A new classification of self-similar solutions of the Navier-Stokes system of equations is presented here. We consider equations of motion for incompressible flow (of Newtonian fluids) in the curl rotating co-ordinate system. Then the equation of momentum should be split into the sub-system of 2 equations: an irrotational (*curl-free*) one, and a solenoidal (*divergence-free*) one.

The irrotational (*curl-free*) equation used for obtaining of the components of pressure gradient ∇p . As a term of such an equation, we used the irrotational *(curl-free) vector field of flow velocity,* which is given by the proper potential (*besides, the continuity equation determines such a potential as a harmonic function*)*.*

As for solenoidal (*divergence-free*) equation, the transition from Cartesian to curl rotating co-ordinate system transforms equation of motion to the *Helmholtz* vector differential equation for time-dependent self-similar solutions. The *Helmholtz* differential equation can be solved by [separation of variables](http://mathworld.wolfram.com/SeparationofVariables.html) in only 11 coordinate systems, so it forms a complete set of all possible cases of self-similar solutions for Navier-Stokes system of equations.

Keywords: Navier-Stokes equations, self-similar solutions, incompressible flow.

1. Introduction, the Navier-Stokes system of equations.

In accordance with [1-2], the Navier-Stokes system of equations for incompressible flow of Newtonian fluids should be presented in the Cartesian coordinates as below:

$$
\nabla \cdot \vec{u} = 0, \qquad (1.1)
$$

$$
\frac{\partial \vec{u}}{\partial t} + (\vec{u} \cdot \nabla) \vec{u} = -\frac{\nabla p}{\rho} + \nu \cdot \nabla^2 \vec{u} + \vec{F}, \qquad (1.2)
$$

- where \boldsymbol{u} is the flow velocity, a vector field; ρ is the fluid density, p is the pressure, ν is the kinematic viscosity, and *F* represents [body forces](http://en.wikipedia.org/wiki/Body_force) (*per unit of mass in a volume*) acting on the fluid and ∇ is the [del](http://en.wikipedia.org/wiki/Del) (nabla) operator. Let us also choose the Oz axis coincides to the main direction of flow propagation.

The system of Navier-Stokes equations is known to be the system of the mixed parabolic and hyperbolic type [3].

2. The curl rotating co-ordinate system.

Using the identity $(u \cdot \nabla)u = (1/2)\nabla(u^2) - u \times (\nabla \times u)$, and then using the curl of the curl identity $\nabla \times (\nabla \times \mathbf{u}) = \nabla (\nabla \cdot \mathbf{u}) - \nabla^2 \mathbf{u}$, we could present the equation (1.2) in the case of incompressible flow of Newtonian fluids as below:

$$
\frac{\partial \vec{u}}{\partial t} = \vec{u} \times \vec{w} + \nu \cdot \nabla^2 \vec{u} - \left(\frac{1}{2}\nabla(u^2) + \frac{\nabla p}{\rho} - \vec{F}\right)
$$
(2.1)

- here we denote *the curl field w*, a pseudovector field (*time-dependent*).

Let us consider equation (2.1) in the *curl* rotating co-ordinate system by adding of the proper *Coriolis force* to the equation of motion (2.1) as below

$$
\frac{\partial \vec{u}}{\partial t} - 2\vec{\Omega} \times \vec{u} = \vec{u} \times \vec{w} + \nu \cdot \nabla^2 \vec{u} - \left(\frac{1}{2}\nabla(u^2) + \frac{\nabla p}{\rho} - \vec{F}\right)
$$
(2.2)

- where Ω - is the angular velocity of curl rotation in the vicinity of initial Cartesian system of co-ordinates. Thermodynamic variables and the net viscous stress are independent of the reference frame; velocity u in the *curl* rotating co-ordinate system coincides with the velocity of flow in previous co-ordinates system (*if vicinity of vortex rotation is negligible*).

Besides, the equality below is valid for the angular velocity of curl rotation in the case of Newtonian fluids [2]:

$$
\Omega = (\nabla \times \boldsymbol{u})/2
$$

So, from the equation (2.2) we obtain

$$
\frac{\partial \vec{u}}{\partial t} = \mathbf{v} \cdot \nabla^2 \vec{u} - \left(\frac{1}{2} \nabla (u^2) + \frac{\nabla p}{\rho} - \vec{F}\right)
$$
(2.3)

Let us denote as below (*according to the Helmholtz fundamental theorem of vector calculus*):

$$
\nabla \times \vec{u} = \vec{w}, \qquad \vec{u} = \vec{u}_p + \vec{u}_w,
$$

$$
\nabla \cdot \vec{u}_w = 0, \qquad \nabla \times (\vec{u}_p) = 0,
$$

- where *u ^p* is *an irrotational* (*curl-free*) field of flow velocity, and *u ^w* - is *a solenoidal* (*divergence-free*) field of flow velocity which generates a curl field *w*:

$$
\vec{u}_p = \nabla \varphi, \qquad \vec{u}_w = \nabla \times \vec{A},
$$

- here φ - is the proper scalar potential, \vec{A} – is the appropriate vector potential. For such a potentials, we could obtain from the equation (1.1) the equality below

$$
\nabla \cdot (\nabla \varphi + \nabla \times \vec{A}) = 0, \implies \Delta \varphi = 0,
$$
 (2.4)

 $-$ it means that φ $-$ is the proper *harmonic function* [3].

Thus, equation (2.3) could be presented as the system of equations below:

$$
\begin{cases}\n\frac{\partial (\nabla \varphi)}{\partial t} = \vec{F} - \frac{1}{2} \nabla \{ (\nabla \varphi + \vec{u}_w)^2 \} - \frac{\nabla p}{\rho}, \\
\frac{\partial \vec{u}_w}{\partial t} = \mathbf{v} \cdot \nabla^2 \vec{u}_w,\n\end{cases}
$$
\n(2.5)

- so, if we solve the second equation of (2.5) for the components of vector *u ^w*, we could substitute it into the 1-st equation of (2.5) for obtaining of a proper expression for vector function ∇p :

$$
\frac{\nabla p}{\rho} = \vec{F} - \frac{\partial (\nabla \varphi)}{\partial t} - \frac{1}{2} \nabla \{ (\nabla \varphi + \vec{u}_w)^2 \}, \qquad (2.6)
$$

- where φ - is the proper *harmonic function*, see Eq. (2.4).

The system of equations (1.1), (2.5) is equivalent to the Navier-Stokes system of equations for incompressible Newtonian fluids $(1.1)-(1.2)$ in the sense of existence and smoothness of a general solution.

3. Classification of exact solutions for Navier-Stokes Eq.

For non-stationary solutions $\partial \partial t \neq 0$, the 2-nd of Eq. (2.5) could be solved analytically only in the cases below:

- 1) $\partial \partial \dot{\theta} t \partial \partial \dot{\theta} z$ it means that the Oz axis represents a preferential direction similar to the time arrow in mechanical processes [4];
- 2) Time-dependent self-similar case, \boldsymbol{u} \boldsymbol{w} = exp(- ω t) \boldsymbol{u} \boldsymbol{w} (x, y, z), ω = const > 0 (*frequency-parameter*).

For the time-dependent self-similar case, 2-nd of Eq. (2.5) should be presented as

$$
\nabla^2 \vec{u}_w + \left(\frac{\omega}{v}\right) \vec{u}_w = 0, \qquad (3.1)
$$

- which is the proper *Helmholtz* differential equation for vector fields *u ^w* [2].

The *Helmholtz* differential equation can be solved by [separation of variables](http://mathworld.wolfram.com/SeparationofVariables.html) in only 11 coordinate systems, 10 of which (*with the exception of [confocal paraboloidal](http://mathworld.wolfram.com/ConfocalParaboloidalCoordinates.html) [coordinates](http://mathworld.wolfram.com/ConfocalParaboloidalCoordinates.html)*) are particular cases of the [confocal ellipsoidal](http://mathworld.wolfram.com/ConfocalEllipsoidalCoordinates.html) system: [Cartesian,](http://mathworld.wolfram.com/CartesianCoordinates.html) [confocal](http://mathworld.wolfram.com/ConfocalEllipsoidalCoordinates.html) [ellipsoidal,](http://mathworld.wolfram.com/ConfocalEllipsoidalCoordinates.html) [confocal paraboloidal,](http://mathworld.wolfram.com/ConfocalParaboloidalCoordinates.html) [conical,](http://mathworld.wolfram.com/ConicalCoordinates.html) [cylindrical,](http://mathworld.wolfram.com/CylindricalCoordinates.html) [elliptic cylindrical,](http://mathworld.wolfram.com/EllipticCylindricalCoordinates.html) [oblate](http://mathworld.wolfram.com/OblateSpheroidalCoordinates.html) [spheroidal,](http://mathworld.wolfram.com/OblateSpheroidalCoordinates.html) [paraboloidal,](http://mathworld.wolfram.com/ParaboloidalCoordinates.html) [parabolic cylindrical,](http://mathworld.wolfram.com/ParabolicCylindricalCoordinates.html) [prolate spheroidal,](http://mathworld.wolfram.com/ProlateSpheroidalCoordinates.html) and [spherical](http://mathworld.wolfram.com/SphericalCoordinates.html) [coordinates](http://mathworld.wolfram.com/SphericalCoordinates.html) [5-6]. Thus, above 11 classes form a complete set of all possible cases of self-similar solutions for Navier-Stokes system of equations.

4. Discussions.

The main result, which should be outlined, is that the initial system of Navier-Stokes equations could be reduced to the equivalent system of equations where for timedependent self-similar solutions the key equation should be the *Helmholtz* vector differential Eq. For such a reduction we should change Cartesian to the curl rotating coordinate system.

The *Helmholtz* differential equation could be solved by [separation of variables](http://mathworld.wolfram.com/SeparationofVariables.html) in only 11 coordinate systems; so, we have classified all the self-similar solutions.

Also we should note that for *Helmholtz* vector differential equation it was proved the existence and smoothness of a general solution.

5. Conclusion.

A new classification of self-similar solutions of the Navier-Stokes system of equations is presented here. We consider equations of motion for incompressible flow (of Newtonian fluids) in the curl rotating co-ordinate system. Then the equation of momentum should be split into the sub-system of 2 equations: an irrotational (*curl-free*) one, and a solenoidal (*divergence-free*) one.

The irrotational (*curl-free*) equation used for obtaining of the components of pressure gradient ∇p . As a term of such an equation, we used the irrotational (*curl-free*) *vector field of flow velocity,* which is given by the proper potential (*besides, the continuity equation determines such a potential as a harmonic function*)*.*

As for solenoidal (*divergence-free*) equation, the transition from Cartesian to curl rotating co-ordinate system transforms equation of motion to the *Helmholtz* vector differential equation for time-dependent self-similar solutions. The *Helmholtz*

differential equation can be solved by [separation of variables](http://mathworld.wolfram.com/SeparationofVariables.html) in only 11 coordinate systems, so it forms a complete set of all possible cases of self-similar solutions for Navier-Stokes system of equations.
