### 16 Glossary

17 **Activity-based approach** A modeling method that ac-  
 18 counts for the interdependent relationships among ac-  
 19 tivities and persons to derive travel demand equations.

20 **Dynamic planning** The incorporation of trends, cycles,  
 21 and feedback mechanisms into a process of actively  
 22 shaping our future. Desired futures are first defined in  
 23 terms of performance measures and a combination of  
 24 forecasting and backcasting methods are used to iden-  
 25 tify the right paths to follow in achieving these futures.

26 **Microsimulation** A method to represent the movement  
 27 in space and time of the most elementary units of  
 28 a phenomenon. When applied in traffic engineering  
 29 the units are vehicles. When applied in travel behav-  
 30 ior the units are persons and households. Multi-agent  
 31 microsimulation allows to also represent human inter-  
 32 action with each person modeled as an agent.

33 **Travel demand** The amount of travel within a time inter-  
 34 val such as number of trips in a day, total amount of  
 35 distance and total amount of travel time, the locations  
 36 (destinations) visited, the means used to reach these lo-  
 37 cations, departure time and arrival time of trips, routes  
 38 followed in reaching these locations, the sequencing  
 39 and assembly of trips in groups, and the purpose or  
 40 activity engaged in at the end of each trip.

### Definition of the Subject

41  
 42 Transportation modeling and simulation aims at the de-  
 43 sign of an efficient infrastructure and service to meet our  
 44 needs for accessibility and mobility. At its heart is good  
 45 understanding of human behavior that includes the iden-  
 46 tification of the determinants of behavior and the change  
 47 in human behavior when circumstances change either due  
 48 to control (e. g., policy actions), trends (e. g., demographic  
 49 change), or unexpectedly (e. g., disasters). This is the key  
 50 ingredient that drives most decisions in transportation  
 51 planning and traffic operations. Since transportation sys-  
 52 tems are the backbone connecting the vital parts of a city  
 53 (a region, a state or an entire country), in-depth under-  
 54 standing of transportation-related human behavior is es-  
 55 sential to the planning, design, and operational analysis of  
 56 all the systems that make a city function.

57 Understanding human nature requires us to analyze  
 58 and develop synthetic models of human agency in its most  
 59 important dimensions and the most elemental constituent  
 60 parts. This includes, and it is not limited to, understand-  
 61 ing of individual evolution along a life cycle path (from  
 62 birth to entry in the labor force to retirement to death) and  
 63 the complex interaction between an individual and the an-  
 64 thropogenic environment, natural environment, and the  
 65 social environment. Travel behavior research is one as-  
 66 pect of analyzing human nature and aims at understand-  
 67 ing how traveler values, norms, attitudes, perception and  
 68 constraints lead to observed behavior. Traveler values and  
 69 attitudes refer to motivational, cognitive, situational, and  
 70 disposition factors determining human behavior. Travel  
 71 behavior refers primarily to the modeling and analysis of  
 72 travel demand, based on theories and analytical methods  
 73 from a variety of scientific fields. These include, but are not  
 74 limited to, the use of time and its allocation to travel and  
 75 activities, methods to study this in a variety of time con-  
 76 texts and stages in the life of people, and the arrangement  
 77 or artifacts and use of space at any level of social organi-  
 78 zation such as the individual, the household, the commu-  
 79 nity, and other formal or informal groups. This includes  
 80 the movement of goods and the provision of services hav-  
 81 ing strong interfaces and relationships with the engage-  
 82 ment in activities and the movement of persons.

83 Travel behavior analysis and synthesis can be exam-  
 84 ined from both objective (observed by an analyst) and  
 85 subjective (perceived by the human) perspectives in an  
 86 integrated manner among four dimensions of time, geo-  
 87 graphic space, social space, and institutional context. In  
 88 a few occasions the models reviewed here include and in-  
 89 tegrate time and space as conceived in science with per-  
 90 ceptions of time and space by humans in their everyday

Please note that the pagination is not final; in the print version an entry will in general not start on a new page.

91 life. For this reason research includes theory formation,  
 92 data collection, modeling, inference, and simulation meth-  
 93 ods to produce decision support systems for policy assess-  
 94 ment and evaluation that combine different views of time  
 95 and space. Another objective of understanding human  
 96 behavior is conceptual integration. Explanation of facts  
 97 from different perspectives can be considered jointly to  
 98 form a comprehensive understanding of people and their  
 99 groups and their interactions with the natural and built en-  
 100 vironment. In this way, we may see explanations of human  
 101 behavior fusing into the same universal principles. These  
 102 principles eventually will lead to testable hypotheses from  
 103 different perspectives offering Wilson's, 1998, famous con-  
 104 silience among, for example, psychology, anthropology,  
 105 economics, the natural sciences, geography, and engineer-  
 106 ing. Unavoidably this is a daunting task with many model  
 107 propositions in the research domain and very few ideas  
 108 finding fertile ground in applications. The analysis-syn-  
 109 thesis path in travel behavior gave us methods that help  
 110 us understand and predict human (travel) behavior only  
 111 partially leaving many gaps [163]. However, policy ques-  
 112 tions are becoming increasingly impossible to address with  
 113 old tools, a large pool of researchers is actively working  
 114 on new methods, and many public agencies commenced  
 115 a variety of tool development projects to fill the travel be-  
 116 havior analysis gaps. To capture these trends, we see mod-  
 117 eling examples with ideas from a transdisciplinary view-  
 118 point and contributors to modeling and simulation from  
 119 a variety of merged backgrounds (e. g., see the evolution  
 120 of ideas in a sequence of the International Association for  
 121 Travel Behavior Research conferences – [www.public.asu.edu/~rpendyal/iatbr/iatbr\\_index.htm](http://www.public.asu.edu/~rpendyal/iatbr/iatbr_index.htm)).

122  
 123 In the next sections the evolving paradigm of modeling  
 124 and simulation is reviewed in detail and three of its fun-  
 125 damental sources are presented. Through the lens of con-  
 126 temporary planning practice the analytical requirements  
 127 for modeling and simulation are discussed. Then, these  
 128 same requirements are refined by examining contempo-  
 129 rary visions about the world surrounding us and the the-  
 130 ories and technologies we can use to build policy analy-  
 131 sis models. This article ends with a section describing the  
 132 emerging modeling and simulation paradigm, a brief sec-  
 133 tion of mathematical models and closes with a summary.

### 134 Introduction

135 The impressive movement forward of transportation  
 136 modeling and simulation emerges from three related but  
 137 distinct sources. The first source is a fundamental change  
 138 in planning practice that one could name *dynamic plan-*  
 139 *ning practice* to indicate the existence of bi-directional

140 time (from the past to the future and from the future to  
 141 today), as well as, assessment cycles and adjustments tak-  
 142 ing place within the short term, medium term, and long  
 143 term horizons. These cycles are also bidirectional in time.  
 144 This source contains three fundamental directions of prac-  
 145 tice that are *inventory creation and maintenance, strategy*  
 146 *measurement and evaluation, forecasting and backcasting*.  
 147 The second source is a vision that generates the substan-  
 148 tive problems that we need to solve and the specific policies  
 149 we need to examine. It is named *sustainable and green vi-*  
 150 *sions*. Problems and solutions in this general area motivate  
 151 and inspire contemporary substance and content of poli-  
 152 cies throughout the world. One can identify three comple-  
 153 mentary and mutually strengthening directions in the  
 154 *economy, environment, and society* that are the three fun-  
 155 damental pillars of sustainability. The third source is the  
 156 never ending research for improved understanding of the  
 157 world surrounding us. This source is named *new research*  
 158 *and technology* to capture the most important elements of  
 159 new discovery and new techniques enabling new discov-  
 160 ery but also modeling and simulation. Key directions of  
 161 inquiry within research and technology are *theory build-*  
 162 *ing, modeling and simulation, and enabling technologies*.

### Dynamic Planning Practice

163  
 164 Dynamic thinking means that time and change are intrin-  
 165 sic in the thought processes underlying planning activities.  
 166 In the past, assumptions about the existence of a tenable  
 167 and general equilibrium and our ability to build the in-  
 168 frastructure needed to meet demand did not require care-  
 169 ful orchestration of actions. This was radically changed in  
 170 the industrialized world to meet specific goals using avail-  
 171 able finite resources to maximize benefits. Together with  
 172 our inability to build at will and a tendency to the preser-  
 173 vation of non-renewable resources (e. g., land and open  
 174 space, fossil fuels, time) we are much more motivated to  
 175 think strategically and to consider in a more careful way  
 176 the performance of the overall anthropogenic system as we  
 177 plan, design, operate, and manage transportation systems.  
 178 Any action of this type, however, requires that we have  
 179 a detailed and accurate picture of our facilities, their in-  
 180 terconnectedness, their status within the hierarchy of move-  
 181 ments, their conditions, and their evolving role. An accu-  
 182 rate and more complete picture like this is called an *invent-*  
 183 *ory* herein.

184 Many planning activities at all geographical levels are  
 185 preceded by data gathering steps of identifying all the  
 186 sources of data and information about the specific study  
 187 area's transportation system and its relationship with the  
 188 rest of the world. These inventories include the typical in-

189 formation about the resident population – demographics  
190 ics and employment, land available and land uses, eco-  
191 nomic development and growth, and so forth. It is worth  
192 pointing out the inventory contains data and relationships  
193 within the geographic area of interest (region) but also  
194 the region’s relationship with other areas with which sub-  
195 stantial flow of people, goods, and communication takes  
196 place. Inventories may also include data and informa-  
197 tion about cultural and historical factors. For example,  
198 statewide plans identify a variety of corridors as buffers of  
199 land and communities around major routes of the move-  
200 ment of people and goods. Some of these routes were cre-  
201 ated centuries ago when pioneers were still exploring un-  
202 charted lands. These routes experienced a major change  
203 when waterways were the main links among economic  
204 and military centers, and they are still evolving. Today  
205 these same routes contain as backbones railways, freeways,  
206 rivers, and often they surround major distribution loca-  
207 tions such as ports and airports. Their nature is heavily in-  
208 fluenced by their historical and cultural context.

209 Travel behavior analysts are familiar with inventories  
210 created for the regional long range plans, which subdivide  
211 the study area in traffic analysis zones with data from the  
212 Decennial Census suitably reformatted and packaged for  
213 use in a specific application (i. e., the long range regional  
214 plan). Then, additional data are assigned to these same  
215 subdivisions to build a richer context for modeling and  
216 simulation. Thus, the inventory for a typical long range  
217 plan is an electronic map of where people live and work,  
218 the network(s) that connect different locations, availabil-  
219 ity of different modes on each segment of the network,  
220 as well as information about travel network performance  
221 (e. g., link capacities, speeds on links, congestion, and con-  
222 nectivity). Today the tool of choice for data storage and  
223 visualization is a Geographic Information System (GIS).

224 One of the thorniest problems within this context is  
225 maintaining an up to date inventory (e. g., characteristics  
226 of the population in each zone, presence of certain types of  
227 businesses, location and characteristics of intermodal fa-  
228 cilities). This is a particularly important issue for periods  
229 in between decennial censuses. Year to year updates are  
230 very often required to provide “fresh” data. Many of these  
231 updates are becoming widely available and much less ex-  
232 pensive than in the past. For example, the inventory of the  
233 highway network, with suitable additions and improve-  
234 ments, is available from the same private providers of in-  
235 vehicle navigation systems. In a similar way, inventories  
236 of businesses and residences can also be purchased from  
237 vendors. Census data, however, are required even when  
238 one uses data from private providers because they con-  
239 tain complementary data (e. g., the age distribution of the

240 resident population) and they tend to provide wider cov-  
241 erage of a country. Although the need for inventories is  
242 undoubtedly extremely important many important issues  
243 are yet to be resolved. This is the core issue of two Trans-  
244 portation Research Board (TRB) conference proceedings  
245 on the National Household Travel Survey [http://www.trb.](http://www.trb.org/Conferences/NHTS/Program.pdf)  
246 [org/Conferences/NHTS/Program.pdf](http://www.trb.org/Conferences/NHTS/Program.pdf) and the US Census  
247 and the Census American Community Survey [http://www.](http://www.trb.org/conferences/censusdata/)  
248 [trb.org/conferences/censusdata/](http://www.trb.org/conferences/censusdata/)). Examples of unresolved  
249 issues include levels of detail we should use in updating the  
250 data we have, treatment of errors in the data and model  
251 sensitivity to these errors, frequency of data updates and  
252 treatment of missing data, and questions about merging  
253 different databases. Obviously, the answers to these ques-  
254 tions are in the form of “it depends”. It depends on the  
255 budget (time and money) available, consequences of er-  
256 rors in the data, and the use of models in decision mak-  
257 ing. In fact, one particular type of data collection is strategy  
258 measurement where some of these questions become even  
259 more important. We turn now to the second dimension in  
260 the dynamic planning practice which is about strategy and  
261 performance.

262 Strategic planning and performance-based planning  
263 changed the way we plan for the future. This has been a 20  
264 year long process in the United States as its transporta-  
265 tion policy at the Federal, State, and Metropolitan levels  
266 is shaped by three consecutive legislative initiatives (IS-  
267 TEA, TEA-21, and SAFETEA-LU). Under all three legisla-  
268 tive frameworks and independently of role, location and  
269 perceived need for investment, the overall goal of fund-  
270 ing allocation has been to maximize the performance of  
271 the transportation system in its entirety and avoid major  
272 new infrastructure building initiatives. As a result, plan-  
273 ning practice at the Federal, State, and local levels is be-  
274 coming heavily performance based and designed in a way  
275 that motivates the measurement of policy and program  
276 outcomes and judging these outcomes for funding allo-  
277 cation. Two examples of performance-based planning are  
278 the Program Assessment Rating Tool (PART) at the fed-  
279 eral level and performance-based transportation planning  
280 at the state level. PART is used to assess the management  
281 and performance of individual programs from homeland  
282 security to education, employment, and training. This is  
283 a tool that offers assessments about programs based on 25  
284 questions divided into sections. For each program a tai-  
285 lored analysis yields summaries that receive a rating from  
286 0 to 100 ranging from ineffective to effective [172]). In  
287 a different way but in the same spirit many states have cre-  
288 ated long range plans that are strategic and they measure  
289 transportation performance. Yearly evaluative updates are  
290 also used for a state’s strategic transportation plan. Af-

291 ter a comprehensive public involvement campaign a few  
 292 themes capturing the desires of the resident population  
 293 are first identified. To these themes technical requirements  
 294 based on planners and agency inputs are added, a large  
 295 number of objectives are created and then a variety of mea-  
 296 sures of performance are developed. These measures are  
 297 given target levels that evolve over time to a desired fu-  
 298 ture performance for the entire state and for a finite num-  
 299 ber of corridors of statewide significance. Yearly evalu-  
 300 ations contain measures of target achievement and they  
 301 should be used to guide an agency in its investments.  
 302 The interface with regions is also included in this perfor-  
 303 mance-based framework. Many infrastructure improve-  
 304 ment projects in the US are selected from lists of projects  
 305 that regions (called Metropolitan Planning Organizations)  
 306 submit to their state to be included in a list of projects  
 307 in the Transportation Improvement Program (TIP) and  
 308 become candidates for funding. Under statewide perfor-  
 309 mance-based planning, these projects are evaluated with  
 310 respect to their contribution in meeting the statewide per-  
 311 formance measures and in some states the performance  
 312 measures of the relevant corridor [122]. Although these  
 313 examples are far ranging in time and space, they contain  
 314 operations components and yearly evaluations that: a) re-  
 315 quire data collection, modeling, and simulation at finer  
 316 spatial and temporal scales than their counterpart plan-  
 317 ning feedbacks used in the long range transportation plan-  
 318 ning practice, and b) need a method that is able to coordi-  
 319 nate the short, medium, and long term impacts. Emerging  
 320 from these considerations are questions about the types  
 321 of consistency we need among geographic scales for plan-  
 322 ning and operations actions to perform evaluations, policy  
 323 requirements for coordination among planning activities  
 324 to ensure consistency, need for suitable methods to coordi-  
 325 nate smaller projects in broader contexts (either of pol-  
 326 icy assessment or geographical area), development of tools  
 327 required to perform measurement of impacts and pro-  
 328 gram evaluation at the newly defined assessment cycles,  
 329 and optimal planning activity with evaluation methods.  
 330 Only a few solutions to the issues above are offered by con-  
 331 temporary projects such as the TRANSLAND project [70].  
 332 Within the context of integration between land use and  
 333 transportation planning and the context of the European  
 334 Union some of the conclusions include a call to strengthen  
 335 regional plans, a stronger emphasis on public transport,  
 336 strategic planning involving all actors, and the packaging  
 337 of policies aiming at the same objectives. These themes are  
 338 very similar to statewide and US Federal and European  
 339 Union levels of planning. Very little, however, is said about  
 340 the assessment methods and the choices we make in im-  
 341 pact estimation. Performance assessment and evaluation

of program effectiveness require the use of the inventory  
 discussed before and a battery of models to forecast future  
 expectations as well as to identify the actions required to-  
 day to achieve desired futures.

As illustrated later in this article a new approach  
 emerges in which models of discrete choice are applied  
 to individual decision makers that are then used to (mi-  
 cro)simulate most of the possible combinations of choices  
 in a day. The result is in essence a synthetic generation of  
 traveling for the entire population. When the microsimu-  
 lation also includes activities and duration at activity loca-  
 tions it becomes a synthetic schedule. In parallel, for fore-  
 casting purposes a synthetic population is first created for  
 each land subdivision with all the relevant characteristics  
 and then models are applied to the residents of each sub-  
 division to represent areawide behavior. Changes are then  
 imposed on each individual as a response to policies and  
 predictive scenarios of policy impacts are thus developed.  
 The evolution of individuals, their groups, and the entire  
 study area can be used for trend analysis that includes  
 details at the level of decision makers (either for passen-  
 ger travel and/or for freight). In addition, progression in  
 time happens from the present to the future and one could  
 identify paths of change by individuals and groups if the  
 application has been designed in the proper way (e.g.,  
 keeping detailed accounting of individuals as they move in  
 time, using models that are designed for transitions over  
 time and so forth). In a forecasting setting progression in  
 time follows calendar time, temporal resolution is most of-  
 ten a year, and the treatment of dynamics is an one-way  
 causal stream to the future.

Within the broader study of futures, forecasting is the  
 method we use to develop *projective scenarios*. Perform-  
 ance-based planning, however, requires tools that can  
 extrapolate from future performance targets the actions  
 required today to reach them. In essence we also need  
*prospective studies* that start from a desirable future and  
 move backwards to identify specific actions that will lead  
 us to that prospect. *Backcasting* was invented in a study of  
 future energy options by [141], to do exactly this through  
 a participatory process. Scenarios in backcasting are the  
 “images” of the future and the possible paths that will  
 take us to that future. A typical application includes the  
 stages shown in Table 1. An open question, however, re-  
 mains with respect to scenario construction and assess-  
 ment. This is particularly important when one considers  
 the serious issues we face with inadequate design of ex-  
 periments/trials in the forecasting setting. Forecasting and  
 backcasting have some important differences in their ob-  
 jectives. On one hand forecasting is employed to identify  
 likely futures and to develop methods to help us iden-

393 tify small changes in our policies. It is also a method to  
 394 extrapolate past trends into the future and possibly ident-  
 395 ify paths of changes that are heavily influenced by habit  
 396 and inertia. Backcasting, on the other hand is designed to  
 397 discover new ways to build desirable futures. It is perfectly  
 398 aligned with strategic planning and it is a better suited  
 399 method for developing a program of conditions to meet  
 400 targets. Many of the models developed to date are designed  
 401 for forecasting applications (either to inform the design  
 402 of forecasting model systems or to create necessary com-  
 403 ponents in the model systems). Yet, planning practice is  
 404 moving towards strategy development and therefore needs  
 405 model components that fit within a backcasting scenario  
 406 building (see the reversed four-step model in Miller and  
 407 Demetsky [120], and its neural network implementation  
 408 in Sadek et al. [143] and the participatory tools in Califor-  
 409 nia (<http://www.sacregionblueprint.org/> – accessed May  
 410 2007).

#### 411 Sustainable and Green Visions

412 Policy actions also view the world surrounding us as an  
 413 integral ecosystem placing more emphasis on its overall  
 414 survival by examining direct and indirect effects of indi-  
 415 vidual policy actions and entire policy packages or pro-  
 416 grams (see the examples in [116]). This trend is not lim-  
 417 ited to transportation. Lomborg [104], shows that a sus-  
 418 tainable and green vision encompasses the entire range  
 419 of human activity and the entirety of the ecosystem we  
 420 live in. Although these are good news, because the ap-  
 421 proach enables analyzes and policies that are consistent in  
 422 their vision about futures, comprehensive views also re-  
 423 veal that the pace of economic growth and development is  
 424 in clear conflict with the biological pace of evolution with  
 425 unknown consequences [162] strengthening the view that  
 426 more comprehensive analytical frameworks are required.

427 In fact, one of the most recent studies on research  
 428 needs, which addresses the transportation and environ-  
 429 ment relationship by the Transportation Research Board  
 430 of the National Academies [167,168], expands the enve-  
 431 lope to incorporate ecology and natural systems and ad-  
 432 dresses human health in a more comprehensive way than  
 433 in the past reiterating the urgency to address unresolved  
 434 issues about environmental damage. As a result, we also  
 435 experience a clear shift to policy analysis approaches that  
 436 have an expanded scope and domain and they are char-  
 437 acterized by explicit recognition of transportation system  
 438 complexity and uncertainty.

439 Reflecting all this, *sustainable transportation* is now of-  
 440 ten used to indicate a shift in the mentality of the com-  
 441 munity of transportation analysts to represent a vision

442 of a transportation system that attempts to provide ser-  
 443 vices that minimize harm to the environment. In fact,  
 444 in one of the most comprehensive reviews of policies in  
 445 North America, Meyer and Miller [116], contrast the non-  
 446 sustainable to the sustainable approaches. They provide  
 447 a compelling argument about the change in these policies  
 448 and pathways toward a more sustainable path. In the US  
 449 during the past twenty years, the need, to examine these  
 450 new and more complex policy initiatives, has also become  
 451 increasingly pressing due to the passage of a series of leg-  
 452 islative initiatives (Acts) and associated Federal and State  
 453 regulations on transportation policy, planning, and pro-  
 454 gramming. The multi-modal character of the new legisla-  
 455 tion, its congestion management systems and the taxing  
 456 air quality requirements for selected US regions have moti-  
 457 vated many new forecasting applications that in the early  
 458 years were predominantly based on the Urban Transporta-  
 459 tion Planning System and related processes but during the  
 460 last five years motivated a shift to richer conceptual frame-  
 461 works. In point of fact, air quality mandates motivated im-  
 462 pact assessments of the so called transportation control  
 463 measures and the creation of statewide mobile source air  
 464 pollution inventories [65,107,154] that require different  
 465 analytical forecasting tools than in any pre-1990 legisla-  
 466 tive initiatives [124]. An added motivation is also lack of sub-  
 467 stantial funding for transportation improvement projects  
 468 and a shift to charge the firms that benefit the most from  
 469 transportation system improvements creating a need for  
 470 impact fee-assessment for individual private developers.  
 471 These assessments create the need for higher resolution in  
 472 the three dimensions of geography (space), time (time of  
 473 day), and social space (groups of people with common in-  
 474 terests and missions, households, individuals) used in typ-  
 475 ical regional forecasting models but also the domain of  
 476 jurisdictions where major decisions are made. They also  
 477 create a pressing need for interfaces with traffic engineer-  
 478 ing simulation tools that are approved and/or endorsed  
 479 in legislation (for examples see Paaswell et al. [126]). An-  
 480 other push for new tools is the assessment of technologies  
 481 under the general name of Intelligent Transportation Sys-  
 482 tems (i. e., bundles of technological solutions in the form  
 483 of user services attempting to solve chronic problems such  
 484 as congestion, safety, and air pollution). Natural and an-  
 485 thropogenic tragic recent events are adding requirements  
 486 for modeling and simulation and urgency in their devel-  
 487 opment and implementation as well as more detail in time  
 488 and space [75].

489 As Garrett and Wachs [46], discuss in the context  
 490 of a lawsuit against a regional planning agency in the  
 491 Bay Area, traditional four-step regional simulation mod-  
 492 els [30,80,125] are outpaced by the same legislative stream

**Travel Behaviour and Demand Analysis and Prediction, Table 1**  
**Backcasting schema**

Content	Method
Determine objectives, purpose of the analysis, temporal, spatial and substantive scope of the analysis, decide the number and type of scenarios. Identify endogenous and exogenous variables	Problem orientation with technical representatives and stakeholders
Specify goals, constraints and targets for each scenario analysis and exogenous variables	Stakeholder creativity workshop and brainstorming sessions
Describe present system (building and updating of inventories), patterns and trends. Define processes, their actors, and determinants of outcomes. Identify exogenous variables and inputs to scenario analysis.	Scenario development by technical experts
Scenario analysis. Select suitable approach, analyze system evolution at end time points and intermediate time points, develop scenarios, iterate to make sure all components are consistent/coherent	Scenario assessment by technical experts and stakeholders
Undertake impact analysis. Consolidate scenario results. Analyze social, economic and environmental impacts. Compare results of the last with targets, iterate analysis with any other step as required to ensure consistency between goals and results	Backcasting workshops and stakeholder consultation (repeat to follow the iterations)
Implement Policy Actions	

of the past 20 years that defined many of the policies described above. Unlike the “energy crisis” of the 1970s, the urgency and timeliness of modeling and simulation is becoming more urgent, more complex, and requires an “integrated” approach. Under these initiatives, forecasting models, in addition to long-term land use trends and air quality impacts, need to also address issues related to technology use and information provision to travelers in the short and medium terms. Similarly, the European Union focuses on issues such as: increasing citizen participation, intra-European integration, decentralization, deregulation, privatization, environmental concerns, mobility costs, congestion management by population segments, and private infrastructure finance (see van der Hoorn [174]). Table 2 provide an overview of policy tools that are loosely ordered from the longer term of land use and governance to medium and shorter term operational improvements depending on the lag time required for their impacts to be realized.

These policy initiatives place more complex issues in the domain of regional policy analysis and forecasting and amplify the need for methods that produce forecasts at the individual traveler and her/his household levels instead of the traffic analysis zone level. In addition to the long range planning activities and the typical traffic operations management activities, analysts and researchers in planning need to also evaluate the following: a) traveler and transportation system manager information provision and use (e. g., location based services, smart environments providing real time information to travelers, vehicles, and operators); b) combinations of transportation management actions and their impacts (e. g., parking fee

structures and city center restrictions, congestion pricing), and c) assessment of combinations of environmental policy actions (e. g., carbon taxes and information campaigns about health effects of ozone).

To perform all this we need tool that also have forecasting and backcasting capabilities that are more accurate and detailed in space and time. In fact, planning initiatives are moving toward parcel by parcel analysis and yearly assessments. It is also conceivable that we need separate analyzes for different seasons of a year and days of the week to capture seasonal and within a week variations of travel. Echoing all this and in the context of the Dutch reality Borgers, Hofman, and Timmermans [21] have identified five information need domains that the new envisioned policy analysis models will need to address and they are (in a modified format from the original list):

1. social and demographic trends that may produce a structural shift in the relationship between places and time allocation by individuals invalidating existing travel behavior model systems;
2. increasing scheduling and location flexibility and degrees of freedom for individuals in conducting their every day business leading to the need to consider additional choices (e. g., departure time from home, work at home, shopping by the internet, shifting activities to the weekend) in modeling travel behavior;
3. changing quality and price of transport modes based on market dynamics and not on external to the travel behavior policies (e. g., the effect of deregulation in public transport);

**Travel Behaviour and Demand Analysis and Prediction, Table 2**  
**Examples of Policy Tools**

Type of policy tool	Brief description	Source of information*
Land use growth and management programs	Legislation that controls for the growth of cities in sustainable paths	<a href="http://www.smartgrowth.org">www.smartgrowth.org</a> , <a href="http://www.awcnet.org">www.awcnet.org</a> <a href="http://www.fhwa.dot.gov/planning/ppasg.htm">www.fhwa.dot.gov/planning/ppasg.htm</a> <a href="http://www.compassblueprint.org">www.compassblueprint.org</a>
Land use design and attention to neighborhood design for non-motorized travel	Similar to the previous but with attention paid to individual neighborhoods	<a href="http://www.sustainable.doe.gov/landuse/luothoc.shtml">www.sustainable.doe.gov/landuse/luothoc.shtml</a> <a href="http://www.planning.dot.gov/Documents/DomesticScan/domscan2.htm">www.planning.dot.gov/Documents/DomesticScan/domscan2.htm</a>
City annexations and spheres of influence	City boundaries are divided into incorporated, within the sphere of influence, and external to manage growth	<a href="http://countypolicy.co.la.ca.us/BOSPolicyFrame.htm">http://countypolicy.co.la.ca.us/BOSPolicyFrame.htm</a> <a href="http://www.ite.org/activeliving/files/Jeff_Summary.pdf">www.ite.org/activeliving/files/Jeff_Summary.pdf</a>
Accelerated retirement of vehicles programs	Programs to eliminate high emitting and older technology vehicles	<a href="http://ntl.bts.gov/DOCS/SCRAP.html">ntl.bts.gov/DOCS/SCRAP.html</a>
Public involvement and education programs	Programs aiming at defining goals based on the public's desires	<a href="http://www.fhwa.dot.gov/reports/pittd/contents.htm">www.fhwa.dot.gov/reports/pittd/contents.htm</a>
Health promoting programs	Programs that promote physical activity in travel to benefit health	<a href="http://www.activelivingbydesign.org">www.activelivingbydesign.org</a>
Safety measures	A process to incorporate safety considerations in transportation planning	<a href="http://tmip.fhwa.dot.gov/clearinghouse/docs/safety/">tmip.fhwa.dot.gov/clearinghouse/docs/safety/</a> <a href="http://www.fhwa.dot.gov/planning/scp/">www.fhwa.dot.gov/planning/scp/</a> <a href="http://www.safetyanalyst.org/">www.safetyanalyst.org/</a>
Emission control, vehicle miles traveled, and other fee programs (including carbon taxes and trading)	Programs that shift taxation from traditional sources towards pollutant emissions and natural- resource depletion agents	<a href="http://www.fresh-energy.org/">www.fresh-energy.org/</a> <a href="http://www.fhwa.dot.gov/environment/">www.fhwa.dot.gov/environment/</a> <a href="http://www.fightglobalwarming.com/">www.fightglobalwarming.com/</a>
Congestion pricing and toll collection programs	A premium is charged to travelers that wish to travel during the most congested periods	<a href="http://www.vtpi.org/london.pdf">www.vtpi.org/london.pdf</a>
Parking fee management	Parking pricing used as a tool to restrict access by space and time	<a href="http://www.gmu.edu/depts/spp/programs/parkingTaxes.pdf">www.gmu.edu/depts/spp/programs/parkingTaxes.pdf</a>
Non-motorized systems	Programs to support walking and biking	<a href="http://www.vtpi.org/tdm/tdm25.htm">www.vtpi.org/tdm/tdm25.htm</a> <a href="http://www.psrc.org/projects/nonmotorized">www.psrc.org/projects/nonmotorized</a>
Telecommuting and Teleshopping	The employment of telecommunications to substitute-complement-enhance travel	<a href="http://www.telework-mirti.org">www.telework-mirti.org</a> <a href="http://www.vtpi.org/tdm/tdm43.htm">www.vtpi.org/tdm/tdm43.htm</a>
Flexible and staggered work programs	Programs that change the workweek of individuals and firms	<a href="http://www.its.dot.gov/JPODOCS/REPTS_PR/13669/section05.htm">www.its.dot.gov/JPODOCS/REPTS_PR/13669/section05.htm</a>
Goods movements (freight) programs to improve operations	A variety of programs to facilitate and minimize the damage for freight movement	<a href="http://ntl.bts.gov/DOCS/harvey.html">ntl.bts.gov/DOCS/harvey.html</a>
Highway system improvements in traffic operations and flow	Improved data collection, monitoring, and traffic management	<a href="http://www.transportation.org">www.transportation.org</a> <a href="http://ite.org/mega/default.asp">ite.org/mega/default.asp</a>
Intelligent Transportation Systems (ITS)	Use of telecommunications and information technology to manage and control travel	<a href="http://www.itsa.org/">www.itsa.org/</a> <a href="http://www.ertico.com/">www.ertico.com/</a> <a href="http://www.its.dot.gov/index.htm/">www.its.dot.gov/index.htm/</a>
Special event planning and associated traffic management	Enhanced procedures to handle the demands of a special event	<a href="http://tmcpsf.ops.fhwa.dot.gov/cfprojects/new_detail.cfm?id=32xxxnew=0">tmcpsf.ops.fhwa.dot.gov/cfprojects/new_detail.cfm?id=32xxxnew=0</a>
Security preparedness through metropolitan planning processes	A process to incorporate safety considerations in transportation planning	<a href="http://www.planning.dot.gov/Documents/Securitypaper.htm">www.planning.dot.gov/Documents/Securitypaper.htm</a>
Individualized marketing techniques with improved information and communication with the "customer"	Public programs to provide personal help in changing travel behavior in favor of environmentally friendly modes	<a href="http://www.local-transport.dft.gov.uk/travelplans/index.htm">www.local-transport.dft.gov.uk/travelplans/index.htm</a> <a href="http://www.travelmart.gov.au/">http://www.travelmart.gov.au/</a>

- 555 4. shifting of attitudes and potential cycles in the popula- 557  
556 tion outlook about travel options; and 558  
557 5. changing scales/jurisdictions (scale is the original term  
558 used to signify the different jurisdictions) – different

559 policy actions in different sectors have direct and in-  
560 direct effects on transportation and different policy ac-  
561 tions in transportation have direct and indirect effects  
562 in the other sectors (typical example in the US is the  
563 welfare to work program).

564 The first substantive implication of all these considera-  
565 tions is an expanded envelope of modeling and simulation.  
566 Many processes that were left outside the realm of trans-  
567 portation modeling and simulation need to be included  
568 as stages of the travel model system. One notable exam-  
569 ple is the inclusion of *residential location choice, work lo-  
570 cation choice, and school location choice* to capture the spa-  
571 tial distribution and relative location of important anchor  
572 points on travel behavior and to also capture the impact  
573 of transportation system availability and level of service  
574 on these choices. In this way when implemented policies  
575 lead to improved level of service and the relative attrac-  
576 tiveness of locations change, shifts in residential location,  
577 work location, and possibly school location can be incor-  
578 porated as impacts of transportation. A similar treatment  
579 is needed for *car ownership and car type choices* of house-  
580 holds or *fleet sizes and composition* for firms. These car-  
581 related choices are expressed as functions of parking avail-  
582 ability, energy and other costs and level of service offered  
583 by the transportation system (highway and transit). To ac-  
584 count for other resources and facilities available for house-  
585 hold travel we also need to consider processes for *driver's  
586 licensing, acquiring of public transportation subscription  
587 (passes), and participation in car sharing programs*. In this  
588 way, variables of car availability and public transportation  
589 availability in households can be used as determinants of  
590 travel behavior. Similar treatment is required for policies  
591 that change attitudes, perceptions and knowledge about  
592 travel options.

593 To address some of the policies of Table 2, we need to  
594 transition to a domain that contains a variety of outputs  
595 that include shares of program participation, sensitivity to  
596 accessibility and prices, and the usual indicators of travel  
597 on networks using input variables from the processes and  
598 behaviors discussed up to this point. Although the number  
599 of vehicles per hour per lane is the typical input of traf-  
600 fic operations software, a variety of other variables such  
601 as speeds on network links and types of vehicles are also  
602 needed for other models such as emissions estimation.

603 Ideally longer term social, economic, demographic, re-  
604 source/facilities, and circumstances of people should be  
605 converted into yearly schedules identifying periods of va-  
606 cation, workdays, special occasions, and so forth. These in  
607 turn should lead to weekly schedules separating days dur-  
608 ing which people stay at home from days during which

609 people go to work and days during which they run errands  
610 and/or engage in other non-work and non-school related  
611 activities. In this way patterns of working days versus not  
612 working days can be derived in a natural (con)sequence.  
613 As we will see in a later section, a fundamental leap of faith  
614 intervenes in practice and converts all this background in-  
615 formation into a representative day that is used to create  
616 a more or less complete sequence of activities and trips  
617 with their destinations and modes used.

618 In this way decisions and choices people make are or-  
619 ganized along the time scale in terms of the time it takes  
620 for these events to occur and their implications. For ex-  
621 ample, decisions about education, careers and occupation,  
622 and residential and job location are considered first and  
623 they condition everything that happens next. These should  
624 be formulated in terms of one or more life course long  
625 projects and not represented by a cross-sectional choice  
626 model. Similarly, decisions about yearly school and work  
627 schedules that determine work days and vacation days in  
628 a year should also be modeled as a stream of interrelated  
629 choices. Conditional on all this are the daily schedules  
630 of individuals and the myriad of decisions determining  
631 a daily schedule, which are modeled in much more de-  
632 tail and paying closer attention to the mutual dependency  
633 among the different facets of a within a day schedule. The  
634 next section explores this further in the context of research  
635 and enabling technology. A section on mathematical mod-  
636 els later in this article shows the beginning of a new way  
637 in modeling a simulation that emphasizes human interac-  
638 tion.

### 639 New Research and Technology

640 The planning and policy analysis discussion identified  
641 many requirements for modeling and simulation. Plan-  
642 ning and policy expanded the context of travel behav-  
643 ior models to entire life paths of individuals and for this  
644 reason a more general modeling framework is emerg-  
645 ing. In fact, modeling made tremendous progress toward  
646 a comprehensive approach to, in essence, build simulated  
647 worlds on computer enabling the study of complex pol-  
648 icy scenarios. Although, passenger travel received the bulk  
649 of the attention, similar contributions to new research  
650 and technology are found in modeling the movement of  
651 goods [151,153]. The emerging framework, although in-  
652 complete, is rich in the directions taken and potential for  
653 scientific discovery, policy analysis, and more comprehen-  
654 sive approaches in dealing with sustainability issues.

655 There are four dimensions that one can identify in  
656 building taxonomies of simulation models. The first is the  
657 *geographic space* and its conditional continuity, the sec-

ond is the *temporal scale* and calendar continuity, the third is interconnectedness of *jurisdictions*, and the fourth and most important is the set of relationships in *social space* for individuals and their communities. The first dimension, *geographic space* here is intended as the physical space in which human action occurs. This dimension has played important roles in transportation planning and modeling because the first preoccupation of the transportation system designers has been to move persons from one location to another (i. e., overcoming spatial separation). Initial applications considered the territory divided into large areas (traffic analysis zones), represented by a virtual center (centroid), and connected by facilities (higher level highways). The centroids were connected to the higher level facilities using a virtual connector summarizing the characteristics of all the local roads within the zone. As computational power increased and the types of policies/strategies required increased resolution, the zone became smaller and smaller. Today, is not unreasonable to expect software to handle zones that are as small as a parcel of land and transportation facilities that are as low in the hierarchy as a local road (the centroid becomes the building on a parcel and the centroid connector is the driveway of the unit and they are no longer virtual).

In modeling and simulation we are interested in understanding human action. For this reason in some applications geographic space needs to consider more than just physical features (p. 387 in [49]) moving us into the notion of place and social space (see also below). The second dimension is *time* that is intended here as continuity of time, irreversibility of the temporal path, and the associated artificiality of the time period considered in many models. For example, models used in long range planning applications use typical days (e. g., a summer day for air pollution). In many regional long-range models the unspoken assumption is that we target a typical work weekday in developing models to assess policies. Households and their members, however, may not always (if at all) obey this strict definition of a typical weekday to schedule their activities and they may follow very different decision making horizons in allocating time to activities within a day, spreading activities among many days including weekends, substituting out of home with in home activities in some days but doing exactly the opposite on others, and using telecommunications only selectively (e. g., on Fridays and Mondays more often than on other days). Obviously, taking into account these scheduling activities is by far more complex than what is allowed in existing transportation planning models. The third dimension is *jurisdictions* and their interconnectedness. The actions of each person are “regulated” by jurisdictions with different and overlapping domains

such as federal agencies, state agencies, regional authorities, municipal governments, neighborhood associations, trade associations and societies, religious groups, and formal and informal networks of families and friends. In fact, the federal government defines many rules and regulations on environmental protection. These may end up being enforced by a local jurisdiction (e. g., a regional office of an agency within a city). On the one hand, we have an organized way of governance that clearly defines jurisdictions and policy domains (e. g., tax collection in the US). On the other hand, however, the relationships among jurisdictions and decision making about allocation of resources does not follow always this orderly governance principle of hierarchy. A somewhat different and more “bottom up” relationship is found in the social network and for this reason requires a different dimension that is the fourth and final dimension named *social space* and the relationships among persons within this space. For example, individuals from the same household living in a neighborhood may change their daily time allocation patterns and location visits to accommodate and/or take advantage of changes in the neighborhood such as elimination of traffic and the creation of pedestrian zones. Depending on the effects of these changes on the pedestrian network we may also see a shift in the within the neighborhood social behavior. In contrast, increase in traffic to surrounding places may create an outcry by other surrounding neighborhoods, thus, complicating the relationships among the residents.

One important domain and entity within this social space is the household. This has been a very popular unit of analysis in transportation planning recognizing that strong relationships within a household can be used to capture behavioral variation (e. g., the simplest method is to use a household’s characteristics as explanatory variables in a regression model of travel behavior). In this way any changes in the household’s characteristics (e. g., change in the composition due to birth, death, or children leaving the nest or adults moving into the household) can be used to predict changes in travel behavior. New model systems are created to study this interaction within a household looking at the patterns of using time in a day and the changes across days and years. It is therefore very important in modeling and simulation to incorporate in the models used for policy analysis interactions among these four fundamental dimensions, which bring us to the next major issue that of scale.

The typical long range planning analysis is usually defined for larger geographical areas (region, states, and countries) and addresses issues with horizons from 10 to 50 years. In many instances we may find that large geographic scale means also longer time frames applied to

760 wider mosaics of social entities and including more diverse  
761 jurisdictions. On the other side of the spectrum issues that  
762 are relevant to smaller geographic scales are most likely to  
763 be accompanied by shorter term time frames applied to  
764 a few social entities that are relatively homogeneous and  
765 subject to the rule of very few jurisdictions. This is one im-  
766 portant organizing principle but also an indicator of the  
767 complex relationships we attempt to recreate in our com-  
768 puterized models for decision support. In developing the  
769 blueprints of these models one can choose from a variety  
770 of theories (e. g., neoclassical microeconomics) and con-  
771 ceptual representations of the real world that help us de-  
772 velop these models. At the heart of our understanding of  
773 how the world (as an organization, a household, a formal  
774 or informal group, or an individual human being) works  
775 are models of decision making and conceptual representa-  
776 tions of relationships among entities making up this world.

777 Transportation planning applications are about judg-  
778 ment and decision making of individuals and their orga-  
779 nizations. There are different settings of decision making  
780 that we want to understand. Three of these settings are the  
781 travelers and their social units from which motivations for  
782 and constraints to their behavior emerge; the transporta-  
783 tion managers and their organizations that serve the trav-  
784 elers and their social units, and the decision makers sur-  
785 rounding goods movement and service provision that con-  
786 tain a few additional actors, Southworth [151]. These in-  
787 clude land use markets (see [www.urbansim.org](http://www.urbansim.org)). Travelers  
788 received considerable attention in transportation planning  
789 and the majority of the models in practice aim at capturing  
790 their decision making process. The remaining settings re-  
791 ceived much less attention and they are poorly understood  
792 and modeled.

793 Conceptual models of this process are transformed  
794 into computerized models of a city, a region, or even a state  
795 in which we utilize components that are in turn models  
796 of human judgment and decision making (e. g., travelers  
797 moving around the transportation network and visiting  
798 locations where they can participate in activities). Models  
799 of this behavior are simplified versions of strategies used  
800 by travelers when they select among options that are di-  
801 rectly related to their desired activities. In some of these  
802 models we also make assumptions about hierarchies of  
803 motivations, actions, and consequences. Some of these as-  
804 sumptions are explicit (e. g., when deriving the functional  
805 forms of models as in the typical disaggregate choice mod-  
806 els or the rules in a production system) and in other mod-  
807 els these assumptions are implicit.

808 When designing transportation planning model inter-  
809 faces for transportation planners and managers we also  
810 implicitly make assumptions about the managers' abil-

811 ity to understand the input, agent representation, inter-  
812 nal functioning, and output of these computerized models.  
813 Our objective is therefore not only to understand travel  
814 behavior and build models that describe and predict hu-  
815 man behavior but also to devise tools that allow trans-  
816 portation managers to understand the assumed behavior  
817 in the models, study scenarios of policy actions, and define  
818 and explain policy implications to others. This, in essence,  
819 implies that we, the model system designers, create a plat-  
820 form for a relationship between planners and travelers.  
821 A similar but more direct relationship also exists between  
822 travelers and transportation managers when we design the  
823 observation methods that provide the data for modeling  
824 but also the data used to measure attitudes and opinions  
825 such as travel surveys. In fact, this relationship is stud-  
826 ied in much more detail in the survey design context and  
827 linked directly to the image of the agency conducting the  
828 survey and the positive or negative impression of the trav-  
829 elers about the sponsoring agency [33]. Most transporta-  
830 tion research for modeling and simulation, however, has  
831 emphasized traveler behavior when building surveys and  
832 their models neglecting the interface with the planners.  
833 The summary of theories below, however, applies to in-  
834 dividuals traveling in a network but also to organizations  
835 and planners in the sense used by H.A. Simon in his Ad-  
836 ministrative Behavior [150].

837 Rational decision making is a label associated with hu-  
838 man behavior that follows a strategy in identifying the best  
839 course of action. In summary, a decision maker solves an  
840 optimization problem and identifies the best existing so-  
841 lution to this problem. Within this more general strategy  
842 when an operational model is needed and this operational  
843 model provides quantitative predictions about human be-  
844 havior some kind of mathematical apparatus is needed to  
845 produce the predictions. One such machinery is the sub-  
846 jective expected utility [146] formulation of human behav-  
847 ior. In developing alternative models to SEU Simon [149]  
848 defines four theoretical components:

- 849 • A person's decision is based on a utility function assign-  
850 ing a numerical value to each option – *existence and*  
851 *consideration of a cardinal utility function*;
- 852 • The person defines an exhaustive set of alternative  
853 strategies among which just one will be selected – *abil-*  
854 *ity to enumerate all strategies and their consequences*;
- 855 • The person can build a probability distribution of all  
856 possible events and outcome for each alternate option –  
857 *infinite computational ability*; and
- 858 • The person selects the alternative that has the maxi-  
859 mum utility – *maximizing utility behavior*.

860 This behavioral paradigm served as the basis for a rich  
 861 production of models in transportation that include the  
 862 mode of travel, destinations to visit as well as the house-  
 863 hold residence (see the examples in the seminal textbook  
 864 by Ben-Akiva and Lerman [9]. It served also as the the-  
 865 oretical framework for consumer choice models and for  
 866 attempts to develop models for hypothetical situations  
 867 (see the comprehensive book by Louviere, Hensher, and  
 868 Swait [108]. It has also replaced the aggregate modeling  
 869 approaches to travel demand analysis as the orthodoxy  
 870 against which many old and new theories and applications  
 871 are compared and compete with. SEU can be considered  
 872 to be a model from within a somewhat larger family of  
 873 models under the label of weighted additive rule (WADD)  
 874 models [127]. Real humans, however, may never behave  
 875 according to SEU or related maximizing and infinitely  
 876 computational capability models (Simon labels this the  
 877 Olympian model, [149]). Based on exactly this argument  
 878 different researchers in psychology have proposed a vari-  
 879 ety of decision making strategies (or heuristics). For exam-  
 880 ple, Simon created alternate model paradigms under the  
 881 label of *bounded rationality – the limited extent to which*  
 882 *rational calculation can direct human behavior* [149,150]  
 883 to depict a sequence of a person’s actions when searching  
 884 for a suitable alternative. The modeled human is allowed  
 885 to make mistakes in this search giving a more realistic de-  
 886 scription of observed behavior (see also Rubinstein [142]).  
 887 Tversky is credited with another stream of decision mak-  
 888 ing models starting with the *lexicographic approach* [169,  
 889 in which a *person first identifies the most important at-*  
 890 *tribute, compares all alternatives on the value of this at-*  
 891 *tribute, and chooses the alternative with the best value on*  
 892 *this most important attribute. Ties are resolved in a hier-*  
 893 *archical system of attributes. Another Tversky model [170*  
 894 *assumes a person selects an attribute in a probabilistic way*  
 895 *and influenced by the importance of the attribute, all alter-*  
 896 *natives that do not meet a minimum criterion value (cutoff*  
 897 *point) are eliminated. The process proceeds with all other*  
 898 *attributes until just one alternative is left and that one is*  
 899 *the chosen. This has been named the elimination by as-*  
 900 *pects strategies (EBA) model. Later, Kahneman and Tver-*  
 901 *sky [86] developed prospect theory and its subsequent ver-*  
 902 *sion of cumulative prospect theory in Tversky and Kah-*  
 903 *naneman [171] in which a simplification step is first un-*  
 904 *dertaken by the decision maker editing the alternatives.*  
 905 *Then, a value is assigned to each outcome and a deci-*  
 906 *sion is made based on the sum of values multiplying each*  
 907 *by a decision weight. Losses and gains are treated differ-*  
 908 *ently. All these alternatives to SEU paradigms did not go*  
 909 *unnoticed in transportation research with early significant*  
 910 *applications appearing in the late 1980s. In fact, a confer-*

911 ence was organized attracting a few of the most notable  
 912 research contributors to summarize the state of the art in  
 913 behavior paradigms and documented in Garling, Laitila,  
 914 and Westin [45]. One of the earlier examples using another  
 915 of Simon’s inventions, the *satisficing behavior – acceptance*  
 916 *of viable choices that may not be optimal* – is a series of  
 917 transportation-specific applications described in Mahmas-  
 918 sani and Herman [110]. Subsequent contributions contin-  
 919 ue along the path of more realistic models and the most  
 920 recent example, discussing a few models, by Avineri and  
 921 Prashker [7], uses cumulative prospect theory giving a pre-  
 922 view of a movement toward more realistic travel behavior  
 923 models. As Garling et al. [45] and Avineri and Prashker [7]  
 924 point out, these paradigms are not ready for practical ap-  
 925 plications, contrary to the Mahmassani and colleagues ef-  
 926 forts that have been applied, and additional work is re-  
 927 quired to use them in a simulation framework for appli-  
 928 cations. Another aspect is contextual *adaptation*. Payne,  
 929 Bettman, and Johnson [127] provide an excellent review of  
 930 decision making models and their differentiating aspects.  
 931 They also provide evidence that decision makers *adapt* by  
 932 switching between decision making paradigms *to the task*  
 933 *and the context of their choices*. They also make mistakes  
 934 and they may also fail to switch strategies. As Vause [175]  
 935 discusses to some length transportation applications are  
 936 possible using multiple decision making heuristics within  
 937 the same general framework and employing a production  
 938 system approach [123]. A key consideration, however, that  
 939 has received little attention in transportation is the defini-  
 940 tion of context within which decision making takes place.  
 941 Recent production systems [5] are significant improve-  
 942 ments over past simulation techniques. However, travelers  
 943 are still assumed to be passive in shaping the environment  
 944 within which they decide to act (action space). This action  
 945 space is viewed as largely made by constraints and not by  
 946 their active shaping of their context. Goulias [58,60] re-  
 947 views another framework from human development that  
 948 is designed to treat decision makers in their active and pas-  
 949 sive roles and explicitly accounts for mutual influence be-  
 950 tween an agent (active autonomous decision maker) and  
 951 her environment.

952 Transportation modeling and simulation experienced  
 953 a few tremendously innovative and progressive steps for-  
 954 ward. Interestingly these key innovations are from non-  
 955 engineering fields but very often transferred and applied  
 956 to transportation systems analysis and simulation by en-  
 957 gineers. These are listed here in a somewhat sequential  
 958 chronological order merging technological innovations  
 959 and theoretical innovations. At exactly the time that the  
 960 Bay Area Rapid Transit system was studied and evaluated  
 961 in the 1960s, Dan McFadden (the Year 2000 Nobel Lau-

reate in Economics) and a team of researchers produced practical mode choice regression models at the level of an individual decision maker (see <http://emlab.berkeley.edu/users/mcfadden/> – accessed June 2007). The models are based on random utility maximization (of the SEU family) and their work opened up the possibility to predict mode choice rates more accurately than ever before. These models were initially named *behavioral travel-demand models* [155] and later the more appropriate term of *discrete choice models* [9] prevailed. Although restrictive in their assumptions, these models are still under continuous improvement and they have become the standard tool in evaluating discrete choices. Some of the most notable and recent developments advancing the state of the art and practice are:

- Better understanding of the theoretical and particularly behavioral limitations of these models [45,50,115];
- more flexible functional forms that resolve some of the problems raised in Williams and Ortuzar [184] allowing for different choices to be correlated when using the most popular discrete choice regression models [14,16,95];
- combination of revealed preference, stated choices by travelers, with stated preferences and intentions, answers to hypothetical questions by travelers, availability of data in the same choice framework to extract in a more informative way travelers willingness to use a mode and willingness to pay for a mode option [10,108]. This latter “improvement” enables us to assess situations that are impossible to build in the real world;
- computer-based interviewing and laboratory experimentation to study more complex choice situations and the transfer of the findings to the real world [111]<sup>TS2</sup>. This direction, however, is also accompanied by a wide variety of research studies aiming at more realistic behavioral models that go beyond mode choice and travel behavior [50]; and
- expansion of the discrete choice framework using ideas from *latent class models* with covariates that were first developed by Lazarsfeld in the 1950s and their estimation finalized by Goodman in the 1970s (see the review in [56], and discrete choice applications in [20]). This family of models was used in Goulias [57] to study the dynamics of activity and travel behavior and in the study of choice in travel behavior [12].

As mentioned earlier the rational economic assumption of the maximum utility model framework (that underlies many but not all of the disaggregate models) is very restrictive and does not appear to be a descriptive behav-

ioral model except for a few special circumstances when the framing of decisions is carefully designed (something we cannot expect to happen every time a person travels on the network). Its replacement, however, requires conceptual models that can provide the types of outputs needed in regional planning applications. A few additional research paths, labeled as *studies of constraints*, are also functioning as gateways into alternate approaches to replace or complement the more restrictive utility-based models. A few of these models also consider knowledge and information provision to travelers. The first aspect we consider is about the choice set in discrete choice models. Choice set is the set of alternatives from which the decision maker selects one. These alternatives need to be mutually exclusive, exhaustive, and finite in number [166]. Identification, counting, and issues related to the alternatives considered have motivated considerable research in choice set formation [77,78,140,158,159]. Key threat to misspecification of the choice set is the potential for incorrect predictions [161]. When this is an issue of considerable threat as in destination choice models where the alternatives are numerous, a model of choice set formation appears to be the additional burden [71]. Other methods, however, also exist and they may provide additional information about the decision making processes. Models of the processes can be designed to match the study of specific policies in specific contexts. One such example and a more comprehensive approach defining the choice sets is the situational approach [25]. The method uses in depth information from survey respondents to derive sets of reasons for which alternatives are not considered for specific choice settings (individual trips). This allows separation of analyst observed system availability from user perceived system availability (e. g., due to misinformation and willingness to consider information). This brings us to the duality between “objective choice attributes” and “subjective choice attributes”. Most transportation applications, independently of the decision making paradigm adopted, assume the analysts (modelers) and the travelers (modeled) measured attributes to be the same. Modeling the process of perceived constraints may be far more complex when one considers the influence of the context within which decisions are made. Golledge and Stimpson (pp. 33–34 in [49]) describe this within a conceptual model of decision making that has a cognitive feel to it. They also link the situational approach to the activity-based framework of travel extending the framework further (pp. 315–328 in [49]).

Chapin’s research [28], providing one of the first comprehensive studies about time allocated to activity in space and time, is also credited for motivating the foundations of

<sup>TS2</sup> Please check reference. There is only a reference for Mahmassani and Jou for the year 1998?

1063 activity-based approaches to travel demand analysis. His  
 1064 focus has been on the propensity of individuals to partic-  
 1065 ipate in activities and travel linking their patterns to  
 1066 urban planning. In about the same period Becker also de-  
 1067 veloped his theory of time allocation from a household  
 1068 production viewpoint [8] applying economic theory in  
 1069 a non-market sector and demonstrating the possibility of  
 1070 formulating time allocation models using economics rea-  
 1071 soning (i. e., activity choice). In parallel another approach  
 1072 was developing in geography and Hagerstrand's seminal  
 1073 publication on time geography [72] presents the founda-  
 1074 tions of the approach. The idea of constraints in the move-  
 1075 ment of persons was taken a step further by this time-ge-  
 1076 ography school in Lund. In that framework, the movement  
 1077 of persons among locations can be viewed as their move-  
 1078 ment in space and time under external constraints. Move-  
 1079 ment in time is viewed as the one way (irreversible) move-  
 1080 ment in the path while space is viewed as a three dimen-  
 1081 sional domain. It provides the third base about *constraints*  
 1082 in human paths in time and space for a variety of plan-  
 1083 ning horizons. These are *capability constraints* (e. g., phys-  
 1084 ical limitations such as speed); *coupling constraints* (e. g.,  
 1085 requirements to be with other persons at the same time  
 1086 and place); and *authority constraints* (e. g., restrictions due  
 1087 to institutional and regulatory contexts such as the open-  
 1088 ing and closing hours of stores). Figure 1 provides a picto-  
 1089 rial representation in space and time of a typical activity-  
 1090 travel pattern of two persons (P1 and P2) and the three  
 1091 types of constraints. H indicates home, W indicates work,  
 1092 L indicates leisure, and S indicates shopping.

1093 Cullen and Godson [31] also reviewed by Arentze and  
 1094 Timmermans [5] and Golledge and Stimpson [49] appear  
 1095 to be the first researchers attempting to bridge the gap be-  
 1096 tween the motivational (Chapin) approach to activity par-  
 1097 ticipation and the constraints (Hagerstrand) approach by  
 1098 creating a model that depicts a routine and deliberated ap-  
 1099 proach to activity analysis. The Cullen and Dobson study  
 1100 also defined many terms often used today in activity-based  
 1101 approaches. For example, each activity (stay-home, work,  
 1102 leisure, and shopping) is an episode characterized by start  
 1103 time, duration, and end time. Activities are also classif-  
 1104 ied into fixed and flexible and they can be engaged alone  
 1105 or with others. Moreover, they also analyzed sequencing  
 1106 of activities as well as pre-planned, routine, and on the  
 1107 spur of the moment activities. Within this overall theoret-  
 1108 ical framework is the idea of a project which according to  
 1109 Golledge and Stimpson [49], *is a set of linked tasks that are*  
 1110 *undertaken somewhere at some time within a constraining*  
 1111 *environment* (pp. 268–269). This idea of the project un-  
 1112 derlies one of the most exciting developments in activity-  
 1113 based approaches to travel demand analysis and forecast-

1114 ing because seemingly unrelated activity and trip episodes  
 1115 can be viewed as parts of a “big-picture” and given mean-  
 1116 ing and purpose completing in this way models of human  
 1117 agency and explaining resistance to change behavior.

1118 Most subsequent contributions to the activity-based  
 1119 approach emerge in one way or another from these initial  
 1120 frameworks with important operational improvements  
 1121 (for reviews see [5,17,89,114]). The basic ingredients of an  
 1122 activity based approach for travel demand analysis [5,84]  
 1123 are:

- 1124 a) explicit treatment of travel as derived demand [112],  
 1125 i. e., participation in activities such as work, shop, and  
 1126 leisure motivate travel but travel could also be an ac-  
 1127 tivity as well (e. g., taking a drive). These activities are  
 1128 viewed as episodes (i. e., they are characterized by start-  
 1129 ing time, duration, and ending time) and they are ar-  
 1130 ranged in a sequence forming a pattern of behavior  
 1131 that can be distinguished from other patterns (i. e., a se-  
 1132 quence of activities in a chain of episodes). In addition,  
 1133 these events are not independent and their interdepend-  
 1134 ency is accounted for in the theoretical framework;
- 1135 b) the household is considered to be the fundamental so-  
 1136 cial unit (i. e., decision making unit) and the interac-  
 1137 tions among household members are explicitly mod-  
 1138 eled to capture task allocation and roles within the  
 1139 household, relationships at one time point and change  
 1140 in these relationships as households move along their  
 1141 life cycle stages and the individual's commitments and  
 1142 constraints change and these are depicted in the activ-  
 1143 ity-based model; and
- 1144 c) explicit consideration of constraints by the spatial,  
 1145 temporal, and social dimensions of the environment is  
 1146 given. These constraints can be explicit models of time-  
 1147 space prisms [130] or reflections of these constraints in  
 1148 the form of model parameters and/or rules in a pro-  
 1149 duction system format [5].

1150 Input to these models are the typical regional model  
 1151 data of social, economic, and demographic information  
 1152 of potential travelers and land use information to create  
 1153 schedules followed by people in their everyday life. The  
 1154 output are detailed lists of activities pursued, times spent  
 1155 in each activity, and travel information from activity to  
 1156 activity (including travel time, mode used, and so forth).  
 1157 This output is very much like a “day-timer” for each per-  
 1158 son in a given region. Figure 2 provides an example of time  
 1159 allocation to different activities from an application that  
 1160 collected activity participation data [2,3]. It displays time  
 1161 allocation by one segment of the population showing the  
 1162 proportion of persons engaging in each activity by each  
 1163 hour of a day. Figure 3 shows the output from a model that

**Travel Behaviour and Demand Analysis and Prediction, Figure 1**

A two-person (P1 and P2) activity-travel pattern and the time and space limits imposed by constraints (source: Pribyl [132])

1164 predicts the presence of persons in each building during  
 1165 each hour of a day engaging in each activity type. Combin-  
 1166 ing an activity model with a typical travel demand model  
 1167 produces “volumes” of individuals at specific locations and  
 1168 on the network of a city as shown in Figure 4 (a more de-  
 1169 tailed description of this study can be found in [67,97,99].

1170 Many planning and modeling applications, however,  
 1171 aim at forecasting. Inherent in forecasting are the time  
 1172 changes in the behavior of individuals and their house-  
 1173 holds and their response to policy actions. At the heart  
 1174 of behavioral change are questions about the process fol-  
 1175 lowed in shifting from a given pattern of behavior to an-  
 1176 other. In addition to measuring change and the relation-  
 1177 ships among behavioral indicators that change in their val-  
 1178 ues over time, we are also interested in the timing, se-  
 1179 quencing, and staging of these changes. Moreover, we are  
 1180 interested in the triggers that may accelerate desirable or  
 1181 delay undesirable changes and the identification of social  
 1182 and demographic segments that may follow one time path  
 1183 versus another in systematic patterns. Knowledge about all  
 1184 this is required to design policies but it is also required to  
 1185 design better forecasting tools. Developments in explor-  
 1186 ing behavioral dynamics and advancing models for them  
 1187 have progressed in a few arenas. First, in the data collection  
 1188 arena with panel surveys, repeated observation of the same  
 1189 persons over time that are now giving us a considerable  
 1190 history in developing new ideas about data collection but  
 1191 also about data analysis [55,61] and interactive and lab-

1192 oratory data collection techniques [34] that allow a more  
 1193 in-depth examination of behavioral processes. The second  
 1194 arena is in the development of microeconomic dynamic  
 1195 formulations for travel behavior that challenge conven-  
 1196 tional assumptions and offer alternative formulations [91].  
 1197 The third arena, is in the behavior from a developmental  
 1198 viewpoint as a single stochastic process, a staged develop-  
 1199 ment process [57], or as the outcome from multiple pro-  
 1200 cesses operating at different levels [59]. Experimentation  
 1201 with new theories from psychology emphasizing develop-  
 1202 ment dynamics is a potential fourth area that is just begin-  
 1203 ning to emerge [60]. Behavioral dynamics are also exam-  
 1204 ined using more comprehensive analyzes [68] and mod-  
 1205 els [136].

1206 These models focus more on the paths of persons in  
 1207 space and time within a somewhat short time horizon such  
 1208 a day, a week, or maybe a month. The consideration of  
 1209 behavioral dynamics has expanded the temporal horizons  
 1210 to a few years. However, regional simulation models are  
 1211 very often designed for long range plans spanning 25 years  
 1212 or even longer time horizons. Within these longer hori-  
 1213 zons, changes in the spatial distribution of activity loca-  
 1214 tions and residences (land use) are substantial, changes in  
 1215 the demographic composition and spatial distribution of  
 1216 demographic segments are also substantial, and changes  
 1217 in travel patterns, transport facilities, and quality of ser-  
 1218 vice offered can be extreme. Past approaches in model-  
 1219 ing and simulating the relationship among land use, de-

1220 mographics, and travel in a region attempted to disengage  
 1221 travel from the other two treating them as mutually ex-  
 1222 ogenous. As interactions among them became more inter-  
 1223 esting and pressing, due to urban sprawl and suburban  
 1224 congestion, increasing attention was paid to their complex  
 1225 interdependencies. This led to a variety of attempts to de-  
 1226 velop “integrated model systems” that enable the study of  
 1227 scenarios of change and mutual influence between land  
 1228 use and travel. An earlier review of these models with  
 1229 heavy emphasis on discrete choice models can be found  
 1230 in Anas [4]. Miller [117] and Waddell and Ulfarsson [180]  
 1231 twenty years later provide two comprehensive reviews of  
 1232 models that have integrated many aspects in the inter-  
 1233 dependent triad of demographics-travel-land use models.  
 1234 Both reviews trace the history of some of the most notable  
 1235 developments and both link these models to the activity-  
 1236 based approach above. Both reviews also agree that a mi-  
 1237 croeconomic and/or macroeconomic approach to model-  
 1238 ing land and transportation interactions are not sufficient  
 1239 and more detailed simulation of the individuals and their

1240 organizations “acting” in an time-space domain need to  
 1241 be simulated in order to obtain the required output for in-  
 1242 formed decision making. They also introduce the idea of  
 1243 simulating interactive agents in a dynamic environment of  
 1244 other agents (multi-agent simulation). The vast literature  
 1245 is reviewed by Timmermans [163] and Miller [118], from  
 1246 different viewpoints about progress made until now. How-  
 1247 ever, they both agree that progress is rapidly made and that  
 1248 integration of land use and transportation models needs  
 1249 to move forward. Creation of integrated systems is further  
 1250 complicated by the emergence of an entire infrastructural  
 1251 system as another layer of human activity – telecommuni-  
 1252 cation. Today telecommunication and transportation rela-  
 1253 tionships are mostly absent from regional simulation plan-  
 1254 ning and modeling as well from the most advanced land  
 1255 use and transportation integrated models. Considerable  
 1256 research findings, however, have been accumulating since  
 1257 the 1970s [53,66,81,96,111,113,121,128,129,144,182]. An-  
 1258 other type of technologies (named enabling herein) helped  
 1259 us move modeling and simulation further.

Travel Behaviour and Demand Analysis and Prediction, Figure 3  
Persons and activities assigned to buildings (source: Alam [2])

A few of the most important technologies are *stochastic simulation*, *production systems*, *geographic information systems*, *interactive and technology-aided data collection approaches*, and more *flexible data analysis techniques*.

*Stochastic microsimulation*, as intended here, is an evolutionary engine software that is used to replicate the relationships among social, economic, and demographic factors with land use, time use, and travel by people. As discussed above the causal links among these groups of entities are extremely complex, non-linear, and in many instances unknown or incompletely specified. This is the reason that no closed form solution can be created for such a forecasting model system. An evolutionary engine, then, provides a realistic representation of person and household life histories (e. g., birth, death, marriages, divorces, birth of children, etc.), spatio-temporal activity opportunity evolution, and a variety of models that account for uncertainties in data, models, and behavioral variation (see [59,117], for overviews and [157] <sup>TS3</sup> for an application).

*Production systems* were first developed by Newell and Simon [123] to explicitly depict the way humans go about solving problems. These are a series of condition-action (note the parallel with stimulus-response) statements in

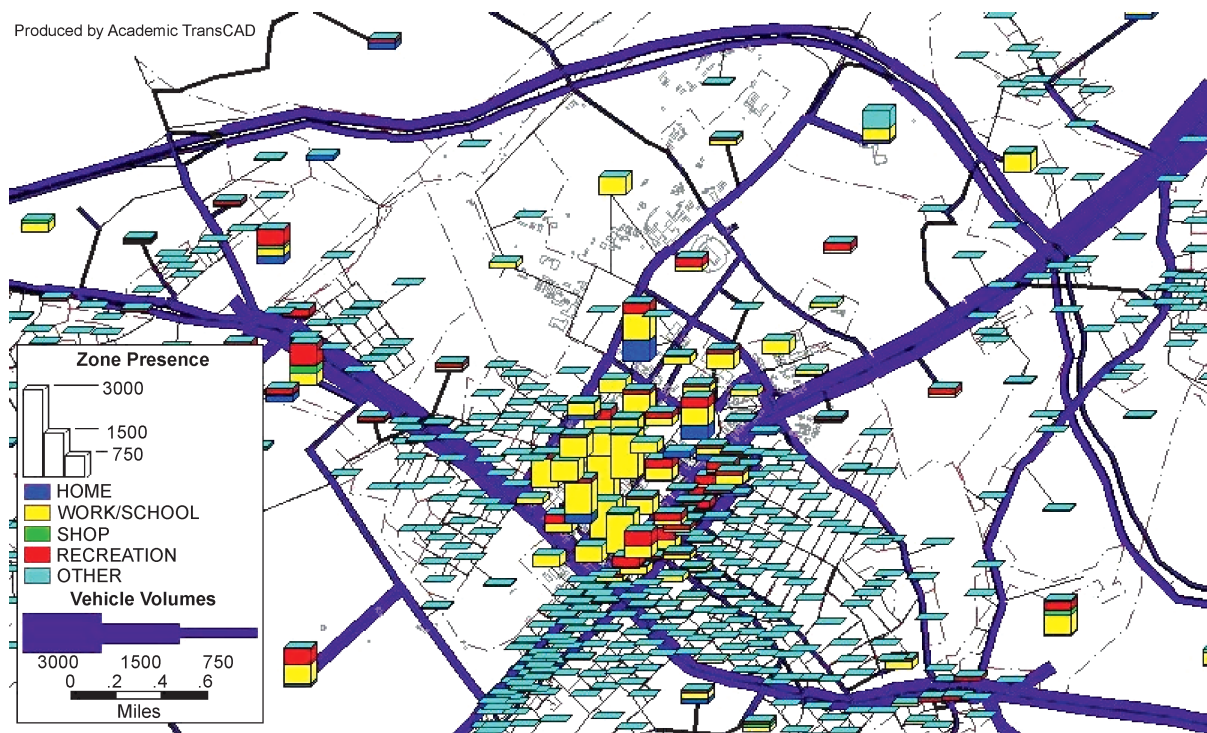

a sequence. From this viewpoint they are search processes that may never reach an absolute optimum and they replicate (or at least attempt to) human thought and action. Models of this kind are called *computational process models* (CPM) and through the use of IF ... THEN... rules have made possible the creation of a variety of new models.

*Geographic information systems* are software systems that can be used to collect, store, analyze, modify, and display large amounts of geographic data. They include layers of data that are able to incorporate relations among the variables in each layer and allow to build relationships in data across layers. One can visualize a GIS as a live map that can display almost any kind of spatio-temporal information. Maps have been used by transportation planners and engineers for long time and they are a natural interface to use in modeling and simulation. GIS today is moving beyond this relational database definition and is transforming the entire field into GI Science, which is beyond the scope of this article.

*Advanced data collection methods and devices* that are technologies that merit a note, although, not strictly developed for modeling. The first is about data collection and particularly data collection using internet technologies to build complex interviews that are interactive and

Travel Behaviour and Demand Analysis and Prediction, Figure 4

Persons and activities assigned to buildings and travel to the network (source: Goulias et al. [67])

dynamic [34]. In the same line of development we also see the use of geographic positioning systems (GPS) that allow one to develop a trace of individual paths in time and space [35,186]. Very important development is also the emergence of devices that can record the bulk of environmental data surrounding a person's movement, classify the environment in which the individual moves, and then ask simplified questions [74].

*Soft computing and non-parametric data analysis* is the last innovation mentioned here. In the data analysis we see greater strides in using data mining and artificial intelligence-born techniques to extract travel behavior patterns [134,160] and advanced and less restrictive statistical methods to discover relationships in travel behavior data (e.g., [88]). Soft computing is increasingly finding many applications in activity-based models (see [www.imob.uhasselt.be](http://www.imob.uhasselt.be)). For a more recent and accessible review see Pribyl [133].

### The Evolving Modeling Paradigm

Policies are dictating to create and test increasingly more sophisticated policy assessment instruments that account for direct and indirect effects of behavior, procedures for

behavioral change, and to provide finer resolution in the four dimensions of geographic space, time, social space, and jurisdictions. Dynamic planning is also stressing the need to examine trends, cycles, and the inversion of time progression to develop paths from the future visions to today's actions. New model developments are also becoming increasingly urgent. Although, tremendous progress has been observed in the past 20 years, development requires a faster pace to create new policy tools. These policy tools need to disentangle the actions of persons under different policy actions and the impact of policy actions on aggregates to identify conflicts and resolutions. Supporting all this is a rich collection of decision paradigms that are already used and a few new ideas are starting to migrate to practice as illustrated below.

Early models incorporating activity-based behavioral processes into applications were published in the late 1970s and early 1980s as proof-of-concept and experimental applications. Following Hagerstrand's time-geography approach, PESASP [103] is one of the first models to operationally show the use of a time-space prism and to account for the relationship among activities. The Cullen and Godson [31] study was also the first comprehensive treatment of activities that brought different research

1354 findings together. In parallel, models were developed that  
1355 were utility-maximizing models such as Adler and Ben-  
1356 Akiva model [1] and much later the Kawakami and Isobe  
1357 model [87]. Following these studies, BSP [79] and Compu-  
1358 tational Algorithms for Rescheduling Lists of Activities –  
1359 CARLA [83] also use the activities within a time-space  
1360 prism paradigm and define the foundations of data col-  
1361 lection for activity-based approaches.

1362 After this period of experimentation three streams  
1363 in model development emerged. The first is in deriv-  
1364 ing representative activity patterns (RAPs) and then us-  
1365 ing regression techniques to correlate RAPs to person  
1366 and household social and demographic data and then  
1367 forecasting. The second development refines the meth-  
1368 ods used to simulate persons and adds to the forecasting  
1369 repertoire other forecasting tasks via *microsimulation*. The  
1370 third is a movement that expands the envelope to include  
1371 cognition and explicit representation of mental processes  
1372 through CPMs.

1373 The Simulation of Travel/Activity Responses to Com-  
1374 plex Household Interactive Logistic Decisions (STAR-  
1375 CHILD – Recker and McNally [138,139] derived RAPs,  
1376 employed a utility-based model and incorporated con-  
1377 straints. It is considered a fundamental transition devel-  
1378 opment from research to practical application of an activ-  
1379 ity-based approach and it is still the foundation of models  
1380 that first derive representative patterns and then forecast  
1381 travel behavior. The more recent SIMAP [100] is a direct  
1382 derivation of STARCHILD. In this line of development,  
1383 Ma [109] created a model system that combined long term  
1384 activity patterns (Long-term activity and travel planning –  
1385 L ATP) with a within-a-day activity scheduling and simu-  
1386 lation (Daily Activity and Travel Scheduling – DATS) in-  
1387 corporating day-to-day variation and history dependence.  
1388 Her model system produced very accurate forecasts. How-  
1389 ever it required panel survey data (the repeated observa-  
1390 tion of the same persons and households over time) that  
1391 are rarely collected. In the L ATP/DATS system longitu-  
1392 dinal statistical models are extracted from longitudinal  
1393 records and they capture important aspects of behavioral  
1394 dynamics such as habit persistence, day-to-day switching  
1395 behaviors, and account for observed and unobserved het-  
1396 erogeneity contributed by the person, the household, the  
1397 area of residence, and the area of workplace.

1398 One of the first models to include a microsimulation in  
1399 its paradigm is ORIENT [152]. This methodology suitably  
1400 refined was demonstrated in a countrywide model for the  
1401 Netherlands developed between 1989 and 1991 and named  
1402 the Microanalytic Integrated Demographic Accounting  
1403 System (MIDAS – Goulias and Kitamura [63,64]). MI-  
1404 DAS integrates demographic microsimulation, with dy-

1405 namic car ownership models and a comprehensive suite  
1406 of travel behavior equations. A cross-sectional version of  
1407 MIDAS using data from the United States was also devel-  
1408 oped by Chung and Goulias [29]. MIDAS-USA simulates  
1409 the evolution of households along with car ownership and  
1410 travel behavior for Centre County, PA, and it is linked to  
1411 a model to assign fees for development using GIS. A more  
1412 ambitious development is the Activity Mobility Simula-  
1413 tor – AMOS – by Kitamura et al. [93], which defines a few  
1414 RAPs as templates. Then, uses a neural network to identify  
1415 choices and a satisficing rule to simulate schedule changes  
1416 due to policies. While MIDAS is a strictly longitudinal pro-  
1417 cess econometric model progressing one year at a time,  
1418 AMOS is constraint-based model designed for much finer  
1419 temporal resolution. DEMOS, developed by Sundararajan  
1420 and Goulias [157] <sup>TSS</sup>, is another MIDAS derivative. DE-  
1421 MOS is an object-oriented environment designed to sim-  
1422 ulate the evolution of people and their households using  
1423 a variety of external data with the core models based on the  
1424 Puget Sound Transportation Panel. It also simulates activ-  
1425 ity participation, travel, and telecommunication market  
1426 penetration using a few representative patterns that were  
1427 derived in Ma’s L ATP/DATS supplemented by telecom-  
1428 munications and travel behavior models.

1429 SCHEDULER (Gärling et al. [43] is the first CPM that  
1430 adds a psychometric cognitive implementation based on  
1431 the Hayes-Roth and Hayes-Roth [73] planning model. In  
1432 SCHEDULER, activities, selected from the long term cal-  
1433 endar that represents a person’s long term memory, com-  
1434 prise a schedule that is “mentally executed”. Models start  
1435 to combine CPM, microsimulation, and data derived be-  
1436 havioral patterns with random utility models to fill dif-  
1437 ferent modeling needs. The Simulation Model of Activ-  
1438 ity Scheduling Heuristics (SMASH – Ettema et al. [38]) is  
1439 a CPM and econometric utility-based hybrid model that  
1440 focuses on the pre-trip planning process predicting se-  
1441 quences of activities. In parallel, COMRADE [37], uses  
1442 competing risk hazard models for activity scheduling and  
1443 incorporates duration models in the system. The Model of  
1444 Action Space in Time Intervals and Clusters (MASTIC –  
1445 Dijst and Vidakovic [32]), identifies clusters in the ac-  
1446 tion space to perform and schedule activities. Time-space  
1447 prisms are also the foundation of the Prism-Constrained  
1448 Activity-Travel Simulator (PCATS – Kitamura [90], Kita-  
1449 mura and Fujii [92]), which is also a utility-based model.  
1450 A direct operational derivative of SCHEDULER [44] was  
1451 developed by Kwan, in her 1994 dissertation [101,102],  
1452 and named GIS-Interfaced Computational-process mod-  
1453 eling for Activity Scheduling (GISICAS). It is a simpli-  
1454 fied CPM, that uses time-space constraints and GIS to  
1455 incorporate spatial information into a behavioral model

to create individual schedules, starting with activities at higher levels of priority. Other models also attempt to recreate personal schedules such as Vause's model [175], a CPM that creates a restricted choice set for creating activity patterns, a model by Ettema [39], and VISEM [41], a data-driven model that is a part of PTV Vision, an urban and regional transportation planning system, that creates daily activity patterns for behaviorally homogeneous groups within the population. Stopher et al. [156] also proposed the Simulation Model for Activity Resources and Travel (SMART) using a time geography framework and a taxonomy of activities in a GIS environment. All these use observed patterns to derive behavioral models. In contrast, Recker [137], developed the Household Activity Pattern Problem (HAPP) as a normative model based on the pick up and delivery time window problem to be used as a yardstick model testing optimal behavioral hypotheses.

The model framework that impacted practice the most in the United States is the Daily Activity Schedule model by Ben-Akiva et al. in [11]. This model, was used to create the Portland Daily Activity Schedule Model [23], advocating modeling lifestyle and mobility decisions on a scale of years. These influence daily activity schedules, which are comprised of primary and secondary tours constrained in time and space. It contains two key elements that simplify activity-based model development and takes advantage of the research surge in developing more general discrete choice models. A similar simplification using conditional probabilities was also developed for Los Angeles by Kitamura et al. [94].

Figure 5 **TS4** shows this hierarchy of decisions and the scheme used to convert the daily pattern into a system of discrete choices. This framework was used to design new models for the regions around San Francisco, New York, Columbus, Denver, Atlanta, and Sacramento [24].

Arentze and Timmermans [5] designed the most complete CPM named ALBATROSS, which is a multi-agent simulation and predicts the time, location, duration, activity companionship, and travel modes subjecting everything to spatio-temporal, institutional, and household constraints. The theoretical underpinnings of this model are by far wider and all encompassing than any other activity-based model. However, it does not simulate route choice and does not produce data suitable for traffic assignment algorithms. Development of the third version of ALBATROSS is currently underway [76]. This model is also representative of raising the ambitions of travel modelers. The Alam Penn State Emergency Management model (Alam-PSEM, Alam and Goulias [3]) is a building-by-building simulation of activity participation and presence at specific locations of a university campus for each

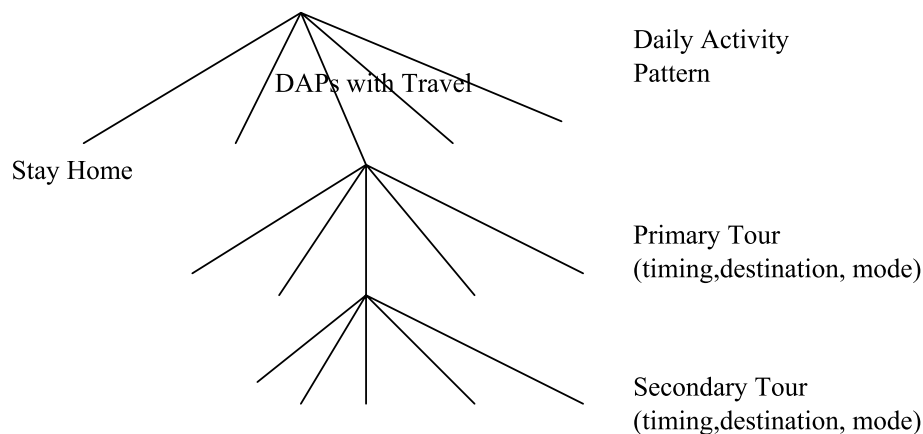

hour of a typical day. In parallel Bhat and his co-workers [15,18] developed the Comprehensive Activity-Travel Generation System for Workers (CATGW), which is a series of econometric models that replicate a commuter's evening mode choices, number of evening commute stops, and the number of stops after arriving home. The models developed by Bhat and colleagues are characterized by the use of hazard/duration regression models that were specifically developed for activity-based approaches and are by far more flexible than other regression methods. Another econometric model, the Conjoint-Based Model to Predict Regional Activity Patterns (COBRA), developed by Wang and Timmermans in [181], generates general patterns of stops for specific activities using a conjoint-based model with stated preference data instead of travel or activity diary data. The Wen and Koppelman model [183] utilizes three layers of decisions that are influenced by exogenous variables to generate activity patterns.

All these models point to new directions such as spatial choice needs to be dealt in more detail [3], activity choice and duration need to be dealt in a way that recognizes satiation in activity participation (e.g., in the duration models of Bhat [15]), sooner or later we will need to account for unobserved patterns and lack of experimental data (e.g., using conjoint experiments Wang and Timmermans [181]), and relations within the household need to also receive attention and inserted in the model hierarchy [183].

Spatial aspects of model development were considered in the CentreSIM regional model [67,98,99] that uses time-of-day activity and travel data for different market segments to predict hour-by-hour presence at locations and travel among zones. In 2004, as a part of the Longitudinal Integrated Forecasting Environment (LIFE) framework [58], Pribyl and Goulias [135] developed CentreSIM (medoid simulation) to derive a few representative patterns and simulate daily schedules accounting explicitly for within-household interactions for entire daily patterns. In the Netherlands, PATRICIA (Predicting Activity-Travel Interdependencies with a Suite of Choice-Based, Interlinked Analyzes), was developed by Borgers et al. [22] to help assess the performance of ALBATROSS. PATRICIA is a suite of linked models that incorporates an expanded set of activity choices, based on 63 distinct patterns, and activity destinations and describes activity transport modes and sequences. AURORA [82,165], which is a complementary model to ALBATROSS, is a utility-based system that models the dynamics of activity scheduling and rescheduling decisions as a function of many choice facets. AURORA is for short-term adaptation and rescheduling using just a few critical pa-

**TS4** Please confirm reference to Fig. 5.

**TS5** Please check url.

**Travel Behaviour and Demand Analysis and Prediction, Figure 5**  
**The Bowman and Ben-Akiva daily activity model formulation**

rameters. The model has since been expanded to include many new facets [76]. A much simpler model is PE-TRA [42] that allows the model to work with a small number of daily travel patterns with some statistical advantages (see also Henson et al. [76]). Microsimulation software experienced another push forward by the development of a multi-million investment in TRANSPORTATION ANALYSIS SIMULATION SYSTEM. This model system was developed in the decade 1995–2005 and one of its versions is now available via a NASA open source license from TMIP at [http://tmip.fhwa.dot.gov/transims/download\\_transims/files/3\\_1\\_1/TSS](http://tmip.fhwa.dot.gov/transims/download_transims/files/3_1_1/TSS). TRANSIMS is a survey data-driven cellular automata microsimulation and was developed by a team at Los Alamos National Laboratory [106]. It was one of the first simulation packages to contain models that create a synthetic population, generate activity plans for individuals using directly observed data in travel surveys, formulate routes on a network based on these, and execute activity plans. Microsimulation models also evolved in the interface between land use and travel behavior. The Integrated Land Use, Transportation and Environment (ILUTE) model [145] model is designed to simulate the evolution of people and their activity patterns, transportation networks, houses, commercial buildings, the economy, and the job market over time. Within this vision, Miller and Roorda [119], developed the Toronto Area Scheduling model for Household Agents (TASHA) that uses *projects* to organize activity episodes into schedules of persons. Schedules for members in a household are simultaneously generated to allow for joint activities. Both ILUTE and TASHA utilize CPMs and econometric utility-based paradigms.

Another microsimulation that uses econometric models to simulate daily activity travel patterns for an individual, is the Comprehensive Econometric Microsimulator for Daily Activity-travel Patterns (CEMDAP) model [19] that is based on land use, socio-demographic, activity system, and level-of-service (LOS) attributes. Key distinctive element of CEMDAP is its reliance on hazard-based regression models to account for the continuous nature time of activity duration. It includes population synthesis as well as the activity-pattern generation and scheduling of children, which is missing from many other simulators. Another model that utilizes constraints is the Florida Activity Mobility Simulator (FAMOS) [131]. FAMOS encompasses two modules, the Household Attributes Generation System (HAGS) and PCATS. Together, they comprise a system for modeling the activity patterns of individuals in Florida. The output is a series of activity-travel records. FAMOS is currently being further enhanced to include intra-household interactions and capture task allocation behavior among household members. Most recently, Ettema et al. [40] developed PUMA (Predicting Urbanization with Multi-Agents), a full-fledged multi-agent system of urban processes that represents land use changes in a behaviorally realistic way. These processes include the evolution of population, businesses, and land use as well as daily activity and travel patterns of people. To simulate activity-travel patterns, an updated version of AURORA by Arentze et al. [6] will be created and also in the model FEATHERS (Forecasting Evolutionary Activity-Travel of Household and their Environmental Repercussions) to simulate activity-level scheduling decisions, within-a-day rescheduling, and learning processes in high resolutions of time and space. Developed as a complement

1623 to ALBATROSS, FEATHERS is econometric utility-based  
1624 microsimulation that utilizes constraints that focuses on  
1625 the short-term dynamics of activity-travel patterns. Mem-  
1626 bers from this same Dutch team also developed MER-  
1627 LIN [173] and RAMBLAS [176].

1628 Microsimulations have continued to gain in popularity  
1629 in the activity-based modeling universe as they move from  
1630 research applications to practice. Besides the Portland  
1631 Daily Activity Schedule Model mentioned previously, New  
1632 York's "Best Practice" Model (2002) and the Mid-Ohio Re-  
1633 gional Planning Commission (MORPC) Model [179] **TS6**,  
1634 both developed by Vovsha et al., and the San Francisco  
1635 model [85] are currently being utilized by their respective  
1636 MPO. The San Francisco model is currently being updated  
1637 to implement enhanced destination choice models and be-  
1638 ing recalibrated using more recent household and census  
1639 data. Four other models for Atlanta, Sacramento, the San  
1640 Francisco Bay Area, and Denver are currently in various  
1641 stages of implementation [24].

1642 Although many past activity-based models have un-  
1643 defined or large time resolutions, STARCHILD already  
1644 in mid-1980s used 15-min temporal resolution. The most  
1645 recent models, however, go even further to simulate  
1646 activities at small time intervals such as 5 min (TA-  
1647 SHA) and 10 min intervals (SIMAP), minute by minute  
1648 (MASTIC, CentreSIM, MASTIC, GISICAS, and RAM-  
1649 BLAS), and second-by-second (TRANSIMS-LANL, AL-  
1650 BATROSS, AURORA, CATGW, CEMDAP, FAMOS, and  
1651 FEATHERS). Many applications, however, operate with  
1652 large resolutions of one hour and they are implemented  
1653 with a target of 30 min to one hour [24]. Spatial resolu-  
1654 tion of the models is still dominated by the zonal level.  
1655 ALBATROSS and MORPC both can operate at the sub-  
1656 zone level. Alam-PSEM, AURORA, CEMDAP, FEATH-  
1657 ERS, GISICAS, ILUTE, PUMA, SIMAP, SMASH, and  
1658 TRANSIMS-LANL utilize data at essentially the building  
1659 or point level. Only two applications have spatial reso-  
1660 lutions below the zonal level (Denver model that con-  
1661 tains a two-stage destination locator to predict the ad-  
1662 dress within a zone and the Sacramento model that op-  
1663 erates at the parcel level). Cognitive theories (models of  
1664 knowledge and memory as well as behavioral process for  
1665 planning activities) were used only in SCHEDULER and  
1666 based on that in ALBATROSS and FEATHERS. Behav-  
1667 ior is most often incorporated as intra-household inter-  
1668 action in ALBATROSS, CEMDAP, FAMOS, FEATHERS,  
1669 ILUTE/TASHA, and CentreSIM as well as some of the ap-  
1670 plications in regions such as MORPC.

## 1671 Examples of Mathematical Models

1672 In this section additional details of two examples of mathe-  
1673 matical models for activity and travel behavior analysis are  
1674 offered. Both examples aim at incorporating human inter-  
1675 action in time allocation models and they are multilevel  
1676 regression models (based on Goulias [59]) and group deci-  
1677 sion making utility maximization models (based on Zhang  
1678 et al. [187]).

## 1679 Multilevel Regression Models

1680 These regression models are known by different names  
1681 in different fields of research such as random coefficient  
1682 models ([69] and p. 669 in [105]) **TS7**, multilevel mod-  
1683 els [48], mixed models [147], and hierarchical linear mod-  
1684 els [26]. They describe the contextual nature of the data  
1685 and/or the way of accounting for dependent variable vari-  
1686 ation from multiple sources. Key advantages of these mod-  
1687 els are: explicit recognition in model formulation of the hi-  
1688 erarchical, multiple level and nested structure of the data  
1689 we analyze, and model specification using three groups  
1690 of regression components in the same regression model.  
1691 The first group assumes constant sensitivity to explana-  
1692 tory variables among the units of analysis representing  
1693 the mean effect of an explanatory variable on the depen-  
1694 dent variable. The second group assumes a random devi-  
1695 ation around this mean and the third group is the usual  
1696 random error term(s) of the regression equation. When  
1697 compared to traditional regression models, which contain  
1698 only one level, multilevel models do not underestimate the  
1699 standard errors of coefficient estimates avoiding overstate-  
1700 ments about the statistical significance of policy variables  
1701 (e. g., we do not exaggerate the effect of taxation on car  
1702 ownership or the effect of time and cost on route choice).  
1703 A system of multilevel regression models can be written as  
1704 follows. **TS8**

$$1705 Y_{tij}^q = \alpha_{tij}^q + \beta_k^q X_{tij} + \gamma_m^q T_{ij} \quad (1)$$

$$1706 a_{tij}^q = \gamma_0^q + v_j^q + u_{ij}^q + \varepsilon_{tij}^q, \quad \text{where } q = 1, \dots, Q, \quad (2)$$

$$1707 \beta_{k1}^q = \gamma_{k1}^q + u_{k1ij}^q, \quad \beta_{k2}^q = \gamma_{k2}^q + v_{k2j}^q. \quad (3)$$

1708 Equation (1), represents  $Q$  equations that are one for  
1709 each  $Y_{tij}^q$  variable that we want to explain and use in travel  
1710 demand forecasting. They can be the amount of time ded-  
1711 icated to activities and travel or distances to specific des-  
1712 tinations or even attributes of routes considered by trip  
1713 makers. The index  $t$  represents the time at which an obser-  
1714 vation was made for a person  $i$  from within a household  $j$

**TS6** Please confirm reference.

**TS7** Please check notation.

**TS8** Please check the following equations and declarations. There are lots of differences to the manuscript. I changed back to the manuscript input.

(with  $t = 1, 2, 3, \dots, T$ ,  $i = 1, 2, \dots$ , number of people in household  $j$ ,  $j = 1, 2, \dots$ , number of households in sample). In this way we can identify change from one time point to another by an individual and study the relationships among individuals within social units (e. g., households, associations, neighborhoods and so forth).

The time points can be the same for all individuals or they may vary depending on the data collection procedures and willingness of respondents to provide information. Equation 1 is called the level 1 model because it is written at the level of the time point (observation occasion). The first term in the right hand side of Eq. (1) is a random intercept,  $\alpha$ , given by Eq. (2). This component has specific meaning. For example,  $\alpha_{ij}^q$  is the mean value of person  $i$  in household  $j$  at time  $t$  for variable  $q$ . The term  $\varepsilon_{ij}^q$  is a random temporal variation (also called within person variation) and it is the deviation of time expenditure around  $\gamma_0^q$ . The term  $u_{ij}^q$  is a random person to person variation (also called within household variation) and it is also a deviation of around  $\gamma_0^q$ . The term  $v_j^q$  is a random household to household variation and it is also a deviation around  $\gamma_0^q$ . These are also called random error components and they are usually assumed normally distributed with  $E(\varepsilon) = E(u) = E(v) = 0$ , with  $\text{Var}(\varepsilon) = \sigma_\varepsilon^2$ ,  $\text{Var}(u) = \sigma_u^2$ , and  $\text{Var}(v) = \sigma_v^2$  to be estimated. It is worth noting that the system of equations represented by Eq. (1) contain a set of gamma coefficients (associated with a matrix  $Z$  representing explanatory variables) that are defined in a similar way as in typical regression models. The  $\beta$ s, however, that multiply the matrix  $X$  are defined as random with a mean and a variation around the means  $\gamma$ s. This variation can be due to the temporal, personal, and/or household levels. In this way, we can define a variety of equations at each of these levels to represent heterogeneous behavior that is either due to temporal fluctuations, personal variation, or household variation. Equation (3) differentiates between  $\beta$ s that vary within individuals and those that vary within households. In this way, at each level we have a level-specific variance-covariance matrix of all the random terms ( $\varepsilon$ s,  $u$ s,  $v$ s). The significance of the elements in each of these three matrices can be tested using goodness-of-fit measures based on the deviance, which is the difference in the  $-2\text{Log}(\text{likelihood})$  at convergence between two nested (in terms of specification) models. In addition, the  $\gamma$ s can also be tested if they are significantly different than zero using a  $t$ -test. The  $\gamma$ s in Eq. (1) are called the *fixed effects* and the remaining terms are called the *random effects* at each of the three levels in the hierarchy. Estimation of all the fixed and random parameters can be accomplished either by Full Information Maximum Likelihood, FIML, applied to  $Y$  directly or applied to the

least-squares residuals, called Restricted Maximum Likelihood-REML that can be used in tandem with a generalized least squares approach. Longford [105], Bryk and Raudensbush [26] and [48] provide a comprehensive review of estimation techniques, their performance assessment, and detailed algorithms.

### Household Utility Models

The second example is also representative of a movement toward more detailed consideration of within household decision making dynamics. Although the model was specified by Zhang et al. [187] for time allocation to shared ( $j$ ) and non-shared activities ( $s$ ), it is a potentially useful model for other trip making decisions. Each person in a household is assumed to form two utility functions. One utility is for the shared activities (i. e., engagement in activities with other household members) and non-shared activities. These utility functions are given by Eq. (4) (shared activity) and 5 (non-shared activity).

$$u_{is} = \exp \left( \left( \alpha_s + \sum_k \beta_{sk} x_{isk} \right) \ln \left( \sum_m \kappa_{sm} \tau_{ism} \right) + \varepsilon_{is} \right) \ln(t_{is}) \quad (4)$$

$$u_{ij} = \exp \left( \left( \alpha_j + \sum_k \beta_{jk} x_{ijk} \right) \ln \left( \sum_m \kappa_{jm} \tau_{ijm} \right) + \varepsilon_{ij} \right) \ln(t_{ij}), \quad (5)$$

where:

- $\alpha_s$  is the constant term for each shared activity  $s$ .
- $\alpha_j$  is the constant term for each shared activity  $s$ .
- $x_{isk}$  is the  $k$ th explanatory variable (and/or attribute) of household member  $i$  for shared activity  $s$ .
- $\beta_{sk}$  is the parameter associated with the  $k$ th attribute of the shared activity.
- $\tau_{ism}$  is the travel time by mode  $m$  for each activity  $s$  by person  $i$ .
- $\kappa_{sm}$  is the parameter associated with travel time by mode  $m$ .
- $\varepsilon_{is}$  is a random error term of the shared activity  $s$  by person  $i$ .
- $t_{is}$  is the amount of time dedicated to activity  $s$  by person  $i$ .
- $\alpha_j$  is the constant term for each non-shared activity.
- $x_{ijk}$  is the  $k$ th explanatory variable (attribute) of household member  $i$  for non-shared activity  $j$ .

1810  $\beta_{jk}$  is the parameter associated with the  $k$ th attribute of  
1811 non-shared activity.  
1812  $\tau_{ijm}$  is the travel time by mode  $m$  for each activity  $s$  by  
1813 person  $i$ .  
1814  $\kappa_{jm}$  is the parameter associated with travel time by  
1815 mode  $m$ .  
1816  $\varepsilon_{ij}$  is a random error term of the non-shared activity  $j$   
1817 by person  $i$ .  
1818  $t_{ij}$  is the amount of time dedicated to activity  $j$  by per-  
1819 son  $i$ .

1820 The overall utility of activity participation and travel  
1821 for each person  $i$  under the assumption of a multi-linear  
1822 utility is given by Eq. (6).

$$1823 \quad u_i = \sum_{j=1}^{J+S} r_{ij} u_{ij} + \sum_{j=1}^{J+S} \sum_{j'>j} \delta_i r_{ij'} r_{ij} u_{ij} u_{ij'} \quad (6)$$

1824 where,

1825  $u_{ij}$  is the utility of activity  $j$  for person  $i$ .  
1826  $r_{ij}$  is the relative interest of person  $i$  for activity  $j$ .  
1827  $\delta_i$  is parameter of activity dependency for member  $i$ .  
1828  $J + S$  is the number of non-shared and shared activities  
1829 for a person within the unit of time under consid-  
1830 eration.

1831 In a similar way the household utility function is  
1832 a multi-linear combination of the individual utilities in  
1833 Eq. (7).

$$1834 \quad \text{HUF} = \sum_{i=1}^n w_i u_i + \lambda \sum_{i=1}^n \sum_{i'>i} (w_i w_{i'} u_i u_{i'}) \quad (7)$$

1835 where,

1836 HUF is the household utility combining the utilities of all  
1837 household members  $n$ .  
1838  $u_i$  is the utility of household member  $i$ .  
1839  $w_i$  is the relative influence of each household member  $i$ .  
1840  $\lambda$  is a parameter of within household interaction.

1841 Under the assumption of maximizing HUF it is possi-  
1842 ble to create a Lagrangian function that accounts for con-  
1843 straints (i. e., total amount of time available, signs of pa-  
1844 rameters and so forth) and through a maximization so-  
1845 lution derive equations that can be used to estimate the  
1846 unknown parameters in Eqs. (4–7) (details are provided  
1847 in Zhang et al. [187] for time allocation). It is worth not-  
1848 ing that Zhang et al. [187], derived two alternate model  
1849 systems by changing the utility functions to represent dif-  
1850 ferent intra-household bargaining models (for a detailed

1851 review see Bengstrom 1995<sup>[TS9]</sup>). Then through a lineariza-  
1852 tion process they developed a system of linear equations  
1853 and estimated the parameters using a multiple equations  
1854 econometric approach (the Seemingly Unrelated Regres-  
1855 sion Estimation, Greene, 1993<sup>[TS10]</sup>) that is a simplifying al-  
1856 ternative to the multilevel models described earlier in this  
1857 section. A more general review of this type of model for-  
1858 mulation is also provided by Timmermans [164].

## 1859 Summary

1860 Similarities and differences among the implemented mod-  
1861 eling ideas are:

- 1862 • A hierarchy of decisions by households is assumed that  
1863 identifies longer term choices determining the shorter  
1864 term choices. In this way different blocks of variables  
1865 can be identified and their mutual correlation used to  
1866 derive equations that are used in forecasting.
- 1867 • Anchor points (Home location – work location –  
1868 school location) are inserted in the first choice level  
1869 and they define the overall spatial structure of activity  
1870 scheduling.
- 1871 • Out-of-home activity purposes include work, school,  
1872 shopping, meals, personal business, recreation, and es-  
1873 cort. These expand the original home-based and non-  
1874 home based purposes in travel behavior and the three  
1875 activity types in home economics (labor for pay, labor  
1876 at home, and leisure).
- 1877 • In-home activities are explicitly modeled or allowed to  
1878 enter the model structure as a “stay-at-home” choice  
1879 with some models allowing for activity choice at home  
1880 (work, maintenance and discretionary). In this way  
1881 limited substitution between at home and outside  
1882 home can be reflected in the models.
- 1883 • Stop frequencies and activities at stops are modeled at  
1884 the day pattern and tour levels to distinguish between  
1885 activities and trips that can be rescheduled with lit-  
1886 tle additional efforts versus the activities and trips that  
1887 cannot be rescheduled (e. g., school trips).
- 1888 • Modes and destinations are modeled together. In this  
1889 way the mutual influence – sequential and/or simulta-  
1890 neous relationships can be reflected in the model struc-  
1891 ture.
- 1892 • Time is included in a few instances in activity-based  
1893 models. For example departure time for trips and tour  
1894 time of day choice are modeled explicitly. Model time  
1895 periods are anywhere between 30 min and second-by-  
1896 second and time windows are used to account for  
1897 scheduling. This modeling component allows to incor-  
1898 porate time-of-day in the modeling suites. It also allows  
1899 to identify windows of activity and travel opportunities.

**TS9** Please check Bengstrom (1995). There is no entry in the bibliography.

**TS10** Please check Greene (1993). There is no entry in the bibliography.

1900 The presence of departure time also enables models to  
1901 trip matrices for any desired periods in a day. In fact,  
1902 output of time periods depends on route choice and  
1903 traffic assignment needs and can be adjusted almost at  
1904 will.

- 1905 • Human interaction, although limited for now to the  
1906 within-household interaction, is incorporated by relat-  
1907 ing the day pattern of one person to the day patterns  
1908 of other persons within a household, their joint activi-  
1909 ties and trip making are explicitly modeled (joint recre-  
1910 ation, escort trips), and allocation of activity-roles are  
1911 also modeled.
- 1912 • Spatial aspects of a region are accounted for using  
1913 methods that produce spatially distributed synthetic  
1914 populations using as external control totals averages  
1915 and relative frequencies of population characteristics.
- 1916 • Accessibility measures are used to capture spatial in-  
1917 teraction among activity locations and the level of ser-  
1918 vice offered by the transportation systems. These are  
1919 also the indicators used to account for feedback among  
1920 the lower level in the hierarchy decisions (e. g., activity  
1921 location choices, routes followed, congestion) and the  
1922 higher level such as residence location choice.
- 1923 • Spatial resolution is heavily dependent on data avail-  
1924 ability and it reached already the level of a parcel and/or  
1925 building at its most disaggregate level. Outputs of mod-  
1926 els are then aggregated to whatever level is required by  
1927 traffic assignment, mode specific studies (nonmotor-  
1928 ized and/or transit) and reporting needs and require-  
1929 ments.

1930 Overall, the plethora of advances includes: a) models and  
1931 experiments to create computerized virtual worlds and  
1932 synthetic schedules at the most elementary level of de-  
1933 cision making using microsimulation and computational  
1934 process models; b) data collection methods and new meth-  
1935 ods to collect extreme details about behavior and to es-  
1936 timate, validate, and verify models using advanced hard-  
1937 ware, software, and data analysis techniques; and c) inte-  
1938 gration of models from different domains to reflect addi-  
1939 tional interdependencies such as land use and telecommu-  
1940 nications.

#### 1941 **Future Directions**

1942 Much more work remains to be done in order to develop  
1943 models that can answer more complex questions in policy  
1944 analysis and for this reason a few steps are outlined here.  
1945 In policy and program evaluation, transportation analysis  
1946 appears to be narrowly applied to only one method of as-  
1947 sessment that does not follow the ideal of a randomized  
1948 controlled trial and does not explicitly define what exper-

1949 imental setting we are using for our assessments. Unfor-  
1950 tunately this weakens our findings about policy analysis  
1951 and planning activities. Although we have many labora-  
1952 tory experiments that were done for intelligent transporta-  
1953 tion systems we lack studies and guidelines to develop ex-  
1954 perimental and quasi-experimental procedures to guide us  
1955 in policy development and large scale data collection.

1956 In addition, many issues remain unresolved in the ar-  
1957 eas of coordination among scale in time and space and re-  
1958 lated issues. In addition very little is known about model  
1959 sensitivity and data error tolerance and their mapping to  
1960 strategy evaluations. This is partially due to the lack of  
1961 tools that are able to make these assessments but also due  
1962 to lack of scrutiny of these issues and their implications on  
1963 impact assessment.

1964 Regarding strategic planning and evaluation, we also  
1965 lack models designed to be used in scenario building ex-  
1966 ercises such as backcasting and related assessments. The  
1967 models about change are usually defined for forecasting  
1968 and simple time inversion may not work to make them  
1969 usable in backcasting. This area does not have the long tra-  
1970 dition of modeling and simulation to help us develop suit-  
1971 able models. Should more attention be paid to this aspect?  
1972 Is there room for a combination of techniques including  
1973 qualitative research methods? What is the interface be-  
1974 tween this aspect and the experimental methods questions  
1975 in program evaluation?

1976 In the new research and technology area, since we are  
1977 dealing with the behavior of persons, it is unavoidable to  
1978 consider perceptions of time and space. What role should  
1979 perceptions of time and space [51] play in behavioral mod-  
1980 els and what is the most appropriate use of these percep-  
1981 tions? The multiple dimensions of time such as tempo, du-  
1982 ration, and clock time Levine (1997)<sup>TS11</sup> are neglected in  
1983 behavioral models – is there a role for them in behavioral  
1984 models?

1985 Human interaction is considered important and is re-  
1986 ceiving attention in more recent research Golob and Mc-  
1987 Nally [54], Chandrasekharan and Goulias [27], Simma  
1988 and Axhausen [148], Gliebe and Koppelman [47], Gou-  
1989 lias and Kim [62], Zhang et al. [187], but only partially  
1990 accounted for in applications as illustrated by Vovsha  
1991 and Petersen [177]. Future applications will increasingly  
1992 pay attention to motivations for human interactions and  
1993 the nature of these interactions within households and in  
1994 a wider social network context.
