Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Evolving Software Architectures from Monolithic Systems to Resilient Microservices: Best Practices, Challenges and Future Trends

Martin Kaloudis
Provadis School of International Management and Technology, Frankfurt, Germany

Abstract—Microservice architecture has emerged as a widely adopted methodology in software development, addressing the inherent limitations of traditional monolithic and Service-Oriented Architectures (SOA). This paper examines the evolution of microservices, emphasising their advantages in enhancing flexibility, scalability, and fault tolerance compared to legacy models. Through detailed case studies, it explores how leading companies, such as Netflix and Amazon, have leveraged microservices to optimise resource utilisation and operational adaptability. The study also addresses significant implementation challenges, including ensuring data consistency and managing APIs. Best practices, such as Domain-Driven Design (DDD) and the Saga Pattern, are evaluated with examples from Uber's cross-functional teams and Airbnb's transaction management. This research synthesises these findings into actionable guidelines for organisations transitioning from monolithic architectures, proposing a phased migration approach to mitigate risks and improve operational agility. Furthermore, the paper explores future trends, such as Kubernetes and AIOps, offering insights into the evolving microservices landscape and their potential to improve system scalability and resilience. The scientific contribution of this article lies in the development of practical best practices, providing a structured strategy for organisations seeking to modernise their IT infrastructure.

Keywords—Service-Orientated Architecture; SOA; microservices; monolithic architecture; migration

I. Introduction

Microservice architectures [1] have gained significant traction in recent years, primarily due to their ability to address the scalability and flexibility limitations of traditional monolithic systems. This architectural paradigm shift is driven by the growing need to manage complex, distributed applications efficiently. By decomposing applications into independently deployable services, microservices offer enhanced modularity, fault tolerance, and adaptability, positioning themselves as a superior alternative to monolithic architectures in large-scale, dynamic environments.

While the benefits of microservices, including independent scalability, enhanced fault isolation, and faster deployment cycles, are well-documented, their adoption is not without challenges. Ensuring consistency in data across distributed services remains a critical issue, particularly in environments where services manage their own databases. Furthermore, the operational overhead of managing an increasing number of APIs can result in significant complexity, particularly as systems grow in scale. These issues underscore the need for robust strategies to mitigate the operational challenges inherent in microservice architectures.

This study contributes to the ongoing discourse by proposing a structured approach to the transition from monolithic to microservice architectures, focusing on best practices derived from industry case studies. While existing literature extensively covers the theoretical benefits of microservices, there is a notable gap in actionable, empirically validated strategies for managing the complexities associated with their implementation. By analyzing case studies from industry leaders such as Netflix and Amazon, this research offers a phased migration strategy that minimizes risks and operational disruption. The novelty of this study lies in its practical framework for managing the inherent challenges of microservices, particularly in the context of large-scale enterprise systems.

II. Theoretical Basics

A. Definition and Characteristics of Microservice Architecture

Microservice architecture is a software development approach in which an application is developed as a collection of small, independent services. Each service fulfils a specific business requirement and communicates with other services via precisely defined APIs [2]. Microservices are small, independent services that fulfil specific business requirements. In [3] it is emphasised that this architecture simplifies the development and maintenance of complex systems due to its loose coupling and high cohesion. The author in [4] emphasises that microservices are particularly suitable for systems that place high demands on scalability and flexibility. One of the features of microservice architecture is decentralisation, in which services, functions and data are decentralised, resulting in a loose coupling of components. This promotes the application's reliability and fault tolerance. Another feature is independent development and deployment, which means that each service can be developed, tested and deployed independently. Errors in one service do not affect the entire application, which increases fault tolerance. Services can be reused in different applications, which increases efficiency and development speed [5].

B. Monolithic Architecture

Monolithic architecture is a traditional approach to software development in which all components of an application are integrated into a single, cohesive code base. This tight integration means that the application is developed, tested and deployed as an inseparable whole. A key feature of this approach is dependent scaling: if one component of the application experiences a higher load and requires more resources, the entire application must be scaled. This can be inefficient and resource-intensive, as the underutilised parts of the application also have to be scaled.

Another feature of monolithic architecture is that development cycles tend to be longer. As all components are closely interlinked, a change in one part of the application potentially affects many other parts. This requires extensive testing and can delay the release of new features. Any change, no matter how small, often requires a redeployment of the entire application, which is not only time-consuming but can also lead to downtime. This downtime can be particularly critical if the application provides business-critical functionality. Monolithic systems (see Fig. 1) have traditionally been favoured for their consistency and simplicity of implementation and management. Developers only have to deal with one code base and one deployment process. This can speed up initial development and simplify management, especially for smaller applications or teams. The clear structure and centralised management of dependencies and configurations make monolithic architectures attractive for many use cases.

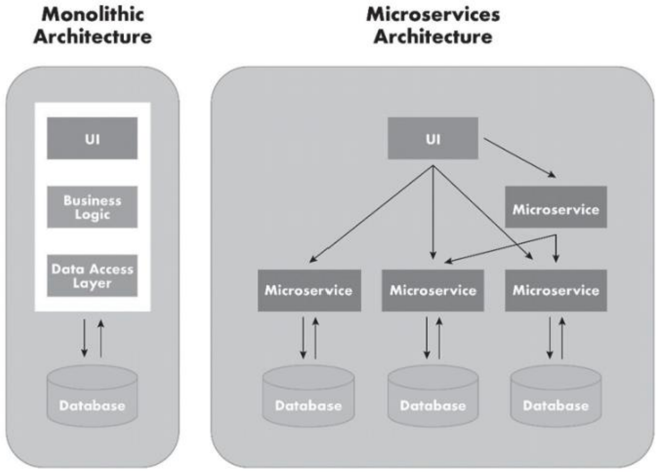

Fig. 1. Monolithic vs. Microservices architecture from [6].

To summarise, although monolithic architecture offers advantages due to its simplicity and consistency, it has significant disadvantages in an increasingly dynamic and scaled IT landscape. The lack of flexibility and scalability as well as the potential risks due to the tight integration of components make it unsuitable for many modern use cases. These disadvantages have led to the development and spread of more flexible and scalable architectures such as microservice architecture, which eliminate the specific weaknesses of the monolithic approach.

C. Microservices Architecture

In contrast to monolithic architecture, microservices divide an application into a collection of loosely coupled, independently deployable services, each of which fulfils specific business requirements. This architecture offers better scalability, flexibility and fault tolerance, but requires advanced knowledge of distributed systems development and DevOps practices. Each microservice has its own database and can be developed, tested and deployed independently, reducing infrastructure complexity and enabling more efficient resource utilisation [2].

1) Decentralisation and loose coupling: The microservice architecture is characterised by a fundamental decentralisation of services, functions and data. Instead of developing a monolithic application that combines all functions and processes in a single, closely linked structure, the microservice architecture breaks down the application into a large number of smaller, independent services. Each of these services, also known as a microservice, is designed to fulfil a specific business requirement or functionality. These services are not only functionally independent, but also often operate in isolated runtime environments and have their own databases. This means that each microservice manages and stores its own data, which ensures better data consistency. This decentralisation leads to a loose coupling of the components. Loose coupling means that the individual services are only minimally dependent on each other. Changes or errors in one service therefore have little to no impact on the other services. This decoupling enhances the overall resilience of the application, defined as its capacity to maintain operational continuity in the presence of faults or failures. Resilience describes the ability of a system to remain functional despite errors or faults. In a monolithic architecture, an error in one component can affect the entire application, whereas in a microservice architecture, an error remains isolated and the other services continue to function normally. This not only reduces fault tolerance, but also increases the overall reliability of the application [2].

One of the critical features of microservice architecture is its ability to scale individual services independently. As each microservice has its own database and is operated independently of the other services, each service can be scaled individually depending on the specific requirements and the load to be managed. This is particularly beneficial in cloud environments where resources can be allocated dynamically. For example, if a particular service has a high volume of traffic, it can be scaled independently of the other services without having to scale the entire application. This leads to more efficient resource utilisation and lower operating costs. Separation into independent services also improves fault isolation. Fault isolation means that problems in one service do not directly affect other services. If a microservice fails or a problem occurs, this error is limited to the affected service and does not affect the entire application. This not only makes troubleshooting easier, but also increases the reliability of the application. Developers can focus on fixing the specific problem without having to worry about changes to one service negatively impacting other parts of the application.

By decentralising services, functions and data, the microservice architecture offers considerable advantages in terms of reliability, fault tolerance, data consistency and scalability. The loose coupling of the services leads to increased robustness of the application, as errors remain isolated and the other services can continue to work undisturbed. Independent scalability enables efficient resource utilisation and reduces operating costs, while improved fault isolation and recovery increases the overall reliability of the application [6].

2) Scalability and fault tolerance: The ability to scale independently is one of the most outstanding features of microservice architecture and brings significant benefits in terms of resource management and increased efficiency. In a conventional monolithic architecture, all components of an application must be scaled together, even if only a small part of the application actually experiences an increased load. This leads to inefficient resource utilisation and increased costs, as not all parts of the application require the same scalability. In contrast, microservices enable targeted and demand-orientated scaling of individual services. Each microservice can be scaled independently of the other services, based on the specific requirements and the current load [7]. Splitting the application into independent services also has a positive effect on the fault tolerance of the entire system architecture. In a monolithic system, an error in one component can affect the entire system and lead to a total failure. This is because the components are closely interconnected and there is a dependency that disrupts the entire operating process. Microservices, on the other hand, isolate these errors to the affected service. If a microservice fails or an error occurs, this has no impact on the other services. The application remains functional and the affected microservice can be analysed and repaired in isolation.

Another aspect that increases fault tolerance is the ability to recognise and rectify errors automatically. Modern microservice architectures often utilise monitoring and management tools that continuously monitor the status of the services and react automatically in the event of anomalies or errors. This can be done by restarting the faulty service, switching to redundant services or dynamically reallocating resources. These automated processes reduce downtimes and improve the overall availability of the application [8]. The resilience, i.e. the ability of a system to recover from disruptions, is significantly improved by the microservice architecture. The loose coupling of the services means that they can work largely independently of each other. This independence allows the system to react flexibly to changes or failures without affecting the entire application. If a service is overloaded by a sudden increase in requests, it can be scaled in isolation to cope with the increased load. Should a service nevertheless fail, alternative services or failover mechanisms can be activated to ensure the continuity of business processes.

3) Independent development and provision: Microservice architecture facilitates the independent development and deployment of software components, yielding considerable improvements in both the efficiency and agility of the development process. In traditional monolithic architectures, all parts of an application must be developed, tested and deployed as a single unit. This means that even small changes to a component require extensive testing and full deployment of the entire application. This dependency leads to longer development cycles, an increased risk of errors and downtime as well as limited flexibility when implementing new functions [5]. A key advantage of this independent development and deployment is improved fault isolation. In a monolithic architecture, an error in one component can affect the entire application, which can lead to extensive downtime and difficult troubleshooting. In a microservice architecture, an error in one service remains limited to that specific service and does not affect the other parts of the application. This independence of services also encourages parallel development by different teams. In monolithic systems, development teams must coordinate their work closely to avoid conflicts, which can slow down development processes. In a microservice architecture, different teams can work on different services at the same time without their work interfering with each other.

The independent development and provision of microservices also supports better scalability of development resources. In monolithic systems, the scaling of development teams is often limited, as all teams have to work on the same code base and coordinate changes. In a microservice architecture, development teams can be scaled flexibly as they work independently on different services. This allows organisations to use their development resources more efficiently and respond more quickly to business requirements, resulting in faster implementation and improving the flexibility and agility of development processes. Improved fault isolation, parallel development by different teams and support for CI/CD practices lead to faster and more reliable releases, higher productivity of development teams and better scalability of development resources [5].

4) Reusability and flexibility in technology selection: Flexibility in technology selection allows teams to develop customised solutions that are optimised for their specific business needs. For example, a team working on a data-intensive analytics service might choose a programming language such as Python, which is known for its powerful data science libraries and frameworks. Another team developing a high-performance, critical real-time service might choose a language like Go or Rust, which are known for their efficiency and low latency. This freedom in technology choice leads to a better customisation of solutions to the specific needs of each service and therefore to business requirements [5]. Another advantage of this flexibility is the ability to introduce and use specialised technologies that are particularly suitable for specific tasks. Teams can select technologies that best fit the requirements and challenges of their specific microservices without having to consider the rest of the application. This can lead to a significant improvement in performance and efficiency. For example, a team working on a machine learning model could use specific frameworks and hardware acceleration to optimise training times and model accuracy [9].

The reusability and technological independence of microservices also help to reduce technical debt. Technical debt arises when short-term solutions are chosen that lead to higher maintenance costs in the long term. By using proven and reusable services, development teams can create consistent and maintainable code bases that reduce long-term maintenance efforts. In addition, flexibility in technology selection allows teams to continuously use the best tools and practices to minimise technical debt [4].

These advantages contribute to the microservice architecture being a favoured choice for modern, scalable and flexible software development projects [7].

III. Why and How Split Monoliths?

Industries such as retail, travel and transport and automotive have increasingly begun to break up their monolithic applications into microservices in order to become more flexible and scalable. This change is being driven by the need to respond more quickly to market changes and reduce total cost of ownership (TCO). However, the transition from monolithic to microservice architectures is a complex process that requires careful planning and a systematic approach. Fig. 2 shows cost-based determination of granularity services.

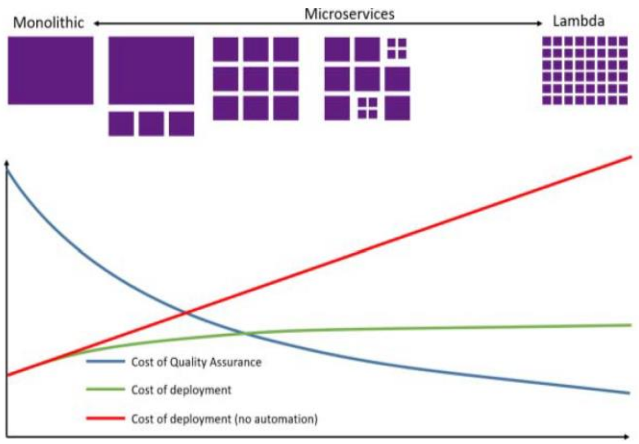

Fig. 2. Cost-based determination of granularity services [10].

A. *Reasons for the Switch to Microservices*

An important reason for this migration is the greater flexibility that microservices offer. In retail, for example, companies can develop and introduce new functionalities faster by splitting their applications into smaller, independent services. This is particularly important in a market that is constantly evolving and where competition is fierce. Retailers need to be able to respond quickly to new trends and customer demands, be it by introducing new payment methods, optimising supply chains or personalising the shopping experience.

B. *Systematic Analysis and Step-by-Step Migration*

The process of migrating from monolithic to microservice architectures often begins with a comprehensive and systematic analysis of the existing architecture. The aim of this analysis is to identify the current dependencies, bottlenecks and weak points. Based on these findings, companies can develop a clear migration strategy that is implemented step by step. A complete switch to microservices in a single step is usually too risky and too complex. Therefore, many companies prefer a step-by-step migration in which they gradually break down the application into microservices.

C. *Identification of Business Areas*

An important aspect of migration is the definition of business units. Business units are functional areas within an organisation that have clearly defined responsibilities. For example, a retailer might define business domains such as inventory management, order fulfilment, customer service and payment processing. Each of these domains can then be implemented as an independent microservice. This clear demarcation makes it possible to reduce the complexity of the overall application and clearly define responsibilities.

D. *Formation of Cross-Functional Teams*

Another important step in the migration process is the formation of cross-functional teams. Traditionally, development and operations teams are separate in many organisations, which can lead to communication problems and delays. However, microservice architecture requires close collaboration between these teams. Cross-functional teams consisting of developers, testers, operations experts and other relevant professionals can make the development and deployment of microservices more efficient. These teams are responsible for the entire lifecycle of a microservice, from development and testing to deployment and maintenance.

E. *Introduction of DevOps Processes*

The introduction of DevOps practices is another key component in the transition to microservices. DevOps stands for the integration of development and operations and aims to improve collaboration between these two areas. DevOps practices include Continuous Integration (CI) and Continuous Delivery (CD), which enable faster and more reliable delivery of software. By using automation tools and processes, companies can increase their efficiency, reduce the error rate and shorten the time to market for new functions.

IV. Challenges of Migration

Overall, the transition from monolithic applications to microservices offers significant benefits for many companies in the retail, travel and transport and automotive industries. By conducting systematic analyses, identifying business units, forming cross-functional teams and implementing DevOps practices, companies can make their IT infrastructure more flexible and scalable. A step-by-step migration minimises risks and enables continuous adaptation to changing market requirements. Research and practical reports prove the positive effects of this transformation on the efficiency and competitiveness of companies [10].

Procedure: The migration from a monolithic to a microservice architecture is a complex process that requires careful planning. It usually starts with the identification and extraction of business domains as independent microservices. Business domains, i.e. specific areas within an organisation, form the basis for the new architecture [11].

Analyse the existing architecture: The first step is to analyse the monolithic system to understand the dependencies between the components. Tools can automatically create dependency diagrams that help to visualise the interactions and control the migration process.

Development of a migration plan: Based on this analysis, a detailed migration plan should be created outlining the steps to minimise risk and ensure continuity. The plan should prioritise the domains to be migrated according to their business value and technical complexity.

Identifying and extracting business areas: Business areas, such as the product catalogue or payment processing in an e-commerce platform, must be clearly defined before they can be implemented as independent microservices.

Support for DDD: DDD helps to manage complexity by dividing systems into manageable units. The concept of "bounded context" ensures that each microservice has clear boundaries, which simplifies development and scaling.

Minimising risk and ensuring continuity: During the migration, mechanisms such as APIs or messaging systems help to ensure communication between microservices and the monolith and maintain continuity during the process.

Iterative development and continuous improvement: Migration should be viewed as iterative. Each migrated domain provides insights for optimising the process for future domains.

Static and dynamic analysis: Static analysis checks the source code to determine dependencies, while dynamic analysis monitors runtime behaviour and helps to prioritise services based on usage patterns.

By combining these approaches, companies can reduce system complexity and build scalable, maintainable architectures.

Development of a comprehensive migration plan: Based on the findings from the static and dynamic analysis, a comprehensive migration plan can be developed. This plan should take into account the identified services and interfaces as well as the prioritised usage patterns. It contains detailed steps for carrying out the migration, including the order of migration of the individual services, the necessary changes to the infrastructure and the implementation of transition mechanisms to ensure business continuity.

Static and dynamic analyses are crucial methods for preparing a successful migration from monolithic to microservice architectures. While static analysis reveals the structure and dependencies of the existing system, dynamic analysis provides valuable insights into the actual usage and performance of the application. By combining both approaches, organisations can develop a solid and low-risk migration strategy that takes into account both technical and operational aspects.

V. Advantages of the Integration of Microservices

Microservices offer numerous advantages that improve software development, reduce operating costs and simplify maintenance. Key benefits include independent development and deployment, efficient resource utilisation, technological flexibility, fault isolation and reusability of services.

One of the most important advantages of microservices is the ability to develop and deploy services independently of each other. In contrast to monolithic architectures, where every change requires extensive testing and a complete deployment of the entire system, microservices allow individual services to be updated independently of each other. This speeds up development, reduces errors and facilitates continuous deployment [11].

Efficient use of resources: Microservices enable independent scaling of services and thus optimise resource allocation. For example, if a service experiences increased demand, it can be scaled independently without affecting the rest of the system. This improves performance and reduces costs, especially compared to monolithic systems where the entire application has to be scaled [12].

Technological flexibility: Each microservice can be developed with the technology best suited to its needs. This allows development teams to innovate and customise solutions more effectively. Teams working on performance-critical components may opt for faster, more efficient languages, while others may favour simple development [13].

Isolation of errors: Errors in a microservice do not affect the entire application, which increases reliability. Isolated errors make it easier to diagnose and rectify problems without causing system-wide downtime [14].

Reusability of services: Microservices are independent units that can be reused in different applications. For example, an authentication service developed for one application can be reused in other projects, which saves development time and ensures consistency and security.

These advantages make microservices a favoured choice for modern, scalable and flexible software systems.

VI. Performance of Microservice Architectures: Case Studies

A. Case Study I: Comparison of Performance

A performance comparison between monolithic and microservice architectures shows clear differences in efficiency and scalability under different load conditions. In this case study, extensive tests were carried out to analyse the performance of the two architectures (see Fig. 3).

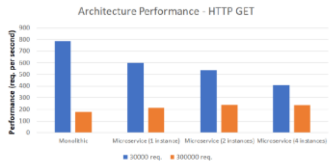

Fig. 8. Architecture performance (HTTP GET) - results

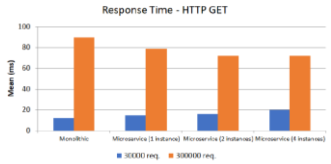

Fig. 9. Response time (HTTP GET) - results

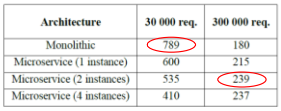
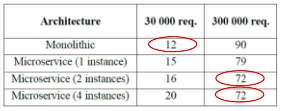
TABLE I. ARCHTECTURE PERFORMANCE – HTTP GET



Architecture	30 000 req.	300 000 req.
Monolithic	789	180
Microservice (1 instance)	600	215
Microservice (2 instances)	535	239
Microservice (4 instances)	410	237

TABLE II. RESPONSE TIME – HTTP GET



Architecture	30 000 req.	300 000 req.
Monolithic	12	90
Microservice (1 instance)	15	79
Microservice (2 instances)	16	72
Microservice (4 instances)	20	72

Fig. 3. Performance test from [15].

Performance under lower load: The tests showed that monolithic architectures work more efficiently under lower load. This is because monolithic architectures combine all components and functions into a single, integrated application. This tight integration enables optimised use of resources and minimal communication latency between components. With low user numbers and few requests, the monolithic architecture is therefore able to deliver stable and fast response times. The reduced complexity and the lack of communication effort between distributed services contribute to greater efficiency under low load.

Performance at higher loads: As the load increases, however, the results change in favour of the microservice architecture. The tests showed that microservices scale better at higher loads and therefore achieve better performance results. In scenarios with increasing numbers of users and requests, the microservice architecture was able to handle the load more efficiently thanks to horizontal scaling. This means that additional instances of the individual microservices were provided to meet the increased demand. Of particular note is the use of replication, where multiple copies of a microservice are operated simultaneously to evenly distribute the load and increase availability. This ability to scale flexibly and on demand leads to improved performance under high load compared to monolithic systems. Fig. 4 shows the performance tests.

Monolithic architectures can therefore be more efficient at low loads, while microservice architectures show their strengths at high loads and scalability. The choice of architecture should therefore be based on the specific load requirements and the expected usage patterns.

B. *Case Study II: Scalability and Reliability*

The scalability and reliability of an application are critical factors for its performance and usability. This case study highlights the differences between horizontal and vertical scaling and shows how the choice of scaling strategy influences the scalability and reliability of the application.

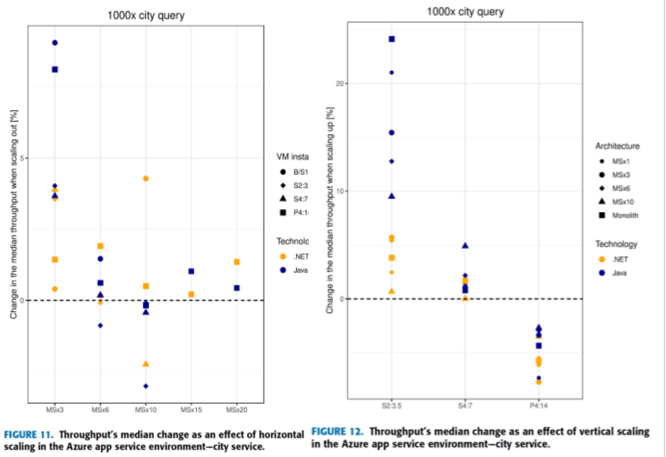


Fig. 4. Performance test from [16].

Horizontal scaling: With horizontal scaling, also known as "scaling out", additional instances of a service are added to cope with the load. This method is particularly suitable for applications with a high load and the need for flexible scalability. Horizontal scaling involves running multiple copies of the service in parallel, which distributes the load evenly. This not only improves performance, but also increases fault tolerance, as the failure of one instance can be compensated for by the other instances. An example of this could be a web server that is supported by additional server instances when data traffic increases in order to distribute requests efficiently and minimise response times.

Vertical scaling: Vertical scaling, also known as "upscaling", involves adding additional resources to a single instance of a service, e.g. more CPU, RAM or storage space. This method is better suited to low to medium load applications where requirements can be met by upgrading existing hardware. Vertical scaling can be easier to implement as no changes to the software architecture are required. However, it comes up against physical and economic limits, as the performance of a single instance cannot be increased indefinitely. A typical example would be a database that is scaled by adding more memory and more powerful processors to enable the processing of larger amounts of data.

C. *Decision Criteria for the Scaling Strategy*

The decision between horizontal and vertical scaling depends on various factors, including the specific requirements of the application, the expected load patterns and the existing infrastructure. Horizontal scaling offers more flexibility and higher fault tolerance, but is more complex to implement and manage. Vertical scaling is easier to implement, but has limited scalability and can reach its limits with very high loads.

Horizontal scaling may therefore be ideal for applications with high loads and flexible scaling requirements, while vertical scaling may be suitable for applications with moderate loads and specific hardware requirements. The decision in favour of one or the other strategy should be carefully weighed up based on the individual requirements and objectives of the application [15].

VII. Results and Best Practices

The scientific literature and documented case studies, for example on the performance of monolithic and microservices architectures, which this article provides an overview of, are diverse. What has been missing so far is a best-practice approach that generically describes how to proceed with a monolithic application landscape in order to achieve a decentralised and resilient microservices architecture - in other words, a kind of "recipe". This is proposed in this article and inductively derived from the existing articles cited above, consolidated and outlined below.

Migrating from monolithic systems to a microservice architecture is a strategically challenging task that requires not only technical expertise, but also careful planning and implementation. There is no "best-of-breed" approach because, as described above, the procedural and technological complexity of application architectures in companies is individual.

However, reference can be made to examples from which a generic migration path can be derived. Based on the case studies analysed above and the scientific work, the author recommends the following best practice derived from case studies and thus a strategy for the analysis and implementation of microservice architectures.

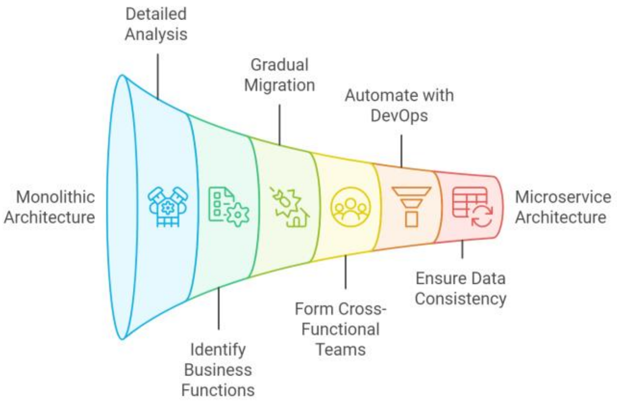

Fig. 5. Migration from monolithic to microservices.

1) Detailed analysis of the existing architecture: A thorough analysis of the existing monolithic architecture is an important first step on the way to a successful migration to a microservice architecture (see Fig. 5). Without a deep understanding of the current components, their dependencies and interactions, splitting them into microservices can lead to unforeseen complications. The migration process should therefore begin with a comprehensive analysis of both the system architecture and the underlying code. Two primary approaches play a central role in this analysis: static and dynamic analysis.

Static analysis: In static analysis, the source code is analysed to determine the dependencies between individual modules and their relationships. This method helps to map the existing structure of the monolith and visualise the connections between the components. The tools used for static code analysis can create dependency diagrams that provide a clear overview of how the system works as a whole. These insights are crucial for identifying potential microservices and ensuring that the modularisation of the system is effective and sustainable [10].

Dynamic analysis: While static analysis focuses on the structure, dynamic analysis captures the behaviour of the application during runtime. Monitoring the real-time behaviour of the system allows engineers to understand usage patterns and critical business processes supported by specific modules. This method provides insight into performance bottlenecks and areas of the system in need of optimisation, which can inform which components should be prioritised for migration into standalone microservices.

Example: Amazon carried out a comprehensive analysis of its monolithic architecture before switching to a microservice architecture. Critical areas such as the product catalogue and the payment system were identified and spun off as independent microservices, which significantly improved the scalability of the system [13].

2) Identification and delimitation of business functions: Decomposing a monolithic system into well-defined business functions is essential for creating clear service boundaries when migrating to microservices. The domain-driven design approach ensures that each microservice corresponds to a logical business domain, resulting in loosely coupled services that can operate independently.

DDD: DDD is a methodological approach that focuses on mastering complexity by modelling business domains. A key concept in DDD is the "bounded context", which delineates a specific area within a business domain where a consistent model is applied. Defining these bounded contexts ensures that microservices have clear responsibilities, reducing interdependencies and simplifying development, maintenance and scaling.

Example: Netflix used DDD to separate user management from its video streaming service. This logical separation enabled independent development and provision of functions and minimised the risk of system-wide failures [13].

3) Gradual migration and minimisation of risks: A phased or step-by-step migration strategy is critical to minimising the risks associated with the transition from a monolithic architecture to microservices. A "big bang" migration - where the entire system is migrated at once - can lead to serious system failures and business disruption. Instead, migrating smaller, less critical components initially allows for a smoother and safer transition.

Step-by-step migration strategy: The aim of a step-by-step migration is to divide the migration process into smaller steps so that individual components of the monolith can be migrated gradually. This approach allows each microservice to be thoroughly tested to ensure that it works independently and integrates smoothly with the remaining monolith. By prioritising low-risk areas, companies can significantly reduce the likelihood of critical failures during migration [12].

Example: Spotify opted for a step-by-step migration by first converting its playlist management system to a microservice. This approach enabled the company to tackle problems in isolation and minimise the risk of widespread outages [5].

4) Formation of cross-functional teams: In addition to the technical changes, the migration to microservices also requires organisational restructuring. The formation of cross-functional teams is essential for the efficient development and maintenance of microservices. These teams consist of employees from different disciplines - development, operations and quality assurance - who work together to provide services more effectively.

Autonomous teams: Each cross-functional team has full responsibility for one or more microservices and works independently within the scope of the services assigned to it. This autonomy enables the teams to develop, deliver and optimise their services without being dependent on other teams, which increases productivity and flexibility within the company.

Example: Uber formed cross-functional teams that were responsible for individual microservices, such as route calculation. These teams worked independently of each other, which enabled faster adaptation to changes in the business model or technology, which significantly improved productivity [12].

5) Automate with DevOps practices: Automation plays a central role in the successful provision and management of microservices. Continuous Integration (CI) and Continuous Delivery (CD) are two key DevOps practices that ensure reliable and rapid delivery of microservices. CI/CD pipelines automate the processes of testing, building and deploying software, enabling faster releases and greater system stability.

DevOps practice: DevOps emphasises collaboration between development and operations teams to ensure continuous improvement of both development and deployment processes. By automating testing and deployment, human error is minimised, allowing teams to release frequent, smaller updates that improve the quality and reliability of the overall system.

Example: Facebook implemented CI/CD pipelines to provide several microservices every day. This enabled faster releases and greater agility in the development process [13].

6) Consideration of data consistency and error tolerance: Ensuring data consistency in distributed systems is one of the biggest challenges in microservice architectures (see Fig. 6). In a microservice system, each service often manages its own database, which can make consistency across the entire system difficult. Two important techniques for overcoming this challenge are event sourcing and the saga pattern.

Event sourcing: With event sourcing, the state of the application is saved as a sequence of events that change this state instead of saving the current state directly in the database. These events are stored in an event log that can be replayed as required to reconstruct the current state. This ensures that all changes are traceable and recoverable and that data consistency is maintained across distributed systems.

Saga pattern: The Saga pattern enables the decomposition of long transactions into smaller, atomic transactions that can be managed by individual microservices. Each transaction is designed to either complete or roll back in the event of an error, ensuring that all services involved either reach a consistent state or return to their previous state, thereby avoiding inconsistencies.

Example: Airbnb uses the Saga pattern to coordinate transactions such as bookings across multiple microservices. This pattern ensures that the system remains consistent even if errors occur in individual services [3].

7) Summary of the 6 phases: Successful migration from a monolithic to a microservice architecture requires a strategic, well-planned approach that takes both technical and organisational aspects into account.

Firstly, a thorough analysis of the existing system is crucial. Using static and dynamic analysis techniques ensures a comprehensive understanding of component dependencies and enables informed decisions on how to split the monolith into manageable microservices. Once the architecture is understood, it is important to identify and delineate the business functions using approaches such as DDD. This ensures that the microservices are aligned with the logical business domains, resulting in clear boundaries, reduced dependencies and more effective scaling. To minimise risks, a step-by-step migration strategy is recommended. Gradually migrating smaller, low-risk components allows for testing and optimisation, reducing the likelihood of critical errors and ensuring a smooth transition. On the organisational side, the formation of cross-functional teams is essential. These teams, made up of experts from development, operations and quality assurance, should be able to manage individual microservices independently to increase both productivity and flexibility. Automating processes through DevOps practices, particularly CI and CD, ensures that microservices are deployed efficiently and reliably. Automation minimises human error and speeds up the development cycle, allowing for frequent, smaller updates. Finally, ensuring data consistency and fault tolerance in distributed systems is a major challenge that can be addressed with techniques such as event sourcing and the Saga pattern. These methods help maintain consistent states and handle failures gracefully to ensure system reliability and robustness.

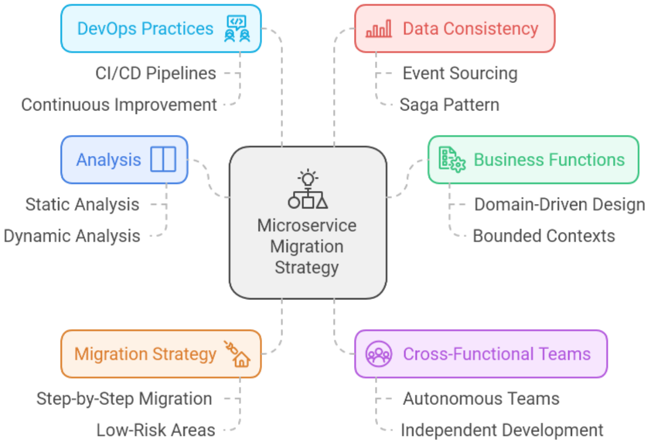

Fig. 6. Challenges and best practices in migrating from a monolithic to a microservice architecture.

If companies follow these best practices an included recommendations, they can minimise the risks of switching to microservices and at the same time benefit from the advantages of a scalable, flexible and resilient system architecture.

VIII. Discussion

A. Data Consistency and Management of Distributed Data

Microservice architecture's distributed nature enables greater flexibility in data management, allowing each service to optimize its data storage based on specific requirements. However, maintaining data consistency across distributed services presents significant challenges. Techniques like event sourcing and the Saga pattern are often employed to ensure synchronized, up-to-date transactions across services. While effective, these methods increase the complexity of system architecture, adding to operational overhead and necessitating advanced technical knowledge [3]. This complexity may not always justify the benefits for smaller organisations or systems with lower scalability needs, where a monolithic approach could be more practical [6].

B. Trade-offs Between Microservices and Traditional Architectures

Microservices offer clear advantages in scalability and fault tolerance, but there are notable trade-offs. For example, smaller organisations may struggle with the overhead of managing numerous independent services, APIs, and maintaining data consistency. Monolithic architectures, by contrast, can offer faster development cycles and simpler management, especially in smaller applications that don't require significant scalability [6]. As discussed by [12], the benefits of microservices tend to emerge in large-scale environments where scalability is critical. Thus, the decision to adopt microservices should be weighed against the organisation's size, technical capabilities, and future growth plans [7].

C. API Management and Overheads

While microservices communicate through APIs, promoting modular design and interoperability, the management of multiple APIs can become a burden as systems grow. This issue, often termed API proliferation, can increase operational complexity and management costs [5]. Solutions like API gateways and service meshes help centralize API management and streamline communication, providing advanced features such as load balancing and security. However, these tools also introduce new layers of infrastructure, which may pose challenges for smaller organisations without the technical resources to maintain them [10].

D. Testing Strategies for Microservices

One advantage of microservices is their ability to support isolated unit testing, reducing the risk of system-wide failures [18] [20]. Automated testing tools can efficiently validate microservices before deployment. However, ensuring that multiple microservices function as a cohesive system requires extensive integration testing, which can slow deployment cycles and increase operational complexity. As emphasized, integration testing in microservices introduces an additional layer of complexity not present in monolithic systems [17].

E. Increased Focus on Emerging Trends

Technologies like Kubernetes, AIOps, and serverless computing are shaping the future of microservices by offering advanced automation and orchestration capabilities. Kubernetes, for instance, simplifies the management of microservices by providing container orchestration tools for scaling and fault tolerance [18]. However, Kubernetes' complexity often requires specialised expertise, making it more suitable for larger enterprises. AIOps—which integrates machine learning to predict system failures and optimize performance—offers significant potential for improving microservice reliability, but also introduces additional complexity [19]. As pointed out, the success of these technologies depends on how well organisations can manage this complexity [8].

F. Linking Case Studies More Critically

The adoption of microservices by companies like Netflix, Amazon, and Uber has been widely documented, but the unique contexts that facilitated their success must be critically evaluated [6]. For example, Netflix's need for high reliability in streaming services and Amazon's demand for rapid scalability due to their e-commerce platform both necessitated the use of microservices [13]. However, smaller companies, or those in industries with lower scalability needs, may not experience the same benefits. Case studies of large companies should therefore be viewed with caution when attempting to generalise these strategies to smaller firms [5].

G. Potential Gaps in Existing Research

Although microservices have been widely adopted across various sectors, there remain gaps in research concerning their implementation in highly regulated industries like fintech and healthcare, where data security and regulatory compliance are crucial [11]. These industries face challenges in adopting decentralised architectures due to the need for strict data governance. More research is needed to explore how microservice best practices can be adapted for these sectors. Moreover, there is limited empirical data evaluating the long-term performance of microservices in such contexts [16].

H. More Quantitative Evaluation

Empirical studies have shown that monolithic systems tend to perform more efficiently under lower loads, while microservice architectures excel at higher loads, thanks to their ability to scale horizontally. Quantitative data on resource utilization, fault tolerance, and operational costs would provide a stronger foundation for decision-making when comparing these architectures [15]. For instance, valuable insights into the performance benefits of microservices under varying conditions is provided [16].

I. Critical Look at Migration Strategies

A phased migration approach, where organisations gradually transition from monolithic to microservice architectures, is often recommended to mitigate risks [7]. This approach allows for continuous testing and ensures that each microservice functions independently before migrating the entire system. However, this can also extend the migration [21] process and lead to technical debt, as both systems must be maintained during the transition. In some cases, a "big bang" migration, where the entire system is migrated at once, might be more efficient, especially for smaller systems [5]. Organisations must carefully assess their specific needs, technical capacity, and risk tolerance before deciding on the best migration strategy [10].

IX. Conclusion

To summarise, the evolution from monolithic to service-oriented and finally to microservice architectures represents a significant advance in the development and maintenance of modern software applications. Microservice architectures address many of the challenges associated with traditional monolithic systems and service-oriented architectures and offer significant improvements in flexibility, scalability and fault tolerance. By splitting complex applications into independent, loosely coupled services, microservices enable organisations to better respond to changing business requirements and optimise resource utilisation. As highlighted in the best practices and recommendations, the key benefits of microservices include their modular structure, which enables independent development, deployment and scalability. This modular approach allows organisations to scale services based on specific requirements without impacting the overall system.

However, data consistency and Application Programming Interface (API) management remain a major challenge and require sophisticated strategies such as event sourcing and the Saga pattern to maintain synchronisation across distributed systems.

The recommended step-by-step migration strategy helps to minimise the risks associated with the transition from monolithic systems to microservices. This step-by-step approach, together with cross-functional teams, ensures a smoother migration process and promotes collaboration between development, operations and quality assurance. In addition, the adoption of DevOps practices such as CI and CD increases the efficiency and reliability of microservice delivery, even though this requires a high level of technical maturity. While the benefits of microservices are obvious, the increased complexity and operational overhead created by their distributed nature, as well as the need for advanced skills in DevOps and container orchestration, present challenges that must be carefully managed. However, the integration of new technologies such as AIOps, Kubernetes and serverless computing increases the potential of microservice architectures and positions them as the dominant model for scalable, flexible and resilient software systems in the future.

Companies that strategically apply these best practices and recommendations will be better equipped to overcome the challenges of microservice architectures while maximising the benefits of scalability, flexibility and fault tolerance in their IT infrastructures.

College of Health and Human Services, University of North Carolina Wilmington, United States[2]

***Abstract*—Geographically-distributed wide-area networks (WANs) offer expansive distributed and parallel computing capabilities. This includes the ability to advance Wide-Area Big Data (WABD). As data streaming traverses foreign networks, intrusion detection systems (IDSs) and intrusion prevention systems (IDSs) play an important role in securing information. The authors anticipate that securing WAN network topology with IDSs/IPSs can significantly impact wide-area data streaming performance. In this paper, the researchers develop and implement a geographically distributed big data streaming application using the Python programming language to benchmark IDS/IPS placement in hub-and-spoke, custom-mesh, and full-mesh network topologies. The results of the experiments illustrate that custom-mesh WANs allow IDS/IPS placements that maximize data stream packet transfers while reducing overall WAN latency. Hub-and-spoke network topology produces the lowest combined WAN latency over competing network designs but at the cost of single points of failure within the network. IDS/IPS placement in full-mesh designs is less efficient than custom-mesh yet offers the greatest opportunity for highly available data streams. Testing is limited by specific big data systems, WAN topologies, and IDS/IPS technology.**

***Keywords*—Information security; network topology; wide-area big data; wide-area networks; wide-area streaming**

I. INTRODUCTION

Increasingly, organizations must collect large amounts of data that is located in physically distanced data centers. Geographically-distributed big data server clusters provide massive scale data analytic capabilities across wide-area networks (WANs). Several big data frameworks in use at the time of this writing such as Apache Spark are deployed within single data centers [1]. However, big data clusters that run in local area networks (LANs) do not necessarily have the same challenges as WANs. For instance, LANs have certain advantages like bandwidth, shorter distance routing, and highly available communication at cheaper costs. LANs also have limitations spanning from local resources to global connectivity [2].

WANs enlarge the capabilities of LANs, offering expansive resources and connectivity for geo-distributed data streaming. For instance, WANalytics research is investigating how to optimize distributed structured query language (SQL) queries across WANs [3]. Subsequently, unsupervised machine learning provides several possibilities to enhance geo-distributed data streaming. For example, a sliding version of the hidden Markov model (SlidHMM) improves bottleneck detection in WAN data analytics [4]. Despite the latter progress, a survey on geo-distributed frameworks found that research is lacking in several areas. This includes decentralized architecture, data streaming, multi-clusters, information security, and privacy [1]. The objective of this work is to investigate the role of information security in geo-distributed big data analytic framework literature and provide subsequent steps toward securing this infrastructure in future research.

Organization of the paper is as follows. The authors perform a review of literature on the influence of information security on geographically-distributed big data systems in Section II. A methodology develops from the review that identifies procedures to test the performance of secured WAN topologies in Section III. The results of the testing and a discussion are given in Section IV and Section V respectively. Finally, Section VI concludes the study.

II. RELATED WORK

To better understand big data frameworks and their geographically-distributed contributions, Bergui [1] performed a survey of existing literature. A theme in progression centers around optimizing big data systems for the ever-increasing changes in network topology. Tuning these systems for WANs is complex, yet not always clear in existing literature. For example, in [1], bandwidth-aware systems do not always use resource managers like yet another resource negotiator (YARN) with specific WAN tuning capabilities. The researchers also emphasize further work is necessary to study information security and system architectures in geo-distributed big data systems. Trust models become more complex when distributing data between different governments. Researchers encourage designing authentication strategies and decentralized architecture frameworks capable of supporting more complex geo-distributed clusters [1].

To better understand research that helps optimize big data systems, the writers review data querying, transfer, placement, and their environments, which includes network topology.

A. Querying Data

Research on optimal geo-distributed computing architectures is ongoing. In study [3], the researchers introduce the term WANalytics, which they contrast with Wide-Area Big Data (WABD). WABD typically copies data from multiple data centers to a single data center where data analytics transpire. WANalytics is designed to support massive scale geo-distributed analytics across multiple data centers. Its goal focuses on reducing expensive WAN bandwidth while maintaining compatibility with data sovereignty restrictions [3].

Initial experimentations demonstrate that WANalytics can reduce data transfer costs by as much as 360 times compared to centralized data center methods. This occurs by allowing users to test SQL queries between data centers in Europe, North America, and South-East Asia. While WANalytics shows tremendous progress toward optimizing geo-distributed computing architectures, information security appears to be distant in this literature [3].

Demand for wide-area data analytics enforces the need to advance the capabilities of geo-distributed big data systems. For instance, Wang and Li [4] propose the Lube system framework to monitor, detect, and resolve bottlenecks in in geo-distributed data analytic queries. Benchmarks show optimizing scheduling policies across distributed data centers can lower query response times up to 33 percent when compared to other big data systems like Apache Spark. Similar to Lube [4], Turbo [5] has the ability to improve geo-distributed data analytics queries at runtime. Using machine learning, Turbo optimizes data analytic query execution plans across multiple physically distanced data centers. In a geo-distributed Google Cloud environment that spanned eight regions, Turbo lowered query completion times by 41% [5].

In study [6], the authors focus on common executions in wide-area network streaming analytics queries. Examples of common execution elements include shared data processing and input data. While improvements are achievable using common query executions in streaming analytics, researchers emphasize that without WAN awareness, weaker performance can exist in geo-distributed data center communications. WAN-aware multi-query optimizations that leverage common executions can reduce WAN bandwidth as much as 33% in contrast to systems that fail to use shared execution components. Therefore, multi-query efficiency may have some dependency on WAN-awareness [6]. Despite the advancements of wide-area data analytics in geo-distributed analytics, many questions remain. Researchers in [1] note that further work is beneficial to address variations in the structure of data, determine the optimal features to reduce query completion times, and construct a larger range of performance metrics to measure bottlenecks. Another complementary vein of research focuses on bulk data transfer.

B. Bulk Data Transfer

Transferring bulk data within inter-datacenter networks requires efficient strategies to reduce associated costs. Multimedia big data such as video streams and gaming content, compete for leftover bandwidth in backbone transport networks that connect geographically-distributed data centers. However, the exponential increase of data transfer these services need can degrade backbone networks [7]. Though certain algorithms can efficiently manage guaranteed traffic and reassignment [8], it is well understood that middleware and control plane protocols are amongst several layers of the architecture that require greater attention in research [9]. As one example of progress toward the latter goal, software defined networking (SDN) helps dissociate the control plane from data paths. This leads to more dynamic adjustment of data routing as network environmental attributes change [10].

Particularly when sending bulk data transfers between geo-distributed data centers, researchers in study [10] highlight three primary services. This includes 1) task admission control, 2) data routing, and 3) store-and-forward. Task admission control rejects or accepts network transfer requests based upon whether they can be completed by a specified deadline. Data routing must choose the best path data should take to reach its destination, which can include rerouting through intermediate data centers. The concept of store-and-forward decides whether it is more efficient to store data temporarily within intermediate data centers and forward it at a more optimal time than the immediate time of execution. If so, decisions must be made to determine where the data is temporarily stored until it reaches its destination [10].

C. Data Placement

Subsequent focus on efficiently distributing data between data centers are algorithms that calculate cloud service provider (CSP) costs [11]. Certain data sent between CSPs can tolerate delays, which can be transferred using store-and-forward intermedia storage nodes with off-peak internet service provider (ISP) bandwidth that is already financed [12]. Multi-rate bandwidth on-demand (BoD) brokers employ scheduling algorithms to optimize the use of this residual bandwidth. As an example, the BoD broker in study [6] uses standby wavelengths within the wavelength division multiplexing (DWDM) layer to decrease peak network bandwidth. Adjustments are possible based on delay-intolerant and delay-tolerant transfer requests. Compared to relational algorithms like First-Come-First-Served (FCFS), more precise use of time slots in all wavelengths is optimal when peak bandwidth results in delayed or blocked requests [7].

When inter-datacenter networks are congested, certain storage decisions can help reduce additional network load. This includes the use of intermedia storage (IS) and edge storage (ES). ES allows certain types of jobs like bulk data transfers to leverage storage at the edge of network domains and forward it during periods of off-peak CSP bandwidth. In study [13], as network load increases there is a linear decrease in the success of bulk transfers. Bulk data transfers are optimal when the allowed wait time is twice the aggregated network load. In summary, the authors found that ES and IS perform similar when peak bandwidth times are small. Medium or less network load results in little difference between ES and IS. However, in this research IS performed significantly better than ES in times of high network load [13].

Research on bulk data transfer across low latency or congested links is helping advance several needs including scheduling optimization [9], bandwidth costs [11], and delay tolerance [12]. In reviewing related literature, information security is not a central component of big data transfers between geo-distributed cloud data centers [7, 10], inter-datacenter bulk transfers [11, 13], or research networks [8]. Additionally, while certain testing considers differences in specific network topology [7, 10] others do not [8, 12]. Therefore, opportunities may exist to study the influence of information security and network topology on bulk data transfers in low latency network environments. To explore this further, the authors turn to the role of network topology and geo-distributed big data systems.

D. Network Topology

Network topology influences several dimensions of geo-distributed big data systems, including the elasticity of nodes in a cluster [12]. A challenge of big data streaming is resource provisioning across shared cloud infrastructure. Particularly when the cloud tenant does not own infrastructure, it can be challenging to decipher the cause of poor performance on collective physical hardware that runs virtual machines (VMs). In study [14], the authors highlight the need for the dynamic rescheduling of big data streaming tasks using multitenant-aware resource provisioning that is independent of the VM hypervisor. Software defined networking (SDN) plays an impactful role in this provisioning by supporting load balancing between cloud-based VM clusters. In contrast to other network topologies, SDN can define its topology in real time. This in turn allows for additional cloud node elasticity [14]. In study [12], researchers focus on optimizing bulk data transfer in a geo-distributed data center system using SDN architecture. SDN elasticity promotes dynamic routing decisions using bulk data transfers in pieces in contrast to handling transfers as endless flows [12].

Like [13], researchers in study [15] highlight a need to optimize big data streaming strategies between geo-distributed data centers. The authors note that traditional methods for distributed data streaming such as task assignment are insufficient when high throughput data exists along with low latency WAN links [15]. Researchers also emphasize the need to perform data mining on data sent between WANs from streaming applications that perform user-clicks, social networks, and Internet of Things (IoT) hardware [16]. A proposed advancement is an SDN-based resource provisioning framework capable of monitoring WANs, identifying an optimal selection of big data worker nodes, and more efficiently assigning tasks to the chosen nodes. In initial tests, SDN resource provisioning results in minimal processing time that is 1.64 times faster on the tested environment, which included Apache Flink, Apache Spark, and Apache Storm [15].

One of the challenges of geo-distributed and wide-area network data analytics streaming is identifying performance problems when infrastructure is not under the control of the customer. Multitenant-aware resource provisioning using SDN network topology is a proposed solution when cloud computing hardware is shared amongst multiple customers [14]. Monitoring and increasing performance of multitenant streaming analytics also requires more advanced worker node and IoT placement strategies in low latency network topology. Streaming platforms like S4, Apache Storm, and Apache Spark were not initially designed for low latency analytics shared between users and applications in distributed IoT systems. However, improvements are being made in the streaming platforms. For instance, Apache Spark supports structured streaming via PySpark, a Python API. Spark streaming has the capability to stream data in micro-batches [1]. In study [16], the GeeLytics platform is introduced as an alternative streaming platform to address low latency networks. This includes more dynamic mechanisms to balance real-time streaming in the cloud and network edges. The proposed design is expected to reduce edge-to-cloud bandwidth use for IoT data analytics. It is also engineered to increase customer insight into multi-tenancy system efficiency [16].

Proposed in study [17], a worker node placement framework focuses on wide-area streaming analytics. It builds upon the Simple Additive Weighting (SAW) method. In this model, a central global manager determines how tasks are assigned across multiple edge data centers using a proposed SAW-based Node Ranking (SNR) algorithm. Task slots are determined based upon the amount of input data and processing power of each slot. Additionally, task slots communicate over the WANs links. This allows the global manager to maintain the status of key link metrics including cost, delay, and bandwidth as well as identify network topology changes. Researchers tested the SNR algorithm on Apache Flink, Apache Spark, and Apache Storm using small, medium, and large graphs to simulate different network sizes. Each big data system shows performance improvements compared to other worker node placement strategies [17].

WAN traffic costs are central to several recent advancements in geo-distributed streaming analytics research. Costs are influenced by network design. For instance, the hub-and-spoke design includes several network edges that interconnect via WANs to a central data warehouse. Popular streaming analytics service providers use this model at the time of this writing [18]. Important to this network model is determining the optimal amount of computation that should exist at the center of the topology or the edge. Based on the hub-and-spoke network topology, researchers have identified staleness or the delay in retrieving data results and WAN traffic as pivotal metrics. Experiments using common analytics from large CDNs highlight the need to minimize both latter metrics [18].

AggNet is a subsequent advancement in research focused on reducing WAN traffic costs. Developed on the Apache Flink framework, AggNet [19] reduces WAN bandwidth by aggregating a percentage of real-time data analytics closer to the location of end users. Aggregation from AggNet implementation has shown 47% to 83% decreases in traffic costs when compared to traditional costs from relevant industry organizations that included Akamai and Twitter [19].

Although the hub-and-spoke network model is a cornerstone in recent geo-distributed streaming analytics work [18-19], researchers understand current network topology must change to meet the future needs of big data analytics. In study [20], researchers argue that high communication cost, data sovereignty, and data privacy challenge the feasibility of central data center designs. Proposing the concept of geo-distributed machine learning (Geo-DML), parameter server (PS) placement remains a challenge for distributing raw machine learning data between WANs. A proposed solution is using approximation algorithms capable of selecting the optimal data center for training using network cost. Results of using this strategy reduce communication cost up to 21.78% over other Internet network topology. However, the potential effect of IDS/IPS hardware is unknown [20].

E. Summary

Several advancements are occurring that improve geo-distributed big data systems. AggNet helps reduce WAN traffic by placing data closer to end users [19]. In study [18], researchers develop a hybrid online algorithm to determine optimal computation at the network edges versus the center in a hub-and-spoke WAN model. In small to large network topology, the SNR algorithm shows capability to optimize tasks across geo-distributed data centers using the simple-additive weighting method [17]. Subsequently, an approximation algorithm finds the best data center as the parameter server for machine learning training on two network topologies, which included a Google private WAN and a United States Internet with nine interconnected data centers [20]. Like research on bulk data transfer between geo-distributed data centers, little emphasis exists on information security in these papers [17-20]. Additionally, network topologies are limited to only a few different types of WANs [20] as well as traditional hub-and-spoke designs [18]. SDN-based networks also show promise in helping optimize resource provisioning but may need additional consideration as they gain more traction in geo-distributed WAN analytics [14].

The research that follows presents an elementary investigation into whether IDS/IPS placement impact the performance of big data systems operating between low-latency network topologies.

III. Methodology

The research design follows the information systems research framework outlined in study [21]. Three pillars of the framework include the environment, information systems research, and the coinciding knowledge base. Within the environment stage of the latter research methodology, this paper focuses on building modern IT infrastructure to support massive-scale data analytics. Subsequently, the research stage focuses on WAN simulations to evaluate supporting network topology for capable big data systems. The researchers add to the existing knowledge base by reporting on the effects of IDS/IPS placement on real-time data streaming systems in network topologies able to migrate into modern SDN-enabled WANs.

Following the design science methodology, business needs are the driver for building new information system artefacts [21]. Wide-area data analytics is gaining traction due to the increased need for businesses to analyze real-time data streams in multiple physical locations [6]. Notably, big data systems in geo-distributed data centers provide immense opportunity to support streaming massive amounts of data on low-latency WAN connections. Provisioning resources across modern SDN WAN architectures, provides big data systems like Apache Spark with more expansive horizontal scalable than centralized data centers [15]. To support the growing business need for geo-distributed streaming, the researchers design and implement current WAN topologies capable of efficiently and securely connecting physically distanced big data systems.

Investigators design and implement three well recognized Software-defined-wide area network (SD-WAN) arbitrary topologies outlined by study [22], including hub-and-spoke, full-mesh, and custom-mesh. Each are implemented across ISP leased lines. The applied network topology uses the specifications engineered by Cisco Systems in their Cisco Extended Enterprise SD-WAN Design Guide. These are located in Fig. 7 Hub-and-Spoke Topology with Cisco IR1101 and Fig. 8 Mesh Topology with Cisco IR1101 and SD-WAN in study [23].

A. Experimental Network

The experimental Cisco Systems network resides in an enterprise-class data center. Within the research network, the authors design and implement wide area network (WAN) data centers in four major United States cities. The central data center is located in New York, New York. From the New York data center, WAN links connect to data centers via routers in the cities of Orlando, Florida, Los Angeles, California, and Seattle, Washington. Router placement and configuration for each WAN parallel Cisco IR1101 and SD-WAN in [23]. WAN network latency between the latter data centers equals averages, at the time of this writing, in milliseconds (MS) published by AT&T in study [24]. The full-mesh network topology, which includes network latency for all WAN links, is outlined in Fig. 1.

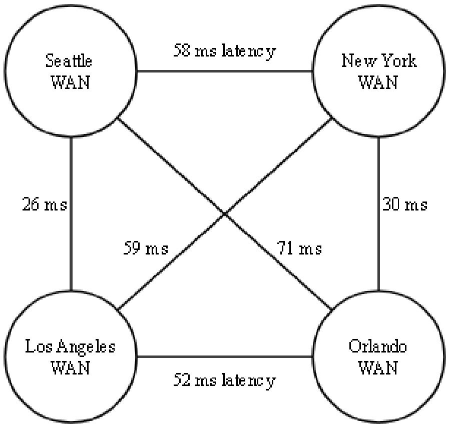

Fig. 1. WAN network latency.

B. Big Data System Architecture

The experimental environment includes four big data server clusters in each data center. Clusters are connected by the WANs and secured by intrusion detection systems (IDSs) and intrusion prevention systems (IPSs). All server and router hardware are the same make and model. Hardware has precisely the same specifications including physical CPUs, memory, and solid state disks. Each data center houses a Dell PowerEdge server running an updated Microsoft Hyper-V Server 2019. Virtual machines hosted in Hyper-V consist of Intel Xeon processors with five physical CPU cores and 24 gigabytes of memory.

Fig. 2 shows the big data system architecture for cluster one (C1) connected to the New York WAN. Each of the four system clusters parallel this architecture. The clusters consist of six big data system VMs running the Ubuntu 22.04 Long Term Support (LTS) server operating system. Two VMs are dedicated Apache Hadoop name nodes. The primary and secondary name nodes connect to four data nodes with a replication factor of three. Data nodes are configured as both Apache Hadoop and Apache Spark worker nodes. Name nodes connect to the WAN through a router and an IDS/IPS. The WAN routers at each site also have one external facing Dell PowerEdge server with 5 physical CPU cores and 24 gigabytes of memory. The latter WAN-connected Ubuntu 22.04 LTS servers measure and collect performance data between the geo-distributed data centers. The edge servers are also the source of all external data streams sent to the big data clusters. Table I shows the corresponding software and versions of the big data systems.

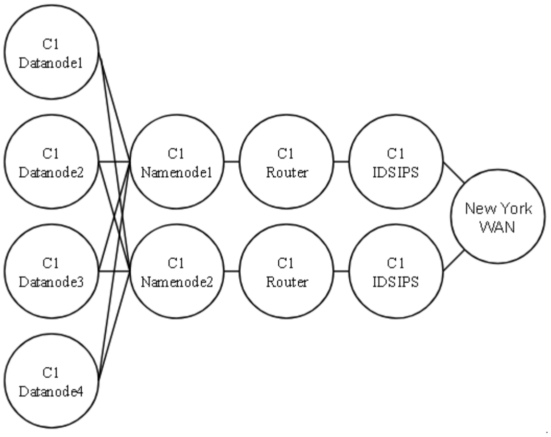

Fig. 2. Cluster architecture.

Experiments use Suricata for the intrusion detection system (IDS) and intrusion prevention system (IPS). Suricata is well supported by the open-source community as a modern world-class IDS/IPS [25]. It allows researchers to customize packet bundling techniques to analyze stream data sets efficiently and effectively [26]. Suricata is compiled with the emerging threats open ruleset [25]. Specific Suricata rules allow the unique public IP addresses of the streaming clients to connect to a primary and secondary name node in each data center cluster. Streams and associated IPS rules use the customized TCP port range of 9990 – 9999 on each big data cluster. With the exception of the experimental data streams and SSH for system administrator IP addresses, no other external traffic is allowed into the data center networks by the IDSs/IPSs.

TABLE I. EXPERIMENTAL SOFTWARE VERSIONS

Software	Version
Hadoop	3.3.6
Iptables	1.8.7
Nmon	16
OpenJDK	8u412
Pdsh	2.31-3
Pyspark	3.5.1
Python	3.10.12
Spark	3.5.1
Suricata	6.0.4
Tcpdump	4.99.1
Ubuntu	22.04.4

C. Streaming Architecture

Within the big data system architecture, the primary and secondary name nodes are configured as Apache Spark streaming servers. Fig. 3 outlines the big data streaming architecture. From an Ubuntu server on each WAN, 1 GB streams are sent to the primary and secondary name nodes. To process the data streams the authors developed a big data streaming application using Apache PySpark. The application facilitates the unstructured data streams to Apache Spark on the primary and secondary name nodes. It uses the Spark context object and PySpark streaming class instudy [27] to develop the streaming functions. Each application instance processes word counts on the data streams. Word counts are aggregated using key value pairs using Spark in-memory computation and subsequently written across the Hadoop Distributed File System (HDFS) for long-term data analytics. HDFS block sizes are configured for 128 MBs.

D. Benchmarking Technologies

Simulation is one of several methods in the design science research framework [21] that helps assess and refine novel artifacts. Central to this work is determining how modern IDS/IPS placements impact the performance of geo-distributed big data system clusters. The researchers use raw network performance statistics between connecting WANs to evaluate real-time data streams. In study [28] researchers evaluate raw network performance using httping and iperf3 on anonymous circuit-based communications. The networking utilities were able to effectively measure the average latency and throughput between hubs in a metropolitan area. Iperf3 is also used in WAN environments to test network capacity. Researchers investigated the transfer of science big data across WANs in study [29] using NVMe over Fabrics (NVMe-oF). NVMe-oF is able to provide enhanced non-volatile memory functionality for storage networking fabrics. Methods in the study successfully use iperf3 to test for bottlenecks in the networks [29].

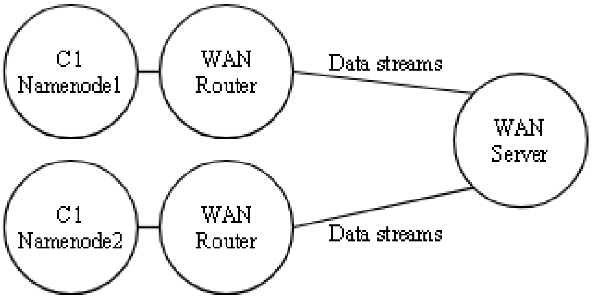

Fig. 3. Streaming architecture.

Like [29] iperf3 measures latency between the geo-distributed data centers in this study. In Fig. 2, iperf3 resides on the name node servers, IDS/IPS servers, and the WAN servers. Network latency is measured between the edge of each WAN and the name node clusters. Similar to study [26], the authors combine TCP packets into streams to analyze the network data. Libpcap, tcpdump [30], and Nigel's performance Monitor for Linux (nmon) [31] facilitate the raw network packet captures. Nmon uses the “-s” option to collect network packets every second throughout the duration of the Apache Spark streaming tests.

In addition to using network bitrate to test data streaming performance, it also determines the optimal location of the IDSs/IPSs in this study. To establish the optimal IDS/IPS placement in each network topology, researchers iteratively run the experiments with each recommendation in the Cisco Extended Enterprise SD-WAN Design Guide [23]. The authors base the final IDS/IPS location selection on the best raw network bitrate for each topology in the testing that follows.

The proposed research methodology uses a design science approach to investigate the impact of IDS/IPS placement on geo-distributed big data systems. It outlines the system architectures and benchmarking processes in the coinciding experiments. Next, the authors implement the proposed tests and report the results of the evaluations.

IV. Results

Hub-and-spoke in Fig. 4 is the first experimental network topology (T1) that tests the IDS/IPS performance of geo-distributed big data systems. WAN connections source from a central data center in New York, NY to the remote cities of Seattle, Los Angeles, and Orlando. The authors automated the tests using the Python programming language and Bourne-Again SHell (bash) scripting. This includes a start and stop script.

A. Experimental Environment

A start script prepares a consistent experimental environment for each iteration of the performance testing. A stop script resets the environment to the original state, ensuring each test begins with the same configuration. The start script begins by starting each Suricata IDS/IPS service and checking the compiled security rules. After the IDS/IPS is functioning properly, the script starts Apache Hadoop and Spark. At this stage, a health check ensures HDFS is operating correctly across the clusters. If the distributed file system is unhealthy, it exits after logging error codes. If HDFS is healthy, TCP ports 9990-9999 open for Apache Spark streaming.

Each name node on four geo-distributed big data clusters runs a parallel Python application that facilitates the system and network performance benchmarking. The Python application invokes the PySpark streaming application, establishing 1 GB data streams to the primary and secondary names nodes. Throughout the experiments, a health check monitors the Apache Hadoop and Spark logs. If the Python application fails in-memory processing or HDFS writes at any time during the real-time stream, the application exits after logging error codes. The start script sleeps for 30 seconds following invocation of the Python application to ensure streaming is functional.

Following successful execution of streaming services, a series of bash shell commands collect and aggregate raw network performance statistics using libpcap, tcpdump, nmon, and iperf3. Data aggregation is per cluster. For example, data combines from the two name nodes and two IDSs/IPSs for each site into a single file. Measurement and results are from transmission control protocol (TCP) network traffic. Tcpdump and nmon results are collected from real-time TCP traffic. Intervals for each tool are set to write performance data every second. Nmon executes with the default settings with the exception of the “-s” syntax for seconds. Iperf3 uses the IP address of each server, the connecting port, and the interval in seconds, and the bidirectional traffic syntax.

Tests invoke in parallel across each cluster using the start script. To ensure saturation, the authors ran the tests ten times for twelve minutes each. Each test produces 720 unique rows of data, of which the middle 600 rows are selected for analysis to avoid potential anomalies at the beginning or ending of the testing. Data analysis begins and ends on the same timestamp for each cluster.

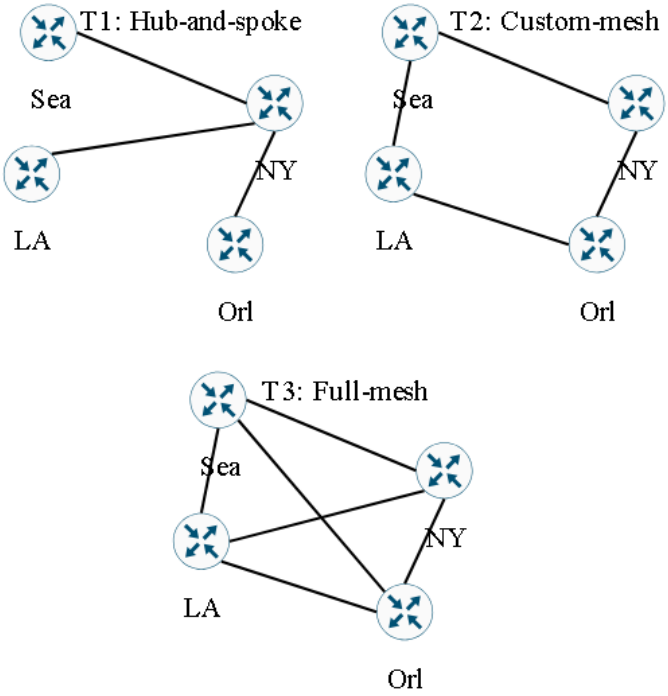

Fig. 4. WAN network topology (T).

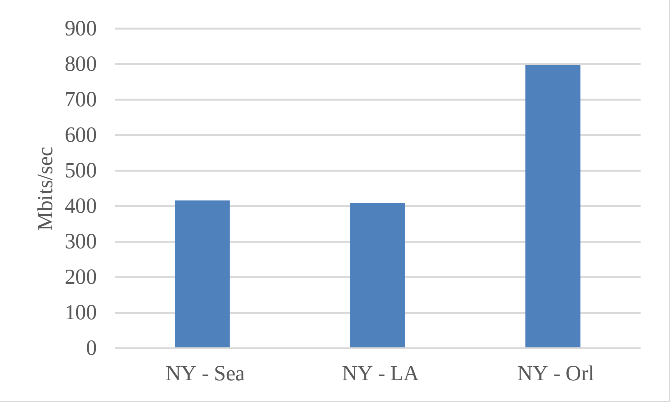

Fig. 5. Hub-and-spoke topology (T1) bitrate.

B. Hub-and-Spoke Topology

Topology 1 (T1) represents the hub-and-spoke WAN experiments. The New York data center connects to Orlando, Seattle, and Los Angeles. WAN latency is 30 milliseconds to Orlando, 58 milliseconds to Seattle, and 59 milliseconds to Los Angeles. Consistent with the cluster architecture in Fig. 2, Spark streams run from the WAN VM through dual Suricata IDSs/IPSs before reaching the primary and secondary Apache Hadoop name nodes. Data streams over three WANs are sent to the primary and secondary name nodes of each big data cluster. The name nodes load balance 128 MB HDFS block writes with a replication factor of three across the data nodes.

Fig. 5 outlines the network bitrate from the WANs to the name nodes measured in megabits per second (mbits/sec). From the New York data center, the rates are 416.496 mbits/sec to Seattle, 409.346 mbits/sec to Los Angeles, and 796.833 mbits/sec to Orlando. The mean bitrate for the hub-and-spoke topology is 540.892 mbits/sec.

C. Custom-Mesh Topology

Topology 2 (T2) represents the custom-mesh WAN experiments. In the custom-mesh network topology, the IDSs/IPSs protect the big data systems at the edge of each LAN. Dual routes exist through each IDS/IPS to the primary and secondary Hadoop name nodes. WANs have redundant paths to each LAN, allowing data streams alternative routes in case of a network failure. Testing establishes a total of eight data streams to Apache Spark. For example, in Fig. 4, New York has a data stream from Seattle and Orlando.

In the custom-mesh topology, the New York data center connects to Orlando and Seattle. WAN latency is 30 milliseconds to Orlando and 58 milliseconds to Seattle. Data streams from New York to Los Angeles route through either Seattle or Orlando. The Los Angeles data center connects to Seattle and Orlando. WAN latency from Los Angeles is 26 milliseconds to Seattle and 52 milliseconds to Orlando.

Fig. 6 outlines the network bitrate from the WANs to the name nodes measured in megabits per second (mbits/sec). From the New York data center, the rates are 795.578 mbits/sec to Orlando and 415.931 mbits/sec to Seattle. Rates from Los Angeles to Seattle are 915.41 mbits/sec and Los Angeles to Orlando 464.22 mbits/sec. The mean bitrate for the custom-mesh topology is 647.729 mbits/sec, which is 106.837 mbits/sec greater than the hub-and-spoke network topology.

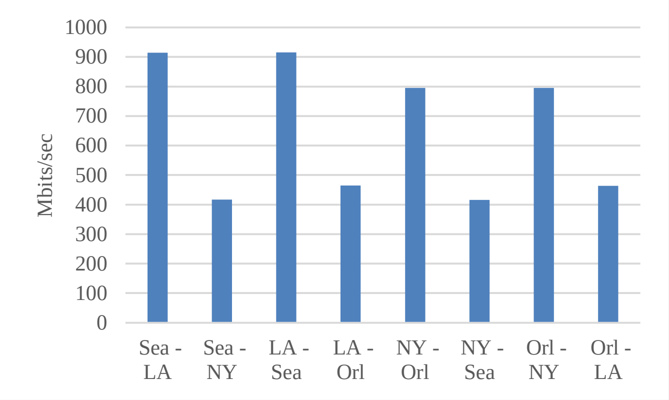

Fig. 6. Custom-mesh topology (T2) bitrate.

D. Full-Mesh Topology

Topology 3 (T3) is a full-mesh WAN design. As highlighted in Fig. 4, data centers have WAN paths to each city, providing the most redundancy of the designs. Twelve data streams are sent to the primary and secondary name nodes of each big data cluster through dual IDSs/IPSs. This is shown in the cluster architecture in Fig. 2.

Within the full-mesh topology, New York has WAN connections to data centers in Orlando, Seattle, and Los Angeles. In sequence, WAN latency from the New York data center to Orlando is 30 milliseconds, to Seattle 58 milliseconds, and to Los Angeles 59 milliseconds. Likewise, the Los Angeles data center connects to Seattle, Orlando, and New York. Los Angeles WAN latency to Seattle is 26 milliseconds and 52 milliseconds to Orlando. Orlando to Seattle WAN latency is the largest at 71 milliseconds.

Fig. 7 shows the network bitrate from the WANs to the name nodes measured in megabits per second. New York data center bitrates are 761.068 mbits/sec to Orlando, 414.98 mbits/sec to Seattle, and 409.33 mbits/sec to Los Angeles. Los Angeles data center bitrates are 462.771 mbits/sec to Orlando and 870.065 mbits/sec to Seattle. Seattle bitrates are 882.696 mbits/sec to Los Angeles, 414.995 mbits/sec to New York, and 341.19 mbits/sec to Orlando. The mean bitrate for the full-mesh topology is 544.637 mbits/sec. The mean rate is 3.745 mbits/sec more than the hub-and-spoke topology and 103.092 mbits/sec less than the custom-mesh topology.

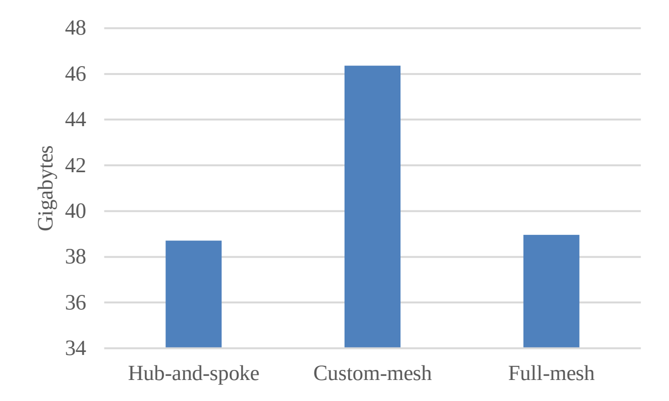

Fig. 7. Mean WAN data stream transfers in gigabytes.

E. Streaming Data Transfers

Fig. 8 highlights the mean data transfer rates of the Apache Spark streams through the WAN links. Fig. 9 illustrates the total data transfer rates of the Apache Spark streams through the WANs.

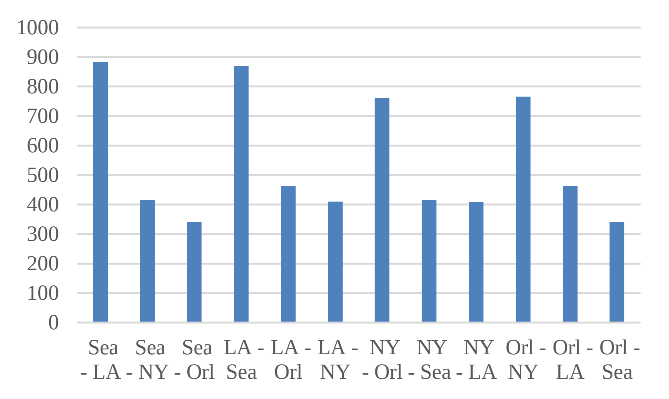

Fig. 8. Full-mesh topology (T3) bitrate in mbits/sec.

Gigabytes were converted from megabytes for the total data stream transfers. Total gigabytes transferred across the WAN network links for the hub-and-spoke network topology is 116.116. Mean gigabytes transferred between the data center sites is 38.705. Custom-mesh produces a mean of 46.364

gigabytes and a total of 370.915 gigabytes. Full-mesh network topology delivers a mean of 38.956 gigabytes and a total data transfer of 467.474 gigabytes.

Full-mesh has a mean data transfer rate slightly greater than hub-and-spoke. On the contrary, mean custom-mesh data transfer produces 7.659 gigabytes more than the hub-and-spoke network topology and 7.408 gigabytes more than the full-mesh topology.

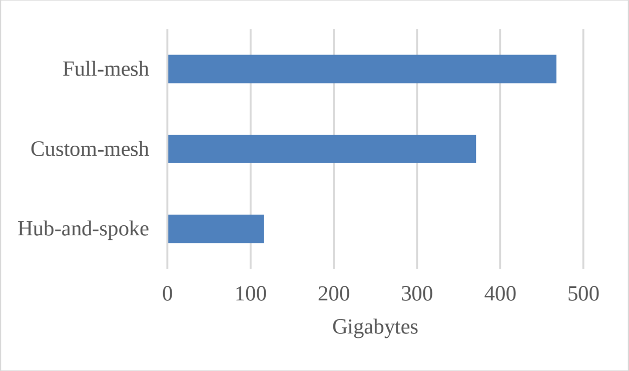

Fig. 9. Sum WAN data stream transfer in gigabtyes.

F. WAN Performance

Table II highlights the total WAN latency of each network topology along with the total amount of data transfer from the data streams. Table II also notes the number of internet service provider (ISP) leased lines used for each WAN topology in the experiments. Hub-and-spoke network topology results in an average of 38.705 gigabytes of data transfer per ISP leased line. Custom-mesh has an average data transfer of 92.728 gigabytes per leased line while full-mesh has an average data transfer of 77.912 gigabytes per leased line.

TABLE II. WAN LATENCY VERSUS DATA TRANSFER

Topology	ISP Leased Lines	Total WAN Latency	Total Data Transfer
Hub-and-spoke	3	147 ms	116.1166 Gbs
Custom-mesh	4	166 ms	370.9158 Gbs
Full-mesh	6	296 ms	467.4745 Gbs

G. Summary

To measure whether IDS/IPS placement impacts geo-distributed big data systems, the researchers study WAN connections between the remote cities of Los Angeles, Orlando, New York, and Seattle. Data centers in each city host big data clusters running Apache Hadoop and Spark. Data streams are sent through the IDSs/IPSs from the WANs to each of the four big data clusters. The researchers develop a novel Python application that uses PySpark streaming classes to facilitate real-time geo-distributed massive data streaming. Performance measures use raw network traffic data to demonstrate the results of three prominent network designs; hub-and-spoke, custom-mesh, and full-mesh. Results illustrate the ability to load balance data streams through IDS/IPS locations with the lowest WAN latency in custom-mesh topology while continuing to offer alternative network paths to geo-distributed data centers. Next, the authors discuss these results.

V. Discussion

Live data streams across four unique geo-distributed data centers show variability in real-life scenarios. Though researchers were able to optimize bandwidth through three different WAN topologies, there are clear performance differences that decision makers should consider when architecting secure clusters for WABD.

A. Geo-Distributed IDS/IPS Placement Performance

Researchers were able to achieve the fastest data streams across geo-distributed data centers using a custom-mesh network design. IDS/IPS placement in the custom-mesh network topology achieves a mean of 106.836 mbits/sec more network bitrate than the optimized hub-and-spoke topology. Similarly, on average the custom-mesh topology is 103.091 mbits/sec faster than the full-mesh design.

In this study, IDS/IPS placement within the full-mesh network design results in slightly faster mean bandwidth available for WABD data streams than the hub-and-spoke network topology. Full-mesh benefits from a mean of 3.745 additional mbits/sec across the WAN architecture. While full-mesh network topology has additional benefits over both hub-and-spoke and custom-mesh such as more fault tolerance, this comes at the cost of expensive WAN bandwidth [22].

In the experiments, hub-and-spoke has three ISP leased lines. Custom-mesh has four leased lines while full-mesh has six leased lines. When reviewing Table II, custom-mesh is able to transfer 54.023 more gigabytes of streaming data through the IDSs/IPSs per leased line than the hub-and-spoke network topology. This comes at a cost of only one additional ISP leased line in these experiments. However, it also adds an extra path of redundancy between each site, eliminating potential single points of failure in the hub-and-spoke network topology.

Custom-mesh also transfers 14.916 gigabytes more data per leased line than the full-mesh topology. Despite this result, full-mesh benefits from an additional redundant path to subsequent data centers. Similar to custom-mesh, full-mesh provides more bandwidth than the hub-and-spoke topology. In comparison, full-mesh produces 39.206 gigabytes more data per leased line than hub-and-spoke. While data centers in the full-mesh design could experience several network failures before losing complete connectivity to another site, it also comes at the cost of three additional ISP leased lines over the custom-mesh topology.

B. Limitations

This paper does not address pricing, which limits the analysis of geo-distributed IDS/IPS placements specific to big data streaming. Although the results of this study give some indication of potential efficiency of various IDS/IPS locations for geo-distributed big data systems, it is financially inconclusive as many variables determine the costs of implementing and maintaining each of the network designs in real-life environments. For instance, in study [15], custom topology resulted in considerable pricing differences for data transfer alone, ranging from $0.02 to $0.25 per GB of data transfer.

Research efforts are advancing big data worker node placement using several available data points. For example, in study [17] the simple-additive weighting method strategically places data streaming tasks using data transmission cost, latency, and bandwidth. However, algorithms lean upon available network data without considering human factors. Future research is important to consider more closely defined pricing models for IDS/IPS placement specific to geo-distributed WAN data streaming.

This paper is also limited to initial benchmarking of three traditional WAN topologies that use manual IDS/IPS placement methods. To advance this research, existing algorithms could consider IDS/IPS latency within avant-garde WAN topologies. For example, the approximate parameter server placement (APSP) algorithm proposed by study [20] could be tested in IDS/IPS environments to identify if the randomized rounding method is still applicable. Similarly, future research could test IDS/IPS locations using WAN topology-aware frameworks introduced in study [15] and study [17].

Finally, IDS/IPS benchmarking is limited to a Python streaming application engineered for Apache Spark. Similar to study [17], researchers may consider other big data streaming systems like Apache Flink and Apache Storm along with varied streaming applications developed in Scala and/or Java.

VI. Conclusion

This paper develops a PySpark streaming application in Python capable of benchmarking geo-distributed data centers secured by IDSs/IPSs. The application sends data streams across the WAN topologies of hub-and-spoke, custom-mesh, and full mesh. In each topology, the researchers optimize IDS/IPS placement using industry best practices and experimentation. The proposed placements show several tradeoffs. Hub-and-spoke has the least aggregate WAN latency and the fewest number of ISP leased lines but at the cost of single points of failure within the WAN topology. Custom-mesh network topology benefits from the fastest raw network performance. It also has dual paths to geo-distributed data centers at a cost of only one additional ISP leased line. Full-mesh offers the most fault tolerance and raw data streaming bandwidth. However, it requires a minimum of two additional ISP leased lines over custom-mesh. In summary, IDS/IPS placement in custom-mesh network topology allows engineers to customize the amount of high availability across WANs while reducing associated costs of leased lines. Advancing this work could include evolving network topology for WANalytics, automating IDS/IPS placement, testing alternative big data streaming systems, and incorporating financial costs into IDS/IPS placement determination. Subsequently, researchers may consider testing existing or new worker node placement algorithms in WABD IDS/IPS environments.

STAR, a Universal, Repeatable, Strategic Model of Corporate Innovation for Industry Domination

Ronald Berman, Nicholas Markette, Robert Vera, Tim Gehle
Grand Canyon University, College of Doctoral Studies, 3300 W. Camelback Road, Phoenix, AZ. 85017, United States

***Abstract*—Within an existing organization, internal expertise, staffing, compensation, information systems, and market focus may complicate the introduction of new ideas while culture and aversion to risk may completely derail the organizations' ability to innovate. The STAR model for corporate innovation provides a theoretical model on how to develop and execute innovative practices to overcome these obstacles and achieve significant market penetration and value. The model is a theoretical framework that empowers organizations of all sizes to construct the necessary structures and advocacy needed to create products, services, and internal processes that enable them to dominate the industry in which they participate. The model also provides the mechanism to support the identification, acceptance, and rapid deployment of relevant new technologies that offer an opportunity to create an unfair advantage, something that is very hard to replicate.**

Keywords—Corporate entrepreneurship; innovation model; market dominance; competitive advantage

I. Introduction

Few companies have strategic architecture to promote the creation and launch of bold new innovations that lead to market dominance. Without a strategic approach, they focus on fragmented tactical isolated activities. Processes do not exist that differentiate between minor product enhancements and bold new initiatives. While every organization has a culture, few, however, encourage and support innovation by fostering input from multiple diverse stakeholders. Innovation is not rewarded. Expertise is not acknowledged. Risk-taking is discouraged. Significant value creation is not considered. Rapid development and prototyping are not permitted until lengthy specification documents are prepared. Metrics do not exist to assess innovation initiatives. Thus, companies may theoretically support the notion of innovation, but the absence of an integrated strategic model limits their ability to actually innovate. These issues cited represent a small subset of the many challenges existing organizations face when attempting to strategically organize for innovation.

When considering the millions of organizations who attempt to innovate, but ultimately fail, understanding how to better conceptualize and enable innovation within an existing organization is crucially important. To begin to understand this important topic, the authors thoroughly reviewed the extant literature then created and deployed a management survey to assess corporate innovation and the necessity to create a management innovation model suitable for use by existing organizations. Survey respondents cited the benefits of innovation while also reporting the challenges encountered in their own organizations and the need to have some type of model. Based on the survey results, the authors propose the STAR model for corporate innovation described in the remainder of this paper.

II. Literature Review

The literature is replete with tactical approaches for start-up companies to create successful new products rapidly and accurately. Over the last 15 years, much of this discussion has been based on the seminal work by Eric Ries [1], who after concluding that many new products fail, proposed tactical novel approaches to product development. Instead of completing a lengthy specifications document that sometime took years to write, he proposed creating a minimum viable product based on perceived customer need. Then, through rapid development and continuous improvement, the product is refined and marketed thereby resulting in accelerated market entry. He argued that continuous improvement and focusing on delivering value to customers produces better results than the creation of traditional business plans.

Ries [2] stressed the importance of employing innovation accounting and continued the use of the term pivot (introduced in 2011) as a structured course correction. He explained that a "pivot" is a change in direction informed by feedback and data from the market, customers, or other sources. In most cases, it is not a complete change in direction, instead, it is a natural part of the iterative process. Ries [3] created a tactical step-by-step guide for implementing lean methodologies in product development. He expanded the discussion and use of a minimal viable product by incorporating practical tools and techniques to create and test customer value propositions. He also supplemented his approach with the creation of a leader's guide in which he suggests the use of innovation accounting methods to measure progress, how to manage entrepreneurial employees, and how to sustain innovation.

Reis successfully proposes tactical approaches for start-ups to create new products more rapidly. Adapting this approach to an existing company has limitations because it is proposed without consideration of an organization's infrastructure, personnel, expertise, staffing and its market focus. He addresses value creation, rapid development, hypothesis testing, and metrics. However, an existing organization is different from a new company. Ries does not address an existing organizations' structure, reward system, company culture and of course risk aversion. Most importantly, Reis does not address how to incorporate existing company resources [4], nor does he critically examine how to scale the initiative [5]. While it is known that there are tactical targeted approaches to enable innovation in start-up ventures, it is not known whether there is a need for a similar approach for existing organizations. Specifically, it is not known whether existing organizations need an integrated strategic structure that provides the framework to enable innovation on an ongoing basis. To that end, the authors initiated a survey to assess whether management within existing companies in the United States supports the need for such a model.

III. Research Methodology

In 2022, a 32-question innovation survey was distributed to managers within existing companies in the United States to assess the current nature of how innovation is enabled within their respective organizations. In as much as there is little data relative to innovation execution within existing companies, the sample population, which includes multiple industries and organizations of all sizes, creates a balanced initial management assessment relative to the innovation process inherent to these organizations.

The sample population consists of managers employed in organizations of varying sizes. As such, 32.9% of the managers represent organizations with two to 100 employees, 34.7% of the managers represent organizations with 101 to 1,000 employees, and 32.4% of the managers represent organizations with 1001 or more employees. The sample population also includes managers employed in over 40 industrial sectors. The largest industry representation consists of Retail (9.3%), Healthcare (8.8%), Manufacturing (7.9%), Information Technology (6.5%), Food Beverage (5.6%), Education (4.6%), Construction (5.6%), Computer Software (4.6%), and Banking/Finance (4.6%).

U.S. managers in this study clearly state that innovation is critical and essential to their firm's success. Eighty-five percent of U.S. managers agreed or strongly agreed that "Innovation is critical to your firm's success," and 81.9% of those same managers agreed or strongly agreed that "Innovation is essential to your organization's survival." Moreover, 88% agreed or strongly agreed that "Innovation is good for your employees" and "Innovation is good for your customers," respectively.

However, in contrast to management's positive perception, the survey results indicate an absence of a corporate innovation model and the necessity to have one. U.S. managers specifically noted that their organizations "needed" certain elements of corporate entrepreneurship and innovation. Seventy percent of U.S. managers agreed or strongly agreed that their organization needs an interconnected (anti-siloed) innovation structure (i.e., ecosystem, finance, marketing, operations, sales, prototyping, internal and external networking) to bring new products to market or to deploy solutions to achieve market leadership. The need for an interconnected innovation model is supported by managers representing organizations of all sizes (Table 1) and industries (Table 2). It increases as the number of employees in the organization grows beyond 100.

While there is an expressed management need for a corporate innovation system, there is an acknowledgment of the absence of key factors included in such a system that drives innovation. Specifically, only 57.9% of management agree or strongly agree that the firm's reward structure promotes innovation. Additionally, only 63% agree that the ecosystem, which consists of climate, environment, and work orientation is important to innovation in their company. Less than 66% indicate that it is easy for non-managers to introduce new ideas. Only 61% indicate that conflicting ideas are welcome in the organization and are well received, and less than 70% of the managers are encouraged to network and share new ideas that may lead to market leadership. Moreover, only 56% respond that the organization creates customer buy-in before launching new products or solutions.

TABLE I. Organizations that Strongly Agree for the Need for an Innovation Structure

Number of Employees	N	% Strongly Agree
2 – 10 employees	13	54%
11 – 50 employees	31	68%
51 – 100 employees	27	63%
101 – 500 employees	34	74%
501 – 1000 employees	41	73%
1001 – 5000 employees	27	81%
5000+ employees	43	72%
Total	216	

Note: The table above represents the response to the question, "Organization needs interconnected structure," based on the number of employees in the manager's organization

TABLE II. Industry Sectors that Strongly Agree for the Need of an Interconnected Innovation Structure

Industry	N	%Strongly Agree
Education	10	80%
Food Beverage	12	75%
Healthcare	19	63%
Information / Tech	14	71%
Manufacturing	17	82%
Retail / Wholesale	20	55%
Total	216	

Note: The table above represents the response to the question, "Organization needs interconnected structure," based on the industry sector of the manager's organization

A. Discussion

Three findings emerged which illustrate the adverse relationship in organizational innovation needs vs. operational deployment. Management overwhelmingly indicates that innovation is crucial to their firm's success, is essential to their organization's survival, is good for employees, is good for customers, and is good for stakeholders. The second finding is much less positive than the first finding, as management indicates that their company is not overly successful in deploying new innovations into the market. In the third finding, management supports a solution through an interconnected innovation structure to bring new products or solutions to achieve market leadership. Moreover, as the number of employees increases, the expressed need for an interconnected innovation structure also increases.

The rationale for the inverse relationship in organizational needs vs operational deployment is complex; however, management cites several possible explanations. They suggest that the lack of organizational innovation collaboration, unaligned reward system relative to the innovative proposals, insufficient time to consider new approaches, and lack of encouragement to share, test, and pilot new ideas, adversely affects innovation. As such, this may explain the rationale for the expressed management need for a formal innovation structure.

B. Argument in Favor for a Model for Corporate Innovation

Researchers have created models to increase the likelihood of desired outcomes. Consider that as early as 1985, Peter Drucker [6] noted that entrepreneurship was an intentional and systematic discipline. Peter Senge [7], and J. Richard Hackman [8] reinforced this noting that the organizational intentionality—structures—increase the likelihood that organizations can learn, adapt, and innovate Knezović and Drkić [9] also commented that specific determinants—psychological empowerment, decision-making process, and organizational processes—precede innovative work behaviors. While some organizations appear to have to some extent an internal innovation model and structure such as Amazon [10], there appears to be paucity in the availability of a universally applicable corporate entrepreneurship and innovation models that can be replicated by organizations in multiple industries and sizes.

Based on system thinking and with recognition of previous research and current managerial survey results, the need for a universal model of corporate entrepreneurship and innovation emerged. What follows is an argument suggesting the creation of The STAR Model for Corporate Entrepreneurship™ (STAR™), a replicable corporate innovation model that relies on predefined organizational structures that increase the likelihood of successful corporate entrepreneurship and innovation.

IV. STAR Model

STAR is a universal, repeatable, integrated strategic model for corporate innovation that empowers companies to create products, services and processes that enable them to dominate the industry in which they participate. STAR is a theoretical framework constructed on the foundation of four building blocks. Organizational structures (S) are the principles and practices that influence organizational outcomes. Think (T) is the process that empowers anyone in the organization to envision and propose bold new ideas that can have the potential to deliver market domination. Advocate (A) is a process that solicits support throughout the organization. Run (R) is a replicable process that provides the framework to go to market at the right time with the right resources. The acronym STAR provides a framework for managers, employees, consultants and academic researchers to conceptualize how to best enable development and execution of innovative practices that result in significant market penetration. The broad universal applicability of the STAR Model is that all tactical elements for market dominating innovation reside in one of the components of the model.

Building on the foundational structural and process focused thinking of thought leaders like Senge, Porter, Kotter, and Hackman, STAR increases likelihood of replicable innovation success. STAR incorporates major tenets necessary to enable successful innovation. This model begins by establishing a structure to foster innovation, followed by the creative proposal to create scalable solutions that address big problems that can propel the company beyond market leadership to market dominance. Throughout the process, advocates are sought out to provide guidance, input, and support to influence senior management approval to go to market at the right time with the right resources.

A. Application of STAR

Implementation of the STAR model produces extraordinary results! In 2019 Levi Conlow co-founded Letric e-Bikes with his childhood friend Robby Deziel. Under the auspices of Grand Canyon University’s Canyon Ventures Center for Innovation and Entrepreneurship, and using the tenets inherent to the STAR model. Mr. Conlow guided Letric e-Bikes to become a $250+ million company in just under three years and the largest and fastest-growing e-bike brand in the United States. In 2021 Forbes took notice of the company’s success and recognized Mr. Conlow as one of the nation’s top 30 under 30 innovators [11]. Lectric’s success can be attributed to excellent leadership and early implementation of the four components of STAR: Structures, Think, Advocate and Run.

The following sections provide additional details relative to each tenet in the STAR model. Corporate entrepreneurs working in institutions of all sizes may adopt the model as an architecture to achieve competitive advantages in the marketplace leading to market disruption and or domination.

V. Structures

Structures are principles and practices that influence organizational outcomes. They are a bias for action. Effective corporate entrepreneurs consciously build organizational structures that align reward systems and energize work into a dynamic innovation engine that seeks bold initiatives. As the foundation of the STAR model, Structures defines how work is done, who is responsible, and how information is shared within the organization. It is defined relative to the (a) creation of the organization's culture, (b) definition of the reward system, (c) creation of work structures, and (d) adoption of an information system.

A. Culture

Culture is the fabric that binds together what is acceptable and what is not acceptable. Culture are those things that we always do, never do, and that which we celebrate and correct. According to Schein [12], culture is present in artifacts, espoused values, and deeply held understandings. It shapes individual behavior through shared values, beliefs, and practices. It provides guideposts of what to do when explicit directions are not readily present. Culture is interwoven with the overall management system and is the unwritten rule book that works alongside the formal organizational structure. A culture that enables independent thought becomes the catalyst for creative thinking.

B. Rewards

Rewards, financial and non-monetary, reinforce and promote the creation of innovative thoughts and actions. Proposing new ideas, questioning old ideas, and exploring new technologies are risky and should be positively recognized. Employees who are rewarded for behaviors consistent with the organization's vision produce more predictable outcomes. If an organization wants empowered, creative, and innovative people, they reward it. As noted by Emilia Bratu [13] when writing about Lockheed's Skunk Works, "Reward performance, not status."

Moreover, when members of a team pivot from their original innovation, innovative organizations reward this. Consider the stories behind both the microwave oven and the Post-it note. Both were happy accidents, but Raytheon and 3M corporation, respectively, rewarded people for applying ideas in new ways. When the developer of a defense radar noticed his candy bar melted in his pocket, he developed the microwave oven. Similarly, when the inventor of a not-very-sticky glue used it on small notes to help him keep his place while singing in the church choir, he created the Post-it note. But, in both cases, there was someone within the organization that rewarded them for their creativity and encouraged them to run with their idea.

C. Work Structure

Work structures define core norms of conduct to balance control and chaos. Too much structure stifles creativity, and too little structure may diffuse outcomes. Work structures are aligned with the organization's culture and reward system. Organizations that find the balance between too much and too little structure unlock the potential of their teams [14]. Moreover, the work structures must reinforce the meaningful nature of the work, the value of the employee's personal contribution, and the opportunity and requirement to propose meaningful enhancements and innovations and receive feedback regarding the results of his or her work.

Work structures must be balanced with the end in mind. Before organizing work, leaders should ask, "What is non-negotiable, and where does the flexibility exist?" The organization of the work must allow for the next microwave oven or Post-it note invention while not detracting from the organization's vision.

D. Information Systems

Information Systems provide the organizational repository for innovative ideas, proposals, and projects, both successful and unsuccessful. The information system provides an objective measure of the level of innovation present within an organization. It offers the ultimate visible feedback loop providing insights into new opportunities. The system enables institutional visibility for anyone to view previously submitted ideas or to propose new ideas. Proposed ideas are automatically routed for review to assess whether the idea provides bold new opportunities or enhancements to an existing product. Ideas are presented to multiple departments within the organization for review. The use of information systems answers the question: What is the level of innovation in the company? Does innovation have the potential to deliver market dominance? What projects are in the process? What projects have been successful? What projects were not successful (and why)?

Information systems inform the organization where it is compared to where it wants to be. Tracking the submission of ideas can help organizations to foster a culture of innovation by demonstrating that the organization values and is committed to supporting new ideas and initiatives.

E. Application of Structures

At the very onset, Conlow through his management team at Lectric E-bikes recognized the need to establish structure to foster innovation and to enable it pervasively throughout the organization. He adopted the STAR model as described in the following statement:

We believe that if you have the right structure, you get the right outcomes. To this end, we push innovation down into every area of the company from design to customer service. At Letric innovative ideas are expected and rewarded. This structure empowers the entire company to focus on solving customer problems that are then incorporated into product design and the sales process.

VI. Think

Think represents the iterative process that empowers anyone in the organization to envision and propose bold new ideas that have the potential to deliver market domination. Building on the structures that precede the outcomes, the Think process rests on concepts well established in literature and industry, then integrates them into a clear model. However, in many cases, Think is viewed in isolation. Specifically, the Think process which is described below includes five stages.

A. Think Deeply

Think Deeply is an inquisitive, creative approach to uncovering important new sizable market opportunities. This is accomplished by critically questioning business, consumer, political, capital, and technology assumptions. Although business assumptions were once true, are they still true? Think deeply to challenge convention. Think to examine what is known. Think to discover what is not known. Think deeply to ask, "What if?" Successful organizations encourage thinking deeply about common things at all levels within the organization. Only one percent of the workforce is in top management. If thinking about innovation is exclusively limited to the top management, organizations will miss the ideas of 99% of their most vital resource—people.

Effective thinking encourages the conflict of ideas without allowing it to become a conflict between people. When ideas are allowed to clash, innovation follows. Good leaders protect the disruptors within their organizations because it is vital to challenge conventional thinking. Innovation comes from ideas, and ideas come from thoughts. Successful organizations encourage thought. Thinking organizations want the best ideas from 100% of their people, not only the top one percent.

B. Hypothesize and Prototype

The hypothesis is a proposal to create a new product or process that addresses a significant market opportunity. It is the natural outgrowth of Thinking Deeply. Hypotheses evolve into early prototyping [15]. At this early phase, a prototype developed within your team may be a presentation, a process flow document, a partial simulation including the market assessment (from the previous phase), or all combined. It does not need to be a fully functioning product or process. Prototypes should not be constrained by company directives and guidelines (except for legal) due to their potentially disruptive nature to the organization. Consequently, successful prototyping circumvents traditional barriers placed in organizations, which are adherence to the status quo operations, existing organizational structure, and the risk-averse nature of human beings.

In some cases, prototypes fail. However, creative organizations are willing to “Fail early to succeed sooner” [16] because early prototypes allow for discovery. Early prototypes, which can be revised over time and provide basic functionality to demonstrate the core idea of the product, are less costly and incur less risk than developing a fully functional product. Contrast this with traditional design models where considerable energy goes into planning, designing, and production. Early prototyping is a disciplined process that allows for issues to be encountered and solved early, thereby minimizing disruption upon entering the market. Addressing unforeseen production issues may be costly and, in some instances, cannot be overcome. Instead of order-to-chaos-to-order, early prototyping compresses the process by moving from chaos-to-order more quickly and efficiently [17]. The industry is replete with examples of this in the marketplace. Steve Jobs and Steve Wozniak’s Apple 1 computer in 1975 is only one example of an early prototype that eventually disrupted the market. Similarly, Lonnie Johnson prototyped the Super Soaker squirt gun, which now accounts for one billion in sales.

C. Investigate

Investigate expands the prototype review beyond the initial development team to include designated groups within the company. Avoid protecting the prototype—do not fall in love with the early version. Encourage your investigators to break and expose weaknesses in the design. Suspend emotions and solicit the user’s ideas. Effective innovators use feedback as the raw material for the next iteration. At this early phase, a prototype developed within your team may be an updated presentation, a refined process flow document, a partial simulation, including the market assessment (from the previous phase), or all combined.

Groups outside your department team__may provide truthful, unbiased input. Soliciting input beyond the development team may increase risk if negative feedback is shared throughout the organization. However, positive feedback helps garner support from advocates who may back the prototype towards company adoption. Investigate answers to the questions: What is good? What works? Does it fix a problem? What does not work? Does it satisfy the identified market opportunity? How can it be improved?

D. Network

In contrast to the Investigate stage, Network expands the initial prototype review to include select customers to solve a specific problem. Corporate entrepreneurs must clearly define and blueprint their solution, then secure an intent to purchase before it is officially built. After examining the wreckage of their failures, many innovators trace their ruin back to this step. They spent valuable time and money building a solution for customers or problems that did not exist. Successful innovators must constantly collaborate with customers to define each of the following:

- The actual problem
- A viable solution
- The price range or budget for the solution
- A comprehensive list of decision-makers
- The timing of delivery, and
- A clear statement of which features are necessary

Gathering feedback from real users helps identify issues or areas of improvement that company employees, from a different perspective, may fail to identify. Soliciting input from customers can be assessed as a higher risk. Receiving and incorporating their feedback early in this stage will make the Advocate dimension of the STAR Model easier. In addition, it is vital in the iterative process of hypothesizing and prototyping, investigating, and networking. Like the Investigate phase, in Network stage answers the questions: What is good? What works? Does it fix a problem? What does it not work? How can it be improved?

E. Kreate

Kreate completes the prototype process and solicits company-wide support for its adoption and go-to-market strategy. The development team may be ready to seek approval to proceed or may need additional work. They may need to acquire the support of an expanded set of Advocates or may need to modify the minimum value proposition (MVP). The Kreate stage answers the questions: What is the value of the innovation? When would you need to enable this innovation? How will this innovation be integrated? What is the anticipated disruption associated with integration? How can this innovation be scaled? The MVP sets the stage for the Advocate dimension of the STAR model.

Once the innovation has been sold internally, corporate entrepreneurs must continue the work of external selling. Corporate entrepreneurs must be in constant communication with their “customer evangelist group”. This customer evangelist group should be representative of the total available market (TAM) you intend to capture. These will be the early adopters, think of them as the equivalent to the Key Advocates discussed in the Advocate section. All innovations are created for specific customers to solve specific problems. Corporate entrepreneurs must clearly define and blueprint their solution, then secure an intent to purchase before the solution is officially built. After examining the wreckage of their failures, many entrepreneurs trace their ruin back to this step; they spent valuable time and money building a solution for customers or problems that did not exist. Successful corporate entrepreneurs must constantly collaborate with customers to define each of the following:

- The actual problem
- A viable solution
- Price range or budget for the solution
- All decision-makers
- Timing of delivery, and
- Exactly which features are necessary

All this is accomplished with a tool often referred to as a requirements document. Each section of this nonbinding document is completed before anything is built. Throughout the process information is constantly verified and refined realizing that it is difficult to succinctly define the problem. Once the document is fully completed then executed by the prospective customer, it's then used to build the solution.

1) Application of think. Mr. Conlow and his team from Letric eBikes implemented the Think process to overcome their initial product failure. Conlow enabled a process to create scalable products and solutions that address big problems that propel the company beyond market leadership to market dominance. Using available research data, it was clear to Conlow that although European customers were aggressively purchasing ebikes, the US market was still in its infancy. Existing bicycle companies with dominant market positions and years of experience had not yet embraced the new technology, and as a result, the US market was wide open.

Lectric's first e-bike design was a total failure. However, Conlow knew from the data that the potential US e-bike market was massive. "The problem was not the market; it was our bike. The solution was simple, listen to the customer and re-work the prototype." Letric learned that their customers did not want to spend another $500 to $1500 on a bike rack to transport their new e-bike. The solution was to build a folding ebike that did not require a bike rack. The reduced price point of an ebike without the bike rack was an incredible innovation that was eagerly accepted by multiple market segments and was difficult to replicate by competitors. Additionally, the folding ebike shipped fully assembled in a box that was smaller than the full-size crates used to ship full-size ebikes. The smaller box made is less expensive to ship and minimized the potential for damage during shipment. The company utilized an organic marketing strategy to launch their newly designed ebike. The campaign deliver $4 million in pre-orders within the first 30 days.

VII. Advocate Process

Advocate is the process of gaining approval for new innovation by securing the active support of individuals both inside and outside of the organization. The Advocate process works in concert with Think by securing individual support across the enterprise and its key customers.

Developing advocates to support a new innovation requires that one understands the neuroscience of risk. Knowing that everyone in your organization comes with their own level of risk tolerance is essential to successfully introducing an innovation. The findings of a study by Mueller et al. [18] support the notion of risk tolerance. A Cornell University publication summarized their findings "Why we crave creativity but reject creative ideas," [19]. The summary noted the following four reasons why novel ideas are often scorned.

- Creative ideas are, by definition, novel, and novelty can trigger feelings of uncertainty that make most people uncomfortable.
- People dismiss creative ideas in favor of purely practical ideas.
- Objective evidence shoring up the validity of a creative proposal does not motivate people to accept it.
- Anti-creativity bias is so subtle that people are unaware of it, which can interfere with their ability to recognize a creative idea.

A. Risk

To offset the natural aversion to accepting new ideas, innovations must be introduced as being of exceptionally low risk, intriguing, and viable if they are to gain public support. Incorporated into STAR, a three-part method of language, reports, and stages can help de-risk any innovation by building trust, thus securing buy-in from others.

1) Language. Language is important. Corporate entrepreneurs should approach potential key advocates and other stakeholders using specific low-risk language. New ideas should be presented with a combination of terms that convey safety and appeal. This combination replaces fear with curiosity. Corporate entrepreneurs may introduce a concept by saying something like,"We've been examining a growing market trend that seems to be going unnoticed by our competitors. We've crafted a test that, if successful, could become a very profitable new revenue source, and we could own this market." Notice the language, "test" is a low-risk term. The word "unnoticed" creates intrigue and introduces the idea of timing. The term "we've" implies that there is a group and there is safety in numbers. "Profitable new revenue source" helps to replace fear with curiosity and appeal.

2) Reports. Progress reports should be delivered to key stakeholders. In-person is the preferred method, as visual evaluation of body language and non-verbal cues provides invaluable insight to know if your conversion strategy is working. Updates should include both problem verification and prototype feedback. While email and video conferencing are acceptable, they do not allow for this type of surveillance. These reports follow a simple format that presents test results with a lucid infographic and no confusing information. Updates should be crisp and direct, long updates can become confusing and derail the innovation. A pithy report builds trust and confidence, anything complicated or confusing can be threatening.

Securing the support of advocates is not done all at once; it is enabled carefully in specific stage. It begins with the innovator securing the support of staff within the department and then expands beyond the department to the entire company and eventually includes select customers. This progression is illustrated in the following five stages:

3) Stage 1: Identify Initial Advocates. By its very nature, innovative proposals of any type are often viewed cautiously. The prospect of something new that potentially may change the existing organizational structure, product mix, company strategy, underlying technology, operational processes, employee reward system, or even staffing levels is a red flag for many employees. For an innovation idea to survive beyond its infancy, the innovator must survive!

Carefully selecting individuals to support a new innovation within an existing organization is of paramount importance to minimize innovator risk. By choosing the right team members, organizations can mitigate potential risks and maximize the chances of successful implementation. Firstly, the selected individuals should possess a diverse set of skills and expertise relevant to the innovation's domain, allowing them to tackle various aspects of the project effectively. Secondly, a well-balanced team that combines both seasoned experts and fresh minds can offer a mix of experience and creativity, leading to innovative solutions while avoiding tunnel vision. Thirdly, individuals with a proven track record of adaptability and openness to change are more likely to embrace the inherent risks associated with innovation, fostering a culture of resilience. Lastly, aligning the team's values and commitment to the organization's mission ensures a shared vision, boosting motivation and dedication to overcoming challenges. Careful selection of team members can enhance the innovation process, diminish the burden on individual innovators, and significantly reduce the overall risk, leading to the organization's long-term growth and success.

4) Stage 2: Build the Network. Once the initial advocates (who provide minimal risk) are identified, the innovator starts expanding the network of potential supporters who have a vested interest in the innovation and who can help spread the word about it. This includes a series of key advocates who have the power and position to enable the innovation to move forward. A key advocate is a respected and trusted leader in your organization, one who curries favor with other leaders and the rank and file. Key advocates mitigate risk in the minds of others. Building trust with at least one key advocate is essential to converting supporters and critics into public champions.

In addition, the advocate base must include customers, employees, influencers, industry experts, and other stakeholders. A thoughtful expanded network approach maps inherent risk of soliciting advice for a new innovation based on potential advocates key attributes: positional power, feedback, influence, knowledge, risk aversion, and status. Each attribute plays a vital role in determining the quality and reliability of advice received. Positional power ensures that the advice comes from individuals with the necessary authority and experience to make informed decisions. Feedback provides valuable insights from various perspectives, enhancing the chances of identifying potential pitfalls and opportunities. Influence signifies the potential impact of the advice on the innovation's trajectory, making it crucial to gauge the credibility of the sources. Knowledgeable advisors possess expertise that can significantly improve the innovation's outcome. Risk aversion is crucial to consider, as overly cautious advice might hinder growth, while recklessness could lead to avoidable failures. Finally, understanding the status of potential advocates helps identify biases that might influence their suggestions. By thoughtfully mapping these risk factors, innovators can solicit meaningful information and support to propel innovations towards success.

5) Stage 3: Develop Your Messaging. To create a powerful network of advocates, a clear and compelling message about your innovation is needed. Be specific, emphasize how the innovation provides unparalleled opportunities for the organization to dominate the sector in which it operates.

Targeting your message is of paramount importance when soliciting support for an innovation that may significantly alter the organization’s current environment. The message influences the success and reception of your idea both internally and with prospective customers. Tailoring your message to a specific audience ensures that the innovation’s unique features, benefits, and value proposition are effectively communicated to customers while concurrently communicating how the innovation will enhance the organization market position and brand. By understanding the needs, preferences, and pain points of the target audience, you can craft a message that resonates with them on a personal level, increasing the likelihood of capturing their attention and generating interest. A well-targeted message also aids in establishing a strong brand identity and positioning in the competitive landscape, fostering customer loyalty and advocacy. Moreover, it enables you to focus marketing efforts and resources efficiently, optimizing outreach and maximizing the return on investment. In essence, effective message targeting plays a pivotal role in not only driving initial sales but also fostering long-term relationships with customers, ultimately leading to sustained growth and success for the new product in the market.

6) Stage 4: Engage, Gather Advice and Refine the Offering. Once the innovator(s) has built the network of advocates, it is essential to engage with them regularly. Engage, listen, and refine. Listen to learn. Learn what may not have been known or seen before engaging. Specifically ask for advice; research has shown this to be more effective than requesting feedback [20]. When seeking advice, an innovator solicits the expertise and knowledge from potential advocates gaining insights and suggestions with relevant experience in the industry or domain. The act of seeking advice is constructive as it provides a personal connection between the innovator and the potential advocate. On the other hand, the act of seeking feedback does not result in enhancing the innovator relationship with potential advocates and may result in vague commentary that does not suggest how to improve the innovation.

Additionally, provide potential advocates with the resources, information, and tools they need to spread the word and build momentum. Be mindful to solicit input yourself; do not rely solely on others for their input. Allow advocates to be part of the team and value their opinions and insights. Time spent engaging your advocates transforms them from casual participants to enthusiastic supporters.

7) Stage 5: Monitor Progress and Adjust Strategies. Monitor the progress of your network of advocates and adjust your strategies as needed. Use data to track engagement and optimize your outreach efforts. A decision must be made to go forward decisively, to abandon the innovation, or to start again. A "go" decision moves into the Run stage of STAR. A "no-go" or "start again" decision leads to a reflective debriefing to leverage lessons learned for the next cycle of innovation using the iterative, perpetual process that is the STAR Model. The "Go" decision requires the consent of the final decision maker(s) for formal approval to move to Run.

B. *Advocates in Action*

Mr. Conlow and his Letric team made expert use of advocates and the advocate process to refine their product, identify their ideal customer profile (ICP), and market to their ideal customers. Mr. Conlow and his marketing team identified three different types of key advocates. These included e-bike experts, technical experts, and their prime customer influencer. Once identified, the Letric team expanded this network of key advocates. This network assisted Letric in developing its messaging, for example, Letric's prime customer are recreational vehicle owners or RVer's, the company engaged a social media influencer with thousands of these subscribers to do a product review of their new e-bike. Letric learned from this influencer, and from talking with their other advocates, prospects, and customers, that their messaging should showcase their new e-bike's folding capability. A folding e-bike precluded the extra expense of a bike rack. RV owners viewed Cetric's e-bike as space and expense saver, and the ideal alternative to hauling a car. Letric's expert use of the advocates and the Advocate process as described in the STAR model empowered the company to create and successfully launch their new e-bike and rapidly drive organic sales to over 150,000 units in their first 30 months.

VIII. Run: The Tactical Application of the STAR Model

Run represents a replicable iterative process, meticulously designed to provide a robust framework for venturing into the market at the right time with precisely calibrated resources. In the dynamic landscape of corporate innovation, Run stands as the tactical embodiment of the STAR model; Structure, Think, Advocate, and Run. This model is not a linear procession; rather, its components continuously evolve, interweave, refine, are rigorously tested, and continually evolve and improve in response to the ever-shifting business landscape.

A. *Run: A Replicable Iterative Process*

Run's foundation rests on the steadfast understanding that markets and the conditions for execution are in a constant state of flux. The notion that any go-to-market plan can be perfect is debunked, for such assumptions can lead to disastrous outcomes. Unlike linear processes, Run is an ongoing journey with no fixed conclusion point. With each iteration, it systematically revisits the operational plan, fostering the nimbleness to address unforeseen obstacles and those entirely novel in nature.

B. *The Ongoing Vitality of Structures*

While Structures are designed earlier in the STAR process, their persistent relevance in Run cannot be overstated. These structural underpinnings encompass the fundamental principles and practices that exert a profound influence on organizational outcomes. A meticulously devised innovation reward system, technology deployment to assess and measure innovations, precise staffing levels, selection of innovation staff, strategic aligned marketing and investor communication plans, and unwavering financial support all contribute to the organization's readiness. This readiness transcends the confines of a single innovation; it pertains to the seamless execution of a continuous stream of innovations. A particular emphasis is placed on fostering an open culture that encourages input from all corners of the organization – an invaluable asset during the dynamic Run phase, where the unexpected demands immediate attention.

C. *From Think to Run: Requirements Revalidation*

The requirements document, initially crafted during the Think phase, undergoes a rigorous process of revalidation in Run This document, conceived months prior to the onset of Run, offers a preliminary definition of the problem, a theoretically viable solution, price range parameters, an ideal delivery timeframe, and delineation of the essential product features. In the ever-fluctuating landscape, Run continually recalibrates this ideal solution, ensuring its alignment with the current environment. Specifications are subjected to relentless assessment to guarantee that the innovation not only provides value but also forges a path to market leadership while remaining eminently achievable. The assessment ambitiously extends to encompass the innovation's producibility, pricing, marketing readiness, distribution strategy, and the organization's preparedness to scale the innovation.

D. *Embracing Change and the Quest for Market Leadership*

Human nature inclines towards the illusion of constancy but Run reminds us of the inexorable nature of change. Failing to acknowledge this reality can be perilous, and the belief in an infallible go-to-market plan can prove catastrophic. It is imperative to remain vigilant, continuously scanning the environment for shifts, changes in internal and external advocate support, the sustained presence of organizational financial support, and the competitive landscape. Furthermore, for those resolute in their pursuit of market leadership, the imperative of scaling innovations takes center stage. This endeavor necessitates considerable foresight, unwavering commitment, and strategic investments.

E. Application Market Dynamics Drive Lectric's e-Bikes Success

The triumph of Lectric e-bikes, a prominent player in the electric transportation market, serves as a compelling case study that aligns seamlessly with the principles of the STAR model, with a notable emphasis on scalability. For organizations determined to be a market leader, their innovations must rapidly scale. This requires foresight, commitment and investment as described by Levi Conlow, CEO and Co-founder of Lectric e-Bikes. “At the end of 2020 and early 2021, we began to scale our operations by making big investments and adjustments for how we bill, manufacture, distribute, and warehouse. That investment is starting to pay dividends now.” offered Conlow. Consistent with the STAR model, scalability was paramount if Lectric’s new e-bike was to establish market dominance. Their timing could not have been better, given the spike in U.S. demand for e-bikes. The Covid-19 pandemic triggered a surge in bicycle sales. Starting in July 20211, the twelve-month sales increased for two-wheelers by 65% to $5.3 billion, according to analyst Dirk Sorenson with market researcher NPD Group. “In the past two years, e-bikes grew by a whopping 240%, which made it the third-largest cycling category in terms of sales revenue behind mountain bikes and children’s bikes and ahead of road bikes”, Sorenson said in a recent report [11]. At the close of 2022, Letric was second only to Tesla in the total number of electric transportation units sold and is poised to pass Tesla in 2024. “The team at Lectric accomplished this through a novel approach of design, marketing, distribution, and customer support, which has earned it thousands of highly satisfied, loyal customers” [11]. Bertram Capital partner Ryan Craig said at the time of the company’s VC’s funding announcement.

Lectric’s forward-thinking approach yielded substantial dividends, in perfect harmony with the STAR model's ethos. Lectric’s timing aligned with the surging U.S. demand for e-bikes amid the COVID-19 pandemic, underscored the model's efficacy. Run, as the tactical application of the STAR model, epitomizes a dynamic, adaptive approach to corporate innovation. It underscores the importance of continuous assessment, embraces change as the one constant, and champions scalability.

In summary, Run, as the tactical application of the STAR model, embodies adaptability, continuous assessment, and scalability. It champions an iterative approach where Structure, Think, Advocate, and Run are interwoven and constantly refined. The success of companies like Lectric e-bikes underscores the efficacy of this model in navigating the ever-evolving landscape of corporate innovation.

IX. Getting Started: Assess Innovation in an Existing Organization

To adopt the STAR model, it is essential that senior leadership first assess the organization’s innovation actions and the associated results. Then, this must be differentiated from management and staff perception regarding innovation in the organization. This can be accomplished in two steps. In the first step, senior leadership should ask three questions:

1) How many new innovations or products were announced by your organization over the last five years? (List only)

2) To what extent did these products significantly grow revenue, market penetration, operating margins, or increase operational efficiency? (from the list, indicate the outcome)

3) Did the new innovations help to create an unfair advantage that will make it difficult for other organizations to replicate? (From the list, Yes, No response only)

In the second step, senior leadership should formally assess corporate innovation readiness by administering the STAR survey. Executing the survey will help leadership determine the extent in which management and non-management believe that innovation is crucial for organizational survival, whether there is support to achieve this, and whether they believe their innovation has been successful. Combining the organization’s perception of innovation with the actual results provides the foundation for senior leadership to begin the strategic transformation of the organization to one that continually enables, enhances, and rewards innovation not just by management but is endorsed throughout the organization.

X. Summary

The absence of a corporate innovation model can be a significant obstacle for companies seeking to drive innovation within their organization. Without a defined approach, companies may struggle to differentiate between regular product enhancement and bold new initiatives and subsequently lose the option to pursue bold market leadership opportunities. Without an integrated model to assess new ideas, prototype a promising idea, solicit internal and external feedback, consider scalability, and develop internal and external advocates, the potential to achieve sustained market leadership is problematic. Therefore, to address this need which is supported by a survey of 200 business managers, the authors propose adopting the STAR model, a teachable, replicable of innovation model. The model includes four tenets:

1) Structures: principles and practices that influence organizational outcomes

2) Think: the process that empowers anyone in the organization to envision and propose bold new ideas that can have the potential to deliver market domination.

3) Advocate: process to gain approval for a new innovation by securing the active support of individuals both inside and outside of the organization.

4) Run: a replicable iterative process that provides the framework to go to market at the right time with the right resources.

The current focus in innovation research is primarily focused on new product creation through the vantage point of start-up companies. Agile development and creative thinking models do exist, but these models do not consider staffing, compensation, technology, leadership authority, culture, risk aversion, and lack of innovation support that many existing organizations encounter that start-up companies do not have. New technologies such as AI provide incredible opportunities for competitive advantage in existing organizations. However, technology alone does not create competitive advantage. Skillful, rapid, cost-effective deployment supported by advocates within the organization and with select customers provides competitive advantage. Although adoption of an innovation model does not guarantee that the organization can outperform its competitors and of course new start-ups, it does improve the odds.

Control-Driven Media: A Unifying Model for Consistent, Cross-platform Multimedia Experiences

Ingar M. Arntzen[1], Njal T. Borch[2], Anders Andersen[3]
NORCE Norwegian Research Centre, Tromso, Norway[1] Schibsted, Tromso, Norway[2]
UiT The Arctic University of Norway, Tromso, Norway[3]

***Abstract*—Many media providers offer complementary products on different platforms to target a diverse consumer base. Online sports coverage, for instance, may include professionally produced audio and video channels, as well as Web pages and native apps offering live statistics, maps, data visualizations, social commentary and more. Many consumers also engage in parallel usage, setting up streaming products and interactive interfaces on available screens, laptops and handheld devices. This ability to combine products holds great promise, yet, with no coordination, cross-platform user experiences often appear inconsistent and disconnected. We present *Control-driven Media (CdM)*, an extension of the current media model that adds support for coordination and consistency across interfaces, devices, products, and platforms while remaining compatible with existing services, technologies, and workflows. CdM promotes online media control as an independent resource type in multimedia systems. With control as a driving force, CdM offers a highly flexible model, opening up for further innovations in automation, personalization, multi-device support, collaboration and time-driven visualization. Furthermore, CdM bridges the gap between continuous media and Web/native apps, allowing the combined powers of these platforms to be seamlessly exploited as parts of a single, consistent user experience. Extensive research in time-dependent, multi-device, data-driven media experiences supports CdM. In particular, CdM requires a generic and flexible concept for online, timeline-consistent media control, for which a candidate solution (State Trajectory) has recently been published. This paper makes the case for CdM, bringing the significant potential of this model to the attention of research and industry.**

Keywords*—*Multi-platform; media control; continuous media; data-driven media; interactive media; orchestrated media

I. Introduction

The landscape of media production and *over-the-top (OTT)* delivery holds immense potential. Advanced production tools, automated AI-based technologies, and a wealth of data sources come together, often in multi-step, distributed production chains. On the client-side, highly capable consumer devices offer further opportunities for adaptation, customization, interactivity and data-driven graphics. Concurrently, consumer preferences are evolving; ranging from those who favor the traditional one-size-fits-all broadcast experience, to those seeking multi-device immersion, interactive engagement, customized multi-device setups, personalized narratives, social interactivity, or advanced accessibility features. This diversification poses a significant challenge for media providers aiming to offer advanced, high-quality user experiences to a sizable audience, while simultaneously managing costs and complexity.

Many media providers offer alternative products on different platforms to address needs for richer and more varied experiences. For instance, coverage of major sports events may include live-produced video channels, VoD services, and Web or native apps with support for live feeds, interactive data visualization, and social integration. Many viewers also see these as complimentary offerings and engage in combined usage to further enrich their experiences. This, though, may be less rewarding than perhaps anticipated. Each product must be configured separately, and there is typically no coordination across platforms. Differences in production delays may also lead to inconsistencies, confusion and spoilers. This significantly limits the value of combined usage, possibly driving viewers back to traditional single-product coverage.

We envision a new class of cross-platform media experiences, where independent products and interfaces may be flexibly combined and coordinated to form a single, consistent, user experience. Users can then enjoy a spectrum of experiences, from lean-back entertainment to lean-forward engagement, from a single-device to multi-platform immersion, or from private to social experiences. Furthermore, by opening up for cross-platform usage, media providers can provide advanced and uniquely adapted user experiences cost-effectively by leveraging the combined powers of existing infrastructure and services, while also ensuring quality and brand control for the user experience as a whole.

Unfortunately, issues with cross-platform user experiences are not easily addressed within the current model. Different products are built from independent technology stacks and define entirely separate user experiences. While some solutions exist for coordination and consistency, they are often application-specific or limited to specific technology options, such as data formats, distribution protocols or presentation frameworks. In contrast, we argue that cross-platform coordination must be independent of platform-specific solutions, and that support for cross-platform media experiences should instead be addressed as a fundamental feature of the media model.

To this end, we propose *Control-driven Media (CdM)*, an extension of the current media model with built-in support for consistent, cross-platform user experiences. CdM promotes *control* as a principal resource type in media systems. Through online control sharing, applications can orchestrate connected interfaces and render data sources and media content consistently across platforms. Moreover, as CdM is compatible with existing infrastructure and workflows, adoption can be incremental and cost-efficient. Furthermore, CdM uniquely targets a generic solution for cross-platform consistency, by addressing fundamental limitations of the current media model.

This paper presents CdM and a range of opportunities implied by the model. Section II presents current approaches to cross-platform media experiences, and remaining challenges, leading up to the problem statement in Section III. Section IV outlines the current media model, before the main contribution, the CdM model, is introduced in Section V. Section VI discusses key opportunities of CdM within the context of online sports coverage. Section VII covers key technical challenges. Section VIII includes evaluation and references to implementation and supporting research. Section IX provides a brief discussion before the paper is concluded in Section X.

II. Background

The online world provides unprecedented opportunities for online media, with a wealth of tools and platforms for capturing, editing, distributing, and rendering of data and media content. Moreover, the ongoing AI revolution promises further opportunities for automation, content generation, personalization, and more. To fully exploit this potential, media systems must meet an increasingly complex set of demands. Media providers seek to build their brands through high-quality user experiences and exciting narratives. There might also be a race for advanced features, like impressive graphics, interactive engagement, device adaptation, social integration, and/or multi-device support. This, though, must be balanced with technical and financial considerations, including performance, scalability, complexity and costs. Users, on the other hand, seek media experiences that are relevant, exciting and distraction-free. Beyond this, users are diverse, and preferences will likely diversify further as offerings become more advanced. For example, some users prefer lean-back storytelling, while others want to engage and actively shape the experience for themselves or others. Some prefer generic broadcast coverage, while others prefer a more personalized narrative. Some want experiences to be social, some seek multi-device immersion, and some have specific accessibility requirements.

Supporting diversity is hard, though, and certain demands may even appear conflicting in terms of technology options. In particular, we recognize two technical approaches for audiovisual user experiences; *continuous media* and *data-driven media*. Media production based on continuous media types (e.g. audio and video) supports high-quality storytelling through precise mixing and scheduling of video sources, audio tracks, and graphical elements. This approach can provide user-friendly, lean-back, and action-packed user experiences, yet primarily the same experience for all viewers. In contrast, data-driven media (e.g. Web/native applications) offer dynamic experiences with flexible options for interactivity, visualization, adaptation, personalization and collaboration. However, data-driven media provide limited support for weaving complex time-dependent, lean-back narratives, particularly if they involve multiple data sources and/or different rendering technologies.

To address complex demands from users and media providers, it appears necessary to leverage the combined power of these approaches. This section presents common ways of combining technologies, highlighting the strengths and limitations of each approach.

1) Embedded media: A common way to combine technologies is to embed continuous media within a data-driven interface. For example, audio and video content on the Web platform may be embedded in Web pages using the *HTML5 Media element* [1]. This way, soccer coverage may include both a video stream and a feed of match events. However, despite being part of the same layout, embedded components technically define separate user experiences. For instance, the video pause button might not apply to the match events feed, which will continue to report game developments, even if the video stream is paused. This creates inconsistency, where the two components display data from the same event but from different time-frames. Media providers may address this by introducing additional coordination between components. For instance, on the Web platform, media players and feeds may be controlled by code. This, though, often leads to custom solutions within specific applications and platforms, and the complexity increases with the number of coordinated components.

2) Overlays: A related method is to layer a transparent, data-driven interface on top of a video display. This technique can for instance be used in video production, to burn graphics onto a video stream. Alternatively, graphics can be overlaid in the user interface, using a *z-index* or similar layering concepts supported by the layout system. This provides additional options for individualized graphics and interactivity, but requires that overlay graphics are synchronized with video progression. This can be accomplished by defining cues, hooks, or events on the video timeline. In the Web platform, this is supported by the concept of data tracks [1] integrated with the HTML5 media element. While this provides coordination between continuous and data-driven media, the approach is most useful when the experience is limited to a single video asset within a single interface or layout.

3) HbbTV: HbbTV (Hybrid Broadcast Broadband TV) [2] is a standards initiative and platform allowing HTML-based graphics to be overlaid on broadcast video content. In HbbTV, the focus is on the set-top box or SmartTV, which supports IP-based data access as well as traditional broadcast distribution. By exposing the media clock of the broadcast stream to the HTML5 processing environment, program-specific or even personalized overlays may be presented on the TV display. Broadcasters may define and deploy such overlays as HTML applications associated with a channel or program. Furthermore, the concept of overlays is also extended to companion devices. This means that smartphones may connect to the HbbTV device to access additional contents or interactive capabilities, synchronized with the broadcast clock [3]. However, the adoption of HbbTV has been slow, as it requires developing and deploying HbbTV-enabled consumer devices. Moreover, as the approach hinges on the existence of a physical device, it does not easily generalize to other media domains or beyond the home environment.

4) Low latency streaming: Another way to combine media content and data-driven graphics, is to coordinate the delivery of multiple data streams. For example, an online lottery might want to stream a video from the lottery drawing, and also provide a separate data stream with the winning numbers, for visualization. This requires some coordination between streams, or else the graphics might spoil the suspense of the video, or even make the lottery appear suspect. One approach is to minimize latency in streaming, thereby also limiting the potential misalignment of streams. Global CDN providers such as Akamai [4], Cloudflare [5] and Fastly [6] provide scalable, low-latency streaming solutions based on Dash [7], HLS [8] or WebSocket [9] protocols. Another option is to leverage support for synchronized stream delivery or fixed end-to-end delays. For instance, in IP-based networks, a fixed end-to-end delay may be achieved by transmitting data to a client ahead of time and then scheduling data delivery to the application in reference to a media clock. However, such methods have some limitations. Due to network jitter, ultra-low-latency streaming may be expensive and provide a reduced user experience. Moreover, synchronizing content using the distribution system increases the complexity of the distribution system itself, which goes against current practices of stateless servers to limit cost and improve scalability. In any case, if consistency is achieved through a specific distribution mechanism, it is also limited to that mechanism.

5) Object-based media: In Object-based Media (ObM) [10]–[12], the challenge of combining technologies is already addressed in production. ObM targets increased support for adaptation, personalization and interactivity in broadcasted experiences. The key idea is to represent media as objects, and let client devices be responsible for assembly into rendered presentations. This way, clients may assemble media experiences differently, be sensitive to device capabilities, local context or user preferences, and leverage data-driven technologies for visualization and interactivity. However, the approach requires changes to media formats, with implications for existing workflows and tools. This is speculated to be a key reason for slow adoption [13]. In addition, ObM is still bound to the single-stream broadcast metaphor. This means that objects are packaged and distributed as one asset, even if each viewer will only make use of a subset of objects. Moreover, the approach does not provide any particular support for multi-device media consumption.

6) Leave it to the user: The last approach, and perhaps the standard solution, is to leave the combination of technologies as an exercise for the viewer. *Formula 1 (F1)* online coverage provides an example of this. *F1TV* [14] offers a number of video streams to choose from, including the professionally produced World Feed, onboard vehicle cameras with team radio for that driver, a produced pit lane feed and even a channel with lap times in tabular form. In addition, the *F1 App* [15] provides an interactive race map and numerous data visualizations for detailed race statistics, which also supports manual time shifting. Viewers may then select the most relevant video feeds and visualizations and use multiple devices to follow multiple interfaces in parallel. As such, this approach supports high levels of customization and personalization. At the same time, to realize this potential, viewers must do all the work. For example, synchronization between interfaces is crucial in a fast-paced sport like F1, yet cumbersome to achieve manually. Moreover, users can not easily know which camera feed is most relevant at any time, or when to switch between views. In short, this approach encourages viewers to act as producers, and leaves media providers with little control over the quality of user experiences.

A. Challenges

Combinations of continuous media and data-driven applications have been attempted in different parts of the technology stack, in production, in distribution, and in presentation, yet each method comes with limitations. Still, combining technology platforms remains an attractive prospect. Online F1 coverage, for instance, showcases a significant potential if only some coordination could be provided between products.

In current systems though, there is limited support for such coordination. Fig. 1 *(left)* illustrates four product interfaces (green rectangles), each defining its own user experience (bubble). This leaves the viewer to mediate between separate user experiences, either compensating mentally for any inconsistencies between them, or manually attempting to correct them, for instance by time-shifting or configuring individual interfaces. Neither option is particularly appealing.

Fig. 1 *(right)* illustrates the basic idea of cross-platform media experiences. Here separate product interfaces (green rectangles) contribute to a single, consistent user experience (bubble). Consistency implies (i) that interfaces operate in reference to a shared media clock, and (ii) that user interactivity is not limited to one product, but applies to the experience as a whole. For instance, if the user selects a different F1 driver, this might potentially affect all interfaces in different ways, including overlayed video graphics in F1TV and the race map visualized by the F1 App.

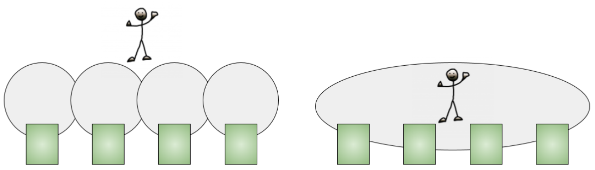

Fig. 1. *(Left)* User engaging with four distinct user experiences (bubbles), defined by four independent products (green rectangles). *(Right)* Instead, the same four products contribute to a single, consistent user experience (user inside the bubble).

To support the notion of cross-platform media experiences, we argue that a solution to coordination is needed, which is not limited to any particular application or platform. We envision an extended media model, with built-in support for coordination. In this model, media products can still be developed for single-platform usage, yet optionally be exploited as parts of larger, consistent, cross-platform media experiences.

III. Problem Statement

Extend the current media model with built-in support for coordination between independent devices, technology types, platforms and product interfaces. The extended model shall

1) support consistent user experiences across platforms *(consistency)*
2) support the combination of continuous and data-driven media *(bridge)*
3) support integration with existing media systems *(compatible)*
4) support high flexibility while limiting complexity *(practical)*

5) support key trends such as automation, adaptation, personalization *(future-proof)*

IV. Current Media Model

Even though *continuous media* and *data-driven applications* represent different technical approaches, we regard them as instances of the same media model. Fig. 2 illustrates this model as a 3-step processing chain (rectangles). The data flow is left-to-right, from data (black) on the left, through assembly (blue) and rendering (green) before reaching the user experience on the right (bubble). User-interactivity (not illustrated) flows in the opposite direction, triggering data updates (black arrow) or control actions (red arrow). Processing steps (data, assembly, render) may be executed within the same process, or be separated by a communication link or a network connection.

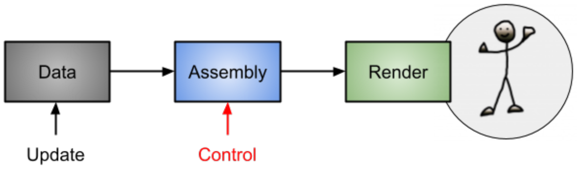

Fig. 2. Conceptual sketch for current media model. The data flow is left-to-right, from data (black) on the left, through assembly (blue) and rendering (green), into the user experience on the right (bubble).

1) Data: Data represents resources for media experiences. Resource types may include common media formats such as audio, video, images, XML/JSON-data, declarative layout or stylesheets. Resource abstractions may include files, streams, databases, or datasets. Resources may be static or dynamic, local or accessed via a network. Access may also be restricted through concepts of ownership and access credentials.

2) Assembly: Assembly (blue) implements a controlled conversion from data sources to render state. This conversion may include processing steps such as selection, filtering, merging, and transforming data from multiple sources. Moreover, assembly is open to dynamic control (red arrow), defining for instance which data sources are selected for rendering, how data is converted into render state, and when. Assembly may also be associated with a media clock, and be expected to update the render state consistently with respect to time progression. This is commonly referred to as playback or sequencing.

3) Render: Render (green) is a function that converts render state into visual display, sound, or other real-world effects. Render components are assumed to be software components, acting as low-latency or fixed-latency proxies for locally connected output devices, such as screens and loudspeakers.

4) User experience: The user experience (bubble) is defined by rendered effects (e.g., audio, visuals, or other). The user may also interact with the media experience, using local input devices such as keyboards, pointing devices and more. User interactivity may result in updates to data sources (black arrow) or control actions (red arrow) targeting the assembly process.

In this model, the assembly step represents the beating heart of the media experience. As either data or control inputs change, the assembly process must continuously reevaluate and adjust the output render state. Over time, this produces a time sequence of render states that defines the progression of the media experience.

A. Continuous Media

Fig. 3 illustrates *over-the-top (OTT)* audio and video production as an instance of the current media model. In this context, data access and media assembly primarily occurs within a production environment. For example, video production may involve a large set of data sources and media contents, mixed together into a single audio or video asset and streamed over a network for playback on viewer devices. Provider-side media assembly may also involve a large production team controlling a number of production parameters, including camera positioning, lighting, sound processing, graphics and visualization, as well as mixing and scheduling. A few aspects of assembly are open to local control by viewers. For instance, media players typically allow viewers to adjust the volume, pause/resume, and select subtitle tracks.

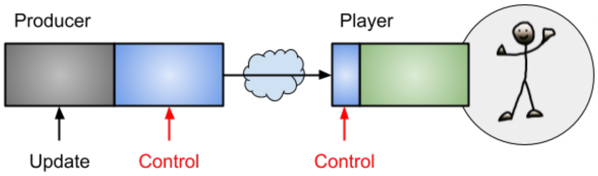

Fig. 3. Data assembled into video or audio streams at the provider side, then distributed for client-side rendering by a media player.

B. Data-driven Applications

Fig. 4 illustrates data-driven Web or native applications as instances of the current media model. In this context, data sources are hosted by servers. Clients connect to fetch or stream data over the network, or receive pushed data. Assembly and rendering can be handled on the client side. For instance, in Web interfaces, clients convert data sources and application state into render state managed by the *Document Object Model (DOM)* [16]. The conversion is defined in application code and may include selection or filtering of data, and also transformations or combinations of data. Moreover, interactive control by the user may trigger changes to the local control state or network-accessible data sources.

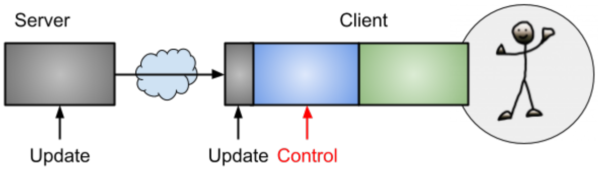

Fig. 4. Web and native applications perform assembly and rendering at the client-side, based on data fetched or streamed from online servers.

V. Control-driven Media

We envision cross-platform coordination as an inherent capability of the media model. Recognizing the central role of *control* in media (see Section IV), we propose a revised media model, where control is redefined from a local signal to an independent, stateful resource, and extended with support for consistent sharing across platforms. This seemingly small change, we argue, comes with profound implications for media systems, applications and user experiences, and also alters the status of control as an object of research, from an application-specific interface feature to a principal system component.

Fig. 5 illustrates the revised media model. Similar to Fig. 2, the model describes a three-step technology stack (Data, Assembly, Render). The difference, though, is that control (red rectangle) is regarded as a special kind of data source and is included in the first step (Data). Like data sources, control sources may be hosted by dedicated online services and accessed by connecting clients.

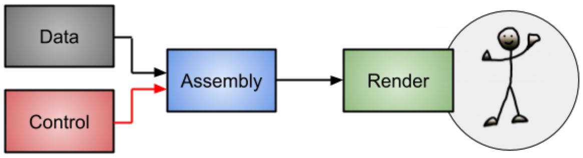

Fig. 5. Control-driven Media, with control represented as a special kind of data source.

Importantly, the revised model does not represent a radical break with the current model. Data sources (black) and render components (green) are unaffected. Assembly (blue) will react to state changes in control sources, instead of live control inputs, but otherwise remain the same. Also, user interactivity (not illustrated) will not target Assembly (blue) directly, but indirectly through modification of data and/or control sources. Beyond this, the model remains the same.

This model is referred to as *Control-driven Media (CdM)*. The name highlights how media production and presentation can be directed through the manipulation of control sources. For example, control sources may define which resources and rendering components are active (e.g. video sources, audio tracks, datasets, layout templates, graphical elements). Control sources may also define values for a variety of interface parameters (e.g. style properties, playback offsets, audio levels, viewport positions). By manipulating the value of such control sources, media experiences will change in predictable ways. As such, control sources represent aspects of application behavior or appearance which are explicitly opened up for external control. The following are defining properties of Control-driven Media.

1) Control is defined as a stateful, shareable resource, local or network accessible.
2) Control is defined in reference to a timeline.
3) Control defines the experience.
4) Assembly is an independent step.

1) Control is a stateful, shareable resource, local or network accessible: Control sources may be local objects. However, with control represented as online resources, considerable opportunities arise with respect to sharing and exchange of control. In particular, control may be distributed in real time between any connected clients across various interfaces and platforms. This may allow media providers to implement production control across a distributed production chain and also across consumer devices. Effectively, this makes consumer devices an integral part of the production infrastructure, blurring the distinction between production and presentation. Online control may also provide a valuable integration point for automated processes, for instance allowing cloud-based AI agents to remote control user experiences in accordance with user preferences. Moreover, online control can be shared between media providers and viewers, opening up for increased collaboration. For instance, when the viewer requests more detailed graphics, the production system can access the online control state for this viewer and implement appropriate changes through modification of relevant control sources.

Control as a stateful resource opens up for a variety of control patterns. Online controls may be private, public, or limited to groups. Access restrictions may also discriminate between roles such as owner, editor or viewer. Online control can support multiple patterns for control exchange (1:1, 1:N, M:1 or M:N) and support both one-way (asymmetric) and multi-way (symmetric) control relations.

2) Control is defined in reference to a timeline: With control as a network-accessible resource, latency is no longer negligible. This is particularly problematic as control signals are often time-dependent. Control actions might refer to a specific offset on a media timeline and/or describe time-dependent transitions. When transferring control signals over a network, such temporal relations must be preserved. Control may also be shared between processes operating in different time-frames. For instance, on-demand consumption requires time-shifted replay of previously recorded control sequences. Moreover, in scenarios with real-time sharing, small skews may be introduced to mask network jitter and avoid buffering issues. To support this, we assert that control must support timeline-consistent sharing between processes. Timeline consistency implies that a control signal can be captured and serialized in reference to a media clock, and reproduced correctly according to a different media clock.

Consistency with a timeline is also a defining characteristic of continuous media. This means that control sources may be regarded as media objects in their own right, and also be described using terminology traditionally reserved for continuous media types. So, like video, control may be captured, recorded, distributed, time-shifted, rewinded, edited, and played back.

3) Control defines the experience: While CdM changes the nature of control, it maintains established distinctions between data and control. Data sources tend to be raw material for an experience, whereas control sources define a particular realization. There might also be a certain asymmetry between the two entities, where data sources may represent large and stable datasets, whereas controls are more lightweight and dynamic. As such, control provides a basis for variation, where different experiences can be produced, without necessarily modifying the data. By opening up for production and distribution of control as a separate and independent resource type, this pattern can be exploited directly in consumer interfaces, providing personalized user experiences as unique permutations of shared data sources and personalized control sources.

> CdM implies a state-based, reactive approach to control. Developers define what is considered control state in a particular application, how control state can be modified, what sharing scope and access restrictions are appropriate, and how control is coupled with application logic (i.e. assembly and interface components). Interface components typically initiate control actions, whereas assembly processes react to changes in control state. If control sources are shared online, this decoupling between producers and consumers of control may apply in the global scope.

4) Assembly is an independent step: In the current media model (see Fig. 2), local control signals dictate that assembly is co-located with the controller, be it the media provider in a studio, or the user in an interactive interface. This forces a choice between provider-side and client-side assembly, with no clear middle ground. With control as an independent resource, assembly instead becomes an independent processing step, with no particular restrictions concerning location. This means that the assembly function can be shifted between locations without modification, for instance between a physical studio and consumer devices, even if rendering technologies may be different for these locations. Moreover, assembly can be split into logical steps and assigned to different nodes in a production chain, such as cloud-hosted production services, edge nodes, and consumer devices (see Fig. 6). Even though nodes may operate in different time-frames, and are not necessarily directed by the same control parameters, the entire chain can still be controlled through the same mechanism.

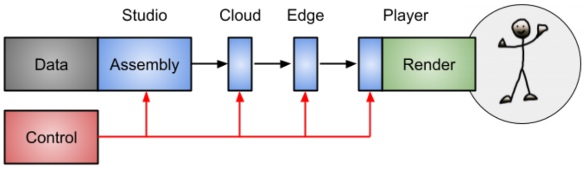

Fig. 6. A stepwise production chain, from physical production studio to consumer device, through cloud-based production and CDN/edge services. Control is time-shifted for each step to allow time for data transfer.

A. Cross-platform Media Experiences

Control-driven Media (CdM) provides a new and highly flexible foundation for cross-platform media experiences. Fig. 7 illustrates three media products $\{P1, P2, P3\}$ hosted by different platforms. Collectively, these products are supported by assembly functions $\{A1, A2, A3\}$ (blue), control service $\{C\}$ (red) and data services $\{D1, D2, D3, D4\}$ (black). Dependencies for each product may be deduced by traversing the graph in reverse, starting from rendering components. For instance, product $\{P2\}$ is defined by render components $\{R2, R3\}$ depending on $\{A2, A3, C, D2, D3, D4\}$.

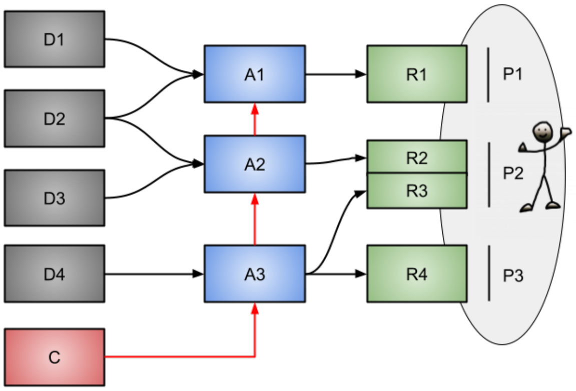

Fig. 7. Cross-platform media experience with three separate products supported by independent technology stacks.

While products $\{P1, P2, P3\}$ may be developed and used independently, they can also be combined to form a larger cross-platform media experience. In principle, this comes down to the scope of control resources, i.e. whether control resources are defined to be exclusive for each product or shared across multiple products. Moreover, with a loose coupling between control resources and application components, aspects of control sharing may easily be changed between applications, interfaces, or even dynamically during a session. Importantly, this means that CdM can support cross-platform media experiences, without requiring architectural changes or significant changes to existing backend systems or render components.

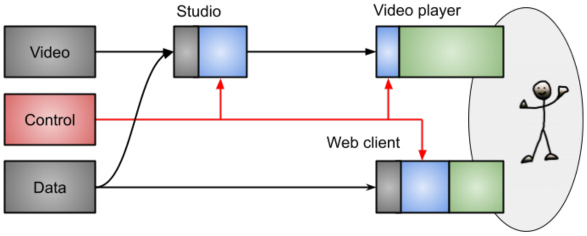

Fig. 8. Cross-platform media experience with video and data-driven visualization.

Fig. 8 illustrates a combined production chain with video content and Web visualization. For instance, in the context of Formula1 racing, *Video* (top, left) could be camera feeds from the track, and *Data* (bottom, left) could be a live dataset with lap times. In the *Studio* (top, middle), a producer may then add data-driven graphics to the video content, for instance switching between a *lower third* with the most recent lap time for the featured driver and a larger table with lap times for different drivers. The *Web client* (bottom, right) may present similar, HTML-based graphics, from the same data source. Furthermore, control sources can be shared between different steps in the production chain. This way, actions taken by the studio producer (e.g. activating or deactivating a graphics element) could also be used to direct Web clients, though time-shifted to match the time-frame of the *Video player* (top, right). The resulting user experience could then be a consistent narrative presented across very different technologies.

VI. Applications

Control-driven Media (CdM) provides ample opportunities for innovation. This section details specific examples in the context of *Formula1 (F1)* racing in order to highlight some possibilities. Still, the themes discussed are likely relevant for a broad range of media applications, and also beyond the world of online sports.

A. Formula 1 Online Coverage

Over recent years, Formula 1 has strengthened its online presence, adding the F1TV [14] streaming service and the F1 App [15] to their classical broadcast offering via TV rights deals. In total, F1 caters to a worldwide audience of motorsport enthusiasts, with an estimated viewership of about 70 million per race in the 2023 season [17]. Ambitions are clearly stated at the F1 site [18]: “Every F1 session live and on-demand.” F1 coverage offers a variety of interfaces into race events, based on vast amounts of data and content streams captured by sensors, cameras and microphones – placed inside vehicles and around the racing track. Products include premixed video channels, specific camera angles or audio tracks, maps with live driver tracking, timetables, interactive visualizations of sensor data and analytics, as well as edited highlights. F1 fans enrich their own experiences by switching between different interfaces, or using multiple interfaces in parallel. In particular, by opening multiple instances of F1TV (5 simultaneous devices are allowed per account) and F1 App on different devices, more screen estate is available for a more immersive experience (see Fig. 9).

Fig. 9. Formula1 online offerings. Image credits formula1.com

B. Case: Adaptive Graphics

Graphics are an essential part of the F1 experiences, amplifying and illustrating important trends and sudden developments from an otherwise overwhelming data corpus (estimated to over a TB of data per race, just from the cars [19]). With adaptive graphics even more opportunities arise. For example, graphics could adapt to custom aspect ratio and personal preferences (e.g. “novice”, “regular”, “engineer”). This is not feasible with traditional video production.

In CdM, graphics can be rendered on the client-side, as video overlays or standalone, data-driven components, while at the same time being controlled from a centralized production system. Client-side graphics can be sensitive to user interactivity and local context (e.g. available display area, GPU support, power-level). Control-driven graphics may also be precisely aligned with video content and connected to live data sources. For instance, during strategically important periods, specific graphics could monitor relevant details for a specific strategic battle. Such graphics already exist, but are only shown sporadically in the World Feed, and normally only for top-team cars involved in a close battle. Furthermore, time-shifted graphics may display up-to-date information, and also remain open for interactive exploration.

C. Case: Immersive Multi-device

F1 is a data-intensive sport, and many F1 enthusiasts are immersing themselves with different views across multiple devices. A successful multi-device setup provides more screen estate to the user experience, and also allows capabilities of different device types to be exploited, for instance by placing video contents on large screens, and interactive features on handheld devices with touch displays. In current offerings, all configuration, synchronization and selections must be done manually by the user.

In CdM, multi-device usage could be simplified by automated configuration. For instance, in response to a pit stop period, video sources and F1 App visualizations could be switched to present relevant data, and personalized HTML-based overlay graphics could be presented consistently with both video content and app visualizations. Control sources may also be used for real-time interactivity between interfaces. For instance, driver selection in the F1 App could affect graphics and content selection across multiple devices. Moreover, control state could also define a mapping between interface components and devices, opening up for automated reconfiguration as devices join or leave the experience [20]. This could for instance be controlled by AI-based agents trained on manual configuration patterns or predefined policies.

D. Case: Lean-back, Lean-forward

F1 advertises a highly customizable product, where viewers can shape their own experience by switching between F1TV streams and interacting with F1 App visualizations. While such interactive engagement is clearly attractive, it may also be taxing in the long run, and even the most forward-leaning F1 enthusiasts may want to lean-back at times, for instance during highly exciting race sequences. In current solutions though, this typically implies a set back to generic broadcast coverage, e.g. the World Feed.

With CdM, the distinction between lean-back and lean-forward coverage can be softened. For instance, by actively controlling aspects of data-driven interfaces, media providers may exploit traditionally lean-forward technologies as part of a produced narrative. Shifting between lean-back and lean-forward modes can also occur seamlessly within the user experience. For instance, switching from lean-back coverage to interactive exploration may simply be a matter of switching control sources, from official provider controls to private controls.

E. Case: Personalization

F1 caters to a highly diverse audience, and many users might appreciate specialized coverage based on preferences such as team affiliation, nationality, language, proficiency level (novice, regular, enthusiast), or accessibility requirements. Individual adaptations, though, are costly in the context of video production.

In CdM, user experiences may to a larger extent be assembled from smaller building blocks (i.e. control and data sources). This provides multiple opportunities for variation. Interfaces may be set up with different versions of data and control sources, and assembly logic may combine them in different ways. This way, CdM may provide the appearance of unique adaptation, even from a modest number control parameters. Personal preferences may also be reconfigured with immediate effects. For instance, changing the proficiency level from “regular” to “enthusiast” may trigger a cascade of changes with low-level control resources, effectively transforming the experience.

F. Case: Social and 3’rd Party Integration

By opening up for collaboration and 3’rd party contributions, media experiences could become both richer and more social. For instance, graphics could indicate the presence of friends watching the same event, and allow viewers to join sessions, or receive reactions from friends who watched earlier. A group of friends could choose to watch the latest F1 race together online, taking turns bringing up interesting stats in the F1 App for all to see and discuss. This notion of collaborative production could also extend to 3’rd party service providers. For instance, a national group for Ferrari fans could provide its members with exclusive contents through the official F1 platform. With a closed production system though, such integrations are often complex and also problematic with respect to content ownership.

In CdM, social and 3’rd party integration can be addressed through control sharing. For instance, by sharing control sources between friends, race events can be presented in synchrony, ensuring that all react to race events at the same time. It would also be possible to follow the experience of a friend or actively direct some aspects of the presentation for a group. Moreover, 3’rd party content sources could be integrated directly into client-facing interfaces, thereby avoiding integration with backend systems.

G. Case: Value-added Time-shifted Coverage

F1 is a live sport, and most F1 viewers prefer to follow live coverage. Still, F1 races are hosted at venues around the world and across many different time zones, making time-shifted consumption a more convenient option in some cases. Time-shifted coverage could also provide other benefits. For instance, production errors could be corrected, and results from time-consuming analysis could be added. A lot of information is also held back during the race itself for strategic reasons. Currently though, time-shifted offerings are limited to replaying the original video content and edited highlights.

In CdM, time-shifted coverage is not limited to video, but may also include replays of data-driven interfaces. The latter implies that time-shifted coverage can remain interactive and open to adaptation. Moreover, control sources can be modified at any time after production, for the benefit of time-shifted viewers. For instance, post-race analysis could optimize control state for the selection and scheduling of video sources (i.e. camera angles) to perfectly capture passes and race incidents as hindsight gives perfect information. This may also apply to live viewers, as live experiences are also time-shifted to some degree, for instance due to delays in production chains for video content.

VII. Technical Challenges

Control-driven Media introduces some new technical challenges. A key challenge concerns the redefinition of *control*, from local signal to online resource. Another important challenge concerns increased complexity in *assembly*, where potentially a large number of data and control sources need to be consistently converted into render state.

A. Control

In CdM, control is a stateful, network accessible resource, defined in reference to a timeline (see Fig. 10).

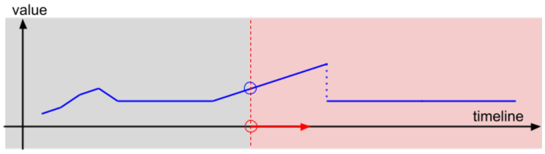

Fig. 10. A control parameter defined in reference to a timeline. The control value (blue) increases and decreases gradually, remains static for a while, increases again, before it is abruptly set to a lower value. By time-shifting the media clock (red ring), past values of the control parameter may be played back again. Illustration adapted from [21]

Challenge 1 - Generic control: The ability to share control is a fundamental property of CdM. Moreover, control sources must support a variety of control patterns to be shared across different time-frames and across a variety of products and application types. To allow such flexible usage, CdM will benefit from a common abstraction for control. At the same time, though, applications are different, and developers must also be able to specify unique control relations and custom control logic. The challenge, then, is to provide a generic and flexible mechanism for control sharing, to be used across very different applications, while at the same time opening up for application-specific extensions or adaptations.

Challenge 2 - State representation: In order to be shared across a network, a serialized format must be defined for control state. One challenge is to define a representation which supports various types of control, including discrete and dynamic state changes. Another challenge concerns the representation of dynamic control signals (e.g. transitions or pointer drags), which must be reproduced with high fidelity for a pleasing user experience, while also minimizing network traffic and latency. Solutions might seek to downsample, approximate and compress dynamic signals ahead of distribution, and correspondingly decompress or upsample signals on receipt. Transitions can be expressed as deterministic mathematical functions, making them particularly effective in terms of network bandwidth.

Challenge 3 - Consistent state sharing: A protocol must also be defined for efficient distribution of control state and changes. Clients observing an online control source need to maintain a consistent view of control state. This may for instance be achieved by receiving the initial state on connect, followed by notifications for subsequent state changes. In a centralized architecture, global ordering for state updates can be used to ensure eventual consistency for observing clients. Different consistency models are possible for control state. A decentralized architecture might also be possible, as long as the consistency model matches application requirements.

Challenge 4 - Low latency: Control sharing over a network implies additional delays for distributing state changes. For instance, in a centralized architecture, update requests must be transmitted from client to a server, before change notifications can be multicast back to observing clients. Internet delays are generally too high for interactive applications, where immediate feedback is expected for interactive control operations. However, this can be addressed by implementing control changes speculatively locally, ahead of Internet distribution, thus removing delay for the local interface. Importantly though, speculative changes may lead to consistency issues, and must occasionally be rolled back if the local ordering of state changes is not consistent with global ordering. In addition, low latency distribution is important for real-time control sharing, and collaborative scenarios in particular. General principles apply for efficient implementation of low latency distribution.

Challenge 5 - Timeline consistent control: Finally, online sharing of control state must also support timeline consistency. This means that the control state must be serialized in reference to a media clock (capture), and correctly reproduced in reference to a different media clock (playback). For example, a live control signal originating from a pointing device may be encoded as a sequence of states, each referring to a segment on the timeline. In playback, these state changes must be repeated at the correct time, including both discrete and dynamic control changes. Reproduction of control state must also be sensitive to changes to the media clock, such as pause, resume or time-shift. Timeline consistency across devices or products requires that devices and products have access to a common media clock.

B. Assembly

In control-driven media, assembly implements a conversion from data sources and control sources, into state prepared for rendering. The objective is to encapsulate application-specific logic and provide simpler resource abstractions matching the requirements of render components. This way, rendering components can be efficient and stateless data sinks, as illustrated in Fig. 11.

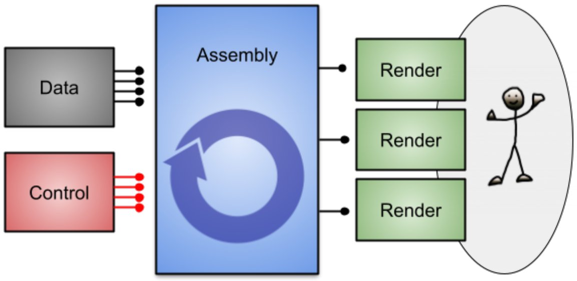

Fig. 11. Assembly converting four data sources and four control sources into three virtual sources of rendering state.

Challenge 6 - Masking heterogeneity: In CdM, assembly (blue) is represented as an independent step, decoupled from data and control sources (black, red) and rendering components (green). By encapsulating application-specific functionality in the assembly step, render components may remain simple, generic, and possibly stateless. This provides opportunities for the reuse of render components across different versions of assembly. Similarly, data and control sources may be reused across different assembly components, or dynamically replaced by alternative sources. To unlock this flexibility, masking heterogeneity will be a key challenge. For instance, by introducing a uniform resource abstraction, assembly functionality may work across input sources with different API or data formats. Similarly, if assembly exports render state in a uniform way, render components may more easily be reused across different assembly components.

Challenge 7 - Timeline consistent render state: The assembly step may also be required to produce render state in accordance with a media clock. While timeline consistency has already been defined for control sources, it may additionally apply to sources of timed data, such as media tracks, logs or timed event sequences. For instance, given a subtitle track, the correct subtitle must be activated and deactivated in render state, during playback. Moreover, if the media clock is altered (e.g. pause, rewind, resume), or if the data source itself is modified (e.g. subtitle edit), render state must be modified accordingly. While this is feasible today using specific tools or ad-hoc solutions, in CdM, timeline consistency is regarded as an integral aspect of state management. The challenge then is to define a practical programming model for time-dependent state assembly, including appropriate concepts and tools.

Challenge 8 - Complexity: The assembly step implements an application-specific conversion from multiple control sources and data sources into active render state. This may involve a variety of standard processing operations such as merging, layering, filtering, aggregation, selection, transformation, etc. There may also be dependencies between sources, constraints, or even conflicts. For instance, a control source specifying more advanced graphics may have to be ignored if the screen is too small, or if power is running low. Moreover, assembly must be well-behaved for a vast set of permutations of control and data sources. This increases code complexity and the burden on developers. The challenge, then, is to allow application-specific and dependable assembly functions to be implemented while limiting the complexity. For instance, framework support for assembly could support advanced processing graphs built from simple, pre-defined processing operations, each open to application-specific parametrization and customization.

VIII. Evaluation

Control and assembly are key challenges in Control-driven Media (CdM). With respect to control, State Trajectory [21] may be a candidate solution. State Trajectory is a unifying concept for interactivity and control in data-driven applications, with built-in support for online sharing and timeline-consistent playback. State Trajectory is supported by implementation and addresses challenges (1-5) in Section VII-A. Concepts and tools for assembly challenges (6-8) in Section VII-B is work in progress. This section presents prior research supporting CdM, and then demonstrates that CdM addresses the problem statement set out in Section III.

A. Prior Research

Control-driven Media (CdM) builds on extensive research over the last 10+ years, in topics such as distributed media synchronization, real-time data sharing, multi-device media experiences, and timeline-consistent, data-driven visualization. Research results include reference implementations for key concepts and services, technical evaluation, and prototype applications.

Addressing the need for timeline-consistent rendering in data-driven media experiences, the Timing Object [22] was introduced in 2015 as a generic concept for media clocks and timeline control. Timing objects are stateful resources that can be shared, observed, and manipulated in application code. Research in media synchronization explored the limitation of audio and video synchronization on the Web platform, demonstrating that echoless synchronization was possible on high-end smartphones as early as 2015 [23]. Sequencing tools for dynamic datasets [24] demonstrated precise synchronization of time-dependent data. Media State Vector [25] demonstrated a scalable solution for online media clocks, with global availability and precision down to a few milliseconds. Effectively, this extended the scope of Timing Objects from a single interface to online multi-device applications.

Together, these concepts define a media model for timeline-consistent, data-driven, multi-device, media experiences [26]. Timingsrc [27] provides reference implementations for time control, media synchronization and sequencing tools for the Web platform. These concepts, along with practical solutions for real-time data sharing, have consistently demonstrated their value as building blocks in data-driven, multi-device media applications.

CdM extends this model by providing a more generalized concept for control. In particular, control in CdM is not limited to media clocks, but can in principle apply to any parameter of a media experience. State trajectories [21] may represent application variables of different types (e.g. int, float, string, object, collection). Moreover, State trajectories track value changes in reference to a timeline, supporting discrete as well as time-dependent (e.g. deterministic, dynamic) changes. State trajectory has been evaluated through implementation, demonstrating a lightweight footprint (CPU, bandwidth, storage), real-time sharing, timeline-consistent playback and a high potential for scaling.

Additionally, CdM extends the scope of assembly. Prior research in data sequencing [24], exclusively addressed timeline consistency for timed data. In CdM, timeline consistency is seen as part of a larger challenge - application state management. It follows that challenges regarding timeline-consistency must be addressed alongside other software concerns, such as modularity, flexibility, composition, customization, and uniformity (masking heterogeneity). To assist developers in reaching these goals, ongoing research targets framework support for assembly in CdM, and development of new and appropriate programming concepts which encapsulate support for timeline-consistency.

B. Addressing the Problem Statement

1) Support consistent user experiences across platforms: CdM provides consistent user experiences across platforms by (i) representing control as an independent system component, open to integration in user-facing products as well as production systems, (ii) opening up for consistent sharing of control between interfaces, and (iii) supporting timeline-consistent assembly of render state.

2) Support the combination of continuous and data-driven media: CdM allows control state to be shared between media players and data-driven interfaces (e.g. overlays, secondary devices), as a basis for consistent presentation and coordination, without introducing any additional limitations. Moreover, in CdM, control sources may be integrated with production systems for continuous media, or time-shifted for direct usage in interactive interfaces on consumer devices.

3) Support integration with existing media systems: CdM does not represent a radical break with existing systems, but rather adds control as a new and independent system component. As such, CdM remains compatible with existing data backends and rendering technologies. Moreover, the added cost of online control is likely modest, as online controls can be massively scaled by dedicated, cloud-hosted services, and do not introduce significant overhead in client interfaces [21]. A stepwise integration path is possible, starting with select render components in specific products.

4) Support high flexibility while limiting complexity: CdM maximizes flexibility by decoupling assembly from control and data sources as well as rendering components. At the same time, CdM provides powerful, generic concepts for control and assembly, encapsulating significant complexity. This combination of decoupling and unified resource representation also makes CdM a practical model for developers, with opportunities for modularity, code reuse, composition, specialization and dynamic recombination.

5) Support key trends, such as automation, personalization, collaboration: In CdM, media experiences are explicitly opened up for external control, through online control sources. This allows automated production processes to monitor live developments, and also direct a narrative through complex control sequences. CdM media experiences are highly flexible, and can support personalization of data, control sources and assembly logic. Moreover, CdM supports collaboration through real-time interactions with control and data, and also collaboration across time-frames, by time-shifting control or data.

IX. Discussion

1) Quality, costs and scalability: Quality, costs, and scalability are important measures for media providers. Importantly, Control-driven Media (CdM) does not significantly alter these measures. Quality, costs and scalability will still be largely determined by existing infrastructure for the production, distribution and rendering of data sources and media content. In comparison, control sources are shown to be lightweight entities (CPU, bandwidth, storage), and may likely be hosted cheaply at a massive scale by dedicated services. On the other hand, CdM may offer improved quality of service, for instance, through provider-driven interface control and consistency in presentation. Such features may be offered to premium subscribers and motivate users to log in to sites that would otherwise be open. CdM may also support high levels of personalization at scale while limiting costs. This could be possible by implementing unique adaptations as part of media assembly on the client side, thus ensuring that consumer devices carry much of the costs. CdM uniquely supports this by offering a common mechanism for production control across the entire production chain, including client-side interfaces.

2) Automation and AI: AI-assisted automation is a hot topic in media production, with opportunities for cheaper production of high-quality content sources. However, automation of the producer role may represent an even larger potential. For instance, AI-based agents could engage in storytelling, weaving together narratives from content sources, datasets, graphical layers and interactive visualizations, adapted to individual preferences, device capabilities or other localized contexts. Essentially, this would correspond to a shift from text-based narratives of first-generation *large language models (LLM)* to true multimodal narration. CdM is well positioned to support this shift. Control sources provide a natural integration point, allowing AI-based agents to monitor control state from consumers, and express narratives through the manipulation of control sources. Moreover, AI-agents do not have to be hosted on consumer devices but may remote control AI-driven experiences from a cloud-hosted production system. Furthermore, AI-based agents may learn directly from live interactivity or be trained by time-shifted replays of historical sessions.

3) Online multiplayer games: CdM bears some similarity to online multiplayer games, where gameplay is driven in real-time by joysticks or fast-paced, pointer-driven interaction. Virtual 3D games also demonstrate a striking potential for client-side rendering, where hardware acceleration (GPU) is exploited to provide rich, smooth and responsive graphics, from a shared data model and a modest number of control parameters (e.g. player position, movement, orientation). However, in gaming platforms such as *Unity and Unreal* [28], [29], control mechanisms are an integral aspect of platform design and are highly optimized with respect to game logic and competitive fairness. In contrast, CdM offers technical solutions for control which may be reused in different applications, or serve as a bridge between platforms. While CdM indeed supports real-time sharing of dynamic control state, support for consistent time-shifting and playback of control may be even more valuable. For instance, in the context of live esports, CdM controls could be used to broadcast control state from competitive gameplay, opening up for slightly time-shifted rendering directly in game engines. Compared to live video distribution, this might offer more flexibility and higher resolution, while also reducing delays and distribution costs.

4) Media orchestration: CdM may also be compared to solutions for command-driven media orchestration. For instance, MIDI [30] is a classic solution for orchestration of equipment related to musical or theatrical performances. MIDI allows command messages to be broadcast within a group of devices, originally restricted to a low-latency, cabled setup. By distributing commands regarding tempo, pitch, notes, volume etc., different instruments may be directed to play in synchrony. MIDI may be used for live collaborative sessions as well as time-shifted performances based on scripted or pre-recorded command sequences. In contrast, CdM models control as a stateful, time-dependent and generic resource, as opposed to transient, application-specific commands. This way, CdM may extend the scope of media orchestration from local to global network, from specific application domain to general usage, and also encapsulate complexity related to time-shifting.

5) A Unifying media model: Finally, CdM may be regarded as a unified model for online media, encapsulating characteristics of classical approaches, such as continuous media, data-driven, interactive media, and command-driven media orchestration. Following this, CdM helps bridge common technical divides, such as one-way broadcast vs multi-way collaboration, single vs multi-device presentation, lean-back storytelling vs lean-forward engagement, or generic coverage vs individual adaptations. With CdM these divisions can largely be reinterpreted as variations in control patterns and sharing scopes. As such, CdM may offer a unifying approach to online media. Moreover, with a more flexible media model, media applications can avoid limitations from early design choices and easily be extended in new directions, if needed.

X. Conclusion

Vast opportunities in media technologies and automation, paired with growing viewer diversity, fuel a demand for increasingly advanced and varied media experiences. To meet the demands of both viewers and media providers, there is an increasing need to leverage complementary technologies, platforms and interfaces as part of a single, consistent user experience. While this challenge is typically addressed within the context of specific applications or platforms, this work shows that a generic solution is possible.

This paper presented *Control-driven Media (CdM)*, an extension of the current media model with built-in support for consistent, cross-platform user experiences. CdM introduces online control as a generic and independent resource type in media systems, thereby opening up for media experiences to be consistently controlled and coordinated across different device types, user interfaces, media products and technology platforms. CdM may also be seen as a generalization over existing approaches; Like continuous media, CdM supports media experiences which are *provider-driven* and *time-driven*. Like Web and native applications, CdM supports experiences which are *data-driven* and *user-driven*. Moreover, CdM is compatible with existing service backends and frontend technologies.

To further demonstrate the flexibility of CdM, the paper also presented a number of opportunities for innovation, relevant for key challenges in the media domain, such as AI-based automation, personalization, collaboration and multi-device support. The evaluation referenced an extensive backlog of supporting research, emphasizing that solutions already exist for key technical challenges.

Finally, by tackling the problem statement from Section III, CdM is confirmed as a practical and forward-looking solution for cross-platform media experiences, with the flexibility needed to address increasingly complex demands from users and media providers.

Acknowledgment

This work was supported by the Research Council of Norway and MediaFutures (Grant number 323302 and 309339).

AI-Assisted Academic Writing: A Comparative Study of Student-Crafted and ChatGPT-Enhanced Critiques in Ubiquitous Computing

Edward R Sykes
School of Computer Science-College of Engineering and Physical Sciences,
University of Guelph, Guelph, Ontario, Canada, N1G 2W1

***Abstract*—This study examines the impact of Large Language Models (LLMs), such as ChatGPT, on the development of academic critique skills among fourth-year Computer Science undergraduates enrolled in a Ubiquitous Computing course. The research systematically evaluates the differences between student-authored critiques and those revised with the aid of ChatGPT, utilizing established readability metrics such as the Flesch-Kincaid Grade Level, Flesch Reading Ease, and Gunning Fog Index. The findings highlight the potential of AI to enhance readability and analytical depth, while also revealing challenges related to dependency, academic integrity, and algorithmic bias. These results extend implications across learning sciences, pedagogy, and educational technology, providing actionable insights into leveraging AI to augment traditional learning methods and enhance critical thinking and personalized education.**

Keywords*—*AI in higher education; AI in academic writing; readability metrics; LLM; ethical considerations

I. Introduction

Generative AI, encompassing technologies such as Large Language Models (LLMs) like ChatGPT, and advanced image generation tools, is profoundly reshaping various facets of the digital and real world. As educators and researchers, it is essential to stay abreast of these advancements to enhance our teaching methods and pedagogical tools, thereby enriching both our own and our students' skillsets.

This research delves into the specific application of LLMs, focusing on ChatGPT, to assess its impact on developing academic critique skills among Computer Science undergraduates enrolled in a fourth-year Ubiquitous Computing course. The core objective of this study is to evaluate and discern the differences between student-authored critiques and those augmented by ChatGPT's assistance.

Through this investigation, we aim to highlight the potential of LLMs to bolster students' critical thinking and writing capabilities. This paper seeks to provide valuable insights into how AI tools can be seamlessly integrated within educational frameworks. Additionally, we explore the transformative role of AI-driven tools in supporting student learning and enhancing the personalized and engaging nature of academic critique processes.

The remainder of this paper is structured as follows: The next section offers a background on Generative AI, focusing on the Transformer architecture, ChatGPT, its applications in education, and readability metrics. In Section III, we outline the methods employed to investigate the effectiveness of ChatGPT as a collaborative tool for supporting technical critique writing. The findings from our quantitative and qualitative analysis are presented in Section IV. Section V reflects on these findings within a broader context, and Section VI concludes the paper while highlighting potential future directions for this line of research.

II. Background

The rapid evolution of Generative AI has profoundly transformed technological capabilities, significantly influencing societal interactions, business processes, and educational methodologies. This section is divided into three main parts. The first part delves into the key technologies that have driven this transformation, highlighting their impact and implications. The second part presents an overview of current applications of Generative AI in the context of education, exploring how these innovations are being integrated into teaching and learning environments. The last section presents an overview of various readability metrics commonly used in the assessment of text.

A. Foundations of Generative AI

Before 2017, Natural Language Processing (NLP) relied heavily on architectures like Constitutional Neural Networks, Recurrent Neural Networks (RNNs), Gated Recurrent Units (GRUs), and Long Short-Term Memory networks (LSTMs) [1]. These architectures were adept at processing sequences and were widely used for various NLP tasks. However, they often struggled with long-range dependencies and were computationally intensive due to their sequential nature, limiting their scalability and performance on larger datasets [1].

NLP took a major leap forward in 2017 with the introduction of the Transformer model by Vaswani et al. [2]. It marked a paradigm shift in sequence modeling, emphasizing the importance of self-attention mechanisms [2]. Essential for developing models that require a complex understanding of sequence data, such as those used in real-time language translation and interactive conversational agents, the Transformer architecture has become a core component of many state-of-the-art AI systems, influencing advancements across numerous fields including healthcare, finance, and autonomous vehicles.

Following the Transformer's success, Google AI's BERT (Bidirectional Encoder Representations from Transformers)

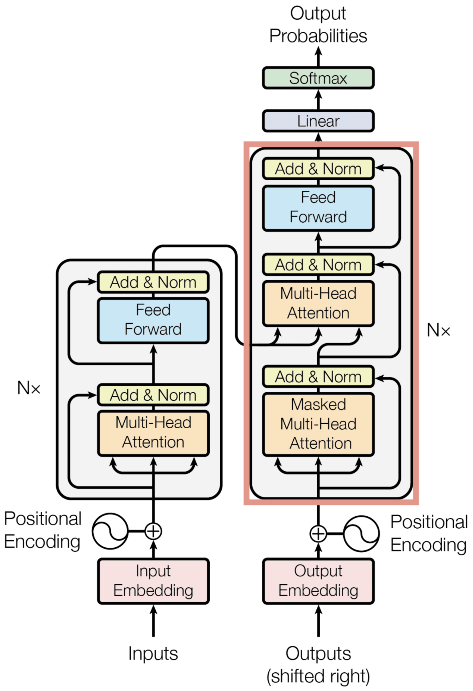

Fig. 1. The Transformer – model architecture [2].

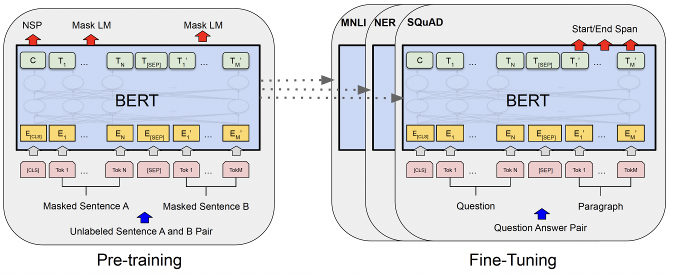

Fig. 2. BERT architectural model [3].

emerged as a significant advancement, leveraging the Transformer's architecture (see Fig. 1) to enhance language understanding [3]. BERT revolutionized natural language understanding by employing a transformer-based mechanism that processes words in the context of the entire sentence, rather than in isolation [3]. This breakthrough has led to substantial improvements in a range of language processing tasks, including translation, text summarization, and sentiment analysis. BERT's architecture leverages a stack of transformer blocks that feature two key components: multi-head self-attention mechanisms and fully connected feed-forward networks. This architecture enables the model to capture complex word relationships and contextual nuances across different parts of the text, facilitating more effective learning and prediction capabilities compared to previous models. BERT is also trained on a large corpus of text in a self-supervised manner using two tasks: masked language modeling and next sentence prediction, which help improve its language understanding. Fig. 2 presents the BERT architectural model, illustrating its deep neural network structure and attention mechanisms that contribute to its powerful performance.

Building on BERT's architecture, RoBERTa (Robustly Optimized BERT Approach) by Facebook AI modified key training methodologies to optimize performance [4]. Specifically, RoBERTa is trained with dynamic masking, full-sentences without NSPloss, large mini-batches, and a larger byte-level BPE [4]. Additionally, RoBERTa includes two other important components that were under-emphasized in the BERT architecture, namely: (1) the data used for pretraining, and (2) the number of training passes through the data. The RoBERTa model is trained on more data, with larger batches and longer sequences. As a result, RoBERTa offers a significant improvement in its language understanding capabilities, pushing the boundaries of what AI can comprehend and respond to, thereby setting new standards for model robustness and accuracy in language tasks [4].

Since 2019, Hugging Face has emerged as a pivotal player in democratizing AI through the development and maintenance of the Transformers library, which provides a vast collection of pre-trained models for a variety of NLP tasks [5]. This open-source library has enabled researchers and practitioners to easily implement cutting-edge models, fostering innovation and accelerating the adoption of AI technologies across industries. Currently, there are over 200 different transformer models available from Hugging Face: https://huggingface.co/docs/transformers/index.

The Generative Pre-trained Transformer (GPT) series, developed by OpenAI, includes notable releases such as GPT-2 in 2019, GPT-3.5 in 2022, and GPT-4 in 2023. Each iteration has progressively expanded the scale and capabilities of language models [6], [7]. With each version, there has been a significant leap in sophistication; for instance, GPT-4 is capable of producing text that closely mimics human writing across a wide range of genres and styles. These advancements underscore the creative potential of AI in generating coherent and contextually relevant text. However, they also bring to light critical ethical considerations, including concerns over misinformation, copyright issues, and the autonomy of AI-driven content creation.

Fig. 3 presents the architecture of the Generative Pre-trained Transformer. The GPT architecture is built upon the foundation of the Transformer model, which utilizes layers of self-attention mechanisms to process text [5]. At the core of the GPT architecture, as illustrated in the figure, is a series of Transformer blocks stacked on top of each other. Each block contains two main sub-layers: a multi-head self-attention mechanism and a position-wise fully connected feed-forward network.

Input embeddings, which convert tokens (words or pieces of words) into vectors of numbers, are first modified by positional encodings to retain the sequence order of the input text. These embeddings then pass through the Transformer blocks, where the self-attention mechanism allows the model to weigh the importance of different words relative to each other, regardless of their position in the text. This is followed by normalization and feed-forward layers that help in refining the representation with nonlinear transformations.

Each attention head in the multi-head attention layer computes an attention score, which represents how much focus to place on other parts of the input sentence as each word

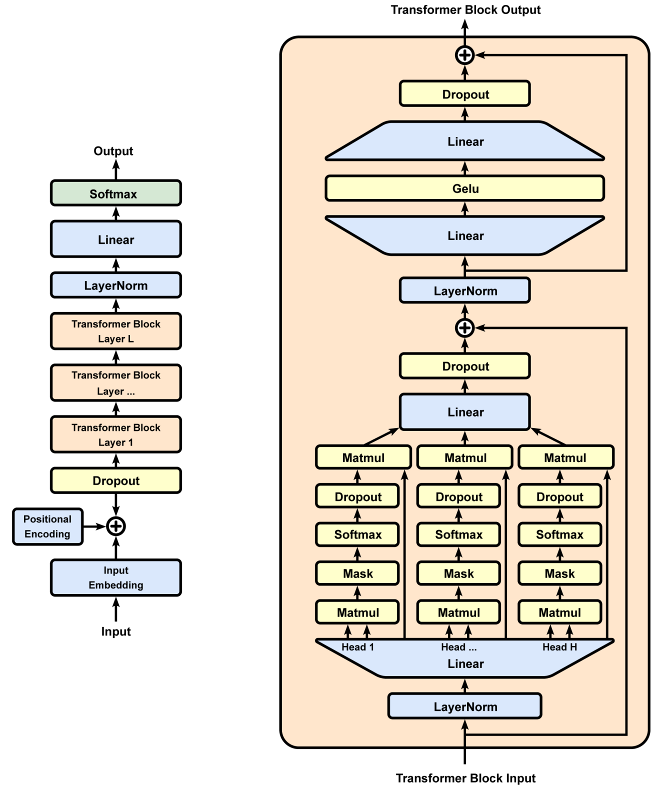

Fig. 3. The GPT Architecture [7].

is processed. The attention outputs are then combined and linearly transformed into the expected dimensions. Dropout layers are incorporated to prevent overfitting by randomly omitting subsets of features during training. The entire process within a Transformer block is designed to be differentiable so that it can be efficiently trained using gradient descent-based optimization.

This architecture enables GPT to generate text by predicting the next word in a sentence based on the words that came before it, learning to generate coherent and contextually relevant language over time. This capability makes GPT highly effective for a range of applications from automated content generation to sophisticated conversation simulations.

In 2020 Facebook AI Research published a paper on Retrieval-Augmented Generation (RAG) which introduces an approach that combines the generative capabilities of models like GPT with the retrieval of factual information during the generation process [8]. This methodology enhances the model's ability to produce relevant and accurate responses by dynamically retrieving context from a vast corpus of data, representing a significant advancement in efforts to bridge the gap between human-like understanding and AI output. Some examples of RAG models include:

1) Call centre agent support: Call centre agents require extensive knowledge of potentially hundreds of products and services, as well as commonly occurring product issues and their resolution. RAG solutions could assist agents in quickly finding answers to client requests.

2) Customer chatbots: RAG is strong enabler for creating customer-facing chatbots to answer frequently asked questions. Combining the natural language abilities of LLMs and the enterprise-specific responses of RAG can deliver a compelling, conversational customer experience.

3) Support / helpdesk: Similar to call centre agents, IT operations and support personnel require deep knowledge of the configuration of complex systems deployments along with knowledge of common and previously seen issues and their resolution. RAG solutions could assist support personnel with quickly finding relevant answers to reported problems and observed issues.

In the context of education, RAG offers transformative potential for educational environments by enhancing personalization, efficiency, and interaction in learning processes [9]. By combining the generative capabilities of models like GPT with dynamic information retrieval, RAG can create tailored educational content, support research and writing, and enhance interactive tutoring systems [8]. RAG's ability to pull relevant data from extensive knowledge bases allows it to generate accurate, context-specific content, making it ideal for developing personalized learning materials and dynamic assessment tools. Additionally, its application in question-answering systems can provide students with precise and informative responses, thereby fostering a deeper understanding of the subject matter [8].

However, the integration of RAG into educational tools must be approached with caution, addressing potential challenges such as ensuring the accuracy and reliability of content, mitigating data biases, and upholding stringent privacy standards. Continuous collaboration with educators, careful dataset curation, and rigorous testing are essential to leverage RAG's capabilities effectively while maintaining educational integrity and compliance [9], [10].

B. ChatGPT in Education

ChatGPT, has been progressively integrated into educational contexts, showcasing potential across various teaching and learning activities. This section explores its primary applications and the emerging studies surrounding its efficacy and challenges in educational settings.

1) Automated content and assessment tools: ChatGPT excels in generating and customizing educational content such as quizzes, reading materials, and assignments. It also offers potential in preliminary assessments by providing feedback on written assignments, which can be particularly beneficial in managing large classes [11].

2) Tutoring and support: As an interactive tutor, ChatGPT responds to student inquiries, assists with homework, and explains complex concepts, offering personalized support outside traditional classroom settings. This 24/7 availability can significantly enhance student learning, especially in subjects requiring frequent practice or clarification, such as languages and sciences [12].

3) Enhancing engagement and language learning: In discussions, ChatGPT can stimulate engagement by posing challenging questions or introducing diverse viewpoints. For language learners, it serves as an invaluable practice tool, facilitating conversation in various languages, which helps improve linguistic fluency and cultural awareness [13].

4) Challenges and ethical considerations: Despite its benefits, the deployment of ChatGPT raises concerns regarding reliability, potential biases, and academic integrity. Misinformation, inherent biases from training data, and the potential for students to misuse essay-writing capabilities require careful consideration and regulation. Ensuring that these tools are used to complement traditional educational methods rather than replace them is crucial for maintaining the quality and integrity of education [14].

The integration of these advanced Generative AI technologies in educational settings offers unprecedented opportunities for enhancing teaching and learning. Educators are leveraging these tools to develop more engaging and interactive learning environments, tailor educational content to individual needs, and foster critical thinking skills [9], [10]. However, this integration also poses challenges, including ensuring the ethical use of AI in classrooms, protecting student data privacy, and maintaining academic integrity.

C. Readability Metrics

The following set of established readability metrics are important in the assessment of text difficulty, engagement, and appropriateness for educational content.

1) Readability metrics used in educational assessments: Understanding the readability of educational content is crucial for tailoring materials to appropriate comprehension levels. This study employs several established readability metrics to evaluate the text complexity and accessibility of student-generated critiques. Below is a detailed explanation of each metric and its significance:

a) Flesch-kincaid grade level: Estimates the U.S. school grade level needed to understand the text. Lower scores indicate easier readability. A score of 12.0, for instance, suggests that the text is suitable for twelfth graders or equivalent [15]. The Flesch-Kincaid grade level is calculated with the following formula:

$$0.39\left(\frac{\text{total words}}{\text{total sentences}}\right)+11.8\left(\frac{\text{total syllables}}{\text{total words}}\right)-15.59 \tag{1}$$

b) Flesch reading ease: Evaluates text simplicity based on the average sentence length and the average number of syllables per word. Scores range from 0 to 100, with higher scores indicating easier readability. For example, texts scoring between 60 and 70 are considered suitable for standard reading, while a score in the range of 10.0 - 30.0 is ranked at the ‘College graduate’ level, typically very difficult to read and best understood by university graduates [16]. The Flesch Reading Ease score is calculated as follows:

$$206.835-1.015\left(\frac{\text{total words}}{\text{total sentences}}\right)-84.6\left(\frac{\text{total syllables}}{\text{total words}}\right) \tag{2}$$

c) Dale-chall readability score: Uses a list of familiar words to assess the grade level. Higher scores indicate more challenging text. A score of 9.0-10.0 suggests that the text is best understood by college-level readers [17]. The Dale-Chall readability score is calculated with the following formula:

$$0.1579\left(\frac{\text{difficult words}}{\text{words}}\times 100\right)+0.0496\left(\frac{\text{words}}{\text{sentences}}\right) \tag{3}$$

d) Automated Readability Index (ARI): Uses characters per word and words per sentence to estimate the grade level required for comprehension. A score of 13.0 indicates that the text is suitable for college freshmen [18]. The ARI score is calculated:

$$4.71\left(\frac{\text{characters}}{\text{words}}\right)+0.5\left(\frac{\text{words}}{\text{sentences}}\right) \tag{4}$$

e) Coleman liau index: Estimates the U.S. school grade level necessary to understand the text, based on characters per word and words per sentence. A score of 11.0-12.0 indicates high school senior level complexity [19]. The Coleman–Liau index is calculated with the following formula:

$$CLI = 0.0588\cdot L - 0.296\cdot S - 15.8 \tag{5}$$

where L is the average number of letters per 100 words and S is the average number of sentences per 100 words.

f) Gunning fog index: Estimates the years of formal education needed to understand the text. A score of 16.0 suggests college graduate level difficulty [20]. The Index is calculated as:

$$0.4\left[\left(\frac{\text{words}}{\text{sentences}}\right)+100\left(\frac{\text{complex words}}{\text{words}}\right)\right] \tag{6}$$

g) Linsear write formula: Calculates the U.S. grade level based on sentence length and the number of easy or difficult words. A score of 8.0 means the text is suitable for eighth graders [21]. (See [21] for the algorithm to compute the Linsear Write value.)

h) SMOG index (Simple measure of gobbledygook): Estimates the years of education needed to understand a text based on the number of polysyllabic words. A score of 17.0 implies graduate-level readability [22]. SMOG is calculated using this formula:

$$1.043\sqrt{\text{num of polysyllables}\times\frac{30}{\text{num of sentences}}}+3.1291 \tag{7}$$

i) SPACHE score: Specifically designed for early readers, assessing sentence length and word familiarity. A score suitable for first to third graders would typically be below 4.0 [23]. This instrument is not suitable for upper level undergraduate or graduate students.

These readability metrics collectively provide insights into the accessibility of written content, ensuring that educational materials are appropriately challenging yet understandable for the intended audience.

2) Additional readability and quality metrics: Beyond traditional readability metrics like the Flesch Reading Ease and Linsear Write Scores, other computational assessments such as the Bilingual Evaluation Understudy (BLEU), Recall-Oriented Understudy for Gisting Evaluation (ROUGE), and Metric for Evaluation of Translation with Explicit Ordering (METEOR) provide a broader evaluation of text quality, especially in contexts involving generative AI. BLEU measures the precision of generated text against reference texts by comparing the overlap of phrases and their order, making it ideal for assessing translation accuracy and content generation tasks in educational tools. This metric is widely used in machine translation to quantify how closely machine-generated text resembles human-like translations. Similarly, ROUGE is crucial for evaluating the coverage and recall of summaries produced by AI, ensuring that essential content is not omitted. It compares the extent to which the generated summaries capture the content present in a set of reference summaries, which is particularly useful in the evaluation of text summarization systems. Meanwhile, METEOR enhances evaluation by incorporating synonymy and stemming, alongside exact word matching, providing a balanced measure of fluency and intent preservation in generated text. Unlike BLEU, METEOR is designed to align more closely with human judgment by accounting for the flexibility in language use. Collectively, these metrics help in assessing the suitability of AI-generated educational content, aligning it with pedagogical goals and learner needs. Their application ensures that educational tools powered by AI not only generate content that is factually accurate but also presented in a manner that is understandable and engaging for students.

In summary, both BLEU and METEOR are traditionally utilized in machine translation to evaluate the alignment of translated text against one or more reference texts. These metrics quantify the extent of word and phrase overlap in the machine-generated text relative to the reference texts. Meanwhile, ROUGE assesses the quality of summaries by measuring the overlap between a generated summary and reference summaries, focusing particularly on the recall of essential content. However, in this study, there are no *reference texts* available that would typically be required for these metrics to function effectively. Consequently, traditional readability metrics, which do not rely on reference texts, are deemed most appropriate for evaluating the critiques created by the students.

In the next section, we present the methodology supporting our investigation into the potential of LLMs to bolster students' critical thinking and writing capabilities.

III. Methodology

This comprehensive study was implemented during the Fall 2023 semester with fourth-year undergraduate students enrolled in the Ubiquitous Computing (UbiCom) course in the Computer Science department[1]. The methodology included multiple components designed to rigorously evaluate the effectiveness of AI-assisted academic critiques.

A. Participants

Participants were recruited through convenience sampling through advertisements throughout the Computer Science Club, course postings, and other mediums available at the education institution. There were a total of 22 participants involved in this study all in their final year of study in their Honours Bachelor of Computer Science baccalaureate degree. There were 5 females and 17 males; the minimum age was 21, the mean was 25, and the maximum age was 31.

B. Detailed Process of Critique Assignment

Each week, students were assigned two academic papers centred around pivotal UbiCom topics such as Smart Homes, Smart Cities, IoT, and Wearable Technology. These topics were chosen to ensure that students were exposed to diverse applications and theoretical advancements within the field of Ubiquitous Computing. The selection process involved curating papers that varied in complexity and scope, providing a robust testbed for critique development. Seminal papers were selected, such as, Mark Weiser's 'The computer for the 21st century' in 1999 [24]. Mark Weiser is often referred to as the father of ubiquitous computing [7].

> *... Now we are in the personal computing era, person and machine staring uneasily at each other across the desktop. Next comes ubiquitous computing, or the age of calm technology, when technology recedes into the background of our lives.* —Mark Weiser

Other papers provided a survey of the state-of-the-art in a specific area (e.g., Smart Cities). For example, 'Systematic literature review of context-awareness applications supported by smart cities' infrastructures' [25].

C. Baseline and AI-Assisted Critique Process

Initially, critiques were written individually, and independently, without the assistance of any Generative AI assistance (e.g., ChatGPT, Bing, etc.) to establish a baseline for each student's analytical and writing abilities. Students were then asked to write critiques with the assistance of ChatGPT, following a structured well-defined methodology. Students were also given a 1-hour training session on effective prompt engineering and how to objectively assess ChatGPT's responses. This session aimed to empower students with the skills needed to elicit detailed and specific feedback from ChatGPT, enhancing their ability to refine their arguments and writing clarity.

D. Continuous Feedback and Iteration

A critical component of the methodology was the continuous feedback mechanism. After each AI-assisted critique, students received personalized feedback from both the course instructor and the AI, highlighting areas of improvement and success. This feedback loop was essential for guiding students' development over the semester and for refining the use of AI in the critique process. The students were asked to elicit feedback from ChatGPT at most 3 times. Please see the Appendix for the full details of the assignment.

E. Comprehensive Evaluation Metrics

The assignments were evaluated using a combination of quantitative and qualitative metrics, as described below.

1) Quantitative metrics: The core metrics were the readability tests. A suite of these tests were applied to each critique, providing a multifaceted view of how readability evolved with AI integration. This included advanced readability formulas that assessed not only text difficulty but also engagement and grade-appropriateness of the content.

[1] This research was approved by Sheridan's Research Ethics Board No. 2023-10-001-022.

Additional metrics collected and analyzed included the critiques' length, structure, and complexity changes from baseline to AI-assisted versions. The specific readability metrics computed were: Flesch-Kincaid Score, Flesch Reading Ease, Dale Chall Readability Score, ARI Score, Coleman Liau Index Score, Gunning Fog Score, Linsear Write Score, and SMOG Score.

a) Statistical analysis: Statistical analyses were performed on the readability data collected. Standard descriptive statistics were computed. Furthermore, we aimed to determine if there were any statistical differences over time in the readability scores, both between and within the groups: 'student-authored only' and 'student-and-ChatGPT-co-authored' critiques. These comparisons were made by examining the weekly critiques for most of the term. Due to the non-parametric nature of the data, one-way repeated measures ANOVAs using the Friedman test were computed.

2) *Qualitative metrics:* Evaluations were further deepened by analyzing the critiques for argumentative depth, logical coherence, and the use of evidence, which were scored using a rubric developed specifically for this course.

a) Educational outcomes monitoring: Beyond the critique process, the study monitored broader educational outcomes, such as student engagement, perceived ease of completing assignments, and overall satisfaction with the learning process. Surveys and interviews were conducted at the beginning, middle, and end of the semester to capture students' attitudes towards the use of AI in their learning process.

b) Ethical considerations and bias monitoring: Given the use of AI in educational settings, the study also addressed ethical considerations, particularly concerning the dependence on technology and the potential for AI to introduce biases into the students' work. Measures were put in place to monitor and mitigate any adverse effects, ensuring that the AI's integration was both responsible and beneficial.

IV. Findings

This section presents the qualitative and quantitative findings from this study.

A. Quantitative Findings

The following section provides an overview of the key findings from using ChatGPT to support co-authoring of academic critiques based on the readability scores for 'student authored' vs. 'student and ChatGPT co-authored.' Table I presents a comprehensive report of the readability analysis including standard descriptive statistics for 'student authored' critiques for the entire term (i.e., weeks 1-8). Each entry represents the group mean for that specific week for the respective readability metric.

It can be seen that the readability generally decreased as the term went on. This was particularly evident for the Flesch Reading Ease which started at 34.74 and declined to 24.32 at the end of the term (week 8). When referencing the mean, the readability levels across the entire group and the term, were: Flesch-Kincaid Score: 14.01 (college/university level), Flesch Reading Score: 30.24 (college/college graduate), Dale Chall: 11.38 (graduate level), ARI: 14.72 (college level), Coleman-Liau: 14.86 (graduate level), Gunning Fog: 16.21 (college senior), Linsear: 15.44 (college senior), and SMOG: 15.39 (undergraduate).

Table II presents the readability analysis including standard descriptive statistics for 'student and ChatGPT co-authored' critiques for the term.

A similar pattern emerged as in Table I. The Flesch Reading Ease started at 26.88 and declined to 15.50 by week 8. Using the mean of the readability scores across the group yielded the following results: Flesch-Kincaid Score: 14.89 (college/university level), Flesch Reading Score: 23.46 (college graduate), Dale Chall: 11.97 (graduate level), ARI: 15.65 (college level), Coleman-Liau: 16.17 (graduate level), Gunning Fog: 17.16 (college senior), Linsear: 15.87 (college senior), and SMOG: 16.00 (undergraduate).

Fig. 4 presents the weekly 'student authored' readability score analysis over the term. The most obvious pattern is the Flesch Reading score which shows a general decreasing trend throughout the term. The other readability scores were relatively consistent throughout the term.

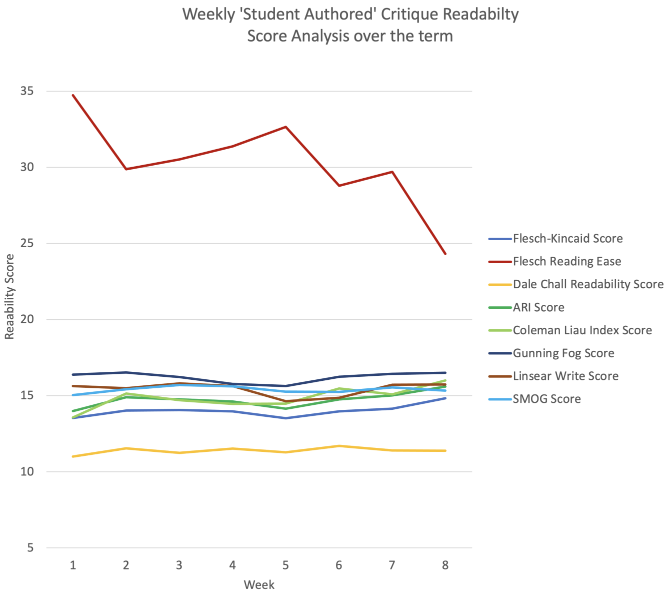

Fig. 4. weekly 'student authored' critique readability score analysis over the term.

Fig. 5 displays the weekly readability score analysis for critiques co-authored by students and ChatGPT over the term. Similar to the trends observed in Fig. 4, the most notable pattern is the general decline in the Flesch Reading Ease score throughout the term. Other readability metrics remained relatively stable over the period.

Statistical Analysis and ANOVA Results Prior to performing the ANOVAs, we verified the necessary assumptions to ensure the appropriateness of the statistical models. These assumptions included the independence of observations, normality of the data distributions, and homogeneity of variances. The Shapiro-Wilk test was used to confirm normality [26], and Levene's test was applied to assess the homogeneity of variances [27].

TABLE I. Comprehensive Readability Metrics with Standard Descriptive Statistics for Student Authored Critiques (weeks 1-8)

Week	Flesch-Kincaid Score	Flesch Reading Ease	Dale Chall Readability Score	ARI Score	Coleman Liau Index Score	Gunning Fog Score	Linsear Write Score	SMOG Score
1	13.54	34.74	11.00	13.98	13.57	16.37	15.63	15.04
2	14.02	29.87	11.53	14.89	15.14	16.52	15.49	15.41
3	14.06	30.52	11.25	14.76	14.70	16.23	15.80	15.71
4	13.97	31.38	11.51	14.62	14.45	15.77	15.63	15.61
5	13.52	32.65	11.28	14.14	14.47	15.63	14.63	15.26
6	13.97	28.79	11.70	14.75	15.47	16.24	14.85	15.24
7	14.15	29.69	11.40	15.03	15.09	16.44	15.72	15.53
8	14.83	24.32	11.39	15.59	15.99	16.51	15.73	15.34
Min	13.52	24.32	11.00	13.98	13.57	15.63	14.63	15.04
Max	14.83	34.74	11.70	15.59	15.99	16.52	15.80	15.71
Mean	14.01	30.24	11.38	14.72	14.86	16.21	15.44	15.39
Std Dev	0.41	3.05	0.21	0.50	0.74	0.34	0.44	0.22

TABLE II. Comprehensive Readability Metrics with Standard Descriptive Statistics for Student and ChatGPT co-Authored Critiques (weeks 1-8)

Week	Flesch-Kincaid Score	Flesch Reading Ease	Dale Chall Readability Score	ARI Score	Coleman Liau Index Score	Gunning Fog Score	Linsear Write Score	SMOG Score
1	14.65	26.88	11.65	15.26	15.12	17.44	16.33	16.40
2	15.02	22.79	12.06	15.88	16.38	17.65	16.18	16.14
3	15.26	20.96	12.18	16.07	16.64	17.48	16.24	16.59
4	14.90	24.95	12.00	15.62	15.62	16.82	16.29	16.29
5	14.01	27.51	11.75	14.75	15.77	16.06	14.44	15.39
6	14.52	24.61	12.09	15.23	16.12	16.96	15.16	15.59
7	14.71	24.49	11.93	15.54	16.11	16.91	15.73	15.96
8	16.06	15.50	12.09	16.85	17.56	18.00	16.55	15.65

Std Dev	0.60	3.83	0.18	0.63	0.73	0.60	0.72	0.43

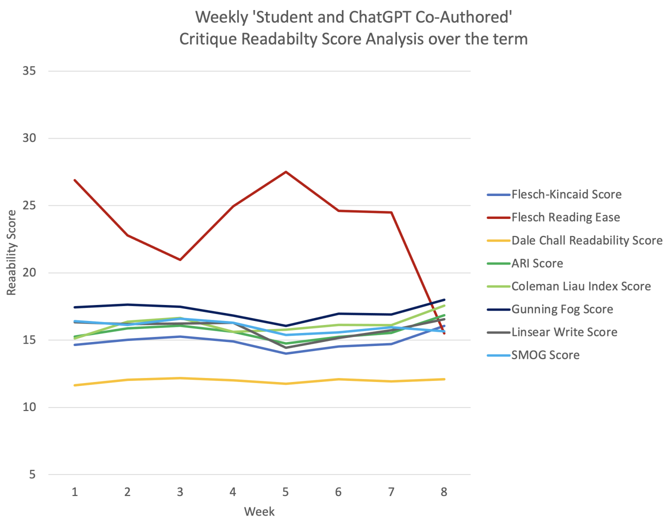

Fig. 5. Weekly 'student and chatGPT Co-Authored' critique readabilty score analysis over the term.

After confirming these assumptions, ANOVAs were conducted for each readability metric to determine if there were statistically significant differences between critiques authored solely by students and those co-authored with ChatGPT. The results are as follows:

- *Flesch-Kincaid Score*: Significant difference; $F(1, 14) = 11.974$, $p = 0.003$.
- *Flesch Reading Ease*: Significant difference; $F(1, 14) = 15.356$, $p = 0.0015$.
- *Dale Chall Score*: Significant difference; $F(1, 14) = 34.994$, $p < 0.0001$.
- *ARI Score*: Significant difference; $F(1, 14) = 10.558$, $p = 0.005$.
- *Coleman Liau Index*: Significant difference; $F(1, 14) = 12.609$, $p = 0.003$.
- *Gunning Fog Score*: Significant difference; $F(1, 14) = 15.076$, $p = 0.001$.
- *Linsear Write Score*: No significant difference; $F(1, 14) = 2.050$, $p = 0.174$.
- *SMOG Score*: Significant difference; $F(1, 14) = 12.707$, $p = 0.003$.

The results indicate that for all metrics except the Linsear Write Score, there were statistically significant differences between the student-authored and ChatGPT co-authored critiques over the eight weeks. These findings suggest that the integration of AI like ChatGPT in the writing process significantly influences the readability and possibly the quality of student critiques.

Interestingly, the decrease in readability scores over time, especially in measures like the Flesch Reading Ease, might reflect a transition towards more complex academic language. This trend could be attributed to the students' exposure to high-quality academic literature and their advancement in understanding and synthesizing complex concepts. It appears that as students engaged with seminal works and sophisticated material, their ability to emulate academic rigour in their own writing improved, leading to the production of text that, while potentially more challenging for lay readers, aligns more closely with fourth-year undergraduate and graduate-level standards. This evolution in writing style underscores the effectiveness of AI tools in fostering higher-order cognitive skills, including critical analysis and academic writing prowess.

1) Individual student performance observations: Deeper investigations on specific participants yielded some interesting results. The following examples illustrate these findings. Participant #23: Flesch Reading Ease: In one critique, the score improved from a very low 4.728 to a higher 10.666. This is a significant improvement in readability, suggesting that the co-authoring process made the document more readable. Gunning Fog Score: In the same document, the score changed from 19.783 to 18.669 with the assistance from ChatGPT. This indicates a reduction in sentence complexity, contributing to better readability.

Participant #22: Flesch Reading Ease: For one critique, the score dropped slightly from 36.667 to 32.726. While this is a decrease, it's still within a range that suggests good readability, possibly indicating a more balanced approach to complexity and readability in the co-authored version.

Participant #3: Flesch Reading Ease: Improved from 23.316 to 27.886 in one document, indicating an increase in readability. Linsear Write Score: Decreased from 13.115 to 12.538, which points towards simpler sentence structure.

B. Qualitative Observations

In several cases, the co-authored documents show an improvement in readability scores, suggesting that ChatGPT can help in making complex academic content more accessible.

Conversely, there are instances where the complexity of the documents increased, possibly reflecting a deeper level of analysis or more advanced vocabulary and sentence structures due to the academic nature of the critiques. Some documents show a balance between maintaining academic rigour and ensuring readability, which is crucial in educational settings.

V. Discussion

The results of this study underscore significant implications for integrating AI, specifically Large Language Models like ChatGPT, into educational settings. The data reveal a discernible trend of fluctuating readability scores throughout the semester, suggesting that while AI tools can enhance the readability of academic critiques, their effectiveness may vary based on the complexity of the assignments and the adaptability of students.

A. Interpretation of Quantitative Findings

The quantitative analysis shows that readability scores, such as the Flesch Reading Ease and Flesch-Kincaid Grade Level, generally declined as the semester progressed. This trend could reflect the increasing complexity of the topics covered in the assignments, requiring a higher cognitive load from students, which might impact their writing clarity when attempting to articulate complex ideas.

Additionally, the decline in readability might also be attributed to a natural evolution in students' writing abilities. Exposure to complex texts is crucial in academic settings as it significantly correlates with improved analytical skills and academic writing proficiency, as discussed in the study by Graesser et al. [28].

This perspective is further supported by cognitive load theory. Engaging with sophisticated texts can enhance cognitive and analytical skills in higher education students, supporting the notion that challenging materials promote academic rigour [29]. The methodology of this study, through its iterative approach, encouraged students to use ChatGPT wisely by reflecting on the AI's suggestions and revising their critiques accordingly. This approach may have impacted the development of cognitive skills such as critical thinking and academic writing.

Furthermore, a study by O'Sullivan et al. (2020) demonstrated the impact of AI tools on learning, suggesting that tools like ChatGPT can foster critical thinking and academic writing skills [30].

Moreover, the statistical analysis employing ANOVA revealed significant differences in readability metrics between critiques authored independently by students and those co-authored with ChatGPT. This result highlights AI's potential to distill complex articles into more accessible academic language, thereby enhancing the accessibility of the critiques. However, it also emphasizes the need for careful integration of these tools to preserve content depth and ensure analytical rigour.

A potential concern with the observed decrease in readability scores could be an over-reliance on AI tools, which might lead to less critical engagement with the material and result in more convoluted expressions in student writings. However, this issue was not observed by the instructor during class work, class discussions, or in the grading of the students' critiques.

B. Qualitative Insights and Student Engagement

Qualitatively, the data indicated significant variation in individual student experiences, with some students demonstrating marked improvements in writing clarity and others showing increased complexity in their expression. This variance suggests a need for tailored approaches in AI integration that consider the individual profiles and needs of students.

C. Challenges and Ethical Considerations

The study also highlights several challenges and ethical considerations. The potential dependency on AI tools raises concerns about the ability of students to develop independent critical thinking skills. Balancing the use of AI for educational benefits while ensuring that students remain the primary agents in their learning processes is crucial. Moreover, ethical issues related to data privacy, bias in AI algorithms, and the authenticity of student work require ongoing attention and the development of robust regulatory frameworks.

D. Educational Implications and Future Directions

This research contributes to the ongoing discourse on the role of AI in education by providing empirical evidence of its benefits and limitations. Future research could explore the long-term impacts of AI integration on student learning outcomes through longitudinal studies. Additionally, investigating diverse educational settings and varied student demographics could help generalize the findings and tailor AI educational tools more effectively.

Overall, AI offers substantial opportunities for enhancing educational practices, but its integration must be managed judiciously to complement traditional learning methods and support the holistic development of students' critical and analytical skills.

VI. Conclusion

This study explored the impact of integrating ChatGPT into academic critique writing, highlighting notable improvements in the writing quality and analytical depth across various metrics. The results affirm the potential of AI tools to not only enhance traditional educational methods but also to personalize and enrich learning experiences for both educators and students.

However, the study's limitations, including its small sample size and the demographic homogeneity of the participants, caution against broad generalizations of these findings. The short duration of the study also limits insights into the long-term effects of AI integration in educational settings. Future research should, therefore, expand these investigations across more diverse educational contexts and over longer periods to better understand the enduring impacts of AI on learning outcomes. It is also essential to address the ethical challenges associated with AI use in education, such as ensuring data privacy and managing the risk of academic dishonesty, through the development of robust ethical frameworks and guidelines.

In an effort to support ongoing research and foster an open academic environment, we have made the following resources available:

- our Jupyter notebook that utilizes Python for reading Microsoft Word documents (i.e., critiques) and computing readability metrics is available at https://bitbucket.org/ed_sykes_team/workspace/overview/. This notebook employs various Python libraries including *os*, *csv*, *aspose.words* (available at https://products.aspose.com/words/), *re*, the *Readability* framework (available at https://pypi.org/project/readability/), and *statistics* to facilitate analysis.
- An Excel workbook containing anonymized data from weeks 1-8, complete with standard descriptive statistics and complete ANOVA statistical analysis results, can be accessed here: https://bitbucket.org/ed_sykes_team/workspace/overview/.

A. Future Research

As AI continues to integrate into educational landscapes, it is imperative for educators, researchers, and policymakers to adopt a balanced approach to its use. This approach should aim to ensure that AI complements traditional teaching methodologies, enhancing educational outcomes while safeguarding the integrity and rigour of academic processes.

The sample size in this study was very small, comprising only 22 participants. Future work should include larger and more diverse samples to cross-validate the findings. Additionally, this study spanned only one semester; future research should consider extending the duration to several semesters or even academic years to assess the long-term effects on student learning outcomes. Conducting such longitudinal studies would yield a more comprehensive dataset.

Lastly, while this paper briefly addressed ethical questions about AI in education, further research is needed to elaborate on measures that could minimize potential biases and ensure academic integrity. Such efforts would pave the way for establishing practical guidelines for educators.

Acknowledgment

Special thanks to all the participants whose cooperation was essential for this research.

Appendix

Weekly Assignment Overview

- ✓ Every week you need to read the required readings (selected articles)
- ✓ Write two 1-2 page critiques on any 2 of the selected articles for each topic
- ✓ Use MS word; double spaced, times new roman, font size 12
- ✓ Note: A sample critique document is provided on the course website.

Critique Paper Structure:

Title Page

A critique of "<title of paper> by <author(s)>"

By: <your name, student #, course code, etc.>

Summary: The section should summarize the purpose, methodology, and main findings of the paper.

Critique: This section should critically examine the paper, identify the pros and cons, limitations, and achievements. Your critique should be objective and factual. There are many sites that can guide you in writing a critique (e.g., University of Calgary, University of Michigan, etc.)

Questions: List 2-4 questions that you have about the paper. The intention is that you can raise these questions during the Discussion period after the Ubicom Topic Presenters give their talk.

Create two versions for each of your critiques:

1) *Student Authored Version:* Without any writing assistance, create a critique of the academic paper by yourself; and
2) *ChatGPT Co-authored version:* Using ChatGPT, ask it to review your critique and provide suggestions for improvement. Reflect on the prompt engineering sessions you had with the instructor and use these suggestions to revise your critque based on your judgement. Repeat this process up to 3 times.

Submission Instructions:

1) Submit these two versions to the course website using the following naming convention for your files:
   'Name_Week_X_Critique_1_Student_Authored_Only.docx'
   'Name_Week_X_Critique_1_Student_ChatGPT_co_authored.docx'

   'Name_Week_X_Critique_2_Student_Authored_Only.docx'
   'Name_Week_X_Critique_2_Student_ChatGPT_co_authored.docx'

2) Print out a hardcopy of critiques and bring them to class so that you can refer to it during the discussion portion of the class. At the end of the class, hand them to the professor.

A Natural Language Processing Model for the Development of an Italian-Language Chatbot for Public Administration

Antonio Piizzi[1], Donatello Vavallo[2], Gaetano Lazzo[3], Saverio Dimola[4], Elvira Zazzera[5]
Tempo S. R. L., Bari, Italy[1, 2, 3, 4]
Kad3 S. R. L., Fasano, Italy[5]

***Abstract*—Natural Language Processing models (NLP) are used in chatbots to understand user input, interpret its meaning, and generate conversational responses to provide immediate and consistent assistance. This reduces problem-solving time and staff workload and increases user satisfaction. There are both rule-based chatbots, which use decision trees and are programmed to answer specific questions, and self-learning chatbots, which can handle more complex conversations through continuous learning about data and user interactions. However, only a few chatbots have been developed specifically for the Italian language. *T*he development of chatbots for Public Administration (PA) in the Italian language presents unique challenges, particularly in creating models that can accurately understand and respond to user queries based on complex, context-specific documents. This paper proposes a novel natural language processing (NLP) model tailored to the Italian language, designed to support the development of an advanced Question Answering (QA) chatbot for PA. The core of the proposed model is based on the BERT (Bidirectional Encoder Representations from Transformers) architecture, enhanced with an encoder/decoder module and a highway network module to improve the filtering and processing of input text. The principal aim of this research is to address the gap in Italian-language NLP models by providing a robust solution capable of handling the intricacies of the Italian language within the context of PA. The model is trained and evaluated using the Italian version of the Stanford Question Answering Dataset (SQuAD-IT). Experimental results demonstrate that the proposed model outperforms existing models such as BIDAF in terms of F1-score and Exact Match (EM), indicating its superior ability to provide precise and accurate answers. The comparative analysis highlights a significant performance improvement, with the proposed model achieving an F1-score of 59.41% and an EM of 46.24%, compared to 49.35% and 38.43%, respectively, for BIDAF. The findings suggest that the proposed model offers substantial benefits in terms of accuracy and efficiency for PA applications.**

Keywords—Natural Language Processing; chatbot; BERT; transformer; Italian language

I. Introduction

A chatbot is an application that uses various techniques to understand user input, interpret its meaning, and generate responses in a conversational manner based on the user input. Implementing a chatbot as a support tool offers several advantages for both the end users and the businesses [1]. First, chatbots can provide immediate assistance to users by helping to reduce the time it takes to solve problems. Second, chatbots can provide 24-hour support, even outside normal business hours, with shorter resolution times and higher user satisfaction. In addition, chatbots can be used to identify common problems and trends through analysis of user questions, enabling the company to proactively address these issues and reduce the number of support requests. It is also cost-effective as it helps reduce the workload of IT staff and the need for additional staff or overtime. A chatbot also offers benefits to the business because it helps reduce the workload of IT staff and the need for additional staff or overtime. Chatbots can be classified into two main variants: rule-based and self-learning. Rule-based chatbots are developed to answer specific questions or perform actions based on predefined rules and logic because the responses are written in advance and correspond to a set of predefined questions or commands. However, these chatbots are limited to understanding complex natural languages and are unable to adapt to new situations. Therefore, chatbots based on Artificial Intelligence (self-learning chatbots) have been developed to overcome these issues. Self-learning chatbots learn from data and user interactions, gradually improving their ability to respond accurately. They can manage more complex conversations and adapt to new scenarios and user requests. However, they require initial training and are more complex to develop than rule-based chatbots. Complexity is to ensure the best response to each and every unpredictable user input. In the context of public administration (PA), a self-learning chatbot should be capable of understanding and interpreting documents provided by users as input in order to generate appropriate responses. For example, such a chatbot could handle requests that involve reading and interpreting official documents, offering precise and relevant answers. A chatbot developed with these requirements would represent a great advantage in terms of time as well as efficiency for public administration staff.

Despite the widespread use of chatbots in various languages, there is a significant gap in the development of advanced NLP models specifically designed for the Italian language, particularly in the context of Public Administration (PA). Most existing chatbots are either rule-based, which limits their ability to handle complex and varied user inputs, or they are designed for languages like English, for which extensive datasets and pre-trained models are available. However, Italian-language chatbots remain underdeveloped due to the lack of comprehensive datasets and specialized models that can accurately process and understand Italian text, especially within the specific and formal context of PA.

This research seeks to address this gap by proposing a novel NLP model based on the BERT architecture, tailored specifically for the Italian language. The model is designed to overcome the limitations of existing approaches by incorporating an encoder/decoder module and a highway network module to enhance the processing of Italian text. By training and evaluating the model on the SQuAD-IT dataset, this study aims to provide a robust solution that significantly improves the accuracy and efficiency of Italian-language chatbots in PA contexts, thereby filling a critical void in current NLP research. In particular, the proposed work presents an NLP model for the development of a QA self-learning chatbot able to read any document and provide relevant and specific responses to users. The proposed model architecture is based on the BERT [2] model architecture, with the addition of an encoder/decoder module and a highway network module to improve the filtering of the input text. Specifically, the encoder module takes as input a sequence of tokens and transforms them into a dense vector representation that captures the semantic and syntactic information of the text. The decoder module takes the vector representation provided by the encoder as input and generates a new sequence of text. The highway network filters irrelevant information before processing the last dense layers. Moreover, the proposed model is trained on the SQuAD-IT dataset to develop a chatbot specifically for the Italian language. Only a few works have used the Italian version of the SQuAD dataset, and the proposed work is intended to present an efficient and suitable architecture for developing an Italian-specific chatbot. The main contributions of the proposed work are summarized below.

1) A customized BERT model architecture with the addition of an encoder/decoder module and a highway network module has been proposed. The proposed model is developed to be integrated into an Italian-specific chatbot to improve the work of PA staff by reducing time and errors in processing and understanding documents.

2) The proposed model is trained and tested on the Italian version of the SQuAD dataset to evaluate the model's ability to process the Italian language.

3) The results of the experiments conducted on the SQuAD-IT dataset show that the proposed model has a good ability to provide exactly the expected answers. Moreover, a comparative analysis shows that the proposed model outperforms compared to other NLP models, such as BIDAF.

II. Related Work

Different types of self-learning chatbots have been developed based on the deep-learning models used. Three macro-categories can be identified: chatbots based on Convolutional Neural Networks (CNNs), chatbots based on Recurrent Neural Networks (RNNs), and chatbots based on hybrid models. CNNs are mainly used for pattern recognition in text data, such as sentences or paragraphs. Subsequently, sentence similarities between question-answer pairs are used to assess relevance and rank all candidate answers. In study [3] a CNN for learning an optimal representation of question-and-answer sentences has been proposed. The CNN encodes the correspondences between words to better acquire interactions between questions and answers, resulting in a significant increase in accuracy. The proposed CNN consists of two distributional sentence models based on convolutional neural networks (ConvNets) that map question-and-answer sentences into their distributional vectors, which are then used to learn their semantic similarity. In study [4], a model that considers both similarities and differences between question-and-answer by decomposing and composing lexical semantics on sentences has been proposed. Given a pair of sentences, the model represents each word as a low-dimensionality vector and computes a semantic correspondence vector for each word based on all the words in the other sentence. Then, based on the semantic correspondence vector, each word vector is decomposed into two components: similar and dissimilar. The similar components of all words are used to represent the similar parts of the sentence pair and the dissimilar components of each word are used to model the dissimilar parts explicitly. Subsequently, the similar and dissimilar components are composed into a single feature vector that is used to predict sentence similarity. In study [5], a CNN with a Siamese structure with two sub-networks processing the question and the candidate response has been proposed. The input is a sequence of words each of which is translated into its corresponding distributional vector, producing a matrix of sentences. Convolutional feature maps are applied to this matrix of sentences, followed by ReLU activation and simple max-pooling to achieve a representation vector for the query and candidate response. CNNs can have difficulty capturing long-term dependencies in text. Therefore, they are combined with RNNs or transformers to improve performance.

RNNs can process data sequences of variable length, making them ideal for text. In research [6], a bilateral multi-perspective matching (BiMPM) model has been proposed. The proposed model encodes the sentences through a bidirectional Long Short-Term memory Network (BiLSTM). The matching between encoded sentences is aggregated through a layer BiLSTM into a matching vector of fixed length. It is used in the last fully connected layer of the proposed model to make a decision. The approach in study [7] extends a long short-term memory (LSTM) proposed as a holographic dual LSTM (HDLSTM). HDLSTM is a unified architecture for both deep sentence modeling and semantic matching. RNNs are less efficient than CNNs and transformers in terms of parallelization and training speed. Therefore, hybrid models that combine the advantages of each model have been developed. RNNs have been combined with CNN [8], with attention mechanisms [9] or with transformer [10], [11]. Minjoon Seo et al. [12] have proposed a Bi-Directional Attention Flow network (BIDAF) that uses a bi-directional attention mechanism to obtain a query-sensitive context representation. The attention layer is not used to summarize the context paragraph into a vector of fixed size, but attention is computed for each time step, and the expected vector in each time step, together with the representations of the previous layers, can flow through the next modeling layer.

The introduction of the transformers in NLP models has led to advantages in efficiency, ability to capture long-range relationships, parallelization, and quality of representations. The transformer architecture allows higher parallelization during training and inference because it does not require sequential computation as in RNNs. This significantly reduces training time compared with RNNs. Therefore, using transformers represents one of the best choices to develop self-learning chatbots.

The proposed model is based on BERT architecture that use transformer to construct deep and bidirectional representations of words so as to capture complex contextual relationships. Moreover, the proposed model implements additional modules in the standard BERT architecture to increase the model's capabilities in providing correct answers.

III. Materials and Methods

The proposed model is based on an extended version of the BERT model by adding an encoder/decoder module and a highway network module. The proposed model is illustrated in Fig. 1. The proposed model consists of four main modules.

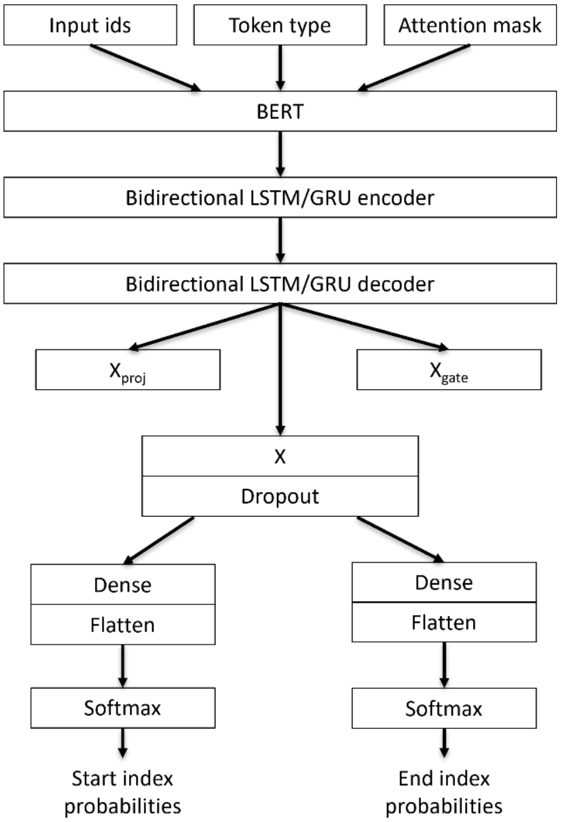

Fig. 1. Proposed model architecture.

A. Input Module

The first module consists of BERT architecture to encode the input into a vector representation that is then processed by the subsequent structures. BERT architecture can be represented as a multilayer bidirectional transformer encoder. BERT's pre-training is based on two different unsupervised tasks: the Masked Language Model (MLM) and Next Sentence Prediction (NSP). In MLM, a portion of the words in the text are masked, and the model must predict them. In NSP, the model must determine whether two sentences appear consecutive in the original text. This pre-training makes the BERT model scalable (fine-tuned) for different tasks, such as QA. BERT takes as input the combinations of the question and context as a single embedded sequence. The input embeddings are the sum of the token embeddings and segment embeddings. Specifically, token embeddings represent the encoding of the question into an embedding vector, and segment embeddings represent vectors indicating the segment to which each token corresponds. The segment embeddings are used to distinguish between question and context in the input text. Let $x = [x_1, x_2, \dots, x_n]$ represents a sequence of input, and e_i represents an embedded achieved combining the token and segment embeddings for each x_i . The sequences of embeddings $E = [e1, e_2, \dots, e_n]$ is the input of the BERT module. The module BERT processes the embedding sequence through L transformer layers to obtain the output sequences $H^L = [h_1^L, h_2^L, \dots, h_n^L]$ where h_i^L is the hidden representation of $x_1$at the L level.

B. Encoder / Decoder Module

The encoder/decoder module consists of two sequential BiLSTM layers. The introduction of this module better captures the context and temporal sequence of words, thus improving the model's overall performance in understanding. Specifically, the BERT output $H^L = [h_1^L, h_2^L, \dots, h_n^L]$ is taken as input to encoder/decoder module to produce a new sequence of hidden representations $H^{BiLSTM} = \left[h_1^{BiLSTM}, h_2^{BiLSTM}, \dots, h_n^{BiLSTM}\right]$.

C. Filter Module

The highway network module aims to filter out irrelevant information before processing the last dense layers. Highway Network transformations are based on a linear combination between the non-linear transformation of the input and the original input following a gate function. The output of the Highway network module is defined in Eq. (1), where ∘ represents the element-by-element multiplication.

$$y_i = T\left(h_i^{BiLSTM}\right) \circ S\left(h_i^{BiLSTM}\right) + \left(1 - T\left(h_i^{BiLSTM}\right)\right) \circ h_i^{BiLSTM} \quad (1)$$

The linear transformation $T(\cdot)$ is defined by Eq. (2), where W_T and b_T are the weights and the bias of the gate function, respectively, and σ represents the sigmoid function.

$$T\left(h_i^{BiLSTM}\right) = \sigma\left(W_T h_i^{BiLSTM} + b_T\right) \quad (2)$$

The non-linear transformation $S(\cdot)$ is defined in Eq. (3), where W_S and b_S are the weights and the bias of the non-linear transformation, respectively, and $ReLU$ is the activation function.

$$S\left(h_i^{BiLSTM}\right) = ReLU\left(W_S h_i^{BiLSTM} + b_S\right) \quad (3)$$

D. Output Module

The output module consists of two fully connected layers with softmax activation function. The output module predicts the start and end positions of the response within the context following Eq. (4) and Eq. (5), respectively.

$$P_{start}(i) = softmax(W_{start}y_i + b_{start}) \quad (4)$$

where, W_{start} and b_{start} represent the weights and bias of the fully connected layer for the prediction of the start token.

$$P_{end}(i) = softmax(W_{end}y_i + b_{end}) \quad (5)$$

where, W_{end} and b_{end} represent the weights and bias of the fully connected layer for the prediction of the end token.

IV. Dataset

SQuAD-IT [13] dataset is a translated and adapted Italian version of the popular SQuAD dataset [14] SQuAD dataset has been developed to evaluate NLP models in English. The main advantage of this dataset is that it is realistic because humans crowdsourced it manually. It includes 536 English Wikipedia articles with more than 100,000 related question-answer pairs. Each crowd-worker was asked to answer up to five questions about a Wikipedia passage, highlighting the answer in the passage. Each question is associated with a segment of text within the article (context), and the answer is a subset of the context. Each question had several specific answers provided by different people. In SQuAD-IT, the texts, questions, and answers in SQuAD have been translated into Italian. The translation aims to maintain the same structure and content as the original dataset but ensures that the sentences are natural and grammatically correct in Italian. SQuAD-IT has been developed to evaluate NLP models that are not limited to English. The use of the SQuAD-IT dataset for the experiments enables the evaluation of the proposed model in understanding the Italian language to develop an Italian-specific chatbot.

V. Experimental Evaluation

Experiments have been conducted to evaluate the proposed model's performance in providing the correct answer in the QA task. The performance has been evaluated in terms of F1-score and Exact Match (EM). F1-score is the harmonic mean of accuracy and recall rate. In other words, the F1-score measures the overlap between the words in the predicted answer and the corresponding words in the correct answer (ground truth). The EM computes the percentage of correct answers generated by the model compared to the ground truth. F1-score and EM have been computed following Eq. (6) and Eq. (7), respectively.

$$F1 - score = 2 \cdot \frac{precision \cdot recall}{precision + recall} \quad (6)$$

$$EM = \frac{\sum_{i=1}^{N} I(pred_i = truth_i)}{N} \quad (7)$$

In Eq. (7), N represents the number of test examples, $pred_i$ and $truth_i$ represent the predicted answer and the correct answer, respectively, and $I(\cdot)$ is a function that returns 1 if the condition is truth or 0 otherwise.

To evaluate the proposed model, the SQuAD-IT dataset has been divided following the train-test split ratio of 80:20, and the proposed model has been trained following the parameters detailed in Table I. The results of the proposed model in terms of F1-score and EM are shown in Table II. The proposed model achieves good performance in providing exactly the correct answer, even considering that it is obtained on an Italian dataset explored by very few studies in the literature. The F1-score of 59.41% indicates a good balance between precision and recall, and an EM of 46.25% indicates that almost half of the answers provided by the model are perfectly accurate. An EM score lower than the F1-score means that the model often approximates correct answers but does not provide correct answers. EM is a very rigorous metric because it measures the percentage of answers that are exactly the same as the correct answers.

TABLE I. Training Parameters for the Proposed Bert-Based Model

Parameter	Value
Encoding dimension	128
Decoding dimension	64
Loss	Sparse Categorical Cross-Entropy
Optimizer	Adam
Batch size	8
Learning rate	5e-5
Number of epochs	6
Dropout	False

TABLE II. Performance Results of the Proposed Bert-Based Model on the Squad-It Dataset

Metric	Score (%)
F1-score	59.4106
EM	46.2544

Moreover, a comparative analysis has been conducted to evaluate the performance of the proposed model compared to the BIDAF model. To a fair comparison, the BIDAF model is trained and tested with the same train-test split ratio used for the proposed model. Table III details the training model parameters used for BIDAF. The comparative analysis shows that the proposed model achieves an improvement of 10.06% in F1-score and 7.81% in EM compared to BIDAF, as shown in Table IV. In other words, the proposed model is capable of providing significantly more correct answers compared to the BIDAF model.

TABLE III. Training Bidaf Model Parameters

Parameter	Value
Loss	Sparse Categorical Cross-Entropy
Optimizer	Adam
Batch size	10
Learning rate	5e-4
Number of epochs	10
Dropout	0.2

TABLE IV. Comparative Analysis

Model	F1-score	EM
Proposed	**59.4106**	**46.2544**
BIDAF	49.3504	38.4313

VI. Discussion

The development of an Italian-language chatbot tailored for Public Administration represents a significant step forward in the application of NLP models to non-English languages. Throughout this study, it became clear that the unique linguistic and contextual challenges of the Italian language, especially in formal and legal settings, demand specialized models that go beyond generic NLP solutions. Our personal insight is that the integration of an encoder/decoder module and a highway network module into the BERT architecture not only enhances the model's ability to process complex input but also addresses the specific needs of the Italian language, which is often syntactically richer and more flexible than English. This study has demonstrated the potential of these modifications to improve the accuracy and relevance of responses in a chatbot context, which is crucial for the efficiency of Public Administration tasks.

Looking towards the future, several areas offer promising opportunities for further exploration. Firstly, the proposed model could benefit from ensembling strategies, where multiple models are combined to refine the accuracy and robustness of the responses. This could help mitigate the limitations observed in exact match accuracy, especially in cases where the model approximates but does not fully capture the correct answers. Additionally, expanding the dataset beyond the SQuAD-IT to include domain-specific data from Public Administration could enhance the model's contextual understanding and make it even more effective in real-world applications. Another avenue worth exploring is the application of transfer learning techniques, where the model could be pre-trained on broader Italian-language datasets and then fine-tuned on Public Administration-specific data. This approach could further improve the model's performance in specialized contexts. Finally, considering the rapid advancements in NLP, future work could also involve adapting the proposed model to more recent architectures like GPT, which might offer even greater capabilities in terms of natural language understanding and generation.

VII. Conclusion

An extended architecture of the BERT model specific to understanding the Italian language has been proposed. The proposed model introduced an encoder/decoder module and a Highway network module before the fully-connected layers into the BERT architecture to improve the ability of the model to capture the context and temporal sequence and to filter out irrelevant information. The proposed model performs well in providing the exact expected answers. Comparative analysis shows that the proposed model outperforms the BIDAF model, providing almost 8% more correct answers. Moreover, the proposed model is one of the first models developed specifically to be able to process Italian language texts, as it was tested with the Italian version of the popular SQuAD dataset. The proposed model represents the ground for developing an Italian-specific chatbot for the PAs. Therefore, the proposed model, implemented in a chatbot, could make the work of PAs more efficient in terms of time and workload reduction. In future, ensembling strategies could be used by combining responses from multiple models to improve overall accuracy and the number of incorrect answers.

Deep Neural Network and Human-Computer Interaction Technology in the Field of Art Design

Lan Guo, Lisha Luo, Weiquan Fan*
College of Fine Arts, Jingchu University of Technology, Jingmen 448000, Hubei, China

***Abstract*—Traditional art design is usually based on the designer's intuitive creativity. Limited by individual experience, knowledge and imagination, it is difficult to create more abundant and higher quality works, and the workload is huge, which limits the production efficiency of artworks. Through deep neural networks and human-computer interaction technology, the quality of art design can be improved; the workload and cost of designers can be reduced, and more artistic inspiration and tools can be provided to designers. The main contribution of this paper is to propose the use of a Cycle Generative Adversarial Network (Cycle GAN) to realize the automatic conversion of text to image and provide an immersive art experience through human-computer interaction technology such as virtual reality. In addition, the target audience of this paper is art designers and researchers of human-computer interaction technology, aiming to help them break through the traditional creation mode and lead art design to diversification and avant-garde. The content loss rate of character image conversion in Cycle GAN was reduced by 74.5% compared with that of human image conversion. The average peak signal-to-noise ratio of figure images generated by Cycle GAN was 57.9% higher than that of figure images generated by the artificial method. The character images generated by Cycle GAN reduce content loss and are more realistic. Deep neural networks and human-computer interaction technology can promote the development and progress of art design, break the traditional creative mode and bondage, and lead art to be more diversified and avant-garde.**

***Keywords*—Deep neural network; human-computer interaction; Cycle Generative Adversarial Networks; art design; image generation**

I. Introduction

Traditional art design often relies on manual production and processing, which requires a longer time and a large amount of labor. This limits the production efficiency and quantity of artworks, making it difficult to meet large-scale market demand. Deep neural networks can automatically generate images, providing artists with ideas and more design options. The sound interaction and motion interaction in the human-computer interaction technology collect the designer's voice input and movement analysis, and deepen the interaction with the art work. Deep neural networks and human-computer interaction technologies provide artists with new ways to create and extend the boundaries of their imagination and creativity. Artists can express their creativity and ideas directly through natural language, without being limited by technology or tools. They can use the language and expression they are familiar with to translate their creative inspiration into images or design works. Although existing research has explored the application of artificial intelligence in art design, most studies have not analyzed in depth the specific advantages of deep learning techniques in improving the quality and design efficiency of artworks, nor have they systematically compared the practicability and effectiveness of traditional methods with emerging technologies.

The deep learning neural network analyzed in this paper is a kind of machine learning technology that mimics human brain neural networks. It can realize automatic learning and processing of massive data by constructing complex networks. This method has been well applied in computer vision and natural language processing. In terms of art design, the use of deep learning neural networks can allow computers to learn different art styles, skills and elements, and then achieve the purpose of artificial intelligence design. In this paper, Cycle GAN is used to automatically generate images. Cycle GAN is a method to understand and process the semantics and grammar of natural language, and corresponding pictures can be automatically generated according to the description of artists. Deep Convolutional Inverse Graphics Networks (DC-IGN) are also used to transform image styles in combination with time or space. Through sound interaction and body interaction in human-computer interaction, artists can interact with their ideas and create the works they want as long as they express them in a natural way. In the existing literature, although some studies have explored the impact of artificial intelligence and digital tools on artistic creation, this paper verifies the actual effectiveness of deep learning in artistic design through empirical research, especially in the innovative application of automatic text-to-image conversion and image style conversion. Further, through detailed technical comparative analysis, this paper demonstrates the remarkable effects of Cycle GAN in reducing content loss and improving realism in art image generation, providing a new creation tool and methodology for art designers.

This paper aims to explore the application of deep neural networks and human-computer interaction technology in the field of art design, especially how to improve the quality and efficiency of art creation through these technologies, while reducing the workload and cost of designers. The goal of the research is to evaluate the performance of Cycle Generative Adversarial Networks (Cycle GANS) in automatic text-to-image conversion, and combine interactive technologies such as virtual reality to enhance the display of art works and the immersive experience of the audience, in order to promote the development of art design in a more diversified and avant-garde direction.

Main contributions:

1) Deep neural network improves the quality of artistic creation: This paper proposes to use deep neural network technology, especially Cycle GAN, to realize the automatic conversion of text to image, so as to assist art designers to create more abundant and higher quality art works, and reduce the labor intensity of designers.

2) Human-computer interaction technology enhances art experience: This paper discusses how human-computer interaction technology, including virtual reality and multimodal interaction, provides a more immersive and interactive experience for art design, and makes the display and viewing of art works more modern and personalized.

3) Significant improvement of art design efficiency and economy: Through practical data and case analysis, this paper shows that the application of deep neural network and human-computer interaction technology in art design can significantly improve design efficiency, reduce costs, and increase the market competitiveness of art works and audience participation.

This paper first sets the research background in the introduction part, and summarizes the research gaps of deep neural network and human-computer interaction technology in art design. Then, the related work section reviews the current status and challenges of the application of artificial intelligence in art design. The main part of this paper is divided into eight core sections: In Section III, the application of deep neural network in image generation and intelligent creation tools is discussed; secondly, Section IV analyzes how human-computer interaction technology promotes art design and display. Finally, the practical effects of these technologies in improving design efficiency, reducing costs, enhancing user experience and economic benefits are evaluated in Section V. In Section VI, the cost-effectiveness of traditional methods and the proposed methods are further compared, and the impact of human-computer interaction design on user satisfaction is deeply analyzed in Section VII. The conclusion in Section VIII summarizes the research results, emphasizes the importance of technological innovation in the field of art design, and puts forward the direction of future research. All citations are listed in the References section, which provides academic support for the research.

II. Related Work

The field of art design often relies on traditional artificial design. The works designed are affected by many factors, and the design time is relatively long. The emergence of the digital age has provided new means for art design. Changsheng WANG's research showed that AI art creation workflows, such as AI image straight-out method, AI-assisted drawing method and ControlNet precision drawing method, effectively improved the creation efficiency and accuracy, and promoted the innovative expression of digital art [1]. Anantrasirichai explored the application of AI technology in the creative industries, analyzed the use of AI in content creation, information analysis, content enhancement, information extraction, and data compression, and noted that AI's potential as a tool to enhance human creativity was greater than its ability as an independent creator [2]. Through practical workshops for Finnish pre-service craft teachers, Vartiainen explored the potential benefits and challenges of text-image generation AI in art design, such as algorithm-based bias and copyright issues, and analyzed the complex relationship between creative production and generative AI [3]. Wang, Xiaolong designed an intelligent management system of art exhibition based on IoT and AI, which had a short response time and could meet the requirements of practical applications. At the same time, the multi-touch system based on BPNN was developed, and the gesture recognition accuracy was high, providing an efficient solution for the field of interactive art [4]. Cetinic comprehensively reviewed the application of AI in art analysis and creation, including tasks such as art digitization, classification and retrieval, as well as the practice and theory of AI in art creation, and looked forward to the future development of AI in art understanding and creation [5]. Mayo emphasized the importance of pre-service teacher education in integrating AI for artistic creation, proposing the need for structured curricula and technical support to train educators and students while addressing biases and ethical issues in the use of AI to drive innovation in art education [6]. Li Sixian discussed the intelligent development of digital media art through interdisciplinary research methods, analyzed the integration of technology, communication and art, as well as the problems and solutions in the wave of intelligence, and aimed to explore innovative strategies for digital media art [7]. In a critical review of the existing literature, it is found that although the application of artificial intelligence in the field of art and design has been extensively explored, the existing theoretical framework has shortcomings in integrating deep learning with human interaction techniques. For example, while some studies demonstrate AI-based image generation techniques, they often do not consider in depth how these techniques integrate with the creative thinking of designers. In addition, although text-to-image generation methods are theoretically innovative, their application and integration in the actual design process have not been fully explored. At the same time, the existing literature also lacks sufficient depth in exploring how human-computer interaction technology enhances artistic experience.

Deep neural networks and human-computer interaction technology bring new ideas to art design. Nie Zexian discussed the application of artificial intelligence and human-computer interaction technology in art design, through machine learning algorithms and visual interaction technology, and analyzed audience responses to improve the expression of artworks. The design of artistic visual communication systems was proposed, and innovation and development in the art field were promoted [8]. Huang Lihua discussed the application of artificial intelligence technology in visual design, proposed the construction of intelligent design systems to improve design efficiency and quality, and explored the man-machine collaboration model to promote innovation and development in the field of art design through deep neural networks and multi-domain expert systems [9]. Liu Lina studied the methods of context awareness and machine learning to enhance user interaction experience in mobile systems, proposed the design principles of interactive display based on intangible cultural heritage, and discussed the application of augmented reality in folk art appreciation, providing new ideas and practical cases for art design [10]. Guo Qiongqiong studied the application of virtual reality technology in product design, and enhanced user experience through dynamic simulation and haptic feedback. She established product models in combination with computer-aided design, and discussed the implementation mechanism of haptic feedback in virtual environment, providing innovative interactive means and design ideas for art design [11]. Li Xiong proposed an intelligent assisted concept sketch design framework based on deep learning, including GAN and style transfer network for sketch generation and rendering, which verified its ability to quickly generate innovative sketches and style transformations through experiments, and developed an intelligent sketch design generator to reduce the threshold for designers to use AI and improve design efficiency and innovation [12]. ChatGPT's performance as a general-purpose AI model on emotional computing tasks highlighted the broad applicability and robustness of deep learning techniques in diverse fields such as art and design without the need for task-specific training [13]. Although existing research has made progress in applying AI to art and design, they have generally failed to delve into the specific advantages of deep learning techniques in improving the quality of art works and the efficiency of design. In addition, existing approaches have limitations in adapting to diverse design needs and delivering personalized art experiences. Through empirical analysis, this study aims to make up for these deficiencies, verify the innovative application of deep learning technology in art design, and explore how to enhance the display of art works and audience experience through human-computer interaction technology.

III. Deep Neural Network in Art Design

A. Image Generation

Deep neural networks can learn and simulate a large amount of image data, to achieve automatic image generation. This provides an entirely new means of creation for art designers, enabling them to better express their creativity and ideas.

At present, the mainstream text-generating image methods need complete text-image data pairs in the training process, which leads to the current methods being mostly trained on some specific data sets, and it is difficult to apply to other scenarios. In recent years, there have been some unsupervised field transitions. Cycle GAN is an image transformation model based on generative adversarial networks that converts text into images without the need for pairs of training data.

Cycle GAN was originally a model for the image domain, but has since been extended to text-image conversion tasks as well. The overall structure of text-image conversion is shown in Fig. 1.

As shown in Fig. 1, text is first encoded by a text encoder into a specific hidden space. By converting text features into vector representations, the encoded text vectors become part of the input generator, which is responsible for converting the text vectors into real images.

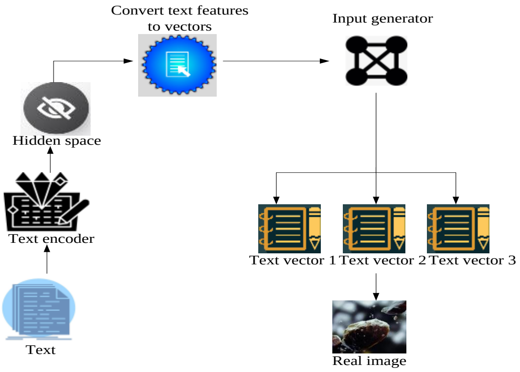

Fig. 1. Overall structure of text-image conversion.

The text is encoded using a pre-trained network to get a semantic embedded representation of the text:

$$w = B_i \cdot L(t) \tag{1}$$

$L(t)$ is the length of text; B_i represents text features at the word level. In order to enhance the diversity of text description, conditional enhancement network is used to make full use of different texts with the same semantics to enhance the semantic information of text vectors. For the obtained text features, it is taken as the input of the network, and the result of data enhancement $F_c(s)$ and noise are taken together as the input f_0 of the first stage image generator:

$$f_0 = F_0\left(z, F_c(s)\right) \tag{2}$$

In the text loop, the cross-entropy loss is used to calculate the consistency between the original text p_t and the reconstructed text s_t. The cross entropy loss L_{cycle} of the text loop is as follows:

$$L_{cycle} = -\sum_{t=0}^{J-1} \log p_t(s_t) \tag{3}$$

For different attribute information, the encoding method is different. For class information, the variational inference method is used to encode. The encoder inputs a given class of information and a noise vector sampled from a standard Gaussian distribution to make variational inferences about hidden variables. Supposing that the posterior distribution of class information follows a multivariate Gaussian, the formula is:

$$L_{cycle}(G, F) = \mathrm{L}_1 \cdot G(x) \cdot \mathrm{F(y)} \tag{4}$$

G and F are generator network and discriminator network respectively; x and y represent distribution obedience in two standard Gaussian distributions respectively.

The attribute vector is transformed into the same dimension as the text vector through a learnable linear layer, and then a neural network is used to jointly learn the text information and the attribute information to obtain the fused conditional vector. Through adversarial training, the generator network can continuously improve the authenticity of the generated image, making it more close to the real image distribution of the target domain or the original domain:

$$L_{GAN}\left(D_M, D_N\right) = sim\left(1-D_M\right)\cdot\left(1-D_N\right) \tag{5}$$

D_M and D_N represent the target domain and the original domain respectively, and the cross-entropy loss function is used to constrain the training of generator network and discriminator network.

After the fused code is transformed into the image space through the network, the attention mechanism is used to introduce the text features at the word level to better constrain the image generation. In order to maintain coherence between text and image, cyclic consistency loss is introduced into text-image conversion module. This loss encourages the generator network to retain as much content and style information as possible in the input image:

$$L_{D_i} = \log D_i\left(x_i\right) - \left[\log\left(1-D_i\left(x_i\right)\right)\right] \tag{6}$$

D_i is the weight hyperparameter, which is used to balance the ratio between the individual subloss functions. By optimizing the total loss function, the parameters of generator and discriminator network can be updated by gradient descent to optimize the performance of the network.

In this paper, text with 10, 20, 30, 40 and 50 characters is selected to analyze the success rate of text generation image of artificial method and Cycle GAN, as shown in Fig. 2. In Fig. 2, the horizontal coordinate represents the characters and the vertical coordinate represents the success rate.

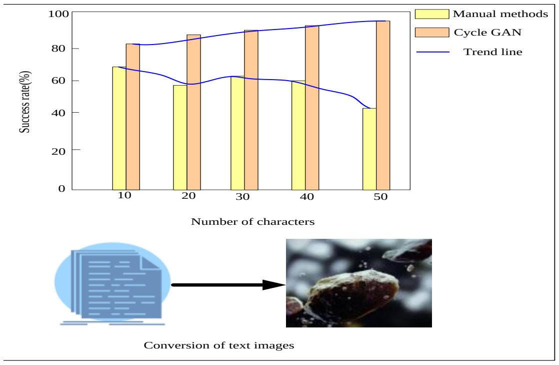

Fig. 2. Success rate of text generation image based on artificial method and Cycle GAN.

As shown in Fig. 2, it can be seen that the success rate of text-image generation in Cycle GAN is always higher than the success rate of text-image generation in artificial methods, which means that the success probability of text-image generation in Cycle GAN is greater.

B. Intelligent Authoring Tools

The wide application of deep neural network enables it not only to be applied in traditional machine learning tasks, but also as an intelligent creation tool to provide better human-computer interactive creation experience and help in the field of art [14-15].

Generative Adversarial Networks (GAN) are composed of a generator network and a discriminator network, which generate images through adversarial training. Image generation and judgment based on generative adversarial network are shown in Fig. 3.

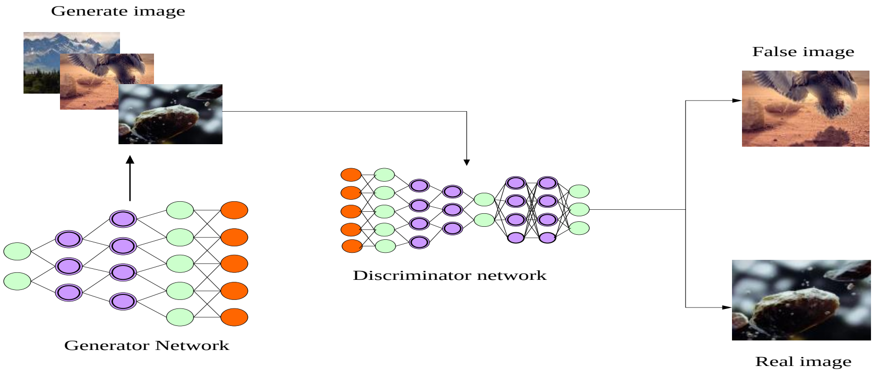

Fig. 3. Image generation and judgment based on generative adversarial network.

As shown in Fig. 3, the generator network is responsible for generating the image, while the discriminator network is responsible for determining whether the generated result is realistic. Through continuous adversarial learning, the generator network gradually improves the quality of generation. The goal of the generator is to produce images that are realistic enough to fool the discriminator so that it cannot tell whether the resulting image is real or not.

The generator's loss function can be implemented by maximizing the probability that the generated image is judged to be true by the discriminator. The specific formula is as follows:

$$\mathrm{L\{G\}} = \xi\left[\mathrm{-logD(G(z))}\right] \tag{7}$$

ξ is random noise sampled from a prior noise distribution. The goal of the discriminator is to judge the difference between the generated image and the real image. The specific formula of its loss function is as follows:

$$\mathrm{L\{F\}} = \mathrm{logD(h)\text{-}log}\left[\mathrm{1\text{-}D}\left(G\left(z\right)\right)\right] \tag{8}$$

L{F} is the loss function of the discriminator and D(h) is the real image. Through repeated iterations, the generator gradually learns how to generate an image that matches the natural language description, while the discriminator gradually learns how to accurately distinguish between the generated image and the real image. This adversarial training process allows the generator to output images that match the natural language description.

In this process, the antagonistic process of training the generator and discriminator enables the generator to generate an image or design that matches the natural language description. Through iterative training, the generator gradually learns how to generate works of art based on natural language, while the discriminator gradually learns how to accurately distinguish between generated works and real works. This adversarial training process enables the generator to output an image or design that matches the natural language description [16-17].

C. Improvement of Creation Efficiency

With deep neural networks, artists can turn their ideas into creative works more quickly. Compared with the traditional artificial design or painting process, the use of intelligent creation tools can greatly shorten the creation time and reduce the workload of modification and adjustment [18-19].

As for the current method of text image generation, the quality of the final generated image depends on the quality of the initial generated image, so there are problems in image generation. Deep neural networks can be used to improve the quality of the initial generated image, and different generation tasks can be performed in different generation stages to improve the quality of the generated image. Deep neural network can fully learn the features of different levels of text generated images, so it has good performance.

The time taken by artificial method and intelligent creation of an inset, animation, trademark, person, build, landscape and animal image are counted respectively. The time taken by artificial method and intelligent creation is shown in Table I.

As shown in Table I, when the type of image needs to be created is determined, the creation time of the artificial method is measured in minutes, while the intelligent creation is measured in seconds. In several image types, the longest intelligent creation time is 32.20 seconds, while the shortest artificial creation time is 2.02 minutes.

D. Image Style Conversion

In the mainstream image style transformation technology, after many repeated operations to achieve the desired effect, some features of the main image are distorted. The most widely recognized is DC-IGN, which takes the full connection of traditional neural networks to replace the convolution operation. It combines time or space, reduces network free parameters, reduces training complexity, and is well used in image style conversion. By using the idea of generative adversarial network and the structure of convolutional inverse graph network, DC-IGN realizes the transformation of image style.

DC-IGN introduces adaptive instance normalization. As long as it inputs a content and a style information by adjusting the input content to match the variance and mean of the input style, it can effectively merge the content of the main and style diagram, and output a new image. It can be calculated using the mean square error as follows:

$$h_t = \mathrm{M}_{\mathrm{SE}}\left(\alpha, \beta\right) \tag{9}$$

Among them, the content feature α of the generated image is extracted from the generated image, and the content feature β of the target image is extracted from the target image.

The style extraction network uses a similar convolutional neural network to take the style image as input and select the feature output of different layers as the style representation of the image. These features reflect the texture, color, and stylistic features of the image. Style loss is used to measure the difference in style characteristics between the generated image and the target image. It is measured by calculating the M_{SE} between the generated image and the target image in a specific layer, and the formula is as follows:

$$r_t = \mathrm{M}_{\mathrm{SE}}\left(\mathrm{Gram}\left(\alpha\right), \mathrm{Gram}\left(\beta\right)\right) \tag{10}$$

$\mathrm{Gram}\left(\alpha\right)$ and $\mathrm{Gram}\left(\beta\right)$ are Gram matrices that generate the stylistic features of the image and the target image at a particular layer, respectively. In order to train a generator in DC-IGN, it needs to define a generator loss function, which consists of content loss and style loss, designed to minimize the goal.

TABLE I. TIMING OF MANUAL METHODS AND INTELLIGENT AUTHORING

Type	Manual Method (Minutes)	Intelligent Creation (s)
Inset	2.44	21.84
Animation	2.02	32.20
Trademark	4.57	23.04
Person	2.05	19.39
Build	2.77	24.96
Landscape	2.61	22.51
Animal	2.38	27.83

DC-IGN can encode not only the content of the image, but also the style information of the image. The style and content of image can be separated, which also deepens the understanding of image processing. It has a broad application prospect and can be used for image processing, video processing and as an auxiliary tool for style design.

IV. Human-Computer Interaction Technology in Art Design

A. Human-Computer Collaboration Design

Human-computer collaborative design refers to the cooperation and interaction between designers and computers to improve design efficiency and quality. By making full use of the computing and processing power of computers, designers can complete design tasks more conveniently and quickly, and obtain better design results [20-21]. In human-computer collaborative design, there are many technologies and tools that can realize the cooperation and interaction between designers and computers, among which sound interaction and somatosensory interaction are some of the common implementation methods [22-23].

1) Sound interaction: Sound interaction technology is a simulation system based on human hearing and understanding systems. When the sound sensor converts the sound signal into an electrical signal, the electrical signal can trigger the circuit in the interactive system to work. In art viewing, when the audience's voice is perceived by the interactive system, it can produce corresponding feedback output after being processed by the pre-set system. The sound interaction technology based on sound sensors can also be subdivided into volume-led interaction systems and speech recognition.

In volume-dominated interactions, the system only needs to sense the absolute volume of urine and faeces at a specific location to respond accordingly [24-25]. However, in the speech recognition interaction, the system also needs to distinguish the content of the sound. If the sound emitted in a specific area is meaningless, it can be judged by the system as an invalid sound and cannot give feedback. Only when the sound is carrying information and is successfully recognized by the system can it produce corresponding feedback based on the content of the sound? For example, the "Ascending the River at Qingming Festival" in the Sound Museum is shown in Fig. 4.

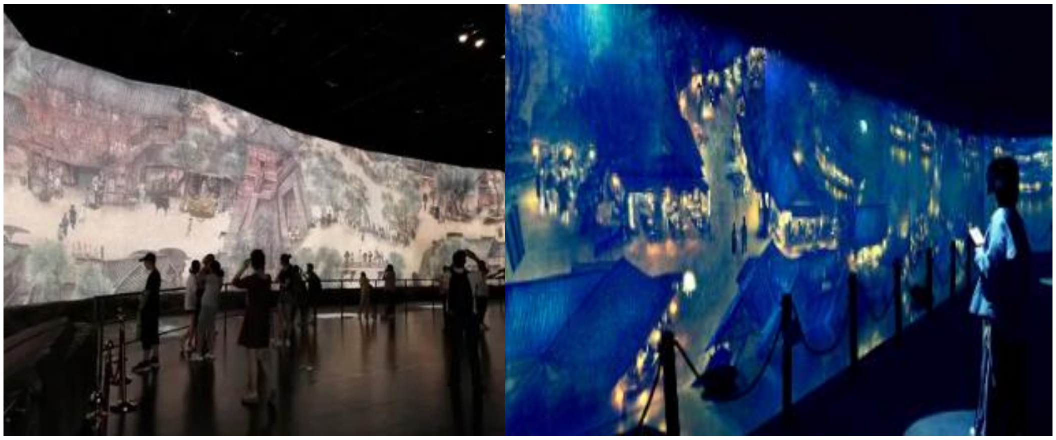

Fig. 4. Heard "Ascending the river at qingming festival" art exhibition.

As shown in Fig. 4, the art exhibition of "Riverside Scene at Qingming Festival" uses holographic projection and holographic sound technology, and through the independently developed soundscape interaction system, the outdoor exhibition restores the life status of folk people in the Song Dynasty, and people interact with the scroll in sound and painting while walking. Through multi-dimensional immersive experience, people can listen to the sound art that has come to modern society through thousands of years.

By simulating the communication between people, voice interaction enables designers to directly interact with computers in a natural way, such as voice input, which greatly reduces the learning cost and improves the work efficiency of designers [26]. Voice input can realize the voice interaction between the designer and the machine, providing a more convenient and natural way of operation. Through a microphone or other audio device, the designer's voice input is collected, and these voice signals are used as input data for subsequent processing.

2) Somatosensory interaction technology: The somatosensory interaction technique is a technique to track, record and dynamically capture human motion trajectory in three-dimensional space by using the mixed method of optical passive and inertial motion measurement. Somatosensory interaction includes gesture interaction and body interaction. Due to the diversity and ambiguity of gesture and body behavior, various combinations can be used to input a variety of information in interaction, as shown in Fig. 5:

As shown in Fig. 5, the somatosensory interaction technology usually relies on infrared sensors, cameras, smart wearable devices and other technologies to achieve the input behaviour in the interaction.

Since people usually use body movements to complete communication with other natural persons in social activities, somatosensory interaction is a simulation of human natural communication behavior, which has the advantage of being easy to use and understand.

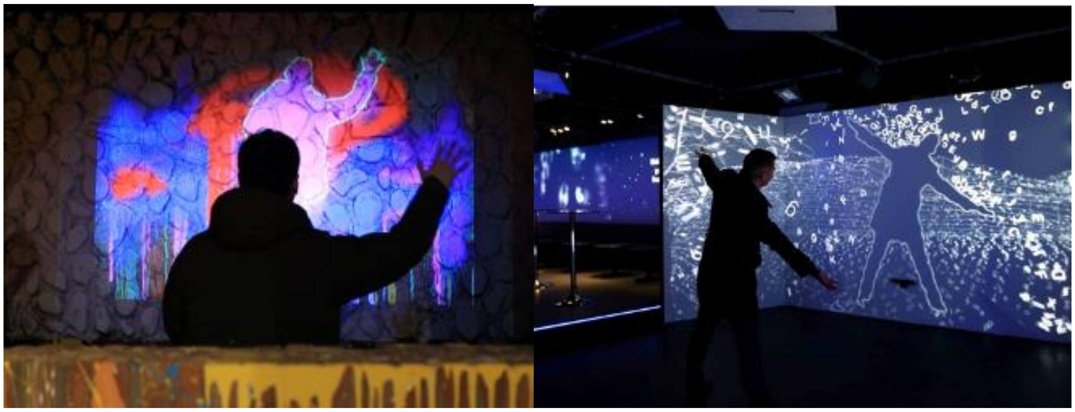

Fig. 5. Somatosensory interactive projection.

B. Art Display

Human-computer interaction technology can combine art display with user interaction. For example, digital artworks can be displayed in a virtual exhibition hall, where the audience can experience and interact through technologies such as virtual reality, increasing the interest and interactivity of the works.

1) Virtual reality: Virtual reality is an information display technology that uses three-digit graphics generation technology, multi-sensor interaction technology and high-resolution display technology to generate a three-dimensional realistic virtual environment [27]. The environment simulated by virtual reality technology is very similar to that in the real world, which is difficult to distinguish, and people can have a sense of immersion in the experience process. The current virtual reality technology has been able to deliver hearing, vision, smell, touch, taste and other feelings, which is a comprehensive simulation system and has brought a huge revolution to the output of interaction design [28].

The Virtual Reality Painting tool allows users to wear a virtual reality headset and handle and then paint in a virtual environment in the form of an aerial drawing. Users can draw lines, shapes and colors in three-dimensional space with the handle, and create three-dimensional works of art by touching and rotating them. This virtual reality painting tool provides an innovative art creation tool that enables artists to paint in completely new ways, creating artwork with three-dimensional and dynamic effects, as shown in Fig. 6.

As shown in Fig. 6, through the immersive experience and interactive nature of virtual reality, the audience can interact more deeply with the artwork and freely explore and create art.

This virtual reality painting tool can also combine traditional painting with technology, providing more possibilities and innovative potential for artistic creation. Virtual reality technology provides the audience with an immersive experience, allowing them to feel the authenticity and emotion of the artwork. It provides artists with new creative tools and ways of expression to create more free and innovative works of art. Virtual reality can break through the limitations of time and space, bring the audience into different art scenes and art history, and expand the dimension of art creation and viewing.

2) Augmented reality: Augmented reality is a technology that integrates virtual information with scenes in the real world [29]. This technology uses multimedia, three-dimensional modeling, intelligent interaction, sensors and other technical means to apply virtual information produced by computers in the real world, which is complementary to the real world, so it is called augmented reality [30-31].

In the art field, augmented reality technology can be used to combine art museum exhibitions with virtual reality. Through the camera of a mobile phone or tablet computer, the audience can interact with these virtual elements by watching, hearing and touching, which entices the understanding and experience of artworks [32-33]. The Museum of augmented reality Art is shown in Fig. 7.

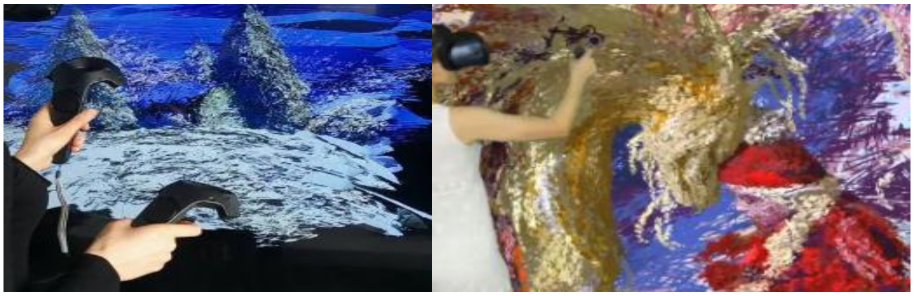

Fig. 6. Virtual reality painting.

Fig. 7. Museum of augmented reality art.

As shown in Fig. 7, the viewer can point the device at the artwork in the museum. Virtual elements related to the artwork would then appear on the screen, such as 3D models, animations, audio, etc.

This augmented reality art museum application expands the form and content of art exhibitions to a certain extent, providing viewers with a richer visual and sensory experience. At the same time, through interaction and participation, the audience can have deeper communication and understanding with the works of art, so as to enhance the sense of participation and the depth of art appreciation [34-35].

Visitors themselves feel and experience art themes through audio-visual touch and even smell, which further broadens the way participants receive information and expands the communication function of art design [36-37]. In contemporary art design, the interactive design running augmented reality technology can better create an immersive display atmosphere and improve the display effect [38-39].

V. Design Effect of Deep Neural Network and Human-Computer Interaction Technology

A. *Image Generation Effect*

The image generated by artificial methods is often a one-of-a-kind work that is not easy to reuse and scale. If multiple similar images need to be generated, the drawing or design work needs to be repeated, which further reduces efficiency and feasibility.

The resulting image fidelity is evaluated using the peak signal-to-noise ratio (PSNR). The sharper image PSNR is between 30 decibel (dB) and 40dB. The higher the PSNR, the more realistic and clear the image. Eight images of people, buildings, landscapes and animals are generated by manual method and Cycle GAN respectively. Compared with the peak signal-to-noise ratio, the average peak signal-to-noise ratio of images generated by different methods is shown in Fig. 8. The horizontal axis represents people, build, landscape and animal; the vertical axis represents the peak signal-to-noise ratio; the unit is dB.

As shown in Fig. 8, the average peak signal-to-noise ratio of person, build, landscape and animal images generated by artificial methods is 23.73dB, 20.58dB, 20.99dB and 21.10dB respectively on the left side of Fig. 8. On the right side of Fig. 8, the average peak signal-to-noise ratio of person, build, landscape and animal images generated by Cycle GAN is 37.48dB, 32.86dB, 33.65dB and 38.04dB respectively.

The average peak signal-to-noise ratio of figure images generated by Cycle GAN is 57.9% higher than that of figure images generated by artificial method ($\frac{37.48\text{-}23.73}{23.73}*100\% = 57.9\%$).

Each layer of Cycle GAN can extract the features of each level of the image, and through the effective combination of the features of each level, it has higher complexity and higher quality. In contrast, in the manual method, it is necessary to undergo many processes of processing and debugging in order to obtain a complete image.

B. *Style Conversion Quality*

Artificial methods often need to manually select features to express the content and style of the image, while deep neural networks can superimpose multiple neurons layer on layer to form a richer and more abstract image feature expression. Because deep neural networks can process any size and any kind of image, artificial methods often have strict constraints on the size and category of images. Therefore, using a deep neural network for image style conversion can adapt to more applications and have wider applicability.

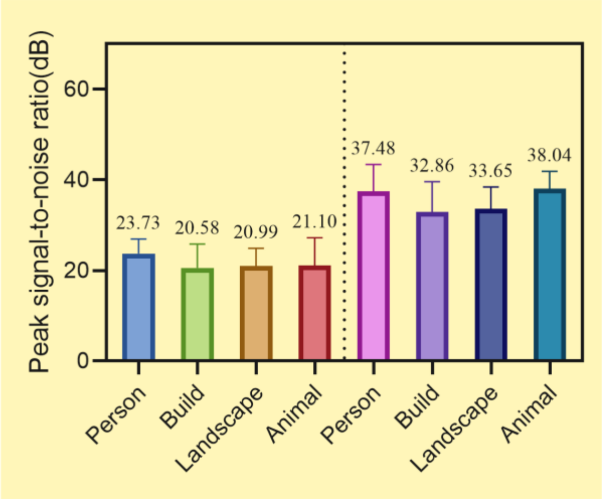

Fig. 8. Average peak signal-to-noise ratio of images generated by different methods.

The content loss rate is used to evaluate the content difference between the converted image and the original image. It can evaluate the style conversion quality of the image. The higher the content loss rate, the worse the style conversion quality. Besides, eight images of people, buildings, landscapes and animals are converted by manual method and Cycle GAN respectively, and their content loss rate is calculated.

The content loss rate of manually converted images is shown in Table II.

As shown in Table II, the average content loss rates of the eight images of person, build, landscapes and animals converted by manual methods are 5.68%, 5.36%, 5.67% and 5.62%, respectively.

The content loss rate of Cycle GAN converted images is shown in Table III.

As shown in Table III, the average content loss rate of each of the eight images of person, build, landscapes and animals converted by Cycle GAN is 1.45%, 1.60%, 1.17% and 1.53%, respectively.

Compared with manual method, the content loss rate of character image conversion in Cycle GAN increases by -74.5%($\frac{1.45\text{-}5.68}{5.68} = \text{-}74.5\%$), that is, the content loss rate of character image conversion is reduced by 74.5%.

Cycle GAN can learn the more complex correlation between image content and style from massive data, and realize rapid transfer of image style through optimization and acceleration technology. Manual methods often take a long time, but Cycle GAN can achieve rapid style change in the case of real-time and interactive.

C. Reduce Design Costs

The cost includes human resource cost, material cost, production cost, equipment cost and site cost. The cost of design work for manual method design and combined method (deep neural network and human-computer interaction technology) is shown in Fig. 9. The horizontal coordinate represents human resources, materials, manufacture, equipment and site; the vertical coordinate represents cost; the unit is yuan.

The left side of Fig. 9 shows the human resource cost, material cost, manufacture cost, equipment cost and site cost of the manual method design work, with the highest cost exceeding 1000 yuan. The right side of Fig. 9 shows the human resource cost, material cost, manufacture cost, equipment cost and site cost of the combined method design work. The maximum cost is less than 1,000 yuan.

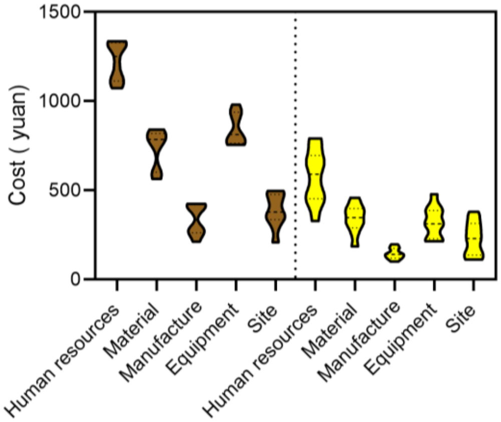

Fig. 9. Cost of manual method design and combined method design work.

TABLE II. CONTENT LOSS RATE (%) OF MANUALLY CONVERTED IMAGES

Image Sequence Number and Average	Person	Build	Landscape	Animal
1	6.88	6.18	5.25	6.19
2	5.34	4.00	5.36	5.84
3	4.50	4.52	6.37	6.93
4	5.79	6.32	6.78	4.81
5	5.47	6.49	6.00	4.65
6	6.89	6.80	5.48	6.04
7	5.89	4.25	5.26	4.38
8	4.70	4.30	4.89	6.14
Average	5.68	5.36	5.67	5.62

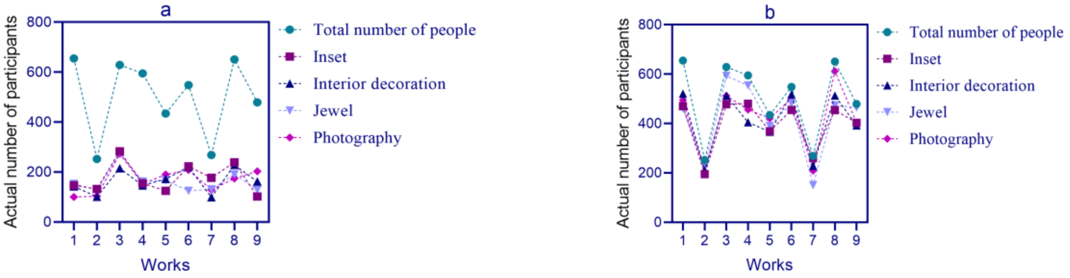
TABLE III. CONTENT LOSS RATE OF CYCLE GAN CONVERTED IMAGES (%)

Image Sequence Number and Average	Person	Build	Landscape	Animal
1	2.48	2.41	2.01	0.62
2	2.37	1.08	0.98	1.81
3	1.16	1.32	2.32	1.26
4	0.76	2.05	0.62	1.06
5	1.13	0.91	0.67	2.19
6	0.53	1.97	0.51	1.20
7	1.89	0.72	1.62	2.03
8	1.26	2.36	0.61	2.03
Average	1.45	1.60	1.17	1.53

Manual methods often take a long time, through the design, production, touching up and other processes, in order to ensure the quality and effect of the work. If the production cycle is too long, it not only causes the rise of production costs, but also misses the changing market demand.

D. Engagement

The display of artworks based on human-computer interaction can bring real experience to visitors no matter in sensory experience, behavior mode, or use environment [40]. This paper selects nine works of illustration, interior decoration, jewelry and photography designed by manual method and combines method respectively to investigate the audience's participation, as shown in Fig. 10. The horizontal coordinate represents the works, and the vertical coordinate represents the actual number of participants.



(a). Audience participation in the artificial design of the work.

(b) Audience participation in the design of the combined method.

Fig. 10. Audience participation in the design of works by manual methods and combined methods.

Fig. 10(a) shows the participation of the audience in the inset, interior decoration, jewelry, and photography by manual methods. It can be seen that the actual number of participants is much less than the total number, and the highest number of participants is less than 400.

Fig. 10(b) shows the audience participation in inset, interior decoration, jewelry, and photography designed based on the combination method. It can be seen that the difference between the actual number of participants and the total number of participants is not very far, and the highest number of participants exceeds 400.

Human-computer interaction emphasizes "people-oriented", providing the computer with the functions of touch, vision, hearing and other aspects, so that users can interact with people through gestures, expressions, eyes, sounds and other ways. The multi-dimensional input and multi-output of computer have greatly increased the frequency band of communication between human and computer [41-42]. With the electronization of information resources, the diversification of information presentation methods, and the continuous improvement of new application requirements for various industries, art design, as the carrier of human spiritual civilization, cultural tradition and scientific knowledge, is gradually becoming the spiritual food of human beings.

E. Economic Benefits

The appearance of human-computer interaction technology has brought great convenience and efficiency to art design. This paper uses virtual reality or augmented reality technology, and art designers can quickly preview and adjust the design effect in virtual reality, thus saving a lot of time and cost. Eight works are randomly selected and the economic benefits they brought are calculated. The income generated by manual method design and combined method design is shown in Table IV (the difference in income in Table IV is the income generated by combined method design minus the income generated by manual method design):

TABLE IV. INCOME FROM MANUAL METHOD DESIGN AND COMBINED METHOD DESIGN (TEN THOUSAND YUAN)

Works	Manual methods	Combining method	Differential income
1	6.01	17.48	11.47
2	8.16	20.72	12.56
3	5.25	15.04	9.79
4	8.33	19.02	10.69
5	8.78	23.51	14.73
6	9.40	24.83	15.43
7	6.45	21.81	15.36
8	8.88	16.17	7.29

As shown in Table IV, the economic income brought by manual method design is less than 100,000 yuan, while the economic income brought by combined method design is more than 100,000 yuan. It can be seen that the economic income brought by the combined method design is higher.

This paper highlights the advantages of the adopted method through in-depth comparison with previous studies. Through quantitative analysis, this study demonstrates the significant effect of Cycle GAN in reducing the content loss rate in automatic text-to-image conversion, as well as the high fidelity achieved in image style conversion. In addition, compared with traditional design methods, this research method has obvious advantages in improving the quality and creation efficiency of artworks, while reducing the production cost and enhancing the market competitiveness of artworks. These comparisons not only validate the validity of this research method but also demonstrate its potential to drive innovation and progress in the field of art design.

VI. DISCUSSION

Fig. 9 shows the overall higher cost of designing work using manual methods. In the manual method, designers, engravers, painters, artisans, etc., have to put a lot of energy into completing a work. It not only requires a high technical level, but also requires them to spend a lot of time on each piece of work. In traditional art design, the materials used are generally very expensive, such as canvas, paint, wood, metal and so on. Such materials are prone to loss and waste in the production process, thus increasing the production cost.

Interactive technology is a kind of technology that appears with the computers and artificial intelligence devices in the information age. Therefore, in everyday use, interactive technologies are often designed to have a technological, futuristic look and style. However, in art design, the fundamental goal of interactive technology is to realize the transmission of artistic ideas. Therefore, in the interactive design of art, attention should be paid to the consistency of the interactive equipment with the displayed theme in terms of appearance, audition style, etc., to avoid conflict or incompatibility with the design theme.

Table IV shows that the economic income brought by artificial method design is not as high as that brought by combined method design. The appearance of human-computer interaction technology has brought great convenience and efficiency to art design. By utilizing virtual reality or augmented reality technology, art designers can quickly preview and adjust design effects in virtual reality, thus saving a lot of time and cost.

The works of human-computer interaction design pay more attention to bringing good experience to users, that is, the indicators based on users' emotions, such as satisfaction. It also has a certain subjectivity, emphasizing that users can be immersed in interactive experiences while obtaining information about artworks. Human-computer interaction plays an important role in realizing human value and satisfying human spiritual needs. In the process of art design, users manipulate some interactive elements on the digital media terminal to get corresponding visual, auditory and tactile feedback. If such feedback is consistent with the user's own knowledge, skills or values, it causes a feeling of pleasure in the "emotional center" of the user's brain, thus satisfying the user's deep understanding of the value and connotation of the work.

The research results show that the application of deep neural network and human-computer interaction technology in the field of art design can significantly improve the quality and efficiency of design works. Compared with traditional design methods, these techniques reduce the content loss rate and improve the realism and clarity of images. In addition, they help to reduce design costs and increase the market competitiveness of art works [43-44]. These findings support the importance of technological innovation within the field of art and design and provide designers with new tools and methods to achieve a more efficient and diverse creative process.

VII. RESEARCH RESULTS

The research results of this paper show that the application of deep neural network and human-computer interaction technology in the field of art design has greatly improved the quality and efficiency of design work. In particular, the automatic text-to-image conversion using Cycle GAN technology reduces the content loss rate by 74.5% compared with the traditional manual method, and increases the peak signal-to-noise ratio of image generation by 57.9%. In addition, through interactive technologies such as virtual reality and augmented reality, the display effect of art works and the immersive experience of the audience have been significantly enhanced. These technologies not only optimize the creative process, reduce costs, but also enhance the market competitiveness of art works and audience participation, and bring innovative development opportunities for the art design industry.

VIII. CONCLUSION

Through empirical analysis, this study verifies the significant effectiveness of deep neural networks and human-computer interaction technology in improving the quality and efficiency of art design. In particular, Cycle GAN technology reduces content loss in the automatic conversion of text to images and enhances the display of artworks and the immersive experience of the audience through interactive technologies such as virtual reality. Based on these findings, it is recommended that art and design practitioners actively adopt these advanced technologies in order to optimize the creative process, broaden the boundaries of creative expression, and improve the market competitiveness of their works. At the same time, further exploration of the application potential of these technologies in different art and design scenarios is encouraged to promote the continuous innovation and development of the art and design industry.

Development of Real Time Meteorological Grade Monitoring Stations with AI Analytics

Adrian Kok Eng Hock, Chan Yee Kit, Koo Voon Chet
Faculty of Engineering and Technology, Multimedia University, Melaka Campus, Malaysia

***Abstract*—Air pollution comes in many forms and the basis of measure is the concentration of particles in the air. The quality of air depends on the quantity of pollution measured by a particle sensor that is accurate down to micron-meter consistencies. The size of the pollutants will be ingested by humans and cause respiratory problems and its effects on health conditions. The research will study the measurement of particles using multiple types of light scattering sensors and reference them to the accuracy of meteorological standards for precision in measurement. The sensors will be subjected to extreme conditions to gauge the repeatability and behavior and also long-term deployment usage. This study is required as when deployed on the field, dust particles will degrade the sensors over time. Early detection of sensor sensitivity and maintenance is therefore considered part of the research. Air particle data is volatile and dynamic over time and with that said, mass deployment of these sensors will give a better measurement of pollution data. However, with more and more data, standard statistics used show a basic level indicator and hence the idea of using machine learning algorithms as part of artificial intelligence (AI) processing is adapted for analyzing and also predicting particle data. There is a foreseeable challenge on this as there is no one machine learning for use only for this and multiple models are considered and gauged with the best accuracy using R2 value as low as 0.75 during the entire research. Lastly, with the seamless Internet of Things sensing architecture, the improved spatial data resolution will be improved and can be used to complement the current pollution measurement data for Malaysia in particular.**

Keywords—Air pollution; air particles; PM2.5; PM10; real time; light scattering sensor; neural networks; AI; machine learning; R2; IoT; WSM

I. Introduction

Pollutants in the air are not clearly visible and they come from many different sources. Air pollution is a mix of particles and gases that can reach harmful concentrations both outdoors and indoors [1]. Its effects range from disease risks such as respiratory to cardiovascular symptoms [2]. Smoke, mold, pollen, methane, and carbon dioxide are just a few examples of common pollutants that can affect the air surroundings [3].

The measurement of air pollution is measured in PM2.5 and PM10. PM refers to particulate matter which means particles in the air. The number 2.5 and 10 is the measurement in microns [4]. Particles the size of 2.5 microns and below are considered harmful as they could enter the blood stream and do damages years before any side effects occurs [5].

A limited number of meteorological stations in Peninsular Malaysia nationwide as shown in Fig. 1 gives a basic level of the air quality readings in the country (https://apims.doe.gov.my/). Systems in place are also located mostly in open areas far from densely populated places such as schools and factories. Data gathered are recorded, processed and shown but there are no algorithms for any preventive methods or predictive approach that could be performed. Only when pollution occurs, the data will be of interest to be monitored [6].

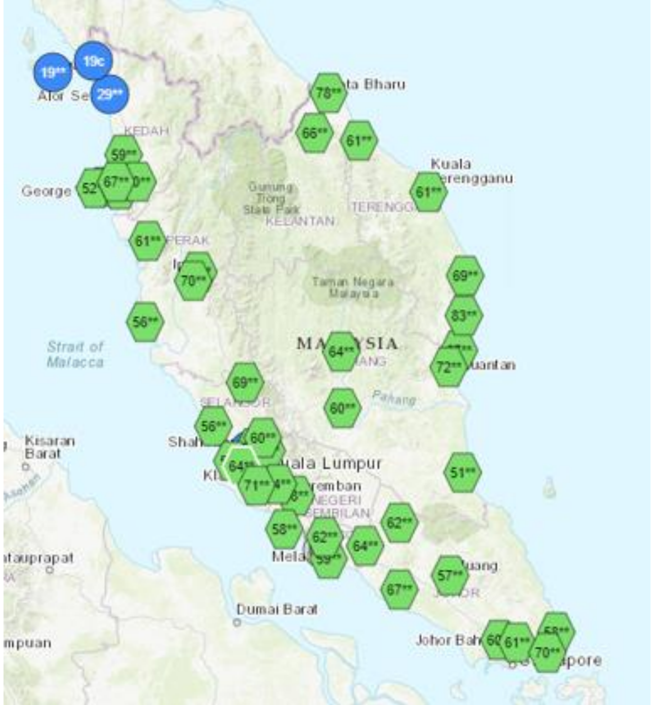

Fig. 1. Installation of meteorological stations in Malaysia.

The presented research focusses on market available particle sensors from various suppliers and the study of correlation of each sensor selection is benchmarked for its performance with the same environment and setup scenarios. The selection of particle sensor used will then be subjected to the meteorological reference to study its difference and an option to apply filtering mechanism for sensor data accuracy and traceability. Interface of the sensors and publishing the data to the cloud will be heart of the hardware being develop [7]. The hardware development will be in a form of an Internet of Things (IoT) node which is portable, energy efficient and ease of deployment and will be connected to the mobile network [8]. Altogether the hardware system will enable ease of deployment for mass monitoring and thus more perimeter of areas will be covered with real time data on concentration of the air pollutions [9]. As more systems deployed, the sensor data generated will be used for ingestion into the machine learning models for advanced processing on the prediction of the particulate matter. Machine learning models will be programed as a custom mode for particle data usage and models will be used based evaluated on based on the outcome of prediction accuracies and errors. In concluding the research presented, the IoT node will be able to measure particle sensor values accurately as of with meteorological standards with real time access and the overall system will be able to alert and provide predictive results based on artificial intelligence algorithms adapted that work behind the scenes [10].

Current and previous case studies and papers on air quality are based on meteorological sensors and as for Malaysia, there are not enough stations for monitoring dynamic conditions on the pollution that is causing the haze pollution. Therefore, additional stations whether it is meteorological or other particle sensor types are required. Cost-effective particle sensors that are used in some of the research are also not correlated to the meteorological side, hence it gives a sense of ambiguity on the results presented [11]. This research therefore would contribute and bridge the gap on these limitations using particle sensors that are based on the accuracy of the known standard with multiple deployment of sensors to complement the measurement data. Moreover, the systems designed and presented here are locally assembled.

The state of system design will be presented in the following chapters which include the study of sensors, the design of IoT and the correlation of the data with the Department of Environment (Malaysia) [12]. The backend of the systems utilizes the node and server architecture with web dashboard for first-hand information of IoT status. Machine learning models are then presented with comparative analysis against with R2 values as a scoring index on how well the models perform.

II. Methodology

A. Particle Sensor Selection and References

Particle measurement is related to the number of particles in an area at a point in time. These particles are extremely small; thus, it needs an accurate and precise sensor to be able to measure the particle sizes. The principle of particle measurement using a laser beam with particles blown over a detector and the reflection of the dust over time is counted and correlated with particle sizes and densities of the internal formulation of the sensor [13].

Three selections of particle sensors are considered from different manufacturers such as Honeywell, Sensirion and from China and shown in Fig. 2 [14]. The sensors are commonly used in industries and the reason of early selection. All three sensors are placed side by side and data is collected over a period of 45 days. This gives an equal level baseline on the particle data captured amongst the sensors being studied. The airflow, height, and simulated pollution levels are then conducted and data collected and compared. The co-relation of measured data is observed with an interval or 10 minutes and shown in Fig. 3 [15]. The hardware controlling the sensors were built to accommodate the three different sensors protocol and data is stored on the local storage. The dynamic range of all sensors are identical with co-relation of more than 90%. All three sensors are seen having the same identical behaviors. The resulting three sensors are equally suitable for deployment and the one being chosen to be used for this research is brand CN which comes with a protective outdoor casing. This sensor is chosen also due to the availability of the calibration certification ensuing the sensor is conformed to the specifications specified.

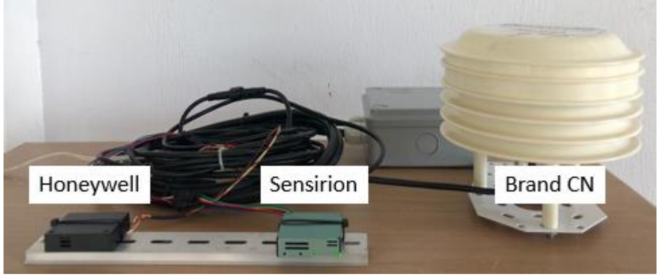

Fig. 2. Particle sensor selection and validation.

The brand CN sensor was then installed on the Department of Environment (DOE) in the Klang Valley meteorological station. There are two sets of the same sensors being placed for the study and comparison of the data repeatability alongside the reference standard. Data from the DOE particle sensor is then compared with the result of capture. Upon analysis, there are noticeable spikes in some of the range of the readings compared with the meteorological and the sensor used for the research. These spikes were due to the sensitivity and dynamic range of the sensors being used compared to the reference standard. Nevertheless, the trend of all the sensors is showing to be of identical trace.

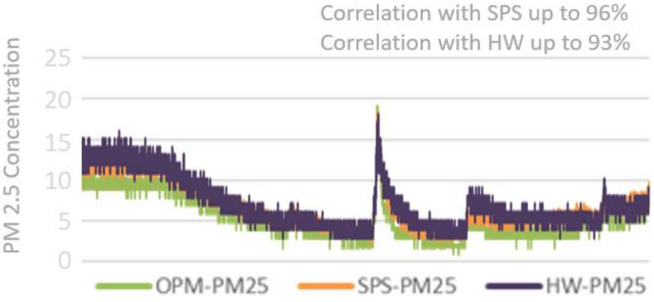

Fig. 3. Particle sensor correlation values and trend.

A study to improve the correlation of the sensor versus the DOE reference was embarked and Kalman filtering technique was adapted due to its usage for in noisy and dynamic sensors such as gyroscope sensors to normalize to the targeted reference [16]. The data that were captured were then passed to the Kalman algorithm to validate the outcome. The Kalman filtering consists of two main steps which are the prediction step and the update step with the following formula in Eq. (1).

$$x\hat{}k \mid k-1 = Fkx\hat{}k-1+Bkuk \qquad (1)$$

where, x^k ∣ k−1 is the predicted state estimate in time k and Fk is the state transition matrix which describes the dynamics of the system, x^k is the previous state estimate, Bk is the control input matrix and uk is the control input at time k.

The Kalman filter estimates the system’s states by predicting its next state using previous estimates and systems dynamics and minimizes the estimation error iteratively in turn makes the particle sensor referenced and improving its states to the known meteorological grade standard. The implementation of Kalman filter in the data processing of particles measurement data is shown in Fig. 4.

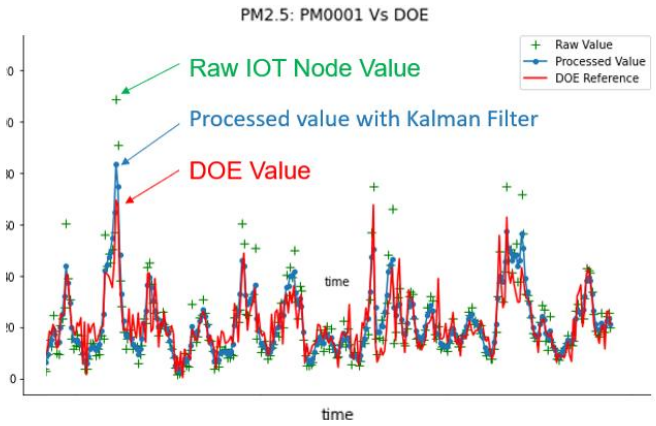

Fig. 4. Data processing using Kalman filtering algorithm.

B. Design of Wireless System Network (WSN) Hardware

Standalone API monitoring sensors form the basis of Wireless System Network (WSN) [17]. The development and requirement of the IoT hardware were carefully architected and specifications were designed to be adaptable and expandable to other types of sensors and connectivity. Other features such as low power usage <1Watts (idle) which is ideal for battery and solar power for off-the-grid deployment [18]. Splash-proof IP rating casings and connectors are also put in place for outdoor usage. The wireless communication used for the IoT nodes is Wi-Fi and option for 4G LTE mobile GSM networks for remote monitoring in rural areas. The communication protocols used were HTTP [19].

There are three iterations of prototypes of the IoT systems being designed and system validation and verification were carried out to finalize the first proper design of the deployment hardware [20]. Some problem that requires improvement such as RS485 protection circuitry were added as the IoT is likely to be damaged due to AC spikes and also lighting surges due to the system being placed open air in the field. Other improvements such as using a DC-DC converter for efficient power delivery versus a linear regulator were improved. This was crucial and required to be done as there are up to thirty-six systems that we build and to be deployed. The systems need to be robust and free of any maintenance or minimal problems on site. Fig. 5 showcases the hardware prototype being tested with the sensor connected to the 4G network while communicating with the server side. The hardware is then constructed and designed onto a PCB for final deployment with the proper housing and mounting in a pole with sensors altogether in one.

The IoT system generates several data from the sensors such as PM2.5, PM10, temperature, humidity, wind speed, direction and GPS location [21]. These sets of data are then pushed to the cloud server network for statistical data generation to build a web-based dashboard [22]. The interval of data transferred is set by default to be 30 seconds and can be triggered on demand as well for comprehensive monitoring if required. All the communication through and from the server is encrypted and error error-checking mechanism is used to ensure data transfer is successful and not corrupted. In the IoT system, there are various internal functions that are running in parallel, therefore the firmware that is built requires the system to be efficient and tasked deterministic and therefore a real time operating system is adapted with the structure is shown in Fig. 6. The structure itself is a simplified state machine architecture and this is the basic building block of the IoT system being built upon.

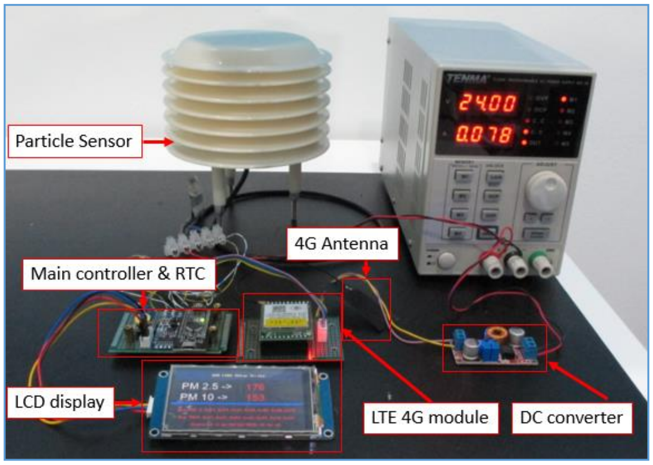

Fig. 5. Prototype IoT module.

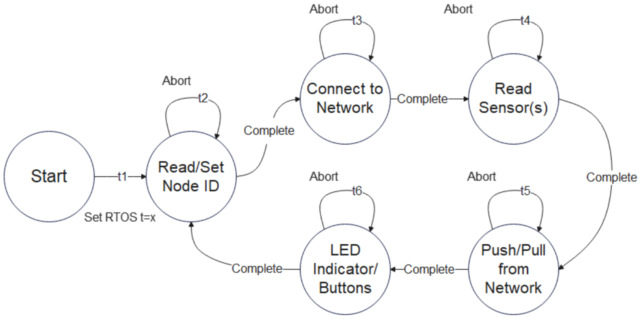

Fig. 6. Real-time operating system structure.

C. Data Processing

When the data is pushed to the cloud, a backend server-client dashboard is built in place to showcase the data based on time and day, and also a classification of API readings according to the standards on the IoT Nodes. This dashboard also serves as an indicator of the status of the connected sensor hardware that was deployed and activated on the field. This enables ease of measurement and also data storage from the sensor networks [23]. Basic analytical information based on mathematical statistic formulas is computed such as high, low, mean values of sensor data [24]. The client-side dashboard is shown in Fig. 7 which shows the real-time status of the connected IoT nodes along with the sensor measurement results.

Upon collecting and analyzing the measurements, the historical data will be used to serve as a base for AI modelling and processing. The AI algorithm will be used for predicting pollution ahead of time [25]. There are up to four types of machine learning models used and compared. They are the linear regression [26], ARIMA, Neural Prophet and the LSTM [27]. There are pros and cons in each algorithm being used and the basis of the modelling is time series type which is suited to the particle data being measured. Multiple machine learning models were studied and compared also as there the outcome of the prediction is different based on how the input dimensions and data types are being ingested and computed internally [28].

III. Results

The overall research results focus on the machine learning computation outcome. The AI modelling uses the 80% training and 20% test case data and all the four models are fed with the same data period for comparison of outcome [29]. The data range used is a year collection of historical data which is from 15th March 2022 to 15th March 2023 on a particular IoT station (KK Nilai). The data that were ingested is from the particle measurement (PM2.5) sensor along with the time series points. There summary of outcome for the algorithm used is shown in Table I.

TABLE I. Comparison of AI Performance Index on Algorithm Used

	Linear Regression	ARIMA	Neural Prophet	LSTM
MAE	18.84	18.51	7.34	7.35
RMSE	22.43	22.00	10.26	9.72
R2	0.26	0.22	0.49	0.75

From the observation on the machine learning models used, it could be concluded that the statistical algorithm types are less accurate in prediction with the R2 value of below ⩽0.26. The Neural network types are suitable for prediction on this particle measurement (PM2.5) data and in the research presented as the R2 score is up to 0.75 with the LSTM method [30]. For pictorial visualization, the Fig. 8, Fig. 9, Fig. 10 and Fig. 11 shows a clear distinction on the statistical algorithm compared to neural types [31]. The prediction of the test data does not really contain any patterns and it could be said as of flat computation. On the other hand, for the neural network types, the prediction pattern can be seen and matching the flow of the test data [32].

Based on overall data and results, neural algorithm method can be seen as performing better as they are inspired by the structure and functioning of the human brain. It is a key component of machine learning, specifically a subset known as deep learning. Furthermore, neural networks are used for tasks such as pattern recognition, classification, regression, and more, by learning from data.

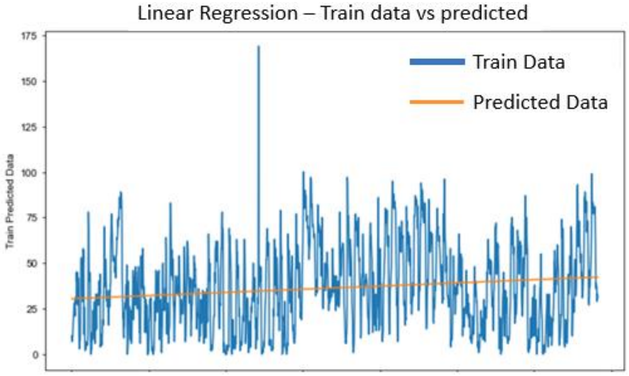

Fig. 8. Linear regression modelling.

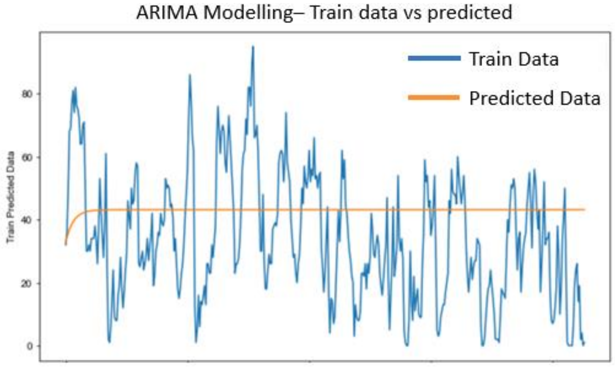

Fig. 9. ARIMA modelling.

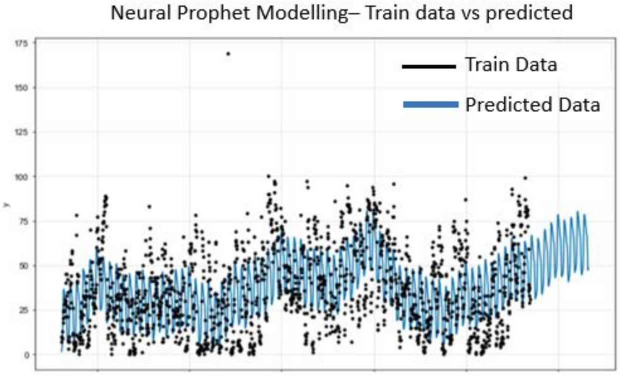

Fig. 10. Neural prophet modelling.

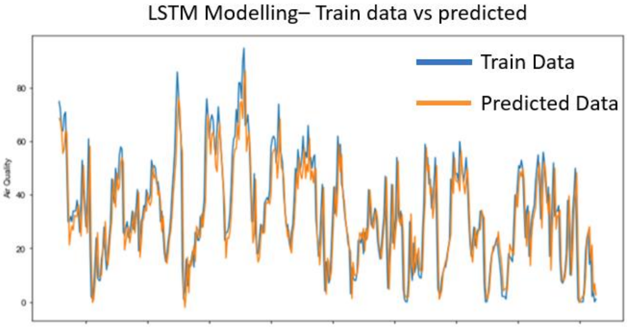

Fig. 11. LSTM modelling.

The LSTM model perform better is also due to the multi epoch used together with seasonality computation for ingestion while the rest uses the basis of time series modelling or single dimensional data for ingestion [33].

IV. Discussion

The successful integration of sensor selection, hardware design, and server-side processing has resulted in a comprehensive air quality monitoring system designed into an IoT based system. The deployment of this system on-site has demonstrated its capability to provide accurate, real-time air quality data, which is essential for informing public health strategies and environmental policies. Measurement of particle data is compared with DOE first hand to gauge the correlation and reproducibility of the measured air quality data [34]. Server based web API displays the IoT stations status with real-time on demand access using 4G GSM network. Future enhancements will focus on expanding the network of monitoring units and incorporating additional data sources to further improve prediction accuracy and system robustness.

There are two known limitations for the research which is on the long-term accuracy and maintenance of the sensors being used for the particle measurement. The Department of Environment (DOE) sensors are maintained regularly and calibrated to a traceable standard [35]. However, this sensitivity or performance of the sensor can be monitored using a machine learning algorithm using abnormal detection.

The second limitation is on the data processing with artificial intelligence algorithms. As the known research uses the data from meteorological sensors, there are years of historical data readily to be used and ingested into the algorithm [36]. The historical data from meteorological sensors contains additional sensor data such as pollution gases which is an advantage when using multivariate [37] AI modelling which serves as a multiple-dimensional processing and greatly influences the prediction outputs [38] [39].

V. Conclusion

From the sensor IoT node deployment to data generation and retrieval, this research presents the sensors being used is able to perform with high standards of measurement by referencing to a known standard. The IoT system hardware itself plays the main part in where sensors are being interconnected and data is fed back to the cloud for processing and storage. A step further in processing the data using AI algorithms is experimented and classification of the trend of data with anomalies seen of the data being produced and rectified with normalization [40]. The demonstrated predicted results using machine algorithm with an RMSE of 9.72 for LSTM is suitable for forecasting and detection of pollution levels ahead in time [41]. Hence, this information could be fed to other broadcast networks for notification. Lastly the presented system is not constrained to air pollution only and can be easily adapted to other types of pollution that compromise quality of life in urban areas, e.g. noise pollution, hazardous gases and more [42].

Acknowledgment

The author wishes to extend his profound gratitude to the Department of Environment Malaysia (DOE) on permission for installing the IoT sensors and data shared during the research. This work was partly financed by iRadar Sdn. Bhd. on hardware, engineer access and countless arrangements for deployment and setup on sites.

CNN-Based Salient Target Detection Method of UAV Video Reconnaissance Image

Li Na
Hainan Vocational College of Political Science and Law, Haikou City, Hainan Province, 570100, China

***Abstract*—In order to address the challenges of image complexity, capturing subtle information, fluctuating lighting, and dynamic background interference in drone video reconnaissance, this paper proposes a salient object detection method based on convolutional neural network (CNN). This method first preprocesses the drone video reconnaissance images to remove haze and improve image quality. Subsequently, the Faster R-CNN framework was utilized for detection, where in the Region Proposal Network (RPN) stage, the K-means clustering algorithm was used to generate optimized preset anchor boxes for specific datasets to enhance the accuracy of target candidate regions. The Fast R-CNN classification loss function is used to distinguish salient target regions in reconnaissance images, while the regression loss function precisely adjusts the target bounding boxes to ensure accurate detection of salient targets. In response to the potential failure of Faster R-CNN in extreme situations, this paper innovatively introduces a saliency screening strategy based on similarity analysis to finely screen superpixels, preliminarily locate target positions, and further optimize saliency object detection results. In addition, the use of saturation component enhancement and brightness component dual frequency coefficient enhancement techniques in the HSI color space significantly improves the visual effect of salient target images, enhancing image clarity while preserving the natural and soft colors, effectively improving the visual quality of detection results. The experimental results show that this method exhibits significant advantages of high accuracy and low false detection rate in salient object detection of unmanned aerial vehicle (UAV) video reconnaissance images. Especially in complex scenes, it can still stably and accurately identify targets, significantly improving detection performance.**

I. INTRODUCTION

The salient target detection of UAV video reconnaissance image is a method that uses computer vision and depth learning technology to quickly identify and locate key targets from the image taken by UAV. It automatically detects salient targets in the image, such as people, vehicles, buildings, etc., by analyzing the texture, color, shape, and other characteristics of the image [1]. The detection of the salient target of a UAV video reconnaissance image has extensive application value in many fields, such as safety monitoring, public safety, environmental monitoring, disaster rescue, etc. [2]. Through real-time monitoring and early warning, this technology can help people find abnormal situations in time, improve monitoring accuracy and response speed, and provide strong support for preventing and responding to various emergencies [3]. Therefore, the detection of salient targets of UAV video reconnaissance images is of great significance in ensuring public safety and improving emergency response capability.

Jirayupat C, et al. proposed a method of detecting salient targets in UAV video reconnaissance images based on chromatography-mass spectrometry [4]. This method pre-processes the image using the chromatography-mass spectrometry method, extracts the salient target features in the image, and then detects the target using the trained machine learning model. By combining image processing and machine learning, the salient target in the UAV video can be quickly and accurately recognized. This method involves the integration of many technologies, including image processing, chromatography, mass spectrometry, and machine learning. This requires researchers to have extensive professional knowledge and skills, and it is difficult to achieve and optimize. Cherri A K et al. proposed a method of detecting salient targets of UAV video reconnaissance images based on a joint transform correlator [5]. This method reduces the size of the UAV video reconnaissance image to speed up the processing time and increase the storage capacity of the recognition system. By using fringe adjustment joint transform correlation technology, multiple targets based on compression are successfully detected. The use of shift phase encoding and reference phase encoding technology can eliminate the false detection and missed detection caused by multiple expected and unwanted targets, thus realizing the detection of salient targets of UAV video reconnaissance images more accurately. This method reduces the size of the UAV video reconnaissance image, which will lead to the reduction of image resolution and will affect the accuracy of salient target detection and detail recognition. Iván García-Aguilar and others proposed the method of detecting salient targets of UAV video reconnaissance images using CNN and super-resolution [6]. This method improves the resolution of UAV video images through super-resolution technology and then uses a convolutional neural network (CNN) for feature extraction and target detection. Train CNN models to identify and locate salient targets. Combining the advantages of deep learning and super-resolution technology, it can accurately detect salient targets in UAV video reconnaissance images of low resolution. In this method, the super-resolution technology is sensitive to the noise in the image, which will affect the accuracy and reliability of target detection. Ezequiel López-Rubio a b and others proposed a method of detecting salient targets of UAV video reconnaissance images based on deep learning and PTZ camera controller [7]. This method uses deep learning to detect the salient target of a UAV video reconnaissance image. This method includes three modules: target detection, salient target detection, and PTZ camera controller. The deep learning network is used to detect the target in the scene. The salient target detection module automatically detects the salient target using the Dirichlet distributed hybrid model, while the PTZ camera controller allows it to follow and focus on the salient target to achieve the salient target detection of UAV video reconnaissance image. This method uses deep learning to detect the salient target, which faces a challenge in the real-time environment. On low-performance hardware, the processing speed cannot meet the real-time requirements, resulting in the limitation of this method in practical applications.

Faster R-CNN can effectively deal with complex factors in drone video reconnaissance images, such as subtle information, lighting changes, and dynamic backgrounds, ensuring high-precision salient object detection under various conditions. Therefore, this paper proposes a CNN-based method of detecting salient targets of UAV video reconnaissance images. By performing haze removal operations in the preprocessing stage, image quality is improved, and the Faster R-CNN framework combined with K-means clustering is used to optimize anchor boxes, achieving accurate detection of targets in complex scenes. Specifically, in response to the limitations of Faster R-CNN in extreme situations, this paper introduces a superpixel saliency filtering strategy and combines it with image enhancement techniques in the HSI color space. This not only significantly improves the accuracy of object detection and image clarity, but also ensures the authenticity and softness of colors, providing more reliable and efficient technical support for drone video reconnaissance. The specific research approach is as follows:

1) After removing haze from drone video surveillance images, a salient object detection framework for drone video surveillance images is constructed.

2) Preset anchor boxes in RPN and determine the final target bounding box through a multi task loss function.

3) Significant object detection calculation is used for undetectable targets, including calculating target similarity and target connectivity maps to obtain target probabilities.

4) The enhancement of saturation and brightness components based on HSI color space improves the accuracy of salient object detection.

II. Salient Target Detection of UAV Video Reconnaissance Image

A. Dehazing of UAV Video Reconnaissance Image

UAV imaging will be interfered with a variety of factors. Due to the presence of haze in the air or chemical particles and other particles, in the propagation process, the light will be scattered or refracted to varying degrees, resulting in some detailed information not being received by the sensor [8]. The haze image degradation model formula is expressed by Eq. (1):

$$A(x) = Z(x)t(x) + \rho[1 - t(x)] \quad (1)$$

In the equation, $A(x)$is the haze image degradation model, $Z(x)$ is a realistic image, $t(x)$ is medium transmission, ρ is atmospheric scattered light.

Light sources are scattered or reflected by the haze present in the air as they travel through the atmosphere. Then the light reflected through the object is also scattered or reflected by the haze [9]. After that, only the energy of$Z(x)t(x)$can reach the sensor. At the same time, the atmospheric scattered lightρgenerated due to the scattering of various particles in the air will also be absorbed by the sensor.

The medium transmission is expressed by Eq. (2):

$$t(x) = h^{-\varepsilon d(x)} \quad (2)$$

The medium transmission is related to the scattering coefficient $\varepsilon$of the atmosphere and also related to the distance $d(x)$from the sensor to the object. When$d(x)$goes to infinity $t(x)$ is close to zero. Then the atmospheric scattered light can be expressed by Eq. (3):

$$\rho = A(x), d(x) \to inf \quad (3)$$

In practical imaging, instead of relying on equations, obtaining the atmospheric scattered light$\rho$is rather a more stable calculation based on Eq. (4). $d(x)$cannot be infinite, but gives a very low transmittance t_0.

$$\rho = \max_{y \in \{x | t(x) \leq t_0\}} A(y) \quad (4)$$

If the atmospheric light in the corresponding area is given, the medium transmission can be calculated based on physical principles, and a clear image can be obtained after the haze is removed. The following procedures are all performed on the dehazed UAV video reconnaissance image.

B. Target Detection of UAV Video Reconnaissance Image Based on Faster R-CNN

After getting a clear image after removing the haze, the corresponding targets can be detected from it. For UAV video reconnaissance, multiple targets need to be monitored at the same time. To detect multiple targets at the same time and ensure detection accuracy, Faster R-CNN is used to build a detection framework, and training is used to adapt to different scenes and target types, to achieve the target detection of UAV video reconnaissance images.

1) Target detection framework: Faster R-CNN (Faster Region-based Convolutional Neural Network) is a new generation of target detection model that optimizes CNN [10]. Faster R-CNN can be seen as a combination of an RPN (Region Proposal Network) and a Fast R-CNN (Region-based Convolutional Network), which share the basic convolutional network [11]. RPN is responsible for generating high-quality proposed target areas in UAV video reconnaissance images, and Fast R-CNN will complete the salient target classification and position regression of the proposed target areas [12]. The improved target detection framework in this paper is shown in Fig. 1. First, the anchor frame is reset by the clustering method to make the reference anchor frame more suitable for the target characteristics of the dataset. Second, a new full connection layer (behind the ROI layer) is added to the Fast R-CNN model to effectively improve the detection performance of the algorithm.

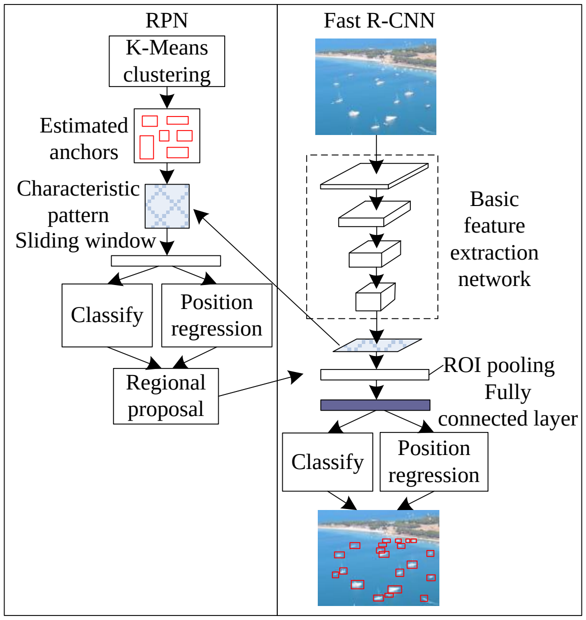

Fig. 1. Improved faster R-CNN target detection framework.

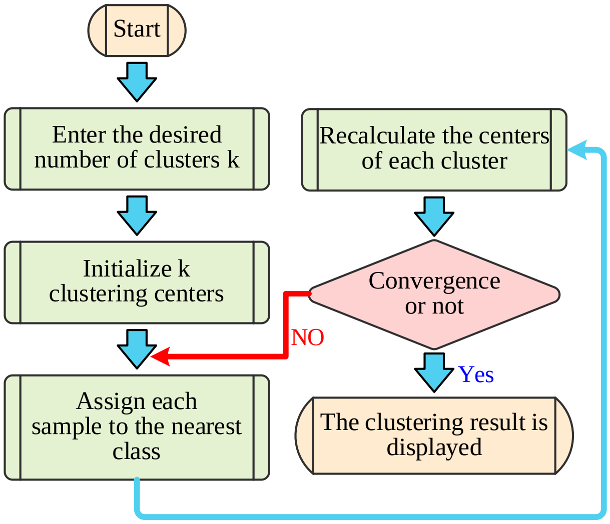
As displayed in Fig. 1, RPN uses a sliding window and anchor mechanism to generate a proposed target area of multi-scale. After the image passes through the basic feature extraction network, a convolution kernel of 3×3 slides on the feature map to get a feature vector of 512 dimensions (corresponding to the VGG model) each time, and then the vector is sent to the full connection layer: (1) Object/non-object binary layer, to predict whether there is a target in the window; (2) Position regression layer, to calculate the position correction of the anchor frame relative to the target boundary frame, and to obtain the position coordinates of the candidate frame. Fast R-CNN and RPN share the feature extraction network. First, ROI pooling is used to obtain the feature representation of each candidate frame, and then ROI features are sent to the full connection layer, and the features are sent to the two parallel task layers: (1) Softmax classification layer, to calculate the probability of candidate frames on the C+1(Class C target + background) class; (2) Position regression layer, to calculate the relative offset between the candidate frame and the target boundary frame, and to further correct the position of the predicted target.

2) Anchor frame setting: In the RPN model, anchor frames with three different aspect ratios are set according to experience. However, for different datasets, the scale of the anchor frame is inconsistent. Choosing an appropriate anchor frame can effectively improve the learning speed of network model training, and can also improve the target detection accuracy of UAV video reconnaissance images [13]. In this paper, K-Means clustering is used to select anchor frames. The algorithm flow is shown in Fig. 2.

- Collect the truth frames of all target samples in the UAV video reconnaissance image set $a = (xmaxmaxmin_{min})$, and set the number of clusters, i.e., the number of anchor frames k, and then randomly selected$k$samples as initial clustering centers;
- Calculate the distances between the remaining target samples and k centers, based on the Euclidean distance. The center with the smallest distance is used as the target sample class;
- Calculate the new clustering center according to the target classification results, and set the clustering center be o. The criterion function is calculated as shown in Eq. (5):

$$I(a,o) = \rho \sum_{i=1}^{k} \left\| a^i - o_c^i \right\|^2 \qquad (5)$$

- Repeat steps (2) and (3) until the error of the criterion function is within the allowable range, and end the loop to obtain the final target classification results.



Start
Enter the desired number of clusters k
Initialize k clustering centers
Assign each sample to the nearest class
Recalculate the centers of each cluster
Convergence or not
NO
Yes
The clustering result is displayed

Fig. 2. Clustering flowchart of anchor frame.

3) Multitask loss function: The multitask loss function in the Fast R-CNN model is mainly composed of the classification loss function and regression loss function [14]. The classification loss function is used for the classification of salient targets in the proposed target areas of UAV video reconnaissance images, and the regression loss function is used for the regression of salient target boundary frames in UAV video reconnaissance images [15]. The loss function definition formula for a UAV video reconnaissance image is expressed by Eq. (6):

$$H[(r_i),(s_i)] = \frac{I(a,o)}{N_{cls}} \sum_i H_{cls}(r_i, r_i^*) \qquad (6)$$

$$+\alpha \frac{1}{N_{reg}} \sum_i r_i^* H_{reg}(s_i, s_i^*)$$

In the equation, r_i is the prediction probability of the i -th anchor, r_i^* is the predicted probability of the actual boundary frame $(GT, Grond \;\; Truth)$corresponding to the i -th anchor.

If the recall rate between the i -th anchor boundary frame andGT,$IoU > 0.7$ (at this point $r_i^* r_i^* = 1$), then the anchor is considered as a salient target. If $0.3 < IoU < 0.7$, then the anchor will not participate in the training. If $IoU < 0.3$ (at this point $r_i^* = 0$), then the anchor is considered as the background.

s_i is a vector, indicated as$s_i\{s_x, s_y, s_w, s_v\}$, corresponding to the four parametric coordinates of the boundary frame of the predicted salient target. s_x, $s_y$are corresponding to the central coordinates of the boundary frame of the salient target. s_w, s_v are corresponding to the width and height of the boundary frame of the salient target.$s_i^*$is the coordinate vector of the salient target GTcorresponding to the anchor.

The classified loss is the logarithmic loss of salient target class and non-salient target class, and the calculation formula is expressed by Eq. (7):

$$H_{cls}(r_i, r_i^*) = -lg[r_i^* r_i + (1 - r_i^*)(1 - r_i)] \quad (7)$$

The regression loss is calculated as shown in Eq. (8):

$$H_{reg}(s_i, s_i^*) = B(s_i * -s_i^*) \quad (8)$$

In the equations, B is the defined robust loss function $(smooth\ H_1)$, and the calculation formula is expressed by Eq. (9):

$$smooth\ H_1(x) = \begin{cases} 0.5x^2 & if\ |x| < 1 \\ |x| - 0.5 & otherwise \end{cases} \quad (9)$$

Using a four-dimensional vector$(x, y, w, v)$for the target display window, respectively represents the center point coordinates, width, and height of the target window. Through the regression learning of the salient target boundary frame in the UAV video reconnaissance image, a relational mapping is found, to obtain the regression target window G'which is close to the real target window G by input of the original anchor C through the mapping method, i.e., given $C = (C_x, C_y, C_w, C_v)$, and look for a relational mapping$f$, and make $f(C_x, C_y, C_w, C_v) = (G'_x, G'_y, G'_w, G'_v)$, of which$(G'_x, G'_y, G'_w, G'_v) \approx (G_x, G_y, G_w, G_v)$.

The following two methods of translation transformation and scaling transformation are used to implement the transition from anchor to approximate GT.

The translation transformation is calculated as shown in Eq. (10):

$$\begin{cases} G'_x = C_w d_x(C) + C_x \\ G'_y = C_v d_y(C) + C_y \end{cases} \quad (10)$$

The scaling transformation is calculated as shown in Eq. (11):

$$\begin{cases} G'_w = C_w\, exp[d_w(C)] \\ G'_v = C_v\, exp[d_v(C)] \end{cases} \quad (11)$$

The amount of translation(s_x, s_y), $(s_x^*, s_y^*)$and the scale factor(s_w, s_v), $(s_w^*, s_v^*)$are expressed by Eq. (12), (13), (14), and (15):

$$s_x = (x - x_c)/w_c; s_y = (y - y_c)/v_c \quad (12)$$

$$s_x^* = (x^* - x_c)/w_c; s_y^* = (y^* - y_c)/v_c \quad (13)$$

$$s_w = lg(w/w_c)\,; s_v = lg(v/v_c) \quad (14)$$

$$s_w^* = lg(w^*/w_c)\,; s_v^* = lg(v^*/v_c) \quad (15)$$

In the equations,x , $y$indicate the coordinates $x$and the coordinates $y$of the center of the predicted target boundary frame. w, v indicate the width and height of the target boundary frame. The coordinate parameters of the boundary frame of the anchor are respectively expressed asx_c , y_c , w_c , v_c . The coordinate parameters of the boundary frame of GT are respectively expressed asx^*, $*\, y^*$, w^*, v^*.

C. Detection of Salient Target of UAV Video Reconnaissance Image

The above calculation formula can be understood as, by the regression learning of the target boundary frame, that is, the regression from the anchor boundary frame to the nearbyGT boundary frame, a boundary frame of the regression target windowG' which is much closer to the actual target window$G$ is obtained. The target is detected according to the boundary frame, but due to some certain occlusion or mistaken recognition of the target as an unrecognized object in the UAV video detection, it is further optimized to achieve salient target detection.

1) Calculation of target similarity: By using Faster R-CNN, through the training of salient target detection in UAV video reconnaissance images, the identification of salient targets within the image can be efficiently identified [16], followed by the extraction of potential targets based on their distinctive features [17]. Following that, begin to create the similarity graph. Faster R-CNN exhibits a notable detection rate; however, it may struggle to detect salient targets in exceptional circumstances. If Faster R-CNN cannot identify the salient target, it will process the entire image as a target.

The likelihood of this window containing a target is denoted by the target similarity score. The pixel-level similarity score [18] is derived from the potential targets to determine the likelihood of a pixel being a component of the target. The pixel-level similarity score is determined as shown in Eq. (16) as follows:

$$PixObj(q) = \sum_{i=1}^{N} e_i\, L_i(x, y) \quad (16)$$

The equation, $e_i$indicates that if the pixel $q$is contained in the target window i detected by Faster R-CNN, $L_i$is a Gaussian filter window of equal dimension to the window, x, $y$is the relative coordinate of pixels$q$ in one of the detection windows, $N$is the number of possible target windows detected by Faster R-CNN.

The sum of the similarity scores of all pixels in the superpixel region is the similarity score of the current superpixel region, defined by Eq. (17).

$$Objectness(Tq_i) = \sum_{i \in M} PixObj(q_j) \quad (17)$$

In the equation, q_j is one pixel in the$i$ -th superpixel regionTq_i. The similarity graph is then further optimized using a threshold-based method, where the threshold is set as 1.5 times the quantity of pixels in the similarity graph divided by the overall number of pixels in the graph.

2) *Calculation of target connectivity graph*: The threshold similarity graph is only a part of the target superpixels that are roughly acquired. This paper adopts the "target connectivity" method, which assigns a value to the predicted target according to the salience value of the superpixel connectivity [19]. Build a graph using superpixels as nodes. The adjacent superpixel nodes have edges, and the weight of these edges is specified as the Euclidean space of the mean Lab color of the two nodes. The target connectivity of the i -th superpixel Tq_i is defined by Eq. (18):

$$F(Tq_i) = \frac{\sum_{m=1}^{N_1} d(Tq_i,Tq_m)\cdot\beta(Tq_m)}{\sum_{m=1}^{N_1} d(Tq_i,Tq_m)\cdot[1-\beta(Tq_m)]} \quad (18)$$

In the equation, $d(Tq_i,Tq_m)$indicates the shortest distance between superpixels Tq_i and Tq_m. If the superpixel Tq_m is predicted as a target in the similarity graph, then assign the value of $\beta(\cdot)$ as 1, and N_1 is the total number of superpixels.

The more superpixel similarities that are predicted as targets, the lower the numerator value and the higher the denominator values, which makes the lower value of F. Set the reciprocal of Fas the target probabilityf_i, which means that the algorithm has identified the possible salient target in the UAV video reconnaissance image. To improve the detection accuracy of the salient target, following image enhancement algorithm is used to improve the detection accuracy of the salient target.

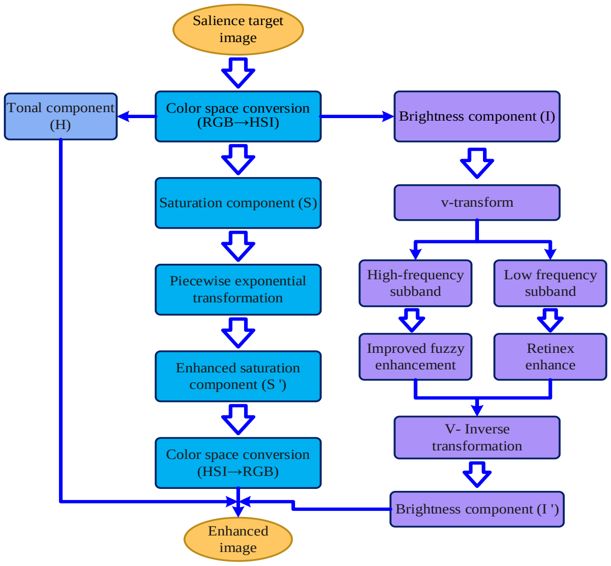
D. Enhancement of Salient Target of UAV Video Reconnaissance Image Based on HSI Color Space

First, convert the low illuminance image from RGB space to HSI space [20], and then different enhancement algorithms are used respectively according to component (S) and component(I). The process of this algorithm is: (1) Color space conversion, from RGB space to HSI space; (2) Enhance components$(S)$and(I)respectively by "Piecewise exponential transformation" and "V-transformation + Retinex enhancement + improved fuzzy enhancement"; (3) Return to RGB color space to get the enhanced image. The flow chart is shown in Fig. 3.

The enhancement algorithms for each stage are described in detail below.

1) *Enhancement of saturation component*: Generally, the enhancement of the saturation component is a simple linear transformation [21]. This paper proposes a piecewise exponential enhancement algorithm, characterized by its nonlinear nature. The saturation levels of distinct areas can be processed individually to enhance the overall visual impact. The salient target image of the UAV video reconnaissance image is divided into three regions based on its saturation level: high, medium, and low. When $x > 0$, $u^x - 1 > x$, and $\lim_{x\to 0}\frac{u^x-1}{x} = 1$, that is, when$x$is extremely small, $u^x - 1$ and$x$are equivalent. Therefore, the low saturation region is stretched by the exponential transformation to enlarge the saturation; for the medium saturation region, only exponential transformation is done to make appropriate adjustments; for the high saturation region, the saturation is reduced appropriately through the reduction of the exponential transformation. The piecewise exponential enhancement algorithm proposed in this paper is expressed by Eq. (19):

$$P'(m,n) = \begin{cases} \eta\left[u^{P(m,n)} - 1\right], & P(m,n) \le 0.2 \\ u^{P(m,n)} - 1, & 0.2 < P(m,n) \le 0.7 \\ \mu\left[u^{P(m,n)} - 1\right], & else \end{cases} \quad (19)$$



Salience target image
Tonal component (H)
Color space conversion (RGB→HSI)
Brightness component (I)
Saturation component (S)

High-frequency subband
Low frequency subband
Piecewise exponential transformation
Improved fuzzy enhancement
Retinex enhance
Enhanced saturation component (S ')
V- Inverse transformation
Color space conversion (HSI→RGB)
Brightness component (I ')
Enhanced image

Fig. 3. Flow chart of image enhancement algorithm.

In the equation, $P$and$P'$are the saturation before and after enhancement, respectively; the parameters η, $\mu$are used to adjust the scaling of the transformation. When$\eta$is 1.2~1.5, and $\mu$is 0.7~0.9, the enhancement effect is the best. In this paper, the value of η is 1.4, and the value of μ is 0.8.

2) *Enhancement of brightness component*: V-transform the brightness component to obtain the V-spectrum matrix. The data of the 1/4 of the upper left corner of the V-spectrum matrix is the low-frequency sub-band $I_L$of the brightness component, with the rest of the data being the high-frequency sub-bandI_H. Different methods of enhancement are used for low and high frequencies.

a) *Low-frequency coefficient enhancement (Retinex):* Because the low-frequency sub-band $\mathrm{I_L}$concentrates the overall information of the brightness of the salient target image of the UAV video reconnaissance image, it depicts the general outline of the image, and the Retinex enhancement algorithm can be used.

Assuming that the brightness low-frequency coefficient is$P(x,y)$, the enhanced low-frequency coefficient is calculated by Eq. (20):

$$\begin{aligned} z(x,y) &= ln\,J\,(x,y) \\ &= ln\,P\,(x,y) - ln[D(x,y) * P(x,y)] \end{aligned} \quad (20)$$

$z(x,y)$ stands for the output image after enhancement and $*$ stands for the convolution symbol; $D(x,y)$ is the center-surround function, a Gaussian filter function is usually chosen as shown in Eq. (21):

$$D(x,y) = \sigma \cdot u^{\frac{-(x^2+y^2)}{c^2}} \tag{21}$$

In the equation, c is the Gaussian surround scale; σ is a constant which makes the integral of $D(x,y)$ as 1. The reflected image$J(x,y)$ represents the intrinsic property of an image and carries detailed information about the image.

The key to Retinex theory is to reasonably assume the composition of the salient target image of the UAV video reconnaissance image [22]. If an image is regarded as an image with noise, then the component of the incident light can be regarded as a multiplicative, relatively uniform, and slowly transformed noise [23]. The Retinex algorithm can fairly estimate the noise present at every position within the image and remove it to acquire a noticeable Impact. The obtained image reduces the impact of incident light [24], and retains the reflection attribute of the object essence, that is, the essence of the image.

b) High-frequency coefficient enhancement (Improved fuzzy optimization): In the sub-bandI_H characterized by high frequency, the wavelet coefficient of noise exhibits a diminutive magnitude, which is further reduced compared to the coefficient of the signal. To enhance the details of the salient target image and suppress noise [25], this paper proposes an improved fuzzy enhancement algorithm, which aims to enhance the clarity of details while simultaneously suppressing noise [26]. The specific algorithm process is outlined below:

Step 1: Construct the affiliation function as shown in Eq. (22):

$$E_{mn} = \frac{x_{mn} - x_{min}}{xmin_{max}} \tag{22}$$

Transforming the high-frequency coefficient into fuzzy sets is aiming to normalize the coefficient in the high-frequency subband to the interval$[0,1]$. In the equation, x_{max}andx_{min}stand respectively for the highest and lowest values of the coefficient in the high-frequency subband; x_{mn} is the coefficient.

Step 1: Design the fuzzy affiliation transformation as expressed by Eq. (23):

$$E'_{mn} = \frac{1}{2} + \left(E_{mn} - \frac{1}{2}\right)^{1/3} \tag{23}$$

This function is a nonlinear and monotonically increasing function and $\left(\frac{1}{2}, \frac{1}{2}\right)$ is its inflection point. It makes the numbers less than $\frac{1}{2}$ shrinking, and makes the numbers greater than$\frac{1}{2}$amplified. When acting on the high-frequency coefficient, it can achieve the purpose of enhancing the details of the salient target image of the UAV video reconnaissance image while suppressing noise.

Step 1: Convert the fuzzy set to the high-frequency subband as shown in Eq. (24):

$$E''_{mn} = E'_{mn} \cdot (xmin_{max} + x_{min}) \tag{24}$$

The enhanced high-frequency coefficients are obtained.

So far, the enhanced low-frequency and high-frequency coefficients are obtained, and then the enhanced brightness component I' is obtained through V-inverse transformation. Finally, the obtained enhanced saturation$S'$and the enhanced brightness I', and the hue component of the salient target image$(H)$are synthesized and converted to RGB space to output the enhanced salient target image.

III. Experimental Analysis

To verify the effect of the method in this paper on the detection of salient targets of UAV video reconnaissance images, the GPU configuration of experimental hardware equipment is selected as displayed in Table I.

The UAV used for reconnaissance shooting is shown in Fig. 4. The configuration parameters are shown in Table II.

TABLE I. GPU Configuration

Name	Parameter
Brand	Shadow Chi
Model	GTXTITAN-6GD5
Craftsmanship	28mm+
Stream processor	2688pcs
Core frequency	954 MHze
Video memory capacity	6G GDDR5+
Video memory bit width	384Bite
Video memory frequency	6008MHz
Graphics card power consumption	300W+
Heat-dissipating method	Cooling fan
Size	280mm×127mm×42mm

TABLE II. UAV Configuration Table

Name	Parameter
Model	RQ-8 drone
Maximum safe takeoff weight	7kg
No-load	6.5kg
Load	2kg
Size	The length is 970mm
	Width 920mm, 500mm after folding
	Height 240mm, folded back 180mm
Wheelbase size	1100mm
Propeller size	26inch
Duration of flight	>50min
Maximum speed	36km/h
Wind loading rating	Strong breeze
Operating radius	>10km
Dynamic type	Whoring polymer cell
Working altitude	4500m
Operating temperature	-20 to 60 degrees Celsius

Fig. 4. UAV used for reconnaissance shooting.

The experimental test dataset consists of images captured by a drone as shown in Fig. 4. This dataset consists of 500 frames of video reconnaissance images captured by drones in different scenes, lighting conditions, and dynamic backgrounds. These images contain complex and subtle information, such as hidden targets, varied backgrounds, and challenging factors such as lighting changes. The dataset is divided into two parts: (1) Training set: containing 300 frames of images, used to train a CNN based saliency object detection model. These images cover various possible scenarios and conditions in the dataset to ensure that the model can learn enough features to cope with complex detection tasks. (2) Test set: Contains the remaining 200 frames of images to evaluate the performance of the trained model on unknown data. These images maintain similar diversity to the training set, but are completely independent to ensure the objectivity and accuracy of the test results.

After completing the above preparations, proceed with the experiment according to the following steps:

Step 1: Dataset preparation and annotation

Collect and organize drone video surveillance images, accurately label salient targets in the images through manual means, and provide accurate data foundation for model training.

Step 2: Remove haze from the image

To remove haze from the original image, improve image quality, reduce the impact of haze on subsequent object detection, and enhance detection accuracy.

Step 3: Faster R-CNN model training

Using annotated training set data, train the Faster R-CNN model to learn the features of salient targets and possess the ability to classify and perform bounding box regression.

Step 4: Test Set Evaluation

Evaluate the trained Faster R-CNN model using an independent test set to validate its detection performance on unknown data, including subjective and objective testing metrics such as accuracy, recall, and F1 score.

Step 5: Extreme situation handling and image enhancement

In response to extreme situations where the Faster R-CNN model cannot accurately detect, methods such as superpixel saliency screening are used for supplementary detection, and HSI color space enhancement is applied to the detected saliency target images to improve image clarity and visual effects.

Step 6: Result analysis and optimization

Conduct a comprehensive analysis of the experimental results, evaluate the advantages and disadvantages of the model, and further optimize the model based on the analysis results to improve detection performance and robustness.

In the test set, 1 frame image is selected to perform the target detection experiment using the trained network, and the detection results are plotted as shown in Fig. 5. And compare these detection results with the detection results of the chromatography-mass spectrometry method in study [4] and the joint transform correlator method in study [5], which are shown in Fig. 6 and Fig. 7. The red boxes are the correct targets, the yellow circles are the false detection, and the blue boxes are the missed detection.

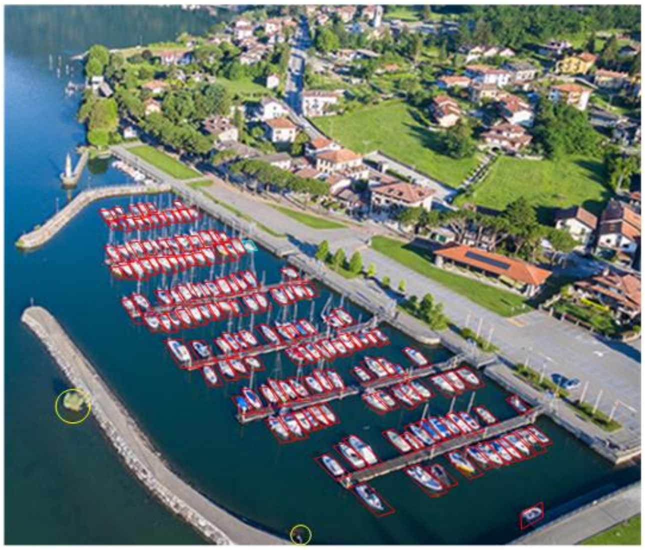

Fig. 5. Detection results of the proposed method.

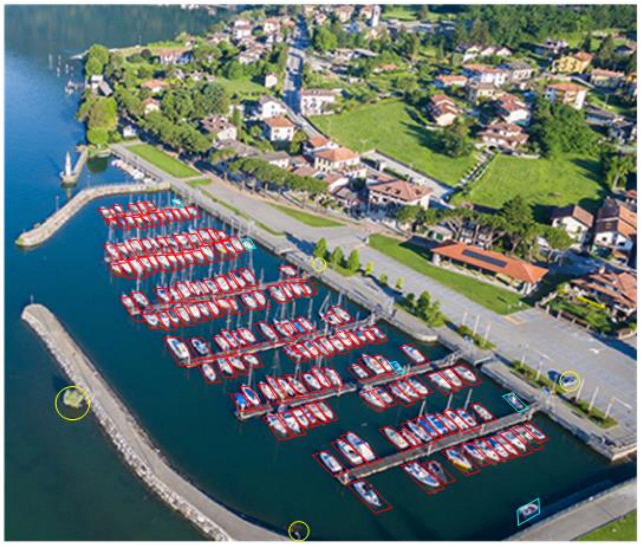

Fig. 6. Test results by chromatography-mass spectrometry.

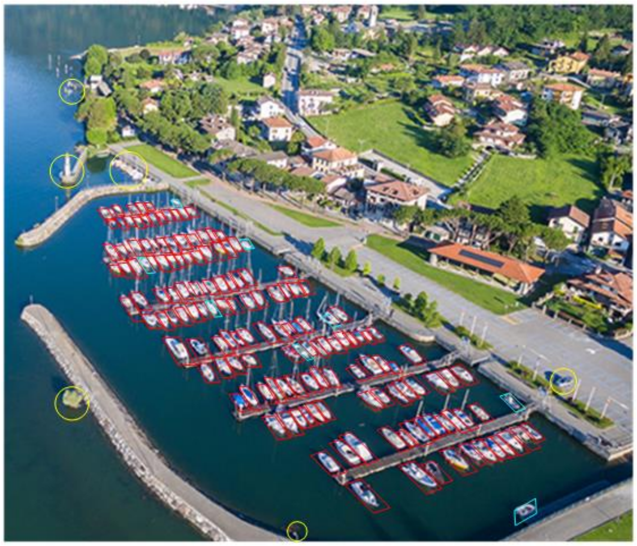

Fig. 7. Detection results of the joint transform correlator method.

From Fig. 5, it can be seen clearly that the method in this study successfully detects all targets, except one missing detection and two false detections. This result shows that the method in this study has high accuracy and reliability in the detection of salient targets of UAV video reconnaissance images. Through the analysis of the results, it can be seen that the method in this paper provides an effective way for the accurate detection of salient targets, with high feasibility and significant effectiveness. In contrast, there are five missed and four false detections in the detection results of the chromatography-mass spectrometry method shown in Fig. 6. This data is significantly higher than the data of the method in this paper, indicating that the effect of the method of chromatography-mass spectrometry in target detection is not ideal. The detection results of the joint transform correlator method in Fig. 7 are even more disappointing, with 8 missed and 6 false detections. This result shows the shortcomings of the method of joint transform correlator in multi-target detection. In conclusion, by comparing the target detection effect of the three methods, it can be seen that the method in this paper has high accuracy and low false detection rate in multi-target detection, and can play an important role in UAV video reconnaissance.

To verify the performance of the salient target detection method in this paper, 1 frame of image is selected in the test set for the experiment. Also compare the result with the experimental result of the chromatography-mass spectrometry method and the joint transform correlator method, as shown in Fig. 8 to Fig. 11.

Fig. 8 shows a scene with multiple targets and a complex background, increasing the difficulty of target detection. By comparing the detection results in Fig. 9, Fig. 10, Fig. 11, and Fig. 8, the advantages of this method in dealing with such complex scenes are evident. In the detection result of this method, salient targets are detected, and there is no false detection or missed detection. On the contrary, both the chromatography-mass spectrometry method and the joint transform correlator method have problems in processing Fig. 8. There are three missed detections in the detection of salient targets by the chromatography-mass spectrometry method, and the detected targets are not clear, which has the problem of shadow occlusion. The detection effect of the joint transform correlator method is worse. There are not only five missed detections but also the green belt in the middle of the road has been detected. In addition, the detected target is accompanied by obvious shadows, which makes the target unclear. By conducting a comparative analysis, it is concluded that the method in this study can detect salient targets more accurately and clearly, which proves the effectiveness of this method in complex scenes.

The frame images in the test set are selected for the image enhancement experiment. Compared with the joint transform correlator method and the chromatography-mass spectrometry method, the original plots and the experimental results of the three methods are shown in Fig. 12 to Fig. 15.

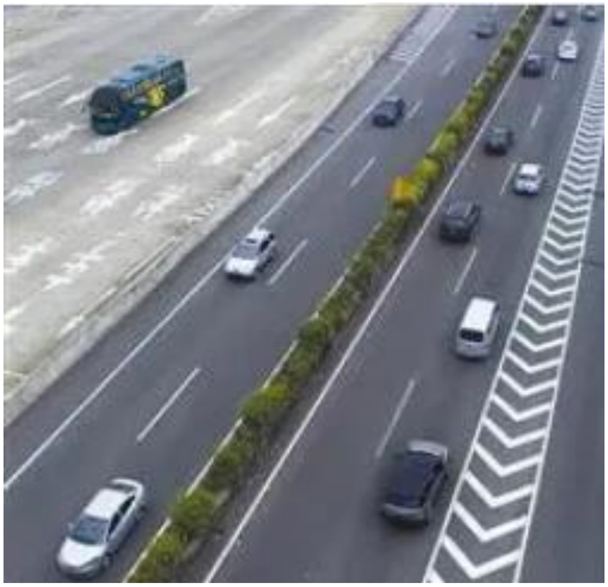

Fig. 8. Original drawing.

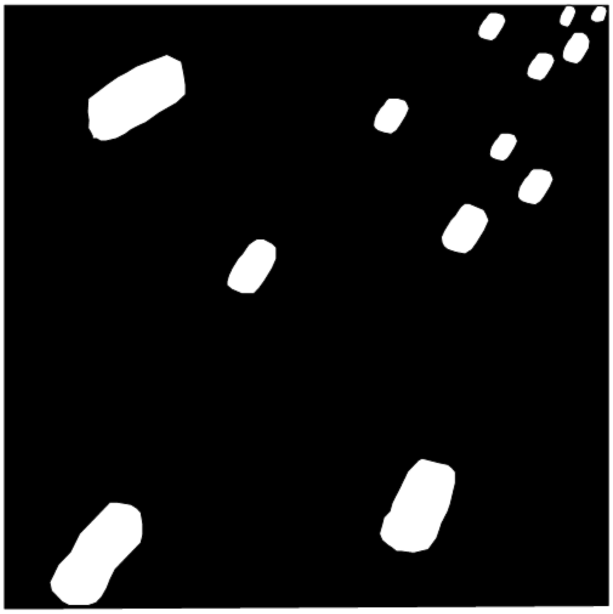

Fig. 9. Result of salient target detection of the proposed method.

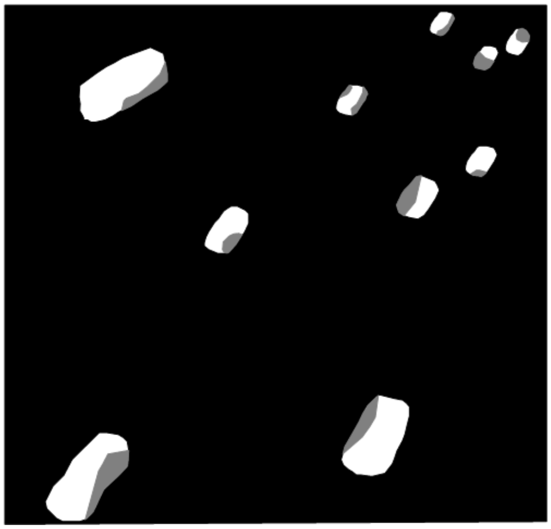

Fig. 10. Result of salient target detection by chromatography-mass spectrometry.

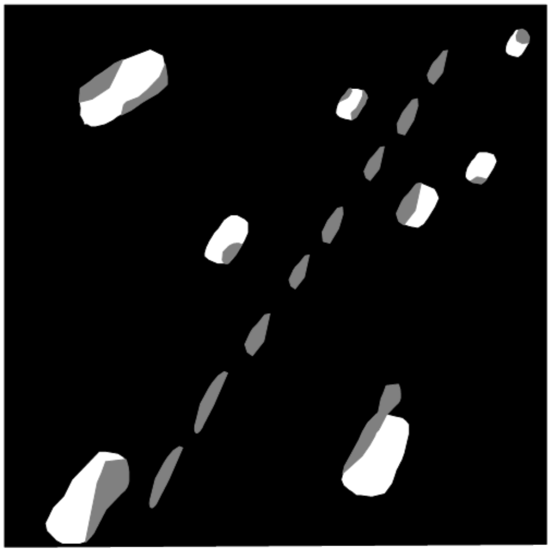

Fig. 11. Result of the salient target detection by joint transform correlator.

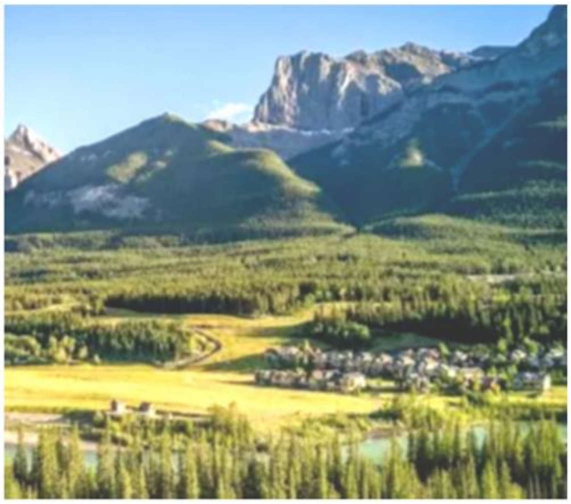

Fig. 12. Original drawing.

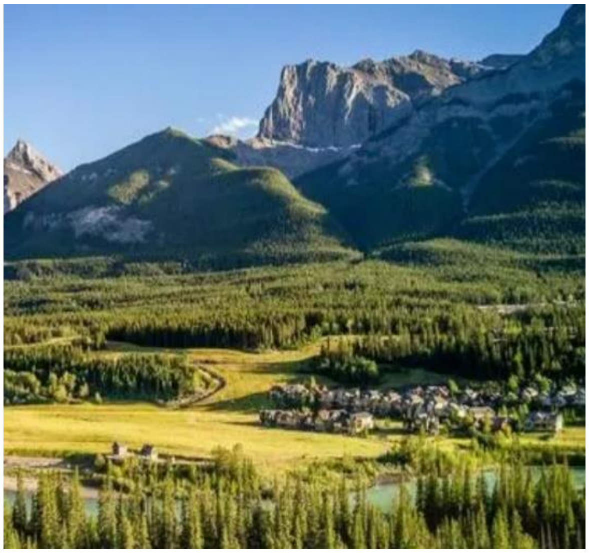

Fig. 13. Enhancement effect of the proposed method.

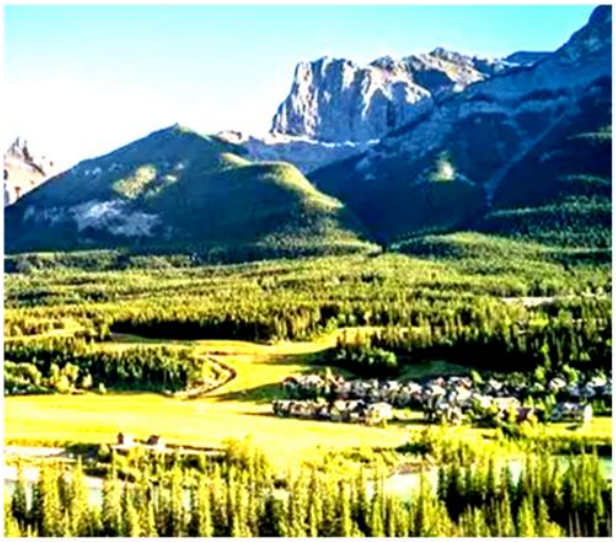

Fig. 14. Enhancement effect of joint transform correlator.

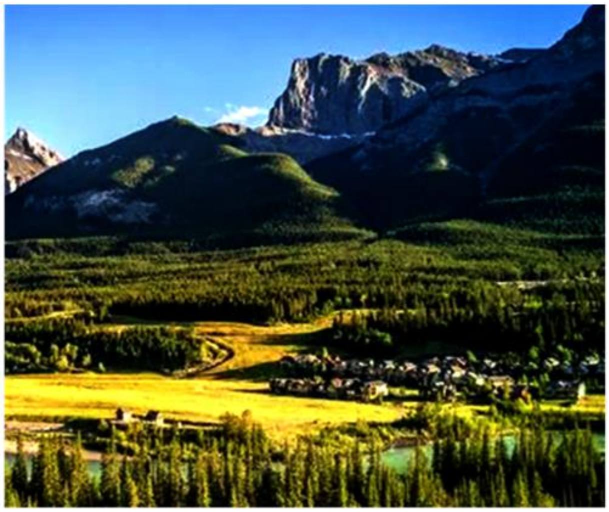

Fig. 15. Enhancement effect of chromatography-mass spectrometry method.

By comparing Fig. 13 and Fig. 12, the advantages of this method in image enhancement are apparent. The original image in Fig. 12 is slightly fuzzy and the details are not clear enough, but after the enhancement processing of this method, the image in Fig. 13 becomes very clear and the details are presented vividly. More importantly, the color of the enhanced image is soft, which is closer to the visual effect of the real scene, providing a good basis for subsequent tasks such as target detection. In contrast, although the joint transform correlator method in Fig. 14 has some effect of enhancement, the color is too bright, even some dazzling, giving a sense of unnatural. This kind of too-bright color will cover up some important details, causing trouble for subsequent tasks. The chromatography-mass spectrometry method in Fig. 15 has insufficient effect of enhancement. The overall image is dark and some details are not clear enough. Such an enhancement effect will make subsequent tasks such as target detection more difficult. In conclusion, the method in this paper performs well in the enhancement of UAV video reconnaissance images. It can not only significantly improve the image clarity, but also maintain the authenticity and softness of colors. The enhancement effect has a positive role in promoting the detection of salient targets.

To further validate the object detection performance of the proposed method, the detection performance of the three methods was compared using accuracy, recall, F1 score, and average detection time as objective indicators. The results are shown in Table III.

TABLE III. UAV CONFIGURATION TABLE

Method	Precision	Recall	F1 Score	Average detection time (seconds)
Chromatography-mass Spectrometry Method	0.75	0.68	0.71	5.2
Joint Transform Correlator	0.80	0.72	0.76	4.8
Proposed Method	0.90	0.85	0.87	0.3

According to Table III, the chromatography-mass spectrometry method shows relatively low accuracy and recall, with values of 0.75 and 0.68, respectively. This indicates that the method has certain errors in distinguishing significant and non-significant targets, and may miss some targets. The joint transformation correlator method has improved in accuracy and recall, reaching 0.80 and 0.72 respectively, demonstrating better object detection capability. The method proposed in this paper performs well in both accuracy and recall, reaching 0.90 and 0.85 respectively, significantly higher than the other two methods, indicating that this method can more accurately identify and detect significant targets. The F1 score of proposed method reached 0.87, which is much higher than that of the chromatography-mass spectrometry method (0.71) and the combined transform correlation method (0.76), further verifying the superiority of the proposed method. In terms of detection speed, the method proposed in this paper demonstrates significant advantages, with an average detection time of only 0.3 seconds, far lower than the chromatography-mass spectrometry method (5.2 seconds) and the combined transform correlation method (4.8 seconds). This indicates that the method proposed in this paper has higher real-time performance in processing drone video reconnaissance images. In summary, the CNN based method for detecting salient objects in unmanned aerial vehicle (UAV) video reconnaissance images proposed in this paper outperforms the compared methods in terms of accuracy, recall, F1 score, and detection speed. The experimental results show that the method proposed in this paper can accurately and efficiently detect salient targets in drone video reconnaissance images, which is of great significance for improving the efficiency and accuracy of reconnaissance work.

IV. CONCLUSION

With the popularization of UAV technology, the application of UAVs in the field of video reconnaissance is more and more extensive. However, the images taken by UAVs are often affected by factors such as illumination variation, camera angles, etc., which brings certain difficulties to target detection. To solve the problem, this study proposes a CNN-based salient target detection method for UAV video reconnaissance images. According to Faster R-CNN, the salient target detection of UAV video reconnaissance images is realized. For the salient target that cannot be detected in extreme cases, the detection is completed using the salient target calculation method of this paper. To make the detection effect better, the salient target enhancement algorithm is set to complete the salient target detection of UAV video reconnaissance image. Through experimental verification, the method of this paper has high accuracy and low false detection rate, can detect salient targets more accurately and clearly, and performs well in the enhancement of UAV video reconnaissance images. However, the effectiveness of this method largely depends on the quality and diversity of the training dataset. If the training dataset cannot fully cover various complex scenarios that may be encountered in practical applications, the generalization ability of the model may be limited. In addition, image differences under different drone platforms and shooting conditions may also affect the detection performance of the model. Therefore, in the future, addressing this issue will be the focus.

Construction of Image Retrieval Module for Ethnic Art Design Products Based on DF-CNN

Yaru He
Chengdu Vocational and Technical College, Chengdu, 610041, China

***Abstract*—With the increasing interest of consumers in ethnic art, more design products with ethnic art characteristics are being displayed. In order to help users easily retrieve related art products, an image retrieval model that can effectively extract data is proposed. The research method strengthens the depth of data mining through weighted methods, main characteristics and local features in images based on the multi-window combination, and uses the deep forest algorithm to expand the decision path and select information gain nodes. By adjusting the weights of convolutional neural networks, the retrieval ability of the model is enhanced. The gradient problem in the propagation process is optimized using residual modules, and the prominent features of the features are strengthened using a bar attention mechanism to optimize the retrieval ability. The results indicated that the loss function of the research model converged within 20 iterations, and the matching degree of the retrieved images in the testing set reached 91.28% after iterative training. The AUC of the research model was 0.876, indicating that the model had a good performance in image retrieval and classification. The retrieval accuracy of the research model was higher than other methods for image data of different specifications. This indicates that the research model has universality for multi-scale image retrieval, which can provide theoretical support for the development of ethnic art design products.**

***Keywords*—Image retrieval; main characteristics; local features; deep forest; convolutional neural network; bar attention mechanism; residual module**

I. Introduction

Ethnic art contains the cultural heritage and artistic ideas of a nation, and products created based on ethnic art have distinct cultural characteristics [1]. More art museums are using ethnic art design as a featured theme to share related types of exhibits. However, the patterns of ethnic characteristic exhibits are usually formed by simple line and pattern combinations, which do not have obvious characteristics of things, making retrieval difficult [2-3]. In order to retrieve images more effectively, various image retrieval method shave been developed. Early image retrieval relied on textual keywords to express image features, using the main parameters of the image as a reference standard, and obtaining retrieval results through data comparison and visual combination. However, method comparison requires manual labeling, resulting in low retrieval efficiency [4]. With the advancement of retrieval technology, content-based image retrieval methods have been proposed. The image search method can avoid manual errors by comparing image attributes with image features to obtain retrieval results. However, the recognition effect on local features is unstable and easily affected by noise [5]. Therefore, D. Lowe proposed the Scale-Invariant Feature Transform (SIFT) feature method and the Local Binary Pattern (LBP) feature method. The local features of the image are enhanced to deepen the model's memory of feature points. Moreover, it has good recognizability for behaviors such as image rotation and scaling, but the method places too much emphasis on local features, resulting in a lack of global perspective [6]. With the development of intelligent technology, Convolutional Neural Networks (CNN) have been applied in image retrieval. The self-learning ability based on CNN can accurately extract image features and enhance the adaptability of network retrieval through dataset training. However, excessive feature vectors may lead to long training time and slow retrieval efficiency of the network. The research aims to design a retrieval module that ensures the accuracy of image retrieval while improving the speed of image retrieval. To optimize the user's search experience and match the search needs of art galleries or museums. Therefore, the DF-CNN algorithm is innovatively proposed for image retrieval in the field of ethnic art products. It strengthens local features through a bar attention mechanism, combines local features with subject features using an overlap pooling method, and optimizes the retrieval speed of the model through parallel multi-channel convolution. A new ethnic art design product retrieval model is constructed to provide certain technical support for the dissemination of ethnic art.

II. Related Work

With the development of Internet technology, the number of image data in the network is gradually rich, but it is difficult to accurately retrieve the required image in a rich database. Therefore, researchers have conducted research on image retrieval methods. Suganyadevi S et al. proposed a research method based on deep learning for medical image retrieval. The method established a learning system by exploring data information in the medical field, and reduced the dimensionality of functions using deep conventional and extreme learning methods to complete the retrieval and analysis of medical images. The results showed that the proposed method was accurate for retrieving medical image data [7]. Kelishadrokhi M K et al. proposed a research method based on novel local texture descriptors and color features for image retrieval problems in computers. The texture and color information database was used to train the image recognition ability. Effective features were extracted using the local neighborhood difference method. The results indicated that the proposed method had a good corresponding effect on computer content image retrieval [8]. Keisham Net al. proposed a research method based on depth search and rescue algorithm for image retrieval on the Internet. The method used advanced visual feature extraction techniques to enhance the feature points of the image, and optimized the feature clustering of the image through feature fusion and filtering. The results indicated that the proposed method significantly improved the efficiency of image retrieval [9]. Wang W et al. proposed a method based on sparse representation and feature fusion for image retrieval in databases. The method used a generalized search tree to retrieve similar scenes in the image and enhanced local features of the image through sparse coding. The results indicated that the proposed method improved the accuracy of database image retrieval [10]. Ning C et al. proposed a method based on deep metric learning for image retrieval of clothing. The method called similar features from the database through pre-set regional scenarios, and optimized the recognition of clothing patterns based on feature similarity comparison and feature point analysis. The results indicated that the proposed method had a fast retrieval speed for clothing patterns [11].

Zhuang H et al. adopted the Deep Forest (DF) algorithm to address the urban land change. A dimensional space was constructed based on terrain modeling. Advanced features in structural data were mined on the basis of deep learning methods, and the changing state of land was simulated through community comparison. The designed method had a relatively accurate prediction level for land change issues [12]. Hamedianfar et al. proposed a method based on the DF algorithm to address the application issues of remote sensing methods. Multi-scale features were established through shallow machine learning, the network architecture was expanded through a time series strategy and remote sensing method was optimized through multiple training methods. The developed method had a good simulation effect on remote sensing data modeling [13]. Shaaban M A et al. adopted a deep convolutional forest to detect text spam emails. Machine learning was used to perform the basic classification of email types. The dynamic deep integration method automatically adjusted the classification complexity and extracted effective features with the help of classifiers. The results indicated that the proposed method accurately isolated phishing emails [14]. Huang et al. proposed a method based on CNN for fault diagnosis in complex systems. The method used sample feature extraction from multivariate time series for multi-layer transmission, optimized data retrieval through sliding processing of data windows, and combined model training to enhance the diagnostic performance. The results indicated that the proposed method had high prediction accuracy for fault diagnosis [15]. Tayal A proposed a research method based on CNN for the diagnosis of retinal diseases. The method automatically identified disease types through the constructed intelligent learning framework, determined disease categories based on the feature set of medical images, and filtered out interference items through image denoising. The results indicated that the proposed method had an assisting role in the diagnosis of retinal diseases [16].

In summary, Kelishadrokhi et al. enhanced the depth of image feature extraction through local texture and color feature recognition, but it affected the retrieval speed of the image. Ning C et al. used deep metric learning to enhance the speed of retrieval, but due to the single feature extraction method, the matching degree of image retrieval decreased. Moreover, a single CNN algorithm lacks feature type differentiation, which can affect the efficiency of ethnic art image retrieval. However, there is currently limited data on the combined application of CNN and DF algorithms in the field. Therefore, research attempts to achieve synchronous improvement in retrieval performance and retrieval speed through the fusion of the two algorithms.

III. Methods and Materials

A. *Design of Image Retrieval Module for Ethnic Art Products Based on DF*

With the exchange and dissemination of culture, ethnic art patterns have gradually emerged as an artwork in the public eye. The application of ethnic patterns has developed from the initial daily life to ethnic art design [17-19]. Art design products with distinctive features during tourism are often given as souvenirs to friends and family. However, faced with a wide variety of ethnic art patterns, the search process is often dazzling [20-22]. In order to efficiently and accurately retrieve ethnic artworks with diverse patterns, the study introduces the DF for the image retrieval process. The DF algorithm, as an efficient classifier, can accurately extract image features from high-dimensional image data and optimize the model's fitting through its self-learning ability [23-25]. The cascading structure processing process of the DF algorithm is shown in Fig. 1.

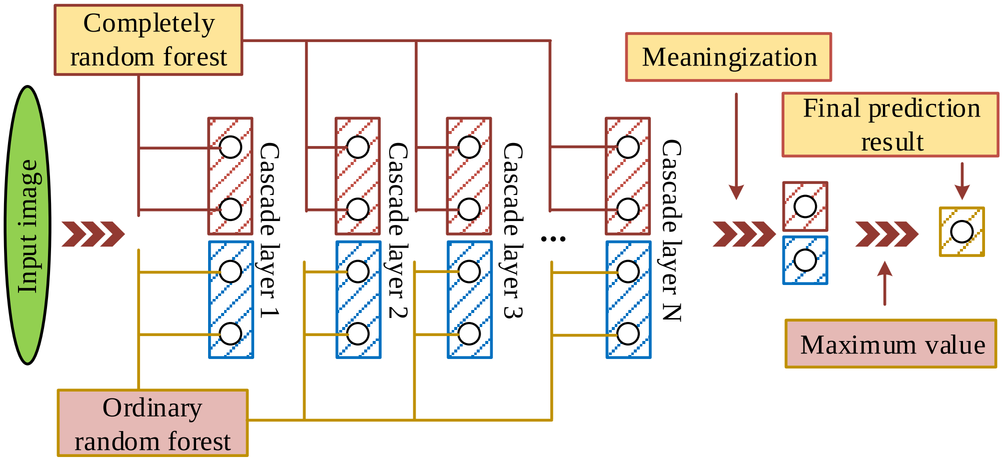

Fig. 1. The cascade structure of deep forests.

In Fig. 1, the DF algorithm processes input data through multiple layers. The process strengthens the data mining depth using the weighted method, and assigns hierarchical weights to the forest based on weight factors. Based on the predicted probability value of the forest, the weight factor's proportion is optimized. Through hierarchical multi-source data synchronization analysis, discrete image features can be effectively detected. To optimize the feature partitioning performance in the DF, the decision tree in the DF algorithm is used for information entropy optimization. The optimization process defines the information entropy of the sample set, as shown in Eq. (1).

$$Ent(N) = -\sum_{i}^{n} \frac{C^i}{N} \log_2 \frac{C^i}{N} \quad (1)$$

In Eq. (1), $Ent(N)$ represents the sample set information entropy. N represents the total sum of the sample set. C^i represents the sample size. The sample ratio is set to $p_i = \frac{C^i}{N}$ during the optimization process. Therefore, the information entropy of the sample set is converted, as shown in Eq. (2).

$$Ent(N) = -\sum_{i}^{n} p_i \log_2 p_i \quad (2)$$

In Eq. (2), p_i represents the sample ratio. Information entropy, as a metric in decision trees, can represent the set purity of a sample set. Based on the difference in information entropy before and after the feature decision dataset, the change in information gain is calculated. The value of information gain is measured by the influence proportion of branch nodes. The gain calculation process is shown in Eq. (3).

$$Gain = (N, a) = Ent(D) - \sum_{v=1}^{V} \frac{|N^v|}{|N|} Ent(N^v) \quad (3)$$

In Eq. (3), $Gain$ represents the information gain of dataset N after being partitioned by feature attribute a. a represents the selected feature attribute. V represents the number of branch nodes that may be formed during the process. N^v represents the sample data when the branch node is V. v represents the range of values for feature attribute a. $|N^v|/|N|$ represents the weight assigned to branch nodes. The feature partitioning of the input image by the decision tree is evaluated by the Gini coefficient, and the evaluation calculation process is expressed as Eq. (4).

$$Gain(D) = \sum_{k=1}^{K} p_k (1 - p_k) = 1 - \sum_{k}^{K} p_k^2 \quad (4)$$

In Eq. (4), $Gain(D)$ represents the Gini index. D represents the selected dataset. D represents the probability of decision-making. K signifies the number of branch nodes in the current dataset D. k signifies the value of the current branch node. To extract features from the entire image layer, dynamic sliding windows are used to scan image information in different regions. The complete feature extraction of the image is completed by concatenating the information from overlapping windows. The research process adopts multi-granularity scanning. The principle of the scanning model is shown in Fig. 2.

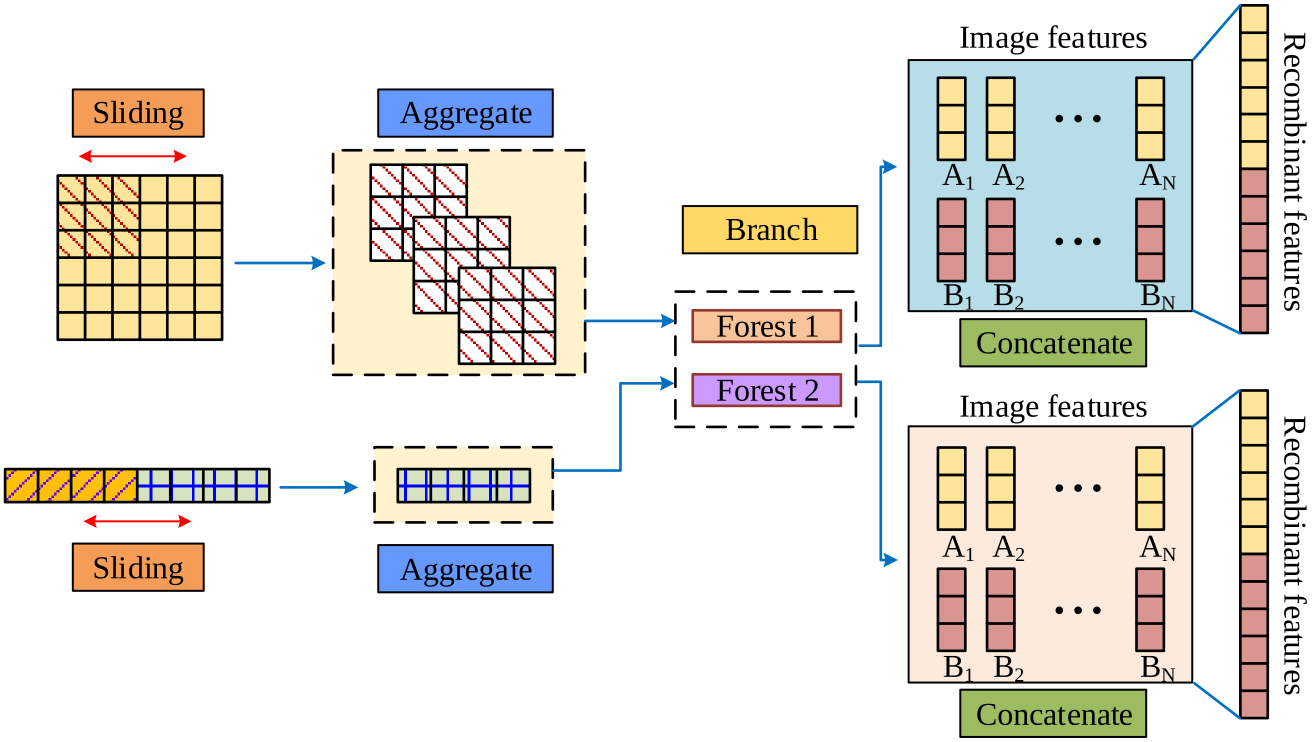

Fig. 2. Multi-granularity scanning process.

In Fig. 2, the multi-granularity scanning process of the DF algorithm uses window frames of different sizes as feature extraction windows. The main and local features in the image are identified through a combination of multiple windows. The feature output extracted by sliding window is used as a probability vector, and the main output and local output are hierarchically placed into a cascaded forest. The image dimension is enhanced through multi-vector scanning and transmission. In order to enhance local data feature processing, both completely random forest and ordinary random forest are used as decision paths, and split nodes with information gain are selected. To address the feature loss caused by dimensional differences, a linear discriminant analysis method is introduced to perform correlation recognition of image features. The mean vector is expressed as Eq. (5) during the calculation process.

$$u_j = \frac{1}{N_j} \sum_{x \in X_j} x\left(j = 0,1 \right) \tag{5}$$

In Eq. (5), u_j represents the mean vector of the classes j in the sample. N_j signifies the number of classes j in the sample. X_i signifies the dimension vector value of the sample. X_j signifies the class sample set of group j. The covariance matrix of sample features is calculated, as shown in Eq. (6).

$$\sum j = \sum_{x \in X_j} (x-u_j)(x-u_j)^T (j=0,1) \tag{6}$$

In Eq. (6), $\sum j$ represents the covariance matrix of the sample. T represents the transpose of a matrix. In order to calculate the projection point positions of two sets of samples, the divergence matrix is calculated in such a way that similar samples are close and dissimilar samples are far away. The optimization objective is rewrite through high-dimensional to low dimensional vector mapping. The maximum eigen value of the matrix is calculated by the generalized Rayleigh quotient. The DF algorithm generates its own feature vectors at each level when transmitting image features step by step. However, the algorithm's extraction step for the image is based on direct learning of the overall features. Too many levels in the cascaded forest may cause the enhanced features to be covered by ordinary feature vectors, resulting in weak fitting of the model to image samples even after learning. Due to the urgent need for retrieving images of ethnic art products in the scene, the study introduces the prior box method in the scanning stage to make the image extraction process faster. The specific working process of the prior box is shown in Fig. 3.

In Fig. 3, the prior box sets the window size that matches the extraction target through rough measurement of the input image. The window is directly generated based on the original image size using clustering algorithm to avoid the occupation of the main features by invalid information windows. The scanning process of the DF algorithm simplifies the traversal and sampling process of image frames, using effective feature data links to generate intersecting anchor boxes, and quickly locking the effective information window for feature transmission through algorithm training. Finally, the clustering pruning module and joint crossover method are used to achieve rapid output of effective information.

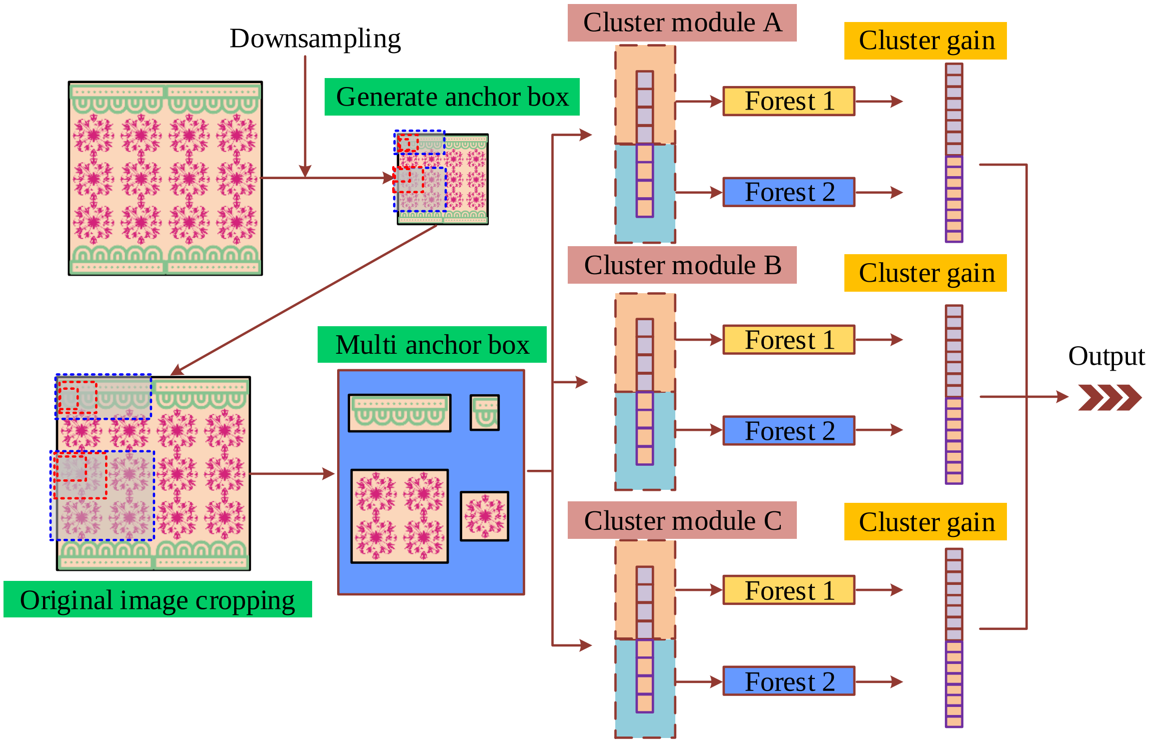

Fig. 3. Prior box workflow.

B. Construction of Ethnic Art Product Image Retrieval Module Combined with CNN

The image retrieval involves users as the main users, so the process inevitably involves personal subjective expression issues [26-27]. There is a semantic gap between the image information subjectively expressed by humans and the actual images recognized by computers. Therefore, the retrieval process needs to convert user expression information into image information and use the computer vision field to process the retrieval problem between images [28-29]. Image retrieval technology based on deep learning has precise and fast processing capabilities for complex and diverse pattern information. The core method of image retrieval technology is the adaptive ability of CNN [30]. Therefore, CNN is combined with DFto jointly construct an image retrieval module for ethnic art design products. The DF-CNN algorithm transmits feature images through sparse connections. The specification of the output feature map is represented by Eq. (7).

$$h_o = \frac{h_{im} + 2\times padding\_size - k\_h}{stride\_h} \tag{7}$$

In Eq. (7), h_o represents the size of the feature window. h_{im} represents the input image size. $padding\_size$ represents the pixel value of edge extension. k_h signifies the length of the convolution kernel. $stride\_h$ represents the step size. The CNN algorithm achieves image recognition through weight feedback and convolution calculation. The CNN is shown in Fig. 4.

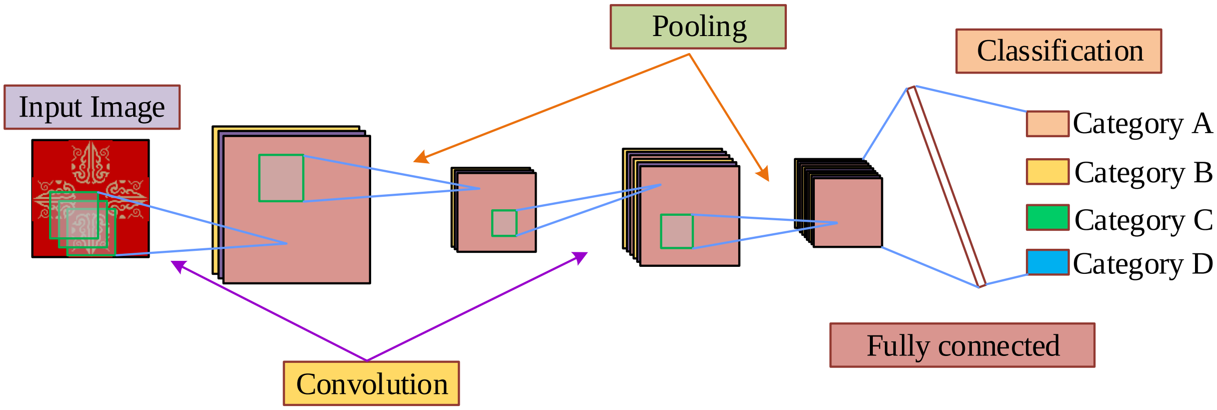

Fig. 4. Convolutional neural network process.

Fig. 4 shows that after the input of the CNN algorithm, the convolutional layers and sub-sampling layers are arranged in an overlapping manner. The collected image features are output through multi-layer convolution and pooling operations. The sub-sampling layer can process and transmit data within the selected range, and the processed features are reduced in model complexity through fuzzy operations. To further enhance the learning ability of the network, ResNet residual network technology is used to complete multi-layer data learning. The calculation process of the residual network is represented by Eq. (8).

$$H(x) = F(x) + x \tag{8}$$

In Eq. (8), $H(x)$ represents the functional expression of the residual process. $F(x)$ represents the module expression function in the residual process. x serves as the feature image for the input stage. The residual formula obtained through transformation processing is Eq. (9).

$$y = R(H(x)) \tag{9}$$

In Eq. (9), y represents the output value. R represents the ReLU activation function used in the network model. The residual module can effectively alleviate the gradient vanishing during signal propagation. The study strengthens the application of residual modules by setting a Bottle-neck structure, further increasing the depth of the network and ensuring that the enhanced deep network maintains efficient learning ability. In order to optimize the process of transforming image features from high dimensions to low dimensions, a 1×1 convolutional layer is added to the original CNN model, and local normalization is adopted after each convolutional layer to enhance the data transmission process. The extracted image features are detected by calculating the similarity between the network input and the matched ethnic art patterns using Euclidean distance. The retrieval results are determined based on the similarity measure. The calculation process of Euclidean distance is represented by Eq. (10).

$$d(x,y)\sqrt{\sum_{i=1}^{n}(x_i - y_i)^2} \tag{10}$$

In Eq. (10), d represents the feature distance. x_i represents the i -th feature of one of the two images used to calculate distance. x_i represents the i -th feature of another image for calculating distance. Ethnic art products prioritize symmetrical or rotated patterns with simple patterns. The processed patterns are arranged and stacked to form complex patterns with distinctive features. Therefore, in image feature extraction, it is necessary to more effectively identify the basic image patterns. To optimize the visual feature extraction efficiency in image retrieval, the bar attention mechanism is used to process different features. The specific working mode is shown in Fig. 5.

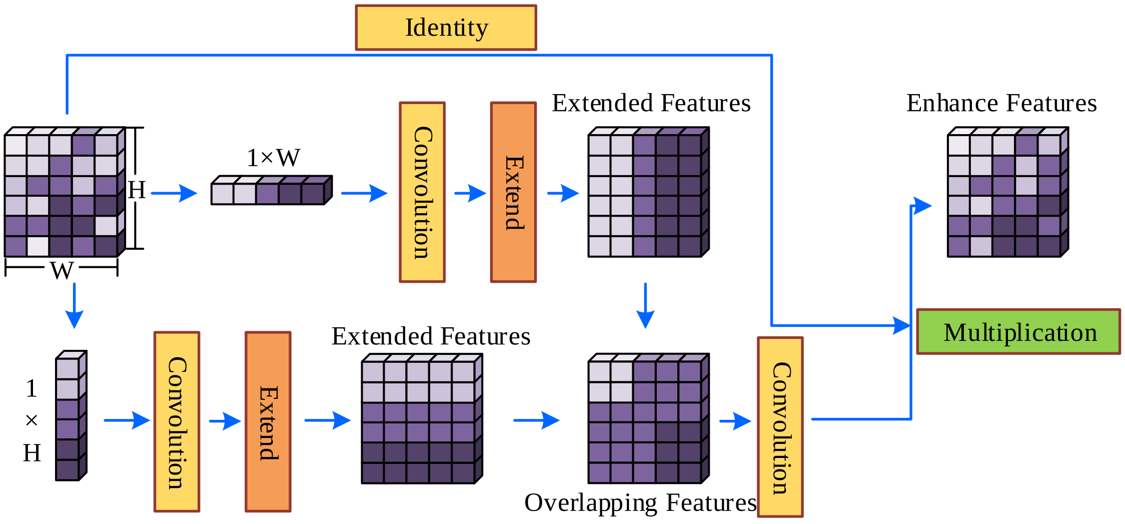

Fig. 5. Bar attention mechanism.

In Fig. 5, the feature extraction mode of the model is composed of a single vertical bar box and a single horizontal bar box. The two sets of standard bar boxes respectively enhance the feature attention points in the current mode, and form a set of enhanced feature data through expansion and combination, filtering out feature maps with less feature information. By optimizing the attention mechanism, the network model magnifies the local feature points of the pattern, resulting in more accurate recognition of effective patterns. The perceptual field of the horizontal bar box in the feature enhancement process is represented by Eq. (11).

$$y_i^h = \frac{1}{W}\sum_{j=1}^{W} x_{i,j} \tag{11}$$

In Eq. (11), y_i^h is the perceived visual field output of the horizontal box. W represents the width value of the space. i signifies the current row value. j signifies the current column value. The perceived visual field of the corresponding vertical bar frame is represented by Eq. (12).

$$y_j^w = \frac{1}{H}\sum_{i=1}^{H} x_{i,j} \tag{12}$$

In Eq. (12), y_j^w D represents the perceived visual field output of the vertical box. H represents the height value of space. Due to the shape setting of the window visual field, a long line connection is established between the discrete region and the main features. The value box of the bar range also makes the feature extraction of the image more targeted, which can enhance attention from two directions and integrate feature maps. To optimize the efficiency of image feature processing, a multi-channel convolution operation is performed, as shown in Fig. 6.

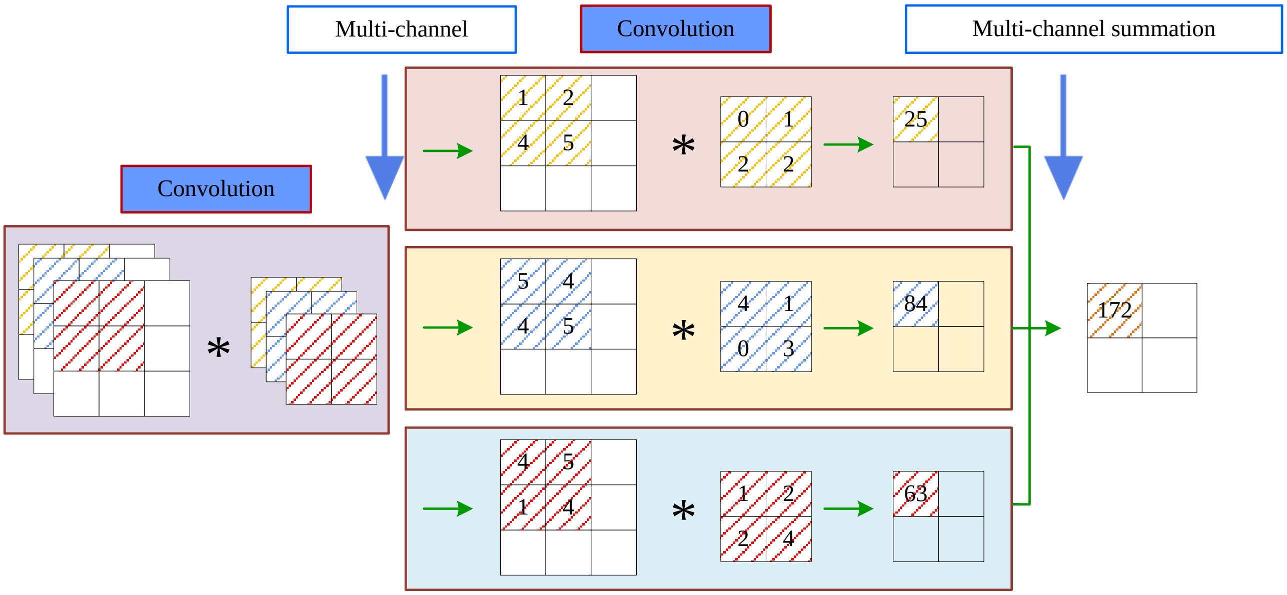

Fig. 6. Multi-channel convolution operation.

In Fig. 6, in the input stage, the convolution kernel dimensionality determines the convolution calculation method. Multiple channels are given priority in completing their respective convolution operations. In the output stage, the sum of convolution values for multiple channels is calculated. The convolution kernel moves with a set stride, and the output size of the feature values is consistent with the dimension size of the convolution kernel. The calculation process of convolution operation is shown in Eq. (13).

$$x^{l+1} = w^l * x^l + b^l \tag{13}$$

In Eq. (13), x^{l+1} represents the output value after convolution operation. x^l represents the operation output of the upper. w^l represents the computed convolution kernel. $*$ represents convolution operation. b^l represents the bias term of the current layer. l represents the number of layers in the convolution operation. To make the self-learning mechanism of the network more efficient, dependency relationships can be established between network channels. The channel attention mechanism can be strengthened through training feedback, which selectively integrates the extracted local features to obtain feature maps with more information. The research model divides adjacent pooling layers using the overlap pooling algorithm, which focuses on global features through the overlapping parts of the region. The specific algorithm process is shown in Fig. 7.

In Fig. 7, it is shown that the feature map after overlapping pooling can cover global features. The input image is convolved and overlapped with pooled feature regions. The overlapped pooled feature map is output using the global average pooling method. The feature maps that have undergone overlapping pooling highlight important features and weaken a small amount of information regions, reducing the image blur problem of global average pooling output. The specification calculation of the new feature map generated by overlap pooling is shown in Eq. (14).

$$n = \frac{m - f}{s} + 1 \tag{14}$$

In Eq. (14), n represents the output value specification. m represents the input value specification. f signifies the size of the convolution kernel. s represents the selected step size. The single channel calculation process of global average pooling is displayed in Eq. (15).

$$\zeta'_n(I) = \frac{\sum_{y_i=1}^{H'}\sum_{x_i=1}^{W'} f(x_i, y_i)}{H' \times W'} \tag{15}$$

In Eq. (15), $\zeta'_n(I)$ is used as the output value of feature map I on channel n. H' represents the height of the newly output feature map. W' represents the width of the newly output feature map. $f(x_i, y_i)$ represents the feature points of the new output feature map. Therefore, when constructing the image retrieval module for ethnic art design products, the DF algorithm is prioritized to enhance feature classification extraction. The DF-CNN is designed in combination with a CNN, and the residual network is used to optimize feature map transmission. The strip attention mechanism and multi-channel operation are used to optimize the image feature extraction process. The global features are integrated through overlap pooling to achieve image retrieval output.

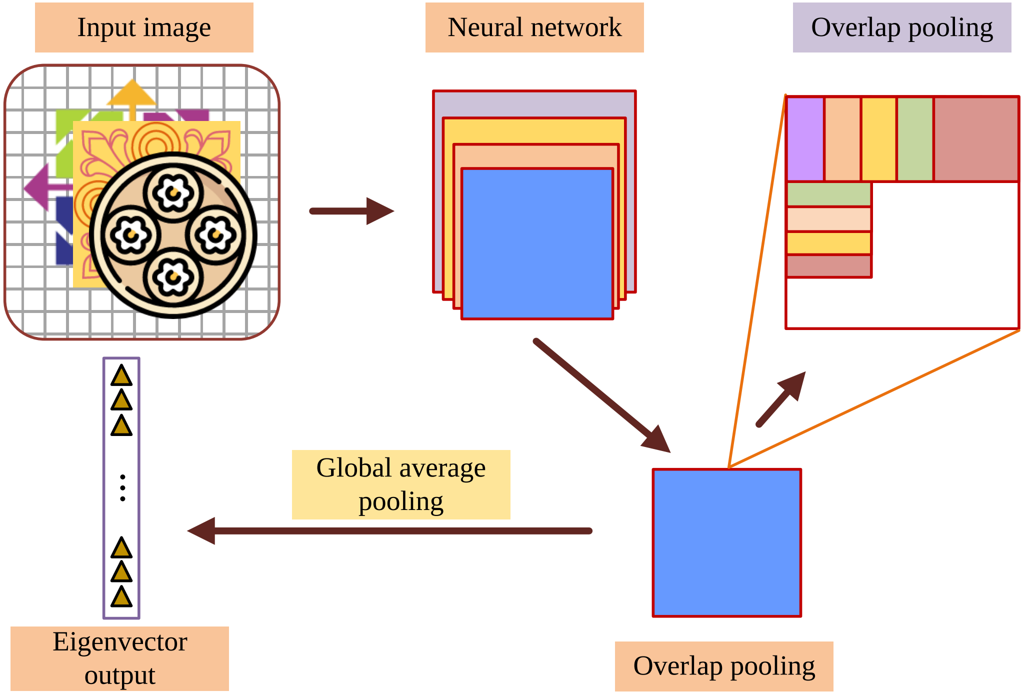

Fig. 7. Overlap pooling and global average pooling.

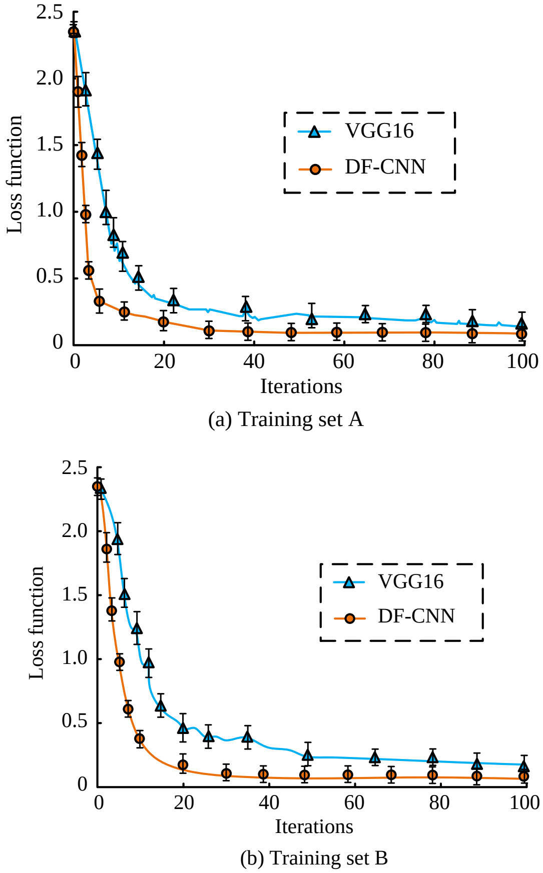
IV. Results

A. Performance Testing of Image Retrieval Model for Ethnic Art Products

To test the image detection performance of the model, a training set is selected to enhance the learning ability of the model. The pre-testing ratio is set to 10%, and the network threshold of the model is 0.5. The sample images are selected from the CIFAR-10 dataset, and 200 images are set for each group based on the shape of the image pattern as test samples. The convolutional layer during the testing process is set to 16 layers, and the fully connected layer is set to three layers. The learning rate is set to 0.001 and the training iterations are 100. The iterative changes of the loss function in the training set is shown in Fig. 8.

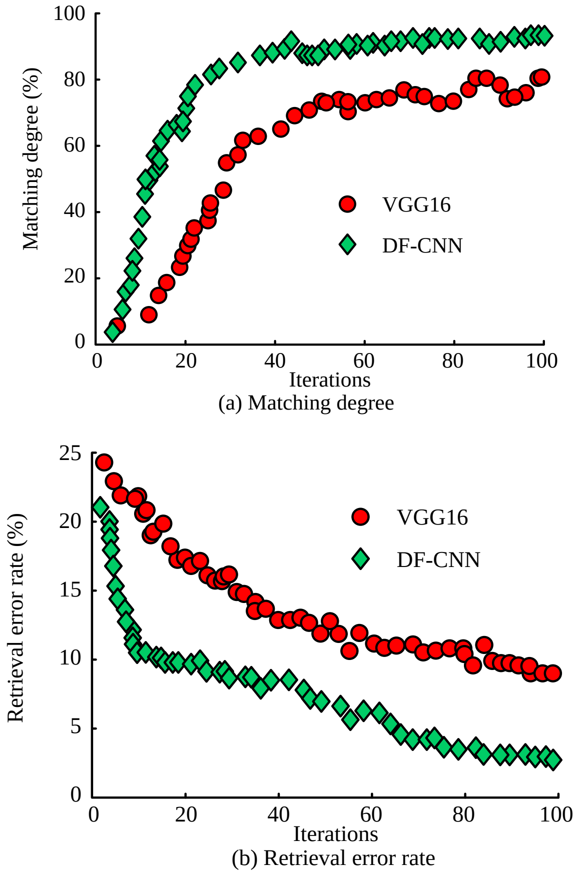


(a) Training set A

(b) Training set B

Fig. 8. Changes in the loss function in the training set.

In Fig. 8 (a), the loss function of the DF-CNN model in training set A decreased with increasing iterations. When the iterations reached 10, it realized stable convergence. The loss function variation of the Visual Geometry Group Network (VGG16) model [31] in training set A also decreased with increasing iterations. When the number of iterations reached 20, the loss function tended to converge, but showed slight fluctuations in subsequent iterations. In Fig. 8 (b), the loss function of the DF-CNN model in training set B was consistent with the results in training set A, but the convergence speed was slightly slower. After 20 iterations, the loss function converged stably. The loss function of VGG16 model in training set B tended to converge after 25 iterations, but the converged loss function value showed a slight rebound. The research model in the training set shows a stable trend and performs better in image detection compared with the VGG16 model. To further validate the pattern retrieval matching of the model in the testing set, the retrieval results of the model for the samples are shown in Fig. 9.



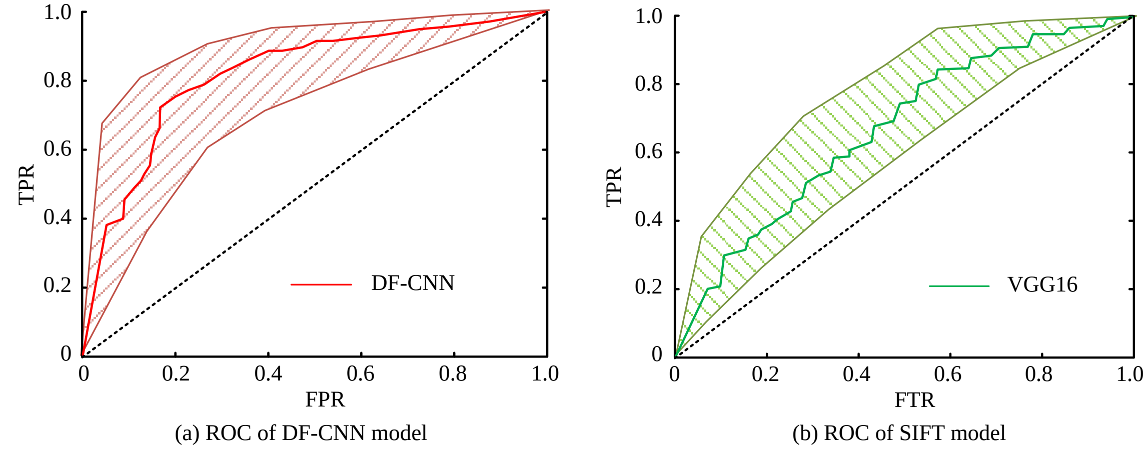
(a) Matching degree

(b) Retrieval error rate

Fig. 9. Pattern retrieval performance in the testing set.

In Fig. 9 (a), the DF-CNN model gradually increased its matching rate with image samples during the iterative learning process. After 23 iterations, the matching degree of the research model reached over 80%. When the model completed learning, the retrieval matching degree of the image reached 91.28%. The VGG16 model had a lower image retrieval matching degree compared with the research model, with an image matching degree of 80.69% after the model completed training and learning. In Fig. 9 (b), the error rate of image retrieval in the DF-CNN model gradually decreased during the iteration process. When the iteration reached 10 times, the image retrieval rate of the model decreased to within 10%. The error rate of the model after training was reduced to 2.91%. The error rate of the VGG16 model in the testing set steadily decreased with increasing iterations, but the error rate optimization effect in the research model during iterations was better than that of the VGG16 model. After 100 iterations of learning, the error rate of the VGG16 model was 9.04%. The trained research model demonstrates good performance in recognizing various types of image patterns, with lower retrieval error rates compared with the VGG16 method, and better image retrieval performance. To ensure the application effectiveness of the research model in image retrieval, the Receiver Operating Characteristic Curve (ROC) is used to evaluate the model.

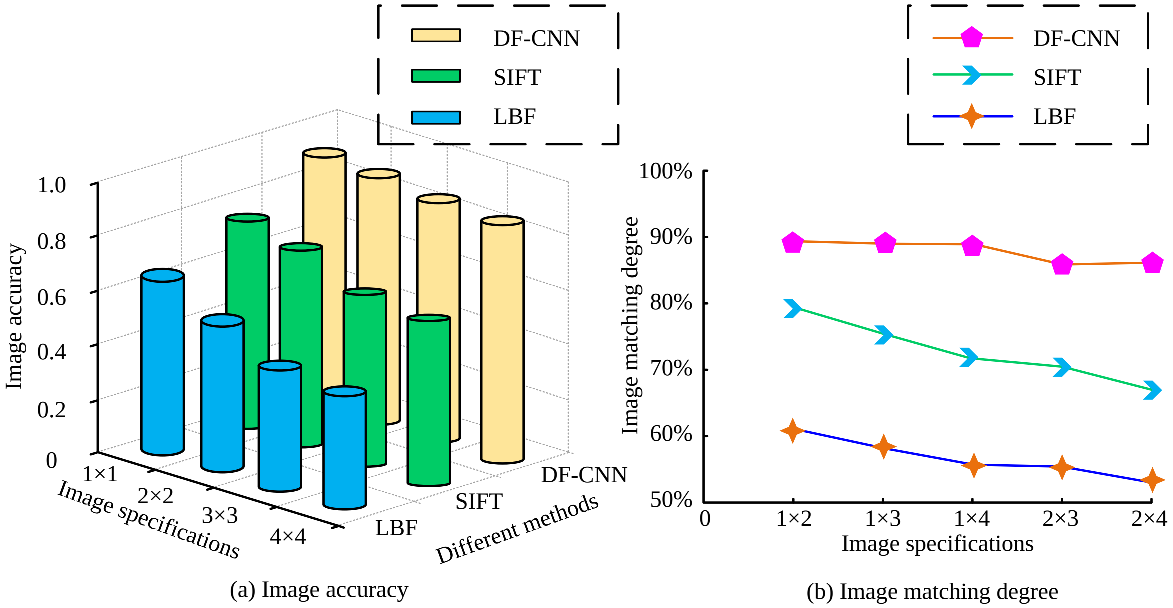
Fig. 10(a) shows the ROC of the DF-CNN model. The ROC curve of the DF-CNN was convex towards the upper left and away from the threshold line, with an Area Under Curve (AUC) of 0.876. Fig. 10(b) shows the ROC curve of the SIFT algorithm. The convex distance of the curve was slightly further to the upper left and the curve range was completely in the lower layer of the research model. The classification performance of the research model performs better throughout the entire process. The ROC curve of the SIFT algorithm was closer to the threshold line and the final AUC value was 0.716. Therefore, the classification performance of the SIFT algorithm [32] is average. This indicates that the image classification performance of the research model has significant advantages, and its ability to retrieve images of ethnic art products is stronger than that of SIFT method in terms of recognition. To further analyze the image comparison ability of the model, the results of non-uniform specification image retrieval under different methods are shown in Fig. 11.



(a) ROC of DF-CNN model

(b) ROC of SIFT model

Fig. 10. Comparison of ROC curves of different models.



(a) Image accuracy

(b) Image matching degree

Fig. 11. Comparison of retrieval effects for multi-specification images.

In Fig. 11 (a), the DF-CNN model exhibits different retrieval accuracy in the selected images of various specifications, with a decreasing trend in retrieval accuracy as the size of the image increases. The retrieval rates of SIFT and LBF algorithms for images of various specifications were consistent with the research method. However, the research model had a relatively small range of accuracy changes for image retrieval of different specifications, with a difference of 4.16% in accuracy under different specifications. The accuracy difference of LBF algorithm and SIFT algorithm for image retrieval of different specifications was 16.21% and 18.97%, respectively. In Fig. 11 (b), the image retrieval accuracy of the three models decreased with increasing image size under irregular image sizes. The DF-CNN model had an average accuracy of 88.49% for non-equal length image type retrieval, while the LBF algorithm and SIFT algorithm had average accuracy of 73.94% and 57.59% for non-equal length image type retrieval, respectively. The results indicate that LBF and SIFT have poor image retrieval performance under the current specifications, while the research model performs well in retrieving images of multiple specifications, which also shows good adaptability in retrieving images with a wide variety of specifications.

B. *Application Effect Test of Image Retrieval Model for Ethnic Art Products*

To visualize the application effect, a designed image retrieval webpage is used to complete the simulation image retrieval of ethnic art design products. The computer processor used for the simulation experiment is Intel(R) Xeon(R)Platinum, and the GPU specification is RTX 2080 8GB*4. An example of retrieving ethnic art images using research methods is shown in Fig. 12.

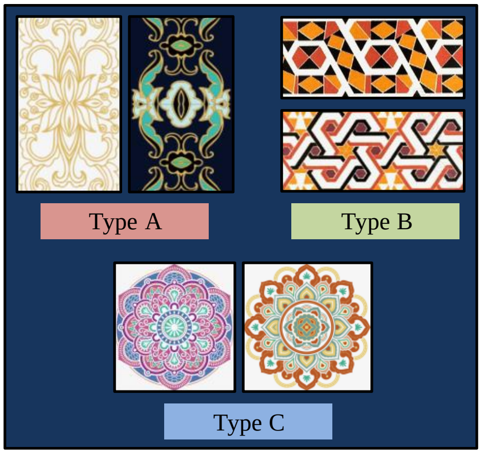


Fig. 12. Retrieve image examples.

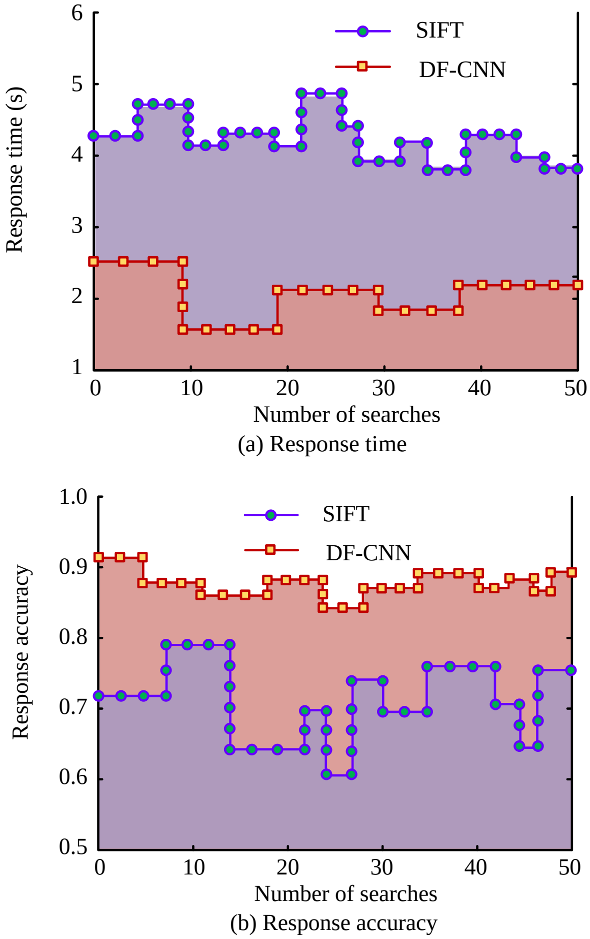
Fig. 12 shows the partial image results obtained through keyword retrieval, indicating a clear distinction in the retrieval types of the images. To further test the detection efficiency of the image, the retrieval response time and response accuracy were obtained through 50 retrieval processes, as shown in Fig. 13.

The average response time of the DF-CNN model for 50 image retrieval processes shown in Fig. 13(a) was 1.87s, with the longest response time of the model for retrieval results being 2.47s and the shortest response time being 1.44s. The average response time of the SIFT model for 50 retrieval processes was 4.21s, with the longest response time being 4.86s and the shortest response time being 3.88s. In Fig. 13 (b), the average image retrieval matching degree of the DF-CNN model in 50 searches was 0.879. The optimal matching degree of the research model for images was 0.913, and the matching degree of the image with the worst retrieval effect was 0.843. The average image matching degree of the SIFT model for 50 retrieval processes was 0.701. This indicates that the research model shows a high search speed in the image retrieval, with a response speed improvement of 51.8% compared with the SIFT algorithm. The DF-CNN model also shows a high matching rate for image retrieval, which is 16.8% higher than the image matching rate of the SIFT algorithm. To compare the image retrieval performance under various conditions, the image retrieval results of the research model within one week are summarized in Table I.



(a) Response time

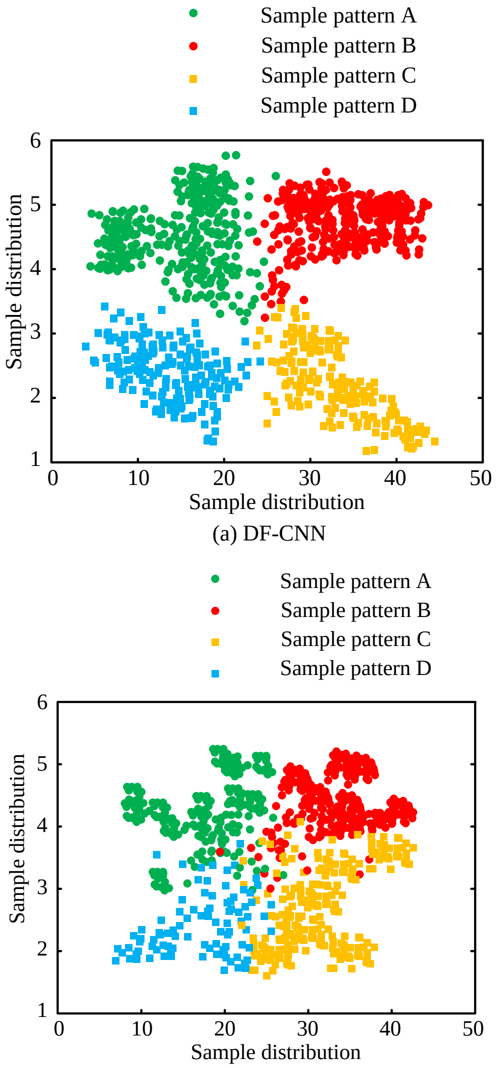
(b) Response accuracy

Fig. 13. Search response during the application process.

In Table I, the three types of models with a code length of 128 had shorter response times for image detection, among which the DF-CNN model had the fastest response speed in the detection process. The three types of models with a code length of 512 showed longer response times for image detection, and the DF-CNN model remained the fastest response speed. However, as the code length increased, the mean Average Precision (mAP) and recall of the three types of models showed an upward trend. The DF-CNN model demonstrated good retrieval precision and sensitivity. Compared with the VGG16 algorithm and DF-CNN algorithm, the mAP value optimization range of the research model was 6.1% -29.8%, and the sensitivity optimization range was 15.33% -36.9%. The research model shows that the retrieval speed of images is faster under shorter code lengths, but the retrieval precision is correspondingly reduced. The retrieval precision of images is improved under longer code lengths, but the corresponding retrieval time is longer. The DF-CNN model shows excellent performance in both detection precision and response time during the detection process. To distinguish and recognize different patterns, the clustering results of detection samples under different algorithms are compared, as shown in Fig. 14.

TABLE I. COMPARISON OF RETRIEVAL PERFORMANCE OF DIFFERENT MODELS

Retrieval Model	Code-Length	Recall	mAP	Time/s	References
DF-CNN	128	53.30%	76.4%	1.64	/
DF-CNN	512	57.40%	90.1%	4.62	/
VGG16	128	46.80%	69.3%	1.82	[31]
VGG16	512	48.60%	84.6%	5.07	[31]
SIFT	128	33.90%	45.3%	2.85	[32]
SIFT	512	36.20%	63.2%	8.74	[32]

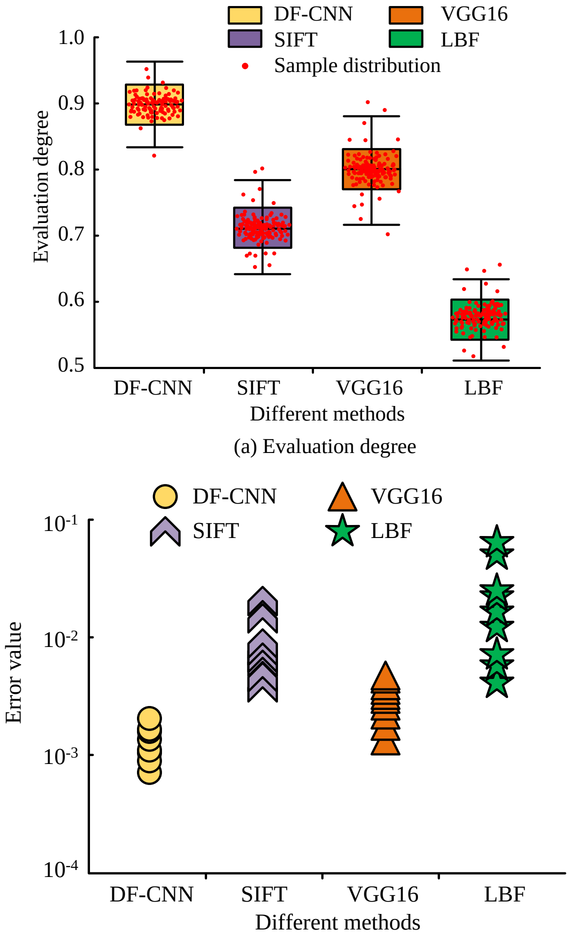


(a) DF-CNN

(b) VGG16

Fig. 14. Clustering of detection samples under different algorithms.

In Fig. 14 (a), the four types of pattern detection samples in the DF-CNN model were clustered separately, and the boundary parts of the four types of samples were adjacent but not intersecting. In Fig. 14 (b), the four pattern type detection samples in the VGG16 model also exhibited their own clustering, but there was partial intersection at the boundaries of the four types of samples. The DF-CNN model showed good recognition performance for four patterns and strong recognition ability for similar images. The VGG16 model can achieve basic recognition and detection for four types of patterns. When the patterns presented in the retrieved images are similar, the VGG16 model may exhibit confusion in image detection. The patterns of ethnic art products may appear similar but not identical, and the VGG16 model shows a significant lack of retrieval ability for such images. The DF-CNN model can accurately identify the differences in such images, indicating that the research model has a better retrieval application effect for ethnic art products. To verify the detection accuracy of the model, the multi-sample image detection accuracy and image detection error values under different models are shown in Fig. 15.



(a) Evaluation degree

(b) Error range

Fig. 15. Image detection accuracy and detection error.

In Fig. 15 (a), the average image accuracy evaluation value of the DF-CNN model in multi-sample image detection was 0.898, with only a few samples scattered outside the detection floating range. The image accuracy evaluation values of SIFT algorithm, VGG16 algorithm, and LBF algorithm were 0.731, 0.804, and 0.579, respectively, and all three algorithms had some samples scattered outside the detection floating range during the image detection process. In Fig. 15 (b), the detection error range of the DF-CNN model in multi-sample image detection was 8.7×10-4-4.3×10-3, while the image detection error ranges of the SIFT algorithm, VGG16 algorithm, and LBF algorithm were 4.7×10-3-4.1×10-2, 1.1×10-3-7.9×10-3, and 4.8×10-3-9.1×10-2, respectively. This demonstrates that the research method has good stability in image detection function. Compared with other algorithms, the image accuracy has always been maintained at a good level. The image detection error of the research model is smaller and the error value is lower compared with other algorithms, indicating that the research model has good image detection ability during operation.

C. Discussion

The above research results show that the research method has good matching performance for the retrieval of images of ethnic art products, and the accuracy of image retrieval is better than that of the SIFT algorithm. Due to the SIFT algorithm's emphasis on local features in image detection, and the lack of significant differences in local features of ethnic art products, the retrieval matching degree of images decreases. The research model utilizes the cascaded structure of the DF algorithm to enhance the depth of image feature mining, strengthen the correlation between retrieval keywords and corresponding images, and thus improve the retrieval accuracy of the design module. At the same time, the retrieval efficiency of the research method also shows significant advantages. In the process of retrieving ethnic art images, the retrieval response time of the research method is significantly better than that of the VGG16 algorithm. The VGG16 algorithm enhances its feature extraction ability through multi-layer convolution, but due to the complex calculation process, the retrieval speed of the algorithm decreases. The prior box design of the research model increases the pre-screening of image features, reduces the computational complexity of the image-matching process, and thus achieves an improvement in retrieval efficiency. It can be seen that the research model achieves synchronous improvement in retrieval matching and retrieval efficiency through the fusion of advantages between different algorithms.

V. Conclusion

In order to enhance the retrieval ability of art galleries for ethnic art patterns, an image retrieval model is constructed by combining the DF algorithm with CNN. The decision tree was used to explore the transformation paths of images, and the overlap window was used to enhance the global features of features. Multi-granularity scanning processes optimized feature loss during dimension transformation. The Euclidean distance algorithm was used to calculate the similarity of image features. Parallel multi-channel convolution was applied to optimize the transmission rate of features, focusing on global features through overlapping pooling algorithm, and completing image retrieval output by combining global and local features. The research results indicated that the error rate of the DF-CNN model was reduced to 2.91% after training, which was 6.13% lower than the retrieval error rate of the VGG16. The difference in retrieval accuracy of the DF-CNN model for multi-specification image retrieval was 4.16%, which was 12.05%-14.81% higher than other algorithms, indicating that the research model had good adaptability to retrieval of various image types and stable retrieval performance for images. In the application process, the average retrieval response time of the DF-CNN model was 1.87s, and the longest response time was 2.47s, which was 51.8% higher than the response rate of the SIFT algorithm. The research model had good image retrieval accuracy while maintaining a high response rate. The average image retrieval matching degree of the model was 0.879, which was 16.8% higher than the SIFT algorithm. The application effect of the research model in practical processes is good, and the efficiency of image retrieval is high. With the widespread dissemination of ethnic art products in more fields, they have also been applied in virtual scenes. However, in the practical application of retrieval methods, virtual scenes are often not included in the retrieval scope, resulting in a lack of retrieval data for virtual scenes. At the same time, the research method has increased the retrieval ability of ethnic art images by adding multiple complex graphic processing layers, which has resulted in a decrease in the retrieval speed of simple images. Therefore, in future research plans, image retrieval scenarios can be expanded to achieve further expansion of retrieval databases. It is possible to attempt to classify the retrieval paths of images, achieving hierarchical processing of simple and complex images, thereby further improving the efficiency of image retrieval and meeting the retrieval needs of different users.

Application of Speech Recognition Technology Based on Multimodal Information in Human-Computer Interaction

Yuan Zhang
Xuchang Vocational Technical College
Henan Province, Data Intelligence and Security Application Engineering Technology Research Center, Xuchang 461000, China

Abstract*—Multimodal human-computer interaction is an important trend in the development of human-computer interaction field. In order to accelerate the technological change of human-computer interaction system, the study firstly fuses Connectionist Temporal Classification algorithm and attention mechanism to design a speech recognition architecture, and then further optimizes the end-to-end architecture of speech recognition by using the improved artificial swarming algorithm, to obtain a speech recognition model suitable for multimodal human-computer interaction system. One of them, Connectionist Temporal Classification, is a machine learning algorithm that deals with sequence-to-sequence problems; and the Attention Mechanism allows the model to process the input data in such a way that it can focus its attention on the relevant parts. The experimental results show that, the hypervolume of the improved swarm algorithm converges to 0.861, which is 0.099 and 0.059 compared to the ant colony and differential evolution algorithms, while the traditional swarm algorithm takes the value of 0.676; the inverse generation distance of the improved swarm algorithm converges to 0.194, while that of the traditional swarm, ant colony, and differential evolution algorithms converge to 0.263, 0.342, and 0.246, respectively. Hypervolume and Inverse Generation Distance Measures the diversity and convergence of the solution set. The speech recognition model takes higher values than the other speech recognition models in the evaluation metrics of accuracy, precision, and recall, and the lowest values of the error rate at the character, word, and sentence levels are respectively 0.037, 0.036 and 0.035, ensuring higher recognition accuracy while weighing the real-time rate. In the multimodal interactive system, the experimental group's average opinion scores, objective ratings of speech quality, and short-term goal comprehensibility scores, and the overall user experience showed a significant advantage over the control group of the other methods, and the application scores were at a high level. The speech processing technology designed in this study is of great significance for improving the interaction efficiency and user experience, and provides certain references and lessons for the research in the field of human-computer interaction and speech recognition.

I. INTRODUCTION

Human-computer interaction (HCI) aims to realize information exchange and interaction between human and computer through computer technology. Single-modal human-computer interaction has been unable to meet the growing user needs, and multimodal human-computer interaction system is gradually becoming a research hotspot [1, 2]. Multimodal human-computer interaction (MMHCI) is a system that uses multiple input and output modes to carry out human-computer interaction, integrating various technologies such as speech recognition, gesture recognition, speech synthesis, expression parsing, etc., which is able to better adapt to the user's personalized needs, and has the advantages of improving interaction experience and interaction efficiency. It has the advantage of improving interaction experience and interaction efficiency [3].

At present, MMHCI is still a relatively new type of human-computer interaction and most of its key technologies are still in the exploration stage. Speech recognition is a key technology in the cognitive decision-making aspect of MMHCI, which affects the overall performance of the system. Currently, Hidden Markov, Recurrent Neural Network, Transformer structure and Connectionist Temporal Classification (CTC) are mostly used in the construction of speech recognition models, but the key technology enhancement of the models focuses on the accuracy rate, feature extraction, etc., and does not pay much attention to the specific speech recognition tasks and application environments. The recognition accuracy, real-time efficiency, semantic and emotional understanding, and single-signal processing of existing speech recognition technology still cannot meet the application requirements of MMHCI [4, 5].

In order to enhance the accuracy, robustness and improve the interactivity and flexibility of speech recognition in the interaction process of MMHCI speech recognition technology, the study utilizes inputs in the form of audio and video formed by multimodal information such as speech, semantics, expression, text and video, and designs a framework for speech recognition model with the help of improved CTC algorithm and a mixture of attention mechanisms. The adaptive multiple search strategy is also implemented on the basis of Artificial Bee Colony Algorithm (ABC) and this is used to complete the improved optimization of speech recognition model.

The study takes MMHCI as the research object, and carries out research on the key technologies of its speech recognition module, which helps to improve the accuracy and robustness of speech recognition, and obtains technological innovations, and provides theoretical support for the speech recognition algorithm of MMHCI. The introduction of ABC algorithm provides a new solution to the optimisation problem of speech recognition. The research is expected to improve the reliability and efficiency of speech recognition technology in practical applications, enriching the user interaction experience; at the same time, it expands the application scenarios of speech recognition, promotes the development of MMHCI, and helps to realize a more intelligent and humanized interaction experience. The optimization research results of the key technologies of speech recognition in MMHCI provide new ideas and technologies for the development of the field of human-computer interaction, and promote the integration of the industrial and computer fields.

The study consists of six main sections, Section II is to carry out a summary of existing related research work in the field of speech recognition and human-computer interaction; then Section III elaborates on the construction and improvement of the speech recognition framework of the CTC joint attention mechanism, and designs the optimization algorithm of the improved ABC speech recognition framework; in Section IV, completes the performance test of the speech recognition model and the application analysis; Discussion is given in Section V and finally, Section VI concludes the paper.

II. Related Work

With the development of computer technology and artificial intelligence, multimodal human-computer interaction and speech recognition technology related to human-computer interaction have become a hot topic of concern in the community. Various neural networks and deep learning are widely used in speech recognition. Among the speech recognition researches in different countries, there have been relatively more researches on the recognition of English, Japanese or Chinese. Mukhamadiyev et al. designed an end-to-end deep neural network-hidden Markov model speech recognition model and a hybrid CTC-attention network with the small language Uzbek as the research object. The method can effectively utilize the connection time classification objective function and achieves improved recognition efficiency and accuracy, with a speech recognition error rate of 14.3% on the Uzbek dataset [6]. Deep learning models have been used effectively in speech recognition tasks, Dua et al. extended the application of convolutional neural networks to the recognition of speech signals and developed a speech-to-text recognition system. The method achieves recognition accuracy of 89.15 per cent and word error rate of 10.56 per cent on continuous and extensive lexical sentences of speech signals of different pitches [7]. Świetlicka et al. have used principal component analysis in combination with multilayer perceptual networks for fluent and interfering speech signals to analyse their application in describing the dimensionality reduction of speech signal variables. The experimental results show that the method achieves 76% total classification accuracy compared to Kohonen network [8]. Based on the network training techniques, Reza et al. designed a stacked five-layer custom residual convolutional neural network and seven-layer bi-directional gated recurrent units, where the network units all contain learnable layer normalization techniques based on element affine parameters. The character error rate of the model is 4.7 and 3.61% based on the public datasets librisspeech, LJ Speech validation [9].

With the rapid development of deep learning, artificial intelligence and other computer technologies, gesture recognition, speech recognition and other technologies related to human-computer interaction have also made great progress. The application of speech recognition technology in the field of human-computer interaction is gradually increasing, and researchers have conducted performance improvement studies around specific application tasks of speech recognition technology. Lv et al. summarized the research on human-computer interaction and speech recognition based on Web of Science, an academic literature database. The study found that intelligent human-robot interaction and deep learning have made great progress in gesture recognition, speech recognition and emotion recognition, and deep learning can effectively improve the recognition accuracy [10]. In order to improve the service quality and control effect of robots, Pan designed a command understanding method based on command intent understanding and key information extraction, as well as a human-robot voice interaction system with good application effect based on microphone array, voice wake-up and speech recognition [11]. Mavropoulos et al. designed an MMHC system based on knowledge representation, speech recognition and synthesis, sensor data analysis and Computer vision designed a MMHCI. The system can collect and monitor patient related information for healthcare [12]. Liu et al. conducted a study on speech interaction based on emotional Internet of Things, designing a multi-stage deep transfer learning scheme for the problem of limited large-scale emotion labeled datasets, and the experimental results show that the model is effective and superior in terms of naturalness and emotional expressiveness [13]. The use of speech recognition technology in the teaching process to assist teachers in correcting the pronunciation of spoken English has significant application effects. Ran et al. improved the speech recognition algorithm based on artificial intelligence speech recognition technology and designed a speech cutting model based on phonemic level speech error correction, including speech front-end processing and feature parameter extraction. The experimental results verify the effectiveness of the model [14].

In summary, there have been many applications and researches on speech recognition technology and human-computer interaction, but the technical improvement of the model mainly focuses on improvement of recognition accuracy and the reduction of error rate, and does not pay much attention to the specific speech recognition task and application environment. Moreover, there are relatively few studies on speech recognition for human-computer interaction with multimodal information, and the application of the existing speech recognition technology in multimodal human-computer interaction system is still immature and poorly adapted. In this study, speech recognition technology is improved by utilizing multimodal information.

III. Optimized Speech Recognition Model Design Based on Multimodal Information

In order to meet the technical demands of multimodal human-computer interaction, the study firstly designs a speech recognition framework for multimodal human-computer interaction based on the CTC and Attention mechanism; then improves and optimizes the CTC-Attention decoding scheme;

and finally introduces the ABC algorithm to improve the global searching ability and adaptive ability of the hybrid speech recognition model.

A. Speech Recognition Model Design Based on CTC and Attention Mechanism

Traditional human-computer interaction is mostly limited to keyboard, mouse or touch screen inputs, with a single mode of interaction, mostly relying on independent speech or gesture recognition. MMHCI technology is an important innovation in the field of artificial intelligence and interaction, integrating multiple input modes, including speech, gesture, touch, facial expression and eye movement, etc., and fusing the input data of different modes. Combining data from various input modes enhances the accuracy and intelligence of responses in multimodal human-computer interaction. At the same time, MMHCI can adaptively learn according to the user's interactive behavior habits and provide more convenient and personalized interactive services. MMHCI integrates multiple technologies such as speech recognition, image recognition, motion sensing, etc., and utilizes multi-modal information to complete the interaction, which involves multiple modules such as information input, multi-modal interaction information fusion and processing, multi-modal interaction information feedback, etc. Speech recognition technology is one of the key components of MMHCI, and it is also the most important component of MMHCI, as it can be used for the interaction between different modalities. Speech recognition technology is an important part of MMHCI, which is the key link to enhance user experience and interaction richness [15]. The MMHCI framework designed in the study consists of three parts: data input, cognitive decision control and output. The cognitive decision control includes the recognition of multimodal information such as speech, image and video, text dialogue, and facial expression. The study is aimed at the improvement of speech recognition accuracy, cross-modal information fusion and recognition efficiency, and the basic techniques such as the CTC algorithm and attention mechanism are utilized for speech recognition.

The speech recognition model designed in the study is an end-to-end encoder-decoder network structure. CTC is an algorithm for processing sequence data, which mainly solves the label alignment problem due to the change in the length of the sequence data [16, 17]. CTC contains a CTC loss function, which can be applied to the sequence data with variable-length labels during the training of the neural network without the need to align the speech. The calculation process of CTC network update is shown in Eq. (1), in which X denotes the speech feature sequence, $X = x_1, x_2, ..., x_T$; Y denotes the text sequence, $Y = y_1, y_2, ..., y_U$; $A(Y)$ denotes the set of all the aligned sequences corresponding to Y , a_i ; a_i denotes the path mapped from X to Y ; P denotes the likelihood probability of the mapping; and $blank(\in)$ is the special character introduced by the CTC to solve the problem of the model's input/output alignment.

$$\begin{cases} CTC_{Loss} = \sum_{(X,Y)\in D} -\log P(Y|X) \\ P(Y|X) = \sum_{A\in A(Y)} P(A|X) = \sum_{A\in A(Y)} \prod_{i}^{T} P(a_i|X) \end{cases} \quad (1)$$

Attention Mechanism (AM) is a model that simulates the mechanism of human attention allocation for solving the problem of information filtering and weighting when processing sequence data. The network architecture of the speech recognition model designed for the study draws on the Transformer model. The Transformer model is a model that solves the sequence-to-sequence problem based on the Attention mechanism, and the structure of the Transformer feature extractor is shown in Fig. 1.

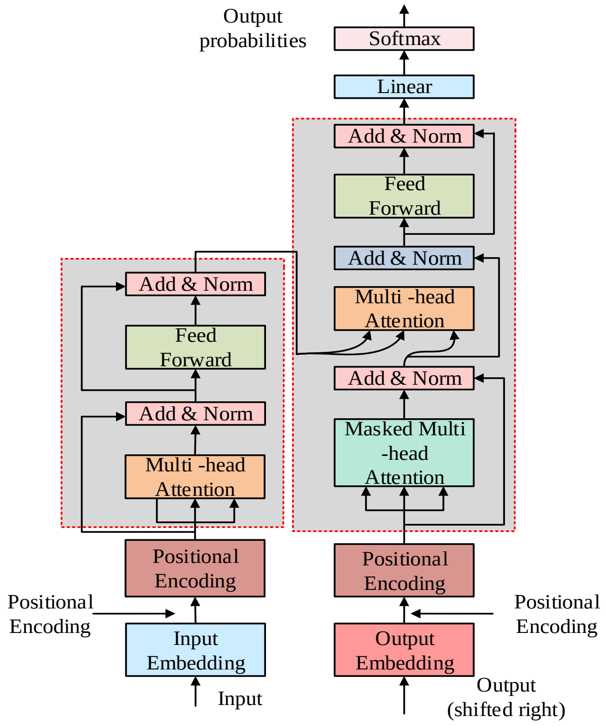

Fig. 1. Structure of transformer feature extractor.

The Transformer model treats the input and output sequences as a series of encoder and decoder stacked layers, with the different layers being composed of Multi-Headed Self-Attention Mechanism (MHSA) and Feedforward neural network (FFN). FFN), AM can weigh different positions in sequence processing. However, Transformer is weak in dealing with fine-grained local feature extraction problems, the study adopts the Conformer model, an improved structure of Transformer, to fully learn the local feature information, and the model structure is shown in Fig. 2. The Conformer model contains a Conformer module, which contains the Self-AM and CNN which is placed between the FFN layers. The Conformer introduces a position-sensitive sinusoidal function when calculating the AM scores, which helps the model to handle the weighting of acoustic features at different time steps. In addition, the Conformer model employs forward weighting and layer normalization to further improve the model performance [18, 19]. The study hybridizes CTC with Conformer model, firstly, Fbank features and 3-dimensional fundamental frequency features are selected for training the speech recognition model, and SpecAugment method is utilized for data enhancement of speech. Then after convolutional sampling, linear mapping and regularization the input encoder Conformer block and finally decoding is done by CTC and AM decoder.

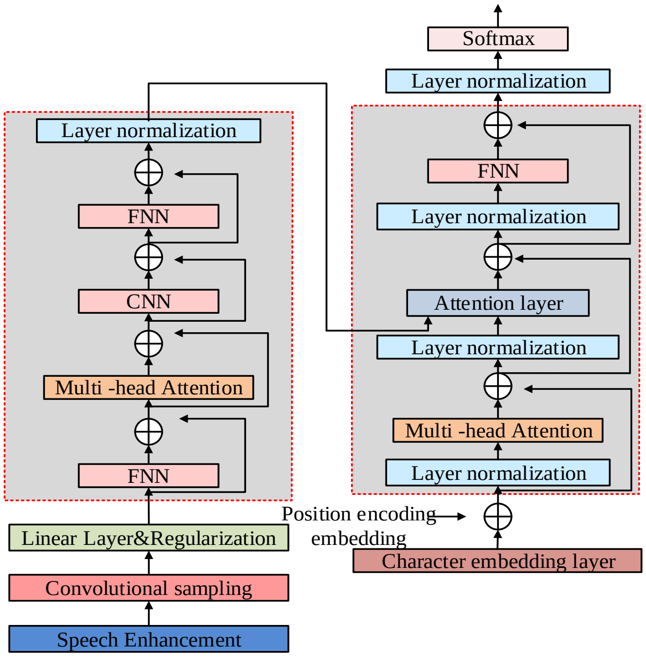

Fig. 2. Structural diagram of the transformer model.

The completion process of the Conformer model is shown in Eq. (2) and x denotes the input.

$$\begin{cases} x_{FFN1} = x + \frac{1}{2} FFN(x) \\ x_{MHSA} = x_{FFN1} + MHSA\left(x + \frac{1}{2} FFN(x)\right) \\ x_{Conv} = x_{MHSA} + Conv(x_{MHSA}) \\ x_{FFN2} = Layernorm\left(x_{Conv} + \frac{1}{2} FFN(x_{Conv})\right) \end{cases} \quad (2)$$

The loss function calculation of the CTC-Conformer hybrid model is shown in Eq. (3), where x, y denotes the acoustic features, the real text, respectively; and λ denotes the hyperparameters balancing CTC and AM.

$$Loss_{combined}(x,y) = \lambda * Loss_{ctc}(x,y) + Loss_{attention}(x,y) \quad (3)$$

The decoding score for the CTC-Conformer hybrid model is calculated in Eq. (4).

$$Score_{final} = \lambda * Score_{ctc} + Score_{attention} \quad (4)$$

B. Improvement of CTC-AM Speech Recognition Framework

CTC-Conformer hybrid model has achieved a large advantage over the traditional Transformer model in speech recognition, but it still has shortcomings such as model convergence difficulty and complex calculation. In this study, improvements are made to AM and CTC algorithms. The decoding process of CTC-Conformer is shown in Fig. 3, as seen in Fig. 3, it is difficult for the model to converge in the face of a longer feature sequence input; and the computational complexity of Self-AM is $O(L^2)$, and the computational complexity of decoding of the hybrid model is higher [20].

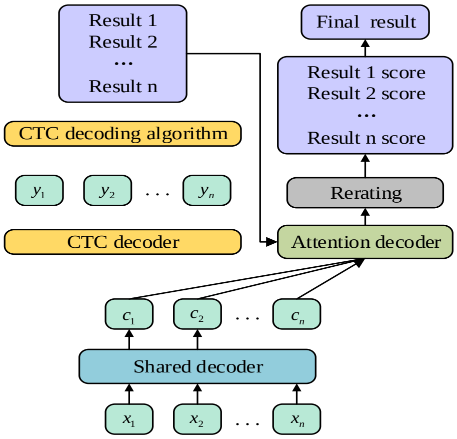

Fig. 3. Schematic diagram of CTC transformer decoding process.

For the long sequence speech recognition task, the study introduces the concept of Probability Sparse (Prob-Sparse). The AM used in the study is soft attention, as shown in Eq. (5). In Eq. (5), Q, K, V corresponds to query, key, and value, respectively; d denotes the sequence dimension;

$$A(Q,K,V) = Soft\max\left(\frac{QK^T}{\sqrt{d}}\right)V \quad (5)$$

The query matrix Q has some sparsity, which will lead to more redundant computation if the attention of all queries of the query vector is computed. The study has calculated the attention score and distribution difference using Kullback-Leibler (KL) scatter, which measures the difference between the generated sample distribution and the target distribution. The calculation procedure is shown in Eq. (6). In Eq. (6), L denotes the length of the sequence; q_i, k_i, v_i denotes the i th line of Q, K, V; and p, U denotes the distribution of the attention scores and the uniform distribution, respectively.

$$KL(p \| U) = \ln \sum_{j=1}^{L} e^{\frac{q_i k_j^T}{\sqrt{d}}} - \frac{1}{L} \sum_{j=1}^{L} \frac{q_i k_j^T}{\sqrt{d}} - \ln L \quad (6)$$

The sparsity metric value $M_{Sparse}(q_i, K)$ of the query matrix Q is calculated from Eq. (6), see Eq. (7). The calculation process can be accelerated by keeping the larger $M_{Sparse}(q_i, K)$ queries. In Eq. (7), K denotes the random sampling of K; L denotes the number of samples.

$$M_{Sparse}\left(q_i,K\right)=\max_j\left\{\frac{q_i k_j^T}{\sqrt{d}}\right\}-\frac{1}{L}\sum_{j=1}^{L}\frac{q_i k_j^T}{\sqrt{d}} \tag{7}$$

L the calculation process is shown in Eq. (8), and r_{sample} denotes the sample sampling factor.

$$L=r_{sample}\ln L \tag{8}$$

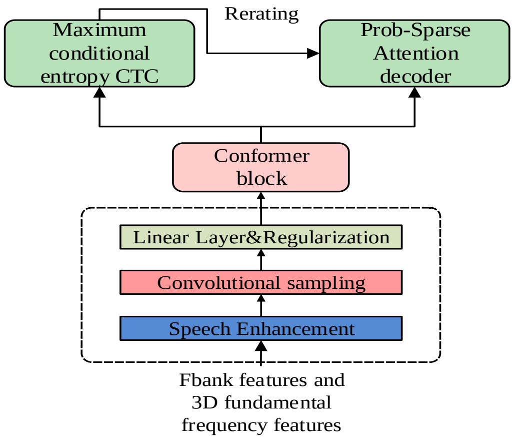
In summary, the computation of Prob-Sparse Attention for the research design is shown in Eq. (9), where I_{Sparse} denotes the index of the L_{Sparse} query and $L_{Sparse}=r_{sample}L$.

$$\left(q_i,K,V\right)=\begin{cases}\sum_{j}^{L}p\left(k_j|q_i\right)v_j & if\ \ i\in I_{Sparse}\\ v_i & else\end{cases} \tag{9}$$

The CTC algorithm employs a dynamic programming algorithm to learn the mapping relationship between sequences, and uses maximum likelihood estimation to learn the probability of mapping paths, but the increase in the length of the input sequences is not conducive to the CTC algorithm to find feasible paths, and the blank labels introduced by the CTC will lead to the model easily falling into the local optimal situation. The conditional probability $p\left(l|X_{1:T}\right)$ for a given target sequence $X_{1:T}$ is computed in Eq. (10), where ϖ denotes the path of temporally concatenated observation labels; l denotes the true output; and B denotes the many-to-one mapping from π to l.

$$p\left(l|X_{1:T}\right)=\sum_{\pi\in B^{-1}(l)}p\left(\varpi|X_{1:T}\right) \tag{10}$$

The training process of CTC is constantly optimizing the CTC loss function $Loss_{ctc}$ to complete, but CTC exists a large number of ϖ, the optimization of the loss function will cause the model to produce poorly aligned output; and the error signal is positively correlated with π, the positive feedback of the error signal makes the probability prone to fall into a certain single path, which leads to the model overfitting phenomenon. In this regard, the study introduces the maximum conditional entropy to improve the CTC, and the network structure of the improved CTC-Attention decoding scheme is shown in Fig. 4.



Rerating
Maximum conditional entropy CTC
Prob-Sparse Attention decoder
Conformer block
Linear Layer&Regularization
Convolutional sampling
Speech Enhancement
Fbank features and 3D fundamental frequency features

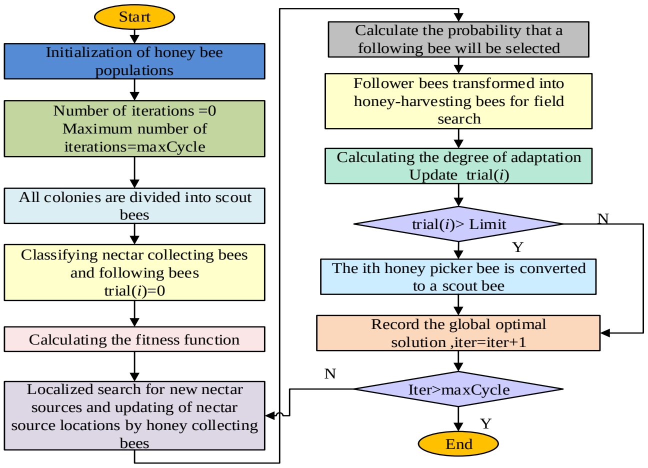
Fig. 4. Network structure diagram of improved CTC attention decoding scheme.

The CTC damage function based on maximum conditional entropy $Loss_{ctc}^{'}$ is calculated in Eq. (11), α denotes the coefficient of maximum conditional entropy regularization; $H\left(p\left(\pi|l,X\right)\right)$ denotes the entropy of feasible paths of input and target sequences. The maximum conditional entropy reduces the influence of the positive feedback of error information on the model training search, and the loss value calculated by Eq. (11) and the loss function value of the attention mechanism can be calculated according to Eq. (3) to obtain the loss value of the hybrid Improve CTC-Prob-Sparse Attention model.

$$Loss_{ctc}^{'}=Loss_{ctc}-\alpha H\left(p\left(\varpi|l,X\right)\right) \tag{11}$$

C. *CTC-AM Speech Recognition Framework Optimized by Fusion and Improved ABC Algorithm*

After the optimization of CTC loss function and AM, in order to realize the adaptive recognition of speech recognition model, the study introduces ABC algorithm to optimize the Improve CTC-Prob-Sparse Attention hybrid speech recognition model. ABC is a swarm intelligence global optimization algorithm that draws on the honey harvesting behavior of honeybee colonies. ABC algorithm divides honeybees into hiring bees, following bees and scout bees, and considers feasible solutions as food sources for bees. The hired bees search for new honey sources based on the old honey source information and determine whether to update the solution based on the evaluated objective function value. The following bee joins the honey source search process based on the information shared by the hiring bee; the scouting bee’s task is to randomly select a new honey source in the whole solution space to try when the hiring bee does not make further progress, and the algorithm flow is shown in Fig. 5. The ABC algorithm is chosen for the study to further improve the global search ability and adaptive capability of the hybrid speech recognition model.



Start
Initialization of honey bee populations
Number of iterations =0 Maximum number of iterations=maxCycle
All colonies are divided into scout bees
Classifying nectar collecting bees and following bees trial(i)=0
Calculating the fitness function

End

Fig. 5. Schematic diagram of ABC algorithm process.

The total number of bees is N_s, the population size of hired bees is N_e, the population of following bees is N_u, and the search space is defined as S. The number of honey sources is equal to the number of hired bees, the search feasible solution for the i th hired bee X_i^j is computed in Eq. (12), $X_{\max}^j, X_{\min}^j$ denotes the maximum and minimum values of the j dimensional components of the honey sources, $j \in \{1,2,..,D\}$, D denote the individual vector dimensions, respectively.

$$X_i^j = X_{\min}^j + rand\left(0,1\right)\left(X_{\max}^j - X_{\min}^j\right) \tag{12}$$

The benefit degree value of the honey source $fitness_i$ is calculated in Eq. (13), where f_i represents the objective function of the optimization problem.

$$fitness_i = \begin{cases} \dfrac{1}{1+f_i} \\ 1+abs\left(f_i\right) \end{cases} \tag{13}$$

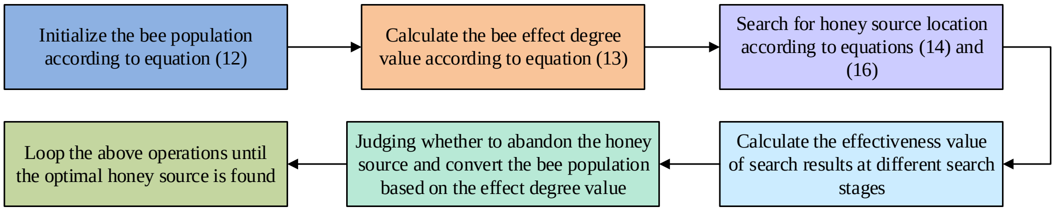
The nectar source $fitness_i$ determines the probability that the following bee will be selected P_i, which is calculated as shown in Eq. (14).

$$P_i = \frac{f_i}{\sum_{n=1}^{N_e} f_n} \tag{14}$$

The search position generation calculation for hired bees is shown in Eq. (15), and the nectar source update occurs when the fitness value of the new search position is larger. However, when the position of the nectar source has not been updated, the hired bees of this nectar source are converted to scout bees, and the position updating process is the same as Eq. (12).

$$\begin{gathered} new\_X_i^j = X_i^j + rand\left[-1,1\right]\left(X_i^j - X_k^j\right) \\ j \in \{1,2,...,D\} \quad k \in \{1,2,...,N_e\} \end{gathered} \tag{15}$$

However, the ABC algorithm still has some application defects, ABC has a good global search ability in the hiring bee, following bee, and scouting bee stages, but the local search ability in different stages is weakened. In this regard, the study introduces the Adaptive Double Search (ADS) strategy, which can improve the convergence of the ABC algorithm, and the improved ADSABC workflow is shown in Fig. 6.



Initialize the bee population according to equation (12)
Calculate the bee effect degree value according to equation (13)
Search for honey source location according to equations (14) and (16)
Calculate the effectiveness value of search results at different search stages
Judging whether to abandon the honey source and convert the bee population based on the effect degree value
Loop the above operations until the optimal honey source is found

Fig. 6. Improved ADSABC workflow.

The search process of ADS is shown in Eq. (16), in which $x_{i,j}$, $x_{r,j}$ and $v_{i,j}$ denote the positions before and after the search of the hired bees following the bees, respectively; $x_{i,Global}$ denotes the global optimal nectar position under the current number of iterations; $x_{best,j}$ denotes the j elements of the global optimal position; α and μ denote the neighborhood search coefficients; and γ denotes the Kersey's variability factor, which helps the following bees to jump out of the local optimum. $\gamma = \tan\left[\left(\xi - 0.5\right)\pi\right]$ The following are used as the random numbers: ξ is the random number, $\xi \in [0,1]$; $\psi\left(t\right)$ is the adaptive adjustment factor, t is the number of cycles, and n is the number of iterations.

$$\begin{cases} v_{i,j} = x_{i,j} + \alpha^{n+1} rand\left(x_{best,j} - x_{i,j}\right) + \left(1-\psi\left(t\right)\right)\beta^{n+1}\left(x_{i,Global} - x_{i,j}\right) \\ v_{i,j} = x_{r,j} + \mu^{n+1} rand\left(x_{best,j} - x_{i,j} + \gamma\right) + \left(1-\psi\left(t\right)\right)\eta^{n+1}\left(x_{r,Global} - x_{r,j}\right) \\ \psi\left(t\right) = 1 - rand^{\left(1-{t}/{MaxCycle}\right)^2} \end{cases} \tag{16}$$

IV. Performance and Application Analysis of Speech Recognition Technology Based on Multimodal Information

In order to test the effectiveness of the research-designed speech recognition algorithm in multimodal human-computer interaction systems, the research designed two parts of performance test experiments, namely, the performance test of the improved ABC algorithm and the performance and application effect analysis experiments of the Improve CTC-Prob-Sparse Attention speech recognition framework.

A. Performance Test of Improved Swarm Algorithm

The performance of the ADSABC algorithm designed for the study is first analyzed by selecting the traditional ABC algorithm, Differential Evolution Algorithm (DE) and Ant Colony Optimization (ACO) algorithms for comparison, which are all based on Java language implementation. The performance and convergence of the optimization algorithms are analyzed by choosing the single-peak functions: The Sphere function, the Schwefel function, and the multi-peak functions, the Rastrigin function, the Griewank function, and the Ackley function.

Forty independent optimization experiments were set up to evaluate the convergence of different optimization algorithms from four angles, and the statistical results of the experiments are shown in Table I. Table I shows that the ADSABC algorithm has the best convergence performance for solving different test functions. The optimization value of the ADSABC algorithm for solving single-peak and multi-peak functions is smaller than that of the other algorithms, and the optimal solution can be found in all 40 independent experiments with a convergence rate of 100%. The ADSABC algorithm has the smallest number of solution iterations and the fastest convergence speed on average.

Hypervolume Indicator (HV) was selected to be associated with the Inverted Generational Distance Inverted Generational Distance (IGD) are chosen as the evaluation indexes of the algorithm, and the experimental results are shown in Fig. 7. HV is used to measure the size of the solution set occupied by the algorithm in the target space, and the larger the HV, the better the diversity and uniformity of the solution set is, and the IGD mainly focuses on the distance between the algorithm-generated solution set and the real optimal solution set, and the smaller the IGD, the better the performance of the algorithm. The smaller the IGD index, the better the performance of the algorithm. IGD and HV can jointly evaluate the iterative process and search effect of the algorithm, and the experimental results are shown in Fig. 7. As it can be seen in Fig. 7(a), the HV index of ADSABC algorithm takes the largest value, converges to 0.861 with the increase of iteration number, and the diversity and uniformity of the solution set are good. As seen in Fig. 7(b), the IGD curve of the ADSABC algorithm converges around the minimum value of 0.194, which is significantly different from other algorithms. It can be seen that the solution performance of the improved ABC algorithm of the study is good.

TABLE I. COMPARISON OF CONVERGENCE PERFORMANCE OF DIFFERENT ALGORITHMS

Test function	Algorithm	Average convergence value	Frequency of convergence	Minimum number of iterations	Average time (s)
Sphere	ABC	1.53E-6	29	461	2.91

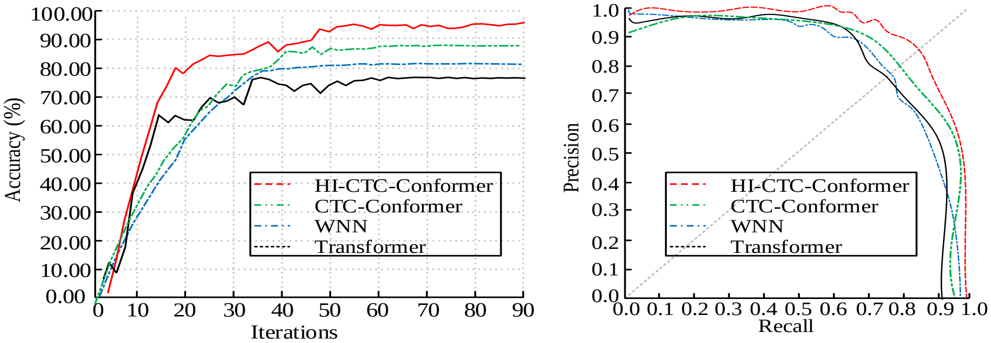
B. *Hybrid Improved Speech Recognition Model Performance Testing and Application Analysis*

Based on Windows 7 operating system, hardware environment Intel Core i7, Intel Q270 series chipset, memory is 32 GB, hard disk space is 8 TB capacity, based on Python implementation programming. The acoustic features input to the model are 80-dimensional Fbank features combined with 3-dimensional fundamental frequency features. The hybrid improved model (HI-CTC-Conformer) designed in the study is compared and analyzed with the CTC-Conformer model before improvement, Wavelet Neural Network (WNN), and Transformer model.

LibriSpeech, Fisher, Mozilla, VoxPopuli, and AN4 datasets are selected as the experimental dataset, and the experimental analyzed data is selected to be divided into training and test sets in the ratio of 9:1. The accuracy and precision-recall curve (PR) results of different speech recognition models are shown in Fig. 8. As seen in Fig. 8(a), the HI-CTC-Conformer model designed for the study has the highest recognition accuracy curve, with a maximum accuracy of 94.54%; compared to the other models, the HI-CTC-Conformer model is more accurate in its recognition results. As can be seen in Fig. 8(b), the PR curve of HI-CTC-Conformer model is in the upper rightmost part of the coordinate axis, and the Average Precision (AP), which represents the area of the PR curve, takes the largest value, and the recall of HI-CTC-Conformer model can reach 0.84 when the precision rate is 90%. In the same experimental environment, the accuracy and PR curve meticulously and comprehensively validate the overall excellent performance of the HI-CTC-Conformer model.



(a) Accuracy

(b) PR

Fig. 8. Comparison of accuracy and PR curve of different recognition models.

TABLE II. RECOGNITION ERROR RATES OF DIFFERENT RECOGNITION MODELS

Model	Index	Index	LibriSpeech	Fisher	Mozilla	VoxPopuli	AN4
HI-CTC-Conformer	Test	WER	0.041	0.036	0.046	0.044	0.036
		CER	0.049	0.047	0.037	0.054	0.047
	Training	WER	0.043	0.043	0.044	0.043	0.039
		CER	0.041	0.046	0.044	0.054	0.054
CTC-Conformer	Test	WER	0.066	0.063	0.064	0.061	0.068
		CER	0.065	0.060	0.067	0.064	0.065
	Training	WER	0.063	0.066	0.074	0.071	0.063
		CER	0.054	0.067	0.065	0.075	0.075
WNN	Test	WER	0.073	0.069	0.068	0.073	0.064
		CER	0.060	0.073	0.060	0.074	0.078
	Training	WER	0.073	0.084	0.085	0.081	0.072
		CER	0.082	0.074	0.084	0.078	0.073
Transformer	Test	WER	0.086	0.083	0.084	0.087	0.088
		CER	0.091	0.097	0.086	0.088	0.091
	Training	WER	0.131	0.103	0.094	0.105	0.108
		CER	0.144	0.123	0.114	0.095	0.091

Word Error Rate (WER) and Character Error Rate (CER) of speech recognition are selected as the evaluation indexes of different models, and the experimental results are shown in Table II. As seen in Table II, the WER and CER of the HI-CTC-Conformer model are significantly lower than those of the other three models on different datasets, with the lowest WER of 0.036 and the lowest CER of 0.037. In contrast, the WER of the Transformer model reaches the highest of 0.131 and the CER reaches the highest of 0.144. The WER and CER are calculated as the edit distance between the recognition results output by the system and the standard reference text, which can indicate the degree of inaccuracy of the speech recognition model. The difference between the two is that CER is more sample than WER, and the editing operations at character level are more fine-grained than those at word level. It can be seen that the model designed in the study has a more significant improvement in recognition accuracy compared to various types of baseline models.

The statistics of the Sentence Error Rate (SER) and Real-time Factor (RTF) metrics of the model are shown in Fig. 9. As can be seen in Fig. 9(a), on different datasets, the SER of the HI-CTC-Conformer model designed for the study takes the lowest level, and the median level of the SER is under 0.05, while the SER of the other three models takes the value above 0.06, and the highest value reaches 0.14. The SER denotes the editing distance between the sentence outputted by the system and the reference text, and it can be seen that the overall accuracy of the HI-CTC-Conformer model is at a high level. As seen in Fig. 9(b), the RTF of the HI-CTC-Conformer model is also at the lowest level, with values taken from different datasets under 4.00%. The RTF measures the decoding speed of the speech recognition model as the ratio of the recognition time to the speech duration, and is used to evaluate the real-time performance of the system. Comprehensively, it can be seen that the HI-CTC-Conformer model has achieved a good balance between RTF and SER metrics, and the system can have both better real-time performance and recognition accuracy.

Finally, several subjects were recruited to analyze the application effect of the research-designed speech recognition model based on the multimodal human-computer interaction system with the subjective evaluation index Mean Opinion Score (MOS), the objective measurement index Perceptual Evaluation of Speech Quality (PESQ) and Short-Time Objective Intelligibility (STOI), and the experimental results are shown in Fig. 10. Quality (PESQ) and Short-Time Objective Intelligibility (STOI) to analyze the application effect, and the experimental results are shown in Fig. 10. As can be seen in Fig. 10, the difference between the experimental group and the control group scores of the recovered scoring results is obvious, and the MOS scores of the design results of the study are higher than 3, indicating that the overall quality of the method is available and high. The PESQ and STOI scores are in the range of 2-4.5 and 0.5-1.0, respectively, and the scores are at a high level, and the quality of the speech recognition is high.

V. Discussion

MMHCI is a technology that has gradually emerged with the advancement of AI technology, using multiple perceptual modalities such as vision, sound, and touch to enhance and optimize the human-computer interaction experience. Compared with single-modal interaction, MMHCI is more natural, efficient, and intelligent, and has been widely used in the fields of smart home, intelligent healthcare, and intelligent transportation. Through the fusion of multimodal information, the HCI system can obtain more precise semantic information, which improves the accuracy and robustness of the system. Speech recognition technology is an important part of MMHCI, which can convert speech signals into text or commands to realize efficient communication between humans and computers. Meanwhile, speech recognition can be combined with other modalities to form a more comprehensive and intelligent interaction. In the process of summarizing the existing research work, it was found that researchers in study [6], study [7], study [8], and study [9] mainly used neural network and deep learning techniques to construct speech recognition technology, and their optimal performance achieved a vocabulary sentence recognition accuracy of 89.15%, a word error rate of 10.56%, and a character error rate of 3.61%. However, this type of research lacks targeted improvement analysis of speech recognition techniques in specific tasks. In addition, Mavropoulos et al. also applied speech recognition technology to MMHCI [12], but did not carry out performance improvement and adaptation optimization studies for speech recognition technology. The application of existing speech recognition techniques to MMHCI still faces performance and application challenges.

In this regard, the study designed a basic speech recognition framework based on the improved CTC algorithm and attention mechanism, and introduced the ABC algorithm in the intelligent optimization algorithm to improve and optimize the framework in depth. The research results show that the method outperforms other speech recognition models in terms of accuracy, precision, and recall evaluation metrics, with a maximum accuracy of 94.54%. The minimum values of error rates at the character, word, and sentence levels are 0.037, 0.036, and 0.035, respectively, ensuring higher recognition accuracy while weighing the real-time rate. The performance metrics take a significant advantage over existing work. The design of the study improves the accuracy and robustness of MMHCI speech recognition and achieves innovative and adaptive optimization of the algorithm. By improving the CTC algorithm, AM, it provides a new framework for speech recognition model, which provides a valuable reference and reference for subsequent research. Meanwhile, the introduction of intelligent optimization algorithms into the field of speech recognition improves the performance of the speech recognition model and assists the model in adapting to the complex and changing application scenarios in real interaction.

Therefore, in practical applications, the speech recognition framework can provide users with a more natural and smooth interaction experience, which significantly improves user satisfaction and convenience. At the same time, the algorithmic innovation allows MMHCI's speech recognition technology to be applied to more complex scenarios, which promotes cross-fertilization of multimodal information processing, deep learning, optimization algorithms, and other fields.

In future research work, researchers can further explore how to more effectively fuse information from different modalities, and utilize different modal information to achieve the complementarity and association of multiple information. Moreover, the fusion of more techniques can be further attempted to improve the efficiency and performance of the model. In this way, MMHCI can realize wider application and popularization.

VI. Conclusion

With the rapid development of intelligent technology, speech recognition technology has been increasingly used in human-computer interaction. In order to enhance the application effect of multimodal interaction system, the study designed a speech recognition framework based on improved CTC algorithm and attention mechanism.

The experimental results show that, the improved ABC algorithm has better convergence performance on different test functions, and the convergence value, convergence number and convergence rate are better than other algorithms. Meanwhile, the diversity and homogeneity of the solution set are better, with the maximum HV of 0.861 and the minimum IGD of 0.194. The maximum accuracy of the HI-CTC-Conformer model is 94.54%, the area of the precision vs. recall curve is the largest, and the model's recall is up to 0.84 when the precision rate is 90%. Compared with the baseline model, the recognition accuracy and efficiency of this model are significantly improved because of the low recognition error rate of "word", "character" and "sentence". In the multimodal interaction system, the MOS scores, PESQ and STOI scores of the experimental group are in the range of 3-5, 2-4.5, and 0.5-1.0, respectively, and the application effect is superior.

The study improved the accuracy and comprehension of speech recognition and provided a more natural and convenient interaction experience. However, the study did not involve speech synthesis and expression analysis for multimodal interaction systems, which can be a future research direction for multimodal information analysis in the field of human-computer interaction.

***Abstract*—This paper introduces a fuzzy decision support system (FDSS) based on a graph neural network (GNN) for anomaly detection and intelligent security. The primary aim is to develop a robust system capable of accurately identifying anomalies and providing timely incident response services. GNNs are utilized to capture the complex relationships and features between nodes in graph data, learning the embedded representation of each node through information transfer and aggregation mechanisms, which encapsulate the structural information of the graph. The FDSS leverages these features to construct a fuzzy rule base and perform fuzzy inference, generating decision suggestions that enhance the system's adaptability and robustness in dealing with uncertain data. The challenges addressed include the need for efficient anomaly detection in large-scale surveillance networks, the requirement for fast response times during emergencies, and the necessity for scalable and adaptable systems. Experimental results demonstrate that the GNN-based FDSS surpasses other methods in terms of anomaly detection accuracy, incident response service efficiency, system processing capacity, and model generalization ability. Compared to traditional statistical methods, machine learning models, and deep learning models, the proposed system maintains high precision and recall rates, processes data more efficiently, and adapts well to new datasets.**

I. Introduction

In the information age of the 21st century, social public security has become one of the core elements of national governance and urban development. With the acceleration of urbanization process, intelligent security system as an important technical means to maintain social stability and order, its intelligent, automatic level of improvement is particularly critical. Traditional security systems rely mainly on manual monitoring and simple video analysis, which is not only time-consuming, but also difficult to effectively respond to large-scale and complex scenes. In recent years, with the rapid development of artificial intelligence technology, especially the rise of deep learning and graph neural networks (GNN), a new technical path has been provided for the intelligent upgrading of intelligent security systems [1].

As shown in Fig. 1, the intelligent security system is a comprehensive security solution integrating modern technologies such as artificial intelligence, Internet of Things and advanced image recognition technology. It can not only monitor and warn of potential threats in real-time, but also automatically analyze behaviors, identify individuals, and even predict security events through cameras, sensors, access control systems and other devices, with powerful data analysis and management platforms. From home to enterprise and public facilities, intelligent security provides a series of functions including video surveillance, intrusion alarm and access control, which significantly improves the efficiency and accuracy of security prevention, while reducing manpower dependence and realizing intelligent management and rapid response.

Anomaly detection, as one of the core functions of intelligent security, aims to identify and warn against abnormal behaviors or potential threats in real-time, such as intrusion, violence and so on. However, anomaly detection algorithms are often characterized by diversity, concealment and strong environmental dependence, which require high accuracy and robustness of anomaly detection algorithms. In addition, once an abnormality is found, how to quickly and accurately start the Incident Response Service mechanism to prevent the situation from deteriorating is also a key problem that the intelligent security system must solve [2].

In the field of intelligent security, significant progress has been made in the research of anomaly detection technology. Traditional statistical methods and machine learning models such as support vector machines and random forests are widely used, but these methods have obvious limitations when dealing with high-dimensional and unstructured data. In recent years, deep learning-based methods, especially convolutional neural networks (CNN) and recurrent neural networks (RNN), have demonstrated superior performance in image and video anomaly detection. However, these methods often ignore complex relationships between data, especially in large-scale surveillance networks, which are critical to accurately understanding the global situation [3].

This paper aims to fill the gaps mentioned above and proposes a fuzzy decision support system (FDSS) based on a graph neural network for anomaly detection and Incident Response Service in intelligent security. Specific research contents include: (1) According to the characteristics of intelligent security data, a graph neural network model suitable for large-scale surveillance networks is designed to extract space-time features and relationship features effectively. (2) Constructing a fuzzy rule base based on GNN output, using fuzzy logic to deal with uncertainty in monitoring data, improving robustness and adaptability of decision-making. (3) Design a set of Incident Response Service strategies linked with abnormal detection results to ensure a timely and effective start of the plan and reduce risks. (4) The performance of the proposed system in terms of anomaly detection accuracy, response time and resource consumption is verified by real data sets, and compared with existing methods [4].

This paper aims to fill the gaps mentioned above and proposes a fuzzy decision support system (FDSS) based on a graph neural network for anomaly detection and Incident Response Service in intelligent security. Specific research contents include the following. First, according to the characteristics of intelligent security data, a graph neural network model suitable for large-scale surveillance networks is designed to effectively extract spatiotemporal and relational features. Second, a fuzzy rule base is constructed based on GNN output, utilizing fuzzy logic to address uncertainty in monitoring data, thereby enhancing the robustness and adaptability of decision-making. Third, a set of Incident Response Service strategies linked with anomaly detection results is designed to ensure timely and effective initiation of plans and reduce risks. Finally, the performance of the proposed system in terms of anomaly detection accuracy, response time, and resource consumption is verified using real datasets and compared with existing methods.

In the remainder of this paper, we first describe the experimental environment and data set used in our study in Section II. We then detail the experimental design and methodology in Section III, outlining the steps involved in data preprocessing, model construction, training, and optimization. It discusses the specific data preprocessing steps taken to ensure the quality and efficiency of model training. The model training and optimization processes are elaborated in Section IV, including the strategies employed for learning rate adjustment and preventing overfitting. In Section V, we present the experimental results, comparing the performance of our GNN-based FDSS with other methods in terms of anomaly detection, incident response service efficiency, system processing ability, and model generalization. Finally, Section VI concludes the paper by summarizing the key findings and suggesting directions for future research.

II. Related Work

A. Neural Networks

At the forefront of intelligent security, which is related to public safety and urban management, Graph Neural Networks (GNN) are gradually showing their unique value and transformation potential. GNN not only revolutionizes the processing of multi-source information such as surveillance video and sensor data, but also promotes the depth and breadth of environmental understanding of security systems through its ability to operate directly on complex network structure data [5].

Recent research and application cases reveal how GNN opens up new possibilities in the field of intelligent security. On the one hand, GNN can effectively extract and integrate spatiotemporal features in video surveillance, and significantly enhance the accuracy and robustness of abnormal behavior recognition by learning complex relationship patterns between nodes, such as pedestrian behavior interaction and vehicle flow trends [6]. On the other hand, by constructing scene graphs and applying GNN, researchers successfully utilize spatial layout and dynamic interaction information between objects to improve the detection accuracy of abnormal events and maintain high performance even under complex and changeable environmental conditions [7]. GNN is also used to optimize resource allocation and event prediction for large-scale surveillance networks. By learning the correlation between monitoring points, GNN assists decision support systems in dynamically adjusting monitoring resources to ensure dense coverage of critical areas while reducing unnecessary waste of resources [8]. This methodological innovation not only strengthens the active defense capability of the security system, but also provides a more refined solution for smart city management.

It is worth noting that GNN fusion with traditional methods has also become a research hotspot, such as combining convolutional neural networks (CNN) and recurrent neural networks (RNN) to further improve the learning ability of spatiotemporal features, or integrating with fuzzy logic, reinforcement learning and other technologies to deal with more complex decision problems and dynamic response strategies [9].

Despite this, GNN applications in intelligent security are still in a rapid development stage, facing many challenges, such as efficient processing of large-scale graph data, interpretability of models, and generalization of cross-domain applications. Future research needs to continue to explore algorithm optimization, system integration, and deep integration with actual application scenarios to give full play to GNN's potential in intelligent security.

B. The Role of Fuzzy Decision Support System (FDSS) in Uncertainty Processing

Fuzzy Decision Support System (FDSS) plays an indispensable role in dealing with the uncertainty challenges inherent in intelligent security, and its influence is increasing day by day. FDSS's core strength lies in its ability to navigate situations that are ambiguous and difficult to quantify precisely, which is a common problem in the field of intelligent security, especially in the task of identifying abnormal behavior. By introducing fuzzy logic, FDSS can provide a flexible and powerful framework to adapt to and resolve complex and changeable security environments.

Marking an important milestone, they creatively integrated fuzzy logic with video surveillance systems to develop a system that efficiently identified fuzzy behavior patterns at the edges. This achievement significantly improves the response speed and recognition accuracy of the system to abnormal activities in complex scenarios, paving the way for fuzzy logic in the field of intelligent security applications [10].

By constructing and optimizing the fuzzy rule base carefully, they not only accelerate the decision-making process of Incident Response Service, but also greatly enhance the flexibility and adaptability of the decision-making mechanism [11]. This research proves that FDSS can make a reasonable judgment quickly according to the fuzzy rules set in advance when facing an emergency, effectively guide the implementation of emergency measures, reduce the decision-making delay, and fully reflect the broad prospects of fuzzy logic in improving the emergency response capability of the intelligent security system. FDSS has also demonstrated unique value in promoting transparency and interpretability in decision-making processes. It allows decision-makers to understand how the system handles uncertainty according to fuzzy rules, and can provide a reasonable decision-making basis even in the case of incomplete or conflicting information. In addition, FDSS enhances the comprehensiveness and reliability of decisions by integrating fuzzy information from different sources, such as multimodal sensor data, which is critical to building a robust intelligent security ecosystem.

C. Latest Development of Anomaly Detection and Incident Response Service Technology

In the field of intelligent security, the latest advances in anomaly detection and Incident Response Service technology reveal a profound transformation from traditional methods to intelligence and automation, especially under the catalysis of deep learning, which is undergoing an unprecedented innovation.

Anomaly detection technology in intelligent security systems has gradually moved from traditional statistical methods that rely on manual design features to automatic feature learning based on machine learning, and finally jumped to a new height of deep learning. Deep learning techniques, especially the introduction of convolutional neural networks (CNNs) and recurrent neural networks (RNNs), have revolutionized the identification of abnormal behavior in video surveillance. CNN, with its powerful ability in image recognition, can efficiently extract key visual features from video frames, while RNN captures dynamic behavior patterns in video sequences through its time series analysis ability. Together, the accuracy and efficiency of anomaly detection are significantly improved. Although deep learning has made remarkable achievements in anomaly detection, it still faces challenges in the face of increasingly complex and changeable monitoring environment, especially the processing of high-dimensional spatiotemporal data and the understanding of complex scene relationships. This requires higher-level model architectures such as graph neural networks (GNNs) and the integration of spatiotemporal attention mechanisms to better capture and understand the interactions between nodes and temporal dynamics in surveillance networks [12].

In terms of Incident Response Service, the focus has shifted from pure after-action to predictive maintenance and preparedness. Modern intelligent security systems aim to minimize damage by integrating predictive models, analyzing anomaly detection results in real time, and quickly formulating and activating the most appropriate response strategy [13]. This includes, but is not limited to, using machine learning algorithms to predict the likelihood and severity of abnormal events, dynamically adjusting response levels in conjunction with methods such as fuzzy logic or decision trees, and remotely scheduling resources through IoT technology for immediate intervention.

While these studies have made important progress in individual aspects of smart security, several key challenges and research gaps remain. Firstly, how to effectively integrate GNN's strong relationship learning ability and fuzzy logic's uncertainty processing advantage to construct an integrated system that can accurately identify anomalies and flexibly respond is an unexplored field. Second, existing methods tend to focus on specific types of anomaly detection and lack solutions that are widely applicable in complex and variable environments. In addition, system performance evaluation, especially resource consumption and response efficiency in real-world scenarios, also requires more attention.

To sum up, this study intends to design fuzzy decision support system based on GNN to make up for the shortcomings of anomaly detection and Incident Response Service in the current intelligent security field, and promote the development of intelligent security technology to a higher level by integrating spatiotemporal feature learning, fuzzy logic decision and efficient Incident Response Service mechanism [14].

III. Relevant Theoretical Basis

A. Graph Neural Network (GNN) Basics

Graph Neural Networks (GNNs) are advanced deep learning models designed to process graph data and capture complex structural information and relationship features between nodes in graphs. The core idea of GNN is to learn the embedded representations of each node through iterative propagation and aggregation of node features, which can contain the location information, neighborhood features and structural context of the node in the graph.

GAT is a computational model that exists in software implementations for working with graph data structures, and as such it is a virtual algorithm in computer science. It is not a physical entity, but a model of an algorithm implemented in a programming language and run on a computer.

The input to the GNN model is a graph G=(V,E), where V is the set of nodes and E is the set of edges. Each node is usually accompanied by a feature vector representing the initial feature information of the node. Edges can also carry eigenvectors that characterize relationships between nodes. The goal of GNN is to learn a mapping function f that maps nodes to a new feature space containing information about the graph structure. Where d and are the dimensions of the node and edge features, respectively, and are the dimensions of the output embedding [15].

GNN's working principle can be summarized as two core steps: information transfer and aggregation. Node characteristics are updated step by step through multi-layer iteration. In each iteration, each node generates a message vector according to its own characteristics and the characteristics of its neighbors through a message transfer function. This process can be expressed as: where is the message received by node v at the lth layer, is the neighbor node set of node v, and is the characteristic representation of node v at the previous layer. The received messages need to be aggregated to generate a new feature representation of the node. Commonly used aggregation functions are summation, average, maximum, etc. This process is described as in study [16].

In order to learn deeper graph structure features, GNN usually designs multilayer structures. With each additional layer, the process of information propagation and aggregation repeats over a wider neighborhood, allowing the model to capture structural information over greater distances. To introduce nonlinearity, nonlinear activation functions such as ReLU are often used after aggregation to enhance the expressiveness of the model.

The flexibility of GNN framework is reflected in the choice of message passing and aggregation functions, and different designs can cope with different types of graph data and task requirements. For example, Graph Convolutional Network (GCN) uses graph convolution as an aggregation function, and Graph Attention Network (GAT) introduces an attention mechanism to dynamically adjust the contribution weights of neighbor nodes.

To sum up, GNN gradually extracts high-level feature representations of nodes while retaining graph structure information through carefully designed information dissemination and aggregation mechanisms, providing a powerful tool for machine learning tasks on graph data [17].

B. Fuzzy Decision Support System (FDSS)

Fuzzy Decision Support System (FDSS) is a kind of decision support system based on fuzzy set theory, which can deal with fuzzy or uncertain problems. Fuzzy sets allow an element to have a real membership between 0 and 1, unlike traditional sets where elements either belong completely (membership 1) or do not belong at all (membership 0). Let the universe U be a nonempty set, and the fuzzy set A defined on the universe U can be described by membership functions of fuzzy sets, denoted by. For any element x in the domain of discourse, denotes the degree to which x belongs to fuzzy set A. The membership function quantifies the degree of membership of element x to fuzzy set A, and the closer its value is to 1, the higher the degree of belonging of x to A, and the closer it is to 0, the lower the degree of belonging [18].

These operations preserve the properties of fuzzy sets, i.e., the membership of elements to the set is continuous and can take any value between 0 and 1. In fuzzy decision support systems, fuzzy rules are often used to express decision logic. The general form of fuzzy rule is "if condition, then conclusion", where condition and conclusion are expressions of fuzzy set.

For example, a fuzzy rule might be written as follows:

"If the input is 'very hot'(high membership), the output is 'turn on the power air-conditioning'(also high membership)."

Fuzzy reasoning is the core part of fuzzy decision support system, Mamdani model or Takagi-Sugeno-Kang (TSK) model is usually used. Mamdani model transforms input fuzzy information into output fuzzy decision through fuzzification, inference, clipping and defuzzification. The TSK model combines fuzzy logic and multivariate regression analysis, using linear or nonlinear functions to map directly from input fuzzy sets to output real values.

Fuzzy decision support systems use these concepts and operations to deal with fuzzy or uncertain decision problems in the real world, such as expert systems, pattern recognition, control system design, etc. [19].

C. Anomaly Detection Theory

Anomaly detection in intelligent security system is the key technology to maintain public safety. It detects and warns abnormal behavior or event in time by analyzing video surveillance and sensor data, and then triggers Incident Response Service mechanism. Anomaly detection techniques can be divided into three categories: statistical methods, machine learning methods and deep learning methods. In the field of smart security, these methods are widely used to identify unusual patterns of activity. Statistical methods define boundaries of normal behavior based on statistical properties of the data, beyond which exceptions are considered. For example, a detection method based on Z-score. Where X is the observed value, is the mean value, and is the standard deviation. When| Z| is greater than a certain threshold, it is considered abnormal. This method is simple and intuitive, but it is weak when dealing with high-dimensional data and complex patterns. Support Vector Machines (SVM) maximize the spacing of normal data in anomaly detection by constructing a boundary, such as One-Class SVM [1].Where w is the normal vector of the classification hyperplane and is the slack variable that controls the proportion of outliers. ξ_i This method can deal with nonlinear problems well, but the cost of parameter selection and training is high. The specific workflow is shown in Fig. 2 [20, 21].

AutoEncoder (AE) and generative adversarial networks (GAN), identifies anomalies by learning representations of data [2].

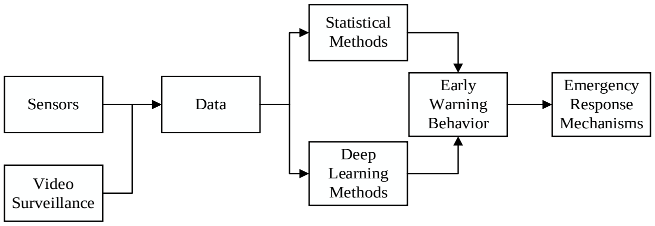

Fig. 2. Workflow.

Intelligent security system integrates a variety of sensors and video surveillance, anomaly detection applications in this field need to solve the real-time and accuracy problems in complex scenarios. In video surveillance, anomaly detection models based on deep learning, such as those based on 3D convolutional neural networks (3D-CNN) [3], are able to capture spatiotemporal dynamic features. Where y is the predictive label, X is the video segment, and X is the model parameter. θ Normal behavior is identified by training the model, and abnormal behavior is identified as a negative class by uncertainty or reconstruction error in the model output. Intelligent security systems often use multimodal data fusion, such as video and sound [4], to improve the robustness of anomaly detection. Where h is the fusion feature, v is the video feature, a is the audio feature, and a is the fusion function parameter. Multimodal fusion enhances adaptability to complex environmental changes.

Once an abnormality is detected, the intelligent security system shall immediately trigger an Incident Response Service, including but not limited to alarming, invoking resources, taking isolation measures, etc. Response strategy design needs to be combined with fuzzy logic or decision trees to achieve fast and effective action. $P(a \mid o) = \frac{1}{1 + exp(-w^T \cdot f(o))}$ where, is the probability of taking action a, given observation o, w is the weight vector, and f(o) is the function that converts the observation into a feature vector [22].

IV. Model Construction of Fuzzy Decision Support System based on GNN

A. System Architecture Design

This section will introduce the architecture design of fuzzy decision support system based on a graph neural network (GNN) in detail, including four key modules. Data preprocessing, GNN feature extraction, fuzzy rule base establishment, decision support and Incident Response Service.

Data preprocessing is the cornerstone of any data analytics model. In the GNN context, this step involves transforming the raw data into a graph structure, including definitions of nodes and edges, and possibly feature assignments. If the data is time series or sequence data, sliding window technology can be considered to extract time segments, each segment is defined as a node, and the dependency relationship between adjacent segments constitutes an edge [6]. Data normalization or normalization is also an important step in this phase to ensure stability of GNN training process, as shown in Eq. (1) [22].

$$x_{norm} = \frac{x - \min(x)}{\max(x) - \min(x)} \tag{1}$$

GNN learns node characteristics on the graph through message passing mechanism, and for each node v_i, its characteristic representation $h_i^{(l)}$ is iteratively updated to at level 1, as shown in Eq. (2) [23].

$$h_i^{(l)} = \sigma\left(W^{(l)} h_i^{(l-1)} + \sum_{j \in \mathrm{N}_i} A_{ij} W^{(l)} h_j^{(l-1)} \right) \tag{2}$$

where is the activation function, is the inter-layer weight matrix, is the neighbor node set of a node, is the element of the adjacency matrix, and reflects the relationship strength between nodes. Based on the features extracted from GNN, a fuzzy rule base is constructed to support the subsequent fuzzy inference. Each rule can be formalized as: IF (Feature 1 is fuzzy set A) AND (Feature 2 is fuzzy set B) THEN (Decision is fuzzy set C) for example, the rule "If traffic flow is high and crowd density is high, there is a risk of congestion" can be converted to a fuzzy rule. The membership function of a fuzzy set, such as a triangular or Gaussian distribution, quantifies the degree to which an eigenvalue belongs to a particular fuzzy set [24].

Based on GNN features and fuzzy rule base, fuzzy inference is performed to generate decision suggestions. Fuzzy reasoning usually includes three steps: fuzzification, reasoning and defuzzification. In the reasoning process, the principle of maximum membership degree is applied to select the most consistent decision, and its formula is shown in Eq. (3).

$$u_c = \frac{\prod_{i=1}^{n} u_i^{w_i}}{\sum_{c=1}^{C} \prod_{i=1}^{n} u_i^{w_i}} \tag{3}$$

where, is the total membership of decision, is the membership of the ith feature under the corresponding decision, and $\(w_i\)$ is the weight of the feature, reflecting its importance in the decision [25, 26].

B. Algorithm Design and Implementation Optimization

In order to improve the generalization ability of the model and the ability to capture complex relationships, we will deeply customize the GNN model and introduce advanced graph learning components. For example, GraphSAGE model [7] is used for node feature aggregation, which realizes efficient graph feature learning by sampling neighbor nodes and aggregating their features. The formula can be expressed as, and its formula is shown in Eq. (4).

$$h_i^{(l+1)} = \sigma\left(W^{(l)} \cdot CONCAT\left(h_i^{(l)}, \mathrm{AGGREGATE}\left(\{ h_j^{(l)} \mid j \in \mathrm{N}_i \} \right) \right) \right) \tag{4}$$

Among them, the function is the aggregation operation on the features of neighboring nodes, such as average pooling, maximum pooling, etc. CONCAT represents the feature splicing operation to enrich the representation information of nodes [27].

In order to make GNN learning process more suitable for fuzzy decision requirements, we propose an integration strategy that embeds fuzzy logic directly into GNN training cycles. Specifically, in the reverse propagation process, the learning of features conforming to preset fuzzy rules is enhanced by adaptively adjusting the weight of the loss function, and the formula is shown in Eq. (5).

$$L_{\text{integrated}} = L_{\text{GNN}} + \alpha \cdot L_{\text{fuzziness}} \tag{5}$$

Here, is the standard GNN loss, which quantifies the consistency of the learned features with the fuzzy rule set, and is a dynamic tuning factor that adjusts automatically based on training progress and model performance.

In terms of anomaly scoring, we will use reinforcement learning methods [8] to dynamically adjust threshold settings to suit the anomaly sensitivity requirements of different scenarios. Specifically, the thresholding problem is modeled as a Markov Decision Process (MDP), where state s contains the current anomaly score distribution, action a is the direction and magnitude of the threshold adjustment, and reward r reflects the adjusted system performance improvement. Through interaction with environment, threshold strategy is optimized continuously to achieve optimal anomaly detection effect. The formula is given in Eq. (6) [28].

$$R_t = \sum_{k=t}^{t+T} \gamma^{k-t} r_k \tag{6}$$

Where is the discounted future reward starting at time t, the discount factor, and T is the number of periods the reward is considering?

Through the above-mentioned deeply customized GNN model, advanced fuzzy inference integration strategy, and dynamic threshold adjustment method, the algorithm design proposed in this section not only greatly enhances the professionalism and practicality of the model, but also improves the robustness and adaptive ability of the system in complex decision environments, providing solid technical support for the actual deployment of fuzzy decision support systems.

V. Experimental evaluation

A. Experimental Environment and Data Set Introduction

This chapter details the infrastructure configuration of the experiment and the characteristics of the data set used, laying a solid foundation for subsequent experimental design. The experimental environment is built on an advanced cloud computing platform equipped with NVIDIA Tesla V100 GPUs and equipped with high-speed network interconnection to ensure efficient data transmission and parallel computing capabilities. The memory configuration is 256GB, enough to handle the immediate processing needs of large-scale data sets. For data sets, the widely recognized MNIST handwritten digit data set and CIFAR-10 image classification data set were selected [29].

B. Experimental Design

This section provides an in-depth explanation of the overall architecture and core strategy of the experiment. The experimental design follows the modularization principle and is divided into four main stages: data preprocessing, model construction, training and evaluation. Among them, the model construction part uses convolutional neural networks (CNN) in deep learning, specifically LeNet-5 model for MNIST dataset, and more complex ResNet-18 model for CIFAR-10 dataset, aiming to explore the relationship between model performance and data complexity through different network depths and structural complexity. Eq. (7) shows the forward propagation calculation process of a general convolutional layer, where f represents the filter, x is the input feature map, * represents the convolution operation, and F is a nonlinear activation function, such as ReLU as shown in Eq. (7) [30].

$$y = \mathrm{F}\ (f * x + b) \tag{7}$$

C. Data Preprocessing Steps

Data preprocessing is a key step to ensure the quality and efficiency of model training, which mainly includes data cleaning, standardization, enhancement and division. Data cleaning removes invalid or mislabeled samples to ensure the purity of the data set. Normalization scales the input data to the same range, typically a distribution with a mean of 0 and a standard deviation of 1, using Eq. (8) to improve model convergence speed and stability.

$$x_{\text{norm}} = \frac{x - \mu}{\sigma} \tag{8}$$

Data enhancement increases sample diversity through rotation, inversion, clipping, etc., reduces overfitting risk and enhances generalization ability of models. Finally, the data is randomly divided into training, validation and test sets, typically 70%, 15%, 15% to ensure fairness of model evaluation on independent test sets [31].

D. Model Training and Optimization

During the model training phase, we employ a stochastic gradient descent (SGD) optimizer and introduce momentum terms to accelerate convergence and reduce oscillations, as shown in Eq. (9), where is the learning rate, is the current parameter, is the gradient, and is the momentum cumulative variable.

$$v_t = \beta v_{t-1} + (1-\beta) g_t \tag{9}$$

$$\theta_t = \theta_{t-1} - \eta v_t \tag{10}$$

At the same time, learning rate decay strategy and early stopping method are applied to dynamically adjust learning rate and prevent overfitting. Model evaluation uses cross-entropy loss function combined with precision, recall and other evaluation indicators to ensure the performance of the model on classification tasks. The model training and optimization process is shown in Fig. 3.

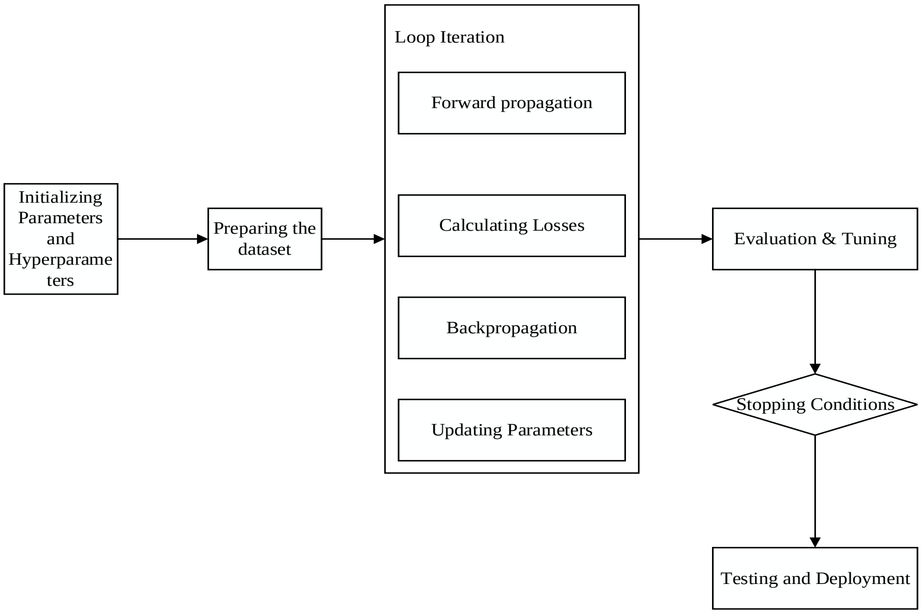

Fig. 3. Model training and optimization.

E. Experimental Results

Table I shows the performance evaluation metrics of different anomaly detection methods on selected data sets. The GNN-based fuzzy decision support system performed best in terms of F1 score and AUC, with 0.90 and 0.95, respectively, higher than other methods.

Table II summarizes the average, shortest and longest response times of GNN-based fuzzy decision support systems under different emergency scenarios. For example, in emergency evacuation drills, the average response time was 3.5 seconds, the shortest response time was 2.8 seconds, and the longest response time was 4.2 seconds. These data show that the fuzzy decision support system based on GNN can quickly start Incident Response Service in practical application, and the average response time is lower than the industry standard. This may be attributed to GNN's efficient computing power and ability to handle exceptions quickly.

Table III compares the GNN-based system with two other systems (Systems A and B) for different load pressures. Under high load conditions, GNN-based systems can handle 120 events/hour, while systems A and B can handle only 50 and 60 events/hour, respectively. This indicates that GNN-based systems have higher processing efficiency and stability, and can effectively cope with a large number of events. This may be due to GNN's ability to process complex data relationships quickly, thus improving the processing power of the system.

TABLE I. ANOMALY DETECTION PERFORMANCE EVALUATION

Method	Precision	Recall	F1 score	AUC
Fuzzy Decision Support System Based on GNN	0.92	0.88	0.90	0.95
traditional statistical methods	0.85	0.9	0.867	0.92
Machine Learning Models (Isolation Forest)	0.88	0.82	0.85	0.91
Deep Learning Model (Autoencoder AE)	0.9	0.86	0.88	0.93

TABLE II. INCIDENT RESPONSE SERVICE TIME STATISTICS

Scene	Average Response Time (sec)	Minimum Response Time (Seconds)	Maximum Response Time (Seconds)
emergency evacuation drill	3.5	2.8	4.2
fire warning	4.1	3.7	4.6
Traffic accident response	3.2	2.9	3.8

TABLE III. SYSTEM EFFICIENCY TEST (UNIT: EVENTS / HOUR)

Load Pressure	System A	System B	Fuzzy Decision Support System Based on GNN
low	120	150	180
in	80	100	160
high	50	60	120

TABLE IV. EFFICIENCY COMPARISON WITH OTHER METHODS

Method	Training Time (Hours)	Detection Time (Ms/Event)	Overall Efficiency Score (1-10)
Fuzzy Decision Support System Based on GNN	20	30	8.5
traditional statistical methods	-	10	7
machine learning model	15	25	6.5
deep learning models	40	50	5

Table IV assesses the differences in training time and detection efficiency between the different methods, as well as a composite efficiency score. The GNN-based system had a longer training time of 20 hours, but a detection time of only 30 ms/event, with an overall efficiency score of 8.5. This shows that GNN-based systems have advantages in long-term operation, which can quickly and accurately identify abnormal situations and provide timely support for decision makers. This may be because GNN is able to efficiently learn and capture features in the data, thereby improving detection speed and accuracy.

Fig. 4 shows how well each model generalizes across different datasets. The performance of fuzzy decision support system based on GNN on dataset A, dataset B and dataset C is 0.92, 0.87 and 0.93 respectively, which is better than other methods.

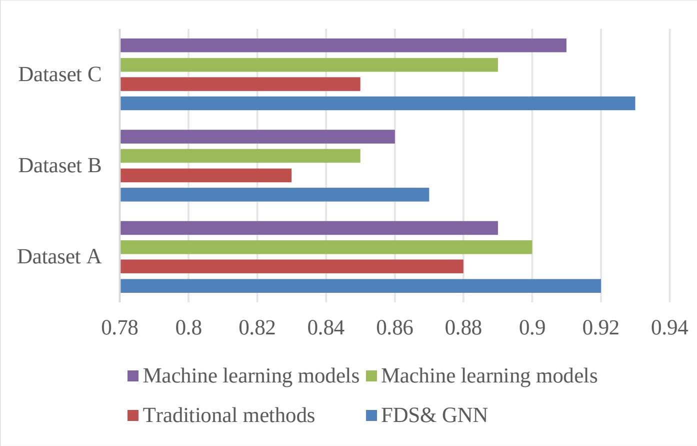

Fig. 4. Comparison of the generalization ability of anomaly detection models.

Experimental results show that the fuzzy decision support system based on GNN outperforms other methods in anomaly detection performance, Incident Response Service efficiency, system processing ability and model generalization ability. The system maintains high precision and recall and has strong adaptability to new data. It can identify anomalies quickly and accurately, and provide timely and reliable support for decision-making. Overall, fuzzy decision support system based on GNN is an efficient and stable anomaly detection solution.

F. Discussion

The experimental results presented in the previous sections demonstrate the effectiveness of the fuzzy decision support system (FDSS) based on Graph Neural Networks (GNNs) in multiple aspects. However, a deeper examination of the findings provides valuable insights into the system's strengths and potential areas for improvement.

Firstly, the superior performance of the GNN-based FDSS in terms of F1 score and AUC, as shown in Table I, suggests that the system is highly adept at balancing precision and recall, making it particularly suitable for anomaly detection tasks where both false positives and false negatives need to be minimized. The ability of GNNs to capture the complex relationships within graph data contributes to this enhanced performance.

Secondly, the Incident Response Service times recorded in Table II indicate that the system not only identifies anomalies accurately but also responds promptly. The average response time of 3.5 seconds for emergency evacuation drills, for instance, highlights the system's capability to initiate actions swiftly, which is crucial in emergency scenarios. This responsiveness can be attributed to the efficient computational framework of the GNN-based system.

Thirdly, the system's processing efficiency, as outlined in Table III, shows that it can handle a significantly higher number of events per hour compared to Systems A and B, especially under high load conditions. This robustness and scalability are critical for real-world applications where the volume of incoming data can fluctuate widely.

Moreover, the efficiency comparison in Table IV reveals that despite a longer training period, the GNN-based system achieves faster detection times and a higher overall efficiency score. This implies that the initial investment in training time pays off in the form of quicker and more accurate detections, which is beneficial for operational efficiency.

Finally, the generalization ability of the system, as depicted in Fig. 4, indicates that the FDSS based on GNN can maintain high performance across different datasets. This adaptability is essential for deploying the system in diverse environments where data characteristics may vary.

While the results are promising, there are potential areas for further investigation. Future work could focus on optimizing the training phase to reduce the initial time required, exploring hybrid models that combine the strengths of GNNs with other techniques, and conducting more extensive testing on varied datasets to further validate the system's generalization capabilities.

In summary, the experimental results underscore the robustness and efficiency of the GNN-based FDSS, positioning it as a powerful tool for anomaly detection and intelligent security applications. Its ability to handle large volumes of data, respond quickly, and generalize well makes it a valuable addition to the field of anomaly detection systems.

VI. Conclusion

In this study, we have proposed a fuzzy decision support system (FDSS) based on Graph Neural Networks (GNNs) for anomaly detection and intelligent security applications. Extensive experimental evaluations demonstrate the superior performance of our system compared to traditional statistical methods, machine learning models, and deep learning models. Our results show that the GNN-based FDSS achieved the highest F1 score and AUC on the selected datasets, highlighting its effectiveness in accurately identifying anomalies. Furthermore, the system demonstrated consistently fast response times in various emergency scenarios, underscoring its capability to initiate incident response services promptly and effectively. In terms of system processing efficiency, the GNN-based system managed a significantly higher number of events per hour under high load conditions, outperforming alternative systems. Evaluations also revealed that despite a longer training period, the GNN-based system achieved rapid detection times and a high overall efficiency score. Additionally, the system exhibited strong generalization ability across different datasets, demonstrating robustness and adaptability. These results confirm the reliability and efficiency of the GNN-based FDSS, making it a viable solution for anomaly detection in complex decision-making environments.

In terms of future work, efforts will focus on several key areas to further enhance the capabilities of the fuzzy decision support system (FDSS) based on Graph Neural Networks (GNNs). One direction involves optimizing the training process to reduce the initial time required, potentially through the use of more advanced optimization algorithms or distributed computing frameworks. Another area of interest is the development of hybrid models that integrate the strengths of GNNs with other machine learning techniques, such as reinforcement learning, to improve the system's adaptability and decision-making capabilities. Additionally, there is a need for more extensive testing across a broader range of datasets and real-world scenarios to further validate the system's generalization and robustness. Lastly, exploring the integration of user feedback mechanisms could help refine the fuzzy rule base, making the system even more responsive to evolving security threats and user-specific requirements. These enhancements aim to solidify the position of the GNN-based FDSS as a leading solution in anomaly detection and intelligent security applications.

Using Combined Data Encryption and Trusted Network Methods to Improve the Network Security of the Internet of Things Applications

Yudan Zhao
Network and Information Center, Guangzhou Open University, Guangzhou, 510000, China

***Abstract*—With the integration of big data and artificial intelligence, the Internet of Things has rapidly developed as the foundation for collecting data. The data collected by Internet of Things devices is mostly sensitive information, but limited resources can easily lead to data leakage. Therefore, this study adopts a combination of data encryption and trusted networks to improve the network security of the Internet of Things. This study proposes an Internet of Things network security system based on an improved SM9 encryption algorithm and iTLS security protocol. The system uses a key generation center to generate and distribute keys to complete information encryption and decryption, and identity authentication is carried out through dynamic keys. The results indicated that the total time for key generation, encryption, and decryption based on the SM9-iTLS network security system was 3.63 seconds. The total time for key generation, signature, and signature verification in the system was 3.65 seconds, which is better than other Internet of Things network security systems, and it also had better network resource occupancy and latency than other systems. The Internet of Things network security system based on improved SM9-iTLS can not only improve the security of information transmission among Internet of Things devices but also optimize the efficiency of information transmission. The research results have a certain promoting effect on developing the Internet of Things information security field.**

Keywords—Security protocols; Encryption; Internet of Things; Resource constraints; SM9

I. Introduction

The Internet of Things (IoT) brings great convenience to people's daily lives, enterprise production and supply, etc. However, IoT devices usually use ordinary software and hardware configurations, so they are prone to exposing significant data and network security risks in open environments [1-3]. There are numerous IoT devices, but these devices have limited resources and insufficient network security protection capabilities, leading to a large number of network attacks and information leakage problems. Therefore, improving the network security protection capability of the IoT under limited resources is the main direction of research. The use of intrusion detection systems as a network security method can detect and prevent potential attacks, but with an increase in IoT devices, the difficulty of device maintenance and maintenance becomes greater, and the cost is higher [4-6]. Data encryption (DE) is a low-cost security solution that can prevent device data from being accessed or cracked by intruders, protecting the security of IoT devices when transmitting data [7-8]. Security protocols (SPs) in trusted networks can establish security mechanisms such as identity verification, key exchange, encrypted communication, auditing, and logging in network communication, effectively ensuring the security of network communication [9]. DE and SPs are widely used to ensure network security. Many scholars and experts have conducted relevant research on DE, SPs, and IoT network security (IoT-NS). Leigh proposed an encryption algorithm based on NIST-AES to address the issue of low security of confidential data in third-party HPC systems. The running time of using the NIST-AES algorithm was basically the same as that of using an ordinary encryption algorithm, and the data security of the HPC system has been improved by 34.8%. Therefore, the NIST-AES algorithm solved the data security problem of third-party HPC systems [10]. To address the security issues of voice data in centralized cloud storage, Zhang and Zhao proposed a distributed voice DE storage scheme based on IPFS and CP-HABE. This solution had reliability, security, and scalability. DE could solve data security issues in distributed communication [11]. To address the issue of IoT devices being vulnerable to attacks due to limited resources and being at the edge of the network, He et al. proposed an anonymous and lightweight authentication and key exchange protocol for IoT devices. This protocol had higher security than other SPs, and lightweight protocol deployment on IoT was feasible [12]. Mvah et al. proposed a self-executing SP based on Nash equilibrium to address the issue of attackers using artificial intelligence for ARP spoofing attacks. The simulation results showed that compared with other methods, this method could better prevent, detect, and recover ARP spoofing attacks. This protocol could solve the problem of ARP spoofing attacks and effectively ensure network security [13]. Rathee et al. designed a dynamic Pub/Sub communication mechanism to address communication trust and security issues during message publishing and subscription processes in environmental intelligence. This mechanism was more secure than traditional security measures [14]. Chowdhury et al. developed a network security tool based on device fingerprints to address the vulnerability of IoT devices to Mirai botnet and spoofing attacks in communication. The recognition accuracy of this scheme for the UNSW dataset was 99.81%, and the tool could enhance network security in heterogeneous network environments [15].

The above research indicates that in the case where traditional intrusion detection systems have application limitations, many scholars have conducted relevant research on DE, SPs, and IoT-NS. However, there is a paucity of research exploring the integration of DE and SPs for IoT-NS. Based on existing research, it is known that both DE algorithms and SPs have the effect of strengthening network security protection. Therefore, this study combines the two to construct a lightweight and high-security IoT-NS protection model. This study designs an improved SM9 encryption algorithm and iTLS SP for IoT network communication and constructs an IoT communication system with dual layer security protection of communication encryption and identity verification. The innovation of the research lies in the cancellation of certificate authentication for both encryption algorithms and SPs. The encryption algorithm uses a private key generator (PKG) to generate and distribute private keys and completes encryption and decryption through private key calculation. The SP completes the handshake protocol through dynamic password calculation. This improved encryption and identity authentication mechanism not only enhances network security but also increases communication speed and occupies fewer resources.

The research content mainly consists of five sections. Section I is the introduction, which analyzes the research achievements in IoT-NS and briefly describes the proposed IoT-NS protection model. Section II is based on the algorithm and mechanism of the improved SM9-iTLS IoT-NS system. Section III tests the research model. Section IV discusses the experimental results. Section V summarizes the research findings.

II. Methods and Materials

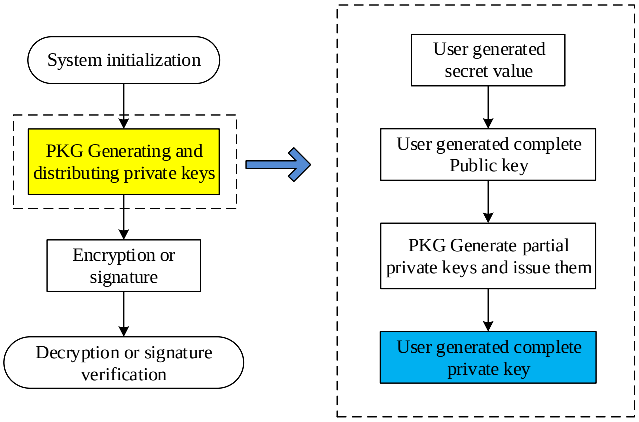
The SM9 encryption algorithm uses highly secure asymmetric encryption technology, but the certificate mechanism of SM9 is prone to vulnerabilities. This study proposes an SM9 algorithm for certificate free encryption and signature. In addition, a lightweight TLS communication protocol has been introduced and optimized, using dynamic keys in the handshake protocol to enhance the security of IoT information transmission through identity authentication. This study combines the improved SM9 encryption algorithm with iTLS SP to construct a secure and low-latency IoT network system [16].

A. Design of Improved SM9 Encryption Algorithm

The identity-based cryptography (IBC) system is a cryptographic technique that facilitates the deployment of asymmetric cryptographic systems. SM9 is a cryptographic algorithm in IBC. SM9 mainly includes encryption, key encapsulation, key exchange, and digital signature. The logic of SM9 utilizes the Abel group discrete logarithmic difficulty formed by the points of elliptic curves over a finite field to achieve encryption, decryption, and digital signature [17-18]. The cracking difficulty of the 3072-bit factorization algorithm is equivalent to that of the 256-bit elliptic curve algorithm, indicating that the SM9 encryption algorithm has sufficiently high security. The PKG of SM9 only generates decryption private keys and uses identity information as the public key, which is beneficial for forming lightweight network encryption. However, this form of encryption that completely entrusts the key to a third party is vulnerable to network attacks. Therefore, this study improves SM9 by designing a certificate-free encryption and signature-based SM9 encryption algorithm. In improving SM9, user public keys are no longer verified through certificates but are generated and distributed using a key generation center, which can improve the network security of IoT devices [19]. In the certificate free encryption SM9 algorithm, the encryption process is completed using two parts: a public key and user identity, while the user decryption operation is decrypted using the generated key. The PKG in improved SM9 calculates the decryption private key for the encryption task. The calculation formula for decrypting the private key is Eq. (1).

$$sk_{SM9} = s(Hash(ID \| hid) + s)^{-1} P_2 \tag{1}$$

In Eq. (1), sk_{SM9} is the decryption private key, and P_2 is the generator of the addition group G_2. PKG calculates and decrypts the private key, and the complete encryption and decryption process is shown in Fig. 1.



System initialization
PKG Generating and distributing private keys
Encryption or signature
Decryption or signature verification
User generated secret value
User generated complete Public key
PKG Generate partial private keys and issue them
User generated complete private key

Fig. 1. The process of PKG calculation and decryption of private keys and complete encryption / decryption.

In Fig. 1, the improved SM9 first performs system initialization, using multiplication group G_1, addition group G_2, and addition group G_2 of prime number q order, and then generates the distributed private key sk_{SM9} by PKG. The improved SM9 is encrypted based on the private key sk_{SM9}, and the encryptor completes the encryption through user ID and the public key calculated by ID. The user calculates the decrypted private key through the private key sk_{SM9} for decryption. The calculation formula for decrypting sk_{SM9} by the user is Eq. (2).

$$sk_{SM9-CLE} = x_{ID}^{-1} s(Hash(ID \| PK \| hid) + s)^{-1} P_2 \tag{2}$$

In Eq. (2), $sk_{SM9-CLE}$ is the decryption private key calculated by the user. P_2 is the generator of the additive group G_2. $Hash$ is the decryption private key generated by the user. x_{ID} is a random value. hid represents the user's key. ID represents the user's identity. s is the primary signature private key of PKG. PKG calculates the public key in the encrypted information based on the user's identity, and the calculation of the public key is Eq. (3).

$$PK = (x_{ID} P_1, x_{ID} P_{pub-e}) \tag{3}$$

In Eq. (3), PK is the public key, which is completely public, and P_1 is the generator of the additive group G_1. After receiving the public key, the sender encrypts the ciphertext based on the public key and user identity. After receiving the ciphertext, the user decrypts it through calculation to obtain the plaintext. The most important thing in decryption is to verify whether the packaging information of the encrypted calculation is consistent with the packaging information of the decrypted calculation. If they are not consistent, decryption cannot be performed. The expression to determine whether the encapsulated information is consistent is Eq. (4).

$$\begin{aligned} w' &= e(C_1, SK) \\ &= e(rx_{ID}(h_{ID}+s)P_1, x_{ID}{}^{-1}s(h_{ID}+s)^{-1}P_2) \\ &= e(P_1,P_2)^{r(h_{ID}+s)x_{ID}x_{ID}{}^{-1}}s(h_{ID}+s)^{-1} \\ &= e(P_1,P_2)^{rs} \\ &= g^r \\ &= w \end{aligned} \tag{4}$$

In Eq. (4), w and w' are the encapsulated information for encryption and decryption calculations. C_1 is ciphertext. The improved SM9 algorithm without certificate encryption has an encapsulation mechanism that can meet the IND-CCA security definition and avoid internal and external attacks in terms of security. In addition, when internal and external adversaries have attack advantages, the algorithm can use the advantages of the adversary to solve difficult problems, indicating that the improved SM9 with certificate free encryption has extremely high security. The data integrity and source verification in IoT data transmission are improved through certificate free signature algorithms, which maintain the computational speed of the SM9 encryption algorithm while ensuring the security of DE to better build lightweight IoT. The calculation of the private key of the certificate free signature algorithm is Eq. (5).

$$sk_{SM9} = s(Hash(ID \| hid)+s)^{-1}P_1 \tag{5}$$

In Eq. (5), PKG uses generator P_1 to calculate the private key. The formula for decrypting sk_{SM9} by the user is Eq. (6).

$$sk_{SM9-CLS} = x_{ID}^{-1}s(Hash(ID \| PK \| hid)+s)^{-1}P_1 \tag{6}$$

In Eq. (6), the user uses the generator P_1 to calculate the decryption private key. The signer signs by transmitting information and the decryption private key $sk_{SM9-CLE}$ calculated by the user. The verifier verifies the signature using the public key and user identity calculated by PKG, and the calculation expression of the public key is Eq. (7).

$$PK = (x_{CD}P_2, x_{ID}P_{pub-s}) \tag{7}$$

The most important thing in signature verification is to verify whether the bilinear pairing results are consistent. If they are the same, it means the signature verification is successful. The expression to determine whether the bilinear pairing results are consistent is Eq. (8).

$$\begin{aligned} w &= u*t \\ &= e(S,P)*g^h \\ &= e(P_1,P_2)^{\frac{l*x*s(h1+s)}{(h1+s)x}}*e(P_1,P_2)^h \\ &= e(P_1,P_2)^{l*s+h*s} \\ &= e(P_1,P_2)^{(l+h)s} \\ &= e(P_1,P_2)^{rs} \\ &= g^r \end{aligned} \tag{8}$$

In Eq. (8), the digital signatures are (h,S), $u=e(S,P)$, $t=g^h$, and $g=e(P_1,P_{pub-s})$. In terms of security, the improved SM9 without certificate signature adopts a step-by-step protocol to complete the verification. The flowchart for proving distribution conventions is shown in Fig. 2.

A2

Fig. 2. The process of proving distribution conventions.

In Fig. 2, the distribution specification sets an attacker A, as well as challenger B of A and challenger C of B. C launches an attack on B, B launches an attack on A, and A responds to B's attack. B utilizes A's response to challenge C, while C utilizes B's attack advantage to solve the q-SDH problem. The improved SM9 algorithm reduces the proof of unforgeability to solving the q-SDH problem to demonstrate the strong security of the algorithm. During the attack, the hash function constructed attack models for two attackers A1 and A2. Due to the forging signatures that can allow attackers to solve q-SDH mathematical problems, which are unsolvable, A1 cannot complete the attack. Similarly, forging signatures can solve the BDHI problem, which is also unsolvable, and A2's attack is also not feasible. Therefore, the improved SM9 without certificate signature is secure and reliable. The formula for forging signatures for A1 and A2 is Eq. (9).

$$\begin{cases} h = H_2(M \| w)S = (r-h)\dfrac{s}{x(h_*+s)}P_1 \\ h' = H_2'(M \| w)S' = (r-h')\dfrac{s}{x(h_*+s)}P_1 \end{cases} \tag{9}$$

In Eq. (9), x is a random unknown number. Challenger C in A2 calculates the solution to the BDHI problem as $e(P_1,P_2)^{1/x}$. The overall structure diagram of the improved certificate free encryption and signature SM9 algorithm is shown in Fig. 3.

In Fig. 3, the improved SM9 encryption algorithm key system structure includes five layers: business processing layer, password service layer, user key layer, PKM key layer, and data layer. This study improves the yellow section, including encryption and signature algorithms, key generation methods, and PKM calculation methods.

B. Construction of IoT-NS System Based on Improved SM9-iTLS

DE focuses on data protection, even if attackers obtain data, they cannot interpret the content of the data. The SP in a trusted network focuses on the rules of communication between devices, and communication can only be established based on these rules. This study integrates DE and SP to jointly build a more secure IoT communication network. IoT devices typically have low protection capabilities and are prone to interception and eavesdropping. This study introduces a lightweight TLS protocol to enhance network security [20]. The standard TLS protocol necessitates the authentication of certificates. In the case of a considerable number of IoT devices with limited computing capabilities, it requires a greater bandwidth, memory, and computational resources, which consequently increases network latency. Therefore, this study designs an improved iTLS protocol to ensure communication efficiency and further increase network security. The device establishes ecure communication throsugh a handshake protocol, and the handshake protocol of iTLS is shown in Fig. 4.

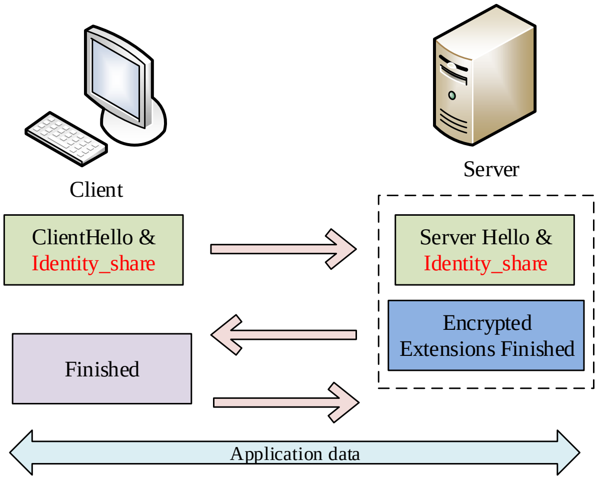

Fig. 4. Completed handshake protocol process of iTLS.

In Fig. 4, an Identity share is added between the client and server to perform key exchange, and a shared key is established through this exchange mechanism. The server extends through Identity share and can provide multiple key exchange parameters, from which the server selects a key for negotiation. This approach increases the flexibility and security of the protocol. In addition, the entire handshake process of iTLS does not require certificate authentication, reducing a significant amount of authentication time. The calculation of the shared key by the server is Eq. (10).

$$shared\_secret = yEK_C \,\|\, e(EK_C + H(ID_C), yP_{pub} + sk_S) \tag{10}$$

In Eq. (10), ID_C represents the identity of the client. EK_C is the temporary public key of the client. P is the generator. H is a hash function. sk_S is the private key generated by KGC on the server. y is the temporary private key of the server. The handshake key in the shared key is obtained using a key derivation function, and the formula for the key derivation function is Eq. (11).

$$handshake\_secret = \text{HKDF-Extract}(ek, shared\_secret) \tag{11}$$

In Eq. (11), HKDF is the key derived function. The client uses the server ID_S and key provided by ServerHello to calculate the shared key, and the expression for the shared key is Eq. (12).

$$shared\_secret = xEK_S \,\|\, e(xP_{pub} + sk_C, EK_S + H(ID_S)) \tag{12}$$

In Eq. (12), EK_S is the temporary public key of the server, and sk_C is the private key generated by KGC for the client. This study aims to enhance protocol compatibility and reduce latency. A compatibility design is adopted to enable iTLS to establish a connection with TLS1.3. The 0-RTT mode of TLS1.3 is introduced, and dynamic keys (IDEK) are used in the 0-RTT mode to improve security. The expression for calculating IDEK on the client side is Eq. (13).

$$IDEK_C = \text{HKDF-Extract}(0, e(sk_C, H(ID_S))) \quad (13)$$

In Eq. (13), the client uses server identities ID_S and sk_C to calculate $IDEK_C$. The formula for calculating IDEK on the server is Eq. (14).

$$IDEK_S = \text{HKDF-Extract}(0, e(H(ID_C), sk_S)) \quad (14)$$

Both parties perform a 0-RTT handshake using the generated dynamic key to complete data decryption. The compatibility design of ITLS's 0-RTT handshake is shown in Fig. 5.

In Fig. 5, the protocol enhances compatibility with TLS1.3 by adding key_share extension and handshake negotiation with TLS1.3. In the 0-RTT mode, the client has added the early_data extension to prove that it will carry an Application data *. The protocol calculates dynamic passwords to protect the security of 0-RTT data, and the server determines whether to perform a handshake based on the properties of bilinear pairs. The bidirectional pair expression is Eq. (15).

$$e(sk_C, H(ID_S)) = e(H(ID_C), H(ID_S))^s = e(H(ID_C), sk_S) \quad (15)$$

The server and client complete handshake negotiation through the early_data extension of Eq. (15), achieving secure connection of IoT devices. This study improves the SM9 algorithm and TLS protocol, integrating the encryption algorithm and SP to construct an IoT-NS system based on the improved SM9-iTLS, as shown in Fig. 6.

Fig. 5. Compatibility design of ITLS's 0-RTT handshake mode.

In Fig. 6, the IoT device is connected to the device service enterprise and transmits communication data. The improved SM9 key system distributes keys to IoT devices and device service enterprises. During the communication process, IoT devices use SM9 keys to negotiate symmetric keys and then encrypt data based on the symmetric keys to decrypt information for device service enterprises. Using the iTLS protocol for device authentication in communication further enhances the security of information transmission. The SM9 key system includes a registration center and a key generation center PKG, mainly responsible for user registration and SM9 key generation and distribution. The IoT network system utilizes SM9 encryption technology and iTLS protocol to achieve identity authentication and encrypted data exchange.

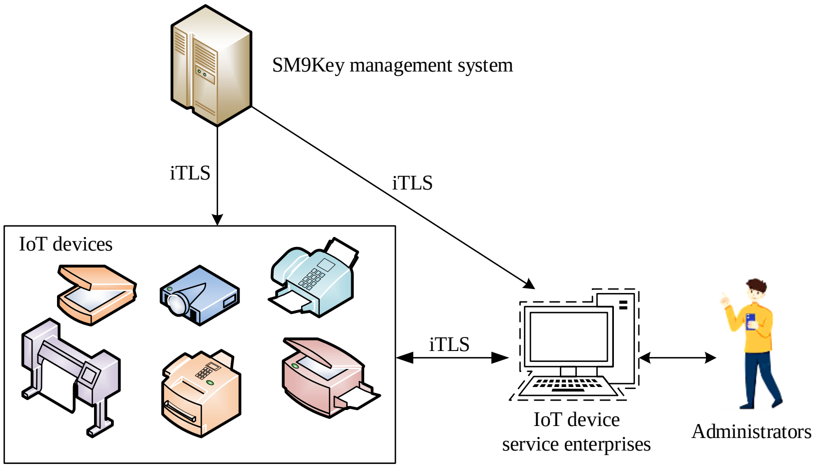

Fig. 6. IoT security management system based on improved SM9 encryption algorithm and iTLS SP.

III. Results

To verify the performance of the system, relevant experiments were conducted in this study. The experiment first conducted a comparative experiment on the improved SM9 encryption algorithm to test its computational efficiency. Then, comparative experiments were conducted on iTLS to test the network latency under iTLS SP. Finally, experimental analysis of the IoT-NS system based on improved SM9-iTLS showed that the proposed IoT-NS system not only enhanced security, but also could respond quickly under the improved encryption algorithm and SP, without causing IoT communication burden.

A. *Experimental Environment and Parameter Settings*

This study used the MIRACL library to test the improved SM9 encryption algorithm. The test code was written on ESP32, and the size of the encrypted information was selected as 120 bits. The elliptic curve of SM9 selected 256 bits to construct an addition group, with two addition groups of 64 and 128 bytes in length. 120 repeated tests were conducted to calculate the average running time of the algorithm. This study implemented SP iTLS experimental analysis in the WolfSSL library written in C language, with security levels of 112 and 128 bit. All experiments selected TLS_AES_128_CCM_SHA256 as the hash function and symmetric encryption cipher suite. The computer used in the experiment had 16GB of memory and an Intel i7 8700 processor. Table I shows the detailed parameter settings for each encryption algorithm in ESP32.

The experiment selected RSA3072, SM9, and improved SM9 for comparative testing, and TLS1.3 and iTLS with RSA, ECC, and 0-RTT authentication modes were used for comparative testing. A comparative experiment was conducted between the IoT-NS system based on ECC-iTLS, RSA-TLS, and ElGamal TLS and SM9 iTLS. The evaluation indicators used encryption, decryption, signature, and signature verification time as the computational efficiency evaluation indicators of encryption algorithms. Communication connection delay was used as an indicator of SP connection efficiency. Traffic overhead was utilized as an evaluation indicator for network resource occupancy.

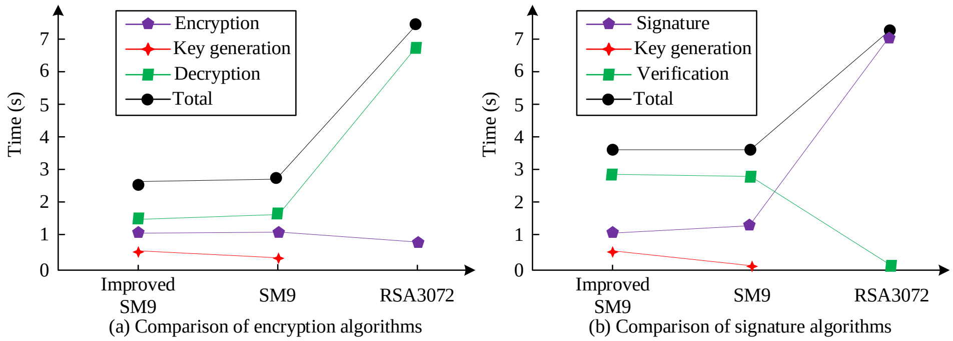
B. Analysis of Improved SM9 Computing Efficiency and iTLS Communication Delay

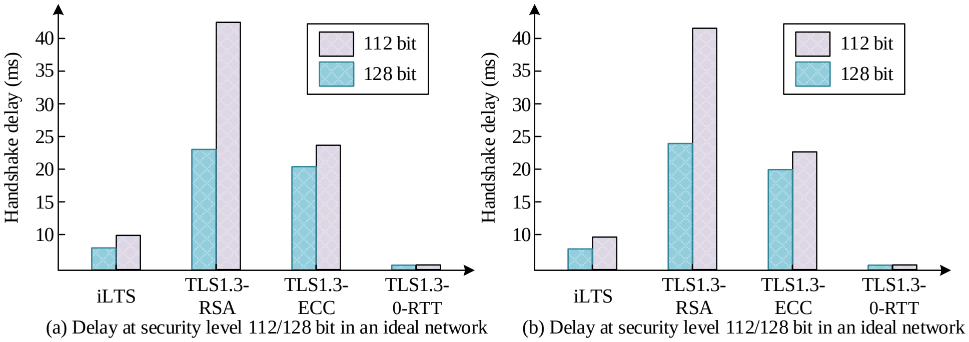
The experiment first compares the improved SM9 algorithm. The calculation time results for the complete encryption solution, encryption process, and complete signature and verification process are shown in Fig. 7.

In Fig. 7 (a), the key generation time of the research algorithm is 0.39s, the encryption time is 1.02s, the decryption time is 1.30s, and the total time is 2.71s. The encryption time of SM9 is lower than that of the improved SM9, but the decryption time and key time are longer, with a total time of 2.74s, which is higher than SM9. The key generation time of RSA3072 is lower than that of the research algorithm, but the decryption time is 6.78s, and the total calculation time is 7.31s. In Fig. 7 (b), the total time for key generation, signature, and signature verification of the research algorithm is 3.74s, and the total time for SM9 algorithm is 3.76s. The signature verification time of RSA3072 is the lowest, with a minimum value of 0.06s, but the key generation time takes 6.88s, resulting in a total time of 6.94s. The experiment sets up an ideal network with zero delay and no packet loss under wireless broadband, and tests the handshake delay of iTLS protocol and TLS1.3 protocol at security levels of 112-bit and 128-bit, as shown in Fig. 8.



(a) Comparison of encryption algorithms (b) Comparison of signature algorithms

Fig. 7. Comparison of encryption and signature verification times of algorithms in ESP32.



(a) Delay at security level 112/128 bit in an ideal network (b) Delay at security level 112/128 bit in an ideal network

Fig. 8. Full handshake delay for iTLS and TLS 1.3 under ideal network conditions.

In Fig. 8 (a), when the security levels are 112-bit and 128-bit, the TLS1.3 protocol delay in the 0-RTT mode is the lowest, with the lowest values of 1.4ms and 1.5ms. The delay of iTLS is 6.4ms and 9.9ms respectively, the delay of TLS1.3-RSA is 23.3ms and 43.9ms, and the delay of TLS1.3-ECC is 21.5ms and 23.7ms. Fig. 8 (b) shows the results of the second group of experiments. The delay of iLTS is 6.7ms at 112-bit security level and 9.7ms at 128-bit security level. The delay of iLTS is slightly increased compared to TLS1.3-0-RTT protocol, which is also improved by TLS, but it is still at a low latency level.

C. Performance Analysis of IoT-NS System Based on Improved SM9-iTLS

This study compares the improved IoT-NS system of SM9-iTLS with the aforementioned IoT security system. The network traffic overhead of each system under 112-bit and 128-bit security levels is shown in Fig. 9.

In Fig. 9 (a), when the security level is 112-bit, the network traffic overhead of the research system is the lowest, with a minimum value of 794 bytes, ElGamal-TLS of 5731 bytes, ECC-iTLS of 2788 bytes, and RSA-TLS of 4312 bytes. In Fig. 9 (b), when the security level is 128-bit, the network traffic overhead of the research system is the lowest, with a minimum value of 1127 bytes, ElGamal-TLS of 6395 bytes, ECC-iTLS of 4623 bytes, and RSA-TLS of 5018 bytes. In summary, the proposed IoT-NS system has the lowest network traffic overhead in tests at different security levels. The experimental results of the complete encryption and decryption time and signature verification time of each system are shown in Fig. 10.

In Fig. 10 (a), the total time for key generation, encryption, and decryption of SM9-iTLS is 3.63 seconds. The total time for ElGamal-TLS is 9.27, ECC-iTLS is 5.33 seconds, and RSA-TLS is 7.31 seconds. In Fig. 10 (b), the total time for key generation, signature, and verification of SM9-iTLS is 3.65 seconds. The total time of ElGamal-TLS is 10.97 seconds, ECC-iTLS is 9.27 seconds, and RSA-TLS is 11.37 seconds. Therefore, the IoT-NS system based on improved SM9-iTLS can ensure good efficiency in information encryption, decryption, and identity authentication during secure communication. To further test and study the performance of the system, comparative experiments are conducted on system communication delay under different network delays, network bandwidth, and packet loss rates, as shown in Fig. 11.

Fig. 11 (a) shows the experimental results under a network delay of 1-256ms. Under different network delays, SM9-iTLS has the lowest communication delay, while ElGamal-TLS has the highest communication delay. Fig. 11 (b) shows the experimental results under different network packet loss rates. When the network packet loss rate is below 15%, the communication delay of each system remains around 0, but as the packet loss rate increases, the communication delay continues to increase, especially ECC-iTLS, which shows exponential growth. When the packet loss rate is 25%, the communication delay of SM9 iTLS is 317ms, RSA-TLS is 5879ms, ElGamal-TLS is 1752ms, and ECC-iTLS is 11674ms. In Fig. 11 (c), under different network bandwidths, the communication delay of SM9-iTLS is the lowest, while ECC-iTLS has the highest communication delay. In summary, under different network quality communication environments, the SM9-iTLS IoT-NS system has the fastest response speed and the least burden on communication.

IV. Discussion

This study compared and analyzed the computational efficiency and communication delay of the improved SM9 encryption algorithm and iTLS SP, and conducted comparative tests on the performance of the IoT-NS system based on the improved SM9-iTLS. The results of this study showed that the SM9 encryption algorithm took a total of 2.71s for key generation, encryption, and decryption, while the total time for key generation, signature, and verification was 3.74s, which is more efficient than other encryption algorithms. This result was similar to the research conclusion of Jing's team on improving the addition and multiplication sets of the SM9 algorithm [21]. The improved SM9 encryption algorithm not only had higher security but also improved computational efficiency. In the comparative experiment of iTLS, at the security levels of 112 and 128 bits, the latency of iTLS was 6.4ms and 9.9ms, slightly higher than TLS1.3-0-RTT, but at a low latency level. This result was similar to the conclusion of Zhang's team in designing SP based on La-TLS network [22]. Therefore, the improved SP could further enhance network security without increasing communication burden. Finally, in the performance analysis of the IoT-NS system based on improved SM9-iTLS, the network traffic overhead of SM9-iTLS was 794 and 1127 bytes at security levels of 112 and 128 bits, respectively. The total time for key generation, encryption, and decryption was 3.63s. The total time for generating, signing, and verifying dynamic keys was 3.65s. When the packet loss rate was 25%, the communication delay of SM9-iTLS was 317ms. Under different conditions, the network traffic overhead, encryption and decryption time, and latency of the research system were superior to other systems. This was similar to the conclusion obtained by Wang's team in the lightweight communication network based on SM9 and TLS improvements designed in 2024 [23]. This result indicated that the IoT-NS system based on improved SM9-iTLS not only enhanced the security capability of IoT device communication but also enhanced the efficiency of network communication.

V. Conclusion

The development of digitalization has brought about an increasing number of IoT devices, but these devices often have weaker self-protection capabilities. This study established a lightweight IoT-NS system by improving the SM9 encryption algorithm and combining iTLS SP with IoT devices. The experimental data demonstrated that the IoT-NS system, based on an enhanced SM9-iTLS, exhibited notable optimization in network resource utilization, computational efficiency, and communication delay, while simultaneously enhancing network security. The research system exhibited superior performance compared to other IoT-NS systems. Therefore, in situations where IoT device resources were limited, using the SM9 encryption algorithm to generate and distribute keys using PKG and the iTLS communication protocol to use dynamic keys for identity authentication, could improve the security of IoT networks. In practical environments, there are significant differences in the configuration of IoT devices. Some devices have strong computing power, but most devices have low computing power. In special environments, the time cost may be high and cannot meet the communication needs. Therefore, improving the hardware environment is the direction of later research. For example, despite the SM9 algorithm's robust security, the public key appends a sequence of inconsequential digits to the initial one, necessitating additional storage space and communication overhead. This is a problem that exists in certificate free systems, and further research can be conducted to improve it. The KGC of a single trust domain network is set by the network manager. However, in multi-trust domain networks, a single KGC greatly limits the scalability of iTLS. Future research will focus on studying cross domain authentication schemes based on identity passwords.

Application and Effectiveness of Improving Retrieval Systems Based on User Understanding in Smart Archive Management Systems

Chao Yan
General Administration Office, YanCheng Polytechnic College, Yancheng, 224005, China

Abstract—**In traditional archive management systems, keyword-based retrieval systems often fail to meet users' personalized and precise retrieval needs. To solve this problem, a knowledge graph is first constructed using bidirectional long short-term memory networks and conditional random fields and combined with user understanding-based semantic retrieval to obtain an improved personalized retrieval system. The research results show that the improved personalized retrieval system has significantly better retrieval accuracy and recall rate than traditional retrieval systems. The improved personalized retrieval system has retrieval accuracy rates of 90.24%, 89.65%, 87.52%, 96.33%, and 95.18% for students, civil servants, demobilized soldiers, law enforcement personnel, and retirees, respectively, and recall rates of 89.35%, 91.57%, 89.34%, 97.54%, and 96.63%, respectively. Applying it to the smart archive management system, the accuracy of archive retrieval, personalized recommendation accuracy, response time, and user satisfaction are significantly better than conventional management systems. The improvement and introduction of personalized retrieval systems based on user understanding and knowledge graphs have achieved significant results.**

Keywords—Knowledge graph; user understanding; retrieval system; smart archive management; BiLSTM-CRF

I. INTRODUCTION

The rapid development of the information age has led to increasing attention to the Smart Archive Management System (SAMS). SAMS is a system that utilizes modern information technologies such as big data, cloud computing, the Internet of Things, artificial intelligence, etc. to intelligently manage archive information. It not only includes digital archival information input, storage, and retrieval, but also includes the protection, analysis, and utilization of archival digital resources, as well as online services and interactive functions. This system aims to improve the efficiency and quality of archive management while facilitating users to quickly and accurately obtain the required archive information. SAMS is mainly used by government agencies, enterprises, educational institutions, research institutions, archive workers, and the general public. It is responsible for managing public archives and providing public services, managing enterprise documents and commercial archives, managing academic and administrative archives of schools, and querying and utilizing archive resources. Traditional archive management methods often rely on paper documents and manual operations, which have problems such as low management efficiency and difficulties in information sharing. In the context of intelligence and automation, providing a more accurate, intelligent, and personalized retrieval system has become an important challenge for smart archive management systems. Traditional retrieval systems use keyword matching, which often makes it difficult to accurately understand the user's query intent and needs. Because relying solely on keyword matching, the system cannot understand the true intention behind the user's query, resulting in the returned results may not be accurate enough or do not meet the user's expectations. And traditional systems lack the ability for personalization. This method does not consider user behavior patterns and preferences, and cannot provide targeted search results, which cannot meet the personalized needs of different users. SAMS has replaced the old AMS because it provides a more efficient and comprehensive management approach. SAMS can improve efficiency, automate processing processes, reduce manual operations, and improve work efficiency. Meanwhile, digital archive information can be quickly retrieved, improving the speed of information acquisition. Cloud storage technology enables remote access and sharing of archival information, advanced data security technologies provide better protection of archival information, and data analysis tools can help decision-makers better understand archival information and make wiser decisions. In the context of intelligence and automation, providing a more accurate, intelligent, and personalized retrieval system has become an important challenge for SAMS [1-2]. Traditional retrieval systems use keyword matching, which often makes it difficult to accurately understand users' query intentions and needs. Therefore, providing personalized and accurate retrieval services has become particularly important for meeting the needs of users. User behavior mainly focuses on the operational behavior of users in the system. User preferences refer to the degree of user preference for the system or information, while semantic understanding is a deep understanding of user input or needs. Choosing to model user behavior is to improve the operational process and efficiency of the system. Choosing to model user preferences is for personalized recommendations and customized services. Choosing to model semantic understanding is to more accurately understand user needs and provide accurate retrieval results. The improvement of retrieval systems based on user understanding can provide users with more adaptive and personalized retrieval results by deeply understanding their query intentions and information needs, as well as modeling and analyzing their behavior patterns and preferences [3-5]. This method can be improved from multiple perspectives, including modeling user behavior, user preferences, and semantic understanding.

Knowledge graph is a structured knowledge representation method that describes the relationships between entities in the real world. Knowledge graph can provide richer and more accurate semantic information, providing strong support for personalized retrieval. By matching users' query intentions with entities and relationships in the knowledge graph, the accuracy and effectiveness of retrieval can be effectively improved [6-7]. The study utilizes bidirectional long short-term memory networks and conditional random fields to construct a knowledge graph, and combines it with user understanding-based semantic retrieval to obtain an improved personalized retrieval system. We hypothesize that combining user understanding with knowledge graph can better understand users' real needs and provide more accurate and personalized archive retrieval services. Applying the improved personalized retrieval system to SAMS will have more impact. The innovation of this study is to use Bidirectional Long Short Term Memory Network (BiLSTM) and Conditional Random Field (CRF) to construct a knowledge graph, namely BiLSTM-CRF. This system can better capture the semantic associations between queries and archives, thus achieving more intelligent and accurate retrieval results. Research has shown that the improved personalized retrieval system has significantly better retrieval accuracy and recall than traditional retrieval systems. Although significant progress has been made in many aspects of existing archive management systems and data processing frameworks, there are still several unresolved research gaps. Firstly, most existing systems lack flexibility and adaptability to meet different user needs. The current system is usually designed to be fixed and difficult to adjust according to the specific needs of different user groups, resulting in poor efficiency and effectiveness in handling cross-domain and diverse data. This limitation is particularly evident in application scenarios that require cross institutional collaboration and cross-platform integration. Secondly, there is a lack of in-depth research on the management of data bias and the handling of dynamic content changes. Although deviation detection has been preliminarily applied in some data analysis fields, its application in data archiving and long-term management is still insufficient. In addition, how to efficiently detect and adapt to changes in archived content to ensure the freshness and relevance of data remains an urgent challenge that needs to be addressed. This study aims to fill these research gaps and propose a flexible and adaptive archive management system framework that can not only dynamically adjust according to the needs of different user groups, but also effectively handle potential biases and content changes in data. By introducing advanced machine learning algorithms and dynamic update mechanisms, this study provides a new solution to improve the accuracy and fairness of data management. This will not only help improve the performance and practicality of existing systems but also promote the development of data archiving management and facilitate cross-industry and interdisciplinary data sharing and cooperation.

II. Related Work

Smart Archive Management (SAM) is a method that utilizes artificial intelligence and automation technology to improve the efficiency and quality of archive management. This technology can draw on the concepts and methods of knowledge graph and semantic retrieval to provide more intelligent and valuable archival services. Li Y proposed a cross domain recommendation method based on user preference perception and graph attention networks to improve the performance of knowledge graph recommendation systems. This method utilized a graph embedding model to obtain preference aware entity embedding, and combined preference features for personalized recommendation. It could effectively alleviate the problem of data sparsity and had good comprehensive performance, which can generate good personalized recommendation results [8]. Sui Y have constructed a model based on causal filters to improve the performance of knowledge graph question answering systems. This model utilized a data-driven approach to cause and effect interference in the relationship representation space, and disconnected other confounding factors in the knowledge embedding space through causal intervention. This method had good robustness and could effectively improve the comprehensive performance of the knowledge graph question answering system [9]. HX A et al. designed a knowledge graph model based on semantic fusion to address the issue of inaccurate semantic expression in knowledge graphs. It extracted subject entities by constructing a deep transformation model and generated candidate answer sets using dynamic candidate paths. This model could effectively solve the problem of inaccurate semantic expression in the knowledge graph, and improve the overall performance of the model [10]. Wang et al. designed a Top-k semantic aware query method based on semantic boundary perception to improve the accuracy of Knowledge Graph Star Query (KGSQ). This method utilized boundary deletion for matching with low semantic similarity, which can improve the accuracy of KGSQ [11].

User understanding can improve retrieval efficiency and accuracy, enhance user experience, and promote the development of personalized services. A deep understanding of user needs and behaviors can help improve the data analysis and processing capabilities behind retrieval systems, enabling them to provide more accurate and effective decision support, such as optimizing resource allocation and guiding policy formulation. In order to explore the impact of clarifying questions on user behavior and the ability to identify relevant information, Zou J utilized implicit interaction data and explicit user feedback to discover that high-quality clarifying questions can improve user performance and satisfaction [12].

Attention mechanisms and models such as BiLSTM can be applied to different stages of semantic retrieval tasks, such as semantic modeling correlation evaluation of queries and document sequences, to improve the accuracy and effectiveness of retrieval. Dong X et al. proposed a cross-modal graph attention method that combines recursive gated neural networks and attention mechanisms to address the semantic gap issue in data in cross-modal retrieval. This method could eliminate heterogeneous gaps between modalities, effectively solving the semantic gap problem of data in cross-modal retrieval [13]. To improve the performance of knowledge graph embedding, Dai has constructed a knowledge graph representation learning model based on generative adversarial networks, using Wasserstein distance instead of traditional divergence. Wasserstein distance could effectively solve the problem of small gradients on discrete data and improve the embedding performance of knowledge graphs [14]. Liu T and other scholars constructed a Chinese WeChat click bait dataset to detect the security of hyperlinks in online social media, and constructed a WeChat click bait detection method based on BiLSTM and multiple features, introducing attention mechanisms. This method could effectively detect bait links and had a high accuracy [15]. Hu Y et al. proposed a semantic behavior prediction method to improve the prediction accuracy of traffic participants' behavior in an autonomous vehicle. This method constructed a universal semantic representation method suitable for the driving environment and converted it into a spatiotemporal semantic map to infer the internal relationship between the two. This method had high prediction accuracy and was beneficial for solving problems under different traffic conditions [16].

In summary, many scholars have conducted research on knowledge graphs, semantic retrieval, and smart archive management, but how to combine them is an unresolved issue [17-18]. Knowledge graphs, semantic retrieval, and smart archive management are interrelated concepts and technologies, and have important application value in the fields of information management and services. Attention mechanisms, bidirectional long short-term memory networks, and semantic retrieval are interrelated and play a role in semantic modeling, correlation evaluation, and information retrieval, aiming to improve the performance and effectiveness of retrieval systems. In view of this, this study will use a bidirectional long short-term memory network to construct a knowledge graph, improve personalized retrieval systems based on user understanding and knowledge graphs, and further enhance SAMS [19-20].

III. Improvement of Retrieval Function in SAMS

To improve the performance and user experience of the retrieval system in SAMS, this study improves the personalized retrieval system based on user understanding and knowledge graph. The first step is to construct a knowledge graph and use the BiLSTM-CRF model to complete the process of entity recognition and relationship extraction in the archival field. Then, combining user understanding and knowledge graph, users' search requirements for keywords can be better understood and met from the traditional semantic retrieval level.

A. Construction of Knowledge Graph Based on BiLSTM-CRF

The knowledge graph network is a relatively structured entity semantic knowledge network used to analyze and express the objective and real world, as well as the relationships among various concepts, entities, etc. A knowledge event graph network is composed of a set of relationships between entities in different time, space, and states. This network forms a new semantic based knowledge network model by describing the interrelationships between concepts and entity concepts [21-22]. Fig. 1 shows the process of constructing a knowledge graph.

Fig. 1 shows the knowledge graph constructed in this study, In Fig. 1, the process of constructing a knowledge graph, it is necessary to first obtain data, transform the data into knowledge, then fuse the knowledge, and provide knowledge graph visualization services. Finally, apply based on knowledge graph. However, this study designs and models the ontology hierarchy, relationships, and attributes of archives. Among them, attribute structure refers to the organizational description of archive metadata and content, clarifying the characteristics and values of each archive item. By establishing a correct ontology hierarchy model, relevant knowledge can be extracted and analyzed, and clear semantic descriptions and relationship explanations can be provided for knowledge concepts within the domain. The data sources of archival knowledge include data extracted from existing business systems and other fields, and the data is divided into institutional, semi-structured, and non-manual structured.

From the knowledge framework of archive ontology language, it can be seen that entity recognition is required for the institutions, characters, files, time, location, etc. of archive ontology language. The language relationships of archive ontology mainly include synonyms, antonyms, context, subclasses, and other relationships [23]. For entity recognition, this study intends to select the BiLSTM-CRF model for extracting relational data and adopt a distributed relational data extraction technology based on remote data supervision to reduce the model's dependence on manually annotated data.

Next, construct the BiLSTM-CRF model. Recurrent Neural Network (RNN) is a type of neural network that performs temporal processing on sequence data. Time series data refers to the data collected at different time points, which reflects the situation or degree to which something, phenomenon, etc. occurs over time. Long Short-Term Memory (LSTM) networks are a new type of RNN that aims to overcome the problems of gradient loss and gradient explosion in long sequence learning. Compared with RNN, LSTM has better performance over longer time series [24]. LSTM is composed of three parts: input gate, forgetting gate, and output gate, achieving protection and control of information. Fig. 2 shows the LSTM's basic structure.

Fig. 1. The construction process of knowledge graph.

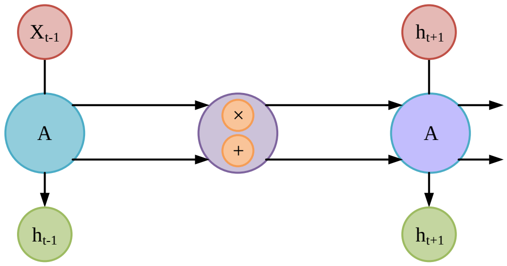

Fig. 2. The basic structure of LSTM.

BiLSTM is an RNN model that can process sequence data and capture long-term dependencies within the sequence. By running both a forward LSTM and a backward LSTM simultaneously, BiLSTM can utilize contextual information to better understand and encode input sequences. CRF refers to the conditional probability distribution modeling of another set of output variables given a set of input random variables. Its characteristic is to perform under the premise that the output variable satisfies the Markov random field [25].

The BiLSTM-CRF model is a neural network model used for sequence annotation tasks. It combines BiLSTM and CRF to simultaneously consider the dependency relationship between contextual information and labels. By utilizing the BiLSTM-CRF model, the process of entity recognition and relationship extraction in the archival field can be completed, as shown in Fig. 3.

After completing entity recognition and relationship extraction in the archival field, it is also necessary to store and retrieve the knowledge graph. Knowledge graphs are generally accessed through graph databases. After constructing and storing the enterprise archival knowledge graph in the graph database, it is necessary to combine advanced graph data retrieval technology to improve and enhance the efficiency of data query and processing in the enterprise archive knowledge graph. Its purpose is to provide support for achieving massive real-time dynamic information queries and data inference analysis.

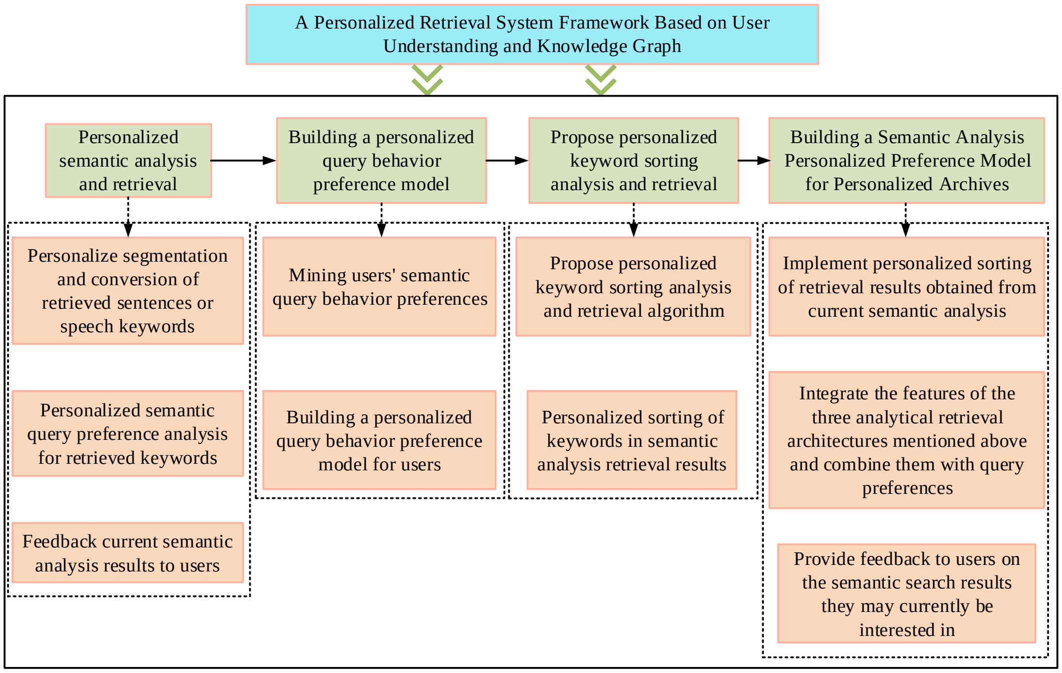
B. Improvement of Personalized Retrieval System Based on User Understanding and Knowledge Graph

Traditional search engines mainly provide search results based on keyword matching, neglecting users' personalized needs and contextual information. However, users' search behavior and preferences are diverse, and traditional methods often find it difficult to accurately understand and meet these personalized needs. With the rapid growth of the internet scale and information content, it has become very important to better understand the semantic relationship between users and information [26]. Fig. 4 is a personalized retrieval system framework based on user understanding and knowledge graph.



A Personalized Retrieval System Framework Based on User Understanding and Knowledge Graph
Personalized semantic analysis and retrieval
Building a personalized query behavior preference model
Propose personalized keyword sorting analysis and retrieval
Building a Semantic Analysis Personalized Preference Model for Personalized Archives
Personalize segmentation and conversion of retrieved sentences or speech keywords
Personalized semantic query preference analysis for retrieved keywords
Feedback current semantic analysis results to users
Mining users' semantic query behavior preferences
Building a personalized query behavior preference model for users
Propose personalized keyword sorting analysis and retrieval algorithm
Personalized sorting of keywords in semantic analysis retrieval results
Implement personalized sorting of retrieval results obtained from current semantic analysis
Integrate the features of the three analytical retrieval architectures mentioned above and combine them with query preferences
Provide feedback to users on the semantic search results they may currently be interested in

Fig. 4. A personalized retrieval system framework based on user understanding and knowledge graph.

From Fig. 4, it can be seen that in the personalized retrieval system framework, the first step is to conduct personalized semantic analysis retrieval. The second step is to build a personalized query behavior preference model. The third step is to propose a personalized keyword sorting analysis retrieval algorithm. The last step is to build a semantic analysis personalized preference model for personalized archives. Integrating the features of the three analytical retrieval architectures mentioned above, combining them with query preferences, to achieve personalized sorting of the retrieval results obtained from current semantic analysis, and providing feedback to users on the semantic retrieval results they may be interested in at present.

Traditional personnel file retrieval and query engines do have some limitations in providing personalized personnel file services. It is usually based on keyword matching and cannot fully understand users' personalized needs and contextual information [27]. Based on this, this study models personal information, enterprise information, and other information in the personnel information system based on user preference for personnel file query and data mining methods, achieving the retrieval of personal information in the personnel information system. Fig. 5 shows the mining framework operation process of user query preferences.

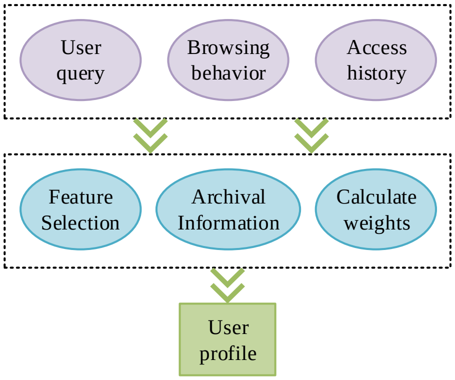


Fig. 5. The mining framework operation process of user query preferences.

In Fig. 5, the mining of user query preferences mainly includes seven steps, aiming to accurately analyze and represent user query preferences. These steps help to understand users' interests and preferences, and provide personalized search results, recommendations, and services based on these preferences.

The user query preference model is an algorithm model that describes the degree of interest of users in different types of archives. Each file object has a weight value that represents the user's level of interest in the file type. The higher the weight, the more interested the user is in this type of file [28]. This study uses probability models to compare and express user preferences for queries. It puts the file related data and file information related data from the user preference database into the user preference database, and generates a user preference probability distribution model for queries through analysis. w_i is defined as a weighting factor, which represents a user's preference for querying type i and file c_i in a short period of time. The calculation process is Eq. (1).

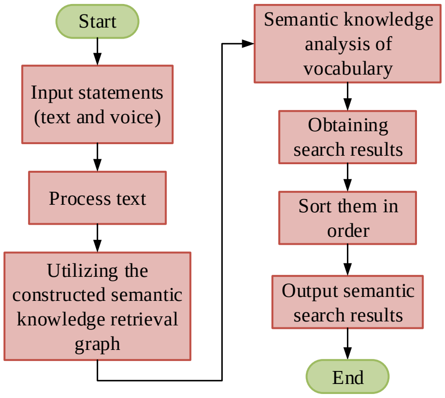
$$w_i = AF\left(c_i, \frac{x+1}{T}\right) \tag{1}$$

In Eq. (1), $AF\left(c_i, \frac{x+1}{T}\right)$ is used to describe the average value of file type c_i that users browse during period T. x represents the number of files browsed within T. By solving the weights of all file types in order, the user's query preference vector based on the file category can be obtained. The query preference characteristics of users are not fixed, and the required file types may also change under different job positions. So, after establishing a user's query preference model, there is a need for an algorithm that can update according to the user's query preferences. By setting an appropriate forgetting time, the problem of user query preference transfer can be solved. This study proposes a new user preference model based on forgetting factor using the Ebbinghaus memory curve. The expression is Eq. (2).

$$F(x) = \exp\left(-\frac{\log_2(t)}{f}\right) \tag{2}$$

In Eq. (2), t represents the time interval between the current date and the query preference creation date. f represents the half-life, which means that half of the time the user forgets will last for at least f days. Then, the user's query preference can be calculated based on the probability model and the user's query preference model [29].

Traditional keyword based retrieval methods cannot understand and meet users' retrieval needs for keywords at the traditional semantic level. Therefore, this study proposes a personalized retrieval method based on knowledge graph, which can better understand and meet users' search requirements for keywords from the traditional semantic retrieval level. Fig. 6 shows the semantic personalized retrieval process of archives based on knowledge graph.



Start
Input statements (text and voice)
Process text
Utilizing the constructed semantic knowledge retrieval graph
Semantic knowledge analysis of vocabulary
Obtaining search results
Sort them in order
Output semantic search results
End

Fig. 6. The semantic personalized retrieval process of archives based on knowledge graph.

In Fig. 6, in the process of semantic personalized retrieval of archives based on knowledge graph, the first step is to input statements, including two types: text and speech. It is necessary to convert speech into text and then process the text. Afterwards, the constructed semantic knowledge retrieval graph can be used for semantic knowledge analysis of vocabulary. Then the search results are obtained and sorted to output semantic search results [30]. If the retrieval vocabulary is not included in the archive knowledge graph, semantic expansion and semantic mapping of the vocabulary are required, and the expanded retrieval vocabulary and the original retrieval vocabulary are added to synonymous concepts and segmentation specialized dictionaries respectively. If the current search term does not exist in the synonym dictionary, semantic similarity needs to be calculated, as shown in Eq. (3).

$$Sim(c,w)=\beta * Sim\_(c,w)+(1-\beta)* Sim\_2(c,w) \quad (3)$$

In Eq. (3), $Sim(c,w)$ is used to describe the minimum editing time distance between two words, calculated as shown in Eq. (4).

$$Sim_1(c,w)=1-\frac{ED(c,w)}{MLen(c,w)} \quad (4)$$

In Eq. (4), $Sim_2(c,w)$ is used to describe the distance from the editor, meaning the maximum semantic cosine length between and $\cos(e_c,e_w)$ represents the maximum semantic cosine distance between two words. Its similarity is equal to the distance between two synonyms and the embedded cosine similarity, as shown in Eq. (5).

$$Sim_2(c,w)=\cos(e_c,e_w) \quad (5)$$

In Eq. (5), e_c and e_w are embedded representations of words c and w. Then, by generating and constructing the inference graph of archival ontology knowledge, an archival knowledge inference system was constructed [31]. Through the Jena inference machine in the archive, semantic inference can be performed on the existing hierarchical knowledge relationships in the document. This enables semantic inference of the existing upper and lower knowledge relationships in archives, as well as better analysis and retrieval of the upper and lower semantics of documents. A key challenge faced by the system in the process of data archiving and management is how to handle potential biases in user data and changes in archive content. To effectively address these issues, the system has introduced a bias detection algorithm that can identify potential biases in the data. For example, in user-generated content, the system can identify anomalies or biases by analyzing data distribution and usage patterns. Through machine learning models, the system can automatically label these potential biased data and make corrections as necessary. This not only helps maintain the objectivity of data, but also improves the accuracy of data analysis results. The study selected 100 different types of individuals aged 18-45 for the experiment, all of whom were from the local archives bureau. The selected individuals were all from different professions and had significant occupational differences. The participants were divided into five groups, with 20 people in each group. Information was collected through a questionnaire survey. In the experiment data collection of this study, the network data are all from the Internet, and the files are stored separately in the database and web pages; the file data is provided by the local archives bureau, which scans paper files, converts them into PDF format electronic files, and saves them in a MySQL database.

IV. Application and Effect Analysis of Improving Retrieval System on SAMS

To verify the performance of the improved retrieval system, the performance of the knowledge graph based on BiLSTM-CRF and the retrieval performance of the preference semantic retrieval model based on user understanding are first analyzed, and the improved retrieval system was applied to the smart archive management system.

A. *Performance Analysis of Improved Personalized Retrieval System Based on User Understanding and Knowledge Graph*

In order to verify the performance of personalized retrieval systems based on user understanding and knowledge graph improvement, knowledge graph, user understanding, and improved personalized retrieval systems were analyzed in sequence. In the experimental data collection of this study, network data was sourced from the Internet, and archives were stored separately in databases and web pages. The piece of data is provided by the local archives bureau, which scans paper files, converts them into electronic files in PDF format, and saves them in a MySQL database. The file data mainly includes retrieval information for specific occupational groups. Table I shows the experimental system settings.

The experimental setup introduced in Table I can meet the experimental analysis of user understanding, knowledge graph, and retrieval system.

For the improvement of user understanding of the smart archive management system, specific occupational groups such as students, civil servants, demobilized soldiers, law enforcement personnel, and retirees were selected for application and effect analysis. These occupational groups represent users in society with different information needs and backgrounds in using archive management systems. Students need academic resources such as historical data and scientific research data, civil servants and law enforcement personnel need policy documents, laws and regulations, work files, etc. Demobilized soldiers and retirees need relevant welfare policies, personal service records, and other information. They need to obtain academic resources, research data, policy documents, welfare policies, laws and regulations, and other information from archives. Obtain information directly from users through methods such as questionnaire surveys, face-to-face interviews, and online interviews. Analyze the logs and usage records of the smart archive management system, and understand the user's usage habits and needs. Study specific cases of user groups using the system, including successful cases and problematic cases. Design representative tasks or scenarios for users from different professions to perform in a smart archive management system, such as retrieving specific information, using a certain service, etc. Collect data through system logs, user feedback, observation records, and other methods, including user operation behavior, task completion time, user satisfaction, etc. Using methods such as statistical analysis, content analysis, and behavioral analysis, analyze data from both quantitative and qualitative perspectives, identify user needs, evaluate system effectiveness, and identify system shortcomings. Firstly, to analyze the performance of the BiLSTM-CRF based knowledge graph and compare it with conventional knowledge graphs. The results are shown in Fig. 7.

Fig. 7(a) and Fig. 7(b) respectively represent the retrieval accuracy and recall of BiLSTM-CRF based knowledge graphs and conventional knowledge graphs. The former has retrieval accuracy rates of 92.34%, 88.61%, 90.22%, 90.08%, and 89.34% for students, civil servants, demobilized soldiers, law enforcement personnel, and retirees, respectively. The latter are 63.15%, 71.54%, 55.63%, 72.06%, and 72.65%, respectively. The recall rates of the former are 84.37%, 81.26%, 85.17%, 84.96%, and 82.33%, respectively, while the latter is 57.29%, 63.84%, 42.65%, 64.13%, and 70.19%, respectively. The retrieval accuracy and recall of knowledge graphs based on BiLSTM-CRF are significantly superior to conventional knowledge graphs. Next, analyzing the retrieval performance of the preference semantic retrieval model based on user understanding, and comparing it with conventional semantic retrieval models. The results are shown in Fig. 8.

Fig. 8(a) and Fig. 8(b) represent the retrieval accuracy and recall rates of the preference semantic retrieval model based on user understanding and the conventional semantic retrieval model, respectively. The former has retrieval accuracy rates of 93.64%, 90.12%, 88.47%, 95.24%, and 89.68% for students, civil servants, demobilized soldiers, law enforcement personnel, and retirees, respectively. The latter are 71.23%, 70.36%, 69.53%, 68.18%, and 71.62%, respectively. The recall rates of the former are 86.55%, 91.62%, 82.18%, 84.23%, and 96.35%, respectively, while the latter are 68.37%, 71.34%, 64.38%, 71.09%, and 80.24%, respectively. The experimental results indicate that, the retrieval accuracy and recall of the preference semantic retrieval model based on user understanding are significantly superior to conventional semantic retrieval models. Then to analyze the personalized retrieval system based on user understanding and knowledge graph improvement, compare it with traditional retrieval systems, and the results are shown in Fig. 9.

In Fig. 9, compared to traditional retrieval systems, the improved personalized retrieval system has better accuracy and recall. The improved personalized retrieval system has retrieval accuracy rates of 90.24%, 89.65%, 87.52%, 96.33%, and 95.18% for students, civil servants, demobilized soldiers, law enforcement personnel, and retirees, respectively. The retrieval accuracy of traditional retrieval systems is 79.63%, 78.27%, 74.57%, 80.24%, and 82.15%, respectively. The recall rates of the former are 89.35%, 91.57%, 89.34%, 97.54%, and 96.63%, respectively, while the latter is 72.14%, 74.54%, 70.68%, 79.27%, and 81.08%, respectively. The experimental results indicate that this study can improve the efficiency and user experience of smart archive management systems through user understanding-based retrieval systems, to achieve more accurate and personalized information retrieval and management.

Fig. 9. Comparison of personalized vs. traditional retrieval systems, showing improvements in user understanding and knowledge graphs.

B. *Analysis of the Application Effect of Improved Retrieval System in SAMS*

In order to comprehensively evaluate the application effect of improving the retrieval system in the smart archive management system, first set goals, determine the user group participating in the evaluation, design representative retrieval tasks, and set a series of quantitative indicators to evaluate system performance. It is necessary to establish a control group in order to more accurately evaluate the improvement effect. In order to ensure the reliability of the experimental results, it is necessary to conduct experimental tests in a controlled environment and minimize the interference of external factors.

To select an archive dataset with a certain scale and diversity, and pre-process it into a format suitable for simulation analysis. 100 individuals aged 18 to 45 of different types were randomly selected to conduct experiments to analyze the application effect of improved retrieval systems in SAMS. Firstly, the accuracy of file retrieval and related personalized recommendations of the participants in the experiment were compared. The participants were divided into five groups of 20 people each, and the results are shown in Fig. 10.

In Fig. 10, the accuracy of file retrieval and related personalized recommendations in SAMS are significantly superior to conventional management systems. The accuracy of the former is more stable and smoother, while the accuracy of the latter shows a decrease. The experimental results indicate that the proposed system model has better performance. Next, to analyze the response time and user satisfaction of different personnel towards improving the retrieval system, as shown in Fig. 11.

In Fig. 11, the response time of SAMS is significantly shorter than that of conventional management systems, while user satisfaction is significantly higher than that of conventional management systems, indicating that the former has better overall performance. The response time of SAMS and conventional management systems is up to 8 seconds and 32 seconds respectively, with the highest user satisfaction of 92.34% and 71.42%, respectively.

V. Discussions

In order to improve the performance and user experience of retrieval systems, the improvement of personalized retrieval systems based on user understanding and knowledge graphs has aroused the interest of researchers and practitioners. Research combines knowledge graphs and user understanding to construct personalized retrieval systems that meet user preferences. In order to meet the personalized needs of different users, the system continuously analyzes users' behavior patterns and preferences through machine learning algorithms and user feedback mechanisms. The system can provide personalized recommendations based on the user's operational history. In order to better understand the application of the system in real-world scenarios, research considers archive management environments of different scales and types. In large multinational corporations, this system can be used to manage millions of employee files and financial records. In government agencies, the system can process historical documents spanning decades. The scalability of the system enables it to handle the transition from paper documents to electronic documents and supports complex permission management to ensure the security of sensitive data. Through distributed storage and processing technology, the system is able to effectively manage and retrieve large amounts of documents, adapting to the constantly growing amount of data. In academic institutions, the archiving and management of research data require extremely high flexibility. This system meets the diverse data management needs of researchers by supporting various data formats and custom metadata tags.

In the actual implementation process, the system will face a series of technical challenges. For example, the real-time requirements of data processing may lead to increased system performance pressure, especially in high concurrency environments. In addition, data privacy and security issues are also a key challenge, and the system needs to effectively prevent potential data leakage risks. There are differences in technology acceptance among different user groups, which may affect the promotion and use of the system. With the continuous development of big data and artificial intelligence technology, the system should introduce more intelligent deviation detection and correction mechanisms to ensure the integrity and accuracy of data. Neglecting this aspect may lead to inaccurate data analysis results and even affect the effectiveness of decision-making. Therefore, I believe that future research should place greater emphasis on identifying and correcting data biases, and developing more robust data management strategies. In addition, the discussion on system scalability and adaptability also made me realize that relying solely on existing technological means is not enough. Interdisciplinary collaboration is needed to combine knowledge and technology from different fields in order to design more efficient and intelligent archiving management systems. This is not only a technical challenge, but also a management and policy issue that requires joint efforts from all parties to promote the development of this field.

VI. Future Work Prospects

This study has achieved preliminary results in the design and development of a flexible and adaptable archive management system, but in order to cope with constantly changing user needs and technological challenges, the following key areas still need to be further explored and improved in future work.

Firstly, improving the scalability of the system is one of the key focuses of future work. With the rapid growth of data volume and user numbers, the system must be able to effectively expand to support large-scale data storage and management. Future work will focus on developing more efficient data storage and retrieval algorithms, while exploring distributed storage and computing technologies to enhance system processing power and response speed. Through these technological means, we hope to achieve seamless system expansion without sacrificing performance. Secondly, in order to better meet the needs of different user groups, we plan to optimize the user interface and interaction design. Different users have different operating habits and needs, and in-depth user research will help collect and analyze user feedback to improve the user experience of the system. By introducing designs that are more intuitive and in line with user psychological models, the aim is to improve the usability and user satisfaction of the system. Future design optimization will include reorganizing information structures, simplifying operational processes, and adding personalized settings options. Thirdly, enhancing the intelligence level of the system is another important direction for future work. Introducing artificial intelligence and machine learning technologies to enable the system to automatically learn and adapt to user behavior patterns, thereby providing personalized services.

In summary, future research will focus on improving system scalability, optimizing user experience, and enhancing intelligence, addressing data bias issues, promoting interdisciplinary collaboration, and conducting long-term evaluations. Through these efforts, we look forward to further enhancing the adaptability and practicality of the archive management system, providing new research directions for the academic community, and offering effective solutions for practical applications. These future jobs will not only contribute to technological advancements, but also bring broader impacts to society.

VII. Conclusion

Traditional archive retrieval systems are often based on keyword matching and cannot understand users' query intentions and information needs. To improve the performance and user experience of retrieval systems, the improvement of personalized retrieval systems based on user understanding and knowledge graph has attracted the interest of researchers and practitioners. Providing personalized and accurate retrieval services has become particularly important for meeting the needs of users. This study combined knowledge graph with user understanding to construct a personalized retrieval system that meets user preferences. The experimental results showed that the retrieval accuracy and recall rate of knowledge graph based on BiLSTM-CRF were significantly superior to conventional knowledge graphs. The former had retrieval accuracy rates of 92.34%, 88.61%, 90.22%, 90.08%, and 89.34% for students, civil servants, demobilized soldiers, law enforcement personnel, and retirees, and recall rates of 84.37%, 81.26%, 85.17%, 84.96%, and 82.33%, respectively. The retrieval accuracy and recall rate of the preference semantic retrieval model based on user understanding were significantly superior to conventional semantic retrieval models. Compared with traditional retrieval systems, improving personalized retrieval systems had better accuracy and recall. The improved personalized retrieval system had retrieval accuracy rates of 90.24%, 89.65%, 87.52%, 96.33%, and 95.18% for students, civil servants, demobilized soldiers, law enforcement personnel, and retirees, respectively. Compared with conventional management systems, SAMS had more comprehensive performance, with a maximum response time of 8 seconds and 32 seconds, and the highest user satisfaction of 92.34% and 71.42%, respectively. This indicates that the improved personalized retrieval system has good performance and has good application effects in SAMS.

A SAMS can integrate information from multiple data sources and connect them in a graphical structure. This type of link helps to discover the relationships between data, providing a more comprehensive and comprehensive perspective. Through semantic technology, SAMSs can achieve intelligent search and question answering functions. Users can ask questions through natural language, and the system will understand the meaning of the questions and find relevant information in the graph network, thereby providing accurate answers. A SAMS can help recommendation systems better understand user needs and interests. By analyzing user behavior and preferences, combined with information from the knowledge graph, recommendation systems can provide more personalized and accurate recommendation results. A SAMS can help computers understand and analyze unstructured data such as text and images. By mapping this data to a knowledge graph network, the system can understand the meaning of the data and extract useful information from it.

There are still some shortcomings in this study, such as a small sample size. Subsequent studies will expand the sample size to verify the stability of research accuracy and other indicators.

Automatic Recognition and Labeling of Knowledge Points in Learning Test Questions Based on Deep-Walk Image Data Mining

Ying Chang, Qinghua Zhu
Beijing Polytechnic, Beijing 100176, China

***Abstract*—This paper deeply studies and discusses the application of image data mining technology based on the Deep-Walk algorithm in automatic recognition and annotation of knowledge points in learning test questions. With the rapid development of educational informatization, how to effectively mine and label the knowledge points in learning test questions from image data has become an urgent problem to be solved. In this paper, we introduce a novel approach that integrates graph embedding technology with natural language processing techniques. Initially, we leverage the Deep-Walk algorithm to embed the knowledge points present in the test question images, effectively transforming the high-dimensional image data into a low-dimensional vector representation. This transformation meticulously preserves the intricate structural information while meticulously capturing the subtle semantic nuances embedded within the image data. Subsequently, we undertake a thorough semantic analysis of these vectors, seamlessly integrating natural language processing techniques, to facilitate automated recognition with unparalleled precision. This innovative methodology not only elevates the accuracy of knowledge point recognition to new heights but also achieves semantic annotation of these points, thereby furnishing richer, more insightful data support for subsequent intelligent education applications. Through experimental verification, the proposed method has achieved remarkable results on multiple data sets, which proves its feasibility and effectiveness in practical applications. Furthermore, this paper delves into the expansive potential applications of this methodology in the realm of image data mining, encompassing areas such as online education, intelligent tutoring systems, personalized learning frameworks, and numerous other domains. As we look ahead, we aim to refine the algorithm, enhance recognition accuracy, and uncover additional application scenarios, thereby contributing significantly to the intelligent evolution of the education sector.**

I. Introduction

As human society progresses towards the era of intelligence, education in my country is undergoing a paradigm shift from traditional models to intelligent education. However, the pressing issue of imbalanced and inadequate education development persists. Recently, various government ministries and commissions have enacted a series of pertinent policies [1, 2] to ensure and expedite this educational transformation. These policies aim to harness the power of artificial intelligence, big data, blockchain, and 5G technology to drive innovation and expedite the evolution of digital education. They strive to unlock the latent potential of digital education, explore novel governance approaches, and seize the opportunities presented by the digital revolution for future educational transformation. Additionally, these policies promote the utilization of information technology to innovate teaching methods, develop teaching aids that align with educational needs, and leverage artificial intelligence to provide teachers with comprehensive assistance in tasks such as resource sourcing, homework grading, and online question answering. Ultimately, the goal is to establish an intelligent, efficient, and comprehensive educational analysis system.

In 2006, Hinton published an article titled "Reducing the dimension of data with neural networks" in "Science" magazine, which opened the prelude to the field of deep learning [3, 4]. Since then, research and applications based on deep learning have achieved great success in many fields, such as speech recognition, object visual recognition and target detection. In this disruptive wave of technology, the field of education has also been greatly impacted. Big data and artificial intelligence technologies can be applied to all stages of the field of education, providing support for new learning methods, improving teaching level and teaching quality, and improving Teaching efficiency and teaching effect, reducing the burden on teachers and students. A large number of intelligent education programs have been applied to actual education and teaching, enriching the forms of education and teaching at this stage. With the large-scale development of online education during the epidemic, this form of educational organization based on the Internet has further entered people's lives. Online education actively responds to the challenges brought by the global COVID-19 pandemic to the way education is organized, helping to minimize the impact of the epidemic on normal teaching order. At the same time, online education expands the supply of educational resources, reduces the differences in education levels in different regions, and further realizes educational equity [5, 6].

In the process of carrying out learning and evaluating learning, subject test questions play a vital role. By mining the deep hidden information in online test questions, it can help teachers and students build an intelligent learning environment and reduce the burden. For example, by analyzing the similarity of the hidden information in the test text, it can quickly locate the approximate question type; Using the hidden information of test text to build an intelligent question bank system, further realize a more intelligent and balanced automatic test paper generation model. Among them, the knowledge points labeling of test questions is the basic work of building an intelligent question bank system.

The labeling of knowledge points in test questions refers to the process of labeling the knowledge points used in answering test questions through a certain method. In teaching activities, knowledge points refer to the basic organizational units and transmission units that transmit teaching information, including concepts, definitions and theorems. A knowledge point is a general description of a certain concept, which usually exists as a goal that teachers and students want to achieve together. There are mainly five types of relationships between different knowledge points, namely, hierarchical relationship, dependent relationship, implication relationship, association relationship and dissociative relationship [7, 8]. Hierarchical relationship refers to the form that the upper layer contains the lower layer, and the lower layer belongs to the previous form. These knowledge points are interrelated and usually form a tree structure. According to the tree structure, different knowledge points can be described as a father-son relationship or a brother relationship.

The traditional method of labeling knowledge points of test questions is mainly manual labeling. Usually, front-line teachers with rich teaching and research experience are used as labeling personnel to label knowledge points of test questions. However, artificial knowledge point labeling methods are highly subjective, usually have cognitive biases, and the accuracy is difficult to guarantee. Furthermore, manual labeling fails to leverage the full potential of labeled test question data efficiently, as incremental test question data continues to require time-consuming manual annotation, hindering the pursuit of more efficient solutions. Consequently, amidst the exponential growth of online test question resources, the costs associated with manual knowledge point labeling—both in terms of time and human resources—have skyrocketed, underscoring the pressing need for alternative approaches.

With the application of artificial intelligence technology in various fields, some scholars use deep text mining technology to try to automatically label knowledge points and have achieved certain results. The method based on deep text mining can automatically learn and discover the potential features of test text from the test question data set and can label the appropriate knowledge points for the test questions according to the learned features. Therefore, it can better solve the problem of manual labeling costs caused by the explosive growth of online test question resources, and help automatically build an intelligent test bank system [9, 10].

Most of the existing knowledge point labeling methods of test questions are migrated from general text categorization methods. Test questions refer to a class of question texts used to test teaching effects. They have strong professionalism and certain structure and are different from texts in general fields. Therefore, methods in general fields cannot be simply transferred directly to knowledge point labeling field to complete labeling. Compared with the text in the general field, the test text contains more types of knowledge point labels, the sparsity is higher, and the workload and difficulty of the test question knowledge point labeling task are greater.

II. Overview of Related Technologies and Theories

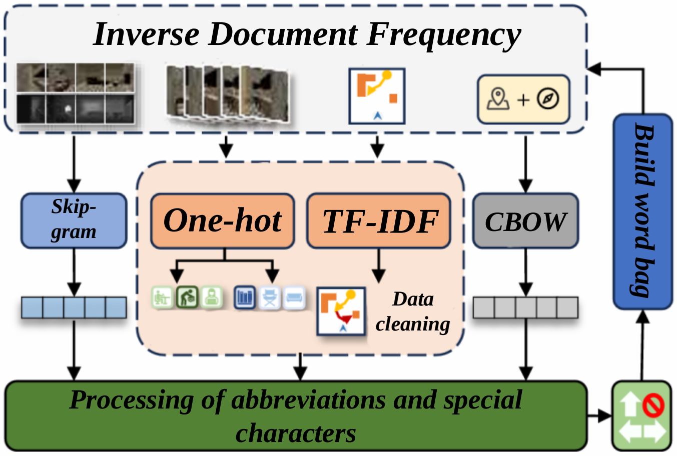
A. *Text Preprocessing*

Text preprocessing is a necessary step in text categorization task, and its effect affects the effect of text categorization to a certain extent. Therefore, different preprocessing methods are generally adopted according to the needs of text categorization tasks. The text of test questions generally has strong specialization and structure, so it is not easy to transfer the preprocessing method of general domain text to the field of test question text processing directly. Therefore, this paper mainly carries out the following operations in terms of text preprocessing:

1) Data cleansing: Cleanse task-independent text in the original text, and design regular expressions to match and delete this part of the text.

2) Chinese word segmentation: Chinese word segmentation methods are broadly categorized into two primary approaches: character-based and word-based, based on the granularity of segmentation. Each of these methodologies carries its unique set of advantages and constraints, underscoring the importance of selecting the optimal granularity tailored precisely to the demands of a given task. Entity recognition demands a high degree of accuracy in word segmentation, as the precision of this initial step directly impacts the overall effectiveness of these downstream applications. Therefore, these tasks usually choose character-based word segmentation methods [11, 12]. In order to achieve better performance, such tasks as text categorization, sentiment analysis, and text summarization, which pay more attention to text semantic understanding, usually choose word-based word segmentation methods. The process of knowledge point identification and labeling is shown in Fig. 1.

3) De-stop words: The accuracy of text classification can be improved by removing stop words in the text. Stop words refer to the words that appear frequently in categorized texts but have little effect on helping to improve the classification effect. For example, and the land of in English text, these words can be found in almost every sentence, but they do not provide much help in the semantic understanding of the sentence. Studies have shown that in a small English paragraph, more than 50% of the words are contained in a list of 135 commonly used words, which are generally considered noise words and should be removed during the text preprocessing stage [13]. There are also many such words in Chinese text. For example, stop words such as He, Ruo, can provide very little information for text categorization tasks, but often introduce more noise information. Deleting stop words helps significantly reduce the size of the text feature space, speed up model calculation and improve the accuracy of text categorization [14].



Inverse Document Frequency
Skip-gram
One-hot
TF-IDF
CBOW
Build word bag
Data cleaning
Processing of abbreviations and special characters

Fig. 1. The process of knowledge point identification and labeling.

4) Handling abbreviations and special characters: In the process of daily life and learning, some words are often set as their own abbreviations. The original meaning of these abbreviations is for the convenience of memory, but after abbreviation, part of the semantic information of the original words will be lost, which is not conducive to the learning of classification models [15]. Therefore, it is necessary to convert these abbreviated words in the processing stage to restore their original text expressions. Most text datasets will contain many unnecessary characters, such as punctuation marks and special characters. These punctuation marks and special characters are very important for human wording, sentence breaking, understanding, etc., but these are not helpful to improve the performance of classification algorithms, and will bring a lot of noise to the learning of the model. Choose to remove these punctuation and characters. The node embedding formula in the Deep Walk model is shown in Eq. (1).

$$W(d,t) = TF(d,t) * log\left(\frac{N}{df(t)}\right) \tag{1}$$

Here, N is the number of documents, and df(t) is the number of documents in the corpus that contain the word t. The first term in the equation improves the recall rate, while the second term improves the precision of the word embedding. Although TF-IDF reduces the problems caused by high-frequency words in documents to a certain extent, it also ignores the relationship between words in the text, and directly ignores the semantic information of words.

Word2Vec is a popular word embedding method that captures the relationship between words in context and embeds words into Euclidean space [16]. The Word2Vec method uses two shallow neural networks with continuous word bags (CBOW) and Skip-gram to create a vector for each word in the library. The day scale of the Skip-gram model is to maximize the probability in Eq. (2).

$$\underset{\theta}{argmax} \prod_{w \in T} [\prod_{c \in c(w)} p(c \mid w;\theta)] \tag{2}$$

Fig. 2 shows image data mining and processing process. As Fig. 2 shows, the purpose of the CBOW model and the Skip-gram model are different. While the CBOW model is tasked with finding words based on a sequence of words, the Skip-gram model is tasked with finding the words most likely to appear near a given word based on that word. Word2Vec has greatly advanced the field of natural language understanding by providing a very powerful tool for capturing similarity relationships between words in a corpus [17].

Prior to delving into Word Frequency-Inverse Document Frequency (TF-IDF), it is imperative to grasp the fundamentals of the Bag of Words (BoW) model, which serves as a cornerstone for text representation. The BoW model simplifies text by transforming documents or sentences into a concise list of word frequencies. This list is compiled during the model's construction process, where each unique word in the vocabulary is first encoded into a one-hot encoding vector. For instance, in the given scenario, assuming a vocabulary size of 19, the model would generate a 19-dimensional vector for each word, with a '1' occupying the position corresponding to the word's index in the vocabulary and all other positions set to '0'. This encoding scheme provides a straightforward yet effective way to represent textual data. Then the bag-of-words model combines word frequency as a feature representation of the document and sentence. However, the word bag model only pays attention to the feature of word frequency when collecting and constructing word bags, and ignores the semantic relationship between words, which cannot help the model learn the deep-seated semantic information of the text well [18].

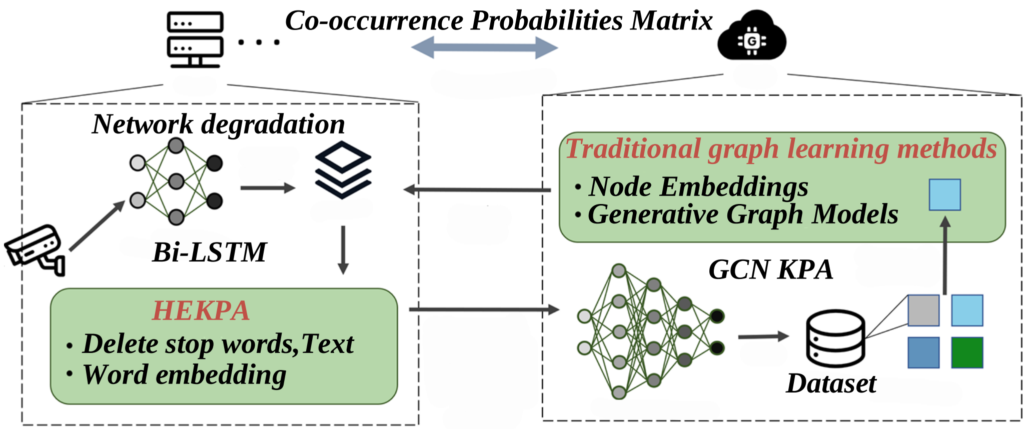


Fig. 2. Image data mining and processing process.

Inverse Document Frequency (IDF) is often used in conjunction with word frequency to reduce the negative impact of frequent words in the corpus. IDF assigns higher weight to high-frequency or low-frequency words in a document: this combination of TF and IDF is called word frequency-inverse document frequency (TF-IDF). Its word embedding is obtained by Eq. (3) as follows:

$$R_{\mathrm{err}} = \sum_{i=1}^{n} \arccos\left(\frac{\mathrm{tr}(R_{\mathrm{out}_i}^{T} R_{\mathrm{gt}_i}) - 1}{2}\right) \tag{3}$$

B. Glove

Another powerful and widely used model is Glove, which calculates word embedding by counting the number of global word co-occurrences across large corpora [19]. Before introducing the Glove model, let's introduce the latent semantic analysis algorithm based on singular value decomposition. This algorithm obtains the vector representation of words and documents by performing singular value decomposition on the word-document matrix. The Glove model combines the ideas and methods of latent semantic analysis algorithm and Word2Vec algorithm, because the author believes that both methods have certain defects. While the Latent Semantic Analysis (LSA) algorithm effectively harnesses global statistical information, its performance in word analogy tasks falls short, suggesting that there is room for enhancement in the generated vectors. In contrast, Word2Vec excels in word analogy tasks, albeit with minimal reliance on corpus statistics, underscoring its unique strengths in this domain [20]. The Glove model combines these two features together, and uses global statistical features and local contextual features of the corpus to help generate a vector representation of the text. For this reason, the Glove model introduces a Co-occurrence Probability Matrix (Co-occurrence Probability Matrix) to achieve this goal. First, the concept of a co-occurrence matrix is introduced. In the co-occurrence matrix X, the rows and columns of the matrix are words in the dictionary. Use xi,j to represent the number of times the word j appears in the context of the word i (usually a window size is set to specify the search distance of the context). The meaning of xi is the number of times the word i appears in the corpus. The co-occurrence probability matrix is obtained by counting the above two values, where the probabilities Pi,j are defined as shown in Eq. (4).

$$P_{ij} = \frac{x_{ij}}{x_i} \tag{4}$$

That is, P is the ratio of the number of times the word appears in the context of word i in the corpus to the total number of times the word i appears. Assuming i = ice, j = steam, k = solid, the feature extraction formula in image data mining is shown in Eq. (5).

$$Ratio = \frac{P_{ik}}{P_{jk}} \tag{5}$$

Using Ratio can also well reflect the relationship between i, j, and k (because the co-occurrence probability Ratio conforms to common sense), so the original author assumed that the word vector of i, j, and k generated by the Glove model can fit this Ratio after some calculation. Make the word vector obtained by Glove consistent with the co-occurrence matrix, so as to reflect the co-occurrence relationship between words, that is, the goal of Glove is defined as shown in Eq. (6).

$$f(w_i - w_j, \tilde{w}_k) = \frac{P_{ik}}{P_{jk}} \tag{6}$$

C. Graph Representation Learning

As a classic data structure, Graph is widely used in various fields of natural science. It is generally believed that a Graph is a set of objects (nodes) and interactions (edges) between objects [21]. The nodes in the social network graph are usually used to represent individuals, and the edges inside are used to indicate that there is a certain connection between two people.

Based on graphs, we can analyze, understand and learn complex systems in the real world. In the past dozens of works, many high-quality large-scale graph data have emerged, such as large-scale social network graphs based on social software, knowledge graphs for general fields, Internet network device topology graphs, and so on. The appearance of these large-scale graphs has greatly promoted the development of graph technology, among which the methods based on machine learning are particularly prominent. Machine learning provides many technical means for modeling, analyzing and understanding this part of large-scale and complex graph data, helping people to further explore and discover the theory and knowledge existing in the complex system behind these large-scale graphs.

Before discussing machine learning methods applied to graphs, a formal definition of what exactly means "graph data" is needed. Formally, the graph G=(V, E) consists of a set of nodes V and a set of edges E between these nodes, and represents the edges from node a∈V to node b∈V as (a, b)∈ E. The formula for the ReLU activation function is shown in Eq. (7).

$$\mathrm{E}[D_{\theta}(x_0 + n; \sigma, c) - x_{02}^{2}] \tag{7}$$

A simple way to store a graph is through the adjacency matrix A ∈ RV, where V is the number of nodes. Each row and column of the adjacency matrix represents a specific node; A in adjacency matrix; To represent the-edge from node i to node j, if (i, j)∈E then Ai, j = 1, otherwise Ai, j = 0. The elements Ai, j in the adjacency matrix can also store any real value instead of 0 and 1. At this time, the real value stored by Ai, j is the weight of the edge (i, j)∈E.

Nodes in the graph usually also have their specific attributes or feature information (for example, profiles and pictures of users in social networks), and in most cases, the real-valued matrix F∈Rd is used to represent the nodes. Attributes or features, the order of the nodes in the real-valued matrix is consistent with the order of the rows and rows in the adjacency matrix. The vector representation of the feature is stored in the real-valued matrix, and d is the dimension of the feature vector. The operational formula for the pooling layer and the weight update formula for the fully connected layer are shown in Eq. (8) and Eq. (9).

$$D_w(x; \sigma, c) = wD_1(x; \sigma, c) + (1 - w)D_0(x; \sigma, c) \tag{8}$$

$$\hat{y}_{j,T_n} = \sum_i w_{ij}\hat{y}_{i,T_n} \tag{9}$$

Graph learning algorithms mainly have two stages of development. The first is the traditional graph learning method based on statistics, and the progressive development is the graph representation learning algorithm based on machine learning. Traditional graph learning methods are basically based on the statistical information of nodes and graphs, which requires a lot of feature engineering, so the information is limited. At the same time, the statistical information designed by hand in traditional graph learning methods is not flexible and cannot be adapted in the learning process, so it needs to be redesigned after the task is shifted. With the development of machine learning, a series of methods have emerged that can get rid of manual feature design and learn features in graphs through adaptive methods-graph representation learning. Existing graph representation learning algorithms are mainly divided into three categories: Node Embeddings, GNN, and Generative Graph Models. The research content of this paper mainly involves node embedding and graph neural networks, and does not involve graph generation models. Therefore, the following will focus on the two-graph representation learning algorithms involved in the text.

III. A Knowledge Point Annotation Model Based on Mixed Label Embedding

A. Test Question Text Data

Test questions refer to a class of question texts used to test the teaching effect, so test text is more professional than daily text, and the format of test text is usually relatively fixed, for multiple-choice questions, fill-in-the-blank questions, or answer questions. format. Generally speaking, test text data has the following two characteristics:

1) Professionalism: The text of test questions demands unwavering professionalism, stemming from their intended purpose. The descriptions within these questions must adhere to stringent standards of accuracy and clarity, with no room for ambiguity or vague expressions. When juxtaposed with everyday language, the text of test questions typically encompasses a greater abundance of subject-specific proper nouns, thereby presenting a unique challenge that to some degree complicates the migration of general domain models into this specialized context. The normalization formula and the threshold processing formula in the preprocessing are shown in Eq. (10) and Eq. (11).

$$q_i(v) = \pi(K_i R_i^T(v - t_i)) \tag{10}$$

$$c(p) = \sum_{i=1}^{N-1} I_i(p) w_i(p) \tag{11}$$

2) Structural: Most of the common test text can be divided into a certain type of question, and each type of question has its fixed format, which will lead to more meaningless symbols in the test questions, thus introducing noise to model learning, so it is necessary to remove these meaningless symbols. However, according to the specific task requirements, specific rules can also be used to extract the structure of the test questions, so that it can be used as additional information to help the model learn. Because the test text has strong specialization and a certain structure, it is not easy to transfer the text preprocessing methods in the general field to the test text for text preprocessing without modification. Fig. 3 shows the distribution map of the raw image dataset.

3) Data cleansing: The text of the test questions in the dataset used in this paper is obtained by crawling from Baidu Question Bank through crawlers. The original text in the dataset will contain some text that is irrelevant to the task. For this type of text, this paper designs regular expressions to match and delete this part of the text.

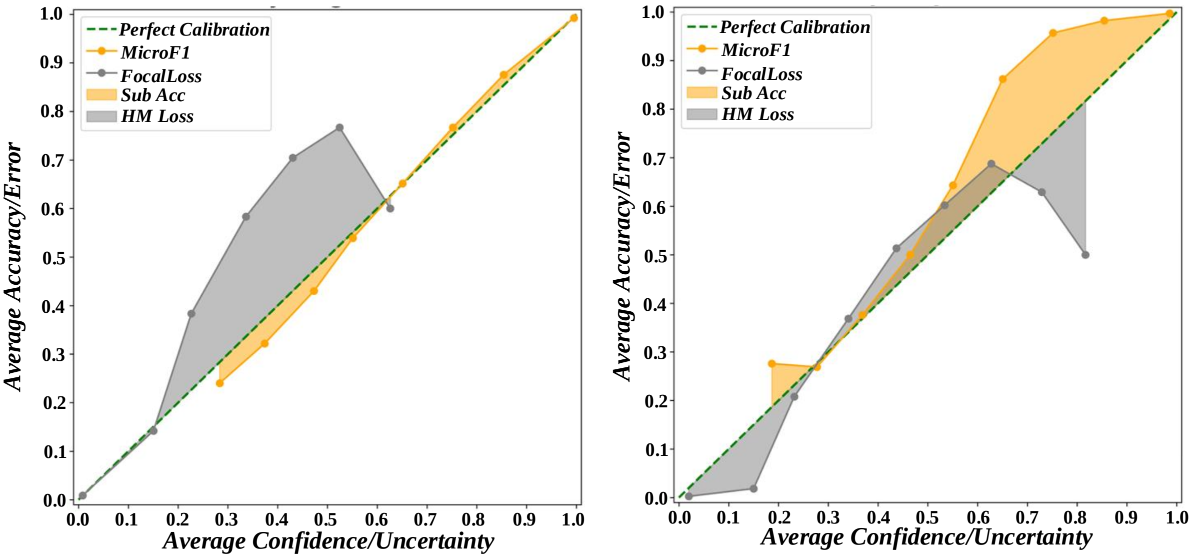

Fig. 3. Distribution map of the raw image dataset.

4) Chinese word segmentation: This paper selects word-based segmentation method to segment the text of the test questions, hoping that the model can better learn the deep-seated semantic information of the text. At present, the research of general Chinese text word segmentation has been relatively mature. There are many word segmentation tools to choose, such as NLPIR, LTP, THULAC, jieba, etc. This paper chooses jieba as a word segmentation tool to obtain word segmentation results. Due to the strong specialization of the test text, the test text usually contains a large number of proper nouns, but the original dictionaries in the existing jieba are designed for general fields, and there will be many mistakes in using the existing jieba directly to segment the test text. Therefore, this paper introduces subject dictionaries to help improve the accuracy of word segmentation and reduce the occurrence of word segmentation errors.

5) De-stop words: One of the basic methods to improve the accuracy of text categorization is to remove the stop words in the text. Stop words refer to the words that appear frequently in categorized texts but have little effect on helping to improve the classification effect. Stop words can provide very little information for text classification tasks, but they often introduce more noise information. Except stop words help to significantly reduce the size of text feature space, help to speed up model calculation and improve the accuracy of text classification. This article includes a list of 859 stop words, which contains most of the Chinese stop words, such as He, Ruo, Yu, Xi, etc.

6) Handling abbreviations and special characters: The inclusion of abbreviations and special characters did not contribute favorably to the model's ability to discern the syntactic and semantic nuances of test questions. Notably, in fields like biology, certain abbreviations of proper nouns are prevalent, designed primarily for mnemonic purposes. However, these abbreviations inherently entail the loss of a portion of the original words' semantic information, which hinders the model's learning process, as it struggles to grasp the full contextual meaning. Therefore, in the text processing stage, it is necessary to convert these abbreviated words to restore their original text expression. In the test text dataset, there are many special characters in addition to the commonly used punctuation marks. These special characters will affect the model's extraction of semantic information to a certain extent, which is not conducive to model learning. This paper will replace these special characters with blank characters in the text preprocessing stage. The gradient calculation formula and the similarity measure formula are shown in Eq. (12) and Eq. (13).

$$\left|B^{l}\right| = K^{2} * F \tag{12}$$

$$L_{ek} = \frac{1}{|P|}\sum_{p\in P}(\|\nabla sdf(p)\|_{2} - 1)^{2} \tag{13}$$

B. Model Construction

Inspired by the dictionary retrieval method, this paper proposes a two-stage automatic labeling model of knowledge points in test questions with mixed label embedding. The model is divided into a classification stage and a labeling stage. In the classification stage, the model classifies the test text into the second level of knowledge points in the knowledge point hierarchy diagram. In the labeling stage, the model obtains a label according to the results of the classification stage and further combines the node embedding and text embedding of the label according to the label-to-label knowledge points [22].

The co-occurrence relationship and the hierarchical relationship between knowledge points can be used as a priori knowledge to guide the model to label. The current method of automatic labeling of knowledge points has the problem of sparse label space. HEKPA guides the model to label knowledge points. The primary consideration is how to obtain the structural relationship.

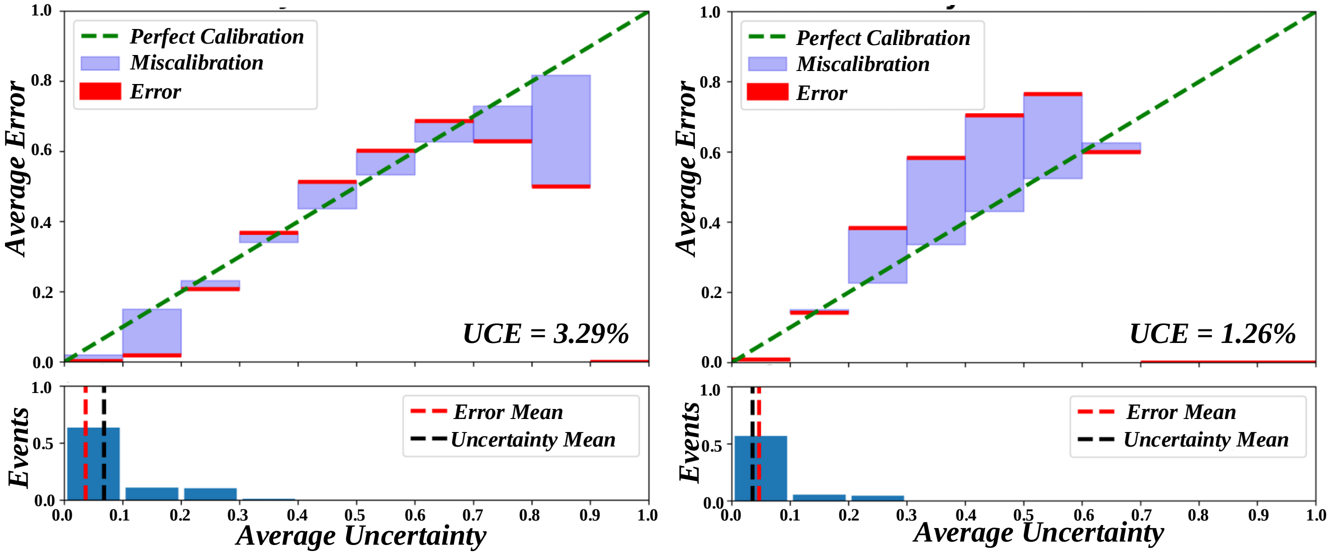

Fig. 4. Comparison diagram of the image feature extraction effect.

Fig. 4 shows comparison diagram of the image feature extraction effect. In Deep-Walk, the random walk algorithm is used to obtain the co-occurrence relationship of nodes in the graph. The results of the random walk with the vertex vi as the starting point are expressed as Wvi, = Wv1, Wv2, …, Wvi, where l is the predetermined random walk step size. After the random walk processes are obtained by using the random walk algorithm, these random walk processes are input into the Word2Vec algorithm as sentence sequences to learn the embedded representation of each node.

IV. A Knowledge Point Labeling Model Based on Graph Convolutional Neural Network

A. Model Construction

To overcome the limitations of shallow node embedding, this chapter presents an end-to-end model, GCN KPA, based on graph convolutional neural networks. This model captures the relationships between knowledge point labels. It features a feature extraction layer using Bi-LSTM to extract text features and a labeling layer that incorporates knowledge point label information using a GNN Network to accomplish labeling tasks.

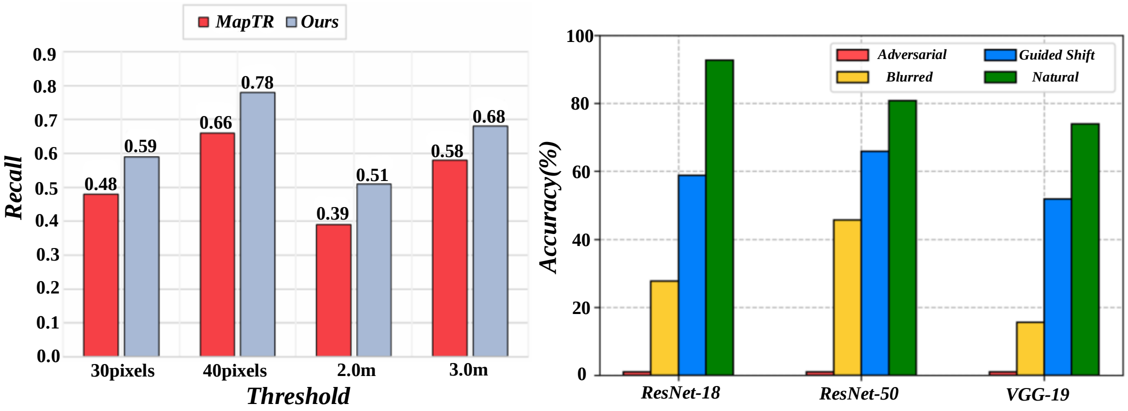

Fig. 5. Deep-walk node embedding visualization graph.

Fig. 5 displays the Deep-Walk Node embedding visualization. GCN-KPA utilizes Bi-LSTM to derive the text representation vector of test questions. Word embedding sequence X, pre-trained by a language model, is processed by Bi-LSTM to extract bidirectional text features. Eq. (14) and Eq. (15) depict random rotation and learning rate decay, respectively.

$$\vec{h}_i = \overline{LSTM}(\vec{h}_{i-1}, x_i) \tag{14}$$

$$L_{mfc} = \frac{1}{K}\sum_{k=0}^{K-1}(1-NCC_k) \tag{15}$$

After acquiring latent semantic hidden states of the text in both directions, they are concatenated to form the final hidden representation of each word. Eq. (16) and Eq. (17) exhibit the dropout layer's mechanism and image classification accuracy calculation, respectively.

$$\hat{C} = \sum_{i=1}^{M} T_i \alpha_i c_i \tag{16}$$

$$T_i = \prod_{j=1}^{i-1}(1-\alpha_j) \tag{17}$$

B. Callout Layer

The structural relationship between labels can help reduce the sparsity of label space and help guide the model to label knowledge points in test questions [23]. In this chapter, we design a classifier based on graph convolutional neural network, which usually has two parts: the eigenmatrix F ∈ Rq representing the nodes of the graph and the adjacency matrix A ∈Rq representing the edges of the graph.

Mula for the confusion matrix and the evaluation index is shown in Eq. (18).

$$G^{(l+1)} = \mathrm{ReLu}(\hat{A}G^{(l)}W^{(l)}) \tag{18}$$

However, only using a simple graph convolutional neural network as the classifier layer of the model will lead to a slower parameter update in the initialization stage, a lower learning rate of the model at the initial stage, and a model that cannot be learned through the back propagation algorithm for a period of time. GCN KPA further introduces Skip Connection to accelerate faster model initialization, the specific definition of the jump connection connection is shown in Eq. (19). The formula of the clustering algorithm in image data mining is shown in Eq. (20).

$$G_s^{(l+1)} = G^{(l+1)} + G^{(l)} \tag{19}$$

$$o = h \odot G_s \tag{20}$$

Fig. 6 shows classification of the model performance evaluation Fig. In a graph convolutional neural network. The calculation for

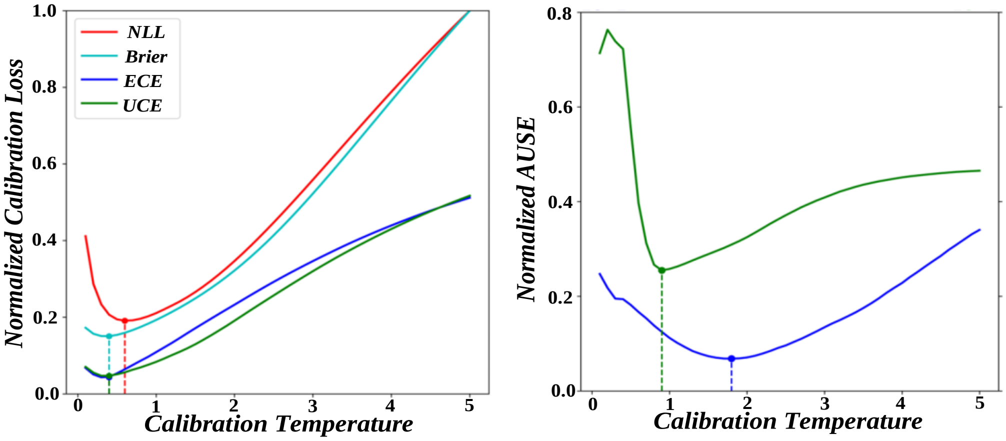

Fig. 6. Classification of the model performance evaluation.

C. Ablation Experiment

Among the three word embedding methods, TF-IDF, Glove and Word2Vec, using Word2Vec to obtain the word embedding representation sequence of text has the greatest improvement to the model, so this chapter defaults to using Word2Vec as the word embedding layer of the model to obtain the word embedding sequence of text [24]. In this section, three sets of ablation experiments were designed:

1) Feature extraction layer ablation experiment: The performance of three feature extraction layers in GCN KPA was studied and compared, with results shown in Fig. 7. Among them, Bi-LSTM performed best, followed by Text CNN, and MLP performed worst. Bi-LSTM extracts latent semantic features of text bidirectionally, hence chosen as the feature extraction layer in this model to enhance annotation accuracy. Fig. 7 displays ablation experiment results.

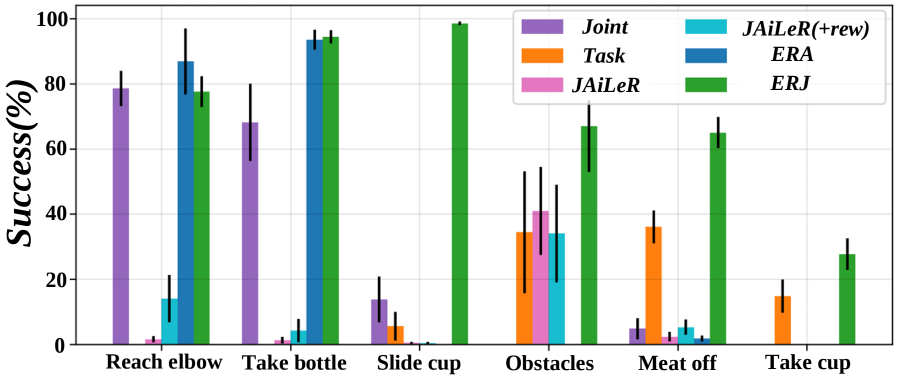

Fig. 7. Results of the ablation experiments of the feature extraction layer.

2) Classifier ablation experiment: Compare the effects of the GCNKPA separator with separate GCN separator and separate FC classifier, results are shown in Table I.

It can be seen from Table I that the model has been greatly improved, which shows that point labels introduced through the graph neural network can be very good [25]. Improve the labeling effect of the model. At the same time, the introduction of Skip Connection further improves the annotation effect of the model. And as shown in Fig. 8, introduce Skip Connection to accelerate model initialization.

TABLE I. COMPARISON OF THE CLASSIFIER EFFECTS

Classifier	Micro F1	Macro F1	H.M Loss	Sub Acc
FC	0.8640	0.7558	0.0116	0.5124
GCN	0.8817	0.8074	0.0100	0.5234
GCN KPA	0.8853	0.8206	0.0097	0.5339

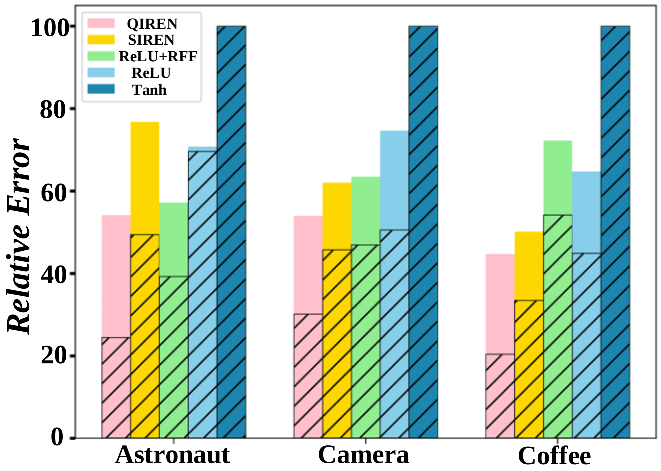

Fig. 8. The annotation effect diagram of the model.

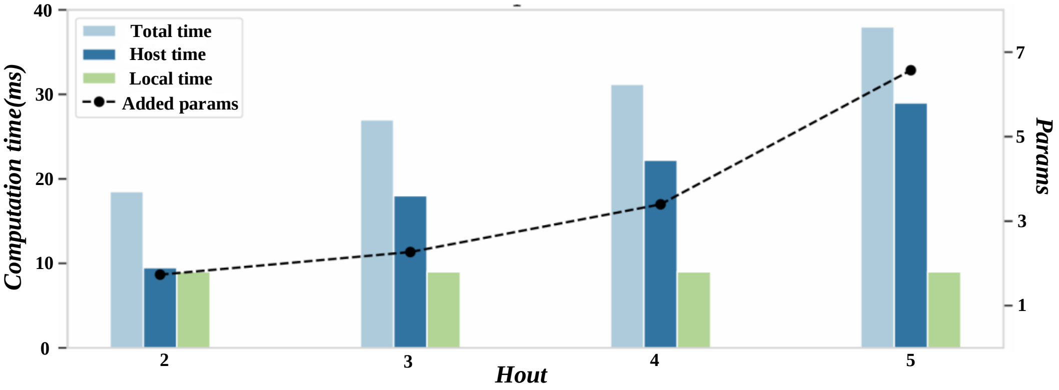

Fig. 9. Comparison diagram of knowledge point identification accuracy and annotation consistency.

Evidently, GCN KPA has demonstrated superior performance across all four evaluation metrics, with a particularly noteworthy enhancement in the MacroF1 indicator, surpassing the gains observed in the other three indicators. This underscores GCN KPA's proficiency in capturing the intricate relationships between labels, enabling it to harness this label information to guide the model's labeling process. Consequently, it mitigates the sparsity of the label space, resulting in a significant improvement in the efficacy of knowledge point labeling [26]. Fig. 9 shows comparison diagram of knowledge point identification accuracy and annotation consistency.

3) Comparison of different Loss functions: The introduction of the Focal Loss function reduces the impact of the unbalanced distribution of labels in the dataset on model learning to a certain extent, and observes the impact of different loss functions on model learning by comparing it with the BCE Loss function commonly used in multi-label text categorization. Detailed experimental results are shown in Table II.

As can be seen from Table II, after replacing BCELoss with Focal Loss, there is an improvement in the three evaluation indicators, but a decrease of 3% in Sub Acc, the most stringent evaluation indicator. This is consistent with the starting point of the Focal loss function design. Focal loss function gives different weights to different samples, reduces the weights of easy-to-classify samples, and allows categories with fewer samples to have higher weights. This makes the model pay more attention to point labels, which is reflected in the experimental results that the improvement rate of MacroF1 is greater than that of MicroF1. At the same time, because the model pays more attention to the part of the label with a small number of samples, the model is more aggressive than before, which leads to the poor performance of the model on the evaluation index Sub Acc. But from the overall experimental results, the introduction of Focal loss makes the model improve most of the evaluation indicators, and can better deal with data sets with unbalanced sample numbers, and better learn knowledge point labels with small sample numbers. Fig. 10 shows performance comparison of the model on different dataset.

TABLE II. EXPERIMENTAL RESULTS FOR THE DIFFERENT LOSS FUNCTIONS

Loss function	Micro F1	Macro F1	HM Loss	Sub Acc
BCE Loss	0.8779	0.8011	0.0106	0.5606
Focal Loss	0.8853	0.8206	0.0097	0.5339

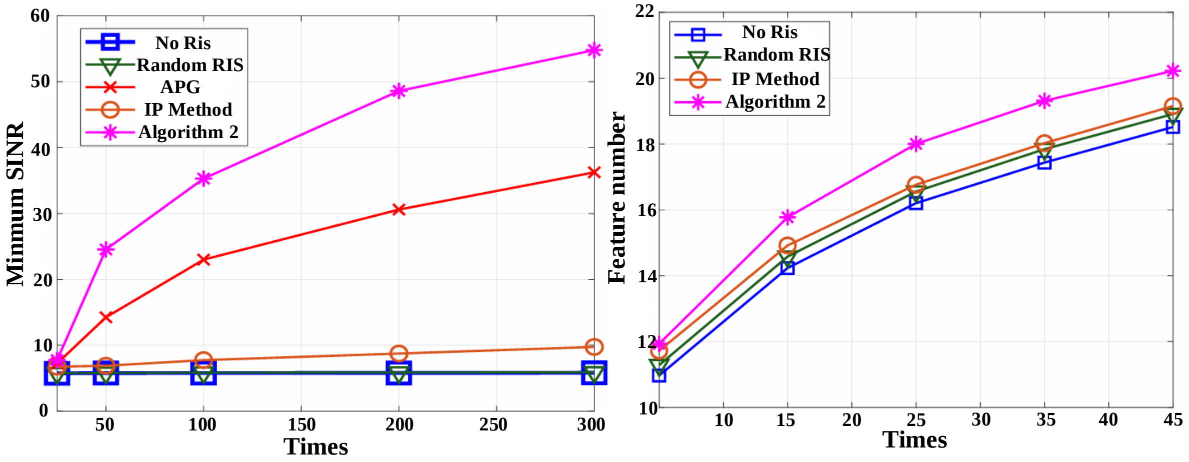

Fig. 10. Performance comparison of the model on different dataset.

V. CONCLUSION AND FUTURE WORK

Aiming at the research of automatic recognition and labeling of knowledge points in learning test questions based on Deep-Walk image data mining, a new method is proposed in this paper. This method combines graph embedding technology and advanced concepts in the field of natural language processing, and realizes the effective recognition and labeling of knowledge points in test questions in image data mining. By deeply exploring the application of Deep-Walk algorithm in graph data embedding, we successfully combine the visual features of images with the knowledge points of test questions, and realize the in-depth analysis and semantic understanding of image data.

The main conclusions of this study are as follows: First, Deep-Walk algorithm shows strong potential in the field of image data mining. It captures the topological structure of images through random walks, and then generates low-dimensional dense vector representations, which provides an effective means for the recognition of knowledge points in test questions. Secondly, combining the visual features of image data with the knowledge points of test questions cannot only improve the accuracy of recognition, but also enhance the semantic richness of labeling, providing strong support for intelligent applications in the field of education.

Anticipating the future, as image data mining technology continues to evolve, the Deep-Walk-based approach for knowledge point recognition and annotation is poised to find broader applications across diverse fields. Concurrently, we remain committed to delving deeper into the realm of algorithms and models, with the aim of enhancing recognition accuracy and refining the granularity of labeling, thereby pushing the boundaries of this technology further. In addition, we will also focus on the fusion of image data and other types of data, as well as cross-domain knowledge migration and sharing, laying a solid foundation for the realization of a wider range of intelligent educational applications.

To sum up, the research on automatic recognition and labeling of knowledge points in image data mining learning test questions based on Deep-Walk has achieved remarkable results, which provides a new idea and method for the intelligent development of education.

Heart-SecureCloud: A Secure Cloud-Based Hybrid DL System for Diagnosis of Heart Disease Through Transformer-Recurrent Neural Network

Talal Saad Albalawi
College of Computer and Information Sciences, Imam Mohammad Ibn Saud Islamic University (IMSIU),
Riyadh 11432, Saudi Arabia

Abstract—**Cardiovascular disease (CVD) has rapidly increased after COVID-19. Several computerized systems have been developed in the past to diagnose CVD disease. However, the high computing expenses of deep learning (DL) models and the complexity of architectures are significant issues. Therefore, to resolve these issues, an accurate diagnosis of CVD disease is required. This paper proposes a hybrid and secure deep learning (DL) system known as Heart-SecureCloud to predict multiclass heart diseases. To develop this Heart-SecureCloud system, four major stages are makeup such as preprocessing and augmentation, feature extraction and transformation, deep learning and hyperparameter optimization, and cloud security. Advanced signal processing and augmentation technologies are applied to ECG data in the preprocessing and augmentation step to enhance data quality. In the feature extraction and transformation step, adaptive wavelet transforms, and feature scaling are used to extract and convert spectral and temporal data. The DL and hyperparameter optimization step utilize a novel hybrid transformer-recurrent neural network model, which is further optimized for accuracy and efficiency using hyperband-GA. Transfer learning refines pre-trained models using domain-specific data. The unique aspect of the Heart-SecureCloud system is its implementation through a secure cloud, which safeguards medical data with encryption and access control mechanisms. The system's efficacy is demonstrated through testing and evaluation on three publicly available datasets, such as MIT-BIH Arrhythmia MIMIC-III Waveform and PTB-ECG. The Heart-SecureCloud DL architecture achieved impressive results of 98.75% of accuracy, 98.80% of recall, 98.70% of precision, and 98.75% of F1-score. Moreover, the Heart-SecureCloud DL underscores its promise for safe medical diagnostics deployment.**

Keywords—Heart disease diagnosis; deep learning; cloud computing; feature extraction; data security; hyperparameter optimization; encryption

I. Introduction

The most common chronic disorders worldwide are cardiovascular diseases (CVDs), which have caused the most morbidity and mortality during the previous decade [1]. The WHO estimates that 17.9 million people die from CVDs yearly, 32% of all fatalities [2]. By 2030, 22.2 million individuals may die from CVDs. Over the past 30 years, CVDs have been the leading cause of death in the US, accounting for 46.2% of deaths in 2017 [3]. CVDs include congestive heart failure, coronary artery disease, congenital heart defects, cerebrovascular disease, and rheumatic heart disease [4]. Nowadays, CVD is caused by heart attacks and strokes. Early and precise prediction of CVD disease improves survival and reduces death [5]. In addition, this improvement can assist experts in treating patients faster, thanks to the potential of machine learning (ML) and deep learning (DL) methods [6]. These methods, by analyzing ECG signals, can significantly enhance our ability to combat CVDs [7].

Artificial intelligence (AI) technologies are advancing rapidly, and cloud security, along with machine learning (ML) and deep learning (DL) approaches, can now be utilized to monitor and even predict cardiovascular diseases (CVD) [8]. Cloud security, a crucial component, involves securing data, applications, and infrastructures hosted in the cloud, ensuring they are protected from unauthorized access and breaches. This is particularly important in the medical and healthcare sectors, where sensitive health data must be safeguarded. Machine learning, a branch of artificial intelligence, involves techniques that extract knowledge from data, often called predictive analytics or statistical learning. Deep learning, a subset of ML, uses neural networks with multiple layers to model complex patterns in data. These techniques, when applied to medicine, have the potential to not just revolutionize but also excite us about the future of healthcare delivery methods. Moreover, the vast amount of data generated by hospitals in a cloud environment presents significant challenges, particularly in selecting the most effective machine-learning techniques for data analysis.

Cardiovascular disease (CVD) has seen a significant rise following the Covid-19 pandemic. In response, numerous computerized systems have been developed to diagnose CVD. However, challenges such as the high computational costs of deep learning (DL) models and the complexity of their architectures remain. To address these challenges, there is a need for an accurate and efficient approach to diagnosing CVD. This paper introduces a hybrid and secure deep learning system called Heart-SecureCloud, designed to predict various types of heart diseases. This study shows multi-layered strategy to establishing a safe and efficient cloud-based deep learning system for heart disease diagnostics. In the Preprocessing and Augmentation Layer, innovative signal processing and data augmentation procedures improve medical voice record input data quality. A unique adaptive wavelet transform, and feature scaling method extracts and transforms spectral and temporal properties in the Feature Extraction and Transformation Layer.

The Hyperband-GA hybrid approach optimizes a Transformer-Recurrent Neural Network (RNN) hybrid model in the Deep Learning and Hyperparameter Optimization Layer for accuracy and efficiency. Pre-trained models are fine-tuned using domain-specific data via transfer learning. Finally, the Evaluation and Security Layer thoroughly evaluates and verifies performance metrics while protecting sensitive medical data with strong encryption and access control. Encrypting data in transit and at rest and using authentication techniques, this layer secures data processing and cloud server deployment. This study makes several significant contributions to the field of heart disease detection.

1) Novel Heart-SecureCloud DL system for effective heart disease diagnosis using advanced signal processing, feature extraction, and hybrid deep learning architectures.

2) The Hyperband-GA hybrid optimization approach improves model accuracy and computational efficiency.

3) This cloud server study integrates a thorough security layer into the cloud-based feature categorization system.

4) High model accuracy (98.75%) and comprehensive security features set a new heart disease diagnosis system benchmark.

Structure of the paper: Section II: Reviews heart disease diagnosis and prognosis approaches and their advances. Section III: Explains speech feature extraction, ML methods, picture augmentation, and data normalization. Section IV reports the experimental setup, findings, and performance evaluation of the proposed system, comparing it to alternative methods. Section V: Summarizes findings, analyzes ramifications, and offers further study.

TABLE I. A TABLE SUMMARIZING THE KEY POINTS AND COMPARISONS BASED ON THE LITERATURE REVIEW

Study	Purpose	Methodology	Results	Limitations
[14]	Detection of CAD using ECG signals	Developed AE, RBFN, SOM, and RBM models; ensemble of AE and SOM	AE: Accuracy 0.974 (MIT-BIH), 0.984 (PTB-ECG); Ensemble: Accuracy 0.984 (MIT-BIH), 0.992 (PTB-ECG)	Needs testing on larger and more imbalanced datasets
[15]	Automated diagnostic systems for CAD, MI, CHF	Developed 16-layer LSTM model	Accuracy 98.5%	Limited to classification of abnormal ECG signals
[16]	Addressing imbalanced data for detection	Developed GAN, LSTM, and ensemble GAN-LSTM models	GAN-LSTM: Accuracy 0.992 (MIT-BIH), 0.994 (PTB-ECG)	Further research needed with different ensemble models and datasets
[17]	Automated detection of ECG arrhythmia	Removed noise, extracted features, used ML and DL models	Accuracy 86.25%	Performance affected by noise in ECG signals
[18]	Distinguish normal and abnormal ECG patients	Used SVM, LR, AdaBoost; ensemble of AdaBoost and LR	Ensemble: Accuracy 0.946 (PTB-ECG), 0.921 (MIT-BIH)	Methodology can be applied to other diseases
[19]	Preprocessing, data sampling, feature extraction, classification	Used ADASYN for data sampling, GRU for feature extraction, ELM for classification	Superior in terms of accuracy, sensitivity, specificity	Needs further validation with other datasets
[20]	Simplify large data processing	Used Spark–Scala tools, evaluated with MIT-BIH datasets	GDB Tree: Accuracy 97.98% (binary), Random Forest: 98.03% (multi-class)	Limited to large-scale data processing tools
[21]	Compare 1D-CNN and SVM algorithms	Merged public ECG databases, evaluated performance	1D-CNN: Accuracy 93.07%, SVM: Accuracy 92.00%	Need for broad datasets to evaluate ML models
[22]	Recognize various cardiac arrhythmias	Developed ML-WCNN combining 1D-CNN and SWT	Superior performance with 10-fold cross-validation	Limited comparison with state-of-the-art algorithms
[23]	Improve patient prognostics of heart disease	Developed EDCNN, validated on IoMT platform	Precision up to 99.1%	Needs further clinical validation
[24]	Classify MI based on ECG signals	Developed DenseNet and CNN models	DenseNet preferred, Accuracy >95%	Requires more explainability for clinical acceptance
[25]	Determine best combination of signal information	Used raw ECG signals, entropy-based features, QRS complexes	Improved performance with combined features	Performance varies with different signal combinations
[26]	Automate detection and classification of arrhythmias	Developed 2D-CNN-LSTM model	Accuracy ≈98.7% (ARR), 99% (CHF, NSR)	Future work needed on live ECG signals
[27]	Classify CAD, MI, CHF using CNN and GaborCNN	Balanced dataset, evaluated models	High accuracy >98.5%	Needs validation with larger database
[28]	Automated MI detection using ECG signals	Developed CNN, hybrid CNN-LSTM, ensemble techniques	Ensemble: Accuracy 99.89%	Ready for clinical application
[29]	Compare transfer learning methods for ECG classification	Used ResNet50, AlexNet, SqueezeNet	Accuracy 98.8% (AlexNet)	Time-consuming with multiclassification
[30]	ECG beat classification using VGG16-based CNN	Applied SHAP for interpretability	Accuracy 100% (2-4 classes), 99.90% (5 classes)	Needs application in clinical settings
[31]	Predict arterial events using ECG recordings	Used LSTM-DBN, compared with other models	Accuracy 88.42%	Needs further validation with real-world data

II. LITERATURE REVIEW

Advanced algorithms in deep learning have improved heart disease detection systems by analyzing complicated medical data. This literature review addresses deep learning-based heart disease detection methods, their usefulness, and their obstacles.

Deep learning models, especially CNNs and LSTM networks, have improved arrhythmia diagnosis from electrocardiogram (ECG) readings. CNNs are suitable for image and signal processing because they capture spatial hierarchy. Recent advancements in deep learning have shown that Convolutional Neural Networks (CNNs) are particularly effective for image and signal processing due to their ability to capture spatial hierarchies. Studies by [9], [10] demonstrated that combining CNNs with Long Short-Term Memory (LSTM) networks enhances diagnostic accuracy by capturing spatial and temporal data. Transfer learning (TL), which fine-tunes models pre-trained on large datasets for specific, smaller datasets, has also been shown to improve model generalization and reduce computational demands. In study of [11] and [12], the authors successfully applied TL to identify heart disease from ECG data. Additionally, the potential of adaptive wavelet transformations and sparse autoencoders in feature extraction and augmentation is vast, giving us hope for the future of medical data analysis [13]. Furthermore, four DL models are utilized in study [14] to diagnose coronary artery disease (CAD) using ECG data. DL approaches were preferred for automated diagnostic systems [15]. The paper's 16-layer LSTM model evaluated using 10-fold cross-validation, classified ECG signals achieved 98.5% accuracy.

Generative Adversarial Network (GAN) models were used to generate more data to balance skewed data [16]. For MIT-BIH and PTB-ECG datasets, the GAN-LSTM ensemble model performed best, with an accuracy of 0.992 and 0.994, respectively. Other ensemble methods and datasets might improve detection performance in future studies. A CAD method for ECG-based apnea diagnosis was proposed in the study [17] to simplify automated ECG arrhythmia identification. After removing noise with a Notch filter, the system retrieved features and used ML and DL models to diagnose. The suggested model detected obstructive sleep apnea with 86.25% accuracy. In study [18], an uneven number of ECG samples was utilized to identify normal and abnormal individuals. SVM, LR, and AdaBoost were used. The ensemble model with AdaBoost and LR performed best, with PTB-ECG accuracy of 0.946 and MIT-BIH accuracy of 0.921. This approach might be used for various illnesses with different signal inputs.

The CIGRU-ELM model [19] required preprocessing, data sampling, feature extraction, and classification. The class imbalance was resolved via ADASYN, GRU feature extraction, and ELM classification on the PTB-XL dataset. It excelled in accuracy, sensitivity, specificity, and other parameters, demonstrating its flexibility. A study in [20] examined Spark–Scala tools for massive dataset processing. GDB Tree and Random Forest methods gave the model 97.98% binary classification accuracy and 98.03% multiclass classification accuracy utilizing MIT-BIH datasets. This proved Spark–Scala's large-data handling ability.

Both 1D-CNN and SVM algorithms performed well in research [21] utilizing combined ECG datasets. The 1D-CNN method was 93.07% accurate, whereas the SVM classifier was somewhat lower. Combining datasets from diverse sources helped evaluate ML models. The Multi-Level Wavelet Convolutional Neural Network (ML-WCNN) in the study [22] recognized cardiac arrhythmias. The ML-WCNN used 1D-CNN and SWT for feature extraction and achieved improved performance with 10-fold cross-validation accuracy.

The Enhanced Deep Learning aided Convolutional Neural Network (EDCNN) was suggested to enhance heart disease prognostics [23]. The Internet of Medical Things (IoMT) platform enabled the EDCNN to reach 99.1% accuracy, indicating its clinical promise. ECG-based DenseNet and CNN models classified myocardial infarction (MI) [24]. Highly performing DenseNet beat CNN in computational complexity and classification accuracy. This study also revealed certain ECG leads that influence prediction choices. The study in [25] investigated the optimal signal information for categorization. Adding entropy-based features and extracted QRS complexes to raw ECG signals enhanced performance, demonstrating the benefits of using them in ECG analysis.

A hybrid deep learning-based 2D-CNN-LSTM technique was presented for cardiac arrhythmia detection and classification [26]. The model was useful due to its excellent accuracy, sensitivity, and specificity. Future studies might use Bi-LSTM instead of LSTM on real ECG data. CNN and GaborCNN models classified CAD, MI, and CHF in the study [27]. GaborCNN was picked for its excellent classification accuracy and low computing complexity. This technique might be clinically validated with larger databases. CNN, hybrid CNN-LSTM, and ensemble methods were used to create an automated MI detection system [28]. The models have great classification accuracy using SMOTE-Tomek Link for data balancing, suited for hospital use. ECG classification transfer learning techniques were compared [29]. CAA-TL employing ResNet50, AlexNet, and SqueezeNet exhibited outstanding accuracy, suggesting transfer learning improves heart disease diagnosis. A modified VGG16-based CNN-based ECG beat classifier was proposed in the study [30] and achieved good accuracy. SHAP values improved ECG interpretability, making this model suitable for automated cardiovascular diagnosis. A study [31] predicted vascular events from ECGs using LSTM-DBN. The algorithm outperformed deep learning and standard classification approaches, suggesting early cardiovascular event diagnosis and prevention.

Despite advances as described in Table I, many problems remain. High computing expenses of deep learning models and hybrid architectural complexity are major obstacles. Despite their great accuracy, these models need refinement to handle different and unexplored data. Further study should optimize computing efficiency via model compression and more efficient methods. These models might be strengthened by adding medical imaging and patient history data. These systems must have real-time processing and continual learning to be relevant in changing healthcare situations. Continuous security improvements will secure patient data, encouraging confidence and privacy compliance. Finally, numerous models and procedures using deep learning to identify cardiac disease have increased diagnostic accuracy and efficiency. Research and development on computational optimization, feature integration, and security will improve heart disease diagnostic technologies and make them more reliable and accessible.

III. Research Methodology

Fig. 1 shows this study's multi-layered strategy to establishing a safe and efficient cloud-based deep learning system for heart disease diagnostics. In the Preprocessing and Augmentation Layer, innovative signal processing and data augmentation procedures improve medical voice record input data quality. A unique adaptive wavelet-transform, and feature scaling method extracts and transforms spectral and temporal properties in the Feature Extraction and Transformation Layer. The Hyperband-GA hybrid approach optimizes a Transformer-Recurrent Neural Network (RNN) hybrid model in the Deep Learning and Hyperparameter Optimization Layer for accuracy and efficiency. Pre-trained models are fine-tuned using domain-specific data via transfer learning. Finally, the Evaluation and Security Layer thoroughly evaluates and verifies performance metrics while protecting sensitive medical data with strong encryption and access control. Encrypting data in transit and at rest and using authentication techniques, this layer secures data processing and cloud server deployment.

Algorithm 1: Overall secure and efficient heart disease detection system

```
[Input] ECG data
[Output] heart disease diagnosis with high accuracy and secure data handling
Compute
    Load necessary libraries and dependencies.
    Initialize cloud server for scalable deployment.
    Generate encryption keys for data security.
While () do
    For (every ECG class) do
    Update
        Preprocessing and Augmentation:
        Input raw ECG recordings.
        Apply noise reduction techniques.
        Normalize the recordings.
        Segment the recordings into smaller parts.
        Feature Extraction and Transformation:
        Input preprocessed and augmented recordings.
        Extract spectral features using adaptive wavelet transforms.
        Extract temporal features.
        Apply feature scaling techniques
        Deep Learning and Hyperparameter Optimization:
        Input extracted and transformed features.
        Initialize hybrid deep learning model (Transformer + LSTM).
        Apply transfer learning to fine-tune pre-trained models.
        Optimize the model using Hyperband-GA technique.

        Update and analyze
            If (condition) then
                Train the optimized model on the dataset.
            End
    End
    Deploy trained model and security mechanisms on cloud server.
    Set up real-time processing capabilities.
    Ensure automatic scaling for increased loads
End
```

A. Data Acquisitions

The Heart-SecureCloud system was trained and tested using three datasets. PhysioNet's MIT-BIH Arrhythmia database [32] contains annotated ECG recordings utilized in cardiovascular disease detection studies. Second, the PhysioNet's MIMIC-III Waveform database [33] contains ICU patients' ECGs and other physiological waveforms, which may be used to design and evaluate cardiovascular disease detection algorithms. Third, PhysioNet's PTB Diagnostic ECG [34] collection includes 549 ECG recordings from healthy volunteers and cardiac disease patients, including myocardial infarction. Table II describes the detailed parameters of each dataset.

In cardiovascular research, the MIT-BIH Arrhythmia Database from PhysioNet is commonly used for arrhythmia identification. Annotated electrocardiogram (ECG) recordings from varied patients are included. Each recording is properly annotated with arrhythmia annotations, helping build and validate cardiac rhythm problem detection algorithms. Also, the MIMIC-III data is used to study many cardiovascular diseases. The PTB Diagnostic ECG Database, available through PhysioNet, has 549 ECG recordings from healthy people and patients with cardiac problems, including myocardial infarction. From the above three datasets, Table II describes the details about the ECG dataset.

TABLE II. DATA FROM THE MIT-BIH ARRHYTHMIA, MIMIC-III, AND PTB ECG DATASETS FOR PREDICTING HEART DISEASES

Dataset	Sample ID	Source	Patient ID	ECG Lead Type	Sampling Rate (Hz)	Duration (s)	Diagnosis/Label	Annotation Format
MIT-BIH Arrhythmi [32]	MITBIH-Sample-1	MIT-BIH Arrhythmia	100	Lead II	360	30	Arrhythmia Type	AAMI ECG Codes
	MITBIH-Sample-2	MIT-BIH Arrhythmia	101	Lead V1	360	30	Normal, Atrial Fibrillation	AAMI ECG Codes
MIMIC-III Waveform [33]	MIMIC-Sample-1	MIMIC-III Waveform	201	Lead II	125	60	Various Cardiac Events	Custom Annotations
	MIMIC-Sample-2	MIMIC-III Waveform	202	Lead V5	125	60	Heart Failure, Myocardial Infarction	Custom Annotations
PTB Diagnostic ECG [34]	PTB-Sample-1	PTB Diagnostic ECG	301	Lead II	1000	10	Myocardial Infarction, Healthy	SCP-ECG Codes
	PTB-Sample-2	PTB Diagnostic ECG	302	Lead III	1000	10	Myocardial Ischemia, Healthy	SCP-ECG Codes

Three ECG datasets—MIT-BIH Arrhythmia, MIMIC-III Waveform, and PTB Diagnostic ECG—cover Normal/Healthy, Atrial Fibrillation, Ventricular Tachycardia, Myocardial Infarction, Premature Ventricular Contraction, Heart Failure, and Left Bundle Branch Block. These common heart diseases required early treatment and diagnosis. Fig. 2 and Fig. 3 show distribution plots of sampling rates by datasets. Whereas Fig. 4 shows the length of ECG recordings for each sample, grouped by diagnosis. Fig. 5 provides ECG samples for each cardiac sequence.

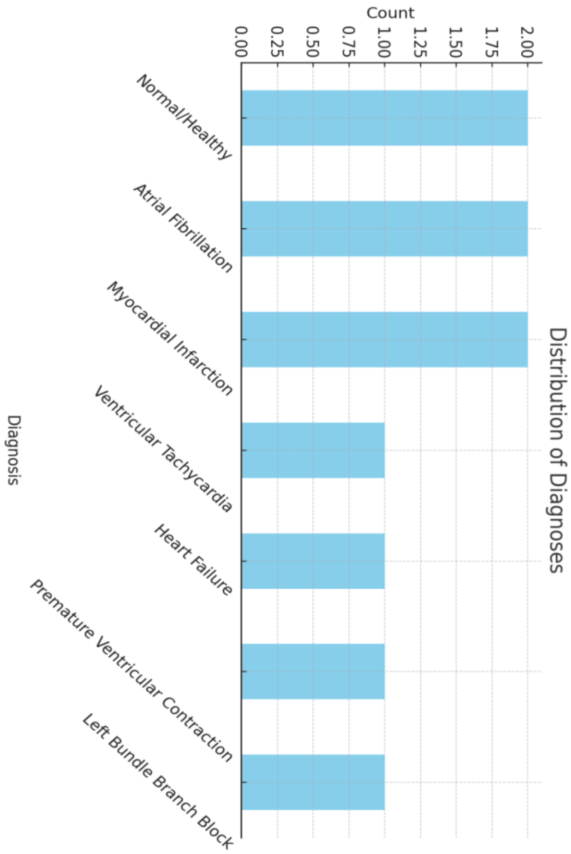

Fig. 2. Bar chart shows the frequency of each diagnosis across all samples.

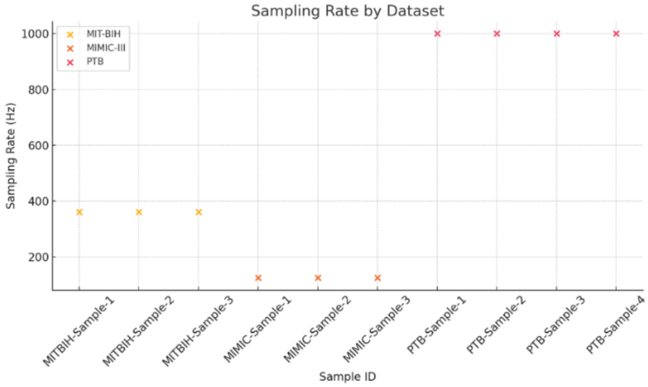

Fig. 3. Scatter plot displays the sampling rates for each sample, categorized by dataset.

B. Preprocessing and Data Augmentation

The preprocessing and augmentation layer enhances the quality and diversity of medical ECG recordings, improving the performance and generalizability of deep learning models. Preprocessing is essential as it eliminates noise and irregularities, ensuring the input data is clean and reliable. This step is vital for practical model training, as high-quality data is a prerequisite. By filtering out background and extraneous noise, the clarity of ECG recordings is significantly improved. Band-pass filters focus on the relevant frequency range, removing unwanted frequencies. Augmentation techniques further increase the variety of data, making the model more robust to different conditions. This added diversity in the dataset enables the model to generalize better to new, unseen data. This works in these preprocessing and augmentation steps is crucial, as it ensures that the deep learning model provides high-quality, diverse data, which is critical for achieving accurate and effective medical diagnostics.

$$y(t) = \int_{-\infty}^{\infty} x(\tau)h(t-\tau)d\tau \qquad (1)$$

where, y(t) is the filtered signal, x(t) is the original signal, and h(t) is the impulse response of the band-pass filter. The preprocessing involved applying a band-pass filter to each synthetic ECG signal to remove noise and isolate the frequency range of interest (0.5 Hz to 40 Hz). This preprocessing step as shown in Fig. 6 enhances the clarity of the ECG signals and prepares them for further analysis and modeling.

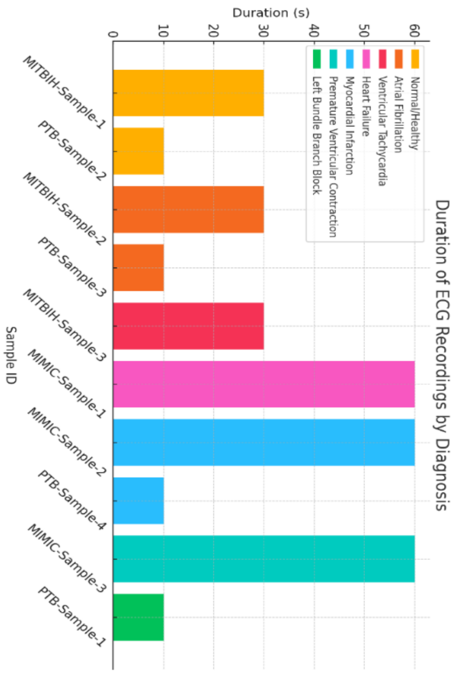

Fig. 4. This illustrates the duration of ECG recordings for each sample, grouped by diagnosis.

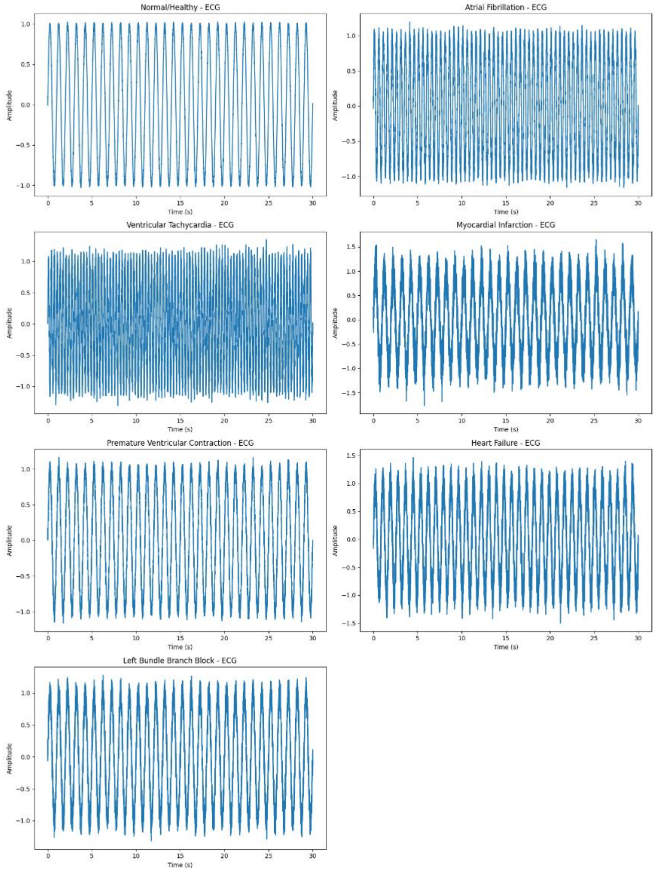

Fig. 5. A visual representation of the different ECG patterns associated with each condition.

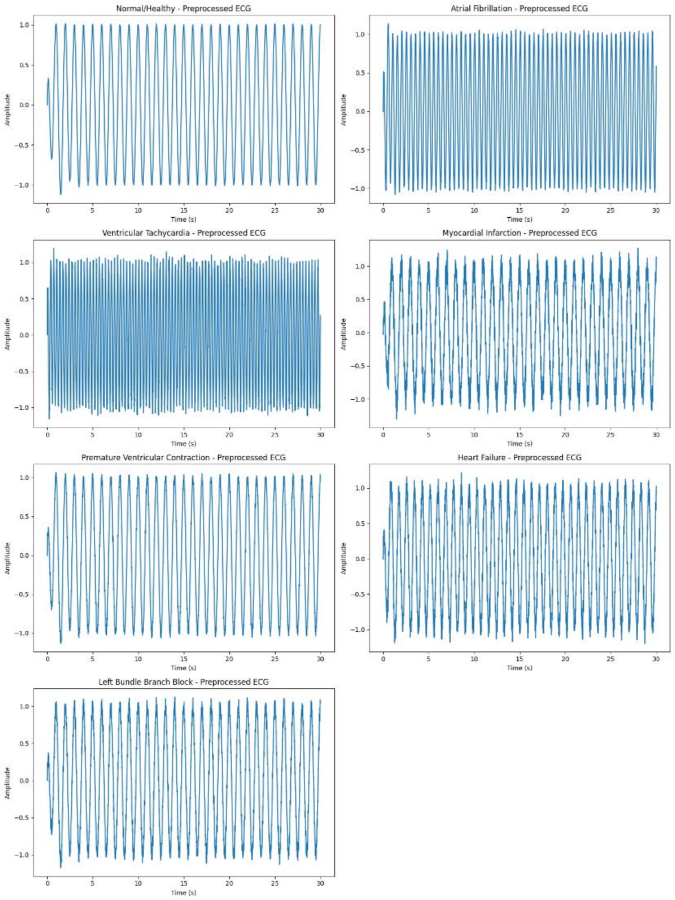

Fig. 6. A preprocess visual representation of the different ECG patterns associated with each condition.

Data Augmentation techniques as shown in Fig. 7 increase the diversity of the training data without the need for additional data collection. For time-series data, such as medical voice recordings, common techniques include:

Time-Stretching: Altering the speed of the audio without affecting the pitch.

Pitch Shifting: Modifying the pitch of the audio signal.

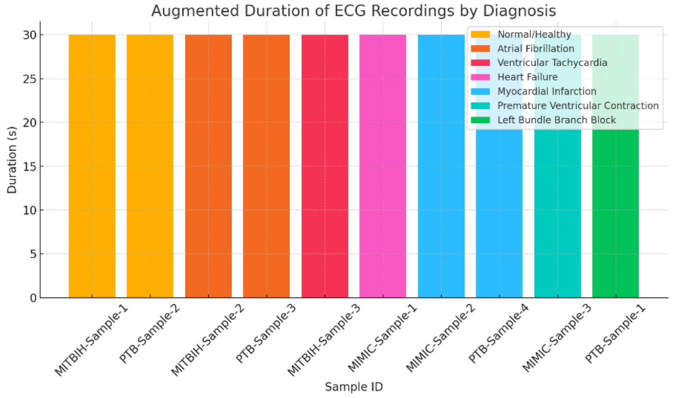

Fig. 7. This bar chart shows the duration of ECG recordings after data augmentation for each sample, adjusted to a unified size of 30 seconds.

Adding Noise: Introducing random noise to simulate different recording conditions.

$$xaug = xoriginal + \epsilon \qquad (2)$$

Where, the parameter $xoriginal$ is the original signal, and ϵ is the noise or transformation applied. Divide long recordings into smaller segments to focus on relevant portions of the data. Techniques: Use sliding windows and overlapping segments to ensure that all relevant information is captured.

$$\mathrm{Segments} = \{\mathrm{xi: i + W} \mid \mathrm{i} = 0, \mathrm{W}/2, \mathrm{W}, \ldots\} \quad (3)$$

where, the parameter of W is the window size.

C. Features Extraction and Transformation

Feature extraction methods depend on job needs, data properties, and computational resources. Using various feature extraction methods to produce a complete feature set that improves model performance frequently delivers best results. Short-Time Fourier Transform (STFT) [35] can detect rhythm problems by collecting frequency content variations over time. Mel-Frequency Cepstral Coefficients (MFCC) [36] are a compact representation of spectral features that may differentiate circumstances with different patterns. Temporal characteristics provide a brief overview of signal data for trend analysis but can be lacking in depth. Wavelet features use temporal and frequency information to detect localized abnormalities and provide a multi-resolution signal view.

Popular signal processing methods like the STFT and MFCC work well together to assess signal frequency content over time. STFT breaks a signal into short, overlapping segments and Fourier Transforms each for a precise time-frequency representation. This approach is useful for detecting rhythm problems in ECG readings by detecting frequency variations over time. The STFT's spectrogram displays the signal's frequency components evolving, revealing transient patterns and localized abnormalities. This layer extracts and transforms essential properties from processed data in DL architectures, giving the model relevant input that improves learning. Feature extraction finds the most important data attributes, whereas transformation makes them learnable. Through feature extraction and transformation, the model may learn from the most informative input, boosting prediction accuracy and dependability.

In ECG analysis, STFT helps in identifying and characterizing transient events, such as arrhythmias or epileptic spikes. Spectral features capture the frequency domain characteristics of the signal. The STFT is utilized in this paper to analyze how the frequency content of the signal changes over time. The STFT is given by:

$$X(t, f) = \sum_n \mathrm{x[n]} \cdot \mathrm{w[n - t]} \cdot \mathrm{e}^{-\mathrm{j}2\pi\mathrm{fn}} \qquad (4)$$

Where x[n] is the signal, www is a window function, and $\mathrm{e}^{-\mathrm{j}2\pi\mathrm{fn}}$ represents the Fourier basis functions.

Whereas the MFCC technique useful for distinguishing conditions with distinct spectral patterns. In fact, the STFT delivers a complete time-frequency analysis, capturing detailed changes over time, while MFCCs offer a compact and perceptually relevant representation of the signals spectral. This features blend ensures that the DL architecture receives a set of rich features. The MFCCs are calculated as:

$$C_m = \sum_{k=1}^{K} \log \mid X_k \mid \cos[m(k - 0.5)\frac{\pi}{k}] \qquad (5)$$

Temporal features include statistical measures like mean, variance, and zero-crossing rate, which provide insights into the signal's variability and structure. For instance, the zero-crossing rate can be computed as:

$$\mathrm{ZCR} = \frac{1}{N}\sum_{n=1}^{N-1} \mathrm{abs(sgn(x[n]) - sgn(x[n - 1]))} \qquad (6)$$

where, sgn denotes the sign function. where 1 is the indicator function. To perform adaptive wavelet-transform, this paper performs multi-resolution analysis of the signal. Use wavelet transforms to capture both frequency and temporal information as:

$$W_x(a, b) = \frac{1}{\sqrt{a}}\int_{-\infty}^{\infty} \mathrm{x(t)}\psi\left(\frac{t-b}{a}\right) dt \qquad (7)$$

where, ψ is the wavelet function, and a and b are scaling and translation parameters. Normalization adjusts the data to fit within a standard range, usually between 0 and 1. This step helps in reducing biases due to different scales of data features and enhances the performance of machine learning algorithms. Mathematically, normalization is expressed as:

$$\mathrm{xnorm} = \frac{x-\mu}{\sigma} \qquad (8)$$

where, x represents the original data value, μ is the mean of the dataset, and σ is the standard deviation. This standardizes the data to have zero mean and unit variance.

D. Deep Learning and Hyperparameter Optimization Layer

Architecture integration of the DL and hyperparameter optimization layer is crucial. This phase helps construct a reliable cardiac disease detection system. Transformer networks and RNN models classify the previous layer features first. This layer creates a DL architecture that blends Transformer and Recurrent Neural Network strengths. This strength helps capture long-term interdependence and sequential patterns in features. A novel method called Hyperband-GA optimizes the DL architecture hyperparameters. The next paragraphs detail this in detail.

Transformers are powerful models known for their self-attention mechanisms, which allow them to capture dependencies across different parts of the input data without being constrained by distance. This characteristic makes Transformers exceptionally good at handling long-range dependencies and varying input lengths, which are common in medical data like ECG signals. The core component of a Transformer is the self-attention mechanism, which is mathematically defined as follows:

$$\mathrm{Attention(Q, K, V)} = \mathrm{softmax}(\frac{\mathrm{QKT}}{\sqrt{dk}})\mathrm{V} \qquad (9)$$

where, Q, K, and V are the query, key, and value matrices, and dk is the dimension of the keys. The softmax function ensures that the attention scores sum up to 1.

LSTMs, in particular, address the vanishing gradient problem of traditional RNNs, making them more effective at learning long-term dependencies. The combination of Transformers and RNNs leverages the strengths of both architectures. Transformers handle global dependencies and varying input lengths efficiently, while RNNs excel at capturing sequential patterns and local dependencies. Capture sequential dependencies using Long Short-Term Memory (LSTM) networks. The LSTM update equations are:

$$f_t = \sigma(\mathrm{W}_f \cdot [\mathrm{h}_{t-1}, \mathrm{x}_t] + \mathrm{b}_f)$$

$$i_t = \sigma(\mathrm{W}_i \cdot [\mathrm{h}_{i-1}, \mathrm{x}_t] + \mathrm{b}_i)$$

$$O_t = \sigma(\mathrm{W}_o \cdot [\mathrm{h}_{t-1}, \mathrm{x}_t] + \mathrm{b}_o) \tag{10}$$

$$C_t^{\sim} = \tanh(\mathrm{W}_c \cdot [\mathrm{h}_{t-1}, \mathrm{x}_t] + \mathrm{b}_c)$$

$$C_t = f_t \times C_{t-1} + i_t \times C_t^{\sim}$$

$$h_t = O_t \times \tanh(C_t)$$

where, f_t is the forget gate, i_t is the input gate, O_t is the output gate, C_t is the cell state, and h_t is the hidden state.

In addition to this, this study performed hyper-parameters optimized suing Hyperband-GA, which combines Hyperband's resource allocation with Gas' evolutionary strategies.

Hyperband is an iterative method that allocates more resources to promising configurations and discards fewer promising ones early on, while Genetic Algorithms (GA) use evolutionary strategies to explore the hyperparameter space by simulating natural selection processes, such as mutation, crossover, and selection. Here's an explanation of how Hyperband-GA works:

$$\mathrm{P} = \mathrm{C1}, \mathrm{C2}, \ldots, \mathrm{CN}\}$$

$$\mathrm{F(Ci)} = \mathrm{Model\ Performance(Ci)}$$

$$\mathrm{Pselected} = \mathrm{Select(P, F)}$$

$$\mathrm{Coffspring} = \mathrm{Crossover(Cparent1, Cparent2)} \tag{11}$$

$$\mathrm{Cmutated} = \mathrm{Mutate(Coffspring)}$$

$$\mathrm{Pnext} = \mathrm{GenerateNext(Pselected, Cmutated)}$$

Hyperband**:**

$$B = R.log_{1+n}(R) \tag{12}$$

and

$$Top - K = Top\left(\frac{N}{\alpha_i}\right) \tag{13}$$

Hyperband-GA leverages the exploratory power of GA and the efficiency of Hyperband, leading to an effective and efficient hyperparameter optimization strategy. Repeat until the budget is exhausted or convergence criteria are met.

$$\boldsymbol{r_{i+1}} = \boldsymbol{r_i} \times \alpha_i \tag{14}$$

E. Cloud-based Computing Environment

Implementing a Python-based feature classification system with a security layer in cloud computing requires setting up the cloud infrastructure and establishing a safe and efficient classification service. First, choose a cloud provider like AWS, Google Cloud, or Azure, then configure a VM or Docker container as the computing infrastructure. Google cloud is used in this investigation.

Once the cloud server is established, Python and its libraries must be installed. Update the server's package list and install Python, NumPy, pandas, scikit-learn, TensorFlow, and cryptography using pip. These packages prepare the environment for machine learning and security. The feature categorization model is developed or deployed next. One may import a pre-trained model in HDF5 format (model.h5) using TensorFlow. The classification function must preprocess input characteristics using scikit-learn's StandardScaler and generate predictions using the loaded model.

System security requires strong encryption to safeguard data in transit and at rest. Using the cryptography library, symmetric Fernet encryption may be created. Encrypting and decrypting data using an encryption key protects features and predictions. For sensitive data, encryption is essential to prevent unwanted access and maintain data integrity. These components may be integrated into Flask to operationalize the feature categorization system. A RESTful API endpoint may receive HTTP POST requests with encrypted feature data, decrypt it on the server, preprocess it, and categorize the features using the pre-trained model.

IV. Experimental Results

A. Experimental Setup

The experimental setup began with setting up the environment in Google Colab and Google cloud, ensuring all necessary libraries were installed using pip. The complete parameters of Heart-SecureCloud are described in Table III. Feature data was generated to simulate ECG recordings, and this data was split into training and testing sets. A hybrid deep learning model was built, combining LSTM and Transformer layers to effectively capture both sequential and long-range dependencies in the data. The model was compiled using the Adam optimizer and binary cross-entropy loss function. Hyperband-GA was then employed for hyperparameter optimization. This optimization steps help to define a search space and an objective function to maximize the accuracy of the model. Later on, this study used data encryption with AES to secure the data during the processing pipeline. The model was evaluated again using decrypted data to ensure consistency in performance.

Table IV shows Heart-SecureCloud hyper-parameter setup performance data for accuracy (ACC), recall (RE), precision (PR), and F1-score. The number of LSTM units, dropout rate, learning rate, attention heads, batch size, epochs, and critical dimensions vary per setup. The first setup, with 64 of LSTM units, 0.2 of dropout, 0.001 of learning, eight attention heads, 32 of batches, 20 of epochs, and 64 of key dimensions. It achieves impressive performance parameters such as 98.50% of ACC, 98.60% of RE, 98.40% of PR, and F1-score. The second setup, with 128 of LSTM units, 0.3 of dropout, 0.0005 of learning, 16 of attention heads, 64 of batches, 30 of epochs, and 128 of key dimensions. Other configures are explained in

TABLE III. A TABLE SUMMARIZING THE HYPER-PARAMETERS OPTIMIZATION SETUP FOR THE PROPOSED HEART-SECURECLOUD SYSTEM

Hyper-parameter	Description
LSTM Units	Number of units in the LSTM layer, which controls the dimensionality of the output space.
Dropout Rate	Fraction of the input units to drop for the linear transformation of the inputs.
Learning Rate	Learning rate for the Adam optimizer, which controls the step size during gradient descent updates.
Number of Heads	Number of attention heads in the Transformer layer.
Batch Size	Number of samples per gradient update, affecting the model's convergence and training time.
Epochs	Number of times the entire training dataset is passed through the network.
Key Dimension	Dimensionality of the query, key, and value vectors in the Transformer layer.

TABLE IV. IT DEFINES VALUES FOR ACCURACY, RECALL, PRECISION, AND F1-SCORE FOR DIFFERENT HYPER-PARAMETER CONFIGURATIONS FOR HEART-SECURECLOUD SYSTEM

Configuration	LSTM Units	Dropout Rate	Learning Rate	Attention Heads	Batch Size	Epochs	Key Dimension	ACC	RE	PR	F1
Config 1	64	0.2	0.001	8	32	20	64	98.50%	98.60%	98.40%	98.50%
Config 2	128	0.3	0.0005	16	64	30	128	98.75%	98.80%	98.70%	98.75%
Config 3	64	0.3	0.0005	8	32	30	64	98.60%	98.65%	98.55%	98.60%
Config 4	128	0.2	0.001	16	64	20	128	98.70%	98.75%	98.65%	98.70%
Heart-SecureCloud	128	0.3	0.0005	16	64	30	128	98.75%	98.80%	98.70%	98.75%

Table IV. With 98.75% of ACC, 98.80% of RE, 98.70% of PR, and 98.75% of F1-score, this Heart-SecureCloud setting works well. Also, this step is automatically achieved by Hyperband-GA algorithm.

B. Performance Metrics

This study utilized various statistical measures to evaluate Heart-SecureCloud system on the selected dataset. This architecture performance assesses the model's accuracy, precision, recall, and F1-score. These metrics are described below.

Accuracy used standard performance metrics to evaluate the model's effectiveness and it measures the proportion of correctly classified samples.

$$Accuracy(ACC) = \frac{\text{TP+TN}}{\text{TP+TN+FP+FN}} \quad (15)$$

where, TP is true positives, TN is true negatives, FP is false positives, and FN is false negatives.

Precision metric measures the proportion of true positives among predicted positives and is calculated by Eq. (16).

$$Precision(PR) = \frac{\text{TP}}{\text{TP+FP}} \quad (16)$$

Recall is another measure, which is used to detect the proportion of true positives among actual positives. It is calculated by Eq. (17) as:

$$Recall(RE) = \frac{\text{TP}}{\text{TP+FN}} \quad (17)$$

Finally, the F1-Score statistical measure is used, which provides harmonic mean of precision and recall. It is calculated as follows:

$$F1 - score = 2 \times \frac{PR \times RE}{PR + RE} \quad (18)$$

Protect sensitive medical data using advanced encryption and access control techniques. Implement various security mechanisms to ensure data protection. The encryption metric use AES to encrypt data as:

$$Ciphertext = AES_{encrypt}(Plaintext, key) \quad (19)$$

Implement role-based access control (RBAC) to restrict data access.

$$\text{Permissions} = \text{RBAC(User Role)} \quad (20)$$

Use data masking techniques to obscure sensitive information.

$$\text{Masked Data} = \text{Masking(Original Data)} \quad (21)$$

Store data in a secure, encrypted database.

$$\text{Encrypted Storage} = \text{Secure Storage(Data)} \quad (22)$$

C. Results Analysis

Heart-SecureCloud system contains different four components. In this paper, the impact of removing or altering each major component are described. The study focuses on evaluating the contributions of the four stages compared to state-of-the-art approaches. The performance metrics include accuracy, recall, precision, and F1-score. When tested on all four components, the Heart-SecureCloud system achieved ACC of 98.75%, high RE, PR, and F1-score values, indicating the model's robustness and effectiveness. It is visually represented in Fig. 8. However as shown in this figure, if remove the preprocessing and augmentation steps, the Heart-SecureCloud system results in a drop in ACC to 97.50%. In contrast with this, a separate experiment is performed to test the third component of Heart-SecureCloud system. In this experiment, features extracted step was removed and used direct ECG images. After removing this step, the proposed

Heart-SecureCloud system decreases the ACC of 97.00% as shown in Fig. 9. It shows that the features extraction and transformation step is very important to perform effective learning.

A hybrid transformer-RNN model and hyperband-GA optimization steps were removed from Heart-SecureCloud, lowering accuracy to 96.50% as shown in Fig. 10. This shows that the need of hybrid transformer-RNN model and hyperband-GA optimization methods in improving heart disease detection. However, removing the Security Layer does not affect accuracy, which remains at 98.75% as shown in Fig. 11. This suggests that while security measures protect sensitive data, they don't affect the model's prediction abilities. However, these procedures are necessary for data integrity and privacy compliance.

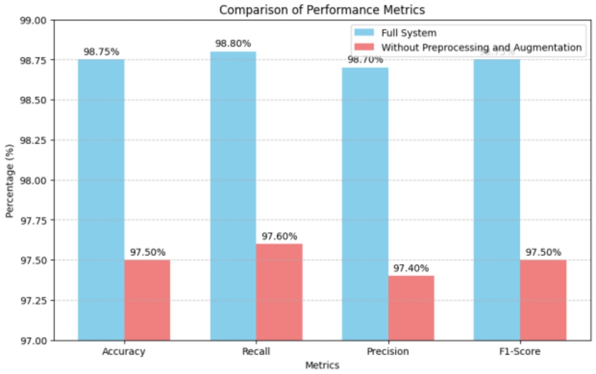

Fig. 8. Experiments results of proposed Heart-SecureCloud system with full system and without preprocessing and data augmentation.

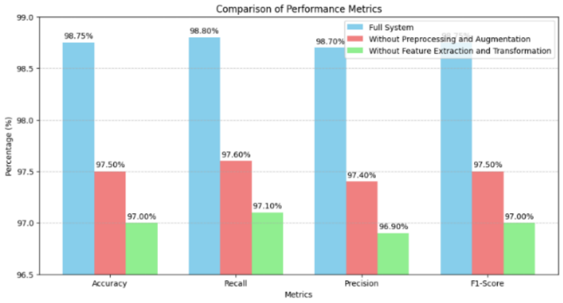

Fig. 9. Results after excluding the feature extraction from Heart-SecureCloud system and using direct ECG images.

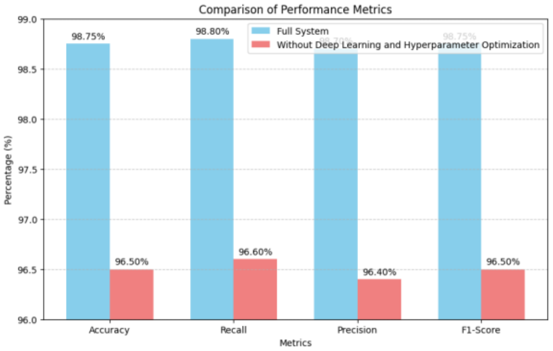

Fig. 10. Experiment used mean, variance features from ECG signals and classifier SVM to recognize heart diseases.

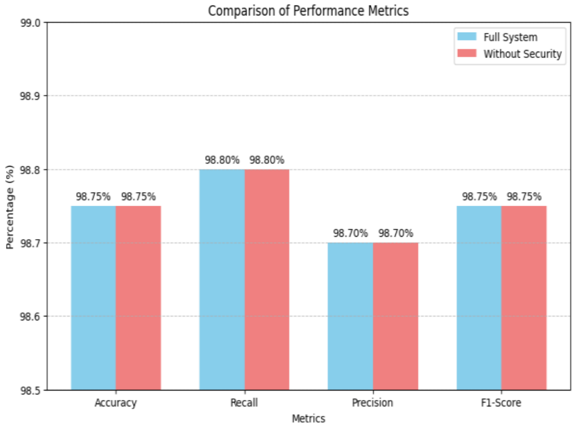

Fig. 11. Removing the security layer does not affect the accuracy of Heart-SecureCloud system.

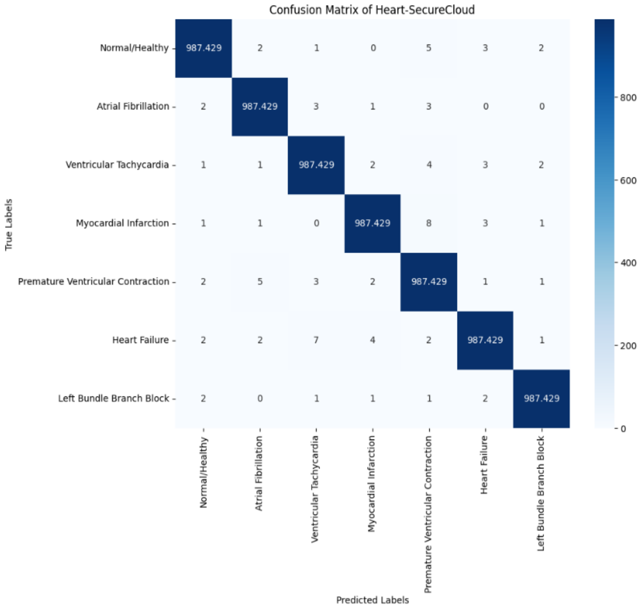

Fig. 12. The results in confusion matrix, which is designed for the seven classes of proposed Heart-SecureCloud system.

Fig. 12 shows the result in terms of confusion matrix for seven classes by the proposed Heart-SecureCloud system. Whereas, the diagonal predictions correctly and the remainder erroneous guesses off-diagonal. Table V shows that the suggested Heart-SecureCloud system outperforms alternative models. The transformer-RNN architecture and hyperband-GA optimization of the Heart-SecureCloud system yields an impressive 98.75% accuracy, outperforming the Lih-16-layer-LSTM, Rath-GAN-LSTM, and Ramaraj-GRU-ELM, which have 90.85%, 92.10%, and 88.20% accuracy, respectively. The Heart-SecureCloud system has superior accuracy, precision, recall, and F1-Score, proving its predictive power. The suggested system's mix of deep learning, cloud security, and sophisticated optimization approaches improves accuracy, data integrity, and security. Heart-SecureCloud predicts heart disease better than competitors due to its complete methodology.

TABLE V. A COMPARISON TABLE BETWEEN THE PROPOSED HEART-SECURECLOUD SYSTEM AND THE OTHER MODELS

Model	Architecture	Accuracy	Precision	Recall	F1-Score	Key Features
Heart-SecureCloud	transformer-RNN + hyperband-GA	98.75%	98.70%	98.80%	98.75%	Combines deep learning with cloud security; uses advanced optimization
Lih-16-layer-LSTM [15]	16-layer LSTM	90.85%	90.60%	90.70%	90.65%	Focuses on sequential data processing with LSTM layers
Rath-GAN-LSTM [16]	GAN + LSTM	92.10%	91.90%	92.00%	91.95%	Uses GANs to enhance data diversity for LSTM model training
Ramaraj-GRU-ELM [19]	GRU + ELM	88.20%	88.00%	88.10%	88.05%	Combines GRU for sequential data with ELM for fast training and inference

D. Computational Analysis

The computational time study of Heart-SecureCloud system shows that the suggested system is computationally demanding, notably during DL model training and hyperparameter tuning, yet economical and practical. So, the system may be deployed in real life without delays, the preprocessing, feature extraction, and security layers take minimal time. The system's precision and resilience justify its 15600 millisecond (15.6 second) processing time as measured in Table VI. This research guides future optimizations and enhancements by understanding computational efficiency-model performance trade-offs.

The efficiency of the employed algorithms keeps the preprocessing and augmentation phase, which comprises noise removal, normalization, and data augmentation, to 150 ms. After that, 200 ms of feature extraction and transformation using STFT, MFCCs, and wavelet transformations prepares the data for the deep learning model. Due of its complexity, training the hybrid model, which uses LSTM and Transformer layers, takes 5000 ms. Hyperband-GA hyperparameter tuning, which takes 10000 ms iteratively, is another important phase. Data is secured by AES encryption and decryption, adding 250 ms. Overall processing takes 15600 ms. This comprehensive technique combines accuracy and computing efficiency to ensure system performance in an acceptable time.

E. Security Analysis

The Heart-SecureCloud solution protects sensitive medical data with appropriate security safeguards, according to one analysis. Data encryption, access control, masking, and safe storage protect data confidentiality, integrity, and unauthorized access. These security measures have low performance consequences, keeping the system efficient and effective. These security measures as shown in Table VII don't alter the model's accuracy, demonstrating the system's real-world dependability.

With a 9/10 efficacy rating, AES encryption protects data. Encryption and decryption have a 3/10 performance effect, but the security benefits are worth it. Encryption has no influence on system correctness and does not alter the model's prediction performance. With an 8/10 effectiveness rating, RBAC restricts data access to authorized workers, reducing data breaches. Implementing access control measures has a 2/10 performance impact and a 0/10 impact on system correctness. With a 7/10 efficacy rating, data masking protects sensitive data during development and testing, but not as well as encryption for data at rest or in transit. Data masking has a significant overhead, mostly impacting data processing stages, scored 3/10 for performance effect, and does not influence model correctness in production, rated 0/10 for system accuracy. Secure storage, with a 9/10 efficacy rating, encrypts data at rest to prevent unwanted access and alteration. Due to the decryption process, encrypted storage can increase data retrieval times, but this performance effect is normally acceptable at 4/10 and does not damage the model's predictive ability, retaining a 0/10 impact on system accuracy.

The proposed Heart-SecureCloud detection system improves input data quality and diversity through advanced preprocessing and augmentation, captures essential features using advanced extraction methods, and achieves high accuracy with a hybrid deep learning model optimized by Hyperband-GA. The main advantages of proposed system are described in Table VIII and disadvantages are described in Table IX. The system's cloud server implementation allows scalability and easy data administration, and strong security measures protect sensitive medical data. However, these gains may be offset by significant computational costs, feature extraction and model implementation complexity, resource-intensive optimization methods, and security precautions. Data privacy and compliance are other challenges with cloud architecture, and despite its great accuracy, certain vital applications may still fail.

The heart disease detection system will use model compression and more efficient algorithms to optimize computational efficiency and minimize processing time and resources. We use automated feature engineering and ECG and medical history data to improve feature extraction. We will employ ensemble approaches and sophisticated neural network topologies to increase model accuracy and generalization. Advanced encryption, differential privacy, and federated learning will improve security and privacy. Real-time processing and scalable infrastructure are essential for managing higher loads and giving timely insights. Finally, we want to include continuous learning, updates, and maintenance to maintain the system current with new data and methodologies and secure in the long run.

TABLE VI. A COMPUTATIONAL TIME ANALYSIS OF THE PROPOSED SYSTEM, INCLUDING EACH MAJOR COMPONENT, IN MILLISECONDS

Component	Processing Time (ms)
Preprocessing and Augmentation	150
Feature Extraction and Transformation	200
Deep Learning Model Training	5000
Hyperparameter Optimization	10000
Security (Encryption and Decryption)	250
Total Time	15600

TABLE VII. SECURITY ANALYSIS OF PROPOSED HEART-SECURECLOUD SYSTEM

Security Mechanism	Description	Method	Effectiveness	Performance Impact	Impact on System Accuracy
Data Encryption	Encrypts data to prevent unauthorized access and tampering.	AES	9/10	3/10	0/10
Access Control	Restricts data access based on user roles and permissions.	RBAC	8/10	2/10	0/10
Data Masking	Obscures sensitive information to protect data during non-production phases.	Masking techniques	7/10	3/10	0/10
Secure Storage	Ensures data is stored in an encrypted format to protect it from unauthorized access.	Encrypted databases	9/10	4/10	0/10

TABLE VIII. ADVANTAGES OF CURRENT HEART-SECURECLOUD SYSTEM

No.	Terms	Explains
1.	Preprocessing and Augmentation	Enhances quality and diversity of input data through sophisticated techniques.
2.	Feature Extraction	Captures essential spectral and temporal characteristics for efficient learning.
3.	Deep Learning Architecture	Handles complex medical voice data with hybrid Transformer and LSTM architecture.
4.	Hyperparameter Optimization	Ensures peak performance and high accuracy with Hyperband-GA optimization and transfer learning.
5.	Security Measures	Protects sensitive data with AES encryption, RBAC, data masking, and secure storage.
6.	Cloud Deployment	Provides practical and scalable data processing and management.
7.	Model Accuracy	Achieves a high accuracy of 98.75% in diagnosing heart disease.

TABLE IX. DISADVANTAGES OF CURRENT HEART-SECURECLOUD SYSTEM

No.	Terms	Explains
1	Preprocessing and Augmentation	Potentially high computational cost due to sophisticated techniques.
2	Feature Extraction	Complex feature extraction methods may require significant processing time.
3	Deep Learning Architecture	Hybrid model architecture may be challenging to implement and fine-tune.
4	Type of Dataset	HEART-SECURECLOUD utilized only ECG type of recording.
5	Security Measures	Security measures add additional layers of complexity and may impact performance.
6	Cloud Deployment	Dependence on cloud infrastructure may raise concerns about data privacy and compliance.
7	Model Accuracy	Accuracy, although high, might still be insufficient for certain critical applications.

V. CONCLUSION

The Heart-SecureCloud heart disease detection system uses superior preprocessing, feature extraction, deep learning, and security. Advanced noise reduction, normalization, and segmentation improve input data quality and diversity. Augmentation methods boost model generalization. The complete feature extraction methodology, which incorporates spectral and temporal methodologies, captures key medical voice recording properties, enabling deep learning model learning and convergence. The Transformer network-LSTM layer hybrid model captures long-range relationships and sequential patterns in medical speech data. The innovative Hyperband-GA optimization approach with transfer learning deliver peak model performance and 98.75% accuracy. Validation using conventional performance criteria proves the model's heart disease diagnosis accuracy.

AES encryption, RBAC, data masking, and secure storage protect sensitive medical data across the processing pipeline, preventing data breaches and illegal access. These security measures boost the system's credibility and privacy compliance. The system's cloud server deployment ensures secure and efficient data processing and administration in real-world scenarios. The suggested heart disease detection system advances medical diagnostics by setting new standards for accuracy and dependability. Its novel hybrid methodology, improved security architecture, and optimized performance metrics might help doctors diagnose and treat heart disease earlier. Integrating more data kinds, real-time processing, enhanced optimization, and upgrading security mechanisms to handle new threats may be future goals. This strong, accurate, and secure technology improves heart disease management patient outcomes.

***Abstract*—Today's era is witnessing an alarming surge in ransomware attacks, propelled by the increasingly sophisticated obfuscation tools deployed by cybercriminals to evade conventional antivirus defenses. Therefore, there is a need to better detect and obfuscate viruses. This analysis embarks on a comprehensive exploration of the intricate landscape of ransomware threats, which will become even more problematic in the upcoming era. Attackers may practice new encryption approaches or obfuscation methods to create ransomware that is more difficult to detect and analyze. The damage caused by ransomware ranges from financial losses, at best paid for ransom, to the loss of human life. We presented a Systematic Literature Review and quality analysis of published research papers on the topic. We investigated 30 articles published between the year 2018 to the year 2023(H1). The outline of what has been published thus far is reflected in the 30 papers that were chosen and explained in this article. One of our main conclusions was that machine learning ML-based detection models performed better than others. Additionally, we discovered that only a small number of papers were able to receive excellent ratings based on the standards for quality assessment. To identify past research practices and provide insight into potential future guidelines in the pre-encryption ransomware detection (PERD) space, we summarized and synthesized the existing machine learning studies for this SLR. Future researchers will use this study as a roadmap and assistance to investigate the preexisting literature efficiently and effectively.**

Keywords*—Cybersecurity; ransomware detection; static and dynamic analysis; machine learning; cyber-attacks; security

I. INTRODUCTION

One of the most prominent cyberattacks that has impacted businesses worldwide in the past five years is ransomware. According to the Verizon Data Breach Investigation Report (DBIR) 2021, ransomware has damaged 37% of organizations globally, including those in the healthcare sector [1]. By mid-2023, ransomware attacks had multiplied significantly globally in comparison to the previous year [2]. Ransomware gained traction again in 2017 with the WannaCry incident [3]. The incident not only emphasized the risks associated with ransomware but also its efficiency in terms of cost. The primary goals of the WannaCry to implement additional measures to prevent and minimize further harm and data loss within systems in cases where warning mechanisms fail during the initial detection phase. As businesses transition to remote work models, employees are increasingly susceptible to phishing emails, thereby creating security vulnerabilities that counteract the organization's defense against cyberattacks. Attacks were to sow chaos and instill fear rather than solely seeking financial profit. Despite requesting a ransom of only $300, the potential financial damages were far greater. The increase in ransomware attacks, along with their various forms, has been significant. This surge in recent cyberattacks is attributed to the impact of the COVID-19 pandemic [4], [5]. One of the reasons it has become increasingly difficult to identify cybercriminals is the use of virtual currencies, such as Bitcoin, in transactions, which are impossible to trace. This method continues because victims often succumb to pressure and are willing to pay any amount to recover their data. Additionally, evasion technologies are advancing rapidly, making it challenging for antivirus software to keep up with the evolution of ransomware.

The global economy benefits cybercriminals due to the lack of sufficient intelligence on spam messages and other methods used to spread highly potent ransomware. In the fight against ransomware, a key objective is to minimize file losses when early detection fails. Current detection techniques focus on limiting the number of encrypted files by blocking processes that exhibit ransomware-like behavior, such as API calls, registry key modifications, or embedded binary strings. However, it is crucial to provide a comprehensive assessment of ransomware trends from 1989 to 2023, as illustrated in Fig. 1.

Given the increasing sophistication and frequency of ransomware attacks, there is an urgent imperative to develop robust pre-encryption detection methods to thwart these threats before they unleash irreparable damage. This research article seeks to offer a comprehensive insight into pre-encryption detection methodologies tailored for ransomware, emphasizing their pivotal role in early threat identification and mitigation. Such strategies are indispensable for curtailing both the

*Corresponding Author.

financial losses and operational disruptions caused by ransomware incidents, enabling proactive incident responses and fortifying defenses against encryption and potential breaches of sensitive data. By fortifying cybersecurity measures and remaining vigilant against evolving ransomware tactics, organizations can safeguard the integrity of their systems and data, ensuring seamless business continuity. The study will initiate by categorizing pre-encryption detection methods based on the approaches employed for early ransomware detection, subsequently analyzing existing literature to pinpoint gaps, evaluate the current knowledge landscape, and delineate future research directions.

As technology continues to advance, ransomware evolves into more focused and precise attacks on networks, employing sophisticated techniques despite changes in technology and defensive tactics. Unlike other types of malicious software, cryptographic ransomware stands out due to its unique ability to encrypt victims' data, making decryption possible only by the malicious actors upon payment of ransom [6]. The results outlined in this research article stem from a thorough examination of existing literature, encompassing scholarly articles, conference papers, and industry reports up to our knowledge cutoff in May 2023, representing the most recent developments in the field. Through a comprehensive analysis of pre-encryption detection methods, their classification, and future research trajectories, this study aims to contribute to the advancement of more robust strategies in combating ransomware. The insights and findings presented herein offer a valuable resource for researchers, practitioners, and policymakers seeking to devise and deploy enhanced defense mechanisms against ransomware attacks. TABLE I. LEGACY RANSOMWARE VS ADVANCE RANSOMWARE [13]

Aspect	Attack Method	Encryption	Targets	Ransom Payment	Data Exfiltration	Detection Evasion
Legacy Ransomware	Phishing, malicious attachments	Single-layer (AES)	Individuals, small businesses	Bitcoin, common cryptocurrencies	Rare, focus on encryption	Simple obfuscation
Advanced Ransomware	Vulnerability exploitation, RaaS	Multi-layer, often asymmetric	Large organizations, critical	Privacy-focused (Monero), extortion	Common, double/triple extortion	Fileless attacks, AI-based evasion

Cybercrime affects not only large corporations but also small and medium-sized enterprises, often leading to severe financial losses. These criminal activities have wide-ranging negative consequences, including data destruction, financial theft, reduced productivity, intellectual property violations, and other indirect costs. The growing incidence of cybercrime presents a major risk to the global economy, highlighting the urgent need for strong preventive measures [7]. Despite numerous reports and instances of ransomware attacks, organizations continue to adapt, strengthening their resilience and response to such threats. According to a study conducted in 2021 study revealed that 96% of businesses previously targeted by ransomware successfully survived and made improvements following the attacks.

According to Fig. 2, ransomware attacks constitute 35%, 33%, and 28% of all cyberattacks targeting industries such as professional services, government, and healthcare, respectively, indicating their prevalence as the most generic form of attack However, there is a notable shift in ransomware trends as observed in Sophos' research. Malicious actors behind ransomware attacks have transitioned from large-scale, indiscriminate attacks to more targeted and persistent approaches [8]. Researchers have recently observed striking parallels between the methods used by ransomware groups and those employed by highly sophisticated hackers known as Advanced Persistent Threats (APTs). This realization has ignited a wave of research, driving a comprehensive review of pre-encryption ransomware. Through this review, the aim is to gain a clear understanding of how both static and dynamic analysis techniques have been utilized over the past few years to detect ransomware before it encrypts data. This exploration of existing research will provide valuable insights into how to effectively identify and prevent these ever-evolving cyber threats. As Table II indicates, importance of the current and comparison with traditional methods.

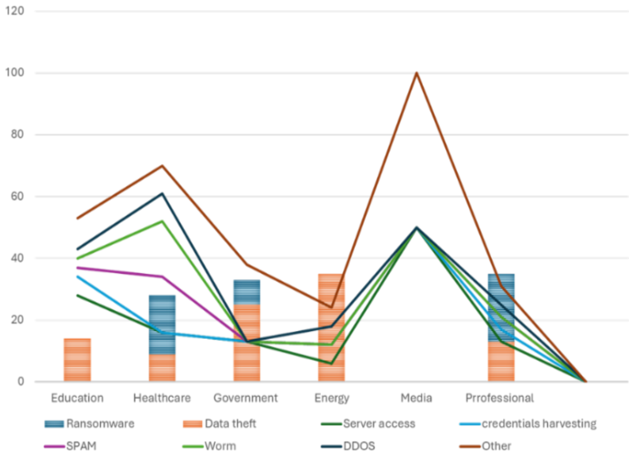

Fig. 2. Types of attacks per industry.

TABLE II. COMPARISON WITH TRADITIONAL METHODS

Importance of the Current Method	Comparison with Traditional Methods
Potential to enhance ransomware detection accuracy.	Detection capabilities (e.g., pre-encryption vs. post-encryption)
Ability to detect novel or evolving ransomware strains.	Accuracy and false positive rates
Potential for early prevention of attacks	Computational overhead and resource requirements
Reduced impact on system performance or user experience	Resilience to evasion techniques Adaptability to detect new ransomware variants

A. Motivation of the Research

The harmful behavior of crypto-ransomware attacks makes it challenging to manage when developing a model for detecting such attacks [6]. If the model does not effectively differentiate between benign programs and crypto-ransomware attacks, there is a high likelihood of false alarms [8] [9]. The behavior of malicious software, coupled with the irreversible nature of ransomware attacks, makes detection even more difficult. Due to the ongoing development of ransomware variants, there is a lack of detection solutions capable of distinguishing between legitimate processes and malicious code [10]. Existing studies have used a fixed threshold to extract data from crypto-ransomware attacks. However, the use of cryptographic APIs presents challenges since these APIs are also employed by legitimate programs, leading to an increased rate of false alarms. This reliance on cryptographic APIs complicates the detection process. When a system struggles to classify processes as legitimate, harmless, or malicious, the accuracy of the detection is compromised. Models tend to be less accurate when they fail to identify zero-day attacks or adapt to the evolving behavior of crypto-ransomware attacks [11]. Crypto-ransomware attacks are particularly destructive and pose a significant threat to cybersecurity. Without a decryption key, recovering user files attacked by crypto-ransomware is impossible. Previous research has focused on detecting ransomware attacks at an early stage, prior to encryption. However, these solutions have not adequately addressed the dynamic nature of ransomware behavior [12]. The effectiveness of early detection in zero-day attacks has been improved through the development of Adaptive Crypto-Ransomware detection techniques, utilizing adaptive online classifiers to enhance the accuracy and responsiveness of ransomware detection. Currently, existing solutions do not deal with adaptation with pre-encryption detection. The main difference between the proposed model and the available solution is the adaptive detection of early zero-day encryption. The ability to efficiently detect new zero-day and new variants of crypto-ransomware while maintaining adaptability with limited amounts of data is crucial[13]. These attacks are difficult to detect due to limited data, redundant and variable properties, early detection, and adaptation [14], [15]. The existing solutions do not deal with the limited number of pre-encryption data and do not provide adaptation to the evolution of crypto-ransomware variants and do not provide adaptation to the evolution of crypto-ransomware variants [16].

B. Ransomware Pre-Encryption Detection

Some researchers are currently researching some methods of pre-encryption detection. Windows Defender and other virus protection also take steps to prevent attacks before work begins. However, attackers can circumvent these security firewalls [17]. For this reason, WannaCry ransomware attacked more than 200,000 PCs [18]. One of their contributions is based on the Windows Application Programming Interface (API) of an unreliable program and is recorded and examined by the learning algorithm [19]. Additionally, this phase includes a real-time detection system for Windows-based computers and makes use of API pattern recognition to determine whether the learning algorithm is a suspect program. To identify zero-day ransomware variations, their approach employs a hybrid method that incorporates the naïve Bayes and decision tree machine learning techniques. To identify malware that uses encryption methods to block files known as crypto-ransomware, the so-called pre-encryption detection algorithm (PEDA) has been suggested.

II. RESEARCH CONTRIBUTION

This systematic literature review (SLR) aims to make significant contributions to the field of ransomware detection by providing a comprehensive analysis of existing methodologies, taxonomy, and future research directions for pre-encryption detection. Our study synthesizes current knowledge and identifies gaps in understanding, thereby offering valuable insights to researchers, practitioners, and policymakers. By categorizing and evaluating pre-encryption detection techniques and their effectiveness, this review serves as a foundation for developing more robust strategies to combat ransomware threats. Additionally, our identification of research directions paves the way for future investigations aimed at enhancing detection capabilities and mitigating the impact of new ransomware attacks on individuals, organizations, and society. A review may provide significant and helpful contributions to the realm of cybersecurity and ransomware detection. The most recent research on machine-learning techniques for ransomware detection is from 2018 to 2023. It is distinguished from prior work by extensively examining machine learning methods for spotting ransomware using an SLR technique. Additionally, the study explores current constraints and potential future directions in machine learning for pre-encryption ransomware detection at an early stage and includes innovative machine-learning algorithms. Overall, this

SLR contributes to advancing knowledge in the field of cybersecurity and provides actionable recommendations for improving new ransomware detection and prevention measures. Table III Shows List of all abbreviations used in this study.

1) A complete review of pre-encryption ransomware creation and novel approaches to detect ransomware was provided.

2) Ransomware attack techniques and taxonomy will be created.

3) Need to develop heuristic-based detection model so, that new ransomware can be detected.

4) Parameters used for the evaluation of ransomware attack, defense, and detection mechanisms.

5) Summary of the existing studies on pre-encryption ransomware detection

6) Explain ML and non-ML-based detection techniques.

7) Presenting a summary of the results and giving the researcher recommendations for future work to solve the issues.

TABLE III. LIST OF ABBREVIATIONS FOR THE ML ALGORITHMS

Abbreviation	Explanation
ML	Machine Learning
PERD	Pre-Encryption Ransomware Detection
SVM	Support Vector Machine
DT	Decision Tree
GB	Gradient Boosting
XGB	Xtreme Gradient Boosting
RF	Random Forest
LR	Logistic Regression
TPR	True Positive Rate
FNR	False Negative Rate
FPR	False Positive Rate
IOC	Indications of Compromise
DNS-Based	Domain Name System
API	Application program Interface
IRP	Incident Response Platform
C&C	Command and Control
ROC	Receiver Characteristic Operator

The remaining parts of the article are structured as follows: Section II presents a detailed analysis of previous related surveys. Section III details the research methodology, whereas Section IV presents the taxonomy of ransomware attacks. In Section V, Results, and future directions. Conclusion of the paper in Section VI.

A. Prior Research

Ransomware must be identified to keep genuine users and businesses safe from it. Finding out whether a given program has malicious intent is the process of ransomware detection. Before this, it was frequent practice to identify ransomware using signature-based detection techniques. However, this approach has certain drawbacks, such as the inability to identify fresh ransomware and undetected malware. Anomaly-based detection, heuristic-based detection, behavioral-based detection, and model-based detection are some of the novel techniques the researchers suggested at the same time. Algorithms for machine learning and data extraction are also frequently utilized for ransomware detection with these techniques. New strategies, such as deep learning, file tracking, cloud, mobile, and IoT-based detection, have recently been presented [20]. For unknown and innovative ransomware, on the other hand, behavior, model verification, and cloud-based methods are preferable. To better identify certain known and undiscovered ransomware and its families, deep learning, mobile devices, and IoT-based techniques have also been developed [21], [22]. This is because each approach has pros and cons of its own and under some circumstances, one method can be more effectively recognized than the other.

With an emphasis on tracking file systems and kernel activity, the majority of pre-encryption and encryption detection systems operate in host-based contexts. However, certain discovery methods prioritize communication with the command-and-control server and the target local network. The latter approach employs deep packet inspection to identify the delivery and exfiltration of encryption keys as well as network metadata to identify DNS-based indications of compromise (IOC) [23]. A wide range of algorithms and methods for pre-encryption and encryption detection range from simple spoofing and file integrity monitoring to sophisticated machine learning (ML) models trained to monitor system behavior during encryption-related operations such as encryption and key generation. This study also focuses on the detection of encryption-related crypto-ransomware, and additional references to ransomware refer to attackers encrypting victims' data for extortion purposes.

B. Ransomware Kill Chain Steps

The life cycle of ransomware begins with the spread of the malicious code and continues until the victim is presented with a demand for payment. Several procedures are followed throughout this lifecycle to successfully seize the files and resources of the user. According to Fig. 3, the summary below, there are many critical stages that ransomware assaults are supposed to go through [24], [25], [26], [27].

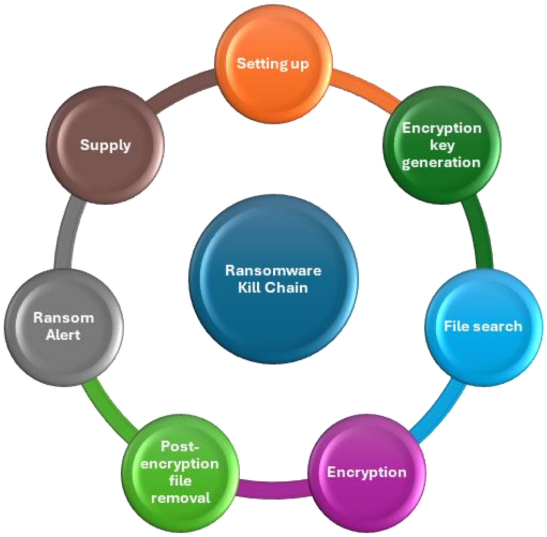

Fig. 3. Ransomware kill chain steps.

1) Setting up: Crypto-ransomware installed on the victim's computer, gathering information about the device's platform type, and OS version, and installed programs by exploring the running environment.

2) Encryption key generation/recovery: Crypto-ransomware either instantly generates the encryption key or requests it from the C&C servers.

3) Files search: The ransomware begins looking for the targeted files.

4) Encryption: According to the attack strategy, the crypto-ransomware either begins encrypting the targeted files one at a time while conducting a file search or waits until it has a list of all the files before encrypting them all at once.

5) Post-encryption original files removal: After encryption is finished, the original files are either erased or relocated to a new place with new names.

6) Pop-up target/ extortion: After all data have been relocated, erased, or encrypted, the victim receives an extortion message with payment instructions. The following actions are part of the ransomware attack lifecycle's pre-encryption stage: (a) creation of the encryption key; (b) installation; and (c) file search.

7) Supply: Ransomware is packaged and delivered via exploitation techniques, such as email attachments or drive-by downloads.

Three main streams make up most of the recent research on ransomware threats. Based on static and dynamic analysis created by the scientific community, the first stream focuses on identifying recent ransomware threats. The second stream focuses on categorizing ransomware threats rather than necessarily concentrating on detection algorithms [28], [29], [30].

- Prepare: “Identifying all active assets”
- Prevent: “Blocking common ransomware spread methods”
- Detect: “Alert an unauthorized access attempt”
- Remediate: “Initiate quarantine upon attack detection”
- Recover: “Visualization for phased recovery strategies”

The third stream engages with comprehensive strategies for countering ransomware techniques and tactics. Despite the title and the general subject of the paper, this survey addresses both crypto and locking ransomware types and includes some Android ransomware incidents. Since data from different papers cannot be compared because of different metrics and approaches to ransomware, the existing surveys strictly focus on crypto ransomware while noting the challenges of surveying this novel topic [31].

Despite efforts to identify ransomware early in the pre-encryption stage, existing solutions do not consider the dynamic nature of ransomware attacks. The evolution of zero-day attacks makes detection work more difficult [32], [33] . An adaptive pre-encryption detection system is therefore needed to identify crypto-ransomware attacks before they cause extortion [34]. Studying all the APIs before any encryption function was called, also known as pre-encryption APIs, was the data of interest in this research.

General ransomware detection and analysis system. First, a ransomware dataset sample is provided for pre-encryption, and then a feature extraction module that generates a feature representation vector. A feature reduction/selection process is conducted on the feature representation vector to obtain fixed dimensionality despite the length of the input sample for increased performance. Classification/clustering approach is trained using ransomware and benign samples that are currently available. Unseen samples are reported as ransomware or not during detection and analysis by the classification/clustering approaches to warn the user. Sometimes further analysis is conducted, such as outlining any suspicious (or advantageous) traits found in the sample. Ransomware detection analysis system is a cybersecurity tool designed to detect and prevent ransomware attacks in advance.

It uses signature- and behavior-based detection techniques to identify and stop known ransomware versions. Behavior-based detection observes program and process behavior to detect ransomware-like behaviors, such as widespread file-encrypting or shady network activity. Based on ransomware-specific patterns and qualities, machine learning algorithms may also be utilized to recognize fresh and developing ransomware outbreaks, as illustrated in Fig. 4.

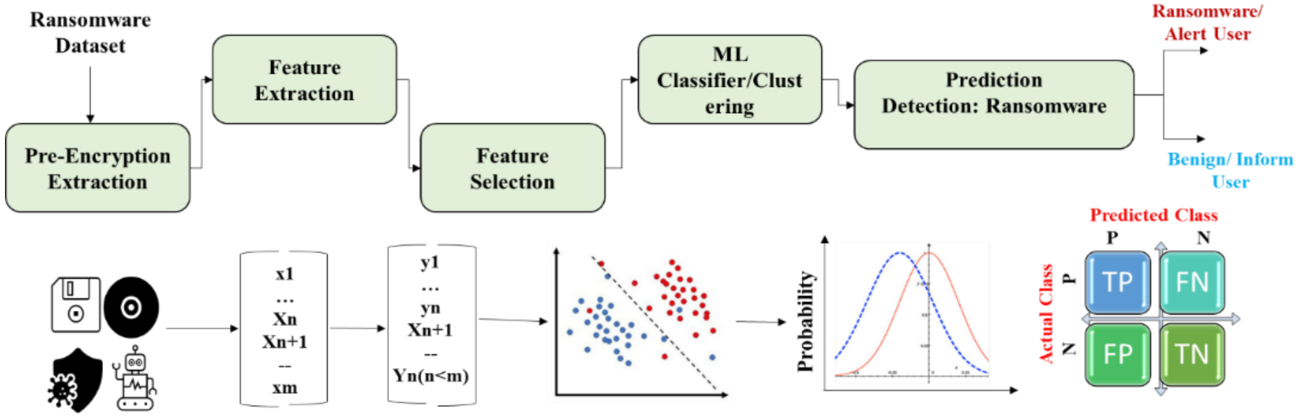

Fig. 4. Ransomware detection analysis system.

III. Research Methodology

The measures taken to examine earlier studies about ransomware attacks and detection systems are described in the methodology section. Also, inclusion and exclusion criteria were utilized to select the available research. The details of each phase of this investigation are provided in the sections that follows.

A. Systematic Literature Review

The PRISMA standards were used for the selection procedure, and the SLR guidelines were taken directly from [35]. The creation of review questions is the primary step. The next stage is to develop and evaluate a review technique, and then we will use the review protocol's criteria to look for primary screen studies as shown in Fig. 5. As Table IV shows different ransomware analysis tools.

TABLE IV. Ransomware Analysis Tools

Tools	Functions	Platform	Key Features	Pricing
IDA Pro	Disassembling and analysis	Win OS, Linux, macOS	Advanced disassembly and debugging capabilities	Contact for pricing
Cuckoo Sandbox	Automated malware analysis	Win OS, Linux	Dynamic behavioral analysis, threat intelligence integration	Open source
YARA	Pattern matching and detection	Win OS, Linux, macOS	Rule-based detection, custom signature creation	Open source
Wireshark	Network traffic analysis	Win OS, Linux, macOS	Packet-level analysis, protocol dissectors	Open source
Volatility	Memory forensics	Win OS, Linux	Memory image analysis, process, and DLL extraction	Open source
PEStudio	Static analysis of PE files	Win OS	Analysis of portable executable files	Free, Contact for advanced pricing
Ghidra	Reverse engineering and analysis	Win, Linux, macOS	Decomplication, the scriptable analysis environment	Open source
Procmon	Process monitoring and analysis	Win OS	Real-time process monitoring, event logging	Open source

B. Data Sources Information

The data sources utilized for the implementation of this article include IEEE Explore, ACM's digital library, Springer, Elsevier, MDPI, and online libraries. A search string is used to browse the code by the recommendations [36], [37]. The information sources that are mentioned in this review have been picked because they have high-quality, high-impact articles. Data sources were looked up in May 2023 utilizing sophisticated search tools. Table V illustrates searched databases sources.

TABLE V. SEARCH DATABASE SOURCES

IV. RESEARCH QUESTIONS

The goal of this study is to examine and assess several machine-learning algorithms for new ransomware detection. Research questions and research objectives (RQs and ROs) have been made to be emphasized in this SLR in Table VI.

TABLE VI. FORMULATED RQS AND ROS

No	Research Questions	Objectives
RQ1	State the current limitations in existing ransomware detection techniques that affect during the early phases.	RO1 To analyze and identify the current limitations and challenges in existing ransomware detection techniques, with a specific focus on their impact on the early phases of new ransomware attacks.
RQ2	What factors contribute to the improvement of pre-encryption for new-ransomware detection?	RO2 To Explore machine learning algorithms to detect unusual pre-encryption ransomware activities.
RQ3	How can the pre-encryption of ransomware be improved using machine learning and non-machine learning?	RO3 To identify the recent advances and techniques to overcome and improve the issue in new-ransomware pre-encryption prevention, and detection.

A. Review Protocol

The SLR metrics produced by [35] search strategy, inclusion and exclusion criteria, quality assessment, data extraction, and data analysis serve as the foundation for the review procedures.

B. Search Strategy

The most pertinent keywords and their variants were used to create the search string by the main goals of this study. Boolean operators and the keywords that were specified were used to create the search query. The search parameters and query strings are shown below in Fig. 6.

- TITLE-ABS-KEY "pre-encryption" OR "ransomware" OR "ransom" OR "malware" AND "security" ((‘‘cybersecurity’’ OR ‘‘security’’ OR ‘‘pre-encryption’’ OR ‘‘ransomware’’ OR ‘‘ransom’’) AND (‘‘ransomware detection’’ OR ‘‘ransom-ware’’ OR ‘‘malware’’ OR ‘‘encryption’’) AND (‘‘machine learning’’ OR ‘‘deep learning’’ OR ‘‘information security’’))
- The timespan to collect the studies is from 2018 to 2023 H1.
- The survey is in the English language medium.
- After finalizing the search terms, the appropriate digital repositories were chosen. We conducted searches across five electronic databases, which are listed below.
  - IEEE Xplore
  - ACM Digital Library
  - MDPI
  - Springer
  - ScienceDirect

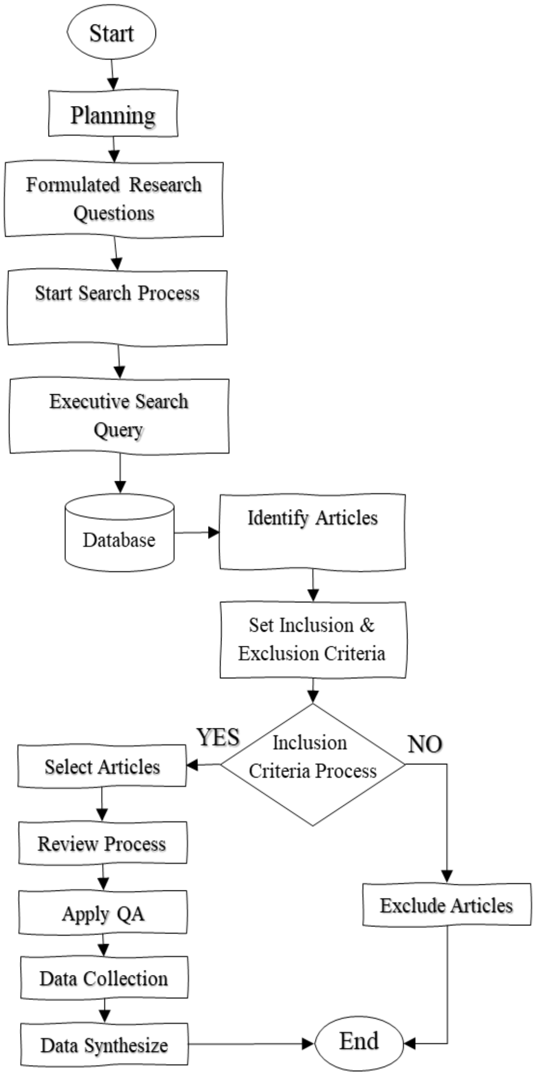

Fig. 6. Scoping review process.

The previously listed five electronic databases, which include the major publications and conferences, are searched. Second, while studies only make up just a small portion of the major research, we also compile the studies that are connected to pre-encryption ransomware detection using static analysis in the reference section. The search period covers from January 2018 to April 2023, and all research related to search phrases has been considered.

C. Inclusion and Exclusion Criteria

For the inclusion and exclusion criteria for this research, to focus on the most important criteria, scholarly works for this SLR. The shortlist is shown in Table VII. According to their capacities, studies are used to determine whether inclusion and exclusion satisfy the requirements.

TABLE VII. INCLUSION AND EXCLUSION CRITERIA

No	Inclusion Criteria	Exclusion Criteria
1	A research article published in English that focuses on the activities, assaults, defenses, and detection methods of ransomware in the Windows operating system, as well as data from peer-reviewed, reputable publications or conference papers included in the above-mentioned databases.	Analyze information from news and magazine publications, non-English articles, and information on the latest ransomware variants and vulnerabilities in other operating systems and mobile devices.
2	The article offers insights and practical advice to protect against ransomware attacks and other cyber threats and the early stage.	The article should discuss papers that investigate the impact of ransomware attacks on businesses or the legal system.
3	The document should provide an in-depth examination of ransomware or any other relevant technological advancement in your writing.	Governmental documents and blogs should not be included in the article.

Three steps made up the selection process. The first step was to look for any possible primary studies. The next step involved examining and reading the titles. Abstracts of all the papers that were returned by the search. So, we discovered every piece of research that met the requirements for inclusion and exclusion. After that every study that had been found was read already being selected for final selection.

Diagram illustrating the preferred reporting items for systematic reviews and Meta-Analysis (PRISMA) flow process showing the ultimate number of studies included in the systematic review and meta-analysis as well as the inclusion and exclusion of studies. Fig. 7 shows selection criteria for this study.

D. Quality Assessment Criteria

We screen the chosen studies following the quality assessment criteria and Score listed in Table VIII, Table IX to evaluate their quality. We determine whether the chosen studies meet these requirements using the cross-checking method to guarantee the reliability of the results. The final studies, which include, are obtained following the stage of quality assessment criteria, concerning the detection of ransomware, there are 103 studies and 2 SLRs related to this.

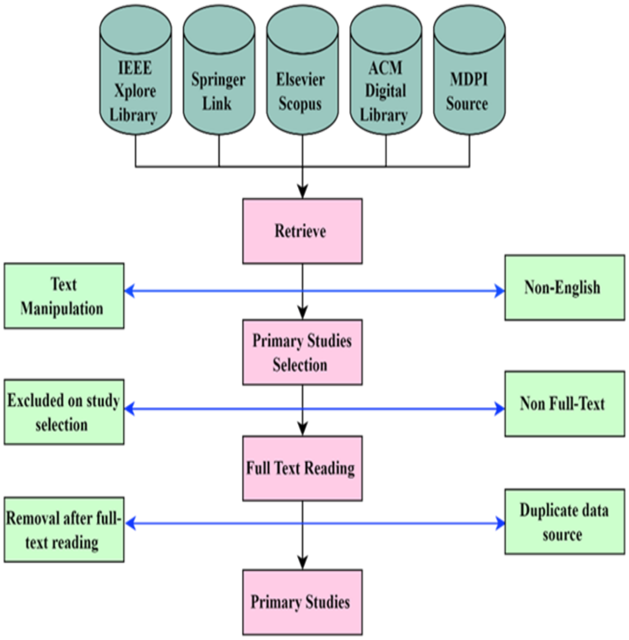

Fig. 7. Study selection criteria.

TABLE VIII. QUALITY ASSESSMENT CRITERIA

No	Quality Assessment Criteria
1	Is the study's direction clear?
2	Is the approach for static and dynamic well stated?
3	Do the experimental datasets provide clear descriptions?
4	Exactly what features are being used?
5	Is the model mentioned clearly?
6	Do the empirical experiments provide a clear description?
7	Are performance metrics given in a transparent manner?
8	Does the research study contribute to this SLR?

TABLE IX. QUALITY ASSESSMENT SCORE

No	Category	Result
1	Systematically Adopted	3
2	Reviewed effectively	2
3	Minor declared	1
4	Does not mention	0

E. Data Extraction

To support the study questions, the required data was acquired, and a detailed analysis was conducted. The following details were extracted from the selected primary studies and entered an extraction form that had been pre-made. Fig. 8 shows extraction of complete information.

- Class, Info, and reference ID
- Publication name
- Country of organization
- Authority of research

- The type of machine learning methods used to mitigate ransomware.
- Algorithms, models, and ideas are essential.
- Categorization of machine learning algorithm with a certain approach and analysis type.
- For ransomware detection process tools were used.

F. Data Analysis

Each main study's data was extracted, and then each research question was addressed with thorough data analysis. Machine learning algorithms that had been implemented were identified to respond to RQ1, and their effectiveness was assessed to respond to RQ2. Related theories or models were found for each category and key features of successful pre-encryption detection as RQ2.1. The outputs of the algorithm were evaluated in terms of their ability to respond to RQ3.

1) Difficulty of problem in practice: It is highly recommended to study the idea of ransomware camouflage to learn more about and develop the field of malware analysis and new ransomware detection. Malware camouflage involves using techniques to hide harmful code, extending its undetected presence by eluding conventional malware detection tools. Malware authors use a variety of strategies, from straightforward ones like encryption to more complex ones like metamorphism. For academics and security experts to create efficient defenses against developing malware threats and improve overall detection methods, they must be aware of various disguise strategies [20].

2) Sophisticated techniques: In the context of ransomware, sophisticated tactics relate to sophisticated and complicated ways employed by attackers to conduct effective and evasive ransomware operations. These strategies aim to circumvent established cybersecurity defenses and increase the difficulty of discovery, prevention, and recovery.

3) Encryption and data exfiltration: Data security and privacy are seriously threatened by ransomware attacks, which are crucially based on encryption and data exfiltration. Effective cybersecurity measures need a thorough understanding of data exfiltration risks, ransomware use of encryption, and related issues.

4) Impact on critical systems: New ransomware attacks can have severe consequences, especially when targeting critical infrastructure systems, healthcare institutions, or government agencies. Disruptions caused by new ransomware can lead to financial losses, endanger lives, or compromise sensitive national security information.

V. Ransomware Detection Taxonomy

The methodologies utilized to identify ransomware, the operation of the machine learning algorithm, the performance outcome, the classification strategy, and the chosen analysis type used to respond to RQ1 through RQ3 are all covered in this part.

The motivating methodology, findings, restrictions, and future directions of the investigated approaches were all covered in the authors' assessment of the ransomware detection methods put out in the literature. They also examined several ransomware detection methods about factors including the operating system for mobile devices and PCs, the cloud, data sources, various machine learning algorithms in use, and result and assessment standards. Fig. 10 demonstrates the ransomware detection environments, along with the many standards and related metrics. The comparison charts of the detection environment, data analysis, machine learning, results, and assessment criteria charts are shown in Fig. 9 to 13.

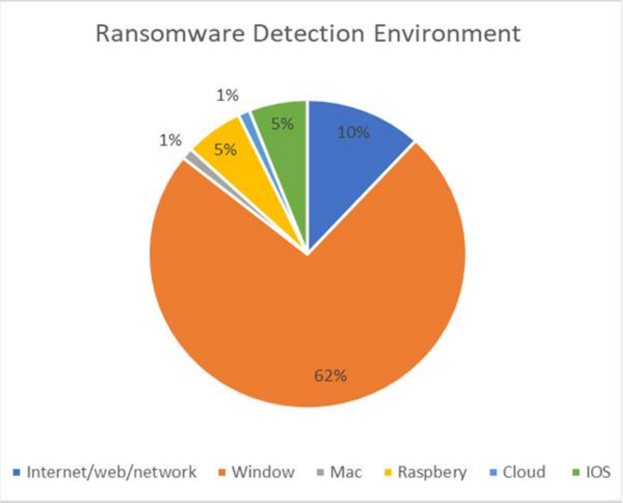

Fig. 9. Ransomware detection environments.

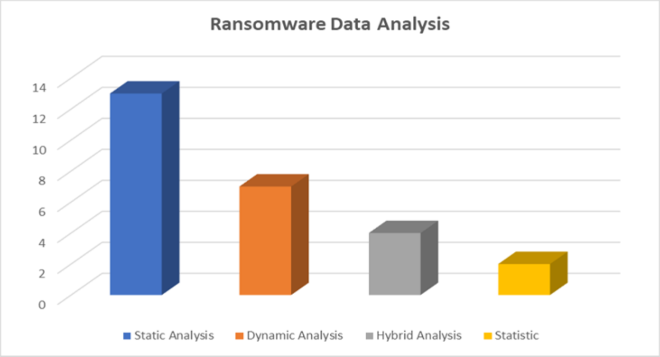

Fig. 10. Ransomware data analysis understanding.

A. Early Detection

Early detection of ransomware is crucial for preventing data encryption and minimizing attacks. The Pre-Encryption Detection Algorithm (PEDA) is a machine learning-based algorithm that detects ransomware behavior patterns before the encryption process begins. This helps identify patterns and characteristics indicative of ransomware before it can cause severe damage. Runtime data analysis captures runtime data during the initial phases of ransomware attacks, allowing for the identification of patterns and indicators of ransomware. However, challenges like accurately defining pre-encryption phases and limited data availability require further research to develop more robust techniques. Combining machine learning algorithms like PEDA with runtime data analysis can contribute to the early detection of ransomware and improve the effectiveness of preventive measures [16].

Ransomware detection environments play a crucial role in safeguarding organizations and individuals from the ever-increasing threat of ransomware attacks. These detection environments are designed to identify and mitigate ransomware activities during the initial stages, before encryption occurs, and severe damage is inflicted.

“Ransomware data analysis understanding" refers to the process of examining, interpreting, and making sense of data related to ransomware attacks. This involves delving into various aspects of ransomware incidents, and analysis techniques as shown in Fig. 10.

A thorough taxonomy of ransomware detection is comparable to an orderly road map of the various kinds, techniques, and strategies applied to the identification and mitigation of ransomware threats in Fig. 11 and classifies the various methods, tools, and approaches used in cybersecurity.

Comparison of the effectiveness of different machine learning classifiers used especially for ransomware detection. It suggests assessing various models or algorithms for ransomware classification, stressing their relative performance and efficacy as shown in Fig. 12.Machine learning classifiers.

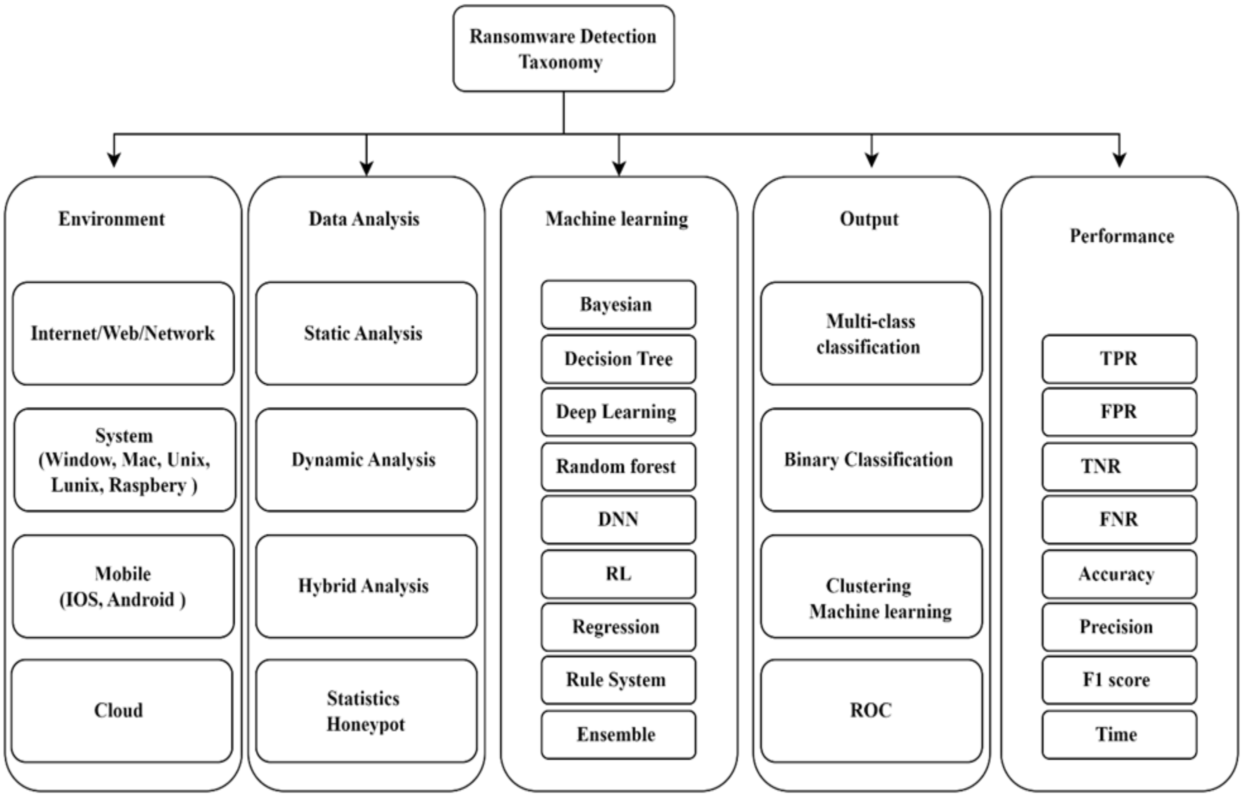

Fig. 11. A comprehensive ransomware detection taxonomy assists cybersecurity.

Fig. 14. Ransomware techniques overview.

Fig. 14 presents a summary of the ransomware approaches discussed in this section, categorized by approach type, analysis features, and availability. However, upon thorough examination of the literature, it became evident that previous studies had certain limitations. Specifically, there was a lack of research focusing on ransomware, with most works primarily utilizing static analysis for detection. Moreover, since ransomware can evade static analysis through code obfuscation techniques, it is crucial to incorporate dynamic analysis. Unfortunately, existing dynamic analysis tools target malicious programs rather than ransomware, and some tools are either immature, outdated or only accessible commercially. Consequently, a need to propose a hybrid system that investigates the effectiveness of integrating techniques, and static and dynamic analysis to detect ransomware more efficiently and accurately, thereby safeguarding system users from falling victim to such attacks. This hybrid system should incorporate various established static analysis approaches and evaluate their ability to differentiate between ransomware apps and benign apps. Based on the results of the static analysis, a decision can be made regarding the need for additional dynamic analysis on these apps. Furthermore, careful consideration should be given to selecting appropriate tools for conducting dynamic analysis. The primary objective is to achieve accurate pre-encryption ransomware detection while minimizing costs. Table X contains the different ransomware detection approaches.

TABLE X. PRE-ENCRYPTION RANSOMWARE DETECTION METHODS

Detection Method	Description
File Signature	Finds ransomware based on known file signatures
Behavior Analysis	Monitors unusual file access or encryption behavior
Heuristic Analysis	Finds potential ransomware based on patterns
Machine Learning	Uses algorithms to detect ransomware-like behavior
Sandbox Analysis	Executes files in a controlled environment for detection

Metrics used to evaluate the efficacy of ransomware detection and mitigation techniques are included, such as detection accuracy, false positive rates, mitigation speed, and recovery efficiency. An examination of these metrics across time or several approaches may be shown in Fig. 15 along with trends.

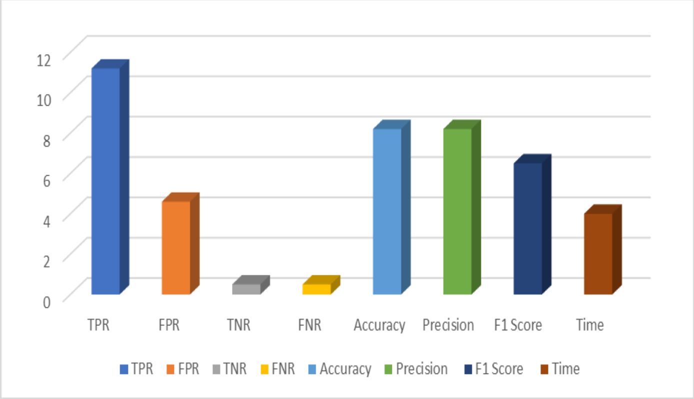

Fig. 15. Performance evaluation metrics of ransomware detection and mitigation.

B. Ransomware Detection Based on Machine Learning

Preventing ransomware is difficult for several reasons. Ransomware often mimics the behavior of legitimate software, operating in a covert manner. As a result, detecting ransomware in zero-day attacks has become a critical priority. The main goals are to prevent system damage caused by ransomware, identify previously unknown malware (zero-day attacks), and reduce detection time. Various tools and techniques are available for detecting ransomware. Static analysis methods, for example, examine source code without executing it. However, these methods tend to produce many false positives and struggle to detect ransomware that has been obfuscated. As Table XI represent existing detection techniques. Attackers frequently develop new variants and modify their code using different packing techniques. To address these challenges, researchers have turned to dynamic behavior analysis, which observes how executed code interacts with a virtual environment. While effective, these methods can be resource-heavy and slow. Machine learning, by contrast, excels at analyzing the behavior of applications or processes. Several machine learning-based detection systems follow well-established methodologies: Table XII summarizes previous studies on Machine learning techniques (behavioral techniques) for ransomware detection.

TABLE XI. EXISTING RANSOMWARE DETECTION TECHNIQUES

1) *File behavior analysis:* Machine learning algorithms can analyze the behavior of files on a system to detect ransomware. By creating baselines of legitimate code executions, the algorithms can detect any behavior that deviates from those baselines.

2) *Network traffic analysis:* Algorithms based on machine learning can analyze network traffic to detect ransomware. By monitoring the traffic patterns and identifying anomalies, the algorithms can detect ransomware attacks.

3) *Dynamic feature dataset:* A dynamic feature dataset can be used to detect ransomware using machine learning algorithms. The dataset contains features that are extracted from the binary file of the ransomware. By analyzing these features, the algorithms can detect ransomware attacks.

4) *Multi-classifier network-based system:* A multi-classifier network-based system can be used to detect ransomware. The system uses machine learning algorithms to analyze the behavior of files and network traffic. By combining the results of multiple classifiers, the system can improve the accuracy of ransomware detection.

C. Limitations of Machine Learning Based Ransomware Detection

The limitations of machine learning-based ransomware detection can be summarized as follows:

1) *False negatives:* Machine learning algorithms can sometimes fail to detect ransomware attacks, resulting in false negatives. This can be due to the lack of training data or the inability of the algorithm to detect new variants of ransomware.

2) *Limited dataset:* The accuracy of machine learning algorithms depends on the quality and quantity of the dataset used for training. A limited dataset may not capture all the variations of ransomware, leading to inaccurate results.

3) *Overfitting:* Machine learning algorithms can sometimes overfit the training data, resulting in deficient performance on new data. This can be due to the algorithm's complexity or the lack of regularization.

4) *Encryption:* Ransomware attacks often involve the encryption of files, which can make it difficult for machine learning algorithms to detect them. This is because the encrypted files may not contain the same features as the original files.

5) *Adversarial attacks:* Adversarial attacks can be used to evade ransomware detection based on machine learning. Attackers can modify the ransomware code to bypass the detection algorithm.

Study has explored the use of machine learning algorithms such as the J48 decision tree and random forest to detect and classify different ransomware families based on TCP malware network traffic [45]. Another study introduced a new approach called WmRmR to detect early ransomware, effectively evaluating the fundamental characteristics of large-scale datasets at low complexity and false positive rates [46]. A related study proposes a detection method focused on analyzing access privileges in process memory and enabling accurate and efficient identification of key functions of ransomware [47]. In the field of ransomware classification, researchers developed an advanced technique to exploit the suspicious behaviors displayed by ransomware, in particular several API requests to find an optimal execution environment. By generating fingerprints of these behaviors from more than 3,000 recently known ransomware samples, the authors achieved an impressive classification accuracy of 94.92% [48]. The redundancy coefficient gradual upweighting (RCGU) approach improves the selection of crypto-ransomware detection features by dynamically adjusting the weight of redundancy terms. The combination of RCGU and other mutual information methods further improved accuracy compared to previous studies [15]. Several studies focused on the detection of Android ransomware. Researchers have been using decoy techniques to detect ransomware in real-time, monitor file systems and running processes, and identify and prevent benign file changes from triggering alerts based on learned encryption behavior [49]. Developed a classification model. Using N-gram sequences from ransomware sample opcode sequences, it is possible to classify families more accurately [50]. The API-based ransomware detection system (API-RDS) was used to study the static and dynamic analytical approach of ransomware detection in mobile devices. Although this approach has not been put into practice or proven through simulation, the author presented it as a framework for the early detection of ransomware, considering the temporal correlations between IRPs and APIs. In the context of network traffic analysis [11]. This study presented a detection approach based on the analysis of file-sharing traffic, effective detection, and prevention of crypto-ransomware activity [51]. The author introduced a unique method for detecting Android ransomware with energy consumption levels [52]. The study incorporated an attention mechanism in learning malware sequences to detect ransomware based on repetitive patterns associated with repeated encryption [53]. The author proposed artificial intelligence-powered hybrid models that would overcome the challenges of detecting ransomware using functions such as assembly, dynamic link libraries, and function calls [54]. Based on the ease of static malware analysis, an approach based on data mining techniques in particular, frequent pattern mining was developed to identify ransomware. Similarly, a pre-distributed model was created using convolutional neural networks to classify binary items and improve performance using transfer learning [55].

D. Non-Machine Learning Based Ransomware Detection

The term "non-machine learning-based ransomware detection" refers to techniques that do not rely on machine learning algorithms but rather are conventional and rule-based. This method is useful in some circumstances since it makes use of predetermined rules, patterns, and heuristics to find ransomware activity. Known signatures or patterns of previously recognized ransomware variants are used to identify and stop ransomware in one popular technique called signature-based detection. Another method is behavior-based detection, which keeps an eye on system activity for ransomware-specific suspicious behaviors such as quick file encryption. Furthermore, even if the precise ransomware strain is unknown, heuristics may be used to spot ransomware-like behavior. Non-machine learning-based techniques may be able to provide quick detection and reaction capabilities shown in Table XIII, but they could have trouble spotting new or polymorphic ransomware versions. The authors also discussed the integration of this contextual detection technique into digital forensics for ransomware mitigation and prevention [57].

A software-defined network (SDN)-based detection technique for Windows computers was also demonstrated in [58]. The technique extracts pertinent HTTP message sequences as key features from network traffic between the crypto-ransomware variants Crypto Wall and Locky. The reading and writing activities of backup files and ransomware samples with significant read/write operations are tracked. The context-aware detection model uses entropy data to spot unusual file activity [24]. The basis for the detection is manipulation files (such as desktop files and/or user files). The system creates a fake user environment and can identify file modifications caused by ransomware. The system keeps track of system modifications as well as their behavior. The detection can spot previously unreported, unknown (zero-day), and evasive ransomware. Passively observes traffic produced by 19 ransomware families using a network prober. Less than 10 files are lost prior to the ransomware activity being detected by the model, which focuses on early detection [59] and examines the characteristics of cryptographic ransomware. To stop ransomware, they suggested deceptive file protection methods. Incorporated a dynamic analysis-based automated malware detection technology. The latter extracts a call to the Application Programming Interface (API) from logs to find ransomware [62]. The researchers demonstrated how their techniques could enhance the automatic analysis of numerous malware samples [63], [64]. To categorize tweets to fulfill the requirement for file protection on rootless devices, they developed and deployed KRProtector, which can recognize ransomware and protect files using deception [65], [66]. The author used static and dynamic analysis of the executable malware to extract both static and running-time behavior. Reverse engineering is used to extract binary signatures using the CRSTATIC model. No matter what kind of malware is being assessed, the authors show that using YARA rules with fuzzy hashing can enhance the evaluation's outcomes [67], [68], [69], [70].

TABLE XIII. COLLECTED STUDIES ON NON ML-BASED RANSOMWARE DETECTION

Study	Methods	Features	Evaluation metrics	Correctness	Platform	Environment
[57]	Rule-based	API calls DLL libraries windows registry	Trigger threshold CAT	-	OS	Cuckoo sandbox
[58]	Software-defined network	HTTP	ROC curve	-	OS-7	Cuckoo Sandbox, VMware
[24]	Hardware-based	I/O requests	Accuracy	96.3%	OS	Cuckoo sandbox
[59]	Rule-based	IP traffic	Overhead detection rate, file lost	100%	OS-7	Virtual
[60]	Decoy-based	File access read/write/remove	Precision Accuracy	96.2%	IoT Android	Real in Android 7.1
[61], [64]	Forensic based	Network sign Function calls	-	-	OS	Real in testbed

VI. Results

The results of primary research are intended to be presented in this section. We begin by outlining the main studies. In terms of fact, we next provide the SLR's findings considering the study's questions.

A. *Study Description*

103 Studies are addressed in this section in terms of publication time.

B. *Publication Time*

Fig. 16 demonstrates that there were 26, 25, 25, 23, 10, and 26, respectively, studies from 2018 to 2023-H1. This data shows that the number of studies in 2018 accounts for the biggest share. The number of research connected to ransomware detection using static analysis and dynamic is increasing from 2018 to 2023, except for certain papers in 2023 (some publications in 2023 are not released, thus the time of these papers in 2023 is from January to May) [71], [72], [73]. This data indicates that pre-encryption ransomware detection has consistently been a popular issue in recent years.

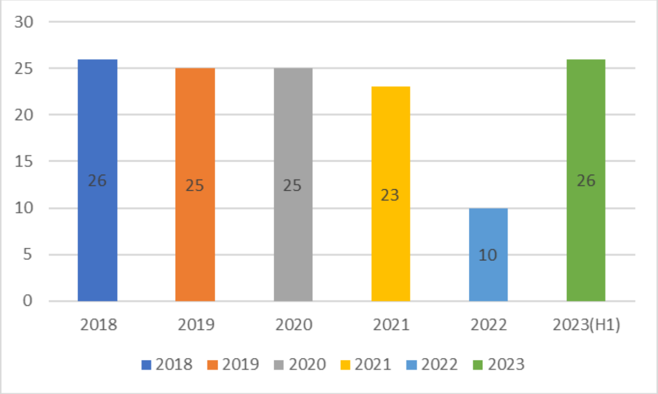

Fig. 16. Year-wise distribution of studies.

RQ1: What are the current limitations/challenges in existing ransomware detection techniques that affect during the early phases?

There are several limitations and challenges in existing ransomware detection techniques that affect early detection. These include:

- Signature-based detection is easily bypassed by malware authors. Signature-based detection relies on identifying known malicious files or patterns. However, malware authors can easily obfuscate their code to evade detection by signature-based tools [74], [75], [76], [77].

- Behavior-based detection can be triggered by legitimate applications. Behavior-based detection looks for suspicious or malicious behavior, such as file encryption or network traffic patterns. However, legitimate applications can also exhibit these same behaviors, which can lead to false positives [78], [79], [80], [81].

- Ransomware attacks are often targeted and stealthy. Ransomware authors often target specific organizations or individuals, and they may take steps to conceal their attack. This can make it difficult for detection tools to identify the attack in its initial stages [82], [83], [84], [85].

- Ransomware is constantly evolving. Ransomware authors are constantly developing new techniques to evade detection. This makes it difficult for detection tools to keep up with the latest threats.

As a result of these limitations and challenges, it can be difficult to detect ransomware in its initial stages. This is why it is important to have a layered security approach that includes a variety of detection techniques. By combining signature-based, behavior-based, and other detection techniques, organizations can improve their chances of detecting ransomware early and preventing a successful attack [86], [87], [88], [89].

- Insufficient data and attack patterns

- Evolving tactics and techniques

- Lack of awareness

- Visibility into systems

The current limitations/challenges in existing ransomware detection techniques during the early phases include insufficient data and attack patterns, evolving tactics and techniques, limited detection capabilities, lack of awareness, and limited visibility into systems. These challenges require innovative solutions and collaborative efforts to combat the rise of ransomware attacks.

RQ2: What factors contribute to the improvement of pre-encryption ransomware detection?

Improving pre-encryption ransomware detection requires the development of advanced detection techniques, such as behavior matching, machine learning, detection of symmetrical and asymmetrical encryption, early detection, high detection rate, and continuous updates. These factors can help improve the detection and prevention of ransomware attacks.

1) Pre-encryption detection algorithms: Pre-encryption detection algorithms, such as the Pre-Encryption Detection Algorithm (PEDA), can detect ransomware before it starts its encryption function. These algorithms use machine learning or behavior matching to identify patterns in the ransomware code and create a signature repository to detect future attacks [19].

2) Adaptive models: Adaptive models that combine machine learning and non-machine learning techniques can improve pre-encryption ransomware detection. For example, an adaptive pre-encryption crypto-ransomware early detection model uses both machine learning and non-machine learning techniques to detect ransomware before it can be executed [90], [91].

3) Behavior matching: Behavior matching can be used to detect small variants of unknown crypto-ransomware. This approach involves comparing the behavior of a file to a known set of behaviors associated with ransomware [92], [93], [94].

4) Improved visibility: Improved visibility into network activities can help detect ransomware during its early phases. This involves monitoring, aggregation, correlation, and analysis of network activities to identify suspicious behavior [95], [96], [97].

Continuous research and collaboration: Continuous research and collaboration are needed to stay ahead of evolving ransomware tactics and techniques. This includes sharing threat intelligence and developing new detection techniques to address emerging threats and evaluation metrics for crypto-ransomware.

Q3 How can the pre-encryption of ransomware be improved using machine learning and non-machine learning?

Improving the pre-encryption detection of ransomware can be achieved through the integration of both machine learning and non-machine learning techniques. Machine learning approaches enhance pre-encryption ransomware detection by leveraging advanced algorithms to analyze data and identify patterns indicative of ransomware behavior. Through feature engineering, anomaly detection, and deep learning models, machine learning can detect ransomware with higher accuracy and adapt to new variants. Ensemble methods and continuous learning mechanisms further enhance the detection capabilities. On the other hand, non-machine learning approaches such as signature-based detection, heuristics, behavioral analysis, and network traffic analysis provide additional layers of defense. By combining these approaches, organizations can leverage the strengths of both methods. As shown in Fig. 17, detection system analyzes ransomware behaviors, utilizing classifiers.

Non-machine learning techniques offer rule-based detection and proactive measures such as authorization, block-listing, and user education. Integrating machine learning with non-machine learning techniques creates a comprehensive defense strategy that improves pre-encryption ransomware detection, providing more effective protection against emerging threats and reducing the risk of successful attacks [98], [99], [101]. Machine learning techniques have progressively been widely used for ransomware detection in recent years due to the rapid growth of these techniques in natural language processing, image recognition, and other areas. Support Vector Machine (SVM), Naive Bayes (NB), Logistic Regression (LR), Ensemble Learning (EL), and neural networks are some of the machine learning models that are frequently utilized in primary investigations [100], [102], [103]. Table XIV shows ML and Non-ML based methods.

By utilizing a combination of machine learning and non-machine learning approaches, organizations can improve pre-encryption ransomware detection, providing more robust and proactive defenses against ransomware threats. The integration of these methods complements each other, resulting in a comprehensive approach that enhances detection accuracy and responsiveness, thus minimizing the potential impact of ransomware attacks (Fig. 18) [93].

To extract configuration, "MalConfScan with Cuckoo" launches malware on the host computer. MalConfScan can extract the configuration of recognized malware from a memory image that is dumped when malware is registered on Cuckoo and executed on the host computer. A report will then display the extracted configuration that can be seen in Fig. 18 [93].

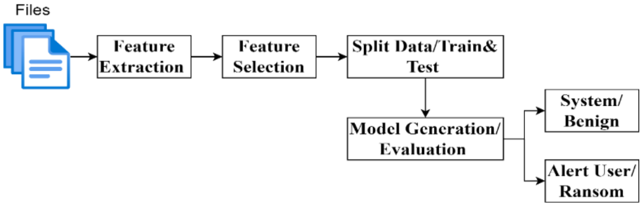

Fig. 17. Machine learning detection for ransomware.

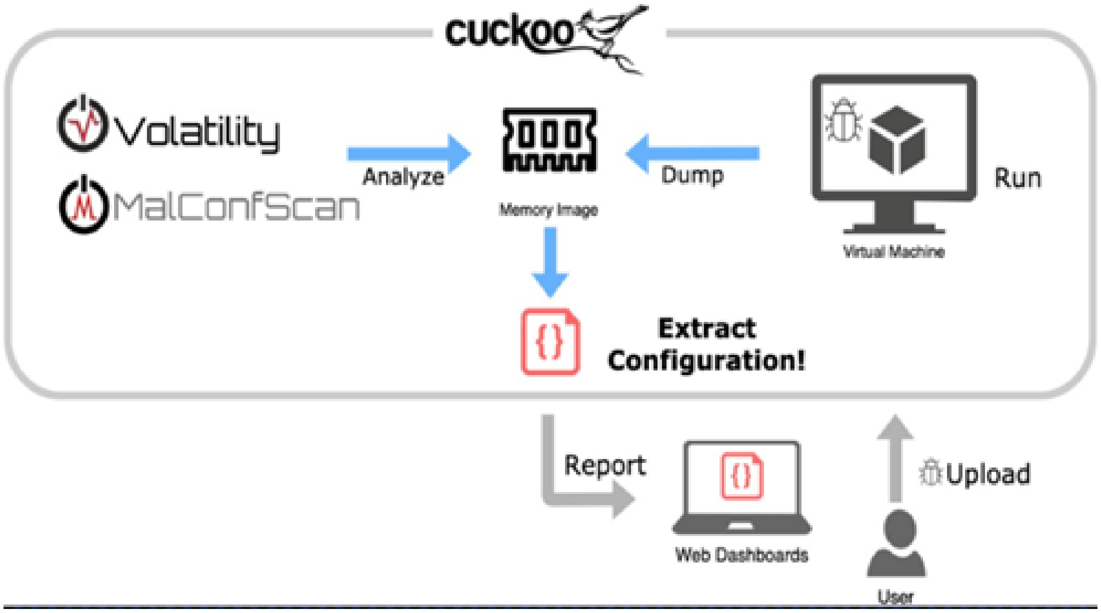

Fig. 18. Non-machine learning detection for ransomware [93].

TABLE XIV. ML AND NON-ML-BASED METHODS

Method	Machine Learning Approach	Non-Machine Learning Approach
Feature Engineering	- Extract relevant and discriminative features from data	- Define heuristics based on known ransomware characteristics
	- Find patterns using deep learning models	- Create rules to detect ransomware behaviors
Anomaly Detection	- Detect deviations from normal system behavior	- Monitor network traffic for unusual patterns
	- Find abnormal file access patterns	- See unusual file encryption behavior
Ensemble Methods	- Combine multiple models to enhance detection performance	- Integrate various detection techniques for comprehensive analysis
	- Reduce false positives through ensemble approaches	- Combine signature-based and heuristic-based detection
Continuous Learning	- Adapt models in real-time with new ransomware samples	- Update signature databases regularly
	- Stay up to date with evolving ransomware variants	- Check for new ransomware families
Dynamic Analysis	- Analyze ransomware behavior in sandboxed environments	- See ransomware actions in isolated systems
	- Find malicious code execution within the sandbox	

VII. RESEARCH DIRECTION

This paper provides a brief overview of machine learning, and deep learning techniques applied to the detection of ransomware. To increase the effectiveness of ransomware detection systems, additional research is required on several open issues.

1) High computational complexity and time: Develop efficient detection systems for new ransomware attacks, considering computational overhead for low-resource devices like embedded systems and IoT.

2) Hardware complexity: Modern systems rely on RAM-intensive hard drives, requiring careful consideration of hardware limitations for sophisticated detection systems and solutions.

3) Evasion and obfuscation: Ransomware detection is dynamic, requiring evasive and secretive methods for accuracy, less false alarms, and dependable handling of escape and confusion.

4) Rich Dataset: Dataset for ransomware attack patterns training machine learning and deep learning models; regular updates needed for effective ransomware detection systems.

VIII. CONCLUSION

This article presents an overview of ransomware detection using heuristic-based machine learning, and non-machine learning technologies. It investigates various ransomware platform detection tools and uses datasets containing different methods. The study provides taxonomy and related concepts for research on new ransomware detection methods, categorizing studies into classical, conventional, and early detection before encryption. It examines the frequency of attack patterns across different platforms and analyzes attacks targeting these platforms. Using heuristic-based machine learning approaches can produce a reliable and precise solution for new ransomware attack patterns. The study aims to encourage academics to use contemporary technologies in ransomware attack detection, evaluating potential solutions and creating more effective models. The main findings and contributions of the reviews shed light on new ransomware detection and pre-encryption strategies. Heuristic-based machine learning should be the focus of future research to identify new ransomware patterns, adjust to changing strategies, and combat evasion methods. In future noise data can be reduced during feature extraction process. Sustained innovation is essential to keep up with the evolution of ransomware.

ACKNOWLEDGMENT

This research is funded by the Fundamental Research Grant Scheme (FRGS) under cost Centre (015MA0-151) from the Ministry of Higher Education (MOHE) Malaysia.

***Abstract*—The categorization of music has received substantial interest in the management of large-scale databases. However, the sound of music classification (MC) is poorly interesting, making it a big challenge. For this reason, this paper has proposed a new robust combining method based on texture feature with Mel-spectrogram to classify Arabic music sound. A music audio dataset consisting of 404 sound recordings for different four classes of Arabic music sounds has been collected. The collected data became available for free on the Kaggle website. Firstly, music sound is transformed into a Mel spectrogram, and then several texture features are extracted from these Mel spectrogram images. A two-dimensional Haar wavelet is applied to each Mel-spectrogram image, and Local Binary Patterns (LBP), Gray Level Co-occurrence Matrix (GLCM), and Histogram of Oriented Gradient (HOG) are utilized for feature extraction. K-nearest neighbors (KNN), random forest (RF), decision tree (DT), logistic regression (LR), AdaBoost, extreme gradient boosting (XGB), and support vector machine (SVM) classifiers were utilized in a comparative analysis of Machine Learning (ML) algorithms. Two different datasets have been employed in order to evaluate the effectiveness of our approach: the collected dataset that the authors had gathered and the global GTZAN dataset. Our method demonstrates superior performance with a five-fold cross-validation. The experimental findings indicated that the XGB exhibited a high accuracy with an average performance of 97.80% for accuracy, 97.72% for F1-Score, 97.75% for recall, and 97.81% for precision.**

***Keywords*—Mel-spectrograms; ML; texture features; MC**

I. Introduction

Music is considered an inseparable part of our culture and tradition [1]. The advent of online social networks and cloud technology have led to a massive rise in the demand for online data storage and data sharing services [2, 3]. Music Information Retrieval (MIR) systems have gained huge popularity in recent years and are used in many fields, such as musical similarity and genre categorization, music emotion identification, music source separation, acoustic descriptions of music, and music transcription [4]. Music classification (MC) has emerged as an important area for digital music services such as Tidal, SoundCloud, and Apple Music and is used for classifying and overseeing extensive musical datasets [5, 6]. Regarding this, musical sound classification is an intriguing area challenge in the field [7]. Among the several methods for representing the contents of an audio clip, extracting distinguishing features is the most widely employed. However, due to the subjectivity associated with the concept of musical genre, as well as the enormous variety of music genres, strong feature extraction has proven difficult. In the Arab world, Arabic music is an essential component of global music, but Western music dominates the field. A machine learning approach is extensively used in music information retrieval applications [7, 8, 9, 10]. As well, texture features have a high capacity for extracting features of musical patterns [11, 12].

In related works, Western music using the GTZAN dataset dominates the field, and Arabic music is not yet equivalent to them. So, Arabic musical instruments must be moved out of the country and promoted for it in the works. Therefore, we hope that this work will contribute to solving this problem and overcoming the absence of a dataset based on Arabic music. Therefore, this paper presents a new robust approach based on ML techniques with texture features and Mel-spectrogram for Arabic music sound classification using a newly collected dataset in favour of this work and became available free for use.

Our contribution can be summarized as follows:

- A music audio dataset consisting of 440 sound recordings for different four classes of Arabic music sounds has been collected. The collected data became available for free at: (https://www.kaggle.com/datasets/emanatyaesmaeil/zekrayati-dataset).
- Gathered and annotated a large corpus of Arabic music clips to cover the lack of a dataset for Arabic music. Although the GTZAN dataset is a benchmark for MGC, it has limitations such as mislabeling, distortions, and replicas (Strum, [13]).
- A new robust feature extraction approach is presented for music signal classification using Mel-spectrogram images. A two-dimensional Haar wavelet is applied to each image and texture features (GLCM, HOG, and LBP) are extracted from all wavelet transform sub-bands.
- Comparative analysis to examine the efficiency of most various machine learning algorithms in Arabic music sound classification and then determine which algorithm is better for this type of data.
- The best accuracy had resulted compared to previous studies using global GTZAN dataset.

The general structure of this paper is as follows: Section II presents the related studies, Section III covers the materials and methodologies, and Section IV provides the results and

*Corresponding Author.

discussion. Discussion is given in Section V. Finally, Section VI covers conclusion and future work.

II. Related Work

Recently, there have been a lot of studies related to music classification. [14]. These works have been supported by recent advancements in machine learning (ML) and deep learning (DL) methodologies. This section provides a thorough overview of many ML and DL applications in the music industry and examination of the prospects for AI in this domain as show in Table I.

In summary, western music dominates the field. Most of the literature focuses on it by using the GTZAN dataset. Arabic music needs to move out of the country, so it is hoped that this paper will make a small contribution to this goal and benefit from the ML approach that has proven its effectiveness in music classification.

III. Materials and Methods

The flow diagram of the suggested model is illustrated in Fig. 1. The following three subsections will describe each of these stages in detail.

A. *Mel-Spectrogram Production Stage*

The Mel-spectrogram is resulted through the following steps:

1) Pre-emphasizing audio which improves clarity and reduces volume.

2) Blocking frames that render every audio frame end-to-end, maintaining audio continuity.

3) Introducing a window function to enhance the role of audio framing and prevent audio discontinuity caused by sampling and quantization.

4) Fast Fourier Transform which transforms the audio from the time domain to the frequency domain.

5) Map the FFT produce to the Mel scale; multiply it by the total number of triangular bandpass filters.

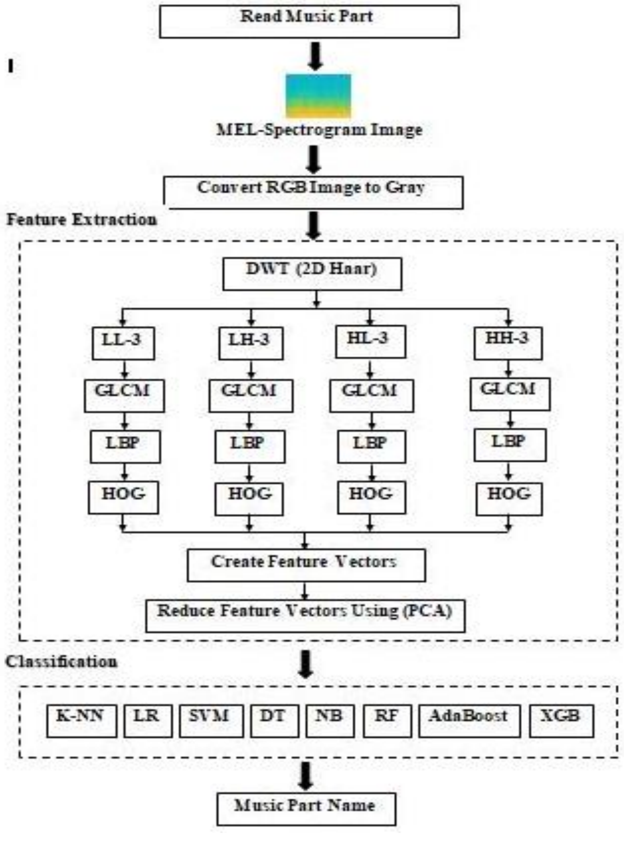

Fig. 1. The proposed system for lute signal classification.

Mel-spectrograms in this study are a two-dimensional representation of input signals. All audio signals are produced using the Short Time Fourier Transform (STFT) with Mel-frequency rather than normal frequency. The parameters used to generate the power Mel-spectrograms are stated in Table II, and Fig. 2 depicts various Mel-spectrograms for the dataset and shows the region of the image used for feature extraction as the black box, and the output is saved as a .png file with a size of 256*256. The output photos are transformed to grayscale before the textural features are extracted.

Parameter	Value
Audio Length (second)	12:91
Window Length (frames)	1024
Overlap Length (frames)	512
FFT Length (frames)	4096
Number bands (Filters)	64

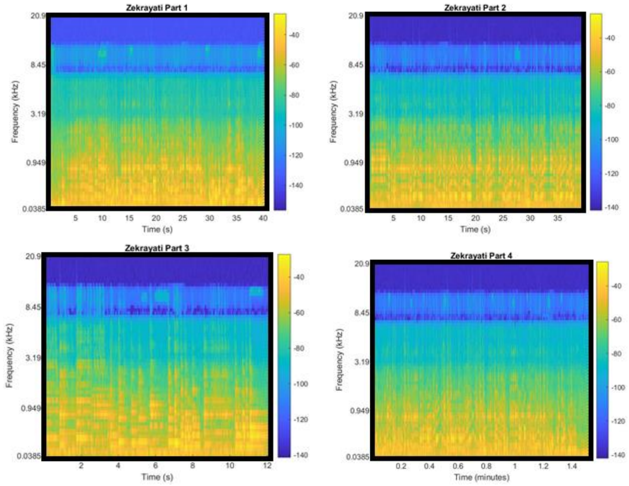

Fig. 2. Mel-spectrogram for some datasets.

B. *Feature Extraction Stage*

The primary phases for feature extraction are as follows:

Step 1: apply the discrete wavelet transforms to the Mel-spectrogram image to extract sub-bands.

Step 2: extracted all of (GLCM, HOG, and LBP) from all wavelet sub-bands and combine all features into one feature vector.

Step 3: reduce the final feature vector by using Principal component analysis (PCA).

1) Discrete Wavelet Transforms (DWT): It is a powerful image signal analysis tool. It has an effective analysis function and multi-resolution analysis capability, making it suited for the image signal analysis area [32]. The spatial domain (DWT or 2D_DWT) is resulted by first applying the output to the DWT along the vertical axis and then applying the horizontal axis to the (1D_DWT). Hence, (2D-DWT) contains four bands: (LL, LH, HL, and HH) bands [33, 34].

Eq. (1) symbolizes the transformation (DWT) of any signal, x(t).

$$x(t) = \sum a_{j.k} \Psi_{j.k}(t) \tag{1}$$

Where $a_{j.k}$ are called wavelet coefficients, $\Psi_{j.k}(t)$ is called the fundamental function. j is the scale and k is mother wavelet translated $\Psi(t)$.

The (2_D DWT) can be achieved by using Eq. (2) to apply DWT across rows and columns of a picture in both the (x and y) dimensions.

$$f(x.y) = \sum_{j.k} C_{j_0}(k.l)\varphi_{j.k.l}(x.y) + \sum_{s=H.V.D} \sum_{j=j_0}^{\infty} D_j^s[k.l]\Psi_{j.k.l}^s(x.y) \quad (2)$$

Where C_{j_0} is the approximation coefficient, $\varphi_{j.k.l}(x.y)$ is scaling function, D_j^s is set of detailed coefficients and $\Psi_{j.k.l}^s$ is wavelet function.

In this work, three level wavelet decomposition has been performed by using 'haar' mother wavelet function as shown in Fig. 3 and the sub bands of level three were used for extracting the features.

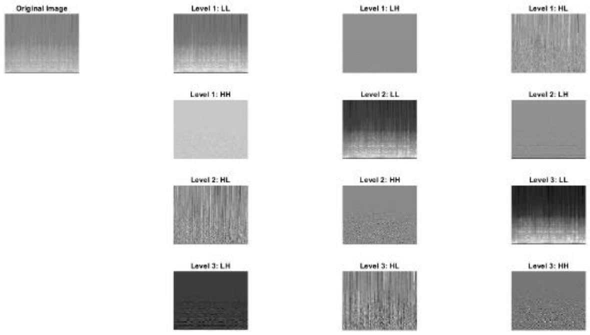

Fig. 3. Three-level wavelet decomposition.

2) GLCM Algorithm: The GLCM texture extraction approach has become more and more popular in recent years for picture classification and detection [35, 36]. It alludes to a widely used technique for characterizing texture through an examination of grayscale's spatial correlation features. It determines the frequency of occurrence for each piece of grayscale data it contains. The GLCM is a (L × L) counting matrix, where each element in the GLCM represents a potential combination of pixels, assuming the original image has (L) grayscale levels. Several studies have demonstrated that this approach is highly adaptable and stable in capturing detailed information such as direction, distance, and variation range between image pixel grayscales. The contrasts and patterns of texture features acquired using this method accurately characterize the properties of picture texture [37]. Some GLCM features [38] used in this work are briefly explained below.

- Contrast: This feature calculates the intensity of a pixel and its surrounding pixels over the entire image. The contrast function also calculates the color and brightness differences between each cellular object and other objects in the same field of view. It can be computed using the following equation.

$$Contrast = \sum_i \sum_j (i-j)^2 p(i.j) \quad (3)$$

For an image, $p(i.j)$ reflects the chance of a pair of pixels with gray level values(i and j)occurring in a specific space and direction.

- Correlation: It computes gray-level linear dependence among pixels at specified distances from one another. The(μ_i and μ_j)are the average of each row and column, and (σ_i and $\sigma_{j)}$ are, correspondingly, the standard deviations for each row and column.

$$Correlation = \sum_i \sum_j \frac{p(i.j)[(i-\mu_i)(j-\mu_j)]}{\sigma_i \sigma_j} \quad (4)$$

- Energy: It calculates regularity or pixel pair repetitions, as illustrated in the equation below. When a pixel pair is repeated multiple times, the energy characteristic returns a higher value.

$$Energy = \sum_i \sum_j p(i.j)^2 \quad (5)$$

- Homogeneity: it is refers to the consistency of element distribution along a GLCM's diagonal. When matrix elements are spread diagonally, homogeneity is high, as calculated by the equation below.

$$Homogeneity = \sum_i \sum_j \frac{p(i.j)}{1+|i-j|} \quad (6)$$

In this study, Mel-spectrogram image characteristics are extracted using the GLCM approach, first set the order of the grayscale co-generation matrix to 16 and selected 0°, 45°, 90° and 135° as the four directions of the grayscale co-generation matrix, The final eigenvalue co-generation matrix was calculated by averaging the four directional matrix eigenvalues. Finally, we retrieved four-dimensional GLCM features for each subband, yielding a final feature vector of 16 features.

3) LBP Algorithm: Local Binary Pattern is a well-known texture descriptor that has been successfully used in works made for several application domains, such as music genre detection [39, 40]. According to [41], it is uses the local neighborhood of a center pixel to find a local binary pattern. The feature vector, which characterizes the image's textural richness, corresponds to the histogram of local binary patterns present in all pixels. There are two basic parameters that can be adjusted to extract the LBP from an image. The first is the number of nearby pixels that will be considered for the central pixel, while the second is the distance between the central pixel and its neighbors. These values are referred to, in turn, as (P and R). Fig. 4 shows examples of Mel-spectrogram images, corresponding maps of LBP values, and the LBP histograms.

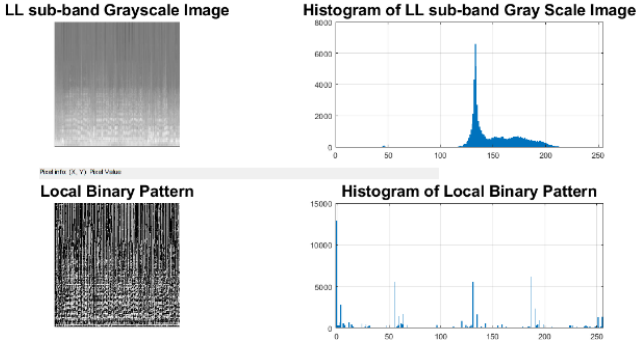

Fig. 4. Local binary patterns visualization.

In this study, 8 neighbors at a distance of 2 was used to extracted 59 features for each sub-bands and the final feature vector for this step was 236 feature value.

4) HOG Algorithm: HOG is a feature descriptor used to detect targets in image processing. It creates features by calculating the histogram of directional gradients in discrete parts of the image [42]. This method consists of two major processes [43]. The first is the histogram extraction, as the gradient of direction and magnitude is retrieved from each pixel in the input image. These steps are used to generate an angular histogram of gradients, which is then applied as an image texture feature vector. The vertical and horizontal components of the image I (i, j) are derivatives of pixel (i, j). They're computed as follows:

$$G_i(i.j) = I(i+1.j) - I(i-1.j) \qquad (7)$$

$$G_j(i.j) = I(i.j+1) - I(i.j-1) \qquad (8)$$

$$G(i.j) = \sqrt{G_i(i.j)^2 + G_j(i.j)^2} \qquad (9)$$

$$\alpha_0(i.j) = \tan^{-1}\left[\frac{G_j(i.j)}{G_i(i.j)}\right].\alpha_0\epsilon\left[-\frac{\pi}{2}.\frac{\pi}{2}\right] \qquad (10)$$

where $G_i(i.j)$, $G_j(i.j)$ are the derivatives in the horizontal and vertical directions at pixel (i ,j).

The second phase involves the generation of the HOG descriptor, which is built based on the gradient of the image. The whole image is split into blocks with sizes [2 2], [4 4], and [8 8]. The gradient direction range [-π/2, π/2] is calculated equally into nine direction intervals (bins). To provide a strong vector to brightness changes, the HOG feature values are normalized by segmenting each bin with the total of the histogram. Fig. 5 shows different block sizes of the sub-band HH of the Mel-spectrogram image.

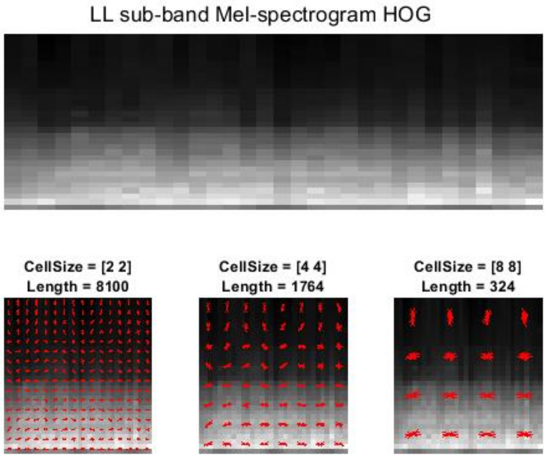

Fig. 5. HOG features of Mel-spectrogram image LL sub-band with different cell sizes.

In this paper the HOG Cell Size of [4 4] is used for extracted 1764 feature value for Each sub-bands of Mel-spectrogram image and the final feature vectored of this step was 7056 feature values.

5) Combining the features of the proposed system and PCA: This part describes a hybrid feature extraction technology. The characteristic of this method is the merger of characteristics derived from HOG, GLCM, WDT, and LBP. The suggested approach is distinguished by its expeditiousness in training the dataset and its demand for computer resources of moderate cost. At first, a Haar 2D wavelet is It is used for extraction 4 sub-bands from the Mel-spectrogram image and extract GLCM, HOG, and LBP for all sub-bands for training the Mel-spectrogram image to create a 440 x 7308 matrix of features. The PCA algorithm [44] is applied to the feature matrix in order to minimize the dimensions and select the most appropriate characteristics for each image.

C. Ml Algorithms

In this paper, many ML algorithms were used to classify the Mel-spectrogram image.

1) K-NN classifier: The K-NN technology is a basic data mining strategy where all samples are assigned to the same group in a feature space, and the algorithm has the same properties for both regression and classification [45]. This technique is considered effective for classification problems.

2) LR classifier: This Classifier [46] is a Strong statistic tool for developing resilient methods. It applies the linear regression principle to classification problems. It predicts dependent data by examining the connection between one or more pre-existing independent variables. The LR formula is represented by the following equation:

$$P = \frac{e^y}{1+e^y} \qquad (11)$$

3) SVM classifier: SVM is a collection of supervised learning algorithms. These are commonly used for classification and regression tasks on both linear and nonlinear data [47]. This method finds a decision boundary among two classes in order to forecast labels using one or more feature vectors. It lacks a natural growth to several courses and performs slowly throughout training.

4) DT classifier: One of the most powerful categorization methods is the DT, which simulates decisions using a tree framework. [48]. Computing the data allows it to classify the dataset and assign values to each of its attributes. The decision tree follows a top-down approach. Information gain is a typical strategy for choosing a decision node in DT. The equation for information gain is as follows:

$$IG(D.A) = Entropy(D) - \sum_{v\in Values(A)}\frac{|D_v|}{|D|}\cdot Entropy(D_v) \qquad (12)$$

5) NB classifier: NB is a class of supervised learning approaches which employ likely reasoning to anticipate the optimal result [49]. Using the Bayes theorem to it is easy to construct the classifier and the Gaussian normal distribution to forecast the class. The collection of probabilities for a certain set of data is determined by counting the value and frequency of the value. The Bayesian formula is:

$$P(H|E) = \frac{P(E|H) \cdot P(H)}{P(E)} \quad (13)$$

6) RF classifier: The RF technique, which is based on Ho's method and was later developed and introduced to the literature by [50], is a collective learning technique that determines the output class by training a large number of decision trees and taking the mode or average of their results. It's a popular algorithm because of its high prediction performance, capacity to deal with imbalance issues, and ability to produce consistent results in a variety of applications.

7) AdaBoost classifier: The adaboost boosting algorithm is a well-known ensemble technique for binary classification [51]. The group moves toward AdaBoost trains and installs trees in a sequential manner. AdaBoost combines a series of weak classifiers to perform boosting. The goal of each iteration of the weak classifier is to correct samples that were incorrectly classified by the preceding weak classifier. AdaBoost uses an iterative approach to help bad classifiers get better by using the mistakes they have made.

8) XGB classifier: XGB is an additional ensemble ML method that tackles regression and classification issues by utilizing many decision trees [52]. To lessen overfitting and boost performance, it uses more regularized prediction models.

Table II illustrates the hyperparameter method for determining the optimal parameters for ML algorithms.

TABLE II. THE FINE HYPERPARAMETERS OPTIMIZATION

Model	Hyperparameters
K-NN	n_neighbors=5, Euclidean distance
LR	solver='linear'
DT	max_depth=100, criterion='entropy'
NB	var_smoothing=1e−04
RF	n_estimators=100, max_depth=50
AdaBoost	n_estimators=20, learning rate=0.5 3.3
XGB	n_estimators=100, learning rate=0.1
SVM	Kernel= RBF, C=3.3

IV. RESULTS AND DISCUSSION

A. Dataset

1) Collected data: In this paper, authors have collected a music audio dataset consisting of 440 recordings for different four classes of Arabic music sounds has been collected.

The collected data became available for free at: (https://www.kaggle.com/datasets/emanatyaesmaeil/zekrayati-dataset).

2) GTZAN dataset: GTZAN [53] was one of the first widely available datasets for MGC and is well-known within the scientific community. This dataset contains (1000) music clips from (10) western music genres. GTZAN's ten genres ('blues', 'classical', 'country', 'disco', 'hip-hop', 'jazz',' metal', 'pop', 'reggae', and 'rock') are evenly distributed, each featuring '100' clips. Each music clip is (30) seconds long. Table III shows the description of the dataset.

TABLE III. DESCRIPTION OF THE DATASET

Class Name	No of file	Minimum duration (s)	Maximum duration (s)
Zekrayati (P_1)	120	12	60
Zekrayati (P_2)	120	26	41
Zekrayati (P_3)	80	12	35
Zekrayati (P_4)	120	46	91

B. Performance Evaluation

The results related to ML models have been measured using the following indicators: accuracy, precision, recall, and F1-score. Equations (14 through 17) employ the confusion matrix to calculate these values. Where (TP=true_positive), (FP=false_positiv), (FN=false_negative), and (TN=true_negative) [54].

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (14)$$

$$Recall = \frac{TP}{TP+TN} \quad (15)$$

$$Precision = \frac{TP}{TP+FP} \quad (16)$$

$$F1 - Score = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (17)$$

C. K-Fold Cross Validation

In this method, epochs are split up into k groups at random, each with roughly the same amount of features. The remaining groups are used to test the learning, while the K-1 groups are used for training. The technique is repeated (k) times, every time with a different group of tests [55]. For performance evaluation, a 5-fold cross-validation procedure is used, and the result is calculated as the 5-fold average.

D. Experiment 1: ML Methods with Proposed Dataset

In this paper, all samples in the proposed dataset converted to Mel-spectrogram images, then three levels of DWT with haar mother wavelet function were used to represent each Mel-spectrogram images, then chosen sub-band of level three for feature extracted by using GLCM, LBP, and HOG and reducing feature vector using PCA, and finally used eight machine learning techniques SVM, K-NN, DT, RF, LR, NB, XGB, and AdaBoost for classification Mel-spectrogram images dataset using 5 k- Fig. 6 depicts the splitting of Mel-spectrogram pictures into 5 k-folds for training and testing. Table IV and Fig. 7 show the level of accuracy ratings of models after applying 5 k-fold. Fig. 8 to Fig. 12 depicts the confusion matrix for various ML methods.

According to Table IV, the XGB model achieves high performance in the music classification when compared to other classifiers. The XGB achieved an average performance of 99.54% for accuracy, 99.44% for F1 score, 99.41% for recall, and 99.51% for precision.

E. Experiment 2: ML Methods with GTZAN Dataset

the approach suggested had been compared to state-of-the-art models that used the GTZAN dataset, comprising DL models, specifically convolutional neural networks, bottom-up broadcast neural networks (BBNN), deep unsupervised representation learning from acoustic data auDeep, and ML SVM for categorizing music genres using MEL-spectrogram images and the GTZAN dataset. The steps of the comparison process can be summarized as follows

Step 1: Convert all class to MEL spectrogram images using window length 1024 with overlap length 512, FFT length 4096 and number bands 64 Fig. 13 shown some MEL spectrogram images for GTZAN dataset.

Step 2: DWT is applied using three levels and calculates GLCM, HOG, and LBP for level 3 for each sub-band, and finally reduces the feature vector to 1000 samples and 100 features using PCA.

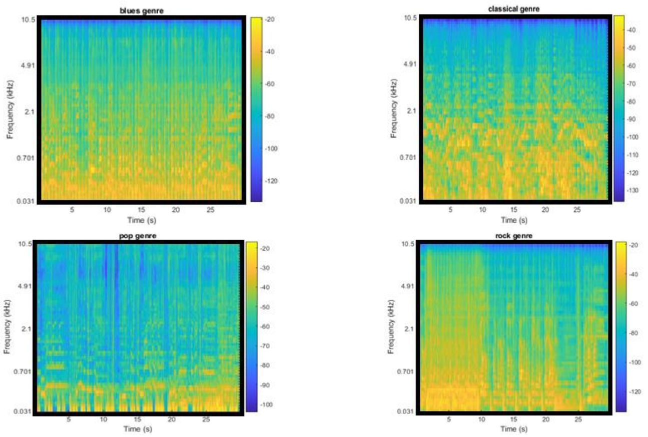

Fig. 13. Mel-spectrogram for some GTZAN dataset.

Step 3: Classification genres using ML models proposed in this paper and the model's performance using Accuracy, F1-Score, Recall and Precision using 5k-fold Fig. 14 shows 5 K-fold split of the GTZAN dataset 20% for testing and 80% for training. Fig. 15 shows the results of ML models for GTZAN dataset. Table V illustrates the accuracy scores and Fig. 16 to 20 shown confusion matrix's.

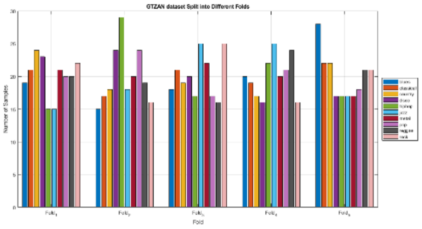

Fig. 14. Using five k-folds, GTZAN splits Mel-spectrogram pictures into train and test.

According to Table V, the XGB model achieves high performance in the music classification when compared to other classifiers. The XGB achieved an average performance of 97.80% for accuracy, 97.72% for F1 score, 97.75% for recall, and 97.81% for precision. Table VI shown comparison accuracy with the GTZAN dataset using XGB classifier.

V. Discussion

One of the main objectives of this work is to evaluate the performance of proposed ML models using two different dataset: the collected dataset that the authors had gathered and the global GTZAN dataset.

For the collected dataset , the XGB model achieves high performance in the music classification when compared to other classifiers. The XGB achieved an average performance of 99.54% for accuracy, 99.44% for F1 score, 99.41% for recall, and 99.51% for precision.

By using GTZAN , According to Table VI, the XGB model achieves high performance in the music classification when compared to other classifiers. The XGB achieved an average performance of 97.80% for accuracy, 97.72% for F1 score, 97.75% for recall, and 97.81% for precision. Table VI shown comparison accuracy with GTZAN dataset using XGB classifier.

TABLE VI. Comparison Accuracy with GTZAN Dataset

Reference	Feature	Model	Accuracy (%)
Liu, Caifeng, et al. [56]	MEL spectrogram	BBNN network	93.9
Nanni et al. [57]	MEL spectrogram	SVM	90.9
Ghildiyal et al. [58]	MEL spectrogram	CNN	91.00
Nakashika et al. [59]	MEL spectrogram + GLCM	CNN	72.00
Yang et al. [60]	MEL spectrogram	CNN	90.7
Freitag et al. [61]	MEL spectrogram	AuDeep	85.4
Proposed Method using XGB	MEL spectrogram + GLCM + HOG + LBP	XGB	97.80

VI. Conclusion and Future Work

ML techniques are beneficial for classification tasks, especially music genre classification, in which music is classified into different genres concerning its features. The objective of this paper is the classification of musical sound using ML techniques with texture features and Mel-Spectrogram. In the methodology, the audio data was transformed into a Mel-spectrogram, then texture features were applied to extract the audio features, and finally, a classification task was carried out using six ML classifiers. We performed a complete comparison of six ML classifiers in this study. By using two different datasets, the experimental findings indicated that the XGB exhibited a high accuracy with an average performance of 97.80% for accuracy, 97.72% for F1 score, 97.75% for recall, and 97.81% for precision. Comparing the reviewed related works mainly implemented using various ML and DL algorithms, our method obtained higher accuracy on automatic classification for music.

Future enhancements: Current work processes audio files that are 30 to 90 seconds long. More research should be conducted to handle audio of any length.as well as , Implementing music genre classification for other audio formats can be investigated, as the established ML models perform well for the (.WAV) format, but there are many other formats available, including MP3, FLAC, and others.

Finally, in future work, the authors can combine CNN approaches with texture features to enhance computational efficiency, minimize processing time, and identify music subgenres.

Abstract—**Accurate defect detection of navel oranges is the key to ensuring the quality of navel oranges and extending their storage life. An improved DeeplabV3+ model integrating attention mechanism is proposed to increase the current low recognition accuracy and slow detection speed of defect detection in navel oranges grading and sorting process. The improved lightweight backbone network HECA-MobileV3 is applied in the DeeplabV3+ model to reduce the amount of computational data and improve the image processing speed. In addition, the Convolutional Block Attention Module (CBAM) and Channel Space Parallel Mechanism CSPM are integrated to the DeeplabV3+ model. ASPP structure is redesigned and the low feature extraction network is optimized to enhance the capture of target edge information and improve the segmentation effect of the model. Experimental results show that the proposed model exhibits a better MIoU and MPA with 89.50% and 94.02%, respectively, while reducing parameters by 49.42M and increasing detection speed by 55.6fps, which are 7.27% and 3.51% higher than the basic model. The results are superior than U-Net, SegNet and PSP-Net semantic segmentation networks. As a results, the proposed method provides better real-time performance, which meets the requirements of industrial production for detection accuracy and speed.**

Keywords—Navel oranges; defect detection; DeeplabV3+; HECA-MobileNetV3; CBAM attention mechanism; CSPM mechanism

I. Introduction

Jiangxi Gannan, home to the world's largest navel oranges plantation, has an annual output of up to one million tons annualy. However, despite its large-scale production, the harvesting and sorting processes still rely heavily on manual methods leading to high labour cost, prominent seasonality and high labour intensity. As the production of navel oranges increases year by year and sales channels continue to expand, the automation of grading and sorting of navel oranges are gradually emerging. After being picked from the trees, navel oranges need to go through disinfection and cleaning, sterilization and waxing, drying and weighing, colour and size grading, skin defect sorting, sugar content density quality analysis, and packaging and labeling before the fruit can be shipped to various parts of the world [1]. At present, the navel orange sorting line can quickly sort navel oranges based on their size and colour, but the recognition of local defects on the skin is not accurate at lower detection rate, which affected the overall quality, delayed the storage time and sorting process of navel oranges. Recent trends in machine vision and advancement in deep learning have led to a proliferation of studies that apply both methods in the field of navel oranges skin defect detection.

The traditional machine vision algorithm is mainly used to grade and classify navel orange defects based on the differences in data such as the RGB colour of the navel orange peel, surface brightness distribution, spectral imaging band curve and edge threshold. Abdelsalam et al. [2] detected the external defects of orange citrus fruits using multi-spectral imaging sensor. They segmented the defects based on the near-infrared (NIR) and RGB images of orange fruits and used threshold technology to detect defects in seven colour components of orange fruits. The overall accuracy of the algorithm exceeded 95%. Rong et al. [3] designed a fast edge detection algorithm for navel oranges surface defects to solve the problem of low defect detection accuracy caused by surface brightness by using the threshold edge segmentation method. Zhang et al. [4] proposed an Otsu threshold segmentation method based on image segmentation according to the different characteristics of navel orange surface defects, and the defect recognition rate is approximately 92.7%. Luo et al. [5] used a visible-near-infrared hyperspectral imaging system with a wavelength range of 325 to 1000 nm to collect citrus hyperspectral images, and used guided soft shrinkage (BOSS) and BOSS-SPA (BOSS-continuous projection algorithm) combined algorithms to optimize the spectral variables. Based on the extracted four defect wavelength images, they proposed a fast multispectral image processing algorithm combined with global threshold theory for rotten orange detection, with an overall classification accuracy of up to 98.6%.

Nowadays, deep learning techniques have been widely applied mainly on 1) object detection and 2) semantic segmentation. Object detection involves recognizing and locating target objects in an image, including algorithms such as R-CNN, YOLO and SSD. Semantic segmentation assigns semantic labels to each pixel in the image, including FCN, U-Net, Deeplab, SegNet and PSPNet. Iqbal et al. [6] determined the difference in fruit surface quality by training the RGB image combination data based on different fruit surface colour data. Asriny et al. [7] applied deep convolutional neural networks to grade the quality of navel oranges, establishing a database of over 1000 navel orange images and achieving a detection accuracy of 96% for different categories of navel oranges. Cai et al. [8] proposed a multi-resolution knowledge distillation strategy by integrating multi-scale pyramid modules and semi-resolution reconstruction branches, training the FastSegfermer model, which effectively improved the segmentation accuracy of the network, achieving a MIoU of 88.78%.

However, it can be concluded that there are several shortcomings in the navel orange defect detection research. The research up to now has been mainly based on traditional machine vision algorithms where the key challenge is the algorithm is too complex with computational burden resulting in difficulty to achieve real-time online detection. Although there are few common types of surface defects such as anthrax, sun spots and scratches, the highest chances to detect the similarity defect are low due to the nature of the fruit. Especially in the same image, precise segmentation is not achievable, particularly for small defects, thus failing to meet the requirements for grading and classification.

With the rapid development of computing power and artificial intelligence, researchers are also developed other fruit and vegetable detection using spectral technology, ultrasonic imaging and deep learning. Da Costa et al. [9] introduced the ResNet50 model into tomato external defect detection with the accuracy rate of 94.6%. Liang et al. [10] proposed a semantic segmentation method based on BiSeNet V2 deep learning for apple defect detection, and its average pixel accuracy MPA value approximately 99.66%. Hao et al. [11] applied the DeeplabV3+ model for kiwi defect recognition, using the lightweight convolutional neural network MobileNetV2 to extract image features, reducing the training time and achieving an average classification recognition rate of 96%. Gu et al. [12] used the phantom network and coordinate attention module to construct CA-ChostNet as the backbone feature extraction network of DeeplabV3+ for tomato target recognition, which reduced the number of network parameters while improving the model's segmentation capacity for small target categories. In order to improve the real-time performance of apple defect detection, Fan et al. [13] reduced the number of channels and network depth in the YOLOV4 network, reducing the size of the network model to 8.82MB with lower detection time of only 8.36ms for each image. It can be concluded that there is growing interest in deep learning application as main method for fruit and vegetable detection.

A. Navel Oranges Defect Types

There is multiple type of navel orange defects which are spots, scars, mildew, damage, blemishes, and enlarged fruit heads. If navel oranges are simply divided into good and defective fruits can cause great waste. Therefore, it is necessary to accurately identify the type and size of defects to better achieve navel orange grading and sorting.

Semantic segmentation algorithms include classic algorithms such as FCN, U-Net, SegNet, as well as modern deep learning algorithms such as PSPNet, Deeplab, and Mask R-CNN. Among them, the Deeplab network is a model with outstanding semantic segmentation performance at present, and has been gradually optimized from DeeplabV1 to DeeplabV3+. In 2018, DeeplabV3+ introduced an encoder-decoder structure, integrated multi-scale information, and improved the accuracy of image segmentation, becoming the most outstanding model for semantic segmentation. In view of the problems existing in the current research on navel oranges defect detection, combined with the problems of DeeplabV3+ model with many parameters and weak extraction of small target boundary features, this study proposes an improved DeeplabV3+ navel oranges defect real-time detection and segmentation model. The main research contributions of this paper are:

1) MobileNetV3 is used to replace the backbone network Xception, and the improved ECA attention mechanism is used to replace the SE mechanism in the MobileNetV3 network, which greatly reduces the amount of calculation parameters and improves the real-time performance of detection.

2) Redesigned the Atrous Spatial Pyramid Pooling (ASPP) structure of the DeeplabV3+ model. The CBAM attention mechanism and the CSPM mechanism are integrated to dynamically adjust the weight share of the feature channel to increase the attention to important areas of the image and comprehensively improve the recognition capacity of different types of navel orange defects.

3) The CBAM attention mechanism is added to the extraction of low-order feature information to make the extracted low-order features more representative and discriminative, and improve the segmentation effect and stcapacity of the model for boundary features.

4) Navel orange images are collected and a database of more than 2,000 navel orange defects is created to reduce model overfitting and provide more accurate and reliable model evaluation.

II. DeeplabV3+ Network Model with Improved Attention Mechanism

A. DeeplabV3+ Model

The Deeplab model was proposed in 2015. Over the years, with the continuous iteration and optimization of algorithms and technologies, DeeplabV1 [14], DeeplabV2 [15], and DeeplabV3 [16] models have been proposed one after another, continuously improving the model structure while improving the image segmentation. To address the issues of reduced image resolution, lower accuracy, and loss of details caused by max pooling and downsampling in deep convolutional neural networks (DCNNs), DeeplabV1 introduces the Atrous convolution algorithm and fully connected CRF structure. This approach expands the receptive field and connects DCNNs with CRF, thereby improving segmentation accuracy. DeeplabV2 improves the model's backbone network from VGG to ResNet and constructs an ASPP structure. This configuration captures information at multiple scales with high accuracy and capacity through parallel sampling. DeeplabV3 enhances the capacity to capture multi-scale information in images by varying the unit dilated rate of Atrous convolutions. To solve the problem of prolonged processing time and incomplete detail information in high-resolution images with DeeplabV3, DeeplabV3+ introduces an encoder-decoder structure, enhancing network capacity while ensuring the accuracy of feature extraction.

DeeplabV3+ consists of DCNN with dilated convolution and ASPP as the main structure of the encoder. Due to pooling and strided convolutions in the feature extraction process, some image details, particularly boundary features, are lost. To address this, the model integrates high-level features from the encoder with low-level features from the DCNN, enhancing boundary segmentation accuracy. The DCNN utilizes the Xception backbone, a complex structure with Entry, Middle, and Exit flow layers, leading to a high number of computational parameters and slower training and inference speeds. The ASPP module includes one 1x1 convolution, three 3x3 convolutions with different dilation rates, and one image pooling layer, aimed at dimensionality reduction, multi-scale context information extraction, and global context capture of the input image, respectively. The decoder connects low-level feature maps from the DCNN through a 1x1 convolution with the encoder's 4x upsampled high-level semantic feature maps. It further refines features with 3x3 convolutions and produces accurate prediction maps after another 4x upsampling. The DeeplabV3+ model architecture is illustrated in Fig. 1.

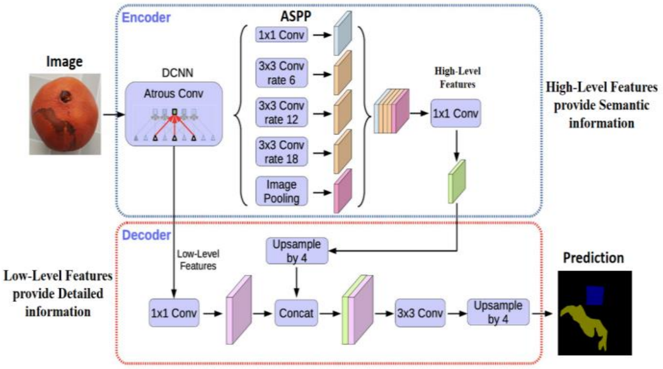

Fig. 1. DeeplabV3+ model structure diagram.

Although the DeeplabV3+ model has demonstrated excellent performance, it still faces challenges such as complex network and large amount of computation, limited capacity to capture details, and strong data dependency. Currently, many scholars have replaced lightweight backbone networks (such as MobileNet and Thin-xception) [17] to reduce the amount of computation and improve real-time performance, or introduced attention mechanisms (such as SE and CBAM) [18] in the model to improve the accurate segmentation of details, or added more multi-scale feature fusion modules (such as FPN [19] and ASPP [20]) to improve the recognition capacity for large-scale targets.

B. *Improved MobileNetV3 Backbone Network*

The DeeplabV3+ model employs the Xception network as the backbone for feature extraction, which inadequate for navel orange grading and sorting since the network required a large number of parameters and not suitable for the real-time application. Therefore, an improved lightweight MobileNetV3 backbone network is proposed to replace Xception.

The MobileNet network was proposed by the Google team in which MobileNetV3 is a lightweight network model that is continuously improved and optimized based on V1 and V2, which achieved excellent performance in tasks such as image classification and semantic segmentation [21]. Since traditional convolutional neural networks have large computational complexity and consume a lot of memory, depthwise convolution and pointwise convolution are combined in MobileNetV1 to construct a deep separable convolution structure, reducing its parameter volume and computational complexity to one square of the convolution kernel. After continuous verification, it was found that most of the computational parameters of V1's depthwise convolution were zero, limiting its effectiveness. Therefore, MobileNetV2 incorporated the inverted residual block and optimized activation functions, resulting in improvements in segmentation accuracy and processing time compared to the V1 structure. MobileNetV3 retains the depthwise separable convolution and inverted residual block from V2, adds the SE attention mechanism, updates activation functions, and redesigns the structure of time-consuming layers [22]. The network structure of MobileNetV3 is shown in Fig. 2.

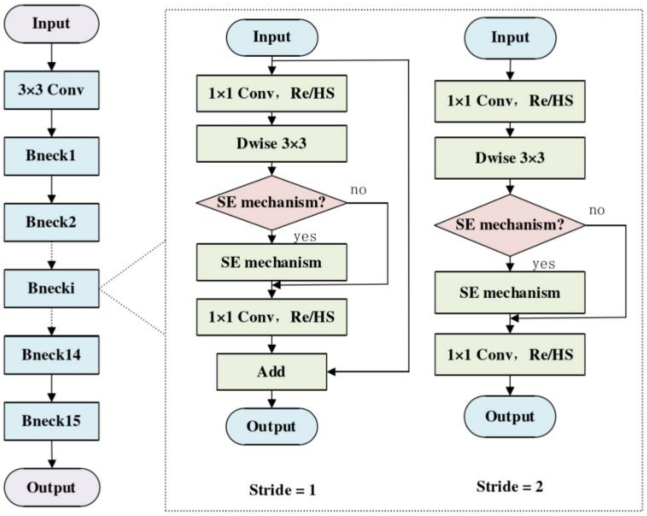

Fig. 2. MobileNetV3 model structure diagram.

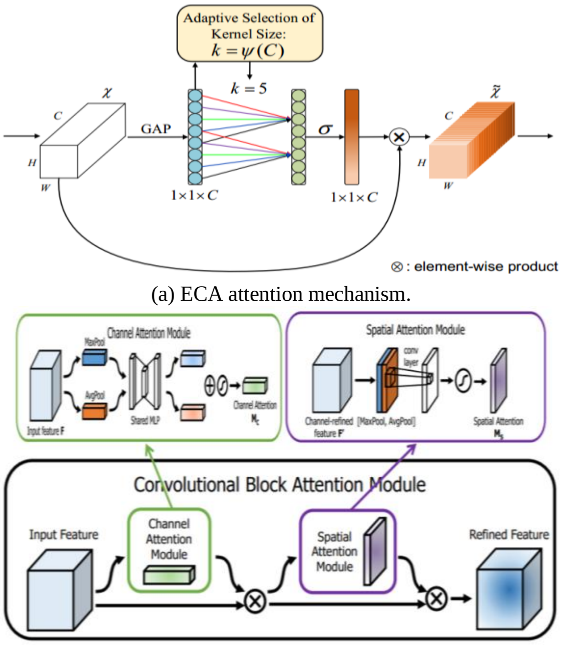
The attention mechanism allows the model to improve its representation ability by focusing on different parts or features of the data during processing data. The main attention mechanisms currently include SE (Squeeze-and-Excitation Networks), ECA (Efficient Channel Attention Module), CA (Coordinate Attention) and CBAM (Convolutional Block Attention Module) [23]. The core idea of the SE module is to enhance the feature map by learning the importance of each channel. The SE module first uses a global average pooling operation to capture the global information of each channel, then learns the weight of each channel through two fully connected layers, and finally uses the sigmoid function to normalize the weight of each channel. The ECA module aims to reduce the computational costs by improving the SE model and capturing inter-channel relationships over a larger spatial range. It captures global information by adaptively determining the size of the one-dimensional convolution kernel through the channel dimension function. Since it does not involve global average pooling, it can reduce the computational cost. The CBAM module connects channel attention and spatial attention in series, allowing the model to dynamically focus on important information in the image in both the channel and spatial dimensions. The structures of the ECA and CBAM models are illustrated in Fig. 3.

Hard-sigmoid is used for the ECA attention mechanism instead of Sigmoid linear activation function as the function offers higher computational efficiency and effectively addresses the vanishing gradient problem. The improved H-ECA attention mechanism is shown in Fig. 4. After feature extraction, the Hard-sigmoid activation function is used to obtain the weight *w* of each channel, and finally multiplied with the corresponding element of the original feature map to obtain the final output feature map.



(a) ECA attention mechanism.

(b) CBAM attention mechanism.

Fig. 3. ECA and CBAM model structure diagram.

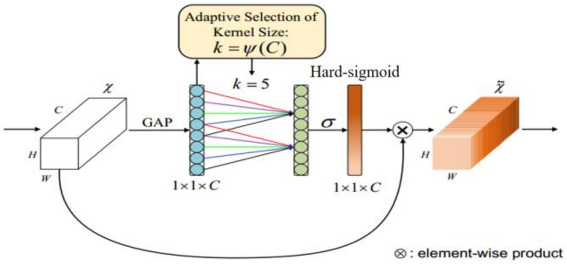


Fig. 4. Improved H-ECA attention mechanism.

To ensure the efficiency of navel oranges sorting, high recognition speed of images during the sorting process is required. The SE attention mechanism with high complexity is used in MobileNetV3, which will affect the response speed and real-time performance of the model. Therefore, to reduce the computational complexity and the number of parameters, the H-ECA mechanism replaces the SE mechanism in *Bneck*, and the feature information of different scales is better captured through local cross-channel convolution operations. The *Bneck* structure diagram of the improved backbone network HECA-MobileNetV3 is shown in Fig. 5.

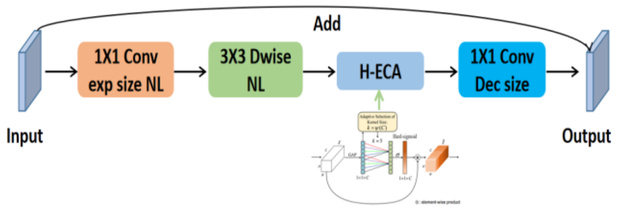

Fig. 5. Improved Bneck structure diagram.

The number of parameters occupied by the attention mechanisms are quantified in both the original MobileNetV3 and the improved HECA-MobileNetV3 networks, as well as their proportion of the total parameters as shown in Table I. The H-ECA attention mechanism replaced the SE attention mechanism in layers 3, 5, 6, 8, 12, 13, 14, and 15. Since H-ECA is not affected by the number of input and output channels, the size of its convolution kernel K is 5, Params = K*1+1, and the calculated Params is 6, accounting for almost 0.00%. It can be seen that the H-ECA attention mechanism occupies only a very small number of parameters.

TABLE I. STATISTICS OF ATTENTION MECHANISM PARAMETERS IN MOBILENETV3 NETWORK BEFORE AND AFTER IMPROVEMENT

Layer	SE		H-ECA	
	Params	Params Proportion	Params	Params Proportion
3	0.003M	0.107%	6	0.000%
5	0.007M	0.228%	6	0.000%
6	0.007M	0.228%	6	0.000%
8	0.105M	3.526%	6	0.000%
12	0.231M	6.722%	6	0.000%
13	0.231M	6.722%	6	0.000%
14	0.460M	13.166%	6	0.000%
15	0.460M	13.166%	6	0.000%
Total	1.504M	43.865%	48	0.000%

C. Improved DeeplabV3+ Network Model

In the actual grading and sorting of navel oranges, a large amount of image data needs to be collected. Even for the same navel orange, images need to be collected from multiple angles, and the detection speed of the results needs to be controlled within the millisecond. At the same time, although the shape of the navel orange does not change much, the details inside the peel are random and variable. The location, size and shape of the defects, the size of the navel and the thickness of the head are all different. Therefore, this study proposes an improved DeeplabV3+ lightweight network model that integrates the attention mechanism. The main improvements are in the following parts:

1) The improved lightweight backbone network HECA-MobileNetV3 is used to replace Xception, which not only reduces the model calculation amount and improves the real-time detection, but also is very easy to add to embedded systems or mobile devices, improving the applicability of the research.

2) In the ASPP structure of the DeeplabV3+ model, the CBAM attention mechanism and the Channel Space Parallel Mechanism (CSPM) were introduced to redesign the ASPP structure. CBAM uses the output of the channel mechanism as the input of the spatial mechanism, with a faster calculation speed and can gradually enhance the expressiveness of the feature map. At the same time, in order to address the key information loss problem that may exist in the CBAM mechanism, a parallel mechanism of channel attention and spatial attention is added to obtain the global dependency information of the input navel orange image in channels and space, and finally the splicing and fusion are passed to the decoding layer.

3) CBAM attention mechanism is added to the backbone network to extract low-level feature information of the image and adaptively adjust the feature map weights that can enhance key low-order features, suppress noise and redundant information, improve the model's generalization ability, and provide clearer and more effective features as shown in Fig. 6.

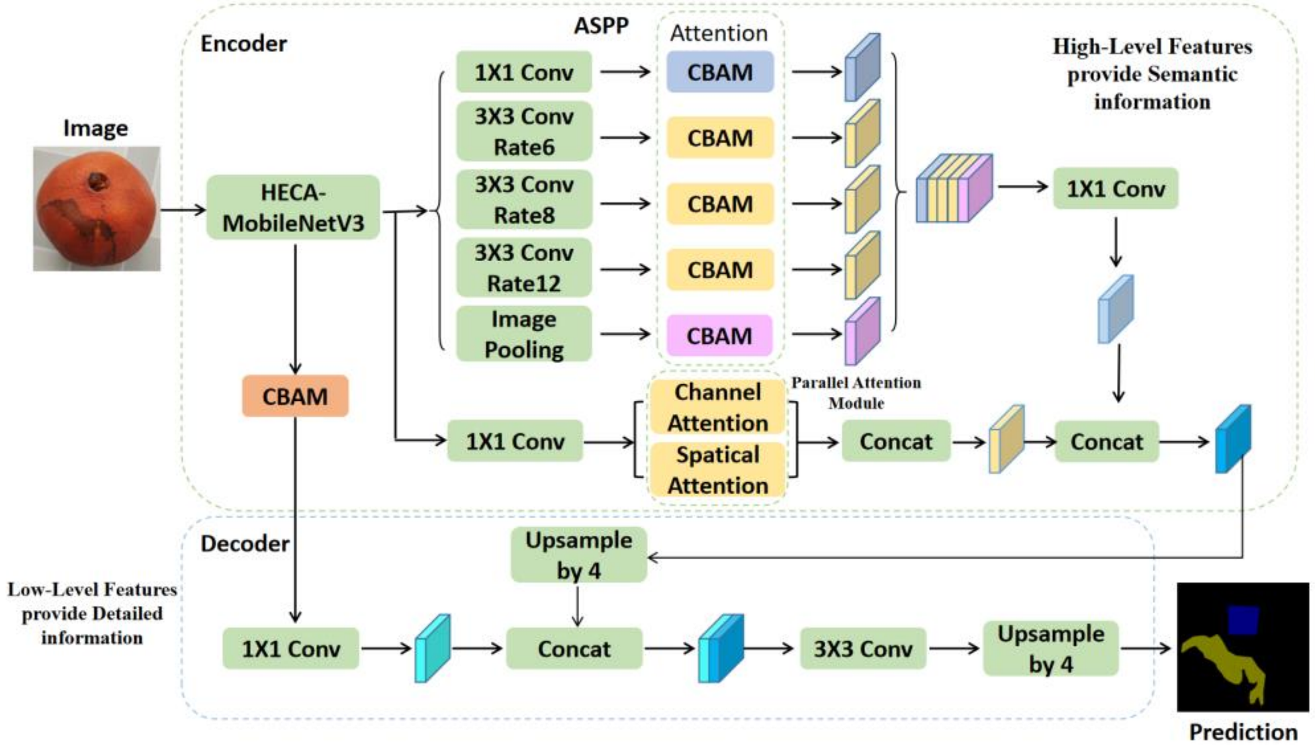

Fig. 6. Improved deeplabV3+ network model.

III. Data Collection and Experimental Evaluation Indicators

A. Data Collection

November to December every year is the harvest season for navel oranges in southern Jiangxi. The shelf life of navel oranges is as long as three to six months. The fruit is available everywhere in the market, which facilitates data collection. In actual fruit and vegetable grading and sorting equipment, multiple industrial depth cameras are often used to collect videos of navel oranges from different angles, convert the videos into pictures, and send them to the controller for intelligent processing [24]. In this study, a smartphone is used to collect image data with a resolution of 3200 x 1440 and 64 mega pixels. All images are collected in a static state, and the size of the collected images is 3472 x 4624. A high-performance computer is used to process image data and optimize, train and analyze deep learning network models. The computer specification is tabulated in Table II.

Various image of navel oranges placed under natural light in the living environment and artificial lighting after harvesting are recorded for database. A total of 800 original images were obtained, including 100 spotted, 100 navel, 100 moldy, 100 thick-heads, 200 damaged, and 200 other defects. Considering the limited number of images, data augmentation techniques were applied using Python's OpenCV and Pillow libraries to rotate, crop, and adjust the brightness of the images to enhance the generalization ability of the model. This process increased the dataset to 2400 images, with the image size is adjusted to 512 x 512.

The collected images were labeled using the *labelme* tool. By segmenting the details of the navel orange peel, six semantic labels were obtained, including spots, mildew, damaged, navel, head hypertrophy and other defects. The *json* file generated by the labeling tool is created as a dataset, and the data was divided into training set and test set in a ratio of 8:2, resulting in 1920 training sets and 480 validation sets.

TABLE II. Computer Hardware and Software Configuration

Hardware and Software	Configuration
Hardware	CPU：Intel(R) Core(TM) i7-14700KF CPU @ 3.4GHz
	GPU：NVIDIA RTX4070Ti Super 16G
	Memory：32G
	Operating System：Windows 11
Software	Deep Learning Frameworks：pytorch 2.2.0
	Image processing software：Open CV 14.2
	Compiled Language：Python 3.12.1

B. Experimental Evaluation Metric Parameters

This study uses the intersection over union (IoU), mean intersection over union (MIoU), and mean pixel accuracy (MPA) parameters to evaluate the accuracy of the model, and uses the parameter quantity and detection speed (FPS) of the model indicators to evaluate the capacity and real-time performance of the model. In all segmentation, recognition, and classification experiments, four types of results exist: true positive (TP), where the actual positive sample is correctly predicted as positive; true negative (TN), where the actual negative sample is correctly predicted as negative; false negative (FN), where the actual positive sample is incorrectly predicted as negative; and false positive (FP), where the actual negative sample is incorrectly predicted as positive. By evaluating the proportions of these outcomes, the effectiveness of the model's predictions can be determined [25]. MIoU is the average IoU of all different semantic categories, where IoU is the ratio of the intersection to the union between the predicted and the ground truth annotations. The formulas for calculating IoU and MIoU are as follows:

$$\mathrm{IoU} = \frac{\text{Predictive Value} \cap \text{True Value}}{\text{Predictive Value} \cup \text{True Value}} = \frac{\mathrm{TP}}{\mathrm{TP}+\mathrm{FP}+\mathrm{FN}} = \frac{\mathrm{P_{ii}}}{\mathrm{P_{ij}}+\mathrm{P_{ji}}+\mathrm{P_{ii}}}$$

$$MIoU = \frac{1}{K+1}\sum_{i=0}^{k}\frac{P_{ii}}{\sum_{j=0}^{k}P_{ij}+\sum_{j=0}^{k}P_{ji}-P_{ii}}$$

MPA is the mean pixel accuracy, which calculates the proportion of correctly classified pixels for each semantic category and determine the average value. Due to the imbalanced distribution of positive and negative samples in this study, this indicator is can be used to measure the proposed method performance. The calculation formula is as follows:

$$\mathrm{MPA} = \frac{1}{\mathrm{K}+1}\sum\nolimits_{\mathrm{i}=0}^{\mathrm{k}}\frac{\mathrm{p_{ij}}}{\sum_{\mathrm{j}=0}^{\mathrm{k}}\mathrm{p_{ij}}}$$

where *i* represents the true value, *j* represents the predicted value, and *k* represents the number of semantic categories.

The size and complexity of the model have a great impact on the requirements of the device’s hardware performance. The number of model parameters is an important measurement indicator, which is related to the number of input and output channels and the size of the convolution kernel; the number of frames per second represents the images that the model can detect per second, and its calculation formula is as follows:

$$\mathrm{Params} = \sum_{\mathrm{l}=1}^{\mathrm{D}}\mathrm{K_l^2C_{l-1}C_l} + \sum_{\mathrm{l}=1}^{\mathrm{D}}\mathrm{C_l}$$

$$\mathrm{FPS} = \frac{n}{time}$$

where K is the convolution kernel size, C is the number of channels, n is the number of images segmented by the model, and time is the total time required for model segmentation.

IV. Experimental Results

This study uses stochastic gradient descent for training. After repeated optimization, the initial learning rate was set to 0.005 and the batch size was set to 8. The data size was 512 × 512, with a batch size of 4, and the number of training iterations is 100. The first 50 iterations were used for frozen training, during which the backbone feature extraction network was frozen to accelerate training, while the remaining 50 iterations were used for unfrozen training to fine-tune the parameters. The Adam optimizer was selected for this study as this optimizer uses the first-order momentum and the second-order momentum, which can dynamically adjust the learning rate and make the model converge faster.

A. Ablation Experiment

To validate the effectiveness of the various improvements made to the DeeplabV3+ model in enhancing the segmentation accuracy for navel orange defects, ablation studies were conducted by modifying the backbone network, adding the CBAM mechanism, and incorporating the CSPM mechanism. The experimental results of these segmentation effects are presented in Table III.

As shown in Table III, the DeeplabV3+ model with the HECA-MobileNetV3 backbone exhibits the lowest parameter count and the highest frame rate after improvements; after incorporating the CBAM attention mechanism into the basic model, MIoU increased by 3.73% and MPA increased by 2.47%. As CSPM attention mechanism is incorporated into the model, MIoU increased by 3.41% and MPA increased by 1.99%; and after adding both CBAM and CSPM mechanisms to the model, MIoU reached 89.50%, an increase of 8.01%, and MPA reached 94.02%, an increase of 3.86%. These results indicate that the improvements proposed in this study effectively enhance the accuracy and precision of navel orange defect segmentation.

B. Cross-Entropy Loss Function

In per-class segmentation experiments, the cross-entropy loss function is often used to check each pixel one by one, and the predicted value is compared with the actual value to average the loss. Since the individual differences of some defective navel oranges are small, it is easy to cause semantic recognition errors of defects. Therefore, the multi-classification cross-entropy loss function is used to measure the segmentation effect. The loss curve for the DeeplabV3+ model only with the HECA-MobileNetV3 backbone is illustrated in Fig. 7(a), while the loss curve for the DeeplabV3+ model incorporating the attention mechanisms is shown in Fig. 7(b).

The horizontal axis represents the number of iterations, and the vertical axis represents the calculated loss value. The train loss represents the loss calculated during training; the val loss represents the loss calculated in the confirmation; the smooth train loss and smooth val loss represent the smooth loss values during training and verification respectively. It was found that the loss values of the two models gradually stabilize with the increase of the number of iterations during the training process. The Deeplabv3+ model improved by the fusion attention mechanism with the smallest loss value, stronger convergence and more stability.

TABLE III. SEGMENTATION ACCURACY OF DIFFERENT BACKBONE NETWORKS AND MODELS WITH ATTENTION MECHANISM

Model	MIoU/%	MPA/%	Params/M	FPS/fps
D+X	82.23	90.51	56.14	15.2
D+M	80.71	89.27	6.61	72.3
D+H	81.49	90.16	**5.83**	**76..5**
D+H+CB	85.22	92.63	6.58	74.1
D+H+CS	84.95	92.15	6.47	74.9
D+H+CB+CS	**89.50**	**94.02**	6.92	70.8

D：DeeplabV3+，X：Xception，M：MobileNetV3，H：HECA-MobileNetV3，CB：CBAM，CS：CSPM

(b) Fusion attention mechanism loss curve.

Fig. 7. Loss curve of multi-classification cross entropy loss function.

C. Comparative Experiments

To ensure the validity of the research, several classical networks were applied to this navel orange dataset for comparative experiments. These experiments aim to verify the effectiveness of the improved DeeplabV3+ model incorporating the CBAM attention mechanism in segmenting navel oranges defects. The experimental results are shown in Table IV.

As shown in Table IV, the DeeplabV3+ model with MobileNetV3 as the backbone network has the fewest parameters and the highest frame rate, but lower MIoU and MPA. The improved DeeplabV3+ model significantly outperforms the other five models in terms of MIoU and MPA. Specifically, the MIoU of the improved DeeplabV3+ model is 21.74%, 16.06%, 13.01%, 7.27%, and 8.79% higher than those of Unet, SegNet, PSPNet, DeeplabV3+ with Xception backbone, and DeeplabV3+ with MobileNetV3 backbone, respectively. In terms of MPA, it is 29.31%, 14.35%, 7.57%, 3.51%, and 4.75% higher, respectively. The improved DeeplabV3+ model reduces the number of parameters by 49.42MB and increases the frame rate by 55.6fps compared to the DeeplabV3+ model with Xception backbone. Although its parameter count and frame rate are slightly lower than those of the DeeplabV3+ model with MobileNetV3 backbone, its MIoU and MPA are significantly higher than those of the unimproved DeeplabV3+ model.

To provide a more intuitive comparison of the segmentation performance of different models, this study selected five representative images for visual contrast. The effectiveness of the improved DeeplabV3+ model incorporating the attention mechanism is compared with Unet, SegNet, PSPNet, DeeplabV3+ with Xception backbone, and DeeplabV3+ with MobileNetV3 backbone in navel orange defect segmentation, as shown in Fig. 8.

The result shows the improved DeeplabV3+ model provides the clearest segmentation boundaries and accurately identifies small defects in navel oranges, achieving higher detection performance compared to other models. The unimproved DeeplabV3+ model performs better than the other networks but still exhibits some issues with fuzzy boundary segmentation and misidentification of small targets. Unet, SegNet, and PSPNet networks also suffer from varying degrees of recognition errors and fuzzy boundary segmentation.

TABLE IV. COMPARISON OF EXPERIMENTAL RESULTS WITH THE CLASSIC NETWORK

Model	Backbone network	MIoU/%	MPA/%	Params/MB	FPS/fps
U-Net	ResNet50	67.76	64.71	23.9	38.9
SegNet	VGG16	73.44	79.67	21.8	45.8
PSP-Net	ResNet101	76.49	86.45	27.6	42.3
DeeplabV3+	Xception	82.23	90.51	56.14	15.2
DeeplabV3+	MobileNetV3	80.71	89.27	**6.61**	**72.3**
Improved DeeplabV3+	HECA-MobileNetV3	**89.50**	**94.02**	6.72	70.8

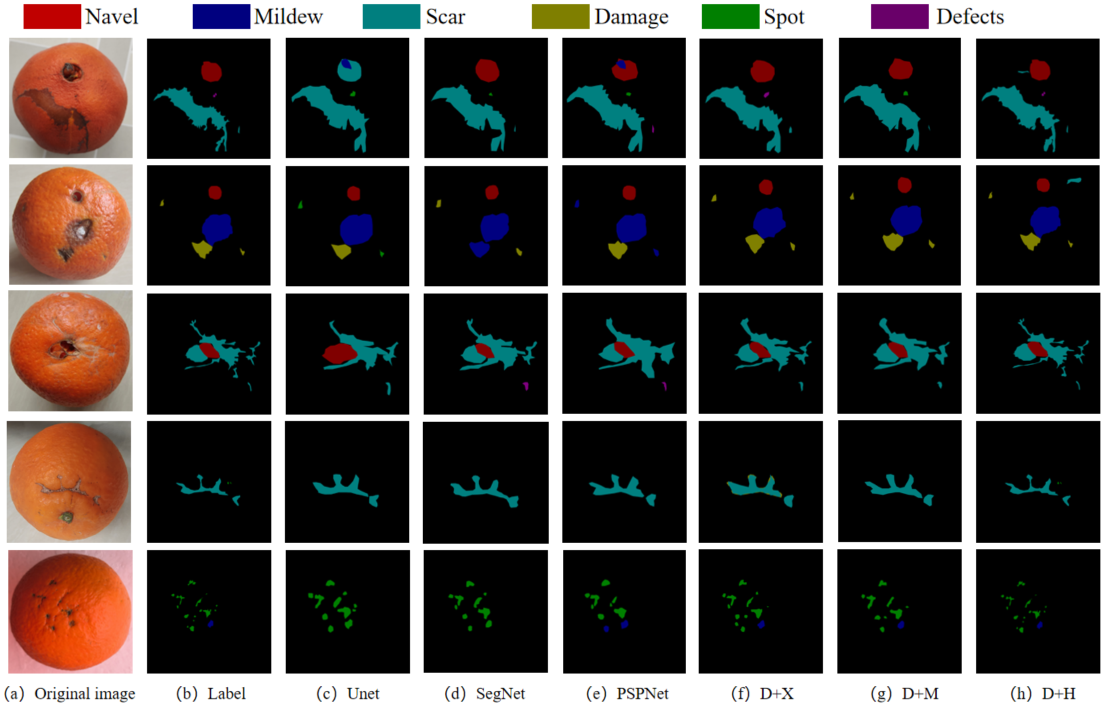

Fig. 8. Effects of navel orange defect segmentation detection using different models.

V. Discussion

Unlike other improved DeeplabV3+ methods, this study does not simply replace the complex Xception network with a lightweight backbone network MobileNetV3, but uses the improved H-ECA mechanism to replace the SE attention mechanism in the MobileNetV3+ structure. The Hard-sigmoid activation function is applied to the ECA structure, which can effectively improve the model calculation efficiency and improve the gradient disappearance problem. ECA is an improved structure based on the SE mechanism. The Hard-sigmoid activation function is combined with ECA and applied to the MobileNetV3 structure, which not only makes the backbone network lighter and ensures the real-time detection, but also effectively improves the ability to extract image features. At the same time, the CBAM and CSPM attention mechanisms are flexibly integrated into the shallow and deep feature extraction networks of DeeplabV3+, and the weights of the feature maps are adaptively adjusted in the two dimensions of channel and space, which improves the sensitivity to navel orange defects, focuses more on high-level semantic information, captures key information that is easily lost in model up and down sampling, integrates global and local features, improves the model's feature representation and generalization capabilities, and achieves more accurate semantic segmentation. Experimental results show that DeeplabV3+ with integrated attention mechanism has faster segmentation speed and higher accuracy.

The improved DeeplabV3+ model integrates attention mechanisms at multiple levels, which plays an important role in the convolution of each layer of the model. It has good segmentation performance for multiple categories of defects on the surface of navel oranges, but for some defects without obvious boundaries and light colors, the segmentation performance of this model is not as good as other defects. In future research, the DeeplabV3+ model will be further improved, such as using a more powerful backbone network, introducing a residual structure, improving the loss function, applying adaptive feature pyramid technology, and proposing a new model structure, which will be applied to navel orange defect segmentation in order to obtain better results, which can further applied to other fruit and vegetable defect detection and other image segmentation fields.

VI. Conclusion

In this paper, an improved new semantic segmentation model DeeplabV3+ model is proposed that incorporates an attention mechanism to solve the problems of low recognition accuracy and slow detection speed of similar defects and small targets in the navel orange defect grading and sorting task. By employing the improved HECA-MobileNetV3 backbone network, the model reduces parameters and enhances real-time detection. The CBAM mechanism is integrated into the ASPP structure and an additional CSPM mechanism is introduced to improve distinguishing and recognition capabilities for similar defect features. Furthermore, CBAM is incorporated into the low-level feature extraction structure to enhance segmentation of small target boundary features. Comparative study with DeeplabV3+ model was conducted resulting in improvement of MIoU of 89.50% and MPA of 94.02%, while reducing parameters by 49.42M and increasing detection speed by 55.6fps. In comparison to other semantic segmentation networks, the proposed model achieves higher detection accuracy and segmentation effectiveness while maintaining advantages in parameter efficiency and speed. The algorithm presented in this paper effectively meets the precision and speed compatibility requirements for navel orange defect grading and sorting in industrial applications.

A Framework for Capturing Quality Requirements by Integrating the Requirement Engineering Elements in Agile Software Development Methods

Yuli Fitrisia[1], Rosziati Ibrahim[2]
Faculty of Computer Science and Information Technology, Universiti Tun Hussein Onn Malaysia, Johor, Malaysia[1, 2]
Faculty of Computer Engineering Technology, Politeknik Caltex Riau, Pekanbaru, Indonesia[1]

***Abstract*—The early phase of Agile Software Development (ASD) methods is Requirement Engineering (RE). Quality Requirement (QR) is a type of RE that needs to be captured at the initial development phase to reduce rework, time, and maintenance costs. However, QR is one of the issues mentioned in ASD, namely the need for more capability to elicit, analyze, document, and manage QR. Therefore, this research aims to propose a framework for capturing QR to address QR issues in ASD by integrating RE elements, namely the RE phases, Documentation, Roles, and RE techniques. This research was conducted in four phases: 1) undertaking a theoretical study, 2) conducting an exploratory study to identify the current practices and issues to capture QR in ASD, 3) constructing the framework by using the RE elements, and 4) evaluating the framework by conducting ASD practitioners' view using questionnaires. The questionnaires were then analyzed using descriptive statistics based on the average mean of each element. The result shows the average mean for all elements (4.25), the average mean of each element for the RE phases (4.36), the documentations (4.11), the roles (4.25), and the RE techniques (4.18). The mean distribution of each element is more than 4 out of 5 indicating that the framework to capture QR is verified. Thus, this framework can be used by ASD practitioners as a guideline to capture QR in ASD methods.**

***Keywords*—Quality requirement; requirement engineering; ASD; framework; ASD practitioners**

I. Introduction

In recent years, software practitioners have used many software development methods. Each software development method has its advantages and disadvantages. For example, traditional software development methods are suitable for requirements that are clearly defined from the initial phase of the Software Development Life Cycle (SDLC) [1]. However, these methods have several issues to be aware of, namely limitations in accommodating requirement change during development, lack of interaction with customer, and the client only seeing the product at the end of the project [2]. These issues are covered by Agile Software Development (ASD) methods [2-4].

ASD is a popular software development method widely used in today's business industry [5-8]. ASD methods have advantages in producing software products faster to markets, being flexible to changing requirements, and increasing customer collaboration [9-10]. In addition, based on the Agile annual report [11], ASD increases collaboration, facilitated teamwork, provided better alignment for business needs, better work environment, and better visibility capabilities in application development.

Requirement Engineering (RE) is the early stage of the Software Development Process, including ASD. It has two types of requirements, namely Functional Requirements (FR) and Quality Requirements (QR), also known as Non-Functional Requirements (NFR). QR presents the quality of the software product. However, the tendency to ignore QR, the product quality can be negatively impacted and even cause software product failure [9-11]. Therefore, it is important to capture QR early in the RE phase of the ASD to reduce time, rework, and maintenance cost.

ASD practitioners also realize the importance of documenting QR [15]. It can help with easy analyses and traceability, gives a ready-to-use template, and eases communication among ASD stakeholders. Roles are people who possess responsibilities for every process in software development. Assigning roles with their expertise helps managing QR and making the QR list consistent and unambiguous [16]. Selecting proper techniques for each RE phase is also important to ensure the phase is well-conducted and reduce the complexity of capturing QR.

ASD has issues in terms of lack of capability to handle QR [9,14-18]. For instance, eliciting and analyzing QR challenges, limited techniques for eliciting, modeling, and linking QRs with functional requirements, and inadequate user stories for specifying QR [12]. The other issues are the lack of QR documentation [9,17], and no explicit practice for QR [21]. Additionally, it also lacks ASD capabilities in managing QR through ASD artifacts, namely user stories, prioritizing functional requirements (FR), and the tendency to ignore QR [19-22]. Based on these previous issues, practitioners realize the importance of capturing QR early in the context of ASD [25]. It is also important for capturing QR systematically, which offers how to capture and validate QR [15,23,24,27]. It is also supported by the result of a survey conducted by López et al. [28] reporting that 50% of practitioners follow QR processes in a systematic, well-defined, or ad-hoc process. It can reduce the complexity of managing QR in ASD and improve product quality and customer satisfaction.

Based on literature studies conducted in this research, identified issues related to capture QR in ASD methods can be solved by implementing approaches, frameworks, and guidelines for QR in ASD. Furthermore, several studies have been conducted to capture QR. The QR elicitation guideline proposed by Younas et al. [29] was implemented to tackle QR in ASD methods at the elicitation phase by using several pieces of documentations, namely the QR glossary, historical data, and checklist table between FR and QR. It also involved the developer team, experts, and customers. A study by Younas et al. [30] proposed the Elicitation of Non-Functional Requirements in ASD using a Cloud Computing Environment. This methodology also involves the same RE phase. The documentations used were project history, template for NFR by Kopczy and system type. Then, the roles involved developer team, customers, and experts. According to Jarzębowicz et al. [31] proposed elicitation practices to capture QR in ASD. The roles involved developer team, customers, products owners, and experts. Another study by Behutiye et al. [32] proposed the QR documentation guideline within ASD. In this guideline, they only proposed documentation for QR. Then, Alhaizaey et al. [33] proposed a framework for Reviewing and Improving Non-Functional Requirements in ASD-based Requirements. This framework was implemented at the elicitation, analysis, and validation phase. The documentations used were FR user story, identified NFR, NFR bibliographic source, glossary and standards, and NFR description. It also involved the developer team and customers. Finally, Sherif et al. [24] proposed a framework to manage NFR in ASD. It was implemented at the elicitation, analysis, documentation, and validation phase. The documentations used were FR user story, checklist-based reading template, system type, domain type, project history, mapping sheet between QR, and QR user story. It also involved the developer team, product owners, and customers.

There are still several gaps in proposed previous solutions to capture QR. It shows that three [29] of six of the previous works implemented to capture QR in the elicitation phase only. However, based on the earlier discussion, it is important to capture the QR to construct the RE phase element by using complete phases, namely elicitation, analysis, documentation, and validation, to produce QR properly. Then, the documentation used in the previous study only focuses on partial documentation for each RE phase [33]. Additionally, several studies did not use a software quality model or standard as a reference to identify the QR [24]. However, it is needed because the quality model or standard has the metrics to measure the QR. It can be used to make sure the QR is measurable. One study focuses on QR documentation only [32]. It should need comprehensive documentation by constructing the documentation for each RE phase to give an easy analysis and get a clear QR list.

The other element is the roles involved. Several previous studies report that the roles did not focus on their expertise and involved the roles needed related to each RE phase [24,33]. The roles should be constructed to be suitable for their expertise and responsibility. As a result, it gives an impact on the process of capturing QR more effectively. In addition, several studies do not mention the RE technique used clearly for each RE phase [29, 31]. Furthermore, it also needs to define the RE technique that will be used in implementing the RE phase systematically.

This paper presents research focuses on addressing three issues according to the gap findings, namely (i) lack of clarity on which the Requirement Engineering phase and the techniques used of the capture QR should be implemented, (ii) lack of documentation of QR, and (iii) the inadequate ability of user stories to capture QR by involving roles to address QR effectively. Based on these three issues, the following Research Questions (RQs) are formed. They are RQ1: how to determine the RE elements and each component in ASD methods, RQ2: how to design the framework for capturing QR using the elements and components of RQ1 and RQ3: how to evaluate the QR framework by using practitioner reviews. Thus, the objectives of this research are as follows: (i) to determine the RE elements and each component in the ASD method, (ii) to design a framework for capturing QR, and (iii) to evaluate the QR framework by using practitioner reviews.

The research significantly contributes to the body of knowledge in the field of Software Engineering, particularly in Requirement Engineering, on how QR is being addressed, captured, and documented in an ASD environment. Moreover, ASD practitioners can use this proposed framework as one of the best practices and guidelines for handling QR in an ASD environment, and the Stakeholders in an ASD environment can gain QR status transparency and track the QR. Then, it systematically captures the QR to reduce the complexity of managing QR in ASD, improve product quality, and finally improve customers' satisfaction.

This paper is outlined as follows: Section II presents an overview of related work and the gaps in previous work, Section III presents the research methodology, including theoretical study, exploratory study, framework design, and framework evaluation, Section IV explains the experimental results and analysis, and Section V presents the conclusion and future work.

II. Related Work

Quality Requirement (QR) is one of the RE types and is an important artifact that plays a crucial role in software project success [34, 35]. It can lead to increased costs or longer time-to-market due to the failure to meet QR needs properly [25,26]. Many software quality standards can be adopted in QR for software development. In the 1970s and 1980s, the authors in [36,37] proposed their own QR taxonomies. The ISO/IEC 25010 standard is the most widespread method of defining, categorizing, and managing QR. This standard is widely adopted in today's industry. It has nine quality categories, namely functional suitability, performance efficiency, compatibility, interaction capability, reliability, security, maintainability, flexibility, and safety [38]. Numerous recent studies have conducted extensive reviews on QR in the Requirement Engineering in ASD methods [13]. A study in [29], Younas et al. proposed activities of NFR Elicit guideline as depicted in Fig. 1.

According to Fig. 1, the first phase is the preliminary requirement to collect FRs that have been identified. The next step is to identify the software type and then to identify the QR from Glossary. It involves the historical data to make predictions about new QR. This elicitation guideline encompasses experts' involvement. This process ends when the experts and users finalize it. This guideline also uses a checklist table between FR and QR to manage changing requirements. In contrast, the limitation of this guideline is the mapping between FR and QR, which is done at the end of the process, for it can take time if there is a change, and the process should be repeated from the beginning. The other limitation is that there is no mapping between QRs to check conflict between them. Then, this guideline is only implemented in the elicitation phase, and there is no clear explanation of how to finalize the QR list between the experts and the users.

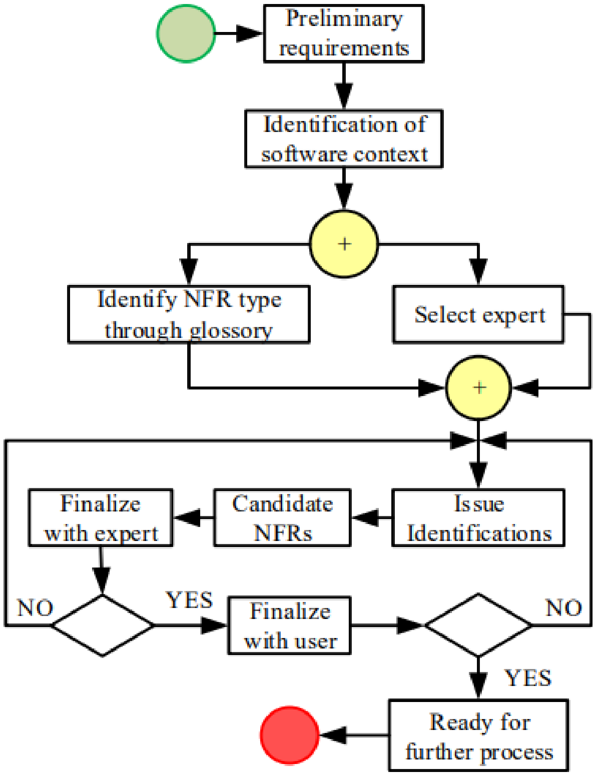

Fig. 1. QR elicitation guideline [29].

Similarly, in a study [30], Younas et al. proposed the Elicitation of Non-Functional Requirements in ASD using a Cloud Computing Environment. This proposed methodology is a continuation of their previous research on the QR elicitation guideline [29] as described in Fig. 2. From Fig. 2, it can be seen the differences of this present study from previous studies are the use of Natural Language Processing (NLP) for QR extraction in the elicitation phase and cloud computing tools for sharing data and communication. However, this methodology has no link between QR to check the conflict, and it is only implemented in the elicitation phase.

Jarzębowicz et al. [31], discussed elicitation practices to capture QR in ASD. The methodologies used in their study were a systematic literature review (SLR) and interviews with ten ASD practitioners. Based on their findings in the SLR study, techniques for elicitation include Customer-Developer meetings, Brainstorming, QR document circulation between Product Owner and QR Stakeholders (e.g., experts), QR catalog, and on the basis of Business Process Models are popular in several studies. The other findings based on interviews with ASD practitioners summarize that ASD practitioners mention that the presence of an analyst role contributes to more thorough QR elicitation. Then, for sources of requirements, several ASD practitioners argue that the Product Owners are capable of giving opinions on QR. In other cases, multiple stakeholders can consider eliciting requirements from their point of view, including other IT systems and document standards. The other sources are software developers and technical experts who will provide inputs based on their expertise. Then, the techniques used for QR elicitation are interviews, and workshops (including brainstorming and other kinds of group work) that are commonly used.

There are efforts to capture QR using the current practice. For instance, the elicit QR is non-verifiable and non-measurable, and not all QR needed in the software development is detected. For example, usability is recognized, but others still need to be defined. Therefore, based on the ASD practitioner's view, they state that it needs an active approach and guidance for all ASD stakeholders.

Another study done by Behutiye et al. [32] proposed the QR documentation guideline within ASD. This guideline, known as ASD QR-Doc, offers 12 recommendations to facilitate the documentation of QR in ASD. The guideline was validated by ASD professionals. They consider the ASD QR-Doc guideline to be straightforward for use in ASD, helpful in the early process and documentation of QR, and not obstructive to the ASD process. However, the guideline is only validated by practitioners, and this guideline needs to be clearly defined when QR is documented in the RE phase.

Fig. 2. QR elicitation methodology using cloud computing [30].

Alhaizaey et al. [33] proposed a framework for Reviewing and Improving Non-Functional Requirements in ASD-based Requirements. It uses NLP and Artificial Intelligence (AI) techniques to automate analyzing QR from user stories. Then, the artifact from this phase is reviewed and inspected for improving the QR. Three artifacts are produced from the previous phase, namely the processed user story, the identified QR, if any, and the description of the QR. The last phase is improving the requirements using four activities, namely rewriting a user story, rewriting [means] part of the user story, including QR as an Acceptance Criteria (AC), and including QR as a Definition of Done (DoD), as depicted in Fig. 3. However, this framework needs to explain how the documentation phase is conducted. It also only involves the developer team and clients to finalize the QR and needs to involve experts in validating the QR list.

Finally, Sherif et al. [24] proposed a framework to manage NFR in ASD called MANoR, which stands for Managing Agile Non-Functional Requirements. It provides two main stages and five main components. The stages are pre-analysis and post-analysis, and the components support various critical functions within requirements engineering, encompassing requirements elicitation, analysis, documentation, and validation. The main steps of the MANoR framework are depicted in Fig. 4. There are four areas for improvement and limitations associated with this approach. Firstly, there is no Quality Model from the glossary that can be used as a source to recommend QR. The quality model, particularly ISO 25010, has an advantage. For instance, it has the metrics to measure the QR lists. Secondly, the expert is not involved in the QR elicitation process, which can help identify QR more effectively. Thirdly, there is no mapping between FR and NFR during the QR analysis process to check for inconsistency. There is also no documentation of QR decisions that will help track them. Fourthly, the validation technique (reading technique) should be mentioned, and QR is only validated by the clients or customers.

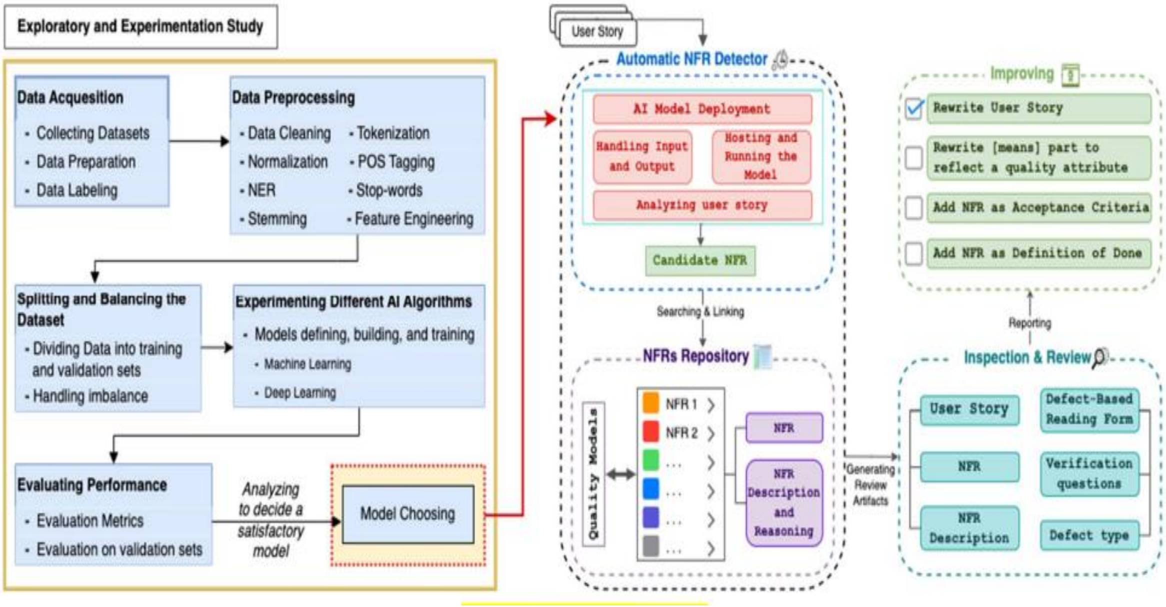

Fig. 3. Framework for elicitation, analysis, and reviewing QR [33].

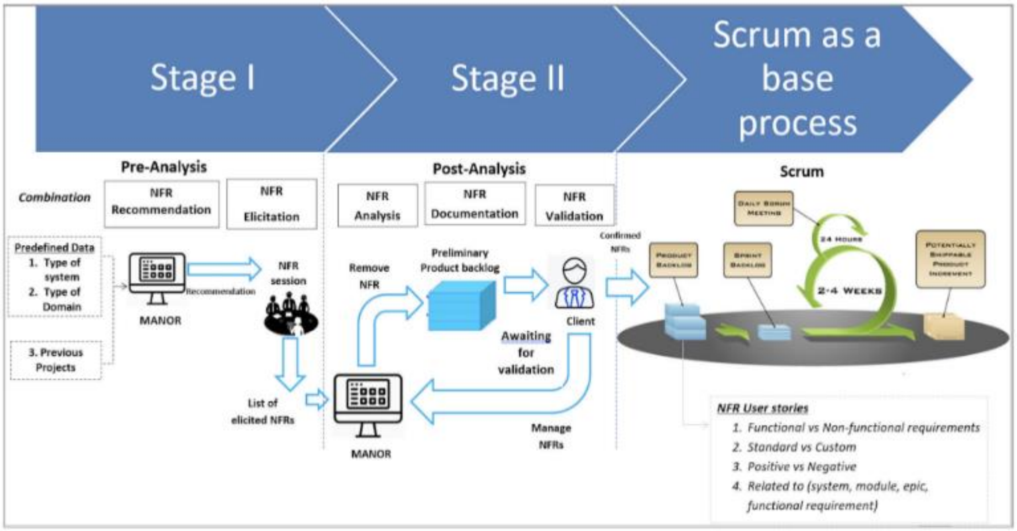

Fig. 4. MANoR framework [24].

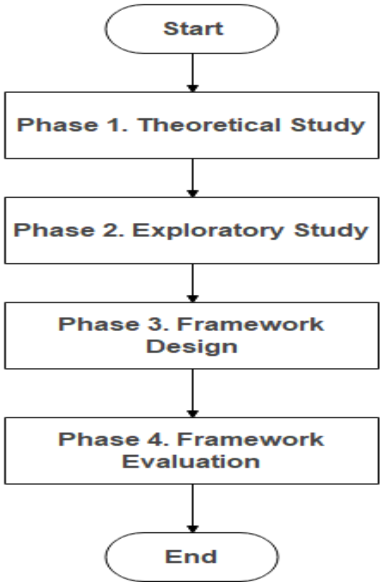
In summary, based on related studies discussed, the solutions focus on capturing QR in ASD from different points of view, namely frameworks, approaches, models, and guidelines as previously mentioned. According to the gaps identified in related work, therefore, this research proposes a framework for capturing the QR by integrating the RE elements in ASD methods comprising 1) the RE phase, 2) documentation, 3) the roles involved, and 4) the RE technique.

III. Methodology

Fig. 5 shows that the research methodology consists of four phases. The first phase is theoretical study, the second phase is exploratory study, the third phase is framework design, and the fourth phase is framework evaluation. Each phase has key activities and outputs of the activities.



Start
Phase 1. Theoretical Study
Phase 2. Exploratory Study
Phase 3. Framework Design
Phase 4. Framework Evaluation
End

Fig. 5. Research methodology.

A. Theoretical Study

The first phase was conducted by reviewing the literature to explore the concept related to the study, current practices, and issues to capture QR in ASD, identifying the element constructed in the framework, and finding the gap by analyzing the related work in ASD from various sources like journals, conferences, books, and other sources. Then, based on the gap finding from existing related work, this study proposes a new solution for the elements and the components to construct for capturing QR in ASD. The outputs of this phase are a clear explanation of current practices and the issues of capturing QR in ASD. It also gets the elements and the components constructed in the framework.

B. Exploratory Study

The second phase was conducted by doing a qualitative study by interviewing ASD practitioners with a small number of respondents to get detailed information about their opinions [39]. The interview aims to explore current practices to capture QR in the ASD industry and the issues based on practitioners' views. The exploratory study was conducted by an online interview involving 30 ASD practitioners. The summary of current practices when capturing QR in ASD is categorized into three phases, namely RE phase, during development, and during product release to market or customers.

The result percentage indicates that the QR is identified majority during development and release to market is 33.33%. Then, during the RE phase and development is 26.67%, during development is 20%, in RE phase is 10%, and product release to market is 10%. The other findings are that QR is identified the majority during development is 80%. Then, during product release to market is 43.33%, and during the RE phase is 36.67%. On the other hand, it also shows the weaknesses of current practice in capturing QR based on interview findings, namely:

- Identified QR in the RE phase: More time is needed in the planning phase. Therefore, it takes time to start the development process. Only the developer team was involved in identifying the QR in the RE phase. Sometimes, people need to be made aware of QR. Consequently, they should have added one more task for improvement, but it took time.
- Identified QR during development: It needs more rework, cost, and time to adjust the QR because it changes most in software architecture, namely in design and code, adding a new story to fix the bug in Product Backlog. It is challenging to identify QR during development because the document is not updated based on requirement changes. Sometimes, the QR is ignored because there is no QR documentation. It can change the project timeline, and the workload also increases a lot.
- Identified QR after release to market or customers: It needs more rework because it changes most in software architecture, namely in design and code. The application appearing on the device does not meet the user's requirements. It needs more time, it can change the project timeline, product backlog items increase, and the workload also increases a lot.

C. Framework Design

The third phase is to construct the framework based on a theoretical study and exploratory study findings. The theoretical study is based on the literature review, and the exploratory study is based on interviews with ASD practitioners. The output of this phase is the proposed framework for capturing QR by integrating the RE element in ASD based on studying the existing model gaps outlined in related work. It preserves the strengths of these existing models and tries to overcome their limitations. It also constructs various aspects for comprehensive QR.

This present study argues that it is important to capture QR by implementing in the RE phases as the foundation of the software lifecycle, which are elicitation, analysis, documentation, and validation [24]. The QR was identified during an initial iteration of Agile Software Development and then refined in further iteration [36,37]. The authors in [31] also found that early identification of QR at the beginning of a software project is better. It also supports an exploratory study; if QR were defined during the RE phase, it would not require much effort for future tasks. When QR is identified early, it can help to produce QR properly, help to identify project effort, cost, and size, and reduce rework.

The documentation/artifact should need comprehensive documentation, usefulness, relevance, and understandability for supporting QR documentation and its impact on ASD practice [32]. The ASD manifesto focuses on the development of working software over comprehensive documentation [42]. However, a lack of QR documentation can cause misinterpretation and rework [31]. It also supports an exploratory study, which makes it challenging to identify QR during development because the document was not updated based on requirement changes, and sometimes the QR is ignored because there is no QR documentation. Therefore, it is important to include documentation as the element to capture QR. Constructing the documentation for each RE phase can give easy analysis, clear tasks, traceability, clear documentation, and well-documented QR [16]. It can help communication among ASD Stakeholders.

The other element is the roles involved. In several previous studies reviewed, it was found that the roles need to include capturing QR to focus on their expertise [31]. The roles for each RE phase need to be constructed in a way that is suitable for their expertise and responsibility [32]. It also supports an exploratory study result, because only the developer team is involved in identifying the QR, sometimes people are not aware of the QR. Consequently, they should have added one more task for improvement, which took more time. Furthermore, it is important to involve roles with their expertise for each RE phase because it can impact the process of capturing QR more effectively. According to Aljallabi et al. [16] stated that it also provides proper QR results with more reliable results due to invented different points of view.

It also needs to define the RE technique that is used to capture QR, which is in line with ASD practice on direct communication [31]. RE techniques were needed to conduct the RE phase systematically by the team [1]. If we can choose the right techniques, it can be produced and conducted to capture QR more effectively and clearly. It also helps to capture the impact of change of requirement, which is understandable by all stakeholders, and check for errors and inconsistencies. Therefore, this research proposes a framework to integrate the RE elements, namely, 1) the RE phase, 2) documentation/artifact, 3) the roles involved, and 4) the RE technique. These four elements are needed to capture QR in ASD. The following sub-sections define the RE element and its relation to the component of each element.

1) Constructing RE phase element: The RE phase was constructed by using the four-phase component of RE as the first element, namely elicitation, analysis, documentation, and validation [1]. It is important to capture QR by using complete phases to produce QR properly [24]. It is also supported by a study [33], who argue that validating the QR is a crucial requirement process as the last phase of RE. Therefore, it should be conducted in all phases of RE to capture the QR.

The elicitation phase is the first phase of RE that aims to understand the tasks performed by stakeholders and how a new system could support their tasks [1]. This phase is the foundation of project success and aims to explain QR to the stakeholders. This session also determines the QR based on the element used. The output of this phase is the list of elicit QR. The second phase is the analysis phase aiming to find consistency between FR and QR [16]. It is also to make sure there is no conflict between QRs [24].

The purpose of the documentation phase as the third phase is to write down software requirements into a Software Requirements Specification (SRS) document [1]. It can be used to document user requirements and system requirements, namely the FR and QR in the user story written in the product backlog. It can also be used to document the decision on the QR. The last phase is the validation phase, which aims to check the requirements meet the customers' expectations [1]. The checking process consists of a validity check, consistency check, completeness check, realism check, and verifiability check. It is also to ensure that the QR list is clearly defined, that there is no error interpretation, to check areas where clarification may be required, and that there is no missing information. According to Sherif et al. [24], this phase also aims to reach an agreement among stakeholders regarding QR on the same view for the software being developed.

2) Constructing QR documentation element: The documentation element used in this framework can provide a ready-to-use template for easy analysis and traceability. It was constructed at each RE phase by integrating documentation components as a reference for capturing the QR. QR should be documented along with FR [43].

System-type document in elicitation helps users identify relevant QR based on different types of systems [40,41]. Domain-type document in elicitation helps users identify relevant QR based on various application domains [44]. ISO 25010 Quality Model in elicitation has advantages, namely providing a more detailed QR and metrics on how to measure the QR [29,30]. Project history document in elicitation is useful to define the QR for the next project based on historical data. [24]. A mapping sheet between FR and QR document is used in the analysis to check the consistency between FR and QR [16]. A mapping sheet between QR document is used in the analysis to check the conflict between QRs [24].

In this research, a separate user story is used to document QR, which consists of the FR user story and the QR user story. This helps to manage QR during the development process, for example, during the sprint [45]. The functional user story in the documentation aims to document functional requirements in ASD. QR user story in documentation to document the Quality Requirements list in ASD. QR decision in documentation as a history to decide the QR [32]. According to Sabaliauskaite et al. [46] Checklist-based reading document in validation is used to check the properties of documents and what problems or defects should be identified based on the list of questions.

3) Constructing the involvement of roles element: The roles constructed into the element of assigning roles with their expertise are helpful for managing QR and making the QR list consistent and unambiguous. Then, different points of view for the validation phase are involved in working together to produce QR, which results in more reliability and understanding for all stakeholders. It is constructed at each RE phase by integrating role components to capture the QR.

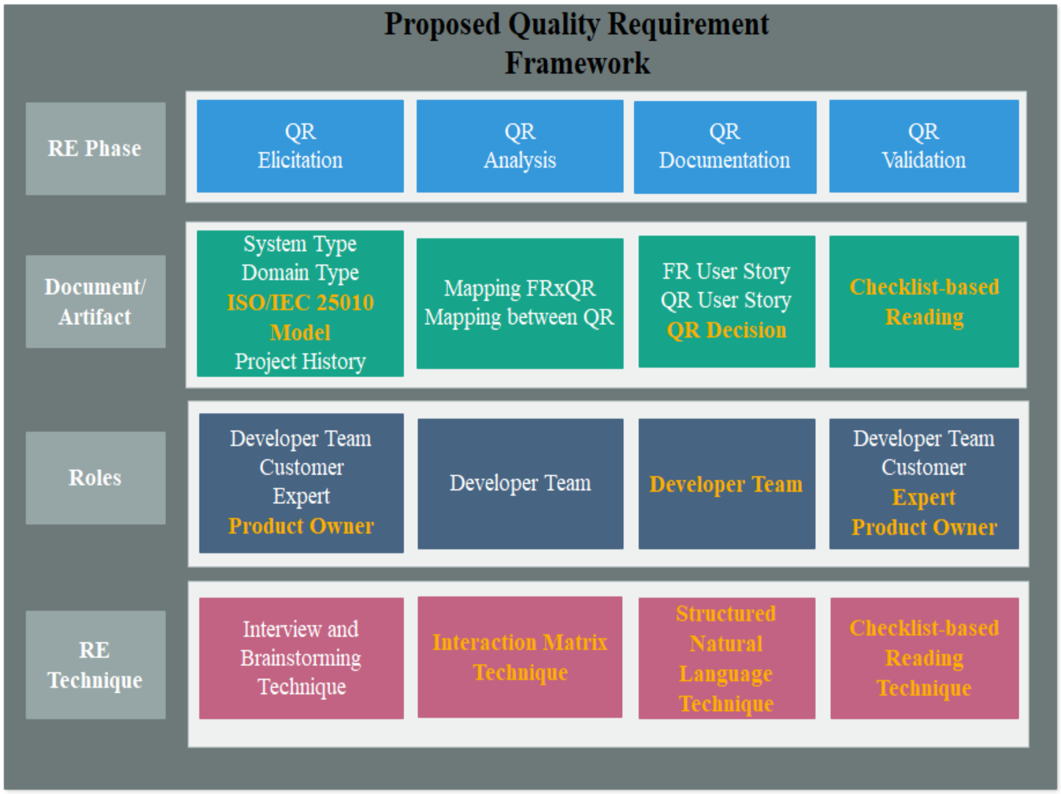
The developer team in elicitation is a person who understands the technical side related to QR that is elicited and is responsible for finishing the QR item in the product backlog [24]. Customers in elicitation are the stakeholders who own the system and need to be explained about QR, which is elicited [29]. An expert in elicitation helps elicit the QR; that is, someone who has more knowledge of QR and is concerned with the fulfillment of QR [29]. The Product Owner in elicitation has the responsibility of managing and optimizing the product backlog to ensure the product value is maximized which aligns with the FR and QR that should be elicited [47]. According to Jarzębowicz et al. [31] QR.

The developer team, in analysis as a technical side, defines consistency and conflict in the mapping sheet according to a clear justification based on the developer's knowledge [16]. The developer team in documentation manages the document if there is a change in these documents. The developer team in validation is a technical team that finishes the QR in the Product Backlog and ensures the QR can be tested. The expert in validation can help refine the QR and interdependencies among QRs and validate the QR. The customer is also involved in validation to make sure the QR list is understandable to the customer. The Product Owner, in validation, ensures the QR list is valid and included in the Product Backlog.

4) Constructing the RE technique element: The RE technique presents how the RE phase was conducted. It was constructed at each RE phase by integrating the components of the RE techniques to capture the QR. The Interview and Brainstorming techniques in elicitation are commonly used and popular techniques in the elicitation phase [31]. The interview aims to discover information and to understand the system to be developed based on asking questions to the stakeholders [1]. Additionally, a study [48] stated that Brainstorming aims to gather information in many creative ways by conducting work group meetings involving roles.

The interaction matrix technique is used in the analysis of two-dimensional requirements to assess the inconsistency between FR vs. QR and the conflict between QR where each requirement is compared to the other [49]. The Structured Natural Language technique in documentation is the documentation technique for writing the FR and QR using natural language on a standard form or template where each field provides information on the requirements [1]. The checklist-based reading (CBR) technique in validation aims to detect defects in the requirements based on a list of questions [49].

There are four major elements constructed in the proposed framework to capture QR, namely: 1) RE Phase, 2) Documentation/Artifact, 3) Roles Involved, and 4) RE technique. Each element has its components for the proposed framework, as depicted in Fig. 6.



Proposed Quality Requirement Framework

RE Phase	QR Elicitation	QR Analysis	QR Documentation	QR Validation
Document/ Artifact	System Type Domain Type **ISO/IEC 25010 Model** Project History	Mapping FRxQR Mapping between QR	FR User Story QR User Story **QR Decision**	**Checklist-based Reading**
Roles	Developer Team Customer Expert **Product Owner**	Developer Team	**Developer Team**	Developer Team Customer **Expert** **Product Owner**
RE Technique	Interview and Brainstorming Technique	**Interaction Matrix Technique**	**Structured Natural Language Technique**	**Checklist-based Reading Technique**

Fig. 6. The proposed QR framework.

D. Framework Evaluation

A practitioner evaluated this framework to verify it. This phase was conducted using quantitative research through questionnaires. The phases are instrument design, instrument validation, pilot study, sampling, data collection, and feedback analyses [50]. The questionnaires consist of two sections: demographic information and elements and the components of the QR framework. These instruments are used to verify the proposed framework to confirm whether the ASD practitioners' review agrees or disagrees with the proposed elements and the components of the framework to capture QR in ASD [50], [51]. The result of the framework evaluation is explained in the following Section.

IV. RESULTS

This section explains the findings of the evaluation by using questionnaires for ASD practitioners classified into sub-sections: A) the Pilot Study, B) Data Collection and Sampling, C) Data Analysis, and D) the Result.

A. Pilot Study

A pilot study was conducted by involving 30 ASD practitioners to check the reliability of the instrument and get feedback for the questionnaires before conducting the sampling survey. The pilot study result shows that it achieves the reliability threshold (> 0.7) based on Cronbach's alpha coefficient [52]. It consists of all elements (0.81), RE phase (0.72), document (0.91), roles (0.90), and RE technique (0.82), which means that the questionnaires are acceptable. The other result is questionnaire feedback from the respondents. The questionnaires were refined to improve the quality and avoid misinterpretation of the questions.

B. Data Collection and Sampling

The respondents of this questionnaire survey are ASD practitioners gathered using Snowball Sampling as one of the non-probability sampling techniques. Then, the questionnaires were distributed using an online survey from various channels, namely alumnae and their networking, colleagues in the industry, and post questionnaires in ResearchGate, LinkedIn Group for ASD, and ASD Community Indonesia. The total number of respondents who filled out the questionnaire was 170 people for one month, as presented in Table I.

TABLE I. QUESTIONNAIRE RESPONSE RATE

Description	Frequency	Percentage
Total questionnaires received	170	100%
Total rejected questionnaires	12	7.06%
Total usable questionnaires	158	92.94%

Table I shows that the total number of questionnaires received was 170, only 12 (7.06%) questionnaires were rejected due to outliers, and 158 (92.94%) questionnaires were used in this research.

C. Data Analysis

The data were analyzed using descriptive statistics. Data preparation aims to ensure that the data are free from errors by processing the cleansing data. It is important to make sure the result is accurate. According to Ibrahim et al. [50], the steps for data preparation start with screening the data and coding data, as well as checking missing data, suspicious response rates, outliers, and normality by using SPSS software.

1) Screening and coding data: This step was done by ensuring the data types were numeric and changing the measure data to scale. It was done at the variable view by changing the code manually.

2) Checking for missing data: This step aims to analyze the data that the respondents fill out. If there is missing data, it can cause an error. Based on the data, no missing values for all items were found. According to Hair et al. [53], if there are missing values, responses can be excluded by less than 10%, and the result is acceptable.

3) Suspicious response rate: This step is to identify the answer pattern if the respondents fill in the same values for all questions [53]. It can be excluded from the data that needs to be analyzed. The result is that no suspicious response rate was found.

4) Outliers: When using parametric or non-parametric tests, outliers can state the error rates and substantial distortions of parameter and statistic estimates [54]. Standardized Z-scores can be used to analyze the outliers based on the variables, and the values are then examined. The acceptable value of the Z-score is between -3.29 and +3.29, which indicates no outliers [55]. According to the Z-scores analysis, 12 outliers were found in this dataset, and it was removed from the dataset.

5) Normality: Before the data can be analyzed, it must meet the normal distribution, where each construct item must meet the normality [56]. The values of skewness and kurtosis can estimate the symmetry and data distribution. The authors in [53] stated that the value of the standard error of skewness close to zero is acceptable. While the authors in [56] stated that the acceptable value of the standard error of kurtosis should not exceed 10. The result shows that the standard error of skewness is 0.19, and the standard error of kurtosis is 0.38. This means that the data are close to the normal distribution and can be used to analyze the dataset.

D. Results

This section explains the results of the framework evaluation using the questionnaires by ASD practitioners. It consists of two sub-sections, namely demographic information and descriptive statistics.

1) Demographic information: This section describes the respondent's background and the organizational background.

a) Respondents' background: This section indicates their position in the organization and years of experience in ASD. According to respondents' positions, programmers are the majority of the respondents, about 46.20%. The second position is System Analyst, about 13.92%, and Quality Assurance (QA)/Tester, about 11.39%, followed by Team Leader, about 10.13% and Project Manager, about 6.33%, Product Owner, about 5.06%, Scrum Master, about 1.90%, and Others about 5.06%. The respondents' experiences with Agile Software Development methods are depicted in Table II.

TABLE II. EXPERIENCE IN AGILE SOFTWARE DEVELOPMENT METHODS

Positions	<1 Year	1-5 Years	6-10 Years	>10 Years	Total
Programmer	2	65	6	0	73
System Analyst	1	19	2	0	22
Quality Assurance/Tester	0	18	0	0	18
Team Leader	1	13	2	0	16
Project Manager	1	3	5	1	10
Product Owner	0	6	1	1	8
Scrum Master	0	1	2	0	3
Others	1	7	0	0	8
Total	6	132	18	2	158

Table II reports that the majority of the respondents' experiences were between 1 and 5 years, comprising 132 respondents, and among them, 65 respondents are programmers. The ASD experiences of more than 10 years are 2 respondents, namely Project Manager and Product Owner presented in Table II.

b) Organizational background: This section describes the organization sector in the industry. The majority of respondents in the organization sector are banking/financial/insurance, about 29.11%. Then, the percentage of Software Houses is 27.22%, the percentage of the Oil and Gas and other mining industries is 13.29%, and other sectors are depicted in Table III.

2) Descriptive statistics: Descriptive statistics is used to measure the tendency and frequency of each item. Table IV presents that the respondents mostly agree (4) and strongly agree (5) for all items based on the Likert scale, which consists of Strongly Disagree (1), Disagree (2), Neutral (3), Agree (4), and Strongly Agree (5).

From Table IV, it can be seen that the average mean of all elements is 4.25. The average mean of the RE phase element is 4.36 confirming that the first research problem in terms of lack of clarity on which the Requirement Engineering phase to capture QR should be implemented is answered. Then, the average mean of the RE technique is 4.18 confirming that the first research problem in terms of lack of clarity on which the techniques used to capture QR implemented is also answered.

The average mean of documents used is 4.11 confirming that the second research problem in terms of lack of documentation of QR is answered. Then, the average mean of roles involved is 4.25 confirming that the third research problem in terms of the inadequate ability of user stories to capture QR by involving roles to address QR effectively is answered.

Table IV presents that our finding extends the previous work of [29-31] on how to capture QR, which was only implemented in the elicitation phase. According to Table VI, each of the RE phases is needed to implement for capturing QR early. It also extends the previous work of [24], according to Table IV, in terms of documentation used, roles involved, and the RE techniques are also needed for each RE phase. Furthermore, it extends the previous work of Alhaizaey et al. [33], according to Table IV, in terms of documentation used and the roles involved are also needed for each RE phase. On the other hand, according to Table IV, our findings are in line with the documentation used [32] and in terms of implementation for capturing QR in all the RE phases [24], as described in the research gap. In summary, this study fills the gaps from previous works by implementing all the RE elements. Additionally, it also uses comprehensive documentation, the roles involved, and the RE techniques for each RE phase. According to the statistical results, the mean distribution is more than 4 out of 5 suggesting that the framework (Fig. 6) used to capture QR is verified and shows a positive impact on dealing with capturing QR in ASD. However, this framework still needs to prove its effectiveness by conducting validation using case studies.

TABLE III. ORGANIZATION SECTORS

Organization Sectors	Frequency	Percentage
Banking/Financial/Insurance	46	29.11%
Software House	43	27.22%
Oil and Gas, and other mining industries	21	13.29%
Education/Training	9	5.70%
Telecommunication	6	3.80%
E-Commerce	5	3.16%
Manufacturing	5	3.16%
Transportation & Storage	4	2.53%
Healthcare	4	2.53%
Agriculture, Hunting & Forestry	4	2.53%
Construction	3	1.90%
Others	8	5.06%
Total	158	100%

RE Technique (validation phase)	Checklist-based reading technique	4	4	4.20	

V. CONCLUSION AND FUTURE WORK

This research proposes a framework for capturing QR by integrating the RE elements in Agile Software Development methods. The research result based on the framework verification using the questionnaire confirms that the ASD practitioners' review agrees with the proposed element and the component to capture QR in ASD. Thus, this framework offers a comprehensive way to handle QR in ASD while aligning with ASD Practice to reduce rework, time, cost, and even project failure. Furthermore, this framework also emphasizes that the RE phase should be iterative along with the process of capturing functional requirements, even requirements (either FR or QR) that arise in the middle of development to accommodate requirement change. For future research, this framework will be validated by using case studies to evaluate its effectiveness, which is in line with the ASD practice, to see the importance and impact of QR on ASD. The case studies will be implemented in selected companies that have used ASD methods for software development.

ACKNOWLEDGMENT

Data Mining for the Analysis of Student Assessment Results in Engineering by Applying Active Didactic Strategy

César Baluarte-Araya, Oscar Ramirez-Valdez, Ernesto Suarez-Lopez, Percy Huertas-Niquén
Universidad Nacional de San Agustín de Arequipa, Arequipa, Perú

***Abstract*—To make improvements in the teaching-learning process in educational institutions such as universities, it is necessary to analyse the results obtained and recorded from applying Active Didactic Strategies and, based on this, to propose improvements that will help to achieve the Student Outcomes established for the subject in question; the problem to be solved is thus defined, and the results to be obtained from the analysis are relevant for the improvement of student performance. The objective is to analyse the results of the student assessment, the basis for the calculation of which is based on the recording of the qualification achieved through the performance indicators defined for each criterion, of the competencies involved and aligned with the Student Outcomes of the problems proposed to the student, applying various data mining techniques. Data mining is used to treat large amounts and types of data to obtain hidden information and reveal states, patterns and trends; as well as in Education to study the behaviour of students in terms of their performance. The methodology used for the development of the work is based on the Cross-Industry Standard Process for Data Mining methodological model, which is widely used in data mining projects. The results obtained reveal that the Student's t-test and Snedecor's F-test are highly significant, as well as the determination of the lowest performance indicators in order to plan future improvement actions towards better student performance and achieve a high level of learning. Concluding that if the same teaching and learning process is applied the result will be very similar, therefore, the students have finished learning very well.**

***Keywords*—Student outcome; problem based learning; assessment; performance indicator; data mining**

I. Introduction

Considering that the main benefit of Data Mining (DM) is the power to identify patterns and relationships in the gigantic volumes of data found in numerous sources.

Also, other aspects such as the growth of data from educational sources ranging from university admissions, academic information systems, monitoring, assessment, graduation, as well as IT and teaching and learning support platforms is enormous.

The analysis of the data recorded is essential to obtain information, reach conclusions and therefore also to see the correlation in the performance of students that allows to produce multiple results, such as passes, fails, dropouts, grades, among others, and to make decisions for improvement. This is how nowadays the further development of DM to discover the knowledge that may be hidden in databases, has allowed to demonstrate its effectiveness in different contexts, being the educational one the one that is growing in its application giving rise to Educational Data Mining (EDM).

The objective of the research work is to apply EDM to analyse the results of the evaluation of students in the area of Engineering when applying Active Didactic Strategies, which in the case of the study is Problem Based Learning in the course of Electronic Business in the Professional School of Systems Engineering (EPIS) [1] of the Universidad Nacional de San Agustín de Arequipa (UNSA) [2]; and thus discover trends, patterns, behaviours based on the available data and analyse the performance of the students according to the results of the evaluations reflected in the grades obtained, as well as the grades given to the different performance indicators determined for each defined criterion and included in the Reports of Deliverables and Formative Research developed by the students during the academic semesters covered in this work. Additionally, combined with a severe statistical analysis to determine patterns of usage.

UNSA's Educational Model is based on the professional training of students based on competences and the application of Active Didactic Strategies [3] to achieve the objectives and competences established for training.

The EPIS 2022 achieved official accreditation certification by the Accreditation Board for Engineering and Technology (ABET) [4], which has as one of its objectives that the University demonstrates that its graduates and trainees achieve the desired competencies and student outcomes.

The research produced is applied and descriptive, the methodology used is based on the Cross-Industry Standard Process for Data Mining (CRISP-DM) methodological model [5].

The main result obtained is that the models used have a high significance according to the t-tests and Snedecor's F-tests to which they are subjected.

It is concluded that, if the same teaching and learning process is applied in the course, the result obtained will be very similar, which allows us to visualise that what is planned and executed is well designed; and therefore the student ends up learning very well.

II. Theoretical Framework

A. Active Didactic Strategies

The EPIS professors plan as one of their objectives to apply a certain Didactic Strategy for the development of the course, taking into account that the students are trained through the competence-based approach being the centre of attention as referred to by [6], by applying an established or agreed active didactic strategy contemplated by [7], [8] without leaving aside what is dealt with by [9] which is improved with technology.

The training of students with Active Didactic Strategies implies autonomous and continuous learning, as concluded by [10], ordering their learning, being a permanent work in the professional training.

In the experience of using the active didactic strategy of Problem-Based Learning (PBL), as a learning methodologies, students work in small groups of three or four members executing the planning, organisation, planning the solution, developing it, validating it and thus satisfying the requirements of the problem or problems of reality.

The application of the aforementioned Active Didactic Strategies encourages students to work in teams, increasing their critical capacity, broadening their knowledge of the problem area, developing the competences of the course and therefore those of their professional training, increasing their abilities as well as their procedural skills, valuing their achievements and thus achieving a certain experience in problem-solving for the good of society.

The adaptation and improvement in the application of the Active Didactic Strategy and its complementary techniques are of vital importance to improve students' performance, and teachers are the ones most called upon to adapt them to the teaching and learning methods for the benefit of the students.

B. Indicator-Based Learning Assessment

The evaluation, reflected in a grade that the student obtains to continue to the next level of their study plan, must be based on data and complementary information, to know the student's knowledge deficiencies, weaknesses, the application of methodologies, methods, techniques, tools, as well as understanding the technologies and their limitations in the application of the probable solutions to the problem being dealt with.

In his proposal [11] he contemplates the Evaluation System based on Performance Indicators for Problem Based Learning, which contemplates in its structure: a) General Competence(s) (of the graduate profile), b) Course Competence(s), c) Student Outcomes, d) Process(es), e) Criterion(s), f) Performance Indicator(s), g) Indicator(s) rating scale that allow a more objective, fair evaluation; and have data that allows its analysis to reach conclusions; to its initial structure was adapted the inclusion of the element 'Student Outcomes', which is related to the other elements and application for the rating in the evaluation.

As a result of the application of the same in study [12] from which the set of stored data of the academic semesters involved in the present work is derived.

The Student Outcomes defined for the NE course based on those of the EPIS for the NE course are:

7.2 Acquire new knowledge in learning using appropriate strategies in the context of technological changes.

8.2 Selects appropriate tools, skills, techniques, methods and/or methodologies specific to the discipline with an understanding of its limitations.

Fig. 1 shows some of the performance indicators graded according to a grading scale, from which the mark obtained by the student for each problem proposed for development is calculated.

Fig. 1. Grading tool for the deliverable report.

Every evaluation must generate complementary information which must be organised, consolidated, analysed, interpreted, communicated to whoever it may concern, generate knowledge and thus be useful for planning, taking actions and decisions. Thus, it is important to analyse the academic performance of students in order to take timely action individually, as a team and globally for all participants.

C. Data Mining

For study [13] 'Data Mining is the process of extracting useful information from an accumulation of data, often from a data warehouse or from the collection of linked data sets' and also for study [14] 'is the process of discovering patterns and other valuable information in large data sets'.

In the DM process [15] refers to the set of methods, techniques and technologies to explore large databases, automatically, in order to find patterns, trends that help to interpret the behaviour of the data in a given context. Also in research [13] notes that it uses statistical analysis, machine learning algorithms in the search in large databases, analysing the data from different angles and thus identifying trends, patterns and unknown associations.

The application of data mining occurs in different contexts of organisations, as for example in study [16], the Data Mining Model for Predicting Customer Purchase Behavior in e-Commerce Context is proposed; it is also in the context of education that DM is increasingly taking place to extract information from data and be used to plan projects, improve processes in teaching and learning.

Given the growth of the application of DM in the educational context, it has given rise to Educational Data Mining (EDM) treated as such in study [17] by contemplating that the usual approaches and assessments are not suitable to discover the revealing information of the student's scores. Therefore, EDM deals with cases of student data research used to investigate associations not preliminarily detected in a student database. Also in study [18] state that EDM focuses on developing methods for discovering that Learning Management System (LMS) data is used to understand and make improvements in virtual learning environments, as well as building analytical models to discover patterns and trends. Many works deal with student performance as in studies [19], [20], [21], [22], [23], [24], and also in study [25] where the detection of factors associated with performance from educational assessment databases is discussed; as well as somehow dealing with KPI indicators to map strategies and performance indicators applying predictive modelling as applied by study [29].

What is normally followed in a DM process is the application of the CRISP-DM methodology in its six phases or stages that ensures that the expected results are obtained.

D. Data Mining Techniques and Tools

Data mining techniques are being increasingly adopted in studies related to data processing in organisations, which use them for data processing, analysis, generation of information for decision making [14].

Data mining tools contain powerful statistical, mathematical and analytical capabilities to examine huge data sets to identify trends, associations, patterns, correlations, intelligence and strategic organisational information to support planning and decision making [13].

In study [19], they have used DM techniques to generate predictive models of academic performance: decision trees and multivariate regression.

On the other hand, in study [17] they use the statistical package for social sciences (SPSS V26) for both descriptive and inferential statistics, using ANOVA as a method of statistical analysis; [21] uses IBM SPSS MODELER 18.1 through classification techniques.

Also, in [20] they use the best known, WEKA classifiers; so also in study [22] additionally use it with clustering; and also [25] use it to develop statistical analysis of massive information from evaluation databases using association, clustering, classification.

In study [23] they use classification with machine learning algorithms; also in study [26] they used Machine Learning techniques.

Also, in research [24], the need to consider qualitative and quantitative elements to predict and evaluate the academic performance of students is highlighted. Through machine learning, educational data is refined, discovering valuable patterns and simplifying complexities through feature selection methods using clustering, classification and regression.

III. Related Work

The field of action and application of DM is very broad in many contexts of activity in organisations; thus, [27] in the field of IT project management, when defining a new project, it is necessary to choose the development team considering characteristics, roles, results of previous projects, experience of the developers, suitability and affinity. As well as in study [16] in the e-commerce environment to predict customer buying behaviour.

In the context of education, the study [19] performs an analysis of the academic performance of students entering a degree programme, relating performance to socio-economic and academic characteristics stored in a database; as well as in study [17] they analyse the performance of students in TOEFL reading, listening and writing scores; study [20] investigates whether there are patterns in the available data that can be useful for predicting performance based on personal and pre-college characteristics, in research [21] as the aim is to automatically classify students based on their academic performance and to identify profiles and trends as well as student attrition; the study[22] uses classification techniques to study and analyse student performance, as well as to help to advise students; the study [25] develops statistical analyses of massive information from student assessment databases, also presenting to the scientific community statistical procedures and techniques that can be valuable and replicable in other educational and/or social spaces; also in study [23] proposes a model for predicting student performance, allowing accurate identification of final grades and providing information to guide educational interventions. Also in study [26], the analysis of students' academic performance is carried out using the Power BI tool, evaluated different machine learning techniques and found Random Forest to be the most efficient algorithm, with the highest accuracy of academic performance. In study [24] their systems collect data from various sources: exams, virtual courses, enrolments, e-learning platforms; the analysis of this data leads to the application of machine learning techniques to predict and evaluate student performance.

IV. Methodology

The methodology used in this work is based on the Cross-Industry Standard Process for Data Mining (CRISP-DM) methodological model. For study [13] there are as many approaches to DM as there are data mining workers. The approach defined depends on the type of questions asked, as well as the content and organisation of the database.

In this regard [5] summarises the phases or stages of CRISP-DM implementation developed from the knowledge discovery processes widely used in organisations, responding directly to user requirements; namely: Business Understanding, Data Understanding, Data Preparation, Modelling, Evaluation, Implementation. Fig. 2 shows the six phases of CRISP-DM.

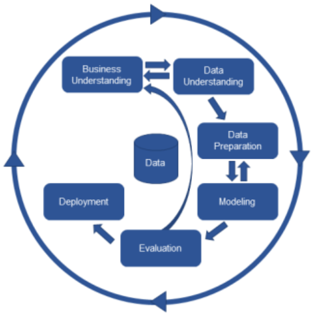

Fig. 2. CRISP-DM model. source (Taylor, 2017).

In many organisations and in research work carried out, the application of CRISP-DM implementation phases is generated according to the problem to be addressed; thus, the study [13] proposes the phases of: Understanding the problem, or at least the research area, Data collection, Data preparation and understanding, User training; also in study [28] in his guide proposes the phases of: : Understanding the business, Understanding the data, Data preparation, Modelling, Evaluation, Virtual, which is closer to the essence of CRISP-DM.

Already in the application of CRISP-DM we have that [20], develops the work with the phases of: Business Understanding, Data Understanding, Data Preprocessing, Modelling, working then the results; in study [18], [21], they use the phases of: Business Understanding, Data Understanding, Data Preparation, Data Preparation, Modelling, working then also the results; in study [26], they deal with the phases: Business Understanding, Data Understanding, Data Preparation, Modelling, Evaluation and Visualisation.

The data mining project uses the tools of: IBM SPSS Modeler V.21 which supports decision tree models, neural networks and regression models; to do statistical analysis of the data, determine relationships between Student Outcomes and their assessments. It is used to perform data capture and analysis, create tables and graphs with complex data; known for its ability to handle large volumes of data as well as perform text analysis among other formats.

IBM SPSS Modeler software offers advanced statistics in addition to many basic statistical functions, including cross-tabulation, frequencies, dual variable statistics such as t-tests and ANOVA, correlation, linear and non-linear models.

RAPIDMINER is a free software tool used for data mining tasks in both research and organisations, supporting single and multidimensional predictive models. It works from nestable operators to compose the models to work with; to do data analysis, determine patterns.

It allows to accelerate the creation, delivery and maintenance of predictive analytics; dealing with large volumes of data from multiple different sources, managed by more business-oriented than technical profiles.

Rapidminer software by the use of its workflow system decreases the use of code for data modelling, speeding up the analysis.

The data mining task is to analyse the university performance of students from their assessments.

V. Development of the Proposal

A. *Research Context*

The experience is developed in the subject of Electronic Business (NE) that correspond to the V semester respectively of the EPIS Curriculum.

From the academic year 2020 to the year 2023, the tool of qualification of the Deliverable Report and Formative Research Report is applied, the result of which by Feedback Report is given to the students so that in work team sessions they analyse, reach conclusions on the qualification of each Performance Indicator, propose improvements and apply them in the development and solution of the following problems.

In the development of the course it is contemplated and ensured that there is alignment between the Student Outcomes, the contents, the evaluation method, the use of the grading tool that encompasses what is proposed by study [11].

B. *Development of the Model*

The data mining work is based on the CRISP-DM research approach as it is a non-proprietary, application-neutral standard for data mining projects and widely used by users.

Phase 1: Understanding the business

The objectives and requirements of the business, which in this case is the education sector, are understood.

The objective of the research is to analyse the results of the student evaluation by applying different data mining techniques.

Among the main requirements are:

- Determine the relationship between Student Outcomes and their Evaluation Process.
- To analyse the results of the application of different data mining algorithms.
- Determine trends or patterns.
- Show the lowest performing performance indicators in order to plan and take future improvement actions.

Phase 2: Understanding the data

It comprises the tasks of initial data collection, establishing its main characteristics such as: structure, quality, identifying likely subsets of the data of interest.

The initial data collection is given by the recording of the ratings made in the respective assessment of each problem addressed through the tool used.

The description of the data is given by the composition of the 1681 records of the grades recorded in the tool in Excel, the data are grouped into two categories:

- Course General Data with the Final Results of the evaluation of each student: Faculty, Professional School, course, credits, type, year, semester, theory group, laboratory group, laboratory subgroup, analysis code, surname and first name, gender; marks for: final, exam and continuous averages, exams 1 2 3, continuous 1 2 3, student results 7.2 and 8.2; dropout.
- Data of the Results of the Grading of the Deliverable Reports made by the students: Problem, problem name, problem score, student performance indicators score, problem assessment criteria scores, student outcomes scores 7.2 and 8.2 of the problem.

The exploration of data by understanding its structure and characteristics.

In the Final Assessment Result 5 categories are considered to appreciate the behaviour of the assessment; Fig. 3 shows the behaviour of the Final Assessment Results variable of the students in the course, appreciating that category 4 with a rating of Very Good with a mark of 14 to 16 prevails, and category 5 with a rating of Outstanding with a mark of 17 to 20 has a significant presence not so in the year 2021.

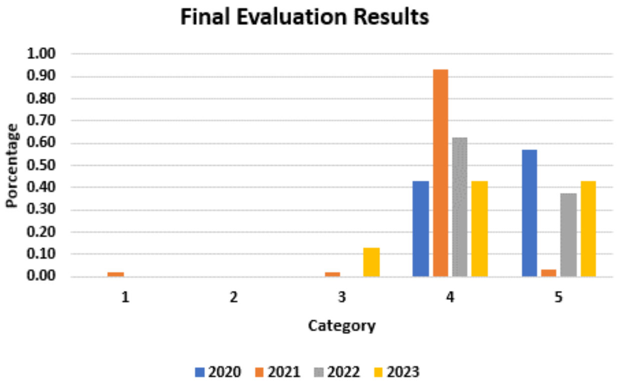

Fig. 3. Final evaluation results.

Fig. 4 shows the behaviour of the variable: Gender of the students, showing that the presence of men prevails, which is derived from the application and entry to study in the study programme.

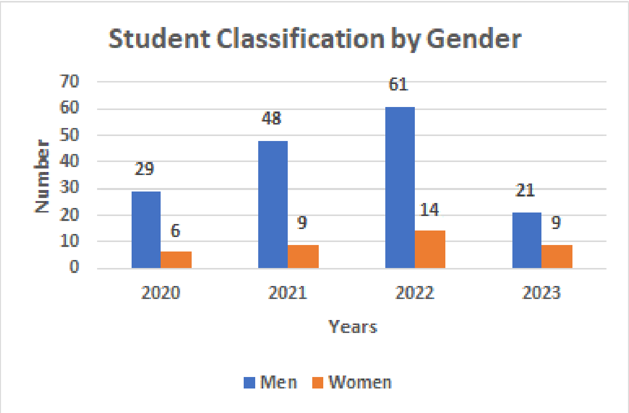

Fig. 4. Classification of students according to gender.

Table I shows the composition of the Theory Groups, Laboratory Groups and Subgroups.

TABLE I. CONFORMATION OF GROUPS AND SUBGROUPS

Year	Groups Theory	Groups Laboratory	Subgroups Laboratory
2020	A	A	5
	B	B	5
2021	A	A	4
	B	B	6
		C	5
2022	A	A	5
	B	B	5
		C	5
		D	5
2023	A	A	4
	B	B	4

Table II shows the problems dealt with in the development of the course by applying Problem Based Learning.

TABLE II. PROBLEMS

Coding	Description
1	Virtual Stores

3	Supply Chain Management - SCM
4	e-Marketplace
5	e-Learning
6	e Employee
7	e-Government
8	m-Business

The data quality check checked the consistency of the data values.

Phase 3: Data preparation

This phase involves the activities to extract the student data from the assessment record and build the final dataset into a dataset described with 112 data for each instance or occurrence that serves for modelling.

The Selection of the data covers the student assessments for the years 2020 to 2023 which are 1681 records of the grades recorded in the grading tool.

Data Cleaning deals with the inclusion of missing data, such as gender; or derived from existing data such as dropout/dropout; and data correction such as replacing blank value with zero in performance indicators.

The Construction and Integration of the data is given by the elaboration of the file containing the two categories: General Course Data with the Final Results of the evaluation of each student and the Data of the Grading Results of the Deliverable Reports made by the students, and thus obtaining the final dataset.

Data Formatting converts the data types for the application of the specific DM technology. The 66 performance indicators are nominal variables with four or five different values.

Phase 4: Modelling

In this phase, the modelling techniques that best enable the analysis of the data of the data mining project are selected. The data are entered into the data mining software, the runs are performed and the results are studied.

In the modelling, the following options have been used:

- Linear Regression, supported by correlation coefficients, Student's t-test and Snedecor's F-test.

The Student's t-test is used when the population does not follow a normal distribution. In this case we do not know the behaviour of the population data so we understand that there is no normal distribution because this t-test is robust to deviations from the normality of the population.

The F-test is used to assess the overall significance of a regression model. This test gives strength to the analysis of variance of linear regression.

According to the systematic review of the research works discussed or reviewed, we did not find a general model that deals with student performance indicators for each of the criteria proposed in an evaluation based on the definition of the rubric that allows us to evaluate the level of performance or performance of a task, which in this case are the proposed problems; Our proposal differs because we reach the level of qualification in the evaluation of the performance indicators defined for each criterion; and we conceptualise a scheme based on periods, groups and subgroups, problems, managing to reach estimated models; therefore, it is determined to use the splines for the determination of patterns.

Phase 5: Evaluation

The models created are measured against the defined objectives; according to the result feedback is given and the resulting modifications are part of the knowledge discovery process.

Phase 6: Implementation and Visualisation

In this phase, the generated models are used by other users to produce business intelligence. Based on the results obtained, there are tables and graphs that allow visualisation, the generation of reports and improvements in the procedures of the processes.

VI. Results

The main objective of the study is firstly to perform the statistical analysis of data to determine the relationship of Student Outcomes and their Assessment Process; secondly to perform the data mining process to determine the existence or not of patterns, correlations or trends in the assessment data.

The results of the statistical analysis of the SPPS Modeler application are shown below.

There is a high relationship between the predictor variables and the R72 model, in the same way, there is similarity with the R82 model, which implies that in the R82 model there is a greater effort on the part of the students to learn. Highly significant results by analysis of variance (F-test). These results are reflected in Table III and Table IV.

On the other hand, the constants of the variables of the estimated models show a highly significant Student's t-test, supporting the result of the correlation coefficient. These results can be seen in Table V.

TABLE III. Results of the Correlation Coefficient for the R72 y R82 Models

Model	R	R^2	R^2 corrected	Predictor variables
R72	0,963	0,928	0,926	(Constant), CO3, EX3, EX1, EX2, CO1, CO2
R82	0,944	0,891	0,887	(Constant), CO3, EX3, EX1, EX2, CO1, CO2

TABLE IV. Analysis of Variance

Model	Sum of squares	gf	Root mean square	F	Significance
R72	547,947	6	91,324	409,448	,000
R82	1002,675	6	167,112	258,653	,000

TABLE V. Student t Test

Predictor variables	Dependent variable			
	Model R72		*Model R82*	
	t	*Significance*	*t*	*Significance*
Constant	3,127	,002	-1,990	,048
EX1	13,743	,000	-3,108	,002
EX2	11,510	,000	1,829	,069
EX3	11,527	,000	2,398	,017
CO1	10,451	,000	10,830	,000
CO2	3,724	,000	13,905	,000
CO3	11,895	,000	5,619	,000

From the application of the Rapidminer tool we have the results of applying splines for the determination of patterns.

Fig. 5 shows that in the RE82 model, students are assertive in the handling of techniques, methods and tools, but they have difficulties in the RE72 model in coping with learning. It can be seen that between grades 13 and 17 students make the greatest effort in learning and applying information technologies; it can also be seen that from grade 18 onwards they culminate with their learning.

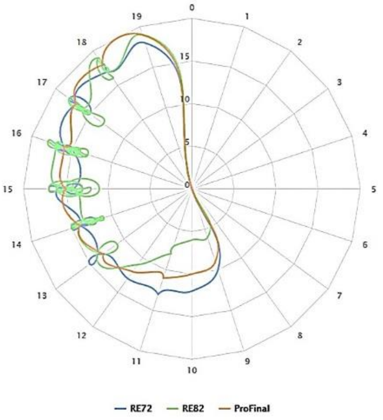

Fig. 5. R72_R82_PFINAL.

Fig. 6 shows the Student Outcome model 7.2 - RE72 which deals with the average exam marks and average continuum marks, indicating that students between marks 13 and 15 have greater practical skills and greater difficulty in theoretical learning; from the upper limit mentioned above, both theoretical and practical aspects are combined to reach the desired level of learning.

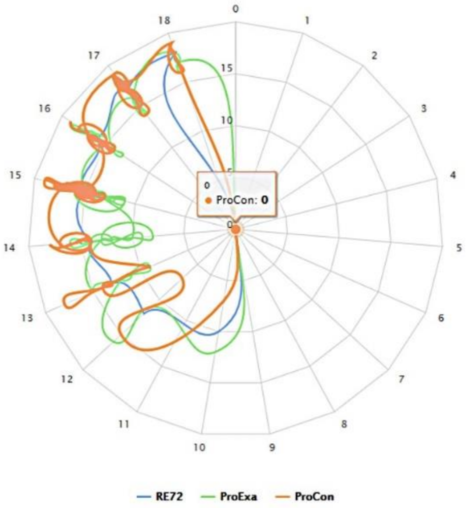

Fig. 6. R72_PEXA-PCON.

On the other hand, Fig. 7 shows the Student Outcome model 8.2 - RE82 which deals with the average marks of exams and the average of continuations, indicating that the student understands the practice better through the use of techniques, methods and information technology tools that work in parallel with the proposed RE82 model; and the theory is adapted according to the practice until mark 18, at which point they are combined with the model, reaching the desired level of learning.

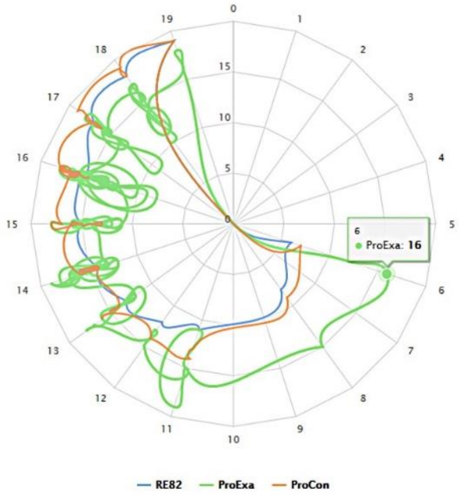

Fig. 7. R82_PEXA-PCON.

From the result of the treatment of the qualification of the performance indicators of the criteria contemplated for the evaluation of the problems proposed and developed by the students, those performance indicators (66 in total) are shown that in the qualification scales have the scale value of Absent (>= to 15%) and/or Regular (>=10%) that allows the teachers to pay attention to reflect weaknesses to improve, and to complement the analysis of the results. and based on the conclusions to raise the improvement actions to raise the level of performance of the students. These actions, when dealt with in the first class, session of the following semester, also encourage students to take into account the fulfilment of the tasks to be completed in all the indicators and thus have a high level of learning.

Table VI shows the performance indicators involved.

TABLE VI. PERFORMANCE INDICATORS INVOLVED

Indicators Involved				
Indicator		***Percentages Scale***		
Cod	***Name***	***Absent***	***Regu lar***	***Total***
12	Organisation of information	6.70	11.30	18.00

It is also emphasised that many efforts are being made to increase the learning levels of Peruvian students, such as the effort being made by UNSA to apply Active Didactic Strategies in the teaching-learning process in order to increase student learning levels.

VII. DISCUSSION

There are several works in Education such as that of [27] in the area of Data Mining; in the selection of computer project teams; as well as in the area of those related to students' academic performance from those of [19], [20], [25], [23], [26],

[24], or to extract academic behavioural profiles such as that of [21] or also that of [22] to help advise students and predict their academic performance.

Having that the prediction of academic performance shows challenges due to the varied factors that influence it as discussed by [24] by referring to [H.A.A. Hamza, P. Kommers, 2018, and M.M.A. Tair, A.M. El-Halees, 2012], having that through prediction by machine learning is instrumental in improving education in various ways, by allowing early identification of deficiencies, academic difficulties, enabling timely interventions and personalized learning plans.

In view of the above and nowadays the availability of information technologies with sufficient capacity to process large and varied types of data has allowed Data Mining techniques to evolve and allow obtaining, processing and detecting information from large amounts of data tools Nghe et al., 2007, cited in [25].

This study uses IBM SPSS Modeler v. 21 software for statistical analysis of the data to determine relationships and Rapidminer software to determine the presence of patterns, showing the potential of techniques and algorithms that respond to the stated objective by applying simple data analysis tools.

Continuous monitoring promotes quality assurance, accountability and a competitive advantage for institutions. Overall, it empowers educators to provide targeted support to plan and make improvement decisions, leading to better student outcomes and a more responsive education system as manifested in [24].

A variety of techniques are also used that based on different algorithms allow the processing of data from a given storage source and the evaluation of the results provided to make appropriate decisions.

VIII. Conclusion

The following conclusions are reached:

The R72 model considers the Student's t-test which is highly significant, which means that the prognosis that can be obtained, the results are totally valid; that is to say that if the same teaching-learning process is applied the result is going to be very similar. Because there is a high relationship between the RE72 (Student Outcome 7.2) and its evaluation process, where the Snedecor's F-test is highly significant. That is, in the teaching and learning process the students have finished learning. Similarly, the R82 model shows similarity with respect to the RE72 model.

According to the result of the analysis students have some difficulty in creating results (in the Deliverable Report) of creating the product. There is a problem in the starting point of the course; and they start to understand in Co1 (Continuous Assessment 1) that deals with the development of the first two (2) problems; which is not enough to pass the EX1 (Exam 1); and from CO2 (Continuous Assessment 2) they correct themselves noticing the improvement in the learning and they manage to finish the learning.

The students in the RE82 model show assertiveness in the handling of techniques, methods and tools; however, in the RE72 model they present certain difficulties in dealing with theoretical learning and at the end of the period they complete their learning.

The Student Outcome model 7.2 - RE72 PEXA-PCON, indicates that the student, in certain sections, presents greater skills for practice and in other sections greater difficulty for theoretical learning; however, from the upper limit, both the theoretical and practical aspects are combined, reaching the desired level of learning.

The Student Outcome Model 8.2 - RE82 PEXA-PCON, indicates that the student understands the practice better through the use of techniques, methods and information technology tools that are performed in parallel with the proposed RE82 model in many sections; and the theory is adapted according to the practice until the upper section, where they are combined with the model, reaching the desired level of learning.

It is possible to determine the highest and lowest performance indicators to which attention should be paid by complementing the factors that influence the lower performance of students and thus plan future improvement actions that allow better performance of students and their level of learning to be at a high level. This is an advantage over other forms of assessment, as it leads to the rating of each Performance Indicator involved in each Criterion, which in its analysis and evaluation makes it possible to determine the status level according to its rating scale and to make decisions to improve student performance.

It allowed us to see the additional particular consideration that can be given to a system by considering, for example, the Hierarchy of levels that the evaluation system contemplates from Faculty, Professional School, Course, Academic Year and Semester, Theory Group, Laboratory Group and Subgroup, Problem.

It allowed to visualise the future applicability of the analysis that can be carried out by the use of other Active Didactic Strategies that are used in other courses in the teaching-learning process.

It is recognised that the scope of future application can be extended to other courses of the EPIS Syllabus, to other Professional Schools of the Faculty, as well as Professional Schools of other Faculties and thus be able to obtain results at Faculty Level, University of the application of the Evaluation by Performance Indicators determined for each of the Criteria contemplated, which differs as a working method with respect to the treatment of students‘ performance dealt with by other works, for the development of students’ Competences when applying Active Didactic Strategies in the teaching-learning process.

Acknowledgment

Thanks to the Universidad Nacional de San Agustín de Arequipa for the support it provides for the development and implementation of proposals that benefit the continuous improvement of student performance through the application of Active Teaching Strategies, with beneficial results for students as well as the teaching-learning process.

Compactness-Weighted KNN Classification Algorithm

Bengting Wan, Zhixiang Sheng*, Wenqiang Zhu, Zhiyi Hu
School of Software and IoT Engineering, Jiangxi University of Finance and Economics, Nanchang 330013, China

***Abstract*—The K-Nearest Neighbor (KNN) algorithm is a widely used classical classification tool, yet enhancing the classification accuracy for multi-feature large datasets remains a challenge. The paper introduces a Compactness-Weighted KNN classification algorithm using a weighted Minkowski distance (CKNN) to address this. Due to the variability in sample distribution, a method for deriving feature weights based on compactness is designed. Subsequently, a formula for calculating the weighted Minkowski distance using compactness weights is proposed, forming the basis for developing the CKNN algorithm. Comparative experimental results on five real-world datasets demonstrate that the CKNN algorithm outperforms eight existing variant KNN algorithms in Accuracy, Precision, Recall, and F1 performance metrics. The test results and sensitivity analysis confirm the CKNN's efficacy in classifying multi-feature datasets.**

Keywords—K-nearest neighbors; feature weight; Minkowski distance; compactness

I. Introduction

In the domains of data science and machine learning, the KNN (K-Nearest Neighbors) algorithm, widely recognized as one of the top 10 classification algorithms [1], plays a crucial role in revealing the inherent patterns and structures of data, effectively grouping data points into distinct categories, especially in market segmentation, social network analysis, bioinformatics, image processing, and other fields [2, 3]. Since Fix and Hodges [4] introduced the KNN algorithm, KNN has emerged as a classic and efficient classification tool widely applied in data mining, data classification, and other fields [5, 6]. For instance, Uddin et al. [5] have applied the KNN algorithm for disease risk prediction, and Han et al. [6] have used it to estimate the photometric redshift of quasars.

However, the KNN algorithm faces several challenges in practice, such as the choice of k value, selection of nearest neighbors, nearest neighbor search, and determination of classification rules [7]. Consequently, researchers have proposed various improvement strategies to enhance the performance of KNN [8-10]. For example, Zhang and Li [8] bolstered the classification performance of the KNN algorithm and reduced computational costs through sparse learning and group lasso techniques. Meanwhile the weighted KNN [11] approach adjusts the influence of each neighbor on the classification decision by assigning different weights, enhancing the efficiency and accuracy of classification. In this method, weights are usually based on the distance or similarity of neighbors to the query point, giving closer neighbors more significant influence in classification decisions. This strategy effectively improves the algorithm's ability to handle uneven distributions or irregular data structures. Nevertheless, weighted KNN algorithms also face challenges. Firstly, selecting and calculating appropriate weights is a crucial issue, as different weight distribution strategies directly affect the accuracy of classification results. Secondly, the algorithm may encounter efficiency issues when handling large datasets, especially in scenarios requiring real-time or near-real-time processing [12]. In response, researchers have proposed various variants of the weighted KNN algorithm, such as the Improved K-Nearest Neighbor rule combining Prototype Selection and Local Feature Weighting (IKNN_PSLFW) algorithm developed by Zhang et al. [13], which combines prototype selection with local feature weighting, and the Option out-of-bag (Opt_OOB), a KNN ensemble learning method based on feature weighting and model selection proposed by Gul et al. [14] Chen and Hao [15] introduced a KNN prediction model based on a feature weight matrix by modifying the standard Euclidean distance. Chen and Gou [16] proposed a series of weighted distance functions for classifying attributes and applied these functions to develop nearest neighbor classifiers.

However, these weighted KNN algorithms, without considering datasets with non-uniform feature distributions, still have room for improvement in classification efficiency for unevenly distributed datasets and may be limited in handling high-dimensional classification problems. Therefore, this paper will consider the compactness of data distribution and introduce a dynamic weight adjustment mechanism based on feature compactness. By reconstructing the feature weights, a new weighted KNN algorithm is proposed. The main contributions of this paper are:

- Inspired by the uneven distribution of data, a weight calculation method based on compactness is proposed;
- Inspired by the weighted KNN, the CKNN algorithm based on weighted Minkowski distance is proposed;
- In real-world datasets, the CKNN algorithm was employed for classification purposes and was subsequently compared and analyzed against recent weighted KNN algorithms. Additionally, the CKNN algorithm underwent a sensitivity analysis along with Friedman’s and Nemenyi’s post-hoc tests. These evaluations demonstrated that the CKNN algorithm possesses specific superior performance characteristics.

The rest of this paper is organized as follows: Section II elaborates on the related research work of KNN; Section III details the construction process of the CKNN algorithm; Section IV implements the CKNN algorithm and compares it with other existing variant weighted KNN algorithms; finally, the advantages and limitations of the CKNN algorithm are analyzed in this section. Finally, the paper is concluded in Section V.

II. Related Work

A. KNN

Based on similarity, the KNN classifier first identifies the nearest k neighbors of an unknown sample [4]. Then, it determines its category based on the most frequently occurring (highest probability) category among the K-Nearest Neighbor. Below is an outline of the basic principles of the KNN algorithm.

Given a set of labeled samples: $D = \{x_1, x_2, \dots, x_n\}$, a training set $D_T = \{(x_i, y_i)\}_{i=1}^{N}$ is constructed, where $x_n \in D$ is a point in n-dimensional space, y_i is the category label corresponding to x_i and N is the number of samples in the training set. For a query point q with an unknown category, KNN first calculates the Euclidean distance between this point and each sample point x_i in the training set, as shown in Eq. (1).

$$D\left(x_i, x_j\right) = \sqrt{\sum_{k=1}^{n} (x_{iv} - x_{iv})^2} \tag{1}$$

Within this framework, x_{iv} denotes the coordinate value of the i^{th}sample point along the v^{th}dimension. Subsequently, the computed distances for N points are arranged in ascending order, from which the nearest k neighbors are selected. At this juncture, the distance set comprising the k nearest neighbors to the query point q can be represented as $D_T^* = \{(\hat{x}_i, \hat{y}_i)\}_{i=1}^{k}$. Subsequently, the category label of the query point q is predicted through the majority vote of its nearest neighbors, resulting in the target equation, as shown in Eq. (2).

$$predicted = argmax_{c \in C} \sum_{i=1}^{k} I(x_i = c) \tag{2}$$

In Eq. (2), C represents the set of all possible categories, k is the number of nearest neighbors, x_i is the category of the ith nearest neighbor, and $I(x_i = c)$ is an indicator function that equals 1 when y_i equals category c, and 0 otherwise. The KNN algorithm is described as shown in Algorithm 1.

```
Algorithm 1: KNN algorithm
Input: A test sample and some training samples
Output: The test sample's category
Process:
1.  For number of training samples do
2.      calculate the similarity between the test sample    and a
        training sample
3.  End for
4.  find the k training samples that are most like the test sample
5.  determine test sample's category
```

However, the classical KNN algorithm has faced several challenges: (1) Noise sensitivity. The KNN algorithm determines a sample's category based on the k nearest neighbors' labels, making it sensitive to noise and outliers. (2) Redundant sample testing. The nearest neighbors are searched for each test sample given, but this is not necessarily optimal for all test cases. (3) Dependence on the hyperparameter k. The performance of the algorithm varies with different k parameters. (4) Poor stability. The algorithm performs well on some datasets and poorly on others.

To address these issues, researchers have proposed various KNN variants. To tackle the challenge of classifying imperfect data in high-dimensional spaces, Gong et al. [17] improved the traditional KNN method by synchronizing neighborhood search and feature weighting, proposing an enhanced KNN algorithm—AEKNN. Bian et al. [18] improved the traditional fuzzy KNN [19] by adaptively selecting the optimal number of nearest neighbors (the k value) for each test sample Gou et al. [20] optimized the classifier by capturing the proximity and geometric characteristics of the K-nearest neighbors and learning the contribution of each neighbor to the classification of the test sample through linear representation methods, thereby reducing the algorithm's sensitivity to k and enhancing its performance.

B. Weighted Distance KNN

In response to issues such as class overlap and the difficulty in choosing the k factor, researchers have embarked on explorations and achieved many research results. For instance, Zhang et al. [13] have developed the IKNN_PSLFW algorithm, which combines prototype selection with local feature weighting. In this method, the prototype selection part divides the training set into multiple pure subsets, where each subset contains instances of only one class label. Following this, the scope of prototype selection and the weights of features are updated through local feature weighting, optimizing the objective function as illustrated in Eq. (3).

$$rw_s = max_{j=1,2,\dots,n} \sqrt{\sum_{j=1}^{d} w_s^j \left(w_s^j - x_i^j\right)^2} \tag{3}$$

In Eq.(3), $w^j = u^j / \sum_{j=1}^{d} u^j$, $u^j = \begin{cases} \frac{1}{v^j}, (v^j \neq 0) \\ 10 \times max\left\{\frac{1}{v^j} \middle| i \neq j, v^j \neq 0\right\}, (v^j = 0) \end{cases}$, and v^j is the variance of the j^{th} feature in the subset. Ultimately, a representative example is chosen from each subset as a prototype, and both the boundary of the subset and the total count of instances it includes are recorded. During the classification phase, depending on the weighted distance between an unknown instance and each prototype, three potential scenarios are identified: the instance falls within the range of a single prototype, within an overlap area, or outside the range of all prototypes, with different rules applied to predict its category accordingly. Throughout the process, there is no need to predetermine the value of k, and the time complexity of the IKNN_PSLFW algorithm is $o(n^2)$. This method effectively reduces the number of instances and overlap areas, thereby enhancing the accuracy and efficiency of classification.

Gul et al. [14] introduced an ensemble learning method for the k nearest neighbor, termed Opt_OOB, predicated on feature weighting and model selection. This method selects the best model by leveraging the out-of-bag prediction error to assemble the ultimate ensemble classification model. This methodology establishes an objective function utilizing the distance Eq. (4).

$$D_w\left(X'_{1\times p'}, X_{1\times p'}\right) = \left\{\sum_{j=1}^{p'} w\left(x'_j - x_j\right)^2\right\}^{\frac{1}{2}} \tag{4}$$

In Eq. (4), feature weights w are determined by $w = argmax_w[min\{d_H(\psi(x))\}]$, to identify Out-of-Bag (OOB) observations during the bootstrap sampling process. Subsequently, the prediction error for each base model on its corresponding OOB observations is calculated. Models are then ranked according to the magnitude of OOB error, and a certain proportion of the best-performing models are selected to form the final ensemble classification model. This method reduces the dependency on the parameter k and ensures the diversity and accuracy of the ensemble model, although its performance may decrease on tiny datasets.

Chen and Hao [15] have proposed a K-nearest neighbors predictive model based on a feature weighting matrix by modifying the standard Euclidean distance. The core of this algorithm lies in improving prediction accuracy by altering the positional relations of sample points. The feature weighting matrix is shown in Eq. (5).

$$P = \left\{\begin{matrix} InfoGain(f_1) & 0 & \dots & 0 \\ 0 & InfoGain(f_2) & 0 & \vdots \\ \vdots & 0 & \ddots & 0 \\ 0 & \dots & 0 & InfoGain(f_n) \end{matrix}\right\} \tag{5}$$

In Eq. (5), $InfoGain(A) = \sqrt{Info(\mathrm{D}) - Info_A(D)}$, $Info(D) = -\sum_{i\in\{-1,\ +1\}} \frac{|C_{\{i,D\}}|}{|D|} log(\frac{|C_{\{i,D\}}|}{|D|})$, and $Info_A(D) = \sum_{j=1}^{v} \frac{|D_j|}{|D|} Info\left(D_j\right)$. Here, D represents the dataset, $|D|$ denotes the size of the dataset, and $C_{\{i,D\}}$ represents the subset of the dataset D that belongs to class C_i. This method has certain advantages for large-scale or complex datasets, but the effectiveness of the model depends on the accuracy of the feature weighting matrix, which requires sufficient prior knowledge or data analysis to determine appropriate weights.

In pursuit of an optimal distance metric for precisely quantifying the dissimilarities among classified samples, Chen and Gou [16] introduced a series of weighted distance functions tailored for categorical attributes, which have been applied to advance nearest neighbor classifiers. The Global Gini K-nearest neighbors (GGKNN) incorporate a weighting scheme as depicted in Eq. (6).

$$\omega_d^{(GG)} = e^{-\frac{M}{M-1}\sum_{s_d\in s_d} P(S_d)\times GG(S_d)} \tag{6}$$

In Eq. (6), $GG(s_d) = -\sum_{m=1}^{M} P(m|s_d) \log_2 p(m|s_d)$, $p(s_d) = \frac{1}{N}\sum_{(X,y)\in tr} I(x_d = s_d)$,and $p(m|s_d) = \frac{\sum_{(X,y)\in c_m} I(x_d=s_d)}{\sum_{(X,y)\in tr} I(x_d=s_d)}$. Herein, tr represents the training dataset, M denotes the number of classes contained within the training dataset, $|s_d|$indicate the discrete values of the d^{th} attribute. The weighting for Global Entropy K-nearest neighbors (GEKNN) is shown in Eq. (7).

$$\omega_d^{(GE)} = e^{-\frac{1}{log_2 M}\sum_{s_d\in s_d} P(S_d)\times GE(S_d)} \tag{7}$$

In Eq. (7), $GE(s_d) = 1 - \sum_{m=1}^{M}[P(m|s_d)]^2$. These methods use global statistical approaches to weight attributes, considering the information from all data points to determine the importance of each attribute. Conversely, the weighting for Local Gini K-nearest neighbors (LGKNN) is shown in Eq. (8).

$$\omega_{md}^{(LG)} = e^{-\frac{|s_d|}{|s_d|-1}\times LG(m,d)} \tag{8}$$

In Eq. (8), $LG(m,d) = 1 - \sum_{s_d\in s_d}[P(s_d|m)]^2$,$p(s_d|m) = \frac{1}{|c_m|}\sum_{(X,y)\in c_m} I(x_d = s_d)$,and c_m represents the m^{th} class within the training dataset tr. The weighting for Local Entropy K-nearest neighbors (LEKNN) is shown in Eq. (9).

$$\omega_{md}^{(LE)} = e^{-\frac{1}{log_2|s_d|}\times GE(m,d)} \tag{9}$$

In Eq. (9), $LE(m,d) = -\sum_{s_d\in s_d}(s_d|m) \log_2 p(s_d|m)$. This employs a local method for computing weights, meaning that it adjusts attribute weights based on the local information surrounding each data point. This method achieves soft feature selection for categorical data, thereby improving the quality of classification.

Furthermore, researchers have introduced multiple variations of the KNN algorithm that utilize weighted distance measures for optimization. Açıkkar and Tokgöz [21] have enhanced the conventional KNN algorithm by introducing a new weighted voting mechanism and adaptive k-value selection techniques. These modifications have improved the performance of the KNN algorithm in scenarios with complex or nonlinear decision boundaries, especially in the context of processing datasets with noise or outliers.

III. Compactness-Weighted K-NN Classification Algorithm

This section delineates an improved K-Nearest Neighbors algorithm (CKNN) predicated on compactness and local feature weighting, devised to augment the classification efficacy of the KNN algorithm. The research methodology unfolds in two pivotal steps: Initially, the compactness for each feature is ascertained, forming the groundwork for the recalibration of feature weights. After that, a CKNN algorithm, hinged on compactness, is introduced.

In most pattern recognition tasks, the relevance of different features differs, particularly in classification tasks. Even if all features in the dataset are relevant, their degrees of relevance may vary. To address this, we propose the concept of feature compactness, as illustrated in Fig. 1.

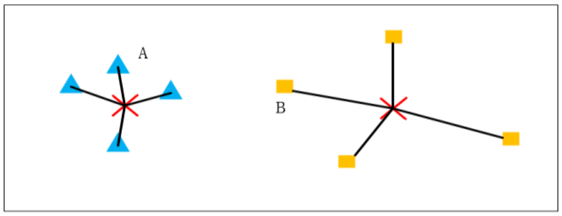

Fig. 1. Feature Compactness, with Feature A having greater compactness than Feature B.

Fi. 1 shows that the sum of distances between the elements in set A and their centroid is significantly less than that in set B, leading to the conclusion that feature A possesses greater compactness than B Various distance metrics are utilized to measure feature compactness, such as Euclidean distance, Manhattan distance, and Minkowski distance. The Minkowski distance [22], in particular, allows for adjusting the parameter p according to different scenarios and is widely employed. Inspired by this, the article adopts the Minkowski distance to measure the distances of features. Within a dataset $X = \{x_1, x_2, \dots, x_n\}$ comprising n samples, each with m features, x_i represents a feature vector of dimension m. Assuming the centroid vector c represents the arithmetic mean of all sample point feature vectors, the compactness c_j for the j^{th}feature, based on the Minkowski distance, is defined as the Minkowski distance between the values of all sample points for that feature and the value of the centroid for that feature. The calculation is as shown in Eq. (11).

$$C_j = \sum_{j=1}^{n} \left| x_{ij} - c_j \right|^p \tag{11}$$

In Eq. (11), n represents the total number of samples in the cluster, C_j denotes the compactness of the j^{th} feature, x_{ij} is the value of the j^{th} feature for the i^{th} sample, C_j is the value of the j^{th} feature of the cluster centroid, and p is the exponent parameter of the Minkowski distance. From Eq. (11), it is inferred that, under the conditions of a given number of samples and a defined centroid, a smaller value of C_j indicates greater compactness, and vice versa.

Specifically, for a given dataset and its corresponding centroid, the initial step involves calculating the difference between each data point and the centroid across all dimensions. Subsequently, these differences are raised to the p^{th} power using the Minkowski formula, where p is a predefined parameter. The steps for solving compactness will be detailed in Algorithm 2.

```
Algorithm 2: Calculate Compactness (CL, P)
Input:  CL: feature vector
        P: Minkowski index
Output: A one-dimensional array containing the disper- sion
        of each feature $S = \{s_1, s_2, \dots, s_k\}$
Process:
1.  Set $C$←The arithmetic mean of the eigen vectors of all
    points in the cluster
2.  For each feature in the feature space do
3.      Add $S$←Discrete degree calculated by Eq. (11)
4.  End for
```

To address the discrepancy that arises from the assumption in the canonical KNN algorithm, where each feature is assigned an equal weight reflecting an assumption of equal contribution to the decision-making process—a scenario often divergent from real-world applications where the importance of features can vary significantly. This study introduces a methodology grounded in compactness to determine the weights of different features. Inspired by the findings in study [23] and assuming a given dataset is presumed to contain K categories, with each category corresponding to a distinct cluster, this paper proposes a novel objective function. This function represents the sum of weighted averages across different classification sets, as calculated in Eq. (12).

$$\text{J} = \sum_{c=1}^{K} \sum_{v=1}^{V} w_{cv}^{\beta} C_{cv} \tag{12}$$

where, K represents the total number of categories, V represents the total number of features, w_{cv} is the weight of the v^{th} feature in the c^{th} category, and β is a weight adjustment parameter. The adjustment parameter β is used to control the extent of the weight influence. When β>1, it indicates a higher emphasis on features with high weights, when β=1, the model degenerates to a traditional equal-weight model. C_{cv} is an indicator measuring the compactness of the v^{th} feature in the c^{th} category, calculated by $\sum_{v=1}^{n} ||x_{cv} - c_v||^p$,, where x_{cv} is the v^{th} feature value of the c^{th} sample, and n represents the total number of samples in the cluster.

By assigning different weights to various classes, the goal is to minimize the weighted average compactness within each class, thereby improving the compactness of classification. To this end, Eq. (12) can be converted into Eq. (13). Within this framework, the degree of classification compactness can be obtained, and the weights of each feature, w_{cv}, can be solved.

$$\sum_{c=1}^{K} \sum_{v=1}^{V} w_{cv}^{\beta} C_{cv} = \sum_{c=1}^{K} \sum_{v=1}^{V} \{ w_{cv}^{\beta} \sum_{v=1}^{n} ||x_{cv} - c_v||^p \} \tag{13}$$

Considering the weights of different features satisfy the constraints: $\sum_{v=1}^{V} w_{cv} = 1$ and w_{cv}≥0, it is evident that Eq. (13) represents a nonlinear programming equation while also satisfying convex function constraints. To enhance the compactness within classes by optimizing feature weights, the Lagrangian function L is employed to minimize Eq. (14):

$$L = \sum_{v=1}^{V} w_{cv}^{\beta} C_{cv} + \lambda \left(1 - \sum_{v=1}^{V} w_{cv}^{\beta} \right) \tag{14}$$

Taking the partial derivative of w_{cv}^{β} in Eq. (14), and then setting it to zero to find the extremum, as shown in Eq. (15):

$$\frac{\partial L}{\partial w_{cv}} = \beta w_{cv}^{\beta - 1} C_{cv} - \lambda = 0 \tag{15}$$

Solving Eq. (15) yields the weight w_{cv}, as shown in Eq. (16):

$$w_{cv} = \left(\frac{\lambda}{\beta C_{cv}} \right)^{\frac{1}{\beta - 1}} \tag{16}$$

Given the weight constraints $\sum_{v=1}^{V} w_{cv} = 1$ and w_{cv}≥0, Eq. (16) can be further derived to obtain Eq. (17).

$$\sum_{v=1}^{V} \left(\frac{\lambda}{\beta C_{cv}} \right)^{\frac{1}{\beta - 1}} = 1 \Leftrightarrow \left(\frac{\lambda}{\beta} \right)^{\frac{1}{\beta - 1}} = \frac{1}{\sum_{v=1}^{V} \left(\frac{1}{C_{cv}} \right)^{\frac{1}{\beta - 1}}} \tag{17}$$

Simplifying Eq. (17) gives the formula for solving weight w_{cv}, as shown in Eq. (18). From Eq. (18), it can be seen that under compact classification, the weight of feature v in category C can be obtained by solving the Minkowski distance.

$$w_{cv} = \frac{1}{\sum_{u=1}^{V} \left(\frac{C_{cv}}{C_{cu}} \right)^{\frac{1}{\beta - 1}}} \tag{18}$$

Building on Eq. (18), it can be determined that the weights of various features can be calculated given a classification. However, in the KNN classification process, both the classification and the weights are the objectives to be determined. Inspired by the varying importance of different features and the concept of compactness as discussed in references, a weighted Minkowski distance based on compactness weights is proposed, as shown in Eq. (19).

$$d_w\left(x_i, x_j\right) = \sqrt[p]{\sum_{v=1}^{V} w_{cv}\left(x_{iv} - x_{jv}\right)^p} \tag{19}$$

In Eq. (19), for given data samplesx_i,x_j∈C, where β is a user-defined parameter, $w_{cv}$is the weight of feature weight v. In this case, the weight of each feature no longer depends on a specific cluster but is based on the feature distribution across the entire dataset. Feature weights should be non-negative and satisfy $\sum_{v=1}^{V} w_{cv} = 1$, and $w_{cv} \geq 0$.

Leveraging the concept of compactness-weighted distances within the framework of the KNN algorithm, this section introduces the Compactness-weighted KNN (CKNN) algorithm. The CKNN algorithm begins by calculating the compactness of each feature in the dataset according to Eq. (11). This calculation necessitates using the Minkowski distance measure to ascertain the compactness of each feature relative to its centroid. Drawing on the principle of compactness, the weights for each feature can be determined using Eq. (18). Subsequently, a compactness-weighted Minkowski distance, as delineated in Eq. (19), is constructed to facilitate the computation of distances between samples. Ultimately, the CKNN algorithm replaces the Euclidean distance traditionally employed in KNN with the weighted Minkowski distance, selects the K-nearest neighbors based on this distance, and utilizes a voting mechanism predicated on the category labels of these neighbors to ascertain the category of the target sample. The steps to implement the CKNN algorithm are outlined in Algorithm 3.

Algorithm 3: Compactness-weighted KNN algorithm

```
Input:  $D_T$ :  Training data set,
        $K$:  The number of nearest neighbors
        $T$:  Test Dataset
        $\beta$:  Minkowski index
Output: $Y$:  classification result
Process:
Set $Y \leftarrow \emptyset$, $C$←calculateCompactness(CL,P), $w \leftarrow \frac{1}{V}$
For The weight of each feature $w$ do
    Update the weight $w_{cv}$ of each feature through Eq. (18)
End For
For Each sample in the test dataset $T$ do
    Set list ←  $\emptyset$
For Training data set $D_T$ do
    Compute weighted Minkowski distance by Eq. (19).
    Add distance to list
    Assign test sample category by majority vote from K nearest neighbors.
    Add Classification Results to Y
End For
Return $Y$ as the classification results for all samples in $T$
```

IV. Algorithm Implementation

This section elucidates the datasets employed by the CKNN algorithm, the performance evaluation metrics utilized, and an analysis of the experimental outcomes. The experiments were conducted on a computer with a 12th Gen Intel(R) Core (TM) i7-12700H CPU, clocked at 2.70GHz, and 16.0GB RAM, running the Windows 11 operating system. The Python3.10 programming language executed the implementation.

A. Dataset and Evaluation Metrics

The implementation adopted five datasets from the UCI Machine Learning Repository (Wine, Breast Cancer, Promoters, Mc2, Car) as benchmark datasets (http://archive.ics.uci.edu/). Table I shows the essential characteristics of the five datasets, including the total number of samples, the number of features, and the number of classes. For datasets with some features as strings, traditional label encoding methods will be used. The Car dataset comprises 1728 samples, representing a multi-sample dataset. The Wine, Mc2, Promoters, and Breast Cancer datasets consist of 13, 39, 57, and 30 feature attributes, thus categorizing them as high-dimensional datasets. Wine and Car datasets have three and four categories, respectively.

To evaluate the classification results, this paper uses four evaluation metrics: Accuracy, Recall, Precision, and F1 (F1-measure) to measure the performance of algorithms. Among them, Recall refers to the ratio of correctly predicted positive instances to positive instances; precision refers to the ratio of correctly predicted positive instances to optimistic predictions. Based on the F1 measure, the experiments used macro-F1 (Macro-F1, the average F1 values within classes) for evaluation [22]. All these indicators range from [0, 1], with values closer to 1 indicating better model performance. Accuracy, precision, recall, and F1 are shown in Eq. (20), (21), (22), and (23) respectively. TP, TN, FP, and FN represent the proportions of true positives, true negatives, false positives, and false negatives in the result data.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{20}$$

$$Precision = \frac{TP}{TP+FP} \tag{21}$$

$$Recall = \frac{TP}{TP+FN} \tag{22}$$

$$F1 = \frac{2 \times Recall \times Precision}{Recall+Precision} \tag{23}$$

TABLE I. BASIC CHARACTERISTICS OF THE DATASETS USED IN THE EXPERIMENT

Item	Dataset	Instances	Features	Classes
1	Wine Dataset	178	13	3
2	Mc2 Dataset	161	39	2
3	Car Dataset	1728	6	4
4	Promoters Dataset	106	57	2
5	Breast Cancer Dataset	699	30	2

B. Analysis of Results

The article selects eight existing improved KNN classification algorithms (KNN [4], FWKNN [15], LEKNN [16], LGKNN [16], GEKNN [16], GGKNN [16], IKNN_PSLFW [13], and Opt_OOB [14]) for comparison with CKNN. Among them, KNN represents the classic K-Nearest Neighbor algorithm. FWKNN is a K-Nearest Neighbor prediction model based on a feature weighting matrix. LEKNN calculates feature weights through local entropy, while LGKNN calculates feature weights through local Gini. GEKNN uses global entropy to calculate feature weights, and GGKNN uses global Gini for the same purpose. IKNN_PSLFW is an ensemble learning method based on prototype selection combined with local feature weighting, and Opt_OOB is a K-Nearest Neighbor ensemble learning method based on feature weighting and model selection. The implementation results are shown in Table II (the highest values for each dataset are indicated in bold).

Table II shows that CKNN exhibits superior performance, especially on the Promoters dataset, where its accuracy reached 0.8439, significantly higher than other algorithms. After comparing the performances of different algorithms across multiple datasets, it was observed that the proposed method demonstrates superiority in all evaluation metrics. Specifically, on the Wine dataset, compared to the Opt_OOB algorithm, CKNN showed improvements of 3.71% in Accuracy, 3.69% in the Recall, 3.42% in Precision, and 3.64% in F1 score, the improvement on the MC2 dataset was even more significant, with CKNN surpassing the LEKNN algorithm by 2.04% in Accuracy. Although the improvements in Recall, Precision, and F1 score were closer, they still reflected our algorithm's advantage. On the Car dataset, compared to the FWKNN algorithm, the improvement was particularly notable, with increases of 1.54% in Accuracy, 2.81% in Recall, 11.17% in Precision, and 7.06% in F1 score. On the Promoters dataset, compared to the second-ranked KNN, there were increases of 6.26% in Accuracy, 6.27% in Recall, 6.25% in Precision, and 6.26% in F1 score. Regarding the Breast Cancer dataset, the method also demonstrated its superior performance. Compared to the IKNN_PSLFW algorithm, CKNN improved by 0.58% in Accuracy, 0.47% in Recall, 0.81% in Precision, and 0.62% in F1 score.

To further comprehensively evaluate the performance of the CKNN algorithm, based on the implementation results in Table II, the following will analyze the Sum of Ranking Differences (SRDs) [24], Friedman test [26], Nemenyi test [27], and Bonferroni correction [28].

First, a comparative analysis of the Sum of Ranking Differences (SRDs) was conducted, a multi-criteria decision-making method that achieves evaluation objectives by calculating the sum of absolute differences between each algorithm's actual rankings and reference rankings. Table II presents the values of four evaluation metrics for various algorithms across five datasets; according to the SRDs method, the reference vector contains 20 elements, each of which is the best score among the algorithms. After scaling the SRD values to the [0, 100] interval, their theoretical distribution approximates a normal distribution. Thus, the normal quantiles of each algorithm can serve as the actual SRD values compared to the reference vector, with the implementation results shown in Fig. 2. The scaled Sum of Ranking Differences (SRD) values are plotted on the x-axis and the left y-axis, while the right y-axis displays the relative frequency (black curve). The Gaussian fitting parameters are m=66.72, s=9.87. The SRD values at the 5% probability level (XX1), the median (Med), and 95% (XX19) are also provided.

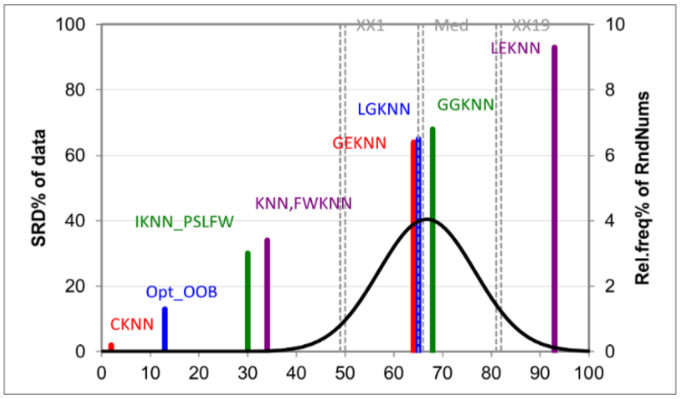

Fig. 2. Evaluation of algorithms using the sum of rank differences.

As can be discerned from Fig. 2, the CKNN algorithm is positioned on the left side of the curve, indicating that CKNN is the algorithm closest to the ideal state. At the same time, CKNN is at a certain distance compared to Opt_OOB and IKNN_PSLFW, signifying a clear advantage of CKNN over Opt_OOB and IKNN_PSLFW. Moreover, aside from GEKNN, LGKNN, GGKNN, and LEKNN, the ranking of the remaining five algorithms shows a significant difference from random ranking (α=0.05).

To highlight the advantages of CKNN, this paper further conducts a Friedman test [26]. Based on the Accuracy, Precision, Recall, and F1 metrics of CKNN, Table III presents the Friedman statistic F_F and the corresponding p-values for KNN, FWKNN, LEKNN, LGKNN, GEKNN, GGKNN, IKNN_PSLFW, and Opt_OOB in terms of accuracy, precision, recall, and F1 metrics. Table III shows that the null hypothesis (i.e., all compared algorithms will have equivalent performances) is significantly rejected at the significance level of α=0.05 for each evaluation metric, meaning there is a significant difference between CKNN and the other algorithms. However, it does not specify which algorithms are superior or inferior.

To further observe the differences among algorithms, this paper uses the Nemenyi test to assess the competitiveness of algorithms. In this test, if the difference in average ranks between two classifiers reaches at least the critical difference $CD=q_{\alpha}\sqrt{\frac{k(k+1)}{6N}}$, it is considered that there is a significant difference in performance between these two classifiers. At a significance level of α=0.05, q_{α} is 3.102, and the CD value is 5.369 (where k=9，N=5). Fig. 3 presents the CD diagram of the nine algorithms under Accuracy, Precision, Recall, and F1 metrics. In Fig. 2, any algorithm whose average rank is within a CD interval of CKNN is highlighted with a red line to show its association; otherwise, it indicates a significant performance difference from CKNN. For example, in recall, CKNN's average rank is 1.20, and with the addition of the CD value, the critical value becomes 6.57. At this point, LGKNN and GEKNN, with average ranks of 7.20 and 6.70 respectively, perform poorly. However, for algorithms within the CD interval, it is currently not impossible to determine the performance gap between them and CKNN.

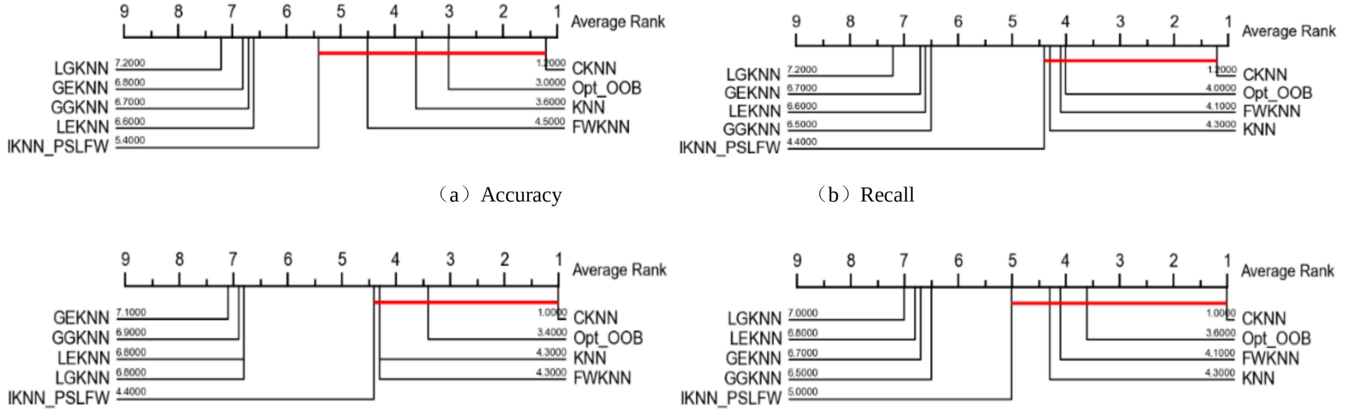
Based on the Nemenyi test, this paper uses the Bonferroni correction [27] to control the type I error (i.e., falsely rejecting a true null hypothesis). Let $\Delta_{\xi}=\bar{\xi}_{algorithm}-\bar{\xi}_{CKNN}$, when Δ_{ξ} is more excellent than CD_{α}, it is marked with "Y", indicating that CKNN outperforms the corresponding algorithm on the respective metric; otherwise, it is not marked. At a significance level of α=0.05, the critical value q_{α} becomes 2.724.

As shown in Table IV, the Bonferroni assessment results indicate that CKNN's performance exceeds that of LEKNN, LGKNN, GGKNN, and GEKNN algorithms.

TABLE III. SUMMARY OF THE FRIEDMAN STATISTIC F_F (K = 9, N = 5)

Evaluation Criteria	F_F	Critical Value (α=0.05)
Accuracy	22.86	15.51
Recall	19.96	
Precision	23.16	
F1 score	21.30	

Note: k represents the number of algorithms being compared; N represents the number of datasets



（a）Accuracy

（b）Recall

（c）Precision

（d）F1 score

Fig. 3. Nemenyi test of CKNN (control algorithm) with other variant KNN algorithms.

TABLE IV. COMPARISON OF CKNN WITH OTHER VARIANT KNN ALGORITHMS

	Accuracy	**Recall**	**Precision**	**F1**
KNN	--	--	--	--
Opt_OOB	--	--	--	--
FWKNN	--	--	--	--
IKNN_PSLFW	--	--	--	--
LEKNN	Y	Y	Y	Y
LGKNN	Y	Y	Y	Y
GEKNN	Y	Y	Y	Y
GGKNN	Y	Y	Y	Y

Confidence intervals [25] are employed to assess the degree of performance improvement among different algorithms. This paper utilizes confidence intervals to evaluate the performance of CKNN against eight compared variant KNN algorithms. Confidence intervals for comparisons among the eight algorithms were constructed to quantify these differences, assuming normality for the ranking differences as depicted in Eq. (24).

$$\frac{\Delta\xi}{\sqrt{\frac{k(k+1)}{6N}}} \sim N(0,1) \qquad (24)$$

At a 95% confidence level, Fig. 4 shows the confidence intervals for Accuracy, Recall, Precision, and F1 metrics for the nine algorithms. From Fig. 4, it is observed that except for KNN, IKNN_PSLFW, and FWKNN, all intervals for Opt_OOB, LEKNN, LGKNN, GGKNN, and GEKNN appear to be less than 0, indicating significant differences between these algorithms and CKNN. For KNN, IKNN_PSLFW, and FWKNN, although the upper bounds of some evaluation metrics' confidence intervals are more significant than or close to 0, the estimated parameter values within the confidence intervals remain below 0, suggesting that CKNN, on the whole, outperforms KNN, IKNN_PSLFW, and FWKNN, with IKNN_PSLFW showing the closest performance to CKNN.

From the analyses based on the Sum of Ranking Differences (SRDs), Friedman test, Nemenyi test, and Bonferroni correction, it is evident that the CKNN algorithm outperforms the compared algorithms, including KNN, FWKNN, LEKNN, LGKNN, GEKNN, GGKNN, IKNN_PSLFW, and Opt_OOB in terms of performance.

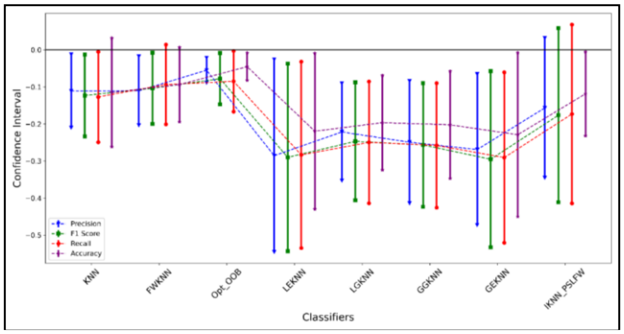


Fig. 4. Confidence intervals for rank differences.

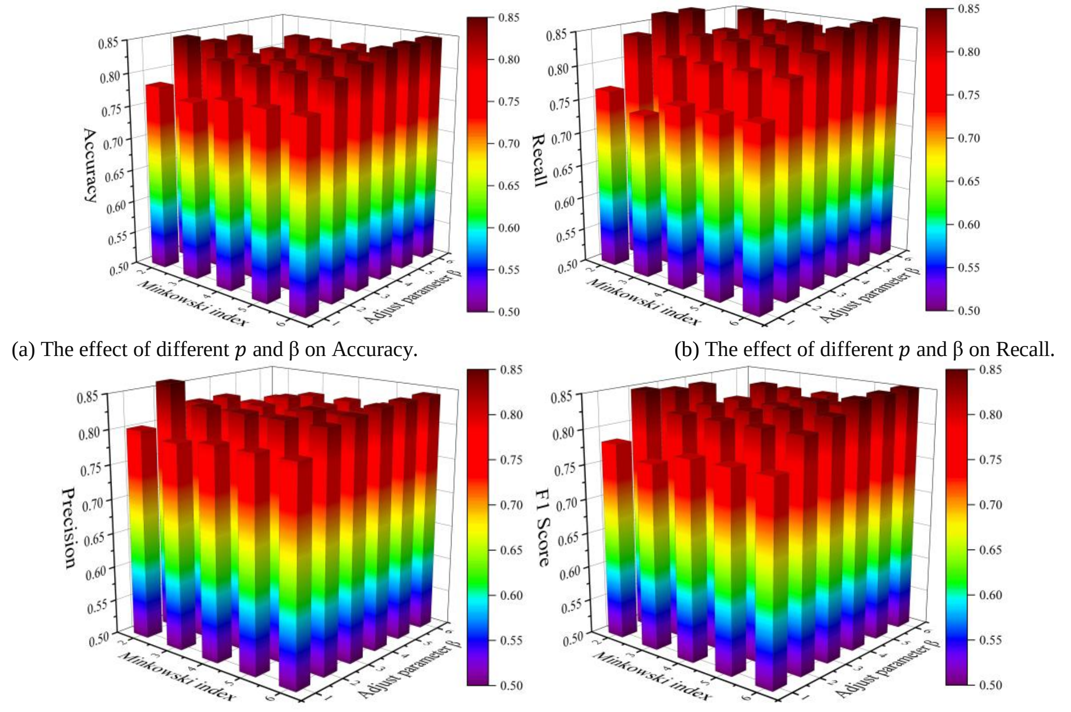
C. Sensitivity Analysis

This section, using the Promoters dataset as an example, will analyze the impact of the Minkowski exponent (p-value) and the tuning parameter β on the performance of the proposed CKNN algorithm. The importance of p and β values in affecting the classifier's performance will be demonstrated through specific experimental results, which are displayed in Fig. 5.



(a) The effect of different p and β on Accuracy.

(b) The effect of different p and β on Recall.

(c) The effect of different p and β on Precision.

(d) The effect of different p and β on F1 score.

Fig. 5. The effect of different Minkowski indices and tuning parameter β on classifier performance.

From Fig. 5, it can be observed that (1) For a specific value of β, the trend of accuracy increasing with an increase in p is quite apparent. The highest accuracy combination occurs at β=6 and p=4, 5, 6, with accuracies all reaching 0.8438. This indicates that a higher combination of β and p values is more likely to produce higher accuracies in this data group. Despite some fluctuations, a general trend can still be seen accuracy tends to increase with an increase in the value of p. The effect of the tuning parameter β seems less direct. However, it can be observed that when the value of the tuning parameter β reaches 6, the accuracy reaches a higher level, especially at higher p values. (2) Recall rates show a certain upward trend with the p increase. Especially at p=3 and subsequent values, recall rates are relatively high, notably at β=2 and β=5, 6, indicating that an increase in p has a positive effect on enhancing recall rates. At β=2, 5, 6 and p=3,4, the recall rates all reached the highest value of 0.8824. Overall, as p increases, there is a trend for an increase in recall rates, although this trend exhibits some fluctuations under different β values. (3) At β =2, precision increases significantly with p, reaching a peak (0.875), then decreasing. For other β values, precision does not vary much across different p values, but overall, when β increases to 6, precision reaches its highest at p=4, 5, 6. This suggests that larger values of β and p might be more beneficial for increasing precision in this specific model. Generally, precision tends to improve with an increase in β, especially at higher p values. (4)F1 score varies under different combinations of β and p. Especially at β=2, the F1 score corresponding to p significantly surpasses other p values, showing the highest score at 0.8485. At β=6 and p=4, 5, 6, the highest F1 scores were observed, each being 0.8571. This finding aligns with previous analyses of precision, suggesting that the model's overall performance may be better with larger values of β and p.

Therefore, CKNN performance metrics (Accuracy, Recall, Precision, and F1 score) generally improve with the increase of the parameter p and perform optimally at larger β values. Reasonable adjustment of the Minkowski index and the tuning parameter β can further optimize the classification performance of the CKNN algorithm.

V. Conclusion

This study proposes an improved K-nearest neighbor (KNN) classification algorithm based on compactness weights, which initially updates feature weights by calculating the compactness of each feature and then employs a compactness-weighted Minkowski distance to calculate the distances between samples, serving as the basis for classification decisions. Experimental results indicate that the CKNN algorithm surpasses traditional KNN and variant KNN algorithms in Accuracy, Recall, Precision, and F1 scores across the selected five datasets, notably showing significant performance improvements on the Promoters dataset.

The analysis of experimental results suggests that when the Minkowski exponent is two and the tuning parameter β is 2, the CKNN algorithm achieves relatively better classification effects. The CKNN algorithm can better balance the local and global information between samples, enhancing classification accuracy. Additionally, the overall results from the SRDs ranking, Friedman test, Nemenyi test, and Bonferroni correction analysis of the CKNN algorithm are superior to those of the compared variant KNN algorithms, confirming the better performance of the CKNN algorithm. Sensitivity analysis results indicate that the performance of the CKNN algorithm is jointly influenced by the Minkowski exponent and the tuning parameter β, and an appropriate selection of these parameters can further enhance the algorithm's performance.

Although the CKNN algorithm proposed in this study enhances the performance of the KNN algorithm, the performance of the KNN algorithm performance remains a key area of research. Therefore, future research will focus on further enhancing the scalability of the K-Nearest Neighbors (KNN) algorithm in large-scale datasets and real-time applications, with an emphasis on exploring parallel processing and distributed computing technologies to improve the efficiency of KNN in big data scenarios. At the same time, by combining the ability of deep learning models to automatically extract features and optimize weights, the KNN algorithm is expected to perform more effectively in handling high-dimensional and unstructured data.

SIEM and Threat Intelligence: Protecting Applications with Wazuh and TheHive

Jumiaty, Benfano Soewito
Computer Science Department-BINUS Graduate Program-Master of Computer Science,
Bina Nusantara University, Jakarta 11480, Indonesia

Abstract—**The consequences of cyberattacks on enterprises are highly varied. DDoS assaults can render an organization's website inaccessible; SQL attacks can compromise the integrity of data in a database, and Brute Force attacks can lead to unauthorized users gaining control over a server or application. Hence, it is crucial for enterprises to be aware of these potential dangers and employ solutions capable of monitoring networks, apps, and servers. In this study, the author employs Wazuh, TheHive, Telegram, and CVSS. Wazuh functions as a tool for monitoring applications and identifying potential security risks. TheHive classifies threats according to their level of importance. Telegram is utilized for dispatching notifications to the administrator. The findings indicate that Wazuh can promptly identify security risks by verifying that the date and time configurations on each utilized server align with the Indonesian time standard. Several vulnerabilities in the applications were successfully detected. The Wazuh server monitors two specific apps, namely Kompetensi and ESPPD. Surveillance commenced on March 20, 2024, at 17:49 and concluded on June 20, 2024, at 01:10, effectively amassing a total of 16,580 logs. 11 essential alert categories require follow-up due to their potential to compromise the system's integrity, confidentiality, and availability. To validate the detection results, the Common Vulnerability Scoring System (CVSS) is used. The assessment of vulnerability levels varies depending on the Wazuh level and CVSS. This arises because CVSS assigns scores based on five exploitability characteristics and incorporates the expertise of specialists to determine the assessment category and evaluate the potential impact of a successful threat. The outcome of this assessment, involving professional expertise, is heavily influenced by the unique attributes of each company. As a result, even when evaluating the same threats, the assessment can yield varying results. Evaluations utilizing Wazuh and CVSS are highly efficient in determining the extent of discovered hazards. By integrating these two technologies, the produced findings become more accurate.**

Keywords—Application server security; application vulnerability; threat detection; SIEM; Wazuh; TheHive; Telegram and CVSS

I. Introduction

The exponential growth of information technology will inevitably lead to a corresponding rise in cyber-attacks. Cyberattacks are directed on individuals and government organizations and enterprises [1]. Distributed Denial of Service (DDoS), SQL Injection, and Brute Force are some of the several types of cyberattacks [2]. Cyberattacks have severe consequences, including financial losses, exposure of personal information, harm to reputation, disruption of operations, and the expenses required to manage the event [3]. To mitigate cyber attacks, enterprises are required to establish robust risk management protocols to safeguard applications from such threats. Some risk management frameworks that can be utilized are NIST Cybersecurity, ISO 27000, ISA/IEC 62443, GDPR, and CIS Controls [4].

Ensuring the security of applications is a crucial component of preserving the overall security of a system. Two tools commonly employed for application monitoring are Open Source Security (OSSEC) and Security Information and Event Management (SIEM). SIEM offers immediate log analysis and management, facilitating prompt identification of threats and expedited reaction to security issues. Utilizing these tools can enhance businesses' ability to identify and mitigate possible security threats with more efficiency [5][6].

SIEM includes two categories of tools: commercial tools and open-source tools. Typically, paid SIEM systems have advanced functionalities, but they come with a higher cost. Some examples of paid SIEM tools include Splunk and IBM Qradar [7]. Nevertheless, the functionalities of open source SIEM can be highly efficient, but need more configuration and manual upkeep. When effectively managed, these open source solutions can offer robust and adaptable security measures customized to the organization's requirements.

Some of the open source SIEM tools include Open-source SIEM (OSSIM), Elasticsearch-Logstash-Kibana (ELK) stack, and Wazuh [8]. Wazuh assists in safeguarding the digital assets of businesses and individuals against security threats. The primary elements of Wazuh consist of the Wazuh indexer, Wazuh server, Wazuh dashboard, and Wazuh agent. The Wazuh agent is installed in the target application that is to be monitored [9]. The Wazuh platform includes SIEM management, allowing for real-time monitoring and detection of incidents through the analysis of event or activity reports within the application [10]. This implementation can further enhance the usefulness of Indeks KAMI as a result of SIEM's capability to assess system vulnerabilities, facilitate monitoring and auditing in relevant work units. This implementation has the potential to increase the value of the Information Security Index (KAMI) by utilizing the capabilities of SIEM to evaluate system vulnerabilities and optimize monitoring and auditing procedures in relevant work units [11]. Furthermore, SIEM has the capability to be integrated with SOAR and Honeyport in order to safeguard crucial assets inside an organization [12].

This research aims to identify application security vulnerabilities within an organizational unit by utilizing

Wazuh, which is seamlessly linked with TheHive. Wazuh serves the purpose of monitoring security threats, whereas TheHive serves the purpose of responding to incidents. Based on the analysis results, it can be inferred that Wazuh has a total of 4,372 rules and 16 levels of vulnerability. These rules will inevitably generate a substantial volume of logs on a daily basis. Not all of these logs pertain to the identification of security threats in applications. Only pertinent rules will be employed, and any rules that are not utilized will be disabled.

The Wazuh server collects logs from agents that are installed on the target monitoring application. The amount of agents that can be assigned to a Wazuh server is flexible and can be adjusted based on the organization's requirements. Wazuh agents are compatible with multiple operating systems, including Windows, Linux, Mac, Solaris, AIX, and hpUX [13].

The Wazuh Dashboard will present logs according to the agent. Administrators have the ability to view comprehensive information on threats, including the detection level of each agent. This will provide challenges for administrators to monitor concurrently. So the optimal approach to facilitate administrators' application monitoring is to establish integration Wazuh and TheHive. TheHive will collect logs from Wazuh and provide them on a unified dashboard page for all agents.

Integrating Wazuh with TheHive is a challenging task because of the absence of a shared network between the Wazuh server and TheHive server. To integrate Wazuh and TheHive on the same network, the zerotier custom platform is required as an additional step. Nevertheless, there are many advantages to be gained from effectively combining two technologies to be concurrently utilized in resolving issues within organizational units. In their research, Muhammad Alfian Fahrudi dan I Made Suartana [14] performed a three-stage testing process to integrate Wazuh with Telegram. The stages included vulnerability evaluation, injection attacks, and brute force. The findings demonstrated that the integration of Wazuh with Telegram enables the identification of potential risks and their subsequent transmission to the administrator through the Telegram application. However, the author's predicted detection time is surpassed due to the substantial data kept on the server, resulting in a lengthy procedure lasting approximately 10 minutes. Another research conducted by Muhammad Dehan Pratama, Fitri Nova and Deddy Prayama [15] the integration of wazuh and suricata. Suricata is utilized for threat detection, whereas Wazuh is employed to showcase the logs produced by Suricata on the Wazuh dashboard. The detection process is specifically aimed at identifying denial-of-service (DoS) assaults inside the flood attack category. Out of the five attack attempts, only two were successfully identified by Suricata. This detection rate was influenced by the use of an AWS Amazon server. Some attacks were promptly rejected by the server, preventing Suricata from detecting them.

Therefore, this study aims to combine the Wazuh and TheHive methods to identify and address instances of application security threats. Real-time threat detection will be implemented by Wazuh. To guarantee the real-time detection of threats, it is necessary to configure the time zone on each server. The identified threats will thereafter be transmitted to TheHive according to the pre-established threat level. Based on the identified dangers, TheHive will generate a case, which will then be partitioned into multiple tasks. By examining the specifics of the identified risks, the duties will be subsequently assigned to multiple teams, including the network security team, vulnerability management team, incident response team, and database security team. Following the successful creation of the case, TheHive will promptly transmit a notification to the application administrator using Telegram. The output generated by Wazuh and TheHive Integration will go through validation using the Common Vulnerability Scoring System (CVSS) 4.0 in order to assess the genuine validity and significance of the identified threats by the system. By including Wazuh, TheHive, telegram, and validation using CVSS, it is anticipated that applications inside these organisational units will be adequately protected against cyber threats.

II. Literature Review

Research reviews are performed to validate the chosen technique and uncover areas of research that have not been explored, so opening up new possibilities for this study. Stefan Stanković, Slavko Gajin, and Ranko Petrović [16], did research on the application of Wazuh for identifying security threats. They specifically focused on using Wazuh to identify attacks on web servers. Web servers are highly susceptible to a wide range of threats. Wazuh will provide a comprehensive and real-time display of the detected attacks. Wazuh is utilized not only for detecting security threats, but also for monitoring integrity, policies, and auditing systems.

Rio Pradana Aji, Yudi Prayudi and Ahmad Luthfi [17] conducted an additional study on Wazuh. They utilized Wazuh to enhance the website monitoring system by employing quantitative forensic investigation techniques to identify brute-force attacks. Wazuh assists businesses in the implementation of Centralized Log Management. Based on the research review, the utilization of Wazuh is currently restricted to the detection of a single form of assault, specifically brute force.

A study undertaken by Manju, Shanmugasundaram Hariharan, M. Mahasree, Andraju Bhanu Prasad and H.Venkateswara Reddy [18] investigated the detection of DDOS assaults by the integration of four tools: wireshark, snort, Wazuh, and splunk. Wireshark is utilized to conduct preliminary surveillance through the analysis of network traffic. In addition, the integration of snort with Wazuh will effectively identify and detect potential security threats. The output is transmitted to Splunk and will be presented in a way that is readily comprehensible to the administrator. The duration of this procedure is around five hours, resulting in a higher level of efficiency compared to the prior duration of seven to eight hours, resulting in a time savings of approximately three hours.

Additional study was carried out by Novianda Shafira Suryawatie Yomo, Ahmas Zafrullah Mardiansyah, and I Wayan Agus Arimbawa [19] utilising Security Information and Event Management (SIEM) with the Wazuh system. An experiment was conducted to assess the security of the University of Mataram academic information system by evaluating the Sql Injection attack utilising the Sql Injection payload inputted into the Burp Suite application.

Anand Groenewegen and Joris Shuko Janssen [20] conducted an evaluation and validation of TheHive Project, an open-source security Incident Response Platform. The objective of this study is to assess the level of maturity of TheHive Project as a security Incident Response Platform. Due to its comprehensive documentation, ease of management, and effectiveness in managing security incidents, TheHive Project is regarded as a mature security Incident Response Platform.

A study undertaken by Bharadwaj Mantha, Yeojin Jung, and Borja Garcia de Soto [21] employed the Common Vulnerability Scoring System (CVSS) to evaluate and quantify cyber vulnerabilities inside the construction sector. The CVSS system assigns a numerical score to individual vulnerability characteristics, therefore enabling the quantification of the security risk level for project participants including owners, contractors, and labour. The susceptibility of numerous leading construction firms was methodically evaluated using CVSS version 3.1, employing criteria including base, temporal, and environmental factors.

Based on the findings of the literature research, there are several efficient frameworks for real-time detection of threats to servers or apps. One such tool is Wazuh, which possesses the capability to be seamlessly incorporated with numerous other tools. This information provides background for the author to undertake research on the integration of Wazuh with TheHive for the purpose of detecting security threats and implementing incident reactions in the case of such threats. This integration not only identifies a single kind of threat, but is anticipated to identify all categories of threats that provide a risk to applications and servers. This research also has the implementation of a Telegram Bot to transmit real-time notifications to administrators. The last phase of the research is the verification process utilising CVSS 4.0.

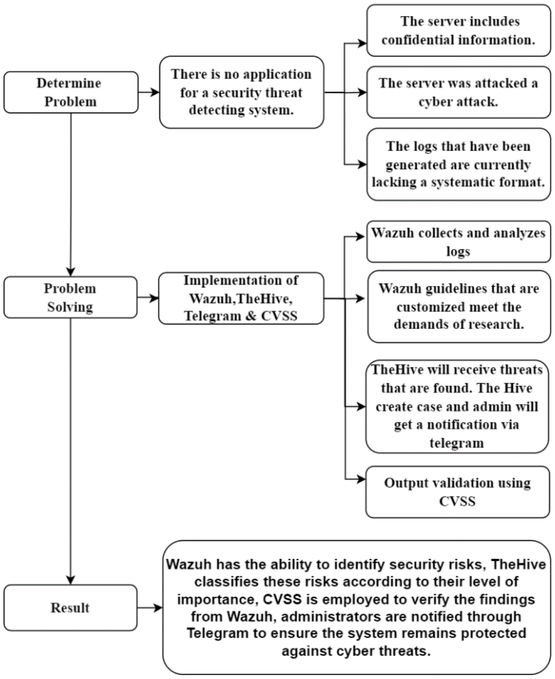
III. Methodology

A. Phases of Research

This project involves the installation and evaluation of integrating Wazuh with TheHive to detect security vulnerabilities on application servers. This procedure involves configuring Wazuh, TheHive, and integrating Wazuh with thehive, as shown in Fig. 1. Subsequently, it is necessary to incorporate rulesets based on the specific requirements of the research. Wazuh is designed to carry out real-time monitoring of logs. Logs that are identified will be shown on the Wazuh dashboard for the purpose of analysis. Logs categorized as vulnerability levels 5 to 15 will be given to TheHive for additional analysis. TheHive will generate a case for the identified threat and break down the case into multiple tasks to be collectively analyzed with the security team, enabling administrators to respond promptly and effectively to the issue.

B. Network Topology

Fig. 2 depicts the functioning of the system, wherein the administrator gains access to the competency application and e-sppd through a VPN connection, using a unique login and password. Both applications require the installation of a wazuh agent, which is responsible for monitoring the logs of application activities. The application is susceptible to cyber attacks. The installed Wazuh agent on the application will transmit logs to the Wazuh server. In addition, the Wazuh server collects logs from the agent and presents them on the dashboard for the administrator to watch. Logs that are being monitored and have high vulnerability ratings will be transmitted to TheHive Server for additional examination. In addition, TheHive will generate a case based on the log and then split it into several tasks. Once the case is created, the administrator will automatically be notified via telegram.



Determine Problem
There is no application for a security threat detecting system.
The server includes confidential information.
The server was attacked a cyber attack.
The logs that have been generated are currently lacking a systematic format.
Problem Solving
Implementation of Wazuh,TheHive, Telegram & CVSS
Wazuh collects and analyzes logs
Wazuh guidelines that are customized meet the demands of research.
TheHive will receive threats that are found. The Hive create case and admin will get a notification via telegram
Output validation using CVSS
Result
Wazuh has the ability to identify security risks, TheHive classifies these risks according to their level of importance, CVSS is employed to verify the findings from Wazuh, administrators are notified through Telegram to ensure the system remains protected against cyber threats.

Fig. 1. Phases of research.

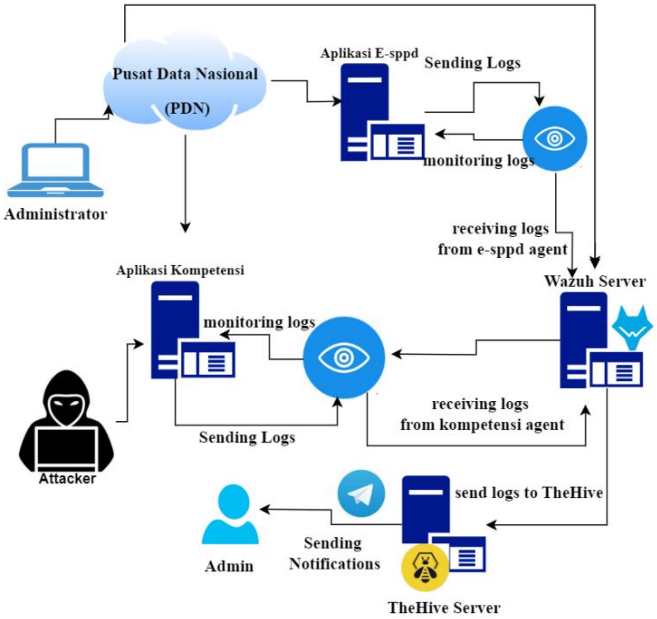


Fig. 2. Network topology.

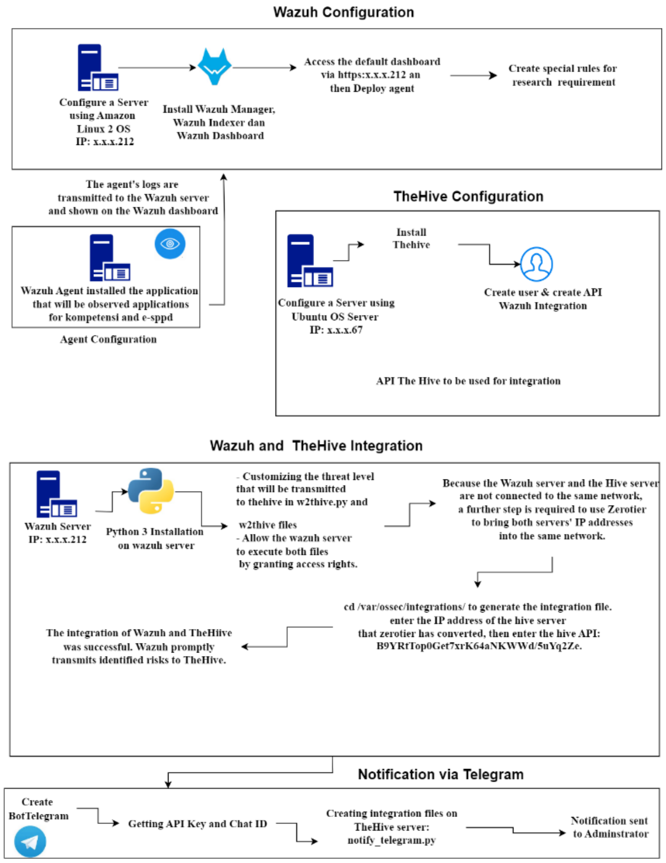
C. Integration Flow of Wazuh and TheHive

Fig. 3 depicts the sequential steps involved in integrating Wazuh and TheHive. The initial step involves setting up the Wazuh server, which is then followed by configuring the thehive server. The subsequent step involves generating an integration file to facilitate the exchange of data between the two servers. Since Wazuh and TheHive are not connected to the same network, it is imperative to utilize zeroTier in order to establish a unified network for both. The integration file additionally establishes the threat level that will be transmitted to TheHive. TheHive will generate a case and partition it into multiple tasks to facilitate the analysis of the danger by administrators. The specifics of the Integration Flow are as follows: transmitted to TheHive. TheHive will generate a case and partition it into multiple tasks, hence facilitating the analysis of the threat for administrators.



Wazuh Configuration
Configure a Server using Amazon Linux 2 OS IP: x.x.x.212
Install Wazuh Manager, Wazuh Indexer dan Wazuh Dashboard
Access the default dashboard via https:x.x.x.212 an then Deploy agent
Create special rules for research requirement
The agent's logs are transmitted to the Wazuh server and shown on the Wazuh dashboard
Wazuh Agent installed the application that will be observed applications for kompetensi and e-sppd
Agent Configuration
TheHive Configuration
Configure a Server using Ubuntu OS Server IP: x.x.x.67
Install Thehive
Create user & create API Wazuh Integration
API The Hive to be used for integration
Wazuh and TheHive Integration
Wazuh Server IP: x.x.x.212
Python 3 Installation on wazuh server
- Customizing the threat level that will be transmitted to thehive in w2thive.py and w2thive files
- Allow the wazuh server to execute both files by granting access rights.
Because the Wazuh server and the Hive server are not connected to the same network, a further step is required to use Zerotier to bring both servers' IP addresses into the same network.
cd /var/ossec/integrations/ to generate the integration file. enter the IP address of the hive server that zerotier has converted, then enter the hive API: B9YRtTop0Get7xrK64aNKWWd/5uYq2Ze.
The integration of Wazuh and TheHiive was successful. Wazuh promptly transmits identified risks to TheHive.
Notification via Telegram
Create BotTelegram
Getting API Key and Chat ID
Creating integration files on TheHive server: notify_telegram.py
Notification sent to Adminstrator

Fig. 3. System overview.

Based on Fig. 3, it can be concluded that the process details include:

- A server is configured with Amazon Linux OS 2 for the purpose of running Wazuh. This server consists of the Wazuh Manager, Wazuh Indexer, and Wazuh Dashboard. To access the Wazuh dashboard, use the designated IP address. Wazuh agents will be deployed on the application that needs to be monitored. The purpose of the agent is to transmit logs to the server, which will subsequently be exhibited on the Wazuh dashboard.
- The Ubuntu OS will host the installation of TheHive server. Once the installation is finished, the dashboard of TheHive can be accessed by using a designated IP address. First, add TheHive user to the system. Then, proceed with the creation of an API for the integration process.
- The integration between Wazuh and TheHive is accomplished using Python 3. The Wazuh server will have Python 3 installed.
- Wazuh and TheHive need to be connected within the same network utilizing zero tiers.
- The integration file will utilize the API provided by TheHive server and the IP generated by zero tier.
- Wazuh will send the logs to TheHive. The logs received by TheHives will be uploaded to the case, at the same time the administrator will receive detailed notifications of the threat.

IV. Result

A. Configuration and Modification of Wazuh Rules

System configuration and integration refer to Fig. 3. To implement Wazuh and TheHive, two servers are needed, namely the Wazuh server and TheHive server. The wazuh server will be installed on the Amazon Linux 2 operating system and TheHive server using ubuntu operating system. To start monitoring applications using agents, the Wazuh server needs to add as many agents as the number of applications to be monitored. The Wazuh server will monitor logs from two agents, the competency agent and the e-sppd agent. An illustration of the Wazuh server can be seen in Fig. 4.

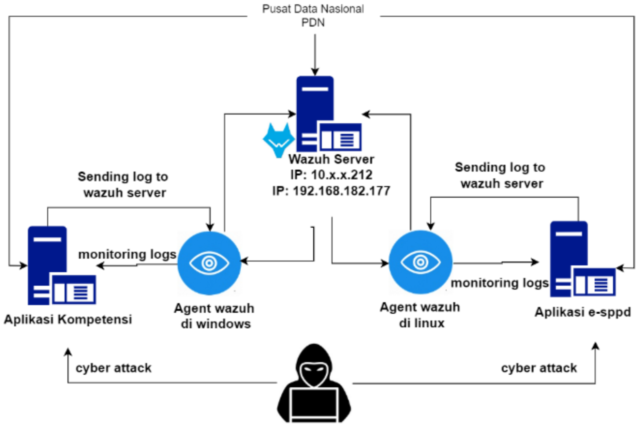


Fig. 4. Server Wazuh illustration.

Configuration stage of the wazuh server:

- Installation of Wazuh package on Amazon Linux server 2 : curl -sO https://packages.wazuh.com/4.4/wazuh-install.sh && sudo bash ./wazuh-install.sh -a
- Checking the Wazuh package that has been installed on the amazon linux server 2: sudo yum list-installed | grep Wazuh.

- After the installation process is complete, the Wazuh dashboard can be accessed using a dedicated ip via https://10.30.x.212.
- The next step is to add an agent. Add agent is done on the server side and the application side will be monitored. On the server side, add agent is done through the Wazuh dashboard then select deploy new agent and adjust the operating system used by the application that will be paired with the agent. The first agent is a competency application using the windows operating system, the agent installation stage from the windows-based application side can be done using windows powershell, the instructions are as follows:
  - Invoke-WebRequest -Uri https://packages.wazuh.com/4.x/windows/wazuh-agent-4.7.1-1.msi -OutFile ${env.tmp}\wazuh-agent; msiexec.exe /i ${env.tmp}\wazuh-agent /q WAZUH_MANAGER='10.30.x.212' WAZUH_AGENT_GROUP='default' WAZUH_AGENT_NAME='kompetensi' WAZUH_REGISTRATION_SERVER='10. 30.x.212'
  - NET START WazuhSvc

The second agent is the e-sppd application that uses the Linux operating system, the agent installation stage from the Linux-based application side can be done using the Linux terminal, the instructions are as follows:

- wget https://packages.wazuh.com/4.x/apt/pool/main/w/wazuh-agent/wazuh-agent_4.7.1-1_amd64.deb && sudo WAZUH_MANAGER='10.30.x.212' WAZUH_AGENT_NAME='esppd' dpkg -i ./wazuh-agent_4.7.1-1_amd64.deb
- sudo systemctl daemon-reload
- sudo systemctl enable wazuh-agent
- sudo systemctl start wazuh-agent

Threats will be identified by the installed Wazuh agent using Wazuh rules. Wazuh's 16 rule classification tiers are organized according to how seriously systems and applications are threatened. These levels are numbered 0 through 15, with each level denoting a distinct degree of intensity. Every rule is intended to identify a range of potentially harmful or suspicious activity on a network or system, from very minor risks to more significant and destructive assaults. Wazuh gives administrators flexibility in responding to various threats by offering 16 levels of rule classification. This allows administrators to tailor actions based on the severity and criticality of each security event that is identified. Furthermore, users may more easily group and arrange security responses thanks to a clear hierarchy in rule classification, which increases handling efficiency for both threats and security incidents as a whole.

Wazuh has 4. 372 ID rules in addition to rule classification, which are grouped according to their functions: syslog, firewall, ids (intrusion detection system), web-log, squid (proxy server), Windows, Wazuh, sysmon (system monitor), powershell, cloudflare (web application firewall), audit detections, Amazon Security Lake, ms-graph (Microsoft Graph), multiverse, sshd (Secure Shell Daemon), fireeye, and unbound (DNS Server). These groups make it simple to arrange and sort rules according to the kind of log or activity being monitored.

In accordance with the requirements of research, Wazuh also makes it easier to add additional decoders and rules. Using the Wazuh dashboard, accessible via the Management menu, one may create custom rules by first selecting rules and then searching for "local_rules.xml" and the specific custom rule that one wants.

B. *Installation Stage of TheHive Server:*

- wget -q -O /tmp/install.sh https://archives.strangebee.com/scripts/install.sh ; sudo -v ; bash /tmp/install.sh. then select 2 which are Install TheHive.
- After the installation process is complete, Thehive dashboard can be accessed using a dedicated ip via http://10.10.x.67:9000/login.
- The next step is to add user mimi@thehive.local and create API Key B9YRtTop0Get7xrK64aNKWWd/5uYq2Ze which will be used in the integration process. after the integration process is complete, the user mimi@thehive.local will receive logs from the Wazuh.

C. *Integration of Wazuh and TheHive Servers*

The Integration Stages are:

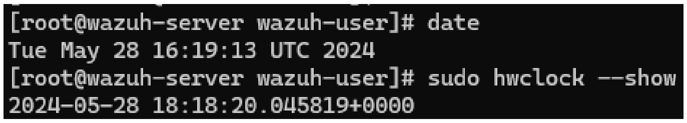
- Installing python 3 on Wazuh server
- Install the Hive Python using PIP (Python Package Index)
- create custom-w2thive.py. and custom-w2thive file which will be used for Wazuh and TheHive integration.
- Customize the custom-w2thive.py and determine the logs that will be sent by Wazuh to TheHive are logs with at least rules level 5 to level 15.
- Continued by customizing the custom-w2thive file.
- Provide access to Wazuh to run the custom-w2thive.py file. and w2thive.:
  - sudo chmod 755 /var/ossec/integrations/custom-w2thive.py
  - sudo chmod 755 /var/ossec/integrations/custom-w2thive

  - sudo chown root:wazuh-user/var/ossec/integrations/custom-w2thive.py
  - sudo chown root:wazuh-user /var/ossec/integrations/custom-w2thive

- The Wazuh Server and TheHive Server are not connected to each other within the same network. An effective resolution is to employ zerotier. The procedure consists of the following steps:
  - Create an network name : mythesis_network
  - Create network_ID : 363c67c55a3f3ff1.
  - Select the format of the desired IP, namely: 192.168.x.x.
  - Install zerotier on both server: curl -s htttps://install.zerotier.com.
  - Connect thehive server with zerotier network ID, with the: zerotier-cli join 363c67c55a3f3ff1.
- After the Wazuh server and Wazuh thehive are in the same network and get the IP from the zero tier. The next step is to create integration files. Integration files can be created through the Wazuh dashboard on the Management menu and then select configuration. IP yang di input pada file merupakan IP dari zerotier. The API used is an API from TheHive server.
- The integration process is completed, TheHive will receive logs from any server starting from rule level 5 to rule Level 15.

D. Threat Detection Results Based on Logs

Based on the application threat detection results from the Wazuh server, there is a discrepancy in the timing between the attack attempt and the log generated by the server. This occurs due to a discrepancy in the date settings between the Wazuh server and the Wazuh dashboard. Presented in Fig. 5 are the unsynchronised date settings.

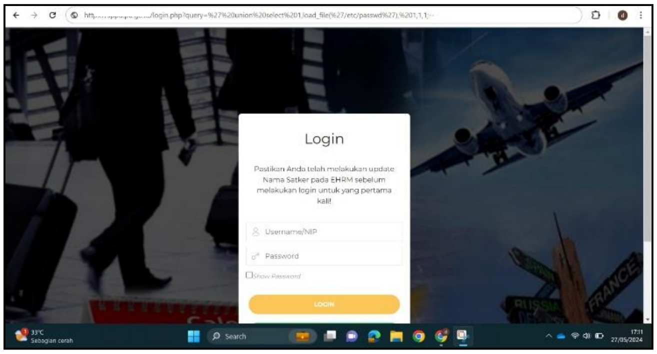


```
[root@wazuh-server wazuh-user]# date
Tue May 28 16:19:13 UTC 2024
[root@wazuh-server wazuh-user]# sudo hwclock --show
2024-05-28 18:18:20.045819+0000
```

Fig. 5. Unsynchronized time display.

The date instruction displays the date and time of the Wazuh server, while the sudo hwclock --show instruction displays the actual date and time. The following is a Sql Injection experiment by inputting the command : https://sppd.pu.go.id/login.php?query=%27%20union%20select%201,load_file(%27/etc/passwd%27),%201,1,1;-- on the web url that will be accessed.

The Sql Injection test in Fig. 6 was conducted on May 27, 2024, at 17:11 but Wazuh recorded the attack at 16:5516.55. Fig. 7 shows Sql injection detection.



http......../login.php?query=%27%20union%20select%201,load_file(%27/etc/passwd%27),%201,1,1;--

id	1716828912.665887

Fig. 7. Sql injection detection.

The attack was carried out using IP 192.168.56.1 but the detection results were noted ip10.x.x.17. If viewed from the IP recorded by the Wazuh as if the attempted attack came from within the organization. This is because of the error in the organization's internal network configuration, this finding will be an input to the internal network improvement. The solution used for time synchronization on wazuh servers and wazuh dashboards is as follows:

- Install ntp: sudo yum install ntp -y
- Change ntp server: Sudo nano /etc/ntp.conf .
- Install ntpdate: sudo yum install ntpdate -y
- Synchronize system time with ntp server: sudo ntpdate -u pool.ntp.org
- If still not synchronized, verify the server time zone: timedatectl.
- Set the time zone to match the server location: sudo timedatectl set-timezone Asia/Jakarta
- Then re-synchroniz: sudo ntpdate -u pool.ntp.org

Furthermore, in addition to performing Sql Injection tests. The Wazuh server additionally monitors two specific apps, namely the competence application and the esppd application. The surveillance commenced on March 20, 2024, at 17:49 and concluded on June 20, 2024, at 01:10, effectively amassing a total of 16,580 logs. There are 11 essential alert categories that require follow-up due to their potential to disturb the system's integrity, confidentiality, and availability. Table I displays a summary of the 11 alert categories.

TABLE I. DETECTED THREATS

No	Alert	Level	Rule.mitre.technique	Amount
1	URL too long. Higher than allowed on most browsers. Possible attack.	13	Endpoint Denial of Service	2
2	Multiple web server 400 error codes from same source ip.	10	Vulnerability Scanning/Reconnaissance	5.388
3	High amount of POST requests in a small period of time (likely bot).	10	Network Denial of Service	857
4	Multiple web server 500 error code (Internal Error).	10	-	2
5	Multiple Windows logon failures.	10	Brute Force	11
6	SQL injection attempt.	7	Exploit Public-Facing Application	100
7	Listened ports status (netstat) changed (new port opened or closed).	7	Netstat Listening Ports	727
8	Host-based anomaly detection event (rootcheck).	7	-	171
9	Integrity checksum changed.	7	Stored Data Manipulation/ Impact	288
10	File deleted.	7	File Deletion/Data Destruction	38
11	Common web attack	6	Process Injection, File and Directory Discovery, Exploit Public-Facing Application	192

Referring to the information shown in Table I, Wazuh will identify a total of 11 risks. These threats will be thoroughly detailed, together with their respective impacts on servers and applications.

1) URL too long. Higher than allowed on most browsers. Possible attack, Identifies a potential attack in which an attacker can take advantage of a vulnerability by transmitting an excessively lengthy URL to the target. The significance of this danger on the system's confidentiality, integrity, and availability is substantial.

2) Multiple web server 400 error codes from same source ip executed across a network that does not necessitate specific circumstances or access privileges and does not need user engagement. Although server availability will be affected by this threat, data confidentiality and integrity will remain unaffected. Yet, these vulnerability screening operations can also serve as the initial stage of more severe attacks.

3) High amount of POST requests in a small period of time (likely bot). The process is executed over the network using POST requests that can be automated by bot programming languages. The present attack does not affect the principles of secrecy and integrity. Nevertheless, this attack will significantly affect availability by inundating the server with a substantial volume of requests, therefore introducing a denial of service (DoS) risk.

4) Multiple web server 500 error code (Internal Error).The exploitation of these vulnerabilities occurs via networks with modest complexity and does not necessitate privileges or user involvement. The aforementioned form of attack has minimal effect on the confidentiality and integrity of data, but significantly affects the availability of services.

5) Multiple Windows logon failures. These vulnerabilities are used on networks with modest complexity and do not necessitate any rights or user involvement. Upon successful execution of this Brute Force attack, the consequences for system confidentiality and integrity are significant, since the attacker gains the ability to view and alter sensitive data. Nevertheless, the effect on the availability of the system is really minimal.

6) The exploitation of Sql Injection attempts over the network can be achieved with minimal complexity and without the need for privileges or user involvement. Should the assault prove successful, the consequences for data confidentiality and integrity are much more pronounced, as the attacker gains access to and can alter sensitive data within the database. However, the effect on system availability is rather minimal, unless the attack results in a server breakdown or overload.

7) Listened ports status (netstat) changed (new port opened or closed). This vulnerability is leveraged across the network with minimal complexity and demands minimal rights without user involvement, rendering it insignificant to system availability, confidentiality, and integrity. Nevertheless, a modification in the state of a port can create new opportunities for attacks, hence enabling an attacker to gain unauthorized access or interfere with services operating on that specific port.

8) Host-based anomaly detection event (rootcheck). This vulnerability is leveraged via local access with minimal complexity and demands minimal rights without actual user involvement. NTFS Alternate Data Streams that are deemed suspicious have the potential to conceal harmful files or content that can be exploited by an attacker. While the effect on data integrity will be significant, the effect on system confidentiality and availability will be quite lesser.

9) Integrity checksum changed. The exploitation of these vulnerabilities occurs via local access with minimal complexity and necessitates elevated privileges without any user involvement. Alteration of system files, such as /usr/bin/cloud-init-per, can significantly affect the integrity and availability of the system, although the effect on system secrecy is rather little.

10) File deleted. This vulnerability through local access, this vulnerability demands high privileges without user interaction and is characterised by little complexity. Deleting certificate key files, such as /etc/ssl/pu_go_id/cert3.key, can significantly affect system integrity and availability by compromising the validity of certificates and causing disruptions to services that rely on such certificates. The effect on the confidentiality of the system is really minimal.

*11)*Common web attack. This vulnerability is exploited over the network with low complexity and without requiring privileges or user interaction. This attack attempts to access sensitive files such as /etc/passwd, which can have a high impact on system confidentiality and integrity if successful. However, the impact on system availability is relatively low.

The findings of this work demonstrate that the integration of wazuh with Thehive effectively detects a range of security concerns. Whereas research undertaken by Muhammad Dehan Pratama, Fitri Nova and Deddy Prayama [15] Wazuh and Suricata focuses on detecting a certain kind of threat, namely The detection procedure is deliberately designed to identify denial-of-service (DoS) attacks that fall within the flood attack category. Meanwhile, the research undertaken by Rio Pradana Aji, Yudi Prayudi and Ahmad Luthfi [17] Wazuh is limited to the identification of a singular type of attack, namely brute force.

E. *Threat Analysis*

Wazuh effectively transmits the identified alert records to TheHive. In addition, the logs will undergo further analysis. Fig. 8 displays the Dashboard view of TheHive.

Fig. 9. The process of creating a case.

TheHive will generate cases based on the collected logs and allocate them into tasks for each team. By dividing the responsibilities in this way, the analysis process can be expedited and enhanced, allowing for a prompter response to identified security threats. Fig. 9 displays the case view, where as Fig. 10 shows the tasks.

The generated case, including the additional tasks, will be assigned to many teams, such as the network security team, vulnerability management team, incident response team, and database security team, to jointly coordinate and carry out a comprehensive investigation of the risk. The generated case is depicted in Fig. 11. A successful case was set up on July 26, 2024 at 10:55 (WIB).

Fig. 11. Cases that have been created.

Once the case and task have been established, the subsequent action involves notifying the administrator through the use of a telegraph. The following is a comprehensive breakdown of the steps:

- Develop a Telegram bot utilizing BotFather.
- Enter the command /start, followed by /newbot, and then provide a name for your bot, for as ThesisMimi_bot. Obtain the API Key: 7346165341:AAFqNsOpcqyg8vJ8ScMzYMQrWE8L3 3hpHb4.
- Enter the word "hello" in the chat with ThesisMimi_bot to obtain the Chat_ID. The result is as follows: {"ok":true,"result":[{"update_id":294625573,"message":{"message_id":2,"from":{"id":1134260586,"is_bot":false,"first_name":"Mimi","language_code":"id"},"chat":{"id":1134260586,"first_name":"Mimi","type":"private"},"date":1718511323,"text":"hello"}}]}
- The subsequent action involves generating an integration file on Thehive server, specifically named as the notify_telegram.py file.

An illustration of the notification received by the application administrator or server is shown in Fig. 12.

Fig. 12. Notification via telegram.

The analysis of Fig. 11 cases that were created on July 26, 2024 at 10:55 (WIB) and Fig. 12 Notification via telegram on July 26, 2024 at 10:56 (WIB) reveals that the time interval between case creation and notification reception by the administrator is a mere one minute. These results demonstrate that the system exhibits a rapid and effective reaction in identifying and issuing alerts to the administrator about possible risks or incidents of security identified.

Whereas research undertaken by Muhammad Alfian Fahrudi dan I Made Suartana [14] The findings demonstrated that the integration of Wazuh with Telegram enables the identification of potential risks and their subsequent transmission to the administrator through the Telegram application. However, this resulted in a lengthy procedure lasting approximately 10 minutes. Meanwhile, the research undertaken by Manju, Shanmugasundaram Hariharan, M. Mahasree, Andraju Bhanu Prasad, and H. Venkateswara Reddy [18] examined the identification of Distributed Denial of Service (DDoS) assaults by combining four tools: wireshark, snort, Wazuh, and spearhead. The duration of this operation was approximately five hours.

F. *Validation of Results using the Common Vulnerability Scoring System (CVSS)*

Exploitability metrics and impact metrics are the primary factors utilized to evaluate the severity of vulnerabilities. Exploitability metrics assess the technical components of vulnerability exploitation, including Attack Vector (AV), Attack Complexity (AC), Attack Requirements (AT), Privileges Required (PR), and User Interaction (UI). The complete description of the Exploitability metrics feature may be found in Table III Impact metrics are employed to evaluate the consequences that would occur if a vulnerability is successfully exploited. These metrics encompass the impact on the confidentiality, integrity, and availability of the vulnerable system. The effect metrics element will be comprehensively explained in Table IV. Table II shows qualitative severity rating scale.

The vulnerability assessment results using CVSS 4.0 will be summarised in Table VI, which includes the Exploitability Metrics from Table III and the Impact Metrics from Table IV. This table additionally incorporates the outcomes of danger detection determined by the rules and degrees of the Wazuh. Prior to that, it is necessary to categorise the 15 levels of risk into five CVSS categories in order to facilitate the comprehension of each identified threat. Table V displays a classification of 15 Wazuh levels into five CVSS categories.

TABLE II. QUALITATIVE SEVERITY RATING SCALE

Category	Score CVSS
None	0.0
Low	0.1 - 3.9
Medium	4.0 - 6.9
High	7.0 - 8.9
Critical	9.0 - 10.0

TABLE III. EXPLOITABILITY METRICS

Metric Name	Metric Value	Description
Attack Vector (AV)	Network (N)	Vulnerabilities that can be exploited remotely over a network
	Adjacent (A)	The vulnerable system is inside the protocol stack, but the attack is limited to the protocol level on logically adjacent topologies.
	Local (L)	Attackers access vulnerable systems through local.
	Physical (P)	This attack requires the attacker to physically touch or manipulate the vulnerable system.
Attack Complexity (AC)	Low (L)	Attackers do not require specific targeting to take advantage of the vulnerability.
	High (H)	Attackers must have additional methods available to bypass existing security systems.
Attack Requirements (AT)	None (N)	Attack success is independent of the deployment and execution conditions of the vulnerable system or there are no attack requirements.
	Present (P)	The success of an attack depends on the conditions that require the preparation of specific targets that must be met in order to achieve vulnerability exploitation.
Privileges Required (PR)	None (N)	No privileges are required for an attacker to successfully exploit the vulnerability.
	Low (L)	Attackers need privileges, but can only access non-sensitive data
	High (H)	Attackers require privileges such as administrator who has full access to vulnerable systems.
User Interaction (UI)	None (N)	Vulnerable systems can be exploited without interaction from the user. remote attackers can send packets to the target system.
	Passive (P)	Successful exploitation of these vulnerabilities requires limited interaction by the targeted user with the vulnerable system. For example: utilizing a modified website to display malicious content when the page is rendered.
	Active (A)	Successful exploitation of these vulnerabilities requires the targeted user to perform specific interactions. For example: importing files into the vulnerable system in a specific way.

TABLE IV. IMPACT METRICS

Metric Name	Metric Value	Description
Confidentiality Impact to the Vulnerable System (VC)	High (H)	Confidential information/data is leaked. the information disclosed has immediate and serious consequences. the attacker has control of the information.
	Low (L)	The attacker has access to some information/data, but the attacker has no control over the information obtained. Leaked information has little impact
	None (N)	The confidentiality of the system is still maintained.
Integrity Impact to the Vulnerable System (VI)	High (H)	Complete loss of integrity. The attacker has full access to the data. Attackers can alter or delete data, leading to immediate and serious consequences on the system.
	Low (L)	Allows modification of data, but the attacker does not have full control over the data. The attacker does not have full control over the data, so it does not have an immediate and serious impact on the Vulnerable System.
	None (N)	System integrity is still maintained.
Availability Impact to the Vulnerable System (VA)	High (H)	Makes the service unavailable
	Low (L)	Performance degrades or interruptions in accessing the system occur. attackers do not have the ability to completely deny service to legitimate users
	None (N)	No impact on availability in Vulnerable Systems.

TABLE V. GROUPING OF 15 WAZUH LEVELS INTO FIVE CVSS CATEGORIES

Wazuh Level	CVSS Score	Description
Level 0	None (Score: 0.0)	It has nothing to do with security.
Level 2	Low (Score: 1.0 - 3.9)	Events that have only a minor impact on security but are not considered a significant threat.
Level 3		
Level 4		
Level 5		
Level 6	Medium (Score: 4.0 - 6.9)	Events that have a moderate impact on security could be a greater threat.
Level 7		
Level 8		
Level 9	High (Score: 7.0 - 8.9)	Events that have a major impact on security and can indicate an active attack or a serious problem requiring immediate action.
Level 10		
Level 11		
Level 12	Critical (Score: 9.0 - 10.0)	The events have had a huge impact on security. Indicates a serious attack to deal with.
Level 13		
Level 14		
Level 15		

A comparative graph of the two tools is created based on the data provided in Table VI. Fig. 12 depicts a comparison between the threat level provided by Wazuh and the CVSS score for different categories of security alerts. The graph displays two values for each sort of alert: the Wazuh level and the CVSS score.

TABLE VI. RECAPITULATION OF WAZUH LEVEL AND CVSS SCORE

No	Alert	Wazuh Level	CVSS Vector		CVSS Severity Level	
			Exploitability	Impact	Score	Descrip
1	URL too long. Higher than allowed on most browsers. Possible attack.	13	AV:N; AC:L; AT:N; PR:N; UI:A.	VC: H; VI: H; VA: H .	8.6	High
2	Multiple web server 400 error codes from same source ip.	10	AV:N; AC:L; AT:N; PR:N; UI:N.	VC:N; VI:N; VA:H.	8.8	High
3	High amount of POST requests in a small period of time (likely bot).	10	AV:N ; AC:L ; AT:N ; PR:N ; UI:N.	VC:N; VI:N; VA:H.	8.7	High
4	Multiple web server 500 error code (Internal Error).	10	AV:N; AC:L; AT:N; PR:N; UI:N.	VC:L; VI:L; VA:H .	8.8	High
5	Multiple Windows logon failures.	10	AV:N; AC:L; AT:N; PR:N; UI:N.	VC:H; VI:H; VA:L.	9.3	Critical
6	SQL injection attempt.	7	AV:N; AC:L; AT:N; PR:N; UI:N.	VC:H; VI:H; VA:L.	9.3	Critical
7	Listened ports status (netstat) changed (new port opened or closed).	7	AV:N; AC:L; AT:N; PR:L ; UI:N .	VC:L; VI:L; VA:L.	6.9	Medium
8	Host-based anomaly detection event (rootcheck).	7	AV:L; AC:L; AT:N; PR:L; UI:N.	VC:L; VI:H; VA:L.	6.9	Medium
9	Integrity checksum changed.	7	AV:L; AC:L; AT:N; PR:H; UI:N.	VC:L; VI:H; VA:H.	6.8	Medium
10	File deleted.	7	AV:L; AC:L; AT:N; PR:H; UI:L .	VC:L ; VI:H; VA:H.	6.8	Medium
11	Common web attack	6	AV:N; AC:L; AT:N; PR:N ; UI:N.	VC:H ; VI:H; VA:L .	9.3	Critical

Description:

- Attack Vector : AV
- Attack Complexity : AC
- Attack Requirements : AT
- Privileges Required : PR
- User Interaction : UI
- Confidentiality Impact : VC
- Integrity Impact : VI
- Availability Impact : VA

- Network : N
- for Attack Vector
- None : N
- for Attack Requirements, Privileges Required, User Interaction
- High : H
- Low : L

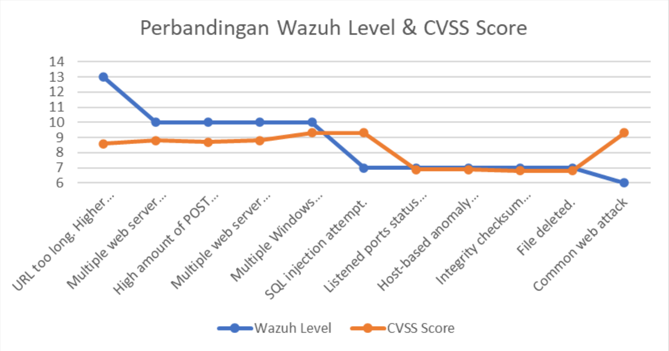

Fig. 13. Comparison chart of wazuh level and CVSS score.

Based on Fig. 13, it can be inferred that there are variations between the Wazuh level and CVSS Score, particularly in relation to the excessive length of the threat URL. Exceeds the maximum limit set by most browsers. There is a potential security breach involving multiple unsuccessful attempts to log in to Windows, an attempt to exploit SQL vulnerabilities, and a common type of attack targeting online applications. The disparity in vulnerability level assessment arises due to the utilisation of CVSS, which assigns a score based on five Exploitability characteristics. This process incorporates the expertise of professionals who determine the assessment category and take into account the potential impact in the event of a successful threat. The outcomes of this evaluation, which involves the expertise of professionals, vary based on the unique attributes of each organisation, although evaluating the same threats.

In general, evaluations utilising Wazuh and CVSS are highly efficient in identifying the severity of identified security risks. By integrating these two instruments, the acquired outcomes become more precise. The purpose of this assessment procedure is to systematically validate the hazards encountered, facilitating the implementation of appropriate mitigation measures. By integrating Wazuh with TheHive and utilising CVSS, organizations can enhance their ability to detect, assess, and address security issues, leading to improved application security.

V. CONCLUSION

Based on the conducted research, it can be inferred that:

1) Wazuh is utilised for the purpose of identifying and recognising potential threats, whilst TheHive is employed to scrutinise and assess the identified hazards. Each of these instruments is customised based on the specific study requirements. This integration also includes supplementary tools, including ZeroTier, which is used to establish a virtual network that links the two entities. Through this combination, Wazuh and TheHive effectively identify and respond to security issues in real-time, promptly notifying administrators via Telegram.

2) All servers should have their date and time settings synchronised to the Indonesian time zone. Synchronisation is crucial as it can impact the formatting of the detection result output in terms of date and time. By adjusting the time parameters appropriately, the resulting information will be more precise.

3) Deploying Wazuh and TheHive on distinct networks offers further advantages to the organisation. By having distinct server locations, the preservation of detection logs is secure, even in the event of one server experiencing a failure. Although integration may pose early challenges, it has the benefit of ensuring the security of log data in case of server issues.

4) Implement Secure Coding Practices, namely employing secure code to mitigate application vulnerabilities. The detection of threats in the form of multiple occurrences of web server 500 error code (Internal Error) twice, and web server 400 error code 2,444 times, suggests that system administrators need to exercise greater vigilance and caution while writing code for the system/application. This highlights a flaw in the code that has to be promptly addressed in order to avoid potential vulnerabilities that could be exploited by attackers.

5) Implement input validation to mitigate the risk of SQL injection, as well as enforce restrictions on the length of URLs received by the server to prevent potential buffer overflow or denial-of-service (DoS) attacks. This step is crucial in order to mitigate potential risks, such as encountering a URL that exceeds the maximum allowable length. Exceeds the maximum limit supported by most browsers. There is a potential attack and an attempt to do SQL injection.

6) Implementing Multi-Factor Authentication (MFA) to monitor user access and ensure authentication and authorisation. The discovered threats involved many instances of failed login attempts, which may suggest unauthorised access attempts or brute force attacks.

7) Assessments combining Wazuh and CVSS 4.0 are highly efficient in identifying the severity of identified threats. By integrating these two instruments, the outcomes achieved become more dependable and precise. The purpose of this assessment technique is to offer a concise and systematic evaluation of the encountered threats.

8) Possibly, TheHive might be integrated with network monitoring tools and intrusion detection systems like Suricata and Zeek (Bro) to enable the comparison of acquired findings for a more thorough study. The speed of technological advancement directly correlates with the increasing magnitude of cyber dangers. In order to enhance their preparedness, security teams should strive to incorporate tools that help streamline their tasks and provide robust security for servers and applications. Suricata and Zeek are mutually synergistic systems, with Suricata functioning as a signature-based detection and prevention system, Zeek providing behavior-based in-depth analysis, and TheHive serving as an incident management platform. The integration of the three components provides organisations with a more comprehensive threat detection system.

9) In the future, it is anticipated that all applications within the Organisational Unit would be able to incorporate wazuh and thehive for the purpose of monitoring servers and apps. This integration will facilitate administrators in monitoring the system, expediting preventive measures, and ensuring the maintenance of system security. This will enhance the efficacy of security management and offer superior safeguarding against prospective risks.

Dynamic Priority-Based Round Robin: An Advanced Load Balancing Technique for Cloud Computing

Parupally Venu, Pachipala Yellamma*, Yama Rupesh, Yerrapothu Teja Naga Eswar, Maruboina Mahiddar Reddy
Department of Computer Science and Engineering, Koneru Lakshmaiah Education Foundation,
Vaddeswaram, Guntur 522302, India

***Abstract*—An imbalance of load is an essential problem in cloud computing where the division of work between virtual machines is not well-optimized. Performance bottlenecks result from this unequal resource allocation, which keeps the system from operating at its full capability. Managing this load-balancing issue becomes critical to improving overall efficiency, resource utilization, and responsiveness as cloud infrastructures strive to respond to changing workloads and scale dynamically. Crossing the load-balancing landscape introduced a new strategy to effectively improve the load-balancing factor and ways to improve load-balancing performance by understanding how existing algorithms work, an effective method of load balancing. The "Dynamic Priority Based Round Robin" algorithm is a new approach that combines three different algorithms to improve cloud load balancing. This method improves load balancing by taking the best aspects of previous algorithms and improving them. It works remarkably well and responds quickly to commands, greatly reducing processing time. This DPBRR algorithm also plays an important role in improving cloud load balancing in many ways, including improving resource consumption, inefficiency, scalability, fault tolerance, cost optimization, and other aspects. Since it is a combination of algorithms, it may have its drawbacks, but its cloud computing enhancements are very useful for doing many tasks quickly. Strength and adaptability are quite effective, as is adaptability.**

***Keywords*—Load balancer; traffic distribution; cloud computing; resource utilization; scalability; Dynamic Priority Based Round Robin (DPBRR)**

I. Introduction

A cutting-edge paradigm in information technology, cloud computing marks a radical shift in the direction of the democratization of data access and decentralization of computational capacity. This cutting-edge technical framework breaks through conventional barriers by providing individuals and businesses with access to an infinite resource, from powerful computer power to endless storage. Cloud computing is a fascinating and amazing computing era that has replaced traditional methods. Cloud computing eliminates this necessity and offers services based on user demand and usage, in contrast to traditional computing, which requires users to maintain internal infrastructure. Users are spared from having to buy and maintain processing, storage, and other hardware. Through the internet, data is accessed and stored [1]. These days, cloud computing is essential because it offers pay-as-you-go on-demand services. To provide high-quality services, suppliers are taking advantage of service models like SaaS, PaaS, IaaS. Over the past five years, the public cloud computing markets have grown significantly, expanding by 21.5% [4].

Workload control is essential for load balancing problems since job arrival patterns are unpredictable and cloud node capacity varies. It also helps to preserve system stability. Schemes for load balancing can be either static or dynamic, depending on how essential System dynamics are [11]. Load balancing is a technique used in distributed systems to distribute the workload among multiple resources. As a result, there is an increase in scalability and effective resource usage. Multiple networked computing devices that collaborate are part of distributed systems. The need for efficient resource allocation grows as workload demand rises. This problem is solved by load balancing, which divides up incoming requests or tasks among the servers, virtual machines, or containers that are available. The task load is typically divided among several virtual machines (VM's) when using the load balancing technique. Without it, there could be SLA violations, assert wastage, execution corruption, and uneven burdens during server construction. Thus, employing an appropriate load balancing technique can enhance server utilization and provide more Quality of Service (QoS) assurance [12]. In a cloud environment, load balancing is accomplished in two steps: first the job is divided among the nodes; second, the virtual machine is monitored, and load balancing activities are carried out using task migration or virtual machine migration approach [5]. Load balancing in the cloud occurs in two stages: first, at the level of physical machines, where the load balancer distributes the load among the VMs connected to each physical device and manages the load of physical machines; second, at the level of virtual machines, where the load balancer manages and balances the load across all virtual machines using different LB algorithms [9].

The paper's content is organized as follows: Section II offers a comprehensive review of the literature on several key Load Balancing methods. In Section III, we review the current state of the art for the for DPBRR algorithm to enhance load balancing and introduce our proposed approach, to distribute tasks evenly among resources based on priority, the jobs with higher priorities will become more significant. We discuss the encryption process in detail. Section IV presents the results and a comparative analysis of our recommended methodology. A thorough explanation of the study paper's findings and closing thoughts is provided in Section V.

II. Literature Review

The research paper titled “A Hybrid Algorithm for Scheduling Scientific Workflows in Cloud Computing” by Muhammad Tahir, Muhammad sardaraz in the year 2019 [1] [10]. The authors put forth an algorithm that uses the PSO

*Corresponding Author.

algorithm to schedule scientific operations in two key stages: task preparation and task scheduling [23]. Throughout the scheduling process, the load balance of cloud resources is tracked by this hybrid method.

The research paper titled "Load balancing in cloud computing – A hierarchical taxonomical classification" by G Kavitha, S Afzal in the year 2019 [2]. It primarily categorized the many load balancing algorithm types with clarity and supplied details about the technique employed, the complexity of the algorithm, and its benefits and drawbacks. It primarily demonstrates the functionality and complexity of the load balancing algorithms, with task scheduling, virtual machine scheduling, and resource scheduling serving as the primary criteria. It also compares the algorithms' operational processes and provides percentages to help readers understand the algorithms, covering all the major LB algorithms.

The research paper titled "A Hybrid Bio-Inspired Algorithm for Scheduling and Resource Management in Cloud Environment" by Rajkumar Buyya, Ram Mohana Reddy G, Shridhar G D in the year 2020[3]. By combining modified CSO and PSO algorithms for job scheduling, the authors presented a hybrid with a bio-effect method for asset allocation. Compared to current scheduling and techniques, this algorithm aims to increase response time, reliability and resource utilization.

The research paper titled "A Hybrid Model for Load Balancing in Cloud Using File Type Formatting" by Adnan Sohail, M Junaid, Ahmed, H Alhakami, Imran Ali Khan, Abdullah Baz in the year 2020 [4]. The main goal is to use support vector machine (SVM) technology, which looks at the quantity and quality of files stored in the cloud. It works based on how well it manages processing speed and SLA.

The research paper titled "Dynamic load balancing algorithm for balancing the workload among virtual machines in cloud computing" by S C Sharma, Mohit Kumar in the year 2017 [5]. Cloud computing technologies are used to reduce waiting time and increase resource usage. Demonstrate that the suggested approach outperforms current algorithms regarding work allocation, workload monitoring and dynamic control. Incoming tasks are also assigned to the most appropriate virtual machine.

The research paper titled "A Load Balancing Algorithm for the Data Centres to Optimize Cloud Computing Applications" by Azween Abdullah, N Z Jhanjhi, M A Alzain, Dalia Abdulkareem Shafiq in the year 2021[6]. Increase cloud asset efficiency rate 78% relative to current traffic distribution algorithms to achieve decent performance and improve metrics. The proposed method prioritizes virtual machines (VMs) for workload scheduling, underutilization, and quality of service (QoS) balancing. The algorithm mainly focuses on optimizing IaaS cloud models to ensure high performance and minimize underload.

The research paper titled "Cloud Dynamic Load Balancing and Reactive Fault Tolerance Techniques: A Systematic Literature Review (SLR)" by A Yousif, M Bakri Bashir, T M Tawfeeg, Alzubair Hassan, Samar M alqhtani, Awad Ali, Rafik Hamza in the year 2022 [7]. To make cloud load balancing more efficient, the authors of this study focus on implementing fault management techniques along with real time workload management. Adaptive load distribution jobs are dynamically assigned to the virtual machine based on current state of the system. (VMs). In addition, a reactive failover method reacts to system failures to keep cloud services stable.

The research paper titled "Dynamic Resource Allocation Using an Adaptive Multi-Objective Teaching-Learning Based Optimization Algorithm in Cloud" by Mohammadreza Ramezanpour, R Khorsand, Ali Moazeni in the year 2023 [8]. The authors recommend a dynamic resource allocation based on the strategy of AMO-TLBO method. By dynamically allocating resources based on application capacity, this strategy saves costs and optimizes resource consumption. The algorithm has been greatly improved using web-based technology. In addition, the recommended strategy outperforms several popular algorithms such as NSGA-II, MOPSO and TLBO.

The research paper titled "Load Balancing in Cloud Environment: A State-of-the-Art Review" by Durgaprasad G, Yogesh Lohumi, M Zubair Khan, Prakash Srivastava, Abdulrahman in the year 2023 [9]. Efficiency, scalability and performance are negatively affected by the load imbalance that cloud computing constantly faces. This essay examines load balancing and improving service quality in an on-demand computing setting. In addition to explaining load balancing solutions, the taxonomy and classification of load balancing algorithms is discussed. A common well-solved problem was server load imbalance.

Finally, a better answer to cloud computing load balancing issues and resource allocation concerns is offered by load balancing algorithms that integrate dynamic priority-based round robin (DPBRR). Task distribution, resource allocation, and workload modification are increasingly important considerations when working with virtual machines. As a result of the round robin process, which distributes jobs among the available virtual machines in a cyclic fashion to give each VM an equal chance, the priorities are dynamically changed in response to workload patterns. Its fault tolerance and high adaptability allow it to function as a reliable balancing load technique in environments of cloud computing by dynamically reallocating and redistributing resources to VMs with lower priority when any VM becomes overwhelmed.

The table highlights the drawbacks of each methodology and limitations. The proposed load balancing algorithm combines the dynamic nature with a priority based round robin algorithm offers a better solution for scalability, resource allocation, task distribution, fault tolerance and more, this can improve the balancing load in cloud environments.

The Table I provides a literature review on existing methodologies for enhancing balancing of load in virtualized computing environments. It provides a comparison of different algorithms, including Improved WRR, PMHEFT, CMODLB, Dynamic load balancing algorithms, SARM, MOABCQ and more.

TABLE I. LITERATURE REVIEW ON EXISTING METHODOLOGIES

III. PROPOSED METHODOLOGY

In this section, we will go over how to enhance load balancing to guarantee cloud computing in this section [18] [19]. Improving application performance through faster response times and lower network latency is the primary goal shared by all users. The suggested method is applied to enhance load balancing performance to resolve this issue. This section describes the methods to make load balancing better.

In Fig. 1, the algorithm of load balancing starts by initializing the distributed system and carefully determining the nodes and their capacity as well as the tasks executed on every node. The load balancing algorithm begins by setting up the distributed system and then calculating the nodes and their capacity together with the tasks that are on each node. When the system detects the disparities in workload distribution load balancing is activated before the activation of load balancing it must meet the set of conditions or its threshold value. The process of monitoring the task priorities, workloads and system status continues with the emphasis on gathering information on resource usage and other metrics. Tasks are distributed according to predetermined standards, which can be critical or urgent, which means that priority tasks are processed in a balancing load procedure. An algorithm is then introduced to analyze the workload of each node to account for prioritized tasks and computing load. Considering the priorities of the tasks and the general load of the system, the purpose of this decision process is to compare the current state of the given system with the set thresholds or requirements. Tasks are chosen for migrations considering the current workload distribution and task priorities, aiming to transfer less important tasks from nodes with high load to nodes with low load. Tasks should be selected for migration based on the current workload distribution and task priorities so that less important tasks can be moved from burdened nodes to less burdened nodes. A relocation strategy is formulated, so that the tasks are migrated along with their priority information intact, and that could involve tasks segmenting or transferring them in their entirety. Communication among the nodes involved in the migration process guarantees the process is done effectively so that the data and state information are transferred smoothly. Tasks' execution on target nodes obeys their priorities. There is ongoing monitoring of the system responses to the load balancer. Based on the results, necessary changes are made in the balancing load strategy. The feedback medium is set to continue to ameliorate the cargo balancing strategy by conforming to dynamic system conditions and returning to the regulator when necessary. Eventually, the termination condition, which is either balancing load or reaching a system stability thing, decides when the algorithm stops working.

A. Proposed DPBRR Algorithm

Initialization: Count the number of nodes in the distributed system, then also the capacities of the nodes and the tasks that are running on each node. Establish a threshold or set of requirements to kick off load balancing once imbalances are discovered.

1) Monitoring: Monitor the workload, tasks priorities and system status around the clock. Find out the data on resource utilization and other important indicators.

2) Task prioritization: Tasks should be sorted according to the priority levels that are defined beforehand such as criticality, importance, or urgency. While balancing load, tasks with more priority should be given preference.

3) Load evaluation: Look at the workload on each node at the instant, considering the priorities of the assigned tasks and the load of the computations.

4) Decision making: Evaluate the necessity of load balancing by comparing the current condition of the system with the previously defined boundaries or limitations. Involve yourself in the decision-making process by considering both task priorities and the overall burden.

5) Task selection: Ascertain which jobs need to be transferred in agreement with the current load allocation and their priorities. Firstly, the movement of less significant tasks from overworked to underworked nodes should be given the highest priority.

6) Migration strategy: Create a task migration plan which should be done with the consideration of priority information. Such a division of labor could be achieved by breaking the task into smaller pieces or by shifting the entire task.

7) Communication: Let know the concerned nodes about the migration plan. Ensure that all the required data and state information is transferred without a glitch.

8) Task execution: Ensure the priority of the assigned priorities when performing the migrated tasks on the target nodes. In addition, monitor the system's reaction and adjust as required.

9) Feedback loop: Design a feedback mechanism that allows for the continuous adjustment of the load-balancing strategy as the system adapts. Repeat the method and return to the observation step.

10) Termination condition: Give the algorithm a stop condition. It might be based on attaining a predetermined degree of load balance, system stability or other specific requirements.

Algorithmic steps for the proposed DPBRR Algorithm

```
Step 1: Develop the Task Priority Queue where each task has priority level.
Step 2: Implement the Round Robin server list by yourself.
Step 2.1: Each server receives a unique server ID.
Step 2.2: To start the process, the CSI (Current Server Index) must be set to 0.
Step 3: The Receive Incoming Requests and Tasks step is the most important step.
Step 3.1: If the task is a high priority, then put it into the priority queue and check whether the resources are available or not.
Step 4: Monitor the Priority Queue and the resources availability all the time.
Step 4.1: Work on the server assigned to you to complete the task and check the status of the task from time to time.
Step 5: When the job is done, disconnect from the server or resource.
Step 5.1: If there are any outstanding high-priority tasks in the Priority Queue, direct the next available server to the highest-priority task.
Step 6: After the high-priority tasks are completed, servers get distributed to lower-priority tasks in Round Robin manner.
Step 6.1: Therefore, we must increase the CSI (server index) while considering resource availability and fairness.
Step 7: Keep an eye on the status of the newly arrived tasks, resource availability, and task completions.
Step 8: Create the termination conditions and terminate the algorithm when the termination criteria are fulfilled.
```

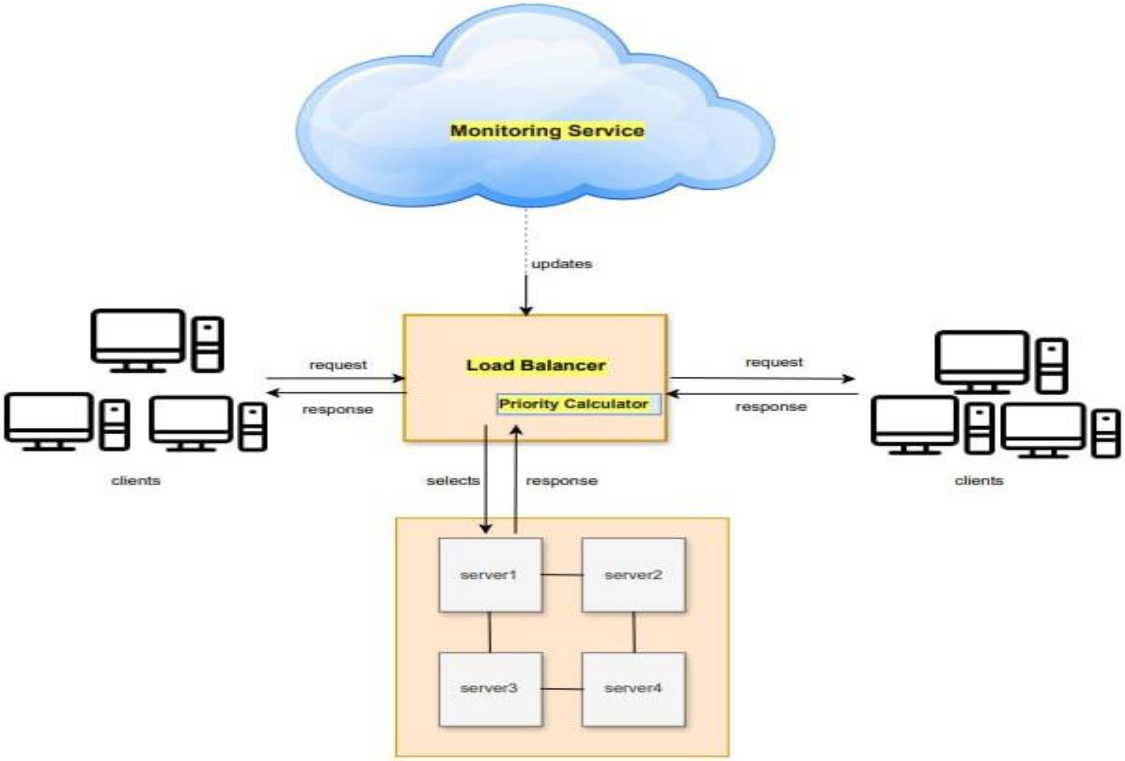

Fig. 1. A Proposed architecture for DPBRR algorithm to enhance load balancing.

- p be the priority
- a be the priority importance
- b be the resource that is available
- c be the load on the system
- q be the index of the resource
- s be the starting index
- j be the particular priority
- T be the total available resources
- Np be the new priority = Np
- Op be the old priority = Op

a) Priority Assignment Equation:

$$p = \alpha * a + \beta * b + \gamma * c$$

b) Task Distribution Equation:

$$q = (s + \Sigma(j)) \% T$$

c) Load Balancing Adjustment Equation:

$$Np = Op + \Delta p$$

These formulas will demonstrate how to compute the available resources, task allocation, and priority factors. When DPBRR applies the equation to distribute tasks evenly among resources based on priority, the jobs with higher priorities will become more significant. Tasks are dynamically altered, and priorities are modified based on changes in priorities as determined by the equations. These suggested equations will aid in effective resource usage and balanced workload distribution within the system.

IV. Result Analysis

This paragraph presents the suggested load-balancing technique as well as experimental results for various load-balancing algorithms. Several parameters are taken into consideration when analyzing it, such as throughput, response time, and resource usage. Existing methods like CMODLB, Kuhn-Munkres, and improved WRR were taken into consideration. As given below.

A. Throughput, Response Time, and Resource Utilization

The amount of material or items passing through a system or process is called throughput, The amount of time taken by a system to respond to a request or input is called Response Time, the efficiency in using the resources is called Resource Utilization, Analysis of CMODLB, Kuhn-Munkres, Improved WRR and proposed DPBRR in Table II, Table III and Table IV.

TABLE II. Computational Throughput Analysis of DPBRR vs. Conventional Algorithms

S.No	Algorithms	Throughput (requests/second)
1	Improved WRR	900 tasks/s
2	Kuhn-Munkres	950 tasks/s
3	CMODLB	980 tasks/s
4	DPBRR	1000 tasks/s

Here, it explores how DPBRR can more efficiently raise the throughput value than other algorithms.

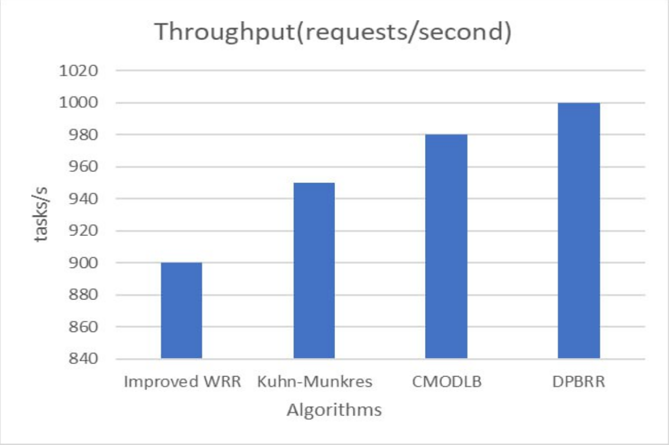

Fig. 2. Computational throughput analysis of DPBRR vs conventional algorithms.

Fig. 2 shows how DPBRR achieves a perfect spectrum since it is faster than other algorithms like Improved WRR, Kuhn-Munkres, CMODLB with a Throughput over 1000 tasks/second. The multi-node adaptive priority-oriented scheduling of this algorithm likely optimizes the resource allocation, with the consequent minimization of latency and improvement in throughput. This benefits DPBRR as businessmen's preferred compute tool in cases where fast processing, well-timed response, and request handling are taken as top priorities, hence, we are distinguishing it as the most efficient algorithm from the others.

Here, it explores how DPBRR can more efficiently decrease the Response time value than other algorithms.

TABLE III. Computational Response Time of DPBRR vs. Conventional Algorithms

S.No	Algorithms	Response Time (milliseconds)
1	Improved WRR	60ms
2	Kuhn-Munkres	55ms
3	CMODLB	52ms
4	DPBRR	50ms

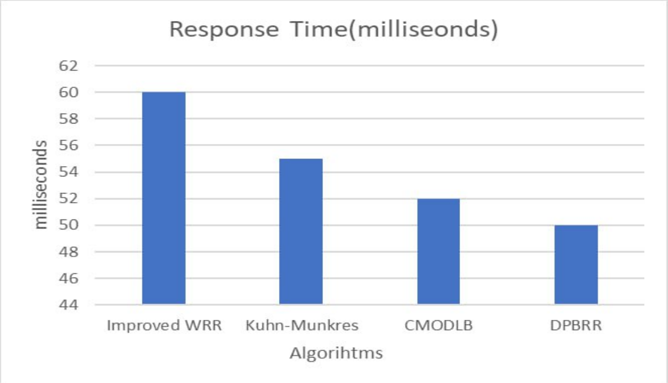

Fig. 3. Computational response time of DPBRR vs. conventional algorithms.

In analyzing the response times of various algorithms from Fig. 3, it is apparent that DPBRR emerges as the most efficient choice. When comparing the reaction times across different algorithms, DPBRR stands out as the most effective option. While Improved WRR exhibits a response time of 60 milliseconds, DPBRR demonstrates a significant improvement with a response time of only 50 milliseconds. Both Kuhn-Munkres and CMODLB show enhancements over Improved WRR, with response times of 55 and 52 milliseconds, respectively. However, DPBRR surpasses them all, showcasing its remarkable ability to handle requests swiftly and minimize system latency. This outstanding performance underscores DPBRR's suitability for scenarios where quick reaction times are crucial, establishing it as the optimal algorithm for maximizing system performance and ensuring prompt request processing.

Here, it explores how DPBRR can more efficiently optimize the Resource utilization value than other algorithms.

TABLE IV. RESOURCE UTILIZATION OF DPBRR VS. CONVENTIONAL ALGORITHMS

S.No	Algorithms	Resource Utilization (%)
1	Improved WRR	75%
2	Kuhn-Munkres	78%
3	CMODLB	72%
4	DPBRR	80%

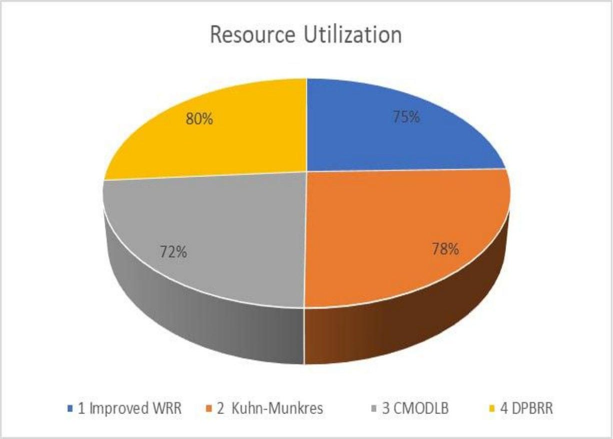

Fig. 4. Resource utilization of DPBRR vs conventional algorithms.

From Fig. 4, the comparisons of resource usage of different algorithms show trends in their effectiveness. The improved WRR consumes resources of 75%, while Kuhn-Munkres raises to 78%. But from the listed algorithms CMODLB has the highest resource consumption of all other algorithms. DPBRR manages to maintain a respectable 80% utilization rate by striking a compromise between resource efficiency and performance. It efficiently optimizes resource allocation and achieves competitive performance. DPBRR is a great option where increasing performance while optimizing resource utilization is crucial because of its balanced resource usage. It manages the system resources even though it does not have the lowest utilization rate.

V. CONCLUSION

In conclusion, the study of Dynamic Priority-Based Round Robin (DPBRR) load balancing is a useful way to solve the important problem of efficient load management in cloud computing settings. DPBRR aims to reduce response time and maximize resource utilization by implementing a dynamic adaptive mechanism that intelligently distributes work across cloud servers. Because DPBRR can dynamically adjust task priorities in response to real-time data, it is particularly useful for workload fluctuations and changing resource demands. Using advanced load balancing technology in virtualized computing, dynamic priority derived from Round Robin is a significant step forward in managing workload imbalances in distributed systems. The recommended approach shows cloud computing load balancing solutions with better performance and economy. By implementing several techniques, DPBRR helps reduce congestion and improve system flexibility and adaptability. The DPBRR study offers a functional and effective way to improve system performance and resource allocation in cloud services, solve important problems, and soon open the door for further developments.

Enhancing BLDC Motor Speed Control by Mitigating Bias with a Variation Model Filter

Abdul Rahman Abdul Majid*
Dept. of Electrical & Computer Engineering-College of Engineering, University of Sharjah, Sharjah, UAE

***Abstract*—Brushless DC motors (BLDC) are integral to a wide array of applications, from electric vehicles to industrial machinery, due to their superior efficiency, reliability, and performance. Effective control of BLDC motors is essential to leverage their full potential and ensure optimal operation. Traditional PID controllers often fall short in handling the nonlinear and dynamic characteristics of BLDC systems, while advanced methods like Active Disturbance Rejection Control (ADRC) introduce additional complexity and cost. This research proposes a Variation Model Filter (VMF) based control system that estimates and compensates for the total bias arising from parameter variations and internal uncertainties. This method simplifies the control process, enhances robustness, and boosts performance without requiring extensive parameter tuning or high costs. Additionally, the paper provides a comprehensive mathematical model for the speed dynamics of BLDC motors. Simulation results based on MATLAB/Simulink indicate that the VMF-based PID control system surpasses both linear ADRC and traditional PID controllers in managing speed dynamics and responding to load disturbances. This approach offers an efficient and cost-effective solution for BLDC motor speed control, with significant potential for broader application and further optimization in motor control systems.**

Keywords*—EV's motors; brushless direct current (BLDC) motor; active disturbances rejection control (ADRC); disturbance rejection; bias estimation; Variation Model Filter (VMF)

I. Introduction

Recent advancements in magnet technology have significantly enhanced the performance and efficiency of brushless DC (BLDC) motors, especially those using permanent magnets. These improvements have driven the growing preference for BLDC motors in various applications due to their high power density and energy efficiency [1]. Unlike their brushed counterparts, BLDC motors provide reliable and smooth operation, precise speed control, and reduced electrical noise, making them ideal for dynamic uses such as robotics and automation [2], [3]. In the electric mobility sector, BLDC motors are increasingly chosen for eco-friendly vehicles, including electric cars, scooters, and urban air transport [3]. Additionally, traditional ceiling fans that typically use split-phase induction motors (SPIMs) are now adopting BLDC motors to benefit from better energy efficiency and voltage regulation [4]. BLDC motors are poised to replace traditional induction motors in various industries, such as automotive, pumping, and rolling, by 2030 due to their superior torque, low noise, simplicity, and ease of maintenance [2]. The market for BLDC motors is expected to grow significantly, reaching an estimated value of 15.2 billion USD by 2025 [2].

Despite these advantages, BLDC motors face challenges, such as limited fault tolerance, high electromagnetic interference, acoustic noise, and torque ripple. They operate as complex, multivariable systems with load perturbations and parameter variations, leading to significant current ripple due to factors like armature reaction and phase conversion. To address these issues and enhance BLDC motor performance, researchers have focused on three main areas: motor material and structure, power electronics and drive circuit topologies, and control systems. Recent advancements in motor design include the development of the spherical brushless DC (SBLDC) motor [3], while innovations in power electronics, such as the switched-inductor Zeta active power factor correction converter (SI-ZS-APFC) [4] and phase current overlap time limiting cell (PCOTLC) [5], have significantly reduced torque ripple. Control systems remain critical for BLDC motors, as they manage the motor's operation and ensure the effectiveness of other enhancements.

Two primary control strategies are used for BLDC motor systems: scalar and vector controllers [2]. Scalar controllers include methods like Proportional-Integral-Derivative (PID), Linear Quadratic Regulator (LQR), and Active Disturbance Rejection Control (ADRC). Vector controllers encompass techniques such as Field-Oriented Control (FOC), Direct Torque Control (DTC), and intelligent methods like Particle Swarm Optimization (PSO) and Model Predictive Control (MPC). Among these, PID controllers are popular in industrial applications due to their simplicity and ease of implementation. However, PID controllers struggle with the nonlinear and dynamic nature of BLDC systems, often resulting in suboptimal performance as they are designed for linear systems and cannot handle rapid parameter changes or load disturbances effectively [1], [2], [6].

Vector control methods, including FOC and DTC, and intelligent techniques like PSO and MPC, offer improved dynamic performance and reduced torque and flux ripples. However, they also introduce higher structural and computational complexity. The literature on BLDC motor controllers lacks comprehensive surveys that compare these advanced control schemes, especially in terms of fault tolerance and reducing electromagnetic interference [2]. ADRC, particularly its linear version (LADRC), offers a balance between simplicity and performance. It estimates and compensates for total disturbances using the Extended State Observer (ESO), making it robust against both internal and external perturbations without relying on specific system models [7], [8].

ADRC, introduced by Jingqing Han in the 1990s and further refined into its linear form (LADRC) by Zhiqiang Gao [9], [10] simplifies parameter tuning and implementation for both Single-Input Single-Output (SISO) and Multi-Input Multi-Output (MIMO) systems. While LADRC is easier to implement, it may not perform as well as the nonlinear version (NLADRC) in complex, nonlinear systems. To bridge this gap, researchers have combined LADRC with artificial neural networks for nonlinear state-error feedback control (SEFC) and used intelligent techniques, like genetic algorithms, for optimal parameter tuning [8], [11]. Also, the authors in study [8] proposed to use neural-network as nonlinear SEFC and linear ESO to estimate the total disturbance, they proposed an intelligent version of ADRC (IADRC). Applications of ADRC in BLDC motor control demonstrate its capability in managing speed and current effectively [7], [12].

The study in [13] asserts that PID controllers are adequate for BLDC motor speed control, comparing them with PI and Fuzzy Logic Controllers (FLC). However, their conclusions are limited due to the absence of analysis on load disturbance response, a critical factor in real-world applications. Moreover, the study did not benchmark PID against robust controllers like Active Disturbance Rejection Control (ADRC), focusing only on traditional methods. The PID gains were also unusually high, questioning their cost-effectiveness and practical applicability. In contrast, research in [7] and [12] highlights more resilient approaches using nonlinear and linear ADRC, offering superior disturbance rejection and robustness, thus better addressing the nonlinear and dynamic challenges in BLDC motor systems.

Nevertheless, ADRC, including its linear form, faces challenges such as estimation errors in total disturbances and uncertainty in system parameters, which can impact control gains and lead to noise amplification [14]. In industrial applications, especially with available mathematical models and adequate sensors, simpler solutions like Disturbance Observer Based Control (DOBC) may suffice. Research suggests that DOBC can outperform ADRC in certain conditions due to its simpler design process [15].

This paper aims to enhance the robustness of PID control for BLDC motors by introducing a Variation Model Filter (VMF)-based approach. Unlike traditional PID controllers, which often require high gain settings and struggle with load disturbances and system uncertainties, the VMF method estimates the total bias within the system. This bias accounts for energy variations caused by parameter changes, internal uncertainties, and external disturbances. By compensating for these factors using a robust control law based on output variations from the desired response, the VMF-enhanced PID control demonstrates superior performance. Simulation results indicate that this new approach not only surpasses traditional PID controllers but also outperforms linear Active Disturbance Rejection Control (LADRC) in managing BLDC motor dynamics effectively.

The paper is structured as follows: Section II provides a detailed mathematical model of the BLDC motor. Section III introduces the VMF approach. Section IV presents simulation results, and Section V concludes the paper.

II. Problem Formulation

To model the voltage in a three-phase BLDC motor, we start with the voltage equation for each winding. This relationship between voltage, current, and back EMF is given by:

$$\begin{bmatrix} v_a \\ v_b \\ v_c \end{bmatrix} = \begin{bmatrix} R_a & 0 & 0 \\ 0 & R_b & 0 \\ 0 & 0 & R_c \end{bmatrix} \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} + \begin{bmatrix} L_a & L_{ab} & L_{ac} \\ L_{ba} & L_b & L_{bc} \\ L_{ca} & L_{cb} & L_c \end{bmatrix} \begin{bmatrix} \frac{di_a}{dt} \\ \frac{di_b}{dt} \\ \frac{i_c}{dt} \end{bmatrix} + \begin{bmatrix} e_a \\ e_b \\ e_c \end{bmatrix} \tag{1}$$

To simplify the modeling of a BLDC motor, several key assumptions are typically made. First, the stator windings are designed as full-pitch windings with a 60-degree phase belt. The air gap magnetic field is assumed to have a trapezoidal distribution with a flat top spanning 120 electrical degrees. We also disregard effects like slot impact, magnetic circuit saturation, magnetic hysteresis, eddy current loss, skin effect, and temperature influence on motor parameters.

Further simplifying, we consider the reluctance between the stator and rotor to be negligible, allowing us to set ; $L_{ab} = L_{ac} = L_{ba} = L_{bc} = L_{ca} = L_{cb} = M$.The three-phase windings are Y-connected and assumed to be symmetric, leading to $R_a = R_b = R_c = R$; $L_a = L_b = L_c = L$; and the condition $i_a + i_b + i_c = 0$; $Mi_b + Mi_c = -Mi_a$. Additionally, mechanical losses and other incidental losses of the motor are not taken into account.

Based on these assumptions, especially the symmetry in windings and negligible reluctance, the voltage equation simplifies to:

$$\begin{bmatrix} v_a \\ v_b \\ v_c \end{bmatrix} = \begin{bmatrix} R & 0 & 0 \\ 0 & R & 0 \\ 0 & 0 & R \end{bmatrix} \begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} + \begin{bmatrix} L-M & 0 & 0 \\ 0 & L-M & 0 \\ 0 & 0 & L-M \end{bmatrix} \begin{bmatrix} \frac{di_a}{dt} \\ \frac{di_b}{dt} \\ \frac{i_c}{dt} \end{bmatrix} + \begin{bmatrix} e_a \\ e_b \\ e_c \end{bmatrix} \tag{2}$$

To derive the current dynamics, we apply Kirchhoff's law to the BLDC motor's equivalent circuit, shown in Fig. 1.

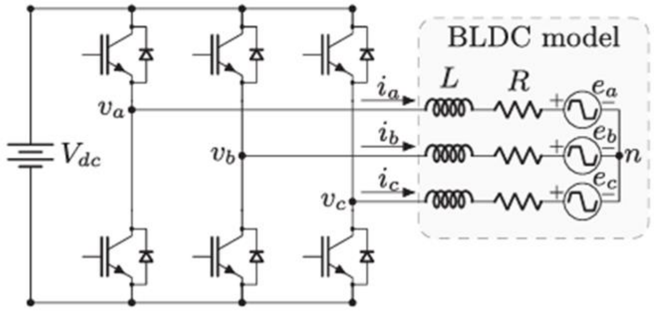

Fig. 1. BLDC motor equivalent drive circuit.

This gives us the following equation for the stator current:

$$\frac{di_s}{dt} = -\frac{R}{L-M} i_s + \frac{1}{2(L-m)} v_L - \frac{1}{2(L-m)} e_L \tag{3}$$

Here, i_s is stator current represents the stator current, while $v_L \in \{v_{ab}, v_{bc}, v_{bc}\}, e_L \in \{e_{ab}, e_{bc}, e_{bc}\}$ are the line-to-line voltage and back EMF, respectively, across different phases.

Given the assumptions about the stator windings and air gap magnetic field, and considering the current dynamic equation, it is feasible to control all three output currents with a single current controller. This leads us to a simplified first-order equation for the current dynamics:

$$\frac{di(t)}{dt} = f_1(i, d_e, t) + b_1 v \qquad (4)$$

In this equation, $f_1(.)$ encapsulates all uncertainties and disturbances in the current dynamics, with d_e representing electrical disturbances in the system given by $d_e = -\frac{1}{2(L-m)} e_L - \frac{R}{L-M} i_s$. The term b_0 is the nominal input gain for current control, equal to $\frac{1}{2(L-m)}$.

Next, we examine the electromagnetic torque, which results from the interaction between the stator winding currents and the rotor's magnetic field. This torque is defined as $T_e = \frac{e_a i_a + e_b i_b + e_c i_c}{\omega_m}$, where ω_m is the rotor speed. Assuming that all the electromagnetic power is converted into rotor kinetic energy, the power equation can be simplified to $P_e = T_e \omega_m$. At steady state, this power can be further expressed as $P_e = \frac{2E_s I_s}{\omega_m} = k_t I_s$. In this context, E_s represents the opposing electromotive force, I_s is the steady-state phase current (max amplitude), andk_t is the motor torque coefficient.

The mechanical movement of the BLDC motor is described by the following equation, which balances the generated torque T_e and the load torque T_L:

$$T_e - T_L = \frac{J d\omega_m}{dt} + B\omega_m \qquad (5)$$

where J denotes the rotary inertia, and B is the damping coefficient. By differentiating this equation and integrating the electromagnetic torque, we derive the second-order speed dynamic equation:

$$\ddot{\omega}_m = \frac{k_t}{J}\frac{di}{dt} - \frac{1}{J}(\dot{T}_L + B\dot{\omega}_m) \qquad (6)$$

Rewriting it more compactly, we get:

$$\ddot{\omega}_m = f_2(\omega_m, d_m, t) + b_2 \frac{di}{dt} \qquad (7)$$

Here, $f_2(.)$ encompasses all uncertainties and disturbances affecting the speed dynamics, with d_m representing mechanical disturbances. The term b_2 is the nominal input gain for speed control, equal to $\frac{k_t}{J}$.

Combining the inner and outer control loops, we propose a comprehensive second-order dynamic model for the BLDC motor speed. By substituting the current dynamics into the speed dynamics, the resulting equation is:

$$\ddot{\omega}_m = f_t(f_1, f_2) + b_0 u(t) \qquad (8)$$

In this final equation, $f_t(.)$ aggregates all the electrical and mechanical uncertainties and disturbances, defined as $f_t = b_2 f_1 + f_2$. The nominal input gain b_0 is given by $b_0 = b_1 b_2 = \frac{k_t}{2J(L-M)}$. The Eq. (4) and Eq. (8) highlight that controlling a BLDC motor involves managing a multi-loop system with an inner loop for current regulation and an outer loop for speed control, as shown in Fig. 2.

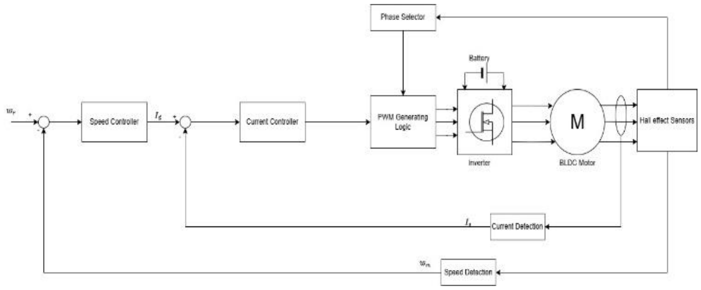

Fig. 2. BLDC motor complete system.

In controlling the speed of BLDC motors, the ADRC framework typically relies on the dynamic equation similar to Eq. (7), where an Extended State Observer (ESO) estimates and compensates for total disturbances primarily in the mechanical domain and some internal uncertainties [7], [12]. However, traditional ADRC designs often overlook electrical disturbances in the current loop, leading researchers to propose a dual-loop ADRC system [12]: one loop for managing electrical disturbances in the current and another for handling mechanical disturbances in the speed. This dual-loop approach provides a more holistic control but adds complexity. Conversely, the bias rejection strategy simplifies the process by focusing only on disturbances and uncertainties that directly impact the dominant state, termed "total bias." This technique, rather than estimating all potential disturbances, concentrates on the most significant ones, making it faster, more cost-effective, and reliable by addressing only the critical issues affecting the system's performance.

III. VARIATION MODEL FILTER (VMF)

To estimate bias accurately in a system, it's essential to develop a mathematical technique that uses a variation function for approximation. This approach involves employing a continuous approximation method based on integral transform to effectively determine and estimate the total bias. The continuous approximation can be expressed through the integral transform:

$$g(s) = \int k(s,t) f(t) dt \qquad (9)$$

Here, $g(s)$ represents known information that might be influenced by noise, while $k(s,t)$ is the kernel function, and s indicates a specific domain. The unknown function $f(t)$ needs to be solved or approximated. In control applications, the system typically operates within defined constraints and spatial domains, making the first kind of Fredholm integral equation suitable:

$$\int_a^b k(s,t) f(t) dt = g(s), \quad c \le s \le d \qquad (10)$$

In this context, $g(s)$ is given within the range $[c, d]$, which may differ from the integral's range $[a, b]$. The kernel function basis technique is often used to smooth and regularize noisy data, minimizing errors over the approximation space. For example, if $f \in L_2[0,1]$, the Riesz representation theorem guarantees a function $\eta_s(t) \in L_2[0,1]$ such that:

$$\int_0^1 \eta_s(t) f(t) dt = \langle \eta_s, f \rangle,\ s = s_1, s_2, \dots, s_n \quad (11)$$

Thus, $\eta_s(t) = k(s,t)$, indicating an appropriate basis can be deduced, and $f(t)$ can be approximated by:

$$f^*(t) = \sum_{i=1}^{n} a_i \eta_s(t) \quad (12)$$

To approximate the total bias in a control system, which represents the unwanted energy within the closed-loop system, leading to output variation from the desired value, we use the general continuous approximation method:

$$N(\delta f, x) = \int k(x,t) \delta f(t) dt \quad (13)$$

Here, $N(\delta f, x)$ is a nonlinear function representing the system's closed-loop output, $k(x,t)$ is the kernel function, and $\delta f(t)$ is the total bias to be estimated. Given engineering applications' spatial and constraint assumptions, the Fredholm integral of the first kind and the Riesz representation theorem provide suitable frameworks. Thus, we propose a linear method for bias estimation:

$$\delta f(t) = \sum_{i=1}^{n} a_i k(x_i, t) = \sum_{i=1}^{k} c v_i(t) = c \sum_{i=1}^{k} v_i(t) (14)$$

This assumes $\delta f(t)$ can be approximated by a finite set of basis functions $v_i(t)$.We can rewrite this method as:

$$\delta f(t) = cV(t) \quad (15)$$

Where $V(t)$ represents the system's total variation, summing all basis functions or a suitably chosen function that provides variation information, and c relates to the regularization gain to enhance robustness. The selection of basis functions is crucial; practical applications often benefit from intuitive and knowledge-based techniques rather than purely mathematical solutions. For dynamic system input smoothing, we use a constant regularization:

$$c = \frac{c_0}{\hat{b}} \quad (16)$$

Where c_0 is a positive constant and $\hat{b}$ is the approximated input gain. The bias estimation method using the operator form in Eq. (15) requires two types of information to find the variation function: global (general) discrepancy and smoothed (processed) discrepancy. These discrepancies reflect how the output deviates from the desired value, providing insights into the variation function. The global discrepancy $n_g(t)$ is calculated as:

$$n_g(t) = y_p(t) - y_m(t) \quad (17)$$

Where $y_p(t)$ is the system's original output and $y_m(t)$ is the reference model or observer output. The smoothed discrepancy $n_s(t)$ is found by filtering or smoothing the actual plant and model outputs:

$$n_s(t) = z_p(t) - z_m(t) \quad (18)$$

Here, $z_p(t)$ and $z_m(t)$ are the filtered outputs of the plant and model, respectively. The variation function $V(t)$ is then approximated as:

$$V(t) = n_g(t) + n_s(t) \quad (19)$$

In summary, variation reflects output deviation due to unwanted energy (bias) in a system. In a closed-loop system, bias arises from varying parameters, uncertainties, noise, and coupling states. The variation model captures this as a function, which serves as a basis to estimate and compensate for the total bias within the system, thereby improving control performance. Fig. 3 shows the Variation Model Filter.

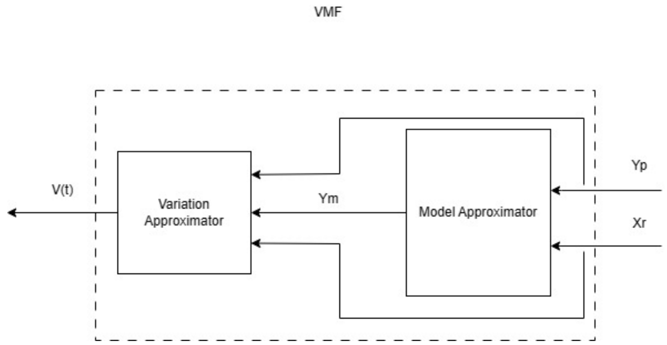

Fig. 3. Variation Model Filter (VMF).

IV. Simulation Results and Discussion

To demonstrate the effectiveness of the proposed control technique, the system was implemented using a MATLAB library example [16], showcasing the capabilities of an ADRC (Active Disturbance Rejection Control) system. This setup allowed for a practical comparison that users could replicate and test independently. The system parameters are listed in Table I, providing the necessary context for the implementation.

TABLE I. System Parameters

Parameter	Value
Number of pole-pair	4
Stator resistance R ($m\Omega$)	1
Self-inductance L (mH)	0.2
Mutual-inductance M (mH)	0.02
Moment of inertia J ($kg.m^2$)	2
Damping coefficient B ($N.\frac{m}{\frac{rad}{s}}$)	0.1
Load when implemented (Nm)	0.1

In Fig. 4, the MATLAB/Simulink model is presented for the speed control of a Brushless DC (BLDC) motor. This comprehensive setup is designed to evaluate and compare the performance of different control strategies. The model includes a block for the BLDC motor and two main controllers: Active Disturbance Rejection Control (ADRC) and Proportional-Integral-Derivative (PID). During testing, either the ADRC or PID controller can be activated to manage the system's response.

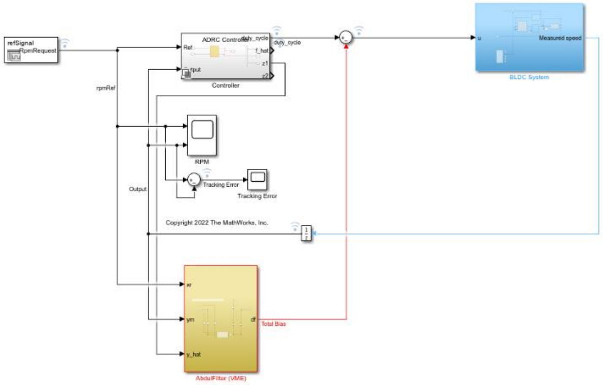

Fig. 4. Simulink Model for speed control of BLDC motor.

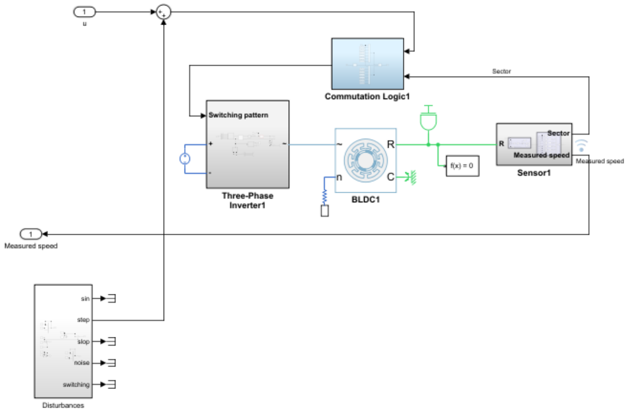

Fig. 5. BLDC motor system.

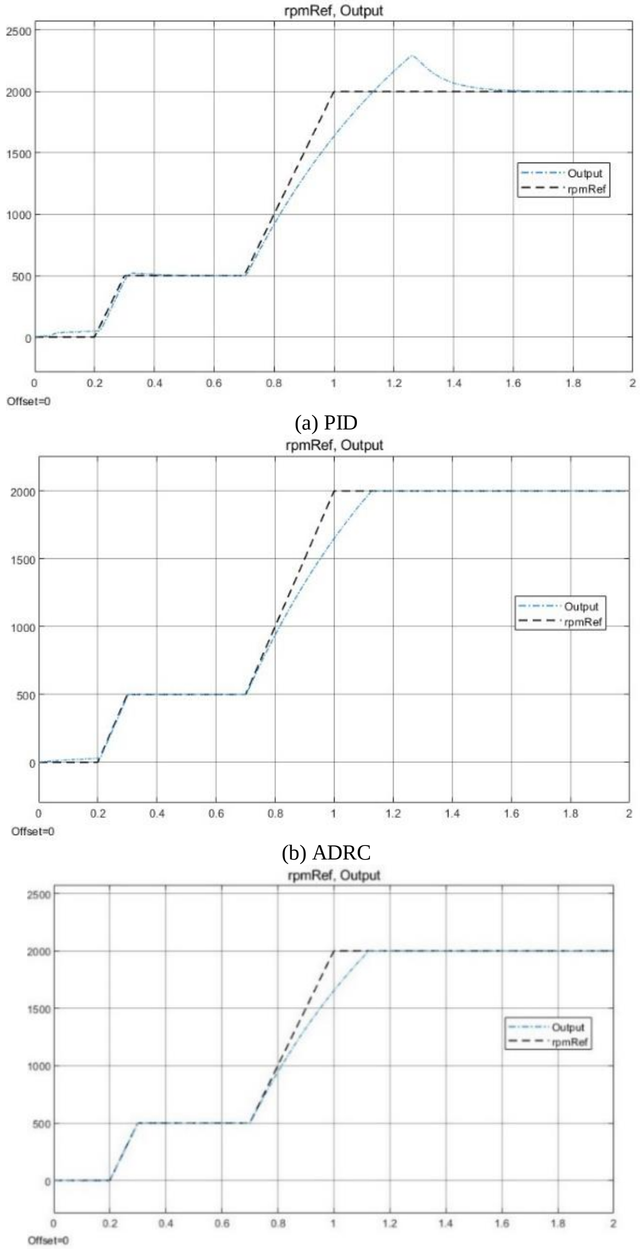
In Fig. 5, the internal structure of the BLDC motor block is delved within the model. This block encapsulates the dynamics and operational characteristics of the BLDC motor with drive circuit, commutation logic, sensor, and disturbance model, providing a detailed simulation environment for analyzing motor behavior under various control strategies.

The controller block in Fig. 4 is pivotal to the model. It includes both ADRC and PID controllers, where only one is activated at a time to control the motor. The ADRC controller uses an Extended State Observer (ESO) to estimate and counteract disturbances, thereby providing a robust control performance. The output of the ESO, denoted as $\hat{y}$ (in model called y_hat), serves as the reference model output. This output, along with the desired speed signal x_r and the actual motor output y_m feeds into the Variation Model Filter (VMF) block.

The VMF block plays a crucial role by comparing these inputs to estimate the total bias in the system. This estimated bias is then used to enhance the performance of the control system, ensuring accurate and reliable speed control of the BLDC motor.

This setup is essential for analyzing how the different controllers handle the nonlinearities and disturbances inherent in BLDC motor systems, ultimately demonstrating the effectiveness of the VMF-based control approach.



(a) PID

(b) ADRC

(c) VMF based PID

Fig. 6. Speed tracking performance without external load disturbances.

Fig. 6 illustrates the application of three different control strategies to manage the speed of a BLDC (Brushless DC) motor without external disturbances: conventional PID (Proportional-Integral-Derivative) control, ADRC, and PID with the Variable Mode Filter (VMF) technique. As seen in Fig. 6(a) and (b), the ADRC control system significantly outperforms the conventional PID controller. This advantage is due to ADRC's ability to estimate and reject all internal and external disturbances using an Extended State Observer (ESO), which captures these disturbances as "total disturbances”. However, in Fig. 6(c), the PID controller with VMF surpasses ADRC in terms of faster response and eliminating overshoot. Fig. 7 consolidates the performance of all three controllers, providing a single display for direct comparison under the same conditions.

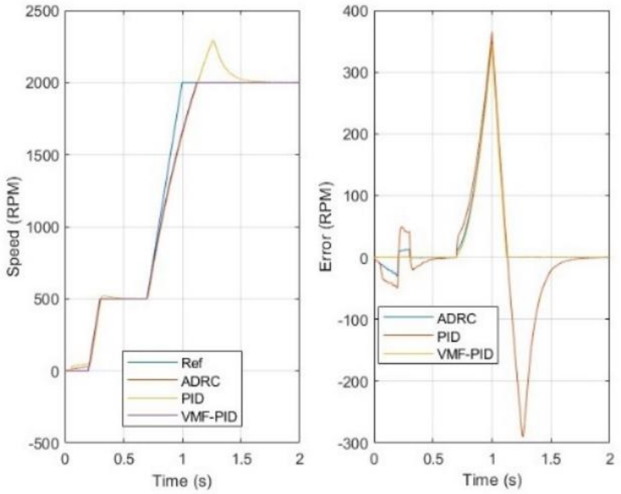


Fig. 7. Performance comparison without external disturbances.

The VMF-based approach, on the other hand, estimates the "total bias" or "discrepancy" in the system. This method simplifies the process by focusing solely on compensating for this total bias, thereby reducing complexity and cost. As illustrated in Fig. 6 and Fig. 7, the PID controller enhanced with VMF not only surpasses the conventional PID controller but also outperforms the ADRC controller in handling system discrepancies.

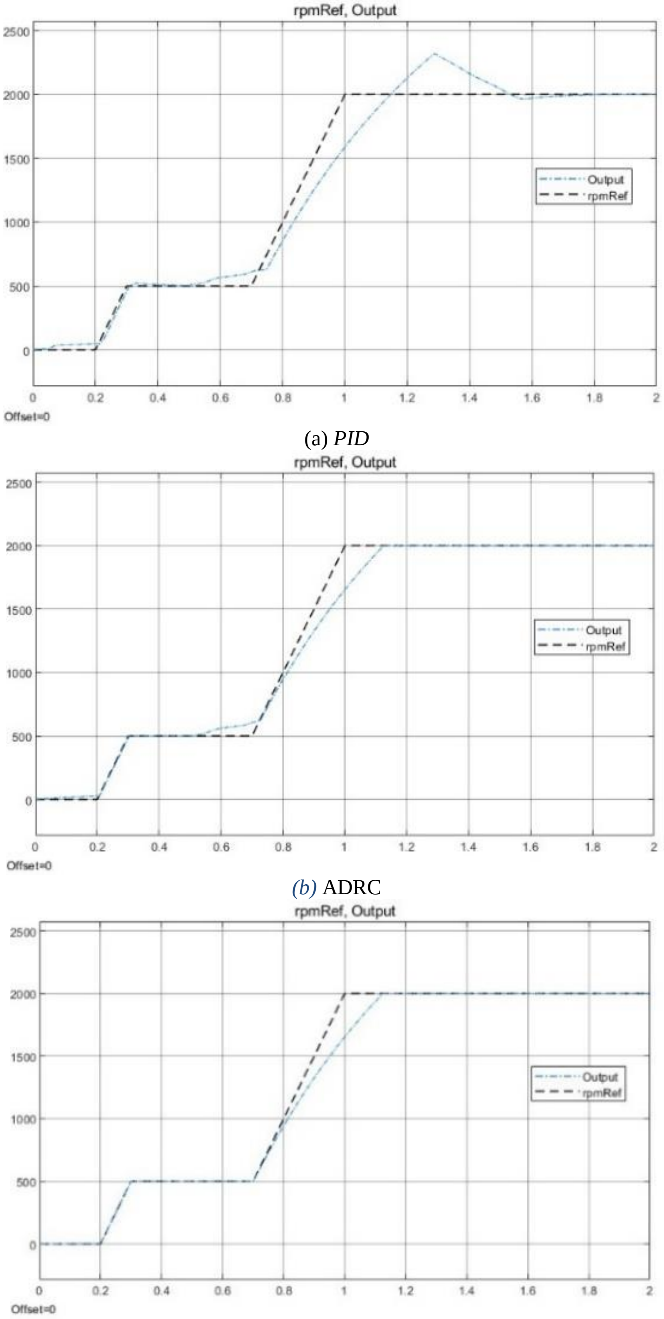
TABLE II. PERFORMANCE COMPARISON

Controller	Rise Time	Settling Time	Overshoot	Normalized MSE
PID	0.1778	0.5011	15.8180	0.0893
ADRC	0.1922	0.1095	0.0570	0.0381
VMF-PID	0.1901	0.1095	0.0058	0.0300

The robustness of these controllers is further evaluated under external disturbances. Table II highlights the performance differences when a load disturbance is applied, specifically observing the transient response as the motor speed changes from 500 rpm to 2000 rpm at 1 second. The comparison includes the normalized mean square error (NMSE), approximated to four decimal places, to quantify the differences among the controllers.

Fig. 8 showcases the speed tracking capabilities of the three control systems when a 0.1 Nm load is applied to the BLDC motor at 0.5 seconds, whereas Fig. 9 shows a performance comparison among them. The VMF-based PID (VM-PID) controller demonstrates superior performance, maintaining more consistent and robust control under load conditions compared to the ADRC controller and the conventional PID controller. This confirms that the VMF-enhanced PID approach is not only effective but also a more reliable solution for controlling BLDC motors, providing better handling of disturbances with less complexity.

Fig. 9 showcases the comparative performance of three different control systems—traditional PID, Active Disturbance Rejection Control (ADRC), and the proposed Variation Model Filter-based PID (VM-PID) controller—under the impact of external disturbances on the BLDC motor. The results indicate that the VM-PID controller significantly outperforms the ADRC and traditional PID controllers when faced with external perturbations. This superior performance is attributed to the VMF's ability to estimate and reject the total bias within the system. By integrating the VMF into the PID controller, it compensates for variations, uncertainties, and disturbances, thus dramatically enhancing the robustness and effectiveness of the traditional PID approach without the complexity associated with ADRC.



(a) *PID*

(b) ADRC

(c) *VMF based PID*

Fig. 8. Speed tracking performance with external load disturbances at 0.5s.

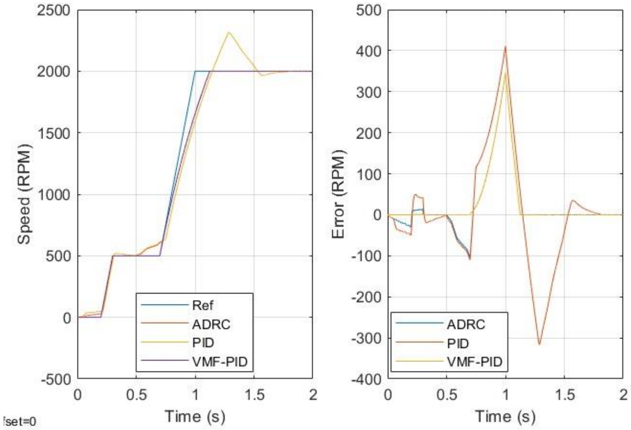


Fig. 9. Performance comparison with external disturbances.

The VM-PID controller's ability to manage and mitigate the effects of external disturbances suggests a promising enhancement over traditional PID control. The VMF allows the system to adapt dynamically to changes and disturbances by continuously estimating and adjusting for the total bias. This makes the VM-PID not only more robust but also simpler and more cost-effective compared to ADRC, which, although effective, requires complex tuning and higher implementation costs. This finding opens up an exciting avenue for further research: the integration of VMF with ADRC. Combining the bias estimation and compensation strengths of VMF with ADRC's adeptness at managing system uncertainties and disturbances could lead to a highly efficient, robust, and adaptive control system for BLDC motors and other applications.

Looking ahead, exploring a hybrid VMF-ADRC approach could provide significant improvements in motor control systems and other robotics systems. Such a combination could leverage the simplicity and robustness of the VMF-based bias compensation with ADRC's sophisticated disturbance rejection capabilities. This integration could result in a control system that not only handles complex dynamics and external disturbances more effectively but also reduces the need for extensive parameter tuning such as nonlinear ADRC cases. Future research could focus on developing and optimizing this hybrid control strategy, potentially setting a new standard for BLDC motor control in applications where both performance and robustness are critical.

It is worth mentioning, that the total bias is related to the dominant states. This means only focusing on the dominant state such as output and estimating anything that affects to those states and this kind of limitation for this technique. Thus, combining this technique with disturbances estimation techniques will dramatically improve the performance of control systems. Thus, it is suggested that in future work combining VMF with ADRC to propose a very robust control system.

In conclusion, the results and comparisons demonstrate the superiority of the VMF technique over traditional methods. The advantages of this approach include:

1) It is a completely model-free method, requiring no prior knowledge of the system model.

2) It enhances both the response and robustness of control systems.

3) The technique is simple to implement and does not require extensive parameter tuning.

V. Conclusion

In conclusion, this paper provides a comprehensive comparative study of control techniques for brushless DC (BLDC) motors, emphasizing a new method based on the Variation Model Filter (VMF). BLDC motors are increasingly popular across various applications due to their high efficiency and performance, necessitating effective control mechanisms to handle their complex dynamics. Traditional PID controllers often struggle with the nonlinear and time-varying characteristics of BLDC systems, resulting in less-than-optimal performance under varying conditions. Although advanced methods like Active Disturbance Rejection Control (ADRC) offer better disturbance management, they introduce additional complexity and cost, which can be a significant drawback in practical applications.

The VMF-based approach proposed in this study provides an innovative solution by focusing on estimating and compensating for the total bias within the system. This total bias encompasses the effects of parameter variations, internal uncertainties, and external disturbances on the dominant states, which are crucial for maintaining robust control. By integrating VMF into the PID control framework, the system can effectively handle these biases, resulting in enhanced robustness and simplified implementation compared to ADRC. Simulation results consistently show that the VMF-enhanced PID controller outperforms both traditional PID and linear ADRC controllers in managing speed dynamics and responding to load disturbances, achieving superior control performance without extensive tuning or added complexity.

This research makes significant contributions by offering a detailed mathematical model for BLDC motor speed dynamics and introducing a new technique for bias estimation. The VMF-based PID control system strikes a balance between performance and simplicity, providing a cost-effective and efficient solution for BLDC motor control. Additionally, this study lays the groundwork for future research, suggesting potential exploration into hybrid approaches that combine the robust bias estimation of VMF with the advanced disturbance rejection capabilities of ADRC. Such combinations could potentially enhance control performance and adaptability further, paving the way for broader applications and optimization of control systems in BLDC motors and beyond.

China First Highway Engineering CO., LTD., Beijing 100024, China[1, 2, 3]
College of Civil Engineering, Xuchang University, Xuchang 461000, China[4]

***Abstract*—Traditional bridge monitoring techniques, which predominantly rely on centralized data processing, often exhibit slow and inflexible responses when managing large-scale sensor network data. This study proposes an integrated edge and cloud computing approach to enhance the response time and data processing efficiency of dynamic bridge structure monitoring systems, thereby improving bridge safety and reliability. The proposed monitoring system leverages both edge and cloud computing, incorporating modules such as sensor data management, structural assessment and warning, data processing, monitoring, and data acquisition and transmission. High-performance and cost-effective sensors are utilized to monitor the real-time dynamic responses of the bridge, including displacement, acceleration, tilt, and stress, as well as external loads and environmental effects. The data processing module employs the modal superposition method, frequency response function, and modal analysis for dynamic analysis, while the cloud computing platform facilitates deep learning analysis and long-term data storage. A real case study demonstrates the system's performance across various settings and operational conditions, highlighting the effectiveness of integrating edge and cloud computing. The results indicate that the integration scheme significantly enhances monitoring accuracy, system stability, real-time response capacity, and data processing efficiency.**

I. INTRODUCTION

As the world's infrastructure ages faster and bridge loads continue to climb, maintaining the durability and safety of bridge structures has become increasingly important for transportation infrastructure managers. Bridges are essential transportation hubs, and public safety and economic prosperity are directly impacted by the state of these structures. Consequently, the importance of monitoring and evaluating bridge health has increased. Recent developments in data collection, processing, and sensing technologies have made dynamic monitoring of bridge structures a hot topic for study. However, a number of challenges face traditional bridge monitoring techniques, including real-time data processing, system adaptability, and data security.

In order to anticipate future failures and safety risks, the goal of health monitoring bridge structures is to gather and evaluate the structural response of bridges in real time. Conventional monitoring techniques typically depend on centralized data processing systems, which frequently experience issues with massive amounts of data, including processing delays, bandwidth bottlenecks, and data loss [1]. Bridge monitoring systems can now collect vast amounts of high-frequency data due to advancements in sensor technology, which place more demands on data processing. Complex sensor data must be processed in real time in modern bridge monitoring in order to assess the structural response of the bridge, identify possible issues, and promptly take corrective action [2]. Thus, it is now a top research priority to investigate new monitoring schemes to guarantee data confidentiality, boost system adaptability, and increase data processing skills.

Many existing structural health monitoring (SHM) systems use traditional wired sensor networks, which are prone to scalability problems. As the number of sensors increases, the complexity of wiring and maintenance grows, leading to higher costs and greater difficulty in system management. Wireless sensor networks (WSNs) have been introduced to address some of these issues, but even WSNs face challenges in terms of signal interference, data loss, and power consumption, especially in large-scale infrastructure like long-span bridges.

While numerous systems claim to offer real-time monitoring, their data processing speeds and transmission methods often lag behind the real-time requirements of critical infrastructures. Most systems are not equipped to handle the massive influx of data generated by high-frequency sampling from multiple sensors, leading to delays in data processing and reporting. Furthermore, interruptions in data transmission due to connectivity issues often result in incomplete or delayed data analysis, making it difficult to monitor structural health accurately in real time.

One major limitation of existing SHM systems is the lack of robust fault tolerance mechanisms. Many systems do not have adequate backup solutions in place to prevent data loss during network outages or hardware failures. The absence of local storage for sensor data during communication interruptions can lead to significant gaps in monitoring, especially during critical events such as natural disasters or severe weather conditions. This undermines the reliability of the data collected and the system's ability to provide timely alerts.

Most traditional SHM systems rely on basic statistical methods for evaluating structural health. While these methods are useful for analyzing deformation, vibration, and load responses, they often fail to provide accurate predictions or insights into long-term structural behavior. The integration of intelligent algorithms such as machine learning, which could predict potential failure points or structural degradation based on historical data, remains underexplored in many existing solutions.

*Corresponding Author

Large volumes of data are produced by bridge monitoring systems, particularly when high frequency sampling is used. Conventional centralized data processing techniques are frequently unable to keep up with the needs of real-time processing [3]. Due to this, data is delayed and any structural anomalies or early warning signals may go unnoticed. Although edge computing, which processes data in real time close to the site of collection, can significantly cut down on transmission delays, it has drawbacks in terms of deep analysis and storage capacity [4, 5]. It is necessary to prevent and address potential security breaches, system malfunctions, and data loss during data transmission and storage with appropriate methods. Temperature, wind speed, traffic volume, and other climatic and operational variables can all have an impact on a bridge's structural response. In order to guarantee the precision and dependability of the monitoring data under diverse circumstances, the monitoring system must be flexible and durable [6, 7].

The three primary data processing methods used in bridge monitoring systems nowadays are distributed data processing, centralized data processing, and edge computing with cloud computing. Among them, centralized data processing techniques mostly depend on a central server for data analysis; however, this approach is less effective at handling large data volumes and is prone to system bottlenecks and data transmission delays [8, 9]. By dividing up the processing work among several sites, distributed data processing techniques boost processing efficiency. However, they also come with high management and maintenance costs and a complex system.

The goal of the new edge-cloud computing solution is to get beyond the drawbacks of the more conventional methods. Cloud computing offers robust storage and deep analytical capabilities, whereas edge computing permits preliminary data processing close to the site of data gathering, reducing the latency of data transmission. This plan can somewhat increase the system’s scalability and real-time data processing [10]. However, there are still difficulties in the process of integrating edge computing with cloud computing, including problems with data security, synchronization, and system complexity.

The contribution of this article is as follows:

- The cloud computing system integrates real-time or near real-time monitoring, which enhances the ability to track bridge deformation and response to external factors like wind loads and traffic.
- The system uses preprocessing to clean sensor data and align it with GPS time, followed by post-processing that produces statistical analyses every 10 minutes. This enables detailed tracking of environmental factors and bridge behavior, ensuring timely identification of structural issues.
- The early warning module, which updates baselines and thresholds iteratively, allows for the proactive identification of abnormal structural behavior, thus enhancing safety management.

The remaining sections of this article are structured as follows:

Related work is given in Section II. Section III presents the bridge diagnostic modeling. Section IV discusses the data processing and monitoring module. It explains the bridge structure evaluation and early warning system. It also describes the software development and sensor system. Section V provides the preliminary analysis of bridge deformation, including statistical evaluations from 2021 and 2022. It covers the initial examination of InSAR image data to monitor ground subsidence. Section VI concludes with the overall findings and implications for future work.

II. Related Work

Several researchers have explored SHM systems for bridges, focusing on real-time data collection, processing, and predictive analysis.

Early SHM systems have primarily relied on wired sensor networks and manual data collection, often requiring substantial human intervention for data processing and analysis. These systems also faced limitations in scalability, real-time monitoring, and the ability to handle large volumes of data. More recent studies have introduced cloud computing platforms for SHM systems, enhancing data storage, processing capabilities, and remote access to monitoring data [3, 9]. For instance, Xie et al. [11] mentions the use of GNSS and acceleration data for bridge vibration analysis, similar to the proposed approach. However, these systems often lack advanced real-time fault tolerance mechanisms and high computational efficiency when dealing with large sensor networks. Bayik has also applied InSAR image processing to detect settlement movements around large-scale infrastructure [12]. However, most studies have treated InSAR data as separate from the real-time SHM system, lacking integration into a unified monitoring platform. This limits their utility for ongoing structural assessment and real-time decision-making.

Existing systems often fail to maintain data integrity during network interruptions or connectivity failures, which can cause significant gaps in data during critical periods. While many studies use basic statistical methods for monitoring, there is limited use of intelligent algorithms that integrate GNSS, acceleration, and environmental data for real-time predictive analysis [13].

The research presented in this paper builds on the work of [14] and others by proposing a **comprehensive cloud-based SHM system** that integrates real-time data processing, intelligent predictive analysis, and fault tolerance mechanisms. Through a backup server capable of storing raw sensor data for up to one month, a feature that existing systems lack.

III. Bridge Diagnostic Modeling

The design of the model and the development of formulas are important components in the dynamic monitoring of bridge structures. A realistic and scientific model should be developed for assessing and forecasting the dynamic response of the bridge in order to achieve an accurate diagnosis of the bridge structure. Based on the integrated edge-cloud computing architecture, a bridge diagnostic model design was developed in this study [15, 16].

A finite element model (FEM), which considers the bridge's geometry, material properties, and boundary conditions, can be used to represent the dynamic response of a bridge structure. The dynamic response of the bridge was simulated using a linear elastic FEM.

The following equation of motion can be used to characterize a bridge's dynamic response:

$$M\ddot{u}(t)+C\dot{u}(t)+Ku(t)=F(t) \tag{1}$$

where, M is the quality matrix, representing the quality distribution of the bridge; C is the damping matrix, representing the damping characteristics of the bridge; K is the stiffness matrix, representing the stiffness characteristics of the bridge; $u(t)$ is a displacement vector, representing the dynamic response of the bridge; and $F(t)$ is an external load vector, representing wind load, traffic load, etc.

Modal analysis was applied to the bridge in order to examine its inherent frequencies and vibration modes. The characteristic equation of the modal analysis is as follows:

$$\left(K-\omega^2 M\right)\phi=0 \tag{2}$$

where, ω is the modal frequency, and ϕ is the modal shape. The bridge's inherent frequency and vibration mode can be determined by resolving the characteristic equation.

A. Evaluation of Structural Health

The structural health of bridges was assessed using the features extracted. The bridge's health index HI can be determined using the following formula:

$$HI=\frac{\bar{d}}{\sigma_b} \tag{3}$$

The presence of structural irregularities in the bridge can be established by comparing the health index of HI with a certain threshold. A warning will be sent out if HI surpasses the cutoff.

B. Wind Speed and Deformation Relationship

The following nonlinear regression model can be used to investigate how wind load affects bridge deformation:

$$\delta_{\text{lateral}}=\alpha\cdot V_{\text{wind}}^2+\beta\cdot V_{\text{wind}}+\gamma \tag{4}$$

where, δ_{lateral} is the amount of lateral deformation; V_{wind} is the wind speed; α, β, and γ are the regression coefficients yielded by the regression analysis.

IV. System Architecture for Cloud Computing

Fig. 1 depicts the general architecture of the Federal Reserve System (FRB) cloud computing system, which is broken down into five subsystems: the data management module, the data processing and monitoring module, the data collection and transmission module, the bridge structure evaluation and early warning module, and the sensor module. The components and interactions between the subsystems are depicted in Fig. 2.

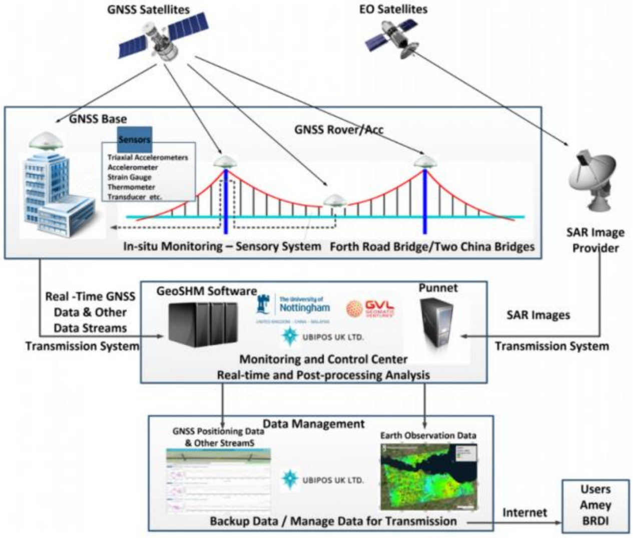

Fig. 1. The overall architecture of the cloud computing system.

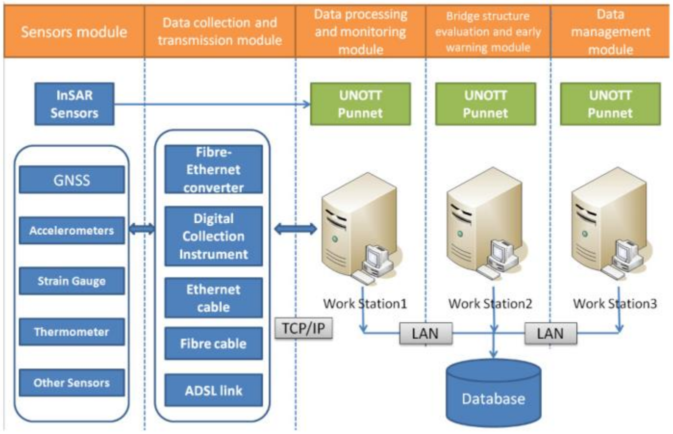

Fig. 2. Data flow and the relationships between the cloud computing subsystems.

C. Sensor Module

The cloud computing's sensor module is made up of various sensor types that can monitor the bridge's displacement, acceleration, inclination, stress, and other structural responses. It can also identify external loads applied to the bridge, such as wind loads and traffic weight, and short- and long-term environmental effects, such as temperature, weather, and ground motion [17, 18]. Fig. 3 illustrates the precise locations of the sensors on the FRB, and Table I lists the different kinds of sensors used in this cloud demonstration project, along with their sampling rates.

Global Navigation Satellite System (GNSS) technology, which makes use of both expensive and low-cost GNSS receivers, forms the basis of the sensor module. A fundamental prerequisite for the creation of an economical sensor module system is the provision of both static profiles and dynamic behavior for both low-cost and high-performance receivers. Three pairs of GNSS receivers were placed across the center and two navigation points in the major region of *B*, in addition to three inexpensive three-axis Sherborne accelerometers. This combination facilitates the integration of acceleration data and

GNSS data for extremely precise measurements of bridge deformation. An accelerometer was also positioned at 1/8 and 3/8 of the major spans, offering more information that could be used to determine the modulation frequency and vibration mode geometries of the FRBs. A triaxial accelerometer was installed atop each of the two major towers since deformation monitoring is critical to their operation. Inclineometers were also erected to show the average deformation at the summits of the towers. In-depth correlation studies of the wind loads on the FRB were made possible by the installation of three anemometers on the structure: two at the top of the two main towers and one at the mid-span. Advanced photovoltaic technology was also used in the cloud computer demonstration project to deliver data on sensors that can negatively impact the main tower foundations and the bridge's overall integrity.

TABLE I. SPECIFICATIONS OF THE SENSORS SET UP FOR THE GEOHAZARD MONITORING REMOTE INITIATIVE

Sensors	Details	Sampling Rates (hz)
GNSS	Leica gro	12
GNSS	Panda DB38	2
Anemometer	Gill windmaster	22
Weather station	Gill Metpak	2
Accelerometer	Sherborne A545-0003-2G	100
Inclinometer	Sherborne LSOP-1	12
InSAR image	EO 1	Image/14 days

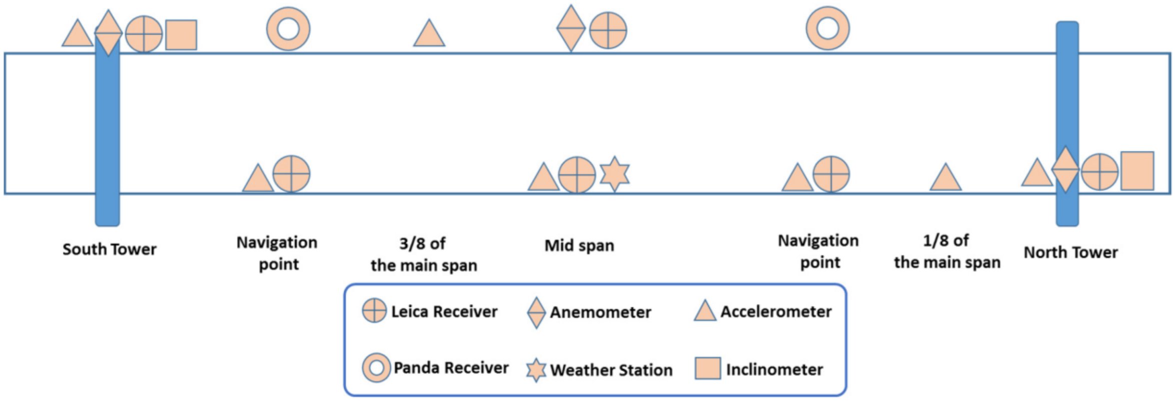

Fig. 3. Installation positions of sensors.

D. Data Collection and Transmission Module

The architecture of the data collection and transmission module installed at the FRB is shown in Fig. 4. The module's primary function is to convey data to a server safely housed in the field control centre using a fiber-optic link for communication with the sensors. Bridge operators can use this server to download data for additional analysis, generate reports on a regular basis, and access monitoring data for real-time monitoring. More crucially, in the event that communication between the bridge site and the main cloud server is lost, this server serves as a backup server, temporarily storing raw sensor data. The backup server is built to hold roughly one month's worth of raw sensor data, which is adequate in the case of a potential connectivity failure given the high sampling rate and numerous sensors.

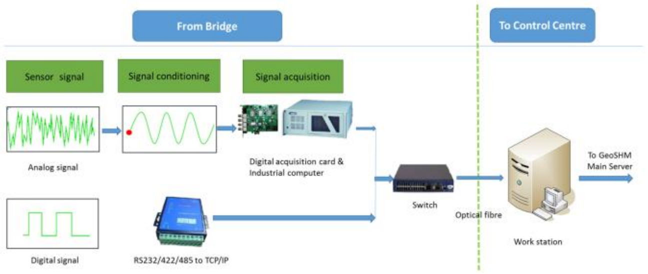

Fig. 4. Schematic diagram of the data collection and transmission module for cloud computing.

E. Data Processing and Monitoring Module

Preprocessing and post-processing units make up the two components of the data processing and monitoring module, which is primarily installed on the primary cloud computing server (Fig. 5). The primary duties of the preprocessing unit are to detect and eliminate anomalies and synchronize all sensor data with GPS time. The preprocessing unit also transforms the bridge deformation data in the bridge coordinate system from the purified GNSS data. The post-processing unit receives the output from the preprocessing unit [19].

The post-processing unit statistically assesses features pertaining to environmental impacts, external loads, and bridge deformation to produce statistical averages that are updated every 10 minutes. These characteristics include the average air temperature, the peak wind coefficient, the average inclination of the main tower, and the mean and standard deviation of the bridge deformation in the span. The cloud computing data strategy provides a precise definition for these low-level aspects.

The cloud computing system has an automatic and advanced system identification algorithm that uses GNSS and acceleration data to predict the modal frequencies and shapes of vibration patterns in order to perform intelligent data analysis. Furthermore, the device possesses real-time or almost real-time monitoring capabilities that leverage the previously mentioned attributes to track bridge deformation in response to wind loads and additional operational and environmental variables [20, 21].

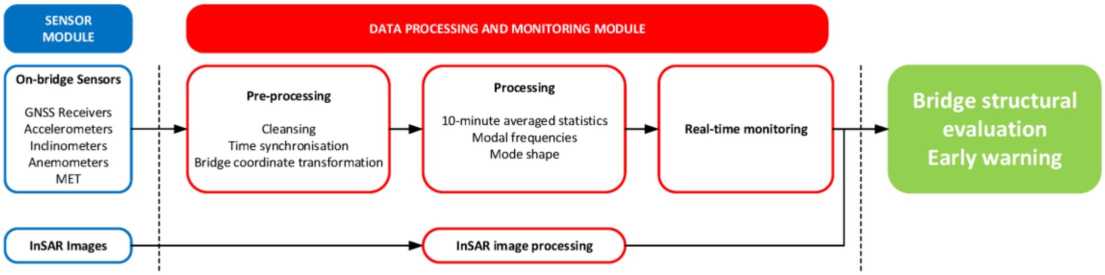

Fig. 5. Main features of the data processing and monitoring module for cloud computing.

It is noteworthy that, because of its low cost and high computational needs, Interferometric Synthetic Aperture Radar (InSAR) image processing is carried out on a monthly basis. This makes sense because, in contrast, settlement takes place over a longer time frame.

F. Bridge Structure Evaluation and Early Warning Module

The design and execution of an alert system based on the requirements of the cloud computing data policy are shown in Fig. 6. This module's performance depends on baselines and thresholds that were initially established using previous monitoring data and bridge operator expertise. These baselines and thresholds were then continuously refined using an iterative update mechanism to accurately reflect the bridge's current condition. When the measured bridge reaction goes over these limits and baselines, an alarm will sound, signaling that the bridge's structural behavior is aberrant.

A more sophisticated structural evaluation process can be utilized to investigate an alarm further after it has been set off. This helps identify whether the alarm is caused by alterations in the operating and environmental circumstances, modifications to the structural system, or the failure of a member. Additionally, the method uses modal parameters taken out of the deformation data to update the structural model in a rolling fashion. By facilitating simulation, the updated model helps bridge operators make better management decisions [22].

When the findings of InSAR image processing are obtained, they are applied to a structural model in order to evaluate how long-term ground motion affects structural stiffness. Bridge stability and long-term safety can be improved with the use of this procedure.

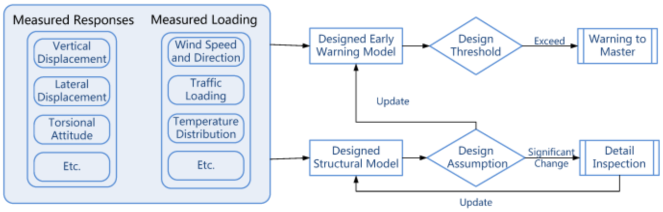

Fig. 6. Module flowchart for cloud computing.

V. Experimentation

A. Software Development and Sensor System Status

A cloud computing web application was developed in terms of software, as seen in Fig. 7. User engagement with the cloud computing system is facilitated by the platform. Some of this web application's functions are available to users, such as real-time monitoring, immediate alarms, and historical data queries. The following section goes into additional detail about a few of the outcomes this web application produces.

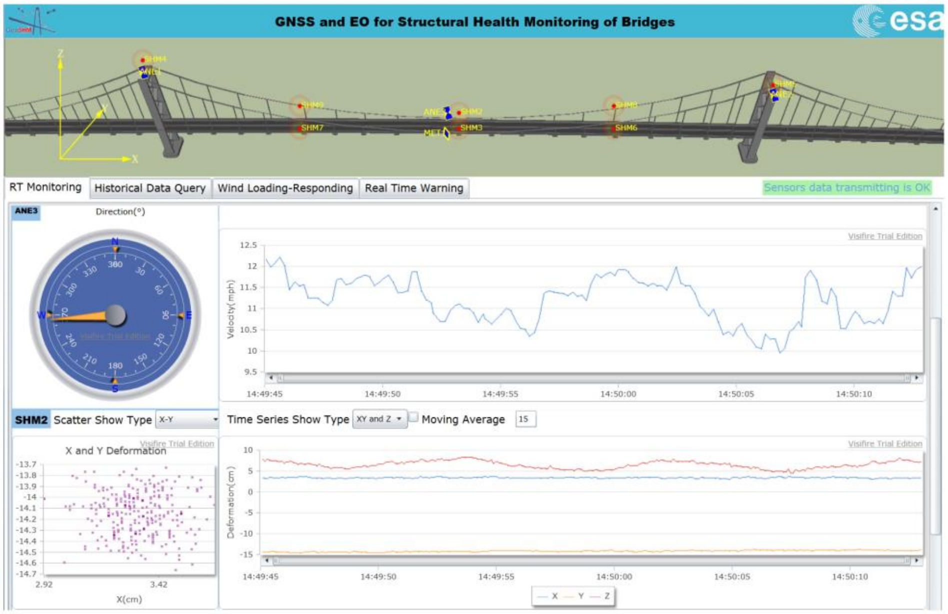

Fig. 7. Web applications for cloud computing.

B. Preliminary Analysis of Bridge Deformation

The cloud computing web application gives customers access to 10-minute average feature statistics from the cloud computing database in addition to real-time monitoring. With the help of this capability, the user may comprehend the bridge's response patterns and history as well as further examine how the bridge reacts to system changes or structural part failures. Furthermore, the 10-minute average statistics for temperature, wind speed, intrinsic frequency, and bridge response evaluation are crucial for establishing baselines, thresholds, and short- and long-term trends. These data are important for developing bridge structure evaluation and warning algorithms, as well as for evaluating the typical structural behavior of FRBs under various operational and environmental situations. This section presents and discusses a few of the evaluations' findings.

The cloud computing web application has the ability to automatically create several kinds of statistical graphs on demand. MATLAB was utilized for their high-resolution presentations. The main focus is on the 10-minute mean and standard deviation responses of the FRBs, along with their relationship to wind speed, air temperature, and traffic. The bridge's response involves deformation in four directions: vertical (along the *z*-axis), torsional (around the *x*-axis), transverse (along the *y*-axis), and longitudinal (along the *x*-axis). The bridge's steady state is represented by the 10-minute mean of its long-term deformation, and its dynamic reaction is shown by the 10-minute standard deviation.

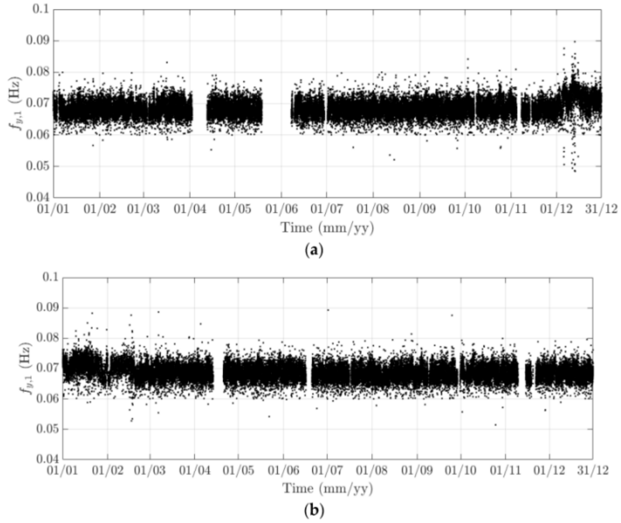

Fig. 16. Intrinsic frequency variations during a 10-minute period for the initial transverse model in (a) 2021 and (b) 2022.

Periodic characteristics of the bridge response and intrinsic frequency were identified through the analysis of the monitoring data for the years 2021 and 2022. These characteristics can be categorized into daily and weekly cycles. Certain data collected by the SHM system on the 560-meter Chinese bridge in Hong Kong, Zhuhai, and Macao bears a striking resemblance to some of these observations [23]. As further discussed in this section, the bridge response and the intrinsic frequency, however, frequently do not follow these patterns. Fig. 8 to Fig. 9 display the 10-minute averaged features for the years 2021 and 2022. Fig. 10 to Fig. 11 offer a thorough examination of a few chosen features for a brief period of time (August 1 to August 14, 2022).

A pattern of diurnal cycles is evident when examining the 10-minute standard deviations of the longitudinal response (Fig. 12), undulation response (Fig. 13), and torsion response (Fig. 14). These 10-minute average figures for the period August 1-14, 2022, demonstrate notable variations between day and night. The variance in traffic flow is closely related to the fact that the standard deviation values are substantially higher during the day than at night. The dynamic reaction is most intense when traffic peaks between 03:00 and 04:00, and it tapers off after 15:00 when traffic starts to decline.

Weekday traffic volume is higher than weekend traffic volume, which also results in a larger standard deviation fluctuation. Furthermore, the analysis of the 10-minute averages of the undulation deformation (Fig. 14), which represents the amount of sag in the mid-span of the FRB, can provide additional insight into the diurnal periodicity. Fig. 18 demonstrates a distinct sag volume difference between day and night; however, this cyclical pattern is less evident because of natural temperature swings. The lower weekend traffic results in a drop in the sag volume at the midspan. The 10-minute natural frequencies of the initial transverse and undulation patterns (Fig. 15, 16, and 17) also depict these diurnal cycles. These frequencies decreased by 7% and 2%, respectively, as a result of warmer daytime temperatures and more mass brought on by traffic; on weekends, this pattern was less noticeable.

There are multiple instances in 2021 and 2022 with bridge response and intrinsic frequency deviating from the average trend: (i) early January 2021; (ii) December 2021 through February 2022; and (iii) late December 2022. During these periods, the intrinsic frequency rises dramatically, particularly during (ii), but the change in standard deviation within a day is negligible. It was discovered that the primary cause of the temperature and traffic fluctuations during these occurrences was the decreased volume of traffic on the bridges. To be more precise, (i) and (iii) are both public holidays (such as Christmas and New Year's), whereas (ii) is connected to the break in the northeast end-connection, which led to traffic restrictions and bridge closures. The 10-min averages of torsional and longitudinal responses were significantly altered by these events, but the 10-min averages of sag deformation were only slightly affected (Fig. 8 and Fig. 14).

Furthermore, an obvious annual cycle can be seen in the 10-minute average heave deformation (Fig. 14). The temperature increase caused the sag in the middle of the FRB span to progressively climb from January through August, eventually reaching a mean value of about 0.4 m. After August, as the outside temperature dropped, the FRB progressively moved back to its former location. There was no discernible annual cycle in the other bridge response or intrinsic frequency components. The data showed more random behavior with no discernible short- or long-term trends, as evidenced by the 10-minute averages and standard deviations of lateral deformations that were mostly impacted by wind speed (Fig. 12 and Fig. 13). On the other hand, as shown in Fig. 12, the analysis of the wind load response demonstrates a quadratic relationship between the mean lateral deformation and the positive component of the mean wind speed. The lower and upper thresholds, denoted as Un, are shown in Fig. 17, where circle is the standard deviation of the data samples for the positive component of mean wind speed within a window of three seconds. Though some data points considerably depart from the specified quadratic curve or exceed the upper threshold, most data points fall between these two criteria.

Upon examining the monitoring data from 2021 and 2022, certain distinctive characteristics of the FRB's structural response under external excitation were discovered. Certain recurrent patterns of bridge response and modal frequencies were affected by temperature. Based on their cause and duration, these patterns were divided into daily, weekly, and annual cycles. Certain departures from these cyclic patterns were found to be triggered by changes in operational conditions brought on by public holidays or FRB closures. Furthermore, in order to guarantee a normal structural reaction of the FRB in the event of severe wind, lower and upper bounds on the wind-induced response were established. It is critical to establish these characteristic behaviors of the FRB for subsequent years of monitoring data analysis, thereby helping identify systematic changes in the structure and their causes, which is an important part of the development of the cloud data strategy.

C. Initial Examination of InSAR Pictures

In this part, some initial findings from the InSAR image processing encompassing the Sanqi Bridge (Shanghai, China) and the surrounding area of the FRB are presented. As depicted in Fig. 18, the movement of subsidence in the vicinity of the FRB is minimal, mostly within a radius of approximately 2 km from the FRB, where its influence is minimal. In certain regions, the movement is at a rate of around 5 mm/year. On the other hand, Fig. 19 for the Sanqi Bridge (Shanghai, China) demonstrates that there are notable settlement movements occurring in the vicinity of the bridge, up to a maximum of 20 mm annually, in the area 1 km away. These settlement patterns move in the direction of the bridge, endangering its structural stability.

VI. Conclusion

This paper presents a cloud-based SHM system for long-span bridges, integrating GNSS, accelerometers, and InSAR technologies for real-time data collection and analysis. The system ensures continuous monitoring through a fiber-optic communication link and a backup server, while the cloud processing module refines data accuracy and evaluates structural responses to environmental factors. We observed cyclical patterns in bridge behavior influenced by traffic and temperature, and detected anomalies linked to specific events. While the system shows promise in providing real-time insights, limitations include the infrequent processing of InSAR data and challenges in scaling to larger infrastructures. Future work will address these challenges and further optimize the system for broader applications in infrastructure monitoring.

Building on our paper, future work could focus on several key areas to enhance and expand the capabilities of the proposed SHM system: Address the infrequent processing of InSAR images by developing more efficient algorithms or increasing processing frequency. This will provide more timely insights into long-term ground movement and its impact on structural health. Explore the incorporation of other sensor types, such as acoustic emission sensors or fiber optic sensors, to capture a broader range of structural responses and potential failure mechanisms. Improve the data processing and analysis algorithms to better handle large volumes of data and detect subtle anomalies. This could involve advanced machine learning techniques or AI-based predictive models.

Optimized Fertilizer Dispensing for Sustainable Agriculture Through Secured IoT-Blockchain Framework

IoT-Blockchain Framework for Sustainable Agriculture

Abstract—**Precision farming is essential for optimizing resource use and improving crop yields to attain sustainable agriculture. However, challenges like data insecurity, fertilizer costs, and inadequate consideration of soil health pose a hindrance to achieving these goals. To overcome these issues, the proposed work presents a novel approach for optimizing fertilizer dispensing by developing a framework connecting IoT and blockchain with a community of greenhouses. The system consists of IoT sensors installed inside the greenhouses to measure soil pH and nutrient values. This collected sensor data is compressed and stored securely and in an off-chain manner by the IPFS (Inter-Planetary File System) hash using the Keccak-256. MetaMask transfers the data for blockchain registration and authentication. The data is then preprocessed using Z-score normalization, Label Encoding, and One-Hot Encoding to obtain a precise analysis. A Deep Learning-based Convolutional Neural Network (DL-CNN) is used to classify soil conditions and determine the appropriate fertilizer requirements. The results of the DL-CNN model are viewed in a dashboard through a Decentralized Application (D-App) that we developed to provide real-time information to consumers, field analysts, and agricultural organizations. Field analysts use the information to establish a control center for precisely applying fertilizers. The proposed method achieves a classification accuracy rate of 98.86%, thus increasing soil health and providing a solution for effectively managing fertilizers.**

Keywords—***Fertilizer dispensing; IoT sensors; blockchain; deep learning; convolutional neural network; greenhouse management; and decentralized application***

I. Introduction

Smart agriculture, also known as smart farming, focuses on using advanced technologies and data-driven operations to improve sustainability in agricultural production [1]. In this area, IoT-enabled sensors are used to monitor some parameters in real-time and provide cutting-edge management of farming data [2]. The use of blockchain technology in the field of smart agriculture guarantees security, transparency, and tamper-proof data storage, as well as the maintenance of trust and provenance along the agricultural chain [3]. Moreover, blockchain in smart agriculture securely transfers and stores data to decide soil health and fertilizer applications [4, 5]. This method optimizes resources, increases crop yields, minimizes environmental impact, and enhances food safety by offering verifiable data to consumers [6]. Blockchain and IoT agriculture improve decision-making and the ability to implement decentralized solutions that help farmers and provide better outcomes [7].

Previous research in smart agriculture has mostly addressed the application of IoT sensors that monitor environmental conditions to improve crop management [8, 9]. The techniques of machine learning (ML), deep learning (DL), and cloud computing have been applied for processing and analyzing the data collected from these sensors [10, 11]. Yet, several of these methods still depend on centralized systems for data storage and processing, which introduces problems regarding data security, flexibility, cost, and accessibility [12, 13]. Although some studies have explored the use of blockchain to secure data transfers, they mostly do not implement DL models for the real-time decision-making process based on soil health parameters [14, 15]. This work addresses these gaps by integrating IoT, blockchain, and DL models into the timely fertilizer distribution and constructing a secure system for monitoring greenhouse conditions.

The main contributions of this work are as follows:

- A novel way of optimizing fertilizer dispensing in the greenhouse environment using IoT sensors, blockchain technology, and DL models to monitor soil health is proposed. It provides accurate soil monitoring and secure data collection and storage to improve fertilizer dispensing accuracy.
- The proposed method uses the Lempel Ziv Welch (LZW) compression method for efficient data storage and transmission. In addition, the use of the SHA-3 (Keccak) hashing algorithm with a chaotic key for data encryption contributes to the improvement of security and makes the system robust against cryptographic attacks.
- This work introduces a DL model defined as a DL-CNN used to predict the soil pH values and NPK levels. Hence, the impact of the application of fertilizers can be determined.

- We have developed a Decentralized Application (D-App) dashboard that provides real-time data regarding soil health and greenhouse parameters. The application allows farmers and other stakeholders to view the key information, make decisions about fertilizer application, and consequently care for the best growing conditions.

The structure of this paper is organized as follows: Section II provides a literature review covering advancements in smart agriculture and the application of blockchain and DL. Section III details the proposed methodology for optimizing fertilizer dispensing using a blockchain method for secure smart greenhouse management. Section IV presents the results and analysis. Finally, Section V concludes the paper.

II. Literature Review

This section examines and explores different modern techniques, technologies, and weaknesses in smart agriculture to improve soil management, crop yield, and overall farm efficiency.

A. Emerging Techniques in Sustainable Agriculture

Wei et al. [16] demonstrated the utility of Capacitive Coupled Contactless Conductivity Detection (C4D) in soil nutrient detection. This method encompasses C4D data and cluster analysis to improve nutrient monitoring and management. Despite that, a very low level of nutrients can limit the method's performance, and the system's efficiency may vary due to different soils.

Thorat et al. [17] proposed the Transition Probability Function (TPF) and Convolutional Neural Network (CNN) for precision farming. In this work, a system identifies pests, prescribes insecticides, and examines the soil nutrients to indicate the most suitable fertilizers. However, the model lacks the integration of sensors like pH, temperature, humidity, and soil moisture sensors to capture a range of environmental data.

Senapaty et al. [18] suggested an IoT-enabled soil nutrient classification and crop recommendation (IoTSNA-CR) system. This model encompassed IoT sensors, cloud storage, and a multi-class support vector machine (MSVM) to classify soil nutrient levels. However, drawbacks include the need for significant investment in sensors and the need to clean data, which is a big challenge.

Pechlivani et al. [19] have coined soil and environmental monitoring using an IoT-enabled device with sensors to collect data on key soil and environmental parameters. The summation of sensors paired with an ESP32 microcontroller, data visualization, an Android app, and 3D printing for control housing. However, the study has inaccuracies in the sensor measurements and more validation in the different agricultural fields.

Indira et al. [20] proposed using Artificial Intelligence (AI), machine learning (ML), and Long-Range (LoRa) technology to transform farming operations. They analyzed these data using AI to provide actionable insights for improving agricultural practices. Nevertheless, challenges stem from issues such as data security and the difficulty of deploying AI in remote areas with limited internet connectivity.

Vincent et al. [21] introduced IoT and Al in agriculture to evaluate land suitability for cultivation. This technique is used for sensor networks to collect data on soil and environmental variables. It also uses the Multi-Layer Perceptron (MLP) neural networks to classify data into four suitability classes. This study has limitations due to incomplete sensor data and overfitting in the MLP model due to its complexity.

Singh et al. [22] focused on developing a portable device for soil nutrient analysis. This method detects soil nitrogen (N) and phosphorus (P) levels to optimize crop yield and minimize fertilizer use integrated with IoT and LED sensors. Yet, its limitations include potential inaccuracies at higher nutrient concentrations and the need for further refinement to improve sensitivity.

Morchid et al. [23] introduced the applications of IoT and sensor technology in agriculture and food security. The paper also enumerates IoT's advantages in agriculture, including efficiency and resource reduction. Nevertheless, it still cannot offer any real-world examples and only speculations about solutions to the challenges.

TABLE I. Analysis and Applications of Blockchain in Greenhouse Agriculture

References	Technique Used	Objectives	Results	Limitation
[26]	Blockchain and IoT	Enhance transparency and traceability in the agricultural process	Improved trust and reliability in food certification	High initial setup cost and complexity
[27]	DL-based Image Processing	Measurement and monitoring of greenhouse environmental parameters	98% success rate in image processing	Limited dataset size for training
[28]	ML (Random Forest)	Classify greenhouse gas (GHG) emissions during groundnut harvesting	Accuracy: 86.46%	Limited by data variability and missing values
[29]	Blockchain and IoT	Ensure anonymity and security in e-voting	High voter privacy and verifiability	Requires computational resources
[30]	RNN and · Blockchain	Secure agricultural data in IoT network	Accuracy: 97.7%,	Design complexity
[31]	Blockchain- consensus algorithm	Ensure a secure and transparent supply chain in smart agriculture	Reduced fraud and counterfeiting	High computational cost
[32]	Blockchain and DL	Ensure food safety and transparency in the supply chain	RMSE values of 872.56	Increased implementation costs
[33]	ML: Multi-regression analysis	Identify the next hop for agricultural data transferring	Improved energy usage efficiency by 13% and 16%	High packet congestion

Nayagam et al. [24] addressed the issue of controlling disease in smart agriculture with IoT technology. It suggested using multiple GPUs in a Parallel and Distributed Simulation Framework (PDSF) with IoT to oversee crop surveillance and pest management. However, multiple GPUs could reduce system performance, and more efficient data processing algorithms are also needed.

Rajak et al. [25] suggested the integration of IoT and smart sensors in agriculture for crop production and minimizing economic losses. Techniques like AI algorithms and ML are used for real-time data processing and precision farming. Yet, high implementation costs and data security concerns impact farmers by making the technology less accessible.

B. Blockchain Integration in Sustainable Agriculture

The literature shows advanced agricultural techniques for improving agricultural practices with several limitations (as shown in Table I). This work proposes an integrated IoT, blockchain, and DL approach to solve this issue to improve soil management and optimize greenhouse agriculture.

III. Proposed Methodology for Optimal and Appropriate Fertilizer Dispensing

The proposed system optimizes fertilizer dispensing by accurately assessing soil conditions. This model employs IoT sensors at different greenhouses to collectively monitor soil nutrition and pH values. The collected data from these sensors is compressed and assigned to the IPFS hash code for secure transfer to the blockchain, specifically in an off-chain setup. This data is transferred to the blockchain using MetaMask for registration and login authentication. Once transferred to the blockchain, the data is input into a Convolutional Neural Network (DL-CNN) model to classify pH value and NPK (Nitrogen, Phosphorous, Potassium) amount in the soil to apply the required fertilizer. The DL model's output can be accessed through a dashboard in a Decentralized Application, thereby providing insights to consumers, field analysts, and agricultural organizations. The Field analysts can use this data for activating the control center which further implements the necessary solutions within the greenhouse environment to provide necessary solutions for using appropriate fertilizer for optimal growing conditions. Fig. 1 explains the overall workflow of this system. It integrates IoT sensors, blockchain technology, and DL models to accurately assess soil conditions and optimize fertilizer application in greenhouse environments.

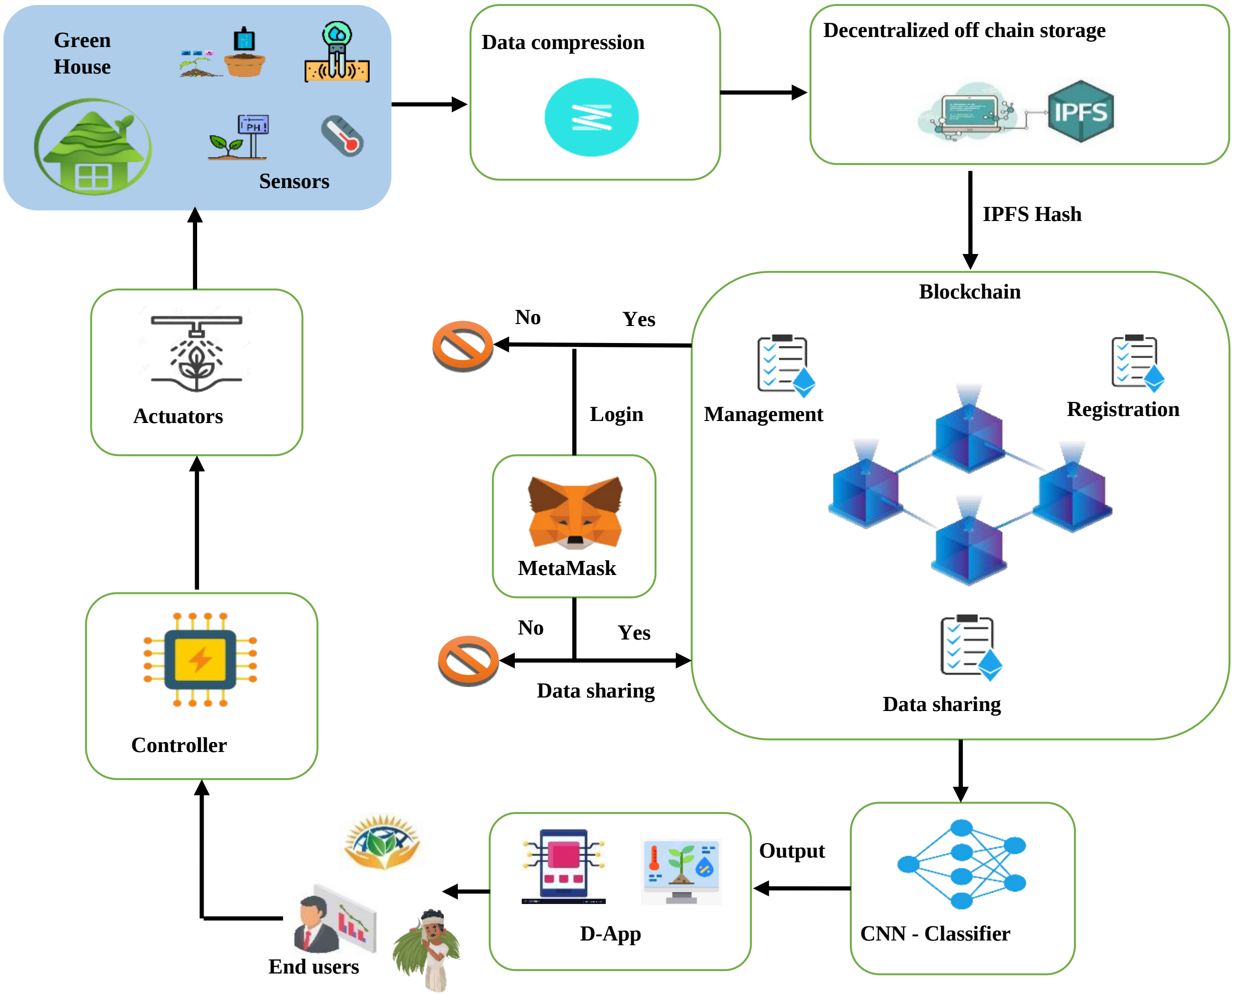

Fig. 1. Workflow of the proposed system.

A. Data Collection

In this framework, IoT sensors, including pH, moisture, temperature, and soil nutrients, are placed across different greenhouses to continuously monitor and collect data on soil conditions. These sensors capture real-time data that reflects the dynamic conditions of the greenhouse environment to provide a dataset for assessing soil health and making informed decisions on resource management.

B. Data Processing

The collected sensor data is compressed using the Lempel-Ziv-Welch (LZW) technique [34] to store large data volumes efficiently. LZW compresses data by replacing repeated sequences of characters with shorter codes. It takes a dictionary filled with all single-character strings. Meanwhile, it checks each sequence against this dictionary. If the sequence is found, it is expanded with the next character and continues. Otherwise, the sequence is added to the dictionary, and the code for the previous sequence is output.

C. Blockchain Configuration

1) Data Collection and IPFS Storage: After the compressed data is collected, it is securely assigned an IPFS (Inter-Planetary File System) hash code for securely storing off-chain. IPFS enables distributed storage, in which data is divided up into small parts, and each is signed with a cryptographic hash using the Keccak-256 algorithm [35]. Such chunks are then shared among several IPFS networks.

2) MetaMask with blockchain integration: Here, MetaMask provides secure data to be transferred to the blockchain through registration and log-in authentication. It makes use of Keccak hashing. If data chunks are stored in IPFS, their hash codes are recorded on the blockchain. Hence, it provides a secure reference to the off-chain data, whereas the blockchain storage requirements are minimized. To improve security, the SHA-3 (Keccak-256) hashing algorithm is used for the encryption process and is combined with the chaotic key for encryption and decryption. A chaotic key, generated with the help of logistic maps, is integrated with the SHA-3 hash to create a secure and unpredictable hash resistant to cryptanalysis attacks. Moreover, this algorithm is used to encrypt IoT devices with low computing resources, which are decrypted upon reaching the blockchain and fed into the DL-CNN model.

Fig. 2 provides the data flow and security mechanisms in this setup. The encrypted data is stored off-chain using IPFS and securely transferred through MetaMask. The data undergoes blockchain validation to improve security for real-time decision-making.

D. Data Classification

1) Data preprocessing: Before the classification step, the data goes through initial processing steps to ensure the optimal format for analysis. Eventually, the Z-score normalization method [36] eliminates the effect of outliers by standardizing the data to have a mean of zero and a standard deviation of one to reduce the influence of extreme values. After that, a Label Encoder [37] is applied to change the strings of the categorical values into integer numbers, thereby enabling numerical analysis. Following this, the One-Hot Encoder transforms these categorical integers into binary format to create a sparse matrix where each category is represented as a separate binary column.

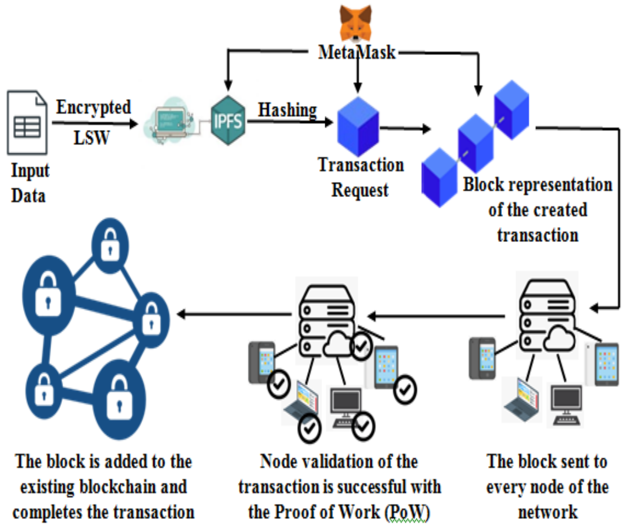

Fig. 2. Blockchain-based data transfer workflow.

2) Classification: The binary numerical data processed through preprocessing is loaded into the DL-CNN [37] model, which predicts the pH (soil acidity or alkalinity) and NPK content (determining the nutrition value of the soil). The CNN architecture features several levels structured for capturing and classifying important data. It starts with a 55*55*3 input layer which are the dimensions of the feed data. This is followed by multiple convolutional layers with different sizes of filters as (4*4) or (3*3). It identifies various features caught in the data. The batch normalization layer is placed after each convolutional layer to improve the stability of learning, and the activation layer employs the P-ReLU function to inject non-linearity. Pooling layers are inserted to reduce the spatial dimensions, decrease the computational cost, and improve the quality of feature extraction. As the network progresses through these layers and captures more intricate patterns in the data. A dropout layer is implemented to avoid overfitting wherein neurons are randomly disrupted with a fraction of them deactivated during training. Finally, the model contains a fully connected layer and a regression layer using Error Regression that classifies the final labeling (soil pH and nutrient content) to recommend the optimal fertilizers.

3) Visualization: The outputs from the DL-CNN model are visualized through the dashboard within a Decentralized Application (D-App). This dashboard offers a user interface for the customers, the field researchers, and the agricultural organizations to access real-time information on soil health, such as pH values and NPK content. By displaying these results in an accessible format, stakeholders understand the soil's condition and make informed decisions regarding fertilizer application and plan crop management.

4) Control center activation: Based on the dashboard's analysis results, field analysts can activate the control center to require modifications within the greenhouse environment. This can involve applying the appropriate amount of fertilizer to improve the quality of the soil and crop growth so that plants receive the nutrients they need for optimal development.

IV. Results and Discussion

The proposed system was implemented on a blockchain platform integrated with Python, utilizing smart contracts and secured data for accurate data handling. The results show the system can accurately classify soil pH and NPK levels, thus enabling precise fertilizer application while maintaining data integrity and security through blockchain technology.

A. Dataset Description

This dataset consists of one million soil samples that have been simulated from different places across the world. Each sample comes with information about soil texture, pH, organic matter content, moisture content, bulk density, nutrient levels (N, P, K), cation exchange capacity, electrical conductivity, color, porosity, and water holding capacity. This dataset, which has been developed for environmental scientists, agronomists, and data scientists, is excellent for research, ML, DL models, and educational purposes.

Dataset link: Global Soil Characteristics Dataset (1 Million) (kaggle.com).

B. Performance Analysis

Table II shows that compression techniques are effective in storing and transferring large volumes of sensor data to the blockchain in a compressed format. LZW ranks a balanced performance, compared to Huffman and Arithmetic. In its case, the LZW may show the best harmony with the compression efficiency and the speed of processing. Thus, it is a perfect choice for real-time applications, where a quick response time and a small storage footprint are crucial.

TABLE II. Comparative Analysis of Data Compression Techniques

Technique	Compression Ratio	Compression Time (s)	Compressed Size (bytes)	Memory Usage (bytes)
LZW	**2.108725**	**17.37507**	**1.31E+08**	**1.31E+08**
Huffman	2.398807	21.33783	1.16E+08	1.16E+08
Arithmetic	2.279311	226.2766	1.22E+08	1.22E+08

Fig. 3 demonstrates the Keccak-256 hash tool interface used in the system. It includes a text field with "Agriculture" which is the default text to be hashed. Below the input fields, "Hash" and "Auto Update" give the users the ability to generate and update the hash of the corresponding text. The resulting hash depicted as an alphanumeric string in the output field proves the capability of the Keccak-256 hashing function in securely changing and verifying data.

Fig. 4 shows a transaction detail from a blockchain explorer. It shows the transaction hash, block number, block hash, contract address, sender and recipient addresses (partially blocked for privacy) the gas used, and input data details. This detailed view checks and observes the transactions carried on the blockchain to ensure security in the management of digital assets within the system.

Fig. 5 illustrates a command line interface that exhibits a program execution output with data storage and verification. The screen displays, "Files are stored in local server" and "Data is already stored for this file name," then "wait - compiling/applying successfully in 65ms (51 modules)" and "true," which means that the "Hash is Stored in a Smart Contract". This output expresses the process of collecting and whether the data is correctly stored. Thus, by proving that the system records the data and verifies it in a blockchain setting.

Fig. 5. Execution output for data storage and verification.

Fig. 6 shows the performance of a DL-CNN model employed for predicting soil states as well as determining the need for fertilizers. Specifically, the metrics of accuracy (98.86%), precision (98.3%), sensitivity (98.3%), specificity (99.15%), F-measure (98.3%), Matthews-correlation coefficient (97.45%), and the negative predictive value (99.15%) highlight the model performance in soil condition classification. This in-depth evaluation establishes the model's high dependability and precision, which are necessary for ensuring accurate fertilizer recommendations.

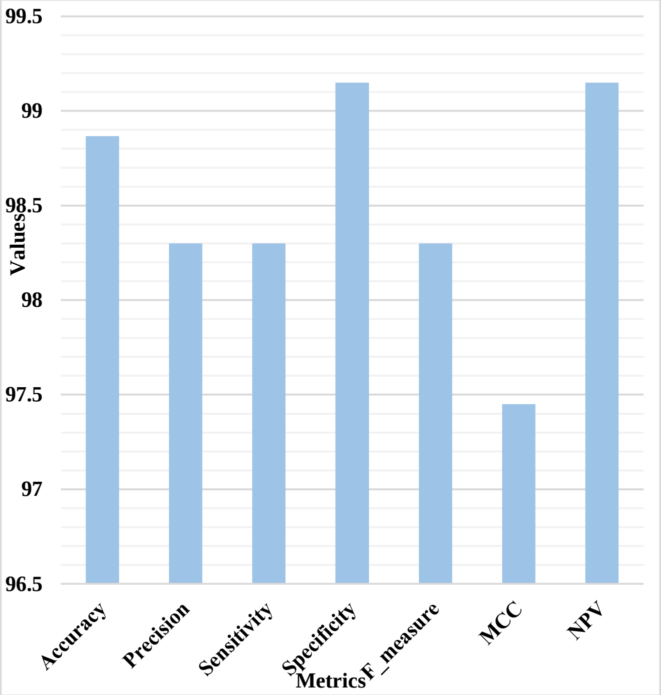

Fig. 6. Performance metrics of the DL-CNN classification model.

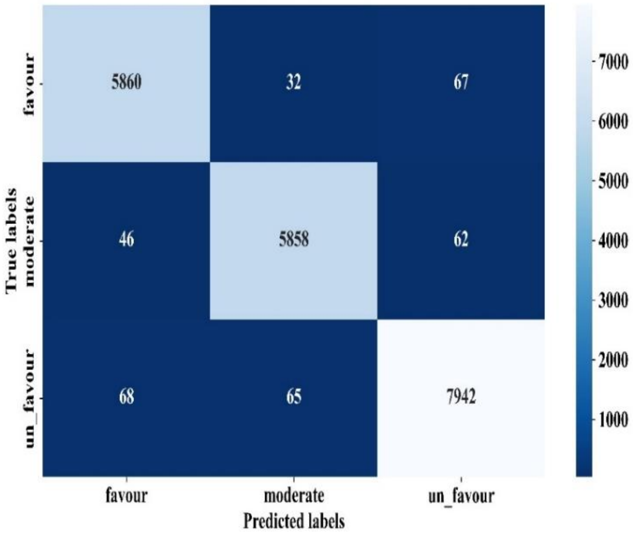

Fig. 7. Confusion matrix for DL-CNN classification model.

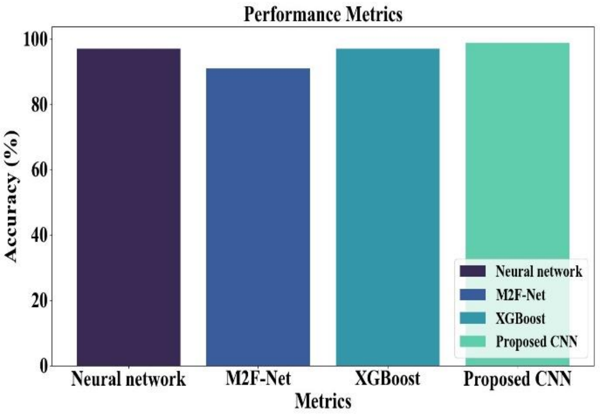
Fig. 7 presents a confusion matrix in evaluating the classification model's performance in predicting soil conditions. This matrix compares actual target values with the model's predictions across three classes: 'favor,' 'moderate,' and 'un favor.' The diagonal cells represent correctly classified instances. It indicates the model’s accuracy for each class, while the off-diagonal cells reveal misclassifications, indicating areas where the model's predictions deviate from actual values. This evaluation gauges the applicability of DL- CNN in the classification of soil pH and NPK by facilitating improvement for accurate fertilizer recommendations.



A suitable name for this figure could be:

Fig. 8. Accuracy comparison for soil condition analysis.

Fig. 8 presents a comparison of the performance of various state-of-the-art methods in terms of accuracy for soil condition analysis. Neural Network [38] with a result of 97%, while Multimodal Fusion Network (M2F-Net) [39] with a score of 91%, and eventually, XGBoost [40] with 97%. At last, the proposed CNN tops the list with an accuracy of 98.86% among all the methods being compared. This outstanding performance of the model is traced back to its architecture, which, in developing CNN, allows it to better identify soil pH and nutrient content classifications.

C. Discussion

This part is intended to demonstrate the proposed system's excellent abilities and working. Fig. 3 uses the Keccak-256 hash tool interface that models the secure hash function of data for trust in blockchain. Fig. 4 shows a detailed view of blockchain transaction information, thereby proving the secure administration and verification of transactions. Fig. 5 shows the output of data storage and verification, which firmly says that the storage of data on the blockchain and the fact that it was validated were successful. Fig. 6 shows the platform with the best performance, with the DL-CNN model reaching the highest accuracy of 98.86%. Thus, it is the most effective method when doing soil condition analysis and fertilizer recommendations. The confusion matrix of Fig. 7 is lastly used to provide the model's accuracy and identify the weak points in the model. Finally, various state-of-the-art methods can be compared with the proposed CNN, which has the highest accuracy and ability to classify soil pH and nutrient content. These results, in totality, assure the productivity and the benefits of relating IoT, blockchain, and DL technologies in smart agriculture to precision and security.

V. Conclusion

This research presents a revolutionizing system for making fertilizer use efficient in sustainable agriculture through the integration of IoT sensors, blockchain technology, and a DL-CNN. The suggested technique effectively addresses key challenges such as lack of data security and precise allocation of resources. The system uses IoT sensors to keep track of soil conditions and the IPFS and blockchain for secure data storage and transfer which guarantees the data conforms data integrity and confidentiality. The DL-CNN model delivers 98.86% classification accuracy, thus highlighting its capability for soil pH and nutrient levels evaluation. The real-time information given by a DE App to make the right decisions about the amount of fertilizer required for soil fertility improvement and, consequently, higher crop yields. Overall, this framework offers a solution for modernizing fertilizer management in agriculture, combining advanced technology with practical applications, guaranteeing increased agricultural output and sustainability. Nonetheless, unsuitable sensors can mislead outcomes, which can significantly impede the system's performance. Further research is likely to cover the remote sensing tools for pest detection and the possibility of the use of drone type of technology for precise water application.

***Abstract*—Finding an Initial Basic Feasible Solution (IBFS) is the first and essential step in obtaining the optimal solution for any Transportation Problem. Numerous approaches are available in the literature to determine the IBFS; however, many of these methods are modifications of Vogel's Approximate Method (VAM) and/or the Least Cost Method (LCM). None of the existing methods directly consider the capacity of distributions among the nodes when selecting the allocation steps. While researchers have proposed various approaches and demonstrated improved solutions with numerical instances, they have not thoroughly investigated the underlying causes of these results. In this article, we explore the impact of capacity distributions among the nodes on the VAM and LCM in an experimental domain. The study introduces a novel and unique Capacity-Influenced Distribution Indicator (CI-DI) designed to control the flow of allocation. Ultimately, we propose a novel Capacity-Influenced approach that embeds both LCM and VAM to determine the IBFS for Transportation Problems (TPs). The novelty of the proposed approach lies in its direct consideration of capacity distribution among the nodes in the flow of allocations, this feature is lacking in LCM, VAM, and other established approaches. The proposed method develops a novel distribution indicator and a novel cost entry embedded capacity-based matrix to control the flow of allocations and thereby finds the IBFS for the Transportation Problem. We have conducted extensive numerical experiments to assess the effectiveness of the proposed approach. Experimental analysis demonstrates that the proposed method is more efficient in finding the IBFS than existing approaches. Moreover, as it uses a one-time generated Distribution Indicator (DI) for all steps of allocation, it is computationally cheaper than VAM, which generates a DI for each step of allocation.**

Keywords*—Transportation problem; least cost method; Vogel's approximate method; cost matrix; transportation tableau; node; capacity; route; capacity-influenced; weighted opportunity cost

I. Introduction

In Transportation Problem (TP), commodities are transported from a set of sources (called source nodes) to destinations (called destination nodes) subject to capacity (supply and demand) constraints in such a way that the total cost of transportation is minimized. TP is a multi-disciplinary field of study [1-3]. It is directly involved with real-life problems [1- 4]. The application of the TP extends beyond its traditional domain and finds relevance in various other fields [4], [8]. These fields include personnel assignment, inventory control, employee scheduling, and more [1-8]. It is known that the general Linear Programming (LP) methods are so tedious and time-consuming [6-8]. Researchers have developed several alternative methods for finding the IBFS by leveraging the special (unique) characteristics of TPs [2-6]. The two well-known classical methods, the LCM and VAM are very simple and can yield better IBFS for TPs [2], [5], [6], [14], etc.

In LCM, the flow of allocation is directly controlled by the cost matrix, with a preference for the least cost. Vogel introduced VAM in 1958 as a modification of LCM. In VAM, the flow of allocation is controlled differently, but it still considers the cost matrix. It begins by developing a control vector called the DI, formed through the manipulation of the cost matrix. Subsequently, the flow of allocation is guided by both the DI and the cost matrix. Based on the LCM and VAM, many researchers proposed several approaches for finding IBFS of TPs [2], [5], [6-13], [14], [21], [22], [23], [29-30], [38-39], [41], [42] etc. For the importance of TPs in real life, researchers are continuously devoted to finding better approaches for solving TPs. It is observed in the literature that most of the approaches are variations of VAM [6-10], [24], etc. A few of the research works related to TPs are pointed out below.

In the article [24], the author introduced the Total Opportunity Matrix (TOM) by manipulating cost entries rather than DI used in VAM to determine the flow of allocations. Authors in the article [1] developed Total Opportunity Cost (TOC) matrix and after that they formed DI tableau for allocation by considering TOC. In the article [43], authors proposed an enhanced version of [10] modified VAM for the unbalanced transportation problem. Both approaches utilize the VAM method, with the modification focused on transforming an unbalanced TP into a balanced one. In [44] author considered balanced transportation problems, with the modification applied solely to the manipulation of the cost matrix. In [45] authors proposed another embedded modified VAM method called Logical Development of Vogel's Approximation Method (LD-VAM) for finding the IBFS in TP. In [39] author introduced a modified VAM in which the modification is directed toward finding the DI, considering the cost matrix as well. Some other modified approaches based on VAM approach are found in the recent publications of [25], [29] [33], [36].

Besides modification of VAM, some other approaches are available in the literature. Recently, in [46] authors, at first, developed TOC then they formed DI tableau for allocation by considering the average of TOC of cells along each row identified as Row Average Total Opportunity Cost (RATOC) and the average of TOC of cells along each column identified as Column Average Total Opportunity Cost (CATOC). Allocations of costs are started in the cell along the row or column which has the highest RATOCs or CATOCs. This approach is also developed by considering only cost matrix.

In the article [35], author proposed a modified method to north-west corner method for finding IBFS. Very recently, some modified approaches based on LCM are found in the publications of [7], [26], etc. Some statistical methods are found in [36], [40]. In [35] authors have presented an alternative method of NWC method by using Statistical tool called Coefficient of Range (CoR) by statistically analyzing the cost matrix. Author, in [47], introduced a new algorithm for solving TPs. They proposed the Gauss Jordan pivoting method to solve the TPs. They consider only cost matrix and iteratively it finds out the solution. This algorithm is faster than Simplex method.

Some heuristic methods of TPs to find out IBFS are found in the articles [3], [9], [11], [12], [20], [21], [37], [48-56]. In fuzzy environment, many research publications are found in the literature of which some recent publications are included in the articles [13], [23], [27], [32]. Researchers also dedicated to find better IBFS for unbalanced TPs [10], [17], [32], [34]. A good survey of TP for finding IBFS is observed in [31], [57-58]. On the other hand, [15], [16] and [17] proposed a new technique for controlling the flow of allocation named Weighted Opportunity Cost (WOC) matrix. The WOC matrix is formed by demand and/or supply as a weight factor corresponding to each transportation cost. Authors in [15], [16] and [17] also considered some numerical instances to test the efficiency of the proposed algorithms. In [59] authors considered a fractional objective function rather than a linear objective to solve TPs. In [60], presented a modified VAM specifically designed for maximizing profit, with the flow of allocation controlled by cost entries as well. Moreover, in recently published articles [61-64], authors have proposed various methods to find the IBFS of TPs in which the flow of allocations is controlled by manipulating only cost entries.

It is observed that many approaches are available in the literature, and researchers are continuously working to develop more efficient methods to solve the TPs. But as far as it is known, none of the approaches is the best for solving all TPs. In our earlier work [15] Jamali also noticed this pitfall and proposed a newer approach to LCM. Though it [15] performed better compared to LCM but it frequently obtains worse IBFS compared to VAM.

It is known that classical methods like the LCM and VAM are relatively less computationally expensive compared to other approaches for finding the Initial Basic Feasible Solution [28] (IBFS) of Transportation Problems (TPs) [18]. Although VAM generally performs better than LCM, there are cases where LCM outperforms VAM. This raises the question: Is the performance variation due to the distribution of node capacities?

Additionally, it is observed that in the transportation sector, increasing the amount of goods often reduces transportation costs. Based on this observation, we investigate how node capacities influence transportation costs. Notably, no researchers have yet developed methods that leverage the effect of node capacity on the allocation and flow of commodities.

In this paper, we extensively examined the impact of capacity distribution among the nodes on classical well-known approaches, namely LCM and VAM, considering the problem mentioned in the existing literature. Next, we developed a capacity-blended flow-controlling matrix based on the cost matrix. Finally, we proposed a novel capacity-influenced approach to find the IBFS of TPs.

The novelties of the proposed approach are explained in the following:

- We propose a novel approach to find better IBFS for the TPs by developing a new, unique distribution indicator (DI) that combines the capacity vectors and DI vector to control the flow of allocation.
- Our approach proposes a more effective solution for the TPs that can overcome the limitations of existing methods, namely VAM and LCM, by addressing the impact of capacity distribution among the nodes.
- Proposed approach introduces a capacity-influenced weighted factor and a capacity-influenced Weighted Opportunity Cost (WOC) Matrix to find a more suitable IBFS in a computationally efficient way for VAM and LCM.
- We extensively verified the impact of capacity distribution and proposed methods have been experimentally verified to evaluate its performance over other approaches using real examples.

The remainder of the paper is organized as follows. Section II explains the mathematical model of TPs. Section III extensively examines the impact of capacity distribution among nodes for both LCM and VAM for TPs. Section IV explains the proposed method of this paper. This section develops and explains proposed mathematical model named as “Capacity influenced weighted factor” to control the flow of allocations. It also develops the formulation of control matrix of the proposed approach. Detailed results of numerical experiments to validate the efficiency of the proposed method is explained in Section V and conclusion of this study is presented in the last section.

II. Mathematical Model of Transportation Problem

By considering the equality characteristics of TPs, it can be represented using a specialized tableau known as the Transportation Tableau (TT). The typical view of TT is shown in Table I. In the TT, O_i indicates the ith source with the amount of availability is ai which is shown in the far-right column. On the other hand, D_j denotes the jth destination with demand b_j, which is shown in the bottom row of TT. In this table, there is an m×n matrix containing cost entries. The cell in the *i*th row and *j*th column is called the C_{ij} cell and the transportation cost is denoted as cij, which represents the unit shipping cost from the *i*th source to the *j*th destination. So, a TT can be viewed as a (m+1) × (n+1) matrix shown in Table I.

TABLE I. A TT OF A TP WITH M SOURCES AND N DESTINATIONS

	Sinks/Destinations

	Demand	b_1	b_2	$\cdots$	b_{n-1}	b_n	

III. IMPACT OF THE CAPACITY DISTRIBUTIONS AMONG NODES ON LEAST COST AND VOGEL'S APPROXIMATION METHODS

First three typical balanced TPs are considered which are presented in the Examples 1(a) – 1(c) and their corresponding comparative analyses are presented in Table II to Table X. It should be noted that in all three TPs, the cost matrices are identical, and the total capacity remains the same. The only difference lies in the distribution of capacity among the nodes. Numerical experiments have been conducted to investigate the effect of capacity on both the LCM and VAM in terms of finding the IBFS and total cost [19].

To examine the effect of capacity on LCM and VAM, we have first compared the step-by-step flow of allocations. The intensive comparison of the step-by-step flow of the allocations procedure of the two approaches is concisely shown in Table XI. It is observed in Table XI that due to the change of capacity distribution among the nodes, the pattern of flow of allocation is changed significantly for both approaches. Furthermore, it is observed that the IBFS obtained using both methods undergo significant changes for each instance.

Now we have compared IBFSs and Total Transportation Costs (TTC) for each instance. The effect of the capacity distribution of nodes for each instance is shown in Table XI. It is observed that only by a change of capacity distribution among the nodes, the total transportation cost for each instance produced by LCM is changed significantly. Similarly, only by a change of capacity distribution among the nodes, the total transportation cost for each instance produced by VAM is changed significantly. It is also observed that the IBFSs produced by LCM of the three instances are changed significantly. Similarly, it is also observed that the IBFSs produced by VAM of the three instances are changed significantly. It has been observed that in Example 1(a), the LCM produced a superior IBFS compared to VAM, with a notable and significant difference between the two solutions. But only the change of capacity distribution, in Example 1(b), VAM produced a better solution compared to LCM. Moreover, in Example 1(c), though LCM produced a better solution, but the difference between the two solutions is not large.

TABLE XI. Comparison Between Three Examples Regarding the Effect of Capacity

	Ex. 1(a) Equal capacity Demand: 20, 20, 20 Supply: 20, 20, 20		Ex. 1(b) Unequal Capacity Demand: 30, 20,120 Supply: 10, 20, 30		Ex1 (c) Unequal Capacity Demand: 30, 20, 10 Supply: 20, 35, 5	
	T. Cast	IBFS	T. Cost	IBFS	T. Cost	IBFS
LCM	**380**	$x_{11}\rightarrow x_{22}\rightarrow x_{33}$ 20→ 20 → 20	520	$x_{11}\rightarrow x_{22}\rightarrow x_{13}\rightarrow x_{33}$ 10 → 20 → 20→ 10	295	$x_{11}\rightarrow x_{22}\rightarrow x_{12}\rightarrow x_{32}\rightarrow x_{33}$ 20 → 20→10 → 5 → 5
VAM	520	$x_{13}\rightarrow x_{21}\rightarrow x_{32}$ 20 →20 →20	**470**	$x_{13}\rightarrow x_{21}\rightarrow x_{22}\rightarrow x_{32}$ 30 →10→ 10 →10	**305**	$x_{13}\rightarrow x_{11}\rightarrow x_{22}\rightarrow x_{12}\rightarrow x_{32}$ 5 → 20 → 20 → 5 → 10

We have performed further experiments to examine the effect of capacity distribution on the flow of allocations of both LCM and VAM. For this numerical experiment, we have considered some more examples shown in Table XII.

We have performed both approaches, namely LCM and VAM to find out IBFS. The experimental result is shown in Table XII. It is observed in Table XII that instances 2(a) –2(c) has the same cost matrix but the capacity distributions are different. Though instances 2(a) – 2(c) have different distributions of capacity, the total supply/demand is equal for each instance. Similarly, instances 3(a) to 3(c) have identical cost matrices, but the capacity distributions vary. Though Examples 2(a) – 2(c) have different capacity distributions but total supply/demand is equal for each instance. It is observed for Example 2(a), that VAM produced a better solution which is also an optimal solution, but only a change of capacity distribution, for Example 2(b) and 2(c), LCM obtained a better solution compared to VAM. Similarly, it is observed that for Example 3(a) LCM produced a better solution which is also an optimal solution, but only a change of capacity distribution, for Example 3(c), LCM obtained a better solution compared to VAM, but for Example 3(b) VAM obtained a better solution compared to LCM. The experimental results are examined intensively. We have found out significant effects of the distribution of capacities on the IBFS of each approach.

IV. OUR PROPOSED METHOD: A NOVEL DISTRIBUTION INDICATOR AND CAPACITY-INFLUENCED APPROACH TO IBFS FOR TRANSPORTATION PROBLEMS

In classical approaches, like North-West Corner Rule [35], LCM, the flow of allocation is controlled directly by the cost entries only. Once again, in some other classical transportation approaches, such as Vogel's VAM method and all its variants, the flow of allocations is controlled solely by the manipulation of cost entries. Moreover, based on our literature review, it is observed that almost all approaches have been developed by manipulating cost entries exclusively. None of these approaches considers the node's capacity when formulating the control matrix for the flow of allocation. However, as observed in the previous section of this article, the distribution of commodities plays a crucial role in controlling the flow of allocations. In the previous investigation section, it is observed that the distribution of commodities significantly alters the performance of the approaches. In this article, we first developed a novel capacity-influenced weighted factor and then proposed a capacity-influenced WOC Matrix-based algorithm to find the IBFS of TPs. These are explained in the following sections.

A. *The Proposed Capacity-Influenced Weighted Factor to Control the Flow of Allocation*

Vogel's method formulates the DI by calculating the difference between the smallest and the next-to-smallest cost entries for each node (supply/destination). In this formulation, DI serves as a weight factor corresponding to the cost entries, controlling the flow of allocations. While existing literature emphasizes DI as a controlling tool, it is observed in the previous section that node capacity also significantly influences allocation flow, alongside cost entries. Therefore, a novel approach is needed to control the flow of allocations in TPs by combining the weight factor DI with the weight factor of the corresponding node's capacity. The primary challenge involves developing a suitable weight factor for the capacity of each node. Subsequently, a new flow of allocation matrix needs to be formulated, incorporating both the capacity of nodes and DI as a combined weight factor for the corresponding cost entries. The first challenge is to find out the weight factor to the cost matrix from the capacity of nodes.

The WOC matrix is a new concept to control the flow of allocations of TP to find out IBFS. In WOC, amount of supply/demand of each route is a weighted factor corresponding to the cost entry. The procedures to find out capacity influenced approach is discussed step by step below:

Step 1: Finding cell weight: At first, we have found out the maximum possible allocation of the cell $\mathrm{C_{ij}}$, which is $(\mathrm{S_i}, \mathrm{D_j})$, where $\mathrm{S_i}$ denotes total supply at node i and $\mathrm{D_j}$ indicates total demand at node j. Therefore, sum over of all possible allocations is as follow:

$$\sum_{i=1}^{p}\sum_{j=1}^{q}\min\left(\mathrm{S_i}, \mathrm{D_j}\right)$$

Therefore, for each cell C_{ij} its weight will be as follows

$$\min\left(\mathrm{S_i}, D_j\right) \Big/ \sum_{i=1}^{p}\sum_{j=1}^{q}\min\left(\mathrm{S_i}, D_j\right)$$

So that total weight becomes one. i.e.,

$$\sum_{i=1}^{p}\sum_{j=1}^{q}\left\{ \min\left(\mathrm{S_i}, D_j\right) \Big/ \sum_{i=1}^{p}\sum_{j=1}^{q}\min\left(\mathrm{S_i}, D_j\right) \right\} = 1$$

But since every cell of cost matrix will contain the factor $1 \Big/ \sum_{i=1}^{p}\sum_{j=1}^{q}\min\left(\mathrm{S_i}, \mathrm{D_j}\right)$, so we have ignored this factor to reduce computational cost. Therefore, for each cell C_{ij} its weight will be just $min\ (S_i\ , D_j)$.

Step 2: The second challenge is to find out the combined weight factor formulated by the weight factor DI and the weight factor WOC to the cost matrix for each route (cell). The proposed modified weight factor, $\mathrm{W_{ij}^{m}}$, for the cell Cij is formulated as follows in equation (1):

$$W_{ij}^{m} = \min\{a_i, b_j\} \cdot \max\{\{D_i^{Ir}, D_j^{Ic}\}, \} \qquad (1)$$

Where a_i is the amount capacity of source node O_i, b_i is the amount of the capacity of destination node D_i. Moreover, D_i^{Ir} is the DI corresponding to the source node i and D_j^{Ic} is the DI corresponding to the sink node j. Then total weight corresponding to all cells will be as in Eq. (2).

$$TW = \sum_{i}^{m}\sum_{j}^{n}\min\{a_i, b_j\} \cdot \max\{\{D_i^{Ir}, D_j^{Ic}\} \forall\ i = 1,2,\dots,m\ ; j = 1,2,\dots,n\} \qquad (2)$$

Then, the actual weight factor corresponding to each route (cell) C_{ij} is

$$AW_{ij}^{m} = \frac{\min\{a_i,b_j\}\cdot\max\left\{\{D_i^{Ir},D_j^{Ic}\right\}}{\sum_i^m\sum_j^n \min\{a_i,b_j\}\cdot\max\left\{\{D_i^{Ir},D_j^{Ic}\right\}}, \forall\, i = 1,2,\dots,m\,; j = 1,2,\dots,n \qquad (3)$$

Here in Eq. (3), $\max\{\{D_k^{Ir}, D_l^{Ic}\}\ \forall\, i,j$, is fixed and constant and also $\sum_i^m\sum_j^n AW_{ij}^{m} = 1$.

But since the term $\frac{1}{\sum_i^m\sum_i^n \min\{a_i,b_j\}\cdot\max\left\{\{D_i^{Ir},D_i^{Ic}\right\}}$ is common to all AW_{ij}^{m} $\forall i,j$ and as AW_{ij}^{m} act as a controller of the flow of allocation and it has no any real effect to measure the total transportation cost, so without loss of generality we can ignore this factor in flow of allocation matrix.

Therefore, the weight factor corresponding to the cell C$_{ij}$ can be expressed as follows in Eq. (4):

$$W_{ij}^{m} = \min\{a_i,b_j\} \times \max\left\{\{D_i^{Ir},D_j^{Ic}\right\} \qquad (4)$$

It is noted that this reduces a significant amount of computational cost. The significance of this weight is that larger weight poses larger possibility to flow of allocation.

Step 3: After the successful formulation of the weight factor corresponding to each cell (route), our next task is to formulate the capacity-influenced WOC Matrix. But now we have to face a problem regarding the accumulation of this weight factor to any cost entries. Since the cell with a lower cost has a preference for allocation first, on the other hand, the cell with a larger weight factor has a preference for allocation first. So, it is not directly possible to formulate a WOC matrix just by simply multiplying the weight factor by the cost entry to find out meaningful elements of the WOC matrix. To overcome this difficulty and for the formulation of a meaningful WOC matrix, we should transform one of the two so that the multiplication of the two will be meaningful. This can be done by inversing the cost elements. Therefore, the weighted opportunity cost corresponding to the cell cost C$_{\text{ij}}$ as stated in Eq. (5) below:

- $W_{c_{ij}}^{m} = \frac{1}{c_{ij}}\min\{a_i,b_j\} \times \max\left\{D_i^{Ir},D_j^{Ic}\right\}, c_{ij} \neq 0$ (5)

Here $W_{c_{ij}}^{m}$ and c_{ij} denote the modified weighted cost factor and actual cost entry corresponding to the cell C_{ij} respectively.

But another problem arises if the cost at any cell is zero. Since when $c_{ij} = 0$ then $\frac{1}{c_{ii}}$ becomes undefined. So, to overcome this difficulty it is needed some more special attention. We can overcome this shortcoming by replacing zero with a significantly large value. So, if there exists any cell whose cost entry is zero, then we can formulate the virtual weighted cost to the cell C_{pq} as follows:

- If $c_{pq} = 0$ and $\{c_{ij}: 0 < c_{ij} < 1, \forall i,j\} = \varphi$, (i.e. null set) then set $W_{c_{ij}}^{m} = \max\left\{a_i, b_j; \forall i,j\right\} \times \min\{a_i,b_j\} \times \max\left\{\{D_i^{Ir}, D_j^{Ic}\right\}$
- Else if $c_{pq} = 0$ and $\{c_{ij}: 0 < c_{ij} < 1, \forall i,j\} \neq \varphi$ (i.e. not null set), then set $W_{c_{ij}}^{m} = \frac{\max\left\{a_i,b_j;\forall i,j\right\}}{[\min\left\{c_{ij}:0<c_{ij}<1,\forall i,j\right\}]} \times \min\{a_i,b_j\} \times \max\left\{\{D_i^{Ir},D_j^{Ic}\right\}$

B. *Proposed Formulation of the Capacity-Influenced Control Matrix*

After development of modified weighted cost factor, we can easily formulate the Modified Weighted Cost (MWOC) Matrix$\left[W_{c_{ij}}^{m}\right]$ which is as follows:

- If $c_{ij} \neq 0$; $W_{c_{ij}}^{m} = \frac{1}{c_{ij}}\min\{a_i,b_j\} \times \max\left\{D_i^{Ir},D_j^{Ic}\right\}$
- If $c_{ij} = 0$ and $\{c_{pq}: 0 < c_{ij} < 1, \forall p,q\} = \varphi$, (i.e. null set) then set $W_{c_{ij}}^{m} = \max\left\{a_i, b_j; \forall i,j\right\} \times \min\{a_i,b_j\} \times \max\left\{\{D_i^{Ir}, D_j^{Ic}\right\}$
- Else if $c_{pq} = 0$ and $\{c_{pq}: 0 < c_{ij} < 1, \forall p,q\} \neq \varphi$ (i.e. not null set), then set $W_{c_{ij}}^{m} = \frac{\max\left\{a_i,b_j;\forall i,j\right\}}{[\min\left\{c_{ij}:0<c_{ij}<1,\forall i,j\right\}]} \times \min\{a_i,b_j\} \times \max\left\{\{D_i^{Ir},D_j^{Ic}\right\}$

C. *Algorithm of Proposed Capacity-Influenced Approach*

Step 1: Form the MWOC weight factor matrix.

Step 2: Allocate (as much as possible), i.e., min {Si, Di}, to the cell (route) which has the largest weight factor.

Step 3: Update the cost matrix by crossing out exhausted cells and corresponding weight factors.

Step 4: Terminate if all demand requirements are satisfied; otherwise, go back to step 2.

Once all cells are allocated, calculate the total transportation cost by multiplying the allocated units with their respective costs and summing up all these products.

V. NUMERICAL EXPERIMENTATION

Now we will implement the proposed method and will compare its performance with existing approaches namely LCM and VAM. For the experimental study we have considered another TP 4 (see Example 4) whose TT is given in the Table XIII.

Example 4:

TABLE XIII. TRANSPORTATION TABLEAU OF TRANSPORTATION PROBLEM 4

	D$_1$	D$_2$	D$_3$	Supply
O$_1$	4	3	5	90
O$_2$	6	5	4	80
O$_3$	8	10	7	100
Demand	70	120	80	

TABLE XIV. MODIFIED WEIGHTED OPPORTUNITY COST MATRIX OF THE PROBLEM 4

	D$_1$	D$_2$	D$_3$	Supply	DI
O$_1$	$\frac{140}{4}$	$\frac{180}{3}$	$\frac{80}{5}$	90	1
O$_2$	$\frac{140}{6}$	$\frac{160}{5}$	$\frac{80}{4}$	80	1
O$_3$	$\frac{140}{8}$	$\frac{200}{10}$	$\frac{80}{7}$	100	1
Demand	70	120	80		
DI	2	2	1		

To find the IBFS of the proposed method, we first need to find out the flow of the control matrix called the Modified Weighted Opportunity Cost (MWOC) matrix shown in Table XIV. To explain how to form the MWOC matrix, let us consider the cell C_{12}. It is observed that the unit cost $c_{12} = 4$ which is not zero. Therefore, the algorithm executes case (a) of the proposed method, formally:

$$W^{m}_{c_{12}} = \frac{1}{c_{12}} \min\{a_1, b_2\} \times \max\{ D_1^{Ir}, D_2^{Ic}\}$$

$$= \frac{1}{3} \times \min\{90,120\} \times \max\{ 1, 2\}$$

$$= \frac{1}{3} \times 90 \times 2 = \frac{180}{3}$$

TABLE XV. MODIFIED WEIGHTED OPPORTUNITY COST INCLUDED TRANSPORTATION TABLEAU PROBLEM 4

	D_1	D_2	D_3	supply	DI
O_1	$\frac{140}{4}$ 4	$\frac{180}{3}$ 3	$\frac{80}{5}$ 5	90	1
O_2	$\frac{140}{6}$ 6	$\frac{160}{5}$ 5	$\frac{80}{4}$ 4	80	1
O_3	$\frac{140}{8}$ 8	$\frac{200}{10}$ 10	$\frac{80}{7}$ 7	100	1
Demand	70	120	80		
DI	2	2	1		

We can represent the cost matrix and the MWOC matrix in a single tableau as shown in Table XV. In Table XV, the entry in the top-left corner of each cell represents the weighted opportunity cost factor associated with that cell, while the entry in the top-right corner represents its transportation cost. The step by step of each allocation's procedure of the proposed MWOC-based approach is shown in Tables XVI to XXI. The IBFS of the problem obtained by the proposed method is shown in Table XVI. It is observed that the TTC for finding the IBFS by the proposed method is 1440.

Now have solved the problem with the existing LCM, VAM, and WOC-LCM and compared it with the proposed method named MWOC-VAM. The comparison is shown in Table XXII. It is observed in Table XXII that the proposed MWOC-VAM needs the least amount of transportation cost to obtain the IBFS compared to all other approaches namely LCM, VAM, and WOC-LCM. It is also observed that the starting allocation of LCM, WOC-LCM, and MWOC-VAM are the same but differ from VAM. It is also observed in the second column of Table XXII that the pattern of the flow of allocation for each approach is different.

TABLE XXII. COMPARISON REGARDING THE FLOW OF ALLOCATIONS AND TOTAL TRANSPORTATION COST TO FIND OUT THE IBFS OF THE PROBLEM 4

Method	Flow of allocations and IBFS	Total Cost
LCM	$x_{12} \rightarrow x_{23} \rightarrow x_{31} \rightarrow x_{32}$ 90→ 80 →70 → 30	1450
VAM	$x_{11} \rightarrow x_{33} \rightarrow x_{12} \rightarrow x_{22} \rightarrow x_{32}$ 70→ 80 →20 → 80 → 20	1500
WOC-LCM	$x_{12} \rightarrow x_{23} \rightarrow x_{32} \rightarrow x_{31}$ 90 → 80 → 30→ 70	1450
MWOC-VAM (proposed)	$x_{12} \rightarrow x_{22} \rightarrow x_{21} \rightarrow x_{31} \rightarrow x_{33}$ 90→ 30 → 50 → 20 → 80	**1440**

Now we have considered another problem 5 (Example 5), whose TT is given in the Table XXIII in which one route has zero transportation cost.

Example 5:

TABLE XXIII. TRANSPORTATION TABLEAU OF TRANSPORTATION PROBLEM 5

	D_1	D_2	D_3	Supply
O_1	1	16	17	10
O_2	**0**	6	8	2
O_3	3	3	7	3
Demand	10	3	2	

We have again represented the cost matrix and the MWOC matrix in a single tableau in Table XXIV. It is observed in Table XXIV that c_{21} = 0 and its corresponding weight cost factor is 120. Once again, let's illustrate how to calculate the weight factor for that unit cost entry. According to the proposed method, since c_{21} = 0, the algorithm executes case (b). Formally:

(b) As $c_{21} = 0$ and $\{c_{pq}: 0 < c_{ij} < 1, \forall p, q\} = \varphi$, (i.e. null set), so

$$W_{c_{21}}^{m} = \max\{a_i, b_j; \forall i, j\} \times \min\{a_2, b_1\} \times \max\{D_2^{Ir}, D_1^{Ic}\}$$

$$=\max\{10,2,3; 10,3,2\} \times \min\{2,10\} \times Max\{1,6\}$$

$$= 10 \times 2 \times 6 = 120$$

It is observed in the Table XXIV that the weight opportunity cost of the cell C_{21} is 120 corresponding to the minimal cost i.e., c_{21} = 0 obtained by the case (b) of the proposed approach. On the other hand, the weight opportunity cost of the cell C_{11} is 150 corresponding to the cost 1 i.e., c_{11} = 1. It is worthwhile to mention here that the weight factor corresponding to the route (cell C_{11}) is largest though it's cost entry is not minimum. Now we have solved the problem with the proposed MWOC-VAM as well as LCM, VAM, and WOC-LCM. The experimental result is shown in Table XXV.

It is observed in Table XVI that the proposed MWOC-VAM and VAM need the least amount of transportation cost to obtain the IBFS compared to all other approaches, LCM and WOC-LCM. It is observed that the starting allocation of VAM and proposed MWOC-VAM are the same but different from both LCM and WOC-LCM. On the other hand, the starting allocation of LCM and proposed WOC-LCM are the same. Moreover, VAM and MWOC-VAM need fewer steps to get IBFS. It is also observed in the second column of Table XXVI that the pattern of the flow of allocation for each approach is different. Now we have considered another problem 6 (Example 6) in which one route has zero transportation cost and some route's transportation cost is less than 1 but getter than zero.

TABLE XXIV. MODIFIED WEIGHTED OPPORTUNITY COST INCLUDED TRANSPORTATION TABLEAU PROBLEM 5

	D_1	D_2	D_3	supply	DI
O_1	$\frac{150}{1}$ 1	$\frac{45}{16}$ 16	$\frac{30}{17}$ 17	10	15
O_2	120 0	$\frac{12}{6}$ 6	$\frac{12}{8}$ 8	2	6
O_3	$\frac{3}{3}$ 3	$\frac{9}{3}$ 3	$\frac{2}{7}$ 7	3	0
Demand	10	3	2		
DI	1	3	1		

TABLE XXV. COMPARISON REGARDING THE FLOW OF ALLOCATIONS AND TOTAL TRANSPORTATION COST TO FIND OUT THE IBFS OF THE PROBLEM 5

Method	**Flow of allocations and IBFS**	**Total Cost**
LCM	$x_{21} \rightarrow x_{11} \rightarrow x_{32} \rightarrow x_{13}$ 2 → 8 → 3 → 2	51
VAM	$x_{11} \rightarrow x_{32} \rightarrow x_{23}$ 10 → 3 → 2	**35**
WOC-LCM	$x_{21} \rightarrow x_{11} \rightarrow x_{32} \rightarrow x_{13}$ 2 → 8 → 3 → 2	51
MWOC-VAM (proposed)	$x_{11} \rightarrow x_{23} \rightarrow x_{32}$ 10 → 2 → 3	**35**

Example 6:

TABLE XXVI. TRANSPORTATION TABLEAU OF TRANSPORTATION PROBLEM 6

	D_1	D_2	D_3	Supply
O_1	0	3	0.5	8
O_2	3	7	10	3
O_3	1	0.7	11	9
Demand	6	6	8	

It is observed in the Table XXVI that c_{11} = 0, c_{13} = 0.5 and c_{32} = 0.7. So, to find out the weight cost factor corresponding to the cost entry 0, the algorithm executes the case (c) of the proposed method. Formally:

(c) As $c_{11} = 0$ and $\{c_{pq}: 0 < c_{ij} < 1, \forall p, q\} = \{0.5, 0.7\} \neq \varphi$, so

$$W_{c_{11}}^{m} = \frac{\max\{a_i, b_j; \forall i, j\}}{[\min\{c_{ij}: 0 < c_{ij} < 1, \forall i, j\}]} \times \min\{a_1, b_1\} \times \max\{D_1^{Ir}, D_1^{Ic}\}$$

$$= \frac{\max\{8,3,9, \quad 6,6,8\}}{[\min\{0.5,0.7\}]} \times \min\{8,6\} \times \max\{1, 0.5\}$$

$$= \frac{9}{0.5} \times 6 \times 1 = 108$$

We have again represented the cost matrix and the MWOC matrix in a single tableau as Table XXVII. It is observed in the Table XXVII that the weight opportunity cost of the cell C_{11} is 108 corresponding to the minimal cost i.e., c_{21} = 0 obtained by the case (c) of the proposed algorithm. Moreover, the weight opportunity cost of the cell C_{13} and C_{32} are 152 and 19.71 respectively which are calculated according to the case (a) as well. Now we have solved the problem by the proposed MWOC-VAM as well as LCM, VAM and WOC-LCM. The experimental result is shown in the Table XXVIII.

It is observed in Table XXVIII that the proposed MWOC-VAM and VAM need the least transportation cost to obtain the IBFS compared to the other two approaches, LCM and WOC-LCM. It is observed that the starting allocation of VAM and proposed MWOC-VAM are the same but different from both LCM and WOC-LCM. On the other hand, the starting allocation of LCM and proposed WOC-LCM are the same. It is also observed in the second column of Table XXVIII that the pattern of the flow of allocation for each approach is different.

To analyze the performance and effectiveness of the proposed method, we considered an additional 10 randomly generated numerical instances. The experimental results are displayed in Table XXIX. It is evident from Table XXIX that the proposed method consistently outperforms both the existing LCM and WOC-LCM approaches. Furthermore, in two instances, the proposed method surpasses VAM, while in other cases, it yields equivalent total costs compared to VAM. It is also observed that the IBFSs obtained by the proposed method are optimal or near optimal.

We collected an additional 8 numerical instances from published international journals/conferences to evaluate the efficiency and effectiveness of the proposed method. In Table XXX, the first column indicates the reference number of the published article. The data presented in Table XXX show that, except for three instances where all approaches obtained optimal solutions, the proposed method consistently outperforms both LCM and WOC-LCM. It is noteworthy that, in four out of eight instances, the proposed method outperforms VAM, while in the remaining instances, both approaches yield similar solutions.

The numerical experiments indicate that the proposed MWOC-VAM consistently performs as well as or better than both VAM and LCM. Furthermore, VAM requires the calculation of the DI at each iteration, which increases its computational cost. In contrast, the proposed MWOC-VAM only needs to compute the DI and WOC once initially, making it more computationally efficient.

VI. Conclusion

IBFS is crucial for obtaining an optimal solution in TP. While various approaches exist in the literature to determine IBFS, most are formulated by manipulating the cost matrix to control allocation flow. In this article, we stand out as perhaps the first to consider the impact of node capacity distribution on the flow of allocations in both LCM and VAM. Through numerical experiments, we observed significant changes in output due to the distribution of capacity among nodes, even when the cost matrix and total supply and demand remained constant. For example, if the cost matrix is identical, the flow of allocations for approaches like NWC, LCM, VAM, etc., remains almost unchanged regardless of the distribution of capacity among nodes. However, by addressing this issue in the formulation of the flow allocation matrix in the proposed method, the flow of allocations varies significantly. To leverage this effect, we introduced a novel tool to control allocation flow. To incorporate the influence of node capacity distribution, we developed a capacity-influenced allocation control matrix, termed Capacity-Influenced Distribution Indicator (CI-DI), along with the distribution indicator defined by VAM. Subsequently, we proposed a capacity-influenced algorithm for finding IBFS in balanced TP. It is observed from the numerical experiments that the proposed method is effective to find out better IBFS of TPs. The proposed approach significantly overcomes the limitations of both LCM and VAM concerning the impact of capacity distribution among nodes. Additionally, it demonstrates enhanced computational efficiency compared to VAM. While VAM requires the calculation of the DI for each allocation step, the proposed method only needs to compute the Capacity-Influenced Distribution Indicator (CI-DI) matrix once. Experimental results lead to the conclusion that practitioners in the supply chain and transportation domain should not only consider cost distributions but also recognize the substantial role of capacity distributions among nodes in controlling allocation flow, leading to the identification of better IBFS. The concept of a capacity-influenced flow of allocation is innovative, providing a new perspective or "window" through which researchers can approach transportation problems and other linear programming challenges. In future work, we aim to develop a hybrid algorithm by integrating the proposed approach with fuzzy-based techniques.

***Abstract*—The digital data consumed by the average user daily is huge now and is increasing daily all over the world, which requires sophisticated methods to automatically process data, such as retrieving, searching, and formatting the data, particularly for classifying text data. Long Short-Term Memory (LSTM) is a prominent deep learning model for text classification. Several metaheuristic approaches, such as the Genetic Algorithm (GA), Particle Swarm Optimization (PSO), and Firefly Algorithm (FF), have also been used to optimize Deep Learning (DL) models for classification. This study introduced an improved technique for text classification, called RSS-LSTM. The proposed technique optimized the hyperparameters and kernel function of LSTM through the Ringed Seal Search (RSS) algorithm to enhance simplification and learning ability. This work was also compared and evaluated against state-of-the-art techniques such as GA-LSTM, PSO-LSTM, and FF-LSTM. The results showed significantly better results using the proposed techniques, with an accuracy of 96%, recall of 96%, precision of 96%, and 95% f-measure on the Reuters-21578 dataset. In addition, it showed an accuracy of 77%, recall of 77%, precision of 78%, and f-measure of 76% on the 20 Newsgroups dataset, while it achieved accuracy, recall, precision, and f-measure of 91%, 91%, 94%, and 90%, respectively, using the AG News dataset.**

Keywords*—Deep learning; text classification; Long Short-Term Memory; Ringed Seal Search; metaheuristic algorithms; Part Swarm Optimization; Genetic Algorithm; Firefly Algorithm; hyperparameter optimization

I. INTRODUCTION

A large amount of textual data and different types of content are distributed to millions of people worldwide on the internet. The significant increase in the size of online data has attracted significant attention nowadays. Because of the large increase in textual data worldwide, the demand for text classification has also increased [1]. Hence, searching for a specific document within a large collection has become a difficult challenge. It examines people's emotions and distinguishes between customer comments on specific topics. Text classification (text categorization or tagging) involves assigning a text document to a set of predefined labels or classes using different machine learning and deep learning methods [2]. Different text classification techniques have been widely employed to categorize and organize content. It is important to gather and categorize documents automatically, according to their content. The primary objective of text classification is to divide unstructured documents into appropriate groups according to their content [3].

Machine Learning (ML) and Artificial Intelligence (AI) have gained significant prominence in recent years, emerging as highly discussed subjects. Numerous machine learning methods have achieved remarkable results in Natural Language Processing (NLP) [4]. However, conventional machine-learning-based text classification techniques have several drawbacks, including dimension explosion, data sparsity, and generalization capacity and selecting the optimal parameters for models. Most earlier research must consider the possibility that data could be misplaced or misconstrued following neural network computations [5]. The development of new machine learning techniques has yielded significant advancements in recent years, and deep learning has received more attention in the context of text categorization [6]. Deep learning techniques have been successful in the past few years, and there has been a significant increase in studies in this field, signifying that deep learning approaches have outperformed traditional machine-learning-based approaches in several text classification tasks, such as sentiment analysis, news categorization, question answering, and natural language inference [7].

Natural Language Processing has prioritized text classification for a long time. Currently, methodologies and techniques constitute integral components of numerous products and are deemed essential for a wide array of applications and devices. Many deep learning architectures, including LSTM Recurrent Neural Network (RNN), Convolutional Neural Network (CNN), and more recent transformers, have been applied to attain various state-of-the-art outcomes in NLP tasks [8]. Text classification is a major process in Natural Language Processing, and recent research has focused on deep learning-based neural network techniques that have shown promise. However, previous studies have often overlooked the potential loss or misinterpretation of information in neural network calculations. A study introduced LSTM-Com, a technique that leverages historical information, such as the original text and hidden layer outputs, to address these issues. LSTM-Com dynamically selects important historical information to compensate for the neural network, resulting in improved performance compared with the baseline in the classification experiments. A Long Short-Term Memory approach overcomes these challenges by performing text classification using historical data, including the original text data and output data

from the hidden layers [9]. Deep learning-based techniques are more beneficial for text classification compared to machine learning that uses traditional text classifiers, which have flaws such as data sparsity, dimension proliferation, and less generality; instead, the classifiers based on deep learning techniques can magnificently overcome these defects because they have strong learning ability with higher prediction accuracy; in contrast, they also avoid a cumbersome feature extraction process [10].

To build an LSTM model for classification, machine learning researchers manually configure certain parameters that are independent of the data. These parameters, such as the network structure and the training process of the LSTM, are known as hyperparameters. A key challenge is to find a set of hyperparameters that yield an accurate model within a reasonable timeframe, which is an integral part of the hyperparameter optimization problem [11]. The optimization of hyperparameters plays an important role in the performance of machine-learning algorithms. The importance of hyperparameter optimization is well recognized; however, there has been limited research to confirm its assumptions. Hyperparameter optimization is crucial for deep learning models because it directly affects their performance and generalization. Without optimal hyperparameters, a model may underfit or overfit, failing to capture the underlying patterns in the data. Tuning helps strike the right balance, maximizing the model's performance on unseen data [12]. Hyperparameter optimization is critical in machine learning. Machine-learning algorithms require the setting of hyperparameters before training the model. These values significantly impact the model’s performance, but finding good ones is complex, which has led machine learning researchers to look into automated methods for hyperparameter searches [13].

A previous study showed that a meta-heuristics-based algorithm has a significant effect on optimization. In addition, when an optimization problem's dimension (the number of routes or furnished) is increased, a study of the Grasshopper Optimization Algorithm (GOA) explains it [14]. The hyperparameters of a CNN significantly affect its performance and adjusting them manually is laborious and ineffective. The Spotted Hyena Optimization (SHO) is a high-level metaheuristic optimization algorithm with sophisticated exploration and exploitation capabilities. SHO produces a set of solutions in the form of hyperparameters that must be tuned. This procedure was repeated until the target optimal solution was attained [15].

Balancing exploration and exploitation play a central role in defining the effectiveness of an evolutionary algorithm. Optimal performance necessitates varying levels of the exploration-exploitation trade-off at different stages of evolution [16]. A study discussed the importance of balancing local exploitation and global exploration in metaheuristic algorithms and elaborated on the effectiveness of the bat algorithm in achieving this balance. Comparing the bat algorithm with the recurrent search approach, the study demonstrates that the bat algorithm is superior; it also explores the consequences of these findings for higher-dimensional optimization problems and applies the bat algorithm to business and engineering design optimization. A healthy search requires balancing exploration and exploitation [17]. A thorough survey is necessary because various techniques, datasets, and evaluation criteria have been proposed in the literature [18]. Firefly cannot offer a robust mechanism for achieving an ideal balance between exploration and exploitation; it cannot set the parameters strongly [19]. The RSS algorithm is a metaheuristic with two searching states (Brownian and Levy) that substitute randomly because of noise and balance exploitation and exploration of the search, the likelihood of finding local optima quickly is very low. Furthermore, RSS uses significantly fewer parameters than GA, PSO, and FF [20].

The performance of LSTM depends on parameter optimization, which is applied to text classification using various metaheuristic algorithms.

Following major contributions through in proposed approach:

- Pre-processing of data to make it efficient for further processing for feature engineering and deep learning model.
- An enhanced LSTM with RSS is proposed for textual data classification. Hyperparameters have a significant impact on the performance of deep learning models. With this measure of data, choosing the appropriate parameters (by optimizing the kernel function) for a neural network has become a huge exploration region in recent research.
- The proposed technique is compared with existing techniques, such as GA, PSO, and FF, using LSTM. To validate the performance of the proposed model for four measuring matrices: Accuracy, Precision, Recall, and F1-Score.
- Evaluate the existing technique and the proposed technique using three benchmark datasets: 20 Newsgroups, Reuters-21578, and AG News.

Section II explains literature, Section III explains the proposed approach, and Section IV explains the results of the experiments and Section V elaborates the conclusion of this study.

II. Literature Review

Text classification applications include spam filtering, contextual search, opinion mining, product review analysis, content management, and text sentiment mining. When tuning the hyperparameter automatically using an algorithm, it is called auto-tuning, which offers an effective way to automatically train the process of a model, although it provides more efficient results [21].

Several studies have described different machine learning and deep learning models, including pre-processing of text classification, related calculations, and test methods [22-24]. A minimalist and multi-propose-based text classification approach, uTC, was tested on 30 different datasets and showed the best accuracy compared with other state-of-the-art classification methods [23]. Another study suggested a method for determining sentiment review comparisons using three feature extraction techniques: Word2vec, Doc2vec, and TF-

IDF. It uses machine learning algorithms, such as SVM, Naive Bayes, and Decision Tree, with a grid search for optimization. The performance of these algorithms was assessed based on accuracy [24]. The advantages and disadvantages of related models are sorted, and the CNN model can capture the important content of the text. By contrast, the RNN model can analyze the context. The deep learning method is applied to text classification, which saves a large amount of workforce and material resources and improves the accuracy of text classification [25].

A sampling technique was proposed to solve the imbalanced class distribution for classifying tweets using Random Forest, Naive Bayes, and XGBoost [26]. In text classification tasks, the long short-term memory network and convolutional neural network models can both achieve high classification accuracy, and different deep learning models propose feature engineering using Term Frequency-inverse Document Frequency (TF-IDF) and also compare it with CNN, LSTM, and LSTM Attention for short- and long-text classification [27]. A hybrid model using CNN and LSTM was proposed for text classification, in which the features of text sentences were extracted using a multi-scale CNN, and the dependence of the text context was then captured using an LSTM model [28]. A supervised weighing scheme called the term frequency-inverse category frequency model proposed for text classification using deep learning was proposed for five different datasets this research covers to overcome the computational cost compared to other deep learning models [29].

Although resource-intensive, hyperparameter optimization is essential for machine learning. A novel technique called AgentHPO, which automates this procedure, examines task data on its own, experiments with different hyperparameters, and optimizes them based on past performance. Compared to conventional methods, this methodology streamlines the setup, lowers the number of trials required, and improves interpretability. Empirical tests reveal that AgentHPO frequently performs better than human trials and yields interpretable outcomes [30].

Multiple hyperparameters need to be set and tuned for the deep learning model's evaluation to predict the early onset of Parkinson's disease using hyperparameter optimization of the deep learning model [31]. The MLearn-ATC algorithm was compared with popular algorithms for classification, including Support Vector Machines, Probabilistic Neural Networks (PNN), K-Nearest Neighbor (KNN), and Naïve Bayes [32], to solve the text categorization issue, they proposed approach was examined using three distinct document datasets: Reuters-21578, 20 Newsgroups, and Real dataset [33].

Comparative investigations on the various feature selection and classification techniques used in sentiment analysis based on Natural Language Processing and contemporary techniques such as the Genetic Algorithm and rough set theory are evaluated. Another study examined the differences between sentiment analysis and standard feature-selection techniques for text categorization [34]. Several studies using supervised and unsupervised learning methods have been conducted to solve the issue of fake news identification. A study was conducted using the ISOT dataset to identify fake news. Long Short-Term Memory is applied in the developed model to distinguish between fake and authentic news, and hyperparameter tuning techniques, including grid search and random search, are proposed to adjust the model's hyper-parameters [35].

A role-based access control (RBAC) strategy is required to precisely identify access permissions to secure data. SQL queries created by authorized users have extremely similar features and are challenging to separate. A CNN-LSTM based on Part Swarm Optimization was proposed for hyperparameter optimization to detect attacks in SQL queries. Stock market uncertainty has a significant impact on many global financial and economic activities. Setting an investment plan or choosing the best time to trade depends on forecasting stock price movement, and a PSO-LSTM-based technique was proposed for stock price forecasting [36]. Convolution layer and Bidirectional LSTM (BiLSTM) with the attention mechanism proposed for text classification, particularly sentiment analysis. However, there is still an issue that LSTM cannot distinguish the different relevance between each part of the document [37].

A cross-entropy trained-based deep learning model called a bidirectional LSTM network is employed to perform text classification, utilizing both supervised and semi-supervised procedures, and an evaluation test using IMDB and AG News Group datasets [38]. The CNN-LSTM-based NC2LO Caledonian crow-optimization-based hybrid approach was applied for short-text classification. It was applied to IMDb, Tagmy News, Twitter, and AG News datasets, for developing tool modeling skills and attainment attracted, this Caledonian crow optimization model employs both social and asocial learning [39]. Another study reviewed metaheuristic optimization algorithms for power systems, focusing on their ability to solve complex optimization problems in environments with limited information and computational resources. It discusses six key challenges in power systems and evaluates the effectiveness of various metaheuristic algorithms in addressing them, evaluating their importance in promoting environmental sustainability and supporting renewable energy sources. The effectiveness of a metaheuristic algorithm is mostly determined by how well it balances globally diversified exploration and local intensive exploitation [40].

A hybrid technique using bidirectional long short-term memory (BiLSTM) and bidirectional encoder representations from transformers (BERT)-based approach was proposed for text mining to understand Chinese railway incidents caused by electromagnetic interference. A text mining technique using TextBlob for sentiment score with TF-IDF vectorization and a Linear SVC classification model was proposed for text mining the Covid-19 vaccination Twitter dataset [41]. Table I gives a comprehensive review of related work.

Ship pilots must have a thorough understanding of the future positions of their ships and their target ship at a given time. However, there are now important problems that need to be resolved regarding forecast accuracy and computing efficiency. The deep, long, short-term memory network architecture and genetic algorithm were developed in this study to address these issues and predict the shipping route of inland water. The GA-LSTM model effectively increased the precision and speed of trajectory prediction [56]. Convolutional neural networks

(CNNs) have gained recognition for their promising performance in text categorization and sentiment analysis because they can preserve a document's 1D spatial orientation, where the order of words is crucial. Research has been conducted using genetic algorithms to automatically determine the ideal network architecture without the need for any intervention from experts [57]. Researchers use machine learning, and some use deep learning models to solve the classification issue, and Artificial Neural Networks (ANN), which are implemented with GA for text classification, although ANN also has the main problem of tuning hyperparameters [53].

A study investigated the impact of LSTM parameter optimization with meteoritic algorithms on text classification performance. The GA-LSTM automatically chooses settings to create the best gene subset. The original Cuckoo Search [58] optimization enters the local optimum because of the high dimensions of the early convergence of complicated issues. CS, PSO, and GA dominate global optimization algorithms in scientific and technological applications. These algorithms have limitations in the development of novel solutions to preserve the equilibrium between exploration and exploitation [59]. Choosing the best hyperparameter of a model has an immediate effect on the model's performance, and another study showed that the Bayesian Optimization [60] technique is a more viable technique for the performance of the K-Nearest Neighbor model than other models [61].

III. Proposed Approach

An improved text classification technique is proposed using Ringed Seal Search, Long Short-Term Memory and the model named RSS-LSTM, which demonstrated a considerable impact of LSTM hyperparameter optimization with RSS by optimization of the kernel. The RSS-LSTM technique proposed herein achieves a balanced approach between exploitation and exploration. The proposed research suggests a strong technique for hyperparameter optimization for text classification that produces more optimized results than the existing methods. This study explicitly compared using 20 Newsgroups, Reuters-21578, and AG News datasets for multiple labeled text classification. In this study, three datasets were taken from the Kaggle and UC Irvin machine learning repositories: 20 Newsgroups, Reuters-21578, and AG News. The datasets were used to evaluate the effectiveness of the RSS-LSTM. The experiment was programmed using the Jupyter Notebook for the proposed RSS-LSTM, at HP Xeone Workstation z440, 32gb RAM and 2.4 processor. The datasets used in this experiment were selected based on the extent to which they liked. There are two parts to the datasets; 30% of the data were chosen for testing, while 70% were used for training.

Fig. 1 shows the proposed model stages, which consist of three major stages: Data Pre-processing, Optimization of LSTM parameters, and performance measurement criteria. The details of the three stages are as follows.

A. *Stage 01*

Pre-Processing: In this stage 01 textual dataset, such as 20 Newsgroups, Reuters-21578, and AG News Group, are pre-processed and used for further experiments. Below list of preprocessing steps performed at this stage:

- Tokenization of datasets and feature extraction.
- Removing spaces and punctuation.
- Removing unnecessary words to proceed with meaningful words.
- Removing emojis and stop words.
- Porter stemmer to remove inflection.

B. *Stage 02*

Optimization of LSTM Parameters: An enhanced method using RSS based on LSTM was implemented in this stage. The performance of the proposed RSS-LSTM method was measured and compared with existing methods, such as GA-LSTM, PSO-LSTM, and FF-LSTM. The proposed RSS-LSTM showed improved results compared to existing techniques.

C. *Stage 03*

Performance Measuring: In this stage, the performance of the proposed model is evaluated, which comprises four measuring criteria: accuracy, recall, precession, and F1-score. The results section of the proposed comparison model explains these measurement criteria and their results. The proposed models focus on optimizing deep learning techniques, such as LSTM, to achieve optimal results. Fig. 1 shows the proposed model. Algorithm 1 shows the Pseudo-code of proposed RSS-LSTM technique.

5.  Search the nearness for a new layer with a Brownian walk
6.  Else
7.  Expend the search for a process for a new layer by using
    levy walk
8.  End if
9.  Evaluating the fitness of each new lair and comparison with
    the previous lair
10. If
11.   $L^{\text{best,k}} > L^{\text{best,k+1}}$
12. Select the new lair
13.   $L^{\text{best}} > L^{\text{best,k}}$
14. Else
15.   Go at 4
16. End if
17. Rank the solutions.
18. Return the best lair of execution
19. The global finest lair is fed LSTM classifier for training
20. Training the classifier (LSTM)
21. End while
22. End
```

D. *Proposed Approach RSS-LSTM Explanation*

A metaheuristic technique called RSS is suggested to address optimization issues. To escape predators, the RSS method relies on the foundation of seal pup behavior to find the best lair. This technique divides the search space into two states: ordinary, routine, and urgent or fast. Under ordinary and urgent states, an intensive and extensive search is performed to find good-quality air and move in it to escape predators [62].

If it identifies the location of the exploration space where ω = 1 (ω= 0 indicate the normal state), ∂ is notified that **Ω** contains β, a predator that is moving and making noise pointed as ω. A state (**Ω**, ρ) for an E event, where **Ω** is referred to as an urgent state if **Ω** comprises β and ∂ members of the event in the exploration space that has noise ω. Let A be an event and the search space be (**Ω**, β, ∂, ρ).

If the search space is now ρ is ω in a state where ω= 0 (shows the outside noise), then ∂ is assumed to be not informed **Ω**, contains β, and (**Ω**, ρ) represents a normal condition, executes a Levy-walk for an urgent ∂ situation and Brownian-walk for a typical normal condition ∂. The proposed RSS-LSTM is discussed in the next section.

Text Classification: The proposed research developed an enhanced technique using Ringed Seal Search and Long Short-Term Memory. The Hyperparameters of LSTM are optimized using the RSS one of the metaheuristic techniques, which overcomes the efficiency of the other techniques PSO-LSTM, GA-LSTM, and FF-LSTM algorithms. The selection of parameters for the classification problem presents one of the primary obstacles to the optimal LSTM. It is a frequent practice to improve LSTMs by utilizing metaheuristic search algorithms that are inspired by nature to achieve better classification outcomes. A brief description of the LSTM classifier is provided below:

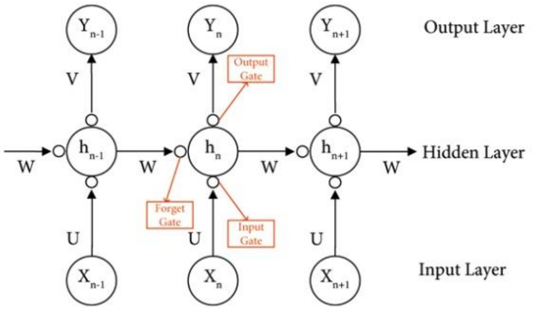

Fig. 2. LSTM Classifier.

As shown Fig. 2 describes the LSTM classifier basic architecture, the input and output data are represented by Xn and Yn, respectively, the weight coefficients are represented by U, V, and W, he is the hidden layer status, and hn is related to the current input Xn input and the previous R hidden layers.

$$h_1 = UX_n + W_{n-1}h_{n-1} + W_{n-2}h_{n-2} + \cdots + W_{n-R}h_{n-R} \quad (1)$$

Finding a hyperplane that appropriately divides the training dataset into two groups and optimizes the LSTM is the main goal. The LSTM classification problem is combined as follows:

$$f_t = \sigma_g(W_f x_t + U_{\mathfrak{f}} h_{t\,-1} + b_f)$$

$$\iota_t = \sigma_g\ (W_i x_t\ +\ U_i\ h_{i-1} + b_i)$$

$$O_t = \sigma_g\ (W_o a_t\ +\ U_o h_{t\,-1} + b_o) \tag{2}$$

$$c_t\ =\ f_t\ \circ c_{t-1}\ + \iota_t \circ \sigma_c\ (W_c x_t\ +\ U_c h_{t-1} + b_c)$$

$$h_t\ = \sigma_t \circ \sigma_h\ (c_t)$$

Hyperparameters of the error terms were represented by C > 0. The normal vector and offset of the separating hyperplane are the variables denoted by the letters w and b in Eq. (2), respectively. The LSTM parameters were optimized using the Ringed Seal Search. The RSS uses how seal pups search to find the best-hidden place to avoid predators. The proposed RSS algorithm presents a sensitive search paradigm inspired by the movement of the seals. Seal pups are always relocated to high-quality lairs. These lairs offer both thermal shelter against low air temperatures and strong wind chills, as well as shielding themselves from predators, similar to bears. A complex lair can be placed in one place for a seal owing to its close movement. When the seal pup moves throughout its multi-chamber cave and searches for a new one, a sequence of events can be recounted. Evolution was accomplished by altering a random value. The starting population of LSTM parameters is represented by a matrix, the chosen parameters are placed in a vector form, and the vector has evolved to find the optimal combinations of parameters in each iteration.

Inspired by nature, when addressing an optimization problem, the RSS always begins with initial values that can be used as the initial state. The first answer is represented by a vector of values (L_i,i =1, 2,3..k_n.) during the optimization process. The RSS algorithm always begins with a multi-chambered initial number of birthing lairs n. Puppies enter a search area to locate new, better lairs to hide themselves. The formation of an array from these starting values in the search space is required to locate a better search space. Eq. (3) and (4) define the number of lairs in the RSS algorithm that corresponds to the lairs for seal pups. Most metaheuristic algorithms start with the initial population, which can be named as starting values or initial values, because to solve an optimization problem, it is necessary to start with some initial values. Eq 3 represents the initial lair

$$L_i, i = 1,2,3,\ldots,n \tag{3}$$

There are chambers m in every lair, arranged at random. Each L contained m chambers. As an example, consider an array of L = [I multiply m] that represents the lair i of a habitat that is now in use,

$$L = [i \times m] \tag{4}$$

The values range from a predetermined bottom bound, L_bj, to the upper limit, U_bj, randomly and consistently in the search space, as described in Eq. (5).

$$L_i = L_b + (U_b +).rand\ \left(size(L_b)\right) \tag{5}$$

$$i = 1,2,3,\ldots,n \tag{6}$$

where i is the lair number, and n is the number of initialized pairs. The seal travels from one lair to another in a particular search pattern, producing new solutions (new lairs) x t+1 for seal *i*. A new lair is located in the Eq. (7)

$$\chi_i^{t+1}\ = \chi_i^{t+1} + \alpha \times \Delta x \tag{7}$$

where a indicates the size of the step in urgent or normal states.

$$\Delta x =\ {}^{\lambda}levy \quad \text{where}\, w\ =\ 1 \tag{8}$$

where ω represents the uniform discrete distribution shown in Eq. (8), (ω = 1 denotes the external noise). For the Levy walk, the random walk is typified by a step size that is determined using an inverse power-law tail probability distribution, as shown in Eq. (9).

$$Levy \sim u\, \overline{t^{-\lambda}} \tag{9}$$

where t is the length and 1< λ < 3. When λ is less than or equal to 3, there is no heavy tail in the distribution, and the sum of all the lengths approaches a distribution.

Anomalous diffusion, in which the mean squared displacement increases linearly with time, characterizes a Levy walk. The Brownian walk, in contrast to the Levy walk, is typified by normal diffusion, where the mean-squared displacement increases linearly.

Eq. (10) illustrates the structure of the Brownian walk search for a new chamber inside a multichambered lair structure.

$$equal\Delta x =\ {}^{\lambda}brownian \quad \text{where}\, \omega\ =\ 0 \tag{10}$$

The search is characterized by the step size described in Eq. (11).

$$S = K\ \times\ rand(d,\ Ndot) \tag{11}$$

K represents the standard deviation of the regular distribution of the diffusion rate coefficient, d denotes the dimensions of the problem, and N dots symbolize the quantity of Brownian particles within the search space.

The proposed RSS-LSTM approach responds to variations in hyperparameters through its ringed seal search optimization process. This process iteratively explores the hyperparameter space to find the optimal set of hyperparameters that minimizes the objective function, which in this case is the performance of the LSTM model in classification. The RSS algorithm perform a balanced exploration that tries new hyperparameters and exploitation that exploits known good hyperparameters to efficiently search the hyperparameter space for optimal solution.

The Brownian Walk function of the algorithm generates a random walk for a specified step size. Given a current value x in the range of the lower and upper bounds [lower_bound, upper_bound], from the uniform distribution, it adds a random value walk [step_size, step_size] to x. Then, the function checks if the new value [new_value] is within the bounds [lower_bound, upper_bound]; if it exceeds the upper bound then it returns the upper_bound, or if it falls below the lower bound then it returns the lower_bound. Otherwise, it returns to a new value, this function is mathematically represented as:

$$\text{new\_value} = \text{walk} + \text{lower\_bound}$$

where,

$$\text{walk} \sim \text{Uniform}(-\text{step\_size}, \text{step\_size}) \tag{13}$$

The final value is then paired to ensure that it remains within the specified bounds.

Using Pareto distribution, the Levy walk function generates a random walk. First, it samples a value r from a Pareto distribution with the shape parameter beta. It then samples an angle u from the uniform distribution [0, 2/pi] and computes a walk value using r×cos(u). Similar to the Brownian walk, the function ensures that the new value remains within the specified bounds [lower-bound, upper-bound]. Mathematically it can be represented as

$$\text{r} \sim \text{Pareto}(\beta)$$

$$\text{u} \sim \text{Uniform}(0{,}2\pi)$$

$$\text{walk} = \text{r} \times \cos(\text{u})$$

$$\text{new\_value} = \text{walk} + \text{lower\_bound} \tag{14}$$

E. Performance Criteria

Accuracy, precision, recall, and f-measure are all important factors to consider when evaluating the efficacy of a classification model in classifying text. Precision is calculated using Eq. (15), and recall is specified in Eq. (16). Eq. (17) and (18) display the Accuracy and F-measure, respectively.

$$Precision\ = \frac{t_p}{t_p + f_p} \tag{15}$$

In the Eq. (15) t_p denotes the true positive rate and f_p shows the false positive rate in precision.

$$Recall\ = \frac{t_p}{t_p + f_n} \tag{16}$$

where t_p describes the true positive rate and f_n denotes the false negative rate in the recall.

Accuracy is defined as the ratio of the number of correctly classified objects to the total number of objects. Inaccuracy and true positive (t_p), true negative (t_n), false negative (f_n) and false positive (f_p) values are calculated as in Eq. (17):

$$Accuracy = \frac{t_p + t_n}{t_p + \ f_p + t_n + \ f_n} \tag{17}$$

The F-measure is the harmonic mean in which, precision and recall are combined, and the traditional f-measure is calculated as in Eq. (18):

$$F - measure\ = \ 2 \times \frac{p \times r}{p + r} \tag{18}$$

where p denotes the precision and r is the recall in the F-measure.

IV. Results

Different experiments were conducted to analyse the data, and the performance of RSS-LSTM was compared with different metaheuristic algorithms associated with LSTM such as GA-LSTM, PSO-LSTM, and FF-LSTM., for three datasets: 20 Newsgroups, Reuters-21578, and AG News were used to test the performance using several measurement parameters, including accuracy, F-measure, precision, and recall. The proposed model was tested using different sets of classes with different iterations.

A. Reuters-21578 Dataset Results

As shown in Table II, it is demonstrating that the proposed technique using RSS-LSTM performs more effectively than the other techniques. For Reuters-21578, RSS-LSTM's accuracy is superior to that of GA-LSTM, PSO-LSTM, and FF-LSTM. Compared to earlier methods, RSS-LSTM significantly outperformed the other methods on the entire dataset. On the Reuters-21578 text dataset, RSS-LSTM produced an accuracy of 96%, GA-LSTM produced 78%, firefly produced 56%, and PSO-LSTM produced 87% as shown in Fig. 3. Compared to the F-measure, RSS-LSTM outperformed GA-LSTM, PSO-LSTM and FF-LSTM, and achieved 95%, 64%, 86% and 54% respectively as shown in Fig. 4. Fig. 5 shows that RSS-LSTM delivered improved results in terms of precision compared to the existing techniques, RSS-LSTM achieved 96%, whereas GA-LSTM, PSO-LSTM and RR-LSTM achieved 72%, 86% and 71% respectively. In the recall scenario, Fig. 6 shows that RSS-LSTM again performs better than GA-LSTM, PSO-LSTM, and FF-LSTM and achieved results as of 96%, 68%, 87% and 56% respectively. The accuracy of the proposed method was superior to that of the other mentioned techniques, as demonstrated in Table II, for the entire dataset. When compared to the GA-LSTM, PSO-LSTM, and FF-LSTM algorithms, the RSS-LSTM approach performed better in terms of accuracy, precision, recall, and f-measure.

TABLE II. Performance of RSS-LSTM among PSO-LSTM and GA-LSTM using Reuters-21578 Dataset

Classifier	Measure criteria			
	Accuracy	F-measure	Precision	Recall
GA-LSTM	0.78	0.64	0.72	0.68
PSO-LSTM	0.87	0.86	0.86	0.87
FF-LSTM	0.56	0.54	0.71	0.56
RSS-LSTM	**0.96**	**0.95**	**0.96**	**0.96**

B. *Result of 20 Newsgroups Dataset*

An experiment using 20 Newsgroups text datasets demonstrated that the proposed RSS-LSTM technique outperformed the GA-LSTM, PSO-LSTM, and FF-LSTM strategies already in use. Fig. 7 shows that the RSS-LSTM generated high accuracy of 77%. While GA-LSTM produced 49%, PSO-LSTM and FF-LSTM provided results of 58% and 21%, respectively as shown in Fig. 7 and Table III. In addition, the F-measure was 77% for RSS-LSTM, compared to 41%, 56%, and 35% for GA-LSTM, PSO-LSTM, and FF-LSTM, respectively as shown in Fig. 8. The RSS-LSTM technique provided better results as of 78% than the existing techniques for 20 Newsgroups dataset in precision comparison as shown in Fig. 9, while GA-LSTM, PSO-LSTM, and FF-LSTM achieved precisions as 50%, 73%, and 21% respectively. Similarly, Fig. 10 shows that RSS-LSTM achieved a higher recall as of 77% in comparison to GA-LSTM, PSO-LSTM and FF-LSTM. RSS-LSTM generated the best accuracy of 77%. The outcome for RSS-LSTM is superior to that of the GA-LSTM, PSO-LSTM, and FF-LSTM methodologies, as shown in Table III and described below.

TABLE III. PERFORMANCES OF RSS-LSTM RESULTS AMONG GA-LSTM, PSO-LSTM, AND FF-LSTM USING THE 20-NEWSGROUP DATASET

Classifier	**Measure criteria**			
	Accuracy	**F-measure**	**Precision**	**Recall**
GA-LSTM	0.49	0.41	0.50	0.49
PSO-LSTM	0.58	0.56	0.73	0.58
FF-LSTM	0.21	0.35	0.21	0.30
RSS-LSTM	**0.77**	**0.77**	**0.78**	**0.77**

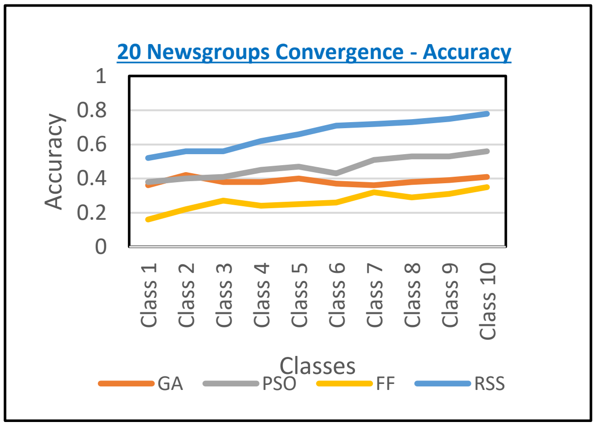

Fig. 7. 20 Newsgroups convergence – accuracy.

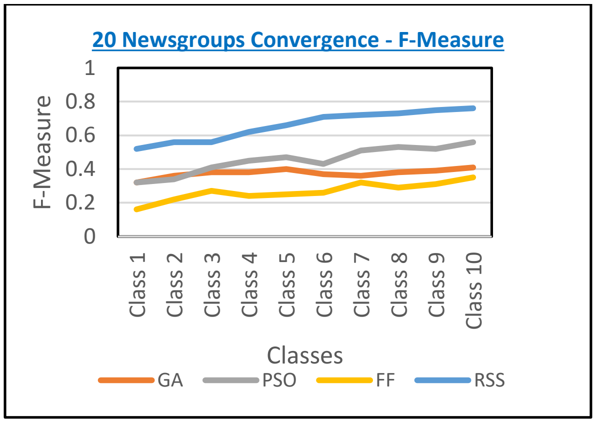

Fig. 8. 20 Newsgroups convergence - f-measure.

C. *Result of AG News Dataset*

Table IV shows the performance measured using the AG News dataset. The performance of the RSS-LSTM optimization approach was tested against those of existing GA-LSTM, PSO-LSTM, and FF-LSTM techniques. The study was carried out for the evaluation matrix, as accuracy, F-measure, precision, and recall are among the metrics used to evaluate RSS-LSTM. Compared to existing GA-LSTM, PSO-LSTM, and FF-LSTM techniques, the RSS-LSTM technique produced greater accuracy than other comparing techniques. Fig. 11 shows that GA-LSTM achieved 86% accuracy, PSO-LSTM and FF-LSTM produced 88% and 80% accuracy, respectively, while the proposed RSS-LSTM produced 91% accuracy.

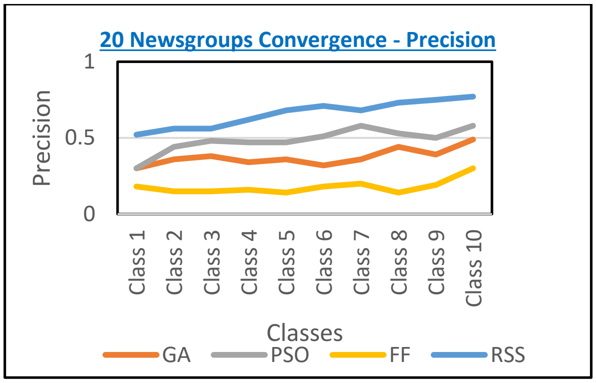

Fig. 9. 20 Newsgroups convergence – precision.

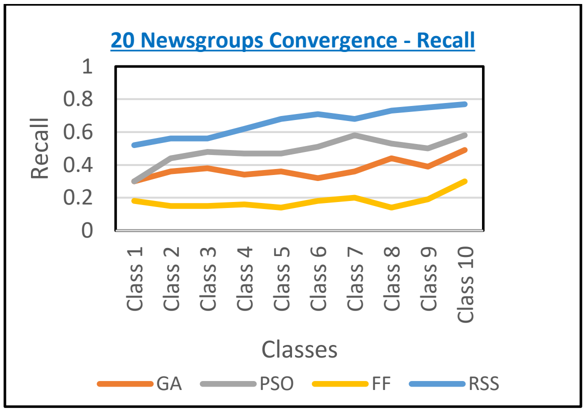

Fig. 10. 20 Newsgroups convergence – recall.

TABLE IV. PERFORMANCES RSS-LSTM RESULT AMONG GA-LSTM, PSO-LSTM, AND FIREFLY-LSTM USING THE AG NEWS DATASET

Classifier	**Measuring Criteria**			
	Accuracy	**F-measure**	**Precision**	**Recall**
GA-LSTM	0.86	0.85	0.86	0.86
PSO-LSTM	0.88	0.84	0.89	0.89
FF-LSTM	0.80	0.78	0.88	0.88
RSS-LSTM	**0.91**	**0.90**	**0.94**	**0.91**

To evaluate the F-measure score, significant results were obtained for RSS-LSTM, GA-LSTM, PSO-LSTM, and FF-LSTM, which were 91 %, 85%, 84%, and for FF-LSTM, 78% shown in Fig. 12. Additionally, RSS-LSTM achieved higher precision and Fig. 13 demonstrated 94% precision compared to 86%, 89%, and 88% precision for GA-LSTM, PSO-LSTM, and FF-LSTM, respectively. The outcome of RSS-LSTM was also measured for recall, and it provided a result of 91%, compared to 86%, 89%, and 88% for GA-LSTM, PSO-LSTM, and FF-LSTM, respectively also shown in Fig. 14. The table below shows that the overall performance of RSS-LSTM is superior to that of the GA-LSTM, PSO-LSTM, and FF-LSTM techniques.

Table V presents the combined results of the proposed RSS-LSTM model compared with GA-LSTM, PSO-LSTM, and GA-LSTM. Additionally, Fig. 15, 16, and 17 provide graphical representations of the results achieved by the proposed model and the compared techniques.

D. Comparison of Models

The proposed RSS-LSTM model was also compared with state-of-the-art deep learning models, such as Support Vector Machine, Stochastics Gradient Descent (SGD), Random Forest (RF), Logistics Regression (LR), K-nearest Neighbour (KNN), Naïve Base (NB), Decision Tree (DT), Autor encoder (AE), AdaBoost (AB) using Reuters-21578, 20 Newsgroups and AG news dataset, where Proposed approached shows the significant results compare to mentioned techniques. Table VI describes the comparison of proposed technique with state of art models used for hyperparameter optimization using different datasets.

Above mentioned Table VII lists the hyperparameters with their ranges that we use in this study.

TABLE VI. Performances RSS-LSTM According with respect to Three Datasets

Ref	Year	Technique	Dataset	Findings
[63]	2023	Support Vector Machine, Stochastic Gradient Descent (SGD), Random Forest (RF), Logistic Regression (LR), K-Nearest Neighbor (KNN)	Reuters-21578	Accuracy achieves using Reuters-21578 dataset as 0.8516, 0.8476, 0.8470, 0.8110, 0.8183, 0.8135
[64]	2022	OPT 175b, Bloom 176B, OPT 30b, OPT 1.3b	AG News	AG news achieve the accuracy as follows using different techniques 68.7, 39.5, 60.7, 37.6
[65]	2020	Naïve Base, SVM, Gradient, Boosting, Random Forest, Logistics Regression	20NewsGroups	Achieve maximum accuracy 67.3, 65.3,59.5,60.1 and 67.4 respectively

TABLE VII. Hyperparameter Ranges

Model	Hyperparameter	Optimization Range
GA-LSTM	Dense units	16 to128
	Learning rate	0.001 to 0.1
	Dropout rate	0.1 to 0.05
PSO-LSTM	Dense units	16 to 128
	Learning rate	0.001 to 0.1
	Dropout rate	0.1 to 0.05
FF-LSTM	Dense units	16 to 128
	Learning rate	0.001 to 0.1
	Dropout rate	0.1 to 0.05
	Dense units	16 to 128
RSS-LSTM	Dense units	16 to 128
	Learning rate	0.001 to 0.1
	Dropout rate	0.1 to 0.05
	Dense units	16 to 128

TABLE VIII. Time Constraints of Hyperparameter Optimization

Algorithm	Complexity	Dataset	Time (std dev)
PSO	O(I×(P×L+P))	Reut-21578	132.49
		20NG	71.23
		AG News	448.02
GA	O(G×P×L)	Reut-21578	220.28
		20NG	119.23
		AG News	500.64
FFA	O(num iterations ×num_fireflies^2 × len(firefly-bounds))	Reut-21578	279.25
		20NG	248.31
		AG News	2253.90
RSS	O(max-iterations × num-lairs × (len(search-space) + max-len))	Reut-21578	110.05
		20NG	67.23
		AG News	836.20

Table VIII describes the complexity equivalences, for PSO I, P, and L indicating the total number of iterations, number of particles in a swarm, and search space (dimensioned of parameters) respectively. For the GA algorithm, G indicates the generation (iteration), P resents the Population size and L resents the number of genes in an individual. The Firefly Algorithm contains a total number of iterations, the number of flies, and the length of parameters for a search space. Ringed Seal Search (RSS) consists of its number of iterations, the number of lairs that describe the search areas, the search space that defines the number of dimensions, and at last, it adds a maximum number of lairs. Additionally, Table VIII shows the standard deviation of temporal demands for each algorithm according to the dataset, low standard deviation values indicate more consistent performance, and they shed light on how variable or consistent the algorithm's execution times are across various datasets, however, these values may also vary depending at the factors such as algorithm’s number of iterations, number of epochs, batch size and other parameters.

Table IX demonstrates the variation of hyperparameters for different datasets.

TABLE IX. VARIATION OF HYPERPARAMETERS USING DIFFERENT DATASETS

Dataset	Technique	Dense Unit	Dropout	Learning Rate
Reuters-21578	GA-LSTM	118	0.3914	0.0087
	PSO-LSTM	16	0.2271	0.0364
	FF-LSTM	37	0.2221	0.0031

V. DISCUSSION AND CONCLUSION

In diverse fields such as bioinformatics, sentiment analysis, online handwritten recognition, and text classification, LSTM is used to apply diverse classification issues. One area where academics are attempting to increase classification accuracy is text classification. Different experiments were conducted to analyse the data, and the performance of RSS-LSTM was compared with that of GA-LSTM, PSO-LSTM, and FF-LSTM. Three datasets, including 20 Newsgroups, Reuters-21578, and AG News, were used to test the performance using several measurement parameters, including accuracy, F-measure, precision, and recall. The proposed model was tested using different sets of classes.

The results presented in Fig. 3, 4, 5, and 6 demonstrate that the proposed approach RSS-LSTM outperforms existing methods, achieving 96% accuracy, 96% F-score, 95% precision, and 96% recall on the Reuters-21578 dataset. Similarly, as shown in Fig. 7, 8, 9, and 10, the proposed method RSS-LSTM outperforms existing approaches on the 20 News dataset, achieving 77% accuracy, 77% F-score, 78% precision, and 77% recall. Furthermore, Fig. 11, 12, 13, and 14 indicate that the proposed approach surpasses existing methods on the AG News dataset, with 91% accuracy, 90% F-score, 94% precision, and 91% recall.

According to the literature review, search methods affect LSTM performance when solving text classification optimization problems. Therefore, to improve the LSTM parameters for enhanced text classification accuracy, this research presented an enhanced technique called RSS-LSTM, conducted using datasets Reuter-21578, 20 Newsgroups, and AG News Dataset, which was used to evaluate the effectiveness of the proposed model. The simulation results demonstrated that in terms of Accuracy, F-measure, Precision, and Recall, the proposed RSS-LSTM surpasses existing techniques. The experimental results on different classes of these three datasets showed that the proposed model performed well in terms of term precision, F-value, precision, and recall. The proposed model also compares with LSTM addresses different types of text classification problems in various fields such as bioinformatics, opinion mining, handwriting, and online recognition. One of the areas where scholastics are endeavouring to increase characterization accuracy is text classification.

A. Future Work

To evaluate the performance of the proposed model with different hyperparameter and ranges. To evaluate the proposed models at images datasets. To assess the effect of different iterations of different algorithms. The proposed technique performs very well as per the given measuring matrix, however detailed temporal demands may also be required in future work using different iteration and parameter settings evaluate the proposed technique with other deep learning models such as Recurrent Neural Network (RNN), Feedforward Neural Network (FNN), Gated Recurrent Unit (GRU) Autoencoders (AE).

Construction of Image Retrieval Module for Cultural and Creative Products Based on DF-CNN

Meng Jiang
School of Art and Design, Henan University of Engineering, Zhengzhou, 451191, China

***Abstract*—With the growth of the cultural and creative product industry, more and more cultural and creative products have been designed and published in different channels. A method based on image retrieval module is proposed to address the search problem of Chinese creative products in online channels. During the process, a cascaded forest is proposed to achieve layer by layer processing, with class vectors as the main transfer content in the entire forest system. An image attribute feature extraction process that introduces extreme gradient enhancement is designed, and the aggregation of multi-scale and multi-region features is utilized to improve image retrieval performance. The experimental results showed that in the similarity test of extracting image feature information when the image contained three composite cultural and creative objects and the total pixel amount of the image reached 7M, the similarity of image feature information was 97.6%. In the analysis of running time, the research method only took 7.4ms to generate search results in seven fields. In the analysis of the proportion of false search content, the research method maintained a false search proportion of within 6.0% when searching for a single cultural and creative product object. This indicates that the research method has higher accuracy and efficiency in image retrieval of cultural and creative products. Research methods can provide certain technical support for the development of the cultural and creative industry.**

Keywords—Image retrieval; class vector; extreme gradient enhancement; Chinese creative products; layer by layer processing

I. Introduction

In today's rapidly developing era of digitization and informatization, the cultural and creative industry has become an important force driving economic growth and cultural inheritance. Cultural and creative products (CCPs), with their unique design and cultural connotations, not only satisfy people's pursuit of a better life but also become an important medium for spreading culture and shaping brand image [1]. However, with the increasing variety of CCPs, efficiently retrieving and identifying these products has become a problem that needs to be solved [2]. Image retrieval is an important retrieval method, and some scholars have conducted relevant research on image retrieval technology. Zhang et al. proposed a research method based on generative adversarial learning for image retrieval in text writing. The process enhanced retrieval efficiency by enhancing the semantics of generated images, and the resolution of generated images was determined by local discriminators. The results indicated that the designed method was efficient and accurate for image retrieval [3]. Humenberger et al. proposed a visual localization-based research method for image retrieval in autonomous driving. The method prioritized the judgment of image types by setting scene road conditions and then used fuzzy matching in dynamic scenes for image localization. The results indicated that the proposed method had good fitness for image retrieval in dynamic scenes [4]. Salih et al. proposed a research method based on double-layer feature judgment for multimedia image retrieval problems. The method filtered out images with deviant types by setting a coarse search layer, and then locked in the required images through subdivision class retrieval. The outcomes indicated that the designed method had high accuracy for image retrieval on multimedia [5]. Wang et al. proposed a research method based on spatial and exchange domains for texture image retrieval. The process used dual-tree complex wavelet transform to decompose the image and re-model it, achieving a complementary global retrieval structure. The outcomes indicated that the designed method improved the retrieval efficiency in the database [6]. Li et al. proposed a research algorithm based on a hash method for image retrieval on the Internet. The algorithm retrieved data patterns by collecting image data in a stationary environment, and simulating image transformations in non-stationary environments to adapt to its retrieval environment. The results indicated that the proposed method was efficient for image retrieval in large datasets [7].

Traditional image retrieval techniques, although achieving certain results in certain scenarios, often fail to meet the high demands of users for retrieval accuracy and efficiency. With the advancement of computer technology, deep learning technology has emerged and made revolutionary progress in the field of image recognition and retrieval [8]. Convolutional neural network (CNN) has become an important technology in the field of image processing due to its powerful feature extraction ability and ability to learn complex patterns. Some scholars have conducted relevant research on CNN. Xin's team proposed a CNN-based feature extraction method for the diagnosis of ocean turbine attachments. This method consists of three steps: data preprocessing, feature extraction, and fault diagnosis. The results indicated that the method could work smoothly in harsh environments [9]. Kumar et al. put forward a training algorithm using Dolphin-SCA to address the compression problem of CNN models applied in tumor classification. During the process, a fuzzy deformable fusion model was used for image segmentation. The experiment findings showed that the proposed method had good diagnostic accuracy [10]. Thirusangu et al. proposed a deep CNN based on the U-Net architecture to address the issue of low resolution in transcranial ultrasound images. During the process, filters were used for preprocessing and the effects of other architectures were compared. The results indicated that the U-Net architecture had better accuracy in identifying SN [11]. Ma proposed a method combining CNN to address the design issue of facial feature tracking systems. During the process, heterogeneous convolution was used to reduce the parameters of the convolution kernel. The search box mechanism was inserted into the network acceptance domain adjustment module, and the attention dispersal mechanism was used to standardize the arrangement of heterogeneous convolutions. The experiment outcomes indicated that the proposed method had good tracking accuracy and interpretability [12]. Ashtiani et al. proposed a method combining CNN technology to address the issue of medical image classification. During the process, the light waves incident on the pixel array were directly processed to obtain image classification results, and linear calculations were performed optically to reduce time consumption. The experiment outcomes indicated that the proposed method had good classification accuracy [13].

In summary, there have been many techniques using CNN for image retrieval and processing, but existing image retrieval techniques often struggle to accurately identify and match complex design elements and cultural connotations in CCPs, resulting in low accuracy of retrieval results. CCP images often contain rich color and texture information, and existing technologies may not be able to fully explore and utilize the useful information in the images when processing such high-dimensional data. Moreover, existing research has mostly focused on specific types of images, lacking the generalization ability for image retrieval in the special field of CCPs, which limits the universality of the technology. A single CNN model may have biases in extracting global and local features, and cannot fully express the complexity and diversity of CCPs. Moreover, a single CNN model usually requires a lot of computing resources. For large-scale image retrieval tasks, a single model may be difficult to meet the real-time requirements [14]. Deep forest (DF) is an ensemble learning method based on decision trees, which inherits the advantages of decision trees in processing high-dimensional data and improves the model's generalization ability and robustness by integrating multiple decision trees. The problems that the research attempts to solve and the gaps that will be achieved with other studies include: (1) developing an image retrieval technology that can accurately identify the design elements and cultural connotations of CCP images, to improve the relevance of retrieval results and make the research method more adaptable to CCP images than other methods. (2) Design an efficient image retrieval algorithm to meet the retrieval needs of large-scale image data and achieve rapid response. (3) Research on an image retrieval model with good generalization ability, which can adapt to CCP images from different sources and styles, and enable the research method to intelligently adapt to the constantly changing content of CCP images. In this context, the study attempts to innovatively combine DF and CNN, and constructs a cascaded forest structure. By combining feature vectors and similarity calculation, a new image retrieval technology for CCPs is designed. It is expected to provide certain technical references for the CCP industry.

The research is mainly conducted in four sections. Section II part is the design of image attribute feature extraction technology based on DF algorithm and CCP image retrieval method combined with CNN. Section III is to analyze the effectiveness of the research method through performance testing and application analysis. Section IV discusses and summarizes the entire text.

II. Methods and Materials

A. *Design of Image Attribute Feature Extraction Technology Based on DF Algorithm*

When designing, searching, and purchasing CCPs, a large amount of retrieval is required, among which image retrieval is a commonly used retrieval method [15]. However, CCPs often have rich designs and diverse styles, which may make it difficult to accurately match and recognize images during image retrieval. The DF algorithm can handle high-dimensional data and complex problems during computation, and can extract complex and diverse attribute features of images [16]. Research uses DF algorithm to design image attribute feature extraction technology for CCP image retrieval technology. In response to the complexity of information contained in CCPs, a cascaded forest is proposed to implement layer by layer processing of DF networks, and its structure is constructed as shown in Fig. 1.

In Fig. 1, each layer in the cascaded forest receives the feature information from the previous layer and the original input feature information, and each layer is an integrated structure of a decision tree forest. To obtain better diversity, a study is conducted to construct a composite forest structure using random forests and completely random forests. The construction of each decision tree begins with a randomly selected set of features. At each node of the tree, the system randomly selects a feature to segment the dataset. The ultimate goal is to grow each leaf node to be pure, meaning that the samples in the leaf nodes belong to the same category. The number of decision trees in the forest is a hyperparameter that can be changed according to different tasks of image retrieval for CCPs. In the entire forest system, class vectors are studied as the main transfer content, and the generation method is shown in Fig. 2.

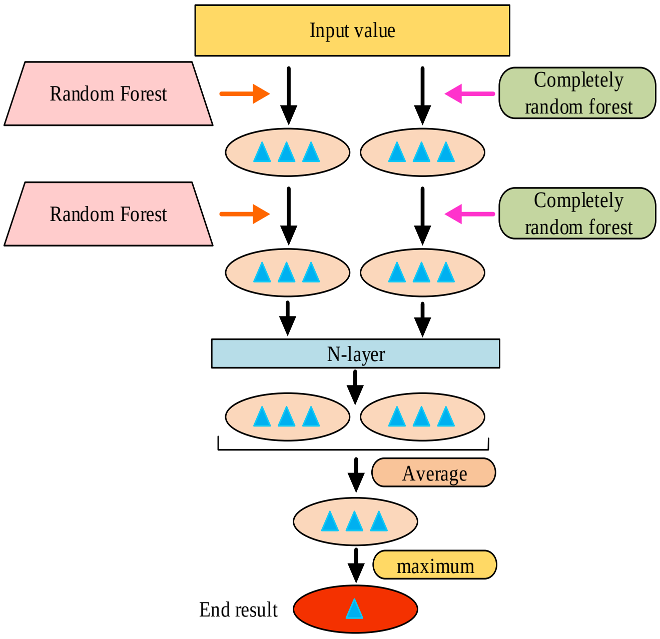

Fig. 1. Cascade forest structure.

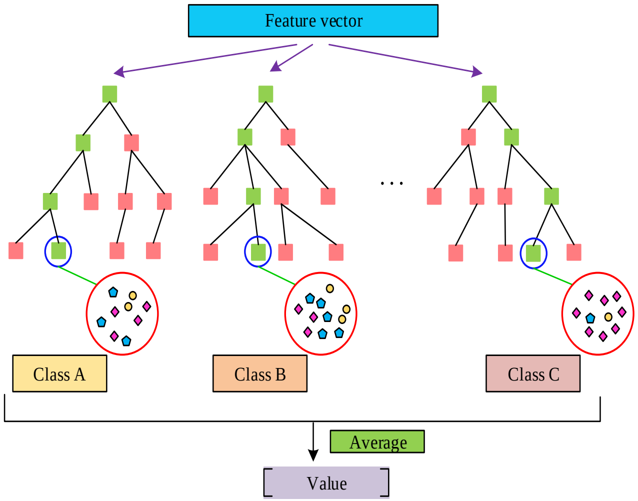

Fig. 2. Class vector generation method.

In Fig. 2, when generating class vectors, at each leaf node of each tree, the class vector is calculated based on the class distribution of the training instance, representing the relative proportion of each type in that node. For each tree in the forest, the separately calculated class vector will be averaged to form the final output of the tree. In addition to the initial layer, the forest at subsequent levels will fuse the class vectors generated by the previous layer with the original input features to form new inputs [17, 18]. Starting from the second layer of forest, regardless of how the number of trees in the forest changes, the dimension of the generated class vector will remain unchanged. The calculation method is to multiply the number of categories by the number of trees in the forest, and then add the dimension of the original features. If there is no significant improvement in performance on the validation set, it will stop the iteration and automatically select the optimal number of layers. When extracting image attribute features, involves the extraction of different attribute features. To improve the universality of the method, extreme gradient enhancement is introduced to optimize the DF algorithm. After a given training set, a tree ensemble model is generated, and then the expected value is obtained, as shown in Eq. (1).

$$\hat{y}_i = \sum_{k=1}^{K} f_k(x_i),\ f_k \in F \tag{1}$$

In Eq. (1), $\hat{y}_i$ represents the expected value. F stands for regression tree. k represents the number of trees. x_i represents the content of the training set. f_k represents leaf nodes. The objective function is calculated from the expected value, as shown in Eq. (2).

$$L(\phi) = \sum_i l(\hat{y}_i, y_i) + \sum_k \Omega(f_k) \tag{2}$$

In Eq. (2), $L(\phi)$ represents the objective function. l represents a differentiable loss function. y_i represents compliance true value. Ω is a regularization function. The loss function is minimized after generating a new tree, as shown in Eq. (3).

$$L^{(t)} = \sum_{i=1}^{n} l\left(y_i, \hat{y}_i^{t-1} + f_t(x_i)\right) + \Omega(f_t) \tag{3}$$

In Eq. (3), $L^{(t)}$ represents the loss function after generating a new tree. f_t stands for new tree. Taylor expansion is performed and different steps of the original function are calculated to simplify the loss function, as shown in Eq. (4).

$$\tilde{L}^{(t)} = \sum_{i=1}^{n}\left[g_i f_t(x_i) + \frac{1}{2} h_i f_t^2(x_i)\right] + \Omega(f_t) \tag{4}$$

In Eq. (4), $\tilde{L}^{(t)}$ represents the simplified loss function. g_i represents the first-order degree of the original loss function. h_i represents the second-order degree of the original loss function. The optimal weight of the leaf node is calculated, as shown in Eq. (5).

$$w_j^* = -\frac{\sum_{i\in I_j} g_i}{\sum_{i\in I_j} h_i + \lambda} \tag{5}$$

In Eq. (5), w_j^* represents the optimal weight of the leaf node. λ represents a constant term that prevents the denominator from being 0. Then the quality of the evaluation tree is calculated, as shown in Eq. (6).

$$\tilde{L}^{i}(q) = -\frac{1}{2}\sum_{j=1}^{T}\frac{\left(\sum_{i\in I_j} g_i\right)^2}{\sum_{i\in I_j} h_i + \lambda} + \gamma T \tag{6}$$

In Eq. (6), $\tilde{L}^{i}(q)$ represents the quality value of the tree. T represents the number of leaf nodes in the tree. γ represents the leaf node coefficient. The process of extracting image attribute features by introducing extreme gradient enhancement is shown in Fig. 3.

In Fig. 3, when extracting image attribute features for CCPs, the original image data is first read and preprocessed before starting feature extraction. The preprocessed image data is input into the DF model for preliminary feature extraction. The initially extracted features are combined with the original image data to form an enhanced feature class vector, which is then fed into the next layer of DF model. After each feature extraction, the effectiveness of the features is evaluated through classification testing. After averaging and maximizing operations, the final feature extraction result of CCP image attributes is obtained.

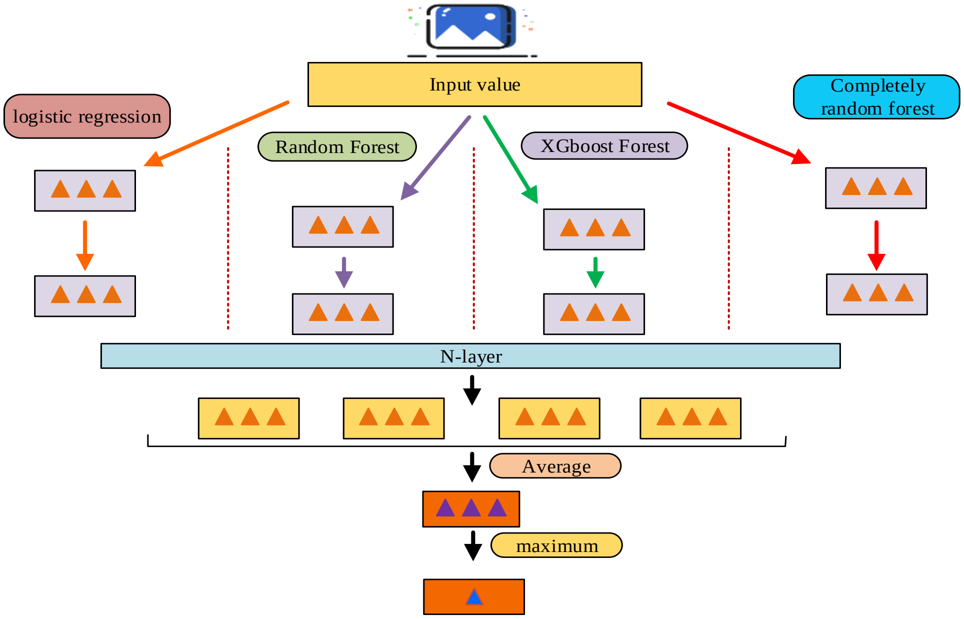

Fig. 3. Image attribute feature extraction process.

B. Image Retrieval Method for Cultural and Creative Products Combined with CNN

After extracting image attribute features, image attribute features can be used as the core data for image retrieval. CNN deep features are a data-driven high-level image feature with good image feature expression ability. They have certain advantages over traditional methods in extracting global, local features, and contextual information from images [19, 20]. Based on the DF algorithm, research designs the image retrieval methods for CCPs combined with CNN. The research uses the aggregation method of multi-scale and multi-region features in CNN and combines them with the spatial and channel weights of depth features to achieve multi-dimensional feature aggregation. When performing multi-region feature aggregation on CCP images, it needs to define several regions and calculate the aggregated feature vector for each region, as shown in Eq. (7).

$$f_{\Re} = \left[f_{\Re,1}, \dots, f_{\Re,\ell}, \dots, f_{\Re,\Im} \right]^{tra} \tag{7}$$

In Eq. (7), $f_{\Re}$ represents the region aggregation feature vector. tra stands for transpose matrix. $f_{\Re,\ell}$ represents the maximum value in the $\Re$ region on the ℓ th feature map. After obtaining the feature vectors of all regions, the normalized features are summed to form a multidimensional aggregated feature vector. When aggregating multi-dimensional features through spatial and channel weights of deep features, feature vectors are generated as shown in Eq. (8).

$$F_{crow} = \left[f_1, \dots, f_\ell, \dots, f_\Im \right], f_\ell = \sum_{y=1}^{H} \sum_{x=1}^{W} \alpha_{xy} \beta_\ell S_\ell (x, y) \tag{8}$$

In Eq. (8), F_{crow} represents the deep feature aggregation feature vector. α_{xy} represents spatial weight. β_ℓ represents channel weight. The feature aggregation process established in the study is shown in Fig. 4.

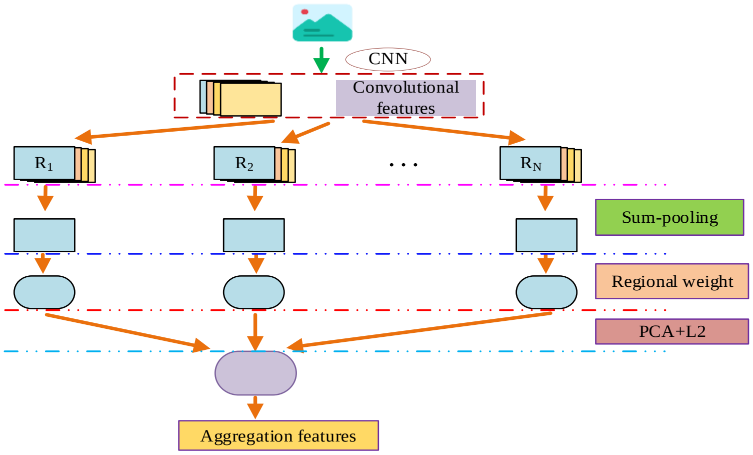

Fig. 4. Characteristic polymerization process.

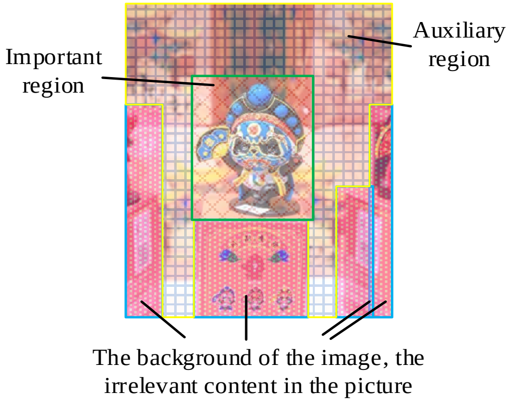
In Fig. 4, when aggregating image features, the feature maps are first divided into sub regions, and the channel sensitivity weights are calculated based on the sparsity and intensity of the non-zero response values of the channels. After obtaining the significance weights of different regions, it calculates the feature vectors of different regions. The feature vectors of each region are normalized, one principal component analysis and whitening process are completed, and then a second normalization is performed. Sum-pooling is performed on the region features that have been normalized twice, and the aggregation results are normalized once to obtain the aggregated feature vectors. To more effectively extract effective information from feature maps, research is being conducted to incorporate channel sensitivity weights for optimization. The channel sensitivity is shown in Eq. (9).

$$\mathbb{N} = 1 - \gamma_\ell \tag{9}$$

In the above equations, $\mathbb{N}$ represents channel sensitivity. γ_ℓ represents the sum of the intensity amplitudes and positive response values of all non-zero response values on each channel. In the image of CCPs, the importance of different regions varies, and the corresponding weights also vary, as shown in Fig. 5.



Important region
Auxiliary region
The background of the image, the irrelevant content in the picture

Fig. 5. Image area weight difference example.

As shown in Fig. 5, there are important areas in the image of CCPs that express the main body of the product, occupying the highest importance. In addition to important areas, there are auxiliary areas that play a secondary role in creating a visual atmosphere and enriching image details. The second most important factors are the background of the image and irrelevant content in the image. The significance weight of a region is defined as shown in Eq. (10).

$$\beta_r = \frac{\sqrt{\sum_{i \in R_r} \sum_{j \in R_r} S^{'}\left(i, j\right)^2}}{\sum \sum_{ij} S^{'} * A_r} \tag{10}$$

In Eq. (10), β_r represents the significance weight of the region. A_r represents the proportion of the size of the target area to the entire feature map. $S^{'}$ represents the sum of the values of all feature maps at each position. (i, j) represents the location of the feature map. The proportion of the target area to the entire feature map is calculated as shown in Eq. (11).

$$A_r = \frac{w_r \times h_r}{W \times H} \tag{11}$$

In Eq. (11), $W \times H$ represents the size of the feature map. $w_r \times h_r$ represents the size of the target area. Region feature vectors are generated as shown in Eq. (12).

$$\hat{f}_r^{\,\ell} = \left(\sum_{i \in R_r} \sum_{j \in R_r} \lambda_\ell S_\ell \left(i, j\right) \right)^\alpha \tag{12}$$

In Eq. (12), $\hat{f}_r^{\,\ell}$ represents the numerical value of the region feature vector on the ℓth feature map. λ_ℓ represents channel sensitivity weight. S_ℓ represents the sum of the values of the feature map at its position. The calculation of channel sensitivity weights is shown in Eq. (13).

$$\lambda_\ell = log\left(\frac{L\mathbb{C} + \sum_{\ell=1}^{L} \gamma_\ell}{\mathbb{C} + \gamma_\ell}\right) \tag{13}$$

In Eq. (13), $\mathbb{C}$ represents a small constant that ensures numerical stability. After extracting the image features of CCPs, the image retrieval module is constructed through feature semantic similarity measurement. In image retrieval, precise matching is often difficult to achieve due to the rich design elements and cultural connotations of CCPs. Fuzzy semantics provides a more flexible matching method, allowing the system to retrieve based on the similarity between image features and query conditions. The semantic similarity between two samples are calculated using fuzzy semantics as shown in Eq. (14).

$$s_{i,j} = \sum_{k=1}^{K} \left(\mu_{\xi_{P_i}} \left(P_j^k \right) + \mu_{\xi_{P_j}} \left(P_i^k \right) \right) \tag{14}$$

In Eq. (14), $s_{i,j}$ represents semantic similarity. $\mu_{\xi_{P_i}}$ represents the fuzzy semantics of templates. P_j^k represents the k nearest neighbor sample among the sample neighbors. The retrieval results are output based on semantic similarity. The operation process of the deep forest convolutional neural network (DF-CNN) CCP image retrieval module designed for research is shown in Fig. 6.

In Fig. 6, when conducting image retrieval for CCPs, after preprocessing the image and query information, the feature representation of the image is extracted. Image features are input into the feature space and an index with the image library is established. The similarity between query information and image library images is measured and matched to obtain corresponding retrieval images and complete sorting. At the same time, the results are fed back to the image library to enrich the search information of the image library. Finally, a list of content for image retrieval of CCPs is obtained, and the retrieval is completed.

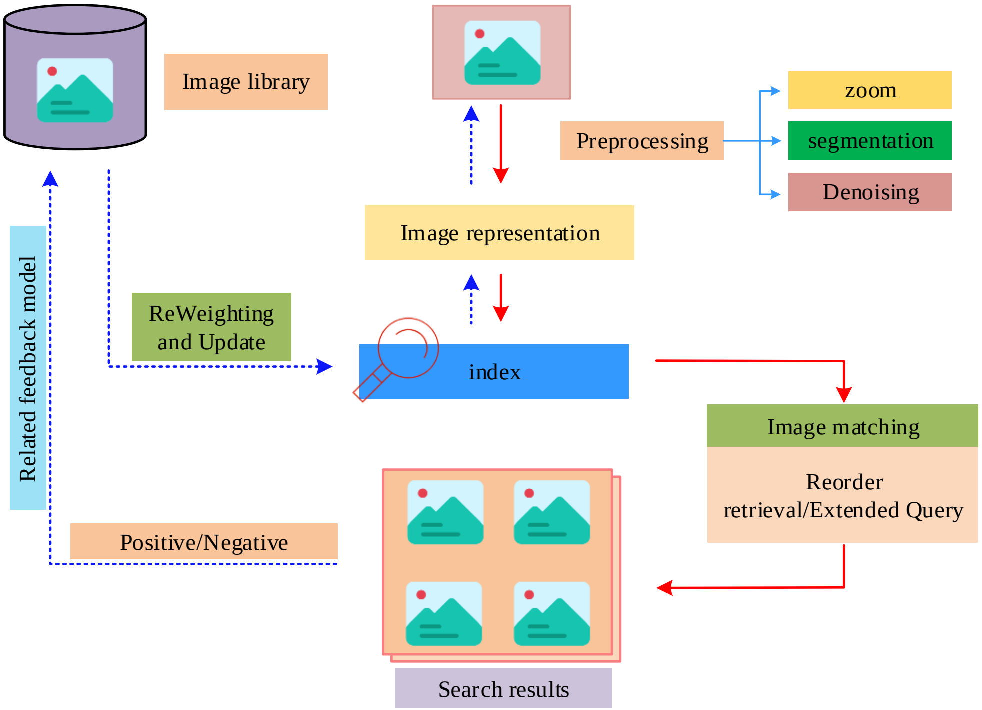


Fig. 6. Cultural and creative products image retrieval module operation process.

III. RESULTS

A. Performance Testing of Image Retrieval Technology for Cultural and Creative Products

To analyze the performance of the image retrieval technology for CCPs designed for research at runtime, ImageNet and Open Images Dataset datasets were selected for testing. When conducting performance testing, the software and hardware environments are shown in Table I.

During testing, the core objects in the dataset images were equated with important areas in the CCP images, and images containing only a single core object and multiple core objects were divided. DF-CNN was compared with the currently advanced Inception Networks and Speeded Up Robust Features methods during testing. The convergence performance of different methods was compared, as shown in Fig. 7.

TABLE I. EXPERIMENTAL SOFTWARE AND HARDWARE ENVIRONMENTAL PARAMETERS

Software and hardware environment name	**Parameter specification**
Device type	Deep learning server
Processor	13th Gen Intel(R) Core(TM) i5-13490F 2.50 GHz
Graphics card	Nvidia GTX 4080
Internal memory	64GB
Hard disk space	1TB
Operating system	Ubuntu 14.04
Experimental platform	Caffe, Python 2.7.12, Matlab R2015b

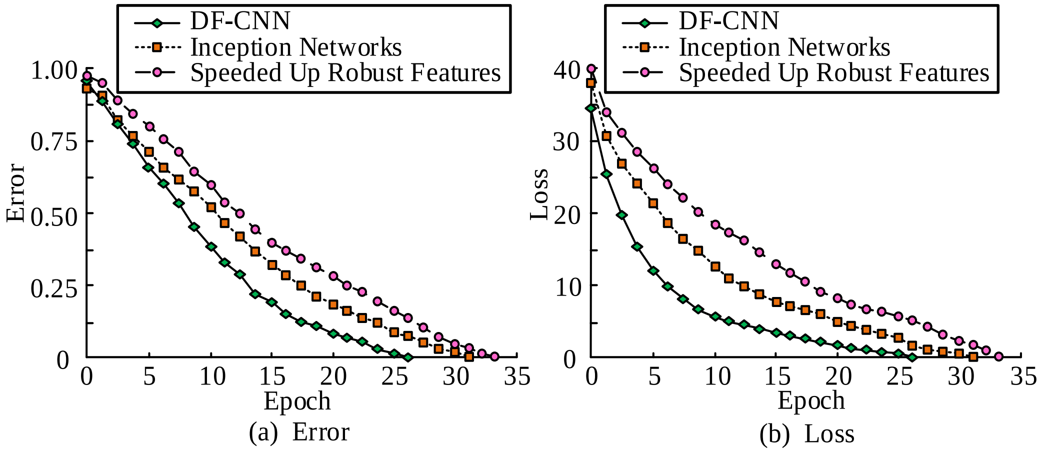

Fig. 7. Convergence performance test.

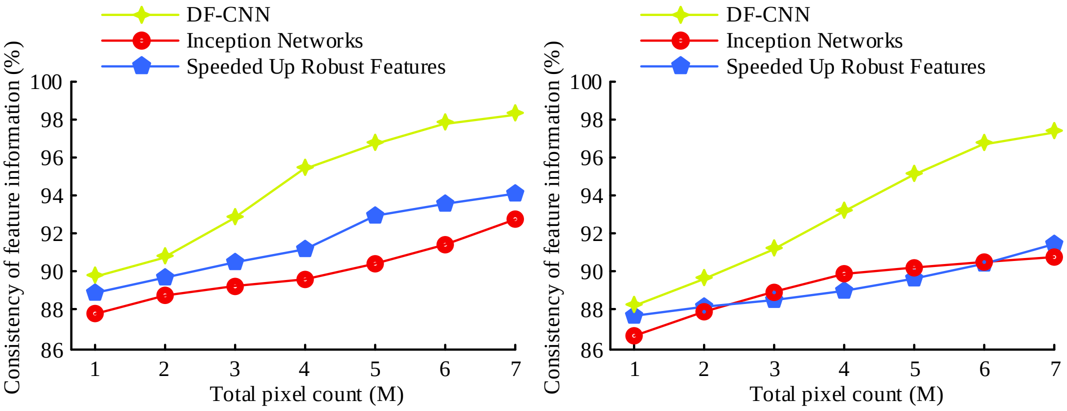
In Fig. 7, the overall convergence trend of performance for different methods during training was consistent. Fig. 7(a) shows that during the error convergence process, the error value of DF-CNN at the beginning of the iteration was lower than that of Speeded Up Robust Features and higher than that of Inception Networks. Within 5 iterations, the error value of DF-CNN rapidly decreased and was already lower than Inception Networks by the 5th iteration. In Fig. 7 (b), during the loss convergence process, the error value of DF-CNN at the beginning of the iteration was 34, which was lower than the Speeded Up Robust Features and Inception Networks. The loss value of DF-CNN decreased rapidly in the early stage and gradually slowed down in the later stage until the training was completed. The DF-CNN proposed in the study only required 26 iterations of training to achieve the optimal error and loss values, which were 7 and 10 fewer than Speeded Up Robust Features and Inception Networks, respectively. This indicates that the research method has better convergence performance and high training efficiency. The consistency of extracting image feature information was tested using different methods in images containing different numbers of pixels, as shown in Fig. 8.

From Fig. 8, the consistency of the results obtained by different methods in extracting image feature information increased with the total number of pixels in the image. Fig. 8 (a) shows that when the image was set to only contain a single cultural and creative object, the image feature information consistency of Speeded Up Robust Features was 94.1% when the total pixel amount of the image reached 7M. The similarity of image feature information in DF-CNN increased rapidly as the total pixel size of the image increased from 1M to 4M, and then gradually slowed down the rate of increase. During the entire process, the similarity of image feature information was 89.8% when the total pixel size of the image was 1M. When the total pixel count of the image reached 7M, it increased to 98.4%. From Fig. 8(b), when the image contained three composite cultural and creative objects, the image feature information consistency of Speeded Up Robust Features was 91.6% when the total pixel amount of the image reached 7M. The image feature information consistency of Inception Networks was 90.7% when the total pixel size of the image reached 7M. The image feature information consistency of DF-CNN was 97.6% when the total pixel size of the image reached 7M. The research method experienced a slight decrease in performance when extracting image features from multiple objects, but the magnitude of the decrease was smaller than other methods. This indicates that the research method has good performance in extracting image feature information.

B. Analysis of the Practical Application Effect of Image Retrieval Technology for Cultural and Creative Products

When analyzing the practical application of image retrieval technology for CCPs designed in research, the study extracted CCP images from a CCP design website as a retrieval image library. The running time of different methods was analyzed, and to improve the accuracy of statistical results, each scheme was repeated 10 times, presented in the form of mean and standard deviation. Seven different search fields were set and abbreviated as A, B, C, D, E, F, and G. The runtime was divided into two different stages: feature extraction and retrieval result generation, as shown in Fig. 9.

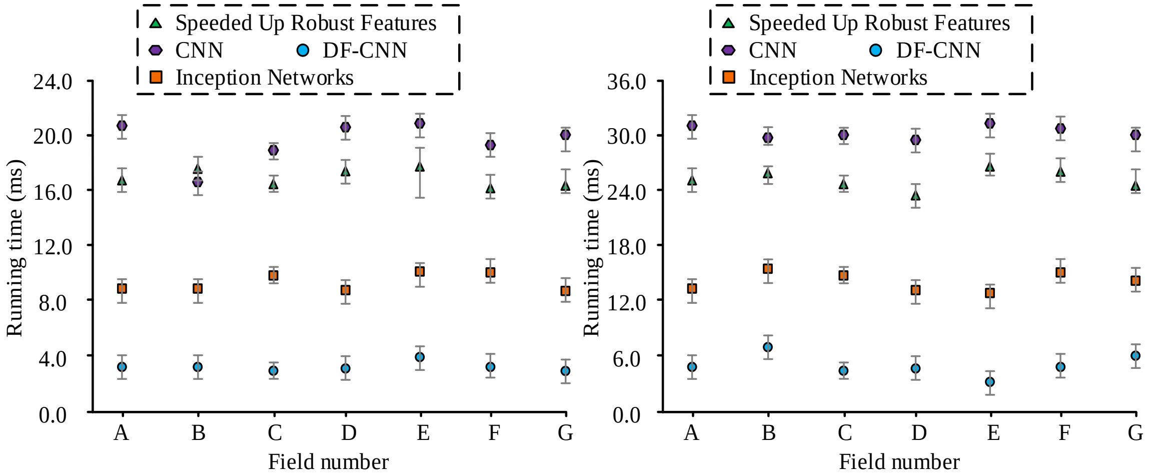
In Fig. 9, the runtime time of different methods was related to the fields and generally remained within a certain range. Fig. 9 (a) shows that during feature extraction, CNN had significantly higher runtime in six out of seven fields compared to other methods. The running time of Inception Networks was significantly lower than that of Speeded Up Robust Features, reaching its lowest point in the D field, between 7.0ms and 8.0ms. The running time difference of DF-CNN in the seven fields was relatively small, with a minimum of 2.3ms and a maximum of only 4.7ms. The fluctuation in time during multiple runs was also maintained within 2.0ms. As shown in Fig. 9 (b), different methods exhibited significant efficiency stratification when generating search results. Among the seven fields, the results were ranked according to the longest running time of CNN, the second longest running time of Speeded Up Robust Features, the third longest running time of Inception Networks, and the shortest running time of DF-CNN. The search result generation time of DF-CNN in seven fields was the highest at only 7.4ms, and the lowest at 1.6ms. The research method had higher operational efficiency at runtime and could complete image retrieval of CCPs at a faster speed. The proportion of false retrieval content in the retrieval results of different methods in practical applications was analyzed, as shown in Fig. 10.



(a) Single cultural and creative object

(b) 3 composite cultural and creative objects

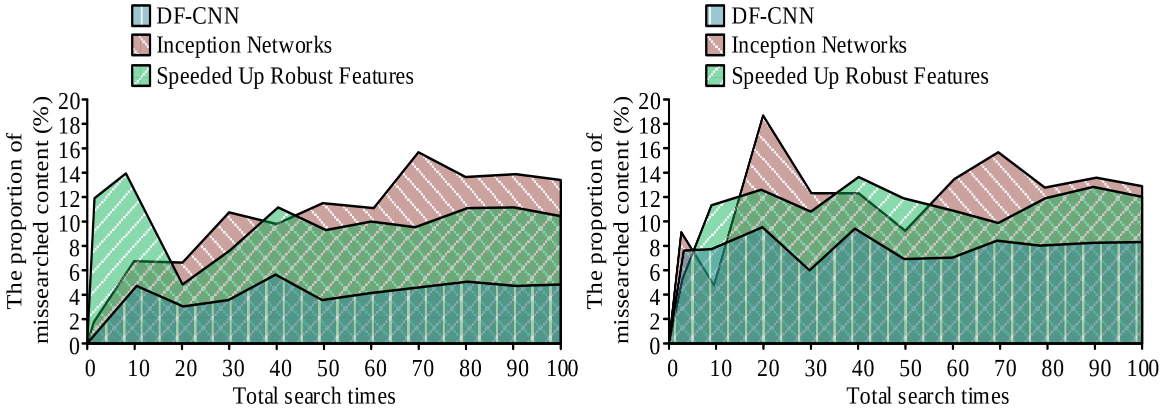
Fig. 8. Extracting the coincidence degree of image feature information.



(a) Feature extraction

(b) Search result generation

Fig. 9. Runtime analysis.



(a) Single cultural and creative object

(b) 3 composite cultural and creative objects

Fig. 10. Analysis of the proportion of false retrieved content.

As shown in Fig. 10, different methods tended to stabilize the proportion of false retrieval content as the number of searches increased when generating retrieval content. Fig. 10 (a) shows that when searching for a single CCP object, Inception Networks had the highest proportion of false searches in 100 searches, reaching 15.8%. When the number of searches reached 80, it tended to stabilize and fluctuated slightly around 13.7%. The false search rate of Speeded Up Robust Features reached a maximum of 14.1% in 100 searches, and stabilized when the search frequency reached 50, mainly fluctuating in the range of 10.0% to 11.0%. The proportion of false searches in DF-CNN remained within 6.0% during 100 search cycles, and tended to stabilize at around 5.0% when the search cycle reached 50. From Fig. 10(b), when searching for three comprehensive CCPs, the proportion of false searches by Inception Networks in 100 search processes ultimately fluctuated around 13.4%. The proportion of false searches in Speeded Up Robust Features ultimately fluctuated around 12.3%. The proportion of false searches in DF-CNN tended to stabilize when the number of searches reached 50, fluctuating around 8.2%. The research method can better exclude irrelevant content when conducting image retrieval of CCPs. The overall content matching of the generated search result list was analyzed, and 20 searches on each key field were performed, as shown in Fig. 11.

In Fig. 11, in the analysis of content matching in search results, the matching degree of the results obtained from multiple searches could be integrated into a range of intervals. When the length of the search result list was 20, the content matching degree of Speeded Up Robust Features mainly fluctuated around 78%. The content matching degree of the retrieval results of Inception Networks mainly fluctuated around 85%. The content matching degree of DF-CNN search results mainly fluctuated around 92%. As the length of the search result list increased, there was a certain degree of decrease in the content matching of the search results for Speeded Up Robust Features and Inception Networks. However, the degree of decrease in the content matching degree of DF-CNN search results was minimal. When the length of the search result list reached 100, the content matching degree of the search results still fluctuated around 91%. The research method could maintain high operational performance and retrieval accuracy for a long time when conducting a large number of CCP image retrieval tasks.

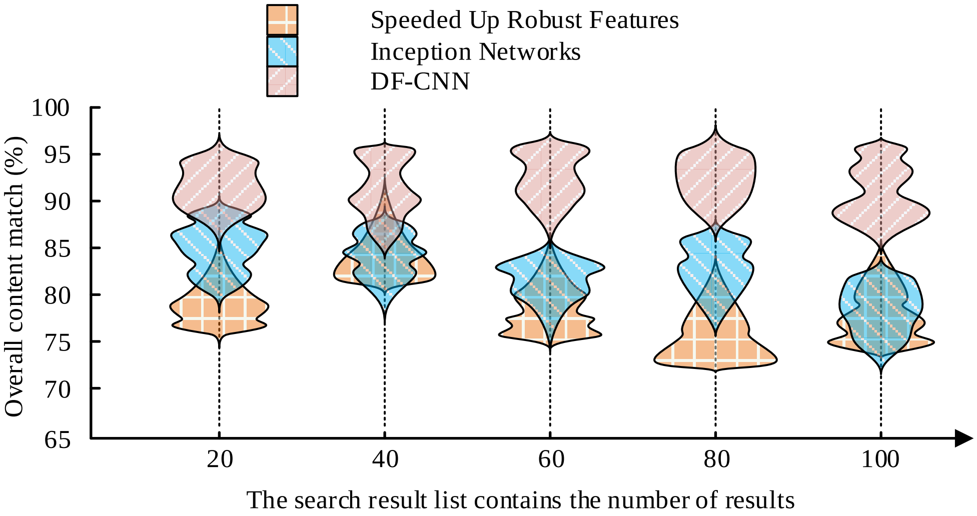


Fig. 11. Search results content matching degree analysis.

IV. Discussion and Conclusion

A CCP search assistance technology based on DF-CNN image retrieval module was studied and designed to enhance the exposure ability of CCPs. In the process, the number of decision trees in the forest was used as a hyperparameter to evaluate the effectiveness of features through classification testing. The aggregated feature vectors were calculated for each region, and region features which completed twice normalization were conducted sum-pooling aggregation. The significance weight of the region was defined. After extracting the image features of CCPs, the image retrieval module was constructed using feature semantic similarity measurement. The similarity measurement was performed on the query information and image library images to match the corresponding retrieval images. Finally, the effectiveness of the method was analyzed. The experimental results showed that in convergence performance testing, the research method only required 26 iterations of training to achieve the optimal error and loss values. When setting the image to only contain a single cultural and creative object for image feature information matching analysis, it increased to 98.4% when the total pixel size of the image reached 7M, indicating that DF-CNN could effectively capture the detailed features of the image when processing high-resolution images, providing richer information for image retrieval. When searching for three comprehensive CCPs, the proportion of false searches in the research method ultimately fluctuated around 8.2%, indicating that DF-CNN could effectively handle the complexity and diversity of features in multi-object images. The content matching degree of research method retrieval results has been fluctuating around 91% for a long time, which means that when using DF-CNN for image retrieval, users can obtain highly relevant results to the query, thereby improving the user experience of retrieval. The research method could generate higher quality retrieval results when conducting image retrieval of CCPs. With the development of technology, the application of 3D images and dynamic images was becoming increasingly widespread. Future work can consider extending DF-CNN to these new image types to meet a wider range of application requirements. However, in actual deployment and application, the scalability and robustness of the model also need to be considered. Future work can explore the combination of image retrieval technology and natural language processing to achieve text-based image retrieval, to improve the accuracy of retrieval and the naturalness of user interaction. At the same time, research can also be conducted on retrieval algorithms that are suitable for 3D models and video content, to meet the market's demand for dynamic and stereoscopic visual content retrieval. User privacy protection in the process of image retrieval should be strengthened and how to provide personalized retrieval services without leaking user data needs to be studied.

Declaration of Competing Interest

We declare that we have no conflict of interest.

Method for Mission Analysis Using ToT-Based Prompt Technology Utilized Generative AI

Satellite Mission Analysis for SaganSat-0 of Remote Sensing Satellite

Kohei Arai
Dept. of Intelligent Information Science, Saga University, Saga City, Japan

***Abstract*—Method for mission analysis using ToT: Tree of Thought-based prompt technology utilized generative analysis AI is proposed. Mission analysis needs methods for simulation of the supposed images which will be acquired with the imaging mission instruments, and the other mission instruments. In order to create simulation images, ToT-based prompt technology utilized generative AI is used. An application of the proposed method is shown for a mission analysis for SaganSat-0 of remote sensing satellite which will carry three mission instruments, a 720-degree camera, a thermal infrared camera and a Geiger counter. The simulated images and the Geiger counter sounds created by the proposed method are shown here together with analyzed results.**

***Keywords*—CoT; ToT; AI; Mission analysis; prompt technology; generative AI; SaganSat-0; remote sensing satellite; 720-degree camera; thermal infrared camera; Geiger counter**

I. Introduction

In recent natural language processing, Chain-of-Thought (CoT) prompting for language models is a technique that includes a series of steps to solve a problem in the prompt (i.e., the text input to the language model) [1]-[10]. The basic CoT prompting mimics the "step-by-step thought process" and includes the flow of reasoning steps as examples/samples for few-shot learning. Namely, LLMs (large-scale language models) such as ChatGPT are not good at inference. If you want them to think logically, you have to ask them questions in a way that encourages logical thinking. This is called CoT prompting. Few-Shot prompting is a method of generating answers by giving a few examples. The idea is to lay the groundwork for thinking by giving examples and having ChatGPT think about it. Zero-Shot prompting is used for difficult questions, but in the sense of giving a few examples, CoT prompting is similar in some ways.

In problem solving, if questions are one of those of which someone has already answered, ChatGPT will give a clear answer. However, if the question has never been answered by anyone, ChatGPT will immediately give you an ambiguous answer. This is true not only for "unknown problems", but also for personal problems that cannot be generalized, such as your own or your company's. For such problems, we need to narrow down the scope of the problem and show the logical path. In short, if we can cover his weakness (inability to deduce or construct logic) on the human side, we can get a very useful answer because ChatGPT has knowledge from all over the world that we personally cannot have. This is the true meaning of "prompt engineering".

According to a paper published by a team at Google's AI research lab in January 2023 [11], "CoT prompts are a technique that does not immediately ask for the answer to a problem, but rather involves intermediate inference steps and then layering step-by-step inferences (chains of thought) to arrive at the answer." In this way, the CoT prompt shows the flow of thought to solve the problem logically and deductively, but because it is one-way, it may lead to the wrong answer in the case of more difficult problems. Therefore, the Self-consistency with CoT prompt was devised, which presents multiple answers and allows the user to choose the appropriate answer from among them. However, for problems that involve complex processes, verifying and evaluating all the answers one by one will not be enough resources no matter how many there are. The Tree of Thoughts (TOT) prompt, announced in May 2023 by a joint research team from Google's DeepMind team and Stanford University, is effective for problems that have multiple paths to the goal and are difficult to arrive at the correct answer [12]-[22].

Like COT, thinking deductively is desired, step by step, but in this case, it is unknown what order to do it in. Even with real problems, it's not uncommon to not know where to start. In such cases, we use the concept of "decision tree" to think about it. There are many options at each stage to get to the goal. This is a way to think about which route to take. This TOT prompt can be applied to solving complex problems. First, we ask participants to come up with some solutions in ChatGPT, and then we evaluate them based on criteria such as feasibility and budget. (For example, (certain/possible/impossible) or "on a 5-point scale.") Then, we dig deeper into the top ideas. A good question would be to ask participants to "dig deeper from a certain point of view." After that, we ask them to summarize their ideas in ChatGPT. "Based on your analysis so far, please rank your ideas in order of highest to lowest." This ToT prompt is close to human thinking, and as the DeepMind team suggested it, it is the logic used in games such as Go-play, Shogi, and autonomous driving.

The purpose of this paper is to present usefulness and effectiveness of the ToT for generation of images, moving pictures, and so on in comparison to the other CoT, plain generative AIs. By using ToT prompt technology, mission analysis (simulation of mission instrument data) is conducted. As an example, mission analysis for SaganSat-0 of remote sensing satellite which carries three mission instruments, 720-degree camera, thermal camera and Geiger counter is conducted. ToT prompts are used for creation of simulation imagery data of the three mission instruments. Furthermore, mission analysis is conducted successfully. SaganSat-0 was launched in the midnight on 5 August 2024 and will be put into the orbit of ISS: International Space Station on 29 August 2024. Therefore, the simulation data will be verified after the SaganSat-0 data acquisition and also confirmed mission analyzed results after that.

In the next section, SaganSat-0 mission is described together with three mission instruments. Then, simulation of these mission instruments data is described with the proposed ToT-based prompt technology. After that, some mission analysis results are described followed by conclusion with some discussions.

II. SaganSat-0

SaganSat0 is a small satellite of the CubeSat (1U) type supported by the Saga Prefectural Space Science Museum. Below is more information about SaganSat0:

Satellite details:

Name: SaganSat0 (SaganSat No. 0)

Type: CubeSat (1U)

Status: Not launched, scheduled for 2024

Launch rocket: Falcon 9 (Cygnus, NG-21)

Project overview: Three mission instruments, 720-degree camera, thermal infrared camera, Geiger counter

Support organization: Saga Prefectural Space Science Museum

Contact: a-ito@yumeginga.jp.nospam

Japanese news:

The Saga Shimbun newspaper has extensive coverage of news about SaganSat0

From these information, SaganSat0 is a small satellite project led by the Saga Prefectural Space Science Museum, scheduled for launch on 5 August 2024 to ISS and will be released from the ISS and putted into ISS orbit in the near future (late of August 2024).

A. Mission Instruments

The SaganSat-0 satellite is equipped with three mission instruments. One of them (Mission 1) is two 360-degree cameras (720-degree cameras) that test the Earth-pointing direction and the deep space direction. The 360-degree cameras take images with a resolution of 800 by 600, and the image size of the two images is about 60 KB (0.45 degrees/pixel) in total. If the radius of the Earth is R, the satellite altitude (ISS altitude = 400km) is H, and the instantaneous field of view is θ, the resolution of the Earth's surface is expressed by Formula (1). The resolution of the Earth's surface is about 3142m.

$$R=H\cdot\tan(\theta) \quad (1)$$

The Earth's spheroid used here is the standard spheroid called GRS80, and the geodetic coordinate system using it has a polar radius of 6356.752 km in ITRF84. The infrared camera for Mission 2 will take images at a resolution of 800 by 650, with an image size of about 40KB; the resolution is 200m, and since the down-link is at 4.8kbps, one set of Mission 1 and 2 data can be down-linked in 21 seconds. Mission 3 data can be down-linked at 42B/21 seconds.

Since the altitude of the International Space Station (ISS) is about 400 km, the range over which a ground station can communicate with the ISS is affected by the curvature of the Earth and the characteristics of the antenna of the ground station, and an approximate method for calculating the basic range is expressed by Formula (2), which calculates the range over which a ground station can communicate with the ISS (line of sight).

$$d=\sqrt{(2hR+h^2)} \quad (2)$$

where: d is the distance above the horizon (km), h is the altitude of the ISS (km), and R is the radius of the Earth (about 6371 km). Therefore, the range over which a ground station can communicate with the ISS is about 2293 km. Within this range, direct communication with the ISS is possible, and since the speed of the ISS is about 28,000 km/h (7.8 km/s), the visible range is about 4.91 minutes = 294.6 seconds. Therefore, about 14 frames of Mission 1, 2, and 3 data can be downloaded.

B. 720-Degree Camera

The 720-degree camera is composed of two 360-degree cameras. Moving pictures and still pictures can be acquired with the different operation modes. Instant Field of View: IFOV of the camera is 0.45 degrees.

C. Thermal Infrared Camera

Arducam：2MP Global Shutter OV2311 Mono Camera Modules Pivariety (NoIR), compatible with Raspberry Pi ISP, and Gstreamer Plugin-Arducam is used for mission #2 of thermal infrared camera. Moving pictures and still pictures can be acquired as well. Swath width is 163 km, Instantaneous field of view is 102m, Frame rate is 30fps for moving picture acquisition, The number of pixels can be selected (1) 1600 by 1300, (2) 800 by 650, Quantization bit rate is 8bit, Transmission bandwidth is 499.2 Mbps, Camera clock is 27MHz in maximum, and it can be transmitted one frame image in every 18.5 seconds for 1600 by 1300 mode, and in 4.6 seconds for 800 by 650 mode, respectively.

D. Geiger Counter

The ISS is located at an altitude of about 400 km, outside the Earth's magnetosphere, making it an environment that is easily affected by cosmic rays: a Geiger counter makes a "click" sound each time it detects radiation (alpha particles, beta particles, gamma rays, etc.). On Earth, the amount of radiation is low, so the sound is heard sporadically, but on the ISS, the intensity of radiation is much higher, so the detection sound is more frequent. For example, natural radiation levels on Earth would make a Geiger counter click a few dozen times per minute, but on the ISS, hundreds to thousands of clicks per minute would be heard.

III. Simulation of Mission Instrument Data with a Simple Prompt of the Generative AI

A. 720-Degree Camera Images

360-degree camera images which will be acquired with 720-degree camera of Mission #1 are tried to create with a simple prompt of the generative AI (ChatGPT, for instance). Two examples are shown in Fig. 1. The prompt is as follows, “Please create 360-degree camera image of the Earth from the altitude of ISS (400km)”. As is shown in Fig. 1, it seems like nighttime scenes of cloudy South American continent with the thin atmosphere and shining the sun.

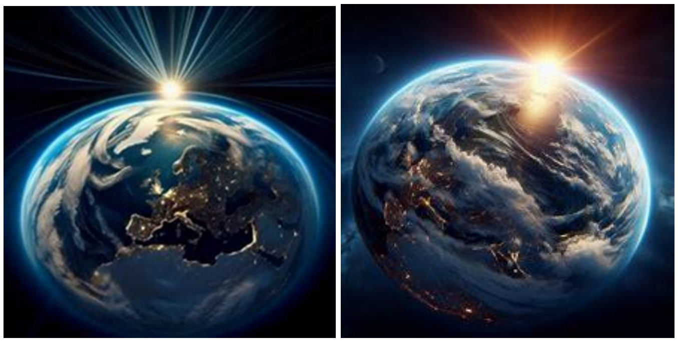

Fig. 1. Two example images which will be acquired with 720-degree camera of Mission #1 created with a simple prompt of the generative AI (ChatGPT).

The following ToT of prompt (“Please decide to choose the Pika[1] generated images or Tenbin AI generated images for creation of 360-degree camera image of the Earth from the altitude of ISS (400 km)”) is attempted to the creation of 360-degree camera images. Tenbin AI is created by GMO[2], Japan which allows the use of more than six generative AI at once free of charge. Such that the decision tree selection of the prompt does work to generate many appropriate images. Fig. 2 shows the images created by the ToT prompt proposed here.

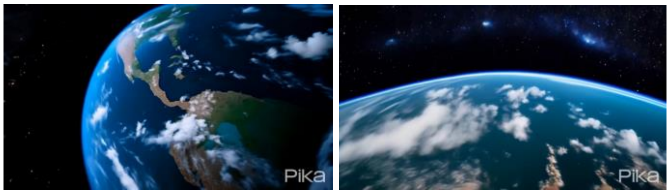

Fig. 2. Two example images which will be acquired with 720-degree camera of Mission #1 created with the proposed ToT prompt of the generative AI (ChatGPT).

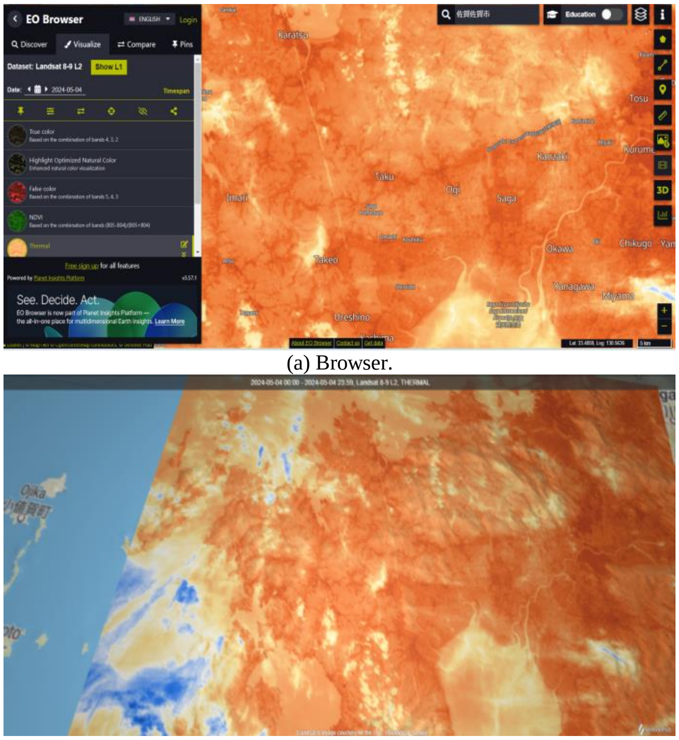
Curvature of the Earth can be seen. At an altitude of 400 km, the curvature of the Earth is clearly visible. The curved horizon is a distinctive feature. Continents and the oceans can also be seen. The vast oceans can be seen together with the spreading continents and their boundaries. During the day, the sunlight reflects beautifully off the land and water surfaces. The thin blue layer of atmosphere that surrounds the Earth can be seen as well. This is the Earth's atmosphere. On the night side of the Earth, scattered city lights can be identified. The boundary between day and night (terminator) divides the Earth into two halves. The night sky features a large number of stars and a clear view of the Milky Way.

B. Thermal Infrared Camera Images

Landsat-9/TIRS-2(Thermal Infrared Sensor-2), OLI-2(Operational Land Imager-2) can be used to simulate the mission #2 of thermal infrared camera images. By using EO (Earth Observation) Browser[3] provided by European Space Agency, simulation images can be simulated. Fig. 3 shows an example of the simulated thermal infrared images with 200 m spatial resolution of Saga city and its surroundings which was acquired on 4 May 2024.



(a) Browser.

(b) 200m resolution of the simulated thermal infrared camera image.

Fig. 3. EO browser and example of the simulated thermal infrared camera image.

The following ToT of prompt (“Please decide to choose the EO browser derived Pika generated images or Tenbin AI-generated images for creation of thermal infrared camera image of a land containing flooding areas are included from the altitude of ISS (400km)”) is attempted to the creation of thermal infrared camera images. Such that decision tree selection of prompt does work to generate many appropriate images. Fig. 4 shows the image created by the ToT prompt proposed here.

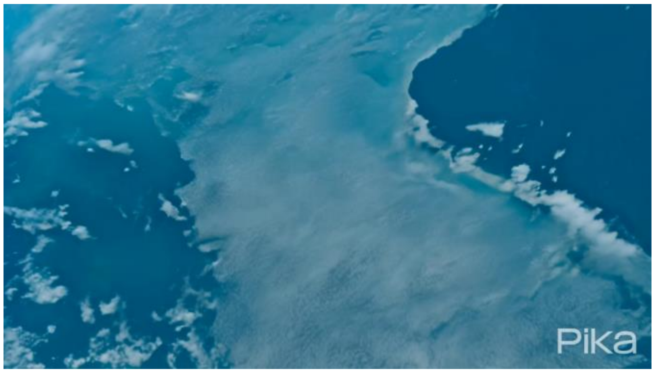

Fig. 4. Example of the simulated thermal infrared camera image.

C. Geiger Counter Sounds

The sound of natural radiation levels on Earth would be tick... tick... tick... tick... tick... tick... tick... whereas the sound of cosmic rays on the ISS would be tick-tock-tock-tock-tock-tock-tock... Thus, while on the ISS in orbit, the sound of the Geiger counter can be heard very frequently, and almost continuously, due to the frequent detection of high energy particles.

Famous links to actual audio data recording the sounds of cosmic rays in ISS orbit are (1) JAXA Kibo Public Relations and Information Center[4] and (2) NASA Glenn Research Center[5]. Listening to these audio recordings gives you an idea of what life is like on the ISS and makes the presence of cosmic rays seem more familiar to you. Geiger counters can detect not only cosmic rays but also other types of radiation such as beta rays and gamma rays, so not all sounds are necessarily caused by cosmic rays.

By using ToT-based prompt technology, the sound of cosmic rays detected by a Geiger counter at an altitude of 400 km on the ISS can generally be simulated with the following prompt. “Choose the generate sounds as a quiet crackling when the satellite altitude is low or popping sound for the relatively higher satellite altitude”. Like a crackling, similar to a light sound like a spark flying. It occurs every time a cosmic ray strikes the detector of a Geiger counter. As a popping sound, a sound similar to a small popping sound (occurs every time a high-energy cosmic ray strikes the detector) is heard. The loudness of the sound depends on the energy of the cosmic ray and the sensitivity of the detector, but generally, the more energetic the cosmic ray, the louder it will be. Also, a more sensitive detector can detect even weaker cosmic rays.

IV. Mission Analysis with the Simulated Images and the Sounds

A. 720-Degree Camera Images

By using generative AI (Tenbin AI) with the following simple prompt of “What insights can you glean from the images you've uploaded?” the following response is obtained.

The uploaded image shows the Earth from space, particularly the North American continent. Key insights from the image include are as follows, (1) Roundness of the Earth: From space, the Earth is clearly spherical. (2) Atmosphere: The atmospheric layer surrounding the Earth is depicted as a beautiful blue atmospheric color. (3) Clouds: Clouds of various shapes are spread across the Earth's surface, indicating the movement of the atmosphere. (4) Land and Ocean: The land of North America and the ocean surrounding it are clearly distinguishable. (5) Stars in the night sky: Countless stars shine against the background of the Earth. (6) Word "Pika" in the bottom left of the image: The word "Pika" is written in the bottom left of the image, which may indicate that the image is part of some kind of content.

B. Thermal Infrared Camera Images Containing Flooding Areas

Thermal infrared imagery creates images based on the temperature of objects. Flooded or submerged areas have a lower temperature than the surrounding land, and therefore appear darker in thermal infrared imagery. For this image, the following methods are used to detect flooded or submerged areas: Simple thresholding method compares the brightness values of all pixels in the image and considers pixels that are lower than a certain threshold as flooded or submerged areas; Object-based segmentation method identifies objects in the image and determines whether they are flooded or submerged based on their temperature and shape; and Machine Learning method uses historical flood data to train a model to automatically detect flooded or submerged areas from thermal infrared imagery.

For the simple threshold method, the histogram shows that the brightness values in the image are relatively evenly distributed. There is a small peak on the left side of the image that could be a flooded or submerged area. Also, all pixels with a brightness value below 100 are considered to be flooded or submerged areas. There are some areas on the left side of the image that could be flooded or submerged areas.

Using Tenbin of generative AI with the prompt of “Extract flooding areas from the simulated thermal infrared image”, mission analysis of flooding area detection is conducted.

The simulated thermal image is converted to gray-scale and has a size of 1125 by 2000 pixels. Fig. 5 shows the gray-scale image. Next, we proceed to detect flooded areas. In thermal imagery, flooded areas usually appear cooler (darker in gray-scale) due to lower water temperature compared to the surrounding land. A thresholding technique is applied to highlight these cooler regions. In the thresholded image, the potentially flooded areas are highlighted in black. These regions correspond to the cold areas in the thermal imagery, indicating the accumulation of water due to flooding. Fig. 6 shows the detected flooding areas.

Other flooding area detection method with the following simple prompt “Detect flooded or submerged areas from uploaded thermal infrared images” using Tenbin of generative AI is attempted. Fig. 7 (a) shows the uploaded thermal infrared camera image with the histogram while Fig. 7 (b) shows the histogram equalized image with the histogram. On the other hand, Fig. 7 (c) shows gray-scale image of the uploaded thermal infrared camera image while Fig. 7 (d) shows

C. New Insights Gained by Combining 360-degree Camera Images and Thermal Infrared Camera Images

Using the Tenbin AI with the simple prompt "Combining visible light images from a 360° camera taken at ISS altitude with thermal infrared images at 200 m resolution allows for many interesting applications" the following responses are obtained,

1) Analyzing the urban heat island effect: By identifying urban structures with visible light images and observing their heat distribution with thermal infrared images, you can investigate temperature rises in urban areas in detail.

2) Early detection and monitoring of forest fires: By identifying smoke and flames with visible light images and identifying high-temperature areas with thermal infrared images, forest fires can be detected earlier and more accurately.

3) Observing ocean surface temperature distribution: By visually identifying ocean currents and eddies with visible light images and observing the distribution of sea surface temperatures with thermal infrared images, studying climate change and its impact on marine ecosystems can be done.

4) Assessing agricultural productivity: Identifying crop types and distribution with visible light images and evaluating crop stress and irrigation efficiency with thermal infrared images can be performed.

5) Volcanic activity monitoring: By observing the shape and plumes of volcanoes with visible light imagery and detecting thermal anomalies with thermal infrared imagery, you can monitor changes in volcanic activity.

6) Urban planning and sustainability research: By examining urban structures and green spaces with visible light imagery and identifying energy-efficient buildings and areas with thermal infrared imagery, you can use this data for urban planning.

7) Observing changes in glaciers and polar regions: By examining the shape and extent of glaciers with visible light imagery and observing temperature changes with thermal infrared imagery, you can study the effects of climate change.

8) Air pollution research: By observing smog and atmospheric conditions with visible light imagery and observing temperature gradients in the atmosphere with thermal infrared imagery, you can study the distribution and dynamics of air pollution.

D. Insights from the Simulated Geiger Counter Sound Data

Geiger counter sound data on the Earth’s surface is simulated by using the Tenbin AI with the simple prompt “Generate Geiger counter sound data which is measured on the ground and the 400 km altitude”. Then the frequency components of the Geiger counter sound data are investigated with Audacity of sound data analysis software tool[6]. Fig. 8 (a) shows the generated Geiger counter sound data measured on the ground and its frequency components while Fig. 8 (b) shows the generated Geiger counter sound data at the 400 km altitude. Meanwhile, Fig. 8 (c) shows its frequency components.

Fig. 8. Generated Geiger counter sound data measured on the ground and at 400 km altitude (SaganSat-0 altitude) and their frequency components.

V. Conclusion

Method for mission analysis using ToT: Tree of Thought-based prompt technology utilized generative analysis AI is proposed. Mission analysis needs methods for simulation of the supposed images which will be acquired with the imaging mission instruments, and the other mission instruments.

In order to create simulation images, ToT-based prompt technology utilized generative AI. An application of the proposed method is shown for a mission analysis for SaganSat-0 of remote sensing satellite which will carry three mission instruments, a 720-degree camera, a thermal infrared camera and a Geiger counter. The simulated images and the Geiger counter sounds created by the proposed method are shown here together with analyzed results. In summary, it is found that ToT-based prompt technology is superior to the other CoT and plain generative AIs.

VI. Future Research Works

SaganSat-0 of remote sensing satellite was launched with launching vehicle Falcon-9 on 5 August 2024 and will be put into orbit at 400 km altitude just same as ISS orbit after being released from the ISS in the near future. Then, three mission instrument data will be acquired after all. Therefore, mission analysis will be made after the actual three mission instrument data are obtained. ToT-based prompt technology will be evaluated by using the actual three mission instrument data through a comparison. Then improvements will take place for ToT prompt technology.

Acknowledgment

The author would like to thank Prof. Dr. Hiroshi Okumura for his valuable discussions for this research works. Also, the author would like to thank Sho Kobayashi and M. Tanaka of Saga Prefectural Space Science Museum Yumeginga for their providing data and information.

***Abstract*—The prevalence of visual impairment among the global population is a growing concern, with rates continuing to rise at an alarming pace. According to statistics from the World Health Organization (WHO), an estimated 2.2 billion people globally live with some form of visual impairment. Several methods exist to aid the blind in everyday navigation, such as walking sticks and guide dogs. However, these aids do not come without their drawbacks. For instance, using traditional guide dogs may not be suitable for some individuals due to allergies, cultural beliefs, or being unable to take care of a living animal due to the level of responsibility required. Innovations such as smart walking sticks and robotic guide dogs are continually being developed to overcome these gaps and cater to the unique requirements of the visually impaired. Hence, this proposed system is equipped with a joystick-controlled robotic guide that mimics the responsibilities of a traditional guide dog. The proposed system features an obstacle avoidance feature that will detect obstacles in its environment to avoid collisions. It will also provide audio feedback through a Bluetooth-connected mobile application when an obstacle has been detected. The proposed system is a product innovation which can be targeted to benefit visually impaired users by providing them with more independence as well as convenience in terms of mobility. Upon performing acceptance testing with the target audience, the system has been found to achieve its target in aiding the guidance of blind individuals.**

I. Introduction

In 2015, the United Nations (UN) created the 17 interrelated global goals, also referred to as the Nation Goals or Sustainable Development Goals (SDGs). By 2030, a more equitable and sustainable future is to have been established, and many of the world's social, economic, and environmental problems are to have been resolved. SDG 9 is about infrastructure, industry, and innovation; HUD is in line with this objective. HUD technology integrated into motorcycle helmets can provide real-time navigation, weather updates, and speed information directly in the rider's line of sight. This not only enhances the riding experience but also promotes road safety by minimizing the need for riders to look away from the road [1-2].

Helmets are protective headwear that shields the head and brain from injury during a range of activities, especially ones that include the risk of impact or falls. As previously indicated [3 - 5], the present generation of helmets is lacking significantly, especially considering the increasing prevalence of the Internet of Things (IoT) [6-9] and its use in the automobile sector, including automated braking, head-up displays, and other features. Helmets are used for many different purposes and can be found in many different forms. Motorcycle riders make up the majority of road users, however, because there is a lack of innovation and products in the ASEAN market, the helmet is seen as a less important part of the IoT. IoT are deployed in several applications for the convenience of users [10-12].

The idea for heads-up display systems was initially created for use in automobiles, including commercial aircraft, cars, and military vehicles. To make sure they are free of any obstructions, any user can flip between the two cameras that surround the car and the aeroplane. Operating the gadget is as simple. The navigation system is one of its main benefits; it keeps the pilot or driver focused on manoeuvring the vehicle rather than getting distracted [3,13]. The LCI-HUD Helmet System makes use of the same capability. The main CPU board is the Raspberry Pi, which is also equipped with Bluetooth.

A camera mounted behind the rider's helmet does double duty as a rearview mirror and, more importantly, closes the blind spot for motorcyclists. On the other hand, the helmet's built-in headset allows the rider to talk hands-free while answering calls or listening to music. A button on their visor controls the display.

A map navigation display appears on the device once the user uses the mobile application to set the destination on the helmet. Using the music application, the rider can also play music via a playlist display on the visor. Rather than pulling over to the side of the road to answer a call, the rider can use [8] to answer hands-free. Information about the caller will be shown on the visor using the HUD system. This reduces the possibility that the rider will drive while distracted.

Fig. 1 illustrates the proposed work, which is an improved low-cost integrated head-up display (LCI-HUD). A multitude of information can be projected onto the HUD by integrating the LCI-HUD with currently running third-party applications. One crucial element is the concept of an inexpensive, multipurpose LCI-HUD. Users can retain their user data using LCI-HUD after installing and registering mobile apps. APIs are used to connect the music and additional third-party extensions. LCI-HUD integrates as a result. LCI-HUD interacts with third-party applications to provide users with immediate access to a range of services, including social media notifications, navigation, and weather updates, on the HUD. This seamless connectivity offers convenience while driving, enhancing the user experience all around. The use of APIs ensures that the LCI-HUD stays up to date with the latest features and advancements in third-party apps.

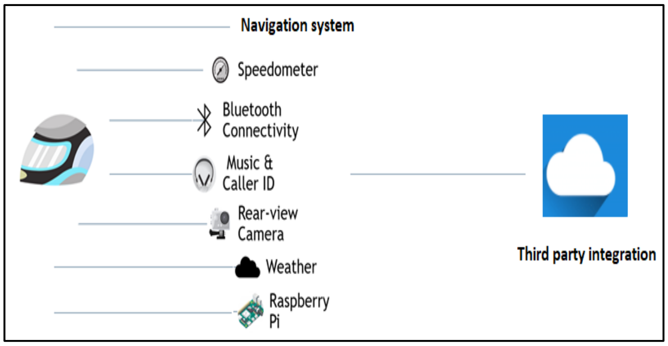

Fig. 1. Integrated heads-up display.

To check blind spots or view dashboard information like the speedometer, riders donning the existing (non-HUD) helmet are compelled to glance away from the road. Additionally, call receiving and navigation are done via external devices like cell phones. Roadside incidents are dangerous because they require quick attention and are easy to miss; using these devices could cause a shift in focus. Driving will become safer and less frequent if drivers maintain their attention on the road. To monitor blind areas or view dashboard information like the speedometer, riders using the existing (non-HUD) helmet are forced to turn their heads and look away from the road. In addition, calls and navigation are handled by external devices, like smartphones. Because road incidents are time-sensitive and easy to overlook, these devices will cause a shift in attention and pose a risk. The number of incidents will go down if drivers keep their eyes on the road for a safer driving experience.

The transparent display of HUD technology allows riders to view data without having to shift their typical range of vision, which is why it is recommended. Driving safety could be increased with the use of HUDs. Head-up display (HUD) navigation on a motorcycle is safer than smartphone navigation, according to a previous study. Additionally, by connecting the LCI-HUD with pre-existing third-party applications, it may show a variety of data on the HUD. There are several features available on the market for a fair price for the proposed LCI-HUD. The LCI-HUD can save user data after users install and register it. The integration of LCI-HUD follows. The small, lightweight additional hardware on the helmet won't restrict rider mobility.

To reduce distraction, motorcyclists can designate their preferred destination on their phone through the navigation module, and it will appear on the visors of their helmets [6]. To lessen the additional weight required to construct a bespoke board with the navigation module and to lower the cost of the hardware, the navigation module will retrieve navigational data from the smartphone. A weather module is added to assist the riders with changes in the weather. When motorcyclists are aware of the weather ahead of time, they may carefully plan their route.

The caller ID module enables the rider to receive a phone call with a pop-out on the rider’s visor. Using a button mounted on the handlebar of the bike, riders can answer or reject phone calls. Passengers can use the Music Module to adjust the music on their phones. To forward or rewind the music, a button is attached. Information is continuously shown on the visor via the Rear-View Camera Module, which is mounted to the back of the helmet and functions like a rear-view camera. By doing this, bikers will be able to avoid their blind spot and feel more confident when changing lanes without looking back.

As seen in Fig. 2, the user must first register for the mobile application. Using Firebase, the user will be able to access and exit the database remotely, and this data will be stored online. The rider and the Raspberry Pi must be connected via Bluetooth. The mobile application primarily controls two functions: music and navigation. The LED button on the Raspberry Pi allows the rider to select the display on the visor. The modular HUD's hardware will feature a camera affixed to the back of the helmet to function as the rear view and more sensors that the user can add in the future. The weather conditions displayed on the visor and data access are also guaranteed by the Raspberry Pi.

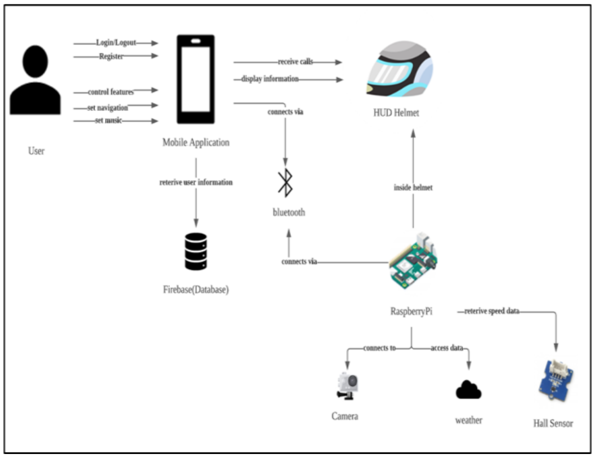

Fig. 2. Rich picture diagram.

II. Literature Review

There are two methods utilised to collect the necessary data: surveys and interviews. The target user base for data gathering is riders, to compare the proposed HUD helmet system with the existing helmet. The plan aims to boost safety while highlighting life experience in contrast to the existing helmet. The surveys will provide quantitative data on user preferences and feedback, while the interviews will offer qualitative insights into user experiences and suggestions for improvement. By targeting riders specifically, the research focused on the primary users of the HUD helmet system to ensure that safety and user experience are prioritized in the development process.

A. *Requirements Phase*

The interviews reveal information on the riders' perspectives and experiences with the existing helmet, as well as any prospective upgrades. The riders' preferences and perceptions of safety elements were quantified using questionnaires. Better user experience and more safety precautions were ensured by customizing the proposed HUD helmet system to the needs and preferences of the target users through their involvement in the data collection process. Motorbike riders were provided with a web-based questionnaire comprising multiple choice questions as part of the quantitative approach. Fig. 3 illustrates riding conditions that can cause distraction. Fig. 3 also presents the data collected on "distraction resulting from current riding experience.

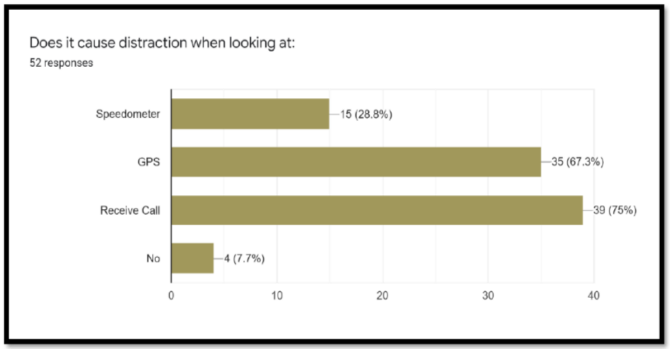

Fig. 3. Distraction due to current riding experience.

The intended LCI-HUD system as well as traditional helmets were the subjects of interviews conducted using qualitative methods. The purpose of the information gathering was to raise awareness about the HUD system in helmets and study any extra features that might be needed, in addition to the basic sensors and features. The HUD Helmet System can help when riding in accordance with the feedback that was received. Since it has features that make riding more convenient, the HUD Helmet System is preferred for use. It also helps to integrate everything together. The interviewee also offers suggestions for future developments that might be made to the HUD Helmet, including voice command, predictive braking distance, lane departure warning, and lane maintain assist. Beyond the advantages of using the existing helmet, the HUD Helmet System also offers the user benefits. To lessen the necessity of constantly checking his phone while riding, another interviewee indicated that he currently wears Bluetooth headphones. In line with other interviewees' responses, the information the respondent desired to have in the helmet—namely, navigation and display speed was also advantageous. Since it needs to determine the speed limit on the road where the rider is, the additional features, like the over-speeding warning message, could be a future enhancement. As conclusion, the interviewee believes that having a HUD helmet system is a good concept since it will assist motorcyclists stay focused because information is displayed on the visor.

B. Design Phase

Fig. 4 displays the activity diagram flow that outlines the riders' involvement, beginning with opening the LCI-HUD app and identifying whether they are first-time users. Once the registration procedure is complete, riders can log in. Riding the LCI-HUD system requires a Bluetooth connection after logging in. Following connection identification, riders can exchange visor information by pressing the LED button. Navigating while maintaining eye contact with traffic is made possible for riders by HUD helmet technology. By putting notifications, speed, and navigational data in real-time right in the rider's line of sight, this technology improves safety. Rider customization and distraction-free connectivity are made possible by the LED button, which allows riders to quickly switch between visor information.

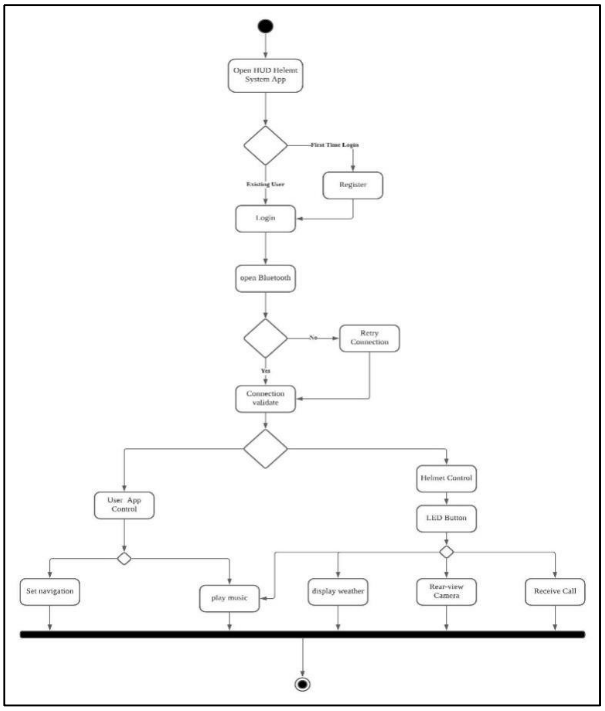

Fig. 4. Activity diagram.

As shown in Fig. 5, the characteristics that are used to specify objects form the basis of the class diagram. The UserID, a primary key that is automatically assigned to the rider at registration, is one of the features in the user database. The Bluetooth host is identified as the user's mobile phone. The further prerequisites are a password, phone number, and email address. The rider and the LCI-HUD system table will be connected via the database table. There are many relations; they are switched between one-to-many in the database and one-to-one in the LCI-HUD system by the database table. This suggests that a single user might be a part of many LCI-HUD systems and accounts. The table contains the board Bluetooth receive address and unique main key for HUD-based helmet system identification. Every user in the database table has a unique identity according to the primary key. There is an assurance that no two users are utilizing the same ID. To enable secure communication and data transfer between the user's helmet system and the LCI-HUD system, the Bluetooth receive address is utilized.

Fig. 6 shows the proposed LCI-HUD system's conceptual configuration. The schematic arrangement of the proposed LCI-HUD system is shown in Fig. 6, which also gives an idea of how the various parts are connected. This diagram facilitates the process of implementing and debugging the system by helping to comprehend its general structure and functionality. The brown cable is a camera module that is attached directly to the CSI port. The black GrovePi+ cable allows the sensor module to be operated directly from a socket. The orange wire, which is connected to the hall sensor and speedometer, respectively, is what powers the LED button. The last cable, which is blue, connects to the headset via the 3.5mm audio connector.

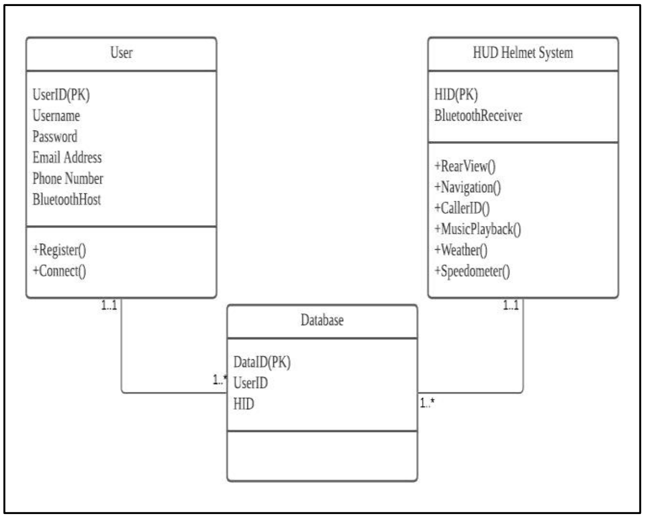

Fig. 5. Class diagram.

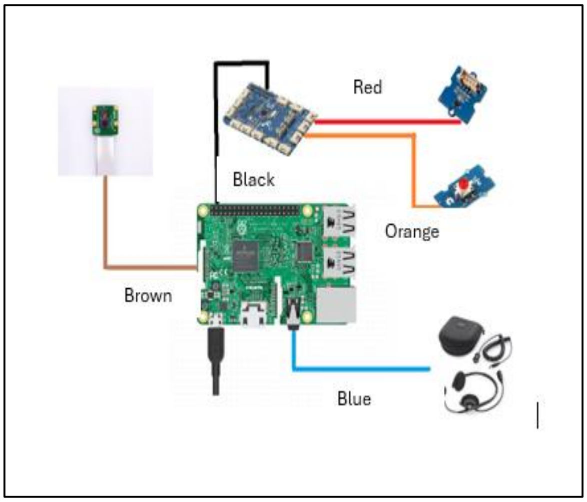

Fig. 6. Schematic layout of the proposed HUD helmet system.

C. Implementation Set-up

A Raspberry Pi, an Android app, and a database were employed as development platforms. Python and a JavaScript file for the LCI-HUD system were used to execute GeanyIED. Using the Pixel 2 as a reliable test bench, Android Studio emulates Android 8.0. Using a mobile app, Google Firebase stores authentication and databases. The users/rider need to register before using the application.

Module design is done in the Geany IDE. The framework of the HUD helmet system is written in Python using the Geany IDE. All the essential tools required for debugging and running code are included. Developers may use Android Studio to create phone apps that function across a variety of devices and run on the Android operating system. Using Firebase DB, the primary software feature, apps linked to the Raspberry Pi (HUD Helmet) can update the database in real time, enabling the Internet of Things. The system begins to communicate with and store information about the user as soon as they register for the first time on the mobile application. Following that, users run the system via Bluetooth. For security purposes, only the user has access to a unique authentication token.

The main objective of the system's implementation and appropriate functioning are its functional prerequisites. The non-functional need focused on the five main elements, along with other demands that were related to the behavior of the system's interactions, or the time required to finish a specific task. Usability, security, accessibility, user engagement, and responsiveness are the non-functional requirements for the suggested HUD Helmet System. The responsiveness criterion makes ensuring that user inputs are processed fast and effectively, and that real-time feedback is provided. The criterion for accessibility makes sure that users with impairments or disabilities can navigate the system with ease. Providing a smooth and simple user experience that makes it easy for users to explore and interact with the system's capabilities is the main goal of the user interaction requirement. The system is safeguarded against unauthorized access and data breaches thanks to the security requirement. Making the system simple to use and intuitive to understand is the main goal of the usability requirement.

III. Results and Discussion

Fig. 7 illustrates the three "modules" that the user of the LCI-HUD App can access on the first page after setup which includes the clock, weather, and rear-view camera. Since it is always necessary for the user to see the blind spot, the rear-view camera module remains stationary. By doing this, the user can continuously monitor the stream from the rear-view camera without ever leaving the first page. The clock and weather modules can also be customized by the user to show information that they want, like the location of weather updates or the format of the time.

The user can choose, edit, or remove data for numerous HUD helmet devices on the left page, as shown in Fig. 8. Users can flip between pages and change the brightness on the right page of the HUD helmet. The right page of the HUD helmet allows for simple page switching, offering a fluid and adaptable experience. Additionally, the brightness control feature guarantees the best possible visibility under different lighting circumstances.

When the user clicks on the red button as shown in Fig. 7. That will be simulated installed in the handler bar of the motorbike this will scroll to the next page as shown in Fig. 9 which at the moment showing the Google map route and music. User are able to expand on this by customizing it for which other widgets that they wish to view at a glance from the LCI-HUD App.

IV. Conclusion and Future Enhancement

The need for IoT devices that bikers could use daily motivated the development of the LCI-HUD. In the Asian market, HUD helmets are extremely expensive and of inferior quality. Additionally, helmets that come with HUDs rarely offer much functionality. The HUD Helmet System application, which has a working prototype included in the LCI-HUD, integrates the Raspberry Pi (Python and JavaScript) with Android Studio. The LCI-HUD was intended to be modular since it is easy to swap out any section with an improved version in the future that incorporates third-party APIs to enable user customization. The LCI-HUD is easily upgraded or replaced by users, due to its modular design, which keeps it up to date with new technologies. Furthermore, the incorporation of third-party APIs creates countless opportunities for user customization and feature growth beyond what is initially provided. When comparing the software features and safety offerings in cars equipped with Google's Android Auto and Apple's CarPlay, it becomes evident that there is significant potential for future growth in integrating similar technologies for motorcycles. Currently, there is a noticeable gap in support for these features and safety measures tailored specifically for bikers. Overall, the LCI-HUD's modular design and integration with third-party APIs make it a versatile and future-proof solution for users looking to customize their experience. Using the ability to easily upgrade and replace components, users can stay ahead of the curve in technological advancements and this reduces e-waste as it promotes backward compatibility and enhancing existing helmet to retrofit with LCI-HUD.

***Abstract*—Feature selection is a critical preprocessing technique used to remove irrelevant and redundant features from datasets while maintaining or improving the accuracy of machine learning models. Recent advancements in this area have primarily focused on wrapper-based feature selection methods, which leverage metaheuristic search algorithms (MSAs) to identify optimal feature subsets. In this paper, we propose a novel wrapper-based feature selection method utilizing the Triangulation Topology Aggregation Optimizer (TTAO), a newly developed algorithm inspired by the geometric properties of triangular topology and similarity. To adapt the TTAO for binary feature selection tasks, we introduce a conversion mechanism that transforms continuous decision variables into binary space, allowing the TTAO—which is inherently designed for real-valued problems—to function efficiently in binary domains. TTAO incorporates two distinct search strategies, generic aggregation and local aggregation, to maintain an effective balance between global exploration and local exploitation. Through extensive experimental evaluations on a wide range of benchmark datasets, TTAO demonstrates superior performance over conventional MSAs in feature selection tasks. The results highlight TTAO's capability to enhance model accuracy and computational efficiency, positioning it as a promising tool to advance feature selection and support industrial innovation in data-driven tasks.**

Keywords—Classification; exploration; exploitation; feature selection; metaheuristic search algorithm; machine learning; optimization; triangulation topology aggregation optimizer

I. Introduction

Recent advancements in data-driven methodologies such as machine learning approaches have demonstrated significant benefits in addressing diverse, complex real-world challenges. Nonetheless, the escalating complexity of datasets from various domains and sources increasingly burdens machine learning models with inefficiencies and elevated computational costs [1]. This burden is often exacerbated by the presence of excessive, irrelevant, and redundant features, particularly when datasets are laden with noise, inconsistencies, and non-contributory information. Such datasets do not enhance model performance and may even compromise system approximation accuracy due to overfitting. Additionally, the presence of a large number of features necessitates the use of more complex machine learning models. These models require extensive data to optimize learning parameters, which can degrade their ability to generalize effectively [1].

To address these challenges, it becomes crucial to select a relevant subset of features while eliminating redundancies from the original datasets. This process not only enhances the efficiency, accuracy, and generalization capability of machine learning models but also serves as a vital preprocessing strategy. Feature selection effectively improves model performance by minimizing redundant input during training. It aims to optimize model efficiency by identifying and employing an optimal subset of features, thus alleviating the detrimental effects associated with the “curse of dimensionality”. This is particularly important when dealing with input datasets that contain an excessively large number of primitive features. Feature selection is instrumental in addressing a wide range of real-world machine-learning challenges, such as food fraud detection, automatic modulation recognition, predictive maintenance, robot path planning, kitchen waste segregation etc. [2-8].

Feature selection techniques are primarily divided into three categories: filter, wrapper, and embedded methods [9]. Filter methods determine feature subsets using statistical techniques that evaluate data dependencies. These methods assign rankings based on criteria such as inter-feature distances, correlations, and consistency indices. Widely utilized filter methods include the correlation coefficient, F-score, and Gini index [10]. Although filter methods are computationally efficient due to their classifier independence, they often do not reflect true feature relevance within specific models, potentially leading to reduced predictive accuracy. Conversely, wrapper methods integrate with a specific classifier, employing classification accuracy to assess feature subset quality [11]. While these methods typically enhance classifier performance, they also increase the risk of overfitting and require extensive computational resources due to repeated classifier executions to ascertain the optimal subset. Embedded methods, merging the benefits of filter and wrapper approaches, interact directly with the classifier while managing dependencies more efficiently to reduce computational demands. Although embedded methods offer a compromise in computational load, they remain more resource-intensive than filter methods.

The feature selection technique proposed in this paper is classified as wrapper-based, typically involves three components [9]: classifiers employed, evaluation criteria for feature selection, and the search algorithms used to derive feature subsets from raw data. Conventional search strategies [11] such as backward elimination, forward selection, greedy search, and complete search often exhibit significant limitations within the wrapper-based framework. These limitations include poor global search abilities, entrapment in local optima, and high computational costs. To address these deficiencies, this study advocates the use of metaheuristic search algorithms (MSAs), which offer superior global search strength, stochastic behavior, simple implementation, and do not rely on gradient information, making them well-suited to address complex optimization challenges [12-16]. A review of how MSAs effectively overcome feature selection challenges is provided [9].

MSAs represent a varied collection of optimization techniques, categorized by their foundational inspirations and search mechanisms [17]. The first category of MSAs is the evolutionary algorithms that are influenced by Darwin's theory of evolution and natural selection. Swarm intelligence algorithms are the second category of MSAs and they are inspired by collective animal behaviors such as flocking and foraging. Human-based algorithms are the third category of MSAs and they mimic aspects of human cognition including learning and social interactions, whereas the last category of MSAS are physics-based algorithms that apply principles from physical sciences and mathematics. Although numerous MSAs have been developed in response to the No-Free-Lunch (NFL) theorem, which asserts that no single algorithm can optimally solve all types of problems, their validation has predominantly been confined to mathematical benchmarks.

While significant theoretical advancements have been made in the development of MSAs, their performance evaluations remain largely confined to theoretical benchmarks. This narrow focus limits our understanding of their practical effectiveness in solving real-world problems, emphasizing the need for more empirical studies. In particular, the practical application of many recently developed MSAs in addressing real-world optimization challenges, such as feature selection, remains insufficiently explored. Moreover, most MSAs have not been rigorously validated in complex, high-dimensional feature selection tasks involving binary decision variables. This gap highlights the pressing need for empirical research that assesses the performance of novel MSAs in feature selection tasks, extending beyond traditional continuous-variable optimization problems.

This paper introduces an advanced wrapper-based feature selection method leveraging the unique search mechanisms of the Triangulation Topology Aggregation Optimizer (TTAO), a novel physics-based MSA proposed by Zhao et al. in 2024 [18]. Inspired by the geometric properties of triangular topology and the principle of triangular similarity, TTAO utilizes the consistent shape but variable sizes of similar triangles to generate diverse triangular topological units that serve as dynamic evolutionary entities throughout the optimization process. This technique aims to enhance the performance of machine learning models by effectively eliminating irrelevant features from datasets. TTAO incorporates two primary aggregation strategies: generic aggregation and local aggregation. Generic aggregation enhances exploratory search by promoting information exchange across different triangular topological units, whereas local aggregation focuses on exploitation, refining the search within individual units. Although initially applied in limited real-world contexts such as transmission expansion planning [19], productivity prediction [20], and controller parameter adjustment [21], where decision variables are real-valued, the application of TTAO to feature selection tasks involving binary decision variables is an unexplored area of research. This study aims to fill this gap by demonstrating how TTAO can be adapted to binary feature selection, presenting a novel conversion mechanism that enables its application in this domain. By expanding TTAO’s utility to feature selection tasks with binary decision variables, this paper contributes to addressing the broader challenge of validating MSAs in real-world optimization problems.

The technical contributions and novelty of this study are summarized as follows:

- We propose an advanced wrapper-based feature selection technique that utilizes the unique search mechanisms of the TTAO to identify optimal feature subsets. This approach aims to achieve high classification accuracy while maintaining low model complexity.
- To our knowledge, this is the first application of TTAO to address feature selection problems involving binary decision variables, which present more complex optimization challenges compared to those with continuous variables.
- A novel conversion mechanism is introduced, transforming continuous decision variables into binary ones, thus adapting the inherently real-valued TTAO for use in binary solution spaces.
- We provide a comprehensive evaluation of TTAO’s effectiveness as a wrapper-based method for feature selection, demonstrating its superior performance against other MSAs using diverse datasets from the UCI Machine Learning Repository.

The remainder of this paper is organized as follows: Section II reviews related work. Section III outlines the formulation of wrapper-based feature selection as an optimization problem and details the search mechanisms of TTAO. Section IV presents performance evaluations of various wrapper-based feature selection techniques. Section V concludes with a summary and future works.

II. Related Works of Using Different MSAs for Wrapper-Based Feature Selection

A wrapper-based feature selection technique incorporates three core components: the classifier types, the search algorithms for discovering optimal feature subsets, and the criteria for assessing the quality of these subsets. MSAs are often favored for wrapper-based feature selection due to their robust global search capabilities and straightforward implementation, as documented in study [9]. These MSAs are particularly effective in identifying feature subsets that optimize classification accuracy while minimizing the complexity of the machine learning model.

Recent developments in MSAs have significantly enhanced the robustness of feature selection methodologies. Various novel MSAs such as the Flow Direction Algorithm [22], African Vultures Optimization Algorithm [23], Sperm Swarm Optimization [24], Grasshopper Optimization Algorithm [25], Artificial Butterfly Optimization [26], have been employed to tackle feature selection challenges. Researchers also continue to refine these algorithms, creating more efficient versions tailored to specific problem characteristics. For example, Zekeri and Hokmabadi [11] introduced a real-value Grasshopper Optimization Algorithm (GOFS), utilizing a mathematical model that leverages repulsion and attraction forces between grasshoppers to effectively navigate the feature space. They enhanced GOFS with an adaptive parameter that modifies the influence zones to improve feature exploration and exploitation. Additionally, they implemented a feature probability factor to eliminate redundant features each iteration. Mostafa et al. [27] developed a Modified Chameleon Swarm Algorithm (mCSA), incorporating a transfer operator and a randomization Levy flight control parameter to fine-tune search behaviors. They also hybridized mCSA with the consumption operator from Artificial Ecosystem-based Optimization to augment its global search capabilities.

Zhang et al. [10] developed a novel wrapper-based feature selection method utilizing the Return-Cost-Based Binary Firefly Algorithm (Rc-BBFA), enhanced with three key modifications to address premature convergence. This version replaces traditional distance-based attractiveness with a return-cost metric to gauge each firefly's appeal. Additionally, a Pareto dominance strategy selects the most attractive firefly based on cost and return values. A new binary movement operator, driven by return-cost attractiveness and supplemented by an adaptive jump, updates each firefly's position within Rc-BBFA. Ma et al. [28] introduced the Multi-Strategy Binary Hunger Games Search (MS-bHGS) to tackle feature selection across 20 benchmark datasets. MS-bHGS incorporates chaotic maps, a vertical crossover scheme, and a greedy selection strategy, enhancing the balancing of exploration and exploitation. Wu et al. [29] enhanced a wrapper-based feature selection method using the Sparrow Search Algorithm, augmented by Quantum Computation and Multi-Strategy Enhancement (QMESSA). This approach integrates an improved circle chaotic map with a quantum gate mutation mechanism to diversify the initial population. Adaptive T-distribution and a novel position update formula were also embedded in QMESSA to boost its convergence speed. capabilities.

Zhong et al. [30] introduced the Self-Adaptive Quantum Equilibrium Optimizer with Artificial Bee Colony (SQEOABC) for feature selection, incorporating quantum theory and a self-adaptive mechanism to improve its convergence. Additionally, SQEOABC utilizes updating mechanisms from the Artificial Bee Colony to enhance the selection of effective feature subsets. Khafaga et al. [31] proposed a novel wrapper-based feature selection method using the Adaptive Squirrel Search Optimization Algorithm (ASSOA), paired with a KNN classifier. This method was applied to ten datasets from the UCI Machine Learning Repository. ASSOA was enhanced with new relocation equations and various movements (vertical, horizontal, exponential, and diagonal) to improve its search capabilities. Furthermore, various feature selection techniques were advanced by combining the Dipper Throated Optimization Algorithm with the Grey-World Optimizer [32] and Sine Cosine Algorithm [33]. These hybrid methods were tailored to identify superior feature subsets, contributing to higher accuracy and reduced model complexity in handling publicly available datasets.

Image Analysis Society (MIAS), the selected features were evaluated using the XGBoost classifier. In a follow-up study, they developed an adaptive binary TLBO with an ensemble classifier combining XGBoost and Random Forest, aimed at the early detection of breast cancer using mammograms from MIAS and the Digital Database for Screening Mammography (DDSM) [23].

III. Wrapper-Based Feature Selection Using TTAO

A. *Solution Representation of TTAO in Feature Selection*

In the context of feature selection, consider a dataset where $|F_o|$ denotes the total number of input features. Within the framework of TTAO, each search agent or vertex of the n-th triangular topological unit is defined by a position vector $X_n = [X_{n,1}, \ldots, X_{n,d}, \ldots, X_{n,D}]$, with D equating to $|F_o|$, representing the dimensionality of the problem. Each dimensional index d corresponds directly to a feature index l. Initially, the decision variables for each search agent are continuous. However, the binary nature required for feature selection dictates that these variables must be converted to binary values – 0 or 1.

To facilitates this conversion, the proposed wrapper-based feature selection technique based on TTAO implements a threshold parameter γ. This parameter is used to transform continuous decision variables into binary decisions by evaluating each real-valued decision variable $X_{n,d}$ against γ:

$$S_{n,l} = \begin{cases} 0, & \text{if } X_{n,d} < \gamma \\ 1, & \text{otherwise} \end{cases} \tag{1}$$

Here, the binary value $S_{n,l}$ determines the inclusion status of each *l*-th feature, where a value of 1 indicates inclusion and 0 indicates exclusion. For example, a status of $S_n = [0,1,1,1,0]$ implies that features at indices *l* = 2 to 4 are selected, while those at indices *l* = 1 and 5 are excluded. This mechanism effectively transforms continuous input values encoded in the search agent into the discrete decisions crucial for effective feature selection.

B. Fitness Evaluation of TTAO Search Agent in Feature Selection

Feature selection plays a crucial role in machine learning by facilitating the identification of an optimal subset of features. This subset not only enhances classification accuracy but also reduces the numbers of utilized features, addressing a twofold challenge: lowering the classifier's error rate and minimizing the ratio of selected features to the total available.

Define ξ_{Error} as the classifier's error rate and $|F_s|$ as the count of features selected for the subset, with $|F_s| \leq |F_o|$. The fitness value, which assess the quality for each search agent of the *n*-th triangular topological unit via the feature status vector $S_n = [S_{n,1}, \dots, S_{n,l}, \dots, S_{n,|F_o|}]$, is given by:

$$F(X_n) = \omega \times \xi_{Error} + \mu \times \frac{|F_s|}{|F_o|} \tag{2}$$

Here, ω is a coefficient ranging from 0 to 1, and μ is defined as $1 - \omega$. These parameters are designed to weigh the impacts of classification error and feature proportionality, respectively. The optimal feature subset minimizes the fitness function outlined in Eq. (2), achieving a balance between high classification accuracy and reduced feature set complexity, thereby simplifying and enhancing the efficacy of machine learning models.

In the wrapper-based feature selection framework using TTAO, the fitness evaluation process, denoted as Algorithm 1, employs the KNN classifier to measure each n-th search agent's performance based on the feature selection status S_n. Feature normalization is applied to scale the selected features between 0 and 1, followed by performance evaluation using K-fold cross-validation with the KNN classifier. A lower $F(X_n)$ value signifies superior fitness, indicative of higher classification accuracy and a smaller number of selected features.

Algorithm 1: Fitness Evaluation Process of Wrapper-Based Feature Selection Using TTAO

```
Inputs: $X_n, F_o, D, \gamma$
    Convert $X_n$ into $S_n$ using Eq. (1);
    Determine $|F_s|$ from $S_n$ and train KNN classifier to get $\xi_{Error}$;
    Calculate $F(X_n)$ using Eq. (2) based on $|F_s|$ $and$ $\xi_{Error}$;
Outputs: $F(X_n)$
```

C. Mechanisms of TTAO to Identify Optimal Feature Subsets

1) Conceptual ideas of TTAO: The search mechanisms of TTAO draw inspiration from the fundamental properties of triangular topology in mathematics. The triangle, recognized as the most basic yet stable shape in planar geometry, serves as a cornerstone in both finite and infinite dimensional spaces. It functions as a graph within its two-dimensional subspace. Due to its inherent simplicity and robustness, the triangular topology is extensively employed as a structural unit in model representation and analysis across a variety of real-world applications. These applications span multiple disciplines, including computational geometry, structural engineering, digital image processing, etc.

The concept of triangular similarity is pivotal in geometry and plays a key role in the search mechanisms of TTAO. The principles of triangular similarity are covered in four theorems:

- Theorem 1: A new triangle formed by drawing a line parallel to one side of an original triangle and intersecting the extensions of the other two sides is similar to the original.
- Theorem 2: Two triangles are similar if their corresponding sides and angles are proportional.
- Theorem 3: A triangle is similar to another if the ratios of their corresponding sides are equal.
- Theorem 4: Triangles that have identical corresponding angles are similar.

TTAO employs these theorems of triangular similarity to direct its search strategy. Throughout its iterative search process, the algorithm continuously generates new vertices in the solution space to construct triangles of varying sizes, each considered an evolutionary unit with three external vertices and one internal random vertex. Additionally, the TTAO utilizes the concept of aggregation to merge vertices with superior traits, enhancing the information exchange within and across different topological units. All triangles within the TTAO framework are equilateral, maintaining geometric consistency by adhering to the second theorem of similarity. The optimization process of TTAO consists of two primary stages: aggregation between and within units, streamlining the exploration and exploitation phases.

2) Initialization phase of TTAO: The initialization phase of TTAO involves randomly generating a diverse set of potential solutions across the solution space. Let N and D represent the population size and problem dimensionality of TTAO, respectively. Each vertex within a triangular topological unit is treated as a search agent or potential solution. Using the floor rounding operator $\lfloor \cdot \rfloor$, the population set of N search agents is organized into $\lfloor N/3 \rfloor$ triangular topological units. Any additional search agents, arising when N is not divisible by 3, are randomly generated within the solution space.

The lower and upper boundary limits of decision variables are denoted as $X^L = [x_1^l, \dots, x_d^l, \dots, x_D^l]$ and $X^U = [x_1^u, \dots, x_d^u, \dots, x_D^u]$, respectively. Let r_0 be a random number between 0 and 1. For each *n*-th triangular topological unit, where $n = 1, \dots, \lfloor N/3 \rfloor$, the position of the first search agent (vertex) is randomly determined within the feasible regions of solution space as follows:

$$X_{n,1} = X^L + r_0(X^U - X^L) \tag{3}$$

3) Construction of triangular topological unit: In addressing multi-dimensional optimization challenges, TTAO constructs equilateral triangles within each two-dimensional projection of a higher-dimensional space. The TTAO leverages transformations between polar and Cartesian coordinate systems to establish the vertices of each triangular topological unit.

For every *n*-th triangular topological unit, a direction vector, denoted as $lf(\cdot)$, is calculated and applied to the first vertex ($X_{n,1}$) to determine the second vertex ($X_{n,2}$) as follows:

$$X_{n,2} = X_{n,1} + lf(\theta) \tag{4}$$

The third vertex $(X_{n,3})$ is then generated by rotating the direction vector $lf(\cdot)$ by $\pi/3$ radians anticlockwise:

$$X_{n,3} = X_{n,1} + lf(\theta + \pi/3) \tag{5}$$

Here, l signifies the length of the edges of the triangular topology unit, given by:

$$l = 9e^{-\frac{t}{T^{max}}} \tag{6}$$

where t is the current iteration numbers, and T^{max} represents the maximum iteration numbers. According to Eq. (6), l decreases as the number of fitness evaluations increases. This adaptive strategy enables broader exploratory moves in the initial stages and more focused exploitation in the latter phases to refine the search in promising regions. The exponential decay ensures l remains positive, preventing excessive exploitation and potential premature convergence.

Moreover, the vectors $f(\theta)$ and $f(\theta + \pi/3)$, directing the edges from the first vertex, are defined respectively as:

$$f(\theta) \ = [\cos\theta_1, \dots., \cos\theta_d, \dots, \cos\theta_D] \tag{7}$$

$$f(\theta + \pi/3) = [\cos(\theta_1 + \pi/3), \dots.,$$

$$\cos(\theta_d + \pi/3), \dots, \cos(\theta_D + \pi/3)] \tag{8}$$

where θ_d for $d = 1, \dots, D$ is a randomly generated angle ranging from 0 to π.

Within each n-th triangular topological unit, a fourth vertex $X_{n,4}$ is derived through an internal aggregation process using a linear combination of the first three vertices, weighted by randomly generated coefficients:

$$X_{n,4} = r_1X_{n,1} + r_2X_{n,2} + r_3X_{n,3} \tag{9}$$

where r_1, r_2 and r_3 are randomly numbers between 0 to 1, ensuring $r_1 + r_2 + r_3 = 1$.

In each iteration, a new triangular topological unit is generated from a vertex and two sides of equal lengths l, which dynamically change throughout optimization process. Within each n-th triangular topological unit, the vertex exhibiting the best fitness during the current iteration is designated as the lead vertex. This lead vertex plays a crucial role in guiding the search process of the other vertices within the same unit. As detailed in subsequent sections, vertices within and across different triangular topological units employ two pivotal search mechanisms: generic aggregation and local aggregation. These mechanisms enable exploration and exploitation, respectively.

4) Generic aggregation of TTAO: Generic aggregation facilitates exploration by enabling the information exchange between the best search agent (vertex) in each triangular topological unit and the best vertex from a randomly selected unit. This mechanism draws inspiration from the crossover operator in genetic algorithm, which creates a new offspring solution by merging genetic information from two parent solutions.

Let $X_{n,best}^t$ denote the best vertex of the n-th triangular topological unit at iteration t, and $X_{n_{rand},best}^t$ represents the best vertex from a randomly selected unit at the same iteration. For each n-th triangular topological unit, a new vertex $X_{n,new1}^{t+1}$ is generated through generic aggregation by linearly combining the dimensional variables of these two superior vertices with different weights:

$$X_{n,new1}^{t+1} = r_4X_{n,best}^t \ + (1 - r_4)X_{n_{rand},best}^t \tag{10}$$

where r_4 is a random number between 0 to 1.

The fitness value of the newly generated vertex $X_{n,new1}^{t+1}$ is evaluated as $F(X_{n,new1}^{t+1})$, and compared against the fitness values of the current optimal and suboptimal vertices in the n-th triangular topological unit, represented as $F(X_{n,best}^t)$ and $F(X_{n,sbest}^t)$, respectively. Here, the suboptimal vertex $X_{n,sbest}^t$ is defined as the search agent with the second-best fitness in the n-th unit. For minimization problems, updates to the optimal and suboptimal vertices of n-th triangular topological unit for the subsequent iteration $(t + 1)$ are made according to the conditions below:

$$X_{n,best}^{t+1} = \begin{cases} X_{n,new1}^{t+1}, & \text{if } F\left(X_{n,new1}^{t+1}\right) < F(X_{n,best}^t) \\ X_{n,best}^t, & \text{otherwise} \end{cases} \tag{11}$$

$$X_{n,sbest}^{t+1} = \begin{cases} X_{n,new1}^{t+1}, & \text{if } F\left(X_{n,new1}^{t+1}\right) < F(X_{n,sbest}^t) \\ X_{n,sbest}^t, & \text{otherwise} \end{cases} \tag{12}$$

5) Local aggregation of TTAO: Local aggregation within the TTAO is pivotal for exploitation, refining searches within promising areas previously identified by the generic aggregation's exploratory processes. This strategy operates within each triangular topological unit, optimizing based on the best available internal information to enhance solution quality. Following generic aggregation, a temporary triangular topological unit is formed among the updated optimal or suboptimal vertex and two other vertices with relatively good fitness. Notably, this temporary unit may not necessarily form an equilateral triangle.

Within each n-th triangular topological unit, the optimal vertex's position is locally perturbed to refine the vicinity around the best current solution, based on the differences between the optimal and suboptimal vertices, thus ensuring the new search direction leverages the promising information. The new vertex generated through local aggregation is given by:

$$X_{n,new2}^{t+1} = X_{n,best}^{t+1} \ + \alpha X_{n,best}^{t+1} \tag{13}$$

where α is a decreasing parameter regulating the local aggregation's scope, defined as:

$$\alpha = \ln\left(\frac{e - e^3}{T^{max}{}_{-1}}t + e^3 - \frac{e - e^3}{T^{max}{}_{-1}}\right) \tag{14}$$

The parameter α progressively narrows the search area across iterations to emphasize exploitation in algorithm's later stages.

After local aggregation, it is crucial that the lead vertex of the triangular topological unit is the optimal within that unit. To assure convergence towards the most promising directions, the fitness of the newly aggregated vertex $X_{n,new2}^{t+1}$, denoted as $F(X_{n,new2}^{t+1})$, is compared against the current optimal vertex's fitness $F(X_{n,new1}^{t+1})$. For minimization problems, the updates of optimal vertex during local aggregation is determined as:

$$X_{n,best}^{t+1} = \begin{cases} X_{n,new2}^{t+1}, & \text{if } F\left(X_{n,new2}^{t+1}\right) < F(X_{n,best}^{t+1}) \\ X_{n,best}^{t+1}, & \text{otherwise} \end{cases} \quad (15)$$

Following this update, new similar triangular topological units are constructed for the subsequent iteration based on these updated optimal vertices, employing Eqs. (4) to (9) to refine the search space further and focus on previously promising areas.

6) Optimization workflow of TTAO for wrapper-based feature selection: Algorithm 2 delineates the workflow of the proposed TTAO-based wrapper feature selection technique. The process commences by loading the dataset and establishing dimensionality D equal to the number of input features, $|F_o|$. Initial setting of TTAO include resetting the iteration counter *t* and determining the number of triangular topological units as $\lfloor N/3 \rfloor$.

To deploy TTAO in searching for optimal feature subsets, initial positions for the first vertices, $X_{n,1}$ for $n = 1, \dots, \lfloor N/3 \rfloor$, of all triangular topological units are randomly generated as per

Algorithm 2: Proposed Wrapper-Based Feature Selection Using TTAO

```
Inputs: $N, \gamma, T^{Max}, F_o$
Load dataset containing $|F_o|$ input features and set the total dimensional size as $D \leftarrow |F_o|$;
Initialize $t \leftarrow 0$, number of triangular topological unit $\leftarrow \lfloor N/3 \rfloor$;
for n = 1 to $\lfloor N/3 \rfloor$ do   /*Random initialization of the first vertices*/
    Randomly generate the first vertex $X_{n,1}$ of each n-th triangular topology unit using Eq. (3);
end for
while $t \leq T^{Max}$ do   /*Iterative search process*/
    Update the value of parameter l using Eq. (6);
    /*Construction of each n-th triangular topological unit*/
    for n = 1 to $\lfloor N/3 \rfloor$ do
        Determine $f(\theta)$ and $f(\theta + \pi/3)$ using Eqs. (7) and (8), respectively;
        Calculate second vertex $X_{n,2}$ of each n-th triangular topology unit using Eq. (4);
        Calculate third vertex $X_{n,3}$ of each n-th triangular topology unit using Eq. (5);
        Boundary checking for $X_{n,2}$ and $X_{n,3}$ to ensure solution feasibility;
        Calculate fourth internal vertex $X_{n,4}$ of each n-th triangular topology unit using Eq. (9);
        Boundary checking for $X_{n,4}$ to ensure solution feasibility;
        Fitness evaluation of all vertices (i.e., $X_{n,1}$ to $X_{n,4}$) using Algorithm 1;
        Identify the vertices with best and second-best fitness as $X_{n,best}^{t}$ and $X_{n,sbest}^{t}$, respectively.
    end for
    /*Generic aggregation*/
    for n = 1 to $\lfloor N/3 \rfloor$ do
        Calculate new vertex $X_{n,new1}^{t+1}$ of each n-th triangular topology unit using Eq. (10);
        Boundary checking for $X_{n,new1}^{t+1}$ to ensure solution feasibility;
        Fitness evaluation of $X_{n,new1}^{t+1}$ using Algorithm 1;
        Update $X_{n,best}^{t+1}$ and $X_{n,sbest}^{t+1}$ along with their fitness using Eqs. (11) and (12), respectively;
    end for
    /*Local aggregation*/
    for n = 1 to $\lfloor N/3 \rfloor$ do
        Update the value of parameter $\alpha$ using Eq. (14)
        Calculate new vertex $X_{n,new2}^{t+1}$ of each n-th triangular topology unit using Eq. (13);
        Boundary checking for $X_{n,new2}^{t+1}$ to ensure solution feasibility;
        Fitness evaluation of $X_{n,new2}^{t+1}$ using Algorithm 1;
        Update $X_{n,best}^{t+1}$ along with its fitness using Eq. (15);
    end for
    /*To check if the population size N is divisible by 3*/
    if $N - \lfloor N/3 \rfloor \neq 0$ then
        $N^{Remain} = N - \lfloor N/3 \rfloor$;
        for i = 1 to $N^{Remain}$ do
            Randomly generate the i-th remaining search agent $X_i^{Remain}$ using Eq. (3);
            Fitness evaluation of $X_i^{Remain}$ using Algorithm 1;
        end for
        Compare the fitness value of $X_{n,best}^{t+1}$ for n = 1 to $\lfloor N/3 \rfloor$ and $X_i^{Remain}$ for i = 1 to $N^{Remain}$;
        Extract the top $\lfloor N/3 \rfloor$ search agents with better fitness to be lead vertices in next iteration;
    end if
    Record the best solution $X^{Best}$ and its fitness $F(X^{Best})$ found in each iteration;
end while
Outputs: $X^{Best}$ and $S^{Best}$
```

Eq. (1). During iterative searching, subsequent vertices of each n-th triangular topological unit ($X_{n,2}$, $X_{n,3}$ and $X_{n,4}$) are constructed using Eqs. (4), (5) and (9), respectively, to form equilateral triangle. Boundary conditions for $X_{n,2}$, $X_{n,3}$ and $X_{n,4}$ are checked to maintain solution feasibility. In the fitness evaluation process using Algorithm 1, continuous decision variables in each vertex of the n-th triangular topological unit are converted into binary selection status vectors (i.e., $S_{n,1}$, $S_{n,2}$, $S_{n,3}$ and $S_{n,4}$) using Eq. (1), and their respective fitness values ($F(X_{n,1})$, $F(X_{n,2})$, $F(X_{n,3})$, $F(X_{n,4})$) are calculated using Eq. (2). Given these fitness values, the optimal and suboptimal vertices for each n-th unit at iteration t are identified as $X_{n,best}^{t}$ and $X_{n,sbest}^{t}$, respectively.

During the generic aggregation, a new vertex $X_{n,new1}^{t+1}$ is formulated for each *n*-th triangular topological unit via Eq. (10). The updates of position vector and fitness of $X_{n,best}^{t}$ and $X_{n,sbest}^{t}$ are performed using Eq. (11) and (12) if $X_{n,new1}^{t+1}$ demonstrates superior fitness. Similarly, during local aggregation, another new vertex $X_{n,new2}^{t+1}$ is generated for each *n*-th triangular topological unit using Eq. (13), with updates to $X_{n,best}^{t+1}$ conducted via Eq. (15) if $X_{n,new2}^{t+1}$ exhibits enhanced fitness. For population where *N* is not divisible by three, remaining search agents are randomly generated within the solution space per Eq. (3) and evaluated using Eq. (2). After completing both generic and local aggregations, the fitness values of the optimal vertices across all $\lfloor N/3 \rfloor$ triangular topological units and the randomly generated search agents are compared, selecting only the best $\lfloor N/3 \rfloor$ agents as lead vertices for the subsequent iteration.

This iterative search process persists until reaching the predetermined termination criterion, typically the maximum iteration number T^{max}. Upon termination, the decision variables in the best solution X^{Best} are translated into a binary feature subset S^{Best}, employed to train machine learning models that are both more accurate and less complex.

IV. Results

A. Datasets Used and Simulation Settings

This performance evaluation study employs ten benchmark datasets from the UCI Machine Learning Repository to assess the efficacy of the proposed wrapper-based feature selection technique utilizing the TTAO. These datasets were chosen based on their diverse characteristics, including varying numbers of input features, instances, and output classes, which represent a wide range of feature selection challenges. The datasets cover different problem domains such as medical diagnosis, survival analysis, signal processing, etc., providing a comprehensive assessment of the algorithm's versatility and robustness.

The number of input features influences the dimensionality of the problem, which is crucial in testing the capability of the algorithm to handle high-dimensional spaces. For instance, datasets like Multiple Features (649 features) and Arrhythmia (279 features) represent high-dimensional feature selection challenges, whereas datasets such as Diabetes and Haberman’s Survival provide lower-dimensional tasks. The diversity in the number of instances, ranging from small datasets like Lung Cancer (27 instances) to larger datasets such as Maternal Health Risk (1014 instances)**,** ensures that the algorithm's performance is evaluated under varying data sizes. Additionally, the datasets include both binary and multiclass classification problems, further demonstrating the algorithm's adaptability to different problem types. Table I presents the detailed characteristics of the ten datasets, including the number of instances, features, and output classes. This diversity in datasets allows for a thorough evaluation of TTAO's performance in feature selection tasks across various real-world applications.

TABLE I. THE CHARACTERISTICS OF 10 BENCHMARK DATASETS USED IN PERFORMANCE EVALUATION

No	Dataset	No. of Instances	No. of Features	No. of Classes
DS1	Lung Cancer Data Set	27	56	10
DS2	Multiple Features Data Set	2000	649	2
DS3	Ionosphere Data Set	351	34	2
DS4	Arrhythmia Data Set	452	279	13
DS5	Echocardiogram Data Set	61	8	2
DS6	Haberman's Survival Data Set	306	3	2
DS7	Diabetes Data Set	768	8	2
DS8	Wine Data Set	178	13	3
DS9	Maternal Health Risk Data Set Data Set	1014	6	3
DS10	Zoo Data Set	101	16	7

This study evaluates the performance of the TTAO in feature selection tasks relative to seven other state-of-the-art MSAs: Bezier Search Differential Evolution (BeSD) [34], Coronavirus Herd Immunity Optimization Algorithm (CHIO) [35], Chaotic Oppositional based Hybridized Differential Evolution with Particle Swarm Optimization (CO-HDEPSO) [36], Differential Squirrel Search Algorithm (DSSA) [37], Flow Direction Algorithm (FDA) [38], Generalized Normal Distribution Optimization (GNDO) [39], and Oppositional and Social Learning with Enhanced Operator with Particle Swarm Optimization (ODSFMFO) [40]. Optimal parameters for these algorithms are adopted as per the specifications in their respective foundational publications.

To facilitate the conversion of real-valued decision variables within the TTAO and other MSAs to binary values for feature selection, the threshold parameter γ is set at 0.5. A KNN classifier with *k* = 5 is utilized to evaluate classification accuracy based on the selected feature subsets. Each dataset is split into two segments, with 80% of the instances designated as the training set and the remaining 20% as the testing set. The population size and the maximum iteration number for all MSAs are standardized at $N = 20$ and $T^{Max} = 200$, respectively. Given the stochastic nature of MSAs, each algorithm undergoes 30 simulation runs to ensure robustness in addressing the feature selection challenges across different datasets.

B. Performance Comparisons on Average Classification Accuracies

Table II presents the average classification accuracy achieved by the TTAO and seven other MSAs, each employed as wrapper-based feature selection techniques. The results reflect the mean values across 30 independent runs for each dataset, labeled as DS1 through DS10. Classification accuracy serves as a crucial validation measure, as it directly indicates how effectively the selected feature subsets enable the KNN classifier to distinguish between instances with high precision. The MSAs yielding higher average classification accuracies demonstrate superior capability in feature subset selection, contributing to improved overall performance. In this context, the MSAs that achieve the highest and second-highest accuracies are highlighted in bold and underlined, respectively, to facilitate a clear comparison. Furthermore, these accuracy results are juxtaposed with those from existing related studies to benchmark the efficacy of TTAO and verify its potential superiority in various classification tasks. This thorough comparison provides a more robust understanding of the advancements TTAO offers over previously proposed methods.

Table II shows that BeSD, ODSFMFO, and DSSA generally exhibit subpar performance when used as wrapper-based feature selection techniques across the ten benchmark datasets. The performance deficits are particularly pronounced in datasets with a large number of features or output classes. Specifically, BeSD recorded the lowest classification accuracies in three datasets (DS1, DS2, and DS6) and the second lowest in another (DS4). ODSFMFO displayed the poorest performance in two datasets (DS3 and DS4) and was second poorest in another two (DS8 and DS9). DSSA consistently ranked as having the second-worst average classification accuracy in four datasets (DS1, DS2, DS6, and DS7). Conversely, CO-HDEPSO and FDA demonstrated moderate performance, with their classification accuracies neither exceptionally high nor low across the majority of the datasets.

The wrapper-based feature selection techniques utilizing the three MSAs, including TTAO, have exhibited exemplary performance across the ten evaluated datasets. Specifically, CHIO recorded the highest average classification accuracy in two datasets (DS1 and DS5) and the second highest in four others (DS2 to DS4 and DS7). GNDO showed robust performance, achieving the highest classification accuracy in three datasets (DS2, DS5, and DS8) and the second highest in two (DS1 and DS9). However, both CHIO and GNDO demonstrated limitations in certain datasets, such as DS8 for CHIO and DS2 and DS10 for GNDO, indicating a need for improved robustness in diverse feature selection scenarios. TTAO emerged as the most effective MSA, securing the highest accuracy in eight datasets (DS1, DS3 to DS8, and DS10) and the second highest in DS9. Its superior performance, especially in datasets with a large number of features or classes (DS1, DS4, and DS10), underscores TTAO's capability to adeptly handle complex feature selection tasks prevalent in real-world applications.

C. *Performance Comparisons on Average Numbers of Selected Features*

While high classification accuracy is essential for effectively solving the given datasets, minimizing the size of the selected feature subset is equally important to prevent unnecessary complexity in the resulting machine learning models. Reducing feature subsets without compromising accuracy leads to simpler, more interpretable, and computationally efficient models, a critical goal in real-world applications. Achieving an optimal balance between classification accuracy and model simplicity is thus a fundamental validation criterion for evaluating feature selection techniques. To assess this trade-off, the average number of features selected by the KNN classifier is used as an additional performance metric in this study.

Table III details the average number of features selected by all MSAs, implemented as wrapper-based feature selection techniques across 30 simulation runs for each dataset. The MSAs achieving the smallest and second-smallest feature subset sizes for each dataset are highlighted in bold and underlined text, respectively. In addition to their poor performance in terms of average classification accuracy, the results also reveal that ODSFMFO and BeSD are notably ineffective in minimizing the number of selected features, often yielding the largest and second-largest feature subsets across most datasets. Specifically, ODSFMFO consistently produced the largest feature subsets in seven datasets (DS1 to DS4, DS7 to DS9) and the second largest in one dataset (DS10). Meanwhile, BeSD was frequently associated with the second-largest feature subsets in six datasets (DS1, DS3 to DS6, and DS8). In contrast, CO-HDEPSO and FDA exhibited moderate performance, maintaining an average number of selected features that was neither particularly high nor low across most datasets.

Moreover, certain MSAs demonstrate inconsistent performance across both evaluation metrics, highlighting their inability to effectively balance the trade-off between model accuracy and complexity. For instance, while CHIO and GNDO achieve competitive average classification accuracies across most datasets, they fall short in consistently identifying smaller feature subsets that could reduce machine learning model complexity. Conversely, DSSA successfully identified the smallest feature subset size for one dataset (DS7) and the second smallest for four others (DS1, DS4, DS6, and DS9). However, DSSA ranks among the poorest in terms of average classification accuracy, as detailed in Table II. Additionally, DSSA was found to select the largest feature subsets for two datasets (DS5 and DS10) and the largest subset for another (DS2), indicating its potential inconsistency in handling datasets with diverse characteristics.

Contrary to the other MSAs evaluated, TTAO has exhibited superior performance by consistently identifying the smallest average number of selected features in eight datasets (DS1 to DS6, DS9, and DS10) and the second smallest in two others (DS7 and DS8). This emphasizes the effectiveness of TTAO's inherent search mechanism in optimally selecting feature subsets across datasets with diverse characteristics, thereby reducing the complexity of the machine learning models. The results presented in Tables II and III affirm TTAO's excellence in harmonizing accuracy with model simplicity, effectively addressing the challenges associated with feature selection.

D. Discussion

A key strength of TTAO lies in its ability to achieve an optimal trade-off between classification accuracy and feature subset size, primarily due to the effective balance it strikes between exploration and exploitation. The presence of both generic and local aggregation mechanisms enables TTAO to explore the search space while refining promising solutions, thus ensuring a well-balanced search process. In feature selection, high classification accuracy alone is insufficient if the feature subset is excessively large, as it can lead to overly complex models that are difficult to interpret and computationally expensive. TTAO addresses this issue by selecting smaller feature subsets while maintaining high accuracy, making it valuable in applications where simplicity and efficiency are critical. This balance is crucial for developing robust machine learning models that generalize well to unseen data. TTAO's consistent ability to reduce feature subset size across diverse datasets without sacrificing accuracy demonstrates the efficacy of its search strategies, allowing it to perform effectively even in high-dimensional spaces or datasets with multiple output classes, where many other algorithms tend to struggle.

Another practical advantages of TTAO over other MSAs is its reduced reliance on extensive parameter tuning. Many MSAs require fine-tuning of algorithm-specific parameters to balance exploration (global search) and exploitation (local search) effectively. In contrast, TTAO's performance depends primarily on the population size N and a few stochastically generated random variables (i.e, r_0, r_1, $r_{1'}$ r_1 and r_4), all of which require minimal adjustment. This reduction in parameter dependency simplifies the application of TTAO to different problem domains. By ensuring that the algorithm performs well without requiring extensive experimentation to find the optimal parameter settings, TTAO is highly adaptable and user-friendly. This makes it particularly attractive for real-world applications where tuning complex algorithmic parameters may not be feasible due to time constraints or lack of domain expertise.

The consistent performance of TTAO across a wide range of datasets indicates its versatility in tackling real-world feature selection problems. Its ability to handle datasets with high-dimensional features and varying class distributions highlights its robustness and generalizability. Furthermore, the efficiency of TTAO to reduce feature subsets without compromising accuracy can have significant practical implications. For example, in industries where computational resources are limited or where model interpretability is crucial (e.g., such as healthcare, finance, or sensor-based monitoring systems), TTAO's approach can lead to more efficient models with fewer features, ultimately reducing training time, memory requirements, and the risk of overfitting.

V. Conclusion

This paper introduces a novel wrapper-based feature selection technique utilizing the Triangulation Topology Aggregation Optimizer (TTAO), which is inspired by the geometric properties of triangular topology and principles of triangular similarity. Unlike its prior applications to real-valued decision variable problems, this study explores TTAO's adaptability to challenging real-world optimization problems with binary solution spaces. To facilitate this adaptation, a conversion mechanism is employed to transform continuous decision variables into binary ones, thus enabling the inherently real-valued TTAO for use in binary domains. TTAO generates diverse triangular topological units of consistent shape but varying sizes, serving as dynamic evolutionary entities throughout the optimization process. It incorporates two primary search strategies, generic and local aggregation, designed to balance exploration and exploitation effectively. Extensive simulations compare TTAO's performance in feature selection against seven other metaheuristic search algorithms (MSAs). The results indicate varied performances among the MSAs, with some underperform across both matrices (i.e., classification accuracy and feature subset size), while others fail to achieve a satisfactory balance. In contrast, the TTAO-based wrapper method excels, demonstrating an outstanding ability to achieve superior classification accuracy while minimizing feature subset size, thereby solving datasets with varied characteristics effectively.

While TTAO has shown excellent performance across the datasets used in this study, its scalability to extremely large datasets (in terms of both the number of features and instances) remains untested. Future research is needed to assess its computational efficiency and performance under more demanding, large-scale conditions. Additionally, the current study has focused on datasets with relatively balanced class distributions. TTAO's performance in highly imbalanced datasets, where classification bias might occur, has not been thoroughly explored and may require algorithmic adjustments to address such challenges. One promising direction for future research is to explore hybridization between TTAO and other MSAs to further improve performance. Combining the strengths of different algorithms could enhance the ability to balance exploration and exploitation, especially for more complex and dynamic datasets. Another potential extension of this work is applying TTAO in a multi-objective optimization framework, allowing the simultaneous optimization of multiple criteria (e.g., accuracy, computational cost, interpretability) to provide more comprehensive solutions for real-world feature selection tasks.

Abstract*—With the deepening of globalization and increasing demands for environmental sustainability, modern supply chains are faced with increasingly complex management challenges. To reduce management costs and enhance efficiency, an experimental approach is proposed based on a Mixed Integer Programming Model, integrating heuristic algorithms with adaptive genetic algorithms. The objective is to improve both the efficiency and sustainability of supply chain management. Initially, the selection of suppliers within the supply chain is analyzed. Subsequently, heuristic algorithms and genetic algorithms are jointly employed to design, generate, and optimize initial solutions. Results indicate that during initial runs on training and validation sets, the fitness values of the research method reached as high as 99.67 and 96.77 at the 22nd and 68th iterations, respectively. Moreover, on the training set with a dataset size of 112, the accuracy of the research method was 98.56%, significantly outperforming other algorithms. With the system running five times, the time consumed for supplier selection and successful order allocation was merely 0.654s and 0.643s, respectively. In practical application analysis, when the system iterated 99 times, the research method incurred the minimum total cost of 962,700 yuan. These findings demonstrate that the research method effectively minimizes supply chain management costs while maximizing efficiency, offering practical strategies for optimizing and sustainably developing supply chain management.

***Keywords*—Mixed Integer Programming Model; sustainable; supply chain management; heuristic algorithm; adaptive genetic algorithm**

I. Introduction

As environmental issues and social responsibilities become increasingly prominent, enterprises must consider not only economic benefits but also the long-term impacts of their operations on the environment and society. Sustainable supply chain management has become an integral part of corporate strategies, demanding that companies maintain supply chain efficiency and cost advantages while also considering environmental protection and social responsibility [1-2]. The complexity of supply chain management arises primarily from multi-stage coordination and the handling of numerous decision variables [3]. Against this backdrop, traditional supply chain management approaches often prove inadequate when faced with growing market demand fluctuations and environmental sustainability requirements, necessitating reevaluation and optimization [4]. Therefore, leveraging modern technologies and algorithms to enhance the flexibility and adaptability of supply chains while achieving environmental and social sustainability goals has become a pressing issue. Data algorithms, particularly Mixed Integer Programming Models, offer new solutions for supply chain management due to their efficiency and precision in addressing complex decision-making problems [5]. These models effectively integrate and coordinate various elements within the supply chain, such as supplier selection, product manufacturing, and finished product consumption, while considering factors like time, resources, and environmental impact. However, relying solely on Mixed Integer Programming Models is insufficient to address all complexities of supply chain issues, especially in large-scale problem-solving and real-time decision optimization. To better address these challenges, the experiment incorporates heuristic algorithms and adaptive genetic algorithms (GA) to jointly enhance the Mixed Integer Programming Model, aiming for a more comprehensive and profound resolution of optimization issues in supply chain management. The aspiration is to provide new perspectives and methods for sustainable supply chain management, assisting enterprises in pursuing efficiency while also achieving environmental protection and social responsibility objectives.

The article is mainly divided into five sections. Section II is a literature review, which mainly analyzes and summarizes the relevant research at home and abroad. Section III is the research method, which analyzes the selection problem of the supply chain in supply chain management, and then uses an interactive product order and supplier selection sorting method to generate the required initial solution. Finally, the adaptive genetic algorithm is used to optimize the supplier selection solution. Section IV is the research results, mainly analyzing the performance and application effects of the improved mixed integer programming method constructed. Section V is the conclusion, which mainly summarizes the content of the entire article and proposes current shortcomings and future research directions.

II. Related Work

In recent years, sustainable supply chain management has become a focal point of attention for both businesses and scholars. Sustainable supply chains not only emphasize traditional costs and efficiency but also involve balancing environmental protection, social responsibility, and economic benefits. Numerous scholars have undertaken summarizations of the design and management of supply chain networks. Researchers, such as Dwivedi et al., addressed the significant complexities between grain supply chain management at different levels and carbon emissions. They combined GAs with quantum GAs and metaheuristic algorithms to analyze the allocation of vehicles and the selection of order sets. The results indicated significantly reduced computation time and enhanced operational efficiency [6]. Sadeghi and the team proposed a novel closed-loop supply chain network approach based on a mixed-integer linear programming model to reduce transportation and management costs in the supply chain. The model covered both fleet transportation routes and locations and was validated through the production of Iranian automotive components, gaining full recognition from management personnel [7]. Manupati et al. introduced a monitoring system based on blockchain technology to comprehensively monitor changes in supply chain performance. Considering carbon emissions constraints, they treated product production, sales, and inventory levels as control factors. Compared to non-dominated sorting GAs, their method demonstrated better feasibility [8]. Isaloo and Paydar presented a supply chain network design based on a dual-objective mathematical programming model to enhance the flow of the entire sustainable supply chain. Through sensitivity analysis of weights, they found the optimal objective solution, validating the superiority of their model [9]. Mogale et al. proposed a data-driven supply chain network approach based on a mixed-integer linear programming model to improve the convenience of grain procurement and transportation in developing countries. The results showed a significant enhancement in grain transportation efficiency and cost reduction [10].

Furthermore, many scholars have conducted analyses on the design and application of Mixed Integer Programming Models. Ahmadini and academic professionals aimed to reduce the environmental impact of pollutants emitted during the preservation and transportation of products. They proposed a green supply chain network based on a multi-project multi-objective inventory model. Simulation experiments verified the practical effectiveness of the constructed method, promoting the rapid development of the manufacturing industry [11]. Researchers, including Zhang Y, addressed the prolonged time consumption in logistics distribution within the supply chain network by proposing a method based on mixed-integer nonlinear programming. The results indicated that the constructed model effectively resolves nonlinear layout optimization issues in logistics transportation [12]. Beiki H and others, in order to tackle the sustainability of supplier selection and order allocation issues, introduced an integrated approach based on language entropy weight and multi-objective programming. The method demonstrated its effectiveness in improving the relationship between supply chain practitioners and suppliers, leading to the maximization of product profits [13]. Li C and colleagues aimed to increase the adoption rate of renewable energy generator units while reducing the complexity of operational decisions. They proposed an operational method based on the MILP-GTEP model. The study extensively explored the relationship between space and time, and the superiority of the experimentally constructed method was validated through a case study from the Texas Electricity Reliability Council, significantly reducing the difficulty of unit power generation [14]. In addressing the issue of maximizing profit extraction in open-pit mining production scheduling, Rivera Letelier O and fellow researchers presented a direct block scheduling and stage scheduling method based on mixed-integer programming modeling. Data revealed that, compared to traditional methods, the average gap during boundary cutting in the experimentally constructed method decreased from 1.52% to 0.71%, demonstrating its significant superiority [15].

In conclusion, with the advancement of globalization and technological innovation, supply chain management is facing unprecedented challenges and opportunities. Despite the availability of numerous technologies and tools to address supply chain network management issues, there are still challenges, such as balancing the computational complexity and solving efficiency of algorithms. In order to enhance the efficiency of enterprise supply chain management and reduce unnecessary time consumption, an experiment proposes a Mixed Integer Programming Model based on heuristic algorithms and adaptive GAs. This model is applied to the supply chain management of sustainable enterprises, with the expectation of promoting the development of sustainable supply chain management.

III. Heuristic Algorithm and GA Algorithm Mixed Integer Programming Model for Sustainable Supply Chain Management

Considering the complexities and variability in supply chain management, especially when facing sustainability challenges, traditional optimization methods often struggle to adapt. Therefore, the experiment introduces a Mixed Integer Programming Model based on a data-driven algorithm to enhance it. This model can not only handle problems involving a large number of decision variables and complex constraints but also flexibly adapt to the dynamic changes and diverse requirements in supply chain management.

A. *Supplier Selection in Supply Chain Management*

In order to provide a clearer description of supply chain management issues, the experiment focuses on supplier selection and product cost aspects, analyzing the management of the supply chain. The study, based on the characteristics of a three-tier supply chain with manufacturing enterprises at its core, makes assumptions about supplier selection in the three-tier supply chain management: first, within the production period of the same product order, the order will not exceed the maximum capacity of total production; second, all products in the order overlap; third, there are restrictions on the maximum capacity of the corresponding manufacturing enterprises, and so on. The operations of multi-supplier supply chain management are illustrated in Fig. 1.

The ultimate goal is to minimize the number of times a supplier is selected. The variability in supplier selection in supply chain management is defined by Eq. (1).

$$\begin{gathered} e_{jkq} \geq y_{jkq} - y_{jkq-1}, \\ \forall i \in \{1, \cdots, N\}, q \in \{1, \cdots, Q\}, j \in \{1, \cdots, M\}, k \in \{1, \cdots, K\} \end{gathered} \tag{1}$$

In Eq. (1), y_{jkq} and e_{jkq} represent binary variables. The calculation of supplier selection is then obtained, as shown in Eq. (2).

$$\begin{cases} T_j = \sum_{k=1}^{K} \sum_{q=1}^{Q} e_{jkq} \geq 0, \forall i \in \{1, \cdots, N\}, q \in \{1, \cdots, Q\}, j \in \{1, \cdots, M\}, k \in \{1, \cdots, K\} \\ T_{total} = \sum_{j=1}^{M} T_j \geq 0, \forall j \in \{1, \cdots, M\} \end{cases} \tag{2}$$

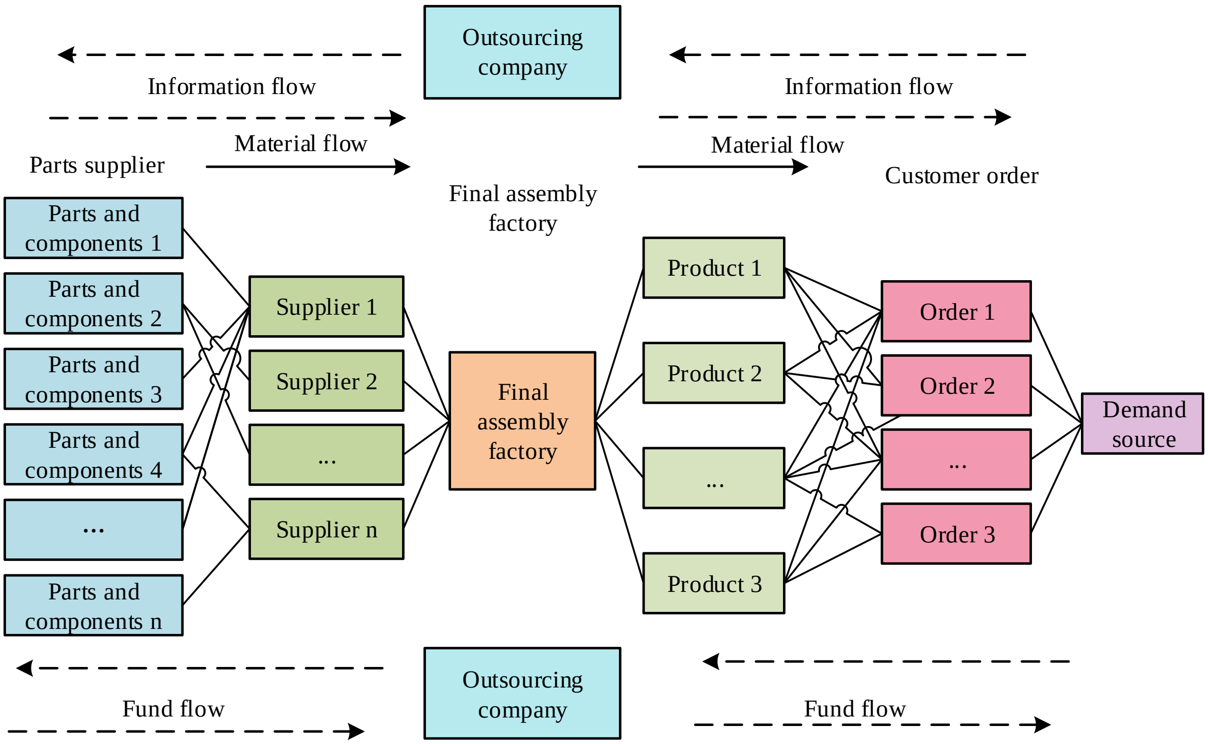

Fig. 1. Multi-supplier supply chain management operations.

In Eq. (2), T_j represents the number of times supplier j is selected, and T_{total} represents the total number of times all suppliers are selected. T_j must be above zero. In the process of supply chain management selection, these are positive integers. Considering the entire production stage, the optimization of the supplier selection frequency in the supply chain management process is achieved, and the objective function $\min_{total}$ of this mathematical model is obtained. However, selecting product suppliers to meet production orders is a highly complex problem that requires consideration of constraints on supplier selection [16]. To some extent, reducing the number of supplier selections must ensure that different products in the total production orders are supplied by at least one supplier, and the corresponding constraint is expressed in Eq. (3).

$$\begin{cases} \sum_{k=1}^{K}\sum_{j=1}^{M}\sum_{i=1}^{N} y_{ijk} \ge 1, \forall i \in \{1,\cdots,N\}, j \in \{1,\cdots,M\}, k \in \{1,\cdots,K\} \\ \sum_{j=1}^{M}\sum_{i=1}^{N} y_{ijk} \le 1, \forall i \in \{1,\cdots,N\}, j \in \{1,\cdots,M\}, k \in \{1,\cdots,K\} \\ \sum_{j=1}^{M} B_{is} \ge \sum_{i=1}^{N} A_{is}, \forall i \in \{1,\cdots,N\}, j \in \{1,\cdots,M\}, s \in \{1,\cdots,S\} \end{cases} \tag{3}$$

In Eq. (3), y_{ijk} and B_{is} are both binary variables. Their values are 1 when the supplier can complete the corresponding task. These constraints reflect the main attributes of supply chain management, optimizing the experimental process.

B. *Initial Solution Generation Method for Supplier Selection in Supply Chain Management Based on Heuristic Algorithms*

The experimental method employs an interactive approach to generate the required initial solutions by ordering product orders and selecting supplier rankings. Initially, orders are selected and sorted according to certain patterns in the interactive process of product orders and supplier ranking [17]. To assess the fulfillment rate of suppliers for products in the k th batch, assume the relationship between supplier j and products corresponds to B_{js}, and the relationship between order i and products corresponds to A_{is}. If the products in the orders cannot be produced by the corresponding suppliers, the decision variable $B_{js}=0$. Otherwise, if production by the supplier is possible, the corresponding pointer variable $B_{js}=1$. Simultaneously, if the number of component types in products from different orders is S_i, including product s, then the corresponding pointer variable $A_{is}=1$, otherwise, $A_{is}=0$. Based on the parameters and principles mentioned above, for a product supplier M, the calculation of the fulfillment rate for the corresponding supplier's product orders is given by Eq. (4).

$$f_{ijk} = \frac{\sum_{s=1}^{S} B_{js}A_{is}}{\sum_{s=1}^{S} A_{is}}, \\ \forall i \in \{1,\cdots,N\}, j \in \{1,\cdots,M\}, s \in \{1,\cdots,S\}\ldots \tag{4}$$

In Eq. (4), the multiplication of B_{js} and A_{is} represents the common product relationship between suppliers and orders. It can be observed that the maximum value of the fulfillment rate of products in the orders does not exceed 1. When $f_j = 1$, indicating a value of 1, all the required products for customers in the supply chain product orders can be provided by that supplier. The enterprise can freely choose suppliers in the process of management and sales. The experiment sets the supply rate of supplier j as f_{ijk} to represent the extent to which the product supplier can meet the demands of a set of customer orders. The calculation is cyclically performed on the order pool within the same batch [18-19]. By cumulatively adding the fulfillment rates of products related to suppliers in all orders, the fulfillment rate f_{jk} of the supplier providing the required products in the k th batch is obtained, as shown in Eq. (5).

$$f_{jk} = \sum_{i=1}^{N} f_{ijk} \tag{5}$$

In Eq. (5), f_j has a value range of [0, n]. After selecting the supplier with the highest product fulfilment rate, it is necessary to decide how to allocate the required quantity of these products to the corresponding suppliers. This requires an appropriate production sequence to reduce the number of supplier transports (i.e., product order selection strategy). To avoid orders being repeatedly assigned while ensuring a complete order is in a corresponding set of orders awaiting production, the supplier's set of orders awaiting production is designated as OA, with specific calculations outlined in Eq. (6).

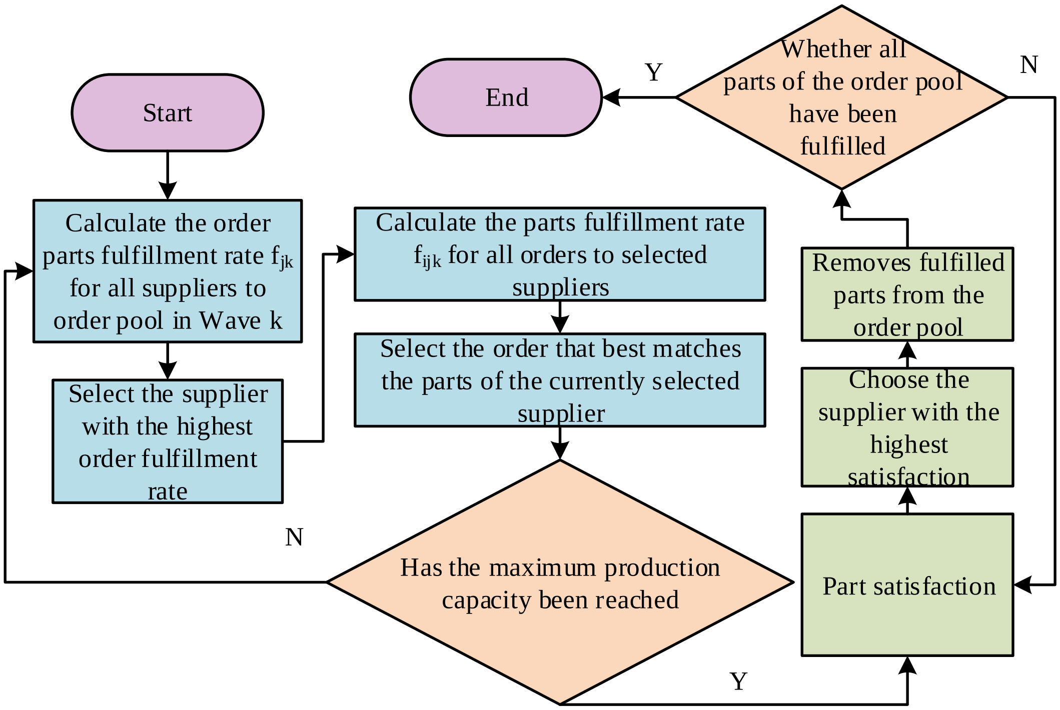
$$OA = \left\{ O_i \middle| f_{ij} > 1, \forall j \in \{1, \cdots, M\}, i \in \{1, \cdots, N\} \right\} \tag{6}$$

In Eq. (6), OA represents the set of orders awaiting production. Additionally, due to various constraints and limitations on supplier production capacities, the production of ordered products by relevant suppliers may be significantly insufficient. To describe these constraints, the experiment introduces a new set of supplier production orders, assuming this order set is OW. The total demand value for orders in this set will not exceed the total production capacity of the factory, as detailed in Eq. (7).

$$OW = \left\{ Oi \middle| f_{ij} > 0, and \quad I_{is} \le L, \forall j \in \{1, \cdots, M\}, s \in \{1, \cdots, S\} \right\} \tag{7}$$

By comprehensively calculating the above equations, a specific method for arranging and managing supplier orders in the Kth batch is obtained. Furthermore, a feasible solution to the problem of selecting multiple suppliers in supply chain management is achieved by fixing the orders of suppliers one by one in priority order.

In Fig. 2, by analyzing the correspondence between suppliers and orders, the priority mechanism for selecting suppliers and orders is clarified. A heuristic algorithm for solving the multi supplier selection problem was developed based on this mechanism. The main process of supplier and order selection for each round of the algorithm is shown in the figure above. This heuristic algorithm can efficiently obtain an initial solution to the studied problem.



Start
Calculate the order parts fulfillment rate f_{jk} for all suppliers to order pool in Wave k
Select the supplier with the highest order fulfillment rate
Calculate the parts fulfillment rate f_{ijk} for all orders to selected suppliers
Select the order that best matches the parts of the currently selected supplier
Has the maximum production capacity been reached
N
Y
Part satisfaction
Choose the supplier with the highest satisfaction
Removes fulfilled parts from the order pool
Whether all parts of the order pool have been fulfilled
Y
N
End

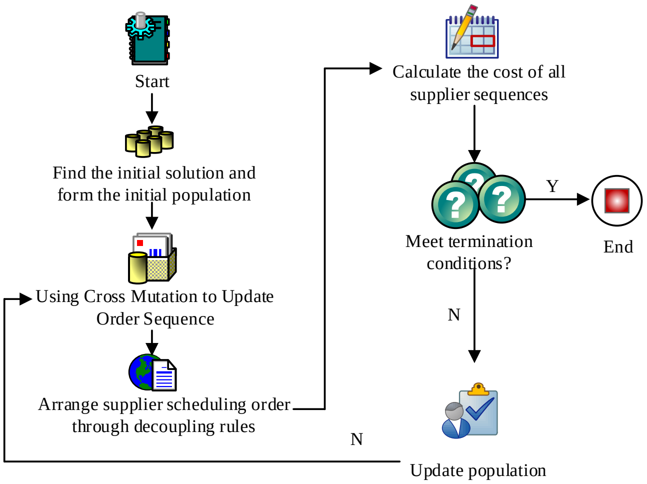
C. Optimization of Feasible Solutions for Supply Chain Supplier Selection Management Based on Adaptive GA

An initial feasible solution is obtained by decoupling the relationship between supplier management and order products. Subsequently, a local search is applied to the feasible solution to obtain an initial population. Iterative updates are performed using a Genetic Algorithm (GA) to generate various order production sequences. In each GA iteration, suppliers for each order group are sorted based on specific constraints, and this sorting is used as the fitness indicator for individuals in the population. After multiple iterations, a cost-optimized selection solution is finally obtained. The solution process of GA is illustrated in Fig. 3.



Start
Find the initial solution and form the initial population
Using Cross Mutation to Update Order Sequence
Arrange supplier scheduling order through decoupling rules
Calculate the cost of all supplier sequences
Meet termination conditions?
Y
End
N
Update population
N

Fig. 3. The whole process of initial solution optimization.

It is important to note that the management and selection problem involving multiple suppliers is, in fact, an NP-hard problem. Due to the high complexity of this problem, experiments result in numerous initial feasible solutions using heuristic algorithms. To preserve the characteristics of these initial feasible solutions to the maximum extent, the experiment introduces a simulated annealing algorithm to expand the search neighborhood of initial feasible solutions. The initial temperature is set as T_0, and the objective function values of the obtained initial feasible solutions are calculated. The generation process of new solutions is illustrated in Fig. 4.

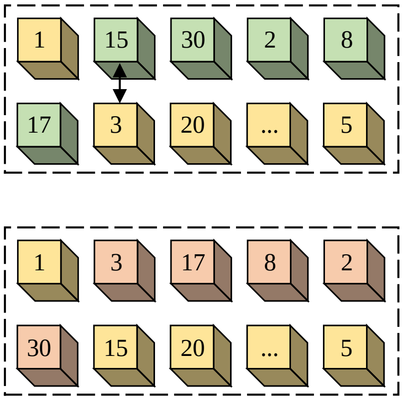


Fig. 4. Value generation method of new solution.

New solutions are evaluated using the Metropolis criterion in the simulated annealing algorithm. When the fitness of the new solution is higher than that of the original solution, the retention probability is 1. For lower fitness, acceptance is probabilistic. The mathematical formula for the Metropolis criterion is shown in Eq. (8).

$$p=\begin{cases}1 & if \quad E(x_{new})<E(x_{new})' \\ \exp\left(-\dfrac{E(x_{new})-E(x_{new})'}{T}\right) & if \quad E(x_{new})\geq E(x_{new})'\end{cases} \tag{8}$$

In Eq. (8), p represents the probability of accepting the new feasible solution. E represents the internal energy corresponding to each state. T represents the current temperature of the system. The experiment adopts an exponential cooling annealing strategy, and the decay function is shown in Eq. (9).

$$T_{n+1}=CT_n \tag{9}$$

In Eq. (9), T represents a constant less than 1. n represents the index of a state. Subsequently, the experiment employs a roulette wheel method to select outstanding individuals and uses a two-point crossover method for individual crossover operations. After randomly generating a crossover probability, two individuals are randomly selected from the population. If the random number is less than the crossover probability, a crossover operation is performed: determining two crossover points, exchanging and repairing the corresponding chromosome segments, and generating two new individuals. The process of crossover operation is illustrated in Fig. 5.

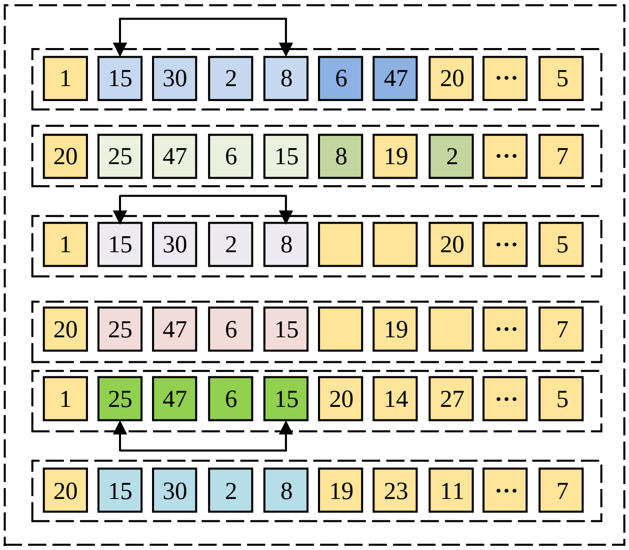

Fig. 5. The whole process of crossover operator calculation.

Similar to the crossover operation, the mutation method selected is two-point mutation. With a certain probability, two points are randomly generated, and natural numbers in the individual are exchanged to obtain a completely new order sequence. The calculation process of the mutation operator is illustrated in Fig. 6.

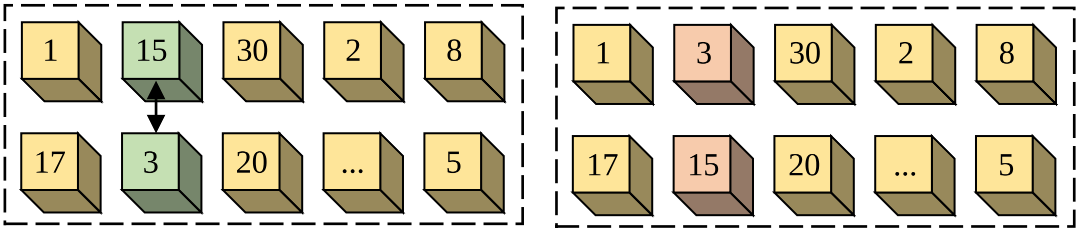

Fig. 6. The whole calculation process of mutation operator.

Based on the decoupling relationship, the order sequence is transformed into a supplier sequence, thereby determining the selection frequency of each supplier. The calculation method of the fitness function is shown in Eq. (10).

$$fitness\_F(x) = \frac{C}{T_{total}}, T_{total} > 0 \tag{10}$$

In Eq. (10), T_{total} represents the total cost of supplier selection. T_{total} represents a positive real number. After successfully obtaining the value of the fitness function, the experiment, to prevent the calculation process from falling into a local optimal solution, further establishes a Genetic Algorithm based on Invasive Weed Optimization (IWO) for adaptive large neighborhood search. In this algorithm, when the cumulative value of random numbers can disrupt the population, the larger the numerical value, the more severe the disruption. The relevant calculation is shown in Eq. (11).

$$\partial = \frac{\sum \lambda - C}{\sum 2\lambda} \tag{11}$$

In Eq. (11), λ represents the cumulative value of random numbers. C represents a constant. ∂ represents the proportion of individual disruption. It is observed that the range of ∂ is [0, 1/2). By controlling the numerical value of C, the degree of individual disruption is controlled. Based on the degree of disruption, the number of individuals to be destroyed in the population is calculated, and inappropriate individuals are randomly removed from the population. Additionally, based on the fitness of individuals, supplier management is ranked, and the optimal individual is selected, forming the final seed individual for the next round of optimization.

IV. Results

In order to validate the superior performance of the constructed method, three existing methods were chosen for comparison with the proposed approach in the context of sustainable pharmaceutical supply chain networks. These methods include the Improved Hybrid Multi-Objective Heuristic Algorithm (IHMOH) based on an improved mixed multi-objective heuristic algorithm, the Supply Chain Closed-Loop Management Method (MINLP) based on a mixed-integer nonlinear programming model, and the Two-Stage Integrated Method for Green Supply Chain Supplier Selection and Order Allocation (FAHP-MILP) based on fuzzy analytic hierarchy process and multi-objective mixed integer linear programming [20-22]. To ensure fairness and reasonableness in the experimental setup, all models shared identical simulation environment parameters, as detailed in Table I.

TABLE I. Settings of Related Parameters

Project	Choice
Graphics card	NVIDIA RTX2080Ti
Graphics card memory	32G
Fresh products	50
Crossover rate	0.7
Mutation rate	0.1
Operating system	Ubuntu18.04
Network architecture	Pytorch v1.2.0
Optimizer	Adam
Programming software	Vscode2017 Anaconda3
CUDA	Cuda 11.0 with cudnn

The selected dataset for the experiment is from the supply chain management system of a well-known company in the United States, and a total of 10000 valid data points were obtained. Before applying the dataset to the model, the following preprocessing steps were performed on all data: data cleaning to remove incomplete or erroneous records; Standardization processing to eliminate the influence of different dimensions; Outlier detection and processing to ensure the reliability of the dataset. These steps are crucial for improving the predictive accuracy of the model. After data preprocessing to remove redundant data, 8000 valid data were obtained, and 80% of the total dataset was randomly selected as the validation set; another 20% is used as the training set. Firstly, the fitness values of the four algorithms were compared when performing tasks on the two datasets, as illustrated in Fig. 7.

Fig. 7(a) depicts the changes in fitness values of the four algorithms on the training set. As the number of system iterations increases, the fitness values of all four algorithms exhibit a rapid and fluctuating trend. At the commencement of the system operation, the fitness value of the research method undergoes a slight variation. Subsequently, at the 22nd iteration, the research method attains its maximum fitness value, maintaining a stable state thereafter with a numerical value as high as 99.67. In contrast, the fitness values of the FAHP-MILP, IHMOH, and MINLP algorithms start stabilizing only after a higher number of iterations, reaching stability at the 157th, 178th, and 176th iterations, respectively, with corresponding values of 81.23, 62.23, and 68.84. Fig. 7(b) illustrates the changes in fitness values of the four algorithms on the validation set. The research method achieves its optimal fitness value of 96.77 after 68 iterations, while the fitness values of the other three methods continue to decrease and remain consistently lower than that of the research method. These results indicate that the research method consistently maintains a higher fitness value, emphasizing its faster convergence speed and higher computational efficiency. Given the varying product categories supplied by different vendors and their differing accuracy in product selection during the management process, the experiment proceeds to compare the accuracy of vendor selection. Specific results are presented in Fig. 8.

Fig. 8(a) displays the vendor accuracy obtained by different methods on the training set. It is observed that as the data volume increases, the accuracy of all four algorithms shows varying degrees of improvement. When the data volume is 112, the research method achieves the maximum accuracy at 98.56%, significantly higher than the accuracy of the other three methods. Fig. 8(b) shows the accuracy of different algorithms in selecting vendors on the validation set. When the accuracy of the experimentally constructed method reaches its maximum value at a data volume of 402, the corresponding accuracy is 98.33%. Additionally, at data volumes of 789, 1544, and 1502, the accuracy of vendor selection for the FAHP-MILP, IHMOH, and MINLP algorithms is 90.15%, 96.32%, and 89.36%, respectively. In summary, the research method exhibits the highest accuracy in vendor selection and can be applied in the development process of green enterprises. Subsequently, the four methods were applied to the training set for a comparative analysis of computation time. The entire experiment was conducted in five cycles, and the specific results for supplier selection time (Supplier option-T1) and successful order allocation time (Order allocation -T2) are presented in Fig. 9.

In Fig. 9 (a)–(d), different research methods and algorithms, namely the research method, FAHP-MILP algorithm, IHMOH algorithm, and MINLP algorithm, were employed. It can be observed that, in the five parallel experiments designed, the research method exhibited significantly less time consumption for adapting to suppliers compared to the other three algorithms. The minimum time for T1 was 0.654s, and for T2, it was 0.643s. This indicates that the research method, while running the supply chain system, has a more agile decision speed and lower time consumption in selecting suppliers. However, the system, despite having faster operational efficiency, also requires an analysis of the overall cost expenditure. To analyze the overall cost expenditure during the operation of the supply chain management system, the experiment proceeded by selecting the data source company as the product supplier and applying the four methods to two datasets. The analysis focused on the variation in supply chain management costs as the data volume increased, as shown in Fig. 10.

Fig. 10. Changes in supply chain management costs under different algorithm operations.

Fig. 10 (a) depicts the variation in supply chain management costs on the training set. When the data volume reached 191, the research method exhibited the minimum management cost, valued at 97.6 thousand yuan. When the data volume reached 268, the FAHP-MILP algorithm's management cost reached its minimum, with a value as high as 135.8 thousand yuan. Fig. 10 (b) illustrates the variation in supply chain management costs when the four methods were applied to the validation set. As the data volume increased to 392, the research method had the minimum management cost at 92.3 thousand yuan. The supply chain management costs of the other three methods were significantly higher, especially when the data volume reached 908, where the MINLP algorithm incurred a very high cost of 158.9 thousand yuan. In summary, the research method demonstrated better cost-effectiveness in handling complex supply chain problems and effectively controlling supply chain management costs. Finally, the four algorithms were applied to the closed-loop supply chain network of a sustainable agricultural products enterprise. This enterprise, a large company in the United States, initiated the implementation of a green closed-loop supply chain network in response to national policies in August 2020. The study selected 50 examples of fresh products owned by the enterprise for closed-loop supply chain network optimization, and the total cost results are shown in Fig. 11.

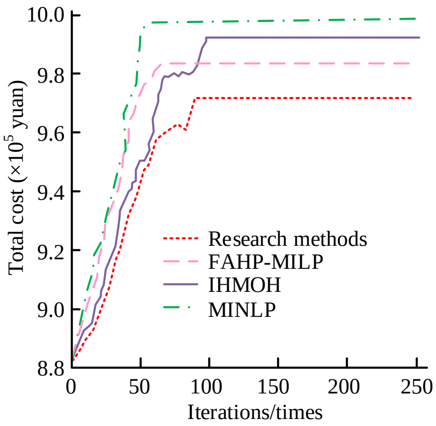

Fig. 11. Total cost under different algorithm operations.

From Fig. 11, it can be observed that the FAHP-MILP algorithm, IHMOH algorithm, and MINLP algorithm incurred higher total costs, with corresponding maximum costs of 983.8 thousand yuan, 975.7 thousand yuan, and 998.8 thousand yuan, respectively. Additionally, when the system reached the 99th iteration, the research method had the least total cost expenditure at 962.7 thousand yuan. Comparatively, although the research method's costs were initially comparable to the IHMOH algorithm, they gradually decreased with iterations and eventually became lower than other algorithms.

V. Discussion and Conclusion

A. Discussion

A mixed integer programming model based on data algorithms has been proposed, which combines heuristic algorithms and adaptive genetic algorithms to improve the efficiency and sustainability of sustainable supply chain management. Through comprehensive analysis and optimization of supplier selection issues in the supply chain, the proposed method has demonstrated significant advantages in multiple aspects. The hybrid model proposed by the research institute effectively integrates the fast convergence characteristics of heuristic algorithms and the global search capability of genetic algorithms, improving the efficiency of solving large-scale supply chain optimization problems. At the 22nd and 68th iterations, the fitness values reached as high as 99.67 and 96.77, respectively, demonstrating the fast convergence and stability of the algorithm. This result is similar to the research findings of scholar Charles D. [18]. In addition, the research method achieved a high accuracy of 98.56% on the training set, significantly better than other existing algorithms. This result is significantly better than Goodarzian F and Ebrahim et al. [20-22]. The proposed method can maintain low management costs and high operational efficiency on both small-scale and large-scale datasets, which has important guiding significance for supply chain management practices. By minimizing supply chain management costs and maximizing efficiency, companies can meet environmental protection and social responsibility requirements while pursuing economic benefits. This is particularly important in the current context of globalization and rapid technological development.

B. Conclusion

To optimize supply chain management and achieve the dual goals of cost efficiency and sustainability, this study proposes a supply chain management approach that integrates a Mixed Integer Programming Model with an improved GA. Firstly, by employing a supplier selection method based on heuristic algorithms, the study successfully generated initial feasible solutions. Subsequently, an optimization method based on adaptive GA was introduced to better adapt to and improve the complexity and dynamism of supply chain management. The data indicates that, on both the validation and training sets, the research method achieved maximum fitness values of 99.67 and 96.77, respectively, when the system iterated to the 68th and 22nd times. In contrast, the fitness values of other methods were significantly below 90.0. On the validation set, the accuracy of the research method reached a maximum of 98.33%. Through five parallel experiments designed, the minimum T1 time and minimum T2 value of the research method were 0.654s and 0.643s, respectively. In practical applications, when the data volume increased to 191, the research method demonstrated the minimum management cost of 97.6 thousand RMB; however, when the data volume reached 268, the FAHP-MILP algorithm exhibited the minimum management cost, reaching 135.8 thousand RMB. Additionally, when iterated to the 99th time, the research method incurred the least total cost, amounting to 962.7 thousand RMB. In summary, the research method not only reduced costs but also enhanced the flexibility and responsiveness of the supply chain. However, the experiment's choice of a single research enterprise, and factors such as supplier selection and product order allocation, which are influenced by various factors, have not been analyzed. Further application and research expansion are needed in the future.

DBRF: Random Forest Optimization Algorithm Based on DBSCAN

Wang Zhuo, Azlin Ahmad*
School of Computing Sciences-College of Computing-Informatics and Mathematics,
Universiti Teknologi MARA, Shah Alam, Malaysia

***Abstract*—The correlation and redundancy of features will directly affect the quality of randomly selected features, weakening the convergence of random forests (RF) and reducing the performance of random forest models. This paper introduces an improved random forest algorithm—A Random Forest Algorithm Based on DBSCAN (DBRF). The algorithm utilizes the DBSCAN (Density-Based Spatial Clustering of Applications with Noise) algorithm to improve the feature extraction process, to extract a more efficient feature set. The algorithm first uses DBSCAN to group all features based on their relevance and then selects features from each group in proportion to construct a feature subset for each decision tree, repeating this process until the random forest is built. The algorithm ensures the diversity of features in the random forest while eliminating the correlation and redundancy among features to some extent, thereby improving the quality of random feature selection. In the experimental verification, the classification prediction results of CART, RF, and DBRF, three different classifiers, were compared through ten-fold cross-validation on six different-sized datasets using accuracy, precision, recall, F1, and running time as validation indicators. Through experimental verification, it was found that DBRF algorithm outperformed RF, and the prediction performance was improved, especially in terms of time complexity. This algorithm is suitable for various fields and can effectively improve the classification prediction performance at a lower complexity level.**

Keywords—Random forest; DBSCAN; feature selection; feature redundancy; classification algorithm

I. Introduction

The correlation and redundancy of features will directly affect the performance of the random forest model. Especially in high-dimensional features, contain a lot of information, but may also contain a lot of useless, correlated or redundant features, making it difficult to distinguish between important and unimportant features, leading to an increase in the computational complexity of the machine learning model, an increase in the time overhead, a decrease in generalization ability, and a tendency to overfit the model [1-3].

Random forest (RF) is a hybrid classification algorithm that uses random sampling and random selection of features to construct multiple decision trees, making the model highly stable. Compared with other classification algorithms, RF has higher classification accuracy, lower generalization error, and faster training speed, so it has been widely applied in the field of data mining in many aspects. Random forest is a general-purpose algorithm with broad application potential in different fields. It has a large number of application cases in disease gene prediction, soil moisture estimation, industrial robot fault diagnosis, and text classification [1, 4-6]. The RF algorithm has many advantages such as high accuracy and strong generalization, but also has limitations. When dealing with high-dimensional data, its feature random selection mechanism causes poor correlation between the selected features and the category variables. In addition, the randomly selected feature variables may have high redundancy, which directly affects the quality of the feature subset in the random forest and weakens the convergence of the random forest, reducing the accuracy, generalization ability, and performance of the random forest model. Most of the current studies solve this problem by preprocessing and feature selection, but this may lead to new problems such as information loss and a dramatic increase in model complexity. These studies often only focus on the algorithm itself and do not consider its practical value. This study aims to improve the performance and efficiency of random forest model prediction by improving the method of random feature selection. This study designs and implements an improved random forest algorithm based on density clustering algorithm and hierarchical feature extraction mechanism. The significance of this study lies in significantly improving the accuracy and complexity of the random forest model prediction, providing practical and theoretical solutions and foundations for the sustainable development of this technology.

The main contribution of this study is to propose an improved random forest algorithm based on DBSCAN and stratified random sampling. This improved method enhances the quality of randomly selected feature subsets, and also confirms that the algorithm improves the accuracy of random forest models in different scale datasets, showing excellent performance in both cases. This study provides a new solution approach and empirical data for improving the random forest model.

The structure of this paper is as follows: Section II reviews related work, discusses the existing research on improving random forest algorithms and the progress in feature dimensionality reduction, and points out the shortcomings of existing studies. Section III provides a detailed description of the improved random forest algorithm design. Section IV validates the performance of the improved algorithm through experiments, including the evaluation of key performance indicators such as Accuracy, Precision, Recall, F1, and running time. Section V discusses the experimental results. Section VI summarizes the theoretical and practical significance of the research findings and provides a look ahead to future research directions.

II. Related Work

Many scholars have conducted relevant research on high-dimensional feature problems. Tang, Zhang et al. [7] used Relief F to calculate feature weights and used the Sequential Backward Selection algorithm to remove redundant features and weakly correlated features. The experiment proved that this method can effectively reduce redundant features. Compared with the methods of support vector machines, AdaBoost, and random forests, it has higher classification accuracy and efficiency. Ahmed, Deo et al. [4] proposed a soil moisture estimation model that uses the Boruta algorithm for feature selection. The model determines which features are significant by comparing the importance of the original features with the importance of the randomly generated shadow features. The experiment proved that the model has feature selection ability.

Rani and Baulkani [8] proposed the Lasso with Graph Kernel Feature Selection (LGKFS) algorithm, which combines the sparsity of Lasso regression and the structural information of GK-FS to reduce the feature dimension. When dealing with complex medical imaging data, the feature dimension is often very high, which may lead to the risk of overfitting in classification models and increase computational complexity. Therefore, effective feature selection becomes a key to improving classification performance. LGKFS algorithm combines Lasso regression and GK-FS algorithm to select the most valuable feature subset from high-dimensional features, thereby reducing the feature dimension and improving classification accuracy. Lasso regression is applied to the extracted features for sparse selection, removing most of the non-important features. GK-FS algorithm is used to further select the features after Lasso screening, based on graph kernel functions to calculate the similarity between features and select the most representative feature subset.

Jalal, Mehmood et al. [6] used boosted sampling and random subspace methods to remove unimportant features, dynamically increasing the number of trees to improve text classification performance. Each feature was assigned a weight, which reflected its importance in the classification task. Features were divided into important and unimportant features based on a set threshold. The choice of threshold depends on the distribution of feature weights and the performance requirements of the model. In each iteration, the random forest was updated based on the classified features. Important features were retained and used to construct new decision trees, while unimportant features were excluded. Meanwhile, the optimal number of trees was sought. This was achieved by gradually increasing the number of trees and evaluating the model performance until the optimal classification effect was reached.

Theerthagiri and Ruby [9] proposed a random forest feature selection algorithm based on recursive feature elimination and voting technology. The importance of each feature is evaluated by recursively building a random forest to assess the importance of each feature. The importance of a feature is evaluated by how it affects the prediction result during the decision tree building process.

Wang, Xue et al. [10] proposed a feature selection method based on variable-sized cooperative evolution particle swarm optimization. It includes a spatial division strategy based on feature importance, an adaptive mechanism for adjusting subgroup size, and a feature deletion and generation strategy based on fitness guidance, using the maximum information coefficient (MIC) to evaluate feature importance. Features with larger MIC values are moved to the set U, and the features in U are sorted and clustered based on their MIC values. Redundant features are deleted through the clustering results.

In high-dimensional data scenarios, to improve the accuracy of biomass estimation using a random forest algorithm, Zhang, Shen et al. [11] used an improved Random Forest algorithm by adding two regularization terms to further control the complexity of the model and improve performance. The L1 regularization selects the sum of the absolute values of the model parameters as the penalty term, thus selecting the most important feature at each node. This method helps to select the features that contribute the most to the model's prediction, reducing the influence of irrelevant or redundant features on the model. The average depth regularization term controls the depth of the tree and the number of nodes, thus limiting the complexity of the model. This limitation reduces the risk of overfitting the training data and improves the model's generalization ability. By limiting the depth and number of nodes, the model is more cautious in the feature selection process and avoids introducing noisy features due to the model being too complex.

To improve the performance of speech emotion classification, Xie, Zhu et al. [2] proposed a two-stage feature selection method based on random forest and grey wolf optimization. In the random forest algorithm, the importance of a feature is calculated based on its ability to increase the purity of leaf nodes. Then, the feature subset with the highest classification accuracy and the least number of features is selected through the iterative process of grey wolf optimization, which is used as the final optimal feature subset.

In summary, the quality of features affects the results of classification prediction, and many experts have conducted a series of optimization studies on feature dimensionality reduction. Currently, most studies mainly use feature selection algorithms to reduce the number of features, but ranking-based feature selection and subset-based feature selection both have certain limitations. Ranking-based feature selection algorithms mainly focus on the importance of individual features and ignore the interaction between features and the overall structure, while subset-based feature selection algorithms consider the combination of features, but may face the problem of large computational complexity and overfitting. Based on these problems, this study combines density clustering algorithm and hierarchical extraction to optimize the random forest algorithm. On the basis of establishing the diversity of random feature selection in the RF algorithm, it eliminates the interference of correlated and redundant features and builds a more predictive random forest, thereby improving the comprehensive performance of the model prediction.

III. Methodology

The RF algorithm has many advantages such as high accuracy and strong generalization, and has wide applications. However, when dealing with high-dimensional data sets, its random feature extraction mechanism reduces the correlation between features and category variables. Moreover, the randomly extracted features may have high redundancy, which lowers the quality of the random feature subset, and weakens the convergence of the random forest, thereby reducing the overall performance of the random forest. Therefore, this paper optimizes the traditional RF algorithm by using the DBSCAN algorithm and hierarchical sampling to change the feature extraction mechanism. By constructing similar feature groups, it reduces the impact of these factors and improves the efficiency of the algorithm.

A. *Random Forest*

Random Forest is a machine learning algorithm that combines multiple decision trees. RF selects multiple subsets of the original sample set by random sampling with replacements from the set to build decision trees. At each node in the decision tree, a random subset of *k* attributes is selected from the set of attributes at the node, and then the best attribute is chosen from this subset for splitting. It is generally recommended that $k = log_2 d$, where *d* is the number of features in the data set [12]. The predictions of each tree are voted on to elect the best result. RF can handle both continuous and categorical variables [13, 14]. It can also rank the importance of features [15].

The architecture of the random forest algorithm is depicted in Fig. 1, and its underlying principles are delineated as follows [16]:

1) Randomly draw n training datasets from the original dataset with replacement.

2) Randomly select *K* features from each training dataset (where *K* is less than the total number of features in the original dataset).

3) Employ a specific strategy (e.g., Gini coefficient) to choose 1 feature from the *k* features as the splitting feature for the node, thereby constructing a decision tree.

4) Iterate through steps 1-3 to construct n decision trees.

5) Utilize each decision tree for result prediction.

6) Aggregate predictions and determine the final prediction result based on majority voting.

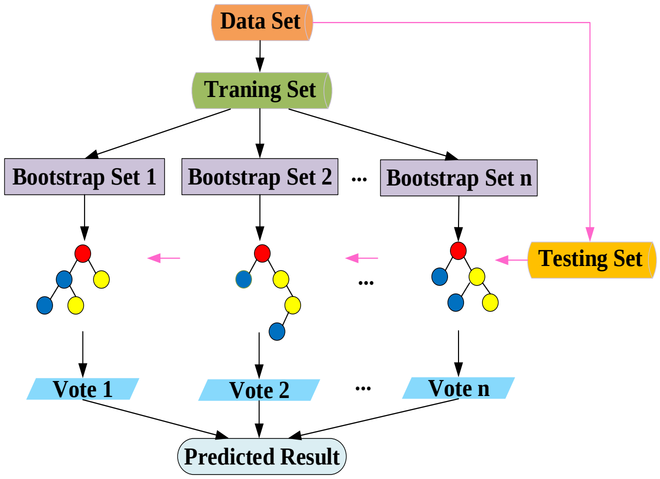

Fig. 1. The architecture of the random forest algorithm.

Random forest uses CART as a single classifier. CART uses the Gini coefficient as a selection criterion for splitting features. The key to building decision trees in random forest is to choose the optimal splitting feature, seeking higher and higher node "purity" in the splitting process [17]. The lower the Gini coefficient of a feature, the lower its impurity, and the feature with the lowest impurity is selected for node splitting. The impurity calculation is repeated for each node. After each split, the overall impurity of the tree decreases, until no features are available or the impurity has reached an optimal level, at which point the decision tree stops growing. The formula for calculating the Gini index is [18]:

$$GI_m = 1 - \sum_{k=1}^{|K|} p_{mk}^2 \tag{1}$$

Where: *K* denotes the number of categories, and P_{mk} represents the proportion of class column *k* in node *m*.

B. *DBSCAN Algorithm*

DBSCAN is a density-based clustering algorithm based on high-density connected regions. It defines clusters as the largest set of points that are densely connected and can group together regions with sufficiently high density and discover arbitrary-shaped clusters in noisy spatial databases. It uses parameters (*Eps*, *MinPts*) to describe the tightness of the sample distribution in the neighborhood. Parameter Eps is the maximum radius of the neighborhood. Parameter *MinPts* specifies the density threshold for dense regions. The working principle of DBSCAN is: randomly select a data point p from the dataset and check whether p's Eps neighborhood contains the minimum number of data points *MinPts*. If this condition is met, a new cluster is created and all identified data are added to the new clustering. Then, all data within the cluster will also be checked in the same way based on these two parameters, in order to add as many other data as possible that have not been checked before. This process is repeated until all data in the dataset are accessed [19, 20].

C. *Stratified Sampling*

Divide the entire sample into distinct strata or categories, and subsequently conduct random sampling from each stratum by selecting a specific number of individuals. Finally, combine the sampled individuals from all strata to form a representative sample. This approach is known as stratified sampling. Through categorization and stratification, it enhances the similarity among individuals within each category, facilitating the selection of a representative survey sample. This method is particularly suitable for complex situations with substantial individual variations and a large population size. The key characteristics of stratified sampling include [21, 22]:

1) Stratification involves the classification of similar individuals into distinct layers, with each layer representing a unique category. This method adheres to the principle of non-overlapping and exhaustive coverage, ensuring that every individual is assigned to one and only one layer.

2) To guarantee an equal opportunity for every individual to be included in the sample, stratified sampling necessitates simple random sampling within each layer. The sample size in each layer is determined proportionally based on the total number of individuals in that layer relative to the overall population size.

D. Design of the DBRF Algorithm

The establishment of a random forest involves two key random processes, one of which is the random selection of features. In high-dimensional datasets, it is highly probable to extract a large portion of irrelevant or redundant features, leading to a decrease in the generalization and accuracy of the RF algorithm. To address this issue, this study proposes an improvement to the traditional random forest algorithm using density clustering. Without removing redundant features and while retaining the original feature information, features are grouped (clustered) based on density to form similar feature groups TG = "TG_1 ,TG_2,…,TG_n". Within these similar feature groups, a certain proportion of features can represent all information for that entire group of features as well as express classification labels C. Features are randomly selected from each similar feature group TG_i in proportion to establish a subset for building individual decision trees. The architecture of the DBRF algorithm is illustrated in Fig. 2.

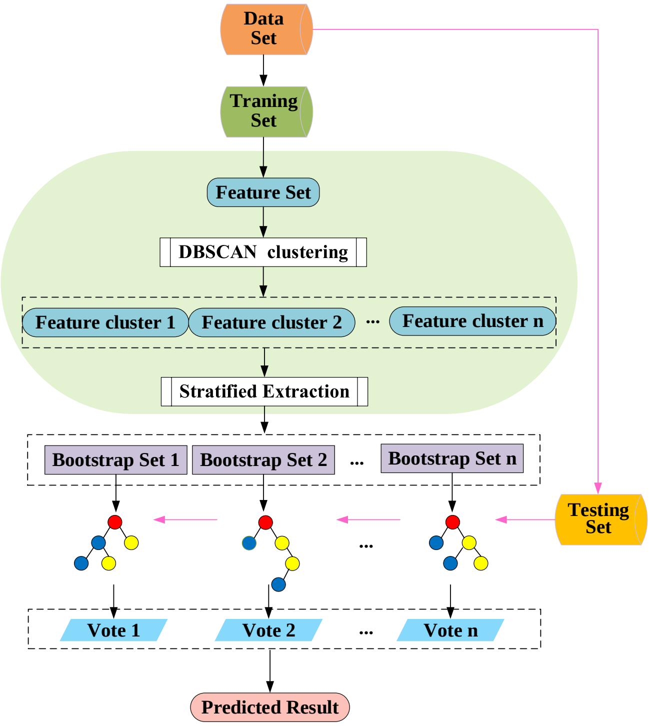

Fig. 2. The architecture of the DBRF algorithm.

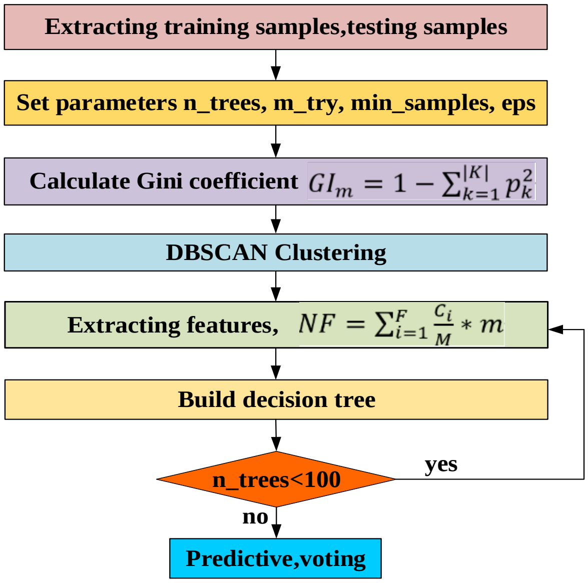
The flowchart of the DBRF algorithm is illustrated in Fig. 3. Initially, a training set and a test set are established. Algorithm parameters such as the number of decision trees (*n_estimators*), maximum number of features for splitting (*max_features*), minimum samples in a cluster (*min_samples*), and neighborhood radius (*eps*) are configured. The Gini coefficient (GI_m) for each feature is computed, followed by DBSCAN clustering to form F similar groups. Features are then extracted from each group based on the proportion NF, and a subset of features is selected from other similar feature groups using the same approach to construct individual decision trees. This process is iterated multiple times until reaching the desired scale for constructing the random forest, at which point it terminates.



Extracting training samples,testing samples
Set parameters n_trees, m_try, min_samples, eps
Calculate Gini coefficient $GI_m = 1 - \sum_{k=1}^{|K|} p_k^2$
DBSCAN Clustering
Extracting features, $NF = \sum_{i=1}^{F} \frac{C_i}{M} * m$
Build decision tree
n_trees<100
yes
no
Predictive,voting

Fig. 3. The flowchart of DBRF.

The flowchart of feature extraction is shown in Fig. 4. After features are clustered, features with similar classification capabilities are grouped into a cluster. Then, features are sampled proportionally from each cluster. This ensures that the extracted features are more representative and do not favor any particular situation. These features are used to build a decision tree. The feature extraction process is repeated until all decision trees have been built.

The formula for proportional sampling is:

$$NF = \sum_{i=1}^{F} \frac{C_i}{M} * m \qquad (2)$$

Where: F is the total number of clusters, C_i is the number of features in the *i-th* cluster, M is the total number of features, and m is the number of features to be extracted.

The pseudocode for feature proportional stratified sampling is as follows:

Algorithm 1: stratified sampling algorithm

Input: a set of similar feature clusters

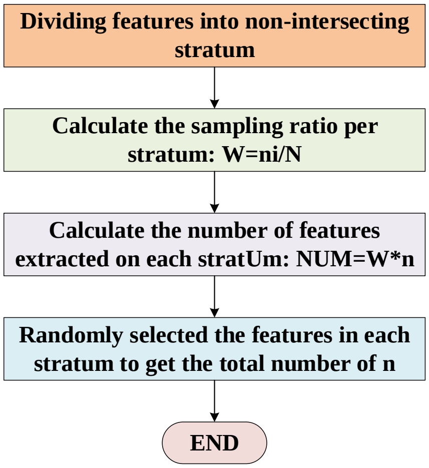
Output: several groups of extracted features.

Method:

(1) According to the total number of features N and the number of features per layer: n_i , Calculate the sampling ratio for each layer $W = \frac{n_i}{N}$.

(2) Calculate the number of features to be extracted from each layer: $NUM = W*n$. And make sure that the total number of features extracted from each layer is n.

(3) Determine the number of features for each layer, then randomly select features from each layer to form a total of n samples.



Dividing features into non-intersecting stratum
Calculate the sampling ratio per stratum: W=ni/N
Calculate the number of features extracted on each stratUm: NUM=W*n
Randomly selected the features in each stratum to get the total number of n
END

Fig. 4. The flow of feature extraction.

Therefore, the pseudocode for the complete DBRF algorithm is as follows:

```
Algorithm 2: DBRF algorithm
Input: Dataset: Data, number of decision trees: n_estimators,
maximum number of features for splitting: max_features,
minimum number of samples in a cluster: min_samples,
neighborhood radius: eps
Output: An RF classifier
Methods:
The dataset is divided into a training set and a testing set;
for i=1 to Num_Features
    Compute the Gini coefficient ($GI_m$) for each feature.
endfor
while( j<= min_samples and k<=eps)
    F = DBSCAN($GI_m$)    // Feature clustering
endwhile
for t=1 to n_estimators
    for f=1 to F
        Extract NF features and construct a decision tree;
    endfor
endfor
```

The time complexity of RF is *O(tfnlog(n))*, where *t* is the number of decision trees built, *f* is the number of features selected at each node, and *n* is the number of samples in the training set [23]. The DBRF algorithm proposed in this paper is divided into two parts: clustering to build similar feature groups and building a random forest model. For the first part, the time is mainly spent on feature Gini coefficient clustering, with a time complexity of *O(mlogm)* [24], where m is the number of features. The second part is the random forest construction. Therefore, the time complexity of the DBRF algorithm proposed in this paper is the sum of the two parts, i.e., *O(tfnlog(n)+m(logm))*.

IV. Experimental Results and Analysis

A. Experimental Data

In order to objectively and comprehensively evaluate the effectiveness and advantages of the DBRF algorithm, the adaptability of the algorithm on different feature dimension datasets was analyzed. Six datasets with different feature dimensions from the UCI were selected, namely SPECT Heart (SPECT), Chess, SCADI, DARWIN, Period Changer (Period), and MicroMass. Table I describes the detailed information of the six datasets. The six datasets were divided into low-dimensional, medium-dimensional, and high-dimensional datasets based on the size of the samples and features [25]. SPECT and Chess belong to low-dimensional feature datasets. SCADI and DARWIN belong to medium-dimensional datasets. Period and Micromass are high-dimensional datasets. At the same time, these datasets include balanced and unbalanced datasets.

B. Experimental Results and Analysis

The experimental environment was set to Windows 11 operating system (64-bit), Intel(R) Core(TM) i7-10510U CPU, 16GB RAM, and Visual Studio Code. To verify the comprehensive performance of the proposed improved random forest, the experimental results of DBRF, RF, and CART classifiers were compared. The experiment used tenfold cross-validation to evaluate the accuracy, precision, recall, F1 score, and running time of the DBRF, RF, and CART models. Their overall performance was compared, highlighting the advantages of the improved algorithm. The experiment parameters were set to *n_estimators=100, max_depth=30, max_features= sqrt(n_features)*. The DBSCAN parameters were set to *min_samples=3, eps=0.02 or eps=0.03.*

TABLE I. The Descriptions of All Datasets

ID	DataSet	Feature Size	Sample Size	Feature Scale	Sample Scale	Balance	DOI
1	SPECT	22	267	Small	Small	unbalance	10.24432/C5P304
2	Chess	36	3196	Small	Large	balance	10.24432/C5DK5C
3	SCADI	205	70	Middle	Small	unbalance	10.24432/C5C89G
4	DARWIN	451	174	Middle	Small	balance	10.24432/C55D0K

6	Micromass	1300	571	Large	Middle	balance	10.24432/C5T61S

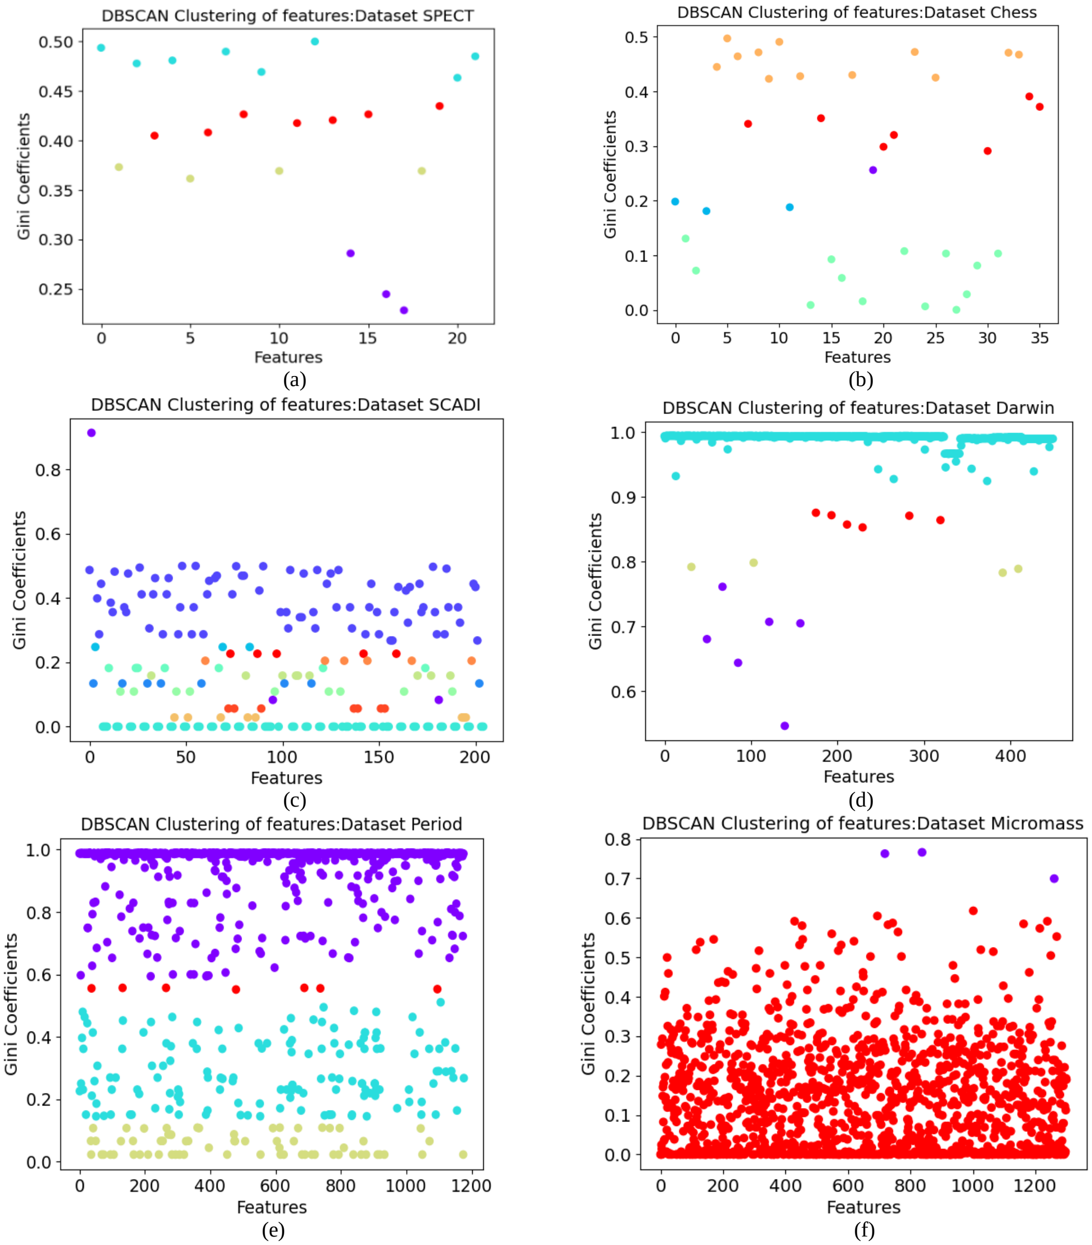

Fig. 5. Clustering results of DBRF on all Datasets (a) SPECT, (b)Chess, (c) SCADI, (d) DARWIN, (e) Period and (f) Micromass.

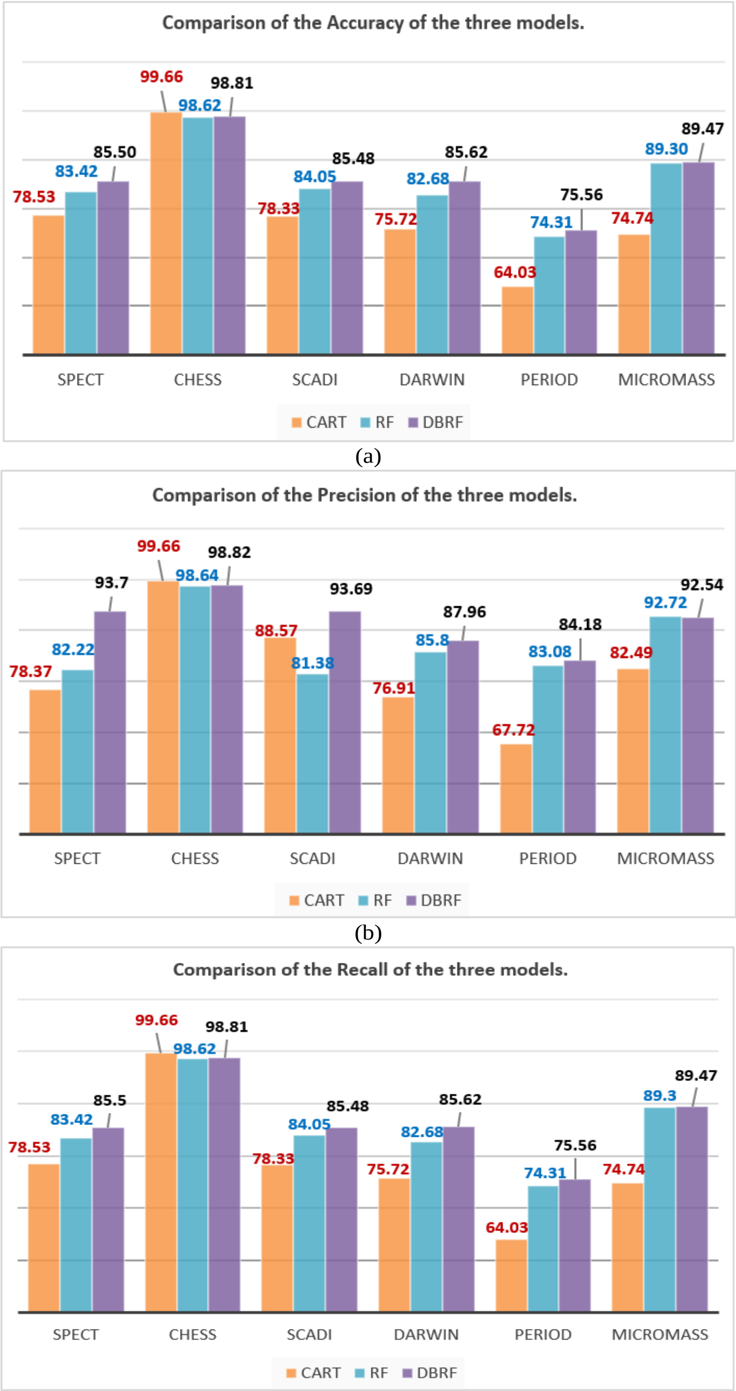
Fig. 5 illustrates the clustering results of DBRF on all datasets. Features clustered together are represented by points of the same color. Table II presents the number of feature clusters for each dataset, along with the maximum and minimum values of elements within each cluster. SCADI exhibits the highest number of similar feature clusters, with 12 clusters containing a maximum of 77 features and a minimum of three features. SPECT, Darwin, and period are all clustered into four similar feature clusters, with the maximum number of features in a cluster being 958 and the minimum being 3. MicroMass has the fewest feature clusters at only 2, with a maximum of 1297 features in a cluster and a minimum of three features. Chess consists of 36 features clustered into five groups, with each group containing between 1 to 13 features.

Fig. 6 shows the performance comparison of CART, RF, and DBRF models on all datasets. Fig. 6(a) shows the classification accuracy of CART, RF, and DBRF prediction models on all datasets. On the chess dataset, the accuracy of DBRF is 0.85% lower than that of CART and 0.19% higher than that of RF. For the other five datasets, the accuracy of DBRF is the highest. DBRF is 6.97% to 14.73% higher than CART and 0.17% to 2.94% higher than RF. This data confirms that DBRF as a composite classifier of CART is superior to CART. Furthermore, the higher accuracy of DBRF than RF indicates that the features extracted by DBRF are more representative and have higher accuracy. Importantly, DBRF performs well on both balanced and unbalanced datasets, demonstrating its versatility. Furthermore, DBRF improves performance on low-dimensional and high-dimensional datasets.

TABLE II. THE CLUSTERING RESULTS OF DBRF

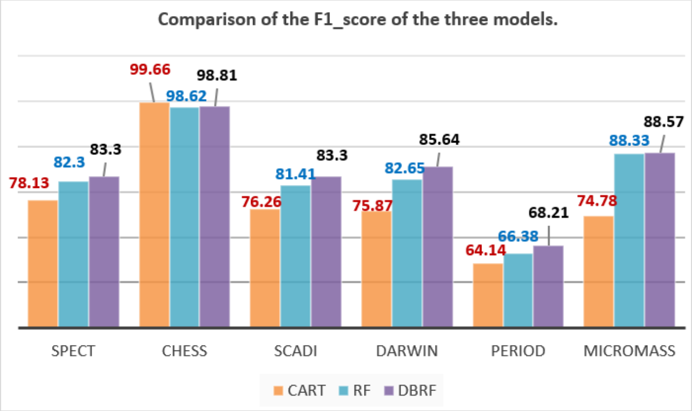
ID	**DataSet**	**Number of clusters**	**Maximum number of features in a cluster**	**Minimum number of features in a cluster**
1	SPECT	4	8	3
2	chess	5	13	1
3	SCADI	12	77	3
4	darwin	4	434	4
5	period	4	958	7
6	micromass	2	1297	3



(a)

(b)

(c)



(d)

Fig. 6. Performance comparison of CART, RF, and DBRF models on all datasets.

Fig. 6(b) shows that the accuracy of DBRF on SCADI is 93.69, while the accuracy of RF is 81.38, which has been significantly improved by 12.31%. In Table II, the number of clusters in the dataset is the maximum value of 12, proving the complexity of the feature distribution. The clustering process can extract comprehensive and representative features, thus significantly improving the accuracy. At the same time, the accuracy of DBRF is the highest in all five datasets, with an improvement of 15.33%, 12.31%, 11.05%, 16.46%, and 10.05% compared to the lowest accuracy.

Fig. 6(c) compares the Recall values of the three models. Similarly, DBRF is at the highest level of Recall value. In the five datasets, DBRF's recall value is absolutely dominant, far higher than the RF and CART models. Compared with the lowest value, the increase in DBRF's Recall value is 6.97%, 7.15%, 9.9%, 11.53%, and 14.73%.

Fig. 6(d) shows the combined measure F1. In the low-dimensional datasets SPECT and Chess, DBRF performed 1.0% and 0.19% better in F1 than RF, respectively. However, the improvement was not significant due to fewer features in the low-dimensional datasets. In the medium-dimensional datasets SCADI and Darwin, DBRF's F1 score was 1.89% and 2.99% higher than RF, respectively. In the five datasets, the improvement in DBRF's F1 value compared to the lowest value was 5.17%, 7.04%, 9.77%, 4.07%, and 13.79%, respectively. In the high-dimensional datasets Period and MicroMass, DBRF improved the F1 score by 1.83% and 0.24% compared to RF, respectively. In the medium- and high-dimensional datasets, CART always performed the worst, thereby highlighting the advantages of ensemble learning models.

Table III shows the running times of the three prediction models on all datasets. For the four datasets including the high-dimensional dataset MicroMass, the DBRF model requires less time than the RF model, further emphasizing its efficiency and universality. Although DBRF adds the feature clustering process, it reduces the running time, indicating that balancing the extraction of typical features is more beneficial for the time efficiency of prediction classification. Since both DBRF and RF require the construction of 100 decision trees, their running times are longer than CART, but they achieve higher accuracy. Therefore, from the comprehensive performance indicators, the prediction classification effect of the DBRF model is better than that of the other two models.

TABLE III. RUNNING TIME OF THE THREE MODELS IN SECOND (S)

Dataset	CART	RF	DBRF
SPECT	2.39	8.32	**5.46**
chess	7.07	84.83	145.25
SCADI	2.91	6.36	**5.82**
darwin	101.21	356.80	**276.60**
period	123.59	76.93	153.39
micromass	464.87	572.17	**526.49**

V. DISCUSSION

This study used different-sized datasets and conducted comprehensive experimental evaluations to verify the effectiveness of the proposed optimization techniques. The performance of the DBRF algorithm was compared with that of traditional RF and CART algorithms. The experiment demonstrated the technical improvements brought about by density-based feature extraction, and the empirical evidence proved the classification efficiency, scalability, and time complexity. Previous research techniques were only applicable to a single application domain [2, 6, 8, 11], while this study tested the proposed method on datasets with multiple different neighborhoods. In low, medium, and high-dimensional datasets, the DBRF achieved significant improvements in all performance indicators compared with the other two models. The maximum improvement in accuracy indicators was 14.73% in the high-dimensional MicroMass dataset. The highest accuracy value was 98.81% in the low-dimensional Chess dataset. The maximum improvement in precision indicators was 16.46% in the high-dimensional period dataset. In the running time indicator, the DBRF model required less time than the RF model in four datasets, including the high-dimensional MicroMass dataset, further highlighting its superiority and generality. Although the DBRF increased the feature clustering process, it reduced the running time, indicating that balancing the extraction of representative features is more beneficial for the time efficiency of predictive classification. In the five datasets, the DBRF achieved the highest values for all four evaluation indicators, including accuracy rate. Therefore, by randomly selecting similar feature groups and extracting features from them, it is possible to effectively avoid the formation of redundant feature subsets in traditional RF and improve the accuracy and overall performance of predictive classification.

In summary, the DBRF algorithm proposed in this paper has better experimental effects than the other two algorithms, showing obvious advantages in high-dimensional data sets, low-dimensional data sets, and data sets with highly redundant features. Future research can further study the improvement of other types of clustering algorithms on random forest feature extraction to achieve higher efficiency and performance improvement. At the same time, it can be made more scalable to enable it to have a wider range of applications.

VI. Conclusion

Due to the correlation among features, redundancy, and a large amount of useless information, the overall performance of the machine learning model is affected. This study optimizes the traditional RF algorithm and proposes a DBRF algorithm based on DBSCAN. The experimental results show that the DBRF algorithm has a higher accuracy index improvement of 6.97%-14.73% and an F1 index improvement of 4.07%-13.79% compared with the other two models. In the 5 datasets, the accuracy rate and other four evaluation indicators of DBRF are the highest. For the four datasets including the high-dimensional dataset MicroMass, the DBRF model takes less time than the RF model, which demonstrates its significant advantage in time complexity. Therefore, the DBRF algorithm achieves the research goal of reducing the influence of feature correlation and redundancy on model performance. In future research, further exploration of other types of clustering algorithms for random forest feature extraction will be conducted to achieve higher efficiency and performance improvement, as well as stronger scalability.

Abstract—**Dispatching ambulances early and efficiently is paramount and difficult in the field of emergency medical services. In this regard, the paper designs a smart ambulance system based on game-building theory. The system employs an advanced Negamax algorithm for optimizing the dispatch of ambulances during emergencies. Besides traditional methods, real-time traffic data, patient condition severity, and dynamic resource allocation also improve the system further. With the integration of predictive analytics and real-time data, it allows dynamic adaptation to changing urban conditions, optimal resource allocation as well as minimizing response time. According to our simulations involving extensive scenarios, our Negamax-based system performs significantly better with respect to average response times when compared with traditional methods averagely reducing them by more than 50%, hence, showing double improvement. The study not only improves efficiency in the operation of emergency services but also presents an expandable framework that can be used for future developments in critical response systems thereby leading to their association with smart city infrastructure and AI-based predictive emergency management.**

Keywords—Emergency medical services; ambulance dispatch optimization; advanced game theory; Negamax algorithm; real-time optimization; predictive analytics

I. Introduction

When it comes to saving lives and improving patient outcomes in urban areas, the speed of action taken by emergency medical services (EMS) is very important [1]. Often, traditional ambulance dispatches rely on static positions and heuristic approaches which are simple and fail to take into account the dynamic nature of urban emergencies and traffic conditions [2]. This research is motivated by the need for a more sophisticated adaptive ambulance allocation approach that can respond to real time conditions, predict patterns of emergency, and optimize resource utilization within complex urban settings.

The subject of this study is to develop and implement an advanced system based on game theory for optimizing the dispatch of ambulances in large urban areas with a high population density, complex road networks, and changing traffic conditions. We go beyond mere distance optimization to consider factors such as real-time traffic information, historical emergency patterns, and dynamic health facility capacity changes. The primary objectives of this research work are as follows:

- To customize the Negamax algorithm (from game theory) [3], [4] with multi-factorial decision-making for ambulance dispatch optimization.
- To combine real-time data feeds like hospital capacities, emergency severity levels, and traffic conditions in the process of optimizing ambulance dispatches.
- To design a scalable platform for handling emergency response coordination throughout the city.

Efficient ambulance dispatch is undoubtedly a crucial aspect. In the cases of cardiac arrests, survival odds are lower by 7-10% per minute delay [5]. It shows how rapid response saves lives. There could be improved resource utilization through efficient dispatch systems which can reduce operational costs and improve coverage with existing resources [6]. In addition, the implementation of smart routing systems [7], [8] could reduce traffic congestions associated with emergency vehicle movements and facilitate urban mobility in general. Moreover, this data can help city planning and health care to optimize resource allocation based on facts instead of assumptions for a better public health outcome as well as improved emergency medical services.

The existing approaches are somehow limited on several accounts which reduce their effectiveness in modern urban environments. To be considered here, traditional ambulance dispatches are often based on static decision-making and use rule-based methods that are easy to apply but do not consider the evolving nature of the emergencies and traffic in urban environments [9], [10]. Although 5G and IoT have emerged and recently integrated into ambulances, they are still unable to relieve the demanding nature of emergency services in the urban environment [11], [12]. Various knowledge-based systems have been developed [13], but they are not capable enough to provide proper time-based optimization and predictive analysis. A few recent research works have tried to include real-time data and predictability in the model [14], [15]. However, there are very few studies that have included a holistic approach of adaptive methods. Moreover, though attempts have been made to solve problems like traffic congestion [16], still it is the dire necessity to design an efficient and enhanced adaptive ambulance allocation model considering the current situation, patterning emergency and the best utilization of resource in the context of urban environment. These drawbacks, which are discussed in more detail in Section II, all point to the need for more flexible, real-time, and big data-based solutions for ambulance dispatching.

To this motivation, we hypothesize that applying a customized version of the Negamax algorithm from game-building theory, combined with machine learning techniques for predictive analytics, can significantly improve the efficiency of ambulance services. We consider the Negamax algorithm because of its efficiency in exploring decision trees and adaptability to adversarial scenarios. In the context of emergency response, it represents the competition between different possible dispatch decisions. Moreover, the Negamax algorithm considers the thinking process of both participants while making a move, which consequently increases the win probability. Our customized version incorporates real-time data updates and considers multiple factors simultaneously, enhancing its suitability for the ambulance dispatch problem. Hence, this approach aims to create a dynamic, predictive, and highly responsive ambulance dispatch system. The system would be able to minimize response times, maximize resource utilization, and adapt to the complex and dynamic environment of urban emergencies.

The paper is organized as follows: Section II covers the literature review. Section III explains the mathematical modeling followed by the proposed system in Section IV. Section V is about experimental evaluation, results, and discussion. The paper is finally concluded in Section VI along with the future research considerations.

II. Literature Review

This section covers the related research works in the domain of smart ambulance system. A smart ambulance system was suggested by Gupta et al. in 2016 using IoT and smartphone technologies [9]. The research was aimed at enhancing the emergency medical response. They proposed a system that has two main modules: (i) Module 1 is about locating nearby ambulances and hospitals using GPS and Google Maps; (ii) Module 2 transmits real-time patient health data from an ambulance to a hospital. They also claimed that there were reduced response times and improved patient care during emergencies.

In 2017, Udawant et al. designed “Green Corridor” smart ambulance system using IoT framework to mitigate traffic congestion issues faced by emergency services [10]. The system reads patients vital signs in an ambulance while transmitting it to hospitals, as well as controls automatically signal lights for clear passage of vehicle when it reaches signals. Authors assessed different MAC protocols for data transmission in the proposed system concluding that CSMA is mostly efficient.

A timely ambulance service was proposed by Marimuthu et al. (2018) that employs the use of an Android application [17]. The proposed service allows for user requests of ambulances and selection of hospitals. Tracking the movement of ambulances in real-time is made possible through GPS and GSM modules while providing an emergency button to assign automatically the nearest ambulance. This application intends to enhance ambulance response durations and provide more effective life-saving services.

In 2021, Zhai et al. proposed a 5G-based smart ambulance structure and evaluated it through simulation experiments [11]. The experiment was conducted on the test platform which consisted of two scenarios namely, remote video consultation with medical data transmission from a moving ambulance and large medical image file transfers under both 4G and 5G networks. The resulting figures indicated impressive enhancements in capacity, speed, and latency for 5G as compared to 4G systems.

Merza and Qudr (2022) presented an ambulance-based healthcare system using Raspberry Pi and Internet connectivity to monitor patients’ vital signs in real-time for data transfer to hospitals [18]. The system incorporates various sensors for ECG, heart rate, respiration, temperature as well as audio/video monitoring thereby improving hospital readiness status and communication between paramedics on board with specialists on call.

In 2022, Sultana et al. defined an IoT-enabled intelligent ambulance routing system using LOADng-IoT routing protocol to reduce emergency response time and enhance patient care [12]. To speed up ambulances to hospitals yet keep transferring the most recent patients’ medical records, this is done by integrating traffic light control, health monitoring sensors and efficient path-finding algorithms. Additionally, authors discuss how the technology can facilitate achieving some of the UN SDGs concerning health, infrastructure and sustainable cities.

In 2023, Chanchai Thaijiam developed a smart ambulance system with knowledge base and decision-making support for improved rescue operations [13]. The design includes wearable biometric sensors, GPS tracking technology. Video conferencing platform was installed in order to have smooth communication between medical personnel in hospital and the emergency team inside ambulances. These systems enhance selection of destination hospitals for patients which is guided by an algorithm that uses decision trees procedure based on certain parameters such as distance or type of injuries.

Siddiqi et al. (2023) developed a smart signalization system for emergency vehicles [14]. The system uses Arduino, GSM modules, and a mobile application and it facilitates the drivers to control traffic signals from afar through SMS. Consequently, it minimizes any delays that may be caused. The system was evaluated by conducting field tests which proved the system's effectiveness for avoiding probable intersections for emergency vehicles. In addition, it maintains minimal waiting time for other traffic on the route.

In 2023, Sutherland and Chakrabortty proposed an optimal ambulance routing model [15]. The model considers multiple ambulances, patient medical severities, dispatching locations, and hospitals. The goal of this model is to enhance response times as well as patient transport efficiency. Simulation results prove the model's resilience under critical situations, therefore, laying a foundation for further studies on ambulance routing optimization.

In 2024, Sakthidevi et al. discussed IoT-enabled smart ambulances and how they can transform emergency response and management of patients [19]. The focus was on real-time monitoring sensors, advanced communication systems, and data processing platforms. The authors contributed to enhance resource allocation, improve response times, and elevate patient outcomes. This paper also focuses on future directions, challenges as well as potential impacts to emergency medical services in the world today.

In 2024, Jeyaseelan et al. put forward an IoT-based smart ambulance system for reducing the time taken in responding to emergencies in cities prone to traffic congestion [16]. The system employs the use of sensors, GPS and wireless communication technology to track ambulances, control traffic signals or even lower speed breakers automatically enabling ambulances to reach hospitals faster as well as safely. Experimental results show high accuracy and availability of the proposed system.

In the present research work, we address several key gaps in the above-reviewed literature. While previous studies have majorly focused on IoT integration, GPS tracking, and basic route optimization; in contrast, our approach leverages advanced game theory, specifically a customized Negamax algorithm, to provide a more adaptive and intelligent solution. The proposed system also incorporates predictive analytics and multi-factorial decision-making, whereas, earlier works primarily considered real-time data transmission and traffic signal control only. Doing this facilitates proactive resource allocation and efficient emergency response. Furthermore, existing research works have confined their scope to either route optimization or patient data transmission. In response, our research integrates these aspects with dynamic resource management across large and complex urban areas. The use of machine learning techniques for emergency prediction and traffic pattern analysis goes beyond the capabilities of systems described in previous literature.

III. Mathematical Modeling

This section describes our mathematical model considered for this research including the customized Negamax algorithm, possible constraints, dynamic updates, and predictive component.

A. Customized Negamax Algorithm

Let $G = (V, E)$ be a graph where V represents nodes (ambulance stations, hospitals, accident locations) and E represents edges (routes between nodes). A time-dependent distance matrix D is considered where $D[i][j][t]$ represents the estimated travel time between node i and node j at time t. Furthermore, a dynamic vector A is also considered where $A[i][t]$ represents the number of available ambulances at node i at time t. Let S be a severity matrix where $S[k]$ represents the severity level of emergency k. Associating all the above notations, the objective function to minimize the total weighted response time T is given in Eq. (1) as follows:

$$T = \sum_{k=1}^{N} min_{i \in V}(D[i][k][t] \cdot I[i][k] \cdot W(S[k])) \quad (1)$$

Where I[i][k] is an indicator function that is 1 if an ambulance from node i is dispatched to emergency location k, and 0 otherwise. W(S[k]) is a weight function based on the severity of the emergency.

For each emergency k, $D[i][k][t] \cdot I[i][k] \cdot W(S[k])$ is calculated for every possible dispatch location i. The minimum of these values is then selected which represents dispatching from the best location. This minimum is then weighted by the emergency's severity. It is done for all emergencies and sum of the results is calculated, giving us the total weighted response time T. The goal of optimization is to find the set of dispatch decisions (represented by $I[i][k]$ values) that minimizes this total weighted response time T, subject to the constraints discussed as follows.

B. Constraints

Following constraints are taken into account while modeling the system:

- Emergency Coverage: It is the first constraint where each emergency must be responded to by at least one ambulance (see Eq. (2)). loc_{emr} represents the emergency locations.

$$\sum_{\mathrm{i} \in \mathrm{V}} \mathrm{I[i][k]} \geq 1, \forall \mathrm{k} \in loc_{emr} \quad (2)$$

- Ambulance Availability: This constraint assures that the number of ambulances dispatched from any node cannot exceed the available ambulances at that node (see Eq. (3)).

$$\sum_{k \in loc_{emr}} I[i][k] \leq A[i][t], \forall i \in V \quad (3)$$

- Response Time Limit: In this constraint, it is assumed that the response time for each emergency should not exceed a maximum threshold T_max (see Eq. (4)).

$$D[i][k][t] \cdot I[i][k] \leq T_{max}, \forall i \in V, \forall k \in loc_{emr} \quad (4)$$

C. Dynamic Updates

Three parameters are dynamically updated in the system viz., traffic conditions, ambulance availability, and emergency severity. For traffic condition; historical data $data_{hist}$, real-time traffic $traf_{rt}$, and time t are considered as shown by the function in Eq. (5). Similarly, dispatch events evt_{dp}, return events evt_{ret}, and shift changes chg_{shf} are considered to update ambulance availability (see Eq. (6)). To update the emergency severity, reported condition $cond_{rep}$, historical data $data_{hist}$, and environmental factors $fact_{env}$ are considered (see Eq. (7)).

$$D[i][j][t] = f(data_{hist}, traf_{rt}, t) \quad (5)$$

$$A[i][t] = g(evt_{dp}, evt_{ret}, chg_{shf}) \quad (6)$$

$$S[k] = h(cond_{rep}, data_{hist}, fact_{env}) \quad (7)$$

D. Predictive Component

Function $P(l, t)$ represents the predictive component as shown in Eq. (8). It gives the probabilistic estimation of an emergency that may occur at location l at time t.

$$P(l, t) = ML\_model(data_{hist}, cond_{rep}, evt_{sch}) \quad (8)$$

It makes the system capable of anticipating where emergencies are likely to occur before they may actually happen. The ML_model is a machine learning algorithm that takes historical data $data_{hist}$, current conditions $cond_{rep}$, and scheduled events evt_{sch} as its input. Historical data consists of past emergency calls, their respective locations, times, and types. It assists the model in identifying different patterns and trends. Similarly, for the current conditions parameter, we consider traffic patterns, weather, ongoing events, and time. For the scheduled events parameter, events that could impact the probability of emergency are considered. They may include sports, concerts or festivals, holidays, and road constructions. Initially, the model is trained on historical data. However, it is continuously updated with new data as it becomes available. The purpose is to make the model rational so that its predictions would improve over time. As the function is probabilistic, it outputs a value between 0 and 1 for each location l at time t. Higher values indicate a higher likelihood of an emergency event. The calculated probability values serve the following purposes:

- To allocate and position the ambulances in high-probability areas proactively.
- Weight adjustment in objective function to prioritize or highlight the areas with higher emergency probabilities.
- To make staffing decisions and shift planning.

Incorporating this predictive component in the system is imperative as it makes the system proactive in making important decisions. In other words, it assists the system in better resource allocation and potentially reducing response times by having ambulances positioned closer to where emergencies are likely to occur.

IV. Proposed System

In this section, we discuss the architecture of our proposed system along with its working.

A. *System Architecture*

The design of the proposed smart ambulance system is made up of several interconnected components/modules that work together to ensure effective resource allocation and ambulance dispatch. The layered architecture of the proposed system is given in Fig. 1. The specific responsibilities for each module are described as follows:

- Data Collection Module: It gathers real-time and historical data from many sources including GPS trackers on ambulances, weather stations, traffic sensors and cameras, hospital information systems, and emergency call centers.
- Data Processing Module: Raw data collected by Data Collection Module is further processed here so that it can be analyzed in depth. This includes activities such as data cleaning, normalization and feature extraction [20], [21].
- Predictive Analytics Engine: The proposed system incorporates a vital component which examines past emergency data against current situations to estimate future emergencies as well as their possible extent. Within this component a suitable machine learning algorithm has been included.
- Traffic Module: It produces and updates time-dependent distance matrix. The matrix shows estimated travel time between different nodes within the network taking into account dynamic traffic conditions.
- Resource Management Module: This module tracks the availability and status of all resources (ambulances) in the system. It is also responsible to update their positions/locations and availability in real-time.
- Dispatch Optimization Engine: This is the core component of our proposed system as the whole research is oriented around this. This engine uses a customized Negamax algorithm (as discussed in Section 3.1) to make optimal dispatch decisions. Each decision takes multiple factors into account for its dispatch [22]. These factors include ambulance availability, predicted emergency severity, and estimated response time.

User Interface Module
Layer 5: Storage
Database Module

Fig. 1. Layered architecture of the smart ambulance system.

- Real-time Communication Module: As the name suggests, this module facilitates seamless communication between various entities of the system. These entities include a central dispatch system, ambulances, and hospitals. Consequently, this module ensures that all entities have access to the latest information.

- User Interface Module: It is important for the dispatchers to monitor the system, view predictions, and override automated decisions (if necessary). This module provides the graphical user interface for the same.
- Database Module: It is imperative to store historical data, real-time information, and system logs for continuous improvement and auditing. This module provides a centralized database to serve this purpose.

B. *System Working*

In the proposed system, different modules work together in a coordinated manner to enhance emergency response. Following steps explain the detailed working of smart ambulance system:

- Step 1: The Data Collection Module begins with continuous data ingestion. This module collects real-time information from trackers on ambulances, weather stations, traffic sensors, hospital capacity systems and emergency call centers. The Data Processing Module then cleans and normalizes this raw data, extracting relevant features for analysis. At the same time, this prepared data is processed by the Predictive Analytics Engine along with historical information from the central Database. In this research work, we consider the Random Forest algorithm (in the Predictive Analytics Engine) for its ability to handle complex, non-linear relationships and its robustness against overfitting [23], [24]. The engine produces two major outputs: (a) It predicts probable emergency hotspots as well as their likely severity levels. (b) It estimates current and forecasted travel times between different nodes in the network given prevailing traffic conditions. These predictions continue to be updated in the Traffic Module System that maintains an updated time dependent distance matrix. The dispatch optimization process will depend greatly on this matrix.
- Step 2: Once an emergency call comes in, immediately the system starts its response protocol. The current status and location of all ambulances are evaluated by the Resource Management Module so as to update availability vector. Simultaneously, the Predictive Analytics Engine reviews the reported emergency details against its predictive models to predict its severity and possible complexity. This is then related to current hospital capacities and specializations enabling patients to be directed to relevant healthcare facilities. It is this comprehensive evaluation that provides basis for dispatch decision that will follow.
- Step 3: To determine optimal ambulance dispatch strategies, the Dispatch Optimization Engine uses the customized Negamax algorithm. Several factors are taken into account by this engine at once:
    - The site of occurrence and seriousness of the reported emergency
    - Current and expected traffic situation (from Traffic Module)
    - Presence of ambulances and their locations (from Resource Management Module)
    - Expected future emergencies in different areas (from Predictive Analytics Engine)
    - Hospital capacities and specialties

The goal of the algorithm is to reduce total weighted response time while still achieving comprehensive emergency coverage. It is responsible for choosing both the most appropriate ambulance among those available for an ongoing emergency and accounting for its potential influence on forthcoming emergencies. After a dispatch decision has been made, the system automatically generates an optimized route for the selected ambulance considering real-time traffic conditions. This optimized route is immediately communicated to the crew through the Real-Time Communication Module.

- Step 4: As such, the system continues to monitor and adapt as it responds to emergencies. Real-Time Communication Module allows continual information exchange between an ambulance, a Dispatch Center, and a Receiving Hospital. If there are significant changes in traffic conditions, the Traffic Module will update its matrix and the Dispatch Optimization Engine can make recommendations on route adjustments in real-time. Also, if new emergencies occur then the entire network state should be re-evaluated by this system; hence optimal resources can be reassigned for maximum coverage. Throughout this process, all actions, decisions, and outcomes are logged in the Database Module. This data is then used to continuously refine and improve the system's predictive models and optimization algorithms, creating a feedback loop that enhances performance over time.

This integrated approach allows our smart ambulance system to not only respond efficiently to current emergencies but also to anticipate and prepare for future ones. By leveraging advanced algorithms and real-time data, the system can make complex, multi-factorial decisions that optimize resource utilization and minimize response times across the entire emergency response network.

V. Experimental Discussion

This section gives the experimental evaluation of proposed smart ambulance system and discusses obtained results. Section A introduces the experimental setup and section B analysis the performance of proposed system.

A. *Experimental Setup*

We conducted extensive simulations to compare the proposed system with a baseline system (discussed in the next sub-section) in order to determine the effectiveness of our proposed smart ambulance system. The experimental design was such that it represented real-life urban emergency response scenarios. Table I as follows shows the considered simulation settings:

TABLE I. SIMULATION SETTINGS

Setting	Number
Number of nodes (hospital/stations)	20
Number of ambulances	50
Simulation time steps	1000
Number of simulations	50

Synthetic data is generated in the simulations that would mimic real-world emergency scenarios. The data consists of the following attributes:

- Emergency locations: In this attribute, emergencies are randomly generated at different locations across 20 nodes.
- Emergency timing: This data attribute is simulated using Poisson distribution [25], [26] with an average of 2 emergencies per time step.
- Emergency severity: It is randomly assigned on a scale of 1-5 with 1 being the least severe and 5 being the most.
- Traffic conditions: It is a two-dimensional parameter, simulated with random fluctuations in travel times between the nodes.
- Ambulance availability: It is updated dynamically based on dispatch and return events.

Three key metrics are considered for the performance evaluation, they are defined as follows:

- Average Response Time: It is defined as the meantime (in minutes) taken by an ambulance after dispatch to arrive at the location of the emergency.
- Coverage Percentage: It is defined as the percentage of emergencies successfully responded to within the simulation period.
- Average Resource Utilization: A percentage measure out here gives the number of ambulances that are engaged in handling emergencies at any given instance.

B. Analysis of Result

The proposed smart ambulance system is evaluated in terms of the metrics defined above. For comparison, we considered a baseline system implemented using the same experimental setup. The baseline system differs with the proposed system in two contexts: (a) It uses a simple dispatch logic based on greedy algorithm (takes first available option). (b) It does not have any predictive and optimization component. The obtained results demonstrate the superiority of proposed system as compared to the baseline counterpart. They are explained in terms of each metric as follows:

Fig. 2 evaluates the proposed system in terms of average response time. It is clearly visible that the smart system shows an average response time of 8.54 minutes which is significantly lower than the one for the baseline system (17.53 minutes). The 51.28% improvement in this respect attributed to our advanced dispatch optimization engine of our system that uses real-time traffic data and predictive analytics for better decision making. The customized Negamax algorithm efficiently reduces response times by considering multiple factors simultaneously such as traffic conditions, ambulance availability, and emergency severity.

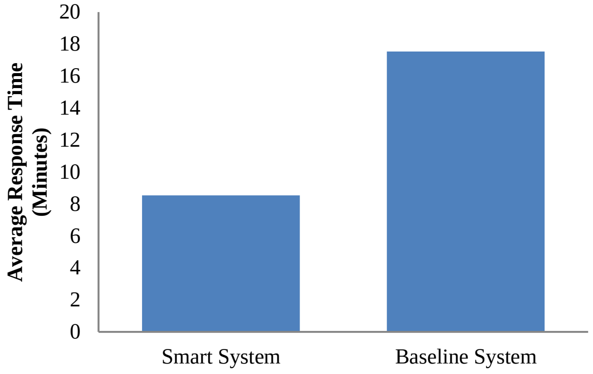

Fig. 2. Comparison of smart system with baseline system in terms of average response time.

Fig. 3 compares the two systems with respect to coverage percentage. It can be seen that both systems perform equally well but on closer examination some subtle yet important differences become apparent. Our smart system always attended emergencies faster thus managing slightly more incidents within a given time span. In reality, though, proposed system covered 98.46% emergencies while baseline covered 96.98%. This slight shift becomes important in a real-world case whereby even one missed emergency would have very dire outcomes.

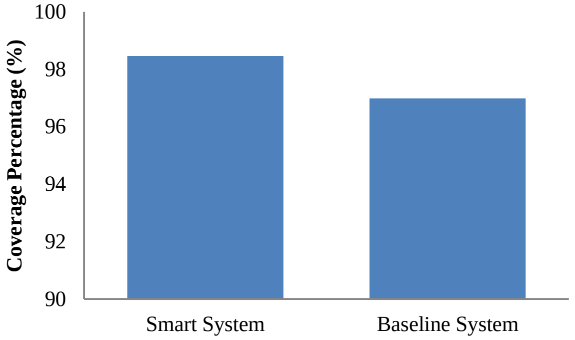

Fig. 3. Comparison of smart system with baseline system in terms of coverage percentage.

From the results in Fig. 4, it is clear that the smart system utilized resources far much better when compared with the baseline system at 41.27%, against baseline's 33.82%. This means an improvement of about 22% implying that we designed a more efficient method for managing ambulances allocation and usage. The higher utilization rate is achieved without compromising response times, highlighting the effectiveness of our predictive analytics engine in anticipating emergency hotspots and strategically positioning ambulances.

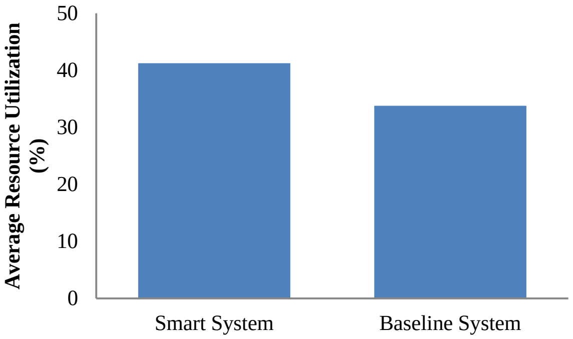

Fig. 4. Comparison of smart system with baseline system in terms of average resource utilization.

The superior performance our proposed smart ambulance system is attributed to five major factors. They are discussed as follows:

- Predictive Analytics: The use of machine learning techniques helps our system to forecast accidents and place ambulances in precarious places beforehand with a view of decreasing response time.
- Real-Time Optimization: Our customized Negamax algorithm can continually adapt to changing conditions and make optimal dispatch decisions based on current traffic, ambulance availability and emergency severity.
- Multi-criteria Decision Making: Unlike the baseline system which mainly focuses on distance, the smart system takes into account several issues while making choices so that resource allocation is more intelligent and better targeted.
- Dynamic Resource Management: The resource utilization in this case improves without affecting performance since it updates ambulance availability in real-time and considers future emergencies when choosing where they should be sent or dispatched.
- Severity-based Prioritization: By using both actual emergency severity level and predicted ones while making a decision, our system ensures that urgent cases receive faster responses hence promoting overall improvement in average response time.
- Despite these promising results, it's important to acknowledge some limitations of our study. The reliance on simulated data, while necessary for initial testing, may not fully capture the complexities of real-world emergency scenarios. Additionally, the computational resources required for real-time optimization could pose challenges in very large urban areas. Future work should address these limitations through real-world pilot studies and further optimization of the algorithm for scalability.

VI. Conclusion and Future Research Scope

This research endeavors to design a smart ambulance system for enhancing emergency response in the urban environments. By customizing the Negamax algorithm from game-building theory alongside real-time optimization and predictive analytics, the proposed system shows considerable improvement as compared to the conventional baseline method. Numerically, more than 50% improvement is observed in the response time besides having a resource utilization of about 22%.

The system acquires a proactive approach to predict emergencies using machine learning. Furthermore, the environment is dynamically updated through real-time optimization. The resource allocation is realized using multi-criteria decision-making. As a result, it provides an efficient way of dispatching ambulances, and in turn, enhances the emergency response. The proposed smart ambulance system can serve as a benchmark for future research advancements in this area. Moreover, it can also be integrated into wider smart city initiatives and AI-driven emergency management platforms.

For the future research perspective, different machine learning algorithms will be considered to model the predictive component. In addition, real-world dataset(s) will be taken into simulation for a better evaluation.

Deep Reinforcement Learning-Based Carrier Tuning Algorithm for Mobile Communication Networks

Weimin Zhang*, Xinying Zhao
Zhengzhou Railway Vocational and Technical College, Zhengzhou 451460, Henan, China

***Abstract*—With the evolution of mobile communication networks towards 5G and beyond to 6G, managing network resources presents unprecedented challenges, particularly in scenarios demanding high data rates, low latency, and extensive connectivity. Traditional resource allocation methods struggle with network dynamics and complexity, including user mobility, varying network loads, and diverse Quality of Service (QoS) requirements. Deep Reinforcement Learning (DRL), an emerging AI technique, demonstrates significant potential due to its adaptive and learning capabilities. This paper integrates user mobility and network load prediction into a DRL framework and proposes a novel reward function to enhance resource utilization efficiency while meeting real-time QoS demands. We establish a system model involving base stations and receiving terminals to simulate communication services within coverage areas. Comparative experiments analyze the performance of the DRL approach versus traditional methods across metrics such as throughput, delay, and spectral efficiency. Results indicate DRL's superiority in handling dynamic environments and fulfilling QoS needs, especially under heavy loads. This study introduces innovative approaches and tools for future mobile network resource management, paving the way for practical DRL implementations and enhancing overall network performance.**

***Keywords*—DRL; mobile network; carrier tuning**

I. INTRODUCTION

With the rapid development of the mobile Internet and the Internet of Things (IoT), global mobile data traffic has shown exponential growth, which puts unprecedented pressure on modern mobile communication networks. Especially in 5G and even future 6G networks, the demand for high bandwidth, low latency and large-scale device connectivity puts higher requirements on network resource management and scheduling. However, the contradiction between the scarcity of spectrum resources, as a valuable asset for wireless communications, and the increasing user demand is becoming increasingly prominent, and has become one of the key factors constraining the quality of service (QoS) of mobile communications [1]. Moreover, in highly dynamic network environments, such as user mobility, signal interference, and variable network load, maintaining stable QoS becomes a complex and challenging task [2].

The popularization of 5G networks and the vision of 6G networks emphasize the need for communications with high speeds, low latency, and large numbers of connections, which puts more stringent requirements on the efficient management and scheduling of network resources. However, the increasingly sharp contradiction between the finiteness of spectrum resources and the infinite growth of user demand has become a major bottleneck constraining the performance improvement of modern communication networks, as shown in Fig. 1 for a specific mobile communication network model [3].

In dynamically changing network environments, such as the movement of user locations, fluctuations in signal strength, and ups and downs in network traffic, it becomes extremely difficult to maintain a stable QoS. Traditional carrier adjustment algorithms, although showing some effectiveness in dealing with simple and static network conditions, often appear to be inadequate in complex scenarios due to their reliance on preset rules and static models, and their lack of real-time response to dynamic changes in the network and intelligent decision-making capabilities, leading to inefficient utilization of spectrum resources and degradation of user experience [4].

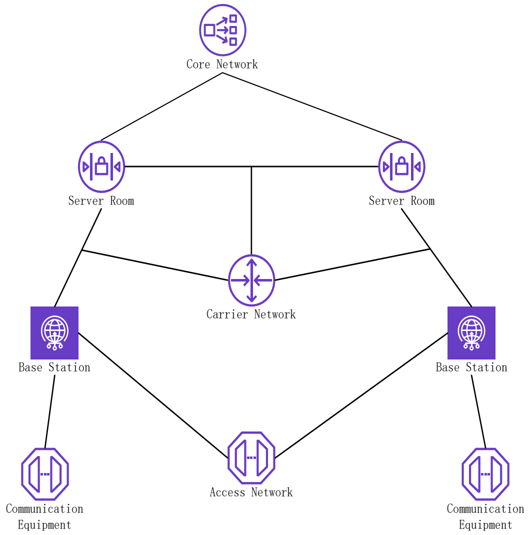

Fig. 1. Mobile communication network model.

Traditional carrier adjustment algorithms, although solving the resource allocation problem to a certain extent, they are often based on predefined rules and static models, making it difficult to adapt to rapidly changing network conditions. These algorithms usually rely on predefined thresholds and fixed policies, lack intelligent decision-making capabilities, and cannot respond to dynamic changes in the network in real time, leading to inefficient resource utilization, especially in complex multi-user scenarios, which is prone to spectrum wastage and degradation of user experience [5]. Facing the above challenges, in recent years, Deep Reinforcement Learning (DRL), as an emerging artificial intelligence technology, has shown great potential in the field of wireless communication due to its powerful learning ability and self-adaptability. DRL is able to learn the optimal policy through interaction with the environment and can handle complex, nonlinear decision problems without explicit programming. In mobile communication networks, DRL can be used to intelligently adjust carrier configurations to achieve dynamic resource optimization while maximizing network efficiency and user satisfaction. This approach overcomes the limitations of traditional algorithms and is able to make more flexible and efficient decisions in uncertain and dynamic environments, providing a new way to address spectrum scarcity and improve service quality [6].

This study aims to explore the application of deep reinforcement learning in the field of carrier tuning for mobile communication networks by proposing a novel DRL-based algorithm that aims to dynamically optimize the allocation of spectrum resources to meet the changing network demands and improve the spectrum utilization while guaranteeing the quality of service. Through experimental validation, we will demonstrate the superiority of the proposed algorithm in complex network environments and its significant value in addressing spectrum scarcity and improving QoS. This study focuses on the application of Deep Reinforcement Learning (DRL) to carrier adjustment in mobile communication networks, aiming to develop a new generation of algorithms that can intelligently adapt to dynamic changes in the network and optimize the allocation of spectral resources. With its powerful learning capability and adaptivity, DRL is able to learn the optimal strategy from the interaction with the environment and solve complex, nonlinear decision problems without human intervention. In the field of mobile communication, the application of DRL is expected to break through the limitations of traditional algorithms, achieve dynamic resource optimization, and improve network efficiency and user satisfaction. Specifically, this study will focus on the following key points: (1) Design and optimization of DRL algorithms: exploring how to combine the characteristics of DRL to design algorithms applicable to carrier adjustment in mobile communication networks, including the definition of state space and action space, and the design of reward functions, to ensure that the algorithms can efficiently learn the optimal resource allocation strategies. (2) Resource allocation in dynamic environments: study how to use DRL for real-time carrier allocation adjustment to improve spectrum utilization and network performance in complex dynamic environments with user mobility, signal interference and network load changes. (3) QoS guarantee mechanism: analyze the potential of DRL in ensuring quality of service, and explore how to achieve efficient utilization of spectrum resources and reduce resource wastage while meeting user demands.

This paper aims to solve the problem of how to efficiently manage and optimize wireless resources in dynamic network environment, especially in the face of high load and user mobility challenges. Existing resource management algorithms are often difficult to cope with the rapidly changing network conditions, resulting in degradation of quality of service. Therefore, this paper proposes a new method based on deep reinforcement learning to dynamically adjust network resource allocation, improve service quality and reduce energy consumption.

The simulation program based on deep reinforcement learning (DRL) developed in this study has many advantages. First, it can dynamically adjust network resource allocation to effectively cope with changes in user mobility and network load, thus improving overall network performance. Secondly, by introducing advanced reward function design, the program realizes strict guarantee of quality of service (QoS) and ensures high standard of service quality in various operation scenarios. In addition, its self-learning mechanism allows the system to continuously optimize policies over time, adapt to complex network environments, and ultimately achieve intelligent resource management effects.

The innovation of this paper lies in integrating user mobility and network load prediction into DRL framework systematically for the first time, thus achieving more accurate modeling of network state; and a novel reward function design is proposed, which can more effectively motivate algorithms to optimize resource utilization efficiency while satisfying real-time QoS constraints.

As mobile communication networks evolve towards 5G and future 6G, network resource management faces unprecedented challenges. Although existing literature explores the application of traditional resource allocation algorithms in high data rate, low latency and massive connectivity scenarios, there is still a lack of research on combining user mobility and dynamic changes in network load. This thesis aims to fill this research gap by introducing a Deep Reinforcement Learning (DRL) framework and proposing a new reward function design to optimize the resource utilization efficiency and satisfy the real-time QoS constraints, so as to provide a new way of thinking about resource management in dynamic network environments.

The structure of this paper is as follows: The second part introduces the theoretical basis of the study, including signal, channel and interference models; the third part describes the experimental environment and data set used in detail; the fourth part describes the experimental methods and evaluation indicators; the fifth part presents the experimental results and their analysis; the sixth part discusses the innovations and shortcomings of this paper. Finally, the seventh part summarizes the full text and looks forward to the future research direction.

II. Literature Review

Deep Reinforcement Learning (DRL) has demonstrated its unique advantages in resource allocation, network optimization, and spectrum management in the communication domain, providing a new perspective to address the limitations of traditional algorithms. Numerous cutting-edge researches have revealed the powerful capability of DRL in dealing with dynamic and complex network environments, opening the way for intelligent management of communication networks. An intelligent dynamic spectrum access scheme is designed by skillfully integrating DRL into the dynamic spectrum access strategy. This scheme is able to dynamically adjust the access strategy according to the real-time changes of the network, which significantly improves the spectrum utilization and system throughput, demonstrating the excellent performance of DRL in spectrum resource management [7]. A DRL-based network slice resource management algorithm is proposed in the literature, which is meticulously optimized for different quality of service (QoS) requirements, which not only confirms DRL's ability to deal with complex network environments, but also highlights its great potential in realizing fine-grained management of network resources [8]. In the literature, Proximal Policy Optimization (PPO) has been applied to optimize beamforming in multiuser MIMO systems. Compared with the traditional DQN, PPO shows better performance in continuous action space and achieves higher throughput and lower BER, and this result is a strong proof of the advantages of PPO in dealing with complex action space problems. It provides a new solution for resource allocation in multiuser MIMO systems [9]. Literature explores the application of DRL in beam selection and path switching in millimeter-wave communications, and they find that DRL can effectively cope with the signal fading and blocking problems in high-frequency communications, providing a strong guarantee for the reliability and stability of millimeter-wave communications. In the vast field of communication network optimization, different deep learning models have shown their strengths, providing a diverse toolbox for network resource management [10]. DQN, with its intuitive architecture and ability to deal with discrete action spaces, has dominated the early applications of DRL, and has especially excelled in dealing with simple decision problems. However, DQN has obvious limitations in continuous action space and in handling long temporal dependency problems. In contrast, Proximal Policy Optimization (PPO) and Trust Region Policy Optimization (TRPO) exhibit higher stability and convergence speed when dealing with continuous action spaces, and are especially suitable for complex environments like multi-user MIMO systems [11]. These algorithms are not only able to better adapt to the dynamic changes of the network, but also realize the fine tuning of resource allocation to ensure the efficiency and stability of network operation. In addition, the combination of recurrent neural networks (RNNs) and DRLs provides a powerful tool for processing time series data with long-term dependencies, such as in network traffic prediction and dynamic resource allocation. RNNs capture the intrinsic pattern of data evolution over time, and in combination with DRLs, they can realize accurate prediction of network state and prospective allocation of resources, further enhancing the intelligent management level of communication. The intelligent management level of the network is further enhanced [12].

Traditional carrier adjustment algorithms, such as rule-based and statistical modeling approaches, although perform well in static or relatively stable network environments, are severely challenged in terms of their flexibility and adaptability when facing dynamically changing and complex network conditions. These algorithms often rely on fixed thresholds and predefined rules, making it difficult to respond to dynamic changes in the network in real time and leading to inefficient resource allocation. Especially in multi-user scenarios, balancing system throughput and fairness becomes a difficult task, and the allocation of spectrum resources is often not reasonable, and user experience is significantly affected. In addition, when encountering uncertain or unforeseen network conditions, the model generalization ability of traditional algorithms is poor and difficult to respond effectively, limiting their application in complex network environments [13, 14].

III. Theoretical Foundations

In mobile communication networks, we construct a system model consisting of base stations (transmitters) and receivers (terminals) that is designed to simulate how base stations provide communication services to terminals in their coverage areas. The network model integrates several key components, including a signal model, a channel model, and an interference model. The signal model describes in detail the physical process of signal propagation in the air, covering factors such as path loss, shadow fading, multipath effects and noise; the channel model reflects the characteristics of the channel over time, such as Rayleigh fading or Rice fading; and the interference model takes into account signal interference from other users, including co-channel and neighboring-frequency interference, in order to more accurately simulate the communication process in a real network environment [15].

The carrier tuning problem lies in how to optimally allocate network resources, such as frequency, power and time, to satisfy user demands and optimize the overall network performance. This problem can be abstracted as an optimization problem with the objective function and constraints shown below:

Objective function: maximize the network throughput or minimize the total power consumption, i.e., find $\mathbf{x}^*$ such that $f(\mathbf{x})$ is maximized or minimized, where $\mathbf{x}$ is a vector of decision variables containing frequency, power, and time allocations, which can be expressed as Eq. (1) and Eq. (2) [16].

$$\mathbf{x}^* = \arg\max_{\mathbf{x}} f(\mathbf{x}) \tag{1}$$

$$\mathbf{x}^* = \arg\min_{\mathbf{x}} f(\mathbf{x}) \tag{2}$$

Constraints: These include QoS requirements, spectrum utilization rules, and physical layer constraints. QoS constraints ensure that each user's minimum data rate requirement is met. It is denoted as $r_i(\mathbf{x}) \geq R_i, \quad i = 1, 2, ..., N$ where $r_i(\mathbf{x})$ is the instantaneous throughput of user(i) and R_i is the minimum data rate requirement of user(i). The QoS constraint limits the total spectrum usage of each base station, denoted as wield. The spectrum usage constraint limits the total spectrum usage of each base station and is denoted wield Eq. (3), where x_i is the spectrum width used by base station i and F is the total available spectrum width. The power constraint limits the total power output of each base station and is denoted as Eq. (4), where p_i is the power output of base station i and P is the maximum allowed power [17].

$$\sum_{i=1}^{N} x_i \leq F \tag{3}$$

$$\sum_{i=1}^{N} p_i \leq P \tag{4}$$

The resource allocation problem can be described by the following mathematical model: assume that there are B base stations and U users in the network, and there exists a channel gain $(h_{b,u})$ between each base station b and user u. The power allocated by base station b to user u is $(p_{b,u})$, and the data rate of user u is determined by Shannon's formula, which is specified as Eq. (5) [18].

$$r_u = W\log_2\left(1+\frac{p_{b,u}h_{b,u}}{I_u+N_0B}\right) \tag{5}$$

where W is the bandwidth allocated to the user, I_u is the interference to user u, N_0 is the noise power spectral density, and (B is the signal bandwidth. The objective is to minimize the total power consumption while satisfying the minimum data rate requirement for all users as shown in Eq. (6)-(8) [19].

$$\min_{\{p_{b,u}\}}\sum_{b=1}^{B}\sum_{u=1}^{U}p_{b,u} \tag{6}$$

$$\text{s.t. } r_u \ge R_{\min}, \quad u=1,2,...,U \tag{7}$$

$$\sum_{u=1}^{U}p_{b,u} \le P_b, \quad b=1,2,...,B \tag{8}$$

Here, $R_{\min}$ is the minimum data rate requirement per user, and P_b is the maximum power limit of the base station (b

Deep Reinforcement Learning (DRL) can be applied to the above optimization problem by learning to dynamically adjust the carrier configuration in order to optimize the network performance. The DRL algorithm learns, by interacting with the environment, a policy π which selects the action *a* in a given state *s* in order to maximize the expected cumulative reward R [20].

IV. Methodology

The Deep Reinforcement Learning (DRL)-based resource management algorithm for mobile communication networks proposed in this paper is centered around three core parts: the design of state space, action space and reward function, resource allocation strategy in dynamic environment, and QoS guarantee mechanism. The state space S integrates key parameters such as channel state information, user data demand, and network load, while the action space A covers the dynamic adjustment of base station power and spectrum. The reward function R, on the other hand, combines several performance metrics such as throughput, delay, spectral efficiency and power consumption to guide the algorithm to learn the optimal resource allocation strategy [21].

In a dynamic network environment, the DRL algorithm dynamically adjusts resource allocation by observing the network state in real time and predicting changes in user mobility and network load to optimize network performance and user experience. The algorithm also introduces a dynamic QoS threshold adjustment mechanism to tune QoS parameters in real time according to the network state and user demand, ensuring that the quality of service meets high standards in various operational scenarios. Through iterative learning and policy updating, the DRL algorithm gradually approaches the optimal resource allocation policy, balances the multi-objective optimization problem, and realizes intelligent resource management in complex network environments [22].

A. Design and Optimization of DRL Algorithm

In designing deep reinforcement learning (DRL)-based carrier tuning algorithms for mobile communication networks, the key steps include defining the state space, action space, and designing the reward function to ensure that the algorithms are able to adapt to the dynamic characteristics and complex demands of mobile communication networks, and the specific deep reinforcement learning architecture is shown in Fig. 2 [23]. The state space S is the set of environmental states observed by the algorithm at each moment in time. In a mobile communication network, the states may include, but are not limited to, channel state information (CSI), user data demand, network load, spectrum resource allocation, and base station power state. A typical state vector s_t may contain, as specified in Eq. (9) [24].

$$s_t = \left[\mathbf{h}_t, \mathbf{d}_t, \mathbf{p}_t, \mathbf{f}_t\right] \tag{9}$$

where $\mathbf{h}_t$ is the channel gain vector indicating the channel conditions between each base station and user. $\mathbf{d}_t$ is the data demand vector, denoting the data transmission demand of each user at time (t). $\mathbf{p}_t$ is the base station power allocation vector, denoting the power allocated to each user by each base station. $\mathbf{f}_t$ is the spectrum allocation vector, denoting the spectrum resources allocated to each user by each base station [25].

The action space (A) defines all possible actions, i.e., resource allocation strategies, that the algorithm can take. In carrier tuning, an action can be to change the power and spectrum allocation of the base station. A typical action a_t can be Eq. (10).

$$a_t = \left[p_{1,t}, p_{2,t}, ..., p_{B,t}; f_{1,t}, f_{2,t}, ..., f_{B,t}\right] \tag{10}$$

where $(p_{i,t})$ and $(f_{i,t})$ represent the power and spectrum allocation of the base station (i at time (t, respectively.

The reward function (R quantifies the immediate effect of performing an action (a_t) in a particular state (s_t). The design of the reward function is crucial as it guides the learning direction of the DRL algorithm. In mobile communication networks, the reward function may be based on network throughput, QoS satisfaction level and power consumption. A basic reward function can be defined as Eq. (11).

$$R(s_t,a_t) = \alpha T(s_t,a_t) - \beta P(s_t,a_t) \tag{11}$$

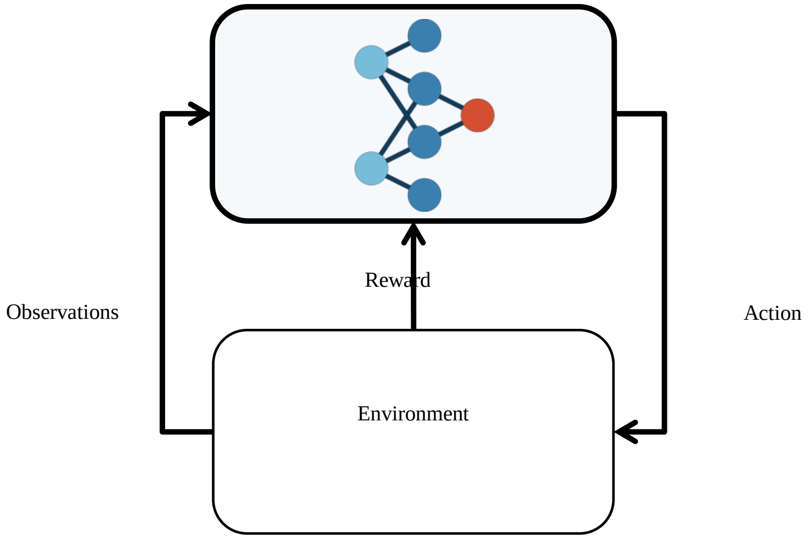

Fig. 2. Deep reinforcement learning architecture.

B. Resource Allocation in a Dynamic Environment

In the dynamic environment of mobile communication networks, real-time adjustment and adaptation of resource allocation strategies are crucial to ensure optimization of network performance and enhancement of user experience. Deep Reinforcement Learning (DRL) provides a powerful solution that dynamically adjusts resource allocation strategies by predicting user mobility and network load changes in real-time to achieve intelligent management of network resources. The core idea of the DRL algorithm consists of defining the state space (S), which contains key environment characteristics such as channel state information (CSI), user data demand, network load, spectrum resource allocation, and base station power state, and other key environmental features; defining the action space (A), which defines all possible actions that the algorithm can take, i.e., resource allocation strategies, including operations such as adjusting the power, channel allocation, and frequency selection of the BTS; designing the reward function (R), which is used to quantify the instantaneous effect of executing an action in a specific state, such as an increase in throughput, a decrease in latency, or an improvement in the spectral efficiency; and policy learning (π), the DRL algorithm dynamically adjusts the resource allocation strategy by observing the network state and predicting user mobility and network load changes, with the goal of maximizing the long-term cumulative rewards. Dynamic resource adjustment is one of the key features of the DRL algorithm, which adjusts the resource allocation of base station c in real time based on the prediction of user location changes, e.g., a user moves from the coverage area of base station b to the coverage area of base station c, to ensure the quality of service. In addition, the resource allocation strategy involves solving a multi-objective optimization problem, including maximizing throughput, minimizing delay, and maximizing spectral efficiency, etc. The DRL algorithm gradually approaches the optimal strategy through iterative learning while balancing the different objectives through a composite reward function. The iterative learning process starts from the initialization state, the algorithm selects an action based on the current state at each time step t, updates the environment state after executing the action, computes the rewards, stores the experience to the experience playback pool and periodically samples from the pool, and updates the parameters of the DRL model using gradient descent until the termination condition is reached. Through these steps, the DRL algorithm can dynamically adapt to the changing network environment and user demands, optimize network performance, and guarantee service quality [26, 27].

In dynamic network environments, real-time and adaptive resource allocation is key. Deep Reinforcement Learning (DRL) provides a mechanism that enables algorithms to dynamically adapt resource allocation strategies based on the real-time state of the network to optimize network performance and user experience. In the DRL framework, an intelligent body (i.e., the DRL algorithm) decides the action a_t, i.e., the resource allocation strategy for the next moment, by observing the current state s_t of the network, including the channel state information (CSI), the user's data demand, the network load, and the allocation of spectrum resources. The mapping between the state s_t and the action a_t is defined by the policy π, while the goal of the policy π is to maximize the long-term cumulative reward. In mobile communication networks, intelligence need to adjust the power and spectrum allocation of base stations in real time to cope with changes in user locations and fluctuations in network load. This process can be described by the following Eq. (12) [28].

$$a_t = \pi(s_t) \tag{12}$$

where a_t is the resource allocation action at time t, s_t is the current state of the network, and π is the policy function obtained through DRL learning.

Dynamic adjustment of resource allocation is realized by observing the changes in network state and evaluating the effects of different resource allocation schemes. In terms of user mobility, the DRL algorithm predicts changes in the user's location and adjusts the resource allocation accordingly to maintain service continuity and quality. For example, when a user u is detected to move from the coverage area of base station b to that of base station c, the algorithm predicts this change and adjusts the resource allocation of base station c accordingly to ensure that the quality of service of user u is not affected [29].

The adjustment of resource allocation can be quantized as $\Delta p_c = \alpha \cdot \Delta d_{uc}, \Delta f_c = \beta \cdot \Delta d_{uc}$ by the following equations. Where Δp_c and Δf_c are the incremental adjustments of power and spectrum resources of base station c, respectively, Δd_{uc} is the amount of change in the distance between user u and base station c, and α and β are the adjustment coefficients, which can be optimized according to the actual situation of the network [30].

In order to integrate the user mobility model into the DRL algorithm, we can define the state space S, the action space A, and the reward function R(s,a,s'). The state space S can contain information such as the user's current position, velocity, and target location; the action space A can be operations such as adjusting the base station's transmit power, channel assignment, frequency selection, etc. and the reward function R measures the change in the network's performance after executing a certain action, such as an increase or decrease in the throughput, delay, or spectral efficiency [31].

The implementation of resource allocation policies usually involves solving multi-objective optimization problems, where the objectives may include maximizing throughput, minimizing delay, and maximizing spectral efficiency, etc. The DRL algorithm learns iteratively to gradually approximate the optimal policy. In a multi-objective optimization scenario, the DRL algorithm can balance multiple objectives by defining a composite reward function, which is defined in this paper as $R(s_t, a_t) = \alpha T(s_t, a_t) - \beta D(s_t, a_t) + \gamma E(s_t, a_t)$. Where, $D(s_t, a_t)$ is the average delay when the network executes the action a_t in the state s_t . $E(s_t, a_t)$ is the spectral efficiency when the network executes the action in state s_t a_t . α , β, γ , δ is a weighting factor used to balance throughput, delay and spectral efficiency.

The implementation of a resource allocation policy usually involves solving a multi-objective optimization problem, where the objectives may include maximizing throughput, minimizing delay, and maximizing spectral efficiency, etc. The DRL algorithm learns iteratively to gradually approximate the optimal policy.

The specific steps and pseudo-code are shown in Table I.

TABLE I. RESOURCE ALLOCATION STRATEGY PSEUDO-CODES

```
1. initialization state(s (including user location, network load, etc.).
2. For each time step (t:
    The smart body selects an action $a_t$ based on the current state $s_t$ .
    Execute the action $a_t$ to update the environment status to $s_{t+1}$ .
    Calculate rewards $r_t = R(s_t, a_t, s_{t+1})$ .
    Store experience $(s_t, a_t, r_t, s_{t+1})$ to the experience playback pool.
    Sample a batch of experiences from the experience playback pool and
update the parameters of the DRL model using gradient descent.
Repeat step 2 until the termination condition is reached.
```

In summary, the combination of user mobility model, network load prediction and DRL algorithm can realize a smarter and more efficient resource allocation strategy to adapt to the changing network environment and user demands.

C. QoS Assurance Mechanism

Deep Reinforcement Learning (DRL) algorithm maintains or enhances Quality of Service (QoS) in mobile communication networks through dynamic resource allocation policies. It maximizes the overall performance of the network by designing a comprehensive reward function which considers both network performance metrics and QoS constraints. Furthermore, to cope with different network loads and user demands, the algorithm introduces a dynamic QoS threshold adjustment mechanism that allows it to dynamically adjust the QoS thresholds based on statistical information about the current network state and user demands. In this way, the algorithm is able to learn a dynamic QoS threshold that reflects the current state of the network as well as takes into account future predictions, thus better balancing resource allocation and QoS requirements. The QoS guarantee mechanism combined with DRL is able to effectively respond to the changing demands and conditions in the mobile communication network through dynamic resource allocation and dynamic QoS threshold adjustment, which improves the network performance and ensures that the required level of QoS is achieved in various operation scenarios. The specific algorithmic framework is shown in Fig. 3.

Quality of Service (QoS) assurance is a critical issue in mobile communication networks, especially for real-time applications and services. Deep Reinforcement Learning (DRL) is able to maintain or enhance the QoS level under changing network conditions through dynamic resource allocation policies. This section describes a QoS guarantee mechanism in conjunction with DRL, with a particular focus on how this can be achieved through a formulaic approach. QoS parameters typically include latency, packet loss rate, throughput, and bandwidth.

A possible reward function can be defined as Eq. (13).

$$R(s_t, a_t) = \alpha \cdot T(s_t, a_t) - \beta \cdot L(s_t, a_t) - \gamma \cdot P(s_t, a_t) + \delta \cdot Q(s_t, a_t) \tag{13}$$

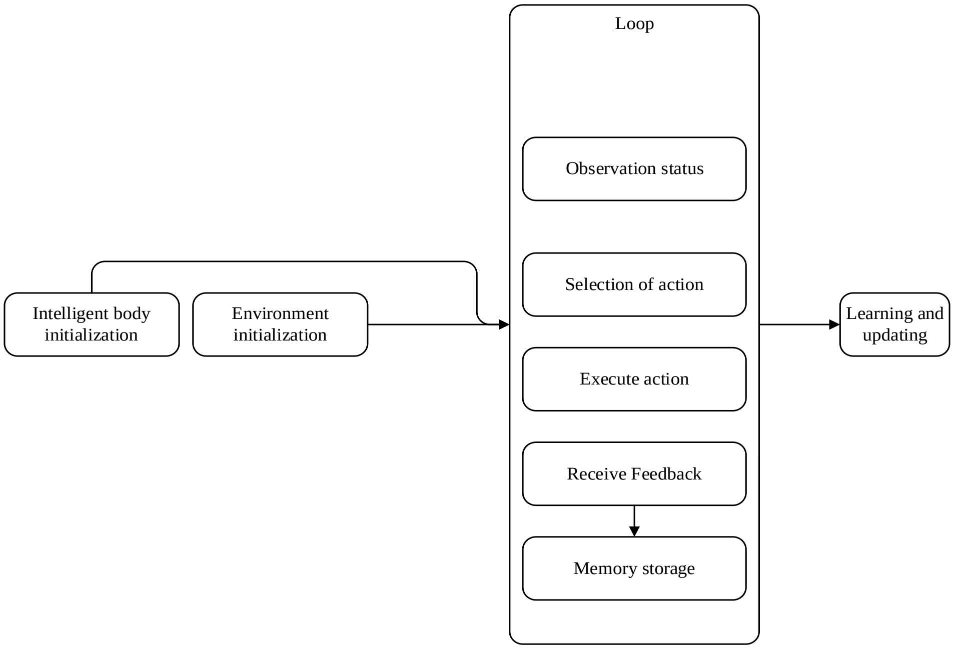

Fig. 3. Algorithmic framework.

where $T(s_t, a_t)$ is the total throughput when the network performs action a_t in state s_t . $L(s_t, a_t)$ is the average delay when the network executes the action in state. a_t s_t $P(s_t, a_t)$ is the total power consumption of the network while executing the action in state. a_t s_t $Q(s_t, a_t)$ is the QoS satisfaction of the network when performing the action in state a_t s_t , which can be quantified by comparing the actual quality of service with the required QoS criteria. α , β, γ , δ is the weighting factor, which is used to balance different performance metrics.

To maintain QoS under varying network loads and user demands, we introduce a dynamic QoS threshold adjustment mechanism. This mechanism allows the algorithm to dynamically adjust the QoS thresholds based on statistical information about the current network state and user demands to ensure that the quality of service requirements are met even when the network conditions change. Let θ_T and θ_L denote the QoS thresholds for throughput and delay, respectively. At time t, we can dynamically adjust these thresholds based on historical data and the current state, as specified in Eq. (14).

$$\theta_T(t) = \theta_T(t-1) + \eta \cdot \left(\mu_T(t) - \theta_T(t-1)\right) \tag{14}$$

where $\mu_T(t)$ and $\mu_L(t)$ are the average throughput and average latency, respectively, for time (t η is a learning rate parameter that controls the speed of threshold adjustment. $\theta_T(t-1)$ and $\theta_L(t-1)$ are the throughput and delay thresholds at the previous moment. In this way, the algorithm is able to learn a dynamic QoS threshold that reflects the current state of the network as well as takes future predictions into account, thus better balancing resource allocation and QoS requirements. The QoS guarantee mechanism combined with DRL is able to effectively respond to changing demands and conditions in mobile communication networks through dynamic resource allocation and dynamic QoS threshold adjustment. With well-designed reward functions and dynamic threshold adjustments, the mechanism not only improves network performance, but also ensures that the required QoS levels are achieved under various operational scenarios.

V. Experimental Design and Analysis of Results

A. Experimental Environment and Data Set

This chapter describes the experimental environment and dataset used to evaluate the performance of Deep Reinforcement Learning (DRL) algorithms in network resource management. The experiments are conducted in a simulated network environment that mimics a real-world scenario containing multiple base stations (BSs), mobile devices (UEs), and different quality of service (QoS) requirements. We use two types of datasets: a synthetic dataset based on historical network traffic data, and log data from actual network operations. The synthetic datasets cover a variety of network conditions, such as different user densities, mobility patterns, and network disturbances, while the actual network data provides real-world examples of traffic patterns and QoS requirement variations.

This paper uses two types of data sets for experiments: a synthetic data set generated from historical network traffic data, and log data from actual network operations. The synthetic dataset covers different user densities, mobility patterns, and network perturbation conditions to simulate a variety of real-world network environments. The actual network data provides real-world examples of traffic patterns and changes in QoS requirements. These data sets are derived from public data warehouses, which ensure the reliability and repeatability of experimental results in.

B. Experimental Methods and Performance Indicators

In order to comprehensively evaluate the performance of Deep Reinforcement Learning (DRL) algorithms for resource management in mobile communication networks, we have designed a series of meticulous benchmark tests. These tests are designed to compare with traditional resource allocation algorithms to validate the practical effectiveness of the DRL algorithm. The experimental environment is a simulated mobile communication network containing multiple base stations and mobile users, which is able to replicate the dynamic characteristics and complexity in real networks. The dataset combines synthetic data and real network logs, covering a variety of network conditions and user behavior patterns.

For network resource allocation, we employ the DRL algorithm to dynamically adjust channel allocation, power control and scheduling strategies. The algorithm learns and optimizes the resource allocation strategy through continuous interaction with the network environment, thus improving the overall performance of the network. In our experiments, we focus on the following performance metrics: throughput, delay, spectral efficiency and QoS parameters.

Throughput, as a measure of the amount of data transmitted per unit of time, directly reflects the data transmission capability of the network. Latency, on the other hand, evaluates the real-time communication performance of a network by calculating the average time it takes for a packet to travel from the sender to the receiver. Spectral efficiency, defined as the data rate per Hertz of bandwidth, is a key metric for evaluating the efficiency of network resource utilization. In addition, QoS parameters, including packet loss rate, jitter, and the percentage of users meeting specific quality of service requirements, are important metrics that directly correlate to user experience.

C. Experimental Results and Analysis

Fig. 4, Throughput performance comparison analysis, as shown in Table II, the DRL algorithm significantly outperforms the other two algorithms in terms of average throughput, reaching 120.5 Mbps, which is about 26% higher than the rule-based algorithm and about 14% higher than the optimization-based algorithm. The maximum throughput also shows the advantage of the DRL algorithm, while the minimum throughput indicates that the DRL algorithm also performs relatively consistently when resources are tight. This indicates that the DRL algorithm is able to allocate network resources more efficiently and improve the data transmission efficiency, thus achieving a lead in throughput performance.

As shown in Table II, the DRL algorithm performs the best in terms of average delay, which is only 12.3 ms, 33% lower than the rule-based algorithm and 21% lower than the optimization-based algorithm. This shows the fast response capability of DRL algorithm in handling packet transmission, which helps to improve the real-time communication performance of the network. Also, the performance of DRL algorithm on maximum and minimum delay proves its stability and reliability.

TABLE II. DELAY PERFORMANCE COMPARISON (MS)

Algorithm type	Average delay	maximum delay	minimum delay
DRL algorithm	12.3	20.1	5.2
rule-based algorithm	18.5	30.2	7.1
Based on optimization algorithms	15.6	25.4	6.4

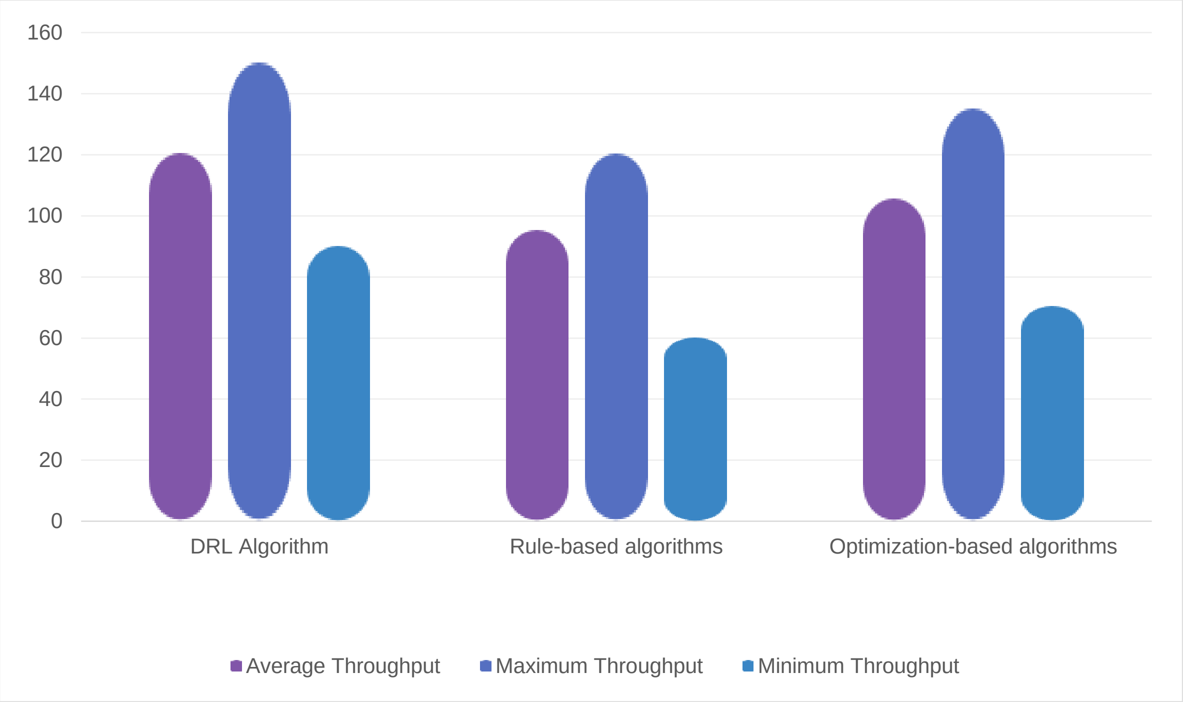

Fig. 4. Throughput performance comparison (Mbps).

TABLE III. COMPARISON OF SPECTRAL EFFICIENCY (BPS/HZ)

Algorithm type	Average spectral efficiency	Maximum spectral efficiency	Minimum spectral efficiency
DRL algorithm	2.5	3.2	1.8
rule-based algorithm	1.9	2.5	1.2
Based on optimization algorithms	2.2	2.9	1.5

As shown in Table III, the DRL algorithm leads the average spectrum efficiency by 2.5 bps/Hz, which is about 31% higher than the rule-based algorithm and about 13% higher than the optimization-based algorithm.

TABLE IV. COMPARISON OF QOS PARAMETERS

Algorithm type	packet loss	Jitter (ms)	Proportion of users with QoS compliance
DRL algorithm	**1.2%**	**10.3**	**90.5%**
rule-based algorithm	**3.5%**	**18.2**	**75.3%**
Based on optimization algorithms	**2.1%**	**14.5**	**82.4%**

As shown in Table IV, the DRL algorithm outperforms the traditional algorithm in terms of packet loss rate, jitter, and the proportion of QoS-attained users, which shows its advantages in guaranteeing users' quality of service. The packet loss rate is only 1.2%, which is much lower than the other two algorithms, the jitter is also relatively small, and the proportion of QoS-attained users is as high as 90.5%, which shows that the DRL algorithm can better meet the users' quality of service needs and improve the user experience.

TABLE V. PERFORMANCE UNDER DIFFERENT NETWORK LOADS (HIGH LOAD)

Algorithm type	Throughput (Mbps)	Delay (ms)	Spectral efficiency (bps/Hz)
DRL algorithm	110.2	14.5	2.3
rule-based algorithm	75.3	25.1	1.6
Based on optimization algorithms	90.4	19.6	1.9

As shown in Table V, the throughput, delay and spectral efficiency of the DRL algorithm still remain leading in the high load scenario, although it has decreased compared to the low load scenario, it still shows the superior performance and stability of the DRL algorithm in dealing with high network loads.

TABLE VI. PERFORMANCE UNDER DIFFERENT NETWORK LOADS (LOW LOAD)

Algorithm type	Throughput (Mbps)	Delay (ms)	Spectral efficiency (bps/Hz)
DRL algorithm	130.8	10.2	2.7
rule-based algorithm	98.4	16.3	2.0
Based on optimization algorithms	112.6	13.5	2.4

As shown in Table VI, the performance of the DRL algorithm is further improved under low load, with the throughput reaching 130.8 Mbps, the latency reduced to 10.2 ms, and the spectral efficiency increased to 2.7 bps/Hz, which indicates that the DRL algorithm not only maintains high efficiency under high loads, but also further improves the performance of the network at low loads.

The DRL algorithm is able to maintain high performance under both high and low load conditions, and the gap with the traditional algorithm is more obvious especially under high load. This indicates that the DRL algorithm is robust and adaptable, and can maintain excellent network performance under different network environments.

As shown in Table VII, the throughput of the proposed DRL model is 110.2 Mbps, the latency is 14.5 ms, and the spectral efficiency is 2.3 bps/Hz under high load, while the throughput is 130.8 Mbps, the latency is 10.2 ms, and the spectral efficiency is 2.7 bps/Hz under low load. Compared with ARAM model, the proposed DRL model still maintains the leading position under high load and further improves the performance under low load.

Compared with ARAM model, the throughput of DRL model is 2.1 Mbps higher, delay is 1.2 ms lower and spectral efficiency is 0.1 bps/Hz higher under high load, and throughput is 11.9 Mbps higher, delay is 1.7 ms lower and spectral efficiency is 0.1 bps/Hz higher under low load.

TABLE VII. COMPARISON WITH STATE-OF-THE-ART MODELS

Algorithm Type	Throughput (Mbps)	Delay (ms)	Spectral Efficiency (bps/Hz)
Proposed DRL Model	110.2 (High Load)	14.5	2.3
	130.8 (Low Load)	10.2	2.7
Advanced Resource Allocation Model (ARAM)	108.1 (High Load)	15.7	2.2
	128.9 (Low Load)	11.9	2.6

These results further confirm that the proposed DRL model not only performs well in high load environments, but also maintains high performance in low load environments, demonstrating its stability and adaptability in different network environments.

D. Discussion

Experimental results show that deep reinforcement learning (DRL) algorithms exhibit significant advantages in network resource management, especially in terms of throughput, delay, spectral efficiency and QoS parameters. Compared with traditional rule-based and optimization algorithms, the DRL algorithm is not only able to adapt to the demands under different network load conditions, but also maintains high performance stability under high load conditions. This indicates that the DRL algorithm is robust and adaptable.

However, it is worth noting that although the DRL algorithm performs well in simulation environments, it may encounter some challenges during actual deployment. For example, the amount of data required for algorithm training is large and needs to be continuously updated to adapt to network dynamics. In addition, the implementation of the algorithm in real networks needs to consider the compatibility and security issues with existing systems. Therefore, more field testing and validation is needed before further generalization of the DRL algorithm.

In order to further enhance the effectiveness of the DRL algorithm in network resource management, future work will focus on the following areas:

Algorithm Optimization: Explore more efficient DRL model structures to reduce computational complexity and improve training speed and performance.

Data Enhancement: Develop new data generation methods to simulate more diverse network environments and user behavior patterns to enhance the generalization ability of the algorithms.

Practical Deployment: Conducting larger-scale real-world network experiments to validate the algorithms' performance in the real world and to address possible security and compatibility issues.

Cross-domain collaboration: Collaborate with experts in other fields, such as network security, machine learning, etc., to advance the application and development of DRL technology in network management.

VI. Conclusion

This study verifies the effectiveness of Deep Reinforcement Learning (DRL) algorithm in network resource management through detailed experiments. Experimental results show that DRL algorithm outperforms traditional rule-based and optimization algorithm in throughput, delay, spectral efficiency and QoS parameters. Specifically, the DRL algorithm achieves an average throughput of 120.5 Mbps, which is about 26 per cent higher than the rule-based algorithm and about 14 per cent higher than the optimization-based algorithm. In terms of latency, the DRL algorithm has an average latency of only 12.3 ms, which is 33% and 21% lower than the rule-based and optimization-based algorithms, respectively. In terms of spectral efficiency, DRL algorithm has an average spectral efficiency of 2.5 bps/Hz, which is also ahead of the other two algorithms. In terms of QoS parameters, DRL algorithm has packet loss rate as low as 1.2%, jitter as low as 10.3 ms, and up to 90.5% of users meet certain QoS requirements.

These results show that DRL algorithm has significant advantages in dealing with dynamic network environment and meeting QoS requirements, especially under high load conditions. In addition, DRL algorithm performs better than traditional algorithm under different load conditions, which proves its robustness and adaptability in complex network environment.

The innovation of this paper lies in integrating user mobility and network load prediction into DRL framework systematically for the first time, and proposes a novel reward function design, which enables the algorithm to optimize resource utilization efficiency while satisfying real-time QoS constraints. However, there are still some shortcomings in the research, such as the performance of the current model in dealing with low-resolution images needs to be improved, and further refinement of the physical layer argument is still necessary.

Future research directions will focus on overcoming existing limitations, including improving image quality processing capabilities and deepening physical layer arguments to further improve the practicality and reliability of algorithms. Overall, this research not only provides new ideas and technical means for solving resource management problems in future mobile communication networks, but also lays a solid foundation for promoting DRL deployment in practical network applications.

Human-Computer Interaction Standardization and Systematization Development

An English Education Informatization Perspective

Xiaoling Lyu[1], Hongmiao Yuan[2]*, Zhao Zhang[3]
School of Foreign Languages, Shanghai Zhongqiao Vocational and Technical University, Shanghai 201500, China[1, 2]

Abstract—Amidst the information technology boom, this study harnesses IT and human-computer interaction to revolutionize English education. Our model, grounded in literature review and fieldwork, implemented teaching experiments that enhanced students' English proficiency by 25%, particularly in listening and speaking. Student engagement and interest surged by 30%, underscoring the effectiveness of standardized, systematized English education in the digital era. The study advocates for broader adoption of informatization in teaching, emphasizing the pivotal role of teachers in facilitating this educational shift. With significant outcomes, our research paves the way for future enhancements in English education, ensuring quality and equity in learning. Our approach addresses the gap between traditional teaching and technological advancements, offering personalized learning experiences that improve student outcomes. It also ensures consistent teaching quality and bridges educational divides. We introduce an informatization-based English education model, supported by literature review, fieldwork, and teaching experiments. Our findings show significant improvements in students' English proficiency, highlighting the model's effectiveness.

Keywords—Human-computer interaction; information technology; English education; standardization; systematization

I. Introduction

Human-computer interaction and intelligent system technologies are widely used in various industries. New embedded system technologies such as flipped classrooms and Internet+ have brought more possibilities to education. Teachers and students can tutor and communicate anytime, anywhere [1]. Teachers and students can tutor and communicate anytime and anywhere. Even if teachers use information technology to teach, they need to advocate student-centered teaching, and the role of teachers in teaching should not be ignored. However, teachers must realize that the arrival of the information technology era has brought challenges to teachers [2]. Teachers should continue to improve their knowledge systems, make efforts to learn information technology, and improve their ability to teach with information technology.

The Ministry of Education pointed out 2022 that there are still some things that could be improved in the current development of education informatization. There are both external and internal factors. The influence of internal factors is mainly the teachers' informatization teaching ability [3]. In the information age, teachers' informatization teaching ability is reflected not only in teachers' ability to apply information technology but also in integrating information technology and teaching content so that information technology is genuinely integrated into teaching [4]. This also brings difficulties for teachers in improving their informational teaching ability. The emergence of English teaching in an informational background provides teachers with a complete knowledge system of informationalized teaching and helps them deeply integrate the content with information technology.

Informationalized Background English Teaching was proposed by American scholars who added technical knowledge to the PCK. The emergence of English teaching in an informational context can help teachers improve the knowledge system of informationalized teaching competence and help them better integrate technical knowledge and content knowledge in the teaching process [5]. English teaching in an informational context describes the body of knowledge that teachers need to teach effectively in the Context of the information age.

In 2017, the Ministry of Education (MOE) suggested that advanced informatization teaching resources can drive and promote higher education teaching reform, break through traditional classroom limitations, and create a flexible and versatile teaching atmosphere [6]. With the addition of listening and speaking tests to the new round of Grade 4 and 6 exams, teachers face significant challenges in teaching to improve students' listening and speaking skills. The improvement of speaking and listening ability needs the support of information technology. Higher education English teachers must continuously improve their information technology teaching ability based on their original teaching ability and use information technology appropriately according to the needs of different teaching contents [7]. Teachers are users of information technology and are given an active role in teaching English in the Context of teachers' informationalized teaching competence. It is necessary to conduct an in-depth study on the informatization teaching ability of higher education English teachers from the perspective of English teaching in an informatization context in order to help higher education English teachers improve their informatization teaching knowledge system and find a suitable way for higher education English teachers to improve their informatization teaching ability.

Previous English education studies concentrated on conventional teaching, with scant attention to IT and human-computer interaction. Although IT's role in boosting learning is recognized, its systematic effect on English education's standardization is under-researched. Our research stands out by utilizing advanced IT and thoroughly analyzing its effects on teaching and student involvement. We present a new model combining literature, fieldwork, and data, showing marked enhancements in English skills, especially listening and speaking. The novelty lies in the model's empirical validation, highlighting significant gains in student performance and interest, bridging a research gap and offering a strong framework for educational advancement.

The era of education informatization brings unprecedented challenges to teachers and students. For English teachers, improving their informatization teaching ability has been an urgent problem [8]. The purpose and significance of this study are to analyze the differences and deficiencies in the informatization teaching ability of higher education English teachers of different teaching ages under different course types from the perspective of informatization contextualized English teaching in order to help teachers reflect on their informatization teaching ability under the guidance of informatization contextualized English teaching, to improve the knowledge system of teachers' informatization teaching ability [9]. In addition, this study also learned about the attitudes of the three developmental pathways of teaching English in an informational context through interviews [10]. Since there is no empirical research on the three developmental paths in China, this study encourages higher education English teachers to design speaking and reading courses from the perspectives of informatization background English teaching and the three developmental paths and to find out teachers' attitudes toward the three developmental paths at the end of the semester. The results of the interviews will likely provide a reference for the informatization teaching ability of higher education English teachers in China [11]. This study used a combination of questionnaire survey, classroom observation, and interviews to explore the differences in higher education English teachers' informationalized teaching competence from the perspective of informationalized contextual English teaching to help higher education English teachers construct and improve their informationalized teaching competence.

Continuing from this intro, Section II reviews literature on English edtech. Section III describes our research approach and data analysis. Section IV shows results, noting student progress. Section V discusses implications for English education. Section VI concludes with findings and future integration suggestions.

II. Theoretical and Contextual Foundations

Against the backdrop of science and technology, information technology has become an indispensable part of people's lives and learning and has shown a normalization trend. This trend also extends to the field of education, prompting teachers to utilize information technology to carry out teaching activities and requiring them to deeply integrate information technology with subject teaching to improve teaching efficiency [12]. Therefore, the rapid development of science and technology and information technology in the new era has put forward requirements for teachers' ability to apply information technology, which is the background of the study in this paper [13]. The second reason is that national policy documents pay attention to and focus on educational information 2022. The Ministry of Education advocates that teachers take the initiative to adapt to the challenges of the informatization society and cultivate students' ability to learn independently, cooperatively, and with inquiry in all aspects. The third reason is the importance of cultivating developed and systematic competence in teaching English as a foreign language to unmotorized teachers. As the leading force for future teachers, improving the standardization and systematization of informalized English teaching teachers will profoundly affect the quality of the training of talents in primary education in China. With a background of growing up in the era of digital natives, they can master information technology and update their teaching philosophy more quickly and are considered to be the promoters of educational reform. The information technology stage is necessary for teachers to integrate information technology and subject knowledge, and the development of teacher trainees' ICT competence plays a specific role in implementing concepts related to the new curriculum standards at the in-service stage. In the standardization of English education, it is usually necessary to set the core issues of standardization, and the principle of setting the core issues is mainly based on the level of information technology application. The Mean and SD tests shown in Table I are both rational value ranges of past research and have statistical significance.

TABLE I. English Standardized Question Set

Project	Mean	Standard Deviation
In the post-pandemic era, I believe it is important to cultivate the information technology teaching abilities of English teachers.	5.014	0.847
I can actively apply information technology to optimize English classroom teaching during the teaching process	5.614	0.664
The deep integration of information technology and teaching by English teachers can help improve students' English learning methods and enhance classroom teaching effectiveness. I believe that the deep integration of information technology and teaching by English teachers can help improve students' English learning methods and enhance classroom teaching effectiveness	5.114	0.814
I can use multimedia computer-assisted English classroom teaching	4.361	0.947
In the process of English teaching, I can use various information-based teaching resources	3.362	0.814
I usually use search engines and major websites to obtain English teaching resources	2.814	0.336
I can use information technology tools, combined with textbooks, to process and process English teaching materials obtained online	1.362	0.947

However, some problems still need to be solved with information technology teachers' ICT competence in China. The study also shows that the overall ICT competence of our student teachers is at an intermediate level, and the use of information technology to support teaching and learning still needs to be improved. There are also problems, such as a weak ability to apply interactive multimedia and a weak ability to optimize teaching practice [14]. The cultivation of information technology application ability of information technology teachers also raises problems such as lack of comprehensive planning, blockage of information technology post-service integration channels, unsystematic curriculum system, and lack of practical support.

The fourth reason is the need to integrate the English language subject with educational technology. The development of ICT skills at the informational level cannot be based solely on specialized IT courses. At the same time, it should be integrated into developing IT awareness and practical skills in all disciplines. English is an essential subject at the primary education level [15]. English teachers should pay attention to the application of modern information technology and make full use of information technology in teaching to promote students' effective learning. To summarize, it is of great practical significance to investigate the current situation of the ICT competence of informationalized English teaching teachers, to find out the existing problems, and to put forward targeted and constructive suggestions to improve the ICT competence of informationalized English teachers, to strengthen the cultivation of informationalized English teachers' information literacy, and to improve the quality of English teaching.

First, this study compared the domestic and international literature on ICT competence to determine this study's research idea and framework. Then, in conjunction with previous research, a measurement tool was developed to understand the ICT competence of Chinese informationalized English teaching teachers. Next, semi-structured interviews will be combined to investigate the factors affecting ICT teachers' competence in standardizing and systematizing English language teaching [16]. Finally, the results of the study will be combined to reflect on the shortcomings of English teaching standardization and systematization competence in the training process of informationalized English teaching teachers and to propose suggestions for cultivating and improving the standardization and systematization competence of informationalized English teachers' English teaching [17]. Based on the theoretical study, through a mixed study of the current situation and problems of ICT competence of informationalized English teaching teachers in three teacher training colleges.

This study deepens the specificity of English ICT skills by combining the literature on the information teaching competence of informationalized teachers with the ICT competence standards for informationalized English teaching teachers [18]. By sorting out the dimensions, structures, and definitions of English teachers' information teaching competence, the theoretical research on English teachers' ICT competence needs more attention and focus, and the more adequate the academic discussion, the more accurate the definition of information teaching competence will be.

The connotation of ICT skills is further refined by exploring the ICT competencies of informational English teaching teachers. Informationalized English teachers are not in-service teachers and pay more attention to the learning and reserve of competence [19]. Therefore, through the construction of the ICT competence of informationalized English teaching teachers and the in-depth understanding of the current situation of ICT skills of informationalized English teachers, this study provides some additions and improvements to the development of the theory of teaching ICT competence of informationalized teachers and also contributes to the development of ICT in teacher training schools [20]. This study provides some data to support the study of the ICT competence of informationalized English teaching teachers at the practical level.

With the continuous development of digital information technology, integrating education and information technology is the trend of future educational development. As another critical component of improving teachers' ICT competence, IT training covers a broader range of areas. It is more potent than in-service training, which can systematically develop and train teachers' ability to standardize and systematize English teaching by setting up relevant courses and practice sessions. Through the informatization stage, teachers can better and faster integrate the means and methods of ICT competence into education and teaching. Therefore, this study contributes to the understanding of informationalized ELT teachers' practice of standardization and systematization of English language teaching competencies. It also explores the factors affecting the standardization and systematization of English language teaching competencies. For individual informationalized English teaching teachers, it can improve their awareness of standardization and systematization competence in English teaching, stimulate their initiative and enthusiasm in learning information technology, and provide a reference for informationalized teachers to develop in-depth competence in the integration of information technology and English teaching [21]. For the training institutions of informationalized teachers, suggestions are made for the relevant departments to develop the ICT competence of informationalized teachers in practice.

III. Research Methodology

A. Study Design

Teaching English in an informational context can help teachers think about what knowledge is needed to integrate information technology into teaching and how teachers should acquire that knowledge in depth. With the integration of information technology and English teaching, teachers must focus on more than just the use of technology and pay attention to the knowledge needed for teachers' informationalized teaching ability. The results of domestic and international studies show that teaching English in an informational background is essential in guiding teachers' informationalized teaching ability. This study examines the differences in informationalized background English teaching demonstrated by higher education English teachers of different teaching ages in different course types, as well as higher education English teachers' reflections on three paths for developing informationalized background English teaching. The three research questions to be addressed in this study are as follows, as shown in Fig. 1:

- What are the characteristics of higher education English teachers' informationalized teaching competencies based on the four components of TK, TCK, TPK, and teaching English in an informationalized context?
- How do higher education English teachers' presentations of the various components of teaching English in an informational context differ across course types?
- From the perspective of teaching English in an informational context, what are the reflections of English teachers in higher education on the three paths of development and suggestions for improving their informational teaching skills?

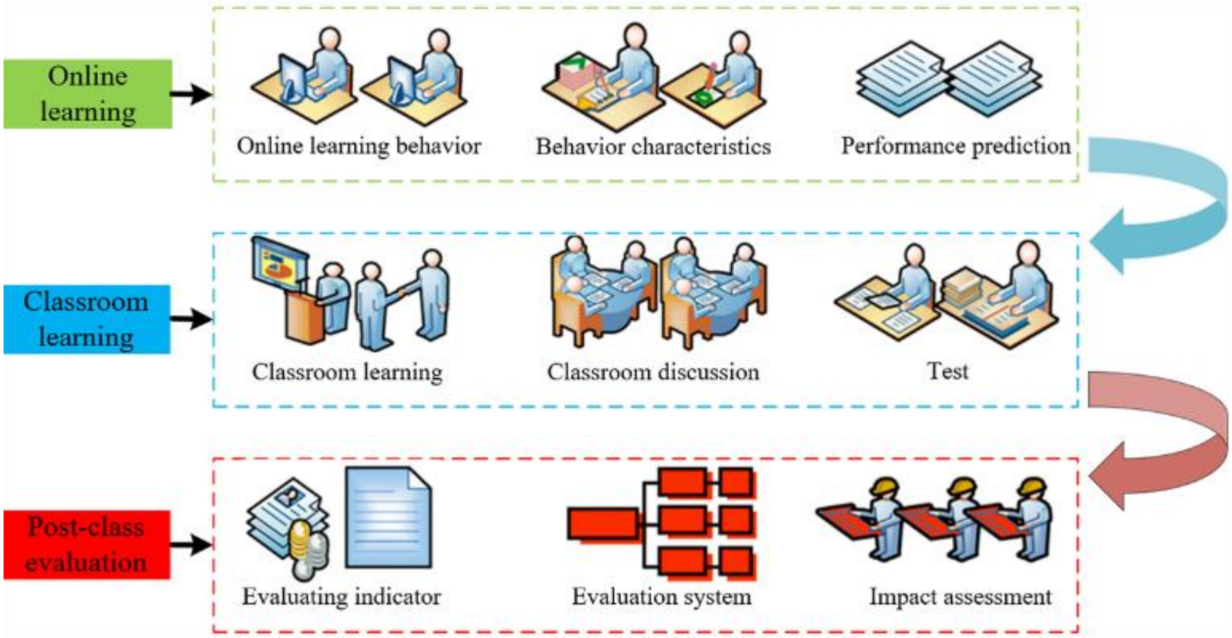

Fig. 1. Integrated learning and evaluation framework.

This study aims to instruct higher education English teachers' informationalized teaching ability from the perspective of teaching English in an informationalized context to effectively improve higher education English teachers' knowledge system and teaching ability. Strategies are provided for higher education English teachers to improve their informatization teaching ability. This study mainly divides the problem setting into three directions: systematic setting under the background of standardized English teaching; Coupling statistics of standardization and systematization in English education; Integration analysis of information-based teaching. As shown in Table II, the systematic setting under the background of standardized English teaching mainly analyzed the problems from the perspective of course preparation, with a Mean value range of 4-7 (P<0.01), and all passed the SD test.

TABLE II. SYSTEMATIZED SETTINGS FOR ENGLISH LANGUAGE TEACHING

Project	Mean	Standard Deviation

I will use various information technology resources to collect different English teaching materials and exercises based on the differences in students' learning situations, in order to assign different levels of homework to students	4.98	0.541

First, quantitative data were collected through questionnaires. Second, qualitative data were collected through classroom observations and interviews. Finally, the above research questions were derived through data analysis. This study takes English teachers in higher education as the research object and uses questionnaires and other methods to conduct the study. Due to the addition of speaking classes in higher education, previous studies needed to have investigated higher education English teachers' informationalized teaching ability under different course types. Therefore, this study was conducted to experiment with higher education English teachers as research subjects.

In order to understand the differences in the components of teaching English in an informational context presented by higher education English teachers in different course types, this study collected data for analysis through classroom observations. One higher education student from eight higher education institutions was selected for classroom observation, and three higher education English teachers of different teaching ages were randomly invited to participate in classroom observation. Based on the teaching age of the English teachers in this higher education, the teaching age in higher education was categorized into three stages: less than ten years, 11-20 years, and more than 21 years. Based on the interview outline, this study conducted semi-structured interviews with three higher education English teachers of different teaching ages. The interviews aimed to understand the reflections of higher education English teachers of different teaching ages on the three ways of developing English language teaching in an informational context.

In order to address the second research question of this study: how do higher education English teachers' presentations of the components of teaching English in an informational context differ across course types? The classroom observation method was used in this study. In order to improve students' listening and speaking skills, higher education added speaking classes to the existing English teaching. With the permission of the school and three teachers, the researcher of this study conducted classroom observations and collected data as a non-participant. The purpose of the classroom observations was to compare the differences in the knowledge components of teaching English in an informational context presented by higher education English teachers of different teaching ages in different types of courses, as well as the deficiencies in the teachers' informational teaching skills after understanding the meaning of teaching English in an informational context. Emphasis was placed on documenting the application of the seven components of informational contextual English teaching in different course types and the frequency of the seven components in different course categories. The Adaptive Classroom Observation Scale rated teachers' teaching based on the seven components of teaching English in an informational context. The differences between the seven informational Context English teaching components in different course types were summarized by analyzing the mean values. Human-computer interaction has to go through a certain process so that it can realize an effective cycle, and the specific process is shown in Fig. 2.

English education modeling in the context of information, as shown in Eq. (1), (2), and (3):

$$q_j^F(t+1) = q_j^F(t) + a_j(t) - \sum_{i\in\Omega_j^f} m_{ij}(t), \forall j \tag{1}$$

$q_j^F(t+1)$ is the iteration result of the q-function; $q_j^F(t)$ is the previous generation value of the *q*-function.

$$f_{ij}^{tran}(t) = \alpha_{ij} m_{ij}(t), \forall j \tag{2}$$

$f_{ij}^{tran}(t)$ is the training function of the f-function of the train and $\alpha_{ij} m_{ij}(t)$ is the lower-level function of the *f*-function.

$$f_{ij}^{work}(t) = \gamma_j (A_j(t) - a_j(t)), \forall j \tag{3}$$

$f_{ij}^{work}(t)$ is the training function for the work of the f function, and γ_j is the coefficient of $(A_j(t) - a_j(t))$.

B. Related Theoretical Designs

In order to address the third research question of this study, what are the reflections of higher education English teachers on the three development paths from the perspective of teaching English in an informational context? What are the suggestions for improving their informationalized teaching skills? The qualitative research method of semi-interviews was used in this study. The interview entailed using three tools: an outline, a tape recorder, and a transcript.

Semi-structured personal interviews were conducted with each of the three higher education English teachers who participated in the classroom observation with their permission. The interview outline was designed from three dimensions: first, to collect the attitudes and reflections of three higher education English teachers of different teaching ages on the three developmental paths from the perspective of teaching English in an informational context; second, to use interviews to share strategies to improve informational teaching competence with three higher education English teachers of different teaching ages, and the last dimension was to understand the factors affecting higher education English teachers' informational factors that affect the development of teaching competence.

The standardization and systematization of English education require relevant coupling statistics, especially considering the mediating effect of information technology background. The mean of the problem and SD test are also included in the table, with a mean of 1-5. Except for the low mean of information technology utilization level (2.624, $P<0.05$), all others meet the ideal range of this study. The specific problem design is shown in Table III.

TABLE III. STANDARDIZED AND SYSTEMATIC COUPLING STATISTICS FOR ENGLISH LANGUAGE EDUCATION

Project	Mean	Standard Deviation
I will use information technology such as English audiovisual teaching resources to introduce scenarios, arouse students' interest, and maintain their attention. I will use information technology, such as English audiovisual teaching resources, to introduce scenarios	4.051	0.947
I will use information technology to design enjoyable English activities, encourage students to participate actively in classroom interaction, change the teaching method of "teachers full of words," and effectively carry out students' independent, cooperative, and exploratory learning. I will use information technology to design some exciting activities to encourage students to actively participate in classroom interaction, change the teaching method of "teachers full of words," and effectively carry out students' independent, cooperative, and exploratory learning	4.821	0.784
I will use various English learning software according to different teaching contents, such as "English Fun Dubbing," "Hundred Words Zhan," "Daily English Listening," "Tianxue.com," etc., to help students improve their information technology literacy and English listening, speaking, reading, and so on. I will use various English learning software according to different teaching contents such as "English Fun Dubbing," "Hundred Words Zhan," "Daily English Listening," "Tianxue.com," etc., to help students improve their information technology literacy and English listening, speaking, reading, and writing abilities. and writing abilities	4.621	1.032

I will handle unexpected information technology issues in the classroom appropriately, such as teaching equipment malfunctions	4.011	1.006
I will use information technology tools to design and distribute survey questionnaires, collect students' English learning situations, and use technical means to analyze data, making appropriate adjustments and guidance for students' future English learning activities. I will use information technology tools to design and distribute survey questionnaires, collect students' English learning situations, and use technical means to analyze data, making appropriate adjustments and guidance for students' future English learning activities	2.624	1.021
I will encourage students to use online English teaching platforms for self-directed learning actively	3.682	1.417

The experimental procedure was divided into five phases: pilot testing, formal distribution of the questionnaire, classroom observation (speaking sessions), classroom observation, and interviews. The experiment started in September 2021, the first semester of the first year of higher education.

The questionnaire was divided into a pilot test phase and a formal questionnaire phase. The pilot test questionnaire was distributed to 20 higher education English teachers during the first week and was modified accordingly by analyzing the data and incorporating teachers' feedback. During the first week, the formal questionnaire was distributed to 146 higher education English teachers who participated in this survey, and the questionnaire took about 15 minutes to answer.

There were 18 weeks in the fall semester of 2021, but weeks 14-18 were mainly review sessions and final exams, so the classroom observations for this study were conducted from week 2 to week 12. A total of 10 classroom observations were conducted in this study; week 6 was a national holiday, so no classroom observations were conducted in week 6. All three higher education English teachers of different teaching ages taught two types of classes: reading classes and speaking classes. The instructional goal of the speaking class was to improve students' listening and speaking skills, so the content knowledge of the speaking class consisted of speaking exercises and listening exercises. Since English classes in higher education are categorized into reading and speaking classes, this study formulates English classes as reading classes, whose goal is to develop students' reading and writing skills. Therefore, the content knowledge of the reading class includes grammar, reading, and writing. Three higher education English teachers observed one speaking class and one reading class per week. Prior to the classroom observations, the connotations of the components of informational contextualized English teaching and the three developmental pathways were communicated to the three first-year higher education English teachers who participated in the classroom observations, and the three teachers were encouraged to informationalize their teaching and learning from the perspective of informational contextualized English teaching and the three growth pathways.

The experimental density of information-based teaching is analyzed using clustering software. The red area represents the standardized and systematic practice of English teaching achieved through good use of information technology during this time period. The blue area represents the low-density clustering area, indicating that there is no standard teaching that has achieved good implementation of information technology. The overall test results are shown on the right side of the picture, as shown in Fig. 3.

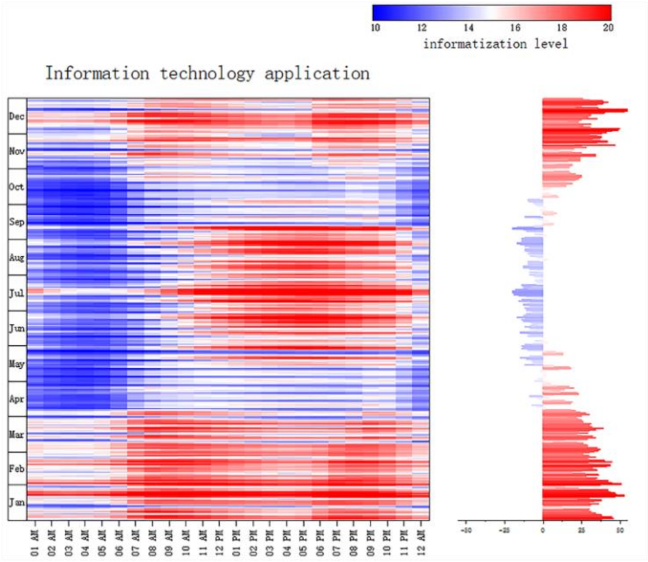

Fig. 3. Application of information-based English language teaching and learning.

Formal semi-structured interviews were conducted in week 13, in which the three teachers were interviewed face-to-face according to the interview outline. The researcher also communicated with the three teachers after class to share new issues identified during classroom observations and to revise the interview outline promptly. The questionnaire data were analyzed mainly using SPSS 22. First, the internal consistency of the reliability of each subscale and the whole scale was tested. Second, the descriptive analysis function in SPSS 22 was used to statistically analyze the data in each subscale, which mainly involved frequency distribution and percentage. The data of classroom observation were mainly from the Classroom Observation Scale. In order to explore the differences in how higher education English teachers of different teaching ages present each knowledge component of informational contextual English teaching in different course types, this paper conducted a descriptive analysis of the collected data. The frequencies and means of the different components of teaching English in an informational context in different course types were analyzed.

The transcription of the interviews was the change of the interview conversation from spoken to written form, which made the results easier to analyze, and the transcription process itself was the initial analysis process. At the end of the transcription process, the transcribed data was sent to the interviewees for confirmation to ensure the validity of the interviews. The interview data were analyzed by dividing the interview outline into dimensions, coding each teacher's interview data according to these dimensions, and organizing the interview data related to the theme of this study. The first dimension is higher education English teachers' reflections on the three development paths from the perspective of teaching English in an informational context; the second dimension is the strategies for improving higher education English teachers' informationalized teaching competence, and the third dimension is the factors affecting the development of higher education English teachers' informationalized teaching competence.

In the process of analyzing the integration of information technology teaching, the main approach is to examine the ways in which teachers can stimulate students' learning enthusiasm in order to achieve the integration of information technology teaching. Even in the issue of "summarizing using information technology", Mean reached 7.824, which achieved good integration of information technology, as shown in Table IV.

TABLE IV. ANALYSIS OF THE INTEGRATION OF INFORMATION-BASED TEACHING

Project	Mean	Standard Deviation
I will use information technology such as English audiovisual teaching resources to introduce scenarios, arouse students' interest, and maintain their attention. I will use information technology, such as English audiovisual teaching resources, to introduce scenarios	4.051	0.074

IV. Results and Discussion

A. English Standardization and Systematization Process

Since the entrance examination reform for higher education institutions has added speaking and listening tests, higher education has reformed the English curriculum and added speaking classes to the original curriculum to cultivate students' speaking and listening skills. Although English-speaking classes in higher education have yet to be fully implemented, English teachers must also develop students' listening and speaking skills in English teaching. With the background of curriculum reform and informationalized teaching and learning, this study used classroom observation to understand the characteristics of informationalized background English teaching exhibited by first-year English teachers in higher education of different teaching ages in speaking and reading classes. The following conclusions were drawn.

First, because speaking classes need to develop students' listening and speaking skills, the three first-year higher education English teachers of different teaching ages used IT more frequently and, on average, in speaking classes than in reading classes. In addition to CK, the other six components (TK et al., PCK, TPK, and teaching English in an informational context) were more frequently used in speaking classes than reading classes, and information technology was more diverse. Teachers have good comprehensive skills in teaching with information technology. It can be found from Ms.C's lessons that although TK, TCK, TPK, and informationalized contextual English teaching are more frequent in speaking classes than in reading classes, Ms.C is influenced by her previous teaching experience and PK, CK, and PCK account for a large proportion of speaking and reading classes. The above analysis shows that courses affect English teachers' ability to teach information technology in higher education. Since speaking classes require information technology to support the presentation of content knowledge, the three higher education English teachers were more likely to use components related to technological knowledge in their speaking classes. Therefore, higher education English teachers of different ages must experiment with using different information technologies to explain content knowledge in their reading classes. Consistent with other quantitative studies, this study also conducted descriptive statistics. However, in this study, information support was further categorized by gender to objectively examine the sensitivity of information technology to gender. Among them, 624 male samples were selected and 1204 female samples were selected, as shown in Table V.

TABLE V. Description of Informational Teaching by Gender Dimension

Dimension (math.)	Distinguishing between the sexes	Sample size	Statistical value M	T	SIG
ICT capacity	male	624	4.05	1.624	0.214
	daughter	1204	3.68		
Basic technical literacy	male	624	4.51	1.051	0.032
	women	1204	3.91		
Technical Support Learning	male	624	4.51	1.324	0.141
	women	1204	3.62		
Technical Support Learning	male	624	4.44	1.214	0.362
	women	1204	3.92		

In the current Context of curriculum reform, the first path (from PCK to informational context English teaching) and the second path (from TPK to informational context English teaching) under informational Context English teaching can meet the needs of two courses. Higher education English teachers can choose the appropriate pathway according to the needs of their courses. For example, teachers can choose the second path (from TPK to teaching English in an informational context) when preparing for speaking classes. The teacher considers the role of technology in the speaking classroom, so the teacher first develops TK and TPK and then combines TPK and PCK to develop informational contextual English teaching. When preparing for the reading lesson, the teacher chooses the first path from PCK to informational contextualized ELT. In reading lessons, teachers focused more on content knowledge, so teachers first developed PK and CK and then used technology to enhance and structure instruction. However, prior teaching experience and less technological knowledge influenced the pathway choice, and only the first pathway was chosen to develop informationalized teaching skills. However, with sufficient technological knowledge, the appropriate path would also be chosen depending on the type of course. In addition to the first and second development paths that can help higher education English teachers develop informational contextualized English teaching, this study provides three strategies for higher education English teachers to develop informational contextualized English teaching and to improve their informationalized teaching competence based on the results of the interviews and the literature review.

The systematic testing of English teaching can be found in Eq. (4) and (5):

$$e_i^t = x_i(t) - y_i(t) + d_i(t) - c_i(t) + z_i(t) + \sum_{\forall k \in I/i} u_{ik}(t), \forall i \quad (4)$$

$\sum_{\forall k \in I/i} u_{ik}(t), \forall i$ is the system composite value of the systematic test.

$$u_{ii}(t) = 0, \forall_i = L \tag{5}$$

$u_{ii}(t) = 0$ is the minimum value of the least squares method.

First, establish a school collaboration mechanism. Research has shown that informational contextual English teaching can help higher education English teachers build a knowledge system of informational teaching ability. Therefore, informational contextual English teaching can be extended to higher education, and higher education English teachers from different schools can regularly engage in collaborative learning. In the exchange and learning, teachers can discuss the connotation of the seven components of informational background English teaching, share how new information technology can be applied to higher education English teaching in the Context of informational background English teaching, and use informational background English teaching to promote the improvement of higher education English teachers' informationalized teaching competence.

Secondly, educational research activities are organized. The school actively conducts teaching and research activities against the background of teaching English in an informational context and organizes public class demonstrations and after-class seminars. When evaluating public courses, teachers can discuss the strengths and weaknesses of public courses against the background of knowledge of teaching English in an informational context. Public classroom demonstrations can help higher education English teachers of different teaching ages learn from each other. Teachers with higher informationalized teaching competence can provide training on informationalized teaching competence to other higher education English teachers. Teachers with high teaching ability can promote new information technology, instruct other teachers on how to apply information technology and develop teachers' ability to integrate information technology with English teaching.

Finally, cultivate teachers' sense of reflection. Informative teaching is new to teachers who implement information teaching. Therefore, besides external help, teachers should know the need to improve their informational teaching ability actively. Teachers should develop the habit of reflecting on informalized teaching from the perspective of teaching English in an informative context so that they can discover the deficiencies of the information teaching knowledge system in the teaching process and improve the implementation process of formalized teaching in time. Teachers should learn to improve their instructional teaching ability gradually through reflection. Higher education English teachers can reflect on the insufficiency of the knowledge of informatization teaching ability based on the informatization background of English teaching, and they can also learn whether the application of information technology in each lesson can help students understand and master the content knowledge through the students' feedback after the lesson. Higher education English teachers should accumulate information technology teaching experience and improve information technology teaching ability through reflection.

Conduct a degree segmentation study on descriptive statistics, using a sample size of 254 for undergraduate students and 663 for master's students. Sensitivity considerations for information technology are divided into three aspects: ICT competence, basic technical literacy, and technical support for learning; Two tests were conducted on technical support learning, as shown in Table VI.

TABLE VI. DESCRIPTION OF INFORMATIVE INSTRUCTION IN THE DEGREE DIMENSION

dimension (math.)	places	sample size	Statistical value M	T	SIG
ICT capacity	undergraduate (adjective)	254	4.01	-1.62	0.974
	bachelor's degree	663	4.41		
Basic technical literacy	undergraduate (adjective)	254	3.58	-0.964	0.914
	bachelor's degree	663	6.36		
Technical Support Learning	undergraduate (adjective)	254	3.51	-0.657	0.635
	bachelor's degree	663	4.05		
Technical Support Learning	undergraduate (adjective)	254	3.3	-0.241	0.874
	bachelor's degree	663	3.91		

B. *Technical Support for Information Technology Teaching*

Most higher education English teachers used to think that they could utilize their informal teaching ability as long as they were skilled in using information technology in teaching. Teachers need to understand the complete knowledge system of informationalized teaching and improve their informationalized teaching ability. The emergence of English teaching in an informational context fills the teachers' knowledge system gap. It helps English teachers in higher education to understand the knowledge that should be included in complete informational teaching. The seven components of informational contextual English teaching can help higher education English teachers improve their professional knowledge and provide guidance for improving teachers' informationalized teaching ability. Higher education English teachers should draw on the knowledge system of informationalized background English teaching, deeply understand and master the connotation of informationalized background English teaching, find out its shortcomings, and improve their knowledge system in time from the perspective of informationalized background English teaching. Through a deep understanding of the specific content of informationization background English teaching, teachers can integrate information technology into teaching, improve the quality of information technology teaching, and perfect how information technology is used. In addition, by applying informationized background English teaching to speaking and reading classes, higher education English teachers can promptly reflect on the deficiencies in teaching and apply the seven components of informationized background English teaching in different course types. In this study, a certain clustering analysis was conducted on the standardization and systematic practice of English education under the background of informatization, which mainly includes five aspects, including "English standardization and systematic practice, English standardization research, English systematic research", etc. Specifically, the darker colors of each aspect represent their quantitative clustering, and the lighter colors represent their spatial clustering, as shown in Fig. 4.

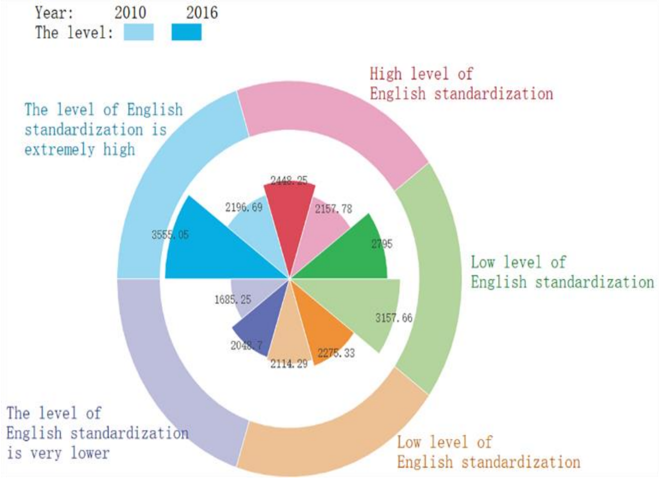

Fig. 4. Systematic research priorities in English language education.

With the support of informational contextualized English teaching, higher education English teachers' ultimate goal is to integrate their teaching so that the seven components of informational contextualized English teaching are integrated into their teaching, thus promoting the improvement of informationalized teaching skills. In order to help teachers develop informational contextualized English teaching, three pathways for developing informational contextualized English teaching are proposed. Applying the three developmental paths to higher education English teaching in China, the first and second of the three developmental paths could help teachers develop an informational background in English teaching. Three higher education English teachers of different teaching ages believed that the first path (from PCK to teaching English in an informational context) was suitable for reading classes, and the second path (from TPK to teaching English in an informational context) was suitable for speaking classes. The third path (PCK and informational contextual English teaching simultaneously) must be more suitable for higher education English teachers to develop informational contextual English teaching. However, with sufficient technological knowledge, the first path can be relied on to design English teaching for the time being. The above interview results provide path support for most higher education English teachers to improve their informationalized teaching ability. Higher education English teachers can choose appropriate paths for different types of courses to help teachers integrate information technology into English teaching. Most higher education English teachers have recognized the critical role of information technology teaching and the effectiveness of information technology background English teaching in perfecting information technology teaching ability. Therefore, teachers' use of informational background in English teaching and the first and second paths to guide informationalized teaching competence can reduce the pressure on teachers to improve their informationalized teaching competence. The above interview results about the paths will be informative for guiding the informatization teaching ability of English teachers in higher education at this stage.

Teachers' sense of responsibility and mission have the most significant impact on their development, and teachers' obligations and responsibilities to students and teaching affect their beliefs and efficiency in teaching and influence their teaching practices. Combined with the results of the interviews, teachers' perceived attitudes toward informationalized teaching can be divided into the following three categories. First, this informationalized teaching English teacher category has a strong sense of educational mission. Teachers in this category have a strong sense of mission and passion for teaching. It believes that English teachers should keep abreast of the times and continuously improve their ICT skills to improve teaching and students' learning efficiency. Teachers in this category consistently spoke highly of IT teaching in their interviews and agreed that integrating the English subject with IT was important.

Secondly, these teachers have a strong sense of mission and are willing to learn IT teaching courses. Information technology teaching English teachers have a strong sense of educational responsibility and mission. It recognizes the critical role of information technology in teaching English. Nonetheless, it could have shown a more vital willingness to use IT in the interviews. It is believed that the reasons for using IT tools in teaching came mainly from the demands of the external environment, including the recruiters' requirements for teachers' technological level and future career development.

Third, this category of teachers needs a stronger sense of mission and is influenced by cultural conceptions of the discipline. This category of informationalized teaching English teachers needs a stronger sense of educational mission and believes that technological tools only play a supplementary role in English teaching and are dispensable. Its conception of teaching is relatively traditional, believing that the English teacher's job is the most important and that he or she should focus on teaching language knowledge and grammar.

In the standardization and systematization of English education under the background of informatization, descriptive statistics should be conducted on the dimension of network devices. A sample of whether online network device information is used was used, with a sample size of 204 for "yes" and 782 for "no". Only a t-test was needed for the "yes" sample, and the specific results are shown in Table VII.

TABLE VII. DESCRIPTION OF INFORMATIONALIZED INSTRUCTION IN THE NETWORK DEVICE DIMENSION

Dimension (math.)	Network device dimension	Sample size	Statistical value M	T	SIG
ICT capacity	be	204	4.01	3.61	0.014
	clogged	782	4.41		
Basic technical literacy	be	204	3.58	4.68	0.019
	clogged	782	6.36		
Technical Support Learning	be	204	3.51	2.617	0.270
	clogged	782	4.05		
Technical Support Learning	be	204	3.3	6.354	0.035
	clogged	782	3.91		

In the interviews, its views strongly reflect the influence of cultural perceptions on the English language discipline. The subject of English is unique among many disciplines because of its dual characteristics of content and medium. Cultural perceptions of their subjects may influence the application of IT in specific subjects by ITEd English teachers. In conclusion, informationalized English teachers have a positive attitude towards teaching IT and are most particular about the importance of IT in English language teaching. They believe that IT supports English language teaching and learning by bringing authentic contexts and rich teaching resources, helping students develop an excellent cultural awareness and a willingness to learn and use new IT in practice. Therefore, the concepts and attitudes towards IT teaching will affect the IT teaching ability of English teachers of IT teaching.

ANOVA showed that there were significant differences in the standardization and systematization skills of ITEd English teachers in terms of teaching practice and that ITEd English teachers with teaching practice were significantly more likely to be involved in teaching practice than those without in all three sub-dimensions of ITEd. In the third section of the questionnaire, "participation in teaching practice" ranked second regarding the importance of influencing factors. Classroom practice and various practical activities of English teachers are essential factors that influence the development of their ICT competence.

In the interviews, all the teachers of IT-enabled English mentioned the critical word “little teaching practice”. They felt they needed more opportunities to integrate IT into their English teaching practice. PET 1, PET 2, PET 4, and PET 6 expressed similar views. They all felt that their teaching practice needed to be improved. Although they had participated in educational internships, they needed more opportunities to practice and improve their ICT skills in natural teaching environments. Therefore, it is desired that the number of practicum opportunities in terms of school curriculum or activity practices and educational internships be increased. Practicum can help individuals analyze and master technology in greater depth and is the ultimate way to consolidate and strengthen their IT teaching skills. Teachers of IT-enabled English with teaching experience can improve their ICT skills by constantly reflecting on and reconstructing their teaching practices after practice, analyzing and judging the appropriateness of the actions and timing of the use of IT in the classroom, and better integrating the subject matter with IT. However, many informationalized teaching English teachers reflected the need for teaching practice in their interviews. Due to the lack of teaching practice, informationalized teaching English teachers could not reflect on and improve the use of IT in the teaching process based on teaching effectiveness, which hindered the development of their IT competence. Therefore, it is significant for informationalized teaching English teachers to participate in teaching practice.

ANOVA showed significant differences in ITE English teachers' standardization and systematization abilities in school technology environments, suggesting that school technology support significantly impacts ITE English teachers' standardization and systematization abilities. Based on the literature review, the following analysis focuses on school support, teacher modeling, and curriculum. School is an essential stage for informationalized English teachers to learn subject knowledge and IT knowledge systematically, and the school environment inevitably affects the development of their ICT competence. In the survey, "school hardware and software support" ranked first in the list of possible factors affecting the growth of ICT competence. The timely updating of teaching equipment and the maintenance and repair of related equipment help to create a favorable IT teaching and learning environment. Several studies have shown that good teaching and learning equipment can significantly increase teachers' motivation to use technological tools.

V. CONCLUSION

In conclusion, this study has addressed the research questions posed in the methodology section, particularly focusing on the characteristics of university English teachers' information teaching capabilities, encompassing the four components of Technological Knowledge (TK), Technological Content Knowledge (TCK), Technological Pedagogical

Knowledge (TPK), and their integration within the context of English education informatization. Our findings confirm that the integration of information technology in English education significantly enhances teaching efficiency and effectiveness. The use of multimedia and digital resources has been shown to enrich the teaching experience, making it more dynamic and engaging, thereby stimulating students' interest and promoting their autonomous learning.

Moreover, our study has demonstrated that informatization significantly improves students' English listening and speaking skills. The utilization of multimedia teaching resources in authentic contexts has enhanced students' language perception and practical language use. Interactive methods, including online communication and simulated dialogues, have been instrumental in greatly improving students' communicative competence.

The study also established the reliability and validity of the questionnaire survey instrument used to collect quantitative data, ensuring that the research findings are robust and trustworthy. The results align with previous research, underscoring the importance of informatization in standardizing educational practices and narrowing the educational resource gap. The adoption of a unified teaching platform and resources ensures the consistency and accuracy of teaching content, contributing to higher quality education.

Furthermore, the research highlights the role of informatization in the systematization of English education, facilitated by big data and artificial intelligence. This systematization allows for a more scientific and precise analysis of students' learning, thereby enhancing teaching outcomes.

In light of these findings, it is evident that the standardization and systematization of English education through informatization play a crucial role in improving teaching effectiveness and stimulating students' learning interests and potential. Looking ahead, there is a clear need to further integrate information technology with English education, continuously optimizing teaching methods to align with the developmental demands of the information age. It is also imperative to focus on educational equity and accessibility, ensuring that every student has the opportunity to receive a high-quality English education.

This study offers valuable insights and lessons for the reform and innovation of English education, anticipating significant advancements driven by information technology. The empirical validation of our model, which has shown substantial increases in student performance and engagement, addresses a critical gap in the current literature and provides a solid framework for future research and practice in English education informatization.Our study, though advancing English education through informatization, has limitations. It is bounded to a specific context, potentially restricting the applicability of results elsewhere. Dependence on technology infrastructure varies and could impact outcomes. Data collection was limited in time, not capturing long-term effects. Future studies should include broader and more diverse samples over longer periods to enhance the model's sustainability and scalability.

Eavesdropping Interference in Wireless Communication Networks Based on Physical Layer Security

Mingming Chen*, Yuzhi Chen
College of Information and Smart Electromechanical, Engineering, Xiamen Huaxia University, Xiamen, 361024, China

***Abstract*—Effective communication security protection can protect people's privacy from being violated. To raise the communication security of wireless communication networks, a collaborative eavesdropping interference scheme with added artificial noise is proposed by combining physical layer security and clustering scenarios to protect the communication security of wireless sensor networks. This scheme adds artificial noise to the transmitted signal to interfere with the eavesdropping signal, making the main channel the dominant channel and achieving eavesdropping interference in wireless communication networks. The results show that after using artificial noise, as the signal-to-noise ratio of the main channel increases from 0 to 20dB, the confidentiality capacity can increase from 0.5 to over 4.0. When the transmission power is 0.4W, the confidentiality capacity reaches its maximum and does not depend on the signal-to-noise ratio. When the number of interfering nodes increases from 1 to 2, the confidentiality capacity increases from approximately 4.7 to around 5.8. The research designed a wireless communication network eavesdropping interference scheme that can effectively protect the information security of the wireless communication network, making the main channel an advantageous channel and achieving complete confidentiality. This scheme can be applied to wireless communication networks to improve the security level of the network.**

***Keywords*—Wireless communication; sensors; network security; eavesdropping interference; clustering scenario**

I. Introduction

With the quick development and popularization of technologies such as mobile networks, the Internet of Things, and smart cities, wireless communication technology is playing an increasingly important role in social life [1]. At the same time, its broadcasting and stacking characteristics pose greater challenges for wireless networks compared to wired networks when facing security issues. The broadcasting characteristics of wireless networks mean that all devices within the wireless range can receive the transmitted data packets. Attackers can deploy their devices near legitimate recipients and intercept transmitted data by listening to wireless signals. The superposition characteristic of wireless networks allows multiple signals to overlap and transmit on the same channel. Attackers can send interference signals, reducing the quality of legitimate signals, making it difficult for legitimate receivers to correctly decode the received data, while attackers attempt to obtain information in chaos. Attackers can set up a fake access point with the same SSID and password as a legitimate wireless access point, luring users to connect to this fake network. Once connected, the attacker can intercept all data transmitted through the access point. As attackers, they usually utilize these two characteristics to reduce decoding efficiency by pretending to be illegal recipients to steal information or sending interfering information as malicious disruptors [2-3]. Therefore, how to ensure information security and reliability in wireless networks has become particularly important. Traditional wireless networks mostly monitor network traffic by deploying wireless intrusion detection systems to detect abnormal behavior or potential attack patterns in a timely manner. Meanwhile, it implements a strong authentication mechanism to ensure that only authorized users can access network resources, to reduce the risk posed by attackers. In the past, wireless network communication security was mainly built on the security framework of wired networks. Physical layer security (PLS) technology involves multiple levels such as wireless signal processing, channel coding, modulation and demodulation, and requires a deep understanding of the physical characteristics of wireless communication. The technical threshold is high. Compared to traditional security technologies based on the application layer and transport layer, research on PLS started relatively late. Therefore, related research and discussion are not sufficient, leading to the neglect of PLS issues in wireless networks at times [4]. The communication security of traditional wireless networks completely depends on key protection. In the open environment, it is difficult to use key technology to encrypt communication information, and the encryption cost is high, which is difficult to apply on a large scale. In fact, PLS is crucial for wireless network security, especially in clustering scenarios of wireless sensor networks, it can provide a new direction of thinking [5]. Currently, PLS has been widely recognized as the most effective way to solve wireless network security issues and has been applied in many cutting-edge technologies [6]. The study combines the clustering scenario of wireless sensor networks with PLS and explores the PLS problem of wireless communication network eavesdropping interference in the clustering scenario. On the basis of not changing the original topology structure of the network, this study proposes to use idle ordinary nodes as collaborative nodes.

In the inter cluster communication process of the head node, to jointly send interference information and interfere with eavesdroppers in other directions.

The main innovation of the research lies in combining clustering scenarios with PLS and proposing a strategy of utilizing idle nodes for collaborative interference. This study not only provides new research directions and possible solutions for

*Corresponding Author.

PLS, but also provides important references for achieving secure communication in clustering scenarios of wireless sensor networks. This method fully utilizes the advantages of network topology without the need for additional equipment or hardware, thus ensuring the implementation of PLS. The research provides a new perspective and solution strategy for wireless communication network security issues at the physical layer. The primary contribution of this research is the utilization of idle nodes in wireless networks to create a synergistic interference effect on the signal information transmitted within the network. This increases the difficulty for attackers to steal network information and reduces the cost of information encryption in wireless network communication, thereby significantly enhancing the security of wireless network communication.

The research will be conducted in seven sections. Section II is an overview of the current status of wireless communication network security research. Section III is a study on wireless communication network eavesdropping interference based on clustering scenarios and PLS. Section IV is an experimental analysis of eavesdropping interference schemes based on clustering scenarios and PLS. Discussion and conclusion are given in Section V and Section VI respectively.

II. Related Works

The security issue of communication networks is one of the main challenges faced by wireless communication networks. Wei Z et al. proposed a new security technology to address the security issues in integrated sensing and communication transmission, to ensure information security (Table I). By embedding information signalling in the detection waveform, the security of transmission was ensured. Meanwhile, sensing capabilities were utilized to obtain target information, which further enhances security [7]. Wang C et al. systematically investigated node capture attacks to alleviate the security issues of user authentication in wireless sensor networks. Countermeasures were proposed for different types of attacks and 61 authentication schemes were evaluated. The results showed that understanding node capture attacks helped in designing more secure authentication schemes [8]. Naghibi M et al. proposed a secure data fusion method to reduce the energy consumption of wireless sensor networks. This method reduces the number of data packets through data aggregation and improves data security by using lightweight symmetric encryption. The simulation outcomes denoted that compared with traditional methods, this method had a higher level of data security [9]. Wu F et al. proposed a new three factor authentication scheme to address the security issues of data transmission in wireless sensor networks. This scheme provided session keys, maintained security through formal verification and informal analysis, and had better security and application value than similar schemes. The simulation results indicated that this scheme had practical prospects [10]. Jia XC analyzed the current resource efficiency and security technologies adopted to meet the strict requirements of wireless sensor networks in terms of resource budgeting and security. A resource efficient distributed state estimation method and a secure distributed state estimation strategy based on different scheduling were proposed. The results showed that these technologies could effectively improve the performance and security of wireless sensor networks [11]. Hu S et al. proposed a distributed machine learning-based communication data management method to address the issues of communication congestion and information leakage caused by data explosion in wireless communication networks. The results showed that this method could effectively prevent the leakage of communication data and improve the smoothness of communication networks [12].

TABLE I. List of Literature Surveys

Author	Method	Shortcoming
Wei Z [7]	Information signaling embedding	High technical costs
Wang C [8]	Attack capture auxiliary node authentication	Complex data processing
Naghibi M [9]	Lightweight symmetric encryption	High technical costs
Wu F [10]	Key encryption	High technical costs
Jia X C [11]	Distributed State Estimation Strategy	Poor timeliness
Hu S [12]	Distributed Machine Learning	Poor timeliness
Li X [13]	PLS Backscatter Communication Network Framework	Focus on improving signal quality, with weak signal protection
Yuan X [14]	Reconfigurable only on the surface	Unable to handle signal leakage issues
Pirayesh H [15]	Frequency hopping spread spectrum	Insufficient anti-interference ability
Yu X [16]	Intelligent reflective surface	High technical costs
Matthaiou M [17]	Intelligent reflective surface	Weak signal processing ability

PLS in wireless sensor networks is one of the effective ways to solve network security. Li X et al. proposed the PLS backward scattering communication network framework to solve the challenges faced by 6G wireless communication networks. This framework aimed to improve the reliability and security of communication. The results showed that the proposed framework could optimize the performance trade-off between reliability and security under a high signal-to-noise ratio (SNR) [13]. Yuan X et al. summarized the current channel state acquisition techniques for wireless communication networks to address the issues of channel state information acquisition, passive information transmission, and low complexity robust system design for reconfigurable intelligent surfaces in wireless network PLS. The results showed that reconfigurable smart surfaces had unique advantages in improving wireless channel capacity [14]. Pirayesh H et al. aimed to comprehensively understand the interference attacks and anti-interference strategies of existing wireless networks. Various interference and anti-interference strategies for existing networks were proposed and analyzed in depth. The results showed that although some progress has been made, the design of anti-interference wireless network systems still faced challenges [15]. To enhance PLS performance, Yu X used intelligent reflective surfaces in challenging radio environments. The joint design of beamformer, covariance matrix, and phase shifter were studied to maximize system and rate while limiting information leakage. Effective algorithms were developed to solve non convex optimization problems. The results showed that intelligent reflective surfaces could significantly improve confidentiality performance, and evenly distributed reflective elements are better [16]. Matthaiou M et al. focused on the key physical layer enabling factors of 6G to meet the ubiquitous, reliable, and low latency connection needs of the future. The challenges related to intelligent reflective surfaces, large-scale multi-input and multi-output without honeycomb, and terahertz communication were proposed. The results showed that 6G would need to overcome challenges such as theoretical modeling, hardware implementation, and scalability, and signal processing played a critical role in the new era of wireless communication [17].

In summary, traditional communication anti-eavesdropping and interference technology is achieved through communication encryption. Although this method has a high communication encryption effect, it requires a large amount of computing resources and is suitable for specialized communication signal anti-eavesdropping and interference. It is not applicable in ordinary scenarios. PLS utilizes intelligent reflector surfaces to achieve anti-eavesdropping protection for communication signals, with low requirements for communication sending and receiving devices, and high applicability in IoT scenarios. However, PLS is unable to handle the attack behavior of eavesdroppers in communication data protection, and its protection capability is relatively weak. In the scenario of clustered routing, the same communication signal will be encrypted and transmitted multiple times, which can enhance the encryption strength of the communication signal. However, communication encryption will further increase the consumption of computing resources. Therefore, the study proposes to use cluster routing to improve PLS, combining the encryption enhancement effect of cluster routing with the low computational requirements of PLS encryption, to protect user communication data in the Internet of Things.

III. Eavesdropping Interference in Wireless Communication Networks Based on Clustering Scenarios and PLS

Clustering scenarios are widely used in wireless sensor networks, and PLS is a common way to protect data communication security. In Section III, the study analyzes the eavesdropping interference based on clustering scenarios and PLS wireless communication networks. Section III contains two sections: the first section is the analysis of artificial noise technology in the PLS field, and the second section is the analysis of collaborative interference based on clustering scenarios.

A. Analysis of Artificial Noise Technology in PLS Field

PLS is a new direction based on information theory, utilizing physical layer characteristics or using physical layer technology to achieve communication security? The existing communication encryption methods mostly rely on complex key encryption technology, which occupies a high amount of computing resources and requires extremely high device requirements, resulting in poor applicability in the Internet of Things. PLS technology is based on the randomness and uniqueness of wireless channels, utilizing their inherent characteristics to achieve secure transmission without relying on complex cryptographic algorithms or key distribution mechanisms [18]. PLS technology does not rely on computational complexity and can be implemented even on devices with weaker computing power. Although PLS based on the eavesdropping channel model has a necessary assumption that the quality of the main channel for legitimate communication is better than that of the eavesdropping channel, Maurer proposed a new method that used wireless channel characteristics to generate the key that information encryption relies on. At the same time, to weaken the premise assumption of eavesdropping channels, technologies such as beamforming, artificial noise, and collaborative interference were also adopted. Therefore, PLS is mainly divided into two directions: keyless security and wireless channel-based key generation. The eavesdropping channel model is shown in Fig. 1.

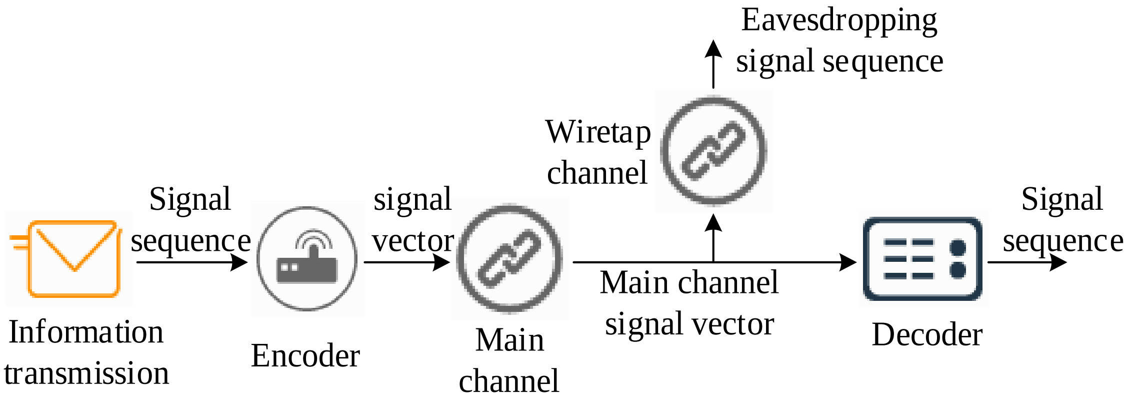

Fig. 1. The eavesdropping channel model.

The topic of the eavesdropping channel model is divided into four parts, namely encoder, main channel, eavesdropping channel, and decoder. In wireless communication systems, information transmission is a complex and constantly evolving process. There is a sequence S with a length of K, which contains communication raw data or information. Before sending, the sequence S is encoded as a vector X with a length of N, which is processed and modified by encoding before being sent through the main channel. After vector X is transmitted through the main channel, a vector Y with a length of N can be obtained. The task of the receiver is to decode the received vector Y to restore the original sequence S. Usually, decoding is a complex process that includes a series of steps such as denoising and demodulation, with the goal of restoring the sequence S as accurately as possible. However, there is a potential security risk involved in this process. In addition to legitimate recipients, there may also be a eavesdropping party attempting to intercept the information being transmitted. The eavesdropping party eavesdrops on the vector Y transmitted through the main channel through the eavesdropping channel, which is problematic and interferes with, just like the main channel. Therefore, the result that the eavesdropper overhears may be a vector Z with various noises and errors of length N. The confidentiality capacity is the main performance indicator of PLS, which is directly related to the channel capacity. In the eavesdropping channel model, when the eavesdropping channel is not considered, the channel capacity of the main channel is denoted in Eq. (1).

$$C_M = \max_{p(x)} I\left(X;Y\right) \tag{1}$$

In Eq. (1), $I\left(X;Y\right)$ means the mutual information between the information content X and Y. C_M means the channel capacity of the main channel. If considering eavesdropping channels, the capacity of the main channel can be defined as Eq. (2).

$$\hat{C}_M = \max_{p(x)} I\left(X;Y\middle|Z\right) \tag{2}$$

The eavesdropping channel can be regarded as obtaining Y through the main channel transmission, and then obtaining Z through the eavesdropping channel. The virtual channel is called, and at this point, a Markov chain is formed between the sequences X, Y, and Z. Based on the Markov chain, Eq. (3) can be obtained.

$$H\left(X\middle|Y,Z\right) = H\left(X\middle|Y\right) \tag{3}$$

In Eq. (3), $H\left(\cdot\middle|\cdot\right)$ represents conditional entropy, which represents the amount of information that X still contains, given all the information of Y. Through the basic properties of mutual information, equation (4) can be obtained.

$$I\left(X;Y\middle|Z\right) = H\left(X\middle|Z\right) - H\left(X\middle|Y,Z\right) = I\left(X;Y\right) - H\left(X;Z\right) \tag{4}$$

According to Eq. (4), Eq. (2) can be rewritten as Eq. (5).

$$\hat{C}_M = \max_{p(x)} \left[I\left(X;Y\right) - I\left(X;Z\right)\right] \tag{5}$$

In the eavesdropping channel model, it is assumed that the sender wants to send a message while also protecting the message from eavesdropping. To achieve this goal and obtain the maximum actual information transmission rate, the confidentiality capacity can be defined as Eq. (6).

$$C_s = \max_{R\in\Re} R \tag{6}$$

In Eq. (6), R represents the actual transmission rate. C_s represents confidential capacity. $\Re$ represents the reachable region of $\left(R,R_e\right)$, as shown in Fig. 2 [19].

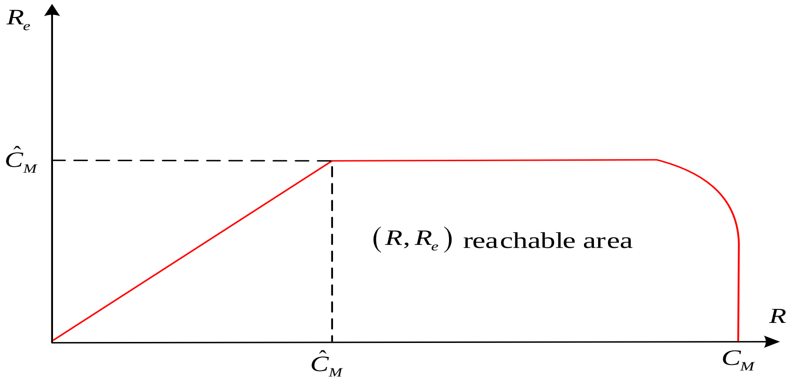

Fig. 2. $\left(R,R_e\right)$ range coverage.

In Fig. 2, the range of R is less than C_M, the range of R_e is less than $\hat{C}_M$, and in $R \le \hat{C}_M$, $R = R_e$ meets the requirements for complete confidentiality. Therefore, when the confidentiality capacity satisfies Eq. (7), communication at a rate of V with C_s as the upper bound can achieve complete confidentiality.

$$C_s = \hat{C}_M = \max_{p(x)} \left[I(X;Y) - I(X;Z) \right] \tag{7}$$

In the eavesdropping channel model, signal receiving channels are divided into legitimate receiving channels and illegal receiving channels. When the signal generator transmits a signal, it will add an error code to the transmitted signal. The frequency of the error code is different from the frequency of the legal channel. When the legal channel receives the signal, it will not receive the error code. The signal reception frequency of the eavesdropping channel is relatively wide, and it will receive a large number of signals when receiving signals. At the same time, it will also receive error codes in the signal, resulting in missing or incorrect received information. This makes the effective information in the signal received by the eavesdropper 0, which can achieve complete confidentiality of information. That is, in the eavesdropping channel model, when the quality of the main channel is higher than that of the eavesdropping channel, non-zero confidentiality ability can be obtained. To ensure that the quality of the main channel is higher than that of the eavesdropping channel, artificial noise can be added to the information to interfere with the eavesdropping channel and reduce its quality, thereby achieving complete confidentiality of the information. The artificial noise scheme design is shown in Fig. 3.

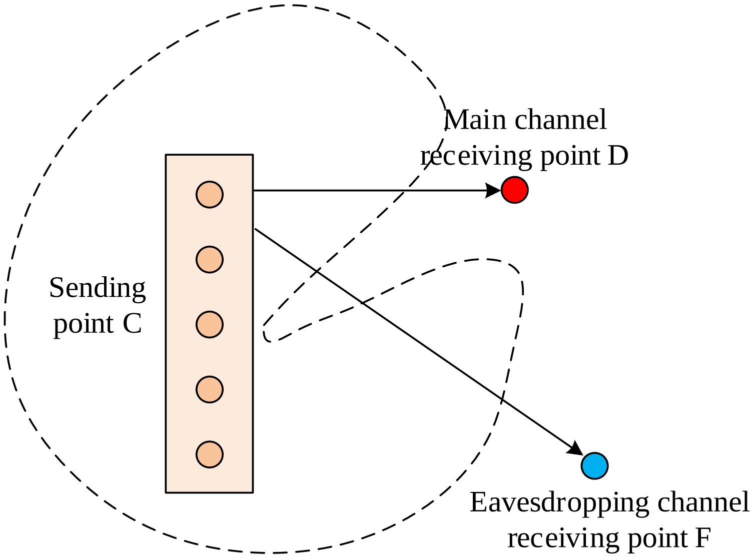

Fig. 3. Artificial noise confidentiality scheme.

In the research-designed artificial noise interference schemes, there is an artificially designed noise between the signal sender and receiver. When using this noise to interfere with eavesdroppers, it is necessary to use a legitimate channel to provide feedback on the channel status to the signal sender. After receiving channel status information, the signal sender sends zero space artificial noise to the legitimate channel based on the channel status. The legitimate receiving channel can process the received signal and extract information based on the zero space artificial noise. Due to the inability of illegal channels to provide feedback on channel status to the sender, zero space artificial noise cannot be obtained. Artificial noise between communication networks can interfere with the transmitted signal, organizing eavesdroppers to read signal information. In this scheme, the received signal z_k of the main channel can be represented as Eq. (8).

$$z_k = h_k x_k + n_k \tag{8}$$

In Eq. (8), h_k represents the main channel vector. x_k stands for sending signals. n_k represents the Gaussian white noise vector of the main channel. The received signal y_k of the eavesdropping channel can be expressed as Eq. (9).

$$y_k = g_k x_k + e_k \tag{9}$$

In Eq. (9), g_k represents the eavesdropping channel vector. e_k represents the Gaussian white noise vector of the eavesdropping channel. When the information sender is equipped with multiple antennas, the transmitted signal can be represented as Eq. (10).

$$x_k = p_k u_k + w_k \tag{10}$$

In Eq. (10), u_k represents the carrier signal. w_k represents artificial noise signal. p_k represents the beam wave vector. Artificial noise signals need to meet Eq. (11).

$$\begin{cases} h_k w_k = 0 \\ h_k p_k \neq 0 \end{cases} \tag{11}$$

At this point, the received signal at the main channel can be represented as Eq. (12).

$$z_k = h_k p_k u_k + n_k \tag{12}$$

The received signal at the eavesdropping channel can be expressed as Eq. (13).

$$y_k = g_k p_k u_k + g_k w_k + e_k \tag{13}$$

In order to make the impact of artificial noise on the eavesdropping channel equal in each direction, it can be designed as Eq. (14).

$$w_k = \Gamma_k v_k \tag{14}$$

In Eq. (14), Γ_k represents the zero space matrix of h_k, and v_k represents an independent and identically distributed Gaussian vector with a mean of 0.

B. *Collaborative Interference Analysis Based on Clustering Scenarios*

Clustering scenario is a commonly used network architecture model in wireless sensor networks. This scheme divides each node in the network into different clusters, with each cluster having a node called a cluster head responsible for managing and organizing communication within the cluster [20-21]. Within each cluster, cluster head nodes manage and control member nodes, collect and summarize data from nodes within the cluster, and then transmit this data to base stations or other cluster head nodes. Clustering can adapt to the dynamic joining and exiting of nodes, and cluster heads can reorganize the cluster structure based on changes in nodes within the cluster, maintaining network connectivity and stability. Moreover, each cluster can be independently managed, while the cluster head can be responsible for monitoring the status of nodes within the cluster and maintaining the stability of the cluster. If some nodes within a cluster fail, the cluster head can reorganize the remaining nodes or collaborate with other clusters to ensure the continuity of network services. In a clustered cluster, data transmission first occurs within the cluster and then communicates with other clusters or base stations through the cluster head. In a clustered cluster, the cluster head can aggregate data within the cluster, reduce redundant data transmission, and improve data transmission efficiency. This approach reduces the need for direct communication between each node and the base station and lowers the communication overhead of the entire network. During the communication process, the cluster head is responsible for collecting and transmitting data within the cluster, while other nodes reduce energy consumption due to reduced direct communication with base stations. The selection of cluster heads can be based on the energy level of nodes, thereby achieving balanced energy consumption and extending the service life of the network. This method can significantly reduce the number of communications between nodes, thereby significantly reducing energy consumption and improving the network's lifespan. In the process of dividing clusters, different goals and standards can be used, such as geographical location, energy consumption, network conditions, and so on. Due to the fact that the nodes in each cluster are usually located in similar areas, the communication distance between nodes is short, which is beneficial for energy conservation and improving network performance. Cluster routing is shown in Fig. 4.

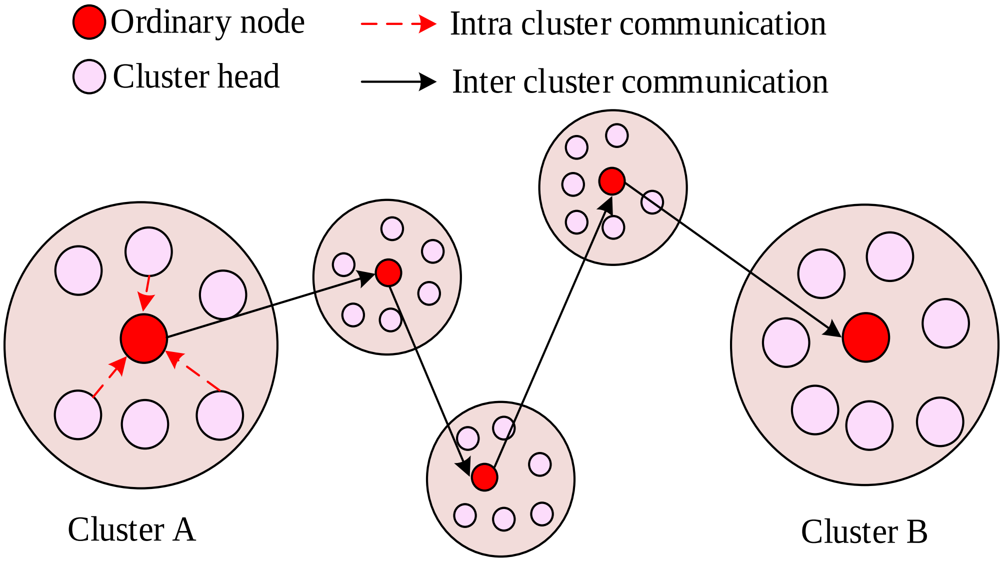

Fig. 4. Clustering routing.

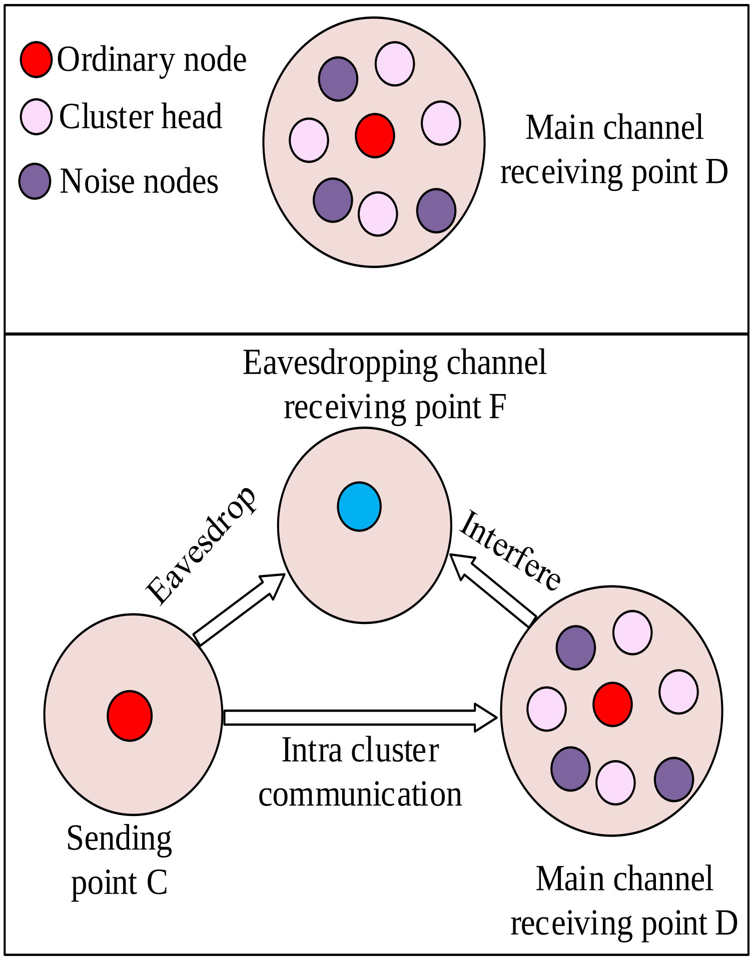
Clustered wireless sensor networks provide a natural scenario for achieving collaborative interference. Firstly, in a clustering network, when cluster head nodes engage in inter cluster communication, ordinary nodes usually do not participate in intra cluster communication to avoid interference between intra cluster nodes. In this process, these temporarily idle ordinary nodes can be selected as interference nodes, jointly generating interference effects and obstructing potential eavesdroppers from obtaining information. Idle nodes within the cluster do not participate in intra cluster communication and can also accept artificial noise outside the cluster. After receiving artificial noise, idle nodes attach it to the communication space within the cluster, and attach it to the periphery of the communication nodes within the cluster, forming an interference protection layer for passing nodes. Secondly, the clustering scenario makes information exchange much more convenient. Cluster head nodes and regular nodes are relatively concentrated in physical locations and close in distance, making information exchange within a small area more convenient and efficient compared to the entire network. Cluster heads can better coordinate with ordinary nodes to generate collaborative interference, while monitoring the effectiveness of interference. In addition, the clustering scenario itself is a network management mechanism with good topology and organization. This structure provides convenience for designing and implementing collaborative interference strategies, making it easier to achieve collaborative actions between the sender and interference nodes. The two-stage collaborative interference scheme is a wireless communication strategy based on PLS. The core of this scheme is to use nodes in the network to collaborate in two stages to generate interference and improve communication security, as shown in Fig. 5.



Ordinary node
Cluster head
Noise nodes
Main channel receiving point D
Eavesdropping channel receiving point F
Eavesdrop
Interfere
Intra cluster communication
Sending point C
Main channel receiving point D

Fig. 5. Two-stage collaborative interference scheme.

The collaborative interference scheme based on clustering scenarios designed for research is based on this framework, which organizes sensor nodes in the network into multiple clusters based on specific algorithms or strategies. In each cluster, a cluster head node serves as the center to manage and command several child nodes to complete their respective tasks. The research assumes that the sender of inter cluster communication is C, the receiver is D, and the illegal eavesdropper is marked as F. C and D are cluster head nodes in two different clusters A and B. Their task is not only to collect data within their respective clusters, but also to transmit information between clusters. At the same time, illegal eavesdropper F is lurking in cluster E, attempting to intercept communication content between C and D through wireless eavesdropping channels. In order to address the potential threat of F, the plan proposes that D will select a portion of ordinary nodes belonging to cluster B under its management as interference nodes, as shown in Fig. 6.

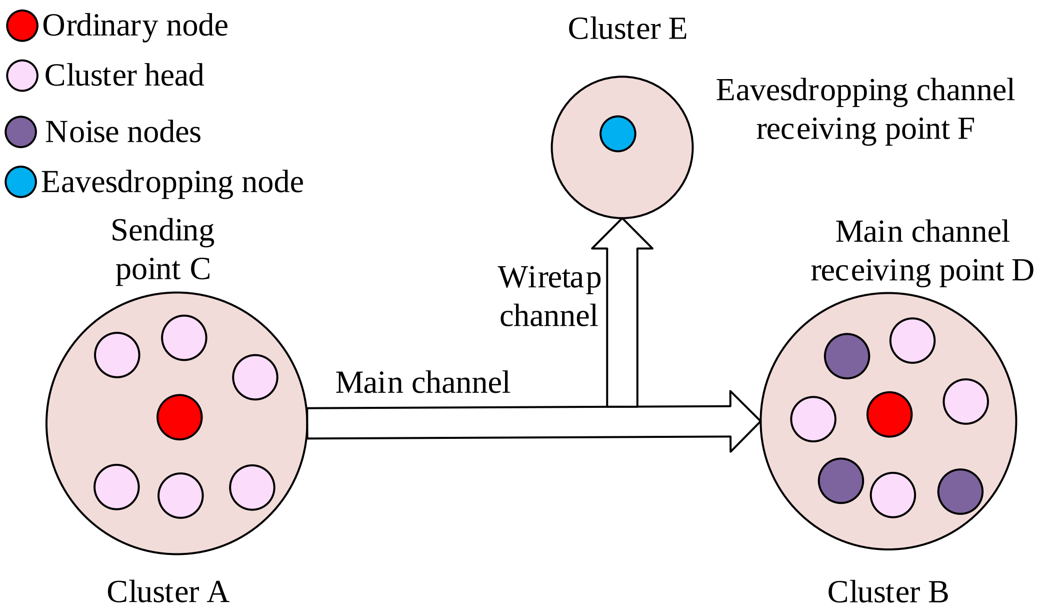


Fig. 6. Topology structure of collaborative interference network based on clustering scenarios.

Interference nodes are dynamically updated and can interfere with F's eavesdropping behavior, thereby protecting the security of information transmission. Due to the dynamic changes of nodes in clustering, it is not possible to select a constant node as the interfering node every time. Therefore, this study designs a strategy for selecting interfering nodes through the principle of reservoir sampling algorithm. Compared with traditional methods such as dynamic frequency hopping, the research-designed method not only protects wireless network communication security through PLS, but also considers the anti-interference ability of the communication channel. The study-designed wireless network communication security protection technology adopts cluster scenario design, which has good adaptability to network environment. Due to the use of PLS technology in the research-designed communication security protection methods, there may be compatibility issues with some systems or equipment. It is necessary to update or design supporting frameworks, develop compatibility layers, and improve the applicability of this technology.

IV. Analysis of Wireless Communication Eavesdropping Interference Schemes Based on Clustering Scenarios and PLS

In Section III, a wireless communication eavesdropping interference scheme based on clustering scenarios and PLS was proposed. To verify the feasibility of this scheme, simulation experiments were conducted in Section IV to analyze it. This part is divided into two sections. The first section is the setting of simulation experiment parameters and environment, and the second section is the analysis of the effectiveness of eavesdropping interference schemes.

A. *Experimental Parameters and Environmental Settings*

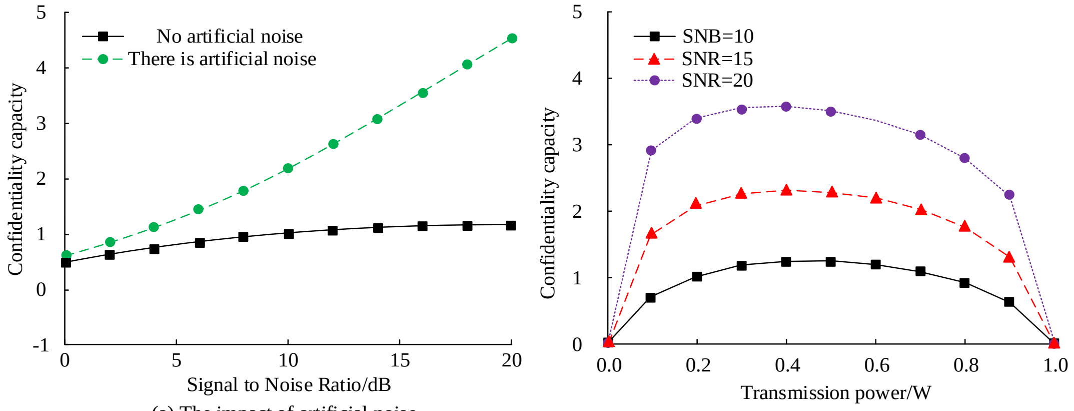
The system used in the study was Windows 10 64 bit, and the device processor was Inter (R) Core (TH) i5-12440. The device had 16GB of memory and the simulation experiment platform was MATLAB. The relevant parameters of the model are denoted in Table II.

TABLE II. MODEL PARAMETER

Parameter	Value	Unit	Parameter	Value	Unit
Total power	1	W	Cluster A radius	5	m
Antenna gain parameters	0.003	/	Cluster B radius	5	m
Main channel path loss index	2	/	Distance between the centers of cluster A and cluster B	15	m
Interference channel path loss index	2.5	/	Minimum node spacing	2	m
Communication bandwidth	5	MHz	Interference node density	0.05	Pieces/m2
Gaussian white noise unilateral spectral density	-174	dB	Eavesdropping node density	0.001	Pieces/m2

B. Analysis of the Effectiveness of Eavesdropping Interference Schemes

To evaluate the effectiveness of the proposed wireless communication network eavesdropping collaborative interference method, the study analyzed the variation of confidentiality capacity with the main channel SNR in the presence or absence of artificial noise, as well as the variation of confidentiality capacity with transmission power under different SNRs. The results are shown in Fig. 7.

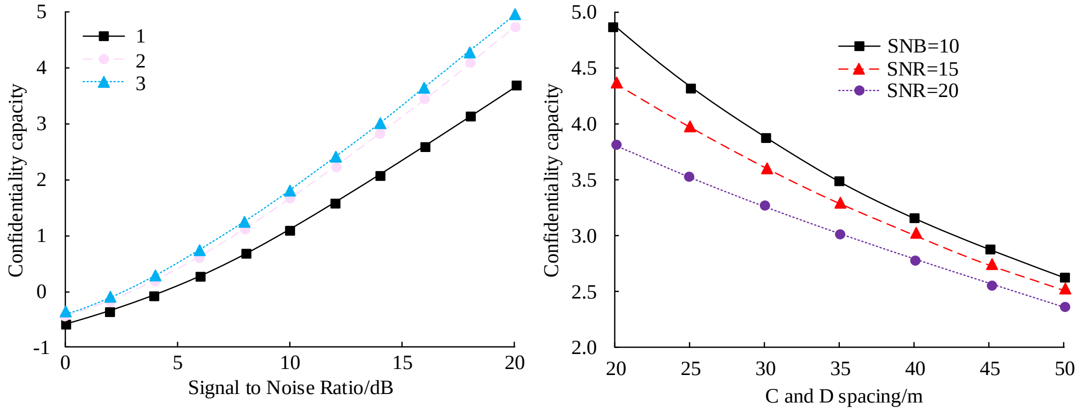


(a) The impact of artificial noise on confidentiality capacity

(b) The impact of transmission power on confidentiality capacity

Fig. 7. The recy capacity with the main channel parameter.

Fig. 7 (a) shows the change of confidentiality capacity with and without artificial noise as a function of the main channel SNR. The system confidentiality capacity remained between 0 and 1 without the addition of artificial noise. After adding artificial noise, the system's confidentiality capacity increased rapidly with the increase of the main channel SNR. When the main channel SNR was 0, the system's confidentiality capacity was about 0.5. When the main channel SNR increased to 20dB, the system's confidentiality capacity increased to above 4.0. Fig. 7 (b) shows the variation of system confidentiality capacity with transmission power under different SNRs. Regardless of the SNR, when the transmission power was 0.4W, the system's confidentiality capacity always reached its maximum value. The study analyzed the relationship between system confidentiality capacity and interfering nodes, as shown in Fig. 8.

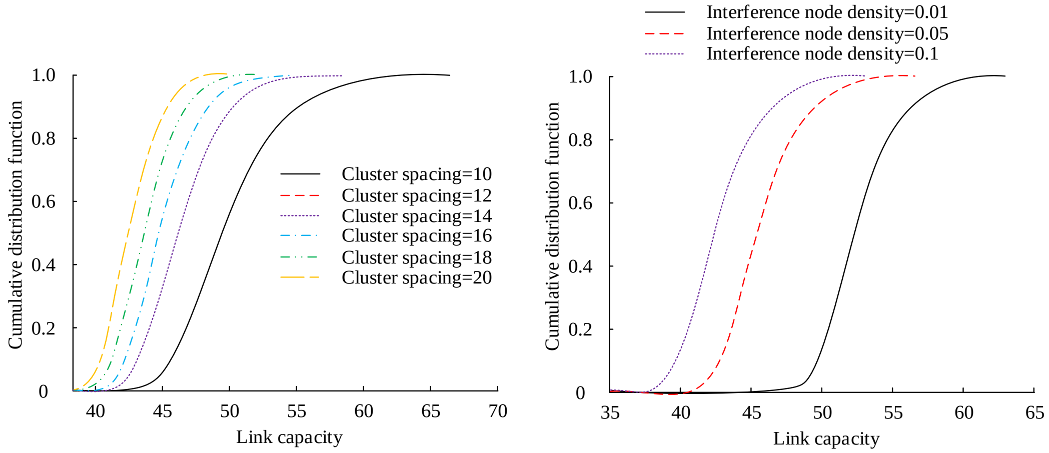


(a) The impact of artificial noise on confidentiality capacity

(b) The variation of confidentiality capacity with the distance between C and D

Fig. 8. Association between system confidentiality capacity and interference nodes.

Fig. 8 (a) shows the variation of system confidentiality capacity with SNR under different numbers of interfering nodes. When the number of interfering nodes was 1, the maximum confidentiality capacity of the system was about 4.7. After increasing the number of interfering nodes by one, the maximum confidentiality capacity of the system was about 5.8. Fig. 8 (b) shows the variation of system confidentiality capacity with the distance between C and D under different interfering nodes and F distances. When the distance between interfering nodes and F was fixed, the system's confidentiality capacity would increase with the increase of the distance between C and D. When the distance between nodes C and D was fixed, the system's confidentiality capacity would decrease as the distance between interfering nodes and F increased. Link capacity is a basic indicator for inter-cluster interference analysis. To assess the effectiveness of the proposed wireless communication eavesdropping interference scheme combining clustering scenarios and PLS, the variation of link capacity with cumulative distribution function was studied and analyzed under different cluster spacing and interference node density. The results are shown in Fig. 9.

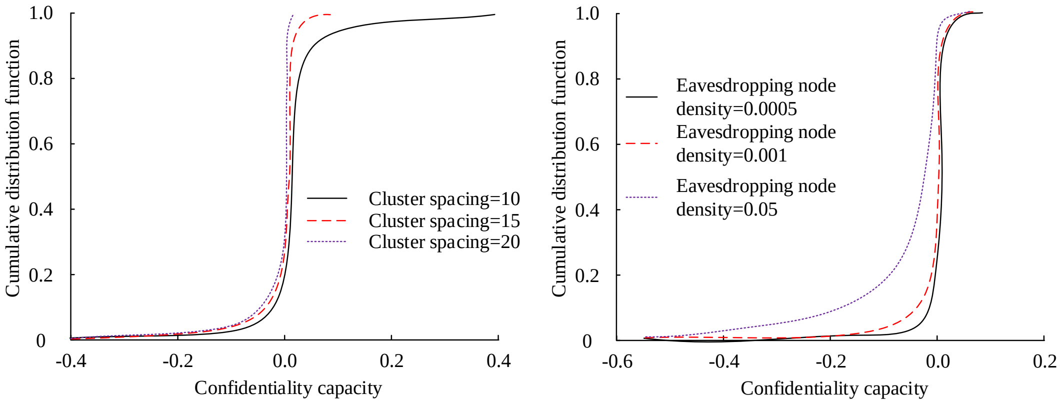


(a) Link capacity distribution under different cluster spacing

(b) The Impact of Interference Node Density on Link Capacity

Fig. 9. Effect of cluster spacing and interference node density on link capacity.

Fig. 9 (a) shows the distribution of link capacity under different cluster spacing. As can be seen, the cumulative distribution function value was 0.6, and when the cluster spacing was 10, the link capacity was about 50. When the cluster spacing was 20, the link capacity was about 30. As the cluster spacing increased, the overall link capacity decreased. As the distance between clusters increased, the loss of the signal during propagation also increased, resulting in a decrease in the energy received by the receiver, thereby reducing the overall communication performance. Fig. 9 (b) shows the distribution of link capacity under different interference node densities. As can be seen, when the cumulative distribution function value was 0.6 and the interference node density was 0.01Pieces/m2, the system link capacity was 54. When the interference node density was 0.1Pieces/m2, the system link capacity was 42. The link capacity would decrease as the density of interfering nodes increased, leading to a decrease in system communication performance. The study analyzed the variation of confidentiality capacity with the cumulative distribution function under different cluster spacing and eavesdropping node densities, as indicated in Fig. 10.

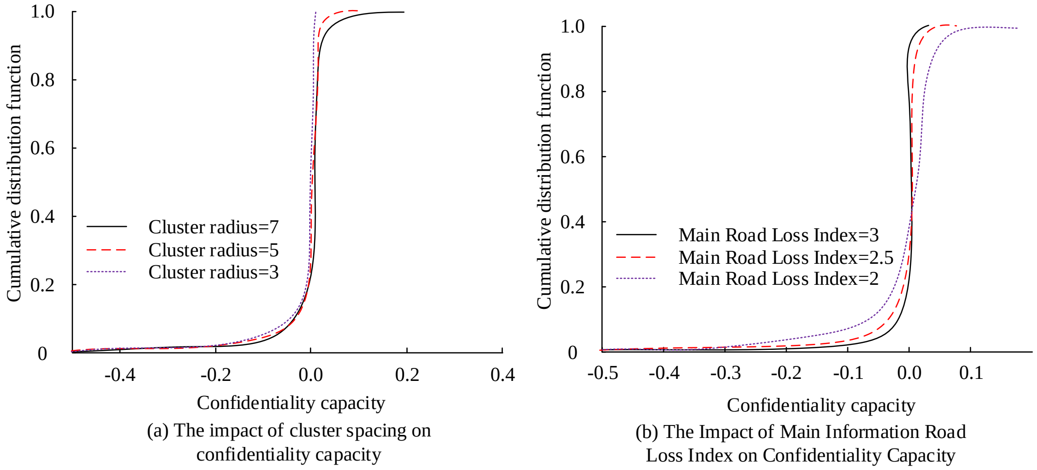


(a) The impact of cluster spacing on confidentiality capacity

(b) The impact of eavesdropping node density on confidentiality capacity

Fig. 10. Effect of cluster spacing and eavesdropping node density on confidentiality capacity.

Fig. 10 (a) shows the distribution of confidentiality capacity under different cluster spacing. As the distance between clusters increased, the signal from sender C to receiver D must be transmitted over a longer distance, which inevitably led to signal attenuation. Signal attenuation means a decrease in signal strength at receiver D, which requires a higher SNR to ensure the same communication quality. However, in actual wireless network environments, it is often difficult to compensate for signal attenuation caused by distance increase due to factors such as system transmission power and environmental noise. Fig. 10 (b) shows the distribution of confidentiality capacity under different eavesdropping node densities. As the density of eavesdropping nodes decreased, the confidentiality capacity of the system was also constantly increasing. The lower the density of eavesdropping nodes and the higher the confidentiality capacity, the better the communication performance of the system. Finally, the study also analyzed the impact of clustering radius, path loss index on the main channel, and confidentiality capacity, as denoted in Fig. 11.



(a) The impact of cluster spacing on confidentiality capacity

(b) The Impact of Main Information Road Loss Index on Confidentiality Capacity

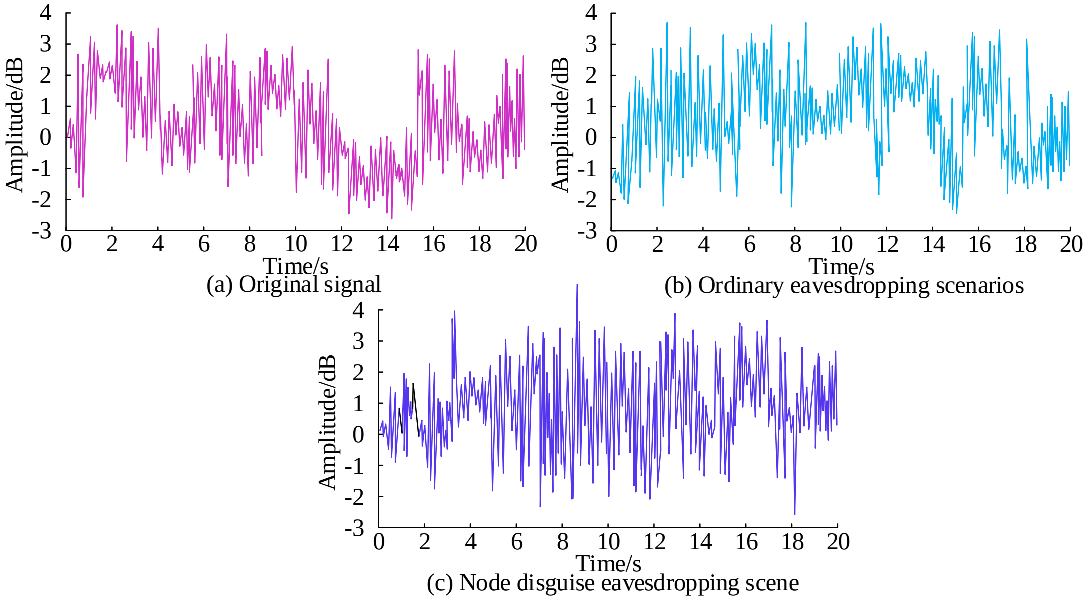
Fig. 11. Effect of branch cluster radius and main channel path loss index on secrecy capacity.

Fig. 11 (a) shows the distribution of confidentiality capacity under different clustering radii. The clustering radius had a relatively small impact on the system's confidentiality capacity. Fig. 11 (b) shows the distribution of confidentiality capacity under different main channel path loss indices. As the main channel path loss index decreased, the confidentiality capacity showed a slight increase trend. To further verify the influence of different parameter settings on confidentiality capacity, the study performed ANOVA on main channel SNR, transmission power and number of interfering nodes, and the results are shown in Table III.

TABLE III. ANALYSIS OF VARIANCE OF MAIN CHANNEL SNR, TRANSMISSION POWER AND INTERFERENCE NODES

Factor	Df1	Df2	F	P
Main channel SNR	3	30	25.6	<0.001
Transmission power	2	20	13.4	<0.001
Number of interfering nodes	4	35	8.9	<0.001

ANO analysis of variance showed that the main channel SNR (*F* (3,30) =25.6, *P* <0.001), transmission power (*F* (2,20) =13.4, *P* <0.001) and the number of interfering nodes (*F* (4,35) =8.9, *P* <0.001) significantly influenced the confidentiality capacity. To further study the eavesdropping interference effect of the design method, the results was compared with the node camouflage eavesdropping scenario, and the results are shown in Fig. 12.



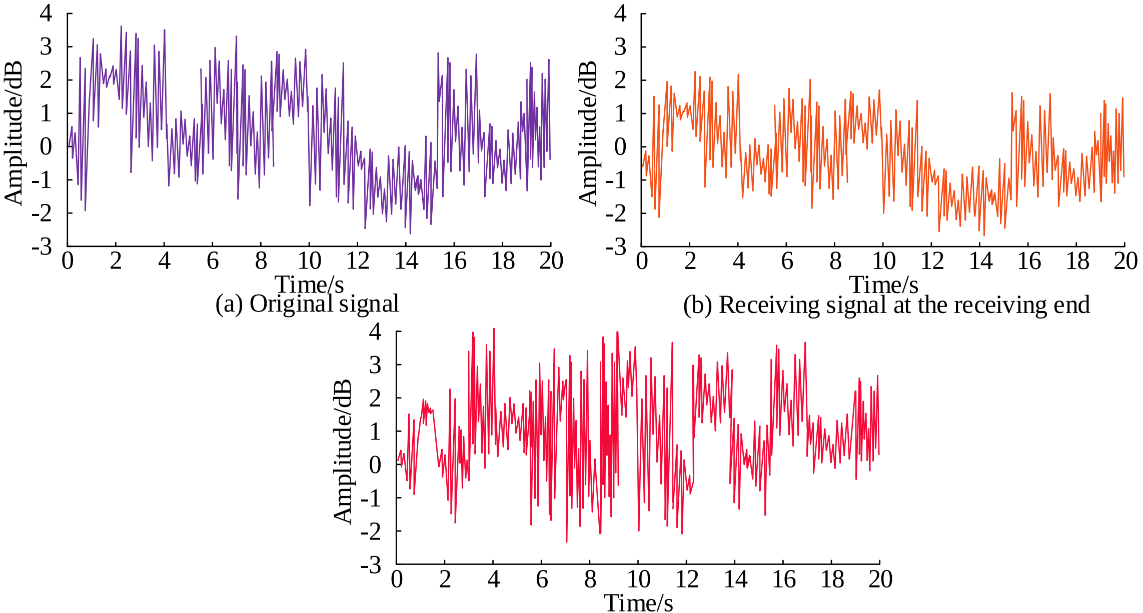
(a) Original signal

(b) Ordinary eavesdropping scenarios

(c) Node disguise eavesdropping scene

Fig. 12. The eavesdropping and interference effects in different scenarios.

Fig. 12 (a) shows the original signal at the transmitting end, Fig. 12 (b) shows the received signal of the eavesdropping channel in a normal eavesdropping scenario, and Fig. 12 (c) shows the received signal of the eavesdropping channel in a node disguised eavesdropping scenario. Regardless of the eavesdropping interference in any scenario, the designed eavesdropping interference scheme could always effectively conceal the true information of the transmitting signal. To further verify the practical application of the wireless communication network, the quality of the signal received by the receiver and the effective information in the eavesdropping information were compared. The results are shown in Fig. 13.



(a) Original signal

(b) Receiving signal at the receiving end

(c) Eavesdroppers receive signals

Fig. 13. The of interference under artificial noise.

Fig. 13 (a) is the original signal, Fig. 13 (b) is the receiving signal of the receiver, and Fig. 13 (c) is the receiving signal of the eavesdropping party. It can be seen that the waveform of the received signal at the receiving end was basically the same as the original signal waveform, but the signal amplitude was weakened, and the overall information was kept intact. The waveform of the signal received by the eavesdropper was quite different from the original signal, and only the individual bands overlapped somewhat, and the original signal information was basically not reserved. Under the interference of artificial noise, the receiving end could still receive the original signal well, and effectively avoid the risk of information leakage. When deploying the artificial noise, if the noise signal characteristics were similar to the emission signal characteristics, the eavesdropping interference effect would be poor. The artificial noise remained unchanged for a long time, which would also lead to the poor eavesdropping interference effect. Therefore, when deploying artificial noise, it is necessary to adjust the artificial noise signal at different time to improve the eavesdropping interference effect of artificial noise. To further verify the effectiveness of network eavesdropping and interference technology based on clustering scenarios and PLS, an experiment was designed to compare the anti-eavesdropping effect of this method with the artificial noise assisted secure wireless communication technology proposed in study [19]. The results are shown in Table IV.

In Table IV, when using the research-designed anti-eavesdropping method, the effective signal proportion in the signal received by the eavesdropper did not exceed 1%. However, when using the method proposed in study [19], the effective signal proportion in the signal received by the eavesdropper could reach up to 2.67%. Research on anti-eavesdropping technology can better protect privacy and security.

TABLE IV. COMPARISON OF THE ANTI-EAVESDROPPING EFFECT

Signal number	Proportion of effective information (%)	
	Proposed method	Reference [19]
1	0.56	1.35
2	0.48	2.67
3	0.95	1.94
4	0.67	2.54
5	0.89	2.13

V. DISCUSSION
