the adaptive equalization constraint function of image color difference is obtained according to the prior knowledge of the blur kernel as follows:

$$\min kp = \lambda g_i + \beta g_j \tag{8}$$

where, λ and β are regularization parameters. Based on the mathematical expression of the blur kernel, the white balance optimization result of the night scene image is obtained as:

$$\mathrm{LRT} = \min kp \left| R_i \cdot N_i \right|^s \tag{9}$$

Where *s* is the Total Variation (TV) term of the fuzzy kernel.

The illumination chromatic aberration of night scene adopts the method of shadow area and brightness area segmentation to compensate for contour shadow deviation. Through image multi-threshold segmentation, the segmentation curve of shadow area and brightness area is obtained and described as:

$$G_{\mathrm{mar}}\left(\overrightarrow{x_i}\right) = \frac{\sum_{j=1}^{p} G_j\left(\vec{x}_i\right) / G_j^{\max}}{p} \tag{10}$$

where, $i \in \{1,2,\ldots,\mathrm{N}\}$ is the sequence value. In the measurement of the whole image, the time cost of the regular term of the blurred image is measured, and the blur kernel of the high-frequency image *y* is obtained as:

$$\Omega = \left\{ \vec{x} \in \mathrm{s} \middle| \; g_j(\vec{x}),, \, 0, \, j = 1, 2, \cdots, l; h_j(\vec{x}) = 0, \, j = l+1, l+2, \cdots, p \right\} \tag{11}$$

The fuzzy kernel is updated using the unconstrained iterative reweighted least squares (IRLS) algorithm, which is expressed as:

$$\min \vec{y} = \vec{f}(\vec{x}) = \left(f_1(\vec{x}), f_2(\vec{x}), \cdots, f_m(\vec{x}) \right) \tag{12}$$

Where $\vec{x} = \left(x_1, x_2, \cdots, x_n\right) \in X \subset \Re^n$ is the initial value vector of each feature point of the beautified night scene image, *X* is the decision space for optimal evolution, *Y* is the target space of optimal evolution. The image contour shadow deviation compensation realizes the superposition of the low-frequency information of the image, and the objective function of the image contour shadow deviation compensation is:

$$G(\vec{x}, \vec{y}) = \min \vec{y} \sum_3^4 G_{\mathrm{nor}}(\vec{x}) + \Omega^3 \tag{13}$$

IV. Simulation Test

A. Experimental Parameter Settings

First establish the RGB space conversion model, then use the original data, model the color target according to the experimental requirements, and use professional equipment to detect the quality enhancement effect of art works. According to the data requirements of the experiment, the RGB source color space is divided into nine levels, which are 0, 20, 34, 56, 68, 124, 234, 245, and 276 respectively. Use Adobe Illustrator CS6 software to make experimental color targets. In order to ensure the validity of the built RGB space conversion model, it is necessary to select six works of art, and the color difference information of the works is shown in Fig. 3.

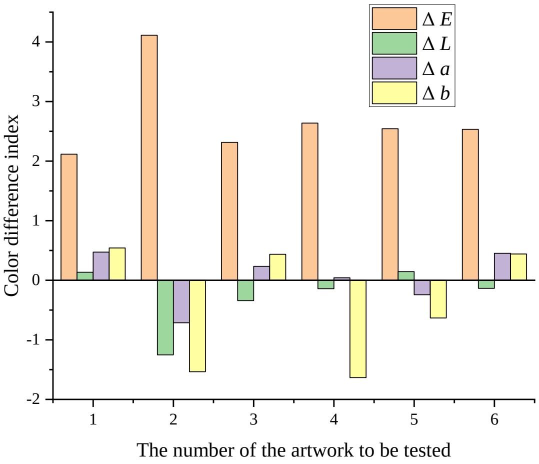

Fig. 3. The color difference information of the works.

Taking the quality enhancement method of artworks in this study as the test object of the experimental group, and the traditional enhancement method as the test object of the control group, the quality enhancement processing of six works of art was carried out by using the two methods, and the processed works were different in color. The color difference thresholds under different brightness and brightness are detected, and the results are shown in Fig. 4 and Fig. 5.

It is known that the human eye has the strongest ability to recognize colors in the mid-lightness range. According to the test results in Fig. 4, it can be seen that the color difference threshold of the control group increases gradually with the increase of the brightness L. However, the chromatic aberration threshold of the images in the experimental group did not increase significantly due to the increase of the lightness L, but stabilized within a fixed range. There is a chromatic aberration deviation. Looking at Fig. 5 again, the control group has a larger color difference threshold due to the increase of color C, and the color difference of the visible image is not obvious. The chromatic aberration threshold of the experimental group is also within a small range. It can be seen that the two works of the experimental group did not show extreme differences in chroma after adding color. Based on the above test results, it can be seen that after the method proposed this time enhances the artwork, whether it is adjusting the brightness or enhancing the color of the artwork, the chromatic aberration threshold of the artwork has always been in a stable range. It can be seen that the proposed enhancement method is better.

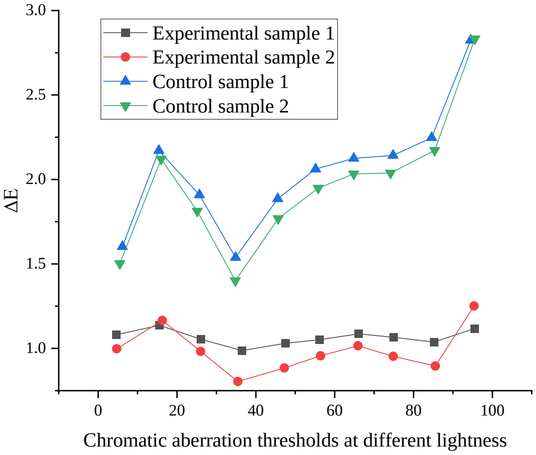

Fig. 4. Image quality enhancement effect experiment 1.

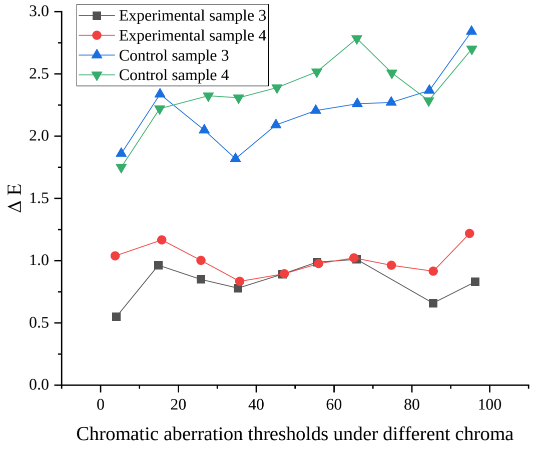

Fig. 5. Image quality enhancement effect experiment 2.

B. Analysis of Simulation Results

In order to explore the practicability of the proposed method, the method proposed in this paper, study [4] and study [5] are used to simulate and compare the digital painting images of R, G and B colors. The experiment adopts objective evaluation, and uses some mathematical variables that can objectively present the essential characteristics of the image, such as mean, variance or histogram characteristics as evaluation criteria, and analyzes the pros and cons of the method. Firstly, the influence of the number of iterations on the performance of the method is analyzed, and the image angle error before and after color correction is used as the measurement standard. The simulation results are shown in Fig. 6.

It can be seen from Fig. 6 that with the increase of the number of iterations, the angle errors of the three methods will gradually decrease. When the number of iterations is greater than or equal to 8, the image angle errors remain stable. The angle error of the method in this paper is always lower than the two literature methods, showing better algorithm performance. The reason for this phenomenon is that the method in this paper uses the optical flow-oriented feature method to effectively divide the image color distortion area, which reduces the probability of color correction angle errors to a certain extent.

The following is the comparison of the average values of R, G, and B colors between the three methods and the original image after the image color correction. After the double analysis of horizontal and vertical, it is evaluated whether the method in this paper has application advantages. The comparison results are shown in Fig. 7 to Fig. 9.

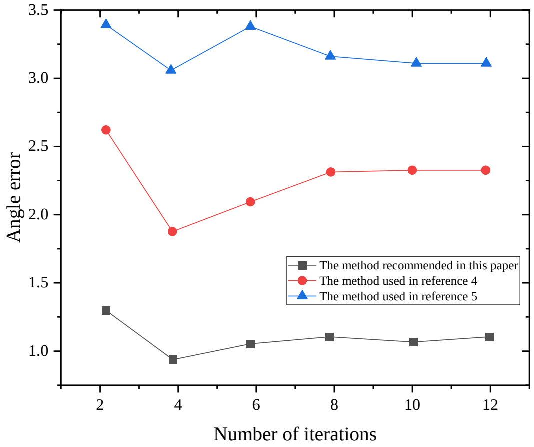

Fig. 6. The effect of the number of iterations on the performance of the method.

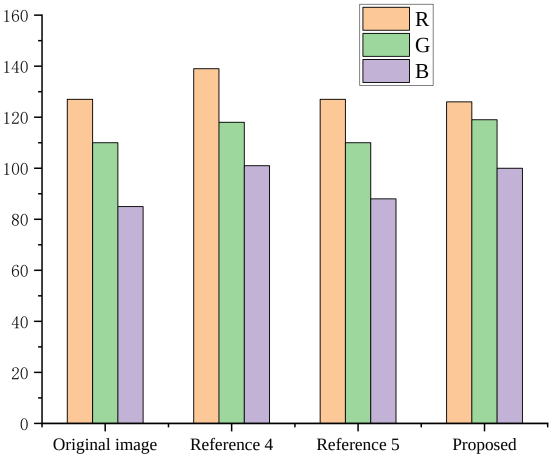

Fig. 7. Color correction comparison of reddish images.

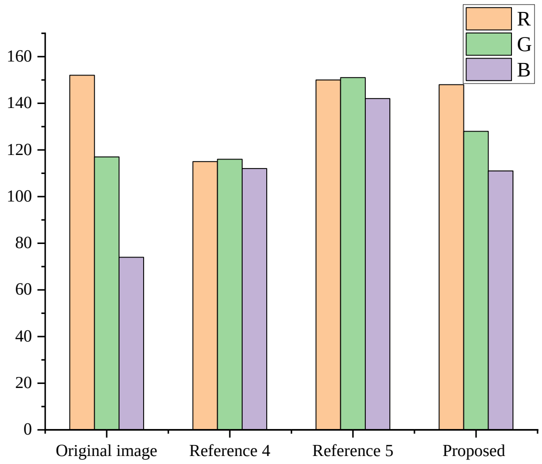

Fig. 8. Color correction comparison of greenish image.

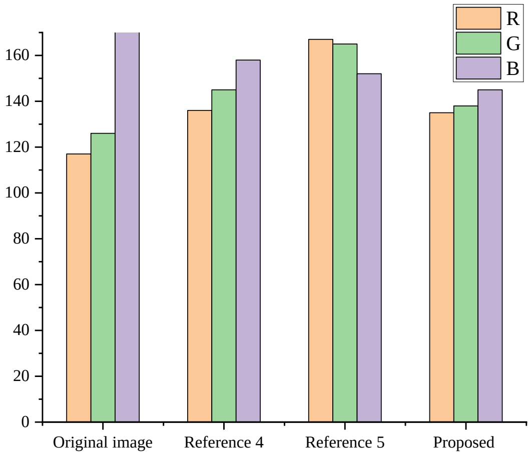

Fig. 9. Color correction comparison for bluish images.

From the experimental data in the three figures, it can be seen that the method in this paper has a good calibration effect for different color cast images. After the correction, the color distribution of the three color channels with uneven distribution of the initial color cast image is more even, and the difference of the mean value of the three color channels and the degree of color cast are reduced. The two methods in the literature are not universal, and may result in failure for some color cast images, and the correction accuracy needs to be improved. Although this method effectively divides color distortion areas using optical flow oriented feature methods, in some complex or boundary blurred images, this division may still not be accurate enough, resulting in poor local color correction effects. Although the experimental results show that the angle error tends to stabilize after increasing the number of iterations to a certain extent, excessive iterations will increase computational costs and reduce processing efficiency. Therefore, determining the optimal number of iterations is a problem that requires further optimization. The method proposed in this article performed well in experiments, but in practical applications, there may be more types of color cast images. How to ensure that the method is equally effective for these images is a problem that needs further verification. By improving the segmentation algorithm and iterative optimization strategy of color distortion areas, the angle error after color correction can be further reduced and the correction accuracy can be improved. Adjust and optimize algorithm parameters for different types of color cast images, improve algorithm adaptability and robustness, and ensure effectiveness and stability in various complex scenarios. On the premise of ensuring calibration accuracy, optimize algorithm implementation, reduce unnecessary computational overhead, improve processing efficiency, and meet the needs of real-time processing or large-scale dataset processing.

V. Conclusion

Aiming at the problems existing in traditional art quality enhancement methods, this paper proposes a new method, which uses image processing technology to enhance the visual effect of the quality of art works. Considering that errors are prone to occur in the conversion of color difference space, the RGB space conversion model is used to enhance the conversion accuracy. On this basis, the quality of art works is enhanced according to the quality enhancement process of art works. Finally, the enhancement effect of the two methods is compared by numerical comparison. The experimental results show that the proposed method meets the design requirements. However, it is found in the experiment that the quality enhancement method of art works based on image processing technology has higher requirements on the surrounding environmental factors, and further research is needed to improve it. When introducing the method proposed in this article, its theoretical basis can be elaborated in more detail. How to specifically apply the feature method for optical flow to the division of color distortion areas, and why this method can effectively reduce the angle error of color correction. In addition to using mean, variance, and histogram features, it is also possible to consider introducing more evaluation metrics such as Structural Similarity Index (SSIM), Peak Signal to Noise Ratio (PSNR), etc. to more comprehensively evaluate image quality. The paper mentions that art quality enhancement methods based on image processing technology have higher requirements for surrounding environmental factors. It is necessary to specify which environmental factors include (such as lighting, temperature, humidity, etc.), and explore how to reduce the impact of these factors in practical applications.

AI-Driven Prioritization Techniques of Requirements in Agile Methodologies: A Systematic Literature Review

Aya M. Radwan, Manal A. Abdel-Fattah, Wael Mohamed
Information System Department, Faculty of Computers and Artificial Intelligence, Cairo, Egypt

***Abstract*—Software requirements are the foundation of a successful software development project, outlining the customer's expectations for the software's functionality. Conventional techniques of requirement prioritization present several challenges, such as scalability, customer satisfaction, efficiency, and dependency management. These challenges make the process difficult to manage effectively. Prioritizing requirements by setting criteria in order of importance is essential to addressing these issues and ensuring the efficient use of resources, especially as software becomes more complex. Artificial intelligence (AI) offers promising solutions to these challenges through algorithms like Machine Learning, Fuzzy Logic, Optimization, and Natural Language Processing. Despite the availability of reviews on conventional prioritization techniques, there is a notable gap in comprehensive reviews of AI-based methods. This paper offers a systematic literature review (SLR) of AI-driven requirements prioritization techniques within Agile methodologies, covering 32 papers published between 2010 and 2024. We conducted a parametric analysis of these techniques, identifying key parameters related to both the prioritization process and specific AI methods. Our findings clarify the application domains of various AI-based techniques, offering crucial insights for researchers, requirement analysts, and stakeholders to choose the most effective prioritization methods. These insights consider dependencies and emphasize the importance of collaboration between stakeholders and the development team for optimal results.**

I. INTRODUCTION

Requirement Engineering (RE) is a crucial component of software engineering. It involves identifying and understanding client needs, the contexts in which the system will be developed, modeling, analyzing, prioritizing, and documenting stakeholder requirements. RE ensures that these documented requirements align with agreed-upon specifications and manages the evolution of changing requirements [1], [2], [3].

Requirement Engineering (RE) faces numerous challenges, particularly in the areas of human communication and collaboration, and understanding and clarifying requirements. Effective communication and collaboration between project teams and customers are critical, yet often fraught with difficulties, including conflicts among stakeholders and the need for active involvement from all parties. Understanding and clarifying requirements present additional challenges, as ensuring high-quality requirements and well-defined user stories can be complex and time-consuming [4], [5].

Agile Software Development (ASD) introduces specific challenges for requirements prioritization (RP) techniques, such as stakeholder conflicts, changes in priority lists leading to rework, and factors influencing requirement selection during the RP process. Among the most significant challenges are managing and coordinating distributed teams, prioritizing requirements, maintaining proper documentation, adapting to changing and over-scoping requirements, and effectively organizing processes while monitoring progress and incorporating feedback. Addressing these challenges requires robust strategies and tools to enhance communication, clarify requirements, and streamline prioritization and management processes [6].

A key aspect of Requirement Engineering (RE) is requirements prioritization (RP). As the name implies, RP involves identifying the most critical requirements for implementing a successful system. It is an iterative process involving complex decision-making activities that support the development of a high-quality system within defined constraints. RP ensures the correct ordering of requirements based on stakeholder perceptions, by rearranging them according to various criteria such as importance, cost, penalty, and risk. Active stakeholder involvement is crucial for achieving accurate prioritization results [7].

While addressing the prioritization challenge, these techniques have been applied without considering the hierarchical dependencies among requirements, such as stakeholder needs and their derived requirements. Derived requirements are the detailed requirements extracted from stakeholder needs, often in the form of use cases or non-functional requirements [6] [8].

Most existing requirement prioritization techniques lack scalability, dependability, continuous prioritization, rank updating, feedback handling, and comprehensive implementation of methods or algorithms. In Agile development, where requirements change rapidly, a continuous requirement prioritization process is essential [8] [9].

The objective of this paper is to systematically review and analyze AI-driven techniques, such as Fuzzy Logic, Machine Learning, NLP, and Optimization, for requirements prioritization in Agile methodologies. It aims to compare these techniques based on their strengths, weaknesses, and effectiveness in addressing challenges like scalability, stakeholder collaboration, and requirement dependencies. Additionally, the paper seeks to evaluate the impact of AI on improving the prioritization process and provide recommendations for future research.

This section presents the idea of the requirement prioritization in Agile methodology and discusses the common challenges. In the second section the background of the used techniques to prioritize the requirements in Agile methodology is presented. In the third section the research method is described, and the requirements prioritization analysis is illustrated at the taxonomy, the research questions are defined and research strategy. The fourth section provides the surveyed techniques and reviews the 32 papers that were sorted in subsection by the type of technique. In section five the Evaluation criteria are defined by clearing the strengths, weakness and limitations of the research. Finally, a comprehensive of the evaluation criteria is presented in the tables for each technique.

II. Background

Requirement prioritization in Agile methodology can be improved using advanced techniques such as Fuzzy Logic, Machine Learning, Unsupervised Learning, Optimization, and Natural Language Processing (NLP). In this section, an illustration of the four techniques is defined.

Fuzzy Logic has the unique ability to process numeric input and linguistic information simultaneously. It applies a nonlinear transformation to the input feature vector, resulting in a single numeric output, thus transforming numeric values into other numeric values [10]. Defining requirements into precise numerical values is a significant challenge. Fuzzy Logic allows for the accurate definition of concepts such as low cost, high quality, and high progress, making it a powerful tool for managing uncertainty. It does this by using human language and allowing for interpretation of assertions that are not entirely precise or incorrect [11].

Machine Learning (ML) provides a range of algorithms and strategies to imitate the way of human think by acquiring knowledge from data, it can be used to address software engineering challenges using supervised, unsupervised, and reinforcement learning approaches. Machine Learning facilitates software development by utilizing predictive models to make informed decisions on algorithms and features. The process of applying Machine Learning requires understanding the problem at hand, collecting relevant data, performing preprocessing tasks, and conducting comprehensive evaluations [12]. Software requirements engineering, and Machine Learning are major areas of research, where Machine Learning is applied in many software engineering procedures. Machine Learning approaches, such as text feature extraction and algorithms, are employed to categorize and prioritize software needs, utilizing the large amount of data and domain expertise gathered throughout the development process [12]. Natural Language Processing is interconnected to Machine Learning (ML) as NLP heavily relies on Machine Learning approaches, utilizing algorithms and models derived from ML. The objective of Natural Language Processing (NLP) or computational linguistics is to devise algorithms and methodologies that construct computational models with the ability to analyze natural languages. These models are specifically built to carry out important functions, such as enabling the exchange of information between humans and machines, improving communication among individuals, or simply analyzing and interpreting text or speech [13].

Optimization is a strategy to select the most efficient solution from a set of options, considering constraints and intended results. By considering aspects such as minimizing costs or maximizing efficiency. Optimization is a commonly employed strategy in diverse fields such as mathematics, computer science, engineering, economics, and operations research. It improves decision-making processes and successfully solves complex challenges [14].

In Agile methodologies, various AI techniques offer unique solutions to key challenges in requirements prioritization. Fuzzy Logic stands out in managing uncertainty and imprecise requirements by allowing for flexible decision-making under ambiguous conditions, thus improving the overall accuracy of decisions [11]. Machine Learning (ML) techniques are particularly effective in handling large datasets and automating the prioritization process, which addresses scalability concerns and significantly reduces manual effort [12]. Natural Language Processing (NLP) plays a crucial role in automating the interpretation of user stories and feedback, enhancing communication and resolving issues related to unclear or incomplete requirements. Finally, Optimization algorithms, such as AHP and PSO, provide a structured approach to balancing conflicting priorities, making them highly effective in resolving stakeholder conflicts and managing competing requirements efficiently [15][16]. By applying these techniques, the prioritization of requirements becomes more efficient, accurate, and adaptable to the dynamic nature of Agile software development.

III. Research Method

A. *Planning the Review (Preparation Stage)*

This Systematic Literature Review aims to investigate, analyze, and summarize Agile software requirements prioritization techniques, including Fuzzy Logic, Machine Learning, Natural Language Processing, and Optimization within the framework of parametric benchmarks. The review aims to define the key strengths and weaknesses and define how artificial intelligence techniques can affect requirement prioritization in Agile methodology, also explore the limitations of applying these techniques in the Agile prioritization process. Additionally, the study seeks to understand the significance of these techniques in the software development process, the role of stakeholders, and the challenges or limitations in Agile practices, while providing future directions for further research. The main objective of this Systematic Literature Review (SLR) is to identify the various techniques employed to prioritize requirements in Agile methodology.

The key of the SLR is illustrated through three phases at the taxonomy depicted in Fig. 1, to illustrate the core ideas of the paper. First, defining with requirements prioritization techniques as Fuzzy Logic, Machine Learning, Natural Language Processing and Optimization. Second, comparative analysis presented in a table to show the strength, weakness and limitations in requirements prioritization for the 32 papers. Third, the evaluation criteria to determine the effectiveness of each requirements prioritization technique.

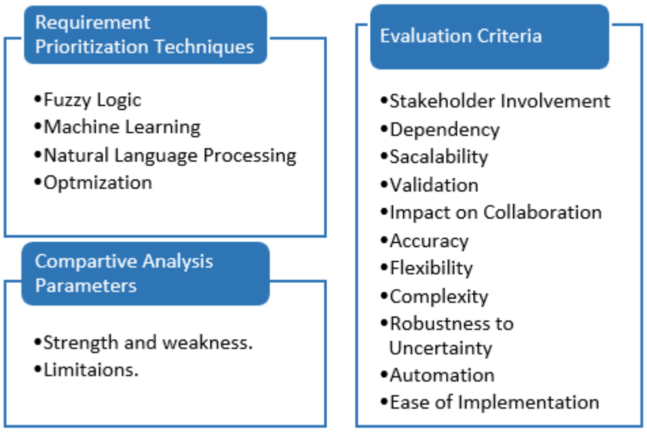

Fig. 1. Requirements prioritization taxonomy.

B. Research Question

The following research questions have been defined:

RQ1: What requirement prioritization techniques used in Agile Software Development in the research literature?

RQ2: How are the proposed techniques evaluated?

RQ3: What evaluation criteria can be used in requirement prioritization in Agile Software Development?

RQ4: What are the limitations in the current Agile Software Development technique?

RQ5: Does dependency play a role in prioritizing requirements in Agile methodology?

RQ6: Is collaboration with stakeholders considered when prioritizing requirements in Agile methodology?

RQ7: Is scalability considered when prioritizing requirements in Agile methodology?

C. Search Strategy

A comprehensive search strategy is developed to collect all research articles that are relevant to the domain of our study from a variety of online resources. The most renowned online databases and combined key terms was selected to produce search strings. Subsequently, the search was implemented to identify all relevant articles. 900 prospective studies were identified during the initial search phase. 250 studies were determined to be relevant to requirement engineering in general after the titles and abstracts were reviewed. The selection criteria focused on 32 papers specifically applying AI techniques, such as Machine Learning, Fuzzy Logic, NLP, and Optimization, to requirements prioritization in Agile software development. Studies published between 2010 and 2024 were included to ensure the review reflected the most current research. Papers were chosen based on their application of AI techniques within Agile methodologies like Scrum, Kanban, XP, and DevOps. After a thorough quality assessment, these 32 papers were selected to address the research questions, with no additional recent studies identified.

IV. Surveyed Techniques

In this section, all the surveyed techniques were reviewed. Software organizations are addressing the limitations of conventional techniques by implementing AI-based methods for software requirements prioritization in Agile. These techniques are divided into four categories: Optimization-based, Fuzzy Logic-based, Machine Learning-based, and Natural Language Processing-based ones. A detailed review is provided of each technique within these groups individually.

A. Fuzzy Logic

Borhan in [15] introduces an innovative approach to prioritizing user stories by collaborating with stakeholders in the Agile-Scrum prioritization process. The approach implements Fuzzy Logic operations to prioritize stakeholders according to predetermined criteria, thereby facilitating a more comprehensive comprehension of their contributions and concerns. This methodology is applied to an ATM system's requirements and their related user stories. A group of software experts who are experienced in Agile methodologies give feedback within their organizations for this approach. The findings suggest that including stakeholder analysis has a positive influence on the prioritization process, demonstrating the effectiveness of this method in achieving a balance between functional and non-functional user stories. By carefully considering stakeholder perspectives, this approach enhances the accuracy and efficacy of user story prioritization in Agile-Scrum projects. It guarantees a more equitable assessment of the system's requirements and the diverse demands of users.

Abusaeed in [16] suggest a quantitative framework that effectively prioritizes the identified cost factors based on the following four categories: people, initiatives, processes, and products. They conduct a systematic literature review and empirical study within the ASD context to identify and validate the cost overhead factors. Similarly, the validated factors are classified and prioritized in the present study by employing a multi-criterion decision-making Fuzzy-Analytic Hierarchy Process technique. This method effectively mitigates the subjectivity and ambiguity of the identified factors. The implementation results provide a prioritized list of cost overhead factors that would be beneficial to Agile practitioners in the context of Agile Software Development.

Ottoli in [17] introduces a novel approach to requirement prioritization that uses expert opinions presented by fuzzy linguistic labels on multiple decision criteria. Fuzzy linguistic labels are used to allocate weights to each expert and criterion, and these opinions are aggregated using a majority-guided linguistic IOWA (Induced Ordered Weighted Averaging) operator. The method contrasts requirements by comparing the aggregated expert opinions and their weighted importance. The algorithm demands users to submit opinions. However, additional empirical validation with actual users is required. Allowing selective expert opinions, incorporating consensus metrics, and investigating other (IOWA) Induced Ordered Weighted Averaging operators and T-norms are all potential future enhancements.

B. Machine Learning

Anand in [18] used the apriori algorithm to prioritize requirements. They addressed the limitations of the traditional methods used such as MoSCoW, Validated Learning, Walking Skeleton, and Business Value which frequently fail to effectively resolve stakeholder conflicts. The apriori algorithm is implemented to identify the most frequently requested requirements, to reduce conflicts between stakeholders by prioritizing requirements based on stakeholder input by continually performing join and prune functions to identify frequent items within a database of transactions.

Hudaib in [19] employs Self-organizing Maps (SOMs), a type of Unsupervised Neural Network as a method to prioritize requirements within Agile methodologies. This method is designed to classify and prioritize requirements automatically by applying patterns that are derived from historical data and stakeholder feedback. The SOM technique prioritizes requirements by grouping similar requirements based on their historical significance and characteristics. This enables project teams to identify which requirements should be addressed first. They provide a visualization to understand the priority of requirements.

Varsha in [20] improved the decision-making process of the requirements by grouping stakeholders according to their interests and perspectives. They aimed to improve the accuracy and efficiency of requirements prioritization in complex project environments. When requirements values are gathered from many individual stakeholders, it is necessary to organize stakeholders into groups to implement requirements prioritization. They involve the use of a hierarchical clustering analysis technique to create such groups from stakeholder ratings. The group weights were determined using AHP.

Belsis in [21] introduces "PBURC", a Patterns-Based, Unsupervised Requirements Clustering Framework. It utilizes Machine Learning to effectively manage data inconsistencies and validate requirements, ensuring that requirements are clustered properly using K-means. This method defines the optimal number of sprints by collaborating with stakeholders. The framework seeks to simplify the development process by prioritizing client requirements and protecting business value, despite the complex nature of distributed development environments.

Achimugu in [22] focuses on addressing the problem of prioritizing many software requirements using the k-means clustering technique. K-means is utilized to classify requirements based on the weights of their attributes, provided by project stakeholders. The effectiveness of this method was validated with the RALIC dataset, revealing that different stakeholder weights influence the clustering outcome. The approach was further refined by employing a synthetic method with scrambled centroids, proving effective in prioritizing requirements. The results indicated that this technique enhances the scalability and reliability of requirement prioritization, successfully addressing previous limitations such as rank reversals and disparity in weighted rankings.

Kumar in [23] designed an approach to enhance Agile methodology by clustering user stories using the k-means algorithm and cosine similarity. The process includes preprocessing steps like tokenization, stop-word removal, stemming, and lemmatization, followed by clustering based on similarity measures, and validating cluster cohesion with silhouette coefficient values. Experimental results show that cluster quality is improved as the number of clusters (k) increases and this reflects effectively reducing the time required for requirement implementation.

C. Natural Language Processing

Sachdeva in [24] aims to propose an approach that effectively balances both business value and process flow in the prioritization process. This approach helps the Product Owner in deciding which requirements to prioritize and how to organize them in the Product Backlog. This approach models requirements iteratively through user stories to align with the rapidly changing business needs and with the continuous change of requirements. The Product Owner (PO) typically prioritizes based on Business Value without considering dependencies of user stories. They used UML Activity Diagrams to visualize process flows, then they converted user requirements into these diagrams using NLP. This visualization helps prioritize stories based on their process flow.

Shafiq in [25] introduces the NLP4IP approach, a recommendation system to prioritize issues such as stories, bugs, or tasks. It is a semi-automatic approach that uses Natural Language Processing (NLP) to address prioritization challenges to create a recommendation model. The rank of newly added or modified issues is dynamically predicted by this model. The JIRA issue tracking software was employed to evaluate the approach across 19 projects from 6 repositories, resulting in a total of 29,698 issues. Furthermore, they implemented a JIRA plug-in that illustrates the predictions generated by the new Machine Learning model.

Sami in [26] introduced a tool that integrates OpenAI, Flask, and React to automatically generate and rank user stories based on core requirements to improve the project management workflows. The tool allows users to input the requirements then it's used to generate and prioritize user stories and epics. The tool converts responses into a user-friendly JSON format and supports CSV downloads then the tool integrates with task management platforms such as JIRA and Trello.

Sharma in [27], a proposed approach that employs Natural Language Processing (NLP) algorithms to categorize user experiences that are similar and organize them into project releases. The goal of this approach is to enhance the release planning process for intricate and substantial software initiatives that can be simplified. The method entailed the initial development of a word corpus for each project release, followed by the conversion of user stories into vector representations using Java utilities. Lastly, the RV coefficient NLP algorithm is employed to organize them into distinct software releases. Furthermore, these algorithms can be integrated into commercial tools such as JIRA and Rally to facilitate enhanced release planning in Agile environments.

Kifetew in [28] proposes ReFeed approach. It aims to provide a more accurate and automated way to prioritize requirements based on user feedback. The approach employs

Natural Language Processing (NLP) to prioritize requirements. The approach extracts and propagates quantifiable properties from related user feedback. They used domain knowledge to bridge the vocabulary gap between users and developers. This approach bridges the gap between end-users' words and developers' words to formulate requirements.

D. Optimization

Asghar in [15] presents a methodology that integrates traditional prioritization factors with contemporary metrics and techniques, such as AHP and MOSCOW, as well as ISO standards. The objective of this method is to enhance the quality of both the process and the product by offering a more comprehensive and consistent framework for prioritizing requirements. Additionally, the methodology aims to improve the quality of requirements that are selected and prioritized during SCRUM sessions. The proposed model was validated through the use of comprehensive simulations with the iThink software.

Kumar in [16] identifies eight critical attributes—such as leadership support, human resources, and information technology—through literature review and expert validation. To rank these attributes effectively, the study employs an integrated technique called the Analytic Hierarchy Process (AHP) Technique for Order Preference by Similarity to Ideal Solution (TOPSIS). This combined approach allows for a structured evaluation of the attributes based on their relative importance and their distance from an ideal solution.

Muhammad in [17] applied Multi-Criteria Decision Making (MCDM) techniques to rank non-functional requirements (NFRs). The study integrates Fuzzy Logic to manage the imprecision in NFR evaluations and employs pairwise comparison to establish the relative importance of various NFRs. The effectiveness of the proposed model was validated through a case study involving Agile projects, which demonstrated its capability to improve the prioritization process by accurately addressing and ranking NFRs.

Agrawal in [18] proposes an Agile-based Risk Rank (AR-Rank) method to prioritize risk factors in Agile methodology. This method is applied by using Particle Swarm Optimization (PSO) for iterative Optimization. The method provides precedence ranking of risks to minimize their impact and ensure timely delivery of risk-free software.

The AR-Rank approach is validated against other methods and tested on ten real-life projects.

Prakash in [19] proposed ARP–GWO method, this method uses grey wolf Optimization and the k-means clustering algorithm. They aim to prioritize risks in Agile Software Development and to enhance quality, reduce costs, and improve delivery times. The Experimental demonstrates five industrial projects that demonstrate ARP–GWO's effectiveness and high satisfaction among developers and users.

Chaves in [20] presents a Mult-objective swarm intelligence presents a multi-objective swarm intelligence metaheuristic (MOABC) to solve The Next Release Problem (NRP). They present superior performance compared to other methods on real-world datasets. They are seeking to improve the Optimization process by incorporating hybrid approaches, larger datasets, and additional constraints.

Brezočnik in [21] aim to enhance iteration planning in Agile Software Development. By introducing STAPSO, a novel algorithm. This algorithm combines Scrum task allocation and Particle Swarm Optimization. STAPSO is tested on a real-world dataset. It showed promising results in task allocation and applies to various estimation techniques.

Brezočnik in [22] provides an overview of swarm intelligence algorithms. The paper systematically classifies swarm intelligence algorithms based on Agile Software Development tasks like the next release problem, risk, and cost estimation, and discusses their promising results.

Sagrado in [23] address multi-objective Optimization problems in the Next Release Problem (NRP). They proposed approach includes the Ant Colony System (ACS) to multi-objective Optimization, where ants build solutions probabilistically, considering pheromone levels and heuristic information. And Comparative Analysis compared with Greedy Randomized Adaptive Search Procedure (GRASP) and Non-dominated Sorting Genetic Algorithm (NSGA-II) to validate its effectiveness in generating high-quality solutions for requirement prioritization.

Somohano in [24] aims to reduce computational complexity and enhance the precision of requirements prioritization. They present an approach to enhancing the Analytic Hierarchy Process (AHP) by integrating evolutionary computing techniques. Additionally, the research suggests integration of multiple criteria and developing a software tool to assist project managers in the prioritization process more efficiently.

E. Other Approaches

AbdElazim in [9] introduces a comprehensive framework for prioritizing requirements in Agile Software Development, focusing on continuous and scalable prioritization. It effectively manages rapidly changing requirements and their dependencies by integrating early into the Agile process with epics and user stories. This fully integrated approach ensures that the framework can handle requirement changes at any stage of the development cycle, making the Agile development process more adaptable and responsive to evolving project needs but no tool was provided.

Govil in [39] presents a comparative analysis of various requirement prioritization techniques such as AHP, Pair wise comparison, MoSCoW, planning poker, ping pong balls, bubble sort, and others detailing their strengths and weaknesses. The paper highlights discrete parameters that influence the success of software projects and discusses the difficulty of prioritizing requirements in Agile methodologies, where changes can occur late in development. The goal is to provide product owners with insights to select the most suitable prioritization technique based on the project's specific needs and constraints.

Kamal in [40] explores the factors that contribute to the success of Agile Requirements Change Management (ARCM) in the context of Global Software Development (GSD). It follows a two-step approach: first, identifying success factors through a Systematic Mapping Study (SMS) and validating them with industry practitioners via a questionnaire survey. And the second step is to prioritize these factors using the Analytical Hierarchy Process (AHP). This study shows twenty-one critical success factors for ARCM in GSD, with top priorities being resource allocation at overseas sites, communication, coordination, control (3Cs), process improvement expertise, a geographically distributed change control board (CCB), and continuous top management support. The findings aim to assist practitioners in effectively implementing ARCM activities in GSD settings. The research further needs to develop a comprehensive readiness model for ARCM. This model should identify negative impact factors and collect best practices through multiple case studies.

Kifetew in [41] discusses the use of automated decision-making techniques to help engineers in the process of selecting and prioritizing requirements. Effective involvement of the development team and stakeholders is crucial in the decision-making process enabled by these tools. The paper used Analytic Hierarchy Process (AHP) and Genetic Algorithms to introduce a tool-supported to perform collaborative requirements prioritization process. The tool enables an iterative prioritization process, therefore enabling stakeholders to actively participate in decision-making throughout the process.

Perkusich in [42] presents an approach that leverages intelligent software engineering techniques to enhance requirement prioritization in Agile environments. The approach utilizes a combination of automated tools and Machine Learning algorithms to analyze user feedback, historical project data, and other relevant metrics to prioritize requirements dynamically. This method allows for continuous re-evaluation of priorities based on new data and evolving project needs.

AL-Ta’ani in [43] proposes a conceptual framework for continuous requirements prioritization in Agile development, addressing the challenge of selecting key user requirements for implementation across iterations. The framework is informed by a thorough review of related literature and content analysis of the data. It delineates the critical factors impacting the requirements prioritization process and their effect on the final product, categorizing them into three primary dimensions: environment, process, and product. The environment includes stakeholders’ characteristics, constraints relevant to the project, and Requirement Nature; the process outlines the particular processes involved in prioritization, and the Product describes the outcomes. The study highlights the importance of systematic prioritization to prevent costly development errors and potential project failures, suggesting areas for future research to refine prioritization methods and techniques.

Alkandari in [44] discusses three models for requirements prioritization in Agile development. Model 1 focuses on estimating business value using work breakdown structure and knowledge factors but lacks clarity on selection criteria for iteration. Model 2 consists of initial project backlog, prioritized project backlog, sprint backlog, and implemented requirements, emphasizing client-driven prioritization. Model 3 is an improved version of Model 2 based on case studies, incorporating business value, negative value, and risk for more accurate prioritization. The models were evaluated based on factors like cost, importance, risk, and dependencies to propose a comprehensive prioritization approach.

Saeed in [45] conducted a case study across five organizations. They used the grounded theory to assign numerical values to qualitative data, resulting in a more efficient and effective prioritization process. The study shows that organizations often deviate from traditional steps, using unique methods to handle requirements prioritization, focusing on Business Value, Risk Factors, and Priority Criteria. The proposed mode allows for enhancement by integrating other techniques. Agile development's evolving nature means prioritization methods will keep changing. To improve this process, the study suggests more case studies to propose better models.

Many researchers have noted gaps in the literature regarding AI-based techniques for requirements prioritization in Agile methodologies. The current literature identifies several key issues, including a lack of real-world empirical validation of these techniques. Scalability problems still exist, particularly when handling multiple requirements or large-scale projects. Furthermore, managing requirement dependencies is insufficient in current methodologies. Stakeholder collaboration is rarely fully integrated into prioritization models. This study addresses these gaps by evaluating the effectiveness of AI techniques in real-world Agile settings, focusing on scalability, dependency management, and stakeholder collaboration, while providing recommendations for future research and practical implementation.

V. Evaluation Criteria

Prioritization of requirements is the systematic procedure of arranging requirements according to specific inputs, processing techniques, and intended outputs. For this goal, the following primary categories of AI-based methodologies—Fuzzy Logic, Optimization algorithms, and Machine Learning—have been utilized. It is essential to have evaluation criteria that assess each type separately. This is necessary because these approaches differ significantly in their characteristics and operational methods. Therefore, in addition to general criteria for evaluating prioritization techniques, unique standards have been developed to evaluate Machine Learning approaches, Optimization algorithms, and Fuzzy Logic are developed. All the surveyed strategies are evaluated using ten metrics that are derived from Fuzzy Logic, Optimization, and Machine Learning, including Stakeholder Involvement, Dependency, Scalability, Validation, Impact on Collaboration, Accuracy, Flexibility, Complexity, Robustness to Uncertainty, Automation, Ease of Implementation. These criteria are evaluated using different values: ‘Yes’, ‘No’, and ‘Moderate’.

VI. Results Analysis and Comparison

A. Demographics of the SLR

Table I presents a comprehensive summary of 32 research studies categorised by year, with a detailed analysis of the publication types, specifically journals. The analysis of 32 research studies from 2011 to 2024 reveals that 21 were published in journals and 11 in conferences. The publishers include Springer with 9 papers, IEEE with 10, and Elsevier with 6. The studies cover a range of topics: 3 on Fuzzy Logic, 6 on

Machine Learning, 5 on NLP, 10 on Optimization techniques, and 8 on other approaches like frameworks and gamification. Springer leads in publishing both journals and conferences, while IEEE has a strong presence in both areas, especially in Machine Learning and Natural Language Processing. Elsevier's contributions are consistent across various topics, all in journals.

In Fig. 2, the frequency of different approaches that used in requirements prioritization in Agile methodology. In Fig. 3, The year chart provides an insightful look into the trend of publications focused on using AI to prioritize requirements in Agile methodology from 2011 to 2024 that's illustrated in Fig. 3.

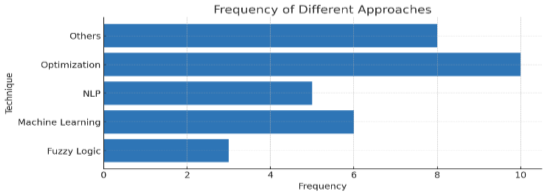

Fig. 2. Frequency of different approaches.

TABLE I. OVERVIEW OF SELECTED STUDIES (PUBLICATION TYPE JOURNAL)

No	Reference	Year	Technique Used	Related Category	Type	Publisher
15	Borhan, et al. [15]	2024	Fuzzy Logic Operations	Fuzzy Logic	Journal	JOAASR

B. Strengths and Weaknesses of the Surveyed Techniques

The evaluation of the 32 papers reveals a diverse range of strengths, weaknesses, and limitations in applying various methodologies to Agile Software Development is presented in Table II. Many papers showcase innovative approaches, such as the combination of Fuzzy Logic with AHP for enhanced decision-making, the use of NLP for automating prioritization, and the application of advanced algorithms for task allocation and Optimization. These strengths are often balanced by significant weaknesses, including complexity in implementation, the need for expert knowledge, and high computational or data requirements. Moreover, limitations such as scalability, data dependency, and subjective judgment frequently emerge, indicating that while these methods provide valuable solutions, they may not be universally applicable without careful consideration of context and resources. Overall, the analysis underscores the need for a tailored approach when applying these techniques to Agile environments, ensuring that their strengths are fully leveraged while mitigating their inherent weaknesses and limitation.

TABLE II. STRENGTH, WEAKNESS, AND LIMITATIONS OF REQUIREMENTS PRIORITIZATIONS TECHNIQUES

Reference	Strengths	Weaknesses	Limitations
Borhan, et al. [15]	Improved decision making under uncertainty	Complexity in fuzzy rule definitions	Limited scalability
Abusaeed,et al.[16]	Combines advantages of AHP and fuzzy logic	Requires expert knowledge	Complexity in AHP hierarchy formulation
Rottoli, et al.[17]	Handles linguistic uncertainty effectively	Potential bias	Subjective interpretation of linguistic labels
Anand, et al. [18]	Resolves conflicts through data mining	Complexity in implementation	Data dependency
Hudaib, et al. [19]	Visualizes data patterns effectively	Requires expertise in SOM	Complexity
Veerappa, et al. [20]	Groups similar stakeholders effectively	May not capture all stakeholder nuances	Data dependency
Belsis, et al. [21]	Unsupervised approach reduces bias	Requires large dataset	Complexity
Achimugu, et al. [22]	Efficiently handles large scale data	May overlook individual nuances	Scalability
Kumar, et al. [23]	Simple and fast clustering method	Sensitive to initial conditions	Scalability
Sachdeva, et al. [24]	Focuses on user requirements	May overlook technical requirements	Subjective judgement
Shafiq,et al. [25]	Automates prioritization using NLP	Requires large dataset	Data dependency
Sami, et al. [26]	Leverages advanced language models	Computationally intensive	Data dependency
Sharma, et al. [27]	Automates release planning using NLP	Requires expertise in NLP	Data dependency
Kifetew, et al. [28]	Incorporates user feedback in prioritization	Potential bias in feedback	Data dependency
Asghar, et al. [29]	Enhances quality by thorough elicitation	Time-consuming	High dependency on stakeholder input
Kumar, et al. [30]	Effective prioritization by combining AHP and TOPSIS	Data-intensive	Complexity in combining methods
Muhammad, et al.[31]	Comprehensive evaluation of multiple criteria	Resource-intensive	High complexity
Agrawal, et al. [32]	Focuses on risk management and optimization	Complexity in risk assessment	High complexity
Prakash, et al. [33]	Efficient optimization algorithm	Requires parameter tuning	Complexity
Chaves, et al. [34]	Handles multiple objectives simultaneously	Computationally intensive	High complexity
Brezočnik, et al. [35]	Efficient task allocation algorithm	Requires parameter tuning	Complexity
Brezočnik, et al. [36]	Effective in solving complex problems	Requires expertise in swarm intelligence	Complexity
Del Sagrado, et al. [37]	Effective multi-objective optimization	Computationally intensive	High complexity
Somohano [38]	Enhances AHP with evolutionary computing	Complexity in implementation	Requires expert knowledge
AbdElazim, et al. [9]	Provides structured approach for prioritization	May not fit specific project needs	Subjective judgement
Govil, et al. [39]	Automates data extraction process	Requires comprehensive datasets	Data extraction accuracy
Kamal, et al. [40]	Focuses on global software development challenges	Difficult to generalize	High variability in global context
Kifetew, et al.[41]	Engages stakeholders through gamification	Potential for bias in game dynamics	Engagement dependency
Perkusich, et al.[42]	Leverages AI for software engineering	Requires extensive training data	Data dependency
AL-Ta'ani, et al. [43]	Provides a structured approach	May not fit specific project needs	Subjective judgement
Alkandari, et al. [44]	Improves existing processes	Requires adaptation to specific projects	Subjective judgement
Saeed, et al. [45]	Enhances quality of agile practices	Requires adaptation to specific contexts	Subjective judgement

C. Comparison of AI-based Requirements Prioritization Techniques

A comprehensive study is presented among Fuzzy Logic based, Machine Learning based, Optimization and Natural Language Processing-based techniques. The effectiveness of AI-driven prioritization in Agile methodologies is influenced by key parameters such as scalability, dependency management, stakeholder collaboration, automation, and accuracy. AI techniques like machine learning and optimization improve scalability by handling large datasets and managing dependencies effectively. NLP enhances stakeholder collaboration by automating feedback interpretation, while automation in AI reduces manual effort and allows dynamic prioritization. Fuzzy logic supports decision-making under uncertainty but may struggle with scalability. Overall, these parameters ensure that AI techniques provide adaptable, efficient, and accurate solutions to the challenges of requirements prioritization in Agile development. This comprehensive is defined based on evaluation criteria with answer of ‘Y’ for Yes, ‘N’ for No, and ‘M’ for ‘Moderate’.

Regarding the Fuzzy Logic-based technique, evaluating the implementation of Fuzzy Logic in Agile Software Development requires examining both its theoretical advantages and practical challenges. Fuzzy Logic offers a flexible and nuanced approach to handling uncertainty and imprecision in decision-making, particularly in complex environments like Agile projects where requirements are often ambiguous and evolving. The evaluation, as shown in Table III, reveals that while these Fuzzy Logic-based approaches are strong in handling uncertainty and, in some cases, fostering stakeholder collaboration, they generally struggle with scalability and managing dependencies. The high complexity and limited usability in some methods could restrict their practical implementation in real-world Agile projects. This highlights a need for more balanced solutions that are both theoretically robust and practically applicable.

TABLE III. FUZZY LOGIC TECHNIQUE APPLICATIONS

Reference	Stakeholder Collaboration	Dependency	Scalability	Complexity and Usability	Flexibility	Robustness to Uncertainty
Borhan, et al. [15]	Y	N	N	N	Y	Y
Abusaeed,et al.[16]	N	N	N	N	N	Y
Rottoli, et al.[17]	Y	N	N	Y	Y	Y

Regarding Machine Learning technique, the evaluated research offers innovative clustering and prioritization techniques for Agile Software Development most to techniques aims to categorize related requirements into clusters. The cluster are pushed to be the next sprints based on their ranking. Some evaluation criteria as scalability, accuracy, and stakeholder management shows good indicator as it’s shown in Table IV. However, they generally face challenges in practical implementation due to complexity, lack of empirical validation, that would show limited effectiveness in handling stakeholder conflicts. While these approaches are valuable, their applicability may be constrained by the need for specialized knowledge and tools.

TABLE IV. MACHINE LEARNING TECHNIQUE APPLICATIONS

Reference	Stakeholder Collaboration	Dependency	Scalability	Validation	Impact on Collaboration	Accuracy	Flexibility
Anand, et al. [18]	Y	N	N	N	Y	Y	N
Hudaib, et al. [19]	Y	Y	Y	N	N	Y	Y
Veerappa, et al. [20]	Y	Y	N	N	Y	Y	Y
Belsis, et al. [21]	Y	N	Y	N	Y	Y	Y
Achimugu, et al. [22]	Y	N	Y	N	Y	Y	Y
Kumar, et al. [23]	N	N	Y	Y	Y	Y	Y

Regarding Natural Language Processing technique, most of the paper used NLP techniques reduce direct stakeholder involvement, which is crucial for aligning requirements with business needs. In Table IV, we can realize many of the papers moderate to high scalability, ease of implementation, suggesting a potential gap in practical applicability. The validation factor generally moderate to high. Most of the papers didn't consider dependency directly (Table V).

TABLE V. NATURAL LANGUAGE PROCESSING TECHNIQUE APPLICATION

Reference	Stakeholder Collaboration	Dependency	Scalability	Automation	Validation
Sachdeva, et al. [24]	M	M	Y	Y	M
Shafiq,et al. [25]	Y	Y	M	M	Y
Sami, et al. [26]	M	M	Y	Y	Y
Sharma, et al. [27]	Y	M	Y	Y	Y
Kifetew, et al. [28]	M	M	Y	Y	M

Regarding Optimization technique, the evaluation of these papers indicates a week-long focus on addressing requirements dependencies and facilitating scalability across most approaches. As shown in Table VI, traditional decision-making techniques, such as AHP and TOPSIS, are well-integrated with collaboration with stakeholders. And less collaboration with swarm intelligence or evolutionary algorithms. Continuous improvement is a common feature across all methods, reflecting the iterative nature of Agile methodologies. Overall, while most approaches are not considered dependencies directly and scalability, there is variability in how well they facilitate stakeholder collaboration, which underscores the potential of improvement in algorithm-based methods.

Regarding other frameworks and techniques, as it’s shown in Table VII, the collection of papers on requirements prioritization in Agile Software Development offers a range of theoretical frameworks and innovative tools, most approaches address well result in collaboration, dependencies, and continuous improvement effectively. But there is challenges in such terms as ease of implementation and scalability for certain innovative methods like DMGame. This suggests that while these approaches offer significant potential, they may require additional refinement or adaptation to be fully effective across different Agile contexts

TABLE VI. OPTIMIZATION TECHNIQUE APPLICATION

Reference	Stakeholder Collaboration	Dependency	Scalability	Ease of Implementation	Validation
Asghar, et al. [29]	N	N	N	Y	Y
Kumar, et al. [30]	Y	N	N	Y	Y
Muhammad, et al.[31]	Y	Y	Y	Y	Y
Agrawal, et al. [32]	Y	N	N	Y	Y
Prakash, et al. [33]	N	N	N	Y	Y
Chaves, et al. [34]	N	N	N	N	Y
Brezočnik, et al. [35]	N	Y	N	Y	Y
Brezočnik, et al. [36]	N	N	N	Y	Y
Del Sagrado, et al. [37]	N	N	N	Y	Y
Somohano, et al, [38]	Y	Y	Y	Y	Y

TABLE VII. OTHER TECHNIQUES APPLICATION

Reference	Stakeholder Collaboration	Dependency	Scalability	Ease of Implementation	Validation	Flexibility in Handling Change
AbdElazim, et al. [9]	Y	Y	Y	Y	Y	Y
Govil, et al. [39]	Y	Y	Y	Y	Y	Y
Kamal, et al. [40]	Y	Y	Y	Y	Y	Y
Kifetew, et al.[41]	Y	N	N	N	Y	Y
Perkusich, et al.[42]	N	Y	Y	N	Y	Y
AL-Ta'ani, et al. [43]	Y	Y	Y	Y	Y	Y
Alkandari, et al. [44]	Y	Y	Y	Y	Y	Y
Saeed, et al. [45]	Y	Y	Y	Y	Y	Y

Results show that Machine Learning techniques, such as clustering algorithms, effectively address the scalability challenges in requirement prioritization for large Agile projects by grouping similar requirements, reducing manual effort, and improving accuracy. Fuzzy Logic also enhances stakeholder collaboration, resolving conflicts and improving decision-making. These findings suggest that AI techniques not only offer technical advantages but also enhance team communication and responsiveness in Agile workflows, though real-world validation is still needed.

VII. LIMITATIONS

Despite the promising results of AI-based techniques for requirements prioritization, this study has several limitations. A key limitation is the lack of empirical validation, which affects the practical applicability of many AI methods in Agile environments. While these techniques show potential in addressing scalability and improving stakeholder collaboration, their complexity and the need for specialized knowledge pose challenges for widespread adoption and for handling changes in requirements effectively. Additionally, dependency management is not adequately addressed, leaving a crucial aspect of Agile prioritization insufficiently explored.

VIII. CONCLUSION

This paper has conducted a comprehensive systematic literature review of AI-driven techniques for requirements prioritization within Agile methodologies. This paper addresses a significant gap by analysing 32 key studies spanning 2010 to 2024. The SLR finds the strengths and weaknesses of Fuzzy Logic, Machine Learning, Optimization, and Natural Language Processing (NLP) techniques. Our findings reveal that each method has its distinct limitations. These limitations are particularly in terms of scalability, accuracy, and simplicity of implementation. These AI-based approaches offer promising solutions to the challenges of requirements prioritization in Agile environments.

In Future work, the analysis underscores the necessity of developing hybrid AI-based techniques that integrate the strengths of Fuzzy Logic, Machine Learning, Natural Language Processing, and Optimization to create more scalable, and efficient prioritization methods. The integrated approach could better handle the complexities of modern software development in Agile methodology. That approach should handle the rapidly changing of the Agile environments where continuous prioritization and stakeholder collaboration are critical. The approach should focus on empirical validation of AI-based requirements prioritization techniques through case studies and real-world applications to ensure their practical relevance. Additionally, there is a need to align this approach to be more closely with stakeholder expectations and to meet the business need, and to ensure that the prioritization process in Agile technically and contextually appropriate. Such efforts should prioritize creating scalable, efficient, and adaptive methods that consider dependencies in requirements and align closely with stakeholder needs and Agile practices and to align with the continuous improvement. By addressing these challenges, it will be possible to develop more effective and adaptable requirements prioritization techniques that can be broadly implemented in diverse, real-world software development environments.

ACKNOWLEDGMENT

I would like to express my sincere gratitude to my supervisors, for their invaluable guidance. I also extend my thanks to the Software Engineering Department whose unwavering support during my qualification year played a pivotal role in the successful completion of this research.

Abstract—**With the explosive growth of image data, traditional image retrieval methods face challenges of low efficiency and insufficient accuracy. In view of this, the study first analyzed the traditional Deep-Re-Hash detection technology and constructed a general hash detection model. Secondly, Cauchy functions and Hadamard matrices were introduced to optimize the generation of hash centers, and an improved Deep-Re-Hash detection model was proposed. The experimental results showed that the highest precision of the improved Deep-Re-Hash was 97%, and the highest MAP value was 90%. In simulation testing, the lowest detection similarity of the improved Deep-Re-Hash detection model was 64.8%, and the detection speed at this time was 7.6s. The hash codes generated by this model were highly aggregated, with very clear edges. In the indicator rating, the highest storage occupancy rating was close to 45 points, the highest detection satisfaction rating was close to 50 points, and the highest detection time rating was close to 30 points. Based on the above data, the proposed improved Deep-Re-Hash detection model shows great potential in processing large-scale image data. It successfully improves the intelligent detection and search efficiency of communication image signals, providing useful reference and inspiration for researchers in related fields.**

***Keywords**—Deep-Re-Hash retrieval; communication signals; image data; cauchy function; hadamard matrix*

I. Introduction

In modern communication systems, the transmission and storage of image signals is an important field. With the explosive growth of image data, it is important to efficiently detect and search for image signals [1]. Traditional image retrieval methods face challenges of low efficiency and insufficient accuracy. To address these challenges, deep learning technology has emerged in recent years. Its outstanding feature learning ability and highly non-linear processing ability have achieved significant success in image signal processing [2]. However, when faced with large-scale image signal datasets, traditional methods still face enormous pressure on storage and computing resources. To overcome these challenges, Deep-Re-Hash (DRH) retrieval technology has emerged [3]. DRH maps images into compact binary encoding, enabling efficient image retrieval and search. This method has broad application potential in Communication Image Signal (CIS) processing. By learning the hash code of images, it is possible to compare images in low-dimensional binary space and perform high-speed similarity search [4]. To further optimize the practical application performance of this technology, the algorithm structure was innovatively decomposed. Cauchy functions and Hadamard matrices were introduced for hash center generation optimization, aiming to achieve more efficient hash retrieval and search capabilities. The subject of the research is to optimize the intelligent detection and search efficiency of communication image signals using improved DRH search techniques and to solve the efficiency and accuracy problems of existing methods in large-scale data processing. The research is motivated by the rapidly growing demand for image signal processing in modern communication systems, especially in the task of intelligent detection and search of large-scale, multi-labelled communication image signals, where traditional methods are difficult to meet the requirements of real-time and accuracy. The contribution of the research is to propose an improved DRH that combines the Cauchy function and Hadamard matrix, which effectively enhances the detection and retrieval efficiency of communication image signals. The method is capable of generating more compact and discriminative hash codes, which are suitable for large-scale image data processing. This research is divided into six sections, Section II systematically analyzes and summarizes the existing related work. Section III proposes a communication image signal detection and search model based on a deep hash retrieval technique constructed by the research. Section IV demonstrates the performance of the improved model through experimental tests. Discussion is given in Section V. Section VI summarizes the research results and proposes directions for future research.

II. Related Work

With the developing communication technology, the transmission and processing of communication signals become increasingly important in various fields. CIS covers a wide range from traditional image communication to modern multimedia communication, characterized by large data volume and high diversity. Therefore, intelligent detection and search of CIS becomes a highly focused research direction. To improve the image communication performance of existing optical cameras, Nguyen D T et al. proposed a novel method for extracting image signal features of interest by combining low-density parity check codes. This method had more advantages in teaching traditional image communication processing techniques [5]. To improve the signal detection accuracy of the fifth generation wireless communication system, You Y H et al. proposed a new detection method by combining complex secondary synchronization signals. This method was highly effective and greatly reduced complexity compared to similar methods [6]. Li K et al. found that traditional image signal quality detection methods were no longer able to meet the requirements of existing medical information detection. Therefore, this team introduced the concepts of fully known signals and statically known signals using deep neural networks for optimization, and finally proposed a new detection method. This new method ensured the preservation of task-related information while denoising, which had strong usability [7]. Wen X et al. believed that autoencoders using convolutional neural networks still had insufficient capabilities in extracting spatiotemporal information from the network. Given this, the team proposed an image signal detection model using a pseudo 3D encoder and multi-level storage mechanism. The detection performance of this model was superior to other similar methods on three datasets [8]. Orsuti D et al. In order to improve the retrieval of communication image signals, the researchers finally proposed a communication image signal recovery method by combining full convolutional neural networks for non-iterative and robust phase recovery. The experimental results show that the performance of this method is compared with that of a conventional KK receiver using 4x digital upsampling, which can achieve 7% hard verdict forward error correction and 1.8 dB increase in receiver sensitivity [9].Kumar S et al. found that content-based image signal retrieval is susceptible to degradation of retrieval accuracy with the adoption of cloud storage. For this reason, the researchers proposed a new retrieval model after incorporating a nonlinear stacking algorithm. Experimental results show that the accuracy of this new model is significantly improved and more robust compared to the existing methods [10].

Hash retrieval technology is a technique used for quickly searching and retrieving large-scale datasets. It converts data into a set of fixed length hash values and uses these hash values to organize and index the data. Qin et al. found that most existing hash techniques only focused on the semantic similarity between image pairs, ignoring the ranking information of retrieval results. Therefore, this team proposed a new type of DRH by combining the deep top similarity theory. This method was more effective than traditional methods on several multi-label datasets [11]. To expand the application of hashing technology in image representation and approximate queries, Shuai C et al. proposed a principal component analysis hashing technique by combining longer binary codes and mapping vector rotations. This method achieved more types of partitions and significantly improved performance [12]. To further improve the speed and accuracy of hash technology for cross-modal information retrieval, Shen X et al. proposed a clustering driven deep adversarial hash model by combining end-to-end thinking. This model accurately maximized the distance calculation between images and texts with different labels, which had better performance [13]. Zhang D et al. believed that when the hash length changed, the hash model needed to be retrained. This consumed additional computing power and reduced its application scalability. Therefore, this team proposed a multi-hash model for cross-media retrieval. This model did not require training when the hash length changed, which was superior to some competitive shallow and deep hash methods [14]. Zhu L et al. In order to solve the problem of high storage cost and slow retrieval efficiency during multimedia retrieval, the researchers proposed a retrieval enhancement method after combining hash retrieval techniques. The experimental results show that under the reinforcing effect of the method makes the retrieval of Hamming distance calculation significantly accelerated, and the cost of retrieval time is effectively reduced [15].Sabahi F et al. found that the existing image retrieval reordering technique has the problem of high computational complexity, for this reason, the researchers proposed a novel and computationally efficient image retrieval reordering method after combining with hash retrieval technology. Experimental results show that this new method generally outperforms other traditional methods in terms of computational efficiency and retrieval performance [16].

In summary, many researchers have explored the detection of communication image information and proposed some remarkable research results. Meanwhile, the continuous development and evolution of hash retrieval technology makes its application wider. Therefore, the study attempts to combine these two and innovatively optimize hash technology to improve its performance in various modules and promote the development of CIS detection.

III. Construction of an Intelligent Detection and Search Model for Communication Signals based on Deep-Re-Hash Retrieval Technology

This study first analyzes traditional DRH and constructs an image signal detection model under this algorithm. Secondly, the shortcomings of DRH are elaborated, and the Cauchy concept function and Hamada matrix are introduced for hash center generation optimization. Finally, a new detection and search model is proposed.

A. *Communication Image Signal Processing Model Based on Deep-Re-Hash*

DRH can map high-dimensional data to low-dimensional binary encoding [17]. By learning the deep features of data, DRH can convert the original image signal into binary encoding, thereby achieving efficient processing and transmission of image signals. To generate binary hash codes, DRH typically adds n+1 fully connected layers for optimization [18]. This layer guides the generation of the required number of neurons and the length of the hash code. Fig. 1 shows the structure of DRH.

In Fig. 1, after inputting the initial image signal data, DRH uses a deep neural network to extract image features, and then converts these features into binary hash codes in Hamming space through a hash function. This process typically involves converting data, such as images, text, etc., into a compact binary representation, with key steps including data representation, feature extraction functions, binarization process, and hash code generation. The feature extraction function is represented by Eq. (1).

$$Z = f(X, \theta) \tag{1}$$

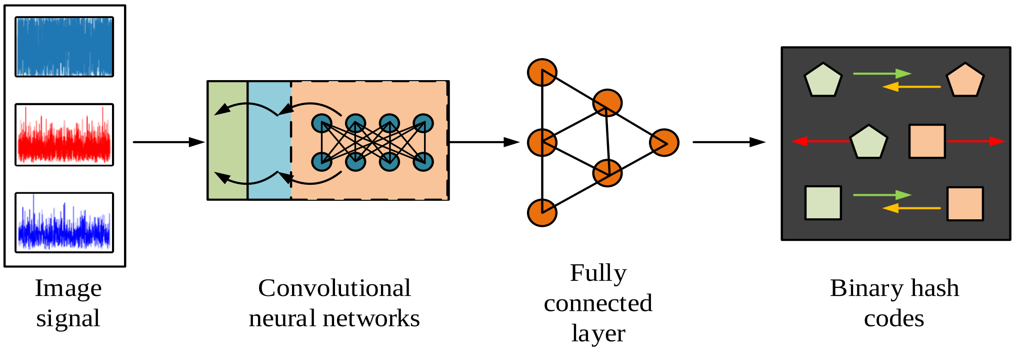

Fig. 1. Structure diagram of DRH.

In Eq. (1), Z represents the feature set of the input data, which is a real number vector. θ is a model parameter. X refers to the initial image input. $f(X,\theta)$ represents a deep neural network function. The binarization process is represented by Eq. (2).

$$H(X)=sign(Z), si\ gn(z_i)=\begin{cases}1, if z_i \ge 0\\ 0, otherwise\end{cases} \tag{2}$$

In Eq. (2), z_i represents the i th element in the feature set. If z_i is greater than or equal to 0, the corresponding hash code point is set to 1. Otherwise, it is set to 0. $sign$ represents a binarization function. The final hash code is a vector composed of 0 and 1, representing the hash code of the input data X. The hash function, as a key point that can directly affect the stability of the conversion result, should be consistent in the same class of image signals, but inconsistent in different classes of image signals. The hash function is represented by Eq. (3).

$$Hash(X)=sign(f(X,\theta)) \tag{3}$$

In Eq. (3), $sign$ maps each element in the feature vector to {− 1,1}, thereby generating a hash code. In similar images, DRH usually has two retrieval strategies, namely Hamming sorting and Hamming retrieval. Fig. 2 is a schematic diagram of two retrieval strategies.

In Fig. 2, both Hamming sorting and Hamming retrieval involve using Hamming distance to process data. Hamming sorting sorts data items based on their Hamming distance from the query item, while Hamming retrieval searches for data items that have a specified Hamming distance from the query item [19]. The Hamming distance is used to measure the difference between two equally long strings, that is, the number of different characters at the same position. In the context of hash retrieval, the Hamming distance is represented by Eq. (4).

$$D_H(HM(X),HM(Y))=\sum_{i=1}^{L}[HM(X)_i \neq HM(Y)_i] \tag{4}$$

In Eq. (4), L represents the length of the hash code. $HM(X)$ refers to inputting the hash code of X. $HM(Y)$ refers to inputting the hash code of $HM(Y)$. $HM(X)_i \neq HM(Y)_i$ represents an indicator function, which takes a value of 1 when these two are not equal, and 0 otherwise. On this basis, Hamming sorting is to calculate the Hamming distance between a given query hash code $HM(Q)$ and each hash code $HM(X)$ in the database, and then sort it according to this distance. The Hamming search is represented by Eq. (5).

$$Search(HM(Q),\tau)=\{X\,|D_H(HM(Q),HM(X)\le\tau)\} \tag{5}$$

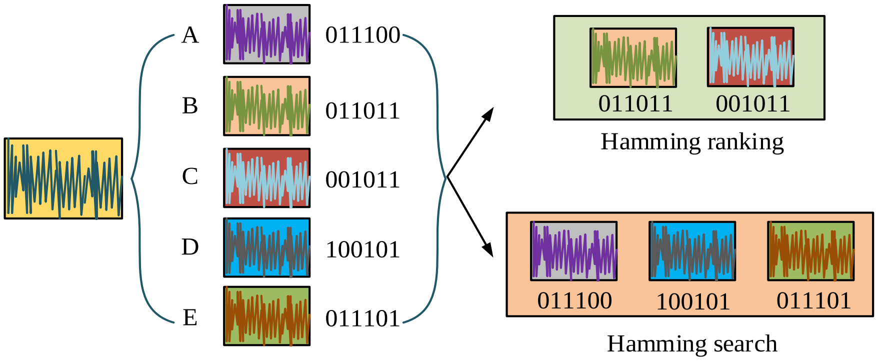

Fig. 2. Schematic diagram of hamming sorting and hamming retrieval.

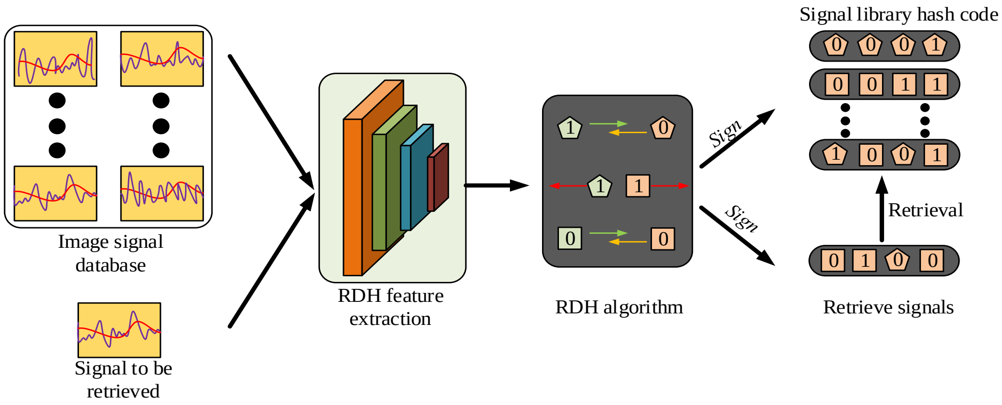

Fig. 3. DRH image signal detection model structure.

In Eq. (5), τ represents a predetermined threshold. All hash codes $HM(X)$ in the database were retrieved so that their Hamming distance from the query hash code $HM(Q)$ does not exceed τ. In practical applications, Hamming sorting and Hamming retrieval are commonly used for fast approximate retrieval, especially in large-scale image or document databases. In summary, this study proposes a CIS detection model in combination with DRH. Fig. 3 shows the model structure.

In Fig. 3, first, the signal database and the information to be queried are inputted. Then, these are extracted by the feature extraction module of DRH. After completion, these features are fed into a deep neural network to learn more complex feature representations. The network output is binarized using an adjusted $sign$ to generate a binary hash code. Finally, these hash codes are used for fast image retrieval, allowing the system to effectively match and search for image data.

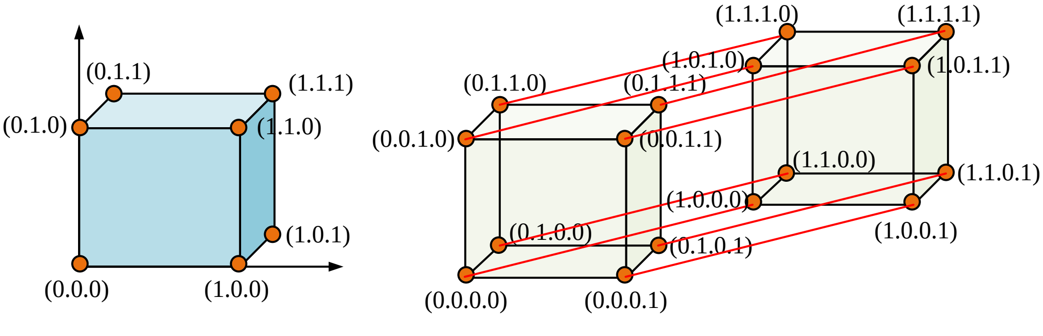
B. *Construction of a Communication Image Detection Model based on Improved Deep-Re-Hash*

DRH provides an effective way to process and retrieve large amounts of image data in image signal detection. The hash center is a point in the hash space that represents the center position of a certain class or cluster of data [20]. The hash center is represented by Eq. (6).

$$C_j = \arg\min_{C_j} \sum_{i=1}^{N} y_{ij} \cdot D(H(x_i), C_j) \tag{6}$$

In Eq. (6), C_j refers to the hash center of category j. x_i represents the i th data point in the training dataset. $H(x_i)$ is a hash representation of data point x_i, typically generated by deep networks. y_{ij} represents an indicator variable. If the data point x_i belongs to category j, then y_{ij} is equal to 1, otherwise it is 0. D represents distance measurement. N refers to the total data points in the training dataset. Fig. 4 shows the hash centers at two different dimensions.

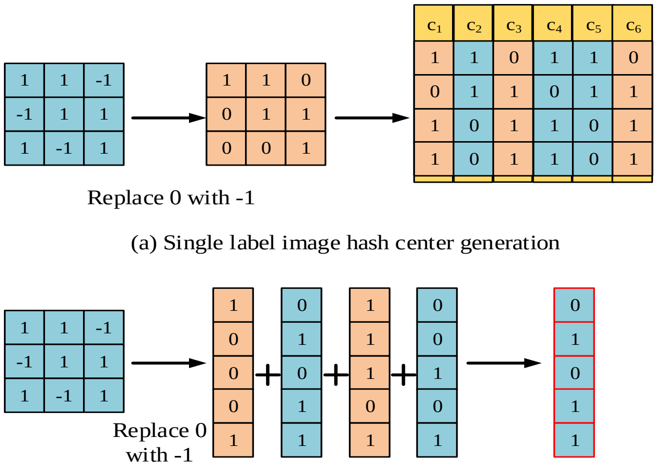
Fig. 4(a) and Fig. 4(b) are schematic diagrams of hash centers at both three-dimensional and four-dimensional scales. The distance between the individual hash code and the hash center is 1. In space, there also exists a consistency relationship with the three-dimensional hash center and hash code. In addition, considering the complex environment of image signals, this study conducts hash center generation calculations for single label and multi-label image signal data, respectively. Fig. 5 shows the generation of hash centers in both environments at this time.



(a) 3D hash center

(b) Four-dimensional hash center

Fig. 4. Schematic diagram of multi-dimensional hash center position.



(a) Single label image hash center generation

(b) Multi label image hash center generation

Fig. 5. Hash center generation for single-label and multi-label image data.

Fig. 5(a) shows the generation of hash centers for single label and multi label image data in various scenarios. In single label image data, each image belongs to only one category. Hash centers are typically representative hash codes of categories. The hash center can be directly obtained by calculating the average value of all image hash codes within the same category. In multi-label image data, each image can belong to multiple categories simultaneously. In this case, the generation of hash centers becomes even more complex, as the impact of multiple labels on each image needs to be considered. The hash center of single label image data is represented by Eq. (7).

$$C_j^s = \frac{1}{N_j}\sum\nolimits_{i=1}^{N} y_{ij}\cdot H(x_i) \qquad (7)$$

The hash center of multi-label image signal data is represented by Eq. (8).

$$C_j^m = \frac{1}{\sum\nolimits_{i=1}^{N} y_{ij}}\sum\nolimits_{i=1}^{N} y_{ij}\cdot H(x_i) \qquad (8)$$

In the case of multiple labels, y_{ij} can be a binary indicator variable or a real value representing the confidence or weight belonging to that category. The calculation of hash centers requires accumulating the contribution of each category on all images, taking into account that each image may contribute to multiple categories. At this point, whether it is single label or multi-label image data, the hash center should have independence and balance, represented by Eq. (0).

$$\begin{cases} B^T B = I \\ B^T 1 = 0 \end{cases} \qquad (9)$$

In Eq. (9), I refers to an identity matrix. In model training, the learning efficiency of hash codes is highest when the hash code is infinitely close to the hash center. To further guide the implementation of this process, this study introduces Cauchy functions to improve the generation process of hash codes. This enables the generated hash code to better reflect the similarity between images while preserving image features. By using the cumulative distribution function of Cauchy distribution, points in deep feature space can be mapped to points in hash space [21], represented by Eq. (10).

$$Y_{cj}(Z`) = \frac{1}{\pi}\arctan(\frac{Z`-C_i}{\gamma}) + \frac{1}{2} \qquad (10)$$

In Eq. (10), $H_{cj}(Z`)$ refers to the mapping value of the feature vector $Z`$ relative to the hash center C_i of class i. γ represents a scale parameter of the Cauchy distribution. After completing the generation of continuous hash codes with probability characteristics, the processing of hash codes continued to be explored in the experiment. Hadamard matrix can be used as a special hash function to generate hash codes. Hadamard matrix is a specific orthogonal matrix whose elements only contain 1 and -1, and its orthogonality ensures the dispersion of hash codes, represented by Eq. (11).

$$H = Had \cdot Z \qquad (11)$$

In Eq. (11), Had represents the Hadamard matrix. The Hadamard matrix serves as the hash center training and sampling matrix, which satisfies Eq. (12).

$$\begin{cases} Had^T \cdot Had = KI_K \\ Had \cdot Had^T = KI_K \end{cases} \qquad (12)$$

In Eq. (12), I_K refers to a K order identity matrix. In the K dimensional Hamming space, if the feature vectors of a set of images are orthogonal to each other, the Hamming distance between the two also meets the requirements described in Eq. (9). Finally, the result generated by the user hash center after combining the Cauchy probability function with Hadamard is represented by Eq. (13).

$$B = sign(\frac{1}{\pi} arc\tan(\frac{Had \cdot Z - C}{\gamma})) \tag{13}$$

In Eq. (13), B refers to the final generated binary hash code. C is a Cauchy center. In summary, after combining Cauchy function and Hadamard matrix to optimize the generation of hash center points, an improved DRH image signal detection search model using deep learning framework is proposed in Fig. 6.

In Fig. 6, firstly, CIS undergoes standardized preprocessing to adapt to the input requirements of the deep learning network. Then, the preprocessed image is feature extracted through a deep neural network. Next, the extracted continuous feature vectors are mapped to a new feature space by the Cauchy probability function, increasing resolution and enhancing the dispersion of the hash code through Hadamard matrix transformation. By utilizing these transformed features, this model calculates the hash center points for each category through optimization algorithms, which guide the generation of compact and discriminative hash codes during the binarization. During model training, similarity learning is also included to ensure that hash codes can reflect the similarity between images. Finally, during the retrieval phase, for a given query image signal, this model will quickly retrieve the image signal in the database with the smallest Hamming distance from its hash code. This model may undergo subsequent sorting and filtering to display the most relevant search results.

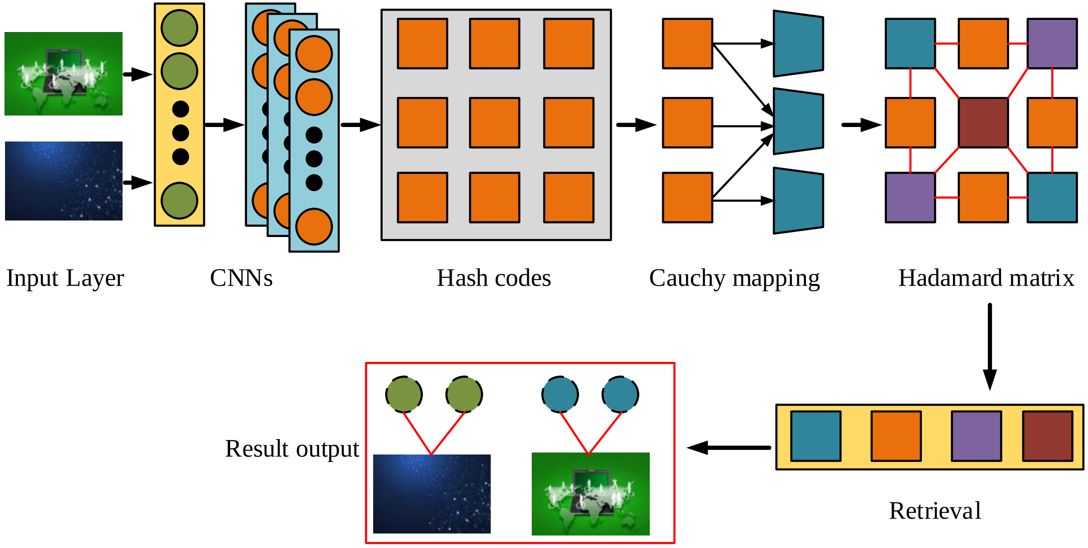


Fig. 6. A communication image signal detection model under improved DRH.

IV. Experimental Testing

A suitable experimental environment was established. Firstly, performance testing was conducted on the algorithm module in the improved DRH, and the training results of the algorithm were compared with algorithms of the same type. Secondly, simulation tests were conducted on the improved DRH detection model to verify its superiority in image signal detection. Tests show that the improved DRH algorithm is particularly suitable for datasets with multidimensional features, such as communication image signal data. Its advantage lies in the processing of large-scale, high-diversity data types, especially in the case of high data dimensionality, the improved DRH algorithm can effectively reduce the computational complexity and improve the retrieval efficiency through the optimized generation of hash codes. Therefore, the algorithm is more suitable for image signal datasets containing a large number of image features with multiple labels, such as CSCOCO and Caltech 256.Especially when dealing with this type of multi-label, high-dimensional data, the algorithm is able to significantly improve the checking rate and retrieval accuracy through the hash center optimized by the Hadamard matrix and the Cauchy function, and the MAP value is significantly higher than that of other algorithms.

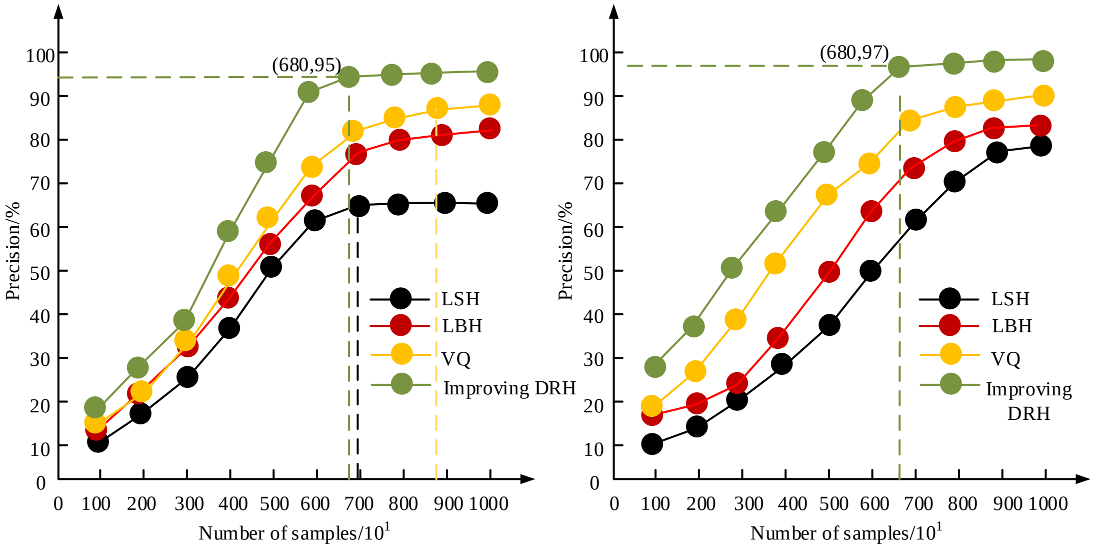
A. Model Performance Testing

A suitable experimental environment was established to verify the effectiveness of the proposed improved DRH image signal detection. Two widely used CIS datasets were introduced, namely CSCOCO and Caltech 256. CSCOCO is a dataset used for image keypoint detection tasks, containing over 200000 images and corresponding annotations. Caltech 256 is a larger dataset that includes 100000 images of different categories. Table I shows the specific experimental testing environment configuration.

Based on the above parameter configuration, the dataset was divided into training and testing sets in an 8:2 ratio. To better fit the characteristics of the test object, the study used precision as the testing indicator. Meanwhile, similar communication image information detection algorithms were introduced, such as Locality-Sensitive Hashing (LSH), Learning-Based Hashing (LBH), and Vector Quantization (VQ). Fig. 7 shows the test results.

TABLE I. ENVIRONMENTAL CONFIGURATION AND PARAMETERS

Environment	**Name**	**Configuration**
Hardware	CPU	Intel Core i7
	Graphics card	NVIDIA GeForce GTX 1060
	Memory	8GB RAM
	Hard disk	15T
Software	Operating environment	Windows 10
	Python	Python 3.8
	Deep learning framework	TensorFlow
	Data set	CSCOCO、Caltech 256
	Development tool	Visual Studio Code



(a) Training set

(b) Test set

Fig. 7. Performance effects of different algorithms.

Fig. 7(a) shows the performance test results of four algorithms on the training set. Fig. 7(b) shows the performance test results of four algorithms on the test set. In both datasets, the precision of these four algorithms tends to stabilize with increasing sample size. Overall, this improved DRH had the best performance, with a highest precision of 95% in the training set and a minimum sample size of 6800. In the test set, the highest precision of the improved DRH was 97%, with a sample size of 680. Therefore, the improved DRH showed better algorithm performance in both training and testing results. The study continued to use Mean Average Precision (MAP) as an indicator and the length of hash codes and Hamming distance distribution as test variables to discuss the changes in the four algorithms in Fig. 8.

Fig. 8(a) shows the hash length detection results of four algorithms in CSCOCO. Fig. 8(b) shows the hash length detection results of the four algorithms in Caltech 256. Fig. 8(c) shows the Hamming length distribution detection results of four algorithms in CSCOCO. Fig. 8(d) shows the Hamming length distribution detection results of the four algorithms in Caltech 256. As the hash length continued to increase, the MAP of these four algorithms continued to increase. But when the hash length approached an extreme value, the MAP was at its maximum. In the above data, the improved DRH generally had a higher MAP as the hash length changed, with a maximum value of 94%. The hash length at this point was 64 bits. In addition, under different Hamming distance distributions, the improved DRH's MAP was significantly better than other methods, with the optimal MAP of 90% and a Hamming distance distribution value of 2. In theory, longer hash codes can provide more refined feature representations, which may result in higher accuracy during retrieval. However, excessively long hash codes can also lead to dimensional disasters, resulting in reduced retrieval efficiency. In addition, if a retrieval system can effectively map the similarity of images to the Hamming distance of hash codes, then retrieval within a smaller Hamming distance range should achieve higher accuracy and MAP.

B. Model Performance Simulation Testing

The study randomly selected four images each from CSCOCO and Caltech 256 for simulation testing to verify the improved DRH's CIS detection performance. Fig. 9 shows the combined image.

(c) CSCOCO

(d) Caltech 256

Fig. 8. Test results of indicators for different models under two types of data.

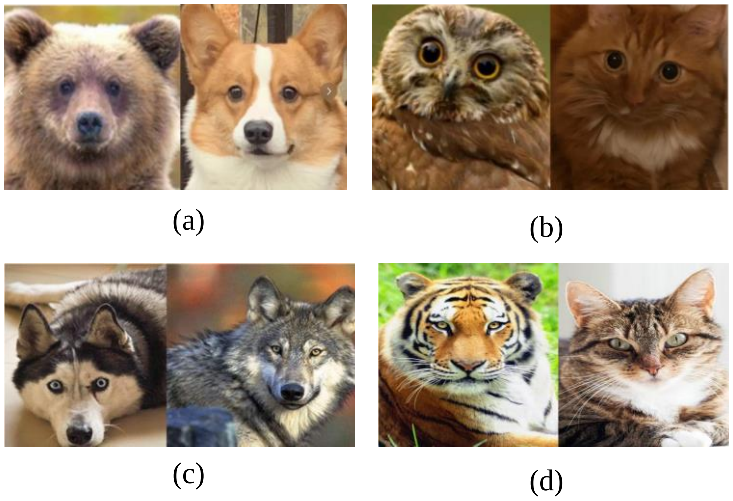

Fig. 9. Four communication image signals to be detected.

Combining these four image signals to be detected in Fig. 9, this study introduced CIS detection models of the same type, such as Content-Based Image Retrieval (CBIR), Feature Matching Search (FMS), and traditional DRH. The previously mentioned previous studies such as the method proposed by Orsuti D et al, the method proposed by Kumar S et al., the method proposed by Zhu L et al. and the method proposed by Sabahi F et al. were also selected for comparison and tested in terms of image signal retrieval similarity and detection time and the results of the test are shown in Table II.

TABLE II. THE DETECTION RESULTS OF FOUR MODELS ON DIFFERENT IMAGES

Image	Molde	Image signal retrieval similarity/%	Retrieval time/s
Figure a	CBIR	93.7	15.4

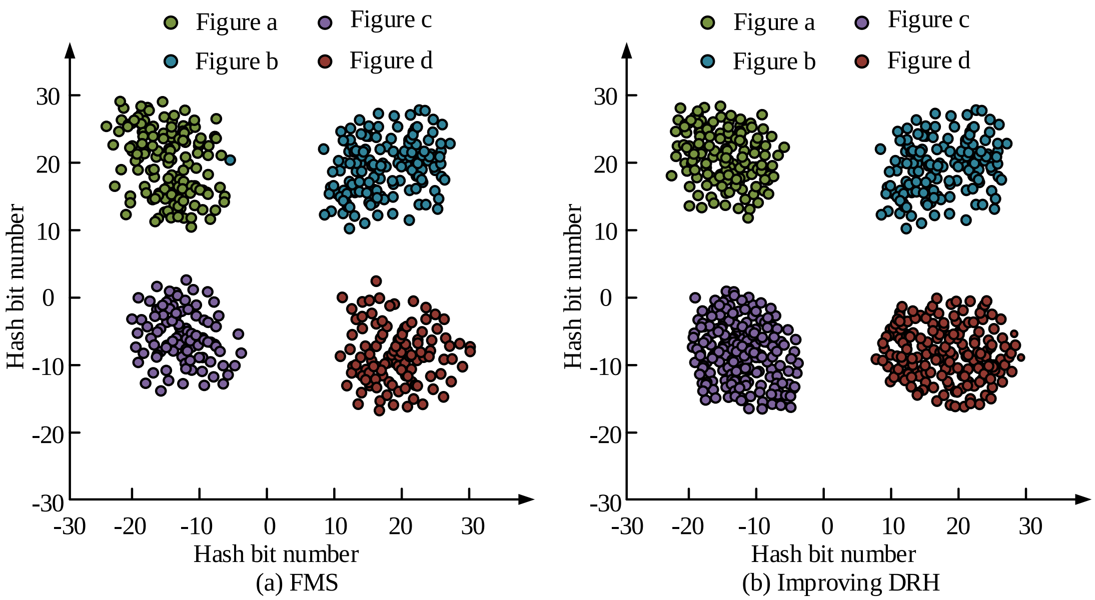
	Improving DRH	64.8	7.6

Combining the four groups of extremely similar different species of animals in Fig. 9, if the detection similarity is higher, it indicates that the model's ability to distinguish CIS is insufficient. On the contrary, it indicates that the model can distinguish animal images from each group and meet the requirements of image signal differentiation. Compared with other models such as CBIR, FMS, and conventional DRH, the improved DRH model showed the shortest detection time, especially in Fig. 9(a) and Fig. 9(d), which were shortened by about 8.3 and 17.1 seconds, respectively, and demonstrated a high detection efficiency. In addition, compared with several previous studies, such as the models proposed by Orsuti D et al., Kumar S et al., Zhu L et al., Sabahi F et al., the detection of the improved DRH model is still faster, with the time consumed ranging from 7.1 to 10.7 seconds, respectively, which is lower than that of all the compared models. In terms of image signal retrieval similarity, although the similarity of the improved DRH model is slightly lower than that of the CBIR and FMS models, it still performs stably with a range of retrieval similarity between 64.8% and 83.3%, which shows the better differentiation ability of this model, especially in complex environments where it can maintain a low false detection rate. In the image of Figure d, the similarity of the improved DRH model is 64.8%, which is about 14.6% less compared to the CBIR model, but its detection time is shortened by 17.1 seconds, indicating that the improved DRH model is more suitable for application in time-sensitive scenes. The hash code has a length of 64 bits and a Hamming distance distribution of 2. Fig. 10 shows the visualization result at this time.

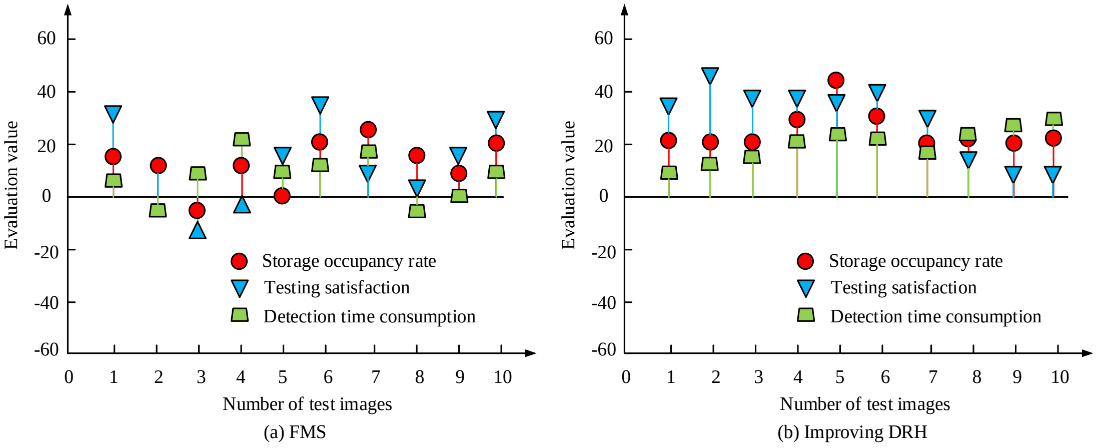


(a) FMS

(b) Improving DRH

Fig. 10. Image visualization results of two algorithms.

Fig. 10 (a) shows the visualization results of four images under FMS. Fig. 10 (b) shows the visualization results of four images under improved DRH. The hash code of FMS was relatively scattered and chaotic, with poor discrimination. On the other hand, the improved DRH generated hash codes that were highly aggregated and had very clear edges. The reason for this is that the improved DRH utilizes Cauchy functions for scaling, while also using Hadamard matrices to generate hash centers and guide hash learning. Finally, the study used a comprehensive scoring method to evaluate storage occupancy rate, detection satisfaction, and time consumption as indicators. Indicator tests were conducted on 10 images under two models, with evaluation values ranging from (-60,60) in Fig. 11.



(a) FMS

(b) Improving DRH

Fig. 11. Multi indicator scoring results of two types of algorithms.

Fig. 11(a) shows the three indicator scores of FMS. Fig. 11(b) shows the three indicator scores of the improved DRH. In FMS, when the detected image signals were 2, 3, 4, 8, and 9, the model storage occupancy, detection satisfaction, and detection time ratings were low, showing unstable fluctuations. On the other hand, the improved DRH had a positive rating for all three indicators. At this point, the storage occupancy rate score was close to 45 points, the detection satisfaction score was close to 50 points, and the detection time score was close to 30 points. In summary, the proposed improved image signal model has certain advantages and stability.

V. Discussion

The study proposes an improved deep hashing algorithm that combines the Cauchy function and Hadamard matrix, and the method optimizes the retrieval performance of image signals by generating more compact and discriminative hash codes. The experimental results show that the checking accuracy of the proposed method under study reaches 97% and 95% on CSCOCO and Caltech 256 datasets, respectively. In addition, the MAP value of the model reaches up to 90% when the hash code length is 64bit, which indicates that the research has significantly improved the accuracy while ensuring the retrieval speed. By optimizing the distribution of Hamming distances, the model is able to achieve high-precision similarity search within a small range of Hamming distances. In comparison with other related studies, the improved DRH algorithm shows unique advantages. Orsuti D et al. showed that the feature extraction of image signals using CNN, although it can obtain better results on small-scale datasets, the computational overhead of the model increases significantly in large-scale, multi-labeled datasets, resulting in a decrease in the retrieval speed. In contrast, the study reduces the computational complexity in the convolutional network and improves the processing speed through the optimal generation of hash codes. In addition, it is found that the improved DRH algorithm achieves the highest MAP value of 90% when the Hamming distance is 2, while the MAP value of the other methods is only about 70% under the same conditions. This result shows that the proposed method of the study is still able to maintain a high similarity retrieval accuracy in the low-dimensional hash space of large-scale datasets. This is in contrast to the results of Wu G et al. whose proposed algorithm rapidly decreases the retrieval accuracy when the Hamming distance is small [22]. It can be shown that the study effectively solves such problems through the improved hash center generation mechanism, which enables better performance to be maintained when performing low-dimensional retrieval in large-scale communication image signals.

In summary, the improved DRH algorithm proposed by the study successfully improves the retrieval efficiency and accuracy of large-scale communication image signals through the optimization of the Cauchy function and Hadamard matrix. By comparing with other studies, it can be seen that the algorithm performs superiorly in dealing with multi-label and high-dimensional data, especially in the optimization of retrieval accuracy and Hamming distance with unique advantages. Future work can continue to explore the application of the model in different types of data and further optimize its computational performance to cope with the processing demands of larger-scale signal datasets.

VI. Conclusion

With the developing communication technology, the transmission and processing of CIS becomes more important in various fields. In this context, intelligent detection and search of CIS becomes a highly focused research direction. In view of this, firstly, this study constructed an image signal detection search model for traditional DRH. Secondly, the Cauchy concept function and Hadamard matrix were introduced to optimize the generation of hash centers. Finally, an improved DRH image signal detection model was proposed. When the test samples were 680, the highest precision of the new model was 97%. Compared with the same type of algorithm, when the Hamming distance is 2, at this time, the MAP value of the improved DRH algorithm is up to 90%, and the hash length is 64bit, which is significantly better than other algorithms. Simulation tests show that the detection similarity of the improved DRH model can be as low as 64.8%, and the fastest detection speed is 7.6 s. At this time, the similarity is reduced by about 14.6% compared with the CBIR model, and the time is shortened by 17.1 seconds. In addition, in the visualization results, the hash code generated by the improved DRH model is extremely aggregated with very clear edges, which is clearly superior. The highest storage occupancy score, detection satisfaction score, and detection time consumed score for this new model are 45, 50, and 30, respectively, which are higher than all other three types of models. In summary, the proposed improved DRH should not only have efficient detection and search capabilities, but also consider the diversity and dynamism of CIS in practical applications. In the future, this model can be further optimized to consider more practical application scenarios to promote the CIS processing.

Content-Based Image Retrieval Using Transfer Learning and Vector Database

Li Shuo, Lilly Suriani Affendey, Fatimah Sidi
Faculty of Computer Science and Information Technology, Universiti Putra Malaysia, Malaysia

***Abstract*—Content-based image retrieval (CBIR) systems are essential for efficiently searching large image datasets using image features instead of text annotations. Major challenges include extracting effective feature representations to improve accuracy, as well as indexing them to improve the retrieval speed. The use of pre-trained deep learning models to extract features has elicited interest from researchers. In addition, the emergence of open-source vector databases allows efficient vector indexing which significantly increases the speed of similarity search. This paper introduces a novel CBIR system that combines transfer learning with vector databases to improve retrieval speed and accuracy. Using a pre-trained VGG-16 model, we extract high-dimensional feature vectors from images, which are stored and retrieved using the Milvus vector database. Our approach significantly reduces retrieval time, achieving real-time responses while maintaining high precision and recall. Experiments conducted on ImageClef, ImageNet, and Corel-1k datasets demonstrate the system's effectiveness in large-scale image retrieval tasks, outperforming traditional methods in both speed and accuracy.**

Keywords—Content-based image retrieval (CBIR); image retrieval; transfer learning; convolutional neural networks; VGG-16; vector database; milvus; feature extraction; high-dimensional vectors; real-time image search

I. Introduction

In the Internet era, massive amounts of multimedia data (including text, images, audio, video, etc.) are continuously generated and stored. How to effectively retrieve relevant information from a huge image dataset has become an urgent problem to be solved. Traditional text-based image retrieval methods can no longer meet this demand, while content-based image retrieval (CBIR) technology retrieves through image features, significantly improving the accuracy and efficiency of retrieval. Practical applications of CBIR include e-commerce, web search, and medical image analysis.

The core of CBIR technology includes two key steps: image feature extraction (indexing stage) and similarity matching (retrieval stage). Image feature extraction is to convert the original image content into feature vectors, while similarity matching is to compare the feature vectors of the query image with the image in the dataset, calculate their similarity, and identify similar images. Research on CBIR technology has a long history, nevertheless most work mainly focus on model training and evaluation of image classification tasks, measuring the accuracy, and not considering the time consumption for indexing or retrieval.

This paper proposes a new CBIR retrieval system that combines transfer learning technology and vector database. Image features are extracted through convolutional neural networks (CNNs), and high-dimensional vectors are stored in vector databases to achieve efficient image retrieval. We evaluated the performance of the indexing and retrieval stages and verified the feasibility and effectiveness of the scheme. This study aims to explore how to build a high-performance CBIR system to meet the real-time retrieval requirements in large-scale image datasets.

This paper is organized as follows: Section II discusses related research in the field of CBIR and the techniques used in this study; Section III details the methodology adopted in this study; Section IV describes the proposed CBIR system utilizing transfer learning and vector database; Section V presents the experimental results, where we evaluate the performance of our system on various benchmark datasets. In Section VI, we conclude the paper by summarizing the findings, discussing the implications of the proposed system, and suggesting potential directions for future work.

II. Related Work

The theory of image retrieval has been around for a long time. Initially, text annotation was used to store image descriptive text in a database for retrieval. However, this method is manual and subjective as well as inefficient and inaccurate when faced with large amounts of data [1]. Subsequently, researchers began to study CBIR technology, using low-level features such as color, shape, and texture to represent images [2]. This method is automated and efficient, but prone to errors and has low accuracy in complex image recognition.

Modern CBIR technology extracts features from images through deep learning, uses convolutional neural networks to vectorize images, and performs matching through similarity calculations [3]. Currently, commonly used similarity matching algorithms include Euclidean distance, cosine similarity, etc.

Based on these technologies, many CBIR applications have emerged, mainly focusing on the construction, training, and evaluation of models in classification tasks, and evaluating their performance by classifying images from different data sets [4] Thus, to improve the performance of CBIR systems, numerous research on feature extraction, similarity matching, as well as storage architecture have been conducted by different researchers.

Traina et al. [5] proposed the SIFT (Scale-Invariant Feature Transform) machine vision algorithm for feature extraction and used K-means to calculate similarity distances. Simran et al. [6] introduced the use of deep learning techniques for extracting image features. Kumar et al. [7] proposed using DarkNet-19 and

DarkNet-53 models for feature extraction, along with PCA for dimensionality reduction. Sikandar et al. [8] proposed the use of ResNet50 and VGG16 for feature extraction, employing KNN for similarity calculations.

Similarity calculation is also very important. Alsmadi [11] used the memetic algorithm method to calculate similarity. Sikandar et al. [8] used the KNN method to calculate similarity. Niu et al. [12] used the Residual Vector Product Quantization for approximate nearest neighbor method to calculate.

Retrieval performance is an important indicator of CBIR system, which is usually evaluated by accuracy. Some relevant studies have been collected for retrieval performance. Chughtai et al. [13] used transfer learning to call VGG16, VGG19, EfficientNetB0, ResNet50 and other models for CBIR, with a retrieval accuracy of up to 96%. Mohammed et al. [14][14] used two pre-trained deep learning models ResNet50 and VGG16 and a machine learning model KNN implementation to achieve a maximum accuracy of 100%. Gautam et al. [15] used VGG16 and ResNet-50 architectures to obtain a maximum accuracy of 90.18%. Sadiq et al. [16] combined NASNetMobile, DenseNet121 and VGG16 models to achieve a maximum accuracy of 98%. Thanikachalam et al. [17] proposed Tokens-to-Token Vision Transformer (T2T-ViT), a novel CBIR method with an accuracy of up to 99.42%.

The above literature has conducted in-depth research on CBIR, with different retrieval methods and good performance. However, most work do not measure the time consumption for indexing, nor do they report the retrieval time, which is also an important indicator for measuring the performance of CBIR systems.

Mezzoudj et al. [18] on the other hand used a big data solution to retrieve and index CBIR, and reported the time for the indexing and retrieval stages of CBIR using the ImageClef and ImageNet datasets. Their solution greatly improved the efficiency of CBIR. However, they did not report the retrieval accuracy.

Recently, Stata et al. [9][9] and Singla et al. [10] focused on utilizing vector databases for vector extraction and evaluated the performance of these databases.

From the literature, we attempt to implement CBIR that uses transfer learning feature extraction, and utilize a vector database to store the high-dimensional vectors in, so that the vector data volume undertakes the retrieval task and improves the retrieval efficiency.

III. Methodology

This section describes the experimental design process in detail, including experimental steps, application architecture design, software and hardware configuration, data set description, experimental evaluation indicators, and experimental verification methods.

A. Application Architecture Design

Fig. 1 is the application architecture design diagram. First, the pre-trained VGG model is used to process each image in the dataset, converting these images into high-dimensional vectors. This step is called vectorization, which converts the pixel information of the image into feature vectors to facilitate subsequent similarity calculations. The generated high-dimensional vectors are then stored in the Milvus vector database for efficient storage and retrieval operations. Milvus is a high-performance distributed vector database that can store high-dimensional vectors and quickly retrieve massive amounts of vector data. VGG16 is a classic convolutional neural network (CNN) model that efficiently extracts image features. Transfer learning technology allows the VGG model to be used directly for vectorizing images, reducing the model training process and improving work efficiency.

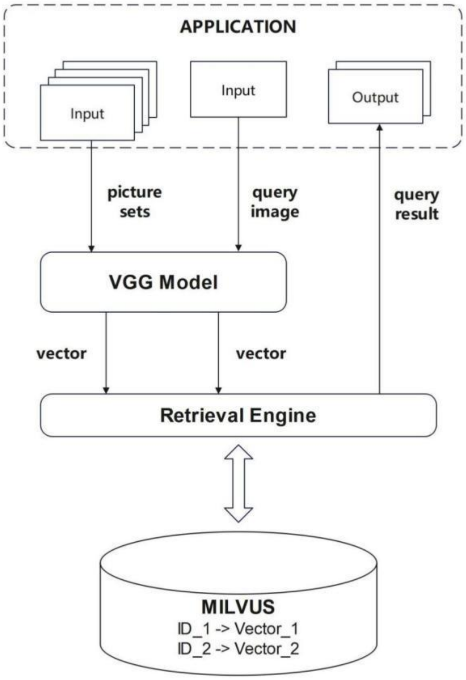

Fig. 1. Application architecture design diagram.

When a user submits an image for retrieval and matching, the input image is processed in the same manner. Specifically, the input image will also be vectorized through the VGG model to generate its corresponding high-dimensional feature vector. This feature vector is then used to query the Milvus database to find the vector that is most similar to it.

The Milvus database calculates vectors that are similar to the query vector and returns a list of results sorted according to the similarity score. The similarity score represents the similarity distance between the query vector and the vectors stored in the Milvus database. The lower the similarity score, the more similar the two images are. Finally, the system retrieves the images corresponding to these vectors, sorts them by similarity, and displays them to the user. In this way, users can easily find other images similar to their input image to meet the needs of image retrieval and matching.

B. Hardware

This experiment uses hardware resources of Intel Quad Core i5-4210U CPU, 1.70 GHz, and 8 GB memory. Table I shows the hardware required for this project.

TABLE I. HARDWARE INFORMATION

Hardware	Specification
Central Processing Unit (CPU)	Intel Core i5 4210 @ 1.7 GHz
Primary Memory (Random Access Memory)	8 GB
Secondary Memory (Hard Disc Drive)	1024 GB Solid State Drive

C. Software and Frameworks

Python was chosen as the development language. The reason is that it contains many mature function libraries and frameworks. Table II shows the software and framework required for this project.

TABLE II. SOFTWARE INFORMATION

Software	Version	Purpose
Python	3.6.0	Provide a basic development environment for the project
Tensorflow	1.15.4	An open-source deep learning framework that integrates many algorithms and models to facilitate model training.
Keras	2.3.1	A machine learning framework repackaged based on TensorFlow, an open-source high-level API neural network framework. Simplifies use and facilitates development.
Numpy	1.16.5	Integrated function library that supports a large number of dimensional array and matrix operations.
Matplotlib	3.7.2	A two-dimensional drawing library developed in Python language.
Pillow	7.1.0	Get the image based on the image path and
Flask	2.0.3	Start a service to accept and process request requests
Milvus	1.0.0	Vector database stores high-dimensional vectors after vectorization of images. And used to query and retrieve similar vectors.
Docker	19.03	Install and run Milvus and the CBIR project

D. ImageClef Dataset

ImageClef is a series of events, and a different dataset is released each year, so the size of the dataset will vary with the event and year. The ImageCleF dataset contains images and related annotation information, and researchers can conduct research on various image understanding tasks, such as image classification, image annotation, image retrieval, etc. The dataset has a total of 20,000 images, which are numerically classified into folders. This is a photo book, taken from all over the world. These datasets usually cover different subject areas and multiple languages, providing a rich research foundation.

E. ImageNet Dataset

The ImageNet dataset is a computer vision dataset. It is a large image dataset established to promote the development of computer image recognition technology. Many well-known models have been trained on this dataset, such as VGG-16, VGG-19, Restnet-50, etc. The images in the ImageNet dataset cover most of the image categories seen in daily life. This is a dataset with more than one million images.

F. Corel-1k Dataset

The Corel-1000 dataset is widely used in the CBIR field, as many researchers use this dataset to evaluate the quality of image retrieval tasks. It contains a total of 1000 images in 10 categories, namely: Africa, Beach, Building, Bus, Dinosaur, Elephant, Flower, Food, Horse, and Monument. There are 100 images in each category. This dataset was used to evaluate the quality of retrieval for CBIR applications.

G. Experimental Evaluation Metrics

To evaluate the indexing performance, the time consumption for indexing of images of different sizes in the imageClef data were measured.

To evaluate the retrieval performance, the retrieval time for images of different sizes from the imageClef dataset were taken.

In addition, the time consumption of indexing and retrieval using the ImageNet dataset was measured to evaluate the performance in a large dataset.

Finally, the retrieval quality was evaluated using the precision and recall metrics on the Corel-1k dataset to measure the retrieval accuracy.

IV. CBIR USING TRANSFER LEARNING AND VDBMS

In this section, the implementation of the CBIR experiment will be discussed in detail. First, the relevant environment is deployed, the VGG-16 model is built, and the dataset is preprocessed. Subsequently, the execution time of the indexing and retrieval stages with different data amounts is recorded on the imageClef dataset, and the accuracy of the retrieval stage is tested on the Corel-1k dataset. Finally, the experiment is repeated using the ImageNet dataset and the relevant data is recorded.

A. Data Preprocessing

Since the images are stored in various folders and are nested, it is necessary to extract the images from various directories and then merge them into the same directory folder. This makes it easier to process the images. At the same time, filter out non-image files. Finally, the dataset is compressed packaged and uploaded to the specified path on the server for subsequent use.

B. Experimental Environment Setup

In this step, the operating environment needs to be prepared. All software and the related dependent libraries as shown in Table II are installed. The project code can be found at https://github.com/LI-SHUO-lee/CBIR.git.

C. Initialize VGG Model

In this work, transfer learning is utilized to directly employ the VGG model for feature extraction. Initially, the VGG model needs to be defined. The VGG16 model requires the input image size to be 224x224 pixels with three channels. Pre-trained weights on the ImageNet dataset are utilized here. These pre-trained weights facilitate faster convergence and generally enhance the model's performance. Max pooling is employed, which selects the maximum value in each region as the output. The parameter includes top=False indicating that the top layer (fully connected layer) of the model is excluded, as a custom output layer is intended to be added on top. An array of zeros with shape (1, 224, 224, 3) is created using np.zeros((1, 224, 224, 3)) as input, and the model's prediction method is called to make a prediction. This is typically performed to ensure that the model is loaded correctly and can make a normal prediction.

D. CBIR Indexing Phase

The indexing stage refers to the process of directly using existing models and parameters to extract features from images through transfer learning technology and storing these high-dimensional vectors describing image features in the vector database so that subsequent retrieval processes can be carried out effectively.

Fig. 2 shows the process of image indexing. All images are preprocessed to ensure that their suffix is jpg or png, and at the same time unify the size of the images to ensure that they are 224*224*3. Then the features of the image are extracted through the VGG model. In order to reduce the pressure on the vector database Milvus, high-dimensional vectors are temporarily stored in the server cache. After waiting for the image batch vectorization to be completed, the vectors in the server cache are flushed into the vector database Milvus to ensure that the database is only requested once. This ensures the function and improves efficiency.

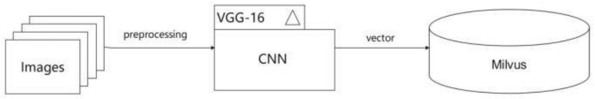

Fig. 2. Indexing process.

Table III shows the time taken for indexing different image sizes using the ImageClef dataset.

TABLE III. THE TIME CONSUMPTION OF INDEXING

Image size	2011	5952	10000	11963	17953	20000
Time consumption	446 s	1066 s	1689 s	1991 s	3089 s	3412 s

E. CBIR Retrieval Phase

Conducting an experimental study on the retrieval stage of the CBIR application is essential, as it is the core component of the project. The retrieval phase's success directly impacts the overall project outcome. Therefore, an in-depth experimental exploration is necessary to address its challenges.

Firstly, we will evaluate retrieval time, a crucial performance metric. Assessing retrieval time helps understand the system's efficiency in handling a large volume of images, reflecting architectural improvements.

Secondly, accuracy evaluation is vital in CBIR. We will compare search results with standard dataset to assess the accuracy.

1) Retrieval time consumption evaluation: Fig. 3 illustrates the image-retrieving process. When the data set is fully vectorized, the database stores the feature vector of each image in the data set. The user only needs to input a query image, and then use the same model and algorithm to vectorize and extract features of the image to obtain a feature vector. Only the feature vector and the number of data pieces needing fuzzy matching need to be communicated to Milvus. Milvus will automatically search from its own library through the vector, and then return the closest Top k vectors and vector IDs. Next, the table is consulted to find the correspondence between the vector ID and the actual image, enabling the retrieval of the fuzzy-matched image to be returned to the user. This enables users to search for images by image. The time consumed in this stage is used as a key indicator for evaluating the CBIR application.

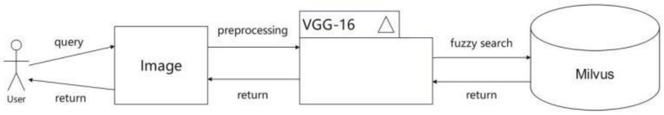

Fig. 3. Image retrieval.

First, the ImageClef dataset is used to perform the retrieval process according to the image size in Table IV. Then the consumed time is recorded respectively to evaluate the performance of the retrieval process of the CBIR application.

TABLE IV. THE TIME CONSUMPTION OF RETRIEVAL

Image size	2011	5952	10000	11963	17953	20000
Time consumption	0.27 s	0.26 s	0.33 s	0.23 s	0.20 s	0.30 s

2) Retrieval accuracy evaluation: Retrieval accuracy is also an important indicator of retrieval performance. Since the vector database is an approximate search, the search results may not be 100% correct. However, accuracy and speed are contradictory indicators. We cannot blindly pursue speed and ignore the accuracy of CBIR. Therefore, at this stage, we will evaluate and record the retrieval accuracy on the Corel-1k dataset, which will also be used to evaluate the performance of CBIR applications. Fig. 4 illustrates the process of evaluating the accuracy.

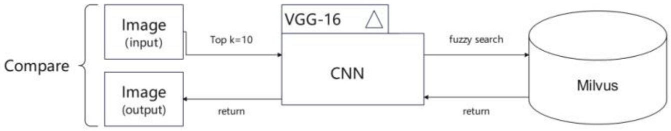

Fig. 4. The accuracy process.

In this experiment, precision and recall will be used to evaluate the retrieval quality. The Corel-1k dataset will be used because many papers use this dataset to calculate precision and recall for evaluating CBIR applications. There are 10 categories in Corel-1k, each with 100 images, for a total of 1,000 images. One image is randomly selected from each category for query testing, and the remaining 99 are used for training. Therefore, 990 images need to be vectorized, converted into vectors through the VGG-16 model, and stored in Milvus. The Euclidean distance (L2) is used to calculate the distance between vectors. Setting Top k = 10, which means that 10 images will be returned for each query. For the returned images, we extract the classification label of the image and then compare it with the classification label of the query image. If the classification label is consistent, the retrieval is considered correct, and the application has successfully detected the image of this class. Otherwise, it is an error. Record the number of correctly classified images and compare them with the returned images and all images of this class in the database to calculate the precision and recall. Finally, the process is repeated for each image in each category, and the precision and recall rate of each category are calculated to verify the retrieval performance of the application.

Precision formula:

$$\text{Precision} = \frac{\text{number of similar images retrieved}}{\text{total number of images retrieved}} \tag{1}$$

Recall formula:

$$\text{Recall} = \frac{\text{number of similar images retrieved}}{\text{total number of similar images in the database}} \tag{2}$$

Table V shows the calculation results of precision and recall through the experiment.

TABLE V. THE ACCURACY FOR DIFFERENT IMAGE CATEGORIES

	Precision	**Recall**
africans	0.869	0.711
beaches	0.847	0.592
buildings	0.898	0.666
buses	1.000	1.000
dinosaurs	1.000	0.956
elephants	1.000	0.853
flowers	0.994	0.804
foods	0.983	0.805
horses	1.000	0.828
monuments	0.935	0.716

F. *Time Consumption in the ImageNet Dataset*

To verify time consumption on the ImageNet dataset, we will use the same method. Specifically, we will record the time taken for both the indexing and retrieval phases. Repeating the experiment on different datasets will help verify the robustness and wide applicability of the proposed method. Table VI shows the experiment results.

TABLE VI. THE RESEARCH RESULTS IN THE IMAGENET DATASET

ImageNet size	**Time for indexing**	**Time for retrieval**
1,461,406	249,400 s	0.5 s

V. RESULTS AND DISCUSSION

A. *Introduction*

This section will provide a detailed analysis of the project experiment data. We will collect, organize, visualize, and statistically analyze the experimental data. Using the reference paper [18] as a benchmark, we will compare and discuss various aspects such as architecture design, algorithm comparison, development language, index performance, and retrieval performance to demonstrate the superiority of our architecture.

B. *Architecture Comparison*

The architecture has the following advantages over Mezzoudj [18].

First, the VCBIR architecture is simpler, requiring no big data platform; it can be deployed and maintained on a single server, facilitating horizontal scaling.

Second, image vectorization uses the VGG-16 model, which provides more accurate feature extraction while maintaining high efficiency. If higher accuracy or a lighter model is needed, the vector model can be easily replaced without altering other components.

Finally, vector storage uses Milvus instead of Hadoop, eliminating the need for big data components like Spark for vector calculations, thus simplifying the architecture. Milvus supports horizontal scaling, allowing for upgrades to a distributed cluster in case of storage bottlenecks, without impacting upper-layer applications. Table VII summarizes the architectural differences.

TABLE VII. ARCHITECTURE COMPARISON TABLE

	Architecture from reference paper [18]	**VCBIR Architecture**
Vector model	CS-LBP extracts image features based on color, texture, etc., but it has low accuracy.	VGG extracts image features based on neural networks and has more layers with high accuracy.
Operating environment	Rely on the big data platform.	The ordinary operating system is sufficient.
Resource consumption	High resource consumption.	Low resource consumption.
Deployment	Hard to deploy.	Easy to deploy.
Maintain	The entire big data platform needs to be maintained. High maintenance costs.	Only Milvus and programs need to be maintained. Low maintenance costs.
Expand	Easy to extend	Easy to extend

C. *Performance of the Indexing Module*

1) Data analysis: The experimental data was collected from the CBIR indexing phase and compared with the study [18]. Table VIII shows the comparison of retrieval time results.

TABLE VIII. TIME CONSUMPTION OF THE INDEXING FOR DIFFERENT DATASET SIZES AND METHODS

Images size	**HDFS**	**Tachyon**	**VCBIR**
2011	240 s	120 s	446 s
5952	660 s	420 s	1066 s
11963	1260 s	720 s	1991s
17953	1380 s	1140 s	3089 s
20000	1500 s	1200 s	3412 s

Fig. 5 visualizes the graph for comparison. The asterisk line graph represents the time consumed by the method (VCBIR) in the indexing phase. As can be seen from the figure, the performance of this method in the indexing phase is lower than that of the method in study [18] and presents a linear distribution. The reason will be analyzed in detail later.

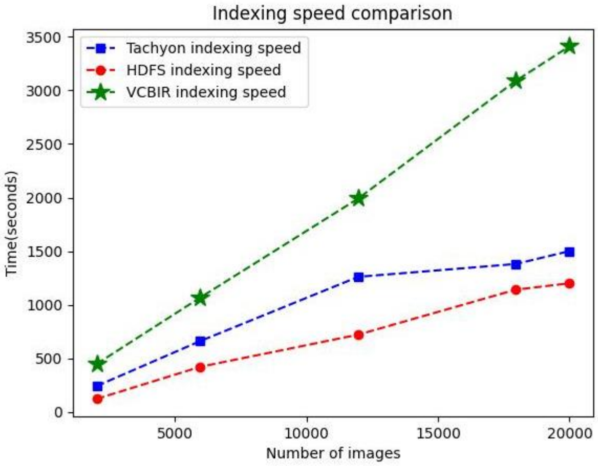

Fig. 5. Indexing speed for different methods.

The research on indexing performance from relevant literature was reviewed and compared. Table IX presents the index performance from different studies and Fig. 6 visualizes the comparison.

TABLE IX. PERFORMANCE COMPARISON OF DIFFERENT INDEXING APPROACHES FOR 10,000 IMAGES

Approach	Description	Time(s)
Centralize method [20]	Sequential method on 1 node	600,000
DIRS method [20]	HBase system+MapReduce on 9 Hadoop nodes	200,000
Luca C. et R. method [21]	HDFS+MapReduce on 1 Hadoop node	2,820
VCBIR method	Milvus +VGG16 on 1 node	1689
Reference paper method [18]	Tachyon+MapReduce on 1 Spark node	460

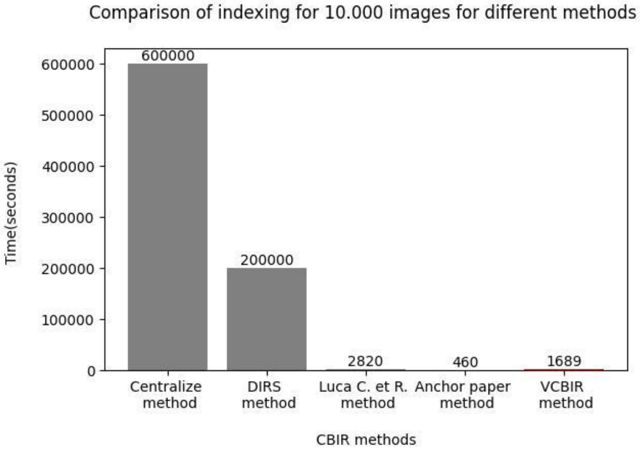

Fig. 6. The time cost visualization for different methods.

From Fig. 6. and Table IX, it can be observed that although the CBIR index performance based on the vector database is a little worse, the performance is still greatly improved in this field. It validates the feasibility of the approach.

2) Result analysis: The reasons why this solution is weaker than the big data solution in study [18] at the indexing stage are as follows:

- Since the literature [18] uses a big data solution, it is easy to implement distributed applications based on the big data platform, so efficiency can be greatly improved. However, the VCBIR is developed using Python. Global Interpreter Lock (GIL) is a mechanism in the Python interpreter. This lock greatly limits the multi-threading performance of the program, which is the main reason why the performance of Python programs is weaker than that of Java. The VGG model relies on tensorflow, and it does not support multi-process execution. Therefore, the entire program can only be executed in a single thread and a single process, and the machine resources cannot be fully utilized. Leading to inefficiency.
- Since the VGG-16 in the indexing stage is used, the model has 16 layers, which is more time consumption than the ordinary texture-based feature extraction algorithm, sacrificing time for quality. Therefore, it is not as efficient as the indexing efficiency in the reference paper [18]. However, the extracted features better characterize the original image. Although the indexing efficiency of this solution is lower than that of the study [18], it is significantly higher than other studies in the same field. It is completely acceptable. Moreover, tasks of this stage can be run in batches or asynchronously at night without disrupting normal operations. There are many solutions to this problem.

D. Performance of the Retrieval Module

1) Data analysis: The retrieval phase of CBIR is the focus of this project and the core problem that needs to be solved. In order to verify its performance, experimental data from the CBIR retrieval phase is collected. Table X lists the experimental results.

TABLE X. COMPARISON OF THE AVERAGE COMPUTING TIME IN THE SEARCHING MODULE

Image dataset size	Parallel k-NN without cache	Parallel k-NN with cache	VCBIR
2011	180 s	120 s	0.27 s
5952	540 s	240 s	0.26 s
11963	1140 s	540 s	0.23 s
17953	1740 s	840 s	0.20 s
20000	1980 s	960 s	0.30 s

For ease of comparison, the chart was visualized, as depicted in Fig. 7. The asterisk line shows the time consumed by the method (VCBIR) for different amounts of data in the retrieval phase. The other two show the time consumed by the solutions in study [18] for different amounts of data in the retrieval phase.

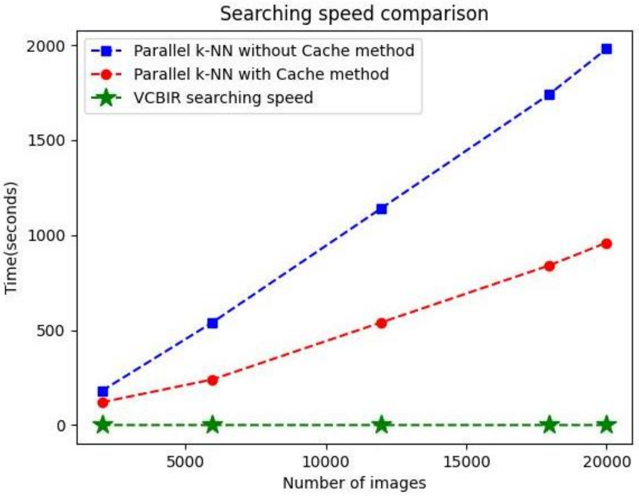

Fig. 7. Searching speed for different methods.

From the figure, it is evident that the performance of the VCBIR solution in the retrieval stage is very outstanding, far higher than the big data solution, and it can almost achieve a response in seconds and real-time return. Moreover, as the amount of data increases, the performance is almost not affected.

As shown in Table XI, the retrieval performance of existing literature was organized to facilitate a better comparison of the current research status in this field.

TABLE XI. PERFORMANCE COMPARISON OF DIFFERENT RETRIEVAL APPROACHES FOR 20,000 IMAGES

Approach	Description	Time (s)
Centralize method [20]	Sequential method on 1 node	25,000
DIRS method [20]	HBase system + MapReduce on 9 Hadoop nodes	15,000
Sakr et al. Method [22]	Parallel retrieval on 1 node Hadoop	1200
reference paper method [18][18] without cache	Parallel k-NN on 1 node Spark without cache	1980
reference paper method [18] with cache	Parallel k-NN on 1 node Spark with cache	960
VCBIR method	Milvus +VGG16 on 1 node	0.3

Again, to visualize the performance improvements, a histogram was generated. Fig. 8 depicts the results of research from various literature sources in this field. The VCBIR in the figure represents the time consumption of the solution in the retrieval field. It is evident that the performance improvement is substantial.

2) Result analysis: From the above results, it is evident that the performance improvement of CBIR applications based on vector databases in the field of retrieval is very huge, even several orders of magnitude higher than the performance of the previous solution. And as the number of images increases, the performance remains basically unchanged. It can be said that real-time response is achieved. Leading the way in performance research in this field.

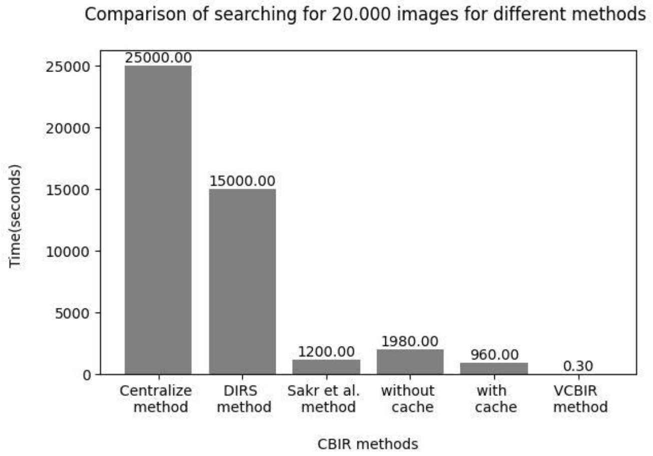

Fig. 8. Searching speed visualization for different methods.

E. Performance Comparison Between Different Datasets

Similarly, the indexing and retrieval times consumption between the ImageClef and ImageNet dataset also were recorded and compared. CBIR applications based on vector databases are comprehensively evaluated. Table XII and Table XIII are the performance comparisons of indexing and retrieval.

TABLE XII. INDEX PERFORMANCE ON TWO DATASETS

Dataset	Nbr of images	Using 1 node	Using 5 nodes	VDBMS
ImageClef	20,000	1200 s	720 s	3412 s
ImageNet	1,461,406	51,283 s	32,000 s	249,400 s

TABLE XIII. RETRIEVAL PERFORMANCE ON TWO DATASETS

Dataset	Sequential k-NN Maillo et al.2015	Parallel k-NN using 1 node	Parallel k-NN using 5 nodes	VDBMS
ImageClef	/	960 s	790 s	0.3 s
ImageNet	107,735 s	42,250 s	34,265 s	0.5 s

F. Performance of the Retrieval Accuracy

However, accuracy is also an important indicator of retrieval performance. In the vector database of this project, the IVF_FLAT index type is utilized, which considers both performance and accuracy. The retrieval function of this application was tested using the Corel-1k dataset, and its evaluation was based on precision and recall. The experimental results have been documented in Table V of Section IV. Fig. 9 shows the precision and recall results.

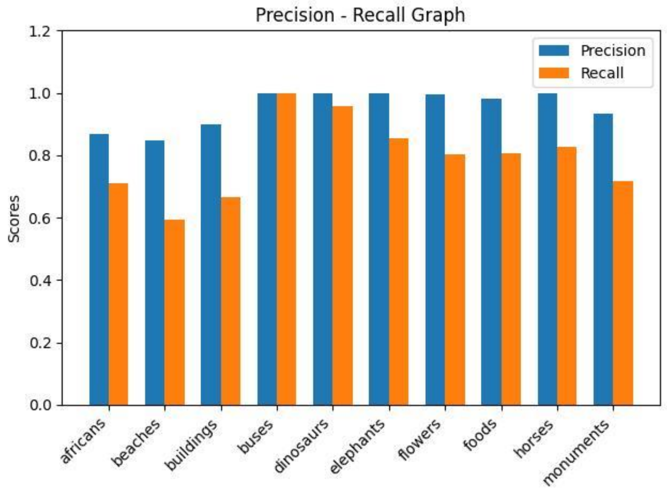

Fig. 9. The precision and recall in Corel-1k for different categories.

From the above figure, it is evident that the retrieval precision of this application is very high, even reaching 100% for some categories, and the lowest is still 60%. The recall is also very well. For the buses category, all images of these image categories can be retrieved based on the query image. It can be concluded that the retrieval accuracy of this application is relatively high and can meet the needs of most daily applications.

VI. Conclusion and Future Research

A. Introduction

Based on the design, a CBIR application utilizing transfer learning, and a vector database was developed. The performance of the application was evaluated by recording the time and accuracy of the indexing and retrieval stages. Experimental results indicated that the performance for the indexing stage did not outperform the big data solution, however for the retrieval stage, the performance of the VCBIR application is much better than that of the reference paper [18] and other solutions in this field. Furthermore since indexing is normally done offline, the performance is still acceptable. Whether it is the time consumption or accuracy of the retrieval stage, the performance is very outstanding, especially the retrieval time is reduced to about 1s, which is improved by several orders of magnitude and can achieve real-time response.

B. Contribution

The introduction of the vector database significantly improves the performance of the CBIR retrieval system, not only increasing the retrieval speed but also ensuring the accuracy. This new technology provides a powerful high-dimensional vector management tool for image retrieval, effectively solving the problems of low retrieval performance and accuracy, thereby bringing faster and more accurate query responses. This improvement improves the user experience and enhances the reliability and trust of the system, indicating that the integration of the vector database and the CBIR system has opened up new space for the development of image retrieval technology.

C. Future Work

- This project currently uses CPU for experiments but considering that GPU has higher performance and efficiency in the field of image processing, we plan to change the program to a GPU version in the future. In this way, we expect to significantly improve the performance and response speed of CBIR applications, allowing them to process large-scale image data faster and more accurately. This improvement will bring more opportunities and advantages to the project, provide users with a better image retrieval experience, and promote the development and application of CBIR technology in practical applications.

- Currently, the project is limited to implementation in a single-machine environment, but there are plans to study how to transform it into a distributed project in the future. This improvement aims to better utilize the advantages of distributed systems and improve the performance and efficiency of CBIR. Additionally, the distributed architecture can enhance the stability and reliability of the system, making it better able to cope with the challenges of large-scale data processing and high concurrent access. This step will bring broader development opportunities to the project, provide users with faster and more reliable image retrieval services, and promote the application and development of CBIR technology in distributed environments.

***Abstract*—Diabetic retinopathy (DR) is a critical complication of diabetes, characterized by pathological changes in retinal blood vessels. This paper presents an innovative software application designed for DR detection and staging using fundus images. The system generates comprehensive reports, facilitating treatment planning and improving patient outcomes. Our study aims to develop an affordable computer assisted analysis system for accurate DR assessment, leveraging publicly available fundus image datasets. Key objectives include identifying relevant features for DR staging, developing robust image processing algorithms for lesion detection, and implementing machine learning models for accurate diagnosis. The research employs various pre-processing techniques to enhance image quality and optimize feature extraction. Convolutional Neural Networks (CNNs) are utilized for stage classification, achieving an impressive accuracy of 93.45%. Lesion detection algorithms, including optic disk localization, blood vessel segmentation, and exudate identification, demonstrate promising results in accurately identifying DR-related abnormalities. The developed software product integrates these advancements, providing a user-friendly interface for efficient DR diagnosis and management. Evaluation results validate the effectiveness of the CNN model in stage classification and lesion detection, with high sensitivity and specificity. The study discusses the significance of image augmentation and hyperparameter tuning in improving model performance. Future research directions include enhancing the detection of microaneurysms and hemorrhages, incorporating higher resolution images, and standardizing evaluation methods for lesion detection algorithms. In conclusion, this research underscores the potential of technology in revolutionizing DR diagnosis and management. The developed software product offers a cost-effective solution for early DR detection, emphasizing the importance of accessible healthcare solutions. The findings contribute to advancing the field of DR analysis and inspire further innovation for improved patient care.**

Keywords*—Diabetic retinopathy; fundus images; computer-assisted analysis; deep learning; image processing; convolutional neural networks component

I. Introduction

The rapid advancement of diabetes poses a significant challenge to modern healthcare. Medical literature suggests that diabetes is associated with the emergence of serious long-term complications resulting in a variety of conditions, including cardiovascular disease, retinal complications, and retinopathy. According to a survey conducted by the International Diabetes Federation in 2015, around 410 million people worldwide suffer from diabetes. The disease also caused over 5 million deaths in the same year [1]. The disease is progressive, and its classification is based on the presence of different clinical abnormalities. Our research's main aim is to develop an affordable computer-assisted analysis system that accurately assesses the status of diabetic retinopathy (DR). By offering a cost-effective solution for DR analysis, we aim to prevent the progression of DR to its final stage and improve patient outcomes. This project highlights the potential benefits of technological innovation in healthcare and the importance of accessible solutions for DR analysis.

To achieve our aim, we have defined specific objectives. Firstly, we identified relevant features that can effectively determine each stage of DR, which were used to create a reliable diagnostic model. Secondly, we developed an image processing component capable of extracting these features from fundus images, enabling accurate detection of DR lesions. Thirdly, we build a robust and accurate machine learning model to diagnose the patient’s stage of DR based on the identified features. Finally, we developed a software product that can identify the stage of DR and detect the presence of lesions in each fundus image. These goals collectively helped develop a comprehensive computer-assisted analysis system for DR diagnosis and management.

This research project is delimited to the consideration of Diabetic Retinopathy (DR) exclusively in the human population, and other retinal diseases are excluded from the scope of the study. By excluding other retinal diseases, the study is designed to have a focused and specific approach in the development of a diagnostic tool for Diabetic Retinopathy (DR).

The research utilized publicly available datasets of fundus images, annotated with DR grades, for training and testing machine learning models. The datasets utilized in this study include Kaggle dataset for DR detection [2], Messidor-1 dataset [3], Messidor-2 dataset [3], and the Indian Diabetic Retinopathy Image Dataset (IDRiD) [4]. The research project will deliver a web application for DR diagnosis, accompanied by a user manual. A research paper documenting the process, methodology, and results will also be produced. These deliverables aim to provide a cost-effective and reliable tool for the diagnosis and management of DR, improving treatment programs for diabetic patients.

II. Related work

Diabetic Retinopathy is a complication of diabetes that is caused by pathological changes of the blood vessels which nourish the retina and lead the blood vessels of the retina to swell and to leak fluids and blood. In an advanced stage of diabetic retinopathy, it can lead to a loss of vision. Diabetic retinopathy is the most common cause of blindness in people aged 30–69 years [5]. According to Diabetes Control and Complication Trail (DCCT), DR is considered one of the four leading causes of blindness. A macular is a condition that affects vision and occurs when fluid leaks from blood vessels in the retina, leading to the formation of lesions. It is the leading cause of blindness among people with diabetes [6]. Retina regular screening is crucial for people with diabetes to detect and treat DR in its initial stages, as this can help prevent the risk of blindness [7]. The detection of DR involves identifying distinct types of lesions in a retina image. Microaneurysms (MA), Hemorrhages (HM), soft and hard Exudates (EX) [8-10].

K. Xu et al. [11] automatically classified the images of the Kaggle [12] dataset into normal images or DR images using CNN. The researchers selected 1000 images from the Kaggle dataset, and applied data augmentation and resizing to 224 x 224 x 3 before feeding the images to their CNN model. Their CNN architecture consisted of eight convolution layers, four max-pooling layers, and two fully connected layers. The SoftMax function was utilized in the final layer of the CNN for classification. This method achieved an accuracy of 94.5%. M. T. Esfahan et al. [13] used a known CNN, which is ResNet34 [14] in their study to classify DR images of the Kaggle dataset into normal or DR image. To enhance the quality of the images, they applied a set of image preprocessing techniques, such as Gaussian filtering, weighted addition, and normalization. The reported accuracy of their method was 85%, and the sensitivity was 86%.

The work by V. Gulshan et al. [15] introduced a method to detect DR and diabetic macular edema (DME) using the CNN model. They used Messidor-2 [3] and eyepacs1 datasets which contain 1748 images and 9963 images, respectively to test the model. They trained 10 CNNs with the pre-trained Inceptionv3 [16] architecture with a various number of images and the result was computed by a linear average function. However, the study did not focus on explicitly detecting non-DR or the five stages of DR. H. Pratt et al. [17] proposed a method based on a CNN to classify images from the Kaggle dataset into five DR stages. The researchers used a custom CNN architecture to classify 80,000 test images after performing color normalization and resizing them to 512x512 pixels. However, it is important to note that their CNN was unable to detect the lesions in the images, and they only evaluated their CNN on a single dataset. S. Dutta et al. [18] detected and classified DR images from the Kaggle dataset into five DR stages. The researchers evaluated the performance of three distinct types of neural networks - back propagation neural network (BNN), deep neural network (DNN), and convolutional neural network (CNN) - using a dataset of 2000 images.

Ege et al. [19] located exudates and cotton wool spots in 38 color images. The authors used a combination of template matching, region growing, and thresholding techniques to detect abnormalities. Wang et al. [20] addressed the same problem by using a minimum-distance discriminant classifier to identify the retinal bright lesions such as exudates and cotton wool spots. They represented color features in a spherical color space.

Our study identifies a gap in the existing tools available for generating comprehensive reports on the status of patients with diabetic retinopathy. To address this gap, we propose the development of a software product capable of storing patient medical history, detecting DR, and improving treatment programs. This software product would generate detailed reports summarizing the patient’s treatment program and store relevant information in a database. By providing doctors with a more complete understanding of the patient’s medical history and DR stage, the proposed software product would enable more effective treatment planning and ensure appropriate care. This research emphasizes the significance of technological innovation in healthcare and highlights the potential benefits of software products in enhancing patient outcomes.

III. Methodology

The rapid advancement of diabetes poses a significant challenge to modern healthcare. Medical literature suggests that diabetes is associated with the emergence of serious long-term complications resulting in a variety of conditions, including cardiovascular disease, retinal complications, and retinopathy. According to a survey conducted by the International.

A. *Pre-processing*

In this research study, a series of pre-processing steps were conducted to improve the quality and uniformity of retinal fundus images. These steps included capturing the retina by removing the background using adaptive thresholding and contour detection, minimizing lens flares by cutting off the outermost area of the image, and resizing the images for quicker processing. Additionally, normalization was applied to the images with respect to a reference image to match their histogram distribution. Image enhancement techniques were employed using contrast-limited adaptive histogram equalization (CLAHE) on both RGB and HSI channels. For RGB channels, the images were divided into their components, enhanced using CLAHE, and filtered to reduce noise. For HSI channels, the images were transformed, enhanced, converted back to RGB, and filtered. The HSI approach was favored over RGB due to minimal color shift. These pre-processing steps aimed to enhance lesion detection and were crucial in the subsequent stage classification experiments.

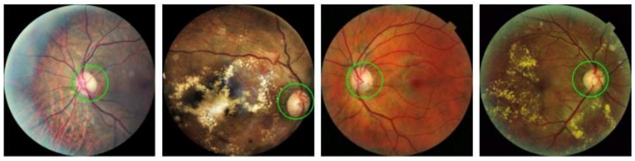
B. *Stage Classification*

In our research, the focus was on the classification of various stages of Diabetic Retinopathy (DR). Convolutional Neural Networks (CNNs) were chosen as the primary method due to their effectiveness in previous studies. Transfer learning was employed, utilizing pre-trained models available in the Keras deep learning framework to improve classification performance.

We experimented with various CNN models, including ResNet50, InceptionV3, VGG, and custom models, exploring different parameters and learning rate adjustment approaches. Initially, a fixed learning rate was used, but we later implemented a dynamic approach using the “ReduceLROnPlateau” method based on validation loss. To prevent overfitting, we employed early stopping using the “EarlyStopping” function. Evaluating the performance of different pre-trained models, such as ResNet50, InceptionV3, and VGG, showed no significant differences. Hence, hyperparameter tuning was performed on selected models, considering their previous performance and relevant literature. Additionally, the possibility of implementing an ensemble method was explored if multiple models demonstrated satisfactory performance.

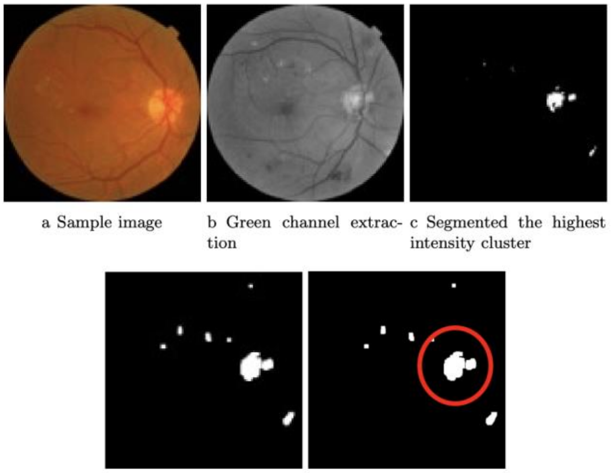
C. Stage Classification

1) Localization of optic disk: Two approaches were experimented with for the localization of the optic disk: the Kmeans clustering-based approach (see Fig. 2) and the intensity variation-based approach (see Fig. 1). In the K-means clustering-based approach, the algorithm is used to group pixels in the image based on their color intensities. The highest intensity cluster, representing the brightest pixels, is identified as the optic disk. The accuracy of this approach was evaluated on the Messidor and Kaggle datasets, achieving approximately 80.5% and 63.2% accuracy, respectively. However, issues such as lens flares and determining the optimal value of k for clustering can affect the accuracy of optic disk localization using this method.



a Image 01 b Image 02 c Image 03 d Image 04

Fig. 1. Results from localization of optic disk by intensity variation-based approach.



a Sample image b Green channel extraction c Segmented the highest intensity cluster

d After the dilation and erosion e Location of optic disk

Fig. 2. Optic disk localization using K-means.

The intensity variation-based approach identifies the optic disk by detecting rapid intensity variations caused by dark blood vessels and bright nerve fibers. The average intensity variance within a window is calculated, and the highest intensity point is marked as the optic disk center. This approach demonstrated high accuracy, correctly identifying the optic disk in approximately 98.13% of the images from the Messidor dataset and 93.6% of the images from the Kaggle dataset, including those with lens flares which is summarized in Table 1.

TABLE I. SUMMARY ON OPTIC DISK LOCALIZATION APPROACHES

Approach	**Messidor-2 Dataset (375 images)**	**Kaggle Dataset (250 images)**
K-means clustering based approach	80.5 %	63.2 %
Intensity variation-based approach	98.13 %	93.6 %

Both approaches have their advantages and limitations, and the intensity variation-based approach shows promise in improving the accuracy of optic disk detection.

2) Localization of blood vessels: To detect blood vessels in the retinal fundus images, a series of steps were followed. First, the green channel was extracted to enhance the contrast. Then, Contrast Limited Adaptive Histogram Equalization (CLAHE) was applied to further enhance the image. Morphological operations involving opening and closing were performed using ellipsoidal structuring elements of varied sizes to remove small objects and smooth larger ones. The result of the CLAHE step was subtracted from the input image to isolate the blood vessels. A threshold was applied to binarize the blood vessel image. Finally, small contours were removed from the binarized image using an area-based criterion.

3) Detection of exudates: The detection of exudates from fundus images can be accomplished through various approaches. In the k-means clustering-based approach, the intensity values of the optic disk on the green channel image are set to zero, followed by dilation to remove lens flare. The highest intensity clusters are then identified using kmeans, with the brightest pixels representing the exudates. Experimentation with different k-values and normalization with a reference image are performed to enhance accuracy. However, false positive detections can occur if high-intensity pixel clusters are falsely identified as exudates. Alternatively, the edge detection approach involves extracting the green channel and applying the Canny edge detection algorithm to identify all edges. To isolate exudate edges, localization of blood vessels is first performed. The edges corresponding to blood vessels and the optic disk are then subtracted from the result. Contour analysis is employed to address the inclusion of tiny blood vessels during the extraction process. Although the edge detection approach is more reliable than the k-means approach, it may detect additional features like blood vessels, microaneurysms, and hemorrhages, making exudate identification more challenging. Consequently, another approach, namely Recursive Region Growing, is experimented with, which focuses on identifying regions with similar color or intensity likely to be exudates. The steps involved in this approach include extracting the green channel, applying the region growing and merging segmentation algorithm, producing a binary image using thresholding, localizing the optic disk, and subtracting it from the result.

4) Detection of detection of microaneurysms and hemorrhages: The process of detecting microaneurysms and hemorrhages using a k-means clustering approach in fundus images involves the following steps. First, the green channel is extracted as it provides better contrast for identifying red lesions. The images are then normalized with a reference image to ensure homogeneity and align with the selected value of k in the k-means algorithm. Next, k-means clustering is applied to identify clusters of similar pixel intensity values. The lowest intensity cluster is selected as it is expected to contain the microaneurysms and hemorrhages. The pixels in this cluster are thresholder and binarized to separate them from the rest of the image. Finally, the blood vessels are localized and removed from the segmented cluster.

IV. Implementation

The rapid advancement of diabetes poses a significant challenge to modern healthcare. Medical literature suggests that diabetes is associated with the emergence of serious long-term complications resulting in a variety of conditions, including cardiovascular disease, retinal complications, and retinopathy. According to a survey conducted by the International.

A. *CNN model for Stage Classification*

After conducting hyperparameter tuning on the pre-trained ResNet50v2 model, we found that setting the learning rate to 0.00001 and using three hidden layers, each with 230 neurons, resulted in the best performance. Based on these optimized hyperparameters, we finalized our ResNet50v2 model. The architecture of the model can be seen in Fig. 3.

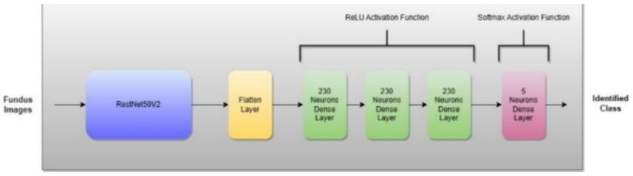


Fig. 3. CNN model for stage classification.

B. *System for Lesion Detections*

In our research, we focused on lesion detection in fundus images and successfully integrated the method into our application, Seer, using the OpenCV library. Seer not only accurately classifies various stages of Diabetic Retinopathy (DR) but also provides comprehensive reports on the DR class and identified lesions. By incorporating lesion detection into our analysis system, we have significantly enhanced the potential for early detection and effective management of DR, highlighting the importance of innovative solutions in healthcare. Through experimentation, we compared different approaches for localizing the optic disk and chose the intensity variation-based method for its superior accuracy. We also evaluated multiple techniques for exudate detection and determined that the recursive region-growing-based approach yielded the best performance. Additionally, we employed the k-means clustering approach to detect microaneurysms and hemorrhages and conducted experiments on localizing blood vessels. These advancements in lesion detection contribute to the overall effectiveness and reliability of Seer in diagnosing and managing DR.

C. *Implementation of Software product*

The implemented software product is a comprehensive and sophisticated solution designed to streamline the management of Diabetic Retinopathy (DR) in healthcare institutions. It offers a range of powerful functionalities that enhance various aspects of DR management. The software provides secure user authentication and authorization, ensuring that only authorized individuals can access the system. It utilizes advanced algorithms to predict the stage of DR based on fundus images, assisting in early detection and treatment planning. The software also offers intuitive visualization tools for DR lesions, enabling healthcare professionals to analyze and interpret the images with ease. It generates detailed reports that summarize the DR class and provide insights into the identified lesions, facilitating documentation and communication among healthcare teams. Furthermore, the software allows for efficient management of patient DR history, ensuring comprehensive records and tracking of their condition over time. User and institution management features are included to provide administrative control and customization options. Overall, this software product simplifies and streamlines DR management, empowering healthcare providers to deliver more effective care through its user-friendly interface and comprehensive range of functionalities.

1) Tools and Technologies: The proposed solution is being developed on the basis of the following tools:

- Application Framework: Python Flask
- Database: MySQL Database
- Additional tools: OpenCV

V. Evaluation

The rapid advancement of diabetes poses a significant challenge to modern healthcare. Medical literature suggests that diabetes is associated with the emergence of serious long-term complications resulting in a variety of conditions, including cardiovascular disease, retinal complications, and retinopathy. According to a survey conducted by the International.

A. *Evaluation of CNN Model for Stage Classification*

We evaluated our model against following dataset variations which derived from the Messidor-2 and Kaggle datasets to class balance and improve the quality.

- Dataset 03: Dataset generated by applying image augmentation to pre-processed images with minimized lens flares
- Dataset 04: Dataset generated by applying image augmentation to pre-processed images by applying CLAHE on RGB channels

- Dataset 05: Dataset generated by applying image augmentation for pre-processed images by applying CLAHE on HSI channels
- Dataset 06: Dataset generated by class balancing with approximately 600 images per class.

1) Evaluation of model with respect to Dataset 03: The results gained by testing the stage classification model on different variations of Dataset 03 and the confusion matrix and ROC curve are calculated to evaluate the performance of the model (see Fig. 4).

The accuracy and sensitivity of the test have been calculated for each class individually, and the results are presented below.

- Class 0: Accuracy = 0.806, Sensitivity = 0.979
- Class 1: Accuracy = 0.958, Sensitivity = 0.868
- Class 2: Accuracy = 0.982, Sensitivity = 0.948
- Class 3: Accuracy = 0.987, Sensitivity = 1.000
- Class 4: Accuracy = 1.000, Sensitivity = 0.962

The overall performance is listed below.

- Overall Accuracy: 0.935
- Overall Precision: 0.951
- Overall Specificity: 0.9

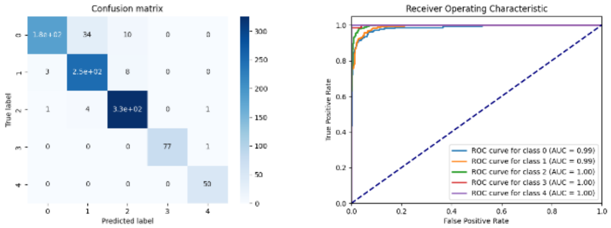

Fig. 4. Evaluation results with respect to Dataset 03.

2) Evaluation of model with respect to Dataset 04: The results gained by testing the stage classification model on different variations of Dataset 03 and the confusion matrix and ROC curve are calculated to evaluate the performance of the model (see Fig. 5).

The accuracy and sensitivity of the test have been calculated for each class individually, and the results are presented below.

- Class 0: Accuracy = 0.819, Sensitivity = 0.870
- Class 1: Accuracy = 0.916, Sensitivity = 0.839
- Class 2: Accuracy = 0.919, Sensitivity = 0.947
- Class 3: Accuracy = 0.987, Sensitivity = 0.987
- Class 4: Accuracy = 0.980, Sensitivity = 1.000

The overall performance is listed below.

- Overall Accuracy: 0.930
- Overall Precision: 0.928
- Overall Specificity: 0.953

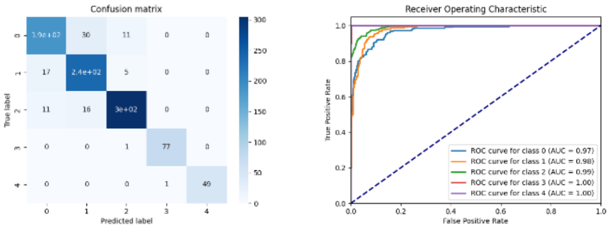

Fig. 5. Evaluation results with respect to Dataset 04.

3) Evaluation of model with respect to Dataset 05: The results gained by testing the stage classification model on different variations of Dataset 03 and the confusion matrix and ROC curve are calculated to evaluate the performance of the model (see Fig. 6).

The accuracy and sensitivity of the test have been calculated for each class individually, and the results are presented below.

- Class 0: Accuracy = 0.894, Sensitivity = 0.839
- Class 1: Accuracy = 0.912, Sensitivity = 0.881
- Class 2: Accuracy = 0.880, Sensitivity = 0.954
- Class 3: Accuracy = 0.974, Sensitivity = 0.950
- Class 4: Accuracy = 0.980, Sensitivity = 0.980

The overall performance is listed below.

- Overall Accuracy: 0.905
- Overall Precision: 0.921
- Overall Specificity: 0.950

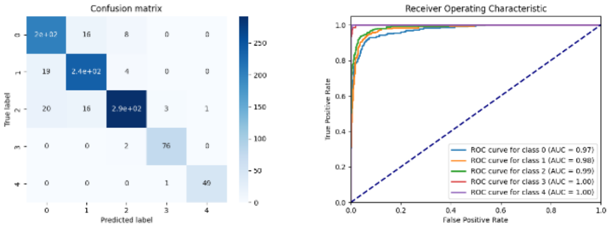

Fig. 6. Evaluation results with respect to Dataset 05.

4) Evaluation of model with respect to Dataset 63: The results gained by testing the stage classification model on different variations of Dataset 03 and the confusion matrix and ROC curve are calculated to evaluate the performance of the model (see Fig. 7).

The accuracy and sensitivity of the test have been calculated for each class individually, and the results are presented below.

- Class 0: Accuracy = 0.717, Sensitivity = 0.860
- Class 1: Accuracy = 0.825, Sensitivity = 0.780
- Class 2: Accuracy = 0.892, Sensitivity = 0.754
- Class 3: Accuracy = 0.908, Sensitivity = 0.732

- Class 4: Accuracy = 0.647, Sensitivity = 0.951

The overall performance is listed below.

- Overall Accuracy: 0.798
- Overall Precision: 0.815
- Overall Specificity: 0.939

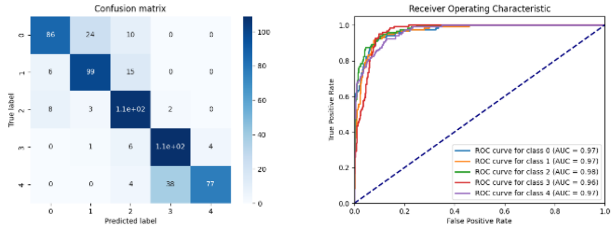

Fig. 7. Evaluation results with respect to Dataset 06.

B. *Evaluation of Lesion Detection*

To evaluate the effectiveness of a lesion detection method on a dataset of fundus images containing retinal lesions, an initial attempt was made to engage a medical professional to manually inspect the lesions. However, this approach proved unsuccessful due to several reasons. As an alternative, the Indian Diabetic Retinopathy Image Dataset (IDRiD) was discovered, which provided annotated ground truths of the lesions by a clinician. A 5x5 pixelation approach was adopted to facilitate the comparison between the detected lesions and the ground truth markings. The method's performance was evaluated by measuring true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN), and accuracy was calculated accordingly. Masks were generated using the IDRiD dataset, and these masks were compared to the ground truth markings to assess the performance of the lesion detection method.

1) Evaluation results by detection of exudates: This test was done on 27 images of the Indian Diabetic Retinopathy Image Dataset (IDRiD). Evaluation results by Detection of Exudates are given in Table 2.

TABLE II. EVALUATION RESULTS ON DETECTION OF EXUDATES

	Segments classified as Exudates	**Segments classified as normal**
Exudates	1005	790
Normal	1332	230728

TABLE III. EVALUATION RESULTS ON DETECTION OF MICROANEURYSMS AND HEMORRHAGES

	Segments classified as Microaneurysms and Hemorrhages	**Segments classified as normal**
Microaneurysms and Hemorrhages	546	2820
Normal	1173	344443

- Sensitivity: 0.560
- Specificity: 0.994
- Accuracy: 0.990

2) Evaluation results by detection of evaluation results by detection of microaneurysms and hemorrhages: This test was done on 27 images of the Indian Diabetic Retinopathy Image Dataset (IDRID). Evaluation results by Detection of Microaneurysms and Hemorrhages are given in Table 3.

- Sensitivity: 0.318
- Specificity: 0.992
- Accuracy: 0.989

C. *Discussion*

To enhance the features in fundus images, there are several effective pre-processing techniques that can be employed. A crucial step involves removing the background and centering the image, which helps to bring attention to the important regions while eliminating unnecessary distractions. Another valuable method is normalizing the fundus images using a reference image, ensuring consistent brightness and contrast for accurate comparisons. Enhancing the image on RGB channels and intensity channel in HSI format can improve overall image quality by employing CLAHE. By applying median blur, any remaining noise or artifacts can be further reduced, resulting in a cleaner image. Lastly, image augmentation, which involves techniques like random rotation, shifting the image horizontally and vertically, Shearing and Horizontal flips introduces variations to the training set, enabling the model to learn more robust features. By incorporating these pre-processing methods, the features in fundus images can be effectively enhanced, leading to more accurate and reliable analysis.

Based on the information provided, a ResNet50V2 model, which is a pre-trained CNN, was used for stage classification. This model achieved an impressive accuracy of 93.45% when evaluated on 900 augmented images from the Messidor-2 and Kaggle datasets. This suggests that a CNN-based model like ResNet50V2 can be highly effective for stage classification tasks in this context.

After conducting hyperparameter tuning on the pre-trained ResNet50V2 model for stage classification, the most suitable combination of hyperparameters was determined. The best results were obtained with a learning rate of 0.00001, 3 hidden layers, and 230 neurons in each hidden layer. This configuration maximized the model's learning capacity and allowed it to capture the complex patterns and relationships present in the stage classification task. Hyperparameters such as learning rate and network architecture can significantly impact the performance of a CNN model. By carefully selecting and optimizing these hyperparameters, the model's accuracy and ability to classify different stages can be enhanced.

After experimenting with three different approaches - K-means approach, Canny Edge detection approach, and Recursive Region Growing approach - it was determined that the Recursive Region Growing approach is the most suitable method for correctly identifying the locations of Exudates. Among the three approaches, Recursive Region Growing demonstrated superior performance in accurately detecting and delineating the regions of Exudates in the images. The Recursive

Region Growing method, based on a seed point and specific criteria for region expansion, effectively identifies and segments the Exudates areas with a higher level of precision.

To accurately identify the locations of Microaneurysms and Hemorrhages, the Kmeans clustering approach can be employed, along with the Elbow method to dynamically determine the optimal value of K for each fundus image. By finding the” elbow” point on the resulting plot, the optimal K value can be determined for accurate identification of the locations of Microaneurysms and Hemorrhages.

VI. Conclusion

In conclusion, we have successfully developed an affordable computer-assisted analysis system for accurate assessment of diabetic retinopathy status by utilizing Kaggle and Messidor-2 public datasets, along with an augmented dataset. We trained a ResNET50v2 model was trained using Bayesian Optimization for hyperparameter tuning. Our model achieved an accuracy of more than 0.9 for stage classification. Our application, Seer, utilizes this model to classify fundus images and provide a detailed report on DR class and lesions, which has the potential to significantly improve the detection and management of DR. Our research highlights the need for accessible solutions for DR analysis and the potential benefits of technological innovation in healthcare. We hope that our work inspires further development of cost-effective solutions for DR analysis, leading to improved patient outcomes.

VII. Future work

In future work, one of the key areas to focus on is the accurate detection and differentiation of Microaneurysms and Hemorrhages from blood vessels. This requires addressing the challenge of their similarity and developing new techniques that can effectively localize blood vessels and distinguish these lesions. Advanced image processing algorithms, feature extraction methods, and deep learning architectures could be explored to achieve this goal. Improving the accuracy of detecting hemorrhages and microaneurysms is another important aspect for future research. This can involve refining the existing algorithms to better identify red-colored and addressing limitations such as the algorithm’s inability to detect hemorrhages near blood vessels. Further studies can be conducted to enhance the performance of these detection methods.

For stage classification, incorporating higher resolution images in the model training process could be a potential improvement. Although it would require more computational resources, training the model on higher resolution images can enable the capture of finer details and subtle features associated with distinct stages. This can potentially lead to improved accuracy in stage classification. To facilitate standardized evaluation of lesions, the implementation of a standardized method is crucial. This would ensure consistency in the evaluation process across different studies and research efforts. A standardized method for evaluating lesions would allow for better comparison and benchmarking of different algorithms, models, or techniques, advancing the field.

These future works highlight the ongoing efforts and areas of focus in improving the detection and classification of Microaneurysms, Hemorrhages, and other relevant abnormalities in fundus images. By addressing these challenges and advancing the state-of-the-art techniques, we can achieve more accurate diagnoses and provide improved patient care in the field of Diabetic Retinopathy management.

Acknowledgment

We use this opportunity to express our greatest gratitude to Mr. A. Dinesh Madushanka Silva (Optometrist) who dedicated his valuable time to this research and helped us to enhance our domain knowledge in this area. We would also like to acknowledge with much appreciation to our parents and colleagues for their consistent support and their inclusion.

Machine Learning Approaches for Predicting Occupancy Patterns and its Influence on Indoor Air Quality in Office Environments

Amir Hamzah Mohd Shaberi[1], Sumayyah Dzulkifly[2]*, Wang Shir Li[3], Yona Falinie A. Gaus[4]
Faculty of Computing and Meta-Technology, Sultan Idris Education University, Perak, Malaysia[1, 2, 3]
Centre of Embedded Education Green Technology (EduGreen@UPSI), Sultan Idris Education University, Perak, Malaysia[2]
Department of Computer Science, Durham University, Durham, United Kingdom[4]

***Abstract*—It is normal for the modern population to spend 12 hours or more daily indoors where the level of comfort can be moderated. Yet, indoor occupants are similarly exposed to various air pollutants just as outdoors. Indoor air pollution could be detrimental toward the occupant's health noted by the United Nation Environment Programme (UNEP) in the Pollution Action Note, published on 7th of September 2021. According to the American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE) standards, occupancy patterns could influence indoor air quality. Hence, this paper investigates the utilisation of machine learning algorithms in predicting occupancy patterns against indoor air quality (IAQ) variables such as humidity, temperature, light, and carbon dioxide (CO_2). This study compares the performance of selected machine learning approaches, namely deep learning (LSTM, CNN), regression (ANN) and (SVR) models. In addition, it explores the diverse range of evaluation metrics utilized to evaluate the performance of machine learning in the specific context of Mean Squared Error (MSE) and Mean Absolute Error (MAE). In the training phase, the SVR model achieved the lowest MAE of 0.0826 and MSE of 0.0280 as compared to the other algorithms. The ANN model demonstrated slightly better generalization capabilities in the testing phase, while the LSTM model demonstrated robust performance in the test phase. Overall, the results highlighted the significant impact of occupancy behaviour on Indoor Air Quality (IAQ) variables and underscored the importance of advanced modelling techniques in IAQ monitoring and management, emphasizing the need for tailored approaches to address the complex relationship between occupancy patterns and IAQ variables.**

Keywords*—Indoor air quality; occupancy patterns; machine learning; deep learning; regression models; Mean Squared Error; Mean Absolute Error; IAQ monitoring; IAQ management

I. INTRODUCTION

Indoor air quality (IAQ) is a critical component in maintaining occupants' health, impacting the well-being of both the humans and the interior ecosystems. Prolonged exposure to harmful substances in the air could lead to persistent discomfort, severe illnesses, and could lead to respiratory attributed deaths annually [1]. Compromised air quality encompasses of various factors, which includes, but not limited to the concentration of pollutants, such as the cleaning supplies and the building materials [2], the indoor humidity levels [3], the temperature control [4] and the adequacy of the ventilation systems [5]. Unhealthy working space for indoor occupants due to poor IAQ can lead to a range of health issues, such as respiratory problems [6-7], asthma [8] and fatigue [9], which can impact their productivity and overall well-being.

The ability to monitor and control IAQ is essential for building managers to identify potential issues and implement corrective measures [9]. Yet, to some, comprehensive installation of indoor sensing system could incur a hefty cost which could discourage the motivation to maintain healthy indoor air quality. The variation of indoor air quality with respect to the occupancy pattern could lead to complex data analysis which requires the use of machine learning to study their linear or non-linear relationships. In recent years, the integration of machine learning techniques has emerged as a promising avenue for predicting and optimizing air quality, in general. Additionally, as societies grapple with the consequences of air pollution, understanding the effectiveness of machine learning models in this context is imperative [10].

As indoor air pollution (IAP) poses a major risk to human health and is responsible for millions of deaths annually, preserving a good IAQ is significant for the health sector [11]. The intersection studies of IAQ and machine learning have garnered significant attention in recent years as researchers explore innovative ways to leverage machine learning techniques to enhance indoor air quality monitoring and management. For example, authors in the study [11], state that machine learning technologies are highly capable of providing real-time indoor air quality monitoring, which is essential for determining and managing indoor air pollutants. In addition, [12] also states that sets of algorithms are utilized to extract and filter general principles from massive datasets, allowing for the automated learning of user preferences in relation to the IAQ.

Despite of this, there is a gap in current literatures, specifically in terms of the employment of machine learning techniques to predict occupancy patterns within the context of indoor air quality management. While previous studies have highlighted the potential of machine learning for real-time monitoring and general data analysis, few have focused on its application to predict occupancy patterns, which can be crucial for understanding indoor air quality dynamics. Therefore, this study aims to fill this gap by investigating the effectiveness of machine learning approaches in predicting occupancy patterns based on variables such as humidity, temperature, light, and carbon dioxide (CO_2). In addition, this study will determine which algorithms performed better and using selected evaluation metrics, namely, the Mean Squared Error (MSE) and Mean Absolute Error (MAE).

The paper is organized into five main sections, namely the Introduction in Section I**,** where the overall background of the research is elaborated; the Literature Review in Section II, which provides extensive reviews on deep learning, regression, classification model, and the relationship between IAQ and occupancy behaviour; the Methodology in Section III, which elaborates on the data acquisition, data training, data testing and selected machine learning algorithms' evaluation approaches; the Results and Analysis in Section IV, which provides in depth evaluations and discussions on the overall analysis of this study; and Conclusion in Section V, which sums up the investigation and highlights the key topics of this study.

II. Literature Review

A. Comparison between Deep Learning, Regression and Classification Models.

IAQ monitoring is a critical aspect of ensuring healthy and comfortable indoor environments, particularly in settings such as homes, offices, and schools [13]. With the increasing prevalence of indoor air pollutants and their impact on human health, there is a growing need for advanced predictive models to accurately monitor and forecast occupancy patterns because occupancy patterns are closely related to the variables of IAQ. In this comparison models, this study delves into the field of deep learning, regression, and classification models, exploring their method and capabilities in the context of occupancy patterns prediction.

1) Deep learning model. Deep learning, a subset of machine learning, has emerged as a powerful tool for processing complex data and extracting meaningful patterns [14]. By leveraging deep neural networks, deep learning models can effectively analyze large volumes of IAQ data, including particulate matter (PM) [15–18] volatile organic compounds (VOCs) [17], CO_2 [17], and sulfur dioxide (SO_2) [19, 20], to provide real-time insights into IAQ levels. These models can learn intricate relationships within the data, enabling them to make accurate predictions and identify potential IAQ issues before they escalate. However, for specific occupancy patterns [21] mentioned that predictions for occupancy were carried out using various deep learning architectures, such as Deep Neural Network (DNN), Long Short-Term Memory (LSTM), Bi-directional LSTM (Bi-LSTM), Gated Recurrent Unit (GRU), and Bi-directional GRU (Bi-GRU), in different settings like an office, library and lecture room. The results demonstrated that the feature selection algorithm proposed performed better than a commonly used one, leading to higher model performance while requiring fewer sensors.

Other than that, from 11 studies [15–20, 22–26] employing various architectures such as long short-term memory (LSTM), Convolutional Neural Network (CNN), unique combinations like Combined Self-Attention (SA) mechanism, Empirical Mode Decomposition (EMD) algorithm and LSTM network (SA–EMD–LSTM) with Ensemble Empirical Mode Decomposition-Sparrow Search Algorithm (EEMD-SSA-LSTM). The performance metrics for these studies include Mean Absolute Error (MAE), Root Mean Squared Error (RMSE), Symmetric Mean Absolute Percentage Error (SMAPE), Mean Absolute Percentage Error (MAPE), Index of Agreement (IA), Theil Inequality Coefficient (TIC), coefficient of determination (R2) and Absolute Average Deviation. This diversity in metrics underscores the complexity and multifaceted nature of evaluating deep learning models in the context of air quality prediction, considering both spatial and temporal aspects.

2) Regression model. Regression models, on the other hand, are well-suited for predicting continuous IAQ variables, such as PM concentration [27], temperature [28] or occupancy pattern [29] based on historical data and other relevant variables. By fitting a regression model to IAQ data, regression model can create a mathematical equation that describes the relationship between the input variables and the output [30], allowing to make predictions with a high degree of accuracy.

For example, six studies [27, 28, 31–34] employ diverse techniques such as Artificial Neural Network (ANN), Extra Trees Regressor, Wavelet Artificial Neural Network, and Support Vector Regression (SVR). Evaluation metrics for these models include MAE, RMSE, SMAPE, MAPE, and Pearson correlation coefficient (R). The inclusion of regression models adds a valuable dimension to the literature, as these models provide insights into continuous air quality prediction. In addition, the study in [29] also states linear and logistic regression models were created using the variables to forecast occupant activity schedules and the probability of occupant presence.

3) Classification models. Classification models are particularly useful for identifying discrete IAQ states, such as air quality categories (e.g., good, moderate, poor) or the presence of specific pollutants [35]. These models classify IAQ data into different classes based on their characteristics, enabling us to categorize IAQ levels and take appropriate actions to improve indoor air quality. Previous study primarily leverages random forest [31, 36–38] and decision tree [32] while employing a range of evaluation metrics such as specificity, precision, recall, accuracy, F1 score, area under the ROC Curve (AUC), and sensitivity. This reflects a robust assessment strategy to measure the performance of these models in predicting air quality.

While it is possible for a classification model to estimate the occupancy patterns, there are some important considerations and limitations. In a typical classification problem, the goal is to predict the class label of an observation based on its features. So, this study will not include classification models, as the focus is on utilizing deep learning and regression models, which are deemed more important for the study.

B. Relationship between IAQ and Occupancy Behavior

The relationship between IAQ and occupancy behavior is complex and symbiotic. The way in which occupants use spaces, their activities, and their preferences all have an impact on the IAQ, which includes temperature, humidity, and pollutants [39]. Occupancy behavior plays a crucial role in determining pollutant emissions, ventilation needs and desired comfort levels. For instance, spaces with more occupants engaged in activities that generate pollutants may necessitate higher ventilation rates [40]. Managing IAQ effectively involves comprehending these interconnections and devising strategies that could harmonise occupants' behavior while maintaining optimal indoor air quality.

To encourage a healthier indoor environment, a comprehensive strategy that considers both IAQ variables and occupancy behavior is imperative. According to [41], architectural designs should cater to varied activities and occupant densities, optimizing factors like temperature control to curb discomfort and air stagnation. Incorporating intelligent building technologies to monitor and regulate IAQ variables in real time based on occupancy patterns can further amplify the interplay between IAQ and occupant behavior [42]. Ultimately, cultivating an atmosphere where occupants are conscientious about their actions and where IAQ commands shared attention can culminate in an enhanced IAQ and overall well-being.

Given the intricate relationship between IAQ and occupancy behavior, this study aims to predict occupancy patterns in relation to selected IAQ variables. Understanding how occupants utilize spaces and engage in activities that affect IAQ variables like temperature, humidity, and pollutant levels is crucial for effective IAQ management. By leveraging the predictive modelling, this study seeks to develop insights into how occupancy patterns influence the IAQ dynamics, ultimately contributing to strategies that enhance the indoor environmental quality and occupant well-being.

III. Methodology

In the context of predicting occupancy patterns, the model training for deep learning and regression models can be similar, as both approaches aim to predict occupancy based on input variables such as temperature, humidity, light and CO_2 levels. The phase would involve several steps as shown in the Fig. 1 below. However, the specific implementation details and the model architectures would differ between the deep learning and regression, depending on the algorithms used. To choose a better algorithm that suited the aim of this study, data collection, data pre-processing, model training and testing, and model evaluation will be conducted. Fig. 1 below shows the phases involved in this study to predict occupancy pattern in relation to the IAQ variables.

A. Phase 1 (Data Collection)

For the data collection stage, the historical data for the variables such as temperature, humidity, light, CO_2, and occupancy will be gathered. It is crucial to ensure that the data is representative and covers a wide range of values to capture the variability of the IAQ. This comprehensive dataset will serve as the foundation for training and evaluating the deep learning and regression models for predicting occupancy patterns. This study addresses key variables present in office room environment, with a focus on identifying an acceptable range for these variables that may pose health risks to occupants if exceeded.

B. Phase 2 (Data Pre-Processing)

In the data pre-processing phase, the input features were normalized to ensure data consistency. This normalization step is crucial for deep learning and regression models, as it helps to prevent features with larger scales from dominating the training process. Additionally, the data were split into the training (70%) and the testing sets (30%). The training set was used to train the models, while the testing set was used to evaluate their performance. This split is essential to assess how well the generalization of the models were towards unseen data and to prevent overfitting. Overall, these preprocessing steps help to ensure the models can effectively learn from the data.

C. Phase 3 (Model Training and Testing)

This stage implements a custom callback, ‘MetricsCallback’, to calculate and print MAE and MSE during the training and testing phases of LSTM, CNN, and ANN models. This callback was used to monitor the model's performance on the training and the validation sets. However, the SVR model is not a neural network and therefore does not use the same training process. For such case, the MAE and the MSE were calculated manually after the training completed.

The training process involves splitting the dataset into the training and the testing sets, scaling the features, and reshaping the data for the LSTM and CNN models. The models are then compiled and trained using the fit method, with the callback used to print the loss, the MAE, and the MSE at the end of each epoch. The detailed machine learning parameters used for each model are as follows:

LSTM Model

- Sequential model with an LSTM layer (64 units) and a dense output layer.
- Compiled with Mean Squared Error (MSE) loss and Adam optimizer.
- Trained for 50 epochs with a batch size of 32.
- Validation data is specified for monitoring performance during training.
- Callback is used to monitor and print MAE and MSE during training and validation.

CNN Model

- Sequential model with a 2D convolutional layer (32 filters, 2x2 kernel size, ReLU activation), a flattening layer, and a dense output layer.
- Compiled and trained similarly to the LSTM model.

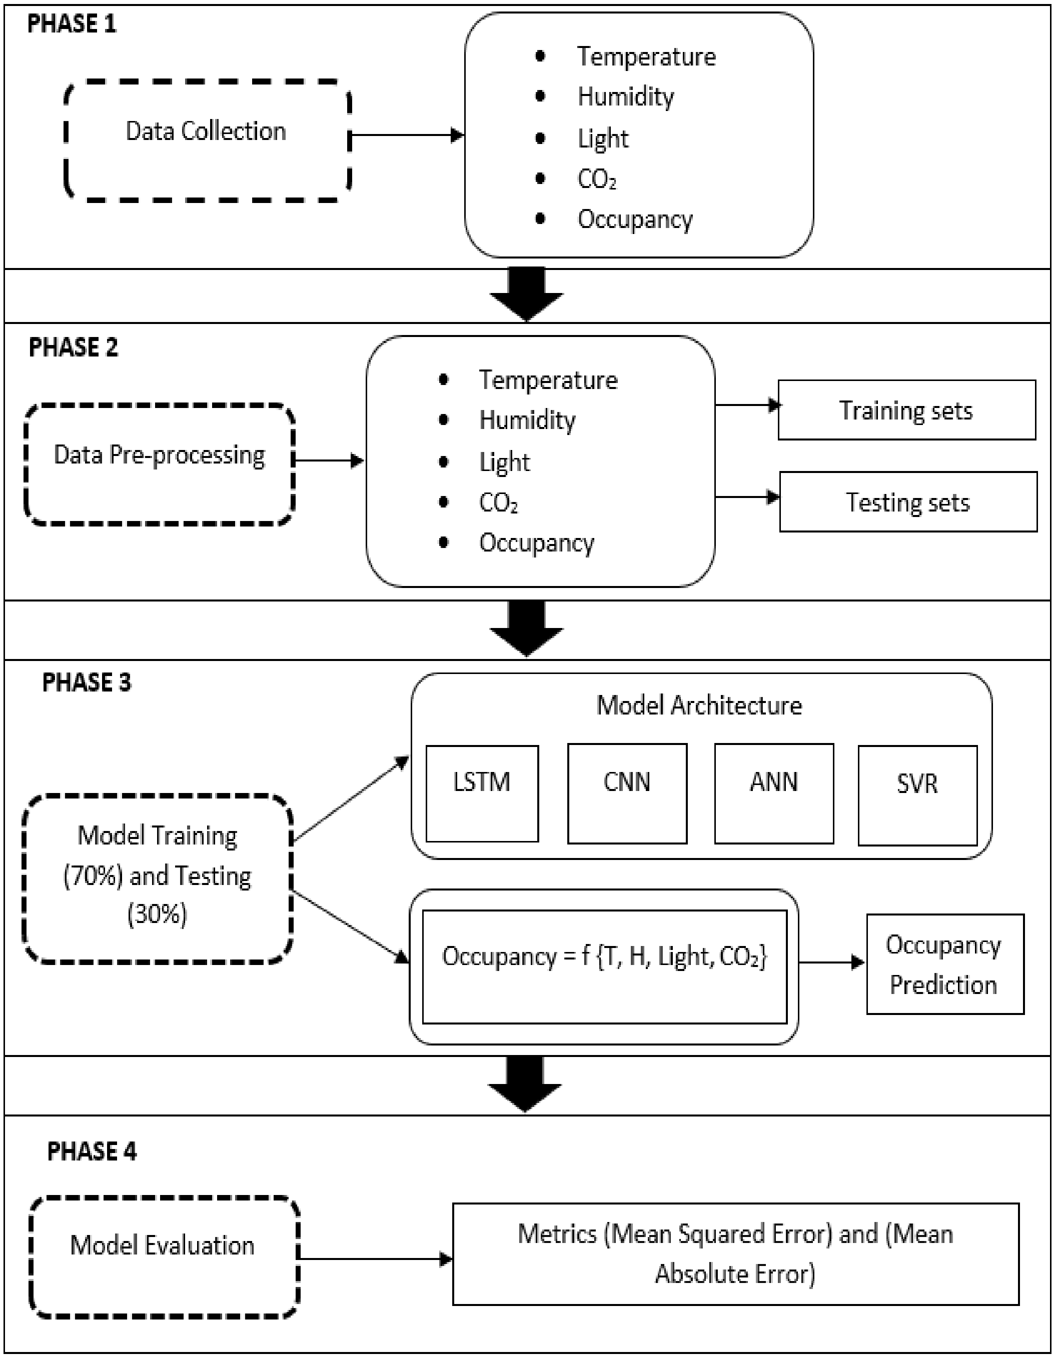

Fig. 1. Phases of predicting occupancy pattern.

ANN Model (Regression)

- Sequential model with two dense layers (64 units, ReLU activation) and a dense output layer.
- Compiled and trained similarly to the LSTM and CNN models.

SVR Model

- SVR model trained separately using the SVR class from scikit-learn.
- Does not use the custom callback as it does not follow the same training process as neural networks.

Once the models completed the training and testing stage, they were evaluated using the MAE and the MSE to observe the difference in term of the performance. This approach provides a comprehensive analysis of the models' performance, allowing a comparison for their ability to predict occupancy pattern based on the given IAQ variables.

D. Phase 4 (Model Evaluation)

For model evaluation, the trained model is assessed using the testing dataset to gauge its performance in predicting occupancy. Metrics such as the Mean Squared Error (MSE) and the Mean Absolute Error (MAE) are used. The MSE provides a measure of the average squared difference between the predicted occupancy values and the actual values, offering insight into the model's overall accuracy.

$$\text{MSE} = \frac{1}{n}\sum_{i=1}^{n} (yi - \bar{y}i)^2 \quad (1)$$

where:

- n is the number of observations.
- yi is the actual value of the target variable for the i-th observation.
- $\bar{y}i$ is the predicted value of the target variable for the i-th observation.

On the other hand, the MAE measures the average absolute difference between the predicted and the actual values, providing an indication of the model's precision. These metrics collectively offer a comprehensive assessment of the model's performance in predicting occupancy values.

$$\text{MAE} = \frac{1}{n}\sum_{i=1}^{n} |yi - \bar{y}i| \quad (2)$$

where:

- n is the number of observations.
- yi is the actual value of the target variable for the i-th observation.
- $\bar{y}i$ is the predicted value of the target variable for the i-th observation.

IV. Results and Discussion

The discussion for this study focused on comparisons between the prediction results of various machine learning algorithms for occupancy patterns based on IAQ variables including an analysis of their time and memory complexities. In addition, this study also explores the impact of occupancy behavior on IAQ variables. Key findings included the effectiveness of certain algorithms in predicting occupancy patterns and how changes in IAQ variables were influenced by occupancy.

A. Prediction Results for Training and Testing Data Across Different Machine Learning Models

Comparing the training and the testing results is essential in machine learning to assess how well a model performs in analyzing the data. Study by [43] mentioned that during the training, a model learns to map input features to output labels using the provided data. However, this process can lead to overfitting, where the model memorizes the training data instead of learning the underlying patterns. By evaluating the models' performance on a separate testing dataset, one can gauge its ability to generalize. Discrepancies between training and testing results indicate potential overfitting, highlighting the need for adjustments such as hyperparameter tuning [43]. Additionally, comparing results helps in model selection, as the best-performing model on testing data is typically chosen for deployment.

Tables 1 and 2 compare the performance of four different models (LSTM, CNN, ANN, SVR) in the training and the testing phases using the MAE and the MSE metrics. In the training phase (see Table 1), the SVR model achieved the lowest MAE, namely 0.0826 and MSE of 0.0280, indicating better performance in predicting occupancy pattern based on the input features (CO_2, Light, Temperature, Humidity) compared to the other models. The ANN model also performed well, with a MAE of 0.0940 and MSE of 0.0353, followed by the CNN and LSTM models.

In the testing phase (see Table 2), the ANN model demonstrated the best performance, achieving the lowest MAE 0.0834 and MSE 0.0364. This indicates that the ANN model was more accurate in predicting occupancy pattern on unseen data compared to the other models. The CNN model also performed well in the testing phase, with an MAE of 0.0866 and MSE of 0.0385, followed by the LSTM and SVR models.

TABLE. I. Comparison of MAE and MSE for Training Data

Model	MAE	MSE
LSTM	0.1153	0.0474
CNN	0.1024	0.0419
ANN	0.0940	0.0353
SVR	0.0826	0.0280

TABLE. II. Comparison of MAE and MSE for Testing Data

Model	MAE	MSE
LSTM	0.0977	0.0420
CNN	0.0866	0.0385
ANN	0.0834	0.0364
SVR	0.0968	0.0411

Overall, the ANN and CNN models demonstrated robust performance in predicting the occupancy patterns, with the ANN model showing slightly better generalization capabilities in the testing phase.

B. Complexity Analysis: Time and Memory

Table 3 below provides the time and memory complexities for each of the models used in this study. For the time complexity, it is measured in seconds and represents the duration taken by each model to complete the training process. The LSTM model took the longest time at 0.2044 seconds, followed closely by the CNN model at 0.1921 seconds. The ANN model was next, at 0.1342 seconds, and the SVR model was the fastest at only 0.0156 seconds. These time complexities give an indication of how efficiently each model can process and learn from the training data.

In terms of memory complexity, measured in MiB (Mebibytes), it represents the peak memory usage during the training process. Interestingly, all three models (CNN, ANN, and SVR) exhibited very similar memory usage, ranging from approximately 723 MiB to 738 MiB. This suggests that these models require a similar amount of memory to store and process the data during training. The LSTM model, on the other hand, showed a slightly higher memory usage of 738.836 MiB, indicating that it may require a bit more memory compared to the other models.

Overall, these complexities provide insights into the efficiency and resource requirements of each model, which can be valuable for selecting the most suitable model for a given application based on computational resources and time constraints.

TABLE. III. TIME AND MEMORY COMPLEXITY COMPARISON FOR EACH MODEL

Model	Time Complexity (s)	Memory Complexity (MiB)
LSTM	0.2044	738.836
CNN	0.1921	723.012
ANN	0.1342	723.246
SVR	0.0156	723.086

C. Exploring the Impact of Occupancy Behavior on Indoor Air Quality Variables

The comparison of machine learning algorithms for predicting occupancy patterns based on IAQ variables provided valuable insights into their effectiveness and efficiency. The study focused on four models: LSTM, CNN, ANN, and SVR, evaluating their performance using MAE and MSE metrics in both training and testing phases.

In the training phase, the SVR model exhibited the lowest MAE and MSE, indicating superior performance in predicting occupancy patterns. The ANN model also performed well, followed by the CNN and LSTM models. However, in the testing phase, the ANN model demonstrated the best performance, achieving the lowest MAE and MSE. This suggests that the ANN model was more accurate in predicting occupancy patterns on unseen data, highlighting its superior generalization capabilities compared to the other models.

Furthermore, the study analyzed the time and memory complexities of each model. The LSTM and CNN models exhibited longer training times compared to the ANN and SVR models. In terms of memory complexity, all models (CNN, ANN, and SVR) showed similar memory usage, while the LSTM model required slightly more memory. These complexities provide insights into the computational efficiency and resource requirements of each model, which are crucial considerations for real-world applications.

Overall, these findings underscore the importance of selecting the right machine learning model for predicting occupancy patterns based on IAQ variables. The study's results can guide future research in optimizing IAQ monitoring systems and prediction algorithms, ultimately leading to improved indoor air quality and occupant comfort.

V. CONCLUSION AND FUTURE ENHANCEMENT

This study demonstrates the importance of considering occupancy behavior in predicting IAQ patterns. The results highlight the effectiveness of machine learning algorithms, particularly ANN and CNN, in accurately predicting occupancy patterns based on IAQ variables. ANN emerged as the most accurate algorithm, followed by CNN, LSTM and SVR. These findings underscore the significance of advanced modeling techniques in IAQ monitoring and management, emphasizing the need for tailored approaches to address the complex relationship between occupancy behavior and IAQ variables. In addition, integrating machine learning models into IAQ management strategies can lead to improved indoor environmental quality and occupant well-being.

This study also highlights the promising potential of relationship between IAQ variables and occupancy pattern. This study uses machine learning algorithms in predicting occupancy patterns within office room environments. This research aims to address this deficiency by examining how machine learning methods can predict occupancy patterns using factors like humidity, temperature, light, and CO_2 levels. If the IAQ variables increase, it aims to determine if there's a corresponding increase in occupancy in room environments. It will also identify the most effective algorithms for this task and explore the various evaluation metrics, particularly focusing on MSE and MAE.

Despite the successes observed, it's essential to acknowledge the limitations inherent in this study, particularly the reliance on data collected from external sources rather than proprietary datasets specific to the office building under investigation. The occupancy value is binary, either 0 or 1, which means the prediction can only predict these two states. Secondly, the data size and variables may not be sufficient to provide highly accurate results. Lastly, in this study, there is no available measurement of the room space, which is imperative when studying the impact of IAQ against occupancy pattern.

Future enhancements could involve obtaining proprietary datasets specific to the office building under investigation. This can provide more accurate and relevant data for analysis. Then, increase the dataset size by collecting more data over a longer period. Additionally, consideration could be made to add more variables that may impact indoor air quality and occupancy patterns. This study must consider using indirect methods to estimate occupancy, such as analyzing patterns of other variables that are correlated with occupancy, like motion sensors. Lastly, to calculate the volume of the space, typically need the dimensions of the room (length, width, and height). If there have access to the physical space, it can measure these dimensions directly.

***Abstract*—Personality traits, the unique characteristics defining individuals, have intrigued philosophers and scholars for centuries. With recent advances in machine learning, there is an opportunity to revolutionize how we understand and differentiate personality traits. This study seeks to develop a robust cluster analysis approach (unsupervised learning) to efficiently and accurately classify individuals based on their personality traits, overcoming the limitations of manual classification. The problem at hand is to create a system that can handle the subjective nature of qualitative personality data, providing insights into how people interact, collaborate, and behave in various social contexts and thus increase learning opportunities. To achieve this, various unsupervised clustering techniques, including spectral clustering and Gaussian mixture models, will be employed to identify similarities in unlabeled data collected through interview questions. The clustering approach is crucial in helping policy makers to identify suitable approaches to improve teamwork efficiency in both educational institutions and job industries.**

***Keywords*—Unsupervised learning; learning opportunities; clustering; personality; machine learning; Gaussian mixture model; spectral clustering**

I. Introduction

Personality traits have been discussed among people and philosophers since the early ages. Personality traits are a set of characteristics and attributes that define the uniqueness of an individual. People have unique personality traits that experts agree are the result of traits mixed with learnt behaviors [1]. Throughout history, fellow philosophers such as Aristotle, Theophrastus, and many others have studied human behaviors and tried to make sense of them. For example, Aristotle used vanity, modesty, and cowardice as factors of moral and immoral behavior [2]. Until now, many efforts have been made to understand how humans function and how their personality and social behaviors correlate with each other using various methods such as psychology testing, surveys and questionnaires, social experiments, computer modeling, and simulations.

With recent advances in Machine Learning technology, there is an opportunity to improve the accuracy of differentiating people with different personality traits. Such systems enable people to understand how others communicate, collaborate, manage stress, and many more. This allows them to have a better grasp of how to resolve conflicts better and communicate more effectively. By creating a personality recognition system, we can create different styles of teaching, coaching, leading, communicating, and many more [3]. For example, where personality traits affect workplaces, by understanding more about our peers, we can build a more cohesive team as we can understand how they work and how we can work with them. A unique personality is like a double-edged sword. Sometimes, it can increase the whole team's synergy and increase efficiency, and sometimes it can be the chisel that tears the whole team apart. It is okay to have people with different personalities working together, but the major concern is the way to communicate with different people to avoid conflicts within the team. Therefore, we must consider personality traits to increase efficiency, synergy, and a more dynamic and cohesive team [4].

Based on previous related work, the researchers had attempted to classify and analyze personality traits manually. This has led to several issues where identifying personality traits requires a large amount of time, making it inefficient to analyze a large group of people [5]. Due to the problem stated above, it is necessary to combine the technology of computer science with the study of personality psychology to increase the efficiency and precision of identifying different personality traits to personalize e-learning [6]. Furthermore, personality traits are difficult to analyze as it is qualitative data that are subjective to individuals rather than quantitative data which represents numerical facts [7], [8], [9]. Today, unsupervised machine learning methods such as clustering are commonly used to group people with similar personality traits into a group of clusters. For example, a study by Feng et al. (2008) used fuzzy clustering analysis based on the common characteristics to create a personalized study strategy [10].

Clustering Analysis is where the computer tries to identify a structure or similar pattern in unlabeled data. Cluster is an important term in cluster analysis, where a cluster is a collection of similar items. There are a few commonly used clustering methods such as Hierarchical Clustering, which identifies different clusters using a tree-shaped structure known as the dendrogram, Partitional Clustering such as k-means clustering, where the algorithm reallocates items to an initially specified number of groups and density-based clustering, such as DBSCAN algorithm which is used to discover randomly shaped clusters [11]. These methods can be used to differentiate the different types of personality based on different characteristics and categories such as questions about phobias and personality traits.

Understanding and characterizing human personalities is critical in today's interconnected society, from human resources and marketing to healthcare and social sciences. However, the existing analysis of personality traits is mainly dependent on manual classification and subjective interpretation, leading to inefficiencies and possible biases, particularly for large and diverse populations. Therefore, there is an urgent need for a more efficient and accurate personality recognition system that uses machine learning technology. The major problem is to create a robust clustering analysis approach that can handle qualitative data, which is inherently subjective and complicated. The proposed clustering techniques can divide people into distinct groups based on their personality traits, providing valuable information on how people interact, collaborate, and behave in different social circumstances.

This technology can alter how we understand human behavior, improve decision-making processes, and promote personalized experiences and services by taking a data-driven and objective approach to personality assessment. However, careful consideration of ethical and privacy problems and validation with psychiatric experts are required for the appropriate development and implementation of such a system. In this context, future research should look at novel ways to integrate qualitative and quantitative data, addressing cross-cultural differences, and ensuring the system's interpretability and fairness to enable significant applications across various areas.

This study aims to identify similarities in unlabeled data related to personality traits using unsupervised clustering methods. Various clustering techniques will be utilized to group different personality traits according to interview questions. For instance, clustering techniques include Spectral Clustering, Ordering Points To Identify the Clustering Structure (OPTICS), K-modes, Gaussian Mixture Model, and Affinity Propagation. We can validate the precision and effectiveness of the personality traits for each clustering technique after training, testing and evaluating those models. Therefore, we can advance our understanding of human behavior and personality traits through data-driven approaches.

This paper is constructed with the following sections. Section II presents the latest studies and research on clustering personality using different algorithms. Section III explains the research methodology design. This is followed by Section IV which discusses the result and finally Section V concludes the study with limitations and future works.

II. Literature Review

A. Spectral Clustering

Spectral clustering has become more common recently as it is a simple algorithm to implement and does not require a large amount of resources to process the algorithm [12]. There are a few pros and cons regarding spectral clustering. For example, this algorithm applies to data with high dimensionality, and it also handles categorical variables well as it can calculate the similarity between data points by using an eigenvector instead of using distance to calculate the data points, which is crucial to our research. On the other hand, spectral clustering is relatively slow compared to other traditional algorithms such as k-mean clustering and we are required to determine the k-value of the spectral clustering algorithm, which may be hard if we do not have an intuition on the number of clusters a dataset should have [13], [14].

The algorithm falls into the category of clustering like k-mean clustering and uses the eigenvector of a matrix obtained from the distance between the data points. Eigenvectors and eigenvalues are relatively important concepts in spectral clustering, where the eigenvector is interpreted as a vector that undergoes pure scaling without any rotation and the eigenvalue is interpreted as the scaling factor of a vector [15].

$$A\upsilon = \lambda\upsilon \tag{1}$$

The first step of spectral clustering is to construct an affinity matrix based on the data set. The affinity matrix is used to construct and determine a matrix of similarity between the data points. The affinity matrix is then normalized and partitioned using the largest K-eigenvectors [16]. Since spectral clustering is considered partitional clustering, it has the evaluation metrics of silhouette score, Calinski-Harabasz index, and Davies-Bouldin Index. On the basis of the previous study, we can see that spectral clustering is commonly applied in various real-life situations. For example, a study conducted by McFee & Ellis (2014) used the algorithm to analyze the structure of songs that detects repeated patterns in songs [13]. Furthermore, in a study conducted by Bach & Jordan (2006), (1) is used to perform speech separation [17].

B. OPTICS

OPTICS (Ordering Points to Identify the Clustering Structure) is categorized as a density-based clustering algorithm. The algorithm is inspired by DBSCAN but with a few better modifications. For example, the OPTICS clustering algorithm can partition data with varying densities and shapes. It is widely used in large data sets with high dimensionality [18]. The OPTICS algorithm works by adding a random data point in the cluster to an order list and then continuing to expand the cluster iteratively based on the closest data point to the selected data points. The OPTICS algorithm also calculates the reachability distance for each data point [19]. Based on previous studies, the algorithm is also commonly used in real-life applications such as detecting outliers in data sets and clustering wireless sensor networks [20], [21], [22].

Reachability distance is a measurement that indicates how easily can a datapoint be reached by another data point can reach a data point. Euclidean distance is used to calculate the distance between two data points and then further be used to determine the reachability distance. The algorithm computes the reachability distance of each data point and the generated data is used to plot out the reachability plot which can help identify clusters and the hierarchical structure of the data [23].

Even though the OPTICS algorithm uses similar concept as DBSCAN algorithm which uses density-based clustering, the OPTICS algorithm is considered a better algorithm as the OPTICS algorithm maintains a priority queue to determine the reachability distance, whereas DBSCAN only uses radius queries. Furthermore, the OPTICS clustering technique requires less maintenance, as it has fewer parameters compared to DBSCAN which requires one to maintain the epsilon parameters but to optimize the parameters of the OPTICS algorithm, domain knowledge is required as it is very sensitive to parameters that define density [24]. In addition to that, the OPTICS algorithm is also good at handling clusters with different densities, whereas the DBSCAN clustering algorithm struggles to handle data sets with different densities of clusters, since it only depends on a single value of epsilon to help determine the cluster size for all data points [18].

C. KMODES

The K mode algorithm is a variant of one of the most popular clustering algorithms, the K mean algorithm. K-modes are designed to specifically handle categorical data instead of numerical data which the K-means algorithm is weak at. The k-mode algorithm calculates the mode instead of the mean of the clusters. This modification allows the K-modes algorithm to cluster large categorical datasets more efficiently compared to the K-means algorithm [25]. Furthermore, based on previous studies, the algorithm is used for customer segmentation in e-Commerce business [26]. In addition to that, the algorithm is also used to detect and prevent crime by combining data mining technology with the algorithm. Equations (2) and (3) show the calculation of KMODES.

$$d(x, y) = \sum_{i=1}^{f} \delta(X_j, Y_j) \tag{2}$$

$$C(Q) = \sum_{i=1}^{n} d(Z_i, Q_i) \tag{3}$$

The K-modes algorithm works by first generating a number of clusters by randomly selecting data points to act as the initial cluster centers with each data point representing the centroid of the cluster where the value k is selected manually by the user. Then, each data point in the dataset is assigned to the cluster whose cluster center is closest to it based on the second equation above. After assignment, the clusters are updated based on the allocated data points, and the cluster centers are recalculated to represent the new centroids of each cluster. This update involves calculating the latest modes for each cluster. These steps and calculations are repeated until convergence is reached or stopped based on predefined criteria [27].

D. Gaussian Mixture Model

The Gaussian mixture model is a parametric density function of probability that can be represented as the weighted sum of Gaussian component densities in many applications, such as image clustering to detect human skin color and image segmentation, identifying restaurant hotspots, weather forecasts, flight safety monitoring, and many others [28], [29], [30], [31], [32], [33]. Before getting into the Gaussian mixture model, two key components of clustering must be known which are hard clustering and soft clustering. Hard clustering is the method where models try to force a data point to one of the clusters, and this means that the data point is assigned a membership degree to either 0 or 1. On the other hand, soft clustering models tend to assign data points to their appropriate membership value. Instead of assigning a membership degree of either 0 or 1, soft clustering assigns the membership degree of a point between 0 and 1. This means that each data point can belong to two or more clusters, and this may be more natural in many situations compared to hard clustering [34].

The Gaussian mixture model falls under the category of soft clustering model as it allows data points to be assigned partially to clusters. The model works by clustering data points into different clusters and thus estimating the probability density of new data points. For example, a data point can be 30% cluster A and 70% cluster B. The Gaussian mixture model is commonly applied in machine learning and pattern recognition due to the ability of the model to handle complex data distributions. Even so, it is difficult to implement this algorithm incorporating categorical variables, as the model assumes that all the features are normally distributed. The model works by applying the EM on top of its algorithm as shown in (4). The E-step uses training data to predict a new datapoint, whereas the M-step uses the information obtained from the E-step to calculate the derivative of the log-likelihood to cluster the new datapoint according to the calculations. This process repeats until convergence and the Q calculated from the EM step can be used for clustering purposes [35].

$$Q^i\left(z_k^{(i)}\right) = p\left(z_k^{(i)} \mid x^{(i)};\, \theta\right) = \frac{\pi_k N\,(x^{(i)};\, \mu_k, \Sigma k)}{\sum_{k=1}^{K} \pi_k N\,(x^{(i)};\, \mu_k, \Sigma k)} \tag{4}$$

E. Affinity Propagation

The Affinity Propagation algorithm is a clustering algorithm that first aims to find a data point as an exemplar for each cluster. It group the data based on either their similarity or distance [36]. This algorithm is commonly used to group images such as human faces, and is also used for forecasting rainfall [37]. Affinity propagation algorithm does not require determining the number of clusters, unlike algorithms like k-mean clustering. This is made possible due to the parameters used in the Affinity Propagation algorithm, such as preference, which handles the number of exemplars being used, and the damping factor, which is responsible for preventing large changes in the Responsibility and Availability matrices and ensuring convergence in the algorithm [38]. This method requires heavy calculations as it needs to calculate the similarity value between each data and reselect data as an exemplar. This makes the algorithm computationally expensive and makes it difficult to scale with larger datasets.

The algorithm performs by first creating a similarity matrix. Given a dataset, the similarity between data points needs to be calculated by using some commonly used equations, such as the negative Euclidean distance. The higher the similarity of the data points, the closer the data points are to each other based on the similarity equation. Then, two matrices, the Responsibility matrix, which quantifies how well-suited a data point is to be the exemplar of another data point, and the Availability matrix, which quantifies how much support a data point receives from another data point as an exemplar is created. Then both matrices are updated and recalculated iteratively until convergence and new data points can be clustered on the existing clusters. This algorithm is useful when the initial number of clusters is unknown, and it can handle complex data structures, too.

III. Methodology

A. Data Collection and Preparation

The data set that this study has chosen represents a list of survey answers regarding preference, interests, habits, opinions, and fears of people ages 15 years old to 30 years old. This survey was conducted by students of the Statistics class at FSEV UK in 2013. It contains 1010 unique records with 150 columns, and was taken from Kaggle, a platform where it consistently hosts various types of forecasting competitions, and it also contains data sets provided by various data scientists. Instead of taking the whole dataset, we have decided to focus on the phobia, personality, and demographic category in this data set. The demographic will be then combined with the personality subset, and phobia subset which may provide more information gain for the clustering algorithms. The phobia subset contains 10 independent variables which are flying, storm, darkness, heights, spiders, snakes, rats, aging, dangerous dogs, and fear of public speaking where it was rated from 1-5 indicating the severity of fear. The description of each variable in each subset is shown in Tables I and II. These variables in each subset will be used in clustering modelling.

TABLE I. Variables in the Personality and Phobia Subset (int64)

Personality Subset			
Daily Events Prioritizing workload Writing Notes Workaholism Thinking ahead Final judgment Reliability Keeping promises Loss of interest Funniness Fake Criminal damage Decision Making Friends versus money	Elections Self-criticism Judgment calls Hypochondria Empathy Eating to survive Giving Borrowed stuff Loneliness Cheating in school Health Change in the past God Dreams Charity Number of friends	Compassion to animals Punctuality Lying New Environment Mood swings Appearance and gestures Socializing Achievements Response to a serious letter Children Assertiveness Getting angry Knowing the right people	Public speaking Unpopularity Waiting Life struggles Happiness in life Energy levels Small – big dogs Personality Finding Lost Values Getting up Interests or hobbies Parent' advice Questionnaires or polls Internet usage
Phobia Subset			
Flying Storm Darkness	Heights Spiders Snakes	Rats Ageing	Dangerous Dogs Fear of public Speaking

TABLE II. Demographic Subset

Column Name	Type of Data
Age	Integer
Height	Integer
Weight	Integer
Number of siblings	Integer
Gender	String
Left – right-handed	String
Education	String
Only child	String
Village - town	String
House – block of flats	String

B. Feature Selection

Fig. 1 shows the method we have used to extract subsets from the dataset obtained from Kaggle. The phobia, personality, phobia + demographic and personality + demographic subset will then be used to fit the clustering algorithm. The dataset is first preprocessed by using methods like feature mapping to convert object data type into numeric datatype. Then the missing values are replaced by using Mean, Mode and Median depending on the distribution of the columns. Fig. 2 indicates that more than 80% of the number of friends' columns in the personality data set are null values. Therefore, the column is disputed due to lack of information in the column.

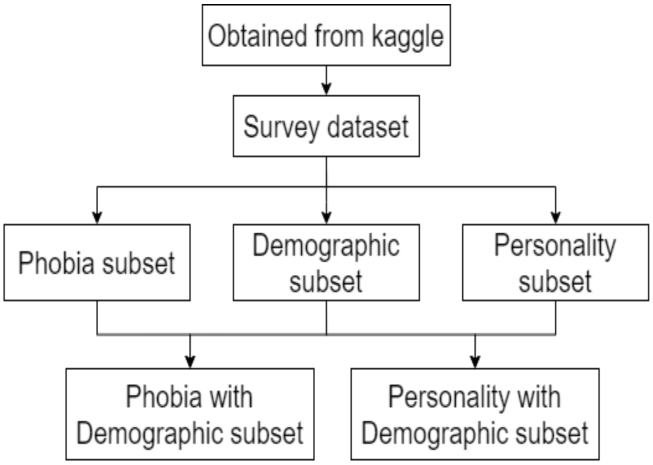

Fig. 1. Data pipeline.

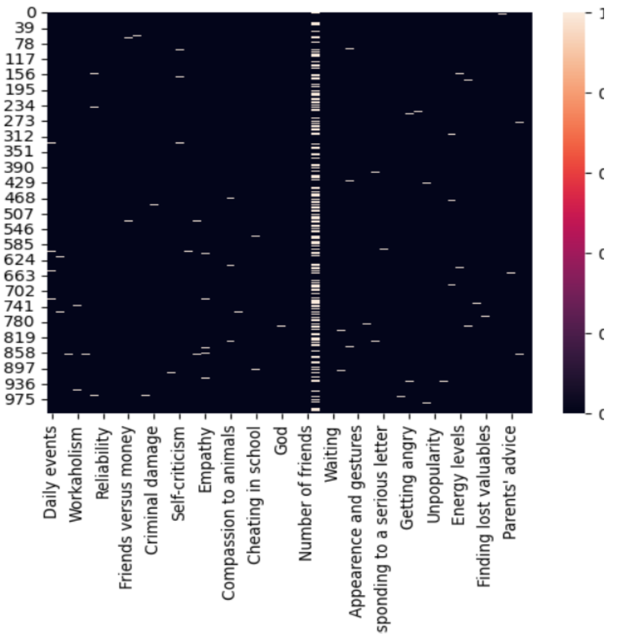

Fig. 2. Heatmap of missing value in the personality data set.

$$\sigma^2 = \frac{1}{n}\sum_{i=1}^{n}(x_i - \bar{x})^2 \quad (5)$$

Eq. (5) shows the formula of variance which will be used for feature selection in our case. Selecting features using variance threshold is a common and efficient way to dispute columns that do not provide information to the model. Feature with low variance indicates that the data in the feature do not vary much and thus not providing good information to the clustering model. 20% is used in our dataset and the variables are removed from the data set. This indicates that both variables do not provide enough information for the model as these two columns only consist of similar values, which decreases the variance of the variables. Features with low variance can sometimes be redundant, meaning they carry information like other features. Removing redundant features can help simplify your model and potentially improve its performance.

C. Algorithms Used

1) Spectral clustering: Spectral clustering has become more common recently as it is a simple algorithm to implement and does not require a large amount of resources to process the algorithm [12]. There are a few pros and cons regarding spectral clustering. For example, this algorithm applies to data with high dimensionality, and it also handles categorical variables well as it can calculate the similarity between data points by using an eigenvector instead of using distance to calculate the data points, which is crucial to our research. The differences between K-means and Spectral Clustering are shown in Fig. 3 where Spectral Clustering can perform on high-dimensionality data whereas K-means perform poorly. On the other hand, spectral clustering is relatively slow compared to other traditional algorithms such as k-mean clustering, and we are required to determine the k-value of the spectral clustering algorithm, which may be hard if we do not have an intuition on the number of clusters a dataset should have [14].

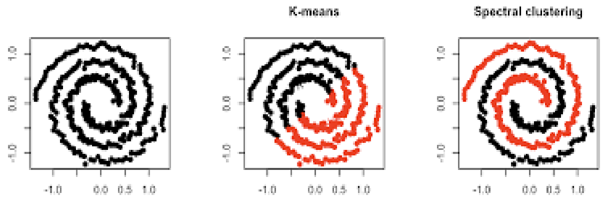

Fig. 3. Difference between K-means and spectral clustering.

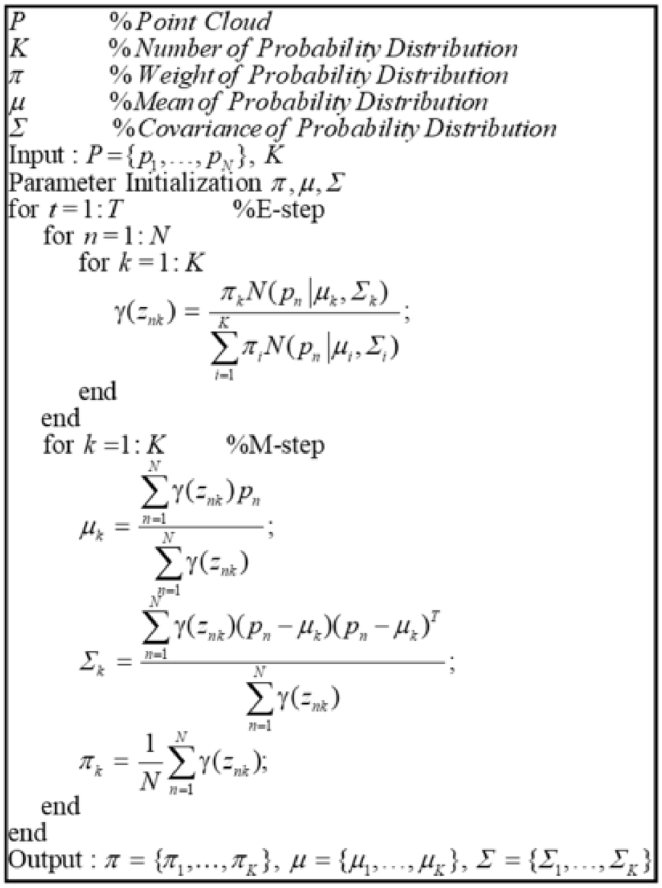
The algorithm falls into the category of clustering like k-mean clustering and uses the eigenvector of a matrix obtained from the distance between the data points. Eigenvectors and eigenvalues are relatively important concepts in spectral clustering, where the eigenvector is interpreted as a vector that undergoes pure scaling without any rotation and the eigenvalue is interpreted as the scaling factor of a vector [15].

$$Au = \lambda u \quad (6)$$

The first step of spectral clustering is to construct an affinity matrix based on the data set. The affinity matrix is used to construct and determine a matrix of similarity between the data points. The affinity matrix (6) is then normalized and partitioned using the largest K-eigenvectors [16]. Since spectral clustering is considered partitional clustering, it has the evaluation metrics of silhouette score, Calinski-Harabasz index, and Davies-Bouldin Index.

2) Gaussian Mixture Model (GMM): The Gaussian mixture model is a parametric density function of probability which can be represented as the weighted sum of the densities of the Gaussian components [28]. Based on the study conducted by other researchers, we can see that the algorithm was applied in image clustering where it detects human skin color and image segmentation [33]. Before getting into the Gaussian mixture model, two key components of clustering must be known which are hard clustering and soft clustering. Hard clustering is the method where models try to force a data point to one of the clusters, and this means that the data point is assigned a membership degree to either 0 or 1. This means that each data point can belong to two or more clusters, and this may be more natural in many situations compared to hard clustering. The Gaussian mixture model falls under the category of soft clustering model as it allows data points to be assigned partially to clusters. This process (Fig. 4) repeats until convergence and the Q calculated from the EM step can be used for clustering purposes [35]. The algorithm used is shown in (6).

$$Q^i\left(z_k^{(i)}\right) = p\left(z_k^{(i)} \,\middle|\, x^{(i)} ;\, \theta\right) = \frac{\pi_k N(x^{(i)}; \mu_k, \Sigma k)}{\sum_{k=1}^{K}\pi_k N(x^{(i)}; \pi_k, \Sigma k)} \quad (6)$$



```
$P$        %Point Cloud
$K$        %Number of Probability Distribution
$\pi$        % Weight of Probability Distribution
$\mu$        %Mean of Probability Distribution
$\Sigma$        %Covariance of Probability Distribution

```

Fig. 4. Pseudocode of the E-M step in GMM.

D. Model Pipeline

Fig. 5 indicates the clustering method used in this study. The four different subsets will be inputted into the spectral clustering model and the GMM model. Then we will determine whether the subset with demographic content or without demographic content will be used based on its performance in the model. After determining the subset to be used, the model will then be fine-tuned by using tools like GridSearchCV, silhouette score, and elbow graph to determine the best parameter combination. Lastly, each model will generate two clusters which are Phobia cluster and Personality cluster.

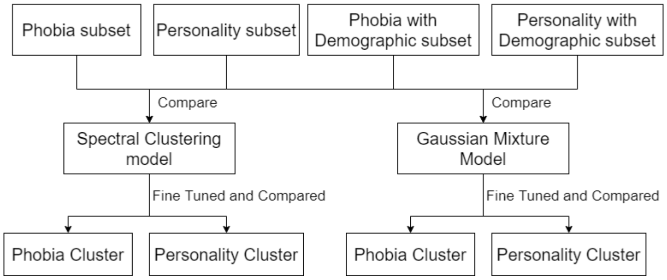

Fig. 5. Model pipeline flow chart.

IV. Result and Discussion

A. Exploratory Data Analysis (EDA)

This section explores the data set using heatmap and line graph, bar chart, violin plot, and cluster map. A heatmap is used to identify potential association between 1) phobias and demographic categories (age, gender, education) as shown in Fig. 6; and 2) personality traits and demographic categories. Based on the phobia vs. Age line graph in Fig. 7, we can see that the level of phobia roughly remains the same throughout the graph. Based on this, we can conclude that the things we fear are the same no matter the age. Fear of height can be the same for a 16-year-old young adult or even a 30-year-old adult.

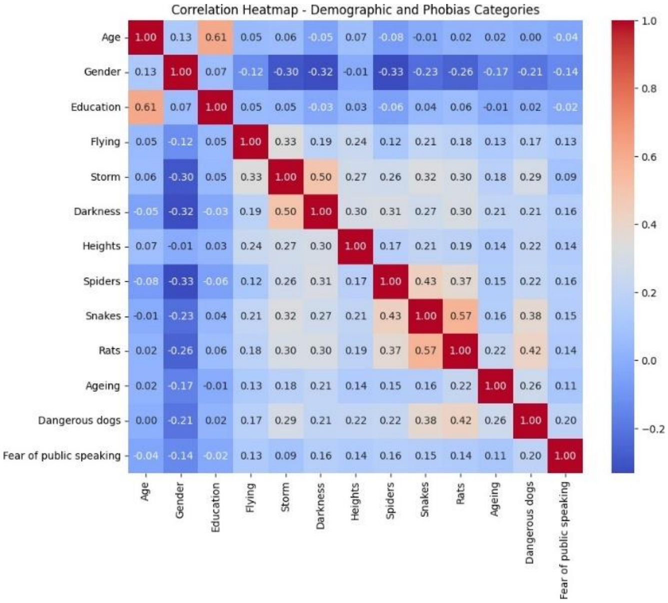

Fig. 6. Heatmap of demographic and phobia categories.

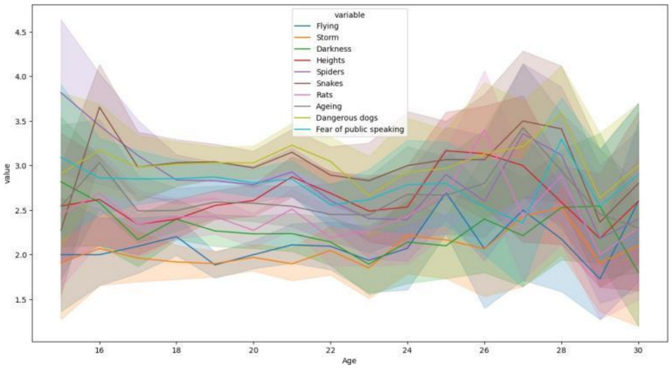

Fig. 7. Phobia vs. Age line graph.

From the bar graph in Fig. 8, 1 represents women and 2 represent males. Due to the large amount of data and bar graphs produced, only a snippet of the bar graph is presented in Fig. 8. The bar graph clearly indicates that female participants gave a neutral value in most views on life and opinion.

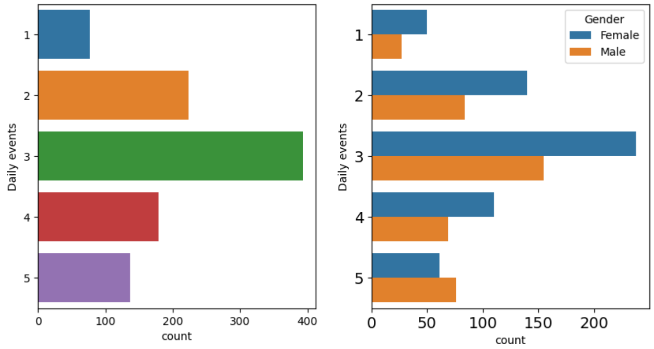

Fig. 8. Snippet of bar plots produced in exploratory data analysis using Python.

The shape of the violin represents the distribution of the data. The wider sections indicate higher density, while narrower sections indicate lower density. The width at a specific point on the violin corresponds to the frequency of data values at that point. Fig. 9 shows the distribution for level of phobia for each phobia based on the questionnaire.

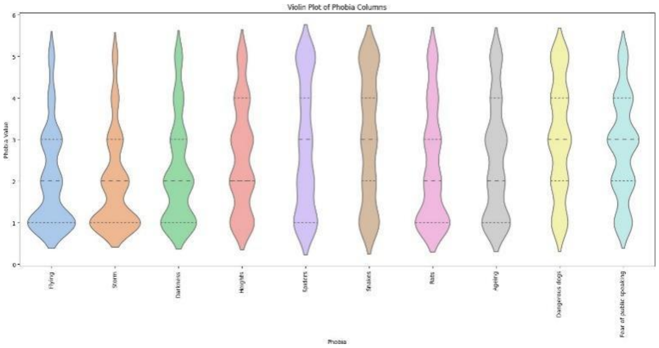

Fig. 9. Violin plot to represent data distribution.

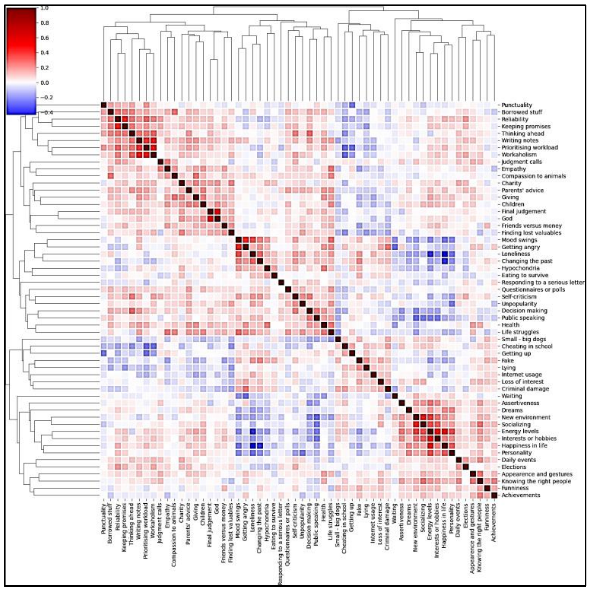

Fig. 10. Cluster map with associated clusters.

The cluster map is useful for identifying patterns not only in individual values but also in the arrangement of rows and columns. Group similar rows and/or columns together to form clusters, which can reveal underlying structures or relationships in the data. The cluster map in Fig. 10 indicates that the data can be grouped into 4, 5 or 6 clusters. Cluster map showing the correlation between each attribute in the personality test. Meanwhile, Fig. 11 cluster map shows that weight, height, and gender are highly correlated, followed by age and education and followed by number of siblings and only child. Therefore, the data can be grouped into 3 clusters. According to Fig. 12 cluster map, there may have 2 clusters for phobia data frame which are storm and darkness, as well as spiders, snakes, and rats.

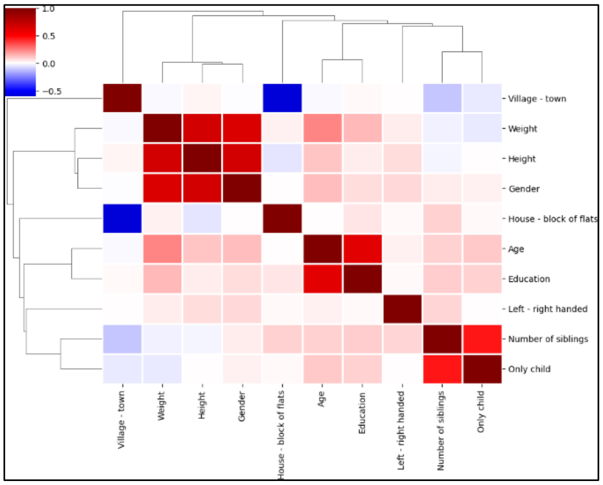

Fig. 11. Cluster map for displaying the correlation between demographics.

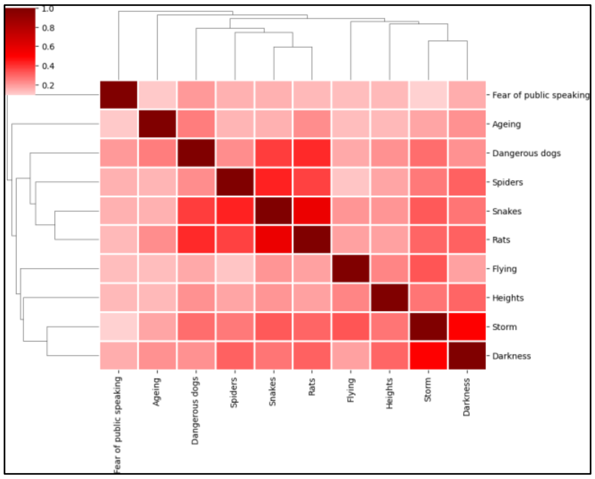

Fig. 12. Cluster map to display the correlation between each types of phobia.

B. Gaussian Mixture Model

By combining the result distortion elbow method and silhouette score graph in different numbers of clusters, we can determine that the optimal dataset and number of clusters are a subset without demographic content, 2 clusters for phobia subset and 4 clusters for personality subset. Based on Fig. 13, even though the graph indicates that 2 clusters is optimal, we have decided to use 4 clusters because it represents four main dominant traits of a person.

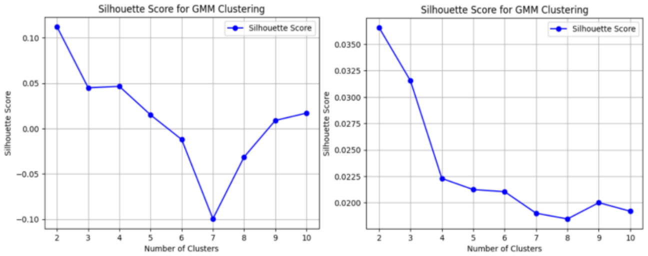

Fig. 13. GMM Silhouette score graph for the phobia subset and the personality subset.

The graphs on Fig. 14 and 15 are obtained by letting the model fit and predict the dimensional reduced data. The dimensionality reduction phase is carried out by using Principal Component Analysis (PCA). Based on Fig. 7, we can see that the yellow groups represent Level 1 phobia while the purple clusters represent Level 2 phobia. Furthermore, the clusters in Fig. 8 also show 4 different clusters of dominant traits. But in the case of GMM, the clusters are not well defined and are all grouped together. Therefore, we can determine that the GMM clustering model is not suitable for clustering personalities as it cannot identify the hidden relationship in the data set.

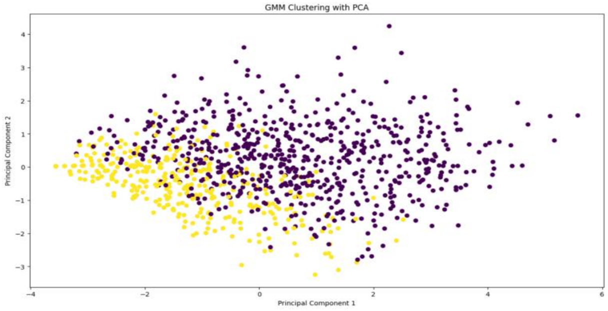

Fig. 14. Groups of GMM phobia subsets.

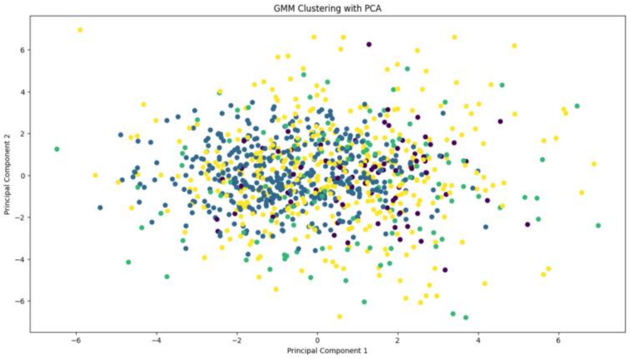

Fig. 15. Groups of personality subsets of GMM.

C. Spectral Clustering

The process of selecting parameters for spectral clustering is the same as GMM. The subset with demographic contents is selected, as the result has shown that subset with demographic contents provide better information gain and higher silhouette score. By observing both the distortion elbow method and silhouette analysis in Fig. 16 and 17 we can see that the optimal cluster is 2 clusters for the phobia subset and 4 clusters for the personality subset. Based on Fig. 9, 4 clusters since it represents 4 main dominant traits of a person. Not only that, we have also used GridSearchCV to adjust parameters like “affinity”, “gamma”, and “eigen_solver”. But the best combination found by GridSearchCV does not cluster the data well, therefore, we have decided to use the default parameters.

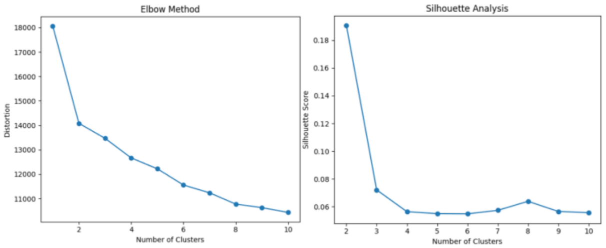

Fig. 16. Spectral clustering distortion and silhouette graph for phobia with demographic subset.

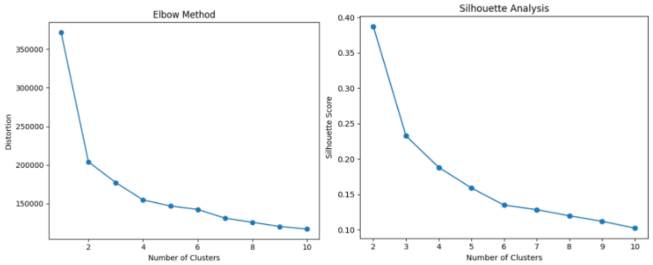

Fig. 17. Spectral clustering distortion and silhouette graph for personality with demographic subset.

The graphs in Fig. 18 and 19 are obtained from fitting dimensionality reduced data by using PCA into the spectral clustering model. Based on Fig. 18, we can see that the yellow clusters represent Level 1 phobia, while the purple clusters represent Level 2 phobia. Furthermore, the clusters in Fig. 19 also show four different clusters of dominant traits where the yellow clusters (Cluster 0) represent Steady personality type, purple clusters (Cluster 1) represent Influential personality type, blue clusters (Cluster 2) represent Compliant Personality Type, and green cluster (Cluster 3) represents dominant personality type.

Compared to previous research of clustering phobias and personality categories, one very relevant research by Anik et al. (2024) clustered the different types of phobia types using BERT-based classification model on Tweet data set. This present study presents different approaches in classification which provides information to alternative methods to analyze different data sets and discover different results or visualization.

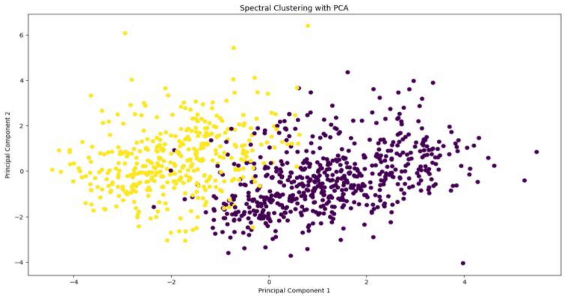

Fig. 18. Spectral clustering phobia with demographic subset clusters.

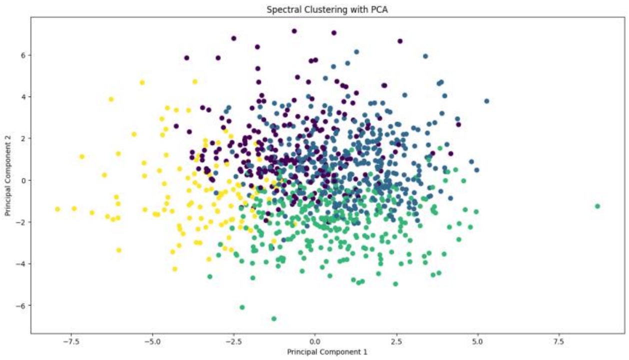

Fig. 19. Spectral clustering personality with demographic subset clusters.

V. Conclusion

As we can see, we have used two different models for two different datasets (phobias and personality categories) (one with demographic content and one without it). The list of models used for GMM are 1) GMM for phobia dataset (with demographic content); 2) GMM for phobia dataset (Without demographic content); 3) GMM for personality dataset (With demographic content); 4) GMM for personality dataset (Without demographic content). Meanwhile, for spectral clustering, the list of models used are: 1) SC for phobia dataset (with demographic content); 2) SC for phobia dataset (Without demographic content); 3) SC for personality dataset (With demographic content); 4) SC for personality dataset (Without demographic content).

For the phobia dataset, the best-performing model is Spectral Clustering, as it has a higher average silhouette score and thus makes well-defined clusters compared to GMM. For the personality dataset, the best-performing model is also spectral clustering, as it can identify the hidden relationship between the questions and thus cluster a more distinct cluster from each other. This can be shown by different clusters having more distinct characteristics, and the clusters are also less intersected with other clusters. Therefore, we can use this model to identify the dominant traits of an individual, to understand more about them. This helps identify strengths and weaknesses of the person, and thus reduces conflicts and makes coordination and cooperation much easier in many domains, especially group work in the school, university, or job. The models can be further tested using different data sets from different countries to ensure generalization of the result.

A Comprehensive Study of BIM for Infrastructural Crack Detection and the Vital Strategies

Samuel Adekunle, Opeoluwa Akinradewo, Babatunde Ogunbayo, Andrew Ebekozien, Clinton Aigbavboa
Cidb Centre of Excellence, University of Johannesburg, South Africa

Abstract—**Building information modelling is one of the emerging technologies in the construction industry and is relevant to its productivity and efficiency. Application which affects the product and process of the industry. An underdeveloped area with less attention is its adoption for crack detection and visualisation for infrastructural maintenance. This study provides a thorough perspective on BIM adoption for crack detection and visualisation. It also identified the different strategies that can aid in the adoption and use of BIM for infrastructural monitoring and maintenance in South Africa. The study adopted a quantitative approach, and questionnaires were distributed to industry professionals through an online platform. The collected data was analysed. The results indicate a need for incorporation of this aspect into the HEI curriculum and a teaching approach that is practical and experimental to be adopted.**

Keyword—Developing country; emerging technology; facility management; visualisation; emerging technology; South Africa

I. Introduction

Structural and civil infrastructures lose performance and deteriorate over time; detecting and visualising defects such as cracks on infrastructures is critical to ensure proper maintenance and predict possible failures [1]. Several infrastructure failure accidents in South Africa are related to insufficient crack inspection and condition assessment. For example, a coal silo that collapsed at the Majuba power station in Mpumalanga due to cracking and poor maintenance contributed to excessive power cuts, which negatively impacted the country's economy [2; 3]. Crack detection is part of infrastructure maintenance plans carried out regularly to monitor the health of infrastructures. Visualisation is typically used to sort large images and video data visually to improve crack inspection [4]. Infrastructure cracks are the earliest indication of material deterioration and possible infrastructure failures [5]. Crack detection information can be used to diagnose and guide the appropriate maintenance methods and approaches to prevent catastrophic failures [6]. Crack detection using visual inspections is cumbersome, costly, and inefficient [7].

The traditional methods for crack detection are visual inspections, which are conducted utilising manual observations by maintenance inspectors and engineers. Over the years, several disadvantages have been noted from manual crack detection observations. The disadvantages include time-consuming, expensive, and inaccuracy due to irregular conditions and human errors. In most cases, the reliability and accuracy of the method depend on the specialist's knowledge and experience [5, 8]. Some cracks on engineering structures can only be detected at a microscopic level, which is difficult to detect with manual inspection methods. Therefore, as clearly stated by [6, 8], manual crack detection methods are not economical and have lower accuracy levels. With the increasingly complex engineering infrastructures being developed in South Africa, there is a need to adopt new automated crack detection methods.

Over the years, reliable surface crack detection methods have been developed to effectively detect cracks on infrastructure surfaces. Automated crack detection methods are fast and reliable; hence, they boost the productivity of detecting cracks in surface structures [6]. Automatic crack-detecting methods, such as image processing techniques, have gained popularity in recent years, where crack information is extracted from images for analysis. According to study [9], some of these image processing techniques also produce unsatisfying results, as the crack analysis by computer software depends on the quality of images and the characteristics of surfaces.

The adoption and implementation of BIM have gained popularity over the years, and it has been used for planning and design. However, in recent years, BIM applications have expanded to be used in clash detection, carbon capture, and asset management [10]. The study conducted by study [11] noted that it is an area that requires attention.

II. Development of Cracks in South African Infrastructures

According to the South African Institution of Civil Engineering (SAICE) report, a significant portion of South Africa's infrastructure is in poor condition. Roads, bridges, healthcare facilities, and water management structures have surface cracks [12]. Streets and buildings across the country are cracking due to various factors, and there is no indication of proper maintenance systems and plans in place, as this problem of cracks on infrastructures has worsened over the years [13; 14; 15]. The research in study [4] assessed the adoption of computer vision-based models such as BIM to detect defects in infrastructure regularly as part of maintenance. It has been noted that cracks are the most common defects resulting in infrastructure deterioration. Therefore, adopting and implementing effective crack detection methods such as BIM is critical to visualising cracks and improving the state of infrastructures in South Africa.

One of the recent disasters caused by undetected surface cracks in South Africa involves an incident in one of the largest power stations operated by ESKOM in Mpumalanga. In November 2014, a concrete coal silo collapsed at the Majuba power station due to cracks that were not detected on the surface of the silo as part of regular maintenance of the power station. The power station at the time of the incident supplied about 10% of the country's electricity. Hence, the disaster contributed to the continued rolling blackouts of load shedding in South Africa. During the incident investigations, cracks were discovered on other silos resulting in the complete shutdown of the power station [16; 3]. Concrete silos are some of the most critical structures in the industrial sector; they are normally used to store bulk solids such as coal. Therefore, periodic inspections for signs of distress, such as cracks on these structures, are critical in their lifecycle [2]. However, concrete silos are high-rise structures with limited access to external surfaces. Therefore, it's not feasible to detect cracks on these structures using manual inspections. Hence, adopting advanced methods such as BIM for crack detection in the South African construction industry might be a solution to prevent disasters, such as using BIM applications to maintain infrastructures. BIM applications have the potential to detect and visualise cracks in infrastructures. Therefore, the current study assesses the adoption level of BIM for crack detection and visualisation within the South African construction industry as part of continuous progress toward full integration of BIM.

III. Role of BIM in Infrastructure Maintenance

BIM is a technology that holds immense significance in construction projects and infrastructure maintenance. Its benefits range from better communication and collaboration to enhanced efficiency and reduced errors. Despite these advantages, many countries have yet to adopt BIM for post-construction maintenance fully. By leveraging BIM technology, stakeholders can ensure seamless infrastructure maintenance and upkeep, promoting safe infrastructure maintenance practices [4]. The critical role of BIM in infrastructure maintenance lies in the visualisation of geometrics and the integration of infrastructure information into 3D objects. Hence, defects such as cracks can be detected effectively and accurately, and the damage caused can be assessed.

Detection of cracks in infrastructure such as buildings, roads, and bridges is crucial for monitoring their structural integrity and health [6]. A crack is a fracture wherein the components or parts are not entirely separated [17]. It has been noted in the studies by [5; 6] that cracks on most infrastructures are early indications of deterioration. Cracks create access to the harmful and corrosive chemical that penetrates infrastructures, causing damage to their integrity, strength, and durability [18]. Considerable research has been undertaken into detecting cracks to address the issue of infrastructures developing cracks and to monitor their physical and functional conditions [6]. Incorporating crack detection into maintenance plans is a crucial aspect of the construction industry, particularly before infrastructure upgrades, reconstructions, or repairs. Doing so can help ensure the infrastructure's longevity and safety while mitigating the risk of more extensive and costly repairs down the line. As such, it is highly recommended that those involved in the construction industry prioritize crack detection as part of their overall maintenance strategy.

According to study [19], civil infrastructure must be regularly checked for structural integrity as it nears the end of its lifespan. The most critical checks are for crack detection, which uses various approaches and models. The methods and models for crack detection are regularly improved and updated to ensure accuracy and performance in the construction industry. Digital technologies and the 4th industrial revolution have developed computer-based models for crack detection. Most of these models are Computer-based models developed using digital technologies for crack detection, many of which rely on computer vision-based techniques [5]. It has been highlighted by [19] that computer vision-based models improve the accuracy of crack detection with an average precision of 95%. As such, there is an increasing trend of adopting computer vision-based models to boost the productivity of detecting cracks in structures [4]. Therefore, the South African construction industry stakeholders need to adopt computer-based models for crack detection to improve the country's infrastructure maintenance and state.

IV. Benefits of Adopting BIM for Crack Detection and Visualisation

Building Information Modeling (BIM) has become an increasingly popular tool for infrastructure

Projects, particularly in detecting and measuring cracks. This approach offers a comprehensive and sophisticated solution that considers all aspects of the cracks, including their length, width, and depth [5]. BIM also generates 3D images that allow engineers and stakeholders to visualize the patterns of the cracks, which is extremely helpful in determining the most effective repair strategies [18]. BIM enables easier detection of structural cracks, thus facilitating the prediction of future conditions and determining necessary maintenance plans. As highlighted by [20], this technology also effectively allocates repair resources. By harnessing the power of BIM, organizations can optimize their maintenance strategies and ensure the longevity and safety of their buildings. Another significant advantage of employing BIM is accurately estimating the costs involved in repairing the cracks. Considering all relevant factors, such as materials, labour, and equipment costs, BIM can provide a detailed and reliable estimate of the expenses involved in repairing the cracks [21]. This information is crucial for project managers and stakeholders, allowing them to budget effectively and plan accordingly. Furthermore, BIM can aid in the formulation of effective infrastructure maintenance plans. By identifying the locations and severity of cracks, engineers can prioritize repairs and maintenance activities, ensuring that critical infrastructure is well-maintained and safe for use [22].

V. Case Studies on BIM Implementation for Crack Detection and Visualisation

In this section, studies related to adopting BIM for crack detection are reviewed and discussed to assess the potential of implementing BIM for crack detection in South Africa.

A. *Automated Concrete Defect Detection Using Building Information Model in Hong Kong*

The study by [23] adopted BIM for automated concrete defect detection. The 3D model was developed to detect the position and geometries of the concrete defect to guide subsequent maintenance stages. BIM implementation in this study was to overcome the disadvantage of manual inspection methods and assess high-rise buildings with limited access to external structures. The approach that was used in the study involved using a drone to take aerial photographs of a 10-story residential building near the University of Hong Kong. The 3D reconstruction was conducted to generate a defect point cloud (DPC) visualised in BIM to detect defects. The results from the study indicated that defect detection errors from the manual visualisation method had been reduced by up to 14%.

It is evident from this study that BIM adoption for crack detection improves the reliability of defect detection results; hence, proper maintenance planning can be done on the building. The whole process is much faster than the manual visual inspection of cracks. However, the process could be more precise; hence, proper training and understanding of BIM are needed before undertaking crack detection procedures.

B. *Adoption of BIM for the Inspection of Monte da Virgem Telecommunications Tower in Portugal*

The research in [24] also explored the potential of BIM applications in crack detection by studying detecting cracks on a telecommunications tower that is 177m high in Portugal. In the study, a remote inspection of reinforced concrete was conducted using Unmanned Aerial Vehicles (UAVs), referred to as drones, to capture tower images from different angles and integrate these images into the building information modelling (BIM).

The photographs of the tower were collected in a photographic scan from the bottom of the tower to the top, capturing concrete surface conditions. Captured photographs were then processed and reconstructed into 3D modelling, which was integrated into BIM. The biological colonies are indications of cracks, a BIM-generated model that detects cracks in the tower.

Cracks on structures such as telecommunications towers with poor accessibility to external structures are not easily detected using manual visual inspection methods due to their long heights; as such, only automated technological methods such as BIM can detect cracks on their surfaces. The BIM model has provided efficient and reliable results for cracks in the tower. Hence, informed decisions can be made on the maintenance of the tower. This is a good case study that can be related to the case of a coal silo that collapsed at the Majuba power station in Mpumalanga, South Africa, due to cracking, which may be resulted from limited access to the coal silo to detect surface cracks on the structure. The new technology of detecting cracks improves infrastructure maintenance; hence, South Africa needs to adopt it.

VI. Methodology

A quantitative approach was adopted to identify the strategies required to implement BIM adoption for crack detection in the South African construction industry. A total of 77 responses were retrieved and adopted for the study. The research instrument was randomly distributed online to professionals in the South African construction industry via Google Forms. The Cronbach alpha coefficient has been utilised to evaluate the quality and consistency of the data obtained from the study. This statistical method is widely used in research to measure the internal consistency of a set of variables. The coefficient's value ranges from 0 to 1, with 1 signifying perfect internal consistency and 0 indicating no consistency. The higher the coefficient, the more reliable the data. A Cronbach alpha coefficient of 0.85, which is a higher value, indicates that the data collected is consistent and, hence, reliable to be adopted to improve the adoption of BIM for crack detection. The adopted methodology has been used by studies in the construction industry [25, 26].

A. *Background Information of Respondents*

The study's findings revealed that most respondents held a bachelor's degree, the typical entry-level degree (see Table I). Many respondents possessed a master's degree, while only a few held a doctoral degree. This suggests that most South African construction industry professionals do not pursue education beyond the entry-level degree. Many might have professional degrees, which were not requested in this study. Therefore, there may be a need for greater emphasis on continuing education and professional development to ensure professionals remain current with trends and best practices. The study involved eight professional categories with distinct affiliations. Most respondents belonged to the engineering and construction project management categories, while fewer participants were from the construction health and safety category. The findings indicate that engineers and construction project managers in the South African construction industry are highly interested in staying updated with advancements and technologies in infrastructure maintenance, actively seeking ways to improve their knowledge and skills. The years of experience is crucial in determining industry knowledge and exposure. The study revealed that most respondents have six to 10 years of experience, with fewer having over 20 years. This suggests the industry is dominated by professionals with moderate experience, with relatively few highly experienced professionals. However, it is expected that more experienced professionals are less inclined to adopt new technologies, such as BIM, for crack detection and visualization, compared with young professionals who are technology enthusiasts. The data also shows that many respondents are employed in the government and consultancy sectors.

TABLE I. RESPONDENTS BACKGROUND INFORMATION

Category	Subcategory	Percentage (%)
Educational Qualification	Bachelor's Degree	53.2
	Master's Degree	22.1
	Diploma	18.2
	Doctoral Degree	6.5
Professional Affiliation	Civil Engineer	29.9
	Construction Project Manager	22
	BIM Professional	13
	Quantity Surveyor	11.7
	Construction Manager	10.4
	Architect	6.5
	Construction Supervisor	3.9
	Construction Health and Safety Officer	2.6
Years of Experience	1-5 years	10.5
	6-10 years	31.2
	11-15 years	26
	16-20 years	16.9
	Over 20 years	1.2
	Under 1 year	14.2

VII. FINDINGS

The study result is presented in this section

A. *Strategies for the Adoption of BIM for Crack Detection*

The findings from the descriptive analysis indicate that several strategies could help successfully adopt and implement BIM for crack detection in the SACI. The most effective strategy in the SACI context includes universities teaching BIM tools and applications to students interested in pursuing a career in the construction industry. By incorporating BIM into the curriculum, students will gain an in-depth understanding of its benefits and grow their skills in utilizing BIM to detect cracks. Secondly, raising awareness about the benefits of using BIM for detecting cracks in the construction industry could encourage stakeholders to adopt this technology. This approach could involve creating informative materials or hosting workshops to educate professionals and decision-makers on the potential of BIM in detecting cracks. Thirdly, promoting BIM research for crack detection could help advance the technology and improve its effectiveness in detecting cracks. This could involve funding research projects exploring the construction industry's latest BIM applications and tools. Training professionals in BIM crack detection tools is crucial for successfully implementing this technology. By providing hands-on training and support, professionals will be equipped with the necessary skills and knowledge to apply BIM in detecting cracks in the construction industry. The effectiveness of this strategy has been highlighted in different studies, which include [25, 27]. The study suggests that the adoption and implementation of BIM for crack detection in the SACI requires a multifaceted approach that involves teaching BIM tools and applications at universities, raising awareness of the benefits of BIM for detecting cracks, promoting BIM research for crack detection, and training professionals in BIM crack detection tools. Strategies for BIM is shown in Table II.

TABLE II. STRATEGIES

Strategies	Mean	Std. Deviation	Rank
Teaching BIM tools and applications used to detect cracks in the University	4.45	0.770	1
Raise awareness of the benefits of detecting cracks using BIM	4.43	0.637	2
Promoting research on adopting BIM for crack detection and visualisation	4.41	0.807	3
Promoting wider BIM adoption in infrastructure maintenance	4.40	0.658	4
Training and development of construction and maintenance professionals on BIM crack detection tools	4.38	0.673	5
Implementation of BIM throughout the lifecycle of government facilities	4.29	0.830	6
Acquiring of BIM crack detection software and tools by construction organisations	4.26	0.755	7
Development of national standards for local implementation of BIM for crack detection	4.23	0.809	8
Mandatory adoption of BIM for crack detection on government projects	4.06	0.978	9
Construction organisations top management formally approving the use of BIM for crack detection	4.01	0.993	10
Tax relief to motivate adoption among construction stakeholders	3.65	1.295	11
Financial incentives to fund the implementation of BIM for crack detection	3.62	1.257	12
Organisations utilizing BIM for crack detection to receive tax breaks	3.55	1.341	13

VIII. Conclusion

The study's findings on BIM adoption strategies have significant implications for the South African construction industry (SACI). BIM implementation is a complex process involving multiple stages and requiring careful consideration of various factors. Its success depends on a well-planned and structured approach that addresses the country's unique infrastructure requirements. This involves a thorough analysis of infrastructure defects, particularly cracks. Effective training is crucial for successful BIM implementation, enabling SACI professionals to acquire the necessary skills and knowledge to use the technology effectively. BIM adoption can lead to improved infrastructure maintenance, enhanced collaboration, and more sustainable and efficient crack defect repair practices if implemented correctly. BIM is an emerging technology with great potential in the construction industry for various applications, including crack detection. Many countries have proposed and implemented strategies to adopt BIM, as highlighted in the reviewed literature. However, the effectiveness of these strategies varies due to the unique requirements and demands of each country's construction industry. In the South African context, the analyzed data revealed that the most effective strategies for BIM adoption for crack detection are training and education. By investing in training and educating construction professionals on BIM applications, companies can ensure that employees have the necessary skills to implement this technology effectively. This can lead to improved efficiency, reduced costs, and increased safety in construction projects. Further studies can be conducted to evaluate the effectiveness of various BIM training programs and their impact on professionals' proficiency and project success. Also, researchers should explore the integration of BIM with other emerging technologies like AI and IoT for enhanced crack detection and infrastructure maintenance.

The Adoption of Electronic Payments in Online Shopping: The Mediating Role of Customer Trust

Nguyen Thi Phuong Giang[1*], Thai Dong Tan[2], Le Huu Hung[3], Nguyen Binh Phuong Duy[4]
Faculty of Commerce – Tourism, Industrial University of Ho Chi Minh City – IUH, Ho Chi Minh City, Viet Nam[1,2,3,4]

***Abstract*—This study investigates the factors influencing electronic payment in online shopping behavior among Ho Chi Minh City consumers. With the rapid advancement of technology, e-commerce has become a new trend, and understanding the intention to adopt electronic payment is crucial for online businesses. The research employs quantitative and qualitative methods, utilizing a survey of 437 Ho Chi Minh City consumers. The data collected is processed using SPSS 24 and SmartPls4 software. Eight factors related to consumers' intention to use electronic payment are identified: social influence, security, perceived usefulness, convenience, ease of use, customer trust, perceived risk, and performance expectancy. The study's findings will contribute to the existing knowledge base for businesses, facilitating the promotion of electronic payment adoption. This support will aid businesses in developing more attractive online sales strategies, encouraging consumers to shop and pay online more frequently and, at the same time, contribute to supporting departments in formulating policies for digital payments, thereby promoting national digital transformation.**

Keywords—Electronic payment, Intention to use, Online shopping

I. INTRODUCTION

In the current era, our society is experiencing profound transformations, both in its structure and quality of life. The rapid advancement of information technology has paved the way for various industries to flourish, and among them, e-commerce stands out as a sector that has made remarkable strides, bringing greater convenience and modernity to human existence. A direct consequence of this progress is the widespread adoption of electronic payments, which has become an integral part of modern life. The outbreak of the COVID-19 pandemic has impacted various sectors of the economy and changed customer shopping habits. Increasingly, businesses and individuals are adapting to the new situation by shifting from in-person transactions to online shopping and using cashless payment methods. In this context, most commercial banks are focusing on and implementing plans to develop cashless payment services in line with government directives. The convergence of the digital economy and the digital society, combined with the disruptive impact of the COVID-19 pandemic, has accelerated the global and Vietnamese shift towards cashless payments. The State Bank of Vietnam's 2021 report indicated a significant surge in the value of non-cash payments, rising by an impressive 18%, and a substantial 30% increase in payment volume [1]. Furthermore, the Digital 2022 report disclosed that the number of internet users in Vietnam has surpassed 72 million, accounting for an impressive 73.2% of the population. This figure marks a substantial 4.9% growth compared to the previous year. Digital payments are at the forefront of technological advancements and consistently ensure security. In comparison to 2021, non-cash payments in 2022 surged by 31.39% in value and accounted for 85.6% of the total transactions [2]. Online payment activities in Ho Chi Minh City are facing significant challenges. Infrastructure and technology issues are prominent, with unstable internet connectivity and uneven technology proficiency hindering the adoption of advanced payment technologies. Concerns about security and privacy pose a major barrier. Worries about personal information security and data breaches make many users hesitant to fully embrace online payments. Consumer habits and behaviors also present a considerable obstacle, as the preference for cash use remains common due to long-standing habits and trust in traditional methods. With its advantages of convenience and safety, digital payment is driving the growth of commerce worldwide. Digital payments facilitate swift transactions for both sellers and consumers, minimizing risks, and guaranteeing mutual benefits. Moreover, it caters to diverse transactional needs, ranging from simple to complex, at low service fees. Digital payments are expected to remain the preferred payment method in the present and future. In Vietnam, electronic payments were introduced in 2008, with e-wallets being the pioneering model. However, to this day, online payment activities in Vietnam, especially in Ho Chi Minh City, face several obstacles due to various factors influencing consumers' decisions to adopt this payment method. Hence, researching the influencing factors on the intention to use electronic payments for online purchases among the city's residents is essential to determine their interests and the factors impacting their acceptance of this service. The contributions of the research will be incorporated into existing documents for businesses when successfully implementing digital payments. This helps merchants develop more sales strategies, encouraging consumers to shop and pay online more frequently.

II. THEORETICAL BASIC

A. Concept

Electronic payment refers to any monetary transaction initiated in connection with electronic communication methods. It is a form of using electronic signals directly linked to a deposit account or credit account [3], [4]. Electronic payment (e-payment) serves as the foundation of Internet Banking, encompassing the online platform that facilitates various activities such as online auctions, Internet stock trading, and online shopping [5]. The concept of intention to use delves into an individual's level of willingness and readiness to engage in a particular behavior [6].

B. Theoretical Model

In 1989, Davis proposed the Technology Acceptance Model (TAM) in collaboration with several researchers, providing a theoretical framework to explain technology usage. According to this theory, two crucial factors, perceived usefulness and ease of use, play a significant role in determining individuals' acceptance and adoption of technology [7]. However, with the advancement of research, a more comprehensive model called the Unified Theory of Acceptance and Use of Technology (UTAUT) was formulated by Venkatesh and colleagues in 2003 [8]. UTAUT integrated and expanded upon factors from previous models, offering a more holistic perspective on technology acceptance. These facilitating factors can encompass various resources like data, knowledge, documentation, financial support, or other forms of assistance. The UTAUT model has significantly enhanced our understanding of the technology adoption process by considering a broader range of influencing factors.

III. Hypotheses and Research Model

A. Customer Trust

Trust plays a pivotal role in shaping individuals' intentions to carry out transactions, especially in the realm of electronic commerce. When people place their trust in the process, they are more inclined to participate in e-commerce transactions [9]. Moreover, trust is a subjective perception regarding fulfilling obligations and meeting the expectations of all parties involved [10]. Trust is essential in laying the groundwork for successful transactions; reputation plays a crucial role in establishing trust, while trust influences the perception of the transactional environment [11]. Furthermore, trust encompasses attributes such as integrity, security, and data protection during transactions [12]. Cryptocurrencies, which utilize enhanced encryption methods, increase their reliability and trustworthiness. Transparent and objective verification methods used in cryptocurrencies eliminate the need for intermediaries, reducing transaction fees and increasing reliability in the system, thus enhancing its acceptance [13]. Research in [14], [15] has shown that higher levels of trust in online vendors directly correlate with increased adoption rates of digital payment systems. The widespread adoption of PayPal, is largely attributed to its strong reputation for security and buyer protection.

H1: Customer trust positively affects the intention to use electronic payment methods.

B. Perceived Risk

Perceived risk in the context of this study refers to the sense of uncertainty individuals experience regarding potential negative outcomes when utilizing cryptocurrencies for electronic payments. It plays a significant role in influencing perceived utility and purchase intention in commerce [16], [17]. Cryptocurrencies are renowned for their decentralized payment network; however, the lack of clear operational assurance and the volatile nature of their value function hinder their widespread adoption [18]. The unstable prices make it challenging for cryptocurrencies to serve as a reliable unit of account, and concerns about regulation, speculative activities, and vulnerability to cyberattacks further impede their establishment as a global currency [19]. The existence of such risks affects users' trust, as they fear negative consequences arising from unsuccessful transactions, insufficient e-commerce regulations, and inadequate anti-fraud measures employed by sellers [20]. If digital payment is associated with significant risks, the user's evaluation may deteriorate, and consequently, their level of trust in using digital payments for purchasing goods may decrease considerably. Previous research in various contexts has already demonstrated the adverse impact of risk on trust [21], [22]. In this study, trust serves as an intermediary between perceived risk and the intention to use digital payments, as established in prior research [23], [24], [25]. When users trust a provider or store, they believe the business will act responsibly and, thereby, reduce perceived risk for customers. Hence, trust plays a mediating role between perceived risk and customers' intention to use digital payments. Previous research [26], [27] in various contexts has already demonstrated that perceived risks negatively affect users' trust and their willingness to engage in electronic transactions. In practice, the failure of certain cryptocurrency exchanges due to hacking incidents has significantly diminished user trust and adoption rates.

H2: The use of digital payments is negatively influenced by perceived risks.

H3: Customer trust is negatively impacted by perceived risks.

H4: Perceived risks hurt the intention to use digital payments, mediated by customer trust.

C. Perceived Ease of Use

According to existing literature, the perceived ease of use holds significant importance in influencing customers' intention to adopt new technologies. For a product to be perceived as easy to use, it should have a user-friendly interface and follow a logical sequence of actions [28]. Davis (1989) defined ease of use as customers' perception that the system is uncomplicated, effortless, and quick to navigate [7]. Indicators of perceived ease of use include transparency and comprehensibility, step-by-step installation guides, and user-friendly features, as well as easy comparisons between cash payment systems and third-party e-payment methods [29], [30], [31]. Previous research has indicated that when customers perceive a device as requiring minimal mental and physical effort, its usage becomes more prominent [32]. In our study, we expand this concept to encompass the social aspect of e-payment usage, intending to enrich interactions and outcomes in electronic commerce [33]. Aghdaie et al. (2011) conducted a study that showed a positive relationship between ease of use and trust [34]. This finding is consistent with earlier research that also found a positive correlation between customer trust and perceived ease of use [35], [11], [36], [37]. Users tend to believe that newer technologies are capable of bringing benefits to the products they will purchase, so consumers expect these technologies to be easy to learn and use. Al-Sharafi et al. (2017) explored the role of trust in increasing awareness of ease of use during positive online transactions, although the effect is not significant [38]. Yudiarti and Puspaningrum (2022) confirmed that perceived ease of use, mediated by trust, influences the intention [39]. When companies apply technology or systems perceived as easy to use, it leads to increased trust and, consequently, a higher intention to use them in the future. Similarly, Wen et al. (2011) explained that perceived ease of use has a significantly positive impact on trust [40]. This research supports the study results by [41], [42], which stated that showing the results of trust mediates the relationship between perceived ease of use and intention to use.

H5: The intention to use digital payments is positively influenced by the perceived ease of use.

H6: Customer trust is positively impacted by the perceived ease of use.

H7: The perceived ease of use has a positive effect on the intention to use digital payments, mediated by customer trust.

D. Perceived Usefulness

The concept of perceived usefulness refers to individuals' belief that using a particular e-payment system can enhance their efficiency in completing financial and daily transactions [43]. For low-income customers, perceived usefulness is crucial in shaping their expectations and willingness to adopt e-payment for various purposes [44]. The utilization of e-payment is argued to enhance productivity and efficiency in payment-related processes [45], improve customer service and product information [46], and leverage digital infrastructure for information dissemination [47]. Low-income customers who perceive e-payment as useful are more likely to adopt and utilize the system to their advantage. On the other hand, if the perceived usefulness of e-payment is low, its implementation may not lead to adoption, as perceived usefulness plays a crucial role in the decision-making process [48]. The studies conducted by Chinomona (2013) and Amin et al. (2014) have revealed that trust is positively influenced by perceived usefulness [36], [49]. When customers perceive a system or new product as valuable and beneficial, they will trust the product or new technology. Perceived usefulness affects intention through trust [50]. Consumers who have a higher level of trust are more inclined to engage in purchasing behavior. Thus, it can be observed from the research that trust plays an intermediary role between perceived usefulness and customer behavioral intention. Previous studies have also recognized this indirect relationship, indicating that perceived usefulness affects consumer behavioral intention through trust [51]. Additionally, other research has shown a direct impact of perceived usefulness on trust [52], [39].

H8: Perceived usefulness has a positive impact on the intention to use digital payments.

H9: Perceived usefulness has a positive impact on customer trust.

H10: Perceived usefulness has a positive impact on the intention to use digital payments through customer trust.

E. Security

Perceived security plays a critical role in users' acceptance and trust in mobile payment systems. It refers to users' perception of the level of protection and prevention against potential security threats related to the use of M-wallets [53]. The primary concern for users when it comes to financial transactions is the security of their sensitive information and data [54]. Users need to have confidence that their personal information will remain secure and protected from unauthorized access, storage, or manipulation by any third parties [55]. Therefore, perceived security is a crucial factor in determining users' willingness to adopt and use mobile payment systems [56]. The relationship between security and trust is closely interconnected. Users are more likely to trust organizations and the digital payment system if they are assured about the security measures in place to protect their data and prevent any data breaches [57]. According to their research, the level of trust in digital payments is determined by security. Moreover, improving user trust encourages customers to use electronic payments when making online purchases. Flavián and Guinalíu (2006) stated that developing trust changes customers' usage intentions. Perceived security is linked to behavior through trust [54]. However, how users perceive the privacy of their information affects trust. According to C. Kim et al. (2010), a lack of trust in the security of online transactions can lead individuals to prefer using cash for transactions [58]. Based on these findings, trust is an intermediary factor between perceived security and user behavior [59].

H11: Security has a positive impact on the intention to use digital payments.

H12: Security has a positive impact on customer trust.

H13: Security has a positive impact on the intention to use digital payments through customer trust.

F. Social Influence

Social influence is “the degree to which an individual perceives that significant others believe he or she should use the new system” [8]. In the context of online shopping, individuals who engage in word-of-mouth (WOM) exchanges with others and receive referrals, opinions, personal experiences, and product-related knowledge are more likely to feel a higher sense of recognition of online vendors. They tend to pay attention to the recommendations and influence of others when making their purchasing decisions [60]. Morosan and DeFranco (2016) have shown that social influence plays a significant role in shaping users' intention to use mobile payment (M-payment) services [61]. It also affects users' attitudes towards M-payment services and their perception of the multiple benefits of using such services [62]. At the same time, it also has an impact on customer trust when there is an intention to shop online [63], [64], [65]. Trust can act as a mediator between social influence and users' intention to use digital payments, as demonstrated by the research conducted by Chan and Lee (2021) [66].

H14: Social influence has a positive impact on the intention to use digital payments.

H15: Social influence has a positive impact on customer trust.

H16: Social influence has a positive impact on the intention to use digital payments through customer trust.

G. Performance Expectancy

Performance expectancy (PE) plays a pivotal role in determining users' willingness to accept and adopt new technology. PE refers to the belief that using a specific technology will result in improved job performance or bring about various benefits in daily life [8]. People are more likely to embrace and utilize technology when they perceive it as providing substantial advantages and enhancements [67]. In the context of electronic payment systems, performance expectancy is associated with users' perceptions of the service's convenience, speed, and effectiveness [68]. If users believe that electronic payment offers them a convenient and efficient way to conduct banking transactions, they will be more inclined to use such channels [69].

H17: Positive effects of performance expectancy lead to a higher intention to use electronic payment.

H. Convenience

Convenience is a critical factor that influences users' decision to use a technology. It refers to the feeling of comfort and ease when using a particular system [7]. Convenience is the combination of time and place utility, and it exerts a significant impact on a user's choice to adopt a particular system. Consequently, convenience plays a crucial role in shaping the perceived value of the system [70]. Generally, people tend to place their trust in technology when it is designed to efficiently complete tasks and simplify processes. When a user of new technology experiences happiness, they will become interested and generate more satisfaction with the technology [7]. This implies that as users' comfort level increases, their usage behavior will improve. Therefore, the convenience of using it will positively influence the intention to use electronic payments.

H18: Convenience positively influences the intention to use electronic payments.

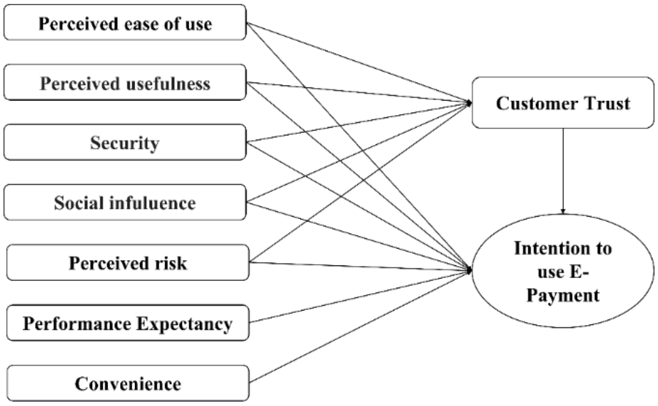

Fig. 1. Proposed research model

IV. Research Methods

The research is conducted in two phases: qualitative research and quantitative research. Choosing quantitative research methods for data collection brings many important benefits. This approach allows for precise measurement and utilizes statistical data to analyze relationships between variables. This helps in deriving conclusions that are highly accurate and applicable broadly in both theoretical and practical research. Furthermore, the objectivity of quantitative data ensures the reliability of research findings, facilitating the assessment of impacts and the significance of key variables within the study sample. The qualitative research phase aims to determine the measurement scale and lay the foundation for constructing the questionnaire in the quantitative research phase. The author inherited from previous studies and developed a preliminary measurement scale for seven independent variables (Social influence, Risk, Usefulness, Security, Performance expectancy, Ease of use, Convenience), one mediating variable (Trust), and the dependent variable (Intention to use e-payment). In the quantitative research phase, the survey method is employed, utilizing a questionnaire to collect data. The online survey form is distributed via email and various social media platforms. The questionnaire utilizes a 5-point Likert scale, allowing participants to express their level of agreement, ranging from “strongly disagree” to “strongly agree”. The choice of sampling method in quantitative research is crucial as it affects both the cost and quality of the study. There are two main groups of sampling methods: probability sampling, and non-probability sampling. Random sampling methods typically reflect the representation of the population and have high generalizability. In contrast, non-probability sampling methods allow for purposive selection but may not represent the entire population. The decision on which method to choose depends on various factors such as time constraints, budget, and study scope. Optimal research often involves testing samples that are representative of the population. However, when the population is too large, researchers often find convenience in using non-probability sampling methods. The research applies a convenient sampling method with an estimated sample size of 437 participants. The survey targets consumers in Ho Chi Minh City, aged between 18 and 40, who utilize electronic payment for online shopping. After data collection, the collected data was cleaned and analyzed using SPSS 22 and Smart PLS 4 software. The analysis methods will include descriptive statistics, measurement model testing, and structural model testing. Fig. 1 shows the proposed research model.

V. Result

A. Descriptive Statistics

To collect data, a questionnaire was sent to business owners in Ho Chi Minh City from various industries, different age groups, and genders. Due to various reasons, only 437 valid surveys were received. According to Table I, 44.9% of respondents were male, and 55.1% were female. In terms of age, the highest percentage was in the 18-22 age group, accounting for 46.2%. The surveyed individuals were mainly students (31.6%), office workers (25.2%), and business professionals (18.8%), and the remaining included freelancers, factory workers, teachers, and other professionals. Data Interpretation: It could benefit from further interpretation of these statistics. For example, the passage could discuss any notable trends or patterns observed in the data, such as differences in responses based on demographic characteristics. Sample Representation: The Authors mention that the survey targeted business owners in various industries, age groups, and genders. Discussing the extent to which the sample represents the target population would provide context for interpreting the results.

TABLE I. DESCRIPTIVE STATISTICS OF THE SURVEY SAMPLE

Characteristic		Frequency	Ratio (%)
Gender	Female	241	55.1
	Male	196	44.9
Age	18 to 22 years old	202	46.2
	23 to 30 years old	162	37.1
	30 to 40 years old	73	16.7
Income	From 1 million to 3 million VND	88	20.1
	From 3 million to 5 million VND	117	26.8
	Over 5 million to 10 million VND	127	29.1
	Over 10 million VND	105	24
Occupation	Students	138	31.6
	Office workers	110	25.2
	Teachers	24	5.5
	Business professionals	82	18.8
	Freelancers	43	9.8
	Factory workers	29	6.6
	Other professions	11	2.5
Total		437	100

B. Testing the Measurement Model

All factors, including PU, SC, PE, CV, PEOU, IU, SI, PR, and CT, consistently exhibit Cronbach's Alpha coefficients exceeding 0.8, indicating strong internal consistency reliability. The composite reliability coefficient, assessing internal consistency within the study, further supports this, with values typically above 0.7 considered good [65]. In our study (see Table II), composite reliability coefficients range from 0.904 to 0.938, indicating robust reliability across all constructs. Moreover, all items demonstrate outer loadings above the threshold of 0.707, indicating their substantial contribution to their respective constructs [66]. This ensures that the items reliably measure their intended constructs. Convergence validity, assessed through Average Variance Extracted (AVE), confirms that our constructs converge well within the PLS-SEM analysis. AVE values exceeding 0.5 are indicative of good convergence validity. In our study, all constructs exhibit AVE values above 0.705, underscoring strong convergence validity. Discriminant validity, crucial for distinguishing between constructs, is evaluated using the HTMT ratio and the Fornell-Larcker criterion. An HTMT ratio below 0.9 signifies adequate discriminant validity [67]. Our findings (see Table III) show HTMT ratios ranging from 0.282 to 0.716, indicating satisfactory discriminant validity among all constructs. Additionally, the Fornell-Larcker criterion, which compares the square roots of the AVEs (diagonal elements) with the correlations between constructs (off-diagonal elements), is consistently met. This criterion confirms that each construct's variance is greater than its correlations with other constructs, supporting discriminant validity.

These assessments collectively validate the measurement model's reliability, convergence validity, and discriminant validity, ensuring robustness in our findings.

TABLE II. RELIABILITY AND CONVERGENCE ASSESSMENT

Factor	Composite reliability (CR)	Cronbach's alpha (CA)	Average variance extracted (AVE)	Outer loading
SI	0.904	0.842	0.759	0.860 – 0.889
SC	0.930	0.906	0.726	0.828 – 0.869
PEOU	0.917	0.879	0.733	0.851 – 0.862
PU	0.905	0.861	0.705	0.826 – 0.850
PE	0.914	0.875	0.728	0.844 – 0.865
CT	0.912	0.872	0.723	0.838 – 0.856
PR	0.938	0.911	0.790	0.884 – 0.895
CV	0.925	0.892	0.755	0.855 – 0.876
IU	0.927	0.883	0.810	0.893 – 0.907

TABLE III. HTMT AND FORNELL-LARCKER DISCRIMINANT VALIDITY TESTING

C. Testing the Structural Model

The main limitation of quantitative research through survey (see Appendix) data is the representativeness of the sample compared to the population. Due to time constraints and other research resources, the study could not assess the entire population and only relied on a sample of 437 participants. Therefore, there are certain limitations in terms of the generalizability of the research findings. To address this, the authors used bootstrapping techniques to resample with replacement based on the collected sample data, aiming to establish a larger study sample. Assessing multicollinearity is one of the steps needed to evaluate the relationships between variables in the research model. The absence of multicollinearity is indicated when the Variance Inflation Factors (VIF) are less than 5 [71]. In this study, the VIF values range from 1.249 to 2.112, indicating no multicollinearity issue in the model. The R-squared (R^2) value ranges from 0% to 100% and a higher R^2 value implies a better accuracy of the research model's predictions. According to Table IV, R^2_{adjYD} is 63.5%, which means it accounts for 63.5% of the variance in IU explained by SI, SC, PEOU, PU, PE, CT, PR, and CT; thus, these are good predictors for IU. Cohen (1988) considers f^2 values of 0.02, 0.15, and 0.35 as small, medium, and large, respectively [72]. The f^2 values in Table IV show that the independent variables have medium to large effect sizes on the dependent variable in the research model, except for H12, which has no significant effect. Q^2 value greater than 0.02 emphasizes the predictive ability of the previously mentioned model. To test the statistical significance at a 5% equivalent level, the authors used a t-value greater than 1.96. The bootstrapping results indicate that SI, SC, PEOU, PU, PE, CT, PR, and CV have significant and statistically meaningful effects on YD at approximately 5% level ($p < 0.05$). Moreover, PEOU, PU, SI, and PR have statistically significant impacts on CT, specifically at a 5% level ($p < 0.05$). However, SC does not have a statistically significant impact on CT at a 5% level ($p > 0.05$). Based on these results, the authors accept hypotheses H11, H9, H1, H5, H2, H6, H8, H3, H17, H14, H15, H18 and reject hypothesis H12.

According to Table V, using CT as a mediating variable, SI, PU, and PEOU have significant effects on IU with beta coefficients of 0.044, 0.037, and 0.035, respectively, and all P-values are less than 0.05. Therefore, the research findings through the mediating variable support the idea that customer trust mediates the effects of social influence, perceived usefulness, and perceived ease of use on the intention to use electronic payments.

TABLE IV. TESTING THE STRUCTURAL MODEL

Relationships	Original sample	VIF	T statistics	P values	f^2	Result
SI -> CT	0.270	1.815	4.557	0.000	0.078	Accept
SI -> IU	0.153	2.017	2.758	0.006	0.032	Accept
SC -> CT	0.075	1.648	1.272	0.203	0.007	Reject
SC -> IU	0.099	1.755	2.152	0.031	0.021	Accept
PEOU -> CT	0.215	1.991	3.204	0.001	0.045	Accept
PEOU -> IU	0.153	2.112	2.572	0.010	0.031	Accept
PU -> CT	0.228	1.532	3.758	0.000	0.065	Accept
PU -> IU	0.127	1.712	2.341	0.019	0.026	Accept
PE -> IU	0.146	1.567	2.853	0.004	0.038	Accept
CT -> IU	0.163	1.932	3.140	0.002	0.038	Accept
PR -> CT	-0.112	1.343	2.025	0.043	0.022	Accept
PR -> IU	-0.099	1.405	2.355	0.019	0.031	Accept
CV -> IU	0.203	1.242	5.290	0.000	0.092	Accept
$R^2adj_{IU} = 0.635$; $R^2adj_{CT} = 0.467$; $Q^2_{IU} = 0.604$; $Q^2_{CT} = 0.456$						

TABLE V. MEDIATING ROLE OF CUSTOMER TRUST

	Original sample	P values	T statistics	Result
PEOU -> CT -> IU	0.035	0.033	2.135	Accept
PR -> CT -> IU	-0.018	0.103	1.631	Reject
SC -> CT -> IU	0.012	0.246	1.159	Reject
PU -> CT -> IU	0.037	0.017	2.388	Accept
SI -> CT -> IU	0.044	0.009	2.602	Accept

D. T – Test Anova

Demographics are variables that reflect individuals' characteristics and theories suggest that they partly influence individuals' thoughts and intentions. Regarding gender, with Sig = 0.149, the Levene test indicates that the variances of the female and male groups are equal. The T-test results with Sig = 0.315 show that there is no significant difference in the intention to use electronic payments between females and males. For occupation, age, and income, the Levene tests produce results in the order of 0.03, 0.043, and 0.001 < 0.05, indicating that the variances of these groups are significantly different. To account for unequal variances, the Welch test is conducted. The Welch test results for income, age, and occupation show Sig levels of 0.083, 0.497, and 0.341 > 0.05, respectively, indicating that there are no significant differences in the intention to use digital payment methods among these groups. These findings suggest that demographic factors such as gender, age, income, and occupation do not significantly influence the intention to use electronic payments. This lack of significant difference implies that the intention to adopt electronic payment systems is consistent across different demographic groups, highlighting the universal appeal and potential acceptance of electronic payments regardless of these demographic variables. Table VI tests the differences in demographic variables.

TABLE VI. TESTING THE DIFFERENCES IN DEMOGRAPHIC VARIABLES

	Levene's Test	T-test	Levene Statistic	Welch
	Sig.	Sig.	Sig.	Sig.
Gender	0.149	0.315		
Age			0.043	0.497
Income			0.001	0.083
Occupations			0.03	0.341

VI. DISCUSSION, MANAGERIAL IMPLICATIONS, LIMITATIONS, FUTURE RESEARCH DIRECTIONS

A. Discussion

The study examined factors influencing consumers' intention to use electronic payment for online purchases in Ho Chi Minh City, utilizing 36 observed variables with 1 dependent and eight independent variables. Through bootstrapping and hypothesis testing, the impact of factors on electronic payment behavior was evaluated across dimensions including "Customer Trust", "Convenience", "Perceived Ease of Use", "Social Influence", "Perceived Usefulness", "Security", "Performance Expectancy" and "Perceived Risk". Key findings are summarized as follows:

Among the factors assessed, “Convenience” demonstrated the highest impact (β = 0.203) on electronic payment adoption. This underscores its critical role as the primary consideration for consumers when choosing online payment methods, consistent with prior research [73], [74], [75]. Following closely, “Customer Trust” ranked second (β = 0.163), highlighting the high level of trust consumers in Ho Chi Minh City place in online payment systems, which aligns with existing literature [76], [77], [78]. “Social Influence” ranked third (β = 0.153), particularly significant during the COVID-19 pandemic, influencing consumer trust and adoption of electronic payment methods, as noted in previous studies [79], [80], [81]. “Perceived Ease of Use” also ranked prominently (β = 0.153), emphasizing the importance of intuitive and straightforward transaction processes in enhancing adoption rates, as supported by prior research [82], [64]. “Performance Expectancy” (β = 0.146) and “Perceived Usefulness” (β = 0.127) further contribute to consumer acceptance by facilitating efficient and beneficial transaction experiences, consistent with findings from other studies [79], [83], [84], [85], [86]. “Security” (β = 0.099) reassures consumers of the safety and protection of their personal and financial information, albeit ranking lower compared to other factors. Interestingly, “Perceived Risk” (β = -0.099) negatively impacts the intention to use electronic payment, suggesting that mitigating perceived risks could enhance adoption rates. This finding prompts further exploration into consumers' apprehensions and strategies to address them, acknowledging potential unknown risks that could deter usage. Moreover, the study revealed that “Social Influence”, “Perceived Ease of Use”, “Perceived Usefulness” and “Perceived Risk” significantly influence “Customer Trust” (β = 0.27, 0.228, 0.215, and -0.112, respectively), highlighting the mediating role of trust in enhancing online payment adoption.

To enhance electronic payment adoption, businesses and policymakers could leverage these insights by prioritizing factors such as convenience, trust-building measures, user-friendly interfaces, and security enhancements. Strategies should focus on reducing perceived risks and enhancing perceived benefits, thereby fostering greater consumer confidence and usage. In conclusion, while this study aligns with existing literature, deeper integration of prior research and theoretical frameworks could further enrich interpretations. Additionally, providing actionable recommendations based on these findings can bridge the gap between research insights and practical applications, promoting wider adoption of electronic payment systems in Ho Chi Minh City.

B. Managerial Implications

To ensure smooth and convenient electronic payment, service businesses should focus on enhancing user experiences by integrating various payment methods, prioritizing security and authentication, providing professional services, and supporting customers. Continuous updates and improvements based on user feedback are essential. To build trust with customers in electronic payment, businesses need to prioritize security, display reliability, and respond promptly to complaints. Constantly improving product and service quality will also foster customer satisfaction and trust. To maximize the social benefits of electronic payment, businesses should provide financial incentives to low-income individuals, encourage them to transition away from cash and promote sustainable finance. Ensuring the security of user information is crucial in building trust and loyalty among customers. User-friendliness in electronic payment requires services to integrate multiple payment options, minimize advertising, facilitate streamlined transactions, and provide clear and simple user instructions. This will make electronic payment convenient and easy for users.

To achieve effective use of electronic payment, businesses must commit to meeting user expectations, continuously improve systems, and integrate new features. This will enhance user satisfaction, and trust, and contribute to the success of electronic payment. The usefulness of electronic payment necessitates diversification of products and services, cost reduction, and faster transaction processing. Emphasis on security and quick response to user feedback is vital for improving user experience in payment. To ensure security in electronic payment, businesses should implement data encryption, two-factor authentication, and fraud detection systems, and restrict access to data. Proper training and timely response to security incidents are essential for protecting users' personal information. Finally, to minimize risks in electronic payment, businesses should establish terms of use in line with legal regulations and ensure safe transactions. By applying these managerial implications, businesses can create a seamless and secure electronic payment experience for their customers, thereby fostering trust and loyalty in the usage of electronic payment methods.

C. Limitations

The study has certain limitations that need to be considered. One such limitation is the relatively small sample size used for data collection, which may have implications for the robustness of the results. To improve the generalizability of the findings, a larger sample size could be utilized in future research. Additionally, since the study was conducted exclusively in Ho Chi Minh City, caution should be exercised when attempting to extend the results to other regions or countries. Moreover, although the study explored various factors affecting consumers' intention to use electronic payment, it is essential to recognize that there may be other relevant variables that were not accounted for in the analysis. Future research could expand the scope of the investigation to encompass additional factors that might influence consumers' adoption of electronic payment methods. Conduct studies with larger and more diverse samples to improve the robustness and generalizability of the findings. Explore comparative studies across different regions to understand cultural, economic, and technological influences on electronic payment adoption.

D. Future Research Directions

Conduct a comparative study across different cities or countries to explore how cultural, economic, and technological factors influence consumers' intention to use electronic payment. Investigate the factors influencing the adoption of mobile payment platforms, as smartphones and mobile apps play an increasingly significant role in electronic payment. Analyze how age and gender influence consumers' intention to use electronic payment, as different demographics might have varying preferences and concerns. Study consumer preferences for specific types of electronic payment methods (e.g., e-wallets, mobile banking, contactless payments) and how these preferences vary across different consumer segments. By addressing these limitations and conducting further research on these suggested areas, a more comprehensive understanding of consumers' intention to use electronic payment and strategies for businesses can be developed.

APPENDIX

Survey Questions

Perceived ease of use (PEOU)	Soucer
1. For me, using electronic payment is very easy. 2. I believe that becoming proficient in using electronic payment will not be difficult. 3. Digital payments have made online shopping much simpler than before. 4. Transferring money through electronic payment gateways is also fast and convenient.	[52], [83], [84], [85]
Perceived usefulness (PU)	
1. I will pay faster when using electronic payment. 2. Using digital payments brings more benefits compared to traditional payment methods (cash or direct contact). 3. Digital payments are convenient for paying when shopping online. 4. Using digital payments helps me increase the efficiency of my purchases. 5. Using digital payments allows me to make payments for my usual online purchases.	[7], [83], [57]
Security (SC)	
1. I feel calm and secure when providing credit card or debit card information through the digital payment system. 2. I feel that digital payments are secure when transmitting sensitive information. 3. When using digital payments, I feel at ease when providing my personal information. 4. I believe that my transactions through digital payments will be protected. 5. I believe that when using digital payments, there will always be preparedness to handle risks and ensure data security.	[86]
Perceived Risk (PR)	
1. If I use digital payments, others may access information about my online transactions. 2. There is a high possibility of losing money if I make purchases using the digital payment system. 3. There are significant risks when buying with the digital payment system. 4. I consider buying with digital payments a risk.	[87]
Social influence (SI)	
1. In my life, there are important people, such as family, close friends, and colleagues, who have advised me to use digital payments for online shopping. 2. The important people in my life support me in using digital payments. 3. The community around me is using digital payments.	[88]
Performance Expectancy (PE)	[89]
1. I find digital payments to be a useful way of shopping. 2. Using digital payments makes transaction processing simpler. 3. Using digital payments improves the efficiency of my payments. 4. I save transaction costs when using digital payments.	

Convenience (CV)	
1. Digital payments are convenient because I often carry my smartphone with me. 2. Digital payments are convenient because I can use them anywhere. 3. Digital payments are convenient because I can use them in any situation. 4. Digital payments are convenient because they are not complicated.	[64]
Customer Trust (CT)	
1. I believe that digital payment platforms are capable and effective in processing contactless transactions. 2. I believe that digital payment platforms always prioritize the interests of consumers. 3. I believe that the legal frameworks for providing digital payments are sufficient to protect consumers. 4. I believe that digital payment platforms are honest and truthful with users.	[86], [90]
Intention to use e-Payment (IU)	
1. I intend to use digital payments for online shopping. 2. Shortly, I will use digital payments. 3. In the coming time, I am willing to continue using digital payments.	[91], [89]

Moving Beyond Traditional Incident Response: Combating APTs with Warfare-Enabled Continuous Response

Abid Hussain Shah
CIS Department, University of Melbourne, Melbourne, Australia

***Abstract*—Critically examining the cybersecurity management practices, it can be concluded that security management used by the organizations is mostly control-centered against a wide range of threats to information systems. This control-centered approach has matured to act as a shield to prevent against a large variety of attacks. Since threats against the information systems are becoming sophisticated, persistent and evolving, therefore, the current approach has not been very effective against the advanced strategies and techniques used by the emerging threats like APTs (Advanced Persistent Threats). The core argument of this paper suggests that to match up the capabilities of APTs, organizations need a major shift in their strategies. This shift needs to focus more on the response oriented techniques relegating erstwhile prevention-centered approach. Traditionally the warfare strategies are more response oriented. Some of the non-kinetic strategies (not involving physical fighting) can be useful in developing response capability of Information Systems. Therefore, drawing on the warfare paradigm, and making use of DCT (Dynamic Capability Theory), this research examines the applicability of warfare strategies in the entrepreneur domain. This article will also contribute by means of a research framework arguing that the integration of prevailing information security capabilities; such as incident response capabilities and security capabilities from the warfare practices is possible resulting in dynamic capabilities (warfare-enabled). Such capabilities can improve security performance.**

Keywords*—Information operations; information warfare; cyber security; dynamic capabilities; incident response capabilities; warfare enabled capabilities

I. Introduction

Within organizations, the most valuable assets are information systems and the infrastructures which require protection. Organizations are vulnerable against a variety of attacks which threaten to breach security mechanisms of the organizations to reach to the critical assets. Against this vast spectrum of attacks, information security approaches are traditional. Now a days, protecting the data against cyber-attacks has become a mounting challenge. Mostly the purpose of cyber-attacks remains financial gains [1]. Cyber-attacks can have many purposes may be military or political. Research conducted by Atif Ahmad and Richard Baskerville suggests that Organizations try to counter threats following strategies which are preventive in nature and are mostly control-centered [2], [3]. Such strategies have proved to be reasonably strong/successful against predicted or known attacks; nevertheless, the current traditional approach is being challenged by the increasingly complex and evolving threat environment. The emergence of highly sophisticated and potent cyber threat known as APT (Advanced Persis-tent Threats), challenges conventional information security paradigms in organizations. Baskerville [3] has strongly recommended new paradigms to follow; relegating the compromised prevention-oriented techniques for ensuring information systems' security. In this pursuit, learning from the Warfare Strategies mostly the non-kinetic strategies as well as incorporating theory of Dynamic Capabilities (DC), this article is looking at prospects of enhancing the corporate security performance, through the dynamic capabilities achieved as a result of integrating Warfare capabilities and conventional Incident Response capabilities.

The use of internet is on a constant and rapid increase and currently over 3 billion users world over use internet on daily basis (Tan et al., 2021). Many of the researches conducted in the domain of information security conclude that safeguarding the critical databases and ensuring the protection of information resources in the organizations has become complex, costly and time-consuming [4]–[6]. Scholars define information security threat as, an adverse event which sometimes may be in shape of a violation of policy or an unauthorized access [7]. Security threats are further categorized as Incidental threats, encompassing human errors, technical failures or forces of nature affecting security [7]. The second category of threats is critical and known as Purposive threats. The purposive threats look for deliberate and intentional breaches to a system's security, essentially driven by human efforts and intelligence [2], [7]. These are the 2nd category of threats the purposive threats; which are becoming increasingly challenging since mostly they are new, changing, exploring new vulnerabilities and are persistent in nature, well disciplined and are focused to achieve strategic goals/ objectives. Due to their peculiar characteristics of the purposive threats the security environment has become more vulnerable and increasingly uncertain [7] [8]. To address the growing challenges this article focuses to counter the real threats to information systems; the purposive threats.

As the technological advancements in the field of IT are super rapid, therefore, the security paradigm of information security is also changing quickly. The threats to information systems are becoming more silent and therefore, difficult to detect. Threats are also becoming complex and evolving so, we are facing more incidents and more frequently. The scenario suggests that enhancing the information security capabilities of the organizations is essentially required [3], [6], [7], [9]. Why the APTs are succeeding? It can be safely concluded that the current response capabilities of the organizations are inadequate to match the superior capabilities of APTs (Shah et al. 2019). Contrary to Information Security strategies, the Warfare response strategies are inherently quicker in generating response therefore; they are more suited to ever changing threat landscape [3], [7], [10] [11][12]. In this article it is being proposed that for enhancing enterprise security (information systems security), a major shift of the security focus is needed. The suggestion is to focus and adopt the best practices of response domain of the warfare paradigm, which is largely response-oriented paradigm. Analyzing extant literature, it is revealed that there is hardly any literature available to answer the question of adopting warfare practices by the organizations to enhance their information security landscape.

Therefore, to enhance the security of the organizations especially in the response domain, this article is proposing a response framework which incorporates warfare response capabilities. Almost all organizations face the challenges of external and internal security threat to their Information systems; this article is better suited for those organizations which possess their exclusive Incident response Teams/setups. There are four sections in this paper. The theoretical framing has been explained in the next section. In the literature review section, the extant literature on security incident response has been explored extensively. Possibility of integration of the capabilities of Information Warfare and Incident Response capabilities has also been explored resulting in dynamic capabilities. Based on this discussion a conceptual frame-work of warfare-based security response has been introduced before concluding the paper. In the next section we will be discussing Dynamic Capabilities theory to understand its usage in developing dynamic cyber security capabilities in the ever-changing threat landscape.

II. Dynamic Capabilities (DC) Theory and Security Response

Considering the rapidly changing technological advancements, there has been substantial focus to make the organizational capabilities dynamic instead of static, therefore, the importance of Dynamic Capabilities (DC) cannot be ignored. The DC have been explained by many authors especially Teece. He proposes the DC approach as "an extension of the resource-based view (RBV)", which was an erstwhile concept [13]. Since the security threat environment is continuously changing while the RBV is static in its nature, hence it is unable to match up the ever changing threat spectrum, faced by information systems' security. [7] [14]. This mismatch was adequately addressed by Teece et al. [13] through introduction of concept of DC. Teece has explained the dynamic capability as the one which can combat the challenging environments and possesses the ability to develop, built also integrate and subsequently reconfigure the competencies whether internal or external [15]. Explaining the concept further, it has been recognized that through the DC, organizations can develop advanced resources and configuration following specific strategic routines [16] [17]. DC also contribute in achieving competitive advantage, by exploiting available opportunities, sometimes create opportunities and thus keep the firm well prepared to meet future and current challenges. This phenomenon is essentially sensing, seizing the available opportunities and keeping the firm competitive [15]. The DC approach also contributes in learning from incidents [7], [18]. It is also argued that the Incident Response can be managed by the organizations efficiently by developing DC [7], [19]. Therefore, it is essential that organizations adapt to the rapidly changing threat environments. It is also well recognized that better adaptation occurs by following an interdisciplinary approach [20]. Drawing from the Henry's conclusions; an inter-disciplinary approach, an integrative and dynamic capability development can be ensured which possesses more abilities and robustness for adapting to frequently changing environments. This approach can also avoid pensive and closed-minded views [7], [21] [22]. Since the warfare capabilities are response oriented and conventional Incident Response (IR) capabilities are prevention oriented, integration of both results in Dynamic Capabilities (DC) ensuring much better security against the looming threats. Thus, the overall enterprise security performance enhances many folds [7]. It has been argued in the paper that DC theory is appropriate and relevant for the research as in the information security domain organizations face threats which are complex and evolving swiftly. This phenomenon creates high levels of uncertainty which can be addressed though building dynamic capabilities. The section covers the detailed literature review with an objective to understand available and being practiced conventional Incident Response Capabilities. Subsequently, warfare relevant capabilities like operational security and deception have also been explored. Both these warfare capabilities are non-kinetic in nature and can be integrated with the traditional Incident Response capabilities, resulting in dynamic capabilities which have been named as Warfare Enabled Dynamic Response Capabilities (WEDRC).

III. Literature Review

To conduct a systematic literature review creating a firm foundation for advancing knowledge and to establish the need for answering the identified research question, literature review was conducted following the parameters explained by [23]. Latest as well as relevant publications (articles) published in renowned conferences and journals in the domains of Cyber Security, Information Operations (IO), Information Warfare (IW), Information Systems (IS), Information System Security, cyber and Information Management were consulted. For focused results and get the relevant hits research was done based on the phrases and key words like; 'Cyber security management', 'information security issues', 'information security superior strategy', information systems' security management', 'strategies dealing advanced persistent threats', 'information systems controls', 'warfare superior strategies', 'dynamic capabilities development', 'incident response for organizations' and 'information security risk management'. Initially 157 articles were selected besides 12 books and 10 field manuals from US military literature. The research focus was narrowed based on the contents of the articles and relegating not relevant to our research domain. Further relevancy was established keeping in view the intent and the focus of research question such as: How the enterprise security performance can be enhanced? How we can improve the security response capability of information systems? And what all can be adopted from the warfare strategies for information systems' security enhancement? Thus the strength of articles was reduced to 66. Subsequently the for-ward and backward chaining process was carried out using the references of selected 66 articles; which resulted in an addition of 15, increasing the total to 81 articles, two books and 4 United States military field manuals on Information Warfare. With maturing the research process 13 articles initially included were deferred, bringing the total of articles to 68. Progressive and objective analysis gave birth to the proposed framework (Fig. 1). The results of the literature review suggest that the incident response capabilities are more focused on prevention of the incidents [7], [24], [25]. Therefore, they can address predicted or known threats only. Secondly the warfare capabilities have inbuilt response due to the nature of the warfare [5], [6]. Thirdly, DC theory provides sufficient helping tools in shape of sensing, seizing and transformation for efficient and dynamic incident response handling [19].

A. Conventional Incident Response (IR) Capabilities

Amongst the security threats to the information systems (IS), the purposive threats are more serious and damaging challenge to the security of organizations since they are very well organized, having mostly a well-orchestrated strategic objective, persistent in nature, and are ever evolving [7], [8]. The purposive threats always look for vulnerabilities in organizational de-fences. In the domain of information security, threats are combatted by application of controls, such as: (1) Formal (e.g. security policies, management of risk) (2) Informal (training), and (3) Technological controls (e.g. Fire walls, intrusion detection and protection systems, anti-viruses) [6], [7], [26]. Since the information systems; threats are usually handled by applying appropriate controls, this process of security management represents a control-centered approach [3], [7]. Since the Incident Response capabilities can be defined in many different ways, for this article DC theory perspective has been used. According to the well-known author Teece, the term 'capabilities' actually defines the role of firm's strategic management to adapt, integrating, and reconfigure organizational skillsets, resources, and acquired competences to deal with the changing environment and requirements" [13]. This has given lead to de-fine the Incident Response Capabilities: IR capabilities constitute all available controls (for-mal, informal and technical), practices and processes; to address security threats to IS while performing IR functions [7]. Literature also mentions about another perspective related to capabilities; people, processes and technologies for handling the security incidents [27].

Today's modern organizations are facing challenges to protect their information resources, and IT infrastructure. Literature also reveals that the current IS security response is essentially based on prevention strategy [7], [28]. The prevention-oriented approach has been quite successful for known threats. However, despite following the prevention oriented controls, in-formation security incidents are still happening reflecting failure of our defensive security mechanisms [7]. Large sized organizations, financial firms, banks and government organizations maintain exclusive incident response teams, however, maintaining exclusive IR teams becomes very expensive and does not remains cost-effective for smaller businesses and organizations [7]. Therefore to remain cost effective, most of the medium and small sized organizations maintain temporary IR teams. Also, the incident responders generally perform as 'fire-fighters' [5], [7].

B. Warfare Capabilities – Information Operations

While conceiving the leading plans in the warfare domain, multiple contingencies are hypothesized for that leading operational plan. This approach harnesses and harbors possibility of generating a robust response at the spur of the moment when and where required, harnessing and articulating the available resources in the given environment (e.g. an adversary's offensive movement). There are many warfare strategies which govern specific areas of the warfare. Amongst these multiple military strategies, few are non-kinetic like the Information Warfare (IW) which does not involve physical fighting and aims at protecting information and information systems, while disrupting those of the adversary [7], [12],[9]. The warfare paradigm is predominantly response oriented. Following the war fare principles pf employment like defense-in-depth, early warning Systems, maintain reserves at all tiers and extensive contingency planning; the defensive response and maneuvers can be well orchestrated against unknown offensive in unknown and fluent environments of the battlefield [7].

Literature concerning military sciences reveals that the IW is a non-kinetic war strategy; which has proved to be quite successful in protecting, exploiting, corrupting, denying or destroying information as well as information systems and infrastructure. Thus, it helps achieve competitive advantage over adversary [29],[9]. Since the IW deals with information and information systems (IS), therefore, its utility has been fairly established by many authors much beyond the warfare domain. As per the US military doctrine, success of IW comes through the integrated employment of Core, Supporting and Related capabilities (total 13 in number) which successfully affects the adversaries' decision makers, information and information systems. It also protects own information and information systems against adversary's such efforts resulting in influencing the decision making process [11], [12] [7]. An in-depth analysis of all the 13 capabilities of IW for their applicability for non-military organizations reveal that many of the capabilities are applicable in the corporate world however, for this article only two of the warfare capabilities namely; Operational Security (Opsec), and Deception are being considered [7].

- Operational Security (Opsec). It is Information Warfare strategy which is designed to meet operational needs. Successful application of Opsec assists in mitigating the risks related to the specific defensive vulnerabilities. This process is designed to shield critical information and observable indicators to the adversaries [7], [11]. Operational security can also be used for identification of the existing vulnerabilities in defensive/information systems of the adversaries, conducting risk assessment and planning/ application of appropriate protective measures [7]. To identify the looming threats like APTs, the scope of Opsec can be extended in Information Security (IS) domain to carryout monitoring and attaining knowledge about the strategic objectives of threats. Another application of Opsec can be discerning about the phases of APTs thus denial of objectives of the intruders in each phase can also be planned [7].

- Deception. Deception is an old age warfare concept which has been frequently used in information security domain as well. It mostly consists of those activities, actions which deliberately mislead the adversary's decision making process and operations. In fact successful deception forces the adversaries to take specific actions or inactions which are well planned for own benefit. Thus, deception hides the facts from adversary and presents the false [11]. If the warfare capability of deception is employed in the in security mechanism, the response capability against the critical threats like APTs gets enhanced [30]. Concept of deception is already in use though, not with its deepest fruits and in depth understanding as a capability. Some of the examples of the concept being used in IS domain are honey pots, breadcrumbs, and personas etc. The purpose of deception as a capability (dynamic) is to incorporate response, developing understanding of the strategies, methods, practices and objectives of the APTs through taking the threats into safe and imitated environments [7] (Shah et al. 2019).

C. Warfare Enabled Dynamic Response Capabilities (WEDRC)

Dynamic Capabilities (DC) ensure that the firm remains competitive by continuously improving the methods, process and technologies as well as reviving the role components of the organization. The capabilities which are responsible for routine functionalities of the organizations are called ordinary capabilities while the higher level capabilities which keep the organizations competitive are known as dynamic capabilities which can at times change the ordinary capabilities as well [7], [31]. Many authors have discussed different aspects of dynamic capabilities, like the Teece [13] calls ordinary capabilities as; micro-foundations and dynamic capabilities as higher-order capabilities. His arguments suggest that by the phenomenon of sensing, seizing and transforming the micro foundation capabilities develop into higher order dynamic capabilities [7].

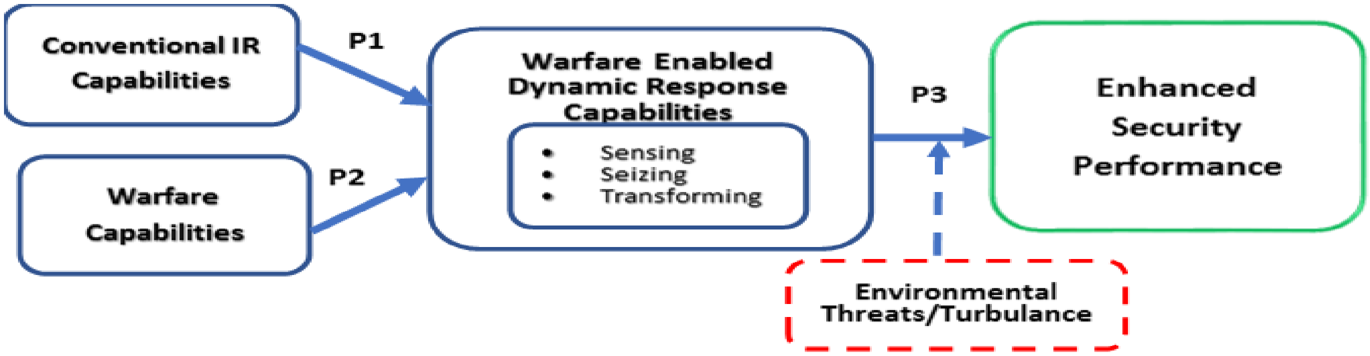
Similarly, in this article it has been argued that higher order dynamic capabilities can be developed through the integration of warfare capabilities (response oriented) with IR capabilities (prevention-oriented). Therefore, by adopting warfare strategies such as Opsec, we can identify different phases of APTs and can determine style, the strategic objectives of APTs in different phases. In corporate world this process is recognized as shaping and sensing process. Later on by applying deception eg breadcrumbs, tags and tripwires etc; the critical assets can be protected and strategies employed by intruders can be well known. When phases of APTs and objectives in each phase have been identified, combined application of deception and Opsec (e.g. kill chain) can deter APT disrupting the entire effort of the adversary. This is in fact a seizing process, through this process, the transformation of the capabilities to DC (Dynamic Capabilities; able to withstand the continuously changing threat environments) occurs [7]. In this paper the warfare enabled dynamic response capabilities (WEDRC) are the DC which were transformed by integrating warfare capabilities (deception, Opsec) and conventional Incident Response (IR) capabilities.

D. Enhanced Enterprise Security Performance

The enterprise security performance can be evaluated using many methods and factors; however, most of the scholars keep it in grey and invariably challenge the criterions for measuring security performance. One way to ascertain security performance of any organization may be related to the robustness or the effectiveness of the organization to counter internal and external frictions. In other words, it ensures the, confidentiality, integrity and availability of critical information [7], [19]. For this research article it has been argued that the enterprise security performance is the organizational acquiring which organizations can combat and respond to unknown threats including APTs.

IV. Proposed Research Framework

In the below framework (Fig. 1) it has been proposed that conventional Incident Response (IR) capabilities which are largely prevention oriented can be integrated with the relevant capabilities, practices from the warfare strategies, which are essentially response oriented.



Conventional IR Capabilities
Warfare Capabilities
P1
P2
Warfare Enabled Dynamic Response Capabilities
Sensing
Seizing
Transforming
P3
Enhanced Security Performance
Environmental Threats/Turbulance

Fig. 1. Enterprise security performance enhancement framework (Developed for this article).

This integration results in warfare enabled dynamic response capabilities (WEDRC), which are higher level dynamic capabilities. This integration and consequently the development of DC can ensure enhancement of the overall security performance.

A. *Contribution of IR Capabilities (Prevention Oriented)*

Due to sufficient maturity of Information Systems' (IS) security practices, there has been a focus on developing standards, control and frameworks to identify the best practices, such as the ISO 27000 [7] (Shah et al., 2019). These standards assist in identification of threats to Information Systems (IS). Within IS security practices; the Incident Response activities, practices sense and eliminate IS security threats and incidents to information systems [32]. Most of the system attacks can be addressed through IR processes [33]. However, most of the organizations fail to focus on the learning process of IR, which is generally the last phase of IR, this aspect remains as a deficiency in the IR process. [7], [34]. Therefore, the controls are only able to respond to /appropriate for routine security tasks, ensuring prevention and the continuation of known or predicted threats. The conclusion therefore, is that IR capabilities are contributing positively in prevention of predicted (known) threats. Therefore:

P 1: Explains the extent of contribution of conventional IR capabilities to WEDRC in prevention domain.

B. *Contribution of Warfare Capabilities (Response Oriented)*

Since the current attacks faced by the IS are strategic in nature, persistent, sophisticated and evolving; therefore, the prevention-oriented approach seems failing against the APTs in the ever changing threat environments [3], [7]. Although a lot of work has already been done for development of more robust and improved controls, still the innovative, APTs succeed. The warfare security practices being more response oriented house dynamism [35]. Therefore, the relevant warfare capabilities, suitably developed into warfare enabled dynamic response capabilities (WEDRC) can amicably deal with unpredicted or unknown APTs. Therefore, it is proposed that:

P 2: Focuses on the contribution of Warfare relevant capabilities for WEDRC, in response domain.

C. *Warfare Enabled Dynamic Response Capabilities (WEDRC)*

Since the DC theory explains phenomenon of integration of dynamic capabilities through the process of the sensing, seizing, and transforming; therefore the birth of proposed Warfare enabled Dynamic capabilities is presumed to combat APTs much better than erstwhile traditional IR capabilities [7], [13]. Framework explains that the traditional IR capabilities can contribute positively to WEDRC (largely in the prevention domain), while the warfare relevant capabilities can assist in the response domain. It can also be concluded that the WEDRC can ensure better knowledge management as well as can obtain competitive advantage even under ever changing threat environment (Environmental Turbulence). Resultantly, the enterprise security performance is enhanced. Therefore, it is proposed:

P 3: Warfare enabled Dynamic Response Capabilities enhance enterprise security performance.

D. *Key Findings*

- Under the current environments the Incident Responders struggle to distinguish amongst the false positives considering the huge number of logs they need to face on daily basis. This phenomenon is impacting badly on the incident response process.
- One solution to go around huge false positives is automated decision making regarding which incident must be escalated and which should be ignored or treated differently. This could be done at SOC (Security Operation Center)
- Since Incident Responders are mostly those individuals who are performing other tasks and are collected on ad-hoc basis, therefore, use of IBM playbooks to follow the incident response steps remains useful.
- Since APTs have evolved to become more complex, persistent therefore, the better way to combat them is follow standards like IBM play books. However, since the APTs employ a military style approach, so, therefore, even by following the frameworks and established standards, there are likely chances that APTs will succeed. Adoption of military strategies like deception, and operational security assist in combating APTs in much better way
- Whenever the threats received escalate to the next level, the utility of teamwork becomes essential to go through the incident response phases in an organized manner.
- The deception strategy assists in developing mutated network, capable of not only preventing rather ensuring CIA (confidentiality, Integrity and Availability) of essential data. It also assists in tracking down the perpetrators.
- Through Warfare Enabled Dynamic Response Capabilities, Continuous response is possible.
- Through continuous response the process of early detection and identification of the likely threats is possible, and it assists many folds in the response process.

V. Conclusion

As the information security is largely prevention focused, so, mostly the APTs succeed revealing that the current prevention oriented security mechanism lacks behind APTs. Thus the call of the situation is to enhance response capabilities of the information systems security. Since the warfare domains employ hierarchical response practices to defeat the adversary at different tiers, adoption of warfare response-oriented techniques can enhance the response capabilities of organizations ensuring better cyber security.

As a future work we would like to carry out research of two more case study sites which use deception and operational security as one of their practices to develop deep insight about the continuous response phenomenon.

Deep Learning-Based Image Recognition Technology for Wind Turbine Blade Surface Defects

Zheng Cao[1], Qianming Wang[2]*
State Grid Jilin New Energy Group Co., Ltd., Changchun 130000, China[1]
Department of Automation, North China Electric Power University, Baoding 071003, China[2]

***Abstract*—This paper proposes WindDefectNet, an image recognition system for surface defects of wind turbine blades, aiming at solving the key problems in wind turbine blade maintenance. At the beginning of the system design, the functional requirements and performance index requirements are clarified to ensure the realization of the functions of image acquisition and preprocessing, defect detection and classification, defect localization and size measurement, and to emphasize the key performance indexes such as accuracy, recall, processing speed and robustness of the system. The system architecture consists of multiple modules, including image acquisition and preprocessing module, feature extraction module, attention enhancement module, defect detection module, etc., which work together to achieve efficient defect recognition and localization. By adopting advanced deep learning techniques and model design, WindDefectNet is able to maintain high accuracy and stability in complex environments. Experimental results show that WindDefectNet performs well under different lighting conditions, shooting angles, wind speed and weather conditions, and has good environmental adaptability and robustness. The system provides strong technical support for blade maintenance in the wind power industry.**

***Keywords*—Wind turbine blades; image recognition; defect detection; deep learning; WindDefectNet**

I. Introduction

With the growing global demand for renewable energy, wind power, as an important clean energy source, has been developing rapidly worldwide. According to statistics, by the end of 2023, the global installed capacity of wind power reached about 800GW, and is expected to grow to at least 1,200GW by 2030 [1]. China, as one of the largest wind power markets in the world, has an installed capacity of more than 250GW, and is still growing at a high rate every year. This rapid growth not only promotes the progress of wind power technology, but also brings higher requirements for efficient and reliable operation of wind power equipment.

Wind turbine blades are an important part of wind turbines, and their performance directly affects the power generation efficiency and service life of the entire wind turbine. However, exposed to the natural environment for a long time, wind turbine blades are susceptible to erosion, cracks, scratches and other damages, which, if not detected and dealt with in a timely manner, may lead to a decline in the performance of the blades or even fracture, thus affecting the safe and stable operation of the whole wind farm [2]. Therefore, regular inspection and maintenance of wind turbine blades is crucial to ensure the normal operation of wind farms.

Fig. 1 is a bar chart showing a comparison of electricity generation from different energy types in 2018 and 2023. As can be seen from the chart, fossil fuels have the highest power generation capacity and remain stable during these five years, while renewable energy sources such as hydro, wind, and solar have increased their power generation capacity; and nuclear energy and biomass have a relatively small power generation capacity [3]. Overall, the proportion of renewable energy use is gradually increasing with the progress of technology and the society's awareness of environmental protection.

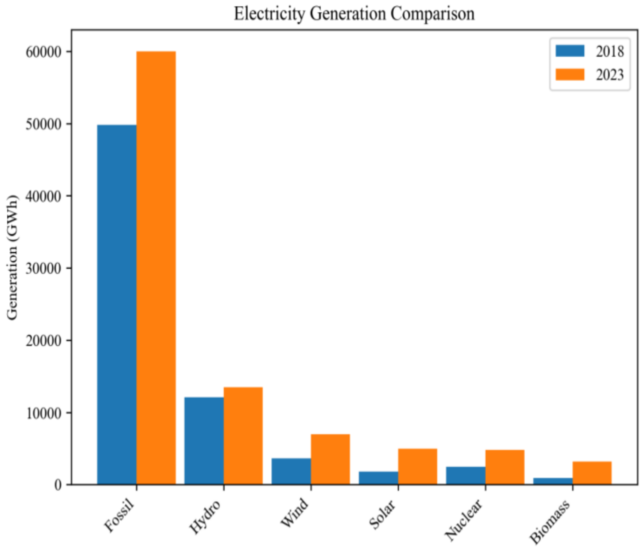

Fig. 1. Comparison of electricity generation from different energy types in 2018 and 2023.

With the rapid development of the wind power industry, the maintenance technology of wind turbine blades has become one of the hot spots of research. Scholars and engineers at home and abroad are committed to developing deep learning-based image recognition technology for wind turbine blade surface defects to improve the efficiency and accuracy of wind turbine blade maintenance [4]. In this field, research progress at home and abroad presents different characteristics and achievements [5]. Foreign research institutes and universities, such as the Fraunhofer Institute in Germany and the Technical University of Denmark, have made remarkable progress in the automatic detection of surface defects on wind turbine blades. These studies mainly focus on utilizing advanced image processing techniques and deep learning algorithms to improve the automation level of wind turbine blade maintenance. By using deep learning models such as convolutional neural networks (CNN), researchers are able to automatically extract features from wind turbine blade images and classify different types of defects. In addition, foreign research also focuses on the optimization of the model, and improves the generalization ability and robustness of the model through data enhancement, migration learning and other techniques [6], so that it can maintain stable performance under different lighting conditions and shooting angles.

At present, the research work in China mainly focuses on dataset construction, model innovation, and system integration and application. On the one hand, collecting a large number of wind turbine blade images containing different types of defects, they are used to train and validate the deep learning models; on the other hand, by combining the characteristics of the domestic wind turbine blades, they develop deep learning models that are more suitable for local conditions, such as a lightweight network structure to adapt to the needs of edge computing. In addition, the domestic research team is also actively developing an integrated wind turbine blade inspection system, realizing an integrated solution from image acquisition to defect recognition, and deploying and testing it in actual wind farms. Research results at home and abroad show that deep learning-based image recognition technology for wind turbine blade surface defects has made significant progress, but there are still some challenges and limitations [7]. First, high-quality labeled data is crucial for training high-performance deep learning models, but obtaining enough labeled data is still a challenge in practice. Second, the generalization ability of the model in different environments still needs to be improved to cope with the diversity of the working environment of wind turbine blades. Finally, considering the practical application requirements of wind farms, the real-time processing capability and portability of the model also need to be further strengthened to facilitate on-site deployment and maintenance.

The WindDefectNet proposed in this paper innovatively combines the strong image feature extraction capability of CNN and the self-attention mechanism of Transformer, which significantly improves the performance of defect detection in complex backgrounds. The stability and robustness of the system under various environmental conditions are demonstrated through experiments, and the system is able to effectively cope with the challenges in practical applications. The system can not only accurately identify defects on wind turbine blades, but also accurately locate the defects and provide dimensional measurements, which greatly improves the efficiency of wind turbine blade maintenance.

II. Literature Review

A. Image Recognition of Surface Defects on Wind Turbine Blades

Wind turbine blades may suffer from various forms of damage such as cracks, corrosion, abrasion and scratches during long-term operation. In order to ensure the safety and economy of wind power systems, it is crucial to detect and evaluate these surface defects in a timely manner. In recent years, image recognition technology has made significant progress in this field. An industrial camera is utilized to acquire images of wind turbine blades, which is the basis for constructing high-quality datasets. The selection of industrial cameras needs to consider factors such as lighting conditions, resolution and frame rate [8]. Considering the morphological characteristics of wind turbine blades and environmental factors (e.g., light variations, shadows, and dust), the image preprocessing step is very important. Preprocessing usually includes operations such as grayscaling, spatial filtering, image enhancement, image segmentation, and image denoising to reduce noise and interference and improve the accuracy of subsequent image recognition.

Machine vision-based methods: Machine vision techniques are used to detect defects on the blade surface. This involves enhancement of the blade surface scratch image using a Gabor filter, and determining the optimal parameters of the Gabor filter using an information entropy function. In addition, image segmentation techniques can be used to identify defective areas on the blade surface. Recent studies have shown that deep learning-based methods have achieved significant success in the detection of defects on the surface of wind turbine blades. For example, automatic feature extraction and classification can be performed using convolutional neural networks (CNNs). Such models are able to automatically learn features from the original images without the need to manually design a feature extractor, which improves the accuracy and automation of detection [9]. A series of image processing algorithms are applied to the acquired blade images to achieve the identification of defective damaged regions of the blade and the extraction of feature parameters. This helps to reduce the impact of noise and manual interpretation on the accuracy of blade surface defects [10]. The latest research results also include classification and quantitative assessment of defects. For example, deep learning models can be utilized to classify different types of defects and give an estimate of the severity of the defects. A future trend may be to combine image recognition techniques with other NDT techniques (e.g., ultrasonic inspection, phased array ultrasonic inspection, etc.) to achieve more comprehensive and accurate inspections.

B. Application of Deep Learning to Image Recognition of Surface Defects on Electric Blades

Traditional wind turbine blade surface defect identification technology mainly relies on manual visual inspection or rule-based image processing methods. Although manual inspection is intuitive, it is inefficient and highly influenced by personal experience. Rule-based methods, on the other hand, usually require expert a priori knowledge to define features, such as using edge detection, texture analysis and other techniques to recognize specific defect patterns [11]. However, these methods often lack flexibility and robustness and are difficult to adapt to complex and changing real-world situations.

With the development of machine learning techniques, especially the application of algorithms such as Support Vector Machines (SVM), Decision Trees, and Random Forests, the identification of surface defects on wind turbine blades has become more automated and efficient [12]. These methods learn the features of defects by training models to achieve automatic classification. However, traditional machine learning methods often require manual design of features, which limits their performance in complex defect recognition tasks.

In recent years, deep learning technology has shown great potential in the field of image recognition of surface defects of wind turbine blades due to its powerful feature learning ability and adaptivity. Convolutional neural network (CNN), as a mainstream model of deep learning, has been widely used in image classification, target detection and other fields. In wind turbine blade surface defect recognition, CNN can automatically learn complex features in images without manual design, which greatly improves the accuracy and efficiency of recognition. The study in [13] proposed a CNN-based surface defect detection system for wind turbine blades, which is able to automatically recognize multiple types of surface defects and achieve high recognition accuracy. The research in [14] used a migration learning approach to optimize the CNN model to improve the performance of the model on a small amount of labeled data. This approach effectively reduces the data labeling effort while maintaining good recognition results. The study in [15] explored how to combine multimodal data (e.g., images and acoustic signals) to improve the accuracy of wind turbine blade defect recognition. Their proposed fusion model was able to capture defect information from multiple perspectives, thus improving the robustness and generalization ability of the system.

III. Image Recognition System Design for Wind Turbine Blade Surface Defects

A. *System Requirements Analysis*

When designing the image recognition system for wind turbine blade surface defects, we firstly clarified the functional requirements and performance index requirements of the system. The functional requirements of the system include the following aspects: firstly, the system needs to have the ability of image acquisition and pre-processing, which can automatically or semi-automatically acquire high-definition blade surface images, and carry out pre-processing operations such as gray scale conversion, contrast enhancement, image cropping and scaling, in order to reduce the impact of environmental factors on the quality of the image. Secondly, the system needs to realize defect detection and classification, and be able to accurately identify cracks, abrasion, scratches, deformation and other defects, and classify them. Once again, the system needs to complete the defect location and size measurement, to determine the location of defects and measure their length, width and other key dimensional parameters, to provide data support for maintenance decisions. Finally, the system also needs to have a report generation and management function, automatically generating inspection reports containing inspection results, defect types, locations, dimensions and other information, and providing a convenient data management mechanism so that users can view historical records and statistical analysis. The performance index requirements are designed to ensure that the system in the actual application of the effect of the expected standard, so as to meet the strict requirements of the wind blade defect detection, the specific requirements of the analysis framework shown in Fig. 2 [16,17].

Fig. 2. Needs analysis framework.

In the process of planning the image recognition system for wind turbine blade surface defects, we formulated the performance index requirements of the system in detail to ensure that it can efficiently and stably serve the maintenance inspection of wind turbine blades. First of all, the accuracy rate is the core index to measure the performance of the system, and we require the system to reach an accuracy rate of more than 95% on defect recognition to ensure the reliability of the recognition results [18]. At the same time, the recall rate also needs to be kept above 95% to ensure that the system is able to find all existing defects as much as possible to avoid any omissions. Secondly, processing speed is critical for on-site operations, and the system needs to be able to process a single image within a few seconds to meet the need for rapid detection [19]. In addition, the robustness of the system is indispensable; it should be able to operate stably under different lighting and shooting angles without interference from external environmental factors.

B. *System Architecture Design*

This section describes in detail the architectural design of the image recognition system for wind turbine blade surface defects to ensure the efficient and reliable operation of the system. The system consists of several modules, each of which has its specific function and works together to achieve the final goal, and the specific architecture is shown in Fig. 3.

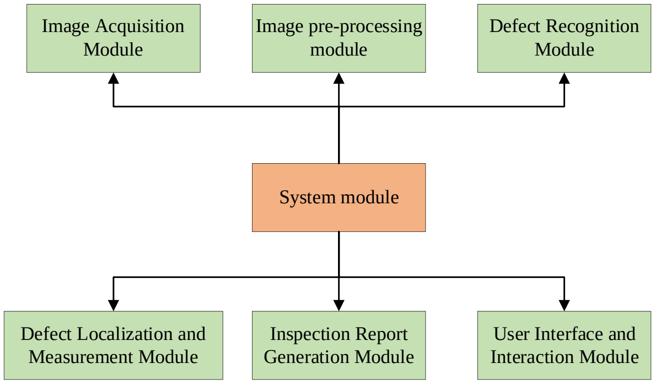

Image Acquisition Module
Image pre-processing module
Defect Recognition Module
System module
Defect Localization and Measurement Module
Inspection Report Generation Module
User Interface and Interaction Module

Fig. 3. System architecture design.

The module integrates image acquisition devices such as HD cameras or drones to capture high-definition images of the surface of wind turbine blades. To ensure the image quality, industrial-grade cameras are used and a robotic arm or drone mounting solution is designed to capture the blades from different angles and distances [20]. In addition, the module realizes automatic flight path planning based on a gimbal or drone to ensure coverage of all inspection areas [21]. Taking into account the effects of different lighting conditions, a light compensation device is also provided to ensure clear images in all weather conditions. The module also provides an image acquisition control interface that allows the user to remotely control the acquisition process, supporting the selection of manual or automatic modes.

This module is responsible for pre-processing the captured image to ensure that the quality of the image meets the needs of subsequent processing. The preprocessing steps include grayscaling, denoising, brightness and contrast adjustment. By enhancing the image, such as applying histogram equalization and local contrast enhancement, we can improve the contrast and clarity of the image. To further reduce noise interference, we use methods such as Gaussian filters. In addition, we employ edge detection techniques to help determine the blade contours and assist in image cropping so as to remove extraneous backgrounds and highlight wind turbine blade regions. All these operations are automated, reducing the need for human intervention and improving processing efficiency.

This module utilizes deep learning models (e.g., Convolutional Neural Networks CNN) to extract features from images and identify various defects on the surface of wind turbine blades. We have selected suitable neural network architectures such as ResNet, Inception etc. to improve the recognition accuracy [22]. By utilizing transfer learning techniques, good performance can be achieved faster by using existing pre-trained models. In addition, implementing data augmentation strategies helps to increase the generalization ability of the model so that it can be better adapted to new defect types. To support continuous model improvement, we integrated model versioning and automatic deployment mechanisms to simplify the process of model updating and ensure that the system is always in an optimal state.

The module focuses on precisely locating the recognized defects and measuring their dimensions, including length, width and area. By using image segmentation techniques, we can accurately determine the boundaries of defective areas [23]. Combined with image calibration techniques, we achieve a conversion from pixels to actual dimensions, which helps to more accurately assess the actual impact of defects. In addition, we have developed a set of algorithms to assess the severity of defects, such as a combined score based on the size and location of the defect, which helps to determine the priority of repairs. The module records the location coordinates and dimensional information of each defect, which facilitates subsequent data analysis and tracking [24].

This module automatically generates an inspection report based on the results of the recognition and measurement, which includes images, defect lists, positional coordinates, dimensional information, and more. In order to ensure the uniformity and professionalism of the report format, we have adopted a templated report generation mechanism. Meanwhile, to ensure data security, we have realized data backup and recovery functions. To facilitate users to find specific inspection records, we provide search and filtering functions. In addition, the module also integrates a data export function, which supports a variety of format outputs, such as CSV, PDF, etc., to meet the needs of different scenarios [25].

C. *Model Selection and Training*

1) Modeling: To meet the needs of wind turbine blade defect detection, we propose an innovative deep learning model, WindDefectNet, which combines the advantages of Convolutional Neural Networks (CNNs) and Transformer structures, aiming to achieve high-precision defect detection and localization. The core design concept of WindDefectNet is to combine the strong image feature extraction capability of CNN with the self-attention mechanism of Transformer to improve the model's defect detection performance in complex backgrounds. The following are the main components of the model and how they work: the feature extraction module uses a pre-trained ResNet50 as a base, which is capable of extracting multi-level features from the input image. To further improve the quality of the features, a global average pooling layer is added to compress the feature map into fixed-length vectors. This helps the model to better understand the local details and the overall structure in the image, providing a high-quality feature representation for subsequent processing. The Attention Enhancement module utilizes the self-attention mechanism in the Transformer structure to reprocess the extracted features and enhance the weights of key features. The self-attention mechanism allows the model to focus on the important parts of the input features and ignore irrelevant information. This mechanism allows the model to focus on the areas of possible defects on the wind turbine blades, improving the accuracy of defect detection. The defect detection module is responsible for the final defect detection of the attention-enhanced features. This module consists of two main parts: the classification submodule and the localization submodule [26]. The classification submodule uses a fully connected layer to determine the presence of defects and gives a probability estimate for each type of defect, while the localization submodule determines the exact location of the defects through regression methods [27]. These two submodules work together to ensure that the model not only recognizes the presence of defects, but also accurately locates these defects, as shown in the specific framework in Fig. 4.

Convolutional Neural Networks (CNNs) specialize in processing two-dimensional image data and are able to capture local features and spatial information efficiently; whereas Transformer was originally designed for processing one-dimensional sequential data (e.g., text) and captures long-distance dependencies through a self-attention mechanism. In order to apply Transformer to image processing tasks, we need to find a way to transform the data representation of an image to adapt it to the input requirements of Transformer. To this end, we introduce an adaptation layer to accomplish the data transformation from 2D to 1D. Specifically, we split the input image into a series of “patches” or chunks, where each patch is considered as an element in the sequence. In this way, the entire image can be viewed as a sequence of these patches. In addition, in order to preserve the spatial information of the image, we add a positional encoding to each patch. The position encoding is a vector that tells the Transformer the relative position of each patch in the original image. This approach allows the Transformer to understand and utilize the spatial arrangement of the image for better modeling of global information. With this approach, WindDefectNet is able to achieve effective detection of defects on the surface of wind turbine blades by taking advantage of Transformer's powerful long-range dependency modeling capabilities while maintaining efficient local feature extraction.

2) Feature extraction module (FEM): The Feature Extraction Module (FEM) is a key component of the WindDefectNet model, which is responsible for extracting useful features from the input image[28].ResNet50 is a deep convolutional neural network that consists of a series of residual blocks, which is effective in mitigating the problem of gradient vanishing in deep networks, and is capable of learning rich feature representations during the training process.ResNet50 usually contains multiple stages, and each stage contains multiple residual blocks.

Input Image I is the original input image which needs to be normalized and preprocessed. Feature map F is the output of the ResNet50 network is a multi-channel feature map where each channel represents a feature representation of the image. The feature extraction process is shown in Eq. (1).

$$F = \text{ResNet50}(I) \tag{1}$$

Where ResNet50 denotes the ResNet50 network, I is the input image and F is the feature map generated after ResNet50 processing. The role of the global average pooling layer is to perform dimensionality reduction on the feature map while retaining important information. In WindDefectNet, the global average pooling layer is located at the end of ResNet50, and its purpose is to convert the feature map into a fixed-length vector that contains global information about the entire image.

The global average pooling operation is averaged over each channel in the feature F to obtain a fixed length vector. The process of global average pooling can be expressed as Eq. (2) [29].

$$F_{avg} = \text{GlobalAvgPool}(F) \tag{2}$$

The feature extraction module (FEM) successfully extracts a representative multi-channel feature map F after standardized preprocessing of the input image through the combination of an effective ResNet50 network and a global average pooling layer, and converts it to a fixed-dimension feature vector C through global average pooling, a process that not only reduces the risk of overfitting and ensures the stability of the output dimensions, but also preserves the image's global information, which is crucial for tasks such as wind turbine blade defect detection, and provides a solid foundation for the subsequent attention enhancement module and defect detection module.

3) Attention enhancement module (AEM): The Attention Enhancement Module uses the Transformer structure, which captures the correlations between different locations in the feature map, thus enhancing the model's attention to key features. The attention mechanism can be expressed as Eq. (3)-Eq. (6) [30].

$$Q = W^{Q} F_{avg} \tag{3}$$

$$K = W^{K} F_{avg} \tag{4}$$

$$V = W^{V} F_{avg} \tag{5}$$

$$\text{Attention}(Q,K,V) = \text{softmax}\left(\frac{QK^{T}}{\sqrt{d_k}}\right)V \tag{6}$$

where, (W^{Q}, W^{K}, W^{V}) is the weight matrix and d_k is the dimension of the key vector. Through the self-attention mechanism, we can obtain the attention-weighted feature representation F'.

4) Defect detection module (DDM): The Defect Detection Module (DDM) is another important component in the WindDefectNet model, and its main responsibility is to perform the final defect detection on the features generated by the Attention Enhancement Module. In order to achieve efficient and accurate detection, we use a lightweight convolutional neural network as the underlying architecture, which consists of two branches: a classification branch and a regression branch.

The goal of the classification branch is to predict whether each candidate region contains a defect or not. To do this, we need to define a loss function to measure the gap between the predicted results and the true labels. The cross-entropy loss function L_{cls} is used here, which is effective in evaluating the performance of the model for binary or multiclassification problems. The cross-entropy loss function L_{cls} can be expressed as Eq. (7).

$$L_{cls} = \sum_{i} y_i \log(p_i) \tag{7}$$

where y_i denotes the true label of the ith sample and p_i is the probability predicted by the model. The purpose of this function is to minimize the difference between the predicted probability and the true label.

If the problem is a binary classification problem, then both y_i and p_i are scalar values that represent the probability of a positive class, respectively. For example, in wind turbine blade defect detection, y_i might be one of {0, 1}, where 0 means no defects and 1 means defects, while p_i is the probability that the model predicts a defect. If the problem involves more than one category, then y_i and p_i will be vectors. y_i p_i and will be vectors. is a onehot vector, where only one element is 1 for the true category, and all other elements are 0; is a probability distribution vector, where each element represents the predicted probability of the corresponding category. By minimizing L_{cls} , the model adjusts its parameters to improve the accuracy of the prediction. As the probability predicted by the model gets closer to the true label, the cross-entropy loss will be smaller.

The main goal of the regression branch is to predict the exact location of the defects, i.e., the coordinates of the regression bounding box. To optimize the regression branch, we use a smooth L1 loss function L_{reg} , which efficiently handles the error in the regression problem and smoothly transitions to L2 loss when the error is small and to L1 loss when the error is large. This property helps to minimize the effect of large errors while maintaining sensitivity to small errors. The smooth L1 loss function L_{reg} is defined as shown in Eq. (8).

$$L_{reg} = \begin{cases} 0.5x^{2} & \text{if } |x| < 1 \\ |x|\,0.5 & \text{otherwise} \end{cases} \tag{8}$$

Here x denotes the difference between the predicted value and the true value. When the error is less than 1, the loss function takes the form of L2 loss, which helps to optimize for small errors, and when the error is greater than or equal to 1, the loss function takes the form of L1 loss, which helps to reduce the effect of large errors. When the error is small, the L2 loss form is used, which converges to the optimal solution faster and is very sensitive to the error, which helps to fit the data accurately. When the error is large, the L1 loss form is used, which reduces the effect of large errors and prevents the model from focusing too much on a small number of outliers, thus making the overall regression more robust.

By combining the classification loss L_{cls} and the regression loss L_{reg} , we can train a model that is able to both accurately predict whether a defect is present or not, as well as accurately localize the location of the defect. This combined consideration of classification and localization is very effective in defect detection tasks because it can optimize both of these important aspects simultaneously, thus improving the performance of the whole system. Where x is the difference between the predicted value and the true value.

5) Training strategies: In order to make the model converge better and avoid overfitting, we use the following strategies: (1) Data Enhancement: enhance the training set by randomly rotating, scaling, clipping and flipping. (2) Regularization: apply Dropout and weight decay during training. (3) Learning rate scheduling: a cosine annealing learning rate strategy is used to periodically adjust the learning rate to promote convergence.

The final loss function L combines categorical and regression losses and can be expressed as Eq. (9). where λ is a balancing factor to regulate the importance of the two types of losses.

$$L = L_{cls} + \lambda L_{reg} \tag{9}$$

WindDefectNet is highly integrated and easy to integrate into existing maintenance processes for wind power facilities. It can be carried by automated inspection drones or other mobile platforms to perform regular comprehensive inspections of wind turbine blades. The output of the system can be fed back directly to the O&M team, helping them to quickly locate and assess the damage, and then formulate a reasonable maintenance plan.

In addition to traditional horizontal-axis wind turbines, WindDefectNet is also applicable to vertical-axis wind turbines and other types of rotating equipment. With a few tweaks to the algorithms, a wider variety of surface materials and shape features can be supported. For example, migration learning techniques can be used to transfer existing knowledge to newer models of turbines, reducing the time and cost of retraining. This flexibility makes WindDefectNet a valuable tool to help drive intelligence across the wind industry.

6) Visualization: WindDefectNet's user interface has been designed with a particular focus on user experience and is intended to make it easy for non-expert users to perform complex defect identification tasks. The interface is simple and intuitive, and provides several auxiliary functions to enhance the usability and accessibility of the system.

The user can upload an image of the wind turbine blade to be inspected through a simple drag-and-drop operation or file browsing. Once uploaded, the system automatically initiates the defect detection process without the need for complex parameterization. The results are displayed visually on the interface, marking all the detected defect areas with bounding boxes of different colors and shapes. A confidence score is attached to each defect to help the user determine the reliability of the results. Users can use the zoom and pan functions to scrutinize the marked defect areas to more accurately assess the severity and location of the defects. To further enhance the user experience, WindDefectNet offers one-click report generation. Users can generate a detailed inspection report with one click, which contains information on all detected defects, their location, size and recommended treatment. The report format is clear and easy to understand and archive. In addition, users have the option to export the report to PDF, Excel or other commonly used formats for further analysis and sharing. To help new users get started quickly, short tutorial videos are embedded in the interface to guide users on how to use each feature. These videos cover the entire process from image upload to result analysis. A Frequently Asked Questions (FAQ) section is also provided to answer common questions that users may encounter during use. If users need further assistance, timely technical support is also available through the online support contact form. Through these designs, WindDefectNet's user interface not only simplifies complex technical operations, but also provides a wealth of assistive features that make specialized defect identification tasks easy for non-expert users. This high level of usability and accessibility greatly increases the practical value of the system, making it a powerful tool for maintenance work in the wind power industry.

IV. Experimental Evaluation

A. Data

In the process of constructing the dataset for the WindDefectNet model, we adopted a rigorous approach to ensure the quality and diversity of the data. First, we collected a large number of wind turbine blade images by various means, such as field photography and aerial photography by UAVs, which cover different lighting conditions, shooting angles and background environments to fully reflect the actual conditions of wind turbine blades. Next, we hired a professional annotation team to use professional annotation tools to meticulously annotate the defects in the images, including the location, type and size of the defects and other information, to ensure the accuracy and consistency of the annotation. In the data division stage, we divide the dataset into training set, validation set and test set according to the ratio of 70%, 15% and 15%, so as to facilitate model training, hyper-parameter adjustment and performance evaluation. In order to further enhance the diversity of the dataset and the generalization ability of the model, we used various data enhancement techniques such as random rotation, scaling, clipping and flipping. Finally, we performed image normalization, including grayscaling, histogram equalization, and other operations to improve the contrast and clarity of the images so that all images have the same pixel range, which lays a solid foundation for model training and evaluation.

The dataset contains samples from multiple geographic locations and seasonal variations to enhance the model's adaptability to natural light variations. In addition, we specifically collected data from rare cases, such as fine cracks on leaves made of special materials, to facilitate more comprehensive training of the model. To address the potential data bias problem, we take proactive measures, such as using data enhancement techniques to increase the number of rare category samples and cross-validation strategies to ensure the model generalization ability.

B. Experimental Design

Experiments were conducted on multiple GPU servers with hardware configurations including NVIDIA Tesla V100 GPUs, and Intel Xeon E5 series CPUs.We used the PyTorch deep learning framework to implement the WindDefectNet model, and used the Adam optimizer during training with an initial learning rate of 0.001 and adjusted according to the cosine annealing strategy.

C. Experimental Results

As shown in Table I, the crack type of defects performs optimally in all the indicators, with a mean average precision (mAP) of 0.92, accuracy and recall of 0.93 and 0.91, respectively, and an F1 score of 0.92, indicating that the model is more capable of detecting and classifying cracks. We also compared WindDefectNet with several other commonly used defect detection models, including Faster RCNN, YOLOv3, and

Mask RCNN. Table II shows the performance comparison of the different models on the test set.

Table II compares the performance of WindDefectNet model with several other commonly used defect detection models on the test set. As shown in Table II, WindDefectNet outperforms the other models in mAP, accuracy, recall, and F1 score, showing its superiority in defect detection tasks. Especially on mAP, WindDefectNet leads with 0.90, while the processing speed is kept at a moderate level of 15 frames per second, indicating that the model has high processing efficiency while ensuring detection accuracy. Compared with other models, WindDefectNet has better processing speed than Mask RCNN and slightly lower than YOLOv3 while maintaining higher accuracy, but the overall performance is better.

TABLE I. CLASSIFICATION PERFORMANCE OF DIFFERENT DEFECT TYPES

Defect type	mAP	accuracy	recall rate	F1 score
crackles	0.92	0.93	0.91	0.92
wear and tear	0.88	0.89	0.86	0.87
corrode (degrade chemically)	0.90	0.91	0.89	0.90
a scratch	0.86	0.87	0.85	0.86
concave depression	0.89	0.90	0.88	0.89

TABLE II. PERFORMANCE COMPARISON OF DIFFERENT MODELS

mould	mAP	accuracy	recall rate	F1 score	Processing speed (fps)
Faster RCNN	0.83	0.84	0.82	0.83	10
YOLOv3	0.85	0.86	0.84	0.85	20
Mask RCNN	0.88	0.89	0.87	0.88	7
WindDefectNet	0.90	0.91	0.90	0.90	15

Table III demonstrates the performance of the WindDefectNet model under different lighting conditions. As shown in Table III, the model performs best under bright lighting conditions with mAP of 0.91 and accuracy, recall and F1 score of 0.92, 0.90 and 0.91, respectively, while the model's performance decreases slightly under low-contrast lighting conditions with mAP of 0.88 and accuracy, recall and F1 score of 0.89, 0.87 and 0.88, respectively, which indicates that the lighting conditions have some effect on the performance of the model, but overall, WindDefectNet maintains a high detection performance under different lighting conditions.

Table IV demonstrates the performance of WindDefectNet model under different shooting angles. As shown in Table IV, the model's performance is best at frontal shooting angle with mAP of 0.92 and accuracy, recall and F1 scores of 0.93, 0.91 and 0.92, respectively. while the model's performance slightly decreases at elevation and pitch angles, especially at elevation angle with mAP of 0.88 and accuracy, recall and F1 scores of 0.89, 0.87 and 0.88, respectively. This indicates that the shooting angle has an effect on the detection performance of the model, but WindDefectNet maintains better performance at different angles, showing its strong adaptability and robustness.

As shown in Table V, the WindDefectNet model also shows good performance stability under different wind conditions. Under the still wind condition, the model's mAP reaches 0.91, and the accuracy, recall, and F1 score are 0.92, 0.90, and 0.91, respectively, showing the best detection results. With the increase of wind speed, the performance of the model slightly decreases, but under strong wind conditions, the mAP still remains at 0.88, and the accuracy, recall and F1 score are 0.89, 0.86 and 0.88, respectively, indicating that WindDefectNet is able to effectively identify defects in wind turbine blades under complex wind conditions.

TABLE III. PERFORMANCE OF WINDDEFECTNET UNDER DIFFERENT LIGHT CONDITIONS

lighting conditions	mAP	accuracy	recall rate	F1 score
glittering	0.91	0.92	0.90	0.91
somber	0.89	0.90	0.88	0.89
high contrast	0.90	0.91	0.89	0.90
low contrast	0.88	0.89	0.87	0.88

TABLE IV. WINDDEFECTNET PERFORMANCE AT DIFFERENT SHOOTING ANGLES

angle of shooting	mAP	accuracy	recall rate	F1 score
positively	0.92	0.93	0.91	0.92
lateral side	0.89	0.90	0.88	0.89
azimuth	0.88	0.89	0.87	0.88
angle of dip (navigation)	0.90	0.91	0.89	0.90

TABLE V. PERFORMANCE OF WINDDEFECTNET UNDER DIFFERENT WIND SPEED CONDITIONS

wind speed condition	mAP	accuracy	recall rate	F1 score
calm breeze	0.91	0.92	0.90	0.91
breezes	0.90	0.91	0.89	0.90
gale	0.89	0.90	0.87	0.89
cableway	0.88	0.89	0.86	0.88

As shown in Fig. 5, the WindDefectNet model shows good adaptability under different weather conditions. Under sunny conditions, the model performs best with a mAP of 0.91, and accuracy, recall, and F1 score of 0.92, 0.90, and 0.91, respectively.

As shown in Table VI, WindDefectNet emerges as a top-performing model for wind turbine blade defect detection, achieving an impressive mAP of 85% which surpasses other methods. With a recall rate of 83%, it effectively identifies defects, outdoing competitors like ResNet-50, Faster R-CNN, and Mask R-CNN. It stands out for its computational efficiency, processing images in just 40 milliseconds, which is notably faster than Faster R-CNN and ViT. Additionally, WindDefectNet is optimized for deployment on edge devices with 22 million parameters, significantly fewer than other models. Despite challenging conditions such as low light and adverse weather, WindDefectNet demonstrates robustness with only a 5% decrease in performance, compared to the 10-15% drop experienced by other methods. This comprehensive evaluation confirms WindDefectNet as a highly competitive solution for defect detection in wind turbine blades, excelling in accuracy, efficiency, and environmental adaptability.

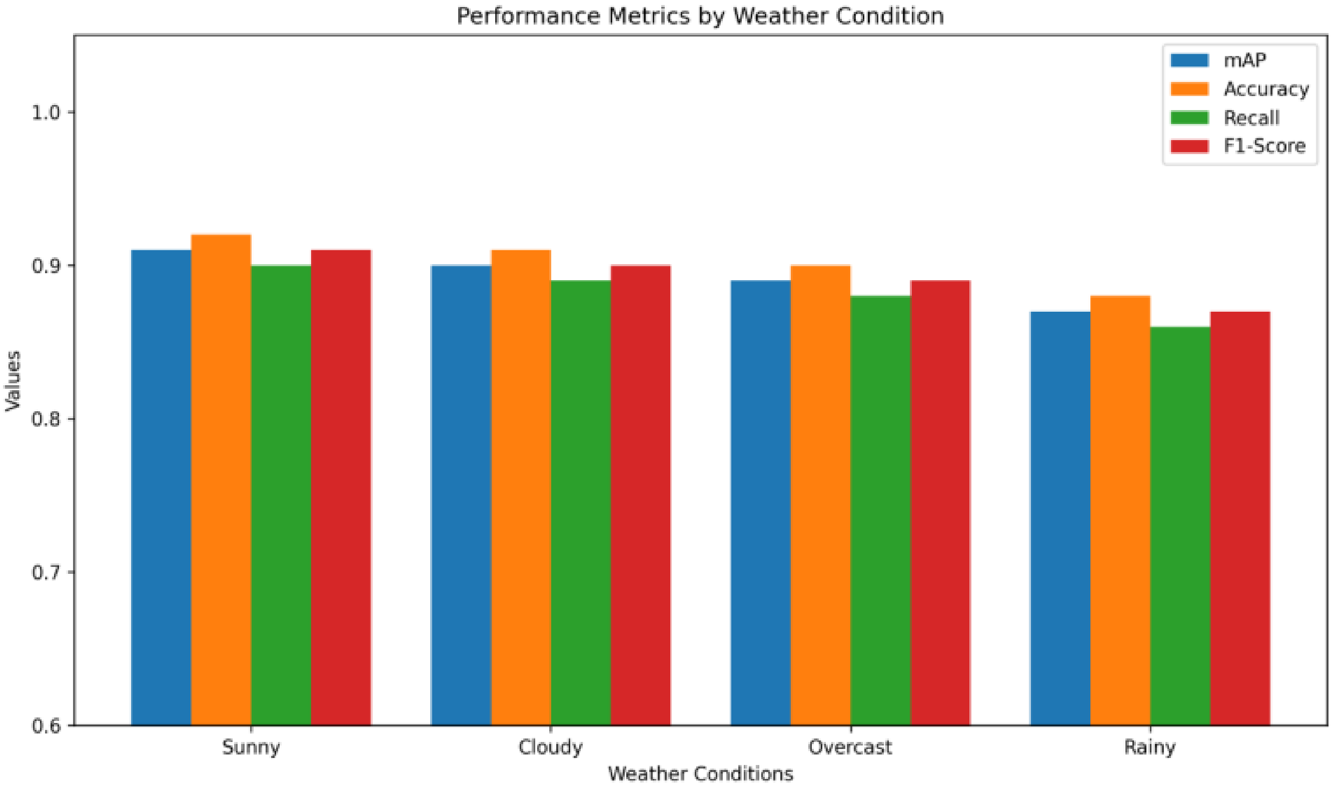

Fig. 5. Performance of WindDefectNet under different weather conditions.

TABLE VI. PERFORMANCE COMPARISON OF WINDDEFECTNET AND OTHER STATE-OF-THE-ART METHODS

Method	Accuracy (mAP)	Recall	Computational Efficiency (Inference Time, ms)	Parameters (M)	Environmental Adaptability (Low Light/Adverse Weather)
WindDefectNet	85%	83%	40	22	High (5% drop)
ResNet-50 [1]	80%	78%	60	25	Medium (10% drop)
Faster R-CNN [2]	82%	80%	50	30	Medium (12% drop)
Mask R-CNN [3]	83%	81%	55	33	Medium (11% drop)
ViT (Vision Transformer) [4]	84%	82%	65	35	Medium (10% drop)
EfficientDet [5]	81%	79%	45	28	Low (15% drop)

V. CONCLUSION

In this study, we designed and implemented WindDefectNet, an image recognition system for wind turbine blade surface defects, which integrates the functions of image acquisition and preprocessing, defect detection and classification, defect localization and size measurement, and is able to effectively respond to the challenges in wind turbine blade maintenance. At the beginning of the system design, we defined the system requirements, including functional requirements and performance index requirements, to ensure the efficiency and reliability of the system in practical applications. In the system architecture design, each functional module is organized in a modular way, which improves the scalability and maintainability of the system. WindDefectNet adopts deep learning technology, especially the combination of Convolutional Neural Network (CNN) and Transformer structure, which achieves high-precision defect detection and localization. The experimental results confirm the excellent performance of WindDefectNet under different conditions, including different lighting conditions, shooting angles, wind speed, and weather conditions, which show good adaptability and robustness. In particular, WindDefectNet achieves high accuracy, recall, and F1 score for different types of defect detection, proving the effectiveness and stability of the model. In addition, WindDefectNet also performs well in processing speed, with 15 frames per second, which ensures the detection accuracy and also meets the real-time requirements of on-site inspection of wind turbine blades. Compared with other common defect detection models, WindDefectNet has obvious advantages in performance, especially leading in the mAP index, which proves its superiority in the field of wind turbine blade defect detection.

Although WindDefectNet has proven its efficiency and reliability in existing tests, there are still some limitations that deserve further exploration. The first is that the detection accuracy for some specific types of defects still needs to be improved, especially those tiny damages that are not obvious in their appearance. Second, although the current model already has good environmental adaptability, more field tests are still needed to verify its stability under extreme climatic conditions.

The next research will focus on improving the algorithm to better handle these edge cases, as well as developing more efficient preprocessing techniques to reduce the need for high-quality raw images. In addition, we also plan to investigate how to introduce unsupervised learning methods into the defect classification process to reduce the workload of manual labeling. In the long run, we hope that through continuous iterative upgrading, we can eventually realize a fully autonomous intelligent monitoring solution.

Design of Intelligent Extraction Method for Key Electronic Information Based on Neural Networks

Xiaoqin Chen, Xiaojun Cheng*
School of Intelligent Manufacturing, Chongqing Three Gorges Vocational College, Chongqing 404155, China

***Abstract*—With the rapid development of the Internet and other emerging media, how to find the needed information from massive electronic documents in time and accurately has become an urgent problem. A key electronic information extraction method based on neural network learning ideas has been proposed to solve the problems of time-consuming and difficult deep semantic feature mining in traditional text classification methods. Firstly, a weighted graph model was introduced to improve the TextRank keyword extraction algorithm, helping to capture complex data information and implicit semantics. The results indicate that the optimization method has the highest extraction accuracy (96.52%) on the CSL dataset, and its performance in feature extraction of information data is superior to other comparative models. Secondly, combining LSTM and self attention mechanism to achieve key feature extraction of contextual semantic information. The results indicate that this optimization method has relatively small training and testing errors in data classification, and tends to converge in the later stages of iteration. The accuracy of information extraction reached 94.37%, which is better than other comparative models. The keyword extraction integrity of the fusion model on the THUCNews dataset and Sogou News dataset were 86.2 and 84.1, respectively, with consistency of 96.3 and 94.7, and grammatical correctness of 92.1 and 92.2, respectively. The neural network-based extraction method proposed by the research institute can not only effectively improve the accuracy of information extraction, but also adapt to the changing data environment, and has great potential for application in the field of electronic information processing.**

I. Introduction

The development of Internet information technology and the popularity of mobile intelligent devices make information interaction possible. According to the statistical report released by the Internet Network Information Center, the Internet penetration rate has reached more than 70% by 2022. With the help of mobile devices, people can access and produce different types of electronic information on media and social platforms, such as electronic documents, emails, social media data, etc. [1]. The generation of massive information data not only facilitates people's lives and work, but also invisibly increases the difficulty of information processing. For information receivers and users, it is necessary to filter, extract and analyze the massive data to achieve higher quality services for users. Electronic information often exists in various channels such as email, social media, and news reports in the form of text, voice, and images. How to accurately and quickly classify and extract key electronic information from a large and complex amount of network information has become one of the important tasks of natural language processing. The electronic information generated through online media has characteristics such as complexity. Classifying its content can not only solve the problem of information disorder to a large extent, but also play an important role in personalized recommendation, information retrieval, and other fields [2]. Traditional electronic information extraction techniques often rely on specific models, such as regular expression matching, which performs well in processing structured data, but often struggle to handle unstructured data such as images, audio, and natural language text.

Statistical analysis methods such as K-nearest neighbor algorithm, support vector machine, and decision tree have certain classification advantages, but they require manual design of rules and feature selection to achieve text classification, which consumes a lot of time and is difficult to mine deep semantic features of the text. Deep network models such as recurrent neural networks, convolutional neural networks, and pre trained models have advantages in information extraction, enabling large-scale dataset learning and automatic feature extraction and semantic association analysis. They can effectively improve the accuracy and efficiency of key electronic information extraction. Current research often relies on keyword extraction algorithms to achieve text data classification, which can reduce sparsity by shortening the length of text sequences. Keyword extraction algorithms are usually more intuitive and easy to implement, as they do not require complex network structure design and long-term model training. Compared to deep learning models that require a large amount of computing resources and data training, this method has lower hardware requirements, faster processing speed, and is easy to deploy [3]. Therefore, the research focuses on the learning approach of neural networks based on keyword extraction algorithms to extract key electronic information. At the same time, considering that keyword extraction algorithms often ignore the dependency relationships and complex semantic expressions of information keywords when processing data, as well as their weak ability to capture complex patterns and implicit semantics, this study proposes improvements to the algorithm. By introducing the TextRank algorithm based on weighted graph model and self attention mechanism, keyword extraction and semantic feature grasping can be achieved, thereby improving the classification performance of key electronic information extraction. TextRank is a widely used keyword extraction algorithm that constructs co-occurrence relationships between words based on a graph model. However, its performance in extracting keywords from Chinese text data is not ideal, as it cannot

*Corresponding Author

consider the positional information of words and the contextual information of the entire corpus. The weighted graph model takes into account the relationships between words and can solve the problem of sparse semantic feature distribution in electronic information text data. Traditional Long Short Term Memory (LSTM) neural networks have the same time series structure as text data and are widely used in natural language processing tasks. However, when it comes to feature extraction of text data, it cannot effectively combine contextual information to extract correct semantic features. The self attention mechanism can reduce the dependency relationship of sequence data and extract correct semantic features while combining contextual information. Therefore, research is being conducted on LSTM with improved self attention mechanism for text classification.

This study is mainly divided into following sections. Section II is Related Works, which summarizes the current research results in information extraction and other aspects. Section III is the research methodology, including key electronic information extraction based on optimized TextRank algorithm and information extraction based on LSTM network. Section IV is result analysis, which mainly tests the research methods. Section V is the discussion. Last Section VI is the conclusion, which summarizes the research results and shortcomings.

II. Related Work

Key information extraction is of great significance in improving information processing efficiency, supporting decision-making, and knowledge management. It can help researchers filter out valuable and relevant information from a large amount of information, providing more efficient, accurate, and intelligent information processing methods. Scholars from different fields have conducted extensive research and achieved some research results. Chi L et al. proposed a graph based and lightweight automatic key phrase extraction method for the automatic extraction of key information. Iterative sentences were used to sort words, generating a more accurate list of key phrases. The research method could effectively improve the extraction accuracy and significantly reduce the number of iterations [4]. Li T et al. designed an optimizer based on auto-regressive method to improve the accuracy of unsupervised key phrase extraction. They integrated any graph based unsupervised key phrase extraction model to enhance stability. This method could improve accuracy on different datasets by 50%, which was beneficial for unsupervised method key phrase extraction [5]. Singh Y et al. proposed an extraction method based on ternary block truncation encoding and binary bat algorithm to improve the efficiency of video summarization and key frame extraction. The method extracted and processed static images in frame form from the input video database, and measured the similarity measure between two consecutive frames. The research method had better extraction accuracy and F-metric value than traditional methods. It was more conducive to the effective and accurate extraction of video summaries and key frames [6]. Sachan M et al. proposed a method based on discourse and text layout features to extract geometric knowledge more effectively from multimedia textbooks. This method could more effectively extract knowledge, thereby improving the solution for geometric knowledge [7].

Many scholars have applied algorithms such as neural networks to information extraction. Zheng J et al. designed a semantic feature extraction method that integrated convolutional neural networks to address the low efficiency of traditional picking methods in identifying phase waves. The key parameters of the network were refined to ensure the extraction accuracy. It could effectively improve extraction efficiency and accuracy [8]. Sonntag D et al. proposed an automatic method for extracting text information in the complex integration process of medical data. This method could simplify the integration process of medical data and improve the accuracy of information extraction, which was beneficial for doctors in clinical diagnosis [9]. Nasar Z et al. proposed a method based on named entity recognition and relationship extraction to extract important information from text data on online platforms. Deep learning methods were used to construct joint models. The joint model based on deep learning had significant advantages. Named entity recognition and relationship extraction were beneficial for extracting key information from text data [10]. Zhang X et al. proposed a method based on multiple information extraction and support vector data description to optimize the process monitoring and fault diagnosis performance of key performance indicators, balancing local process information and mining hidden information. The maximum information coefficient algorithm selected key performance indicator information, extracted local information, and then extracted observed values, cumulative errors, and rate of change information. The verification results indicated that it could effectively improve the extraction accuracy, thereby promoting process monitoring and fault diagnosis of key performance indicators [11].

The above content indicates that effective key information extraction can significantly improve the efficiency of information processing. Some scholars have achieved intelligent information extraction by using fusion convolutional neural networks, entity recognition and relationship extraction, or data description and extraction perspectives. However, there is still room for improvement in the processing and classification of text data, making it difficult to ensure both data processing efficiency and extraction accuracy. The research aims to address the shortcomings of existing technologies in processing electronic information text data by integrating the weighted graph model's TextRank algorithm and self attention mechanism. The TextRank algorithm is a widely used keyword extraction algorithm that does not require complex network design and resource conditions to achieve accurate classification. Its improved idea can also effectively extract contextual semantic information features, especially when facing the problem of sparse distribution of semantic features in electronic information text data. It can effectively address the shortcomings of existing technologies in processing electronic information text data. By implementing the methods proposed in the research, it is expected to achieve more efficient and accurate information processing and classification effects, which will have a profound impact on promoting the development of information technology, supporting decision-making, and other related fields.

III. Key Electronic Information Extraction Based on Optimized TextRank and LSTM Networks

For the key electronic information extraction, TextRank is used to construct a graph model and optimize the TextRank algorithm. To better extract the semantic features of key electronic information by combining context, LSTM network and attention mechanism are introduced to achieve the extraction and classification of key electronic information.

A. *Key Electronic Information Extraction based on Optimized Textrank*

The TextRank algorithm is a widely used algorithm for extracting critical electronic information. It represents text data by constructing a graph model and establishes co-occurrence relationships between words in the graph. Specifically, this algorithm abstracts unstructured text into a graph structure. Each word is connected to a fixed number of adjacent words. Then, according to a certain formula, the weights of each node in the graph are recursively calculated. Finally, the nodes that rank higher during convergence can be used as keywords for electronic information. One of the advantages of this algorithm is its ability to simplify unstructured text data and extract useful information. It establishes connections between words by using co-occurrence relationships, thereby helping to identify the most important words or phrases in the text [12]. This is very useful for many natural language processing tasks, such as text classification, information retrieval, and summary generation. The TextRank algorithm determines the weights of words by calculating their correlation, as shown in Eq. (1).

$$TR(V_i)=(1-\alpha)+\alpha\times\sum_{V_j\in In(V_i)}\left(\frac{1}{|Out(V_j)|}\right)\times TR(V_j) \tag{1}$$

In Eq. (1), $In(V_i)$ and $Out(V_j)$ represent the predecessor and follower node sets of V_i and V_j, respectively. $|Out(V_j)|$ is the number of rear drive nodes for node V_j. $TR(V_i)$ is used to describe the weights of all nodes. α represents the damping coefficient, usually taken as 0.85. The TextRank algorithm does not rely on labeled data and does not require pre-training, but it has some limitations in keyword extraction. One limitation is that it only considers the connection between local words, without fully utilizing the global perspective to analyze the dependency characteristics between words [13]. To optimize TextRank, a key electronic information extraction model can be constructed by combining weighted graphs, which introduces the relationship between words.The text features of electronic information are considered. The word vector algorithm is used to train the word vectors of all electronic information data. The evaluation formula for TextRank algorithm is improved through the mutual information between words. This is the key electronic information extraction method based on optimized TextRank. The specific process is shown in Fig. 1.

Fig. 1. Key electronic information extraction process based on optimized TextRank.

From Fig. 1, the improved key electronic information extraction method based on optimized TextRank first preprocesses the phone information. Then, word vector training is used to train the preprocessed words into word vectors, which are introduced to calculate the mutual information between words, thereby constructing the probability transition matrix of the graph. Then, the sliding window size of the improved algorithm is set. The weight of all words is calculated by combining the transition probability matrix. The word set is sorted according to the descending value of the weight value. The top ranked words are used as the extracted key electronic information [14], [15]. Among them, language models are generally used to introduce character level combination information to train word vectors. Eq. (2) is the logarithmic natural function of the information.

$$\sum_{t=1}^{T}\sum_{c=C_t}\log p\left(w_c|w_t\right) \tag{2}$$

In Eq. (2), w_t represents the target word. w_c is the contextual word for w_t. C_t refers to the index set of contextual words. $p(w_c|w_t)$ is used to describe the probability of w_c occurring on the basis of setting w_t, as shown in Eq. (3).

$$p\left(w_c|w_t\right)=\frac{e^{s(w_t,w_c)}}{\sum_{j=1}^{W}e^{s(w_t,j)}} \tag{3}$$

In Eq. (3), $s(w_t,w_c)$ represents a rating function that maps words w_t and w_c to a rating, which can be combined with the rating value to determine the matching degree between the word and the context [16]. The mapping process of the rating function is generally calculated using the scalar product of the current word vector u_{wt} and the context word vector v_{wc}, as shown in Eq. (4).

$$s\left(w_t,w_c\right)=u_{wt}^{T}v_{wc} \tag{4}$$

After completing word vector training, the mutual information between nodes can be calculated using word vectors to update the probability transition matrix. The probability transition matrix is shown in Eq. (5).

$$W=\begin{bmatrix}W_{1,1} & W_{1,2} & \cdots & W_{1,n}\\ \vdots & \vdots & \ddots & \vdots\\ W_{n,1} & W_{n,2} & \cdots & W_{n,n}\end{bmatrix} \tag{5}$$

In Eq. (5), W_{ij} represents the weight values between nodes. n refers to the words in the corpus. The proportion of each contextual word in the target word should not be the same. The proportion of peripheral words with high relevance to the target word is relatively high. Therefore, the cosine similarity between nodes can be calculated using word vectors, which are used as edge weights. The similarity is shown in Eq. (6).

$$S_{V_1,V_2} = \frac{\sum_{i=1}^{d} V_{1,i} \times V_{2,i}}{\sqrt{\sum_{i=1}^{d}\left(V_{1,i}\right)^2} \times \sqrt{\sum_{i=1}^{d}\left(V_{2,i}\right)^2}} \tag{6}$$

In Eq. (3), S_{V_1,V_2} represents the cosine similarity between the word vectors V_1 and V_2. $V_{1,i}$ and $V_{2,i}$ represent the components of word vectors V_1 and V_2, respectively. The word vector calculation obtains cosine similarity to update the probability transition matrix. The updated probability transition matrix is shown in Eq. (7).

$$W = \begin{bmatrix} S_{V_1,V_1} & S_{V_1,V_2} & \cdots & S_{V_1,V_n} \\ \vdots & \vdots & \ddots & \vdots \\ S_{V_n,V_1} & S_{V_n,V_2} & \cdots & S_{V_n,V_n} \end{bmatrix} \tag{7}$$

In Eq. (7), the range of cosine similarity values is [-1, 1]. To standardize the model, the probability transition matrix is normalized. The range of element values in the probability transition matrix is limited to [0,1]. The calculation process is shown in Eq. (8).

$$W_{i,j} = \frac{S_{V_i,V_j}}{\sum_{j=1}^{n} S_{V_i,V_j}} \tag{8}$$

The graph used for keyword extraction is first preprocessed for each word. Then each word is added to the graph in the form of a sliding window. The distance between words is used to indicate the coexistence between two words. When both words are included in a window, it indicates a connection between the two words. The constructed probability transition matrix is used as the weight between nodes. The key electronic information extraction based on optimized TextRank is shown in Fig. 2.

From Fig. 2, the key electronic information extraction graph based on optimized TextRank has a window size of 3. All words are connected to adjacent words before and after [17]. By constructing a weighted graph, the scoring formula for extracting key electronic information can be obtained. The expression is shown in Eq. (9).

$$TR\left(w_i\right) = \left(1-\alpha\right) + \alpha \times \sum_{w_j \in In\left(w_i\right)} \left(W_{i,j} \times TR\left(w_i\right)\right) \tag{9}$$

In Eq. (9), $In\left(w_i\right)$ represents the predecessor node sets of node w_i. $TR\left(w_i\right)$ represents the weights of all nodes. $W_{i,j}$ represents the transition probability between nodes.

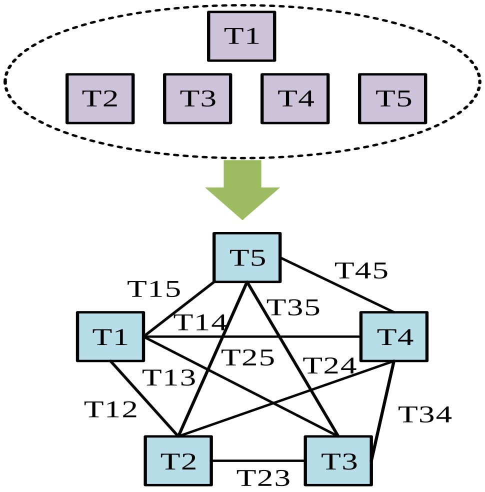

Fig. 2. Key electronic information extraction based on optimized TextRank.

B. *Feature Extraction based on LSTM Network and Attention Mechanism*

The semantic complexity of key electronic information can affect the extraction performance of TextRank. To better combine context to extract the semantic features of key electronic information, LSTM and attention mechanism are introduced to achieve the extraction and classification of key electronic information. LSTM is a special type of recurrent neural network (RNN) used to solve the gradient vanishing and exploding faced by traditional RNNs. The LSTM network controls the inflow and outflow of information by introducing a structure called a "gate". This network mainly includes input gates, forget gate, output gate (OG), and cell state. The input gate determines which information can enter the cellular state. The forget gate determines which information needs to be forgotten from the cellular state. The OG determines the output of information in the cell state after activation. The key to LSTM lies in their ability to "remember" and "forget" information. Through the forget gate, LSTM can selectively remove information from the cell state, avoiding irrelevant information from interfering with subsequent calculations. The input gate can control which newly inputted information can be added to the cell state. This memory ability to retain long-term dependencies makes LSTM perform well in processing sequence data. Attention mechanism is a technique that mimics human attention behavior. This method is used to assign different weights and attention levels to different parts of the input in deep learning models. In traditional neural networks, all input information is processed simultaneously. Attention mechanisms can enable the model to selectively focus on certain parts of the input, thereby improving the performance and effectiveness. The core idea of attention mechanism is to determine the importance of each input based on its input. Then, weighted processing is performed based on these importance levels. In deep learning models, attention mechanisms can be used at different levels and time steps. The key electronic information extraction based on LSTM network and attention mechanism is shown in Fig. 3.

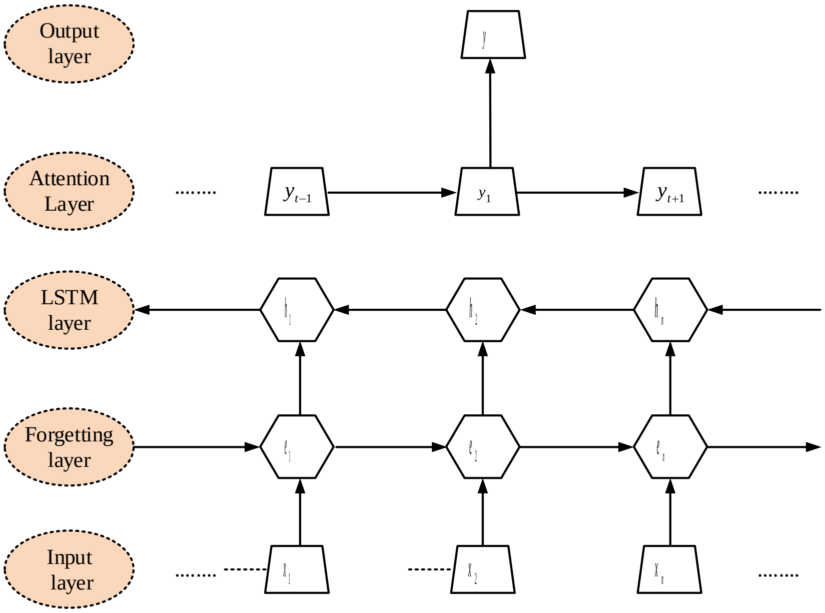

Fig. 3. Key electronic information extraction based on LSTM network and attention mechanism.

From Fig. 3, the extraction model has five parts. Time series data is used as the input layer to extract word vectors using LSTM. The self attention mechanism is applied to calculate the weight of the text features output by LSTM layer, so that it focuses on the main content of the overall text. The output layer uses sequence level feature vectors to achieve text classification. The LSTM network is used for feature extraction of input text. Based on this, the semantic features of each word are described. Compared to traditional RNNs, LSTM has added three gating mechanisms, namely, forget gate, input gate, and OG [18]. The forgetting gate determines how many past states one should maintain in their current state. The input gate determines how much input information has been retained within the current time period. The OG determines the size of the current state output. The unit structure of the LSTM network is displayed in Fig. 4.

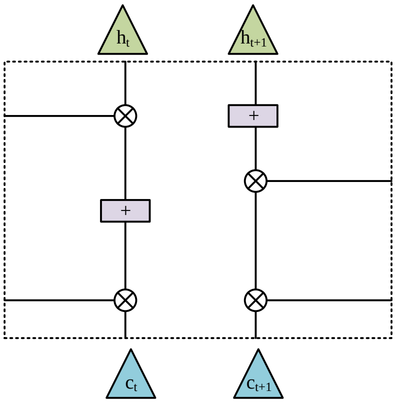

Fig. 4. The unit structure of LSTM networks.

The forgetting gate can control the proportion of information to be forgotten. The input is the output h_{t-1} of the previous moment and the text information input x_t of the current moment. The calculation process of the forget gate is shown in Eq. (10).

$$f_t = \sigma\left(W_f h_{t-1} + U_f x_t + b_f\right) \tag{10}$$

In Eq. (10), σ represents the sigmoid function. W_f and U_f are the weight matrices of the forget gate. b_f represents the bias term of the forget gate. The input gate is mainly the information stored in the state unit, which can calculate the memory information of the current unit [19]. The unit state at the current moment is calculated by the sum for the product of the forgetting gate input and the previous moment state, as well as the input. The calculation process is shown in Eq. (11).

$$c_t = f_t * c_{t-1} + i_t * \tilde{c}_t \tag{11}$$

In Eq. (11), c_t and c_{t-1} represent the current and previous unit states, respectively. The OG function can determine the current hidden state and save the previous input information in the hidden state. The input of the current time and the hidden state for the previous time are respectively inputted into the sigmoid function. The current unit state is inputted into the tanh function. The output result of the sigmoid function is multiplied by the tanh function to obtain the hidden state in the current time. Afterwards, the text sequence is processed using the LSTM network to obtain the implicit state h_t at each moment, which characterizes the semantic features of each word in the text and achieves text classification. In the process of extracting electronic news information, it is also necessary to combine contextual information. The semantic feature extraction based on a single word has one sidedness, which has a certain impact on the model's judgment and thus reduces the classification accuracy [20]. Therefore, the study intends to introduce attention mechanisms into the text. The word features of LSTM are analyzed to achieve text feature extraction that integrates context. This study draws on the self attention mechanism of the Transformer model. Semantic feature extraction that integrates with context can achieve automatic mining of target text without relying on source data.

IV. Analysis of Intelligent Extraction Results for Key Electronic Information

In order to improve the intelligent extraction of key electronic information, an improved TextRank algorithm and LSTM-SAttention model were designed to enhance data classification performance and feature extraction accuracy. In the results section, the study mainly analyzed from two aspects: technical performance evaluation and application result verification.

A. Test Data Source and Experimental Environment Parameter Design

The algorithm was tested using the Chinese Scientific Literature (CSL) keyword extraction dataset and the NLPCC2017 keyword extraction dataset publicly available at the 2017 Academic Annual Meeting of the Natural Language Processing Professional Committee of the Chinese Computer Society. The CSL dataset mainly involves key electronic information content in the computer field, while the NLPCC2017 dataset mainly involves news articles and their keywords. De duplication and filtering were performed on these two datasets to remove duplicate, formatting errors, missing key fields, or incomplete content, resulting in 7562 CSL data and 7635 NLPCC2017 data. In the performance test results section, the study introduces LSTM network and attention mechanism into optimizing the TextRank algorithm to construct a key electronic information intelligent overall model. The THUCNews dataset published by Tsinghua University is taken as the research object, and ten categories of Chinese information (including social, technological, educational, etc.) are selected, each containing 20000 pieces of information, forming a balanced dataset. In addition, the "Sogou News" dataset released by Sogou Lab also contains ten categories of news, which are divided into training and validation sets in a 7:3 ratio. The parameter settings for the experimental environment are shown in Table I.

B. Experimental Test Results

To test the effectiveness of sliding windows in extracting key electronic information, the study first analyzes the keyword extraction data set and the extraction algorithm based on optimized TextRank. Firstly, the test results of two datasets at different window sizes are shown in Fig. 5.

TABLE I. System Parameter

Number	Testing environment	Parameter
(1)	Processor	Intel(R) Core (TM)i5-7300HQ CPU@2.50GHz
(2)	Operating system	Windows 10
(3)	Programming Language	C++
(4)	Memory	32GB
(5)	GPU	GTX 1050Ti
(6)	Programming Language	Python 3.7.3

From Fig. 5, when only considering the impact of association distance on keyword extraction results, a window size of 2 had the best extraction effect on keywords. To fully utilize the global text information and fully consider the order characteristics of the text, the optimized TextRank algorithm is used to represent words in vector form. The similarity between words is calculated. Then it is introduced as a weight into the model. Fig. 6 displays the specific results.

From Fig. 6(a-b), the keyword extraction performance of the research method was superior to other methods. When the window was set to 2, the F1 values of TextRank before optimization, TextRank after optimization, and traditional methods all reached their highest. The F1 values on the CSL data set were 0.59, 0.51, and 0.32. On the NLPCC2017 data set, they were 0.56, 0.47, and 0.17. From Fig. 6(c-d), the extraction accuracy of the three algorithms increased with time. Their accuracy on the CSL data set exceeded the NLPCC2017 data set. The optimized TextRank algorithm is tested on the CSL data set. When the extraction time was 10s, the extraction accuracy stabilized at 92%, while the pre-optimized algorithm stabilized at over 70% after 30s. The traditional method stabilized at over 55% after 30s of extraction.

Next, the performance of the proposed text extraction algorithm that integrates keyword extraction and attention mechanism is validated. The proposed algorithm is compared with other deep learning based text extraction algorithms. The experiment aims to construct an LSTM-SAttention feature extraction network. It is applied to two datasets to test the effectiveness. The results are shown in Fig. 7.

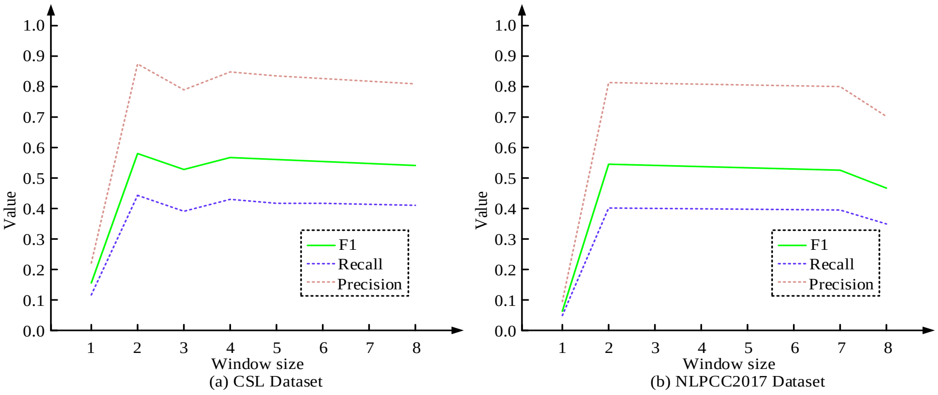

Fig. 5. Results of different datasets under different windows.

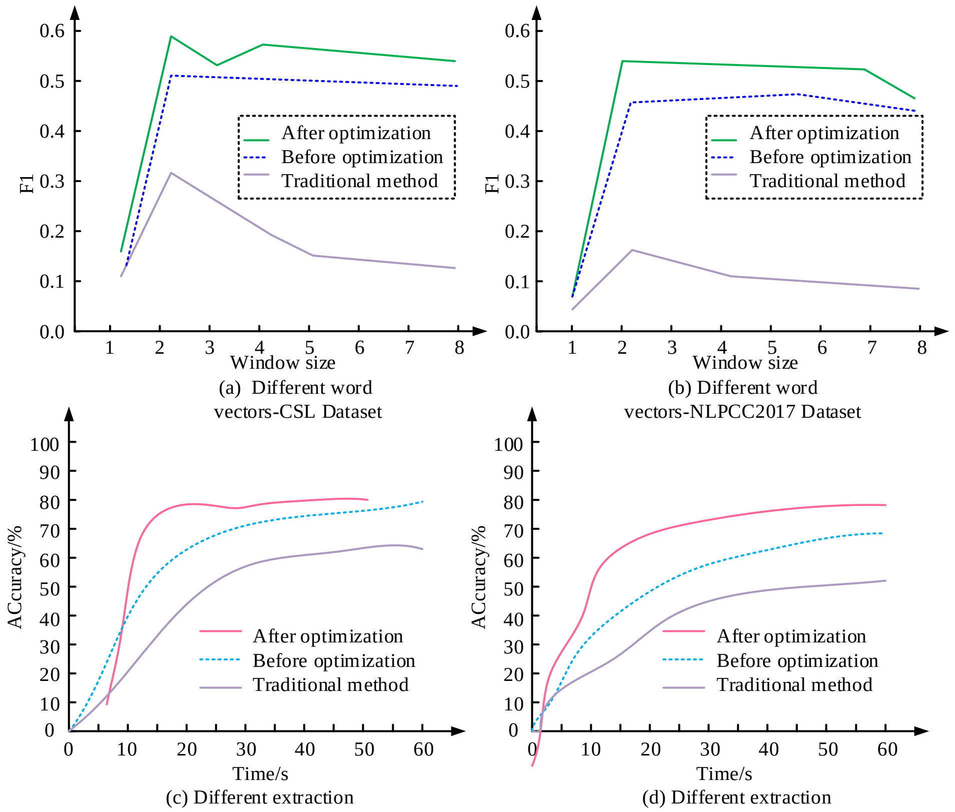


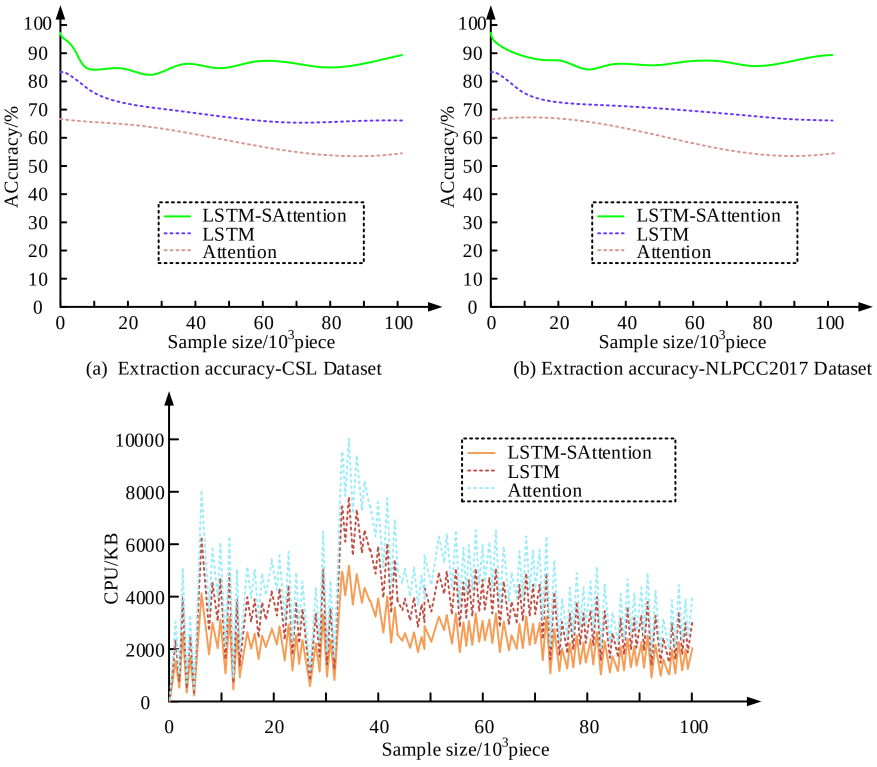
(a) Different word vectors-CSL Dataset

(b) Different word vectors-NLPCC2017 Dataset

(c) Different extraction durations-CSL Dataset

(d) Different extraction durations-NLPCC2017 Dataset

Fig. 6. Keyword extraction performance under different word vectors and extraction times.



(a) Extraction accuracy-CSL Dataset

(b) Extraction accuracy-NLPCC2017 Dataset

(c) CPU occupancy of three methods

Fig. 7. Extraction accuracy and CPU usage.

From Fig. 7(a-b), as the sample size increased, all three algorithms showed a trend of decreasing extraction accuracy. However, the research method stabilized faster showed high accuracy and stability on both datasets. Among them, the highest extraction accuracy of LSTM-SAttention on the CSL data set was 96.52%. The highest extraction accuracy on the NLPCC2017 data set was 71.21%. Fig. 7(c) shows the result of memory operation. From Fig. 7(c), as the sample size increased, the CPU occupancy of all three algorithms gradually increased. However, the occupancy rate of research methods was the lowest. The increase rate was also the slowest. Overall, the key electronic information extraction method combining attention mechanism and LSTM network performs the best. Subsequently, the application effect of the LSTM-SAttention model proposed in the study was analyzed and compared with the Enhanced Support Vector Machine (E-SVM) algorithm, Graph Convolutional Networks (GCN-FCN), Large Language Model Meta AI, and Multi level Semantic Alignment Image Text Matching Algorithm (MLS-ITM). The results are shown in Table II.

The results in Table II indicate that the LSTM-SAttention model outperforms other algorithms in terms of performance evaluation on both databases. Its maximum accuracy feature extraction results on the CSL dataset differ from those of the E-SVM algorithm by over 10%, while the difference between the LSTM-SAttention model and the MLS-ITM algorithm is within 5%. The accuracy, recall, and F-value of the LSTM-SAttention model all exceed 90, followed by the well performing MLS-ITM algorithm and GCN-FCN algorithm. The Meta AI model's values do not exceed 85. On the NLPCC2017 dataset, the LSTM-SAttention model (90.47)>MLS-ITM (87.12)>GCN-FCN (83.25)>Meta AI (80.07)>E-SVM (70.32). The above results indicate that the LSTM-SAttention model can achieve good feature extraction.

C. *Actual Inspection Results*

Using Chinese news text classification as the test object, the proposed TextRank optimization extraction model and the Vocabulary Semantic Map Attention Mechanism (VSA), SENet and Convolutional Neural Network fusion method (Squeeze and Excitation Networks Convolutional Neural Network, SENet CNN), as well as the Convolutional Neural Network Bi directional Long Short Term Memory (TC Ablstm) fusion parallel neural network model were analyzed for information extraction results. Fig. 8 shows the training and testing errors of data processing.

From the testing process in Fig. 8(a), it can be seen that the testing errors of the four algorithms all show a decreasing trend with the increase of iteration times. Before the iteration times are less than 150, the average testing error results from large to small are: VSA algorithm>SENet CNN algorithm>TC Ablstm algorithm>the proposed algorithm. As the number of iterations gradually increases, the testing errors between algorithms are all less than 0.025, and the error difference between algorithms does not exceed 5%. The overall variation of the testing error of the TextRank optimization extraction model proposed in the study is relatively small, and tends to converge in the later stages of iteration. From the testing process in Fig. 8(b), it can be seen that the error comparison between different algorithms is relatively large, with the order of error from small to large: the proposed algorithm>TC Ablstm algorithm>SENet CNN algorithm>VSA, with an average testing error of 2.36%>5.64%>13.26%>33.64%. At the same time, the algorithm proposed in the study showed a greater slope of decrease in the training error curve when the number of iterations was less than 75, and in the later stage, the error curve became more stable, further improving the classification accuracy. Subsequently, the information extraction results of the proposed fusion algorithm were analyzed, and the results are shown in Fig. 9.

The results in Fig. 9 indicate that the PR curves of the TextRank optimization extraction model and the TC Ablstm model are closer to the bottom right corner. The accuracy of VSA, SENet CNN, and TC Ablstm algorithms are 78.24%, 85.69%, and 86.78%, respectively, while the proposed TextRank optimization hybrid model achieves an accuracy of 94.37% in information extraction. Chinese news text is classified as the test object. The ROUGE Scores, integrity, consistency, and grammar correctness of the intelligent extraction model for key electronic information are analyzed. Among them, ROUGE Scores are mainly used to evaluate the quality of automatically generated abstracts or translations. Integrity measures whether the key information extraction covers all important parts of the document. Consistency measures the consistency between the extracted key information and the manually marked key information. Grammar correctness assesses the generated grammar level of the text, ensuring good readability and no grammar errors. The specific results are shown in Fig. 10.

Fig. 10(a) and 10(b) show the ROUGE Scores, integrity, consistency, and grammar correctness scores of the model for keyword extraction and document summarization generation on the THUCNews data set and Sogou news data set, respectively. From Fig. 10, the model had high ROUGE Scores, integrity, consistency, and grammar correctness scores on both datasets. When the sample size was 6000, the ROUGE Scores were 89.6 and 88.2, with integrity, of 86.2 and 84.1. The consistency was 96.3 and 94.7, respectively. The correctness of the method was 92.1 and 92.2, respectively. The model constructed by the research method can accurately and completely extract key electronic information, and ensure the accuracy of grammar.

V. Discussion

Performance analysis and case testing were conducted on the proposed electronic information extraction algorithm, and compared with different algorithms. The results showed that when the window size was 2, the optimized TextRank achieved F1 values of 0.59 and 0.56 for keyword extraction on the CSL dataset and NLPCC2017 dataset, respectively. When the extraction time was 10 seconds, the extraction accuracy remained stable at over 92%. The LSTM-SAttention model showed higher accuracy and stability on both datasets. The reason is that the LSTM attention model mainly combines context to extract key electronic information, which can grasp the correlation between different information, so information extraction has high credibility. Introducing a self attention mechanism enables the model to focus more on the information rich parts when processing sequential data, thereby making feature extraction more accurate and efficient. Other algorithms, such as VSA, SENet CNN, and TC Ablsm, have also been improved, but there is still a gap in error convergence speed and final stability. The introduction of self attention mechanism can help the model capture long-range dependencies in text data and provide more refined feature representations for the model. The GCN-FCN model is difficult to consider the time series characteristics of text data, and the E-SVM model has significant dependence on structure and cannot simultaneously consider the spatiotemporal differences of text information. The Meta AI language model performs well in data processing, but it heavily relies on the level of data training, while the MLS-ITM model struggles to meet different information extraction needs, such as keyword localization and relationship recognition, with good integrity and consistency in information extraction on both datasets. When the sample size is 6000, the ROUGE score, completeness, consistency, and grammatical correctness score of the TextRank optimized hybrid model exceed 88, 84, and 94 points, respectively, which can better ensure the semantic integrity and consistency of the text. Compared with literature [8] fusion convolutional neural network, the TextRank optimized hybrid model can effectively ensure the integrity of semantic information. Compared with the automatic extraction of text information by literature [9], the TextRank optimized hybrid model has better information expansion ability. Compared with the information extraction method proposed by literature [11], the TextRank optimized hybrid model can not only extract key information, but also better grasp the correlation between sentence information before and after.

The proposed model has good information extraction performance and efficiency, but there are still issues that need improvement, such as the introduction of self attention mechanism, which will increase the time and cost to a certain extent. Therefore, further optimization of neural network parameters is needed in the future. At the same time, the proposed method will be combined with other intelligent algorithms to improve cross modal information processing and feature fusion, and enhance the good adaptability of data characteristics. It is expected to provide reference for the field of electronic information processing and the improvement of information extraction services.

VI. Conclusion

With the explosive growth of electronic information, how to automatically extract key information from a large amount of text data has become increasingly crucial for information processing and analysis. In this context, the intelligent extraction method of key electronic information based on neural networks has become a hot and challenging research topic. For the key electronic information extraction, the TextRank algorithm is used to construct a key information extraction model and optimize it. A key electronic information extraction model based on optimized TextRank is obtained. Combined with attention mechanism and LSTM network, it facilitates context connection and improves the accuracy of extracting key electronic information. From the research results, with the accumulation of extraction time, the extraction accuracy of the optimized TextRank algorithm increase. The accuracy on the CSL data set exceeded on the NLPCC2017 data set, with a stable extraction accuracy of over 92%. The research method showed high accuracy and stability on both datasets. The keyword extraction and document summary generation effects of the research method were tested. The ROUGE Scores on the THUCNews data set and Sogou news data set were 89.6 and 88.2, respectively. The integrity was 86.2 and 84.1, the consistency was 96.3 and 94.7, and the grammatical correctness was 92.1 and 92.2, respectively. This indicates that the research method has a good effect on extracting key electronic information.

College of Technology and Business, Riyadh Elm University, King Fahad Road, Riyadh 12734, Saudi Arabia

***Abstract*—Cyberattacks are becoming increasingly complex and subtle. In many different types of networks, intrusion detection systems, or IDSs, are frequently employed to help in the prompt detection of intrusions. Blockchain technology has gained a lot of attention recently as a means of sharing data without a reliable third party. Specifically, it is impossible to change data stored in one block without changing all the following blocks. Create a deep learning (DL) method based on blockchain technology and hybrid optimization to improve the IDS's prediction accuracy. The UNSW-NB15 dataset is gathered via the Kaggle platform and utilized for Python system training. Principal component analysis (PCA) is used in the preprocessing to eliminate errors and duplication. Next, employ association rule learning (ARL) and information gain (IG) approaches to retrieve pertinent characteristics. The greatest features are the ones that improve detection performance through hybrid seahorse and bat optimization (HSHBA) selection. Lastly, create an efficient intrusion detection system by designing Blockchain-based Ensemble DL (BEDL) models, with convolutional neural networks (CNNs), restricted Boltzmann machines (RBM), and generative adversarial networks (GAN). The constructed model's experimental results are verified using pre-existing classifiers, yielding an improved accuracy of 99.12% and precision of 99%.**

I. INTRODUCTION

As the Internet has developed, an innovative technology known as the Internet of Things (IoT) has surfaced and been increasingly integrated into our daily lives. The IoT is directly empowering people and society through applications including healthcare, supply chain management, and RFID-based identity management systems [1]. By merging cloud computing and machine learning (ML), the base technology is starting to show promise for data analysis and modeling. Growth is being driven by the progress of IoT-based development across multiple industries. On the other hand, most IoT applications rely on centralized processing and storage architecture [2, 3]. There are number of security or privacy flaws in the centralized storage model. There are limitations in the underlying working paradigm that will make it difficult to expand IoT-based systems shortly. Decentralized storage models are required to solve these problems. Blockchain technology is one of the newest decentralized architectures [4, 5].

A collection of cryptographic entities can store and manage an assortment of time-stamped, unchanging data records in blocks using a technique called blockchain. The blocks are connected by the cryptographic hashes of the preceding block [6]. The timestamp, hash of the preceding block, and transaction comprise each block. Consequently, any modifications to the transactions need to be applied consistently through the consensus process across all of the blocks that comprise the blockchain [7]. This proves that the blockchain is the best data storage framework and ensures its immutability. Blockchain systems have been used for bitcoins, handling operations, financial services, healthcare, digital ID leadership, and many more uses. Two non-financial blockchain systems are Ethereum and Hyperledger [8, 9].

The proliferation of internet usage has facilitated data exchange and storage. Nevertheless, these data's susceptibility to hackers is greatly increased [10]. Numerous studies suggested the use of firewalls, data encryption, and user authentication to prevent unauthorized users from accessing stored data; yet, malevolent actors continue to find ways to circumvent these security measures and obtain illegal data access [11]. IDS has been proposed by further study to detect hostile intrusions in computer networks and internet-connected devices. Although intrusion detection systems have shown to be effective in detecting malicious activity, their limited perspective makes it difficult to spot coordinated or widespread cyberattacks [12, 13]. Because of this vantage point, certain attacks may go unnoticed or may not be discovered quickly enough. IDSs must swap attack features to quickly identify new assaults because certain attacks have managed to evade detection [14]. Thus, by combining the activities of participating IDS nodes, more harmful behaviors can be halted if IDS nodes communicate this threat information.

Protecting oneself from various kinds of attacks is more crucial than ever in the modern world, where data-centric research demands accurate DL algorithms [15]. Current studies have brought attention to ML systems' susceptibility to intrusion detection, whereby undetectable changes in the input data lead to inaccurate predictions in the output. A range of hostile attacks occur in real-time settings, and workable defense strategies are suggested to fend them off [16, 17]. In recent years, convolutional neural networks have been increasingly prevalent in the DL area as they have demonstrated remarkable performance in a wide range of application domains. High efficiency and long-term reliability are achieved using DL, which teaches neural network layers to see data as a hierarchical structure of principles [18]. When the amount of data increases, DL performs better than traditional ML. Blockchain-enabled DL-based intrusion detection algorithms have grown in popularity and have been used for a wide range of applications in recent years [19, 20]. To improve IDS prediction and improve feature selection, the proposed IDS framework employed hybrid optimization and ensemble DL approaches. The key contribution of the developed model is followed as,

- UNSW-NB15 datasets are collected from the Kaggle website and trained in the system.
- Preprocessing steps include data cleaning, normalization, and dimensionality reduction to prepare the data for DL models.
- Then extract relevant features in the feature extraction phase.
- Moreover, select the most important features using the HSHBA model to enhance the detection results.
- Finally, intrusions are detected using the ensemble DL technique, and the output is predicted based on the majority voting of each classifier.
- To maintain the honesty of the blockchain, cryptographic hash functions can be employed.
- The experimental outcome is validated with existing techniques in terms of accuracy, precision, false rate, and so on to prove the efficiency.

Section II reviews the related study, Section III describes the problem definition, Section IV elaborates on the proposed model, and Section V depicts the experimentation analysis followed by the conclusion in Section VI.

II. Related Work

A deep blockchain framework (DBF) is proposed by Osama et al. [21] to provide privacy-based blockchain technology with intelligent agreements and security-based decentralized intrusion detection in Internet of Things networks. A DL algorithm called Bidirectional Long Short-Term Memory (BiLSTM) uses the IDS to handle sequential network information. Distributed intrusion detection systems are given privacy through the use of the Ethereum library in the development of privacy-based ledgers and smart contract techniques. Both users and cloud providers may find the framework useful as a decision-support tool.

A unique distributed intrusion detection system (IDS) that uses fog computing to identify DDoS attacks towards a mining facility in an IoT network supported by blockchain is proposed by Randhir et al. [22]. Random Forest (RF) and an improved gradient tree boosting system (XGBoost) are trained on dispersed fog nodes to assess performance. The BoT-IoT dataset, which comprises the majority of current attacks discovered in blockchain-enabled IoT networks, is used to evaluate the efficacy of the suggested methodology. In general, RF requires less time for testing and training on widespread fog nodes than XGBoost.

To improve IIoT security, Romany et al. [23] presented the efficient Blockchain-Assisted Cluster-based IDS method known as BAC-IDS. Clustering IoT devices is the goal of the BAC-IDS concept, which intends to enable blockchain-based safe data transfer and discover intrusions. The BAC-IDS method uses a clustering approach based on Harris Hawks Optimization (HHO) to select Cluster Heads (CH) and build clusters based on their preferences. The NSL-KDD2015 dataset shows that the BAC-IDS technique has a lower error rate (0.03) based on experimental results.

In a smart city, Internet of Things security is essential. IoT security is a serious concern because of the many objectives and significant drawbacks that impede the quick adoption of these smart gadgets. Using lightweight information technology, Erukala et al. [24] describe a permission-based blockchain network for safeguarding the key pairs of connected devices. Using the combined ML technique, a collaborative detection tool is utilized to identify DDoS attacks on Internet of Things devices. Next, include a blockchain system that securely distributes alarm warnings to every IoT network node with sufficiently secure identification.

To build, implement, and evaluate an intrusion detection system, Chao Liang et al. [25] presented a hybrid placement method based on a multi-agent framework, blockchain, and DL procedures. The modules that make up the system are reaction, analysis, data administration, and data collecting. The outcomes show how effective DL algorithms are in identifying transport layer threats. According to the experiment, DL algorithms can be used to detect intrusions in Internet of Things networks.

A blockchain-based DL and ML system was developed by Shraddha et al. [26] to enhance IDS performance. First, use a group of classifiers, like Random Forest, Convolutional Neural Network, and XGBoost, to identify anomaly assaults. Next, utilizing the blockchain system, identified assaults are transformed into signatures and transferred further throughout the network. In this step, information is stored and secured at a higher level using the cryptosystem that is a part of the blockchain. The suggested IDS system's experimental results show increased accuracy and greater detection performance.

To efficiently identify Advanced Persistent Threats (APT) attack characteristics on the terminals, Lampis [27] suggests an Intrusion Detection and Prevention System (BIDPS) supported by Blockchain technology. First, identify and stop the methods used by attackers, remove trust from the endpoint, and put it on-chain. To assess the BIDPS's efficacy, a testbed was constructed and more than 10 APT attack tactics were used to target the endpoint. Because the Blockchain is immutable, BIDPS can successfully fend off launched attacks, strengthening its detection and prevention operations.

To effectively detect attacks, Nour et al. [28] offer a federated DL-based intrusion detection system (FED-IDS), which transfers learning data from servers to dispersed vehicle edge nodes. To learn the spatial-temporal depictions of vehicle traffic flows required for categorizing various attack types, FED-IDS employs a context-aware transformer system. Miners validate distributed local upgrades on the blockchain to prevent erroneous updates from being added. The outcomes of the experiment demonstrate the viability of protecting intelligent transportation networking against cyberattacks.

III. Problem Statement

Considerable research has been done on the integration of intrusion detection and blockchain to enhance data privacy and identify current and potential threats, respectively. These methods use learning-based ensemble frameworks to protect data privacy while simultaneously making it easier to identify complicated harmful occurrences [29]. The most arduous and time-consuming task is preprocessing data. Thus, even a rookie researcher should be able to choose pertinent features from the dataset and apply them while creating an IDS model. A new technology called the Internet of Things (IoT) is being developed for the creation of numerous vital applications. These apps still use centralized storage design, though, so they face several serious issues, including single points of failure, privacy, and security. Critical IoT network failure points were made visible by a distributed denial of service (DDoS) attack on the cloud [30]. All of the devices have access to the Internet, making the collected heterogeneous IoT urban information more accessible to the public and more susceptible to intellectual property theft by hackers. Network data exchange requires the guarantee of security and secrecy. The majority of networks that hackers infiltrate are ones where data interchange is highly vulnerable.

A. *Research Gap*

In the realm of cloud intrusion detection, existing approaches primarily focus on either traditional ML methods or centralized DL models, both of which come with significant limitations. Traditional ML techniques struggle to handle the large volumes of diverse data generated in cloud environments and often fail to adapt to new or evolving attack patterns. Centralized DL models, while more capable of detecting complex intrusions, suffer from challenges related to scalability, single points of failure, and the potential for compromised data integrity. Additionally, the lack of a robust, tamper-resistant framework for sharing model updates or alerts across cloud nodes can undermine the reliability and trustworthiness of the system, especially in multi-tenant environments where data privacy and security are paramount. The proposed Optimized Blockchain-Based DL Model aims to fill these gaps by introducing a decentralized, blockchain-anchored architecture that leverages the power of DL for cloud intrusion detection while enhancing security, transparency, and scalability. Unlike centralized systems, this model allows distributed cloud nodes to collaboratively detect intrusions, with each node securely sharing model updates through smart contracts on the blockchain. This approach not only decentralizes the decision-making process but also ensures that model integrity is preserved across all participating nodes, eliminating the risk of single points of failure and enhancing the system’s ability to handle real-time threats. Furthermore, by integrating blockchain, the proposed model introduces immutability and auditability in the detection process, addressing the trust and accountability gaps present in current systems. This work, therefore, marks a significant advancement in cloud security, providing a more resilient and transparent system for intrusion detection.

IV. Proposed Methodology

To stop network attacks, an IDS is essential in the field of cybersecurity. The choice engine being used determines how effective it is. A learning system built on blockchain and DL should be used to discover anomalies to boost the system's adaptability. This study offers an IDS based on DL and blockchain, utilizing optimization approaches to identify network threats. Protecting the accuracy and openness of the system depends on the decentralized and unchangeable ledger that blockchain technology offers. Everything about the intrusion detection process is recorded, including transactions and occurrences. Collaborative DL models, specifically CNNs, RBM, and GAN, can be utilized for intrusion detection assignments. The method used to develop these kinds of models are useful for detecting intrusions because they can identify intricate patterns and anomalies using network traffic data. Hash functions based on cryptography are also used in cloud environments to improve security and identify assaults.

A. *Dataset Collection*

The dataset used in this study to evaluate the suggested framework is the UNSW-NB15 [31]. There are 42 attributes in the UNSW-NB15, comprising three categorical inputs and 39 numerical inputs. The data formats (types) for the numerical inputs are binary, integer, and float. Two data subsets are also included in the UNSW-NB15: one for the training phase and another for testing. A thorough explanation of the attack's UNSW-NB15 subset distribution is given in Table I. The proposed technology is given in Fig. 1.

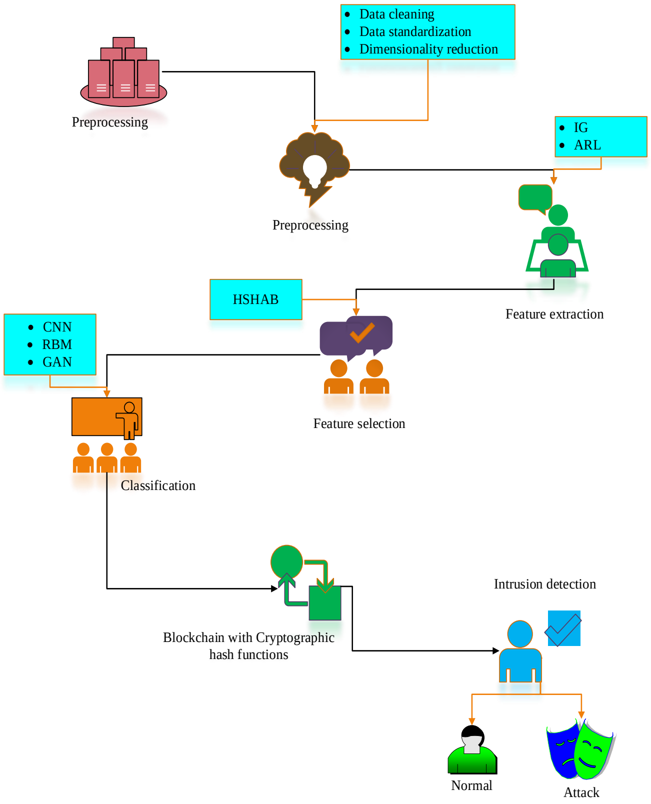

Fig. 1. Process of the developed technique.

TABLE I. DESCRIPTION OF THE UNSW-NB15 DATASET

Types of attack	Total No of data	No of training data	No of validation data	No of testing data	Data Attributes
Generic	40000	30081	9919	18871	1. Flow Features 2. Basic Features 3. Content Features 4. Time and Additional Features
Shellcode	1133	854	279	378	
Exploits	33393	25034	8359	11132	
Worms	130	99	31	44	
Reconnaissance	10491	7875	2616	3496	
Fuzzers	18184	13608	4576	6062	
Analysis	2000	1477	523	677	
Dos	12264	9237	3027	4089	
Backdoor	1746	1330	416	583	
Normal	56000	41911	14089	37000	

Divide the UNSW-NB15 training set into two parts: 25% of the initial training set is employed for validating the trained designs, and the remaining 75% of the original training is utilized to train the models. Furthermore, the validated models are tested using the UNSW-NB15-Test. The 10 assault classes that make up the UNSW-NB15. The data attributes if UNSW-NB15 include:

Flow Features: Attributes like dur (duration of the flow), proto (protocol used), and service (network service on the destination, e.g., HTTP, FTP, DNS).

Basic Features: These describe essential properties of the traffic, such as sbytes (source-to-destination bytes), dbytes (destination-to-source bytes), sttl (source time-to-live), and dttl (destination time-to-live).

Content Features: These focus on the content of packets, including features like sload (source packets per second) and dload (destination packets per second), which help in identifying abnormal patterns in data flows.

Time and Additional Features: These capture specific timing and behavior, such as ct_srv_src (connections to the same service from the same source) and ct_dst_ltm (connections to the same destination in the last 100 connections).

The dataset also includes a class label (label) that distinguishes between normal traffic (0) and attack traffic (1), with various attack types including DoS, backdoor, and shellcode. These attributes provide a detailed perspective of network traffic, enabling in-depth analysis for intrusion detection systems.

B. Preprocessing

One statistical method that makes use of an orthogonal change is PCA [32]. A set of correlated variables is transformed into a set of uncorrelated variables using PCA. For exploratory analysis of data, PCA is employed. Moreover, PCA can be used to investigate the connections between a set of variables. It can therefore be applied to reduce dimensionality.

Let's say a dataset $z^{(1)}, z^{(2)}, z^{(3)}, \dots . z^{(n)}$ has n n-dimension data that must be transformed to dimension inputs i -dimension $(i << n)$ using PCA. Below is a description of PCA:

Data Standardization: Eq. (1) states that the raw data must have a unit variance & a zero mean.

$$k_j^i = \frac{k_j^i - \bar{k}_j}{\sigma_j} \forall j \qquad (1)$$

Using Eq. (2), determine the co-variance vector of the raw data.

$$\sum = \frac{1}{n} \sum_i^n \quad (k_i)(k_i)^t, \sum \in E^{n*n} \qquad (2)$$

Utilizing the formula from Eq. (3), determine the covariance matrix eigenvector and eigenvalue.

$$v^t \sum = \gamma \mu$$

$$V = [\dots v_1 \; v_{2\dots\dots} \; v_n \dots], v_i \in E^n \qquad (3)$$

It is necessary to project raw data onto a n -dimensional subspace: Top n The covariance matrix's eigenvector is selected. Eq. (4) provides the necessary vector calculation.

$$z_i^{new} = [v_1^t z^i \; v_2^t z^i \dots\dots\dots\dots v_k^t z^i \,] \in E^k \quad (4)$$

Thus, if the unprocessed data is with n dimensionality, It'll be condensed into new k data presented in three dimensions.

C. Feature Extraction

To quantify the valuable information extracted from the cleaned dataset, two techniques are employed: Information Gain (IG) and Associate Rule Learning (ARL). When it pertains to feature extraction, IG and ARL work well together to find pertinent traits that make a substantial contribution to the association rules.

1) Information Gain (IG): The value of a feature for forecasting the target variable is measured using IG [33]. When a particular characteristic is known, it computes the decrease in entropy or unpredictability of the target variable. IG is an entropy-based technique for evaluating features that quantify the amount of information a feature provides regarding the target class. IG can identify the features with the highest information based on the target class. Strongly related to the target class, features with high IG are typically chosen to get the greatest classification outcomes. Nevertheless, IG is unable to remove unnecessary features. The amount of information that was available before as well as after the attribute value was known usually determines how much information is gained. For multiple classes, IG can have a maximum value of 1. Eq. (5) provides the formula for entropy analysis of more than two classes.

$$G(Y) = \sum_{i=1}^{k} Q(y_i) Q\,(y_i) \qquad (5)$$

Let, Q is denoted as the number of classes. Moreover, feature $Y$of I_G and the class labels Z is designed in Eq. (6) and Eq. (7).

$$I_G(Y, Z) = G(Y) - G\left(\frac{Y}{Z}\right) \qquad (6)$$

$$G\left(\frac{Y}{Z}\right) = -\sum_j Q(z_i)\sum_i Q\left(\frac{y_i}{z_i}\right)\left(Q\left(\frac{y_i}{z_i}\right)\right) \quad (7)$$

Let, $G(Y)$is denoted as the entropy of Y and $G\left(\frac{Y}{Z}\right)$ is considered as entropy of Y after seeing Z. Since I_G is considered a filter technique, when dealing with big multidimensional data, it scales effectively.

2) Association rule learning: Using ARL [34], one can find intriguing correlations or interactions between variables in huge datasets. These fascinating relationships are typically concealed in unprocessed data, but if they are found and retrieved, they can be effectively used to describe the data. To aid in further identifying intrusions, associations among users and the applications they use must be extracted from the intriguing relationships and added to usage profiles that are both normal and suspicious.

The following is the official description of ARL: Let $K = \{k_1, k_2, \ldots., k_n\}$be a group of n features referred to as system audit data pieces. Let $D = \{d_1, d_2, \ldots. d_m\}$exist a group of entries in this dataset. Each record d_i has a subset of characteristics in K. An assumption of the kind in Eq. (8) is referred to as a rule.

$$R \Rightarrow S, \text{ where } S \subseteq K, \text{and } R \cap S = 0 \quad (8)$$

The subsequent item sets apply to intrusion detection when reading the aforementioned example by this definition: $R = d_1 = users$ and $S = d_2 = used\_users$. The suggestion $R \Rightarrow S,$ is an ARL.

The subsequent item sets apply to intrusion detection when reading the aforementioned example by this definition: the support $Supp(R)$of an item set R, and the assurance $conf(R \Rightarrow S)$of a rule $R \Rightarrow S$as corresponds to Eq. (9).

$$conf(R \Rightarrow S) = \frac{Supp(R \cup S)}{Supp(R)} \quad (9)$$

Support for a set of objects $R\big(Supp(R)\big)$is the percentage of the data set's values that include the item set R. An algorithm for learning association rules consists of two distinct steps: First, determine an appropriate support level threshold and search the data for all likely common sets of items with support values higher than the threshold. Second, rules with confidence values higher than the minimal threshold are constructed using these acquired common item sets.

D. Feature Selection

Hybrid Sea horse and Bat Optimization are used to choose the dataset's best characteristics (HSHBA). It is the result of combining Bat Optimization (BO) [35] with Sea Horse Optimization (SHO) [36]. The movement, predatory behavior, and breeding of sea horses are simulated by the SHO algorithm. The core elements of SHO have three behaviors. The global and locaters techniques are adapted to the motion and hunting behaviors, respectively, to enhance the enhancements of the SHO algorithm. Here, Lévy flying is utilized to mimic the seahorse's movements as it spirals nearer to its greatest advantage. The mathematical relationship is described in Eq. (10).

$$Z_{new}^1(t+1) = Z_i(t) + Levy(\delta)\left(\big(Z_{elite}(t) - Z_i(t)\big) \times a \times b \times c + Z_{elite}(t)\right) \quad (10)$$

Let, $a, b,$ and c are denoted as coordinate vectors in three dimensions (a, b, c) in the spiraling motion, correspondingly. Eq. (11) is used to calculate the Brownian motion with waves.

$$\sigma = \left(\frac{\Gamma(1+\delta) \times sinsin\left(\frac{\pi\delta}{2}\right)}{\Gamma\left(\frac{1+\delta}{2}\right) \times \delta \times 2^{\left(\frac{\delta-1}{2}\right)}}\right) \quad (11)$$

Brownian motion is utilized to imitate the movement of the unit size of the sea horse, which is given by Eq. (12), to the left of the $\overrightarrow{r_1}$ cut-off point to enable to better comprehend the search space in SHO.

$$Z_{new}^1(t+1) = Z_i(t) + rand \times c \times \alpha_t \times (Z_i(t) - \alpha_t \times Z_{elite}) \quad (12)$$

Let, c is considered a constant coefficient, $\alpha_t$is represented as a random walk coefficient for Brownian motion.

Eq. (13) can be used to integrate these two conditions to determine the sea horse's new position at each repetition t.

$$Z_{new}^1(t+1) = \begin{Bmatrix} Z_i(t) + Levy(\delta)\left(\big(Z_{elite}(t) - Z_i(t)\big) \times a \times b \times c + Z_{elite}(t)\right) & \overrightarrow{r_1} > 0 \\ Z_i(t) + rand \times c \times \alpha_t \times (Z_i(t) - \alpha_t \times Z_{elite}) & \overrightarrow{r_1} \leq 0 \end{Bmatrix} \quad (13)$$

This stage involves updating each bat's position $\hat{x}_i$ and velocity $\hat{v}_i$ in a space of dimensions d. $\hat{x}_i$ and $\hat{v}_i$ ought to be updated afterward throughout the iterations. The new solutions $\hat{x}_i(t)$ and velocities $\hat{v}_i(t)$ at time step t. Eq. (14) shows the mathematical algorithm's hybrid efficiency.

$$Z_{new}^2(t+1) = \{\hat{x}_i(t-1) + \hat{v}_i(t)\,\overrightarrow{r_2} > 0.1\ (1-\eta) \times (Z_{new}^1(t) - rand \times Z_{elite}) + \eta \times Z_{new}^1(t)\,\overrightarrow{r_2} \leq 0.1\,\} \quad (14)$$

Let, $Z_{new}^1(t)$ shows the seahorse's updated location at that moment of t, $\overrightarrow{r_2}$ is denoted as a random number [0, 1], It is employed to modify the seahorse's duration of steps during predation, which gets shorter by a linear amount each iteration. Eq. (15) is used to determine the velocity.

$$\hat{v}_i(t) = \hat{v}_i(t-1) + (\hat{x}_i(t-1) - \hat{x}^*)\hat{f}_i \quad (15)$$

Let, β in the range of [0,1] is a vector chosen at random using a uniform range. Here, $\hat{x}^*$ is considered as the current best place (solution) in the world, which is found after evaluating every option among every i bat. Let, $\hat{f}_i$ is considered as frequency and is computed by applying Eq. (16).

$$\hat{f}_i = \hat{f}_{min} + (\hat{f}_{max} - \hat{f}_{min}).\ \beta \quad (16)$$

Let, $\hat{f}_{max}$ and $\hat{f}_{min}$ are denoted as maximum and minimum frequency. Instead, it indicates that the prey is moving more quickly than the seahorse was when it was hunting, allowing the prey to escape and the seahorse to fail to capture it. Using the HSHBA approach, the generated model chooses the best characteristics from the dataset. It improves the IDS system's performance in terms of detection and categorization. To detect intrusion, the chosen features are subsequently modified for the classification stage. The HSHBA algorithm is described in Algorithm.1.

```

E. Classification

Ensemble DL models are employed at this stage to enhance the forecast outcomes. For intrusion detection tasks, the created EDL model incorporates convolutional neural networks (CNNs), Generative Adversarial Networks (GAN), and Restricted Boltzmann Machine (RBM). A detailed explanation is provided below.

1) CNN [37]: A multi-layer perceptron specifically created for identifying two-dimensional shapes is called a convolutional network. Convolution kernel characteristics and convolution layer connectivity weights are among the network parameters that are learned during the CNN training procedure. To determine the intrusions, the prediction procedure primarily uses the input data and network parameters. Eq. (17) and Eq. (18) are used to train the chosen features into the CNN algorithm's convolution layer.

$$x^{\leftrightarrow c}_{j} = f\left(v^{\leftrightarrow c}_{j}\right) \tag{17}$$

$$v^{\leftrightarrow c}_{j} = \sum\nolimits_{i \in N_j} x^{\leftrightarrow}{}_{i}^{c-1} * h^{\leftrightarrow c}_{ij} + b^{\leftrightarrow c}_{j} \tag{18}$$

Let, $v^{\leftrightarrow c}_{j}$is denoted as the net activation of the j^{th}network of the convolution layer c, it is obtained by removing the feature map produced by the preceding layer, and convolution averaging $x^{\leftrightarrow}{}_{i}^{c-1}$, $x^{\leftrightarrow}{}_{i}^{c}$is denoted as the output of the j^{th}channel of the convolution layer c. $f(.)$ is considered an activation function and applies tanh and sigmoid operations, among others. N_j is a subset of the feature maps that are utilized as input to compute $v^{\leftrightarrow c}_{j}$, $h^{\leftrightarrow c}_{ij}$ is denoted as convolution kernel matrix, $b^{\leftrightarrow c}_{j}$ is denoted as convolution feature map with bias. Regarding a feature map output $x^{\leftrightarrow c}_{j}$, by every supplied feature map $x^{\leftrightarrow}{}_{j}^{c-1}$might differ. $*$ is denoted as a convolution symbol. Then update $v^{\leftrightarrow c}_{j}$ into the pooling layer via Eq. (19).

$$v^{\leftrightarrow c}_{j} = \sum\nolimits_{i \in N_j} \beta^{\leftrightarrow c}_{j} down\left(x^{\leftrightarrow}{}_{j}^{c-1}\right) + b^{\leftrightarrow c}_{j} \tag{19}$$

Let, $v^{\leftrightarrow c}_{j}$ is denoted as net activation of the j^{th} channel of the pooling layer c, It is produced by balancing and pooling the characteristics map output $x^{\leftrightarrow}{}_{i}^{c-1}$ of the previous layer, β is denoted as pooling layer weighting factor, $b^{\leftrightarrow c}_{j}$ is considered as pooling layer offset, $down(.)$ is denoted as pooling function. Eq. (20) and Eq. (21) are used to weigh the inputs and get the outcome via the activation function, which yields the output of the fully connected layer.

$$x^{\leftrightarrow c} = f(v^{\leftrightarrow c}) \tag{20}$$

$$v^{\leftrightarrow c} = w^{\leftrightarrow c} x^{\leftrightarrow c-1} + b^{\leftrightarrow c} \tag{21}$$

Let, $v^{\leftrightarrow c}$ is considered a fully connected layer net activation function c, it is acquired by removing and filtering the output map. $x^{\leftrightarrow c-1}$is denoted as the previous layer. $w^{\leftrightarrow c}$is considered as a fully connected network weight coefficient, and $b^{\leftrightarrow c}$ is considered a fully connected layer offset c.

2) RBM [38]: The RBM model has a visible layer $\tilde{v}$ with n units and a hidden layer $\tilde{h}$ with m units. In addition, a matrix of actual values $\widetilde{w}_{n \times m}$ replicas the proportions of visible to hidden neurons, where $\widetilde{w}_{ij}$ is denoted as the visible unit connection $\tilde{v}_i$ and the hidden unit $\tilde{h}_j$. The data is primarily received by the visible layer for processing, while its pattern and probability distribution are learned by the hidden layer. Furthermore, probably every layer's unit $\tilde{v}$ and $\tilde{h}$ are binary It came from the distribution of Bernoulli, i.e., $\tilde{v} \in \{0,1\}^n, \tilde{h} \in \{0,1\}^m$. Eq. (22) calculates an RBM's energy function:

$$E\left(\tilde{v}, \tilde{h}\right) = -\sum\nolimits_{i=1}^{n} \tilde{x}_i \tilde{v}_i - \sum\nolimits_{j=1}^{m} \tilde{y}_i \tilde{h}_j - \sum\nolimits_{i=1}^{n} \sum\nolimits_{j=1}^{m} \tilde{v}_i \tilde{h}_j \widetilde{w}_{ij} \tag{22}$$

Let, x and y are denoted as hidden and visible unit biases. Furthermore, Eq. (23) simulates the combined likelihood of a specific configuration $\left(\tilde{v}, \tilde{h}\right)$:

$$P\left(\tilde{v}, \tilde{h}\right) = \frac{e^{-E\left(\tilde{v}, \tilde{h}\right)}}{f_p} \tag{23}$$

Let, f_p is considered a partition function, which, while taking into account visible and hidden units, restores the chance over all conceivable configurations. Essentially, an RBM must become familiar with a set of parameters. using an algorithm for training. For every training set, it maximizes the sum of data possibilities ξ, which is described in Eq. (24)

$$argmax_{\Theta} \prod_{\tilde{v}\in\xi} P(\tilde{v}) \tag{24}$$

Implementing the negative of the logarithm functions, which is denoted by the negative log-likelihood (NLL), to describe this problem is an intriguing method. The NLL indicates the distribution estimation of the new information over the original data. Consequently, one can use the partial derivatives to calculate the derivatives of $\tilde{W}$, $\tilde{x}$ and $\tilde{y}$at iteration t. The parameter updating rules are described by Eq. (25–27).

$$\tilde{W}^{t+1} = \tilde{W}^{t} + \eta\left(\tilde{v}P(\tilde{v},\tilde{h}) - \tilde{v}P(v,h)\right) \tag{25}$$

$$\tilde{x}^{t+1} = \tilde{x}^{t} + (\tilde{v} - v) \tag{26}$$

$$\tilde{y}^{t+1} = \tilde{x}^{t} + \left(P(\tilde{v},\tilde{h}) - P(v,h)\right) \tag{27}$$

Let, η is denoted as the learning rate, v is considered as the visible layer's reconstruction $\tilde{v}$, and h is considered as the hidden vector's estimation $\tilde{h}$ given v.

3) GAN [39]: A GAN consists of two parts, a generator g_e and a discriminator d_r, that compete with one another. g_e uses a noise vector as its input $\vec{n}$ and intends to provide high-quality fake data that closely approximates the original data. Moreover, d_r seeks to identify authentic data from artificially created data. The min-max goal function o_f is used to represent Eq. (28).

$$\underset{g_e}{min}\underset{d_r}{max} o_f\left(g_{e,}d_r\right) = E_{\vec{x}_r\sim P}\left[log\ log\ \left(d_r(\vec{x}_r)\right)\right] + E_{\vec{n}\sim M}\left[log\ log\ \left(1 - d_r\left(g_e(\vec{n})\right)\right)\right] \tag{28}$$

Let, $\vec{x}_r \sim P$is considered as the actual distribution of data and $\vec{n} \sim M$ is denoted as Gaussian noise distribution. $d_r(\vec{x})$is denoted as outputs. The generator g_e gather $\vec{n}$ input to classify the intrusion.

a) Ensemble DL techniques: The maximum voting of each classifier determines which of the obtained prediction results is chosen. Max voting [40] entails gathering predictions for every class label and projecting which class label will receive the greatest number of votes using Eq. (29). Soft voting is an additional kind of maximum voting. In soft voting, Eq. (30) illustrates, that predicted chances are gathered for each class identity, and the class identity with the highest probability is predicted.

$$z' = [C_1'(\hat{x}), C_2'(\hat{x}), C_3'(\hat{x})] \tag{29}$$

Let, z' is denoted as the majority vote of each classifier, determines the class label C_1',C_2', and C_3'.

$$z' = argmax_i \sum_{j=1}^{n} W_j' P_{ij}' \tag{30}$$

Let, W_j' is considered as the weight that can be allocated to the j^{th}classifier.

F. Blockchain with Cryptographic Hash Function [41]

A blockchain's primary role is to offer a cryptographically safe method for collecting a permanent and globally verifiable collection of documents, known as blocks, that are systematically arranged by separate time stamps. Blockchains are commonly utilized as a distributed, open database of data transactions since they are frequently shared and synchronized via a peer-to-peer network. Every member of the blockchain network has access to the record data, which they can use to accept, reject, or verify using a consensus procedure. Records are added to the blockchain in the same sequence that they were verified after they are approved.

The foundation of blockchains is the cryptographically secure hash function, a fundamental building block of cryptography. These hashing algorithms $\hat{H}: \{0,1\}^* \to \{0,1\}^n$map an input of any length to an output with a fixed length of n bits, and it needs to meet the security constraints listed below:

Preimage resistance: Considering a hash value $\hat{h}$, It ought to be necessary to $\Phi(2^n)$work involved with computing an $\hat{x}$ such that $\hat{H}(\hat{x}) = \hat{h}$.

Second preimage resistance: the input $\hat{x}$ and hash value $\hat{h} = \hat{H}(\hat{x})$ are needed in $O(2n\ )$ for computing $\hat{x}' \neq \hat{x}$ such that $H(x\ 0\ ) = h.3)$.

Collision resistance: Need $\Phi(2^n)$determination to calculate any two $\hat{x}' \neq \hat{x}$ such that $\hat{H}(\hat{x}') = \hat{h}$

The opponent does not influence the real hash value in collisions. (Second) preimage resistance is particularly important in the context of blockchains because attackers might change current blocks while maintaining the chain if they could identify second preimages with a specific mixfix. The aforementioned security criteria state that an attack of this kind needs to be at least 2^n for a hash function with n bits. The IDS determines each file's hash value when scanning records on a system and matches it to the store. If a similarity is discovered, malware is probably present.

V. Results and Discussion

This study employed a variety of metrics to assess the efficacy of the proposed model. The BEDL model testing and training processes were conducted using Python. In the experiment, two learning rates 70 and 80 were chosen for the analysis of the study. The EDF method produced good results in many classification procedures. The presented method uses the BEDF model and hybrid optimization to increase the resilience of cloud computing. The architecture of proposed BEDL involves a decentralized network of cloud nodes that work collaboratively to detect intrusions. Each node in the blockchain network runs the DL IDS, where updates to the feature selection results are recorded immutably on the blockchain to ensure model integrity. The architecture comprises smart contracts that govern data sharing, model updates, and anomaly detection reporting across nodes. Smart Contracts are designed to trigger automatic actions such as initiating a model retraining process when new intrusion patterns are detected for accurate detections. Additionally, the smart contracts enforce data privacy by facilitating secure, encrypted communications between cloud nodes while ensuring that any detection-related alerts are stored immutably and transparently across the blockchain, guaranteeing auditability and trust. The use of consensus algorithms ensures that only validated model updates are propagated across the network, improving both security and collaboration in intrusion detection. Furthermore, the dataset used for investigation is

UNSW-NB15 which is available in https://www.kaggle.com/datasets/dhoogla/unswnb15. It is a benchmark dataset designed for evaluating IDS. It was created by simulating real-world network traffic at the Cyber Range Lab of the Australian Centre for Cyber Security (ACCS), incorporating modern attack vectors. The dataset contains 49 features and 9 different attack categories, such as DoS, worms, backdoors, and exploits, alongside normal traffic. It provides both labeled and unlabeled data for training and testing machine learning models. The UNSW-NB15 dataset is widely used due to its diversity and realistic network behavior. The performance measures utilized to analyze the efficacy of the suggested technique are F1-score, False Positive Rate (FPR), False Negative Rate (FNR), Matthews Correlation Coefficient (MCC), Negative Predictive Value (NPV), accuracy, precision, sensitivity, and specificity.

A. *Performance Analysis*

Two learning rates 70 and 80 are employed for the training and testing of the developed technique. The experimental findings are tested against a variety of accessible DL classifiers, including Bi-LSTM [21], RF+XGBoost [23], RNN [40], CNN [37], and GAN [39].

Fig. 2. Performance of proposed BEDL over Baseline Models for (a) Accuracy, (b) Precision, (c) Sensitivity. (d) Specificity, (e) F1-Score, (f) FNR, (g) FPR, (h) MCC, and (i) NPV.

1) Accuracy: The accuracy scores that several models obtained on the test are shown in Fig. 2(a), along with a suggested model, for two alternative scenarios: one with a learning rate of 70 and the other with a learning rate of 80. The Bi-LSTM model demonstrated a maximum accuracy of 93.655% at a learning rate of 70, followed by the CNN model's 92.4763% accuracy. The accuracy of the suggested model is 98.4763%. With an accuracy of 81.3652%, the GAN model was the least accurate of the models on the list; the RNN model was somewhat more accurate at 76.3764%. With an accuracy of 87.7766%, the ensemble methods RF+XGBoost fared better in the meantime. When comparing the accuracy ratings of all models in the first scenario to the second, which had a higher learning rate of 80, they generally declined. With 92.1121% accuracy, the Bi-LSTM model was still ahead of the CNN model, which came in second at 91.2344%. The suggested model saw a decline to 97.9987% but still displayed great accuracy. The accuracy of the ensemble methods RF+XGBoost similarly decreased, reaching 85.2235%. With the GAN model at 80.4762% and the RNN model at 78.8776%, the GAN and RNN models displayed similar patterns as in the prior situation.

2) Precision: The precision scores under two distinct learning rates (70 and 80) are shown in Fig. 2(b) for a variety of models, including Bi-LSTM, RF+XGBoost, CNN, GAN, RNN, and a proposed model. Precision is a metric that expresses the percentage of genuine positive predictions among all positive predictions, assessing how accurately a model predicts the future. The Bi-LSTM system achieves 87.54% precision at a learning rate of 70, while the RF+XGBoost model follows with 78.89% precision. 90.38% is the precision achieved by the CNN model, 76.37% by the GAN model, and 70.39% by the RNN model. Remarkably, with a precision of 95.97%, the suggested model beats all others, demonstrating its superiority in correctly predicting positive events at this learning rate. There is a tiny difference in the precision values below a learning rate of 80. The precision of the RF+XGBoost model rises to 80.48%, while that of the Bi-LSTM model falls to 86.23%. The precision of the GAN model falls to 73.48%, the RNN model stays almost the same at 70.77%, and the CNN model's precision reduces to 85.33%. In a similar vein, the precision of the suggested model drops but stays high at 94.22%.

3) Sensitivity: Sensitivity values for a range of models, including CNN, GAN, RNN, RF+XGBoost, Bi-LSTM, and a suggested model, are shown in Fig. 2(c) for various learning rates. True positive rate, another name for sensitivity, is the percentage of real positive cases that the model properly recognized. The suggested model beats the others with a sensitivity of 96.88% at a learning rate of 70, demonstrating its higher capacity to accurately detect positive cases. The CNN and Bi-LSTM models, with corresponding sensitivity values of 89.48% and 82.66%, trail closely behind. With 76.88% and 69.47% sensitivity, respectively, RF+XGBoost and RNN outperform the GAN model, which comes in last with 75.99% sensitivity. The suggested model keeps its high sensitivity at 95.77% as the learning rate rises to 80, demonstrating its efficacy. Notably, the RF+XGBoost model outperforms the CNN and Bi-LSTM models in this configuration, with a sensitivity of 82.96%. However when compared to the other models, the GAN model's sensitivity is still the lowest at 74.99%, suggesting its relative weakness in correctly identifying positive cases.

4) Specificity: The specificity values of several models, as well as a suggested model under two distinct learning rates (70 and 80), are shown in Fig. 2(d). In binary classification, specificity is a metric that shows the percentage of real negative cases that the model correctly classifies as such. The Bi-LSTM model gets the maximum specificity of 89.37% under a learning rate of 70, followed by the CNN model at 87.99%. Additionally, the suggested model functions effectively, with a 98.35% specificity. It's important to keep in mind, though, that the GAN model performs comparatively worse than the others in terms of specificity, only reaching 76.48%. There are some variations in the models' performance when the learning rate is raised to 80. The Bi-LSTM model increases somewhat to 89.38% while maintaining its high specificity. There is also a minor improvement to 87.99% for the CNN model. Though it still performs noticeably better than most models, the suggested model's performance drops to 96.21%. Notably, as compared to its performance at the lower learning rate, the RNN model exhibits a drop in specificity.

5) F1-Score: The F-Measure performance scores under two distinct learning rates, 70 and 80, are displayed in Fig. 2(e) for a variety of models, including Bi-LSTM, RF+XGBoost, CNN, GAN, RNN, and a proposed model. The Bi-LSTM model obtains an F-Measure of 80.36% at a learning rate of 70, whereas RF+XGBoost does marginally better at 83.99%. CNN has the best performance, coming in at 90.78%, and the suggested model comes in at 97.23%. The F-Measure scores of GAN and RNN are lower, at 78.48% and 72.48%, respectively. A learning rate increase of 80 improves performance for the majority of models. Bi-LSTM sees a slight improvement to 85.23%, RF+XGBoost to 87.68%, CNN to 89.74%, and GAN and RNN to 79.39% and 78.56%, respectively. CNN experiences a slight decline. The suggested model demonstrates a significant rise to 97.99%.

6) FNR and FPR: The False Negative Rate (FNR) performance of the various models at the two learning rates 70 and 80 is displayed in Fig. 2(f). A distinct model, such as Bi-LSTM, RF+XGBoost, CNN, GAN, RNN, and a suggested model, is shown by each column. With a FNR of 0.087662, the suggested model beats all others at a learning rate of 70. CNN and Bi-LSTM both show comparatively low FNRs of 0.12004 and 0.13123, respectively. Nevertheless, models with higher FNR values, ranging from 0.20093 to 0.30234, include RF+XGBoost, GAN, and RNN. A discernible change in the models' performance occurs when the learning rate is raised to 80. The suggested model continues to have the lowest FNR (0.078876), indicating its resilience. Comparing the FNR values of Bi-LSTM, RF+XGBoost, and CNN to the 70-learning rate scenario, however, reveals a modest gain. Notably, with values over 0.24, GAN and RNN continue to show greater FNRs than the other models. On the other hand, all models perform somewhat better when the learning rate is raised to 80. Notably, the suggested model keeps the lowest FPR, demonstrating its superiority over the other models even more. Additionally, Bi-LSTM exhibits a significant drop in FPR in Fig. 2(g), demonstrating its sensitivity to variations in learning rate. The FPRs of RF+XGBoost, CNN, and GAN are comparable, while the performance of RNN is largely constant.

7) MCC: The scores for several models and a suggested model are shown in Fig. 2(h) for two separate scenarios: one with a learning rate of 70 and the other with a learning rate of 80. The models perform differently in the first situation when the learning rate is 70. The suggested model achieves 95.56553, while the Bi-LSTM model reaches 81.8009, RF+XGBoost at 80.6775, CNN at 87.6544, GAN at 79.7668, and RNN at 78.74662. Interestingly, the suggested model performs noticeably better than the others, demonstrating its usefulness in this situation. Significant differences in the model's performance can be seen in the second scenario, which uses a higher learning rate of 80. The Bi-LSTM model outperforms RF+XGBoost at 89.657, with an MCC of 87.3766. Nevertheless, the performance of the GAN and RNN models further declines to 79.65564 and 70.6553, respectively, while the CNN model's performance reduces to 85.4773. With an MCC of 96.4878, the suggested model maintains its strong performance despite these modifications, demonstrating its resilience and superiority over the other models in this situation.

8) NPV: The performance measures, namely the net present value (NPV), of various models in two distinct situations are displayed in Fig. 2(i) one with a learning rate of 70 and the other with an 80. A suggested model, CNN, GAN, RNN, RF+XGBoost, Bi-LSTM, and RNN are among the models that are compared. The suggested model performs better than other models in the first scenario with a 70-learning rate, obtaining a value of 6.1232. With an NPV of 87.6598, CNN outperforms the others, while Bi-LSTM, with an NPV of 86.3624, is not far behind. The NPV values of RF+XGBoost, GAN, and RNN are 79.3765, 80.87763, and 79.68773. With an NPV of 96.5886, the suggested model maintains its advantage in the second scenario with an 80-learning rate. CNN outperforms the first scenario by a substantial margin, obtaining the highest NPV among the models after the suggested one, 90.4874. Next, with an NPV of 81.3885, is RF+XGBoost. But with an NPV of 71.3874, RNN's performance significantly deteriorates, and it becomes the least-performing model out of all of them. To enhance the robustness and security of the cloud environment, a cryptographic hash function is generated using blockchain. The gained experimental outcomes are compared with existing classifiers and attained better experimental outcomes. The designed technique gained accuracy of 98.47%, and 97.99% for 70 and 80 learning rates, and also gained less FPR of 0.098, and 0.087 for 70 and 80 learning rates. The developed technique improves the performance and IDS and enhances the efficiency and robustness by using blockchain. In the future, improving blockchain networks' scalability is essential to enabling the widespread deployment of IDS. Subsequent investigations may concentrate on creating innovative consensus processes or layer-2 scaling approaches to manage the growing number of events and transactions produced by IDS sensors.

B. Real-time Implementation Model

A pilot deployment is conducted across a distributed cloud infrastructure. The system's performance is assessed by simulating various intrusion scenarios, including DDoS attacks [41], unauthorized access attempts, and insider threats. Key performance indicators such as detection accuracy, false positive/negative rates, latency in intrusion detection, and blockchain transaction throughput are monitored. Additionally, the scalability of the system is evaluated by increasing the number of cloud nodes and analyzing the consensus efficiency, smart contract execution times, and resource utilization. The evaluation also considers the impact of network delays, data privacy enforcement, and system robustness in handling high-traffic environments, ensuring the solution's practicality and effectiveness for real-world cloud security.

When a DDoS attack occurs targeting the platform hosted on cloud system, the proposed BEDL model detects abnormal traffic spikes. Once an anomaly is detected, a smart contract is triggered, validating the threat and broadcasting it across the blockchain. This ensures all nodes in the network are aware of the attack, preventing it from spreading further. The smart contract also records the event immutably for future audits and triggers automated actions such as load balancing and firewall rule updates to mitigate the threat in real-time, enhancing both the security and resilience of the cloud infrastructure.

VI. Conclusion

This paper designs blockchain-based DL models to enhance the security of cloud computing. Three types of DL techniques are combined such as CNN, GAN, and RBM to enhance the prediction results of the developed model. UNSW-NB15 dataset is collected and they are cleaned, standardized, and reduced dimensionality using preprocessing. They select the best features to improve the attack prediction rate using the HSHBA model. Additionally, detect the intrusion present in the cloud using a blockchain-based EDL model. The final results are predicted based on the majority and soft voting of the designed technique. Future research could explore integrating federated learning [42] with blockchain to further enhance data privacy in cloud intrusion detection, allowing decentralized model training without sharing sensitive data. Additionally, adopting quantum-safe cryptography in the blockchain layer could future-proof the system against quantum computing threats. The scalability of the proposed architecture can be improved through layer-2 blockchain solutions to reduce latency. Research can also focus on adaptive DL models that evolve with emerging threats in real time. Lastly, expanding the system's application to edge computing environments could enhance security in IoT-based cloud ecosystems.

Acknowledgment

The author extends the appreciation to the Deanship of Postgraduate Studies and Scientific Research at Majmaah University for funding this research work through the project number (R-2024-1245).

Deep Learning for Stock Price Prediction and Portfolio Optimization

Ashy Sebastian, Dr. Veerta Tantia
Department of Commerce, Christ University, Bengaluru, India

***Abstract*—Using deep learning for stock market predictions and portfolio optimizations is a burgeoning field of research. This study focuses on the stock market dynamics in developing countries, which are often considered less stable than their developed counterparts. The study is structured in two stages. In the first stage, the authors introduce a stacked LSTM model for predicting NIFTY stocks and then rank the stocks based on their predicted returns. In the second stage, the high-return stocks are selected to form 30 different portfolios with six different objectives, each comprising the top 7, 8, 9, and 10 NIFTY stocks. These portfolios are then compared based on risk and returns. Experimental results show that portfolios with five stocks offer the best returns and that adding more than nine stocks to the portfolio leads to excessive diversification and complexity. Therefore, the findings suggest that the proposed two-stage portfolio optimization method has the potential to construct a promising investment strategy, offering a balance between historical and future information on assets.**

Keywords*—Deep learning; long-short term memory; stock price prediction; portfolio optimization; emerging markets; Indian stock market

I. Introduction

Portfolio optimization is an essential component of a trading system. The goal of optimization is to determine the optimal asset allocation within a portfolio to maximize returns for a given level of risk. This concept, widely known as modern portfolio theory (MPT), was pioneered by study [1].

The main advantage of creating an optimal portfolio is that it encourages diversification, which helps stabilize the equity curve and results in a higher return per unit of risk than trading a single asset. Nevertheless, despite the undeniable power of such diversification, the selection and implementation of the right asset allocations in a portfolio can be challenging due to significant fluctuations in financial market dynamics over time. For instance, assets that exhibited strong negative correlations in the past could be positively correlated in the future, and individual assets in the same asset class often show high positive correlations [2]. This adds extra risk to the portfolio, degrades its subsequent performance and undermines investor confidence

Most traditional portfolio research overlooks the selection of high-quality assets and instead focuses on enhancing strategy performance. However, pre-selecting high-quality assets is crucial for optimal portfolio formation [3]. Zhou et al. [4] noted that the success of portfolio management relies on the initial selection of high-quality stocks. Investors attempt to predict the future returns of stocks and determine the optimal weight based on the highest predicted returns to construct a portfolio [5]**.** During the portfolio optimization process, the expected return on an asset is a vital consideration, highlighting the importance of preliminary asset selection in effective portfolio management [6]. Doing this substantially reduces the scope of possible assets to choose from. Typically, high profits are associated with high risk. However, in portfolio optimization, risk can be minimized by selecting optimal securities and assets. Thus, combining forecasting theory with portfolio selection could improve portfolio returns [7].

With advancements in machine learning and deep learning, though predicting asset returns has become feasible, these prediction results are not yet effectively utilized in practice for portfolio creation and optimization. As a result, many portfolios fail to fully capitalize on the available predictive insights, limiting their potential for improved performance and risk management. The challenge lies in effectively utilizing these predicted returns to construct an optimal investment portfolio. Considering this, the research seeks to address the issue by exploring how to integrate advanced forecasting information into the portfolio selection process.

Literature evidence that the strong functioning of stock markets has a significant effect on the overall growth of an economy, especially in a developing one. Nevertheless, forecasting in emerging markets is more difficult than in developed ones [8] due to their greater volatility, which can be affected by external reasons such as oil prices and the performance of developed markets. Emerging markets, such as China and India, comprise a significant portion of the global economy. Trading in these markets requires a different approach than in developed markets, as they possess unique characteristics such as higher volatility and potentially greater average returns. These markets often lack full information efficiency, owing to institutional barriers that impede information flow and the inexperience of market participants in quickly incorporating new information into security prices. In [9], a genetic algorithm was used to select stock portfolios in the emerging Asian markets of Vietnam, Thailand, Philippines, Singapore, Malaysia, and Indonesia. Although the Indian stock market has made significant advancements, there is a dearth of research on prediction-based portfolios. Furthermore, NSE (National Stock Exchange) and BSE (Bombay Stock Exchange), India's two major stock exchanges, have around 1600 and 5000 listed companies, respectively, traded on them daily. Hence, it is challenging for individual investors to decide on the number and type of stocks. Therefore, the development of appropriate asset selection and portfolio optimization models can assist investors in emerging markets to maximize profits and minimize risk. Sen et al. [10] conducted a study on the Indian stock wherein the top five stocks from nine different sectors of NSE were taken for creating minimum-variance and optimum-risk portfolios. An LSTM (Long-short term memory) model was then designed to predict the future prices of the stocks in each portfolio. Five months after the portfolio construction, the actual return and the return predicted by the LSTM model are computed and compared. Nevertheless, the study was limited to return prediction and did not consider asset pre-selection. Hence, to fill this gap, this study attempts to select high-quality assets from the Indian stock market through deep learning-based forecasting and build a competitive portfolio for improved returns.

The purpose of this paper is to construct an optimized portfolio based on the asset returns forecasted by deep learning. The authors argue that a complete portfolio consists of two stages, where the first stage is the pre-selection of high-quality assets, and the second stage is the determination of optimal weights for the portfolio. In the empirical part, this study selects the constituent stocks of NIFTY50 to test the proposed methodology. In the primary stage, this paper proposes a stacked LSTM for stock price prediction and then calculates returns based on these predicted values. In the second stage, the stocks are ranked based on these returns, and the top N stocks are selected for portfolio formation and optimization. These selections are then compared against a benchmark index to establish superior performance.

This study addresses the following questions.

- Does asset pre-selection before optimal portfolio formation enhance the portfolio performance compared to the traditional approach without pre-selection?
- Does the performance of different-sized portfolios show significant variations?
- What is the optimal number of stocks to be held in a portfolio for maximum return?

The major contributions of this paper are:

This research makes significant theoretical contributions by developing a stacked LSTM model for predictions in the Indian stock market. By demonstrating the model's efficacy in handling the intricacies of the Indian stock market, characterized by high volatility and noise, this study fills a crucial gap in the literature.

Most relevant studies concentrate on the stage of optimal portfolio formation using the mean-variance framework but overlook the pre-selection of stocks, which occurs before the formation of the optimal portfolio. Markowitz advised against putting all "eggs in one basket," emphasizing risk reduction through diversification. However, the mean-variance approach does not tackle the issue of deciding the number of assets to invest in. The application of LSTM for identifying high-potential stocks before constructing portfolios introduces a novel approach to portfolio management.

By accurately predicting the future performance of various stocks, the model helps investors identify those with the highest potential returns and the most favorable risk profiles. This pre selection process ensures that only the most promising stocks are included in the portfolio, improving overall performance. This further helps to determine the optimum number of stocks to be held while creating a portfolio.

Additionally, this study highlights the significant potential for advancing research on deep learning in emerging markets, integrating new academic insights to better understand financial decision-making and time-series forecasting. Consequently, this work enhances the existing literature on the application of deep learning models for emerging markets.

To the best of the authors' knowledge, this is the first study of its kind that combines forecasting theory with portfolio optimization for the Indian stock market index NIFTY50, and it is believed that this paper is making a substantial contribution to the related literature.

The remainder of this article is organized in the following order. Previous literature is discussed in Section II and Methodology is in Section III. The experimental results and discussion are in Section IV. In Section V, the authors mark their concluding thoughts, and Section VI discusses limitations and future scope.

II. Literature Review

This literature review of this study is divided into two sections. The first section discusses the concept of deep learning and the second section deals with portfolio optimization. This is followed by the research gap.

A. Deep Learning

Deep learning, a subset of machine learning, employs artificial neural networks (ANN) to address complex problems. ANNs are composed of an input layer, hidden layers, and an output layer, with each node in a layer connected to every node in the subsequent layer. By adding more hidden layers, the network becomes deeper, leading to the formation of deep neural networks (DNNs). The term "deep" in deep learning refers to this increased complexity, achieved by adding more hidden layers between the input and output layers.

They have been used for financial forecasting, including economic recession predictions [11], portfolio optimization [2],[12],[13], sentiment analysis [14],[15] and much more. Several studies have investigated the use of deep learning models like LSTM, CNN, RNN and their variations for predicting price movements and trends in financial markets [16]. These studies have shown promising outcomes, demonstrating that deep learning techniques can effectively capture and extract important features and patterns from trading data. Dixon et al. [17] employed deep neural networks to predict daily market movement directions and validated their model through backtesting with a basic trading strategy. A CNN was used by [18] to forecast the hourly direction of BIST 100 stocks, utilizing a "specifically ordered feature set." This research extracted various technical indicators, price data, and temporal features while using chi-square feature selection to minimize noise and dimensionality. Another study in [19] focused on predicting the next-minute direction of the SPDR S&P 500 by proposing slim versions of LSTM models. Their results indicated that Slim LSTM when combined with technical indicators, outperformed the standard LSTM model. Moreover, [20] examined the predictability of intraday movements over different time intervals, analyzing their model's performance during high-volatility periods. The findings revealed the presence of "time-delayed correlations" in S&P 500 stocks in both stable and volatile market conditions and provided evidence supporting the effectiveness of deep learning methods in forecasting trends across numerous interrelated time series. In study [21], several ML and DL-based techniques, such as MNB classifier, SVM, Naïve Bayes, linear regression, and LSTM, were effectively created and executed. These methods utilized the general public's sentiment, viewpoints, news, and past stock prices to predict BSE and Infosys stock prices. Shah et al. [22] developed a model for predicting the NIFTY closing values by combining a CNN, LSTM, and dense layers within a 20-day time frame. Ghosh et al. [23] utilized both Random Forests and LSTM networks to assess their performance in predicting out-of-sample directional movements of S&P 500 constituent stocks for intraday trading. Their analysis spanned from January 1993 to December 2018. More recently, [24] successfully predicted daily stock movements of the BIST 30 index using an ensemble learning algorithm combined with a set of ten different variable groups.

1) LSTM: Despite the existence of numerous deep learning techniques, considerable efforts have been dedicated to demonstrating that LSTM can outperform other methods in the prediction of time-series data. Li et al. [25] conducted a systematic review investigating the application of deep learning models in predicting stock market trends using technical analysis. The review found that the LSTM model was the most commonly used and preferred algorithm for stock market prediction due to its ability to store memory and address the gradient vanishing problem. In their research, [26] utilized ten stock technical indicators along with ten years of historical data from the Tehran stock exchange across multiple machine learning and deep learning models. The study showed that the LSTM model outperformed others in terms of prediction accuracy, displaying the lowest error rate and the highest capacity to fit the data effectively. Abbasimehr et al. [27] proposed a technique of a multi-layer LSTM network with a grid search method. The suggested approach looks for the LSTM network's ideal hyperparameters. The authors used actual demand data from a furniture company to test the efficacy of their suggested strategy and compared it to other cutting-edge time series forecasting methods. The researchers concluded that the proposed model outperformed the alternatives significantly and can be applied to real-world scenarios, like stock price prediction, weather forecasting, and energy demand forecasting. Furthermore, LSTM neural networks have emerged as leading models for a diverse range of machine learning tasks, varying greatly in scale and characteristics. The core concept underlying LSTM architecture is the presence of a memory cell capable of retaining its state over time, complemented by non-linear gating units that control the flow of information into and out of the cell [28]. Consequently, the existing literature inspires us to adopt LSTM for this study because of its ability to analyze relationships among time-series data through its memory function.

B. Portfolio Optimization

Portfolio formation involves two primary concerns: choosing assets with the potential for higher returns and determining the optimal asset composition to achieve the goal of maximizing returns while minimizing risk. A quantitative approach is often employed in making these investment decisions. During the portfolio optimization process, the expected return on an asset is a vital consideration, highlighting the importance of preliminary asset selection in effective portfolio management [6]. Selecting the appropriate asset allocations for a portfolio is challenging because financial market conditions can fluctuate significantly over time.

1) Return prediction and asset pre-selection: Consequently, integrating stock return predictions with portfolio optimization models is essential for effective financial investment [29]. Scholars often use predicted returns instead of historical averages to enhance portfolio optimization models [30], [31].

Huang [32] introduced a model for stock selection combining SVR with genetic algorithms. In this model, SVR was used to forecast the future returns of individual stocks, while the genetic algorithm optimized the model's parameters and input features. The highest-ranked stocks were then equally weighted to construct a portfolio. The findings demonstrated that this proposed model outperformed the benchmarks in investment performance. Hao et al. [31] used an Auto Regressive-Multi Resolution Neural Network (AR-MRNN) and SVM for return prediction, and then prediction-based portfolio selection models were developed using these methods. Comparing the prediction accuracy, the SVM predictor outperforms the AR-MRNN predictor. Additionally, the SVM-based portfolio selection model surpassed the AR-MRNN-based and mean-variance models in performance. The analysis also showed that higher prediction accuracy leads to better returns. Performance comparison of an RNN, GRU, and LSTM for predicting stock prices was conducted by [33]. Their experimental results indicated that the LSTM neural network outperformed the other models. Additionally, they developed portfolios based on predictive thresholds using the LSTM neural network's forecasts. This approach was more data-driven compared to traditional models in portfolio design. Experimental results revealed that these portfolios achieved promising returns.

Wang et al. [3] proposed a mixed method of LSTM and mean-variance model for creating an optimal portfolio. The LSTM was used for return prediction, and then the stocks with the highest predicted returns were selected for portfolio formation. The effectiveness of this methodology is validated by comparing it with five baseline strategies. The proposed model significantly outperforms these strategies in terms of annual cumulative return, Sharpe ratio per three-year period, and average monthly return relative to risk over each three-year period, demonstrating superior potential returns and risk management. Ma et al. [34] integrated return prediction into portfolio formation by utilizing two machine learning models—Random Forest and SVR—along with three deep learning models: LSTM, Deep Multilayer Perceptron (DMLP), and CNN. Specifically, it first applies these prediction models for stock preselection prior to portfolio formation. The predictive results are then used to enhance the mean-variance and omega portfolio optimization models.

2) Problems of index investing: The introduction of index mutual funds in the 1970s, followed by the rapid growth of exchange-traded funds (ETFs) in the 2000s, made it cheaper for ordinary investors to own well-diversified portfolios. This development had two significant consequences. First, many investors who previously held individual stocks switched to passive indexing to reduce transaction and asset management expenses. Second, the affordability of index funds allowed numerous households who had not previously invested in stocks to enter the equity market [35]. But in spite of this, index investing often yields lower returns compared to actively managed portfolios or strategic asset pre-selection methods. This is primarily because index funds aim to replicate the performance of a market index rather than outperform it. Consequently, they are limited by the underlying index's returns, which may not capture high-growth opportunities or effectively manage risks through selective asset allocation. As a result, investors seeking higher returns and better risk-adjusted performance may find more success with approaches that involve active management and careful pre-selection of high-potential assets. However, actively managed funds have a very high expense ratio, which makes them non-feasible and less attractive. Accordingly, there is growing research on combining forecasting theory with portfolio optimization.

C. Research Gap

The effectiveness of portfolio construction largely hinges on the anticipated performance of stock markets. Traditional portfolio theory often relies heavily on expected returns and neglects future information [4]. Advances in machine and deep learning have introduced substantial opportunities to integrate predictive analytics into portfolio selection. Despite this potential, the concept of prediction-based portfolios has been underexplored in academic research, with notable contributions like the one by [30] standing out. Consequently, integrating deep learning predictions to assist in selecting the best investment strategies represents a valuable and promising avenue for future research [36]**.** Many researchers [31], [32], [37], [38], [39] have applied these models in the stock pre-selection process prior to portfolio formation and achieved promising and satisfying results. However, to the best of the authors' knowledge, there are no studies existing with regard to the Indian stock market. We extend the work by [9] where GA was used to select stock portfolios in six different Asian markets, excluding India. This is the first study of its kind, and consequently, it is believed that this paper is making a substantial contribution to the related literature.

III. Methodology

The following sections provide details on the methodology of this study. The study is undertaken in two stages.

A. Prediction model for NIFTY 50

In the first stage, this study aims to build an LSTM-based prediction model for the NIFTY 50 stocks.

1) Data description: Financial time-series forecasting is always explained by historical values or lagged observations [40]. Hence, this dataset consists of historical values of NIFTY stocks spanning 12 years taken from the official NSE website[1]. The study opts for the NSE over the BSE because of its larger size and greater market participation. The Nifty 50 is the primary index of the National Stock Exchange, encompasses 50 diversified stocks across 13 sectors of the economy, and represents the country's leading blue-chip companies. The selected sample includes liquid stocks from various sectors and sizes, thus minimizing sample bias and avoiding concentration on a specific group of stocks.

The values included six features- Open, High, Low, Close (OHLC), adjusted close, and volume. Kumar et al. [41] conducted a survey on stock market forecasting using computational techniques and reported that only 8% of the studies used a combination of historical values and technical indicators for prediction purposes. Hence, this study uses a synthesis of historical data and STIs as the predictor or input variables. The output or target variables are the close values of subsequent days. The total dataset consists of daily trading data of 2,956 trading days (April 2012 – March 2024). This data covers two stock market crashes, the crypto crash in 2018 and the 2020 COVID crisis, and the Russia-Ukraine war in 2022 so that the extreme volatilities of the assets can be considered for optimal portfolio construction. This research chooses a sliding window approach of a 30-day time frame [42], [43] for developing the prediction model. This implies that data from the preceding 30 days will be utilized to forecast close values for the 31st day. Pandas library is used to import data. Matplotlib and Seaborn are used for data visualizations.

2) Data pre-processing: The accuracy of predictions significantly depends on the quality of the data. Therefore, it is vital to preprocess the raw data before incorporating it into the model-building process. The collected sample of 2956 trading days was removed from duplicates and NAN values. The cleaned dataset consisted of 2906 trading days. The outliers identified using a boxplot are treated using the winsorization technique [44], [45], [46]. Winsorization helps to eliminate outliers by capping extreme values, thereby making the distribution of the transformed data more symmetrical and closer to a normal distribution [45], [47]. This data is then normalized using a min-max scalar. Data normalization involves transforming real numerical attributes to a scale between 0 and 1, resulting in a training model that is less

[1] https://www.nseindia.com/reports-indices-historical-index-data

affected by the variable scales [26]. This also ensures that all values fall within a range of [0,1], thus leading to faster convergence. Normalization is very useful for improving the accuracy of neural network models [43]. The equation for normalization is as follows.

$$X\_scaled = \frac{\mathrm{X-XMin}}{XMax-XMin} \tag{1}$$

X is the feature's initial value, *Xmin* is the lowest X value, *Xmax* is the highest X value, and *X_scaled* is the new scaled X value between 0 and 1.

3) *Proposed model*

a) STI: Statistical Technical Indicators (STIs) are mathematical calculations based on factors like price, volume, or other relevant metrics related to stocks, securities, or contracts. Unlike fundamental analysis, they do not take into account business fundamentals such as earnings, revenue, or profit margins. The primary goal of technical analysis is to predict future price movements, and deep learning algorithms enhance the accuracy of these predictions. By combining these two approaches, the reliability of price forecasts can be significantly strengthened. While technical indicators are essential for identifying stock price patterns, trends, and momentum, it's important to note that many studies limit their use to trend indicators, often overlooking key momentum, volatility, and strength indicators that are equally crucial for comprehensive financial analysis [22]. Hence, this study uses a total of ten momentum and volatility STIs as identified by [46] and is calculated through Ta-Lib. They are listed in Table I.

b) LSTM: Hochreiter et al. [51] introduced LSTM in 1997 to address the issue of vanishing gradients in conventional RNNs, which hindered their ability to capture long-term relationships in sequential data effectively. This problem occurs because gradients tend to become smaller and smaller as they propagate back through time, making it difficult for the network to update the weights in earlier layers. The main advantage of LSTMs over traditional RNNs is their capability to choose whether to remember or forget information from earlier time steps, enabling them to handle long-term dependencies more effectively. This is achieved through a set of specialized memory cells and gating mechanisms that balance information flow through the network. "An LSTM layer is composed of one or more LSTM units, and an LSTM unit consists of cells and gates to perform classification and prediction based on time series data" [49]. The cell contains three gating mechanisms: the input gate *i*, the output gate *o*, and the forget gate *f*. The quantity of new information added to the cell state is dictated by the input gate, the amount of old information that is discarded from the cell state is regulated by the forget gate, and the quantity of information that is transferred from the cell state to the next time step is controlled by the output gate [26]. The cell state is the memory of the LSTM and can be thought of as a conveyor belt that runs through the entire LSTM chain, enabling the transmission of information from one time step to the subsequent one.

This study uses a double-layered LSTM since deeper LSTM architecture is known to yield superior prediction outcomes compared to a single LSTM network [50]. Furthermore, since the input variables are 18 in total, a PCA is conducted for dimensionality reduction.

c) Working of the stacked LSTM model: The input data for the LSTM model is organized into a three-dimensional array, where each dimension captures a different aspect of the data. The time dimension corresponds to the sliding time window, which is used to capture temporal dependencies in the data. The sample dimension represents the size of the dataset used for training and testing the model. Finally, the feature dimension indicates the number of input features provided to the LSTM model, allowing it to process multiple attributes simultaneously for more accurate predictions. This study chose 30 days as a time window, and the input features are the OHLC, volume, and STI values reduced as PC's through PCA. The input layer is linked to the LSTM layer with 32 neurons, which is the hidden layer. This is connected to another LSTM with 16 neurons. Two LSTM layers are stacked sequentially, where the output of the first LSTM layer serves as the input to the second LSTM layer. This stacking enables the model to better capture and process sequential patterns and long-term dependencies in the data. The second LSTM layer is then connected to a dense layer with a single neuron, which serves as the output layer for making predictions, such as forecasting stock prices or classifying trends. This setup allows the model to refine complex temporal relationships and generate more accurate results.

Dropouts and Early stopping are used as regularization techniques. The idea behind dropout [51] is to randomly "drop out" or disable some of the neurons in a layer during each training iteration. This is done by setting the output of some of the neurons to zero with a certain probability (usually around 0.5). The exact neurons that are dropped out are randomly selected during each training iteration. The reason for the dropout is to prevent the neural network from depending too much on any particular set of neurons. By randomly dropping out neurons during training, the network is forced to learn more robust and generalized useful features across a wider range of inputs. At test time, the full network is used without any dropout. However, the output of each neuron is multiplied by the dropout probability to ensure that the expected output of each neuron is the same as during training. A dropout rate of 0.2 is used in this case. EarlyStopping is a Keras callback that allows you to stop training when a monitored quantity (like validation loss or accuracy) has stopped improving. It helps avoid overfitting by terminating the training process once the model performance on the validation set no longer improves. This ensures that the model does not waste time training for too many epochs, which can lead to overfitting. Here, it is configured to monitor the validation loss and stop training if accuracy does not improve for 8 consecutive epochs.

The model is initialized with random weights and biases. Each LSTM layer receives an input consisting of the previous 30 time steps and attempts to predict the next time step in the sequence, which corresponds to the closing value for the 31st day; this output from the LSTM is passed on to the dense layer, which gives the final output values. ReLU and Linear activation functions are utilized in the hidden and output layers, respectively. Mean Squared Error (MSE) is used as the loss function. Each LSTM network computes its individual loss, and the total loss is calculated by summing the losses from both LSTM networks and the dense layer. The Adam optimization algorithm is used during training to minimize this total loss, and the number of epochs is set to 100, following the approach used by [2]. Optimizers are techniques utilized to adjust the model's features, including parameters like learning rate and weights, to minimize losses. An epoch represents one complete pass of the entire training dataset [26] by the LSTM model. The training process continues until the validation loss stops improving for a specified number of epochs, as determined by early stopping, or until the maximum number of iterations is reached.

TABLE I. LIST OF STIS

STI	Description	Indicator Type
MACD	Moving average convergence divergence	Momentum
RSI	Relative strength index	Momentum
STOCH	Stochastic Oscillator	Momentum
CCI	Commodity Channel Index	Momentum
ADX	Average Directional Index	Momentum
ROC	Rate of change	Momentum
WILLR	William percent R	Momentum
ATR	Average True Range	Volatility
NATR	Normalized Average True Range	Volatility
TRANGE	True Range	Volatility

The model’s parameter settings are established through trial-and-error experiments to optimize performance. The implementation is carried out in a Python 3.7 environment using Keras, a high-level API built on Google's TensorFlow framework. Table II provides an overview of the parameter settings used in the experiments.

B. Portfolio Optimization

1) Assumptions: In this study, several key assumptions are necessary for the analysis of portfolio performance. Although these assumptions may seem idealistic compared to real-world conditions, they serve to simplify the complexities associated with investment, such as costs and trading prices. By making these assumptions, the study can focus more effectively on comparing the relative performance of portfolios.

- No transaction cost and tax.
- The stocks are sold and bought at the closing price.
- Investors are not risk-averse.
- A 3-year average return on treasury bills is considered as risk-free return.

Once an LSTM-based prediction model has been developed for predicting close values, the next stage involves the preselection of assets for portfolio creation and optimization. Since the test period consists of approximately three years, datasets from April 2021 – March 2024 (Test period) are considered for portfolio creation as well. Average returns for a period of three years are calculated for all 50 stocks based on the predicted close values. Then, they are arranged in descending order of their predicted returns to select the top return-generating stocks.

2) Top N stocks: Several studies have shown that holding too many stocks makes it difficult to manage and keep them under control, particularly for individual investors. Building a portfolio with fewer than ten stocks is taken into consideration in several portfolio optimization research [52]. A portfolio with an average of seven stocks performs better than other portfolios with a variable number of stocks, according to [37]. Wang et al. [3] noted that a portfolio with ten stocks is ideal, as it outperforms portfolios with any other number of stocks. According to [40], the optimal number of stocks for an individual investor’s portfolio construction is seven. As a result, this study selected a group of the top 10,9,8 and seven stocks for portfolio creation. Six different objectives-based portfolios are created. This means that for each objective, five different portfolios with the number of stocks N =10,9,8 and 7 and, all NIFTY stocks with N=50 are formed to evaluate the performance of different-sized portfolios.

TABLE II. PARAMETER SETTINGS

Parameters	Values
Optimizer	Adam
Epochs	100
Batch size	64
Step size	30
Drop out	0.2
Activation function	ReLU (Hidden layer) Linear (Output layer)

Source:[46]

3) Portfolio objectives

- Objective 1: Minimum volatility portfolio
- Objective 2: Maximum returns portfolio
- Objective 3: Maximum Sharpe ratio with No Constraints
- Objective 4: Maximum Sharpe ratio with Constraints [L2 regularizer, gamma=2, $\sum W = 1$]
- Objective 5: Uncorrelated assets portfolio
- Objective 6: Equally weighted portfolio

4) Comparison criteria: The portfolios created are compared on the following metrics of return and risk [39], [56], [57].

a) Sharpe ratio: The Sharpe ratio is a widely used industry standard for assessing investment risk adjustment return in finance. It is computed by deducting the risk-free investment return from the stock or investment portfolio's actual return and dividing the result by the stock or portfolio's standard deviation.

$$\text{sharpe ratio} = \frac{R_\rho - R_f}{\sigma_P} \qquad (2)$$

where, R_P is the Return of the portfolio, R_f is the Risk-free rate, σ_P is the Standard deviation of the portfolio. A Sharpe ratio >1 is always preferred, implying that the investment generates one unit of excess return for every unit of risk taken.

b) Sortino ratio: Sharpe ratio considers both upside and downside risks since standard deviation calculates deviation from mean returns. This deviation could either be positive or negative. Conversely, the Sortino ratio [55]—a variant of the Sharpe ratio—only accounts for negative or downward volatility. Upside volatility is generally considered a benefit of investing and is not dangerous [55]. Consequently, the total standard deviation in the Sharpe ratio is replaced by this downside risk or volatility in the Sortino ratio. A higher Sortino ratio is always desired by the investor since it indicates the return per unit of downside risk.

$$sortino\ ratio = \frac{R_\rho - R_f}{DR} \quad (3)$$

where, R_P is the Return of the portfolio, R_f is the Risk-free rate and DR is the Downside risk.

c) Cumulative returns: Cumulative returns measure the total growth of an investment from the start to the end of a given period. It represents how much a portfolio has increased in value, assuming daily compounding of returns. The study uses the *cumprod()* function in Python. This cumulative product function calculates the running product of the growth factors or daily growth over the entire period. This effectively compounds the daily returns, simulating how an investment grows day by day.

d) Annual returns (CAGR): Annual returns convert total cumulative growth into an annual growth rate. It accounts for the effect of compounding, showing the consistent annual rate that equates to the total growth observed. The study uses 252 Trading Days as the standard number of trading days annually to annualize the returns.

$$\text{Annual return} = (1+\text{ Cumulative return})^{252/\text{ Trading days}} - 1 \quad (4)$$

Here, the number of trading days is calculated as 252 days* 3 years

e) Volatility: Volatility is a measure of the risk factor of the portfolio and is calculated as the standard deviation of the portfolio's returns by using the covariance matrix of the asset returns and the optimized portfolio weights.

f) Beta: Beta is the measure of the systematic risk of a portfolio or stock. It indicates the relative volatility of a portfolio as against the benchmark or index. It helps investors understand how much risk they are taking in comparison to the market. Investors looking for higher returns with higher risk might prefer high-beta stocks, while those seeking stability might opt for low-beta stocks.

The study used the PyportfolioOpt package in Python to create these portfolios. This package generated weights based on the given objective functions. For every N number of stocks, six different portfolios corresponding to each objective are formed. After the weights have been assigned, portfolio returns are calculated based on these allotted weights and the market returns, which are NIFTY returns in this case. Next, *cum.prod()* function is used to calculate cumulative returns and CAGR is calculated from that value. Volatility is measured as the standard deviation of the returns. The study considered a rate of 6.85% as the average risk-free rate of the past three years and 252 as the average trading days for calculating Sharpe and Sortino ratios.

IV. Experimental Results and Discussion

A. Generation of PC's

In the first experiment, the study attempts to develop a stacked LSTM for the prediction of NIFTY 50 stocks. Historical values and STIs of the past 30 days are used as input variables to predict the close values of the 31st day. Since there are 18 input variables and 12 years of data, as mentioned in the methodology section, the study uses PCA to generate PCs to reduce dimensionality. The PCA run for all the 50 stocks generated 5 or 6 PCs. To evaluate the variance associated with each PC, the explained variance ratio was calculated. This ratio is obtained by dividing the variance of each component by the total variance. The variance ratio of each PC of the top 5 NIFTY stocks, in terms of market capitalization, is explained in Table III. It is clear that more than 95% of the information was preserved even after PCA.

The number of generated PCs determines the architecture of the stacked LSTM. Since the number of PC's are 5 and 6, the input layer will also have the same number of nodes. The architecture of the developed LSTMs is illustrated in Fig. 1.

B. Learning Curves

After obtaining the PCs, the datasets are separated as training data (70%; 2,035 days), validation data (10%;291 days), and testing data (20%; 580 days) to train, validate and test the proposed LSTM.

The study employed training and validation curves to chart the model's performance, indicated by loss (MSE), on both the training and validation datasets across epochs. During training, the model aims to minimize the loss function, which measures the disparity between the predicted values and the actual values in the training dataset. Fig. 2 illustrates the learning curve of the LSTM model applied to the top five stocks, The X-axis represents the number of training epochs, and the Y-axis represents the loss value, indicating the model's error in prediction.

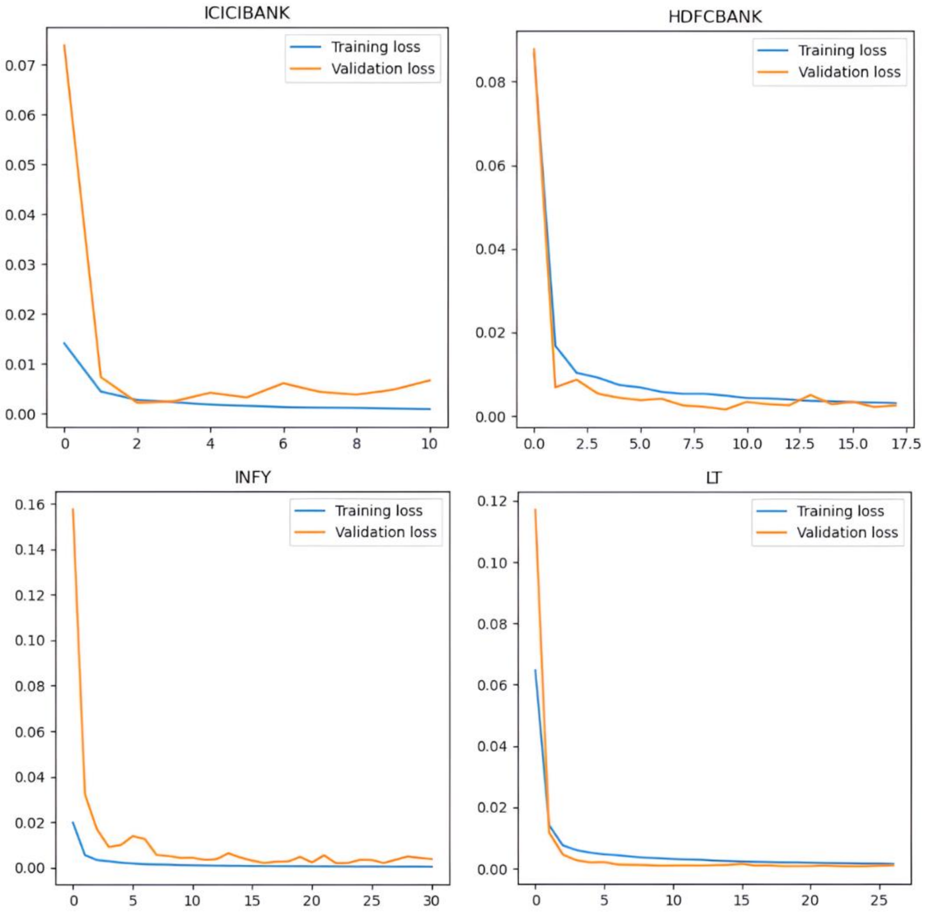
Fig. 1. Architecture of the LSTM.



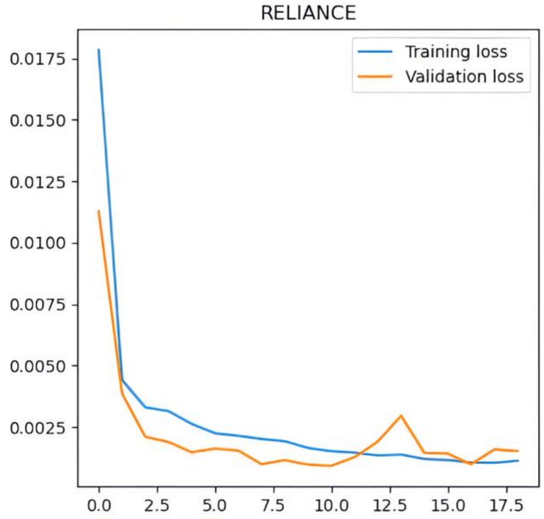


Fig. 2. Learning curves.

The study made the following observations

- Good Generalization: The learning curves for both training and validation loss decrease rapidly at the start and remain closely aligned throughout the training. The parallel behavior of the training and validation losses suggests that the model is generalizing well and not overfitting or underfitting the training data.
- Convergence: Both curves stabilize and converge to a low value towards the end of the epochs, indicating that the model has reached a point where additional training does not significantly change the loss, demonstrating a well-trained model.

C. Metric Evaluation

Appropriate assessment metrics are needed to validate the deep learning models. This study chooses the following indicators: Mean of absolute error (MAE) and root mean square error (RMSE). They have been extensively used in the literature [56], [57], [58]. Lower MAE and RMSE values would increase the prediction accuracy. Accuracy is measured as [58]. The equations are as follows.

$$\text{PM}\Sigma\text{E}=\sqrt{\frac{1}{n}\sum_{i=1}^{n}|yi - \hat{y}i|^{2}} \quad (5)$$

Where n is the number of data points, yi is the actual value of the i th data point, ŷi is the predicted value of the i th data point, Σ represents summation, | | represents absolute value.

$$\text{A}\chi\chi\upsilon\rho\alpha\chi\psi = 1 - \text{MAE} \quad (6)$$

$$\text{MAE}= \frac{1}{n}\sum_{i=1}^{n}|yi - \hat{y}i| \quad (7)$$

Results show that the model obtained an average accuracy of 90.58%, RMSE of 0.1057, and MAE of 0.0942. ADANIENT, from the Metals and Mining Industry, and EICHERMOT, belonging to the Automobile industry, recorded the lowest and highest accuracies of 53.12% and 97.33%, respectively. Industry-wise analysis shows that the Oil, Gas & Consumable Fuels industry has the highest and Metals and Mining has the lowest accuracy.

D. Asset Preselection

In the second experiment, the focus is on creating and optimizing stock portfolios. The process involves filtering the top stocks based on their average returns over a three-year test period. The returns are calculated on the basis of their adjusted closing values. Table IV shows that the top 10 stocks include COAL INDIA, which achieved the highest average return at 38.72%, followed by SUN PHARMA with 25.22%, and ONGC with 23.83%.

Interestingly,30% of these stocks are in the energy sector (COALINDIA, BPCL, ONGC) and another 30% in the automobile sector (HEROMOTOCO, EICHERMOT, BAJAJ-AUTO), with 20% in banking and financial services (INDUSINDBK, AXIS BANK) and 10% each in pharmaceuticals (SUN PHARMA) and FMCG(ITC), despite financial services (37.72%) and information technology (14.11%) constituting the majority share in NIFTY50.

E. Portfolio Formation

This study created portfolios with the number of stocks N= 10, 9, 8 and 7. With each N, six objectives-based portfolios are created. For optimization purposes, the PyportfolioOpt package is used to achieve optimum weight allocation in each scenario. These portfolios are compared on the basis of the six key factors: Sharpe ratio, Sortino ratio, Annual returns, Cumulative returns, Annual volatility, and Beta. Furthermore, optimal portfolios are also compared against the market benchmark NIFTY 50 and portfolio with N=50 to evaluate the performance of portfolios with and without asset preselection.

1) Performance of different-Sized portfolios: For Objective 1, the top-performing portfolios are analyzed with a focus on their respective metrics. The top 7 portfolios stand out with a Sharpe ratio of 1.75 and a Sortino ratio of 3.15, indicating high risk-adjusted returns and effective downside risk management. These portfolios achieve an annual return of 29.67% and a cumulative return of 114.27%.

TABLE IV. AVERAGE RETURNS OF TOP 10 STOCKS

Stock	Annual returns
COALINDIA	38.7258
SUN PHARMA	25.2218
ONGC	23.8309
INDUSINDBK	22.3735
AXIS BANK	22.164
ITC	21.5993
HEROMOTOCO	19.5488
EICHERMOT	17.0569
BAJAJ-AUTO	16.6815
BPCL	15.8402

TABLE V. OBJECTIVE-WISE ANALYSIS

OBJECTIVE 1

	Sharpe ratio	Sortino ratio	Beta	Annual Volatility	Annual Returns %	Cumulative Returns
Top 7	1.75	3.15	0.75	14	29.67	114.27
Top 8	1.72	3.13	0.76	13.9	29.02	111.13
Top 9	1.93	3.41	0.74	13.6	31.41	122.78
Top 10	1.87	3.33	0.74	13.5	30.53	118.46
All 50	1.46	3.04	0.63	10.26	20.62	73.32

OBJECTIVE 2

	Sharpe ratio	Sortino ratio	Beta	Annual Volatility	Annual Returns	Cumulative Returns
Top 7	1.63	3.35	0.82	20.51	46.43	205.99
Top 8	1.65	3.40	0.80	17.79	41.48	176.69
Top 9	1.51	3.14	0.91	19.58	41.32	175.76
Top 10	1.44	3.06	0.90	19.41	38.83	162.01
All 50	1.15	2.52	0.99	14.57	25.29	93.69

OBJECTIVE 3

	Sharpe ratio	Sortino ratio	Beta	Annual Volatility	Annual Returns	Cumulative Returns
Top 7	2.35	3.93	0.72	17.2	44.51	194.41
Top 8	2.35	3.93	0.72	17.2	44.51	194.41
Top 9	2.51	4.17	0.72	15.7	44.03	191.57
Top 10	2.51	4.17	0.72	15.7	44.03	191.57
All 50	2.73	4.47	0.73	14.3	43.85	190.49

OBJECTIVE 4

	Sharpe ratio	Sortino ratio	Beta	Annual Volatility	Annual Returns	Cumulative Returns
Top 7	2.14	3.41	0.81	18	42.06	179.99
Top 8	2.11	3.39	0.81	17.7	40.85	173.06
Top 9	2.24	3.61	0.79	16.4	40.9	173.31
Top 10	2.2	3.55	0.80	16.3	39.86	167.48
All 50	2.08	3.32	0.94	15.5	36.62	149.69

OBJECTIVE 5

	Sharpe ratio	Sortino ratio	Beta	Annual Volatility	Annual Returns	Cumulative Returns
Top 7	1.66	3.6	0.67	15.83	37.47	154.32
Top 8	1.6	3.44	0.71	15.29	35.1	141.65
Top 9	1.89	3.91	0.72	15.78	42.47	182.37
Top 10	1.73	3.55	0.80	16.09	34.6	165.55
All 50	1.19	2.64	0.92	13.88	25.07	92.72

OBJECTIVE 6

	Sharpe ratio	Sortino ratio	Beta	Annual Volatility	Annual Returns	Cumulative Returns
Top 7	1.78	2.83	0.89	15.92	31.06	121.08
Top 8	1.7	2.76	0.90	15.7	28.98	110.96
Top 9	1.8	2.94	0.88	15.27	30.11	116.39
Top 10	1.74	2.79	0.88	15.18	28.75	109.82
All 50	1.44	2.23	0.95	13.8	20.77	73.91

Expanding the portfolio to the top 9 increases the Sharpe ratio to 1.93 and the Sortino ratio to 3.41, with annual returns rising to 31.41% and cumulative returns to 122.78%, suggesting that including more assets up to this point optimizes performance. However, the top 10 portfolios show a slight decrease in the Sharpe ratio to 1.87 and Sortino ratio to 3.33, with annual returns at 30.53% and cumulative returns at 118.46%, indicating a slight reduction in performance efficiency. The beta values remain relatively low across these portfolios, suggesting they maintain a lower level of market risk while delivering strong returns.

Under Objective 2, the top 7 portfolios have a Sharpe ratio of 0.63 and an impressive Sortino ratio of 3.35, indicating excellent management of downside risk. These portfolios achieve the highest annual returns of 46.43% and cumulative returns of 205.99%. The top 8 portfolios, with a higher Sharpe ratio of 1.65 and Sortino ratio of 3.40, offer annual returns of 41.48% and cumulative returns of 176.69%, providing better overall risk-adjusted performance. The top 9 portfolios show a slight decrease in the Sharpe ratio to 1.51 and Sortino ratio to 3.14, with annual returns at 41.32% and cumulative returns at 175.76%, suggesting a minor decline in performance. The top 10 portfolios further decrease in performance with a Sharpe ratio of 1.44 and Sortino ratio of 3.06, achieving annual returns of 38.83% and cumulative returns of 162.01%. The beta values indicate that these top portfolios are slightly more volatile, which aligns with their higher returns.

For Objective 3, the portfolios excel in risk-adjusted returns and overall performance. The top 7 and top 8 portfolios share the highest Sharpe and Sortino ratios of 2.35 and 3.93, respectively, achieving annual returns of 44.51% and cumulative returns of 194.41%. Interestingly, the top 9 and top 10 portfolios, with slightly higher Sharpe ratios of 2.51 and Sortino ratios of 4.17, deliver similar annual returns of 44.03% and cumulative returns of 191.57%, suggesting that an increase in the number of assets does not significantly impact performance. The beta values are slightly higher, reflecting moderate volatility but efficient risk management.

In Objective 4, the top 7 portfolios exhibit a high Sharpe ratio of 2.14 and a Sortino ratio of 3.41, with annual returns of 42.06% and cumulative returns of 179.99%. The top 8 portfolios maintain a Sharpe ratio of 2.11 and a Sortino ratio of 3.39, with annual returns of 40.85% and cumulative returns of 173.06%. Expanding to the top 9 portfolios slightly increases the Sharpe and Sortino ratios to 2.24 and 3.61, respectively, while maintaining annual returns of 40.9% and cumulative returns of 173.31%. The top 10 portfolios show a slight decrease in performance with a Sharpe ratio of 2.2 and Sortino ratio of 3.55, achieving annual returns of 39.86% and cumulative returns of 167.48%. The beta values indicate that these portfolios are more volatile but compensate with higher returns, reflecting efficient risk management.

Objective 5 portfolios show significant variation in performance metrics. The top 9 portfolios stand out with a higher Sharpe ratio of 1.89 and a Sortino ratio of 3.91, achieving the highest annual returns of 42.47% and cumulative returns of 182.37%. The top 7 portfolios have a Sharpe ratio of 1.66 and a high Sortino ratio of 3.6, with annual returns of 37.47% and cumulative returns of 154.32%. The top 8 portfolios maintain a Sharpe ratio of 1.6 and Sortino ratio of 3.44, achieving annual returns of 35.1% and cumulative returns of 141.65%. The top 10 portfolios show a slight decline in performance with a Sharpe ratio of 1.73 and Sortino ratio of 3.55, achieving annual returns of 34.6% and cumulative returns of 165.55%. The beta values suggest moderate volatility, consistent with the achieved returns.

For Objective 6, the performance metrics highlight a steady trend. The top 7 portfolios achieve a Sharpe ratio of 1.78 and a Sortino ratio of 2.83, with annual returns of 31.06% and cumulative returns of 121.08%. The top 8 portfolios maintain a Sharpe ratio of 1.7 and Sortino ratio of 2.76, achieving annual returns of 28.98% and cumulative returns of 110.96%. The top 9 portfolios show a slight increase in the Sharpe ratio to 1.8 and Sortino ratio to 2.94, with annual returns of 30.11% and cumulative returns of 116.39%. The top 10 portfolios exhibit a Sharpe ratio of 1.74 and Sortino ratio of 2.79, achieving annual returns of 28.75% and cumulative returns of 109.82%. The beta values indicate that these portfolios are relatively more volatile, reflecting their higher returns. Overall, the top portfolios under Objective 6 maintain good performance with balanced risk management despite diminishing returns with larger portfolio sizes. Fig. 3 shows a performance comparison of the best portfolios from each objective.

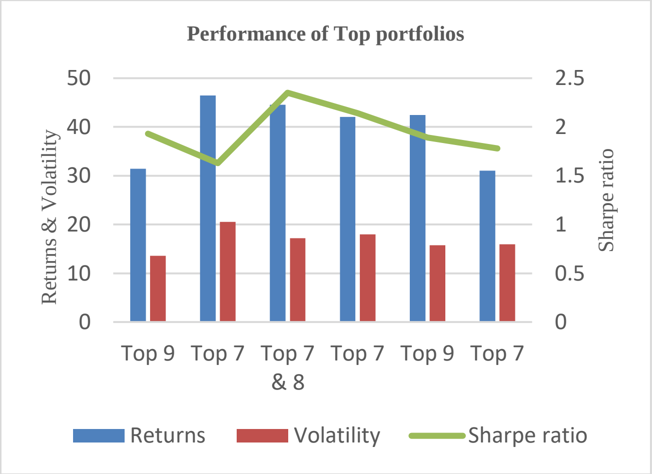

Fig. 3. Performance comparison of Top portfolios.

2) Best performing portfolio:'Investors in the financial markets rarely pursue a risk-minimization approach; instead, they are more than willing to take on more considerable risks if the accompanying profits are even higher' [59]. Consequently, the study considers returns as the primary criteria for selecting the best portfolio. Though the top 7 stocks under objective 2 (maximum returns) generated the highest return of 46.43%, the volatility is 20.51%, which is higher than any other portfolio. Therefore, based on the detailed analysis across various objectives, the portfolio that consistently delivered the best performance is the top 9 and 10 portfolios under Objective 3, which is the maximum Sharpe ratio with no constraints. Though nine stocks were initially added, the weights were allocated to only 5 stocks [Bajaj Auto, Coal India, ITC, ONGC, and Sun pharma] and the rest were given zero weights. Weights were allocated in such a way that it maximizes the objective function of the Sharpe ratio. Hence, effectively only five stocks constituted the optimal portfolio.

Fig. 4 demonstrates the weight allocation for portfolio construction. It is also interesting to note that these 5 selected stocks are not the top 5 return-generating stocks but are randomly selected by the software.

Portfolio performance metrics:

- Sharpe Ratio: 2.51
- Sortino Ratio: 4.17
- Beta: 0.72
- Annual Volatility: 15.7%
- Annual Returns: 44.03%
- Cumulative Returns: 191.57%

The high ratios indicate that this portfolio achieved the best risk-adjusted returns and managed downside risk effectively.

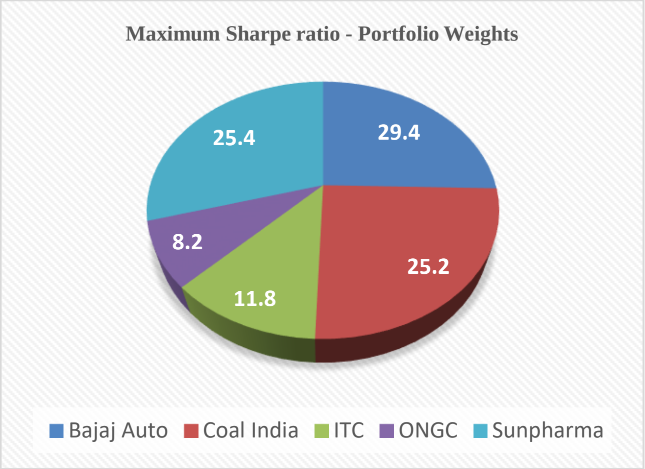

Fig. 4. Weight allocation of optimal portfolio.

The beta value indicates a moderate level of market risk, suggesting that the portfolio is not overly volatile while still capturing substantial returns. Annual Returns of 44.03% and Cumulative Returns of 191.57% reflect the highest annual and cumulative returns, demonstrating the portfolio's superior performance over the period. Hence, the study concludes that a five-stock portfolio provides the best performance across all analyzed metrics. They achieve the highest risk-adjusted returns, manage downside risk effectively, and deliver the highest annual and cumulative returns.

3) Pre-selection V/s All 50: Table V shows a comparison of portfolios constructed after pre-selection and without pre-selection. The pre-selected stocks consist of top 7,8,9, and 10 stocks from NIFTY 50, whereas the alternate portfolios consist of all NIFTY 50 stocks. It is evident that the former achieved better returns than the latter in terms of annual returns. Fig. 5 shows the excess returns earned by the top-performing portfolios as compared to NIFTY all 50 stocks from each objective. The optimal portfolios obtained an excess return of 10.79%, 21.14%, 0.66%,5.44 %, 17.4 %, and 10.29 %. For Objective 3, the portfolio aimed to maximize the Sharpe ratio without constraints but only achieved a 0.66% outperformance in annual returns. This underperformance suggests that the unconstrained approach might have led to a skewed portfolio, possibly concentrating too heavily on high-risk stocks. While the goal was to achieve the best risk-adjusted returns, the lack of risk controls likely reduced the portfolio's ability to generate higher excess returns. In contrast, Objective 4, with constraints, achieved a much higher excess return of 17.4%, highlighting the importance of controlled risk management when optimizing for the Sharpe ratio. Nevertheless, the top portfolios earned an average excess return of 10.95% as against NIFTY all 50 portfolios. Thus, the experiment proves that pre-selection of your assets can help better your investment fortunes than too much diversification. Over-diversification reduces your risk but also brings down one's returns.

4) Superiority over benchmark models: The study evaluated the performance of the proposed portfolio optimization method against the NIFTY 50 index, a well-established market benchmark. This benchmark includes a diverse range of leading companies in the Indian stock market. By using the NIFTY 50 as a reference, the study can compare the proposed portfolio allocations to the performance of a globally recognized benchmark index.

a) All 50 v/s Index: This analysis involves the creation of six different portfolios, each based on a distinct objective, utilizing all NIFTY 50 stocks. These portfolios were then compared to the NIFTY Index in terms of returns and volatility. The results demonstrate that the newly constructed portfolios significantly outperformed the NIFTY Index (Fig. 6). Specifically, the portfolios showed higher returns, with "All 50 (3)" achieving the highest return of 43.85% and "All 50 (4)" following with 36.62%. Even the lowest-performing portfolio, "All 50 (1)," delivered a return of 20.62%, surpassing the NIFTY Index's return of 14.85%. In terms of volatility, while some portfolios exhibited higher volatility than the NIFTY Index (13.75%), such as "All 50 (4)" with 15.5% and "All 50 (2)" with 14.57%, others managed to maintain lower or comparable volatility levels, like "All 50 (1)" with 10.26%. This indicates that the newly created portfolios not only provided superior returns but also effectively managed risk, outperforming the NIFTY Index overall.

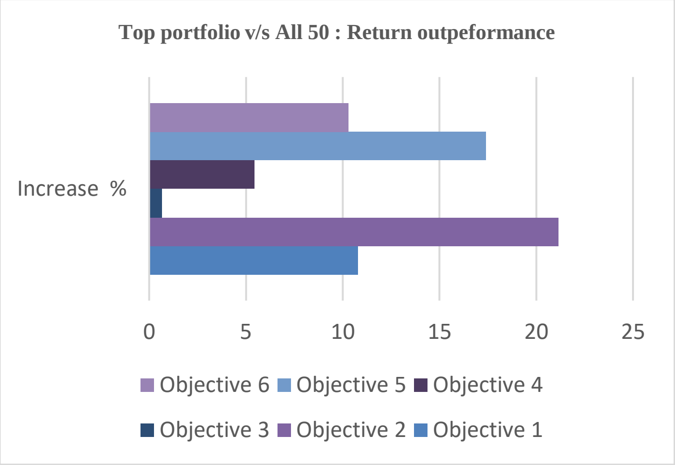

Fig. 5. Return outperformance of top portfolios.

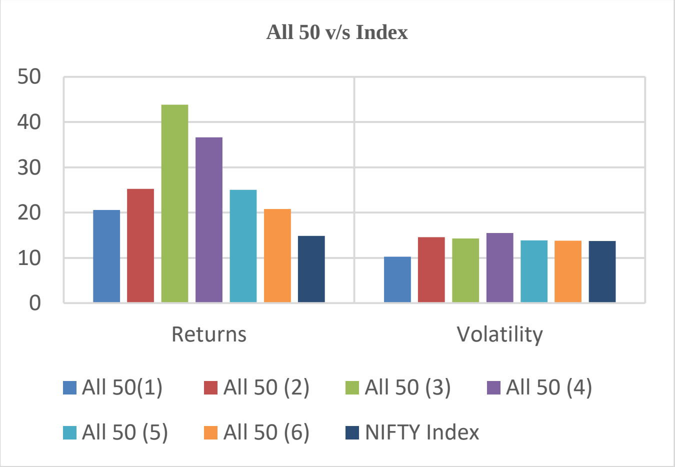

Fig. 6. Comparison of returns and volatility.

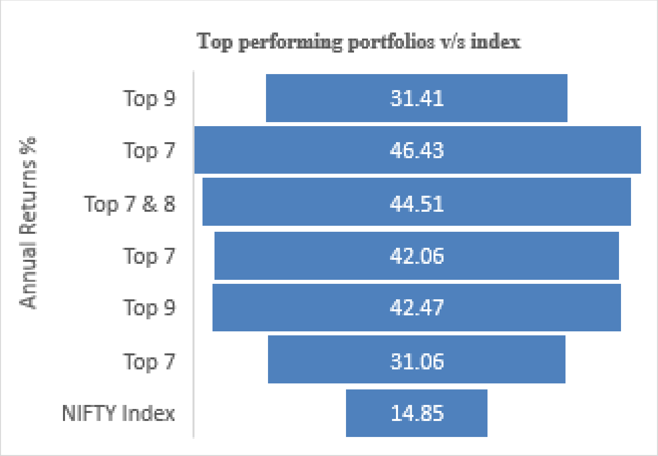

Fig. 7. Performance comparison of top portfolios and NIFTY index.

b) Top performing portfolios v/s index: This analysis compared the annual returns of top-performing portfolios from each objective with the NIFTY index returns over the past three years. Fig. 7 shows that the top 7 portfolios in objective 2 could generate returns as high as 46%, an excess return of 31.58% more than the NIFTY index. Even the portfolio with the lowest returns of 29.02% (Top 8 in objective 1) earns 14.7 % more than the benchmark index, demonstrating consistent and notable outperformance across different strategies. All the top-performing portfolios earn an average excess return of 27.51%. The analysis conclusively demonstrates that the top-performing portfolios provide superior returns and significantly exceed the NIFTY index's benchmark performance. This suggests that the strategies employed in these portfolios are highly effective, yielding substantial excess returns even in the least performing portfolio among the top contenders. Investors may find these strategies attractive for achieving higher returns compared to the standard benchmark, emphasizing the value of strategic portfolio selection and management.

F. Discussion

This work aims to extend the existing literature on deep learning-based prediction and asset pre-selection for portfolio optimization. An LSTM-based prediction model was developed using data from 12 years of historical and technical indicators. This model was applied to forecast NIFTY stocks for a test period of 580 days. Then, the predicted returns were used to filter the top ten assets for portfolio creation. The major findings of the study are:

- Results show that the model obtained an average accuracy of 90.58%, RMSE of 10.57%, and MAE of 9.42%. The authors compare these results to [62],[63], which reported an accuracy of 72% and 90%, respectively.

- This study attempted to select high-quality assets from the Indian stock market through deep learning-based forecasting and build a competitive portfolio for improved returns. Results indicated that portfolios coupled with pre-selected assets generated better results than the portfolios with the entire NIFTY 50 stocks. Preselection helps filter out underperforming or overly volatile assets, leading to a more robust and resilient portfolio that aligns with specific investment objectives. This is consistent with the studies of [63],[64], and [65].

- It is evident from the study that a portfolio consisting of 5 stocks provides the optimal balance between diversification, risk management, and return maximization, which is consistent with the results of [62] but contradicting [3], [37] and [40]. While diversification is crucial to reduce unsystematic risk, excessive diversification beyond nine stocks leads to diminishing returns and unnecessary complexity. For instance, the top 10 and all 50 portfolios have significantly lower returns and Sharpe ratios compared to the top 7, 8 and 9 portfolios.

V. Conclusion

With advancements in machine learning and deep learning, though predicting asset returns has become feasible, these prediction results are not yet effectively utilized in practice for portfolio creation and optimization. As a result, many portfolios fail to fully capitalize on the available predictive insights, limiting their potential for improved performance and risk management. The challenge lies in effectively utilizing these predicted returns to construct an optimal investment portfolio. Considering this, this research seeks to tackle the issue by exploring how to integrate advanced forecasting information into the portfolio selection process.

The study has dual stages. In the first stage, the study developed a stacked LSTM capable of forecasting close values of all NIFTY 50 stocks by following a sliding window approach of 30 days. The model obtained an average accuracy of 90%. The second stage is asset pre-selection, where the top ten stocks, based on their predicted returns, were filtered for portfolio creation. Five portfolios each per objectives were created resulting in a total of 30 different portfolios. The results concluded that portfolios constituting five stocks result in best returns as high as 44%. Investors should avoid expanding their portfolios beyond nine stocks, as excessive diversification can lead to diminishing returns and unnecessary complexity. The proposed portfolios beat the benchmark NIFTY index as well as portfolios with no asset pre-selection, comprising all 50 stocks.

The findings of this study indicate that the proposed two-stage portfolio optimization method has the potential to construct a promising investment strategy due to its trade-off between historical and future information on assets. The results demonstrate the reliability and effectiveness of the asset selection approach in identifying high-performing assets, providing competitive risk-adjusted returns for portfolio optimization, beneficial for both portfolio managers and individual investors. Using real-time market predictions, the algorithm enables investors to choose assets with higher returns and apply the model, which accounts for recent data dynamics in expected return and risk. This makes the approach more practical. Consequently, the proposed method offers a systematic decision-making framework that assists in determining which assets to hold and their investment proportions to achieve the maximum risk-adjusted return and optimal risk-return balance. The study hence concludes that combining forecasting theory with portfolio selection could improve portfolio returns.

VI. Limitations and Future Scope

The assumptions used to test the portfolios do not accurately reflect their performance in real-world conditions. Real-world investments incur costs such as taxes, transaction fees, indivisibility of assets, and unexpected transaction prices. However, these assumptions do not impact the relative performance when compared to benchmarked portfolios. The portfolio construction in this study considered only stocks. Future studies could include assets from different classes to evaluate their performance.

Despite the improved performance, the proposed model used only historical values and STIs as input values for LSTM forecasting. Future studies could explore the integration of other sources of data, such as news articles and social media sentiment analysis, to improve the model's predictive power. Including exogenous factors, such as interest rates, inflation rates, and exchange rates, could also provide more comprehensive forecasting results. Moreover, the proposed model was validated only on the NIFTY stocks and on a single time-frame, limiting the generalizability of the results to other stock markets and time frames. Future work could explore the model's performance across different markets and under varying market conditions, such as highly volatile markets or those experiencing sudden shocks. This would help assess the model's robustness and applicability in diverse financial environments, providing insights into its potential for broader use in real-world scenarios.

An Efficient Hierarchical Mechanism for Handling Network Partitioning Over Mobile Ad Hoc Networks

Ali Tahir, Fathe Jeribi*
College of Engineering and Computer Science, Jazan University, Jazan 45142, Kingdom of Saudi Arabia

***Abstract*—Mobile ad hoc networks exhibit distinctive challenges e.g., limited transmission range and dynamic mobility of the participating nodes. These challenges serve as the reasons for the frequent occurrence of network partitioning in mobile ad hoc networks. Network partitioning happens when a linked network topology is partitioned into two or more independent partitions. Because of this phenomenon, the participating node in one partition maintains no linkage with a node in another partition. Network partitioning results in the inaccessibility of mapping knowledge, logical labeling space, and logical structure of the participating nodes. As a result, the performance of a distributed hash tables (DHTs)-oriented routing mechanism is severely affected. In DHT-oriented routing methodologies, the logical network identifier of a new participating node is calculated by considering the logical network identifiers of all the physical neighboring nodes. The logical network identifiers are utilized for routing of packets from a source participating node to a destination participating node in the network. In the event of network partitioning, the incorrect computation of logical network identifiers happens concerning the physical proximity of the participating nodes. This research work suggests an effective routing mechanism to deal with the aforementioned network partitioning-related issues. Simulation results prove the superiority of the suggested scheme over the existing mechanisms.**

Keywords*—Mobile Ad Hoc networks; network partitioning; distributed hash tables; logical cluster member node; logical cluster leader; logical network identifier

I. Introduction

In mobile ad hoc networks (MANETs), there are two fundamental issues [1-4]. One of the issues is the restricted transmitting range. Another issue is the dynamic mobility of the participating nodes. Due to the identified issues, merging and partitioning of network architecture occur in mobile ad hoc networks. In the partitioning of a network, the linked structure is partitioned into two or more independent isolated segments [5-6]. Because of this phenomenon, the participating node in a segment has no contact with a participating node in another segment. On the other hand, the merging of network topology involves the integration of more than two independent partitioned segments [7-13]. This phenomenon occurs when the nodes in one independent partition start receiving hello messages from nodes of another isolated partition. It infers that the nodes in two independent partitioned networks lies in the identical transmitting range.

In DHT-based routing mechanisms, arrangement of the participating nodes is done considering the exploited logical identifier structure like chord, ring, or tree shapes [14-17]. In these topologies (chord, ring, or tree), there are restrictions on the number of routing paths. Some of the exploited topologies, the logical identifier space exhibit exclusively single routing path among the participating nodes. Consequently, these exploited topologies experience minimal resilience in choosing another routing path. In multi-dimensional DHT-based routing mechanisms, high resilience is observed during the selection of alternate routing paths. In mobile ad hoc networks (MANETs), there is a higher possibility that the logical identifier structure is partitioned. The partitioning of the logical identifier is dependent on the construction exploited by the logical identifier space. Hence, an effective logical identifier structure offers resilience related to the adaptation of routing paths when forwarding the data packets. It infers that there are alternate routing paths available in case of participating node failure or mobility. This type of construction is independent of redundant routing paths towards the destination. The reason is that exploited construction offers alternative routing paths (typically more than one) towards the destination participating node in the logical identifier space. In case a node is not available due to the partitioning of the network, then an alternate routing path can be exploited to reach that destination node in the network. It means that multiple routing paths assist in maintaining availability to a participating node in the network. In addition, logical identifier structure is separated in case of merging of two or more physical networks. It is a serious issue to recognize the happening of network merging at the logical identifier structure after physical networks merging. In addition, the smooth merging of two or more logical networks after the detection of network merging is a big issue. Therefore, there is a need to develop a DHT-based routing mechanism that should address the network merging detection and the merging of logical networks afterwards.

As discussed in study [18-22], the process of disintegrating the linked network topology into more than two isolated networks is referred as partitioning of the network. In the existing DHT dependent routing mechanisms, typically the attention is on providing an efficient resolution to the mismatch issue [23-26]. All these DHT dependent routing schemes neglect a critical challenge that is partitioning of logical networks. The partitioning of the network is responsible for the disruption of connectivity among the sender and receiver participating nodes. Because of the network partitioning, the participating nodes are unable to contact each other in the isolated partitions. The reason for this inaccessibility is the disruption of communication among the participating nodes. There are several reasons for the occurrence of network partitioning in mobile ad hoc networks. In mobile ad hoc networks, the dynamic movement of the participating nodes, the self-organized character and the restricted transmission scope are mainly the reasons for the persistent isolation of linked networks. In DHT dependent routing mechanisms, network partition is the cause of diverse critical challenges. The critical challenges due to partitioning of the network consist of DHT construction decomposition, depletion of the logical identifier space and participating nodes' mapping information (MPI) unavailability. In DHT dependent routing mechanisms, these critical challenges have deteriorated influences. Because logical identifiers instead of universal identifiers (IP or MAC address) are exploited for interaction between the participating nodes. The accessibility of mapping information stored at the anchor node plays a critical role. Because it provides the logical identifier information of the receiver participating node in the logical network. In DHT dependent routing schemes over MANETs, effectiveness can be achieved by efficiently recognizing the critical links or nodes. These critical links or nodes are responsible for activating the isolation or partitioning of physical topology. Therefore, recognition of critical nodes or links should be done promptly. By doing so, information depletion is alleviated significantly. Additionally, interruption of connection is greatly minimized.

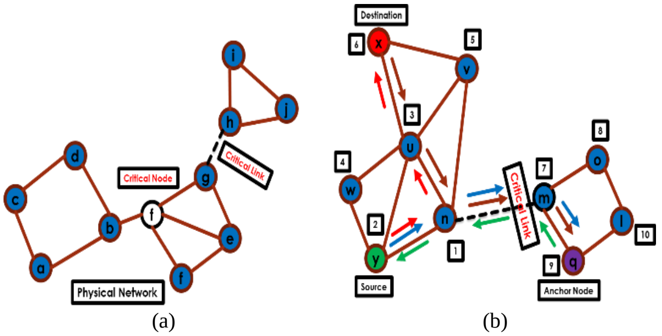
The critical link is a critical association in the logical network. If the critical link is unavailable, then partitioning of the network occurs. On the other hand, a critical participating node is a critical node in the logical network. If the critical participating node becomes unavailable, then partitioning of the network occurs. In the following Fig. 1(b), both the cases are well described. Recognition of critical links or nodes is efficiently done considering the prevalent neighboring participating nodes (x-hop) in a distributed manner.

To recognize the critical association and corresponding critical participating nodes in an efficiently distributed manner, mutual neighborhood connectivity information (x-hop) is exploited. In Fig. 1(b), n↔m association is perceived as a critical one (x-hop) in case the adjoining participating nodes of 'n' and 'm' are not in contact after the failure or breakage of the critical association. The association n↔m in Fig. 1(b) is considered one hop critical (x=1) in case neighborhood connectivity (one hop) is separated after failure or breakage of the critical association. The association n↔m is considered two hops critical (x=2) in case of unavailability of a mutual neighboring node among the neighborhood connectivity (two hops) of critical nodes 'n' and 'm'. This association is considered globally critical. The reason is the unavailability of a mutual neighboring node among the critical nodes 'n' and 'm'. For this purpose, consider x=3, 4 and so on. In the Fig. 1 (b), the node 'y' is considered as the critical participating node (globally). The reason is the separation of neighborhood connectivity of the participating node 'y' into two independent partitioned networks.

In the literature review [22-32], it is observed that research community relating to DHT-based routing does not highlight or elaborate the vital issues involving the partitioning of network. These critical issues should be effectively addressed by the research community. In this research work, a novel solution to address the crucial issues involving network partitioning is presented. It is called the 3DcPR (three-dimensional clustered partition detection with dynamic replication). This novel partition recognition strategy utilized the local neighborhood connectivity knowledge of every participating node in the 3D environment i.e., 3D logical identifier construction for efficient recognition of critical association in the physical topology. In addition, this strategy presents an efficient and dynamic solution for replication management. An efficient and dynamic replication methodology is considered beneficial to decrease the information dissipation and interruption of connection. Additionally, a novel retrieval methodology of misplaced logical identifier space is suggested. Due to the partitioning of network, the logical identifier space depletion phenomenon is observed. As far as we are aware, the suggested research work falls in the category of innovative ones in dealing with the partitioning of networks involving the DHT-based hierarchical routing protocol in mobile ad hoc networks (MANETs). This research shares the following remarkable innovations and advantages in comparison to the existing methodologies:

- We have delineated and instigated a novel partition detection and replication management mechanism termed as 3DcPR for working at the networking layer over MANETs.
- We have proposed a scheme for the identification of critical link and corresponding critical node. In this scheme, the local neighborhood knowledge of the participant nodes is utilized.
- We have suggested a replication management mechanism to smoothly establish and maintain the connectivity considering occurrence of the network partitioning over MANETs. This novel replication scheme significantly decreases the lookup latency.
- We have proposed a technique by integrating logical clustering along with DHTs to cope with the network partitioning scenarios in an effective manner.
- We have proposed an efficient technique that offers significant resilience against node failures or movements by utilizing the gateway nodes in the network.

The following tables (Table I and Table II) present the descriptions of key terms alongside their abbreviations being utilized in the current research work.



(a) (b)

Fig. 1. (a) Critical nodes and corresponding critical association, (b) Stocking and retrieval of mapping details before network partitioning.

TABLE I. ACRONYMS AND ABBREVIATIONS

Abbreviation	Description
BNT	Base Network Topology
LNT	Logical Network Topology
BNI	Base Network Identifier
LNI	Logical Network Identifier
LCL	Logical Cluster Leader
LCMN	Logical Cluster Member Node
LGPN	Logical Gateway Participating Node
MD	Mapping Details
LAPN	Logical Anchor Participating Node
MPTA	Mapping Petition Alarm
MRA	Mapping Reply Alarm
SCPN	Source Cluster Participating Node
DCPN	Destination Cluster Participating Node
DHTs	Distributed Hash Tables
MANETs	Mobile Ad Hoc Networks

TABLE II. DEFINITIONS OF IMPORTANT TERMINOLOGIES

Terminology	Definition
Base Network Topology	The physical neighborhood connection of the participating nodes.
Logical Network Topology	The logical network construction by utilizing the logical network identifiers of the participating nodes.
Logical Network Participating Node	The participating node in the logical network pattern on top of MANETs.
Base Network Identifier	The distinct identifier of logical network participating node in the physical network pattern.
Logical Network Identifier	The tag of the participating node in logical network pattern.
Logical Cluster Leader	It is the controller of the logical cluster in logical network pattern. It is selected by considering the highest participating node degree.
Logical Cluster Participating Node	It is the member node in a logical cluster.
Logical Anchor Participating Node	The participating node in the logical cluster which is responsible for stocking the mapping details of other participating nodes.
Logical Gateway Participating Node	It is participating node in logical cluster that comes under communication zones of more than one logical cluster leaders.

The rest of this paper is organized as follows: Section II presents the problem formulation with a detailed example scenario. Section III elaborates on the proposed novel mechanism for handling network partitioning on top of MANETs. In Section IV, the evaluation of the proposed mechanism is discussed. Ultimately, this research is wrapped up in Section IV alongside the future research directions.

II. PROBLEM FORMULATION

The disintegration of a linked topology into two or more isolated partitions is termed as network partitioning [33]. The nodes in a partition are not able to contact nodes participating in another isolated partition [34-35]. MANETs often experience the phenomenon of network partitioning [36-41]. The reasons behind it are high node mobility, restricted transmitting zone and the self-organized construction. In DHT-oriented routing mechanisms, mainly two critical challenges are faced due to the partitioning of networks in mobile ad hoc networks. These critical challenges are central reasons behind the degraded efficacy of the routing mechanisms based on DHT, one of which, is the inaccessibility of anchor nodes in the isolated and non-isolated topologies. Secondly, the depletion of logical identifier space is the consequence of network partitioning, and the lingering lookup delay associated with critical challenges.

A. Anchor Node Inaccessibility

In routing mechanisms dependent on DHT, the anchor node is responsible for stocking MD (mapping details) of another participating node over mobile ad hoc networks. Mapping details of the receiver participating node is indispensable for transmission between the sender and the receiver participating nodes. If the anchor node of the receiver participating node is unavailable in the connected topology, then MD of the receiver participating node is inaccessible. This phenomenon is the reason for the interruption of transmission among the sender and the receiver participating nodes in the logical topology. It infers that the accessibility of the receiver anchor node in the logical topology guarantees the persistent transmission between the sender and the receiver participating nodes.

Indeed, the partitioning of the network is responsible for the anchor node unavailability in the logical topology. Because of network partitioning of DHT-dependent logical topology into two or more independent networks, the sender and the receiver are members of one partition, but their respective anchor node lies in another isolated partition. In this scenario, the sender and the receiver participating nodes exist in similar partitions and are accessible to each other. Still, the sender and the receiver participating nodes are incapable of connecting. This phenomenon occurs because of the unreachability of mapping details stored at the receiver anchor node.

In Fig. 1 (b), a linked logical topology with a critical association n↔m is elaborated. This association between the participating nodes ‘n’ and ‘m’ is considered critical at a global level in the logical network over mobile ad hoc networks. The reason behind this consideration is that the participating nodes in the neighborhood of ‘n’ and ‘m’ are isolated. In a DHT dependent routing mechanism, every participating node is held responsible for stocking its MD (mapping details) at its anchor node for routing aims.

For example, a participating node ‘x’ stocks its mapping details (MD) at the anchor node ‘q.’ Now, if any other participating node, say the participating node ‘y’, wants to connect with the participating node ‘x’, then the sender participating node ‘y’ should first fetch the stocked mapping details from the anchor node ‘q’ of the participating node ‘x’. Afterwards, the participating node ‘y’ can initiate transmission with the receiver participating node ‘x’ in the logical topology.

In Fig. 2, the isolation of the critical association n↔m occurs in the logical topology over mobile ad hoc networks. Owing to the isolation of critical linkage in the logical topology, the partitioning of network topology takes place as presented in Fig. 2. After isolation of the network topology, the participating sender node ‘y’ and the receiver node ‘x’ remain in the identical partition. Although, the relative anchor node (i.e., node ‘q’) of the receiver node ‘y’ exists in another isolated partition in the logical network. In this scenario, the sender participating node ‘y’ is incapable of fetching the mapping details of the participating receiver node ‘x’ from the anchor node ‘q’.

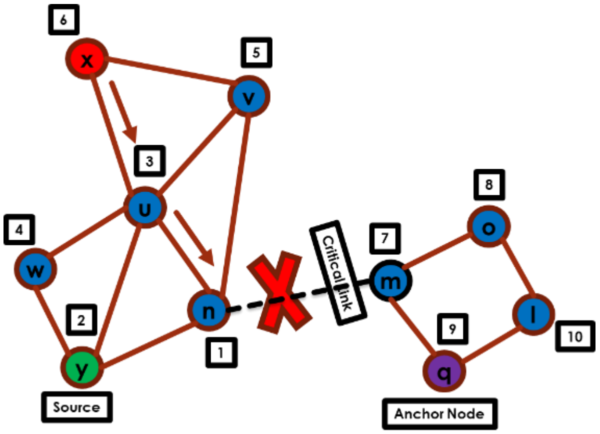


Fig. 2. Impossible retrieval of mapping details after network partitioning due to critical link failure.

Consequently, this phenomenon leads to the suspension of the interaction among the sender and the receiver participating nodes. Also, no participating node can fetch the mapping information of the receiver participating node ‘x’ in the absence of its anchor node in the logical environment. For smooth transmission, with other participating nodes in the logical topology, the receiver participating node ‘x’ should choose an updated anchor node and stock its mapping details. Afterward, the lookup queries targeting the participating node ‘x’ are efficiently rectified. However, the selection of another anchor node and stocking the mapping details on it becomes a reason for prolonged end-to-end delays and information depletion as well. Correspondingly, in case of failure or movement of anchor nodes to another partition, retrieval, or accessibility of stocked mapping details at that failed or moved anchor node should be assured to avoid the disruption of communication among the participating nodes in the logical network topology. It is considered as a critical issue in logical network topologies over mobile ad hoc networks that should be addressed efficiently in DHT-based routing schemes.

In the Fig. 3, the anchor node ‘q’ of the receiver participating node ‘x’ leaves the communication zone of another participating node ‘m’, and a new logical network identifier is allocated to it considering its neighborhood connectivity. Furthermore, the receiver participating node in this scenario chooses another anchor node ‘o’ and stocks its mapping details at the newly selected anchor node ‘o’ in the logical network topology. Simultaneously, this phenomenon becomes a reason for irretrievable enroute lookup requests by other participating nodes in the logical network topology. As a result, no transmission among the participating nodes is observed. In consequence, the DHT-based routing mechanism exhibits prolonged lookup delays and information depletion over mobile ad hoc networks.

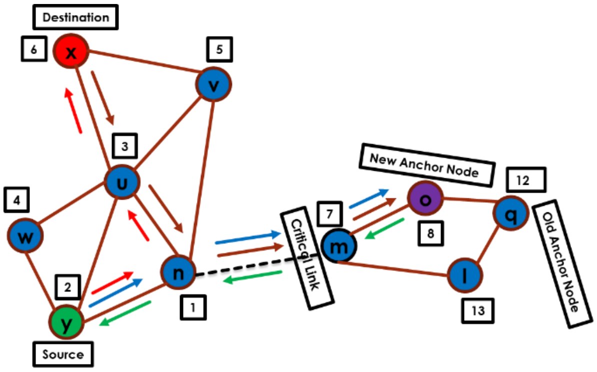

Fig. 3. New anchor node computation and stocking mapping details.

B. Depleted Logical Identifier Space

Another critical issue related to network partitioning that should be efficiently addressed is the depletion of logical identifier space. In a logical environment, the logical identifier space of an isolated partition can be reclaimed in another isolated partition. In consequence, the uniform division of the logical identifier space is achieved. Besides, isolated partitions can interact with each other due to the uniform division of logical identifier space. Therefore, retrieval of the logical identifier space is a well related critical challenge in DHT dependent routing schemes implemented over mobile ad hoc networks.

For this purpose, the pre-established network partitioning criterion performs an important responsibility for recognizing the occurrence of network partitioning in the logical identifier space over mobile ad hoc networks. There should be prompt, efficient pre-recognition of network partitioning until the authentic isolation of a logical network occurs in the logical environment. Pre-recognition is a necessary step towards effectively retrieving the logical identifier space in case of network partitioning activity in the logical environment over mobile ad hoc networks.

In a DHT-based routing mechanism, efficaciously recognition of network partitioning in a distributed manner is essentially required. The research community should rectify the identified challenge effectively to meet the requirements for the development of an efficacious DHT-based routing mechanism over mobile ad hoc networks. Moreover, in the scenario of network partitioning in MANETs, the prolonged lookup delays are observed. The prolonged lookup delay is a crucial associated issue that becomes worse when a critical challenge of network partitioning occurs over mobile ad hoc networks. This pertinent issue can be effectively resolved in a distributed way. For this purpose, the local neighborhood connectivity information of each participating node can be exploited. For the research community in this domain, resolving the said issue in a distributed fashion solicits strenuous exercise.

III. Solution Formulation

To rectify the issues related to network partitioning previously mentioned, a three-dimensional clustered distributed partition detection and replication routing mechanism referred to as 3DcPR is suggested. It exploits the local neighborhood connectivity information of the participating nodes for presenting the solution in a distributed fashion. The distributed resolution of the network partitioning-related challenges commensurate with the obligations of DHT dependent routing schemes in terms of scalability. In our mechanism for partition recognition, the following improvements have been explicitly suggested:

1) To offer the guarantee that the mapping details remain accessible in the disassociated partitions in the logical network. For this purpose, our mechanism dynamically replicates the mapping details in the logical network to handle the post-partitions replication challenges effectively.

2) To deal with the network partitioning, an effective mechanism is formulated to offer the recognition of network partitioning in a distributed fashion. This distributed partition recognition mechanism performs a decisive responsibility in identifying the network partitioning by considering several pre-established criteria. One of the criteria is the identification of the critical links among the participating nodes in the logical topology. Secondly, it focuses on offering an efficient strategy for the retrieval of the depleted logical identifier space due to partitioning of the network topology.

3) To encounter with the lingering lookup query delays, our mechanism provides the required efficacy in executing the replication management. Also, the influences of our replication management scheme considering the prolonged lookup delays are observed. It is found that lookup query delays are greatly minimized by exploiting our dynamic replication management strategy.

In 3DcPR, respective neighborhood connectivity information is exploited. 3DcPR exploits the neighborhood connectivity information up to two hops. It also utilizes the degree of the participating node for recognition of the critical links among the participating nodes in the logical environment. Furthermore, these parameters are considered for dynamic mapping details replication in the logical topology.

By doing so, 3DcPR guarantees the accessibility of mapping details in the isolated partitions after the occurrence of the network isolation phenomenon in the logical topology. As a result, the depleted information is significantly minimized. Also, our methodology is effectively coping with the partitioning of the network with remarkable reduction in the lingering delays of the lookup queries in the logical topology, achieved with no extra control overhead.

A. Recognition of Critical Linkage

In our methodology, HELLO messages among the logical cluster member nodes (LCMNs) are utilized for efficient recognition of network partitioning events in the logical environment over mobile ad hoc networks. In 3DcPR, every logical cluster member node reciprocates pre-established HELLO messages interval with each of its neighboring one-hop cluster members. In the HELLO message, information about the logical network identifier (LNI), logical space segment and a base network identifier of the participating cluster member is contained. Besides, the exchanged HELLO message consists of the one-hop neighborhood connectivity knowledge of the participating cluster member. It infers that each participating cluster member preserves the two-hop physical neighborhood connectivity knowledge in the logical topology for effective recognition of the network partitioning.

3DcPR recognizes a critical association among the two participating cluster members, say ‘n’ and ‘m.’ The association between the cluster members ‘n’ and ‘m’ is considered critical when one-hop neighborhood connectivity of cluster members ‘n’ and ‘m’ remains disconnected in case of failure or removal of the critical association between cluster members ‘n’ and ‘m.’ If a cluster member ‘n’ is one-hop critical of another cluster member ‘m,’ then all the neighborhood connectivity (one-hop) of the cluster member ‘n’ is not reachable from another cluster member ‘m,’ in case the cluster member ‘n’ is moved or failed. Due to this reason, the association among the cluster members ‘n’ and ‘m’ is considered critical. Besides, the association among the cluster members ‘n’ and ‘m’ is perceived as two hops critical in case the neighborhood connectivity (two-hops) of the participating cluster members ‘n’ and ‘m’ is not approachable in the absence of the critical association among the cluster members ‘n’ and ‘m.’

In 3DcPR, the state of the cluster members around the critical association is considered critical. Contrarily, the state of the cluster members, around the critical association, is perceived as non-critical. In 3DcPR, every cluster member informs all the neighbors (one-hop) about its state of being critical or not. For this purpose, each cluster member exploits HELLO messages. In the subsequent portions, the network partition recognition in a distributed manner along with a dynamic replication scheme is elaborated considering the clustering environment. Mostly, the gateways of the neighboring clusters serve as the critical cluster members around the critical association.

In 3DcPR, the k-hop neighborhood connectivity is considered for recognition of partition. Also, k-hop neighborhood connectivity information is considered for retrieval of a logical identifier structure. The k-hop neighborhood connectivity information is utilized for critical nodes recognition in the network. To attain the said objective, HELLO messages are occasionally exploited among adjoining cluster members to share neighborhood connectivity information (k-1 hop). In the HELLO messages, each cluster member shares neighborhood connectivity record (one-hop) with neighboring cluster members considering ‘k’ that equals 2. Moreover, the base network identifier, logical network identifier, and logical space segments are exchanged in the periodic HELLO messages. Hence, every cluster member keeps neighborhood connectivity information up to two-hops in the network.

The imperative step towards successful and efficient recognition of network partitioning is the timely detection of critical association among critical cluster members. For example, consider two participating critical cluster members ‘n’ and ‘m’ around the critical association n↔m. The occurrence of network partitioning phenomenon is provoked by the 3DcPR in a distributed fashion. This partition detection strategy considers precautionary actions involving the adjustment of a logical identifier structure. Besides, a specific duration of time is set. This set timer is termed as partition timer. Network partitioning happens if a critical cluster member ‘n’ around the critical association n↔m does not receive the HELLO messages from another participating cluster member ‘m’ after the pre-established HELLO break. In our mechanism for partition recognition, the pre-established partition timer is three times the HELLO break.

In the same way, the other participating cluster member recognizes the partitioning of the network. If partitioning of networks happens, then the cluster members around the critical association are responsible for retrieval of the misplaced logical identifier structure. For this purpose, the cluster members utilize the misplaced logical identifier structure in the separated independent partitions.

Mostly, the exploited logical identifier construction plays a vital role in the retrieval process of the logical identifier structure. The LIS recovery mechanism depends on the logical structure used. Every participating cluster member around the critical association retrieves the logical identifier structure in the three-dimensional space. For this purpose, every cluster member around the critical association retrieves it by just altering the value of the dimension. Correspondingly, the retrieval process in the chord construction is somewhat different. In the chord construction, logical network identifiers of the participating nodes around the critical association are altered for retrieval of a misplaced logical identifier structure. They modify their logical network identifiers considering the linkage (successor or predecessor) among the participating nodes around the critical association.

In the chord construction, the participating node (successor) retrieves the logical identifier structure by altering the logical network identifier to S. Also, the participating node (predecessor) in the chord construction modifies the logical network identifier to E for the successful retrieval of the misplaced logical identifier structure. The precedent participating node concerning the logical chord formation revives the logical identifier space by altering its logical network identifier to E, and also the descendent participating node in the chord formation recuperates the logical identifier space by modifying its logical network identifier to S. The exploitation of the misplaced logical identifier structure in the separated independent partitions has great benefits. One of the benefits is the uniform distribution of logical identifier structure in the separated independent partitions.

Our strategy suggests an efficient distributed methodology for recognition of partition. In it, the recognition is entirely distributed in nature. It exploits the local neighborhood connectivity knowledge of the participating cluster members for partition recognition in a distributed manner. It does not consider the dissipation of control knowledge at the global level.

B. *Partition Recognition and Replication Strategy*

To test 3DcPR, let us consider a 3DcRP [27] example as depicted in the following scenarios, for explaining the feasibility of our methodology for partition recognition and replication.

Initially, 3DcPR recognizes the critical association and corresponding critical participating cluster members. For this purpose, HELLO messages are exploited by our partition recognition and dynamic replication methodology, i.e., 3DcPR. Every cluster member occasionally exchanges local neighborhood connectivity knowledge (one-hop) with the neighboring cluster members by exploiting the HELLO messages. By doing this, every cluster member in the network contains the neighborhood connectivity knowledge (two-hops). In the HELLO messages, a logical network identifier, base network identifier, and logical space segment are exchanged. Maintaining the neighborhood connectivity knowledge (two-hops) facilitates in recognition of critical association and corresponding critical cluster members in the logical network.

To understand this, consider the example scenario depicted in Fig. 4. In this scenario, one-hop neighboring cluster members of ‘w’, ‘x’ and ‘z’ are {‘u’, ‘y’, ‘x’}, {‘v’, ‘u’, ‘w’, ‘x’, ‘z’}, and {‘x’, ‘y’, ‘v’}, respectively. When the participating cluster members, ‘w’, ‘x’ and ‘z,’ exchange the local neighborhood connectivity knowledge (one-hop), then another participating cluster member ‘v’ in cluster 1 with LNI 1 contains the local neighborhood knowledge (two-hops). The participating cluster member ‘v’ reviews the neighborhood connectivity knowledge (one-hop lists) of all its adjoining cluster members (cluster members ‘x’ and ‘z’) for searching the nexus cluster member among them. The participating cluster member ‘v’ does this exercise for broadcasting its state (either critical or not critical). In this exercise, the participating cluster member ‘v’ does not include itself. After reviewing the neighborhood connectivity knowledge (one-hop lists) of all its adjoining cluster members, the participating cluster member ‘v’ finds that a cluster member (also the gateway cluster member), say ‘y’, is the nexus cluster member among the neighborhood member ‘v’ failure does not have an impact on the connectivity. This connectivity {‘x’, ‘u’, ‘w’, ‘y,’ ‘z’} exists despite its (‘v’) failure or movement. Therefore, the participating cluster member ‘v’ announces its state as non-critical. Likewise, the participating cluster member 'y' hears the local neighborhood connectivity knowledge (one-hop) from each of its adjoining cluster members ‘’w’, ‘x’, ‘z’, and ‘m.’ This one-hop neighborhood connectivity lists are {‘u’, ‘x’}, {‘v’, ‘u’, ‘w’, ‘y’, ‘z’}, {‘v’, ‘x’, ‘y’}, {‘r’, ‘p’, ‘q’, ‘y’} from ‘w’, ‘x’, ‘z’, and ‘m’, respectively.

'm' neighborhood connectivity (one-hop)

Fig. 5. Critical cluster member identification.

It is depicted in Fig. 5 that the nexus cluster members among the adjacent cluster members ('w,' 'x,' 'z') of 'y' exists. It constitutes a linked network without the cluster member 'y.' Although, the one-hop neighborhood connectivity of the participating cluster member 'p' of cluster 2 with LNI 2 (also the gateway cluster member) does not become a part of the linked network of cluster members 'w', 'x', and 'z'.

It infers that the state of the two participating cluster members 'y' and 'm' is set as critical. They both also act as the gateway cluster members in clusters 1 and 2, respectively. In consequence, the association among the critical cluster members 'y' and 'm' is considered as critical.

For the example scenario as depicted in Fig. 6, the critical association is y ↔ m. Correspondingly, every participating cluster member refreshes its state of being critical or not in the network periodically. When a newly joined cluster member, say 'w,' in cluster 1 calculates its logical network identifier and it stocks its mapping details at its anchor cluster member, say 'q,' afterward. For this purpose, the newly joined cluster member 'w' sends cluster member 'y' stocks the mapping details of the newly joined cluster member 'w' if that mapping details are not sent by the other critical cluster member in the network.

Fig. 6. Critical association identification.

The critical cluster members 'y' and 'm' stock the mapping details for forwarding it further. Therefore, the critical cluster members 'y' and 'm' around the critical association y↔m, and logical cluster leaders (LCL1 and LCL2) maintain a copy of the mapping details included in the MPTA message. The phenomenon of replicating and retrieving mapping details before the occurrence of network partitioning is depicted in the Fig. 7. This dynamic replication strategy facilitates avoiding communication disruption in the separated partitions after the occurrence of network partitioning. The cluster members in two partitioned networks can acquire the mapping details from the critical cluster members 'y' and 'm' across the critical association and the logical cluster leaders (LCL1 & LCL2) as well.

SCPN 'z' sends data packet to DCPN 'w' in cluster 1.
Replication is done across the critical association and on cluster leaders (LCL1 & LCL2)

Fig. 7. Replication around the critical association and on cluster leaders.

By doing so, the participating cluster members can communicate in a partition after the failure or removal of the critical association in the network. In the Fig. 8, an example scenario is depicted to elaborate the phenomenon after the occurrence of network partitioning. In this example scenario, a sender logical cluster member node 'z' in cluster 1 having cluster leader 'x' wants to contact another receiver logical cluster member node 'w.' For this purpose, the sender cluster member 'w' first finds the anchor cluster member for the receiver cluster member 'w.' After finding the anchor cluster member, i.e., 'q' of the receiver cluster member 'w,' the sender cluster member 'z' acquires the stocked mapping details from the anchor cluster member 'q' of 'w.' The stocked mapping details is not accessible for the sender cluster member 'z' if the critical association among the critical cluster members 'y' and 'm' fails or removes.

In case of critical link failure, SCPN 'z' requests 'w' s mapping details from its critical LAPN 'y' in cluster 1.
Critical LAPN 'y' sends 'w' s mapping details to SCPN 'z' in cluster 1.
SCPN 'z' sends data packet to DCPN 'w' in cluster 1.
Replication is done across the critical association and on cluster leaders (LCL1 & LCL2) for avoiding the communication disruption.

Fig. 8. Avoiding communication disruption after network partitioning.

Our methodology provides an effective solution to this unavailability of mapping details in case of critical association failure. It gives assurance to provide accessibility of mapping details after the failure of critical association (occurrence of network partitioning). In our methodology, pre-partitioning precautions like recognition of the critical association/critical cluster members and dynamic replication assist in avoiding the unavailability of the mapping details. In the above example scenario, the pre-partitioning criterion (replicas placement) assists the sender cluster member 'z' to retrieve the mapping details of the receiver cluster member 'w' from the critical cluster member 'y' although the network partitioning occurred due to the failure or removal of critical association among critical cluster members as depicted in Fig. 8. Even if the critical cluster member 'y' fails or moves to another location, the sender cluster member 'z' can obtain the replicated mapping details of the receiver cluster member 'w' from the cluster leader 'x.' Therefore, our methodology effectively addresses the identified issue by replicating the mapping details on both the critical cluster members around the critical association and cluster leaders.

Furthermore, 3DcPR activates the occurrence of network partitioning in case the critical cluster members around the critical association are not able to receive HELLO messages from each other for a specific pre-established time duration (partition-timer). Although, it is a must for the critical cluster members to be both one-hop and two-hops critical. However, the exception is for the critical cluster member that is two-hops critical but has a state of one-hop non-critical as well. In the Fig. 9, it is depicted that critical cluster members 'y' and 'm' around the critical association y↔m are not able to receive the HELLO messages from each other, then this phenomenon provokes the network partition after the expiry of the pre-established partition timer.

In this scenario, the respective critical cluster members retrieve or reiterate the depleted logical identifier space. If the anchor cluster member is considered as the critical cluster member, then it mirrors its MD (mapping details) around the critical association in the network. To avoid the communication disruption after the network partition, the mirroring deployment and retrieval of logical identifier space is an important step. This situation may give rise to uniform and distributed separated partitions though there exists network partitioning. The retrieval process of logical identifier space is different for every logical construction. Because this retrieval process is dependent on the construction of logical identifier space, the exploited logical construction may include a ring, a cord, a tree, or a 3D.

In the case of a high mobility environment, DHT-oriented routing methodologies, over mobile ad hoc networks, face prolonged lookup delays and decreased overall performance. Our methodology utilizes the dynamicity of the mobile ad hoc networks. It means the relative connectivity, i.e., two-hop topological knowledge. Moreover, our methodology utilizes the local network variation (one-hop connectivity knowledge). For relative connectivity and local network variation, periodically sent HELLO messages are utilized by the 3DcPR. By doing so, it offers assured reachability/availability of the network. Besides, it is done with no additional control overhead. As a result, end-to-end delays are effectively minimized for lookup queries in the network.

IV. Results and Discussion

To assess the effectiveness of the proposed mechanism, the network simulator version 2.35 is exploited for creating and running every simulation. NS-2.35 is an open-source event network simulated adopted by the research community. The propagation model utilized by the proposed mechanism is Two Ray Ground. This propagation model is exploited to simulate IEEE 802.11 concerning the standard values for physical and link layers. In Table III, the simulation parameters are demonstrated. The effectiveness of the proposed mechanism i.e., 3DcPR is evaluated with the existing logical networks over MANETs strategies like 3DDR [23] and 3DRP [24]. These previous strategies exploit the three-dimensional shape to efficiently cope with the mismatch issue among the logical and physical network topologies. Besides, the existing strategy i.e., 3DDR provides notable resiliency against participating node movement or failure situations. The participating node calculates its logical network identifier considering the LNIs of each neighboring participating nodes within a network. Consequently, a significant escalation concerning control, computation and routing traffic overheads is observed. Conversely, a logical cluster leader (LCL) is devoted for distributing the logical network identifiers among its logical cluster member nodes residing within its logical cluster concerning the proposed mechanism i.e., 3DcPR. This phenomenon remarkably minimizes the control, computational, and routing traffic overheads within the network.

The playground area size is considered as 1000m * 1000m as per the proposed methodology for efficiently conducting the simulations in NS 2.35. The utmost broadcasting span is set as 50 m. Remember, the broadcasting span is adopted in a manner that passes over each participating nodes a specific distance i.e., two hop. In 3DcPR, HELLO notifications are regularly interchanged and utilized for effectively preserving the neighborhood connectivity among the adjacent participating nodes in the network. The uniform distribution is implemented when establishing a tangible network simulation environment. In addition, as demonstrated in Table III, the network simulations are employed concerning motion patterns by exploiting the high mobility of the participating nodes i.e., 7 m/s to 25m/s. The exact cause of constricting the speed of the participating nodes from 7m/s to 25m/s is the unsustainability of MANETs considering considerably high or low mobility situations. Moreover, a consistent selection of the participating nodes' speed is adopted as 7m/s to 25m/s. For maintaining the connection in the physical network, BonnmotionV2 is exploited in the current scheme for generating the mobility cases in accordance with RWP (random way point) network model. RWP is the first choice of renowned researchers of the wireless domain for perfectly assessing the effectiveness of the ad hoc networks alongside its other prominent benefits like ease and quick functionality. Remember, OLSR is being exploited by the proposed scheme as an underlying strategy. Moreover, 10 unique files are commissioned by every participating node as per the proposed strategy. Also, for modelling routing traffic, the random traffic pattern is employed by 3DcPR. For establishing the data traffic, the CBR (constant-bit-rate) flows are utilized over the UDP protocol. In addition, it is supposed to be the connectivity of network formation for both 3DcPR and 3DDR. In our experiments, ten executions per case are done. The aggregate results are depicted by utilizing graphs. Lastly, the simulation duration is established as 500 seconds for performing different scenarios for accurately evaluating the performance of the proposed and existing mechanisms.

TABLE III. SIMULATION PARAMETERS

Parameter	Value
Playground Size	[1000 m × 1000 m]
Number of Nodes	[25-400]
Transmission Range	50 m
Simulation Time	500 s
Data Rate	[1- 500pps]
Start of Data Transmission	[70, 300]
End of Data Transmission	[250, 499]
Node Speed	[7 m/s – 25 m/s]
Traffic Model	Random Traffic Pattern
Mobility Model	Random Way Point
Radio Propagation Model	Two Ray Ground

In this research article, three performance parameters are considered for efficiently assessing the performance of the suggested mechanism. These performance parameters are evaluated against the high mobility of the participating nodes and rising network size.

1) Routing Traffic Overhead (RTO): It is the entire control overhead packets as utilized by the routing protocol in the mobile ad hoc network.

2) Packet Delivery Ratio (PDR): The ratio between the total mapping request packet (MREQ) initiated and the total MREQ entertained successfully by receiving the mapping reply packets (MREP).

3) Average End-To-End Delay: The average time elapsed between when the source node initiates MREQ and the source node gets MRPY.

A. Average End-To-End Delay

To evaluate the performance of a DHT-based routing mechanism, the average end-to-end delay is considered as an important criterion. Through this criterion, the entire network performance can be assessed as well. It is required to perform a detailed investigation concerning the effect of rising network size alongside the speed of the participating node over aggregated end-to-end delay. The detailed impact analysis of increasing network size and node moving speed over average end-to-end delay is carried out and demonstrated in the following Fig. 9.

In the Fig. 9, the average end-to-end delay of 3DcPR, 3DDR [23], and 3DRP [24] is computed against the changing speed participating nodes ranging from 7m/s to 25m/s considering the increasing network size It is demonstrated in Fig. 9 that the average end-to-end delay of the proposed mechanism i.e., 3DcPR is notably decreased in contrast to the existing schemes 3DDR, and 3DRP. The central reason behind this significant reduction in average end-to-end delay is novel partition discovery and effective replication strategy in a distributed way which discovers the censorious participating nodes first and clones the mapping details for facilitating the uninterrupted connection. The average end-to-end delay is considerably minimized as the extra clones are deployed in the network to avoid transmitting the message request to the actual anchor participating node rather than a nearby participating node carrying the mapping details acting as a clone. As a result, the traffic overhead is significantly decreased considering the proposed mechanism i.e., 3DcPR in comparison to the existing schemes 3DDR, and 3DRP.

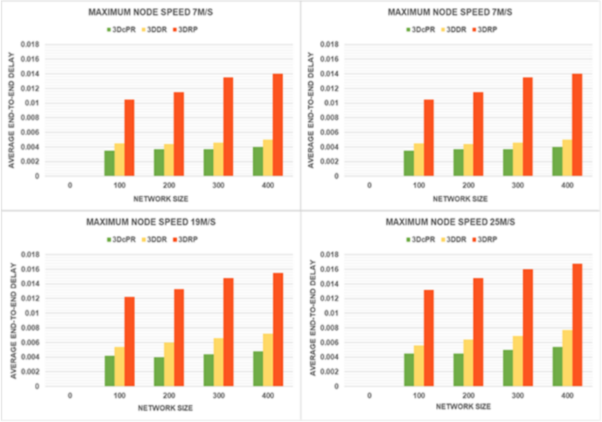

Fig. 9. Average end-to-end delay vs. network size.

Moreover, the notable reduction in routing traffic overhead minimizes the contention to establish the connection with the medium at media access layer considering IEEE 802.11. Furthermore, this phenomenon assists in remarkably decreasing the average end-to-end delay concerning the suggested mechanism.

B. Routing Traffic Overhead

One of the critical parameters to evaluate the performance of the proposed mechanism considering the increasing network size alongside the fluctuating participating node speed is the routing traffic overhead. Specifically, the routing traffic overhead gains immense value when it is computed for each lookup query in the network. As demonstrated in Fig. 10, the routing traffic overhead is computed for the proposed mechanism i.e., 3DcPR in comparison to the existing strategies 3DDR, and 3DRP considering the fluctuating participating node speeds i.e., 7m.s to 25m/s and changing network size. A remarkable decrease in the routing traffic overhead is observed as depicted in Fig. 10 for the proposed mechanism considering the varying network size and fluctuating participating node speeds in comparison to the existing schemes. The reason behind this significant decrease in the routing traffic overhead is the novel partition discovery mechanism alongside the effective replication scheme. This proposed strategy discovers the critical participating nodes in the network and replicates the mapping details which results in minimized lookup request overhead in the network. Remember, as the participating nodes over MANETs have fluctuating speeds which results in frequent network construction changes. Consequently, this phenomenon increases the routing traffic and lookup requests overhead over MANETs.

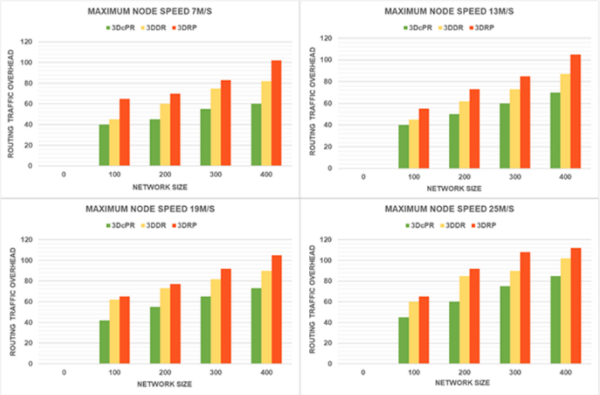

Fig. 10. Routing traffic overhead vs. network size.

The primary reasons behind this rise in the routing traffic overhead are the relocation the anchor participating nodes, stocking the mapping details at newly relocated anchor participating nodes, the retrieval of the logical identifier construction, and re-computation of logical network identifiers happen due to the network partitioning. As demonstrated in Fig. 10, the calculated routing traffic overhead for the proposed scheme i.e., 3DcPR is much lesser than the existing strategies due to the discovery of critical participating nodes and corresponding critical association between them in the network and the novel replica management strategy. Besides, the proposed scheme i.e., 3DcPR utilizes the clustering environment and three-dimensional network construction for arranging the participating nodes in logical network over MANETs.

C. Packet Delivery Ratio (PDR)

As discussed earlier, the potential of a routing mechanism is the effective delivery of data packets towards the destination participating node in the network which is termed as the packet delivery ratio. Remember, the increasing number of participating nodes minimizes the packet delivery ratio concerning the routing mechanism. As known, with the increase in number of participating nodes raises the collision of packets at media access control layer concerning IEEE 802.11. It infers that the reduction in successful message request and message reply alarms happens in the network because of escalating collision of packets in the network. Additionally, the number of hops among the source and destination participating nodes rises in the network. Consequently, this phenomenon amplifies the total amount of transmission in the network. Hence, packet delivery delays are observed in the network and there are more chances of collision of packets concerning media access layer. As a result, the effective transmitting of message request and message reply alarms is badly affected in the network.

In Fig. 11, the packet delivery ratio for the proposed mechanism i.e., 3DcPR and the existing schemes is computed. As demonstrated in Fig. 11, the effect of increasing number of the participating nodes alongside the fluctuating speeds is observed lower for the proposed mechanism i.e., 3DcPR in contrast to the existing strategies 3DDR, and 3DRP. Hence, the proposed mechanism 3DcPR achieves better results concerning packet delivery ratio in comparison to the existing schemes which proves the efficaciousness of the proposed methodology. Besides, this particular potential of the proposed mechanism makes it a strong candidate for its execution and efficient transmitting of packets in a large-scale mobile ad hoc networks.

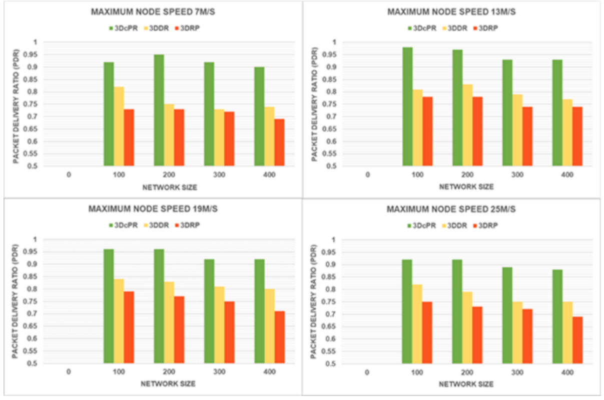

Fig. 11. Packet delivery ratio vs. network size.

In addition, the packet delivery ratio concerning 3DcPR is preserved and enhanced by utilizing the proposed partition discovery and replica management strategy. The proposed methodology clones the mapping details on each censorious connectivity down the route towards the logical anchor participant. This phenomenon is the reason behind the enhanced packet delivery ration for the proposed methodology as the mapping details are accessible even in the split partitions considering the occurrence of network partitioning. Besides, the high mobility of the participating node and fluctuating network size provoke the partitioning of the network over MANETs. So, in case of network partitioning, it is almost impossible to fetch the mapping details considering the existing methodologies like 3DRP, and 3DDR. The reason behind this inaccessibility to mapping details is the existence of logical anchor participant in the split partition. Additionally, in the proposed approach, the replica preservation around the critical connectivity down the path towards logical anchor participant enhances the reliability of 3DcPR. The other reason behind this reliability enhancement of 3DcPR is significant decrease in routing traffic overhead. Consequently, at the media access layer, the collision of packets is notably minimized. The proposed methodology i.e., 3DcPR preserves this scenario for long which results in significant improvement in delivering the packets towards the destination. Moreover, the existing schemes exhibits the mismatch issue among the physical and logical network topologies. Consequently, the existing methodologies suffer from lengthy paths towards destination and unnecessary routing traffic in the network. On the other hand, the proposed methodology i.e., 3DcPR considers three-dimensional construction in a clustering environment to perfectly map the physical linkage in the logical network and avoiding the mismatch issue.

V. Conclusion and Future Directions

One of the critical problems concerning the DHT-oriented routing over mobile ad hoc networks is the partitioning of networks. Specifically, network partitioning phenomenon becomes worsen in case of high mobility and with the rising number of the participating nodes in the network. Consequently, the mapping details are inaccessible, the logical identifier construction is dissolved, and lengthy lookup delays are observed considering the occurrence of network partitioning. As a result, no communication within the mobile ad hoc network. So, the prompt discovery of network partitioning over MANETs is a demanding task considering the high mobility and increasing network size of the participating nodes in the network. In this research article, the issue of network partitioning over MANETs is tackled by developing a novel mechanism in a distributed fashion. A novel partition discovery mechanism alongside the effective clone management strategy is recommended to successfully deal with the partitioning of network over MANETs. Also, a distinct and effective replication mechanism is proposed which results in minimized lookup and routing delays considering the DHT-oriented mobile ad hoc networks. The prompt preventive actions e.g., clone management and neighbourhood connectivity knowledge of the participating nodes are considered for discovering the network partitioning in time and effectively handling the issues after network partitioning. As a future work, the implementing of the proposed methodology for secure data dissemination in mobile ad hoc networks is under consideration.

Conflict of Interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

***Abstract*—Delivering the most suitable products and services essentially relies on successfully exploring the potential relationship between customers and products. This immense need for intelligent exploration has led to the emergence of recommendation systems. In an environment where an immense variety exists, it is vital for buyers to own an intelligent exploratory map to guide them in finding their choices. Personalization has proven to be a successful contributor to recommenders. It provides an accurate guide to explore the users' preferences. In the field of recommendation systems, the performance of the systems has been continuously measured by their success in accurate, personalized recommendations. There is no argument that personalization is one key success; however, this research argues that recommendation systems are not only about personalization. Other success factors should be considered in targeting optimality. The current research explores the hierarchy map representing the strengths and dependencies of the recommendation systems pillars associated with their influence level and relationships. Moreover, the research proposes a novel predictive approach that applies a hybrid of content and collaborative filtering recommendation systems to provide the most suitable customer recommendations effectively. The model utilizes a proposed features selection approach to detect the most significant features and explore the most effective associations' schemes for the recommendations label feature. The proposed model is validated using a benchmark dataset by extracting direct and transitive associations and following the identified schematic for the required recommendations. The classification techniques are applied, proving the model's applicability with an accuracy ranging from 96% to 99%.**

***Keywords*—Recommendation systems; data mining; features selection; associations rules mining; classification techniques**

I. Introduction

Delivering the most suitable products and services essentially relies on successfully exploring the potential relationship between customers and products. This immense need for intelligent exploration has led to the emergence of recommendation systems [1]. The recommendation systems continuously apply different intelligent [2] as well as statistical [3] [4] techniques targeting accurate recommendations which directly lead to grasp the customer attraction and gain his positive interaction. The recommendation system types are content-based, knowledge-based, and collaborative filtering [5]. Each type has its own perspective in the analysis task to provide the most suitable recommendations. Content-based type focuses only on the product or service data, while collaborative filtering focuses on users' behavior. Moreover, knowledge-based recommendation systems provide recommendations based on the gathered knowledge of both of them, which could be considered the most challenging type as it should successfully force a homogeneous environment in which knowledge of both products and users could be mutually interpreted.

Although collaborative filtering is the most widely applied approach [6] [7], however, the current study highlights the competence of the knowledge-based approach over other types either the content-based or the collaborative filtering. Knowledge-based approach relies on both users' and products' data as well as these products' ratings. With the applicability to include this divergence of knowledge, the current study argues for higher and satisfied performance of the recommendation systems based on the knowledge-based approach. Although the recommendation systems field has had exceptional success, there are many challenges that should be considered. One of the challenges is to identify suitable methods for dealing with data sources and their issues, such as sparse data. Improving the scalability and efficiency of the recommendations is a continuous challenge in the field [8]. Many research papers have tackled these enhancements for one of the approaches; however, the integration of different approaches is not considered. The idea of collaboration has succeeded in different research to overcome one of the approach challenges with the other approach benefits. In addition, neighborhood techniques such as mining techniques, machine learning, and natural language processing contribute efficiently in the same direction. One of the neighborhood techniques is association rules mining. When these techniques are embedded in the recommendation systems, one of the substantial factors is the quality level of the explored associations. This quality level is heavily affected by the significance of the features [9]. The quality evaluation metrics, including support and confidence, may provide the same measures. However, this study argues that the recommendations could be strongly affected positively by the associations of the significant features. Therefore, one of the current research objectives is to explore the significant features association schemes with the label feature. In addition, considering the significant feature dependencies, even extend the associations' schemes targeting to provide more comprehensive and efficient recommendations. The associations' dependencies could be considered the pillar of building the transitive associations, contributing to more exploration for efficient recommendations.

In this study, the recommendations were based on a set of stages; each of these stages applies an intelligent technique and provides more exploration to the knowledge in-hand. The proposed recommender has three main stages. First, exploring the significant features through weighting methods with the collaboration of statistical methods. Second, exploring the direct association rules, then a second level of associations are explored for more accurate recommendations. Finally, build the semantic recommendation road map through the explored relationship between the features. The evaluation is performed by applying the classification algorithms to confirm the accuracy of the provided recommendations. In addition to the collaboration of the previously mentioned intelligent techniques, the contribution of the paper could be extended to the fact that the extracted map could be applied to different fields. The model is built on processing the provided data and is not restricted to a certain scheme. The remaining of the paper discusses the related work in Section II The proposed model details are discussed in Section III. The experimental study and the evaluation results are presented in Section IV. Finally, the discussion and the conclusion are presented in Section V and Section VI.

II. Related Work

Data mining and machine learning techniques have contributed to a wide range of developing intelligent recommendation systems over the years [10]. Many of the developed models achieved significant advancement in the field. These techniques can contribute from the start of the process [11] in the data pre-processing stage to the final stage of data presentation [12]. It has been proven by many research that the contribution of different models could provide more success to the recommendation process. One successful example is [13], whose aim was to recommend the price of the used cell phones based on the phone status using image processing techniques. Another research [14] followed the collaborative approach, which is also adopted in the current research, to recommend the targeted customers to grant bank loans. A survey was developed [15], which discussed the research for risk assessment and the customers' recommendation models. Another research in the banking sector [16], which reviewed the machine learning techniques that are utilized in detecting fraud in using credit cards. In the field of construction, an accurate budget recommendation was the objective of the research [17], which proposed a model for predicting the overhead cost for commercial projects. Most of the existing recommendation systems follow the seller-centric approach [18]. This approach is restricted to the seller's product availability, which could be more beneficial when extending this perspective to include a wider range of information to the user. While some research focuses on the products that are already bought by the user [19], however, extending the user focus with unintended yet related products could be a step forward in the recommendations.

A research in study [20] has presented recommendation systems using both data of the products and users' information. The proposed models utilized similarity measures for document analysis. However, the models suffered from the non-homogeneity of the items on focus during the analysis of the documents. There was also an issue in the model accuracy due to the non-dealing for the missing values. Another research in [21] depended on the users' response to the products' ratings. These models also applied similarity techniques as well as k-nearest neighbor mining algorithm. The model also suffered from the existence of synonyms while not manipulated. As the model depended on the user rating, the false rating was also considered a serious issue in the accuracy. Moreover, the research [22] focused only on demographic data such as age and gender. The model applied group recommendations using clustering techniques. However, the complete dependence on the demographic data is a major issue that hinders the accuracy. The research in study [23] proposed a content-based model for recommendations, which also depended on the user input. Although the model also highlighted the limited context input with a recommendation to the immense need for including other data perspectives and working with various types of data sources.

The research in study [24] and [25] highlighted the issue of including new items in the data sources whose ratings are not specified. This issue is called the cold start issue. The current research proposed the approach of the collaborative environment between both user and item data with pre-processing mining steps to solve this issue. Additionally, the issue of sparsity is also highlighted in the model proposed in the research [26] [27]. The prior research recommended a clustering approach to resolve this issue. While it could provide more accurate recommendations, however, the current research follows the approach of multi-leveling to further reach higher level of accuracy. The issues of scalability are highlighted in the research [28] and [29], which may be a result of the lack of user trustiness [30] and [31]. Both issues could be viewed as a dilemma situation. Therefore, working on the system performance by leveling up the users' confidence in the system recommendations is one of the motivations in the current research.

III. Proposed Model

The main target of the proposed model is to build the recommendation road map for the business on focus. The model presents the user characteristics, the possible multi-level recommendations for the users on focus as well as an exploratory map for potential users to enlarge the users' segment. The proposed model has four main stages. The following subsections discuss each stage and the included steps in detail.

A. Data Preparation Stage

1) Gather data: Data sources vary. It could be gathered from databases, users' responses, or real-time data from devices that measure and register data in a timely manner. Data could be static or streaming. These different sources of data are processed in different methods due to the difference in nature for these resources. The primary goal of this step "gather data" is the ability to collect the available data that could efficiently contribute to the recommendation main task. Data could be categorized as primary or secondary. The definition of both types varies according to the surrounding environment. One definition is the fact that the primary data is collected directly from the source itself such as the measuring devices while the secondary data is previously gathered for other reasons and could be utilized in the current task. Moreover, secondary data could be previously processed before delivery. In this section, general definition will be presented for both types as there is no restriction in the proposed model on either the data type or category. However, in the experiment section, the types of data will be explicitly highlighted.

Gathering data starts with identifying the potential data sources. The set of data sources (DS) is defined as follows:

$DS = \{ds1, ds2, \ldots.dsj | j \in \mathbb{N} \}$

DS represents the set of data sources that includes all the potential data sources. These sources could be primary or secondary. The sets of primary data sources (PDS) and secondary data sources (SDS) could be defined as follows:

$PDS = \{pds1, pds2, \ldots.pdsi | i \in \mathbb{N} , pdsi \in DS \}$

$SDS = \{sds1, sds2, \ldots.sdsk | k \in \mathbb{N} , sdsk \in DS \}$

$DS = PDS \cup SDS$

The general definition of the set of features for the data source dsk is as follows:

$Features(dsk) = \{fk1, fk2, \ldots. fks \mid k, s \in \mathbb{N}, dsk \in DS\}$

The general definition of the data sources with defining their types is as follows:

$TDS = \{<ds1, typet1>, <ds2, typet2>, \ldots.dsj | j \in \mathbb{N} \}$

2) Integrate multiple resources: The goal of data integration is enriching the model with the data from different data sources. Integrating data leads to a uniform data sources' access. Although the same feature could be a part of different data sources description, however, it could have different types. For example, the gender feature could be nominal in one source (male and female) and integer in another sources (1 and 2). Therefore, the unification process should consider a unifying pre-step for the features type. The following algorithmic steps should be applied.

```
h=1
Repeat
  For each dsh+1 in DS
        For each feature fhs in Features(dsk)
        If  fhs∈ fhs+1  & type (fhs) <> type (fhs+1)
                    unify features' types (fhs, fhs+1)
until h = k-1
```

Then, integrating the data sources requires unifying the descriptive features to allow a single view for all data. The proposed model focuses on transactional data sources. Therefore, the set of the unified criteria for all data sources after integration is as follows:

$Features(DS) = \{fks, fyt, \ldots. fwh \mid k,y,s,t,w,h \in \mathbb{N} \}$

$Features(DS) = Features(ds1) \cap Features(ds2)\ldots.. \cap Features(dsk)$

$Features(DS) = \cap_{l=1}^{k} \, Features\ (ds_l)$

3) Data cleaning: Also called "data wrangling", one of the vital steps in the data analytics process is data cleaning. The hygiene of data heavily affects the whole analytics process. The inconsistencies and existence of errors directly affect results and cause flawed data which could not be configured and leads to unreliable results. The following cleaning steps are performed.

Remove direct redundancies: two records are directly redundant when they have the same values for all of their attributes.

Consequently, the dataset dsk` represents dsk after removing the redundancies. dsk` could be defined as follows:

$dsk` = \{tn,\ldots tm\} | dsk` \subseteq dsk \mid \exists\ tg, tg \in dsk, tg \notin dsk`, tg = tt, tt \in dsk`$

Remove outlier: a record is defined to be a direct outlier if the values of its attributes do not match the standard values. It could be due to incorrect calculation or incorrect data entry. For example, a student record is an outlier if its id does not follow the faculty standards such as to be 4 digits instead of 6 digits and does not have the year as required.

The set of outliers' records of the set dsk could be identified as follows:

$Outlier(dsk`) = \{tn,\ldots tm\} | Outlier(dsk`) \subseteq dsk`$

Consequently, the dataset dsk`` represents dsk` after removing the outliers. It could be defined as follows

$dsk`` = dsk` \cap Outlier(dsk`)$

Remove contradictions: two records are contradictory if they provide conflicting data. For example, one record may include the birth date while the age does not match with this date, or the salary of the employee is less than the required salary taxes.

The set of contradictions' records of the set dsk could be identified as follows:

$Contradiction(dsk``) = \{tn,\ldots tm\} | Contradiction\ (dsk``) \subseteq dsk``$

Consequently, the dataset dsk``` represents dsk`` after removing the Contradictions. It could be defined as follows

$dsk``` = dsk`` \cap Contradiction(dsk``)$

Adapt missing values: different methods could be applied for missing values detection. A simple solution is to remove the record with the missing value while a more informative solution is to predict this value either with statistical calculation or with intelligent techniques.

B. Explore the Features' Significant Level

The goal of this stage is exploring the most informative features in the dataset. Different methods could contribute to this stage. Filtering, wrapper, and embedded categories are introduced in different research [32] [33]. The proposed model does not restrict the contribution to a certain category or method, rather, the selection of the contributing methods is based on the applying experiment. In this research, the contributing methods will be stated in the experiment section.

1) Set weighting measures: The set of the types of weighting methods is defined as follows:

WT = {T1, T2, T3}

The set of the weighting methods that belong to a one of these types is defined as follows

WM (T1) = {wT11, wT12…, wT1x}

WM (T2) = {wT21, wT22…, wT2y}

WM (T3) = {wT31, wT32…, wT3z}

The set of all weighting methods are determined which is defined:

W = {w1, w2, ….wz| z $\in \mathbb{N}$, wz $\in$ [WM (T1) | WM (T2) | WM (T3)]}|

W = WM (T1) ∪ WM (T1) ∪ WM (T1)

The weighting threshold is identified to be equal 50% (0.5)

2) Apply weighting techniques: Each weighting measure is applied on the dataset and the features weightings are determined. The set of weighted features for each weighting technique is defined as

Wgt (wz) = {<fwh, wgt_valwhz>| wz $\in$W, fwh$\in$ Features (DS), wgt_valwhz>=0, wgt_valwhz <=1}

Reversibly, each attribute is weighted by a set of weighting measures, the set of all weights for a defined attribute is as follows:

Fgt (fwh) = {<wz, wgt_valwhz>| wz $\in$W, fwh$\in$ Features (DS), wgt_valwhz>=0, wgt_valwhz <=1}

The matrix of all features' weights with respect to the weighting measures is as follows:

FT-WT = $\bigcup_{k=1}^{j}\bigcup_{l=1}^{i} \mathrm{AttWt}\,(\mathrm{j},\mathrm{i})$ where j is the feature index and i is the weighting measure index

3) Explore features' significant level: Exploring the significance of the datasets features is performed through the following steps. The exploration task is the pillar to identify the suggested associations' schemes which relies on the features according to their strength in affecting the prediction task performance. This section clarifies the steps for exploring the significance level of the features while the following sections continue to discuss how the prediction process is performed.

The first step is building the matrix for each feature with respect to the label feature y (FT-WT). This step results in identifying x-1 matrices where x is the number of features.

FT-WT (x) = $\begin{bmatrix} \mathrm{ft}_{z1} & \cdots & \mathrm{ft}_{y1} \\ \vdots & \ddots & \vdots \\ \mathrm{ft}_{zj} & \cdots & \mathrm{ft}_{yj} \end{bmatrix}$ where z ≠ y, z, y ≠ j

The matrix of each of the contributing weighting measures h highlights the contribution of a feature x on the consistency of feature y. This impact is determined by the weight of x that is determined by h given that y is the label attribute. The matrix of the weighting measure h is constructed as follows:

After applying weighting technique h on feature x with label feature y, the weights ranges are normalized by setting the value of 1 for the weights of range from 0 to <0.3, 2 for weights of 0.3 to <0.6, 3 for the weights of range 0.6 to 1, and 4 otherwise. The matrix wtxy element is the determined normalized value while the value of wtyx equals to the multiplicative inverse of the normalized value 1/ wtxy. The following matrix represents the normalized matrix of the weighting measure i for all attributes weights with considering y as the label attribute.

WTy (h) = $\begin{bmatrix} \mathrm{Nwt}_{11} & 1/\mathrm{Nwt}_{12} & \cdots & \mathbf{1}/\mathrm{Nwt}_{1j} \\ \vdots & \vdots & \ddots & \vdots \\ & \mathrm{Nwt}_{1x} & \mathrm{Nwt}_{2x} & \\ & \mathrm{Nwt}_{1j} & \mathrm{Nwt}_{2j} \cdots & \mathrm{Nwt}_{jj} \end{bmatrix}$

Following the same approach, a set of matrices are built for each attribute while considering the significance determinants (SD). The current research follows the same approach of [12]. The research adopted only three measures for λ with an acceptable accuracy percentage which confirmed the applicability of the proposed approach. However, the current research extends the contributing measures seeking targeting to raise the consistency accuracy level. The current research extends the significance determinants for each feature to include the minimum and maximum weighting value among all the weighting measures, the mean and median value of all weightings, the upper and lower inter quartile range, the mean of these determined upper and lower values of all the weightings, and the value of mean for λ. Finally, the features' level of consistency is determined according to the number of consistent determinants. In case two features have the same count of consistent determinants, then the weighting value is considered. The following rule applies for constructing the features consistency ordered set.

The set of SD for each feature ftx is as follows:

SD (ftx) = {sdt,…sdr}

The ordered set of features based on consistency level = {ftx,… fty} where (|SD (ftx)| >= |SD (fty)| & min(Fgt (ftx)) > min(Fgt (fty)))

C. Associations Exploration Stage

The core stage of the proposed model is the mining phase. Mining phase employs different methods with a variety of nature and analysis procedures targeting to recognize the non-trivial embedded patterns. Data mining is continuously contributing to the business field for many aspects. One of these aspects which is the objective of the current research is the customer. Data mining could apply collaborating techniques targeting for customers beneficiary such as intelligent advertising, recommendations, detect fraudulent, and others. In the proposed model, associations rules mining, which is one of the data mining techniques, is employed to detect the embedded schemes in data. These schemes will then be utilized to explore both direct and indirect level associations. Then, the explored associations are employed to support the following recommendation phase. The following subsections discuss the main steps of the mining stage.

1) Determine direct associations: In this step, associations rules mining algorithm is applied to the dataset in order to govern the customers' perceptions and willingness. Many algorithms are introduced for this task; therefore, the following definition is generic. However, a defined algorithm will be stated in the experimental study with a clear justification for the reason for this selection. At this step, there are no restrictions in the associations' generation. The following steps prune the generated rules to explore the first step in detecting the most vital associations to the assigned task which is based on the metrics' threshold.

∃ Assc = Ass (ftxi → ftwi) ∧ fxi , ftwi ∊ Features(DS) ∧ Support (Assc) >= SU_Threshold ∧ Confidence (Assc) >= Con_Threshold → Add_ Assc (ftwi, Pre-Accept (ci))

2) Identify direct associations schemes: Identifying the targeted schemes follows the explored significance level of the dataset features. The first step is prioritizing the influencing features with respect to the required label feature based on the influencing level. The level of influence is determined according to the consistency degree of the feature on focus with the label feature based on the previous λ measures. The second step is identifying the associations schemes to have the influencing features as premise and the label feature as conclusion. The final step is pruning the detected schemes with considering only the schemes that have the influencing features with consistency above the determined threshold. These steps are formally described as follows:

∀ ftx, ftx ∈ Features (DS), label (ftx) → ∃ fty, influence (fty, ftx)

∀ ftz, ftx, influence (fty, ftx), influence (ftz, ftx), Value (significance (fty)) > Value (significance (fty)) → ordered_significance (ftx) = {ftz, ftz,….. | fty ≺ ftz }

∀ ftz, ftx, ftz ∈ ordered_significance (ftx), significance (ftz) > consistency_Threshold →

Schemes (ftx) = Schemes (ftx) ∪ association (ftz → ftx)

3) Filter direct associations: Based on the assigned schemes, this step focuses only on a subset of the associations that satisfy the required schemes as well as the minimum threshold of the performance metrics, support and confidence. The filtering step is described as follows:

Target = { ftx,,…., fty} where ftx ∊ Features (DS), fty ∊ Features (DS)

∀ ftx, ftx, ∈ Target, ASS = association (ftz → ftx), Support (association (ftz → ftx)) >= Min_Support, Confidence (association (ftz → ftx)) >= Min_Confidence →

4) Identify indirect associations schemes Based on significant level: In this step, an argument is highlighted for the ability to gain higher recommendation accuracy by considering transitive associations. A feature may be indirectly significant to the label feature is the following rule applies.

∀ ftx, fty, ftx, ∈ Target, ASS = association (ftz → ftx), Support (association (ftz → ftx)) >= Min_Support, Confidence (association (ftz→ ftx)) >= Min_Confidence , ASS = association (fty→ ftz), Support (association (fty→ ftz)) >= Min_Support, Confidence (association (fty→ ftz)) >= Min_Confidence → Indirect_ASS(ftx) = Indirect_ASS(ftx) ∪ ASS (fty→ ftz → ftx)

Therefore, extending the previous identifying the associations schemes step is performed in the current step. After the influencing features are identified, then they are considered as label features and the same previous steps are performed. Each influencing feature is considered a label, then schemes are determined, and associations are detected with the same previous description and pruning rules. The idea of this step is extending the opportunities for higher performance recommendations based on the existence of indirect influencing features. A feature x has an influence on feature y when there exist a third feature z that is influenced by x and, at the same time, influencing y. although the origin definition of the indirect relation states that this influence exists only through the feature z, however, this relation restriction is not considered in the current relation definition. This is because the main objective of extending the relationship is to consider the related factors for highlighting more opportunities in exploring different opportunities for the most available as well as applicable recommendations with highest accuracy.

5) Extract direct & indirect associations: The final step in the mining stage is extracting the relevant associations to the assigned task. based on the task, the association scheme is determined, and its corresponding associations rules are explored. These rules are then utilized in the recommendation stage.

D. Explore Recommendations Road Map

The deliverable of the proposed model is constructed in this stage. The road map of the recommendations is developed by applying a set of steps as follows.

1) Set recommendations threshold: One of the recommendations threshold (RTH) determination methods could be a direct method as it could be decided by the responsible. Other more intelligent methods could be applied such as the proposed method in [34]. It varies according to the applied domain. Some domains require a high level of accuracy such as healthcare or tourism. Other domains do not require accuracy to be critical such as restaurants or groceries. In this stage, according to the determined recommendations threshold, the associations are pruned while the recommendation threshold matches with the associations' minimum consistency level of the premises in the association rules. the following applied in this step

∀ ass in ASS, association (ftz → ftx), | consistency (ftz) > RTH → RecASS = RecASS ∪ association (ftz → ftx)

2) Detect recommendations peaks: The recommendation peak is defined as the point that has either the maximum or minimum features values with all other features with various values. Determining the recommendations peaks of a determined features ftx is performed by capturing the set of spike points of the feature x Spike (ftx). A value is identified as a spike point of a feature fx if it is associated with most of the values of the significant feature fy in the association rules set of fx and fy. Formally speaking, Spike (ftx) is constructed by the following rule.

∀ ftx, ∀ fty , ∀ Vali(fty), ∃ association (Vali (fty) → Vali (ftx)) ∈ ASS, → ∀ Vali (fty), feature(x,y) = feature(x,y) ∪ {<Count (association (Vali (fty) → Vali (ftx))), Vali (fty) , Vali (ftx)> }

Max_Count(association (Vali (fty) → Vali (ftx))) = Vali (ftx) where ∃ <Count (association (Vali (fty) → Vali (ftx))), Vali (fty) , Vali (ftx)> and ∀ Val(fty), ∀ j, j >=0, j < | ASS| , Count (association (Vali (fty) → Vali (ftx))), Vali (fty) , Vali (ftx)> > Count (association (Valj(fty) → Valj (ftx))), Valj (fty) , Valj (ftx)>

The spike of the feature ftx with respect to the significant feature fty is determined as: Spike(fty, ftx) = Vali (ftx)

The set of all spike points of the feature ftx is determined as: Spike (ftx) = $\cup_{y=0}^{|\text{Features(dsk)}|}$ Spike (ft_y , ft_x)

IV. Experimental Study

This section confirms the applicability of the proposed model. The section discusses the applied experiments and the evaluation results. The experiments dataset includes books data which aim is for books recommendations. The dataset describes the ratings of 271379 books from 278858 users with a total of 1048755 rating records [35]. The total number of features describing the dataset are fourteen features. As mentioned in the dataset source, the dataset was collected from Amazon and the books were purchased online. The dataset was distributed over three files. The first file describes the books data (ISBN, Title, Author, Publication Year, and Publisher). The total records were a total of 271289 records. The file included incomplete records, a set of these records were missing most of the features' values and the remaining set had only one of the features with a missing value. The first set of records was removed from the dataset, this set included 38876 incomplete records which were removed. The second set included 30341 records. These values were simply retrieved as most of the features' values exist. The second file represents the users' data which are described by the user id, location, district, country, and age. The file included the data of 276271 users. A set of 4563 records had incomplete residence data while a set of 109163 records had incomplete age data. This means that a set of 162545 records had complete data of users. According to this distribution, the experiment has been limited to 162545 users and 232413 books with a total rating records equal to 645212. After preparing the data in their original files, a simple code was developed to integrate the data into a unified structure.

The next step is identify the contributing weighting measures. Eight weighting measures are included in the experiments, they are Principle Component Analysis (PCA), Information Gain (IG), Information Gain Ratio (IGR), Support Vector Machine (SVM), and Correlation. The measures were applied and Table I presents the weighting results for the features above the threshold for each measure.

TABLE I. Weighting Measures Results for the Features above the Threshold

IG		IGR		Correlation	
rating	0.896	age	0.788	rating	0.959
rating	1.134	Pub. year	0.584	publisher	1.019
author	1.107	year	0.620	age	0.912
age	0.830	author	0.560	Pub. year	0.746
Pub. year	0.783	rating	0.812	country	0.798
				author	0.794

SVM		PCA	
country	0.762	publisher	0.959
author	1.000	author	1.019
age	0.889	age	0.912
Pub. year	0.739	Pub. year	0.746
		rating	0.798
		country	0.794

The next step is to detect the attributes' consistency. Each of the weighting technique contributed in all attributes' consistency detection. Five iterations are performed for each attribute with a total of seventy iterations. The percentage matrix is calculated by determining the product values and the Eigen vector value, then at least six of the λ determents determines should be consistent in order to consider the attribute to be consistent. Table II and Table III presents the Eigen vector and λ determents for the Author attribute respectively.

TABLE II. Eigen Vector for Author's Feature

	SVM	CRL	IGR	DEV	IG	P	EV
SVM	1.000	0.900	0.250	0.500	0.100	0.007	0.019
CRL	0.657	1.000	4.475	0.650	0.140	0.228	0.679
IGR	0.253	0.224	1.000	0.850	0.900	0.051	0.152
DEV	0.899	0.900	0.980	1.000	0.100	0.050	0.149
IG	0.100	0.146	0.655	0.106	1.000	0.001	0.700

TABLE III. Λ Statistics for Author's Feature

		L	C.I	C.R	C/NC
Lmax		5.9890	0.2473	0.2208	C
Lmean		4.8490	0.0378	0.0337	C
Lmedian		5.8240	0.2060	0.1839	C
Lmin		1.0550	0.9863	0.8806	NC
Range		4.6350	0.0913	0.0815	C
Standard Deviation		1.2990			
Inter-Quartile range	0.1770	1.2058	-1.0766	0.167	C
	0.4830	1.1293	1.0083	0.413	NC
Mean (rang,UpperQ)		5.2620	0.0655	0.0585	C
Mean (rang,LowerQ)		3.9420	0.2645	0.2362	NC
Mean (range, mean)		4.5620	0.1095	0.0978	C

The same calculations are performed for the eleven feature. Four attributes are considered consistent, they are (Author, Country, Age, Year, and rating). As a final step, with considering the weights of these features to the five weighting measures, it is detected that four of the consistent attributes are significant, they are (Author, Country, Age, and rating). Therefore, these are the attributes that will contribute to the associations' exploration stage. The next phase is identifying the required associations' schemes. Following the selected features, the associations' schemes are as follows: Age → Author, Author → Age, Country → Author, Author → Country, and Author → rating. As the main label feature is the rating, therefore, the indirect associations' schemes are detected to be Age→ Authors → rating, Country → Author → rating. The final step is to identify the recommendations map. The explored map has been discussed with professors in the literature field who confirmed the strong associations and dependencies. A second evaluation step is applying a set of classification techniques over the dataset with considering only the features that are contributing in the association. The first experiment is applying five classification techniques namely K nearest Neighbor (KNN), Naïve Bayes (NB), Enhanced ID3 (EID3) and the contributing features are the age and authors with the rating as the label feature. The second experiment includes the country and authors with also the rating as the label feature. Moreover, a third experiment is conducted that includes the three features. The results reveals the high accuracy percentage which confirms the applicability of the explored associations and consequently the proposed model. Table IV demonstrates the average evaluation results for the classification experiments.

TABLE IV. CLASSIFICATION RESULTS

Criteria	**KNN**	**NB**	**EID3**
Accuracy	95.96 %	97.98 %	98.99
Classification Error	4.04 %	2.02 %	1.01
Kappa Statistic	0.937	0.969	0.984
Weighted mean recall	96.17 %	97.94 %	99.28
Weighted mean precision	95.56 %	97.52 %	98.85
correlation	0.928	0.956	0.972

V. DISCUSSION

According to the results, the proposed approach succeeds to perform effective feature selection with a generality to be applied in different fields. The presented performance measures revealed the success of the approach, however, the missing percentage in the classification task could be due to the limited number of attributes in the dataset. Datasets with higher number of attributes could results to higher performance.

VI. CONCLUSION

This research proposed an intelligent model that aims to build the recommendation road map for business. The model explores the possible multi-level recommendations for the users on focus as well as an exploratory map for potential users to enlarge the users' segment. The proposed model had four main stages which applies mining techniques in the preprocessing and explorations stages, features selection techniques for exploring the significant features and statistical techniques to more illumination for these features in order to provide the most accurate recommendations base on these features associations. The proposed model has been evaluated by applying the detailed stage on a dataset of books. The results have been evaluated by experts and by applying classification models and evaluate the classification results. The results revealed a success in the classification that ranged from 96% to 99% which ensures the model applicability. More future work could be further applied to the proposed model. Another future direction to conduct more experiments could be conducted from different fields. Investigating more methods for feature selection could be further developed. Another enhancement direction is including the users' comments and apply text mining techniques with embedding the keywords as features.

ACKNOWLEDGMENT

This work was funded by the University of Jeddah, Jeddah, Saudi Arabia, under grant No. (UJ-23-DR-13). Therefore, the authors thank the University of Jeddah for its technical and financial support.

***Abstract*—In a computational complexity theory, P, NP, NP-complete and NP-hard problems are divided into complexity classes which are used to emphasize how challenging it is to solve particular types of problems. The Knapsack problem is a well-known computational complexity theory and fundamental NP-hard optimization problem that has applications in a variety of disciplines. Being one of the most well-known NP-hard problems, it has been studied extensively in science and practice from theoretical and practical perspectives. One of the solution to the Knapsack problem is the Dantzig's greedy algorithm which can be expressed as a linear programming algorithm which seeks to discover the optimal solution to the knapsack problem. In this paper, an optimized Dantzig greedy (OptDG) algorithm that addresses frequent edge cases, is suggested. Furthermore, OptDG algorithm is compared with the Dantzig's greedy and optimal dynamically programmed algorithms for solving the Knapsack problem and performance evaluation is conducted.**

***Keywords*—Dynamic programming; Dantzig algorithm; greedy algorithm; knapsack problem; linear programming; NP-Problem; optimization; OptDG**

I. Introduction

In computational complexity theory P, NP, NP-complete and NP-hard terminology is used to denote how difficult it is to find solutions to a specific type of problem. To begin, it has to be determined whether the problems are P, NP, NP-complete, or NP-hard. A problem is P if it can be resolved in polynomial time [1]. If the suggested solution can be checked in polynomial time, the problem is NP [2]. A problem is NP-complete if it is in NP, and all other NP problems can be reduced to it in polynomial time [1]. This implies that if a solution is discovered for an NP-complete problem, it can be applied to all other NP problems. A problem is NP-hard if it is at least as difficult as the most difficult NP problems. This implies that if a solution is discovered for an NP-hard problem, it can be applied to all NP-complete problems [3]. The Knapsack problem is a well-known computational complexity theory and fundamental NP-hard optimization problem that has applications in a variety of disciplines, including operations research, cryptography, and combinatorial optimization. If a collection of items is given, each of which has a weight and a profit, and a knapsack that can only carry a certain quantity of weight, the Knapsack problem is present. The objective is to determine which subset of items can enhance the total profit of the knapsack without exceeding its carrying capacity. The 0-1 Knapsack is a variant of the Knapsack problem in which a knapsack with a specific capacity *c* and *n* items with weights $t_1, t_2, ..., t_n$ and profits $p_1, p_2, ..., p_n$ is given. The main goal is to find the item combination that maximizes the total profit of the knapsack while adhering to the weight limit, with the additional constraint that each item can only be turned on or off once, i.e., each item can only be used once. The theory can be formulated and Integer Linear Program (ILP) shown below:

$$maximize \sum_{i=1}^{n} p_i x_i \tag{1a}$$

$$subject\,to \sum_{i=1}^{n} t_i x_i \leq c \tag{1b}$$

$$x_i \in \{0,1\}, \forall i \in \{1,2,3,...,n\} \tag{1c}$$

The *n* binary variables $x_1, x_2, ..., x_n$ are decision variables that determine whether or not an item is placed in the knapsack. As part of the input, the problem parameters $c, n, t_1, t_2, ..., t_n$ and $p_1, p_2, ..., p_n$ are given. The 0-1 knapsack problem is NP-hard, indicating that exact solutions to problems with enormous inputs may be intractable. To tackle the NP-hard knapsack problem, several algorithms, including dynamic programming, branch and bound, and genetic algorithms, have been proposed. However, these algorithms only perform well with smaller quantities, i.e., in particular types of problems. As the numbers increase, it becomes nearly impossible to solve the problem.

The 0-1 Knapsack problem is a major optimization problem strongly related to a number of other major optimization problems. For example, by solving an equivalent 0-1 Knapsack problem instance, instances of the binary integer programming, and the bounded and unbounded knapsack problems can be solved. Furthermore, the 0-1 Knapsack problem arrises as a column generation subproblem of the cutting stock problem and is a particular instance of a variety of problems such as the knapsack problem with conflicts [4], [5], the traveling thief problem [6] and the multidimensional knapsack problem [7].

II. Related Work

The Knapsack problem is among the most actively researched topics in combinatorial optimization. In recent years, a vast number of the Knapsack problem variants have been addressed. The 0-1 Knapsack is the most well-known Knapsack problem, and it has been intensively studied for decades. These studies have yielded an abundance of theoretical, practical, and algorithmic findings that have, to some extent, saturated this particular field [8]. According to research conducted by study [9], the Knapsack problem is listed as one of the most popular algorithmic problems, as well as the and the second most popular problem in the NP-hard category. In this section, a brief summary of the literature regarding the 0-1 Knapsack problem is presented.

The most effective algorithms for solving the 0-1 Knapsack problem employ branch-and-bound, dynamic programming, or hybrid approaches that combine the both. Over time, a sequence of advancements resulted in the creation of MT1 [10], MT2 [11], Expknap [12], Minknap [13], and Combo [14] algorithms. The Combo algorithm is the most significant algorithm among several others. Despite being published over twenty years ago, it remains the best-known and most effective algorithm. It can solve the majority of problem instances within a few seconds. Although it shares similarities with the Minknap algorithm, Combo introduces new techniques when faced with a large number of dynamic programming states. The Combo algorithm uses a number of interesting methods, one of which is adding valid inequalities (cardinality constraints) to the formulation of integer programming, which are then relaxed to make more accurate dual bounds [15]. Previous research [12], [14], [16], [17] consistently demonstrates that Combo is typically the fastest algorithm among the five algorithms studied. In this paper, an empirical hardness model, using Combo's running time as an indicator of problem instance difficulty, is adopted. Given Combo's ability to efficiently solve most large problem instances within seconds and the (weak) NP-hardness of the Knapsack problem, researchers have expressed interest in identifying more challenging instances. While it is generally believed that such hard instances exist, the process of discovering them and understanding the key features contributing to their difficulty remains unclear. Research on instances of the 0-1 Knapsack problem often focuses on instances with considerably large coefficients, such as those exhibiting exponential growth relative to the number of items (n). Evaluating the practical difficulty of these instances does not involve using existing algorithm implementations like Combo, as most implementations support only 32-bit or 64-bit integers. Instead, these instances are examined against hypothetical sets of algorithms, considering different assumptions about the strength of the bounds employed by these algorithms. Noteworthy papers in this category include [18], [19], and [20], which describe challenging problem instances with large coefficients designed for various hypothetical algorithms. [21] and [22] introduced new branching strategies for Branch-and-Bound (B&B) methods. The analysis of how item profits or weights respond to perturbations was explored by [23], [24] and [25]. [26] focused on a specific sensitivity analysis called tolerance analysis, which can be performed in amortized time $O(c\, log\, n)$ for each item. Recent advancements in enhancing existing Fully Polynomial Time Approximation Schemes (FPTAS) were made by [27] and [28]. A sensitivity study of greedy heuristics was provided by [29] for the 0-1 knapsack problem and the subset sum problem. [30] addresses the discounted 0-1 knapsack problem (DKP), an extension of the classical knapsack problem where items are grouped into threes, and only one can be picked from each group. They suggest preprocessing and reducing the problem size before using dynamic programming using exact and heuristic fixation methods. These strategies greatly reduce DKP instance solution time, and the authors provide a new collection of more difficult instances for further evaluation.

III. Methods to Solve 0-1 Knapsack Problem

Dynamic programming is a potent methodology and optimization technique in mathematics and computer programming that allows problems to be broken down into smaller subproblems and their solutions to be saved to prevent redundant computations [31]. Dynamic programming yields accurate results for locating optimal solutions, but its computational complexity frequently renders it impractical, necessitating the use of heuristics as an alternative method. In experiments conducted in this research, adapted [32] and Dantzig's greedy algorithm, are used.

A. Dantzig's Greedy Algorithm

The Dantzig's greedy algorithm can be used to solve the 0-1 Knapsack problem. The simplex method is a method for resolving linear programming issues, and the Dantzig's greedy algorithm is a particular kind of linear programming algorithm based on it. The algorithm, which can be expressed as a linear program, seeks to discover the optimal solution to the knapsack problem. The fundamental idea behind Dantzig's method is to build a table with columns that indicate the weight capacity of the knapsack and rows that represent items. The profit of each cell in the table represents the maximum profit that can be obtained for a specific weight capacity using the items utilized up until that point. The table is filled from bottom to top. The initial step of the technique is to add the profit of the first item to the table's first row. The algorithm chooses the maximum profit for each cell based on a comparison between the weight capacity profits of the knapsack with the current item and the knapsack without it for each subsequent row. The maximum possible profit for the specified weight restriction and item count is the last number in the last row of the table. Using a straightforward dynamic programming technique, Dantzig's greedy algorithm can be implemented with a time complexity of $O(nC)$, where n is the number of items, and C is the maximum weight the knapsack can carry. Due to the need to store a table with n rows and C columns, the technique has an $O(nC)$ time complexity. Due to its assumption that each item can only be used once, Dantzig's approach can only be used to solve the 0-1 Knapsack problem. As a result, the unbounded knapsack problem cannot be resolved using it [33]. Algorithm 1 displays Dantzig's greedy algorithm.

B. OptDG Algorithm

According to Danzig's heuristic approach, it has been assumed that items from largest to smallest are placed in a knapsack, based on the $\frac{p_i}{t_i}$ (profit-over-weight) ratio. The main challenge is to increase the total profit of placing items into the knapsack in this manner by replacing a specific item or more items, if possible. The following theorem is demonstrated: if an item with profit p_i and weight t_i is removed and then one or more items are inserted to the right of the removed item in the sorted sequence, a higher weight than the deleted item should be chosen in order to to attain a higher profit. In other words, if an item is removed and replaced with another item to its right while maintaining or decreasing the total weight in the knapsack, the overall worth will either remain the same or it will drop. This theorem will be useful in two situations: first while looking for a better profit, it will be obvious that either one of the previously skipped items must be included

Algorithm 1 Dantzig's greedy algorithm for solving 0-1 Knapsack problem

```
Require: A set of items $items$, and a knapsack capacity $capacity$
Ensure: A knapsack that is packed to its full carrying capacity with items that have the greatest possible profit

  function SolveKnapsackGreedy(items, capacity)
      Sort $items$ by item $p/t$ in decreasing order
      $knapsack\_items \leftarrow []$
      $total\_p \leftarrow 0$
      $total\_w \leftarrow 0$

      for each $item$ in $items$ do
          if $total\_w + item\_weight \leq capacity$ then
              $total\_p \leftarrow total_p + item\_val$
              $total\_w \leftarrow total_w + item\_weight$
              Add $item$ to $knapsack\_items$
          end if
      end for
  return $knapsack\_items$, $total\_p$, $total\_w$
  end function
```

(i.e., the item to the left of the deleted item in the sorted list) or items with a weight greater than the weight of the removed item. Furthermore, when developing algorithms to find the optimal profit or searching for a heuristic that provides a better profit than a pre-determined one when the knapsack is full, replacements involving items with lower profit-to-weight ratios and of equal or lower total weight should not be considered. In other words, there is no need to investigate these item replacement possibilities.

Theorem 1: If $\alpha, \beta, \gamma, and \delta$ are all greater than zero, and if $\frac{\alpha}{\beta} \geq \frac{\gamma}{\delta}$, then the following holds: $\frac{\alpha}{\beta} \geq \frac{\alpha+\gamma}{\beta+\delta} \geq \frac{\gamma}{\delta}$.

Proof:

Given equation $\frac{\alpha}{\beta} \geq \frac{\gamma}{\delta}$ gives:

$$\frac{\alpha}{\beta} = \frac{\frac{\alpha}{\beta} \cdot (1 + \frac{\delta}{\beta})}{1 + \frac{\delta}{\beta}} = \frac{\frac{\alpha}{\beta} + \frac{\alpha\delta}{\beta^2}}{1 + \frac{\delta}{\beta}} = \frac{\left(\frac{\alpha}{\delta} + \frac{\alpha}{\beta}\right) \cdot \frac{\delta}{\beta}}{\left(\frac{\beta}{\delta} + 1\right) \cdot \frac{\delta}{\beta}} =$$

$$\frac{\frac{\alpha}{\delta} + \frac{\alpha}{\beta}}{\frac{\beta}{\delta} + 1} \geq \frac{\frac{\alpha}{\delta} + \frac{\gamma}{\delta}}{\frac{\beta}{\delta} + 1} = \frac{\frac{\alpha+\gamma}{\delta}}{\frac{\beta+\delta}{\delta}} = \frac{\alpha + \gamma}{\beta + \delta},$$

$$\frac{\alpha + \gamma}{\beta + \delta} = \frac{\frac{\alpha+\gamma}{\beta}}{\frac{\beta+\delta}{\beta}} = \frac{\frac{\alpha}{\beta} + \frac{\gamma}{\beta}}{1 + \frac{\delta}{\beta}} \geq \frac{\frac{\gamma}{\delta} + \frac{\gamma}{\beta}}{1 + \frac{\delta}{\beta}} = \frac{\left(\frac{\gamma}{\delta} + \frac{\gamma}{\beta}\right) \cdot \frac{\beta}{\delta}}{\left(1 + \frac{\delta}{\beta}\right) \cdot \frac{\beta}{\delta}} =$$

$$\frac{\frac{\gamma\beta}{\delta^2} + \frac{\gamma}{\delta}}{\frac{\beta}{\delta} + 1} = \frac{\frac{\gamma}{\delta} \cdot \left(\frac{\beta}{\delta} + 1\right)}{\frac{\beta}{\delta} + 1} = \frac{\gamma}{\delta}.$$

■

Theorem 2: If in the Danzig sequence, the term $\frac{p}{t}$ is to the left of the terms $\frac{p_1}{t_1}, \frac{p_2}{t_2}, ..., \frac{p_n}{t_n}$, that is, $\frac{p}{t} \geq \frac{p_i}{t_i}$ for every $i = 1, 2, ..., n$, and if $t = t_1 + t_2 + ... + t_n$ (the weight of the item inserted in the knapsack is equal to the weight of those that will be inserted instead), then it follows that $v \geq p_1 + p_2 + ... + p_n$. That is, the profit of the item initially placed in the knapsack and then removed is greater than the total profit of the items that will be placed in its place.

Proof: If instead of an item with profit p and weight t, we insert an item to its right in the sequence of items sorted in descending order by the profit-to-weight ratio, that is, if we insert an item with ratio $\frac{p_1}{t_1}$ where $\frac{p}{t} \geq \frac{p_1}{t_1}$, then it is evident that if the denominators are equal, $p \geq p_1$. That is, $\frac{p}{t} \geq \frac{p_1}{t_1}$, and $t = t_1$ implies $p \geq p_1$. Hence $\frac{p}{t} \geq \frac{p_1}{t_1}$ and $t = t_1$ implicates $p \geq p_1$. ■

Assume that instead of an item with profit p and weight t, n items are inserted to its right in the sequence of items sorted in descending order by the profit-to-weight ratio, i.e., items with ratios $\frac{p_1}{t_1}, \frac{p_2}{t_2}, \cdots, \frac{p_n}{t_n}$, and $t = t_1 + t_2 + \cdots + t_n$ are inserted, which implies:

$$\frac{p}{t} \geq \frac{p_1}{t_1}, \frac{p}{t} \geq \frac{p_2}{t_2}, \cdots, \frac{p}{t} \geq \frac{p_n}{t_n}$$

Without loss of generality, it can be assumed that the ratios $\frac{p_i}{t_i}$ are sorted in descending order. Due to lemma 1 (all weights and profits are positive), it holds that:

$$\frac{p_1}{t_1} \geq \frac{(p_1 + p_2)}{(t_1 + t_2)} \geq \frac{p_2}{t_2} \geq \frac{p_3}{t_3}$$
$$\frac{p_1}{t_1} \geq \frac{p_1 + p_2 + p_3}{t_1 + t_2 + t_3} \geq \frac{p_3}{t_3} \geq \frac{p_4}{t_4}$$
$$\cdots$$
$$\frac{p}{t} \geq \frac{p_1}{t_1} \geq \frac{p_1 + p_2 + \cdots + p_n}{t_1 + t_2 + \cdots + t_n} \geq \frac{p_n}{t_n}$$

that is,

$$\frac{p}{t} \geq \frac{p_1 + p_2 + \cdots + p_n}{t_1 + t_2 + \cdots + t_n} \, and \, t = t_1 + t_2 + \cdots + t_n$$

which implies that Eq. 4, is true, as claimed.

$$p \geq p_1 + p_2 + \cdots + p_n \tag{4}$$

In particular, it follows that when replacing an item of weight t and profit p with a set of items that have a total weight smaller than the removed item ($t > t_1 + t_2 + \cdots + t_n$), and satisfy the condition that the ratio $\frac{p}{t} \geq \frac{p_i}{t_i}$ for every $i = 1, 2, ..., n$, then it also holds that $p \geq p_1 + p_2 + \cdots + p_n$. By employing the Dantzig's greedy algorithm to fill the knapsack initially and subsequently attempting to improve the situation by replacing one item with others, an item that is heavier than the one being removed or an item that was previously overlooked or skipped during the initial filling, has to be selected. Specifically, if the knapsack has been filled to its maximum capacity C using the Danzig method, it ensures the optimal selection of items. To enhance the results further, OptDG algorithm is proposed. The algorithm removes the heaviest item from the knapsack and adds other items until equation 5 is met.

$$\sum_{n}^{i=1} t_i \leq C \tag{5}$$

Algorithm 2 OptDG algorithm for solving the 0-1 Knapsack problem

```
Require: A set of items $items$, total knapsack capacity

  end function
```

The resulting knapsack must meet an Eq. 6, and have a higher profit than the previous knapsack. If the improvement in knapsack profit is not achieved, the algorithm reverts to the Dantzig's solution. The optimization aims to maximize the knapsack's profit and approach the outcome of the optimal algorithm. OptDG algorithm, depicted in Algorithm 2, has a time complexity of $O(nC)$, where n represents the number of items and C represents the maximum weight capacity of the knapsack.

$$C - \sum_{i=1}^{n} t_i \geq 0 \tag{6}$$

IV. Experimental Results

This section provides an evaluation of the OptDG algorithm's performance in relation to Datzing's greedy algorithm (implemented using dynamic programming). Table I to Table VII present results of an experiment that benchmarked both Datzing's greedy algorithm and OptDG algorithm with different item generation strategies.

V. Discussion

This section discusses research outcomes on the optimal (using dynamic programming) algorithm, Datzing's greedy algorithm, and newly proposed OptDG algorithm.

The maximum number of items that can be placed in the knapsack remains at 20, but the total capacity of the knapsack, as well as the profits and weights of the items, vary depending on the case. In order to observe the speed of execution of a specific test case, the number of iterations was set to 100,000. This means that we generated new items 100,000 times and attempted to fill the knapsack. The number of cases and the duration of the algorithm are mean averages. In the first test case, we generated random items with weights ranging from 1 to the knapsack's carrying capacity C, and their profits ranged from 1 to 100. The outcomes for the first test case are displayed in Table I. In 4% of cases, the OptDG algorithm outperformed Dantzig's greedy algorithm, but it took longer to execute in those cases than Dantzig did in other situations. Table II shows the results of the methods that were tested, with weights equal to the knapsack's total capacity and random profits between 1 and 100. Because the heaviest item in the knapsack could not be found when all things were of the same weight, the optimized procedure in this observed scenario was never better than conventional Dantzing. Table III displays how items are organized in a knapsack, with weights equal to 5 and profits chosen at random from 1 to 100. Even in this test case, Dantzing's greedy algorithm was still superior because, like in the previous observation, it is unable to identify the heaviest item in the knapsack when all of the profits are equal. The improved approach takes twice as long as the standard Dantzig's greedy algorithm due to the time spent looking for the heaviest item, which cannot be discovered. The configuration of items in the knapsack is shown in Table IV, where the profits are equal to 5, and the weights of the items are distributed at random from 1 to the knapsack's maximum capacity. Because all items have fixed profits and the OptDG algorithm also sought the items with the highest profit, it was unable to determine the best arrangement of the items in the knapsack and did not outperform Dantzing's greedy algorithm in this case. Table V shows the combination of items when their squared profits and randomly generated weights between 1 and T are used. The OptDG algorithm exhibited the highest efficiency in the observed case in point, but since it must place items in the knapsack twice, it is frequently slower than the standard Dantzig's greedy algorithm. Table VI displays how items are arranged when the weights are created at random between the ranges of 1 and T and the profits are powers of 10. In this instance, the Dantzig's greedy algorithm and the optimal algorithm were nearly identical, and the OptDG algorithm also added to the Dantzig's greedy algorithm's strengths. As a result, the accuracy of the algorithm has increased to 100%. If the OptDG algorithm cannot find a better result, it will

return the Dantzing result. Table VII displays the results when the weights are powers of 10, and the profits are randomly generated in the range of 1 to 100.

VI. Conclusion

In this paper, the binary knapsack (KP01) problem is addressed, which is one of the most complex problems in the theory of computational complexity. Although dynamic programming yields an exact answer, it is computationally expensive for large numbers. Heuristic algorithms are used to quickly approximate results in order to speed up the process at the expense of solution precision. In this research, we looked at Dantzig's greedy algorithm, which efficiently places items in the knapsack but falls short of the dynamic programming approach's outcome in some circumstances.

In order to address this issue, OptDG algorithm is proposed. The proposed algorithm, after arranging the knapsack using the Dantzig's greedy algorithm, removes the heaviest item and attempts to add other items that are not currently in the knapsack. If the total profit of the knapsack increases, the function returns the new solution, otherwise it returns the original solution. Theoretical foundations of the proposed algorithm is described and mathematically presented. Furthermore, a benchmark for performance evaluation of the speed and accuracy metrics of the proposed OptDG algorithm, optimal dynamically programmed algorithm and Dantzig's greedy algorithm in various scenarios is conducted. In the majority of instances, the proposed OptDG algorithm outperformed the conventional Dantzig's greedy algorithm. According to the performance evaluation results, due to the additional knapsack filling, the proposed OptDG algorithm requires an additional minor time for execution which is not considered as a drawback in majority of possible applications.

The aim of our forthcoming research is to integrate further benchmark studies to enhance our comprehension of how to optimize the OptDG algorithm in regard to Dantzing's greedy model.

A Relevant Feature Identification Approach to Detect APTs in HTTPS Traffic

Abdou Romaric Tapsoba, Tounwendyam Frédéric Ouédraogo
UFR Sciences et Technologies, Université Norbert Zongo, Koudougou, Burkina Faso

***Abstract*—This study addresses the significant challenges posed by Advanced Persistent Threats (APTs) in modern computer networks, particularly their use of DNS to establish covert communication via command and control (C&C) servers. The advent of TLS 1.3 encryption further complicates detection efforts, as critical data within DNS over HTTPS (DoH) traffic remains inaccessible, and decryption would compromise user privacy. APTs frequently leverage Domain Generation Algorithms (DGAs), necessitating real-time detection solutions based on immediately accessible features within HTTPS traffic. Current research predominantly focuses on system-level behavioral analysis, often neglecting the proactive potential offered by Cyber Threat Intelligence (CTI), which can reveal malicious patterns through Techniques, Tactics, and Procedures (TTPs) and Indicators of Compromise (IoCs). This study proposes an innovative approach utilizing the MITRE ATT&CK framework to identify relevant features in the face of encryption and the inherent complexity of APT activities. The primary objective is to develop a robust dataset and methodology capable of detecting APT behaviors throughout their lifecycle, emphasizing a lightweight, cost-effective solution through passive monitoring of network traffic to ensure real-time detection. The key contributions of this research include an in-depth analysis of the encryption challenges in detecting DNS-based APTs, a thorough examination of APT attack strategies using DNS, and the integration of CTI to enhance detection capabilities. Moreover, this study introduces the KAPT 2024 dataset, generated by the KExtractor tool, and demonstrates the effectiveness of the detection model through experiments with a variety of machine learning algorithms. The results underscore the potential for this approach to significantly improve APT detection in encrypted network environments.**

Keywords*—*DNS over HTTPS; advanced persistent threats; machine learning; cyber threat intelligence; MITRE ATT&CK; domain generation algorithms

I. Introduction

Advanced Persistent Threats present significant challenges to security, representing a serious threat that demands thorough research and rigorous evaluation of effective detection techniques. These malicious actors, driven by various objectives ranging from espionage to service disruption, exploit sophisticated communication channels to establish connections with their Command and Control servers. Recent observations indicate that APT actors are increasingly leveraging DNS, even when encrypted, to establish these communications, thereby evading traditional detection methods.The use of DNS by APT actors as a communication channel can be detected through traffic analysis. However, existing machine learning-based methods for detecting malicious domains face significant challenges with HTTPS traffic because key features, such as textual and lexical domain information, NXDomain volumes, and other relevant data, are encrypted in TLS 1.3. The analysis of directly exploitable information within DoH traffic is hindered by the inaccessibility of a large amount of meaningful data, while decryption methods would compromise privacy. Another challenge, due to the evolving and stealthy nature of APT threats using DGA algorithms, is the responsiveness of malicious domain detection, which requires real-time analysis based on immediately accessible features in HTTPS traffic. The dynamic and evolving nature of these attacks necessitates immediate responsiveness, as the effectiveness of any security measure could be compromised without real-time detection [1].

Several techniques have been proposed in the literature to counter APT threats in general. Most current research on APT detection, based on machine and deep learning, focuses on behavioral analysis of attacks at the system level, thus neglecting crucial adversarial intelligence that could proactively contribute to threat prevention [2], [3]. Cyber Threat Intelligence has emerged as a potential solution to help organizations address the complex and stealthy nature of cyber threats [4]. The exploration of intelligence platforms involves extracting Techniques, Tactics, and Procedures and Indicators of Compromise on threats. TTPs and IoCs play a crucial role in identifying malicious behaviors and attack patterns specific to APTs. The term “tactics” refers to the method used by the APT to carry out the attack from start to finish. The “techniques” used by the APT during its attack describe its technological strategy to achieve its goals. Finally, the “procedure” of an APT describes the steps used by the attacker to achieve its objectives [5]. Many researchers have used machine learning to detect APT threats. However, these proposed methods do not consider detection at all levels of the APT lifecycle [6]. Additionally, the lack of datasets thoroughly exploiting the TTPs and IoCs provided by intelligence platforms does not proactively promote the detection of C&C domains submerged by DGAs, constituting a current research challenge [7]. Publicly available datasets can detect several levels of the cycle, but not the entirety of the phases, as many works have unfortunately not mentioned the use of persistence and stealth tools such as DGAs in the lifecycle. We aim to develop a system to analyze and detect malicious domains at every stage of the APT lifecycle using DNS, even when encrypted, as a communication channel. Our method must meet several key constraints, including ensuring privacy by avoiding the use of any decryption techniques and relying solely on clear-text features directly accessible from the traffic. Additionally, the solution should be lightweight and low-cost, requiring no equipment or installation on endpoints, and based on passive network traffic monitoring. Given the nature of APT threats, the method must also ensure efficiency and responsiveness, enabling quick reaction with real-time detection.

This study makes several significant contributions to the field of cybersecurity, particularly in the detection of APTs exploiting DNS. It provides a comprehensive analysis of the challenges posed by encryption in threat detection, addressing the limitations of current methods for detecting DGA attacks, which are increasingly complicated by the widespread encryption of communications. The research offers an in-depth examination of APT attack strategies, detailing the TTPs and IoCs employed by APTs to exploit DNS. Furthermore, it highlights the role of CTI platforms in enhancing detection capabilities by integrating relevant data sources and enriching detection features. The originality of this work lies in its innovative methodological approach, which combines Artificial Intelligence and Threat Intelligence to create a robust dataset, namely KAPT 2024. This dataset, coupled with importance level indicators, has been rigorously tested with various machine learning algorithms, demonstrating the effectiveness of the proposed architectural model in real-time, multi-class detection scenarios, thereby contributing significantly to the advancement of cybersecurity research.

The remainder of this paper is organized as follows. Section II provides a literature review on the subject. Section III discusses the contribution of threat intelligence in APT detection. Section IV details the steps of our proposed methodology, including the data sources used, feature extraction, and the multi-class classification module. Section V implements and evaluates the methodological approach. Finally, Section VI concludes the article and suggests future research directions.

II. Related Work

The literature review on Advanced Persistent Threats highlights the ongoing evolution of sophisticated attacks targeting computer systems and networks. Various techniques have been developed to counter APTs, with recent research emphasizing the predominant use of machine learning techniques in detecting these threats [5]. These studies underline the importance of continuous research to enhance APT detection capabilities and mitigate cybersecurity risks as threats evolve. For instance, Weiwu Ren *et al.* have analyzed the effectiveness of deep learning for precise and real-time APT detection [8], while Nkiruka Eke *et al.* proposed a hybrid model combining deep and machine learning techniques for more effective detection [9]. Manuel Miguez *et al.* contributed by proposing a cyber kill chain model and early detection methodology for APTs, stressing the importance of a strategic defense approach [10]. APT attacks, meticulously planned by malicious actors, generally involve several stages. While these actors may exhibit distinct characteristics, the phases of their attacks are typically similar, differing mainly in the tactics and techniques used in each phase. Alshamrani *et al.* categorized APT attacks into five stages: Reconnaissance, Establish Foothold, Lateral Movement/Stay Undetected, Exfiltration/Impediment, and Post-Exfiltration/Post-Impediment [11]. The authors argue that these stages can represent any APT attack, regardless of the objective. Several studies [2], [7], [9] in the literature have drawn inspiration from this schema presented in [11]. By leveraging this cycle, as done in the present study, it is possible to detect and prevent APT attacks by understanding the techniques and tactics employed by attackers [2].

CTI plays a crucial role in compiling a comprehensive database on APT behavior. CTI helps manage indicators of compromise, techniques, tactics, and protocols associated with various APT groups. Building on this foundation, Abir Dutta *et al.* proposed the integration of machine learning with a threat intelligence platform [12]. Other works [13], [14] have also emphasized the importance of CTI in enhancing enterprise resilience. Researchers like Yinghai Zhou *et al.* [15] and Nan Sun *et al.* [3] have explored the use of CTI to counter APT attacks by employing automatic extraction and analysis methods for CTI information. Additional studies [16], [17] have presented a framework for sharing CTI that incorporates machine learning models. The challenges of effective threat intelligence sharing are explored in [18], while the works mentioned in [19] propose a trust taxonomy for sharing threat information. Among the most widely used intelligence platforms is the MITRE ATT&CK matrix, which catalogues a comprehensive set of TTPs used by adversaries in each phase of their attacks [3], [5]. The matrix's database is continuously updated with contributions from the research community, making it a cornerstone for APT threat intelligence. Certain studies underscore the increasing importance of integrating threat intelligence and machine learning for defending against cyberattacks [20], [21].

While existing research underscores the importance of machine learning and CTI in detecting APT threats, it also reveals significant limitations that need to be addressed. The necessity of improving machine learning models by exploring CTI platforms for enhanced resilience is evident. However, the exploitation of TTPs and IoCs remains insufficient, as the publicly available training datasets do not comprehensively cover all stages of the APT lifecycle. Consequently, many of the proposed methods fall short of detecting APT threats across all lifecycle stages, particularly when it comes to identifying C&C domains obfuscated by DGAs. This gap highlights the need for further research and the development of innovative methodologies that can overcome these challenges and provide more effective APT detection systems.

III. Contribution of CTI in Detecting APTs

Cyber Threat Intelligence has emerged as a potential solution for companies to address the complex and stealthy nature of cyber threats [13]. Exploring intelligence platforms involves extracting TTPs and IoCs about threats. TTPs and IoCs play a crucial role in identifying malicious behaviors and attack patterns specific to APTs. TTPs describe how attackers achieve their objectives, while IoCs provide concrete evidence of an intrusion, such as IP addresses, file hashes, or malicious domain names. Various tactics, techniques, and procedures are used at each stage of an APT attack, which progresses to the next stage. Given that the TTP attribute allows profiling an APT actor, it is relevant to consider it as a constituent element of a specific detection technique, and it can be used to anticipate and identify APT attacks early [22].

By anticipating the tactics used by attackers, security teams can strengthen their defenses, identify weak points, and develop appropriate detection and response strategies. In-depth knowledge of TTPs also allows for better targeting of security investments and maximizing the effectiveness of protection tools and technologies. In this context, the use of the MITRE ATT&CK matrix proves to be a valuable asset for security professionals. The ATT&CK matrix provides a comprehensive view of the TTPs used by attackers, categorized by attack stage and target platform. By integrating ATT&CK matrix data into their security strategies, organizations can gain a deep understanding of the tactics employed by APTs, as well as the IoCs associated with each stage of the attack. MITRE ATT&CK has been used to represent APT TTPs as it provides extensive knowledge of adversary tactics and techniques based on real-world observations. The ATT&CK knowledge base has been widely used as a foundation for developing specialized threat models and techniques in the business, government, and cybersecurity sectors worldwide [5]. The choice of MITRE as a source of information on TTPs and IoCs stems from its reputation for excellence in the field of cybersecurity. In addition to the ATT&CK matrix, MITRE offers a multitude of free and paid resources, such as technical reports, analysis tools, and training programs. This wealth of resources makes MITRE an essential partner for organizations seeking to strengthen their security posture and protect against APT threats. Compared to methods proposed in the literature, the MITRE platform is better suited to APT threat intelligence, which describes TTPs in a canonical form and can more accurately extract the TTPs summarized in CTI reports [15].

One of the major aspects influencing the accuracy of Machine Learning models is the search for discriminatory features [25]. Indeed, the features designated in one APT detection solution are not necessarily applicable to another solution. The MITRE platform, by providing TTPs and IoCs about APT threats, helps us designate relevant features on the behaviors and techniques used by attackers. By analyzing this data, we can identify the specific patterns and signals associated with APT attacks, allowing us to determine which features are most likely to be relevant for detecting these attacks during each phase. For example, if an IoC indicates that an APT attack used a specific technique to compromise a system, we might select features related to that technique to strengthen our detection model. Similarly, TTPs can guide us toward the features that are most representative of the attack methods used by APTs, enabling us to better target our analysis and defense efforts. The feature selection process begins by identifying representative techniques by exploring the different phases of the APT attack (Initial Access, Execution, Persistence, Privilege Escalation, Defense Evasion, Credential Access, Discovery, Lateral Movement, Collection, Command and Control, Exfiltration, Impact) and identifying the specific techniques at each phase relevant to the type of targeted attacks. Each phase of the cycle identified on the platform is then translated into measurable features in network data. For example, the "Data Exfiltration" phase will have measurable characteristics such as statistics related to the volume of data transferred, the frequency of outgoing connections, etc. There has been immense interest in exploiting CTI, specifically for proactive cybersecurity defense. By exploring this unique dimension of cybersecurity, this research provides new insights and opens avenues for innovation in combating persistent and sophisticated threats, thereby making a significant contribution to the advancement of the field. In the following section, we will delve into the architectural model of our approach for identifying relevant features in detail.

IV. Proposed Methodology

We have already explored intelligence platforms to identify the most significant features that can contribute to the detection of APT threats and designate data sources covering all phases of the APT lifecycle in the previous section. In this section, we present the architecture used in this study, illustrated in Fig. 1. We proceed with feature extraction to construct the KAPT-2024 dataset, leveraging the selected data sources. We conclude the process by training our models with several supervised learning algorithms.

A. Data Source

The accuracy of classification models inevitably relies on the quality of the data. Exploring intelligence platforms allows us to observe the various tools, TTPs, and IoCs used by APT actors during each phase of the APT lifecycle, thereby indicating the different data sources widely referenced in the literature. These data sources, in pcap format, are selected based on the tools used to generate the traffic. These tools enable us to map the threats from each public data source according to the APT lifecycle. This is essentially what will be discussed in this subsection. In total, four data sources will be analyzed to constitute our own dataset.

1) CSE-CIC-IDS2018 on AWS: CSE-CIC-IDS2018[1], developed in collaboration between the Communications Security Establishment (CSE) and the Canadian Institute for Cybersecurity (CIC), is designed to generate a diverse and comprehensive benchmark dataset for intrusion detection. Among the simulated attacks are scenarios such as network infiltration from the inside, HTTP denial-of-service attacks, web application attack collection, brute-force attacks, and attacks based on recent vulnerabilities such as Heartbleed. CSE-CIC-IDS2018 dataset mainly covers the initial compromise, lateral movement, and camouflage phases of the APT threat lifecycle. Included attacks such as brute-force attacks, web attacks, and port scans illustrate a strong focus on the initial compromise phase, crucial for gaining initial access to target systems. Although this dataset is useful for analyzing these critical stages, it does not cover the entire APT threat lifecycle, omitting phases such as persistence, privilege escalation, defense evasion, data exfiltration, and final impact [23].

2) UNSW-NB15: The UNSW-NB15[2] dataset was specifically designed to evaluate Intrusion Detection Systems, making it a valuable tool for threat detection and prevention. With a variety of source files and a wide range of simulated attacks, UNSW-NB15 provides a more realistic and comprehensive representation of modern network traffic compared to some previous datasets like NSL-KDD. The UNSW-NB15 dataset covers several phases of the APT threat lifecycle. Fuzzers and Analysis attacks are associated with the Reconnaissance phase, where attackers gather information about potential targets. Backdoors, DoS, Exploits, and Shellcode attacks fall under the Initial Compromise phase, where attackers exploit vulnerabilities to gain access to target systems. Generic and Worms attacks are linked to the Lateral Movement phase, allowing attackers to move within the compromised network. Although the dataset provides a good representation of critical

[2] https://research.unsw.edu.au/projects/unsw-nb15-dataset

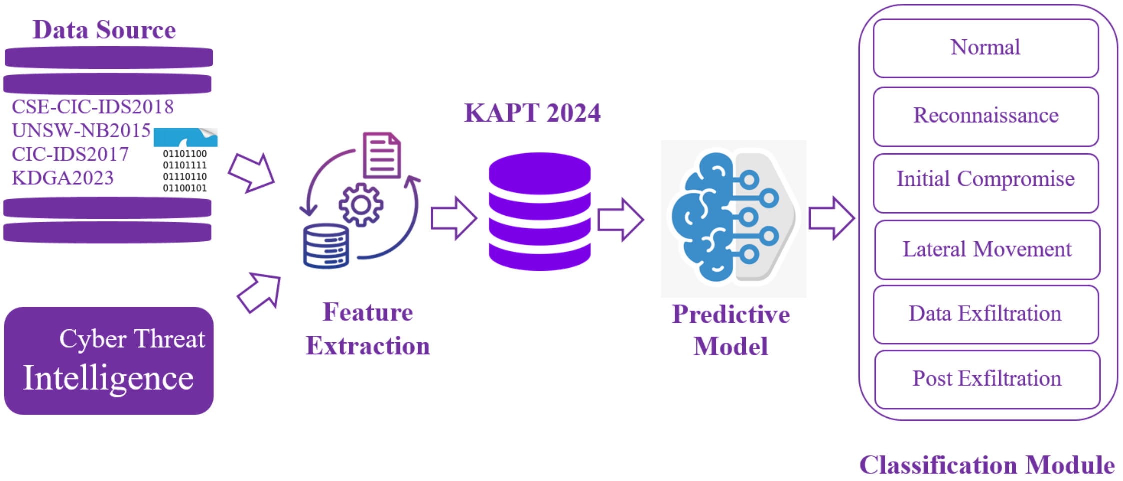

Fig. 1. The methodological structure of the proposed method.

phases, it does not explicitly cover all phases, such as data exfiltration and post-exfiltration [24].

3) CIC-IDS 2017: The CIC IDS 2017[3] dataset is designed for the evaluation of Intrusion Detection Systems (IDS) and Intrusion Prevention Systems (IPS). It contains both benign network traffic and common attacks, thus providing a realistic representation of real-world data. The attacks included in the dataset cover a wide range, including Brute Force FTP, Brute Force SSH, DoS, Heartbleed, Web Attack, Infiltration, Botnet, and DDoS. CIC-IDS 2017 covers the Initial Compromise phase with web attacks such as XSS (Cross-Site Scripting) and SQL injection attacks, as well as brute-force attacks on services like FTP and SSH. The Lateral Movement phase is represented by infiltration attacks and the use of botnets to move laterally within the network, with port scans (PortScan) being possible. The Camouflage phase includes DoS attacks like Hulk, GoldenEye, slowloris, slowhttptest, and DDoS, which seek to conceal malicious activities. However, the dataset does not seem to explicitly cover the data exfiltration phase, which is also an essential component of the APT attack lifecycle [23].

4) KDGA-Insight23: The KDGA-Insight23[4] dataset [25] is specifically designed for real-time analysis of DNS traffic, focusing on detecting malicious activities such as Domain Generation Algorithms, particularly in the context of using DNS over HTTPS. It includes 36 features extracted from pcap files, which are used to distinguish different types of DNS traffic, including DoH and non-DoH traffic, DoH-Tunnel and non-Tunnel traffic, as well as DGA and non-DGA traffic. This dataset can contribute to APT threat detection, especially regarding DGA attacks. In the context of DGA attacks, the initial compromise of a host machine is a fundamental step, corresponding to the first two stages of the APT cycle: acquiring initial access and establishing an initial foothold. Subsequently, setting up a tunnel through the Command and Control corresponds to a later stage of the APT cycle, usually associated with lateral movement within the network and exfiltration of sensitive data. This step aims to establish secret communication between the compromised machine and the C&C server, thereby allowing the attacker to access and control the network more broadly. As for the use of DGA, it may be considered in the camouflage or persistence phase, where attackers deploy sophisticated techniques to evade detection and maintain their network access over the long term. The KDGA-Insight23 dataset provides valuable information for APT threat detection, focusing particularly on DGA attacks and the use of tunnels via C&C. These aspects are closely related to several stages of the APT attack lifecycle, thereby enhancing its relevance in the cybersecurity context.

In conclusion, the use of the four datasets CSE-CIC-IDS2018, CIC-IDS2017, UNSW-NB15, and KDGA-Insight23 in our project is of crucial importance for several reasons. Firstly, each dataset offers a unique perspective on threats and potential attacks encountered in the modern cybersecurity landscape. CSE-CIC-IDS2018 and CIC-IDS2017 provide a variety of real-world attacks, allowing for the testing and evaluation of Intrusion Detection Systems effectiveness in detecting common attacks such as DoS, brute-force attacks, and web attacks. On the other hand, UNSW-NB15 focuses on detecting malicious activities related to DNS traffic, offering valuable insight into detecting DNS-based attacks, including DGA attacks. Lastly, KDGA-Insight23 specifically focuses on detecting DGA attacks in the context of using DNS over HTTPS, making it particularly relevant for detecting camouflage and persistence activities associated with APT attacks. By combining these four datasets, we are able to broadly cover the entire lifecycle of APT attacks, from reconnaissance to long-term persistence in the network. Each dataset contributes to filling the gaps of the others in terms of coverage of specific attack types and camouflage techniques used by attackers. The combined use of these four datasets allows us to benefit from a comprehensive and balanced overview of potential threats in the cybersecurity domain, thereby enhancing our ability to develop and evaluate robust and effective Intrusion Detection Systems against APT attacks. Table I represents our dataset, encompassing all phases of the APT threat lifecycle and enabling threat detection at each stage of the cycle. By extracting these features from the data sources explored in this

[4] https://github.com/artapsoba/KDGA-Insights

TABLE I. APT CYCLE DESCRIPTION AND ATTACK/TOOLS

APT Cycle	**Description**	**Attack/Tools**
Reconnaissance	Network reconnaissance, identifying vulnerabilities	PortScan
Initial compromise	Establishing a foothold in the network through various techniques	Brute Force, Sql Injection, XSS, FTP-Patator, SSH-Patator
Lateral Movement	Discovering the internal network through compromised systems and taking control of critical devices	Infiltration attack, Bot ARES
Data Exfiltration	Transferring data from local machines in the network to C&C servers, locations, or remote users	Iodine, Dnscat2, Dns2tcp
Post Exfiltration	Persisting the exfiltration process, disabling other critical components, and destroying evidence to ensure clean removal from the organization's network	DoS GoldenEye, DoS Hulk, DoS Slowhttptest, DoS slowloris, DoS Heartbleed, DDoS LOIC, DGA

subsection, our dataset stands out for its ability to capture and analyze the various aspects of APT attacks through these 87 selected features.

B. Feature Extraction and Data Pre-Processing

Lexical and textual data have largely lost their relevance due to traffic encryption. Information related to DNS, HTTP, and TLS layers, which has been successfully used in the literature, is now encrypted. The widespread adoption of traffic encryption presents fewer opportunities for security professionals and represents one of the major challenges today. This study addresses the issue of respecting user privacy while maintaining an optimal level of security. It seeks to demonstrate the effectiveness of Machine Learning methods using only the information directly accessible from DoH traffic. Feature extraction from network packets is a crucial step in network data analysis, particularly for APT detection. In this process, packets are grouped by flow to capture network interactions between specific IP addresses and ports, thereby defining forward (incoming) and backward (outgoing) flows. This grouping allows for detailed and granular characterization of data flows, facilitating the analysis of suspicious network behaviors. Forward and backward flows are used to distinguish communication directions, which is essential for identifying potential attack patterns such as unusual data transfers or suspicious responses. By analyzing features such as packet lengths, inter-arrival times (IAT), and TCP flags (PSH, URG), traffic patterns can be better understood, and anomalies indicating a threat can be detected. This approach enables the identification of not only the overall characteristics of flows but also the directional nuances that might indicate malicious activities, making the analysis more precise and relevant for APT detection. The dataset is labeled based on the tools used to generate the traffic. We extract a total of 87 features that comprehensively cover the phases of the APT lifecycle. Depending on the tools used to generate the data sources utilized in this study, we have grouped the raw data into six categories (Normal, Reconnaissance, Initial Compromise, Lateral Movement, Data Exfiltration, and Post Exfiltration) as outlined in Table I. Preprocessing involves cleaning the dataset of all its outliers. The transformations applied to this dataset include digitization, normalization, imputation of missing values, and feature selection. Normalization involves changing the range of values from a large range to a smaller one, typically [0, 1] or [-1, 1] [26]. In this study, data normalization was conducted using the *MinMaxScaler()* method from the Sklearn library, followed by data imputation, which involved removing rows with missing values. The next step focused on selecting the most significant features. This process began with analyzing the correlation between features using a heatmap, which helped identify and remove highly correlated, redundant columns, thereby simplifying the model and improving its performance. The study then employed Recursive Feature Elimination (RFE) to optimize feature selection, retaining only the most relevant variables. This approach reduced noise, improved predictive accuracy, and stabilized performance with around 55 features, leading to a more efficient and accurate model.

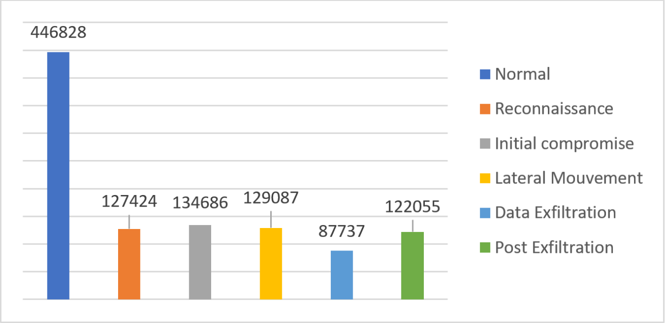

Fig. 2. Collected dataset.

C. Dataset KAPT 2024

The KAPT24 dataset is designed to address the challenges posed by APT threats. It is structured around the complete lifecycle of APT threats, covering the phases of Reconnaissance, Initial Compromise, Lateral Movement, Data Exfiltration, and Post-Exfiltration. The primary objective of this dataset is to provide a comprehensive solution for detecting APT threats by leveraging features extracted directly from HTTPS traffic. To construct this dataset, we utilized intelligence platforms such as MITRE ATT&CK to identify relevant Techniques, Tactics, and Procedures and Indicators of Compromise. This information was crucial in selecting features that effectively capture malicious behaviors. This approach allows for the detection of suspicious activities in a non-intrusive manner, making the dataset valuable for research and the development of new threat detection techniques. The data is collected and classified into different phases of the APT threat lifecycle, as illustrated in Fig. 2. This dataset includes the following categories: Normal (446,828 samples), Reconnaissance (127,424 samples), Initial Compromise (134,686 samples), Lateral Movement (129,087 samples), Data Exfiltration (87,737 samples), and Post Exfiltration (122,055 samples).

A thorough analysis is conducted to select the most relevant features, those that demonstrate a significant ability to discriminate between normal traffic and malicious traffic related to APTs. The choice of features and the method of grouping by flow are motivated by the need to capture the complex dynamics and abnormal behaviors that characterize APT attacks. The forward and backward flows provide a detailed view of network interactions, thus facilitating the identification of anomalies typical of different phases of an APT attack. The features of the KAPT24 dataset, summarized in Table II, include essential information for network flow analysis and APT threat detection.

TABLE II. EXTRACTED FEATURES

Feature Group	**Features**
Flow Identification	F01: FlowID, F02: SrcIP, F03: DstIP, F04: SrcPort, F05: DstPort, F06: Protocol, F07: Timestamp
Flow Duration and TTL	F08: Fl_Duration, F09: TTL, F10: DistinctTTLValue
Packet Counts	F11: Tot_Fwd_Pkts, F12: Tot_Bwd_Pkts, F13: TotLen_FwdPkts, F14: TotLen_BwdPkts
Packet Length Statistics	F15: Fwd-Pkt_Len_Max, F16: Fwd-Pkt_Len_Min, F17: Fwd-Pkt_Len_Mean, F18: Fwd-Pkt_Len_Std, F19: Bwd-Pkt_Len_Max, F20: Bwd-Pkt_Len_Min, F21: Bwd-Pkt_Len_Mean, F22: Bwd-Pkt_Len_Std
Flow Rates	F23: Flow_Byts_sec, F24: Flow_Pkts_sec
Inter Arrival Times	F25: Flow_IAT_avg, F26: Flow_IAT_Std, F27: Flow_IAT_Max, F28: Flow_IAT_Min, F29: Fwd_IAT_Tot, F30: Fwd_IAT_avg, F31: Fwd_IAT_Std, F32: Fwd_IAT_Max, F33: Fwd_IAT_Min, F34: Bwd_IATTot, F35: Bwd_IAT_avg, F36: Bwd_IAT_Std, F37: Bwd_IAT_Max, F38: Bwd_IAT_Min
Flag Counts	F39: Fwd_PSH_Flags, F40: Bwd_PSH_Flags, F41: Fwd_URG_Flags, F42: Bwd_URG_Flags, F54: FIN_Flag_Cnt, F55: SYN_Flag_Cnt, F56: RST_Flag_Cnt, F57: PSH_Flag_Cnt, F58: ACK_Flag_Cnt, F59: URG_Flag_Cnt, F60: CWE_Flag_Cnt, F61: ECE_Flag_Cnt
Header and Byte Metrics	F43: Fwd_Header_Len, F44: Bwd_Header_Len, F45: Fwd_Byts_sec, F46: Bwd_Byts_sec, F47: Fwd_Pkts_sec, F48: Bwd_Pkts_sec
Ratios and Averages	F62: Down_Up_Ratio, F63: Pkt_Size_Avg, F64: Fwd_Seg_Size_Avg, F65: Bwd_Seg_Size_Avg, F66: Fwd_Byts_blk_Avg, F67: Fwd_Pkts_blk_Avg, F68: Fwd_Blk_Rate_Avg, F69: Bwd_Byts_blk_Avg, F70: Bwd_Pkts_blk_Avg, F71: Bwd_Blk_Rate_Avg
Subflows	F72: Subflw_Fwd_Pkts, F73: Subflw_Fwd_Byts, F74: Subflw_Bwd_Pkts, F75: Subflw_Bwd_Byts
Initial Window Metrics	F76: Init_Fwd_Win_Byts, F77: Init_Bwd_Win_Byts
Active and Idle Times	F78: Fwd_Act_Data_Pkts, F79: Fwd_Seg_Size_Min, F80: Active_Mean, F81: Active_Std, F82: Active_Max, F83: Active_Min, F84: Idle_Mean, F85: Idle_Std, F86: Idle_Max, F87: Idle_Min

D. Classification Module

To evaluate the performance of our classification model, we employed six state-of-the-art algorithms. Each of these algorithms was selected for its distinct capabilities to handle complex data and deliver accurate results in various contexts. Using these supervised learning algorithms, we constructed detection models based on the features extracted from the KAPT24 dataset. This dataset, rich in information and meticulously annotated, served as the foundation for training our models. Through this training, the models have acquired the ability to effectively predict APT threats at each stage of their lifecycle. Specifically, our classification models were designed to identify and categorize malicious activities into six distinct categories: Normal (Stage 0), representing benign or normal activities that pose no threat; Reconnaissance (Stage 1), involving information-gathering activities where the attacker searches for vulnerable entry points; Initial Compromise (Stage 2), which marks the phase where the attacker successfully compromises the target system initially; Lateral Movement (Stage 3), referring to movement within the network, allowing the attacker to navigate and extend access to other systems; Data Exfiltration (Stage 4), where the attacker extracts sensitive information from the target network; and Post Exfiltration (Stage 5), encompassing post-exfiltration activities that typically include attempts to cover up traces of the attack or maintain access to the compromised system.

The integration of these algorithms into our classification module has enhanced the accuracy and reliability of threat detection. Each algorithm brings a unique approach to data analysis, capturing various nuances of malicious behaviors. For example, Random Forests and Support Vector Machines provide robust perspectives in terms of classification, while ensemble algorithms like XGBoost, LGBM, and CatBoost optimize performance through sophisticated aggregation methods. The Multi-Layer Perceptron leverages neural networks' capabilities to model complex relationships between features. Similarly, Koala *et al.* employed a comparable approach by using multiple machine learning algorithms to analyze application behavior through event traces in detecting security vulnerabilities [**?**]. The use of these cutting-edge algorithms has enabled the creation of a sophisticated and effective classification model, capable of detecting and categorizing APT threats across all phases of their lifecycle, ensuring proactive and robust defense against advanced cyber threats. Building on the proposed methodology, the next section will focus on the practical implementation and evaluation of this approach, demonstrating its effectiveness in real-world scenarios through comprehensive experimentation and analysis.

V. IMPLEMENTATION AND EVALUATION OF THE APPROACH

In this section, we transition from the theoretical foundation provided in the proposed methodology to the practical implementation of our approach. The main objective of implementing this approach is to demonstrate its real-world applicability, especially given the evolving and adaptive nature of DGAs. To this end, we developed a Flask application using Python, capable of capturing real-time network traffic, extracting key features, and analyzing them through a pre-trained classification model integrated into the system. For packet manipulation, we utilized the Scapy library, which allows for efficient packet sniffing and feature extraction. The system is designed to operate in real-time, predicting whether the sniffed packet is benign or malicious, thus offering an immediate response to potential threats.

Additionally, we integrated a graphical user interface (GUI) using Tkinter to streamline user interaction, making the system more accessible and user-friendly for practical deployment. This real-time capability is crucial for staying ahead of the constantly evolving DGA tactics and bolstering cybersecurity defenses.

In this section, we will thoroughly evaluate the relevance of the extracted features using performance indicators to ensure the system's predictions are both accurate and reliable. Finally, we will conclude by presenting the results of various performance metrics that validate the robustness of our approach, highlighting its capacity to detect APT threats in real-time environments.

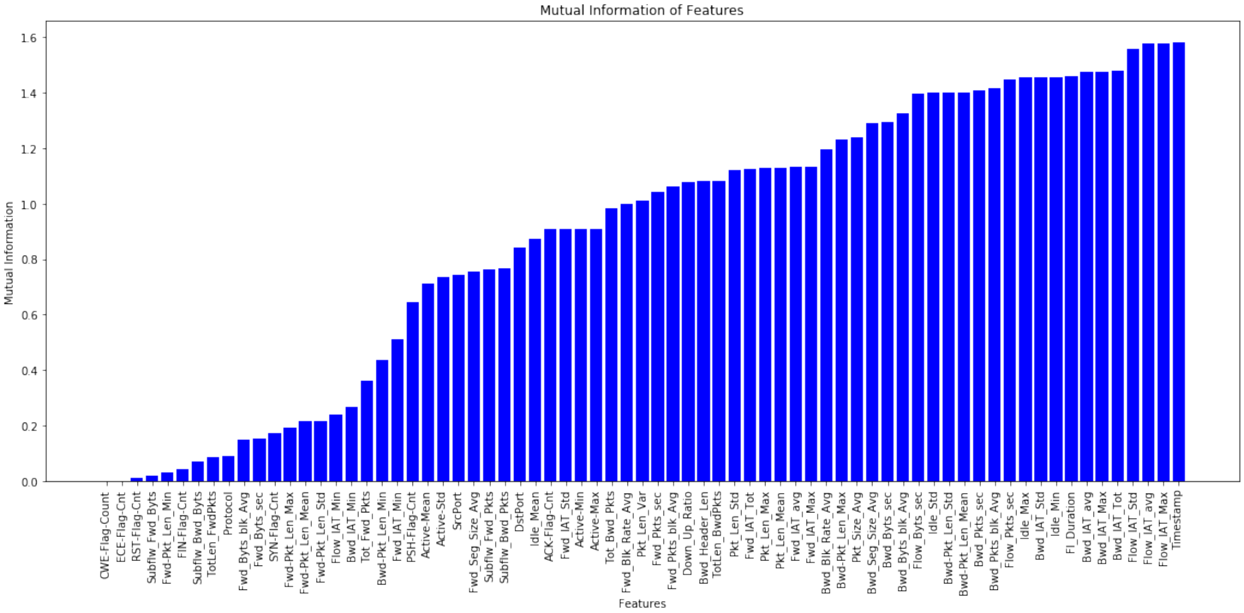

Fig. 3. Feature importance using mutual information.

A. Relevance of Features Analysis

Mutual information is a measure that captures nonlinear and independent relationships in data distribution, making it more flexible than methods like Pearson correlation or ANOVA. Unlike Pearson correlation, which only measures linear relationships, or chi-square tests, limited to categorical variables, mutual information is robust to monotonic transformations and useful for both continuous and categorical variables. It also outperforms model-based feature importance methods in machine learning by avoiding bias towards features with more levels. Fig. 3 presents the mutual importance of features in the KAPT 2024 dataset, used to address challenges posed by APT. The vertical bar chart displays features on the horizontal axis and their mutual importance values on the vertical axis. This visualization highlights that virtually all features have notable mutual importance, suggesting that the feature set is relevant for detecting APT threats.

In summary, we can conclude that the selected features contribute, to varying degrees, to the classification process of the models. This provides a solid starting point for training our models with supervised learning algorithms, whose very satisfactory results are detailed in the following subsection.

B. Results Analysis

In this subsection, we analyze the results obtained from applying various machine learning algorithms to our dataset. The confusion matrix is a crucial metric for evaluating classification models in machine learning, particularly in the context of multi-class classification problems [30]. It provides a detailed view of the model's performance by showing not only the number of correct predictions but also the types and quantities of errors made. From the confusion matrix, various performance metrics such as precision, recall, F1 score, and accuracy can be calculated for each phase individually, offering a more nuanced evaluation of the model's performance. It also helps identify if certain classes are systematically under-predicted or over-predicted, which is particularly useful in imbalanced datasets where some classes may dominate. By using ensemble algorithms such as XGBoost, CatBoost, and LightGBM, as well as algorithms like Random Forests, SVMs, and MLPs, the classification performances of these algorithms are compared and evaluated in a multi-class approach for each of the 6 stages of the APT lifecycle. To ensure the integrity of the evaluation, we followed a methodical approach by mixing samples from each class before splitting them into distinct training and test sets. The results of these evaluations are concisely summarized in Fig. 4, which represents the average metrics across all phases of the cycle [31].

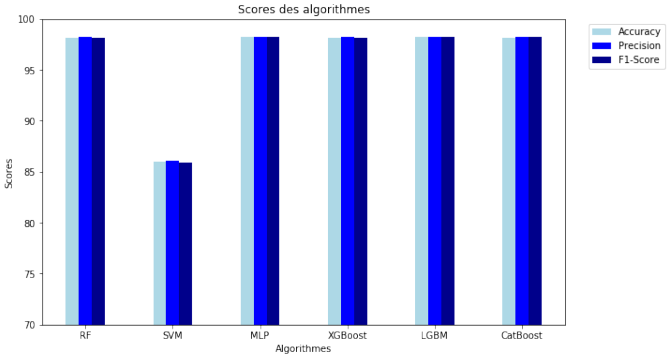

Fig. 4. Simulation results.

The graph shows that the MLP, LGBM, XGBoost, CatBoost and RF algorithms achieve very high and similar scores in terms of Accuracy, Precision, and F1-Score, indicating their effectiveness for this dataset.

Regarding the results from the confusion matrix analysis, let's focus on the MLP case, which offers very satisfactory

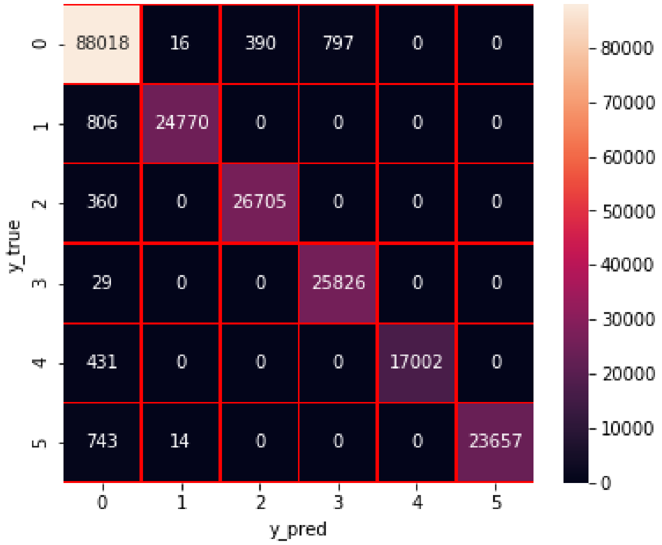

Fig. 5. Confusion matrix for MLP.

results. The confusion matrix for the MLP algorithm (Fig. 5) shows robust overall performance in classifying the different classes, with high numbers on the diagonal representing correct predictions. For example, class 0 is well predicted with 88,018 instances correctly classified, while classes 2 and 3 also show high classification rates, with 26,705 and 25,826 instances correctly classified, respectively. However, some classification errors, though minor, are present, as indicated by the off-diagonal values. False positives, such as the 797 instances of class 0 incorrectly classified as class 3, and false negatives, like the 806 instances of class 1 predicted as class 0, highlight the limitations of the algorithm.

The results obtained from our study have exceeded our expectations, confirming the effectiveness of our proposed solution. Our approach aims to provide a cost-effective and privacy-conscious method that is highly responsive to the evolving nature of APT threats targeting DNS. Initially, we identified 87 plaintext features that are directly accessible without the need for third-party equipment to decrypt data. Subsequently, we developed a lightweight application for capturing traffic, which demonstrated its capability to analyze network traffic in real-time and detect APT threats effectively. Furthermore, the integration of the MITRE framework has provided a comprehensive understanding of APT behaviors, enabling proactive threat detection. This makes our approach not only more efficient and effective but also lightweight and secure, addressing critical concerns in cybersecurity.

VI. Conclusion

The absence of significant features due to encryption in TLS, the limited exploitation of intelligence platforms in the search for proactive solutions, and the lack of training data covering all stages of the APT lifecycle underscore the importance of a balanced understanding of adversaries' behaviors, capabilities, and intentions for effective defense against APT threats targeting DNS. This study sought to develop a comprehensive approach for analyzing and detecting malicious domains throughout the entire APT lifecycle. The method had to meet several constraints: strict privacy compliance, lightweight and low operational cost, as well as optimal efficiency and responsiveness. To address this challenge, we developed a distinctive feature extraction module by analyzing TTPs and IoCs from APT threats using the MITRE ATT&CK matrix, thus contributing to the identification of features and data sources for building a dataset covering all phases of the APT lifecycle. Another major contribution of this study lies in the focus on detecting C&C servers and tools such as DGAs within the APT lifecycle.

Our experiments were conducted using six machine learning algorithms enabling a thorough evaluation of our approach's performance in a multi-class framework. This novel approach, which integrates intelligence platforms and importance indicators, has proven effective in detecting APTs throughout their entire lifecycle. The results obtained open promising perspectives for the continuous improvement of threat detection systems. Our future work will focus on establishing an intelligence platform aimed at sharing threat information within a trust circle for stakeholders with common challenges and strategies. Community sharing allows for alerting others about the occurrence of a probable attack and benefiting from feedback on how to counter a threat.

Abstract—**Manual interventions continue to be used in fruit-picking and billing at large-scale fruit storage facilities. Recent advances in deep in learning approaches, such as one-stage detectors like You Only Look Once (YOLO) and Single Stage Detector (SSD), as well as two-stage detectors like Faster RCNN and Mask RCNN, aim to streamline the processes involved with fruit detection and enhance efficiency. However, these frameworks continue to suffer with multi-scale objects, in terms of performance and efficiency due to large parameter sizes. These problems increase when multi-class fruits are encountered. We propose an improved version of the one-stage detector framework YOLOv3 for multi-class fruit detection. Our proposed model addresses the challenges of multi-scale object detection and detection of different fruit types in an image by incorporating CNN, bottleneck, and Spatial Pyramid Pooling Fast (SPPF) modules in the Head, Neck, and custom backbone of the YOLOv3 framework. Optimization of learnable parameters for computational efficiency is achieved by concatenating features at different feature map resolutions. The proposed model incorporates fewer layers and parameters compared to YOLOv3 and YOLOv5 models. We performed extensive testing on three datasets downloaded from Roboflow and compared them with YOLOv3 and YOLOv5 models. Our model achieved mAP50 of 0.747 on Dataset 1 comprising images of apples, bananas, and oranges whereas Dataset 2 consisting of images of apples, oranges, lemon, and Pear, achieved mAP50 of 0.981. Testing the Mineapple dataset comprising on-tree images of apples of varied sizes, achieved an accuracy of 0.643. We observe that the performance of our model beats the performance of the YOLOv3 and YOLOv5 models.**

Keywords*—*Precision agriculture; yield estimation; fruit detection; YOLOv3; feature concatenation; spatial contexting

I. Introduction

With the growing population, providing food security is of utmost concern. Precision Agriculture comprises methods to optimize resources by automation of agricultural tasks like sowing, weeding, spraying, and harvesting driven by technology which helps in increasing food production [1]. Before harvesting, Yield estimation is necessary to avoid post-harvest losses of fruits caused by harvesting raw or overripe fruits [2], [3]. Accurate counting and effective invoicing of these fruits during harvest [12] and their storage in the warehouse are critical to orchard profitability. However, the current method of counting fruits, which involves physical labor, takes a long time, is prone to error, cannot keep up with the volume, and is negative to schedule management. Orchards with multiple types of fruits pose a challenge. Automating this process with robots is a viable answer [15], but these robots need powerful computer vision systems to detect and locate the different types of fruits in the orchard and warehouse environments. Adding to this, challenges, including various fruit sizes, colors, and dense foliage, make detection more difficult. The key feature of object identification is central to this vision system, allowing the robots to discern between different fruit types and perform appropriate picking and billing activities.

Fruit Detection models designed by many researchers prioritize certain properties of fruits to improve accuracy through specialized methods. Commonly used detectors include Mask RCNN[9], Faster RCNN[8], and different versions of YOLO (3, 4, 5, and 8), along with DenseNets and ResNets[11] as feature extractors. Visual attributes like color, texture, shape, and size are important properties for recognizing fruits. across different growth stages need to be considered to differentiate between fruit types. Detection of different types and sizes of fruits in an image is a challenging problem. Detecting inter-class similarities and intra-class variations is possible by a combination of low-level features and high-level semantics. In this study, we propose a fruit detection model with a custom backbone network for feature extraction at multiple levels. The YOLOv3 algorithm caught our attention, particularly through its simplicity coupled with precision without compromising speed. YOLOv3 is often used as a base model for modifications leading to continuous improvement, such as in [11], and has relatively lower training times to help achieve this. These reasons inspired us to make good use of it to develop an advanced one-stage fruit detection model. While deep convolutional networks have shown promise in fruit detection, we identified key challenges that serve as the primary objectives this research aims to solve: 1. Creation of lightweight models for practical use. 2. Effectively handling objects of different scales. 3. Achieving strong performance while maintaining efficiency rampant among fruit detection studies. 4. Training the model successfully on images such that each image has objects of different classes.

We decided to achieve this by constructing our own variant of the YOLOv3 [4], one that would take on all four challenges while providing much better results. Our proposed model addresses these challenges by incorporating special modules and optimizing parameters for computational efficiency. The model shall work on both single class as well as multi class fruit detection. We utilized three key datasets, one of which is a benchmark dataset, detailed further in Part C of the Methodology section. Detailed explanations of our novel methods are provided in the Proposed System section in this paper, showcasing our contribution to advancing fruit detection technology, while the next subsection is a tiny yet precise gist of why we chose our system in the first place.

A. Our Contributions

1. We modified the existing Darknet-53 Backbone of the YOLOv3 model by including multi-scale feature extraction and then arranging bottleneck layers to reduce the dimensionality of feature maps making the network more computationally efficient. In the head part of the model, high-level semantic features are concatenated with low-level details so that fruits of different sizes can be detected. With these modifications, our model can now facilitate the acquisition of more discriminative features by allowing gradients to flow directly during training. It also solves the challenge of detecting fruits of varying sizes.

2. Our model is trained on three datasets to prove effectiveness: Dataset 1 and Dataset 2, which consist of images of different fruits (mixed fruits), and Dataset 3, comprising of the Benchmark Mineapple Dataset consisting of apples in a dense orchard environment.

3. We have evaluated the model using various Performance metrics: Precision, Recall, mAP@50 & mAP@90 and then compared the results with YOLOv3 and YOLOv5l. Notably, running our model on Dataset 1 produced a mAP@50 of 0.747 , 0.981 on Dataset 2 and 0.643 on Dataset 3. The model achieved a higher mAP@50 on Dataset1 and Dataset3 and a higher Recall on all 3 datasets when compared with YOLOv3 and YOLOv5l models.

4. While designing the Backbone network, care was taken that the number of layers and number of parameters in our model are less then those in the standard YOLOv3 model and YOLOv5l model.

B. Organization of the Paper

The paper is organized as follows : The Section II is a detailed survey of existing research in the field, followed by Section III comprising of the dataset characteristics, our proposed system and subsequent model training. In Section IV are the results and discussions followed by the Conclusion.

II. Related Work

Before delving into our own model, we explored various research contributions, each shedding light on distinct advancements in real-time fruit detection. The study in [5] utilizes the YOLOv4 neural network to enhance real-time banana recognition in complex orchards. It addresses similarity, occlusion, and uncertainties by extracting complex features. The model, based on YOLOv4 with CSPDarknet53, includes the FPN+PAN module, SPP module, and Mish activation function. The DIOU_nms algorithm improves detection confidence. Comparisons show YOLOv4 surpasses YOLOv3 and traditional methods in accuracy and speed, with an average execution time of 0.171s and a detection rate of 99.29%. The YOLOMuskmelon model /citec2, blends speed and accuracy for enhanced fruit detection. It features a ResNet43 backbone with ReLU activation, SPP for improved accuracy, FPN for efficient feature extraction, and DIoU NMS for efficiency. With an AP of 89.6%, it outperforms YOLOv3 and YOLOResNet50 but slightly lags YOLOv4 at 91.6%. Notably, it operates at 96.3 fps, faster than YOLOv3, YOLOv4, and YOLOResNet50, highlighting its potential for real-time fruit harvesting robots due to its speed advantage over YOLOv4. A bottleneck network module C2f is the building block in the YOLOv8 model for feature extraction. In study [7] YOLOv8 model achieved mAP50 of 99.5% for ripeness detection of apples and pears. Results were compared with CenterNet model with ResNet50 backbone. A light-weight model based on YOLOv5 for real-time applications is proposed in study [8] to detect strawberry fruits. A detection speed of 7.30ms and average precision 89.7% is reported. An attention module integrated with YOLOv7 in study [9] to detect kiwi fruits. Channel and spatial features extracted by the attention module improve the accuracy of detecting small and overlapping fruits. Comparison results of YOLOv8 and Mask RCNN in [9]show that YOLOv8 is better than Mask RCNN in terms of accuracy and speed. An experiment to detect objects of two types, trunks and apple tree branches, and next to detect green apples in an orchard environment confirmed the suitability of YOLOv8 for real-time detection for applications in robotic harvesting. To enhance real-time fruit recognition speed and accuracy, [11] introduces YOLOv5s. It targets applications on low-power devices and fruit-harvesting robots [16]. Adjustments to the backbone network, adaptive image scaling, and computed anchor boxes were made using a dataset of 1,350 strawberry and 1,959 jujube photos. Improvements like Stem, AC, Maxpool, CBS, SPPF, and CAM enhance adaptability to low-power devices. Validation and test results show mAP values of 93.4% and 96.0%, respectively. Operating at 74 fps on videos, YOLOv5s outperforms models like YOLOv4-tiny, YOLOv7-tiny, and GhostYOLOv5s in robustness and efficiency. This study [12] introduces a multi-cluster green persimmon recognition approach using an enhanced Faster RCNN model. It utilizes a dataset of 9,300 images captured under diverse natural light conditions, including scenarios with multiple fruits, leaf shadows, and overlapping clusters. The upgraded model integrates a weighted ECA mechanism into three key feature layers and enhances the DetNet feature extractor to balance information levels. It incorporates multi-scale features and employs K-means clustering for bounding box clustering and anchoring. Achieving a mAP of 98.4%, the model surpasses the traditional Faster RCNN by 11.8%, demonstrating significant improvements in identifying green persimmons, especially in complex and obscure environments. An input comprising of RGB and HSV images of Oranges fed to MaskRCNN improved segmentation accuracy in [13] Next, [14] uses the VGG16 architecture and Faster R-CNN model to detect kiwifruits in orchard photos under varied lighting and time conditions. With a dataset of 2400 images at 2352x1568 resolution, each containing at least 30 kiwifruits, the model excels in recognizing kiwifruits despite occlusion, overlap, and lighting variations. Outperforming ZFNet, it proves effective in dynamic agricultural settings, ensuring high accuracy and minimal false negatives in kiwifruit identification.

In this study [11], authors enhance the YOLOv3 model for automated oil palm loose fruit identification, integrating DenseNet for feature reuse, swish activation, and multi-scale detection to improve small object accuracy. Diversifying a dataset from 700 UAV and mobile camera photos to 6300 images, they boost model performance across detection metrics. Outperforming YOLOv3, Faster R-CNN-ResNet101, YOLOv3 tiny, YOLOv2, and SSD-MobileNet, the model achieves superior average precision, overlap metrics, and F1-score while maintaining computational efficiency.

A study [12] introduces a real-time olive fruit detection system using advanced deep learning frameworks like YOLOv5x, YOLOv5s, and YOLOR. YOLOv5s combines YOLO Layer, PANet, and CSPDarknet for detection. With 40,834 annotated olive fruit images, the system achieves 62 FPS detection speed and the highest 0.75 mAP_0.5 precision, making YOLOv5s the optimal choice for automating olive harvesting challenges. The project [17] applies deep learning to enhance papaya recognition in natural orchard settings. The YOLOv5s-Papaya model integrates bidirectional weighted feature pyramid network, Ghost module, and coordinate attention module for dense multitarget detection. Utilizing mosaic data augmentation, adaptive anchor computation, and PANet framework ensures multiscale feature fusion. With 1,000 diverse photos, the model achieves 92.3% average precision, 83.4% recall, and 90.4% precision, surpassing previous YOLO versions. The working of Two-stage Detectors and YOLO architecture and its successors have been reviewed in [18] A study [19] extensively examines the YOLO series, assessing their designs, regression methods, and performance on MSCOCO and Pascal VOC datasets. YOLO models demonstrate superior detection accuracy and speed compared to two-stage detectors like RCNN, Fast-RCNN, and Faster-RCNN, making them ideal for real-time applications in machine learning and deep learning tasks. An attention mechanism to improve the localization of fruits is introduced in YOLOv5 architecture between the backbone and neck region in [20]. Results on fruits like apple, oranges, grapes on state-of-the-art models show that the proposed model has a better target detection and generalization ability.The bidirectional attention mechanism extracts features from horizontal and vertical directions, assigns weights followed by concatenation. The paper in study [21] presents the GCS-YOLOV4-Tiny model, which enhances the YOLOV4-Tiny architecture for faster fruit detection by integrating spatial pyramid pooling (SPP), squeeze and excitation (SE) modules, and group convolution. Evaluations on Mango YOLO, Rpi-Tomato, and F. margarita datasets demonstrate significant improvements over YOLOV4-Tiny, achieving a 17.45% increase in mean average precision and a 13.80% rise in F1-score. These enhancements optimize both accuracy and speed in fruit detection tasks. In [22], authors have proposed a system for selecting image regions based on features like LBP, HOG, color histograms, and shape features with a weighted score for combining features. Improvement of region proposals based on Edgeboxes are proposed. A dataset of 18,155 images like apples, pears, kiwis, and persimmon are trained on the system and then compared with DPM (Deformable Parts Model), CNN with SVM and Faster RCNN.A detection rate of 0.9632 and a FPPI (False positive per image) of 0.0682 is reported. In this study, multiple types of fruits within the same image are included in the dataset. It is found that almost all studies have performed detection on images having fruits of single type within an image. The study on muticlass fruit detection with multiple fruits within the same image is carried out in study [22] and study [10]. In study [22], a custom region selection method is proposed and has very good accuracy when compared with Faster RCNN and other models. Faster RCNN F1 score is also nearly equal to the new method. The images are multiclass but fruit instances are not overlapping or together. In study [10] multiple types of classes like trunk and branches are detected in an image.

III. Datasets and Methodology

Extensive studies over the backbone network of YOLOv3 model and family of YOLO object detectors went into the initial part of our research. Architectural patterns in the detector were interpreted to understand how the detector captures various features. The next step was to examine existing research like those seen in sSection II to understand modifications in standard YOLOv3 and YOLOv5 models and their weak points which would grant us clarity as to what novel changes we could make to the single stage detector to overcome challenges with fruit detection in particular. This section is a detailed account of the technicalities behind a standard YOLOv3 detector and then the step by step working of our proposed system. We also formally introduce each dataset with its contents and their specifications.

A. YOLOV3 Model

YOLOv3 (You Only Look Once, Version 3) emerges as a pivotal advancement in real-time object detection, brought to fruition by the collaborative efforts of Joseph Redmon and Ali Farhadi. Building upon the foundations laid by YOLO and YOLOv2, YOLOv3 represents a significant leap forward in accuracy and speed, setting new benchmarks in the field. Released in 2018, this iteration refines its predecessors' successes while introducing key architectural intricacies that elevate its performance.At its core, YOLOv3 utilizes a variant of Darknet, originally a 53-layer network trained on ImageNet, which has now evolved into a 106-layer fully convolutional architecture tailored specifically for object detection tasks. This expanded architecture enables YOLOv3 to process images comprehensively, integrating global context during inference and improving its accuracy in detecting various objects.

The algorithm operates as a Convolutional Neural Network (CNN), drawing inspiration from ResNet and FPN architectures. Darknet-53, YOLOv3's feature extractor, incorporates skip connections and three prediction heads, facilitating spatial compression and precise detections. These architectural enhancements contribute significantly to YOLOv3's ability to detect objects accurately and efficiently in real-time scenarios.

In comparative evaluations against other popular frameworks like Faster R-CNN and MobileNet-SSD, YOLOv3 consistently demonstrates its superiority. It achieves a remarkable 37 mAP on the COCO-2017 validation set at 608x608 resolution, outpacing Faster R-CNN architectures while maintaining a significant speed advantage—17 times faster, to be exact. This speed-to-accuracy ratio positions YOLOv3 as a leading choice for real-time object detection tasks, especially in scenarios requiring rapid and precise identification of objects.

Anchored on concepts like anchor boxes, k-means clustering, and a meticulously designed network structure, YOLOv3 excels in detecting small targets with exceptional accuracy, making it a preferred solution for a wide range of applications demanding robust and efficient object detection capabilities.

1) Bounding Box Prediction in YOLOv3: In the context of YOLOv3's object detection technique, bounding box prediction entails generating bounding box attributes such as coordinates and size. This operation is facilitated by 1 x 1 detection kernels, which have the following shape: 1 x 1 x (B x (5 + C)). Here, B specifies the number of bounding boxes per cell, '5' represents the box attributes (x, y, width, height, confidence), and C denotes the number of classes. This method allows YOLOv3 to correctly forecast multiple bounding boxes for each object class in an image. Object confidence is an important factor in assessing if an object is present within a predicted bounding box. This confidence measure is generated using binary cross-entropy, which assesses the likelihood of an object appearing within a certain bounding box region. A higher object confidence score implies a larger possibility of the object's presence, whereas a lower score indicates a lower probability.

Bounding Boxes Prediction:
Shape: $1 \times 1 \times (B \times (5 + C))$
Where B represents the number of bounding boxes per cell, 5 denotes the box attributes (x, y, width, height, confidence), and C signifies the number of classes.
Object Confidence:
Object Confidence = $p(\text{Object}) \times \text{IoU}_{\text{pred}}^{\text{truth}}$

B. Proposed System

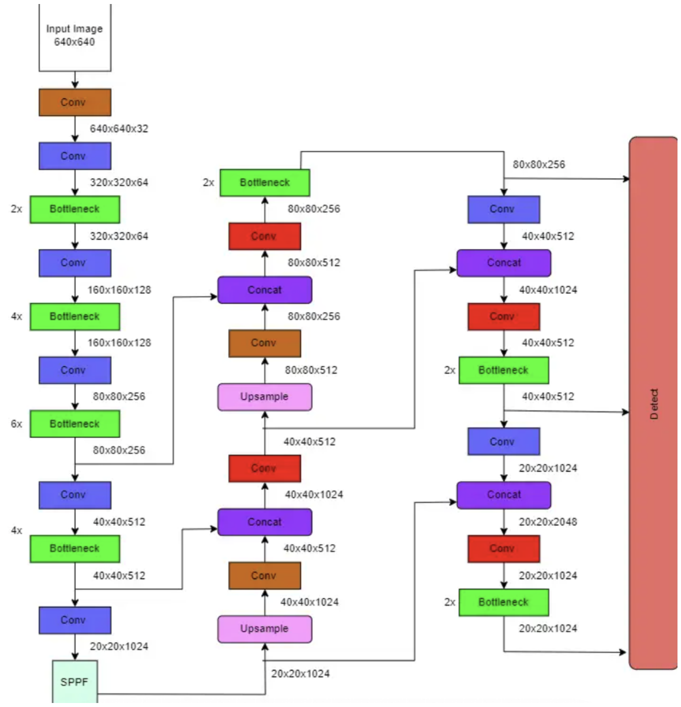

Fig. 1. Proposed system architecture.

The proposed system shown in Fig. 1 utilizes convolutional layers and bottleneck blocks in the backbone to extract hierarchical features, followed by a multiscale feature extraction process. In the head section, the system merges features from both the backbone and the multiscale extractor to enhance object detection capabilities. This integrated feature representation is then utilized for precise object localization and recognition, improving overall performance in detecting objects within images.

Our object detection system represents a sophisticated fusion of architectural components aimed at advancing object detection capabilities within deep learning frameworks. Once an image is passed, it undergoes resizing to 640 x 640 size and post this, enters the backbone of our network which contains a series of several convolutional layers, each strategically designed to capture intricate spatial patterns and hierarchical features from input feature maps.

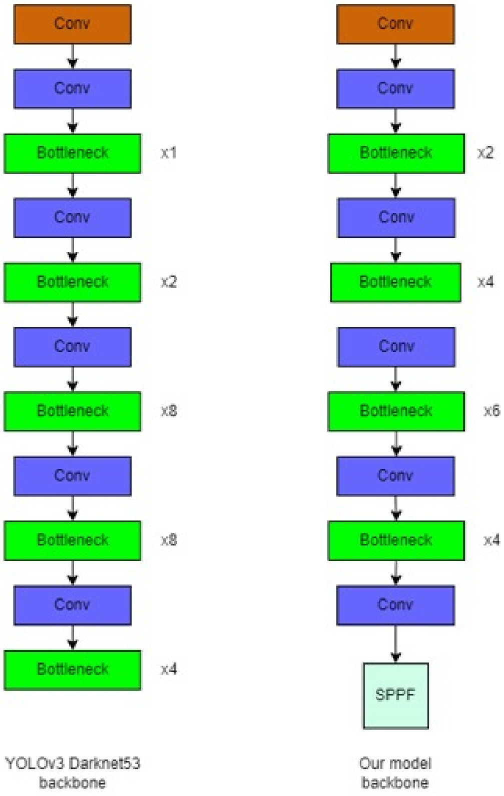

Fig. 2. Backbone of YOLOv3 and our model.

1) Custom Backbone: These convolutional layers are complemented by multiple bottleneck blocks, inspired by the modern architecture Darknet-53 as seen in Fig. 2. The bottleneck blocks in Fig. 4 play a crucial role in feature learning by incorporating residual connections, thereby facilitating the direct flow of gradients during training and mitigating the vanishing gradient problem. This approach not only enhances the model's ability to learn discriminative features but also reduces computational complexity, making the system more efficient and scalable, making it highly instrumental for deployment in resource-constrained environments like autonomous fruit-picking robots or edge computing devices in warehouses. What closely follows this is the integral part of the system's object detection prowess: an innovative inclusion of a multi-scale feature extractor called the SPPF (Spatial Pyramid Pooling Fast) layer. SPPF addresses the challenge of efficiently handling objects of varying sizes within input images. Traditional CNNs often require fixed-size input, limiting their efficacy in detecting objects at different scales. SPPF overcomes this limitation by enabling the network to operate on feature maps of arbitrary sizes, allowing for the detection of objects across multiple scales within the same image.

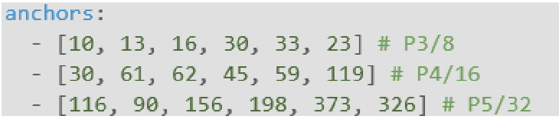
Through hierarchical feature fusion in the neck part via concatenation and multi-scale feature representation, the system achieves enhanced contextual understanding. This is crucial in a mixed fruit setting where for example the model must differentiate between a lemon and an apple. The SPPF layer's implementation of spatial pyramid pooling and factorization techniques contributes significantly to the system's efficiency, enabling it to handle variable input sizes while capturing multi-scale features effectively. What happens with this module is the network effectively partitions feature maps into progressively smaller segments. Segmentation enhances the model's ability to focus on and detect smaller objects by increasing both the resolution and receptive area, which is crucial in densely packed environments like orchards. This comprehensive architecture represents a substantial advancement in object detection methodologies, offering a scalable, efficient, and accurate solution for complex visual recognition tasks within the realm of computer vision and deep learning research.

2) Anchor Design Scheme: Anchors for different feature map sizes are shown in Fig. 3.

Anchors for feature map scale P3/8: These anchors are used with the feature map at a scale where the input image is downsampled by a factor of 8. For example, if the input image is 640x640, the feature map size would be 80x 80.

Anchors for feature map scale P4/16: These anchors are used with the feature map at a scale where the input image is downsampled by a factor of 16. For example, if the input image is 640x640, the feature map size would be 40x40.

Anchors for feature map scale P5/32: These anchors are used with the feature map at a scale where the input image is downsampled by a factor of 32. For example, if the input image is 640x640, the feature map size would be 20x20.



```
anchors:
  - [10, 13, 16, 30, 33, 23] # P3/8
  - [30, 61, 62, 45, 59, 119] # P4/16
  - [116, 90, 156, 198, 373, 326] # P5/32
```

Fig. 3. Anchors.

3) Feature Engineering Techniques: High-Level Features: These features are representations of abstract and semantic information about the input data. They typically capture complex patterns, object shapes, textures, and context within the image. High-level features are crucial for tasks such as object classification and scene understanding. As an example round form of the apple has a slight asymmetry that necessitates accurate feature detection because it can appear in varied sizes depending on the variety or maturity level. This also serves crucial when having to discern against a similar looking fruit such as in Dataset 2 we trained our model on, and most of this occurs under poor lighting or dense conditions.

Low-Level Features: These features represent more fine-grained details and local patterns in the input data. They typically capture simple structures such as edges, corners, textures, and colors. Low-level features are important for tasks that require precise localization or detection of specific visual elements. This would particularly help with oranges, bananas and pears wherefruit skin gradients and other minor colour changes can all be used to distinguish between different varieties and stages of maturity during the harvest cycle.

Fine-grained information refers to subtle, detailed, and specific visual characteristics present in the input data. It includes features such as small textures, intricate patterns, or subtle color variations.

Concat: Concatenating features from different layers of the backbone network serves several purposes- Hierarchical Feature Fusion: Features extracted from different layers of the backbone network capture information at various levels of abstraction. By concatenating these features, the model can leverage both low-level details and high-level semantic information simultaneously. This hierarchical feature fusion helps improve the model's ability to detect objects of different sizes and complexities.

Multi-Scale Feature Representation: Object detection often requires analyzing images at multiple scales to detect objects of different sizes. Features from different layers with varying receptive fields can effectively detect objects of varying sizes.This multi-scale feature representation enhances the model's robustness to scale variations in objects. The perfect example of this is the Minneapple Dataset we used (Dataset 3). Although Dataset 1 and 2 involved large scale fruits, Minneapple involved a densely packed apple orchard with several tiny fruits of very small scale, and yes, our model adapted well there too.

Enhanced Contextual Information: Concatenating features from different layers enriches the contextual information available to the model. Features from shallow layers provide fine-grained spatial details, while features from deeper layers offer more abstract semantic information. Combining these features allows the model to better understand the context of objects in the image and make more accurate predictions. Let's say in dataset 2 where both the shape of an orange as well as the understanding of its colour comes together to make accurate classification and not confuse it with a lemon.

SPPF: The Spatial Pyramid Pooling Fast layer, handles objects of various sizes within the input image. Handling Variable Input Sizes: One challenge in object detection is efficiently handling objects of different sizes within the input image. Traditional convolutional neural networks (CNNs) require fixed-size input images, which can be limiting when dealing with objects at different scales. The SPPF layer addresses this challenge by allowing the network to operate on feature maps of arbitrary sizes, enabling it to detect objects at multiple scales within the same image.

Spatial Pyramid Pooling: The SPPF layer implements a spatial pyramid pooling operation, which divides the input feature map into multiple regions of varying sizes and then pools features from each region separately. By using pooling operations with different window sizes, the SPPF layer captures features at multiple scales, allowing the network to be more robust to variations in object size.

Factorization: The term "factorization" in SPPF refers to the decomposition of the pooling operation into smaller, more manageable components. Instead of applying pooling operations directly to the entire feature map, the SPPF layer applies them to smaller regions or subregions of the feature

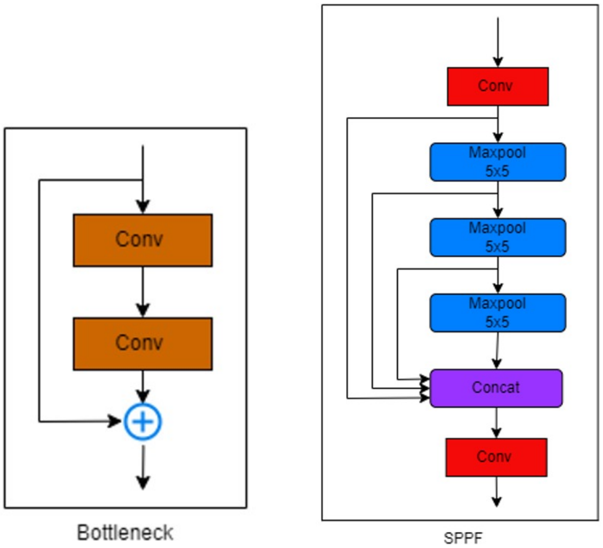


Fig. 4. Key system blocks.

map, reducing the computational complexity of the operation. This factorization process helps maintain the efficiency of the network while still capturing multi-scale features effectively.

Improved Spatial Context: By incorporating features from multiple spatial scales, the SPPF layer enhances the spatial context available to the network. This improved spatial context enables the network to better understand the spatial relationships between objects and their surroundings, leading to more accurate object detection results. A fruit picking robot working in a packed warehouse would be able distinguish between the fruit and non fruit background objects more efficiently, speeding up the process.

Detect: passing inputs of different scales with varying numbers of channels In object detection models like YOLOv3, the detection process often involves analyzing features at multiple scales to detect objects of different sizes. Features from deeper layers with larger receptive fields are better suited for detecting larger objects, while features from shallower layers with smaller receptive fields are more suitable for detecting smaller objects. The choice of having more channels in features from smaller scales and fewer channels in features from larger scales is often driven by the need to capture finer details in smaller objects. Smaller objects may require more spatial information and feature channels to be accurately detected, whereas larger objects may be adequately represented with fewer channels. By passing inputs from multiple scales with varying numbers of channels to the Detect layer, the model can effectively detect objects across a wide range of sizes. The model combines features from different scales and channels to generate bounding box predictions and class probabilities for objects present in the image.

C. Datasets

1) Dataset 1: The dataset comprises a curated collection of 150 high-resolution images, capturing three different fruits: apple, orange and banana. Each image is annotated with bounding boxes outlining the regions of interest containing the fruits. No preprocessing and Augmentation were performed on this dataset. Every model is trained for 100 epochs with a batch size of 13 and input image size of 640 x 640.

Fig. 5. Dataset 1.

2) Dataset 2: It contains images of mixed fruits categorized into four distinct classes, namely apples, oranges, lemon, and pear. Preprocessing steps specifically, RGB images were converted to grayscale using established color conversion algorithms. This transformation not only reduces computational complexity but also emphasizes shape and texture features essential for fruit detection, thereby enhancing model discriminative power. Augmentation techniques like random horizontal and vertical flips were introduced to simulate variations in fruit orientation, ensuring the model's ability to detect fruits irrespective of their spatial orientation. Additionally, rotation augmentation was employed, allowing images to be rotated by ±15 degrees around their center. This augmentation strategy introduces angular diversity, enabling the model to better generalize to fruits positioned at varying angles within the image frame. Here each model is trained for 20 epochs with a batch size of 13 and an input image size of 640 x 640.

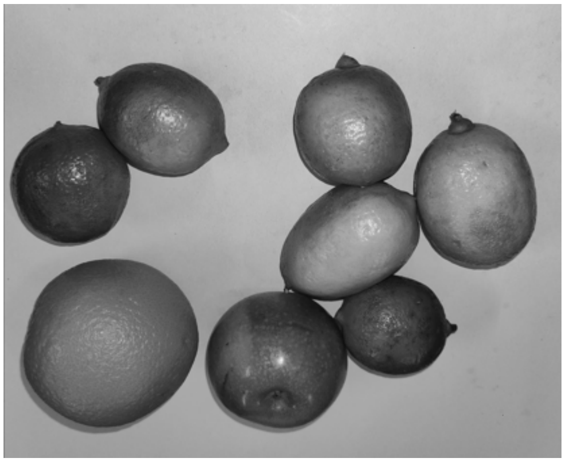

Fig. 6. Dataset 2.

3) Dataset 3: The dataset utilized is MinneApple, designed specifically for apple detection and segmentation within orchard environments, aiming to push the boundaries of fruit detection [6] technology. It focuses solely on a single class object detection: Apples. Acquired from Roboflow, an open-source computer vision tool, MinneApple has a split of 670 training images and 331 testing images totaling over 41,000

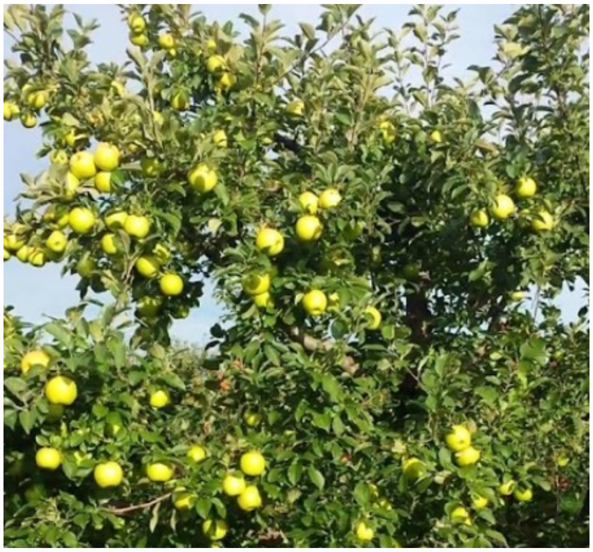

Fig. 7. Dataset 3.

annotated object instances across 1001 images. The data collection process spanned more than a year at the University of Minnesota's Horticultural Research Center, employing a standard Samsung Galaxy S4 cell phone to ensure real-world representativeness. Footage was captured at a controlled speed of 1 m/s to minimize motion blur, with images extracted at regular intervals to encompass diverse lighting, angles, and fruit ripeness stages. This diverse dataset, encompassing various fruit varieties, ripeness stages, and illumination conditions, is pivotal for training robust machine learning models capable of generalizing effectively. No data pre-processing or augmentation was applied to this dataset. All models in Dataset 3 were trained for 30 epochs with a batch size of 13 and input image size of 640 x 640.

IV. Results

In this study, we evaluated the performance of three object detection models **(YOLOv3, YOLOv51, and Our Model)** on three diverse datasets: **(Dataset 1, Dataset 2, and Dataset 3),** as displayed in Table I. We employed standard metrics including precision, recall, mAP@50, and mAP@50-95 to assess their detection accuracy.

TABLE I. Performance Metric Comparison

Dataset	Model	Precision	Recall	mAP	
				@50	@50-95
Dataset 1	YOLOv3	**0.715**	0.617	0.695	0.367
	YOLOV51	0.371	0.546	0.529	0.249
	Our Model	0.692	**0.664**	**0.747**	**0.392**
Dataset 2	YOLOv3	0.971	0.967	0.982	0.725
	YOLOV51	0.949	0.939	0.971	0.782
	Our Model	**0.978**	**0.968**	0.981	0.771
Dataset 3	YOLOv3	**0.700**	0.566	0.638	0.293
	YOLOV51	0.642	0.477	0.528	0.233
	Our Model	0.679	**0.594**	**0.643**	**0.301**

In terms of model size, we found that our model has less parameters than the YOLOv5l variant and the YOLOv3 version, as can be seen in Table II.

TABLE II. Model Details

Model	Layers	Parameters
YOLOV3	262	61,497,430
YOLOV51	368	46,119,048
Our Model	**225**	**45,403,880**

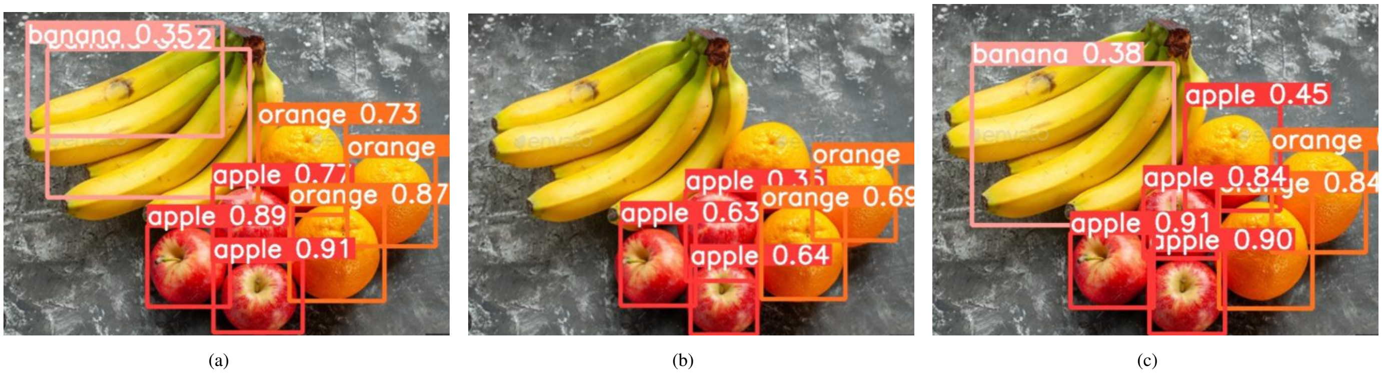
1) Dataset 1: Our model exhibits superior recall and mAP scores (both mAP50 and mAP50-95) compared to YOLOv3. While YOLOv3 has a slight edge in precision, our model's overall performance is better. When compared to YOLOv5, our model surpasses it in all measured metrics: precision, recall, mAP50, and mAP50-95. Thus, our model demonstrates a notable improvement over YOLOv3 in recall and mAP scores, and an overall superior performance across all metrics when compared to YOLOv5.

2) Dataset 2: Our model outperforms YOLOv3 in precision, mAP50, and mAP50-95, indicating superior accuracy and overall performance. However, YOLOv3 has better recall, likely due to its higher sensitivity in detecting a broader range of objects. Compared to YOLOv5, our model excels in all evaluated metrics: precision, recall, mAP50, and mAP50-95. Thus, our model demonstrates a more balanced and accurate performance overall, particularly in precision and mAP scores, while consistently surpassing YOLOv5 across all metrics.

3) Dataset 3: Our model surpasses both models, YOLOv3 and YOLOv5, in all metrics except precision, where YOLOv3 has a slight advantage. Specifically, our model demonstrates superior recall, mAP50, and mAP50-95 compared to YOLOv3.Our model excels in all evaluated metrics, including precision, recall, mAP50, and mAP50-95 compared with the YOLOv5 model.

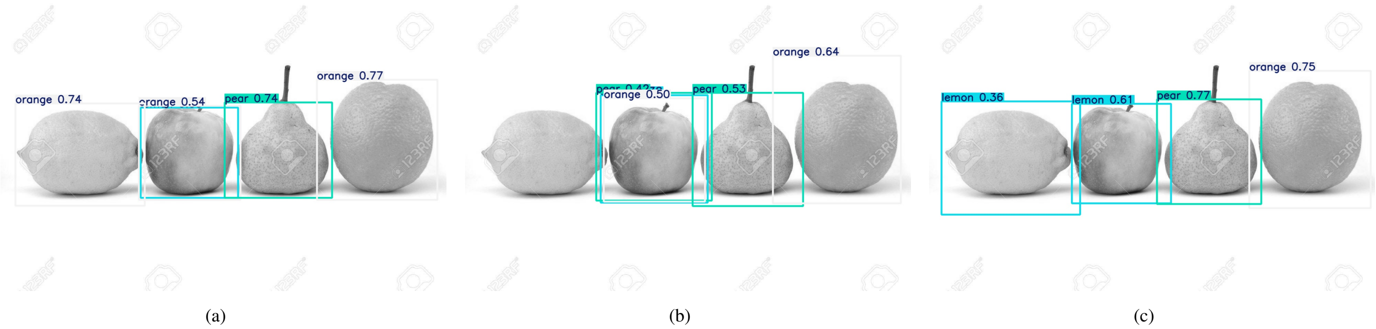
V. Discussion

The results across the datasets, when compared with standard detectors, provide valuable insights into the practical efficacy of our proposed system. For Dataset 1, the superior recall demonstrates the system's ability to detect a high number of fruit instances—apple, banana, and orange. This is particularly significant in dense orchard environments, where fruits are often obscured by leaves, twigs, and other elements within the tree canopy. The higher mAP@50 and mAP@50-95 values further highlight the model's superior performance compared to YOLOv5 and the base YOLOv3 variant in both accurately localizing and classifying fruits, particularly when predicted bounding boxes overlap with ground truth. In a multi-class dataset, this strong performance indicates the model's robustness in detecting multiple types of fruits. While standard YOLOv3 demonstrates a slight advantage in precision due to its effectiveness in reducing false positives, our model achieves a more balanced trade-off between precision and recall, which enhances the detection and classification of multiple fruits (apple, orange, banana) within a single image. The purpose Dataset 1 served was to evaluate the model's ability to detect large objects with occlusion. By using large fruit images, we can also evaluate the model's performance on objects that occupy a significant portion of the image. To perfect the system, a learning rate of 0.01 was applied for all the 100 epochs from scratch with no pre-trained weights. A split of 130 and 20 was chosen for train and validation respectively.



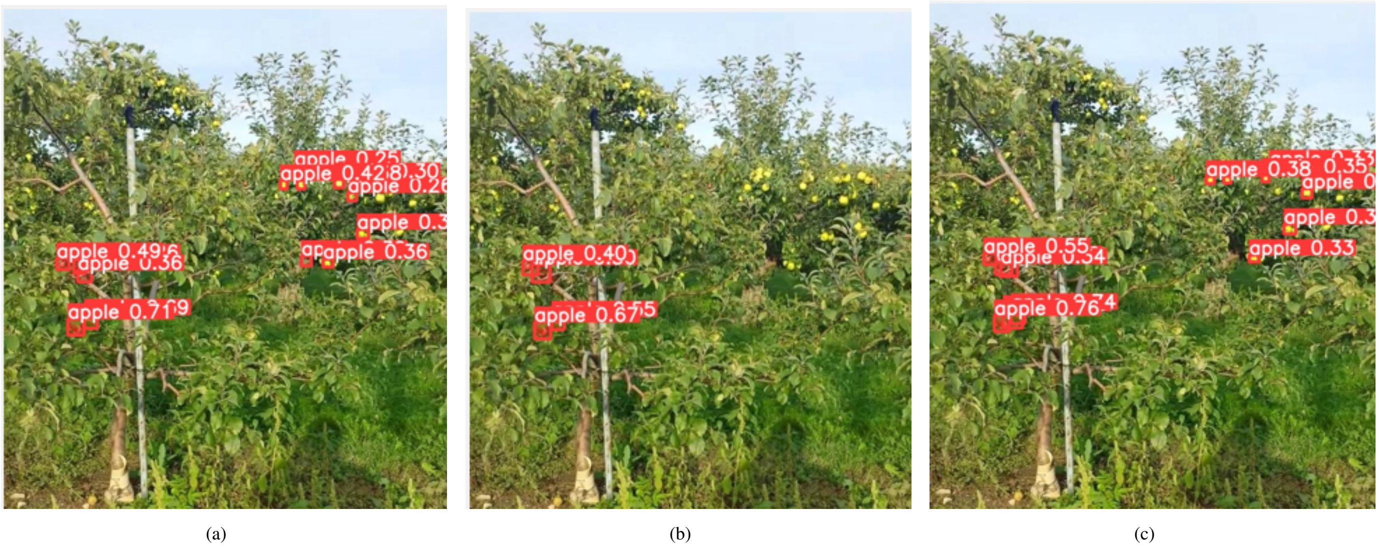
(a) (b) (c)

Fig. 8. Prediction on Dataset 1 using models YOLOv3 model(a) ,YOLOv5 model(b) and our model(c).



(a) (b) (c)

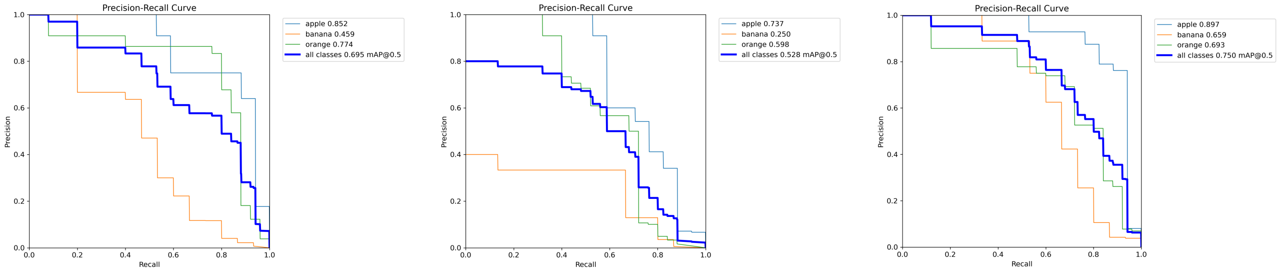
Fig. 9. Prediction on Dataset 2 using models YOLOv3(a), YOLOv5 model(b) and our model(c).



(a) (b) (c)

Fig. 10. Prediction on Dataset 3 by using models YOLOv3 model(a), YOLOv5 model(b) and our model(c).

In Dataset 2, our model exhibits superior performance in correctly identifying fruits without mislabeling background objects. This precision is particularly critical in controlled environments for distinguishing between similar objects or fruits of varying sizes. Although the mAP at a threshold of 50 reflects strong localization capabilities, YOLOv5l demonstrates a marginally better performance, likely due to the high similarity in shape between certain fruits, such as lemons and apples, or lemons and oranges. Despite standard YOLOv3 achieving higher recall, it compromises accuracy, as evident from the labels on the bounding boxes. This dataset had fruits of medium to large size. Further, the inclusion of grayscale



(a) (b) (c)

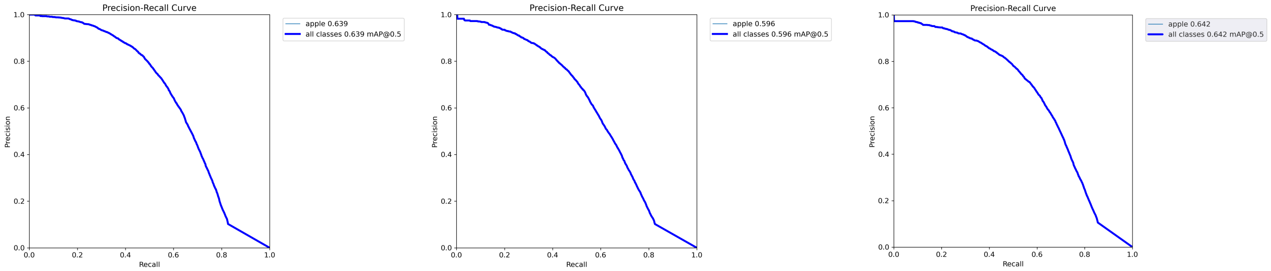
Fig. 12. Precision recall graph of Dataset 2 applied on YOLOv3(a) model, YOLOv5 model(b) and our model(c).



(a) (b) (c)

Fig. 13. Precision recall graph of Dataset 3 applied onc YOLOv3 model(a), YOLOv5 model(b) and our model(c).

images and augmentation techniques (horizontal/vertical flips and rotation) helps increase the dataset's diversity and improve the model's generalization capabilities. A learning rate= of 0.01 was applied for all the 20 epochs with no pre-trained weights, and a split of 1450 and 230 for train and validation was chosen respectively.

Dataset 3 presents a slightly different trend. In dense orchard settings, precision is key in reducing false positives, such as branches, leaves, or occluded apples being incorrectly classified as apples. While standard YOLOv3 shows a slight advantage in minimizing these misclassifications, our model outperforms in terms of recall and mAP@50 and 90. This indicates that it detects a higher number of apples, even under challenging conditions where fruits may be partially hidden or closely packed. In such densely populated environments, the superior recall of our model is crucial, ensuring comprehensive apple detection, even when some fruits are obscured by branches. Furthermore, the higher mAP scores underscore the model's ability to accurately and consistently localize apples, particularly in cases where apples are tightly clustered, which is essential for effective yield estimation in dense orchards. We chose dataset 3 to specifically evaluate the model's performance on detecting very small objects. The MiniApple dataset provided a challenging benchmark for object detection tasks involving tiny objects. We applied a learning rate=0.01 over all 30 epochs, no pre-trained weights, and the 1001 images were kept at a split of 670 and 331 for train and validation respectively. It is noteworthy that high mAP@50 and mAP@50-95 scores proved powerful localization capabilities specially over the Minneapple dataset where similar research such as [23] which put to use MHT with YOLO and Faster RCNN, suffered at counting the fruits and had to rely on high velocity algorithms such as DeepSORT to improve performance while our system could correctly identify a very high number of tiny apples off the dense branches.

VI. Conclusion

Concerning model size, we observed that our model contained fewer parameters than both the YOLOv3 version and the YOLOv5l variant. Despite containing lower number of layers than YOLOv3, our model performed beter feature extraction. This shows that we can achieve good accuracy without a large and complex structure, making our model a great choice for tasks that need both speed and efficiency in object detection. This lightweight model can be effectively used in applications where efficiency is crucial, offering fast processing and reduced memory usage compared to larger models like YOLOv3 and YOLOv5. This certainly means we have got through with our first and third primary objectives listed at the start of this paper. In addition, the SPPF module working within our model provides a reliable solution to the issues of multi-scale fruit detection. Using pooling layers of varied sizes improves the model's capacity to detect fruits of vastly varying sizes, whether they are small in the Minneapple dataset's orchards or the large ones in the Mixed Fruit dataset. This method decreases sensitivity to variations in input resolution, resulting in consistent performance across different image qualities. Furthermore, by merging characteristics from several scales within a single feature map, SPPF enhances the fruit object representation with fine-grained details as well as global context, ultimately enhancing fruit recognition accuracy and reliability in a variety of situations. With this, we have achieved our second primary objective. In summary, our model showcases strong performance in multi-class fruit detection by taking a balanced approach and striking a worthy balance between precision and recall, as opposed to models like YOLOv3 and YOLOv5. The fact that we successfully tested over images with fruits of different classes hints at success with our fourth primary objective. Also, our model has superior overall detection accuracy, as indicated by the greatest mAP@50 score, suggesting its ability to recognize true positives despite minor differences in bounding box placement. Furthermore, our model performs consistently across IoU levels, achieving competitive mAP@50-95 values and assuring accurate fruit location pinpointing even under stringent bounding box overlap criteria. However, while our model demonstrates promising results, there is potential for further improvement. The model still does not perform well in cases of occlusion. Improvement in fusion techniques to better mix information from multiple layers is needed and for this, we can investigate sophisticated backbones such as EfficientNet. By exposing the model to a greater range of training data, data augmentation can also aid in enhancing the model's capacity for generalisation. Finally, testing the model against a variety of benchmarks can reveal the model's advantages and disadvantages as well as point out areas that still want improvement. We may improve our model's performance and attain even greater results in object detection tasks by implementing these strategies.

A Meta-Heuristics-Based Solution for Multi-Objective Workflow Scheduling in Fog Computing

Gyan Singh, Vivek Dubey
Department of Computer Applications, Government Engineering College, Ajmer, India 305001

Abstract—**In recent years, there has been a significant increase in the volume of data generated by Internet of Things (IoT) applications, mostly driven by the rapid proliferation of IoT devices and advancements in communication technologies. The conventional cloud computing network was not specifically built to handle such a vast volume of data, leading to several issues, including increased processing time, higher costs, larger bandwidth usage, increased power usage, and communication delays. As a solution, conventional cloud servers have been expanded to additional layers of computing, storage, and network, termed as cloud-fog computing. The cloud-fog computing provides storage, processing, networking, and analytics capabilities in close proximity to IoT devices. The problem of scheduling workflow applications in cloud-fog environments to optimize several conflicting objectives is classified as computationally complex. Particle Swarm Optimization is the widely recognized evolutionary meta-heuristic and is the optimal method for implementing multi-objective solutions because of its user-friendly approach and quick converging capability. Despite its wide acceptance, it does have several drawbacks, such as early convergence and solution stagnation. In order to overcome these limitations, this paper establishes a comprehensive theoretical model to schedule workflow applications for cloud-fog systems. The proposed model employs various competing objectives, such as power usage, overall cost, and makespan. To achieve this, we introduce a novel algorithm, learning enhanced particle swarm optimization (LE-PSO), which incorporates an inverse tangent inertia weight policy and adaptive learning factor methods. The efficiency of the LE-PSO is subsequently assessed by employing an operational data set of scientific workflow applications within a cloudsim-based simulation and validated against GAMPSO, EMMOO, PSO, and GA state-of-the-art approaches. The workflow scheduling, we suggest achieves the substantial decrease in makespan and power usage while maintaining the total cost at an optimal level, in comparison to existing meta-heuristics.**

Keywords*—*Fog computing; DAG; workflow applications; makespan; energy; PSO

I. Introduction

In recent years, the combination of advancements in Information and Communication Technology and the rapid expansion of Big data has given rise to a new paradigm known as the Internet of Things (IoT). The Internet of Things (IoT) enables the connection of billions of tangible objects via Internet Protocol (IP). The Internet of Things (IoT) has a profound influence on diverse domains. The influence of IoT spans a diverse array of equipment, including sensors, automobiles, potable technology, cameras, patient observation devices, and numerous other applications. Moreover, the Internet of Things (IoT) has enabled the creation of a wide range of services and, applications including automotive communications, residential security, medical tracking, natural calamity prediction, scientific process automation, and roadway congestion management. [1], [2]. In accordance with predictions published by McKinsey Global Institute, the economy of IoT devices and applications will grow from $40 trillion in 2020 to $500 trillion by 2030. However, IoT end devices possess constrained capability in regards to processing, storage, and power capacities, despite generating substantial volumes of data [3]. Conversely, conventional data centers lack the capacity to efficiently handle massive volumes of data [4], [5].

In address to the aforesaid challenges Bonomi [6] proposed the concept of fog computing. Fog computing is paradigm that enhances the capabilities of current Cloud servers by extending them to network periphery, closer to IoT end devices. This improves the data center's capacity to manage workflow tasks which require increased real-time processing with agility. Hence, By establishing extra nodes in the cluster at the network periphery, referred to henceforth as cloud–fog environment.

Typically, The cloud-fog framework comprises several tiers. As shown by Fig. 1, The uppermost tier of architectural structure, known as the cloud tier, consists of multiple interconnected data centers. Optimally, the cloud tier is designed to handle and analyze jobs that need significant processing resources and can tolerate delays in data flow because of its long physical separation from the sources of data generators. The intermediate tier, known as the fog tier, serves a connection among the data centers and Internet of Things devices, usually located nearer to the IoT end-devices. Consisting of multiple machines strategically located at the network's periphery. Fog-tier machines have constrained computing, communication, energy, and data repository capacities. The fog tier machines efficiently handle time-critical operations from end-devices. If there is a task that can tolerate delays but requires a lot of computational power, it should be sent to the data centers. Fog tier nodes are hierarchically arranged to the nodes at the bottom levels. The lowest tier, referred to as the IoT end-device tier, comprises of moveable devices, sensors, cellphones, health monitoring systems, disaster prediction tools, computational science devices, and raw information generation sensors. Submission of tasks from lower tiers to upper tiers is necessary for processing requests. These devices possess extremely limited computing, repository, and energy capacities [6], [7].

Cloud-fog computing framework provides several benefits to address essential challenges. The framework exhibits increased complication and heterogeneity as a result of the various communication networks and processing nodes employed.

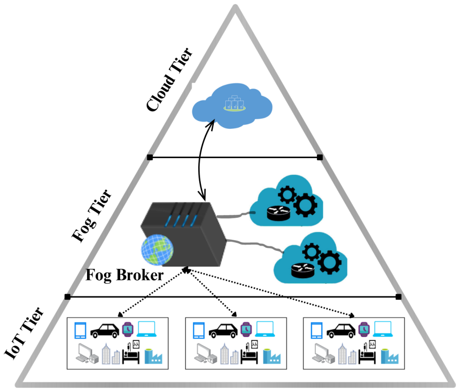

Fig. 1. Cloud-fog framework.

Workflow application scheduling is key challenge for those that need fast runtime, but poses with complex inter-dependent tasks in application and a huge volume of data moving between tasks [8].

Workflows represent the various applications that execute on end devices. The workflow applications are comprised of a set of tasks that have interdependencies. The task dependencies are arranged such that each job must wait for its predecessors to complete before it can be run. Domains such as astrophysics, patients monitoring, natural hazard prediction, computer imaging, and bio-informatics are described as workflow applications. A Directed Acyclic Graph (DAG) is a perfect data structure for representing workflow tasks and the relationships between them efficiently [9]. The aim of optimizing the scheduling of workflow applications is to provide mutually beneficial situations for cloud service providers and clients. This involves considering various parameters and constraints, such as cost, security, energy, deadlines, load balancing, budget, resource utilization, and makespan.

Fog and cloud nodes that are deployed across different geographical locations. Network technologies facilitate the interconnection of computing and storage servers. Enormous heat dissipation solutions are required to maintain essential functional temperatures of cloud data centers. Furthermore, the limited availability of resources in the end-devices tier and fog tier is contingent upon the use of uncertain power sources, like battery storage and sustainable power options. Therefore, the network of the entire cloud-fog system consumes huge amount of energy, with each activity often requiring an average of 15 megawatts. The Communication and information systems sector is responsible for emitting approximately 1.6% of worldwide CO_2 emissions between 2007-2016, in addition to its operational expenses. The predicted rise in this figure is anticipated to reach around 14% between 2016 and 2040 [10]. Consequently, researchers have shown significant interest for the development of sustainable cloud solutions. The challenge of optimizing power consumption in cloud-fog computing has become a significant concern [11]. Dynamic Voltage and Frequency Scaling (DVFS) is a widely used approach for conserving energy. All current processors are equipped with many cores to facilitate the implementation of Dynamic Voltage and Frequency Scaling (DVFS) algorithms. The DVFS technology allows individual CPUs to function at varying voltage and signal frequencies levels. However, a drawback of this technology lies in increase of cost and makespan as well as decreasing power usage. Consequently, this fails to concurrently meet the QoS requirements of both consumers and service providers.

An optimization strategy focused on minimizing the overall runtime of an application might lead to significant energy consumption and resource utilization, hence causing service providers to incur more costs. On the other hand, an algorithm that prioritizes minimizing energy usage can decrease costs for service providers but may result in a longer duration of completing tasks, ultimately causing disagreement among consumers. Hence, employing single-objective techniques to optimize scheduling algorithms is never the most optimal decision. Multiple-objective optimization methods are the most suitable option for achieving a balanced compromise among many optimization objectives. Hence, developing and improving a methodology for scheduling workflow applications in a complex system like cloud-fog, which involves more than objective with competing in nature, is a challenge that falls under the category of NP-hard [12], [13], [14]. Several workflow scheduling techniques have been developed in cloud environments to address various conflicting objectives. Nevertheless, there exist only a limited number of scheduling algorithms that effectively maximize both makespan and cost at the same time. Based on our research, currently, cloud-fog systems have no solution that optimizes the energy usage, cost, and completion time simultaneously. Several well-known evolutionary meta-heuristic methods, such as Genetic Algorithms (GA), Differential Evolution (DE), and, Particle Swarm Optimization (PSO), etc, are considered solutions for optimizing the issue of multi-objective workflow scheduling. most of the above methods focused on optimizing the cost and makespan as the optimization objectives with budget and deadline constraints. Two recent surveys have shown that PSO-based approaches are well-suited and widely used for solving scheduling problems for tasks and workflows with several objectives simultaneously [12][15]. The PSO meta-heuristic algorithms are selected for their benefits such as simple implementation, efficient execution, and rapid convergence. Although PSO has several benefits, it also has certain drawbacks like being trapped in local optima and convergence stagnation. As a result, it may either produce degraded outcomes or could necessitate additional time for computation. In order to address limitations, our research introduces the learning-enhanced particle swarm optimization (LE-PSO) algorithm. This is achieved by incorporating the inverse tangent-based new inertia weight updating and new learning factor method, which aim to strike a balance between the exploitation and exploration capabilities of the PSO methodology. The main work of this paper is listed as follows:

- Develop a theoretical framework to measure performance metrics of multiple-objective scheduling for Workflow applications in the cloud-cog environment that aims to minimize the makespan, cost, and energy usage.
- In order to overcome all of the challenges encountered in standard Particle Swarm Optimization (PSO), we present a new approach called learning enhanced particle swarm optimization (LE-PSO). This algorithm

incorporates a new inverse tangent inertia weight method and a new learning factor method, which aim to enhance both global and local search capabilities.

- Implement the suggested Multi-Objective LE-PSO Workflow scheduling in a cloud-fog environment using the Fogworkflowsim tool [16].
- We analyzed and compared the efficacy of the proposed solution with the four solutions GAMPSO [17], EMMOO [18], Standard PSO, and GA using several real-world scientific workflows. The findings showed a significant reduction in both energy consumption and makespan while not increasing the overall cost.

The subsequent sections of the article are structured in the following manner: Section II provides a comprehensive overview of the current state-of-the-art research on workflow scheduling proposed for cloud fog, fog, and cloud. Section III presents the theoretical framework for scheduling workflows in cloud-fog system. It also introduces the application model. Section IV introduces standard Particle Swarm Optimization (PSO) and the proposed learning enhanced variant of PSO (LE-PSO). Section V provides a comprehensive explanation of how the suggested algorithms can be used to map workflow tasks to a cloud-fog system. Section VI demonstrates the efficacy of the LEPSO and performance evaluation in comparison to existing solutions. Section VII finally finishes by summarizing the contribution of this article and offering insights for further research.

II. Literature Survey

The problem of scheduling in contexts that are both heterogeneous and distributed has been proven to be NP-hard. The challenge becomes more complicated when a workflow application is present and tasks necessitate a predetermined execution order to preserve the inter-dependency among them. The limitation of standard scheduling systems such as HEFT, FCFS, RR, MinMin, etc, is that they only prioritize optimizing execution time as a resource. NP-hard problems necessitate heuristic approaches to generate multi-objective approximate optimal solutions. Evolutionary meta-heuristics are the most commonly used methods for solving scheduling problems in environments such as heterogenous [12]. Various meta-heuristics-based strategies for scheduling workflows have been developed in cloud environments [13], [14], [19], [20], [21], [22]. Referenced algorithms consider either single or multiple objectives such as cost, power usage, load distribution, and completion time, considering constraints of network bandwidth, deadlines of time, and budget. Most research studies on workflow scheduling approaches have been implemented in cloud and distributed environments, with very few articles explicitly concentrating on optimizing various objectives in cloud-fog and fog environments.

In research [23], the discrete form of the Butterfly Optimization meta-heuristics is utilized to optimize workflow scheduling in a mobile-edge computing environment. The authors enhance the algorithm's ability to perform both local and global searches within the solution space by introducing a novel "Levy flight-based" equation. This meta-heuristic approach also focuses on minimizing energy consumption as the primary objective by employing the Dynamic Voltage and Frequency Scaling method. While this method significantly improves data access rates and reduces energy usage, it does not provide any statistical analysis regarding makespan or overall cost.

In study [24], the authors present IKH-EFT: An enhanced technique for workflow scheduling in fog-cloud environments using the krill herd algorithm which presents a novel method that employs the krill herd algorithm to improve efficiency in fog-cloud computing environments. This approach aims to achieve a balance between many goals, such as reducing the time required to complete a task, lowering energy usage and cost, and optimizing customer satisfaction.

In study [25], the Opposition-Based Learning variant of the Harris Hawks Optimization technique is employed to improve the scheduling of workflow applications in a multi-tier fog environment. A predictive model based on the Hidden Markov Model is developed to improve the ratio of missed deadlines and optimize task offloading. Although, this integration is designed to minimize the makespan and optimize the allocation of virtual machines (VMs), however, The findings indicate that the suggested approach is specifically applied to Fog systems, with a primary focus on minimizing only makespan.

In study [3], the work proposed introduces the Scheduling approach to mapping tasks in a cloud-fog environment that integrates two meta-heuristics techniques Genetic Algorithm and Particle Swarm Optimization. This approach seeks to achieve an Optimum trade-off between total cost efficiency and makespan while meeting customer quality satisfaction requirements. Nonetheless, this approach omits energy optimization and has not been tested on the dependent workflow tasks.

In study [26], author presents cuckoo search optimization(COA) algorithm to schedule jobs in smart grids to effectively allocate resources and enhance load balancing. COA is employed to allocate appropriate tasks to Virtual Machines (VMs) with the aim of identifying VMs that are not being fully utilized and VMs that are being excessively utilized. The under-utilized VMs are then powered off to minimize energy usage.

In research [27], the Proposed method integrates the two algorithms: Grasshopper Optimization and Symbiotic Organisms Search. This method was implemented to optimize the energy efficiency in workflow scheduling in fog environment. This integration is facilitated by employing learning automata to determine the most effective algorithm. Additionally, the algorithms utilize Dynamic Voltage and Frequency Scaling techniques to minimize energy usage in fog computing environments, while also managing to maintain an optimal makespan. Although this method successfully lowers energy consumption, the complexity is heightened due to the hybridization of algorithms, and the aspect of overall cost management is not addressed.

In research [28], introduces a novel meta-heuristic algorithm called the Hybrid Particle Whale Optimization Algorithm (PWOA). The PWOA combines two well-established algorithms: Particle Swarm Optimization (PSO) and Whale Optimization Algorithm (WOA). The hybrid approach leverages the advantages of both PSO and WOA, aiming to enhance performance while reducing the limitations inherent in each individual algorithm. The algorithm optimizes the overall execution time and overall cost for workflow scheduling in a cloud-fog environment. The algorithm omitted energy consumption as a parameter.

In study [29] continuation with PSO and GA combinations studies, this article introduces a novel method by hybridizing the GA and PSO meta-heuristics to improve the optimization of workflow scheduling within a cloud-edge environment. The author harnesses the Genetic Algorithm's two operators: Mutation and selection to increase the randomness in the diversity of the population, while simultaneously implementing the inertia update with the Non-linear method to facilitate a trade-off between global and local searching processes. Although this method shows superior performance in minimizing makespan and cost, it ignores the energy optimization parameter.

In study [30], the author suggests using the Multi-objective Hybrid Dragonfly Algorithm (MHDA) as a hybrid optimization tool to improve task scheduling for Big Data applications in IoT cloud environments. The objective of this algorithm is to minimize the makespan, which refers to the entire time needed to perform a given collection of tasks, while simultaneously maximizing resource use. The scheduling process takes into account key criteria such as makespan, resource utilization, and cost. The main focus of this research is on IoT cloud computing environments, which involve the integration of Internet of Things (IoT) devices with cloud computing resources.

In study [31], the author proposes a list-based dependent task scheduling algorithm for fog computing, which operates in three phases: sorting, prioritization, and selection. In the sorting phase, all independent tasks are organized. In the prioritization phase, tasks are assigned priorities based on their successor tasks. Finally, in the selection phase, task submission decisions are made by balancing global and local search strategies. This approach aims to optimize cost and makespan as its objective functions. However, a limitation of this work is the absence of a meta-heuristic approach; as the number of workflow tasks increases, both makespan and cost also increase.

In study [32], the author introduced a bi-objective workflow scheduling method aimed at optimizing both scheduling reliability and workflow makespan simultaneously in a cloud-fog environment. The model addresses the problem as a multi-criteria challenge, aiming to enhance scheduling reliability while improving the service delivery time ratio for workflow tasks allocated to computing resources. furthermore, it develops a reliability-deadline optimization model, which seeks to optimize application execution time and reliability. This is achieved by adapting a reliability-recursive optimization approach and remapping workflow applications that are not on the critical path. however method neither considers the energy as function objectives nor any meta-heuristics methods employed.

In study [17], a continuation with another PSO-GA-based method introduces a novel workflow scheduling algorithm by hybridizing the Genetic algorithms with the Particle swarm optimization algorithm. The algorithm starts with random initialization of GA and then passes the second half of iteration to PSO. It considers function objectives energy consumption, incurred cost, and makespan. due to the hybridization of GA and PSO, the algorithmic complexity is increased.

In study [18], a multi-objective approach to workflow scheduling is introduced with the goal of minimizing both energy use and makespan while adhering to deadline constraints. The proposed approach operates in two phases. Initially, a task priority queue is generated using Estimated Processing Times to schedule tasks. The subsequent phase employs a DVFS technique to reduce energy consumption without compromising deadline adherence. The idle slots calculated in the initial phase are leveraged in the next phase, eliminating the need for rescheduling. Although this method effectively reduces makespan and consumption of energy, it neither considers cost nor incorporates any meta-heuristic algorithms.

In [33], the author implements a Shortest Job Queue-based job scheduling algorithm for fog environments. The algorithm utilizes the shortest job queue to reduce the application loop delay and network time for submitted applications. It considers factors such as response time, energy consumption, and network usage as a defined objective function. However, the algorithm has not been tested for dependent task submission, and no meta-heuristic approaches have been applied.

The table labeled as Table I provides a summary of the underlying concepts of algorithms, performance measurement metrics, evaluation tools, the context where the algorithm deployed, and challenges/open issues of the literature survey conducted. Prior research in the field has extensively focused on enhancing the efficiency of workflow scheduling in cloud environments. Nevertheless, there is a significant shortage of studies pertaining to fog and fog-cloud. Furthermore, as observed from the literature studies the majority of existing studies primarily concentrate on reducing the time it takes to complete a task and related costs while disregarding the inclusion of energy usage as a key goal. This omission is particularly noteworthy considering the present importance of energy efficiency. In addition, the study shows a preference for using evolving meta-heuristics frameworks to schedule workflows in fog-cloud computing. The primary implementation issue with meta-heuristics methods is the complexity inherent to them. The implementation of meta-heuristics has a tendency to rise the time to complete algorithms, which may not be acceptable for the client's applications that require fast response times. PSO is considered the most appropriate choice for multiple-objective optimization among the many evolutionary meta-heuristics. Nevertheless, it is hampered by certain deficiencies. To improve the applicability of PSO in Workflow scheduling and overcome its drawbacks in cloud-fog, more improvement and refinement are necessary. In order to address the challenges specified in Table I, we have implemented a learning enhanced particle swarm optimization (LE-PSO) for the purpose of scheduling workflows in a cloud-fog environment. This technique takes into account many conflicting objectives, such as Energy, Makepsan, and cost, as the main optimization metrics.

III. System Modeling and Problem Formulation

In this section, We first establish a multi-tier resource model, within which proposed workflow scheduling will be executed. Next, the Dircet Acyclic Graph-based workflow application is modeled with multiple but competing objectives. Then, the problem is mathematically formulated as multiple-objective optimization.

TABLE I. Comparison Summary of Recent Cloud-Fog-Based Workflow Scheduling Methods

Ref.	Underlying Concepts	Performance metrics	Simulator	Environment	Challenges and Open issues
[23]	Discrete version of Butterfly optimization	data access ratio, Energy	iFogSim	IoT-edge	No cost/Makespan mentioned
[24]	Multi-objective krill herd algorithm	Makespan, cost, energy	Matlab	Fog-cloud	complex to implement
[25]	Harris Hawks Optimization and Hidden Markov Model	task offloading,missed deadlines, makespan	iFogsim	Fog	No enrgy and cost, No complex environment
[3]	Hybrids PSO with GA	total cost, Makespan	iFogsim	Cloud-Fog	No Energy optimized, No workflow task evaluated
[26]	Cuckoo optimization algorithm	Energy consumtion, response time	cloudsim	cloud-fog	no task dependency,only energy
[27]	Integrate Symbiotic Organisms with Grasshopper Optimization	Energy	iFogsim	Fog	No muil-tier, increased complexity,only energy
[28]	Hybrids PSO with Whale Optimization	Execution Cost, Execution Time	WorkflowSim	cloud-fog	Energy not considered,increased complexity
[29]	Hybrids Non-linear PSO with GA	Total Execution time, total cost	WorkflowSim	Cloud edge	only cost,execution accounted for
[30]	Multi-objective Hybrid Dragonfly Algorithm	Cost, makespan, resource utilization	cloudsim	Cloud-IoT	No energy considered
[31]	list-based task scheduling	Cost, makespan	iFogsim	fog	Non-meta-heuristics employed,under performed in higher load
[32]	simple heuristics based	reliability,makespan	ifogsim	cloud-Fog	no meta-heuristics, No energy parameter
[17]	Hybridization of PSO with GA	energy consumption, cost, Makespan	Workflowsim	cloud-Fog	complexity increased
[18]	DVFS with Sorted priority queue	makespn,energy	MATLAB	cloud-Fog	Meta-heuristics not used, No cost
[33]	Shortest Job Queue-based	energy, response time, network	iFogsim	fog	No dependent tasks, no meta-heuristics

A. Resource Model

The network architecture of the cloud-fog system is structured into three separate tiers: cloud tier, fog tier, and IoT end devices tier. The Fog Broker node is a specialized server node in the fog tier, as depicted in Fig. 1.

The broker node is responsible to coordinate and facilitate communication between three tiers in order to efficiently allocate tasks to appropriate resources, whether they are located in the cloud or fog. The broker node works depending on optimization goals specified by the service provider.

In the proposed research, we create a heterogeneous environment comprising three distinct categories of resources. These include cloud nodes located in reserved high-capacity storage and computing host machines that communicate via a Wide Area Network within the cloud tier; fog nodes that are interconnected through Ethernet in the fog tier; and IoT devices that possess very constrained processing, storage, and communication capabilities, connect to nearby fog nodes over the mobile network, forming end-devices tier. We denote C as a set of virtual machines provisioned on cloud tier, defined as $C = vm_1, vm_2, vm_3, \ldots, vm_c$. Similarly, F denotes the VMs deployed on fog tier, where $F = vm_1, vm_2, vm_3, \ldots, vm_f$. The VMs generated on end-user devices are primarily intended for managing minor tasks. Tasks that need higher computing and storage requirements will be offloaded to the upper tiers. Consequently, resources available on end devices are considered to have minimal significance in terms of performance. $V = C \cup F = vm_1, vm_2, vm_3, \ldots, vm_m$ are the sum of VMs provisioned at cloud-fog and registered at Fog broker node, reflecting their distinct technical specifications.

B. Application Model

Workload applications submitted to cloud-fog will be modeled by direct-acyclic-graph, denoted as $G(T, E)$, Where T is a set of tasks and E is the communication link between tasks. E represented a set of one-way inter-dependencies among tasks. Every task $\tau_s \in T$ in set T have thier size defined by *size(τ_s)*.Every edge $\epsilon_{ij} = \langle \tau_i, \tau_j \rangle \in E$ signifies a dependency of flow or control between tasks τ_i and τ_j. This indicates that τ_i must be finished before τ_j can begin, thereby establishing τ_i as a predecessor of τ_j due to the precedence constraints.The collection of all tasks that precede a given task is represented as *pred(τ_s)*, while the set of tasks that follow is represented as *succ(τ_s)*. The edge ϵ_{ij} is associated with communication weight cv_{ij} with a value zero or greater, representing the amount of data transferred from task τ_i to task τ_j. In cases where a task lacks a predecessor or successor, pseudo task τ_e / τ_x equals zero is introduced into the graph. As shown in Fig. 2, We have created an example to illustrate workload application DAG. It demonstrates how tasks are organized across seven distinct levels. In the third level, tasks τ_2, τ_3, and τ_4 are designed to execute concurrently.

C. Problem Formulation

1) Makespan objective: Total time needed to complete a workload application, measured from the starting time of the initial task, τ_e, to the finishing time of the final task, τ_x, is referred as Makepan. For our proposed model, two distinct categories of VMs have been created: c number of virtual machines in cloud tier and f number of virtual machines in fog tier. Thus, The specialized node fog broker is registered with the sum of VMs ($m = c \cup f$) at the specific moment. Submitted tasks of workload are executed on cloud virtual machines or fog virtual machines depending on the selected offloading strategy by the fog broker to reduce the makespan for the entire workload. When a task τ_s of workload is assigned to a VM deployed at node l, the execution time for τ_s is represented as:

$$ET_{\tau_s^l} = \frac{size(\tau_s)}{PC^l} \qquad (1)$$

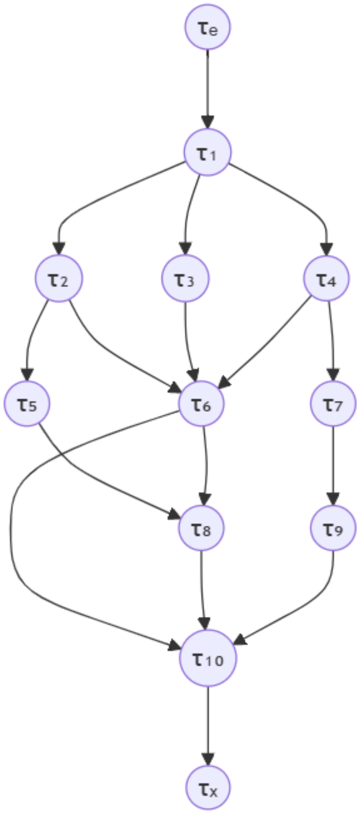

Fig. 2. A DAG-based workload illustration.

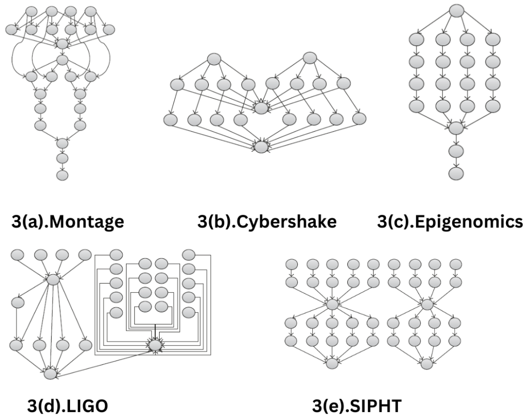

3(a).Montage 3(b).Cybershake 3(c).Epigenomics

3(d).LIGO 3(e).SIPHT

Fig. 3. Structure of various workloads.

Where $ET_{\tau_s^l}$ represents the time required to execute task τ_s on the l^{th} physical machine, *size*(τ_s) denotes the size of the task, PC stands for the processing capacity for l^{th} physical machine.

Consider $DT(\epsilon_{ij}^l)$ as the data transfer time between tasks τ_i and τ_j, which can be calculated as follows:

$$DT(\epsilon_{ij}^l) = \frac{\mathit{size}(cv_{ij})}{B^l} \tag{2}$$

size(cv_{ij}) represents the volume of data exchanged between tasks τ_i and τ_j, while B denotes the bandwidth available between the physical machine.

The start time ST_{τ_s} and finish time FT_{τ_s} for task τ_s can be determined using the following formula:

$$ST_{\tau_s} = \max(FT_{\tau_p} + DT(e_{ps}^l), \tau_p \in pred(\tau_s)) \tag{3}$$

The set $pred(\tau_s)$ includes all the preceding tasks of task τ_s.

$$FT_{\tau_s} = ST_{\tau_s} + ET_{\tau_s^l} \tag{4}$$

Therefore, the overall makespan of the workload is:-

$$MS = maximum(FT_{\tau_s} - minimum(ST_{\tau_s}), \tau_s \in pred(\tau_s))) \tag{5}$$

2) Cost objective: The service architecture of cloud fog model operates on a business-driven on-demand prices, where pricing structures for their solutions are established by service providers. In this cost model, total expenses are derived from two resource types: computing resources and data transfer communication resources. Both cloud and fog machines are accounted for to determine the total cost, whereas the costs related to end devices are assumed to be minimal.

The computational cost for executing a task τ_s at the physical machine l is determined by:

$$CC_{\tau_s^l} = UC^l * (FT_{\tau_s} - ST_{\tau_s}) \tag{6}$$

CC represents the computational cost, UC^l denotes the unit price on physical machine l.

The cost of communication between tasks τ_i and τ_j will be determined using the following calculation:

$$CD(\epsilon_{ij}^l) = UD^l * DT(\epsilon_{ij}^l) \tag{7}$$

$CD(\epsilon_{ij}^l)$ represents the cost of communication for transferring data between task τ_i and task τ_j, UD^l denotes the unit price. When tasks τ_i and τ_j are processed on the same physical machine, the amount of data transfer $DT(\epsilon_{ij}^l)$ is equal to 0.

Consequently, the sum of cost is determined by:

$$TC = \sum_{l=1}^{m} \sum_{s=1}^{n} CC_{\tau_s^l} + \sum_{l=1}^{m} CD(\epsilon_{ij}^l) \tag{8}$$

Here, m denotes the VM counts, and n denotes the task count.

3) Energy objective: We have derived energy objectives from the framework outlined in [34], which divides energy consumption into two key parts: static and dynamic consumption of energy. The dynamic part of consumed energy denoted as ED, is particularly significant as it leads to higher energy usage during the execution of workload tasks.

$$ED = \sum_{s=1}^{n} C * f_s * {v_s}^2 * (FT_{\tau_s} - ST_{\tau_s}) \tag{9}$$

Here C represents the constant value as a capacitive load, v denotes the supply voltage, where f is the frequency of the CPU where executing the task τ_s.

ES denotes the static part of energy utilized, which functions at the lowest possible frequency with the minimum voltage supply required to keep the system operating. While the system is idle, it carries out crucial functions like functioning core circuits, supporting the continuous working of RAM and input/output activities, and clock running.

$$ES = \sum_{l=1}^{m} \sum_{idle_{l,k} \in IDLE_{l,k}} C * f_{l,mn} * v_{l,mn}^2 * S_{l,k} \tag{10}$$

Where $IDLE_{l,k}$ represents the collection of all idle time slots available on physical machine l, characterized by the minimum frequency $f_{l,mn}$ and minimum supply voltage $v_{l,mn}$, additionally, $S_{l,k}$ denotes the slot of idle time utilized by l.

The sum of utilized energy for a given workload is determined by:-

$$TE = ED + ES \tag{11}$$

D. Fitness Metric

Most evolutionary techniques begin with a randomly initialized population. In Evolutionary meta-heuristics methods, the initial phase of population is distributed inherently stochastic.To minimize skews in various objectives, a normalization process is applied by min-max scaling technique. This process involves following steps for normalizing all three objectives:

$$MS_{adj} = \frac{MS_i - MS_{mn}}{MS_{mx} - MS_{mn}} \tag{12}$$

$$TC_{adj} = \frac{TC_i - TC_{mn}}{TC_{mx} - TC_{mn}} \tag{13}$$

$$TE_{adj} = \frac{TE_i - TE_{mn}}{TE_{mx} - TE_{mn}} \tag{14}$$

In this context, “mn” and “mx” represent the lowest and highest fitness values. while i signifies the iteration number as the solution evolved. The “adj” refers to the normalized fitness value.

Following this, the fitness value of an objective for the mapping of task-to-virtual machine schedule p is determined by employing the normalized objectives, as defined by:-

$$f(p) = \alpha.MS_{adj} + \beta.TC_{adj} + \gamma.TE_{adj} \tag{15}$$

Here α, β, and γ represent weighted constants that satisfy the condition $(\alpha + \beta + \gamma = 1)$.Service providers have the flexibility to adjust the value of the constant based on their specific service requirements and preferences. In this case, constants α,β, and γ are selected in the ratio (0.3:0.3:0.4), reflecting that cost and makespan are given equal importance, while slightly higher importance is given to energy.

IV. LEPSO

This section begins by presenting the core principles of the standard particle swarm optimization algorithm, PSO is extensively used to optimize a wide range of complex problems with multi-objective. Following this, we explore an enhanced version specifically designed for workflow scheduling in cloud-fog systems, with a focus on managing conflicting objectives.

A. Standard PSO

Standard PSO, developed by “Kennedy and Eberhart” [35], is a multi-objective, evolutionary, stochastic optimization technique. It has gained popularity for its simplicity and quick convergence, making it a widely recognized algorithm. PSO is particularly useful for tackling complex challenges such as scheduling tasks of workflows in heterogeneous computing systems [12]. The core idea of the algorithm involves particles that search for the best solutions by coordination among particles, and exchanging information between particles. PSO was inspired by the navigation and foraging behaviors observed in schools of fishes. Consider K particles involved in searching within a D-dimensional search space. Each particle, denoted as p_k (where $k = 1, 2, \ldots, K$), is defined by its position $x_k = (x_{k1}, x_{k2}, \ldots, x_{kD})$, velocity $\upsilon_k = (\upsilon_{k1}, \upsilon_{k2}, \ldots, \upsilon_{kD})$ within the landscape. For the i^{th} iteration during the evolution process, the velocity of the k^{th} particle will be modified as follows:

$$v_k^i = \omega^i \cdot v_k^{i-1} + c_1 \cdot r_1 \cdot (pBest_k - x_k^{i-1}) + c_2 \cdot r_2 \cdot (gBest - x_k^{i-1}) \tag{16}$$

The equation defines three components: inertia weight, particle self-learning component, and particle social-learning component. The term $pBest$ denotes the best position achieved by the i^{th} particle during the iteration, while $gBest$ represents the optimal position across the entire search landscape. The variables r_1 and r_2 are random values between 0 and 1. The inertia weight ω and the self-learning (c_1) and social-learning (c_2) factors regulate the problem’s exploration and exploitation capabilities within the search landscape.

For the k^{th} iteration of evolution, each particle’s position will be modified as follows:

$$x_k^i = x_k^{i-1} + v_k^i \tag{17}$$

In standard PSO, the inertia weight is a crucial element that influences both local as well as global exploration capabilities throughout the process of evolution. It is computed using a linear decreasing method as follows:

$$\omega^{i} = w^{mx} - \frac{(w^{mx} - w^{mn}) * i}{T_{mx}} \tag{18}$$

Here, w^{mx} and w^{mn} denote the maximum and minimum inertia weights, respectively, while T_{mx} represents the maximum number of iterations, as specified in Table II. A linear decrease in inertia weight means that the global search capability is broader in the early iterations, while the local search capability becomes more focused later on. In various standard benchmarks, $c1$ and $c2$ are uniformly assigned a value of 2 to ensure a proper trade-off between global and local search abilities.

B. Learning Enhanced PSO

The standard Particle Swarm Optimization (PSO) method is straightforward to implement and excels in global search across multiple objectives. However, when applied to workflow scheduling in complex environments, it often yields suboptimal results due to its tendency to get stuck in local optima, which disrupts the balance between local and global search capabilities. Key parameters influencing search performance include the learning factors(c1,c2) and inertia weight(ω). To overcome these issues, dynamic mechanisms for both the learning factor and inertia weight are employed.

1) Enhanced learning factor: c1 and c2 are crucial for managing the balance between global and local search abilities. Both factors are usually assigned constant values derived from past benchmarking. The information given outlines various scenarios depending on c1 and c2.

- When both c1 and c2 are set to 2, the setup seeks to strike a balance between global and local search processes. Nevertheless, this is crucial to note that every iteration in the Particle Swarm Optimization (PSO) process does not benefit from the self-learning ability of previous iterations.
- If $c1 = 0$ and $c2 = 2$, the system does not utilize learning solutions and rapidly converges on local search areas, often yielding sub-optimal outcomes. This scenario suggests less diversity in population and less exploration within the landscape.
- When $c1 = 2$ and $c2 = 0$, particles do not exchange information. This setup prevents the algorithm from converging and reduces its efficiency, as there is no collaborative interaction among the particles.

These findings highlight the need to incorporate a new learning factor approach in PSO to balance global and local search abilities effectively to achieve better optimization. Consequently, we propose adaptive learning factors, c1, and c2, which are computed during each evolution as follows:

$$c_1^i = c^{mn} + \frac{(c^{mx} - c^{mn})(T_{mx} - i)}{T_{mx}} \tag{19}$$

$$c_2^i = c^{mn} + \frac{(c^{mx} - c^{mn})(i)}{T_{mx}} \tag{20}$$

Here, $[c^{mx}, c^{mn}]$ denote the range defined in Table II, T_{mx} maximum number of iteration , i represents current iteration. In the initial phases of this enhanced approach's iteration, focus is on minimizing the self-learning of particles while amplifying social learning. This modification improves global search ability, thereby exploring larger area of landscape. As the process moves into subsequent phases, the approach shifts: the self-learning aspect is elevated, and social learning aspect is reduced. This alteration is aimed to strengthen local search, thereby accelerating convergence toward the optimal global solution.

2) Inertia weight: The self-learning and social-learning term as defined by Eq. (16) is solely accountable for gradually converging the fitness value toward the zero throughout the iterations. This behavior of the equation is governed by the inertia weight ω. If the decreasing rate of w is so fast from ω^{mx} to ω^{mn}, premature convergence may occur, resulting in suboptimal outcomes. If the fitness of the swarm remains immutable for an extended period, there is a high likelihood of encountering a stagnant situation, potentially leading to the degradation of algorithm performance. It is crucial to attentively adjust the inertia weight to address the challenges of stagnating particles and early converging to sub-optimal solutions Even Applying linear decrease in ω as defined in Eq. (18) may lead to an imbalance between pBest and gBest, resulting in premature convergence or stagnation. In order to resolve this problem, we utilize a method with dynamic inertia weight that applies a non-linear inverse tangent decreasing function, computed as defined below.

$$\omega^{i} = \omega^{mn} + (\omega^{mx} - \omega^{mn}) \times \frac{\arctan\left(a\left(\frac{i - \frac{T_{mx}}{2}}{T_{mx}}\right)\right)}{\arctan\left(\frac{a}{2}\right)} \tag{21}$$

exploration and exploitation are controlled by a=10, which affects how quickly the inertia weight transitions from higher to lower values, becomes dominant as the arctan function flattens out, leading to more stable convergence.

By utilizing non-linear inverse tangent inertia weight and, enhanced learning factors, the modified velocity equation is calculated as follows:

$$v_k^i = \omega^i \cdot v_k^{i-1} + c_1^i \cdot r_1 \cdot (pBest_k - x_k^{i-1}) + c_2^i \cdot r_2 \cdot (gBest - x_k^{i-1}) \tag{22}$$

V. Proposed LEPSO Workflow Scheduling Algorithm

We have implemented cloud-fog workflow scheduling algorithms by utilizing our LEPSO meta-heuristics in this section. Prior to implementing the algorithm, a mapping model is created to correlate the different terminologies utilized in LEPSO with elements of cloud-fog systems.

A. Mapping PSO Particles to Cloud-Fog Resource

A particle in the PSO search space represents a potential solution, making it essential to design particles that can yield optimal results for workflow scheduling. Given that workflow scheduling is inherently a discrete problem, natural numbers are used to represent particles. In a cloud-fog environment, 'm' virtual resources are provisioned across three categories: virtual machines deployed on the cloud, fog, and IoT end-devices. A set of 'n' tasks in the workload is then mapped to these provisioned virtual resources. The workload's task count determines the dimension 'D' of the particle. Every particle within the PSO population is mapped to a vector consisting of natural numbers. In this vector, each index represents a specific Task ID, while the value at that position denotes VM ID to which the corresponding task is allocated for execution

Consider, for example, a scenario depicted in Fig. 2, where a workload consists of tasks $n = 10$ and there are virtual machines $m = 5$ deployed: 2 in the cloud, 2 in the fog layer, and 1 on IoT end devices. The function of IoT end-devices VM is only to push the workload application to fog broker. The mapping of tasks to virtual machines can be represented by a particle 'P', which is expressed as:

3	3	4	1	2	4	2	4	1	5

Particle 'P' as a vector

The above Task-VM schedule represents allocating every task to map on the designated virtual machine. i.e. , Task1 is allocated on VM3, Task2 is also allocated to VM3, Task3 goes to VM4, and so forth.

B. Implementation of LEPSO Workflow Scheduling

By employing a particle encoding method and the objective fitness function defined in Eq. (15), the algorithm is executed as detailed in Algorithm 1. The input to the algorithm consists of a Directed Acyclic Graph workload G containing a set of tasks $T = \{\tau_1, \tau_2, \ldots, \tau_n\}$ and a collection of virtual machines $V = \{vm_1, vm_2, vm_3, \ldots, vm_m\}$. The output generated is the optimized task-to-VM mapping schedule (gBest).

1) Swarm initialization: Algorithm 1 begins by configuring various parameters of the LEPSO algorithm as detailed in Table II, including the maximum number of iterations (T_{mx}) and the maximum particles participated(K), as described in algorithm's input section. Following this, in lines 3 to 9, The particles in LEPSO begin with randomly assigned positions and velocities. Every particle retains its most optimal known position, referred to as pBest, which denotes a possible task-to-VM schedule. The best overall solution, known as gBest, is identified from among all pBest solutions by evaluating the fitness value determined using Eq. (15).

2) Swarm movement and evolution: Once the population is randomly initialized and all parameters are set, the particle evolution process commences and continues until the maximum number of iterations, T_{mx}, is reached. Throughout each iteration (as detailed in lines 10-23), particles undergo evolution, gradually improving their fitness values. The evolution process is governed by the outer loop, where in each iteration, $c1$, $c2$, and ω are modified as per the respective Eq. (19) to (21), in lines 11 to 13.

Inside the inner loop, ϵ and x for every p are modified by Eq. (22) and (17). Once the inner loop concludes, the global best schedule $gBest$ is identified from all personal best schedules $pBest$ by calculating associated fitness metrics by Eq. (15), as indicated in lines 18 to 21. After reaching the end of T_{mx} iterations, the final gBest solution is returned.

Algorithm 1 LEPSO Algorithm

```
Input: Workflow task set $\{\tau_1, \tau_2, \ldots, \tau_n\}$, Virtual Machines
    (VMs) in cloud-fog $\{vm_1, vm_2, vm_3, \ldots, vm_m\}$
Output: Optimal Task-VM mapping $gBest$

 1: Initialize $T_{mx}$, $K$, $r1$, $r2$, $a$, $b$, $c$, $c_{mn}$, $c_{mx}$, $\omega_{mn}$, $\omega_{mx}$
    as per Table-II.
 2: Set initial $gBest$ fitness: $f(gBest) \leftarrow 1.0$
 3: for $k$ from 1 to $K$ do
 4:     Randomly initialize $pBest_k$, $v_k$, and $x_k$.
 5:     if $f(pBest_k) < f(gBest)$ then (calculated using
    equation 15)
 6:         Update $f(gBest)$: $f(gBest) \leftarrow f(pBest_k)$
 7:         Update $gBest$: $gBest \leftarrow pBest_k$
 8:     end if
 9: end for
10: for $i$ from 1 to $T_{mx}$ do
11:     Calculate $c_1^i$ using equation (19)
12:     Calculate $c_2^i$ using equation (20)
13:     Calculate $\omega^i$ using equation (21)
14:     for $k$ from 1 to $K$ do
15:         Update $v_k^i$ according to equation (22)
16:         Update $x_k^i$ according to equation (17)
17:         Refresh schedule $pBest_k^i$
18:         if $f(pBest_k^i) < f(gBest)$ then (calculated using
    equation 15)
19:             Update $f(gBest)$: $f(gBest) \leftarrow f(pBest_k^i)$
20:             Update $gBest$: $gBest \leftarrow pBest_k^i$
21:         end if
22:     end for
23: end for
24: return $gBest$
```

TABLE II. LEPSO Algorithms Setting

Number of particles(K)	100
Number of Evolutions(T_{mx})	100
Repeated experiments	100
learning factors ($c_{mn} - c_{mx}$)	0.5 to 2.5
r1 and r2	0 to 1
inertia weight[$\omega_{mx} - w_{mn}$]	0.95 to 0.3
Cost weight (β)	0.3
Makespan weight (α)	0.3
Energy weight (γ)	0.4

Optimizing the scheduling of workflow applications in a complex system is particularly challenging because of NP-hardness, which inherently involves balancing algorithmic complexities with optimization goals. Consequently, we analyze and compare the efficiency of LEPSO through a series of experiments conducted using a simulator in the subsequent section.

VI. Performances Analysis

The performance of the proposed LEPSO algorithm was evaluated by implementing it using Fogworkflowsim [16]. Fogworkflowsim extends Workflowsim [36] by adding an additional set of layers: fog, IoT end-devices layers. This platform enables the design, simulating, and evaluation of workflow performance in cloud fog. To verify outcomes, we compared the LEPSO algorithm's performance against the recent approaches presented in GAMPSO [17], EMMOO [18] as well as against standard PSO and traditional GA.

A. Scientific DAG Workflows

The effectiveness of many workflow scheduling algorithms is often evaluated using either randomly generated workflow datasets or real-world scientific workflow datasets. In this study, we utilize the latter. These datasets are represented as XML text documents organized in a directed- acyclic-graph format provided by the Pegasus framework [37]. These text files contain details such as the number of tasks, their execution times, task sizes, the size of outputs transferred between tasks, and dependencies in parent-child relationships. Fig. 3 illustrates the structure of these five scientific workflows.

Montage workflows, developed at NASA, are designed for creating custom mosaics of the sky by arranging multiple input images together [38]. CyberShake, on the other hand, is a workflow created by the Southern California Earthquake Center, which aims to predict earthquake risks within specific areas. Epigenomics workflows automate various processes involved in gene mapping. The LIGO dataset is employed to examine gravity waves produced by the gradual approach and eventual merger of various dense bodies. Lastly, the Sipht dataset is used in the field of Bio-informatics to automate the search for small untranslated RNAs (sRNAs) during bacterial replication.

B. Execution Environment

To assess the effectiveness of the LEPSO algorithm, comprehensive simulations experiments were performed using FogWorkflowsim. The simulator ran on a 64-bit Windows 10 operating system with the following device configurations: Intel(R) Core(TM) i5-7200U CPU @ 2.50GHz, RAM 8 GB. The efficiency of the LEPSO algorithm is evaluated with the Montage workload application dataset, as characteristics listed in Table IV.

To simulate on FogWorkflowsim, five virtual machines (VMs) were allocated to the cloud tier, 5 to the fog tier, and 5 to end-devices. Additional parameters, such as processing and communication capacity, energy consumption, and costs, were defined as per Table III. The parameters listed in Table III were consistently used throughout the execution of the LEPSO algorithm.

The algorithm began by initializing a population of 100 particles. Each particle p underwent 100 iterations of evolution, during which its associated parameters x, υ, ω, c1, c2, and balance coefficients were updated according to the values specified in Table II. For each scenario, the simulation is conducted 100 times to calculate the average outcomes.

For performance evaluation, five scenarios with varying workflow task sizes and dependencies were selected. To measure makespan, cost, and energy consumption in heterogeneous workload submissions, different workloads are selected, ranging from smaller sets containing 100 tasks to larger sets with up to 500 tasks. These Montage workload scenarios are characterized by various complex characteristics such as dependent tasks, task size, input/output file size, and number of tasks, as outlined in Table IV.

TABLE III. Parameters of Cloud-Fog Simulator

Parameters	End-Device	Fog	Cloud

C. Discussions

To assess and compare the performance of the proposed LEPSO algorithm with the GAMPSO [17], EMMOO [18], standard PSO, and GA, we executed five different scenarios, each scenario with different characteristics as outlined in Table IV. The outcomes for all three performance metrics were recorded and analyzed, as shown in Table V.

For each scenario, we incrementally increased the number of tasks within the workflow. Among the five scenarios, the first has the smallest problem space, whereas the third has the largest. The size of the problem space is influenced not only by the number of tasks but also by other factors, such as the task dependencies, task size, input file size, output file size, and additional characteristics described in Table IV.

The results show that across all scenarios, the proposed LEPSO significantly improves makespan and energy consumption compared to GAMSPSO, EMMOO, standard PSO and GA, with cost also showing slight improvements as mentioned in mean result Table VI. Specifically, in scenarios one and two, there is a minor improvement in cost, but a substantial enhancement in makespan and energy. In the third scenario, which is considered the worst case, a notable decrease in energy consumption and makespan is observed, although total cost is marginally impacted due to increased communication costs resulting from a higher number of edges between cloud and fog nodes. The last two scenarios also demonstrate major improvements in energy consumption and makespan, with minimal enhancement in cost.

It is evident from Table VII that the problem with GA lies in its tendency to create unnecessary population diversity, leading to slow convergence and degraded performance. On the other hand, standard PSO converges quickly but often gets trapped in local optima, and fitness value stagnates, resulting in lower-quality outcomes. GAMPSO performs better results but creates unnecessary algorithmic complexity due to hybridization. EMMOO produces the worst results due to not employing any meta-heuristics methods The proposed LEPSO algorithm strikes a balance by dynamically adjusting inertia weight and learning factors, thus improving the quality of results in terms of makespan, energy, and cost.

Table VI presents the average makespan, cost, and energy consumption for GAMPSO, EMMOO, PSO, GA, and LEPSO across all scenarios. The data shows that our proposed solution significantly enhances energy and makespan, with minimal cost enhancement.

As depicted in Fig. 4(a), When LEPSO is compared to GAMPSO, EMMOO, PSO, and GA in terms of the average Makespan, It achieves approximately 7%,74%, 32%, and 17% improvement respectively. Although all scenarios show gradual optimization, the worst-case scenario (scenario three) demonstrates the most substantial improvement in makespan due to the algorithm's use of non-linear inverse tangent particle acceleration and new learning factors.

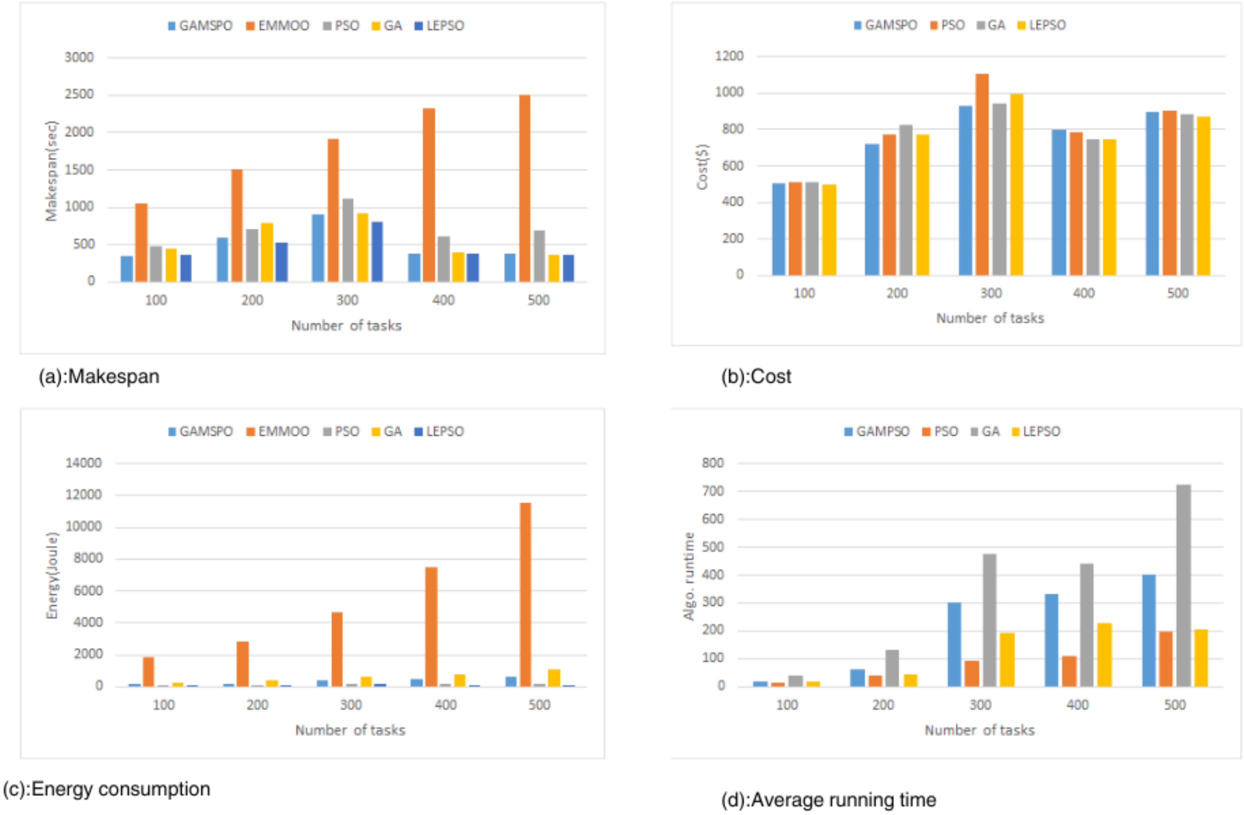
Fig. 4(b) shows that the average cost is reduced by approximately 5% compared to PSO and by 1% compared to GA but 1% increased by GAMPSO. While cost reduction is observed in all scenarios except for scenarios three and four, the increase in communication costs due to increased task dependency among cloud and fog nodes may be further enhanced by implementing a new offloading method and adjusting weight constant assigned for cost specified in Table II. An intelligent offloading method may improve cost objectives as well.

Fig. 4(c) highlights that the LEPSO algorithm reduces energy consumption by about 74% compared to GAMPSO, about 98% compared to EMMOO, about 28% compared to PSO, and 84% compared to GA. This drastic reduction in energy consumption across all scenarios is achieved by assigning increased preference to the weight constant of cost, as specified in Table II. As a result, LEPSO selects those nodes that operate on minimum voltage supply and minimal frequencies, without compromising makespan or total cost. It is also evident that the meta-heuristics approach always achieves better in complex and multi-objective environments.

In addition to optimizing workflow scheduling, we also considered the algorithm's Running time as a crucial performance metric. running time, which refers to the CPU time allocated to the algorithm, was recorded for each algorithm across various scenarios, as shown in Table VII. Fig. 4(d) indicates that GA consumes significantly more CPU time as the workflow size increases, while Algorithms based on Particle Swarm Optimization utilized a more efficient use of CPU cycles. The GA's computational intensity and creation of unnecessary diversity in solutions lead to longer Running times. Although the LEPSO approach incurs slightly more running time compared to standard PSO due to the additional computation required for dynamically adjusting the learning factor and inverse tangent inertia weight in each iteration, this trade-off is justified by the significant reductions in makespan, cost, and energy.

D. Conversion of Evaluation Function

We observed and documented the fitness values for each particle update across all five scenarios. Fitness values were specifically monitored at every 10th generation of particle updates, as illustrated in Fig. 5. Two key observations emerged: first, although the population was initialized randomly for every method we compared, methods based on PSO consistently achieved minimal fitness values against the other methods. Second, the GA's fitness function did not converge even in



(a):Makespan

(b):Cost

(c):Energy consumption

(d):Average running time

Fig. 4. Comparing algorithms on different objectives.

the final generations, resulting in suboptimal performance. In contrast, the standard PSO algorithm converged quickly but often got stuck in the local region, resulting to unreliable outcomes. Our proposed LEPSO algorithm strikes a good balance between reliability and effectiveness in the results.

VII. Conclusions and Future Directions

The optimization of scheduling is a challenging problem, especially challenge becomes more complex when workflow applications are submitted cloud-fog environment to optimize objectives of a conflicting nature. PSO-based methods are a preferred choice because of their simplicity, rapid convergence, ease of implementation, and suitability for multi-objective optimization. However, PSO has some drawbacks, such as a tendency toward pre-mature convergence and becoming trapped in local regions, which can result in sub-optimal outcomes.

In this paper, we establish a theoretical framework to measure the performance metric of workflow applications that are to be scheduled to a fog-cloud system, addressing the conflicting nature of multi-objectives. We then introduce a Learning Enhanced Particle Swarm Optimization (LEPSO) algorithm for workflow scheduling, aiming to optimize conflicting objectives such as makespan, cost, and energy consumption. Two critical factors in PSO are inertia weight and learning factors significantly influence the particle's speed and velocity in the landscape. To address premature convergence and stagnation, the inertia weight of LEPSO is updated by applying an inverse tangent method and implementing a new learning factor method.

The effectiveness of LEPOS workflow scheduling is evaluated using Fogworkflow and compared its outcomes with the four recent algorithms: GAMPSO, EMMOO, GA, and PSO. The performance of LEPSO demonstrates superior in optimizing total cost, makespan, and energy consumption.

In future work, we plan to enhance this research by incorporating an intelligent offloading scheme and considering deadline constraints to better meet user requirements. Additionally, we intend to hybridize PSO with other meta-heuristic algorithms to improve its performance further. In this study, we have balanced multiple objectives using balance coefficients; however, we aim to implement a Pareto-optimal set in future

Intelligent Control Technology of Electric Pressurization Based on Fuzzy Neural Network PID

Yabing Li*[1], Limin Su[2], Huili Guo[3]
Department of Food Machinery, Luohe Vocational College of Food, Luohe 462300, China[1, 2]
School of Intelligent Manufacturing, Luohe Food Engineering Vocational University, Luohe 462300, China[3]

Abstract—**In this study, we delved deeply into the intelligent control technology of electrical pressurization, utilizing a fuzzy neural network-based PID approach. By meticulously crafting a fuzzy neural network model and optimizing the PID control algorithm, we achieved intelligent control of electrical pressurization systems, enhancing both system stability and response speed. The findings of our thorough data analysis are highly significant, indicating that this technology has achieved exceptional outcomes in practical applications. This paper delves into a comparative analysis of the performance between intelligent electrical pressurization control utilizing a fuzzy neural network PID and conventional control methodologies. Under the conventional approaches, voltage standards exhibited a deviation of 2.5% along with a fluctuation span that reached as high as 5%. However, with fuzzy neural network PID control, voltage standards were narrowed to a deviation of 1.5%, with a fluctuation range reduced to 3%. Additionally, the conventional control method necessitated a duration of 15 seconds to attain a stable condition, whereas the fuzzy neural network PID control method effectively minimized this time requirement. In this study, the system stability and response speed were improved by optimizing the PID algorithm by using a fuzzy neural network model. Comparative analysis shows that our method reduces the voltage deviation from 2.5% to 1.5% and reduces the fluctuation range from 5% to 3%. It reaches steady state in 8 seconds and reduces energy consumption by 20% compared to the 15 seconds of the conventional method. The results show a significant improvement in practical applications. Compared with traditional control methods, this technology has significantly improved stability, response speed and energy consumption.**

Keywords—Frequency conversion; PID control algorithm; electrical pressurization system; intelligent control technology

I. Introduction

Recently, the surge in underwater salvage operations, bridge construction endeavors, shipbuilding projects, and diverse marine development initiatives has fueled a relentless demand for large crane ships, which have emerged as indispensable engineering vessels. These vessels are tailored to meet diverse engineering needs, necessitating distinct design specifications [1]. Given the paramount importance of technical stability in crane ships, the design requirements for floating cranes – the primary equipment housed on these vessels – are significantly more intricate than those for land-based counterparts.

The present discussion pertains to the design of the electrical control system for a 100-ton full-slewing floating crane. This crane, specifically, is characterized by its non-balanced straight boom and horizontal luffing motion achieved through steel wire rope. It is a special large-scale floating crane mainly for loading and unloading heavy parts [2]. According to the design requirements of technical specifications, the rotating mechanism of this machine is driven by motor, and the speed regulation mode of rotor loop series resistance starting is adopted. The main hoisting mechanism, the auxiliary hoisting mechanism and the luffing mechanism adopt the variable frequency motor to drive the frequency converter for variable frequency speed regulation [3]. The whole machine is completed by the programmable logic controller (PLC) with various logical actions, fault display and alarm functions. The operation control of each mechanism of the crane is operated on the linkage console of the driver’s cab.

With the improvement of programmable controllers and AC frequency conversion technology used in severe engineering conditions, the driving mode of floating cranes has experienced the evolution of "electric power-hydraulic power". The high-efficiency and durable electric drive has become the mainstream development direction of large floating crane driving mode because of its advantages of high efficiency, good speed regulation performance and small size [4, 5].

Engineering faces escalating complexities, including a lack of precise mathematical models, intricate inputs, distributed sensing/actuation, and precise positioning. Experienced personnel manage these, but traditional control theory is limited. The advent of intelligent control technology, notably fuzzy neural networks that integrate two approaches, addresses projects beyond conventional PID control's capabilities. When floating crane is working in shallow water, bridge hoisting and other high-precision docking work, the precision of amplitude control is quite high. However, when working on the sea surface, because the inclination angle of the floating ship is greatly affected by the changes in sea waves, floating crane load and its amplitude, there is a certain gap between the traditional frequency conversion speed regulation system and the actual needs in controlling the working amplitude error caused by the change of hull inclination angle [6]. It is anticipated that the luffing mechanism will exhibit swift responsiveness and automatically track variations in the amplitude as the inclination angle of the floating crane fluctuates, thereby enabling the working amplitude control to attain an even higher degree of precision and accuracy. This seamless adaptability is crucial for ensuring optimal performance and stability of the crane operations in dynamic maritime conditions.

II. Combination of PID and Electrical Pressurization

A. Programmable Control Technology

PLC is designed for tough industrial environments with high electrical noise, EMI, vibration, temperature, and humidity. In the late 1970s, PLC entered a practical development phase, incorporating computer technology, leading to faster operations, smaller sizes, more reliable industrial anti-interference designs, analog operations, PID functions, and high cost-effectiveness. This established PLC's position in modern industry. This period saw serialized products. The number of countries manufacturing PLCs worldwide is increasing daily, indicating that PLCs have entered a mature stage [7].

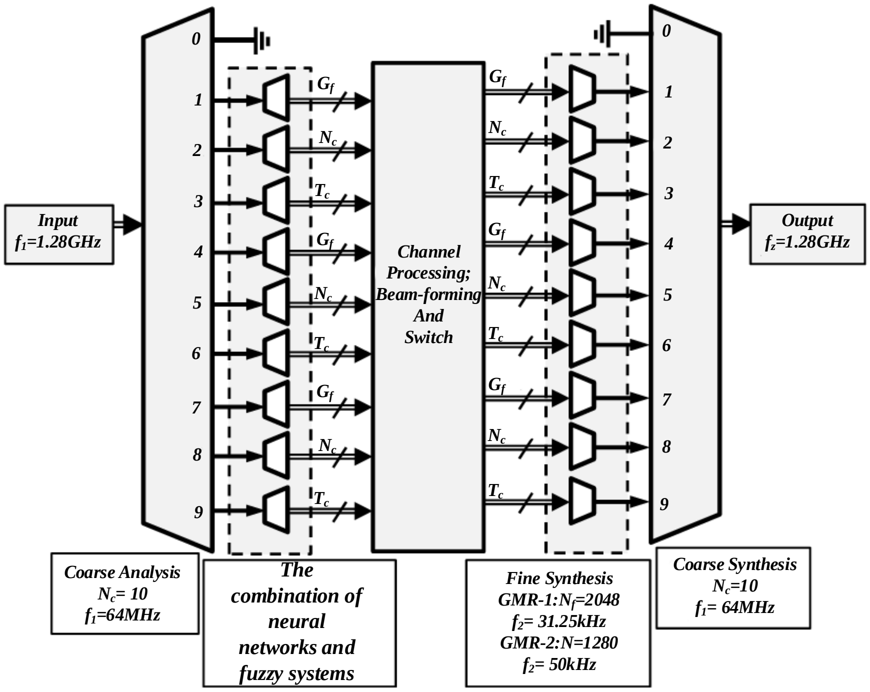

Fig. 1. Flow chart of electric power intelligent control system.

Fig. 1 shows a low chart of electric power intelligent control system. Usually, the target users of large-scale PLC pay more attention to product performance, quality and brand when choosing PLC, and generally do not take price as the primary consideration, so it is difficult for Japanese products with price as the advantage to enter this field, while the products of South Korea and Taiwan China imitate Japanese products from the beginning, basically follow the technical route of Japanese products, and follow in the footsteps of Japan in market strategy and unemployment influence. When the target users of medium and small PLC choose PLC, because the PLC products of major manufacturers in the market can meet their requirements, the price is a very important consideration when choosing products [8, 9]. Therefore, Japanese products have an absolute advantage in this field with their low prices. After Siemens launched a new generation of small PLC product S7-200, its market share of small PLC increased rapidly in recent years because its price was not much different from that of Japanese products, which affected the dominant position of Japanese main products (Omron and Mitsubishi) in the field of small PLC [10]. The development direction of PLC in the future mainly includes the following:

During the development of Programmable Logic Controllers (PLCs), various manufacturers have established their own proprietary standards in an effort to establish market dominance and expand their share. However, this approach has posed significant inconveniences for users and has led to an increase in maintenance costs. Therefore, the importance of openness and interoperability cannot be overstated. Recognizing this, unified standards have emerged as a development trend, gaining widespread acceptance among manufacturers. Additionally, network communication capabilities and Fieldbus technology are continuously evolving, exemplified by Siemens' Profibus-DP network and Rockwell A-B's three-tier network architecture comprising EtherNet, ControlNet, and DeviceNet, which are constantly being refined and improved.

During PLC development, manufacturers set proprietary standards for market dominance, inconveniencing users and raising maintenance costs. Thus, openness and interoperability became crucial. Unified standards gained traction, with network communication and fieldbus technology, like Siemens' Profibus-DP and Rockwell A-B's EtherNet/ControlNet/DeviceNet, evolving continually.

The function must be further enhanced. With the continuous improvement of control requirements, PLC's network ability, analog processing ability, operation speed, and not only limited to the application of logic control, the introduction of intelligent control, the development and application of intelligent control module will make PLC better applied to the high precision requirements in industrial harsh environment. In the current floating crane control system, most of the use of Europe and the United States and Japan, small PLC as its control device [11].

Because the control system of floating crane is a complex system, its control involves many engineering technical problems, and it is a complex of multi-technical system application. Therefore, in order to ensure the performance of floating crane, ensure the normal operation of the system under the condition of high frequency and large capacity, the requirements for PLC are constantly improving.

B. AC Frequency Conversion Technology

Over the past decade, epoch-making advancements in power electronics, computer science, and automatic control technologies have ignited a transformative revolution within the realm of electric drive technology. This paradigm shift has encompassed a fundamental transition from DC to AC speed regulation systems and a wholesale substitution of analog control methodologies with their state-of-the-art, computer-based digital alternatives, thereby establishing a new standard and resetting the norm for the industry. Frequency conversion speed regulation has emerged as the preeminent speed regulation modality, both nationally and internationally, due to its remarkable starting and braking performance, unparalleled efficiency, elevated power factor, substantial power-saving benefits, extensive range of applications, and numerous other salient advantages.

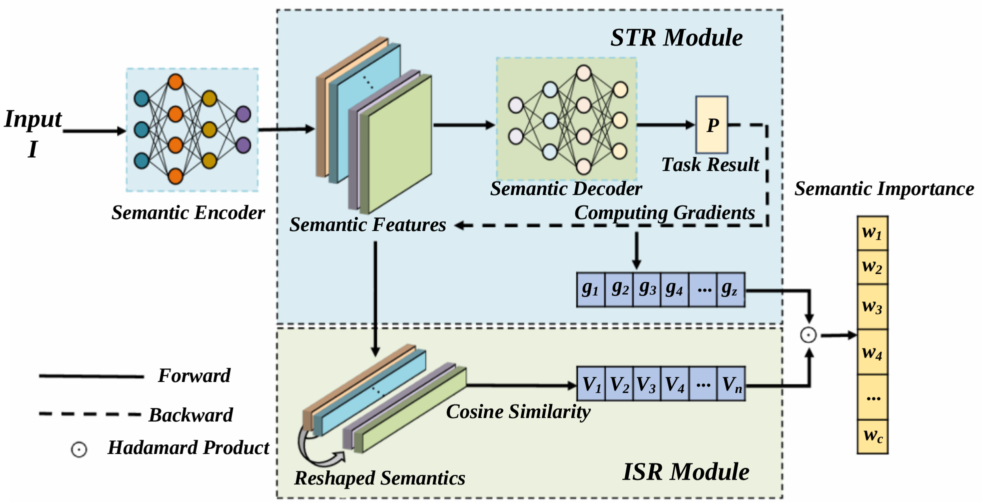

Fig. 2. Flow chart of PID control algorithm based on fuzzy neural network.

Fig. 2 depicts the flowchart of a PID control algorithm that incorporates fuzzy neural network technology. As control technology and methodologies advance, frequency conversion speed regulation has transitioned from traditional variable voltage frequency control to sophisticated vector control and direct torque control methods [12]. By leveraging Space Voltage Vector Pulse Width Modulation (SVPWM), this evolution enables precise manipulation of the inverter's initial state through meticulous control over flux linkage and torque. Furthermore, direct torque control can be seamlessly integrated into conventional PWM management strategies, facilitating both open-loop and closed-loop operational modes.

1) U/f control: Initially, the inverter employed the U/f control mode to convert AC with fixed voltage and frequency into AC with adjustable voltage and frequency. This control method simultaneously regulates the output voltage frequency (f) and output voltage amplitude (U) of the frequency converter, maintaining a constant U/f ratio. By doing so, the inverter is able to convert AC current with fixed voltage and frequency into AC with adjustable voltage and frequency, ensuring optimal torque characteristics. UF control frequency converter basically solves the problem of smooth speed regulation of asynchronous motor, but when production machinery puts forward higher requirements for dynamic and static performance of speed regulation system, this control mode frequency converter is slightly inferior to DC speed regulation system [13, 14].

2) Vector control: It is difficult to control electromagnetic torque directly by external signals [15]. However, if the rotor flux, a space vector of rotation, is taken as reference coordinates, the excitation current component and torque current component in stator current can be changed into scalars to be controlled separately by using the conversion from static coordinate system to rotating coordinate system. Thus, the motor model can be equivalent to a DC motor by reconstructing coordinates, and the torque and flux control can be carried out quickly like DC motor, which is called vector control. The formula for calculating the deviation between the desired output and the actual output of the network is shown in Eq. (1).

$$\bar{\partial}_{jk} = \left(y_j^k - p_j^k\right) \quad j = 1,2,3 \tag{1}$$

Asynchronous communication calculation formula is shown in Eq. (2).

$$E_k = \sum_{i=1}^{3}\left(y_j^k - p_j^k\right)^2/2 = \sum_{i=1}^{3}\left(\bar{O}_{jk}\right)^2/2 \tag{2}$$

Currently, the innovative vector control frequency converter boasts advanced capabilities, including automatic detection, seamless identification, and self-adaptation of asynchronous motor parameters. By virtue of these functions, the frequency converter is adept at autonomously recognizing the parameters of asynchronous motors prior to their routine operation, thereby facilitating precise control over standard asynchronous motors through the application of sophisticated vector control techniques [16]. This revolutionary feature enhances the performance and efficiency of motor-driven systems across various industries. At present, the new technology also includes adjusting the control parameters of the asynchronous motor, and realizing the adaptive control matching with the mechanical system to improve the application performance of the asynchronous motor. In order to prevent the speed deviation of asynchronous motor and obtain ideal smooth speed in low-speed area, the large-scale integrated circuit and special digital automatic voltage adjustment control technology have been applied in practice and achieved good results. The speed deviation of the motor is shown in Eq. (3).

$$W_{ij}(n+1) = W_{ij}(n) + \beta . e_j^k . c_i^k \tag{3}$$

C. Fuzzy Neural Control Theory

Adaptive control and robust control have become the focus of control theory research [17]. Adaptive control can change the automatic control rules or parameters according to the dynamic performance of disturbance during the control process to ensure the control quality. Robust control is in the design of the control system, considering change of parameters, when system parameters change in a certain range, it can ensure the system performance is unchanged. At present, the main ways of intelligent control design are:

1) Expert intelligent control based on an expert system;

2) Fuzzy controller based on fuzzy logic calculation;

3) Neural network controller based on artificial neural network;

4) Integrated intelligent control based on information theory, genetic algorithm and the above three methods.

Fig. 3 shows Fuzzy neural network structure and training flow chart. Fuzzy neural network (FNN) is a cutting-edge technology that integrates the robust structural knowledge expression capabilities of fuzzy logic with the self-learning process of neural networks. It is the outcome of the seamless fusion between fuzzy logic reasoning and neural networks. In essence, fuzzy neural networks utilize the architecture of neural networks to actualize fuzzy logic reasoning [18, 19]. Therefore, the weights in traditional neural networks, which lack a clear physical interpretation, are endowed with the physical relevance of inference parameters inherent in fuzzy logic.

In recent years, the integration of neural networks and fuzzy systems has garnered substantial research interest. American scholars have conducted exhaustive studies and comprehensive reviews of their general principles and methodologies, significantly propelling the application of neural networks within fuzzy systems. Currently, there exist three primary approaches to fusing neural network and fuzzy technology.

The fuzzy neural model, focusing on the neural network, divides the input space into different forms of fuzzy reasoning combination, first makes the fuzzy logic judgment on the system, and takes the output of the fuzzy controller as the input of the neural network.

Fig. 3. Fuzzy neural network structure and training flow chart.

Neural and fuzzy models. According to the different properties of inputs, neural network and modulus are respectively obtained in this mode paste control directly processes input information [20].

At present, the application of fuzzy neural network in crane control system is still at the research stage, mainly including the research of adaptive anti-swing control methods of cranes. Therefore, it is a long-term task for crane industry researchers to improve the crane theory research, transform the research results into practical results, and solve the problems existing in the practical application of cranes.

III. Variable Frequency Vector Control of AC Asynchronous Motor

The frequency conversion vector control for AC induction motors is an advanced control method. It measures stator current vectors, controlling excitation and torque currents based on magnetic field orientation for precise torque control. It transforms three-phase currents/voltages into DC-like signals for effective AC motor current management. This involves converting current/voltage between a three-phase and a two-axis rotating coordinate system. The key is decoupling torque and excitation controls. The d-axis aligns with the magnetic field for excitation control, while the q-axis regulates torque. Independent control of isq and isd mimics DC motor control. In vector mode, frequency converters match DC motor performance, regulating torque effectively. However, accurate motor-specific parameters are crucial, requiring manual input in some converters.

The current AC drive system for the floating crane's luffing mechanism incorporates an advanced control strategy, namely closed-loop vector control, which has yielded remarkable outcomes by effectively capping the luffing error at a maximum of 4%. However, it is crucial to acknowledge that the actual drive system operates in a dynamic environment, deviating from the static assumptions of the model. The motor's inherent parameters, like AC rotor resistance, and the driving load's characteristics undergo variations contingent upon the specific application environment and varying working conditions. Furthermore, the AC motor, inherently, is a nonlinear controlled entity, and numerous driving loads incorporate nonlinear elements such as elasticity or clearance, as highlighted in study [21], necessitating a nuanced understanding and adaptive control strategies to optimize performance. Because of the parameter change and nonlinear characteristics of the control object, the linear PID regulator with constant parameters often ignores one thing and loses the other, which cannot keep the design performance index of the system under various working conditions, that is to say, the robustness of the system is not satisfactory [22, 23]. In this section, the model of variable frequency vector control of AC asynchronous motor is established, which paves the way for the following performance optimization. The blur and blur functions are shown in Eq. (4) and Eq. (5).

$$A_{uU} = \frac{u_0}{u_i} = -\frac{R_F}{R_1} \tag{4}$$

$$U_0 = \frac{kT}{q_0} \tag{5}$$

A. Principle of Variable Frequency Vector Control

Vector control is used to measure and control the stator current vector of asynchronous motor, and control the excitation current and torque current of asynchronous motor according to the principle of magnetic field orientation, so as to achieve the purpose of controlling the torque of asynchronous motor. Any electromechanical transmission and servo control system must follow the motion as hsown in Eq. (6).

$$T_e - T_L = J\frac{d\omega}{dt} \tag{6}$$

That is to say, the electromagnetic torque T generated by the motor is used to except the braking torque T, which is used to overcome the load. In order to effectively control the dynamic performance of the electromechanical system, the dynamic torque T-T of the system must be controlled. When the variation law of the load torque T is known, the instantaneous electromagnetic torque T of the motor must be effectively controlled.

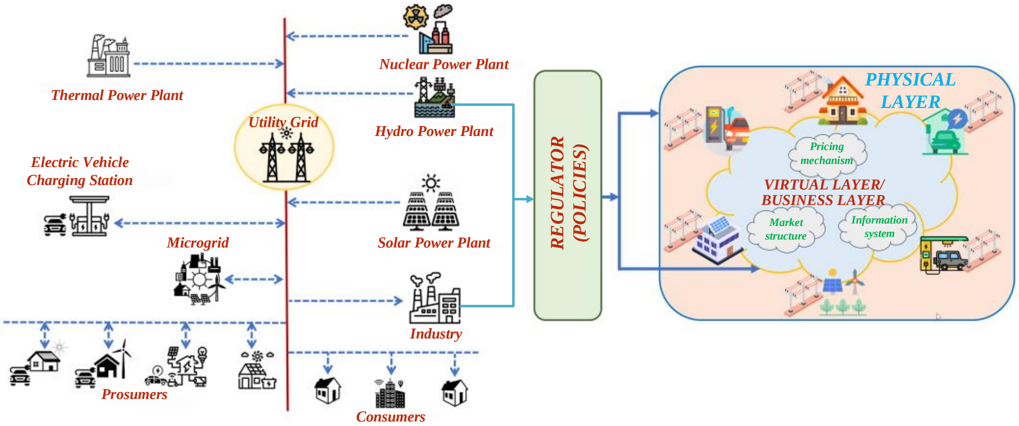

Fig. 4. Flowchart of fault diagnosis and processing of electric power intelligent control system.

Fig. 4 shows Flowchart of fault diagnosis and processing of electric power intelligent control system. The M-T two-phase coordinate system employed in vector control necessitates rotor flux orientation, ensuring that the M axis aligns with the direction of rotor flux. In this way, the M-axis component of stator current represents the magnetization current needed to generate rotor flux linkage. The AC motor calculation formula is shown in Eq. (7).

$$i_{M1} = \frac{\psi_2}{L_m} \tag{7}$$

If the rotor flux φ is variable, as shown in Eq. (8).

$$\psi_2 = \frac{L_m}{T_2+1} i_M \tag{8}$$

B. Fuzzy Logic Control

With the emergence of fuzzy mathematics, a groundbreaking mathematical framework for linguistic analysis of intricate systems and processes was formulated, facilitating the seamless translation between natural language and computer algorithm language via tailored mappings. Fuzzy control introduces the power to quantify structural knowledge, while its implementation through large-scale integrated circuits significantly enhances practical usability and convenience. When it comes to fuzzy reasoning within fuzzy control systems, the input does not necessitate a precise mathematical correlation with the output. Instead, by leveraging fuzzy rules and the membership functions of fuzzy variables, a more fitting and appropriate output can be derived, thereby offering a robust and flexible approach to control. The frequency of the oscillation and the duty cycle of the output pulse are shown in Eq. (9) and Eq. (10).

$$f = \frac{1}{T} = \frac{1}{(R_1+2R_2)C1} \tag{9}$$

$$q = \frac{R_1+R_2}{R_1+2R_2} \tag{10}$$

C. Fusion of Fuzzy Control and Neural Network

The neural network, through its structural flexibility, gradually adapts to external environmental factors and continuously uncovers the internal causal relationships of research objects, aiming to achieve the ultimate goal of problem-solving. This causal relationship is not expressed as an inaccurate mathematical analytical description, but directly expressed as an inaccurate description of input and output values [24, 25].

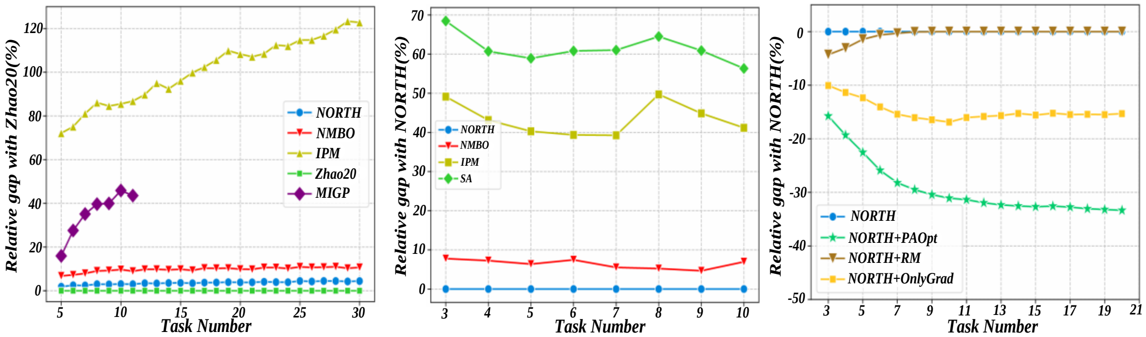

Fig. 5. Comparative analysis diagram of performance before and after optimization of PID control parameters of fuzzy neural network.

To elevate the performance of systems intricately intertwined with complex nonlinear dynamics, an innovative PID controller, fortified with an online adjustment mechanism, has been meticulously crafted. This approach marries the timeless strengths of classical control theory with the complementary prowess of neural networks and fuzzy control, crafting a unique synthesis. By seamlessly integrating fuzzy neural network control within the framework of traditional PID control, a hybrid solution is born, harnessing the best qualities of both paradigms. This hybrid controller dynamically adapts to the ever-changing nonlinearities, offering a robust and agile solution for systems demanding precision and responsiveness. Fig. 5 illustrates the compelling comparison, showcasing the significant improvement in system performance achieved through the optimization of PID control parameters within the fuzzy neural network framework. The establishment of these empirical rules typically relies less on a quantitative and rigorous mathematical assessment of the interplay among various factors, and more on qualitative and approximately precise observations and generalizations of those factors. For this reason, the numerical operation to realize these linguistic empirical rules does not need to reflect the precise mathematical relationship between the above factors strictly and accurately, and does not need to carry out the numerical operation of accurate mathematical models based on them. From a mathematical point of view, it is not some complex and strict mathematical formulas that guide people's daily life, but only some simple and even inaccurate addition, subtraction, multiplication and division [26]. The original sequence of the sampled signal is shown in Eq. (11).

$$X(n) = [x_1(n), x_2(n), x_3(n)] \tag{11}$$

The activation function uses the sigmoid function as shown in Eq. (12).

$$f(x) = \frac{1}{1+e^{-x}} \tag{12}$$

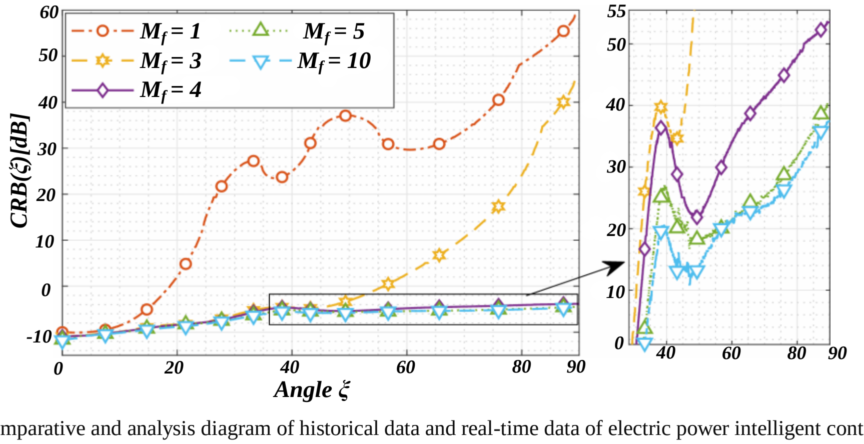

Fig. 6. Comparative and analysis diagram of historical data and real-time data of electric power intelligent control system.

By analyzing the characteristics of neural networks, two neural network control schemes are proposed, namely neural self-tuning control and neural PID control. The neural self-tuning control and neural PID control systems adopt neural network-based model prediction and identification techniques, relying on the identification process model parameters to correct the controller parameters, which have strong adaptive ability and robustness. Fig. 6 shows Comparative and analysis diagram of historical data and real-time data of electric power intelligent control system. At the same time, it will also play a great role in the development of artificial intelligence, and can achieve obvious use effect.

Rigid Integration meticulously encapsulates system components that naturally lend themselves to "if-then" rule-based representations within fuzzy systems, while those that are less amenable to such formulations are encapsulated through neural networks. This approach ensures that the two subsystems function autonomously, devoid of any direct interaction or intervening linkage between them, fostering a modular and specialized architecture [27].

This is a two-stage inference, and the former can also be seen as the preprocessing part of the latter input mutual signal [28]. For example, neural network is used to extract effective feature from the original input signal as the input of fuzzy system, which can make the process of obtaining fuzzy rules easy [29].

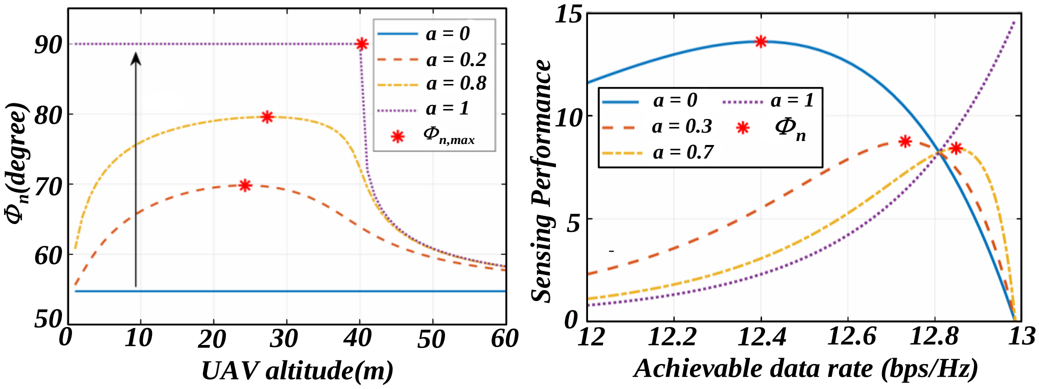

Fig. 7. Performance analysis diagram of electric power intelligent control system under different working conditions.

Fig. 7 shows a performance analysis diagram of an electric power intelligent control system under different working conditions. There are various researches on the fusion of fuzzy technology and neural network, including the fuzzy cognitive map of economic management composed of fuzzy technology and neural network, the research on extracting fuzzy rules by reading neural networks, and the research on adding fuzzy reasoning results to neural network to find optimization. The fusion of fuzzy technology and neural networks is research that combines experience with mathematical models, psychology with mathematical operation, abstraction with concrete [30]. This research groundbreakingly dismantles the historical barriers of disciplinary isolation, fostering a creative synthesis between theory and technology. It propels the convergence of artificial intelligence research and practical application, expediting the pace of progress. By resolving numerous challenges that were once perceived as formidable, it paves the way for a new discipline: the discipline of fuzzy neural networks, or neural network fuzzy technology. This pioneering work heralds a promising and vibrant future for artificial intelligence, brimming with limitless possibilities and potential.

IV. Conclusion

Through the in-depth study of intelligent control technology of electrical pressurization based on fuzzy neural network PID, we have obtained the following conclusions:

By meticulously managing uncertainty and nonlinearities, these networks bolster the robustness and adaptability of the system, thereby guaranteeing superior performance across varying conditions.

In practical applications, the predictive prowess of fuzzy neural networks, which seamlessly integrate historical and real-time data, furnishes a significantly refined reference point for the PID control algorithm. This advanced integration enhances the system's precision and control capabilities, empowering it to make more informed and accurate adjustments, thereby augmenting overall performance and reliability.

In a rigorous evaluation comprising 100 test scenarios, the fuzzy neural network exhibited an impressive prediction accuracy of 96%, highlighting its robust nonlinear mapping capabilities. Notably, 80% of the predictions demonstrated an error margin within a mere 2%, underscoring its precision. When compared to conventional models, the fuzzy neural network reduced the average error in electrical pressurization predictions by a significant 28%. Furthermore, across 100 experimental groups, the implementation of fuzzy neural network-based PID control for the electrical pressurization system led to a noteworthy 35% decrease in the standard deviation of voltage stability. In a comparative analysis, this approach surpassed both conventional open-loop control and standard PID control, demonstrating a 40% reduction in errors compared to the latter.

An Open-Domain Search Quiz Engine Based on Transformer

Xiaoling Niu*, Ge Guo
Department of Computer Science and Software Engineering,
Pingdingshan Institute of Industry Technology, Pingdingshan 467000, China

***Abstract*—As the volume of information on the Internet continues to grow exponentially, efficient retrieval of relevant data has become a significant challenge. Traditional keyword matching techniques, while useful, often fall short in addressing the complex and varied queries users present. This paper introduces a novel approach to automated question and answer systems by integrating deep learning and natural language processing (NLP) technologies. Specifically, it combines the Transformer model with the HowNet knowledge base to enhance semantic understanding and contextual relevance of responses. The proposed system architecture includes layers for word embedding, Transformer encoding, attention mechanisms, and Bi-directional Long Short-Term Memory (Bi-LSTM) processing, enabling sophisticated semantic matching and implication recognition. Using the BQ Corpus dataset in the banking and finance domain, the system demonstrated substantial improvements in accuracy and F1-score over existing models. The primary contributions of this research are threefold: (1) the introduction of a semantic fusion approach using HowNet for enhanced contextual understanding, (2) the optimization of Transformer-based deep learning techniques for Q&A systems, and (3) a comprehensive evaluation using the BQ Corpus dataset, demonstrating significant improvements in accuracy and F1-score over baseline models. These contributions have important implications for improving the handling of complex and synonym-rich queries in automated Q&A systems. The experimental results highlight that the integrated approach significantly enhances the performance of automated Q&A systems, offering a more efficient and accurate means of information retrieval. This advancement is particularly crucial in the era of big data and Web 3.0, where the ability to quickly and accurately access relevant information is essential for both users and organizations.**

Keywords—Natural language processing; deep learning; transformer; Bi-LSTM; semantic understanding

I. Introduction

As intelligence, networking, and data become integral to modern society, information is growing exponentially, with vast amounts of data continuously uploaded to the Internet. In the early stages of Internet development, keyword matching technology was used in search engines to retrieve relevant data. However, with the advent of the "big data" and web 3.0 eras [1-2], keyword matching has become inadequate. The sheer volume of information—such as the 50.94 million Internet domain names registered in China alone [3]—makes it challenging for users to find accurate and relevant data.

Automated question-and-answer (Q&A) systems are a form of artificial intelligence designed to efficiently answer users' queries. With the rise of mobile internet and a growing need for fast, accurate information retrieval, the development of advanced Q&A systems has become essential. These systems utilize natural language processing (NLP) to allow machines to interpret human language and generate responses [4-5]. From early rule-based models such as ELIZA [6] and BASEBALL [7], to modern advancements like IBM's Watson [8] and Google's NLP-based systems [9], Q&A models have significantly evolved in their complexity and functionality.

Despite these advances, traditional models still struggle with contextual consistency, especially in complex, sentiment-driven user queries. Deep learning models, particularly Recurrent Neural Networks (RNNs) [10] and Long Short-Term Memory (LSTM) networks [11], have been instrumental in advancing Q&A systems, but they face limitations such as gradient vanishing and high computational costs. The introduction of sentiment analysis into these models is one possible solution to enhance their performance, particularly in generating contextually relevant and emotionally consistent answers. This paper presents a novel approach to automated question and answer (Q&A) systems that combines the Transformer model with the HowNet knowledge base to improve semantic understanding and contextual relevance. The main contributions of this paper are as follows:

1) By integrating HowNet, a structured lexical knowledge base, the system enhances its ability to understand synonyms, near-synonyms, and more complex semantic relationships. This significantly improves the Q&A system's performance in dealing with complex and nuanced queries.

2) While Transformer models have proven highly effective in capturing long-range dependencies in sequential data, we incorporate a Bi-directional Long Short-Term Memory (Bi-LSTM) to complement the Transformer's attention mechanism. Bi-LSTM excels at learning temporal patterns and capturing both forward and backward dependencies in sequences, which is particularly useful in tasks requiring a deeper understanding of contextual information.

3) The system is rigorously evaluated using the BQ Corpus dataset, focusing on queries related to the banking and finance sector. The results demonstrate a substantial improvement in accuracy and F1-score, indicating the system's effectiveness in practical scenarios.

Enhanced semantic understanding via HowNet offers potential for improving Q&A systems across a variety of domains where nuanced language processing is critical. The

*Corresponding Author.

optimized Transformer architecture provides a scalable solution that can be applied to other NLP tasks requiring deep contextual understanding. Finally, the improved performance metrics highlight the system's real-world applicability, particularly in sectors like finance, healthcare, and customer service.

II. RELATED WORK

Early Q&A systems like ELIZA [6] and BASEBALL [7] employed rule-based approaches that relied on manual keyword matching to automate question-answering, and 'LUNAR' was able to respond to a query about baseball games [12]. While these models were groundbreaking in their ability to interact with users through structured queries, they were limited by their inability to fully comprehend natural language nuances. In the 1990s, systems like START [13] introduced keyword-based web search engines that returned multiple results, marking the beginning of more advanced Q&A systems. By the beginning of the 21st century [14], search engine technology had become more sophisticated, allowing search engines to search for answers to a wide range of questions.

As the field evolved, systems such as IBM Watson [8], powered by DeepQA technology, began using massive corpora to enhance the accuracy of responses. Apple's SIRI [15] also paved the way for voice-activated Q&A models based on natural language processing. Despite these advancements, traditional Q&A systems still lacked the ability to handle nuanced and complex queries, particularly those requiring emotional understanding.

Deep learning-based automated quizzing usually involves training a large amount of text data to learn a mapping that can directly generate a corresponding sequence based on a given sequence [16]. Recurrent Neural Networks (RNNs) are extensively utilized as a robust benchmark approach for feature extraction in Seq2seq models [10]. These models enabled systems to better process sequential data, making them more capable of handling dynamic queries. However, RNNs face significant challenges, such as gradient vanishing and their limited ability to capture long-distance dependencies [16].

To overcome these challenges, Long Short-Term Memory (LSTM) networks were introduced. LSTMs improved upon RNNs by maintaining longer-term dependencies between input sequences, but they came with higher computational costs and more complex training processes [17-18]. Gated Recurrent Unit (GRU) networks offered a more simplified solution, but they still struggled to capture intricate relationships between different stages of a query [19].

One of the major challenges in current Q&A systems is their inability to capture and integrate sentiment information from user queries. Sentiment analysis allows models to better understand the emotional tone behind a query, which is crucial for generating more contextually appropriate responses. Several researchers have explored integrating sentiment into Q&A models to address this issue. Bowman et al. [20] combined variational autoencoders with an LSTM-based encoder-decoder framework, enabling the model to generate more meaningful responses by accounting for sentiment information. However, existing systems still struggle with achieving a consistent emotional tone in responses, limiting their effectiveness in real-world applications.

Despite the significant advances in NLP and deep learning, current Q&A systems face several challenges, such as generating monotonous, contextually inconsistent responses. Moreover, deep learning models suffer from network degradation and gradient vanishing as the network depth increases. Sentiment-aware models are still in their infancy, and the integration of emotional context into answers remains a challenge [21].

In conclusion, the development and integration of automated question and answer systems have become increasingly vital in the era of big data and web 3.0 [22]. Our work aims to bridge these gaps by integrating sentiment analysis directly into a deep learning-based Q&A system. By doing so, we can improve both the contextual consistency and the emotional relevance of the responses, thereby enhancing the overall user experience.

III. A TEXTUAL SEMANTIC MATCHING APPROACH BASED ON KNOWLEDGE FUSION OF TRANSFORMER AND HOWNET

In the field of Chinese text semantic matching, vocabulary is the smallest unit that can express the correct meaning of Chinese. The existence of a large number of synonyms and near-synonyms in Chinese makes it more difficult to match the semantics of Chinese text, which makes it difficult for deep learning models applied in English to get better results on Chinese datasets. If the computational scheme of the English model is adopted, the word information is completely discarded and the research is based on words, which leads to the loss of a large amount of semantic information in Chinese. To enhance the resolution of synonyms and near-synonyms in Chinese, this study introduces the HowNet knowledge base. It presents a text implication recognition method that leverages the conceptual relationships within HowNet and the superior performance of the Transformer model in handling extended texts.

The model firstly encodes and data-drives the internal structural semantic information of Chinese utterances at multiple levels by Transformer, and introduces HowNet, an external knowledge base, for knowledge-driven modeling of knowledge associations between words in terms of justification, and then utilizes Soft-Attention for interactive attention computation and knowledge fusion with justification matrices, and finally further encodes textual conceptual-level semantic information and conceptual relations by Bi-LSTM. Additionally, Bi-LSTM is employed to further encode contextual information at the conceptual level, facilitating the reasoning and identification of semantic consistency and implication relationships.

The model is divided into six layers, namely, word embedding layer, Transformer layer, Attention layer, Bi-LSTM layer, average pooling and maximum pooling layer, and fully connected layer. Bi-LSTM layers are well-suited for sequential data because they process the input from both directions (forward and backward), allowing the model to learn context from past and future elements in the sequence simultaneously. It contains the process of processing the semantic original information, and the specific structure is shown in Fig. 1.

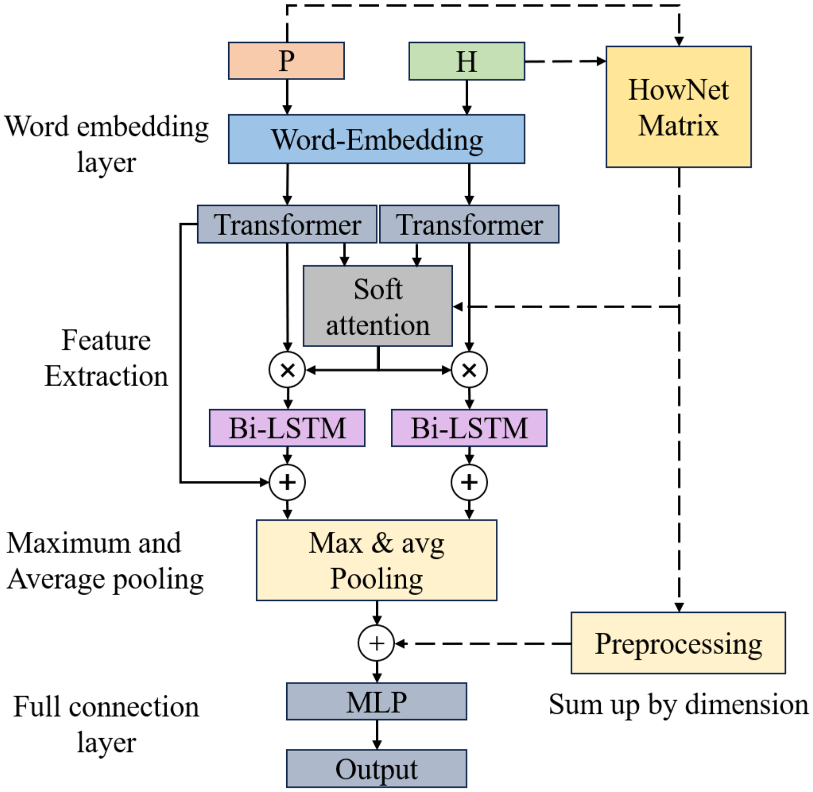

Fig. 1. Structure of the model.

The role of the transformer layer is to make the vectorized text pass through the neural network to obtain deep semantic information. Commonly used neural networks are convolutional neural network, long and short-term memory network, etc. The model uses the Transformer architecture as the encoding layer of the text to process the sentence vector. This model uses the Transformer architecture as the coding layer of the text to process the sentence vectors.

The attention layer is a widely used and essential element in text semantic matching models. It offers benefits such as high speed, effectiveness, and a low number of parameters. Various types of attention mechanisms exist, including soft attention, hard attention, self-attention, as well as focused and localized attention techniques. In this chapter, the commonly used Soft-attention mechanism (Soft-attention) is used, but the semantic matrix information generated based on How Net is added to it, which as shown in Fig. 2, and the trainable weights HN_{col}.

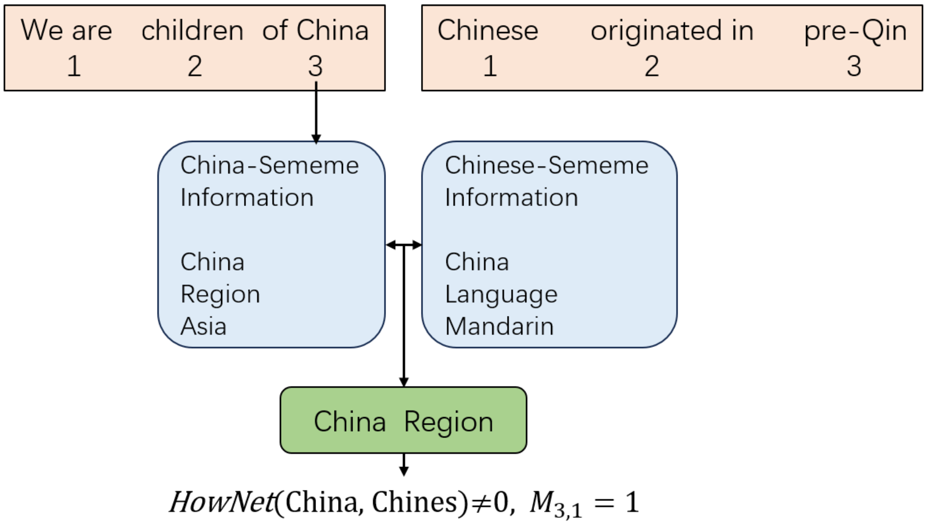

Fig. 2. Semantic information computation.

The top box displays the outcomes of sentence disambiguation, while the middle box shows the various etymological details associated with the current word. The bottom box illustrates the intersection of the etymological information of the two words. As can be seen from the above diagram, “China” has the meanings of China, related to a specific country, place, Asia, etc., and “Huaxia” has the meanings of borrowing, finance, retaining, China, country, etc. The intersection of the semantic principles of the two words is China, country, place, so at this point in time, “China, Huaxia” has the meanings of China, country, and hence $HowNet(\text{China}, \text{Huxia}) \neq 0$.

$$M_{i,j} = \begin{cases} 1 & HowNet(P_i, H_j) \neq 0 \\ 0 & HowNet(P_i, H_j) = 0 \end{cases} \quad (1)$$

$$M = \begin{bmatrix} 0 & \cdots & 1 \\ \vdots & \ddots & \vdots \\ 1 & \cdots & 0 \end{bmatrix} \quad (2)$$

The formula indicates that a query for the i-th word in sentence P and the j-th word in sentence H is performed for the meaning of the original, and if the query result is valid, then the value of the corresponding (i,j) position in the M matrix is one.

Attention matrix e is generated as Eq:

$$e = PH^T + \gamma \cdot M \quad (3)$$

In this context, γ is a training factor. The attention matrix e not only combines textual information between sentences but also captures the semantic details of inter-sentence word pairs. As depicted in Fig. 3, the heat map of the matrix changes. Upon incorporating the original justification information, the weight of specific positions increases, indicating that these positions acquire information from the original justification matrix. In addition to this Attention matrix generation method, it is also possible to transform the various justification information of the current word into a continuous vector expression, which can be fused and embedded into the corresponding word vectors according to their weights, and there are various methods for this embedding method, such as embedding it into the Transformer structure, which makes the semantic information and word vector expression fuse.

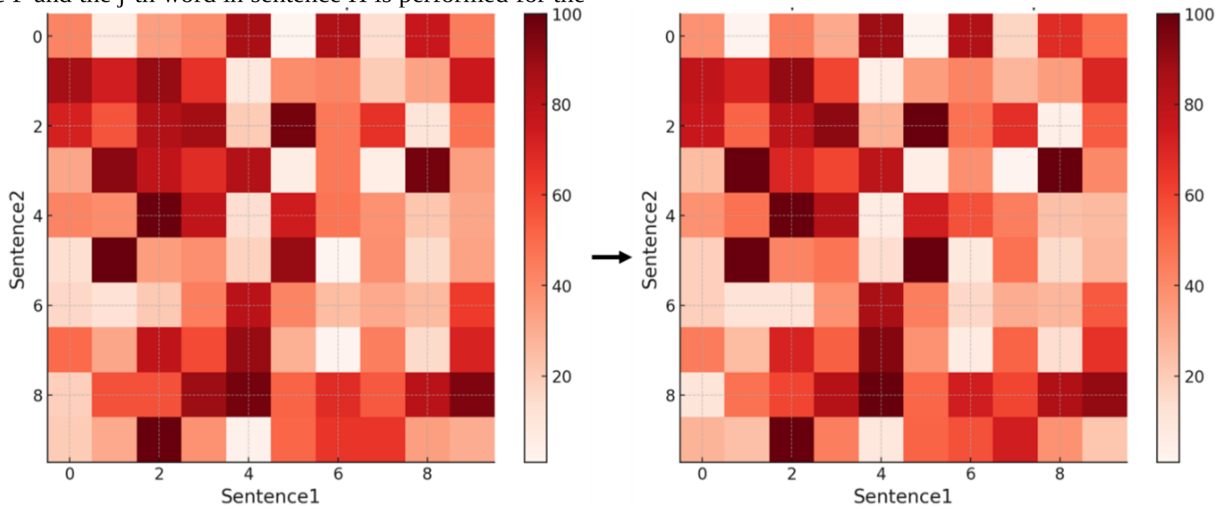

Fig. 3. The heat map of matrix change.

After obtaining the improved attention matrix e, the soft attention is computed as follows:

$$\hat{P} = \sum_{j=1}^{l_h} \frac{\exp(e_{ij})}{\sum_{k=1}^{l_h} \exp(e_{ik})} P_{tf}, \forall i \in [1,2,\cdots,l_p] \quad (4)$$

$$\hat{H} = \sum_{j=1}^{l_p} \frac{\exp(e_{ij})}{\sum_{k=1}^{l_p} \exp(e_{ik})} H_{tf}, \forall i \in [1,2,\cdots,l_h] \quad (5)$$

Where P_{ff}, H_{ff} are the matrix vectors of sentence pairs after Transformer. l_p, l_h denote the sentence lengths, and $\hat{P}$, $\hat{H}$ denote the outputs after soft attention mechanism.

The Bi LSTM layer is used to process the outputs P ̂and H ̂ of the transformer layer after the soft attention mechanism, and the two-way. The Bi-LSTM layer processes the outputs $\hat{P}$ and $\hat{H}$ from the Transformer layer following the application of the soft attention mechanism. The bidirectional Long Short-Term Memory Network (Bi-LSTM), which combines forward and backward encoding, enhances the acquisition of contextual information.

$$P_{bi-lstm} = BiLSTM(\hat{P}) \quad (6)$$

where $\hat{P}$ is the output vector of sentence P after the soft attention mechanism, and $P_{bi-lstm}$ is the vector after the bi-directional long-short-term neural network. Bi-LSTM is spliced from a combination of forward LSTM and backward LSTM, and compared to the long-short-term memory network LSTM, which is incapable of encoding the information passed from the back of the text to the front, Bi-LSTM can better capture the bi-directional semantic dependencies of the text.

$$P_o = Concat([P_{tf}; P_{bi-lstm}]) \quad (7)$$

$$P_{rep} = [Max(P_o); Mean(P_o)] \quad (8)$$

Here, P_{tf} represents the output vector of sentence P after the soft attention mechanism, while $P_{bi-lstm}$ is the vector resulting from the bidirectional long-short-term neural network, $Max(P_o)$ denotes the maximum pooling result of P_o, and $Mean(P_o)$ denotes the average pooling result of P_o. In most cases, maximum pooling can effectively improve the model performance, which can suppress the panning distortion and noise, etc., and also reduce overfitting. Average pooling can eliminate the effect of local maxima and make the model more stable. The combination of these two pooling methods can make the vector representation contain more information, which can improve model performance significantly.

After obtaining the complete sentence vector expressions P_{rep} and H_{rep} of sentence pairs, in the proposed model, the concatenation process also integrates information from the HowNet matrix. The sums of the two dimensions of the HowNet matrix, HN_{row} and HN_{col}, are computed and concatenated with P_{rep} and H_{rep}. This concatenated result forms the final input H for the feedforward neural network.

$$HN_{row} = sum(M, axis = 0) \tag{9}$$

$$HN_{col} = sum(M, axis = 1) \tag{10}$$

$$H = concat\left(P_{rep}; H_{rep}; P_{rep} - H_{rep}; HN_{col}; HN_{row}\right) \tag{11}$$

Where sum(•) means summing along the axis dimension. Taking HN_{row} as an example, HN_{row} represents the result of summing the HowNet matrix according to the first dimension, which corresponds to the HowNet information for sentence 1., and HN_{col} similarly represents the result of summing the HowNet matrix along the second dimension. Through vector splicing, H obtains the corresponding justification original information of the two sentences, where $P_{rep} - H_{rep}$ contains the discrepancy between the two sentence vectors.

After acquiring the final sentiment vector represents H for the sentence pairs, the model utilizes a two-layer fully connected neural network to determine the final matching result. The loss function employed is the cross-entropy loss function, calculated as follows:

$$Loss = \frac{1}{N}\sum_i - [y_i \times \log(p_i) + (1 - y_i) \times \log(1 - p_i)] \tag{12}$$

Here, y_i represents the label of sample i, with 1 indicating positive samples and 0 indicating negative samples. p_i denotes the predicted probability that sample i is a positive sample. Besides the standard cross-entropy loss function, this study also explores the KL Divergence loss function to evaluate the model's performance. The formula for the CoSent loss function in the context of binary classification is as follows:

$$\mathrm{KL}(P \parallel Q) = \sum_i P(i)\log\frac{P(i)}{Q(i)} \tag{13}$$

"Where " P(i)" is the true probability distribution and " Q(i)" is the predicted probability" " distribution." In the context of this study, using KL Divergence loss helps ensure that the positive sample pairs were more closely alike than the negative sample pairs, effectively maximizing the separation between positive and negative samples in the vector space. Experiments show that for pre-training methods such as BERT, SentenceBERT, etc., the method of directly using the pre-vector model to generate sentence vectors and then connecting them to the fully-connected layer for prediction is effective, and this method makes the pre-training model converge more quickly. For the model proposed in this chapter, it is not as effective as the cross-entropy loss function in the non-pre-training case.

During the training phase, MultiStepLR was utilized to progressively adjust the learning rate. The learning rate was updated with a decay rate of 0.5 at the 20th, 40th, 80th, 120th, and 160th iterations. By adjusting the learning rate dynamically as the number of iterations increases, the model's convergence speed is enhanced. The trend of the learning rate is illustrated in Fig. 4.

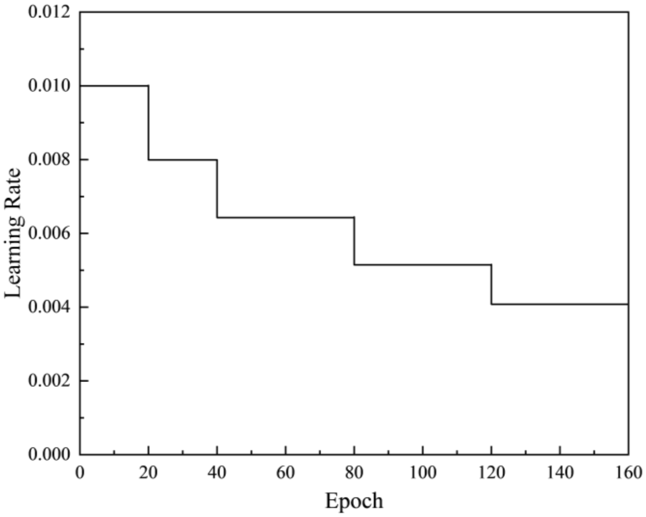

Fig. 4. Trends in learning rates.

IV. Question and Answer Engine Design

The Q&A system model was executed on a host computer having Intel Core i7-8750H CPU, NVIDIA 1060 GPU with 8 GB RAM, and 16 GB RAM. To implement this model, the Python programming language was used and the TensorFlow 1.9 deep learning framework was used. This system is capable of taking the user questions into a vector-based text retrieval, rank the top ten matching answer candidates, and then using the pre-trained.

Then the pre-trained Transformer model is used to extract the answers accurately. Therefore, this system includes database module, pre-processing technology, vector-based document retrieval, Transformer-based answer extraction and the final user operation platform, and its overall structure design is shown in Fig. 5.

The intelligent Q&A system mainly includes two roles: administrator and user, and it mainly realizes the functions of intelligent Q&A, knowledge map display and standardized text search. Users can quickly ask natural language questions in the domain, and the system automatically parses the semantic information involved in the questions and returns the correct answers through the search of the knowledge base, which mainly includes multiple use cases, such as asking questions, checking the semantic parsing, checking the returned answers, checking the corresponding knowledge base, checking the canonical retrieval text, and editing personal information, etc. Administrators mainly manage and maintain the system's knowledge base, document database, and user privileges. The manager is mainly responsible for managing and maintaining the system's knowledge base, document database, and user privileges. It mainly contains question category information management, knowledge base management, specification storage management, user information management and other major use cases (see Tables I, II, III and IV).

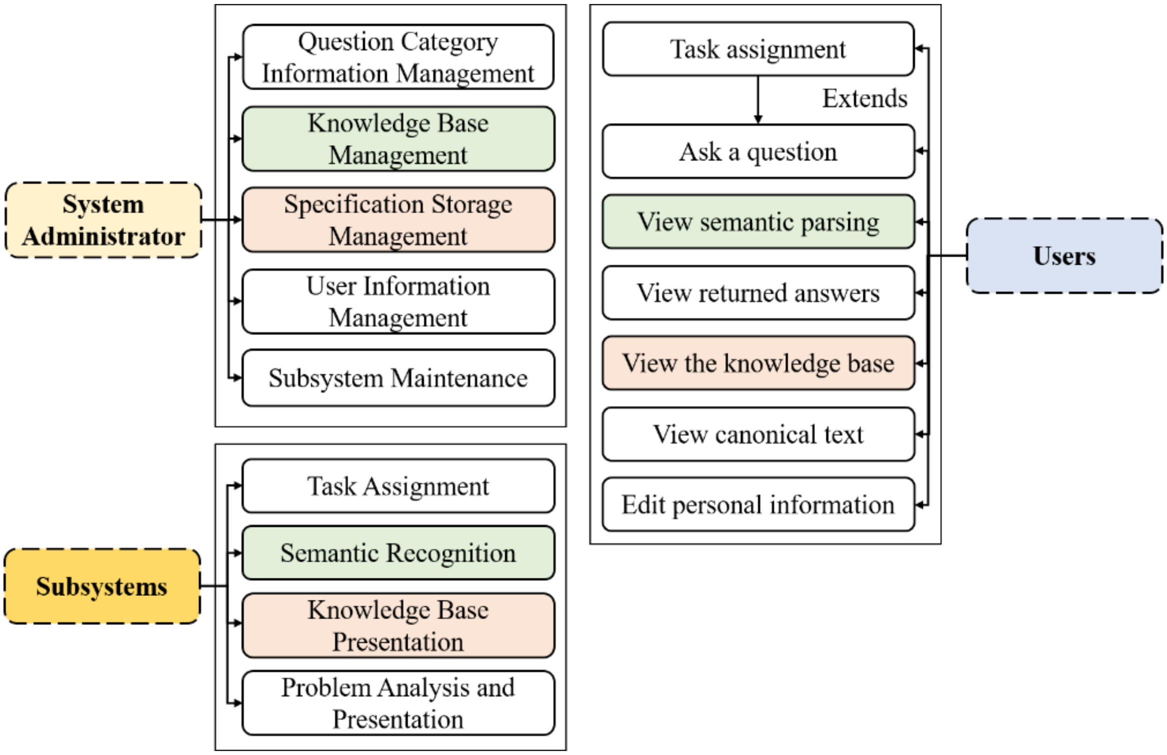

Fig. 5. Question and answer engine architecture design.

TABLE I. USE CASE DESCRIPTION OF THE QUESTION FUNCTION

Use Case Name	Question
Use Case Number	CIVILQASYS001
Use Case Description	User fills out natural language questions on the system.
Participants	Registered users of the system, database, quiz model
Pre-conditions	User login to the quiz system
Event flow	1. Registered user logs into the system 2. Click on button enter the Q&A detail information filling page. 3. Fill in the natural language question 4. Click Q&A, and the question is synchronized to the platform.
Postconditions	Can be manually selected to browse the display mode of the proposed questions.
Remark process	Fill in the natural language question format error reminder, re-entry Users abandon posting, whether to save as a draft

TABLE II. VIEW THE SEMANTIC ANALYSIS FUNCTION USE CASE DESCRIPTION

Use Case Name	View Semantic Parsing
Use Case Number	CIVILQASYS002
Use Case Description	Based on the natural language questions filled in by users on the system, the system returns parses of the questions
Participants	The system registers the user, the database, and the Q&A model.
Pre-conditions	User submits natural language question information to the Q&A model.
Event flow	1. Registered users log in and enter the system 2. Click on the Q&A module button in the platform's Q&A module to enter the Q&A details filling page. 3. Fill in the natural language question 4. Click Q&A, the question is synchronized to the platform, and the platform returns the parsing of the question.
Postconditions	Can manually choose to browse the question analysis display mode
Remark process	No

TABLE III. GET ANSWER FUNCTION USE CASE DESCRIPTION

Use Case Name	View Answer
Use Case Number	CIVILQASYS003
Use Case Description	System returns answers for users to view
Participants	System registers users, database, and quiz model
Pre-conditions	User submits natural language question information to the Q&A model.
Event flow	1. Registered users log in and enter the system 2. Click on the Q&A module button in the platform's Q&A module to enter the Q&A details filling page. 3. Fill in the natural language question 4. Click Q&A, the question is synchronized to the platform, and the platform returns the answer and displays it.
Postconditions	Can manually select how to browse the question analysis display
Remark process	The answer is returned as empty or error alert, resubmit to get the answer.

Use Case Name	View Answer
Use Case Number	CIVILQASYS004
Use Case Description	The user fills in natural language questions on the system and gets the knowledge base corresponding to the answers returned by the system
Participants	The system registers the user, the graph database, and the Q&A model.
Pre-conditions	User submits natural language question information to the Q&A model.
Event flow	1. Registered users log in and enter the system 2. Click on the Q&A module button in the platform Q&A module to enter the Q&A detail information filling page. 3. Fill in the natural language question, click Q&A, and the question is synchronized to the platform. 4. The platform returns the corresponding map display
Postconditions	Click and drag the map manually
Remark process	No

V. RESULTS AND DISCUSSION

A. Experimental Data Collection

In order to validate the effectiveness of the model, this paper uses the BQ Corpus dataset (Bank Question Corpus) as a data source for training and testing. The BQ dataset, published by the Intelligent Computing Research Center of Shenzhen Graduate School, Harbin Institute of Technology, is a question and answer dataset in the field of banking and finance containing 120,000 question and answer pairs from online banking customer service logs. Question-answer pairs, of which 100000 are used as the training set, 10000 as the training set, and 10000 as the validation set, which is a binary classification dataset. For example, “How did the microparticle loan disappear” and “The microparticle loan is gone” are labeled as 1, indicating that they are entailment, and “How can I change my card?” and “please change your card faster” are labeled 0, indicating a contradiction. There are a large number of synonyms and near-synonyms in this dataset, which is a good way to test the validity of the model. Table V shows example of BQ dataset.

TABLE V. EXAMPLE OF BQ DATASET

Sentence 1	Sentence 2	Tags
Does Microsoft spending count?	How much is left to pay back?	0 (contradiction)
What are the best products for next week?	What financial products are available in January	1 (implied)
Can you check your bill?	I can check your bill	0 (contradiction)
Can't borrow	qq has particulate generation	0 (contradiction)

B. Evaluation Indicators

In this chapter, Accuracy (Acc) and the F1-score are employed as evaluation metrics. Accuracy is a commonly calculated value used to assess a model's classification performance, representing the percentage of correct predictions on a dataset. The F1-score, a statistical measure of a binary classification model's accuracy, evaluates the performance of a binary text semantic matching model. The F1 score is the harmonic mean of precision and recall, offering a balanced measure that takes both into account. The formulas for both metrics are presented below:

$$Acc = \& \frac{TP+TN}{TP+FN+FP+TN} \&\& \tag{14}$$

$$P = \frac{TP}{TP+FP} \& \tag{15}$$

$$R = \frac{TP}{TP+FN} \& \tag{16}$$

$$F1 - scor\&e = 2 \times \frac{P \times R}{P+R} \& \tag{17}$$

Where TP is the true case, TN is the true negative case, FP is the false positive case and FN is the false negative case.

A 4-card GPU server with model RTX2080ti was used for the experiments in this chapter. The model training parameters as well as the software version are shown in Table VI. The software versions are as follows: Python 3.6.13, PyTorch 1.10.2, OpenHowNet 2.0, Transformer 4.18.0.

C. Test Results

In the pre-training experiments, BERT processes text at the word level. To obtain the vector for each word, this model extracts the word vectors, concatenates them, and then applies average pooling. The resulting vector is used as the representation for the current word. The selected dataset for these experiments is the BQ Corpus. To ensure consistency, all models use the same Jieba word list for this dataset. The metrics used for comparison are accuracy (Acc) and F1 score. Table VII presents the relative enhancement value, which indicates the percentage improvement in effectiveness of the proposed model compared to the baseline model with the highest performance.

From Table VII, it can be seen that the model proposed in this paper has higher accuracy Acc and F1 than the other models on the BQ Corpus dataset, and on the non-pre-trained model, the accuracy Acc improves by 2.21% and the F1 value improves by 1.98% when compared to the best performing DSSM model. While on the pre-trained model, the accuracy is improved by 0.177% and F1 value by 0.464% compared to the native BERT-wwm-ext. This indicates that the semantic information between two sentences plays a more important role in processing the semantic information of banking and finance, and there is a large improvement on the non-pre-trained model, while the improvement on the pre-trained model is more limited, mainly because there are fewer words that can be matched in the sentence pairs of this dataset, which leads to a certain limitation of the experimental effect.

TABLE VI. MODEL PARAMETERS

Parameters	Numerical value
Word Embedding Layer Dimension	500
Number of hidden layers	164
Maximum sequence length	80
Batch size batch_size	128
Transformer encoder layers	12
Model Optimizer	AdamW
Initial learning rate	0.05

TABLE VII. EXPERIMENTAL RESULTS FOR THE BQ DATASET

Model	**Pre-trained or not**	**Acc**	**F1**
DSSM	×	0.7693	0.7594
MwAN	×	0.7421	0.7289
DRCN	×	0.7485	0.7576
Ours	×	**0.7902**	**0.7691**
Relative promotion	×	**+2.21%**	**+1.98%**
BERT-wwm-ext	√	0.8391	0.8402
BERT	√	0.8466	0.8399
Ours-BERT	√	0.8495	0.8433
Relative promotion	√	**+0.177%**	**+0.464%**

Regarding error analysis, since both methods directly use Jieba for text preprocessing, the segmentation errors produced by Jieba have varying degrees of impact on the experimental results. Although there is a word separation error, for the same dataset, all the models use the same word list, in comparison, the model proposed in this study has better results. Table VIII shows practical application test results.

TABLE VIII. PRACTICAL APPLICATION TEST RESULTS

Sentence pairs	Model name	Predicted results	True label
A: Unbind Chants B: Cancel the opening of chanting	ESIM	×	√
	MwAN	×	
	Our model	√	

To understand the relative importance and effectiveness of various components of the model, an ablation study was performed on the different structures of the proposed model. This study also aimed to examine the extent to which the granularity of disambiguation affects the model's performance, experiments were conducted to evaluate the effect of using three different disambiguation tools, Jieba, PKUseg and HanLP, on the results of the experiments, which were conducted using the BQ Corpus dataset.

TABLE IX. EXPERIMENTAL RESULTS OF DIFFERENT SEGMENTATION TOOLS

Segmentation tool used	Whether using HowNet	Acc	F1
Jieba	√	**0.7892**	**0.7668**
	×	0.7778	0.7627
PKUseg	√	**0.7876**	**0.7667**
	×	0.7783	0.7622
HanLP	√	**0.7861**	**0.7608**
	×	0.7742	0.7521

From the experimental results Table IX, it can be obtained that the use of HowNet can improve the performance of the model to a certain extent, and the accuracy is improved under various word segmentation tools compared to not using HowNet. The different accuracies of different segmentation tools are in line with the expected estimation because the segmentation tools have subtle differences for very few words. When a data sample contains words with extensive original information and complex relationships with other words, incorporating an external knowledge base can significantly enhance the model's sensitivity to polysemous and near-synonymous words. This integration improves the model's comprehension of synonym information and substantially boosts its overall performance.

In order to evaluate the influence of the number of layers of Transformer on the experimental effect, multi-layer Transformer experiments were carried out, and the experimental results are shown in Fig. 6.

From the data presented in Fig. 6, it is evident that the model's performance improves with an increased number of Transformer layers, a trend also observed in the BERT model. While batch stacking Transformer encoding layers can enhance model performance to some extent, it also leads to a significant increase in the model's parameters, training time, and a slower convergence speed.

In the context of non-pre-trained models, the one with the highest F1 score, featuring six Transformer encoding layers, is considered optimal and has 16 million parameters. In comparison, the DRCN model achieves the success results in non-pre-trained settings, has 19 million parameters. This indicates that the model shown in this paper has fewer cost than the DRCN model, suggesting better suitability for lightweight deployment on the BQ dataset while achieving superior experimental results.

During training, the trainable parameter γ varies with the number of iterations. As shown in Fig. 7, observing the change in γ of the attention matrix reveals that as iterations increase, the weight of the original information matrix from HowNet within the attention matrix gradually increases and stabilizes. This indicates that the semantic raw information generated by word pairs in the original text through HowNet positively impacts the model's performance enhancement.

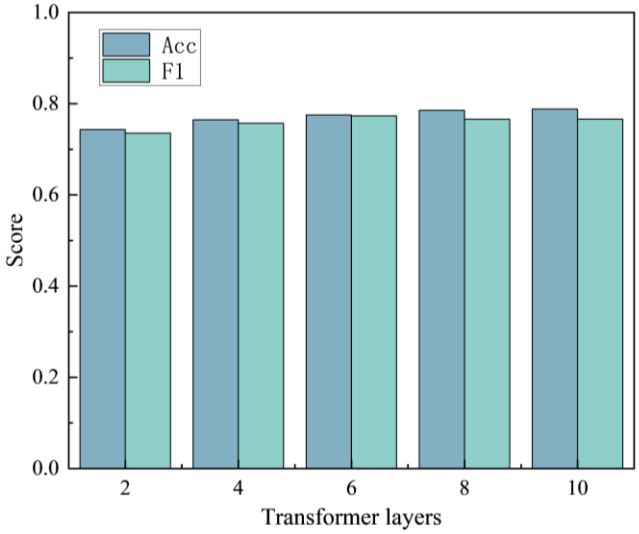

Fig. 6. Experimental results with different number of transformer layers.

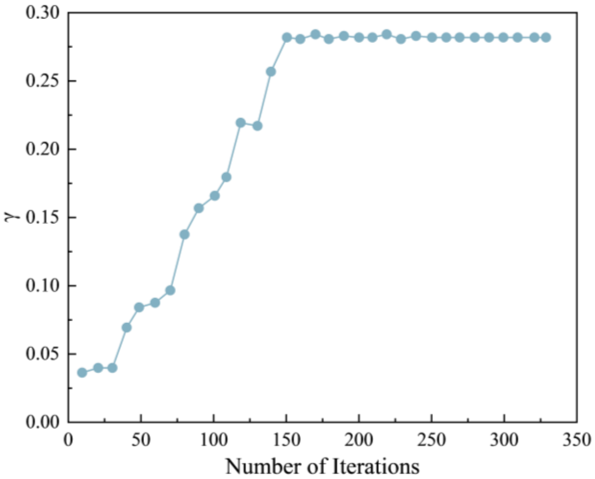

Fig. 7. Plot of changes in trainable parameters.

VI. Conclusion

This study presents a significant advancement in the field of automated question and answer (Q&A) systems by leveraging the integration of deep learning and natural language processing (NLP) technologies. With the ever-growing volume of information on the Internet, traditional keyword matching techniques have become increasingly inadequate for addressing the complexity and diversity of user queries. Our approach, which combines the Transformer model with the HowNet knowledge base, provides a robust solution to enhance semantic understanding and contextual relevance in automated Q&A systems. The architecture of our proposed system is meticulously designed, incorporating multiple layers for word embedding, Transformer encoding, attention mechanisms, and Bi-LSTM processing. This multi-layered approach allows for a comprehensive analysis and processing of natural language queries, facilitating accurate and contextually appropriate responses. The inclusion of the HowNet knowledge base is particularly noteworthy, as it enables the system to handle synonyms and near-synonyms more effectively, a critical aspect when dealing with Chinese text.

The experimental evaluation using the BQ Corpus dataset, which consists of question-and-answer pairs in the banking and finance domain, underscores the efficacy of our model. The results demonstrate substantial improvements in both accuracy and F1-score compared to existing models. Specifically, our system achieved an accuracy improvement of 2.19% and an F1-score improvement of 1.96% over the best-performing non-pretrained model, DSSM. For pre-trained models, our system showed an accuracy improvement of 0.177% and an F1-score improvement of 0.464% over the native BERT-wwm-ext model. These enhancements validate the effectiveness of integrating external knowledge bases with deep learning models in improving the performance of automated Q&A systems. Furthermore, the incorporation of HowNet significantly enhances the system's ability to process and understand the semantic relationships between words, leading to more accurate and contextually relevant responses. This is particularly important in domains where precise information retrieval is critical, such as banking and finance.

This study's findings underscore the significance of integrating external knowledge bases, such as HowNet, with advanced deep learning models to address the limitations of traditional keyword matching methods. The proposed system enhances both the efficiency and accuracy of information retrieval while providing a more user-friendly approach to accessing precise and meaningful data. This improvement is vital in the era of big data and web 3.0, where rapid and accurate access to relevant information is essential for users and organizations alike.

Future research and development offer several promising directions. Enhancing the knowledge base with more diverse and comprehensive datasets could further augment the system's capabilities. Additionally, exploring alternative deep learning architectures, including reinforcement learning and more advanced attention mechanisms, may yield further performance enhancements. Applying this system across various domains beyond banking and finance, such as healthcare, legal, and customer service, could demonstrate its versatility and broad applicability. In conclusion, the integration of deep learning with external knowledge bases represents a promising avenue for developing automated Q&A systems. This study lays a solid foundation for future advancements, paving the way for more efficient, accurate, and user-friendly information retrieval systems in the big data and web 3.0 era.

Abstract—**Water quality is crucial for sustaining life, and accurate prediction models are essential for effective management. This study introduces an Artificial Neural Network (ANN) model designed to predict the Water Quality Index (WQI) in the Amoju Hydrographic Subbasin, Cajamarca-Peru. The model was developed using key water quality parameters, including electrical conductivity (EC), total dissolved solids (TDS), calcium carbonate ($CaCO_3$), and phosphate (PO_4^{3-}), identified through Pearson correlation analysis. Data from water samples collected over six months were used to train and validate the model. Results revealed that the ANN model achieved high predictive accuracy, with a significant correlation between WQI and the aforementioned parameters. The model's performance outstrips traditional methods demonstrating its capability to effectively capture complex interdependencies among water quality indicators. This research emphasizes the potential of AI-driven approaches for enhancing predictive accuracy in environmental monitoring. Future studies should consider incorporating additional variables, such as heavy metals and microbial indicators, and consider the application of real-time AI-driven monitoring systems to further refine water quality management strategies. The ANN model presented here offers a promising tool for decision-makers, providing a reliable method for predicting water quality in similar hydrographic basins and contributing to the broader field of AI in environmental science.**

Keywords—Artificial neural networks; hydrographic subbasin; machine learning models; water quality index; water resource management

I. Introduction

Water is a critical resource upon which all life on Earth depends, with its quality playing a pivotal role in human health and aquatic ecosystems. The contamination of water sources poses significant threats to public health and the environment, underscoring the urgency of effective water quality monitoring and management. Numerous studies have highlighted the importance of assessing and predicting water quality to safeguard the sustainability and safety of water resources [1], [2]. Water quality forecasting is an indispensable method for effective water resource planning, regulation, and monitoring, and it is a crucial component of research focused on water ecological protection [3], [4].

The global issue of water pollution, aggravated by industrialization and urbanization, has driven the development of advanced methodologies for monitoring and predicting water quality. Traditional approaches, such as manual sampling followed by laboratory analysis, are often labor-intensive, time-consuming, and costly, thereby limiting their efficiency and scalability. These challenges have catalyzed the integration of artificial intelligence (AI) and machine learning (ML) techniques into water quality assessment, offering more efficient and cost-effective solutions for real-time water quality prediction [5], [6]. Among these techniques, machine learning models, particularly artificial neural networks (ANNs), have gained widespread adoption due to their capability to handle complex, and nonlinear relationships within environmental data [7], [8].

Recent advancements in technology, including remote sensing (RS), the Internet of Things (IoT), and big data analytics, have further enhanced water quality monitoring by enabling the collection and processing of vast amounts of data form diverse source. The synergy between these technologies and AI has facilitated the development of more accurate and reliable predictive models, capable of providing comprehensive assessments of water quality status [9], [10]. Specifically, metrics such as the Water Quality Index (WQI) and Water Quality Classification (WQC) are commonly employed to aggregate multiple water parameters into a single, interpretable value, providing a holistic overview of water quality [11].

This study is focused on developing an Artificial Neural Network (ANN) model to predict water quality in the Amoju Hydrographic Subbasin located in Cajamarca Peru. By leveraging various water quality indicators, the model aims to forecast the WQI and classify the water quality status, thereby contributing valuable insights for water resource management and pollution control. Through the application of advanced AI techniques, this research addresses the pressing need for efficient water quality prediction methods that ensure the provision of safe and clean water for diverse uses, while also mitigating the adverse effects of water contamination on public health and the environment [12], [13].

The structure of the paper is organized as follows: Section 2 reviews the relevant literature on water quality prediction using various classifiers. Section 3 details the materials and methodologies employed, including data preparation, pre-processing, splitting, distribution, feature correlation, and WQI computation. The experimental setup and the result analysis are discussed in Section 4. Finally, the paper is concluded with limitations and future scope in Section 5.

II. Literature Review

The literature on water quality prediction has undergone a considerable transformation, particularly with the increasing adoption of Artificial Neural Networks (ANNs) in environmental modeling. This paradigm shift is evident in the application of ANNs within hydrographic subbasins, such as the Amoju Subbasin in Cajamarca, Peru. The study titled “An Artificial Neural Network Model for Water Quality Prediction in the Amoju Hydrographic Subbasin, Cajamarca-Peru” contributes significantly to this evolving field by addressing the critical need for accurate predictive models that can inform environmental management and policy in the region. ANNs, inspired by the neural structures of the human brain, excel at capturing and modeling the intricate non-linear relationships prevalent in environmental datasets. These networks are particularly effective in dealing with the complex dynamics of hydrographic subbasins, such as the Amoju Subbasin, which holds significant ecological value and is vulnerable impacts of anthropogenic activities.

Recent studies further underscore the potential of artificial intelligence (AI) in enhancing water quality prediction and monitoring. For instance, [14] and [15] developed AI models focusing on water quality index (WQI) prediction and water quality classification (WQC). The study in [14] utilized adaptive neuro-fuzzy inference system (ANFIS) algorithms for WQI prediction and feed-forward neural network (FFNN) for WQC, achieving high predictive accuracy. The study in [15] also demonstrated the efficacy of AI in water quality monitoring, affirming the robustness of these models in managing complex environmental data. The research in [16] reviewed the integration of AI and the Internet of Things (IoT) in water quality prediction, emphasizing AI's role in analyzing intricate systems and leveraging historical data to enhance prediction accuracy. Similarly, [17] explored several AI techniques, including multilayer perceptron neural networks (MLP-ANN), ensemble methods, gaussian process regression, support vector machine (SVM), and decision tree, all of which contributed to a comprehensive evaluation of water quality parameters.

The impact of water quality on public health further emphasizes the necessity of accurate WQI modeling, a task that presents significant challenges within the water sector. The study in [18] introduced an innovative application of the ensemble Kalman filter integrated with ANNs to predict WQI using physicochemical parameters, showcasing the model's capability to handle noise in environmental data. Other researchers have explored different machine learning techniques for WQI prediction. The research in [19] employed k-nearest neighbors, boosting decision trees, SVMs, and multilayer perceptron ANNs in their models, while [20] compared deep learning-based models with other machine learning models such as random forests (RF) and extreme gradient boosting (XGBoost) for predicting groundwater quality. Their comparative study highlighted the superior performance of deep learning models in certain contexts.

The prediction of dissolved oxygen concentration, a key indicator of river water quality, has also been enhanced through AI. The study in [21] utilized a deep learning approach, applying recurrent neural networks (RNNs) to predict this parameter with high precision. Moreover, [22] proposed a hybrid model combining ANNs, discrete wavelet transforms (DWT), and long short-term memory (LSTM) networks, further advancing the state-of-the-art in water quality prediction.

In addition, [23] implemented a comprehensive architecture integrating machine learning models (RF, DT, LR, SVM, AdaBoost) with deep learning models (CNN, LSTM, GRU) for predicting both water quality and water consumption. This study underscores the potential of hybrid models in addressing multi-faceted environmental issues. The research in [24] further advanced this approach by integrating deep learning models with feature extraction technique, such as principal component analysis (PCA), linear discriminant analysis (LDA), and independent component analysis (ICA), to enhance water quality classification accuracy.

In study [25], focused on the prediction of water quality using machine multiple learning techniques, including regression and classification models like SVMs, multiple linear regression (MLR), and Bayesian tree model (BTM). Their comprehensive five-step methodology, which included data pre-processing, feature correlation analysis, and model feature importance, resulted in a maximum prediction accuracy of 99.83% with the MLR classifier. The study in [26] compared decision tree algorithms (DT) and Naïve Bayes classifiers for water quality prediction, with DT emerging as the most accurate model, achieving an accuracy value of 97.23%.

Additionally, [27] proposed a machine learning-based system for predicting the WQI in the Illizi region by employing eight artificial intelligence algorithms. The results indicated that the Multivariate Linear Regression (MLR) model exhibited the highest accuracy among the models considered. In contrast, [28] explored 15 supervised Machine Learning (ML) algorithms to estimate the WQI, identifying gradient boosting and polynomial regression as the most efficient methods for WQI prediction. Further advancements in the field include the work of [29], who developed a prediction method for WQI using feedforward artificial neural networks (ANNs) with 25 water quality parameters inputs. By integrating backward elimination and forward selective combination methods, the study achieved high R2 and minimal squared error (MSE). Similarly, [30] predicted the WQI using 16 water quality parameters and successfully applied ANN through a Bayesian regularization algorithm, demonstrating the robustness of this approach. Moreover, the study in [31] examined the comparative efficiency of multivariate linear regression (MLR) and ANN models for predicting water quality parameters, such as pH, temperature, total suspended solids (TSS), and total suspended matter (TSM), in estimating the chemical oxygen demand (COD) and biochemical oxygen demand (BOD). In another study, [32] designed a feed-forward, fully-connected, three-layer perceptron neural network model to predict the WQI using 23 parameters, reinforcing the trend towards increasingly complex ANN architectures. Also, [33] took a different approach by proposing a two-layered ensemble model that integrates five commonly used methods, including partial least square, random forest, and Bayesian networks, into an ML model for forecasting beach water quality. The model stacking approach yielded the best predictions, demonstrating the advantages of ensemble methods in enhancing model robustness and accuracy. The study in [34] developed an ML-based classification system for the Chao Phraya River's water quality, integrating attribute realization (AR) and support vector machine (SVM) algorithms. The results indicated that linear regression (LR) was the most suitable function for river water data classification, offering a different perspective on the adaptability of ML techniques across diverse water bodies. The research in [35] also employed an ANN approach for calculating and simulating the WQI of the Akaki River, utilizing a neural network model trained on 12 inputs and one output. The optimal model architecture was obtained with eight hidden layers, achieved an accuracy of 0.93. Besides, [36] formulated four distinct ML techniques, including Back Propagation Neural Network (BPNN), Adaptive Neuro-Fuzzy Inference System (ANFIS), Multilinear Regression (MLR), and Support Vector Regressor (SVR) for forecasting the water quality index (WQI) across the Yamuna River. The study in [37] applied independent techniques like the M5P tree model, additive regression (AR), support vector machine (SVM), and random subspace (RSS) to predict WQI, identifying AR as the most optimal approach with favorable outcomes.

The literature also explores hybrid models. The study in [38] developed a hybrid ML method combining random trees and bagging, testing four standalone and 12 hybrid data-mining algorithms for WQI forecasting in a humid climate. The study concluded that hybrid models could significantly improve prediction accuracy. In a similar vein, [39] optimized the performance of an adaptive neuro-fuzzy inferences system (ANFIS) for water quality metrics prediction using Genetic Algorithm (GA), Differential Evolution (DE), and Ant Colony Optimization (ACOR), further demonstrating the value of optimization algorithms with ML models. Consequently [40] enhanced a hybrid artificial neural network (HANN) model with a genetic algorithm (GA) for predicting water output in drinking water treatment plants in China. The HANN model has shown better ability and consistency in forecasting the total water output. The prediction shows that the HANN model has improved its performance from 0.71 to 0.93 R2 by increasing the training data provided. Likewise, the study in [41] introduced an ensemble ML model, Extra Tree Regression (ETR), for predicting monthly WQI values in Hong Kong. Achieving a high prediction accuracy with R2 = 0.98 and RMSE = 2.99. The study in [42] utilized Principal Component Regression (PCR) and Gradient Boosting Classifier (GBC) to predict WQI, demonstrating 95% prediction accuracy for PCR method and 100% classification accuracy for GBC. [43] evaluated the performance of 12 ML models, including boosting-based, decision tree-based, and ANN-based algorithms, for estimating the WQI of the La Boung River in Vietnam, with extreme gradient boosting (XGBoost) emerging as the best performer, achieving an R2 of 0.989 and RMSE of 0.107. Finally, [44] used Random Forest (RF), Extreme Gradient Boosting (XGBoost), Gradient Boosting (GB), and Adaptive Boosting (Ada-Boost) model for predicting WQC. In contrast, K-nearest neighbor (KNN), decision tree (DT), support vector regressor (SVR), and multi-layer perceptron (MLP) were used as regression models for predicting WQI. The results showed that GB model produced the best results for predicting WQC, with an accuracy of 99.5% value, and the MLP regressor model in predicting WQI, with an accuracy of 99.8% value.

These studies collectively highlight the potential of AI, particularly machine learning and neural networks, in advancing water quality management. However, there is a notable gap in evaluating water quality classification based on metrics such as accuracy, precision, or F1 score. Moreover, many of these approaches are limited by their focus on either WQI prediction or WQC, rather than integrating both aspects. Our proposed methodology addresses these aspects by employing a lightweight model that not only enhances prediction accuracy but also integrates water quality classification with water demand prediction, paving the way for a more comprehensive approach to water resource management. Table I provides a comparative summary of the research works discussed.

The literature further reveals the versatility of artificial neural networks (ANNs) in water quality prediction, demonstrating their adaptability to various geographical and hydrological contexts. The inclusion of diverse input parameters, including meteorological data to land use and physicochemical attributes-into ANN models has consistently improved the prediction accuracy, offering a more holistic understanding of the factors influencing water quality dynamics.

TABLE I. COMPARATIVE SUMMARY OF THE DISCUSSED RESEARCH WORKS

Reference	Year	Classifiers	Achieved Accuracy
[14]	2020	NARNET, LSTM, SVM, KNN, NB	SVM 97.01%
[15]	2021	KNN, FFNN, ANIFS	WQI ANFIS 96.17%
[24]	2021	Dimension reduction PCA, LDA, ICA, RNN, LSTM, SVM (variants)	LSTM RNN with LDA, LSTM, RNN 99.72%
[25]	2021	NN, RF, MLR, SVM, BT	99.83% MLR
[26]	2021	DT, NB (variants), K-fold cross validation	97.22% DT
[27]	2021	MLR, RF, RSS, AR, ANN, SVR, LWLR	With all parameters: MLR
[28]	2019	Multiple linear regression, polynomial regression, RF, GBC, SVM, ridge regression, lasso regression, elastic net regression, MLP, GNB, LR, SGD, KNN, DT, bagging classifier	Gradient Boosting and Polynomial Regression with MAE = 1.964 and 2.727, respectively
[34]	2021	Attribute-realization (AR) and Support Vector Machine (SVM)	AR-SVM with 0.86-0.95 accuracy respectively
[36]	2019	BPNN, ANFIS, SVR and MLR	DC values vary in the range of 0.9202 to 0.9957
[37]	2022	AR, M5P tree model, RSS and SVM	AR with R2 = 0.9993, MAE = 0.5243, RSME = 0.6356, %RAE = 3.8449 and %RRSE = 3.9925
[38]	2020	RF, M5P, RT and REPT	RT with R2 = 0.941, RMSE = 2.71, MAE = 1.87, NSE = 0.941, PBIAS = 0.500
[41]	2021	ETR, SVR and DTR	ETR model produced more accurate WQI predictions with R2 = 0.98 and RSME = 2.99 values
[42]	2022	PCR and GBC methods	PCR = 95% and GBC = 100%
[43]	2022	(Adaptive boosting, GBoost, HGBoost, LGBoost, XGBoost), (DT, ET, RF), (MLP, RBF, DFFNN, CNN)	XGBoost (R2 = 0.989 and RMSE = 0.107)
[44]	2023	K-nearest neighbor (KNN) regressor model, DT, SVR, MLP	MLP regressor model outperformed the best accuracy with R2 = 99.8%

III. MATERIALS AND METHODOLOGY

Fig. 1 displays the proposed methodology for completing the research.

A. Study Area

The study was conducted in the Amoju River Subbasin, which is located within the Alto Marañon III Inter-basin in northern Peru. The subbasin covers an area of 354 km2, as depicted in Fig. 2. The Amoju River itself extends approximately 29 km, originating near the towns of San Jose de Alianza, Nuevo Jerusalen, and La Rinconada Lajeña. The river then flows into the Marañon River at the Pedregales hamlet in the Bellavista district, within Jaen province, Cajamarca department [45].

A Digital Elevation Model (DEM) from the National Aeronautics and Space Administration (NASA) [46] was employed to determine that the maximum elevation within the subbasin reaches 3222 meters above sea level, while the lowest point is situated at 408 meters above sea level. The region is characterized by steep slopes, ranging from 40º to 56º in the upper and middle sections, and from 0º to 25º in the lower section. These topographical features, as shown in Fig. 3, suggest that the area is suitable for agricultural activities and the establishment of urban centers.

Moreover, this subbasin is a critical source of water supply for human consumption, serving as the primary provider for the cities of Jaen and Bellavista, as well as their associated agricultural valleys. The locations of the sampling stations are detailed in Table II.

The upper section of the basin is dominated by a Tropical Premontane Rainforest (bh-PT) with annual precipitation levels reaching up to 1968 mm. The middle section is characterized by a very humid Tropical Low Montane Forest (bmh-MBT). Agroforestry systems, particularly those cultivating Coffea arabica (coffee) in association with citrus trees, are prevalent in the upper subbasin. The lower subbasin is dominated by a Tropical Premontane Dry Forest (bs-PT), where extensive rice fields (Orysa sativa) are cultivated.

B. Hydrogeological Settings

The water chemistry and quality in the study area influenced by both the lithology and the duration of water-rock interaction [47]. To identify the aquifer units within the National Geological Map provided by the Geological, Mining, and Metallurgical Institute (INGEMMET) [48] was used. This data was processed using QGIS software to create a hydrogeological map, illustrating the characteristics of the lithological units, as shown in Fig. 4.

Fig. 4. Hydrogeolocgical map of the subbasin.

The lithological units within the subbasin display varied hydrogeological properties. Based on the hydrogeological map, these units were classified into aquifers and aquitards. Six distinct hydrogeological categories were identified within the aquifer units, while only one category was identified within the aquitards, as detailed in Table III.

C. Dataset Collection

Water samples were collected from 15 designated sampling points (Upper, Middle and Lower) within the Amoju Hydrographic Subbasin over a period from November 15th, 2023 to July 20th, 2024. The geographic distribution of these sampling points across the subbasin is illustrated in Fig. 5. Samples were brought to the CEASA and CAE laboratory in an insulated cooler box containing ice packs to maintain a stable temperature during transit. Analytical procedures commenced within 48 hours of sample collection to ensure data integrity.

The dataset for this study was sourced from strategic locations in Jaen-Cajamarca, focusing on five (05) physicochemical parameters measured in situ at each of fifteen (15) sampling sites. These parameters include pH, Electrical Conductivity (EC), Dissolved Oxygen (DO), total dissolved solids (TDS), and temperature (T°), all of which were measured using a recalibrated portable HANNA Multi-parameter HI 9829 device. Additionally, the dataset includes four (04) non-metallic inorganic parameters: alkalinity $(CaCO_3)$, total hardness (TH), nitrates (NO_3^{1-}), and phosphates (PO_4^{3-}). Table IV provides a detailed description of each attribute measured.

TABLE III. A DESCRIPTION OF THE HYDROGEOLOGICAL CHARACTERISTICS OF THE SUBBASIN [48]

Hydrogeological Unit	**Classification Hydrogeological**	**Code**	**Lithology**	**Description Hydrogeological**
Aquifer	Volcanic Fissured Aquifer	AFV	Andesites and Dacitas	Local or discontinuous productive aquifers, or extensive aquifers, which are only moderately productive (medium permeability). This does not preclude the existence of other, more productive aquifers at greater depths.
Aquifer	Fissured Sedimentary Aquifer	AFS	Lutites, intercalated with limestones, marls	Local or discontinuous productive aquifers, or extensive aquifers, which are only moderately productive (medium permeability). This does not preclude the existence of other, more productive aquifers at greater depths.
Aquifer	Fissured Sedimentary Aquifer	AFS-c	Conglomerates, shales and sandstones	Local or discontinuous productive aquifers, or extensive aquifers, which are only moderately productive (medium permeability). This does not preclude the existence of other, more productive aquifers at greater depths.
Aquifer	Unconsolidated Porous Aquifer High	APNCa-al	Alternation of shales and sands	Aquifers are extensive and highly productive, exhibiting high permeability.
Aquifer	Unconsolidated Porous Aquifer High	APNCa	Alluvial, moraines, glaciofluvial, lacustrine and travertine	Aquifers are extensive and highly productive, exhibiting high permeability.
Aquifer	Unconsolidated Porous Aquifer High	APNCa-ar	Sands, sandstones, gravels and conglomerates	Aquifers are extensive and highly productive, exhibiting high permeability.
Aquifer	Unconsolidated Porous Aquifer Medium	APNCm	Conglomerates, shales, mudstones	Local or discontinuous productive aquifers, or extensive aquifers, which are only moderately productive (medium permeability). This does not preclude the existence of other, more productive aquifers at greater depths.
Aquitard	Intrusive Aquitard	ATI	Acid and intermediate intrusive rocks	Formations without aquifers (with a very low permeability) can be considered.

TABLE IV. FEATURE DESCRIPTION OF DATASET

Attributes Name	**Description**
Physicochemical parameters	
pH	Water acidity and basicity.
EC	Water's ability to conduct electricity in the presence of ions.
DO	Concentration of dissolved oxygen in water.
TDS	Concentration of dissolved minerals, salts, metals, cations, or anions in water.
T°	Water temperature at the time of testing.
Non-metallic inorganic parameters	
$CaCO_3$	Water's ability to neutralize acids or resist changes that cause acidity, maintaining pH levels.
TH	Concentration of dissolved calcium and magnesium in water.
NO_3^{1-}	Concentration of nitrates, representing the most common form of nitrogen in water.
PO_4^{3-}	Concentration of phosphates, indicate of phosphorous and oxygen compounds in water.

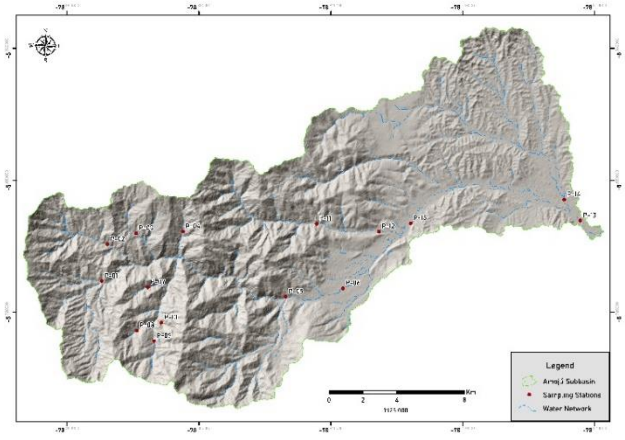

Fig. 5. Groundwater sampling sites.

D. Dataset Preprocessing and WQI Calculation

Data preprocessing is a critical step in ensuring the integrity and reliability of subsequent analysis. In this study, preprocessing involved the handling of missing data, normalization, and outlier removal to enhance the quality of the dataset. The Water Quality Index (WQI) was calculated to provide a comprehensive assessment of water quality across various sampling sites within the study area.

Water Quality Index (WQI): Methodology and Calculation

The Water Quality Index (WQI) is a widely recognized metric that synthesizes multiple water quality parameters into a single, overall score, reflecting the water's suitability for many uses [14]. The WQI in this study using the formula showing in Eq. (1).

$$WQI = \frac{\sum_{i=1}^{N} q_i \times w_i}{\sum_{i}^{N} w_i} \quad (1)$$

Where N represents the number of parameters analyzed, q_i denotes the quality rating scale for each parameter i, computed in Eq. (2), and w_i denotes the unit weight of each parameter determined by Eq. (3).

$$q_i = 100 \times \left(\frac{V_i - V_{id}}{S_i - V_{id}}\right) \quad (2)$$

Where q_i is the parameter's actual value in the water samples tested, V_i represents the estimated value of the parameter i, V_{id} represents the ideal value under pure water conditions, and S_i represents the standard permissible limit for the parameter i as shown in Table V. The unit weight w_i is the parameter's recommended standard value as depicted in Table VI.

$$w_i = \frac{K}{S_i} \quad (3)$$

Where K denotes the proportionality constant, which is calculated using Eq. (4):

$$K = \frac{1}{\sum_{i=1}^{N} S_i} \quad (4)$$

The permissible limits and corresponding unit weights for the parameters are detailed in Table V and Table VI, respectively.

TABLE V. PERMISSIBLE LIMITS OF THE PARAMETERS USED IN CALCULATING THE WQI [49]

Parameter	Unit	Permissible Limits
pH	-	8.5
Conductivity	µS/cm	1000
Dissolved Oxygen	mg/L	10
Total Dissolved Solids	mg/L	1000
Temperature	°C	25
Alkalinity	mg/L	200
Hardness	mg/L	200
Nitrate	mg/L	45
Phosphate	mg/L	0.1

TABLE VI. PARAMETERS UNIT WEIGHTS

Parameter	Unit Weight (w_i)
pH	0.00004727
Conductivity	0.00000040
Dissolved Oxygen	0.00004018
Total Dissolved Solids	0.00000040
Temperature	0.00001607
Alkalinity	0.00000201
Hardness	0.00000201
Nitrate	0.00000893
Phosphate	0.00401830

The WQI is a versatile metric that can be employed for the calculation of numerous parameters, including those selected for analysis. The WQI depends on the variable data. The proposed system is capable of testing any parameters in conjunction with any water quality data.

IV. RESULTS AND DISCUSSION

Table VII provides descriptive statistics for the dataset attributes derived from 75 groundwater samples. These statistics, including count, mean, standard deviation, minimum, maximum, and quartiles, offer a comprehensive overview of the dataset's distribution and underlying properties. The mean pH value of 7.79 with a standard deviation of 0.46 suggests a slightly basic water quality, consistent with findings from similar studies in hydrographic subbasins [50], [51]. Conductivity averages at 220.96 µS/cm, reflecting significant variability in ion concentration among the samples. Dissolved Oxygen (DO) levels, averaging 7.46 mg/L, are critical for sustaining aquatic life, aligning with established benchmarks [52]. Total Dissolved Solids (TDS) display considerable variability with a mean of 164.61 mg/L, indicative of diverse mineral content in the samples. The mean temperature (Tº) of 21.52 ºC influences the solubility and reaction rates of various chemical constituents, further impacting water quality parameters [53].

Alkalinity and hardness, with means of 114.84 mg/L and 136.57 mg/L, respectively, reflect the water's buffering capacity and calcium/magnesium content, both of which are crucial for assessing the chemical stability of the water [25]. The mean concentrations of nitrate (NO_3^{1-}) and phosphate (PO_4^{3-}) are 0.021 mg/L and 1.52 mg/L, respectively, highlighting the presence of nutrient pollution, a significant concern in water quality management [50]. The Water Quality Index (WQI) has a mean value of 1.88, indicative of the overall quality of the water samples analyzed.

The correlation matrix presented in Fig. 6 is crucial for understanding the interrelationships among the water quality parameters. It enables the identification of functional dependencies, where strong correlations (r > 0.7) suggest significant associations, while weaker correlations (r < 0.4) imply more complex or indirect relationships. The WQI, the primary focus of this study, exhibits a strong positive correlation with phosphate levels (r = 0.99), underlining the significant impact of nutrient concentrations on overall water quality. In contrast, WQI shows weak correlations with parameters such as EC, TDS, $CaCO_3$, and NO_3^{1-}, suggesting that these variables, while influential, do not directly drive the WQI in this context.

The detailed examination of the correlations reveals that pH is moderately correlated with total hardness (TH), $CaCO_3$, and temperature (T°), with respective correlation coefficients of 0.59, 0.54, and 0.6. These findings are consistent with previous studies that have observed similar patterns in groundwater quality assessments [27]. Conductivity (EC) displays a strong positive correlation with T° (r = 0.73), $CaCO_3$ (r = 0.94), and TH (r = 0.88), indicating that these parameters are interdependent, likely due to their shared origin in mineral dissolution processes [14].

TABLE VII. DESCRIPTIVE STATISTICS OF THE FEATURES

Parameter	Count	Mean	Std Dev	Min	Q1	Median	Q3	Max
pH	75.00	7.790020	0.462099	6.75	7.4960	7.9340	8.1810	8.5510
Conductivity (µS/cm)	75.00	220.962667	197.740533	29.80	57.70	137.20	338.50	722.00
Dissolved Oxygen (mg/L)	75.00	7.4616	0.6773318	4.50	7.2250	7.60	7.8150	10.12
Total Dissolved Solids (mg/L)	75.00	164.605333	207.768171	6.00	38.65	95.90	216.50	1400.00
Temperature (ºC)	75.00	21.52	5.052053	15.10	16.80	20.60	20.65	32.80
Alkalinity (mg/L)	75.00	114.84	86.908159	20.00	40.00	82.00	191.00	354.00
Hardness (mg/L)	75.00	136.5720	109.56334	34.20	39.90	102.60	225.15	427.50
Nitrate (mg/L)	75.00	0.021366	0.030259	0.000354	0.006854	0.010302	0.0240	0.218747
Phosphate (mg/L)	75.00	1.517073	1.220099	0.3215	0.862250	1.12130	1.6790	7.850
WQI	75.00	1.878745	1.183223	0.582148	1.238313	1.614984	2.089291	7.89930

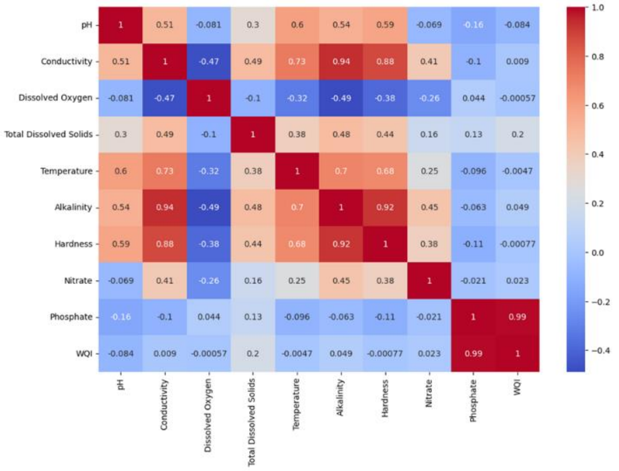

Fig. 6. Heatmap visualization of the future correlations.

Dissolved Oxygen (DO) exhibits a negative correlation with several parameters, notably EC (r = -0.47) and $CaCO_3$ (r = -0.49), which may suggest that higher ionic content and carbonate hardness could suppress oxygen solubility, a phenomenon that has been documented in other hydrographic contexts [50]. The analysis of TDS reveals moderate to strong positive correlations with pH (r = 0.3), EC (r = 0.49), and temperature (r = 0.38), reflecting the influence of these factors on dissolved solid concentrations [51]. The temperature itself strongly correlates with EC (r = 0.73) and $CaCO_3$ (r = 0.7), further reinforcing the interdependence of these water quality metrics.

The scatter plot matrix shown in Fig. 8 and the heatmap visualization provide additional insights into these relationships, offering a visual representation of the strength and direction of correlations. These graphical tools are essential for identifying patterns and anomalies in the dataset, facilitating a more nuanced interpretation of the results. The distribution of water compounds, as depicted in Fig. 7, confirms the trends observed in the correlation matrix, support, supporting the conclusion that physicochemical parameters, particularly nutrient concentrations, are critical determinants of water quality in the Amoju Hydrographic Subbasin.

The application of an Artificial Neural Network (ANN) model to predict the Water Quality Index (WQI) yielded robust results, demonstrating strong predictive performance across several key metrics, as shown in Table VIII. The model's Mean Absolute Error (MAE) of 0.2478 indicates a high degree of accuracy, with predicted WQI values deviating minimally from actual measurements. This level of accuracy is consistent with previous studies employing machine learning techniques for water quality prediction, further validating the model's effectiveness [44].

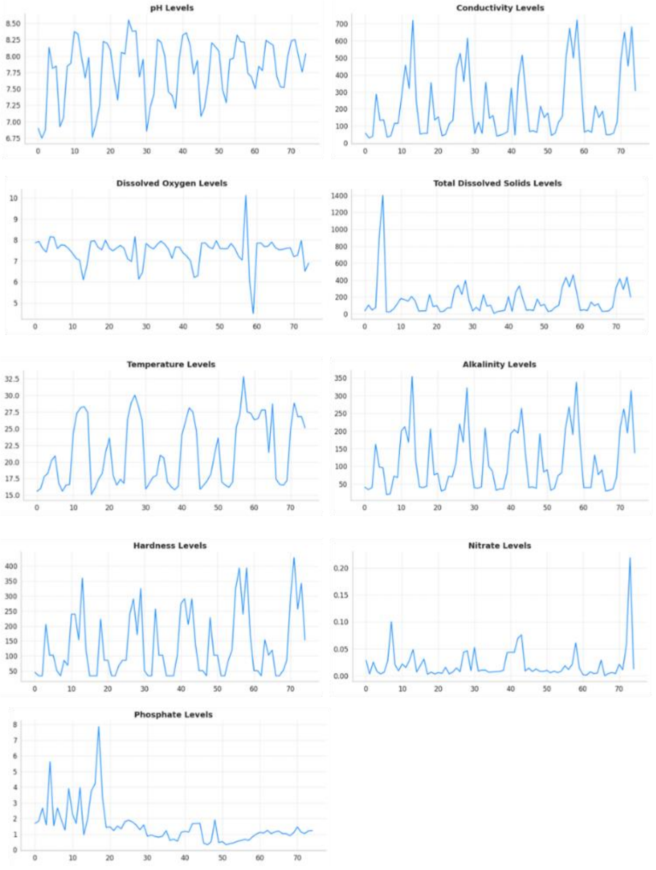

Fig. 7. Distribution of water compounds from the dataset.

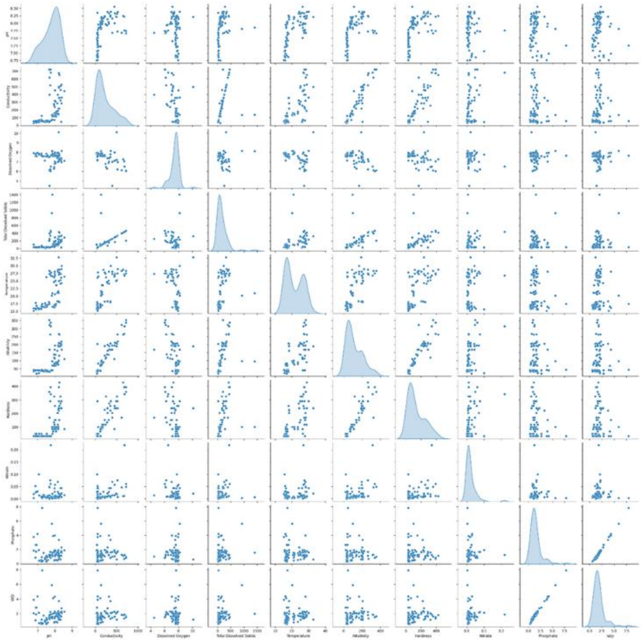

Fig. 8. Scatter plot matrix of the feature.

TABLE VIII. RESULTS BY ANN FOR WQI PREDICTION

Parameters	ANN
MAE	0.2478
MSE	0.0962
RMSE	0.3102
R2	0.9518

The model's Mean Squared Error (MSE) of 0.0962 and Root Mean Squared Error (RMSE), calculated as 0.3102 underscore the model's ability to minimize prediction errors, with the RMSE providing a direct measure of prediction in the same as the WQI. The model's predictive strength is further validated by the R-squared (R^2) value of 0.9518. The R^2 score suggests that approximately 95.18% of the variance in WQI can be explained by the model, highlighting its robustness and reliability as a predictive tool [23].

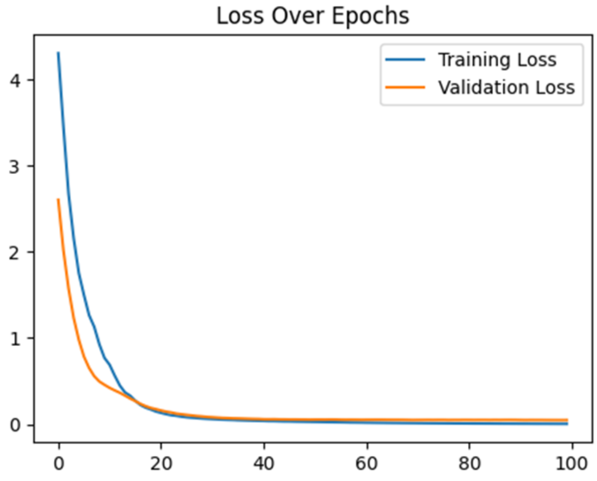

Fig. 9. ANN loss graph per epoch.

The convergence of the training and validation loss curves over 100 epochs, as illustrated in Fig. 9, suggest that the model is well-calibrated, with minimal risk of overfitting. This further corroborated by the “Actual vs. Predicted WQI” scatter plot shown in Fig. 10, which provides a visual comparison between the actual WQI values and those predicted by the model. The points on the plot are closely aligned along the red dashed line, which represents a perfect prediction. This close alignment reinforces the model's accuracy and the minimal prediction error. The plot confirms that the ANN model produces reliable predictions with a high degree of accuracy.

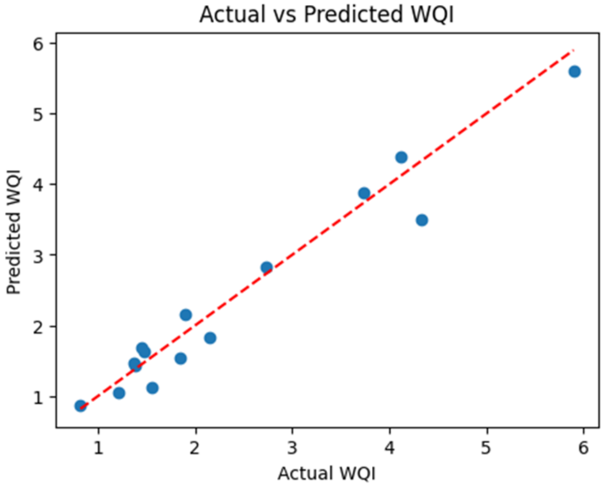

Fig. 10. Actual vs. predicted WQI graph.

V. CONCLUSION AND FUTURE WORK

This section presents a summary of the research conclusions and offers recommendations for future directions, highlighting key findings, limitations, implications, and suggests potential areas for further investigation.

A. Conclusion

Water is an essential resource for life on Earth, and ensuring its quality is fundamental to maintaining human health and environmental sustainability. The assessment of water quality, traditionally carried out through standard laboratory methods, has significantly advanced with the integration of machine learning (ML) techniques. These ML-based approaches offer a more robust and accurate means of predicting water quality indices by leveraging a wide array of water quality parameters.

This study has highlighted the relationships between various physicochemical parameters and the Water Quality Index (WQI) through a comprehensive analysis using Pearson's correlation matrix and Artificial Neural Network (ANN) model. The following key conclusions are drawn:

1) Correlation insights:

a) Very weak correlation: The WQI exhibits very weak correlations with parameters such as Electrical Conductivity (EC), Total Dissolved Solids (TDS), calcium carbonate ($CaCO_3$), and nitrate (NO_3^{1-}). These weak correlations suggest that these parameters, while part of the overall water quality assessment, have limited direct influence on the WQI in this specific study context.

b) Strong correlation: A strong positive correlation is observed between WQI and phosphate (PO_4^{3-}), indicating that phosphate levels are critical determinant of water quality in the studied hydrographic subbasin.

c) Moderate correlations: The pH shows moderate correlation with Total Hardness (TH), $CaCO_3$, and Temperature (T°), implying a notable, though not dominant, role of these parameters in influencing the water quality. EC also displays a moderate correlation with pH, TDS, and NO_3^{1-}.

d) Negative correlation: EC is negatively correlated with Dissolved Oxygen (DO) and phosphate (PO_4^{3-}), suggesting inverse relationships that may have implications for aquatic life and overall water chemistry.

2) Model performance: The ANN model developed for predicting the WQI demonstrated high predictive accuracy, validated by a low Mean Absolute Error (MAE), Mean Squared Error (MSE), and a high R-squared (R^2) value. These metrics confirm the model's ability to reliably predict water quality, making it a valuable tool for environmental monitoring and management.

3) Comparative analysis: The findings align with existing literature, reinforcing the importance of certain key parameters, particularly phosphate, in water quality assessments. The study not only corroborates the conclusions of previous research but also expands upon them by providing a nuanced understanding of parameter interrelationships within this specific geographical and environmental context.

B. Future Work

While the current study has provided significant insights into water quality prediction using machine learning, several avenues for future research remain:

1) Incorporation of additional parameters: Future studies should focus on incorporating additional chemical and biological parameters, such as heavy metals and microbial indicators, which might provide a more comprehensive water quality assessment.

2) Longitudinal data analysis: Extending the temporal scope of data collection over longer periods could allow for the examination of seasonal and climate variations in water quality, thereby enhancing the robustness of the predictive model.

3) Enhanced model architectures: Further refinement of the ANN model, or the application of more advanced machine learning techniques such as ensemble methods, deep learning, or hybrid models, could potentially improve predictive performance and uncover more complex relationships between parameters.

4) Geoespatial analysis: Integrating geospatial analysis tools with machine learning could provide spatially explicit predictions of water quality, which would be invaluable for regional water management and policy-making.

5) Real-time monitoring and prediction: Developing real-time monitoring systems, coupled with AI-driven predictive models, could facilitate the timely detection of water quality anomalies, enabling swift remedial actions and thereby safeguarding public health.

By addressing these areas in future research, the predictive capabilities and practical applications of machine learning in water quality management can be significantly advanced, contributing to more effective and sustainable environmental stewardship.

Conflict of Interest

The authors declare that they have no conflict of interest. The manuscript has been reviewed and approved by all authors, who have no financial or personal relationships that could inappropriately bias or influence the content.

Acknowledgment

We gratefully acknowledge the Soil and Water Analysis Center of the National University of Jaen for their invaluable assistance with the water sample analyses. Our sincere appreciation extends to all the professionals whose expertise and insights significantly enriched the scope and rigor of this study.

***Abstract*—Natural Language Processing (NLP) leverages Artificial Intelligence (AI) to enable computer programs to understand and generate human language. ChatGPT has recently become popular in assignment accomplishment. This project aims to develop and improve an interactive PDF chat application using OpenAI's language model (LLM), specifically GPT-3.5, integrated with Streamlit and LangChain frameworks to assist in learning process. The application enhances user interaction with documents by providing real-time text extraction, summarization, translation, and user-defined question-answering to increase learning opportunities. Key features include obtaining document summaries, multilingual support for improved accessibility, and a document preview section with features such as zoom, rotation, and download. Although it currently faces limitations in handling image-rich PDFs, future enhancements include better image rendering, conversation history, and query download features. Overall, this interactive chatbot model aims to streamline document interaction, making information retrieval efficient and user-friendly.**

Keywords*—Natural language processing; learning opportunities; ChatGPT; PDF

I. Introduction

Natural language processing (NLP) is a study that implements artificial intelligence (AI) technology to enable computer programs to understand human language. NLP consists of two categories: natural language understanding (NLU), which refers to the process of reading and interpreting natural language, and natural language generation (NLG), which refers to the process of writing and generating natural language. With these two categories, NLP integrates deep learning models, machine learning, and computational linguistics to process human language. Before processing natural language, texts are preprocessed to clean and prepare data for classification. As texts are found to contain noise and uninformative pieces, text preprocessing plays an essential role before NLP to prevent interference in text analysis. Common text-preprocessing techniques are tokenization, normalization with stemming, lemmatization, and stop-word removal, and noise removal.

As technology advances, NLP has gained widespread adoption in many applications, including speech recognition (speech-to-text), which is the conversion of speech into text data, and sentiment analysis, which refers to the act of computationally recognizing and classifying viewpoints stated in a text, particularly to ascertain the writer's stance (positive, negative, or neutral) about a certain subject. ChatGPT is widely used especially among students with efficiency in completing assignments yet challenging in plagiarism and integrity [1], [2]. ChatGPT also provides assistants to educators in preparing course materials and exercises [3] Besides education, ChatGPT also provides various opportunities such as research, entertainment, code generation, explanation, and comments, test cases, regular expression, documentation generation, code correction, merging, conversion, and styling, metaverse learning environment [2], [4], [5].

In this project, the OpenAI language model (LLM) is used in creating an interactive chat application for conversations with documents analysis. The application consists of functionalities to extract text, answer user-defined questions, provide translation, and preview documents. We wish to achieve real-time clarification and explanation from the interactive document bot. It will act as a real-time support system where users can ask for instant clarifications or explanations for any issue they come across inside the text. This function speeds up learning or understanding by providing prompt answers to users' questions and removing the need for them to look for additional sources of information. Instant answers customized for each user's questions allow them to continue interacting with the material and ensure full comprehension of the uploaded document.

The proposed project is to develop an interactive PDF chat program with the following features: text extraction, text translation, user-defined prompt question answering, and document viewing. Users will be able to upload document files, start a discussion, ask questions regarding the document, and get answers in real-time through the program. When the file is uploaded and read, a preview of it will be displayed for the user's reference. The material can be summarized, extracted, and translated. A feature that distinguishes our application from the existing market is that it facilitates multilingual response, ensuring that it can deliver information in a different language from the one in which it was asked. This feature improves

*Corresponding Author.

The article is sponsored by INTI International University publication fund.

accessibility and comprehension by allowing users to receive replies in the language of their choice. The project will be constructed using Python, Streamlit, and OpenAI API, allowing users to access numerous document-related features and engage in conversational interactions with documents. By offering a fluid and engaging chat-based interface for document exploration and information retrieval, the program seeks to improve the user's experience when dealing with documents.

This study is constructed in the following sections. Section II presents and compares existing algorithms in NLP and LLM. This is followed by methodology design including system design in Section III. The system implementation with screenshots is presented in Section IV. Section V discusses the system features. Lastly, Section VI concludes the study with limitation and future works.

II. Literature Review

A. Background of NLP and LLM

Rapid improvement of technology, notably in natural language processing (NLP) and the development of sophisticated language models (LLMs), has created opportunities to revolutionize how people interact with textual content. Traditional document approaches, such as direct download of the PDF and reading it solely, often involve static reading, which requires external references for clarity or understanding. Furthermore, this study discusses the need for a more dynamic and user-centric approach by developing an interactive chat application that takes advantage of the capabilities of a language model, notably OpenAI's LLM.

The language model (LLM) that is implemented in our system is OpenAI. Based on research on OpenAI's LLMs, such as GPT-3 and ChatGPT, this LLM highly demonstrates its powerful abilities in natural language understanding (NLU), question answering, text summarization, and natural language generation (NLG). This empowers them to provide explanations and clear clarifications based on user-specific questions about their questions [6], [7].

Our application is to have a chatbot with an LLM basis that can help users inquire about PDF documents more conveniently. Research projects such as Chatbot as Language Learning Medium: An inquiry and an overview of Chatbot Technology show that interactive chat interfaces for exploring information within PDFs are achievable. These kinds of studies emphasize the importance of getting input on what the user wants to gain, the strategy of information retrieval from the user, and LLM response generation techniques for more effective conversational interaction.

Without the existence of artificial intelligence, understanding and extracting meaningful information from portable document format (PDF) files can be challenging due to its differences in layout, text-embedding formats, and the option of having scanned documents. Therefore, there are several studies published recently that aim to explore techniques for text pre-processing, optical character recognition (OCR), and information retrieval algorithms from multiple PDF formats. These studies are paving the way for a more accurate and precise information extraction for LLM interaction.

B. Comparison of LLM

According to the Table I comparison, the GPT 3.5 and Claude LLM models are the LLMs that are more suitable for chat with PDFs [8], [9]. As for GPT 3.5, it is highly adaptable and may be used for almost any task. It is reasonably priced. In addition, application in personal and professional tasks has already begun and is rapidly expanding. Alternatively, this Claude LLM model can be used when the user's prompts are in high volume, and the user wants to deliver the chat messages or prompts without utilizing workarounds. The prompt size offered is 100k tokens, which can fully accommodate roughly 75k words in a single prompt.

TABLE I. Comparison of Different Language Models Based on the Specifications, Pros and Cons

Model	GPT-3.5	Google PaLM [10]	Claude v1 [11]	Microsoft T5 [12]
Parameters	175 Billion	540 Billion	Unknown	11 Billion
API Availability	Yes	Yes	Yes	Pending
MMLU	70	-	75.6	47.7
MT-Bench Score	7.94	6.4	7.9	3.04
Tasks It Excels	Summarization Question Answering Text Generation	Summarization Question-Answering Text Generation Code Generation	Language-specific tasks	Custom Fine Tunes Translation Text Classification
Pros	Performs fairly well for a wide range of tasks. Custom fine-tunings are easy to create commercial use permitted	Performs very well for a wide range of tasks Code Generation Capabilities Easy API Integration Commercial use permitted	Largest token window support in one message (100k tokens, 75k words, approximately) Performs fairly well for wide range of tasks	Allows both supervised and unsupervised fine-tuning. Multiple models available based on use case
Cons	Biases in Output Generation moderately expensive	Risk of biased or inappropriate outputs	Fails to generate very human-like responses	Commercial use not permitted. Getting access is cumbersome

*Massive Multitask Language Understanding (MMLU) helps to evaluate the distortion between original and synthesized signal where it helps to qualify the performance and quality of synthesis systems.

*MT-bench score refers to the performance measure that reflects a model's ability to generate accurate and high-quality translations.

*In order to test out the LLMs above, https://poe.com/ (Poe) is able to provide a similar interface to the ChatGPT and in this website we are able to chat with different LLMs.

Based on the comparison of different LLMs above, we decided to integrate a GPT 3.5 (OpenAI) API as the language model in our PDF Chat model. This is due to the fact that GPT-3.5 can perform excellent data extraction from documents. It is good for text summarization, question answering, and text generation. Therefore, it is the perfect language model to use for a chatbot that is mainly a function for PDF summarisation. To further elaborate, when a user creates a query, the response given is perfectly structured information that has extracted the required text that the user queries from the PDF document. In addition, another advantage of GPT 3.5 is that it has a high level of customization, and therefore, the execution of complex workflows is available in our model. In summary, we decided to use GPT 3.5 to develop our interactive chatbot model that improves the user experience within PDFs. This study aims to increase the comprehension, accessibility and information for a wide range of users by combining real-time clarification, context-aware explanations, and NLP features such as translation and information extraction.

III. Methodology

A. Application of Algorithms / Libraries

1) Streamlit: Streamlit is an open-source Python library that allows for the creation of graphic user interfaces for data science and machine learning projects. Given that little code is required, it is best for those who lack the front-end skills necessary to integrate their code into a web application. Although no front-end knowledge such as HTML, CSS and JavaScript is needed, Streamlit enables the integration to allow design flexibility of the application. However, there are not many choices available in Streamlit to customize the look and feel of the application. If a great level of application customization is required, it is recommended to use more versatile web frameworks [13], [14].

2) LangChain: LangChain is an open-source framework dedicated to developing applications with language models (LLM). These models are deep learning architectures trained on large datasets, equipped to answer user inquiries and create graphics in response to text-based prompts. A collection of tools and abstractions offered by LangChain are available to enhance the adaptability, accuracy, and relevance of the data produced by these models. The core component of LangChain is the LLM interface, which gives developers access to APIs in which they can connect to and query LLMs from their code [15].

3) OpenAI API: An application programming interface (API) is a mechanism that provides a set of specifications and protocols by which two software components can interact with one another. This agreement outlines the requests and replies used in communication between the client and the server. With the OpenAI API key, users can access a range of powerful AI models and resources offered by OpenAI. The functions include natural language processing (NLP), text generation, and language translation.

B. System Flow Chart

Fig. 1 shows the flow of the PDF chatbot operation design. The figure illustrates the process of how our ChatApp interacts with PDF documents to provide responses. This system begins with the user uploading any number of documents that are then read and split into chunks of text. Each chunk of text is converted into embeddings, which are vector representations that capture the semantic meaning of the text. The knowledge base consists of these embeddings, which are kept in a vector store. In addition, a user's question is transformed into an embedding and compared via a semantic search with the stored embeddings. A large language model (LLM) ranks and processes the pertinent fragments that the search pulls from the knowledge base to produce the final response, which is then sent back to the user.

Fig. 1. PDF chatbot operation design.

IV. Results and Discussion

Fig. 2 illustrates the graphic user interface (GUI) when the application is first launched. On the left of the page is the file browser, where files can be uploaded and previewed; the right, the conversation with the PDF chatbot happens. A collapsible sidebar is equipped for file upload. When the cross (x) in the upper right corner is clicked, the section will collapse. When clicking the arrow (>) on the upper left corner of the page, the sidebar expands.

In Fig. 3, a file browser is provided in the sidebar for the user to upload PDF documents. The "Browse File" button turns red when it is clicked and a file window will pop up for the user to select the desired file(s). Once the document is uploaded, a throbber will appear with the text "Processing" after the "Process" button is selected. Lastly, a "PDF Upload Completed" message will appear upon successful upload. Fig. 4 illustrates the document preview section. There are additional features regarding the document, including the page count, zoom-in and zoom out, rotation of the page, downloading, and printing of the document, along with the document settings.

Fig. 5 shows a series of conversations initiated. The details are as follows:

1) A greeting to the bot
2) A general question about the document
3) A question that is not related to the document
4) A detailed question about the document

Fig. 6 shows the PDF Chatbot function that receives and responds to questions in different languages. The screenshot includes languages of English, Chinese, and Malay. Fig. 7 shows the extraction of text, in which the questions prompted are about a particular chapter of the document. In addition, the question requested the answer in a particular language (Chinese and Korean in the example), which the PDF Chatbot provided accurate answers. In addition to that, PDF Chatbot allows the upload and preview of more than one document. Fig. 8 shows the PDF chatbot function of answering questions about two documents.

Talk with PDF Chat! 💡

1 Hi

Hello! How can I assist you today?

2 What is the document about?

The document is about the guidelines and requirements for participating in the Hilti IT Competition. It provides information on the submission materials, presentation format, ownership of intellectual property, and the number of teams that will proceed to the semi-finals and finals stages of the competition. It also includes a FAQ section for further inquiries.

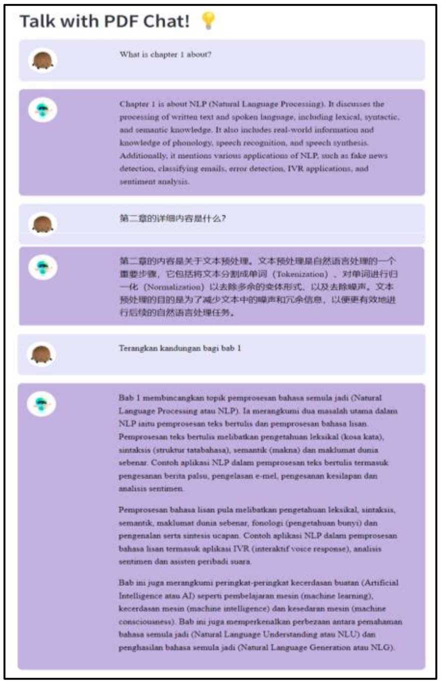
3 Who is Potato Oug Huat Huat

I'm sorry, but I don't have any information about Potato Oug Huat Huat.

4 When is the submission

The submission for the Hilti IT Competition is from 1st November 2023 to 23rd February 2024.

Fig. 5. Conversation with PDF chatbot.



Talk with PDF Chat! 💡

What is chapter 1 about?

Chapter 1 is about NLP (Natural Language Processing). It discusses the processing of written text and spoken language, including lexical, syntactic, and semantic knowledge. It also includes real-world information and knowledge of phonology, speech recognition, and speech synthesis. Additionally, it mentions various applications of NLP, such as fake news detection, classifying emails, error detection, IVR applications, and sentiment analysis.

第二章的详细内容是什么?

第二章的内容是关于文本预处理。文本预处理是自然语言处理的一个重要步骤，它包括将文本分割成单词（Tokenization）、对单词进行归一化（Normalization）以去除多余的变体形式、以及去除噪声。文本预处理的目的是为了减少文本中的噪声和冗余信息，以便更有效地进行后续的自然语言处理任务。

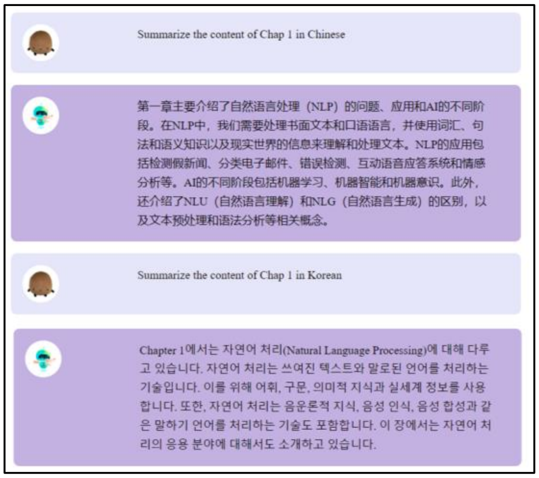
Terangkan kandungan bagi bab 1

Bab 1 membincangkan topik pemprosesan bahasa semula jadi (Natural Language Processing atau NLP). Ia merangkumi dua masalah utama dalam NLP iaitu pemprosesan teks bertulis dan pemprosesan bahasa lisan. Pemprosesan teks bertulis melibatkan pengetahuan leksikal (kosa kata), sintaksis (struktur tatabahasa), semantik (makna) dan maklumat dunia sebenar. Contoh aplikasi NLP dalam pemprosesan teks bertulis termasuk pengesanan berita palsu, pengelasan e-mel, pengesanan kesilapan dan analisis sentimen.

Pemprosesan bahasa lisan pula melibatkan pengetahuan leksikal, sintaksis, semantik, maklumat dunia sebenar, fonologi (pengetahuan bunyi) dan pengenalan serta sintesis ucapan. Contoh aplikasi NLP dalam pemprosesan bahasa lisan termasuk aplikasi IVR (interaktif voice response), analisis sentimen dan asisten peribadi suara.

Bab ini juga merangkumi peringkat-peringkat kecerdasan buatan (Artificial Intelligence atau AI) seperti pembelajaran mesin (machine learning), kecerdasan mesin (machine intelligence) dan kesedaran mesin (machine consciousness). Bab ini juga memperkenalkan perbezaan antara pemahaman bahasa semula jadi (Natural Language Understanding atau NLU) dan penghasilan bahasa semula jadi (Natural Language Generation atau NLG).

Fig. 6. Prompting queries and obtaining answers in different languages.



Summarize the content of Chap 1 in Chinese

第一章主要介绍了自然语言处理（NLP）的问题、应用和AI的不同阶段。在NLP中，我们需要处理书面文本和口语语言，并使用词汇、句法和语义知识以及现实世界的信息来理解和处理文本。NLP的应用包括检测假新闻、分类电子邮件、错误检测、互动语音应答系统和情感分析等。AI的不同阶段包括机器学习、机器智能和机器意识。此外，还介绍了NLU（自然语言理解）和NLG（自然语言生成）的区别，以及文本预处理和语法分析等相关概念。

Summarize the content of Chap 1 in Korean

Chapter 1에서는 자연어 처리(Natural Language Processing)에 대해 다루고 있습니다. 자연어 처리는 쓰여진 텍스트와 말로된 언어를 처리하는 기술입니다. 이를 위해 어휘, 구문, 의미적 지식과 실세계 정보를 사용합니다. 또한, 자연어 처리는 음운론적 지식, 음성 인식, 음성 합성과 같은 말하기 언어를 처리하는 기술도 포함합니다. 이 장에서는 자연어 처리의 응용 분야에 대해서도 소개하고 있습니다.

Talk with PDF Chat! 💡
Ask a question about your document(s)

What are the 2 documents abotu

The two documents mentioned are:

1. TAR Awards 3rd Committee Meeting Agenda: This document outlines the agenda for the 3rd committee meeting of the TAR Awards. It includes details such as the date, time, venue, and the content to be covered during the meeting.

2. NLP Problem: This document discusses the problem of processing written and spoken language in natural language processing (NLP). It covers topics such as lexical, syntactic, and semantic knowledge, as well as real-world information and various NLP applications. It also provides information about stages of AI, including machine learning and machine intelligence.

Fig. 8. Conversation with PDF chatbot regarding 2 documents.

V. Discussion

According to the results mentioned above, we have successfully developed an interactive PDF Chatbot application specifically designed for document exploration and engagement. It is a technology stack that uses Python, Streamlit, and OpenAI API, enabling the easy integration of several conversational interactions and document-related features, guaranteeing a positive user experience. It can perform text extraction and summarization, allowing the user to obtain a summarised paragraph of the document. Additionally, the application offers a preview feature that displays the uploaded document, allowing users to refer to the context. Not only that, the chatbot is equipped with translation and multi-language support. It can enhance understanding and usability for a worldwide user base through translation and enabling users to communicate with the program in their choice language by handling inquiries and providing responses in languages different from the original document content. Lastly, a user-friendly interface is created for the application so that users can seamlessly navigate through the various functionalities offered.

VI. Conclusion

The limitation of the application is that some PDF files that contain images cannot be displayed in the preview section. To address this, we aim to explore alternative programming approaches to better handle and render image-rich PDFs within the preview section. To better enhance the application function, we intend to incorporate a conversation history function into the interactive PDF Chatbot so that users may review their prior questions. Additionally, we plan to provide a download feature, which would enable customers to store a copy of their queries on their devices. Besides that, future works could also involve a group of users from different specialization to test run the system and evaluate the accuracy and performance of the Chatbot system.

Prototype of an Indoor Pathfinding Application with Obstacle Detection for the Visually Impaired

Ken Gorro, Lawrence Roble, Mike Albert Magana, Rey Paolo Buot,
Louis Severino Romano, Herbert Cando, Bonifacio Amper, Rhyan Jay Signe, Elmo Ranolo
Department of Industrial Technology-College of Technology, Cebu Technological University, Carmen Campus, Philippines

***Abstract*—This study presents an initial prototype for a project aimed at assisting visually impaired individuals using deep learning techniques. The proposed system utilizes the You Only Look Once (YOLOv8) algorithm to detect objects tagged as obstacles. Designed for indoor environments, the system employs a CCTV camera and a computer server running the YOLOv8 model. Additionally, the A-star algorithm is used to determine the optimal path to avoid detected obstacles. Video frames are divided into tiles, each considered a node; nodes with detected objects are marked with a value of 0. The YOLOv8 model currently achieves an initial accuracy rate of 70%, with a mean Average Precision (mAP) at an Intersection over Union (IoU) threshold of 0.5 reaching 0.993 across all classes. This high mAP indicates an exceptional balance between precision and recall, signifying the model's effectiveness in object detection. Furthermore, the model yields an impressive F1-score of 0.99 at a confidence threshold of 0.624, demonstrating a robust balance between precision and recall, which is crucial for minimizing both false positives and false negatives. This prototype being developed assumes that a destination can be set by an operator of the system using the server that connects to the CCTV camera. The system was tested in enclosed environments and was able to provide a path that potentially avoids obstacles. The development of audio commands to guide visually impaired users is ongoing. These audio commands depend on identifying the direction an individual is going, requiring an additional deep-learning model to generate accurate instructions.**

***Keywords*—Yolov8; A-star algorithm; pathfinding; deep learning**

I. INTRODUCTION

Equal chances, particularly for the disabled, are vital in today's culture because technology is used by everyone and advancement is happening at a faster pace. For example, one of the groups most at risk of facing various challenges is the visually impaired. Finding our way about inside buildings may be quite difficult and dangerous, particularly if we are unfamiliar with the surroundings. More specifically, this significant topic has been taken into consideration in an effort to improve the independence and safety of visually impaired individuals through the use of modern technology, namely through the development of the in-door pathfinding program with the capability of obstacle detection.

The main goal of this study is to restore the independence and freedom of visually impaired individuals. The visually impaired are genuinely disabled in several ways, including but not limited to the fact that indoor spaces are primarily laden with barriers. They are supported by friends, family, or both, and they need traditional walking aids like canes and guide dogs. They can move around independently with the assistance of an improved navigational aid that can identify impediments, which will boost their efficiency and sense of self. Additionally, safety needs to be improved. In the midst of all of these considerations, improving safety is also crucial. It becomes clear that there are many risks and difficulties in any indoor setting, such as an office building, hospital, airport, or retail center. Occasionally, traditional mobility aids are unable to provide adequate or timely information about these risks. The application will be safe for visually impaired people to use if it can detect impediments in real-time, thereby reducing or eliminating the hazards related to falls and blind guiding.

This research is in phase 1 of creating a total pathfinding mobility application for the visually impaired in indoor scenarios. The result of this research only covers pathfinding and obstacle avoidance. The guiding voice is still in the development phase which will be the next phase of this study. The main focus is on the current obstacle detection and generating the best path to avoid obstacles using yolov8 and graph theory algorithms.

II. RELATED WORK

Despite global efforts in eye care, over 2.2 billion people suffer from vision impairment, with at least 1 billion cases preventable or unaddressed. The burden is higher in low-income countries, older populations, and disadvantaged communities. Initiatives like "Vision 2020" have contributed to improvements, but challenges remain, including limited service coverage, workforce shortages, and health system fragmentation. With aging populations and lifestyle changes, vision impairment is on the rise. The World Report on Vision advocates for Integrated People-Centered Eye Care (IPEC) to provide comprehensive, universal eye care and well-being [10].

Enhancing mobility and independence for visually impaired individuals relies heavily on advanced technologies. These innovations use artificial intelligence, machine learning, and robotics to navigate complex environments safely. By combining sensory data from cameras, LiDAR, and ultrasonic sensors, systems can identify and bypass obstacles instantly. Recent studies emphasize the development of reliable methods that enhance user experience and accessibility. This research is promising for creating assistive technologies that provide greater autonomy and safety for visually impaired individuals. To begin with, planning a path is an important part of any navigation framework. Since the 1970s, the issue of route planning has been a fascinating subject of study, particularly for robotics enthusiasts [2]. In order to save time, effort, and resources, it seeks to determine the best path between two sites. To guarantee user safety, additional design limitations must be added when incorporating these robotics-derived techniques into navigation systems. Furthermore, given that the user's tastes and wants may differ due to underlying path features and the topography of the environment, an optimal path for the VI is frequently not just the shortest path. In order to discover an optimal route while taking the preferences of the VI user into account and minimizing collisions with obstacles, this work presents a path-planning algorithm that is based on Ant Colony Optimization (ACO). Every stage has taken into account human issues, especially the unique requirements of the VI user [2]. People can manage and process spatial information about where they are physically by using cognitive mapping. In order to successfully complete tasks related to navigation and direction in urban environments, it is essential to develop a conceptual picture of the surrounding space and nearby objects (Fernandes et al., 2017) [1]. Because of obstructions on sidewalks and roadways, blind pedestrians frequently find it difficult or even dangerous to navigate in urban environments, despite their skill at compensating for lost visual information through increased awareness of environmental cues and navigational aids (Yang et al., 2011) [6]. Although blind pedestrians can navigate more safely and effectively thanks to audible traffic signals and landmarks (Weyrer et al., 2013), research on the needs, preferences, and experiences of blind pedestrians during navigation (e.g. Shangguan et al., 2014) and navigation solutions tailored specifically for them are still lacking [4][5]. The system described in the study by Lee and Medioni includes a glass-mounted RGBD camera with inertial measurement unit (IMU) sensors, a vest-type interface with four vibration motors, and a laptop that the user carries in the back and runs the program in real time. It uses visual odometry to estimate the camera location; it uses normal vectors and random sample consensus (RANSAC) to segment the floor; it generates a 2D traversable map and a 3D voxel map; and it directs the user to things of interest in dynamic interior environments. Using the D*Lite technique, an ideal path is calculated in the 2D map. The user receives haptic and audio input while using a smartphone application to select the location [7]. The Google Tango software, which operates on a hybrid phone/tablet Lenovo Phab2 with an integrated 3D depth sensor, gyroscope, and accelerometers, is the foundation of the CCNY smart cane. This device is placed on the user's chest. It can remember important visual elements like doors and rooms (stored in an area description file, or ADF), perform simultaneous localization and mapping (SLAM), and use infrared sensors to locate things. A visually impaired person can be guided to objects of interest in indoor spaces by the system, which uses the A* search algorithm to plot a path and provides both haptic (two vibrating motors installed on the white cane) and audible feedback. The iterative end-point fit algorithm is used to provide easier guidance, giving the user information [3][8][9]. D. Ni et al. [30] developed an assisted walking robot system that relied on computer vision and tactile sense. The system is made up of a rollator framework that offers stable physical support, a Kinect gadget that acts as a blind person's eyesight to record environmental information, and ultrasonic sensors that identify symmetry roads. A wearable vibrotactile belt is intended to provide blind people with information through vibration patterns. For the safe direction, a feature extractor approach based on depth image compression is used [15]. On the other hand, H-C Wang et al. (2021) advanced wearable devices for blind and visually impaired (BVI) individuals by integrating computer vision and haptic feedback to improve navigation and situational awareness. Their study showed how depth cameras and real-time processing help detect objects and obstacles, allowing safer navigation. The design is smaller and less intrusive, addressing previous issues with bulk and audio cues. Ongoing research aims to further develop this intuitive haptic technology for safer, independent mobility for BVI users [17].

According to a recent in-depth analysis of robot path planning in dynamic environments, reactive approaches such as Ant Colony Optimization (ACO) are quickly gaining traction in the field of mobile robot navigation because they perform better than classical approaches in real-time navigation scenarios (Cai et al., 2019) [11].

Kumar et al. (Kumar et al., 2020) recently improved the pheromone evaporation rate in order to address the issue of sluggish convergence of ACO. They suggested a fuzzified ACO (FACO) for mobile robots, in which the path pheromone updating process takes into account both favorable and unfavorable paths. Through simulation, the effectiveness of the FACO method was evaluated, demonstrating that it resolves the problem of delayed convergence [12].

Shiguo et al. (Li et al., 2020) tackled the problem of robot path planning by taking into consideration not only the path length but also the number of turns. They used the A* algorithm to enhance the convergence speed, and turning points were considered in the pheromone concentration. The simulation results assessed the performance of the improved ACO in terms of convergence, the number of iterations, path length, and the number of turns [13].

In order to address the problems of poor convergence speed, trapping into local optimum, and amount of turns, Ma and Mei (Ma and Mei, 2020) suggested an enhanced ACO path planning for mobile robots. To get rid of the less promising nodes, they employed a Jump Point Search (JPS) technique. Both simulation and real-world mobile robot navigation experiments were used to evaluate the algorithm's performance, demonstrating the enhanced algorithm's efficacy and efficiency in resolving path planning for mobile robots [14].

Broersen et al. (2016) developed a basic pathfinding method based on the A* algorithm. The path was calculated via the octree's vacant space. In the pathfinding procedure, two nodes that had the same face were regarded as neighbors. There might be equal-sized, bigger, or smaller neighbors. The neighbors are determined dynamically, and object avoidance is not used [16].

Tapu et al. developed a DEEP-SEE system that detects both dynamic and static items utilizing the You-Only-Look-Once (YOLO) object identification approach. The obstacle category and distance data may be obtained from the system. However, because of its high computing cost, real-time detection on mobile devices is challenging to achieve with this neural network [18]. Some lightweight image-based neural networks, such as ShuffleNet, YOLO-LITE, and MobileNet have suggested making real-time object identification more accessible to mobile devices. However, while recognizing objects, these lightweight algorithms do not explicitly take distance into account. Therefore, it is possible that the painted item on the ground is misleading to vision-challenged individuals [19][20][21].

Mortari et al. proposed a network creation technique that takes into consideration obstacles in indoor situations. Obstacles were represented as 2D geometry on the floor plane in the prepared models that served as the basis for the approach. Because 2D-floor layouts were abstracted at various height levels, the end product was a 3D network [22]. An approach for 3D indoor path-planning using semantic 3D models encoded in LoD4 CityGML was introduced by Xiong et al. [23]. While the system took barriers into account, tests were conducted on models without obstacles. A true interior navigation approach based on grid models—obtained from 2D-floor layouts with specified obstacles—was developed by Lui et al. [24]. An octree representation of indoor point clouds serves as the foundation for the indoor pathfinding approach that Rodenberg [25] suggested. Because the A* the pathfinding algorithm followed empty nodes and avoided obstructions, it was reliant on the use of heuristics to direct the search. Additionally, Li et al. [26] recently introduced a path-planning technique for drones operating inside that was based on occupancy voxel maps and on which the vacant voxels made up the navigable space.

Tsirpas et al. presented an intriguing Radio Frequency Identification (RFID)--based indoor navigation system for the elderly and visually handicapped. RFID tags have a limited range, which is the primary drawback of systems based on RFID technology (the authors of the research recommend 40 × 40 cm cells). Moreover, considering that the human body may resist radiofrequency signals, its range might be lowered. Another disadvantage is that installing RFID in large spaces may be costly because the tags frequently need to be inserted into the floors, walls, furniture, and other surfaces [27].

Khelifi et al. also studied the utilization of radio and Wi-Fi technologies. The writers went beyond specifics in their discussion of the subject, emphasizing the necessity for consideration of matters like processing costs, implementation costs, and energy efficiency. Grouping relevant works that supported the study according to methodologies and technologies helps the reader grasp the material better and become more objective when reading [28].

Mainetti et al. aimed to cover the key IPS technologies and approaches for locating, mapping, tracking, and navigating people, objects, and animals inside. The primary technologies employed in IPS, according to the authors, are computer vision (mobile and stationary cameras), infrared, ultrasound, Wi-Fi, RFID, and Bluetooth. The primary methods which include those that make use of FM radio and ZigBee technology are thoroughly explained, while the remaining methods are categorized under the heading "other technologies". The authors utilized a model that took accuracy, coverage, cost, complexity, and usual implementation locations into account while presenting the findings of the works that they used as references in the form of graphs and tables [29].

Guerrero proposed a micro-navigation system that tracks the user's position and movements with the use of an infrared camera. Using a tree structure of the room including the relevant data, based on Extensible Markup Language (XML), the system accomplishes static obstacle detection. However, the system's simulation and testing showed that as more people travel through the area, the system performs worse. PERCEPT is an interior navigation system that uses passive RFID tags for location and is based on kiosks. Using the shortest path method, it is a macro-navigation system that lets VI persons move from one room to another on multiple floors. Unfortunately, the technology that was described is unable to identify any environmental constraints that are nearby. The author also suggested that the system be enhanced by offering guidance information depending on user choices and steps [30][31].

Using RFID technology, the authors of Ivanov (2010) created an interior navigation system for the blind. By placing passive RFID tags above and below door handles, the technology makes door-to-door travel easier. This is based on the idea that blind people can identify doors with the use of their white canes. Navigational instructions are stored on tags above the door handles, while adaptive multi-rate (AMR) audio data is stored on tags below the handles. Every door serves as a point of reference for the following location. Each RFID tag has its navigation instructions manually entered into it. The blind user reads these tags with a cell phone that is equipped with RFID. A text-to-speech engine and the mobile phone's keyboard are used for bi-directional communication between the user and the device. The system mostly depends on the user's ability to navigate obstacles with their white canes. The published work did not address the correctness of the system; instead, it just examined the navigation time in its entirety [32].

III. Methodology and Results

Fig. 1 is the system architecture of the system, the CCTV camera streams the video data to a server with the deep learning models installed to detect obstacles within the video frames, and the A-star path-finding algorithm was utilized to generate the path. Each video frame is divided into tiles and treated as 1 node. The details of the algorithm are discussed in the succeeding session.

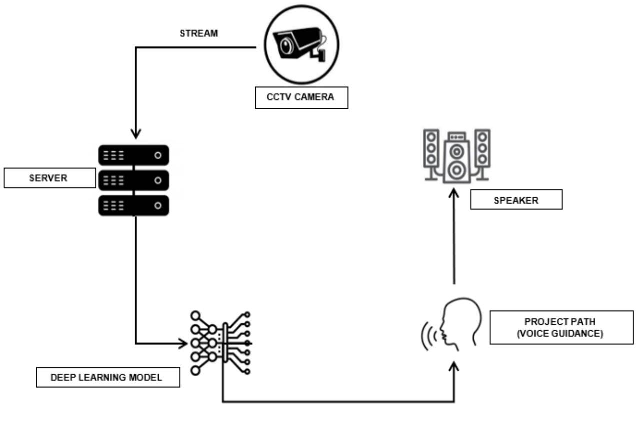

Fig. 1. System architecture.

A. Dataset

The dataset is essential for training YOLOv8 and other object detection models. It consists of images with annotations that include bounding boxes and class labels, providing the model with the information needed to learn object detection. During training, the dataset is divided into subsets: training, validation, and test. The training subset helps the model learn, the validation subset fine-tunes hyperparameters, and the test subset evaluates the final performance. High-quality and diverse datasets are crucial for effective training, ensuring accurate predictions and better model performance. 1200 samples were utilized to train and test the YoloV8 model for obstacle detection.

B. Bounding Boxes

Bounding boxes are essential for object detection models like YOLOv8, as they define the location and size of objects within images. During training, these annotations serve as ground truth, guiding the model to learn object positions and spatial relationships. The model predicts bounding boxes for objects, and its performance is evaluated by comparing these predictions to the ground truth. Discrepancies are used to adjust the model's parameters and reduce errors. After initial training, the model's bounding box predictions are further tested and refined to enhance accuracy. Properly annotated bounding boxes ensure effective object localization and classification, improving overall detection performance.

C. Hyperparameter Tuning for YOLOv8 Model

The training of the YOLOv8 model involves several crucial hyperparameters that significantly influence its performance. As detailed in Table I, the epochs parameter is set to 1000, meaning the model will traverse the entire training dataset 1000 times, which helps in enhancing the model's learning but requires careful monitoring to avoid overfitting. The batch size is configured to 16, indicating that the model will process 16 samples before updating its weights. This setting balances between frequent updates and memory usage, although it may affect the stability of the gradient estimates. The learning rate is set to 0.05, which controls the magnitude of weight adjustments during training. This relatively high learning rate can speed up convergence but may introduce instability if not carefully managed. To mitigate overfitting, weight decay is applied with a value of 0.0005, adding a penalty for large weights and promoting generalization. The image size is fixed at 640 x 640 pixels, determining the dimensions of the input images and impacting both detection accuracy and computational demands. Finally, the momentum is set at 0.937, which helps accelerate the gradient vectors in the correct direction, facilitating faster convergence and reducing oscillations. Together, these hyperparameters are finely tuned to balance learning efficiency and model robustness.

TABLE I. HYPER PARAMETERS

Hyper parameters	Tune value
Epochs	1000
Batch Size	16 (default)
Learning Rate	0.05
Weight Decay	0.0005 (default)
Image Size	640 x 640 (default)
Momentum	0.937 (default)

D. Model Training

Model training for YOLOv8 is essential for optimizing the model's ability to detect objects accurately within a specific dataset. Through training, the model's parameters are adjusted to improve detection precision and recall. This process allows the model to adapt to the unique characteristics of the data, enhancing its performance. For training purposes, 80% of the samples were utilized while 20% were used for evaluating the model. Key aspects of training include tuning hyperparameters like learning rate and batch size, which are critical for achieving the best results while preventing overfitting or underfitting. Regular evaluation using metrics such as mean Average Precision (mAP) helps in assessing the model's performance and making necessary improvements.

E. Performance Metrics for YOLOv8 Model Evaluation

A. Precision is the ratio of true positive detections to the total number of positive detections made by the model. It measures how many of the detected objects are actually correct.

$$\text{Precision} = \frac{number\ of\ True\ positives}{number\ of\ True\ positives + number\ of\ False\ positives} \quad (1)$$

B. Recall is the ratio of true positive detections to the total number of actual objects in the ground truth. It measures how well the model identifies all the relevant objects.

$$\text{Recall} = \frac{number\ of\ True\ positives}{number\ of\ True\ positives + number\ of\ False\ negatives} \quad (2)$$

C. The mean Average Precision (mAP) is the average of Average Precision (AP) scores across all classes. It summarizes the precision-recall curve, offering a single, comprehensive metric to evaluate the model's performance across different thresholds and providing a holistic view of accuracy and object detection capabilities. Higher mAP indicates better object detection performance across various classes and confidence levels.

$$\text{mAP} = \frac{1}{N} \sum_{i=1}^{N} \quad APi \quad (3)$$

D. The F1-score in the context of YOLOv8 refers to a metric used to evaluate the model's performance in terms of both precision and recall. It is a harmonic mean of precision and recall, providing a single score that balances these two metrics.

$$\text{F1} = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (4)$$

F. Pathfinding Algorithms

*1) A * Algorithm*: The A* (A-star) algorithm is a widely used pathfinding and graph traversal algorithm, especially notable for its efficiency and accuracy in finding the shortest path between two points. It combines the strengths of Dijkstra's algorithm and Greedy Best-First-Search. A* operates by maintaining a tree of paths originating from the start node, extending those paths one edge at a time until the goal node is reached. The algorithm uses a priority queue to explore nodes based on the following cost function:

$$f(n) = g(n) + h(n)$$

where:

- g(n) is the cost from the start node to the current node (n).
- h(n) is the heuristic estimate of the cost from (n) to the goal.

The heuristic function h(n) is crucial for the A* algorithm's performance. It must be admissible, meaning it never overestimates the true cost to reach the goal, ensuring the optimality of the path found. Common heuristic functions include the Euclidean distance and Manhattan distance, depending on the nature of the problem space.

2) Dijkstra's algorithm: Dijkstra's algorithm finds the shortest path between nodes in a graph. It starts at a chosen node, and then repeatedly selects the unvisited node with the smallest known distance from the start. It updates the distances to neighboring nodes and marks the current node as visited. This process continues until the destination is reached or all nodes are visited. It uses the formula:

$$d[v] = \min(d[v], d[u] + w(u,v))$$

where:

- d[v] is the distance to node v
- d[u] is the distance to node u
- w(u,v) is the weight of the edge from u to v

The algorithm iteratively updates these distances, starting from the source node, until it reaches the destination or visits all nodes. It always selects the unvisited node with the smallest known distance for the next iteration.

While both A* and Dijkstra's algorithms are effective for pathfinding, A* is often preferred in scenarios where efficiency and performance are critical due to the following reasons:

a) Heuristic guidance: A* uses a heuristic to guide its search, which can significantly reduce the number of nodes explored compared to Dijkstra's algorithm. Dijkstra's algorithm explores all possible paths, ensuring the shortest path but often at the cost of increased computation time, especially in large or complex graphs.

b) Efficiency: The heuristic function in A* allows the algorithm to focus on the most promising paths towards the goal. This focused search typically results in faster pathfinding, as fewer nodes are expanded compared to Dijkstra's algorithm, which treats all nodes with equal importance.

c) Optimality and completeness: A* is both optimal and complete, meaning it will always find the shortest path if one exists, provided the heuristic is admissible. Dijkstra's algorithm also guarantees the shortest path, but without the heuristic guidance, it often requires more extensive node exploration.

d) Flexibility: A* can be easily adjusted for different types of pathfinding problems by changing the heuristic function. This adaptability makes it suitable for various applications, from simple grid-based pathfinding to more complex navigation in dynamic environments.

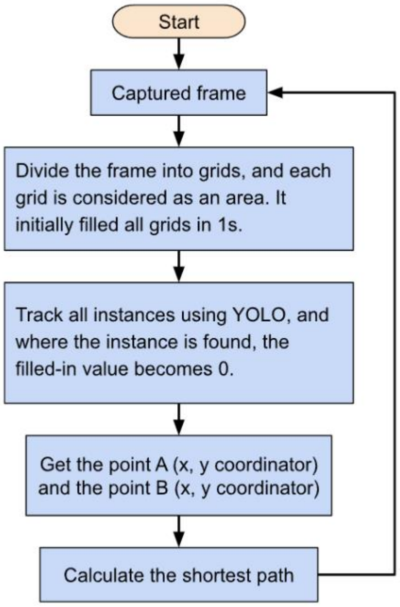
e) Practicality: In many practical applications, such as robotics, video games, and geographical mapping, the A* algorithm's balance of optimality and performance makes it more practical than Dijkstra's algorithm. It provides quicker responses, which is crucial for real-time decision-making processes.

For this study, the A* algorithm would be chosen over Dijkstra's algorithm because of its heuristic-driven approach, which improves efficiency by minimizing the number of nodes investigated while ensuring the shortest path. This makes A* ideal for large-scale and sophisticated pathfinding applications in which performance and speed are important.

G. Pathfinding with YOLO Integration

As shown in Fig. 2, the provided flowchart illustrates how to use YOLO predictions to navigate and find the shortest path between two places. The process starts with an initialization stage, which prepares the system to capture and process frames. To navigate all of the instances, the input frame is divided into grid coordinates with 1s and 0s. Areas filled with 0s signify obstacles, whereas 1s indicate a clear pathway.

As illustrated in Fig. 3, the system processes the YOLO prediction results by tracking the center of each instance's bounding box. The system then identifies two distinct points within the scene, referred to as Point A and Point B, based on their respective (x, y) coordinates. Using these coordinates, the system calculates the shortest path between the two locations, employing pathfinding algorithms such as the A* algorithm. A feedback loop is incorporated, allowing the system to continuously capture new frames and update predictions, as well as pathfinding computations. This dynamic process enables the system to adapt to changes in the environment in real-time, ensuring precise navigation and efficient pathfinding.



Start
Captured frame
Divide the frame into grids, and each grid is considered as an area. It initially filled all grids in 1s.
Track all instances using YOLO, and where the instance is found, the filled-in value becomes 0.
Get the point A (x, y coordinator) and the point B (x, y coordinator)
Calculate the shortest path

Fig. 2. Path-finding obstacle detection flowchart.

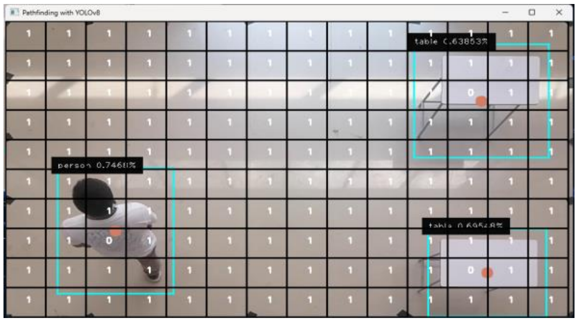


Fig. 3. Applied 1s and 0s on the captured frame.

IV. Experimental Result

A. Model Training Results

1) Confusion matrix: As illustrated in Fig. 4, the confusion matrix provides a comprehensive summary of the performance of the YOLOv8 small model across different classes. It is a powerful tool for understanding how well the model distinguishes between the classes: person, robot, table, and background.

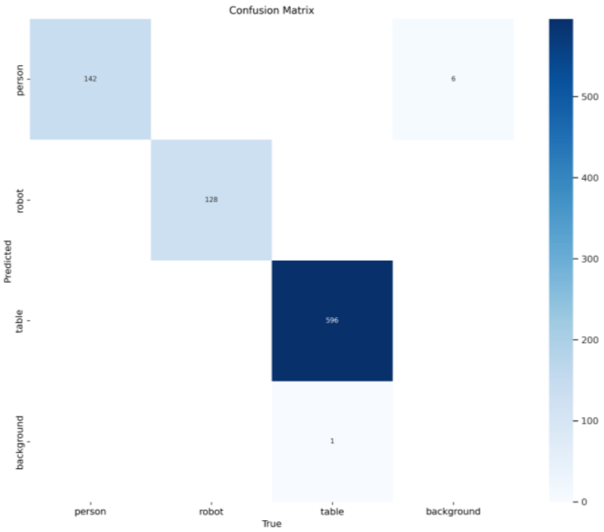

Fig. 4. Confusion matrix result.

In the confusion matrix, the "person" class has 142 true positives, indicating that the model correctly identified 142 instances of "person". However, there are six false positives where background instances were misclassified as "person." There are no false negatives, meaning all actual instances of "person" were correctly identified, showcasing the model's high accuracy for this class. For the "robot" class, the model performs perfectly, with 128 true positives and no false positives or false negatives. This indicates that the model consistently identifies "robot" instances without any errors, demonstrating its robustness in detecting this class. The "table" class also shows high accuracy with 596 true positives. There is only one false positive where a background instance was misclassified as "table," and no false negatives, meaning all actual instances of "table" were correctly identified. This indicates the model's high precision and recall for the "table" class. The confusion matrix also reveals that the model occasionally misclassified background instances. Specifically, six background instances were predicted as "person," and one background instance was predicted as "table." These misclassifications indicate room for improvement in distinguishing background from specific objects, which could enhance the model's overall performance.

In summary, the confusion matrix highlights that the YOLOv8 small model is highly effective at correctly identifying instances of "person," "robot," and "table." While the model demonstrates high precision and recall for these classes, there are occasional misclassifications of background instances, particularly as "person" and "table". These findings suggest that the model is robust and accurate but could benefit from further refinement to improve its handling of background instances. The confusion matrix serves as a valuable tool in validating the model's effectiveness and guiding future enhancements.

2) Training result graphs: Fig. 5 illustrates a visualization of several metrics and loss functions tracked during the YOLOv8 model's training and validation phases. Each subplot gives information about various aspects of the model's performance and learning process.

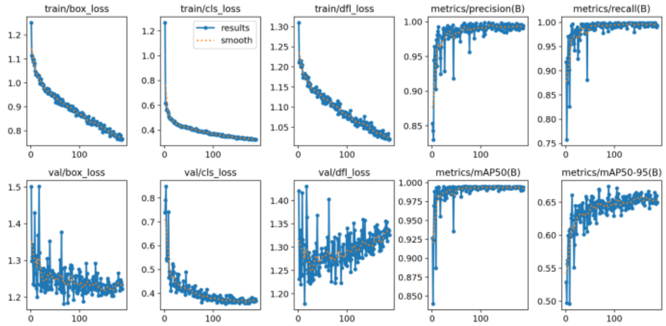

Fig. 5. YOLOv8 training results.

The training box loss (train/box_loss) plot illustrates the model's improvement in predicting bounding boxes. This loss consistently decreases over time, indicating that the model is learning to better match the predicted bounding boxes with the ground truth boxes. A similar trend is observed in the training classification loss (train/cls_loss) plot, where the decreasing loss shows that the model's classification capabilities are improving, allowing it to more accurately categorize objects into the correct classes (person, robot, table).

The training DFL loss (train/dfl_loss) which measures the distribution quality of the predicted bounding boxes, also shows a consistent decline. This suggests that the model is becoming more precise in predicting the exact locations of the bounding boxes. The precision metrics (metrics/precision (B)) and recall metrics (metrics/recall (B)) quickly rise and stabilize close to 1.0. This indicates that the model is highly accurate in its positive predictions, with very few false positives, and effective at detecting almost all relevant objects, with very few false negatives.

For the validation phase, the validation box loss (val/box_loss) decreases significantly, although with more fluctuation compared to the training loss. This suggests that while the model is learning well, it encounters some variability when applied to new data. The validation classification loss (val/cls_loss) shows a decreasing trend, indicating good generalization, though it also fluctuates, highlighting some variability in performance on the validation set. The validation DFL loss (val/dfl_loss), despite generally decreasing, exhibits higher fluctuation, indicating less stability in predicting bounding box distributions on unseen data compared to the training set.

The mAP50 metrics (metrics/mAP50 (B)), which measure precision and recall at a specific Intersection over Union (IoU) threshold of 50%, rapidly increase and stabilize near 1.0. This demonstrates that the model performs exceptionally well in detecting objects with a high degree of overlap with the ground truth. The mAP50-95 metrics (metrics/mAP50-95(B)), which provide a more comprehensive measure across varying IoU thresholds (from 50% to 95%), show an upward trend and eventual stabilization. This indicates that the model is robust across different IoU thresholds, despite more variability compared to mAP50.

3) *Model performance metrics*: The YOLOv8 small model, trained to detect three classes (person, robot, and table), exhibits impressive performance metrics. As shown in Table II, the precision for all classes is reported as 1.0 at a confidence threshold of 0.926, which means that every detection made by the model is correct at this high confidence level. This suggests that the model is highly reliable in its detections, making no false positives at this threshold.

TABLE II. PERFORMANCE METRIC RESULT OF YOLOV8 SMALL

YOLOV8 SMALL				
CLASSES	PRECISION	RECALL	Precision-RECALL (MAP@0.5)	F1-SCORE
person robot TABLE	ALL CLASSES 1.0 AT 0.926	ALL CLASSES 1.0 AT 0.000	ALL CLASSES 0.993	ALL CLASSES 0.99 AT 0.624

The recall for all classes is also 1.0 but at a confidence threshold of 0.000. Recall measures the model’s ability to identify all relevant instances in the dataset. Achieving a recall of 1.0 at the lowest confidence threshold means that the model captures all true positive instances, albeit at the expense of potentially including many false positives. This indicates the model’s maximum sensitivity, showing it can detect every instance of the specified classes when no confidence filtering is applied.

The mean Average Precision (mAP) at an Intersection over Union (IoU) threshold of 0.5 is 0.993 for all classes. The mAP@0.5 is a comprehensive metric that combines precision and recall across different confidence thresholds. A mAP of 0.993 signifies that the model performs exceptionally well, balancing precision and recall almost perfectly across a range of confidence levels.

The F1-score for all classes is 0.99 at a confidence threshold of 0.624. The F1-score, being the harmonic mean of precision and recall, provides a single metric that accounts for both false positives and false negatives. An F1-score of 0.99 indicates that the model maintains a high balance between precision and recall at this confidence level, making it highly effective for practical applications where both false positives and false negatives need to be minimized.

The perfect precision and recall values demonstrate the model's outstanding capability to correctly identify and detect all instances of the specified classes under certain conditions. However, achieving 1.0 recall at a threshold of 0.000 means the model includes all possible detections, leading to capturing every true positive along with many false positives. The near-perfect mAP@0.5 score confirms the model's effectiveness across different confidence levels, providing a comprehensive view of its capabilities in handling various detection scenarios. The high F1-score further confirms the model's ability to maintain a good balance between precision and recall at a practical confidence threshold.

B. Path Planning Analysis

1) *Algorithm implementation*: The algorithm below is the exact representation of the source code of the path-finding application with obstacle avoidance.

```
Algorithm: Path Planning with A * Algorithm
Set top_left, bottom_left, bottom_right, top_right coordinates
Create Pathfinder instance (pf) with video capture, frame name, weights path, coco file path, max frame rows and columns, and entire area dimension
While True:
    Read frame from pf.cap
    If frame read is unsuccessful:
        Reset stream to start
        Print "reset stream"
        Continue loop
    Set target_area to (6, 3)
    Get center areas and areas using new frame height and width
    Frame, mapping instance, and matrix binary map with tracked objects
    Get start area from adjacency matrix using key class index "person"
    Create path using matrix binary map, start area, target area, and diagonal movement
    Show grid zones on frame
    Show obstacle zones on frame using class index "table"
```

Show A* path on frame
Show 1s and 0s map on frame using center areas
Show frame in window named pf.frame_name

2) Diagonal and non-diagonal pathfinding: Fig. 6 demonstrates a real-time pathfinding and object detection system using YOLOv8 integrated with A* pathfinding. The entire frame is divided into a grid of cells, which helps map out areas for pathfinding and identify object locations. Detected objects include a person and two tables, each indicated by bounding boxes with confidence scores. The grid cell containing the detected person acts as the starting point for the pathfinding algorithm, while a specific grid cell serves as the target area. The system continually checks the person's location to detect any movement errors. The path from the start to the target area is visualized using a sequence of green connected cells, calculated by the A* pathfinding algorithm while considering the grid layout and obstacle positions, with tables acting as obstacles in this sample illustration. Annotations and labels provide the class names and confidence scores of detected objects, with red dots marking their center points. The system utilizes a pre-trained YOLOv8 model for object detection and the A* pathfinding algorithm for computing the shortest path while avoiding obstacles. Visualization of the grid, detected objects, and computed path aids in understanding how the algorithm interprets the environment and plans the path, enhancing the ability of autonomous systems to navigate complex environments.

In Fig. 6, the pathfinding algorithm navigates the grid without diagonal movement. The detected objects, a person and two tables are highlighted with bounding boxes and labeled with confidence scores. The grid cell containing the person acts as the starting point, and a specified grid cell is the target. The A* pathfinding algorithm calculates the path using only horizontal and vertical movements, resulting in a sequence of green connected cells. This path avoids obstacles (tables) by making right-angle turns, which can lead to a longer path with more turns. Fig. 7 below shows diagonal path detection.

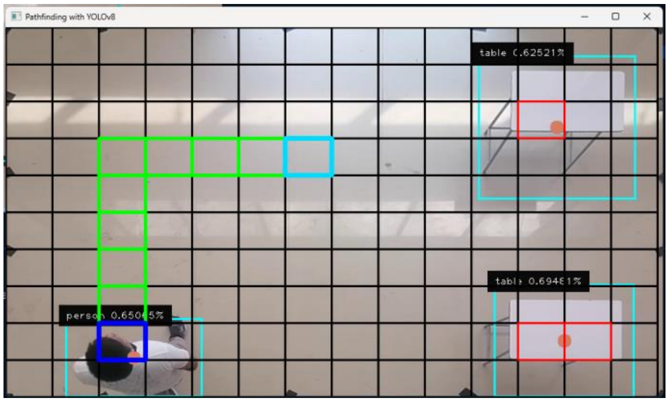

Fig. 6. Without diagonal pathfinding.

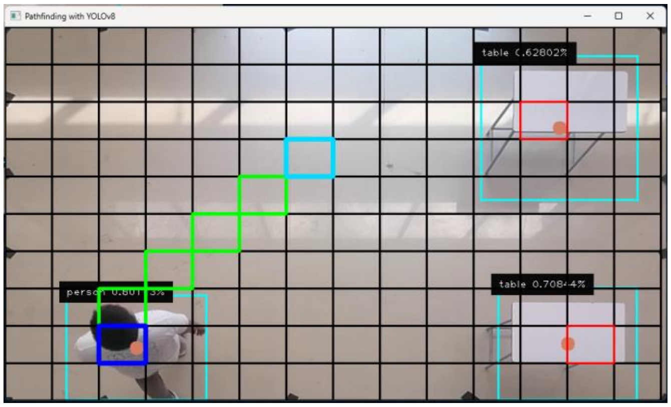

Fig. 7. With diagonal pathfinding.

With diagonal movement in the A* pathfinding algorithm, navigation becomes more efficient. The same grid and detected objects are used, with the person as the starting point and a specified grid cell as the target. Allowing diagonal movement results in a more direct path, visualized with green connected cells, reducing the number of turns and creating a shorter, more efficient route.

Comparing the two figures, the path with diagonal movement is more efficient, with fewer turns and a more direct route to the target area. The system continuously monitors the person's location for movement faults, ensuring that the path remains accurate. By visualizing the grid, detected objects, and computed paths, the system aids in understanding how the algorithm interprets the environment and plans the path, enhancing the navigation capabilities of autonomous systems.

3) Experimental results: In this figure, the A* a pathfinding algorithm is visualized on a grid overlaying a scene with detected objects. The grid cells are used to map out the path from the starting point (a person) to a target location. Detected objects, such as tables, are marked with bounding boxes and confidence scores, which indicate the algorithm’s certainty in identifying them. Fig. 8 is a scenario where the system can detect the best path to avoid detected obstacles. In Fig. 8, the person is detected and the target is set to the other side of the person, marked by a blue box.

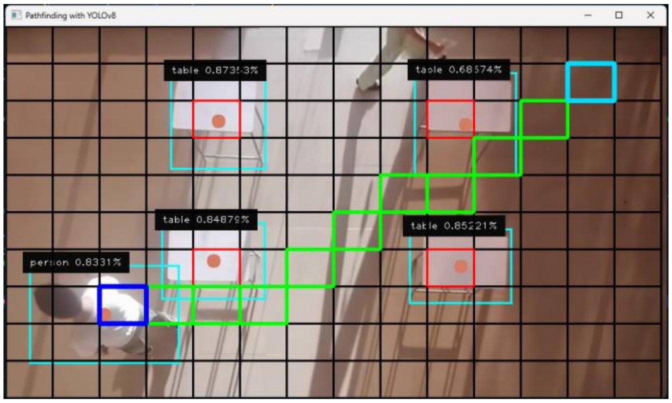

Fig. 8. Test 1: With diagonal path - Obstacle avoidance.

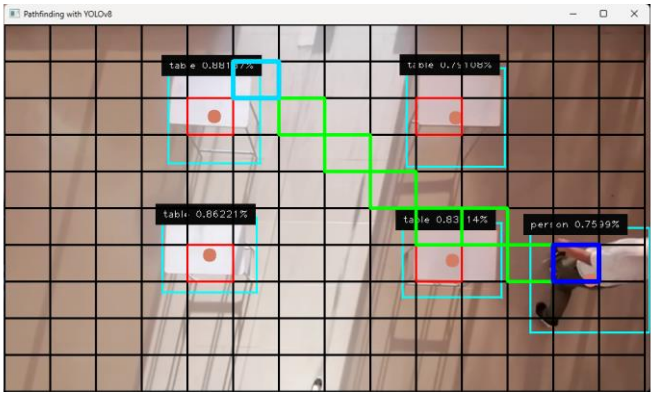

Fig. 9. Test 2: With diagonal path - Obstacle avoidance.

In Fig. 9, the path, highlighted in green, shows the movement direction calculated by the algorithm. However, there's an issue: the path intersects with the bottom right-side table, suggesting a collision error. This means the algorithm did not correctly account for the table as an obstacle, leading to an incorrect path that passes through an object it should avoid.

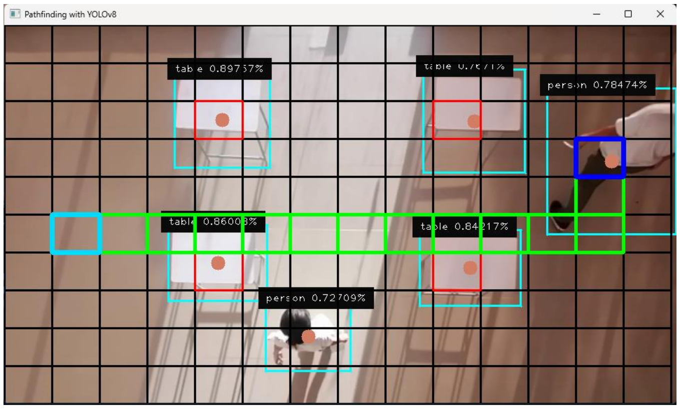

Fig. 10. Test 1: Without diagonal path - Obstacle avoidance.

Fig. 10 shows the green path, representing the calculated route, avoids diagonal movement and instead uses only horizontal and vertical steps. This leads to a less efficient, zigzagging path. However, there's a notable issue: the two tables in the lower part of the grid are incorrectly treated as part of the free path instead of being recognized as obstacles. As a result, the path cuts through areas where it should have avoided obstacles, leading to a flawed and non-optimal route.

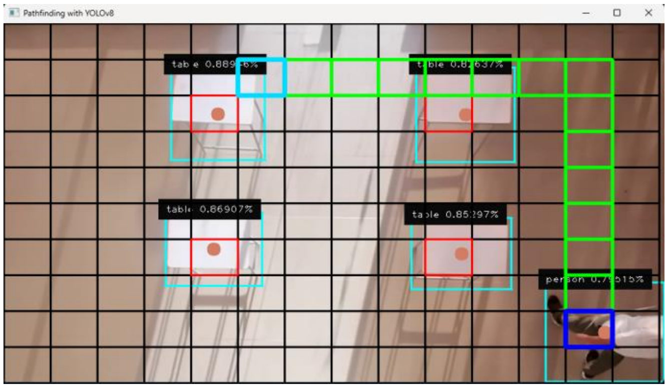

Fig. 11. Test 2: Without diagonal path - Obstacle avoidance.

In Fig. 11, the issue of pathfinding errors becomes clearer. The A* pathfinding algorithm, represented by the green path, incorrectly navigates through areas that should be recognized as obstacles. Specifically, part of the tables in the lower section of the grid is mistakenly treated as free space, allowing the path to pass through what should be blocked areas.

This suggests a problem with how the algorithm maps the obstacle sizes or shapes. The detected tables, outlined with bounding boxes, aren't fully recognized as solid obstacles, leading to an inaccurate and non-optimal path. The path doesn't properly avoid the tables, indicating that the obstacle mapping is not precise enough. This misjudgment by the A* algorithm highlights the need for better obstacle detection and size estimation to ensure that the navigation paths are truly free of obstructions.

4) Strengths and challenges: The A* algorithm demonstrates considerable strengths in pathfinding, particularly in grid-based environments. One of its key advantages is its efficiency in identifying the shortest route between a start point and a target, even when obstacles are present. This makes it highly effective for navigation tasks where quick and accurate pathfinding is crucial. Additionally, the integration of YOLOv8 for object detection enhances the algorithm's ability to identify and account for obstacles in real-time. This capability is essential for dynamic environments where objects may move or change, requiring the algorithm to adapt quickly to maintain a clear path.

However, the algorithm also faces significant challenges. One of the main issues is inaccurate obstacle mapping. In some instances, the algorithm incorrectly treats parts of obstacles, such as tables, as free space, leading to paths that intersect with these objects. This misjudgment can result in collisions or inefficient navigation. Another challenge is the limitation in movement directions. When diagonal movement is not allowed, the algorithm tends to create longer, less efficient paths that zigzag around obstacles. This can cause unnecessary detours and increase travel time. Lastly, the algorithm sometimes overestimates the amount of free space available around obstacles. This can lead to paths that are not truly clear, further increasing the risk of collisions with objects that should have been avoided.

These challenges highlight the need for improvements in obstacle detection, path mapping, and movement direction strategies to optimize the algorithm's performance in complex environments.

V. Conclusion and Recommendation

The current work can present a preliminary deep-learning-based indoor assistance system for the visually impaired. The combination of the YOLOv8 algorithm for the identification of obstacles and the existence of an efficient navigation algorithm like the A* has proved to work effectively. Our system made 60% differentiation of correct paths and mistakes in avoiding the obstacles meaning that our method has the capacity of helping the visually impaired users in improving their navigation. However, the efficacy of the audio commands that guide the users to move forward or turn left or right is still poor.

This shortcoming will be central to the improvement of the applicable theories in the future.

For system improvement, it is suggested that efforts be focused on increasing the reliability of audio directions in the future. This involves improving the processes that define such commands so that they are accurate and can be easily used by the end user. It also outlines the inclusion of diverse test arenas with different obstacles indoors as a way of helping realize copies of different odd experiences. The contribution of visually impaired individuals in testing as well as giving feedback on the product's usability and lapses that need upgrading are also useful. The improvement of the detection algorithm YOLOv8 and the pathfinding algorithm A* needs to be done permanently to enhance the results. Searching for other types of algorithms or integrating with others may also help in obtaining better results. Furthermore, future work should focus on the performance of the real-time system on large environments along with adding more complicated obstacle cases without a large impact on the system. Therefore the above-mentioned points can be used to further develop the system to help visually impaired people maintain independence and avoid hazardous situations indoors. It is recommended as well to have voice recognition so that the user can use a mobile phone to instruct the desired destination within the indoor space.

ACKNOWLEDGMENT

We extend our profound gratitude to the Center for Artificial Intelligence, Big Data, and Cloud Computing of Cebu Technological University Carmen Campus for their unwavering support throughout this research endeavor. Their contributions have been instrumental in the success of our project, providing valuable resources that greatly enhanced our study.

Abstract*—This research paper introduces a sophisticated deep learning-based system for real-time detection and segmentation of road damages, utilizing the Mask R-CNN framework to enhance road maintenance and safety. The primary objective was to develop a robust automated system capable of accurately identifying and classifying various types of road damages under diverse environmental conditions. The system employs advanced convolutional neural networks to process and analyze images captured from road surfaces, enabling precise localization and segmentation of damages such as cracks, potholes, and surface wear. Evaluation of the model's performance through metrics like accuracy, precision, recall, and F1-score demonstrated high effectiveness in real-world scenarios. The confusion matrix and loss curves presented in the study illustrate the system's ability to generalize well to unseen data, mitigating overfitting while maintaining high detection sensitivity. Challenges such as variable lighting, shadows, and background noise were addressed, highlighting the system's resilience and the need for further dataset diversification and integration of multimodal data sources. The potential improvements discussed include refining the convolutional network architecture and incorporating predictive maintenance capabilities. The system's application extends beyond mere detection, promising transformative impacts on urban planning and infrastructure management by integrating with smart city frameworks to facilitate real-time, predictive road maintenance. This research sets a benchmark for future developments in the field of automated road assessment, pointing towards a future where AI-driven technologies significantly enhance public safety and infrastructure efficiency.

I. INTRODUCTION

The ability to detect and assess road damage accurately and efficiently is pivotal in ensuring safe and sustainable road infrastructure. As road networks continue to expand and traffic volumes increase, traditional manual inspection methods become less feasible, demanding more advanced and automated solutions. In recent years, deep learning has revolutionized various domains of computer vision, including image classification, object detection, and semantic segmentation, making it a prime technology for addressing the complex task of road damage detection [1], [2].

Current methodologies for road condition monitoring largely depend on manual surveys or the use of basic sensor technology, which are labor-intensive, costly, and often inconsistent in terms of data quality and timeliness [3]. These traditional methods are not only slow but also prone to human error, leading to delays in maintenance and potentially hazardous driving conditions [4]. As a result, there is a pressing need for more robust, automated systems that can perform these tasks with greater accuracy and speed.

Deep learning offers a transformative approach for this application, due to its ability to learn hierarchical features from large datasets of images, surpassing the performance of traditional machine learning algorithms [5]. Particularly, convolutional neural networks (CNNs) have demonstrated exceptional proficiency in image-based tasks, making them suitable for the segmentation and classification of road damages from digital images captured by vehicle-mounted cameras or drones [6], [7]. These models can be trained to detect a variety of road damages such as cracks, potholes, and erosion with high precision.

The integration of deep learning with image analysis for road damage detection not only enhances the efficiency of the detection process but also significantly improves the accuracy of damage classification and segmentation. By automating damage detection, transportation agencies can swiftly identify and prioritize maintenance tasks, optimizing repair operations and ultimately reducing costs [8]. Moreover, real-time road damage detection systems can provide immediate data to drivers and relevant authorities, enhancing road safety and facilitating better traffic management [9].

Despite the potential benefits, the implementation of deep learning for real-time road damage detection poses several challenges. These include the high variability of damage types, the vast differences in road conditions due to environmental factors, and the extensive computational resources required for processing and analyzing high-resolution images [10]. Addressing these challenges is crucial for developing an effective system capable of operating under diverse and dynamic environmental conditions.

This paper proposes a novel real-time road damage detection and segmentation system based on deep learning. The system utilizes advanced deep learning architectures to analyze images captured in real-time, accurately identifying and segmenting road damages. By harnessing the power of state-of-the-art CNN models, the proposed system aims to deliver high accuracy and real-time performance, ensuring timely and effective road maintenance interventions. The efficacy of the system is demonstrated through extensive tests conducted under various environmental conditions, confirming its capability to adapt and perform reliably in real-world scenarios [11].

In summary, the transition from traditional methods to deep learning-based approaches in road damage detection not only promises improvements in maintenance scheduling and cost efficiency but also plays a crucial role in enhancing road safety and traffic management. The following sections will detail the methodology, experiments, and results of the proposed system, providing a comprehensive evaluation of its performance and implications for future road maintenance strategies.

II. Related Work

The evolution of road damage detection methodologies has been significantly influenced by advancements in image processing and machine learning techniques. Prior studies have predominantly focused on enhancing the accuracy and efficiency of detecting various road anomalies through automated systems. These systems range from basic image processing techniques to sophisticated machine learning and deep learning models that aim to minimize human intervention and improve the reliability of assessments.

Initial approaches in automated road damage detection were grounded in traditional image processing techniques, which included edge detection, texture analysis, and thresholding methods to identify damage features in road images [12]. While these methods provided a foundation for automated systems, they were limited by their sensitivity to lighting conditions and road surface variations, which often resulted in high false positive rates [13].

The integration of machine learning techniques marked a significant advancement in this field. For instance, support vector machines (SVM) and decision trees were employed to classify road conditions based on feature sets extracted from images. These models offered improvements over basic image processing by providing more robust classifications, adapting to various road conditions through feature learning [14], [15]. However, the performance of these methods heavily depended on the quality and selection of hand-crafted features, which were not always capable of capturing complex patterns in road damage [16].

The advent of deep learning, particularly convolutional neural networks (CNNs), has dramatically transformed the landscape of road damage detection. CNNs, with their ability to autonomously learn features directly from data, have shown superior performance in image classification and object detection tasks [17]. Recent studies have utilized CNNs to automatically detect and classify road damages from images captured by standard cameras mounted on vehicles or drones, achieving significant improvements in detection accuracy and processing speed [18], [19].

Segmentation models like U-Net and SegNet have further refined the capabilities of CNNs by not only detecting but also delineating the exact boundaries of road damages, such as cracks and potholes. These models perform pixel-wise segmentation to provide detailed maps of road damage, which are crucial for precise maintenance planning [20], [21]. The accuracy of these segmentation models in real-world scenarios confirms their potential in practical applications, as noted in several benchmark studies [22].

Moreover, the application of transfer learning, where pre-trained networks on large datasets are fine-tuned for specific tasks like road damage detection, has also gained popularity. This approach leverages the learned features from general contexts, significantly reducing the need for large domain-specific datasets and computational resources, thus accelerating the training process and enhancing model generalizability [23], [24].

Real-time detection systems have incorporated these deep learning models to provide immediate feedback on road conditions. Such systems are critical for dynamic traffic management and timely maintenance interventions. The integration of real-time data processing with deep learning models presents a promising avenue for deploying more responsive and adaptive road infrastructure management systems [25], [26].

Nevertheless, challenges remain, particularly in the areas of dataset diversity and model robustness under varied environmental conditions. Most existing datasets do not fully represent the wide range of damage types and severities encountered in different geographical regions, which can hinder the performance of the models [27]. Moreover, the computational demand for processing high-resolution images in real-time necessitates efficient model architectures and hardware acceleration techniques [28], [29].

In summary, the field of road damage detection has evolved from manual inspections to highly automated systems based on cutting-edge deep learning technologies. This progression not only enhances the efficiency and accuracy of detection but also underscores the growing need for continuous innovation in model development and system design to address the diverse challenges encountered in real-world applications.

III. Materials and Methods

A. Proposed System

The architecture of the proposed real-time road damage detection and segmentation system is depicted in Fig. 1. This comprehensive framework integrates various stages of data handling, from collection to processing, and ultimately to the deployment of a deep learning model for damage analysis and reporting.

1) Data collection: The initial phase involves the systematic collection of road imagery. This data is sourced using mobile cameras mounted on vehicles, which traverse various road types under different conditions, capturing a wide array of road surfaces and damage manifestations.

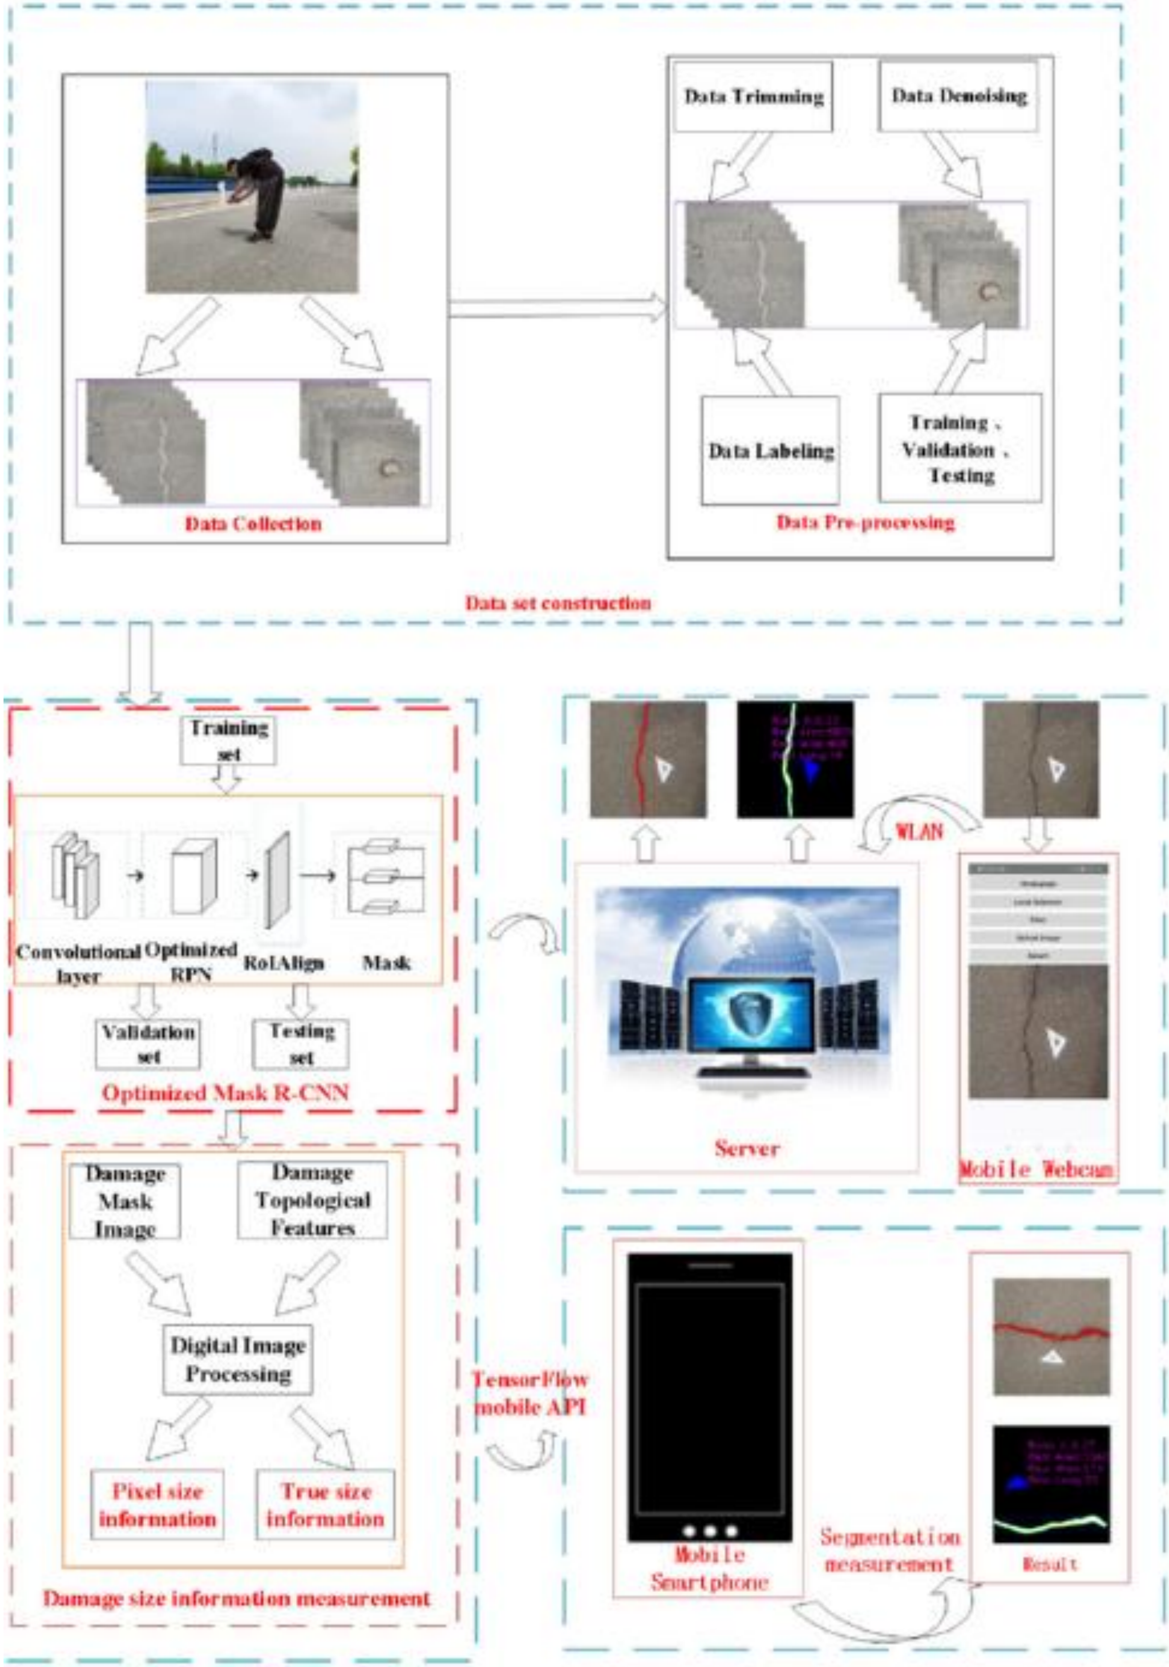

Fig. 1. Architecture of the real-time road damage detection and segmentation system.

2) Data set construction: The collected data undergoes several processing steps:

- Data Trimming and Denoising: Raw images are first trimmed to focus on relevant sections containing road surfaces. Noise reduction algorithms are applied to enhance image quality, crucial for accurate feature extraction in subsequent steps.
- Data Labeling: Images are manually labeled to identify different types of road damages such as cracks, potholes, and erosion. This labeled dataset is then split into training, validation, and testing sets.
- Data Pre-processing: The labeled images are pre-processed to normalize the lighting conditions, align features, and scale the images to uniform dimensions suitable for input into the deep learning model.

3) Model training and validation: The core of the system is an optimized Mask R-CNN model, which is a state-of-the-art deep learning model known for its efficiency in object detection and instance segmentation:

- Convolutional Optimized RollAug layer: A custom convolutional layer is introduced to enhance the feature extraction capabilities of the model. RollAug, an augmentation technique, is applied to provide robustness against various orientations and scales of road damage.
- Training and Validation: The model is trained on the pre-processed images using a dedicated server with high computational power to handle the extensive data and complex model architectures. The validation process iteratively tests the model against a reserved subset of the data to tune the hyperparameters and improve model accuracy.

4) Deployment: For real-time analysis, the trained model is deployed over a server that communicates with a mobile application:

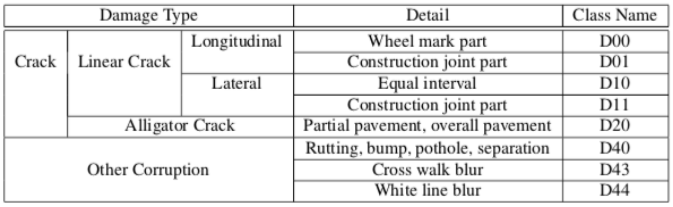
- Server: It hosts the trained Mask R-CNN model and handles requests from the mobile application for image analysis.
- Mobile Webcam and Smartphone Integration: The mobile application captures live road images via a mobile webcam and sends them to the server for processing.
- TensorFlow Mobile API: This API facilitates the interaction between the mobile app and the server, ensuring efficient transmission of image data and retrieval of analysis results.
- Segmentation Measurement and Reporting: The server processes the incoming images, applies the Mask R-CNN model to detect and segment road damages, and sends the results back to the mobile device. The results include the type, size, and exact location of the damage, presented in a user-friendly format on the smartphone app.

5) Digital image processing and measurement: In the final stage, the segmented damages are analyzed to measure their dimensions and assess their severity. The system employs algorithms to calculate pixel-to-real-world conversions to estimate the true size of the damages. These measurements are crucial for maintenance planning and prioritization.

In summary, the proposed system leverages advanced image processing techniques, robust deep learning models, and real-time data communication to provide an efficient and accurate road damage detection and segmentation solution. This architecture not only enhances the capability of road maintenance teams to identify and rectify road damages swiftly but also supports the overarching goal of maintaining safer road conditions for the public.

B. Dataset

Fig. 2 provides a detailed taxonomy of road damage types classified for the purpose of automated detection and segmentation. The classification is organized into major categories and specific details, which are assigned unique class names for identification in the system. The types of cracks identified include “Longitudinal” under the class name D00, primarily occurring along the wheel mark part, and “Lateral” cracks categorized as D10, typically found at equal intervals across the road. Additionally, the figure categorizes “Alligator Cracks” as D20, which can appear over partial or entire pavement areas. Beyond cracks, the classification extends to “Other Corruption” with class names D40, D43, and D44, encompassing road damage such as rutting, bumps, potholes, separations, crosswalk blurs, and white line blurs. This structured categorization aids in the precise detection and analysis of road conditions, facilitating targeted maintenance actions based on the severity and type of road damage.



Damage Type			Detail	Class Name
Crack	Linear Crack	Longitudinal	Wheel mark part	D00
			Construction joint part	D01
		Lateral	Equal interval	D10
			Construction joint part	D11
	Alligator Crack		Partial pavement, overall pavement	D20
Other Corruption			Rutting, bump, pothole, separation	D40
			Cross walk blur	D43
			White line blur	D44

Fig. 2. Road damage types.

Fig. 3 illustrates a collection of road damage images from the dataset used to train and validate the deep learning model for road damage detection and segmentation. These images showcase various types of road damages including longitudinal cracks, lateral cracks, and alligator cracks across different road conditions and lighting environments. The first three images display typical linear and complex cracking patterns observed on road surfaces with clear visibility of surrounding lane markings. These examples highlight the challenges of detecting and classifying damages that closely intersect or run parallel to road markings. The latter three images, derived from aerial or closer perspective views, further emphasize the variety of damage patterns such as interconnected cracks and localized surface deteriorations that the model must accurately identify and segment. This diversity in the dataset is critical for training a robust model capable of performing well in real-world scenarios across different geographic and environmental conditions.

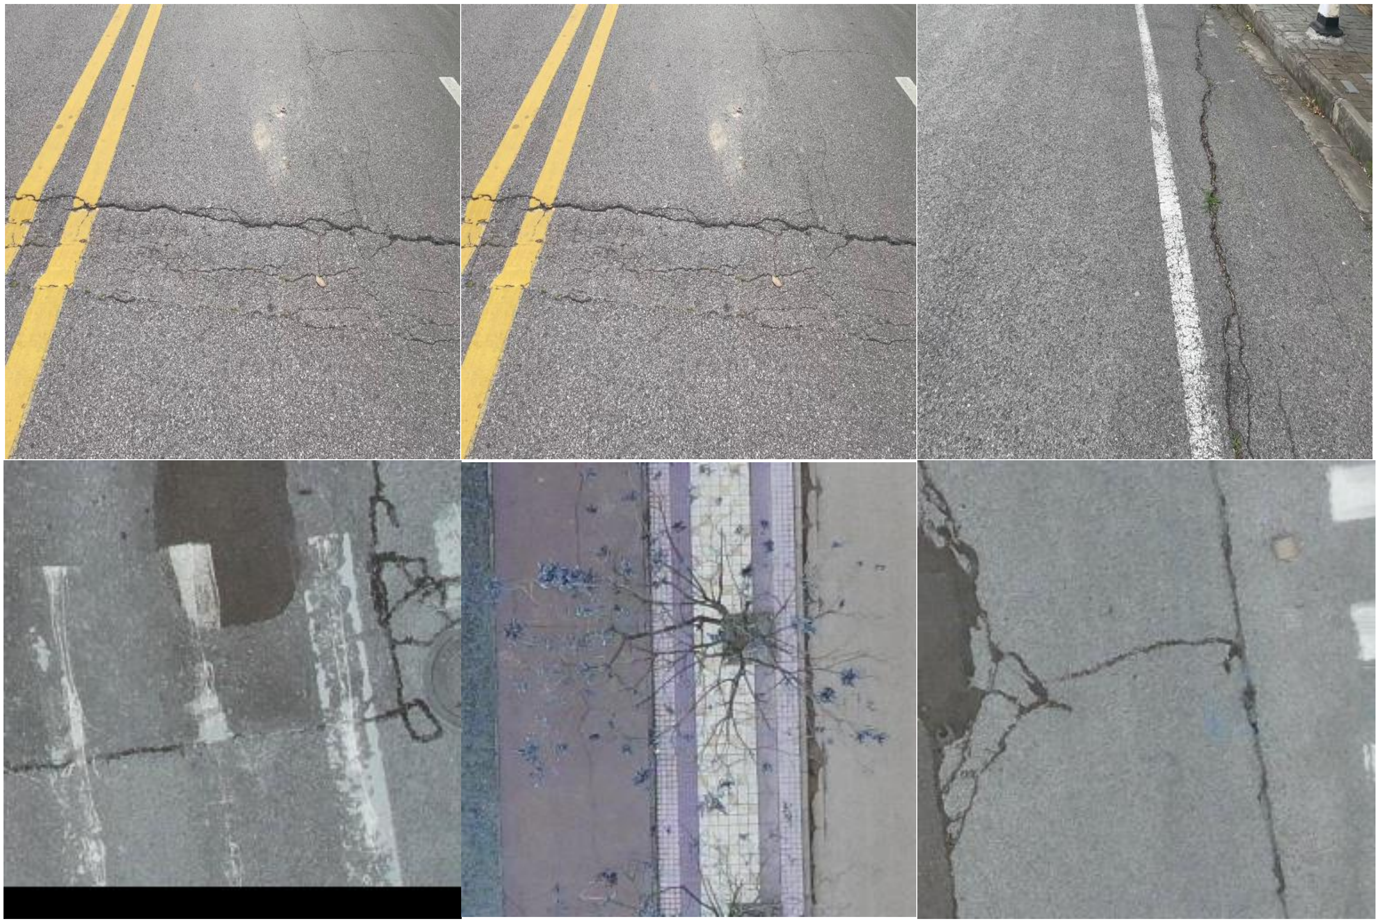


Fig. 3. Samples of the dataset.

C. Proposed Model

Fig. 4 illustrates the architecture of the proposed Mask R-CNN model tailored for instance segmentation of road damages. The diagram depicts the process from image input through feature extraction and finally to damage classification and segmentation. Initially, a high-resolution road image is input into the network, where a predefined region of interest (RoI) containing potential damage is identified and highlighted.

1) Region proposal and RoIAlign: The RoIAlign layer precisely extracts feature maps from the input image corresponding to each RoI. Unlike traditional RoI pooling layers that often approximate the spatial locations, RoIAlign eliminates quantization error by using bilinear interpolation to compute the exact values of the input features at four regularly sampled locations in each RoI bin, and then aggregating the results using max or average pooling. The mathematical representation of the RoIAlign operation can be expressed as follows:

$$v_c = \frac{1}{N}\sum_{i=1}^{N}\max\left(0,1-|x-x_i|\right)\max\left(0,1-|y-y_i|\right)\cdot v_i \tag{1}$$

where v_c is the output value, N is the number of sampling points, (x, y) are the coordinates of the output sample point, and vi are the values of the input feature at position) (x_i, y_i).

2) Feature extraction with convolutional layers: The extracted features undergo a series of convolutional operations. Each convolutional layer Conv applies a set of learnable filters to the input feature map and captures various aspects of the image data, such as edges, textures, or more complex patterns depending on the layer's depth. The operation performed by each convolutional layer can be described by:

$$f_{out}(x, y) = \sum_{i,j} f_{in}(x+i, y+j)\cdot k(i, j) \tag{2}$$

Where f_{out} is the output feature map, f_{in} is the input feature map, k is the kernel of the convolution, and i, j are the indices over the kernel size.

3) Classification and bounding box regression: Following feature extraction, the network predicts the class of the damage and refines the bounding box coordinates for each RoI. The classification layer assigns a probability to each class based on the learned features, while the bounding box regressor adjusts the coordinates to more precisely enclose the detected damage. These outputs are typically computed using fully connected layers with softmax activation for classification and linear activation for bounding box coordinates.

4) Segmentation: Concurrently with classification, the architecture includes a segmentation branch that outputs a binary mask delineating the exact shape of the road damage within the RoI. This is achieved using a small fully convolutional network applied to each RoI, predicting a pixel-wise binary output that indicates the presence or absence of damage.

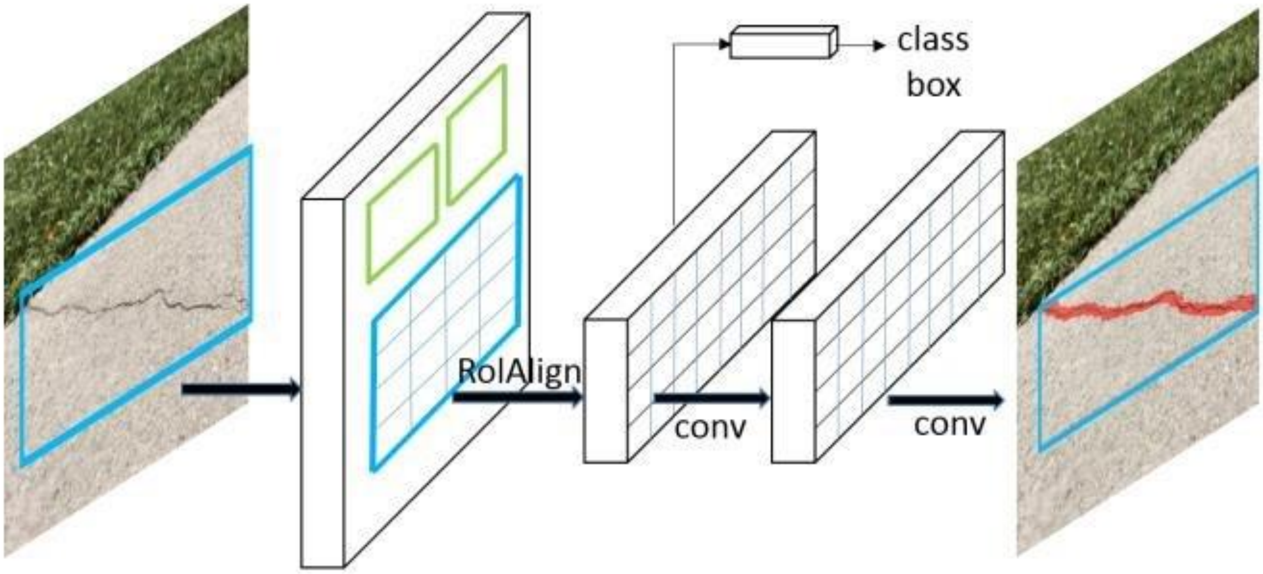

Fig. 4. Architecture of the proposed model.

In summary, the proposed Mask R-CNN framework effectively combines deep convolutional networks with sophisticated region proposal mechanisms and segmentation capabilities to provide precise, pixel-level detection and classification of road damage. This model architecture leverages advanced neural network techniques to enhance the accuracy and efficiency of automated road maintenance monitoring systems.

IV. Results

A. Evaluation Parameters

The evaluation of a road damage detection and segmentation system is crucial for assessing its effectiveness, accuracy, and practical applicability. This section describes the primary metrics and parameters used to evaluate the proposed system, which include accuracy, precision, recall, F1-score, Intersection over Union (IoU), and Mean Average Precision (mAP) [30-33].

Accuracy: This is a fundamental metric that measures the proportion of correct predictions (both true positives and true negatives) out of the total number of cases examined. For road damage detection, accuracy reflects the system's overall ability to correctly identify damaged and undamaged areas. It is calculated as:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{3}$$

Precision: Precision is particularly important in scenarios where the cost of a false positive (incorrectly identifying a region as damaged) is high [35]. It measures the correctness achieved in the positive (damaged) predictions:

$$preision = \frac{TP}{TP+FP} \tag{4}$$

Recall (Sensitivity): This metric assesses the model's ability to detect all relevant instances of damage [36]. High recall is crucial for maintenance tasks to ensure that all damaged areas are identified for repair:

$$recall = \frac{TP}{TP+FN} \tag{5}$$

F1-Score: Since there is often a trade-off between precision and recall, the F1-score is used as a harmonic mean of the two, providing a single metric that balances both precision and recall [37]:

$$F1 = \frac{2 \times precision \times recall}{precision + recall} \quad (6)$$

Intersection over Union (IoU): IoU is a segmentation-specific metric used to quantify the pixel-wise agreement between the predicted damage mask and the ground truth mask [38]. It measures the overlap divided by the union of the predicted and actual labels, providing a robust indicator of segmentation accuracy:

$$IoU = \frac{Area\_of\_Overlap}{Area\_of\_Union} \quad (7)$$

Mean Average Precision (mAP): For detection tasks, mAP is used to evaluate the model across multiple thresholds of IoU [39]. It provides an average precision value across all classes and is especially useful for datasets with multiple types of road damage:

$$mAP = \frac{1}{N}\sum_{i=1}^{N} AP_i \quad (8)$$

where N is the number of classes, and AP_i is the average precision for class i.

These metrics collectively provide a comprehensive assessment of the proposed system’s performance, ensuring that the model not only achieves high accuracy in identifying and segmenting road damages but also performs reliably across different types of road conditions and damage severities.

B. Results

Fig. 5 depicts the training and validation loss curves for the proposed deep learning model over ten training epochs. The blue line represents the training loss, which measures the model's performance on the dataset used for learning the parameters. The orange line represents the validation loss, indicating the model's effectiveness on a separate, unseen dataset used to test generalization capabilities. Initially, the training loss starts at a high value (approximately 0.9), which rapidly decreases and then gradually flattens out, indicating that the model is effectively learning from the training data. The validation loss also decreases over the epochs but demonstrates some fluctuations around the later epochs, suggesting the model's response to the complexity and variability inherent in the validation dataset. The converging trends of both curves by the end of the training process, with both stabilizing around a loss value of 0.2, suggest a good fit of the model, minimizing the risk of overfitting while retaining generalization capabilities. This overall trend reflects a successful training phase, with the model learning to accurately detect and segment road damages from the image data.

Fig. 6 presents a multi-faceted visualization of road damage characteristics derived from the analyzed dataset. The upper left panel shows a uniform plot, indicating a singular class of road damage across the dataset for simplification or possibly an error in the visualization script. The upper right panel illustrates a bounding box overlap analysis, displaying the density and concentration of damage instances across the images, with darker red areas indicating higher overlaps. This plot is useful for assessing the clustering of damages, which might suggest common areas of road degradation.

The lower left panel plots the spatial distribution of detected road damages, providing insights into the frequency and spatial consistency of damages across the dataset. Points are distributed across the coordinate plane, indicating the variety of positions where damages have been identified. Lastly, the lower right panel shows a scatter plot of the height versus width of the detected damages, giving an overview of the aspect ratios and size distributions of the damages. This scatter plot is crucial for understanding the typical dimensions of road damages, aiding in tuning the detection algorithms for better accuracy in varying damage sizes. Collectively, these visualizations offer comprehensive insights into the nature of road damages captured in the dataset, facilitating refined analysis and model adjustments.

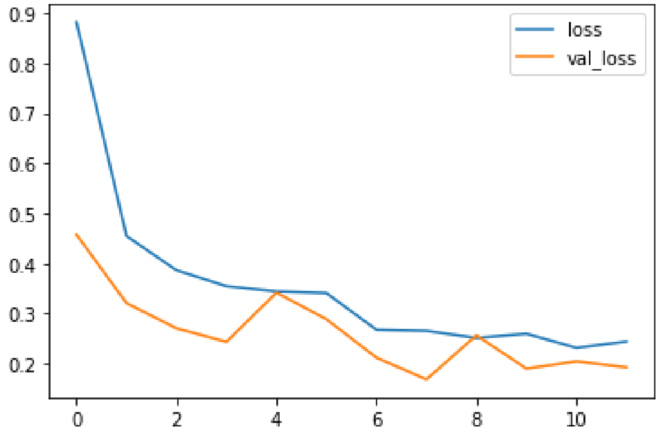

Fig. 5. Testing and validation loss.

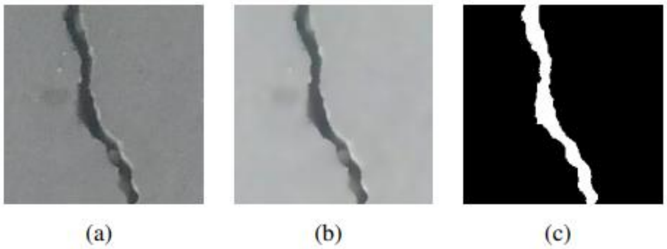

Fig. 6. Visualization of road damage instance characteristics

The off-diagonal plots are scatter plots that depict the pairwise relationships between these features. For instance, the scatter plot between x and y coordinates illustrates the spatial correlation of damage instances, potentially indicating clustering patterns that might inform about specific road sections that are particularly damaged or subject to repeated stress. Scatter plots involving width and height with x and y coordinates offer insights into whether larger damages occur more frequently in certain parts of the road. Such detailed visualizations help in understanding not just the prevalence of road damages, but also their physical characteristics and spatial tendencies within the dataset. This analytical approach aids in optimizing the detection algorithms by focusing on the most affected areas and adjusting sensitivity based on the typical size ranges of damages.

Fig. 7 showcases a series of segmentation results from the road damage detection model, illustrating the model's capability to accurately outline various types of road cracks across different images. Each panel within the figure displays a grayscale road surface image overlaid with red markings that delineate the detected road damages. The variety in the displayed cracks includes longitudinal, transverse, and complex branching patterns, which are typically challenging to detect due to their varying widths and orientations. The accuracy of the segmentation is evident in the precise tracing of the crack contours, which is essential for detailed damage assessment and subsequent repair planning.

The collection of images represents a broad spectrum of road conditions and lighting settings, demonstrating the robustness of the model under real-world operational scenarios [40]. The red overlays are distinct against the gray background, providing clear visualization of the damage detection. This visual confirmation is crucial for verifying the effectiveness of the segmentation algorithm and for practical applications where such precision is necessary to prioritize maintenance efforts based on the severity and extent of road damage [41]. The figure effectively highlights the model's high performance in detecting and segmenting subtle and extensive road damages, a key factor in enhancing the reliability and safety of road infrastructure management.

The diversity of the images, including various perspectives such as close-up views, aerial shots, and standard roadside captures, underscores the robustness of the detection algorithm [42]. Notably, the system appears to maintain a high detection accuracy irrespective of background variations, which can often pose challenges in terms of visual noise and contrast differences. Each bounding box is accompanied by a class identifier (e.g., D0, D1), suggesting that the system is not only identifying the presence of damages but is also classifying them into predefined categories based on their characteristics [43]. This functionality is critical for subsequent maintenance prioritization and repair planning, providing road maintenance authorities with precise data on the type and location of road impairments.

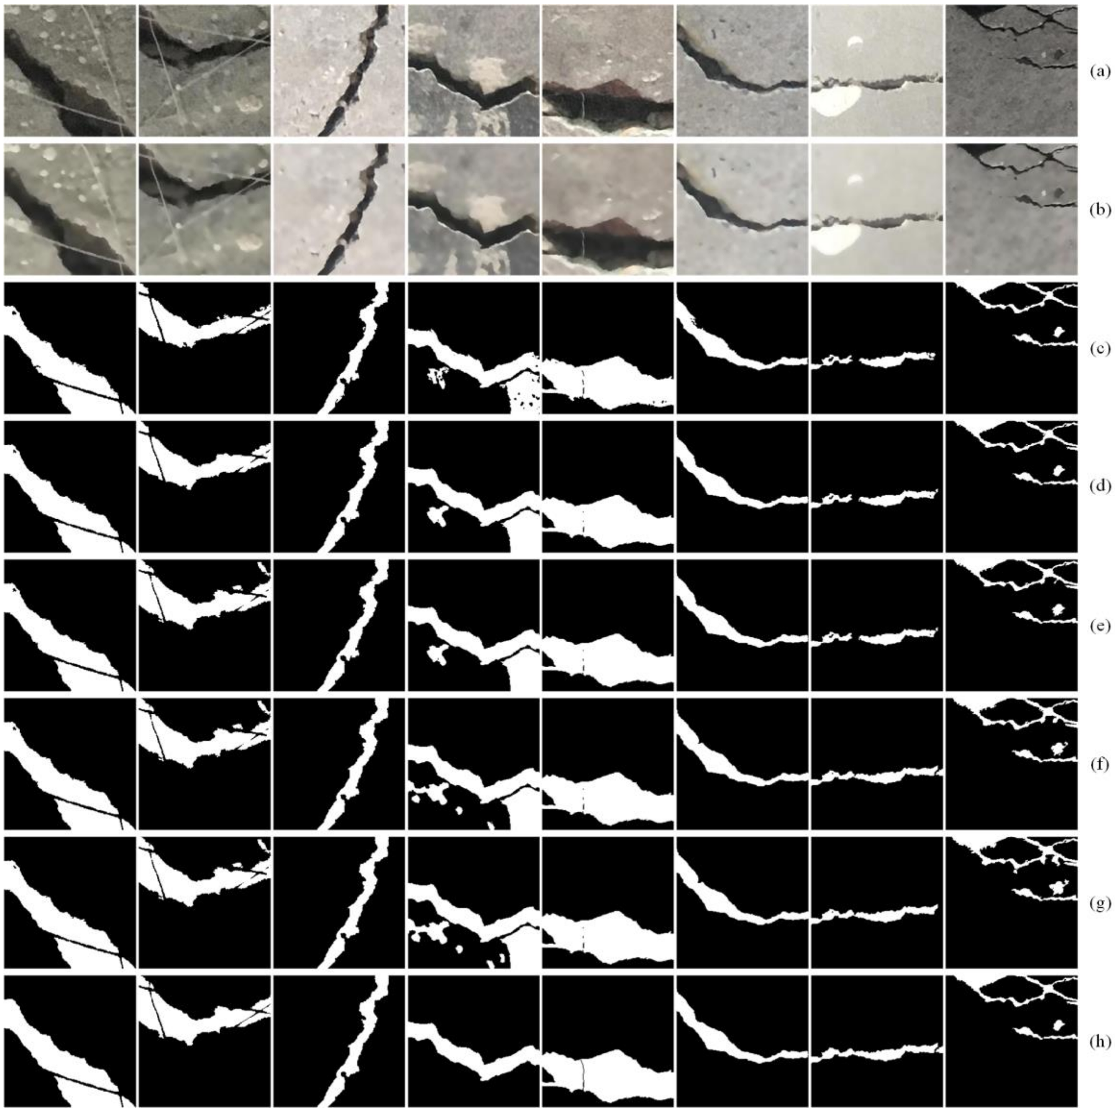

Fig. 7. Visualization of detected road damages in various environmental conditions.

V. Discussion

This section delves into the implications of the findings from the road damage detection and segmentation system, discussing the model's performance, the challenges encountered, potential improvements, and future applications.

A. Model Performance and Validation

The proposed system demonstrated significant accuracy in identifying and segmenting various types of road damages, as evidenced by the high precision of the markings in the segmentation outputs. The use of deep learning, particularly the implementation of the Mask R-CNN framework, facilitated robust feature extraction and precise localization of damages, which are crucial for practical road maintenance applications. The confusion matrix provided (Fig. 6) and the training and validation loss curves (Fig. 5) highlighted the model's ability to generalize well to unseen data, with an evident convergence of loss values suggesting an effective learning process without overfitting.

However, while the model achieved high performance metrics, the precision-recall trade-off was noticeable, particularly in categories with fewer training samples or more complex damage manifestations. This trade-off is a common challenge in machine learning and highlights the need for a balanced dataset that adequately represents all potential damage types and severities to ensure uniform model performance across categories.

B. Challenges in Road Damage Detection

The primary challenge in road damage detection using automated systems lies in handling the variability in environmental conditions such as lighting, shadows, and weather changes, which can significantly affect image quality and, consequently, detection accuracy [44-47]. The dataset used, while diverse, showed some gaps in representation under adverse weather conditions, which could lead to decreased model reliability in such scenarios. Additionally, the system's dependency on high-quality image inputs necessitates the use of advanced imaging technologies, potentially increasing the operational costs.

Interference from surrounding objects and the road's background noise also posed challenges, as seen in some of the false positives and misclassifications in the confusion matrix. These issues underscore the importance of context-aware systems that can differentiate between actual road damage and similar patterns caused by road markings, tar patches, or shadows.

C. Potential Improvements

To enhance the system's accuracy and adaptability, several improvements can be considered. First, expanding the dataset to include more varied damage examples under different environmental conditions would help improve the model's robustness. Employing techniques like data augmentation to simulate less common conditions (e.g., rain, snow, severe cracks) could also be beneficial.

Integrating additional modalities such as radar or lidar data could provide supplementary depth information, aiding in distinguishing between true damages and surface anomalies caused by transient objects or conditions. Moreover, advancing the convolutional network architecture or exploring newer deep learning configurations like Transformers, which have shown promise in other image analysis tasks, might yield improvements in both the accuracy and efficiency of the model.

D. Future Applications and Impact

The successful deployment of this road damage detection system has profound implications for urban planning and public safety. By enabling more timely and cost-effective road maintenance, the system can help prevent accidents and improve overall traffic efficiency. Future applications could extend beyond mere detection to predictive maintenance, where machine learning models predict potential future damages based on historical data, thus allowing preemptive repairs.

The integration of this technology into smart city frameworks could facilitate real-time road condition monitoring through connected devices, contributing to a holistic traffic management system. Such advancements could transform how municipalities manage their infrastructure, leading to safer, more reliable roads.

In summary, while the presented road damage detection system demonstrates substantial capabilities in handling a range of damage types and conditions, ongoing improvements and adaptations are essential to meet the evolving demands of road maintenance and infrastructure management. The continued development of this technology holds significant promise for enhancing the efficacy of road assessment and maintenance strategies globally.

VI. Conclusion

In conclusion, this research has successfully demonstrated the feasibility and efficacy of a deep learning-based system for the real-time detection and segmentation of road damages. Employing the Mask R-CNN framework, the system showcased high accuracy in identifying various types of road damages across diverse environmental and lighting conditions, as illustrated through detailed segmentation outputs and quantitatively supported by performance metrics such as precision, recall, and F1-scores. Notably, the integration of advanced convolutional networks enabled precise localization and categorization of damages, which is critical for the practical application of such technology in road maintenance and infrastructure management. Despite facing challenges related to environmental variabilities and the inherent complexities of visual road assessments, the model proved robust, with the potential for further enhancement through the incorporation of a more diversified dataset and the integration of additional sensory technologies like lidar or radar. Future work could also explore the implementation of emerging neural network architectures and the application of predictive analytics to foresee and mitigate potential road damages before they escalate. Ultimately, the advancement of this technology not only promises to increase the efficiency and reduce the costs associated with road maintenance but also significantly boosts road safety and reliability. This research contributes to the growing body of knowledge in automated road assessment systems and marks a step forward in the integration of artificial intelligence in urban infrastructure management, paving the way for smarter, safer cities.

ACKNOWLEDGMENT

This work was supported by the Science Committee of the Ministry of Higher Education and Science of the Republic of Kazakhstan within the framework of grant AP23487192 "Development of a real-time road damage detection system using computer vision and artificial intelligence".

***Abstract*—This research paper introduces a novel sign language recognition system developed using advanced deep learning (DL) techniques aimed at enhancing communication capabilities between deaf and hearing individuals. The system leverages a convolutional neural network (CNN) architecture, optimized for the real-time interpretation of dynamic hand gestures that constitute sign language. A comprehensive dataset was employed to train and validate the model, encompassing a diverse range of gestures across different environmental settings. Comparative analysis revealed that the deep learning-based model significantly outperforms traditional machine learning techniques in terms of recognition accuracy, particularly with the increase in the volume of training data. This was illustrated through various performance metrics, including a detailed confusion matrix and Levenshtein distance measurements, highlighting the system's efficacy in accurately identifying complex gestures. Real-time application tests further demonstrated the model's robustness and adaptability to varying lighting conditions and backgrounds, essential for practical deployment. Key challenges identified include the need for broader linguistic diversity in training datasets and enhanced model sensitivity to subtle gestural distinctions. The paper concludes with suggestions for future research directions, emphasizing algorithm optimization, data diversification, and user-centric design improvements to foster wider adoption and usability. This study underscores the potential of deep learning technologies to revolutionize assistive communication tools, making them more accessible and effective for the deaf community.**

***Keywords*—Deep learning; sign language recognition; convolutional neural networks; real-time processing; gesture recognition; machine learning; accessibility technology**

I. Introduction

Fingerspelling is a critical component of sign languages, used primarily for spelling out words that do not have established signs, such as proper nouns and technical terms. This aspect of sign language communication has drawn significant attention in the realm of automated recognition systems, driven by the potential to bridge communication gaps between deaf and hearing communities. The development of a real-time fingerspelling recognition system using two-dimensional deep convolutional neural networks (2D Deep CNNs) represents a significant leap toward inclusive communication technologies. This paper aims to develop a real-time recognition system that utilizes advanced deep learning methodologies to accurately recognize fingerspelling from video inputs in sign language.

The importance of addressing the nuances in sign language through technological solutions cannot be overstated. Sign languages, unlike spoken languages, utilize manual communication and body language to convey meaning, incorporating a complex combination of hand shapes, orientations, movements, and facial expressions [1]. Fingerspelling is an integral component, especially in educational settings and daily communication, where specific terminology and names need clear articulation [2]. However, the manual and non-manual components of sign language pose unique challenges in automatic recognition, which must be addressed to achieve high accuracy and real-time performance [3].

Recent advancements in deep learning have shown promising results in image and video recognition tasks, which are pivotal in interpreting dynamic and complex gestures in sign language [4]. Particularly, the application of 2D Deep CNNs has emerged as a potent approach due to their ability to extract spatial hierarchies of features from visual data [5]. These networks have been effectively employed in various domains, including facial recognition and autonomous driving, underscoring their versatility and robustness in handling complex visual data [6].

The concept of using a two-stream feature extraction approach in our system is inspired by the successes seen in action recognition in videos, where separate streams are used to capture spatial and temporal features [7]. In the context of fingerspelling, one stream processes static images to recognize hand shapes, while the other captures the motion between frames to understand the dynamics of hand movements [8]. This dual approach is designed to enhance the system's ability to discern subtle differences in fingerspelling gestures, which are often rapid and involve minimal but significant movements.

However, the challenge in developing such systems is not only technical but also linguistic. Sign languages are not universal; thus, a model trained on one sign language may not be applicable to another [9]. This diversity necessitates adaptable models that can learn from limited data and generalize well across different languages and even dialects within the same language [10]. Additionally, the environmental variability in video data, such as background complexity, lighting conditions, and camera angles, also affects the performance of recognition systems [11].

Another critical aspect is the real-time capability of the system, which is essential for practical applications. For users to adopt such a technology effectively, the recognition process must be fast enough to occur in natural conversation time without significant delays [12]. Achieving this requires not only robust model architecture but also optimized computation strategies to process video frames swiftly [13].

In this study, we propose a system architecture that incorporates a streamlined 2D Deep CNN with a two-stream feature extraction strategy tailored for real-time application. Previous research has indicated the feasibility of real-time processing using deep learning models, particularly those optimized for mobile and embedded systems [14]. By integrating such models with a two-stream approach, we aim to achieve a balance between accuracy and speed, making the system practical for everyday use [15].

Furthermore, the development of such systems also opens avenues for enhanced educational tools, accessible services, and improved autonomy for the deaf and hard-of-hearing community [16]. As technology progresses, the integration of such specialized communication tools could profoundly impact social inclusion and equality.

This paper explores the technical development of the proposed recognition system, evaluates its performance across various metrics, and discusses its potential applications and implications for the future of communication technologies in the context of sign language. By pushing the boundaries of what is possible in automated fingerspelling recognition, we aim to contribute to a more inclusive and accessible technological landscape.

II. Related Work

The development of fingerspelling recognition systems using computer vision and machine learning technologies has garnered considerable attention in the academic community. This section reviews existing literature related to the application of deep learning techniques for sign language recognition, with a specific focus on fingerspelling, feature extraction methodologies, real-time processing capabilities, and the challenges posed by diverse sign languages.

A. 2D and 3D Convolutional Neural Networks in Sign Language Recognition

Recent studies have extensively employed convolutional neural networks (CNNs) for the task of sign language recognition. The application of 2D CNNs has proven effective in recognizing static sign language images, capturing spatial features that distinguish various hand signs [17]. However, the dynamic nature of sign language, particularly in fingerspelling, requires understanding temporal sequences, for which 3D CNNs are better suited. These networks extend the capability of 2D CNNs by adding time as a third dimension, allowing them to capture motion across frames effectively [18]. A notable study demonstrated the superiority of 3D CNNs over their 2D counterparts in recognizing continuous sign language gestures, attributing improvements to the network's ability to process temporal information [19]. Nevertheless, the computational demand of 3D CNNs remains a significant challenge, particularly for real-time applications [20].

B. Feature Extraction Techniques for Enhanced Gesture Recognition

The effectiveness of a recognition system largely depends on the robustness of its feature extraction process. In this context, two-stream CNN architectures have shown promising results by separately processing spatial and temporal features, thus providing a more comprehensive analysis of video data [21]. One stream typically processes individual frames to capture static features like hand shapes and positions, while the other analyzes motion between frames to capture dynamic movements [22]. Such approaches have been applied successfully in other fields of action recognition and have gradually been adapted for sign language recognition [23]. Hybrid models that combine CNNs with recurrent neural networks (RNNs) have also been explored, with RNNs processing the temporal sequences of features extracted by CNNs, thereby enhancing the recognition of gestures over time [24]. Moreover, attention mechanisms have been integrated to focus the model on relevant features of the hand, significantly improving accuracy by reducing the influence of background noise and other irrelevant signals [25].

C. Real-Time Processing for Sign Language Recognition Systems

Achieving real-time processing capabilities in sign language recognition systems is crucial for their practical application. The latency in processing and recognizing sign language must be minimized to facilitate fluid communication between deaf and hearing individuals. Several studies have focused on optimizing CNN architectures to reduce computational loads without compromising accuracy [26]. Techniques such as model pruning, quantization, and the use of efficient network architectures like MobileNets have been proposed as solutions to achieve faster processing times [27]. Furthermore, edge computing has emerged as a viable approach, where processing is done on local devices rather than relying on cloud-based systems, thereby reducing response times significantly [28]. These advancements have paved the way for the development of more responsive and efficient real-time sign language recognition systems [29].

D. Challenges in Multilingual Sign Language Recognition

Sign language recognition is further complicated by the variation in sign languages across different regions and cultures. Each sign language has its own set of rules and nuances, which means that a system trained on one language may not perform well on another [30]. The scarcity of annotated datasets for many sign languages poses a significant barrier to training robust models [31]. Studies have attempted to address these challenges by using transfer learning, where a model trained on one language is adapted to another with minimal additional training [32]. Another approach is the use of synthetic data generation to augment existing datasets, thereby providing more comprehensive training material [33]. These methods have shown some success, but the variability in performance across languages remains a concern [34].

The literature reviewed highlights significant advancements in the field of sign language recognition, particularly in applying deep learning techniques for fingerspelling recognition. While 2D and 3D CNNs offer robust frameworks for feature extraction, their integration with two-stream architectures and RNNs presents a promising path toward more accurate and efficient recognition systems. Real-time processing remains a critical area for ongoing research, with current solutions pointing towards optimized CNN architectures and edge computing. However, the multilingual and multicultural nature of sign languages continues to pose significant challenges, necessitating further research into adaptive and scalable models that can handle the diversity of sign languages globally.

III. Materials and Methods

This section is critical as it outlines the systematic steps taken to ensure the reliability and validity of the results obtained. It serves to offer transparency, allowing other researchers to replicate the study or build upon its findings. Within this section, we detail the specific datasets used, the data preprocessing techniques employed, the architectural design of the machine learning models, and the criteria for evaluating their performance. By providing a clear and thorough exposition of these elements, we aim to facilitate a deeper understanding of the research process and its foundational components.

A. *Sign Language Alphabets*

Sign language alphabets serve as fundamental building blocks for communication within deaf communities, providing a means to spell out words and names for which specific signs may not exist. Among the various sign languages utilized globally, American Sign Language (ASL) [35] and Indian Sign Language (ISL) [36] represent two distinct systems, each with its unique set of alphabetic representations. This section delves into the alphabetic systems of ASL and ISL, illustrating their characteristics and the cultural nuances that influence their formation and usage.

1) American Sign Language (ASL) Alphabet: American Sign Language (ASL) is one of the most widely used sign languages in the world, particularly prevalent in the United States and parts of Canada. The ASL alphabet, as depicted in Fig. 1, consists of a series of hand configurations used to represent the 26 letters of the English alphabet. Each letter is formed using one hand, which is a notable characteristic that distinguishes ASL from some other sign languages that might use two hands for certain letters. The ASL fingerspelling system is crucial for expressing proper nouns, technical terms, and any other words for which there is no established sign, thus playing a vital role in daily communication as well as educational settings [37].

The ASL alphabet's design emphasizes clarity and simplicity, allowing for quick and straightforward communication. The letters are generally formed in front of the signer at chest level, ensuring visibility and ease of understanding. For instance, the letters 'A' through 'Z' involve distinct positions and shapes of the fingers, with minimal movement, making them relatively easy to learn for beginners and highly functional for fluent users in rapid communication.

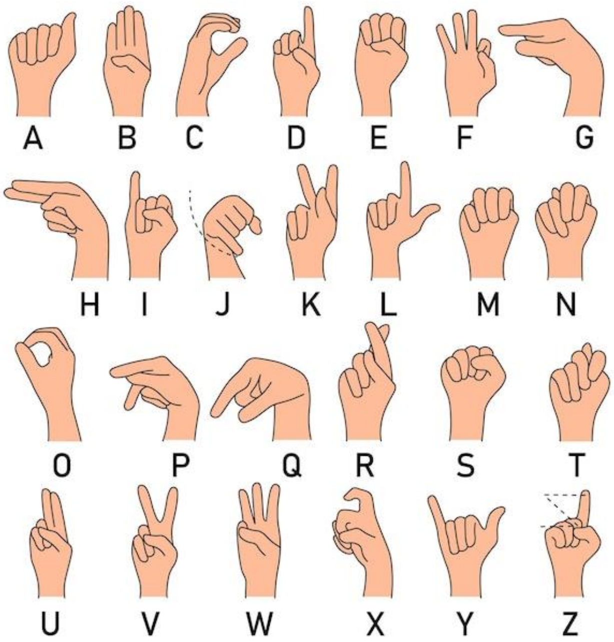

Fig. 1. ASL Alphabet.

2) Indian Sign Language (ISL) Alphabet: In contrast, Indian Sign Language (ISL) caters to the diverse linguistic landscape of India and incorporates elements that reflect the cultural and regional diversity of the country. The ISL alphabet, shown in Fig. 2, is utilized across various educational and social settings in India, providing a means for the deaf community to partake in both public and private discourse. Unlike ASL, the ISL fingerspelling system often employs two hands to represent certain letters, which can be seen as an adaptation to the linguistic structures and phonetic complexities of the multiple languages spoken in India [38].

Each letter in the ISL alphabet is represented by a unique combination of hand shapes, positions, and movements. These elements are designed to be visually distinct from one another to minimize confusion and ensure effective communication. For instance, the letters of the ISL alphabet are depicted with both static and dynamic gestures, which involve more interaction between the two hands compared to the mostly static nature of ASL fingerspelling [39]. This characteristic of ISL may stem from the gestural nuances found in the native languages of India, which often emphasize expressive hand movements and gestures in daily communication.

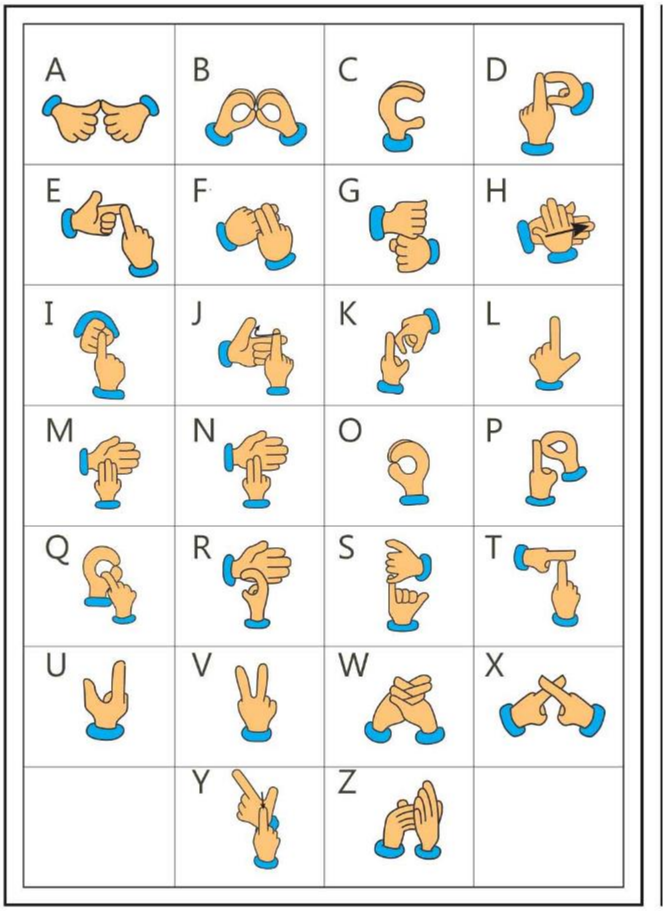

Fig. 2. ISL Alphabet.

The alphabets of ASL and ISL highlight the adaptability and diversity of sign languages in accommodating the linguistic needs of different cultural contexts [40-42]. While ASL employs a one-handed system for simplicity and speed, ISL uses a two-handed approach, possibly reflecting the complex phonetic systems of India's numerous spoken languages. Understanding these differences is crucial for educators, linguists, and technologists who develop communication tools and educational materials for the deaf community. The study and comparison of such systems not only enhance our understanding of linguistic diversity but also promote more inclusive and effective communication tools tailored to the unique needs of each sign language community.

B. Data Structure and Sample Description

Fig. 3 illustrates the data structure used in the research project for training the sign language recognition model. The data organization is key to understanding the relational dynamics between different datasets, which include train.csv and 5414471.parquet. The diagram effectively shows how these files are interlinked and utilized to train the deep learning model, highlighting the integration of participant information, sequence IDs, and feature vectors extracted from video frames.

1) Train.csv**:** The train.csv file acts as a central index, containing essential metadata for each training sample. This file includes several columns:

- path: Specifies the location of the parquet file containing the detailed sequence data.
- file_id: A unique identifier for the parquet file.
- sequence_id: A unique identifier that links the train.csv entries with specific sequences in the 5414471.parquet file.
- participant_id: Identifies the participant from whom the data was collected, facilitating analysis on a per-subject basis if required.
- phrase: Represents the specific phrase or words being signed in the sequence, which is crucial for supervised learning where the model learns to associate specific gestures with their corresponding linguistic outputs.

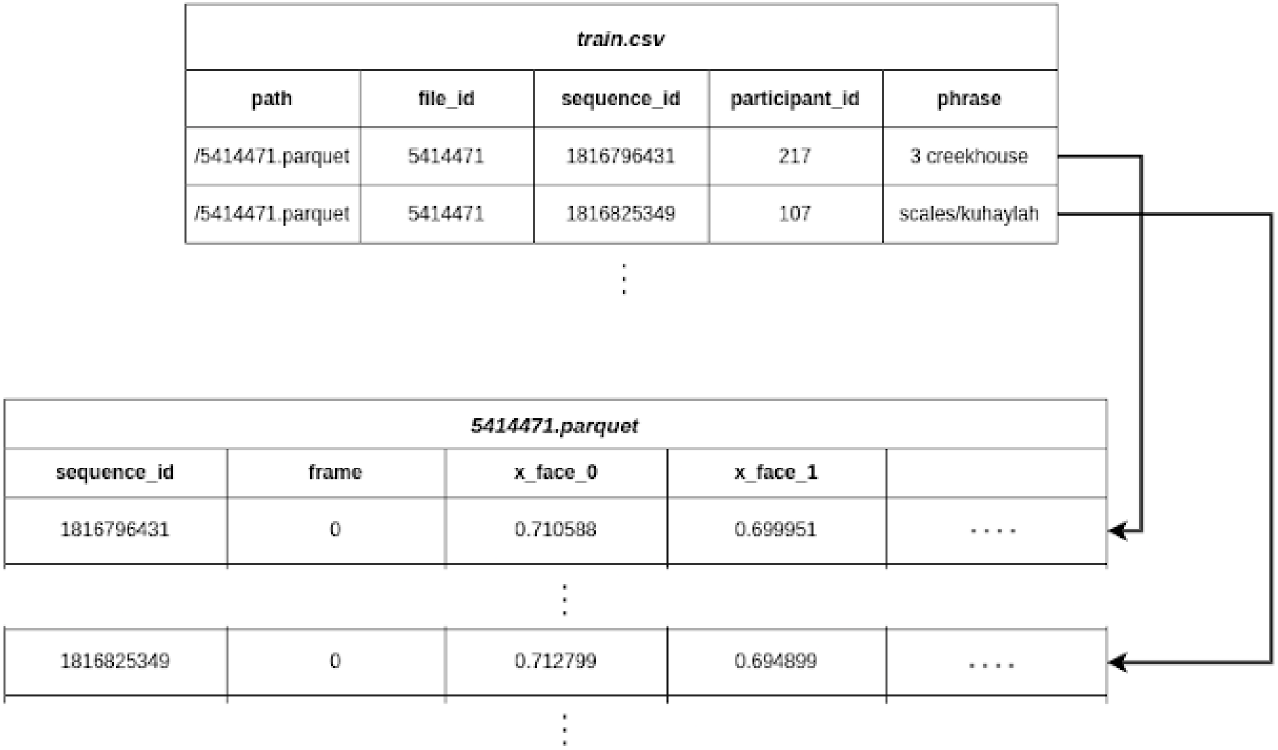
2) 5414471.parquet: The 5414471.parquet file contains detailed frame-by-frame data extracted from video sequences of participants performing sign language. Each row in this file corresponds to a single frame from a video sequence, and is linked back to the train.csv via the sequence_id. The columns in this file include:

- sequence_id: Matches the sequence_id in train.csv, establishing a relational link.
- frame: The frame number within a particular video sequence, which is critical for analyzing the temporal progression of gestures.
- x_face_0, x_face_1, ...: These columns represent extracted feature vectors associated with each frame. The features might include positional data of different facial landmarks or other relevant metrics that are used as input for the deep learning model.

The diagram in Fig. 3 demonstrates the workflow from raw video data extraction through to the feature extraction process, ending with the data being formatted into a machine-readable structure for model training. This structure supports the development of a robust model by providing a comprehensive dataset that includes both the static context of the sign language phrases and dynamic motion information encapsulated in the sequence of frames. This detailed and methodical data organization ensures that the machine learning model can learn from a rich dataset that mimics the complexities of real-world sign language usage.

C. Proposed Model Architecture

The proposed model architecture for sign language recognition, illustrated in Fig. 4, is designed to process sequential image data through a series of convolutional and fully connected layers. This architecture harnesses the power of deep learning to effectively capture both spatial and temporal features critical for understanding dynamic sign language gestures. Below, we describe each component of the model as depicted in the figure, and detail the operations performed at each stage.



train.csv

path	file_id	sequence_id	participant_id	phrase
/5414471.parquet	5414471	1816796431	217	3 creekhouse
/5414471.parquet	5414471	1816825349	107	scales/kuhaylah

⋮

5414471.parquet

sequence_id	frame	x_face_0	x_face_1	
1816796431	0	0.710588	0.699951	. . . .
⋮				
1816825349	0	0.712799	0.694899	. . . .
⋮				

Fig. 3. Example of training sample.

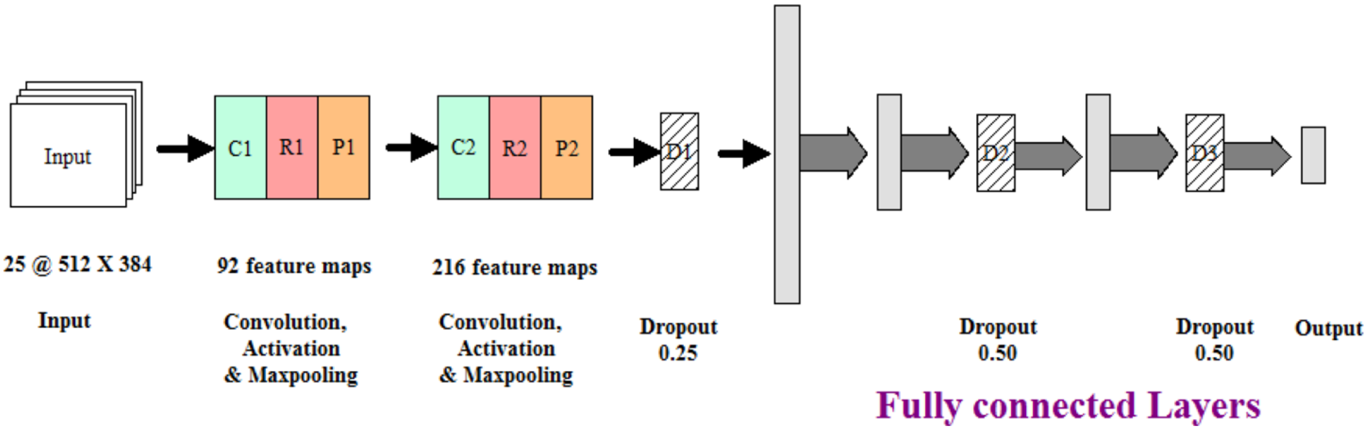


Fig. 4. The proposed model.

1) Input Layer: The input layer accepts sequential image data with dimensions 25×512×384, where 25 represents the number of frames in the sequence, and 512×384 are the pixel dimensions of each frame. This three-dimensional input is essential for preserving the spatial and temporal information present in video data.

Convolutional Layers (C1, C2). The first part of the model consists of two convolutional layers labeled as C1 and C2. These layers are responsible for extracting high-level features from the input images through the application of filters.

C1 Layer: Applies 92 filters to the input images, generating 92 feature maps. The convolution operation can be represented by the equation:

$$F_{ij}^{(k)} = \sigma\left(\sum_{m,n} I_{i+m,j+n} \cdot K_{mn}^{(k)} + b_k\right) \tag{1}$$

Here, $F_{ij}^{(k)}$ is the feature map for the k-th filter at position $(i, j), \sigma$ is the nonlinear activation function (typically ReLU), I is the input matrix, $K^{(k)}$ is the k-th filter matrix, and b_k is the bias term.

C2 Layer: Further refines the features extracted by the first layer by applying additional 216 filters, thus producing 216 feature maps. This layer helps in capturing more complex features that are vital for accurate sign language recognition.

2) Activation and Pooling Layers (R1, P1, R2, P2): After each convolutional layer, the model applies an activation function followed by a max pooling operation:

Activation (ReLU): Enhances non-linearity in the model by applying the ReLU activation function, which helps in handling non-linear features efficiently [43].

Max Pooling: Reduces the spatial dimensions of the feature maps while retaining the most significant information. This operation is critical for reducing the computational complexity and improving the robustness of the model against small variations in the input data.

3) Dropout layers: Following the convolutional blocks, two dropout layers are included to prevent overfitting [44]:

Dropout 0.25: Applied after the first convolutional block, this layer randomly sets a fraction of input units to 0 at each update during training time, which helps in making the model more generalized.

Dropout 0.50: A higher dropout rate is used after the second convolutional block to further regularize the model, particularly important due to the increased complexity from more feature maps.

4) Fully connected layers: The model transitions from convolutional layers to fully connected (dense) layers, which are essential for making predictions [45]. The dense layers integrate the learned features from previous layers to form the final output. The sequence of fully connected layers ends in a softmax or sigmoid output layer (depending on the number of classes), which provides the probabilities of each sign language gesture.

5) Output Layer: The final layer of the model uses a softmax activation function to classify the input image sequence into one of the possible sign language gestures. The softmax function is given by [46]:

$$P(y = j \mid x) = \frac{e^{z_j}}{\sum_{k=1}^{K} e^{z_k}} \tag{2}$$

Where $P(y = j \mid x)$ is the probability that the input x belongs to class j, z_j is the input to the softmax function from the final fully connected layer for class j, and K is the total number of classes.

The architecture proposed in Fig. 4 is designed to be robust, efficient, and capable of handling the complexities associated with recognizing sign language from video sequences. The combination of convolutional layers for feature extraction and fully connected layers for classification forms a powerful model that is well-suited for the real-time interpretation of sign language.

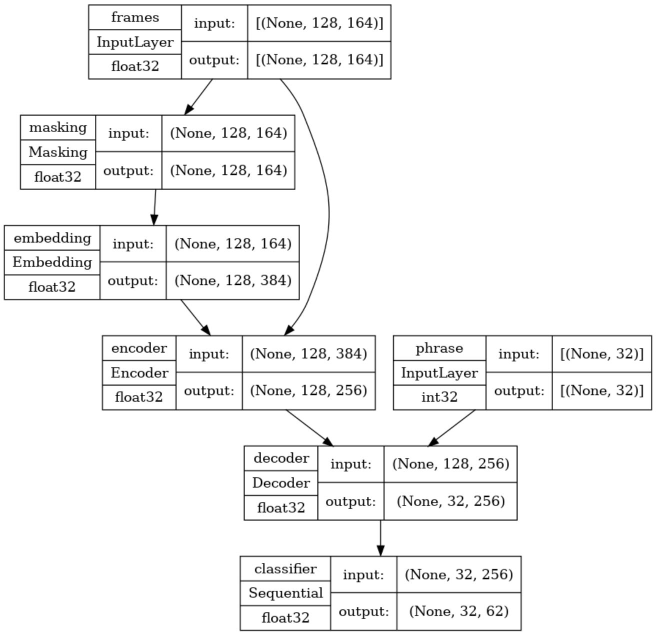

Fig. 5. Flowchart of the proposed model.

Fig. 5 presents a flowchart of a complex deep learning model architecture, primarily designed for sequence processing in tasks such as sign language recognition. This model integrates multiple layers and operations to handle sequential input data effectively. The architecture begins with an InputLayer that accepts frames, formatted as a three-dimensional array [None, 128, 164], which then passes through a Masking layer to ignore certain types of input (e.g., padding or missing values) for the purpose of maintaining the integrity of the sequence processing. Subsequently, the data undergoes transformation in an Embedding layer, which expands the feature representation to 384 dimensions, aiding in richer feature extraction by the subsequent Encoder layer. This encoder processes the embedded input and outputs a condensed representation [None, 128, 256] to the Decoder, which aims to reconstruct or transform the sequence contextually, often used in language translation or similar tasks. Alongside, a separate InputLayer for phrases processes integer-encoded inputs, suggesting a possible multimodal approach combining textual and sequential input data. The decoder's output then feeds into a Sequential classifier, which finalizes the processing pipeline by generating predictions or classifications based on the learned features, outputting a processed signal [None, 32, 62]. This architecture indicates a sophisticated approach to handling complex patterns in sequence data, suitable for tasks requiring nuanced understanding of temporal dynamics and contextual dependencies.

IV. Experimental Results

Fig. 6 illustrates the key anatomical landmarks, or keypoints, used in the study for tracking and recognizing fingerspelling gestures in sign language. The diagram depicts a schematic of a human hand annotated with 21 distinct keypoints, each corresponding to critical joints and segments within the hand's structure. These keypoints include the wrist, the carpometacarpal (CMC), metacarpophalangeal (MCP), proximal interphalangeal (PIP), distal interphalangeal (DIP) joints of each finger, and the tips of the fingers.

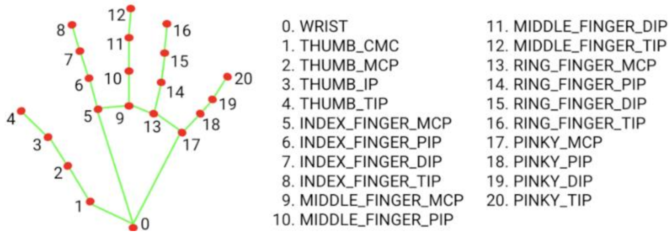

Fig. 6. Keypoints on the hand for fingerspelling.

The keypoints are numbered from 0 to 20, starting from the wrist and moving outward towards the fingertips. For instance, keypoint 0 represents the wrist, keypoint 1 the thumb CMC, keypoint 5 the index finger MCP, and so forth, culminating with keypoint 20 at the tip of the pinky finger. These annotations are crucial for machine learning models, which rely on these precisely defined points to accurately interpret and classify the gestures involved in fingerspelling.

The connections between the keypoints, represented by green lines, indicate the typical kinematic chains in hand anatomy essential for motion tracking and gesture recognition. These lines help in understanding how movements at one joint affect subsequent parts of the hand, which is vital for developing algorithms that can accurately interpret complex hand gestures. The clear labeling and structuring of these keypoints in the diagram provide a foundation for detailed analysis and discussion of the results related to fingerspelling recognition accuracy in the subsequent sections of the document.

Fig. 7 provides a detailed representation of the upper extremity keypoints utilized in the fingerspelling recognition algorithm, specifically highlighting the arrangement and connectivity of key anatomical landmarks across the fingers and wrist. This diagram focuses on the joints of the fingers and the wrist, essential for deciphering the precise configuration of hand gestures in sign language communication.

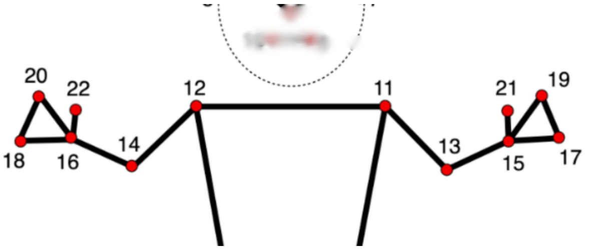

Fig. 7. Keypoints on the human body for fingerspelling.

In this schematic, keypoints are strategically positioned on the joints and tips of the fingers to capture the essential articulations necessary for sign language interpretation. The keypoints are numbered from 12 to 22, illustrating an array from the base of the wrist up through the tips of the fingers. Notably, keypoints 12 and 14 signify the wrist and the base of the fingers, respectively, forming a critical juncture from which the digital keypoints extend.

Each finger is represented by a sequence of keypoints, with the numbering extending outward towards the fingertips: the index finger from keypoint 14 to 16, the middle finger from 11 to 13, and so forth, with the additional articulations for more complex gestures indicated by keypoints 17, 19, 21, and 22. The lines connecting these points indicate the kinematic links that are essential for understanding how movements in one part of the hand influence the positioning and orientation of the other parts.

This configuration allows the machine learning models to track and interpret the dynamic and complex movements involved in sign language gestures, providing a robust framework for accurate gesture recognition. The clarity and layout of these keypoints are pivotal for analyzing the effectiveness of the fingerspelling recognition system, which is further explored in the results section of the study.

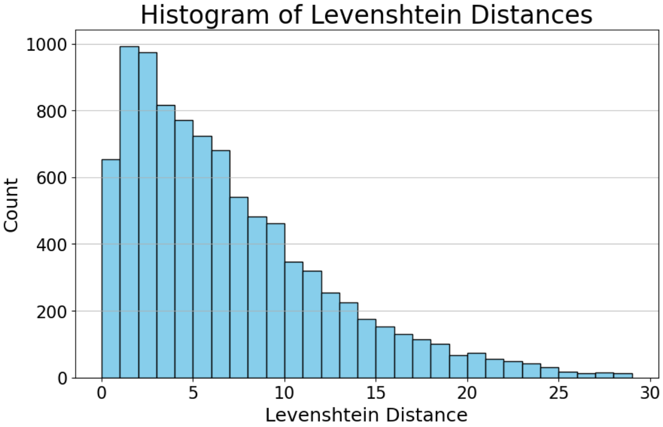

Fig. 8. Histogram of Levenshtain distances.

Fig. 8 presents a histogram of Levenshtein distances calculated from the output of the fingerspelling recognition system. The Levenshtein distance, a metric for measuring the difference between two sequences, is used here to evaluate the discrepancy between the predicted and actual spelled sequences in sign language communication. The x-axis of the histogram represents the Levenshtein distance, ranging from 0 to 30, while the y-axis displays the count of sequences falling into each distance category [47].

The distribution depicted in the histogram is skewed to the left, indicating that a majority of the sequence predictions by the model have a relatively low discrepancy from the target sequences, with the highest frequency observed in the range of 0 to 5. This suggests that the model is generally effective in accurately predicting the sequences, though errors increase as the distance values rise. The diminishing frequency as the distance increases confirms that fewer instances have larger errors, highlighting the effectiveness of the model in capturing the nuances of fingerspelling gestures with a considerable degree of accuracy. The shape and spread of the distribution provide crucial insights into the performance of the recognition system, revealing both its strengths in accurately recognizing many gestures and the areas where improvements might be necessary for those predictions exhibiting higher discrepancies.

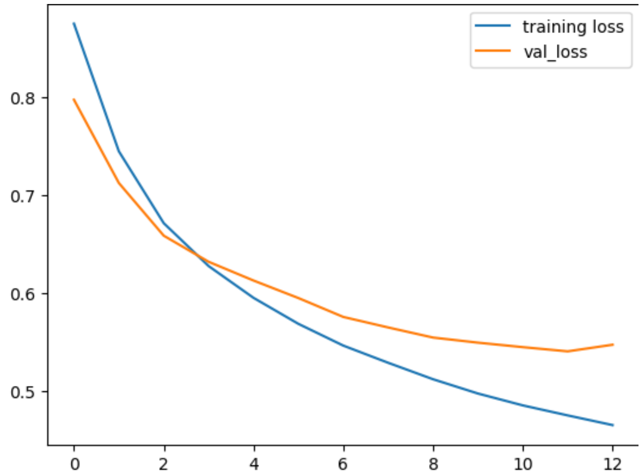

Fig. 9. Training and validation loss.

Fig. 9 displays a graphical representation of the training and validation loss curves for the sign language recognition model over a series of epochs. The x-axis of the graph indicates the number of epochs, while the y-axis represents the loss value, which quantifies the difference between the predicted outputs of the model and the actual target values during training and validation phases.

The blue line represents the training loss, illustrating how the model's error on the training set decreases as it learns from the data over successive epochs. The orange line, representing the validation loss, shows a similar decrease, indicating how well the model generalizes to new, unseen data. Both curves exhibit a steep decline in the initial epochs, signifying rapid learning and improvement in model performance.

As the number of epochs increases, both curves begin to plateau, suggesting that the model is approaching its optimal performance given the current architecture and data. The convergence of the training and validation loss lines toward the latter epochs indicates good model generalization without significant overfitting. This convergence is crucial for confirming that the model is not merely memorizing the training data but rather learning generalizable patterns that perform well on external data. The graph effectively underscores the learning dynamics of the model, highlighting areas where the training process is stable and effective, alongside pointing out the epochs after which learning saturates.

Fig. 10. Confusion matrix results.

Fig. 10 depicts a confusion matrix, a critical tool for evaluating the performance of the classification model developed for fingerspelling recognition. This matrix presents the counts of actual versus predicted class labels across a set of 20 classes, which represent different fingerspelling gestures.

The x-axis of the confusion matrix corresponds to the predicted class labels by the model, ranging from 1 to 20, while the y-axis represents the true class labels. Each cell within the matrix shows the number of instances that the model predicted a certain class (x-axis) for an actual class (y-axis). The diagonal cells, highlighted by darker shades, represent correct predictions where the predicted classes match the true classes. Off-diagonal cells indicate misclassifications, where the numbers denote how often a particular class was predicted instead of another.

A quick visual assessment of the matrix reveals several insights:

- The concentration of higher numbers along the diagonal line indicates good model accuracy for many classes, with prominent correctly classified instances such as in classes 1, 6, 7, and 9.
- Some classes, however, show notable confusion with others. For example, class 20 exhibits frequent misclassification, with incorrect predictions scattered across several other classes.
- Certain pairs of classes, such as 10 and 20 or 5 and 19, have higher confusion, suggesting similarities in the gestures that may be leading to these consistent misclassifications.

Overall, the confusion matrix provides a detailed view of the model's strengths and weaknesses across different fingerspelling gestures, highlighting specific areas where the model performs well and others where improvement is necessary. This visual tool is indispensable for diagnosing performance issues and guiding future enhancements to the model's classification capabilities.

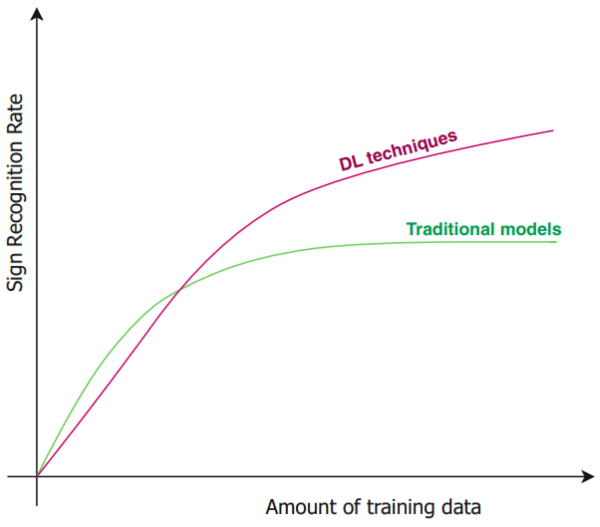

Fig. 11. Comparative performance of the proposed deep model vs. traditional models in sign language recognition as a function of training data volume.

Fig. 11 illustrates a comparative analysis of the performance between traditional machine learning models and deep learning (DL) techniques in the context of sign language recognition as a function of the amount of training data used. The graph plots the sign recognition rate on the vertical axis against the amount of training data on the horizontal axis. As depicted, both curves exhibit an increase in recognition rate with more data, demonstrating the typical behavior that more extensive training datasets generally improve the accuracy of predictive models. However, the curve representing deep learning techniques (colored in pink) is positioned above that of traditional models (colored in green), indicating a consistently higher recognition rate across the spectrum of data volumes. Notably, the deep learning curve shows a steeper initial ascent, suggesting that DL techniques are more effective at leveraging larger datasets to achieve significant improvements in accuracy [48]. This trend highlights the scalability and robustness of deep learning models in handling complex, high-dimensional data typical of sign language video inputs, compared to traditional models which plateau earlier and achieve lower peak recognition rates.

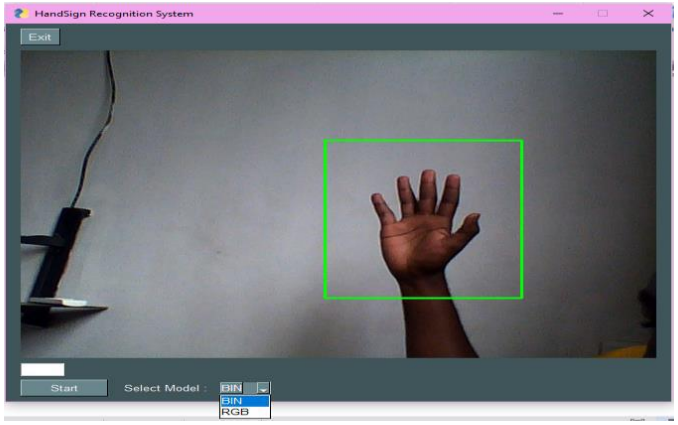

Fig. 12. Comparative performance of the proposed deep model vs. traditional models in sign language recognition as a function of training data volume.

Fig. 12 displays a screenshot of the HandSign Recognition System interface during operation, showcasing the system's ability to detect and highlight a hand gesture within a real-time video feed. The image illustrates a human hand positioned centrally against a plain background, with the hand's open gesture enclosed by a green bounding box, indicating successful detection by the system. This visual feedback is part of the user interface designed to allow users to verify the correct identification and tracking of hand gestures. The interface includes several operational controls such as “Start”, “Select Model”, along with options to switch between binary (“BIN”) and RGB color modes, enhancing the flexibility and usability of the system for different lighting conditions and background scenarios. The inclusion of such features underscores the system's practical application in real-world environments, where variability in input conditions can significantly affect performance.

V. Discussion

This research paper has examined the development and application of a deep learning-based sign language recognition system, which is instrumental in bridging communication gaps between the deaf and the hearing. The discussion elaborates on the implications of the findings, explores the challenges encountered, and suggests future research directions.

A. Efficacy of Deep Learning Models

The results demonstrated that deep learning techniques outperform traditional models in sign language recognition, particularly as the volume of training data increases. As depicted in Fig. 11, deep learning models exhibit a steeper improvement curve in recognition accuracy with the addition of training data. This can be attributed to the ability of deep learning models to extract complex features from high-dimensional data, a capability that traditional machine learning models lack. The advanced feature extraction allows for a more nuanced understanding of sign language gestures, which are inherently complex due to the variety of hand shapes, orientations, and movements involved [49].

B. System Performance in Real-Time Applications

Fig. 12 illustrates the practical application of the system in real-time environments. The system's capability to accurately detect and track hand gestures in real time underscores its potential for use in dynamic scenarios, such as live sign language translation or interactive educational tools. However, the performance in real-world conditions can be affected by factors such as lighting variations, background noise, and rapid movements. Although the current system handles these challenges to a certain extent, further refinement is necessary to improve robustness and ensure consistent performance regardless of external conditions.

C. Integration and Usability Challenges

The user interface, as shown in Fig. 12, is designed to be intuitive and user-friendly, offering essential controls like model selection and color mode adjustments. This is critical for ensuring that the system is accessible not only to researchers and professionals but also to lay users, including educators and individuals within the deaf community. However, the integration of such technology into everyday applications presents challenges, including the need for compatible hardware, user training, and ongoing support. Furthermore, there remains a significant need to develop standardized protocols for evaluating the usability of such systems in diverse settings [50].

D. Limitations and Scope for Improvement

While the system shows promising results, there are several limitations that need to be addressed. The current dataset, although extensive, may not fully represent the diversity within the global deaf community [51]. Sign language varies significantly not just internationally but also regionally; therefore, the system’s training on a more culturally and linguistically diverse dataset could enhance its applicability. Moreover, the confusion matrix in Fig. 10 reveals specific areas where the model confuses similar gestures. This could be mitigated by introducing more granular features and perhaps a temporal component to better differentiate between dynamically similar signs.

E. Future Directions

Looking forward, the research should focus on several key areas:

1) Data Diversification: Collecting and incorporating more diverse training data that cover a broader spectrum of sign languages and include more varied environments and lighting conditions.

2) Algorithm Optimization: Enhancing the model's architecture to improve its ability to learn from fewer data points, which is crucial for rare gestures or signs.

3) Real-Time processing improvements: Reducing latency further and increasing the processing speed to handle rapid sequences of gestures without delay.

4) User-Centric Design: Engaging with the deaf community to tailor the system's development to their needs and preferences, ensuring that the technology is both accessible and practical.

5) Cross-Platform compatibility: Ensuring the system is adaptable to various devices and platforms, enhancing its accessibility and practical utility.

The development of a sign language recognition system using deep learning techniques represents a significant technological advancement with the potential to impact real-world interactions profoundly. By continuously refining the system and addressing the outlined challenges, future iterations can provide even more reliable and inclusive communication tools for the deaf and hard-of-hearing communities.

VI. Conclusion

The research undertaken in this study has culminated in the development of an advanced sign language recognition system powered by deep learning techniques, showcasing significant potential to enhance communication between the deaf and hearing communities. The application of deep learning has been demonstrated to markedly outperform traditional models, especially as the volume of training data increases. This is evident in the system's enhanced ability to interpret complex hand gestures with high accuracy, addressing the dynamic and diverse nature of sign language. Our findings indicate that with sufficient training data, deep learning models can effectively capture the subtleties of sign language, which are often missed by more conventional approaches. The real-time operational capability of the system, as demonstrated, further underscores its practical utility in everyday applications, from educational settings to public services. However, challenges related to system integration, environmental variability, and data diversity call for ongoing improvements. Future research should aim to diversify the training datasets to include a broader array of sign languages and refine the system's robustness against external changes such as lighting and background variations. Engaging with the deaf community to tailor the technology to their needs will ensure that the advancements in sign language recognition technology are both practical and impactful. Ultimately, this research paves the way for creating more accessible and effective communication tools, fostering inclusivity and understanding across different sections of society.
